EFFECTS OF FOLIAR UREA, POTASSIUM AND ZINC SULPHATE TREATMENTS BEFORE AND AFTER FLOWERING ON GRAIN YIELD, TECHNOLOGICAL QUALITY AND NUTRIENT CONCENTRATIONS OF WHEAT

BARUT, H.

East Mediterranean Agricultural Research Institute, 01321 Adana, Turkey
(e-mail: barut.hatun.hb@gmail.com; phone: +90 322 334 0055)

(Received 30th Dec 2018; accepted 27th Feb 2019)

Abstract. This study was carried out under field conditions to determine the effects of foliar urea, potassium sulphate (K_2SO_4) and zinc sulphate heptahydrate ($ZnSO_4.7H_2O$) treatments at vegetative and generative periods on yield, technological quality and mineral element concentrations of wheat (*Triticum aestivum* L. cv. Altinbasak). Experiments were conducted in two experiment groups (foliar treatments of 0% (Control); 0.5% Urea; 1% Urea; 0.5% $ZnSO_4.7H_2O$; 0.5% Urea+0.5% $ZnSO_4.7H_2O$; 1% Urea+0.5% $ZnSO_4.7H_2O$; 0.5% K_2SO_4 and 1% K_2SO_4 were performed in the first experiment and foliar 0%; 0.5% Urea+0.5% K_2SO_4; 0.5% Urea+1% K_2SO_4; 1% Urea+0.5% K_2SO_4; 1% Urea+1% K_2SO_4 were performed in the second experiment). All treatments increased yield and sedimentation values as compared to the control treatments. In the first experiment, 0.5% urea treatment was prominent for yield, nitrogen and protein and urea+$ZnSO_4.7H_2O$ treatments for grain zinc and iron concentrations. In the second experiment, 1% urea+0.5% K_2SO_4 treatments were prominent for protein and grain nitrogen concentrations and 1% urea+1% K_2SO_4 and 0.5% urea+0.5% K_2SO_4 treatments for yield.
Keywords: *nitrogen, sulphur, micronutrients, gluten, Zeleny sedimentation*

Introduction

Cereals are staple foods, and are significant sources of nutrients in both developed and developing countries. Therefore, nutritional quality of cereals should be improved. Foliar fertilization seems to be a practical way to eliminate nutritional problems and to improve product quality. In this sense, foliar nitrogen (N) treatments had significant effects on yield and quality parameters (Shah et al., 2003; Rahman et al., 2014). Especially, foliar application of urea was demonstrated to be an efficient method of N fertilization in grain cereals in 1950's (Finney et al., 1957). Foliar applications of potassium (K) (Hamouda et al., 2015) and zinc (Zn) (Habib, 2009) had also positive effects on grain yield and quality of wheat. It was recommended by Wang et al. (2017) that foliar N and K treatments could be used to maximize plant respond to Zn treatments.

Prevention of sulphur (S) release to atmosphere with environmental measures, high-cost and resultant decreasing uses of S fertilizers, again decreasing uses of S-containing N and phosphorus (P) fertilizers, excessive nitrogenous fertilizer uses, breeding of high yield varieties and similar factors have made S deficiency in soils and plants a widespread problem. Insufficient S levels prevent grain cereals from reaching their actual potential in yield, quality and protein content. Insufficient S also hinders efficient use of N applied to soils (Sahota, 2006). It was reported that N and S nutrition had significant effects on grain yield and protein concentration of wheat. Wheat S need is less than N need. However, in sulphur deficiency, non-protein N compounds (free amides: asparagine, glutamine) are accumulated, and synthesis and accumulation of S-containing amino acids (cysteine, methionine) in grains decreased (Zhao et al., 1999a;

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43254342

Granvogl et al., 2007). Under S deficiency, these N forms increase and signal is passed from the shoots to roots as if there was sufficient N, thus less N is up taken by the plants from the nutrient ambient. When the plants are nourished with sufficient S, protein N, organic S and SO_4-S concentrations increase, but nitrate and soluble organic acid concentrations decrease (Marschner, 1995). Such findings revealed that S-deficiency destroyed plant N metabolism (McGrath and Zhao, 1996). Nitrogen and S are the basic components of proteins, therefore a balance between N and S is a critical issue for bread making quality of wheat (Randall and Wrigley, 1986). Sulphur not only influences N use and protein quality, but also plays a significant role in baking quality (Ryant and Hřivna, 2004).

Recent studies revealed that cereal grains were poor in mineral element concentrations. For instance, Zn concentrations of wheat grains (generally 25-30 mg kg^{-1}) were quite below the requirements for healthy human nutrition or the recommended levels (Erdal et al., 2002; Cakmak, 2008). Previous studies also indicated that grain Zn and Fe concentrations could be improved with N treatments, and Zn and N treatments had a synergic effect in increasing Zn concentrations of wheat grains (Kutman, 2010; Shi et al., 2010). In another study, increasing Zn and Fe concentrations of wheat grains grown under field conditions were reported with increasing N treatments (Cakmak et al., 2010). When the sufficient Zn levels were supplied to plants, both soil and foliar N treatments were reported to increase grain Zn concentrations (Kutman et al., 2010). Analyses for grain mineral nutrient concentrations revealed that there were significant correlations between grain Zn and Fe concentrations and S concentrations (McDonald and Mousavvi, 2009).

The objective of the present study was to evaluate the effects of urea, K_2SO_4 and $ZnSO_4.7H_2O$ treatments on yield parameters, technological quality and grain nutrient concentrations of Altinbasak bread wheat cultivar.

Materials and methods

Seed and soil materials

Altinbasak bread wheat cultivar commonly grown in Çukurova region was used as the seed material of the present study. Field experiments were conducted over the experimental fields of Eastern Mediterranean Agricultural Research Institute. Experiments were carried out at Dogankent station (36°85′ N, 35°34′ E) during the wheat growing seasons of the years 2014-2015 and 2015-2016. Soil physical and chemical characteristics of the experimental site are provided in *Table 1*.

Table 1. *Soil physical and chemical characteristics of the experiment site for 2014-2015 and 2015-2016 growing seasons*

Field experiments

Experiments were conducted in randomized blocks – split plots experimental design with 4 replications. Experiments were set up on 7 November 2014 in the first year and on 14 November 2015 in the second year. Treatment periods (before flowering – BF, after flowering – AF) were placed in the main plots and foliar treatments were placed in sub-plots (1.4 x 5 = 7 m^2). Sowing density was arranged as 450 seed per m^2. At sowing, 70 kg ha^{-1} phosphorus and 160 kg ha^{-1} nitrogen fertilizers were also applied (in DAP and urea forms). Nitrogen was applied at sowing and tillering stages. Weed control was practiced at tillering stage with 200 ml ha^{-1} Terdok 240 EC. At the end of tillering period, 2-4 D Amine was applied against broad-leaf weeds.

Before flowering (BF) period; foliar treatments were performed once at stem elongation stage (Zadoks 34-36) and once at booting stage (Zadoks 47-49). After flowering period; foliar treatments were performed once at early milk stage (Zadoks 73-74) and once at early dough stage (Zadoks 83-84) (Zadoks et al., 1974). Any surfactant was not used in the fertilizer solutions (w/v). Generally, a typical foliar Zn fertilizer solution contains 2-5 g zinc sulphate heptahydrate ($ZnSO_4.7H_2O$) per liter (Cakmak and Kutman, 2018). In present study, foliar treatments of the first experiment were: 0% (Control); 0.5% Urea; 1% Urea; 0.5% $ZnSO_4.7H_2O$; 0.5% Urea+0.5% $ZnSO_4.7H_2O$; 1% Urea+0.5% $ZnSO_4.7H_2O$; 0.5% K_2SO_4 and 1% K_2SO_4. Foliar treatments of the second experiment were: 0% (Control); 0.5% Urea+ 0.5% K_2SO_4; 0.5% Urea+1% K_2SO_4; 1% Urea+0.5% K_2SO_4; 1% Urea+ 1% K_2SO_4. Only water was applied to control plots. In the other plots, 1000 ml solution was used for each one of 7 m^2 plots as to homogeneously wet the entire plot at stem elongation and booting stages before flowering and at early milk and early dough stages after flowering.

Plots were harvested by a combine, and total grain yield was expressed in kg per hectare at 11% moisture basis. Harvest date was 29 May 2015 in the first year and 13 June 2016 in the second year. Following harvests from 5 m x 1.4 m (7 m^2) plots, grain yields per hectare were determined. The 1000-grain weights were determined in accordance with Ozkaya and Ozkaya (2005). Grain samples were ground and wet-digested in a microwave digester using 2 ml of 35% H_2O_2 and 5 ml of 65% HNO_3. After the digestion, K, S, Zn and Fe were analyzed by an inductively coupled plasma optical emission spectrometer (ICP-OES; Varian-Vista Pro). LECO TruSpec C/N Analyzer (Leco Corp. St Joseph, MI, USA) operating in accordance with Dumas method was used to determine nitrogen concentrations. Reference leaf samples from National Institute of Standards and Technology (Gaithersburg, MD, USA) were used to check the related element (S, K, Zn and Fe) measurements. Total protein concentration of the grain was calculated as 5.7 x N concentration (Zhao et al., 1999b). Wet gluten concentration was measured in a FOSS NIRS 6500 System according to standard method ICC 155 (International Association for Cereal Chemistry, 1994). Zeleny sedimentation was determined by using ICC method 116/1 (International Association for Cereal Chemistry, 1994).

Soil analysis

Available soil Zn, Fe, manganese (Mn) and copper (Cu) concentrations were determined according to Lindsay and Norvel (1978), available P concentration in accordance with Olsen et al. (1954). Soil K concentrations were measured in accordance with the ammonium acetate (pH: 7, 1N) method of Carson (1980). Soil pH was detected

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43254342

according to Jackson (1959). Soil organic matter content was determined following the Walkey-Black wet-etching method (Jackson, 1959). Soil texture was determined according to Bouyoucus (1951). Soil lime content was determined according to Allison and Moodie (1965) and soil salinity was determined from saturation paste extracts according to Wheatstone bridge method (U. S. Salinity Laboratory Staff, 1954). For soil soluble SO_4-S analyses, dried and sieved (< 0.18 mm) 5 g soil sample was placed into 250 ml Erlenmeyer flasks, supplemented with 50 ml 0.1 M LiCI solution and shaken for 30 minutes. Soil suspension was then filtered through filter papers and resultant extract was read at 182.037 nm wave length of an ICP device for soluble SO_4-S quantity (Arkley, 1961).

Weather conditions

A total of 687 mm rainfall was received in the 2014-2015 growing season and 348 mm in the 2015-2016 growing season. While the precipitations of the first year were above the long-term averages (about 25% greater than the averages), precipitations of the second year were quite below the long-term averages (about 38% less than the averages). Temperatures of the experimental years were close to long-term averages (*Table 2*).

Table 2. *Weather conditions of experimental site for 2014-2015 and 2015-2016 growing seasons and long-term averages (1978-2016)*

Statistical analysis

JUMP software was used for statistical analyses. Following ANOVA, significant factor means were compared by TUKEY's multiple range tests. The significance levels were taken as $P<0.05$ (*) and $P<0.01$ (**).

Results and discussion

Effects of treatments on grain yield, 1000-grain weight, protein, wet gluten and Zeleny sedimentation

There were significant differences in the yields of the years because of climate factors (*Table 3*). Rainfalls and temperatures are the most significant climate factors influencing plant growth and development. Total precipitations of the second year (348 mm) were quite lower than the precipitations of the first year (687 mm) (*Table 2*).

*: p<0.05; **: p<0.01; NS: not significant

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43254342

Therefore, yields of the second year were lower than the yields of the first year in both experiments (*Table 4*). Considering the treatment periods, the differences in yields of before flowering (BF) and after flowering (AF) periods were not significantly different (*Table 4*).

In the first experiment, effects of treatments on yields were found to be significant (*Table 3*). With regard to general averages of treatments, yields of 0.5% Urea+0.5% $ZnSO_4.7H_2O$ and 0.5% $ZnSO_4.7H_2O$ treatments were placed in the same statistical group with the control treatment (*Table 5*). The greatest yield (974 kg da^{-1}) was obtained from 0.5% Urea treatments (*Table 5*). Jakhro et al. (2000) reported that urea treatments increased plant height, number of tillers, spike lengths, harvest index, grain yield, hay yield and protein content of wheat grains. Khan et al. (2009) applied 4% urea at 6 different concentrations and at consecutive 3 stages (tillering, stem elongation and booting) and reported 32% increase in wheat grain yield. Considering the general averages of treatments of the first experiment, it was observed that foliar zinc treatments did not result in significant differences in yields. Foliar urea and zinc combined treatment (1% Urea+0.5% $ZnSO_4.7H_2O$) slightly increased yields as compared to the control treatment (*Table 5*). With regard to general averages of the treatments of the second trails, 0.5% Urea+0.5% K_2SO_4 and 1% Urea+1% K_2SO_4 treatments resulted in significant increases in yields as compared to the control treatments (*Table 5*). In the first experiment, foliar K_2SO_4 treatments (0.5% K_2SO_4, 1% K_2SO_4) before flowering slightly increased grain yields as compared to the control treatment (*Table 5*). Such a positive impact probably resulted from both K and S. Thusly, foliar potassium treatments had positive effects on physiological parameters especially in grain-fill period (Zareian et al., 2013) and yield values (Hamouda et al., 2015). Similarly, Gupta et al. (2004) reported significant increases in yield and yield components with S treatments. It was reported in a study carried out in Germany, yield increase rates improved by 17% with S treatments and the yield increase supplied by S treatments varied between 5-30% (Zhao et al., 2002). Zinc sulphate and K_2SO_4 sources are commonly preferred in foliar fertilization practices (Singh et al., 2013).

While the treatments did not result in significant differences in 1000-grain weights of the first and second experiments, years created significant differences (*Table 3*). In the first experiment, 1000-grain weight of the first year (45.8 g) was greater than the second year (33.9 g). Similar decrease trends were also observed in the second experiment (*Table 4*). The differences between the treatment periods (BF and AF) were not found to be significant in both experiments (*Table 3*). General averages of 1000-grain weights in before and after flowering periods were not significant in both experiments (*Table 5*).

In the first experiment, treatments resulted in significant differences in grain protein concentrations of both periods. The highest protein concentration was found in the second year with 1% urea application of BF period. Together with decreasing 1000-grain weights, grain protein concentrations increased in the second year (concentration effect) as compared to the first year. Similar findings were also observed in the second experiment (*Table 4*). With regard to averages of treatments, the greatest grain protein concentration in the first experiment was obtained from 0.5% urea treatment (12.9%) and the lowest value was observed in control treatment (12.1%) (*Table 5*). In the first experiment, as the averages of treatments, all treatments increased grain protein concentrations as compared to the control treatments (*Table 5*).

In the second experiment, the greatest grain protein concentration was obtained from 1% Urea + 0.5% K_2SO_4 treatments (13.5%) and the other treatments had similar protein concentrations with the control treatments (*Table 5*). Present protein concentrations (*Table 4*) were all within 11-14% limit values specified by Mailhot and Patton (1988) for bread making. Grain protein concentrations of the 23 bread wheat genotypes varied between 7.99-13.31% (Soboka et al., 2017).

In the first experiment, the greatest wet gluten concentration (27.09%) was obtained from 1% urea treatment of AF period (*Table 6*). Similarly, increasing wet gluten levels were reported with increasing nitrogen doses (Erekul et al., 2012). In present study, the lowest wet gluten concentration (24.85%) was obtained from 0.5% $ZnSO_4$ treatment of BF period (*Table 6*). In the second experiment, wet gluten concentrations did not change with treatments (*Table 6*). In both experiments, greater wet gluten concentrations were observed in the second year, but the differences in wet gluten concentrations of the years were not significant (*Table 6*). Considering the general averages of the treatments, effects of treatments on wet gluten concentrations were not found to be significant in both experiments (*Table 5*).

The sedimentation values of the wheat cultivar in this research, characterizing the swelling capacity of gluten, exceeded the nominal value (20 ml) for bread wheat in both years (*Table 6*). In both experiments, Zeleny sedimentation values of treatment periods were not found to be significant (*Table 3*), but the treatments were found to be significant (*Table 3 and 5*). In the first experiment, the greatest Zeleny sedimentation value was obtained from 1% Urea, 0.5% K_2SO_4 and 1% K_2SO_4 treatments and the lowest value was obtained from the control treatments (*Table 5*). Slightly greater Zeleny sedimentation values were observed from single $ZnSO_4.7H_2O$ and combined urea treatments as compared to the control treatment (*Table 5*). The increases in Zeleny sedimentation values with the separate urea and K_2SO_4 treatments of the first experiment as compared to the control treatments were also observed with urea and K_2SO_4 combined treatments of the second experiment (*Table 5*). Zeleny sedimentation

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43254342

values should be above 37 ml for a quality bread making. The greater the values over this value, the greater the quality will be. While 43 ml is assessed as moderately well, the values over 50 ml were assessed as the 1st Class wheat. In another study, Zeleny sedimentation (ml) values were classified as; > 30 ml very well; 25-30 ml well; 20-25 ml moderate and <20 ml poor (Unal, 2002). In present study, all treatments of both experiments yielded Zeleny sedimentation values above 50 ml (*Table 5*).

It was reported in a previous study that urea treatments applied at flowering period significantly increased protein, Zeleny sedimentation and wet gluten values of bread wheat cultivars (Varga and Svečnjak, 2006). Late period urea treatments were also reported to increase protein and wet gluten contents of wheat cultivars (Peltonen, 1992).

Effects of treatments on grain nitrogen (N), potassium (K), sulphur (S), zinc (Zn) and iron (Fe) concentrations

With regard to effects of different foliar fertilizer treatments applied before and after flowering on grain N, K, S, Zn and Fe concentrations, it was observed that years created significant differences (*Table 3*). Because of greater precipitations of the second year (*Table 2*), nutrients concentrated in the grains and greater values were observed in the second year (*Table 7 and 8*).

Treatment periods did not have significant effects on grain N, K, S, Zn and Fe concentrations in both experiments (*Table 3*). Treatment periods did not have significant effects on grain K concentrations in both experiments (*Table 3*). In the first experiment, the greatest grain K concentration was obtained from 0.5% K_2SO_4 treatment. In the second experiment, treatments did not have significant effects on grain K concentrations (*Table 9*).

With regard to effects of general averages of treatments on N concentrations, it was observed that all treatments increased N concentrations as compared to the control treatment (*Table 9*). In the first experiment, the greatest N concentration (2.26%) was observed in 0.5% urea treatment and the lowest N concentration (2.12%) was observed in control treatments (*Table 9*). In the second experiment, the greatest N concentration was obtained from 1% Urea + 0.5% K_2SO_4 treatments (*Table 9*). Especially in the second experiment, AF treatments were more effective on mean N (*Table 7*) and protein concentrations (*Table 4*) than BF treatments. Thusly, N treatments close to flowering were reported to influence N uptake and protein contents (Banziger et al., 1994).

The critical extractable S level is commonly reported as 10 mg S kg^{-1}, but is known to vary from 8 to 25 mg kg^{-1} (Mukhopadhyay and Mukhopadhyay, 1995) and 8 to 12 mg kg^{-1} as reported by Tandon (1991) depending on soil, crop, extractant and laboratory procedures. For wheat, the critical level for soil available S concentration was reported as 12 mg kg^{-1} (Rodríguez et al., 2001; Alfaro et al., 2006). According to the survey study results in Ankara, Turkey, more than 50% of the soil, plant straw and grain samples contained lower S than the critical limits (Inal et al., 2003). As the average of the first and the second year, there was 10.7 mg/kg available S in soil (*Table 1*). This value did not result in S deficiency. In both experiments, treatment periods, treatments and interactions did not have significant effects on S concentrations (*Table 3*). Grain S concentrations lower than 1.2 mg g^{-1} and grain N:S ratios higher than 17:1 appear to be critical values for S deficiency (Randall et al., 1981). In present study, S concentrations of both experiments were greater than 1.2 mg g^{-1} and N:S ratios were lower than 17:1. Sulphur plays a significant role in methionine (21% S) and cysteine (27% S) formation, chlorophyll and protein synthesis, seed oil contents and nutritive quality accumulation (Tandon, 1986; Jamal et al., 2005). Sulphur status of wheat grain also influences quality parameters (Marschner, 1997; Zhao et al., 1999a; McGrath, 2003; Honermeier and Simioniuc, 2004). Grain N:S ratio influences bread-making quality and rheological characteristics of the dough.

In recent studies, a new strategy called as "*agronomic biofortification*" have come into prominence. In this strategy, selection, breeding and molecular methods are employed and improvement of grain micro nutrient contents and bio-availabilities are targeted. Such a strategy gained a great support because of sustainability and widespread impacts (Ortiz- Monasterio et al., 2007; Cakmak, 2008).

Considering the effects of different foliar fertilizer treatments before and after flowering periods on grain Zn and Fe concentrations, it was observed that both the years and the treatments were found to be significant (*Table 3*). Treatment periods (BF and AF) were not found to be significant (*Table 3*). In *Table 8*, 0.5% $ZnSO_4.7H_2O$, 1% Urea+0.5% $ZnSO_4.7H_2O$ and 0.5% Urea+0.5% $ZnSO_4.7H_2O$ treatments resulted in significant increases in grain Zn concentrations as compared to the other treatments for both years and BF-AF periods. Similarly, higher grain Zn concentration results were obtained from the general averages of treatments (*Table 9*). Zinc sulphate heptahydrate and urea combination was more effective on grain Zn concentrations as compared to single $ZnSO_4.7H_2O$ treatment (*Table 8 and 9*).

Table 9. *Effects of different foliar fertilizer treatments and combinations on general mean of grain N, K S, Zn and Fe concentrations of Altınbaşak bread wheat cultivar*

It was stated in previous studies that when the sufficient Zn levels were supplied to the growth ambient for plants, both soil and foliar N treatments increased grain Zn concentrations (Kutman, 2010; Kutman et al., 2010; Cakmak et al., 2010). Yılmaz et al. (1997) indicated that soil, foliar, seed and combined Zn treatments yielded significant increases in plant and grain Zn concentrations. It was also reported that foliar zinc treatments improved Zn concentrations of the grains and especially of the endosperm (Jiang et al., 2007; Cakmak et al., 2010; Xue et al., 2012; Zhang et al., 2012).

As compared to control treatments in the second experiment, combined urea and K_2SO_4 treatments yielded significant increases in grain Zn concentrations (*Table 9*). Especially, the effects of 0.5% Urea + 0.5% K_2SO_4 treatments were more remarkable. Such a value was still behind the effects of urea+ $ZnSO_4.7H_2O$ treatments of the first experiment on Zn concentrations.

Orman and Ok (2012) reported that S treatments did not have significant effects on grain Zn concentrations under sufficient Zn conditions, but increased grain Zn concentrations under insufficient Zn conditions. In the same study, S treatments did not have significant effects on grain Fe concentrations under both sufficient and insufficient Zn conditions. Considering the general averages of the treatments of the first experiment, the greatest Fe concentration was obtained from combined urea and $ZnSO_4.7H_2O$ treatments and the lowest Fe concentration was obtained from 1% K_2SO_4 treatment (*Table 9*). Similar findings were also reported by the other researchers (Cakmak et al., 2010; Kutman, 2010; Kutman et al., 2010; Shi et al., 2010). In a study conducted by Kutman (2010), increasing N treatments increased Zn and Fe concentrations by up to 100%. Such an impact of N on Zn concentrations disappeared

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43254342

under insufficient Zn conditions; on the other hand, combined high N and Zn treatments resulted in synergic effect. Significant correlations were reported between the N transported to the grain by remobilization and Zn and Fe supplied to the grain by remobilization (Kutman et al., 2011). There are also some genetic findings about the close relationships between the nitrogen transported from aged leaf tissues into the grain and grain Zn and Fe concentrations (Uauy et al., 2006; Distelfeld et al., 2007; Waters et al., 2009).

Conclusion

It was concluded based on present findings that foliar fertilizer treatments generally had positive impacts on quality of wheat grains. In this sense, it was observed in both experiments that all treatments increased yield and sedimentation values as compared to the control treatments. In the first experiment, 0.5% urea treatment was prominent for yield, nitrogen and protein and urea+$ZnSO_4.7H_2O$ treatments for grain zinc and iron concentrations. In the second experiment, 1% urea+0.5% K_2SO_4 treatments were prominent for protein and grain nitrogen and 1% urea+1% K_2SO_4 and 0.5% urea+0.5% K_2SO_4 treatments for yield. Further research is recommended to be conducted with greater number of wheat genotypes about the effects of combined urea, K_2SO_4 and $ZnSO_4.7H_2O$ treatments on wheat yield, quality and grain Zn and Fe levels.

Conflict of interests. The author has not declared any conflict of interests.

Abstract. Bayan Obo mine in China is the largest iron-niobium-rare-earth symbiotic and associated mine in the world. Its exploitation has brought great economic benefit over the years. At the same time, many environmental problems arise. One of the most serious problems is tailings. Based on the theory and method of life cycle assessment, the environmental problems caused by integrated exploitation technology for tailings in Bayan Obo mine have been studied. Environmental impact assessment method TRACI 2.1 developed by Environmental Protection Agency of the United States has been chosen in this study. Through the study of resource consumption, energy consumption, pollution input by raw materials, pollution from industrial emissions etc. of each process, 10 types of environmental impacts have been studied and their values have been calculated. Results show that the main environmental impact types are Human toxicity non-cancer, Human toxicity cancer, Ecotoxicity, Global warming air, Human health particulate air, respectively. And the pollution input by raw materials is much greater than that from industrial emission, which provides a typical case and support for green purchasing, green manufacturing, process improving etc.

Keywords: *life cycle impact assessment; life cycle inventory; environmental load; rare-earth; green manufacturing*

Introduction

Bayan Obo mine, the largest iron-niobium-rare-earth symbiotic and associated deposit in the world, is located 149 km north of Baotou city, Inner Mongolia Autonomous region, China (*Fig. 1*). Beside rare-earth resources, the mine also contains other elements of interest, including iron, niobium, scandium, fluorite, sulphur and potassium etc. These resources also have an extremely high integrated exploitation value (Smith et al., 2015). Bayan Obo tailings ponds accumulated a large amount of iron tailings and rare-earth tailings due to the large scale mining for half a century. The integrated exploitation technology is a comprehensive method including beneficiation method and metallurgical method, which can extract the remaining useful elements from the tailings of Bayan Obo mine.

Six million tons oxidized ores are mined by Bayan Obo mine each year and 3.8618 million tons tailings are produced (Li et al., 2015a). These tailings bring a series of environmental problems including land occupation, radiation, dust pollution and groundwater pollution etc. The remaining elements in tailings such as iron, rare-earth, sulphur, fluorine, niobium, scandium etc. still have an extremely high recoverable

DOI: http://dx.doi.org/10.15666/aeer/1702_43434359

value. Recycling these elements not only can generate considerable economic benefits, but also can greatly reduce environmental hazards. Currently, environmental problems caused by tailings generally are used some methods called “End-of-pipe Treatment”. These methods cure the symptoms, not the disease-temporary medical relief. However, using the Life Cycle Assessment Method to analyze environmental problems produced in the process of integrated exploitation of tailings, can calculate their environmental pollution values in advance from the beginning of technology designing and achieve the goal of green production from the origin.

DOI: http://dx.doi.org/10.15666/aeer/1702_43434359

There are a lot of assessment methods at present (Ni et al., 2018; Zhai et al., 2018; Zhao et al., 2018; Zhou et al., 2018; Li et al., 2017; Yang et al., 2017; Jin et al., 2015; Li et al., 2015b; Song et al., 2015; Yan et al., 2014). Most of the methods are based on the current situation, and only the Life Cycle Assessment (LCA) starts from the source. LCA method assesses the entire life cycle of a product, technique, or activity in relation to its environmental impact, including the initial collection of the raw material, the production, transportation, sale, use, recycling, maintenance, and disposal of the product. The life cycle assessment method is an advanced method used to determine the comprehensive environmental impact of a process. It has been widely applied as an advanced method in modern environmental management (Mazzi et al., 2017).

At present, life cycle assessment of rare-earth is mainly on rare-earth oxide, neodymium-iron-boron (NdFeB) permanent magnet material and related products containing rare-earth elements at home and abroad (Vahidi and Zhao, 2017, 2018; Zapp et al., 2018; Lima et al., 2018; Weng and Mudd, 2017; Schulze et al., 2017; Vahidi et al., 2016; Weng et al., 2016; Jin et al., 2016; Zaimes et al., 2015; Li et al., 2015c; Koltun and Tharumarajah, 2014; Navarro and Zhao, 2014; Sprecher et al., 2014). However life cycle assessment for tailings integrated exploitation of Bayan Obo mine is rare. This study can quantitatively analyze the environmental influence of useful elements in tailings in the process of integrated exploitation, which is benefit for improving mineral processing technology and achieve green purchasing (Liobikienė et al., 2017) and green manufacturing (Ahn et al, 2013). Meanwhile, it provides the basis for improvement and optimization of integrated exploitation technology of Bayan Obo mine.

Study methods

Assessment method

At present, the LCA methods mainly include CML (Centrum voor Milieukunde Leiden), EDIP (Environmental Design of Industrial Products), EI (Eco-Indicator), EPS (Environmental Priority Strategy), ES (Eco-Scarcity), ReCiPe, BEES (Building for Environment and Economic Sustainability), NOGEPA (Netherlands Oil and Gas Exploration and Production Association), TRACI (Tool for the Reduction and Assessment of Chemical and other Environmental) and so on. In CML method, weight of environmental impact factor mainly is the global average value, which will bring some error if it is used in a specific area. EDIP method is similar to CML method, which will has some error if a specific country is studied. Meanwhile, due to the early development, this method lacks timely update. EI and EPS methods have few environmental impact types, which cannot cover overall environmental impact. Using ES method requires some adjustments according to the change of country or area. ReCiPe method is not perfect in some calculation methods. BEES and NOGEPA are two methods that are developed on TRACI. The improved parts of these methods are limited in use and not widely applicable.

Based on the reasons mentioned above, this study selected TRACI 2.1 assessment method developed by Environmental Protection Agency of the United States (USEPA) in 2002 to assess the environmental influence of tailings integrated exploitation technology for Bayan Obo mine in China. This assessment method was developed for sustainable indexes, LCA, industrial ecology and impact assessment of process design, which was a kind of impact assessment methods for treating chemical emissions,

DOI: http://dx.doi.org/10.15666/aeer/1702_43434359

resource utilization and environmental load source etc. Environmental impact factors considered by TRACI 2.1 were 10 types: AD (Acidification), EP (Eutrophication), GWA (Global Warming Air), ODA (Ozone Depletion Air), HHPA (Human Health Particulate Air), HTC (Human toxicity cancer), HTNC (Human toxicity non-cancer), ET (Ecotoxicity), SA (Smog Air) and RFF (Resources, Fossil fuels). The characterization unit, normalization references and weight factors of TRACI 2.1 are seen in *Table 1*.

Data from USEPA (Norris, 2002) https://nepis.epa.gov/Adobe/PDF/P100HN53.pdf

Data quality

The data related to integrated exploitation technology of Bayan Obo tailings were mainly acquired from patents (Zhang et al., 2015), statistical yearbooks (Baotou steel group, 2016; Baotou steel group, 2014), published books and literatures (Yang, 2017; Lu and Liu, 2016; Hu, 2014; Ji, 2013; Zhang et al., 2010; Xuan et al., 2009; Cheng et al., 2007; Che and Yu, 2006; Mei et al., 2006; Zhang et al., 2002; Xie et al., 2000; Tian and Lu, 1999), and real production data of enterprises. The data acquisition time is from 2014-2018 (The application of integrated exploitation technology to Bayan Obo tailings starts from 2014). The data also had been logged by Baotou Iron & Steel (Group) Co. Ltd.

The data can be divided into four types: energy, material, emission and front-end data. The first two data had been acquired from beneficiation plant of Bayan Obo mine, whose GPS coordinates is 41°47′30″N and 109°51′51″E. The data of pollutant emission were acquired from environmental impact assessment report of integrated exploitation project for Bayan Obo tailings in 2016 and the People’s Republic of China National Standard “Emission Standards of Pollutants from Rare Earths Industry” (Liu et al., 2015; Hu et al., 2013; Chen et al., 2012; Xiao et al., 2003).

Front-end data used in the study were from GaBi database. GaBi covers more than 12000 life cycle inventory data, which is the largest life cycle inventory data set, covered more than 40 industries in the world so far (the database has been updated to 2018). Data of electricity, steam and water were from the China mean value; input of other materials were from global mean value, European Union (EU) mean value, or Germany mean value. Because of the similar energy structure between China and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43434359

Germany whose energy supplies mostly have been dominated by coal (Bonatz et al., 2019), the environmental impact of material production in Germany can substitute that of China. If GaBi database lacks China mean value, global mean value and EU mean value, Germany data were chosen, which can approximately substitute China data (Mo and Zhang, 2003).

For materials not in the database, we created some new data models or used some similar materials in database to substitute the original materials (Cao, 2017).

Goal and scope

Based on the integrated exploitation technology of tailings in Bayan Obo mine as the research goal, according to the collected data and materials, this study conducts a study on LCA of this technology. The purpose was to analyze environmental load, environmental impact types in each production stage and identify the key processes causing pollution and environmental impact types, which can provide basic data for life cycle assessment of integrated exploitation technology of tailings in Bayan Obo mine. Meanwhile, it can promote green purchasing, green manufacturing and sustainable development of rare-earth industry and tailings integrated exploitation industry.

In this study of LCA, system functional unit has been chosen as3.8618 million tons of rare-earth tailings, which is an average quantity of tailings annual output. System boundary was from rare-earth tailings to scandium concentrate (500 ppm) (*Fig. 2*), which included processes of rare-earth flotation, iron flotation, sulfur flotation, fluorite flotation, niobium flotation and scandium magnetic separation etc. namely comprehensively recycling rare-earth concentrate, iron concentrate, sulfur concentrate, fluorite concentrate, niobium concentrate and scandium concentrate from rare-earth tailings.

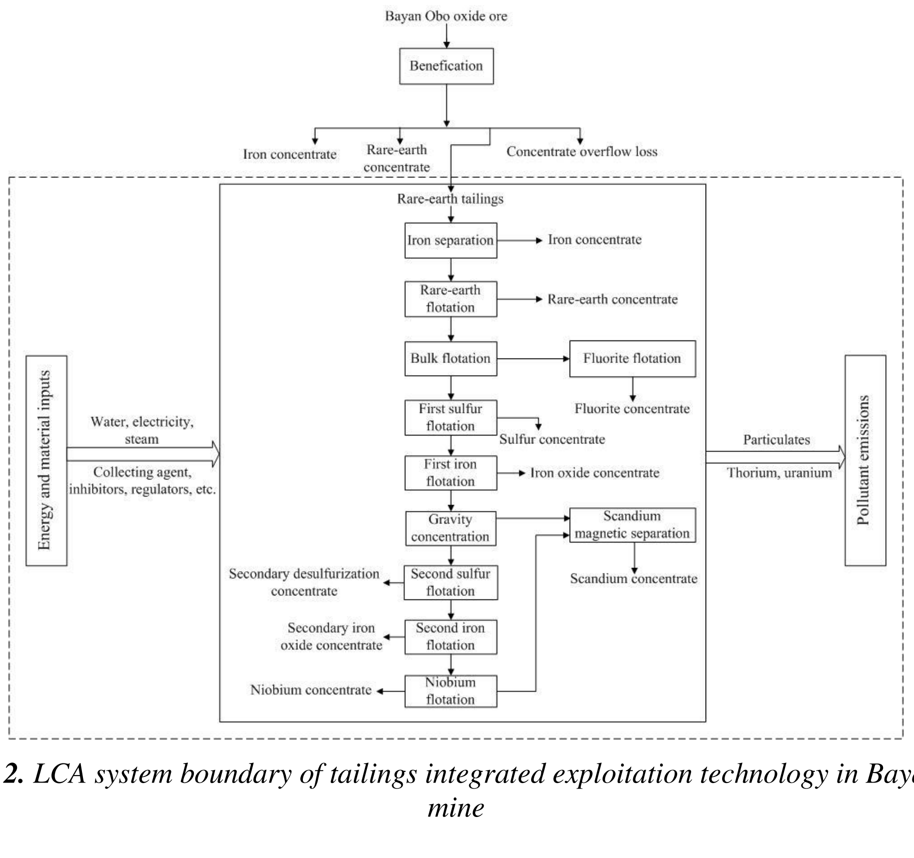

Figure 2. *LCA system boundary of tailings integrated exploitation technology in Bayan Obo mine*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43434359

Life cycle inventory (LCI)

Integrated exploitation technology of tailings in Bayan Obo mine is a kind of process which can comprehensively recycle rare-earth concentrate, iron concentrate, sulfur concentrate, fluorite concentrate, niobium concentrate and scandium concentrate from Bayan Obo mine. In this technology, wastewater had achieved zero discharge. Types of energy included electricity, water and steam. Raw materials consumption mainly included collecting agents, inhibitors, regulators etc. in each beneficiation process. Pollutant discharge mainly included thorium, uranium, sulfur dioxide, carbon dioxide etc. The LCI data is shown in *Figure 3*.

Life cycle impact assessment (LCIA)

LCIA was the key procedure of LCA. This stage needs to quantitatively assess potential environmental impacts. At present, the methods used internationally are mainly qualitative analysis and quantitative calculation, which generally include three stages: characterization, normalization and weighting.

Characterization

Characterization was quantitatively analysis contributions of each environmental factor on specific environmental impact types, and then converted them into unified unit. Characterization results are shown in *Table 2*.

Table 2. *Characterization results of LCI data*

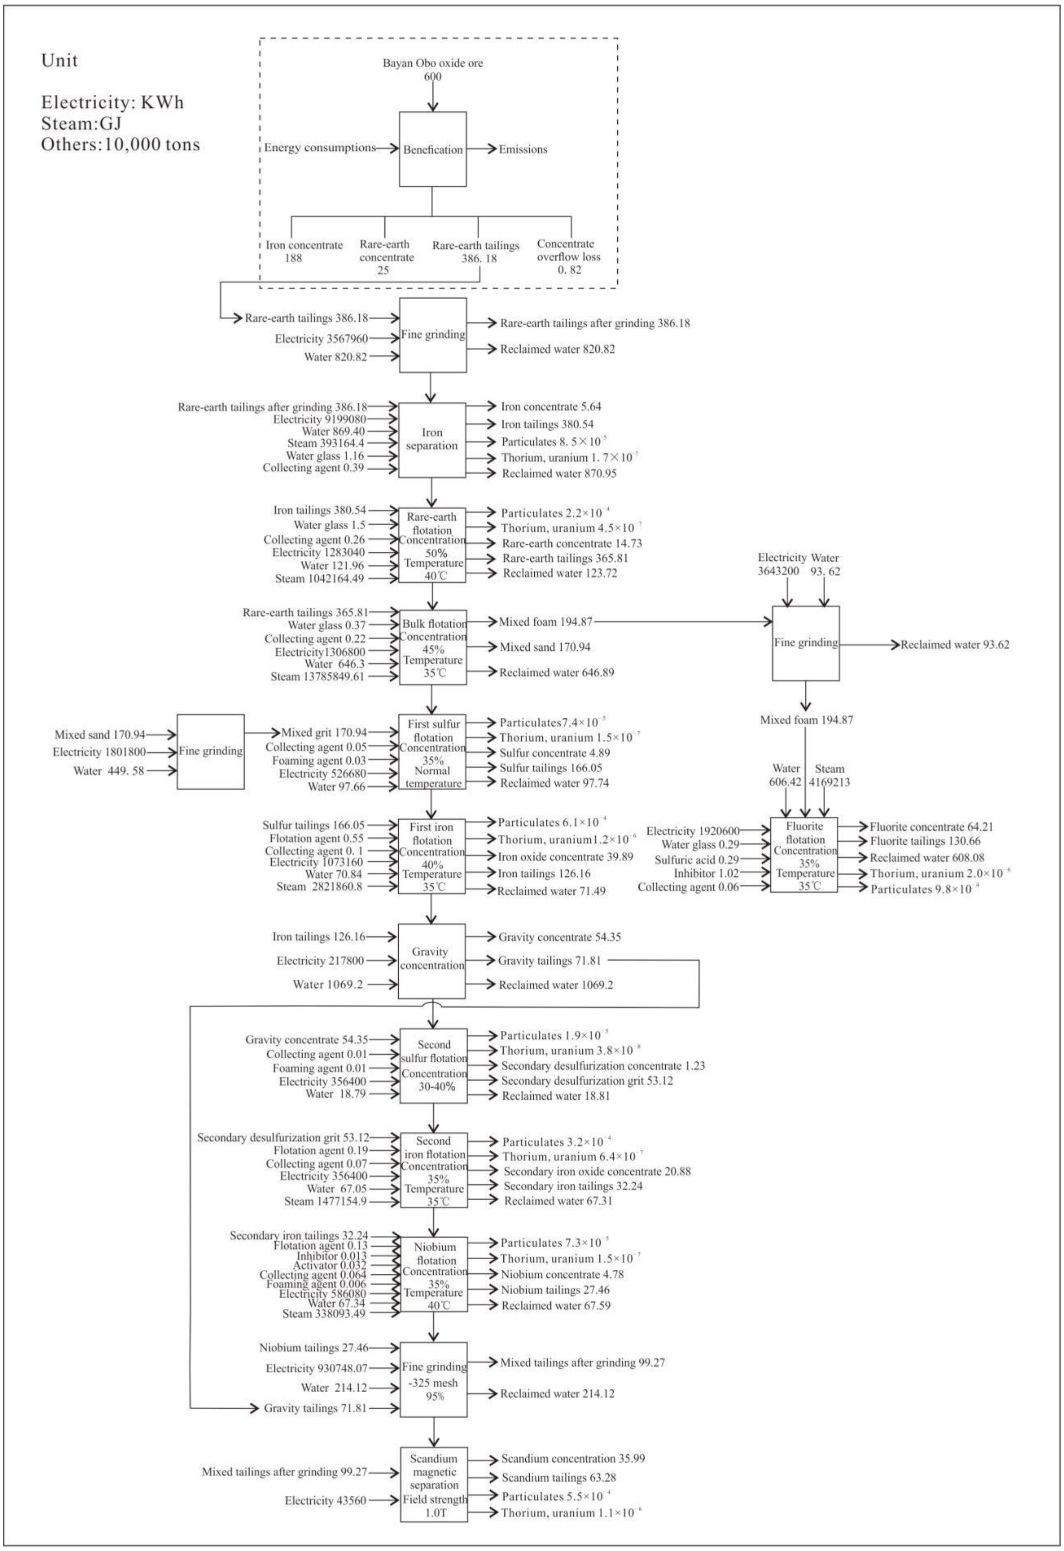

Figure 3. *LCI data of integrated exploitation technology for tailings in Bayan Obo mine*

Normalization

Normalization is a calculating process that using the acquired characterization values divided corresponding normalization reference values, respectively. In the end, this calculation can get some data without unit. After normalization process, these environmental impact types are comparable due to the removal of previous units. Normalization reference value of each environmental impact type is closely related to the severity of itself. Relative levels of various environmental impact types can be compared preliminarily after this procedure.

Normalization reference values of this study are provided by TRACI 2.1 in GaBi 8.0 software. The calculation results are shown in *Table 3*.

Weighting

Through characterization and normalization, summary value of specific assessment subject on each environmental impact type can be gotten. Each environmental impact type is assigned specific weighting factor, on the basis, normalization values were weighted. Then the comprehensive impact values get. Through this procedure, the total environmental impact of study object can be assessed. Meanwhile, the proportions of different environmental impact types in the overall environmental impact can be obtained. Through this result, the impact degree of different environmental impact types to the total environment can be analyzed and quantitative data can be calculated.

TRACI 2.1 environmental impact weight-values were used to get quantitative results of the total environmental impact. Calculation results are shown in *Table 4*.

Results and interpretation

According to the weighting results, environmental impact type values of integrated exploitation technology for tailings in Bayan Obo mine have been calculated (*Fig. 4*).

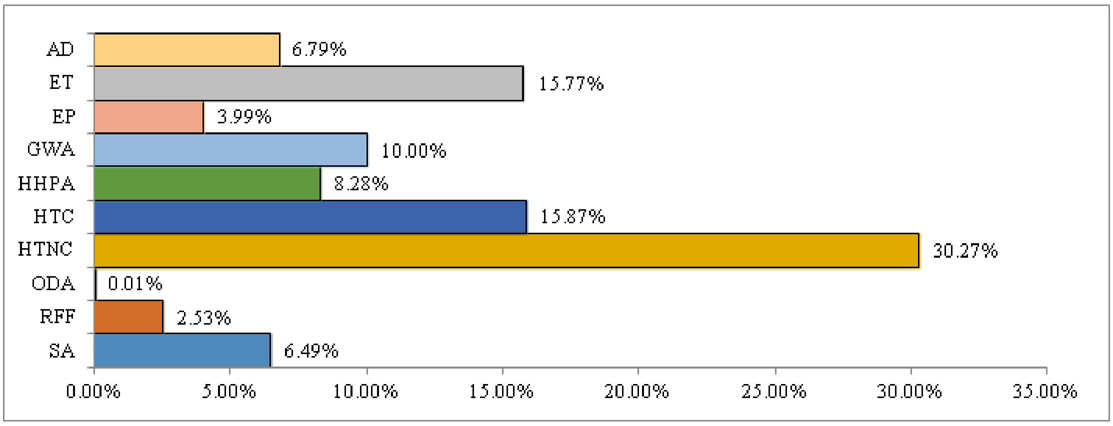

Figure 4. *Proportion of each environmental impact type in the total environmental impact*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43434359

From *Figure 4,* the potential environmental impacts of integrated exploitation technology for tailings in Bayan Obo mine was HTNC, HTC, ET, GWA, HHPA, AD, SA, EP, RFF and ODA sorted by numerical value. Among these types, HTNC was the main environmental impact type, accounting for 30.27% of the total environmental impact. HTC was the next, accounting for 15.87% of the total environmental impact. ET, GWA and HHPA accounted for 15.77%, 10.00% and 8.28%, respectively.

The most serious impact process in HTNC was iron flotation, whose contribution rate was 22.64% (*Fig. 5*). The contribution rate of fluorite flotation, bulk flotation and rare-earth flotation were 18.82%, 17.80% and 15.29%, respectively. Steam was the main factor influencing HTNC in the stage of iron flotation, accounting for 96.33% (*Fig. 6*), which was mainly caused by organic matters discharge such as trichlopropane, trichloro ethylene etc.

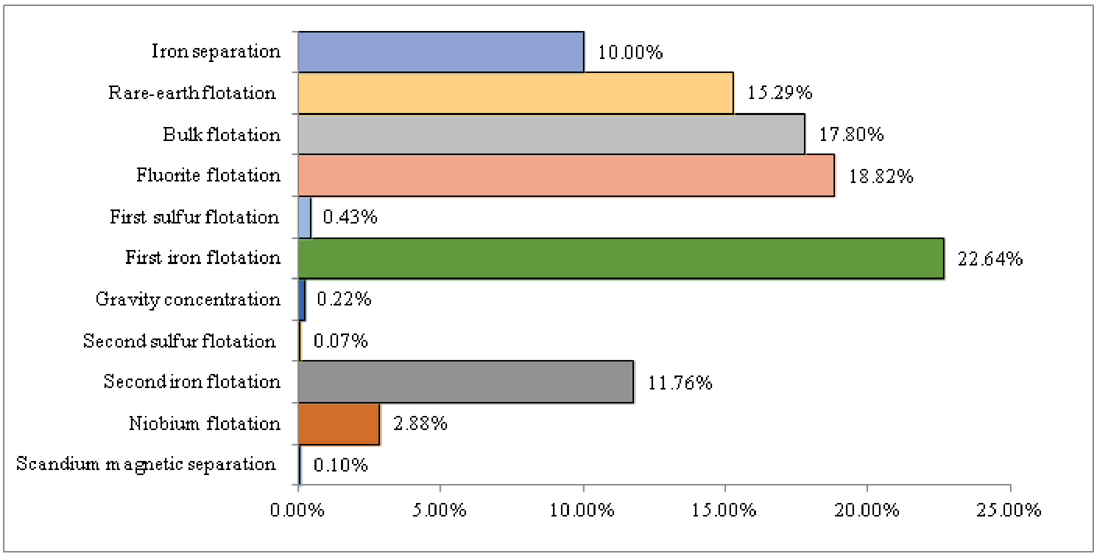

***Figure 5.** Proportion of HTNC in each process*

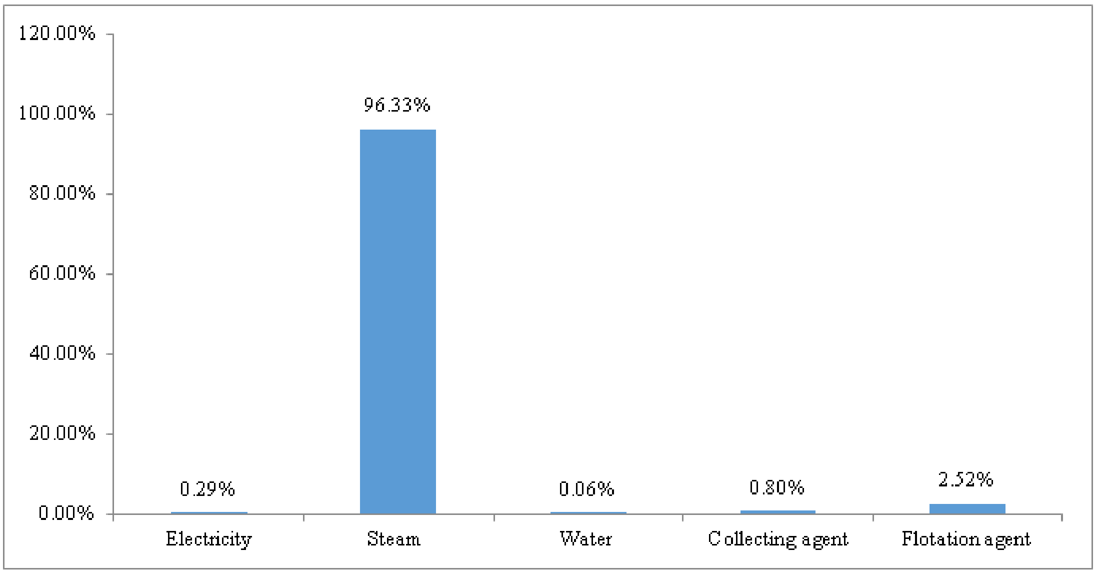

***Figure 6.** Proportion of environmental impact of each input in iron flotation in HTNC*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43434359

From the LCA results of integrated exploitation technology for tailings in Bayan Obo mine, the second environmental impact type is HTC, in which, the most serious impact process was rare-earth flotation (*Fig. 7*), accounting for 31.97% of the total environmental impact of HTC. The next was iron separation process, accounting for 27.62%. Water glass was the main factor influencing HTC in the stage of rare-earth flotation, accounting for 83.16% (*Fig. 8*). The next was collecting agent, accounting for 11.87%. The main reason was discharge of arsenite, cadmium and benzene etc. in the manufacturing process of water glass and collecting agent.

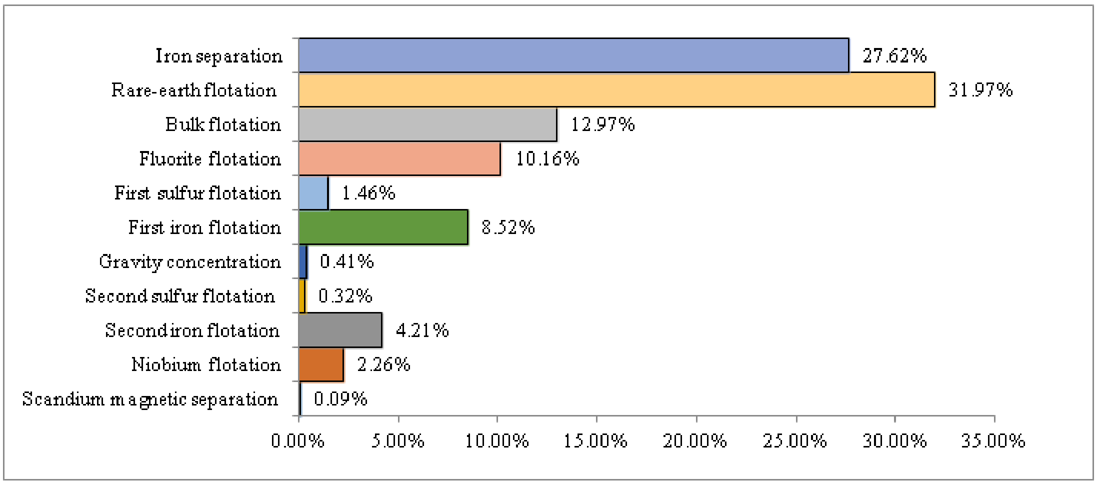

Figure 7. *Proportion of HTC in each process*

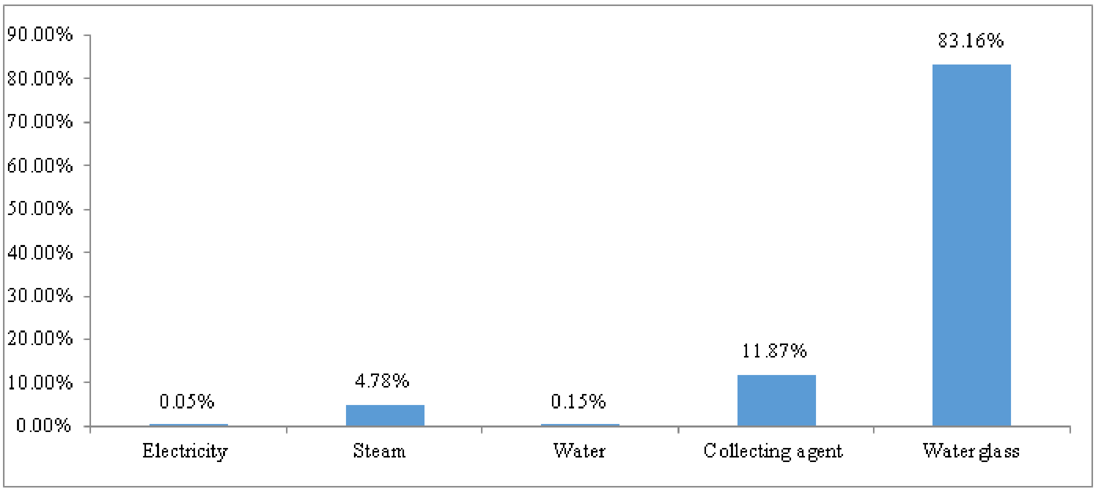

Figure 8. *Proportion of environmental impact of each input in rare-earth flotation in HTC*

The first environmental impact type, namely HTNC was mainly generated from iron flotation and the next was fluorite flotation. The second environmental impact type, namely HTC was mainly generated from rare-earth flotation and iron separation. The most serious impact in ET was rare-earth flotation and the next is iron separation. GWA was mainly generated from iron flotation and fluorite flotation. ODA was the least serious environmental impact among the total environmental impact types, which

mainly generated from rare-earth flotation and iron separation (*Fig. 9*). From the above, the pollution caused by iron flotation was much higher than other processes.

The integrated exploitation technology for tailings in Bayan Obo mine covers 11 processes including iron separation, rare-earth flotation, bulk flotation, fluorite flotation, first sulfur flotation, first iron flotation, gravity concentration, second sulfur flotation, second iron flotation, niobium flotation, and scandium separation magnetic. The proportion of each environmental impact type in these processes is different (*Fig. 10*).

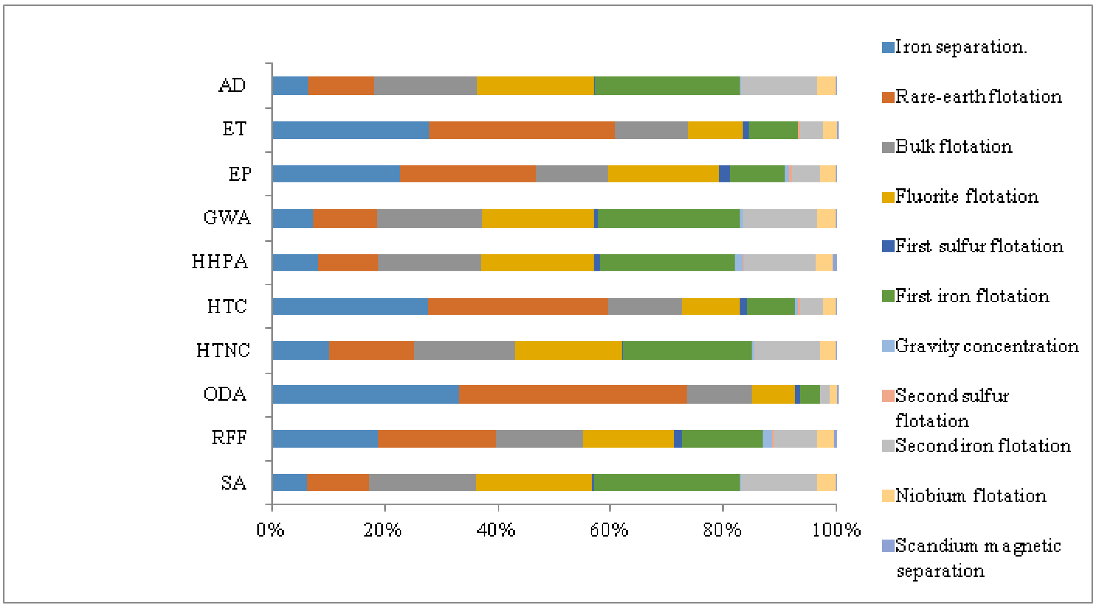

Figure 9. *Proportion of environmental impact of each process in each environmental impact type*

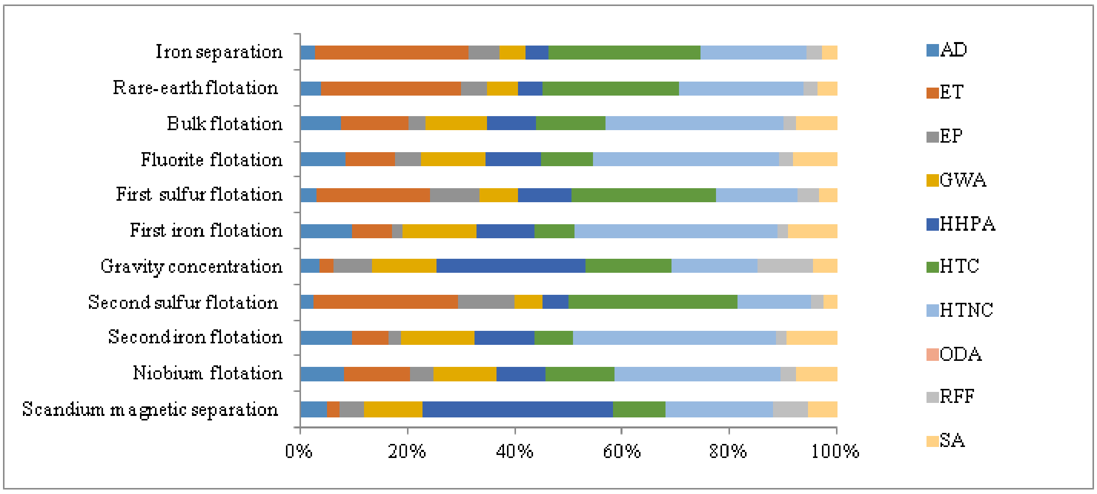

Figure 10. *Proportion of each environmental impact type in each process*

From the figure, in the processes of rare-earth flotation and iron separation, ET was the most important environmental impact type. HTC took second place. In the processes of bulk flotation and niobium flotation, HTNC was the major environmental impact

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43434359

type. HTC was the secondary. In the processes of first sulfur flotation and second sulfur flotation, HTC and ET were the major environmental impact types. In the processes of fluorite flotation, first iron flotation and second iron flotation, the most important environmental impact type was HTNC, and the next was GWA. However, in the process of gravity concentration, the main environmental impact type was HHPA, accounting for 27.88%. The next was HTC, accounting for 15.97%. In addition, in the process of scandium magnetic separation, HHPA and HTNC were the major environmental impact types, accounting for 35.59% and 20.06%, respectively.

In LCA of integrated exploitation technology for tailings in Bayan Obo mine, proportion of each environmental impact type in the total environmental impact is different (*Fig. 11*). The environmental impact order of these processes was rare-earth flotation, iron flotation, fluorite flotation, bulk flotation and iron separation etc. Environmental impact of rare-earth flotation was the most serious, accounting for 19.94% in the total environmental impact. Iron flotation was the next, accounting for 18.23% in the total environmental impact. Scandium magnetic separation had the minimal impact on environment, accounting for 0.15%. In the process of rare-earth flotation, the major environmental impact type was ET.

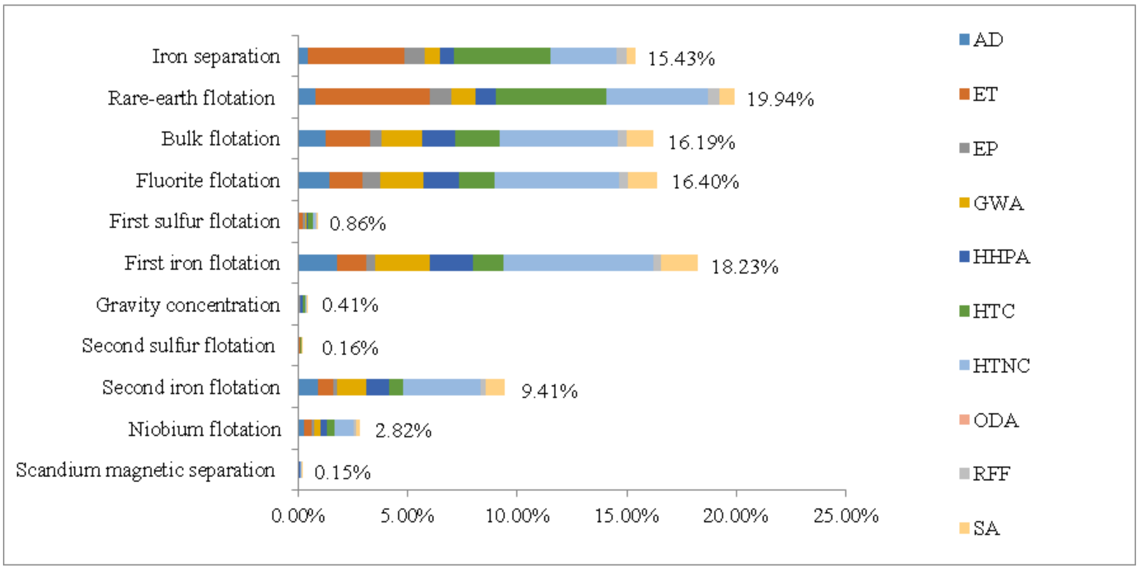

Figure 11. *Proportion of each environmental impact in the total environmental impact*

Conclusions and suggestions

Conclusions

(1) In LCA environmental impact types of integrated exploitation technology for tailings in Bayan Obo mine, HTNC is the main impact type and HTC is the next. All of these indicate that the major environmental problem in the processes of this technology is human health damage. The most serious process in HTNC is iron flotation. Steam is the major impact factor in HTNC, accounting for 96.33%. The most serious process in HTC is rare-earth flotation. Water glass is the major impact factor in HTC, accounting for 83.16%. From the above, it shows that environmental impact brought by raw material actually is much higher than that caused by pollution discharge in these actual processes.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43434359

(2) In the total environmental impacts, flotation makes the heaviest pollution. Environmental pollution of some flotation processes is due to the production of flotation agents, such as rare-earth flotation. Environmental pollution of the other flotation processes is due to the pollution brought by energy production which meets the need of processes, such as iron flotation. Environmental impacts of rare-earth flotation and iron flotation account for 40%, which is the largest proportion of the total environmental impacts.

Suggestions

(1) Based on this study, future studies about LCA of integrated exploitation technology for tailings in Bayan Obo mine may do some research into the different minerals such as rare-earth, iron, niobium, scandium et al. Meanwhile, the researchers should pay more attention to collecting or measuring the emission of wastewater and waste-gas in order to conduct a more accurate and objective assessment. Based on this study, the ecological design of products can be carried out, which could solve the problem of "end-of-pipe treatment" for comprehensively utilizing tailings.

(2) Because of the environmental impact brought by raw material is actually much higher than that caused by pollution discharge in the processes of tailings integrated exploitation of Bayan Obo mine, the rare-earth industry needs investigation and management in the selection and purchase of raw material. Therefore, green purchasing for flotation agent, inhibitor and collecting agent etc. is needed.

(3) If the producing technology and purchasing channel of raw material cannot be changed, the enterprises can conduct some contrast tests to find environmental friendly material for replacing previous material in technology. For the heaviest pollution of rare-earth flotation and iron flotation, technology itself should be deeply studies. The rare-earth industry not only keeps seeking green environmental substitute, but also needs to improve technology itself, reduce intermediate links as much as possible and improve the utilization rate of equipments.

Abstract. Seaweed extracts have been used as biostimulant or biofertilizers in agriculture to improve growth and development in plants, and enhance yield. There are a wide variety of commercial seaweed products for use on plant growth promotion. In this study, a greenhouse experiment was carried out to evaluate the effect of Stimplex®, a commercial liquid seaweed extract derived from *Ascophyllum nodosum*, on growth of ornamental pepper (*Capsicum annuum* L.) plants. Containing a complex array of bioactive compounds, Stimplex® is a premium organic biostimulant that promotes the growth, development, and yield in a wide range of conventional and organic grown horticultural and ornamental crops. Ornamental pepper plants were treated with Stimplex® as either a soil drench or foliar spray at 0, 0.25, 0.50, 0.75, and 1.0 ml·L^{-1} concentrations. The treatments were repeated at 10-day intervals until the end of the experiment. Application of Stimplex® to ornamental pepper plants improved stem diameter, plant height, number of leaves and leaf area, leaf chlorophyll content, shoot fresh weight, shoot dry weight, root fresh weight and dry weight compared to the control plants. The results of this study indicate that Stimplex® may be a viable tool for improving growth of ornamental pepper plants.
Keywords: *Ascophyllum nodosum, sustainable, biostimulant, relative chlorophyll content, biofertilizer*

Introduction

It is necessary to develop sustainable alternatives for agricultural production because of the growing consumer demand for agricultural products, increased costs of chemical fertilizers, and more importantly the detrimental effects of the residuals from chemical fertilizers and pesticides. In recent years, the use of biostimulants to promote plant growth in sustainable agriculture has gained increasing attention worldwide (Nardi et al., 2016). The use of biostimulants in agriculture has been estimated to increase at an annual rate of 13.58% during the forecast period, 2017-2022 and it is projected that the global market for biostimulants will reach to $3.68 billion in annual revenue by 2022 (Anonymous, 2017). Kauffman et al. (2007) defined the word biostimulant as "biostimulants are materials, other than fertilizers, that promote plant growth when applied in low quantities." Companies in the biostimulant sector have created an association called 'European Biostimulants Industry Council' (EBIC) in Europe. The EBIC proposes the following definition for the biostimulant: Plant biostimulants contain substance(s) and/or microorganisms whose function when applied to plants or the rhizosphere is to stimulate natural processes to enhance/benefit nutrient uptake, nutrient efficiency, tolerance to abiotic stress, and crop quality (EBIC, 2018). A wide range of compounds, including humic and fulvic acids, seaweed extracts, protein hydrolysates and other N-containing compounds, chitosan and other biopolymers, beneficial

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43614375

microorganisms, and other potentially bioactive agents act as a biostimulant (Calvo et al., 2014; du Jardin, 2015). There are broad variety of commercial biostimulant products are available for use on plant growth promotion. One of these commercial products is Stimplex®. It is a concentrated liquid crop biostimulant extracted from seaweed (*Ascophyllum nodosum*) which stimulates plant growth and development, promotes yield, earlier maturity, improves resistance to some environmental stresses, improves fruit quality, increases fruit set in a wide range of conventional and organic grown horticultural and ornamental crops (Crouch et al., 1992; Zhang and Ervin, 2004; Spann and Little, 2010; Sidhu and Nanswani, 2016). Stimplex® contains trace amounts of some elements, vitamins, amino acids, auxins, cytokinins and natural chelating agents such as mannitol, fucoidins and alginic acids. It also induces the plant's own production of natural growth substances such as auxins and cytokinins to stimulate cell division and cell elongation initiating the development of larger root systems and promoting growth and yield (Crouch et al., 1992; Crouch and van Staden, 1993; Reitz and Trumble, 1996; Stirk et al., 2003; Spann and Little, 2010; du Jardin, 2015; Anonymous, 2018). Numerous studies have revealed that seaweed extracts promoted growth, increased yield and quality of horticultural crops such as grapes (Norrie and Keathley, 2006), apple (Basak, 2008), olives (Chouliaras et al., 2009), watermelon (Adbel-Mawgoud et al., 2010), cucumber (Sarhan et al., 2011), broccoli (Mattner et al., 2013), spinach (Fan et al., 2013), eggplant (Nandwani et al., 2015), strawberry (Nika et al., 2018), maize (Zermeno-Gonzalez et al., 2015), and tomato (Hernández-Herrera et al., 2014; Ali et al., 2016; Sidhu and Nandwani, 2017). To our knowledge no information on the application of Stimplex® to ornamental pepper plants has been published. The objective of the present research was to determine effective doses and application methods of Stimplex®, a commercial liquid extract of *Ascophyllum nodosum*, on growth of the ornamental pepper (*Capsicum annuum* L.) plants.

Materials and methods

Location and characteristics of the study area

The greenhouse experiment was conducted during the spring-summer 2016 at the Agricultural Sciences Research Center of Bingol University, in Bingol, Turkey (38°53'N, 40°29'E, at 1139 m altitude). The experiment was carried out in heated polycarbonate-covered greenhouse with natural daylight conditions at average day/night temperature of 29/18 °C and relative humidity of 60%.

Plant material

Seeds of ornamental pepper (cv. 'Thai Hot') were used as plant material. The 'Thai Hot' ornamental pepper plants are compact, and grow up 30 cm tall. The fruits on them grow up to 2.5 cm long, point upwards from the plant. It matures abut 80-85 days. This variety produces large numbers of fruits (averages 200 fruits per plant). The fruits range from green to yellow, orange, and deep red. The fruits are edible, although they are extremely hot. Thai ornamental hot peppers have a Scoville rating of 50,000 to 100,000.

The ornamental pepper seeds were surface sterilized with 1% (w/v) sodium hypochlorite for 15 min and rinsed thoroughly three times with distilled water. The sterilized seeds were sown into 70-cell plastic trays filled with a media consisting of peat and perlite in the ratio of 4:1 and grown on a greenhouse bench. The trays were

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43614375

irrigated as needed. Uniform 4-week-old pepper seedlings were transplanted into plastic pots (12 cm in diameter and 11 cm in deep) filled peat/perlite substrate in the ratio of 4:1. The pots were irrigated regularly and fertilized with 20-20-20 N-P-K soluble fertilizer to supply 200 mg.L^{-1} N weekly.

Biostimulant treatment

Stimplex® liquid commercial concentrate of *Ascophyllum nodosum* (Acadian Seaplants Limited, Dartmouth, NS, Canada) was used as biostimulant in this experiment. Stimplex® contains 99% *Ascophyllum nodosum* extract, 0.01% kinetin and other ingredients determined to be non-hazardous. Three days after transplanting, ornamental pepper plants were treated with Stimplex® crop biostimulant as either soil drench or foliar spray at 0, 0.25, 0.50, 0.75, and 1.0 ml.L^{-1} concentrations containing of 0.1% Tween 20 (Sigma Chemical Co., St. Louis, Mo.) as a wetting agent. Plants sprayed or drenched with water containing 0.1% Tween 20 served as the control. Foliar applications were applied with an atomizer to run-off, ensuring that upper and lower leaf surfaces were fully wetted, and the soil surface was covered during application to prevent soil contamination. Soil drench treatments were applied using 100 mL of biostimulant solution per pot. Treatments were repeated at 10-day intervals until week 10 (i.e., the end of the experiment).

Plant growth components evaluated

At the end of 10-week growth period, all replicates per treatment sampled for measurement of number of true leaves, leaf area using LI-3100C portable area meter (LI-COR Biosciences, Lincoln, Nebraska, USA)., open flowers (at anthesis), and leaf relative chlorophyll content of three recently mature leaves per plant using Minolta SPAD-502 Plus chlorophyll meter; Minolta Camera Co., Osaka, Japan), crown diameter, plant shoot fresh and dry weight, root fresh and dry weight, plant height. For dry weights, plant shoots and roots were dried separately in a forced air oven at 70 ^{o}C until dry weights remained constant.

Experimental design and statistical analysis

The treatments were arranged in a complete randomized design. One pot represented the experimental unit and each treatment contained five replicate pots. All data were subjected to analysis of variance using the general linear model program of SAS (version 9.1.3; SAS Institute, Cary, NC). Means comparison was performed using the Tukey's honestly significant difference test at $P \leq 0.05$.

Results

Stem diameter

The effect of Stimplex® treatments on basal stem diameter of ornamental pepper is depicted in *Figure 1*. There was a significant difference ($P \leq 0.01$ between Stimplex® levels in the increment of stem diameter at the end of 10-week growth period. The stem diameter ranged from 3.49 to 4.40 mm and the average stem diameter was 3.98 mm. Ornamental pepper plants treated with 0.75 and 1.00 ml.L^{-1} Stimplex® exhibited the highest increment of stem diameter (4.33 and 4.40 mm, respectively). The plants treated

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43614375

with 0 ml.L^{-1} Stimplex® (control) had the lowest increment of stem diameter (3.49 mm), which was closely followed by plants treated with 0.25 and 0.50 ml.L^{-1} Stimplex® treatments (*Fig. 1*). Both spray and drench treatments significantly increased stem diameter, but variation in method of application was not significant. Interaction between Stimplex® levels and application methods were also found non-significant for stem diameter.

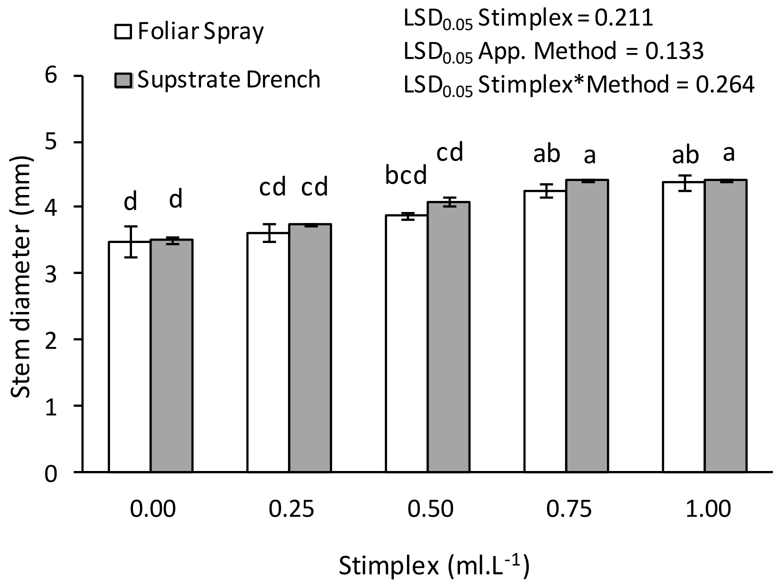

Figure 1. *Effect of Stimplex® treatments applied as foliar spray and substrate drench on stem diameter of ornamental pepper. Levels not connected by same letter are significantly different at $P \leq 0.01$ by Tukey's honestly significant difference test. Values represent average (n = 5 plants); bars represent standard error*

Plant height

Application of Stimplex® significantly increased plant height ($P \leq 0.01$). As shown in *Figure 2,* plant height ranged from 19.18 to 26.43 cm and the average plant height was 23.01 cm at the end of 10-week growth period. Ornamental pepper plants treated with 0.75 and 1.00 ml.L^{-1} Stimplex® treatments exhibited the greatest increment of plant height (26.16 and 26.43 cm, respectively). The plants treated with 0 ml.L^{-1} Stimplex® (control) had the lowest plant height value (19.18 cm), which was closely followed by plants treated with 0.25 and 0.50 ml.L^{-1} Stimplex® treatments (*Fig. 2*). Variation in method of application was significant ($P \leq 0.01$) and the substrate drench method was found to be significantly effective than the foliar spray application in terms of plant height (*Fig. 2*). No significant interaction effect between Stimplex® levels and application methods were observed for the plant height.

Number of leaves

The effect of Stimplex® treatments on number of leaves per plant is presented in *Figure 3.* The number of leaves ranged from 41.00 to 46.00 leaves per plant and the average number of leaves was 43.63 at the end of 10-week growth period (*Fig. 3*). Application of Stimplex® significantly increased the number of leaves ($P \leq 0.01$). Ornamental pepper plants treated with 0.75 and 1.00 ml.L^{-1} Stimplex® treatments

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43614375

showed the highest number of leaves (45.62 and 46.00, respectively), whereas the values of plants treated with 0.25 and 0.50 ml.L^{-1} Stimplex® treatments were not significantly different than the values of control plants treated with 0 ml.L^{-1} Stimplex® (41.00). Variation in method of application was significant ($P \leq 0.05$) and the substrate drench method was found to be significantly effective than the foliar spray application in terms of number of leaves (*Fig. 3*). No significant interaction effect between Stimplex® levels and application methods were observed for number of leaves.

Leaf area

The average leaf area per plant is illustrated in *Figure 4*. The leaf area per plant ranged from 235 to 353 cm^2 $plant^{-1}$ and the average leaf area was 294 cm^2 $plant^{-1}$ at the end of 10-week growth period. The plants treated with 0.75 and 1.00 $ml.L^{-1}$ Stimplex® treatments produced the highest leaf area (348 and 353 cm^2 $plant^{-1}$, respectively), whereas the leaf area values of plants treated with 0.25 and 0.50 $ml.L^{-1}$ Stimplex® treatments were not significantly different than the values of control plants treated with 0 $ml.L^{-1}$ Stimplex® (235 cm^2 $plant^{-1}$). Variation in method of application was significant ($P \leq 0.05$) and the substrate drench method was found to be significantly effective than the foliar spray application in terms of leaf area per plant. There was no significant interaction between Stimplex® levels and application methods for the leaf area.

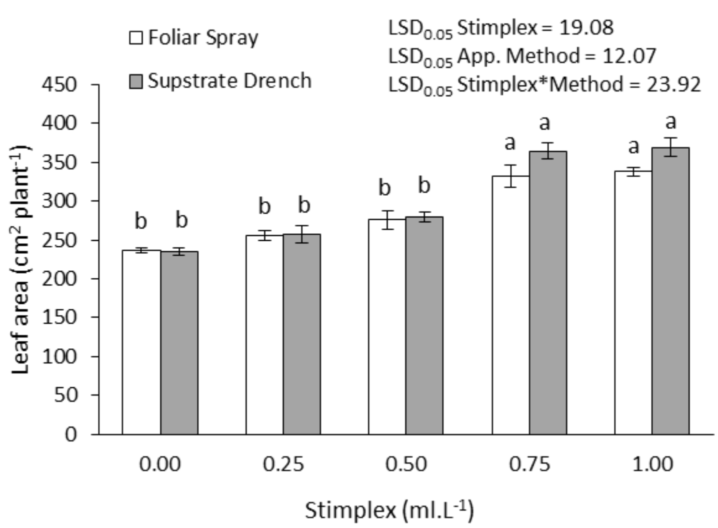

Figure 4. *Effect of Stimplex® treatments applied as foliar spray and substrate drench on leaf area of ornamental pepper. Levels not connected by same letter are significantly different at $P \leq 0.01$ by Tukey's honestly significant difference test. Values represent average (n = 5 plants); bars represent standard error*

Number of flowers

Application of Stimplex® either as foliar spray or substrate drench significantly increased the number of flowers ($P \leq 0.01$). The 0.75 and 1.00 $ml.L^{-1}$ Stimplex® treatments resulted in the highest number of flowers (23.62 flowers), whereas the values of plants treated with 0.25 and 0.50 $ml.L^{-1}$ Stimplex® treatments were not significantly different than the values of control (0 $ml.L^{-1}$ Stimplex®) plants (20.87 flowers). There were no significant differences between the two application methods of Stimplex® in the number of flowers. No significant interaction effect between Stimplex® levels and application methods were also detected for the number of flowers (*Fig. 5*).

Chlorophyll content

The effect of Stimplex® treatments on leaf chlorophyll content (SPAD) presented in *Figure 6*. Results revealed that application of Stimplex® either as foliar spray or substrate drench significantly increased leaf chlorophyll content of ornamental pepper ($P \leq 0.01$). The plants treated with 0.75 and 1.00 $ml.L^{-1}$ Stimplex® treatments showed

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43614375

the highest number of flowers (57.86 and 58.70 SPAD, respectively). The plants treated with 0 ml.L^{-1} Stimplex® (control) had the lowest chlorophyll content (50.71 SPAD), which was closely followed by plants treated with 0.25 and 0.50 ml.L^{-1} Stimplex® treatments (*Fig. 6*). There were significant differences between the two application methods of Stimplex® in the chlorophyll content. Beneficial effect of Stimplex® in enhancing chlorophyll content was more apparent in substrate drenched plants than foliar sprayed plants. There were also significant interaction effects between Stimplex® levels and application methods on chlorophyll content. The highest chlorophyll content was obtained from interactions of substrate drench × 0.75 or 1.00 lg.L^{-1} Stimplex® levels.

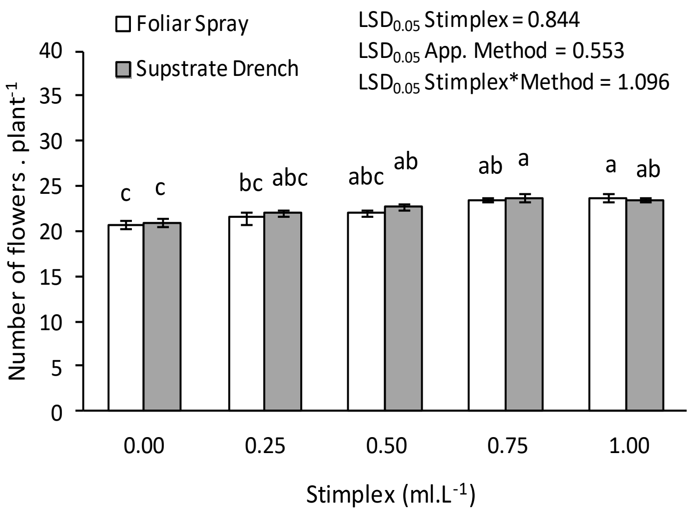

***Figure 5.** Effect of Stimplex® treatments applied as foliar spray and substrate drench on number of flowers of ornamental pepper. Shoot fresh weight

Results indicated that application of Stimplex® either as foliar spray or substrate drench significantly increased shoot fresh weight of ornamental pepper plants ($P \leq 0.01$). As presented in *Figure 7,* the shoot fresh weight ranged from 15.67 to 20.30 g and the average shoot fresh weight was 22.45 g at the end of 10-week growth period. Ornamental pepper plants applied with 0.75 and 1.00 ml.L^{-1} Stimplex® treatments as foliar spray or substrate drench showed the highest shoot fresh weight values (20.30 and 20.22 g, respectively). The control plants (0 ml.L^{-1} Stimplex®) had the lowest shoot fresh weight value (15.67 g), which was closely followed by plants treated with 0.25 mg.L^{-1} Stimplex® (*Fig. 7*). There were no significant differences between the two application methods of Stimplex® in the shoot fresh weight. No significant interaction effect between Stimplex® levels and application methods were also detected for the shoot fresh weight.

Shoot dry weight

As shown in *Figure 8,* the shoot dry weights ranged from 2.11 to 2.46 g and the average shoot dry weight was 2.29 g at the end of 10-week growth period. Ornamental pepper plants treated with 0.75 and 1.00 ml.L^{-1} Stimplex® treatments produced the greatest shoot dry weight values (2.45 and 2.46 g, respectively), whereas the values of shoot dry weights of plants treated with 0.25 and 0.50 ml.L^{-1} Stimplex® were not significantly different than the values of control plants (2.11 g). Similarly to shoot fresh weight, there were no significant differences between the two application methods of Stimplex® in the shoot dry weight. No significant interaction effects between Stimplex® levels and application methods were also observed for the shoot dry weight.

Root fresh weight

Application of Stimplex® either as foliar spray or substrate drench significantly increased root fresh weight of ornamental pepper plants ($P \leq 0.01$). The 0.75 and 1.00 ml.L^{-1} Stimplex® treatments resulted in the greatest root fresh weight values (7.31 and 7.49 g, respectively). The plants treated with 0 ml.L^{-1} Stimplex® (control) had the lowest root fresh weight (5.69 g), which was closely followed by plants treated with 0.25 and 0.50 ml.L^{-1} Stimplex® treatments (*Fig. 9*). There were significant differences between the two application methods of Stimplex® in the root fresh weight ($P \leq 0.01$). Beneficial effect of Stimplex® in enhancing root fresh weight was more evident in substrate drenched plants than foliar sprayed plants. No significant interaction effect between Stimplex® levels and application methods were found for the root fresh weight.

Root dry weight

The root dry weights ranged from 0.73 to 0.90 g and the average root dry weight was 0.81 g at the end of 10-week growth period (*Fig. 10*). Results indicated that application of Stimplex® either as foliar spray or substrate drench significantly increased root dry weight of ornamental pepper ($P \leq 0.01$). The plants treated with 0.75 and 1.00 ml.L^{-1} Stimplex® treatments showed the greatest root dry weight values (0.87 and 0.90 g, respectively). The plants treated with 0 ml.L^{-1} Stimplex® (control)

DOI: http://dx.doi.org/10.15666/aeer/1702_43614375

had the lowest root dry weight value (0.73 g), which was closely followed by plants treated with 0.25 and 0.50 ml.L^{-1} Stimplex® treatments (*Fig. 10*). There were significant differences between the two application methods of Stimplex® in the root dry weight ($P \leq 0.05$). Substrate drench applications gave better response and increased the number of flowers more than foliar applications. No interaction effect was detected between Stimplex® levels and application methods on the root dry weight of ornamental pepper plants.

Discussion

Seaweed concentrates have been reported to trigger early flowering and to increase number of flowers in crop plants. In this study, Stimplex® treatments increased the flower number in ornamental pepper plants. The promotion of flowering following application of Stimplex® was observed in some other plant species For example, Li and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43614375

Mattson (2015) reported that substrate drench at 5–10 ml.L^{-1} significantly increased flower number of petunia and tomato. They used higher concentrations than ours. This could be explained by the fact that different plant species can have different responses to the application methods and rates of seaweed concentrates. Sarhan and Ismael (2014) also verified positive effects of seaweed extract on flower number by reporting that treatment with seaweed extracts significantly enhanced number of flowers and fruit setting percentage in cucumber. This can be attributed to the fact that the seaweed extracts have been reported to contain significant amounts of auxins, cytokinins, and betaines, which affect cell division during the early stages of growth along with the induction of flower formation and number (Roussos et al., 2009).

In the current study, the Stimplex® treated ornamental pepper plants had higher leaf chlorophyll content (SPAD) than those in the control plants. Leaf chlorophyll content was enhanced following seaweed application in a number of previous studies (Eris et al., 1995; Blunden et al., 1997; Spinelli et al., 2010; Fan et al., 2013; Jannin et al., 2013). It was also previously shown that cytokinin-like effects and betaines in seaweed (*A. nodosum*) extracts might be responsible for this effect (Whapham et al., 1993). Blunden et al. (1997) reported that application of an extract of *A. nodosum* resulted in higher concentrations of chlorophyll in the leaves of tomato, bean, wheat, barley, and maize plants in comparison to control plants. They also suggested that the enhanced leaf chlorophyll content of plants treated with seaweed extract was dependent on the betaines present. Betaines, while not traditionally included among the known classical plant hormones, are found in seaweeds and their extracts (MacKinnon et al., 2010). Recently, Fan et al. (2013) observed that the transcription of betaine aldehyde dehydrogenase and choline monooxygenase were greater in seaweed (*A. nodosum*) treated leaves compared to the control. Contrary to some earlier research findings, no beneficial effects were detected for seaweed (*A. nodosum*) applications on chlorophyll content of spinach grown under both normal and stress situations (Xu and Leskovar, 2015).

Numerous studies have revealed seaweed extracts promoted vegetative growth of horticultural crops (Arthur et al., 2003; Morales Payan, 2004; Spinelli et al., 2010; Kumari et al., 2011; Zodape et al., 2011; Zulaikha, 2013; Hernández-Herrera et al., 2014; Selvakumari and Venkatesan, 2017; Yildiztekin et al., 2018). In accordance with these earlier studies, application of Stimplex® to ornamental pepper plants improved stem diameter, plant height, number of leaves and leaf area, shoot fresh weight, shoot dry weight, root fresh weight and dry weight compared to the control plants in the present study. In a previous study, application of seaweed (*A. nodosum*) extract solution at 1% concentration to roots produced transplants with increased root length and shoot length compared to control in tomato (Poincelot, 1993). Spinelli et al. (2010) reported that seaweed extract derived by the algae *A. nodosum* increased the vegetative growth of strawberry up to 10%. They also reported that the most significant result was the increment of the plant biomass: the shoot dry matter was increased up to 27% and root dry matter up to 76%. In another study, Kumari et al. (2011) reported an increase in root length, shoot length, and fresh weight in tomato treated with drench and foliar applications of liquid seaweed extracts. Similarly, at 21 days following application, addition of 0.1 g L^{-1} of seaweed extract to the growth medium significantly increased spinach fresh weight and dry-matter content by 58% and 23%, respectively (Fan et al., 2013). In broccoli grown in greenhouse, drench application of seaweed extracts increased leaf area, stem diameter, and both shoot and root biomass (Mattner et al.,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43614375

2013). Recently, Zermeno-Gonzalez et al. (2015) reported that the application of biological fertilizers derived from seaweed extracts to the soil and foliage on forage maize resulted in an increase in plant height (17.3%), stem diameter (10.5%) and plant dry weight (14.8%) compared to the control plants. In the study conducted by Xu and Leskovar (2015), *A. nodosum* seaweed extract treatments increased leaf fresh weight and dry weight.

It is possible that the beneficial effects of Stimplex® on growth parameters could be ascribed to the presence of macro and micro nutrients as well as growth promoting substances like cytokinins other constituents in the seaweed extract. Seaweed ingredients contains some macro and microelement nutrients, vitamins, amino acids, auxins, and cytokinins that affect cellular metabolism in treated plants, leading to enhanced growth (Crouch and van Staden, 1993; Khan et al., 2009; Craigie, 2011; Spann and Little, 2010; du Jardin, 2015). Zodape et al. (2011) have indicated that increased plant height of tomato treated with seaweed sap might be due the macro and micro nutrients as well as growth promoting substances like cytokinin promoting growth. Ramamoorthy et al. (2007) indicates that application of seaweed extract as foliar spray enhances the growth of the plants by making the growth promoting substances available to the plants through absorption and translocation. Rayorath et al. (2008) provided evidence that components of the commercial seaweed (*A. nodosum)* extracts regulate the concentration and translocation of auxins which could account for the enhanced plant growth. Khan et al. (2011) reported that that Stimplex® treatment resulted in increased cytokinin-like responses in *Arabidopsis thaliana* plants, which suggests that the seaweed extracts have compounds that may have contributed to cytokinin-like activity. Cytokinins induce cell division and proliferation, increasing the sink activity of roots, resulting in growth stimulation (Nelson and Van Staden, 1984). Increases in lateral root formation, total root volume, and root length have been observed and attributed to the presence of auxins and cytokinins in seaweed extracts (Crouch and Staden, 1993; Stirk and van Staden, 1997; Arthur et al., 2003; Khan et al., 2011; Sarhan and Ismael, 2014; Vijayanand et al., 2014).

Conclusion

Broadly, application of seaweed extracts as organic biostimulant has received a greater acceptance in agriculture because of their potent plant growth-enhancing properties. The interest in seaweed extracts to enhance agricultural productivity continues to grow globally. A number of commercial seaweed extract products are available for use in agricultural and horticultural crops. The application of Stimplex® seaweed extract (0.75 and 1.00 ml.L^{-1}) to the growing substrate and foliage caused improvement in plant growth parameters of ornamental pepper. The growth parameters increased with increasing concentrations of Stimplex®, up to 0.75 ml.L^{-1}, but increasing concentration beyond 0.75 ml.L–1 did not have any further effect on plant growth. The results of this study indicate that Stimplex® may be a viable tool for improving growth of ornamental pepper plants. Furthermore, the preparation of the product is handy and it has no hazardous side effects and offers ecofriendly production of the agricultural produce. However, further study is needed before adopting this practice.

Abstract. A field study was conducted during the period 2014–2015 at the Czesławice Experimental Farm in Poland. The aim of this study was to determine the technological characteristics of the grain and flour of winter spelt (*Triticum aestivum* ssp. *spelta*) two cultivars ('Rokosz' and 'Schwabenspelz') depending on the density of sowing and crop protection methods. The present study showed that crop protection method and seeding rate did not cause most of the quality characteristics of spelt grain and flour to significantly vary. Both the Polish cultivar 'Rokosz' and the German cultivar 'Schwabenspelz' exhibited similar technological quality of grain and flour under organic farming and chemical crop protection conditions. Therefore, both these cultivars can be recommended for cultivation in organic farms. In 'Rokosz', gluten content, Zeleny sedimentation value, and dough development time increased with increasing protein content, whereas gluten weakening decreased, which is the evidence of a higher quality and baking value of this cultivar relative to 'Schwabenspelz'.
Keywords: *chemical and pro-ecological protection, sowing rate, farinographic features of flour and dough, quality characteristic of grain, winter spelt cultivar*

Introduction

Spelt wheat (*Triticum aestivum* ssp. *spelta*) is one of the oldest wheat subspecies (Szumiło and Rachoń, 2015; Stankowski et al., 2016). Numerous archaeological studies show that it originated from the south-western region of Asia (Krawczyk et al., 2008a; Cacak-Pietrzak et al., 2013), but for a long time it has also been grown in Germany, Switzerland, Belgium, Slovakia, the Czech Republic, Italy, Canada, and the USA (Stankowski et al., 2016). Despite the fact that in large-area cultivation it was replaced by the more threshable and productive common wheat (Podolska et al., 2015; Ugrenović et al., 2018), in recent years the beneficial properties of spelt wheat are being discovered anew. This species owes its renewal predominantly to the growing interest in healthy food and organic farms, where spelt is frequently grown due to its high resistance to adverse environmental conditions, diseases, and pests (Kraska et al., 2013; Callejo et al., 2015; Rachoń et al., 2016; Babenko et al., 2018). Moreover, spelt wheat has a long stem and high tillering ability, and hence it exhibits high weed competitiveness (Rachoń et al., 2016).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43774395

According to 2015 data of the Central Statistical Office, in 2015 nearly 270,000 organic farms with an area of more than 11.1 million hectares were recorded in the EU, which accounts for 6.2% of the total agricultural land area. In the same year, in Poland there were more than 22,000 organic farms with an area of over 580,000 ha, which accounts for 3.8% of Poland's total agricultural land area (Statistical Yearbook of Agriculture, 2017).

Consumers seeking food of high nutritional value readily choose spelt products, driven by the nutrient richness and health-enhancing properties of spelt wheat (Callejo et al., 2015; Rachoń et al., 2016; Boukid et al., 2018). Spelt grain is most often used to make whole grain food products, e.g. bakery products, pasta, muesli, or cereals (Benincasa et al., 2015; Boukid et al., 2018). Compared to common wheat, eating spelt grain products prevents hypertension, reduces blood cholesterol level, improves the functioning of the digestive system, and aids the nervous system (Solarska et al., 2012; Spychaj-Fabisiak et al., 2014). The most important technological parameters of spelt flour are similar to those of common wheat flour, but the observed differences weigh in favour of spelt flour (Rachoń et al., 2011). It contains more protein, including gluten, vitamins A, E, D, B, PP, micro- and macronutrients, fats, and necessary amino acids (Lacko-Bartošová, 2010; Escarnot et al., 2012; Biel et al., 2016a; Zorovski et al., 2018). Its total protein content ranges from 13 to 19% DM (Biel et al., 2016c). Gluten obtained from spelt flour added to low protein flour increases the amount of protein and improves the technological properties of such flour (Rachoń et al., 2011). Due to the poorer milling properties of spelt grain, lower milling yields are obtained from it compared to common wheat grain (Krawczyk et al., 2008b). Flour extracted from spelt grain is a good raw material to produce high quality bakery products (Pruska-Kędzior et al., 2008). Spelt bread loaves bake well, do not crumble when cut, and smells and tastes slightly of walnut (Callejo et al., 2015). It should be noted that spelt dough can have a looser texture than dough made of common wheat flour (Biel et al., 2016b). This is due to the spelt gluten which is characterized by high weakening, while the dough by excessive extensibility (Krawczyk et al., 2008a). The rheological properties of spelt flour and dough primarily depend on the gluten content and a proper gliadin-to-glutenin ratio (Callejo et al., 2015; Biel et al., 2016b).

The study hypothesized that spelt grain and flour obtained from organically grown spelt (no crop protection, mechanical weed control) would have similar or more favourable technological properties than grain and flour obtained from a chemically protected crop (herbicide protection, complete chemical crop protection). An assumption was also made that an increased seeding rate (500 grains per m^2) of spelt wheat (which is the common practice in organic farms) will not result in a deterioration of the technological quality of this plant. The aim of this study was to compare the technological quality of grain and flour of two winter spelt cultivars grown under different agronomic conditions.

Materials and methods

A field study was carried out for two growing seasons 2013/2014 and 2014/2015 in the village of Czesławice where the Experimental Farm (51°18′23″ N, 22°16′2″ E) belonging to the Lublin University of Life Sciences, Poland is located (*Fig. 1*). The experiment on growing spelt wheat was established on a loess-derived *Luvisol*, classified as good wheat soil complex and soil class II. The arable layer of the soil was characterized by high availability of phosphorus (P_2O_5 – 175.1-178.2 mg kg^{-1} soil) and potassium (K_2O – 141.9 -159.4 mg kg^{-1} soil) as well as medium availability of magnesium (Mg – 79-85 mg kg^{-1} soil), slightly acidic pH (in 1 M KCl – 6.1-6.4), and a humus content of 1.59-1.63%. The

DOI: http://dx.doi.org/10.15666/aeer/1702_43774395

experiment was conducted in three replicates. Two winter spelt wheat cultivars, the German cultivar 'Schwabenspelz' (*Fig. 2*) and the Polish cultivar 'Rokosz', were the object of this research.

The experiment included the following factors: I – seeding rate: 1) optimum – 350 plants per m^2; 2) increased – 500 plants per m^2; II – crop protection: 1) pro-ecological: A – treatment without protection against pathogens (control treatment), B – harrowing in early spring at the beginning of the growing season; 2) chemical: C – application of the herbicides Sekator 125 OD (a.i. amidosulfuron, iodosulfuron, mefenpyr-diethyl) at a rate of 150 ml ha^{-1} and Attribut 70 WG (a.i. propoxycarbazone-sodium) at a rate of 60 g ha^{-1} at BBCH 22-24 stages of spelt wheat; D – application of complete chemical protection – the herbicides Sekator 125 OD (a.i. amidosulfuron, iodosulfuron, mefenpyr-diethyl) at a rate of 150 ml ha^{-1} and Attribut 70 WG (a.i. propoxycarbazone-sodium) at a rate of 60 g ha^{-1} at BBCH 22-24 stages of spelt wheat; the growth retardant Cerone 480 SL (a.i. ethephon) at BBCH 30-31 stages at a rate of 0.75 l ha^{-1}, the fungicide Wirtuoz 520 EC (a.i. prochloraz, tebuconazole, proquinazid) at BBCH 24-25 and 32-33 stages at a rate of 1.0 l ha^{-1} as well as the insecticide Decis 2,5 EC (a.i. deltamethrin) at BBCH 37-39 stages at an amount of 0.25 l ha^{-1}.

Figure 1. *Localization of the study site*

Figure 2. *'Schwabenspeltz' cultivar of spelt wheat*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43774395

Mineral fertilization was applied at the following rates: N – 50 kg ha^{-1}, P_2O_5 – 60 kg ha^{-1} and K_2O – 70 kg ha^{-1}. All phosphorus and potassium fertilizers and part of nitrogen fertilizers (20 kg N) were applied before sowing the spelt wheat. The remaining portion of nitrogen fertilizers was applied right after the beginning of the growing season. The sown and harvested plot area was 13.5 m^2 (5.0 × 2.7 m). Winter wheat was the previous crop for spelt wheat. Tillage was typical for common wheat cultivation. The spelt wheat was sown on September 23, 2013 and September, 25, 2014 and it was harvested on August 12, 2014 and August 11, 2015.

Temperature range in both vegetation seasons of wheat spelt were similar. Mean temperature in season 2013/2014 was 8.7 and in season 2014/2015 was 0.1 higher (*Table 1*). Season 2013/2014 could be described as very wet as rainfall was by 281 mm higher than in season 2014/2015. In year 2014 the highest rainfall was in May, June and August. In year 2015 high rainfall was in May but August was very dry with only 5.9 mm of rain.

Table 1. *Rainfall and air temperature in the growing season of spelt wheat, according to the Meteorological Station in Czesławice*

2013/2014	11.3	9.5	4.9	1.7	-2.9	0.3	4.9	8.9	13.0	15.2	19.6	18.3	8.7
2014/2015	14.0	9.7	4.6	-0.1	1.0	-1.1	2.8	6.5	11.5	16.1	19.0	21.9	8.8

The following parameters were determined: 1000 grain weight (TGW) was determined according to PN-EN ISO 520:2011E. Clean material was placed in an automatic seed counter and 4 × 250 seeds were counted and weighed with an accuracy of 0.1 g. Test weight was determined according to PN-EN ISO 7971-1:2010P. To analyse α-amylase activity, SWD-SŻ type instrument (Sadkiewicz® Instruments, Bydgoszcz, Poland), was used, in which falling number was measured using the Hagberg-Perten method, according to PN-EN ISO 3093:2010E. The grain was milled in a laboratory 6-roller mill manufactured by the Research Institute of the Bakery Industry in Bydgoszcz. The milled flour was sieved in a laboratory sifter to obtain appropriate fractions for the individual assays, on sieves with proper mesh sizes (265 µm – for farinographic evaluation, 230 µm – for determination of gluten quantity and quality, 150 µm – for determination of sedimentation value). Determination of gluten content and weakening was performed according to PN-EN ISO 21415-2:2015-12E using the Gluten index system (Perten Instruments). Sedimentation value was determined according to PN-EN ISO 5529:2010E. This assay was performed on an apparatus consisting of a measurement panel and the Sadkiewicz vortex mixer (Sadkiewicz® Instruments, Bydgoszcz, Poland), SWD-89 model. Analysis of the farinographic properties of the dough was carried out on a farinograph (Brabender) using a 50 type head according to PN-EN ISO 5530-1:2015-01E. The following parameters were determined – flour water absorption, dough development time, dough stability, and degree of softening after 10 min and after 12 min.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43774395

The obtained results were statistically analysed by two-way analysis of variance using a completely randomized design. Statistical software FR-ANALWAR 5.2. was used for calculations. Confidence half-intervals were calculated by Tukey's test at a significance level of 0.05. Significant differences between these two groups of treatments: organic protection (treatments A and B) and chemical protection (treatments C and D), were evaluated based on the Scheffe test (α = 0.05).

Results

Conducted research showed that in 2014 and 2015 experiment factors had significant influence on weight of 1000 grains of spelt wheat 'Rokosz' cultivar (*Tables 2 and 3*). In the first year of research the greatest TGW was described in cultivar with complete chemical protection (treatment D) but in 2015 in harrowing treatment (B) (*Table 2*). In both years increase in seeding rate had untoward influence on grain size 'Rokosz' cultivar (*Table 3*).

In 'Schwabenspelz' cultivar, during the experiment (2014-2015), crop protection had significant influence on this parameter (*Table 4*). In 2014 the greatest TGW was described in treatment B but in 2015 in the treatment D. Increase in seeding rate in 2015 significantly decreased of TGW of 'Schwabenspelz' spelt wheat (*Table 5*). Mean results from 2014-2015 did not confirm that crop protection and seeding rate had significant influence on grain size of both studied cultivars and there was also no difference between pro-ecological and chemical crop protection (*Tables 2* and *3,4,5*).

In the research years methods of crop protection had significant influence on test weight 'Rokosz' and 'Schwabenspelz' cultivars (*Tables 2* and *4*). In 2014 and 2015, in both cultivars, the greatest test weight was amongst grains from treatment with complete chemical crop protection, furthermore in 'Schwabenspelz' cultivar test weight in 2014 did not vary much between treatments B and D. In the first year of research increase in seeding rate, from 350 to 500 grains per m^2, significantly decreased test weight of 'Rokosz' and in 2015 increased test weight of 'Schwabenspelz' cultivar (*Tables 3* and *5*). Mean result from research years did not confirm statistically significant relation between experiment factors and test weight.

In both research years crop protection had significant influence on falling number (*Tables 2* and *3,4,5*). In 2014 'Rokosz' cultivar shown the greatest falling number in treatment B and D (*Table 2*). In 2015 the greatest falling number was amongst treatment where herbicide was used (treatment C). In the first year of the study, which was characterized by o lot of rainfall (*Table 1*), in 'Schwabenspelz' cultivar, the falling number was very low. The greatest falling number (126 s) was found in the treatment D (*Table 4*). In 2015, positive influence on falling number of grain had pro-ecological crop protection (treatments A and B) of 'Schwabenspelz' spelt wheat (*Table 4*). Seeding rate significantly modified the falling number in the 'Schwabenspelz' cultivar only. In each year of the study the increase in sowing rate adversely affected this feature (*Table 5*). Mean result from research years, as in the case of the feature discussed earlier, showed no significant influence of experiment factors on falling number of spelt wheat grains.

Crop protection methods caused significant differences in the amount of gluten in 'Rokosz' grain (*Table 2*). In the first year of research, the greatest gluten content in grains from treatment B was found, while in 2015 from control (A) and mechanical weed management (B) treatments. Mean from 2014-2015, the gluten content in the treatment with complete chemical protection was significantly lower than in the treatment where only the herbicide was applied (C) and in the treatment with harrowing

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43774395

(B), whereas it did not differ significantly with the control treatment. It was statistically proven that pro-ecological crop management affected more favourably the trait described compared to chemical crop protection (*Table 2*). In the second year of study, in ‘Schwabenspelz’ cultivar significantly influence of crop protection on this feature was observed (*Table 4*). The highest content of gluten was in grain from the harrowing treatment (B). With regards to this cultivar, despite no significant differences, pro-ecological technologies also positively influenced grain gluten content (*Table 4*). In the case of the studied cultivars, the seedling rate did not significantly modify this feature (*Tables 3* and *5*).

In the years of research, the crop protection methods significantly differentiated the gluten weakening in grain of both spelt wheat cultivars (*Tables 2* and *4*). In 2015, in ‘Rokosz’ cultivar the highest gluten weakening was observed in the conditions where only herbicide was used (C), and the smallest in the control treatment (A) (*Table 2*). In both years of research in the grain of ‘Schwabenspelz’ cultivar harvested from the complete chemical protection treatment (D) was found the smallest gluten weakening (*Table 4*). In 2014, the highest value of discussed parameter in grain was recorded in the treatment C, while in the second year of research (2015) in variant B (*Table 4*). Mean result from research years did not confirm statistically significant influence of crop protection on gluten weakening in the grain of both spelt wheat cultivars.

In the 2014 and 2015, gluten index of grain of studied cultivars varied significantly (*Tables 2* and *4*). In 2014, in the ‘Rokosz’ cultivar, the gluten index in the variant with complete chemical protection (treatment D) was significantly higher than in treatment C, where only the herbicide was used (*Table 2*). In 2015, the value of the discussed parameter was different, as it was the highest in the treatments C and D, while the lowest gluten index was shown in the grain from the control treatment (A). In ‘Schwabenspelz’ cultivar, in the second year of research (2015) the value of the gluten index varied significantly (*Table 4*). The highest value of this indicator was obtained in the treatment C, where only the herbicide was used, and significantly lower in the treatment A and D. Mean results from 2014-2015 showed that the use of only herbicide (treatment C) in the crop protection of spelt wheat of the ‘Schwabenspelz’ cultivar significantly affects increase in the gluten index in comparison to other crop protection methods. In both spelt wheat cultivars the statistical analysis did not confirm the effect of seeding rate on gluten weakening and the gluten index (*Tables 3* and *5*). In the case of both cultivars, the values of gluten index were below normal in all treatments of experiment.

In 2014, in ‘Schwabenspelz’ cultivar significant influence of the crop protection on the value of the Zeleny sedimentation value was demonstrated (*Table 4*). In the treatment with complete chemical crop protection (D) a significantly lower Zeleny sedimentation value was obtained compared to other treatments. In 2014, in ‘Schwabenspelz’ cultivar proved the effect of seeding rate on Zeleny sedimentation value. A negative effect on the value of this indicator had increased seeding rate (*Table 5*).

All the grain quality characteristics were statistically proven to significantly vary between the cultivars studied, except for the sedimentation value (*Table 6*). ‘Schwabenspelz’, compared to ‘Rokosz’, showed better parameters with regard to TGW, gluten content, and falling number. On the other hand, ‘Rokosz’ was characterized by a significantly higher test weight and more favourable parameters of gluten weakening and index than ‘Schwabenspelz’.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43774395

Table 6. *Quality characteristic comparison of the spelt wheat grain cultivars 'Rokosz' and 'Schwabenspelz' (mean for 2014-2015) (ns* – not significant at p≤0.05)*

Cultivar	1000 grains weight (g)	Test weight (kg hl^{-1})	Falling number (s)	Gluten content (%)	Gluten weakening (mm)	Gluten index (%)	Zeleny sedimentation value (ml)
Rokosz	32.77	76.23	335.72	24.76	2.03	51.09	16.45
Schwabenspelz	37.78	70.00	209.69	36.88	7.34	36.66	16.40
Mean	35.28	73.11	272.70	30.82	4.69	43.88	16.43
$LSD_{0.05}$ (Tukey test)	1.76	2.40	30.13	1.77	0.62	3.38	ns*

All studied parameters of both cultivars except for the gluten index and Zeleny sedimentation value differ significantly depending on the growing season (*Figure 3*). 'Rokosz' cultivar was characterized by a significantly higher TGW (A), test weight (B), falling number (C) and gluten weakening (E) in 2015 compared to 2014. Only gluten content (D) was significantly higher in the first year of experiment. In 2014 'Schwabenspelz' cultivar was characterized by significantly higher 1000 grains weight (A) and gluten content (D) than in the next year. In 2015 test weight (B), falling number (C) and gluten weakening (E) were characterized by significantly higher values.

When analysing the quality characteristics of spelt flour obtained from 'Rokosz', it was revealed that crop protection method caused significant differences in flour water absorption (*Table 7*). In all experimental treatments, the evaluated cultivars exhibited flour water absorption below 53% (*Tables 7* and *8*). For mean result from research years significantly the highest value of this trait was found in the mechanical weed management treatment (B), while it was significantly lower when complete chemical protection was applied (treatment D). In the second year of the experiment, a significant influence of the method of crop protectiom methods on degree of dough softening after 12 min was observed. Mechanical weed management (B) caused a significant increase in this parameter (121.75 min) compared to the control (A) and herbicide treatment (C). Crop protection methods did not significantly differentiate other analysed parameters of flour and dough. In both years of the experiment, a significant effect of the seeding rate of the Rokosz cultivar on the parameters of flour and dough was observed (*Table 8*). In 2014, this factor significantly differentiated only the dough development time, which was significantly longer when the optimal seeding rate was used (2.18 min). In 2015, the optimum seeding rate had a significant impact on the dough development time and dough stability, resulting in an increase of these parameters to respectively 2.18 min and 2.64 min. The degree of dough softening after 10 and after 12 min significantly increased in the variant of increased seeding rate.

During the experiment, in 'Schwabenspelz' cultivar, a significant influence of crop protection methods on flour water absorption and dough stability was observed (*Table 9*). In the first year of research, the flour obtained from the grain from the control treatment (A - 55.78%) was characterized by the highest water absorption, while in the second year of the experiment the flour obtained from harrowing treatment (B - 50.73%). In 2014, the dough made from grain harvested from the complete chemical protection treatment (D) was characterized by the highest stability, whereas in 2015 the highest value of this feature was found in the herbicide treatment (C) and in the complete chemical protection treatment (D), which did not significantly differ.

ecological crop protection variants (treatments A and B), and statistically the same as in the treatment C. Seeding rate did not significantly affect the tested parameters of flour and dough obtained from the grain of 'Schwabenspelz' cultivar (*Table 10*). In 2015, only significant differences in water absorption of flour were demonstrated. The flour from grain obtained from the increased seeding rate treatment was characterized by significantly higher water absorption compared to the optimum seeding rate treatment.

Table 9. *The impact of crop protection on farinographic features of flour and dough of the spelt wheat cultivar 'Schwabenspelz' (A[1] – control treatment, B[2] – harrowing in early spring at the beginning of the growing season, C[3] – application of the herbicides, D[4] – application of complete chemical protection, FU[5] – farinographic unit, ns[*] – not significant at $p \leq 0.05$)*

The performed variance analysis proved significant differences in dough stability and degree of softening between the cultivars evaluated (*Table 11*). 'Rokosz' was characterized by higher dough stability and a lower degree of softening after 10 and 12 min. Despite that no significant differences were revealed, this cultivar showed lower flour water absorption and shorter dough development time compared to 'Schwabenspelz'.

Table 11. *Comparison of the farinographic features of flour and dough of two cultivar of spelt wheat (mean for 2014-2015) (FU[1] – farinographic unit, ns[*] – not significant at p≤0.05)*

Cultivar	Water absorption of flour (%)	Dough development time (min)	Dough stability (min)	Degree of dough softening after 10 min (FU[1])	Degree of dough softening after 12 min (FU)
Rokosz	51.78	1.68	2.73	102.59	122.50
Schwabenspelz	52.44	1.89	1.71	129.66	152.00
Mean	52.11	1.79	2.22	116.13	137.25
$LSD_{0.05}$ (Tukey test)	ns[*]	ns	0.31	10.84	12.85

Water absorption of flour and dough development time of 'Rokosz' cultivar were significantly higher in 2014 compared to 2015 (*Figure 4*) (A-B). The other parameters of this cultivar were statistically the same (C-D). In the first year of experiment 'Schwabenspelz' cultivar was characterized significantly higher water absorption of flour and dough development time (A-B). Dough stability of this cultivar was significantly higher in 2015 compared to 2014 (C). Degree of dough softening after 10 min and after 12 min similarly to the 'Rokosz' cultivar, did not differ statistically.

The relationship between the quality characteristics and grain protein content (*Table 12*) differed for both cultivars studied.

Table 12. *Straight correlation coefficients and simple regressions for the relationship between protein content (x) and qualitative characteristics (y) of grain, flour and dough of two cultivars of winter spelt (n=16) (r_{emp}[1] – Pearson correlation coefficient, R^2 – coefficient of determination, FU[3] – farinographic unit, * – significance level 0.05, ** – 0.01, *** – 0.001)*

Quality parametr	r_{emp}[1]	Significance	R^2	Regression equation
Rokosz				
Gluten content (%)	+0.81	***	0.76	$y = -19.8 + 0.431x$
Gluten weakening (mm)	−0.61	*	0.66	$y = 10.4 - 0.0813x$
Zeleny sedimentation value (ml)	+0.53	*	0.34	$y = 10.8 + 0.0514x$
Dough development time (min)	+0.71	**	0.82	$y = -1.06 + 0.0268x$
Schwabenspelz				
Gluten content (%)	+0.76	***	0.56	$y = 8.18 + 0.223x$
Dough stability (min)	−0.65	**	0.38	$y = 3.15 - 0.0112x$
Degree of dough softening after 12 min (FU[3])	+0.52	*	0.42	$y = 61.8 + 0.707x$

In 'Rokosz', with increasing protein content the amount of gluten, flour sedimentation, and dough development time increased, whereas gluten weakening decreased – which is evidence of its better quality. The values of determination

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43774395

coefficients (R^2) indicate that from 34% to 82% of the variability of these features is explained by the presented regression equations. 'Schwabenpeltz' was characterized by a positive relationship between protein content and gluten content – 56% of the variability was explained by the regression equation. As regards the other characteristics for which a statistically proven relationship was found (dough stability and weakening), gluten quality deteriorated with increasing protein content.

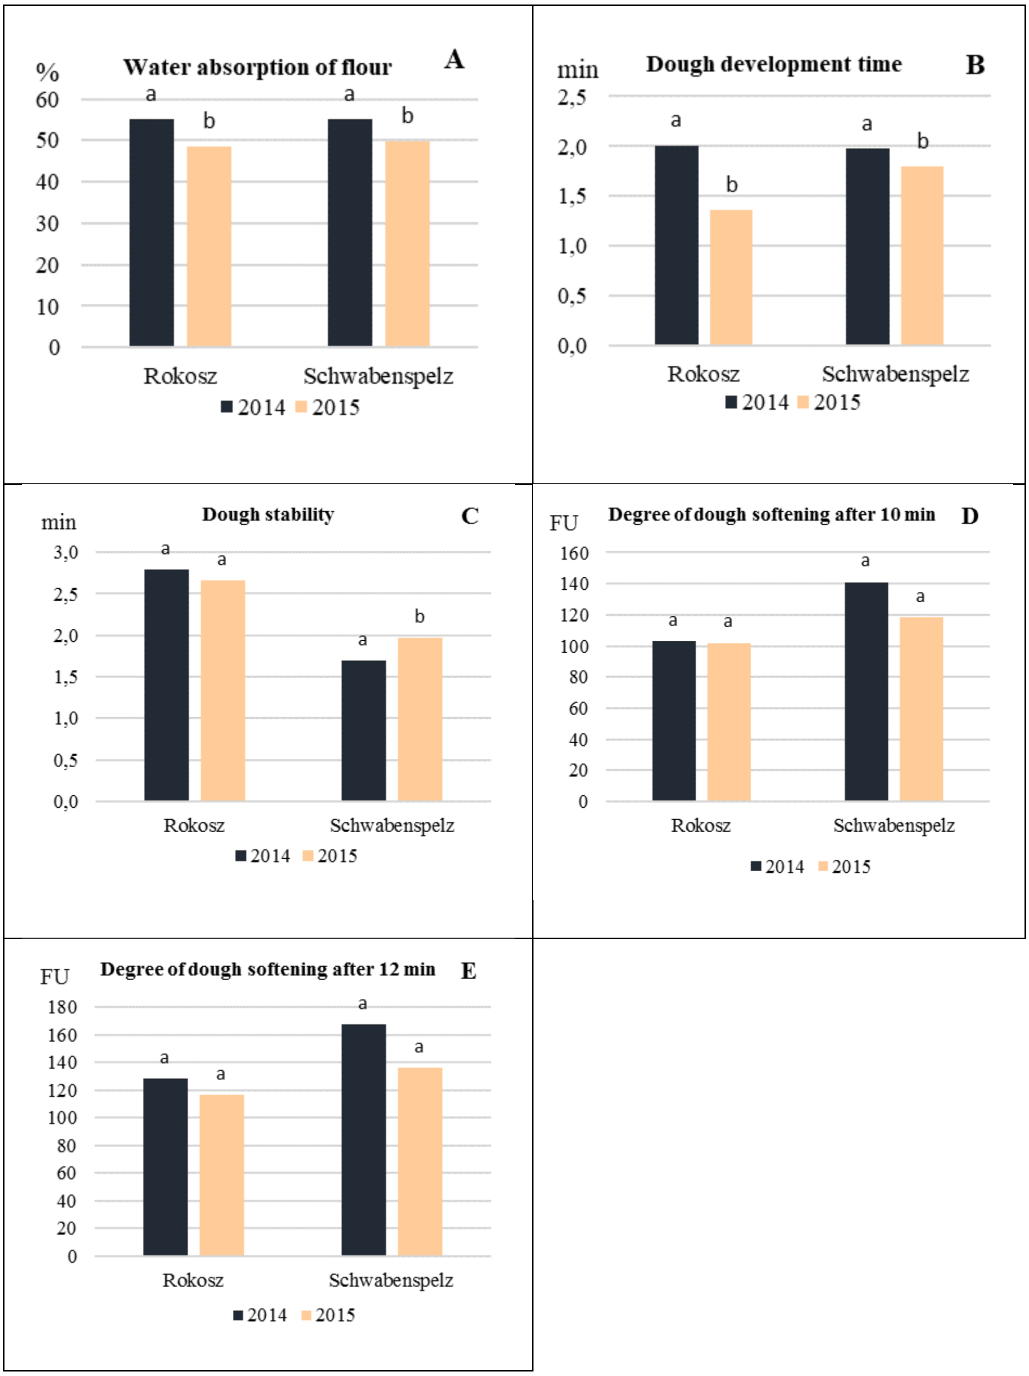

Figure 4. *(A-E) Farinographic features of flour and dough of the spelt wheat cultivars 'Rokosz' and 'Schwabenspelz' during the study years (independent on experimental factors) (different letters indicate significant difference at* $p \leq 0.05$*)*

Discussion

Grain size is characterized by TGW. In the present study, TGW of cultivar 'Rokosz' was 32.77 g, while for 'Schwabenspelz' it was 37.78 g. The values of this trait were lower than those obtained by Capouchová (2001) (TGW = 52-54 g), Krawczyk et al. (2008b) (TGW = 38.7-52.7 g), Biel et al. (2016b) (TGW = 38.5-46.2 g), Andruszczak (2017) (39.3-50.7 g) and Petrenko et. al. (2018) (TGW = 56.5–56.7 g). As regards the test weight of 'Rokosz' grain, other authors reported similar values of the trait in question for different spelt wheat cultivars (Bastard, Oberlander, Burgdorf, Weisser, Schweizer, and Schwabenkorn) and lines (Makowska et al., 2008; Krawczyk et al., 2008b; Podolska et al., 2015; Biel et al., 2016b; Stankowski et al., 2016; Petrenko et al., 2018). Podolska et al. (2015) and Dorval et al. (2015) did not show seeding rate to have a significant effect on 1000 grain weight.

Falling number is a measure of α-amylase activity (the higher the falling number, the lower the activity) (Rachoń et al., 2011). The processing suitability of flour can be determined on this basis. In this study, the falling number for 'Rokosz' was 335.72 s, whereas for 'Schwabenspelz' 209.69 s, which is evidence of the latter cultivar's higher amylolytic activity. Podolska et al. (2015) obtained slightly lower values for 'Rokosz', whereas the grain falling number of other cultivars and lines studied by Stankowski et al. (2016) ranged from 188 to 308 s, Biel et al. (2016b) – 134-295 s, Rachoń et al. (2016) – 334 s, Krawczyk et al. (2008b) – 259-287 s, and Petrenko et al. (2018) – 287-303 s. Dorval et al. (2015) did not show seeding rate to have a significant effect on this parameter.

Gluten content and quality are an important indicator of baking quality of flour because they give proper elasticity to dough, and a spongy structure and springiness to bread. The average gluten content in 'Rokosz' spelt grain tested was 24.76% and weakening was 2.03 mm, whereas in 'Schwabenspelz' grain these values were 36.88% and 7.34 mm, respectively. Rachoń et al. (2013) found a significantly higher gluten content in spelt grain as affected by complete chemical protection (42.5%) compared to the herbicide treatment (37.2%). In other study, Rachoń et al. (2016) showed an increased content of gluten (44.9%) in wheat grain spelt under the influence of increased chemical protection intensity. In the study by Podolska et al. (2015), an increasing trend in the amount of gluten in 'Rokosz' grain was observed with a simultaneous increase in the seeding rate from 400 to 500 seeds per 1 m^2. It was only when 600 seeds were sown that a significant decrease in this parameter occurred. These authors found much higher gluten weakening (6.3-6.5 mm) than in the present study, but seeding rate did not cause significant differences in this trait. Andruszczak (2018) did not find a significant effect of seeding rate on the content of gluten in the spring spelt grain.

Gluten index shows the quality of gluten and what grain and flour can be used for. Wheat flour used to make bakery products should be characterized by the gluten index at a level of 60-90%. Determinations above and below this range indicate low baking quality (Stępniewska, 2015). This study showed the gluten index of 'Rokosz' (51.09%) to be significantly higher than in 'Schwabenspelz' (36.66%), but these values do not qualify the cultivars in question for material of high baking value. Podolska et al. (2015) found similar values of this indicator and seeding density did not result in significant differences in it.

The Zeleny sedimentation value was almost identical in both cultivars, averaging 16.43 ml, and the experimental factors did not cause variations in it. In the study by

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43774395

Stankowski et al. (2016), lower values of the investigated trait were observed (14.5 ml) compared to the present study. On the other hand, Podolska et al. (2004), who proved a significant increase in values of the parameter studied with increasing intensity of chemical crop protection, found a higher sedimentation value. Likewise, Andruszczak (2017) demonstrated that under complete chemical crop protection spelt wheat was characterized by a significantly higher sedimentation index than under extensive cropping conditions. Krawczyk et al. (2008a) proved that the Zeleny sedimentation value of the studied cultivars and lines ranged 30-40 ml. In the study on the cultivar 'Rokosz' conducted by Podolska et al. (2015), this value was at a level of 29-29.5 ml and it was not dependent on seeding rate. Andruszczak (2018) also did not find a significant effect of seeding rate on this parameter. Rachoń et al. (2011) obtained similar values for line STH 3 (28.2 ml), whereas for line 715 they were significantly lower (20.7 ml).

According to Mikos and Podolska (2012), water absorption of spelt flour may reach even 65%. 'Schwabenpeltz' was characterized by slightly higher flour water absorption compared to 'Rokosz', which is evidence of higher dough yield (*Table 6*). In the study by Podolska et al. (2015), in which seeding rate did not affect significantly this parameter, similar results were obtained (53-53.3%). The spelt wheat lines evaluated by Rachoń et al. (2011) exhibited slightly higher water absorption (56.7-59%). Cultivar 'Blauer Samtiger'evaluated in other study by Rachoń et al. (2016) are also characterized by a higher water absorption (65.2%) than in the present study.

Dough stability is one of dough quality indicators and characterizes the resistance of flour to mixing (Rachoń et al., 2011). In 'Rokosz', this parameter was on average 2.73 min and significantly higher than in 'Schwabenspelz' (1.71 min) (*Table 6*). Information on higher values of the trait in question can be found in available scientific literature. The studies by Biel et al. (2016b), Rachoń et al. (2016) and Stanowski et al. (2016) demonstrated dough stability values at a level of 3.5, 5.8 and 4.48 min, respectively. Podolska et al. (2015) did not show seeding rate to have a significant effect on this parameter, but a decreasing trend in these values could be observed with increasing plant density – from 3.2 min at a seeding rate of 400 seeds per 1 m^2 up to 3.0 at a rate of 600 seeds. The higher the sum of the dough development time and dough stability, the longer the dough should be mixed. Therefore, spelt doughs require longer mixing than doughs made of common wheat flour (Krawczyk et al., 2008a).

The variance analysis proved significant differences in the degree of softening between the cultivars evaluated (*Table 6*). 'Schwabenspelz', compared to 'Rokosz', showed longer development time and a higher degree of softening. A higher value of the trait in question was obtained in the research conducted by Makowska et al. (2008) and Stankowski et al. (2016), which indicates that dough is characterized by a high degree of softening. Evaluating 5 spelt wheat cultivars, Makowska et al. (2008) demonstrated that their degree of softening was at a level of 107-142 FU, whereas in the study by Stankowski et al. (2016) it was on average 95.9 FU after 10 min and 122 FU after 12 min. According to Wiwart et al. (2017) and Geisslitz et al. (2018), only some cultivars of spelt wheat have high breadmaking potential.

Similarly as in the present study, spelt wheat cultivars are characterized by high variation in chemical composition and grain technological quality also in the evaluation of other authors (Capouchová, 2001; Lacko-Bartošová et al., 2010; Świeca et al., 2014; Andruszczak, 2017). Weather conditions also have a great impact on grain quality of this species since they additionally increase intervarietal variation (Lacko-Bartošová et

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43774395

al., 2010; Wojtkowiak and Stępień, 2015). According to Pruska-Kędzior et al. (2008), in technological terms spelt wheat can be considered among the most valuable cereals. Most authors stress that it is a species that tolerates well extensive cropping without plant protection chemicals and is characterized by favourable grain and flour characteristics under organic farming conditions (Capouchová, 2001; Kwiatkowski et al., 2015). Nevertheless, Andruszczak (2017) demonstrated that application of complete chemical crop protection contributed to an improvement in some grain quality parameters.

Conclusions

The present study showed that crop protection method and seeding rate did not cause most of the quality characteristics of spelt grain and flour to significantly vary. Both the Polish cultivar 'Rokosz' and the German cultivar 'Schwabenspelz' exhibited similar technological quality of grain and flour under organic farming and chemical crop protection conditions. Therefore, both these cultivars can be recommended for cultivation in organic farms. In 'Rokosz', gluten content, Zeleny sedimentation value, and dough development time increased with increasing protein content, whereas gluten weakening decreased, which is evidence of better quality and baking value of this cultivar relative to 'Schwabenspelz'.

Currently, there is a continuous necessity to look for effective agrotechnical solutions that can be introduced to the organic farming. Due to the high nutritional value of spelt wheat and its usefulness for tillage under organic farming conditions, it is necessary to select cultivars of this species that best tolerate pro-ecological cultivation and which are characterized by the high technological values. It seems be necessary to undertake research into non-chemical methods of limiting the presence of pests, such as: sowing rate, mechanical crop protection, use of biostimulators, etc. in this crop.

(Received 9th Jan 2019; accepted 26th Feb 2019)

Abstract. This paper deals with the effects of *Trichoderma harzianum* application and boron (Nitrabor) topdressing on the growth, yield, and quality of spring broccoli. A field experiment was carried out in central-eastern Poland, in 2014-2015.The experiment was established as a split-block design with three replicates. There were the following combinations of *Trichoderma harzianum* treatment: added to the nursery substrate; added to the nursery substrate and as topdressing in a form of spray after seedlings were planted out; as pre-planting treatment just before seedlings were planted out, followed by topdressing in a form of spray; control without *Trichoderma harzianum*. Two types of late topdressing for broccoli were used: nitrogen topdressing or Nitrabor to the soil. The treatment significantly increased the marketable yield of broccoli curds. This increase relative to control ranged from 17 to 49%, depending on the *Trichoderma harzianum* treatment. The best results were obtained when boron topdressing was combined with *Trichoderma harzianum* added to the nursery substrate and then the fungus was applied in a form of spray after seedlings were planted out. Broccoli inoculation with *Trichoderma harzianum* also increased L-Ascorbic acid content in the plants. Topdressing with boron significantly increased the marketable yield of curds, their weight, the diameter of their circumference, the diameter of the stem, the leaf greenness index value (SPAD), as well as the content of dry matter, total sugars, and L-Ascorbic acid.
Keywords: *bio-stimulators, Brassica oleracea L. var. italica, mineral fertilization, nutritional value, yield*

Introduction

Broccoli (*Brassica oleracea* var. *italica*) is an important vegetable grown worldwide. The plant originates from the Mediterranean region and belongs to the *Brassicaceae* family. It is tasty and more nutritious than any other vegetables of the same kind, considered a valuable source of vitamins, antioxidants, glucosinolates, and other compounds of proven anticancer activity (Parente et al., 2013). Broccoli is an important component of human healthy diet, and demand for this vegetable on Polish and international markets is constantly growing. Its producers use new growing methods enhancing its growth and improving its quality. Hence, there is a need for research to improve the yield of broccoli and to increase its production; some biological agents should be implemented either on their own, or in combination with mineral fertilisers to increase its cultivation and production.

Among various biological methods currently used, microbial inoculants applied at the seedling stage could prove promising. Several symbionts like arbuscular mycorrhizal fungi and *Trichoderma* ssp. can be implemented for broccoli cultivation.

The efficacy of *Trichoderma* as a biostimulator agent has been proven when fungal species have been applied to soil, seeds, or plants. Their benefits are related to increased

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43974407

nutrient solubility, improved nutrient uptake by roots, and to the mode of action of plant growth promoting bacteria (Molla et al., 2012; Martínez et al., 2015). *Trichoderma harzianum* releases volatile organic antibiotic compounds against pathogenic fungi, and it also stimulates plant growth (Vinale et al., 2008). *Trichoderma* species improve the growth and development of plants grown in vitro, in greenhouses, and in the field. Some studies have demonstrated beneficial effects of *Trichoderma* spp. on vegetable plants, like cabbage, cucumber, tomato, and lettuce, stimulating seed germination, or vegetative and generative growth (Bal and Altintas, 2006; Studholme et al., 2013).

Boron represents one of the essential micronutrients necessary for proper plant growth, the latter becoming limited both when it is deficient or at elevated level (Davies et al., 2011). It increases the growth and yield of plants because it stimulates division and elongation of the cell and development of its walls. Boron plays an important role in the metabolism of carbohydrates and proteins (Goldbach and Wimmer, 2007; Miwa et al., 2007). It is also crucial for the development of nitrogen-fixing cyanobacteria (Bolanos et al., 1996; Bonilla et al., 1997). Boron deficiency causes many anatomical, physiological, and biological disorders (Brown et al., 2002; Xu et al., 2007). Vegetable plants with the highest demand for boron include, among others, broccoli.

The natural content of boron in the soil depends mainly on the type of material from which it has developed. Clay soils are generally rich in boron, in contrast to sandy ones, in which this chemical element may be present in small amounts. Boron concentration in soils varies from 2 to 200 mg B kg^{-1}, but generally less than 5-10% of its content is in a form available to plants (Diana, 2006). In Poland sandy soils dominate, and with the content of this chemical element being too small it is necessary to apply boron with mineral fertilizers to the soil or as a foliar spray (Szulc and Rutkowska, 2013).

The purpose of this research was to determine the effect of *Trichoderma harzianum*, applied as a biostimulator to nursery substrate and after seedlings were planted out, and of boron topdressing on the size and quality of the broccoli yield.

Material and methods

Experimental site

The experiment was carried out between 2014 and 2015 at the Experimental Station of the Siedlce University of Natural Sciences and Humanities, located in central-eastern Poland (52°03'N, 22°33'E). The soil was classified as luvisol (IUSS, 2015) with the average organic carbon content of 0.97%, the humus layer reaching the depth of 30-40 cm, and pH_{KCl} of 6.0. The content of available forms of nutrients ($mg \cdot kg^{-1}$) was as follows: 4.7 NO_3-N, 2.5 NH_4-N, 12 P, 27 K, 10.8 Mg, 87.5 Ca, 0.11 B.

Experimental design

The experiment was established as a split-block design with three replicates, and it included two factors: factor I – mineral fertiliser, factor II – different methods of using *Trichoderma harzianum* (*Table 1*). The studies used Trianum-G and Trianum-P produced by the Koppert B.V. company (Netherlands). Trianum-G is microbiological granular containing spores of *Trichoderma harzianum (T. harzianum)* Strain T-22 Rifai (1.5×10^8 spores per 1 g). It is insoluble in water and used as pre-planting treatment, mixing granules with the soil. Trianum-P is a microbiological product in a form of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43974407

granules to prepare aqueous suspension. It contains 1.5 × 10^9 spores of *T. harzianum* Strain T-22 Rifai per 1 g. The combinations of Trianum-G and Trianum-P application are presented in *Table 1*. In the experiment both Trianum-G and Trianum-P were used in doses recommended by the manufacturer. Nitrabor (Yara Poland) contains calcium nitrate with 15.4% N (including 14.1% NO_3-N and 1.3% NH_4-N), 25.6% CaO, and 0.3% B. It is recommended for use on vegetable plants, especially on species that require increased doses of boron.

***Table 1.** Factors of the experiment*

	Two mineral fertiliser combinations	
Factor I	NPK	Basic pre-planting treatment NPK (206 kg N, 146 kg P_2O_5, 273 kg K_2O per 1 ha – in the form of ammonium nitrate, granular superphosphate and 60% potassium chloride, respectively) + nitrogen topdressing to the soil (62 kg·ha^{-1} – in the form of ammonium nitrate)
	NPK+B	Basic pre-planting treatment NPK (206 kg N, 146 kg P_2O_5, 273 kg K_2O per 1 ha – in the form of ammonium nitrate, granular superphosphate and 60% potassium chloride, respectively) + Nitrabor topdressing to the soil (400 kg·ha^{-1})
	Five combinations with *Trichoderma harzianum*	
Factor II	Th_0	control – without *Trichoderma harzianum*
	Th_1	*T. harzianum* added to the substrate before planting seeds (Trianum-G 750 g per 1 m^3 of the substrate)
	Th_2	*T. harzianum* added to the substrate + spraying plants in the field with *Trichoderma harzianum* (Trianum-G 750 g per 1 m^3 of the substrate + Trianum-P 40 g·100 m^{-2} dissolved in 15 dm^3 H_2O, plants sprayed 21 days after transplanting seedlings to the field)
	Th_3	*T. harzianum* added to the soil before transplanting seedlings (Trianum-G 1 g per 1 plant)
	Th_4	*T. harzianum* added to the soil before transplanting seedlings + spraying plants in the field with *Trichoderma harzianum* (Trianum-G 1 g per 1 plant + Trianum-P 40 g·100 m^{-2} dissolved in 15 dm^3 H_2O, plants sprayed 21 days after transplanting seedlings to the field)

Seedling preparation

Broccoli seedlings 'Wiarus' (PNOS, Poland) were grown in a non-heated greenhouse. Seeds were sown in the successive growing seasons on 17 and 20 March to multi-trays with the size of 400 × 600 mm and 54 cells with the diameter of 54 mm. 60% of the seedlings were produced on substrate without *Trichoderma harzianum*, and 40% on substrate with *Trichoderma harzianum* (Trianum-G). The Aura substrate produced by Hollas - Greenyard Horticulture Poland Ltd. was used for the production of seedlings. It was made of de-acidified 'highmoor' peat with 5.5-6.5 pH and salinity not greater than 2 g NaCl per litre. The substrate was enriched with mineral fertiliser containing NPK (14-16-18%) and Mg (5%). On average nutrient content in the substrate was as follows (in mg·dm^{-3}): 238 NO_3-N, 18 NH_4-N, 70 P, 207 K, 1016 Ca, and 158 Mg.

Field work

The crop preceding broccoli was triticale. In the autumn the field was ploughed, and in the spring, two weeks before seedlings were planted, disc harrowing was used. After that, mineral fertilizers were applied up to the optimal level for broccoli: 206 kg N, 146 kg P_2O_5, 273 kg K_2O per 1 ha. Seedlings were planted on 18 and 22 April, at a spacing of 50 × 50 cm. The area of a plot (unit) was 9 m^2 (3 m × 3 m), with 36 plants in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43974407

each of them. The area of the whole field together with paths between experimental combinations and replicates was 650 m^2. Then *Trichoderma harzianum* was added to adequate plots, in accordance with the combinations set out in *Table 1*. For three weeks the plants were covered with Pegas Agro 17UV polypropylene fibre (Rybnik, Poland). After removing the fibre the plants were topdressed with mineral fertilizers. To plants with the NPK treatment 62 $kg \cdot ha^{-1}$ of nitrogen was applied (the same amount of nitrogen as the NPK applied, together with B, in a form of Nitrabor. On the NPK+B combination a Nitrabor dose of 400 $kg \cdot ha^{-1}$ was used, which made it 1.2 $kg \cdot ha^{-1}$ of Boron. The Nitabor dose to be applied in the experiment had been determined by taking into account boron content in the soil and in the fertilizer, as well as broccoli requirements for this chemical element. 21 days after planting seedlings *Trichoderma harzianum* was applied as a spray to Th_2 and Th_4 combinations (*Table 1*).

Sample collection and laboratory analysis

Broccoli was harvested by hand on 12 June in 2014, and on 11 June in 2015. The area of each plot to be harvested was 3 m^2. Marketable yield, weight of marketable curd, length of curd circumference, and stalk diameter were determined during the harvest. From each plot a broccoli sample was also taken (four randomly selected curds) for chemical analysis to determine: dry matter content by drying to the constant weight at 105°C; L-ascorbic acid content with the Tillmans method (PN-A-04019, 1998); monosaccharide content with the Luff-Schoorl method (EU, 2009); protein content with the Kjeldahl method (using a factor of 6.25). Seven days before the plants were harvested the leaf greenness index (SPAD) of broccoli curds was measured with SPAD-502 Plus Chlorophyll Meter (Konica Minolta Inc., Tokyo, Japan).

Statistical analysis

The results were statistically processed with ANOVA for the split-block design. The significance of differences was determined with Tukey's test at the significance level of $P \leq 0.05$. All the calculations were performed with Statistica software (version 10, Statsoft, USA).

Weather conditions

The basic weather conditions of the experimental area in individual experimental years are presented in *Table 2*. To assess pluvio-thermal conditions during the growing season Selyaninov's hydrothermal coefficient was calculated (Eq. 1):

$$K = \frac{M_O \times 10}{D_t \times days} \qquad \text{(Eq.1)}$$

where: K – hydrothermal coefficient for individual months; M_o – total monthly precipitation; D_t – mean daily temperatures in a particular month (Szymańska et al., 2017).

During the broccoli growing season from April to June 2014 the air temperatures and rainfall were higher than in 2015. However, the second year, 2015, turned out to be more favourable for broccoli growth. High air temperatures during the final ten days of April and in May 2014 negatively affected survival and growth of seedlings despite the large amount of rainfall. This translated into the smaller yield of curds.

June	15.3	55.4	1.20 qd	16.5	43.3	0.87 d
Mean	12.9	-	-	12.3	-	-
Total	-	192.8	-	-	173.7	-

T – temperature; P – precipitation; K – Sielyaninov's hydrothermal index: d – dry, qd – quite dry, o – optimum, h – humid, vh – very humid

Results and discussion

For two years of the research the marketable yield of broccoli curds was on average 13.1 $t{\cdot}ha^{-1}$, and the mass of the marketable curd was 352.5 g (*Table 3*). In 2015, when weather conditions for broccoli growth were more favourable, the yield was 20.2% higher than in 2014.

Table 3. *The effect of different treatment combinations on the yield of broccoli and the weight of curds*

Similarly, the weight of the marketable curd was significantly higher. Inoculation of broccoli with *Trichoderma harzianum* contributed to the growth of the marketable yield of curds relative to uninoculated control. The effect was especially visible in 2015, when a significant increase in the yield compared to control was observed on all combinations of *T. harzianum*, regardless of the manner of application. The average increase in the curd yield for both years ranged from 17.5 to 49%, with the highest for

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43974407

the Th_2 combination (*T. harzianum* added to the nursery substrate and as topdressing in a form of spray after seedlings were planted out). The beneficial effect of broccoli inoculation with *T. harzianum* on the curd marketable yield was recorded only in 2015. Tanwar et al. (2013) also noted a significant increase in the weight and size of broccoli curds as a response to inoculation with *Trichoderma viride*. Abd Alla and El-Shoraky (2017) found a significant increase in the yields of white cabbage and cauliflower after *Trichoderma harzianum* inoculation. Altintas and Bal (2008) noted an upward trend in the yield of onion after applying *T. harzianum*, but the increase, when compared with control, was not statistically significant.

Regardless of the manner of *Trichoderma harzianum* application there was a beneficial effects of boron treatment on broccoli yields. The marketable curd yield on plots with Nitrabor (NPK+B) increased on average by 2.68 $t \cdot ha^{-1}$ in relation to the combinations without boron (NPK). The largest marketable yield was reported after combined application of *Trichoderma harzianum* (Th_2) and NPK+B topdressing. An increase in the yield of broccoli curd as a response to boron application was also noted by Moniruzzaman et al. (2007), Hussain et al. (2012), Singh et al. (2015), Islam et al. (2015) and Farooq et al. (2018). Additionally, Moniruzzaman et al. (2007), Hussain et al. (2012) and Singh et al. (2015) observed a statistically significant increase in the mass of curds. Optimum levels of NPK and boron applied to broccoli positively affect photosynthetic efficiency and improve other processes like enzyme activation, protein and carbohydrate accumulation, and translocation of sugar and starch; because of all that the yield also increases (Shahah et al., 2010; Singh et al., 2015).

There was no effect of *Trichoderma harzianum* on the curd circumference length and stem diameter. It was noted, however, that the SPAD value evolved under the influence of the inoculation, depending on how it was applied (*Table 4*).

Compared to control a significant SPAD increase was reported on Th_2 and Th_4 combinations, where *T. harzianum* was applied additionally as a spray. The results indicated that this kind of treatment increased the amount of nitrogen taken up by plants. A significant increase in chlorophyll content in broccoli leaves after vaccination of the substrate with *Trichoderma viride* was noted, among others, by Tanwar et al. (2013). Harman et al. (2012) and Hermosa et al. (2012) report that *Trichoderma* strains colonise plant roots, establishing chemical communication and systemically altering the expression of numerous plant genes that alter plant physiology and may result in the improvement of abiotic stress resistance, nitrogen fertiliser uptake, and photosynthetic efficiency.

Both NPK+B topdressing significantly increased curd circumference length, the diameter of the stem, and the SPAD value compared with the basic fertilization (*Table 4*). Similar results were obtained by Husain et al. (2012) and Singh et al. (2015). Regardless of the dose size, they recorded a significant increase in the diameter of broccoli curds and stems after boron treatment. Similarly, Chatterjee and Bandyopadhyay (2017) recorded a significant SPAD increase in cowpea after boron application. The increase was directly proportional to the applied doses. In the present experiment, there was no significant effect of the interaction of *T. harzianum* and boron on the circumference length, the diameter of the stem, and the SPAD value.

The average content of dry matter in broccoli curds was 11.61%, with protein constituting 4.04% in fresh matter (FM), total sugars 2.66 $g{\cdot}100g^{-1}$ FM, and monosaccharides 1.68 $g{\cdot}100g^{-1}$ FM (*Table 5*).

Table 5. *The effect of different treatment combinations on dry matter, protein, and sugar content in broccoli*

DOI: http://dx.doi.org/10.15666/aeer/1702_43974407

There was no significant effect of *Trichoderma harzianum* inoculation on the above content. However, the amount of dry matter and total sugars in plants was dependent on fertilizer treatment. Broccoli plants treated with boron contained significantly more dry matter and less total sugars than those grown without the Nitrabor fertilizer. A significant increase in dry matter content in broccoli curds as a response to boron was also noted by Islam et al. (2015). Ningawale et al. (2016) recorded an increase in dry matter content in cauliflower heads treated with Borax, but the increase was statistically insignificant. In the studies of Patel et al. (2017) broccoli treated with boron and without it had similar content of sugars, but Meena et al. (2015) found a significant increase in the content of total sugars and monosachcarides in the fruits of tomato treated with this chemical element. In the present experiment there was no significant effect of the interaction between *T. harzianum* and boron on the content of dry matter, protein, and sugars in broccoli. It was found, however, that weather conditions throughout the research differentiated the content of dry matter and monosaccharides in broccoli curds. In 2014 dry matter content was lower and monosaccharide content was greater than in 2015.

Ascorbic acid (AA) content in broccoli curds was on average 67.20 mg per 100 g FM (*Table 6*). With 2.95 mg·100g^{-1} FM in 2014 it was higher than in 2015, and this difference was statistically significant. There was a significant effect of broccoli inoculation with *Trichoderma harzianum* on AA content. On average, for both growing seasons, broccoli grown on plots with *T. harzianum* contained more AA than on the control plot. In the case of Th_2 and Th_3 combinations these differences were statistically significant. The beneficial effect of *T. harzianum* on AA content in broccoli was especially visible in 2015. Similarly, in the studies of Hale et al. (2012) it was found that *T. harzianum,* added to compost and applied in a form of solution in the cultivation of tomato, significantly influenced the growth of the content of AA, protein, and total sugars in fruits.

Table 6. *The effect of different treatment combinations on ascorbic acid content in broccoli (mg 100·g^{-1} FM)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43974407

A significant increase in AA content (on average by 1.35%) in broccoli was also noted after application of Nitrabor, a fertilizer containing boron. Beneficial effects of boron on the content of ascorbic acid in broccoli was also observed by Islam et al. (2015), and in the fruit of tomato by Lester (2006). However, in the studies of Patel et al. (2017) and Meena et al. (2015) there were no significant changes in the content of vitamin C in broccoli heads and tomato fruits after boron treatment, compared to plants treated with basic fertilizer.

Combined application of *T. harzianum* and boron had a significant impact on the amount of ascorbic acid. The highest amount of AA was recorded in plants topdressed with boron and with *T. harzianum* added to the substrate during seedling production and then sprayed on plants in the field (Th_2), and when *T. harzianum* were applied in the field first as pre-planting treatment and then as a spray (Th_4).

Conclusions

1. Trichoderma harzianum, irrespective of the application combination, had a significant impact on the growth of the marketable broccoli curd yield.
2. The highest yield increase was recorded after applying Trichoderma harzianum to seedling substrate, supplemented with spraying plants with Trichoderma harzianum during their growth. Favourable yield parameters resulted from greener leaves, with more efficient photosynthetic production.
3. Boron nutrition favourably affected yield parameters studied in the experiment. As a chemical element affecting synthesis and transport of carbohydrates boron contributed to a substantial increase in the curd marketable yield (on average by 16.2%), curd weight (on average by 4.6%) and an increase in the content of dry matter, total sugars, and L-Ascorbic acid in broccoli tissues in comparison to that after mineral fertilization without the addition of boron.
4. In the production of broccoli, the use of Trichoderma harzianum can be recommended, especially as a combined application, first to the seedling substrate, and then in a form of spray in the field, supplemented with boron.

21280 Diyarbakır, Turkey
(e-mail: tutkunmuhittin@yahoo.com; phone: +90-412-241-1000; fax: +90-412-241-1048)

(Received 31st Jan 2019; accepted 28th Feb 2019)

Abstract. This study aimed to determine the best model to explain the variations in the live weight of Holstein bulls using non-linear function models such as Brody's, Gompertz's and Richards Logistic. For this purpose, live weight records of 51 Holstein Fresian male calves reared in Dicle University Cattle Research Farm were used. In order to estimate the best model, the coefficient of determination (R^2) and the residual mean squares (RMS) statistics were utilized. The coefficient of determination (R^2) for Gompertz's, Richards Logistic and von Bertalanffy models were found to be 0.999, 0.999, 0.998 and 0.999 respectively. Residual mean squared were found to be 21.41, 16.82, 50.94 and 22.21, respectively. As a result, the Richards model used in the study was found to be the best fitted model based on RMS and R^2 criteria. It is the more suitable model due to its accurate ability to predict mature weight, which is an important selection goal.
Keywords: *bodyweight, growth, Holstein bull, inflection point, Richards*

Introduction

The increase in size, number or mass with time is the primary definition of growth but does not include the phenomenology and etiology of growth, such as the energy transactions in the growing animal including metabolism, nutrition and genetics (Parks, 1982).

Growth is usually defined as an increase in tissue mass caused by hyperplasia early in life and hypertrophy later in life (Owens et al., 1995). The accurate knowledge of the growth curve is important due to its relation with the efficiency of production (Fitzhugh, 1976).

Prediction of growth in animals can be found by age-weight graphical plotting using mathematical models (Bathaei and Leory 1996).

Growth curve study in cattle has mainly used non-linear models that relate the animal weights to ages (Garnero et al., 2006; Forni et al., 2009; Souza et al., 2010).

In beef cattle, different equations for growth model have been used and compared in Hereford (Brown et al., 1976), Angus (Beltran et al., 1992), Retinta Cattle (López de Torre et al., 1992), Belgian Blue (Behr et al., 2001), Salers (Garcia et al., 2008) and Nelore (Forni et al., 2009).

The many equations that have been used to predict growth for cattle include Gompertz, Robertson's logistic, Brody, Bertalanfy, Feller, Weiss and Kavanau, Fitzhugh, Richards, Laird, and Parks equations. Detailed descriptions for the models were summarized by Parks in 1982. The most used models to describe growth patterns in beef cattle are: Brody, Bertalanfy, logistic, Gompertz and Richards (Brown et al., 1976, Fitzhugh Jr 1976). Difficulties in obtaining convergences within Richards and Janoschek functions have been reported by Sarmento et al. (2006).

The objective of the study was to assess and compare the non-linear models by Gompertz, Richards and Logistic for goodness of fit of the weight-age data for Holstein Frisan bulls.

Materials and methods

The experiment was conducted in Dicle University, Cattle Research Center in Diyarbakir Province, Turkey (37°57'41 N and 40°13'54 E, 650 m asl) (*Figure 1*).

Figure 1. *Study location map*

The material of this study consisted of monthly live weight records of 51 Holstein Fresian male calves from 4th. to16th. month reared in Dicle University Cattle Research Farm. The research did not require the Bioethical Committee's Certification.

The study material consisted of monthly live weight and body measurement records of 51 male Holstein-Friesian bulls collected between the years 2016 and 2018. The study was carried out in two different locations. First stage was between the days born-120 d. in private farm and second was in Cattle Research Farm of Dicle University. Calves born in private dairy farm received milk as much as 10% of their body weight with starter feed after 2 weeks. Calves were weaned at the 9th of weeks. Different amounts of concentrate and roughage were provided ad libitum to the bulls considering the average live weights obtained from the monthly measurements.

All data of means and standard errors of weights during different age stages were analyzed using SPSS (Statistical Package for the Social Sciences, version 10). Non-linear models of Gompertz (1825), Richards (1959), von Bertalanffy (1957) and the Logistic model introduced by Verhulst (1838) were fitted to the weight-age data using non-linear regression procedure option.

Assessment of goodness of fit among three models was applied having the highest determination coefficient (R^2) percentage. Models parameters (A, b, k, and M) were iterated at a set of a maximum of 150 times the initial of their values using the Levenberg-Marquardt method option.

The used model functions (Gompertz, Richards, Logistic and von Bertalanffy) to fit Holstein male growth curve present in *Table 1*.

Table 1. *Non-linear functions used for modeling the growth curves [Yt= weight (kg) at time (month). A= asymptotic weight. b= scale parameter. k= maturing index. e= logarithm base. m= inflection point. ε = random error]*

Model	Function
Gompertz	$Y_t = Ae^{-b\exp(-kt)} + \varepsilon$
Richards	$Y_t = A(1 - be^{-kt})^m + \varepsilon$
Logistic	$Y_t = A(1 + e^{(-kt)})^{-1} + \varepsilon$
Von Bertalanffy	$Y_t = A*(1-B*\exp(-k*t))^3$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44094416

In the mathematical expressions, yt represents the weight of the animal at a given age (t); parameter A is the asymptotic weight, if $t \rightarrow \infty$; when the adult weight of the animal is not reached, this reflects in an estimate of the weight of the last weighings; b is a constant without biological interpretation, but it is important to model the sigmoidal format of the growth curve from birth (t = 0) until the adult age of the animal ($t \rightarrow \infty$); K is the maturity index, which expresses the ratio of the maximum growth rate in relation to the adult size, where lower k values indicate delayed maturities and higher k values indicate accelerated maturity; M is the parameter that shapes the curve; e is the natural base logarithm; the L parameter has no biological meaning, but together with K constitutes b, which has the function of modeling the sigmoidal curve; and ε represents the random error associated with each weighing (Marinho et al., 2013)

The statistical criteria and biological interpretation of the parameters were used to compare the non-linear models for goodness of fit. The statistical criterias were mean square error (MSE) and coefficient of determination (R^2).

Weight and age at the point of inflection were calculated as *Eq.1* for logistic; *Eq.2* for Gompertz; and *Eq.3* for Richards.

$$Y_i = A/2 \; and \; t_i = ln(B)/k \qquad \text{(E.q.1)}$$

$$Y_i = A/e \; and \; t_i = ln(B)/k \qquad \text{(Eq.2)}$$

$$Y_i = A/(d + 1)^{1/d} \; and \; t_i = -1/k * ln|d/B| \qquad \text{(Eq.3)}$$

By using the three obtained equations in terms of the formula, then the predicted growth curves were plotted and presented with observed live weight data.

Results

The observed live weight of Holstein bulls and standard error was shown below. According to the data obtained an average birth weight and final live weight was found as 33.41±0.84 kg and 553.66±7.41 respectively during the 16 month of age (*Table 2*).

Growth curve parameters (A, b and K) from tree non-linear (Gompertz, Richards and Logistic) models with their relative determination coefficient (R^2) and residual mean squared values was shown in *Table 3*.

The models explaining the growth of Holstein bulls according to R^2 and RMS values were arranged in terms of efficiency as Gompertz, Richards and Logistic. Comparison of the models based on the coefficient of determination (R^2) showed that Richards model led to an improved fit of data compared to Gompertz Logistic and von Bertalanffy equations (0.999, 0.998 and 0.997 and 0.999 respectively). The Richards and von Bertalanffy model having the highest coefficient of determination (0.999) and the lowest residual mean squared (16.82and 22.21) value was the best model explaining the growth of the Holstein bulls (*Table 3*). Considering that lowest RMS value determines a greater reliability of the model, so Richards function have the best fit with 16.82 RMS value. The highest value for the coefficient A was obtained with von Bertalanffy model. The value of the coefficient K was found similar in all models.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44094416

The results indicate that all the growth functions were easily fitted to the observed data by nonlinear regression. The estimated growth curve patterns compared with the observed live weights for Holstein bulls was shown in *Figure 2*.

Inflection point traits

The estimates of weight and age at the inflection point was reported in *Table 4*. Age at the inflection point (t_i) is the maximum growth rate longitudinal time frame of live weight. Different from the values of t_i estimated by using Richards model (400.14 days) and von Bertalanffy (396.72 days) were found similar to each other, those calculated using Gompertz and Logistic were lower and similar to each other (327.72 and 306.75 days, respectively). Moreover, the highest value of ti was obtained using the Richards model (400.14 days) with a Wi of 545.01 kg. By using Gompertz, Logistic and von Bertalanffy equations the values of Yi obtained as 362.89, 463.88 and 336.47 kg, respectively (*Figure 3*).

Table 4. *The inflection point traits by different non-linear models*

	Gompertz	**Richards**	**Logistic**	**von Bertalanffy**
Weight at the inflection point (Y_i), kg	362.89	545.01	336.47	463.88
Age at the inflection point (t_i), day	306.75	400.14	327.72	396.72
Shape parameter (d)	-	10.63	-	-

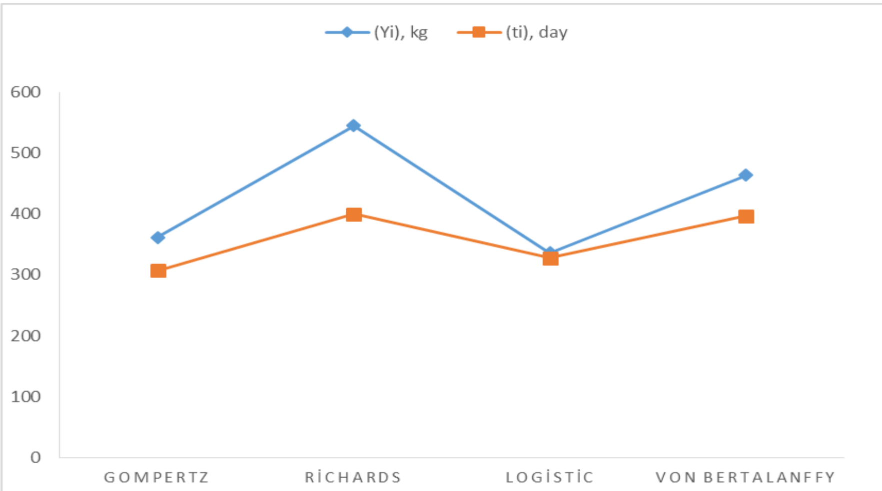

Figure 3. *The inflection point traits (Y_i and w_i) curve by different non-linear models*

The Logistic and Gompertz models overestimate the initial weights as 38% and 4 % respectively. The Richards and Von Bertalanffy underestimate as 2.39% and 12.27% respectively. Overestimation of the final weights by Gompertz and von Bertalanffy was 11% and 4.47, underestimation of those was 5.92% and 3.90 % respectively (*Table 5*).

Table 5. *Overestimation and underestimation of initial and final live-weights by different non-linear models (OE: Overestimation; UE: Underestimation)*

	Initial live weights		**Final live weights**	
Models	OE%	UE%	OE%	UE%
Logistic	38	-	-	5.92
Gompertz	4	-	11	-
Richards	-	2.39	-	3.90

DOI: http://dx.doi.org/10.15666/aeer/1702_44094416

According to different non-linear models, over-underestimate curve of initial and final live weights plot was shown in *Figure 4*.

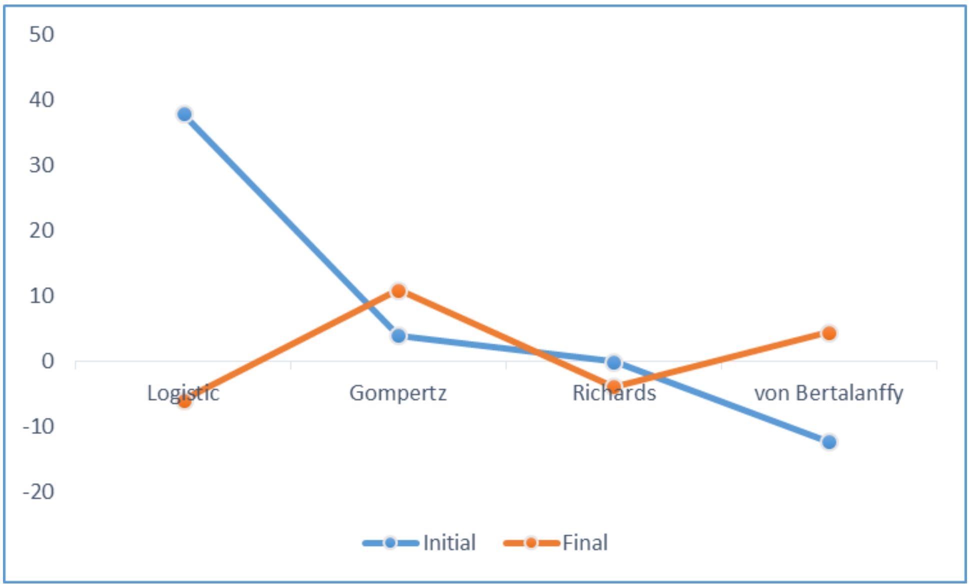

Figure 4. *Over-underestimate curve of initial and final live weights plot*

Discussion

According to findings Richards and Gompertz model was found the best overall fit for the growth of Holstein bulls.

Selvaggi et al. (2017) reported that the Logistic and Richards models provided the best fit, being useful to study the growth of Padolica bulls. Various studies reported that different growth functions gave a best data fit in cattle. In particular, DeNise and Brinks (1985) and Beltran et al. (1992) reported the Richards function as the best for cattle. Conversely, Mazzini et al. (2003) stated that Brody and Richards functions were inadequate to describe the growth pattern of Hereford bulls. Mgberel and Olutogun (2002) stated that Richards model with least residual mean squares was the best fit to the observed growth pattern of male and female N'Dama cattle.

Koşkan and Özkaya (2014) obtained the highest R^2 values of 0.992 and 0.991 respectively by using the Logistic and Gompertz model.

In a recent study conducted by Gano et al. (2015) on Parda de Montaña breed, the Richards function provided the best goodness of fit as also suggested by DeNise and Brinks (1985) and Doren et al. (1989). Furthermore, Gano et al. (2015) reported that the von Bertalanffy function also described the dataset satisfactorily, whereas the logistic equation had the worst fit. Goldberg and Ravagnolo (2015) analyzed the growth curves for Angus cows using different nonlinear models and the results showed that the Richards model was the best to fit the data

The best estimations according to the birth weights were obtained from the Gompertz and Richards models, even if the estimations were lower by R and higher by G than the actual weights. On the other hand, in their study Perotto et al. (1992) stated that the G and L models estimate birth weights higher than the actual values and the R model would be more convenient to estimate birth weights.

DOI: http://dx.doi.org/10.15666/aeer/1702_44094416

Conclusions

On the basis of our results, Richards model is the best fitted model based on RMS and R^2 criterias which is adequate to establish mean growth pattern of Holstein bulls. Although Richards is a four-parameter model having more computational difficulty, it is the more suitable one due to its accurate ability in predicting mature weight, which is an important selection goal. The growth curve parameters will provide an opportunity to design selection strategies since they may be included in genetic improvement programs as successfully done in other species as well. Richards growth curve model should be used for the other cattle genotypes because there are differences in their growth patterns.

Abstract. The goals of this research were to analyze the phytochemical, antioxidant, antibacterial, and allelopathic activities of extracts collected from *P. atlantica* subsp. *Kurdica* fruit and root. The fruit extract showed the highest phenolic (5.20 mg GAE/g dry extract) and flavonoid contents (1.01 mg QR/g dry extract). Qualitative and quantitative analysis of the diverse, biologically active elements from crude extracts displayed different compounds with varying molecular weights using gas chromatography–mass spectrometry. Likewise, both extracts possess unique phytochemical constituents. Additionally, the fruit extract has strong antioxidant and antibacterial properties compared to the root extract. The results of the allelopathic assay revealed strong and significant effects of both extracts on germination, seedling growth and root length for the test crops and weeds. According to the bioactivity analysis, the result of the variable importance in the projection (VIP) revealed that fruit extracts possessed a stronger biological activity than root extracts. The principal component analysis (PCA) plot detected a relationship between different constituents and biological activeness of both extracts and divided them into four clades. The results of this study showed that *P. atlantica* subsp. *Kurdica* may serve as a powerful natural antioxidant, antibacterial and herbicide source.
Keywords: *Mt. Atlas mastic tree, GC/MS, total phenolic and flavonoid contents, bioactivity analysis, radical scavenging, allelopathy*

Introduction

Isolation and recognition of phytochemical constituents from several innate sources can be interesting to scientists (Wheelwright, 1974). The World Health Organization (WHO) focuses on the advancement of native medicaments and ethnomedicines, conducting many investigations on natural therapies in order to search alternative medicines and innovative phytochemical mediators to control eczema, paralysis, diarrhoea, throat infections, jaundice, asthma and stomach pain and kidney stones (Borrelli and Izzo, 2000). North of Iraq, an area with high plant diversity, appears to be excellent for these studies. One of the plants with several industrial and medicinal properties, is the mastic. The *Pistacia* genus is held by the family Anacardiaceae; this genus comprises 11 shrub species belonging to the order Sapindales. *P. atlantica* is a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44174429

long-lived and dioecious plant, with different sorts of blooms. The trees rise up to 7 m in height, with branches spreading and growing erect to form a thick crown. It originates from Asia and the Mediterranean (Rougemont, 1989). In the north of Iraq, *P. atlantica* grows in natural forests, where it is used for several traditional meals and remedies, typically utilizing its gum and aromatic fruits.

Different phytochemical compounds, such as essential oils, phenolic, flavonoid compounds and several fatty acids like eicosanoic, linolenic, palmitic, lignoceric, palmitoleic, pentadecanoic, hexadecanoic and octadecanoic have been recognized in *P. atlantica* (Adams et al., 2009; Trabelsi et al., 2012). Due to their abundances in these bioactive compounds, *P. atlantica owns* some pharmacological characteristics and beneficial usages. Likewise, microorganism resistance is a contest for health and nourishment manufacture, and the search for substitute natural antimicrobial mediators endures (Soković et al., 2010). Contamination and illness as a result of multidrug-resistant (MDR) bacteria in both community and hospital situations have been difficult for many decades, for example, methicillin-resistant *Staphylococcus aureus* (MRSA) is presently unaffected by several antibiotic remedies (Dubey et al., 2013). Different organs like stem, leave and bark, as well as components from *P. atlantica*, demonstrated significant allelopathy and antimicrobial (Tahir et al., 2019). Nevertheless, there has been no information of extracts obtained from the *P. atlantica* subsp. *Kurdica* root, as alternative spontaneous products to reduce the free radical and to control the weeds and bacteria. Established along the request for natural products as an antiradical, and to control microorganisms and weeds, the current investigation was conducted to screen the ethanolic extract composition, antioxidant, antibacterial, and allelopathic activities in fruit and root of *Pistacia atlantica* subsp. *Kurdica.*

Materials and methods

Sampling site

The plant materials were collected in the Sarga mountain in the municipality of Sharbazher, Sulaimani, Iraq (Altitude: 35.85759, Longitude: 45.59086 and level sea: 1352.1 masl). Fruits and roots of *P. atlantica* subsp. *Kurdica* were acquired at 11:00 A.M. in August 2018. The plant was characterized and authenticated at the College of Agricultural Sciences of the University of Sulaimani by the taxonomist Assistant Professor Dr Rupak Abdulrazaq. A voucher specimen (NRT 03) was prepared. The plant materials were dried at 41 °C for eight days.

Chemicals agent

Ethanol and methanol, potassium acetate, Folin–Ciocalteau reagent, gallic acid and quercetin, aluminium chloride hexahydrate, 2,2-diphenyl-1-picrylhydrazyl (DPPH) and 2,2′-azinobis-3-ethylbenzothiazoline-6-sulphonic acid radical (ABTS) were purchased from Sigma-Aldrich (Munich, Germany).

Extract isolation

The phytochemical of fruit and root were obtained by the Soxhlet method by placing 85 grams of dried-ground tissues of *P. atlantica* subsp. *Kurdica* in a cellulose thimble. An amount of 220 mL of ethanol (Pure ethanol) was practiced for the extraction using a standard Soxhlet method for 150 min in a Soxhlet extraction system (BÜCHI Extraction

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44174429

System Model B-811). The solvent from extracts was then expelled utilizing a vacuum a vacuum rotary evaporator.

Determination of total phenolic compounds

The Folin-Ciocalteau method was applied to determine the amount of total compounds of phenolic acids as described by Singleton et al. (1999) with little modifications. The sample test contained 0.03 mL of each extract (root or fruit), which mixed with 1.7 ml Folin-Ciocalteau (diluted ten times). After 4 min of incubation, 1.3 mL of sodium carbonate solution (10%) was complemented. The calibration curve was determined by mixing aliquots of 5, 10, 15, 20, and 25 µg/mL gallic acid solutions with the same reagents, as the sample tests. The blank contained all solutions with 0.03 mL of distilled water in the state of plant extract. All test tubes were kept for 48 min in the dark at 39 °C. The absorptions of the samples were determined with a spectrophotometer at 750 nm. Each sample was repeated three times. The quantity of phenolic compounds in samples was determined by the calibration curve ($y = 0.0267x - 0.0269$, $R^2 = 0.99$) and expressed in mg gallic acid equivalent/ g dry extract using this formula:

Total phenolic content (mg gallic acid equivalent/g dry extract) = sample concentration calculated from the calibration curve of gallic acid in mg/mL × [extract volume (mL)/weight of the dry extract (g)].

Determination of total flavonoid compounds

The $AlCl_3$ method was used by three triplicates to determine the total flavonoid content of ethanolic fruit and root extracts (Madaan et al., 2011). A stock solution of quercetin was composed by dissolving 10.0 mg quercetin in 10 mL pure methanol, then the series of standard solutions of quercetin in concentration 0.005, 0.010, 0.020, 0.040 and 0.080 mg/mL were prepared by using pure methanol. Three mL of a solution composing of 1 mL of methanol 80%, 0.33 mL of 2% $AlCl_3$, 0.07 mL of 1 M potassium acetate and 1.60 mL of autoclaved distilled water was supplemented to 40 µl of the sample extract or 1 mL of the standard solutions. The mixture was hardly agitated and incubated for 32 min at room temperature. The absorption of the reaction compound was estimated at 415 nm against the blank (contains all above reagents and 40 µL of distilled water in the state of plant extract). The equation of linear regression of the standard curve ($y = 0.0243x + 0.0005$, $R^2 = 0.99$) of the series of quercetin dilutions, was plotted by MS Excel software and exploited to calculate the total flavonoid content by using this formula:

Total flavonoid content (mg quercetin equivalent/g dry extract) = concentration of samples derived from the quercetin calibration curve in mg/mL × [volume of the extract (mL) / dry extract weight (g)].

Qualitative and quantitative screening of ethanolic extracts by GC/MS

The qualitative and quantitative screening of constituents was accomplished using GC/MS. The GC/MS analysis was completed by using Shimadzu GC-QP 2010 Ultra gas chromatograph, The GC oven temperature was stated at 40 °C and then progressively upturned to 280 °C at a rate of 15 °C min^{-1}. Helium was exploited as a healer gas; inlet pressure was 96.1 kPa; linear velocity was 47.2 cm sec^{-1}. Column flux was 1.71 mL min^{-1}; injector temperature 280 °C; injection mode: split. MS scan

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44174429

conditions: source temperature 200 °C; interface temperature 280 °C; detector gain 0.69 kV + 0.10 kV and mass range of m/z 50-800. The constituents of the extracts in different parts were set by matching the retention indices with those of recognized constituents stored in the NIST library (2005) or either those of the literature. Peak area concentrations of the constituents were calculated to based on GC peak areas.

Antibacterial test

The antibacterial activity was measured by the agar-well diffusion method (Mounyr et al., 2016). The bacteria employed in this exploration, were *Staphylococcus aureus (*ATCC® 6538P™), methicillin-resistant *Staphylococcus aureus* (MRSA: Clinical isolates), *Bacillus subtilis* (ATCC® 6633™) and *Bacillus cereus* (Clinical isolates). Test microorganisms were initially cultivated in nutrient broth at 37 °C. The antibacterial potential of *P. atlantica* subsp. *Kurdica* was studied using the ethanolic extracts dissolved in Tween-80 (1%). For each pathogenic bacterium, a suspension (10^7 CFU/mL) was first dispersed generally on the solid agar surface. At that point, a hole with a diameter of 0.60 cm has penetrated with an autoclaved cork borer, and a volume (80 µL) of the extract solution (255 mg/mL) was inserted into the well. For 15 h, the plates were incubated at 37 °C and the diameter of the suppression areas was calculated in millimeters.

Ability of radical scavenging extracts by DPPH assay

The antioxidant ability of both extracts was determined using the method, 1-diphenyl-2-picrylhydrazyl (DPPH) radical-scavenging as defined by Shimada et al. (1992) with some amendments. Two mL (6×10^{-5} M) of DPPH solution was mixed with 20 µL sample. A control with methanol and a DPPH solution have also been implemented. The samples and control were incubated in the dark at 23 °C for 31 min and absorbed against a blank containing only methanol at 517 nm. The triple experiment was conducted. The inhibition percentage of samples were calculated from the data of absorbances by the formula:
% inhibition = [(Absorbance of control - Absorbance of the sample) / Absorbance of control] × 100.

Radical scavenging ability of extracts by ABTS radical cation

The free radical scavenging activity of root and fruit extract was set by 2,2′-azinobis-3-ethylbenzothiazoline-6-sulphonic acid radical (ABTS) radical cation decolorization assay (Re et al., 1999). ABTS radical cation was made by the mixing of ABTS (7 mM) in water and 2.45 mM of potassium persulfate (1:1). The mixed solution was hoarded in the dark at 21 °C for 15 h before use. For obtaining an absorbance of 0.700 ± 0.002 at 734 nm, the ABTS radical cation solution was made weaker with methanol in ratio 1:37.50. Seven µL of root or fruit extract was added to 2.993 mL of diluted ABTS radical cation solution. A control solution contained 7 µL of methanol and 2.993 mL of diluted ABTS radical cation solution. After 8 min of incubation, the absorbance was read against the blank (methanol) at 734 nm. All tests have been repeated three times. Percent of inhibition was calculated using the formula:
ABTS cation scavenging (%) = [(Absorbance of control-Absorbance of the sample)/Absorbance of control] × 100.

Allelopathy assay

The allelopathic power of the root and fruit extracts was performed on the seed germination parameters, of four plant species: wheat (*Triticum aestivum* L. variety Aras), barley (*Hordeum vulgare* L. variety Alkher), wild mustard (*Sinapis arvensis* L.), and narbon vetch (*Vicia narbonensis* L.*)*. Plant seed was sterilized with NaClO (0.90%) for 12 min and washed with autoclaved distilled water six times. Five replicates, each comprising of 15 seeds, were exercised for each of the control, 1.10 and 2.20 mg/mL plant extracts, using sterile Petri dishes (0.90 cm diameter) padded with three-sterile filter papers (Whatman). The plant extracts were mixed in a distilled water-acetone mixture (98:2) (Tahir et al., 2018). Nine mL of distilled water/acetone (control) or 9 mL different doses of the two plant extracts (1.10 or 2.20 mg/mL) were added to each Petri dishes. In order to prevent loss of moisture and microbial contamination, the dishes were covered with parafilm and deposited in a dark incubator at 19 °C for 7 days. In the eighth day, the germination percentage [%G = (Total germinated seeds/15) × 100] and seedling growth were measured. A seed was considered as a germinated seed when the appearance of the radicle become obvious (*Figure 1*).

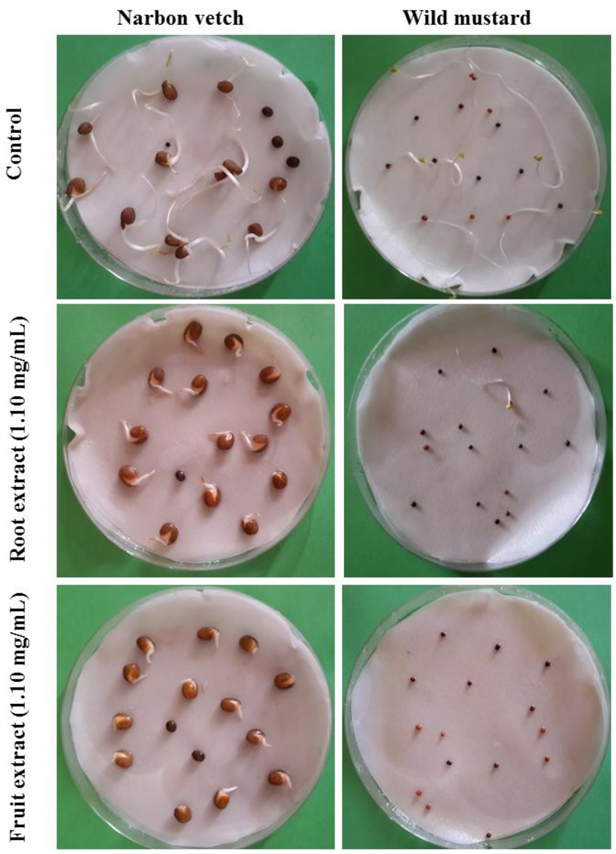

Figure 1. *Allelopathy effects of P. atlantica subsp. Kurdica fruit and root extracts on the germination parameters of two weeds: narbon vetch and wild mustard*

Statistical data analysis

Data on bio-activities were submitted to the analysis of variance (One way-ANOVA) using XLSTAT 2016 software. Means were matched by Duncan's new multiple range

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44174429

test at the 5% significance level. The data was exposed to a PCA analysis using the software XLSTAT 2016 to define the relation between chemical components and inhibitory effects.

Results and discussion

Screening of the polyphenolic constitutions

The results of the phytochemical contents of the fruit and root ethanolic extracts are detailed in *Figure 2*. The polyphenolic constitutions were considered by the Folin–Ciocalteu method and there was not significant variance ($p < 0.05$) among all tested samples for total phenolic content (TPC), while significant differences were noticed between the extracts collected from fruit and root for the flavonoid content (TFC). The maximum values of phenol and flavonoid compounds with 5.20 mg gallic acid equivalents/g and 1.01 mg quercetin equivalents per gram of dry extract, were registered by fruit extract. The outcome showed that fruit extract was rich in polyphenolic compounds. The TPC amount in both extracts was varied from the earlier assessments in methanolic, water, butanol and ethyle acetate extracts of the same species and another plant part (Ben Ahmed et al., 2017; Benamar et al., 2018; Tahir et al., 2019). Likewise, the variation between our results and other researchers in the quantity of polyphenolic compounds in *P. atlantica* may be contributed to a growing region, growing season, growth stage. solvent, a method of extraction and plant organ.

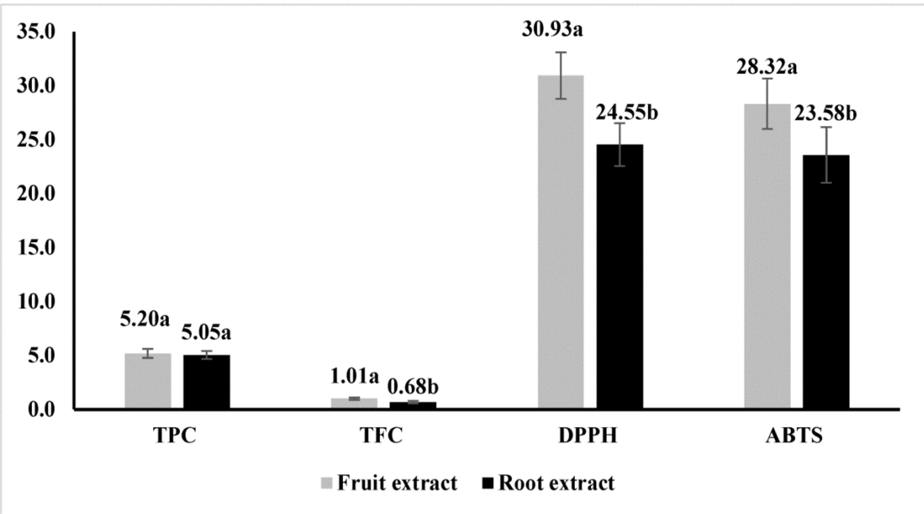

Figure 2. *Total phenolics (TPC in mg gallic acid equivalent/g dry extract), total flavonoids (TFC in mg quercetin equivalent/g dry extract) contents and antioxidant potentials (%) in P. atlantica subsp. Kurdica fruit and root extracts. The letters attached to each bar by the different letters mark substantial differences according to Duncan's multiple-range test. Each value is an average of three replicates*

GC/MS analysis of the extracts

Chromatographies analysis of the extracts allowed 26 compounds to be detected (*Table 1*). Several classes of compounds, including essential oil, polyphenol, and aliphatic compounds, were noticed in these extracts. Among its 18 components detected

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44174429

in the fruit extracts, 6 constituents dominated the composition of this extract, with a content of 72.83%. Constituents: 2-isoamyl-6-methylpyrazine (38.57%), oxalic acid, hexadecyl 2-methyl phenyl (9.26%), (NB)-O-[(diethyl boryl oxy)(ethyl) boryl]-caprolactone oxime (7.19%), pyrogallol (6.78%), 3-cyclopentylpropionic acid, 3-methyl phenyl ester (5.62%), and benzoic acid, 3-hydroxy-benzoic acid (5.41%) were the predominated components. Among the detected fractions, seventeen compounds were limited to fruit extracts. As displayed in the GC/MS analysis of the root extracts, 9 compounds were determined. Among them, five constituent concentrations were ranged from 5 to 37%. The major ones were 2-fromyl-3-benzyl-3-cholestanol (36.97%), l-(+)-ascorbic acid 2,6-dihexadecanoate (15.98%), cis-9-hexadecenal (9.83%), alpha-amyrenone (6.34%) and 1-heptacosanol (5.62%). Eight of ten compounds were constricted to this organ. Variations in the extract composition among the different tissues can be expounded by the volatility and biotransformation of monoterpenes, which often occur in several metabolic pathways leading to a mixture of products and, which may undergo spontaneous auto-oxidation (McGarvey and Croteau, 1995). To our awareness, there are no works on the chemical composition, antioxidant, antibacterial and allelopathic activities of the ethanolic extracts from *P. atlantica* subsp. *Kurdica* root. Hence, our findings are of attentiveness. In the previous works of *P. atlantica*, various compounds of several phytochemical clades have been known. Most of the predominated components found from different parts of *P. atlantica* subsp. *Kurdica*, have made it as a fountain of pharmaceutical and industrial usages. For instance, 2-isoamyl-6-methylpyrazine is used as foodstuffs (Xu-Yan et al., 2012). Studies revealed that pyrogallol had antibacterial properties averse to food-borne gram-positive (Han and Wang, 2017). Compound l-(+)-ascorbic acid 2,6-dihexadecanoate recognized as an antioxidant food additive (Cort, 1974). Previous investigations using α-amyrenone have proved its pharmacological potential as a new healing tool for the controlling of painful and inflammatory sicknesses (Quintão et al., 2014).

Antioxidant spectrophotometric assay

The effectiveness of the radical scavenging associated with the site and the number of compound hydroxyl groups. Most components with the OH group in *ortho* position of the ring, showed the greatest powerful scavengers of DPPH radical while the constituents with more of OH in the structure were the most powerful ABTS radical scavengers (Baba and Malik, 2014). The antioxidant ability of different extracts of fruit and root was conducted using DPPH and ABTS assays as shown in *Figure 2*. Then, a lower percentage value designates a lower antioxidant activity. As reported in the DPPH method, the antioxidant activity was ranged significantly from 24.55 to 30.93%. Fruit extract had the maximum DPPH scavenging activity (30.93%), while the lowest action (24.55%) was stated by root extract. In the ABTS radical, the scavenging activities in the various extracts were difference significantly and ranged from 23.58 to 28.32%. The fruit extract exhibited the maximum antiradical ability by ABTS. Interestingly, the consequences of antioxidant activities revealed that fruit extract appears to heavily affect the radical scavenging ability. These findings suggested that the antioxidant powers of fruit extracts can be attributed to their high flavonoid quantity. Our results of antiradical ability are lower than the output (87.00-97.50%) obtained by Hatamnia et al. (2014) and Hatamnia and Malekzadeh (2015). Several factors could be clarified this variation like the genetic variability of the plant, harvesting time of the samples, a method of extraction and the effect of the climate.

Antibacterial activity of different extracts

The tested extracts of *P. atlantica* subsp. *Kurdica* fruits and roots held the antibacterial potent versus Gram-positive than Gram-negative bacteria. The cause of the increased sensitivity of Gram-positive bacteria than Gram-negative bacteria could be related to their differences in cell membrane structures. The antimicrobial potentials of *P. atlantica* subsp. *Kurdica* fruit and root extracts were determined primarily by the disc diffusion technique against different Gram-positive bacteria strains, which commonly encountered in infectious diseases. As stated in *Figure 3*. It can be noted that both plant extracts, revealed varying grades of antibacterial potential against the four bacterial strains tested. The effects of both extracts varied considerably from all bacteria tests except methicillin-resistant *S. aureus*. The zones of fruit extract inhibition against four types of bacteria were ranged from 3.38 to 7.35 mm. The ethanol fruit extracts exhibited the strongest anti-*S. aureus* activity with an inhibition zone diameter of 7.35 mm and a feeble activity against methicillin-resistant *S. aureus* (6.40 mm). The extracts of root presented a relatively moderate activity principally against all bacterial species with the inhibition diameters ranged from 3.38 to 7.13 mm. This extract of plant parts showed a small activity mainly against *B. subtilis* (3.38 mm) and the maximal inhibition zones against *B. cereus*. It has been described in this section that the zone of inhibition could

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44174429

be importantly affected by the structure of crude extracts that are a combination of phyto-components which may impact the diffusion power of the active elements. Similar results have been obtained from an investigation carried on *P. atlantica* subsp. *Kurdica* leaf, stem and bark by Tahir et al. (2019).

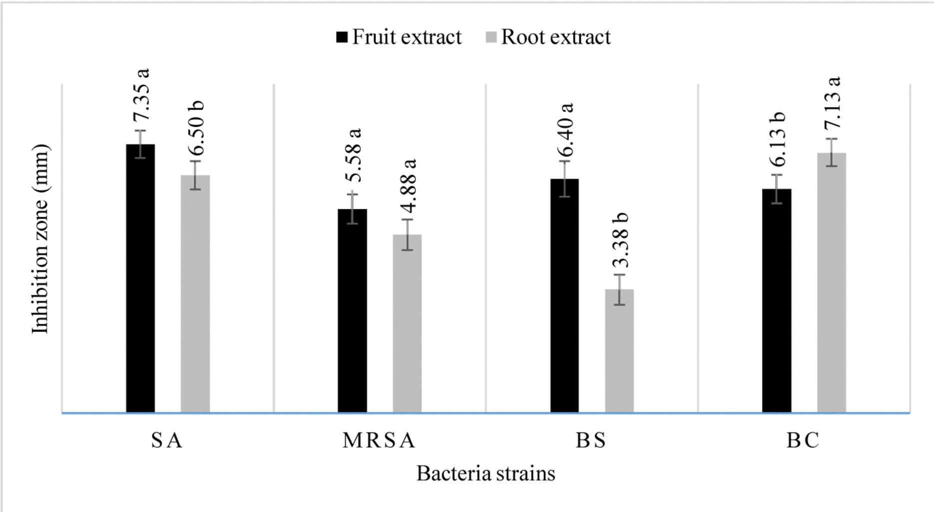

Figure 3. *Inhibition zones (mm) of the fruit and root extracts against four different species of bacteria. SA: S. aureus, MRSA: methicillin-resistant S. aureus, BS: B. subtilis, BC: B. cereus. The letters attached to the numbers of each bar by the different letters refer to substantial differences based on Duncan's multiple-range test. Each value is an average of three replicates*

Responses of crop and weed species to different extracts

All the applied concentrations of fruit extracts significantly blocked the germination and growth of the test plant species (*Table 2*). Fruit extracts at 2.20 mg/mL were more effective than fruit extracts at 1.10 mg/mL. The highest preventing of germination percentage (81.36% on wild mustard), root length (95.06% on narbon vetch) and shoot growth (88.34% on barley) were recorded by fruit extracts at a concentration of 2.2 mg/mL, while the lowest values of blocking of germination percentage (3.41% on bread wheat), root elongation (59.67% on wild mustard) and shoot length (56.20% on wild mustard) were reported by fruit extracts at 1.1 mg/mL concentration. All the doses of root extracts significantly inhibited the germination and growth of test crops and weeds. Root extracts at 2.20 mg/mL concentration were comparatively more toxic. The results presented that fruit and root extracts seemed more active in preventing bread wheat and narbon vetch germination. In addition, both extracts had more phytotoxic power against root elongation of all test species because of its directness contact with the extracts. Overall, the reduction of germination parameters was attributed to the presence of some allelochemical compounds in both extracts such as alpha-amyrenone, benzoic acid, 3-hydroxy-benzoic acid, pentadecanoic acid and -(+)-ascorbic acid 2,6-dihexadecanoate (Javaid et al., 2006; Ferreira et al., 2017). In addition, these allelochemical compounds modify the central vascular cylinder, layers of cortex cells and the mitochondrial metabolism, thereby altering some physiological and metabolic reactions related with growth of the plants (Gatti et al., 2010). Similarly, Tahir et al. (2019) found that the bark, stem and leaf extracts of *P. atlantica* subsp. *Kurdica* significantly decreased the growth of some crops and weeds.

Relationship between chemical components and bioactivity parameters

The objective of variable importance in projection (VIP) was to identify and select the most important predictor variables. In a given model, a variable with a VIP score near or above 1 can be considered important. As displayed in *Figure 4,* the fruit extract had a high impact (VIP > 1) and it was considered as variable importance in the bioactivity assays. For reducing the multidimensional structure of the data and providing a two-dimensional map to explain the relationship and variance between the data obtained from phytochemical and bioactivity analysis of both extracts, a PCA plot was performed and two main PCAs for the analyzed two extracts accounted for 100% of the total variation, PC1 for 88.32% and PC2 for 11.68% (presented in *Figure 5*). The plot obtained from PCA using the linkage method among classes indicated the presence of four clusters:

a. Group 1 with higher concentrations of pyrogallol (C4), benzoic acid, 3-hydroxy-benzoic acid (C5), 3-cyclopentylpropionic acid, 3-methylphenyl ester (C7), Oxalic acid, hexadecyl 2-methylphenyl (C8), and (NB)-O-[(diethylboryloxy)(ethyl)boryl]-caprolactone oxime (C9). Moreover, a positive correlation with total phenolics content, total flavonoids content, inhibition growth of *S. aureus* (SA), methicillin-resistant *S. aureus* (MRSA), and *B. subtilis* (BS).
b. Group 2 with high amount of 9,12-octadecadienoic acid (C1), Cis-9-hexadecenal (C2), 1-heptacosanol (C3), l-(+)-ascorbic acid 2,6-dihexadecanoate (C10), Alpha-amyrenone (C12), high inhibition growth of *B. cereus* (BC), high germination inhibition of wheat (INW) and narbon vetch (INNV).
c. Group 3 with a high content of 2-isoamyl-6-methylpyrazine (C6), high inhibition of germination of barley (INB) and high radical scavenging activity (DPPH and ABTS).
d. Group 4 with a high concentration of 2-fromyl-3-benzyl-3-cholestanol (C11) and high blocking of germination in wild mustard (INM)

Conclusions

Qualitative and quantitative analysis of the diverse biologically active elements from crude extracts of *P. atlantica* subsp. *Kurdica* displayed different types of molecular weight compounds in each extract. The high radical scavenging and antibacterial capacity are detected in the ethanol fruit extract compared to the root extract. The current work determines that fruit and root extracts have significant herbicide effects on the germination and growth of seedlings in four plants. Fruit and root residues of *P. atlantica* could be disseminated on wilderness, causing to the leaching of allelochemical compounds that would prevent or decrease the seed germination of weeds. Therefore, both extracts are considered to be new natural sources of antioxidants, antibacterial and weedicides. The prospect investigates on *P. atlantica* may be conducted on the following characteristic:

a. More resources are needed to verify the primary mechanisms of *P. atlantica* extracts as inhibitory agents.
b. For making the bio-weedicide to control the weeds. It is important to purify individually the allelopathic components, which have the inhibitory properties, presenting in the *P. atlantica* extracts.

(Received 26th Jan 2019; accepted 28th Feb 2019)

Abstract. The objective of this study is to evaluate economically the passive solar heating system. Data collected from tomato greenhouses in the Agriculture Research Center of Northern Greece was analyzed. For Comparison, two other conventional heating systems were used: the traditional anti-frost system and the diesel-fired furnace system. Models have been constructed to assess each heating method and several approaches of appraisal such as net present value, internal rate of return, benefit/cost ratio and payback period were measured in order to fulfill the assessment. The importance of the passive solar system was revealed not only as an energy-saving method but also as a significant contributor to farmer's income and an appropriate system avoiding the risk of high initial investment, which is generally associated with unconventional systems. Meanwhile, it was indicated that the diesel-fired furnace system is ineffective compared to the passive solar system, this ineffectiveness is particularly due to its high fuel consumption and relatively high initial investment. Finally, sensitivity analysis highlighted the importance of the product price in affecting benefits and indicating that income will increase dramatically with earlier production.
Keywords: *cost-benefit analysis, energy conservation, farm income, renewable energy, stochastic efficiency*

Introduction

Out-of-season production of good quality vegetables, ornamentals, and fruit in greenhouses in the Mediterranean is greatly influenced by energy costs. Tataraki et al. (2018) have stated earlier that the greenhouse heating costs have increased dramatically and the use of other sources of energy in response to escalating costs and occasional scarcities of petroleum shall be investigated (Bustos et al., 2016).

Several heating systems are used in the Mediterranean, it can be generally classified into conventional and non-conventional sources. Conventional sources include: Solid fossil fuels, Oil (fossils), Gas (natural) and Hydraulics. Non-conventional sources include: Solar, Wind, Biomass, Geothermal and Waste and reject energy (Balana et al., 2015).

Methods of investment appraisal which takes into account the time value of money are based on compound interest principles. The Net Present Value (NPV) method involves calculating the present value of a project's cash flows, both positive (inflows) and negative (outflows). Buchholz et al. (2017) defined the NPV of a project as the difference between the present values of its future cash inflows and outflows: all annual cash flows should be discounted to the zero points in time (the start of implementation) at a predetermined discount rate (Gautam et al., 2017).

Another way of using discounted cash flows to measure the overall of a project is to find the discount rate which makes the NPV of the cash flow equal to zero. This

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44314446

discount rate is termed the Internal Rate of Return (IRR) and represents the average earning power of the money used in a project over its life (Boardman et al., 2017). Larson and Gray (2013) defined the IRR as the maximum rate of interest that can be paid to finance a project without causing harm to the shareholders.

Besides NPV and IRR, a number of other measures of investment performance are in use, the most common of which is the pay-back period criterion, defined as the period of time by which the investments will be covered by the returns (Boardman et al., 2017). The pay-back period is defined as the length of time required for the stream of cash proceeds produced by an investment to equal the original cash outlay required by the investment (Nowotny et al., 2016).

Dixon et al. (2013) has defined the benefit/cost ratio as the present value of benefits over the present value of the costs. The corresponding decision rule requires that the project is accepted if the benefit/cost ratio is greater than one to compute the benefit/cost ratio, the discount rate must be determined. Dixon et al. (2013) has stated probably the best discount rate is the opportunity cost of capital. Another which is often chosen for the benefit/cost ratio calculation is the borrowing rate for the project. A third rate sometimes suggested is the social rate of return, which may more adequately reflect the time preference of society than does the opportunity cost of capital (Benli, 2013).

Ranking projects or alternatives is an important step in evaluation. Differences occur when two or more appraisal methods may yield differing orderings when applied to the same project. Brigham and Ehrhardt (2013), Boardman et al. (2017) and Johnson and Pfeiffer (2016) have suggested several methods of solving the problem.

According to Dogbe et al. (2013), Break-Even Analysis (BEA) establishes the lowest production and/or sales levels at which a project can operate without endangering its financial viability. In the manual for evaluation of industrial projects (Song et al., 2013), the term Break-Even Point (BEP) is used to indicate a level of operation at which a project yields neither profit nor loss, expressed as a volume of sales revenue.

Dogbe et al. (2013) and Elhag (2016) state that sensitivity analysis may be used in the early stages of project preparation to identify the variables in the estimation for which special care should be taken. According to Elhag (2014) and Boardman et al. (2017), sensitivity analysis consists of varying key parameter values, usually one at a time but sometimes in combination, and assessing the effect of such changes on the central tendency estimate of profitability (or the optimal solution).

In this study, three methods of greenhouse heating, two conventional methods (the Anti-Frost System (AFS) and the Diesel-Fired Furnace System (DFS)) and an unconventional method (the Passive Solar System (PSS)), all of which are used in greenhouses producing off-season tomatoes, were evaluated for production and gross returns, and the magnitude of the benefits provided by such technology, using different approaches of appraisal (net present value, internal rate of return, benefit/cost ratio and pay-back period).

Materials and methods

Data collection

Data are obtained from experiments conducted at the National Agricultural Research Foundation (NAGREF) in the region of Thessaloniki for 3 years started from 2012 and lasted until 2014. The designated study area is a semi-arid Mediterranean environment with a cold variant: the summer is hot and dry; the winter is cold and rainy.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44314446

Production and gross returns

A comparison of production and gross returns were made between the three greenhouses. The output of each greenhouse was the statistical mean of the production of tomatoes for three years (2012-2014). Production and gross returns were estimated for the total area of each greenhouse.

Fuel consumption

Annual fuel consumption was estimated as the average fuel consumption for the three years for each greenhouse for tomatoes and the average of two years for melons for each greenhouse.

Labor costs

Labor costs intervene in this analysis, particularly in the installation cost of the three systems in consideration, and especially for the PSS, which is more time-consuming. It intervenes also in the harvest costs.

Maintenance costs

Maintenance costs apply, especially to the PSS. At the beginning of each season, farmers need to fill the plastic tubes and position them, and later empty them and prepare them for the next season. AFS and DFS also have maintenance costs, but these were considered negligible in the calculations.

Models

The problems were formulated to allow the determination of the NPV as a measure of investment worth and to permit comparisons with investment alternatives. Partial budgeting procedures were used in which values with and without the PSS in the first case and with and without the DFS in the second case were used to calculate the NPV and other economic parameters: IRR, benefit/cost ratio and pay-back period (Udayakumara and Gunawardena, 2018).

Model for evaluating the PSS

Simulation methodology was used to evaluate the worth of the investment under various influences occurring in the Thessaloniki region. Three factors as having a major impact on the production benefits (Levidow et al., 2014) were incorporated into the analysis: (1) recoverable yield, which increases with suitable temperature; (2) fuel consumption, which depends on the type of heating system; (3) price of the crop, which varies over the harvest period, with generally higher prices earlier in the season. Following Boardman et al. (2017), the effect of inflation was ignored by assuming that it acts in the same way on revenues and costs and the effects cancel each other. The specific expression was extracted from that utilized by Elhag (2017) and modified to the needs of the problem:

$$NPV = -\sum_{t=1}^{8} \frac{\frac{[1-(-1)^t]IS_t}{2}}{(1+R)^t} + \sum_{t=1}^{8} AR_t + SF_t - AE_t - MN_t + \frac{IC_1}{(1+R)} + \frac{IC_5}{(1+R)^5} \quad \text{(Eq.1)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44314446

where:
IS_t = purchase price, including the cost of installing the PSS in year t for a 0.1 ha greenhouse;
IC_i and IC_S = purchase price, including the cost of installing the AFS in years one and five for a 0.1 ha greenhouse;
ARt = additional annual returns;
SFt = annual fuel costs saved;
AEt = additional annual harvest costs;
MNt = additional annual maintenance costs;
R = interest rate;
t = year of operation;
where:
$AR = \sum_i^n P_i\,(Q_{is} - Q_{ic})$;
$SF = H(F_c - F_s)$;
$AF = K(Q_s - Q_c)$;
and where:
Pi = price of the crop on Day i (dr/kg);
Qis = production of greenhouse S on Day i (kg);
Qic = production of greenhouse C on Day i (kg);
H = fuel price (dr/1);
Fc = annual quantity of fuel used in greenhouse C (1);
Fa = annual quantity of fuel used in greenhouse S (1);
K = harvest costs (dr/kg);
Qa = annual production of greenhouse S (kg);
Qc = annual production of greenhouse C (kg);
n = number of harvest days.

Model for evaluating the DFS

This model was similar to that used for the PSS, with certain parameters altered, such as the life of the system and the electricity needed to operate it. The assumptions used for the evaluation of the PSS were also made.

The NPV was determined by considering the monetary flows of the two greenhouses F and C, using the following expression which also extracted from that utilized by Agil and Hosseinian (2014) and modified to the needs of the problem:

$$NPV = \frac{-IF + IC_1}{(1+R)} + \frac{IC_5}{(1+R)^5} + \sum_{t=1}^{8} \frac{AR_t - CF_t - AE_t - EC_t}{(1+R)^t} \quad \text{(Eq.2)}$$

where:
IF = purchase price, including the cost of installing the DFS, for a 0.1 ha greenhouse;
ICi and IC5 = purchase price, including the cost of installing the AFS in years one and five for a 0.1 ha greenhouse;
ARt = additional annual returns;
CFt = additional annual fuel expenses;
AEt = additional annual harvest costs;
ECt = annual electricity consumption by the furnace;
R = interest rate;
t = year of operation;

where:
$AR = \sum_i^n P_i \left(Q_{iF} - Q_{iC}\right)$;
$CF = H(F_F - F_c)$;
$AF = K(Q_F - Q_C)$;
and where:
Pi = price of the crop on Day i (dr/kg);
QiK = production of greenhouse F on Day i (kg)
Qic = production of greenhouse C on Day i (kg)
H = fuel price (dr/1);
Ff = annual quantity of fuel used in greenhouse F (1);
Fc = annual quantity of fuel used in greenhouse C (1);
K = harvest costs (dr/kg);
Qf = annual production of greenhouse F (Kg);
Qc = annual production of greenhouse C (kg);
n = number of harvest days.

Results

Evaluation of the PSS

Variables used in the evaluation of the PSS with no distinction between varieties are depicted in *Table 1*. This evaluation is based on the application of the model which gives the NPV. Interest is high in Greece: an annual rate of 20% was assumed ($R = 0.2$). An assisted computer program was used for financial analysis; the application of the discount cash flow approach is illustrated in *Table 2*.

NPV

The formal selection criterion for NPV is to accept all investments with a positive NPV. The use of the PSS, over an 8-year period, produced an NPV of almost 5,500.0 euro, indicating a significant increase in earnings of greenhouse farmers and a contribution to energy saving.

Table 1. *Base case values for variables included in the model evaluating the PSS.*

8	127.92	0.23	29.81	1726.98	402.39	372.58
Total	**3044.07**	**3.84**	**1548.16**	**14366.83**	**6966.66**	**5418.50**

NPV at 20% = 6966.66 - 1548.16 = 5418.50. Benefit/cost ratio at 20% = 4.5
C.O.F = cash outflows; D.F = discount factor; D.C.O.F = discounted cash outflows; C.I.F = cash inflows; D.C.I.F = discounted cash inflows; D.C.F = discounted cash flows

IRR

The IRR was not taken into consideration because all the terms of the discounted cash flows are positive (*Table 2*). In this case, the NPV is positive at each value of interest rate, so that the NPV does not cross the interest rate axis and the determination of the IRR is impossible.

Benefit/cost ratio

The evaluation of a project by the benefit/cost ratio method requires acceptance of the project if the ratio is greater than one. The ratio here was 4.5, confirming the NPV method and indicating the profitability of the PSS when it replaces an AFS.

Evaluation of the PSS by variety (Arietta)

The evaluation of the PSS for each tomato variety is similar to that above, which did not distinguish between varieties; the only change concerns the additional annual returns (AR) and the additional annual harvest costs (AE). Financial analysis for each variety is presented in *Table 3* and the financial analysis of Arietta variety is presented in *Table 4*. The determination of the IRR is impossible for all varieties since the terms of the discounted cash flows columns are positive so that the NPV will never be zero.

Evaluation of the DFS

Several parameters were determined before calculation, summarizing the variables included in the case of no distinction between varieties (*Table 5*). As in the case of the evaluation of the PSS, the discount rate was assumed to be 20% and an assisted computer program was used to determine the parameters (NPV, IRR, and benefit/cost ratio). *Table 6* summarizes the discounted cash flow approach.

NPV at 20% = 5528.98- 5547.26= -18.28. IRP = 19.6%. Benefit/cost ratio at 20% = 0.997. Pay-back period = 5 years

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44314446

NPV

The application of the model leads to an NPV of -18.28 euro. Thus, there is no need, in terms of profitability, to replace the AFS by the DFS despite its effectiveness in increasing production and gross returns.

IRR

Here, the conditions of Vafaeipour et al. (2014) for the existence of the IRR are satisfied; the IRR was 0.196, slightly lower than the assumed discount rate.

Benefit/cost ratio

Using the benefit/cost ratio to evaluate the DFS, a ratio of 0.997 was found. This value is less than one, so this system did not add anything when it replaces the AFS. This confirms the results for NPV and IRR, which also showed the ineffectiveness of the DFS compared with the AFS.

Pay-back period

The stream of expected proceeds was not constant from year to year. The pay-back period was determined by adding up the proceeds expected in successive years until the total was equal to the original outlay. Subtracting cash inflows from cash outflows (*Table 6*) showed that investment will be covered by the returns after 5 years, which is the pay-back period.

Evaluation of the DFS by a variety

The only changes concerned the AR and the AE. Financial analysis for each variety is presented in *Table 7* and the financial analysis of Arietta variety is presented in *Table 8* in which NPV, IRR, benefit/cost ratio and pay-back period are illustrated. Thus, it is profitable to replace the AFS by the DFS only for arietta; NPVs for the other varieties were negative, varying between -1162.29 euro (dombo) and -223.85 euro (ramy), the IRRs were lower than the assumed discount rate (20%), and the benefit/cost ratios were less than one. The implementation of the DFS was also characterized by a long pay-back period, more than 8 years for dombo.

Risk and uncertainty

Because the PSS appeared to be an efficient method for greenhouse heating, NPVs were estimated by assuming changes in certain critical factors expected to affect the results such as discount rate, fuel price, and product price. The analysis did not distinguish between varieties.

Table 7. *Financial analysis of the DFS for the four tomato varieties*

8	825.31	0.23	192.30	1806.98	421.02	228.73
Total	**9517.01**	**3.84**	**5594.51**	**15180.80**	**7554.61**	**1960.10**

NPV at 20% = 7554.61 - 5594.51 = 1960.10. IRR = 62.5%. Benefit/cost ratio at 20% = 1.35. Pay-back period = 3 years

Effect of the discount rate

To determine the effect of the discount rate on the NPV, decreases, and increases in this discount rate were examined. Thus, the NPV is related to the discount rate: when this rate decreased by 50%, the NPV increased by 39%; the NPV increased by 6% when the discount rate decreased by 10%. However, when the rate increased by 10%, the NPV decreased by 5.5% and a 50% increase in the discount rate caused a 24% decrease in the NPV. Such changes in the interest rate are more significant when the percentages are lower (*Fig. 1*).

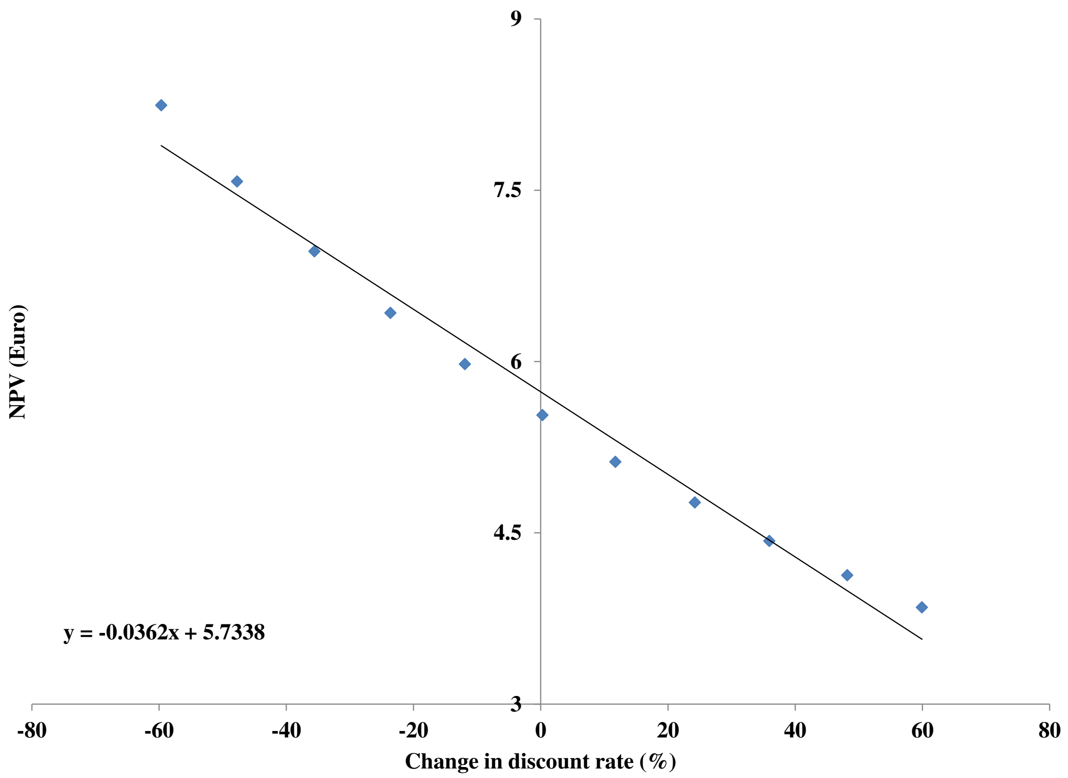

Figure 1. *The effect of a change in discount rate on the NPV for the PSS*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44314446

Effect of the fuel price

The effect of the fuel price on farmer income with the PSS instead of the AFS is summarized in *Figure 2*. The effect of a change in the price of fuel on NPV is not important: an increase of 10% caused an increase of 1%, and a decrease of 10% caused a decrease of 1%. The relationship between fuel price and NPV is linear so that the NPV increased by 5% when the fuel price increased by 50%. The effect of fuel price on NPV is considerable when a DFS is used. In this case, an increase in fuel price affected dramatically and negatively the benefits obtained by farmers utilizing the DFS: an increase of 10% caused a decrease of more than 1500% in the NPV.

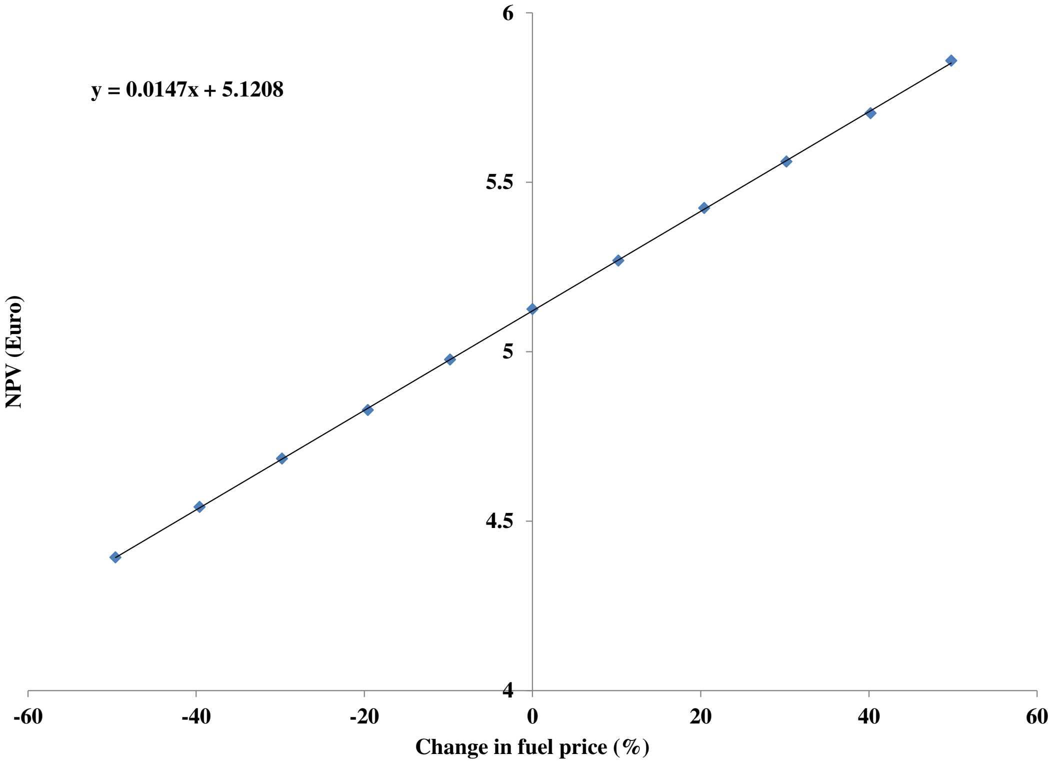

Figure 2. *The effect of a change in fuel price on the NPV for the PSS*

Effect of the product price

The product price is an important factor which affects the NPV. To demonstrate this effect, the NPV was calculated for decreases and increases in price (*Fig. 3*). Product price has a considerable effect on NPV since an increase of 10% caused an increase of 11% in the NPV. There is a linear relationship between product price and NPV, so that if the price increases by 50%, the NPV increases by 55%.

Generally, renewable energy sources require a large initial investment, but they have relatively low operating costs. The PSS significantly reduced energy consumption. The reduction in fossil fuel needs was from 80% compared with AFS to more than 2000% compared with the DFS. For an initial investment, the PSS is only 17% of the cost of the DFS, and slightly higher than the AFS. Besides its low initial investment, the PSS also has the advantage of low annual costs (13% that of the DFS and 63% that of the AFS).

Discussion

The effect of heating systems on production and gross returns

The effect of the heating methods was that greenhouse C (AFS) had the lowest annual average production for tomato crop, greenhouse F (DFS) was 10% for tomatoes, greenhouse S (PSS) had the largest annual average production for both crops. The low production of greenhouse C was due to inefficient heating which did not maintain a uniform temperature and which may have damaged the plants (Wright, 2012).

The heating systems permitted early production which led to higher market prices. The average market price for crops grown in greenhouse C was the lowest particularly because of the competition from other field crops; since the harvest in this greenhouse started at the end of May for tomatoes (Dannehl et al., 2012).

Furthermore, gross return of tomatoes in greenhouse S was 23% greater than that in C, in agreement with Esen and Yuksel (2013), who stated that gross return of tomatoes in greenhouse with the PSS exceeds that in the control by an average of 22%, gross return in greenhouse F exceeded that of C by 19%. However, in term of production, those percentages were only 16% and 10% respectively. Gross return of melons in greenhouse F was 50% greater than that of C, with 44% more production; greenhouse S was 66% and 60% more in gross return and production, respectively. These results show how early production allows farmers to exploit the higher market prices; the earlier the production, the higher the market price achieved, this accords with Gandhi and Zhou (2014), who stated that early production permits to increase dramatically gross return.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44314446

Evaluation of the considered heating systems

The analyses of production and gross returns show that the PSS and the DFS should be accepted over the AFS for greenhouse heating. This acceptance should be affirmed by a financial analysis which permits the adoption or the rejection of technological innovation, which is determined not by its contribution to the increase of production or to the increase of output value, but by the magnitude of the net benefits that can be provided (Cerón-Palma et al., 2012). It was clearly seen that it is on the profit of the farmers to replace the AFS by the PSS, since the NPV is positive and equal to 5500 euro in the case of tomatoes over an 8-year period (2012-2014), with 2012 as the base year.

Presented results indeed manifest PSS's importance as a significant contributor to farmer's income, thus a farmer with a 0.1 ha greenhouse cultivated with early spring tomatoes, will add annually about 750 euro just by utilizing the PSS and the greater the area cultivated, the greater the income added, thus a farmer who has five 0.1 ha tomato greenhouse will add approximately 3650 euro/year to his net benefits just by introducing this renewable energy-saving method (Jamel et al., 2013; Nabat et al., 2015).

As well as the NPV method, the benefit/cost ratio which was greater than 1 for the tomato crop indicates the importance of this system, the pay-back period is so short (less than one year) avoiding the problem of risk and confirming the decision provided by the previous discounted techniques (NPV and benefit/cost ratio) this is especially due to the low initial investment and fuel consumption characterizing PSS. The IRR method was not taken into consideration because this investment project does not meet the conditions imposed by Vafaeipour et al. (2014).

Besides its effectiveness in term of income and net benefits, the PSS presented the advantage of an energy-saving method which is very important particularly for a country like Greece, which is characterized by its heavy dependence (more than 70%) on primary energy from imported oil (Mourmouris and Potolias, 2013) and (Markaki et al., 2013), thus the reduction in fuel consumption was more than 20 times when compared with the DFS in the case of tomatoes.

On the other hand, the implementation of a DFS for heating tomato greenhouses against an AFS is not profitable: NPV was negative, IRR was lower than the assumed discount rate, benefit/cost ratio was less than one and pay-back period of 5 years is relatively long compared to the project life, at a much higher risk characterizing this system (Mehrpooya et al., 2015). The exception of arietta variety which had a positive NPV and an IRR greater than 20% and a relatively short payback period is especially due to its considerable difference in term of production between greenhouses F and C, which permitted to produce higher additional annual returns (AR) (Mekhilef et al., 2013).

It is important to note that despite its effectiveness in term of production and gross returns, the DFS did not provide any benefits for farmers when it replaces the AFS, this is particularly due to its relatively high initial investment and its large fuel consumption (Sueyoshi and Goto, 2015).

Sensitivity analysis

Sensitivity analyses were performed by varying certain critical factors such as discount rate, fuel price and product price over the range established, keeping the other

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44314446

variables at base case levels, this showed how the value of the NPV changes with variations in the value of any variable. Product price was the most important factor affecting the NPV: a price increase of 10% caused an increase of 11% in the NPV for tomatoes, and there was a linear relationship between product price and NPV, in an agreement with Vafaeipour et al. (2014), who stated that product price appears to cause the greatest effect on estimated income benefits. Thus farmers should choose the most appropriate heating system to have early production and therefore higher prices and benefits (Orgerie et al., 2014).

However, an increase in fuel price decreases income significantly when a DFS is used against an AFS; an increase of 10% caused a decrease of more than 1500% in the NPV of tomatoes, increasing risk associated with the implementation of the DFS because fuel prices generally increase with time, especially for oil-importing countries such as Greece (Markaki et al., 2013).

The NPV is also related to the discount rate: an increase of 10% caused a decrease of 6% in the NPV's of tomatoes. It is also important to note that a change in the discount rate is more significant in the case of negative change: for example, when R increased by 50% (R = 30%) NPV decreases by 24%, but a decrease of 50% (R = 10%) caused an increase of 39% in the NPV, giving an advantage to farmers from countries with low-interest rates (Vadiee and Martin, 2014).

Risk and uncertainty associated with renewable energy

In contrast to the use of fossil fuel energy sources, renewable energy sources generally require a large initial investment because of the large initial costs. This is especially important in countries which have high-interest rates (Mohammed et al., 2014). The relatively large initial investment required means that such projects will have relatively long pay-back periods and therefore, they involve much higher risk than that associated with fossil fuels (Castilla, 2013).

Renewable energy projects also face uncertainty regarding possible changes in economic conditions between the time the initial investment takes place and the length of the project's useful life. Of course, there is a wide range of risk associated with different renewable energy sources. Economic uncertainty is mainly due to possible changes in future energy prices. For example, few who anticipated the decrease in crude oil prices in 1985 and 1986, and many analysts were surprised to discover that 1986 real oil prices were at the pre-1973 level (Xu et al., 2014).

PSS differs from other renewable energy systems in that it has a low initial investment (17% of that of conventional DFS), thus indicating its advantage in avoiding the risk of high initial investment which is generally associated with renewable energy (Mourmouris and Potolias, 2013). In term of operating costs, the PSS has the advantage of renewable energy sources, which are characterized by the low operating annual costs. Thus by the low initial investment and the low annual costs, it may be useful to encourage the use of the PSS for greenhouse heating (Foteinis and Tsoutsos, 2017).

Conclusions

The evaluation of the current system in comparison with the most common non-renewable greenhouse heating system revealed its importance not only as an energy-saving technology, with considerable reductions in fossil fuel consumption, but also as a significant contributor to farm income. The implementation of the passive solar system

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44314446

instead of the traditional anti-frost one has dramatically increased production and gross returns particularly through its promotion of early production. The financial analysis which is based on different methods used as a basis on which to assess the investment profitability of a project (NPV, IRR, benefit/cost ratio and pay-back period) demonstrated that the adoption of the passive solar system significantly increases the earnings of greenhouse farmers. This study also revealed the advantage of this system in avoiding the risk of high initial investment which generally associated with renewable energy systems, and sensitivity analysis indicated the importance of product price in affecting benefits, thus early production allows farmers to exploit the higher market prices. This system is appropriate for any region whose climatic conditions are sufficiently similar to those of northern Greece. Financial analysis also revealed that investment in a diesel-fired furnace system did not provide any considerable benefits when it replaces an anti-frost system; its inefficiency is particularly due to its relatively high initial investment and its large fuel consumption.

For further consideration where the costs are not the only issue, the major obstacle to the wide application of renewable energy sources is higher risk and, uncertainty and not simply the cost of the energy utilized. Therefore, the main role of the public in such projects should be directed toward sharing some of the risk involved in construction and the operation.

Abstract. Drought is an important factor that restricts the growth of common bean. In the present study, Longyundou 10 (non-drought-resistant variety) and Longyundou 17 (drought-resistant variety) were selected to analyze the effects of drought stress on endogenous hormones and osmotic regulatory substances of common bean at seedling stage. Under mild drought stress, the ABA accumulation and response of drought-resistant Longyundou 17 were stronger than that of no drought-resistant Longyundou 10. The effects of CTK and IAA on drought resistance of common bean at seedling stage are complicated. Under normal water condition, the soluble protein content of Longyundou 10 was slightly higher than that of Longyundou 17. However, there was no significant difference in the degree of inhibition between Longyundou 10 and 17. Therefore, we believe that the soluble protein of common bean has little effect on resisting the threat of drought stress. The content of proline and soluble sugar in common bean responded strongly to drought stress, these two osmotic regulatory substances in drought-resistant varieties were higher than those in drought-resistant varieties. Therefore, ABA, proline and soluble sugar content can be used as important indicators for breeding of drought-resistant Varieties of common bean at seedling stage.
Keywords: *common bean, drought stress, ABA, proline, soluble sugar*

Introduction

Common bean (*Phaseolus vulgaris* L.) is the most popular edible bean widely cultivated in more than 90 countries and regions around the world (Acostagallegos et al., 2007). Common bean is rich in protein, unsaturated fatty acid, dietary fiber and other nutrients (Kuto et al., 2003; Yang et al., 2016). Drought stress is not only a hot research topic, but also a common adversity for crop growth. It is also a decisively restrictive factor for sustainable agricultural development which always threatens food security (Schindler et al., 2007). With the change of global climate, the drought situation in common bean producing areas is getting worse and worse. According to statistics, 60% of common bean producing areas in the world suffer from drought, and the yield reduction in Kenya and South Africa is as high as 80% (Beebe et al., 2008; Franca et al., 2000).

Under drought conditions, it is a complex physiological change for plants to respond to adversity. Many researches reported that drought causes responses of endogenous

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer1702_44474457

hormones in plants, which regulate and control plant physiological activities to adapt to drought stress (Yordanov et al., 2000; Sauter et al., 2001; Farooq et al., 2009). Abscisic acid (ABA), indole acetic acid (IAA) and cytokinin (CTK) are drought stress response hormones (Bartels et al., 2005; Acharyaet a., 2009; Tang et al., 2005), which can regulate plant physiological and biochemical processes and enhance drought resistance of crops. ABA exists in almost all higher plants and participates in many physiological processes during plant growth and development, such as stomatal movement, fruit maturation, seed dormancy and germination (Cutler et al., 2010). Under drought stress, ABA concentration in plants increased, which promote stoma to close to reduce transpiration loss, thereby to enhance plant drought resistance (Schroeder et al., 2001; Verslues et al., 2005).

IAA is a kind of plant endogenous hormones containing an unsaturated aromatic ring and an acetic acid side chain. Most IAA is concentrated in tissues and organs with strong division and growth metabolism, such as in root tips, young leaves, developing seeds and fruits. Drought stress can affect the change of IAA concentration. The mechanism of IAA drought regulation is complex. CTK is a kind of adenine derivative. Under drought stress, the regulation mechanism of CTK varies in drought degrees and crops. Osmotic regulation is the physiological mechanism which plants are adapted to water stress. Under water stress, plant cells can actively change the content of osmotic regulatory substances of small molecules or their existing state in plants to regulate osmotic potential in vacuoles and ensure normal growth and development of plants. Soluble sugars, proline and soluble proteins are considered to be important osmotic regulatory substances in plants, which can respond positively to drought stress. It has been reported that under drought stress, the proline content of wheat leaves increased and the soluble protein content decreased (Bai et al., 2007). Proline and soluble sugar are the main osmotic regulatory substances of common bean, which can maintain the leaf water balance (Li et al., 2014). Under drought stress, the content of osmotic regulatory substances in common bean was different among different drought-resistant varieties (Rosales et al., 2012; Lizana et al., 2006).

Drought is the second major factor restricting the production of common bean besides diseases (Schneider et al., 1997). Therefore, drought resistance of common bean has become one of the important indexes in breeding and production (Li et al., 2014; Cortés et al., 2012). In the present study, the changes of endogenous hormones and osmotic regulatory substances in common bean were studied in order to provide technical guidance and theoretical support for efficient production and breeding of drought-resistant of common bean varieties.

Materials and methods

Both Longyundou 10 (non-drought-resistant variety) and Longyundou 17 (drought-resistant variety) were provided by Crop Breeding Research Institute of Heilongjiang Academy of Agricultural Sciences, Heilongjiang province, China.

The experiment was carried out in an artificial climate chamber with humidity of 60%+10%, 27 °C under 16-h light conditions, 16 °C under 8-h dark conditions. The experimental plots were completely randomized with three replications and three water treatments at each site. Mild drought stress (LS): Relative water content of soil (RWC) = 60% + 5%; severe drought stress (SS): RWC = 45% + 5%; control: RWC = 75%+5% under normal water condition. Seeds were planted in plastic pots

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer1702_44474457

filled with a potting mixture of 3 perlite : 3 vermiculite : 4 nursery soil. Each plastic pot contained 2 kg potting mixture and 3 seeds. From sowing to the appearance of the second true leaf, the soil was controlled under normal water condition (RWC = 75% + 5%). When the second trifoliate leaves are fully developed and mature, the soil moisture content of each treatment was monitored and controlled to reach the set target by weighing method every morning and evening.

On the 2nd, 4th, 6th, 8th, 10th, 12nd, 14th and 16th days after drought stress treatment, the parietal lobe of the second mature trifoliate were taken from 9:00 to 9:30 a.m. The contents of ABA, CTK, IAA, free proline, soluble sugar and soluble protein were determined by ELISA. All the kits are provided by Shanghai Enzyme-linked Biotechnology Co., Ltd. Microsoft Excel 2010 and SPSS 18.0 software are employed for data collation and analysis.

Results

Effects of drought stress on ABA content of common bean

ABA is a stress response hormone, which can accumulate rapidly when stress occurs and play a significant role in plant response to stress. As shown in *Figure 1,* at the beginning of severe drought stress, ABA content of Longyundou 17 increased abnormally. In addition, the accumulation of ABA content in common bean leaves showed a single-peak curve at seedling stage. The peaks of ABA content of Longyundou 17 in mild drought stress, severe drought stress and control treatments were 941.81 ng g^{-1}, 829.97 ng g^{-1} and 747.16 ng g^{-1}, respectively. The peaks of ABA content of Longyundou 10 in mild drought stress, severe drought stress and control treatments were 849.33 ng g^{-1}, 731.04 ng g^{-1} and 724.58 ng g^{-1}, respectively.

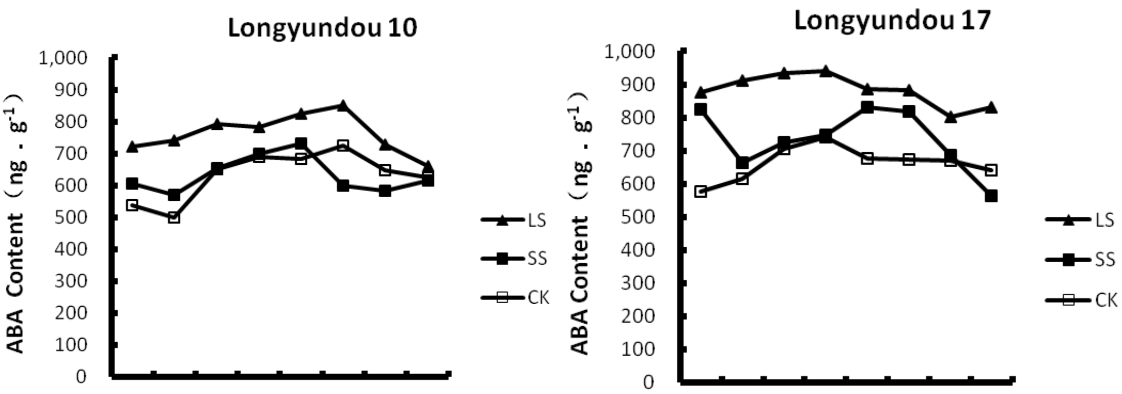

Figure 1. *Changes of ABA content in common bean leaves under drought stress*

Under mild drought stress, the accumulation of ABA in leaves increased significantly, but with the increase of water stress time, the content of ABA in severe drought stress began to decrease and accumulated slowly, which indicated that mild drought stress stimulated the ABA response. Common bean could alleviate the effect of water stress through the accumulation of ABA in a certain period of time, but severe drought stress can destroy the formation and accumulation of ABA.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer1702_44474457

ABA content in leaves of drought-resistant variety Longyundou 17 was slightly higher than that of Longyundou 10. Under drought stress, the increase of ABA content was also greater than that of common bean varieties with weak drought resistance. On the 12th day after severe drought treatment, ABA content of Longyundou 10 was lower than that of normal water treatment, while Longyundou 17 decreased on the 16th day after severe drought treatment, indicating that the accumulation and response of ABA under drought stress were stronger than those of non-drought resistant varieties.

Effect of drought stress on CTK content of common bean

As shown in *Figure 2,* under normal water condition, CTK content fluctuated in the leaves of common bean at seedling stage, but there is no distinct tendency. Under drought stress, CTK content increased first, then decreased, and then increased again. The performance of CTK content was different among different varieties, which indicated that the role of CTK in drought resistance of common bean at seedling stage is complex.

There were no significant differences in CTK content of Longyundou 10 among drought stress treatments, but the change tendency was slightly different. When Longyundou 10 was treated with severe drought stress for 2-4 days, the content of CTK content increased significantly, with an average increase of 50.6% compared with the control. After 6 days of treatment, CTK content declined sharply, slightly lower than the control treatment on the 8th day, and increased again after 12 days of treatment. Under mild drought stress, the CTK content in Longyundou 10 was significantly higher than that under normal water condition after 2nd-6th and 16th days of treatment, but increased slightly after other treatments, even decreased slightly on the 8th day of treatment.

Except for the 4th day after treatment, the CTK content of Longyundou 17 under severe stress treatment was higher than that in mild stress treatment. The CTK content under drought stress was higher than that under no stress treatment, indicating that drought stress stimulated the CTK production in Longyundou 17.

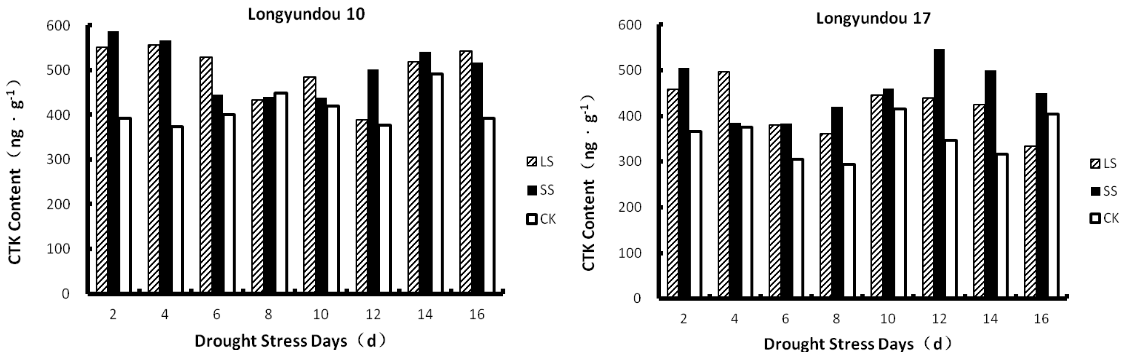

Figure 2. *Changes of CTK content in common bean leaves under drought stress*

Effect of drought stress on IAA content of common bean

As shown in *Figure 3,* IAA content of common bean showed a downward trend of fluctuations under drought stress. The change of IAA content under drought stress was more complex. The changes of IAA content under both severe and mild drought stress were alternate, and no drought stress showed greater impact on IAA content. At the initial stage

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer1702_44474457

of drought stress, IAA content was higher than that under no stress. However, with the prolongation of drought stress time, IAA accumulation was inhibited and content began to decline. Especially from the 8th day after drought treatment, IAA content of Longyundou 10 was lower than that of control. The IAA content of Longyundou 17 was slightly higher than Longyundou 10 in all treatments.

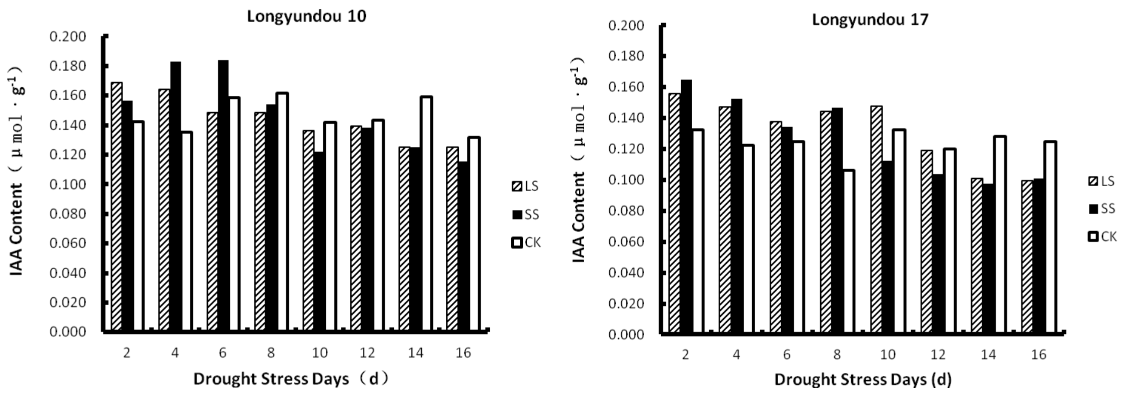

Figure 3. *Changes of IAA content in common bean leaves under drought stress*

Effects of drought stress on free proline content of common bean

In *Figure 4,* under different degrees of drought stress, the free proline content in common bean leaves increased significantly with the maximum increase more than 1.6 times than that under non-drought stress, while free proline accumulation fluctuated under mild drought stress.

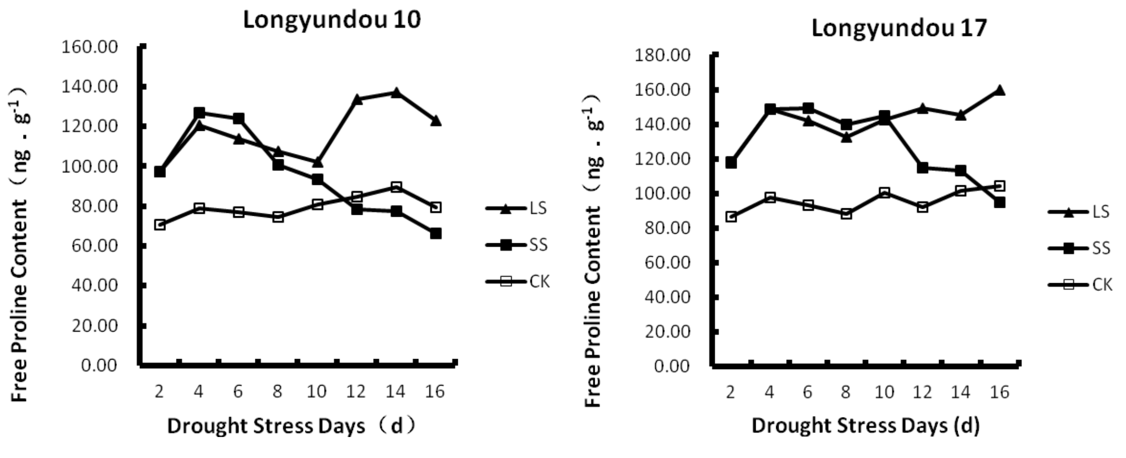

Figure 4. *Changes of free proline content in common bean leaves under drought stress*

Under severe drought stress, free proline content tends to increase at first and then decrease. At the beginning of drought treatment, the content of proline under severe drought stress was higher than that under other water treatments. With the prolongation of drought stress time, the accumulation of proline under severe drought stress was inhibited and the content of proline decreased. Longyundou 17 maintained high free proline accumulation within 10 days under severe drought stress, but began to decrease 12 days after treatment, which was lower than that under mild drought stress. The free proline content of Longyundou 10 under

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer1702_44474457

mild stress was higher than that under severe stress after 8 days of drought treatment, which indicated that Longyundou 17 could maintain higher free proline accumulation for a long time under severe stress than Longyundou 10, and its osmotic regulation ability was also higher than Longyundou 10. The free proline content of Longyundou 17 was higher than Longyundou 10 in all treatments, and the increase of free proline under drought stress was also higher than Longyundou 10, indicated that free proline was an important osmotic regulatory substance of drought resistance of common bean.

Effect of drought stress on soluble sugar content of common bean

Figure 5 shows that the accumulation of soluble sugar content in common bean leaves showed a single peak curve, and the peak appeared at different times according to different varieties under drought stress. The peaks of soluble sugar content of Longyundou 17 appeared on the 10th and 8th day after severe drought stress, and the peaks were 6.52 mg g^{-1} and 5.61 mg g^{-1} after mild drought stress, respectively, which were 2.2 times and 1.84 times higher than those under normal water condition. Under severe and mild drought stress, the peaks of soluble sugar content of Longyundou 10 appeared on the 8th day after stress, and the peak values were 4.63 mg g^{-1} and 3.78 mg g^{-1}, respectively, which increased 1.6 times and 1.3 times as much as that under normal water condition. The soluble sugar content of Longyundou 17 was higher than that of Longyundou 10 at all stages and treatments. In the early stage of drought stress, the soluble sugar content of common bean increased significantly. With the prolongation of drought time, the accumulation of soluble sugar was seriously inhibited, especially under severe drought stress, the content of soluble sugar decreased sharply. The decrease of soluble sugar content in Longyundou 17 occurred 14 days after drought treatment with the soluble sugar content decreases by 16.9% and 22.5% under severe and mild drought stress, respectively, compared with those in normal water. Under drought stress, the content of soluble sugar in Longyundou 10 decreased earlier than that in Longyundou 17. After 10 days of severe drought stress, the content of soluble sugar in Longyundou 10 was significantly lower than that in normal water.

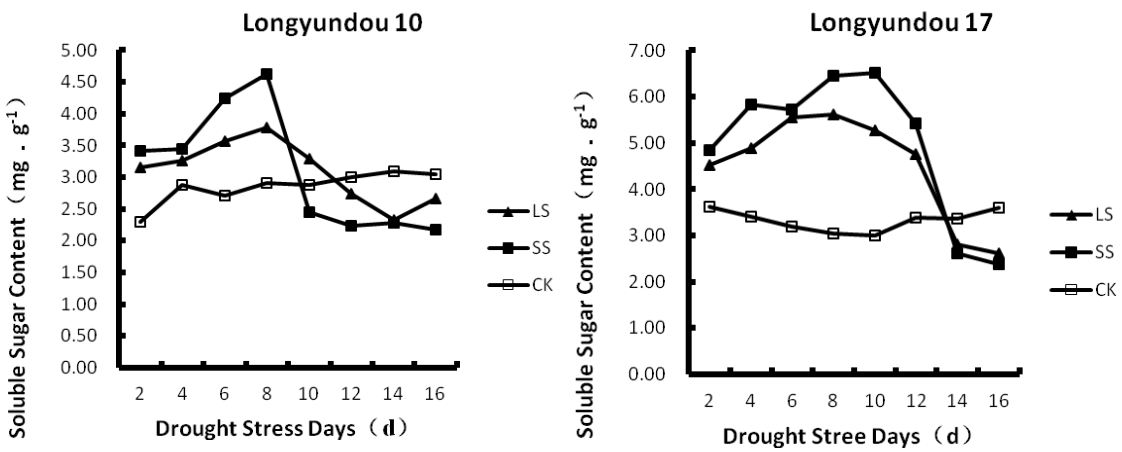

Figure 5. *Changes of soluble sugar content in common bean leaves under drought stress*

Effect of drought stress on soluble protein content of common bean

In *Figure 6,* the accumulation of soluble protein in common bean leaves at seedling stage showed a fluctuating upward trend under normal water conditions. The

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer1702_44474457

accumulation dynamics of soluble protein showed irregular changes under drought stress. At the initial stage of drought stress, soluble protein content increased, especially under severe drought stress. However, with the increase of drought stress time, the accumulation of soluble protein in common bean was inhibited, and the content was lower than that in normal water condition. Under normal water condition, the soluble protein content of Longyundou 10 was slightly higher than that of Longyundou 17.

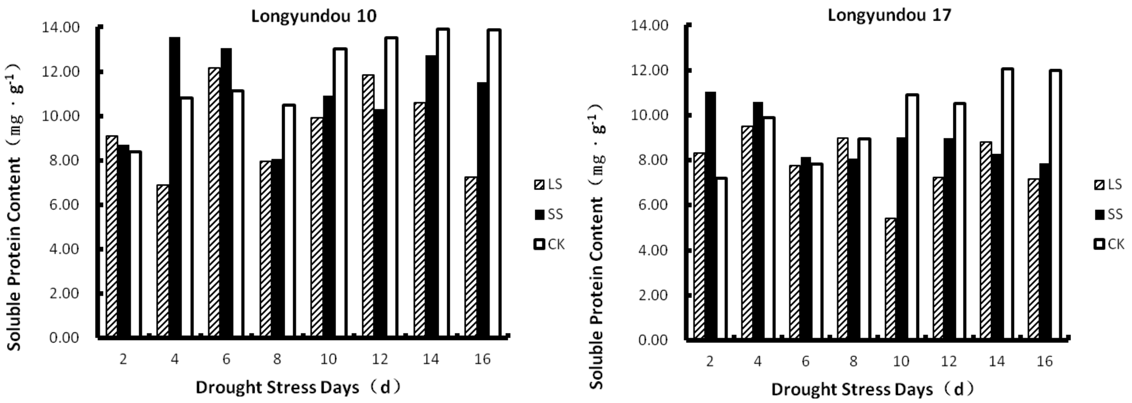

Figure 6. *Changes of soluble protein content in common bean leaves under drought stress*

Discussion

Changes of endogenous hormones in common bean under drought stress

Many researches have proved that plant endogenous hormones play an important regulatory role under drought stress (De Ollas et al., 2016; Sharp et al., 2004; Kurepin et al., 2015; Forner-Giner et al., 2011). Different crops and their ABA, IAA and CTK contents have different response mechanisms. Plant hormone ABA plays an important regulatory role in plant growth, development, stress resistance, stomatal movement and gene expression (Neill et al., 1999).

In the present study, ABA accumulation in common bean leaves increased significantly under mild drought stress, indicating that mild drought stress stimulated the ABA response, but severe drought stress would destroy the formation and accumulation of ABA. The ABA content in drought resistance variety Longyundou 17 was significantly higher than that in non drought-resistant variety Longyundou 10. Therefore, we believe that ABA can be used as important drought resistance indexes of common bean at Seedling Stage.

CTK is formed and accumulated in the root system, which is transported to the the aboveground part. At the same time, CTK is formed in large quantities in the root system under drought stress. In our study, CTK increased in the leaves of common bean seedlings under drought stress, especially in common bean varieties with stronger drought resistance. Drought stress stimulated the CTK production in Longyudou 17, suggested that moderate drought stress exercise is helpful to the stress-resistant growth of common bean.

Endogenous IAA is synthesized by plant apical tissues and growing leaves as a growth hormone. Under drought stress, the change of IAA content increases in some plants (Zhao et al., 2012; Mei et al., 2017), while decreases in others (Zhang et al., 2018; Chang et al., 2012). In the present study, IAA content in common bean leaves

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer1702_44474457

decreased in a fluctuation way under drought stress. IAA content alternate change under severe stress and mild stress. No change was observed in IAA content under two drought stresses, indicating that the mechanism of IAA response to drought stress was complex, which was consistent with previous studies.

Changes of osmotic regulatory substances in common bean under drought stress

Osmotic regulation is not only an important way for plants to resist drought adversity, but also an important physiological mechanism for plants to induce protective response under drought stress (Cabuslay et al., 2002; Alla et al., 2012; Moustakas et al., 2011). Under drought stress, osmotic regulatory substances such as proline and soluble sugar accumulate constantly in plant cells, reduce cell osmotic potential and improve water retention capacity through response, thus enhance drought resistance of crops. However, there are some differences in the accumulation of osmotic regulatory substances among different crops (Osmotic et al., 2010; Trung et al., 2018). In the present study, two common bean cultivars with obvious difference in drought resistance were chose to analyze osmotic regulatory substance changes under drought stress. These results showed that different osmotic regulatory substances had different responses. Among them, the contents of soluble sugar and proline were correlated with the drought resistance of cultivars. The drought-resistant varieties had higher expression level under drought stress compared with non drought-resistant varieties, but the soluble protein did not show the same conclusion.

Conclusion

Endogenous hormones and osmotic regulatory substances showed differences in different degrees of drought stress and among common bean varieties. When common bean was subjected to mild drought stress, the endogenous hormones and osmotic regulatory substances of common bean showed a positive response. The contents of ABA, proline and soluble sugar in drought-resistance common bean varieties were higher than those in varieties with weak drought resistance. Therefore, these substances could be considered as important indicators for drought resistance breeding.

The accumulation of endogenous hormones and osmotic regulatory substances in common bean was severely affected when drought stress lasted for a long time. Although common bean could respond to drought stress, the accumulation of related regulatory substances would be inhibited with the persistent threat of drought stress. This also indicated that the tolerance of common bean to drought stress was weak at seedling stage. Therefore, it should pay special attention to water management in seedling stage in the production of common bean.

In the present study, we discussed the response mechanism of endogenous hormones and osmotic regulatory substances of common bean under drought stress, and found the response law. We will further study the response mechanism at molecular level, especially for ABA, proline and soluble sugar, which can be used as physiological indicators of drought resistance of common bean, and explore and utilize related genes to change the physiological and biochemical characteristics of common bean for the improvement of drought-resistance of common bean.

(Received 22nd Jan 2019; accepted 22nd Feb 2019)

Abstract. Net primary productivity (NPP) is a vital dataset to assess carbon cycling, carbon budget and interpreting global warming. There are many approaches to calculate NPP, and Carnegie-Ames-Stanford approach (CASA) is one of the most popular approaches that was applied in this study. Black pine forest NPP was calculated with the CASA model in a transection zone between humid black sea and dry middle Anatolia region of Turkey for the year of 2016. Model parameters and homogeneity were tested with one-way ANOVA. Results was showed that annual NPP values were varied from 194 to 1213 (g C m^{-2} $year^{-1}$) for pure black pine stands. Model validation was made with stand increment, growing stock, and stand carbon values. Correlation co-efficiencies were obtained to be 0.92 and 0.85 respectively. It was found that NPP was higher in young stands where the mass accumulation potential was higher than areas, where crown closure was between 11% and 70%. According to this study, young stands should be established in the forests that were operated with the highest NPP objective. NPP models that can be used on a global scale is required intense data and time consuming. In addition, it has been determined that mechanical models which are allowed more practical calculation and can be used with the stand parameters easily.
Keywords: *black pine ecosystem, CASA model, forest productivity, stand attributes, forest characterization*

Introduction

Net primary productivity (NPP) is an important indicator on terrestrial carbon cycle from local to global scales. It is the net amount of carbon the plant cover receives after the photosynthetic activity. The sum of autotrophic respiration and NPP is gross primary productivity (GPP). GPP is a parameter that is not directly measured and also measurement of autotrophic respiration is laborious (Gower et al., 1999; Berberoğlu et al., 2007; Ardö, 2015; Chen et al., 2016; Wang et al., 2018).

NPP is an important key variable in terms of carbon trading, which was established by 180 countries in 1997 Kyoto Protocol to reduce carbon emissions and global warming. Countries that has high carbon emissions, have been allowed to purchase more carbon dioxide emissions to the atmosphere from the countries with lower carbon emissions thanks to this agreement (Dong and Whalley, 2010; Klein et al., 2016). Forests are our one of the most efficient weapon in the battle with global warming and climate change. NPP can be used as indicator and control variable on this issue. It will be right strategy to cultivating forests with maximum NPP in this struggle in appropriate regions according to the ecological requirements.

There are many models that can be used to calculate NPP. These models are divided into three categories (Cramer et al., 1999; Schloss et al., 1999; Ruimy et al., 1999). First group is based on satellite data such as CASA (Potter et al., 1993), GLO-PEM (Prince, 1991),

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44594473

SDBM (Knorr and Heimann, 1995), TURC (Ruimy et al., 1996) and SIB2 (Sellers et al., 1996). Second group is based on seasonal biogeochemical fluxes such as HRBM3.0 (Esser et al., 1994), CENTURY4.0 (Parton et al., 1993), TEM4.0 (McGuire et al., 1995) and SILVAN2.2 (Kaduk and Heimann, 1996). Third group is based on seasonal biogeochemical fluxes and vegetation structure such as BIOME3 (Haxeltine and Prentice, 1996), DOLY (Woodward et al., 1995) and HYBRID3.0 (Friend, 1995).

Spatial NPP models particularly CASA model are widely applied from regional to global scale accurately using remotely sensed datasets (Turner et al., 2006; Wang et al., 2013). Liang et al. (2015) and Chen et al. (2016) used the CASA model to research the temporal and spatial changes in NPP of different vegetation types, from 1982 and 2010-from 1984 to 2014, respectively. Liu et al. (2018) estimated aboveground NPP using CASA model for forest ecosystems. Tripathi et al. (2018) selected CASA model to explore the spatio-temporal patterns of NPP for 2009 and 2010 years in forest plantations. Li and Zhou (2015) predicted NPP using CASA model for forest types and reported that how NPP changed by forest stand age.

In our study, we focused on areas where covered by black pine. Black pine trees have been started to use main afforestation tree against soil erosion and to mitigate the some land degradation effects in Turkey during the more than ten years. So this study also important to understand the black pine tree contribution to carbon budget of the country. The objectives of this study were; (i) to calculate the NPP with CASA model, (ii) to validate the CASA model system for pure black pine stands under continental climate conditions, (iii) to research model possibilities of NPP with stand parameters and (iv) to determine the optimal stand criteria for maximum NPP in pure black pine areas.

Materials and methods

Study area

The study area is located on the Black Sea backward region of Turkey (*Fig. 1*). The coordinates of the study area are between 33°21'56" - 33°25'27" north latitude and 33°34'22" - 33°20'01" east longitude. The study area is about 18488.30 ha and pure Anatolian black pine (*Pinus nigra subsp. Pallasiana var. Pallasiana (Arnold)*) stands are covered totally 5517.44 ha areas. There are also Scots pine (*Pinus sylvestris*), Poplar (*Populus sp.*) and Oak (*Quercus sp.*) in the region. The elevation has been varied between 1000 and 1600 m.

Climate type of the study area is defined as semi-arid, mesothermal with excessive wetness during winters. Mean, maximum and minimum annual temperature are 11, 18 and 5 °C, respectively. This area is one of the transection zones between Euro-Siberien and Irano-Turanian phytogeographical regions. Mean annual precipitation is 412 mm. Daily total highest precipitation in the region is 74 mm.

Materials

Three main materials were used in the study to be forest inventory, satellite dataset and climate dataset (*Table 1*).

Forest inventory

Data from national forest management inventories were used. Sample plots were taken systematically at intervals of 300 × 300 m. According to the crown closure of the sample plots, sample point size was chosen from low (11-40% = 800 m^2), medium (41-70% = 600 m^2) and full crown closure (71-100% = 400 m^2). Then, diameter at breast height (DBH, 1.30 m), age and height were measured in all trees with a diameter greater than 7.9 cm in each sample plot (Anonymous, 2008). Stand map was prepared using combine inventory method through satellite image or aerial photograph and field measurements and 2015-2016 plot measurements were used in this study. Detailed stand area, stand increment and growing stock tables were added to forest management plan.

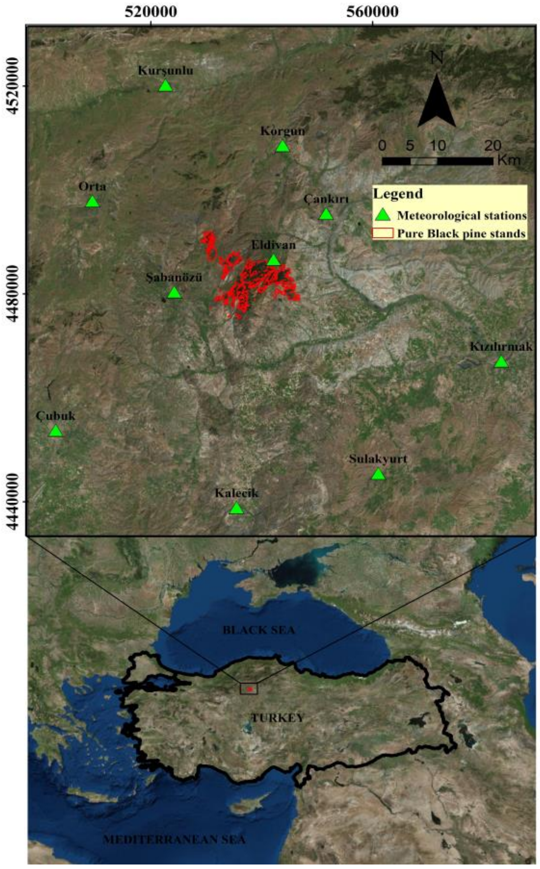

Figure 1. *Study area*

Table 1. *Characterizations of the study materials*

Dataset	Usage purpose	Source
Forest inventory	Ground truth of NPP, comparison analyses	Republic of Turkey, General Directorate of Forestry
Satellite dataset	NPP calculations	USGS Landsat database
Climate dataset	NPP calculations	State meteorological works of Turkey

Satellite data

Landsat 8 satellite images were acquired for each month of 2016 from the United States Geological Survey Earth Explorer data portal (USGS, 2000). Band 4 (Red), Band 5 (Near Infrared) and Band 7 (Short-wave Infrared) were used to run the CASA model for twelve months of a year.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44594473

Meteorological data

Climate data were included daily mean, maximum, minimum temperature, precipitation and solar radiation with the same periods of Landsat image's records (2015-2016) and obtained from 10 Turkish State Meteorological Service climate stations. Monthly mean, maximum, minimum temperature and solar radiation were interpolated with appropriate interpolation techniques such as ordinary kriging and radial basis function. Climate data maps prepared for the study area were produced with 30 m spatial resolutions. Data interpolation and analysis were performed using.

Methodology

The CASA model

Carnegie, Ames, Stanford Approach (CASA) model was used to predict Black pine NPP in local scale (Potter et al., 2003, 2004). This model is run based on photosynthesis progress of a plant. It was designed for global studies, however; it is contained plant specific variables and it may be used for the local studies for modifying the variables such as maximum light use efficiency and photosynthesis temperature range.

The CASA model was used for predicting NPP in the study area. It is defined as follows (*Eq. 1*):

$$NPP = \varepsilon_n x \, APAR \quad \text{(Eq.1)}$$

where APAR is absorbed photosynthetically active radiation (MJ/m^2 month) and ε_n is light use efficiency (g C/MJ).

$$\varepsilon_n = \varepsilon_{max} \, x \, f(T) x \, f(W) \quad \text{(Eq.2)}$$

Maximum light use efficiency (ε_{max}) for evergreen needleleaf stands was separated into three age classes. Mean ε_{max} of young, middle age and mature stands are 0.72, 0.57 and 0.52 (g C/MJ), respectively (Li and Zhou, 2015).

Temperature on the maximum light use efficiency of vegetation (T) is defined as follows (*Eq. 3*):

$$f(T) = (T - T_{min}) x (T - T_{max}) / ((T - T_{min}) x (T - T_{max})) - \left(T - T_{opt}\right)^2 \quad \text{(Eq.3)}$$

where T is the atmospheric temperature (°C); and T_{min}, T_{opt}, and T_{max} are the minimum, optimal, and maximum temperatures (°C) for photosynthetic activities, respectively (Huang et al., 2010).

Water on the maximum light use efficiency of vegetation (W) is defined as follows (*Eqs. 4* and *5*):

$$W = (1 + LSWI) / (1 + LSWI_{max}) \quad \text{(Eq.4)}$$

$$LSWI = (p_{nir} - p_{swir}) \, / \, (p_{nir} + p_{swir}) \quad \text{(Eq.5)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44594473

where LSWI is the land surface water index and $LSWI_{max}$ is the maximum LSWI. The variables p_{nir} and p_{swir} represent the surface reflectance of the NIR and MIR bands in Landsat 8 images, respectively (Huang et al., 2010).

$$APAR = FPAR \ x \ PAR \quad \text{(Eq.6)}$$

Fraction of photosynthetically active radiation (FPAR) is defined as follows (*Eq. 7*):

$$FPAR = \frac{(NDVI - NDVI_{min}) \ X \ 0.95}{(NDVI_{max} - NDVI_{min})} + 0.05 \quad \text{(Eq.7)}$$

where NDVI is Normalized Difference Vegetation Index, $NDVI_{max}$ and $NDVI_{min}$ are the maximum and minimum Normalized Difference Vegetation Index, respectively (Los et al., 2000; Zhu et al., 2006; Huang et al., 2010; Chen et al., 2016).

Photosynthetically active radiation (PAR) is defined as follows (*Eq. 8*):

$$PAR = Sr \ x \ 0.50 \quad \text{(Eq.8)}$$

where Sr is solar radiation (MJ/m^{-2} day^{-1}) (Potter, 1993, 1998; Huang et al., 2010).

Tree cover classification

Stand map was acquired from Turkey General Directorate of Forestry to determine the pure black pine cover. The stand map is contained the classification of the area according to the tree type, development age and crown closure. Within these areas, there may be areas that are not covered by trees because it was obtained as polygons and caver degree is variable inside the polygons. Therefore, only forest covered areas were extracted from the polygons applying a supervised classification approach. NPP will be calculated for pure black pine areas, so the opening areas had to be removed. We used maximum likelihood classification method (MLC) that is one of the most effective parametric classifier when there are enough training points for forest cover classification (Şatır and Berberoğlu, 2012). Almost 270 training points were used to be forest and non-forest areas, and 100 points were used for accuracy assessment. This area is not too complex, also it is included only black pine forest formation so point samples were enough for the classification.

Calculating carbon stock

Initial parameter in calculating the carbon stock was total stand growing stock volume (V), and it was obtained from stand map and forest management plan. Other parameters were above-ground biomass (AGB), below-ground biomass (BGB), above-ground carbon (AGC), below-ground carbon (BGC), dead wood biomass (DWB), dead wood carbon (DWC), litter carbon (LC) and forest soil carbon (FSC). The carbon stocks in the biomass were calculated using AGC, BGC, DWC, LC and FSC (*Eq. 9;* Tolunay, 2011; Değirmenci and Zengin, 2016). The equations of these parameters were presented in *Table 2*.

$$Carbon \ stock = AGC + BGC + DWC + LC + FSC \quad \text{(Eq.9)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44594473

Table 2. *Carbon stock coefficients*

Cover type	Parameter	Equation
Coniferous	AGB	V x 0.446 x 1.212
	BGB	AGB x 0.29
	AGC	AGB x 0.51
	BGC	BGB x 0.51
	DWB	AGB x 0.01
	DWC	DWB x 0.47
	LC	Area (ha) x 7.46
	FSC	Area (ha) x 76.56

Variance analysis

Digital Elevation Model (DEM), forest management plan and stand map were used for calculating testing parameters to be age, site index, crown closure and elevation. Homogeneity between NPP and these parameters was tested using one-way ANOVA by followed Duncan procedure. Classes were created for elevation, age, crown closure and site index (*Table 3*). Elevation was between 1000 and 1600 m in the study area. It was separated into six classes. Age was created as a seven classes with a period of 20 years. There are no stands of the sixth age class in the study area. Crown closure was divided into three classes by coverage of ground cover. Site index was determine according to dominant height at standard age (100) and separated into three classes.

Table 3. *Classes for variance analysis*

Criteria	Value	Class	Criteria	Value	Class
Age (year)	0-20	1	Elevation (m)	1000-1100	1
	21-40	2		1101-1200	2
	41-60	3		1201-1300	3
	61-80	4		1301-1400	4
	81-100	5		1401-1500	5
	121-140	6		1501-1600	6
Site index (m)	20-24	1	Crown closure (%)	11-40	1
	15-19	2		41-70	2
	10-14	3		71-100	3

The validation of CASA model

NPP was predicted using the CASA model and we did not have actual values to validation of the model. So, stand increment, growing stock and stand carbon were used for the CASA model validation. The relationships between these parameters and NPP were compared. Relationship levels were determined by calculating correlation (r) and coefficient of determination (R^2). In addition, CASA model was compared and validated in many studies (Cramer et al., 1999; Potter et al., 2012), and these were showed that this model was provided significant results when it was applied correctly.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44594473

Results

Study results were presented in three stages to be; mapping the tree cover, mapping of the NPP, and defining the relationship between NPP and some forest stand variables.

Mapping the tree cover in black pine stands

The CASA model used for NPP computation was created for tree covered fields. It was necessary to remove the opening areas. So the NPP was more consistently calculated in terms of spatial position. For the operation of this process, Landsat 8 satellite image was used for supervised classification (kappa = 0.92, overall accuracy = 96.4%). The opening and tree cover areas were determined and NPP was calculated to tree cover areas (*Fig. 2*).

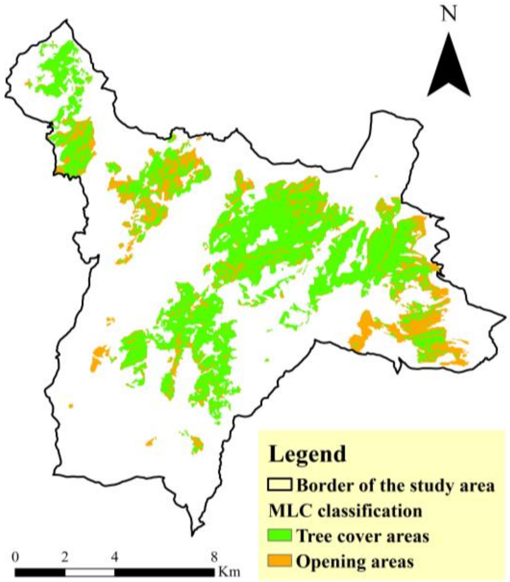

Figure 2. *Tree cover map of the black pine stands*

Mapping the NPP using CASA model

The CASA model was used to predict NPP values of the pure black pine forests in 2016. NPP values were integrated with forest stand map and calculated variables such as stand increment, growing stock and stand carbon in 676 plots. Descriptive statistics for NPP, stand increment, growing stock and stand carbon were presented in *Table 4*. The NPP values ranged between 15.16 and 1893.93 (ton C year^{-1}) with a mean value of 382.82 (ton C year^{-1}). Mean values of stand increment, growing stock and stand carbon were defined to be 20.90, 548.79 and 677.57, respectively.

Table 4. *Descriptive statistics of the NPP and forest attributes*

Variable	N	Min	Max	Mean	SD	Skew	Kurt
NPP (ton C year^{-1})	676	15.16	1893.93	382.82	385.26	1.651	2.306
Stand increment (m^3)	676	0.60	175.39	20.90	27.07	2.468	6.756
Growing stock (m^3)	676	7.32	4010.47	548.79	746.09	2.024	3.813
Stand carbon (ton C year^{-1})	676	45.30	4221.33	677.57	716.82	1.831	3.193

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44594473

Monthly mean NPP values were calculated for all months of 2016 (*Fig. 3*). The highest mean NPP was calculated in May to be 120.83 (g C m^{-2} $month^{-1}$) and the lowest mean NPP was calculated in February as 5.89 (g C m^{-2} $month^{-1}$). According to the monthly analyses, there was a significant improvement on NPP in March, April and May. However, NPP was decreased fast after the September. The highest NPP value was predicted to be 1213.40 (g C m^{-2} $year^{-1}$) and the lowest NPP value was 193.70 (g C m^{-2} $year^{-1}$) per unit area over the year (*Fig. 4*).

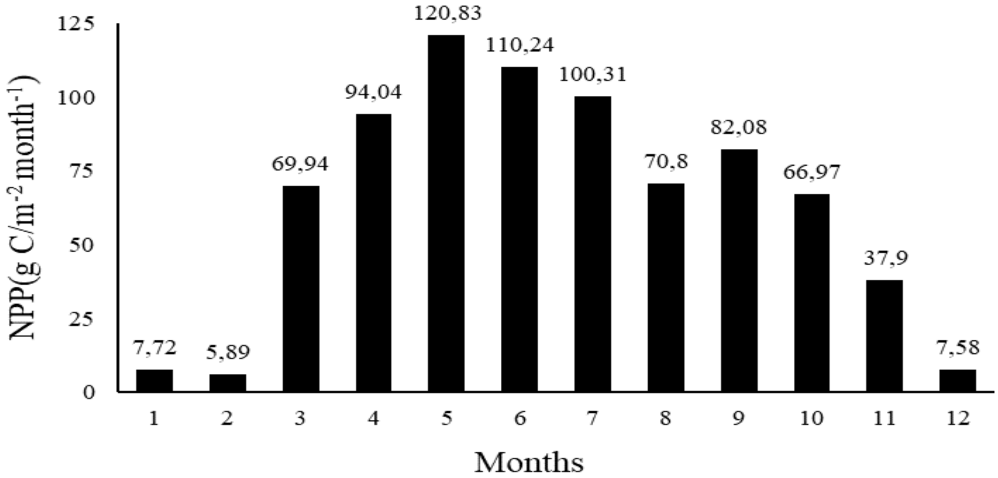

***Figure 3.** NPP distribution in the pure black pine stands for months of 2016*

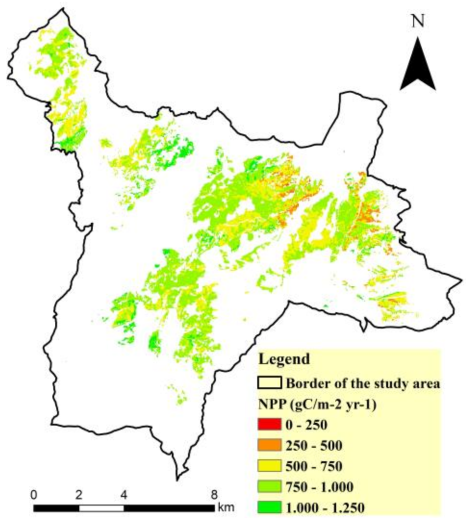

***Figure 4.** Spatial distribution of NPP derived from the CASA model in the black pine stands for the year 2016*

Defining the relationship between NPP and some forest attributes

Relationship levels between the calculated NPP data and stand increment, growing stock and stand carbon were showed in *Table 5* and *Figure 5*. The highest correlation was obtained with stand carbon (r = 0.92), and the lowest correlation was defined with stand increment (r = 0.87). Linear models and relationships were created between NPP

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44594473

and these variables. Linear model results were showed that predicted NPP and calculated stand variables related with NPP were matched, and NPP prediction was significant for this area.

Table 5. *NPP models and performance criteria*

Variable	N	Model	r	R^2	p
Stand increment (m^3)	676	NPP = (12.351 × Stand increment) + 124.69	0.87	0.75	0.000
Growing stock (m^3)	676	NPP = (0.4552 × Growing stock) + 133.04	0.88	0.78	0.000
Stand carbon (ton C $year^{-1}$)	676	NPP = (0.4954 × Stand carbon) + 47.155	0.92	0.85	0.000

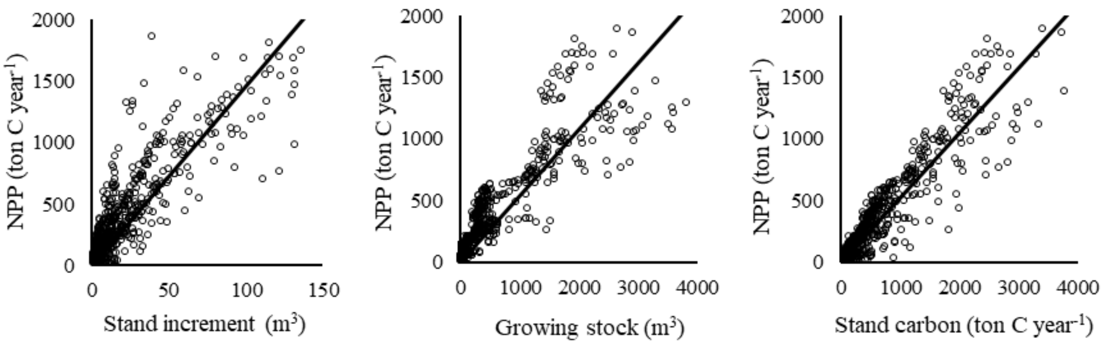

Figure 5. *Comparison between NPP and validation parameters*

Results of the one - way ANOVA test were summarized in *Table 6*. Duncan test showed that NPP values were statistically different by age (F = 88.465, p < 0.05), elevation (F = 39.354, p < 0.05), site index (F = 63.118, p < 0.05) and crown closure (F = 23.114, p < 0.05). According to the results, age classes were divided into 5 groups (a < b < c < d < e), elevation classes were divided into 3 groups (a < b < c), site index and crown closure classes were divided into 2 groups (a < b). Results showed that NPP was higher in young and low-medium closed stands than old stands in an altitude of 1300-1600 m with an average dominant height of 12-17 m.

Table 6. *Comparison of stand parameters in terms of NPP according to one-way ANOVA by followed Duncan*

Criteria	Class	N	Mean	Criteria	Class	N	Mean

Discussion

NPP was quite low in the first two months of the year. This situation was caused by the seasonal low temperature, solar radiation and leave chlorophyll activities (NDVI). NPP was increased rapidly in March and reached the highest value in May because of ideal weather conditions (precipitation, temperature and solar radiation) for black pine photosynthesis process. Summer temperatures were between 19–22 °C, and the highest temperature were recorded in August based on the nearest climate station. Therefore there was a little increase in September due to lower temperature than August. According to the NPP and temperature relationships, the ideal temperature for the black pine vegetation was defined to be 14.5–15 °C. NPP of the black pine vegetation was impacted from the temperature rise in June, July and August, negatively. NDVI in the last three months of the year was decreased regularly based on the weather conditions in these months. Particularly, temperature, precipitation and solar radiation were indicative on anomalies in seasonal transition (*Fig. 3; Table 7*).

Table 7. *The monthly mean parameter values used in the CASA model*

Month	Mean temperature (°C)	Mean precipitation (mm)	Mean solar radiation (MJ/m^{-2})	NDVI	NPP ($g\ C\ m^{-2}$)
January	-1.30	57.66	5.542	0.255	7.72
February	0.27	39.15	8.809	0.186	5.89
March	5.04	49.29	13.677	0.343	69.94
April	9.96	41.10	16.776	0.367	94.04
May	14.69	73.47	20.521	0.455	120.83
June	19.31	54.60	22.474	0.442	110.24
July	22.79	20.77	23.479	0.429	100.31
August	22.89	29.76	20.964	0.401	70.80
September	17.83	17.40	16.739	0.376	82.08
October	12.18	42.47	11.364	0.356	66.97
November	5.38	24.00	7.934	0.305	37.90
December	1.46	48.36	5.972	0.229	7.58

There are many different models that can be used to calculate NPP. Schloss et al. (1999), Cramer et al. (1999) and Ruimy et al. (1999) compared the different global NPP models. Ruimy et al. (1999) evaluated twelve global NPP models and assessed the performance of the models. LUE was derived from models and obtained the linear correlation coefficients with NPP. The highest correlation between NPP and LUE was obtained with SIB model ($r = 0.71$). APAR was also used in evaluation of the models. The highest accuracy was obtained by CASA model based on APAR ($r = 0.98$).

The CASA model is widely used in both locally and globally scales for NPP calculation. Taskınsu Meydan and Berberoglu (2008) performed NPP calculations for black pine stands in Mediterranean part of Turkey. Productivity evaluation can be made for northern and southern regions between continental and sub-Mediterranean climate zones. In this study, the lowest NPP value of the year was obtained in February (5.89 g C m^{-2} $month^{-1}$), and the highest NPP value was obtained in May (120.83 g C m^{-2} $month^{-1}$). In the study conducted at the Mediterranean region, the lowest and highest values were detected in March and June (0.28-52.25 g C m^{-2} $month^{-1}$), respectively (*Fig. 6*). NPP

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44594473

obtained for the northern region was obviously higher than southern region of Turkey. The average for all months was 64.53 g C m^{-2} year^{-1} for the northern region and 19.79 g C m^{-2} year^{-1} for the southern region. Evrendilek et al. (2006) was estimated the NPP of conifer forests in the eastern Mediterranean region of Turkey. They presented that the annual total NPP of black pine forests was 1302.00 g C m^{-2} year^{-1}. It was 774.30 g C m^{-2} year^{-1} in our study. Because, studies were applied in different regions that has been various climatic conditions, and difference of the NPP values were significant even if they have similar land cover.

Figure 6. *Comparison of monthly NPP values for pure black pine stands between southern and northern Turkey*

Besides the climatic features, forest forms and land cover types were also affected to the NPP. Ma et al. (2008) were estimated the annual average NPP for *Pinus elliottii* plantation. They focused 20 years period from 1885 to 2005. The average yearly GPP was predicted 630.88 g C m^{-2} year^{-1} by their study. In our study, the yearly NPP value was around 775 g C m^{-2} year^{-1}. In our work was done in natural pine forest, and their work was conducted in pine plantation areas that was included different pine species from our study. However, it can be seen clearly in Ma et al. (2008) that NPP values have been variable based on climatic effects.

Pei et al. (2018), Zhang and Zhang (2017) and Chen et al. (2016) were calculated the annual mean NPP using CASA model for different land cover types in China. Pei et al. (2018) obtained the NPP for evergreen broadleaf forest (EBF, 774 g C m^{-2} year^{-1}), deciduous broadleaf forest (DBF, 471 g C m^{-2} year^{-1}), evergreen needleleaf forest (ENF, 308 g C m^{-2} year^{-1}), deciduous needleleaf forest (DNF, 444 g C m^{-2} year^{-1}) and mixed forest (MIF, 460 g C m^{-2} year^{-1}). Zhang and Zhang (2017) reported that the NPP in ENF, DNF, DBF and MIF were 489.73, 415.71, 954.19 and 650.94 g C m^{-2} year^{-1}. Chen et al. (2016) calculated the NPP for EBF (771 g C m^{-2} year^{-1}) and DBF (734 g C m^{-2} year^{-1}). These differences in the NPP of land cover types were particularly affected by climate and topographic factors (Zhang and Zhang, 2017). Donmez et al. (2016) calculated the NPP using CASA model for 2000-2010 and estimated for 2070-2100 period using RCP climate scenarios in the eastern Mediterranean region of Turkey. The annual mean NPP was calculated 1042 g C m-2 year-1 for ENF between 2000 and 2010. The highest and lowest NPP values were obtained for DBF (1529 g C m^{-2} year^{-1})

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44594473

and shrubland (452 g C m^{-2} $year^{-1}$) cover types, respectively. The highest and lowest grand mean change according to RCP climate scenarios was obtained for the DBF (-3.2%) and shrubland (0.7%) cover type between 1476-1483 g C m^{-2} $year^{-1}$ and 454-457 g C m^{-2} $year^{-1}$, respectively.

NPP is generally higher at young stands that are accumulating biomass in forest ecosystems (Field et al., 1995; Li and Zhou, 2015; Wang et al., 2018). As a result of the one-way ANOVA test applied to age classes ($6 < 3 = 5 < 4 < 2 < 1$), NPP was higher in young stands that were 1st and 2nd age classes. The areas with an average dominant height of 12-17 m were more favorable than other areas for NPP ($1 < 2 = 3$). Black pine covered areas in the study area were 5517 ha. Nearly half of the black pine areas (2303.19 ha) was located to 2nd-3rd site index and 1st-2nd-3rd age classes. Thus, the NPP in areas with lower dominant height was found to be higher than other places because, these areas were covered by young stands with a high NPP. Wang et al. (2018) researched the relationship between age and NPP for broadleaved and conifer forests under the various site conditions. They reported that NPP of young forests increases rapidly, reaches the highest value in mature forests and decreases in old forests. In addition to the forest age, site conditions also affect the NPP. Chen et al. (2002) indicated that NPP was increasing faster in area of the high site index. That is, site index is critical in identifying the relationship between NPP and age.

When the results were examined in terms of the elevation that a linear relationship was appeared between NPP and elevation in negative way. Donmez et al. (2015) reported that there were an inverse relationship between NPP and elevation ($R^2 = 0.8129$). Both studies were similar results in same points of view. This study was carried out for an area of 1000000 ha and an elevation range of 0-2300 m. These results for site index and elevation have been influenced by the local and managed forest area.

NPP was higher in stands with low-medium crown closure (11-70%) than high crown closure areas because of the efficient sun light availability. NPP may be high because the rate of fall to the surface of rain and the rate of water utilization of plants are high (especially in arid or semi-arid climates). These effects may have an enhancing effect on photosynthesis. So it may be caused NPP to increase.

Conclusions

In this study, NPP was predicted using CASA model for pure black pine stands in the Black Sea backward region of Turkey. The CASA model can be used efficiently that the region where this study was conducted. The satellite and climate data were required to run the CASA model and it was effort and time consumed. In addition, there was also the possibility of modeling with the stand increment ($r = 0.87$), growing stock ($r = 0.88$) and stand carbon ($r = 0.92$) parameters that were correlated positively with the NPP in the study. Results of the variance analysis showed that optimal stand criteria for maximum NPP were detected in 0–40 years of age and 12-17 m mean dominant height, 11-70% of level of crown closure and 1300-1600 m of elevation. It was believed that these results can be helpful to create forest management plans considering maximum NPP operating objective studies in forest ecosystems or afforestation studies. Recently, black pine trees were used in afforestation in all around the Turkey to be coniferous, and this study can be a good guide to use the black pine for carbon absorption more efficiently. It is also very important to create a sustainable carbon budget strategy in country scale.

(Received 23rd Jan 2019; accepted 6th Mar 2019)

Abstract. In this paper, the relations between live weight (LW) gain of the grazing cows and rangeland condition (RC), LW gain and concentrate supplement and LW gain and genetics of the grazing cows were investigated to quantify LW and body condition score (BCS) losses driven by rangeland degradation to estimate the threshold RC over which rangelands can compensate these losses. This study was conducted in Erzurum Province, Turkey. LW gains were estimated using farmer- animal- and rangeland-related variables during June-August and June-October periods. RC was calculated employing the classical condition assessment method. Ordinary least squares (OLS) were used in data analyses. The results show that a 10% enhancement or setback in RC can result in about 10 kg LW gain or loss per head. The financial equivalent of these LW gain or losses was 314.6 Turkish lira (TRY) or 59.0 USD (I TRY = 0.1875 USD) per farm, which accounts 15.5 TRY or 2.9 USD per hectare of rangeland. It is concluded that rangeland with an RC value below 4.3 requires restoration and that cows of higher genetic merit more than crossbred genotypes are not suitable for extensive production in the study area and areas sharing similar agroecological conditions.
Keywords: *threshold rangeland condition, rangeland restoration investments, grazing cows, live weight gain, body condition score, genetic merit, concentrate supplement, Erzurum, Turkey*

Introduction

As a natural resource, rangeland is the common name for extensive natural landscapes, such as grasslands, shrub lands, woodlands, wetlands and deserts. It is the most common land type that about 50% of the total land area of the world is covered with rangelands (Holechek et al., 2004). Beside the immeasurable outputs of ecosystem services such as biodiversity, soil fertility, water quality, pollination, they ensure the sustainability of extensive livestock production by providing free of charge forage for the farm animals (Williams et al., 1968; Altın et al., 2005). For that reason, extensively managed livestock production is the most sustainable and common form of agriculture. Although they produce relatively agriculturally low value, rangelands have significant overall, economic and social value due to their geographic magnitude (Schacht and Reece, 2009). For that reason, rangelands with low-input, extensive livestock production have been a way of life and important in sustaining livelihoods for centuries in many areas worldwide (Williams et al., 1968; Gintzburger et al., 2006; Pardini, 2009).

However, heavy grazing is reported to be the most important factor causing the deterioration on rangelands. through replacement of species of higher nutritive value with those of lower nutritive value over time. Especially in public rangelands, continuous heavy grazing, irregular and misuse, accelerated with other type of pressures, such as increasing land demand for industry, urbanization and crop cultivation, results in irreversible changes in botanical composition and undesired

DOI: http://dx.doi.org/10.15666/aeer/1702_44754497

species become dominant (Gökkuş and Koç, 2001; Holechek et al., 2004; Pardini, 2009). Thus, these valuable ecosystems have been degraded over time and they lost their hay production potential. Because, rangeland degradation means losses of livestock revenues for the national economy, rehabilitation and restoration of the degraded natural rangeland sites is of great importance to increase and maintain productivity.

Rangeland condition is defined as an evaluation of the existing state of health of the vegetation cover in a definite site relative to an expected norm with a given set of prevailing environmental and managerial factors, which measures range deterioration and improvement (Heady, 1975; Koç et al., 2003; Ludwig and Bastin, 2008).

As in intensive livestock production systems, extensive, rangeland dependent dairy cattle production is profitable only with high milk yields and the birth of a calf each year per head of dairy cows, both of which require optimal care and feeding conditions. Dairy cow energy reserves are important indicators of these optimal care and feeding conditions, reflecting the animals' underlying physiological state. Because rangelands have been the main feeding sources especially during the grazing seasons (Kara et al., 2009; Ünal et al., 2010; Sayar et al., 2015), energy reserves of the grazing animals are, of course, closely linked to rangeland condition in extensive production.

One method for determining an animal’s energy reserves is the body condition score (BCS). The BCS rates farm animals according to visual and/or tactile appraisals of specific body regions made by trained staff to assess body energy reserves (Aktaş et al., 2011; Berry et al., 2011; Anonymous, 2012). In their review, Bewley and Shulz (2008) concluded that changes in BCS throughout lactation can have an impact on milk yield, herd health, reproductive performance, and animal well-being. Therefore, management of BCS must play a key role in achieving profitable animal production by maximising animal potential.

Modified versions of the BCS have been used in many countries for different kinds of farm animals since it was first developed for sheep by Jefferies (1961). Different countries employ different BCS scoring systems (e.g. 1–4, 1–5, 1–8, 1–9, and 1–10 scales). In all systems, thin animals receive lower scores than fat animals (Bewley and Schulz, 2008).

In addition to BCS, live body weight (LW) is routinely used to estimate the body energy reserves of farm animals. Although changes in LW are influenced by factors other than fat content (e.g. endogenous water and protein content, changing organ weights, gastrointestinal contents, and foetal development) (Schroder and Staufenbiel, 2006), thereby rendering interpretation of LW changes difficult (Morris et al., 2002), it is accepted that LW and LW changes have effects similar to those of BCS (Roche et al., 2007) and that monitoring LW after parturition can be used as a management tool to prevent reproductive problems (Řehák et al., 2012).

Consequently, the relation between BCS and LW has been the subject of numerous studies. Otto et al. (1991) calculated an r^2 of 0.62 for the relation between BCS and LW in US Holstein cows. Enevoldsen and Kristensen (1997) reported correlations between BCS and LW of 0.53, 0.34, and 0.57 for Danish Friesian, Danish Jersey, and crossbred Jersey × Red Danish cows, respectively. Yıldız et al. (2011) reported a correlation of 0.4 between BCS (1–5 scale) and LW for Brown Swiss × Simmental crosses. Berry et al. (2011) reported a moderate correlation (r = 0.49) between BCS (1–5 scale) and LW for Irish Holstein-Friesian dairy cows in pasture-based dairy cattle production.

Although LW explains only 25–62% of the variation in BCS changes, it is still used as an indicator of BCS losses or gains in cows (Anonymous, 2012). In fact, these values underestimate the accuracy of LW as an indicator of BCS since BCS is affected by body shape, and more fat is needed for each additional BCS point on a large-framed than on a small-framed cow, because visual changes in BCS take longer to become apparent (minimum 4 weeks) than do changes in LW (1 or 2 weeks) (Moran, 2005).

Morris et al. (2002) reported that 15-kg and 30-kg LW increments were necessary to increase BCS by one unit in 1–10 and 1–5 systems, respectively. Berry et al. (2006) reported that, on average, 1 BCS unit equalled 31 kg in LW. In a later study, Berry et al. (2011) reported a 50-kg LW change per unit change in BCS, varying from 39–66 kg, depending on the parity and stage of the inter-calving interval.

The BCS of farm animals fluctuates throughout the year, and different BCSs have been suggested for certain stages of cow production cycles to maximize economic returns through optimizing milk production while minimizing health and reproductive disorders (DEFRA, 2001). During the parturition and dry-off periods, optimum BCS is expected to be 3 and 4, respectively, and to be between 2 and 3 during peak milk yield (Serin, 2004; DeLaval, 2006; Hulsen, 2007; OMAFRA, 2015). The reason for low BCS during peak milk yield is insufficient daily nutrient intake coupled with higher energy requirements, which lead to a negative net energy balance. To cover the energy gap, the energy reserves of the body are mobilised, which brings about BCS losses after calving. Gallo et al. (1996) pointed out that BCS is lowest in the third and fourth months of lactation in low- and high-yielding animals, respectively, and it is compensated for only in the middle of or at the end of lactation, although replacement of decreased body fat reserves starts in the seventh and twelfth weeks after calving.

With one third of total rangeland asset, Eastern Anatolia ranks first among the geographical regions of Turkey. Not only is arable land limited due to varied topography but also crop pattern because of short vegetation period and low mean temperature. Consequently, rangeland dependent extensive animal production has been an important component for livelihoods of the rural people from past to present. In this region and especially in the study area, calving occurs in February and March, and rangeland grazing starts by early May (Kara et al., 2009). The beginning of the grazing season coincides with the 60^{th}–90^{th} day of lactation, when BCS is lowest. In the study area, cow BCS is likely < 2.5, and even drops as low as 2.1 (Aktaş et al., 2011).

Given that the only nutrient source for grazing cows is rangeland herbage (except in the early and late grazing season; Kara et al., 2009), high-quality rangeland is necessary to compensate for BCS and LW losses and achieve profitable production in extensive farming. However, the decades-long use of rangeland above its carrying capacity has resulted in deteriorating rangeland quality and losses in herbage production potentials. Therefore, rehabilitation of degraded rangeland can lead to LW and BCS gains, ultimately leading to an increase in beef and milk production for the local farmers whose livelihoods depend on animal production.

Although an increasing awareness has been developed on the importance of rangelands worldwide and the governments allocate considerable funds to restore degraded rangelands it is necessary to keep the rangelands on the top of the list in the agenda in facilitating sustainable fund allocation to rangeland restoration investments providing cause-effect results with some concrete data. This article covers an on-farm research study of 11 carefully selected villages and their rangelands in a socioeconomic environment. By connecting rangeland and grazing animal attributes in extensive dairy

DOI: http://dx.doi.org/10.15666/aeer/1702_44754497

cattle production at farm level, I aimed to quantify LW and BCS losses driven by rangeland degradation to estimate the threshold RC over which rangelands can compensate BCS and LW losses, and under which restoration is required.

I also aimed to grasp attention of the policy makers to the importance of rangeland restoration efforts and discuss the importance of sustainable rangeland use from a different view point by revealing the effect of rangeland degradation on LW and BCS losses and calculating the cost equivalent of the feeds required to compensate for the LW or BCS losses. Study results may also be important for researchers and the others having an interest on rangeland-animal relationships prevailing under on-farm conditions. Although the study presents results and arguments from Erzurum Province, Turkey, the findings are expected to be relevant to countries sharing similar agro–ecological conditions, production patterns, and cultural and historical backgrounds.

Materials and methods

Materials

The primary study materials were vegetation study results and LW records of lactating cows in farms selected from the study villages. Secondary materials included official records of the Eastern Anatolia Agricultural Research Institute and other relevant official institutions.

Methods

Study area

The study area covers Erzurum Province, which is representative of the entire region in terms of topography, altitude, climate, and production pattern (*Fig. 1*). It has 12% and 10% of the total meadow and rangeland pastures in Turkey, respectively (TURKSTAT, 2013). A continental climate prevails, with long harsh winters and short hot summers. The lowest and highest recorded temperatures between 1975 and 2006 were −37.2°C and 36.5°C, respectively, while average annual temperature and rainfall were 5.5°C and 453 mm, respectively. The number of frosty days was 154, and the number of days with snow cover was 113 (TÜMAS, 2013). The average annual rainfalls in 2006 and 2007 were 357.4 mm and 436.6 mm, respectively, of which 43.4 and 134.1 mm were recorded from June–August in the first and second grazing seasons, respectively, a difference of 90.7 mm. Despite the positive difference in annual precipitation between the first and second study years, there was considerably more rain in September–October in 2006 than in 2007 (*Table 1*).

Indigenous cattle breeds and their various crosses constitute the largest ruminant population, whereas Red Karaman sheep and Anatolian Black goats make up the small-ruminant assets in the region (Kara and Kızıloğlu, 2012). They are hardy and well adapted to natural rangeland. In *Figure 2* are presented some photos to illustrate the study area rangelands.

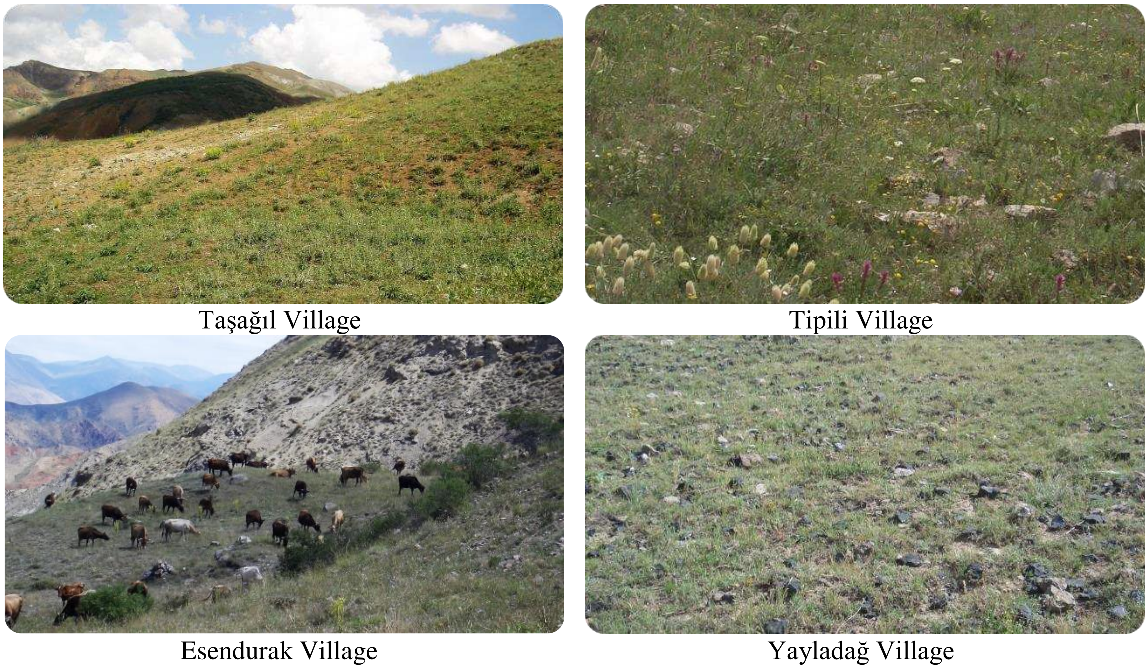

Figure 2. *The study area rangelands*

Selection of villages

Based on how well they represented the surrounding area and province as a whole, villages were selected from different districts, both east–west and north–south, that were free of nomadic movements and boundary problems and for which rangeland demarcation and allocation studies were completed. In total, 11 villages were selected from Aşkale, Yakutiye, Tortum, Narman, Pasinler, Köprüköy, and Horasan districts. Although the selected villages dispersed in different districts of Erzurum province, there was no significant differences among them regarding climatic conditions, production techniques, customs and the habits. At least, it was assumed that the only factors differentiate the villages from each other were the condition of their rangelands, the altitude and the stocking rate.

Vegetation studies and calculation of the rangeland condition

Vegetation studies were carried out in 2006 to determine the botanical composition and conditions of the village rangeland. They were conducted in 12 representative sites in rangelands of each village with four replications along 100-m transects in easterly, westerly, southerly, and northerly directions, following Koç and Çakal (2004). The condition of the rangeland was determined following the methods of De Vries et al. (1951), cited in Koç et al. (2003), using the vegetation study data for each site in every village.

Rangeland condition was calculated according to the Rangeland Quality Degrees method (De Vries et al., 1951, cited in Koç et al., 2003), using the equation given below.

$$R_{Condition} = \sum P_i \times QS_i \qquad \text{(Eq.1)}$$

In *Equation 1*, P_i shows the relative abundance of each species, calculated as the proportion of individuals of i^{th} species to the total number of individuals encountered in the studied site, as QS_i represents the quality score of the i^{th} species. Quality score reflects the values given to each species according to the grazing and productivity traits of the encountered species such as productivity, post-grazing regeneration ability and palatability, varying between -1 to 10. Poisonous plants take -1 point as the scores 1 to 10 indicate the degree of other desirable traits (Koç and Gökkuş, 1996; Altın, 2001; Koç et al., 2003). In this method, vegetation cover is accepted as the product of climate and soil, as such that information on climax vegetation is not needed.

The arithmetic means of 12 sites in each village were used as a measure of the village's overall degree of rangeland quality. Rangeland condition was given a value between 0 and 10 (0–2.0: very poor, 2.1–4.0: poor, 4.1–6.0: moderate, 6.1–8.0: good, and 8.1–10.0: very good).

LW measures

The LWs of grazing lactating cows from the selected farms were measured and recorded by the study staff using digital scales three times per year during the study: at the beginning (early June), in the middle (late August), and at the end of the grazing season (late October). The scales were calibrated at the time of each weighing in every study village.

To reveal the effect of concentrated supplements on LW gain, each lactating grazing cow was regularly supplied with supplements on a daily basis (1 kg manufactured milking concentrate) during the grazing season. About half the study farms were provided with milking concentrate (16% crude protein and 2,400 Kcal kg^{-1} metabolic energy) in the first year, and the rest were provided with it in the following year. The amount of concentrate was standardised using a 1-kg capacity pan.

Data analysis

Forage allowance is high in June to August and thereafter continuously declines until the end of the season due to grazing and the maturation of the vegetation respectively. For that reason, the LW gain of the grazing cows in randomly selected farms in 11 studied villages was calculated for two periods (June–August and June–October) for each lactating cow by subtracting the initial LW from that measured in the middle and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44754497

at the end of the grazing season. In the socioeconomic environment of extensive production systems, many factors interact and affect the LW gain of grazing animals. Some of these factors relate to farmers (age, education) and some relate to the attributes of the grazing animals (e.g., lactation order and LW at the beginning of the grazing period), whereas other factors are related to the rangeland itself (e.g., rangeland condition, bare ground, altitude, and stocking rate), which determine herbage production and quality.

Considering the fact that most of the variables under consideration are affected by more than one cause in the real world, it is important to isolate multiple independent variables affecting the dependent variable in the model of interest. This feature can be achieved at *ceteris paribus*, which means "holding other things constant". The assumption of *ceteris paribus* is important to determine causation, especially in economics. Linear regression, on the other hand, is the workhorse of the econometrics and ordinary least squares (OLS) method is the most popularly used method to estimate the regression coefficients and describes well the relationship between dependent and independent variables in the presence of *ceteris paribus* assumption (Gujarati, 2012).

Moreover, the linear estimators, i.e., the regression coefficients, are easy to understand and simple to deal with. It is easier to explain the effect of independent variables on a dependent variable (Gujarati, 1995). However, Baltagi (2005) warns that individuals, firms, states, countries, etc., are heterogenous units and if not controlled this heterogeneity, the studies considering other than the panel data will have the risk of obtaining biased results. The most prominent techniques used to analyze panel data are fixed effect and random effect models. If a specific set of N entities (e.g., firms, countries, cities or the villages as in the present study) is focused on and the inferences have to be restricted to the behavior of these entities or whenever the aim is to analyze the impact of variables that vary over time, the fixed effects model is appropriate and therefore should be used (Baltagi, 2005; Torres-Reyna, 2007).

In the present study, however, as stated earlier, the study villages share the same agro-ecological conditions and production pattern, habits and customs inherited from the past. I assumed that heterogeneity among the villages was solely due to rangeland condition, altitude, and stocking rate. Further, I also assumed that heterogeneity among the farmers was due to their age and education level. As observation units, the cows were differentiated in terms of their lactation orders, initial LWs and breeds, all of which were controlled with relevant variables in the models.

In this study, I would like to reveal the effect of rangeland condition on LW gain in a two-year study and rangeland condition is a long-time concept (Heady, 1975), i.e., it is time invariant and does not change for several years. For that reason, it had a fixed value for each village during the study years. Only the average rangeland condition and average altitude value were calculated and assigned to each selected village, which is a significant limitation and makes it impossible to run fixed effect panel data models for the study data. In case of setting or treating the village variable as a panel variable, the rangeland condition, stocking rate, and altitude variables are dropped out. Whereas the rangeland condition is the backbone of the research and dropping it out would render the whole study inconclusive.

On the other hand, unlike the fixed effects model, the variation across entities is assumed to be random and uncorrelated with the predictor or independent variables included in the model (Torres-Reyna, 2007). The random effects model is appropriate if a set of N entities are randomly selected from a large population. If there is a reason to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44754497

believe that the differences across entities (the villages here) have some influence on the dependent variable (e.g., rangeland condition in the present study), then RE seems to be the most appropriate and so should be used (Baltagi, 2005; Torres-Reyna, 2007). Nevertheless, following the Breusch-Pagan Lagrange Multiplier test with a null hypothesis suggesting the use of simple OLS regression, we found it to be more appropriate (p>0.05) for the present study (Torres-Reyna, 2007; Gujarati, 2012).

OLS linear regression model can be written as in *Equation 2* given below (Gujarati, 1995);

$$Y_i = \beta_1 + \beta_2 X_{2i} + \beta_3 X_{3i} + \cdots + \beta_k X_{ki} + u_i \qquad \text{(Eq.2)}$$

where;

- Y represents dependent variable.
- X represents explanatory (independent variables).
- β_1 represents intercept.
- β_2 to β_k represent slope coefficients.
- k represents kth coefficient.
- i represents ith observation.
- u represents random or stochastic error term.

In a linear regression analysis following assumptions should be met (Gujarati, 1995);

- There is no multicollinearity (exact linear relationship) among the independent variables.
- Error term has a homoscedastic (constant) variance.
- Error terms are not correlated with each other, that is, there is no autocorrelation among error terms.
- Error terms are normally distributed.

In the regression models, categorical variables were represented by dummy variables whose number was less by one than that of the classification of the qualitative variables (Gujarati, 2012). In our study, the variable of the cow breed had three categories including local cattle breed. Thus, it was represented by two dummies of crossbred and purebred. Since the dummy variable for local breed was not included in the regression models, coefficients of other dummy variables should be interpreted in relation to reference category (local breed) as coefficients of other continuous independent variables represent the marginal change in dependent variable as a result of one-unit change in the continuous dependent variable of interest at *ceteris paribus.*

LW gain of the grazing cows was considered to be a function of the continuous and discrete variables given in *Table 2*.

The F-test and Ramsey RESET test were used to determine the significance and the omitted variables of the model, respectively. Multicollinearity was controlled with the variance inflation factor. Heteroskedasticity was tested with the Breusch-Pagan test, and the normality assumption was controlled with skewness and kurtosis tests, along with the Graph Method (Neter et al., 1989; Gujarati, 1995; Callaghan and Chen, 2008; Park, 2008; Cameron and Trivedi, 2010). Autocorrelation was not tested due to the fact that it is the problem of time series data and the data used in the present study is cross-sectional (Gujarati, 1995).

The skewness and kurtosis tests appeared to suggest that the assumption of the normality of the residual was violated. However, despite some small deviations that

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44754497

could be omitted, the normal probability and quantile-quantile plot distributions of the residuals indicated this was not the case (Park, 2008; Anonymous, 2013).

As the variable 'altitude' caused serious multicollinearity problem and inconsistent estimators for the models, it was omitted. Similarly, 'concentrate supplement × season' and 'concentrate supplement × animal breed' interactions were not included into the model because they also caused serious multicollinearity problems. According to the variance inflation factor values (range: 1.02–2.38, mean: 1.48), the regression models without altitude variable and above-mentioned interaction terms did not have a serious multicollinearity problem (Gujarati, 1995; Callaghan and Chen, 2008; Park, 2009). However, the Breusch-Pagan test revealed that the model had heteroskedasticity problem ($p < 0.01$) and to correct this problem Robust Standard Errors procedure was applied (Gujarati, 2012). Moreover, the Ramsey RESET test proved that the model had no omitted variable bias ($p=0.32$). Stata SE 14 software package was used for all analyses.

Table 2. *Explanations of the study variables*

Variables	Explanations
LW Gain-1	LW gain of grazing dairy cows during June-August period (kg.head^{-1})
LW Gain-2	LW gain of grazing dairy cows during June-October period (kg.head^{-1})
Distance	Approximate distance between village and rangeland site (m)
Farmer Age	Age of the farmer (year)
Schooling	Education level of the farmer (in schooling years)
Rangeland Condition	Rangeland condition (rangeland quality)
Altitude	Average altitude of the village rangelands (m)
Lactation Order	Lactation order (number of giving birth) of the cows
Initial LW	Live weights of the cows at the beginning of the grazing period (kg)
Stocking Rate	Rangeland stocking rate (animal unit (AU) per hectare)
Bare Ground	Bare ground percentage of the village rangeland (%)
Season	Grazing season (1 = Second year; 0 = First year)
Crossbred	Crossbred cows (If crossbred 1, otherwise 0)
Purebred	Purebred cows (If purebred 1, otherwise 0)
Concentrate Supplement	Supplement feed during grazing season (1 = Yes, 0 = No)
Season × Supplement	Season (Year) × Supplement feed interaction
Crossbred × Supplement	Crossbred × Supplement feed interaction
Purebred × Supplement	Purebred × Supplement feed interaction
U	The error term

The data for the variables of rangeland condition, altitude, distance, and bare ground were obtained from the vegetation studies and the live weight data were obtained from the live weight measures of the farm animals as stated earlier. The data used for stocking rate calculations were from the official records of the provincial and district directorates of agriculture.

Results

Vegetation survey results

The rangeland attributes of the study villages are presented in *Table 3*. As mentioned by Kara et al. (2015), 140 different species were found in the studied rangeland, of which 26, 24, and 90 were species of legumes, grasses, and other families respectively.

Medicago varia (5.0%), *Astragalus lineatus* (3.3%), *Astragalus microcephalus* (1.9%), *Trifolium hybridum* (1.7%), *Coronilla varia* (1.4%), and *Astragalus lagurus*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44754497

(1.3%) were the most common legumes, whereas *Festuca ovina* (13.3%), *Stipa lagascae* (3.3%), *Agropyron intermedium* (3.1%), *Dactylis glomerata* (1.5%), *Bromus tectorum* (1.3%), and *Phleum montanum* (1.3%) were the most common grasses. The most widespread species of other families were *Thymus pubescens* (6.7%), *Artemisia spicigera* (3.4%), *Salvia candidissima* (3.0%), *Eryngium campestre* (2.8%), *Galium verum* (2.6%), *Achillea millefolium* (2.4%), *Verbascum cheiranthifolium* (2.1%), *Plantago atrata* (2.1%), *Helichrysum plicatum* (2.0%), *Tanacetum balsamita* (1.7%), *Alyssum pateri* (1.5%), *Acantholimon caryophyllaceus* (1.4%), *Artemisia austriaca* (1.4%), and *Euphorbia virgata* (1.3%).

Table 3. *Rangeland attributes of study villages*

Villages	Species Richness	Of Species Found in Rangeland Vegetation (%)			Rangeland Condition (in fragments of 10)	Bare Ground (%)	Altitude (m)

Descriptive statistics

Average number of lactating cows per farm was 8.5 head. They had an average LW of 287.1 ± 1.8 kg at the beginning of the grazing season and gained 16.1 ± 0.9 kg and 14.9 ± 1.0 kg per head in June–August and June–October, respectively. The lactation orders of the cows were between 1 and 13. The rangeland condition of the study village rangeland varied from 2.53 to 4.18, indicating poor to moderate condition. About 24% of the rangeland area was bare, without any plant covers. The average stocking rate in the studied villages' rangeland was 0.68 AU (1 AU equals to 500 kg LW) per hectare varying between 0.1 and 3.0.

Multiple regression analysis

The factors affecting LW gain per head of dairy cows in June–August and June-October periods in two grazing seasons were examined using OLS regression (*Tables 4 and 5*).

Season, farmer age, rangeland condition and breed of the cows had all positive and very significant effects ($p < 0.01$) as concentrate supplements had also significant impact ($p < 0.05$) on LW gain of the grazing cows (*Table 4*). Additionally, the effects of initial LW of the cows, stocking rate, and bare ground of the rangelands on LW gain were all negative and very significant ($p < 0.01$). Distance from the village to rangeland, schooling years of the farmers and lactation order of the grazing cows had not significant effect on LW gain ($p > 0.05$).

Similar results can be seen in *Table 5*, with the exceptions that contribution of age and schooling years of farmers were negative and insignificant, as effect of bare ground was positive but not meaningful. Again, the effect of concentrate supplement shifted from significant to very significant as the effect of distance was altered to marginally significant.

The OLS regression results revealed that season had a strongly significant effect on LW gain in both models. There was a positive LW gain difference between the first and second grazing seasons; specifically, there was a difference of about 16.1 and 14.9 kg per head in June–August and June–October, respectively (*Table 6*).

***Table 6.** LW gain of cows by grazing season*

Grazing Season	June–August Period			June–October Period		
	N	Mean	Se	N	Mean	Se
2006	492	4.71	1.199	492	2.16	1.224
2007	527	26.79	1.063	527	26.83	1.290
Total	1019	16.13	0.870	1019	14.92	0.971

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44754497

The effect of cow breeds or genetic on LW gain was also very significant ($p < 0.001$). According to *Table 4* and *Table 5* crossbred and purebred cows gained 9.1 and 23.6 kg per head more LW than local cows during June–August and 10.6 and 26.0 kg per head during June–October periods respectively at *ceteris paribus*.

However, when I consider the non-supplemented groups in both grazing seasons, it is obvious that performances of the different breeds or genotypes differed in June–August and June–October periods of the grazing seasons. Indigenous or local cows seemed to be hardier and more insensitive for environmental conditions whereas high genetic merit cows, crossbred and especially purebred cows, are more sensitive. For example, considering the June–August period high genetic cows acted in opposite directions. They lost much weight in draught season as gained much in humid season (*Fig. 3*).

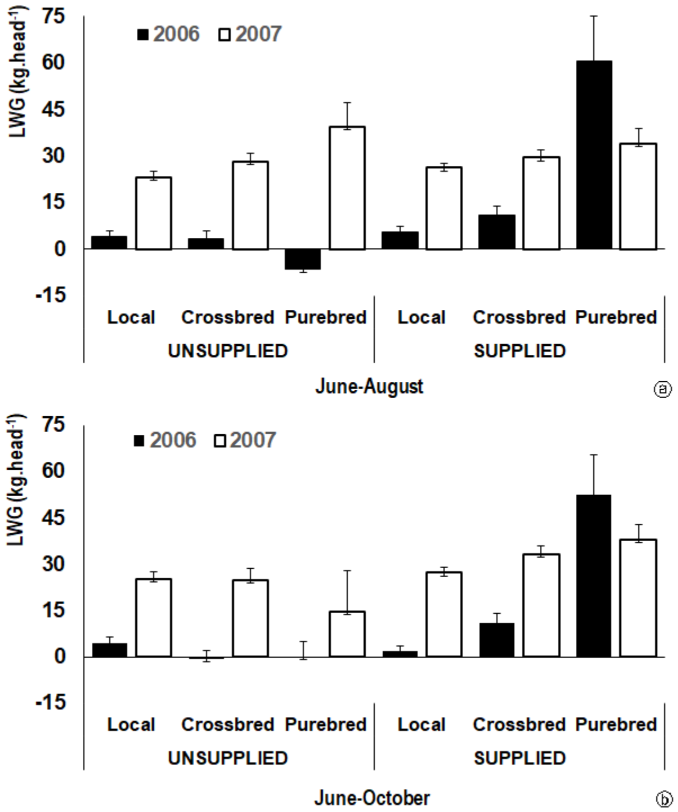

Figure 3. *Effect of concentrate supplement on LW gain by grazing seasons and cow breeds a) June–August period, b) June–October period*

Yet, as the season advanced, purebred cows did not maintain LW gain and lost much of what they gained during June–August period in humid season. It is also obvious that purebred cows lost LW during June–August period as local and crossbred cows gained some LW in draught season (2006). Again, another remarkable finding is that purebred cows balanced the LW losses at the end of June–October period through the late rainfalls in the draught season (*Fig. 3 and Table 1).*

The use of concentrate supplement during the grazing season improves LW gain because it enhances animal performance, thereby increasing LW. For that reason, the effect of concentrate supplement on LW gain was also significant ($p < 0.05$) and very significant ($p < 0.01$) in June–August and June–October periods, respectively.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44754497

Concentrate supplementation increased LW 3.1 kg per head and 4.4 kg per head in these periods respectively (*Tables 4 and 5*).

More importantly, however, the LW gain due to supplement feed was well below that due to rangeland condition. *Tables 4 and 5* show that a 10% increase in rangeland condition was associated with 12.3±1.6 and 13.4±2.0 kg LW gains per head of cow in June–August and June–October, respectively. This is 3.5 and 2.8 times the LW gain (3.5±1.5 kg and 4.8±1.6 kg, respectively) provided by a daily supplement of 1 kg of concentrate in June–August and June–October, respectively.

LW losses as proxies for BCS losses due to rangeland degradation

RC was found to be one of the most important factors affecting LW gains in extensive dairy farming *(Tables 4 and 5*). LW gain as a result of the impact of RC can be converted to BCS following Berry et al. (2011).

Berry et al. (2011) quantified 39 kg LW per 1-unit BCS (1–5 scale) for Holstein-Friesian cows with a LW of 564 kg; this would be 6.9% of the total LW of the cow. The average amount of weight gain/loss for every unit of BCS change was found to be equivalent to 6.58% of a cow's total LW on the 1–10 scaling BCS system used in New Zealand (Anonymous, 2012). These two conversions of LW gain or loss for every unit of BCS are roughly the same despite the different scaling systems. However, this can be explained by the fact that the 10-point scale is essentially a 5-point scale, as, in practice, only 3–7 is generally used in New Zealand (Morris et al., 2002).

This study related BCS to changes in LW due to the impact of RC throughout the June–August grazing period. To this end, the findings reported by Berry et al. (2011) regarding the relation between the BCS and LW for the post-calving stage (101st to 200th day) were adapted for the present study.

As previously stated, in north-eastern Anatolia, calving occurs in February and March, and rangeland grazing starts by early May (Kara et al., 2009). Therefore, the beginning of the grazing season occurs between the 60th and 90th day of lactation, coinciding with the time of the lowest BCS (*Fig. 4*).

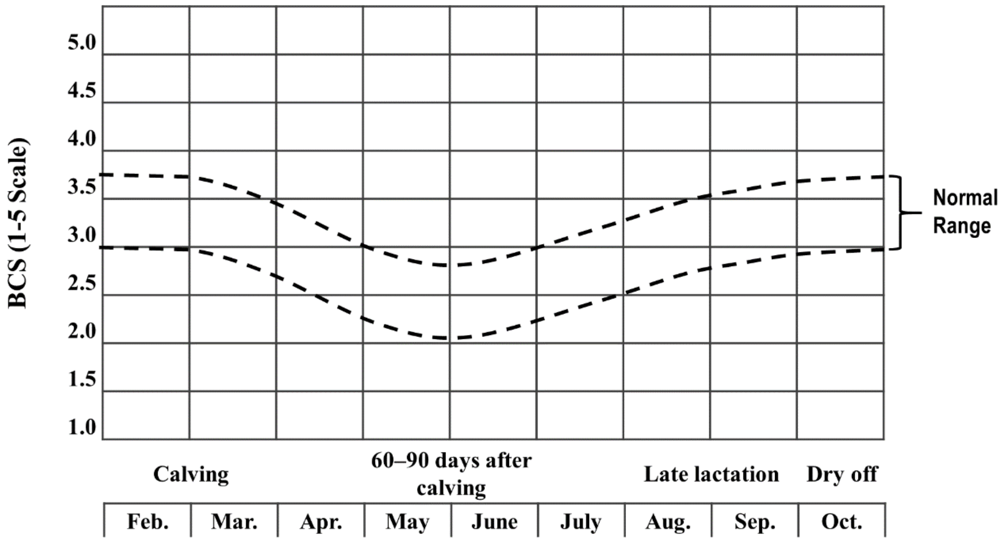

Figure 4. *Approximation of BCS changes in dairy cows after calving in the extensive dairy farming system in Erzurum province, Turkey, Source: Adapted from Hulsen (2007)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44754497

The grazing period considered in the present study roughly overlapped with the post-calving stage reported by Berry et al. (2011). The relation between BCS and LW for post-calving reported by Berry et al. (2011) was adapted for this study, although the breed and parity of the grazing cows in the study area were mixed. However, Nielsen et al. (2003) documented no significant effect of breed or parity on the relation between LW and BCS.

The average LW of the cows at the beginning of the grazing period was 287.1 ± 1.8 kg per head of cow. Using the rate of 6.9% LW gain per BCS point from Berry et al. (2011), I calculated 19.8 kg LW (287.1 kg × 6.9%) per BCS point at this stage. Because a 10% increase or decrease in RC would cause a 12.3±1.7 kg LW gain or loss (*Table 4*), it can be inferred that a 10% (one unit) degradation in RC will cause more or less a 0.5 point of BCS loss in the study area and in areas with similar conditions.

The average LW gain at the end of the June–October period was about 15 kg (302.0 kg−287.1 kg). That is, the BCS of grazing cows increased by only 0.75 points, not fully compensating for a 1-point BCS loss.

This study also revealed that, after August, grazing cows started to lose LW (*Table 6*), although expected to compensate fully for BCS losses before dry off. As calculated above about 20 kg of LW gain were required to increase BCS by one point.

Financial equivalent of LW and BCS losses due to rangeland degradation

The financial equivalent of LW and/or BCS losses due to the degradation of rangeland used by grazing dairy cows can be quantified by calculating the cost of feed required to compensate for BCS or LW losses. In calculation, barley, the most frequently and easily accessible feed on the farms, was considered. In general, one kg of barley contains 90% dry matter and has a metabolic energy value of about 13 mega joules per kg dry matter (Anonymous, 2015). Following this, financial equivalent of LW losses per farm due to 10 percent rangeland degradation (the energy cost to achieve the same amount of LW gain) are given in *Table 7.*

Table 7. *Cost equivalent of LW losses per farm due to 10 percent rangeland degradation*

Number of Lactating Cows per Farm (head)	(a)	8.5
LW Gain per Cow[1] (kg) in Grazing Period	(b)	12.3
Energy requirement for 1 kg LW gain (MJ)[2]	(c)	44.0
Total Energy requirement to re-gain LW loss in case of 10% degradation in RC (MJ)	(d=bc)	541.2
Energy Content of Barley DM[3] ($MJ.kg^{-1}$)	(e)	13.0
Total Barley Requirement per farm Containing 90% DM (kg)	$(f=ad(0.9e)^{-1})$	393.2
Average Barley Price[4] ($₺.kg^{-1}$)	(g)	0.8
Cost Equivalent of LW Loss per Farm Due to Rangeland Degradation (₺)	(h=fg)	314.6

Source: [1]from *Table 4*; [2]Anonymous (2012); [3]Anonymous (2015); [4]ETB (2018)

The financial equivalent of LW and/or BCS losses in the case of a 10% setback in RC due to rangeland degradation was 314.6 Turkish lira (TRY) per farm. Thus, it can be inferred that, *ceteris paribus*, farmers operating under 10% better rangeland conditions will likely save 314.6 TRY, or 59.0 USD (I TRY = 0.1875 USD).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44754497

I further estimated that the LW or BCS gain or loss per unit of rangeland area in response to a 10% enhancement or deterioration of RC was 15.5 TRY or 2.9 USD per hectare of rangeland (*Table 8*). Thus, *ceteris paribus*, farms operating with 10% poorer rangeland condition are likely to pay an extra 15.5 TRY per hectare of rangeland to compensate for the LW or BCS loss compared with their counterparts operating with rangeland in better condition.

Table 8. *Estimated total LW or BCS gain or loss per unit rangeland area due to a 10 percent enhancement or setback in RC*

Total Number of Farm Households	(c)	768
Energy Feed Cost Equivalent of LW Loss per Farm Due to Rangeland Degradation[1] (TRY)	(d)	314.6
Total Energy Feed Cost Equivalent of LW Loss (TRY)	(e=cd)	241 612.8
Estimated Cost Equivalent of LW Loss per Unit Rangeland Area (TRY.ha^{-1})	(f=eb^{-1})	15.5

Source: [1]from *Table 7*

Estimation of the threshold RC value for rangeland restoration

The total contribution to LW gain made by both rangeland and concentrate supplements at the end of June–October was about 15 kg (*Table 6*). The marginal contribution of RC to LW gain was about 10 kg (12.3±1.7 kg in *Table 4* and 13.4±2.0 kg in *Table 5*), and the gap was an extra 10 kg of LW gain for full compensation of a 1-point BCS loss (20 kg) after calving in the absence of supplement use during the grazing season. This is possible in the case of a 10% enhancement (one-point increment) in RC. Because the average RC was calculated to be 3.3 for the studied rangelands (*Table 3*), it can be inferred that rangeland with a 4.3 RC (= 3.3+1.0) is able to recover BCS losses in full. In another word, rangeland with an RC value below 4.3 is in need of restoration to recover its herbage production potential and fully compensate for the BCS losses of grazing cows.

Discussions

According to OLS regression results, farmer age had significant ($p < 0.01$) positive effect on LW gain (*Table 4*). Contrary to expectations (Rogers, 1983; Lionberger, 1960) but being in tune with Schmit et al. (2007), an explanation for the positive sign and the significance of the variable “farmer age” might be that older farmers are more experienced, and they are more successful in animal keeping. They might have possibly engaged in training activities previously and been able to take timely measures reducing the possibility of unwanted outcomes. On the other hand, although not significant, a positive sign for the schooling variable suggests that the more the schooling years of farmer, the more LW gain per head cow during June–August period. However, it turns to negative for the June–October period probably due to outshining effect of forage scarcity towards the end of the grazing season.

The LW gain differences between the first and second grazing seasons can be explained by higher annual total precipitation in the second year of the study (357.4 mm

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44754497

in 2006 vs. 436.6 mm in 2007) and the difference in precipitation between 2006 and 2007 grazing seasons (90.7 mm in June–August vs. 5.2 mm in June–October periods) (*Table 1*). Higher levels of precipitation, especially in June–August period, result in greater herbage production (O'Connor and Rouxt, 1995; Khumalo and Holechek, 2005; Browning et al., 2012), which, in turn, result in higher LW gains.

Of particular note is that the LW gains were lower considering the whole season (June–October period) than that in June–August period in average and especially in draught season. This can be explained by the greater herbage mass during June–August and the decrease in rangeland herbage due to grazing coupled with the decreasing nutrient content of maturing plants over the course of the season (Cook and Harris, 1950, 1979; Cogswell and Kamstra, 1976; Mermer et al., 2011; Koç et al., 2014).

Although, concentrate supplements increased LW gain across all data-collection periods, LW gains driven by concentrates were more distinctive in draught season of the year 2006 than the humid season in the year 2007. Again, cows lost some what they gained during June–August period as the range forage decreases in amount and maturates due to grazing and lignination during the first grazing season of 2006 (Cook and Harris, 1950; Cogswell and Kamstra, 1976; Mermer et al., 2011; Koç et al., 2014).

The present study also revealed that re-scaling effect (Hammami et al., 2009) was of question regarding genetic merit x environment interaction in both years (i.e. genetic merit x humidity and genetic merit x concentrate supplement). That is, performances of the high and low genetic cows differed significantly under different environmental conditions. As seen in *Fig. 3*, the effect of concentrate supplementation was not the same across the all genotypes. Conforming to Ferris et al. (1999) and Kennedy et al. (2002), local cows responded the least of higher genetic merit cows to concentrate supplementation. In both grazing seasons, 2006 and 2007, purebred cows benefitted the most from the concentrates. However, in humid season responses to concentrate supplementation among the breeds were not as more distinctive as in draught season. This was more likely because of substitution effect since concentrate supplementation can increase total dry matter intake only in case of low herbage allowance (Stockdale, 2000; Delaby et al., 2001; Bargo et al., 2002; Vázquez et al., 2006; Sheahan et al., 2011; Ueda et al., 2016). Due to abundant rangeland forage allowance during humid season and especially in June–August period, concentrate supplementation did not increase total digestible dry matter intake. However, the positive effect of supplements was more obvious in June–October than in June–August, likely because of alleviated substitution effect (Stockdale, 2000) due to decreased forage till the end of the season (*Fig. 3*).

The OLS regression analysis also revealed that initial LW had a negative and significant effect on LW gain (*Tables 3 and 4*). This negative effect might be related to the maturity of the cows. Young animals have lower body weight and make higher body weight gains due to development, whereas heavier cows are likely to be mature animals that do not develop as much as young ones. Furthermore, large-frame animals have higher maintenance requirements even after dry-off due to the higher energy requirements of larger vital organs (DiCostanzo et al., 1990), which may cause cows to suffer longer periods of negative net energy balance (Řehák et al., 2012). It should also be remembered that cows usually mature until the age of 5 years (Tüzemen, 1990; Çakır et al., 1995). Therefore, less LW loss and a short period of recovery can be explained by the growth of young animals.

Similar to previous reports, I found that a high stocking rate had a negative and significant ($p < 0.05$) effect on LW gain (*Tables 4 and 5*). A low stocking rate may

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44754497

result in high output per animal due to selective grazing, or vice versa, because a high stocking rate reduces the degree of selectivity (Hull et al., 1965). Moreover, rangeland herbage production will decrease under heavy or above-carrying-capacity grazing conditions, which result in insufficient dry matter intake and poorer performance of grazing animals (Gökkuş and Koç, 2001).

The results also show that the bare ground rate had a very significant negative effect on LW gain (*Table 4*) for the period June–August because more bare ground indicates lower levels of herbage production in the rangeland. However, although not significant, the positive relationship between LW gain and the bare ground in the model for June-October period could be explained with the regrowth of grasses with late rainfalls in the season remembering the relatively high correlation (r=0.4778) between the percentage of grasses in botanical composition and high bare ground in the rangeland sites.

On the other hand, the village herds graze under the guidance of herders. In their excursions that start with sunrise and end at sunset (Kara et al., 2014), the total distance they walk every day is several times more than the actual distance between the village and the grazing site decided for the day. The actual distance varies between 360 m and 6800 m, making an average of 2350 m in the study area. This implies that the greater is the distance between the village and the target grazing site for the day, the more is the total walking distance for that day. In the present study, the effect of distance on LW gain was shifted from insignificant in June–August period (*Table 4*) to marginally significant in the June–October period (*Table 5*). This result suggests that energy cost of walking long distances becomes more apparent as the season proceeds most likely due to decrease in the forage and its lignination because the cost of walking could have only a minor effect on the energy requirement of the grazing cattle (Di Marco et al., 1998) and can be tolerated with abundant rangeland forage allowance. Accordingly, Pratumsuwan (1994) reported that dairy cows with a high productivity can walk horizontally at a comfortable walking speed up to 7.5 km per day with no significant effect on their milk production if the pasture allowance is not restricted. Similarly, D’Hour et al. (1994) pointed out that walking distances above 6.4 km only brought about modifications in the yield and composition of the milk.

Conclusion

The aim of this study was to estimate the threshold RC over which rangelands can compensate BCS and LW losses, and under which restoration is required. This was achieved by revealing the effects of RC on the LW and BCS gains or losses of grazing dairy cows in the presence of farmer, animal- and rangeland-related factors in a socioeconomic environment other than research station trials executed under controlled conditions. This makes the present study important not only for policy makers but also researchers and the others having an interest on rangeland-animal relationships prevailing under on-farm conditions.

Regression analysis showed several significant relations with LW gains in June-August and June–October. Therefore, the dataset and models can be used to draw useful inferences, because the signs of all variables in the models can be explained.

To achieve profitable dairy production by maximising animal potential, it is important to manage BCS, and BCS losses after calving should be compensated for. To this end, RC was shown to be one of the most important factors affecting LW gain or

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44754497

loss, and I used this as the proxy for BCS gain or loss during the grazing season. It is critically important to compensate for LW losses and maintain BCS in extensive dairy cattle production. Even a 10% reduction in RC will likely cause a 0.5-unit BCS loss in the grazing period when animals are not generally fed with concentrate supplements. The financial equivalent of this LW or BCS loss was calculated to be 314.6 TRY (59.0 USD; 1 TRY=0.1875 USD) per farm and 15.5 TRY (2.9 USD) per hectare of rangeland. However, it should be noted that economic losses may not be limited to energy feed cost equivalents and may include losses related to health disorders, low reproductive performance, and low milk yields. Similar to previous studies, this study showed that concentrate supplements are ineffective during the June–August period, especially in years of good herbage production. Therefore, supplemental feed may not be a good solution to compensate for the BCS or LW losses in June–August.

Nevertheless, this study made it obvious that, after August, grazing cows start to lose LW (*Table 5*), although they were expected to fully compensate for BCS losses before dry off. I calculated that a LW gain of about 20 kg was required to increase BCS by one unit. The LW gain at the end of the June–October period was about 15 kg, representing the total contribution of rangeland and concentrate supplement together. However, an additional 5-kg LW gain was required to compensate fully for the 1-unit BCS loss (*Table 6*). As a short-term solution, grazing cows in the study area and in areas with similar conditions should be given concentrates after August when rangeland herbage is scarce and fully maturated, which in turn, as stated earlier, brings about a more apparent effect of walking long distances on LW gain.

The present study also revealed that Local or indigenous cows exhibited more stable performance in all environmental conditions (*Fig. 3*). For that reason, I suggest that in extensive dairy production in the study area and the areas sharing similar agroecological and geographic conditions, high genetic merit purebred cows are not a good selection although they have rapid LW gain and so the cows to be used in extensive production should not be higher genetic merit than crossbred genotypes are.

Finally, I estimated that the threshold RC at which grazing cows fully compensated for BCS losses was 4.3. Therefore, rangeland with an RC value below 4.3 requires restoration to recover its herbage production potential and fully compensate for the BCS losses of grazing cows. It is evident that rangeland restoration investments are crucial, even considering only BCS losses and disregarding other benefits of rangeland. Yet, follow-up studies are needed to support the findings of this study.

This work is part of research project numbered TAGEM/HAYSÜD/05/01/01/01, and entitled “Analysis of the factors affecting milk production and live weight gain in cattle farms dependent on natural grazing lands in Erzurum”. The research is financially supported by the former Ministry of Agriculture and Rural Affairs, Turkey. The author extends his gratitude to the Rangeland and Animal Science Teams of Eastern Anatolia Agricultural Research Institute for their valuable work on rangeland vegetation surveys and farm animal live weight records in the study area.

Abstract. Potato late blight caused by *Phytophthora infestans* dominates the entire world where potatoes and other Solanaceae crops are grown. In this study, the effects of potassium phosphite (KPhi) based fungicide on two potato varieties infected by two strains of the pathogen were studied. Tubers coming from foliar spray of potassium phosphite wounded and/or inoculated with pathogens were sampled at 0, 6, 12, 24, and 48 hours. Phytoalexins, phenols, β-1, 3-glucanase (PR-2), chitinase (PR-3), peroxidase (POD), polyphenol oxidase (PPO), superoxidase dismutase (SOD) and catalase (CAT), were analyzed. Results demonstrated that plants applied with KPhi produced tubers with enhanced resistance to the pathogen than their untreated plants. Moreover, tuber slices from KPhi applied plants following infection showed a significant increase in the contents of phytoalexins and phenols. PR-3 activities were induced by KPhi and wounding with the highest level at 48 hours. The activities of PR-2 were not significantly induced by KPhi or wounding, but its content was significantly increased by pathogen infection with the highest in untreated tubers after 48 hours. The KPhi treated tubers produced more enzymatic activities significantly after wounding and pathogen infection than those that were not treated. Our findings suggested that KPhi stimulates a quick and vigorous response in tubers against the pathogen infection via activation of defense responses, such as defense biochemical compounds, pathogenesis-related enzymes and antioxidant enzyme activities.
Keywords: *potassium phosphite, potato late blight, antioxidants enzymes, pathogenesis-related (PR) enzymes, Phytophthora infestans*

Abbreviation: KPhi - Potassium Phosphite, PR-2 - β-1, 3-glucanase, PR-3 - chitinase, POD - peroxidase, PPO - polyphenol oxidase, SOD - superoxidase dismutase, CAT - catalase, BABA - ß-aminobutyric acid, ROS - Reactive Oxygen Species, SAR - systemic acquired resistance, FW - fresh weight，GAE – gallic acid equivalent

Introduction

Solanaceae is an important plant family which has a diverse group of plants, ranging from wild species to several economically important cultivated crops. Potatoes (*Solanum tuberosum* L.) belongs to this family and it is the first non-grain food crop worldwide and third highly consumed food crop in the world, after wheat and rice (Norton and Swinton, 2018). Global potato production in 2017 was revealed as 376.8 million metric tons with

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44994514

major production from developing countries. Nowadays, China is leading potato producers throughout the world accounting for 99.1 million tons, followed by India and the Russian Federation (Norton and Swinton, 2018).

The causative agent of potato late blight is oomycete *Phytophthora infestans* (Mont.) De Bary. It is one of the most devastating plant diseases throughout the world. This disease causes leaf death, which leads to significant yield reductions. The pathogen can also infect tubers which cause storage reduction as well as reduced seed quality. Pathogenic infections trigger plant defense responses by changing their biochemical contents. Biochemicals can limit the multiplication of pathogens, making the host environment unsuitable for growth of pathogens or directly by targeting and eliminating the attack of the microorganism (Hammerschmidt, 1999).

Activating the plant's immune system by different chemical and symptomatic factors could be an alternative way to increase plant resistance to biotic stresses (Lim et al., 2013). It has been reported that various chemical and biological compounds can trigger plant defense reactions without a real attack of pathogens. These compounds are known as resistance inducers or plant enhancers (Silva et al., 2011). Phosphite ($H_2PO_3^{2-}$, Phi), an alkaline salt of phosphorous acid (H_3PO_3) and phosphonate [$HPO(OH)_2$], is commonly known for controlling plant diseases by enhancing plant defense responses (McDonald et al., 2001). Phi has direct effects on inhibiting oxidative phosphorylation in oomycete metabolism (Lobato et al., 2008), and indirect effects that stimulate host protection responses eventually inhibit the pathogen growth (Daniel and Guest, 2005). It plays an important role as a fungicide, fertilizer or biostimulator or can work with at least one of these properties in various research systems (Thao and Yamakawa, 2009). Also, Wang-Pruski et al. (2010) and Borza et al. (2017) also report a comprehensive protective effect of Phi, which increased when applied in combination with a chlorothalonil protective herbicide. Further, Borza et al. (2014) studied foliage and postharvest treatments of Phi and its uptake and translocation in leaves and tubers. Machinandiarena et al. (2012), Wiesel et al. (2014) showed that Phi triggers disease resistance through increased hydrogen peroxide (H_2O_2) production, gene expression of pathogenesis-related (PR) protein PR1, glucanase (PR 2) and phenylalanine ammonia lyase, and increased soluble protein accumulation in *Arabidopsis*, potato and tomato plants (Chandrasekaran et al., 2017; Silva et al., 2011).

Potassium phosphite (KH_2PO_3) has been applied on plants to induce resistance to various oomycete pathogens, such as *Phytophthora* species (Kim et al., 2010) and *Pseudoperonospora* species (Silva et al., 2011). KPhi has been studied to inhibit normal metabolism of oomycetes, limiting their growth and stimulating defense mechanisms of plants, as well as boosting the synthesis and transportation of secondary metabolites (Kuć, 2001). KPhi can entourage reposition of defense molecules (Dalio et al., 2014; Ramezani et al., 2017), such as phytoalexin and phenols that are defensive chemicals for resistance to diseases and to overcome pathogenic attacks. The accumulations of phytoalexins and phenols were recorded in potato tubers after plants were treated with ß-aminobutyric acid (BABA) (Olivieri et al., 2009). KPhi can induce plant resistance by initiating hypersensitive reactions, resulting in programmed cell death of infected cells, increasing activities of phenylpropanoid biosynthetic enzymes, resulting in increased acquired systemic immunity against pathogens (Eshraghi et al., 2011). PR proteins are vital factors for the interaction of plants with pathogens and many groups of PR proteins can be a part of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44994514

first defense responses against pathogens (Kadota et al., 2014). Two PR proteins, chitinase and ß-1, 3-glucanase, were investigated in potato tubers in this study. Chitinase hydrolyzes chitin in cell wall of fungi (Dehestani et al., 2010), while the ß-1, 3-glucanase plays key role in plant defense responses to pathogen infections by catalyzing the cell wall cleavage of many pathogens (Adams, 2004). It has been shown that ß-1, 3-glucanase activity is correlated with systemic acquired resistance (SAR) that protects plants from various biotic stresses. Cellular defense function against oxidative stress can also be measured by increased POD, PPO, SOD, and CAT (Debnath et al., 2018b; Majer et al., 2014). Also, Lobato et al. (2011) studied that, after KPhi-treated potato leaves were mechanically wounded and/or infected by different pathogens, phytoalexins, antioxidant enzyme activities, and pathogenesis-related protein production were increased. In this study, we analyzed the protection function of KPhi against two pathogenic strains of *Phytophthora infestans*, in stored tubers obtained from the plants foliar treated with KPhi during the growing season. We also measured the contents of phytoalexins and phenols, and the enzymatic activities of chitinase, ß-1, 3-glucanase, POD, PPO, SOD and CAT, in two tubers of two potato varieties that vary in their resistant levels to Late blight.

Materials and Methods

Experiment location

The plants were grown in the College of Horticulture greenhouse at Fujian Agricultural and Forestry University, Fuzhou city (latitude 260, 5 '16 "N, longitude 190, 14 '6" E, altitude 42.09 m), in China between February, and May 2017 from October 2017 to January 2018. During the growing seasons, the temperatures in the greenhouse varied between 15-24°C and natural daylight cycle were 10-14 hours.

Biological samples

Two Chinese potatoes (*Solanum tubrusum* L.) varieties Xingjia No. 2 (moderately resistant to late blight) and Zhongshu No. 3 (moderate susceptible to late blight) were used in this study. Xingjia No. 2 was provided by Institute of Agricultural and Forestry Sciences in Daxinganling region, Heilongjiang Province; Zhongshu No. 3 was provided by Institute of Vegetables and Flowers, Chinese Academy of Agricultural Science. Pieces of seed potatoes (~ 50 g of weight with 2-3 eyes) were planted in 5-liter plastic pots containing a mixture of vermiculite, peat and perlite (1: 3: 1, v/v) in the greenhouse. Plants were watered by using a sprinkler irrigation system. The plants were grown between February 26, 2017 and May 25, 2017 and repeated once from October 15, 2017 to January 15, 2018. In each season, 50 plants were used for each variety. The 50 plants were divided into two groups of 25 each: Group 1 was sprayed with water; Group 2 was sprayed with 1% KPhi biweekly, total three times during the growing season. Plants from different treatment groups were randomized in the greenhouse. KPhi was first sprayed to the leaves 35 days after the emergence. The second spray was 15 days after the first spray and the third spray was 15 days after the second spray. The control plants applied with sterilized water. Two strains of *Phytophthora infestans* (Pi) (Mont.) ASO and 1-12-25, isolated from Yunnan province by personnel of College of Plant Protection at Fujian Agriculture and Forestry University, were used in this study. They were grown on Zhongshu No. 3 potato tuber

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44994514

slices and kept at 18°C and 90% RH. After seven days, mycelium was collected in sterile distilled water and stimulated to release zoospores by incubation at 4°C for 6 hours. After filtration through 5 layers of cheesecloth, the sporangial suspension was observed under a microscope for quantification before use as an inoculum. The rate of sporangia was adjusted to 4 x 10^{-4} sporangia/mL using a hematocytometer (Lobato et al., 2011).

KPhi stock solution, preparation and treatment

To prepare the KPhi stock solution (1%), the phosphorous acid crystals (Sigma-Aldrich) was neutralized with potassium hydroxide (KOH) by slowly mixing of phosphorous acid and potassium hydroxide solution until the pH was adjusted to 6.3. KPhi stock solution was diluted to 1% (1 g/100 mL) and sprayed to plants at the value of 30 mL per plant (4.5 L/ha) using a hand sprayer. Greenhouse plants were treated by KPhi three times during the growing season. KPhi was first sprayed to the leaves 35 days after the emergence. The second spray was 15 days after the first spray and the third spray was 15 days after the second spray. The control plants applied with sterilized water.

Wounding procedure and sample preparation

Tuber wounding procedure was performed according to the mechanism described by Kim et al. (2010) with a small modification. Collected tubers were first peeled, and internal flesh tissues were cross-sectioned by a mandolin cutter to pieces of about 10 mm thickness. The pith of the tubers was removed and tuber pieces were placed on a rack with a wet paper towel in five litter plastic boxes with lids at 18ºC in the dark up to 7 days. Water was added to the bottom of the boxes in order to keep the humidity. Periderm samples were collected at 0, 6, 12, 24, 48 hours and seven days after wounding. Samples were immediately frozen in liquid nitrogen and stored at -80ºC until use.

Late blight resistance evaluation

Tubers from plants of Xingjia No. 2 and Zhongshu No. 3 treated with KPhi and control were stored at 8°C and 55% RH for three months. The tubers were then washed in distilled water, sterilized by soaking in 2% sodium hypochlorite for 5 min and rinsed with distilled water and then used for phytopathological tests. Tubers slice (5-6 cm in diameter, 10 mm thickness) were infected with 50 µL of sporangia suspension (4 × 10^{-4} sporangia/mL) and incubated at 18°C in darkness. The disease severity symptom was evaluated on the upper surface of potato slices seven days after infection according to the method described by Lobato et al. (2008). The disease severity was recorded with the scale from 1 to 10, where 1 = no lesions, 2 = a few circles, 3 = up to 5%, 4 = 5–10%, 5 = 10–25%, 6 = 25–50%, 7 = 50–75%, 8 = 75–85%, 9 = 85–95% and 10 = 95–100% of leaf area with late blight symptoms (Lobato et al., 2008). Two strains of *Phytophthora infestans* (Pi) (Mont.) ASO and 1-12-25 were used in this study, and a total of 25 tubers in each variety and each treatment were used in three replications. The negative control has KPhi treated tuber slices but not infected by *P. infestans*.

Extraction and determination of phytoalexin and phenol contents

Phytoalexins was extracted and measured according to the method described by Lobato et al. (2008) Tubers (1 g) were mixed in 10 mL chloroform/methanol/acetic acid (50:5:45

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44994514

v/v/v) using a blinder. The homogenate was kept overnight at room temperature (15°C) and then filtered through cheesecloth. Chloroform and 0.2 M acetic acid were added in equal volumes to the filtered mix. The blends were shaken well and let stand to separate into two layers. The top chloroform layer containing phytoalexins was removed and evaporated in 60°C an electrothermal blast dryer (Shanghai Yiheng scientific instrument Co., Ltd.) until it is dry. The dried sample is dissolved into 1 mL of cyclohexane and 2 mL of sulfuric acid (H_2SO_4) were added to the solution. The mixture was stirred and centrifuged at 12,000 rpm for 30 min. Then the red color of the lower sulfuric acid layer was measured at 500 nm with a spectrophotometer (METASH UV5100H) to determine the concentration of phytoalexin as µg/g FW. Phenols were extracted according to the Folin-Ciocalteu colorimetric procedure with minor modifications (Škerget et al., 2005). Briefly, 0.5 g of the tuber sample was homogenized with 2.5 mL Folin-Ciocalteau 0.2 N (Solarbio Life Sciences) for 5 min and then 2.0 mL sodium carbonate (75 g/L) was added. The mixture was kept at room temperature for 2 hours before it was measured at 760 nm using a spectrophotometer (METASH UV5100H). The phenol concentration was represented as gallic acid equivalent (GAE) (mg) on fresh weight (FW) (mg GAE/g FW).

Measurement of antioxidant enzyme activities

The square cut (100 mg) in the central part of tuber disks was grounded in a mortar and pestle at 0, 6, 12, 24 and 48 hours after inoculation or wounding. The mixture was filtered through four layers of cheesecloth and centrifuged at 12,000 rpm for 15 min. The supernatant, which represented the soluble tuber extract, was immediately processed.

The activity of chitinase and ß-1, 3-glucanase, was measured spectrophotometrically using the [Commercial chitinase and ß-1, 3-glucanase Assay Kits (GA-1-Y and JDZM-2-G), Beijing Suolai Bao Technology Co., Ltd, China] following the procedures described by the manufacturer.

POD was measured using the method by Shannon et al. (1966). The assay mixture containing 2.5 mL of phosphate buffer, 0.2 mL of suitably diluted tuber extract, and 0.1 mL of o-dianisidine (50 mg of o-dianisidine was dissolved in 50 mL of methanol) was incubated at 28°C in a water bath for 2 min. The reaction commenced by adding 0.2 mL of H_2O_2 (0.6%) and the absorbance was recorded at 470 nm against reagent blank.

PPO it was measured in 1 ml reaction mixture consisting of 20 µl of raw extract, 35 mM sodium phosphate buffer pH 6 and 100 µl 0.2 M catechol. The reaction was initiated by the addition of catechol to the mixture and absorption 420 nm was measured in 1 minute. Total SOD activity was determined by it is the ability to inhibit the photochemical reduction of nitro blue tetrazolium (NBT) in a spectrophotometer at 560 nm as previously described (Cakmak and Marschner, 1992). The assay of CAT activity was based on its ability to decompose H_2O_2, with the absorbance of the supernatant at 240 nm (Choo et al., 2004).

Statistical analysis

All the experiments were organized in a complete random block design (CRBD) with three biological replicates for each treatment and repeated at least three times. The surface area showing damage symptoms data were analyzed by the *t-tes*t, phytoalexin and phenol contents, as well as enzymatic activities, were analyzed for significant variances and differences using one way ANOVA. SPSS (version 22, SPSS, Chicago) was used for

DOI: http://dx.doi.org/10.15666/aeer/1702_44994514

means value analysis. Differences between means were detected, when using Tukey's test (P < 0.05) and graphs generated by Microsoft Office Excel 2016.

Results

Effect of KPhi on late blight suppression

The effects of leaf treatments of KPhi in greenhouse conditions have caused reduced sensitivity to *Phytophthora infestans* in the tubers. The comparison between inoculated tuber pieces of Xingjia No. 2 and Zhongshu No. 3 showed a decreased diameter development of pathogen growth from the plants treated with KPhi in both cultivars (*Figure 1A*). Data in *Figure 1B* showed a significant effect of the KPhi treatment, which caused reductions in lesion size caused by *P. infestans* in tubers of both cultivars. Also, it is confirmed that Xingjia No. 2 was less susceptible to both strains of *P. infestans*, and Zhongshu No. 3 showed higher susceptibility to *P. infestans* as seen in the control tuber slices (*Figure 1, A and B*). As well, the two strains showed a different range of aggressiveness, ASO is more aggressive that of 1-12-25 (*Figure 1, A and B*).

Effect of foliar application of KPhi on disease severity in tuber slices against Phytophthora infestans (B). Means that not sharing a common letter within a graph are significantly different at p-value < 0.05 according to the Tukey's test. The experiments included three biological replications and were performed two times*

Effect of KPhi on phytoalexin and phenol accumulations in tubers

The contents of phytoalexins and phenols were quantified in tuber pieces taken from plants treated by KPhi or non-treated and infected by ASO isolate of *P. infestans* (*Figure 2*). The highest amount of phytoalexins was accumulated a week after infection with *Phytophthora infestans*, while the lowest was measured in non-treated tubers (*Figure 2, A and B*). Phytoalexin contents were 3 fold increased in the treated inoculated tubers, followed by un-treated tuber (CPi) (*Figure 2 A and B*). Wounding treatments (PhiW) also showed a 1 fold increase than their controls (*Figure 2, A and B*). The lowest phytoalexin detected in healthy tubers. As shown in *Figure 2*, 48 hours after infection Xinjia No. 2 tubers produced a higher accumulation of phytoalexin than Zhongshu No. 3. The phenol contents were increased 3 fold in KPhi treated plants (PhiPi), followed by untreated plants

(CPi) 48 h after tubers inoculation (*Figure 2, C and D*). Wounding (CW) increased phenol contents in both Xingjia No. 2 and Zhongshu No. 3 (*Figure 2, C and D*). Pathogen infection (CPi) increased the phenol contents in both Xingjia No. 2 and Zhongshu No. 3 when compared with their controls. Phi treated samples (Phi) also had a significant increase in phenol contents when compared with the controls in both cultivars, but wounding after Phi treatments (PhiW) only increased phenol contents in Zhongshu No. 3 (*Figure 2, C and D*). The highest content of phenols was detected after inoculation of KPhi treated tubers in both cultivars; while the lowest were found in non-inoculated tubers of both cultivars (*Figure 2, C and D*).

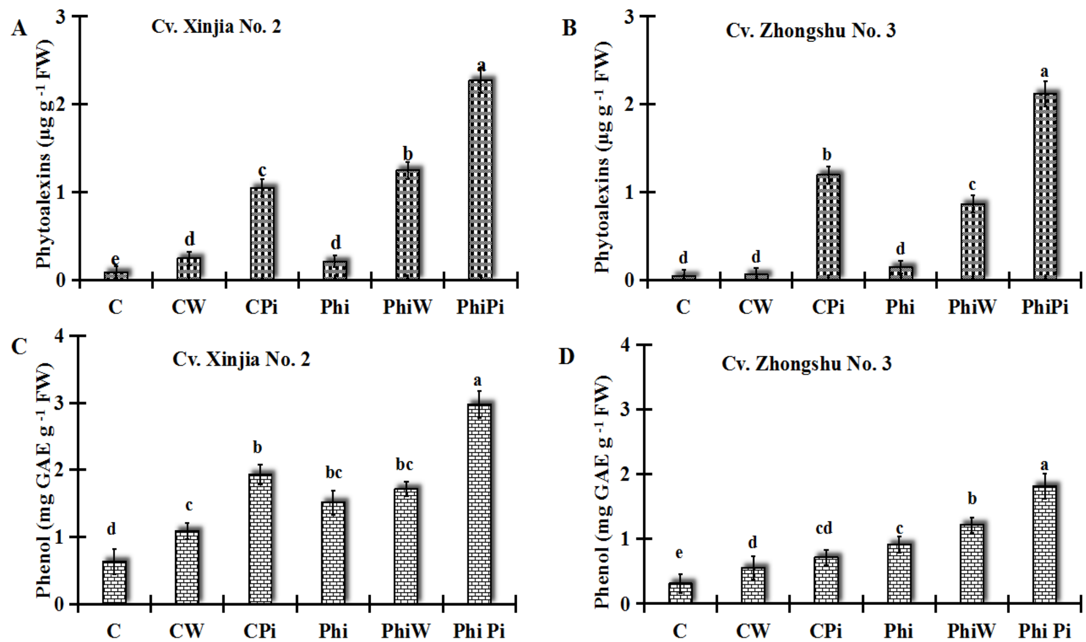

***Figure 2**. Effects of KPhi application on phytoalexin contents of Cv. Xingjia No. 2 (A) and Zhongshu No. 3 (B), and phenol contents of Cv. Xingjia No. 2 (C) and Zhongshu No. 3 (D). Phytoalexin and phenol were quantified in tuber pieces after wounding (W), and inoculation by P. infestans (Pi) ASO isolate. Effect of KPhi on chitinase and ß-1, 3-glucanase activities in tubers

In this study, the effect of KPhi on chitinase and ß-1, 3-glucanase activities after wounding and inoculation with ASO isolate strain were determined at various time points. Tuber slices from KPhi-treated (Phi) and control plants (C), wounded (W) or inoculated with a pathogen (Pi) were measured at 0, 6, 12, 24 and 48 hours after the treatments (*Figure 3*). A gradual increase with time in chitinase activity after wounding and pathogen infection was observed in control potatoes of both cultivars. The level of chitinase activities in both cultivars without treatments was similar (*Figure 3, A and B*). Wounding

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44994514

(CW) increased the chitinase activities in both cultivars, similarly to the Phi treatments (CPhi). The infection treatments (CPi) also showed a similar response as with wounding in both cultivars. Both wounding and pathogen infections in Phi treated tubers had significantly increased the chitinase activities in both cultivars (*Figure 3, A and B*).

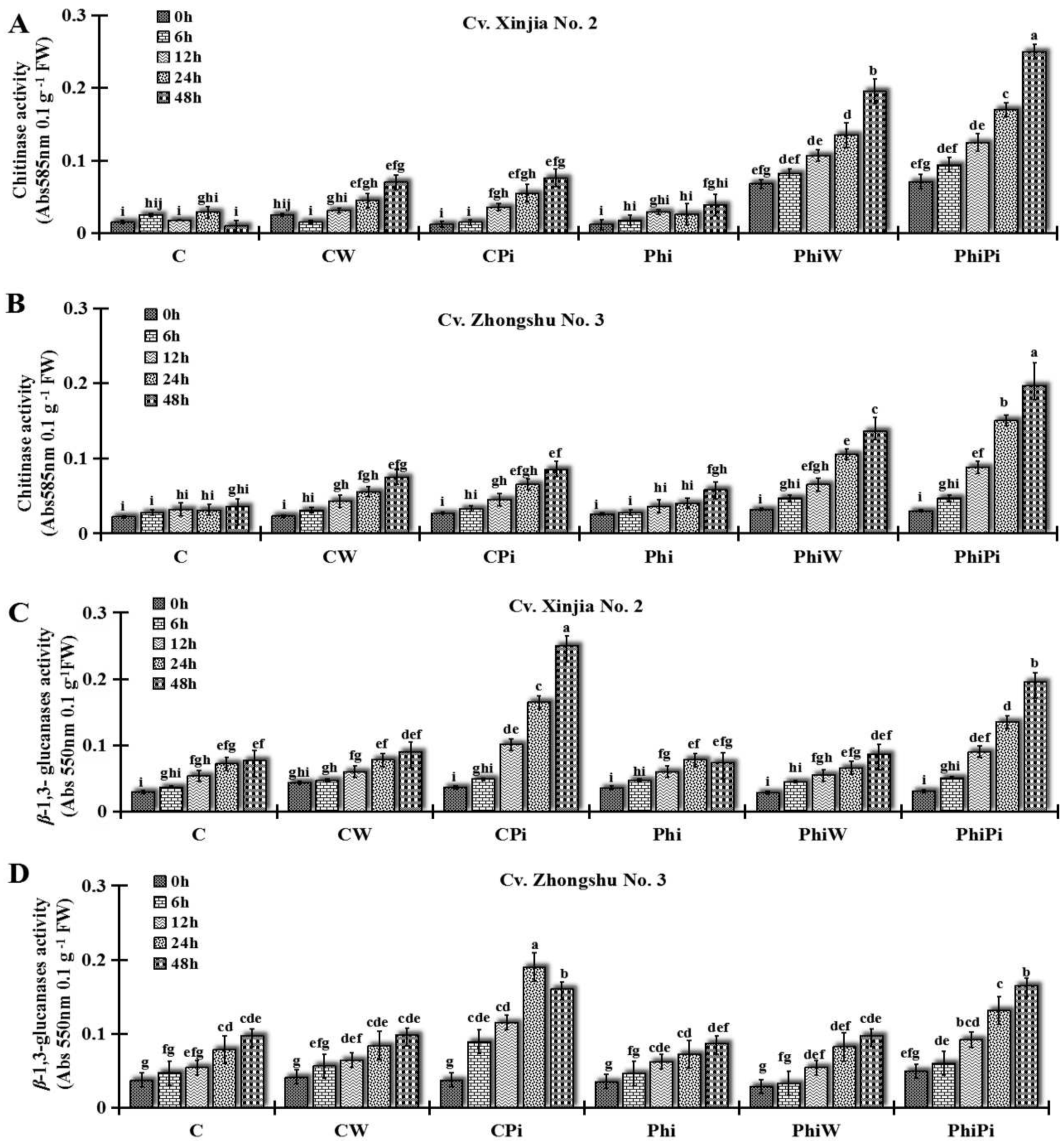

***Figure 3.** Effects of KPhi application on chitinase activities in Xingjia No. 2 (A) and Zhongshu No. 3 (B) tubers, and β-1, 3-glucanase activities in Xingjia No. 2 (C) and Zhongshu No. 3 (D) tubers. Activities of chitinase and β-1, 3-glucanases were analyzed from tuber after wounding or inoculation with P. infestans for 0, 6, 12, 24, and 48 h, respectively. Means not sharing a common letter within the same letter in the graph are significantly different at P< 0.05 according to Tukey's test The experiments included three biological replications and were performed three times. C, control tubers; CW, control + wounded; CPi, control + inoculation with ASO isolate; Phi, tubers taken from KPhi applied plants; PhiW, tubers treated by KPhi + wounding; PhiPi, tubers from KPhi treated plants + inoculation with ASO isolate. FW, fresh weight*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44994514

In wounded tubers taken from plants applied with KPhi, the rate of chitinase activity was increased 2 folds by 48 hours in KPhi treated tubers in Xinjia No. 2. In infected tubers taken from plants applied with KPhi, the rate of chitinase activity was increased 3 folds by 48 hours in Xinjia No. 2 tubers and then about 2 folds in Zhongshu No. 3. It is noted that the enzyme activities of wounded and inoculated tuber slices from Xingjia No. 2 after Phi treatments were higher when compared to that of Zhongshu No. 3 (*Figure 3, A and B*).

In contrast to chitinase, ß-1, 3-glucanase activities did not change significantly in potatoes tubers of KPhi treated plants when compared with that of the controls in both cultivars (*Figure 3, C and D*). Wounding treatment did not significantly alter the enzymatic activities in these samples either. The ß-1, 3-glucanase activity was increased sharply 48h after *P. infestans* infection in untreated tubers (CPi) more dramatic of cultivar Xingjia No. 2 (*Figure 3C*). An approximately two-fold increase in ß-1, 3-glucanase activity was recorded 24 hours after pathogen infection in Xingjia No. 2 cultivars when compared to control (*Figure 3C*). In Zhongshu No. 3, approximately 3 folds increase were noted at 24 hours after pathogen infection in untreated samples (CPi) and about 2 folds increase from the KPhi treatment plants and wounded tubers (PhiW) (*Figure 3D*) when compared to their corresponding controls. The ß-1, 3-glucanase activity increased significantly in potato tubers 24 hours after infection with a pathogen (CPi) (*Figure 3D*) followed by treated (KPhi) tubers and control after infection, compared to healthy tubers (*Figure 3, C and D*).

Effect of KPhi on POD and PPO in tubers

Inoculation by ASO late blight strain caused an increase in reactive oxygen species (ROS) response and up-regulation of antioxidant enzymes in the defense system to alleviate ROS-mediated damages. The POD and PPO activities were measured spectrophotometrically at various time points in tubers after wounding or inoculation by a pathogen (*Figure 4*). The highest POD activities values were recorded 48 hours after the pathogen inoculation, both in control (CPi) and KPhi treated plants (PhiPi). At 48 hours, the enzymatic activities increased up to 4 folds in Xingjia No. 2 and about 4 folds in Zhongshu No. 3 in the inoculated potatoes taken from tubers applied with KPhi compared with the tubers from the untreated plants (*Figure 4, A and B*). Meanwhile, the PPO activities showed similar increases, but the highest activities were detected at 12 hours after the inoculation (CPi) in Xingjia No. 2, and 24h after infection (CPi) in Zhongshu No. 3 (*Figure 4, C and D*). At these time points, the tubers obtained from the plants treated with KPhi presented increases in the PPO activities, approximately 4.8 times in Xingjia No. 2 and 4-times in Zhongshu No. 3 in comparison to the inoculated potatoes collected from untreated plants (*Figure 4, C and D*).

Effect KPhi on SOD and CAT response after inoculation by late blight

SOD and CAT activities were analyzed in a spectrophotometer at 0, 6, 12, 24 and 48 hours after pathogen inoculation with ASO isolate on KPhi and control tubers. As shown in *Figure* 5 (A and B), the lowest SOD activity was found at 0 hours while the highest value of SOD was found at 48h after inoculation (CPi) in Xingjia No. 2 (*Figure 5A*) and 24 hours after inoculation (CPi) in Zhongshu No. 3 (*Figure 5B*). The KPhi treated samples 48 hours after infection (PhiPi) had increased the SOD activity by about 3 folds in Xingjia No. 2, while it has increased by around about 2 folds in the Zhongshu No. 3 24hours after infection (*Figure 5, A and B*). Wounding did not significantly increase the SOD activities in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44994514

Phi treated samples. The CAT activity was found to be the lowest at 0 h in both cultivars and increased in the KPhi treated at 48 hours after inoculation (PhiPi) to about 4 folds in Xingjia No. 2 (*Figure 5C*) and only about 3 folds after inoculation in Zhongshu No. 3 cultivar (*Figure 5D*). Control samples at 24 hours had an increase of about 2 folds after inoculation (CPi), in contrast to the activities of controls inoculated by the late blight pathogen (*Figure 5, C and D*).

Discussion

In the present study, the action of KPhi on physio-biochemical contents and the enzyme activities of the potato plant in response to *Phytophthora. infestans* and wounding was studied, using two potato cultivars with different degrees of horizontal resistance against the two late blight isolate strains (*Figure 1*). It is demonstrated that the applications of KPhi on leaves results in the postharvest tubers with notably decreased disease symptoms after infection with two *P. infestans* pathogen strains. The significant protection was observed in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44994514

moderately resistant Xinjia No. 2, after postharvest. These results were consistent with previous studies in potato. A study reported by Mayton et al. (2008) who analyzed various compounds of Phi on the protection against *P. infestans* in leaves and tubers of postharvest potato. Their experiments showed that *P. infestans* infection on leaves was well controlled by Phi as effective as a conventional fungicide against tuber late blight. Comparable to our results, Lobato et al. (2011) showed that the use of KPhi on the leaves resulted in a series of postharvest defense reactions at field conditions. Phytoalexin and phenol accumulations were related to defense reactions of the potatoes and our results showed great increase phytoalexins and phenols in potatoes tuber treated with KPhi compared to untreated slices from the control plants and wounded samples. This effect was relatively high in moderately resistant cultivar Xingjia No. 2 (*Figure 2, A and C*), and lower in the more susceptible cultivar. Zhongshu No. 3 (*Figure 2, B and D*). This means that KPhi has been able to activate a general defense response in the potato plants and the response is cultivar dependent. The involvement of phytoalexins and phenols in response to Phi were reported and various works had been reviewed by Gray et al. (2018). Plants produce enzymes, such as chitinases and ß-1, 3-glucanases (Silva et al., 2011) which can break down cell wall compounds of pathogens. These enzymes are essential determinants of plant resistance to fungi attack (Funnell and Phillips, 2004). Since these enzymes are PR proteins and their stimulations in the tubers after wounding or inoculation have been reported (Alexandersson et al., 2016; Lobato et al., 2017). Chitinases play essential roles in activating defense response in plants, alone or in combination with ß-1,3-glucanases (Mauch et al., 1988). Our results represented an increase in chitinase activity after infection by late blight pathogen. KPhi treated tubers at 48 hours after infection, clearly indicated the presence of the increased enzymatic activities (*Figure 3, A and B*). This result also confirms the efficacy of anti-fungal function of KPhi, as pointed out by Deliopoulos et al. (2010).

In the present study, ß-1, 3-glucanase was not significantly induced by KPhi after inoculation by the pathogen in Xingjia No. 2, and the highest enzymatic activity was found in untreated tubers 48 h (*Figure 3C*). Likewise, KPhi had a less effect on Zhongshu No. 3, with the highest activities of this enzyme found at 24 hours after inoculation in untreated tubers (*Figure 3D*). Compared to our results, cucumber plants inoculated with *Pseudoperonospora cubensis* showed a quick increase in chitinase and ß-1, 3-glucanase activities, which causes the degradation of the cell wall of fungi (Moazzameh et al., 2018). Greater induction of ß-1, 3-glucanase in the treated plants indicates that the activity of ß-1, 3-glucanase can weaken the fungi cell wall and prevent hypha colonization (Menu-Bouaouiche et al., 2003). Lim et al. (2013) used iTRAQ-based quantitative proteomics to identify significant changes in defense proteins including pathogenesis-related, stress-responsive and detoxification-related proteins in potato leaves after treatment with Phi. They identified that 93 (62 up-regulated and 31 down-regulated) differentially regulated proteins were identified in the leaf proteome of Phi-treated plants. To find out whether oxidation enzymes caused by stress can participate in the KPhi-induced defense mechanism, the activity of POD, PPO, SOD and CAT were measured in tubers after harvest. The increases in POD and PPO activities were highlighted that these enzymes could be a part of KPhi defense responses.

The antioxidant POD enzyme is necessary for inducing systemic resistance and could be used as a biomarker of induced resistance in plants (Kuć, 2001). The POD and PPO

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44994514

activities is increased after wounding or inoculation with a pathogen in tubers taken from plants applied with KPhi (Lobato et al., 2011). In their studies, KPhi application on infected plants showed a direct relation between disease reduction and the enzyme activity. Similarly, in our result, the POD and PPO activities were increased significantly in contrast to the control plants 12 and 48 and hours after inoculation in both cultivars (*Figure 4*). Foundation PPO enzymes to wounding and enzymatic browning had been investigated in many plants (Demiİr and Kocaçalişkan, 2001). This enzyme plays a significant role in confirm of alkaloids under biotic and abiotic stress (Bilková et al., 2005). PPO activity in this study had increased at 12 hours in inoculated tubers collected from KPhi used plants in Xingjia No.2 (*Figure 4C*) and 24 hours after infection in Zhongshu No. 3 (*Figure 4D*). Similar to our results, Lobato et al. (2011) also showed that KPhi promoted POD and PPO activities after plants were infected by late blight.

It is known that SOD plays a substantial role in stress tolerance of plants and it is the first path of protection against damaging effects of high levels of ROS. Several environmental stresses usually lead to an increase in ROS production. As showed in *Figure 5 (A and B)*, the highest rate of SOD was found at 48 hours in Xingjia No. 2 (*Figure 5A*), followed by Zhongshu No. 3 (*Figure 5B*) in both varieties. Similar to our results, Mofidnakhaei et al. (2016) showed that potassium phosphite affected plant growth, and enzymatic activities of POD, SOD and CAT in cucumber plants challenged with *Pythium ultimum*.

Furthermore, CAT is necessary for ROS detoxification under stress situations by degrading H_2O_2 into H_2O and O_2 (Debnath et al., 2018a). In this study, CAT activity was increased in the plants treated with KPhi after inoculation by *P. infestans* in cv. Xingjia No. 2 (*Figure 5C*) and Zhongshu No. 3 (*Figure 5D*) in the potato tubers, respectively, compared to the wounded or control samples (*Figure 5C and 5D*). This is the first report demonstrating the responses of CAT and SOD to KPhi.

Conclusions

Plant defense pathways use some physiological and biochemical means to enhance resistance against pathogen invasions. KPhi induced the biochemical compounds and enzymes activity. Increased contents of phytoalexins and phenols were needed for plant defense processes. These metabolites will help plants to improve their resistance to pathogens.

Additionally, KPhi can increase the defense enzyme activities, inducing chitinase, ß-1, 3-glucanase activities and boosting production of antioxidants enzymes. The detailed analysis of cell wall composition and structure will elucidate and confirm our ideas of Phi involve in inducing resistance. KPhi treatment considerably mitigated POD, PPO, SOD and CAT activities which leads to late blight tolerance in potato plants. Finally, our data showed a partial characterization of some biochemical markers and certain phytopathological features involved in the response by KPhi in two cultivars with different degree of multigenic resistance to *Phytophthora infestans*. We believe this increased tolerance triggered by KPhi is belong to cell wall amplification and increased productions of biochemicals and a group of enzymatic antioxidants activities.

Furthermore, our data supported the application of KPhi as a priming inducer to enhance cell defense mechanisms. This suggests that the response to foliar KPhi treatment

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_44994514

could have a useful effect on physio-biochemical events and promoting tuber resistance against *Phytophthora infestans* if used in an IPM program. Overall, our data support the fact that KPhi improves resistance by improving cellular defense biochemical compounds, PR enzymes and key antioxidants enzymes activities.

Authors' contributions. M. A. Mohammadi conceived, performed, designed and conducted the research and wrote the manuscript. Yupi Xi and Beibei Zhang assisted in performing experiments. Xiaoyun Han analyzed the data. Faxiu Lan contributed reagents/ materials/ analysis tools. Gefu Wang-Pruski and Zhizhong Zhang conceived, instructed research work, supported financially and administratively and final approval of the manuscript. All of the authors revised, discussed and commented on the manuscript.

Acknowledgments. This experiment conducted in the Joint FAFU-Dalhousie lab, College of Horticulture, Fujian Agriculture and Forestry University, Fuzhou, 350002, China. The financial support for this research is from the Foundation for Fostering Young Talents and Scientific Research Starting Foundation for Mingjiang Scholars from College of Horticulture, FAFU. Additional funding from Ming Jiang Scholar fund from Fujian Province and FAFU (116-114120019) and Special Innovation Foundation (CXZX2016108, CXZX2017168) from FAFU, China also contributed to this work. We want to express our appreciation to all lab mates, Abdul Waheed Ph.D. candidate college of plant protection, Fujian Agriculture and Forestry University for his valuable suggestions.

Competing Interests. The authors state that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interests.

(Received 30th Jan 2019; accepted 28th Feb 2019)

Abstract. The immunohistochemical distribution and expression of the three markers in cardiomyocytes were evaluated in three groups of mice: a control group, mice exposed to 5 mg/kg b.w./day sodium dichromate (group A) and mice exposed to 100 mg/kg b.w./day lindane (group B). All mice were sacrificed after 2 months of chronic exposure to the chemicals. Hematoxylin eosin staining revealed thickening of the anterior walls and thinning of the posterior walls of the left ventricle. Anterior and posterior vessel wall densities increased by a factor of about 1.5 in group A and about 2 in group B compared to the control group. Posterior wall vessel diameters declined by a factor of 3.7 in group A and 2.9 in group B. Immunohistochemical staining showed that sodium dichromate was associated with significantly lower expression of CD117 ($p = 0.019$) and p53 ($p = 0.002$) than in controls, whereas VEGF expression increased ($p = 0.03$). In mice exposed to lindane, the results showed an opposite, though not significant trend, namely increased levels of CD117 and p53 and decreased levels of VEGF expression with respect to the control group. We observed significant changes in ventricular wall thickness, vessel density, vascular growth factor expression and mast cell apoptosis, directly correlated with exposure to lindane.
Keywords: *VEGF, CD117, p-53, aral sea area pollutants, chromium industry*

Introduction

Among global environmental contaminants with pathogenic effects on the human body, those associated with the atmosphere, water, plants and soil are particularly prominent. Despite recent scientific and technological advances, the state of the environment continues to deteriorate year by year with negative impacts on human health.

Widespread use of chemical compounds in non-ferrous metallurgy and agriculture have increased the chemical burden of the human body. Chemicals including organochlorine pesticides are widely used to increase soil fertility, protect gardens and crops from insects, prevent infectious diseases and so forth. Chromium (VI) microelements and organochlorine pesticides, despite their different chemical nature, have toxic effects and trigger irreversible processes that affect organ histology. Structural changes in organs can lead to functional disorders in the same organs (Sánchez-Bayo et al., 2011; Cholewa et al., 2015).

The toxicity of hexavalent chromium and organochlorine pesticides has been shown to inhibit metabolic processes through genotoxic, embryotoxic, teratogenic and carcinogenic effects.

Sodium Dichromate is an orange to red colored, crystalline, inorganic compound that emits toxic chromium fumes upon heating. This chemical is used in drilling muds, in metal treatments, in wood preservatives, in the production of dyes and organic chemicals and as a corrosion inhibitor (PubChem, 2019a).

Lindane is the gamma-isomer of benzene hexachloride, a colorless to white colored, synthetic, crystalline solid. It emits toxic fumes of hydrochloric acid and other chlorinated compounds when heated to decomposition. Lindane is used as an insecticide for hardwood logs, lumber, and crops (PubChem, 2019b).

Intensive production of various substances and products is accompanied by release of many residues, the harmful environmental effects of which have now reached a critical level. These residues may contain organochlorine compounds classified as persistent organic pollutants. Residues of pesticides and herbicides are particularly significant. Their toxicity to humans ranks them near the top in the hierarchy of global problems, while their intense and long-term effects lead to various diseases (Yunbo et al., 2016; Thompson et al., 2011; Yazicioglu et al., 2013; Seidler et al., 2013).

These substances have acute and chronic effects on human and animal health, depending on the type of pesticide, its route of intake, the dose, the moment and duration of exposure, the subject's age, gender and genotype, and geographic differences (Reid et al., 2013; Mehrpour et al., 2014).

The geographical location of our research team gives it a special interest in environmental health, since the Aktobe region includes part of the Aral Sea disaster area (Palmerini et al., 2017) and a chromite mining and smelting industry (Zhumalina et al., 2018). Environmental deterioration caused by Aral Sea disaster has created a hazardous situation for the health of approximately 3.5 million people. Due to this ecelogical circumstance, high levels of dichlorodiphenyltrichloroethane and other persistent organic pollutants appeared in the soil, air and water, as well as at every level of the food chain, including humans (Ataniyazova et al., 2001).

There is increasing evidence that exposure to these pollutants and chemicals can increase the risk of cardiovascular disease. Studies into the effects of pesticides on myocardial tissue reported cardiomyocyte decompensation, circulatory and lymph flow disturbances and changes in myofibrils (Stojanovic et al., 2016; Liu et al., 2017). In particular, complex irreversible processes in blood microcirculation and myocardial ultrastructure were found (Rückerl et al., 2007). Immunohistochemistry is an important tool in experimental research, in which monoclonal and polyclonal antibodies are applied to detect the distribution of an antigen in blood vessels and cardiac tissue (Duriyan et al., 2012).

Due to the high prevalence of cardiovascular disease in ecologically impaired regions, we focus here on the morphofunctional state of heart tissue. Our aim was to evaluate morphological changes in cardiac muscle tissue through an experiment involving chronic exposure of mice to sodium dichromate and lindane.

Materials and methods

Ethics

The design of the study was approved by the Local Ethical Commission of the Marat Ospanov West Kazakhstan State Medical University on 30th November 2015 (protocol no. 11) in line with the European Convention for the Protection of Vertebrates used for experimental and other purposes (Strasbourg, 1986).

Exposure to sodium dichromate and lindane

Sixty outbred white mice weighing 20-35 grams (females and males) (Laboratory of the Scientific and Practical Center of Marat Ospanov West-Kazakhstan State Medical

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45154525

University, Aktobe, Kazakhstan) were kept in the laboratory under a 12:12 h light-dark schedule (lights on 7 am to 7 pm) at 27 °C ± 2 and 70% humidity with free access to unlimited water and food. The mice were divided into control (20) and experimental (40) groups. The experimental groups were divided into subgroups: group A: 20 mice exposed to 5 mg/kg b.w. per day sodium dichromate ($Na_2Cr_2O_7$) (Rasool et al., 2014) (Sigma-Aldrich (MERCK, Darmstadt, Germany) and group B: 20 mice exposed to 100 mg/kg b.w. per day lindane ($C_6H_6Cl_6$) (Vijaya Padma et al., 2013) (Sigma-Aldrich, MERCK, Darmstadt, Germany). The chemicals were administered orally through a smooth plastic tube attached to a syringe. The mice were sacrificed under ether anesthesia after 2 months of exposure to the chemicals.

Histology and immunohistochemistry

Paraffin embedded histological samples were fixed for hematoxylin eosin (HE) (Van Gieson) staining. Immunohistochemistry was conducted by a commercial laboratory subcontractor according to Thermo Fisher Scientific and Keele et al. (2008) protocols.

Three commercial monoclonal antibodies were used for immunohistochemical study: CD117/c-Kit/SCF-receptor rabbit monoclonal antibody, VEGF (SP28) rabbit monoclonal antibody and p53 monoclonal antibody (DO-7), all from Thermo Fisher Scientific.

To identify heart MCs, proto-oncogene c-Kit encoding a transmembrane tyrosine kinase receptor protein, c-Kit (CD117), is used. This antibody recognizes the extracellular domain and is expressed by a variety of normal and abnormal cell types, including cardiac MCs (Lammie et al., 1994).

VEGF expression levels are indeed directly correlated with endothelial status. This vascular layer contains a variety of receptors for interactions with bacteria, chemical particulate, vasoactive substances, hemostatic factors, immune factors, complement components and more (Berendt et al., 1989). The endothelium is therefore very sensitive and easily damaged.

Considering the importance of the above factors, we selected CD117 and p53 as markers to identify mast cells and apoptosis.

Another criterion for evaluating heart tissue ageing is the level of apoptosis. Apoptosis is a cell response to a wide range of toxic substances and leads to necrosis (Neuman et al., 2001, 2002). In vitro studies have proven that exposure to chemicals can induce oxidative stress and trigger apoptosis by activating apoptosis-initiator caspase-9 and apoptosis-effectors caspases-3 to 7 (Zerin et al., 2015). Since tumor suppressor Trp53 (p53) inhibits cell growth after acute stress by regulating gene transcription, it is an appropriate marker to study apoptosis in heart tissue (Mak et al., 2017).

Sections 3 µm thick were applied to high-adhesive glass slides, treated with L-polylysine and dried at room temperature for 24 hours. The staining was performed manually and using an AUTOSTAINER-360 (THERMO, UK) with NovoLinc polymer imaging systems (“NovoCastra”, Great Britain). Controls for reaction sensitivity and specificity were unimmunized rabbit and mouse sera, and sections of control heart tissue.

Morphometric analysis of anterior and posterior walls of the left ventricle was performed with an Olympus model BX41 microscope at 40X magnification and “ImageJ” software. VEGF, CD117 on mast cells and apoptosis marker p53 were evaluated to determine toxic effects on heart tissue. Fluorescence microscopy was used

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45154525

to calculate the percentage of cells expressing VEGF, CD117 and p53 in representative frontal serial sections of the left ventricle. Cells were counted in three sections of similar sizes of the left ventricle of each mice heart.

Statistical analysis

The data was analyzed using the MedCalc software (MedCalc Software, Mariakerke, Belgium). The t-test was applied to the parameters of morphometric analysis. The Mann-Whitney test for independent samples was used to test for cell count differences in tissue sectionsbetween the control population and the population of exposed mice. Differences were considered statistically significant at $p < 0.05$.

Results

Hematoxylin-eosin staining

HE staining showed significantly higher thicknesses of the anterior left ventricular wall in experimental groups A and B than in the control group. Inversely, the posterior left ventricular wall was thinner (*Fig. 1; Table 1*). Vessel diameters were also significantly smaller. On the other hand, anterior and posterior wall densities increased in both experimental groups, reaching almost double the control density in group A ($p < 0.0001$) (*Table 1*). Regarding the localization of vascularization, in the control group, vascular density was higher close to the epicardium, whereas in the experimental groups it was intense in the myocardium and endocardium. In group A, vessel walls were thinner and more compressed than in group B.

Immunohistochemistry

Expression of immunohistochemical markers varied in relation to chemical exposure. Results are summarized in *Table 2*.

Immunohistochemical staining showed that sodium dichromate significantly lowered expression of CD117 ($p = 0.019$) and P53 ($p = 0.002$) with respect to the control population and increased VEGF expression ($p = 0.03$). In mice exposed to lindane, the results showed the opposite sign, with non-significant increases in CD117 ($p = 0.08$) and P53 expression ($p = 0.76$) and a non-significant decrease in VEGF ($p = 0.62$) with respect to the control group (*Figs. 2* and *3*).

Discussion

A major criterion for evaluating aging processes is the biological age of blood vessels, in turn linked to the microstructural properties of the vascular wall. This is why it is important to study aging of heart vessels, i.e. the level of angiogenesis and apoptosis, particularly under conditions of exposure to chemicals (Saghiri et al., 2015; Haberzettl et al., 2012; Chin, 2015).

Researchers have confirmed that stress caused by exposure to chemicals and other factors predisposes to coronary heart disease and impairs heart function through stimulation of mast cells (MCs), leading to local inflammation (Alevizos et al., 2014). MCs contain mediators, such as cytokines, histamine, proteases and leukotrienes, and play an important role in inflammatory reactions, neovascularization and repair after myocardial injury (Galli and Wershil, 1995; Church and Levi-Schaffer, 1997; Welle, 1997; Hara et al., 1999; Zhang et al., 2006; Marone et al., 1995; Kennedy et al., 2005). Mast cell number and density are reported to be elevated in patients with cardiomyopathy (Patella et al., 1998). Acute stress of experimental myocardial infarction in rats was associated with increased MC density in affected areas during tissue remodelling. Researchers (Hara et al., 1999) reported that MCs caused apoptosis of cardiomyocytes and proliferation of non-myocardial cells, thus aggravating pathological heart conditions (Engels et al., 1995).

Chemical exposure causes pathological conditions in the vascular wall and affects vascular wall matrix remodeling.

CD117 plays an essential role, among others, in the regulation of cell survival and proliferation. Importantly, c-kit expression had been associated with heart repair after myocardial infarction (Cimini et al., 2007), where it establishes a proangiogenic milieu in the infarct border zone by increasing VEGF (Fazel et al., 2006).

The main distinguishing sign of endothelial aging is increasing vascular permeability, VEGF migration and reduction of regenerative capacity (Brandes et al., 2005). Our observation of increasing numbers of VEGF-expressing cells and their uneven concentrated distribution in the endothelium are polymorphic changes that indicate cell migration and damage to the vascular wall.

Gogiraju et al. revealed that p53-rich endothelial cells contribute to scarcity of blood vessels and development of fibrosis during cardiac hypertrophy and that apoptotic endothelial cell death plays an important role in chronic heart disease (Gogiraju et al., 2015). The present study showed that expression of CD117 and p53 decreased in the sodium dichromate experimental group with respect to controls, while VEGF expression is increased. It is known that lindane can cause abnormal heart rhythm (Sauviat and Pages, 2007) as well as histological alterations mainly in the left ventricular wall (Sauviat and Pages, 2002) and our morphological analyses confirms significant changes in heart tissue. However we did not observe any significant change in the three markers evaluated in the present study.

In healthy tissues, p53 function is inactive until induced by toxic or oncogenic stress (Sauviat and Pages, 2007). Biochemical stress activates beneficial gene sets, including proteins involved in excitation-contraction coupling, energy metabolism and response to oxidative stress through inhibition of hypertrophic signaling and apoptosis (Lammie et al., 1994). An increased rate of endothelial cell apoptosis reduces the regenerative capacity of the endothelium and leads to endothelial senescence (Barnabas et al., 2013).

DOI: http://dx.doi.org/10.15666/aeer/1702_45154525

Chronic exposure to sodium dichromate and lindane modified the micro-structure of the left ventricle of the heart by increasing vessel wall density, narrowing the vessel lumen and increasing the number of small capillaries.

Conclusions

Exposure to lindane fosters aging processes in heart tissue due to an increase in the number of mast cells, which leads to apoptosis, cardiomyocyte necrosis and proliferation of non-myocardial tissue. Further research is needed to fully understand the effects of chronic exposure to chemicals and find out possible solutions for mitigating pollutants' effect by continuing experiment with protective pharmaceuticals against the risk of the occurance and progression of cardiovascular diseases. These prelimary findings justify the necessity of taking special preventive actions targeted to the zones exposed to chemical hazards.

Acknowledgements. We thank Professor Jürgen Hescheler, Dr. Marek Molcanyi and Mrs. Suzanne Wood of the Institute of Neurophysiology, University of Cologne, for their advice and for administration of the initial stage of the research, Dr. Matteo Bertelli Dr. Paolo Enrico Maltese and Dr. Yeltay Rakhmanov from MAGI, International Institute for Diagnostics and Research of Genetic and Rare Diseases, Rovereto, Italy for their help in writing this article, commercial laboratory subcontractor "Avizzena Medical Center", Novosibirsk, Russian Federation, for providing laboratory facilities, and Helen Ampt for revising the English.

(Received 28th Jan 2019; accepted 27th Feb 2019)

Abstract. This study was carried out with the purpose to assess some biological parameters of the red Californian worm (*Eisenia foetida*) in vermicompost, to which two types of wood vinegar, manufactured from poultry manure (A) and nutshell (B), have been applied. The study was implemented under laboratory conditions with Coincidence Parcels Trial Layout and 5 repetitions in 2018. Profile Analysis Technique was used in the in the investigation of wood vinegar types and the effect of various doses on the weight gain and number of worms on a weekly basis, while Factorial ANOVA was used in the investigation of their effects on cocoon numbers. The Profile Analysis proved that the interaction between Week × Dose × Vinegar type was important in regards to both the weight and number of worms (P = 0.00). The Factorial ANOVA carried out to investigate the effects of the vinegar type and doses on the cocoon number showed that the Dose × Vinegar type interaction was important (P = 0.00). Therefore, the effects of the vinegar type on the number and weight of worms differed depending on the dosage. In general, it was noted that 3%- and 5% dosages of vinegars had positive effects on *Eisenia foetida,* while the dosage of 100% had toxic effects. Based on the findings, it is possible that wood vinegars have a potential use with various purposes including bio-pesticides or worm manure.
Keywords: *agricultural, bio-economy, bio-pesticides, cocoon, pyrolysis liquids, worm*

Introduction

Although earthworms are not abundant in number, they are probably significant factors for sustaining soil productivity in various ways (Edwards and Bohlen, 1992). These living beings are accepted as important indicators of chemical toxicity in the soil ecosystem (Bustos-Obregón and Goicochea, 2002; Yasmin and D'Souza, 2010). Wood vinegar (WV) is a liquid produced through carbonization (pyrolysis liquids) that has been found to had been produced as early as the time of the Neanderthals (Tiilikkala et al., 2010; Cai et al., 2012). Kim et al. (2008) stated with reference to Jang that WV is a clear liquid containing 80-90% water with the rest being water-soluble organic compounds exceeding 200 in number. Jothityangkoon et al. (2008) stated that the main components of WV were acetic acid paired with organic acids and phenolic compounds, alkanes, alcohols and esters. This product is used as manure, insect repellant or organic fungicide in agriculture. Furthermore, there are studies showing that WV has effects that improve the soil and promote plant growth. As examples of such studies, Jothityangkoon et al. (2008), Yin (2008), Baimark and Niamsa (2009), Velmurugan et al. (2009), Chalermsan and Peerapan (2009), Oramahi and Yoshimura (2013), Hagner (2013), Namlı et al. (2014), Koc et al. (2017), De Souza Araújo et al. (2018) and Oramahi et al. (2018) have performed studies concerning the antifungal activities of WV. Studies of Yatagai et al. (2002), Oramahi and Yoshimura (2013) are notable on the issue of anti-termite effects of WV. It was stated by the studies of Shi (2003), Jothityangkoon et al. (2008), Yin (2008), Rakmai (2009), Cai et al. (2012) that WV affects plant growth. Regarding the antibacterial effectiveness of WV, positive remarks of Chalermsan and Peerapan (2009), Eric et al. (2012), Duan et al. (2016), Yang et al. (2016), Chukeatirote et al. (2018) and De Souza Araújo et al. (2018) can be noted. Koç et al. (2018) have found significant relations between treatments with WV and nematodes in the soil. Shi (2003) and Rakmai (2009) have obtained findings indicating the activities of WV that increase the edaphon and the number of bacteria in the root area of plants. There are also studies by Inoue et al. (2000), Yatagai et al. (2002), Jothityangkoon et al. (2008), Diba et al. (2009), Kiarie-Makara et al. (2010), Pangnakorn et al. (2011), Wititsiri (2011), Hagner (2013), Oramahi and Yoshimura (2013) explaining the insecticide or insect-repellant effects of WV. Cai et al. (2012) have reported that WV promotes the development of reactive oxidative species (ROS)-sensitive mutant worms, the lifetime of worms is prolonged and their body size increased. Mu et al. (2003) have stated that WV is a good resource for organic agriculture and is widely used in Japan, both in agriculture and daily life. Kim et al. (2008) have stated that the annual production of WV is around 14.000 tons. Hagner (2013) has stated in his study that there is little information on the toxic effects of WV, while Rakmai (2009) stated referring to Ikeshima that this substance has no toxic effects on humans or animals. Tiilikkala et al. (2010) have reported that pyrolysis liquids have the potential of replacing pesticides and synthetic chemicals in biocide form in the future, and this is based on bio-economic knowledge and depends on its development. As seen in the studies cited above, is it clear that WV has multiple effects.

This study has been carried with the purpose of determining some biological parameters of the red Californian earthworm (*Eisenia foetida*) in vermicompost after application of two types of wood vinegar obtained from poultry manure (A) and nutshell (B).

Materials and methods

This study was carried out under laboratory conditions in 2018. The vermicompost required for the experiments was obtained from 100% cow manure, and cocoons were obtained through reproduction from stock cultures of *Eisenia foetida* individuals. Wood vinegar (WV), was obtained from a firm developing WV products from poultry manure (A) and nutshell (B) using a gasification machine and bio-coal (Namlı et al., 2014). Vinegar obtain from nutshell (B) is light brown in color, and is characterized by a burning smell. Vinegar obtained from poultry manure (A) however, is darker in color as compared to vinegar B, is more consistent and has a stronger odor. The study was implemented using the Coincidence Parcels Trial Layout with 5 repetitions (*Fig. 1*). After placing 100 g vermicompost in 300 cm^3 plastic containers, the solution was treated with WV using a 10-mL injector. One percent, 3%, 5%, 10%, 25% and 100% WV doses were used in the treatments, and only tap water was injected into the control group. WV treatment was performed only once. Following these procedures, 10 cocoons were placed in each container. The ambient temperature of the study was kept between 20 and 29 °C and the humidity was kept between 70 and 90% (Gunadi et al., 2002). With the purpose of maintaining the ambient humidity, 10 mL tap water was administered to the samples periodically with 2 day intervals. Live weight, number of cocoons laid, and the number of young individuals coming out of cocoons were determined weekly until the young individuals laid cocoons themselves. Profile

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45274538

Analysis was used during the investigation of the effects of different doses and vinegar types on weekly body weight gain and number of worms (Mendeş et al., 2007). Factorial ANOVA was used to investigate the effects of the factors mentioned above on the number of cocoons, and Tukey's Multiple Comparison Test was used in determining the different groups (Winer et al., 1991; Mendeş, 2012). The abovementioned analyses were carried out using the SPSS (Ver. 21.0) statistical package programs.

***Figure 1.** Photo of the experimental culture*

Results

Findings related to the weights of worms

Profile Analysis results for WV(A) and WV(B) are presented in *Figures 2* and *3,* respectively. Results of Profile Analysis indicated that the Week × Dose × Vinegar type interaction is significant (Wilks' Lambda = 0.253; F = 3.61; P = 0.00). Meaning that the effect of vinegar type on weekly body weight gain of worms varied based on the doses (*Figs. 2* and *3; Table 1*). When only week 5 is taken into consideration in comparison with the controls, treatments with WV (B) have not resulted in much difference between the body weights of worms (*Fig. 3; Table 1*). However, treatments with WV (A) 1%, 25% and 100% had negative effects while treatments with 3% and 5% had positive effects (*Fig. 2; Table 1*).

Findings on the number of worms

Profile Analysis results for WV(A) and WV(B) are presented in *Figures 4* and *5,* respectively. Results of Profile Analysis indicated that the Week × Dose × Vinegar type interaction is significant (Wilks' Lambda = 0.05; F = 7.83; P = 0.00). Meaning that the effect of vinegar type on weekly number of worms varied based on the doses (*Figs. 4* and *5, Table 2*).

It can be noted that treatments with 1%, 25% and 100% WV (A) have negative effects on the number of worms in comparison with controls, while 3% and 5% doses have positive effects (*Fig. 4; Table 2*). It was also seen that the 100% dose of WV (B) had negative effects in comparison with the controls, while treatments with 3%, 5% and 10% WV had positive effects (*Fig. 5; Table 2*).

Findings related to cocoon numbers

Factorial ANOVA was used to analyze the data set. Results of ANOVA showed that the Dose × Vinegar type interaction is significant ($P = 0.00$). Therefore, the effect of vinegar type on number of cocoons varied based on the doses (*Table 3; Fig. 6*). Upon comparison of WV (A) treatments with the controls, doses of 3% and 5% exerted positive effects on the number of cocoons, while treatments of 1%, 25% and 100% doses had negative effects. A smaller numbers of cocoons was produced under treatments with WV (B) compared to the controls (*Table 3*).

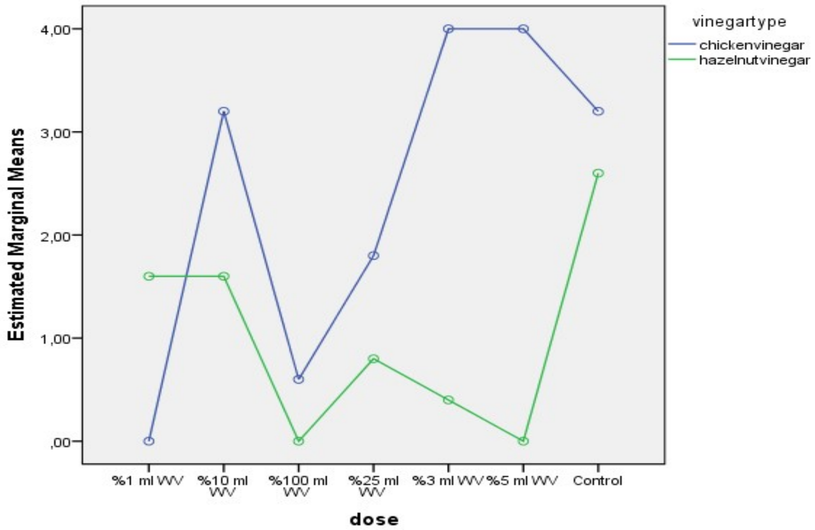

Figure 6. *Changes in the number of cocoons based on dose and vinegar type*

Discussion

Chemical pesticides and fertilizers used in agricultural activities pollute the environment, damage biodiversity and exert negative effects on human health. This situation can be eliminated through the use of alternative methods such as organic pesticides and manures. Wood vinegar (WV) is an organic product that can be degraded in a short time produced from plant and animal waste. Treatments with WV (A, B) have been found to have effects on the body weight, number of worms and number of cocoons depending on the type of vinegar, dose and the week of measurements. Of these vinegar types, WV (A) is thought to have exerted positive effects on the numbers of worms and cocoons particularly in doses of 3% and 5% (*Table 3*), while WV (B) has positive effects particularly on the number of worms in 3%, 5% and 10% doses (*Table 2*). These results are consistent with the findings of Cai et al. (2012) indicating that WV exerts positive effects on the development, lifetime and body size of worms. Furthermore, the fact that WV has positive effects on plants and other living beings in the soil is supported by the findings of Shi (2003), Jothityangkoon et al. (2008), Yin (2008), Rakmai (2009) and Cai et al. (2012). However, studies indicating the negative effects of a 1% dose on worms has been attributed to either an adverse factor in the test apparatus or to some toxic effect. Generally, the 100% dose and partially 25% dose of WV have been determined to exert negative effects on the biological parameters of worms. These results are supported by the findings of Inoue et al. (2000), Yatagai et al. (2002), Jothityangkoon et al. (2008), Yin (2008), Baimark and Niamsa (2009),

Velmurugan et al. (2009), Chalermsan and Peerapan (2009), Diba et al. (2009), Kiarie-Makara et al. (2010), Pangnakorn et al. (2011), Wititsiri (2011), Eric et al. (2012), Oramahi and Yoshimura (2013), Hagner (2013), Namlı et al. (2014), Duan et al. (2016), Yang et al. (2016), Koc et al. (2017), De Souza Araújo et al. (2018), Oramahi et al. (2018) and Chukeatirote et al. (2018), agreeing that WV can exert bactericide, fungicide, anti-termite and insecticide effects. However, it can easily be seen from the examination of figures and tables of these studies that the effect of types and doses of WV differ weekly. It is estimated that this can be attributed to the statements of Kim et al. (2008) and Jothityangkoon et al. (2008) in their respective studies, stating that vinegar consists of water-soluble substances exceeding 200 in number and the main components are acetic acid paired with organic acids, phenolic acids, alkanes, alcohol and esters.

Conclusion

As a result of this study we can conclude that types and doses of wood vinegar can have positive effects on certain parameters of *Eisenia foetida*. It is thought that the 3% and 5% doses in particular exert positive effects on worms, while the dose of 100% has toxic effects. Vinegar types with all their characteristics may have a potential use in agriculture, or more precisely in organic agriculture and worm manure production.

Acknowledgements. I hereby present my great appreciations to Prof. Dr. Mehmet MENDEŞ for his help in the interpretations of the statistical analyses of this study and to Science Expert Birgül ILIKHAN for her help in laboratory works.

Abstract. In this study, a direct approach to fabricating silver nanoparticles (AgNPs) via the leaf extract of common grape (*Vitis vinifera*) has been demonstrated. The produced particles were found with a maximum wavelength of 452.47 nm, spherical shape and the crystal size of 18.53 nm through UV-Visible spectrophotometry, XRD (X-ray diffraction) and SEM (Scanning electron microscopy) characterization methods. Furthermore, the functional groups involved in the reduction were specified with FTIR (Fourier transform infrared spectroscopy), the elemental compounds were identified with EDX (Energy dispersive X-Ray spectroscopy) and the degradation points were determined with TGA-DTA (Thermal gravimetric analysis) methods. AgNPs were found to be effective against hospital pathogens, namely Gram-negative *Escherichia coli* ATCC 25922, Gram-positive *Staphylococcus aureus* ATCC 29213 and *Candida albicans* fungus at the concentrations of 0.314, 0.078 and 0.334 µg mL^{-1}, respectively.
Keywords: *green synthesis, metal nanoparticles, grape leaf extract, characterizations*

Introduction

Nowadays, nanoparticles are widely used. These particles have found their use in different areas such as electronics, photography, material science, dye removal, cosmetics, biomedicine, bioremediation etc. (Saha et al., 2017; Swamy et al., 2015; Chaudhry et al., 2018). Green synthesis, which includes biological methods, is highly advantageous compared to physical and chemical methods due to it being environmentally friendly and not using toxic chemicals during any step (Sinsinwar et al., 2018; Ramkumar et al., 2017; Pantidos and Horsfall, 2014). Particles between the sizes of 1-100 nm are defined as nanoparticles. These nanoparticles can be obtained through biological, physical and chemical techniques (Ahmed et al., 2017). Since it is inexpensive and easy to obtain, the use of plants for the synthesis of nanoparticles is becoming increasingly common. Due to the strong antimicrobial activity of silver (Ag) against fungi, viruses, and bacteria, AgNPs have been a subject of study by researchers from many different fields in recent years, and it has been stated that AgNPs have anti-inflammatory properties in addition to their antimicrobial properties (Shah et al., 2017). Silver nanoparticle synthesis and phytochemicals in plant leaf extracts create AgNPs by reducing Ag^+ ions present in the medium to Ag^0 and also provide stability (Geethalakshmi and Sarada, 2010; Prakash et al., 2013; Ahmed et al., 2018). Green synthesis is an important phenomenon that must be taken into consideration, especially since it supports the use of non-toxic chemicals, and environmentally friendly, renewable materials (Kaushal et al., 2016). Plant-based green synthesis generally uses different parts of plants (leaves, roots, seeds and fruits) (Majeed et al., 2018).

In this research, the green synthesis, which is an environmentally friendly, easy and simple method, was used to synthesize AgNPs from the leaf extract of the common grape (*Vitis vinifera*) and its antimicrobial effect on microorganisms was investigated.

Materials and methods

Preparation of Vitis vinifera extract and silver nitrate ($AgNO_3$) solution

Collected grape leaves from Mardin region in Turkey were initially washed with tap water, then washed with distilled water and finally dried under room conditions. After the drying process, the dried leaves were grounded, then boiled with distilled water and filtered at room temperature using coarse filter paper followed by Whatman 1 filter paper and the extract was obtained for the synthesis of AgNPs. Afterwards, 1 mM solution was prepared using solid $AgNO_3$ (purity 99.8%, Sigma-Aldrich).

Synthesis and characterization

The leaf extract and the $AgNO_3$ solution were mixed in a ratio of 1: 4, and after the color change in a few minutes, subsequently the formation and presence of silver nanoparticles were observed with Perkin Elmer one UV Visible spectrophotometer. After centrifugation with OHAUS FC 5706 at 10.000 rpm for 5 min, the resulting nanoparticles were dried. Then the RadB-DMAX II computer controlled X-ray diffractometer for XRD, the scanning electron microscope EVO 40 LEQ for SEM-EDAX, the Perkin Elmer Spectrum One for FTIR, and the Shimadzu TGA-50 for TGA-DTA were used to determine the characterization of the synthesized AgNPs.

Determining antimicrobial effects of silver nanoparticles

The antimicrobial effects of the obtained AgNPs were examined on pathogenic microorganisms, Gram-negative *Escherichia coli* ATCC 25922, Gram-positive *Staphylococcus aureus* ATCC 29213 bacteria and *Candida albicans* yeast. The minimum inhibitory concentration (MIC) was determined by the micro dilution method. In the experiments, Mueller-Hinton medium, the solutions including a certain amount of microorganism, which were prepared according to 0.5 McFarland standard, and appropriate concentrations of the AgNP solution were added to 96-well microplates and wells were incubated at 37 °C overnight (El-Batal et al., 2018; Vishwasrao et al., 2018; Dhand et al., 2016). The next day, the MIC was determined by the well in which the reproduction ended. To compare the effects of AgNPs, commercially available vancomycin, colistin and fluconazole antibiotics and a 1 mM $AgNO_3$ aqueous solution were used on *S. aureus*, *E. coli*, and *C. albicans*.

Results and discussion

After a few minutes of mixing the grape plant and the $AgNO_3$ solution, a dark coffee color change was observed indicating the formation of AgNPs by vibrations on the plasma surface (Alruqi et al., 2018). Data with the maximum absorbance of 452.47 nm were obtained (*Fig. 1*). The maximum absorbance in the synthesis with green tea and turmeric extracts was found to be 450 nm (Selvan et al., 2018). In another study conducted with the green synthesis, it was stated that the maximum absorbance was at 460 nm (Begum et al., 2009).

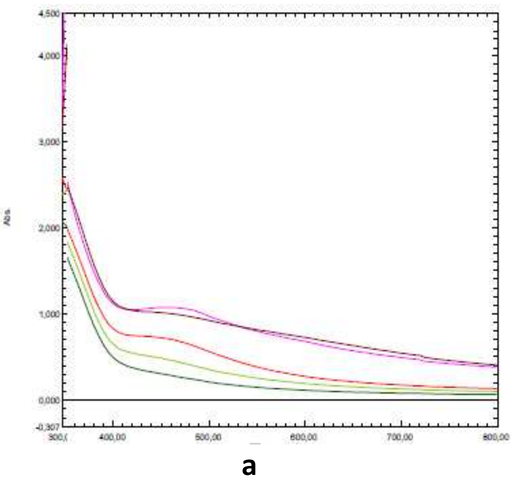

***Figure 1. a.** Time-dependent formation of AgNPs in UV spectroscopy. **b.** Maximum absorbance of synthesized AgNP in UV spectrophotometry*

Functional groups involved in the reduction were evaluated via FTIR analysis. It was thought that the shifts at 3332, 2127 and 1635 cm^{-1} were caused by the active role of -OH, -CN and C = O groups in the reduction (*Fig. 2*). Similar groups were evaluated in the nanoparticle synthesis study with *Matricaria chamomilla* extract (Dadashpour et al., 2018). Other study results also support these findings (Selvakumar et al., 2018).

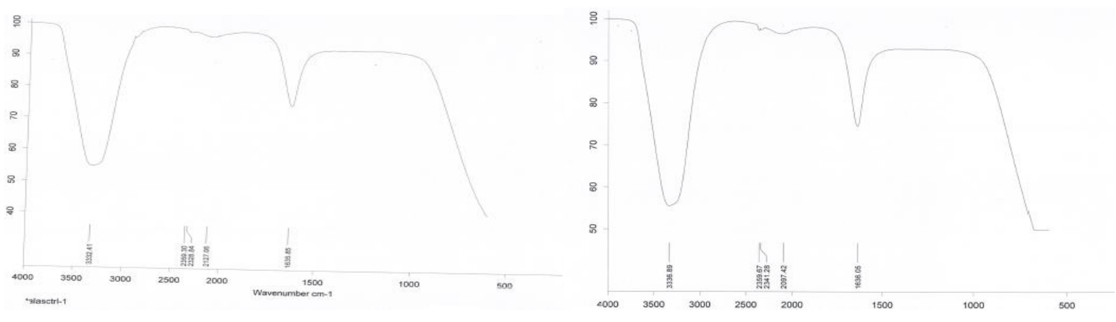

***Figure 2.** UV-vis spectrum of plant extract and UV-vis spectrum of synthesized AgNPs*

The crystal structure of the obtained AgNPs particles was found by the 2θ values of 38.52°, 44.71°, 64.85° and 77.72° from the peaks which were located at (111), (200), (220) and (311) (*Fig. 3*). In the study with *Melissa officinali*, the peaks at (111), (200), (220) and (311) were associated with AgNPs (de Jesús Ruíz-Baltazar et al., 2017). The

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45394546

orientation at (111), (200), (220) and (311) were also connected to AgNPs in the nanoparticle synthesis research of *Coffea arabica* extract (Dhand et al., 2016).

The crystal dimensions of AgNPs were determined as 18.53 nm using Debye-Scherrer equation [D = Kλ / (β cos Sch)].

In other studies on the synthesis of AgNPs, the crystal dimensions of the nanoparticles were calculated using Debye-Scherrer equation (Pugazhendhi et al., 2018; Rajesh et al., 2018; Jogaiah et al., 2017).

It was seen that AgNPs were spherical in SEM images, and according to EDAX, there were peaks of Ag metal in the elemental composition (*Fig. 4*). It was reported that the AgNPs obtained in a study with *Physalis angulata* extract also have a spherical shape (Nishanthi et al., 2018). Many researchers have reported having synthesized AgNPs in spherical shapes (Premkumar et al., 2018; Alam et al., 2018; Ibrahim et al., 2016).

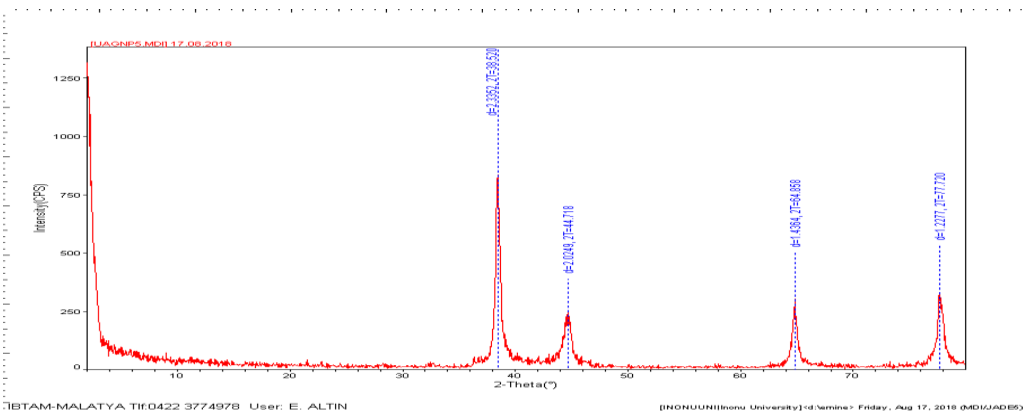

Figure 3. *X-ray diffraction (XRD) analysis*

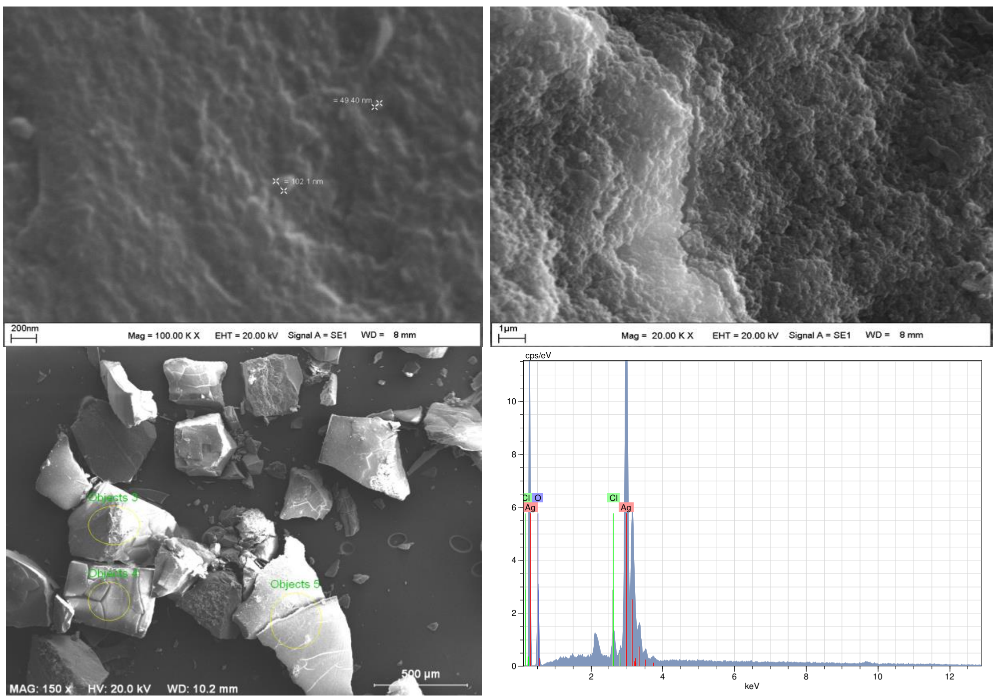

Figure 4. *SEM-EDAX results of AgNPs*

APPLIED ECOLOGY AND ENVIRONMENTAL RESEARCH 17(2):4539-4546.

DOI: http://dx.doi.org/10.15666/aeer/1702_45394546

The TGA and DTA analyses of the AgNPs were evaluated between 30-900 °C with a heating rate of 10 °C min^{-1} and a flow rate of 20 mL min^{-1} in N_2 (g) atmosphere. The TGA curve indicates the mass loss of the nanoparticles versus the temperature, and the DTA curve shows the highest decomposition temperature at all levels of the degradation (Baran et al., 2018).

The loss of mass at 30-201 °C was caused by moisture, while the loss of mass at 201-515 °C was due to phytochemicals in the plant extract and the green synthesized AgNPs were gradually degraded between 515-810 °C (*Fig. 5*).

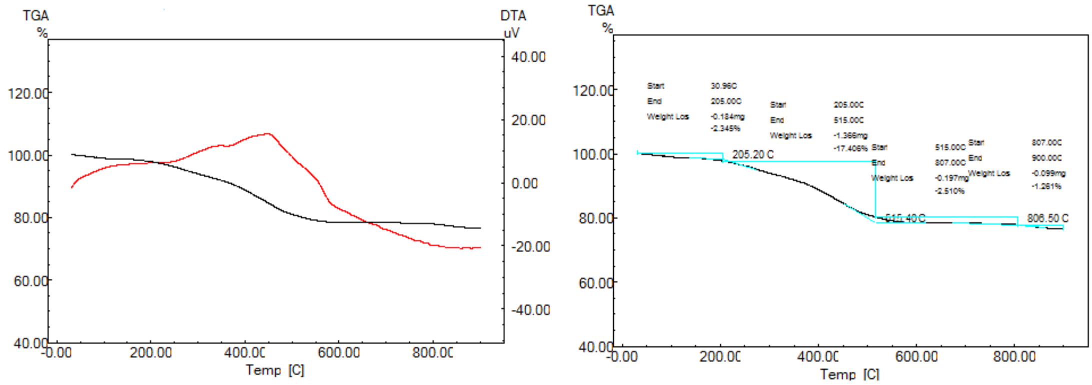

Figure 5. *TGA-DTA results of synthesized AgNPs*

The minimum inhibitory concentrations (MIC) of AgNPs on Gram-negative *Escherichia coli* ATCC 25922, Gram-positive *Staphylococcus aureus* ATCC 29213 bacteria and *Candida albicans* microorganisms were found to be 0.078, 0.314 and 0.331 µg mL^{-1}, respectively (*Table 1*). In the green synthesis and characterization of AgNPs from *Abelia grandiflora*, MIC values of Gram-negative and Gram-positive bacteria were found to be 3.12 µg mL^{-1} for *E. coli* and 12.5 µg mL^{-1} for *S. aureus* (Sharma et al., 2014).

Table 1. *MIC values of synthesized silver nanoparticles (AgNPs), silver nitrate, vancomycin, fluconazole and colistin antibiotics on S. aureus, C. albicans and E. coli*

Organism	AgNP (µg mL^{-1})	Antibiotic (µg mL^{-1})	Silver nitrate (µg mL^{-1})
S. Aureus ATCC 29213	0.314	0.50	0.50
E. coli ATCC 25922	0.078	0.12	1.00
C. albicans	0.331	0.06	0.50

Conclusion

In this research, synthesis of AgNPs was performed using the common grape (*Vitis vinifera*) leaf extract. It was determined that AgNPs had spherical shapes with sizes around 75 nm according to the data obtained from the SEM images, and also had a crystal size of 18.53 nm according to XRD results. FTIR results showed that the functional groups involved in the reduction were -OH, -CN and C=O. The antimicrobial effect of nanoparticles was determined to be significant on *E. coli* ATCC 25922 and *S. aureus* ATCC 29213 strains. In the light of these results, the usage of the nanoparticles

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45394546

obtained by an environmentally friendly synthesis can be improved for the medical industry due to their biocompatibility as antimicrobial agents. With their antimicrobial effect, AgNPs are thought to be effective in bioremediation of wastewater due to their rapid and efficient synthesis, as well as their being used in many areas such as shelf life extension, cosmetics, and others.

Abstract. The water ecological security of a river basin affects the vigorous growth of the regional economy and the healthy development of the ecological environment. Based on river physics, chemistry, and biological indicators, this study constructed a comprehensive assessment index system for the water ecological security of the Xiangjiang River Basin in China. The system consisted of 6 elements, and 18 indicators. This study used the analytic hierarchical process (AHP) to evaluate the water ecological security of the upstream, midstream, and downstream environments of the Xiangjiang River Basin. The results show that the overall ecological security of the upper and midstream portions of the Xiangjiang River Basin is relatively good, while the downstream section is at a general level. The three indicators that are given the most weight in the indicator system are the fish bio-loss index, the degree of ecological flow satisfaction, and the compliance rate of the water function zone. The less significant indicators are the natural wetland retention rate, riparian vegetation coverage, riparian human activity, and riverside connectivity. The research results of this study can provide a reference for the ecological restoration of regional rivers and the protection of Xiangjiang River.
Keywords: *ecological security, water environment, indicator system, AHP, Xiangjiang River Basin*

Introduction

Xiangjiang River, the mother river of Hunan Province, is an important tributary of the Yangtze River and the largest tributary of the Dongting Lake water system. The location of Xiangjiang River Basin is both in the radiating zone of the Yangtze River Economic Belt and in the South China Economic Circle. This basin is located in the most densely populated and economically developed region in Hunan Province and is an important grain production base in China. In the past two decades, with the increase in water consumption due to urbanization as well as industrial water and agricultural irrigation, some wastewater has been directly discharged into the Xiangjiang River, causing serious pollution concerning heavy metals, fecal coliforms, ammonia nitrogen, total phosphorus and chemical oxygen demand. When the indicators of the presence of these pollutants exceed standard values, aquatic biodiversity is reduced, which brings about problems with watershed resources and the ecological environment, and the pressure of sustainable development increases dramatically. In 2013, in order to protect the Xiangjiang River, the Government of Hunan Province issued the “Regulations on the Protection of the Xiangjiang River in Hunan Province” and launched the “No. 1 Key Project” for implementing the protection and treatment of the Xiangjiang River, which was then comprehensively carried out.

A river is the core of a river basin ecosystem. Rivers are often regarded as ecological corridors to provide good habitats for animals and plants. They are also sources of matter and energy (He, 2017). A river ecosystem is one of the most complex ecosystems on the planet. Water ecological security has evolved from environmental changes and ecological risk analysis. Since the International Institute for Applied Systems Analysis (IIASA) was first proposed in 1989 (Ji and Long, 2016; Pan et al., 2017), the concept of water ecological security has not been scientifically defined. At present, there are two levels of understanding of water ecological security: the generalized concept and the narrow concept (Chen and Zhou, 2005; Chen et al., 2013). According to the generalized concept, water ecological security is a complex ecosystem safeguard composed of natural water ecological security, economic-ecological security, and social-ecological security (Zhang et al., 2013; Chen et al., 2016). According to the narrow concept, water ecological security concerns the safety of the “human” aspect, which includes the safety of natural and semi-natural ecosystems (Wang and Hu, 2013). The foundation of water ecological security assessment involves establishing a scientific indicator system and evaluation criteria. At present, there are some typical evaluation systems, such as the indicator species ecosystem evaluation method (Zhang et al., 2017), biological integrity index (Schnier et al., 2016), and the PSR (Pressure-State-Response) model (Sun et al., 2016). The PSR model was proposed by Canadian statisticians David J. Rapport and Tony Friend in 1979 (Rapport et al., 1979) and later developed by the Organisation for Economic Co-operation and Development (OECD) and the United Nations Environment Programme (UNEP) in the 1980s and 1990s. Based on the PSR framework, in order to better characterize the role of non-environmental indicators in ecosystem health assessment, the United Nations Commission on Sustainable Development (UNCSD) established the Driver-State-Response (DSR) framework in 1996 (Doran, 1996).

The assessment of water ecological security involves the analysis of numerous factors using various methods. The existing water ecological safety assessment framework, however, often attaches importance to ecological health, while ignoring the assessment of ecosystem service functions and ecological risks. Due to different interpretations of various indicators, the selected evaluation indicators differ. Even the same evaluation indicators can be given different evaluation connotations. Liu et al. (1989) used the cultivated land area as an indicator to characterize the ecological state. Other researchers believe that agricultural and urban land represent the pressure of human production and lifestyle on aquatic ecosystems (Li et al., 2012). In addition, existing evaluation indicators are mostly based on the entire basin, administrative divisions, fixed wide grid, and different ecosystem types (Nödler et al., 2016). These indicators have the advantage of reflecting the integrity of the basin through convenient data collection, but they also

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45474574

have shortcomings, such as the one concerning the spatial differences that cannot adequately reflect ecological security. Therefore, a series of indicators are needed to measure the water ecological security statusIn this paper, based on the comprehensive assessment of the water ecological security in the Xiangjiang River Basin, the water ecological characteristics of the Xiangjiang River Basin are understood. The research results provide basic support for watershed water ecological protection and restoration, and provide scientific basis for the formulation of water resources and water ecological security planning by the national and local governments in China.

Materials and methods

Overview of the study area

The Xiangjiang River Basin (110°31′E–114°15′E, 24°31′N–29°52′N) is located south of the Yangtze River, and north of the Nanling Mountains in China. It has a subtropical humid climate and is greatly affected by monsoons. The average annual temperature of the basin is 17.4°C. The average annual evaporation of the basin is 1275.5 mm. The average annual precipitation in the basin is 1490 mm. The spatial and temporal distribution of rainfall is uneven. From April to June, the rainfall was concentrated, and the average annual rainfall is 617.9 mm, accounting for 42.9% of the whole year; from July to September, the average annual rainfall is 318.2 mm, accounting for 22.1% of the whole year; from October to March, the rainfall is only 504.7 mm, accounting for 35.0% of the whole year. In terms of geographical distribution, there is a trend of more rainfall in the north and south, and less rainfall in the central areas.The main stream of the Xiangjiang River is 856 km long, with a drainage area of 94,600 km^2. A total of 85,400 km^2 of the drainage area is in Hunan Province, accounting for 90% of the total basin area. To be specific, the Xiangjiang River Basin refers to the section of the basin in Hunan Province. The Xiangjiang River Basin includes important urban centers such as Yongzhou City, Chenzhou City, Hengyang City, Shaoyang City, Loudi City, Zhuzhou City, Xiangtan City, Changsha City, Yueyang City, and Yiyang City. The elevation of the basin is high in the southwest and low in the east. The Xiangjiang River flows into Dongting Lake from the south. The water system in the basin is complicated, consisting of many tributaries. There are 2,157 tributaries in the basin with lengths greater than 5 kilometers. The two sides of the main stream of the Xiangjiang River are in the form of asymmetrical feathers. The right bank covers an area of 67,316 km^2, accounting for 71.2% of the total area of the basin. The main tributaries of the Xiangjiang River (the Xiaoshui River, Chonglinshui River, Leishui River, Mishui River, Lushui River , and Liuyang River) flow from the right bank into the main stream. The area of the left bank is 27,433 km^2, accounting for 28.8% of the total area of the basin. The main tributaries (the Qishui River, Zhengshui River, Juanshui River, Lianshui River, and Weishui River) flow from the left bank. The distribution of water system and hydrological stations as shown in *Figure 1*.

Division of evaluation units

Based on the boundaries of municipal administrative divisions within the basin, this study comprehensively considered the spatial overlapping relationships among natural geographic units, administrative divisions, and watershed environmental management

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45474574

units of the basin and the consistently divided evaluation unit of the combination. Using the ArcHydro hydrological analysis module of ArcGIS software, the ASTER GDEM V2 (30 m resolution) data jointly measured by National Aeronautics and Space Administration (NASA) and Ministry of Economy, Trade and Industry (METI) was used as the basic DEM data for river network information extraction in the Xiangjiang River Basin. Finally, areas in Yongzhou City and Chenzhou City were designated as the upstream evaluation units; areas in Hengyang City and Zhuzhou City were designated as the mid-stream evaluation units; and areas in Changsha City, Xiangtan City, and Loudi City were designated as the downstream evaluation units. *Figure 2* is a interpretation map of the catchment area of the Xiangjiang River Basin.

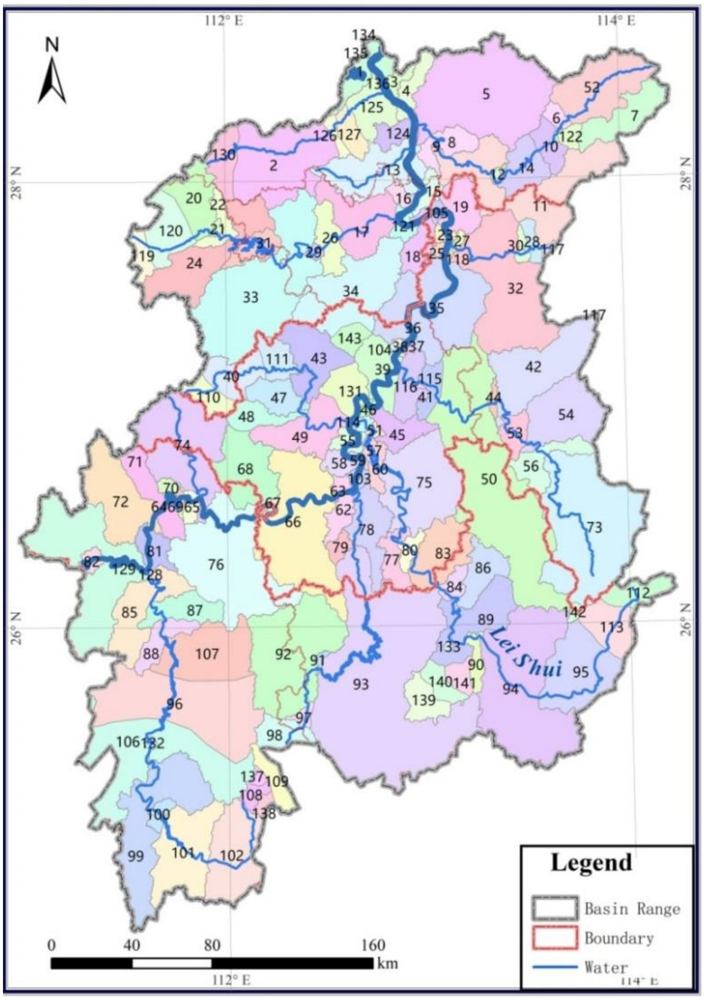

***Figure 2.** Interpretation map of the catchment area of the Xiangjiang River Basin*

Construction of a comprehensive evaluation index system

According to previous research, the water ecosystem safety of a river basin means that the basin ecosystem is in a stable and sustainable state, maintaining physical, chemical, and biological integrity, providing humans with different ecological products or service functions, and having a certain resilience with respect to natural and human interference, as well as adjustment and repair capabilities. While assessing the water ecosystem safety through a series of indicators, we often tend to the principles of science, systems, conciseness, and operability. There are many water ecosystem safety assessment methods according to the previous studies (Dai et al., 2015; Lin et al., 2016; Wang et al., 2016). Among them, the AHP is a useful tool for providing qualitative and quantitative assessment to decision makers, which enables managers to evaluating the complicated indicator system (Yoshimatsu and Abe, 2006; Haji et al., 2016). In this study, therefore, the AHP was used to construct a comprehensive evaluation index system for water ecological security in Xiangjiang River Basin. This indicator system contains 18 indicators related to six aspects: hydrology and water resources, physical structure, water quality, biology, water ecological management, and social service functions (*Table 1*).

Table 1. *Comprehensive evaluation index system for water ecological security in the Xiangjiang River Basin*

Target layer	Factor layer	Indicator layer	Indicator description	Data Sources
Water ecological security	Hydrology and water resources	The flow process variation degree	Reflects and evaluates the influence of water resources development and utilization above the monitoring section of river reach on the hydrological situation of river reach	Hunan Hydrological Network (http://61.187.56.156/wap/index_sq.asp) The flow and water level data of all hydrological stations in the basin of the Xiangjiang River Basin from 1996 to 2015
		The degree of ecological flow satisfaction	Reflects the degree of ecological flow satisfaction of the main section	Hunan Hydrological Network (http://61.187.56.156/wap/index_sq.asp) Three stations from Guiyang, Hengshan and Xiangtan from 1996 to 2017
	Physical structure	Riverbank Stability	Shows whether the indicators reflect the stability of the river bank , i.e., is readily eroded	The main river course is counted by Google Earth software. 12 sampling points are selected randomly and evenly in the main river course within the scope of the river basin. The statistical time is 2017.
		Vegetation coverage on river banks	Reflects whether the structure and function of the riparian zone are in good condition	NDVI product data using the official MODIS website (https://modis.gsfc.nasa.gov/) MOD13Q1 satellite.
		Degree of human activity in the riparian zone	The focus of the survey is to assess nine types of human activities in the riparian zone and its adjacent area: riverbank rigid masonry, sand mining, coastal buildings (houses), roads (or railways), landfills or dumps, riverside parks, degree of impact on water ecosystems, pipelines, mining, agricultural farming, livestock farming, etc.	Monitoring of riverside belts on the left and right sides of the river in an on-site survey (2017)
		River connection barrier condition	The main survey assesses river migration of biological species such as fish and the blocking of water flow and nutrient transport, which can be used to characterize river water ecological security.	Statistics of the main river channel using Google Earth software. The statistical time is 2017.
		The natural wetland retention rate	Reflect the pros and cons of the state of the river's ecological environment	Land use classification product data using the MODIS website (https://modis.gsfc.nasa.gov/) MOD12Q1 satellite.
	Water quality	Dissolved Oxygen Concentration	Dissolved oxygen is very important for aquatic animals and plants. DO values that are too high or too low are harmful to aquatic organisms, and the suitable range is 4-12 mg/L.	Observation data of hydrological station from Hunan Hydrological and Water Resources Survey Bureau in 2015
		Oxygen-poor organic pollution status	Reflects the content of organic matter in water, based on the permanganate index, chemical oxygen demand, five-day biochemical oxygen demand, ammonia nitrogen and four other items to evaluate the oxygen consumption of rivers	Observation data of hydrological station from Hunan Hydrological and Water Resources Survey Bureau in 2015
		Heavy metal pollution status	Five items , i.e., arsenic, mercury, cadmium, chromium (hexavalent) and lead were selected to assess the metal pollution status of water.	Concentration data of measured heavy metal pollutants at hydrological stations from Hunan Hydrological and Water Resources Survey Bureau in 2015

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45474574

Target layer	Factor layer	Indicator layer	Indicator description	Data Sources
		Water function area compliance index	Reflects the level of ecological environmental protection and resource utilization	Assessment of the monitoring sections of the upstream, midstream and downstream of the Xiangjiang River Basin. The proportion of the number of compliance points in the water functional zones during the year of 2015.
	Biology	Fish Bio-Loss Index	Reflects the quality of aquatic ecosystems	Survey data on fishery resource flows obtained from 8 sampling points in the Xiangjiang River Basin (November-December 2008, February-December 2009 and February-September 2010, 30 times in total)
	Water ecological management	Sewage centralized treatment efficiency index	Reflects the ability of water ecosystems to treat wastewater	Sewage treatment plant operation survey data
		Soil erosion control index	Reflects the intensity of soil erosion and the implementation of control measures	Urban soil erosion area survey data, the third remote sensing survey of soil and water loss in hunan province organized by Hunan Water Resources Department in 2015.
		Hazard Source Risk Index	Reflects the extent to which the source of the hazard affects the ecosystem	Hazard source survey and evaluation data of major industrial parks (2017)
	Social service function	Flood Control Indicators	Reflects the safe discharge capacity of the river	Data sourced from the "Xiangjiang River Basin Comprehensive Planning Report"
		Public Satisfaction Indicator	Reflects the public's satisfaction with river landscapes, aesthetic values, etc.	Collected and processed relevant information through questionnaires
		Centralized drinking water source safety guarantee compliance rate public satisfaction index	Reflects the safety of water	National Safe Drinking Water Source Safety Assessment Indicators

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45474574

Indicator calculation method and indicator assignment

Based on the river water environment and ecological characteristics of the Xiangjiang River Basin, the standard values for river water ecology evaluation were determined. The calculation and assignment of each indicator utilized the following principles: (a) If there were specific applicable standards and industry norms in the country, the national standards and norms were preferred; (b) the relevant research results in China and abroad were used for reference; (c) indicators were standardized. The closer a detected indicator is to the natural state or the less a detected indicator is affected by human activities, the higher the score given to the indicator.

The flow process variation degree (C11) indicator can be calculated by the following equation (*Eq. 1*):

$$FD = \left\{\sum_{m=1}^{12}\left[\frac{q_m - Q_m}{\bar{Q}_m}\right]^2\right\}^{1/2}, Q_m = \frac{1}{12}\sum_{m=1}^{12} Q_m \qquad \text{(Eq.1)}$$

where q_m is the measured annual monthly runoff and Q_m is the annual natural monthly runoff. The annual average natural runoff is then evaluated. And the final score is shown in *Table 2*.

Table 2. *Flow process variation degree indicator score*

Flow process variation index	Score
0.05	100
0.1	75
0.3	50
1.5	25
3.5	10
5	0

The degree of ecological flow (EF) satisfaction (C12) can be calculated by the following equation (*Eq. 2*):

$$EF1 = min\left[\frac{q^d}{\bar{Q}}\right]_{m=4}^{m=9}, \mathrm{EF2} = \min\left[\frac{q^d}{\bar{Q}}\right]_{m=10}^{m=3} \qquad \text{(Eq.2)}$$

where q^d is the estimated annual runoff, which is the average annual runoff; EF1 is the lowest percentage of the daily average flow from April to September; and EF2 is the lowest percentage of the daily average flow from October to March. Based on the hydrological method to determine the ecological base flow, the EF1 and EF2 assignment values were calculated according to *Table 3*, with the minimum value of the assignment taken as the final assignment of the indicator.

Riverbank Stability (C21): The Riverbank Stability Index (BKSr) was assessed based on the current status of riverbank erosion, including erosive erosion that has occurred or is likely to occur.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45474574

The calculation of BKSr can be expressed as follows (*Eq. 3*):

$$BKSr = \frac{SAr + SCr + SHr + SMr + STr}{5} \quad \text{(Eq.3)}$$

where BKSr is defined as the bank slope stability index score, SAr is the bank slope dip score, SCr is the bank slope coverage score, SHr is the bank slope height score, SMr is the river bank matrix score, and STr is the slope foot scour strength score. The specific scoring criteria are shown in *Table 4*.

Table 3. *Staging base flow standard and score*

Grading	Qualitative description	Recommended base flow standard (annual average flow percentage)		Score
		EF1: General water period (October-March)	EF2: Fish spawning period (April-September)	
1	maximum	200%	200%	100
2	optimal	60-100%	60-100%	100
3	excellent	40%	60%	100
4	very good	30%	50%	100
5	good	20%	40%	80
6	general	10%	30%	40
7	poor	10%	10%	20
8	very poor	<10%	<10%	0

Table 4. *Evaluation criteria for river bank stability indicators*

Bank slope characteristics	Stable	Basically stable	Secondary unstable	Unstable
Score	90	75	25	0
Slope inclination (degrees) (<)	15	30	45	60
Vegetation coverage (%) (>)	75%	50%	25%	0%
Slope height (m) (<)	1	2	3	5
Matrix (category)	Bedrock	Rocky bank	Clay river bank	Non-clay river bank
Riverbank scouring	No flushing signs	Mild scouring	Moderate scouring	Severe scouring
General characterization	In the near future, the river bank will not be deformed and destroyed, and no soil loss will occur.	The riparian structure has signs of loosening development and soil erosion, but it will not be deformed and destroyed in the near future.	The development trend of loose cracks on the river bank is obvious. Under certain conditions, the river bank can be deformed and destroyed, with moderate soil erosion.	The water and soil loss on the river bank is serious, and large deformation and damage may occur at any time, or damage may have already occurred.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45474574

Vegetation coverage on river banks (C22): Also known as changes in biomass indicators; vegetation can be separated from water and soil. This process is closely related to plant transpiration, interception of sunlight, photosynthesis, and net primary productivity. This coverage is calculated as follows (*Eq. 4*):

$$NDVI = \frac{Band2 - Band1}{Band2 + Band1} \quad \text{(Eq.4)}$$

where Band2 and Band1 are derived from MOD13Q1 satellite band data. And the final score is shown in *Table 5*.

Table 5. *Riverbank vegetation coverage index score table*

NDVI	Score
0.4	100
0.3	74.9
0.2	47
0.1	24.6
0.05	9.7
0	0

Degree of human activity in the riparian zone (C23): A riparian human impact assessment was performed in the assessment of the river section using a method for reducing the corresponding score for each human activity. A river section with all 9 types of activities listed below was given 100 points, with corresponding points being deducted according to the type of human activity and its position, with a lowest score of 0. The specific scoring criteria are shown in *Table 6*.

Table 6. *Standards for human activities in the riparian zone*

NO.	Type of human activity	Location		
		Inside the river (within the waterline)	Riparian zone	The riparian zone is adjacent to the land (within 10 m of a small river and within 30 m of a large river)
1	Rigid masonry		-5	
2	Sand mining	-30	-40	
3	Coastal buildings (houses)	-15	-10	-5
4	Highway (or railway)	-5	-10	-5
5	Landfill or dumping		-60	-40
6	Riverside park		-5	-2
7	Pipeline	-5	-5	-2
8	Agricultural cultivation		-15	-5
9	Livestock farming		-10	-5

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45474574

River connection barrier condition (C24): The final score of C24 is from *Table 7*.

Table 7. *Dam barrier identification table*

Fish migration barrier	Water quantity and material circulation barrier characteristics	Score
Unobstructed	No regulation of runoff	0
There is a fish channel and it is running normally	Adjusting the runoff, the discharge flow meets the ecological base flow	-1
No fishway, blocking the migration of some fish	The runoff is regulated, and the discharge flow does not satisfy the ecological base flow	-2
The migration channel is completely blocked	Partial time leads to interruption	-20

The calculation of the natural wetland retention rate (C25) can be expressed as follows (*Eq. 5*):

$$NWL = \frac{AW}{AWR_n} \quad \text{(Eq.5)}$$

where NWL is the natural wetland retention rate, AW is the natural wetland area (km^2) for the assessment base year, and AWR_n is the historical wetland area (km^2). The final score of C25 is from *Table 8*.

Table 8. *Natural wetland retention rate assignment standard table*

Natural wetland retention rate	Score	Description
93%	100	Close to reference conditions
86%	75	Small difference from reference conditions
72%	50	Moderately different from reference conditions
44%	25	A large difference from reference conditions
16%	0	Significantly different from the reference status

Dissolved Oxygen Concentration (C31): The monthly average concentration of 12 months was used to classify the data into 2 groups, the flood season and the non-flood period. The scores of the flood season and the non-flood period were then evaluated. The specific scoring criteria are shown in *Table 9*.

Table 9. *DO water quality indicator score criteria*

DO (mg/L) (>)	Saturation rate 90% (or 7.5)	6	5	3	2	0
DO indicator assignment	100	80	60	30	10	0

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45474574

Oxygen-poor organic pollution status (C32): Permanganate index, 5-day biochemical oxygen demand, and ammonia nitrogen were assigned separately. The monthly average concentration of the 12-month evaluation year was selected and the average value was calculated based on the flood season and the non-flood period. The scores of the flood season and the non-flood period were separately assessed. The average of the scores of the three water quality projects was taken as the oxygen-consuming organic pollution status. The indicator calculation can be expressed as *Eq. 6*:

$$OCPr = \frac{(CODMNr + BODr + NH3Nr)}{3} \quad \text{(Eq.6)}$$

The specific scoring criteria of C32 are shown in *Table 10*.

Table 10. *Oxygen consumption index*

Permanganate index (mg/L)	2	4	6	10	15
5-day biochemical oxygen demand (BOD5) (mg/L)	3	3.5	4	6	10
Ammonia nitrogen (NH3-N) (mg/L)	0.15	0.5	1	1.5	2
Score	100	80	60	30	0

Heavy metal pollution status (C33): The average monthly concentrations of mercury, cadmium, chromium, lead, and arsenic concentrations were determined according to 12 months of assessment. The averages were determined based on the flood season and non-flood period. The scores of the flood season and non-flood period were then evaluated. The minimum score was divided into the scores of the water quality project, and the lowest scores of the 5 water quality projects were assigned as the indicators of the heavy metal pollution status. The calculation can be expressed as *Eq. 7*:

$$HM\ Pr = Min(Arr, Hgr, Cdr, Crr, Pbr) \quad \text{(Eq.7)}$$

where $HM\ Pr$ is the heavy metal pollution index factor and Arr, Hgr, Cdr, Crr, and Pbr are factors assigned to the corresponding metals. The specific scoring criteria are shown in *Table 11*.

Table 11. *Standards for assigning indicators of heavy metal pollution status*

Arsenic	0.05	0.025	0.1
HG	0.00005	0.0001	0.001
Cadmium	0.001	0.005	0.01
Chromium (hexavalent)	0.01	0.05	0.1
Lead	0.01	0.05	0.1
Score	100	60	0

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45474574

Water function area compliance index (C34): The water function area that met the number of assessments during the year at least 80% of the time was defined as the water quality standard water function area. The calculation method for the water quality compliance index of the water function area was that 20 points were deducted when the river section was not up to standard.

Fish Bio-Loss Index (C41): This index refers to the assessment of the difference between the current number of fish species in a river segment and the number of fish species in the historical reference system. The surveyed fish species did not include alien species. The fish bio-loss index is calculated as follows (*Eq. 8*),

$$\mathrm{FOE} = \frac{\mathrm{FO}}{\mathrm{FE}} \quad \text{(Eq.8)}$$

where FOE is the fish bio-loss index, FO is the number of fish species obtained from the survey of a particular river segment, and FE is the number of fish species in the section based on historical assessment.

Sewage centralized treatment efficiency index (C51): From a basic survey of the operational status of sewage treatment plants in the Xiangjiang River Basin, the scores of the sewage centralized treatment efficiency indicators could be determined. The specific scoring criteria are shown in *Table 12*.

Table 12. *Sewage centralized treatment efficiency index score*

Sewage centralized treatment efficiency index	Score
1	100
0.95	80
0.8	70
0.75	50
0	0

Soil erosion control index (C52): This index indicates the intensity of soil erosion and the implementation of control measures throughout the river. The calculation of this index can be expressed as follows (*Eq. 9*):

$$\mathrm{SECI} = \frac{\mathrm{SEC}}{\mathrm{SE}} \quad \text{(Eq.9)}$$

where SECI represents the soil erosion control index, SE represents the area of soil erosion in the region, and SEC represents the planned area of key treatment of soil erosion in the region.

Hazard Source Risk Index (C53): This index refers to assessed sources of heavy metal pollution and sources of toxic and hazardous substances in the riparian zone and its adjacent land areas. For the assessment of river segments, a hazard source risk assessment was carried out using a method in which each hazard source reduces the total number of points by its corresponding score. River segments without danger

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45474574

sources were assigned a value of 100 points, and the corresponding points were deducted according to the type of danger source and its position, untila minimum value of 0 points. Each state-level industrial park in a river segment has an association deduction of 5 points was reached. Each provincial industrial park results in a deduction of 3 points.

Flood Control Indicators (C61): River Flood Control Indicators (FLD) are used to assess the safe discharge capacity of a river course. The calculation of this index can be expressed as follows (*Eq. 10*):

$$FLD = \frac{\sum_{N=1}^{NS}(RIVL_n \times RIVWF_n \times RIVB_n)}{\sum_{N=1}^{NS}(RIVL_n \times RIVWF_n)} \quad \text{(Eq.10)}$$

where FLD is the river flood control index and $RIVL_n$ is the length of river segment nthe number of river segments divided by the river according to the flood control plan is evaluated. $RIVB_n$ is assigned according to whether the flood control project of a given river segment meets the planning requirements, where $RIVB_n = 1$ when the standard is met and $RIVB_n = 0$ when the standard is not met. $RIVWF_n$ is the recurrence period of the planned flood control standard for a given river segment (e.g., 100 years). The scoring criteria are shown in *Table 13*.

Table 13. *Flood control index assignment standard*

Score	100	75	50	25	0
FLD	100%	75%	50%	25%	0%

Public Satisfaction Indicator (C62): This indicator is calculated based on the public participation survey statistics. The public questionnaire included many parameters: the basic information of the participants, the relationship between the participants, the participants' assessment of the river's water volume, water quality, river beach conditions, fish status and the river suitability, the participants' understanding of the above aspects, and an overall assessment of the river conditions.According to the *Technical Guidelines for River and Lake Health Evaluation*, scores are assigned according to the total number of responses for options in the table, with the assignment criteria shown in *Table 14*.

DOI: http://dx.doi.org/10.15666/aeer/1702_45474574

Centralized drinking water source safety assessment index (C63): The drinking water source refers to the water source area that provides residents' living and public service water intake projects. This index was calculated using the centralized drinking water source safety assessment index system from the *National Important Drinking Water Source Safety Assessment Guide*. This guide includes a water quality assessment of 30 points, a water quality assurance assessment of 40 points, a monitoring assurance assessment score of 15 points, and a management assurance assessment score of 15 points. The maximum evaluation of the centralized drinking water source is 100 points. The average value was taken as the safety assurance assessment index of the centralized drinking water source.

Index weight calculation

This study selected the current mature and general AHP method to calculate the index weights, which can make this process clear, quantifying qualitative problems and requiring fewer data. There are three basic steps. The first step was the establishment of a hierarchical structure. The second step concerned the construction of a pairwise comparison judgment matrix. The third step involved the hierarchical ranking calculation and consistency test, followed by an n index weight calculation. The AHP method generally uses a scale of 1–9 and its reciprocal when constructing the pairwise comparison judgment matrix (*Table 15*).

Table 15. *Judgment matrix scale and its corresponding meanings*

Scaling	Implication
1	Equally important to a function
3	Slightly more important relative to a certain function
5	Significantly important relative to a function
7	Strongly important relative to a function
9	Extremely important relative to a function
2,4,6,8	Intermediate conditions between two adjacent judgments (Reciprocal, results of geminate contrast and reversal, namely index *i* is relative to index *j*)

Building a judgment matrix

Experts in three related fields (#1, #2, #3) determined the importance of the indicators. The importance judgment matrices of the factor layer and the indicator layer were obtained. The final weight determination depended on the average values of the three experts (*Tables 16,17,18*).

There are many methods for normalizing the eigenvectors of the judgment matrix. The maximum eigenvalues and eigenvectors of the judgment matrix were calculated using the square root method. The judgment matrix is $U = (u_{i,j})_{n\times n}$, where $u_{i,j}$ indicates that the importance of factor *i* is higher than that of factor *j* relative to the previous level. n is the order of the matrix.

The specific calculation steps can be expressed as follows:

(1) The calculation of the product of each row element of the judgment matrix can be expressed as (*Eq. 11*):

$$M_i = \prod_{j=1}^{n} u_{ij} \qquad \text{(Eq.11)}$$

(2) The calculation of the nth root of M_i can be expressed as (*Eq. 12*):

$$\overline{W_i} = \sqrt[n]{M_i} \qquad \text{(Eq.12)}$$

(3) The normalization can be expressed as (*Eq. 13*)

$$W_i = \frac{\overline{W_i}}{\sum_{j=1}^{n} \overline{W_j}} \qquad \text{(Eq.13)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45474574

Then, $W=(W_i, i=1,2,\cdots,n)$ indicates the relative priority of each factor, which is the element that constitutes the feature vector W of the judgment matrix, namely, the ranking weight of the corresponding factor of the same level for the relative importance of the previous level factor.

Consistency calculation

(1) The calculation of the maximum eigenvalue of the judgment matrix can be expressed as (*Eq. 14*):

$$\lambda_{max} = \sum_{i=1}^{n}\left(\frac{\sum_{j=1}^{n} U_{ij} W_j}{n W_i}\right) \quad \text{(Eq.14)}$$

(2) The calculation of the computational judgment matrix consistency index can be expressed as (*Eq. 15*):

$$\mathrm{CI} = \frac{\lambda_{\max} - n}{n-1} \quad \text{(Eq.15)}$$

(3) The calculation of the consistency check coefficient of the judgment matrix can be expressed as (*Eq. 16*):

$$CR = \frac{CI}{RI} \quad \text{(Eq.16)}$$

When CR is 0.1, the maximum eigenvalue can be calculated as: $\lambda'_{max} = CI(n-1)+n = 0.1RI(n-1)+n$. RI is the average random consistency indicator, which is related to the order n of the judgment matrix. When $i = 1,2,\cdots,n$, the corresponding RI value is shown in *Table 19*.

Table 19. *Average stochastic consistency indicators*

n	1	2	3	4	5	6	7	8	9
RI	0.00	0.00	0.58	0.90	1.12	1.24	1.32	1.41	1.45
$\lambda'_{\max}$	-	-	3.116	4.27	5.45	6.62	7.79	8.99	10.16

In the *Table 19*, n=1 or 2 and RI=0, because the 1st- and 2nd-order judgment matrices are always consistent.

When n ≥ 3, CR < 0.1, and $\lambda_{max} < \lambda'_{max}$, the consistency of the comparison judgment matrix is considered to be acceptable; otherwise, the judgment matrix should be properly corrected until λ_{max} is smaller than λ'_{max} in order to pass the consistency test and ensure the obtained W is valid.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45474574

Hierarchical sorting calculation

Calculating the relative importance scale (also known as the weight vector) of all elements in the same hierarchy to the highest level (total target) is called the total ranking of the hierarchy. The steps for total hierarchical ordering are shown below.

A. The first step is to calculate the weight vector of the importance of all factors at the same level relative to the highest level. This process is carried out from top to bottom and layer by layer.

B. The second step is to calculate the weight vector of nk-1 elements relative to the total target for the k-1th layer:

$$W^{(k-1)}=(W_1^{(k-1)}, W_2^{(k-1)}, \ldots, Wn_{(k-1)}^{(k-1)})^T \tag{Eq.17}$$

C. The k^{th} layer has nk elements. The single criterion weight vector for an element j of the previous level (k-1) is

$$P_j^{(k)}=(W_{1j}^{(k)}, W_{2j}^{(k)},. .., W_{nj}^{(k)})T \tag{Eq.18}$$

(for the unqualified relationship with the jth element of the k-1 layer, the corresponding Wij takes a value of 0);

D. The weight vector of the k^{th} layer relative to the total target is

$$W^k=(P_1^{(k)}, P_2^{(k)},. . . , P_{k-1}^{(k)})W^{(k-1)} \tag{Eq.19}$$

Determination of safety assessment criteria

Based on domestic and foreign research results (Jain et al., 2016; Sun et al., 2016; Zhang et al., 2017; Lyu et al., 2018)[22–25], as well as consultation with experts, the safety assessment grades were determined. The safety assessment scores can be obtained after the standardization of each level of indicators. They are then divided into 5 grades (*Table 20*).

Table 20. *Classification of comprehensive assessment of water ecological security in river basins*

Security Level	Very unsafe	Unsafe	General	Safe	Very safe
Indicator score interval	[0, 10)	[10, 30)	[30, 70)	[70, 90)	[90, 100]
Mean score	5	20	50	80	95

Results

Indicator comprehensive value

Through the calculation of indicators and according to the criteria for the corresponding indicators, the evaluation results for each indicator were determined, as shown in *Table 21*.

Comprehensive assessment results of water ecological security in the Xiangjiang River Basin

The comprehensive assessment values of the hydrological and water resources, physical structure, water quality, biological, aquatic ecological management, and social service functions of the upstream, midstream, and downstream portions of the Xiangjiang River Basin were calculated separately. On this basis, overall assessments for the upstream, midstream, and downstream portions of the Xiangjiang River Basin were obtained. The comprehensive evaluation index values of ecological security status are shown in *Table 23* for upstream assessment results, *Table 24* for midstream assessment results, and *Table 25* for downstream assessment results.

Table 23. *Results of comprehensive assessments of water ecological security in the upstream portion of the Xiangjiang River Basin*

Objective	Health status of the upstream portion of the Xiangjiang River Basin	
Function	Composite indicator score	Evaluation result
Hydrology and water resources	74.6	Safe
Physical structure	67.9	Average
Water quality	93.2	Very safe
Biology	54.3	Average
Water ecological management	71.2	Safe
Social service function	60.9	Average

Discussion

Through the study of water ecological security assessment at home and abroad, it can be seen that the index system is the key point of water ecological security assessment in river basins, and it is worth further study.

Weight comparison of evaluation indicators

The calculation results of the weights of each indicator from the comprehensive assessment index system for water ecological security are shown in *Figure 3*.

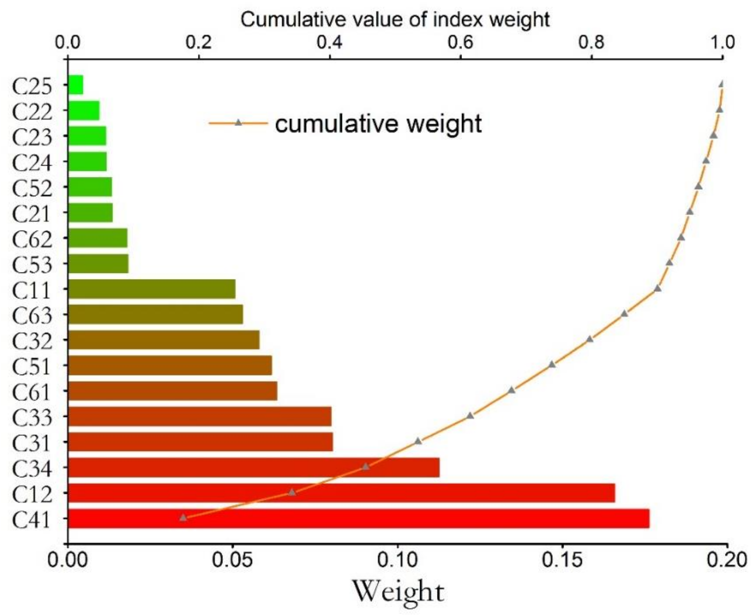

***Figure 3.** Comparison of various indicator weights of water ecological security*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45474574

The figure reflects the importance of indicators in terms of water ecological security assessment. The three most significant indicators are the fish biological loss index, the ecological flow satisfaction level, and water function area compliance, which are important indicators of biological, hydrological, and water resources in the factor layer. The three least important indicators are natural wetland retention, riparian vegetation coverage, and riparian human activity. These indicators reflect the physical structure of the factor layer. Because the indicators with larger weights have a greater impact on the water ecological security of the Xiangjiang River Basin, it is necessary to pay more attention to these indicators.

A comparative analysis of the current status of evaluation indicators

Figure 4 shows the status of the indicators of the upstream, midstream, and downstream portions of the Xiangjiang River Basin after investigation, reflecting the current safety status of each indicator. The comparison shows that the safety status of the upstream water ecosystem is significantly better than those of the middle and downstream ecosystems, and the comprehensive assessment result of the water ecological security in the midstream is better than that in the downstream section. In terms of specific indicators, i.e., the upstream ecological flow satisfaction level, river bank stability, riparian vegetation coverage, riparian human activity, natural wetland retention, dissolved oxygen concentration, oxygen-consuming organic pollution, water functional zone compliance indicators, and fish life, the scores of the biological loss indicators are higher than those of the middle and downstream sections. In the midstream portion, the soil erosion control index, hazard source risk index, public satisfaction index, and centralized drinking water source safety guarantee compliance rate are better than in other river sections. The downstream river section is superior to the other two river sections in the social service function criterion layer. However, other criterion layers of the downstream section perform poorly. Overall, the natural ecosystem of the upstream portion of the Xiangjiang River Basin is larger, making the water ecology healthier, but there are still some problems in ecological water management. As an important area where soil erosion control has been conducted, the midstream section of the river has done well in terms of ecological water health management, but there are also problems concerning the low retention rate of natural wetlands and the low vegetation coverage on river banks. The ecological quality of the aqueous environment in the downstream reaches of the river is poor. However, this section performs well in terms of water ecological management.

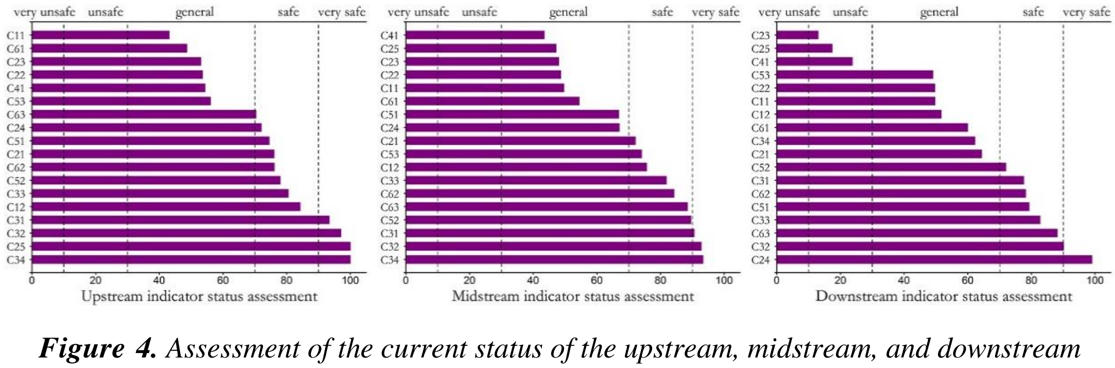

***Figure 4.** Assessment of the current status of the upstream, midstream, and downstream sections of the Xiangjiang River Basin*

Variation characteristics of indicators

A comprehensive analysis of the variation of the indicators of the upstream, midstream, and downstream sections of the ecological water security of the Xiangjiang River Basin is shown in *Figure 5*. In terms of health status, there are 8 indicators of the upstream and midstream sections that are better than the those of the downstream section. These indicators include the water function area compliance indicators, natural wetland retention rate, oxygen-consuming organic pollution status, dissolved oxygen concentration, ecological flow satisfaction degree, river bank stability, fish bio-loss index, and degree of human activity in the riparian zone.

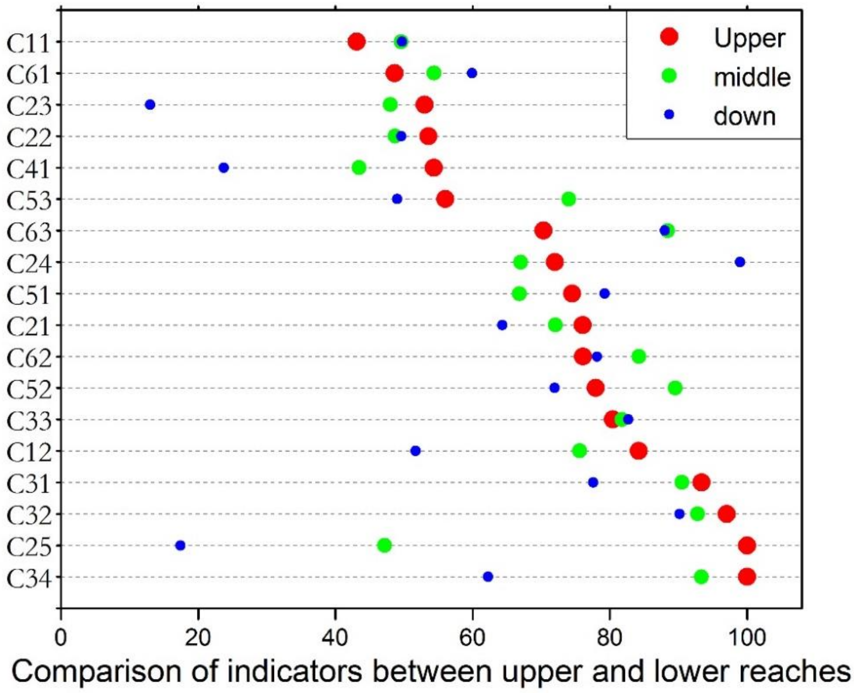

Figure 5. *Variations of current indicators of the upstream, midstream, and downstream sections of the Xiangjiang River Basin*

These indicators are mainly related to hydrology and water resources, physical structure, water quality and biological elements. It is indicated that from the upstream to the downstream sections of the Xiangjiang River Basin that the health status of the indicators transitions from good to bad, and this situation needs to be paid enough attention. It is worth noting that the natural wetland retention rate along the entire river basin ranges from upstream to downstream is good, general and very poor, indicating that the health level of the index has changed dramatically. In addition, with respect to the entire basin of Xiangjiang River, five indicators (the degree of variation in the flow process, the flood control index, human activity intensity in the riparian zone, riparian vegetation coverage, and the fish bio-loss index) are always at unhealthy levels. This fact merits the attention of concerned researchers and citizens.

Contribution value of indicators

Using the weighted values of each indicator of the Xiangjiang River Basin along with the health status of the selected indicators, the contributions of the upstream, midstream, and downstream components of the Xiangjiang River Basin to the total water ecological security can be obtained, as shown in *Figure 6*. Among them, the top 3 contributing values of the upper reaches are the water function zone compliance index, the ecological flow satisfaction degree, and the fish bio-loss index. The midstream contribution value is consistent with that of the upstream The top 3 contributing values in the lower reaches are water function area compliance, ecological flow satisfaction level and heavy metal pollution status.

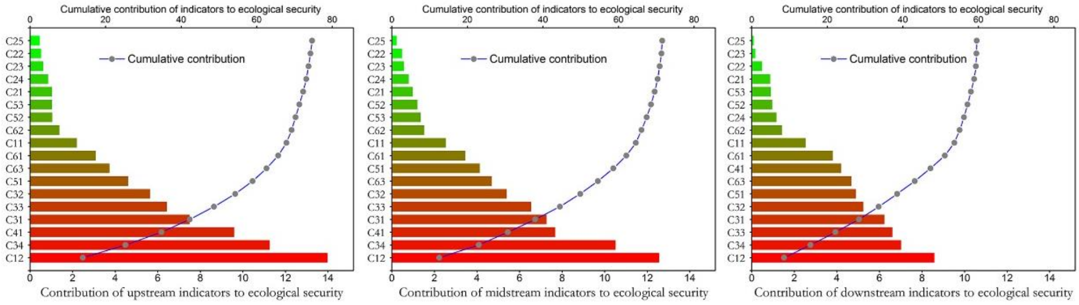

Figure 6. *Contribution of the indicators of the upstream, midstream and downstream sections of the Xiangjiang River Basin to water ecological security*

Conclusions

This study considered the effects of physical, chemical, and biological indicators on the stability and sustainability of watersheds from the perspective of water ecological security. The AHP method was used to calculate the comprehensive evaluation index system of the water ecology of the Xiangjiang River Basin. The top 3 indicators reflecting the health of the river are the fish bio-loss index, the degree of ecological flow satisfaction, and the water function area compliance. These are important indicators of biological, hydrological and water resources, as well as water quality in the factor layer. The last three indicators of importance are the natural wetland retention rate, riparian vegetation coverage, and riparian human activity. These indicators represent the physical structure in the factor layer. A comprehensive assessment of the water ecological security of the Xiangjiang River Basin showed that the water quality in the upstream portions of the Xiangjiang River Basin is satisfactory, and the hydrological water resources and water ecological management have been improved, while the physical structure and biological and social service functions are at an average level. The overall ecological security status of the upstream portion of the river is good. The water quality, water ecological management, and social service functions of the midstream are satisfactory. The hydrology and water resources, physical structure and biology are at an average level, and the overall situation of the midstream is safer than the downstream. The water quality, water ecological management and social service functions of the downstream section of the Xiangjiang River Basin are good. The hydrology and water resources and physical structure are at a general level, while the biological health status is unsafe. The overall ecological safety and health status of the

DOI: http://dx.doi.org/10.15666/aeer/1702_45474574

downstream is at an average level. Based on the health status of the upstream, midstream, and downstream portions of the Xiangjiang River Basin, it can be said that the upstream ecological security level is better than the middle reaches, and that the middle reaches better than the downstream portions.

Abstract. Knowledge of soil moisture temporal stability under different wetness conditions is critical for hydrological and environmental management decisions. This study analyzed the soil moisture (mean relative difference, MRD) and its associated temporal stability (standard deviation of the relative difference, SDRD) at two depths (10 and 30 cm) during the entire, dry, intermediate and wet periods on a mixed land use (tea garden and forest) hillslope. In addition, the influences of environmental factors on MRD and SDRD were also investigated. Results showed that the MRD of soil moisture had a strong spatial dependence (nugget/sill ratios < 0.25) at each depth during different hillslope wetness periods. The widest range (correlation length) was found during the dry period. In addition, spatial patterns of MRD and SDRD were mainly influenced by topographic factors such as elevation. Correlations between MRD and SDRD were in the order of dry > intermediate > wet conditions. Hillslope wetness conditions had substantial influence on the temporal stability of soil moisture, showing that soil moisture patterns were more stable during wet periods than during dry periods. Therefore, the presentative locations identified with the entire dataset are not always appropriate for estimating hillslope mean soil moisture under all wetness conditions.

Introduction

Soil moisture is an important variable influencing water and solute fluxes in the earth surface (Vereecken et al., 2007; Feng et al., 2017; Liao et al., 2018a, 2018b). It is a major component of the hydrologic cycle, controlling runoff, infiltration and evapotranspiration processes at various scales (Pachepsky et al., 2003). In addition, soil water movement has substantial influence on nutrient loss and availability (Zhu et al., 2009; Schmidt et al., 2011). Therefore, soil moisture variations are critical in hydrological, ecological and environmental management (Fu et al., 2003; Zhu et al., 2017).

Soil moisture variations were influenced by environmental factors, such as soil properties and topography (Lark, 1999; Qiu et al., 2003; Vereecken et al., 2007; Brocca et al., 2007; Zhu and Lin, 2011). The relationships between environmental factors and soil moisture were often modelled using multiple linear regression (Nyberg, 1996; Qiu et al., 2010; van Arkel, 2012). Some studies have shown that there is a significant

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45754593

correlation between soil moisture and environmental factors, while others have indicated that the relationship is insignificant (Famiglietti et al., 1998; Western et al., 1999; Qiu et al., 2001). This may be due to differences in climate, topography, soil, vegetation, scale, time and depth of sampling methods (Famiglietti et al., 1998). The wetness conditions in the study area were also found to affect the relationships between environmental factors and soil moisture content. Previous studies proposed that topography has dominant control on soil moisture distribution under wet soil condition, while soil properties have primary control on soil moisture distribution under dry soil condition (Grayson et al., 1997; Pachepsky et al., 2003; Penna et al., 2013).

Although soil moisture exhibits a high spatio-temporal variability at various scales due to the variations in climate, topography and soil properties, its distribution often shows a similar spatial pattern at different dates (Hu et al., 2010; Penna et al., 2013; Li and Shao, 2014; Qiu et al., 2017). This phenomenon has been called temporal stability by Vachaud et al. (1985), who described it as the time-invariant association between a spatial location and classical statistical parameters. The main purpose of temporal stability analysis of soil moisture was to identify reliable locations that can represent the mean soil moisture content of the entire study area (Grayson and Western, 1998; Jacobs et al., 2004; Zhao et al., 2010).

Relationships between soil moisture temporal stability and environmental factors have often been investigated to identify the best representative locations. Previous studies have found that environmental factors (e.g., soil properties and topography) significantly affected soil water temporal stability (Thierfelder et al., 2003; Vivoni et al., 2008; Brocca et al., 2009; Hu et al., 2010). For example, Vivoni et al. (2008) found that sampling locations with mid elevation tended to have a more pronounced temporal stability. Hu et al. (2010) showed that soil texture can significantly affect the temporal stability of soil water content in the LaoYeManQu watershed, China. In addition, the wetness conditions in the study area had large influence on soil moisture temporal stability. Zhao et al. (2010) observed that the ranked positions of the labelled representative location change with different wetness conditions. This implies that the location with the most pronounced time stability may be different for each wetness condition. Some studies have also demonstrated that soil moisture spatial patterns were more stable during wet periods than during dry periods (Hupet and Vanclooster, 2002; Zhou et al., 2007; Williams et al., 2009; Zhao et al., 2010). This is related to an enhanced capillary movement of water from the subsoil to the topsoil, thereby decreasing temporal stability in topsoil moisture. However, others have shown that a higher degrees of temporal stability in dry conditions than in wet conditions (Martínez-Fernández and Ceballos, 2003; Lin, 2006; Penna et al., 2013). For example, Lin et al. (2006) found more frequent conditions of marked persistence of soil moisture patterns during a long dry-down period in June. Penna et al. (2013) observed a slightly higher degree of temporal stability in dry conditions and for deeper layers. The mixed results suggest that the effect of wetness status on temporal stability was complex and has not been fully understood.

Therefore, the objectives of this study are to provide a comprehensive investigation on the temporal stability of soil moisture content under different hillslope wetness conditions. For this purpose, a typical mixed land-use (tea garden and forest) hillslope was considered for which soil moisture content at two depths (0-20 and 20-40 cm) was repeated measured from January 2013 to December 2015 (a total of 32 sampling days) in 77 sites. The dataset obtained was analyzed for temporal stability analysis. The

DOI: http://dx.doi.org/10.15666/aeer/1702_45754593

hypotheses of this study are i) the controlling factors of soil moisture and its temporal stability vary with hillslope wetness condition, ii) the temporal stability of soil moisture are different during different hillslope wetness conditions.

Materials and methods

Study hillslope

This study was conducted on a hillslope (31°21′N, 119°03′E) (has an area of 0.6 ha) in the hilly area of Taihu Lake Basin, China (*Fig. 1*). This study area is feature with a north subtropical-middle subtropical transition monsoon climate with four distinctive seasons. The annual mean temperature is 15.9°C and the annual mean precipitation is 1157 mm. Green tea (*Camellia sinensis (L.) O. Kuntze*) and Moso bamboo (*Phyllostachysedulis (Carr.) H. de Lehaie*) are dominant on the hillslope. The elevation of the hillslope ranges from 77 to 88 m and the slope ranges from 0 to 21%. The soil type of the hillslope is shallow lithosols according to the FAO soil classification (Orthents according to Soil Taxonomy). Parent material is quartz sandstone. Soils are described as silt loam texture with silt content > 60%. Surface (0-20 cm) soil organic matter contents were about 2% on both hillslopes. The depth to bedrock varies from <0.3 m at the summit slope position to about 1.0 m at the foot slope position (Liao et al., 2016).

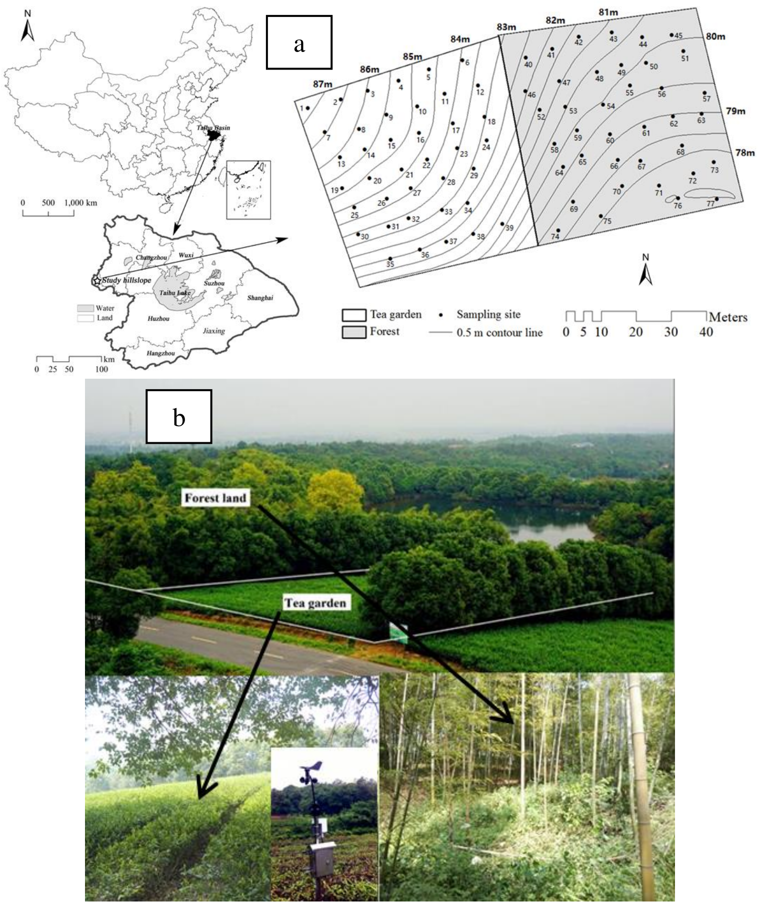

Figure 1. *(a) Location of the study area and sampling sites on study hillslope and (b) photographs from the hillslope*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45754593

Soil moisture measurement

For monitoring volumetric soil water content, access polyvinyl chloride tubes were installed at 77 sites on the hillslope (*Fig. 1*). A portable time-domain reflectrometry TRIME-PICO-IPH soil moisture probe (IMKO, Ettlingen, Germany) was used at 32 dates from January 2013 to December 2015. Volumetric soil water was measured at the depths of 0 to 20 cm (denoted as 10 cm) and 20 to 40 cm (denoted as 30 cm) each time (note that the TRIME-PICO-IPH probe has a length of 18 cm). Due to the shallow soil depths at some locations, only 73 sites had soil moisture readings at 30 cm depth. For each site, the TRIME-PICO-IPH probe was twisted in the access tube to face different directions and 2-3 readings were then taken. The average of these readings was used as the final water content for each site on a specific date. In addition, an outdoor mini weather station was set up to measure rainfall and air temperature. The amounts of precipitation were 889.5 mm, 1296.4 mm and 1617.0 mm in year 2015, 2016 and 2017, respectively.

Soil properties and terrain attributes

Around each soil moisture access tube (within 1-m distance), soil samples at each depth interval were collected using a hand auger. Three subsamples were collected for each site and then fully mixed. These samples were air dried, weighted, ground and sieved through a 2 mm polyethylene sieve. Particles larger than 2 mm (rock fragments) were weighed to determine the rock fragment (RF) content. Soils that passed through the 2 mm polyethylene sieve were used to analyze the particle size distribution using the Malvern Mastersizer 2000 laser analyzer (Malvern Instruments Inc., Worcestershire, UK). The fractions of <0.002 mm (clay), 0.002–0.05 mm (silt), and 0.05–2 mm (sand) were determined for each soil sample. The percentage of the organic matter in the soil was measured by the titration method, which is based on the oxidation of organic matter by $K_2Cr_2O_7$. In addition, the depths to bedrock (DB) of all 77 sites were also determined when installing the access tubes for soil moisture measurements and taking soil samples using a hand auger.

A high-resolution (1 m) digital elevation model (DEM) of the study hillslopes was derived from a 1: 1000 contour map. Terrain attributes including elevation, slope, plane curvature (PLC), profile curvature (PRC), and topographic wetness index (TWI) were determined from this DEM in ArcGIS 10.0 (ESRI, Redlands, CA).

Temporal stability analysis

The temporal stability of soil water content for each soil depth was analyzed using the approach proposed by Vachaud et al. (1985):

$$\theta_j = \frac{1}{N}\sum_{i=1}^{N}\theta_{ij} \quad \text{(Eq.1)}$$

$$\delta_{ij} = \frac{\theta_{ij} - \theta_j}{\theta_j} \quad \text{(Eq.2)}$$

$$MRD = \frac{1}{M}\sum_{j=1}^{M}\delta_{ij} \quad \text{(Eq.3)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45754593

$$SDRD = \sqrt{\frac{1}{M-1}\sum_{j=1}^{M}\left(\delta_{ij} - MRD\right)^2} \quad \text{(Eq.4)}$$

where θ_{ij} is the soil water content at location i in day j; θ_j is the arithmetic mean of soil water content in day j; N is the number of locations; δ_{ij} is the relative difference of soil water content at location i and day j; and M is the number of sampling days, in this case, $M = 17$. MRD is the arithmetic mean relative difference of soil water content at location i; SDRD is the standard deviation of relative difference. The SDRD is the temporal stability of soil water at location i. Smaller SDRD means temporally more stable.

Classical statistics

First soil moisture, soil properties and terrain attributes were investigated using univariate descriptive analysis. The spatial mean soil moisture and corresponding coefficient of variation (CV) were calculated. Correlation analysis was conducted to investigate the relationships between soil moisture contents under different wetness conditions. Stepwise regression (SR) analysis was then conducted to investigate the relationships between environmental factors (e.g., soil properties and topography) and soil moisture and its temporal stability. A backward method regression (Norusis, 1994) was selected and the level for entry in the regression model was set at $p < 0.10$, while a 0.05 significance level was applied to retain the variables in the model. In addition, the *t*-test was used to test the significant of differences in SDRD among different wetness conditions.

Dominance analysis was used to quantify the relative influence of soil properties and topography on MRD and SDRD. Budescu (1993) defined dominance as a pairwise relationship that can be tested for all pairs of variables included in the model. Given a single dependent variable (y) and k explanatory variables (x_1, x_2, …, x_k) (determined by SR analysis), the independent effect of predictor x_1 (I_{x1}) denotes the average contribution of variable x_1 to the variance in y over all 2^k-1 possible submodels. The independent effect of each variable is computed by comparing the fit of all models containing a particular variable to the fit of all nested models lacking that variable, through the process of hierarchical partitioning. Thus, for variable x_1,

$$I_{x_1} = \sum_{i=0}^{k-1}\frac{\sum(R^2_{y,x_1x_h} - R^2_{y,x_h})/\binom{k-1}{i}}{k} \quad \text{(Eq.5)}$$

where x_h is any subset of i predictors, x_1 excluded; R^2 is the coefficient of determination. Because dominance analysis utilizes an all possible models approach, it provides a more robust assessment of variable importance, relative to single-model approaches, by assuring that the contribution of a particular variable is neither enhanced nor masked through its correlation with other explanatory variables (Murray and Conner, 2009). All classical statistics were conducted using the *regress* function of MATLAB software (The MathWorks Inc., USA) and SPSS statistics 17.0 (SPSS Inc., Chicago, IL, USA).

Geostatistics

The spatial dependence of soil moisture content was analyzed using semivariograms γ, which were calculated as follows:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45754593

$$\gamma(h) = \frac{1}{2N(h)} \sum_{i=1}^{N(h)} [Z_i - Z_{i+h}]^2 \qquad \text{(Eq.6)}$$

where $N(h)$ is the number of distance pairs within a given distance class, Z_i is the measured variable at location i and Z_{i+h} is the variable at locations separated from i by the distance h that fall within the distance class (Yates and Warrick, 1987). Four semivariogram models (spherical, exponential, linear and Gaussian) were used to describe the semivariograms and the best-fitted models with the largest coefficient of determination (R^2) were selected. Then the geostatistical parameters were obtained, including nugget, sill and effective range. The ratio between nugget and sill was used to characterize the spatial dependencies of soil water content. Smaller nugget/sill ratio indicates stronger spatial dependency. All the geostatistical computations were conducted using GS+ 7.0 (Gamma Design Software LLC., Plainwell, MI, USA).

Results and discussion

Temporal variations of hillslope wetness conditions

From January 2013 to December 2015, a substantial fluctuation of the hillslope mean soil water content was observed for each depth (*Fig. 2*). This fluctuation was influenced by climate factors, such as precipitation and evapotranspiration.

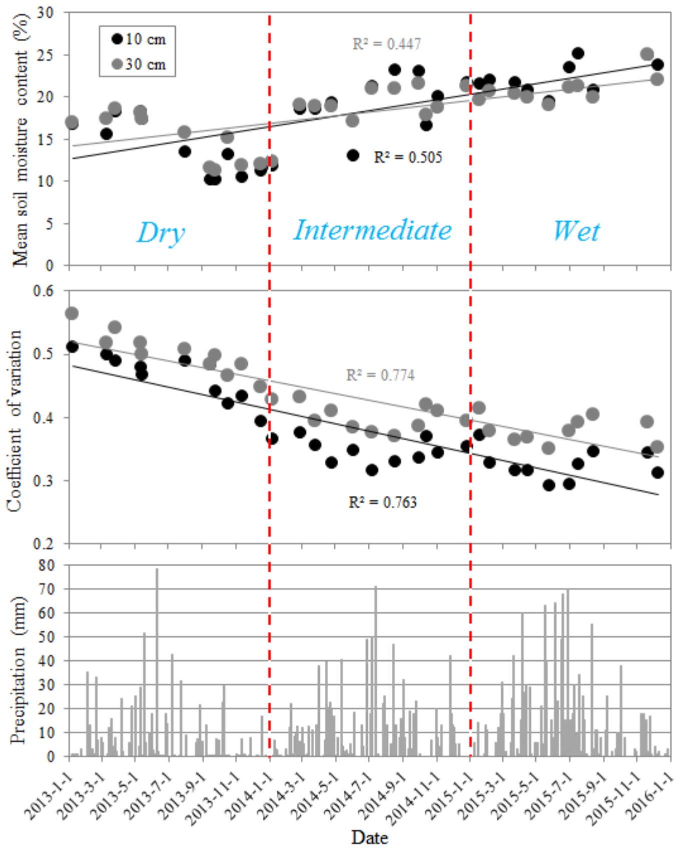

Figure 2. *Time series of precipitation, average soil water contents and corresponding coefficients of variation at two depths*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45754593

The mean soil moisture contents of were 10.18-25.15% and 11.24-24.90% at 10- and 30-cm depths, respectively. An increasing trend of mean soil moisture with time was found at two depths, which can be fitted by a linear function (R^2=0.505 for 10 cm ($P<0.01$) and R^2=0.447 for 30 cm ($P<0.01$)). The reason is that the amount of precipitation increased yearly (890.5, 1296.4 and 1617.0 mm for the year 2013, 2014 and 2015, respectively). Therefore, hillslope wetness conditions can be classified as dry, intermediate and wet periods, corresponding to year 2013, 2014 and 2015, respectively. The mean soil moisture contents were 14.10, 18.82 and 22.38% at 10 cm depth during dry, intermediate and wet periods, respectively, while these values were 15.06, 18.82 and 20.85% at 30 cm depth during dry, intermediate and wet periods respectively (*Table 1*). In addition, seasonal patterns of mean soil moisture were similar from one year to the next year. The highest mean soil moisture content was observed in summer season (from July to September) due to intense and heavy rainfalls occurred, while the lowest value was measured in winter and spring seasons (from November to March) due to the relatively low precipitation.

Table 1. *Statistics of soil moisture at two depths under different hillslope wetness conditions*

	10 cm			30 cm		
	Dry	**Intermediate**	**Wet**	**Dry**	**Intermediate**	**Wet**
No. of locations	77	77	77	73	73	73
No. of sampling times	11	11	10	11	11	10
No. of measurements	847	847	770	803	803	730
Mean (%)	14.10	18.82	22.38	15.06	18.82	20.85
SD (%)	3.29	3.73	1.91	2.85	2.63	1.66
CV	0.23	0.20	0.09	0.19	0.14	0.08

SD: standard deviation; CV: coefficient of variation

The corresponding CV values were 0.293-0.510 and 0.351-0.562 at 10- and 30-cm depths, respectively (*Fig. 2*). The soil moisture at 30 cm depth was found to have stronger variability than that at 10 cm depth. Temporal series of CV for each depth can also be fitted by a linear function (R^2=0.763 for 10 cm ($P<0.01$) and R^2=0.774 for 30 cm ($P<0.01$)). The temporal variations of CV showed the opposite trend as compared to those of the mean soil moisture for each depth (*Fig. 2*). This suggests that the spatial heterogeneity of soil moisture content increases as the soil gets drier. Previous studies also found an increase in spatial variability with decreasing mean soil moisture (Famiglietti et al., 1999; Choi and Jacobs, 2010; Brocca et al., 2012; Korres et al., 2015).

Influencing factors of MRD

At 10 cm depth, the MRD of soil moisture content was mainly influenced by elevation, PLC, DB and RF during the entire period, while at 30 cm depth, it was affected by elevation, PRC, DB, RF and Sand (*Table 2*). Negative coefficients for elevation, PLC, RF and sand and positive coefficients for other factors were observed, indicating that elevation, PLC, RF and sand were significantly ($P<0.05$) negatively correlated with soil moisture, whereas PRC and DB were significantly ($P<0.05$) positively correlated with soil moisture. The results are consistent with previous studies (Tromp-van Meerveld and McDonnell, 2006; Brocca et al., 2007; McMillan and Srinivasan, 2015). The R^2 values of stepwise regression models were 0.649 and 0.643 at

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45754593

10 and 30 cm depths, respectively. This suggests that environmental factors can explain nearly 65% of variation in soil moisture at each depth. The accuracies of soil moisture predictions in our study were comparable with those reported by previous studies (Western et al., 1999; Qiu et al., 2010). The importance of the variables was sequenced as elevation>DB>PLC>RF according to standardized regression coefficients at 10 cm depth (*Table 2*). However, the *I* values for elevation, PLC, DB and RF were 0.373, 0.040, 0.120 and 0.116, respectively (*Table 3*). This indicates that elevation is the most important variable, while PLC is the least important variable among the four variables. This suggests that the use of standardized regression coefficients would result in wrong conclusions regarding the relative importance of the variables influencing soil moisture variations.

SC: standardized coefficient; *I*: independent effect; PLC: plane curvature; DB: depth to bedrock; RF: rock fragment; PRC: profile curvature

The factors influencing the MRD of soil moisture content were slightly different for each period at both depths (*Table 2*). However, topography was always found to explain more variability (49.2-61.5% for 10 cm and 42.7-45.9% for 30 cm) in soil moisture than soil properties (0-12.6% for 10 cm and 13.2-18.5% for 30 cm) under different hillslope wetness conditions. Our results are not consistent with previous studies that indicated a larger influence of soil properties than topography on soil moisture under dry conditions

(Grayson et al., 1997; Pachepsky et al., 2003; Penna et al., 2013) or wet (Laio et al., 2002; Baroni et al., 2013) conditions. This may be related to relatively homogeneous soil properties on study hillslope.

Spatial patterns of MRD

The MRD dataset under different hillslope wetness conditions had low skewness (0.181-0.383) and kurtosis (-0.620--0.145), thus meeting the requirement of a normal distribution for kriging prediction. The semivariogram of MRD provided a clear description of its spatial structure with some insight into possible processes influencing its spatial distribution (*Table 4*). The semivariograms of MRD at 10 cm depth were well fitted with the spherical and Gaussian model under the entire and wet periods, respectively, whereas the remaining semivariograms were well fitted with an exponential model. The nugget/sill ratios of the fitted semivariogram models for MRD under different wetness conditions were less than 0.25, indicating that soil moisture had a strong spatial dependence on study hillslope. Range can reflect some information about spatial dependency of environmental variables (Wu et al., 2009). The semivariogram of MRD had 95.1-115.8 m of range at 10 cm depth, while the semivariogram of MRD had 38.7-62.1 m of range at 30 cm depth. This means that soil moisture at 10 cm depth had stronger spatial structure than at 30 cm depth. In addition, for each depth, the largest range was found during the dry period. This is related to the fact that when soil is dry the soil moisture is relative uniform (Lv et al., 2016).

S-spherical model; E-exponential model; G-Gaussian model

From the maps of predicted MRD developed by kriging (*Fig. 3*), we found that the MRD had strong spatial variability on study hillslope.

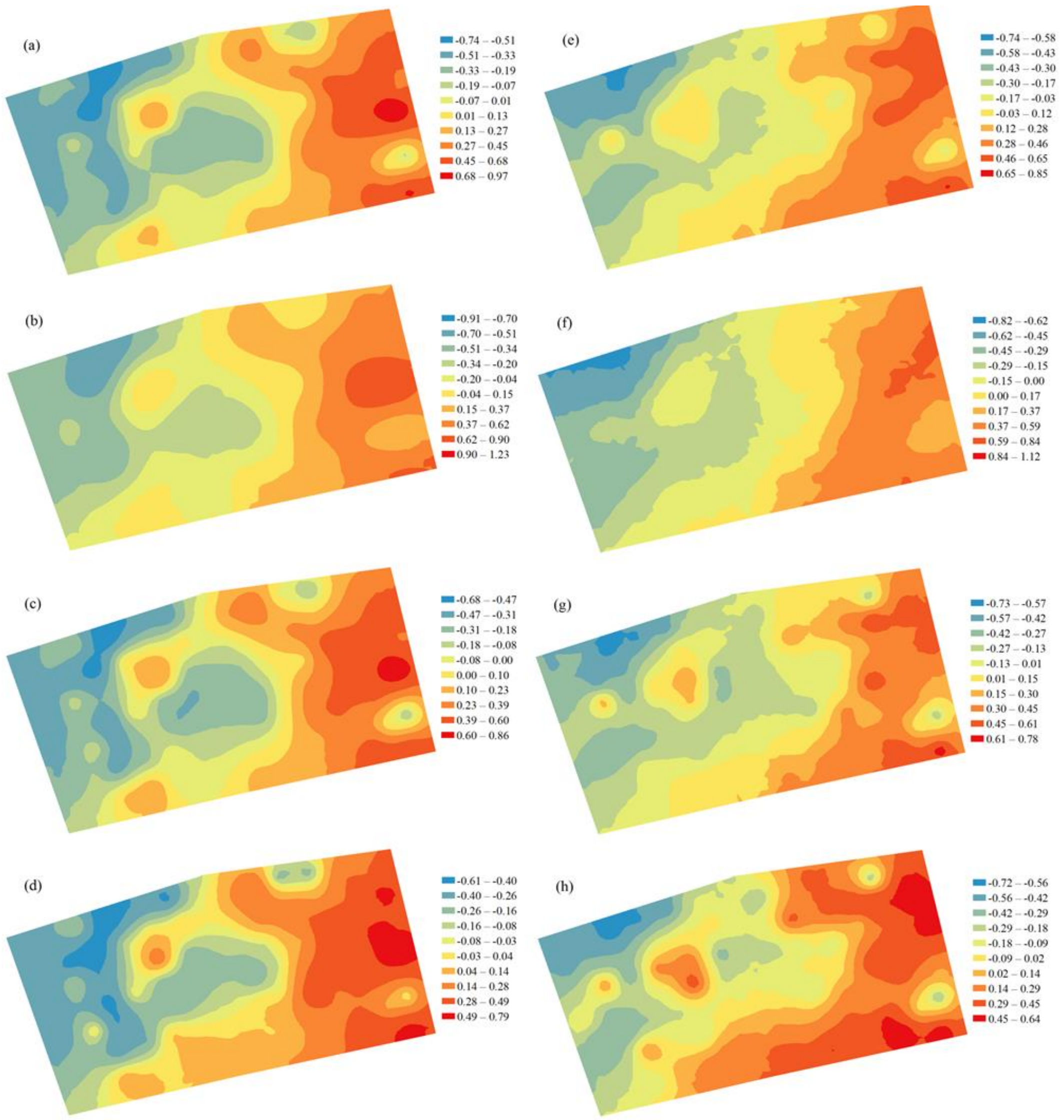

Figure 3. *Spatial distribution of mean relative difference at depths of 10 (a-d) and 30 cm (e-h) during the entire (a,e), dry (b,f), intermediate (c,g) and wet (d,h) periods*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45754593

The MRD values in the northwestern region of the study hillslope were generally lower, whereas the MRD values in the southeastern region were generally higher. Spatial patterns of MRD were similar to that of elevation (*Fig. 1*). This suggests that elevation had large influence on soil moisture variations, which is consistent with the results of stepwise regression (*Table 2*). In addition, the distributions of soil moisture presented a similar spatial pattern for each depth under different hillslope wetness conditions. Correlation matrix of MRD is shown in *Fig. 4*, including all possible combinations, even between different soil depths. Interestingly, all correlation coefficients were larger than 0.7, indicating the pronounced stability of soil moisture at two depths. Generally, lower values of correlation (but still fully above the statistical significance level, $p<0.01$) were associated to comparisons of MRD between two soil depths. In addition, for each depth, the correlation between MRD during wet period and MRD during dry period was weakest among all cases, indicating that soil moisture patterns during dry and wet periods were different to some extent.

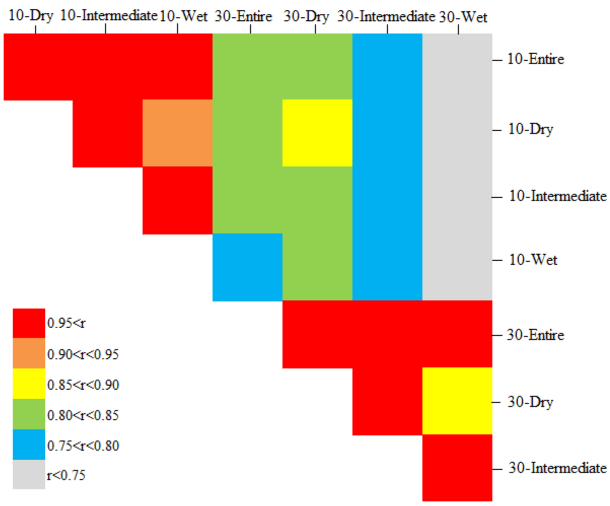

Figure 4. *Correlation matrix of mean relative differences under different hillslope wetness conditions at two depths*

Relationships between MRD and SDRD

During the entire period, MRD was positively significantly ($P<0.01$) correlated to SDRD for each depth (*Fig. 5*), which implies that the value of SDRD tended to be lower for the drier locations. This is consistent with the results of Martínez-Fernández and Ceballos (2003) and Hu et al. (2010). Correlation coefficients between MRD and SDRD at 10 cm depth during dry, intermediate and wet periods were 0.659 ($P<0.01$), 0.468 ($P<0.01$) and 0.320 ($P<0.01$) respectively, while these values at 30 cm depth during dry, intermediate and wet periods were 0.582 ($P<0.01$), 0.277 ($P<0.05$) and 0.231 ($P<0.05$), respectively. This indicates that the correlations between MRD and SDRD at each depth were in the order of dry > intermediate > wet conditions. Hillslope wetness conditions had substantial influence on temporal stability of soil moisture. This is different from the finding of Martínez-Fernández and Ceballos (2003) that the amount of rainfall was not seen to modify the patterns of temporal stability. In addition, stronger correlations were found at 10 cm depth than at 30 cm depth. This is probably due to stronger variability of soil moisture at 30 cm depth than that at 10 cm depth.

DOI: http://dx.doi.org/10.15666/aeer/1702_45754593

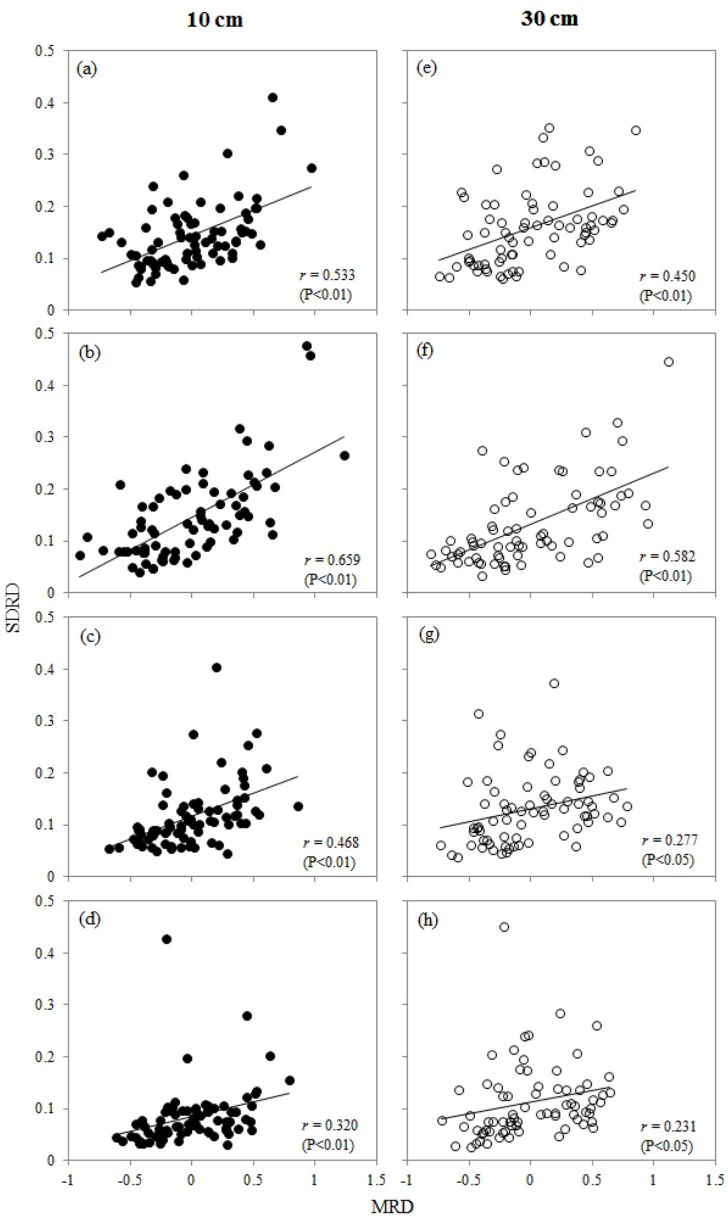

***Figure 5.** Relationships between mean relative difference and standard deviation of relative difference at depths of 10 (a-d) and 30 cm (e-h) during the entire (a,e), dry (b,f), intermediate (c,g) and wet (d,h) periods*

From *Fig. 6*, it can be seen that there is a significant difference (P<0.05) in hillslope mean SDRD at 10 cm depth between dry (0.145), intermediate (0.117) and wet (0.085) periods. For 30 cm depth, hillslope mean SDRD under wet condition (0.112) was significantly less than those under dry (0.133) and intermediate (0.131) conditions. As a result, soil moisture patterns were more stable during wet period than during dry period. This is consistent with most previous studies (Gómez-Plaza et al., 2000; Williams et al., 2009; Zhao et al., 2010; Penna et al., 2013). Conversely, the results by Martínez-Fernández and Ceballos (2003) and Lin (2006) reveal a constant higher degree of temporal stability during dry conditions. This suggests that relatively homogeneous soil properties favor the temporal persistence of soil moisture patterns in wet conditions.

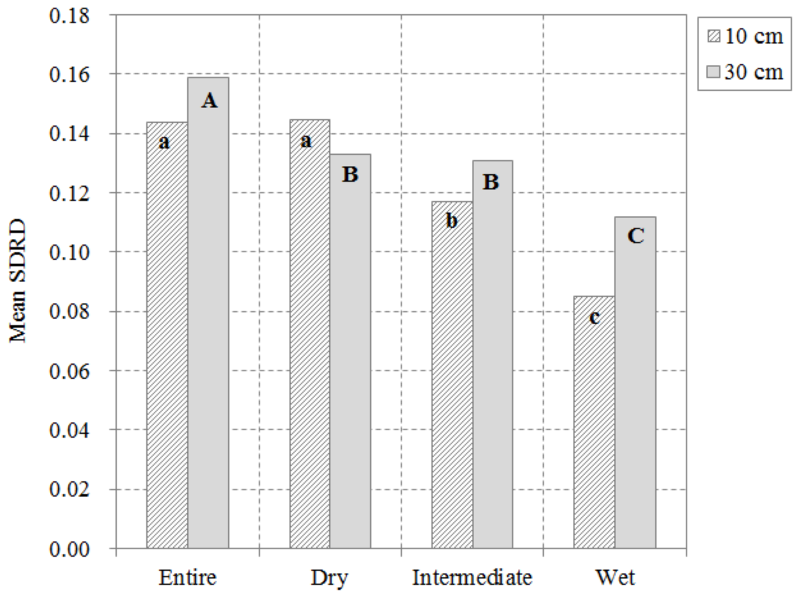

Figure 6. *Standard deviation of relative difference at different hillslope wetness conditions. The same lowercase and capital do not show significant difference at p<0.05*

Identification of representative locations

The rank ordered MRD and its associated SDRD, as well as locations with absolute MRD less than 5% and the driest and wettest 10 locations are shown in *Fig. 7*. Obviously, the rank of MRD varied with soil depth. This is consistent with previous studies (Starks et al., 2006; Hu et al., 2010). During the entire period, locations 4 and 9 can be representative of dry conditions at 10 cm depth, and locations 77 and 63 of wet conditions. In addition, the absolute MRD of locations 11, 10, 46, 59 22, 54, 12, 65, 53 and 34 were less than 5% at 10 cm depth. Among these 10 locations, the SDRD of location 22 was smallest. Therefore, location 22 can directly represent the hillslope mean soil moisture content at 10 cm depth. Likewise, location 60 can be representative of 30 cm depth. As can be seen in *Fig. 8*, there is a close linear regression between the measured moisture contents at the representative locations and the hillslope mean values (R^2=0.882 and root mean squared error (RMSE) =1.55% for 10 cm; R^2=0.729 and RMSE=2.62% for 30 cm). This indicates that locations 22 and 60 are appropriate for estimating hillslope mean soil moisture with an acceptable degree of accuracy at depths of 10 and 30 cm, respectively, regardless of the hillslope wetness conditions.

At 10 cm depth, locations 35, 22 and 22 can best represent the hillslope mean soil moisture content under dry, intermediate and wet conditions respectively, while locations 60, 60 and 19 can be representative of 30 cm depth under dry, intermediate and wet conditions respectively (*Fig. 7*). This implies that the presentative locations identified with the entire dataset are not always appropriate for estimating hillslope mean soil moisture under all wetness conditions. Therefore, location 22 was replaced by location 35 for predicting hillslope mean soil moisture content at 10 cm depth under dry period, while location 60 was replaced by location 19 at 30 cm depth under wet period. It is found that the accuracy of the linear regression was substantially improved after correction (R^2=0.926 and RMSE =1.28% for 10 cm; R^2=0.794 and RMSE =1.90% for 30 cm) (*Fig. 8*).

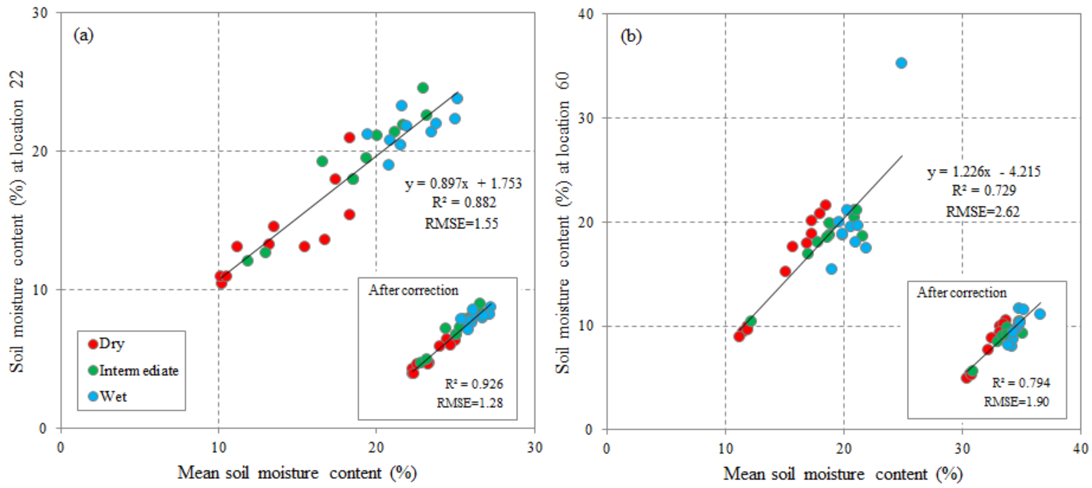

Figure 8. *Hillslope mean soil moisture content versus the representative point moisture content at the depths of 10 (a) and 30 cm (b). Results after correction (location 22 was replaced by location 35 for predicting hillslope mean soil moisture content at 10 cm depth under dry period, while location 60 was replaced by location 19 at 30 cm depth under wet period) are shown in the lower right corner of the figure*

Influencing factors of SDRD

At 10 cm depth, the SDRD was mainly influenced by PLC, slope and RF during the entire period, while at 30 cm depth it was affected by only elevation (*Table 5*). Negative coefficients for all variables were observed, indicating a significant (P<0.05) negative correlation between these variables and SDRD.

a: No sound stepwise regression model was found

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45754593

The R^2 values of stepwise regression models were 0.289 and 0.155 at 10 and 30 cm depths, respectively. This suggests that environmental factors can only explain 28.9% and 15.5% of variation in SDRD at depths of 10 and 30 cm depths, respectively, which is comparable to the finding of Hu et al. (2010). Topography explained more variability (18.8% for 10 cm and 15.5% for 30 cm) in SDRD than soil properties (10.1% for 10 cm and 0 for 30 cm). Therefore, topography had dominant control on soil moisture temporal stability on study hillslope. This is consistent with the study by Grayson and Western (1998) and Vivoni et al. (2008).

The R^2 of regression equations for SDRD at 10 cm depth were 0.370, 0.193 and 0.117 under dry, intermediate and wet periods, respectively. This indicates that environmental factors can explain the most variability (37.0%) in SDRD during the dry period. This may be attributed to the fact that the strongest correlation between MRD and SDRD was found during the dry period. Similarly, topography can explain the most variability (42.6%) in SDRD at 30 cm depth during the dry period. However, topography did not significantly affect the SDRD during the intermediate period. This may be attributed to the relatively weak correlation between MRD and SDRD at 30 cm depth during this period. Overall, hillslope wetness conditions can modify the effects of environmental factors on temporal stability.

Conclusions

Topography had larger influence on soil moisture content denoted as MRD than soil properties at each depth under different hillslope wetness conditions. The MRD of Soil moisture had a strong spatial dependence on study hillslope. However, soil moisture at 10 cm depth had stronger spatial structure than at 30 cm depth in terms of effective range. In addition, for each depth, the largest effective range was found during the dry period.

The value of SDRD tended to be lower for the drier locations. Correlations between MRD and SDRD at each depth were in the order of dry > intermediate > wet conditions. Therefore, hillslope wetness conditions had substantial influence on temporal stability of soil moisture. Soil moisture patterns were more stable during wet period than during dry period.

At 10 cm depth, location 35 can best represent the hillslope mean soil moisture under dry condition, while location 22 can be representative under intermediate and wet conditions. However, at 30 cm depth, location 60 can be representative under dry and intermediate conditions, while location 19 can be representative under wet condition. In addition, topography had dominant control on soil moisture temporal stability at each depth on study hillslope.

(Received 24th Jan 2019; accepted 8th Mar 2019)

Abstract. Forest covering 28.6% of Turkey is an important area of employment. In this study, the awareness of the employees of Erzurum Forest Nursery Directorate has been attempted to be investigated by applying the Law No. 6331 on occupational health and safety. In the study, a questionnaire consisting of 36 independent questions, 8 independent and 28 dependent variables were prepared. The data obtained from the questionnaires was evaluated in the SPSS 20.0 program, and frequency distributions were determined. In addition, Chiropractic Analysis was performed to see if there is a statistical relation between dependent and independent variables in the questionnaires. According to the results; the ratio of General Occupational Health and Safety Education is 82.3%. However, the percantage of those using Personel Protective Equipment was lower 70.5%. Nearly all of those who stated that they had health problems in the institution were married women over the age of 40. If these groups are generally considered to be physically active and do not have job descriptions, the measures to be taken are: To ensure that dangerous situations affecting the health of employees are identified and removed from the scene by means of the risk assessment team established in accordance with Law No. 6331 on occupational health and safety.
Keywords: *forest workers, nursery workers, Law No. 6331, occupational health and safety, personal protective equipment*

Introduction

Providing legal protection to all employees to protect their rights that arise from work life is a requirement of the principle of social law state (Kılıç, 2006). Forestry employees working in forestry sector have been deprived of the legal protection that is normally provided by the Labor Law for many years.

Although partly, forestry employees have been included in the Turkish Labor Law for the first time with the Law 4773, which is also known as the Law on Job Security. However, since emerging new concepts that have appeared with the international commitments of Turkey and since the Law 1475 remained insufficient in covering today's needs in work life, the Law 4857, which was enacted in 2003, has taken its place as the basic law of labor legislation. The Law 4857 expanded the scope of Law 1475 by significantly changing it, and now it is a modern Labor Law with new principles and amendments it brought.

With some limitations, forestry employees were also included in Labor Law 4857 and in the regulations issued in accordance with this Law. Although there are limitations, it must be considered as an important step taken in this area for the legal protection of forestry employees (Engür, 2014).

In forestry sector, compared to other sectors, because of the fact that seasonal employment is excessive and employment status is temporary, many problems

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45954606

preventing the establishment and management of an insurance system have become inevitable; and the social security of the employees in this sector has not been established completely. This situation has been an obstacle for the necessary care to be taken for the implementation of relevant measures in terms of occupational accidents and diseases (Tunay and Emir, 2015).

The occupational health and safety issue constitute a very important aspect of today's business life and labor law. Occupational health and safety measures intend to ensure that occupational accidents and diseases do not occur or are reduced to an acceptable level.

The most important factor making businesses successful or unsuccessful is the human factor. Based on this understanding, an increasing interest has emerged in the psychological and physical conditions of employees and their behaviors related to their jobs. People spend most of their time at work; and the productivity increases as much as they can be happy at work. For this reason, the importance of the occupational health and safety concept is increasing with each passing day (Zorlu, 2008).

Parallel to the industrialization of countries, the problem of ensuring that employees work in health and safety has emerged as one of the most important problems that need to be solved. The concern for not making employees pay for the cost of industrialization and technological developments that are benefited by all people in the society constitutes one of the main aims of contemporary societies (Ekin, 2009).

The purposes of the studies conducted on occupational health and safety may be listed as follows;

- Protecting Employees.
- Contributing to Create Safe Working Environments.
- Ensuring the Productivity of Working is Achieved.
- Providing Opportunities for Employees to Sustain Their Work Lives (Bayılmış, 2013).

For this reason, investments made on the measures intended to ensure occupational health and safety will help to protect the health and safety of employees, avoid occupational risks, eliminate the risk and accident factors, and improve the health and safety conditions continuously at workplaces (Oğuz, 2010).

It is a fact that occupational health and safety measures can only become effective with joint understanding of employees, employers and the state. However, when forestry sector is compared with other sectors, it is clear that this triple mechanism has not gone beyond creating awareness. This situation stems from the different characteristics of forestry business in terms of work life, and prevents the implementation of the provisions of the Law on Occupational Health and Safety in this field (Tunay and Emir, 2015).

According to Poschen (1993), ILO defined forestry activities as "3-D" profession, in other words, a dirty, difficult, and dangerous work (Menemencioğlu, 2006). When this is considered, it becomes compulsory for forest employees to be careful, practical, intelligent, think in a sophisticated manner, be healthy, endure with effective body structure, have appropriate equipment at work, love the nature and walking, and be responsible people (Acar and Şentürk, 1997).

In this study, the purpose was to evaluate the effect of Occupational Health and Safety Law 6331 on forest employees who work under difficult conditions. For this reason, Erzurum Forest Tree-nursery Directorate was chosen as the Study Area; and the effects of the Occupational Health and Safety law on the awareness levels of the nursery employees were examined.

Material and Method

The case study area

The material of the study consisted of 102 nursery personnel who worked at the 4 Forest Nurseries in Erzurum Forest Nursery Directorate, and Questionnaire forms that consisted of 36 questions. In addition, previous studies in the literature that were conducted in this field and the records of Erzurum forest nursery directorate were also made use of.

Erzurum Regional Directorate of Forestry of which the Erzurum Forestry Nursery Directorate is the sub-unit, and which is selected as the Study Area, covered the cities of Erzurum, Erzincan, Kars, Ardahan, Iğdır and Ağrı consisting of 10 forest management directorates of Erzurum, Oltu, Şenkaya, Erzincan, Refahiye, Kars, Sarıkamış, Ardahan, Iğdır and Ağrı. Nearly 2.6% of Turkey’s population lives in this region (TUİK, 2018). Acording to General Directorate of Forestry (GDF) records, the total area of the region is 8.849.193 ha, about 5% of which forested (GDF, 2018).

In the study area, the high amount of the area that is the subject to forestation is noteworthy. In the area, 5000 ha forestation and 8000 ha erosion control works are performed. These activities constitute the most important forestry activity of the area. To cover the need of seedlings that are used in the forestation and erosion control works in the area, there are 4 nursery engineering units (Sarıkamış, Ağrı, Erzincan and Erzurum), with their headquarters in Erzurum with a capacity of 20 million seedlings a year. A total of 102 employees work in these units.

Sampling method

The data obtained from the face-to-face questionnaires that were carried out with 102 employees in the nurseries, which were included in the study, were converted into a matrix in computer medium. This matrix was made by encoding the answers that were given to each question in numbers. The matrix that was generated from the encoding was analyzed in the SPSS 20.0 Program; and the frequency distributions were determined. As the data did not show normal distribution, the Chi Square (χ^2) Analysis was made to determine whether there were statistically significant relations between the dependent and independent variables in the questionnaires. The analyzes were carried out by employing the SPSS 20.0 Program.

Results

Erzurum Forestry Directorate has nursery engineering units in Erzurum, Erzincan, Erzincan, Ağrı and Sarıkamış. As it may be understood in the data given in *Table 1* below, the number of people who participated in the questionnaire was 102. It was understood that there were no employees in Ağrı Engineering Unit. It was also understood that many of the employees (66%) were employed in Erzurum Nursery Engineering Unit.

It was understood in the analyses of the questionnaires that a total of 9.8% of the nursery employees were female; and 90.2% were male. In addition, it was also determined that 6.9% of the employees were literate, 26.5% were primary school graduates, 45.1% of were secondary education graduates, 21.6% had undergraduate and post-graduate education levels. When the ages of the nursery employees were examined, it was determined that the highest rate was 39.2% in the 41-50 age group.

	Driver	20	5	1	-	**27**
	Office worker	15	4	2	-	**30**

The fact that the rate of the participants saying "Yes" to the question "Is OHS training necessary?" at a rate of 95% clearly shows that these trainings are necessary for the employees (*Table 2*). All women believe that training is necessary. When the physical conditions of the workplace and the OHS culture of the employees were compared before and after the enacted law, it is possible to claim that the OHS culture improved at a significant level.

The nursery employees who thought that the trainings on the OHS Law 6331 was necessary believe that it would be adequate if these trainings were organized once a year at a rate of 20.6%; and 6.9% believed that there is no need for these trainings; 69.6% believed that these trainings should be organized every 6 months; 2.0% believed that these trainings should be organized every 3 years; and 1% believed that these trainings should be organized every 5 years. Such trainings should be organized in each month of the year; and the OHS issue should be kept active on the agenda of employees. It is considered that in this way, a contribution will be made to the development of OHS culture; and the demands of the employees will be covered.

Nursery employees were asked whether the OHS trainings they participated in covered the nursery issues or general OHS issues; and the employees stated that the issues were on nursery issues at a rate of 32.4%. In this context, 15.7% stated that the issues were on general forestry issues; 39.2% stated that the issues were on basic OHS issues; and 12.7% answered as "None" to this question. The distribution of the answers in this context shows that the employees have demands on the work they do, which is also a sign that they care about this issue.

After the Law No. 6331 on Occupational Health and Safety was enacted, and after the trainings, the employees were asked "Have you experienced any changes in your work life?". The answer to this question was "Yes" at a rate of 80%. A total of those

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45954606

who said "Yes" to this question said "Our working environment became safer" at a rate of 21.6%; 19.6% of the participants said "We were given more care by our employers"; 17.6% said "Our work started to be more regular and systematic"; and 17.6% said "We started to use personal protective equipment". The fact that there were very positive answers at a rate of 80%to the questionnaire shows that positive and valuable feedbacks are received about the law. Here, we see that male employees said "Yes" at a higher percentage than female employees.

Table 2. *Occupational health and safety knowledge level of forest nursery workers*

	Yes		**No**		**Total**	
	Female	**Male**	**Female**	**Male**	**Yes**	**No**
Do you have a written job description with clear and defined boundaries?	2	51	8	41	**53**	**49**
Is your opinion applied in the arrangements regarding the working place and working conditions?	2	52	8	40	**54**	**48**
Are adequate security measures taken?	5	76	5	14	**81**	**19**
Do you participate in studies outside the nursery?	2	10	8	82	**12**	**90**
Do you have a transport limit during operation?	1	40	9	52	**41**	**61**
Do you take personal protective measures when working with substances that threaten human health?	2	12	8	80	**14**	**88**
Do you think that the way you transport and store the chemical substances you use is done in accordance with the occupational safety rules?	1	24	9	68	**25**	**77**
Have the necessary training been given to transport, storage and use of chemicals?	2	28	8	64	**30**	**72**
Do you have any health problems that you think arises from nursery work?	8	13	2	79	**21**	**81**
Do you have any currently diagnosed chronic diseases?	7	9	3	77	**16**	**86**
Are personal protective equipment suitable for your work?	4	56	6	36	**60**	**42**
Do you use the personal protective equipment that you use to maintain and maintain the work properly?	2	80	8	12	**82**	**20**
Did you experience any occupational accidents or diseases after you entered work?	2	23	8	69	**25**	**77**
Have you received basic training in Occupational Health and Safety?	10	8	-	84	**18**	**84**
Do you think OHS trainings are necessary?	10	85	-	7	**95**	**7**
Have you been informed about how to safely and correctly use equipment equipment in the nursery in OHS trainings?	10	77	-	15	**87**	**15**
Is training on effective use of personal protective equipment provided?	10	62	-	30	**72**	**30**
After the entry into force of the Occupational Health and Safety Law No. 6331, and after the trainings, have you experienced any changes in your working life?	6	74	4	18	**80**	**22**
Do you think there is a decrease in the number of occupational accidents and occupational diseases in the nursery after the entry into force of the Occupational Health and Safety Law No. 6331?	10	80	-	12	**90**	**12**

The relation between gender, workplace and working conditions

In the answers that were given to the question “Is your opinion asked about the regulations about your work place and working conditions?”, it was examined whether there were statistically significant differences between the genders (female/male); and it was determined that there were significant differences (*Table 3*). According to this result, there is a statistically significant relation between working conditions and gender variable.

Table 3. *Relationship between gender and workplace and working conditions*

Workplace and Conditions	Gender			
	Female		Male	
	Number of people	%	Number of people	%
Yes	2	20.0	52	56.5
No	8	80.0	40	43.5
Total	10	100.0	92	100.0

Chi Square =13.812; sd 2; 0.01<0.05

The relation between the work done de facto and security measures

The employees were asked “Are adequate security measures taken at the unit where you work?”. It was examined whether there were statistically significant differences between the work done *de facto* (body employees, fertilization, drug-spraying employees, packaging and sales employee, drivers and office employees) in the answers given to this question, and significant differences were detected as a result of the analyses (*Table 4*). A statistically significant relation was detected between the dependent variable “Are adequate safety measures taken at the unit where you work?” and the independent variable “the work done *de facto*”.

Table 4. *The relation between work done de facto and security measures*

was under the title of "the health conditions of the employees", a statistically significant relation was detected between this dependent variable and the independent variable (the work done *de facto*).

Table 5. *The relation between work done de facto and health problems*

The relation between the educational status and OHS basic trainings

It was examined in the answers given to the question whether there was a statistically significant difference between the educational status (literate, elementary, secondary, faculty and postgraduate or doctorate level) and it was found that there was a significant difference in the answers given to the question "Have you received basic training on occupational health and safety?" (*Table 6*). A statistically significant relation was detected between the dependent variable "Have you received OHS Basic Training?", which is under the title "Evaluation of Existing OHS Trainings", and the independent variable "educational status", which is under the "general information about employees" heading.

Table 6. *The relationship between educational status and OHS basic trainings*

Discussion

According to the study results, it was observed that the Nursery Directorate did not employ women over 40 years of age who had relatively low educational levels at jobs that required muscle strength; and instead, women were generally employed in more physical works like removing weeds or hoeing preferably in the nursery field, which do not relatively require training and qualifications to increase their productivity. In addition, the fact that there were no job definitions for women is considered as a condition that needs correction by the nursery directorate.

It was observed that single employees who were under the age of 40 and who had low education levels were preferably employed in physical works outside the nursery. In addition, it was also determined as a negative situation in terms of work efficiency and safety that married women who were older than 40 years of age and who had low

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45954606

educational levels thought that they could not rest with regular intervals. Here, it may be understood that the provisions stated in the labor legislation and the current Collective Labor Agreement (CLA) are not covered in the workplace. When the working years of these groups were examined, it was observed that many of them had been doing the same work at the same workplace for more than 15 years.

It was also observed that since the drivers and office employees worked in closer positions to the management staff, their job descriptions were made in general. It is considered that since the drivers and office employees share the same medium with the administrators, and as they are close and necessary for the job they do, they read and understand the business legislation and CLA, their job descriptions are made, and they are given more place in the management and in the organization. It is also considered that they are more satisfied with their jobs because of their proximity to decision-makers and due to the more comfortable working environment compared with other groups. Unfortunately, this comfort is relatively seen in the work environment where employees work with their physical strengths. This situation is the opposite in employees who work in the field, and creates dissatisfaction. To eliminate this, more trainings, seminars and information meetings must be held. In addition, the work done by employees must be defined, in other words, the work must not be in an open-ended structure.

When the health status of the employees working at the nursery was examined, it was considered that women face more health problems compared to men, which is considered to be due to the fact that they work in more bodily works. It is necessary that women employees are made to use the personal protective equipment that is provided to them and their working conditions are improved.

When the surgery status of the employees was considered, it was seen that the employees who had higher education levels had more surgeries. It is considered that employees who had high education levels took both reactive and proactive measures and treatments, and those who had low education levels might not have reached the adequate level in terms of awareness in this respect.

It was noteworthy that female employees who were above the age of 40 stated that they were dissatisfied with the suitability of their KKDs to the work, and that they had very low occupational accident rates; however, they had health problems. Although their work involves bodily work, it is possible that they have occupational diseases rather than occupational accidents. They might especially have diseases like muscle and joint disorders. In addition to this, the employees who had primary and secondary education levels also considered that the KKD that was provided to them was inappropriate. It is considered that this group has a relatively higher rates in terms of work accidents. The high risk of occupational accidents in this group might be associated with the fact that they do work that require physical strength. The groups that have high work accident rates may be listed as follows; the male employees who had been working at Erzurum and Sarıkamış nurseries for more than 15 years. Many of these employees work with physical strength.

According to the mandatory provision of the OHS Law 6331, it is compulsory to provide employees with basic OHS trainings in accordance with the danger class of their works; however, the rate of those who declared that they were not provided with any trainings in the institution was 17.6%. It was determined in the files that the training programs were organized previously. It was seen that those who were married and who

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45954606

were over 40 years of age complained more about the inadequacy of training on tools, equipment and correct use of KKD.

The entire master and doctorate education groups and most of the faculty group said "Yes" to the question on whether the basic trainings of OHS were received. The highest rate of those who said "No" is secondary education and literate group. The rate of saying "No" in secondary education is 50%. It was seen in the distribution of the training subjects that the employees made evaluations on the general OHS and the work they did. This demand complies with the legislation. In the answers that were given to the question about the correct use of tools, equipment and KKD, it was seen that as the education level increased, the satisfaction also increased. In general, the employees who were elderly, women, married and had low education levels were dissatisfied with this issue.

The office employees and drivers of Erzurum Forest Nursery Directorate face dangerous situations less in terms of working environments than physical workers. Here, the group that must be examined is the body workers. The dangerous situations body workers face in the work environment are more than the other groups. For example, the risk levels of a person who works in pruning and the risk level of a person who works at a desk in an office are different. For this reason, the fact that a significant relation was detected between the work done *de facto* and the safety measures in the Chi-Square Test, which shows that this issue should be paid attention. The answer that was given by the employees to the question "Are adequate security measures taken in the unit where you work?" comes to the forefront in this respect. The rate of the employees who did body works and who said "No" was 66.7% among the employees that said "No". This rate is very high compared to the 20.6% rate in the overall average.

The relation between the work done and health problems was examined, and a statistically significant relation was detected. In this respect, 79.4% of the employees said "No" to the question "Do you have any health problems that you think stem from nursery work?"; and 20.6% said "Yes". Here, 20.6% of 84.6% who said "Yes" were physically employed. The high rates of the employees who did body works and who said "Yes" to the question "Do you have any health problems that you think stem from nursery work?" means that this is a negative situation that is worth to investigate. This is a very important finding for determining and following-up the occupational diseases at workplaces by doctors who work in these workplaces.

The relation between educational status and OHS basic education was examined; and a statistically significant relation was determined. In this respect, it was determined that 82.4% of the participants said "Yes" to the question "Have you received basic education on occupational health and safety?", and 17.6 said "No". Here, the entire postgraduate and doctorate groups and most of the faculty groups said "Yes". The highest rate in the respondents is in the secondary education and literate group. The rate of those who said "No" at secondary education level was 50%. It is considered that the reason may be that the employees who were from secondary education level and who were literate were preferred in jobs other than nursery; and that there were employees who were off duty on the given date caused this situation. Organizing the training programs in a planned and announced manner can reduce this rate. One of the main mandatory provisions of the OHS Law 6331 is to provide OHS basic training in hours and periods that are proper for the danger class of all employees without considering the danger class.

As a result of the present study, it was determined that approximately half of the employees did not have job descriptions. This situation poses a contrary situation to the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45954606

labor legislation and CLS in the workplace. It is a legal liability that administrations make the job descriptions of all employees as soon as possible, and make a notification to relevant employees concerned.

It was observed that those who had worked for more than 15 years had more health problems compared to those who had worked less. It is considered that this is because of the fact that employees face more health problems with their furthering age. It is stated in the relevant article of the CLS that is in force that those who work bodily for more than 15 years must be employed in lighter jobs. In case this is applied, it is considered that such employees will be less affected by health problems.

It may be seen more probable that nursery employees experience occupational diseases rather than occupational accidents. They may especially face disorders like muscular joint disorders. It is possible to reduce these diseases to acceptable levels with relevant preventive measures. The measures that will be taken must be determined by a risk assessment report that will be prepared by a commission that will be formed by employers or their representatives. For example, ergonomics trainings may be provided to employees for the solution of this issue. Mechanical and automatic systems may be established to improve thermal comfort conditions. Suitable personal protective equipment may be provided to employees in this context. Such measures may be diversified and multiplied by the abovementioned commission. In addition, it is considered that the KKDs of the employees at the primary and secondary level are unsuitable; and that the rate of occupational accidents will be higher for this group. This situation may be associated with the fact that such employees work in jobs that require body strength, which constitutes the risk of occupational accidents. Again, it may be possible to decrease the risk to an acceptable level with preventive measures in this respect. Dangerous situations faced by employees included in this category must be eliminated with priority. If such situations cannot be eliminated, the source of the danger must be eliminated. Here, engineering and managerial methods must be used. And finally, employees must be made to use appropriate KKD.

In the forestry sector, it is extremely important that legal arrangements are made to ensure that occupational health and safety services are performed in a conscious manner, and that relevant regulations that will cover all the regulations and working conditions are issued and implemented (Tunay and Emir, 2015).

It is considered that the fact that the rate of those who considered that the OHS trainings had positive contributions in the work life and that the rate of those who thought that work accidents and occupational diseases decreased after the implementation of Law 6331 was determined to be 88.2% shows that the implementations of the law was perceived well by employees and had a good impact on their conscious levels.

Conclusion

The aim of the present study was to evaluate the effects of Occupational Health and Safety Law (OHS) on forest nursery workers in Erzurum Forest Nursery Directorate. OHS is aimed to permanently improve the health and safety of workers. This matter is supported by the state with national strategy and policies.

Participation of workers to OHS administration (OHSA) was included in many OHSA standards and guidance. OHSA models should emphasize the active participation of workers as a critical factor to improve OHS performance (Walter and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_45954606

Frick, 2000). Empowering of workers and giving them feeling of autonomy and control are the important factors in terms of OHSA success (Hale and Hovden, 1998). Nevertheless, properly training and informing of the workers, and giving them a chance to investigate the problems and communicate with each other’s to provide active participation is necessary.

The study showed that the workers in forest nursery directorate had enough knowledge about OHS and OHS applications were properly conducted based on laws. The use of personal protective equipment and periodical training of the workers are also in important matters regarding OHS. Raising the awareness of workers with regard to OHS culture, precautions improving their safety and health, and encouraging workers to communicate with administrators regarding OHS problems and risks which they observe and encounter are suggested. All demands from workers should be evaluated and taken due precautions.

As a result, it should be concentrated on training and educations regarding OHS to get better results and provide the workers a better environment not adversely affect their physical and mental health.

Abstract. *Trichoderma* species are used as biological control agents against plant pathogenic fungi. In addition, some isolates of *Trichoderm*a species produce metabolites that promote plant growth. In this study, it was aimed to determine the effect of local isolates of *Trichoderma* sp. and a commercial microbial fertilizer containing *Trichoderma harzianum* on the growth of barley. The experiment was carried out according to the randomized plots experimental design. Barley seeds were inoculated with spore solutions of local isolates and then compared with controls (without inoculation and commercial fertilizer). Plant height, root length, root dry weight, shoot dry weight and chlorophyll content were determined. The effects of isolates were different. In this study, plant height was increased with the application of local isolates. The difference between isolates was statistically significant. Isolates were determined to have positive effects on barley growth.
Keywords: *Trichoderma sp., plant growth promoting, barley, biostimulant, photosynthetic pigment*

Introduction

One of the alternatives used in fertilization programs in environmentally friendly production techniques is microbial fertilization. Microbial fertilizers are defined as commercial formulations of live microorganisms which are involved in the removal of plant nutrients necessary for the plant used in agricultural production (Akladious and Abbas, 2014). Microbial fertilizers are used in agriculture for many purposes, such as increasing plant growth, yield, and nutrient intake, controlling soil-borne diseases, decomposing organic residues, improving soil structure and productivity and providing resistance to diseases and pests (de Santiago et al., 2011; Ousley et al., 1993). This strengthening effect in plants can also lead to a decrease in the use of pesticides and fertilizers. In many developed and developing countries, intensive studies have been carried out to obtain biological or microbial fertilizer formulations considering clean environment and healthy crop production (Kucharski et al., 1996; Vessey, 2003). Microorganisms such as *Bacillus* spp., *Azotobacter* spp., *Trichoderma* spp., *Rhizobium* spp., *Azospirillum* spp. and *Saccharomyces* spp. are used as microbial fertilizers (Sharma et al., 2003; Vazquez et al., 2000).

Trichoderma is a soil fungus found in many parts of the world (Hoyos-Carvajal et al., 2009). *Trichoderma* spp. are the most studied microorganisms which are used as microbial fertilizers and biological control agents against fungal pathogens (Hoyos-Carvajal et al., 2009).

In addition to its ability to promote plant growth, *Trichoderma* spp. isolates have been used for many years in the biological control of many fungal induced plant diseases (Woo et al., 2006). It is known that *Trichoderma* spp., which is colonized in the root, stimulates

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46074614

resistance to plant diseases as well as it promotes shoot and root growth, increases yield, resistance to abiotic stress conditions, promotes nutrient intake and use and increases photosynthesis (Inbar et al., 1994; Yedidia et al., 2001; Harman et al., 2004; Harman, 2006).

Datnoff and Pernezny (2001) reported that *Trichoderma* spp. preparates were increased the growth of tomato seedlings in greenhouse and field conditions. In recent years the use of microorganisms that promote plant growth has increased. Therefore, studies are carried out to reduce environmental pollution by reducing the use of chemical fertilizers (Kucharski et al., 1996; Hermosa et al., 2012). Some *Trichoderma* isolates stimulated the plant against abiotic and biotic factors, increased the germination rate and percentage of the seeds, the fertility of the fertilizers, the nutrient intake from the soil and directly affected the plants (Shoresh ve ark., 2010).

de Santiago et al. (2011) and Zhang et al. (2013) were reported that the application of *Trichoderma* species in various plants were increased the root growth of the plants, yield, leaf area, the weight of fresh seedlings. Dissolution of insoluble minerals for plant growth (Altomare, 1999; Küçük et al., 2008; Rawat et al., 2011), indole acetic acid, siderophore, 1-aminocyclopropane-1-carboxylic acid (ACC) deaminase production (Viterbo et al., 2010) as effective factors in plant growth were studied.

It is known that nitrogenous fertilizers accumulate in agriculture crops which increase nitrate ratio in drinking and irrigation waters and adversely affect human and animal health (Bashan, 1998; Rennie and Heffer, 2003). The use of microorganisms in agriculture has been gaining importance in recent years in order to eliminate these problems and to reduce the use of chemical fertilizers. Barley has an important in the agriculture of Turkey and has an important role in the reduction of fallow land (Karakaya et al., 2016).

The cultivation and production of barley is done in all regions of Turkey. While most of the barley produced in Turkey is used in feed industry, some are used directly in animal feed and some in beer industry. Since barley is mostly used as animal feed, the seeds are inoculated with microorganisms in order to increase the protein content in barley (Karakaya et al., 2016). In this study was carried out in greenhouse conditions to investigate the effects of three different *Trichoderma* sp. isolates and commercial microbial fertilizer containing *T. harzianum* applied to seed on the growth of barley plant.

Materials and methods

The local isolates (T4, T7 and T11 isolates) of *Trichoderma* sp., were obtained from the Microbiology laboratory of Harran University. The isolates (*Fig. 1*) were stored in Potato Dextrose Agar (PDA) media and stocked at +4 °C until use. *Trichoderma harzianum* Rifaii KRL-AG2 was used as a commercial microbial fertilizer. Commercial microbial fertilizer was received from Biyoglobal A. Ş., Turkey.

The effect of isolates on plant growth

Barley (*Hordeum vulgare* L.) seeds were immersed in 70% ethanol for 3 minutes, 2% NaOCl for 2 minutes and washed several times with sterile distilled water. *Trichoderma* sp. isolates were incubated in PDA containing petri dishes for 7 days at 25 °C. Spore solutions of isolates (10^6 cfu/ml) were then prepared. Sterilized seeds were incubated for 3 hours in spore solution and sown in sterile soil. Soils were taken from Osmanbey Campus Harran University, Turkey where no adaptation was made before. The soil

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46074614

samples were sterilized in autoclave for consecutive three days. Steriled soils were filled in 2 kg pots. The diamonium phosphate fertilizer (10 kg/da) was given to the soil. Plants were grown in natural light greenhouse for 1 month. Akhisar varieties were used as barley varieties. The seeds were obtained from GAP Research Institute.

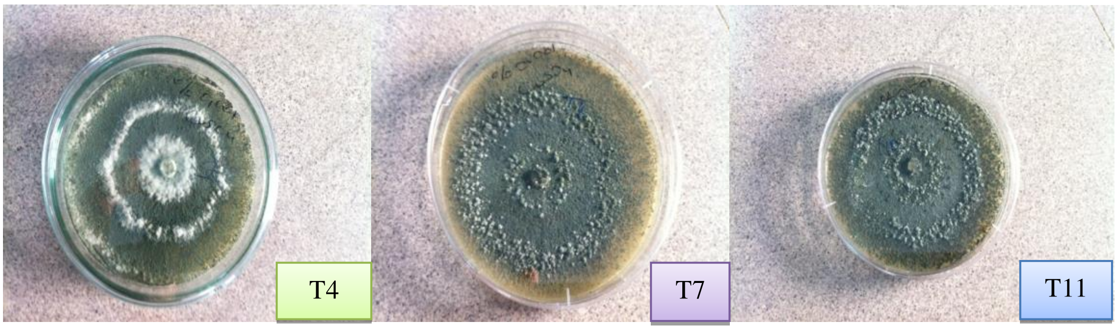

Figure 1. *Trichoderma sp. isolates used in the study*

In each pot, plant height, shoot dry weight, root dry weight and root lenght were determined. The photosynthetic pigments extracted from the leaves (chlorophyll a, b, carotenoid) were made according to Akladious and Abbas (2014).

The soil pH was determined by pH meter in a 1: 2.5 soil mixture. The organic matter content of the soil was made according to the method determined by Walkley (1964). The distribution of soil particles was determined by the Bouyoucours hydrometer (Bouyoucos, 1951) and the total nitrogen content was determined by the Kjeldahl method (Bremner, 1982).

Indole acetic acid (IAA) production of isolates

Spore solutions of *Trichoderma* isolates (10^6 conidia / ml) were prepared. Spore solutions (0.1 ml) were inoculated onto the agar surface and coated with a nitrocellulose membrane, petri dishes were incubated at 25 °C for 7 days. Then, the membrane disc was removed, the filter paper (Whatman no 2) saturated with the salkowski reagent was placed. After 5-10 minutes, IAA production by isolates was determined by color change (Hoyos-Carvajal et al., 2009).

Solubility of phosphorus

The isolates were inoculated into the medium containing 0.1 g/l bromocresol purple using tribasic calcium phosphate as the phosphorus source. 48 hours after incubation, the color of the medium from purple to yellow showed that the isolates can dissolve the phosphate (Vazquez et al., 2000).

Statistical analysis

The data obtained from the study were analyzed in JMP 11 statistics program.

Results and discussion

In this study, the effect of three isolates of *Trichoderma* sp. on the growth of barley and some plant growth-promoting metabolites were investigated. Phosphate solubility

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46074614

and indole acetic acid production as a metabolite were evaluated. Phosphorus is a very hard to reach nutrient. Its low amount adversely affects plant growth (Raghothama, 1999). All of our isolates were able to dissolve phosphorus.

Siderophores are iron chelating ligands which may be useful to plants by increasing the solubility of ferric iron (Fe III) not present for plant nutrition. This element is assimilated by stem cells in reduced form (Fe II). Fe III is dominant especially in the aerated soils. *Trichoderma* may reduce Fe (III) by chelators such as siderophores (Altamore et al., 1999; Jalal et al., 1987; Zhao and Zhang, 2015). Jalal et al. (1987) reported that *T. virens* produced hydroxamate siderophore as a Fe III chelating mechanism. According to these researchers, *Trichoderma* sp. transformation into solvable forms by chelation and reduction. Both mechanisms play a role in the stimulation of growth and biocontrols of plant pathogens (Qi et al., 2012; Vessey, 2003; Woo et al., 2006). Siderophores can support rhizosphere colonization and plant growth in synergy with other substances and are the effective mechanism of some microorganisms to increase plant growth (Sharma et al., 2003).

Production of plant growth hormones is another mechanism that increases the growth of plants. The tested isolates produced auxin hormone, which increased plant growth. It has been reported that *Trichoderma* isolates synthesize auxin hormones in their interaction with both plant pathogens and plants (Hermosa et al., 2012; Shayakhmetov, 2001). In this study, it was determined that isolates produced indole acetic acid.

In pot experiment, the pH of the soil used is 7.8. The clay ratio is 53.12%, silt ratio is 24% and sand ratio is 22.8%. The organic matter content of the soil is 1.71%, total nitrogen is 0.18% and K_2O content is 97.2 kg/da. The effects of *Trichoderma* applications on barley plants are given in *Table 1*. When *Table 1* is examined, the effects of *Trichoderma* applications differed. It was determined that the applications increased the plant height statistically ($p < 0.05$).

Table 1. *Effects on barley shoot and root dry weight, root lenght, plant height of treatments*

Treatment	Plant height (cm)	Shoot dry weight (g/plant)	Root dry weight (g/plant)	Root lenght (cm)
T4	18.3a	14.6b	2.66a	15.5a
T7	16.7ab	13.9bc	2.78a	14ab
T11	16.3ab	16.4a	2.05ab	13.1b
Commercial fertilizer	16.2ab	12.5c	2.69a	10.8c
control	14.7b	10.6d	1.33b	10.3c

Trichoderma sp. T4 application was the longest plant height (18.3 cm) cm, followed by T7 and T11 isolates respectively (*Fig. 2*). The shortest plant height was obtained from untreated control application (14.7 cm). The effect of *Trichoderma* applications on root length in barley plants was statistically significant ($p < 0.01$). The highest root length was taken from T4 application. The effects of isolates on barley shoot and root dry weight were different. The highest shoot dry weight was obtained from T11 application. All of the applications increased root weight relative to control (*Table 1*). *Trichoderma* isolates were found to be effective on chlorophyll content in barley plants ($p < 0.01$) (*Table 2*). A significant increase in plant growth of cucumber plants inoculated with *Trichoderma harzianum* was determined (Yedidia et al., 2001).

Compared to control, *Trichoderma* sp. isolates increased plant height by 24.4% (T4), 13.6% (T7) 10.8% (T11 and commercial preparation). These results are consistent with the studies of the researchers (Hoyos-Carvajal et al., 2009; Kaveh et al., 2011; Ousley et al., 1993). In plants inoculated with *Trichoderma* sp., the amount of root were increased (Ousley et al., 1993). Therefore plants receive more water and nutrients. In this study the applications with *Trichoderma* sp. were increased the root length of plant between 5.8 and 50.4%. Datnofff and Pernezy (2001) explained that *Trichoderma* sp. increased the growth of tomato seedlings. In this study the the applications with *Trichoderma* sp. isolates were increased the root weight increased between 52 and 109% (*Table 1*). The contents of photosynthetic pigment were increased in plants treated with *Trichoderma* sp. isolates (*Table 2*). The results are similar to those of the investigators (Ousley et al., 1993).

DOI: http://dx.doi.org/10.15666/aeer/1702_46074614

Trichoderma isolates transformed minerals such as phosphorus, manganese, and copper iron into the soluble form (Altomare et al., 1999). Thus, roots can easily get the nutrients they need from the soil and the plant growth rate has increased (Küçük et al., 2008; Altomare et al., 1999). Yedidia et al. (2001) reported that *T. harizanum* applied cucumber; increased the 90% of phosphorus intake and 30% increase in iron intake iron intake.

Conclusion

In this study, the effect of *Trichoderma* sp. isolates and commercially available *Trichoderma harzianum* on barley growth was evaluated. As a result; the establishment of the *Trichoderma*-plant interaction can support the biological control activities by revealing the defense mechanism of the host plant. *Trichoderma* sp. isolates may contribute to increasing plant growth by affecting the microbial population in the rhizosphere. In this study, it was determined that *Trichoderma* sp. isolates could be used in the growth of barley plants. The effects of the isolates tested on plant growth has been different. It was observed that the isolates had a positive effect on the plant growth characteristics of the barley plant. *Trichoderma* isolates have shown that they play a role as plant growth promoters. In future studies, it is necessary to determine the effects of *Trichoderma* sp. isolates on plant growth in stress conditions. Thus, the isolate or isolates of *Trichoderma* sp. that are effective can be an alternative to chemical fertilizers.

Abstract. Choosing vegetable crops in greenhouse farming plays a significant role in the feasibility of sustainable farming practices. The selected crop affects the economic and environmental conditions which in turn influence the sustainability of farming practices. Therefore, a systematic approach is needed to prioritize the most suitable vegetable crop for sustainable farming practices. The current research focuses on prioritizing vegetable crops grown in green house farming in the environment of the Kingdom of Saudi Arabia (KSA), which takes into account comprehensive criteria related to sustainable farming practices. Five major criteria including crop field area, crop field production, cost of production, price of sale and the usage of water have been selected for the five major vegetable crops grown in the green chamber farming of KSA to determine the most sustainable one. The multiple attribute-based decision making (MADM) model has been developed taking into account the KSA Green House Chamber farming system. The research work reported in this study provides useful information for greenhouse farming in Saudi Arabia in particular and also helps policymakers to formulate effective regional policies to improve the gross domestic product and make farmers self-reliant.
Keywords: *Crop Prioritization; Multiple Attribute Decision Making (MADM); Sustainable Farming Practices; Fuzzy Delphi Method (FDM); Nonlinear Programming (NLP)*

Introduction

In the greenhouse farming system vegetable cash crop prioritization is significant for sustainable farming practices which help the economic development of the nation and promote self-reliance (Nambiar et al, 2001). Due to technological advancement in the farming sector in terms of farm instruments, availability of seeds, manure and irrigation facilities there is considerable increase in farm yields, but as a result of the high rate of population growth the achieved benefit is not sufficient (Pramanik, 2016). There is a misbalance between supply and demand due to the exponential growth of the local and global population. Sustainable greenhouse farming can provide a better solution to bridge the gap between supply and demand (Roy and Chan, 2012). Sustainable greenhouse farming combines the environmental, economic and social factors to achieve the growth and upliftment of humanity, its surrounding life and the environment (Cocklin, 1995).

Greenhouse sustainable farming practices include environmental, economic and social aspects, which are linked to farmers with improved equity, self-sufficiency, reduced risk and good quality of life (Peacock and Sherman, 2010). The economic factors include the crop yield, the system profitability, the economic gain of the farmers, the security of the food for the society. The environmental conditions in semi-arid and arid climatic zones are not favorable for farming because of harsh and extreme temperature. Many agricultural programs were started at different times to ensure food security and rural development (Bailey and Willoughby, 2013). The environmental factors include the nutrient content of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46154629

agricultural soil, the market value of the yield and its quality, the quality of the irrigation water as per the FAO and the carbon credit of the farm and greenhouse gases contribution. The main limiting factor in greenhouse farming is soil and water therefore it is necessary to promote the innovative technologies at the same time spreading the awareness to greenhouse farming community, among the innovative technologies promotion of vegetable cash crops, hydroponics, seawater harvesting also promotion of bio-salinity research and rainwater harvesting.

The selection of a particular set of crop patterns depends on many criteria that can vary from place to place, so that it is difficult to decide on an optimal crop pattern (Qureshi et al., 2018). This may be treated as a system where we have the system input then change within the system and system output the farming vegetable cash crop system requires all the essential parts to produce certain cash crop with relation to surrounding environmental conditions. In the greenhouse farming system largely depends on the tools (Management Policies, Optimum use of Manpower, Mechanizations, Farming Materials, Farming Methods, Economy, Production and Sale).

In the greenhouse farming system management aspects is the important component of the farm if we emphasis this based on system engineering then the components are policies related to farm management, utilization of optimum manpower, the mechanization of the system, the materials of the farming, the farming techniques, the economic aspects of the farm and yield with market value. The second aspect is utilization of sustainable greenhouse farming activities such as economic use of natural resources such as irrigation water, natural soil, wind, sun light and manure, use of natural pesticides (Garg and Dadhich, 2014). The last component is production of cash crops for the benefit of the farmers with focus on environment, economic and social. For achieving the sustainable farming the system input, the system output and things happening within the system should all should be integrated. The employed manpower should be aware with the sustainable farming activities. Mechanized greenhouse farms and equipment viz. plougher, tractors, crusher are used at various stages of the farming activity starting from the preparation of land up to cultivation in the greenhouse the care is also taken to maintain the internal environment for the maximum possible yields it also include the process of plowing, seedling, manure, water and pests applications etc. In Saudi Arabia, water as an important natural resource specially used in sophisticated irrigation system such as drip irrigation and sprinkler systems. Availability of sufficient funds to run the activities and marketing strategies to get the better return are the important aspects of management practices. The prioritization of vegetable cash crops in greenhouse farm can be considered as a strategic decision which may benefit to different stake holders. The climatic factors, economic factors, sustainability, the vegetable crop selection practice in greenhouse are considered to be an important decision which helps the decision makers. Therefore, the crops selection practice is vital for sustainability and better socio-economic conditions.

Review of literature

The concept of farming sustainability criteria was inducted by Gowda and Jayaramaiah (1998) also extended by Qureshi and Singh (2017) using system approach and management tools. The concept of index was introduced to get the sustainability indicators for the selected criteria and prevailing climatic conditions by Dillon et al. (2009). In order to measure the farm sustainability for the temporal variation (Nambiar et

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46154629

al, 2001). The concept of farming sustainability assessment was performed by Zhen et al. (2005). Also a crucial study on the field level management of soil nutrient was carried out by Zhen et al. (2006). The environmental and socio-economic factors were considered and the analysis was carried out by Sydorovych and Wossink (2008; 2009) classified sustainability indicators based on the comprehensive data. A study carried out in the Bangladesh related to farming sustainability indicators by Roy and Chan (2012). A study was carried out for the crop selection process using the agricultural landscape by Sorensen et al. (2015).

The different criteria which may be non-dimensional and dimensional in nature can be efficiently handled in the decision making process using the multiple attribute decision models (MADM) this modeling method is used in the prioritizing the alternate solutions even in the case of complicated criteria involved (Rao and Patel, 2010; Venkata Roa, 2008; Geng and Wardlaw, 2013). The diffusion and flow of trace metal in river Ganga a study using MCDM was reported by Srinivas et al. (2017). In the two districts in the Uttar Pradesh state of India viz. Raebareli and Unnao in India, groundwater quality assessment was carried out using GIS and MCDM by Agarwal and Garg (2016) at the same time an spatial vulnerability of flood mapping keeping in view the effect of climate change using MCDM was reported by Song and Chung (2016).

The MADM methods were applied in the various fields of Environmental Engineering and Water Resources Management such as agricultural irrigation water management and water tariff, flood related problems and decision making, at the basin level integrated water resources management, management of city water supply scheme, planning of water quality and quantity at the sustainable level, reduction of water loss due to major and minor reasons in water supply lines, ground water and surface water contamination due to anthropogenic activities and control using modeling techniques by various researchers (Raju et al., 2000; Chitsaz and Banihabib, 2015; Raju and Vasan; Azarnivand et al., 2015; Geng and Wardlaw, 2013; Mutikanga et al., 2011; Carroll et al., 2013; Roozbahani et al., 2012; Behzadian et al., 2010; Latinopoulos, 2008; Srdjevic et al., 2004). The MADM methods are also applied in the area of waste management choices (Karagiannidis and Perkoulidis, 2009), interventions in anaerobic digestion process to manage the feed stock (Rao and Baral, 2011), in the area of manufacturing systems (Rao and Patel, 2010), energy sector such as power plants (Garg et al., 2007) and in the area of robotics for robots selections (Bhangale et al., 2004).

In present study MADM methods are used to prioritize the vegetable cash crops in greenhouse farming system using techniques such as WPM,SAW,TOPSIS and PROMETHEE and the results were compared using optimization package LINGO (LINGO, 2006). The objective of the research as per these backgrounds discussed here are the prioritization of vegetable cash crops in greenhouse farming system taking in account the important criteria for the sustainable farming practices. The development of multi attribute based decision model (MADM) to prioritize the vegetable cash crops in greenhouse farming system. The overall paper is arranged in five parts first part deals with the introduction, the second part deals with the materials and methods, the third part deals with multi attribute based decision models, fourth part deals with the results and discussions and the fifth and last part deals with the conclusions.

In the coming parts the construction of decision matrix is carried out to prioritize the vegetable cash crops grown in the Greenhouse for sustainable farming practices and maximum returns for five most preferred vegetable crops viz. (Cucurbitaceae, *Solanum lycopersicum, Capsicum annuum, Solanum melongena, Abelmoschus esculentus*) with

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46154629

respect to different dimensional and no dimensional criteria (crop field area, crop field production, cost of production, price of sale, usage of water) based on the importance of the objective under study. The constraints of minimum available farming area has been fixed as per the percentage of system of pattern of cropping (Cucurbitaceae 35%, *Solanum lycopersicum* 36%, *Capsicum annuum* 10%, *Solanum melongena* 11%, *Abelmoschus esculentus* 7%) of farming area in Greenhouse system. In order to control the dominance of most profitable crop the farm area constraints for certain crops are fixed as minimum in the total farming area. The type of the soil in the farming area varies farm are sandy clay loam, clay loam and clay. The water production function (WFP) is referred as the ratio of crop production and water use that is the influencing factor of the model. The price of the crop product is decided based on the guideline of the Ministry of Agriculture Saudi Arabia.

The constraints such as farming area, crop yield, cost of crop production per unit area, price of crop product per unit mass. The cost of farming was qualitative (value based) and irrigation water use is quantitative. Depending on the expert opinion of farming area the inter relationships between the attributes has been established. The beneficial attributes are the farm area and farm yield whereas the non-beneficial attributes are the price of sale and cost of production. In the present study the qualitative attributes were considered and put under the ranked value judgement with a fuzzy conversion scale. The crisp score were obtained using the fuzzy set theory (Chen and Hwang, 1992). The decision matrix shown in *Table 1* is formed based on the data collected through different departments, experts' opinion.

Table 1. *Model Attribute Simulation of Green House Vegetable Cash Crops used*

S. No.	Cash Crops used (Alternatives)	Crop Field Area (CFA) (m^2) '000	Crop Field Production (CRF) (Kg/m^2)	Cost of Production (CP) (USD/m^2)	Price of sale (PS) USD per Kg
1.	Cucurbitaceae (A1)*	109800	15.4000	4.04	1.07
2.	Solanum lycopersicum (A2)*	110000	16.8000	4.68	1.07
3.	Capsicum annuum (A3)*	35000	13.4000	4.80	1.07
4.	Solanum melongena (A4)*	34000	9.7000	4.40	0.80
5.	Abelmoschus esculentus (A5)*	21000	1.6000	3.20	2.13

* Cucurbitaceae (A1) = Cucumber; Solanum lycopersicum (A2) = Tomato; Capsicum annuum (A3) = Green pepper; Solanum melongena (A4) = Eggplant; Abelmoschus esculentus (A5) = Okra

Materials and methods

Study area

In the Kingdom of Saudi Arabia greenhouse farming is promising venture. Recognizing its yields per unit area of the farm and the effective use of scare natural resource viz. water and soil. Saudi Arabia is putting the sincere efforts to enhance the greenhouse farming activities. The trend in increase in the greenhouse farm in past twenty

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46154629

years double in the numbers and more than eighteen times in yields. The number and production in greenhouse farms has increased from 104 and 26 tons in the year 1984 to 295 and 142 tons in 1999. In the Saudi Arabia Greenhouse chambers mostly produce vegetables which is around 42% of the total production the Cucurbitaceae and *Solanum lycopersicum* are the most produced vegetable crops producing more than 85% of the total production (Ministry of Agriculture and Water, 2001).There are many factors which affects the prioritization of crop type in Greenhouse farming. The criteria like available irrigation water in terms of quality and quantity, nutrient value of soil, financial conditions, climatic conditions, skill level of workers etc. play important role in agricultural farming.

In this paper the effort is made for the sustainable greenhouse farming for efficient greenhouse farming expansion is the need of the hour and this should be exploited and utilized in precise and most efficient way in Saudi Arabia. The figure below shows the green chamber farms located at 18°06'25.2"N, 42°53'45.3" E (DMS WGS 84) in the Asir region (*Fig. 1*).

Figure 1. *Green Chamber Farms in Aseer Region in the Kingdom of Saudi Arabia*

The MADM methods

Weighted Product Method (WPM) method

In this method all possible alternative is compared with the other alternative by taking the product of number of ratios, one for every selected criterion. The relative weight of the concern criterion is taken as the power to the ratio, (Chen and Hwang, 1992) as mentioned below (*Eq.1*):

$$P_i = \prod_{j=1}^{M} \left[(m_{ij})_{normal} \right] w_j \qquad \text{(Eq.1)}$$

The (m_{ij}) normal is normalized value of an alternative with respect to an attribute is raised to the with the relative weight of the concern attribute. The best alternative is selected with the value with highest P_i.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46154629

Simple Additive Weighting Method (SAW) method

This method was first developed by (Edwards et al., 1982). The mathematical form of this method (*Eq. 2*) can be written as follows:

$$P_i = \prod_{j=1}^{M} \left[(m_{ij})_{normal} \right] w_j \quad \text{(Eq.2)}$$

The different terms in the above equation can be defined as, P_i is overall score of the crop alternative (A_i), W_j is the weight of importance of jth criterion, m_{ij} is the measure of the performance of the jth performance criterion and the (m_{ij}) normal represents the normalized value of m_{ij}. This method can be also used for non-identical units of measure when the values of decision matrix is normalized.

The Technique for Order of Preference by Similarity to Ideal Solution method (TOPSIS)

The TOPSIS process is carried out in six steps as follows:

Step 1. Creation of evaluation matrix:

Create an evaluation matrix consisting of m alternatives and n criteria, with the intersection of each alternative and criteria given as x_{ij} we therefore have a matrix $(x_{ij})_{mxn}$. This matrix is considered as a decision matrix with the dimensions mxn. This matrix formation takes care of the dimensional and non-dimensional units.

Step 2. Creation of relative importance matrix:

The relative importance of one attribute is compared with the other attribute. This also helps in calculating the weight of each criteria (Saaty, 1980).

Step 3. Development of normalized decision matrix (*Eq.3*):

The matrix $(x_{ij})_{mxn}$ is then normalized to form the matrix

$$R = (r_{ij})_{mxn} \quad \text{(Eq.3)}$$

using the normalization method (*Eq.4*):

$$r_{ij} = \frac{x_{ij}}{\sqrt{\sum_{i=1}^{m} x_{ij}^2}}, = 1,2,\ldots,m, j = 1,2,\ldots,n \quad \text{(Eq.4)}$$

Step 4. Development of weighted normalized matrix:

Calculate the weighted normalized decision matrix (*Eqs.5*):

$$T = (t_{ij})_{mxn} = (w_j r_{ij})_{mxn}, i = 1,2,\ldots,m \quad \text{(Eq.5a)}$$

$$w_j = W_j / \sum_{j=1}^{n} W_j, j = 1,2,\ldots,n \quad \text{(Eq.5b)}$$

Where

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46154629

$\sum_{j=1}^{n} w_j = 1$

So that, and W_j is the original weight given to the indicator $v_j, j = 1,2, \ldots, n.$

Step 5. Determination of best and worst conditions (*Eq.6*):

$$A_w = \{\langle max(t_{ij}|i = 1,2, \ldots, m|)j \in J_-\rangle, \langle min(t_{ij}|i = 1,2, \ldots, m|)j \in J_+\rangle\} \equiv \{t_{wj}|j = 1,2, \ldots, n|\} \quad \text{(Eq.6)}$$

Determine the worst alternative (A_w) and the best alternative (A_b) (*Eq.7*):

$$\mathrm{A_b}=\{\langle \min(\mathrm{t_{ij}}|\mathrm{i} = 1,2, \ldots, \mathrm{m}|)\mathrm{j} \in \mathrm{J_-}\rangle, \langle \max(\mathrm{t_{ij}}|\mathrm{i} = 1,2, \ldots, \mathrm{m}|)\mathrm{j} \in \mathrm{J_+}\rangle\}\equiv\{\mathrm{t_{wj}}|\mathrm{j} = 1,2, \ldots, \mathrm{n}|\} \quad \text{(Eq.7)}$$

Where,

$J_+ = \{j = 1,2, \ldots, n|j|\}$

associated with the criteria having a positive impact, and

$J_- = \{j = 1,2, \ldots, n|j|\}$ associated with the criteria having a negative impact.

Calculate the distance between the target alternative i and the worst condition A_w as below mentioned (*Eq.8*):

$$d_{iw} = \sqrt{\sum_{j=1}^{n} (t_{ij} - t_{wj})^2}, i = 1,2, \ldots, m \quad \text{(Eq.8)}$$

and the distance between the alternative i and the best condition A_b (*Eq.9*):

$$d_{ib} = \sqrt{\sum_{j=1}^{n} (t_{ij} - t_{bj})^2}, i = 1,2, \ldots, m \quad \text{(Eq.9)}$$

Where d_{iw} and d_{ib} are L2-norm distances from the target alternative i to the worst and best conditions, respectively.

Step 6. Euclidean distance:

Calculate the similarity to the worst condition as mentioned below (*Eq.10*):

$$S_{iw} = d_{iw}/(d_{iw} + d_{ib}), 0 \leq S_{iw} \leq 1, i = 1,2, \ldots, m \quad \text{(Eq.10)}$$

$S_{iw} = 1$ if and only if the alternative solution has the best condition; and

$S_{iw} = 0$ if and only if the alternative solution has the worst condition.

Step 7. Prioritization of alternatives:

Rank the alternatives according to $S_{iw}(i = 1,2, \ldots, m)$

Fuzzy Delphi Method (FDM)

The general Delphi method and the fuzzy set theory was clubbed together for the first time by (Ishikawa et al., 1993) and developed the method known as Fuzzy Delphi Method (FDM). In order to solve the fuzziness of general understanding of professional ideas (Noorderhaben, 1995) used the FDM. The fuzziness of the general opinion of the professional could be solved using FDM, and can be evaluated on a more flexible scale.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46154629

The questionnaires can be improved for its quality and efficiency thus more parameters could be screened through the fuzzy set theory. The fuzzy numbers used for this purpose is shown in *Table 2* and the fuzzy scale is shown in *Figure 2*.

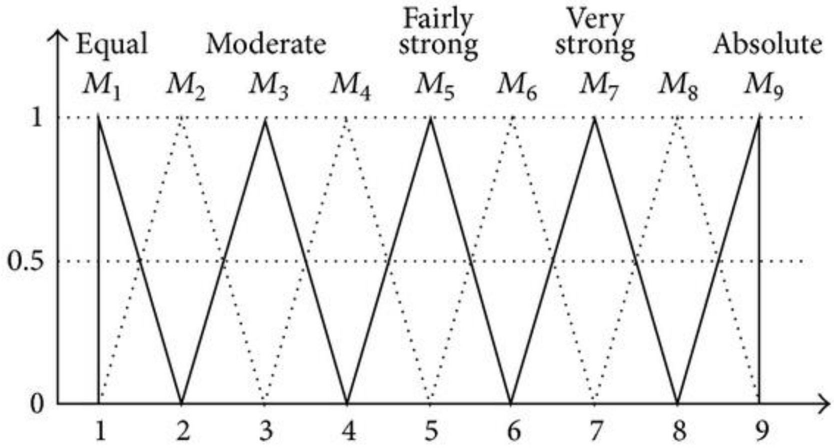

Figure 2. *The fuzzy number scale (Li et al., 2013)*

Table 2. *Fuzzy numbers and definition*

Fuzzy numbers	Definition
1 (1,1,1)	Equally important
2 (1,2,3)	Equally to moderate important
3 (2,3,4)	Moderately more important
4 (3,4,5)	Moderately and strongly important
5 (4,5,6)	More strongly important
6 (5,6,7)	Strongly and very strongly important
7 (6,7,8)	More very strongly important
8 (7,8,9)	Very strongly to extremely important
9 (8,9,9)	Extremely more important

The steps involved in Fuzzy Delphi Method (FDM) are as follows:

a. The decision group opinion data base generation:

The linguistic variables in the questionnaire is used to generate the score of factors important in the study as per the expert opinion.

b. The triangular fuzzy numbers set up:

As per the experts opinion triangular fuzzy number generated are used to get the evaluated values and their significance triangular fuzzy number for the alternate factors are generated. In this study the geometric mean model proposed by (Klir and Yuan, 1995) is used for FDM to get the general understanding of group decision. The formula used is given as follows. Assuming n number of professional whose element is given by number i and the significance of number j then the fuzzy weight.

$\widetilde{w_{ij}} = (a_{ij}; b_{ij;}\ c_{ij}), i = 1,2; \dots\dots\dots; n; j = 1,2; \dots\dots\dots; m$ then the $\widetilde{w_j}$ fuzzy weighting of no. j element is presented as $\widetilde{w}j = (a_{j;}\ b_{j;}\ c_j); j = 1,2; \dots\dots, m.$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46154629

Among which $a = Max_i a_{ij}, b_j = \frac{1}{n\sum_{n-1}^{n} bij}, c = Max_i C_{ij}$

c. Defuzzification

The absolute value S_j is obtained by using the ordinary center of gravity method the process is called defuzzification and the parameter used is fuzzy weight w_j is calculated as follows in *Equation 11*.

$$S_j = \frac{(a_j + b_j + c_j)}{3} \quad where\ j = 1,2,3, \dots \dots \dots, m \qquad \text{(Eq.11)}$$

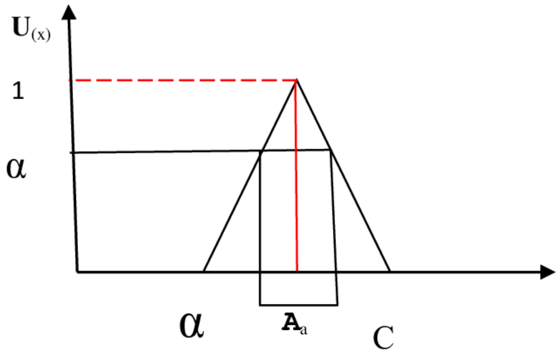

Figure 3. *Fuzzy Delphi method diagram (Moradi et al. 2014)*

If $S_j \geq \alpha$, then the no. j factor is the evaluation index

If $S_j < \alpha$ then delete no. j factor

The solution obtained using FDM is reported in *Table 6* and the important criteria with their definition is mentioned in *Table 3*.

Table 3. *Important criteria and definition*

Criteria	Abbreviation	Definition
Crop Field Area	CFA	The study taken here is the Greenhouse chamber so the land area located, under this category around 42% of the land out of total vegetable crops grown in KSA is put.
Crop Field Production	CRF	This is the yield of crops in ton per unit area of the land in ha for example in the case of Cucurbitaceae 154 ton/ha.
Cost of Production	CP	This include all type of the expenditures involved per unit production of the crop for example in the case of Abelmoschus esculentus it is SR 21562/ha.
Price of sale	PS	This the rate received in the market per unit produce of the crop on average in the case of Cucurbitaceae it is around SR4/Kg.
Usage of water	US	This is amount of water required per unit area of the land per cropping period it is quantitative value (ha-m) but if we compare crops with each other it can be taken as qualitative.

The Nonlinear Programming (NLP) model and solution

In the NLP model the objective function is to maximize the profit and the constraints were set up on the availability of water quantity using the Lingo (Shrivastava et al., 2012). The defined objective function of the problem is as follows (*Eq.12*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46154629

$$MaximiseF = (PY - C)A \tag{Eq.12}$$

In the above equation the function F stands for the net profit, SR (Kingdom of Saudi Arabia, Currency); P is the market value of vegetable in SR/kg; C is the cost of cultivation in SR/ha; Y is the yield of vegetable per unit area of the land in Kg/ha; A is the total area of cultivation in ha. The model took in account the various constraints. The water availability for the groundwater source is considered as a constraint. The total area is divided in sub area on the basis soil and land availability constraint. The agricultural land area to some crops is fixed as minimum so that the crop with high market value should not dominant over the complete agricultural area. The cultivated area and irrigation water depth is considered as positive decision variable.

Results and discussion

In TOPSIS model the formulation matrix developed as shown in Table 1 is utilized in this section to develop the normalized matrix as written by *Equation 13* in order to remove the dimensions the entry in the matrix from 0 to 1.

$$\begin{bmatrix} \downarrow^{\rightarrow} & CFA & CFP & CP & PS & UW \\ A1 & 0.998 & 0.917 & 0.790 & 0.750 & 0.817 \\ A2 & 1.00 & 1.00 & 0.683 & 0.750 & 0.670 \\ A3 & 0.318 & 0.798 & 0.666 & 0.750 & 0.568 \\ A4 & 0.309 & 0.577 & 0.728 & 1.00 & 0.761 \\ A5 & 0.191 & 0.095 & 1.00 & 0.375 & 1.00 \end{bmatrix} \tag{Eq.13}$$

From the decision matrix in *Equation 13*, the normalized matrix is developed as shown in *Equation 14*.

$$\begin{bmatrix} 0.670 & 0.546 & 0.451 & 0.446 & 0.470 \\ 0.671 & 0.596 & 0.390 & 0.446 & 0.386 \\ 0.213 & 0.475 & 0.381 & 0.446 & 0.327 \\ 0.207 & 0.344 & 0.416 & 0.595 & 0.438 \\ 0.128 & 0.057 & 0.571 & 0.223 & 0.576 \end{bmatrix} \tag{Eq.14}$$

The relative importance matrix developed is shown in *Equation 15* this is based on analytic hierarchy process first developed by (Saaty, 1980), then the weight of all the criteria is computed as shown in *Equation 16*. The consistency ratio (CR) is 0.08 which is less than 0.1 hence it depicts good consistency with the decision.

$$\begin{bmatrix} \downarrow^{\rightarrow} & CFA & CFP & CP & PS & UW \\ CFA & 1 & 4 & 3 & 2 & 5 \\ CFP & 1/4 & 1 & 1/3 & 1/2 & 2 \\ CP & 1/3 & 3 & 1 & 4 & 1/3 \\ PS & 1/2 & 2 & 1/2 & 1 & 1/2 \\ UW & 1/5 & 1/2 & 1/3 & 2 & 1 \end{bmatrix} \tag{Eq.15}$$

As per the method proposed by (Saaty, 1980) the weight for all the criteria is calculated and reported in the following *Equation 16*.

$$\left(W_j = (0.47240 \;\; 0.11030 \;\; 0.19210 \;\; 0.11960 \;\; 0.10550)\right) \tag{Eq.16}$$

http://www.aloki.hu • ISSN 1589 1623 (Print) • ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46154629

In *Equation 17* the weighted normalized matrix is written which is obtained by multiplying weights into normalized matrix.

$$\begin{bmatrix} 0.316 & 0.060 & 0.087 & 0.053 & 0.049 \\ 0.316 & 0.066 & 0.075 & 0.053 & 0.041 \\ 0.101 & 0.052 & 0.073 & 0.053 & 0.034 \\ 0.098 & 0.038 & 0.079 & 0.071 & 0.046 \\ 0.060 & 0.006 & 0.109 & 0.027 & 0.061 \end{bmatrix} \qquad \text{(Eq.17)}$$

In the next step the positive-ideal (best) and the negative-ideal (worst) is calculated (*Eq. 18*) as depicted in the *Table 4* subsequently the positive and the negative separation measure were calculated as shown in *Table 5* the relative closeness value is calculated for all the options and is shown in *Table 3*.

$$\begin{bmatrix} A11 & A12 & A13 & A14 & A15 \\ B11 & B12 & B13 & B14 & B15 \\ C11 & C12 & C13 & C14 & C15 \\ D11 & D12 & D13 & D14 & D15 \\ E11 & E12 & E13 & E14 & E15 \end{bmatrix} \qquad \text{(Eq.18)}$$

Table 4. *For different attributes best (+ve) and worst (-ve) Results*

S. No.	Ideal Best	Ideal Worst
1.	$I_{CFA}^{+} = 0.316$	$I_{CFA}^{-} = 0.060$
2.	$I_{CFP}^{+} = 0.066$	$I_{CFP}^{-} = 0.006$
3.	$I_{CP}^{+} = 0.109$	$I_{CP}^{-} = 0.073$
4.	$I_{PS}^{+} = 0.071$	$I_{PS}^{-} = 0.027$
5.	$I_{UW}^{+} = 0.061$	$I_{UW}^{-} = 0.061$

Table 5. *For the positive ideal and negative ideal solution separation measure*

S. No.	Positive Separation Measure	Negative Separation Measure	Relative Closeness
1.	$P_{Cucurbitaceae}^{+} = 0.031$	$P_{Cucurbitaceae}^{-} = 0.264$	$P_{Cucurbitaceae} = 0.895$
2.	$P_{Solanumlycopersicum}^{+} = 0.043$	$P_{Solanumlycopersicum}^{-} = 0.264$	$P_{Solanumlycopersicum} = 0.859$
3.	$P_{Capsicum\ annuum}^{+} = 0.221$	$P_{Capsicum\ annuum}^{-} = 0.067$	$P_{Capsicum\ annuum} = 0.233$
4.	$P_{Solanum\ melongena}^{+} = 0.222$	$P_{Solanum\ melongena}^{-} = 0.068$	$P_{Solanum\ melongena} = 0.235$
5.	$P_{Abelmoschus\ esculentus}^{+} = 0.267$	$P_{Abelmoschus\ esculentus}^{-} = 0.554$	$P_{Abelmoschus\ esculentus} = 0.554$

Table 5 shows the calculation details of relative closness for the crops , $P_{Cucurbitaceae}$, $P_{Solanumly\ copersicum}$, $P_{Capsicum\ annuum}$, $P_{Solanum\ melongena}$ *and* $P_{Abelmoschus\ esculentus}$. The Fuzzy Delphi Method (FDM) model formulation is discussed as above. The detail calculations and results obtained are in *Table 6*.

The MADM techniques are used here to prioritize the vegetable cash crops grown in Greenhouse chamber in local climatic and socio-economic conditions which prevails the different criteria for the different attributes in the Kingdom of Saudi Arabia. The MADM techniques adopted here are the (WPM, SAW, TOPSIS and FDM). In order to analyze the alternatives, four methods (SAW, WPM, TOPSIS and FDM) of MADM approach is used in the present study. The selection index values computed by all the techniques are shown in *Table 7* the crop prioritization is carried out by the highest index value for first and the lowest index value for the last crop. This is observed that some variations are there when we apply the different techniques due to its different mathematical formulation for the similar parameters. The WPM and SAW methods give the Cucurbitaceae is on top priority followed by Solanum lycopersicum same trend was found by TOPSIS and FDM. The variation is found in the case of Abelmoschus esculentus and Solanum melongena may be due to inclusion of logical interrelationship among the criteria's are taken in account by estimating the separation measure to the pairwise comparison and ideal solution. The *Table 6* depict the result of MADM approach used. In comparison with the NLP model results TOSIS and FDM performance was satisfactory. In NLP model and all other MADM techniques the Cucurbitaceae followed by Solanum lycopersicum is most preferred crop, the NLP is solved using LINGO model. For most sustainable Greenhouse practices the importance should be given to land availability, social-economic and environmental factors.

***Table 7.** Tabulated values of index using WPM, SAW, TOPSIS and FDM method*

Index values	WPM	SAW	TOPSIS	FDM
PCucurbitaceae	0.894	0.900	0.895	8.445

Conclusions

In this research work the prioritization of most commonly grown vegetable cash crop is made based on the MADM modeling in The Kingdom Saudi Arabia for the sustainable agricultural practices and local climatic and socio-economic conditions this will help the policy maker and Greenhouse farmers in sustainable agricultural practices. The results obtained were analyzed and compared with LINGO model results. The different major criteria selected in the prioritization are the farming area, irrigation water required per unit area, market value of crop yield per unit mass, cost of farming per unit area were decided for each vegetable cash crop grown in the Greenhouse from the collected data source. The methodologies used in simulation modeling are WPM, SAW, TOPSIS and FDM were employed for ranking to each selected crops. The results calculated by WPM and the SAW were little different may be because of weightages chosen to each criteria may not be in comparison of it. The output from the TOPSIS and FDM helped strongly in prioritization of the vegetable cash crops. These two methods permit the policy maker and farmers (decision makers) inclusion or removal of any attribute based on the importance of the criteria with respect to goal of the study. The best possible close hypothetical solution is obtained measuring separation measure, ideal best and ideal worst using TOPSIS method. The prioritization of vegetable cash crops was carried out by FDM method. The results were compared with LINGO model results and found to be satisfactory. Since the computation time required in NLP is more so the quick decision can be taken by MADM. The recommendations for future work are that the system-based process need to be adopted by incorporating multi-criteria methods and using these methods more in the process of crop selection, the other aspect takes into account the more sustainability-based criteria and ecological aspects in order to improve decision making process.

(Received 8th Jan 2019; accepted 14th Feb 2019)

Abstract. Nitrogen (N), an essential macronutrient for crop growth and development, is well known for its economic losses and environmental hazards due to imbalanced application. Oat (*Avena nuda* L.), a food and fodder crop, is well adapted to marginal soils and requires minimum water and nutrients to produce biomass. A hydroponic experiment was conducted in China Agricultural University, Beijing, China to evaluate the morphological and physiological adaptations of oat to organic N (ON) and low N (LN) with respect to chemical N (CK as control). The results have shown that oat responded to different nitrogen supplies with response to LN having been the dominant one. Lowest SPAD value, net photosynthesis rate, transpiration rate, gas exchange and stomatal conductance showed that the oat was under LN stress. Highest level of root dry mass, as indicated by increased R/S ratio and C/N ratio, was at the cost of minimum nitrogen utility as depicted by increased nitrogen utilization efficiency in roots under LN. Accumulation of total soluble proteins and sugars elaborated the carbon allocation to nitrogen deprived roots. As a result of sufficient biomass provision in LN root, total root length increased which was coupled with increased concentrations of indole-3-acetic acid, gibberellic acid and zeatin riboside whereas decreased concentration of abscisic acid. Overall, oat is found to be a nitrogen use efficient crop which responded to LN through enhanced root system through biomass accumulation by the provision of nitrogen metabolites.
Keywords: *root architecture, photosynthesis, nitrogen utilization efficiency (NUtE), nitrogen metabolites, hormonal accumulation*

Introduction

Nitrogen (N) is an important macronutrient required for the biosynthesis of chlorophyll, nucleic acids, amino acids, proteins and some organic acids. Its essentiality is obvious from its involvement in most of the biological and physiological processes such as photosynthesis, biomass production, hormonal accumulation, carbohydrate allocation, plant root architectural growth and development of reproductive organs of plants (Zhao et al., 2005; Miller and Cramer, 2005). To produce 1 kg biomass most of the non-legume plants absorb 20 to 50 g of N from the soil (Robertson and Vitousek, 2009). Nitrogen is present in soils in a patchy manner either as inorganic form (nitrate or ammonium) or organic form (amino acids, peptides and proteins). Plants uptake different nitrogen forms from the soil through roots with nitrate being the most preferential form (Yuan et al., 2007; Puangfoo-Lonhienne et al., 2008 and Wang et al., 2012). Being highly mobile element, nitrogen is subjected to losses once applied to the soil as inorganic form whereas nitrogen released by organic forms is slow which cannot meet the plant requirement.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46314653

Hence, farmers are compelled to use chemical nitrogen fertilizers which, more often than not, which damages soil physical and chemical health, and toxifies the environment. Approximately 10^{11} kg N per annum is applied in the soil globally with the aim to get highest crop production (Glass, 2003; Tilman et al., 2011; Liu et al., 2013; Chandna et al., 2011; Rawat et al., 2012). Hence, high levels of soil N are susceptible to losses (Zhu et al., 2002; Ju et al., 2004) which ultimately can reduce the N use efficiency (NUE) (Ata-Ul-Karim et al., 2014). On the other hand, deficiency of N reduces the biosynthesis of chlorophyll, affects plant organ development and finally results in reduced crop yield (Marschner, 1995). Plants have developed morphological and physiological alterations over evolution to cope with heterogeneous environmental conditions. Nitrogen is present in soil solution in mineral as well as organic form (Nasholm and Persson, 2001); thus, it depends on the adaptability of a plant to dwell under the conditions of its high or low availability (Glass, 2003; Garnett et al., 2009). The primary response of a plant to low external nitrogen availability is to modify its root system. Most plants expand their root system to capture N by exploring as much rhizosphere as possible (Palta, et al., 2011). Leguminous crops form root nodules to fix atmospheric N but non-leguminous crops like maize, rice produce longer roots (Wang et al., 2003; Chun et al., 2005a) whereas, foxtail millet produces shorter and thicker roots facilitating carbohydrate allocation perhaps through wider xylem vessels (Nadeem et al., 2018). Hence, the diversity is observed in the adaptive measures of different crops under different rhizosphere condition.

Naked oat (*Avena nuda* L.) and hulled oat (*A. sativa* L) are two types of oats cultivated in China. The fast growing nature of oat capacitates itself to produce ample quantity of fresh fodder within short period of time with high nutritional values. The high protein and β-glucone content along with the presence of hypo-glycemic fiber content in oat grain increase its value as a human food. Generally, rice, wheat, maize and other high yielding cereal crops generally occupy most of the agricultural land but crops like oat find very limited area and interest to be cultivated worldwide. Current study was aimed to characterize root morphological and physiological adaptations of oat in order to maximize its nitrogen utilization efficiency (NUtE) in terms of biomass accumulation under different nitrogen supplies. The findings revealed oat as an extremely large root crop under low nitrogen (LN) condition with remarkable nitrogen use efficiency and biomass accumulation.

Materials and methods

The hydroponic experiment was carried out during April-July in a standard growth chamber with 28/22 °C alternate day night temperature, 14/10 h (day/night) photoperiod, 65% relative humidity and 300 µmol photons m^{-2} s^{-1} illumination in China Agricultural University, Beijing, China. High quality seeds of oat (*Avena nuda* L.) variety Baiyan 2 were collected from Baicheng Academy of Agricultural Science, Jilin, China. Deionized H_2O was used to wash the seeds followed by sterilization with 10% H_2O_2 solution for 30 min and soaking in saturated $CaSO_4$ solution for 5 h with continuous aeration. Seeds were germinated on moist tray in the growth chamber. After emergence of approximately 2 cm primary roots, seedlings were wrapped with two layers of deionized water saturated filter paper, enfolded in cylinder shape and placed vertically in a growth holder containing distilled water to assure a continuous water supply to the seedlings. 12 uniform and consistent seedlings with two fully emerged leaves were selected and transplanted into well aerated 5-L vessels containing nutrient solution. The total nutrient solution (as

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46314653

control or CK) consisted of 2 mM NH_4NO_3, 0.75 mM K_2SO_4, 0.25 mM KH_2PO_4, 0.1 mM KCl, 0.2 mM Fe-EDTA, 0.65 mM $MgSO_4$, 2 mM $CaCl_2$, 1×10^{-3} mM $ZnSO_4$, 1×10^{-3} mM MnSO4, 5×10^{-6} mM $(NH_4)_6Mo_7O_{24}$, 1×10^{-4} mM $CuSO_4$, and 1×10^{-3} mM H_3BO_3. 2 mM NH_4NO_3 was replaced by 4 mM glycine ($C_2H_5NO_2$) as a source of organic nitrogen (ON). Low nitrogen (LN) treatment contained 10% of 2mM NH_4NO_3 used in control (CK). Every treatment had six replicates. Each container had 12 plants. Oat seedlings were grown in nutrient solution for 21 days in total having 25% of CK solution for 3 days, 50% of CK solution for 4 days, 100% of CK solution for 7 days followed by the treatment application (CK, ON and LN) for 7 days. The pH of the nutrient solution was adjusted to 5.8-6 and the nutrient solution was changed every 2 days. The whole experiment was repeated three times.

Plant roots and shoots were harvested, frozen in liquid N and stored in -80 °C for amino acids, soluble proteins, soluble sugars and hormone analysis. Root samples were, washed with deionized water 3 times, surfaced dried using a blotting paper prior to storage. For other physiological analysis, shoot and root samples were harvested and dried in an oven at 105 °C for 30 min and then at 70 °C until constant weight.

Gas exchange and SPAD values (Soil and plant analyzer developer) measurements

On the morning of 21st day, between 8.00 to 9.00 am, the 3rd fully expanded leaf of every plant of every replicate was measured in three points carefully with the help of a portable chlorophyll meter (SPAD-502, Minolta, Japan). Every pot had 12 seedlings. The three SPAD reads of every seedling were averaged to get 12 SPAD reads from every pot which served as technical replicates. On the same day a portable gas exchange system (LI-6400, LI-COR Biosciences, Lincoln, NE, USA) was used to measure photosynthetic rate (Pn), gas exchange (Ci), stomatal conductance (gs) and transpiration rate (Tr). Measurements were taken on 6 cm^2 leaf area segment next to the mid-rib of the 4th leaf. Readings from 12 seedlings per pot served as 12 technical replicates and 6 pots of every treatment served as 6 biological replicates. Photosynthetic photon flux density provided by a red/blue LED light source (6400-02B, LI-COR Biosciences, Lincoln, NE, USA) was fixed to 600 μmol m^{-2} s^{-1} and the concentration of ambient CO_2 was adjusted to 400 μmol mol^{-1} by CO_2 injection as reported by Geilfus et al. (2011).

Root length analysis

The root system was separated into crown and lateral roots. Each kind of roots was counted manually and crown roots were measured with a ruler. Roots were scanned using a scanner (Epson 1680, Indonesia). WinRHIZO software (version 5.0) (Regent Instruments Inc., Quebec City, QC, Canada) was used to analyze the scanned images to get total root length and average diameter following previously described methods (Peng et al., 2010). Lateral root length was obtained by subtracting crown root length from total root length. Lateral root density was defined as the number of lateral roots per unit length of crown root containing lateral roots. Each sample had three technical and six biological replicates.

N concentration analysis in the shoot and root

The dried plant samples were weighed and ground into fine powder. 0.3 g of ground sample was taken for digestion by H_2SO_4–H_2O_2 followed by total N analysis using a modified Kjeldahl digestion method (Baker and Thompson, 1992).

DOI: http://dx.doi.org/10.15666/aeer/1702_46314653

Analysis of mineral concentration

For the analysis of mineral contents of the plant using inductively coupled plasma-mass spectrometry (ICP-MS; Agilent Technologies 7700 Series, Böblingen, Germany), the dried (60 °C) plant tissues were ground into fine powder. 100 mg of fine powder was digested with 10 mL of 69% HNO_3 (ROTIPURAN Supra for ICP, 69%) in an 1800 W microwave oven (MARS 6 Xpress; CEM, Matthews, MC, USA) at 100 °C for 2 min, at 120 °C for 1 min and at 180 °C for 20 min followed by 20 min of cooling. Samples were diluted to 100 mL using sterilized deionized water (18.2 MΩ cm conductivity) and stored at 4 °C till analysis. Similar procedure also followed for blank digestions. A certified reference material NCSDC 73350 from the Beijing vegetable research institute (Beijing, China) was used for standardized analytical technique. Internal macro- and micronutrient standards and reference material samples were tested as internal control.

Hormone extraction and quantification by enzyme linked immunosorbent assay (ELISA)

Approximately 0.5 g fresh plant sample was ground into powder and homogenized by using 2 mL of 80% methanol (containing 40 mg l^{-1} butylated hydroxytoluene as an antioxidant), incubated 48 h at 4 °C, and then centrifuged at 1900 × g for 15 min at 4 °C. The supernatant was passed through C18 Sep-Pak cartridges (Waters Corp.), and the hormone fraction was eluted with 10 mL of 100% (v/v) methanol and then 10 mL ether. The elute was N_2-dried at 20 °C. The N_2 dried extracts were dissolved in 2.0 mL phosphate-buffered saline (PBS) containing 0.1% (v/v) Tween-20 and 0.1% (w/ v) gelatin (pH 7.5) to analyze the concentration of free indole-3-acetic acid (IAA), abscisic acid (ABA), gibberellic acid (GA) and zeatin riboside (ZR) by enzyme linked immunosorbent assay (ELISA) following a well-established protocol (Weiler et al., 1981).

Extraction of metabolite and analyses

The soluble proteins were extracted and analyzed by using a standard kit (Coomassie Protein assay reagent; Bio-Rad, Hercules, CA, USA) with bovine serum albumin as a reference. Chlorophyll was extracted from 0.2 g fresh leaf disks using 25 mL mixture of alcohol and acetone (1:1 v/v). The absorbance of the extract was measured at 663, 645, and 470 nm using a UV-VIS spectrophotometer (UV-2600, Shimadzu, Japan) to estimate chlorophyll a, chlorophyll b and total carotenoids according to the previously described methods Wellburn and Lichtenthaler (1984). The concentration of total free amino acids was measured according to the Rosen ninhydrin colorimetric method using leucine as a standard (Rosen, 1957). The concentration of soluble sugars was determined using a commercially available kit (Boehringer Mannheim, Germany). Individual amino acids profile was analyzed using Waters e2695 HPLC (Waters Corp, Milford, MA, USA) by incubating 100 mg of fresh tissue powder with 1.5 mL of the 5% (w/v) Trichloroacetic acid (TCA) solution for 1 h at room temperature. ~50 mg plant tissues were loaded into an Elementar vario Macro CN (Elementar Technologies, Hanau, Germany) analyzer for the C: N ratio analysis.

Statistical analysis

Statistical analysis was performed using a windows software package (IBM SPSS Statistics 22). Means of different treatments were compared using the least significant

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46314653

difference at a 0.05 or 0.01 level of probability. Correlation analysis was performed using Pearson correlation function of SPSS. Graphical rendering was carried out using sigma plot 13.0 windows software. All the data were presented as means ± standard errors (SE) of six replicates.

Results

Root and shoot morphology of oat and biomass accumulation

Oat seedlings were subjected to control (CK), organic nitrogen (ON) and low nitrogen (LN) treatments for one weak. At harvest, the seedlings showed obvious symptoms of various nitrogen regimes having green, mild green and light green (yellowish) shoot color in CK, ON and LN respectively (*Fig. 1A, B*).

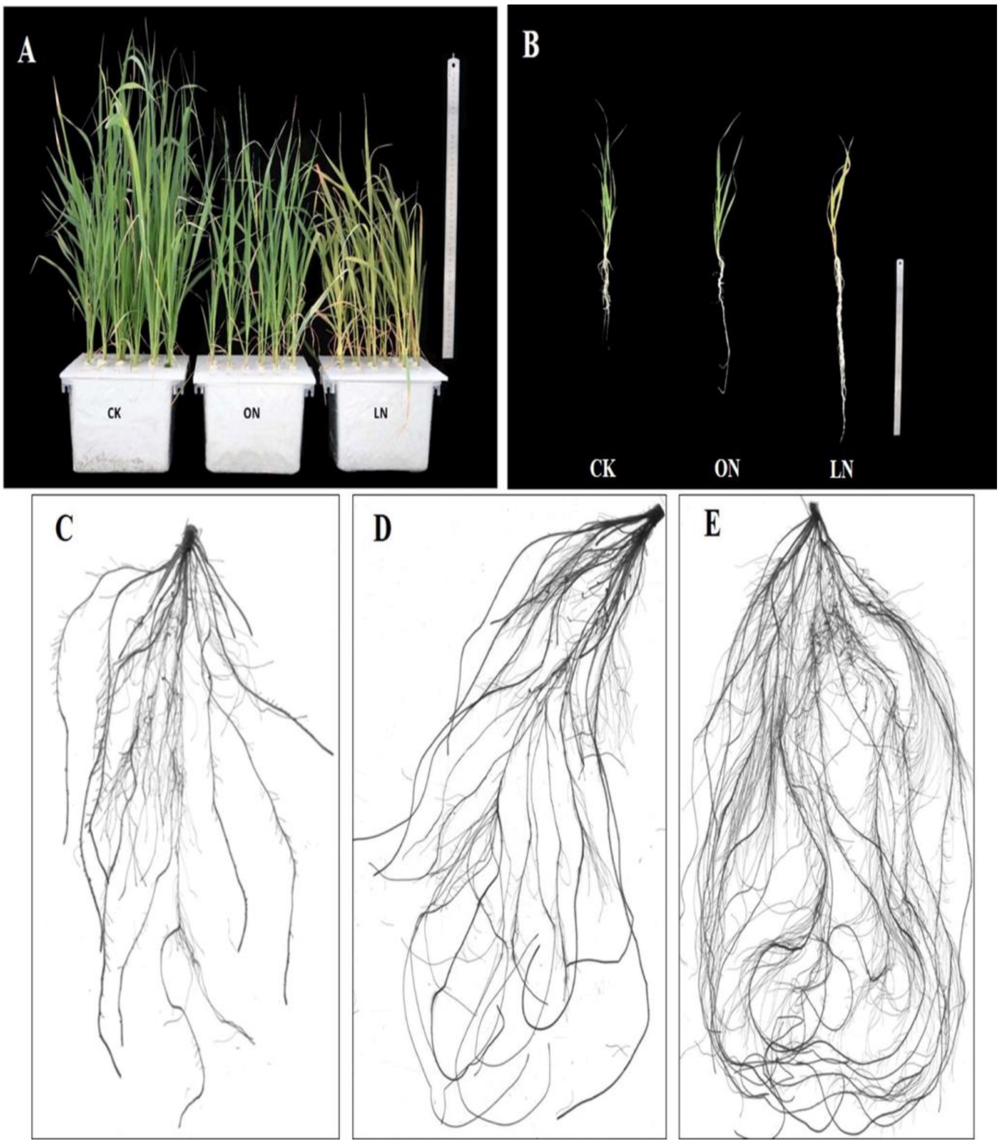

Figure 1. *Shoot and root responses of oat to different form and level of N. Plants grown under CK, ON and LN condition in hydroponic pots (A), plants with the intact root and shoot (B), The whole scan picture of root under Ck (C), ON (D) and LN (E). Treatment CK = control, ON = organic N, LN = low N*

DOI: http://dx.doi.org/10.15666/aeer/1702_46314653

During the harvesting time, each seedling under LN condition revealed the deficiency symptoms of N. Limitation of N generally hinders oat plant growth. In current study, shoot length, leaf area and shoot dry weight decreased whereas root dry weight and root to shoot ratio increased in ON and LN treatments (*Fig. 2A-E*). Reduction in plant height was observed in the ON and LN treatment which was almost 14% and 28%, respectively, in comparison with CK (*Table A1* in the *Appendix*). Compared to CK and ON treatment 45.77% and 35.77% less shoot dry weight and 82.61% and 31.25% higher root DW was produced under LN condition, respectively, (*Table A2*). Interestingly, root to shoot ratio resulted in 241.27% and 109.76% increment in LN treatment with respect to CK and ON respectively. Similar was the case in ON treatment where 62.7% increase in root to shoot ratio was observed as compared to CK (*Table A2*). Talking about root architectural traits (*Fig. 1C-E*), LN treatment increased total root length (112.3% and 64.65%), crown root length (116.27% and 75.91%), lateral root length (111.57% and 63.46%), crown root number (96.67% and 40.47%), and lateral root number (34.1% and 16.39%) and density (128.21% and 67.92%) with respect to CK and ON whereas, ON treatment only increased lateral root number (15.22%) and length (29.43%) and total root length (28.78%) significantly as compared to CK (*Table 1; Table A3* and *A4*). Average diameter of roots decreased in LN significantly (*Table 1*).

Attributes of photosynthesis and nitrogen accumulation

We found a continuous and significant decrease in SPAD value, Chlorophyll a, b and total carotenoids from CK to LN (*Fig. 3A-D; Table A5*). Moreover, net photosynthesis (Pn), intercellular carbon dioxide (Ci), transpiration rate (Tr) and stomatal conductance (g_s) followed the same pattern across all three treatments (*Fig. 4A-D*). Shoot and root nitrogen concentrations were decreased in the order of CK>ON>LN (*Fig. 5A, B; Table A6*), and vice versa for whereas for carbon to nitrogen (C/N) ratio and nitrogen utilization efficiency (cumulative biomass per unit of nitrogen; g DW g^{-1} N in the plant; NUtE) in both shoot and root (*Fig. 5C-F*).

Free amino acids, total soluble proteins, total soluble sugars, amino acid profile and mineral status of oat

Low nitrogen treatment reduced total free amino acids (-26.78% and -18.97%) in shoot as well as root (-36.03% and -25.76%) with respect to CK and ON however, no significance was found between CK and ON (*Fig. 6A, B; Table A7*). Total soluble proteins and sugars in shoot of oat decreased significantly (CK>ON>LN) and vice versa in roots without any significance between CK and ON (*Fig. 6C-F*). Total soluble protein synthesis in shoot was found to be the least under LN treatment having decrements of -73.42% and -48.78% from CK and ON respectively, however, in roots they were increased up to 195% and 99.71% from CK and ON respectively under LN treatment (*Table A7*). Similarly, total soluble sugars in shoot of oat seedling were found to be minimal (-57.73% and -33.87%) whereas highest in roots (159.68% and 80.9%) under LN treatment with respect to CK and ON (*Table A7*). In current study amino acids profile of shoot and root of oat seedlings under CK, ON and LN treatments was generated and found that 18 amino acids (Glu, ser, Gln, Ala, β-Ala, Val, Asp, Asn, Lys, Ile, Gly, Tyr, Trp, His, Leu, Orn, Cit, Tau) in shoot and 15 amino acids (Glu, Ser, Gln, Arg, Ala, β-Ala, Asp, Lys, Gly, Tyr, Leu, Orn, Cit, Tau) in root were decreased in LN treatment as compared to CK; however, Thr increased in both shoot and root of LN seedlings (*Table 2*). Among these amino acids Ala, β-Ala and Lys are the amino acids

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46314653

which co-decreased significantly in shoot and root following the order CK>ON>LN (*Table 2*) As far as mineral accumulation in shoot and root of oat seedlings is concerned, P, Mg, Na, Cu, B, Mn and Zn concentration increased while that of K and S decreased in LN root and shoot as compared to CK and ON (*Table 3*).

Error bars represented standard error of six biological replicates, different letters indicate significant differences (P < 0.05). Treatment CK = control, ON = organic N, LN = low N*

Alterations in hormone accumulation

Plant growth and development is regulated by plant hormones (Beveridge et al., 1997; Marsch-Martinez and de Folter, 2016). In this study, the concentrations of indole-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46314653

3-acetic acid (IAA/auxin), gibberellic acid (GA3) and zeatin-riboside (ZR; a kind of cytokinins) decreased in shoots of ON as well as LN treated oat seedlings (*Fig. 7A, C, G*). In contrast to shoot, the concentration of aforementioned hormones reversed and increased in roots of LN treated seedlings as compared to CK and ON (*Fig. 7B, D, H*). On the other hand, abscisic acid concentration increased in both ON and LN treated shoots as compared to CK (CK < ON < LN) with LN treated shoots depicting the highest number than the rest and vice versa in roots (*Fig. 7E, F*).

Discussion

Nitrogen is an important macronutrient for plant growth and development. As an imperative component of chlorophyll, it is required for proper functioning of photosynthesis apparatus whereas being a building block of peptides, it is required for protein biosynthesis (Hirel et al., 2007; Wang et al., 2012). Owing to the heterogeneous availability of nitrogen in soil, the adaptation of plants to uptake nitrogen from its immediate vicinity becomes vital (Wang et al., 2007), hence different plants respond to external N availability differentially through physiological, morphological and molecular adaptations. Legumes form nodules to fix atmospheric nitrogen whereas non-legumes like maize, rice and foxtail millet may alter their root architecture in order to explore the nitrogen patches in soil (Postgate, 1998; Wang et al., 2003; Chun et al., 2005a; Nadeem et al., 2018). Long-term nitrogen deficiency hinders plant root and shoot growth (Chun et al., 2005b; Guo et al., 2005; Goron et al., 2015). It is well established that rice and wheat crops produced longer root system under nitrogen deprivation in order to explore as much soil surface as possible to reach nitrogen rich patches (Cai et al., 2012; Guo et al., 2014). Oat can be cultivated in marginal lands with little nutrient and/or water requirements. The morphological and physiological adaptation of oat to chemical nitrogen (CK), organic nitrogen (ON) and low nitrogen (LN) remains unknown to date. In this study, oat produced the longest root system, shortest shoot and smallest leaf area under LN as compared to CK and ON whereas it produced the longer root system, shorter shoot and smaller leaf area under ON with respect to CK (*Figs. 1A-E* and *2A, B*) as a primary response to various nitrogen regimes.

Table 2. *Amino acid concentrations (µmol g^{-1} FW) in shoot and root of oat grown hydroponically low N, organic N and Control (high chemical N) condition*

Large root system, hormonal variations and subsequent biomass accumulation in oat

Nitrogen starvation produced larger root system in maize (Han et al., 2015). Roots are the means by which plants uptake nutrients and these are the organs directly sensing their availability. In current study, oat seedlings exposed to LN treatment produced largest root system in terms of crown root number and length, lateral root number, length and density, and total root length. In ON treated seedlings, lateral root number, length and total root length increased as compared to CK only (*Table 1*). The enhancement of total root system of oat under low nitrogen and lateral root system under ON could be due to increased carbon allocation from shoot towards the root as shown by subsequently decreased shoot dry weight and increased root dry weight and root to shoot ratio under ON and LN treatments (*Fig. 2C-E*). Consistent with the previous studies (Han et al., 2015; Nadeem et al., 2018) the specific root length (SRL) of oat was found to be 6227 cm g^{-1}, 5760 cm g^{-1}, and 7145 cm g^{-1} under CK, ON and LN treatments respectively. Extremely large SRL of oat under LN indicated its adaptation and primary response strategy to explore nitrogen under nitrogen limitation conditions. On one hand the increased total root length under LN was due to increased crown root number and length, and lateral root number and length whereas on the other hand it could also be due to decreased average root diameter (*Table 1*) which illustrated the longitudinal growth of roots. It is well established now that if only NO_3^- used as a source of N (no NH_4^+) LN caused reduced total root length including crown and lateral root length and number in maize (Wang et al., 2005; Tian et al., 2008; Gao etal.,2015). Hence the differential response of oat to ON treatment in terms of root system architecture remained consistent with previous findings and it could be the innate response of oat where different plant species respond to different nitrogen sources differentially. A significant positive correlation was revealed between concentration of P, Mg, Cu, Mn, Zn, B and Na in root tissue with root morphological traits (*Table A8*). These attributes possibly influenced the ion balance within oat root leading to alterations in root morphology which needs to be further investigated in future. The most crucial role played by hormones is to regulate the speed of growth and development of the individual parts of the plant to adapt the surrounding environment (Wolters and Jürgens, 2009). Auxin is the most essential hormone which modulates different physiological processes of the plants, i.e. cell division, elongation and differentiation of different parts of plant (Reed, 2001) including root growth and development regulation (Jiang and Feldman, 2003). Gibberellic acids have crucial role of plant organ differentiation and development, regulation of the tall phenotypic character of plants (Yamaguchi, 2008), shoot internode extension, enlargement of leaf surface area and enhancement of apical dominance. Cytokinins help to regulate the mobilization of carbohydrate and N signaling (Ashikari et al., 2005; Sakakibara, 2006). On the other hand, the special cytokinin "zeatin-riboside" helps in the bio-synthesis and maintenance of auxin (Jones et al., 2010). IAA, GA3 and ZR decreased in ON and LN shoot whereas increased in respective roots in this study (*Fig. 7A-D, G-H*). This finding is in accordance to shorter shoot and larger root system observed in ON and LN treated oat seedlings (*Fig. 2A; Table 1*). ABA stimulates plant capacity to cell division or intermediates adaptive responses to the stress environment as well as N starvation (Chin and Beevers, 1970; Santner et al., 2009). This study found increased ABA concentration in LN shoot followed by ON and CK shoot whereas, in total contrast to shoot, the concentration of ABA totally reversed in roots of oat seedlings having least concentration under LN followed by ON and CK (*Fig. 7E, F*). This finding illustrated that oat roots were not under stress in LN condition and can act as the basis to develop plant varieties which can adapt to stress conditions efficiently.

Nitrogen concentration, mineral accumulation and photosynthesis

Chlorophyll (Chl) concentration in plant leaves affects photosynthesis by regulating photosynthetic capacity and ultimately plant growth (Li et al., 2018). The most important source of energy required for plant growth is photosynthesis (Baker, 2008). A photosynthetic reaction is generally split into three steps: primary reaction, electron transport and photophosphorylation, and carbon assimilation. Chl a and Chl b are the most essential pigments to complete primary reaction. Chl a can absorb red to orange light whereas Chl b absorbs blue to purple light. SPAD value, Chl a, Chl b and total carotenoids decreased under ON and LN treatment in current study (*Fig. 3A-D*) which resulted in subsequent decreases in net photosynthesis (Pn), intercellular carbon dioxide (Ci), transpiration rate (Tr) and stomatal conductance (gs) (*Fig. 4A-D*). The reason to this could be the decreased N concentration in shoot of oat under ON and LN treatment (*Fig. 5A*) which could have hindered chlorophyll biosynthesis and disturbed the functioning of photosynthesis apparatus. These findings are consistent with previous study in sorghum (Muchow and Sinclair, 1994) and corn (Zhao et al., 2003; Long et al., 2004). Another possibility could have been the gradually reduced leaf area due to less N accumulation under ON and LN (*Fig. 1B*) which provided less surface area for light absorption and hence resulted in malfunctioned photosynthetic bio-machinery similar to maize (Zhao et al., 2003). Another reason which could have led to decreased photosynthesis was the reduction of potassium (K) concentration and increment in sodium (Na) concentration in LN shoot (*Table 3*). Lower the ratio of K/Na, lower will be the opening of stomata (Willmer et al., 1983) which could have reduced stomatal conductance in current study gradually from CK to LN conditions.

Nitrogen metabolism, carbon accumulation and re-allocation

In the process of inorganic N assimilation amides and amino acids are the first stable products (Yang et al., 2015) and act as the building blocks for proteins. The changes in several amino acids concentration or total free amino acids accumulation regulates many processes in plants including the N metabolism process and storage (Miller and Cramer, 2005; Cañas et al., 2009). The free amino acids concentration in the plant shoot

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46314653

and root tissues has been reported to fluctuate significantly with different N levels and sources. A higher N dose can boost the concentration of total free amino-acid in leaves of many plant species (Yang et al., 2015). The total free amino acids concentration in wheat root was dramatically decreased due removal of the N from the nutrient solution (Rodgers and Barneix, 1989) but drastically increased upon resupply of NH_4^+ or NO_3^- the N-deficient plants (Causin and Barneix, 1993). Free amino acids concentration in shoot and root of oat seedlings in current study decreased in ON and LN treatments (*Fig. 6A, B*) which is consistent with related low nitrogen concentrations in shoot and root under ON and LN (*Fig. 5A, B*) resulting in lesser biosynthesis of amino acids. Reduced free amino acids concentration resulted in reduced soluble proteins biosynthesis in shoot under ON and LN treatments respectively (*Fig. 6C*). Similar trend was observed for total soluble sugars concentration in shoot under ON and LN respectively (*Fig. 6E*). In contrast to shoot, total soluble sugars and total soluble proteins concentrations increased in root of oat seedling under both ON and LN treatment (*Fig. 6D, F*) probably due to the co-transport of carbon and amino acids to nitrogen deficient root. This phenomenon resulted in increased carbon and nitrogen metabolites accumulation in nitrogen deficient root leading to a larger root system (*Fig. 1B, D, E*) to cope nitrogen limitation. There occurred a positive correlation of total soluble proteins and total soluble sugars with shoot and root dry weight (*Fig. 8B, C, E, F*) whereas the correlation of free amino acids with shoot dry weight was positive but that of with root dry weight remained negative (*Fig. 8A, B*) which again emphasized our argument of possible co-transport of carbon and N-metabolites to N-deficient root as an adaptive response to cope low nitrogen.

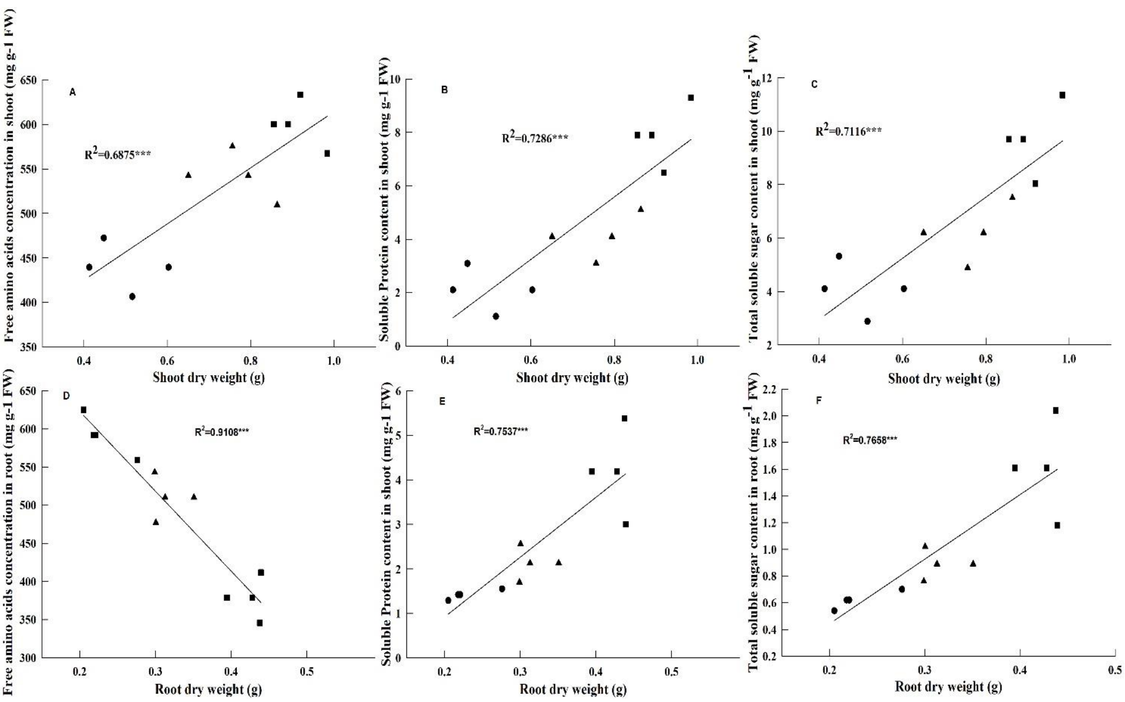

Figure 8. *Relation between N metabolites and root and shoot dry weight of oat. Free amino acids and shoot dry weight (A), SOLUBLE protein and shoot dry weight (B), soluble sugar and shoot dry weight (C), free amino acids and root dry weight (D), soluble protein and root dry weight (E) and soluble sugar and root dry weight (F). Values were obtained from four replicates*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46314653

Furthermore, free amino acids to N concentration ratio, total soluble proteins to N concentration ratio and total soluble sugars to N concentration ratio significantly increased in LN roots (*Table 4*) which further elucidated the shoot to root transport of carbon and nitrogen metabolites in order to let oat roots acclimatize to N-deprivation. In the mechanism of ammonium assimilation, the first product is glutamine and glutamate is its precursor whereas asparagine, aspartate and serine generally form the dominant pool of the amino acids in the leaves of many plants (Yang et al., 2015). Sometimes other amino acids may also become dominant depending on the plant species and N concentration of the surrounding environment (Xu et al., 2012; Pratelli and Pilot, 2014). Particularly, Gln and Asn are the most crucial mediators for synthesis and integration of different amino acids and also storage proteins (Miller and Cramer, 2005; Seebauer et al., 2004). Lower N concentration in shoot and root might have contributed to decreased biosynthesis of Gln (*Table 2*). Similar was the case with Asn in both shoot and root which could have altered protein synthesis negatively as revealed by decreased soluble proteins concentration in the LN shoot (*Table 2, Fig. 6C*). Altogether, the amino acid profile depicted a complicated regulation of N-metabolism which needs to be further dissected in future studies. shoot due to Carbon to nitrogen ratio was the highest in shoot as well as root under LN followed by ON treatment (*Fig. 5C, D*). Similar was the trend of nitrogen utilization efficiency (NUtE) (*Fig. 5E, F*). These results further suggested the higher accumulation of carbon in shoot and root and subsequent re-allocation within the oat tissues as the N availability shifted from CK to LN conditions.

Table 4. *Nitrogen metabolites/ N concentration ratio in oat shoot and root after harvesting*

	Treatment	Free amino acids/N concentration ratio	Soluble protein/N concentration ratio	Soluble sugar/N concentration ratio
Shoot	CK	12.99 ± 0.5c	0.17 ± 0.01a	0.21 ± 0.01a

Conclusion

Nitrogen, a vital macronutrient for crop growth and development, is often subjected to losses through various means and causes environmental hazards through its excessive deposition in the ecosystem. Hence, nitrogen use efficient crops can minimize the use of chemical nitrogen and thus reverse the environmental deteriorations. In this study, Oat (a cereal crop) was studied for its adaptation to different nitrogen regimes (CK, ON, LN). Root dry weight, R/S ratio, C/N ratio and NUtE increased under LN treatment which indicated the allocation of carbon to continuously growing root as suggested by increased crown root number and length, lateral root number and length, and total root length under low nitrogen. Highest levels of total soluble proteins and total soluble sugars were in total contrast to lowest N concentration in roots under LN which further emphasized the carbon provision of roots at the cost of minimum photosynthesis.

DOI: http://dx.doi.org/10.15666/aeer/1702_46314653

Furthermore, highest levels of IAA, GA3 and ZR in Low nitrogen roots was perhaps the innate adaptive strategy of oat allowing the roots to expand under low nitrogen stress as shown by highest level of abscisic acid. Altogether, these findings suggested that oat is an extremely nitrogen use efficient crop which can be well adapted to N-poor soils.

Abstract. A soil-borne fungal parasite (*Plasmodiophora brassicae Woron*) has regularly caused 50-60% reductions in the seasonal yield of a 35 years old cabbage plantation under garlic revaccination in China. We investigated the impact of soil conditioners on soil chemical properties and bacterial communities in order to recommend actions to address increasing frequencies of root-resistant cabbage infections. The results showed urease and polyphenol oxidase activities increased by 10.4-15.8% in the topsoil after two-years of quicklime and organic fertilizer application. High throughput sequencing data showed significant increases in the relative abundance of bacteria with potential for biocontrol (*Xanthomonadales*, *Pseudomonas*, and *Bacillus*) under lime and bioorganic fertilizer. Also, according to a forward-selection CANOCO analysis, in this case the two most important variables contributing to the variation in bacterial communities' composition were soil organic matter and total nitrogen.
Keywords: *soil-borne parasites, antibiotic bacteria, high throughput sequencing, lime, soil enzyme activities*

Introduction

Agricultural cropping systems are intensive and involve crop rotations among a limited number of species under specific climatic conditions in China (Chen et al., 2015). Extensive intensification of cropping has been achieved through high inputs of chemical fertilizers, which, in turn, seriously degraded soil physicochemistry and reduced the diversity and abundance of soil bacteria communities (Xiong et al., 2015). Continuous cropping can decrease soil pH from neutral to acidic levels (Wang et al., 2014), and can increase root exudates, such as amino acids, phenolic acids, root cap cells, cellular debris, etc. (Wei et al., 2015b). These changes to agricultural soils and their bacterial communities increase the vulnerability of crops to pests and diseases (Yin et al., 2010). Consequently soil-borne parasites become particularly difficult to control with alternative pesticide techniques due to the long-term survival of resistant spores and eggs in the soil (Fukuta et al., 2013). Manipulation of soil conditioners is one potential approach to address soil-borne parasites. As the capacity to process soil nutrients varies among groups of microorganisms, soil fertilization and acidity manipulation can influence growth and competitiveness of microorganism in different ways, and therefore affect the diversity, biomass, and activity of the soil microbial community. Chagnon and Bradley (2013) provide evidence that the relative availability of soil nitrogen (N) and phosphorus (P; i.e., soil nutrient stoichiometry) controls the competitive balance between these two fungal guilds. Species richness and functional group richness affected community stoichiometry, especially by increasing C:P and N:P ratios. Compost application to agricultural fields is an excellent natural approach to

fighting plant pathogens. Lime products have been used to destroy *Salmonella* or other pathogens present in soil and manure, and do not require any specialized equipment to apply, so lime can be recommended for temporal use, e.g., for rapidly destroying *Salmonella* or other pathogens. Lime amendments can be beneficial to acidic soils, which, in any case, require regular lime amendments (Dowling et al., 2015). Quicklime application can improved the effects of mechanical soil aeration, which can restrain pathogenic microorganism growth by reducing soil moisture and enhancing soil permeability (Wei et al., 2015a).

Microorganisms respond quickly to modifications in the vegetation or soil properties. Understanding the relationships between soil conditioners and microbial community structure and composition may significantly contribute to our knowledge regarding the development of better fertilizer regimes for extensive vegetable cropping systems (Glaser et al., 2015). When compared with traditional techniques for determination of the biological diversity, such as Polymerase Chain Reaction-Denaturing Gradient Gel Electrophoresis (PCR-DGGE) , fluorescence *in situ* hybridization (FISH), and terminal restriction fragment length poly-morphisms (T-RFLP), high-throughput sequencing technologies can significantly expand investigations into species and functional diversity of microbial populations (Diaz et al., 2012).

As stated above, it appears that both soil acidity and nutrient levels can be manipulated to control fungal pathogens and improve the bacterial diversity and biomass in agricultural fields. In the agricultural site studied here, a soil-borne fungal parasite (*Plasmodiophora brassicae Woron*) often causes 50-60% seasonal yield losses for the autumn cabbage crop in 35-year revaccination. We tested the hypothesis that: Soil conditioners effective in controlling pathogens may favor the development of bacteria with potential for biocontrol. We assessed the potential of these alternative control methods in soil-borne parasites and looked for significant insights into species and functional diversity of microbial populations.

Materials and methods

Experimental site and crop management

This experiment was carried out on a field site located in Baicheng County of Acheng City in Heilongjiang Province, China (45°32′N, 126°58′E and altitude 151 m). The site soil is classified as fine Mollisols Albolls Argialbolls Argiaquic. The experimental site is located within a temperate continental monsoon climate with mean annual precipitation of 600 mm and mean temperature of 4°C. For at least 35 years before the experiment (see *Table 1*), the field site crop rotation had involved early garlic (*Allium sativum L*, April to July), late Chinese cabbage (*Brassica campestris L. spp*, July to October) and winter fallow (October to April). Continuous cropping changed the soil physicochemical properties and microbial community structure and has resulted in the establishment of a fungal pathogen.

Field experiment design

This two-year experimental manipulation of soil conditioners controlling (lime, Effective Microorganisms EM, bio-organic fertilizer) soil remediation under a continuous cropping system started in 2014, and involved six soil treatments. The six treatments were located on adjacent plots and included: (1) untilled soil (NTS) within an

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46554676

undeveloped field, means healthy soil; (2) continuously tilled soil (CTS) within a field with continuous crop production growing garlic and cabbage with raw chicken manure application (*Table 1*); In order to discuss the effects of soil conditioners on soil restoration under a 35 years old cabbage plantation under garlic revaccination. (3)-(6) treatments were set. It is forbidden to use raw chicken manure during the whole growth period. Chemical fertilizers are normally applied in accordance with conventional planting practices. (3) organic fertilizer treatment (OFT), based on a field with continuous crop production growing garlic and cabbage with base fertilizer and 1500 kg/ha bio-organic fertilizer application; (4) quicklime and organic fertilizer treatment (LOF), within a field with continuous crop production growing garlic and cabbage with 4000 kg/ha quicklime and 1500 kg/ha bio-organic fertilizer application; (5) quicklime treatment (LIM), within a field with continuous crop production growing garlic and cabbage with 4000 kg/ha quicklime (equivalent to CaO 2026 kg/ha) application; (6) EM treatment (EMT) within a field with continuous crop production growing garlic and cabbage with 5000 ml/ha EMT diluted 100 times and sprayed onto the soil after garlic and Chinese cabbage harvest. The EMT treatment also involved a supplemental application at the bulbil differentiation stage of garlic and the rosette stage of Chinese cabbage. Bio-organic fertilizer (decomposed biological organic fertilizer with microbial fungicide) included moisture content 30.0%, organic matter 25.5%, N% 2.69%, P_2O_5% 0.96%, K_2O 0.49%, bacillus bacillus and bacillus granulus ≥0.2 billions/gram. Besides the untilled soil treatment, others treatments applied the same concentration chemical fertilizer (667 m^2 Garlic, N 15 kg, P_2 O_5 20 kg, K_2 O 15 kg; 667 m^2 Chinese cabbage, N 15 kg, P_2 O_5 7 kg, K_2 O 12 kg;). The experiment was laid out as a randomized design of the six treatments with three replicates. Each plot was 60 m^2 in area and surrounded by a 30 cm buffer to prevent the water and nutrient exchange between adjacent plots.

Table 1. *Cropping model and manure input before experimental field*

Schedule	Cropping method and manure input	Planting method and density
Late April	Grown early garlic, The proper 42% compound fertilizer (N-P_2O_5-K_20=20:8:14) application and dressing ratios for garlic(Allium Sativum L.) were 600kg /ha and 2:1.	Chinese cabbage was planting by plot, with the width of 2.2 meter x length 100 meter. It is generally advisable to plant 3,800 plants/667 m^2.
Early July	Harvested early garlic	
Middle July	Applied 37500 kg/ha raw chicken manure	Garlic Seeding density using traditional narrow ridge system
Late July	Grown late Chinese cabbage, Fertilizer applied N 124 kg/ha, P_2O_5 90 kg/ha, K_2O 150 kg/ha. Chemical fertilizers are 46 % urea, 46 % triple-superphodate, 50 % potassium sulfate	45 cm x 6 cm, 24,700 plants/667 m^2
Early October	Harvested late Chinese cabbage	
Middle October	Applied 46875 kg/ha raw chicken manure and winter fallow until next April	

The nutrient content of raw chicken manure: Moisture content 50.5%; Organic matter 25.5%; N% 1.63%; P_2O_5 % 1.54%; K_2O 0.85%

Soil sampling

Soil samples were collected in October 2015 after the Chinese cabbage harvest. Soil samples, up to a depth of 0.60 m, were collected using an 85 mm diameter soil corer and divided into three depth layers (0–0.20, 0.20–0.40, and 0.40–0.60 m). For each treatment, three replicate samples were collected according to a completely randomized

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46554676

design. Each replicate was composed of three subsamples, which were mixed and transported to the laboratory on the same day. Soil samples for microbiological analysis were subsequently wet sieved (4 mm mesh sieve) and stored at -80°C.

Soil chemical properties and microbial biomass

The air-dried soil sieved by (0.25 mm) was analyzed for organic C by vitriol acid potassium dichromate oxidation method (SOC), total N by the Kjeldahl method (TN) and total P by the $HClO_4$-H_2SO_4 method (TP), and soil pH was measured in a 1:2.5 (soil:water) mixture using the potentiometric method. Other parameters and specific analysis methods were determined as described by Forster (1995). Microbial biomass C (C_{mic}) and biomass N (N_{mic}) contents were determined on the 4°C component using the chloroform-fumigation–extraction method (Vance et al., 1987). Extracts were filtered through Whatman no.42 filter paper and analyzed for organic C content with an elemental analyzer (TOC-VCPH/CPN, Shimadzu, Kyoto, Japan).

Soil Enzyme activity measurements

In order to investigate changes to soil biological functions, activities of key enzymes were determined immediately after air-drying soil (<1 mm). Soil urease (EC 3.5.1.5) activity (URE) was measured by incubating 5 g of soil in 0.5 M urea as substrate in 0.1 M phosphate buffer at pH 7.1 under 37°C for 2 h. The formation of ammonium was determined spectrophotometrically at 578 nm and URE activity was expressed as μg NH_4–N g^{-1} soil h^{-1} (Nannipieri et al., 1974). Soil sucrase (EC 3.2.1.26) activity (SUC) was measured by incubating 3 g soil (d. w.) according to Kandeler et al. (1999). The activity of SUC was expressed as mg glucose g^{-1} soil h^{-1} (Kandeler et al., 1999). Soil catalase (EC 1.11.1.6) (CAT) was measured by incubating 5 g soil in 5 ml of a 0.3% H_2O_2 solution for 30 min at 30°C. The suspension was titrated with a 0.1 mol L^{-1} $KMnO_4$ solution. The activity of CAT was expressed as 0.1 mol L^{-1} $KMnO_4$ ml g^{-1} soil 30 min^{-1} (Author, 1964). Polyphenol oxidase (EC 1.10.3.1) activity (PPO) was determined as described by Peruccia (2000), and expressed as mg purpurogallin g^{-1} soil 2 h^{-1}. Determinations for all soil samples were performed in triplicate, and all values were reported as averages of the three determinations. All rates were standardized to oven-dried soil mass.

Soil DNA extraction and PCR amplification

Microbial DNA was extracted from soil samples using the E.Z.N.A.® soil DNA Kit (Omega Bio-tek, Norcross, GA, U.S.) according to the manufacturer' s suggested protocols. For each sample three-four subsamples were independently taken and went through the extraction. Then the extracts from one sample were pooled together and the extracted DNA was stored at -20°C until the subsequent sequencing procedure. The V4-V5 region of the bacteria 16S ribosomal RNA gene was amplified by PCR (95°C for 3 min, followed by 27 cycles of 95°C for 30 s, 55°C for 30 s, and 72°C for 45 s, and a final extension at 72°C for 10 min) using primers (515F 5'-barcode-GTGCCAGCMGCCGCGG)-3' and 907R 5'-CCGTCAATTCMTTTRAGTTT-3', where 'barcode' is an eight-base sequence unique to each sample. PCR reactions were performed from triplicate 20 μL mixtures containing 4 μL of 5 ×FastPfu Buffer, 2 μL of 2.5 mM dNTPs, 0.8 μL of each primer (5 μM), 0.4 μL of FastPfu Polymerase, and 10 ng of template DNA.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46554676

Illumina MiSeq sequencing

Amplicons were extracted from 2% agarose gels and purified using the AxyPrep DNA GelExtraction Kit (Axygen Biosciences, Union City, CA, U.S.) according to the manufacturer' s instructions. After extraction, amplicons were quantified using QuantiFluor™ -ST (Promega, U.S.). Purified amplicons were pooled in equimolar quantities and paired-end sequenced (2×250) on an Illumina MiSeq platform according to standard protocols. The raw reads were deposited into the NCBI Sequence Read Archive (SRA) database (Accession Number: SRP******).

Sequence data processing

Raw fastq files were demultiplexed and quality-filtered using QIIME (version 1.17) according to the following criteria: Operational Units (OTUs) were clustered using UPARSE (version 7.1 http://drive5.com/uparse/) and a 97% similarity cutoff. Chimeric sequences were identified and removed using UCHIME. The phylogenetic affiliation of each 16S rRNA gene sequence was determined through comparisons with the Silva (SSU115) 16S rRNA database using RDP Classifier (http://rdp.cme.msu.edu/) and a confidence threshold of 70% (Amato et al., 2013).

Data analysis

Treatment effects were tested for through analysis of variance (ANOVA) using SPSA17.0, and differences among treatments were compared using Duncan' s multiple range test ($P < 0.05$). The community richness index and community diversity index were calculated as well as data preprocessing, operational taxonomic unit-based analysis and hypothesis tests were performed using mothur (http://www.mothur.org/). The histogram was created using OriginPro 10.1. Variation in community composition across the different treatments as analyzed using a principal coordinate analysis (PCoA) performed using CANOCO 4.5. Multivariate analyses investigating the relationships between environmental variables (OM, TN, available P, NH_4, and pH) and community composition were performed through a redundancy analysis (RDA) using CANOCO 4.5. The RDA invoked a manual forward-selection procedure to identify the significance of environmental variables ($P<0.05$) using a Monte Carlo test.

Results

Continuous cropping with two crops in a monoculture system caused Chinese cabbage root disease and decline of yield

Plasmodiophora brassicae Woron is a slime fungus. The dormant sporangia forms in the host cell, spherical or ovate, thin, colorless, single cell, size 4.6 to 6.0×1.6 to 4.6 (μm), germination produces swimming spores. The Spore is pear-shaped or spherical, 2.5 to 3.5 μm in diameter. From the root hair of cabbage to the host cell, after a series of evolution and expansion, it enters the formation layer from the root cortex, stimulates the division and expansion of the host parenchyma cells, causing the root system to form a tumor, and finally the pathogen forms a large number of dormant sporangia in the host cell. After the tumor decays, dormant sporangia enter the soil for wintering. Bacteria hibernate sporangia in the soil or adhere to the seeds over the winter, and can survive in the soil for 10 to 15 years. The sporangia spreads through rainwater, irrigation

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46554676

water, pests, and agricultural operations, and the germination produces swimming spores that invade the host. After about 10 days, the roots grow tumors. Bacteria can develop at 9 to 30°C, with a suitable temperature of 23°C, a suitable relative humidity of 50% to 98%, and a suitable pH 6.2. Soil water content is less than 45% and pH is greater than 7.2 or more, then pathogenic bacteria die. The disease first appears scattered in fields, but in successive seasons it will infect the entire field, reducing the yield significantly of garlic and resulting in no yield at all of cabbage in the CTS treatment (*Table 2*). The addition of agricultural lime and nutrition management is the common method for its control. But the mechanic of reducing the occurrence of cabbage clubroot in already-infected fields is not clear and this can be discussed in the next sections.

Table 2. *Soil properties in different tillage and fertilization treatments*

Treatments	pH (1:2.5H_2O)	Total N (mg/kg)	Total P (mg/kg)	Available N(mg/kg)	Available P(mg/kg)	Organic Matter (g/kg)	Garlic yield (t/ha)	Chinese Cabbage yield (t/ha)

NTS represents untilled soil, CTS represents continuously tilled soil, OFT represents organic fertilizer treatment, LOF represents quicklime and organic fertilizer treatment, LIM represents quicklime treatment, EMT represents effective microorganisms treatment. Values are mean±standard deviation (n=3). Values within the same column followed by the different letters indicate significant difference (Duncan’ s multiple range test (P＜0.05))

Effects of continuous ecological factors controlling on soil chemical properties

In this content, the soil conditioners controlling (Lime, EM, bio-organic fertilizer) significantly influenced ($P<0.05$) soil properties including soil pH, the concentration of TN, OM and so on (*Table 2*). Soil pH of the CTS treatment was significantly lower than for all other treatments, with the greatest difference (18.3%) occurring between the CTS treatment and NTS treatment. Compared with the CTS, all the fertilizer and regulators treatments significantly increased the garlic yield and total N, whereas TP, available P, available N and OM did not significantly differ among CTS, EMT, and LIM. There was no significant difference observed among all treatments for the Chinese cabbage yield. Changes to soil properties may affect soil enzyme activities and the composition and abundance of bacterial communities, which were further examined using qPCR techniques and the Illumina MiSeq platform.

Soil enzyme activities

Soil enzyme activities were significantly influenced by soil depth (*Figure 1*). The EMT treatment had a particularly strong stimulatory effects on PPO, URE, and SUC activities, achieving 89.7%, 15.4%, and 11.4% increases in activity respectively in shallow soil layer (0-20 cm) when compared with activities in the same soil layer for the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46554676

CTS treatment. Likewise, Lime and organic fertilizer boosted URE, SUC, and PPO activities. The NTS treatment increased URE, SUC, and PPO activities, resulting in a 53.0%, 54.7%, and 183.4% increase in activity, respectively, in the shallow soil layer (0-20 cm), when compared with activities in the same soil layer for the CTS treatment. On the other hand, the CTS treatment stimulated CAT activity by 49.0% compared to under the NTS treatment. Among all treatments, URE and PPO activities were highest under the LOF treatment, where they were 3.84% and 22.5% greater, respectively than under the OFT. The URE and PPO activities under the LOF treatment were also 6.96% and 33.7% higher, respectively than under the LIM treatment. Under the LIM treatment, SUC activity was 2.90% and 6.46% greater than under the LOF and OFT, respectively. Under the OFT, SUC activity was 9.22% higher than under the EMT. CAT activity was highest under the EMT, followed by LIM, OFT, and then LOF.

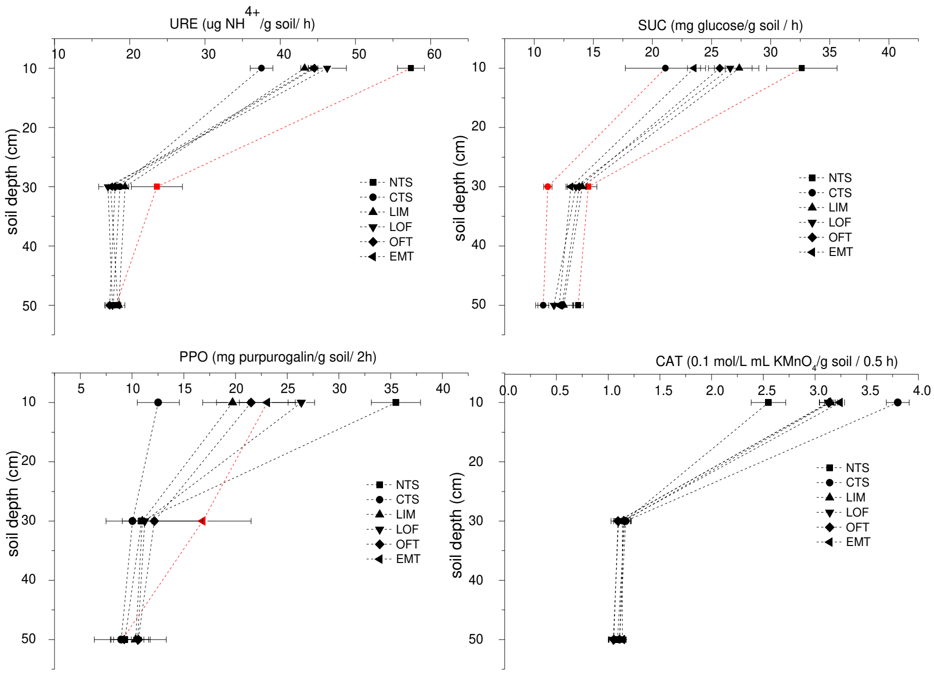

Figure 1. *Soil URE, SUC, PPO, CAT activities depending on soil depth and different treatments. Errors bars represent standard error(n=3)*

The activities of URE, SUC and PPO were consistently higher in the shallow soil layer (0-20 cm) than in the middle (20-40 cm) or deep layer (40-60 cm). SUC activity in 20-40 cm soil layer was 29.9% higher than in the 40-60 cm soil layer. Within the middle soil layer (20-40 cm), SUC activity was highest under the NTS treatment, followed, in order of decreasing SUC activity by LIM, OFT, LOF, EMT, and then CTS. The activities of SUC, PPO, and CAT did not significantly differ between the middle and deep soil layers.

In the shallow soil layer, the soil enzyme activities significant correlated with the soil chemical properties (see *Table A1*). There was a positive correlation between the activities of hydrolytic enzymes and pH and total N. We also found significant reductions in catalase activity with increasing levels of organic matter and total N.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46554676

Microbial C and N

Different treatments caused a shift of the soil microbial biomass carbon and nitrogen in soil samples (*Figure 2*). The organic fertilizer and EM inoculant addition increased C_{mic} and N_{mic} contents relative to the CTS, EM inoculant addition resulted in the highest soil C_{mic} and N_{mic} contents. The addition of the organic fertilizer did increase C_{mic}, but N_{mic} in the LOF treatment was higher than the OFT treatment under the same input of organic fertilizer. In this study, the C_{mic}/N_{mic} ratio was the highest in the treatments of CTS and LIM followed by the OFT and EMT; the other two treatments were significantly lower (*Figure 2*). Fertilizer input type and soil pH showed significant impacts on C_{mic}, N_{mic} and C_{mic}/N_{mic} ratio. The higher rate of input significantly increased both C_{mic} and N_{mic} and decreased the C_{mic}/N_{mic} ratio. There was a significant interaction between input type and level for C_{mic} and C_{mic}/N_{mic}.

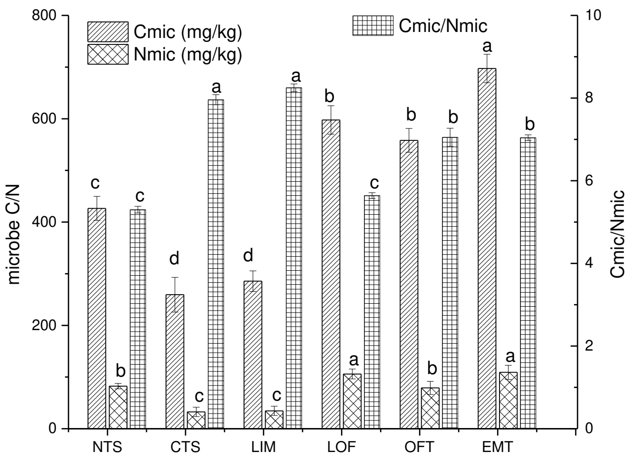

Figure 2. *Soil microbial biomass (Cmic and Nmic) in different treatments determined by the chloroform-fumigation–extraction method. Error bars indicate the standard deviation of relative biomass between three duplicate samples. The same column followed by the different letters indicate significant difference (LSD, P<0.05)*

Bacterial community composition and diversity

After two years of soil nutrition management 16S rRNA high-throughput sequencing showed bacterial community profiles to markedly differ among treatments. The Illumina-based analysis of the V3 region of the 16S rRNA gene resulted in recovery of 118, 101 high quality sequences from the six soil treatments (*Table 3*). More than 17,000 valid reads were obtained for each replicate through a sequence optimization process, and the bacterial community richness index was calculated. After quality control filtering, median sequence length of each read was 396 bp (*Table A2*). The Good' s coverage values (*Table 3*) exceeded 98% at a 97% similarity cutoff, indicating that sequence reads were sufficient to capture the bacterial diversity within these soils. Based on Mothur clustering, the number of OTUs within soil samples ranged from 919-1364, depending on treatments. The lowest number of total OTUs was observed under the NTS treatment. The highest Shannon and Chao 1 indices occurred under the EMT and OFT treatments, which suggested that bio-organic fertilizer facilitated bacterial community diversity. Rank-abundance curves can be used to explain species abundance

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46554676

and evenness of species distribution. The Rank-abundance curves for the six soil samples were shown in *Figure 3*, and it can be seen that these six curves were not flat at the end, which reflected the uneven distribution of species. The asymptote of the OFT, EMT, and LIM treatment curves appeared to occur at higher x-axis values than that of the NTS treatment curve, which indicated that bacterial community abundance in the treatments of OFT, EMT, and LIM treatments were significantly higher than the treatment of NTS. The highest bacterial abundance occurred in the treatment of OFT. Thus, two-year continuous controlling cropping increased the bacteria community diversity.

Table 3. *Summary of the pyrosequencing sequencing data and diversity estimates*

Sample	Number of reads	97% sequence identity			
		Number of OTUS	Good's coverage ratio C(%)	Shannon index (H')	CHAO1 estimator
CTS	17450	1179	98.6	5.92	1393
EMT	17209	1287	98.5	6.12	1445
LIM	19993	1285	98.9	5.95	1427
LOF	19048	1199	98.6	5.43	1397
NTS	26386	919	99.4	4.82	1032

Chao: community richness, Coverage: sampling coverage, Shannon: community diversity

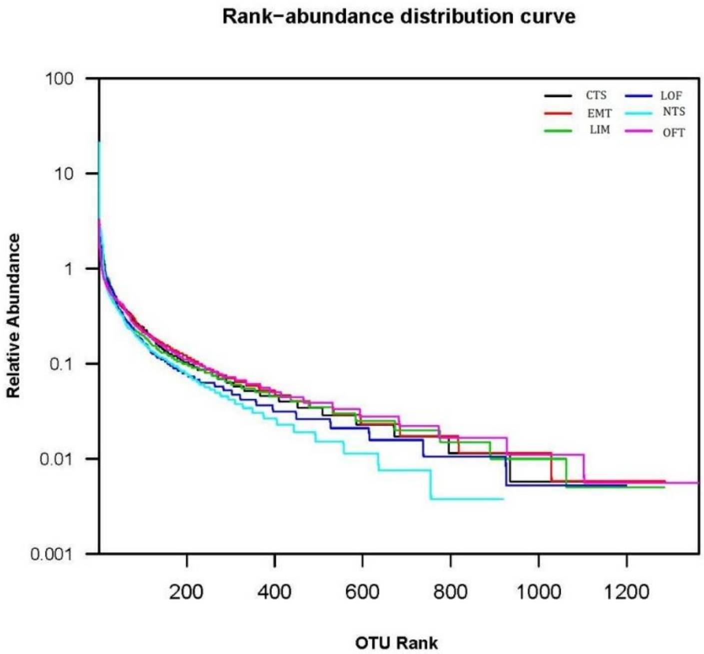

Figure 3. *OTU Rank-abundance curves for the OTUs in the soil samples of different treatments*

All sequences were classified into 51 phyla or groups using Mothur program. The overall bacterial composition was relatively consistent across treatments, whereas the distribution of each phylum or group varied among treatments (*Figure 4*). Under all treatments, *Proteobacteria*, *Acidobacteria*, *Bacteroidetes*, *Planctomycetes*, and *Actinobacteria* were the five most dominant phyla, accounting for > 70% of the total

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46554676

reads. Significantly more unclassified species were detected under the CTS, EMT, LIM, LOF, and OFT treatments, which was in accordance with the higher diversity indices for these treatments. Compared with the other treatments, soils from the EMT had significantly higher percentages of *Actinobacteria* (1.3–6.5-fold), *Armatimonadetes* (1.2–7.3-fold), *WA3* (1.0–4.8-fold), and *Chlorobi* (1.6–34.5-fold), and lower percentages of *Planctomycetes* (CTS: 5.6%, EMT: 5.1%, LIM: 5.8%, NTS: 6.8%, LOF: 3.8%, and OFT: 6.1%). The percentages of *Actinobacteria* and *Firmicutes* were lowest in soils from the LOF treatment. More *Cyanobacteria* were detected in soils from the CTS treatment than from the LIM or LOF treatments, and the lowest number of *Cyanobacteria* was found in soil from the NTS treatment. A higher percentage of *Lysobacter* was found in NTS than it in other treatments. All fertilization treatments significantly impacted bacterial community structure. The abundance of *Lysobacter*, *RB41*, *Steroidobacter*, and *Planctomycetaceae* was lower in the NTS than in the LOF treatment soil. Compared with the CTS, *Xanthomonas*, *Oxalobacteraceae*, *Lineage_IIb*, and *Nitrospira* relative abundances increased in the EMT and OFT treatment soils, whereas *Haliangium* and *Sphingomonas* relative abundances decreased under these two treatments. The relative abundance of all 50 detected genera is listed in *Table A3*. *Lysobacter*, *Rhodospirillaceae*, *Comamonadaceae*, *KCM-B-112*, *Xanthobacteraceae*, and *Sporocytophaga* abundances were significantly greater in NTS treatment soil compared with CTS treatment soil, whereas *Acidobacteriaceae*, *Arenimonas*, *Sorangium*, *Rhizobium*, *Lineage_IIb,* and *Flavobacterium* abundances were higher in CTS than in NTS.

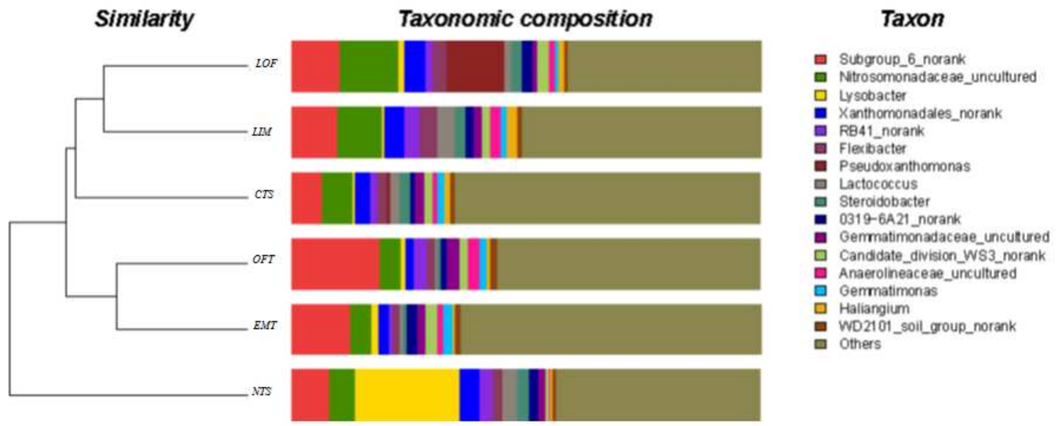

Figure 4. *Comparison of the bacterial communities at the gene level. The branch structure is used to describe and compare similarities and differences between multiple treatments. The hierarchical clustering according to beta diversity distance matrix (Hierarchical clustering) analysis. A tree structure was constructed by using the unweighted pair group method with arithmetic mean (UPGMA) algorithm*

On a genus level, all 412 detected genera were observed in soils from all treatments, except for *Xanthomonas,* which was not detected in NTS or LIM treatment soils, and *Sporocytophaga,* which was not detected in EMT or LOF treatment soils. Results of the cluster analysis for the 100 most abundant genera (assessed through counts of OTUs) within soil samples from the six treatments are displayed on a heatmap (*Figure A3*). Soils from the six treatments were classified into two groups (continuous cropping and untilled soil) according to their bacteria genera composition (*Figure 4*). The continuous

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46554676

cropping group (EMT, OFT, CTS, LIM, and LOF) subdivided into a bio-fertilizer and non-bio-fertilizer group. The untilled soil group was made up of only the NTS treatment. The taxonomic information for the OTUs was used to develop the phylogeny. The phylogenetic classification was used to analyze the relationships between microbial ancestry and abundance within soil samples from the different treatments.

In order to further investigate bacterial community composition among the different treatments, we performed a PCoA on the relative abundance of bacterial genera (*Figure 5*). Data are presented as a 2D plot to better illustrate the relationships. The PCoA clearly separated CTS from NTS. Values for LIM, LOF, EMT, and OFT grouped together along the PC1 axis. Although EMT and OFT were relatively similar, the different bio-organic fertilizer significantly affected the soil microbial community. NTS had a significantly higher PC1 value, and EMT had a higher PC2 value than other treatments.

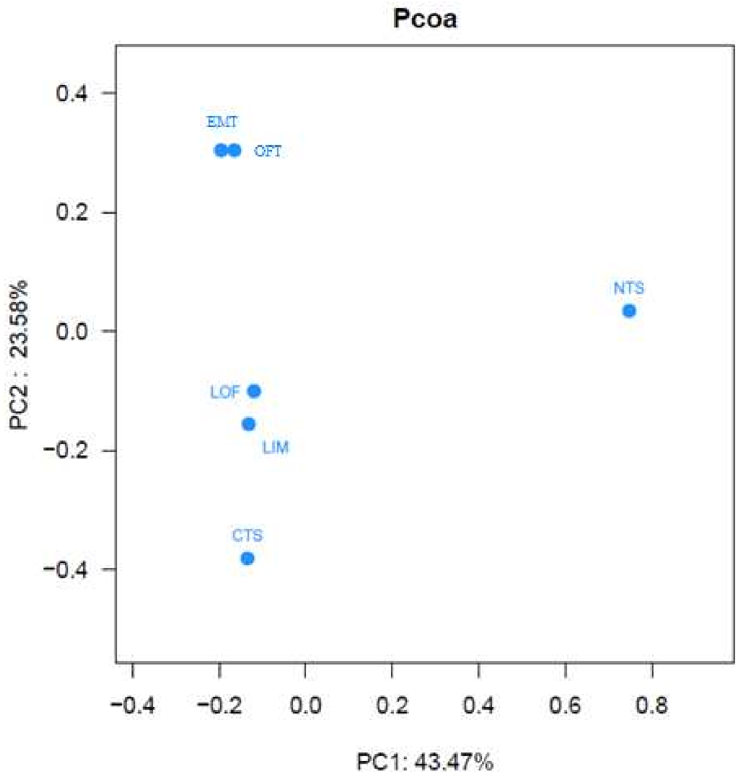

Figure 5. *Principal co-ordinates analysis (Pcoa) on the relative abundance of bacterial genera. Principal components (PCs) 1 and 2 explained 43.47% and 23.5% of the variance, respectively*

Relationships between bacterial community composition and environmental variables

According to the forward-selection CANOCO, soil organic matter and total N concentration, which accounted for 27.4% and 1.75% of the variation in bacteria community composition, were the two most important contributors to the variation among bacterial communities (*Figure 6*). All environmental variables together explained 79.3% of the variation in microbial communities composition among treatments. The soil properties, in order of decreasing influence on the bacterial community composition were: OM, TN, GY, TP, pH, CCY, available N, available P.

DOI: http://dx.doi.org/10.15666/aeer/1702_46554676

The correlation (or covariance, depending on the standardization option used in the analysis) between phyla and environmental variables can be approximated through projections of two perpendicular vectors, representing each of the phyla and environmental variable. Most of the abundant phyla were significantly correlated with at least one environmental factor. However, *Sphingomonas*, *Nitrospira*, *Haliangium*, *Myxococcales*, *Flexibacter*, and *Nitrosomonadaceae*were did not significantly correlated with any of the environmental factors. The abundances of *Chitinophagaceae*, *Aquicella*, *Xanthomonadales*, *Solimona*, *Bacillus*, *Gaiella*, *Piscinibacter*, *Gemmatimonadaceae* were positively correlated with soil TN, OM, pH, and available N, whereas *Planctomycetaceae*, *Comamonadaceae*, *Lysobacter*, *Xanthobacteraceae*, and *Sporocytophaga* were positively correlated with TP. The phylum was correlate with garlic yield and Chinese cabbage yield, for some orders, such as *Nitrosomonadaceae*, *Haliangium*, *Flexibacter*, etc.

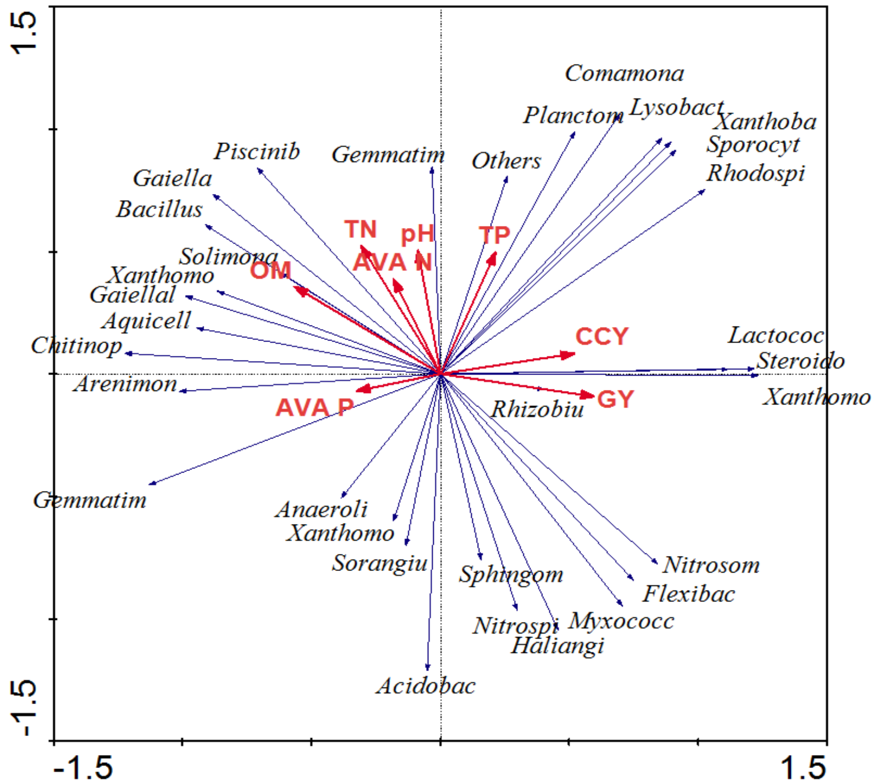

Figure 6. *RDA of soil bacterial communities and soil characteristics for each treatment. Soil factors indicated in red line include AVA P (available phosphorus), AVA N (available N), OM (organic matter), TN (total nitrogen), TP (total phosphorus), GY (garlic yield), CCY (Chinese cabbage yield), pH*

Discussion

This research approach provides insight into how soil chemical and biological properties, total bacterial community structure and soil extracellular enzyme activities respond to the contrasting lime, bioorganic fertilizer and EM to control and suppress the clubroot. Short -term soil conditioners significantly impacted soil nutrient availability, and in turn affected soil microbial community structure and function. Bacterial

DOI: http://dx.doi.org/10.15666/aeer/1702_46554676

community diversity, biomass and enzyme activities involved in nutrient transformations were enhanced in treatments receiving annual applications of soil conditioners and chemical fertilizers.

Continuous cropping with two crops in a monoculture system caused root disease and decreased soil nutrient levels and pH

This Clubroot is a major issue when brassica crops are grown in short rotations (McGrann et al., 2016). Clubroot has spread rapidly across the major Chinese brassica growing regions and become established as a serious threat to production (Shakeel et al., 2016).

Many indicators of soil quality can be manipulated through long-term raw manure and mineral fertilization under monoculture continuous cropping systems. Continuous cultivation over 35 years can cause reductions in soil pH, TN, and OM compared with NTS treatment soil. Long-term raw manure fertilizer application and monoculture cropping can decrease soil pH (Wang et al., 2015). Previous studies have found the magnitude of raw manure fertilization effects on microbial biomass to be pH-dependent, which agrees well with the results reported in this study. This was also observed in our trial where microbial biomass increased with amendments application rate, regardless of the input type (*Figure 2*). The mechanism underlying declines in pH and nutrient levels with long-term monoculture cropping may be an accumulation of organic acids caused by repeated raw manure application, and leading to that in an accumulation of organic acids which decrease the ability to keep water and fertilizer deteriorated soil structure. This is consistent with the previous reports (Gaind and Singh, 2016). In this case, the similar effects on available nutrients can be concluded from the data. These findings suggest that soil pH influenced microbial activity resulting in different rates of N and P mineralized, which is supported by the variation in activities of enzymes involved in N and P cycling (e.g. urease and phosphatase) observed in this study.

Effects of soil amendments on soil pH and nutrients

It is difficult to control clubroot because the pathogen survives long periods in the soil for a long time as resting spores. Previous research has provided evidence that soil pH can influence clubroot, and liming arose as a conventional technique to control the clubroot through its influences on soil pH (Chai et al., 2014).

Niwa et al. (2007) found neutralization of soil using $Ca(OH)_2$ and $CaCO_3$ to suppress clubroot infections. Clubroot is suppressed effectively under soil of neutral pH in the presence of calcium, which has led to the hypothesis that either spore germination or root-hair infection, each part of the primary phase of the clubroot life cycle, is inhibited under such conditions (Niwa et al., 2008). In addition to these abiotic factors, it has been suggested that the microbial community can contribute to clubroot suppression. Ruaro et al found a negative correlation between severity of clubroot infection and foliage N, Ca, Mg, and B concentrations and a reduction in infection when soil was adjusted to pH 6.5 and treated with calcium nitrate (Ruaro et al., 2009). Therefore, in soils with abundant nutrients and nearly neutral pH levels, the infection of host plants with the clubroot fungus is suppressed. In this case, pH and total N and SOM content increased markedly contrasted in LOF ,OFT and EMT. Available nutrient and carbon concentrations affected the physiology of the host plant and subsequent disease development.

Soil amendment strategies increased bacterial richness and enzyme activities

Otherwise the untilled soil(NTS), contrasted with infected soil(CTS, LIM, LOF, EMT and OFT), is healthy and retained higher biomass. In terms of microbial activity, functional diversity was suppressed in the diseased soil samples. Activities of soil enzymes, including urease, phosphatase, and sucrose, were also reduced in infected soils. Soil urease, phosphatase, and catalase activities were determined in order to assess the potential turnover rates of soil carbon and nitrogen (Zhang et al., 2016). Enzymatic activities in diseased soils were inhibited by 45.1 to 169.2% in the LOF, EMT, OFT, LIM and CTS. In our study, the higher soil microbial biomass under the EM and organic fertilizer treatments may have been due to the addition of microbial population in the treatment and the additional C, which activates the soil indigenous microbiota. The lime was added into the infected soil that resulted in the increased pH and induced the bacterial growth. Our results corroborated findings of previous researchers. They have suggested lime and bio regulators can stimulate enzyme activities (Shrestha et al., 2015). We also found soil amendments to infected soil altered soil pH and available nutrients in favor of increasing top soil enzymatic activities and bacterial richness. It was interesting to note that we observed greater increases to soil pH through organic fertilizer application than previous studies. This suggests a threshold effect of the influences of ecological factors on enzyme activities and bacterial biomass in diseased soils (Lagerlof et al., 2015). The activity of Polyphenol oxidase was significantly higher than other treatments in the top soil. Polyphenol oxidase (PPO) is an extremely effective soil acidity and nutrient modifier. Studies have shown that PPO can contribute to pathogen resistance, especially resistance to opportunistic pathogens. Another potential effect of PPO is elevated oxidative stress in the soil (Yakushev et al., 2014). Previous researchers have suggested that potential enzyme synthesis rates were determined by microbial community composition. Although further research on the relationships between individual microorganism species, functional activities, and soil-borne pathogens is required, our results provide strong evidence of links between the microbial community composition and functional activities.

Soil amendment strategies changed bacterial community compositions

Many factors may affect the structure and function of bacterial communities within the rhizosphere soil (Simmons et al., 2016). In our study, the Chao 1 index, which is representative of bacterial phylotype richness levels, showed healthy soil (NTS) to have the highest bacterial diversity among the six treatments (*Table 3*). Diseased soil had lower bacterial richness than healthy soil. The phylum assignment results identified 99.99% of the 16S rRNA sequence reads as bacteria belonging to 16 phyla; *Lysobacter* was the dominant phylum in the healthy soil samples (NTS) (*Figure 4*). The *Xanthomonadale*and *Bacillus* phyla were significantly more abundant in healthy rhizosphere soil than in diseased soil ($P<0.05$). Otherwise, the abundances of the *Gemmatimonas*, *Acidobacteriaceae*, *Sorangium,* and *Rhizobium* phyla were higher in diseased samples (CTS) (*Table A3*). These results suggest that that the bacterial community structures were similar in diseased and healthy soils. *Lysobacter* and *Xanthomonadale*, two mainly species within the Stenotrophomonas genus were multidrug-resistant opportunistic pathogens (Dhawan et al., 2016). This was interesting because it was generally accepted that these phyla are sensitive to changes in nutrient levels. Our results provided strong evidence that these phyla respond to soil-borne

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46554676

pathogens when the rhizosphere soil was amended, although mechanisms underlying this process were not addressed in this study. Kobayaschi et al. (2011) have also shown *Lysobacter*to possess antifungal properties, specifically against *Phytophthoracapsici*, a destructive pathogen of pepper plants (Ko et al., 2009). Previous studies have concluded that shifts in soil microbial community abundance and composition can significantly influence nutrient cycle dynamics and improve resistance to pathogens (Chavez-Romero et al., 2016). Therefore manipulations of soil acidity to a suitable pH and addition of organic manure can effectively improve soil resistance to various pathogens.

Relationships between soil properties and bacterial community composition

We hypothesized that populations of bio-control bacteria will be stimulated by adjusting the content of different substrate in soil so as to reduce the number of pathogens microbial and achieve the goal of preventing risk of cabbage infected by pathogen. Our hypothesis could be proved by the results of recent two years trial experiment (see *Figure 4*). The observed changes to bacterial community composition can be explained by the strong influences of soil amendments on soil chemistry, such as nutrients bioavailability. The higher TN, pH and OM in the surface layer soil significantly increased these bacterial phylotype richness compared with untilled soil. Similar effects were seen for total phosphorus and plant yield (*Figure 6*). These results may be explained by effects of different C substrates on host plants (Bergkemper et al., 2016). Another mechanism through which soil bacterial communities can be modified is resource availability. Large amounts of antibiotics were introduced to the soil environment with manure amendment, and a previous study showed cow manure to shift the bacterial community structure in clay soil (Fernandez et al., 2016). The relative abundance of antibiotic bacteria (*Xanthomonadales*, *Lysobacter*, *Pseudomonas*, and *Bacillus*) present within the soils treated with the bio-organic fertilizer was greater than for the soils treated with lime because of the greater organic matter and total nitrogen content of the bio-organic fertilizer. These results were similar to the observation of a previous study (Wang et al., 2016). The cause of antibiotic resistance is multifaceted, including over use, inappropriate use, and regulatory incompetence, and results in a deficiency of useful antibiotics for clinical use. The results of this study suggest that bio-organic fertilizer can be used to suppress crop pathogens.

Conclusions

Severity of brassica crop infection with clubroot is known to be linked to pH and soil nutrient content. Soil amendments, which raise pH and/or soil nutrients content, can be applied to control clubroot infection of vegetable brassica crops and manipulate bacterial community abundance and composition. The results of this study provide important insights into the influences of soil amendment strategies on the microbial community structure within monoculture agricultural systems and identify the major factors shaping microbial communities. Therefore, further research focuses on revealing the relationship between soil microbial diversity and function, and establishing a direct and quantitative relationship between soil microbial diversity and function. And the relationship between soil microbial diversity and pathogenic function of pathogenic bacteria could been revealed furtherly.

Abstract. In arid regions, vegetation growth relies on water availability. Climate change can alter water cycling with subsequent effects on vegetation growth. This study examined the effects of projected climate change on vegetation greenness in the middle-reaches region of the Heihe River Basin, the second largest inland basin in China. The relationship between the Normalized Difference Vegetation Index (NDVI), an indicator of vegetation greenness derived from remote sensing data, and meteorological factors of precipitation and temperature was simulated using a modified statistical vegetation index simulation model. The model predicted that along with increases in precipitation and temperature, spring and autumn NDVI will rise about 3.8% and 7.9% by the 2050s, respectively. NDVI in summer increases about 3.9%, as increased precipitation may be superior to higher rates of soil water evaporation due to rising temperature. Hydrological processes in the Heihe River Basin are highly influenced by both climate change and human activities. The findings of this study are valuable for the development of water resource management policies that balance the water demands of both human society and the natural ecosystem.
Keywords: *NDVI, remote sensing, arid region, vegetation greenness, climate change*

Introduction

Drylands occupy more than 40% of terrestrial Earth (Slaymaker et al., 1998). The land area desertified or prone to desertification has been estimated as 57–65% of the total area of dryland ecosystems (UNEP, 1992). Land degradation in drylands has negative influences on global food security (MEA, 2005; Tscharntke et al., 2012; Weston et al., 2015). Natural vegetation plays an important role in maintaining dryland ecosystem functions (Lal, 2004; Zethof et al., 2019). As a result of the tight coupling among water, energy and biogeochemical cycles in drylands, vegetation dynamics strongly influences water cycling and responses to climate change and human activity in these systems (Wang et al., 2012; Ott et al., 2016). Natural vegetation in arid regions is particularly affected by temperature and precipitation at different temporal and spatial scales (Stellmes et al., 2010; Gessner et al., 2013; Li et al., 2015). Better understanding

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46774691

of plant growth responses to climatic changes will provide important insight into hydrological processes in drylands because plant growth relies on water availability.

Determination of the influence of climate change on vegetation requires long-term observation. Field observations of vegetation growth, however, are time- and labor-consuming. Remote sensing is an effective alternative way to monitor temporal trends in vegetation growth and changes in ecosystem function (Pouliot et al., 2009; Li et al., 2013; Wu et al., 2014; Liu et al., 2016). Among numerous vegetation indexes derived from remote sensing, the Normalized Difference Vegetation Index (NDVI) is widely regarded as a good proxy for terrestrial vegetation growth. NDVI, the ratio of the difference in near-infrared and red reflectance and the sum of these two variables, estimates the photosynthetically active radiation absorbed by photosynthesizing tissue (Fensholt et al., 2004). Trend analysis of NDVI data has generally been used to detect changes in vegetation dynamics at continental or regional scales. Many studies (e.g., Piao et al., 2006; Fensholt et al., 2012; Krishnaswamy et al., 2014; Wu et al., 2014) have reported strong correlations between NDVI and meteorological factors including temperature and precipitation. Los et al. (2006) built a statistical vegetation index simulation (SVIS) model to estimate the coupling strength of NDVI with temperature and precipitation using a satellite-derived monthly vegetation index and meteorological data. The model is potentially useful for predicting the response of natural vegetation to climate change in regions where field data are sparse.

The Heihe River Basin in arid northwest China is the second largest inland basin in China. The basin is adjacent to the north edge of the Qinghai-Tibetan Plateau and is characterized by diverse geomorphology. As the transition zone between the upper-reaches region of the Heihe River Basin in the southern Qilian Mountains and the lower-reach region in the northern Alxa Desert, the middle-reaches region is ecologically unique (Lu et al., 2003). It is well known for its irrigated agriculture using river water and pumped groundwater, which alters natural water cycling. Thus, natural vegetation in this region is vulnerable to both climate change and human activities (Qi and Luo, 2007; Sun et al., 2015). The objective of this study is to explore how the greenness of the Salsola passerina, which is an annual C4 plant and one representative plant in the middle-reaches region, responses to future climate changes by using a modified version of the SVIS model forced with a future climate change scenario. The prediction made by the model is important to develop water resource management policies that balance the water demand of human society and the natural ecosystem. A high-resolution meteorological forcing dataset was used as model input to account for the high spatial heterogeneity in dryland precipitation and temperature. The future climate change scenario was built by using the downscaled ensemble output of 16 general circulation models (GCMs).

Materials and methods

Study area

The Heihe River Basin (*Fig. 1*) originates in the Qilian Mountains in the northern edge of the Qinghai-Tibetan Plateau, covering an area of about 142,900 km^2. The elevation of the basin gradually decreases from the high mountain area in the south to the northern high-plain area. The Heihe River Basin is not influenced by the East Asian monsoon and has a very dry climate, with an average annual precipitation of 100–450 mm. Differences in geomorphology divide the basin into three regions: the upper-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46774691

reaches region is in the Qilian Mountains; the middle-reaches region is part of the Hexi Corridor Plain; and the lower-reaches region is on the Alxa Plateau. The middle-reaches region is the most populated. River water and pumped groundwater are the main water resources for irrigation and domestic use. Gobi and cropland are the dominant types of land cover. Cropland is mainly distributed in the oases near the main stream, and Gobi mainly occurs between the northern edge of the Qilian Mountains and the river. The Salsola passerina is one representative natural plant in the Gobi region.

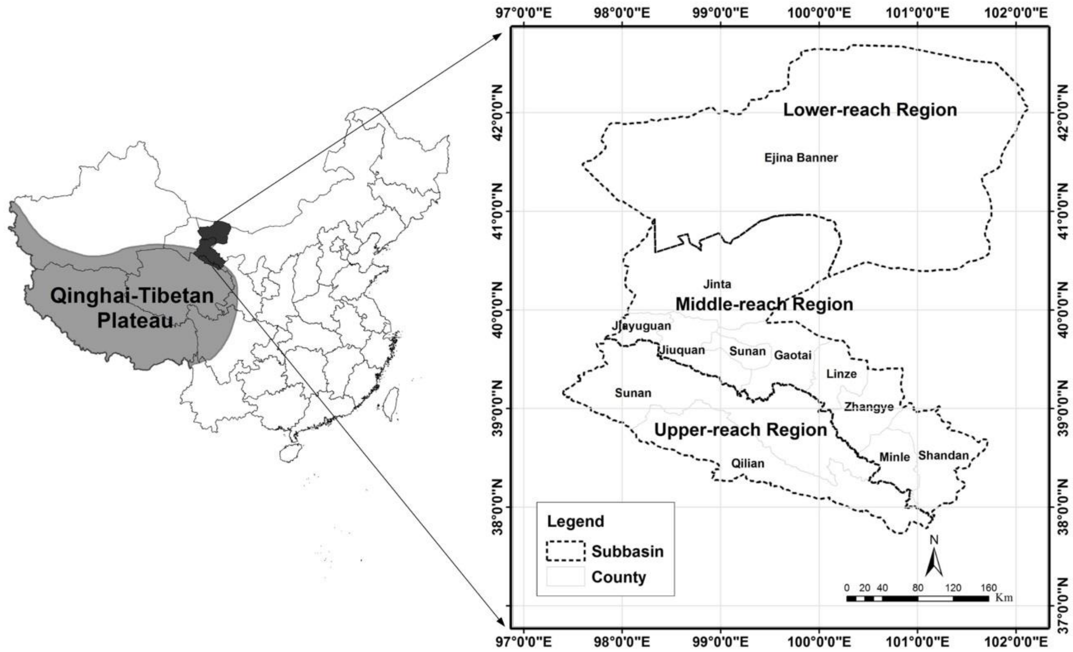

Figure 1. *Heihe River Basin and its location in China*

Dataset and preprocessing

The third generation of Global Inventory Modeling and Mapping Studies (GIMMS) NDVI dataset used in the study extends from 1982 to 2010 with an 8-km resolution and was obtained from NASA Ames Ecological Forecasting Laboratory (http://ecocast.arc.nasa.gov/data/pub/gimms/). The GIMMS data are derived from imagery taken from National Oceanic and Atmospheric Administration (NOAA, USA) satellites. Based on a field survey in 2014, a pixel of the NDVI dataset in which Salsola passerina was the dominant vegetation was selected for simulation. The location of the pixel and the characteristic landscape in this area are shown in *Figures 2* and *3*, respectively. To reduce the noise in the data, the maximum value composite method was used to generate 8-km resolution monthly NDVI data from the two images of each month. The averages of monthly NDVI and its standard deviation for 1982–2010 are shown in *Figure 4*. A sharp increment is found between March and April. And the NDVI in November is much lower than that in October. Following the definitions of Piao et al.(2011), NDVI averages from April to October represented the annual growing season, while April and May were considered spring, June to August were considered summer and September and October were considered as autumn. *Figure 5* shows the time series of growing season NDVI for the period of 1982–2010. No statistical trend has been detected at temporal domain.

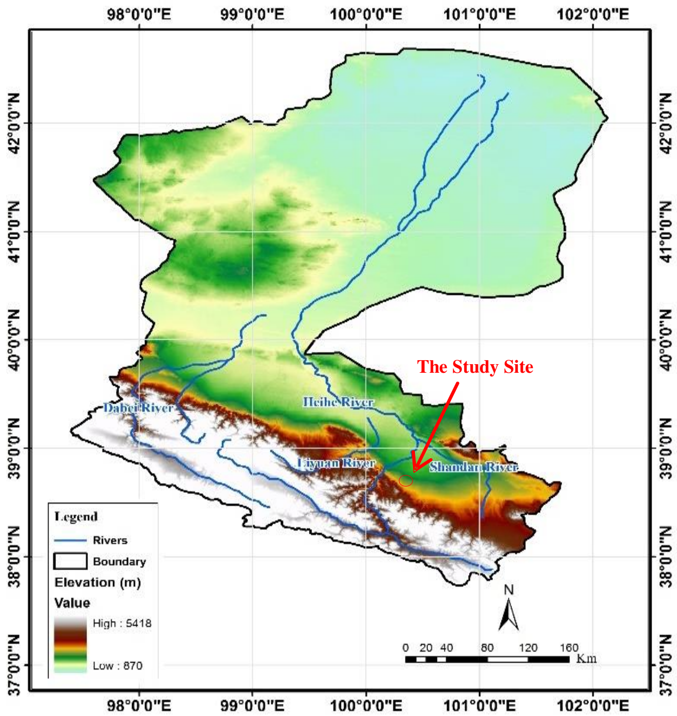

Figure 2. Location of the study site in the Heihe Basin

Figure 3. Landscape at the study site during a field survey in June 2014

The meteorological dataset used in the study covers 53 years (1958 to 2010) with spatial and temporal resolutions of 5 km and 3 h, respectively, and was developed by the Land-Atmosphere Interaction Research Group at Beijing Normal University (http://globalchange.bnu.edu.cn/research/forcing). Seven meteorological variables (i.e., air temperature, air pressure, relative humility, wind speed, precipitation, shortwave radiation and longwave radiation) were produced by combining gauge observations with reanalysis data or remote sensing data (Li et al., 2014; Huang et al., 2014). The air temperature and precipitation data from the above mentioned meteorological dataset are used in this study. Within the spatial extent of the selected NDVI pixel, air temperature and precipitation data for 1982 to 2010 were resampled to produce corresponding meteorological data. The monthly total precipitation and mean air temperature were given as the respective sum and average of the data within each month.

Statistical vegetation index simulation model

The SVIS model is a conceptual model that investigates the relationship between vegetation greenness derived from remote sensing data (NDVI) and meteorological variables using multiple linear regression analysis. SVIS can predict monthly NDVI using precipitation and temperature data from the current month and the two previous months to account for the time-lag effect of meteorological factors on vegetation growth. The feasibility of the model was verified by Los et al. (2006). The model is defined as *Equation 1:*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46774691

$$V_t = a + \sum_{i=-2}^{0} b_{t,2+i} p_{t+i} + \sum_{i=-2}^{0} c_{t,2+i} T_{t+i} + \sum_{m=-2}^{-1} d_{t,2+m} V_{t+m} \quad \text{(Eq.1)}$$

where P and T are the precipitation and temperature of the current month (t) and two previous months (t-2) and (t-1); V_t, V_{t-1} and V_{t-2}, are the NDVI of the current month t and two previous months (t-2) and (t-1); and a, b, c and d are parameters describing relationship between NDVI and the two meteorological variables.

In this study, rather than using multiple linear regression analysis, an Artificial Neural Network (ANN) was used to describe the relationship between NDVI and the meteorological variables. The development of ANN was inspired by the functionality of biological neural networks such as the human brain. Biological neural networks learn quickly from experiences and interactions between the internal and external environment to establish pattern recognition. ANN is recursive and can continually learn from the given dataset, which has proven to be efficient and time saving. ANN can also be used for the simulation of complex and nonlinear processes. The ANN model used in this study is of the form (*Eq. 2*):

$$V_\mathrm{i} = f\left(P_i, P_{\mathrm{i}-1}, P_{\mathrm{i}-2}, T_i, T_{\mathrm{i}-1}, T_{\mathrm{i}-2}\right) \quad \text{(Eq.2)}$$

where V_i, P_i and T_i are the NDVI, precipitation, and temperature of the ith month in a year; and P_{i-1}, P_{i-2}, T_{i-1} and T_{i-2} are the precipitation and temperature of two previous months *(t-1)* and *(t-2)*, respectively. f represents the nonlinear relationship between the meteorological input and NDVI output derived from the ANN. The model performance indicators were the squared correlation coefficient (R^2) and the mean absolute difference (*MAD*) as *Equations 3–4:*

$$\mathrm{R}^2 = \frac{\left[\sum_{i=1}^{n}\left(V_{obs,i} - V_{obs,a}\right)(V_{sim,i} - V_{sim,a})\right]^2}{\sum_{i=1}^{n}\left(V_{obs,i} - V_{obs,a}\right)^2 \sum_{i=1}^{n}\left(V_{sim,i} - V_{sim,a}\right)^2} \quad \text{(Eq.3)}$$

$$MAD = \frac{1}{n}\sum_{i=1}^{n}\left|V_{obs,i} - V_{sim,i}\right| \quad \text{(Eq.4)}$$

where $V_{obs,i}$ and $V_{sim,i}$ are the observed (GIMMS dataset) and simulated NDVI at time step i, and $V_{obs,a}$ and $V_{sim,a}$ are the average observed and simulated NDVI over the whole training or validation period. The simulation is made for the period of 1982 to 2010. In order to make the training period cover various climatic condition of the study site, the data of even-numbered years in this period were used to train the model. And data of odd-numbered years were used for model validation.

Future scenarios under climate change

After development, the model was applied to predict vegetation greenness under future climate change scenarios. The GCMs need to be downscaled because their outputs are too coarse to describe climatic characteristics at the regional scale. Moreover, uncertainties in climate projections from GCMs require consideration. To make a more reliable future regional climate change scenario, usually an ensemble

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46774691

analysis combing multiple GCM analysis and quantifying the probability of future climate is conducted. The Climate Wizard dataset (available at: http://www.climatewizard.org/index.html), projections of future temperature and precipitation derived from ensemble average of 16 Coupled Model Intercomparison Project phase 3 (CMIP3) GCMs, is adopted in this study to reduce possible uncertainties of GCMs. The monthly precipitation and mean temperature was downscaled to the resolution of 50 km using an empirical statistical method (details are available in Palmer et al., 2004). The data of the 2050s (2040–2069) for A1B scenario (medium CO_2 emission) were used to build regional climate change scenario of the mid-21st century at the study site. According to the intergovernmental panel on climate change special report on emission scenario, the A1B scenario corresponds to rapid growths in economy and global population, which reaches peaks in the mid-21st century and declines following a slowing growth, and is a moderate scenario for greenhouse gas emission. This study focus on how the vegetation growth responses to intermediate climate change scenario and discussions about extreme scenario are out the scope of this study. Therefore, the climate projection under A1B scenario is used in our research. It is widely used for examining potential vegetation response in the future to climate changes in previous studies (e.g., Alo and Wang, 2008; Smith et al., 2011; Waha et al., 2013). Percentage change in monthly precipitation between projections for the 2050s and the past 50 years was used to scale monthly precipitation data for 1982–2010. The absolute difference in monthly temperature between the projected (2050s) and historical (past 50 years) climate was added directly to monthly temperature data for 1982–2010. Using the future climate change scenario as input, the NDVI prediction made by the ANN model represents the status of vegetation growth in the 2050s. NDVI simulated using meteorological data from 1982–2010 was considered the baseline. The differences between the two simulations are considered as the impact of climate change on vegetation growth. Model prediction excluded the winter period and was conducted only for months during the growing season (April to October).

Results and discussion

Seasonal fluctuation in vegetation greenness and meteorological factors

Time series of monthly precipitation, temperature, and NDVI in the Heihe River Basin from 1982 to 2010 revealed unimodal seasonal patterns (*Figures 6* and *7*). Intra-annual variation patterns in the two meteorological variables were consistent with that of NDVI. All three variables showed periodic variation with maximum values in summer or fall and minimum values in winter. Average summertime NDVI was 0.38. Average wintertime NDVI was 0.11, indicating the existence of a winter dormant period. Analysis of the multi-year averaged NDVI data from 1982 to 2010 indicated that from the beginning of spring (April) to the beginning of summer (June), NDVI increases with an average magnitude of 0.32 (*Table 1*). NDVI remained high during the two subsequent summer months. *Table 1* also shows that NDVI decreases with an average magnitude of 0.20 from the end of summer (August) to the beginning of winter (November).

For both temperature and precipitation, absolute values of the increases from the beginning of spring to the beginning of summer were smaller than that for the decrease from the end of summer to the beginning of winter (*Table 1*). In contrast, the magnitude of increase in NDVI was greater than the magnitude of decrease in the same periods, indicating a time lag in NDVI response to changes in precipitation and temperature. This time lag was the justification for the use of both the current and the previous two months' meteorological data for monthly simulation of NDVI.

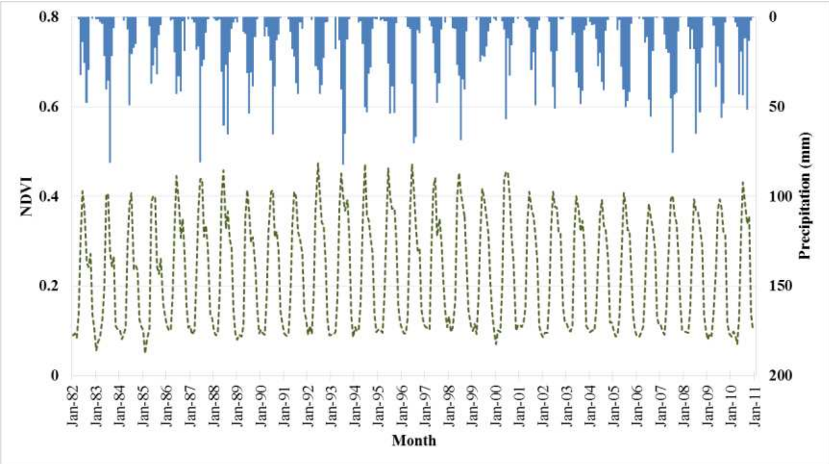

Figure 6. *Time series of monthly NDVI (green dashed line) and precipitation (blue bars) for 1982–2010*

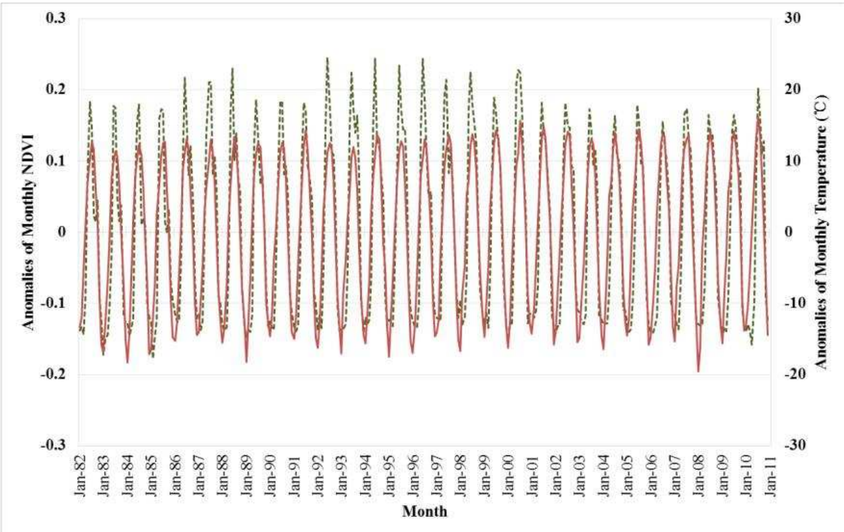

Figure 7. *Anomalies of monthly NDVI (green dashed line) and temperature (red line) for 1982–2010*

Influence of future climate change on vegetation greenness

The monthly observed and simulated NDVI values from 1982 to 2010 are shown in *Figure 8*. Simulations reproduced the timing and range of variation in NDVI reasonably well. The scatter plot of observed to simulated NDVI values demonstrated a strong correlation from the low to high ranges of NDVI (*Fig. 9*). Although R^2 and *MAD* values were lower for model validation than for model training period (*Table 2*), model performance was high enough for both to justify the use of the model for prediction.

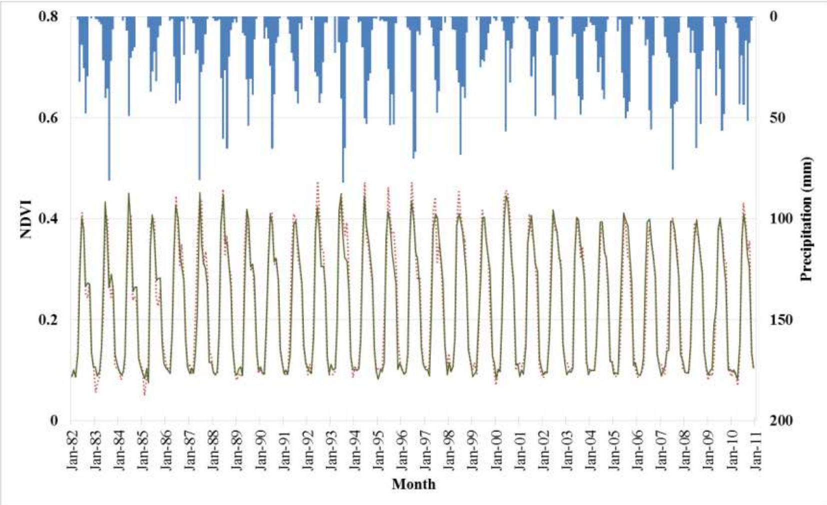

Figure 8. *NDVI simulations from 1982 to 2010 in the study area (precipitation: blue bars; observed NDVI: red dashed line; simulated NDVI: green line)*

Table 2. *Model performance for training and validation periods*

Performance indicators	Training period (even-numbered years for the period of 1982 to 2010)	Validation period (odd-numbered years for the period of 1982 to 2010)
R^2	0.979	0.922
MAD	0.0117	0.0243

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46774691

Projected monthly meteorological data for the 2050s under the A1B scenario were used as input for the modified SVIS model to simulate future variation in vegetation greenness. *Figures 10* and *11* depict the changes in monthly precipitation and mean temperature in the Heihe River Basin between the baseline and future climate scenario for the 2050s. Simulations predicted increases in mean monthly precipitation in all months except July, with particularly high increases (>30%) from November to March. Monthly mean temperature was predicted to increase in all months in the 2050s scenario, with an average increase of 2.77 °C. Both precipitation and rainfall were predicted to increase in spring, summer and winter (*Fig. 12*).

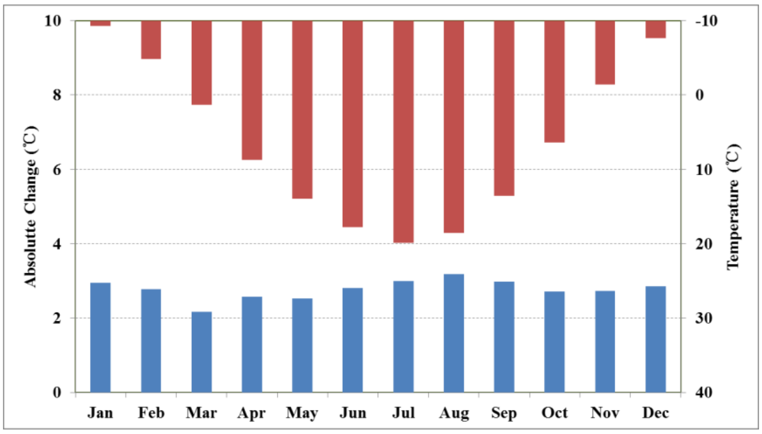

Figure 10. *Monthly temperature in the baseline period (red bars) and absolute changes of monthly temperature between baseline period and the projected climate scenario for the 2050s (blue bars)*

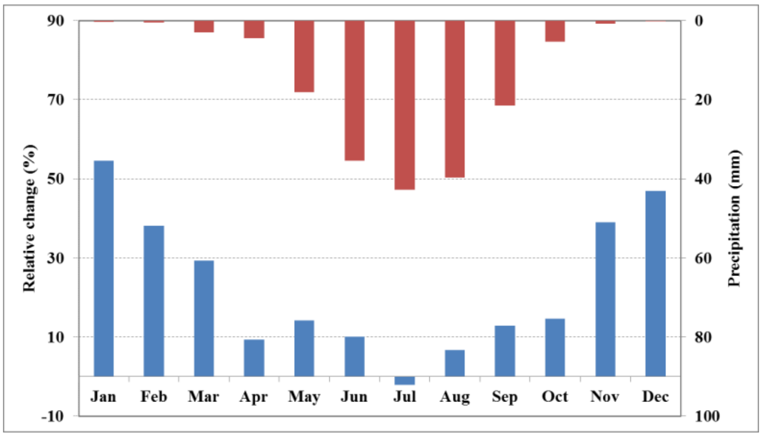

Figure 11. *Monthly precipitation in the baseline period (red bars) and absolute changes of monthly precipitation between baseline period and the projected climate scenario for the 2050s (blue bars)*

Future climatic scenario and predicted seasonal changes in NDVI are shown in *Figure 12*. Compared with the baseline period, spring and autumn NDVI were predicted to increase 3.8% and 7.9%. Increased precipitation would raise soil water content, benefitting vegetation growth. Carl et al. (2013) demonstrated that global warming may cause temporal shifts in phenology. More specifically, Piao et al. (2008) and Richardson

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46774691

et al. (2010) indicated that increasing spring and autumn temperature extend the length of growing season and correspondingly the days for biomass growth becomes more available. Yang et al. (2012) indicates that, among different climate factors, temperature and precipitations have closest relations with NDVI. Together, for the study site, increased temperature and precipitation may explain projected increases in NDVI with climate change of spring and autumn. In summer, there is an increase of 3.9% for future NDVI. Both temperature and precipitation rises in summer of the 2050s. Rising temperature would increase the energy available for soil water evaporation and thus reducing the soil water content available for vegetation growth. However, the reduction in soil moisture may be compensated by the increases in precipitation and these increases even finally lead to a rising in soil moisture, which may be the reason that NDVI become higher in summer of the 2050s.

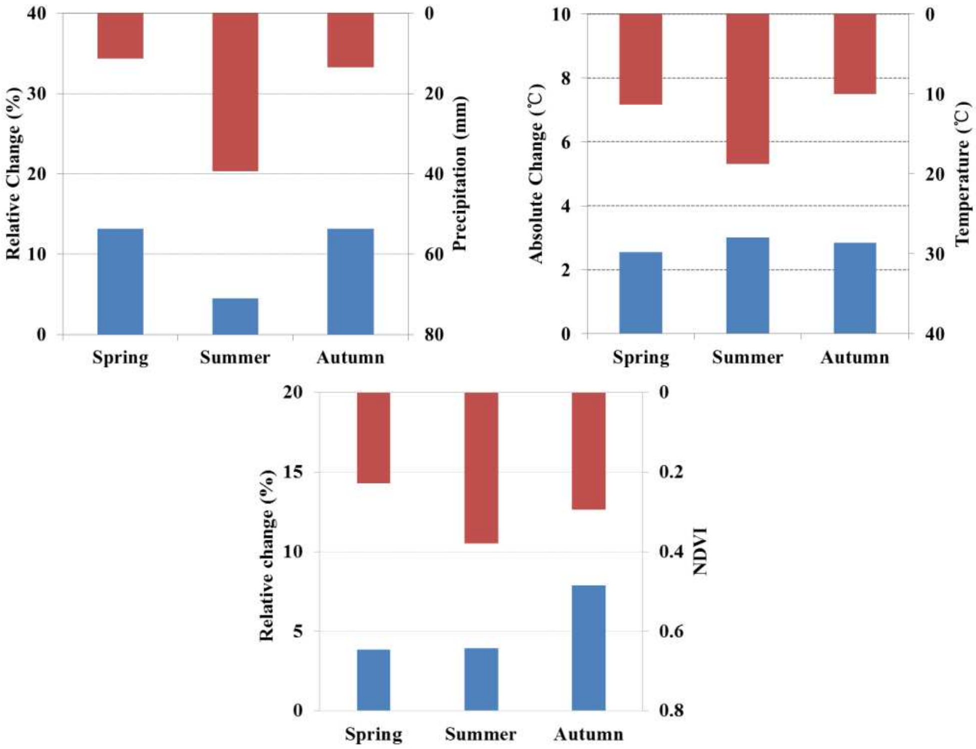

***Figure 12.** Average changes (blue bars) in seasonal mean precipitation, temperature and simulated NDVI between baseline (red bars) and the projected climate scenario for the 2050s*

Our prediction shows that for this dominant shrub in the study area, i.e. Salsola passerina, the vegetation greenness become better with the increases in temperature and precipitation. By using a dynamic global vegetation model forced with future climate change scenario, similar results are obtained by Gao et al. (2016) in the Qinghai-Tibetan Plateau, which is adjacent to the Heihe River Basin. Different results are revealed in the study of Gremer et al. (2015), which found that C4 grassland cover negatively responded to mean annual precipitation in the dryland across the south western United States. It is indicated that how natural vegetation responses to climate changes also depends on vegetation type and geophysical conditions. Similarly, Zhang et al. (2016) demonstrated that different vegetation types had very different sensitivities to climate factors in arid Central Asia. The results from model simulation in this study show that

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46774691

the increased vegetation greenness is caused by the increases of temperature and precipitation. Tang et al. (2017) demonstrated that the sensitivity of vegetation growth to the temperature and precipitation may decrease if these two climatic variables keep increasing in the Shiyang River Basin, which is also located in Northwest China and close to the Heihe River Basin. To further improve our understanding about influences of climate change on natural vegetation in dryland, regional studies based on long-term physiological and phenological observations are necessary.

Conclusions

This study focused on predicting the climate change response of Salsola passerina, a representative vegetation type in the middle Heihe Basin, China, using a modified SVIS model. The relationship between satellite-observed NDVI, an indicator of vegetation greenness, and meteorological forcing (temperature and precipitation) were evaluated with the model using 29-year datasets. The performance of both model training and validation justified use of the model for prediction. Climate change scenario data for the 2050s were constructed using the ensemble average of downscaled output from sixteen GCMs for a medium CO_2 emission scenario (A1B). NDVI was projected to increase 3.8% and 7.9% in the spring and autumn, likely because of greater soil water content with increasing precipitation and extension of growing season due to higher temperatures. Projected NDVI rises about 3.9% in the summer seasons, suggesting that increase of soil moisture due to greater precipitation is superior to loss of soil moisture caused by higher temperature. This study focused on the influence of climate change on the growth of Salsola passerina. Further understanding of how natural vegetation in the middle Heihe River Basin will react to a changing environment requires the direct incorporation of soil moisture into the SVIS model. Reliable estimation of soil moisture in this region needs a coupled model of both surface water and groundwater to account for human activity such as the use of river water and pumped groundwater for irrigation.

Abstract. This experiment was conducted to reveal the effects of PGPR and IBA on rooting characteristics of Ramsey "Salt Creek" (*Vitis champini*) under the nursery. Hard wood cuttings of Ramsey were subjected to PGPR (EMA1, EMA6, EMA24, EMA MEDIA, EMA CALLUS, EMA QUICK DIP) with dipping times of 1h, 6h, 24 h. IBA concentration was 25, 2000, 4000 ppm with dipping time of 24 h in the case of long-soak method, and of 4 seconds in quick dip method. Data were recorded on specific rooting and shooting characteristic. Results obtained from treatments showed significant differences at $p \leq 0.01$ for specific rooting characteristic, like rooting rate (%), rooting degree (0-4), root length (cm), root fresh and dry weight (g) under the interaction between PGPR and IBA concentration and dipping time. The rooting rate of EMA1 was 56.7%, and was better than in IBA treatments. Rooting degree (0-4) was 3.5 with EMA1 and 3.3 with EMA MEDIA. The highest root lenght (cm) were obtained in IBA25 (37.6) EMA MEDIA (37.2) and EMA1 (34.1). The best result on fresh root weight (g) was determined with EMA1 (9.8) and EMA6 (9.5). As a conclusion, inspected rooting characteristics generally increased with the EMA1 and EMA6 treatments.
Keywords: *Vitis vinifera*, *nursery, cutting, dipping, rooting*

Introduction

One of the most cultivated fruit species is grape (*Vitis vinifera* L.) which is originated from temperate zones of Asia minor in the regions between the south of the Black and the Capsian seas and subsequently spreading towards tropical areas to the west and to the east (Vaddar, 2007; Galavi et al., 2013).

Phylloxera, an insect from North America, was detected in France in 1868. The spreading of Phylloxera in most of the French and European vineyards was extremely rapid. *Vinifera* is susceptible to the attack of phylloxera. Phylloxera attacked vineyards worldwide from the European grapevine cultivars and spreaded from vine to vine. It caused great damage all over the world. Grape plants died rapidly and in huge numbers after the roots of vinifera grapevines were attacked by phylloxera. While the phylloxera damages the roots of European vine species, *V.vinifera*, it cannot harm the roots of the American vine species. Phylloxera resistant rootstocks play an important part in viticulture. Grape rootstocks have been bred to provide resistance to phylloxera (*Daktulosphaira vitifoliae* Fitch). This situation makes the use of American vine rootstock in the production of suspended seedlings inevitably (Carew et al., 2004). Today, vinegrowers have to graft *V.vinifera* cultivars onto resistant rootstocks such as North American species (Baydar and Ece, 2005; Lowe and Walker, 2006; Sabır, 2011; Teker et al., 2014).

Grape is one of the most important horticulture crops of Turkey. Traditionally, grapevines have grown on their own roots, this is still a common practice in Turkey, but establishing vineyard with phylloxera resistant rootstocks is necessary for modern Turkish viticulture. In recent years, vineyards have established the usage of rootstock. Most vinegrower prefer rooted american grapevine cutting for establishing vineyard because it is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46934705

more economical than grafted seedlings. They plant rooted american rootstock, then they make cleft grafting in the vineyard. For this reason, well rooted and full grown American rootstock cutting is very significant.

The rootstock ‘Ramsey’ (*Vitis champini*) which has great potential to be used as grape rootstock owing to its resistance to phylloxera and nematode is one of the most important rootstocks used in Turkey, especially drought climatic conditions, calcareous and high salinity soils. Ramsey cuttings are difficult to root, for this reason the root stocks cutting are dipped in 1500 to 2000 ppm of indolebutyric acid (IBA) solution in nursery.

Plant growth-promoting rhizobacteria (PGPR) are free-living soil bacteria that can affect plant growth by the synthesis of phytohormones and vitamins, inhibiting plant ethylene synthesis, enhancing stress resistance, improving nutrient uptake and mineralising organic phosphate (Barnaval et al., 2014; Daler and Çetin, 2017). PGPR can influence the expression of root traits, such as root branching intensity, average root diameter, but mainly research has been conducted to reveal the effects of PGPR on plant growth, graft success and vegetative growth (Sabır, 2013; Karaca and Sabır, 2018). Grapevines form mutualistic symbioses with PGPR that have shown enhanced plant growth and nutrition. In the field, PGPR may be low or nonexistent (in fumigated soils), suggesting the need for PGPR inoculation of grapevine plants at the nursery. Addition of PGPR inoculum to roots could be an effective strategy for increasing nursery production (Aguin et al., 2004). Using PGPR is important in nursery. Hence, future studies will focus on enhancing nursery methods to improve successful rooting rate. PGPR can have effects on initiating easy rooting of rootstock plants like Ramsey. This study was performed in nursery, in order to identify the effects of different doses of PGPR and IBA concentrations on american rootstock scion. The effectiveness of root zone inoculation with PGPR and IBA to improve successful rooting rate on Ramsey scion were studied.

Materials and Methods

This study was carried out at Tekbağ Nursery Co. Ltd. in Manisa, Turkey, in 2017-2018.

Plant Material

Hardwood cuttings of Ramsey rootstocks were used as plant propagation materials in this study. Ramsey has high vigour, nematode (Meloidogyne) resistance and salt tolerance, moderate to high phylloxera resistance, moderate tolerance of drought and lime, but can suffer from zinc deficiencies in high pH soils. However, it has the lowest success of rooting and affinity ratio when it is compared to other rootstocks (Lowe and Walker, 2006).

The cuttings were collected from dormant vines. All cuttings were taken from the same parts (between 3^{rd}–10^{th} nodium) of mother vines. They were placed in cold storage at 1–5°C and high relative humidity until the experiment. The plant materials were cut into 40 cm sections with an average of four nodes each. A total of 1800 cuttings were collected for two years.

Plant Growth-Promoting Rhizobacteria (PGPR) and IBA Applications

Plant Growth-Promoting Rhizobacteria (PGPR) and indolebutyric acid (IBA) have been applied to increase development of cuttings.

Plant Growth-Promoting Rhizobacteria: PGPR used in the research is EM•A that was obtained from the “EM AGRITON” company in the form of ready-to-use solution. It

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46934705

provides all the useful properties of active microorganisms technology. This is a one hundred percent organic product containing lactic acid bacteria (Lactobacillus Fermentum, L. Plantarum, L. Rhamnous, L. Delbrueckii), yeast (Saccharomyces Cerevisiae), phototrophic bacteria (Rhodopseudomonas Palustris) and Bacillus Subtilis. It has a 1.9×10^{8} ** total microorganism count ($^{**}6.1\times10^{7}$ aerobic, mesophilic bacteria; 1.3×10^{8}, anaerobic microarofil bacteria; 6.0×10^{5}; yeast; < 100 mildew) and a 3.89 pH.

Indolebutyric acid: IBA is a plant hormone in the auxin family and is an ingredient in many commercial horticultural plant rooting products. Generally, IBA is used to initiate root formation in nursery.

Methods

In the experiment, IBA was applied to Ramsey cuttings with different methods at different time and doses (Alley, 1980; Kroin, 2008). **EM•A** was applied to cuttings with different methods at different time and doses. All applications of **EM•A** and IBA used in the research are given in *Table 1*.

After treatments, cuttings were planted in plastic pots containing uniform mixture of peat (1.034% N, 0.94% P_2O_5, 0.64% K_2O, pH 5.88, Klassman®) and inert perlite (0–3 mm in diameter) in equal volume. Before planting, 5 cm top parts of the cuttings were covered with red colored paraffin which melts at 70°C. They were placed in a greenhouse at 28°C and 60% relative humidity for 6 weeks after preparation.

Table 1. *Introduction of applications*

EMA1	10 cm bottom parts of cuttings were immersed in EM•A solution at a dose of 100 mg/L for 1 hour and then planted in pots.
EMA6	10 cm bottom parts of cuttings were immersed in EM•A solution at a dose of 100 mg/L for 6 hour and then planted in pots.
EMA24	10 cm bottom parts of cuttings were immersed in EM•A solution at a dose of 100 mg/L for 24 hour and then planted in pots.
EMA MEDIA	EM•A at a dose of 100 mg/L was injected into the rooting media shortly after planting.
EMA CALLUS	Callus tissue was formed at the bottom of the rootstocks in the stratification room with 28 ° C temperature and 85% humidity in 21 days. The callus tissue at basal ends of cuttings were immersed in EM•A solution at a dose of 200 mg/L using quick dip method (4 second). After, cuttings were planted in pots.
EMA QUICK DIP	The basal ends of cuttings were immersed in EM•A solution at a dose of 200 mg/L using quick dip method (4 second) and then cuttings were planted in pots.
IBA25	10 cm bottom parts of cuttings were immersed in IBA solution at a dose of 25 mg/L for 24 hour (basal long-soak method) and then planted in pots.
IBA2000	The basal ends of cuttings were immersed in IBA solution at a dose of 2000 mg/L using quick dip method (4 second) and then cuttings were planted in pots.
IBA4000	The basal ends of cuttings were immersed in IBA solution at a dose of 4000 mg/L using quick dip method (4 second) and then cuttings were planted in pots.
CONTROL	Cuttings are directly planted in pots without any application.

Evaluation of Growth Parameters for Ramsey

For the analyses of root distrubution of the cuttings to PGPR and IBA plant materials were visually evaluated 6 weeks after operation for root distrubition. The growth of the cuttings was assessed by rooting rate (%), rooting degree (0-4), root number, root length (cm), fresh root weight (g), dry root weight (g), stoma number, shoot length (cm), shoot weight (g), number of internodes on main shoot, lenght of lignified summer shoot (cm),

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46934705

leaf area (LA, cm^2), leaf weight (gr), correlation between leaf area and leaf weight following the PGPR and IBA applications.

Statistical Analysis

A completely randomized simple factorial design with three replications (30 cuttings in each replication) was used in the experiment. The data were subjected to analysis of variance by SPSS (SSPS Inc. 10.0, USA, 1999) software, and differences between means were determined by Fischer's Least Significant Difference (*LSD*) test.

Results

All data examined in the research are given in *Table 2, Table 3* and *Table 4* for experimental years.

Applications were determined to have a statistically significant effect (P=0.001) on the rooting rate (%) for Ramsey grapevine rootstock in 2017 and 2018 experimental years. The EMA1 and EMA6 applications in the first experimental year were included in the same statistical group for rooting rate (%) 56.7 (a), 50.0 (ab), respectively (*Table 2, Fig.1)*, on the other hand in the second year EMA1 and EMA6 applications were in the same statistics group, 56.7 (a), 56.7 (a), respectively (*Table 3*, *Fig.1*).

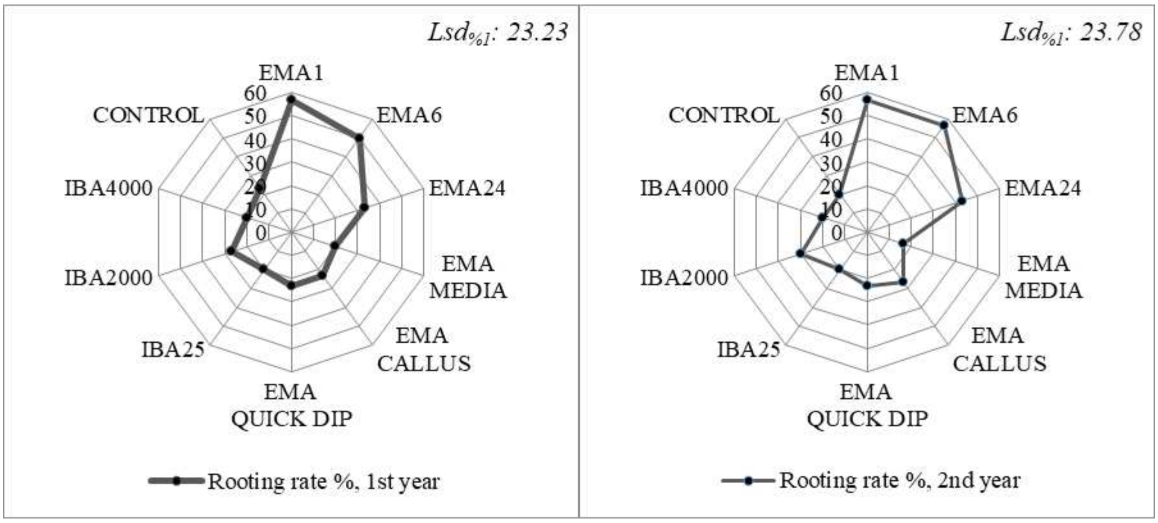

Figure 1. *Rooting rate (%) for 2017 and 2018 application years*

When we extend the statistical evaluation by considering the year as a factor, EMA1 and EMA6 applications were included in the same statistical group for rooting rate (%) performances in both experimental year, 56.7 (a), 53.3 (a), respectively (*Table 4*).

The fresh root weight (g) was measured with a 0.0001 g sensitive analytical balance and indicated in grams (g). Applications were determined to have a statistically significant effect on fresh root weight (g) in the first year, the best results were determined with EMA6 (10.6 a) and EMA1 (9.4 ab) (*Table 2*, *Fig. 2*). On the other hand there was no difference between applications in the second year (*Table 3*, *Fig. 2*). When both application years were evaluated together, EMA1 (9.8 a) and EMA6 (9.5 ab) were determined to be in the same statistical group like in the first year (*Table 4*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46934705

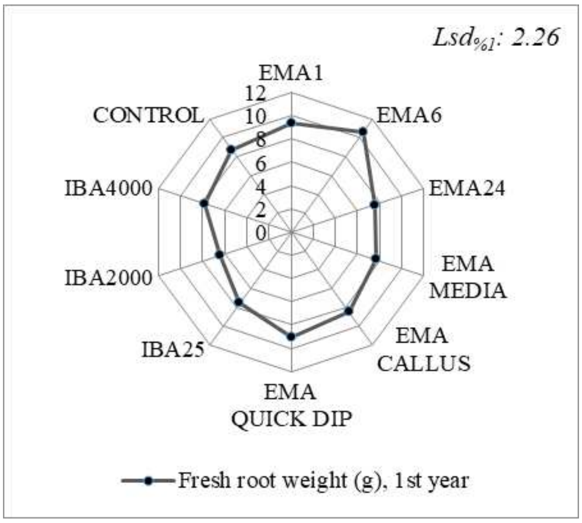

Figure 2. *Fresh root weights (g) for 2017 application year*

While the best result with dry root weight was determined with EMA6 (6.7 a) and CONTROL (6.2 a) in the first year (*Table 2*), in the second year, CONTROL (6.2 a), EMA1 (5.9 ab) and EMA24 (5.9 ab) applications were obtained in the same statistical group (*Table 3*, *Fig. 3*). In both year, best results were obtained form EMA1 (9.8 a) and EMA6 (9.5 ab) (*Table 4*).

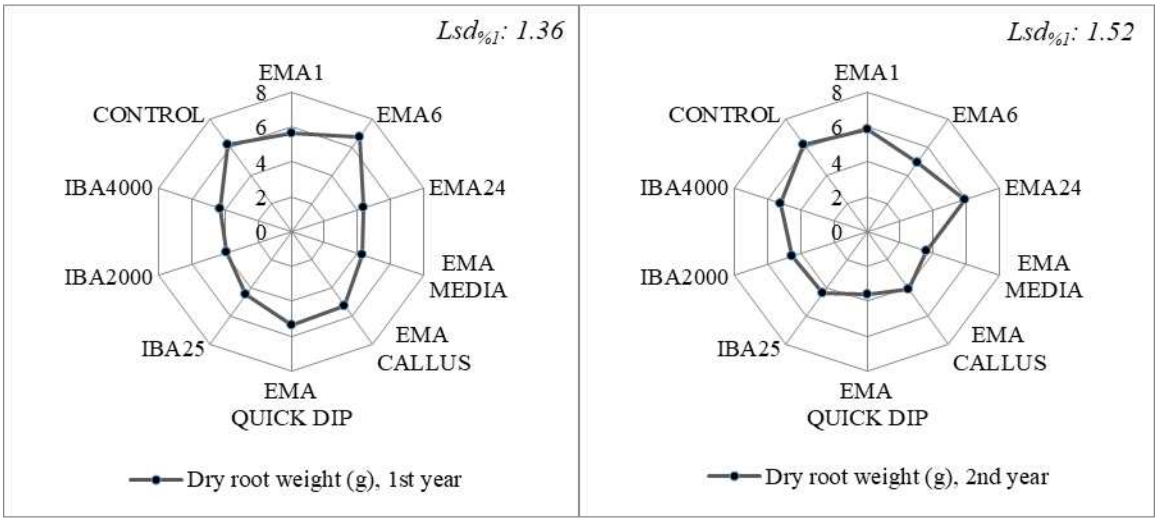

Figure 3. *Dry root weights (g) for 2017 and 2018 application years*

Stoma number was found 38.3 (a) with EMA CALLUS for the first year (*Table 2*). In the second year, EMA1 and EMA QUICK DIP application were in the same statistical group, 30.7 (a) and 29.7 (a), respectively (*Table 3*, *Fig. 4*).

When cuttings analyzed for shoot length (cm), number of internodes on main shoot, lenght of lignified summer shoot (cm), shoot weight (g) and root number, there were not significantly influenced by PGPR and IBA treatment for 2017 and 2018 treatment years (*Table 2*, *Table 3*). When we extended the statistical evaluation by considering the year as a factor, same results were obtained for all these values (*Table 4*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46934705

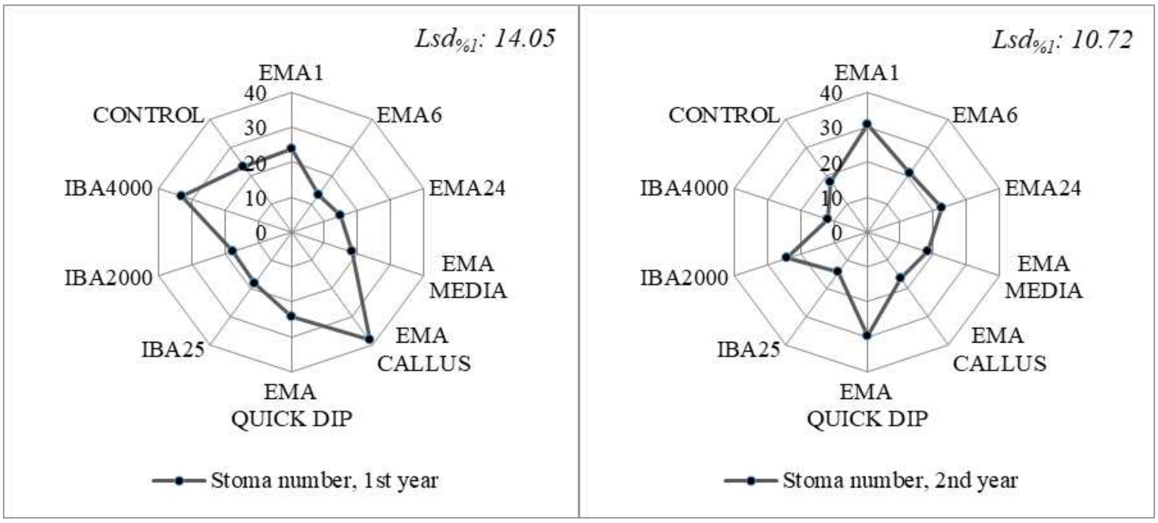

Figure 4. *Stoma number for 2017 and 2018 application years*

There was no significant difference in the success of root lenght (cm) PGPR and IBA applications in the first year of application (*Table 2*). The highest positive effect of PGPR application on root lenght (cm) of Ramsey was observed in the second year in EMA MEDIA (41.2 a) and EMA1 (35.0 ab), they were in the same statistical group (*Table 3*, *Fig. 5*).

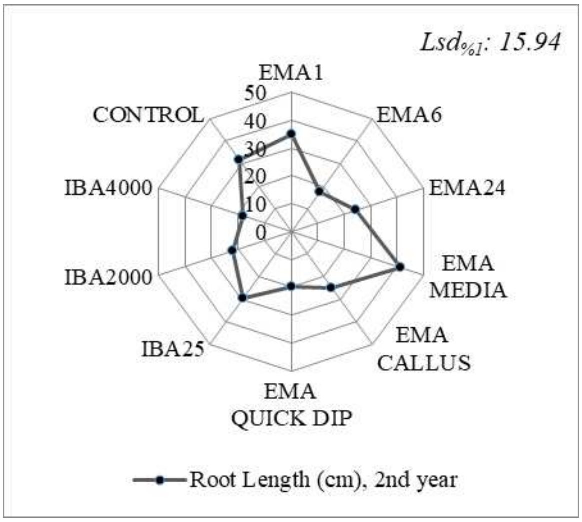

Figure 5. *Root length (cm) for 2018 application year*

The effect of EMA MEDIA (37.2 a), IBA25 (37.6 a) and EMA1 (34.1 ab) for root lenght (cm) were observed in the same statistical class in both year (*Table 4*).

The root number was not affected by PGPR and IBA applications. No statistical difference was found (*Table 2*, *Table 3*, *Table 4*).

When it comes to the effect of PGPR and IBA application on Ramsey rooting degree (0-4), it is observed that PGPR inoculated plants have the highest level of rooting degree at EMA MEDIA (3.7 a), IBA4000 (3.7 a) and EMA1 (3.3 ab) and these were in the same statistics group for the first year (*Table 2*). There was no statistical difference between the second year applications, but the EMA1 had the highest 3.7 value (*Table 3*, *Fig. 6*).

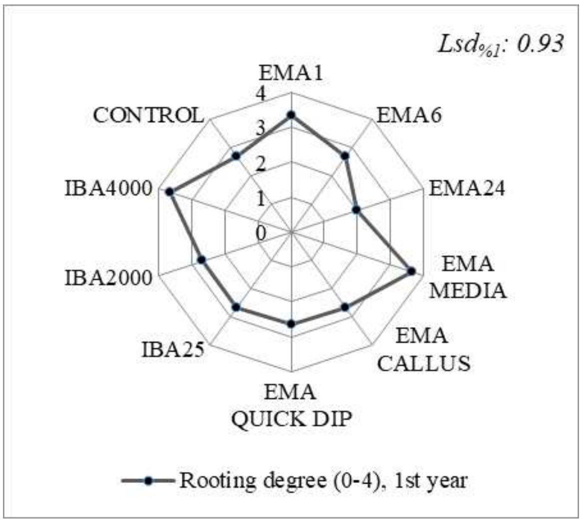

***Figure 6**. Rooting degree (0-4) for 2017 application year*

An overall evaluation of the data demonstrated that there were statistically important increases in the rooting rate (%) of Ramsey by EMA1 (3.5 a) and EMA MEDIA (3.3 ab) of PGPR when the two-year data is evaluated (*Table 4*).

In the first year, EMA1 (53.5 a), EMA QUICK DIP (52.5 a), CONTROL (52.0 a) and EMA24 (50.9 a) gave the best results for leaf area (cm^2) (*Table 2*), statistics groups changed in the second year, but EMA1 (51.6 a) application gave the best result again. EMA MEDIA (51.7 a), IBA25 (50.1 a) and IBA2000 (49.9 a) were found to be of the same importance (*Table 3*). Eventually, the leaf area was affected positively by EMA1 (52.6 a) application in both year (*Table 4*).

The leaf weight (g) value was not affected by PGPR and IBA applications, no statistical difference was found between applications in year 2017 and 2018 (*Table 2*, *Table 3*). When the two experimental years were evaluated together, the leaf weight value was increased by EMA1 (1.35 a) (*Table 4*).

As a result of the measurement of leaf area and leaf weight (g) values, it was determined that these two criteria were directly proportional to each other. It was determined that leaf weight increased as leaf area value increased (*Fig. 7*).

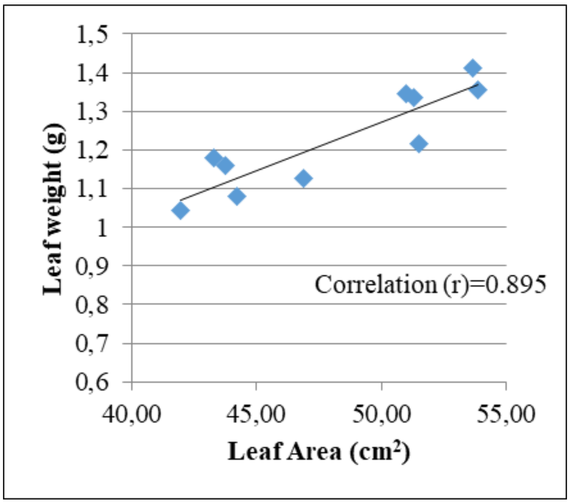

***Figure 7.** Correlation between leaf area and weight for both experimental years*

Discussion

Intensive nursery practice in viticulture still relies on the use of plant hormones like auxin to provide dense root formation and healty root development. It is very well known that IBA can stimulate root formation of cuttings. The essential role of IBA has been documented on induction of rooting and root formation (Galavi et al., 2013). Hartmann et al. (1997) reported that IBA application have impressive results in rooting the semi-hardwood cuttings in apple, plum and olive. Therefore, use of IBA has been recommended for rooting of grapevine rootstocks cuttings on the basis of the evidence reported in the literature by a great number of researchers (Yağcı, 2015). On the other hand, excessive use of hormone causes problems not only in terms of financal cost but also in terms of the cost to the environment. Therefore, the development and application of sustainable agricultural techniques is vital to decrease environmental pollution (Sabır, 2013). Many research on viticulture using PGPR resulted in enhanced plant growth, disease resistance, improved nutrient fixation or solution and graft success. Using different hardwood grafting type and varieties, Köse et al. (2003) and Köse et al. (2005) demonstrated that there were statistically important increase in the survival of grafts in relation with PGPR applications. In the current studies, PGPR inoculation alone or in combination markedly helped the young plants to survive and success in rooting.

This report provides the first data to demonstrate that PGPR applications can increase rooting rate (%) and full rooting characteristics in hardwood cuttings of Ramsey grapevine rootstocks. In order to determine rooting criteria of hardwood cuttings applied in the seedling production process different concentration and dipping times were tested with PGPR together with IBA applications. In contrast to the results at IBA and control, applications with PGPR increased rooting rate (%), rooting degree (0-4), root length (cm), fresh and dry root weight (g). All of these characteristics for cuttings are of the same importance in nursery practice.

PGPR and IBA applications did not have a specific influence on the root number at the base of Ramsey hardwood cuttings. However, the PGPR and IBA applications manifested their specific characteristics and showed significant variation in the number of roots, in the increasing variation of IBA4000 (8.3), EMA MEDIA (7.7), IBA25 (7.3) in the first year, and of IBA25 (8.3), EMA24 (8.3) and EMA1 (7.3) in the second year. Root number similarly responded to the change in both year in EMA MEDIA (8.2), IBA25 (7.8), EMA24 (6.8) and EMA1 (6.7).

Application of treatments, resulted in rooting rate (%) with EMA1 and EMA6 to be 56.7 a, 53.3 a, respectively (*Table 4*). Interesting thing is, IBA4000 applications have reduced rooting rate (20.0 c) in our researche. It is very well known that the hormones can stimulate root formation of cutting (Köse et al., 2003). Furthermore, Yağcı, (2015) reported the effects of IBA doses (1000, 2000, 4000 mg/L) on grafted sapling (different grafting combinations; Hamburg Misketi, Tekirdağ Çekirdeksizi, Italia and Trakya İlkeren cuttings/Ramsey rootstock). According to the researcher, the effect of IBA applications on rooting rate (%) was statistically significant. On the other hand, 4000 mg/L of IBA application adversely affected rooting rate (%), the best effect of different levels of IBA on rooting rate (%) was obtained at 2000 mg/L IBA. Some studies have reported that higher concentrations of IBA can adversely affect the rooting of cuttings (Cerveny and Gibson, 2005; Galavi et al., 2013). These results support our research. As for rooting rate (%) around hardwood cuttings of Ramsey rootstocks, had also remarkably positive influences with the highest degrees being promoted by EMA1 and EMA6 for both experimental years (*Table 4*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_46934705

Even if the values of fresh root weight (g) were in positive order with EMA1 (9.8 a), EMA6 (9.5 ab), dry root weight (g) have reduced in CONTROL (6.2 a), EMA1 (5.8 ab) and EMA6 (5.8 ab) applications (*Table 4*).

As reported in some studies, IBA2000 and IBA4000 applications have reduced fresh and dry root weight (g). These results support our research. Researchers believe that high concentrations of IBA can cause damage to the cutting base (Kelen and Demirtaş, 2001; Galavi et al., 2013; Yağcı, 2015).

Correlation analyses were carried out on the parameters indicating leaf area (cm^2) and leaf weight (g). It was determined that leaf weight increased as leaf area value increased (*Fig. 7*).

When the effect of PGPR and IBA application of Ramsey hardwood cuttings is examined stoma number of the cuttings was affected by EMA CALLUS (38.3 a) in the first year (*Table 2)*. It is observed that the inoculated plants have the highest amount of stoma number with EMA1 (30.7 a) in the second year. EMA1 and EMA QUICK DIP application were in the same statistical group, 30.7 a and 29.7 a, respectively (*Table 3*).

On the other hand, an overall evaluation of the data demonstrated that there were statistically important increases in the rooting rate (%) and rooting degree (0-4) of Ramsey by EMA1 application. It is important to determine whether there is a positive relationship between these characteristics.

Comparing root lenght (cm) among the experimental groups for the two years showed a significantly ($P<0.05$) positive effect in IBA25 (37.6 a), EMA MEDIA (37.2 a) EMA1 (34.1 ab) (*Table 4*).

In *Table 4*, where the values obtained in terms of rooting degree, it is seen that plants formed root development level on a scala of 0-4 when they are inoculated with EMA1 and EMA MEDIA. There were found statistical differencies for root development level on a scala of 0-4 with EMA1 (3.5 a) and EMA MEDIA (3.3 ab), these were in the same statistical class. Köse et al., (2003) reported that positive effects of bacterial applications on rooting of rootstock having low rooting rate may be explained by auxin and/or auxin like plant growth promoting substance production of bacterial strains. They found that the bacterial combination decreased the rooting rate and rooting degree.

Conclusion

In conclusion, Ramsey is resistant to phylloxera and salt tolerance but its use is very limited due to the difficulties in rooting ability of the cuttings. Some treatments including plant growth regulators, especially IBA and other chemical substances have been applied on the cuttings for increasing the rooting percentage. The aim of this study was to investigate the effects of the PGPR, it was used with different application time on the rooting of Ramsey rootstock, having different features (with callus and without callus). These applications were compared with the most common IBA treatment and control group plants. Our results suggest that PGPR applications may have a great potential to stimulate the rooting of hardwood cuttings of grapevine rootstocks, with low rooting capability. In our study, it seems that PGPR application has a positive effect on rooting rate (%), fresh and dry root weight (g), root length (cm), rooting degree (0-4) and leaf area (LA, cm^2) of rootstocks with EMA1 and EMA6 applications. The EMA1 and EMA6 applications may be of benefit for Ramsey rootstocks, particularly for organic farming.

(Received 3rd Jan 2019; accepted 28th Feb 2019)

Abstract. This research aims to find out the marketing problems of the beekeepers in Muğla province, Milas district of Turkey and offer potential solutions. The main material of the research is the data gained via surveys, performed as face-to-face interviews with beekeeping farmers in Milas district. According to the data of Milas District Agriculture and Forestry Directorate, 721 beekeepers constitute the main part of the research. The proportional sample size has been determined as 62 people. The most significant problems that farmers face during the production are diseases and pests by 53.2%, while the most significant problem during marketing is the low selling price of honey by 80.6%.
Keywords: *beekeeping, beekeepers, honey, economy, price*

Introduction

Beekeeping is seen as a strategically important sector that should be supported in order to protect biodiversity and transfer it to next generations, provide food security, increase diversity, support domestic economy by increasing employment, and prevent erosion threat (Yılmaz, 2015).

Global climate change is one of the most important problems facing today's societies. The agricultural sector, which meets the food, nutrition and fiber needs of the society, is one of the most vulnerable sectors against climate change (Arbuckle et al., 2013). Honey bee is the most valuable pollinator of agricultural products worldwide economically. Approximately 73% of the plants cultured in the world are pollinated by bees (Reddy et al., 2012). One of the main factors affecting honey production is the climate (Malisa and Yanda, 2015). That is, beekeeping sector is dramatically affected by drought and climate change. Sustainability of soil and water resources is of vital importance for beekeeping. Sustainability of soil and water resources is of vital importance for beekeeping because the bee needs healthy vegetation and flora. On the other hand, seasonal effects of global warming negatively affect bees. The effect of climate change on bees may cause the bees not to fulfill the function expected of them in pollination. This reduces the quality and quantity of crop production and can lead to economic loss of beekeepers.

Beekeeping is not a soil-based production field, for that reason it can be an only income source for the farmers who have no or limited land. Running with a limited budget, establishing and running the business with low expenses, generating income in short terms, marketing bee products easily and providing bee and bee breeds domestically are the most significant reasons that make beekeeping attractive (OGM, 2013).

Beekeeping activities which is an important sub-sector of livestock provides a prominent added value. As a sub-sector of livestock and agriculture, beekeeping activity creates a significant added value for the economy. Sustainability of the added value is directly related to developing marketing opportunities for the products and analyzing marketing problems. Besides of having great geographical features and rich flora, Turkey has a significant place in global beekeeping sector with its colony assets (Köseman et al., 2016). Beekeeping in Turkey is an agricultural occupation done to produce honey only. Most of the beekeeping businesses are family-run businesses (Şahinler and Gül, 2003).

By the year of 2016, there are 90 564 654 bee hives in the world and they produce 1 786 996 ton honey approximately (FAO, 2018). By the same year in Turkey, these numbers are respectively 7 900 364 and 105 727.435 tons (TSI, 2018). Namely, Turkey produces 8.72% of the hive assets and 5.92% of honey production in the world. By the year of 2017, there are 83 210 beekeeping businesses in Turkey. By the same year, the number of total hives is 7 991 072. In Muğla province where the research is conducted, there are 6000 families that are bekeeping farmers in 334 villages. In Muğla province, the main product of beekeeping is pine honey; and Muğla provides 70-75% of the production in Turkey. In Muğla 35000-40000 people are employed in beekeeping sector (Şahin, 2015). By 2017, Muğla supplies 11.99% of the hive assets and 13.86% of honey production in Turkey (TSI, 2018).

Being the capital of beekeeping production, Muğla province Milas district has a significant potential in terms of beekeeping activities in Turkey. Beekeeping activities which is no longer a side income started to be basic living source for most of the families in rural areas in Milas district. By 2017, 15.39% of the beekeeping businesses of Muğla province is located in Milas district. By 2017, 18.04% of the natural honey produced in Muğla province and 2.06% of the beewax have been produced in Milas district. On the other hand, 17.74% of the total hive assets of Muğla province (old and new) is located in Milas district (TSI, 2018).

Main aim of the study is to indicate the structure of beekeeping production and marketing in Muğla province Milas district. Within this scope, firstly socio- economic structure of the beekeepers, the production and marketing structure of beekeeping goods produced in businesses and problems of the farmers that they face during production and marketing phase have determined; possible solution offers for the problems have suggested.

Materials and methods

Study area

The geographical position of Milas is 37° 18′ 59″ North and 27° 47′ 2″ East. Milas is located in the southwest of Turkey within the borders of Aegean Region in the Menteşe Mountainous area. Administratively, it is a central district located within the borders of Muğla province (*Fig. 1*). It is bordered by the city of Muğla and Yatağan district in the east, Yenihisar district of the city of Aydın in the west, Kocarlı, Karpuzlu and Çine districts in the north, Gökova Bay in the south and Bodrum district in the southwest (Çakar, et al., 2011).

It is possible to examine agriculture in Milas as fruit and vegetable, grain and industrial plant production. Because of its climate and geographical structure, Milas is one of the rare place where many products can be grown. Its primary agricultural products are olive, forage plants, wheat, barley, grain corn, cotton, tobacco, vegetables and citrus fruits. Milas is the most important olive and olive oil production area of the Aegean region. Industrialization related to olive cultivation has been the primary key industry of Milas for a very long time. Animal husbandry is also important in the district. Beekeeping and honey production as well as fish farming have a significant for district (Anonymous, 2015).

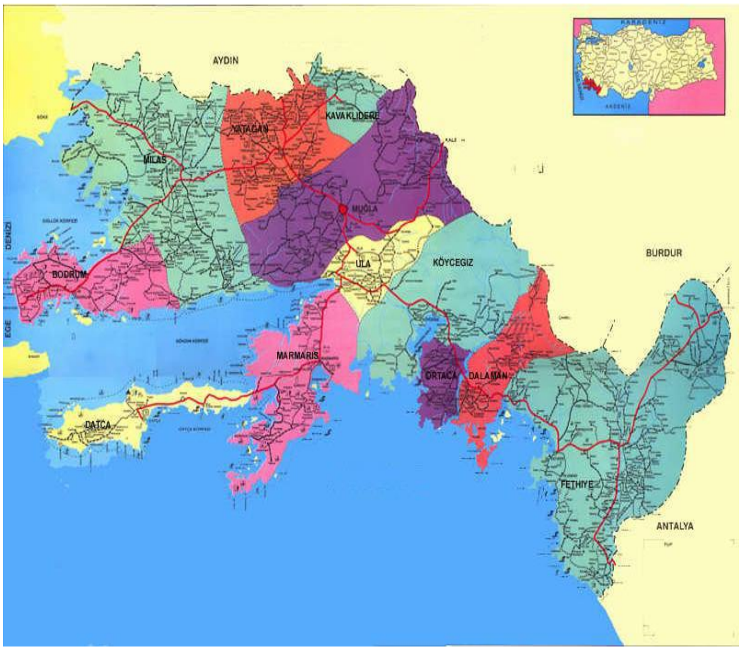

Figure 1. *Map of Muğla Province. (Source: Anonymous, 2004)*

Method applied when collecting data

The main material of the research is data gained via surveys with face-to-face interviews done among the beekeeping farmers in Milas district of Muğla province in Aegean Region. According to the records of Agriculture and Forestry District Directorate of Milas, 721 beekeepers constitutes the main part of the research. Having specified by proportional sample volume (Newbold, 1995), interviews were done with the farmers. 90% confidence interval and 10% error margin is taken as a basis in the research. The data of the study were obtained from the face-to-face surveys conducted with beekeepers in Milas district in April-May 2017. Nine neighbourhood (village) of the district is examined as the scope of the research.

$$n = \frac{Np(1-p)}{(N-1)\sigma_P^2 + p(1-p)} \quad \text{(Eq.1)}$$

In *Equation 1:* N = total number of farmers as interview; N = population; P is taken as 0.50 to be able to reach maximum sample volume; (1 - p) = 0.5; σ_{px}^2 = variance. In the calculation, total number of the farmers that is to be interviewed is figured as 62.

DOI: http://dx.doi.org/10.15666/aeer/1702_47074724

Method applied when analyzing data

After acquiring the data for the research, assessment phase has been started. The data from the surveys has been coded and recorded. Definitive statistical analysis is used in order to assess the data.

Results

General features of farms and farmers

The ages of the farmers range from 27 to 74, and average age of the farmers is 48. When it comes to adaptation of new techniques and technologies, education level of the beekeepers has an important role (Ogunjimi et al., 2016). The education level of the beekeepers participating in the current study was found to be low. In the research, average education year of the famers is figured as 5.9. Average household population of beekeepers is 3.6. It has been calculated that average agricultural experience of the farmers is 26.3 years, average experience as beekeepers is 19.5 years. It is found that 64.5% of the farmers who participated in the research took out loan. In the research, it is specified that only 9.7% of the farmers have business records regularly.

88.7% of the farmers (55 farmers) who participated in the research have other agricultural activities than beekeeping. Average business width of the farmers is figured as 23.1 decares. It is seen in the research that five farmers have no agricultural land. It is determined that 98.2% of the beekeeping businesses continue their agricultural activities on property land, 1.8% of them continue agricultural activities on rented land. 61.8% of the farmers make mixed production (crop+animal production), 32.7% make only crop production, 5.5% make only animal production.

Farmers who participated in the study stated that 38.1% of their agricultural income came from beekeeping activities. 25.8% of the farmers participating in the survey have non-agricultural income. Farmers are engaged in professions such as local headman, coffeehouse owner, fisherman, labourer apart from agriculture. There are farmers who are retired and traders, as well.

Findings related to production and marketing

6.5% of the farmers participating this research stated that they started beekeeping with old type hive, 88.7% of them started with buying colonies with modern hives and 8.1% of them started with buying swarm.

The reasons for farmers' to do beekeeping are examined and for this purpose *Table 1* is formed. The first reason of farmers' to do beekeeping is that there is no other source of income (37.1%). This is followed by the habit inherited from family (33.9%) and ability to access to the product in short time (29%).

Honey can be defined as the natural product in which the plant nectars, the secretions of the alive parts of the plants or the secretions of plant-absorbing insects that live on the living parts of the plants, are collected by the honeybee (Apis mellifera) and combined with their own specific substances, decreasing the water content and storing it in the honeycomb (Anonymous, 2005). Beekeeping activities can be considered as an important rural development tool, which provides a certain rate of income to a large number of farmers, in rural areas. Undoubtedly, the first condition for farmers to earn income from beekeeping activities is that they produce clean, hygienic and good quality honey. Determination of product properties, honey additives and residue levels of honey produced by farmers can be measured by honey analysis. For this reason, it is very important for farmers to make honey analysis for honey they produced. In the study, it was determined that the farmers' honey analysis rate is quite low. It was determined that only two producers had honey analysis.

Table 1. *Reasons for farmers to do beekeeping*

Reasons to do beekeeping	n	%
Ease of maintenance	10	16.1
Short production period	18	29.0
Habit inherited from family	21	33.9
Curiosity, hobby	15	24.2
There is no other source of income	23	37.1
Because the product is suitable the region	2	3. 2

*Total passes 100% since there are more than one answer

The presence of colony in the production of bee products is of great importance. Naturally, as the number of colonies increases, the production amounts of bee products are expected to increase. For this reason, in this study, farmers' colony assets are investigated. In the study, the percentage of farmers indicating the increase in the colony assets in the last three years was 17.7% and the percentage of farmers indicating the decrease in it was 48.4% (*Table 2*).

Table 2. *Change in the colony assets in the last three years*

	n	%
Increased	11	17.7
No change	21	33.9
Decreased	30	48.4
Total	62	100.0

The migratory beekeeping is based on the principle of transporting colonies from one region to another in order to benefit from different flowering periods in plants and to protect the bees from adverse winter conditions. 77.4% of the farmers participating in the research is doing migratory beekeeping, 22.6% is doing fixed beekeeping.

It was determined that the farmers moved their hives to various provinces such as Kayseri, Ankara, Eskişehir, Sivas, Konya, Nevşehir, Tekirdağ, Niğde, Kütahya, Afyonkarahisar, Kars, Sakarya, Edirne and Burdur. A farmer who stated that he was a fixed beekeeper stated that he had moved his hives to the neighbouring villages. It is specified that the farmers usually go in May and return in August. When the farmers' honey harvesting frequency was examined, it was concluded that half of the farmers participating in the study do harvesting twice a year. 30.6% of the farmers harvest three times a year (*Table 3*).

In the study, the average number of hives owned by farmers was found as 162 units. Today, beekeeping business is one of the means of living of many families in rural areas. The products obtained from beekeeping business, such as pollen, propolis, beeswax and primarily honey, provide a significant added value in the income of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_47074724

producers engaged in beekeeping in rural areas (Çukur et al., 2016). 98.4% of the farmers interviewed in this study were identified to produce honey, 46.8% of them produce beeswax and 29% of them produce queen bees (*Table 4*).

Table 3. *Farmers' honey harvesting frequency*

	n	**%**
Once in every three weeks	2	3.2
Once in a month	6	9.7
Twice a year	31	50.0
Three times in a year	19	30.6
Four times in a year	1	1.7
Once in a year	3	4.8
Total	62	100.0

Table 4. *Number of farmers producing bee products*

Number of farmers producing extracted honey	61	98.4
Number of farmers producing comb honey	17	27.4
Number of farmers producing beeswax	29	46.8
Number of farmers producing swarm	23	37.1
Number of farmers producing queen bee	18	29.0
Number of farmers producing pollen	7	11.3

The average production quantities of bee products are shown in *Table 5*. From the farmers participated in this research, it is determined that the average amount of extracted honey production was 2334.5 kg, the average comb honey production amount was 81 kg and the average beeswax production amount was 48.9 kg. In the study, average extracted honey production per hive was calculated as 14.41 kg.

Table 5. *Average production amount of bee products*

	Production amount
The amount of extracted honey (kg)	2334.5
The amount of comb honey (kg)	81.0
The amount of beeswax (kg)	48.9
The amount of swarm (unit)	10.2
The amount of queen bee (unit)	16.3
The amount of pollen (kg)	3.8

It was specified that 87.1% of farmers have problems with honey production. Farmers who have problems with honey production are asked about their problems and *Table 6* is formed according to the answers. Diseases and pests (53.2%) and negative effects of global warming (41.9%) are among the most important problems of beekeepers.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

When the sales status of bee products is examined, it was specified that 91.9% of the farmers sold extracted honey and 16.1% sold comb honey and beeswax (*Table 7*).

Table 7. *Number of farmers selling bee products*

	n	%
Number of farmers selling extracted honey	57	91.9
Number of farmers selling comb honey	10	16.1
Number of farmers selling beeswax	10	16.1
Number of farmers selling swarm	2	3.2
Number of farmers selling pollen	2	3.2

When the average sales amount of bee products were examined in the study, it was identified that the average amount of extracted honey sales of the farmers is 2323.7 kg, the average comb honey sales amount is 75.7 kg and the average beeswax sales amount is 12.4 kg (*Table 8*).

The farmers' sales prices of bee products are shown in *Table 9*. As shown in the table, the sales price of comb honey is 5.96 €, extracted honey is 2.16 €, beeswax is 7.09 €, pollen is 7.70 € and swarm is 77.03 €.

Table 8. *The average sales amount of bee products*

	Sales amount
The sales amount of extracted honey (kg)	2323.7
The sales amount of comb honey (kg)	75.7
The sales amount of beeswax (kg)	12.4

Table 9. *Actual and expected average sales prices of bee products. (Source: TCMB, 2018)*

	Sales price (TL)	Sales price (€)	Expected sales price (TL)	Expected sales price (€)
Comb honey	23.2	5.96	45.5	11.68
Extracted honey	8.4	2.16	14.4	3.70
Beeswax	27.6	7.09	41.9	10.76
Pollen	30	7.70	100	25.68
Swarm	300	77.03	400	102.71

*As of 15 May 2017 1 Euro = 3.8946 TL

Sales prices of bee products and sales prices of bee products according to farmers are shown in *Table 9*. As it is seen from the table, sales prices of bee products are well below the sales prices expected by farmers. The price differences were calculated as 5.72 € in comb honey, 1.54 € in extracted honey, 3.67 € in beeswax, 17.89 € in pollen and 25.68 € in swarm.

Farmers' extracted honey selling areas are presented in *Table 10*. As it can be seen from the table, the majority of the farmers sell extracted honey to the merchant (75.8%).

Table 10. *Farmers' selling places of extracted honey*

	n	%
Directly to the customer	6	9.7
Merchant	47	75.8

*Total passes 100% since there are more than one answers

In this study, it is determined that 99% of the produced honey is sold while 1% is preserved for home consumption.

Reaching agricultural information at the right time has a vital importance for the success of farmers. The access of farmers to reliable, timely and necessary information will reduce the risks and uncertainties of farmers and help them to make the right decision (Mbagwu, et al., 2018). Access to agricultural marketing information of farmers and other agricultural stakeholders can be improved through accessible agricultural marketing information systems (Amer et al., 2018). Agricultural information is a critical component in increasing small-scale agricultural production and in reaching farmers' profitable markets. In the case of reaching market information by farmers, yield increase will be achieved (Wawire et al., 2017). Access to the market is one of the most important factors affecting the performance of agriculture and plays an important role in developing and diversifying the means of living of small farmers in developing countries. Inadequate access to market information leads to moral damage and high transportation costs and hence prevents some farmers from accessing the market (Okello et al., 2014). By means of reaching agricultural markets, small-scale farmers are able to increase agricultural production, realize economic growth and reduce hunger and poverty (Magesa et al., 2014). Market information flow to small-scale farmers is poor. This complicates farmers' access to the market (Matto, 2018; Wawire

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_47074724

et al., 2017). In this study, when farmers' status of access to information related to domestic (market price, production, demand) and foreign (market price, production, demand) markets is examined, it was determined that 48.4% of the farmers have access to the information related to domestic market and 17.7% of the farmers had access to the information related to the foreign market.

When the extracted honey sales of the farmers is examined, it is determined that in general they sell the extracted honey in cash (69.4%) (*Table 11*). Examining the months of extracted honey sales of the farmers, it draws attention that honey is sold intensively in September, October and November (*Table 12*).

Agricultural marketing, especially in developing countries, plays an important role in reducing poverty sustainably and ensuring household food safety (Katengeza, 2012). 83.9% of farmers were found to have problems with honey marketing when this problem was examined. Low sales price of honey (80.6%), unfair competition (38.7%), fluctuations in market prices (27.4%), and inability to access market related information (21%) are amongst the most important problems faced by farmers in honey marketing (*Table 13*).

Discussion

This study was carried out in order to reveal the production and marketing structures of bee products of beekeepers in Milas district of Muğla province. Farmers participating in the research can be said to be middle-aged. In a research done by Adedeji et al. (2016), it is specified that 90% of the beekeepers is in 40- 49 age range.

*Total passes 100% since there are more than one answers

It was determined that the farmers participating in the study were highly experienced in beekeeping (19.5 years). In a research done by Belie (2009) in Ethiopia, average experience of the beekeepers is figured as 14.5 years. In a research done by Ceyhan and Canan (2017) average age of beekeepers is figured as 49, average experience is figured as 21 years.

In the study, it was determined that most of the farmers received loans (64.5%). In a research done by Belie (2009), it is determined that 85% of the beekeepers take out loan.

It was determined that very few of the farmers participating in the study kept their business records regularly (9.7%). In a research done by Mujuni et al. (2012) in Uganda, it is found that 10% of the beekeepers keep a record of hive numbers. In a research done by Şeker et al. (2017), it is pointed out that 69.1% of the beekeepers do not have a record.

It was determined that a significant number of farmers participating in the research also carried out other agricultural activities besides beekeeping. In a research done by Burucu and Bal (2018) in Kastamonu province, it is seen that 66.7% of the farmers conduct other agricultural activities than beekeeping. In a research done by Tullu (2014) in Ethiopia, it is found that the income of the farmers is supplied from beekeeping by 40%, other animal activities by 33% and crop production by 27%. In a research done by Abazinab et al. (2016), it is indicated that 63.4% of the income of the farmers is supplied by beekeeping activities. 8.82% of the farmers who participated in the research done by Kekeçoğlu et al. (2013) perform only beekeeping, the ones who does other agricultural activities and beekeeping activities are found to be 49.26%. In a research being conducted by Kalayu et al. (2017), 27.7% of farmer income is determined from crop production, 23.8% from animal production, 16.9% from beekeeping activity and 15.4% from irrigation. In the study conducted by Chauhan and Sharma (2000), it was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_47074724

determined that 69% of household income of farmers came from beekeeping. In a research done by John (2014) in Tanzania, 52.50% of the farmers' basic income source was determined to be beekeeping.

High majority of the beekeepers (88.7%) participating in the current study started the business of beekeeping with colonies in modern hives. Guyo and Legesse (2015) found that 92% of the farmers started beekeeping by trapping swarms while 7% of them started with the gift hives received from their family. In the research conducted by Tesfaye et al. (2017), it was determined that the 98.3% the farmers start beekeeping by trapping swarms and 1.7% of the farmers start with inherited hives from family. Abazinab et al. (2016) specified that 71.7% of the farmers started beekeeping via trapping swarms, while 28.3% of them started beekeeping through the gifted hives from family. In the research conducted by Gebreyohans and Gebremariam (2017), it is determined that 38% of the farmers started beekeeping through the gifted hives from family, 35% of them started via purchasing the hives and 15% of them started beekeeping using the hives retrieved from governmental and non-governmental organizations.

In the research, the most important reason for farmers to start beekeeping was determined to be obtaining yields in a short time. In the research done by Burucu and Bal (2018) in Kastamonu province, the first reason of farmers' to start beekeeping is the habit inherited from family by 67.90%. In the study conducted by Tunca and Çimrin (2012), it was determined that beekeeping activities is the only source of income for 17% of the farmers and additional source of income for %57 of them. In a research conducted by Borum (2017) in South Marmara Region, it is determined that 83.75% of the farmers do beekeeping as side job and hobby. In a research conducted by Şahinler and Gül (2003) in Hatay province, it is specified that 38.95% of the beekeepers do beekeeping to make a living, 42.11% of them do it with the aim of side income and 18.95% of them pursue it as a hobby.

The colonies possessed by nearly half of the beekeepers participating in the current research have decreased in the last three years. In a research conducted by Potts et al. (2010) that involves 18 European countries, it was determined that the number of hives decreased in central European countries while it increased in some Mediterranean countries. Demir et al. (2017) found that 8.8% of the farmers were considering to leave the beekeeping in the future. In the study conducted by Çevrimli and Sakarya (2018), the rate of farmers who is considering to increase the number of bee hives in the next years was found to be 57.5%.

It was determined that most of the beekeepers (77.4%) participating in the current research perform migratory beekeeping. In a study conducted in Croatia by Barlovic et al. (2009), it was determined that one third of the farmers were migratory beekeepers. In a study conducted in India by Sharma et al. (2013), it was found that the farmers were carrying 250-300 hives to 300-800 km away. Another study by Adgaba et al. (2014) found that 93% of the farmers were migratory beekeepers.

Environment, climate and flora have important effects on the number of harvests made. Therefore, the number of harvests may vary from region to region. It was found that half of the participating beekeepers have two honey harvests a year. In a study conducted by Gebremeskel et al. (2014), the rate of farmers who harvested once a year is specified as 61.5%, twice a year is 36.5% and three times a year is 1.9%. In their study, Kiros and Tsegay (2017) shows that more than 70% of the farmers harvested honey once a year while 25% harvest three times a year. In a study conducted by

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_47074724

Abejew and Zeleke (2017), it is specified that 34% of farmers harvest more than twice per year. In a study conducted by Abazinab et al. (2017), it is showed that the rate of farmers who harvested once a year is 37.8%, twice a year is 52.8% and three times a year is 9.4%. In the study conducted by Gebreyohans and Gebremariam (2017), it was found that 75% of the farmers harvested in September and October and 34.16% in July and August.

When the literature is reviewed, it is seen that there are significant differences between the numbers of hives possessed by beekeepers because many factors can be effective on the number of hives possessed. The participating beekeepers were found to have 162 hives on average. In a study conducted by Sarab et al. (2018) in Iran the average number of hives was found as 176. In another study conducted by Kadirhanoğulları (2016) in Iğdır province, it was determined that each business has 67 units of bee hives on average. In another study conducted by Tarekegn et al. (2017), it is determined that the families doing beekeeping business has 19 hive assets on average. In the research done by Moniruzzaman and Rahman (2009), the average number of hives owned by farmers was found as 28. In the research conducted by Kezic et al. (2008), farmers with up to 60 hives were referred as hobby beekeepers, farmers who has between 61 to 150 hives were referred as part-time beekeepers and farmers with more than 151 hives were referred as professional beekeepers. In that research, it was determined that 56% of farmers were doing beekeeping as hobby, 31% of them were part time beekeepers and 13% of them were professional beekeepers. In the study conducted by Kutlu (2014) in Gaziantep province, it is determined that the rate of farmers who consider beekeeping as the main source of income is 54%, as a side income is 37% and as a hobby is 9%.

Almost all of the participating farmers (98.4%) were determined to produce honey. In the study conducted by Öztürk (2017), it was determined that 82.5% of the farmers produce only honey and 17.5% produce pollen and royal jelly besides honey production. In the study conducted by Grgic et al. (2018) in Croatia, the yield of honey per hive was found to be 18.33 kg. In the study conducted by Yıldırım and Ağar (2008) the yield of honey per hive was found to be 10.72 kg. In the study conducted by Onurlubaş and Demirkıran (2017), it was determined that on average the farmers produced 2555.75 kg of honey annually. In the study conducted by Peter (2015), the average honey yield per hive in South Africa during the 2007/08 period is reported to be 12.77 kg. In a study conducted by Vural and Karaman (2009) in Bursa province, the average hive asset of farmers was found to be 168.40 and the average honey production was 4527.33 kg.

It was determined that the most important problem faced by the beekeepers during the production phase was diseases and pests. Effective and proper fight against bee diseases and pests is seen as very important in terms of the sustainability of beekeeping in the district. In other studies on the subject, diseases and pests have been found to be an important problem. In the study conducted by Ahikiriza (2016), it was concluded that limited information about production, diseases and pests, low colony assets and fires are the most important problems related to production. In a survey conducted by Yemane and Taye (2013) in Ethiopia, it was determined that the problems of beekeeping were insufficiency of beekeeping equipment, inadequate colony assets, high prices of modern hives, pests and beekeepers' lack of knowledge. In a study conducted by Ogunjimi et al. (2016) in southwest Nigeria, it was determined that the most important problems of the beekeepers regarding the production were the lack of information about beekeeping, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_47074724

lack of loan opportunities and the existence of insufficient processing technologies.. In the study conducted by Aksoy et al. (2017) in Erzurum province, the most important factors affecting honey production are found to be unsuitable climate conditions and winter loss. In the study conducted by Gebreyohans and Gebremariam (2017), 83.3% of the farmers stated that they see bee pastures as the most important problem especially in the dry season. In the study conducted by Ogunjimi et al. (2016), it is determined that the most important problems related to beekeeping is inadequate training related to beekeeping practices, insufficient loan opportunities and lack of beekeeping equipments.

In the current study, the most important bee product sold was found to be honey. In their study, Adedeji et al. (2016) stated that 74% of farmers produce honey for commercial purposes. In the study conducted by Burucu and Bal (2018) in Kastamonu province, it is determined that 82.72% of the farmers sell their honey.

In the research, it was determined that there were significant differences between the actual sales prices of bee products and the sales prices expected by the farmers for their products. In a research done by Kezic et al. (2008), it was found that the average selling price of honey for beekeeping professionals was 2.07 €/kg. In a study conducted by Cejvanovic et al. (2011) in Bosnia and Herzegovina the wholesale price of honey was found to be 2.11 €/kg. In a research conducted by Saner et al. (2004) in İzmir and Muğla provinces, the farmers' wholesales price of the extracted honey is calculated to be 1.65 €/kg. In a research conducted by Demir et al. (2017), it is specified that only 37.5% of the farmers were satisfied with the current honey prices. In a research conducted by Köseman et al. (2016) it is found that the rate of the farmers stating that in the last five years their beekeeping income is decreased is 38.3% while the farmers stating that their income has increased and decreased in this period is 39.6%.

In the study, it was determined that high majority of the beekeepers were found to be selling their products to traders. It was specified, by Onurlubaş and Demirkıran (2017) in their study in Edirne province, that 37.5% of the honey produced by the farmers was sold directly to the consumers.

It the current study, it was also found that the amount of honey allocated to the consumption of the beekeepers' their own families is very low (1%). In their study, Shibru et al. (2016) found that 95.8% of the farmers sold the honey immediately after the harvest while 4.2% of them stocked the honey for home use. In a study conducted by Girma et al. (2008) it is determined that 90% of the honey is sold and 10% is consumed at home. In their study Lemita (2010) found that farmers sold 97% of the produced honey in local markets for cash and 3% of them consumed at home. In a study conducted by Kinati et al. (2013) in Ethiopia, it is determined that 75% of the honey sold after between one and six months, while 1.7% of it is stocked more than two years by the farmers. In the study conducted by Ambaw and Teklehaimanot (2018), it was determined that 39.7% of the farmers did not stock honey while 41.7% of them stocked from one to six months.

In this study, it was also determined that honey was sold in almost all months. In the research conducted by Abebe (2009) in Ethiopia it was found that farmers sold 27% of the honey in December, 25% of it in January and 18% of it in February.

The low sales price of honey was determined as the most important problem faced by beekeepers in marketing. In the study conducted by Kadirhanoğulları (2016), it was determined that the lack of effective marketing cooperatives to market the produced honey was stated as the biggest problem of all the farmers. In a study conducted by

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_47074724

Kumar (2013) in India, low honey sales prices, high cost of transporting hives from one place to another and financial difficulties experienced during the purchase of raw materials have been identified as problems by farmers.

Conclusion

Bees are vital for the continuity of the ecosystem as they ensure the pollination of plants. Beekeeping is a very important agricultural activity in terms of diversifying agricultural income and agricultural activities in rural areas and increasing agricultural income. Beekeeping has an important place both in Muğla and Milas.

The average honey production per hive in Turkey is about 14.63 kilograms (Şahin, 2015). In the research, the average extracted honey production per hive was found to be 14.41 kg, this figure appears to be slightly less when it is compared to average production of Turkey. It is thought that productivity will increase due to the modern beekeeping techniques of the farmers. Therefore, relevant agricultural extension programs should be organized. It was determined that 87.1% of farmers had problems with honey production. Diseases and pests (53.2%) and negative effects of global warming (41.9%) are among the most important problems of beekeepers. Beekeeping courses should be organized in order to solve the problems of farmers related to production, to increase their technical knowledge on bee farming and diseases and pests. Farmers should be educated with practical trainings.

It is stated that 83.9% of farmers have problems with honey marketing. The most important problem farmers face with honey marketing is the low price of honey (80.6). There are no beekeeping cooperatives in the research area. This reduces the bargaining power of beekeepers and beekeepers sell bee products at low prices. In the research, it was determined that the sales prices of bee products were significantly lower than the sales prices expected by farmers. On the other hand, it has been determined that the farmers' rate of accessing information about market is low. In addition to the beekeeping techniques, farmers have to know and follow supply, demand, domestic and foreign markets, sales, price formation etc. closely. Agricultural marketing extension can be defined as a training program that provides information that farmers need to solve marketing problems. Therefore, an agricultural marketing extension program should be applied to meet farmers' needs, and farmers' problems about the market should be solved.

(Received 5th Jan 2019; accepted 26th Feb 2019)

Abstract. This paper presents the first quantitative ethnobotanical knowledge and practices of using native plants for different ailments from Namal Valley of Pakistan. Data was gathered by interviewing 350 informants through semi-structured questionnaires. A total of 217 taxa belonging to 166 genera and 70 families were documented. Fabaceae and Asteraceae families were found to be the most cited families (with 19 and 18 species receptively). Herbs represent the most cited life form (71%) and flower was the most widely used part (34.8%) with decoction as main mode of the utilization (41.5%). On the basis of use values, the most commonly used ethnobotanical taxa in the Valley were reported to be *Euphorbia heterophylla* (0.7) and *Merremia dissecta* (0.6). The highest RFC value was noted for *Aloe vera* (0.14) while highest ICF value was estimated for dental problems category (0.7). Maximum similarity index was found in the studies with Bana Valley (JI 23.9). Similarity percentage of plants uses ranges from 0% to 15.7 (Bana Valley), while dissimilarity percentage varies up to 32.5% (Soon Valley). This study highlights the medicinal flora of study area that will serve as baseline for conservation and sustainable utilization through future research on bio prospecting of potential species to develop novel drugs.
Keywords: *medicinal flora; conservation; Fabaceae; novel drugs; informant consensus factor*

Introduction

Ethnobotanical studies on medicinal flora are crucial for developing novel drugs based on traditional knowledge of the local people (Heinrich and Gibbons, 2001; Mesfin et al., 2009; Vitalini et al., 2013). The usage of medicinal plants for medicinal and therapeutic purposes has been studied and documented globally (Kunwar et al., 2015; Bulut et al., 2017; Fortini et al., 2016; Menale et al., 2016; Shah and Rahim, 2017). The role of herbal treatment in curing various diseases is vital because of the fact that a large number of ailments are cured by plant based medications (Rehecho et al., 2011). In this context ethnobotanical researches demonstrate high significance and prominence of medicinal plants in cognitive pluralistic perspective. Such studies not only play an important role in upgrading the social status and economic values of an area but also preserve the aboriginal medico-ethnobotanical data of the indigenous communities that consequently preserve the global heritage (Sanz-Biset et al., 2009). Medicinal plants are considered very important among the rural communities due to their potential to cure health related problems for which several of remote communities are unreachable of modern health care facilities (Heinrich, 2000; Tabuti et al., 2003; Verma and Singh, 2008). Out of approximately 6000 plants species in Pakistan 600 to 700 are reported to have medicinal value. Among them 456 plants species are used in

the formulation of approximately 350 synthetic drugs (Ahmad and Husain, 2008). Pakistan has variations on climatic conditions, ecological zones and topography where diverse flora of medical importance flourishes in dry to temperate habitats. Limited number of ethnobotanical expeditions have been conducted in well-known valleys of Pakistan (Ahmad et al., 2014; Amjad, 2015; Bano et al., 2014; Haidar and Qaiser, 2009; Haq, 2012; Hazrat et al., 2011; Khan et al., 2010; Khan et al., 2013; Khan and Khatoon, 2008; Shah and Rahim, 2017; Zabihullah et al., 2006) but most of the remote valleys are still unexplored There could be hundreds of plant species growing in these valleys having medicinal, industrial and economic potential. Local communities of various regions use these species in different ways on the basis of their cultural beliefs and inherited experience. However, little attention is being paid to the conservation and sustainable utilization of several of potential species. Salt Range of Pakistan is one of such region which is least explored regarding the documentation of medicinal wealth present in several of its valleys. Namal Valley is among the most fascinating area awaiting systematic study of its ethnobotanical knowledge associated with native flora of the region. Recently (Shah et al., 2018) has documented sixty eight (68) medicinal plants used in snakebite and scorpion sting used by the inhabitants of this valley who are predominantly pastoralists, peasants and farmers. Namal Valley is naturally gifted with diverse flora with social, economic and environmental importance. The objectives of this study were to collect record and document information regarding the plants used ethnobotanically by the aboriginal people especially with respect to the medicinal wealth of the plants. This extensive study carried out throughout the Valley revealed an exhaustive list profile of medicinal plants, based on quantitative evaluations adopting several ethnobotanical indices like use value (UV), frequency of citation (FC), relative frequency citation (RFC), family importance value (FIV), informant consensus factor (ICF) and the Jaccard index (JI).

Material and Methods

Study area

Geographically, the study area was located in the northwest of Punjab Province geographically ranging at 71 °48°45° E longitude and 32°40°10° N latitude, spreading over an area of 5.5 square kilometers. The valley is bounded by Salt Range Mountains and touches western border of Mianwali district (*Fig. 1*). Historical and scenic places of the Valley include Namal College Mianwali, Namal Dam, Namal Lake, Sulphur spring and shrines of Hafiz Jee and Khaki Shah. Namal valley is included among the oldest civilization in Pakistan. Raring of cattle and goats provides a livelihood for the local people Most part of the Valley is covered by forests and pastures The climate of the Valley is characterized by cold, dry weather at high altitudes and humid, warm in low altitude-lying areas. Several native tribes with a rich historical background and that use the native medicinal flora and have their own traditional healers known as tabeeb or hakeem are in the Valley. These tribes are awan, malik, niazi, shah, mian etc. Climate variation and complex topography gives way to diverse flora and fauna in the Valley. Valley is carpeted with *Dodonaea viscosa*, *Prosopis glandulosa*, *P. juliflora*, *Tamarix aphylla*, *T. dioica*, *Tephrosia pupurea*, *Withania coagulans*, *Pluchea arabica*, *Pulicaria glutinosa* and *Rhazya stricta* in the low altitudes while *Acacia modesta* mixed with *Salvadora oleoides* are commonly seen in high altitudes. *Viola cinerea* and *Pseudogaillonia hymnostephana* are among the rare taxa of the Valley that have also rare occurrence not only from the Pakistan but also globally (Shah et al., 2018).

Ethnobotanical data collection

Data were collected from all the villages of the Valley from 2013-2016 representing all the seasons following the method of (Martin, 1985; Heinrich et al., 2009). A total of 16 field trips (representing all seasons) were carried out to collect plants and to document ethnobotanical information. Keeping in view the aim of quantitative approach to record ethnobotanical information, the participant observation method was used along with open-ended interviews and questionnaires. Knowledgeable people of the Valley including 12 traditional healers, shepherds, herbal medicinal venders, were consulted. The people in the local area speak Saraiki language and therefore, interviews were conducted in Saraiki language. All the documented data was later translated into English. A total of 350 informants (240 males and 110 females) of all group ages (25 to ≥ 65) were interviewed. Information regarding vernacular names, ethnobotanical uses etc. was recorded and the details are presented in *Table 1.*

Collection and taxonomic identification of plants

Plants were collected with the help of traditional healer and local respondents just after the formal and informal discussion on ethnobotanically important plants of the area. Local informants guided researchers to the natural habitat of the discussed species and in some cases also helped to collect voucher specimens. After recording information about plants, voucher specimen were pressed in the field and dried properly. Plants were identified following the Flora of Pakistan (Nasir and Ali, 1970-2001). The list of plant species used ethnobotanically in the area was checked and updated after verification from the online website (http://www.theplantlist.org) of the Royle Botanic Garden, Kew, assessed on April 3, 2014. Voucher specimens were preserved and deposited in the Herbarium of University of Sargodha for their taxonomic identification by comparison with specimen in the herbarium and for future reference.

Quantitative analyses of ethnobotanical data

Ethnobotanically important plant species were arranged in alphabetic order by botanical name, family, habit, parts used, modes of utilization and disease treated. Different quantitative indices including use value (UV), frequency of citation (FC), relative frequency citation (RFC), family importance value (FIV), informant consensus factor (ICF) and the Jaccard index (JI) were applied to analyze the documented data.

Use Value (UV)

The UV is a quantitative index used to determine the relative importance of an indigenous plant species. According to Phillips et al. (1994), the use value was calculated by using the formula :

$$UV = \sum U / n \qquad \text{(Eq.1)}$$

Where, "U" refers to the number of uses mentioned by the participant for a given species and "n" refers to the total number of informants interviewed that used the given species. High UV score indicates that there are many use reports for that plant and vice versa.

Frequency of Citation (FC) and Relative Frequency Citation (RFC)

The Frequency of Citation (FC) is number of informants mentioning the use of plant species.

Moreover, Relative Frequency Citation (RFC) index was evaluated by using the formula :

$$RFC = FC / N \left(0 < RFC < 1\right) \qquad \text{(Eq.2)}$$

N is the total number of informants participating in the study. The RFC index ranges from "0" when nobody referred to a plant as useful to "1" when all informants referred to as useful. (Vitalini et al., 2013).

Informant Consensus Factor (ICF)

Informant Consensus Factor (ICF) was calculated using the formula (Heinrich et al., 1998):

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_47254805

$$ICF = \left(Nur - Nt\right) / \; Nur - 1 \qquad \text{(Eq.3)}$$

Where, “Nur” refers to the total number of use reports mentioned for a particular disease category and “Nt” refers to the total number of plant taxa used for particular disease category. This formula was opted to find out the homogeneity in the ethnomedicinal information documented from the traditional informants.

To calculate ICF, reported medicinal plant species were grouped into 16 categories of various diseases reported in the study area by the informants. ICF is useful to focus and to determine the consistency of the data concerning certain sorts of disease categories (Canales et al., 2005; Heinrich et al., 1998). The result of this consensus ranges from 0 to 1. A high value (close to 1) predicts that plants are used by the high percentage of the informants for a number of illness related to that comprehensive category, whereas, the low value (close to 0) shows that the plants are selected arbitrarily for a few or a single complaint or that informants did not share or exchange facts and data about the usage of plants (Abu-Irmaileh and Afifi, 2003; Akerele, 1988; Kloutsos et al., 2001). Medicinal plants for which very few diseases are referred are supposed to be pharmacologically less active and thereby have low lower ICF values (Gazzaneo et al., 2005; Sharma et al., 2012; Teklehaymanot, 2009), *Table 2*.

Jaccard Index (JI)

Jaccard index is used to compare the reported data with that of other ethnobotanical studies conducted in other areas of Pakistan and abroad (González-Tejero et al., 2008). JI is calculated by using the formula :

$$JI = c \times 100 / a + b - c \qquad \text{(Eq. 4)}$$

Where, “a” is the recorded number of species of the study area “A”(Namal Valley) and “b” is the documented number of species of the area “B”. Where “c” is the number of species common to both “A” and “B”. As far as indigenous communities are concerned, “a” is the number of species reported by indigenous community “A”, “b” is the number of species cited by the indigenous community “B” and the “c” is the number of species reported by both “A” and “B” communities, *Table 2*.

Results

A total of 350 local informants were interviewed. The age of informants ranged from 25 years to above 65. Education wise, 24.3% informants were illiterate, 20% completed their five years education, 18.6% completed their eight years education and only 13.1% informants had higher education (University level). A total of 217 plant species belonging to 166 genera and 70 families were collected from the Valley. The ethnobotanical uses of plants (vernacular name, habit/type, part used/ mode of utilization, disease treated and other information like UR, UV, FC, RFC, previous report) are included in the *Table 1*. The highest number of reported species belong to family Fabaceae (19 species) followed by Asteraceae (18 species), Poaceae (13 species), Euphorbiaceae and Solanaceae (9 species each) and Lamiaceae and Moraceae (8 species each) etc. Most of the documented species were herbs (71%), followed by shrubs (15%) and trees (14%) (*Fig. 2*).

The high numbers of species recorded in the present work were wild (92.6%). In the current study, the most frequent plant part used ethnobotanically by the local people was flowers (35%), followed by leaves (18%), whole plant (12%), pods (10%), twigs (8%), aerial parts (8%), rhizome and seeds (3% each), stem (1.6%) and fruit (1%) (*Fig. 3*). A total of 261 preparations were recorded and the most preferred method of preparation was decoction (41%), followed by infusion (18%), raw form (14%), paste (8%), juice (5%), cooked form (3%), latex, smoke, poultice and powder (2% each), oil, ash and extract (1% each) (*Fig. 4*).

Discussion

Ethnobotanical knowledge plays an important role in exploring the human-plant relationship and medicinal uses of native flora. In this study possession of traditional knowledge about medicinal plants was found among the people with low level of education and among the age group of 46-<65. This is because inhabitants of the study area are mostly associated with raring of animals and other depends on available land for farming, they have least concern about acquiring higher education. But due to intimate relation with nature they have enough knowledge about the use of these plants. On the other hand, the informants who are educated are unaware from the uses of plants because of least interaction with the nature.

Highest use report of plants belonging to Fabaceae and Lamiaceae is due to their dominance and wider occurrence as easily available plants are likely to be used frequently by local inhabitant (Agelet and Valles, 2001; Johns et al., 1990) Similar findingis reported by Cornara et al., (2009); Giday et al., 2009; Saslis-Lagoudakis et al., 2011; Teklehaymanot, 2009). Moreover, the ascendancy of these families reveals the presence of a wide range of bioactive compounds in respective taxa belonging to these families. The diversity of bioactive compounds and secondary metabolites may be the reason for the multi-species use one or more health problems, as a single compound may not be the reason of efficacy (Verpoorte et al., 2005). The Poaceae had less aforementioned proceedings in ethno botanical investigations (Cakilcioglu and Turkoglu, 2010; Kadir et al., 2012; Rokaya et al., 2010) conducted at global level. In present study the reason of frequent use of family Poaceae is mainly the dependency of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_47254805

locals for fuel (e.g., *Saccharum bengalense*, *S. revennae*, *S. spontaneum* etc.), thatching (*Arundo donax*, *Phragmites australis* etc.) , forage (*Cymbopogon commutatus*, *Cynodon dactylon*, *Cenchrus echinatus*, *Chloris gayana*, *Coix lacryma-jobi*, *Dactyloctenium aegyptium*, *Desmostachya bipinnata*, *Dichanthium annulatum* etc.) and other ethnobotanical uses (medicinal) as compared to medicinal values, because lush herbaceous plants are abundant in study area. Such findings indicate great reliance of inhabitants on a diversity of plant species to treat ailments, and represent a good sign of the intense facts on plant based treatments (Nadembega et al., 2011). Among the reported plant species, some medicinal plants were of high indigenous priority thus are commonly cited by majority of the respondents. The highly cited medicinal plant species those having at least 32 citations or more (*Table 1*) were *Aloe vera, Calotropis procera*, *Mentha longifolia*, *Tamarix dioica*, *Ziziphus nummularia*, *Nerium oleander*, *Salvadora persica*, *Ziziphus mauritiana, Tamarix aphylla*, *Typha angustata, T. latifolia, Peganum harmala, Tribulus terrestris, Acacia modesta, Albizia procera, Eruca sativa, Ricinus communis, Withania coagulans, Withania somnifera, Morus alba, Conyza canadensis, Ocimum basilicum, Rumex dentatus* and *Urtica dioica.* These plants may reported frequently due to their abundance in the area and there is prevailing beliefs among the inhabitants to consider these plants medicinally effective, as majority of informants stated that maximum treatment were cured at domestic level because of unavailability of healthcare services and high cost of synthetic medications. The reason of frequent citation of these plants may be the presence of valuable and pharmacologically active bioactive compounds. Favorable climatic and topographic conditions of the study area might have positive contribution toward the rapid adaptation of herbaceous flora as compared to other life forms (Ayyanar and Ignacimuthu, 2011; Giday et al., 2003; Mesfin et al., 2012; Uniyal et al., 2006). According to most of the informants the fast restoration and higher potency of herbs is the main reason to have higher preferences for medicinal purposes and herbs are ephemeral in habit. Similar results were also discussed in previous documentations (Megersa et al., 2013; Upadhyay et al., 2010; Upadhyay et al., 2007). Herbs are rich in bioactive compounds (Srithi et al., 2009). The major use of flower is unique to this study when, compared with other ethnomedicinal studies (Rahman et al., 2016; Shah and Rahim, 2017) conducted in Pakistan. Local people believe that collecting a plant in flowering period is very important for the effectiveness of the formulation. This may be due to the richness of essential oils or the existence of bioactive compounds in flowers as compared to other parts. However, collection of premature flower and its excessive use may have negative impacts on plants sustainability. Furthermore, over-exploitation of seeds and roots for local uses can lead to a drastic decline in the populations of medicinal plants (Ghimire et al., 2008) and consequently an expatriation of medicinal species from the area. Therapeutic uses of leaves are defensible (Giday et al., 2003; Zheng and Xing, 2009) which is reported as the second highest part used in this study. Use of leaves in traditional medication is a common practice which is also reported in several other studies (Asase et al., 2010; Asase and Oppong-Mensah, 2009; Koudouvo et al., 2011; Nadembega et al., 2011; Nguta et al., 2010). The use of leaves may be of high preference due to its photosynthetic function and presence of secondary metabolites for defense from herbivores which could be medicinally important for curing various ailments in humans (Bhattarai et al., 2006; Ghorbani, 2005). In addition, leaf collection is ecologically sustainable and is easy to collect as compared to other plant parts (Giday et al., 2009).

Boiling the dried and stored plant parts for herbal preparation is considered more effective as compared to other methods. It is a general observation that heating process

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_47254805

speed up several biological reactions ensuring the extraction of countless vigorous compound (Al-Adhroey et al., 2010; Chen et al., 2008; Han et al., 2007; Zhang et al., 2005). Second rated mode of utilization reported in the area was infusion. Fresh and healthy plant parts are used for making infusions. Local people believe that infusion is one of the highly effective recipe which is easy to prepare and several effective compounds that plays a crucial role in the medication will not degraded during the process of preparation (Dike et al., 2012; Idowu et al., 2010). A handful amount (quantity that can be held or griped in a hand) of a patient is considered as an exact dose for medication from generation to generation. In the study area this is the most common way to measure a dose of drug required for different age groups from children to adults. Doses are taken twice or thrice a day depending upon the condition of the disease treated. Water was main and common solvent used in herbal remedies (Andrade-Cetto, 2009; Lee et al., 2008; Poonam and Singh, 2009; Prashanth et al., 2001; Ssegawa and Kasenene, 2007) since most of them were prepared as decoction or infusion. This practice is highly convenient because water is easily accessible, the easiest vehicle for herbal preparation and also expected not to disturb the chemical composition of the active constituents (Nunkoo and Mahomoodally, 2012). Some other ingredients sugar, salt, honey, olive oil, mustard oil and lemon are also added to improve the taste and to have additional effective that can help to reduce nausea, vomiting and constipation.

Quantitative analysis of ethnobotanical data

Use value (UV), Frequency of citation (FC) and Relative frequency citation (RFC)

Use value implies the relative significance of plant species on the basis of number of informants (FC) who mention the uses reported for respective plant species. The plant species with high UV (*Eq.1*) are suggested for further pharmacological and phytochemical screening to develop new drugs.

Relative frequency citation (RFC) (*Eq.2*) is a quantitative index that estimates the local reputation of every plant species used by the ethnic folks (Vitalini et al., 2013). It is calculated from Frequency of Citation (FC) divided by the total number of informants (N) who participated in the survey (Tardío and Pardo-de-Santayana, 2008) (*Table 1*).

The high RFC value suggests that these plants were known to majority of the informants. The high values of RFC help to identify species for which an appropriate conservation and sustainable utilization strategies should be formulated to ensure regular supply of raw materials for the future (Asase et al., 2005).

Comparison of different indices

Informant consensus factor (ICF) (*Eq.3*) values of reported medicinal plants were calculated for the categorized ailments (*Table 1*). Fifteen primary ailment categories were identified: *Table 3*. ICF values range from 0 to 0.7 (*Table 3*). Highest ICF value (0.7) was reported for oral and dental problems group, followed by respiratory problems (0.4), gastrointestinal problems, antidote and skin problems (0.3 each). The reason of high ICF could be the common happening of these illnesses in the community due to poor sanitation practice, low economic status and lack of adequate modern health care of in the Valley (Bieski et al., 2015). High ICF values undoubtedly disclose a noteworthy number of reports on the use of these taxa for a group of health problems (Baydoun et al., 2015). The slightest agreement among the informants was detected for plants used for group of sexual disorders, ear, nose and throat problems (ENT), eye ailments and other diseases which include pain, small pox, mumps, insect repellent, antitumor and anti-allergic, all these groups containing the zero ICF value. The least

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_47254805

value of ICF for ear, nose and throat problems (ENT) and eye diseases is in accordance with other studies (Bibi et al., 2015; Jamila and Mostafa, 2014). These low ICF values could be credited to the trend of folks in native or urban societies to use conventional medicines for curing predictable diseases, even in current times (Upadhyay et al., 2011).

Table 3. *ICF Value of medicinal plants used for treatment of various diseases (ICF*=Informant Consensus Factor)*

Disease category	No. of use reports	No. of taxa	ICF*
Respiratory problems	78	49	0.4
Urinogenital diseases	9	7	0.25
Gastrointestinal problems	145	99	0.3
Musculoskeletal disorders	56	46	0.2
Sexual disorders	53	53	0
Skin problems	83	61	0.3
Glandular disorders	29	28	0.03
Antidote	22	16	0.3
Cardiovascular diseases	51	46	0.1
Neurological disorders	20	18	0.1
ENT problems	13	13	0
Eye ailments	3	3	0
Fever	68	55	0.2
Oral and Dental problems	19	7	0.7
Hair problems	6	5	0.2
Others	10	10	0

Comparative analysis of documented data with previous literature

To conclude whether the usage of plants by communities of Namal Valley were previously reported or not for medicinal value, a literature study on ethnobotanical use was done and comparative results are listed in *Table 1*. Twenty three research papers from different valleys were selected to compare the data and it was observed that various plants have novel use reports and some plant species like *Viola cinerea*, *Pulicaria glutinosa* and *Pseudogaillonia hymnostephana* from the study area are reported for the first time and previously with no or rare use reports. In this study a total of 217 plant species were documented. Literature review of described medicinal plants have shown that the similarity of uses varies from 0% to 15.7%, while dissimilar uses range up to 32.5% (*Table 2*) (*Eq.4*). In our study high degree of similarity was found with studies directed in Bana Valley in Kotli, Pakistan by Amjad. (2015) and Soon Valley in Khushab, Pakistan by Shah and Rahim. (2017) with JI 23.9 and 14.9 respectively (*Table 2*). The cause of maximum similarity index may be the resemblance in plant diversity and their multipurpose uses against numerous health related problems in the study area. Noteworthy multiethnic discrepancy may be the cause of deviation in JI that are topmost symbolic of variation in habitation and populace (Leonti et al., 2009). The resemblance and inconsistency in ethnomedicinal studies appear to point out the significance of tribal wakefulness of medicinal plants in miscellaneous regions where chronological (Moerman, 1998) environmental (Ladio et al., 2007), phytochemical and organoleptic (Leonti et al., 2003) structures add in their assortment.

Limitations of the study, insights gained and approaches for improvements

This study was primarily aimed to document indigenous ethnobotanical knowledge of native communities of Namal Valley and evaluates their reliability within Pakistan and globally. However, few limitations still exists regarding sufficient interpretation of data. For example the native people have no acquaintance of common names/ vernacular names of some plant and similarly no report about their ethnomedicinal value and their use is confined to fuel, forage, thatching etc. Another obstruction of the study was that it did not investigate into the danger of invasive species and, documentation and dispersal of the introduced species.

Side effects of medicinal and other plants

In this study the documented ethnobotanical data generally elaborate the medicinal usage of the indigenous plant species, but it was observed that informants were much careful in using some of the plants such as *Achyranthes aspera, Calotropis procera, Cannabis sativa, Croton bonplandianum, Cuscuta reflexa, Datura metel, Dodonaea viscosa, Euphorbia helioscopia, E. heterophylla, E. hirta, E. peplus, E. prostrata, E. serpens, Heliotropium currasavicum, H. europaeum, Ipomoea carnea, Lantana camara, Lathyrus aphaca, Nerium oleander, Ricinus communis, Rhazya stricta, Solanum elaeagnifolium, S. xanthocarpum, S. nigrum, S. surattense, S. incanum*. The inhabitants are fully aware about the fact that these plants can cause symptom of toxicity including abortion, restlessness, depression, skin inflammation, vomiting, abdominal pain, nausea, impotency, sterility, dizziness and hallucination. People have a general knowledge about toxic signs and their interpretation of toxicity is based on the observation from generation to generation. Foremost taxonomic classification level for assessing the efficacy of plant to native societies is family (Thomas et al., 2009). Same is factual for the toxicity of plants (Huai et al., 2010). Fabaceae, Asteraceae, Euphorbiaceae and Apocynaceae have been described as the chief families comprising toxic plants in various studies (Levetin and McMahon, 2008; Huai et al., 2010; Ozturk et al., 2008). The reason of toxicity of these families is the presence of different toxins such as alkaloids, dicoumarin, glycosides, photosensitizing compounds, saponin, selenium (Fabaceae), acrid substances, alcohol, alkaloids, glycosides, nitrogenous compounds, photosensitizing compounds, saponins, selenium, volatile oils (Asteraceae), acrid substances, croton oil, photosensitizing compounds, biterpinoids, triterpenoids, steroids, alkaloids, cyanogenic glycosides and glucosinolates (Euphorbiaceae) and resin, glycosides (Apocynaceae) (Barla et al., 2006; Madureira et al., 2004; RIZK, 1987; Yamamura et al., 1989; Zhang and Guo, 2006). Further study of herbal toxicity in human is needed to certify safety and boost patient confidence about herbal remedies.

Conclusions and recommendations

This study exposed that traditional medication, mainly comprising the practice of medicinal plants playing a substantial role in curing the basic healthcare necessities of the inhabitants of Namal Valley, Pakistan. Usage of traditional medicine as a dominant part of their beliefs, inadequate access to recent health care conveniences and the cheerful prosperity of natural assets could be deliberated as the key influences for the prolongation of these traditional practices. The instant and thoughtful hazard to the native medicinal flora in the study area appears from the growing impact of overharvesting, overgrazing and deforestation due to human activities. There is dire necessity for thoughtful exertions to create awareness in the native people so that the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_47254805

proper actions should be taken to protect the suitable surroundings/habitations mandatory to defend and conserve the medicinal plants in their natural ecosystems. Because of lack of written documents of conservation of plants and habitats, researches like this study is compulsory to protect primeval retentions, to encourage the flow of information to the younger generations, to preserve ethno-biodiversity and to deliver a beginning point for further pharmacological, biological and chemical investigations on medicinal objects.

Acknowledgements. The authors appreciatively thank all the guides the traditional healers who accepted to participate to the study. The study was supported by Higher Education Commission Pakistan (Programme No. 20-1599/ 09/3007).

(Received 26th Jan 2019; accepted 8th Mar 2019)

Abstract. Taking the core area of Jiangsu Yancheng Wetland National Nature Reserve as a case, spatial and temporal changes of habitat quality were analyzed from the viewpoint of *Red-crowned crane* (*Grus japonensis* (Statius Müller, 1776)), and other rare birds. The results showed that the area of mudflats and *Suaeda salsa* marshes decreased, the area of *Spartina alterniflora* marshes, *Phragmites australis* marshes, aquaculture ponds and roads increased during 1983 to 2011. The value of habitat degradation index increased from 0.006 to 0.024 during 1983 to 2011, which meant the habitat degradation was becoming more serious. The spatial distribution of habitat degradation had been a distinct longitudinal band from an obvious lateral belt. The value of habitat quality index decreased from 0.863 in 1983 to 0.742 in 2011, which meant the habitat quality became worse due to the expansion of aquaculture ponds and *Spartina alterniflora*. Based on 1983, the value of habitat scarcity index increased from -0.10 to 0.173 during 1997 to 2011, indicating that the ecosystem function was declining. The values of habitat scarcity index of *Suaeda salsa* marsh and mudflat were obviously rising and were also the highest which were 0.628 and 0.637 in 2011, respectively. It indicated that *Suaeda salsa* marsh and mudflat became more and more scarce. They needed more protection and restoration.
Keywords: *landscape change, habitat quality, spatial differentiation, InVEST, coastal wetland*

Introduction

Habitat quality is one of the important service functions of the ecosystem and the objective existence of the essential attributes of the ecological environment (Xiao, 2011). However, with the increase of human disturbance, especially the change of land use mode, intensity and pattern caused by large-scale human activities, it had a heavy impact on the quality of biological habitat, and even affected the biodiversity of the entire region, and even subsequently the planet (Zhong et al., 2017). Therefore, the study of regional habitat quality was of great significance for maintaining regional ecosystem stability and improving ecosystem functions.

On the whole, the habitat quality assessment research can be divided into two categories. First, the habitat quality assessment based on on-the-spot investigation was mostly limited to a small scale, such as small cities, rivers, nature reserves and so on. Belt transect method or quadrat method was often used to investigate animals and plants, so as to obtain parameters related to habitat quality, constructing an assessment system and using certain mathematical methods to evaluate (Wu et al., 2015), which was mainly used to predict the spatial distribution of habitat or select location of nature reserves in the future, which can analyze the spatial distribution of species and habitat conditions, and assess the suitability of the species habitat (Chen et al., 2016). For example, Guo et al. (2016) evaluated the regional habitat quality of Zagunao river valley in the upstream of Minjiang River by using Analytic Hierarchy Process (AHP) according to 9 factors such as topography, soil, water and vegetation. However, this method is time-consuming and labor-consuming, making it difficult to observe for a long time.

The second is the index system model based on landscape pattern. With the widespread use of remote sensing and Geographic Information System (GIS) technology, integrating the landscape pattern and the distribution of threat sources into the habitat quality model, establishing a structural spatial display model has become a new research focus, is suitable for large and medium-sized research on the spatial and temporal changes of habitat quality, and is the basis for the identification, definition and conservation of ecosystem health (Gong et al., 2018). Artificial Intelligence for Ecosystem Services (ARIES), Multiscale Integrated Models of Ecosystem Services (MIMES) and Integrated Valuation of Ecosystem Services and Tradeoffs (InVEST) models have done creative research in this respect, among which the InVEST model is the most mature and most widely used ecological function evaluation model at present, and the method of evaluating habitat quality based on habitat threaten is widely used (Bhagabati et al., 2014). Terrado et al. (2016) did a comparative analysis of the calculation results of habitat quality module in model with the results of biodiversity observation. Research showed that there was a significant correlation between them, proving the reliability of the InVEST model. Chu et al. (2015) studied the changes of landscape pattern and habitat quality in Liaoning coastal zone from 2000 to 2010 by using the InVEST model, pointing out that reclamation of wetlands and urbanization expansion were the main reasons for the degradation of habitat quality. Wang (2016) evaluated the changes of habitat quality in Sanjiangyuan from 2000 to 2010 based on the InVEST model, and pointed out that the improvement of habitat quality in Sanjiangyuan in the past 10 years was a manifestation of the effectiveness of ecological restoration and construction. Bai et al. (2015) studied the changes of habitat quality in Minjiang River Basin from 2000 to 2010 by using the InVEST model, and pointed out that the interference of roads, industrial land, residential areas and mining sites were the main driving factors for the changes of habitat quality.

Yancheng Coastal Wetland is located in the central coast of Jiangsu Province of China, and is one of the most typical and representative distribution areas of muddy coastal wetlands in China and even the world, integrating intertidal beaches, tides, rivers, salt marshes, *Phragmites australis* marshes and *Spartina alterniflora* marshes. Over the years, under the dual influence of nature and human activities, especially under the high-frequency and high-intensity human production activities, the natural wetland area has been reduced and biodiversity has been lost, and the problem of ecological environment quality has become increasingly prominent, which has become one of the current focus issues, especially the study of suitability of *Red-crowned Crane* habitat. Sun et al. (2011) and Ou et al. (2015) pointed out the impact of changes in wetland landscape structure and connectivity under the influence of human activities on the habitat quality, especially on the habitat suitability of *Red-crowned Cranes*. Liu et al. (2016) studied the population dynamics of Red-crowned Cranes and their selection of habitat in Yancheng coastal wetland. Wang et al. (2015) selected nine ecological factors such as land use status, plant coverage, soil environment, biomass, water quality, water supply, biodiversity, wetland threated status and annual growth rate of wetland degradation, taking GIS technology,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48074821

and the ecological suitability of nature reserves was analyzed quantitatively by using AHP and factor weighted superposition. However, the study on the spatial differentiation of habitat quality with long time series, quantification and visualization is rarely reported in Yancheng coastal wetland. Therefore, taking the core area of Jiangsu Yancheng Wetland National Nature Reserve Rare Birds as an example, this paper studied the spatial and temporal changes of the habitat quality of the core area from 1983 to 2011 by using the habitat quality module in the InVEST model, and analyzed the impact of landscape changes on the habitat quality, which can provide a reference for the construction and management of Yancheng Coastal Wetland.

Material and methods

Study area

Yancheng coastal wetland is located in the central coastal area of Jiangsu Province of China, facing the Yellow Sea in the east. The coastline is 582 km long and the wetland area is 4.53×10^5 hm^2. It is the largest tidal flat coastal wetland in the Asian continent. The nature reserve is located in the transition zone between subtropical and warm temperate zone. The monsoon is remarkable and the climate is mild. The annual precipitation is about 1000 mm. Jiangsu Yancheng Wetland National Nature Reserve • Rare Birds (32°20′N～34°37′N，119°29′E～121°16′E) was established in 1983. It was upgraded to a national nature reserve in 1992. It is an important member of World Biosphere Reserve, Northeast Asia Crane Protection Network and East Asia--Australian Wader Migration Network. It has been entered into the International List of Important Wetlands. The study selected the core area of Jiangsu Yancheng Wetland National Nature Reserve • Rare Birds (*Fig. 1*) as the case area. The core area is to Xinyanggang River in the north, to Doulonggang River in the south, to the seawall road in the west, and to edge of mudflats (-3 m isobath) in the east. It is a typical silt-type tidal flat wetland with a total area of 1.92×10^4 hm^2. The landscape types in the core area are divided into natural wetlands, constructed wetlands and non-wetlands. Natural wetlands include *Phragmites australis* marsh, *Spartina alterniflora* marsh, *Suaeda salsa* marsh, mudflat and river. Constructed wetlands are culture ponds. Non-wetlands are roads.

Data sources

We used MSS image in 1983 (M4119037_037119831114), TM image in 1997 (P119737_5t19920607) and ETM image in 2011 (L71119037_03720110924) as the data sources. At the same time, we also used 1:200,000 geomorphic map, 1:200,000 vegetation map and 1:200,000 land use map of Xinyangang River estuary in "atlas of comprehensive survey of coastal and tidal marsh resources in China - fascicule of Jiangsu" which was published by the State Oceanic Administration of China and the State Bureau of Surveying and Mapping of China in 1988.

In ENVI 4.7, we first removed the trips 0n the image in 2011 by using the stripper tool. Then, we used the FLAASH module to perform atmospheric correction on remote sensing images. After atmospheric correction, we performed geometric correction of remote sensing images through GPS positioning in the field, in which the correction accuracy was less than 0.5 pixels. We classified remote sensing images in 1983 and 1997 by using the maximum likelihood method in supervised classification. Based on the principal component analysis, we combined the multispectral band with the panchromatic band for

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48074821

the image in 2011 (Serious phenomenon of foreign body with spectrum). We used a combination of unsupervised classification and decision tree classification, and used survey data of field to verify, so that computer interpretation and visual interpretation could be combined to achieve image interpretation accuracy of more than 95%. We produced a series of landscape types of the study area in 1983, 1997, and 2011 by ArcGIS.

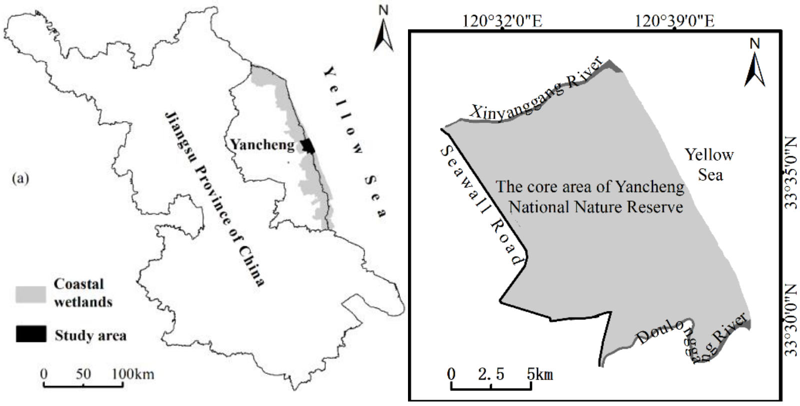

Figure 1. *Location and scope of the study area. (a) The study area is located at the core zone of Yancheng National Nature Reserve, which is situated on the center of the coastal of Jiangsu Province, China. (b) The scope of the study area*

Methods

The InVEST model was developed by Stanford university, the Nature Conservancy (TNC), the World Wildlife Fund (WWF) and other research institutions to evaluate Ecosystem service functions and their economic value, and support Ecosystem management and decision-making (Hall et al., 1997; Sharp et al., 2017; Zhang et al., 2017).

Habitat Quality Module in InVEST 3.2 was a combination of the landscape type map and the threat factors of biodiversity to generate a map of habitat quality. The Habitat Quality Module was based on the type of landscape that had different levels of sensitivity to different threat factors. It clearly characterized the response of various landscape types to threat factors and assessed the interaction between threat factors. The better the habitat quality was, the higher the degree of biodiversity conservation would be in the region. The more frequent human activities were, more threat factors there were, and more changes the landscape had, the greater impact on habitat quality it would have. Therefore, using the Habitat Quality Module could effectively analyze the relationship between landscape changes and habitat quality. The basic data required for the operation of the Habitat Quality Module included the map of landscape type, the map of threat factors, the influence distance table of threat factors and the table of sensitivity of landscape types to threat factors (Nelson et al., 2009; Goldstein et al., 2012; Mdk et al., 2013; Chaplinkramer et al., 2015; Zhang et al., 2016; Zhao et al., 2017).

Map of landscape types

Taking the series of landscape maps of the study areas in 1983, 1997 and 2011 as the basic data, and choosing the map of 1983 as the baseline. We also set the unified grid size to 30m×30m.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48074821

Threat factors

Based on the landscape type of Yancheng coastal wetlands, we selected aquaculture ponds, rivers, roads and *Spartina alterniflora* (Invasive species) that were affected by human factors greatly as threat factors. Since there were no aquaculture ponds in the study area in 1983, the pond was not used as a threat factor in 1983. We referred to the relevant literature (Yuan et al., 2009; Sun et al., 2011; Meng et al., 2012; Yang et al., 2014), combined with the characteristics of the study area, set the maximum influence distance of the threat factors, the weight of the threat factors, and the linear correlation of the decline as shown in *Table 1*.

Table 1. *Attribute table of ecological threat factors*

Threat factors	Maximum impact distance (km)	Weight	Linear correlation of regression
Aquaculture pond	1	0.6	0
River	3	0.4	1
Road	5	0.6	1
Spartina alterniflora	3	0.8	0

A table of threat factors in the model, includes the relative impact of threat factors on habitat types and the distance at which habitat degradation occurs. There are two kinds of calculation formulas for the influence distance of threat factor, such as *Eqs. 1* and *2*.

$$i_{rxy} = 1 - \frac{d_{xy}}{d_{rxy}} \text{ if linear} \tag{Eq.1}$$

$$i_{rxy} = exp\left(-\frac{2.99}{d_{rxy}}\right) \text{ if exponential} \tag{Eq.2}$$

In *Equations 1* and *2*, i_{rxy} represents the degree of influence of the threat factors $\boldsymbol{r}$ in the grid unit $\boldsymbol{y}$ on the habitat grid unit $\boldsymbol{x}$; d_{xy} represents the distance between the two grid units $\boldsymbol{x}, \boldsymbol{y}$; and d_{rxy} represents the maximum influence distance of the threat factors (Sharp et al., 2017).

Sensitivity of landscape types to threat factors

Habitat suitability was bigger if it was closer to the original ecological system. Based on the function of maintaining the stability of the coastal wetland ecological environment, as well as the foraging and habitat environment standards for rare species of *Red-crowned crane*, we set the highest habit suitability was 1, the lowest was 0.

Different landscape types had different sensitivities to threat factors. Compared with the artificial landscape, the natural landscape had significantly weaker anti-interference ability to the threat factors and had greater sensitivity. We set the sensitivity range between 0 and 1, and the higher the sensitivity was, the larger the value would be. If the landscape type was not sensitive to the threat factors, it was represented by 0, and if it was extremely sensitive to the threat factors, it was represented by 1 (Bao et al., 2015; Li et al., 2016;

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48074821

Zhang et al., 2018). The sensitivity index of each landscape type to the threat factors in the study area was shown in *Table 2.*

Table 2. *Habitat suitability and sensitivity to threat factors of different landscape types*

Landscape types	Habitat suitability	Culture pond	River	Road	*Spartina alterniflora*
Aquaculture pond	0.5	0	0.5	0	0.5
River	0.5	0.5	0	0.8	0.5
Mudflat	0.8	0.5	0.3	0.3	0.8
Road	0	0	0	0	0
Phragmites australis marsh	1	0.3	0.6	0.6	0.5
Spartina alterniflora marsh	0.5	0.5	0.5	0.7	0
Suaeda salsa marsh	1	0.5	0.8	0.5	0.8

Habitat degradation index

The degree of habitat degradation was closely related to the sensitivity of landscape type to threat factors, the number of threat factors, the influence distance of threat factors and the weight of threat factors. The model assumed that within a certain range, the closer the habitat to the threat factor was, the higher the sensitivity and the habitat degradation index would be. The formula for calculating the habitat degradation was as follows.

$$D_{xj} = \sum_{r=1}^{R} \sum_{y=1}^{y_r} \left(\frac{w_r}{\sum_{r=1}^{R} w_r}\right) r_y i_{rxy} \beta_x s_{jr} \quad \text{(Eq.3)}$$

In *Equation 3*, D_{xy} is the habitat degradation index, which characterizes the degree of habitat degradation; R refers to the number of threat factors; y_r refers to the number of grid cells on the threat factor layer; w_r refers to the weight value of the threat factor; $r_y$refers to the number of raster unit threat factors in the layer; β_x refers to the degree of protection; s_{jr} refers to the sensitivity of the threat factor, and the value range is from 0 to 1.

Habitat quality index

Habitat quality Index depends on habitat degradation index and habitat suitability. In general, habitat quality index increases with the increase of habitat suitability and decreases with the increase of habitat degradation Index. Therefore, the more frequent the landscape type changes were and larger the scope was, the higher the degree of habitat damage would be, greater the adverse impact on species survival and reproduction it would have, and worse the habitat quality would be. The higher the habitat suitability was and the better the habitat environment of the species was, the higher the habitat quality would be. The habitat quality index was calculated as follows.

$$Q_{xj} = H_j \left(1 - \frac{D_{xj}^Z}{D_{xj}^Z + k^Z}\right) \quad \text{(Eq.4)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48074821

In *Equation 4*, Q_{xj} refers to the habitat quality index; H_j represents the habitat suitability; D_{xj} is the degree of habitat degradation; *k* is the half-saturation coefficient, we set it to 15 in the study (It is half the raster resolution). *z* is generally set to 2.5.

Habitat scarcity index

Habitat scarcity could reflect the scarcity of the overall habitat of the region and the scarcity of a certain landscape type. The more the habitat scarce was, the more protected it should be. The higher the habitat scarcity index was, the lower the scarcity degree would be. It could be calculated as follows.

$$R_j = 1 - \frac{N_j}{N_{jbase}} \quad \text{(Eq.5)}$$

$$R_x = \sum_{x=1}^{X} \sigma_{xj} R_j \quad \text{(Eq.6)}$$

In *Equation 5*, R_j is the habitat scarcity index of landscape type j. N_j is the number of grids of landscape type j in the current or future map. N_{jbase} is the number of grids of landscape type j in the baseline landscape map. If there is no landscape type j, $R_j = 0$.

In *Equation 6*, R_x is the habitat scarcity index. σ_{xj} is the discriminant coefficient of the landscape type j.When the grid is the current landscape type j, $\sigma_{xj} = 1$, otherwise $\sigma_{xj} = 0$.

Results

We loaded the resulting image of the model run (including the habitat degradation raster map and the habitat quality raster map) into ArcGIS, analyze the degree of habitat degradation and habitat quality in each year by reclassifying images furtherly. It was possible to compare the degree of habitat degradation and the changes in habitat quality through grid calculation.

Landscape changes

From the perspective of landscape composition, the landscape types of the study area were mainly aquaculture pond, *Phragmites australis* marsh, *Suaeda salsa* marsh, *Spartina alterniflora* marsh and mudflat. Comparing the changes during 1983 to 2011 (*Table 3*), it could be found that the area of aquaculture pond, *Phragmites australis* marsh, and *Spartina alterniflora* marsh in the study area increased, while the area of *Suaeda salsa* marsh first increased and then decreased. *Phragmites australis* marsh increased from 19.62% in 1983 to 31.46% in 2011, and the growth was faster and faster. *Spartina alterniflora* marsh increased from 1.69% in 1983 to 23.77% in 2011, and the expansion rate was getting faster and faster. The area percentage of *Suaeda salsa* marsh was 26.85%, 29.13% and 9.98% in 1983, 1997 and 2011, respectively, and it first increased and then decreased, and it decreased rapidly, the main reason for the increase was that *Spartina alterniflora* marsh had not formed a close interlaced zone with

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48074821

Suaeda salsa marsh, and there were original ecological evolution sequences of mudflat to *Suaeda salsa* marsh between 1983 and 1997. The sharp decrease between 1997 and 2011 was due to the two-way extrusion of *Phragmites australis* marsh and *Spartina alterniflora* marsh, and the area of *Suaeda salsa* marsh continued to shrink. Mudflat decreased from 46.93% in 1983 to 17.63% in 2011, and the rate of reduction was also increasing faster, mainly due to the expansion of *Suaeda salsa* marsh and *Spartina alterniflora* marsh. The area of the aquaculture pond had changed greatly, from 0% in 1983 to 12.11% in 2011. The road area had nearly doubled in 2011 compared with 1983. According to the two periods, it could be concluded that the effect of human activities on the study area was continuous and stable.

Table 3. *Area changes of landscape types in the study area*

Landscape types	1983		1997		2011	
	Area ($\times 10^2 hm^2$)	The percentage (%)	Area ($\times 10^2 hm^2$)	The percentage (%)	Area ($\times 10^2 hm^2$)	The percentage (%)
Aquaculture pond	0	0	11.67	6.06	23.32	12.10
River	6.41	3.33	4.16	2.16	4.11	2.13
Mudflat	90.39	46.93	63.72	33.08	33.95	17.62
Road	3.04	1.58	4.81	2.50	5.64	2.93
Phragmites australis marsh	37.79	19.62	42.65	22.14	60.6	31.46
Spartina alterniflora marsh	3.25	1.69	10.51	5.46	45.8	23.77
Suaeda salsa marsh	51.71	26.85	55.13	28.62	19.23	9.98

According to the area and number of landscape patches, it could be found that the number and area of landscape patches changed significantly from 1983 to 2011 and the number of patches increased from 53 to 291, an increase of 294.34%; the average patch area decreased from 363.47 hm^2 66.20 hm^2, a decrease of 81.79%. The landscape fragmentation trend in the study area was obvious, and the landscape segmentation phenomenon was intensified. The contagion index and aggregation index were reduced from 61.50 and 96.05 to 45.84 and 89.36, respectively. The mean shape index dropped from 1.59 to 1.30, indicating that the landscape in the study area was gradually increased by human disturbance, and the landscape patch shape tended to be regular.

Habitat degradation analysis

The degree of habitat degradation had certain reference value in predicting the possibility of habitat damage in the future. The degree of habitat degradation directly reflected the threat of threat factors to landscape types and was directly proportional to them. The higher the degree of habitat degradation was, the greater the impact of the threat factors on the region would be. The core area of the Jiangsu Yancheng Wetland National Nature Reserve • Rare birds had a high degree of ecological environmental protection and a low degree of habitat degradation generally. However, in terms of time, habitat degradation was becoming more and more serious, and the value of habitat degradation index was increasing more and more quickly. The value of habitat degradation index was 0.006, 0.009 and 0.024, in 1983, 1997 and 2011, respectively. It can be seen from *Table 4* that the value of habitat degradation index was most

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48074821

concentrated between 0 and 0.02 and the area percentage were 100%, 90.73% and 44.39% in 1983, 1997 and 2011, respectively. In 1983, the degree of habitat degradation was low, and the value of degradation index was all concentrated in the range of 0-0.02. In 1997, the value of habitat degradation was still low, but compared with the 1983, the area percentage in the range of 0.02-0.04 was 9.27%, the area with the value between 0.04-0.06 was very small. In 2011, the habitat degradation was intensified, and the area percentage of degradation ranging from 0 to 0.02 was less than half of that in 1997, the area ratio in the range of 0.02-0.04 reached 30.19%, the area ratio in the range of 0.04-0.06 reached 22.99%, the area ratio in the range of 0.06-0.08 was 2.43%, and the highest value of habitat degradation index reached 0.072.

Table 4. *Habitat degradation degree classification statistics from 1983 to 2011*

Grading ranges	1983		1997		2011	
	Area ($\times10^2hm^2$)	The percentage (%)	Area ($\times10^2hm^2$)	The percentage (%)	Area ($\times10^2hm^2$)	The percentage (%)
0-0.02	192.60	100	174.78	90.73	85.51	44.39
0.02-0.04	0	0	17.85	9.27	58.17	30.19
0.04-0.06	0	0	0.02	0	44.28	22.99
0.06-0.08	0	0	0	0	4.69	2.43

It can be seen from *Fig. 2* that what had no habitat degradation or low degree of degradation were mainly threat factors themselves, namely *Spartina alterniflora*, roads, aquaculture ponds and rivers. The region with the higher value of habitat degradation index was mainly located in the neighborhood of the threat factors. From 1983 to 2011, as the intensity of threat factors increased, the area of the region with the high value of habitat degradation index also expanded, directly causing the value of habitat degradation index to become higher. In 1983, the areas with the high value of habitat degradation were mainly located on both sides of Xinyanggang River and Doulonggang River and the spatial differentiation of habitat degradation had obvious lateral belt distribution. In 1997, the area with the high value of habitat degradation was mainly distributed around the breeding ponds, the Doulonggang River, and the large *Spartina alterniflora* plaques in the south of the study area. In 2011, the areas with the high value of habitat degradation were mainly distributed in the interlaced belts between aquaculture pond and *Phragmites australis* marsh, *Salsa* marsh and *Spartina* marsh, mudflat and *Spartina* marsh. The spatial differentiation of habitat degradation had a distinct longitudinal band distribution.

Habitat quality assessment

During 1983 to 2011, the habitat quality of the core area of Yancheng Wetland National Nature Reserve was degraded. The value of habitat quality index decreased slightly from 0.863 to 0.846 during 1983 to 1997, the habitat quality declined obviously from 1997 to 2011, it fell from 0.846 to 0.742, a decrease of 12.29%.

The value of habitat quality index was divided into four sections: 0-0.25, 0.25-0.5, 0.5-0.75, and 0.75-1, which indicated that the habitat quality grades were poor, medium, good, and excellent respectfully. It can be seen from *Table 5* that the habitat quality of the study

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48074821

area was high generally, and the grade of habitat quality were mostly excellent, and then medium and poor successively, there was no distribution at the good grade. Thus, in terms of regional differences, the habitat quality in the study area showed a "polarization" trend. According to the changes of the area ratio in the three levels, it showed "two increasing and one decreasing". The area of the excellent habitat quality was in a state of decline, and the area ratio had decreased from 93.57% in 1983 to 59.08% in 2011, the decline reached 36.86%, and the decline from 1983 to 2011 was getting faster and faster. The areas of poor and medium habitat quality were increasing, and the area of poor habitat quality increased from 1.40% in 1983 to 2.91% in 2011, which was more than doubled. The area of medium habitat quality increased from 5.03% in 1983 to 38.01% in 2011, an increase of more than 6.5 times, and the increasing speed of the areas of poor and medium habitat quality were becoming faster and faster.

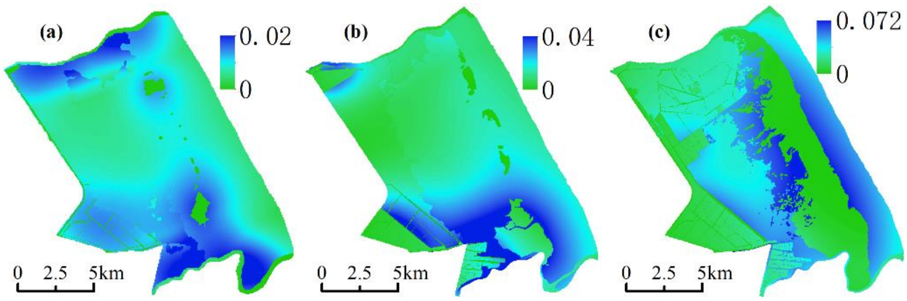

***Figure 2.** Habitat quality degradation index distribution maps. (a)It is a habitat quality degradation index distribution map in 1983. (b) It is a habitat quality degradation index distribution map in 1997. (c) It is a habitat quality degradation index distribution map in 2011*

***Table 5.** Habitat quality classification statistics from 1983 to 2011*

Grading ranges	1983		1997		2011	
	Area ($\times10^2$hm^2)	The percentage (%)	Area ($\times10^2$hm^2)	The percentage (%)	Area ($\times10^2$hm^2)	The percentage (%)
0-0.25	2.70	1.40	2.77	1.44	5.61	2.91
0.25-0.50	9.69	5.03	26.61	13.81	73.22	38.01
0.50-0.75	0	0	0	0	0	0
0.75-1.00	180.21	93.57	163.27	84.75	113.82	59.08

From the spatial differentiation maps of habitat quality (*Fig. 3*) and the habitat quality change maps (*Fig. 4*), it can be seen that the areas with relatively poor habitat quality were mainly concentrated in roads, rivers, aquaculture ponds and *Spartina alterniflora*. Especially the expansion of the aquaculture pond and *Spartina alterniflora* led to a rapid increase of the area with lower-level habitat quality. The areas with relatively good habitat quality were mainly in the original ecological vegetation distribution area, including *Phragmites australis* marsh, *Salsa* marsh and mudflat. The area where the habitat quality changes were located in the landscape interlaced belt, that was, the area where the landscape type changes, including the *Phragmites australis* marsh--aquaculture pond

Habitat scarcity evaluation

The higher the scarcity index was, the more stable the overall ecosystem tended to be, and the ecosystem structure and function would decline. The lower the scarcity index was, the more fragile the ecosystem would be, but at the same time, it tended to be the more susceptible and need to strengthen protection. Based on the conditions of no introduction of *Spartina alterniflora* in the mudflat in 1983, the scarcity index was -0.10 in 1997, the scarcity index was 0.173 in 2011, and the scarcity index was rising, indicating that the ecosystem was stable and the ecosystem function was declining when the region was in human activities and invasion of alien species. The value of R_j was close to 1 and the current or future landscape type was more important to biodiversity conservation when the type of landscape was rare. The R_j value of *Salsa* marsh and the mudflat were obviously rising, and they were closer to 1. In 2011, the R_j values of salsa marsh and the mudflat were the highest, 0.628 and 0.637 respectively, indicating that these landscape types were decreasing and became more and more scarce in the study area. They needed more protection and ecological restoration.

Discussion

The spatial and temporal changes of habitat quality in the core area of Yancheng Wetland National Nature Reserve • Rare birds are mainly caused by human activities and the expansion of *Spartina alterniflora*. The study area focused on protecting the wintering habitat of *Red-crowned cranes*. In order to create good artificial habitats for rare species such as *Red-crowned cranes*, it began to establish some artificial wetlands in 1993, and implemented a large area of *Phragmites australis* marsh recovery work. Driven by economic interests, some of the projects had changed the original plan, and the area of *Phragmites australis* base and aquaculture pond were mainly based on economic development, had increased significantly. As a result, the area of aquaculture ponds in the study area has increased from 0% in 1983 to 12.10% in 2011, and the increase in two periods almost the same, further illustrating the sustainability and stability of human activities. The aquaculture ponds were mainly developed from *Phragmites australis* marsh, and the original ecological landscape was transformed into a threat factor, which caused the habitat to degenerate and the habitat quality decreased. On the other hand, the artificial embankment not only generated a new threat factor, but also changed the hydrological process, blocked the intrusion of tidal water, effectively stored fresh water, further affected the soil hydrological properties, and accelerated the speed of the transformation of *Suaeda salsa* marsh to *Phragmites australis* marsh and changed the landscape structure of the wetlands.

In the 1980s, *Spartina alterniflora* was successfully introduced in the coastal of Jiangsu Province. After the formation of a large-area community in the 1990s, the area expanded rapidly, forming a coastal vegetation with a few kilometers wide and a north-south coastal wetland. Although *Spartina alterniflora* had played an active role in protecting beaches, it was a threat factor for habitats of rare species such as *Red-crowned cranes*. On the one hand, the superior silt-promoting function of *Spartina alterniflora* resulted in a significant increase in the elevation of the beach surface and the thickness of the silt reached 1.5 m on the spot, which made it difficult for the tide to pass through *Spartina alterniflora* marsh and reach *Suaeda salsa* marsh. The habitat of *Suaeda salsa* caused significant degradation. On the other hand, on the lower edge of *Suaeda salsa* marsh, the settlement of *Spartina alterniflora* made the repeat of the niche, while the ecological amplitude characteristics of *Spartina alterniflora* and the sexual and asexual dual reproduction mode made it the inter-species competition was in a dominant position, and eventually *Suaeda salsa* marsh was constantly replaced by the *Spartina alterniflora* marsh. In the landscape composition of the study area, *Suaeda salsa* marsh, which is inhabited by rare species such as *Red-crowned cranes*, has been transformed into a habitat quality threat factor, resulting in a decline in habitat quality.

Human activities and the expansion of *Spartina alterniflora* have made the core area of Yancheng Wetland National Nature Reserve • Rare birds more threatening, ecosystem function decline, ecological restoration will become an important research topic in the region. At present, positive results have been achieved. The core area had basically completed “removing aquaculture ponds and restoring marshes” project, the buffer zone “removing aquaculture ponds and restoring marshes” was also actively carried out. However, the threat of *Spartina alterniflora* expansion is still growing and will continue to threaten the habitat quality of the study area. On the one hand, it is necessary to control the expansion of *Spartina alterniflora*, maintain a moderate scale, give full play to its revetment function, and reduce the threat to landscape habitats. On the other hand, it is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48074821

necessary to actively restore *Suaeda salsa* marsh, restore the evolution sequence of mudflat to *Suaeda salsa* marsh, maintain biodiversity and improve regional habitat quality.

Conclusion

The landscape composition of the core area of Yancheng Wetland National Nature Reserve• Rare birds is mainly aquaculture pond, *Phragmites australis* marsh, *Suaeda salsa* marsh, *Spartina alterniflora* marsh and mudflat. From 1983 to 2011, the change of landscape composition showed that the aquaculture pond, *Phragmites australis* marsh and *Spartina alterniflora* marsh increased continuously, and the increasing speed became faster and faster. The area of mudflat decreased, and the area of *Suaeda salsa* marsh first increased and then decreased, and the corresponding decrease was faster and quicker. The landscape changes are mainly conversions of mudflat into *Spartina alterniflora* marsh and *Suaeda salsa* marsh, *Suaeda salsa* marsh into *Phragmites australis* marsh and *Spartina alterniflora* marsh and *Phragmites australis* marsh into culture pond.

From 1983 to 2011, although the habitat quality of the core area of Yancheng Wetland National Nature Reserve • Rare birds were at the excellent level, the degradation trend was also obvious. From 1997 to 2011, the value of habitat quality index decreased from 0.846 to 0.742, a decrease of 12.29%. The areas with relatively poor habitat quality mainly concentrate on the distribution areas of threat factors such as *Spartina alterniflora* marsh, roads, aquaculture ponds, rivers, etc. The area with relatively good habitat quality mainly distributed in the original ecological vegetation distribution areas, including *Phragmites australis* marsh, *Suaeda salsa* marsh and mudflat; and the area of habitat quality change were located in the landscape ecotone. The value of habitat degradation index was increasing. The spatial heterogeneity of the habitat degradation was characterized by a transition from a transverse strip distribution to a longitudinal strip distribution. The habitat scarcity index increased significantly, indicating that the ecosystem of the study area was stable and the ecosystem function was declining.

The degradation of coastal wetland habitat seriously threatened the habitat of Red-crowned Crane and other rare species. Yancheng coastal wetland had joined the World Heritage List, and scientific protection and restoration is imminent. According to the characteristics of Yancheng coastal wetland, systematically analyzing the degradation mechanism of coastal wetland habitat quality, clarifying the mechanism of ecological restoration from the perspective of landscape structure and ecological process, reconstructing and optimizing regional habitat ecological protection network, and carrying out ecological restoration technology integration and demonstration in typical areas need to be strengthened in the future research.

(Received 5th Feb 2019; accepted 6th Mar 2019)

Abstract. This paper attempts to disclose the farmers' selection bases among different eco-compensation options for the reduction of fertilizer use, a typical non-point source (NPS) of water pollution. Firstly, the reduction methods were divided into six types. Then a survey was carried out on the farmers near two water bodies in south-eastern China's Zhejiang Province, namely, Qiaodun Reservoir and Siming Lake Reservoir. It was found that when multiple options are available, financial compensation is the most favoured one among farmers, followed by technical learning and policy compensation; the organic fertilizer has the lowest acceptance. Next, a simultaneous bivariate probit model was established to illustrate the effect of each factor on farmers' selection between intellectual and non-intellectual technical compensations, and between alternative and organic fertilizers. Meanwhile, the farmers' intentions on policy compensation were examined by the binary probit model. The modelling results show that: the farmers prefer compensation options that complement each other and wish the government could offer integrated compensation plans of these options; the age and education level of house owner, coupled with family income, farmland area, farmland fragmentation, production efficiency and farmers' willingness to reduce fertilizer application all have important impacts on the selection of compensation means.
Keywords: *chemical fertilizer, non-point source (NPS) pollution, direct eco-compensation, reservoir, farmers' participation*

Introduction

Humans freely receive ecological services from properly-functioning ecosystems like the aquatic ecosystem, i.e. the ecosystem in a body of water (Karabulut et al., 2016). Water bodies are the sources of water supply to urban and rural areas, and require strict measures on environmental safety (Ademila and Saloko, 2018; Joldeș et a., 2017; Jian, 2018; Li et al., 2015; Ganiron, 2017; Grafton et al., 2017; Tian et al., 2018). However, fresh water resources have been utilized in a non-sustainable way, as they are widely viewed as inexhaustible, free or low-cost public resources (Perry and Berry, 2016; Yihdego and Khalil, 2017). To solve the problem, China has restricted and even banned the development of many water bodies, and invested more into the construction of sewage pipes and other discharge facilities. These moves have paid off: industrial point source (PS) pollution is placed under control, and domestic wastewater can now be disposed of satisfactorily (Moges et al., 2016; Fales et al., 2016).

Despite the above efforts, the agricultural non-point source (NPS) pollution in crop farming still poses a challenge to the safety of water bodies, because the NPS pollution is highly dispersed, concealed, random, uncertain, extensive and undetectable (Álvarez et al., 2017; Smith et al., 2017; Herrera et al., 2017). This universal problem, especially the fertilizer NPS pollution, has attracted much attention from scholars around the world (Jin, 2013; Pott and Fohrer, 2017). Studies have

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48234838

shown that dissolved fertilizer, a main pollutant to water quality, can enter water bodies through surface runoff, farmland irrigation and drainage (Kreuger et al., 2008; Kronvang et al., 2008; Neumann et al., 2011; Sun et al., 2012).

On the correlation between agriculture and water quality, irresponsible use of farmland has been widely regarded as the primary cause of agricultural NPS pollution to water bodies (Rodrigues et al., 2018; Corneil et al., 2018; Li et al., 2015). Since the "household responsibility system" was implemented in late 1970s, Chinese farmers have been officially recognized as the basic units of agricultural production, management and decision-making (Ji et al., 1999). The agricultural NPS pollution can be attributed to the irrational decisions of farmers under various factors, ranging from social environment, item property, individual preference to laws and regulations (Feng et al., 2006; Liang et al., 2015). The farmers tend to make irrational decisions when they are worried about the yield and production scale, unclear of the pollution source or the importance of pollution control, and in lack of practice instructions or convenient farming techniques (Zhang, 2015).

One of the viable options to reduce agricultural NPS pollution to water bodies lies in conservation tillage (Doreen et al., 2018). This is a tillage system that creates a suitable soil environment for growing a crop and that conserves soil, water and energy resources mainly through the reduction in the intensity of tillage, and retention of plant residues. However, the conservation tillage may bring the risk of output reduction, and make farming income uncertain. As a result, many farmers are reluctant to implement conservation tillage without proper compensation, even if they are risk takers (Klemme, 1985).

In the last two decades, many international organizations and governments have provided eco-compensations for protective actions aiding water bodies (Wunder, 2015; Ze et al., 2017). A perfect eco-compensation mechanism helps to enhance the values and benefits of ecological services, remove policy constraints on farmers' demand for individual development, and arouse the enthusiasm of farmers in pollution control activities (Xie and Li, 2016; Vogl et al., 2017; Villarroya et al., 2014; Chang et al., 2013). Out of the many eco-compensation policies, financial compensation like transfer payment has long been the most effective way to prevent agricultural NPS pollution to regional water bodies, because it is easy to quantify and measure. As farmers now expect more diverse means of compensation, it is imperative to develop various compensation mechanisms according to local conditions (Research Group on Eco-Compensation Mechanism and Policies in China, 2007).

The farmers must make prudent choices among various compensation mechanisms. After all, not every form of compensation is effective, and some may even have negative consequences. For example, over compensation may dampen the farmers' enthusiasm about sustainable farming and environmental protection, in that the subsidy to be received is negatively correlated with the environmental improvement (Aretino et al., 2001). Moreover, subsidy may distort the resource allocation, giving subsidized farmers more market power over the unsubsidized (Macintosh and Denniss, 2004). Rationality and fairness are two key attributes of a good compensation mechanism. If either of them is overlooked, the compensation will not achieve the desired goals.

Currently, the government, the dominating party of eco-compensation practices, fails to understand the wishes of farmers or their reasons to change behavior (Huber et al., 2012). With the changes in farmers' demand, the compensation effectiveness now

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48234838

hinges on the rationality of the compensation means, in addition to the amount of compensation. However, there is no consensus on what makes a compensation policy rational. Some scholars held that farmers are biased towards cash compensation (Xu et al., 2013; Yang and Cai, 2012), while some others believed that farmers prefer technical compensation (Shi et al., 2014). To sum up, these discussions show that the limitations should be considered in the design of any compensation method, because the farmers' preference for compensation means varies with regions, cultures and populations. This means the choice of compensation tools should be discussed from a more microscopic perspective. Therefore, this paper explores farmers' choice between different compensation means for the abandonment of chemical fertilizer, a typical NPS of agricultural pollution to water bodies.

Selection bases of compensation means

Classification of compensation means

The compensation methods for prevention and control of agricultural NPS pollution mainly fall into four categories, namely, financial compensation, physical compensation, technical compensation and policy compensation. The details on these types of compensation are provided below.

(1) Financial compensation

As its name implies, financial compensation refers to the direct financial incentives for farmers to adopt protective measures, or the financial subsidy for the cost of taking such measures. It is commonly applied in China's "Grain for Green" program.

(2) Physical compensation

Physical compensation, e.g. seed compensation and gasoline compensation, is a collective term for any compensation means that improves the productive capacity of ecological service providers through the provision of production factors or living factors.

(3) Technical compensation

Technical compensation is either intellectual or non-intellectual. The intellectual technical compensation aims to enhance the implicit, materialized technologies, such as the farmers' ability of unified farmland management, through training, demonstration and subsidies. By contrast, the non-intellectual technical compensation mainly subsidizes farmers for the implementation of knowledge-based technologies.

(4) Policy compensation

Policy compensation generally means the preferential policies issued by the superior government to the lower government, giving the recipients various preferential treatments on agricultural structure, employment and social security.

Each of the above compensation methods has its advantages and disadvantages. In fact, the selection of compensation means is tradeoff between financial and non-financial compensations, between transfusion and hematopoietic compensations, as well as between coupling and decoupling compensations.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48234838

Typical selection bases

For the farmers who have adopted conservation tillage, eco-compensation may exist in direct forms as funds, physical objects, technologies or policies, and in indirect forms as government-funded projects on environmental protection, economic construction and social security. The direct compensation boosts the income and productivity of the farmers, while the indirect compensation benefits the farmers through the improvement of the social environment.

In this paper, the direct compensation is taken as the example to illustrate the bases of farmers' selection among different compensation means. This is because direct compensation reminds farmers of the purpose of compensation, while giving them direct benefits. Moreover, direct compensation can be investigated by closed and open questionnaire surveys, which are familiar to farmers.

Considering the important supplementary function of policy compensation, this paper makes "other jobs" an indicator of policy compensation related to agricultural activities. Here, "other jobs" refers to the jobs created by agricultural restructuring and offered by other industries, with the aim to encourage farmers to stop un-green farming practices, such as planting polluting crops.

In view of the general fertilization techniques of farmland, our questionnaire offers the farmers different combinations of compensation options targeting six conventional control methods for NPS pollution of chemical fertilizer. These control methods directly affect the farmland management (*Table 1*):

1. Financial compensation;
2. Physical compensation: Grain compensation;
3. Technical compensation: Training on "formula fertilization by soil testing" (FFST) (technical learning); provision of FFST fertilizer (alternative fertilizer); subsidies for commercial organic or green manure (organic fertilizer);
4. Policy compensation: Provisions of other job opportunities (other jobs).

The above compensation means all belong to direct compensation. The financial compensation and physical compensation are transfusion compensation, while technical compensation and policy compensation are hematopoietic compensation. Moreover, financial, physical and technical compensations fall in the category of coupling compensation, while policy compensation fits into decoupling compensation.

Materials and methods

Study area overview

Our research targets Qiaodun Reservoir in Yuyao City and Siming Lake Reservoir in Cangnan County, southeastern China's Zhejiang Province. The two medium-sized reservoirs are the major sources of water supply to the county. However, both water bodies have suffered from severe eutrophication, and face potential agricultural pollution.

Thanks to the provincial eco-compensation practices, the local farmers are now aware of conservation tillage, laying a good basis for our survey. However, the farmers mainly rely on agriculture for a living and have not acquired sufficient knowledge on scientific farming. Since rice is the dominant crop in the study area, rice growers were selected as the research objects.

Survey design description

From March 2014 to January 2015, our survey was carried out in 12 villages near Qiaodun Reservoir and 9 villages near Siming Lake Reservoir. These villages were identified by stratified random sampling, considering such factors as rice planting area, economic development and location. In each village, 30 farmers were selected for the one-on-one interview, which was designed to acquire their basic information and selection bases for compensation means.

A questionnaire was prepared for the interview. Since real-world eco-compensations often combine multiple methods, our questionnaire offers the farmers with six compensation options targeting conventional control methods for NPS pollution of chemical fertilizer, and asks them to choose three compensation methods out of the six options.

Based on the questionnaire, the interview was conducted in three steps: (1) Present the compensation options, ask the farmer to select the most desired option, and mark the selected option with the number "1"; (2) Ask the farmer to select the next desired option from the unselected options, and mark the selected option with the number "2"; (3) Ask the farmer to select the next desired option from the unselected options, and mark the selected option with the number "3".

The option selected in Step 1 is the compensation means with the maximum utility. The farmers have basically the same demand for compensation means, except a slight difference between individuals. The general principle is that the attributes and features of the selected option must satisfy the farmers' requirements of use. In other words, the compensation options are selected based on the farmers' demand and preference on the attributes of such options.

A total of 360 questionnaires were sent out to the villages near Qiaodun Reservoir and 270 to those near Siming Lake Reservoir. In the end, 323 and 218 valid questionnaires were returned from the two groups of villages, respectively.

Sample features

Table 2 sums up the features of the interviewees. It can be seen that 90% of the interviewees are males, which reflects the high labor intensity of rice production. Besides, the preference for food crop planting increases with the age of farmers, as over 80% of food crop growers are over 50.

Methods and modelling

The farmers' willingness to select a compensation means is a binary discrete choice variable. Both financial and physical compensations belong to transfusion compensation, and directly make up for the economic losses of farmers. There might be some correlations between the two compensation options, because they tend to be selected by farmers under the same influencing factors. The same relationship may exist between intellectual and non-intellectual technical compensations.

Since financial and grain compensations are independent of each other, there are four possible choices for farmers: selecting both options, selecting financial compensation, selecting grain compensation and selecting neither option.

Let Y_1 and Y_2 be the selection of financial compensation and that of grain compensation, respectively. If the farmer being interviewed selects financial compensation, the value of Y_1 should be recorded as 1; otherwise, the value of Y_1 should be recorded as 0. Similarly, if the farmer selects grain compensation, the value of Y_2 should be recorded as 1; otherwise, the value of Y_2 should be recorded as 0. Then, the four possible choices can be expressed as (1,1), (1,0), (0,1) and (0,0), respectively.

In light of the above, a simultaneous bivariate probit model was established to illustrate the effect of each factor on farmers' selection (Greene, 2008). Extended from the probit model, the established model is suitable for simultaneous equations satisfying the following two conditions: the random perturbations of the equations are inter-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48234838

correlated, such that the equations can be estimated at the same time; the model has two output variables. The mathematical expression of the model is shown in *Equation 1.*

$$\begin{cases} Y_1^* = \beta_1 + \beta_1' X_1 + \varepsilon_1 \\ Y_2^* = \beta_2 + \beta_2' X_2 + \varepsilon_2 \\ E(\varepsilon_1) = E(\varepsilon_2) = 0 \\ \operatorname{var}(\varepsilon_1) = \operatorname{var}(\varepsilon_2) = 1 \\ \operatorname{cov}(\varepsilon_1,\ \varepsilon_2) = \rho \end{cases} \tag{Eq.1}$$

where Y_1^* and Y_2^* are unobservable potential variables depicts the farmer' evaluation of financial and grain compensation, respectively; X_1 and X_2 are influencing factors of the farmer' selection; β_1, β_1', β_2 and β_2' are estimation parameters; ε_1 and ε_2 are random perturbation terms that obey bivariate normal distribution, ρ is the correlation coefficient of ε_1 and ε_2.

If $Y_1^* > 0$, the financial compensation has a positive utility and is favored by the farmer. In this case, the output variable Y_1 equals 1. Otherwise, $Y_1 = 0$. If $Y_2^* > 0$, the grain compensation has a positive utility and is favored by the farmer. In this case, $Y_2 = 1$. Otherwise, $Y_2 = 0$.

Under the condition of a significant ρ value, ε_1 and ε_2 are irrelevant if $\rho = 0$, that is, the two equations of our model can be estimated separately, and the estimated results agree with the results of simultaneous estimation; if $\rho > 0$, Y_1 and Y_2 complement each other; if $\rho < 0$, Y_1 and Y_2 exclude each other.

The simultaneous bivariate probit model was also adopted to analyze the farmers' selection between intellectual and non-intellectual technical compensations, and between alternative and organic fertilizers; the farmers' intentions on policy compensation were examined by the binary probit model.

Variable selection

As shown in *Table 3,* the influencing factors in this research include personal information, farmer productivity, family information, farmland features, farmland management, village economy and regional variable. Specifically, personal information covers the age (age) and education level (edu) of house owner; family information refers to the annual family income (inc); farmland features include farmland area (ara) and farmland fragmentation (ldf); farmland management features refers to production efficiency (eff) and farmers' willingness to reduce fertilizer application (wtr); Regional variable (reg) refers to the investigation site the farmer belonged to, Qiaodun reservoir watershed or Siming Lake reservoir watershed.

Results

With the aid of Stata 9.0 software, the simultaneous bivariate probit model and the binary probit model were adopted for the empirical analysis on farmer's selection of eco-compensation options for chemical fertilizer reduction. The estimation results and significance test results are listed in *Table 4*.

As shown in *Table 4,* all four models have high goodness of fit, and some coefficients of the influencing factors passed the significance test and fulfilled the

http://www.aloki.hu • ISSN 1589 1623 (Print) • ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48234838

expectations. The correlation coefficient of model 1-1 was significant on the 1% level, revealing the correlation between the selection of financial compensation and that of grain compensation. Meanwhile, the positive value of the correlation coefficient (ρ = 0.4668) shows the complementary effect between the two compensation options: a farmer is more likely to choose grain compensation, if he/she has chosen financial compensation. Similarly, the estimation results of model 1-2 demonstrate that intellectual and non-intellectual technical compensations complement each other, i.e. a farmer tends to select both options at the same time. However, the correlation coefficient of model 1-3 failed the significance test, indicating that farmers' selection of alternative fertilizer is independent from that of organic fertilizer. The binary probit model estimation results of Model 1-4 demonstrate that farmers' choice of other jobs are easily influenced by age of house owner, education level, farmland fragmentation, farmers' willingness to reduce fertilizer application, and regional variable. The impacts of different influencing factors are detailed below.

(1) Age of house owner

The age of house owner has a positive impact on farmers' selection of financial compensation ($p < 1\%$). Then, it can be deduced that old farmers are willing to accept grain compensation, considering the complementary effect between financial and grain compensations. This deduction is proved by the results in the above table: the age of house owner has a positive impact on farmers' selection of grain compensation. These relationships can be explained as follows. Compared with young farmers, old farmers are concerned with collective interests and government instructions, and thus expect a limited compensation for chemical fertilizer reduction. Therefore, financial compensation, known for its simplicity, directness and flexibility, wins more recognition among old farmers than young farmers.

Table 3. *Influencing factors*

Type	Variable	Variable definition	Average value	Standard deviation
Personal information	Age of house owner	Actual years reported by farmers (years)	1.9630	0.5794

The age of house owner has a negative impact on farmers' selection of intellectual compensation (p < 10%). This is because old farmers are confident about their farming experience, and find re-education unnecessary. In addition, non-intellectual compensation is positively affected by the age of house owner, due to the positive impact of the age on organic fertilizer. In fact, the age is negatively correlated with alternative fertilizer. After all, old farmers are very aware of long-term ecological benefits, as organic fertilizer is the most effective way to reduce chemical fertilizer in individual farmland management.

Furthermore, the age of house owner has a negative impact on policy compensation (other jobs) (p < 1%), i.e. old farmers do not like job opportunities other than farming. There are two possible reasons: old farmers want to maintain a stable income and consumption structure, rather than take the risk of reemployment or job-hopping; most employers only recruit people under 60.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48234838

(2) Education level

The education level only directly affects the selection of grain compensation and policy compensation (other jobs): it is negatively correlated with the selection of grain compensation ($p < 5\%$), and positively with that of policy compensation ($p < 1\%$). A possible reason lies in the strong learning and cognitive abilities of well-educated farmers. These farmers are good at acquiring information, clear about government intentions and concerned with rights. In their eyes, compensation is often insufficient and poor in quality. Thus, many of the well-educated farmers want to have other job opportunities. It is worth mentioning that 83% of well-educated respondents are younger than 50, which confirms the negative correlation between age and policy compensation.

(3) Annual family income

The annual family income mainly has a negative impact on farmers' selection of financial compensation ($p < 10\%$). Rich families are not very dependent on farm income. Their engagement in agricultural activities is mainly a pursuit for high-quality food. Farmers from these families are discouraged by the labor-intensity and strict requirements of conservation tillage. Therefore, financial compensation is not favored by rich families. On the contrary, farmers from poor families prefer financial compensation, and often ask for excessively high compensation due to the poor awareness of scientific farming and conservation policies. Apart from this, the annual family income has a very limited impact on the selection of other compensation options.

(4) Farmland area

The farmland area has a negative impact on farmers' selection of financial compensation ($p < 5\%$). The farmers with lots of farmland prefer non-financial compensation, because of the positive correlation between farmland area and the risk of yield loss under self-management. This is partly verified by farmers' selection of non-intellectual compensation. As shown in *Table 4,* the selection of non-intellectual compensation is positively affected by the farmland area ($p < 10\%$), so does organic fertilizer ($p < 10\%$). In addition, it can be seen from farmers' selection of organic fertilizer in different farmland areas that: farmers managing a larger farmland are more willing to make long-term investment. The reason is very simple: such farmers hold a favorable opinion of farming and want to enhance crop yield with organic fertilizer.

(5) Farmland fragmentation

Farmland fragmentation has a negative impact on farmers' selection of policy compensation ($p < 5\%$), which goes against the conventional knowledge that farmers are eager to change jobs when their farmland is fragmented, as fragmentation pushes up transport cost and hinders mechanized farming. Here, farmland fragmentation has no significant impact on other coupling compensation, indicating that farmers' demand for compensation remains constant despite difference in farmland conditions. Even if the farmland is highly fragmented, the farmers will not choose other jobs, because they rely on agriculture for a living. Lacking the knowledge of other jobs, they hope to maintain the current production scale, and safeguard the basic livelihood.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48234838

(6) Production efficiency

Production efficiency has a positive impact on farmers' selection of financial compensation ($p < 10\%$), and a negative impact on that of intellectual technical compensation and alternative fertilizer ($p < 5\%$). The higher the production efficiency, the more favorable is financial compensation among the farmers. This agrees well with the provision condition of financial compensation: farmers must know the way to allocate fund to farmland management in an efficient manner. The same explains why farmers do not want technical compensation, especially intellectual compensation like education and training, when the production efficiency is already high.

(7) Farmers' willingness to reduce fertilizer application

Grain compensation ($p < 1\%$) and policy compensation ($p < 10\%$) are positively affected by farmers' willingness to reduce fertilizer application, while intellectual technical compensation and alternative fertilizer ($p < 1\%$) are negatively affected. In other words, the farmers willing to reduce fertilizer application prefer financial compensation to technical compensation, as such farmers are optimistic about the yield loss. Note that some of these farmers are willing to reduce the amount of fertilizer as a way of conservation tillage. They are willing to bear yield loss as long as it can be eventually compensated. Thus, these farmers have a low demand for intellectual technical compensation and alternative fertilizer.

(8) Regional variable

Regional variable has a positive impact on financial compensation, grain compensation and policy compensation ($p < 1\%$), and a negative impact on intellectual and non-intellectual technical compensations ($p < 1\%$). Overall, the farmers living near Qiaodun Reservoir are more likely to accept financial and policy compensations and less likely to accept technical compensation than those near Siming Lake Reservoir. This conclusion is consistent with the actual situation. In the periphery of Qiaodun Reservoir, more than 60% of family income is from agriculture, owing to the dense population, poor traffic and lack of competitive industry. By contrast, those living near Siming Lake Reservoir have plenty of job opportunities in other industries, and farming income only accounts for 10% of family income.

Discussion

This paper explores the farmers' selection of compensation means for chemical fertilizer reduction, and divides the reduction methods into six types, namely, financial compensation, grain compensation, technical learning, alternative fertilizer; organic fertilizer, and policy compensation. Through a questionnaire survey, the farmers' acceptance of different compensation options was summed up as: Besides the popularity option of financial compensation, the farmers are willing to accept non-financial compensation means, and the options with features of transfusion and coupling compensations; the stability is the top concern in the selection process, while function and flexibility are also considered; when multiple options are available, financial compensation is the most favorite one among farmers, followed by technical learning and policy compensation; the organic fertilizer has the lowest acceptance. Next, a simultaneous bivariate probit model was established to illustrate the effect of each

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48234838

factor on farmers' selection between intellectual and non-intellectual technical compensations, and between alternative and organic fertilizers. Meanwhile, the farmers' intentions on policy compensation were examined by the binary probit model. The following conclusions were drawn through the empirical analysis on the modelling results.

The farmers' selection process is greatly affected by their awareness of the yield loss risk incurred by the reduction of chemical fertilizer. This risk is difficult to control at least in the short term if the farmers abandon long-term fertilization. However, chemical fertilizer is more controllable than pesticide, and the reduction consequences are not hard to predict. Our research reveals that farmers prefer the combination of compensation options that complement each other, and wish the government could provide compensation in a concentrated and practical manner.

The age of house owner is the key determination of the farmers' selection process. Old farmers are more conservative about alternative options, and stick to financial compensation and grain compensation. By contrast, young farmers are willing to improve farmland management and learn new techniques through intellectual technical compensation.

The education level of house owner has a negatively impact on the selection of grain compensation and intellectual technical compensation. Well-educated farmers are interested in non-financial compensation and policy compensation (other jobs).

The farmland area is negatively correlated with the selection of financial compensation. The farmers owning a large piece of farmland tend to choose alternative options and non-intellectual technical compensation.

The farmland fragmentation suppresses farmers' demand for non-agricultural job opportunities. Even if the farmland is highly fragmented, the farmers will not choose other jobs when they rely on agriculture for a living.

The production efficiency and farmers' willingness to reduce fertilizer application have similar effects on farmers' selection process. The farmers with high production efficiency are willing to reduce the use of chemical fertilizer and receive financial compensation instead of technical compensation. The farmers living near Qiaodun Reservoir, where the social and economic environment is relatively inferior, are more likely to accept financial and policy compensations and less likely to accept technical compensation, than those living near Siming Lake Reservoir. Even so, these farmers expect the government to provide intellectual technical compensation to control the risk of yield loss. In a word, the farmers living near Qiaodun Reservoir demand more opportunities for personal development.

Conclusions

Based on the above discussions, the following measures were designed for the government to encourage farmers' participation in fertilizer reduction and protect the quality of water bodies.

(1) Integrate different compensation options into a scientific and rational plan for farmers.

Considering the complementary effect between different compensation options, the government is advised to combine several compensation options that serve the same purpose and suit the same type of farmers into an integrated compensation plan, in light

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48234838

of the local conditions. Such a plan could promote the farmers' awareness of fertilizer pollution and boost their willingness to adopt reduction measures.

(2) Highlight the guidance of financial compensation on farmers' behaviors.

The financial compensation improves the direct income of any type of farmers, and thus enjoys a high acceptance among them. Despite its obvious incentive effect, the financial compensation should not be provided in advance, due to the presence of moral hazard. Instead, this compensation option should be given after the fertilizer reduction, and used to reward the farmers' purchase of techniques.

(3) Improve the acceptance of technical compensation through various channels.

The rejection of technical compensation is mainly attributable to the myth that farming is an empirical, not technical, process, as well as the farmers' poor awareness of environmental protection and blind trust in traditional low-cost, efficient but polluting tillage methods. To solve the problem, the government should provide regular training in the field and through channels like TV, radio and the Internet, remind the farmers of the importance of water conservation and the harm of chemical fertilizer to water bodies, and subsidize the purchase of alternative techniques to fertilizer application.

(4) Create job opportunities for farmers less willing to cut fertilizer application.

For various reasons, farmers may reject any compensation for fertilizer reduction. These farmers often have a special preference for jobs in other industries. Thus, it is suggested that the government implement "agricultural to non-agricultural" plans, giving these farmers new job opportunities. In places with good agricultural conditions, efforts should be made to develop green agriculture (e.g. family farm and ecological farm) and plant crops (e.g. potatoes and corns) requiring little fertilization. In places with poor agricultural conditions, the excess labor forces should be transferred to the downstream through ecological migration or non-agricultural reemployment. The emigration will benefit the ecology of the water bodies.

On the whole, the paper focuses on discussing whether there is a substitution relationship or complementary relationship between farmers' acquisition intentions of same type of compensation tools, and proposes that various means of compensation should have corresponding optimal providing ways (providing separately or in combination). As the acquisition and adoption of a single compensation tool is not the major concern of the study, there is no further research on the hematopoietic compensation type compensation, "other jobs" as career transfer, which can thoroughly eradicate pollution and is conducive to farmers' creating income. Farmers' career transfer involves the transportation and interconnection of agricultural labor in different employment areas. There are still lots of practical problems crying out for solution such as "what kind of local career transfer mode should be established", "how to formulate farmers' career transfer compensation scheme", "how to guarantee the continuity of employment", "how to ensure the stability of farmers' incomes", and so on. Therefore, it is an area worth further research.

Abstract. Despite its positive impacts on traffic convenience and resource delivery, metro construction tilts the balance of groundwater resources and destabilizes the groundwater environment. This paper explores the impacts of shield tunnel construction on groundwater environment from the design and construction to an operating metro project, and verifies these impacts through an analysis on the tunnel project in Jinan Metro Line R3. The research shows that the grouting in shield tunneling has a local influence on the groundwater quality and pH, which attenuates with the increase of distance to the tunnel axis; the scope of influence is constrained by the formation lithology. Then, the backpropagation (BP) neural network was adopted to predict the ejection volume of groundwater, and the main influencing factors of water environment were disclosed by analytical hierarchy process (AHP). Finally, the author discussed the key techniques and prevention systems for prevention of the impacts of shield tunnel construction on water environment.
Keywords: *shield tunnel, backpropagation (BP) neural network, prediction of spring flow, analytical hierarchy process (AHP), key to groundwater control*

Introduction and survey of literature

Metro construction makes traffic convenient and efficient, enhances the overall competitiveness of cities, and improves people's living standards. However, the construction process also has negative impacts on groundwater environment.

During the construction of metro tunnels, dewatering is a necessity for engineering excavation. The rapid discharge of water from the tunneling section undermines the groundwater regulation and the spatial distribution of water resources. With the advancement of the tunnel, an increasing part of the water environment is destroyed, which changes the conditions of water-soil conservation and aggravates the imbalance between surface water and groundwater system. Zheng et al. (2016) and other scholars classified the impact of soft soil, high water level, liquid-rich powder, sand layer and underground engineering construction on the environment and the causes of disasters. Luo et al. (2018) analyzed the characteristics of urban underground engineering, and discussed the environmental hazards of underground engineering construction.

Surface subsidence caused by instability of tunnel excavation will lead to complex environmental problems. Li (2014) analyzed the influence of excavation disturbance zone on surface and surface deformation, and made exploratory research for the selection of excavation design methods and schemes, subsidence prediction and damage evaluation. Surface subsidence changes the water supply, runoff and discharge modes of surrounding water-bearing strata, thus damaging the overlying aquifer and breaking the balance of water environment. Guo (2018) put forward the countermeasures to reduce the adverse impact of tunnel construction on the water environment and improve the stability of the water environment system. In the process of tunneling, the water quality of the water environment will be damaged. According to the target layer, criterion layer, element layer and index layer, Fu (2018) constructed the index system and factor set of the influence of underground waterproof construction on water quality in urban tunnel engineering, and analyzed the influence of main pollutants discharged in the process of underground waterproof construction on water quality in urban tunnel engineering. Engineering wastewater discharged into the water environment without treatment will cause pollution of surface water resources, environmental degradation and other ecological problems.

Materials and methods

Analysis on the impacts of metro construction on groundwater environment

Overview of metro construction

The metro tunnel usually passes through several formations with complex geological conditions and diverse geological features. These formations differ greatly in water content, compressibility, void ratio, strength, as well as surface water reserve and topography. Therefore, the tunneling technique needs to be selected in light of the specific geological environment and hydrological conditions.

The shield method is a fully mechanized “deep bore” construction approach. As the shield tunnel boring machine (TBM) advances underground, the surrounding rock is supported by the shell and segments to prevent the tunnel from collapsing, while the soil on the tunnel face is excavated by the cutting device and transported outside the tunnel by the conveyor (Li, 2018). The advancement is propelled by the pressure of jacks in the rear of the shield TBM. In addition, the precast concrete segments are pieced up to form the tunnel structure.

Analysis on the impacts during the construction

Metro construction involves the pouring of concrete and the use of other chemicals (Zheng et al., 2016). The injected grouts have a certain impact on the quality and pH of the water in the surrounding rock. During the construction, the grouts, which contain lots of additives, are injected with the advancement of the shield TBM and added again after the installation of the segments (Guo, 2018). The grouts are prepared from a single type of liquid or two types of liquids. To make the single-liquid grout, the raw material needs to be mixed into a flowing liquid in a stirrer, and then solidified on the working face through flow and plastic condensations. The two-liquid grout generally refers to chemical grouting, i.e. mixing liquid A (cement) and liquid B (water glass) into a colloidal solution, whose viscosity increases with time, and relocating the solution to flow and plastic condensation zones (Cai et al., 2018). The mix ratios of the two types of grouts are listed in the *Tables 1* and *2*.

The injection of a large amount of grouts can easily pollute groundwater resources. What is worse, epoxy resin and other compounds commonly used in the construction are highly toxic and harmful to the human body (Huang et al., 2018). During the tunneling process, the deep groundwater and shallow groundwater are mixed together. The pollutants in the shallow groundwater will diffuse into the deep groundwater, affecting the direction of the water vein and water quality.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48394854

The impacts of tunneling on water environment are constrained by the formation lithology. The permeability and compactness of the stratum both have an impact on the stability of water environment, which is negatively correlated with the distance to the tunnel axis.

During the construction, the dewatering well directly bears on the water level in the formation, resulting in temporary reduction of water level in local areas and damages to the soil structure. When water is discharged through the well, the groundwater level dropped across the board around the well. The curve on water level variation takes the shape of a funnel. Within the scope of influence, the soil layers will witness a continuous decline in the amount of pore water and the loss of water pressure balance. Meanwhile, the sediment will flow out from broken filter tube and filter layer of the well, reducing the natural compactness, water content and stability of the soil layers.

Table 1. *Common mix ratio of single-liquid grout*

Cement (kg)	Fly ash (kg)	Bentonite (kg)	Sand (kg)	Water (kg)	Additives
58	410	33	440	335	To be determined through experiment in light of the field conditions

Table 2. *Common mix ratio of two-liquid grout*

Water-cement ratio	Liquid A : Liquid B (volume ratio)	Coagulation time (s)
1:1	1:1	20~48

Analysis on the long-term impacts after the completion

Since the metro construction tilts the original balance of the groundwater environment, the long-term impacts on water environment can be evaluated against the reserve and ejected amount of groundwater. The latter can be predicted using the backpropagation (BP) neural network below (Isah et al., 2017; Li, 2017; Neelapu et al., 2018; Sánchez-Escalona and Góngora-Leyva, 2018; Sun et al., 2017a).

Let n, m and r be the number of neurons on the input layer, output layer and hidden layer in the BP neural network, which will be trained by K samples. The corresponding K input-output pairs can be expressed as $(X_k, Y_k), k = 1,2,\cdots,k$, where $X_k = (x_1, x_2,\cdots,x_n)$ is the input vector of the k-th sample and $Y_k = (y_1, y_2,\cdots,y_n)$ is the output vector of the k-th sample. Meanwhile, the expected value vector, the input layer-to-hidden layer weight matrix, and the hidden layer-to-output layer weight matrix are denoted as$D_k = (d_1, d_2,\cdots,d_n)$, $V = (V_1, V_2,\cdots,V_n)$,$V_j = (V_{j1}, V_{j2},\cdots,V_{jn})^T, j = 1,2,\cdots,n$, and $W = (W_1, W_2,\cdots,W_m)$ $W_i = (w_{i1}, w_{i2},\cdots,w_{in})^T, j = 1,2,\cdots,r$, respectively. The threshold of each hidden layer neuron and that of each output layer neuron can be expressed as $\alpha = (\alpha_1, \alpha_2,\cdots,\alpha_r)$ and $\beta = (\beta_1, \beta_2,\cdots,\beta_m)$, respectively. The initial weights and thresholds are configured by random.

Activation function: this function describes the change between the input and output of the neuron. The signals received by the hidden layer and the output layer are excited or suppressed by the calculation of the activation function. Here, the sigmoid function is selected as the activation function *Equation 1:*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48394854

$$f(net) = \frac{1}{(1+exp(-net))} \quad \text{(Eq.1)}$$

where net is the summation unit.

Summation unit *Equation 1* represents the weighted summation of the input signals of the hidden layer (He, 2018). Since the weighted input of the hidden layer unit j is $netb_j = x_k \cdot v_j + a_j$, the actual output of the hidden layer unit *Equation 1* can be expressed as *Equation 2:*

$$b_f = (netb_j), j = 1,2 \cdots, n \quad \text{(Eq.2)}$$

Thus, the output matrix can be obtained as $B_k = (b_1, b_2, \cdots b_r)$.

Summation unit *Equation 2* represents the weighted summation of the input signals of the output layer. Since the weighted input of the output layer unit i is $nety_j = b_k \cdot w_i + \beta_i$, the actual output of the output layer unit *Equation 2* can be expressed as *Equation 3:*

$$y_i = f(nety_i), i = 1,2 \cdots r, j = 1,2, \cdots, n \quad \text{(Eq.3)}$$

Error calculation and backpropagation: Taking the root mean square errors of the output value and the expected value as the loss functions, the error index function of learning a single sample and the global error index function of learning the entire training set can be respectively expressed as *Equations 4* and *5:*

$$E_k = \frac{1}{2}\sum_{i=1}^{m}(y_i - d_i)^2 = \frac{1}{2}\sum_{i=1}^{m}\{f\{[\sum_{j=1}^{r} f(x_k \cdot v_j + \alpha_j) \cdot w_{ij}] + \beta_i\} - d_i\}^2 \quad \text{(Eq.4)}$$

$$E = \sum_{i=1}^{k} E_k \quad \text{(Eq.5)}$$

The learning and training of the BP neural network generally rely on the negative gradient descent method to adjust weights and thresholds. Based on *Equations 1–3,* the adjusted values of the weights and thresholds can be obtained through derivation by the complex function chain law, as shown in *Equations 6–9:*

$$\Delta v_j = -\mu \frac{\partial E_k}{\partial v_j}, j = 1,2, \cdots, n \quad \text{(Eq.6)}$$

$$\Delta \alpha_j = -\mu \frac{\partial E_k}{\partial \alpha_j}, j = 1,2, \cdots, r \quad \text{(Eq.7)}$$

$$\Delta \beta_j = -\mu \frac{\partial E_k}{\partial \beta_j}, j = 1,2, \cdots, m \quad \text{(Eq.8)}$$

$$\Delta w_j = -\mu \frac{\partial E_k}{\partial w_j}, j = 1,2, \cdots, r \quad \text{(Eq.9)}$$

where $\mu \in (0,1)$ is a constant representing the learning efficiency.

The adjusted weights and thresholds are adopted for the calculation of the next training sample. The learning should be terminated when the global error reaches the pre-set value after learning all training samples. Otherwise, the weights and thresholds should be initialized again for a new round of training until the said termination condition is satisfied.

Evaluation of the negative impacts of metro construction on water environment

Analysis on the negative impacts on water environment

The negative impacts on water environment can be determined through the judgement of water environment damages caused by human activities and their impacts (Dai and Lv, 2018). In this paper, the analytical hierarchy process (AHP) is employed to scientifically assess water environment problems induced by tunnel construction (Dai and Zhao, 2018). The assessment was carried out in the following steps.

(1) Setting up the judgement matrix: Denote the target as A, the factors as u_i and u_j (*i*, *j* = 1, 2, ⋯, n) and the importance of u_i to u_j as u_{ij} (Sun et al., 2017b). On this basis, construct the A-U judgment matrix P below:

$$p = \begin{bmatrix} u_{11} & u_{12} & \cdots & u_{1n} \\ u_{21} & u_{22} & \cdots & u_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ u_{n1} & u_{n2} & \cdots & u_{nn} \end{bmatrix}$$

(2) Calculating the importance rank: Find the eigenvector w corresponding to the largest characteristic root λ_{max}, according to the judgement matrix, as shown in *Equation 10:*

$$P_w = \lambda_{max} \cdot w \qquad \text{(Eq.10)}$$

Normalize the obtained eigenvector w, that is, sort the importance of all evaluation factors, yielding the weight distribution.

(3) Consistency test: Check if the weights are reasonable through consistency test on the judgement matrix, as shown in *Equation 11:*

$$CR = \frac{CI}{RI} \qquad \text{(Eq.11)}$$

where CR is the random consistency ratio of the judgment matrix; CI is the general consistency index of the judgment matrix, as shown in *Equation 12:*

$$CI = \frac{\lambda_{max}}{n-1} \qquad \text{(Eq.12)}$$

The RI is the mean random consistency index of the judgment matrix P. If the CR of the judgment matrix P is smaller than 0.1 or $\lambda_{max} = n$ and CI = 0, then the judgment matrix has satisfactory consistency; otherwise, the elements in the matrix should be adjusted to ensure the consistency. The negative effect of water environment is evaluated by ahp to realize the health analysis of water environment (Yang, 2018).

Results

Analysis of the influence of Jinan subway construction on groundwater environment

Jinan, the capital of Shandong Province, China, is widely known as the City of Springs. It is said that “every household in the city has a willow-shaded spring at the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48394854

doorstep." There are many water bodies in the city, including the Yellow River, the Yufu River, the Beisha River, the Xiaoqing River and the Daming Lake. Unfortunately, the construction of Jinan Metro Line R3 has disturbed the topography, stratum altitude, stratum lithology and geological structure, hindered the ejection of underground springs and damaged the balance of groundwater environment. Located in the east of the city, Line R3 is a 49.4 km-long north-south express line linking up transport hubs like the new East Railway Station and Yaoqiang Airport. Many water bodies are scattered along the route of the line, such as the Xiaoqing River, the Daxin River, the Zhangma River, the Longji River, the Hancang River and the Mengjiazhuang Reservoir.

The construction area of Line R3 spans northward to the west of the springs in the Baiquan Spring Area, and belongs to the discharge zone of the area. The relative location between the project site and the Baiquan Spring Area is shown in *Figures 1* and *2*.

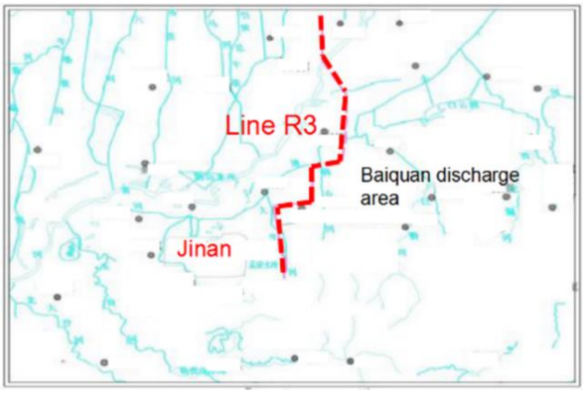

Figure 1. *Project site of Jinan Metro Line R3*

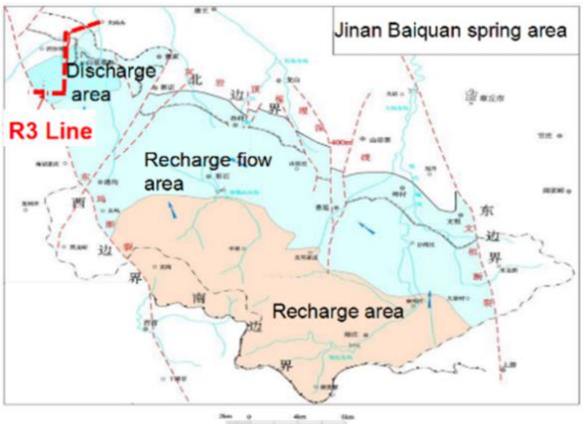

Figure 2. *Baiquan Spring Area*

The Mengjiazhuang~Long'ao section, an important passenger section of Line R3, is located in Lixia District of Jinan. Starting from the Mengjiazhuang Station, the metro line goes north along the Longding Avenue to the headquarters of the Armed Police Fire Corps, and then turns slightly towards the west, crossing the Daxin River and a mountain, and finally reaches the Long'ao Station on the Olympic West Road to the west of the Municipal Procuratorate. In this section, the crossings are mostly

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48394854

underground, along the road direction. The main environmental risk sources include the Daxin River, the DN1000 raw water pipe at the river bottom, and several roads undercrossed by the metro line, as well as the developed caverns near the side-crossing of the Daxin River Bridge. In the target section, the 1,816.811 m-long right line is designed between SK1 + 909.933 (right) and SK3 + 726.744 (right), while the left line of the same length is designed between XK1 + 909.933 (left) and XK3 + 726.744 (left). Constructed by shield tunneling, the tunnel in the section has a standard single-hole single-line circular profile. The left and right lines are both composed of straight segments, three circular curve segments with radius R = 1,000 m, and gentle curve segments. The line spacing is 13~14 m, and the covering soil is 2.3~80 m thick.

The construction area is dominated by south-north flowing pore water, which is replenished by the upstream runoff, karst water from the roof, and the atmospheric rainfall. The water is eventually discharged into the Xiaoqing River.

Since Line R3 lies in the discharge zone of Baiquan Spring Area, the first tunnel segment (north) in the Mengjiazhuang~Long'ao section passes through a 1,232.266 m-long layer of moderately weathered limestone and marlstone, while the second segment (south) through a 584 m-long gravel layer and the enrichment zone of karst groundwater in Baiquan Spring Area. Considering the dense water outlets, a huge amount of two-liquid grout was injected in actual construction. The liquid B is sodium water glass $Na_2O \cdot nSiO_2$, a popular chemical in civil engineering. The relevant chemical reaction can be described by the following formula:

$$xCa(OH)_2 + Na_20 \cdot nSi0_2 + mH_20 = xCaO \cdot Si0_2 \cdot yH_20 + 2NaOH$$

The product NaOH is alkaline. The two-liquid grout affects the pH of the water system around the grouting project and changes the pH of the local groundwater. The analysis results on local water sample are presented in *Figure 3*.

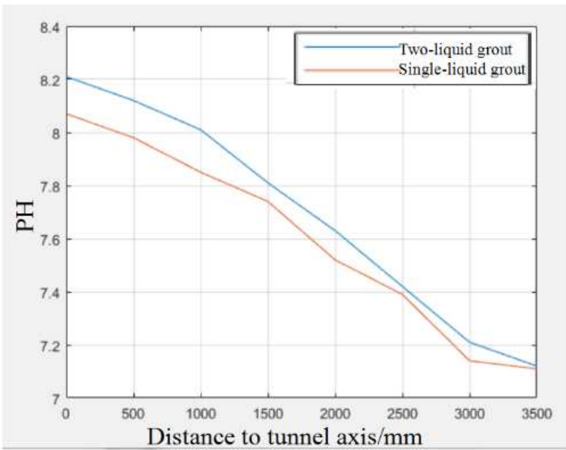

Figure 3. *The pH curve of local water sample*

As shown in *Figure 3,* the two grouts significantly pushed up the pH of the water around the tunnel, and the two-liquid grout had a greater impact on the pH than any single-liquid grout. This is because the two-liquid grout, as the main filling material, exerted an impact on the pH of the water in the secondary grouting, and the grouting process damaged the internal environment of the rock and soil, affecting the flow path

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48394854

of the water system. The author carried out an experiment on how much the tunnel blocks the water system, which shows that the grouting enhanced the water blocking effect by 20%~30% from that of cylinder volume of the tunnel.

Through investigation, it is learned that the scope of influence on water environment is maximal at the crossing through the gravelly soil layer, followed in descending order by the crossing through moderately weathered limestone and diorite, and the crossing through the silty clay layer.

As shown in *Table 3*, the impacts of the tunnel project on water environment belong to the 0~5,000 m from either side of the tunnel axis in the gravelly soil layer. Specifically, the severely affected area generally concentrates in the 0~1,500 m from either side of the tunnel axis. This area is characterized by the water seepage from Mengjiazhuang Reservoir, the depletion of surface water, wells and springs in the surroundings, the settlement, subsidence and cracking of the ground, and the complete change of the land use. The heavily affected area concentrates in the 1,500~3,000 m from either side of the tunnel axis. This area is characterized by the severe leakage of surface water, though not complete dry, obvious reduction of groundwater level, small local ground subsidence and change of local land use. The general affected area concentrates in the 3,000~5,000 m from either side of the tunnel axis. This area is characterized by the slight leakage of surface water and unobvious change of groundwater level.

Table 3. *Influence of formation lithology on water environment during metro construction*

	Gravelly soil layer	**Moderately weathered limestone layer (fragmented, with moderately developed caverns)**	**Moderately weathered limestone and diorite layer**	**Silty clay layer**
Permeability coefficient (10^{-6} cm/s)	8000	9000	6000	50
Scope of influence (relative to the tunnel axis)	0~ 5000 m	0~ 3000 m	0~ 2000 m	0~ 1000 m
Affected areas (relative to the tunnel axis)	0~ 1500 m	0~ 1000 m	0~ 800 m	0~ 500 m
Phenomena in the severely affected area (relative to the tunnel axis)	Water seepage from Mengjiazhuang Reservoir; depletion of surface water, wells and springs in the surroundings	Severe leakage of surface water, though not completely dry; obvious reduction of groundwater level	Slight leakage of surface water; unobvious change of groundwater level	Slight leakage of surface water

In the moderately weathered limestone layer (fragmented, with moderately developed caverns), the tunnel project has a moderate scope of influence on water environment, which covers the 0~3,000 m from either side of the tunnel axis. Specifically, the severely affected area generally concentrates in the 0~1,000 m from

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48394854

either side of the tunnel axis. This area is characterized by the severe leakage of surface water, though not complete dry, obvious reduction of groundwater level, small local ground subsidence and change of local land use. The general affected area concentrates in the 1,500~2,000 m from either side of the tunnel axis. This area is characterized by the slight leakage of surface water and unobvious change of groundwater level.

In the moderately weathered limestone and diorite layer, the tunnel project has a small scope of influence on water environment, which covers the 0~2,000 m from either side of the tunnel axis. Specifically, the severely affected area falls in 0~800, which is characterized by the slight leakage of surface water and unobvious change of groundwater level.

In the silty clay layer, the impacts of the tunnel project on water environment belong to the 0~1,000 m from either side of the tunnel axis. The severely affected area falls in 0~500 m, which is characterized by the slight leakage of surface water.

Near the target metro section, the large surface water systems include the Daxin River, which has a large north-south height difference, and the Mengjiazhuang Reservoir, which is rich in water resources. The groundwater beneath the riverbed is formed by the infiltration of rainwater along the gravel and bedrock fissures. The groundwater level is not uniform and varies greatly from season to season. The field survey on the reservoir confirms that there are 33 spring water outlets in the reservoir area (*Figures 4* and *5*), including 9 active springs and 24 inactive ones.

Figure 4. *Geographical map of Mengjiazhuang Reservoir*

Figure 5. *Distribution of spring water outlets near Mengjiazhuang Reservoir*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48394854

Here, the water ejection volume of each inactive spring is estimated by the BP neural network (Fu, 2018), while the water amount of the 9 active springs are analyzed by water volume monitoring. As shown in *Table 4,* the water ejection volume of spring outlet A was reduced by 26% and that of spring outlet I was reduced by 3%, due to the tunnel blockage and geological disturbances.

Table 4. *Daily ejection volume of active springs*

Spring No.	A	B	C	D	E	F	G	H	I
Pre-excavation ejection volume (m^3/d)	2.051	0.304	4.547	0.841	0.592	2.820	1.426	0.975	0.106
Post-completion ejection volume (m^3/d)	1.518	0.274	4.092	0.774	0.539	2.679	1.369	0.678	0.103
Reduction (%)	26	15	10	8	9	5	4	11	3

The measuring points were arranged at an interval of 200 m to monitor the groundwater level near Mengjiazhuang Reservoir. Then, the variation in the ejection volume of each active spring was predicted based on the monitoring data. The deviation between the predicted value and the original value was plotted as a curve in *Figure 6*. It can be seen that the predicted value agrees well with the original value, indicating that the prediction result is close to reality.

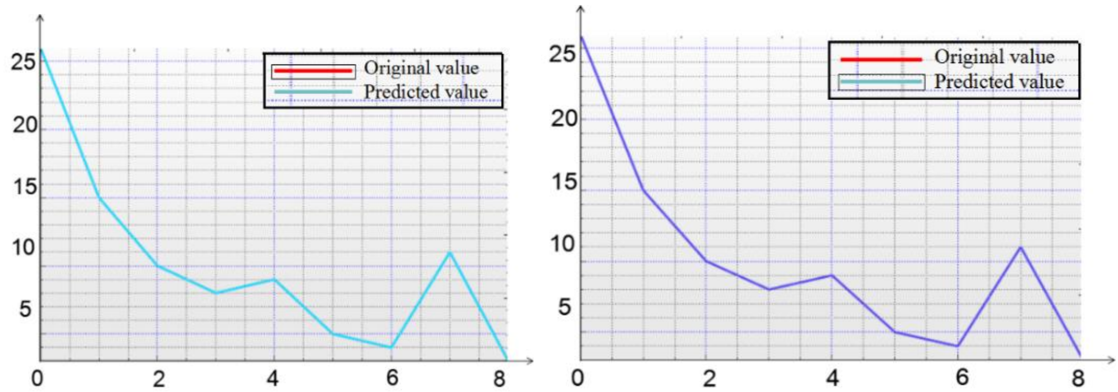

Figure 6. *Deviation between the predicted value and the original value*

The analysis on the prediction result shows that the metro tunnel construction caused an average reduction of 16% in the ejection volume of the active springs near Mengjiazhuang Reservoir. Besides, the ejection volume is correlated with the location of water outlets: the closer to the tunnel, the more the reduction in the ejection volume; the inverse is also true.

Analysis of the negative effects of subway construction on water environment

The target tunnel was divided into four parts (*Table 5*) according to the difference in geological conditions and covering soil environment of Line R3. Through the AHP, the judgment indices were allocated to three categories, namely, engineering geological conditions (Fang et al., 2018), hydrogeological conditions, and tunnel engineering

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48394854

conditions, and sub-divided into 13 special groups. Finally, 80 experts were invited to evaluate these indices. In this way, the author acquired the weights of the negative impacts of metro construction on water environment in the target metro section.

Table 5. *Division of groups and categories*

No.	Mileage	Length/m	Crossed stratum	Overlying stratum	Roof depth/m	Construction environment
A	SK3+726.7~SK3+400	326.7	Moderately weathered limestone	Plain fill, silty clay, gravelly soil	15.23-28.33	Crossing rainwater box culvert and tourist road
B	SK3+400~SK2+460	940	Moderately weathered limestone	Plain fill, moderately weathered diorite, gravelly soil	2.31-80	Crossing a mountain, karst caves, the Daxin River and DN1000 raw water pipe
C	SK2+460~SK2+280	180	Moderately weathered limestone, gravelly soil	Plain fill, silty clay	11.15-12.55	Crossing DN600 rainwater pipe; the stratum is soft on the top and hard on the bottom
D	SK2+280~SK1+909.9	370.1	Gravelly soil, silty clay	Plain fill, silty clay	10.47-13.1	Crossing the planed road and DN400 heat pipe

The weights (*Fig. 7*) were determined through selection of the evaluation method, construction of the evaluation model, the identification of the evaluation indices and the weight analysis.

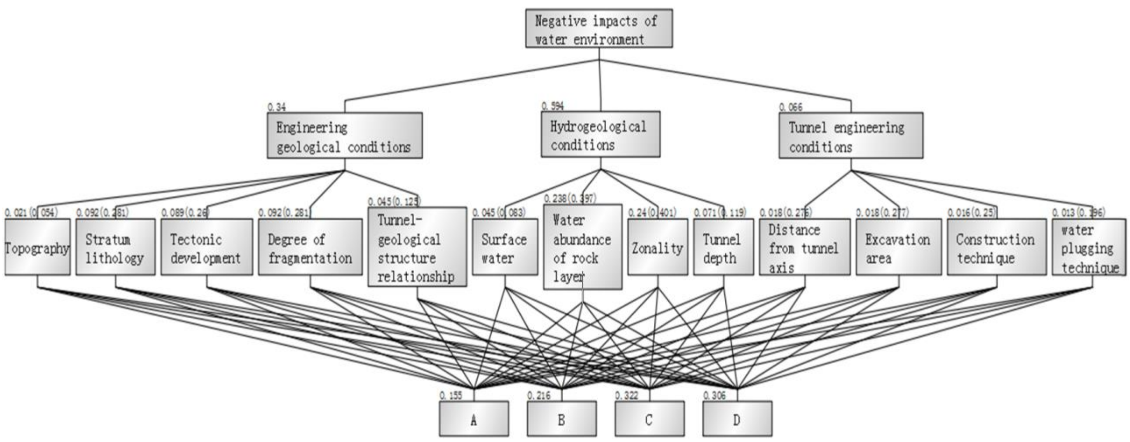

Figure 7. *AHP analysis on tunnel water environment*

The AHP weight analysis reveals that the negative impacts on water environment mainly come from the hydrogeological conditions (Tang et al., 2019). In the target tunnel, the SK2 + 460~SK2 + 280 segment had the greatest negative impacts on water environment, followed by the SK2 + 280~SK1 + 909.9 segment and the SK3 + 726.7~SK3 + 400 segment.

Discussion

Prevention of the impacts of metro construction on groundwater environment

Key prevention technologies

To reduce the impacts of metro construction on groundwater environment, it is necessary to step up prior control, rationalize route selection and optimize the design. The design plan should be pertinent and the planned route should be optimized according to the survey report. If a section of poor geological conditions is unavoidable, the best construction plan must be prepared in light of the geological conditions and construction technologies.

As mentioned before, the shield tunnel has a certain blocking effect on the flow of groundwater. It is impossible to identify the direction of all spring waters through geological survey, for the water flow of most small springs, generated the infiltration of surface water, may be affected by the stratum and groundwater level. To minimize the impacts of formation damage on spring water, fixed-point monitoring should be carried out on the water pressure of the water and soil layer near the tunnel, and recharge technique should be adopted to replenish the spring water.

As a permanent project, the tunnel will have an impact on the groundwater environment. In the short term, the local osmotic pressure of the water will be greatly affected, which will change the flow direction of the groundwater. The sealing effect of the multi-layer grouting on the water will induce changes to the groundwater system. To reduce the damage of grouts on water environment, it is advised to adopt high-quality shield segments, enhance the water resistance of the segments, standardize the field construction process, and cut down the amount of secondary grouting.

Considering the health impacts of groundwater quality and pH, the tunneling damages on water environment must be minimized. To lower the material pollution to water environment, the possible measures include replacing toxic compounds with green materials and traditional construction techniques with advanced techniques.

Main prevention techniques

The in-process control and post-action control should also be enhanced during metro construction. The water level should be reduced to about 50 mm below the excavation face when the last 3~5 ring segments are installed, so that no water or sand will flow out at the tunnel breakthrough. To meet this goal, it is recommended to implement in-situ dewatering at the recharge well (Guo et al., 2018). The process flow of this technique is shown in *Figure 8*. It can be seen that the pumping device is used to lower the water level of the excavated soil layer to below the excavation face.

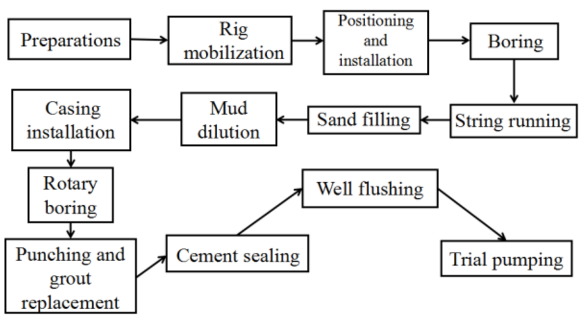

Figure 8. *In-situ dewatering at the recharge well*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48394854

As the water is injected back into the well, the groundwater level around the well will gradually rise, and the post-injection water level is called the recharge level. The water injected into the well can seep into the aquifer, owing to the water head difference between the recharge level and the groundwater level. When the recharge well is under construction in the foundation pit, the static water level and the dewatering-induced water level variation should be observed, so as to determine the remaining construction of the well. The recharge should commence if the groundwater level changes by over 300 mm per day, and stop if the recharge amount reaches 80% or the ground heaves. The recharge water mainly comes from the groundwater in the pumping well within the foundation pit. No additional pressure is needed in the early phase of the recharge. However, a proper amount of external pressure should be applied if the groundwater level cannot meet the target or the recharge amount is difficult to increase. Note that the recharge pressure should not be too large, but controlled within 0.5 MPa. During the recharge, the water level should be monitored every 12 h in the observation wells inside and outside the foundation pit. Meanwhile, the pumping well in the foundation pit should continue to operate.

Key techniques for water environment management in Jinan

The areas with developed water systems should be avoided in the design phase of the metro tunnels in Jinan. To protect springs, the metro lines should be circumvent springs and avoid water veins. Special efforts should be paid to set up a wide network of water level monitoring systems, covering 2~3 times the area of normal water level detection systems. In addition, the shield segments must contain sealing strips and receive testing before use, aiming to minimize the risk of water leakage due to broken sealing strips.

According to the above design requirements, the in-situ recharge should be performed in time after the dewatering of the tunnel and stations in the target section. The in-situ recharge of groundwater can be controlled in an automatic and precise manner, through the coordination between pressurized recharge well, large variable diameter pressurized recharge well, surrounding water environment detection system, integrated pumping and recharge device and smart control system. The test data show that the overall recharge rate surpassed 80%, indicating that the proposed techniques can effectively protect the total amount of water resources, stabilize the groundwater pressure and maintain the balance of the groundwater environment.

Prevention system

The metro construction brings a wide range of far-reaching and long-lasting damages on water environment (Zhang et al., 2017). To protect the water resources of Jinan, the author set up a prevention system against the negative impacts on water environment, covering the entire process from design, construction, operation to maintenance. As shown in *Figure 9,* the proposed system relies on big data collection and analysis platforms (e.g. digitalization, the Internet of Things, cloud computing and collaborative management), integrates underground engineering construction techniques, and involves such systems as organizational system, capital system and institutional system. The system supports real-time warning or adjustment according to geological, hydrological, and engineering inspection data, realizes the intelligent decision-making on the prevention of negative impacts on water environment, and achieves the dynamic optimization of water environment treatment techniques and processes.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48394854

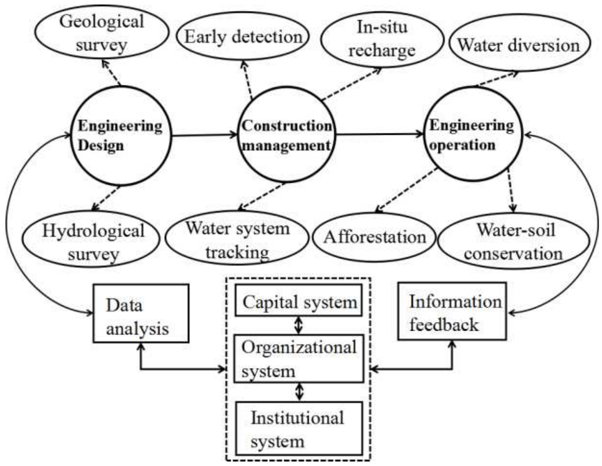

Figure 9. *The whole process prevention system against negative impacts on water environment*

During the engineering design, the survey data on water level are is analyzed by cloud computing and collaborative management system, and the results are directly applied to the construction management. The construction plan is guided by the real-time data on the field water environment, which are collected through water system tracking and early detection during the design and construction management, laying a solid basis for emergency instructions and groundwater protection.

In this paper, the in-situ recharge in Jinan uses an intelligent control system for integrated pumping and recharge. Coupled with the prevention system, the intelligent control system can promote the protection of water environment. During the project operation, water-soil conservation and afforestation work will be carried out to protect the soil and water resources in a targeted manner. The whole system forms a closed-loop control through the feedback mechanism, which can effectively reduce the negative effects of underground engineering on water environment and protect water environment.

Conclusions

During metro construction, it is imperative to maintain the original groundwater quality and flow, reduce the impacts on the surrounding water environment, and coordinate the relationship between metro construction and water environment.

(1) In this paper, the impacts of shield tunnel construction on groundwater environment are analyzed in the entire process from construction to operation. The research shows that the shield grouting can affect the quality and pH of groundwater in local areas, and the effect attenuates with the increase of the distance to the tunnel axis. These results were verified through the analysis on the construction of a section in Jinan Metro Line R3.

(2) The impacts of metro tunnel construction on water environment are constrained by stratum lithology, and abide by a certain law. This law was identified as “small in the distance and big on the contrary”, based on the data collected from the section between Mengjiazhuang Station and Long’ao Station in Jinan Metro Line R3.

(3) The BP neural network was adopted to predict the reduction of groundwater flow induced by metro construction. Meanwhile, the ejection volumes of 24 active springs

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48394854

near Mengjiazhang Reservoir were predicted. Through these predictions, it is concluded that the ejection volume of the local springs will be reduced by 16% on average.

(4) The main factors were acquired concerning the impacts of metro construction on water environment through the AHP. The analysis shows that the negative impacts on water environment in the target section mainly come from hydrogeological conditions, and peak in the SK3 + 726.7~SK3 + 400 segment.

(5) The author put forward the key prevention techniques for the negative impacts on water environment, and constructed a five-in-one prevention model for negative impacts on water environment, which consists of a construction system, a data analysis system, an organizational system, a capital system and an institutional system.

(6) During the construction of metro tunnels, Multi-angle analysis technology and judgment indicators can better protect the groundwater environment. In-depth exploration of the influence factors of underground engineering on the water environment and comprehensive analysis of the negative effect data of groundwater environment will be the focus of future research on the impact of underground engineering on the water environment and prevention.

(Received 5th Feb 2019; accepted 6th Mar 2019)

Abstract. Based on the data on the Chinese industrial sector in 2009~2015, this paper empirically analyses the effect of research and development (R&D) subsidy on energy consumption and energy structure of the industry in China. The research results show that the R&D subsidy slowed down the growth of the total energy consumption in the Chinese industrial sector and promoted the optimization of the energy structure in the short term. On this basis, the author investigated how these impacts varied within so called pollution departments. The investigation reveals a significant impact of R&D subsidy in high-pollution departments: the subsidy greatly suppressed the energy consumption and optimized the energy structure of these departments; for low-pollution departments, the R&D subsidy had no major impacts on energy consumption or energy structure.
Keywords: *R&D subsidy, compensation effect, price effect, scale effect, regression analysis, heterogeneity analysis*

Introduction

Over the years, China has consumed a large amount of basic resources, especially energy, for industrial development. With abundant coal and limited oil, China's industrial development relies on the direct use of coal and the consumption of secondary energy (e.g. thermal power) produced from coal. The coal-based energy structure has brought serious pollution. In his report at the 19th National Congress of the Communist Party of China (CPC), Xi (2017) said, "To ensure harmony between humanity and nature, we must realize that lucid waters and lush mountains are invaluable assets and act on this understanding, implement our fundamental national policy of conserving resources and protecting the environment." Under his call, the government, researchers and the public began to focus on industrial development and environmental issues, striving to optimize consumption and energy structure, and achieve sustainable development (Shang and Zhu, 2018).

In addition to promoting stable economic growth, technological progress can reduce pollution and facilitate energy conservation and emission reduction in the industry. The R&D activities have significant public attributes and positive externalities. By subsidising the research and development (R&D) of manufacturers, the government can correct market failures in R&D activities, lower the R&D risks of enterprises, and improve the technical level of the industry as a whole (Xu et al., 2014). Despite the numerous studies on the relationship between R&D subsidy and technological innovation (Wu and Liu, 2014; Xiao and Lin, 2014; Zhao and Yao, 2017), there are still two unresolved questioned: Is it possible for the government to simulate technological progress of producers through R&D subsidy, thus improving the overall energy

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48554867

conservation of the industry? Are there any differences in the energy-saving effects of government R&D subsidy for industries at different levels of pollution or technology? Answering these two questions will help China formulate future industrial subsidy policies, transform and upgrade the industry, and achieve energy conservation and emission reduction.

As mentioned before, the previous studies on R&D subsidy mainly tackle the following issues: how does R&D subsidy impact enterprise R&D inputs (Busom, 2000; Jiang and Huang, 2010), whether R&D subsidy affects innovation efficiency (Lv and Sun, 2014) and what is the crowding-out effect of R&D subsides (Lach, 2002; Wallsten, 2000). However, there is little report on the influence of R&D subsides over socioeconomic development or environmental improvement (Song, 2018). Particular attention should be paid to the positive externalities of subsidy, a common financial remedy to market failures, on a social basis. Therefore, this paper intends to expand the scope of existing research into the relationship between R&D subsidy and innovation.

Moreover, China is now faced with serious resource misallocation due to the legacy of the planned economic system. The problem is particularly severe in the field of science and technology (Han and Zheng, 2014). Against this backdrop, some inefficient industries waste R&D subsidy in blind expansion of low-efficiency production, rather than develop and upgrade technology. The resulting pollution and excess capacity hinder the industrial transformation and upgrading and harm the environmental protection in China. As a result, this research aims to help the government design and develop more flexible and effective R&D subsidy policies.

Overall, this paper attempts to disclose the effects of R&D subsidy on energy consumption and energy structure, and discover the far-reaching impact of R&D subsidy on China's environment, laying a valuable basis for the pursuit of an ecological civilization.

Materials and method

Theoretical analysis

The R&D subsidy affects energy consumption and energy structure through three channels, namely, the compensation effect, the price effect and the scale effect. Below is a detailed description of each channel.

Compensation effect

The public attributes of producers' technical R&D activities often result in high cost, high risk and a long-term investment (Danneels and Kleinschmidtb, 2010). Owing to the spill-over of producers' R&D activities, the expected returns are reduced to a level far below the generated social benefits. Hence, the producers are deprived of the resources for further R&D activities (Cohen and Levinthal, 2015). The government's R&D subsidy partially offsets the producers' loss of expected returns caused by technology spill-over, and compensates or even enhances the expected returns of the producers' R&D activities. This brings positive signals and stimuli to producers' R&D behaviour. Meanwhile, the government's R&D subsidy partially lowers the risks generated by R&D activities, suppresses the negative impact of uncertain R&D outcome on the expected returns, and arouses producers' interest in and continuous inputs to R&D (Lichtenberg, 2001). To sum up, the government's R&D subsidy can

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48554867

bolster the R&D inputs of the producers, and promote the technological progress and innovation ability of the producers and whole industry. This, in turn, encourages the energy conservation and emission reduction in the whole industry, leading to lower energy consumption and more efficient energy use.

Price effect

The price effect is demonstrated in the indirect impacts on the efficiency and price of energy production. On climate change policies, Sinn (2008) discovered the "green paradox": the policies against climate change will lead to the growth in energy consumption and the accumulation of greenhouse gases. Sinn presented the following explanation to the transmission mechanism of "green paradox": all industries will enjoy more efficient production and better technologies thanks to technological progress; in the energy industry, the results of technological progress are demonstrated as improved efficiency of energy production and the reduced energy price; as the price drop reduces production costs, producers tend to consume more energy and release more greenhouse gases. Maria et al. (2014) analysed the coal prices in the US from 1986 to 1994, noting that the reduction of energy price caused by technological progress has increased energy consumption. Thus, the R&D subsidy, through the technological progress in the energy industry, can lower the energy supply price, and in turn affect the total energy consumption in other industries.

Scale effect

The scale effect of government R&D subsidy mainly comes from the crowding-out effect, which propels the expansion of production scale. When the government subsidises producers' R&D activities, the government funds will displace the producers' R&D inputs (Guellec and Van Pottelsberghe, 2003), allowing producers to invest the inputs to expanded reproduction. The expansion of production scale will push up energy consumption. This situation is clearly seen in high-pollution industries. In China, high-pollution industries are large in scale, high indebted, and have a low the added value of products. These industries often spend spare funds on the expansion of production scale, aiming to reduce unit cost of products and realize returns to scale. To some extent, this explains the expansion and overcapacity of some traditional industries in China, despite the continuous growth in R&D subsidy in recent years.

Samples and data sources

The relevant data on R&D subsidy and energy consumption of the energy industry from 2009 to 2015 were adopted for this study. The data in 2009 and 2010 were adjusted according to the latest classification method for industrial sectors issued by China in 2011. For instance, the plastic products industry and rubber products industry were merged into the rubber and plastic products industry, while the automobile manufacturing industry was combined with the manufacturing industries for railway, shipping, aerospace and other transportation equipment into the transportation equipment manufacturing industry. After the adjustment, the data were divided into 36 industrial sectors according to the 2011 industrial sector classification method, excluding those on the other mining industry. The data on R&D subsidy were extracted from *Statistics Yearbook on Science and Technology Activities of Industrial Enterprises* and *China Statistical Yearbook on Science and Technology*, the data on energy were

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48554867

extracted from *China Energy Statistical Yearbook*, and the data on other indices of industrial economy and development were extracted from *China Industry Statistical Yearbook*. To eliminate the interference of price on the empirical results, the relevant economic indices were deflated against the benchmark of the 2009 price.

Definition and measurement of variables

The explained variables in this paper are the total energy consumption and energy structure.

The former describes the general trend of consumption. Here, its value is expressed as standard coal converted from the data released by the statistical department. The energy structure reflects the composition of energy consumption. It is usually expressed as the ratio of the total coal-based energy consumption to the total energy consumption. The total coal-based energy consumption equals the sum of the standard coal converted from the consumption of each type of coal-based energy.

The government's R&D subsidy is treated as an explanatory variable in this research. From the data on R&D funds, the subsidy funds allocated by the government directly to the industries were identified manually.

A total of six control variables are adopted for this research. Among them, the industry scale was described by the proxy variable of the number of employees in the industry in the current year; the fixed assets investment was extracted directly from the data released by the statistical department; the energy price index was the ex-factory price of power fuel released by the statistical department (the value was converted against the benchmark price in 1985 to eliminate the interference of price on the empirical results); the export volume, the total revenue and the R&D expenditure were directly extracted from the data released by the statistical department and subjected to deflation. The meanings of the above variables are given in *Table 1*.

Table 1. *Meanings of variables*

Variables	Description	Unit
Energy consumption	The amount of energy that one industrial sector consume in 1 year	104 tons of standard coal
Energy structure	Ratio of coal-based energy to total energy	%
R&D subsidy	Funds that the government allocates to enterprise for R&D	104 Yuan
Size	Size of one industrial sector	104 persons
Fixed asset investment	Expenses for the construction and purchase, such as capital construction, renovation and major repairs, etc	109 Yuan
Energy prices index	An index of the price of energy purchased by producers	
Export	The total revenue that a producer sell its products abroad	109 Yuan
Revenue	The total revenue that a producer sell its product or service in 1 year	109 Yuan
R&D expenditure	Total expenditure invested by producers for scientific research and development activities	104 Yuan

Construction of regression equations

The following econometric equations were established to test the impact of government R&D subsidy on energy consumption and energy structure. In *Equations 1*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48554867

and *2,* the current year data on R&D subsidy are taken as the explanatory variables, aiming to measure the short-term impact. In *Equations 3* and *4,* the subsequent year data on R&D subsidy are taken as the explanatory variables, aiming to measure the long-term impact.

$$EC_{it} = \alpha_0 + \alpha_1 Subs_t + \alpha_2 Size_{it} + \alpha_3 FI_{it} + \alpha_4 P_{it} + \alpha_5 Exp_{it} + \alpha_6 R_{it} + \alpha_7 RD_{it} + \varepsilon_{it} \quad \text{(Eq.1)}$$

$$ES_{it} = \alpha_0 + \alpha_1 Subs_t + \alpha_2 Size_{it} + \alpha_3 FI_{it} + \alpha_4 P_{it} + \alpha_5 Exp_{it} + \alpha_6 R_{it} + \alpha_7 RD_{it} + \varepsilon_{it} \quad \text{(Eq.2)}$$

$$EC_{it} = \beta_0 + \beta_1 Subs_{it-1} + \beta_2 Size_{it} + \beta_3 FI_{it} + \beta_4 P_{it} + \beta_5 Exp_{it} + \beta_6 R_{it} + \beta_7 RD_{it} + \varepsilon_{it} \quad \text{(Eq.3)}$$

$$ES_{it} = \beta_0 + \beta_1 Subs_{it-1} + \beta_2 Size_{it} + \beta_3 FI_{it} + \beta_4 P_{it} + \beta_5 Exp_{it} + \beta_6 R_{it} + \beta_7 RD_{it} + \varepsilon_{it} \quad \text{(Eq.4)}$$

where EC is the total energy consumption; ES is the energy structure; Subs is the R&D subsidy; Size is the industrial scale; FI is the total fixed asset investment; P is the energy price index; Exp is the export volume; R is the total revenue; RD is the R&D expenditure; the subscript i refers to the industry; the subscript t refers to the year.

Results

Statistical description

According to the statistical description of data in *Table 2*, the energy consumption ranged between 69,543.27 and 110.10, revealing a huge gap in energy consumption among different industries; the minimum energy structure stood at 0.02 only, a mirror of the intensive and efficient use of non-coal-based energy in some industries, which explains the massive gap in total energy consumption among different industries; the industries also differed greatly in the amount of R&D subsidy, indicating the sharp difference in R&D level and technical level among the industries.

Table 2. *Statistical description of data*

Variables	Observations	Mean	Std. dev	Min	Max	Unit
Energy consumption	252	5085.74	11270.81	110.10	69543.27	10^4 tons of standard coal
Energy structure	252	0.28	0.19	0.02	0.81	%
R&D subsidy	252	110326.80	227060.60	194	1790916	10^4 Yuan

Variable correlation analysis

Table 3 records the results of correlation analysis on the variables. The analysis focuses on the correlations between government R&D subsidy and the two explained variables. As shown in Table 3, the R&D subsidy is positively correlated with the total

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48554867

energy consumption and negatively with the energy structure. These correlations were subjected to empirical analysis in the next section.

Table 3. *Variable correlation analysis*

Analysis of empirical results

Before the regression analysis, the collinearity between the variables was tested. The results show no sign of collinearity. Next, the correlations between R&D subsidy and the two explained variables were tested and analysed on Stata 14.

Table 4 shows the effect of R&D subsidy on the total energy consumption. Under the control of time trend, Models (1) and (2) are a random effect model and a fixed effect model on the short-term effect, respectively. The results of the random effect model were adopted according to the Durbin–Wu–Hausman test. The results of Model (1) show that, in the short term, the R&D subsidy had a significant negative correlation with the total energy consumption. This means the energy consumption will decline with the increase in the R&D subsidy. The results also prove that the total energy consumption is positively correlated with the industrial scale, the total revenue and the R&D expenditure, but negatively with the fixed asset investment and the export volume.

Under the control of time trend, Models (3) and (4) are a random effect model and a fixed effect model on the long-term effect, respectively. The results of the fixed effect model were adopted according to the Durbin–Wu–Hausman test. It can be seen that the growth in total energy consumption was significantly suppressed with the increase in R&D subsidy.

Table 5 describes the effect of R&D subsidy on the energy structure. The results of Model (5) were verified by Durbin–Wu–Hausman test. According to these results, the R&D subsidy improved the energy structure and reduced the ratio of coal-based energy in the energy consumption of production in the short term. In particular, the energy price index significantly boosted the improvement of the energy structure. Hence, the R&D subsidy can elevate the efficiency of the energy industry to a certain extent and thus reduce the price of energy supply and service. In the long run, R&D subsidy did not exert a significant impact to improvement of the energy structure. According to the results of Durbin–Wu–Hausman test, the R&D subsidy in the subsequent year had no major impact on the improvement of the energy structure.

In summary, the above results indicate that R&D subsidy alleviated the growth trend of the total energy consumption and improved the energy structure in the short term.

Pollution heterogeneity-based analysis

After examining the impact of R&D subsidy on energy consumption and the energy structure of the entire industrial sector in China, this paper further explores whether the impact differs with the pollution levels. According to the *Guide for Environmental Information Disclosure of Listed Companies* issued by the Chinese Ministry of Ecology and Environment, the 36 samples were divided into high-pollution departments (16) and low-pollution departments (20), and subjected to analysis separately. The results are listed in *Tables 6* and *7*.

In *Table 6*, Models (9) and (10) are about the short- and long-term impacts of R&D subsidy on energy consumption in different pollution industries, respectively. For high-pollution departments, the R&D subsidy exerted a significant negative impact on energy consumption in both short- and long-term, indicating that the subsidy can indeed curb the growth of energy consumption in high –pollution departments. As shown in Models (11) and (12), the R&D subsidy had no significant effect on energy consumption of low-pollution departments. In high-pollution industries, the R&D subsidy can promote the upgrading of industrial technology, and thus bolster the implementation of energy

DOI: http://dx.doi.org/10.15666/aeer/1702_48554867

conservation and emission reduction. The bolstering effect is particularly obvious in energy-sensitive areas like high-pollution departments. By contrast, low-pollution departments are not sensitive to energy demand, for they emphasize on with the improvement of product technology over the change of production technology.

Table 7 illustrates the impacts of R&D subsidy on the energy structure in different pollution departments. As shown in models (13) and (14), the R&D subsidy exerted a significant negative impact on energy structure in both short- and long-term for high-pollution departments, indicating that the subsidy reduces the use of coal-based energy in these departments; for low-pollution departments, the R&D subsidy had no significant short- or long-term effect on energy consumption. This situation can be attributed to two factors. First, the R&D subsidy promotes the industrial transformation and upgrading, especially in high-pollution industries. These departments are less dependent on traditional coal-based energy, due to the improvement in production flow and processes. The consumption of coal-based energy is further reduced by the increase in total factor productivity induced by the R&D subsidy. Second, the R&D subsidy drives the development of new energy production, leading to lower prices of energy

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48554867

supply and energy service. Thus, the traditional departments could use new energies at a much lower cost, which indirectly optimizes the energy structure of high-pollution departments.

Discussion

In China, the R&D subsidy has a direct and targeted effect on the total energy consumption. For one thing, the Chinese government wants to promote industrial transformation and upgrading through subsidising the R&D activities of enterprises in an industry. The subsidised enterprises are required to invest the subsidy to R&D activities. In this way, the R&D subsidy pushes up industrial R&D expenditure, and in turn the overall technical level and productivity of the industry. This is conducive to the energy conservation and emission reduction in the short- and long-term, and the efficiency of energy use, which slows down the growth of energy demand in China's industrial sector. For another, the R&D subsidy favours high and new technology enterprises. Since these enterprises are more likely to receive a huge amount of R&D

DOI: http://dx.doi.org/10.15666/aeer/1702_48554867

subsidy, the high and new industries will expand at the cost of the traditional industries. The spill-over effect of these industries will spread new technologies across different sectors, slowing down the growth of energy demand in China's industrial sector.

The short-term optimization of the energy structure relies on the changing scale of different industries. For one thing, low-pollution and high-tech industries expand exponentially under the R&D subsidy. These industries consume much more power and new energy than the traditional ones, which lowers the total consumption of traditional energy. For another, the traditional industries are shrinking and reorganizing. To control pollutant emissions, the Chinese government has implemented strict policies on emission control, and even shut down some small enterprises with high pollution and high energy consumption. For industrial transformation and upgrading, the government require traditional industries to merge and reorganize, in addition to issuing R&D subsidy to enterprises. To realize economies of scale and energy conservation, some traditional enterprises have implemented bankruptcy procedures and resource

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48554867

restructuring of their subsidiaries, and directly diverted the R&D subsidy to technical progress. These measures have improved the energy structure of traditional industries to a certain extent, and affected the energy structure of the entire industrial sector in the short term.

Conclusions

This paper studies the impacts of R&D subsidy on industrial energy consumption and the energy structure, and further analyses how these impacts vary between high- and low-pollution departments. It is concluded that the R&D subsidy has indeed slowed down the growth of energy consumption in China's industrial sector, thanks to the positively impact on technology level. According to pollution heterogeneity-based analysis, the slowdown effect is attributed to the change of energy consumption in China's high-pollution departments. In other words, the change of energy consumption in high-pollution departments determines the shift in energy consumption of China's industrial sector. It is also concluded that the R&D subsidy has optimized the energy structure of high-pollution departments through the technical progress and substitution effect. The technical progress is the result of the industrial transformation and upgrading in each department, while the substitution effect means the displacement of traditional coal-based energy with low-price new energies. As a result, high-pollution departments are the main beneficiaries of the R&D subsidy, and the key to energy conservation and emission reduction in China.

The author put forward the following recommendations according to the research conclusions. First, the high-pollution departments should receive even more R&D subsidy. The subsidy should be directed at the optimization of the production flow in high-pollution departments, aiming to boost the innovation in production flow and product technologies. This will benefit industrial transformation and upgrading, as well as energy conservation and emission reduction. More R&D subsidy should be allocated to industries that have successfully upgraded and transformed their technologies, turning them into leaders in industrial transformation and upgrading.

Second, the receivers of the R&D subsidy should be further clarified. The existing distribution mode of R&D subsidy must be replaced with one that allocates special funds to key receivers. For high-pollution departments, a group of enterprise with strong technical skills and in good business conditions should be selected to enjoy special funds for technical transformation and upgrading. For enterprises and departments with weak technical skills and in poor business conditions, the R&D subsidy should be gradually reduced to prevent misappropriation. For low-pollution departments, more R&D subsidy should be allocated to some key industries to improve the scale and technology of high and new industries.

Third, the technological progress should be further shared between different departments. The spill-over and transformation of technological results are important drivers of energy conservation and emission reduction in China. The government should encourage high and new technology enterprises, especially new energy enterprises, to implement technological transformation, and promote the introduction and application of new energies and new technologies in high-pollution departments. These moves will optimize the energy structure of the entire industrial sector, curb the growth of energy consumption, and suppress pollutant emissions.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48554867

For the future studies, some research issues need to be given further discussion. On one hand, the researchers should pay more attention to the relationship between R&D subsidy and innovation. R&D subsidy provides more support for enterprises on technology development because those enterprises would invest more funds in technology development after getting R&D subsidy. And that, for the measurement of innovation, the researchers should select a new method of measuring innovation instead of patent used in previous articles. On the other hand, the researchers focus not only on innovation but also other approaches of technological progress, such as technological cooperation and technological exchange.

Abstract. In response to the commitment that China will begin a comprehensive national carbon emissions trading system in 2017, and considering the needs of a green development strategy, in this paper we adopt a coal-fired power generation company as the research object to study its typical carbon emissions characteristics. Through theoretical analysis and modelling dominated by energy characteristics, the energy flow analysis is separated from the material flow analysis, and we construct an "energy flow—value flow" analysis model. Based on the link between energy use and carbon flow, we divide carbon flow cost into two parts: low carbon control costs and internal and external damage costs. A quality cost control idea is introduced to build a quantitative carbon flow cost control model, and we study the relationship between the total cost of carbon flow and the control of carbon pollution. The case calculation shows that coal enterprises should begin by examining their energy flow, invest reasonably in measures to control carbon, improve their energy efficiency, enhance their control of carbon flow costs and actively focus on relevant policies that control carbon flow effectively; following this process will allow them to be proactive in the new carbon market.
Keywords: *energy flow analysis, value flow analysis, carbon flow, cost control model, model application*

Introduction

Emitting greenhouse gases (primarily CO_2) cause externalities that have environmental effects on all of mankind (Cao and Zhang, 2010; Lodi et al., 2017). Since the Kyoto Protocol promulgated in 1997, the external costs of greenhouse gas emissions have been gradually internalized by market mechanisms (Liu and Huang, 2011). Thus, if today's businesses ignore the costs associated with greenhouse gas emissions, they may face difficulties in terms of environmental payments (Zhang et al., 2005). After extensive long-term economic development, China has begun to emphasize the transformation and upgrading of its economic structure. In particular, industries that have traditionally emitted high levels of carbon dioxide, such as power generation, steel, and coal among others, are now being strictly regulated to protect the environment (Capoor and Ambrosi, 2009; Zhang, 2017). The National Development and Reform Commission announced in January 2016 that progress has been made toward implementing a national carbon emissions trading market (Lu et al., 2010; Tu and Ma, 2018), and China pledged in 2017 to begin its carbon emissions trading system. In this context, clarifying the cost of carbon flow for enterprises will help them control costs, enhance their corporate image, and enable them to occupy a strong competitive position in the new carbon market.

The 13th Five-Year Plan (2016-2020) emphasized the importance of low carbon development, required enterprises to take the initiative to control carbon emissions and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48694882

strengthen control of their energy consumption. Controlling carbon emissions requires tracking the carbon flow path and calculating relevant costs. The core of studying carbon flow cost involves quantifying the flow of carbon energy inside the enterprise. From an economic standpoint, both carbon energy and value flow during an enterprise's production and management, and both flows affect the enterprise's financial costs (Wang, 2015). Therefore, we focus on the dual nature of energy and value flows, with high carbon emissions from coal-fired power generation enterprises as our research object. This paper constructs a simulation of carbon flow cost control based on "energy flow-value flow" to provide a model for the concrete implementation of carbon flow cost control.

Research methods

Energy flow, value stream analysis method

Energy flow analysis is a category of material flow analysis. During the 1980's, scholars studied the interaction between economic systems and the natural environment and developed a system known as material and energy flow accounting (MEFA) (Chang, 2012). In 2001, through an analysis of the energy flow of national economic systems, Harberl and others put forward a material and energy flow accounting framework and applied it to analyze sustainable development problems (Helmut et al., 2004). Teresa Torres applied material and energy flow accounting to analyze the status of clay in roofing tiles (Torres et al., 2008). Chinese scholar Li Xingji, after analyzing the role of logistics in urban pollution, put forward the idea of using energy flow accounting to protect the urban environment (Li, 1979). Liu et al. (2011) and other scholars wrote that energy flow accounting helps reduce environmental pollutants, because it provides a theoretical basis for enterprises' efforts to save energy and reduce emissions (Liu et al., 2017). The core of energy flow analysis is the concept of energy flow management (Bendriss et al., 2017; Makni et al., 2017). Quantitatively analyzing energy flows produced by social economic activities will help us to understand and best utilize the flow and flux of energy.

In 1997, the value stream concept was proposed by James Martin, an American management scientist, who believed that value streams exist in a group from the beginning to the end of continuous activities, and that customers were satisfied by consuming all kinds of resources as cost flows (James, 1997). Womack et al. (1997) and other scholars proposed that resources, time and costs could be saved by using value stream analysis to analyze production and maximize product values (Lalami et al., 2017). Xiao and Liu (2004) and others scholars wrote that "flow" can be used to reveal the direction, speed and strength of the interactions among different elements, and that the concept of "flow" could be used to measure the value of diverse elements dynamically. The practical application of value stream analysis requires the collection of information and the analysis of data. By managing value stream analysis, enterprises can gain a competitive advantage (Zhang and He, 2002).

Existing research has focused mostly on material flow and value stream analysis, without stripping out source analysis. This paper focuses on the costs of the carbon flow of coal-fired power enterprises, for which energy is the main input material. We argue that an energy flow and value stream analysis method is more targeted than a material flow and value stream analysis.

The relationship between energy utilization and carbon flow cost

Carbon element flows are the carrier of fossil energy. The energy input mainly consists of the combustion of coal in coal-fired power enterprises, and energy is released by the oxidation of carbon. Along the flow path of this fossil energy, carbon is transformed during the different production processes and eventually is fixed into products or becomes CO_2 emissions that are released into the external environment. Scholars such as Yin et al. (2013) wrote about a "low-carbon revolution" that would focus on energy saving and emission reduction; use less coal, oil and other carbon-containing energy sources; and ultimately reduce the negative effects on the external environment. Following the internal transport path of carbon energy and calculating the value stream may help enterprises understand the value of energy flows in their production processes and allow them to control the cost of their carbon flows. There are six strands energy flow that influence the unit process of carbon flows in coal-fired power enterprises, as shown in the following *Figure 1:*

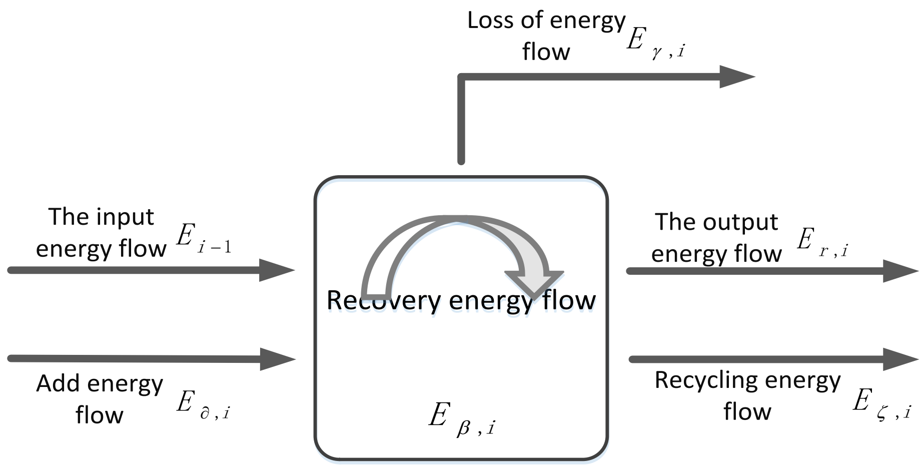

Figure 1. *Coal-fired power generation enterprise unit process flow diagram*

As *Figure 1* shows, the energy flow suggests that the process of the i-1 is the i process of energy flow, and it represents the flow of external added energy, including fuel, electricity, steam and other means. *Figure 1* also suggests that the output of energy is an energy flow loss. It shows that the recovery of energy refers to the process of recycling during the production of energy flow.

Concept and classification of carbon flow cost

Scholars of ecology, energy science and engineering have written that carbon flow draws on the resource flow cost and the concept of energy and value flow; however, they have not focused on carbon flows. Qi et al. (2010) proposed studying carbon flows from a homogeneous carbon source to carbon sequestration. In a coal-fired power generation enterprise, carbon energy is also produced in the process of the treatment.

Carbon flow cost may be evaluated by examining environmental and carbon costs. Gray and Bebbington (1993) used the concept of life cycle to argue that carbon costs include all costs associated with carbon emissions that may occur in the production process. Wang et al. (2011) wrote that carbon costs may be divided into ex ante costs,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48694882

testing costs and loss costs. Considering the production cost, the cost of detection and prevention before and after the production of carbon flows, and the cost of these carbon flows, cost may be divided into four categories: the cost of carbon flow prevention, inspection costs, and the carbon emissions themselves (including carbon trading and carbon tax).

Model design

Content of carbon flow cost control

Carbon cost flow control is also dependent on the concepts of carbon costs and environmental cost control. USEPA introduced relevant environmental cost control tools and pointed out that government and enterprises should jointly bear the responsibility for controlling environmental costs. Gray and Bebbington (1993) wrote that comprehensive control should be based on the life cycle of carbon costs. Wang et al. (2011) proposed using the PDCA (plan, do, check, and action) method to control the environmental costs of enterprises. Zhou et al. (2016) believe in controlling the cost of carbon emissions and carbon emission reductions. He and Li (2015) proposed focusing on logistics to optimize energy flows and help companies control the cost of carbon energy.

The existing research on the cost control of carbon flows generally does not focus on the idea of “low carbon”, and little research has been done on the development of China’s carbon market and the specific characteristics of Chinese enterprises. This paper focuses on the quality cost control model and the characteristics of the carbon flow costs of coal-fired power generation enterprises to establish a carbon flow cost control model.

Classification of carbon flow cost control factors

In the middle of twentieth century, American quality management experts Feigenbaum (1961) and Juran (1988) put forward the concept of “total quality management” for the purpose of achieving high quality products with few defects. In this paper, we regard damage to the internal and external environment as a quality defect. Combined with considering the characteristics of carbon flow costs incurred by coal-fired power generation enterprises, this paper divides the carbon flow cost control model into two categories: low carbon control costs and internal and external costs, specific classification as shown in *Table 1*.

Low carbon control costs

Low carbon control costs are mainly divided into two categories: prevention costs and testing costs. The prevention cost is what the enterprise must spend in order to improve energy efficiency, reduce carbon waste emissions, and achieve a “low carbon” design. In a certain range, the cost of prevention is inversely proportional to the cost of the carbon. Detection of cost measures the cost of carbon flows, including training costs and labor costs; these element of the cost remains relatively stable.

Internal and external damage costs

This section contains two factors: the internal loss cost of carbon flow and the external environmental damage cost. The carbon flow internal loss costs include loss cost, processing cost, resource utilization cost and profit loss. Negative cost relative to the cost

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48694882

of products includes the output of the products. Processing cost refers to the use of carbon emission reduction devices and the cost of processing. Resource utilization cost and income includes enterprise measures and carbon recycling resources. Carbon flow external environmental damage cost includes 5 elements: (1) carbon waste emissions cost; (2) carbon trading costs and benefits (enterprises must buy emissions quotas issued by the government according to their actual carbon emissions); (3) costs or gains from the sale of surplus quota; (4) carbon taxes, and (5) fines.

If the penalties (costs incurred) for not controlling carbon emissions are increased, then pollution will be reduced, and the cost of internal and external loss will be reduced. However, the cost of internal and external losses will increase. In order to better express the relationship between the two, this paper introduces the quality cost control model.

Table 1. *Classification of carbon cost control model factors in coal-fired power generation enterprises*

Carbon flow cost control model factor classification		
Low carbon control cost	Preventive cost	Design labor cost Equipment purchase Surrounding greening Equipment update and maintenance
	Detection cost	Testing training fee Detection of labor costs
Internal and external damage cost	Internal loss cost of carbon	Lost cost Treatment cost Resource utilization cost and benefit
	Carbon and sulfur external environment loss cost	Carbon waste disposal costs CO_2 Emission cost Carbon trading costs and benefits Carbon tax Fine

Construction of carbon flow models of cost control

Conventional quality cost control models

Mathematical models express the quantitative relationship between quality cost based: C: Quality costs, C_1: Cost identification of prevention, C_2: Quality loss cost, q: average rate of products $(0 \leq q \leq 1)$, F: Unit cost of nonconforming, d: Unqualified product rate $[d = 1 - q(0 < d < 1, 0 < q < 1)]$, x: and thus Output.

From *Equation 1, Equation 2* is obtained.

$$Fdx = C_2qx \quad \text{(Eq.1)}$$

$$C_2 = \frac{Fd}{q} = \frac{F(1-q)}{q} \quad \text{(Eq.2)}$$

Set: K for C_1 with $\frac{d}{p}$ scale factor, then *Equations 3-4* are obtained.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48694882

$$C_1 = \frac{Kq}{d} = \frac{Kq}{1-q} \tag{Eq.3}$$

$$C = C_1 + C_2 = \frac{Kq}{1-q} + \frac{F(1-q)}{q} \tag{Eq.4}$$

C is minimized, that is $C_1 = C_2$, when *Equations 5-6* are obtained.

$$q = \frac{1}{\sqrt{\frac{K}{F}}+1} \tag{Eq.5}$$

$$C = C_1 + C_2 = 2\sqrt{KF} \tag{Eq.6}$$

Early quality cost control models for quality and cost control and management thinking. However, in practice there are quality limitations and problems such as lack of theoretical calculations, such that the intersection curves represent only the low total cost and are contrary to the actual situation. Based on Japan’s successful zero defects theory, there has been improvement in quality cost control models.

Improving cost control model of carbon flow

Japan scholar Dr’s study points out that: “the concept of quality usually refers to the same utility function under products to users with less failure, low energy consumption, long life, high efficiency characteristics, comprehensive loss.” Thus, a product can be drawn to society brought about by the total loss of a function expression, provided with $T_{(q)}$ said. $T_{(q)} = C_{(q)} + L_{(q)}$, Which $C_{(q)}$ the cost function for the enterprise, $L_{(q)}$loss function, $q$the quality characteristics of the product vector. When quality level $q = 1 - d$ ($d$is the carbon losses and the pollution of the environment), then the carbon emissions control level is equal to the success rate of carbon emissions. Taking into account the recent coal-fired power plant investment and production decisions made for long-term economic benefit, we can establish the following mathematical model (*Eq. 7)*.

$$T_{(q)} = C_{(q)} + L_{(q)} \tag{Eq.7}$$

$T_{(q)}$ represents the total cost of the carbon flow and for low carbon costs under control, $L(q)$ is the internal and external damage costs.

Low-carbon model

We used the Cobb Douglas function to represent the relationship between preventive costs C_1 and testing costs C_2 (*Eq. 8*).

$$q = AC_1^{\alpha} C_2^{\beta} \tag{Eq.8}$$

Constraint conditions (*Eq. 9*):

$$C_1 + C_2 = C_{(q)} \tag{Eq.9}$$

Using the Lagrange multipliers method provides *Equation 10*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48694882

$$\varphi(C_1, C_2, q) = AC_1^{\alpha} C_2^{\beta} - \lambda[C_{(q)} - (C_1 + C_2)] \quad \text{(Eq.10)}$$

where λ is the Lagrange multiplier and *Equation 11* can be obtained.

$$C_{(q)} = q^{\frac{1}{\alpha+\beta}} / [A(\frac{\alpha}{\alpha+\beta})^{\alpha}(\frac{\beta}{\alpha+\beta})^{\beta}]^{\frac{1}{\alpha+\beta}} \quad \text{(Eq.11)}$$

Let $a_1 = [A(\frac{\alpha}{\alpha+\beta})^{\alpha}(\frac{\beta}{\alpha+\beta})^{\beta}]^{\frac{-1}{\alpha+\beta}}$, $b_1 = \frac{1}{\alpha+\beta}$, *Equation 12* can be obtained.

$$C_{(q)} = a_1 q^{b1} \quad \text{(Eq.12)}$$

Internal and external damage cost model

Businesses must pay for ecological damages caused by the pollution they emit. When the deviation $|q - 1| = 0$ shi, then internal and external losses are at a minimum, and constant $L(1) = a_2$ and $a_2 \neq 0$. In$q = 1$, we have the Cheng Tailei series, *Equation 13* can be obtained.

$$L_{(q)} = L(1) + \frac{L'(1)}{1!}(q-1) + \frac{L''(1)}{2!}(q-1)^2 + \frac{L'''(1)}{3!}(q-1)^3 + \ldots \quad \text{(Eq.13)}$$

$L_{(q)}$ in $q = 1$ obtains the extreme-one derivative $L'(1) = 0$. In addition, taking into account the deviation $|q - 1|$ value minimum, and the Taylor expansions, we find that the fourth and following are much smaller than the third, and the internal and external damage cost functions $L_{(q)}$ yield the approximate expression (*Eq. 14*):

$$L_{(q)} = L(1) + \frac{L''(1)}{2!}(q-1)^2 \quad \text{(Eq.14)}$$

Order $a_2 = L(1)$, $b_2 = \frac{L''(1)}{2!}$, *Equation 15* can be obtained:

$$L_{(q)} = a_2 + b_2(q-1)^2 \quad \text{(Eq.15)}$$

Total cost of carbon control model

As mentioned above, the total cost of carbon $T_{(q)}$ comprises low carbon, control costs and external costs, and thus *Equation 16* can be obtained from *Equations 12* and *15:*

$$T_{(q)} = C_{(q)} + L_{(q)} = a_1 q^{b1} + a_2 + b_2(q-1)^2 \quad \text{(Eq.16)}$$

where $a_1 = [A(\frac{\alpha}{\alpha+\beta})^{\alpha}(\frac{\beta}{\alpha+\beta})^{\beta}]^{\frac{-1}{\alpha+\beta}}$, $b_1 = \frac{1}{\alpha+\beta}$, $a_2 = L(1)$, $b_2 = \frac{L''(1)}{2!}$.

Equation 16 shows the total cost of carbon $T_{(q)}$. Numerically, it is low carbon cost $C_{(q)}$ with internal and external damage costs $L_{(q)}$ overlaid. $C_{(q)}$ has a relationship with q in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48694882

the form of indices, Therefore, the logarithmic processing on both sides of *Equation 17* is obtained.

$$log(C_{(q)}) = log^{a_1} + b_1 \, log^q \quad \text{(Eq.17)}$$

$log(C_{(q)})$ with log^q constitutes a slope b_1. The intercept of log^{a_1} A is a linear relationship, yielding a different$q$. $C_{(q)}$ values can be obtained by linear regression a_1 and b_1. The values obtained $C_{(q)}$ with q have a relationship.

On the other hand, $L_{(q)}$with$q$provides a functional quadratic expression, but when $(1-q)^2 = q_1$ are the variables, we get *Equation 18*.

$$L_{(q_1)} = a_2 + b_2 q_1 \quad \text{(Eq.18)}$$

As can be seen in the $L_{(q_1)}$ with log^q formation of slope b_2, the intercept a_2 is a linear relationship, and the different values for q, $L_{(q)}$, a_2 and b_2 can be obtained by linear regression.

For the $C_{(q)}$, $L_{(q)}$ and $L_{(q_1)}$ expressions, we can discuss q and the $T_{(q)}$ impact of its extremes.

Application of carbon flow models of cost control

Data collection and processing

This paper takes a large coal-fired power plant as its study object; such plants use inputs like water, coal, oil, natural gas and other types of raw energy, convert them into electric secondary energy forms, which become inputs in the power grid and provide energy to users. A typical energy conversion of a coal-fired power plant consumes many resources. Power plants convert the chemical energy of fuels (mainly coal into electrical energy via the transformation process shown in *Figure 2*. *Table 2* provides carbon cost data for a coal-fired power plant during the period from 2010 to 2015. *Table 3* shows more data for the same time period.

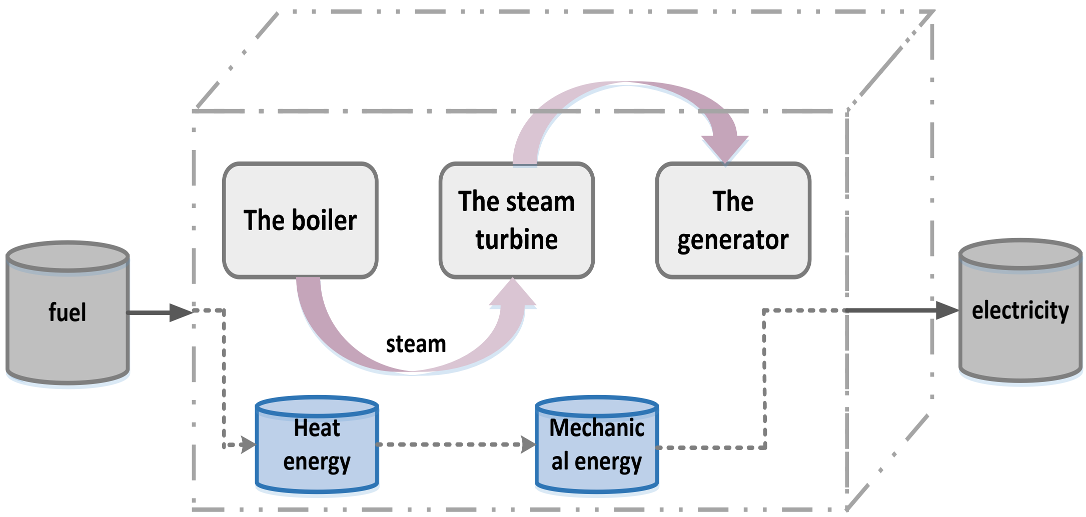

Figure 2. *Energy transformation diagram of a coal-fired power plant*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48694882

Table 2. *Carbon costs of a coal-fired power plant from 2010~2015*

Cost of carbon flow classification	Cost items	2010	2011	2012	2013	2014	2015
Low carbon cost	The cost of prevention	94.40	109.50	129.20	140.50	186.51	259.40
	Testing costs	19.07	27.20	40.30	63.80	72.70	88.90
	Subtotal (C)	113.47	136.70	169.50	204.30	259.21	348.30
Internal and external damage costs	Carbon flow loss cost	629.80	553.01	420.76	358.90	320.80	301.60
	Carbon external environmental damage costs	361.69	326.04	252.04	179.24	125.12	102.09
	Subtotal (L)	991.49	879.05	672.80	538.14	445.92	403.69
Total (T)		1,104.96	1,015.75	842.30	742.44	705.13	751.99
Comprehensive compliance rate (%)		87.27	88.98	90.72	92.14	93.71	95.46

Table 3. *Statistics for a coal-fired power plant for the period 2010~2015*

Vintage	2010	2011	2012	2013	2014	2015	Energy-saving Total (tce)
Electricity generation (million kWh)	5,401.48	6,505.38	6,000.00	6,000.00	6,000.00	6,000.00	437.57
Power supply coal consumption (g/kWh)	310.32	309.47	307.94	305.70	303.90	302.13	
Standard coal (tce)	41.27	62.10	91.80	134.40	108.00	106.20	

From *Tables 2* and *3*, one may see the relationship among energy-saving, internal and external damage costs and the costs of low carbon control (see *Fig. 3*). The increase in energy-saving, source reduction, and low carbon control cost allows for a reduction in carbon-containing waste material and in internal and external damage costs.

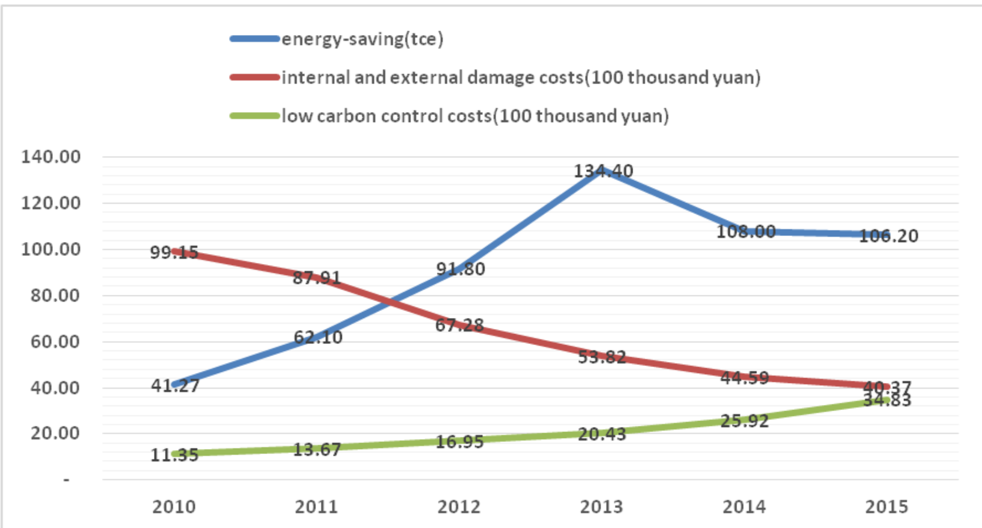

Figure 3. *The relationship among energy-saving, internal and external damage costs and low carbon control costs*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48694882

Results and discussion

Based on the expression of functions $C_{(q)}$ and $L_{(q)}$ in combination with the data in *Table 2*, we used MATLAB software and an analysis of statistical regression models to calculate the variable parameters of our model. The results of the main performance parameters of the model are shown in *Table 4*. As calculated by *Equations 19* and *20,* the original scattered data points and the fitting result curves are shown in *Figure 4*. From *Table 1*, we can see the equivalent substitutions for $C_{(q)}$ and $L_{(q)}$ and the significant linear relationship q. The R^2values were 0.986 and 0.978, and the significance levels F were 422.26 and 261.932. The F values show that the statistical equations and the calculated P order of magnitude 10^{-6} were far less than the criterion value of 0.05. This proves that this paper constructed a regression model with high reliability.

Table 4. *Calculation results of* $C_{(q)}, L_{(q)}$ *and* $T_{(q)}$

	R^2	F	P	MSE
C(q)	0.986	422.26	8.6e-7	17.7885
L(q)	0.978	261.932	3.53e-6	29.1789
T(q)	--	--	--	46.5544

$$C_{(q)} = 669.73q^{13.74} \quad \text{(Eq.19)}$$

$$L_{(q)} = 337.5 + 40460(1\text{-q})^2 \quad \text{(Eq.20)}$$

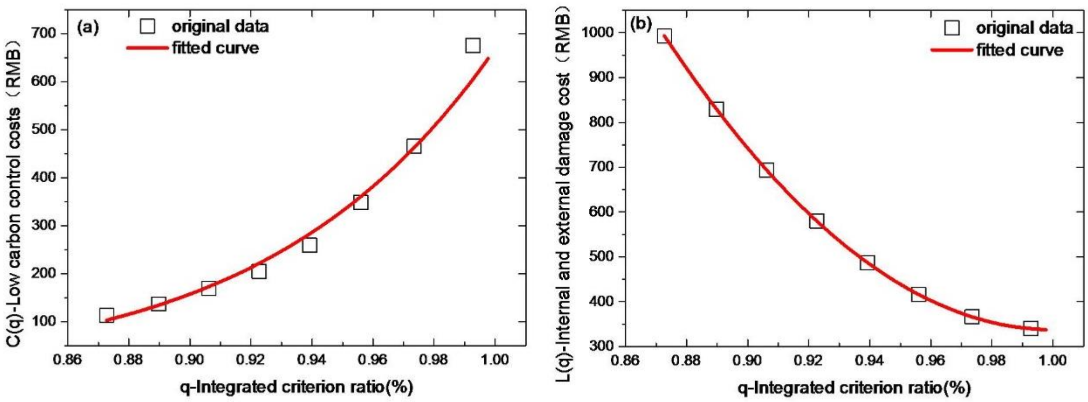

Figure 4. *Comparison of scatter plots and fitting curves*

As can be seen from *Figure 4*, *Equations 19* and *20* fit the regression of low carbon cost control, and of the internal and external damage costs, with the original plot value and the change trend of q. When the variable q is gradually increased, the corresponding function $C_{(q)}$ (low carbon control costs) gradually increased, and $L_{(q)}$ (the value of internal and external damage costs) gradually decreased.

According to the relationship between $C_{(q)}$ and $L_{(q)}$, the total carbon flow cost control function is obtained (*Eq. 21*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48694882

$$T_{(q)}=C_{(q)}+L_{(q)}=669.73q^{13.74}+337.5+40460(1-q)^2 \qquad \text{(Eq.21)}$$

We then combine *Equations 19* and *20* to draw $C_{(q)}$, $L_{(q)}$, $T_{(q)}$ and q with the change of the curve, as shown in *Figure 5*.

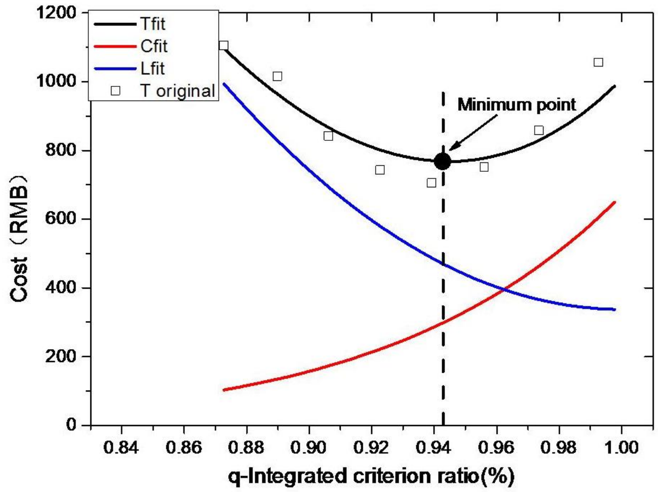

Figure 5. *Comparison of scatter plots and fitting curves*

Figure 5 shows that q has different effects on $C_{(q)}$ and $L_{(q)}$ trends, and $T_{(q)}$ decreases gradually with the increase of q, and after reaching its lowest point, it then increases gradually again. The minimum value as the black circle in the x = 0.942 graph represents the position and the corresponding gross $T_{(q)}$ is 768.0516.

Table 2 shows that in 2010, coal-fired power plants implemented certain low carbon control cost measures, and while the effect on the cost of carbon flow control was not obvious, the potential for a reduction in emissions is enormous. Beginning in 2011, power plant shave been gradually screened for small energy sources. Significant increases have been made in the research and development of low carbon technology, and energy utilization rates have improved. In 2014, the total carbon flow cost reduction was 3,998,300 yuan, compared with a 2010 decrease of about 36.18%. Low carbon control costs doubled, compared to the cost of internal and external damage, which decreased to 44.97% in 2010. In particular, the reduction of coal consumption reduced the cost of carbon flow. Improved technology, low carbon control costs, and energy conservation clearly help to reduce the total carbon flow cost. When the pollution control level is more than 94.2%, the rate of the enterprise’s low carbon cost increases more than the rate of internal and external damage costs declines, which leads to an increase in the total carbon flow cost. Therefore, in the long run, low carbon cost control is not possible for coal-fired power generation enterprises. Enterprises should avoid excessive investment in low carbon balance, and in the control of costs, because these measures result in unnecessary waste. *Figure 5* shows that the carbon flow cost curve improves, according to the specific situation of enterprises, depending on the low carbon control and damage cost functions. The lowest total cost of carbon flow is calculated on this basis, and likely the two intersection functions may also be offset, if we used an improved model data to compensate for the lack of the original model.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48694882

Conclusion

Against the background of climate warming, the analysis and control of carbon flow cost is an important condition to understand in order for industrial enterprises to realize sustainable development. In this paper, based on the concept of “energy flow and value flow,” and using an improved model of carbon flow cost control, the following conclusions and implications are obtained:

Coal-fired power generation enterprises should take the initiative to control the cost of carbon flow, at a reasonable increase in the cost of low carbon control inputs. Low carbon control costs should reduce the cost of carbon flow, which is an important guarantee for an enterprise. However, because low carbon cost control is not possible, enterprises should aim to achieve the optimal emissions compliance rate to control their carbon flow cost, as well as to avoid losing control because of a lack of investment, and to avoid wasting resources by focusing too much on low carbon investment control.

Further increasing R&D investment and power will maximize the utilization rate of energy and reduce the coal consumption. Based on the “energy flow, value flow” concept, enterprises should pay attention to the optimization and control of carbon flow cost from the source. First, they should choose low pollution sources of energy and materials and reduce their unit energy flow. Second, they should increase low carbon technology development and invest more in carbon flow loss processing equipment to ensure the transition to becoming green, low carbon enterprises.

Coal-fired power generation enterprises should combine their own characteristics to improve the cost control system of their carbon flow. The key to improving carbon flow cost curves is determined according to the actual situation of the enterprises, as well as to their low carbon control and damage cost functions. Given this, in this paper, we used statistical analysis software to find a comprehensive compliance rate for the control of carbon flow in a coal-fired power enterprise; this rate is of practical significance for the enterprise’s cost control.

The accounting of carbon flow costs in coal-fired power generation enterprises is relatively wide-ranging. To accurately calculate and achieve carbon flow cost control, a lot of in-depth and meticulous research is needed. Future research can consider the following aspects. (1) It is relatively easy to quantify the cost of low carbon control and the internal loss of carbon flow. However, the technology that can be used to determine the external loss cost according to the degree and type of energy damage needs to be further improved. In addition, accurate accounting of carbon emissions remains a challenge. These will affect the collection of cost data, which in turn affects the model analysis. (2) We may have different classifications for various cost items of coal-fired power generation enterprises. After accurate accounting of carbon flow costs, it is necessary to further study the classification according to what standards. (3) When testing the model, the target company needs a large amount of carbon flow cost data for many years. The lack of data will affect the model rationality test. In the future, more data can be collected to test the model.

Abstract. Dehydration causes loss of wheat (*Triticum aestivum* L.) yield. Inoculation of wheat with *Azospirillum brasilense* improves its tolerance to drought. Although up-regulation of *DREB2* gene has increased drought tolerance of wheat, less information exists about *DREB2* expression under inoculation with *A. brasilense*. In this study, the physiological responses of different pairs of six wheat cultivars with *A. brasilense* Sp7 and Sp245 strains were evaluated to drought and the tolerant (Roshan-Sp245), sensitive (Shahpasand-Sp7), moderately tolerant (Roshan-Sp7) and moderately sensitive pairs (Shahpasand-Sp245) were selected. Afterward, in the second experiment, *DREB2* expression of the selected pairs was evaluated under inoculation and/or dehydration (ψ_w = -90 MPa) at 0, 120 and 360 minutes. At 120 min, *DREB2* expression was more in the tolerant and moderately tolerant pairs than others and also higher in inoculated and/or dehydration conditions. Root's *DREB2* was up-regulated almost 700-fold in the tolerant and moderately tolerant pairs under dehydration. In contrast, in the sensitive cv., *DREB2* expression did not change due to dehydration or inoculation. This could be the effect of compatibility or homology of *A. brasilense* strains and wheat cultivars which affected *DREB2* expression. Therefore, *DREB2* expression had a significant effect on increased drought tolerance in tolerant and moderately tolerant pairs.

Introduction

Drought is one of the major or more significant stresses which adversely affect the plant water status and crop yield (Kramer and Boyer, 1995; Bray, 2000). Dehydration or loss of water causes reduction of cell turgor pressure, an increase in negative water potential and consequently less plant production (Liu et al., 2005). *Azospirillum brasilense* is one of the PGPRs (Plant Growth Promoting Rhizobacteria) that can associate with wheat and increase crop quality and quantity through suitable physiological and biochemical modification in plants (Dobbelaere et al., 2003; El-Samad and Hetta, 2005; Pereyra et al., 2006; Hungria et al., 2010; Veresoglou and Menexes, 2010). The effect of PGPRs on dehydration responsive genes in plants has been evaluated but not well studied specifically about the *DREB2* gene expression during inoculation of wheat with *A. brasilense*. Therefore, the objective of this study is to evaluate the effect of *A. brasilense* on *DREB2* gene expression in wheat cultivars under dehydration condition.

Review of Literature

The ability of *Azospirillum* to establish an association system with plants such as wheat through which it promotes better growth and development (Dobereiner and Day, 1976; Bashan and Holguin, 1997) is due to its capacity for N_2 fixation capacity (Bermner et al., 1995) and production of some bacterial compounds having plant phytohormone properties such as nitric oxide, IAA (indole-3-acetic acid) polyamines and amino acids (Hartmann et al., 1994; El-Khawas and Adachi, 1999; Pakdaman et al., 2014). These bacterial compounds produced in wheat rhizosphere caused structural changes in wheat roots, stimulated root growth and increased water and minerals absorption by the plant (Perrig et al., 2007; Amooaghaie et al., 2004; Casimiro et al., 2003; Correa-Aragunde et al., 2004). These advantages for plants are also reported at dehydration condition for different pairs of plant and bacteria especially at the early stage of growth (Bashan and Holguin, 1997; Hartmann and Baldani, 2006; Yang et al., 2009). For instance, promotion of dehydration tolerance is reported in different associated pairs obtained from some *A. brasilense* strains and wheat (*Triticum aestivum* L.) cultivars (Díaz-Zorita and Fernández-Canigia, 2009).

PGPRs can affect the expression of stress-responsive genes and thus modulate plant responses to stress (Jakab et al., 2005; Gachomo et al., 2014; Barnawal et al., 2017). For example, up-regulation of *RD29A* gene in *Arabidopsis* plants inoculated with a PGPR strain (*Bradyrhizobium japonicum* IRAT FA3) was observed when compared to non-inoculated plants (Jakab et al., 2005; Gachomo et al., 2014). *DRE/CRT* (Dehydration responsive element/C-repeat), a cis-acting element in the promoter region of *RD29A* (Yamaguchi-Shinozaki and Shinozaki, 2005; Jia et al., 2012; Gachomo et al., 2014) interacts with a series of transcription factors known as DREBs proteins (DREB/CBF; DRE-binding factor/C-repeat binding factor) inducing a set of downstream dehydration responsive genes that improve dehydration tolerance of plants (Baker et al., 1994; Sakuma et al., 2002; Yamaguchi-Shinozaki and Shinozaki, 2005). *DREBs* genes family which encode DREBs proteins has a main role in the gene expression and regulation of plant’s response to dehydration stress (Sakuma et al., 2002; Yamaguchi-Shinozaki and Shinozaki, 2005; Agarwal et al., 2006, 2010). A rapid and transient increase in *DREB2* expression causes an increase in the regulatory and/or functional proteins which shows the upstream role of *DREB2* in a signaling pathway and improves plant tolerance to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48834902

short-time dehydration. Recently, the effect of some PGPRs such as *Arthrobacter protophormiae* (SA3), *Dietzia natronolimnaea* (STR1) and *Bacillus subtilis* (LDR2) on *TaCTR1/TaDREB2* expression (Barnawal et al., 2017) and improvement of wheat tolerance to abiotic stress has been reported but, the effect of *A. brasilense* on *DREB2* expression is not well studied in inoculated wheat (*T. aestivum* L.) cultivars under dehydration condition.

Materials and methods

Primary experiment

A primary experiment (unpublished data) was conducted to choose the most tolerant and sensitive cultivars to drought as well as drought tolerant and sensitive associated pairs among the combination of six wheat cultivars of common wheat (*T. aestivum* L.) named Roshan, Sardari, Tabasi, Shahpasand, Omid and Shoaleh inoculated with two strains of *A. brasilense* called Sp7 (as standard strain) and Sp245 (reported to produce significant ABA). The seeds were prepared from Agriculture and Natural Resources Research Center, Isfahan, Iran. The strains of *A. brasilense* strains were obtained from Research Association of AMP Research Unit Microbe-Plant Interactions, Germany.

The growth and biochemical parameters of six wheat cultivars as well as their combinations with two strains of *A. brasilense* (Sp7 and Sp245) including roots and shoots dry weight (RDW, SDW), average roots length (ARL), number of main roots (NMR) and the number of root branches (NRB), maximum shoot length (MSL) as well as total protein of roots and shoots (RTP, STP), PAL enzyme activity in roots and shoots (RPAL, SPAL) and activity of TAL enzyme in roots and shoots (RTAL, STAL) were measured. Adopted method of Bradford (1976) was used for protein assay and the method of Beaudoin-Egan and Thorpe (1985) was used for TAL and PAL enzymes activity analysis. The experiment was conducted under drought condition (40% of field capacity) and compared to 80% moisture content (data were not shown). Then, the data was ranked for the best and the worst responses to drought (*Appendix 1*). Afterward, according to the measured parameters, the two cultivars of Roshan and Shahpasand were selected as drought tolerant and sensitive cultivars, respectively. Simultaneously, the associated pairs of cultivar-strain including Roshan-Sp245, Roshan-Sp7, Shahpasand-Sp7 and, Shahpasand-Sp245 were selected as tolerant, moderately tolerant, sensitive and moderately sensitive to drought within all possible combinations of wheat cultivars and *A. brasilense* strains (*Appendix 1*). Then, in the second experiment, the selected cultivars and associated pairs were evaluated for *DREB2* gene expression under optimum (ψ_w = 0 MPa) and dehydration (ψ_w = -90 MPa) conditions.

Second experiment

A. brasilense strains were cultured on solid NFB (Nitrogen free basal) medium and incubated at 32°C. Then the bacteria were cultured in liquid NFB medium enriched with ammonium chloride (0.1% w/v, 1 g L^{-1}) and incubated at 30°C for 48 h. Bacterial concentration of 10^8 CFU mL^{-1} was adjusted by reading optical density at 600 nm using McFarland table (Krieg and Dobereiner, 1984; McFarland, 1907).

Seeds were sterilized using the method adopted by Sweet and Bolton (1979). Then the sterilized seeds were incubated in sterile distilled water at room temperature for 3 h. Wheat seeds were shaken in high phosphate Nfb (HPNfb) liquid medium enriched with

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48834902

0.1% ammonium chloride contain 10^8 CFU mL^{-1} of *A. brasilense* stain and shake in 100 rpm for 3 h (Shaker Model INFORS AG, BOTTMINGEN) (Okon et al., 1977). Under sterile laminar airflow, the seeds were left to reduce the seeds moisture down to almost 14%.

Sterilized wheat seeds (Shahpasand as sensitive and Roshan as tolerant cultivar) were planted on sterile water agar (8% w/v) and kept in dark at room temperature for 48 h for germination. The uniform small seedlings were transferred into test tube (3 × 25 cm) containing 40 ml of autoclaved MS medium (30 g sucrose, 7 g agar, pH ~ 6.5) (Murashige and Skoog, 1962) and then located in growth chamber at 22 ±2°C, 60% RH, and photoperiod of 16 L/8 D (210 photons m^{-2} s^{-1}) for 3 more days. Half of the seedlings (5-day-old) were inoculated with specific *A. brasilense* strains.

To inoculate seedling, Nfb liquid medium enriched with 0.1% ammonium chloride containing 10^7 CFU ml^{-1} concentration of *A. brasilense* Sp245 and Sp7 was prepared. Then under sterile laminar airflow, 1 mL of Nfb liquid medium containing Sp245 or Sp7 was added separately into each test tube, containing three 5-day-old seedlings and kept for 2 more days. After 2 days, seedling's roots were checked for the number of bacteria. To do so, the samples of seedling's roots were stained with Iodonitrotetrazolium chloride (INT) dye (0.25% w/v aqueous solution) and then many cross-sections of root were provided manually (Sriskandarajah et al., 1993). Afterward, the presence of the bacteria within root cross-sections was checked using a light microscope. Meanwhile, the number of bacteria colonies (CFU mL^{-1}) within the roots was counted. To do so, the root samples were placed in 95% (v/v) ethanol for 3 sec, then in 0.01% (w/v) $HgCl_2$ for 15 sec and washed several times with sterile water for surface-sterilization (Sriskandarajah et al., 1993). Then, 1 g of root samples were grounded using 5 mL of 1X phosphate buffered saline (PBS) (pH ~ 7.4) at the sterile condition and serially diluted (10^{-1} up to 10^{-9}) (Stets et al., 2015). 5 μl of the final dilution (10^{-9}) were cultured on solid medium (8% w/v agar) of HPNfb enriched with ammonium chloride (0.1% w/w) and incubated at 32°C for 72 h. At last, the number of colonies formed on the plates was counted and considered as bacterial population in 1 g of tissue fresh weight. The number of bacteria in root was almost 10^8 CFU mL^{-1} for Sp245 and 10^7 CFU mL^{-1} for Sp7.

One series of 7-day-old seedlings (including non-inoculated and inoculated with *A. brasilense* strains) were transferred into sterile test tubes (3 × 25 cm) which had been saturated with water vapors (RH ≈ 100%) at 25°C (Thomson, 1872). According to Kelvin equation and after equilibrium of water vapor pressure, this was equal to maximum water potential (ψ_w = 0 MPa) and was considered as optimum water condition (Butt et al., 2006). The second series of 7-day-old seedlings were transferred into sterile test tubes with RH equal to 50% (ψ_w = -90 MPa) at 25°C as dehydration treatment. After implementation and equilibrium of treatments, plant samples were collected at 0, 120 and 360 minutes. Samples were separated immediately into shoot and root and frozen in liquid nitrogen to store at -80°C for RNA isolation.

Total RNA extraction and quantitative Real-Time PCR (qRT-PCR) analysis

Total RNA of the shoot and root samples of wheat cultivars were extracted using Irizol kit (Irizol RNA Biotech, Iran) at 4°C. To remove the possible DNA contamination, the RNA samples was treated with RNase-free DNase I (TaKaRa, Japan).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48834902

About 1 µg of total RNA was used to synthesize first-strand cDNA primed with oligo (dT) in a 10 µl reaction mix using reverse transcriptase (TaKaRa, Japan) according to the instructions of the manufacturer. QRT-PCR was performed using SYBER-Green dye (TaKaRa, Japan) on real-time PCR machine (Bio-Rad, USA) in triplicate. The *ARF* (ADP-ribosylation factor) gene (AB050957) was used as the reference gene. The primers (*ARF*, F: 5′-CTGACGCCGAGGATATCCA-3′; R: 5′-GCCTTGACCATACCAGTTCCA-3′) used for Real-Time PCR analysis were designed using AlleleID, version 7. The amount of transcript accumulated for the *DREB2* as the target gene (AY781345) (*DREB2,* F: 5′-AAGAAAACAGGCGACAAGAT-3′; and R: 5′- GTTGTTGGTTCACTTCTTTC -3′) (Egawa et al., 2006) normalized to ARF gene as internal control. The value of *DREB2* transcript level was reported relative to the ARF gene ($-\Delta C_T$) which is the negative difference between the threshold cycle (C_T) of the target gene and C_T of the reference gene. Then, the relative expression of *DREB2* in treated conditions (inoculated and/or dehydrated) was calculated using the $2^{-\Delta\Delta C_T}$ method relative to control condition (non-inoculation and optimum water condition) (Livak and Schmittgen, 2001). The real-time reaction efficiencies of the target and reference genes (E = 0.93 and 0.96, respectively) were assumed to be equal, nearly 1. The PCR cycling conditions including an optimum concentration of primers and cDNA as well as optimum temperature for *ARF* and *DREB2* genes were set up. So, real-time PCR program was: incubation at 95°C for 10 min, 95°C for 10 s, 58°C for 25 s for 40 cycles, 72°C for 30 s and 72°C for 7 min.

Statistical analysis

The primary experiment was conducted in a split plot layout with 3 replicates. The main plot was wheat cultivars, sub-plot was bacterial strains and sub-sub-plot was water condition. The second experiment also carried out as split-plot with 3 replicates. The main plot was sensitivity to drought, inoculation as sub-plot and water condition as sub-sub-plot.

The ANOVA were obtained using SPSS and the mean values were compared using Duncan῾s multiple range tests at 95% confidence interval.

Results

According to the primary experiment, the associated pairs (wheat cultivars-*A. brasilense* strains) including tolerant (Roshan-Sp245), moderately tolerant (Roshan-Sp7), sensitive (Shahpasand-Sp7) and moderately sensitive (Shahpasand-Sp245) to drought were selected (*Appendix 1*). Physiological responses in drought condition are presented in *Tables 1 and 2*.

Physiological responses of sensitive and tolerant associated pairs to drought

Cross-inoculation of Roshan and Shahpasand cultivars with Sp245 or Sp7 strains formed different associated pairs with different physiological responses in optimum water condition ($P \leq 0.05$) (*Tables 1-4*). In optimum water condition, most physiological parameters increased (except for NMR and SPAL) ($P \leq 0.05$) when inoculated tolerant cultivar (Roshan- Sp245) compared to non-inoculated one (Roshan). However, in Roshan-Sp7, ARL, RDW and, RTP were the only parameters positively affected by inoculation in optimum water condition (*Tables 3 and 4*). Although,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48834902

inoculation of the sensitive cultivar (Shahpasand) with Sp7 did not significantly affect any of the physiological parameters at optimum water condition in Shahpasand-Sp245, NRB, SDW, RTP and, RPAL increased due to inoculation ($P \leq 0.05$) (*Tables 1-4*). It seems that Sp245 has more homology or compatibility potential to associate with different wheat cultivars than Sp7.

Table 1. *Average values of growth parameters including maximum shoot length (MSL), average root length (ARL), number of main roots (NMR), number of root branches (NRB) and shoot and root dry weight (SDW and RDW, respectively), in non-inoculated cultivars (Roshan and Shahpasand as tolerant and sensitive to drought, respectively) as well as different pairs of wheat cultivars and A. brasilense strains (Sp245 and Sp7) including Roshan-Sp245 (tolerant), Roshan-Sp7 (moderately tolerant), Shahpasand-Sp7 (sensitive), Shahpasand-Sp245 (moderately sensitive) under drought (40% FC) and optimum water conditions (80% FC). Data represent the mean values ± SE (n = 3). Different letters in the mean values indicated the difference between the mean values (Duncan's multiple range tests, P≤0.05). MSL and ARL are in cm plant^{-1}; SDW and RDW are in mg plant^{-1}. FC, stand for moisture content at field capacity*

*: Indication increased NRB from 0

The selected cultivars or associated pairs showed different physiological responses to drought ($P \leq 0.05$) *(Tables 1-4)*. At drought condition, MSL, ARL and, RDW in Roshan cv. (drought tolerant) did not decrease as compared to optimum water condition, but these parameters were decreased in Shahpasand cv. (*Tables 1 and 3*). In drought condition, RDW decreased in all pairs with the highest in Shahpasand-Sp7 and the lowest in Roshan-Sp245. SDW of Roshan cv. in non-inoculated and inoculated status did not change in drought condition but SDW of Shahpasand cv. and inoculated Shahpasand cv. with any of two strains were decreased. The drought condition had a negative effect on NMR of Shahpasand with Sp7. However, NRB increased in all cultivars and pairs except for Shahpasand-Sp245 under drought condition ($P \leq 0.05$) (*Tables 1-4*).

STAL and RTAL were increased in inoculated Roshan cv. with Sp245 or Sp7 but they decreased in Shahpasand cv. with both strains. In contrast, SPAL in Roshan cv. and Roshan inoculated with Sp245 or Sp7 were increased in drought condition but they did

not change in Shahpasand cv. or Shahpasand with Sp7 or Sp245. STP did not change due to drought in all cultivars and pairs except for Roshan-Sp245. Meanwhile, RTP did not change in Roshan-Sp245 and Shahpasand-Sp7 but it was increased in Roshan-Sp7 and decreased in Shahpasand-Sp245 under drought condition (*Tables 2 and 4*).

The dual effects of inoculation and drought were evaluated by comparing an inoculated cultivar which was grown under drought condition with the respective non-inoculated cultivar at optimum water condition (named control). When inoculated Roshan cv. with Sp245 or Sp7 under drought condition were compared with control, ARL, NRB, RTP, SPAL, RTAL and, STAL were higher in inoculated one. In contrast, RDW, SDW, ARL, MSL, RPAL, RTAL in Shahpasand cv. with Sp7 or Sp245 under drought condition were lower than control. Simultaneously, MSL, NMR and STP in inoculated Roshan cv. and RTP, STP and, SPAL of inoculated Shahpasand cv. did not show any changes. However, NRB increased in inoculated Shahpasand cv. as compared to control (*Tables 1-4*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48834902

In brief, the most beneficial changes in the physiological parameters were observed in the tolerant pair (Roshan-Sp245) followed by moderately tolerant (Roshan-Sp7), moderately sensitive (Shahpasand- Sp245) and sensitive pairs (Shahpasand-Sp7) at either drought or optimum water conditions (*Tables 1-4*).

DREB2 expression in selected pairs under different water potentials

At optimum water potential (ψ_w = 0 MPa), *DREB2* expression in the roots of inoculated seedlings (*Tables 5, 6*) was less relative to non-inoculated cultivars (ranged from 0.05 up to 0.57- fold for tolerant to sensitive pairs ($P \leq 0.05$)). However, their expressions were similar at 0, 120 and 360 min after dehydration imposed (*Table 5*). *DREB2* in the shoots of all selected pairs were up-regulated as compared to non-inoculated cultivars. *DREB2* up-regulation was more in the shoots of tolerant and moderately tolerant pairs than the sensitive and moderately sensitive pairs ($P \leq 0.05$) (*Table 6*). Therefore, at optimum water condition, *DREB2* down-regulated in the roots (*Table 5*) but up-regulated in the shoots of tolerant and sensitive pairs relative to non-inoculated cultivars.

Table 5. *DREB2 expression (fold) in different times (0, 120 and 360 min) after dehydration (ψw = -90 MPa) imposed in the roots of different associated pairs of wheat cultivars and A. brasilense strains (Sp245 and Sp7) as responded to drought including: tolerant (Roshan-Sp245), moderately tolerant (Roshan-Sp7), sensitive (Shahpasand-Sp7), moderately sensitive (Shahpasand-Sp245). The result was compared to optimum water condition (ψw = 0 MPa). Data represent the mean values ± SE (n = 3). Different letters in the mean values indicated the difference between the means (Duncan's multiple range tests, P ≤ 0.05)*

Dehydration had a significant effect on *DREB2* expression of roots and shoots in inoculated and non-inoculated cultivars ($P \leq 0.05$) (*Tables 5, 6*). The result showed that in the tolerant cultivar (Roshan cv.) at 120 min after dehydration, *DREB2* ($2^{-\Delta\Delta C_T}$) up-regulated 2.7 and 3.4- fold in the roots and shoots, respectively as compared to optimum

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48834902

water condition. In the sensitive cultivar (Shahpasand cv.), *DREB2* did not change in the roots or shoots due to dehydration ($P \leq 0.05$) (*Table 5*). At 360 min, *DREB2* expression acts vice versa under dehydration, means, down-regulated in the roots of Roshan (0.5-fold) and up-regulated (2.6- fold) in the shoots, but in Shahpasand, *DREB2* up-regulated in the roots (1.9- fold) and down-regulated in the shoots (0.6- fold).

The change in *DREB2* expression due to dehydration in non-inoculated cultivars, and selected association pairs (the inoculated cultivars) had different sensitivity to drought (*Table 5*). For example, at 120 min after dehydration, *DREB2* up-regulated in the roots of tolerant, moderately tolerant, sensitive and moderately sensitive pairs (778, 711, 21 and 19- fold, respectively) while, *DREB2* up-regulated (1-fold) in the shoots of tolerant and moderately tolerant pairs and down-regulated (almost 0.4- fold) in the sensitive and moderately sensitive pairs (*Tables 5, 6*). However, at 360 min, *DREB2* up-regulation in the roots of all pairs were so less (ranged from 3.4 to 5.5- fold). In contrast, *DREB2* down-regulated due to dehydration in the shoots of the tolerant, moderately tolerant (0.2- fold), sensitive and moderately sensitive pairs (0.4- fold) (*Tables 5, 6*).

Table 6. *DREB2 expression (fold) in different times (0, 120 and 360 min) after dehydration (ψ_w = -90 MPa) imposed in the shoots of different associated pairs of wheat cultivars and A. brasilense strains (Sp245 and Sp7) as responded to drought including: tolerant (Roshan-Sp245), moderately tolerant (Roshan-Sp7), sensitive (Shahpasand-Sp7), moderately sensitive (Shahpasand-Sp245). The result was compared to optimum water condition (ψ_w = 0 MPa). Data represent the mean values ± SE (n = 3). Different letters in the mean values indicated the difference between the means (Duncan's multiple range tests, $P \leq 0.05$)*

To evaluate dual effects of inoculation and dehydration in each pair, the inoculated seedlings which exposed to dehydration condition were compared to the respective non-inoculated seedlings grown at optimum water condition. The result showed that at 120 min after dehydration, transcripts level of *DREB2* (-ΔCT) in the tolerant and moderately

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48834902

tolerant pairs was more than tolerant cultivar grown at optimum water condition (11.4- fold for roots and 2.3- fold for shoots). Meanwhile, in dehydrated roots of sensitive and moderately sensitive pairs, transcripts level of *DREB2* was more than non-inoculated and non-dehydrated roots (1.5- fold) but in their shoot *DREB2* was less than non-inoculated ones at optimum water potential (2.6 and 2.4- fold, respectively) ($P \leq 0.05$) ($t = 120$).

In the last measurement after dehydration (360 min), the transcripts level of *DREB2* in the tolerant and moderately tolerant pairs decreased (almost 5 and 6-fold for roots and almost 1-fold for shoot, respectively) as compared to non-inoculated cultivars grown under optimum water potential while in the sensitive and moderately sensitive pairs, there was no change in the roots but it was lower in the shoots (3.7 and 3.4-fold, respectively) ($P \leq 0.05$).

Discussion

The primary experiment was necessary to find out the most sensitive and tolerant cultivars to drought among the usual cultivated wheat cultivars (Roshan, Sardari, Tabasi, Shahpasand, Omid and Shoaleh). Then finding the compatible (or homologous) and incompatible (heterogonous) pairs among association pair of these six cultivars with two strains of *A. brasilense* (Sp7 and Sp245) under drought condition (Baldani et al., 1983; Jain and Patriquin, 1984; Amooaghaie et al., 2004). This is important due to the complexity of interaction between bacteria and host plant which can affect the successful infection, the establishment of bacterial in host plant and the following appropriate physiological responses (Jain and Patriquin, 1984; Sumner, 1990; Baldani et al., 1986, 1987). According to the physiological parameters such as growth and defensive parameters as well as total protein content, the two cultivars of Roshan and Shahpasand were determined as the most tolerant and sensitive cultivars to drought, respectively (Baldani et al., 1983; Estabrook and Sengupta-Gopalan, 1991; Vasse et al., 1993; Santos et al., 2001). Simultaneously, the best partner of wheat cv. and *A. brasilense* strains as tolerant pair to drought was Roshan-Sp245 (homologous) and the worst as the most sensitive pair was Shahpasand-Sp7 (heterologous). Also, other pairs from cross-inoculation of Roshan and Shahpasand cultivars with Sp245 and Sp7 strains indicated that Roshan-Sp7 as moderately tolerant and Shahpasand-Sp245 as moderately sensitive pairs.

Physiological responses of the selected pairs to drought

Cross-inoculation of Roshan and Shahpasand cultivars (as tolerant and sensitive to drought, respectively) with *A. brasilense* Sp245 and Sp7 strains make different associated pairs with different physiological responses in drought and optimum water conditions. Inoculation of Roshan cv. with *A. brasilense* Sp245 improved the growth of wheat seedlings except for NMR and SPAL. Similar results have been reported that Sp245 caused higher shoot length, root length and the number of roots (Baldani et al., 1987; Hamdia et al., 2004; Akbari et al., 2007; Cohen et al., 2008; Spaepen et al., 2009). Also, in the moderately tolerant (Roshan-Sp7) pair, ARL, RDW and RTP increased due to inoculation at optimum water condition (*Tables 3 and 4*). The positive effect of *A. brasilense* to promote wheat growth could be partly related to the production of more roots and consequently uptake more water and nutrient from the soil (Casimiro et al., 2003; Correa-Aragunde et al., 2004). However, inoculation of Shahpasand cv. (sensitive

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48834902

to drought) with Sp7 (sensitive association pair) did not show any positive effect on the growth parameters but in Shahpasand-Sp245 (moderately sensitive), NRB, SDW, RTP and, RPAL increased due to inoculation. Regarding to previous works, it can be concluded that any strain of bacteria should be homologous to specific wheat cultivar to expect stimulation effect on growth parameter (Baldani et al., 1983; Amooaghaie et al., 2004). In this experiment, not only Sp245 was in favor of tolerant cultivar, but also did a good job with Shahpasand cultivar. In contrast, Sp7 act in favor of Roshan cv. but has no effect on Shahpasand cultivar.

The effect of any bacterial strain on growth and development of wheat cultivars is neither the same nor ended to the growth parameters because in some cases there are no changes in growth indexes but biochemical parameters were affected. For example, total protein of roots (RTP) did not change in Roshan and Shahpasand with Sp7 at optimum water condition, meanwhile, other parameters behave differently (*Tables 2 and 4*). In contrast, RTP in the tolerant and moderately sensitive pairs of Roshan and Shahpasand with Sp245 were increased due to inoculation. An increase in the protein of plants have been reported in an association of different plant species and bacterial strains ((Vasse et al., 1993; Gamas et al., 1998). For example, different strains of *A. brasilense* have been caused an addition of total protein in wheat and tomatoes (Saubidet et al., 2002; Mangmang et al., 2015).

PAL and TAL activity in the roots and shoots of Roshan cv. inoculated with Sp245 were increased compare to non-inoculated cultivars at optimum water condition but there was no change in other association pairs except for RPAL in the moderately sensitive pair (Shahpasand-Sp245) which increased by 28%. *A. brasilense* Sp245 may enhance the defensive mechanism of wheat cultivars via changing the activities of these enzymes same as other PGPRs, then less reduction in growth parameters was observed in Rhoshan-Sp245 compare to other pairs (Maksimov et al., 2015). There is an evidence that an establishment of a proper relation between plant and bacteria can stimulate the biosynthesis pathway of phenolic compounds as a plant defense mechanism (Vasse et al., 1993). TAL and PAL enzymes are involved in the biosynthesis of phenolic compounds via biosynthesis pathway of phenylpropanoids (Lawton et al., 1983; Nemat Alla et al., 2002). Therefore, increase in the activity of TAL and PAL can cause more phenolic compounds in inoculated plants with a homologous bacterial strain which is an efficient mechanism to deal with the adverse effects of reactive oxygen species during the infection process (Estabrook and Sengupta-Gopalan, 1991). This may be a reason for the less damage to the growth rate in this experiment in inoculated as well as drought conditions.

All growth parameters in non-inoculated tolerant cultivar did not change due to drought condition (except more number of root branches, NRB). However, the most growth parameters in sensitive cultivar were severely decreased. Other reports also show that the reduction in growth parameters in the sensitive cultivars of wheat is more than the tolerant cultivars (Liu et al., 2004). Significant reduction in dry weight and other growth parameters of the sensitive cultivars under drought condition may be due to reduced plant water potential and impairment of mineral absorption and less photosynthesis, protein synthesis and carbohydrate metabolism (Tekle and Alemu, 2016). Among the growth parameters, the number of root branches was increased due to drought in both sensitive and tolerant cultivars with the different rate. Development of an extensive root system in drought condition is an avoidance mechanism to obtain more water from the rhizosphere to protect themselves against drought stress (Liu et al.,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48834902

2004). The root and shoot elongation not only was observed in drought condition but also osmotic stress can cause higher root length and also higher activity of PAL and TAL enzymes in wheat seedlings inoculated with *A. brasilense* strains (Nabti et al., 2010; Hamdia et al., 2004).

Drought condition caused the addition of total protein in root in non-inoculated tolerant cultivar but no change in the sensitive one as compare to optimum water condition. Addition of total protein due to drought stress indicated the role of organic osmolytes in osmotic adjustment for adaptation of plant to drought stress (Serraj and Sinclair, 2002).

Dual effect of inoculation and drought condition simultaneously caused mostly higher growth parameters in Roshan with Sp245 (except for NMR and MSL) as well as with Sp7 (except ARL and NRB), while the growth parameters in Shahpasand cv. (except for NRB) were significantly decreased as compared to non-inoculated cultivars at optimum water condition. Similar studies showed that inoculation of wheat with Sp245 strain increased growth parameters more than Sp7 due to the capability of Sp245 to colonize interior parts of wheat root unlike the Sp7 (Michiels et al., 1991). The Sp245 strain could improve drought tolerance of wheat by the production of ABA, a key phytohormone in plant response to drought stress (Michiels et al., 1991; Cohen et al., 2008).

Dual effect of inoculation and drought condition show that Roshan cv. with Sp245 caused an increase in PAL and TAL activities compared to non-inoculated cultivars at drought or optimum water condition. It has been suggested that inoculated of wheat cultivars with Sp245 has a positive effect on the activity of these enzymes either at drought or optimum water condition. Hence, *A. brasilense* Sp245 can enhance the defensive mechanism of wheat at the drought condition (Maksimov et al., 2015). PAL and TAL have a main role in drought tolerance in wheat plants through phenylpropanoids biosynthesis pathway and accumulation of more phenolic compounds in plants (Redmann, 1974; Kaur and Zhawar, 2015).

Therefore, it can be concluded that positive effects of inoculation on biochemical properties of the wheat cultivars are mostly related to homology properties of wheat cultivar and bacterial strain not to the sensitivity of cultivar to drought. This is the reason that Roshan (tolerant) and Shahpasand (sensitive) cultivars with Sp245 showed the better results than Sp7. However, the dual effect of inoculation and drought condition represents the interaction effect on the association of wheat cultivar with the strain of bacteria when compared to separate effect.

DREB2 expression of the selected association pairs in different water potentials

At optimum water condition (ψ_w = 0 MPa), *DREB2* of inoculated cultivars was down-regulated in the root but up-regulated in the shoot of all selected pairs relative to the respective non-inoculated cultivars. It seems that over-expression of *DREB2* in the shoot of inoculated seedlings may be due to the basic effect of *A. brasilense* strains on the wheat seedling. However, the positive effect in the shoot of tolerant and moderately tolerant pairs is more than sensitive and moderately sensitive pairs. The effect of some other PGPRs such as *Arthrobacter protophormiae* (SA3), *Dietzia natronolimnaea* (STR1) and *Bacillus subtilis* (LDR2) on *TaCTR1*/*TaDREB2* expression in wheat has been shown the enhancement of Ta*DREB2* gene expression encoding for a transcription factor and improving the tolerance of plants to abiotic stress conditions (Barnawal et al., 2017).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48834902

DREB2 expression in non-inoculated cultivars and the cross-inoculated with *A. brasilense* strains was also varied under dehydration condition. *DREB2* up-regulated in root and shoot of non-inoculated tolerant cv. but did not change in the sensitive cv. due to dehydration. *DREB2* up-regulation has been reported in dehydration condition in the tolerant cv. of wheat. For example, Shen and colleagues (2003) reported that drought stress increased *TaDREB2* gene expression in tolerant cultivars of wheat. Meanwhile, transgenic *RD29A-GmDREB* wheat plants had a better tolerance compared to wild type plants which shows the contribution of these two genes in wheat drought tolerance (Shiqing et al., 2005). At 360 minutes after dehydration imposed, *DREB2* down-regulated in the root of Roshan and up-regulated in the shoot. As an early gene, *DREB2* expression is rapid and transient (peaking at 2 or 3 hours) and then their mRNA levels will decrease (Yamaguchi-Shinozaki and Shinozaki, 2005; Agarwal et al., 2006, 2010). *DREB2* down-regulation at longer time of dehydration (360 min) in the tolerant cv. may be due to the transient role of this transcription factor. In contrast, in the sensitive cv., *DREB2* up-regulated at this time in the root and down-regulated in the shoot. It seems that in the sensitive cv. at the shorter time (120 min), dehydration could not make *DREB2* up-regulation unless dehydration duration would be longer. Longer dehydration (360 min) means more loss of water potential and more osmotic signals which were produces by the root cells (Taylor et al., 2000; Stein et al., 2000; Rock, 2000; Liu et al., 2005). Likely, the production of signals for stimulation of *DREB2* expression was enough only for the roots of sensitive cv. but not for its shoots. This is the reason for *DREB2* down-regulation even at 360 min after dehydration applied.

In this experiment, up-regulation of *DREB2* in the tolerant and moderately tolerant pairs and its down-regulation in the sensitive and moderately sensitive pairs at dehydration supported the role of *DREB2* gene as an essential early stress-responsive gene in plant tolerance to dehydration (Yamaguchi-Shinozaki and Shinozaki, 2005; Fujita et al., 2011). The early genes encode regulatory proteins such as transcription factors, signal transduction related proteins, osmolytes biosynthesis (Agarwal et al., 2010). There is evidence for better growth of recombinant *E. coli* cells expressing *SbDREB2A* (obtained from *Salicornia brachiata*) in the culture mediums enriched by NaCl, PEG, and mannitol due to the role of plant's *SbDREB2A* in the regulation of other stress-regulated genes. This function represents certain interactions between the plant's *SbDREB2A* with a transcriptional network of the bacterial cells (Gupta et al., 2010). According to our results, it seems that there is probably proper crosstalk between the transcriptional network of *A. brasilense* Sp245 (the most homologous strain) with Roshan (the most proper cultivar of wheat) which causes highest *DREB2* up-regulation in the root of the tolerant pair. *DREB2* up-regulation in the root of tolerant pair was more than the shoot which might be due to the localization of *A. brasilense* Sp245 in the root of Roshan cv. and supports this crosstalk between the transcriptional network of bacteria and plant. *DREB2* up-regulation in the root (778-fold) of tolerant pair was more than shoot (1.2-fold) but in the tolerant cv. *DREB2* expression was less in the root than the shoot under dehydration condition. This result supports the role of Sp245 to change *DREB2* expression in the root of Roshan cultivar. In the sensitive cv., unlike the tolerant cv., *DREB2* expression did not change.

Dual effects of dehydration and inoculation on *DREB2* expression in the tolerant and sensitive pair were different. This effect was positive in the tolerant and moderately tolerant pairs but it was mostly negative or ineffective in the sensitive and moderately sensitive pairs. Meanwhile, the quantity of dual effect was dependent on dehydration

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_48834902

course. According to our result, it is suggested that inoculation of wheat with *A. brasilense* Sp245 can provide a proper tool to improve tolerance of wheat to dehydration via regulation of *DREB* expression.

Conclusion

In conclusion, the effect of inoculation on physiological (growth and biochemical) parameters of wheat seedlings in the sensitive and moderately sensitive pairs was less than the tolerant and moderately tolerant pairs at drought or optimum water condition. The dual effects of dehydration and inoculation on *DREB2* expression were positive in the tolerant and moderately tolerant pairs and mostly negative or ineffective in the sensitive and moderately sensitive pairs. However, these effects were depending on the duration of dehydration. It seems that dehydration alone could not cause up-regulation of *DREB2* in non-inoculated wheat cultivars unless the time of stress would be enough meanwhile over-expression of *DREB2* in inoculated wheat cultivars with *A. brasilense* after dehydration may be more due to the effect of the bacteria on wheat seedlings. The authors feel further research is needed to find out the details of the effect of *A. brasilense* on *DREB2* gene expression in wheat including signal transduction pathways and their components using wheat and or *A. brasilense* mutants.

Acknowledgements. Authors wish to thank Dr. Michael Rothballer from AMP Research Unit Microbe-Plant Interactions for providing the bacterial strains. Financial support by the University of Isfahan is gratefully acknowledged.

APPENDIX

Appendix 1. *The averages of ranking numbers in the associated pairs between wheat (Triticum aestivum L.) cultivars (Omid, Roshan, Sardari, Shahpasand, Shoaleh and Tabasi) and two strains of A. brasilense (Sp7, Sp245) at optimum water content (80% FC) and drought condition (40% FC) based on growth and biochemical parameters. At 80% FC, the minimum and maximum numbers show the most compatible (homologous) and most non-compatible (heterologous) association pairs, respectively; At 40% FC, the minimum and maximum numbers show the most tolerant and most sensitive association pairs to drought, respectively; At 40% FC, Tabasi cultivar is not included due to lack of its successful association with both bacterial strains under optimum water condition) (NI: non-inoculated)*

Pairs		**Ranking number**	
Wheat cultivars	***A.brasilense* strains**	**80% FC**	**40% FC**

Abstract. Fisheries resources in inshore regions of the South China Sea (SCS) have been depleted by overfishing. Purpleback flying squid (*Sthenoteuthis oualaniensis*) fishery is considered as a potential resource in the open SCS. However, little is known about their optimal habitat. Here, habitat suitability index (HSI) models were constructed using the external envelope and arithmetic mean methods to identify optimal habitats of purpleback flying squid. The matched fishery and environmental data (sea surface temperature, sea surface height anomaly, and ocean net primary productivity data) were collected from 2010 to 2014 in the open SCS. We calculated catch per unit effort (CPUE) and fishing effort to estimate the suitability index. The estimated suitable ranges for sea surface temperature, sea surface height anomaly, and net primary productivity were 27.1–30.4 °C, 0–0.15 cm, and 236.2–492.8 mg C/m^2 d based on the HSI model incorporating fishing effort. The corresponding suitable ranges estimated by the HSI model incorporating CPUE were 27.4–30.7 °C, 0.03–0.18 cm, and 238.4–475.5 mg C/m^2 d, respectively. When HSI values for 2014 were >0.6, the HSI model based on fishing effort explained 72.6% of the fishing effort and the average CPUE was 4.29 t/d. The HSI model based on CPUE explained 66.39% of the fishing effort for 2014 and the average CPUE was 4.23 t/d. The accuracy of the forecasting model based on fishing effort was higher than that based on CPUE. This HSI model can be used to aid in the management and conservation of purpleback flying squid in the SCS.
Keywords: *ocean remote sensing, SCS, ecological model, fishery resources, catch per unit effort*

Introduction

Commercial fisheries in the South China Sea (SCS) contribute to the tota China's marine fishery by 27.4% (Qiu et al., 2008). However, fisheries resources have depleted because of overfishing in coastal regions of the SCS. More fishing activities spread to the open SCS, capturing cephalopods as main targets (Chen et al., 2013). Specifically, purpleback flying squid (*Sthenoteuthis oualaniensis*), a cephalopod species inhabiting warm waters, is widely distributed in the open SCS (Siriraksophon et al., 2001a, 2011b; Zhang et al., 2015b). As a potential commercial fishery resources for sustainable exploitation, the available annual capture is estimated between 1.3 and 2.0 million tons in the SCS, while the actual capture was 0.05 million tons in 2011 (Siriraksophon et al., 2001a; Ji et al., 2015). Thus, purpleback flying squid fishery will play a crucial role in the SCS's fishery. Although it has been considered to support potentially a more robust fishery in the open SCS because of its abundance, short life span, fast growth rate, high

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49034913

fecundity, and high nutritional value (Chen et al., 2013; Zhang et al., 2015b; Yu et al., 2012), there is no complete and scientific research about the relationship between purpleback flying squid and environmental factors in the open SCS. It is crucial to sustain and protect the fishery in the SCS under environmental changes in future (Ji et al., 2015).

Commercial fisheries data at large-scale are available as an important index to understand status of fishery resource (Hilborn and Walters, 1992). Catch and effort from commercial fishery were commonly used to develop models to predict distribution of fish species (Morris and Ball, 2006; Tian, et al., 2009). The catch per unit effort (CPUE) is commonly used to analyze the relationship between environmental variables and fish habitat, but commercial fisheries CPUE is influenced by other variables. Thus CPUE must be standardized to be a reliable abundance index (Zhang et al., 2015a). In addition, comparison of fishing effort and CPUE as an abundance index are be necessary especial for purpleback flying squid with high swimming speed (Tian et al., 2009; Zhang et al., 2015a; Pedro et al., 2006).

Habitat suitability index (HSI) model is suitable for describing and evaluating habitat qualities and species distributions (US Fish and Wildlife Service, 1981), including management of species, ecological environmental restoration (Duel et al., 1996; Gore and Hamilton, 1996; Maddock, 1999), and forecasting of central fishing grounds (Tian et al., 2009; Li et al., 2015). In addition, it has been applied to investigate relationships between fishing ground and relevant environmental factors effecting distribution of flying squid species in northwestern Indian Ocean (Yu et al., 2012), northwestern Pacific Ocean (Tian et al., 2009). Currently, large variation in spatial distribution of capture for purpleback flying squid fishery in the SCS existed, with overfishing in the coastal regions and underutilization in the open regions.

The HSI model for purpleback flying squid in the western Indian Ocean was applied to construct relationships between its catch and habitat factors (Chen et al., 2007), while, due to the dataset with short time series and mere catches of Chinese's vessels they used, their study is limited to illustrating general theoretical relationships to explore and protect this species. Thus, more accurate estimations are needed to identify the suitable habitat for purpleback flying squid. To aim this, using the HSI model, a full and specific fishery dataset (2010-2014) in the SCS were used to investigate optimal habitat with high production and corresponding habitat factors, including sea surface temperature (SST), sea surface height anomaly (SSHA), and net primary productivity (NPP). Additionally, the final goal is to effectively develop purpleback flying squid fishery by predicting locations of fishing grounds of purpleback flying squid in the open SCS.

Material and methods

Data

Commercial fishery data of purpleback flying squid were obtained from the SCS's dynamic fishing and monitoring network. This data recorded the date, location, catches and number of nets for each fishing activities from 2010 to 2014. In addition, the full ranges of these activities covered the area of 105°–120°E, 5–25°N (*Fig. 1*). Changes in monthly number of nets for purpleback flying squid over this time period were illustrated in *Figure 2*.

DOI: http://dx.doi.org/10.15666/aeer/1702_49034913

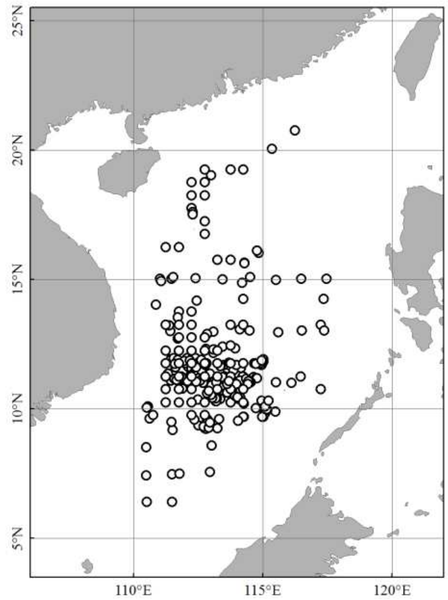

Figure 1. *The location of fishery data collected during 2010–2014 in the open South China Sea*

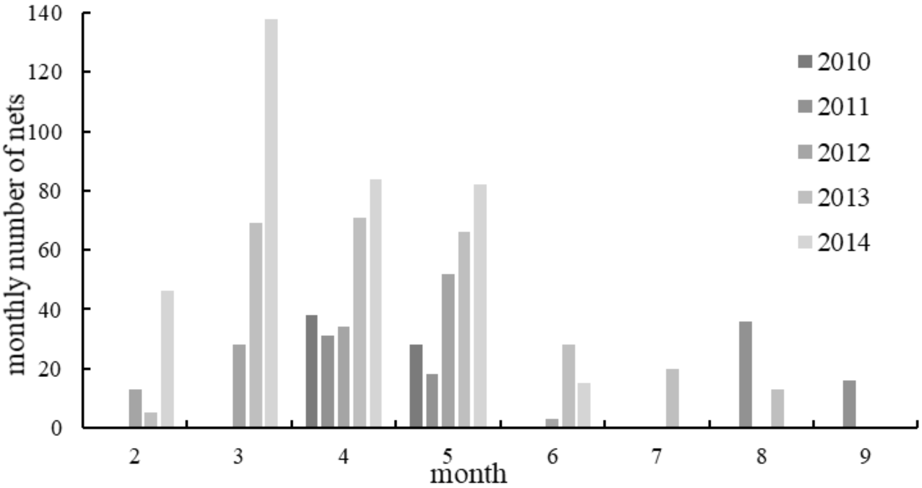

Figure 2. *Changes in monthly number of nets for purpleback flying squid during 2010–2014 in the open South China Sea*

Environmental data included SST, SSHA and NPP. The daily SST data were derived by the remote sensing system research company located in Northern California (http://www.remss.com/measurements/sea-surface-temperature). These data were the optimally interpolating SST products merging from microwave and infrared SST maps at an approximately 9 × 9 km resolution. The daily SSHA images were downloaded from Centre National d'Etudes Spatiales (CNES) data center (http://www.aviso.altimetry.fr/en/data/products/sea-surface-height-products.html), and merged based on altimeter data (Topex/Poseidon, JASON-1, Jason-2, Envisat, ERS-1, ERS-2, and Cryosat-2) at a 0.25 × 0.25 degree resolution. The 8 day average global ocean net primary production (NPP) data products were obtained from the Oregon State University College of Science

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49034913

(http://orca.science.oregonstate.edu/1080.by.2160.monthly.hdf.vgpm.m.chl.m.sst.php), and were estimated based on MODIS at a 1/6 degree spatial resolution. All environmental data covered the full ranges of fishing grounds over the entire study period.

Methods

Data processing

All environmental data were processed at a 0.5 × 0.5 degree resolution and matched to the ranges of the fishing grounds using MATLAB 2012b (The MathWorks, Inc., Natick, Massachusetts, United States).

The nominal catch per unit effort (CPUE) for each cell was calculated in *Equation 1* as follows:

$$CPUE_{i,j} = \frac{\text{Catch}_{i,j}}{effort_{i,j}} \tag{Eq.1}$$

where $Catch_{i,j}$ and $effort_{i,j}$ is the total weight of catches, and numbers of nets for the ith and jth cell, respectively.

The nominal CPUE in *Equation 1* hardly indicates the true abundance of fishery over the entire fishing geographical locations and periods, because many factors can affect their accuracies (Zhang et al., 2015a; Maunder et al., 2006). Thus, to remover these effects, a standardized CPUE was computed using a support vector machine method following Yang et al. (2015). See Yang et al. (2015) for the detail processes for standardizing CPUE.

Building a suitability index (SI) model

A number of models and methods have been used to forecast the location of fishing grounds (e.g., Lee et al., 2005; Grant et al., 1988; Georgakarakos et al., 2006; Skov et al., 2008). HSI models appear to perform well for identifying the location of purpleback flying squid fishing grounds (Tian et al., 2009; Li et al., 2015). A number of methods have been used to calculate the Suitability index (SI) in HSI models, including the external envelope method, BP neural networks, and non-linear regression (Chen et al., 2009; Yu et al., 2012; Frenkel et al., 2017). Among these, the external envelope method appears more suited for cephalopoda (Fang et al., 2014; Gurkan, 2016).

Effort can be used as an index of fish presence or provide general information on the utilization of fishery resources (Andrade et al., 1999; Swamy et al., 2017). And we want to know whether swimming speed has an effect on catch, we adopted effort as a variable to build model. The correlation between effort and Standardized CPUE was analyzed, P value is 0.7724, which means there is no significant correlation between effort and standardized CPUE in other words.

Thus, we modeled the relationships between effort or standardized CPUE, and SST, SSHA, and NPP using the external envelope method during the years 2010–2013. When effort or standardized CPUE is highest, the SI value is 1, and when effort or standardized CPUE is 0, the SI value is 0 (Mohri et al., 1999). We calculated SI using *Equations 2* and *3:*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49034913

$$SI_{effort} = \frac{effort_{i,j}}{\text{effort}_{\max}} \quad \text{(Eq.2)}$$

$$SI_{CPUE} = \frac{CPUE_{i,j}}{CPUE_{\max}} \quad \text{(Eq.3)}$$

where SI_{effort} (SI_{CPUE}) represents SI values computed based on effort (CPUE), $effort_{ij}$ ($CPUE_{ij}$) represents the effort (CPUE) at the location represented by longitude i and latitude j, and $effort_{\max}$ ($CPUE_{\max}$) represents the maximum of all effort (CPUE) data.

Building the HSI model

Prior research suggests that the arithmetic mean method (AM) is a better predictor of the fishing ground location than the geometric mean method (Li et al., 2015; Mejia-Sanchez et al., 2018). Thus, we used the AM method to calculate HSI values during HSI model establishment. The HSI was calculated using *Equations 4* and *5:*

$$HSI_{\text{effort}} = (SI_{SST\_effort} + SI_{SSHA\_effort} + SI_{NPP\_effort})/3 \quad \text{(Eq.4)}$$

$$HSI_{CPUE} = (SI_{SST\_CPUE} + SI_{SSHA\_CPUE} + SI_{NPP\_CPUE})/3 \quad \text{(Eq.5)}$$

where HSI_{effort}, and HSI_{CPUE} represent HSI values calculated based on effort and CPUE, respectively. $SI_{\text{SST\_effort}}$, $SI_{\text{SSHA\_effort}}$, and $SI_{\text{NPP\_effort}}$ represent SI values computed based on effort using SST, SSHA, or NPP as the variable, respectively. $SI_{\text{SST\_CPUE}}$, $SI_{\text{SSHA\_CPUE}}$, and $SI_{\text{NPP\_CPUE}}$ represent SI values computed based on CPUE using SST, SSHA, or NPP as the variable, respectively.

HSI model verification and comparison

The HSI values in 2014 were obtained using the models described above, and divided into five classes: 0–0.2, 0.2–0.4, 0.4–0.6, 0.6–0.8, and 0.8–1 (Yu et al., 2012; Li et al., 2015). Then, the cumulative effort and catch was counted separately in each class (Tian et al., 2009). The habitats with HSI values >0.6 were considered to represent habitat near the center of the fishing grounds (Yu et al., 2012; Yuan et al., 2017). Percentages of effort with HSI values >0.6 computed by HSI models based on effort and CPUE, respectively were compared to get an optimal model for studying habitant of purpleback flying squid.

Results

Relationships between fishing effort, CPUE, and environmental factors

Figure 3 illustrated relationships between the SI based on fishing effort (*Fig. 3a-c*) and CPUE (*Fig. 3d-f*) and environmental factors. For the SI from the fishing effort, the optimal ranges for SST, SSHA, and NPP are 27.1–30.4 °C, 0–0.15 cm, and 236.2–492.8 mg C/m^2 d., respectively. For the SI from CPUE, the corresponding suitable ranges are 27.4–30.7 °C, 0.03–0.18 cm, and 238.4–475.5 mg C/m^2 d, respectively.

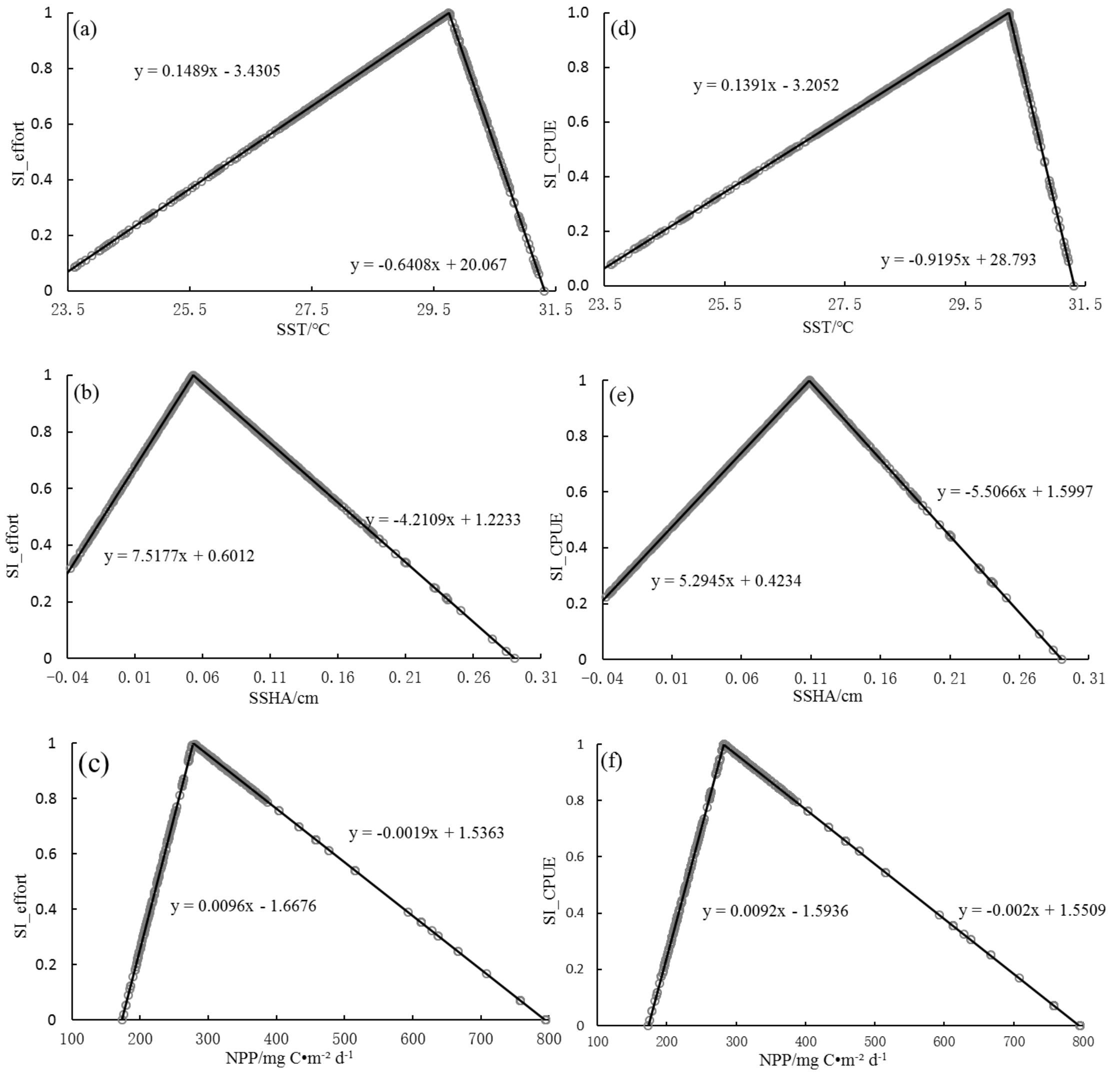

***Figure 3.** The suitability index curves based on fishing effort and catch per unit effort (CPUE) during 2010–2013 in the open South China Sea*

Models comparisons

Regions with a HSI value greater than 0.6, are considered as the preferred fishing grounds for purpleback flying squid in the open SCS. Thus, in this study, 72.45% of the catches and 71.88% of fishing effort in whole fishing grounds is with HSI over 0.6 based on HSI model from fishing effort during the period from 2010 to 2013 (*Table 1*), while, 68.86% of the catches and 70.24% of fishing effort in whole fishing grounds is with HSI over 0.6 based on HSI model from CPUE.

Verification and comparison of fishing ground distribution

When HSI is >0.6, the HSI model based on fishing effort verifies fishing effort in 2014 with 72.6% accuracy and the average CPUE is 4.29 t/d. Similarly, the model based on CPUE is 66.39% accurate and the average CPUE is 4.23 t/d (*Table 2*). The accuracy of the forecasting model based on fishing effort is higher than that based on CPUE. Thus, the HSI model based on fishing effort is the best available model for

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49034913

forecasting the distribution of habitats suitable for purpleback flying squid in the open SCS. The precision of this forecasting model is 72% when actual fishing effort can be used as an index to judge the accuracy of main fishing grounds. Catch and HSI values of SST, SSHA and NPP in 2014 were calculated using above HSI model based on fishing effort illustrated in *Figure 4*.

Discussion

Changes in the fishing ground were impacted by multi-factors, e.g. life history for each fish species, supply of food, and changes in environmental factors (Chen et al., 2007; Yan et al., 2012). Among these factors, the later one can directly affect fish's life cycle by, e.g. food supplication or distribution of prey resources (Yu et al., 2016). For detail, SST can determine the general distribution patterns by affecting the processes of birth, reproduction, and migration (Ji et al., 2015; Zhang et al., 2015a).

Sea surface height (SSH) data reflects the influence of the direction and velocity of water flow, the interaction of cold and warm water masses, and other dynamic environmental variables (Shao et al., 2008; Song, 2014), which, in turn influence the distribution of fauna and the formation of fishing grounds (Shao et al., 2008). SSHA reflects the difference between sea surface height and mean sea level. Thus, SSH or SSHA data are often used in assessments of the relationship between environmental factors and fisheries (Song, 2014). NPP data have been used to model tuna, mackerel, and squid resources in other regions (Zainuddin et al., 2006; Yu et al., 2016). To our knowledge, this is the first study to evaluate the utility of using NPP to predict purpleback flying squid distribution in the open SCS. Our analysis suggests that it is feasible to build an HSI model based on SST, SSHA, and NPP to describe the fishing distribution of purpleback flying squid in the open SCS. For the period 2010–2013, the suitable range of SST, SSHA, and NPP was 27.1–30.4 °C, 0–0.15 cm, and 236.2–492.8 mg C/m^2 d, respectively. This is consistent with prior studies that estimated the range of suitable SST for purpleback flying squid was 27–29°C in the northwestern waters of the Indian Ocean (Yu et al., 2012; Luo et al., 2015) and an optimal SSHA of 0.00 in the northwest Indian Ocean (Shao et al., 2008).

Conclusions

Analysis of the HSI models

Because of sovereignty disputes in the SCS, the spatial scale of fishing is limited. To ensure forecasting accuracy, we used daily records of environmental data rather than monthly. Additionally, because of the influence of atmospheric climate on oceanic variables, the environmental factors that exhibit high spatial and temporal resolution with respect to the distribution of purpleback flying squid should also reflect the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49034913

influence of season on distribution of purpleback flying squid. We compared two HSI models, one based on fishing effort and the other based on CPUE using the external envelope method. The precision of the HSI model based on fishing effort (72.6%) was higher than the HSI model based on CPUE (66.39%). Thus, the HSI model based on fishing effort appears to provide more realistic results when his values >0.6.

Improvement of the HSI model

Although the HSI model described in this paper has high forecast precision, it could be improved by increasing the amount of fishing data used to parameterize the model. Additionally, although we used three commonly referenced environmental variables, purpleback flying squid may be influenced by other environmental factors that were not considered (Jia et al., 2004; Yu et al., 2012). Thus, we recommend developing the current HSI model to incorporate more fishery data and test the influence of other environmental factors (e.g. currents, sea surface salinity) and interactions among variables.

(Received 5th Nov 2018; accepted 25th Jan 2019)

Abstract. The present study aimed to investigate the oviposition deterrent and adult emergence inhibition activities of non-polar solvent extract of *Cymbopogon nardus* whole plant against *Culex quinquefasciatus* mosquito with effect on non-target organisms. During the oviposition deterrent activity, the 1000 ppm concentration of extract showed maximum (71.9±3.3 %) effective repellence (ER). The lowest concentration (31.25 ppm) caused 13.4±1.3 % ER. The oviposition activity index (OAI) of the gravid female *Cx. quinquefasciatus* was estimated. For each concentration, negative OAI value was found. The negative OAIs values indicated that the n-hexane extracts of *C. nardus* whole- plant is oviposition repellent. Lowest OAI value was exhibited by 1000 ppm extract solution. During the adult emergence inhibition (EI) activity, the *C. nardus* n-hexane extract solutions restricted adult emergence. There occurred 31±17.9 % adult emergence from the containers containing 1000 ppm extract solution. From the container containing 125 ppm extract solution, 82.3 ± 5.6 % adult emerged. The 1000 ppm of extract solution caused 66.2 ± 19.5 % EI. At 125 ppm extract solution, 12.2 ± 6.5 % EI was observed. There was a positive correlation between extract concentration and EI % (R square =0.86). The EI_{50} value of *C. nardus* was 515.2 ppm. During the study of effect of *Cymbopogon nardus* whole-plant n-hexane extract on non-target aquatic insects i.e., damselfly and dragonfly nymphs, the extract caused no mortality of any nymph up to 500 ppm. However, at 1000 ppm concentration, the plant extract caused some mortality (5 %). During the study of effect of extract on grass carp fish (*Ctenopharingodon idella*), there occurred no mortality during 24-hour exposure. During the study of effect of extract on rabbits, there occurred no mortality and found no significant alterations in the normal biochemical and hematological parameters. Photomicrographs of microtome sections of liver and kidney of extract treated rabbit groups showed normal histoarchitecture. From the findings of the present research, it was concluded that the n-hexane extract of *C. nardus* whole-plant possesses oviposition deterrent and adult emergence inhibition activities against *Cx. quinquefasciatus*. It was also concluded that the n-hexane extract of *C. nardus* whole plant is least toxic to damselfly and dragonfly nymphs. The extract does not cause mortality or behavioural

abnormality in fish. The ingestion of *C. nardus* whole-plant n-hexane extract in rabbits do not cause mortality or alterations in the normal biochemical and haematological parameters of rabbits.
Keywords: *effective repellence, oviposition activity index, damselfly and dragonfly nymphs, grass carp, rabbit, biochemical and haematological parameters*

Introduction

Mosquitoes are constant threats to human by transmitting several diseases such as malaria, filariasis, West Nile Virus infection, dengue fever and yellow fever (Farajollahi et al., 2011). Three genera viz; *Anopheles*, *Aedes* and *Culex* are more important as many of their species are vectors of diseases in human and other animals. *Culex quinquefasciatus* is a well-known culicine mosquito that causes serious nuisance through its irritating biting and is the vector of *Wuchereria bancrofti,* that causes lymphatic filariasis in humans (Rajasekariah et al., 1991). This disease has affected more than 100 million people in Asia, Africa, Central- and South America and the Pacific (Simonsen, 2009). In Pakistan, Beg et al. (2001) reported confirmed cases of tropical pulmonary eosinophilia in indigenous patients however this disease is very rare in Pakistan.

Synthetic chemical insecticides such as organochlorine and organophosphate compounds are commonly applied for the control of mosquitoes (Ghosh et al., 2012). The frequent application of synthetic chemical insecticides has caused the development of insecticide resistance in insect pests, contamination of the environment, and adverse effects on non-target organisms (Lee et al., 2001). Alternative approaches which are environment friendly should be adopted for controlling mosquito population (Ghosh et al., 2012). Biological control is the environment friendly and effectual means of managing pest. The biological control agents include some larvivorous fish (Walton, 2007), predatory insects (Mandal et al., 2008), protozoans (Das et al., 2016), bacteria (Phillips, 2001) and plants (Ajaegbu et al., 2016).

Plant-based insecticides have got attraction (Sivagnaname and Kalyanasundaram, 2004; Singh et al., 2006) as they are biodegradable, effective and environment friendly (Wang et al., 2000; Nerioa et al., 2010). Extracts of some plant have been reported for their larvicidal (Al-Mehmadi et al., 2010; Rawani et al., 2014), pupicidal (Kovendan et al., 2012), adulticidal (Jayapriya and Gricilda-Shoba, 2015; Ajaegbu et al., 2016) and insect repellent (Bekele and Petros, 2017) activities against mosquitoes.

In addition to the use of plants as general toxicants against mosquito larvae or adults, plant-based insecticides also deter the female adult mosquitoes from egg laying (Prajapati et al., 2005). The oviposition deterrent effect of plant extract may be due to the changes induced in the physiology and behavior of the female adult mosquitoes reflected by their egg-laying capacity. Some phytochemicals act as growth regulators or chemosterilent while some produce olfactory stimuli acting as repellent or attractant (Prathibha et al., 2014). The plants that possess insect repellent property may also exhibit oviposition deterrent and adult emergence inhibition properties (Rajkumar and Jebasan, 2009). The oviposition deterrent and adult emergence inhibition activities of some insecticidal repellent plant have been reported (Prathibha et al., 2014; Elango et al., 2012). The plant *Cymbopogon nardus* (Linn.) belongs to the family Poaceae and locally called Sargarai in Dir Lower, Khyber Pakhtunkhwa, Pakistan. The essential oil of *C. nardus* has been reported for its insect repellent activity against mosquitoes (Silva et al., 2011). The present study aimed to determine the oviposition deterrent and adult emergence inhibition activities of *Cymbopogon nardus* against *Culex quinquefasciatus*.

Synthetic chemical insecticides also kill non-target organisms along with the target insect pests (Zacharia, 2011; Morrissey et al., 2015), but botanical pesticides are claimed to be safe or least toxic for non-target organisms (Rawani et al., 2014). Few studies have been conducted on the mosquitocidal activity of plant extracts in which the effect of plant extract on non-target aquatic insects (*Chironomus*) (Chowdhury et al., 2009), fish (*Gambusia affinis*) and tadpole (*Bufo*) (Adhikari et al., 2012) and even mammal (mice) (Carvalho et al., 2003) have been studied. According to the results of these studies, plant extracts appeared safe for non-target organism. The present research also aimed to study the effect of *Cymbopogon nardus* whole-plant n-hexane extract on non-target organisms i.e., damselfly and dragonfly nymphs and grass carp fish due to their habitat similarity with mosquito larvae. Synthetic chemical insecticides damage body organs in mammals if ingested (Tomlin, 2000; Soni et al., 2011). During the present research, the effects of oral administration of *Cymbopogon nardus* whole-plant n-hexane extract on some biochemical and haematological parameters of mammal i.e., rabbits were also studied.

Materials and Methods

Preparation of plant extract

Cymbopogon nardus (Linn.) whole-plant was collected from non-cultivated fields in Chakdara, Dir Lower Khyber Pakhtunkhwa, Pakistan and authenticated by an expert in plant taxonomy at the Department of Botany University of Malakand. The plants were shade dried and then ground into powder form by using electric grinder. During the present research, 1500 grams powder of *C. nardus* was soaked in 7500 ml non-polar solvent i.e., n-Hexane in 15-liter plastic bucket. After soaking for three days, the plant material was filtered through Whatman filter paper 42. The filtrate was evaporated through rotary vacuum evaporator and extract in dense solution form was then poured from the bulb of rotary evaporator into a clean dry glass beaker and placed under running fan for an hour. Finally, n-hexane extract of *C. nardus* whole-plant was obtained in oily paste form.

Laboratory rearing of Culex quinquefasciatus mosquito

Colony of *Cx. quinquefasciatus* was established in the laboratory (*Figure 1*) at the University of Malakand, Chakdara, Dir Lower, Khyber Pakhtunkhwa, Pakistan. For this purpose, larvae of *Cx. quinquefasciatus* were collected by using a rectangular plastic dipper (38 cm length, 28 cm width and 6.5 cm height) from a ditch containing stagnant water at the campus of university of Malakand. The larvae were brought in 700 ml plastic containers with water from the collection site to the laboratory and reared for establishing a colony. The larvae were provided with larval food comprising of dog biscuit and dry yeast powder in the ratio of 3:2. The pupae emerged were transferred to a 500 ml plastic jar containing 300 ml non-chlorinated tap water and placed in mosquito cage (45 cm × 45 cm × 45 cm). The adults emerged were fed with carbohydrate food by providing cotton pad soaked in 10 % sucrose solution. The female adult mosquitos laid eggs in the jar containing water inside the cage which then hatched into larvae. For confirmation of species proper literature was used for identification of both larvae and adults (Harbach, 1988). Powdered yeast and dog biscuit in 2:1 ratio was provided as food to the larvae. The adults obtained were initially provided with 10% sucrose and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49154931

later blood fed periodically by allowing mice for eggs development. Larvae and adults of *Cx. quinquefasciatus* were available.

Figure 1. *Picture of laboratory reared colony of Cx. quinquefasciatus established during the present experiments*

Oviposition deterrent bioassay

During this bioassay, guidance was taken from the method of Xue et al. (2001). Three concentrations i.e., 1000, 250 and 31.25 ppm of *C. nardus* whole-plant n-hexane extract were selected during this study. The selection was based on the fact that these concentrations showed highest, moderate and lowest larval mortality during our study on larvicidal activity of *C. nardus* whole-plant n-hexane extract against *Cx. quinquefasciatus* (Ilahi and Yousafzai, 2017). 1000 ml stock solution of 2000 ppm extract was prepared in non-chlorinated tap water in glass flasks containing 1.6 % acetone and 0.05 % tween 80. From the stock solution, 200 ml solution of 1000 ppm, 250 ppm and 31.25 ppm were prepared in three 400 ml polyethylene containers by applying dilution equation, $C1V1=C2V2$. The 1000, 250 and 31.25 ppm extract solutions were placed inside the mosquito cages A, B and C, respectively. A control container containing 200 ml non-chlorinated tap water with 1.6 % acetone and 0.05 % tween 80 was also placed inside each cage. The experiment was run in triplicates. Into each mosquito cage, 100 blood fed and gravid female *Cx. quinquefasciatus* mosquitoes caught from the existing laboratory colonies were introduced. The mosquitoes laid eggs after 2 or 3 days of introduction. For each jar, total number of eggs and rafts were counted under dissecting microscope. The oviposition data was presented as percentage of effective repellence (ER %) and oviposition activity index (OAI). Positive OAIs are considered as attractants, while negative OAIs are considered as repellents (Govindarajan et al., 2011). The ER % was calculated by using the following method of Rajkumar and Jebasan (2009) (*Eq.1*):

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49154931

$$ER\% = \frac{NC - NT}{NC} \times 100 \qquad \text{(Eq.1)}$$

Where ER: Effective repellency; NC: Number of eggs in control; NT: Number of eggs in treatment. The oviposition activity index (OAI) was calculated by using the following formula of Kramer and Mulla (1979) (*Eq.2*):

$$OAI = \frac{NT - NC}{NT + NC} \qquad \text{(Eq. 2)}$$

Where Nt: total number of eggs in the treatment container, Nc: total number of eggs in the control container. The oviposition data for each extract was presented as mean ER % and mean OAI.

Egg rafts and eggs of *Cx. quinquefasciatus* are shown in *Figure 2* and *Figure 3*, respectively.

Figure 2. *Egg rafts deposited by Culex quinquefasciatus during the present experiments*

Figure 3. *Microscopic picture of Culex quinquefasciatus eggs in rafts taken during the present experiments*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49154931

Adult emergence inhibition bioassay

During the present study, the effect of n-hexane extracts of *C. nardus* whole- plant on the adult emergence of *Cx. quinquefasciatus* was studied in the laboratory at 1000, 500, 250 and 125 ppm. The selection of theses concentrations was based on the fact that these concentrations showed highest, moderate and lowest mortality during our study on larvicidal activity of *C. nardus* whole-plant n-hexane extract against *Cx. quinquefasciatus* (Ilahi and Yousafzai, 2017). Guidance was taken from the work of Elimam et al. (2009) who followed the procedure for testing insect growth regulators. 300 ml extract solutions of 1000, 500, 250 and 125 ppm were prepared in four 600 ml polyethylene containers from a 2000 ppm stock solution containing 1.5 % acetone and 0.05 % tween 80. A 600 ml control polyethylene container containing 300 ml non-chlorinated tap water (with 1.5 % acetone and 0.05 % tween 80) was also placed along each concentration. One hundred 3rd instar larvae of *Cx. quinquefasciatus* were transferred from the mosquito breeding containers to each treatment container. One hundred 3rd instar larvae of *Cx. quinquefasciatus* were also transferred to the control containers. This experiment was run in four replicates. The duration of the test was long therefore yeast was provided to each container as larval food at interval of two days. The jars were capped with gauze to prevent the escape of emerging adult mosquitoes. The jars were daily checked for the appearance of pupae and adults. The adults appeared were caught with the help of mouth aspirator and then put into a clean dry reagent bottle and anaesthetized by applying cotton swab soaked in diethyl ether. The experiment was conducted during 14-25 August 2016, and the maximum temperature inside the laboratory was 30°C to 34°C. The observations were continued till all the larvae or pupae in the control have died or emerged as adults. At the end of experiment the number of adults emerged was noted for each treatment and control container. The number of adults emerged in control and each of the treatment containers was noted. The effect was expressed as percentage of emergence inhibition (EI %). The EI % was calculated by using the following formula used by Elimam (2007) (*Eq.3*):

$$EI = 100 - \left[\frac{T \times 100}{C} \right] \quad \text{(Eq. 3)}$$

Where T represents percentage emergence in treatment container and C represents percentage emergence in the control container.

Adult emergence in control was more than 95 % therefore there was no need of correction of data by abbot formula. Adult emergence inhibition data was presented as mean EI %. The mean EI % data was subjected to log probit analysis (Finney, 1971) for calculating EI_{50} (a measure of the extract concentration that caused 50 % EI) value using SPSS 16 software.

Effect of plant extract on non-target organisms

During the present research, the effect of *C. nardus* whole- plant n-hexane extract on the following non-target organisms was also studied:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49154931

Effect on damselfly and dragonfly nymphs

Damselfly (order Odonata, sub order Zygoptera) and dragonfly (order Odonata, sub order Anisoptera) nymphs of early instars (4 to 5 instar) were collected from the puddles on the bank of River Swat near the campus of University of Malakand. Collection of nymphs and experiments were conducted during August 2016 (maximum temperature 30-33^{0}C). Damselfly and dragonfly nymphs were collected from pond at the campus of University of Malakand by using a rectangular plastic dipper. The nymphs were transported in plastic jars containing water of the collection site to the laboratory at University of Malakand within 30 minutes of capture. In the laboratory, the nymphs along with water of collection site were transferred to a wide plastic tray (40 cm length, 30 cm width and 8 cm height). Before conducting experiments, the nymphs were fed with dried yeast powder and mosquito larvae. The specimens were identified to the species level with the help of literature (Gardner, 1960; Yousuf et al., 1996; Anjum, 1997; Mitra 2002; Din et al., 2013). Large number of nymphs were belonging to a damselfly species, *Ischnura elegans* and a dragonfly species, *Sympetrum decoloratum*.

During this study, 1000 ppm solution of *C. nardus* whole- plant n-hexane extract was prepared in tap water containing 0.8 % acetone and 0.02 % tween 80. This 1000 ppm extract solution was serially diluted by factor of two, thus six solutions of 1000, 500, 250, 125, 62.5 and 31.25 ppm were arranged in 400 ml polyethylene containers. Volume of testing solution in each polyethylene container was 250 ml. A 400 ml polyethylene control container containing 250 ml non-chlorinated tap water with 0.8 % acetone and 0.02 % tween 80 was also kept. For exposing the nymphs to the toxic effect of plant extract, the following method of Hardersen and Wratten (1996) was followed: seven intact 6th to 7th instar nymphs of each nymph species were placed separately in seven plastic containers (six extract concentrations and one control). In short, 14 containers were arranged for the nymphs of two odonate (damselfly and dragonfly) species, seven for each species. The experiment was run in triplicate and the period of exposure was 72 hours. Following standard toxicity protocols, the nymphs were not fed during the 72 hours exposure (ASTM standard E47, 2008). After 72 hours of exposure period, the numbers of dead and live nymphs were noted. The criterion for death was lack of response to prodding.

Effect of plant extract on freshwater fish

During this study, the toxic effect of *C. nordus* whole-plant n-hexane extract on fresh water fish was studied. Grass carp (*Ctenopharingodon idella*) was selected as test fish for this study because it is commercially important and is widely cultured in fish farms. Healthy grass carp fish of 11.6±1.3 cm length were brought from fish hatchery at Thana Malakand Agency to the laboratory in round plastic jar of 5.5 L volume. The jar was containing water of pond from which fish were collected. The time taken in bringing the fish to laboratory was less than 30 minutes. The fish were brought safe to the laboratory (no fish was died or sluggish). In the laboratory the fish were maintained in small fish aquaria (45cm length, 40 cm width and 40 cm height) containing non-chlorinated tap water. The aquaria were receiving solar illumination through windows and oxygenated by using air pumps. Fish were exposed to a single concentration of *C. nardus* whole-plant n-hexane extract that was ten times higher than its LC50 value for *Cx. quinquefasciatus* 4th instar larvae during our study on larvicidal activity of *C. nardus*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49154931

whole-plant n-hexane extract against *Cx. quinquefasciatus* (Ilahi and Yousafzai, 2017). The LC50 value of *C. nardus* whole- plant n-hexane extract against *Cx. quinquefasciatus* 4th instar larvae was 599.6 ppm. The ten times value of LC50 was 5996 ppm. 20 liters extract solution of 5996 ppm concentration (containing 1.5 % acetone and 0.05 % tween 80) was prepared in non-chlorinated tap water in a fish aquarium (45 cm × 40 cm × 40 cm). A control aquarium containing non-chlorinated tap water with 1.5 % acetone and 0.05 % tween 80 was also arranged. Six grass carp fish were placed in each aquarium (total 12 fish in 2 aquaria). The behavior and mortality in fish of each aquarium was checked for 24 hours. After 24 hours, the extract solution in the aquarium was replaced with clean non-chlorinated tap water and observed for mortality for a further period of 24 hours. Experiment was conducted during August 2016 (maximum temperature <33°C).

Effect of plant extract on rabbit (Oryctolagus cuniculus)

During the present research, the effect of oral administration of high dose of *C. nardus* whole-plant n-hexane extract on some biochemical and hematological parameters were studied in rabbits. For this purpose, male domestic rabbits (*Oryctolagus cuniculus*) weighing 700-900 grams and 5-6 months of age were purchased from local market. They were housed in wide and well-ventilated chambers in Animal House at the University of Malakand, Khyber Pakhtunkhwa, Pakistan. The rabbits were fed on green vegetables and chaw pellets and allowed tap water ad libitum. The animals were kept in such condition for five days for acclimation before start of the experiments. In total, eight rabbits were divided into two groups (A and B), four in each. Rabbits of group A were orally administered *C. nordus* n-hexane extract in 4 ml vegetable oil at a dose of 1000 mg per kg body weight per oral. Group B was control and the rabbits of this group were orally administered only 4 ml vegetable oil per Kg body weight per oral. The mortality and behavior of rabbits were monitored for 48 hours. This study was approved by University of Malakand Animal Ethics Committee. Experiment was conducted during September 2016 (maximum temperature <31°C).

After 48 hours, the animals were sequentially anesthetized with inhaled diethyl ether. Each rabbit restricted on the dissecting board was dissected and 3 mL blood was collected from the heart chambers by cardiac puncture with a 21 Gauge needle mounted on 5 mL syringe and then expelled gradually into Ethylene Diamine Tetra-acetic Acid (EDTA)-coated tubes for estimation of hematological parameters i.e., blood cells count (RBCs, WBCs and platelets count), and hemoglobin concentration. Another 3 ml blood was collected by the same method in sterile tubes with coagulant for estimation of biochemical parameters i.e., ALT, AST, ALP, albumen and globulin. The data was presented as mean with standard error. The data was analyzed by un-paired sample T-test for determining significant difference between the extract treated and control rabbit groups. For these analyses a computer software, SPSS 16 was used.

During this study the, liver and kidney tissues were processed for paraffin embedding and sections of 5-micron thickness were taken by a microtome. The sections were stained with hematoxylin and eosin, slides were prepared and then examined under microscope for histopathological changes and images were captured through attached CCTV camera. The data was presented as mean with standard error. The data was analyzed by un-paired sample T-test in One-Way ANOVA for determining significant difference between the extract treated and control rabbit groups. For these analyses a computer software, SPSS 16 was used.

Results

Oviposition deterrence

Table 1 shows the range of number of eggs laid by the gravid female *Cx. quinquefasciatus* adults in control containers and in extract solution containers (1000 ppm, 250 ppm, 31.2 ppm). In control containers, the number of eggs was in the range 997-1937, in containers with lowest concentration (31.2 ppm), the number of eggs was in the range of 887-1614 but in containers with highest concentration (1000 ppm) of extract, the number of eggs was in the range of 287-707. *Figure 4* shows the percentage of effective repellency (ER %) of *C. nardus* whole-plant n-hexane extract against *Cx. quinquefasciatus*. The highest concentration (1000 ppm) of *C. nardus* n-hexane extract greatly affected the egg laying capacity of the gravid female *Cx. quinquefasciatus* mosquito. Maximum ER % was observed for the container containing 1000 ppm extract solution (ER %=71.9±3.3) followed by 250 ppm (ER %=44.3±7.4) and 31.25 ppm (ER %=13.4±1.3). *Table 1* also shows the oviposition activity indices (OAI) of each concentration of the *C. nardus* whole- plant n-hexane extract. The 1000 ppm concentration of the plant extract exhibited minimum OAI value (mean OAI= -0.5±0.1) followed by 250 ppm (mean OAI= -0.3±0.1) and 31.25 ppm (mean OAI= -0.1±0).

Table 1. *Effect of C. nordus whole-plant n-hexane extract on oviposition activity indices (OAI) of Cx. quinquefasciatus*

Concentration (ppm)	No. of eggs (range)	OAI	Statistics
1000	287-707	-0.5 ± 0.1^{a}	Sig= 0.005

Adult emergence inhibition

Table 2 shows the adult emergence inhibition activity of *C. nardus* n-hexane extract against *Cx. quinquefasciatus.* More than 90 % emergence of adults occurred from the control containers. The emergence of adults was restricted in those containers that were

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49154931

containing *C. nardus* extract solutions. There occurred 31±17.9 % adult emergence from the containers containing the highest extract concentration (1000 ppm). There occurred 82.3 ± 5.6 % adult emergence from the containers containing the lowest extract concentration (125 ppm). The highest extract concentration caused 66.2 ± 19.5 % emergence inhibition (EI), while the lowest extract concentration caused 12.2 ± 6.5 % emergence inhibition (EI). There was a positive correlation between extract concentration and EI % (R square =0.86). The EI_{50} value of *C. nardus* was 515.2 ppm.

Table 2. *Adult emergence inhibition activity of C. nordus against Cx. quinquefasciatus*

Concentration (ppm)	E % in treatment (Mean± SE %)	E % in control (Mean± SE)	EI % (Mean± SE)	R Square	EI_{50} (ppm)
1000	31 ± 17.9	94.3 ± 2.4	66.2 ± 19.5	0.86	515.2
500	43.8 ± 16.8	95.0 ± 1.8	54.0 ± 17.7		
250	66.5 ± 14.4	93.8 ± 3.3	29.3 ± 13.8		
125	82.3 ± 5.6	94.0 ± 1.4	12.2 ± 6.5		

Mean values with different letter represent significant difference at P<0.05 significance level.

Effect on damselfly and dragonfly nymphs

The effect of different concentrations of *C. nardus* whole- plant n-hexane extract on damselfly and dragonfly nymphs has been shown in *Table 3*. Up to 500 ppm concentration, the *C. nardus* whole- plant n-hexane extract caused no mortality of damselfly or dragonfly nymphs. Only at 1000 ppm concentration, the extract caused 3.3 ± 1.6 % mortality of nymphs of each species, therefore table was not arranged for showing the effect of plant extract on non-target organisms. There also occurred no mortality in nymphs of control group.

Table 3. *Effect of C. nardus whole plant n-hexane extract on non-target damselfly (Ischnura elegans) and dragonfly (S. decoloratum) nymphs*

Concentration (ppm)	*I. elegans*	*S. decoloratum*
1000	3.3±1.6	3.3±1.6
500	0	0
250	0	0
125	0	0
Control	0	0

Effect on freshwater fish

Grass carp fish, *Ctenopharingodon idella*, were exposed to 2040, 5007 and 5996 ppm concentration of *C. ambrosioides*, *C. botrys* and *C. nardus* whole- plant n-hexane extracts, respectively. The behavior and mortality of fish in each aquarium was checked for 24 hours. The extracts did not cause mortality in fish for 24 hours period of exposure.

Effect of plant extract on rabbit

During the present research, the effect of oral administration of high dose of *C. nardus* whole- plant n-hexane extract on the normal levels of some biochemical parameters i.e.,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49154931

ALT, AST, ALP and creatinine and hematological parameters i.e., RBCs, WBCs and platelets count, and hemoglobin concentration, of male domestic rabbits (*Oryctolagus cuniculus*) were studied. Each extract was orally administered to rabbit group (four rabbits in a group) at a dose of 1000 mg per Kg body weight per oral. There occurred no significant change in the serum level of ALT, AST, ALP and creatinine of extract treated rabbit group when compared to control rabbit group (P>0.05) (*Table 4*). Similarly, there occurred no significant change in the RBCs, WBCs and platelets count and hemoglobin concentration of extract treated rabbit group when compared to control rabbit group (P>0.05) (*Table 5*). The photomicrographs of liver and kidney microsections of extract treated rabbit groups showed normal histoarchitectures (*Figure 5*).

Table 4. *Effect of larvicidal extracts (n-hexane extracts) of three whole- plant on some biochemical parameters of normal rabbits. N=4*

Plants	ALT (U/L)	AST (U/L)	ALP (U/L)	Creatinine mg/dl
C. nardus	47.3±4.4[a]	47.8±8.9[a]	116.6±24.3[a]	0.5±0.2[a]

Discussion

During the present research, the n-hexane extract of *C. nardus* whole- plant showed oviposition deterrent activity against *Cx. quinquefasciatus* mosquito. During the oviposition deterrent activity, most of the gravid female *Cx. quinquefasciatus* mosquitoes preferred to lay eggs in the control container or in the container that contain extract solution of lower concentration (*Table 1*). The extract solution of highest concentration was least preferred by the gravid female mosquitoes for oviposition. The oviposition deterrent activity was expressed in percentage of effective repellency (ER %) and oviposition activity indices (OAI). Extract solution of highest concentration (1000 ppm) showed high ER % whereas the extract solution of lowest concentration (31.2 ppm) showed low ER % (*Figure 4*). The oviposition activity index (OAI) of the gravid female *Cx. quinquefasciatus* at each tested concentration of extract was estimated (*Table 1*). Negative OAI value was observed at each tested concentration of plant extract. The negative OAIs values indicated that the n-hexane extracts of *C. nardus* whole- plant is oviposition deterrent (Govindarajan et al., 2011). Lowest OAI value (-0.5 ± 0.1) was exhibited by highest concentration (1000 ppm) of extract solution. The oviposition deterrent activity of some plants against mosquitoes has been reported. For example, Reegan et al. (2015) reported that all the tested concentration of n-hexane extract of *Limonia acidissima* cause 100 % ER against *Cx. quinquefasciatus* and *Ae. aegypti*. Elimam et al. (2009) studied the oviposition deterrent activity of aqueous leaves extract of *Calotropis procera* against gravid female *Anopheles arabiensis* and *Cx. quinquefasciatus*. All the tested concentrations (1000, 500 and 200 ppm) caused more than 95 % ER against *An. arabiensis* and *Cx. quinquefasciatus*. In the reported study of Elango et al. (2009), the OAI values of acetone, ethyl acetate, and methanol extracts of *Aegle marmelos*, *Andrographis lineata* and *Cocculus hirsutus* against *Anopheles subpictus* at 500 ppm were -0.86, -0.87, -0.90 -0.78, -0.87, -0.86, -0.91, -0.94, and -0.86 respectively. Prathibha et al. (2014) studied the OAI value of *Eugenia jambolana*, *Solidago canadensis*, *Euodia ridleyi* and *Spilanthes mauritiana* against *Ae. aegypti*, *An. stephensi* and *Cx. quinquefasciatus.* The OAI value of *E. jambolana*, *S. canadensis*, *E. ridleyi* and *S. mauritiana* at 100 ppm against *Cx. quinquefasciatus* were −0.81, −0.84, −1.0 and −1.0, respectively. The oviposition deterrent effect of the plant extract may be due to the changes induced in the physiology and behavior of the adult mosquito species reflected by their egg-laying capacity (Prathibha et al., 2014). Some phytochemicals act as growth regulators or chemosterilent while some produce olfactory stimuli acting as repellent or attractant (Prathibha et al., 2014). Rajkumar and Jebasan (2009) reported that the plant extarcts that exhibited appreciable insect repellency were oviposition deterrent. Similarly, Mehra and Hiradhar (2002) reported that those plant extracts showed appreciable oviposition deterrent activity which were insect repellent.

During the present research, the n-hexane extract of *C. nardus* whole- plant showed adult emergence inhibition activity against *Cx. quinquefasciatus* mosquito (*Table 2*). During this study, maximum emergence of adults occurred in the control containers (>90 %). Emergence of adults was restricted in those containers which were containing extract solutions. The percentage of adult emergence inhibition (EI %) increased with increasing the concentration of extract solution. The EI_{50} value of *C. nardus* whole-plant n-hexane extract was EI_{50}=515.2 ppm. The biological activity of the plant extract might be due to the presence of various bioactive phytocompounds, including phenolics, terpenoids, and alkaloids, existing in plants, may jointly or independently contribute to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49154931

produce adult emergence inhibition activity (Arivoli and Tennyson, 2011). The plant extracts have the potential to inhibit the growth of various developmental stages during the life historey of mosquitoes (Arivoli and Tennyson, 2011). Plant extracts have the potential to delay larval development, extend pupal duration, inhibit moulting, cause morphological abnormalities and mortality during moulting and melanization processes in mosquitoes (Shaalan et al., 2005). The adult emergence inhibition activity of some plants such as *Abutilon indicum* (Arivoli and Tennyson, 2011), *Aegle marmelos*, *Andrographis lineata*, *Andrographis paniculata*, *Cocculus hirsutus*, *Eclipta prostrate* and *Tagetes erecta* (Elango et al., 2012), *Azadirachta indica* (Howard et al., 2009), *Eucalyptus citriodora* (Singh et al., 2007) and *Balanites aegyptiaca* (Wiesman and Chapagain, 2006) has been reported against mosquitoes.

During the present study, the effect of *C. nardus* whole-plant n-hexane extract on non-target insects i.e., damselfly and dragonfly nymphs, fish i.e., grass carp and mammal such as rabbits was also studied. During the study of effect of extract on non-target insects i.e., damsel and dragonfly nymphs, the extract caused no mortality of any nymphs up to 500 ppm. However, at 1000 ppm concentration, the plant extract caused some mortality (5 %) of the nymphs (*Table 3*). This concentration of *C. nardus* whole-plant n-hexane extract caused 71.9 % effective repellence during oviposition deterrent activity and 66.2 ± 19.5 % inhibition during adult emergence inhibition activity against *Cx. quinquefasciatus*. These findings showed that *C. nardus* whole plant n-hexane extract is efficient ovipositor deterrent and adult emergence inhibitor against mosquitoes but least toxic for non-target insects such as damselfly and dragonfly nymphs.

During the study of effect of extracts on non-target grass carp fish (*Ctenopharingodon idella*), the extracts did not cause mortality in fish for 24 hours exposure. Few such studies have been reported in which the effect of plant extracts has also been studied on non-target organisms. For example, Chowdhury et al. (2009) studied the larvicidal activity of *Solanum villosum* leaves against *Anopheles subpictus* with effect on non-target *Chironomus circumdatus* larvae. The extract was found safe for the non-target *C. circumdatus* larvae. Adhikari et al. (2012) studied the repellent and larvicidal activities of *Swietenia mahagoni* against the *Cx. quinquefasciatus* larvae. They also studied the effect of the same extract on some non-target aquatic organisms i.e., *Gambusia affinis*, tadpole of *Bufo* and *Chironomus* larvae. They observed no toxicity of plant extract in these non-target organisms.

During the study on non-target mammals, the effects of oral administration of high dose of extract on some biochemical parameters i.e., ALT, AST, ALP and creatinine (*Table 4*) and some hematological parameters i.e., RBCs, WBCs and platelets count, and hemoglobin concentration (*Table 5*) were studied in domestic rabbit. There occurred no mortality and found no significant change in the biochemical and hematological parameters of rabbits. Photomicrographs of microtome sections of liver and kidney of extract treated rabbit groups showed normal histoarchitecture (*Figure 5*). Carvalho et al. (2003) reported the larvicidal efficacy of the essential oil from *Lippia sidoides* against *Aedes aegypti*. In addition, they also studied the toxicity of the essential oil in mice. They injected intraperitonially the diluted and pure form of hydrolate in amount of 30 ml per kg body weight into the mice. The injection did not cause any adverse effects or mortality. The results of the present study revealed that *C. ambrosioides*, *C. botrys* and *C. nardus* whole- plant n-hexane extracts exhibit strong mosquitocidal activities but have no apparent deleterious effect on mammals (rabbit).

Conclusion and Recommendations

1.) From the findings of the present research, it was concluded that the n-hexane extract of *C. nardus* whole-plant possesses oviposition deterrent and adult emergence inhibition activities against *Cx. quinquefasciatus*. Further studies are recommended for elucidating the oviposition deterrent and adult emergence inhibition activities of *C. nardus* whole-plant n-hexane extract against a wide range of mosquito species and exploring active compound responsible for such activities.

2.) It was also concluded that the n-hexane extract of *C. nardus* whole plant is least toxic to non-target insects i.e., damselfly and dragonfly nymphs. There occurs no mortality or behavioural abnormality in fish i.e., grass carp when exposed to high concentration of *C. nardus* whole-plant n-hexane extract. The ingestion of *C. nardus* whole-plant n-hexane extract do not cause mortality or alteration in the biochemical and haematological parameters of rabbits. The findings of our research encourage the use of botanical insecticides for mosquito control because they are ecofriendly and safe for non-target organisms.

Abstract. *Ocotea quixos* (Lam.) Kosterm. (Ishpingo) is a tree that grows in humid tropical forests in South America (310-1200 masl). It is used for food and medicine, since it possesses essential oils with antiplatelet and antithrombotic properties, among others. In Ecuador, the wild populations of Ishpingo have been reduced ecosystem transformation, deforestation and clonal cultivation. This study compared the genetic variability of three regions of chloroplast DNA (i.e., matK, rbcLa and psbA-trnH) and one nuclear region (i.e., ITS) in Ishpingo from 5 provinces of the Ecuadorian Amazon. Based on the obtained alignments, the phylogeny was performed by using the maximum likelihood criterion with a bootstrap of 1000 replicates and with the Jukes-Cantor correction. The genetic variability was determined using the DNA conservation coefficient and the Nei (π) nucleotide variability coefficient. The nucleotide variability of matK, rbcLa and psbA-trnH regions was low ($\pi \leq 0.005$) due to their high conservation degrees. The ITS region presented a superior variability ($\pi = 0.11$) by grouping the samples that were analyzed into two clades. The regions that were analyzed were not useful for the study of genetic variability in Ishpingo. Therefore, it is recommended that new chloroplast and nuclear DNA regions be analyzed to allow studies on the population genetics of this species in Ecuador to be carried out.
Keywords: *Ocotea, chloroplast, DNA, Amazonia, genetic variability*

Introduction

Ocotea quixos (Lam.) Kosterm. (Ishpingo, Ishpink or Canela Amazónica), is a perennial tree that reaches a height of 2 to 25 m (Cazorla, 2013; Palacios, 2016). It is distributed in the humid tropical forests of the Amazonian region of Colombia, Ecuador, Peru and Brazil (310-1200 masl) (Cárdenas et al., 2015).

In 2007, *Ocotea quixos* was banned from commercialization for six months due to the significant reduction from wild populations (Grijalva et al., 2012). In the Ministerial Agreement No. 167, published in the official Register No. 18 on February 8, 2007, it was reported that the main causes of the population reduction of *Ocotea quixos* are the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49334948

expansion of the road network, the transformation of ecosystems, deforestation and the clonal cultivars of the species (Ministerio del Ambiente de Ecuador, 2010).

The lack of genetic studies on the *Ocotea quixos* populations of Ecuador suggests that the genetic variability of Ishpingo may be declining. The objective of this study is to compare the genetic variability of the three regions of chloroplast DNA (i.e., MatK, rbcLa, psbA-trnH)) and a region of nuclear DNA (i.e., ITS) in *Ocotea quixos* to establish possible regions for future population genetics studies on Ishpingo.

Materials and methods

Botanical samples and the 38 foliar tissue samples of Ishpingo (*Ocotea quixos*) species were collected. The samples were obtained from 11 locations in 5 provinces of the Ecuadorian Amazon, where Ishpingo is traditionally cultivated. Botanical specimens were morphologically identified with the help the herbarium of Pontificia Universidad Católica del Ecuador.

Prewashes were performed according to the division protocol of polyphenols and polysaccharides as proposed by Porebski et al. (1997). After washing, Doyle and Doyle's simple foliar DNA extraction protocol (1987) was performed. To determine the presence of the DNA, a horizontal electrophoresis was performed in agarose gel at 1%.

The chloroplast DNA regions (i.e., matK, rbcLa, psbA-trnH) and the nuclear ITS region, defined for the Barcode system, were amplified by specific primers (*Table 1*).

Table 1. *Primers for the amplification of DNA regions*

Primers	Sequence (5'->3')	Reference

matK-3FKIM (R)	CGTACAGTACTTTTGTGTTTACGAG	Lahaye et al. (2008)
rbcLa (F)	ATGTCACCACAAACAGAGACTAAAGC	CBOL Plant Working Group et al. (2009)
rbcLa (R)	GTAAAATCAAGTCCACCRCG	Levin et al. (2003)
psbA (F)	GTTATGCATGAACGTAATGCTC	Kress and Erickson (2007)
trnH (R)	CGCGCATGGTGGATTCACAAATCC	Kress and Erickson (2007)
ITS leu1 (F)	GTCCACTGAACCTTATCATTTAG	Bolson et al. (2015)
ITS 4 (R)	TCCTCCGCTTATTGATATGC	White et al. (1990)

The sequencing and purification of the samples were carried out at the company Macrogen (South Korea) using Sanger's simple sequencing method.

The sequencing analysis was carried out using the MEGA7 program. The MUSCLE algorithm was used to align the sequences, maximum likelihood trees were used for the phylogeny, and the Bootstrap method was performed with 1000 replications. The substitutions that were assessed were nucleotides, and Jukes-Cantor's substitution model (Jukes and Cantor, 1969) was used. The trees were rooted following the criteria of external groups or "outgroups", using the species Ocotea veraguensis and Ocotea porosa. The genetic variability was analyzed with the conservation coefficient, and Nei's variability nucleotide coefficient was determined by the "estimation analysis of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49334948

diversity with the specific data model" (Nei and Li, 1979) and was estimated with Tamura-Nei's model (Tamura et al., 2013).

Results and discussion

The DNA of 35 samples was obtained (*Fig. 1*) once the washings were done. The DNA obtained had no signs of degradation and was pollution-free; the band obtained corresponded to the expected size: > 2000 pb with a concentration of approximately 40-100 ng/µL.

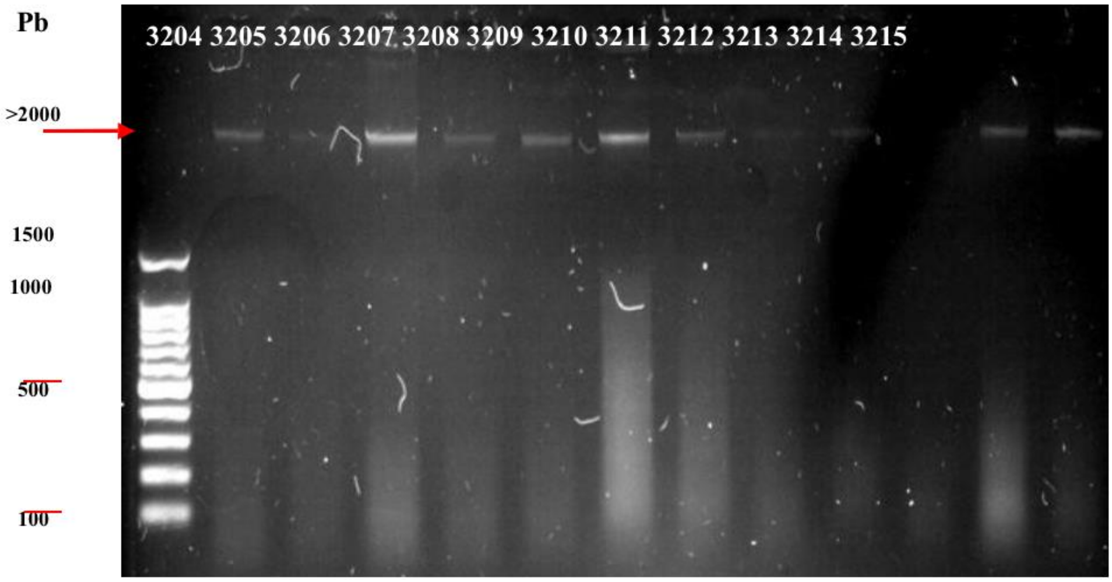

Figure 1. *DNA extraction with previous washings following the protocol of Porebski et al. (1997), and the simple extraction protocol of foliar DNA by Doyle and Doyle (1987), agarose gel at 1%. (Note: First molecular marker, samples 3204-3215 (+), sample 3213 (-))*

Out of the 35 sequences of the ITS region obtained, 28 consensus sequences were achieved. The average length of the sequence was 777 pb.

The region presented 428 polymorphic areas, a conservation region coefficient of 0.298 and a nucleotide variability coefficient of 0.1137. ITS presents a low conservation rate due to the great length variability of the sequence, and its incomplete concerted evolution led to the presence of divergent homologous copies within the samples (China Plant BOL Group et al., 2011).

The phylogenetic tree of the ITS region presented two clades; the samples grouped in the first clade were associated with the *Ocotea quixos* control sequence, and in the second clade, a polyphyletic grouping was observed with a branch support of 100% (*Fig. 2*). The presence of two clades may be because ITS has higher discrimination levels and interspecific variability followed by Gao et al. (2010); however, new studies have proven that there are several limitations associated with the ITS region, especially in phylogenetic inference (Gardes and Bruns, 1993), such as in the existence of extensive variations in genome sequences, which are determined by the formation events of duplications, the genomic accommodation of pseudogenes and an incomplete homogenization arrangement). These phenomena create relationships of paralog

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49334948

sequences that potentially confuse the accuracy of phylogenetic reconstruction. Homoplasy is higher in ITS than in other DNA regions due to the orthologous/paralogs confusion, compensatory change in bases, problems in alignment due to the accumulation of deletions, and errors in the sequence (Grudinski et al., 2014). Despite being a quasi-universal sequence used in plants for phylogenetic studies, its complex and unpredictable evolutionary behaviour reduces its usefulness in phylogenetic analyses. The use of single-copy nuclear genes is suggested by Alvarez and Wendel (2003).

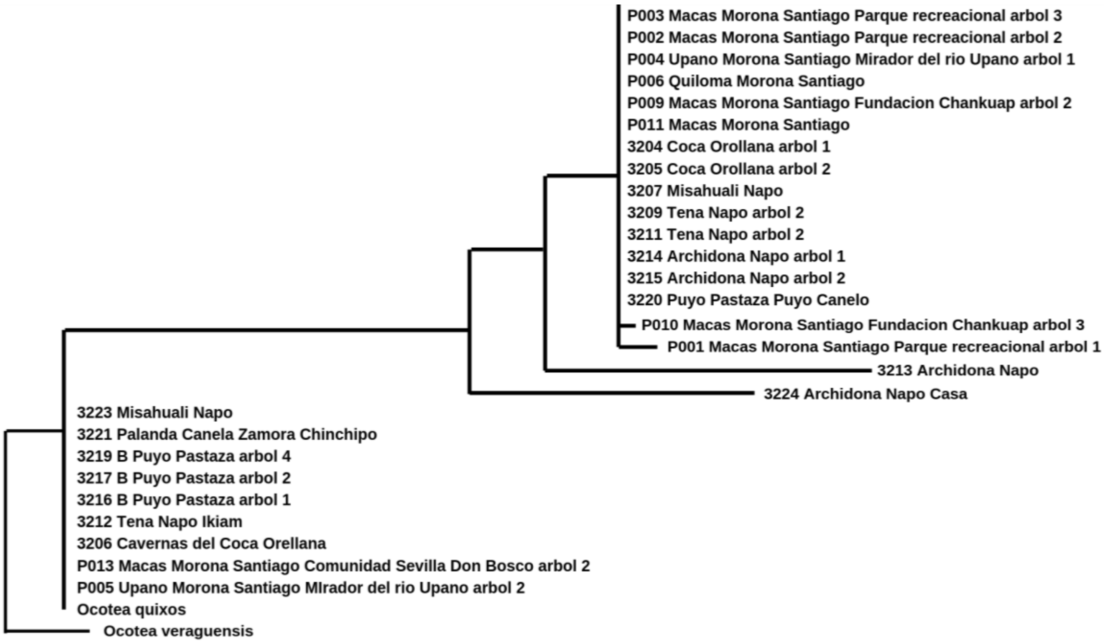

Figure 2. *Maximum likelihood tree ITS region. (Note: A defined clade and a grouped clade can be observed with the O. quixos sequence obtained from GenBank using the MEGA 7 program)*

Comparison of nucleotide variability among the regions matK, rbcLa, psbA-trnH and ITS: The psbA-trnH region has a variability coefficient of $\pi = 0.0051$ higher than those of the matK and rbcLa regions. This region has mononucleotide repetitions that increase its variability (Kress and Erickson, 2007). Despite this increase, the nucleotide variability coefficient is low <0.1, as mentioned by Jakobsson et al. (2013), and does not provide high nucleotide substitution rates due to its short length in the *Ocotea genus*, so its nucleotide variability is low (Liu et al., 2012).

The ITS region presented the highest variability coefficient ($\pi = 0.1137$) among the four regions. One of the main reasons for this increase in the genetic variability is due to the homology problem of the sequences that this region has; i.e., the appearance of divergent copies in the samples, which can lead to an increase in the genetic variability, stated by Hollingsworth (2011) and Hollingsworth et al. (2011).

Conclusions

DNA regions matK, rbcLa and psbA-trnH in *Ocotea quixos* are preserved (nucleotide variation coefficient $\pi \leq 0.005$) for the study of genetic variability in this

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49334948

population. The ITS region had highest substitution rates in nucleotides ($\pi = 0.1137$) in the sequences of the *Ocotea quixos*. This variability is associated with the amount of inscriptions in the DNA sequence that increase the nucleotide variability. The genetic variability coefficient obtained in the DNA regions of *Ocotea quixos* was low ($\pi = 0$-0.1137), which suggests that the genetic variability of the species is threatened by deforestation and the cultivation of clones.

Considering our study findings, we highly recommend to continue our research in order to establish possible regions for future population genetics studies on Ishpingo.

(Received 8th Nov 2018; accepted 5th Mar 2019)

Abstract. The Province of Pichincha, Ecuador is home to the calderas and flanks of the Pasochoa volcano, where the Pasochoa Wildlife Refuge (RVSP for its Spanish acronym) is located. This area is one of the few places that conserves some of the most important remnants of the Andean native forest. This study seeks to determine the biodiversity and water quality of the Pasochoa Wildlife Refuge by studying its aquatic macroinvertebrates. The data for this work were obtained from five sampling points located between the caldera and outside the RVSP. This effort was carried out along the stream that descends from the Pasochoa volcano at an altitude of 3014 meters above sea level (masl) to 2667 masl. Water samples were also obtained for a physical-chemical analysis. Preliminarily, a total of 6149 invertebrates, corresponding to 3 phyla, 10 orders and 36 families, were captured as indicators of water quality. The most abundant phylum was Arthropoda, with 6130 individuals. Additionally, specimens of annelids and mollusks were recorded. The greatest abundance was recorded for the families of Elmidae (Coleoptera) and Leptoceridae (Trichoptera), with 2059 and 1071 individuals, respectively. According to the families that indicate water quality, it fluctuates between very good to regular in PMM-01, which is an area with anthropic influence.
Keywords: *environmental indicators, water quality, species richness, abundance, environmental quality*

Introduction

Modelling the environment and water resources are essential to improve and protect water quality (Eurie et al., 2015; Forio et al., 2016). Today, water monitoring has become particularly important due to the increasing human activity that often leads to water quality deterioration (Yillia et al., 2008; Holguin-Gonzalez et al., 2013; Kibena et al., 2014). Selecting the right indicators for monitoring has become essential and often the most challenging task of environmental studies and applied conservation science (Game et al., 2016). We have chosen macroinvertebrates for determining water quality considering that they are well-known indicators in environmental monitoring and assessment worldwide (Forio et al., 2016).

The Pasochoa Wildlife Refuge (RVSP) is located in the caldera and in the flanks of the Pasochoa volcano, in the province of Pichincha, Ecuador. This area is one of the few places that conserves some of the most important remnants of the Andean native forest.

According to our bibliographic review, quantitative-type floristic investigations have been carried out within the protected area, such as those by Valencia and Jorgensen (1992), while other studies have consisted of rapid sampling where physical backups are not available. In terms of fauna, bird lists have been compiled by Sierra (1996), and the baseline list was recorded by Fundación Natura (1990). Studies referring to both terrestrial and aquatic insects are practically nonexistent for the sector. According to the map of vegetal coverage by the MAE (2013), the vegetal formation is a high-altitude evergreen mountain forest in the northern part of the Eastern Cordillera of the Andes. Its altitude range is from 3000 to 3700 masl, and the grassland of the moors ranges from 3400 to 4300 masl. The area has an average annual rainfall of 1200 mm, an average annual temperature of 10°C and a relative humidity that is almost higher than 80% (Valencia and Jørgensen, 1992).

In this study, aquatic macroinvertebrates were used as indicators of environmental quality. Aquatic macroinvertebrates have received much attention in studies regarding the ecosystems of running waters because they are transformers and integrators of allochthonous organic matter (leaves, seeds, branches, fallen trunks, etc.), the main inflows of energy to the fluvial systems and useful biological indicators.

Materials and methods

The Pasochoa Wildlife Refuge is located in the Province of Pichincha, Cantón Mejía, in the parish of Uyumbicho, Ecuador. It contains 520 hectares, which are covered mostly by Andean forest and, to a lesser extent, by herbaceous moorland. For the sampling points, the area of the caldera was prioritized because it is a pristine area, has been conserved and contains remnants of a mature forest. The second sampling point corresponded to the area outside the wildlife refuge where anthropic influence exists due to the presence of livestock and pastures. Then, the two areas were compared and evaluated. The data for this work were obtained from five sampling points along the stream that descends from the Pasochoa volcano from an altitude of 3014 to 2667 masl. The sampling points can be seen in *Figure 1* (López-López and Sedeño-Díaz, 2014).

The macroinvertebrates were collected through a “Surber” network in five sampling points (*Fig. 1*) along a 100 m-long transect according to the proposal of Roldán (2003) (Brito and Pinto, 2014). At each sampling point, we examined the riverbed of each body of water for a lapse of one minute to capture the existing macroinvertebrates, covering all possible microhabitats (riparian vegetation, sandy areas, rocky areas and algae). In addition, the ecological quality protocols for Andean rivers that were proposed by Encalada et al. (2011) were applied (Damanik-Ambarita, 2016; Carter, 2017; Mariadoss and Abril, 2015).

The samples were cleaned to later extract the macroinvertebrates and deposit them in correctly labeled plastic containers with 70% alcohol. Field work was executed following the rules and regulatory guidelines outlined by the Environment Ministry’s research permit.

To determine aquatic invertebrates, which were deposited in the aforementioned containers, the specimens were separated and identified at the family taxonomic level according to the protocols proposed by Encalada et al. (2011). To identify the

DOI: http://dx.doi.org/10.15666/aeer/1702_49494956

invertebrates, we used the taxonomic keys of Fernández and Dominguez (2009). The invertebrate collections will be displayed in the Gustavo Orcés Natural History Museum at the Escuela Politécnica Nacional, under patent No. 04-2014-FAU- DPAP-MA (Knowl, 2016; Stancheva and Seath, 2016).

The analyses related to the abundance, diversity, and species accumulation curves were performed according to Colwell (2006) and Oksanen, 2015 using the EstimateS 8.2.0 programs and PAST (Paleontological Statistics version 1.12) according to Hammer et al. (2003).

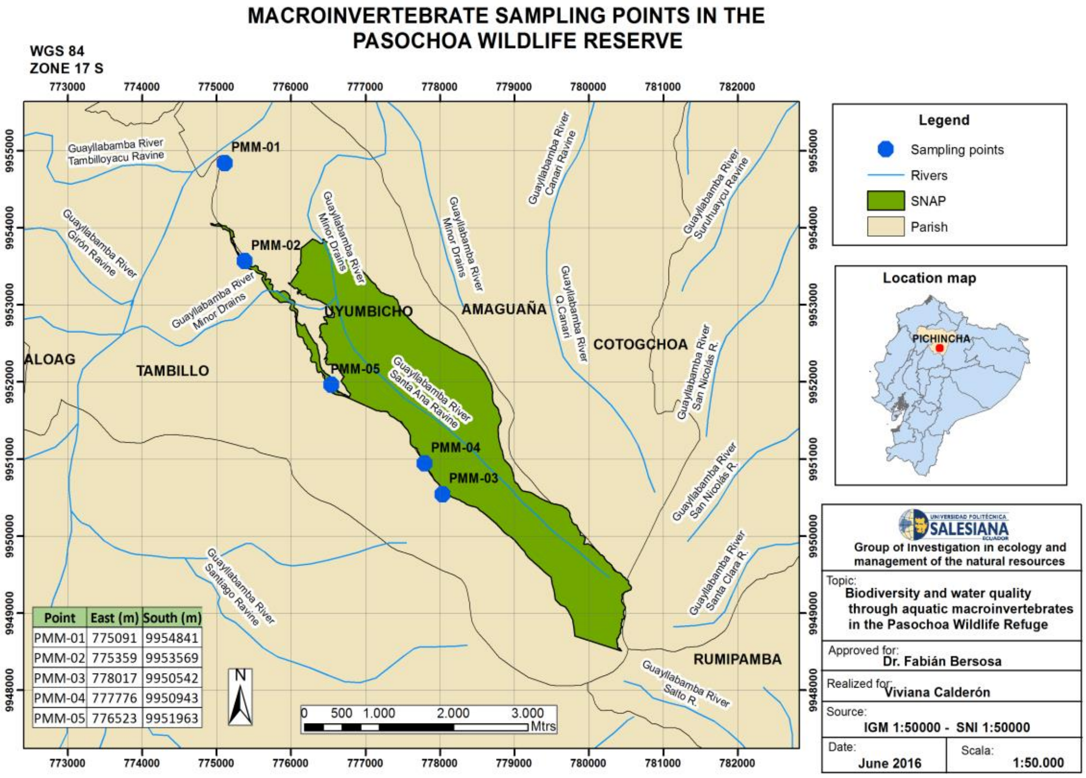

Figure 1. *Sampling points for macroinvertebrates in the Pasochoa Wildlife Reserve. "PPM-01" = Point 1; "PPM-02" = Point 2; "PPM-03" = Point 3; "PPM-04" = Point 4; "PPM-05" = Point 5; "Este" = East; "Sur" = South. Legends: "Puntos de muestro" = Sampling point, marked with blue dots; "Ríos" = Rivers, marked with green line; "Parroquias" = Parishes*

The analyzed parameters were divided into two groups. The first group is related to finding out the level of intromission of human effluents, such as gray and black waters, discharges from tourism or agriculture, and so on. Here, we measured the 5-day dissolved oxygen, Biochemical Oxygen Demand (BOD5), phosphorus, ammonia, nitrate and nitrite, the last three of which are indicators of pollution temporality (Cheeme, 2018). The second group of indicators focused on change in water quality due to human or natural causes. The indicators used were pH, calcium hardness, turbidity and total solids. The presence of calcium hardness, increased BOD5 and decreased dissolved oxygen could be the result of diffuse soil contamination from fertilizers (Schahrakane, 2018).

Results

A total of 6149 invertebrates were captured, corresponding to 3 phyla, 10 orders and 36 families, that indicate the water quality. The most abundant phylum was Arthropoda, with 6130 specimens. Additionally, specimens of annelids and mollusks were recorded (*Table 1*).

The greatest abundance was recorded in the families of Elmidae (Coleoptera) and Leptoceridae (Trichoptera), with 2059 and 1071 individuals, respectively. The greatest abundance was recorded in Point 5.

The determination of the quality of water in the sector by means of physical chemical parameters has not been done previously, but as regards the diversity in the present study, 3 phyla, 10 orders and 36 families were found in front of the study by Gallegos, 2013, which mentions 4, 13 and 34 respectively

Low values of dissolved oxygen were observed for all points, which are not due to temperature but to the existence of an organic load from three thousand meters high. This is corroborated by the BOD5 measurements that are accentuated in Point 4, where it reached 36 mg/l. With these levels of dissolved oxygen, fish cannot exist. From Point 2 onwards, there is a continuous presence of ammonia, which causes the depletion of dissolved oxygen and an increase in the nitrogen-bearing BOD5, which is oxidized slowly into nitrate and quickly into nitrite.

The increase in BOD5 and calcium hardness and the decrease in dissolved oxygen demonstrate the diffused intrusion of runoff water from crops with agrofertilizers.

The pH is basic, probably due to the type of riverbed in the upper part of the volcano, which decreases downstream. Turbidity increases as the water descends; the same is true for solids in the water, probably because of erosion and an increase in the organic load.

Current water quality does not present levels of eutrophication, but its decontamination is required for the water habitable by fish, and safe for human use. The results of the analyses, location and distance between the points are presented in *Table 2*.

Conclusions and recommendations

Values of BOD5 vary between 0.9-36 mgL^{-1} in our study that are comparable to other study (Naciph, 2016) findings (BOD5 vary between 5-40 mgL^{-1}) where San Pedro River was analysed. It is reassuring that the diversity and abundance values in our study are significantly higher than the values in Naciph's study where the same method (Encalada et al., 2011) was applied for specimens separation and for family taxonomic level identification. In our study 36 families were detected, while in Naciph's study only 12. This is due to the sad fact that San Pedro River is highly contaminated (FONAG, 2011) and can not be used for irrigation without pre-treatment (Naciph, 2016).

To aid reader understanding in the topic our preliminary study should be extended to other study areas, such as the lower part of the volcano, where areas of influence, such as cattle, urbanisation and plantations, exist.

According to the families that indicate the quality of water, the water quality fluctuates between very good to regular in Point 2, which is an area with anthropic influence. The current water quality does not present levels of eutrophication, but decontamination is required for the water to be safely used by humans.

Abstract. The paramo is a high mountain ecosystem with cold and humid climate, it has high amount of sunlight and cloudiness, furthermore, organic matter has low decomposition rates, hence, leaf litter degradation gets 40% per year as maximum. In the last 70 years, the air temperature near the surface of the Tropical Andes has increased significantly up to 0.34 °C/decade. In the same region, it is estimated that in this century the average temperature will vary from <+ 1.60 °C to >+ 2.61 °C, which exceeds the threshold of natural climatic variability. On the other hand, although precipitation along the Andes has not shown an increase or diminish pattern between 1955 and 1994, it is projected that by the year 2100, it will decrease in the outer tropics and will increase in the interior tropics. In this paper, we discuss how the decomposition of organic matter in paramo areas is influenced by climate change and analyze how current trends of variation in temperature are projected to affect ecosystem processes. Previous studies have determined that the increase of the atmospheric temperature (as long as the humidity remains stable or increases), generates higher decomposition rates, so that an increase of 1 °C in the atmospheric temperature would also mean an increase in the rate of decomposition of up to 10%. These changes would cause the release of the carbon accumulated in the soil to the atmosphere as CO_2, which would be a determining factor for climate change.
Keywords: *CO_2, global warming, greenhouse gases, organic matter, temperature*

Introduction

The paramo is a high mountain ecosystem in the humid tropic, it is located in the Andes, the Afroalpine zone, Indonesia and Papua New Guinea (Buytaert et al., 2011). This ecosystem has a cold and humid climate, with high amount of sunlight and cloudiness, its temperature gets an anual average of 10 °C at 3000 m a.s.l. and reaches 0 °C at 4600 m a.s.l. (Llambí et al., 2013). Climate conditions in this region are variable, so that, the daily thermal amplitude ranges between 10 and 15 °C in the air and in clear days it reaches 50 °C in the soil surface (Llambí et al., 2013), while precipitation ranges between 700 mm to 3000 mm/year (Llambí et al., 2013). Despite climate conditions, there is a high biological diversity and endemism, approximately 3400 species of vascular plants inhabit the paramo of South America and 60% are endemic (Luteyn, 1999; Rangel Churio, 2000).

Paramo is considered as a carbon sink, it can store a higher quantity of carbon per hectare than tropical forests (Hofstede et al., 2014). It accumulates between 119 and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49574970

397 tons per hectare (t/ha) in 0 to 40 cm depth, (Castañeda–Martín and Montes–Pulido, 2017) meanwhile bofedales show an approximate accumulation of carbon of 30 kg m² (Segnini et al., 2010).

In addition to carbon storage in mineral soils, there is also accumulation of organic matter in peat bogs (Hofstede et al., 2014). In the north of Ecuador, it was estimated the average organic matter quantity in two peat bogs is 1282 t/ha (Hribljan et al., 2016), with an accumulation of 4.6 t/ha/year (Chimner and Karberg, 2008). Moreover, paramo vegetation contributes with fresh organic matter to soil, which means about 6 to 13 t/ha/year (Escobedo–Urquizo, 1980).

On the other hand, despite the importance of paramo through supplying environmental services such as water provision, climate regulation and carbon accumulation in soil), it is one of the more vulnerable terrestrial ecosystems to global climate change (Buytaert et al., 2011; Ruiz et al., 2008). It is found within alpine life zones that are highly sensitive to climate change because its distribution has been closely related to temperature and precipitation patterns (Cuesta et al., 2017). Likewise, if high mountain ecosystems lose humidity and the annual average temperature gets higher, it would cause an increasing conversion of organic matter into atmospheric carbon, which would favor climate change conditions (Buytaert et al., 2011; Jones et al., 2005).

In the same way, an increasing environmental temperature would augment the evaporation and evapotranspiration, altering the precipitation patterns (Arnell, 1999), which could cause a deficit in water supply to populations that depend directly on water from the paramo, like Quito and Bogotá (Buytaert et al., 2011).

In the Tropical Andes region, environmental temperature has shown an increasing trend of 0.11 °C/decade from 1939 to 1998 and 0.34 °C/decade from 1974 to 1998 (Buytaert et al., 2014). Regarding precipitation, changes have not been significant in all the region (Vuille et al., 2003). Nevertheless, records from weather stations indicate higher precipitation levels for Ecuador, but lower levels Peru and Bolivia (Buytaert et al., 2014).

The aim of this paper is to comprehensively review the state of knowledge of decomposition and climate change in paramo ecosystems to understand the consequences on ecological processes, and to obtain ideas to develop strategies to mitigate the effects of climate change.

Decomposition and climate projections

Climate projections for the Andean Region show an increase in the average temperature up to 5 °C on the eastern flank of Ecuador and Peru (Herzog et al., 2012). Precipitation has a mixed pattern: increasing in the eastern and western flanks and decreasing in the inter Andean region up to 15% (Vuille et al., 2008; Urrutia, 2008; IPCC, 2013; Kirtman et al., 2013)

Predictions of global climate models and regional models for the Andean region have a high range of uncertainty due to lack of meteorological stations at altitudes above 3000 m a.s.l. (Buytaert et al., 2014). However, these projections are important to analyze the effects that climate change could have on the stability of ecosystems, environmental services and ecological processes (IPCC, 2007), especially because climate change has the capacity to alter physical and biological processes, threatening survival of endangered species (Carroll et al., 2015). For example, many studies have

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49574970

focused on assessing the influence of climate change on certain species, and some results suggest that climate change conditions could lead to changes in communities composition, populations declines, range shifts, changes in relative abundance and high extinction risks (Gillings et al., 2015; Bush et al., 2016; Wang et al., 2016; Dalamsuren et al., 2017; Pecl et al., 2017; Urban, 2015).

Decomposition comprises physical and chemical processes that allow the reduction of macromolecules into their essential components (Aerts, 1997) generating CO_2 and soluble forms of nutrients that can be recycled in plants and other organisms (Cronan, 2018). Most of the organic matter that is involved in this process in terrestrial ecosystems are derived from plants (leaf litter, stems, root exudates) (Carter et al., 2007), while influential factors are: weather, chemical composition of leaf litter and soil organisms (Coûteaux et al., 1995; Aerts, 1997, 2006).

Concerning climate, temperature and soil moisture (commonly referred to as climate decomposition index) have shown to be the best predictors of decomposition rates (Parton et al., 2007)), they can slow or accelerate organic matter decomposition (Davidson and Janssens, 2006; Coûteaux et al., 2002).

As shown, it is evident that decomposition is different in every ecosystem (Zhang et al., 2008; Djukic et al., 2018). This was verified by assessing decomposition rates in three regions of the planet: Tropical, Temperate and Mediterranean, the average values obtained per year were 2.33, 0.36, 0.35 respectively, showing that in humid tropics the decomposition rate is higher than in the temperate and Mediterranean zones (Aerts, 1997).

Regarding chemical composition of organic matter, leaf litter quality has a significant and predictable influence on the temperature sensitivity of organic matter decomposition (Fierer et al., 2005), besides, it is also important during decomposition phases due to its effects on humus formation (Coûteaux et al., 1995). Likewise, certain plant species have low decomposition rates compared to their high lignin content (Zhang et al., 2008) or presence of polyphenols that inhibit degradation (Hättenschwiler et al., 2005).

Although bacteria and fungi are the main decomposer organisms, macroinvertebrates also play a fundamental role, starting the process of litter crushing (Ulyshen, 2016). While more organisms participate in degrading organic matter, an increase in the rate of decomposition is generated (Smith and Bradford, 2003; Wall et al., 2008).

Given the sensitivity of decomposition to climatic conditions, it is understood that global warming will increase litter decomposition rates, through direct effects and through indirect effects on leaf litter quality and soil organisms (Aerts, 2006).

Organic matter decomposition in paramo ecosystems

Decomposition process in paramo ecosystems is mainly limited by atmospheric temperature that shows a high daily variation (temperature differences higher than 20 °C between night and day are common) (Hofstede et al., 2014). On the other hand, in paramo ecosystems with volcanic origins, an important factor is the presence of vesicles that organic matter generates with aluminum from volcanic ashes, turning into chemical complexes that are resistant to organisms degradation (Hofstede et al., 2003, 2014; Bottner et al., 2006).

As mentioned before, although bacteria communities are important for decomposition (Bottner et al., 2006; Pansu et al., 2004), invertebrates also play an

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49574970

important role in the disintegration of organic matter (Ulyshen, 2016), its diversity is associated with the presence of vegetation (Ewers et al., 2015) and, richness of soil fauna together with climate are associated with decomposition rates globally (Wall et al., 2008).

Concerning leaf litter quality, decomposition process in paramo do not depend on lignin concentration. As paramo vegetation is mainly composed by rosettes, cushions, shrubs and herbs (Ramsay and Oxley, 1997) it is not woody, then its lignin content would be low (Coûteaux et al., 1995). Nevertheless, some species contain aromatic resins that decrease the rate of decomposition (Smith, 1981).

Several studies have analyzed decomposition processes in High Andean ecosystems focusing research in: 1) the effect of human activities on decomposition (Jiang et al., 2015; Ossola et al., 2016; Urbina and Benavides, 2015), 2) influence of altitude in organic matter decomposition (Coûteaux et al., 2002; Röderstein et al., 2005) and 3) factors that influence on organic matter decomposition (Bottner et al., 2006; Pansu et al., 2004, 2007; Ibrahim et al., 2015; Martinez et al., 2007; Pinos et al., 2017).

Climate change and organic matter decomposition

It is expected that in this century, the increasing CO_2 concentrations and other greenhouse gases in Earths atmosphere cause warmer surface temperatures and changes in precipitation patterns (IPCC, 2013). These environmental changes could affect the carbon cycle, modifying the function and ecosystem services (Dukes et al., 2005).

In order to determine the influence of climate change on ecosystems, models have been generated to simulate the response of the decomposition process to climate change, which have made it possible to determine that an increasing atmospheric temperature will produce a decrease of 54 gigatons (Gt) in the global carbon stock of the soil for 2100 (Jones et al., 2005).

In addition, some studies have shown the influence of climate change on the decomposition process, so that, it was determined that the increase in soil temperature accelerates the decomposition process in Arctic soils (Robinson et al., 1995), while in other study, researchers determined that the decomposition process is limited by moisture in the xeric zones and in the mesic zone it is determined by temperature (Shaw and Harte, 2001). On the other hand, a research using experimental microcosms, determined that the change of climatic conditions in a short term (from days to decades) strongly influences the decomposition process of litter (Strickland et al., 2015).

Climate change and organic matter decomposition in Andean paramos

In the Tropical Andes, atmospheric temperature near surface has increased significantly in the last 70 years (Vuille et al., 2008). A regression analysis with ordinary least squares indicates a warming of 0.10 °C/decade and a general temperature increase of 0.68 °C since 1939 (Vuille et al., 2008). Furthermore, it is suggested that in this century, in a scenario with a balanced use of fossil fuels and energies of non–fossil origin (scenario of A1B emissions), the temperature for Tropical Andes region will probably vary from <+ 1.60 °C to >+ 2.61 °C, exceeding the threshold of natural climatic variability (+ 1.78 °C) (Ruiz–Carrascal et al., 2017).

In the case of precipitation, there are no reports of increasing or decreasing patterns at a regional levels between 1955 and 1994 (Vuille et al., 2003). For the period 2071–2100 in a scenario of A1 emissions (rapid economic growth at global level, a maximum

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49574970

of the worlds population by the middle of the century and a rapid introduction of new and more efficient technologies) precipitation along the Andes would present a mixed pattern of increase and decrease that goes from –50 to 250% (Urrutia, 2008). In general terms, it is projected that for the second half of the 20th century, rainfall will decrease in the outer tropics and increase in the interior tropics (Urrutia, 2008; Vuille et al., 2008).

According climatic projections for the Andean Region (10°–20°S) (Herzog et al., 2012), with a high population growth (scenario of A2 emissions), an increase in average temperature and precipitation would occur by the end of the 21st century, for example, on the western flank of the northern Peru, the increase in rainfall would be up to 70%, while in the Inter Andean region of Colombia a decrease of up to 15% will occur; and an increase of 5 °C of temperature is projected in the eastern flank of Ecuador and Peru (Herzog et al., 2012).

In the Fifth Report of the Intergovernmental Panel on Climate Change (IPCC) results of projections for an immediate climate change (Period 2016–2035 regarding 1986–2005 in RCP4.5 scenario comparable with B1) in the Andean Region suggest an increase in temperature of up to 1.5 and an increase in precipitation of up to 10% (IPCC, 2013; Kirtman et al., 2013).

An eventual change in the temperature and humidity of the paramo soil would lead to a modification in decomposition processes. It is necessary to consider that high Andean ecosystems would be more sensitive than the humid tropical forest in conditions of increasing temperature, with a trend to increase the rate of decomposition, therefore carbon sink ecosystemic services would be affected. In addition, it is important to mention that it is unknown how microbial communities would participate in different climate change scenarios (Hofstede et al., 2014).

While preparing this document, a considerable amount of information about the impact of climate change on soil and biodiversity was found. However, in the few investigations found about the effect of climate change on the decomposition process in the paramo (*Appendix 2*), it was determined that the increase in atmospheric temperature accelerates decomposition rates.

Climate change in the Andean Region will increase decomposition and mineralization rates up to 10% (Salinas et al., 2011). In situ studies through an altitudinal gradient, have allowed to project the changes of climatic conditions, being able to determine that the decomposition rate in the Andean paramo will be influenced by an increase in the air temperature (Espín Meneses, 2012). Furthermore, even if atmospheric temperature increases, when humidity decreases, decomposition rate decreases too, it happens not only due to its direct incidence on degradation process but also because it alters abundance and richness of decomposing organisms (Looby and Treseder, 2018).

Conclusions

Despite the importance of decomposition process in the functioning of ecosystems and although since 1939 there have been alarming reports of a general increase in temperature of 0.68 °C for Tropical Andes region, there are few studies about the influence of climate change on decomposition in paramo areas, in other words, knowledge about this issue is currently scarce.

Decomposition process at biomes scale is controlled by climate, then climate change can directly affect the functioning of ecosystems. Studies about this issue mention that

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49574970

the rate of decomposition increases with higher temperatures (only when humidity is maintained or increased), then an increase of 1 °C in atmospheric temperature could cause the decomposition rate to increase by up to 10%.

Projections suggest that in this century, paramo areas will have constant humidity and increasing temperatures exceeding 2 °C. According to this climate scenario, the rate of decomposition would increase, causing the carbon accumulated in the organic matter of the soil to be emitted back into the atmosphere

Exploring studies about the effect of climate change in decomposition rates in paramo ecosystems is still a challenge, we need to conduct experimental research in order to understand how ecological processes work in this ecosystem. Generating knowledge will provide people new ideas to mitigate effects of climate change for present and future scenarios.

APPENDIX

Appendix 1. *Studies about decomposition process in paramo ecosystems*

Authors	Year	Title	Conclusions	Decomposition %
Hofstede	1995	The effects of grazing and burning on soil and plant nutrient concentrations in Colombian paramo grasslands.	There is greater decomposition in sites with high affectation by grazing and burning than in sites without disturbances.	In areas without disturbance, litter loss is up to 11.3 ± 4.64% per year. While in areas exposed to livestock and fire, the decomposition rate is 34.3 ± 8.03% per year.
Chapela et al.	2001	Ectomycorrhizal fungi introduced with exotic pine plantations induce soil carbon depletion.	Paramo soil with Pinus radiata plantations contain less carbon than paramo grassland. It is caused by the introduction of ectomycorrhizas in the roots of the pines.	The soil of the pine plantations of 10 to 20 years, show 30% less C than soils of pasture paramos.
Coûteaux et al.	2002	Decomposition of standard plant material along an altitudinal transect (65–3968 m) in the tropical Andes.	Decomposition rates decrease along with decreasing temperatures (while altitude is higher).	Five altitudes were assessed: 95, 165, 780, 1800, 3400 y 3968 m a.s.l., carbon loss percentage in the first year was 78.7, 76.6, 67.5, 62.9, 40.4 and 42.8 respectively.
Sarmiento and Bottner	2002	Carbon and nitrogen dynamics in two soils with different fallow times in the high tropical Andes: indications for fertility restoration.	In an agricultural area of the Andean region above 3000 m a.s.l., decomposition of straw in a restored soil is significantly faster than in a degraded soil.	Soil carbon loss was expressed as the initial percentage of 14C added to the soil (mineralized). The percentage of mineralization of 14C after 12 weeks of incubation was 43.9% in the restored soil and 42.9% in the degraded soil.
Pansu et al.	2004	Comparison of five soil organic matter decomposition models using data from a 14C and 15N labeling field experiment.	The best model of organic matter decomposition of soil (MOMOS) uses kinetic constants: three entries of microbial biomass MB and two MB outputs mortality and respiration constants. This model significantly improved the predictive quality and robustness of MB-14C and -15N predictions.	In 720 days, 80% of 14C was lost in the analyzed samples. This decomposition percentage was obtained in the five models of soil organic matter decomposition.

DOI: http://dx.doi.org/10.15666/aeer/1702_49574970

Röderstein et al.	2005	Above-and below-ground litter production in three tropical montane forests in southern Ecuador.	Decrease in temperature while altitude increases, influence the carbon cycle of montane forests. The decrease in temperature along the slope affects decomposition.	The litter mass decreased to less than one third (862 to 263 g m^{-2} y^{-1}) with increasing altitudes (1890 m to 3060 m). While litter production of fine roots increased in an approximated factor of four (506 to 2084 g m^{-2} y^{-1}).
Bottner et al.	2006	Factors controlling decomposition of soil organic matter in fallow systems of the high tropical Andes: a field simulation approach using 14 C- and 15 N-labelled plant material.	The relation between C and N is determinant in decomposition. If the C:N relation in the plant material increases, the decomposition rate decreases and the mortality of the microbial biomass increases.	For N-rich plant material (N + treatment), the total of 14 C remaining at the end of the experiment was similar in the Gavidia paramo and in Puna de Patacamaya: 25% of the initial 14 C.
Pansu et al.	2007	Modelling the transformations and sequestration of soil organic matter in two contrasting ecosystems of the Andes.	The dynamics of 14C and 15N were very different in the two systems. In the puna, the transformation processes stop during the long dry periods, although the annual total mineralization is greater than in paramo.	In dry puna, the 66% of the 14C initially added was mineralized during the first wet season (first 120 days). Subsequently, the mineralization was almost paralyzed until the end of the dry season (on day 400), then 73% of the aggregate 14C was mineralized after the second wet season (on day 500) and 75% on day 690 after the first rain that followed the last long dry period. In humid paramo, only 42% of the 14C added was mineralized during the initial phase of the process, then mineralization progressed slowly, until approximately 65% of the 14C was mineralized after 1 year, and the 75% after 2 years.
Martinez et al.	2007	Succession pattern of carrion-feeding insects in Paramo, Colombia.	The succession of scavenger insects can be an indicator of the state of decomposition and the time elapsed after an organism death.	After 83 days, 83% of the initial weight of Sus scrofa corpse had been lost. Five stages of decomposition were identified with indicator species: Calliphora nigribasis in the fresh

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49574970

				stage; Compsomyiops verena in the swollen stage; Compsomyiops Bolivian during active decomposition; Stearibia nigriceps and Hydrotaea sp. during the advanced decay and Leptocera sp. for dry remains.
Garrido	2011	Study on radial growth, exchange and leaf decomposition of three Polylepis species (Rosaceae) in two locations of the Ecuadorian Andes.	There is a highly significant difference among species. Polylepis reticulata had the least decomposition, attributed to climatic conditions as soil moisture and temperature, since they are better predictors of decomposition than quality of its organic matter.	The global average for the remaining biomass percentage of leaf decomposition is 75.44%. P. reticulata shows a lower decomposition with a mean of 86.67 + 7.015% Standard deviation (D.E.), P. pattern shows an average of 75.809 + 12.183% D.E. and P. incana had a greater decomposition with an average of 63.83 + 16.467% D.E.
Ibrahim et al.	2015	Modelling carbon turnover through the microbial biomass in soil.	Comparison of predictions with collected data in the field showed that the model is capable of simulating transformations and movement (plant-soil-atmosphere) of the carbon depending on the parameters previously defined	The predictions of the model showed a higher microbial content of C and a higher microbial respiration activity in the wheat plots than in vean plots. The metabolic coefficient (mg CO^2/g MB C) after 9 months was 0.04 in wheat and 0.025 in bean.
Urbina and Benavides	2015	Simulated small scale disturbances increase decomposition rates and facilitates invasive species encroachment in a high elevation tropical Andean peatland.	Decomposition rate in soil surface (0-10 cm) triples in fertilized soils with physical disturbances in comparison with the control (soil without additions of foreign materials or physical disturbances).	Decomposition rate in the control was 0.09 ± 0.001 and in the plots with fertilized soils with physical disturbances was 0.25 ± 0.005.
Pinos et al.	2017	Leaf litterfall and decomposition of polylepis reticulata in the treeline of the Ecuadorian Andes.	Temperature was one of the main regulators for decomposition rates of litter. Humidity was not controlled, then it is not a limiting factor in decomposition.	Decomposition rate of litter of Polylepis reticulata was 0.38 ± 0.02 per year. The study was conducted in an altitudinal range of 3700 to 3900 m a.s.l.

Appendix 2. *Studies about the effect of climate change in decomposition process in paramo ecosystem*

Authors	Year	Title	Conclusions	Decomposition %
Salinas et al.	2011	The sensitivity of tropical leaf litter decomposition to temperature: results from a large-scale leaf translocation experiment along an elevation gradient in Peruvian forests.	When samples were grouped between species and elevations, soil temperature explained 95% of the variation in the rate of decomposition, but no direct relation with soil humidity or precipitation was observed.	Heating of 0.9 °C in the last decades could have increased decomposition and mineralization rates of nutrients by 10%.
Espín	2012	Altitudinal patterns of litter decomposition in two paramo localities with different climatic regimes.	Using an altitudinal gradient to outline possible in situ scenarios on climate change is valid. It is useful to determine that there is a strong relation between temperature and decomposition rate in the Andean paramo.	Decomposition rates of litter could increase up to 5% per year with every 1 °C additional average diurnal temperature.
Salcedo	2014	Effects of the increasing temperatures and fires on Mesofauna (Arthropods) of the Soil and the Decomposition of Litter in a paramo Ecosystem in the North of Ecuador.	In a cold ecosystem such as paramo, an increase in temperature could be expected to determine greater decomposition of litter; however, the results of the study showed an opposite pattern, perhaps as a result of a decrease, at least temporarily, in the moisture content of the ground.	Decomposition rate in the treatments that were heated with cameras (which increased the temperature between 0.89 °C and 2.06 °C in the day and between 0.66 °C and 0.86 °C at night) They were between 3 and 4% slower than treatments that were not heated with cameras. The treatment with the slowest decomposition was camera/burning (54.5% ± 1.38), while the highest decomposition was recorded in the plots with the control treatment (49.7% ± 1.2).
Looby and Treseder	2018	Shifts in soil fungi and extracellular enzyme activity with simulated climate change in a tropical montane cloud forest.	Fungi abundance and alpha diversity increased significantly with warmer temperatures and drier conditions. Concerning composition of fungal community, it showed a change with increasing temperatures	With a 4 °C increase and 20% of humidity decrease, fungal abundance and richness grew in 50%.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49574970

			($F = 4.31$, $R2 = 0.170$, $P < 0.001$) and decreasing humidity ($F = 4.30$, $R2 = 0.170$, $P < 0.001$). Alterations in the composition of the community was associated with changes in the richness of certain fungal phylum. There was a general increase in Ascomycota richness with warmer temperatures and drier conditions. While, the richness of Cryptomycota decreased in translocated soils to warmer and drier conditions.

Abstract. Honeybees are valuable pollinators strongly influencing ecosystem conservation, stability, genetic variation and ecological relationships in the floral diversity, plant community, evolution, and specialization. Honeybee is an excellent model organism for research on learning and memory among invertebrates. In their behavior, the subjective evaluation of a sucrose stimulus influences the behavioral performance. Here we report comparative behavioral data on the sensitization, habituation, short-term and long-term memory of *Apis cerana* and *A. mellifera* in China, using different sucrose concentrations. *A. mellifera* foragers have higher sucrose responsiveness than *A. cerana* foragers when tested using a proboscis extension response (PER) assay. Sensitization and habituation are well-known forms of non-associative learning. *A. cerana* took less number of habituation trials as compared to *A. mellifera*. Thus, these results significantly showed that *A. cerana* took less time to dishabituate. The sensitive stimuli of *A. cerana* against lemon extract were more than *A. mellifera*. In addition, although *A. mellifera* showed more sensitive stimuli against apple extract than *A. cerana cerana*, *A. mellifera* displayed significantly more learning and memory behavior than *A. cerana* after 2 and 24 hours.
Keywords: *olfactory learning, honeybee, proboscis extension response, odors, sensitization*

Introduction

In ecosystem functioning, diversity is a major and important component (Tilman et al., 2001; Duffy et al., 2007). Honey bees are key contributors and the best pollinator species in the world in natural ecosystems and functions (Ebeling et al., 2011). Species richness can stabilize and play an important role in ecosystem services, including pollination to environmental disturbance and variability pollination. Honeybees are crucial to ecosystems and environment, wild plant growth, wildlife habitats, and biodiversity as a pollinator and food source. The eastern honeybee (*Apis cerana*) is a species of honeybee found in southeastern and southern Asia, including China, Pakistan, Korea, Malaysia, Japan, Bangladesh, Nepal, Papua New Guinea, Australia Solomon Islands and India (Engel, 1999; Oldroyd and Wongsiri, 2009). The western honeybee or European honeybee (*Apis mellifera*) is the most common of the 7–12 species of honeybee worldwide. The genus name *Apis* is Latin for "bee", and *mellifera* is the Latin for "honey-bearing", referring to the species' production of honey. As the wasps come close to the honeybee nest (*Apis cerana cerana*), extra guard bees are alerted, which in turn increases their chance of being killed by heat-balling bees. Heat balling is a distinctive defense system in which several hundred bees surround the wasp in a tight ball and vibrate their muscles in an effort to produce heat and effectively kill the wasp inside. *Apis mellifera* colonies can reach sizes of up to 50,000 or more individuals, *Apis cerana* colonies are relatively small, with only around

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49714984

6,000 to 7,000 workers. *Apis cerana* is found predominantly in the Eastern Asian region of the world, while *Apis mellifera* is found predominantly in the Western European and African region of the world (Winston, 1991). *A. cerana* recruits threefold more guard bees to stave off predation than *A. mellifera*. Honeybees avoiding wasps' predation behavior, *A. cerana* can efficaciously escape from wasp's predation through changing flying behavior, but *Apis mellifera* cannot. *Apis cerana* has been recognized as a lower pathogen occurrence species versus *Apis mellifera*. Hygienic response (removing freeze killed brood and opening cell caps) of *Apis cerana* is faster and better than *Apis mellifera* (Lin et al., 2016). *A. cerana* visited more flowers and took greater time for completing a single foraging trip on apple bloom than *A. mellifera* (Ahmad et al., 2017). The honeybees must have to learn and memorize the color of flower, how to navigate, and what plants are rich food source. Learning and memory are basic and essential capabilities for dance communication and foraging behavior. Flowers shape, odor, and color are learned during foraging (Sandoz et al., 2002; Hooper et al., 2005; Haddad et al., 2011).

Most animal species are capable of discriminating between varieties of odors. This ability is usually crucial for the organization such as feeding, mating, and social communication, as well as for the processes of learning and memory that are associated with these behaviors (Leonard et al., 2011). Insects constitute successful models for the study of learning and memory due to their remarkable learning abilities (Menzel, 1999; Mizunami et al., 2004; Davis, 2005; Giurfa, 2007). Among insects, honey bees (*Apis mellifera*) are reported to have the highest and broadest range of learning abilities (Menzel, 1999; Giurfa et al., 2001; Giurfa, 2007; Sandoz, 2011; Giurfa and Sandoz, 2012). Honey bees are able to associate a food reward with different sensory stimuli such as odors, colors and visual patterns, tactile or thermal stimuli (Menzel, 1999; Giurfa, 2007). Both *A. mellifera* and *A. cerana* are kept in China, with about four million colonies and three million colonies, respectively (Hongliang, 2007). *A. cerana* colonies are mainly kept in mountainous locations, while *A. mellifera* colonies are usually transported across the country to follow the blooming of flowers (WANG et al., 2007). Honey bees (*A. mellifera*) are well known for their communication and orientation skills and for their impressive learning capability (Menzel and Giurfa, 2001; Menzel et al., 2006). Because the survival of a honeybee colony depends on the exploitation of food sources, forager bees learn and memorize variable flower sites as well as their profitability. Forager bees can be easily trained in natural settings where they forage at a feeding site and learn the related signals such as odor or color. Appetitive associative learning can also be studied under controlled conditions in the laboratory by conditioning the proboscis extension response (PER) of individually harnessed honey bees (Bitterman et al., 1983; Kesner and Olton, 2014).

The proboscis extension reflex is a classical behavioral trait used to determine the learning behavior of honeybees' response to odors. The PER is the behavior of a honey bee that extends her proboscis when a drop of sucrose solution at sufficient concentration is applied to the antennae (Pankiw and Page, 2003). However, studies on learning and memory of honeybees have mostly used harnessed individuals and olfactory learning protocols when the goal was to achieve full control of behavior by the experimenter. The most popular protocol used to this end is the olfactory conditioning of the PER, which is a case of classical conditioning (Takeda, 1961; Vareschi, 1971; Bitterman et al., 1983; Giurfa and Sandoz, 2012). The PER is a reflexive response of hungry bees which is part of their feeding behavior while foraging or within the hive (Frings and Frings, 1949). It occurs when the antennae, tarsi or mouthparts come in contact with sucrose solution; the bee then reflexively extends its proboscis (PER) to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49714984

reach the sucrose solution and drink it. Odors generally do not evoke the PER in bees naïve to the experimental conditions. During conditioning, an odor (CS) is presented in close temporal association with sucrose solution (US). At the end of training, the odor alone elicits the PER, indicating that the bee has learned the odor-sucrose association (Takeda, 1961; Bitterman et al., 1983). PER is usually recorded as a dichotomous response (1 or 0), which can thus be used as an index for learning and memory performances. The protocol of olfactory PER conditioning, first established by (Takeda, 1961) and was later standardized by (Bitterman et al., 1983).

Habituation and sensitization are two well-known forms of non-associative learning, which change the response probability of an animal towards a stimulus following repeated exposure to the same stimulus (habituation) or exposure to a strong yet different stimulus (sensitization). Habituation is a response decrement to a monotonously repeated stimulus (Braun and Bicker, 1992). While sensitization implies that a strong or particularly salient stimulus enhances the response of the bee to a test stimulus (Menzel, 1999). A honeybee extends its proboscis when its antennae are stimulated with a sucrose solution whose concentration exceeds its sucrose response threshold. When low-concentrated sucrose solutions are repeatedly applied to the antennae of a bee with a short interval between two stimulations ("inter-trial interval"), the proboscis extension response habituates (Braun and Bicker, 1992; Menzel., 1993; Scheiner et al., 2004). The bee no longer shows proboscis extension when its antennae are stimulated with this sucrose stimulus. Similar to habituation, the degree of sensitization depends on the gustatory responsiveness of the bee and the strength (i.e. the sucrose concentration) of the sensitizing stimulus (Menzel el al., 1993; Scheiner el al., 2004).

Sensitization can be easily tested in honeybees using an odorant and a sucrose stimulus. Most bees do not show spontaneous proboscis extension when their antennae are stimulated with an odorant such as carnation, citral or geraniol. When their antennae are briefly stimulated with a high-concentrated sucrose solution (30% or 50% for example) and with an odorant immediately afterward, the bees become sensitized to the odorant (Menzel et al., 1993; Hammer et al., 1994). Honey bees display proboscis extension in response to antennal stimulation with the odorant, which previously did not evoke a visible response. Note that sensitization to an odor is different from classical olfactory conditioning because: (1) it does not require repeated pairings of odor and sucrose solution, as well as (2) it only occurs up to two minutes after olfactory stimulation. For a century now, honeybee (*A. mellifera*) has been a key insect model in which behavioral, neuroanatomical, and neurophysiological approaches have been performed to unravel the basis of olfaction and olfactory learning. Honey bees are social insects which present a wide range of behaviors relying on olfaction both within and outside of the colony (Seeley, 1995).

The honey bee is well-known for its excellent associative learning capacities in a wide range of assays (Menzel and Müller, 1996; Menzel and Giurfa, 2001; Giurfa, 2007; Matsumoto et al., 2012). Both in the field and under the controlled conditions of a laboratory, bees reliably learn and remember odors, shapes and surface structures. Learning of colors is much more complicated under laboratory conditions (Gerber and Ullrich, 1999; Mota et al., 2011). Bees can be trained in classical and operant conditioning paradigms. In classical conditioning, honey bee learns to associate an originally neutral stimulus (conditioned stimulus, CS) with a biologically relevant stimulus (unconditioned stimulus, US), while in operant conditioning, a bee evaluates its own behavior and its consequences (Menzel, 2012).

DOI: http://dx.doi.org/10.15666/aeer/1702_49714984

Any study of memory must carefully separate the effect of storage and recall mechanisms (Spear et al., 1990). The results reported here indicate a complex relationship between olfactory storage and recall mechanisms in the honeybee. That is, what is recalled after memory consolidation (Erber et al., 1980) can be slightly different from the conditioning event, and a lack of a response does not necessarily imply forgetting (Spear et al., 1990). Associative learning is an essential component of the bee's central place foraging behavior and dance communication.

Materials and Methods

Insect

Experiments and observations were conducted with colonies of *Apis cerana* and *A. mellifera* from March to August 2017. Three colonies of each species (*A. cerana* and *A. mellifera*) were set up at an apiary of the College of bee science, Fujian Agriculture and Forestry University, Fuzhou, China. All colonies were queen right and housed in standard Lang troth hives.

Catching bees

A pyramid (height 24.5 cm, apex 3.5 cm × 3.5 cm, base 18 cm × 18 cm) made of UV-translucent Plexiglas was used to catch bees when they departed from the hive and flied toward the sky (*Fig. 1A*). The Plexiglas was UV-transparent; in order to offer a complete view of celestial cues and thus lure the departing bees into the pyramid, the pyramid was closable at the apex and at the base. For catching bees, the pyramid was held at a frontal distance of about 10–20 cm from the hive entrance, with the base open and the apex closed. Unexpected movements and standing directly in front of the hive entrance (instead of laterally) were avoided to prevent arousing guard bees. When enough bees were caught, the base was closed and the pyramid was taken to the laboratory. In the laboratory, the pyramid was darkened (except for its apex), for instance by placing a thick cloth over it. Because of their positive photo taxis behavior, bees then tended to leave the pyramid one by one through the apex. Honey bees were individually captured into glass vials. Vials were then placed in crushed ice as long as it is necessary to render the bees motionless (usually between 3 and 5 min) so that they were harnessed individually. Cooling time was kept to a minimum as extended cooling impair learning performances (Frost et al., 2011) and survival in the harness.

Harnessing bees

As soon as the bees ceased their movements, they were being placed in the harnessing tubes. Each bee was fixed within a tube using a piece of adhesive tape placed at the level of the neck, the rest of the body being concealed within the tube. Once fixed in the tube, the bee should only be able to freely move its mouthparts and antennae, thus hiding other body parts from possible contacts with sucrose stimulation. The forelegs of the bees, for instance, should not be able to move freely but should remain enclosed within the tube to avoid interference with olfactory and sucrose stimulation. Each harness tube should be numbered to allow individual identification of the bees throughout the experiment. A rack with numbered boreholes was useful for handling and identifying harnessed bees.

Sucrose concentration

Explicit control of the bee caste used for conditioning is recommended because foragers are the individuals that exhibit the highest appetitive motivation for sucrose within the hive (Scheiner et al., 2001) and they are, therefore, more appropriate for appetitive olfactory conditioning. Catching and harnessing the bees were conducted as described in section 2.2 and 2.3. Capture of bees departing from the hive in the morning or late afternoon (avoiding mid-day times when young bees performed their first orientation flights) enhanced the probability of obtaining empty foragers for experiments. Empty foragers (i.e. with empty crop) were necessary to ensure highest appetitive motivation for the experiments. After immobilization, the foragers were mounted in the holding tubes like other bees. One hour after mounting, responsiveness to sucrose was tested using the PER. Water and the following six sucrose concentrations were applied to the antennae of each bee: 0.1%, 0.3%, 1%, 3%, 10% and 30% (w/v). With each sucrose concentration, it was recorded whether proboscis extension occurred. The inter-trial interval was 2 min. The sum of the responses to water and the six sucrose concentrations represents the gustatory response score (GRS) of an individual and is a measure of its responsiveness to sucrose (Scheiner et al., 2004). Forager's bees were tested sequentially with the series of sugar solution, starting with the lowest concentration. Water was used between each sugar solution to reduce possible sensory

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49714984

sensitization to antennal touch (Pankiw et al., 2001). The PER was recorded as '1' if a bee extended her proboscis after both of her antennae were touched by a toothpick pre-soaked with a sucrose solution, and '0' if she did not respond. The responsiveness of 30 bees to each sucrose concentration was expressed as "percent of bees showing PER (%PER)" by dividing the number of bees that responded to sugar by the total number of tested bees. For example, if 5 bees out of 15 responded to 10% sugar solution, then the %PER for this concentration was 5/15= 33%. The %PER is a more refined response as compared to PER score because the PER score is a summed response across all the sugar concentrations. Three colonies of each species were measured for this experiment (with N = 3 × 2 × 30 =180 bees tested for both species) (Friedrich, 2004; Yang et al., 2013).

Habituation

Catching and harnessing the bees were conducted as described in section 2.2 and 2.3. All the bees were fed three drops of 30% sucrose solution and put in an incubator for one hour. Bees were stimulated five times with 30% sucrose to induce dishabituation. Habituation of PER was tested by repeated stimulation of an antenna (30% sucrose Solution) at an inter-stimulus interval of 1 s. The number of PER occurring before five consecutive response failures defines the habituation criterion (Braun and Bicker, 1992; Müller and Hildebrandt, 2002; Scheiner et al., 2004; Pirk et al., 2013).

Sensitization

Catching and harnessing the bees were conducted as described in section 2.2 and 2.3.use olfactory learning machine for lemon extract for 4 seconds. Two minutes after testing the initial responsiveness to a lemon odor stimulus, the honeybee was sensitized by antennal stimulation with sucrose (30% sucrose solution). After 20 s, the second odor apple stimulus was presented to test for sensitization (Iqbal and Mueller, 2007).

Learning and memory

Catching and harnessing the bees were conducted as described in section 2.2 and 2.3.A conditioning trial contained pairing an odor stimulus (apple extract) (conditioned stimulus, CS) with a sucrose reward (30% sucrose solution) (unconditioned stimulus, US). After the animals received three successive conditioning trials at an inter-trial interval of 2 min, memory tests were performed 2 h and 24 h after training.

Statistical analysis

The significance of the finding for the sucrose responsiveness experiment was tested by two-way ANOVA, two-way ANOVA comparison shows response of *Apis mellifera* and *Apis cerana* of different sucrose concentrations (Pérez Claudio et al., 2018; Afik et al., 2006). All observed scores of both groups were compared using a *t*-test or nonparametric equivalents. More than two groups were compared using analysis of variance (ANOVA) or nonparametric equivalents with respective post-hoc tests. Response frequencies were compared using Chi-square tests or multiple-measurement ANOVA (for further details see the BEEBOOK paper on statistical methods (Pirk et al., 2013). The entire data of learning and memory were analyzed through One-Way Analysis of Variance (ANOVA) and the means were compared by Tukey's test ($P \leq 0.05$) with the help of KyPlot™ v5.0 program (KyensLab Inc., 2017).

Results

Sucrose responsiveness in honey bee foragers

Apis mellifera showed significantly more proboscis extension response than *A. cerana* foragers (F=2.879, df=5 and P<=0.05). The mean proboscis extension response of *Apis mellifera* was significantly higher at 30% and 10% of sucrose respectively (*Fig. 1*). The lowest concentration causing proboscis extension was observed on *A. cerana* at 0.10% of sucrose (*Fig. 2*).

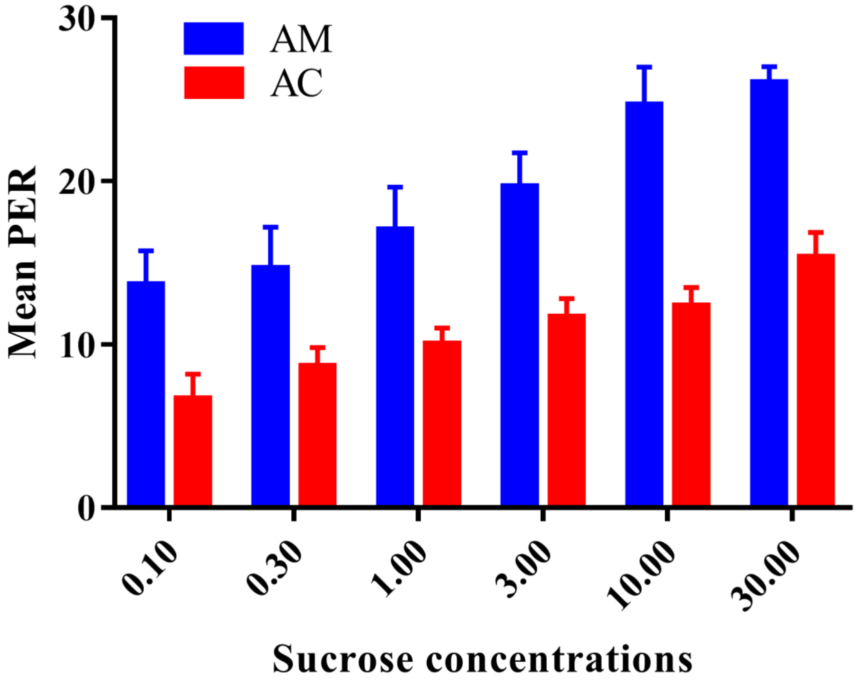

Figure 2. *Percentage of bees showing proboscis extension response (mean ± SE) of foragers of Apis mellifera and A. cerana across different sucrose concentrations. The following data based on three colonies of each species of honeybee. (N = 3 × 2 × 20 = 120 bees).N (total number of species), 3 (three colonies of each species), 2 (two species Apis cerana cerana, Apis mellifera L. were studied) and 20 (number of bees from each colony of both species)*

Habituation

Habituation represents the gradual decrease in responsiveness during a continuous series of repeated stimulations. When the bees were habituated, sucrose stimuli would no longer elicit PER. The habituation rate was assessed by counting the number of trials until no visible movement of the proboscis occurred in five subsequent trials (Braun and Bicker, 1992). *A. cerana* took less number of habituation trials as compared to *A. mellifera*. Thus, our results indicated that *A. cerana* took less time to dishabituate (*Fig. 3*). After A (1-20) and B (21-40), habituation trials 77.78% and 15.56% bees of *A. cerana* showed proboscis extension response respectively (*Fig. 3*).

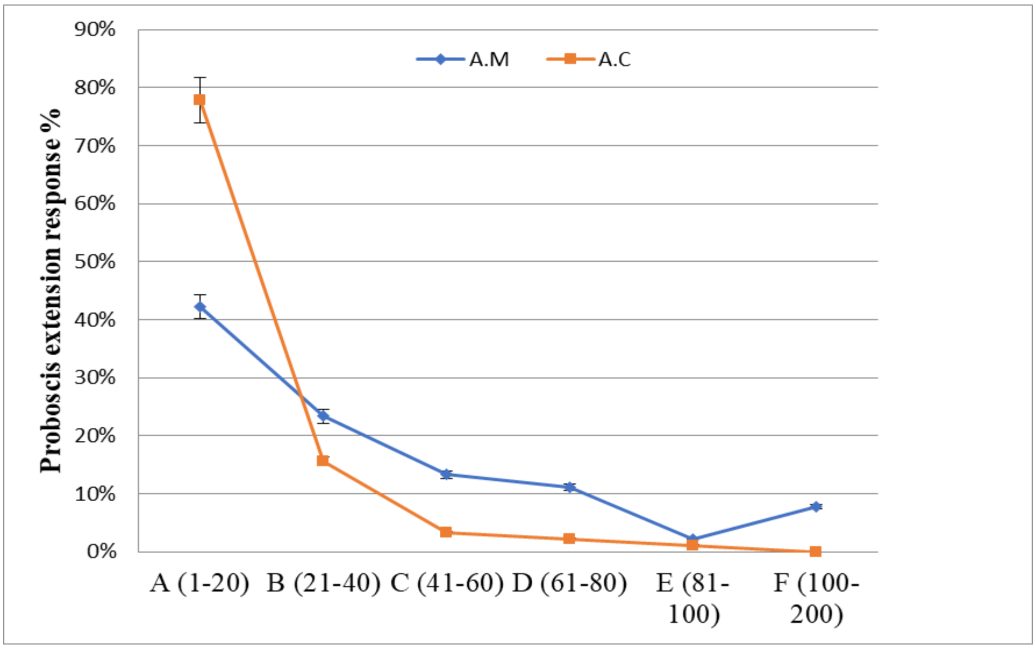

Figure 3. *Percentage of Apis cerana and A. mellifera responding to the appetitive stimulation during trials; (A) Habituation of PER (N=16); (B) Dishabituation of PER (N=10)*

Learning and memory

Apis mellifera showed significantly stronger learning and memory behavior than *A. cerana* after 2 h and 24 h (df=3, F=18.512821 and P<=0.05). The learning and memory behavior of *Apis mellifera* and *Apis cerana* after 2 h and 24 h was 62.22%, 27.28%, 51.11%, and 28%, respectively (*Fig. 4*).

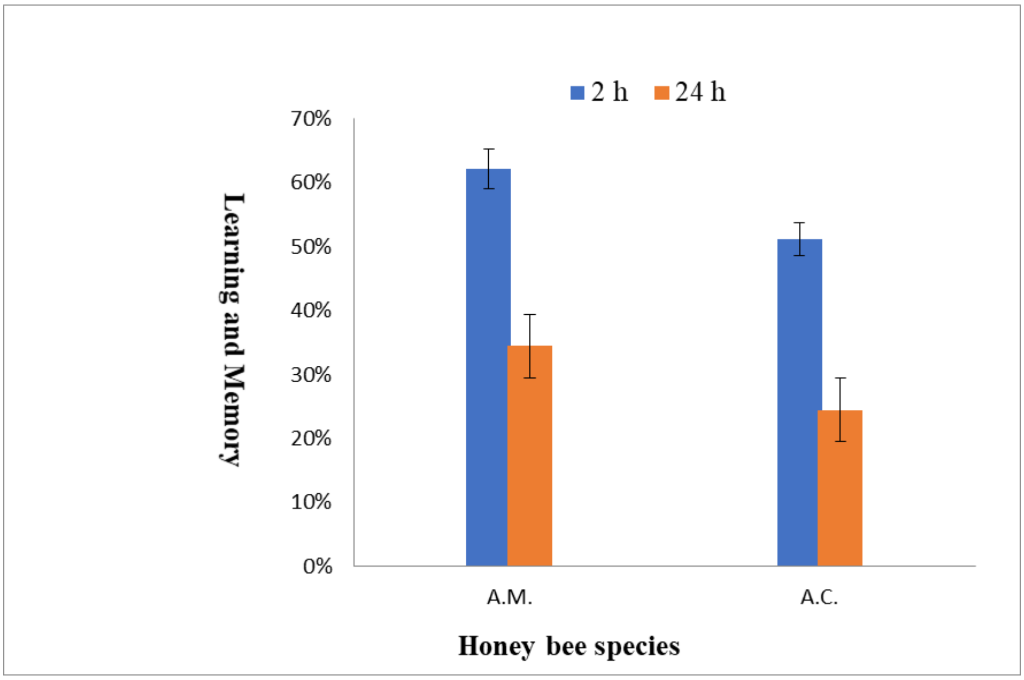

Figure 4. *Percentage of learning and memory (mean ± SE) of Apis mellifera and A. cerana after 2 h and 24 h treatment of 30% sucrose solution. The following data based on three colonies of each species of honeybee. (N = 3 × 2 × 2 0 = 120 bees)*

DOI: http://dx.doi.org/10.15666/aeer/1702_49714984

Sensitization

The sensitive stimuli of *A. cerana* against lemon extract were more than *A. mellifera* (F=18.512821, df= 2 and P>0.05 NS). The percentage of the sensitivity of *A. cerana* and *A. mellifera* was 29.31% and 4.44% against lemon extract, but *A. mellifera* were more sensitive against apple extract than *A. cerana*. For apple extract, the sensitive responses of *A. mellifera* and *A. cerana* were 11.63% and 2.13% (*Fig. 5*).

Discussions

Highly responsive bees respond to sucrose solution at concentrations as low as 0.1% or even to water, whereas unresponsive bees only respond to 30% of sucrose or higher sucrose concentrations (Scheiner et al., 2004). This study reported that sucrose responsiveness between two species *A. mellifera* and *A. cerana*. We demonstrated proboscis extension response (PER) percentage of foragers. These two honeybee species showed different response patterns at different sucrose concentrations when sucrose concentration was low then its proboscis extension response is also low. However, the results in this study indicated that *A. mellifera* foragers had significant higher proboscis extension percentage than *A. cerana* foragers at 30% sucrose. Our finding fits well and strongly agreed with previous studies (Scheiner et al., 2004; Yang et al., 2013). *A. mellifera* was more responsive than *A. cerana*. According to previous research work, *A. mellifera* foragers were more responsive to sucrose. Our conclusion showed that *Apis mellifera* has higher sucrose responsiveness than *Apis cerana*. The results of Yang et al. (2013) helped to confirm our conclusion.

Non-associative forms of learning change the behavior of an animal because of the exposure to a stimulus. If the response decreases as a result of repeated stimulation, the animal may have habituated rather than undergone motor fatigue or sensory adaptation (Carew, 1987; Menzel, 1999; Kandel et al., 2000). Habituation signifies the gradually diminish in responsiveness during a continuous series of frequent stimulations. In our

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49714984

finding *Apis cerana* took less time as compared to *Apis mellifera*. The proboscis extension reflex is an appetitive component of the bee's feeding behavior that is elicited by touching one antenna with a droplet of sugar water. Repetitive stimulation leads to a decrement and finally to the disappearance of the response. This experiment was designed to analyze the role of individual sucrose responsiveness in non-associative habituation and to study the effect of sucrose concentration used as habituating stimuli on non-associative habituation. A wide range of habituation patterns in Drosophila have been investigated, as well as the proboscis extension response, visual escape jump landing response (Braun and Bicker, 1992). Honeybee foragers must fly many kilometers - even more than 6-10 kilometers away - try to collect nectar and pollen. Therefore, they must learn and remember not only the shape and color of the flowers, as well as how to reach them. This experiment was designed to analyze the role of individual sucrose responsiveness in non-associative habituation and to study the effect of sucrose concentration used as habituating stimuli on non-associative habituation (Abramson, 1997;) Giurfa, 2007; Giurfa and Sandoz, 2012; Matsumoto et al., 2012). Memory was developed in a trial and time dependent way that indicates processes of memory formation that can be transmitted to particular areas of the honeybee brain and cellular and molecular processes. *Apis mellifera* showed significantly stronger learning and memory behavior than *A. cerena* after 2 h and 24 h. The finding of this study demonstrated that the percentage of learning and memory behavior of *Apis melliferra* was significantly higher than *Apis cerana* after 2h and 24h as a resulted by Chen (2001), Qin et al. (2012). This could be due to *Apis mellifera* strain introduced in China has been subjected to intensive artificial selection to be better manageable, while *Apis cerana* bees were managed well in a half wild condition. These two species of honeybees may have distinct responses to harnessing.

The findings of sensitization study clearly determine that the sensitive stimuli of *A. cerena* against lemon extract were more than *A. mellifera*, but *A. mellifera* were more sensitive against apple extract than *A. cerena*. In addition, the results of this study showed significant differences between *Apis Cerana* and *Apis mellifera* in response to lemon and apple extract as revealed by Chen (2001), *Apis cerana* has an excellent sense of smell than *Apis mellifera*. Introduced over 100 years ago, in majority regions of China, *Apis mellifera* is completely developed and adapted to nectar sources and climate. Despite that, to be sure those *Apis mellifera* bees are not adapted pretty well such as *Apis cerana*, whose homeland and region is here Qin et al. (2012).Individual sucrose responsiveness and the sucrose concentration used as reward strongly affect associative PER learning. In previous studies comparative behavioral data of color and grating learning and memory for *Apis cerana* and *Apis melliferra* in China. This study provides the first evidence of the learning and memory difference between *Apis cerana* and *Apis melliferra* under controlled conditions, and it is important for the further study of the mechanisms of learning and memory in honeybees (Giurfa et al., 2001). Yang (2009) described that the niche between *A.cerana* and *A.mellifera* is overlap among *Apis cerana* and *Apis mellifera*; both of these species have their own characteristic to diminish competition in food. *Apis cerana* is able to collect sporadic nectar flowers, while *Apis mellifera* takes advantage of large flower fields. *Apis cerana* meets the significantly lower selectivity pressure to learn how odors and rewards are associated. This may be possible reasons why *Apis cerana* did poorer performance than *Apis mellifera*. After the achievement, there was no distinction in the memory retaining of different odors between these both sibling species. Both species distinguished between experienced scent and un-experienced scent. These findings are consistent with earlier odor learning and odor discrimination studies in bees (Bitterman et al., 1983).We still

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49714984

cannot exclude the possibility that rather unspecific parameters could have also influenced our experiments. For example, the two species may have had distinct abilities to adapt to the confined test conditions or may have required different amounts of food in order to achieve satiation meaning that the reward value of the sucrose solution could be different for each species. *Apis cerana* had lower PER scores than *A. mellifera* in the first three trials of the acquisition phase, suggesting that it was a slow learner. Which may attribute to the reasons that the strain of *A. mellifera* introduced in China had been subjected to intense artificial selection to be more docile. While the *Apis cerana* we utilized were managed in a half-wild situation. Thus, these two bee species could have different reactions to harnessing.

We suggested that *Apis Cerana* could be investigated by applying classic olfactory PER protocol. Moreover, further work is necessary to reveal the physiology of the olfactory learning method based on this cognitive research.

Conclusion and future

The most significant and our overall finding show that *Apis mellifera* foragers are able to store reward information and have better learning and memory versus *Apis cerana cerana*. But these experiments were first and basic step to understanding the learning, memory and behavior of both species. Various experiment and studies need to explore on different aspects of learning and memory for example different age bees, use of different odor, different kind of behavior, level of brain biogenic amines, and protein synthesis and gene expression in different age bees.

(Received 1st Dec 2018; accepted 12th Feb 2019)

Abstract. Water consumption is increasing at an alarming rate all over the world. Iran is currently facing high water stress as a consequence of mismanagement. The aim of this study is to evaluate the agricultural ground and surface water footprints in the Tehran province of Iran in order to establish agricultural ground and surface water scarcity indices. Blue and green water footprints were evaluated based on the water footprint method. The volume at which ground and surface water is generated was obtained via fieldwork and GIS (Geographic Information System) data for the first time. In addition, an indicator for evaluating the agricultural ground and surface water scarcity index was established. The total groundwater footprint for the production of crops in Tehran was half of the total water footprint in 2014-2015. The results showed very high agricultural groundwater stress and moderate surface water stress. Groundwater abstraction for the agricultural sector was more unsustainable than surface water. Besides, agricultural ground and surface water scarcity indices are more suitable than existing indicators because they disclose environmental impact of crops production and help stakeholders to assess groundwater and surface water management policies. The agricultural water footprint should be reduced to sustain agricultural water consumption in Tehran.
Keywords: *agricultural water footprint, water management, CROPWAT model, GIS data, water scarcity*

Introduction

Freshwater as an essential resource for humans and the ecosystem should be considered a mandatory requirement for sustainable development (Chenoweth, 2008). Agriculture is the sector with the highest water consumption in the world (Rijsberman, 2006). The use of freshwater resources for agricultural activity contributes to the reduction in water availability for other users (Rijsberman, 2004). Iran is facing severe water scarcity, lack of precipitation, population growth and mismanagement, as well as inefficient water use in the agricultural sector (Madani, 2014). Moreover, per capita water consumption was 7 m^3 in 1956 but later decreased to 2.160 m^3 in 1996, which further dropped to 1.900 m^3 in 2006 (Zehtabian et al., 2010). Agricultural activity is responsible for more than 92% of freshwater consumption (Zehtabian et al., 2010). Moreover, the number of drying lakes and rivers is increasing in Iran. For instance, the Zaiyanderoad and Oromeyeh lakes have dried in recent years (Madani, 2005; Fathian et al., 2014). Besides that, the groundwater level in Iran is dramatically declining as a consequence of decreasing rainfall and water mismanagement (Khaki et al., 2018). The rate of reduction in groundwater level in Iran from 2002 to 2012 was -0.89 cm/year (Khaki et al., 2018). Groundwater in arid climates is mostly used for the irrigation of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49854997

crops (Zektser and Everett, 2004). It is documented that groundwater is identified as a crucial natural resource in most countries due to low probability of pollution, uniform distribution, good quality, and not being affected by evaporation (Zektser and Everett, 2004). Besides that, increasing groundwater demand and inappropriate groundwater management create concerns for groundwater shortages and over-exploitation of this limited water resource (Gleeson et al., 2012). Most water management methods are interlinked with surface water and there is a lack of attention to groundwater management, resulting in an increase in water depletion (Gleeson et al., 2012). Unsustainable groundwater abstraction is evident in many regions (Umar, 2004). The agricultural sector is responsible for more than 70% of freshwater abstraction and 90% of consumptive water use in the world (Fiedler and Zhang, 2009). Thus, it is essential to know the type of water source for irrigation in order to know the anthropogenic impact on water resources (Burke, 2002). Recently, due to the rapid reduction in groundwater level, identifying the type of blue water (the volume of irrigation (Hoekstra et al., 2011)) resource is regarded as an important topic in terms of interest (Siebert et al., 2010). It is claimed that groundwater for irrigation accounts for 43% of total water consumption on the global scale (Siebert et al., 2010).

In the past decades, many studies have investigated water scarcity indicators to evaluate water scarcity and contribute water management methods. The Falkenmark indicator is based on water resources available per person at a national scale. It is described as a ratio of the total water availability for human needs. A water scarcity index (WSI) lower than 500 shows that the area is a water scarcity area (Falkenmark and Lundqvist, 1998). In the Smakhtin water scarcity method (2004), water scarcity is modified via considering environmental water requirement in the water stress formula. WSI equals to the amount of water extraction divided by available water quantity after taking away the environmental water requirement on an annual scale (Smakhtin et al., 2004). Water scarcity is defined as a function of water availability to the population (Rijsberman, 2004). Moreover, physical water stress areas are arid areas with dense populations such as Central Asia, West Asia, and North America, with accessibility to less than 1000 m^3 per capita per year (Rijsberman, 2004). Ma et al. (2015) investigated water stress as a fraction of total water footprint to water availability (Ma et al., 2015). Zeng provided a simple method to evaluate water stresses in different regions. This index is a component of quantity and quality of blue and green water (the volume of rainwater (Hoekstra et al., 2011; Zeng et al., 2013). Raskin index is based on water use per resource (WUPR), which is a suitable index for evaluating environmental impact on aquatic ecosystems (Raskin et al., 1996). Hoekstra evaluated monthly water stress at a global scale. Blue water stress is described as a fraction of blue water footprint to blue water availability after subtracting the environmental flow requirement (Hoekstra et al., 2012). Available water quantity is the amount of water in internal resources plus the amount of entering from outside resources in river basin (Liu et al., 2017). Moreover, Variability of monthly blue water scarcity evaluated at river basin scale by Zhuo et al. (2016, 2019). Green water stress equals to the amount of green water footprint divided by available green water quantity (Veettil and Mishra, 2016). Besides, in the Pfister method, a monthly water stress index is introduced, which is the ratio of water consumption to the modified water availability. This is the square root of the variation factor (Pfister and Bayer, 2014). Xinchun evaluated water stress in the agricultural sector using total water footprint. Water stress in the agricultural sector is found using

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49854997

green, blue, and grey water footprints. Water stress is defined as the ratio of total water footprint in the agricultural sector to total water availability (Xinchun et al., 2017).

On top of those methods, different dimensions of water stress indexes should be considered to provide more information about water stress. There is a lack of attention on separately evaluating blue water stress as groundwater and surface water scarcity. In this study, ground and surface water footprints are assessed separately to evaluate surface and groundwater stresses in the agricultural sector. Besides, Groundwater and surface water footprint were evaluated in the water footprint method in one category as blue water footprint, while in this study, these kinds of waters were evaluated separately as groundwater footprint and surface water footprint.

The objective of this study is to evaluate the agricultural ground and surface water footprints in the Tehran province in order to establish agricultural ground and surface water scarcity indices.

This study yields useful information for managing and achieving sustainable ground and surface water consumption. Moreover, When WF was accounted with the water scarcity index, it could produce an effective investigation result for water management and decision makers by providing them with useful knowledge (White, 2015).

Materials and methods

Study area

The Tehran province is situated in the north of the central plateau of Iran with a population of more than 12 million people (approximately 18% of the Iranian population) (Statistical Center of Iran) and situated in 35.724842° N, 51.381653° E. The southern part of the province has a semiarid climate but the northern part experiences a mountain climate. The province covers an area of 18,909 km^2. *Figure 1* shows the average monthly precipitation and average monthly temperature during 2007–2015 obtained from the Mehrabad weather station (IMO, Iran Meteorological Organization). The Jajrud and Karaj rivers are the largest rivers in the Tehran province. Around 60% of water withdrawal in Tehran is abstracted from groundwater including wells, springs and qanats (Ministry of Energy in Tehran).

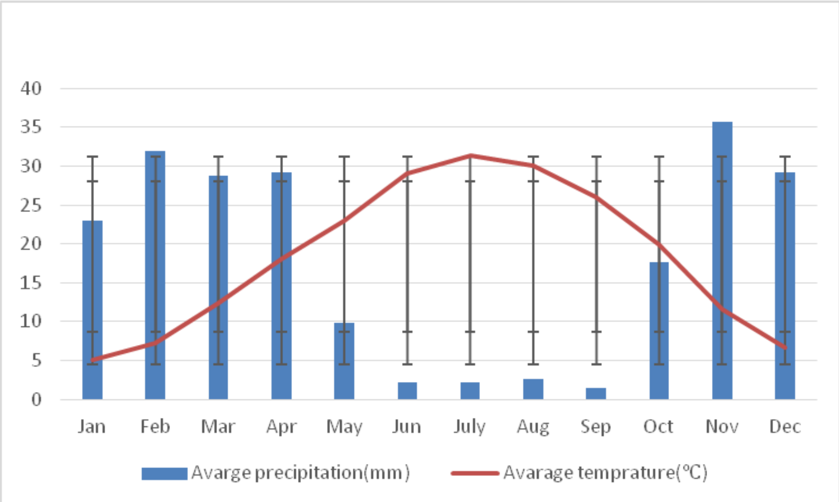

Figure 1. *The plot of average temperature and average precipitation with related standard deviation (2007-2015)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49854997

Data

Climate data were obtained from the Mehrabad Weather Station (Iran Meteorological Organization, 2018). The data for crop yield were obtained from the Ministry of Agriculture, Jahad, in Tehran (IMAJ, Iran's Ministry of Agriculture Jihad, 2018). Crop parameter data (KC [crop coefficient], day of crop growth, depth of root, critical depletion, yield response, and crop height) were obtained from OPTIWAT (Optimization Water use in agriculture) software (Alizadeh and Kamali, 2009), which is local databases for Iran. The volume of production by ground and surface water were obtained using field work and GIS data (*Fig. 2*) (obtained from the Ministry of Energy in Tehran). The ground and surface water use and availability were obtained from the Ministry of Energy in Tehran (*Fig. 3*).

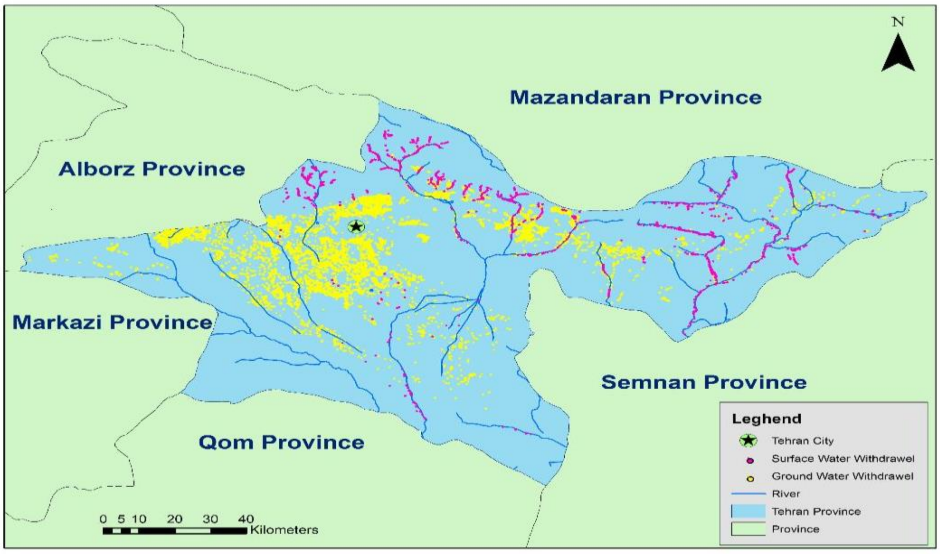

***Figure 2.** Surface and groundwater withdrawal for agricultural sector in Tehran province*

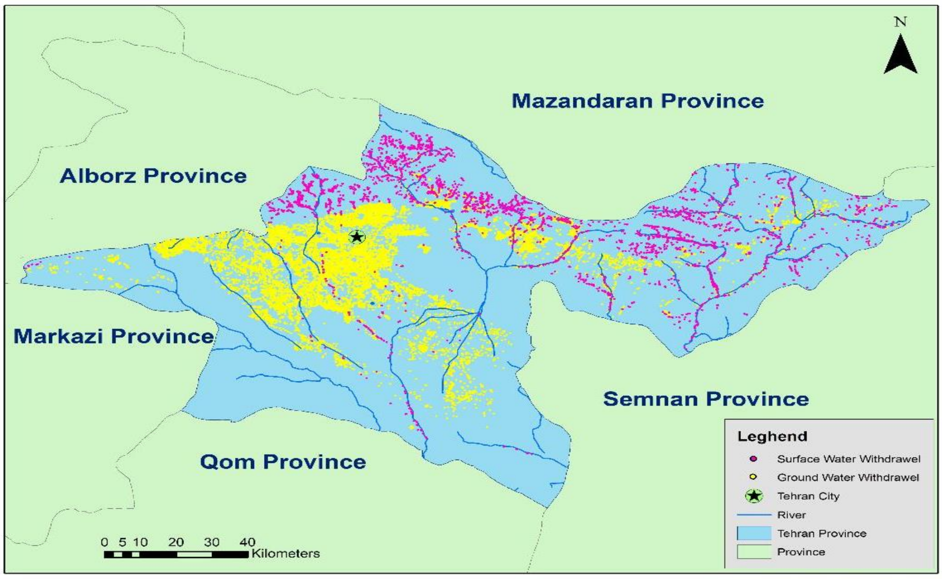

***Figure 3.** Total surface and groundwater withdrawal of Tehran province*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49854997

The primary crops cultivated in Tehran are apple, apricot, cherry, sour cherry, pear, plum, almond, walnut, pistachio, pomegranate, peach, wheat, alfalfa, barley, bean, cotton, maize, tomato, potato, grapes, melon, watermelon, and onion. In this study, the water footprint of these crops was evaluated from 2007 to 2015.

Evaluation of agricultural ground and surface water stress indices

The agricultural ground and surface water stress indices (AWSI ground and AWSI surface) were evaluated separately in this study (*Fig. 4*). The agricultural water stress index is the fraction of water used (WW) to water availability (WA), as per *Equation 1* (Xinchun et al., 2017).

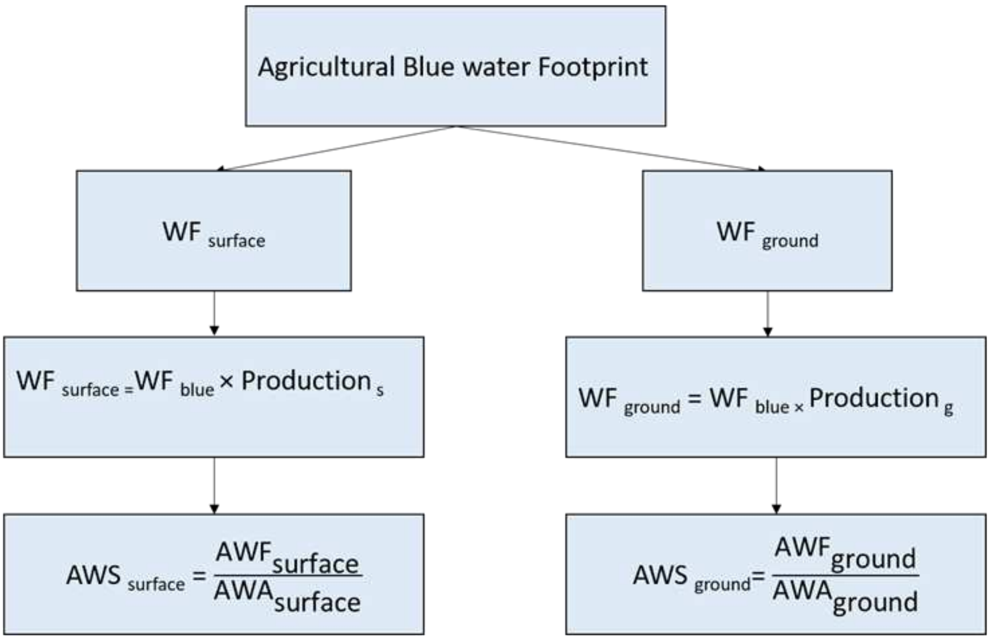

Figure 4. *The accounting framework for computing the ground and surface water stress in agricultural sector. $WF_{surface}$ = surface water footprint, WF_{ground} = groundwater footprint, Production $_g$ = the volume of production by groundwater, Production $_s$ = the volume of production by surface water, $AWS_{surface}$ = Agricultural Surface Water stress, AWS_{ground} = Agricultural Groundwater stress, $AWA_{surface}$ = Agricultural Surface Water Availability, AWA_{ground} = Agricultural Groundwater Availability*

$$WSI = \frac{WW}{WA} \quad \text{(Eq.1)}$$

In this study, AWSI was evaluated as the agricultural groundwater stress index (AWS ground) and agricultural surface water stress index (AWS surface). AWS surface is the fraction of surface water footprint (m^3/year) to the agricultural surface water availability (m^3/year), as per *Equation 2*. Similar consideration can be done for the evaluation of agricultural groundwater stress AWS ground.

$$AWS_{surface} = \frac{AWF_{surface}}{AWA_{surface}} \quad \text{(Eq.2)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49854997

$$AWS_{ground} = \frac{AWF_{ground}}{AWA_{ground}} \quad \text{(Eq.3)}$$

Water scarcity is ranked as presented in *Table 1.*

Table 1. *Baseline score for assessment of water stress index*

AWSI < 0.1	Low water stress
0.1 < AWSI < 0.5	Moderate
0.5 < AWSI < 0.9	Severe water stress
AWSI > 0.9	Extreme water stress

Evaluation of agricultural blue and green water footprints

The methodology used for the evaluation of water footprint was based on a method by Hoekstra The blue and green water footprints of crop production in the Tehran province was assessed for years 2014 to 2015. The CROPWAT software was used to evaluate crop water requirement and irrigation based on soil, climate and crop data (Allen et al., 1998).

The blue water and green water footprints of different crops were evaluated using *Equations 4* and *5* (Hoekstra et al., 2011).

$$WF_{blue} = \frac{CWU_{blue}}{Yeild} \quad \text{(Eq.4)}$$

$$WF_{green} = \frac{CWU_{green}}{Yeild} \quad \text{(Eq.5)}$$

where, WF_{blue} and CWU_{blue} are the blue water footprint and crop water use (m^3/ha), respectively, yield (ton/ha) (Hoekstra et al., no date). The reference crop evapotranspiration (ET_0) was evaluated based on the Penman-Monteith equation (Allen et al., 1998)

Crop water use was evaluated by multiplying 10 with ET (evapotranspiration) (Hoekstra et al., 2011; *Eqs. 6* and *7*).

$$CWU_{green} = 10\sum_{d}^{lgp} ET_{green} \quad \text{(Eq.6)}$$

$$CWU_{blue} = 10\sum_{d}^{lgp} ET_{blue} \quad \text{(Eq.7)}$$

where, ET_{blue} and ET_{green} were the evapotranspiration of blue water and green water, respectively. The assessment was based on growing time from planting to the harvesting period as a whole. To convert water depth in mm into water per surface area (m^3/ha) a factor 10 was applied (Hoekstra et al., 2011). The calculation of Evapotranspiration was started from the time of planing (d = 1) and continued until the harvesting time (lgp is the days of growing crops) (Hoekstra et al., 2011).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49854997

ET_{blue} and ET_{green} were accounted for using the CROPWAT software (Allen et al., 1998). An assumption was taken with climate data and the crop parameter. Climate data included maximum temperature, sum of precipitation, wind speed, humidity, sunshine, and crop parameter. ETblue was accounted for by subtracting effective rainfall (eff_{rain}) from evapotranspiration (ETc). However, ETgreen was considered as the minimum effective rainfall and evapotranspiration, given by *Equations 8* and *9,* respectively (Hoekstra et al., 2011).

$$ET_{blue} = Eff_{rain} - ETc \qquad \text{(Eq.8)}$$

$$ET_{green} = Minimum(Eff_{rain} \& ETc) \qquad \text{(Eq.9)}$$

Evaluation of groundwater and surface water footprint

Groundwater footprint was calculated by multiplying the blue water footprint (m^3/ton) and the volume of production by groundwater P_{ground} (ton/year), as per *Equation 10*. The same method was used to evaluate the surface water footprint, as per *Equation 11*.

$$WF_{ground} = WF_{blue} \times P_{ground} \qquad \text{(Eq.10)}$$

$$WF_{surface} = WF_{blue} \times P_{surface} \qquad \text{(Eq.11)}$$

Evaluation of production by ground and surface water

The volume of production by ground and surface water was obtained via fieldwork and GIS data (obtained from the Ministry of Energy in Tehran) (*Fig. 2*). First, the volume of crop production in each region was accounted for. Then, GIS data were contributed to know the type of water used (groundwater and surface water) for the agricultural sector and volume of water used. Fieldwork contributed to discovering the volume of production by groundwater and surface water exactly.

Results

Table 2 shows the yield, the volume of production by ground and surface water, ground and surface water footprint, and cultivated area in the Tehran province. The production of wheat consumed was 158, 973,775.35 m^3/year of groundwater and 58,626,083.65 m^3 of surface water. Alfalfa consumed 92,250,581.5 m^3 groundwater and 75,477,748.5 m^3 of surface water. The result illustrates that wheat has the largest groundwater footprint. Alfalfa has the second largest groundwater footprint, followed by barley. Besides that, the groundwater footprint for the production of all crops was bigger than surface water footprint unlike pistachio, which had a somewhat larger surface water footprint (*Table 2*). Besides that, the largest groundwater was related to cereal (wheat, barley, and maize) production because cereal is produced in a large scale. After cereal production, apple consumed the largest groundwater footprint because it is produced on a large scale. Pistachio and cotton with large virtual water (m^3/year) have low groundwater and surface water footprint because the production is at a low scale.

Figure 5 shows that green water footprint contributes the least to the total water footprint in the Tehran province. The production of grapes contributed to the largest green water footprint in comparison with other crops. Besides that, the production of all crops consumed larger groundwater. The production of cotton consumed the lowest groundwater and surface water because it was produced in a low volume.

Groundwater footprint makes up 52% of the total water footprint. This means that the production of crops in Tehran has a groundwater footprint that is one half of the total water footprint. Meanwhile, surface and green water footprints account for 28% and 20% of total water footprint, respectively (*Fig. 6*). The ground and surface water footprints for the production of crops were 585 and 322 million m^3/year, respectively, accounting for 59% and 28%, respectively, of total water consumption in the Tehran province (2014-2015). However, the green water footprint is the lowest contributor to the total water footprint in the Tehran province, accounting for 20% of total water footprint.

DOI: http://dx.doi.org/10.15666/aeer/1702_49854997

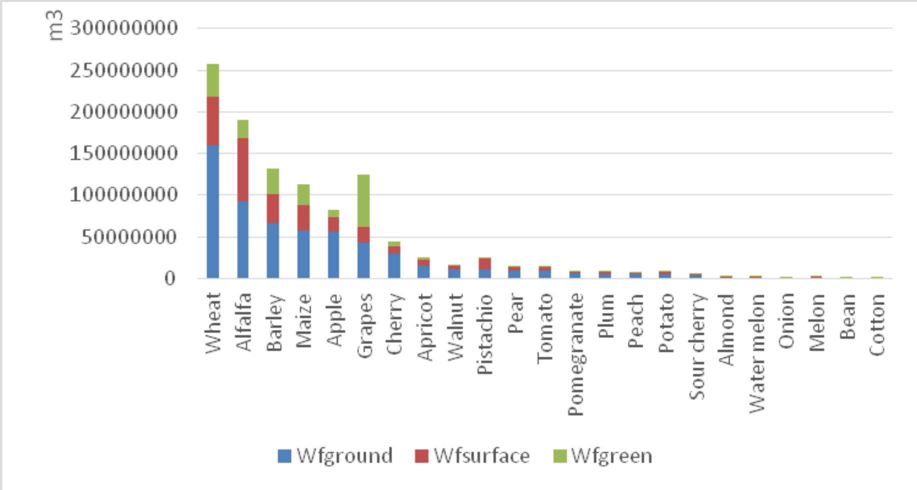

Figure 5. *Ground, surface and green water footprints (cube meter/year) in Tehran province (2014-2015)*

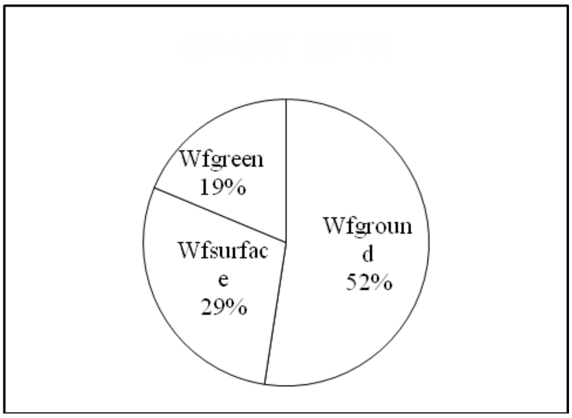

Figure 6. *The proportion of surface, ground, and green water footprints in the total water footprint (2014-2015)*

Ground and surface water scarcity

Ground and surface water scarcity is evaluated based on ground and surface water footprints. The result illustrates that the agricultural sector in the Tehran province is under high water stress. The production of agricultural crops relies on groundwater resources. The agricultural groundwater and surface water stresses accounted for 0.95 and 0.4, respectively. It can be observed, therefore, that groundwater stress is very high. The Tehran province is under moderate surface water stress for the production of crops. Additionally, agricultural water consumption is unsustainable since the production of crops contributes to high groundwater stress and moderate surface water stress.

Discussion

In this study, the agricultural ground and surface water stress indices were established and determined. Besides that, this indictor divided blue water stress into groundwater and surface water stresses. These indices are different from the previous

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49854997

water stress indicator, which was based on green and blue water footprints and water availability (Xinchun et al., 2017). Besides, the Falkenmark and Raskin indexes are based on water resources available per person and water use per resource (WUPR), respectively (Falkenmark and Lundqvist, 1998; Raskin et al., 1996). Currently, most water scarcity assessments focus on blue water and total water scarcity indexes (Pfister and Bayer, 2014; Hoekstra et al., 2012; Liu et al., 2017; Zhuo et al., 2019). Other evaluations are based on total water stress (Smakhtin et al., 2004; Ma et al., 2015; Zeng et al., 2013). However, in most methods, there has been a lack of attention on the evaluation of ground and surface water scarcity. In this study, ground and surface water footprints are assessed separately to separately evaluate surface and ground water stresses in the agricultural sector.

The investigations of groundwater and surface water footprints conducted separately as a component of blue water was a difficult process since it was time consuming and laboring. This study used GIS data which contains information about the sources of water consumption (groundwater and surface) and the volume of production in each region to evaluate the surface WF and ground WF. However, in some places, there were both groundwater and surface water, and evaluation was done according to field work and using GIS data.

The green water stress was not evaluated since it did not impact blue water availability (Pfister and Bayer, 2014). However, Savenije believed that it should be accounted for because it can reduce blue water consumption (Savenije, 2000). Evaluation of water footprint at the local scale can be produced more accurately than in the country or global scale (Ababaei and Etedali, 2016).

Having knowledge of groundwater will prevent over-exploitation of limited water resources. Additionally, it also contributes to optimal priority being given to ground and surface water consumption in the agricultural sector (Tillotson et al., 2014). Determining the kind of water resource can determine illegal groundwater withdrawal.

According to this research, the agricultural groundwater consumption in Tehran province is more unsustainable than its surface water's. Besides, Tehran province is under sever groundwater stress, similar to what found by (Karandish et al., 2018). Moreover, some other studies at country scale observed that groundwater consumption in Iran is unsustainable (Gleeson et al., 2012). Besides that, groundwater depletion occurs in Iran (Mekonnen and Hoekstra, 2016). Moreover, Iran as a semiarid region is under high water stress (Wada et al., 2011)

Besides, the result indicates that crop production in Tehran has the largest ground and surface WF compared to other countries, similar to Hoekstra's result who claims that water footprint of Iran is high due to low productivity and high evapotranspiration (Hoekstra and Chapagain, 2007; Fader et al., 2011). Moreover, wheat is produced on a large scale. In other words, the production of wheat should be reduced on a large scale since the production of wheat has consumed a large ground and surface water footprint. Furthermore, arid climates have larger water usage than humid regions (Ibidhi and Ben, 2018). Besides that, since the production of all the crops is highly reliant on ground and surface water, it will be beneficial to reduce the production of these crops inside Tehran.

Decision makers should increase water saving by importing water intensive crops such as wheat since Tehran province is under severe agricultural groundwater scarcity. Virtual water trade plays an important role in mitigating water shortages in water-stressed areas (Qian et al., 2018).

However, the production of grapes is consumed more in green water. It is recommended that the production of grapes be increased, which has lower ground and surface water footprint. Besides that, the volume of cereal production (wheat, barely, and maize) should be reduced since the production of these three crops consumed 282,636,105.5 and 125021423.53 groundwater and surface water respectively.

Conclusion

Tehran's total water footprint (excluding grey water footprint) in the agricultural sector was 1,115,962,823.8 m^3/year (2014-2015). Groundwater footprint was 585,041,121.97 m^3/year, accounting for 52% of total water footprint. Surface water footprint was 321,943,927.03 m^3/year, accounting for 29% of total water footprint. Green water footprint was 208,977,774.8 m^3/year, accounting for 19% of total water footprint. Groundwater consumption contributed the largest share of blue water footprint in the Tehran province. Additionally, more than half of the total water consumption in Tehran was due to the groundwater footprint. Groundwater resources include wells, qanat and springs. Groundwater consumption has led to water scarcity in many parts of the province. Green water footprint contributes to the lowest share of total water footprint. The production of crops in Tehran is relatively reliant on limited groundwater resources. Therefore, the environmental impacts of blue water footprint cannot be overlooked. Thus, it is essential to establish an indicator for blue water scarcity based on ground and surface water stresses at the regional scale. This indicator reveals information about the status of ground and surface water resources at the provincial scale. Moreover, the result of this research provides beneficial information for decision makers in the water sector to help alleviate pressure on ground and surface water consumption. For instance, policy makers can prioritize water consumption to reduce water scarcity.

The productions of wheat, alfalfa, and barley have the largest groundwater footprint because these crops are produced at a large scale. Moreover, agricultural groundwater stress in the Tehran province is very high, which is 0.95. Agricultural surface water stress was only at a moderate level, which was 0.4. Besides that, the production of agricultural crops in the Tehran province is unsustainable. Agricultural water footprint should be reduced in order to achieve sustainable agricultural water consumption in the Tehran province. It is suggested that future water stress assessments evaluate the environmental impact of ground and surface water consumption separately using the life cycle impact assessment method. Despite Tehran being under severe groundwater stress, some agricultural crops produced extra and are imported to other regions (apple and barley) (excluded from this paper) that are produced in a large scale. The decision maker should reduce the production of cereal, which consumes a large volume of groundwater and surface water footprint. Besides that, the production of apple and barley for exporting purposes should be reduced. Water management should relocate crop production in Tehran. The production of grapes can be increased while the production of cereal should be reduced. Besides that, agricultural ground and surface water scarcity indices are more suitable than existing indicators because they disclose environmental impact of crops production and help stakeholders to assess groundwater and surface water management policies.

Abstract. Black pine forests of the Western Balkans constitute a significant complex of azonally and orographically-edaphically conditioned forests, on the ophiolite massifs of central and eastern Bosnia, as well as western and, to a certain extent, central Serbia. CA and Cluster analysis showed that there was no overlap in the floristic composition, which means that there are significant differences between the studied stands. Stands in Bosnia and Herzegovina (B&H) are floristically richer with 152 taxa recorded, while stands in Serbia had 82 taxa recorded. On the territory of B&H, communities grow under the conditions of maritime and humid climate; while in Serbia they grow in continental climate with less rainfall and significant exposure to sub-Mediterranean weather. In black pine forests in B&H two types of soil were described: eutric humus-siliceous, and brown soil on serpentinite; while in Serbia, there was only one type - eutric humus-siliceous. No significant differences were found in the spectrum of life forms. In the spectrum of floral elements, mesophilic floral elements (Central and Sub-Atlantic) were dominant on the territory of B&H; while stands in Serbia, were richer in xerophilous floral elements (Mediterranean, Balkan, Balkan-Apennine). Shannon-Wiener index and evenness index showed higher values in B&H.
Keywords: *Balkan, Pinus nigra, forest plant communities, floristic similarity, phytosociology*

Introduction

Area of Southern Europe, Iberian, Apennine and the Balkan Peninsula, along with the Crimea, Anatolia and the Caucasus mountains, is generally accepted as a refuge area, within which many tree species managed to survive during the glacial and post-glacial periods (Hewitt, 1999; Jasińska et al., 2014). Balkan Peninsula was one of the most significant refuge areas in Europe, because it had a warmer climate due to its geographical position, thus the glaciation was not fully expressed. This especially pertains to the western parts of the peninsula, where temperature changes during the glaciation were relatively small (Bennett et al., 1991). The plant cover of serpentinite is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49995010

a segment of flora and vegetation of the Balkan Peninsula extremely rich in species, many of which are endemic. Serpentinite has a high percentage of Mg (18-24%), Fe (6-9%) and heavy metals (Ni, Co, Cr, Mn), but a low content of Ca (1-4%), and Al (1-2%) (Alexander, 2004). Soils formed on ultramafic rock, which includes serpentinite, can contain several hundred times more nickel (Ni), an element toxic to plants (Altinözlü et al., 2012), than other soils. Soils on serpentinites have unfavorable chemical composition, are shallow, rocky, often formed on steep slopes, so they are unsuitable for most plants and represent a stressful environment for their growth (Kazakou et al., 2008).

On the Balkan Peninsula, on serpentine bedrock, population of black pine occupies a significant area. Black pine (*Pinus nigra* Arn.) belongs to the group of Mediterranean pines, has a disjunct range and is present in North Africa, western Europe (Spain), running across the northern Mediterranean and to the Black Sea on the east (Afzal-Rafii and Dodd, 2007; Rubio-Moraga et al., 2012). Black pine is a typical South European forest tree species that is ecologically and economically important in a very wide distribution area (Gülsoy and Çinaŗ, 2019). Black pine forests in the area of the Balkan Peninsula occupy different geological substrates. They represent a significant complex of azonallly and orographically-edaphically conditioned forests on the ophiolite massifs of central and eastern Bosnia and western and central Serbia. Many authors consider this forest a relic due to a dominant role of black pine (*Pinus nigra* subsp. *gocensis* Vid.), which is, along with disjunctive areas of some subspecies, a typical tertiary relic (Tatić and Tomić, 2006). Black pine forests on the serpentines are highly dynamical systems, and their development goes in two directions: towards sessile forests at low altitudes, and towards the beech-fir forests at higher altitudes (Jović and Tomić, 1985). The aim of the paper was to broaden the knowledge on the black pine forests on serpentine bedrock and to compare the floristic data in order to determine the differences between the studied forests in the territory of Serbia and B&H.

Material and methods

Study area

Research included natural stands of black pine on serpentine bedrock in Serbia and B&H (*Fig. 1*). *Figure 2* illustrate the habitat of studied stands. Black pine stands in the area of the B&H are described in three locations (*Table 1*): Dobojsko-Derventski (DD) and Usorsko-Ukrinski (UU), which belong to the Central Bosnian ophiolite range, as well as in the area of Višegrad (V), which is located in eastern B&H. The average value of precipitation in Višegrad, at 416 m a.s.l. is 738 mm, and in Doboj, at 147 m a.s.l. it is 972 mm.

Black pine stands in Serbia are described in Pešter (P), in southwestern Serbia, as well as on Kopaonik (K), which is located in central Serbia. On Pešter, at 1038 m a.s.l, the average value of precipitation is 712 mm, and on Kopaonik, at 1097 m a.s.l, it is 885 mm.

Field work and data analysis

The study of floristic composition of the investigated stands was based on a total of 28 phytocoenological relevés. They were made by the classical method of Zurich-Montpellier school of phytosociology (Braun-Blanquet, 1964) and they are taken from

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49995010

literature. 15 relevés (Novaković-Vuković, 2015) were sampled in the black pine forest on serpentinites of Pešter (P) and Kopaonik (K) - Serbia, and 13 relevés, also in the black pine forest, were recorded on serpentines of Višegrad (V), Doboj-Derventa (DD) and Usorsko-Ukrinska (UU) area - B&H (Blagojević, 2016). Field research was carried out in the period from 2009 to 2011 in Serbia and in the period from 2013 to 2015 in B&H. Syntaxonomic names were given according to Tomić and Rakonjac (2013). Spectra of floral elements were performed based on the systematization of phyto-geographical elements (Gajić, 1980); floral elements that were not found in this source were supplemented according to Stevanović (1992) and Oberdorfer (2001). The spectrum of life forms, which is based on the division of Raunkiaer (1934), was determined according to Kojić et al. (1997), and partially according to Mueller-Dombois and Ellenberg (1974).

In order to determine the similarity in the floristic composition between the studied stands, Bray-Curtis cluster analysis (measuring similarity) with the option "Group Average" in BIODIVERSITY PRO (McAleece et al., 1997) was performed. DCA vegetation data analysis was performed using the statistical software CANOCO 4.5 (Lepš and Šmilauer, 1999). The cover-abundance score obtained for each species within a relevé was transformed using the method of Van Der Maarel (Van Der Maarel, 1979). Indices of diversity and evenness (Shannon-Wiener diversity index and Evenness) were calculated using the program JUICE 7.0.166 (Tichý, 2002).

Shannon-Wiener diversity index is a mathematical measure of species diversity in a community. It is derived from a formula:

$$H' = -\sum pi \ln pi \quad pi = ni / N,$$

where "N" represents total species count, and "*ni*" ground coverage of *i*-species.

Species evenness shows how close in numerical values each species in an environment is. Species evenness index is calculated using the formula (Pielou, 1975):

$$EH = H' / H'max = H'/\ln N,$$

where "N" is number of species (taxa) in a phitocenological sample.

E_H ranges between 0 and 1. Lower evenness between species in a community (and presence of dominant species) will result in lower E_H letter.

Results

The black pine stands in the Višegrad, Dobojsko-Derventska and Usorsko-Ukrinska area (B&H) were recorded at the altitudes ranging between 293 and 590 m and at all aspects, but preferably at warmer ones (S, SW). The community grows on slopes of varying steepness; it has been recorded on flat ground or on a very mild slope (2°), but the majority of stands have been recorded on very steep slopes (25-33°). At all three sites, stands of black pine were situated on two types of soil: eutric humus siliceous and brown soil on serpentinite. There were 152 taxa recorded in 13 phytocoenological relevés. For a complete inventory see *Appendix.*

Stands on Pešter and Kopaonik (SRB) were located at the altitude of between 900 and 1219 m, where stands on the Kopaoniku are located at altitudes between 900 and 963 m, while stands on Pešter occupy narrow range of altitudes between 1180 and 1219 m. Stands of black pine on Kopaonik occupy mainly western aspects (NW, SW), while stands on Pešter occupy various aspects, but more often cooler ones (N, E, NE). Common to both sites is that slopes are steep to very steep (20-35°). There were 82 taxa recorded in 15 phytocoenological relevés. Black pine stands in Serbia were recorded on one type of soil, eutric humus siliceous, provided that on Kopaonik it is medium skeletal eutric humus siliceous on serpentinite, while on Pešter it is colluvial eutric humus siliceous soil.

High floristic similarity of studied stands is visible on the graph (*Fig. 3*), which was expected because in both cases the pine forests grow on serpentine bedrock. However, it is notable that studied stands make two separate groups: relevés from Serbia are concentrated along the y-axis, relevés from B&H show greater dispersion along the x-axis. The graph shows following mutual species as isolated: *Pinus nigra,* cinquefoil

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49995010

(*Potentilla heptaphylla*), deutscher backenklee (*Dorycnium germanicum*), wood false brome (*Brachypodium sylvaticum*). Within relevés from Serbia, xerophilous species of the *Erico-Pinetalia* order: burnet rose (*Rosa spinosissima*), ironwort (*Stachys scardica*), Balkan daphne (*Daphne blagayana*), rabbit tail (*Sesleria serbica*), *Pinus nigra,* owl-head clover (*Trifolium alpestre*), etc. appear as isolated. Within relevés from B&H, species of wide ecological amplitude: common bracken (*Pteridium aquilinum*), *Festuca rupicola,* bird's-foot trefoil (*Lotus corniculatus*), wild strawberry (*Fragaria vesca*), mountain melick (*Melica nutans*) etc. appear as isolated, as well as some mesophilous species: tuberous comfrey (*Symphytum tuberosum*), sessile oak (*Quercus petraea*), blackberry (*Rubus hirtus*). The presence of mesophilous species and species of wider ecological amplitude in the black pine forests in the area of B&H indicates more mesophilous conditions within these forests in the Illyrian province. It should be noted that beech in Serbia is described as *Fagus moesiaca*, whereas in B&H it is described as *Fagus sylvatica.* Sessile oak is also treated dually, in Serbia as Balkan oak (*Quercus dalechampii*), in B&H as *Quercus petraea*, which slightly affected the arrangement of phytocoenological relevés in the coordinate system.

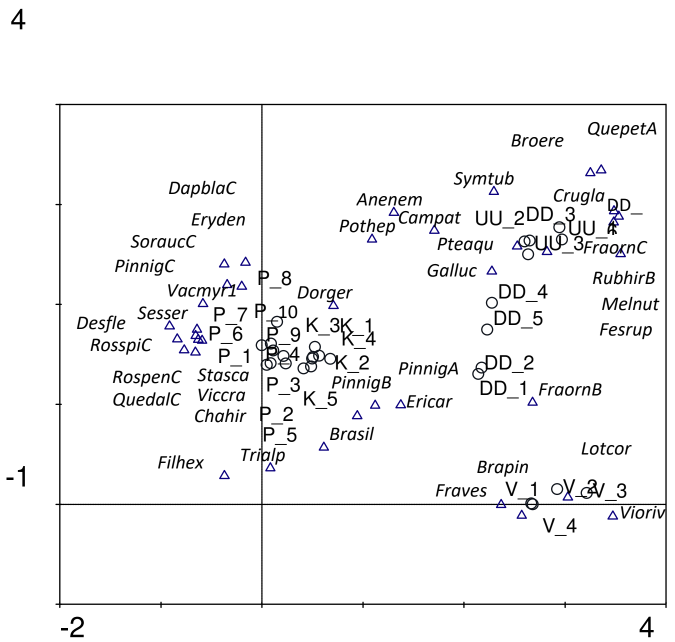

Figure 3. *DCA ordination bi-plot, fit range for species 30-100%, 38 species (○ - relevé representation, Δ - species representation). Cluster analysis (*Fig. 4*) also showed that studied stands compose two separate groups: one group includes phytocoenological relevés from Serbia and the other group includes phytocoenological relevés from B&H. There is no overlapping between the studied stands of two countries, which suggests that there is clear floristic differentiation between them.

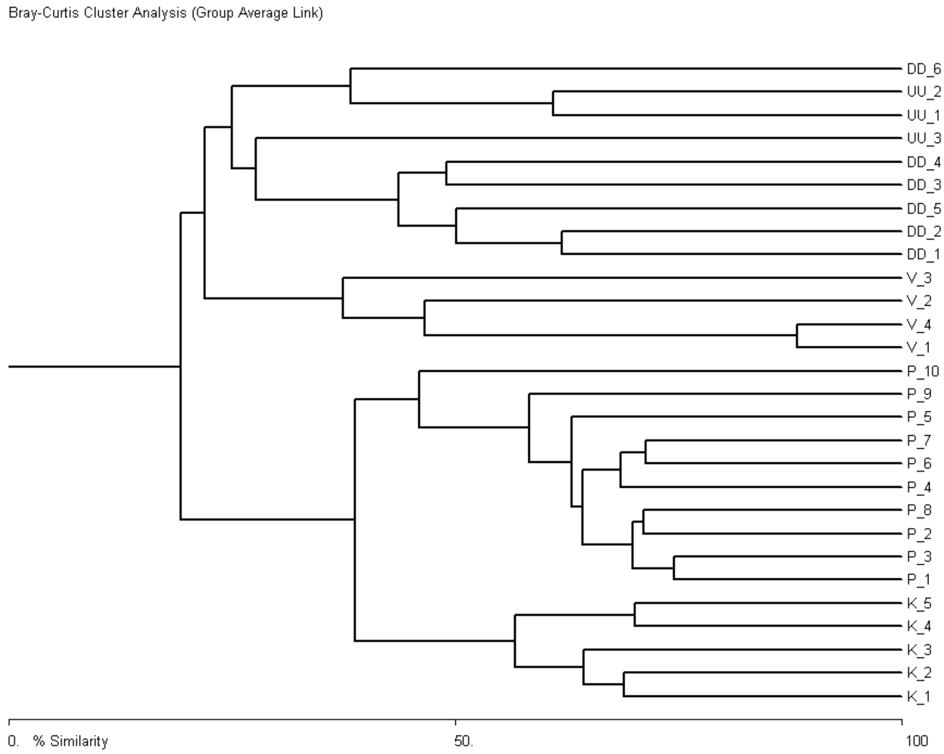

Figure 4. *Cluster analysis of studied stands of black pine in Serbia and B&H. (Abbreviations for locations: DD - Dobojsko-Derventski, UU - Usorsko-Ukrinski, V - Višegrad - B&H; P - Pešter, K - Kopaonik – Serbia)*

In the spectrum of life forms no significant differences between two countries (*Table 2*) were observed. Hemicryptophytes are a dominant life form in both Serbia and B&H, with nearly equal representation. Phanerophytes are slightly more numerous in Serbia than in B&H (22% to 15.8%), while chamaephytes are more common in B&H than in Serbia (15.7% to 12.2%). Other life forms are almost evenly represented.

Table 2. *Spectrum of life forms in the black pine forest in Serbia and B&H*

Life form	Serbia	B&H
Phanerophytes	22%	15.80%
Chamaephytes	12.20%	15.70%
Hemicryptophytes	50%	53.30%
Geophytes	12.20%	11.20%
Therophytes	1.20%	0.70%
Lianas	0.00%	0.70%
Therophytes/chamaephytes	2%	2.60%

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49995010

In the spectrum of floral elements (*Fig. 5*) more significant differences were observed, in comparison to the spectrum of life forms. In the spectrum of floral elements, the collective group of Central-European floral elements is dominant in both countires, with larger abundance in B&H than in Serbia (27%: 22%). A high presence of this group of floral elements indicates syndinamic connection between xerophilous black pine forest with more mesophilous sessile oak and beech forest. It is followed by a group of species of broad ecological amplitude of the Eurasian distribution type, with equal presence in both countries. If more xerophilous floral elements are observed separately (Sub-Mediterranean, Balkan, Balkan-Apeninian), it is noted that their presence is significantly higher in Serbia than on the territory of B&H (24.5% to 19%). The largest presence of sub-Mediterranean floral element is on Kopaonik (Serbia), as a result of exposure of this mountain massif to sub-Mediterranean. On the other hand, the mesophilous floral elements (Central-European and Subatlantic) are more numerous in B&H than in Serbia (31.6% to 24.4%). Greater presence of mesophilous floral elements in B&H and xerophilous in Serbia is a consequence of, first of all, different climatic influences - higher humidity in Illyrian province, to which study stands in the B&H belong.

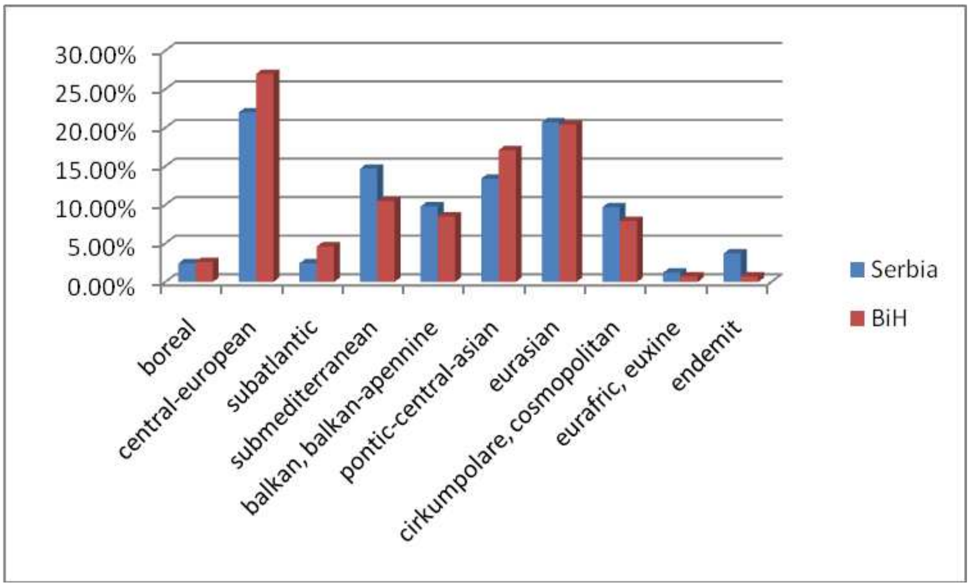

Figure 5. *The spectrum of floral elements in the black pine forest in Serbia and B&H*

For diversity analysis (*Table 3*) Shannon-Wiener diversity index of ground flora was used, which is sensitive to rare species (Heuserr, 1998). Diversity index (Shannon-Wiener index) shows higher value in B&H than in Serbia, which was expected, because the black pine stands in B&H have more species per phytocoenological relevé. Evenness index also shows higher value in B&H, where the spatial distribution of species is more regular than in Serbia, given that the index value approaches the number 1. Species winter heath (*Erica carnea*), *Brachypodium silvaticum,* bilberry (*Vaccinium myrtillus*)*, Sesleria serbica*, may be denoted as species that reduce the Evenness index value in Serbia, considering their number and coverage; while in B&H these are *Erica carnea,* heath false brome (*Brachypodium pinnatum*)*, Pteridium aquilinum,* erect brome (*Bromus erectus*)*,* etc.

Locality	Average Shannon-Wiener index	Average Evenness index
Serbia	2.35	0.64
B&H	2.57	0.74

Discussion

Black pine is one of the main important tree species in the Mediterranean region, but, this species is also tolerant to cold temperatures and can occur at higher elevations of up to 1800 m a.s.l. (Kara and Topacoglu, 2018). Although the observed stands in Serbia and B&H are located at different elevations, distribution of pine forest types is not primarily determined by elevation, but rather by relief, exposure, slope, character of the soil, as well as exposure to the winds (Pavlović, 1951). Since black pine stands on the territory of B&H belong to the Illyrian province, and stands in Serbia to Moesian and transitional Illyrian-Moesian province, significant differences in floristic composition are observed between them. Illyrian province is characterized by significantly higher amount of precipitation, compared to Moesian province, so ti is considered more humid. On the other hand, Moesian province climate is more continental: average temperature differences between summer and winter are more extreme, yearly amounts of precipitate are lower, and summer heats are followed by the lowest amounts of water residues. Generally speaking, Moesian vegetation, compared to Illyric, is much more xero-termophillic, and notably more resistant to high summer temperatures and drought (Jankovic, 1984). Of course, besides the macroclimate, microclimate also exhibits impact on vegetation. The elements of microclimate are interdependent, so that the changes in one of the elements affect other elements. The intensity of the trend of these changes depend on the type of forest, its structure, geographical location, canopy closure and other features (Babić et al., 2015).

The main characteristic of black pine forests on serpentine is presence of winter heath (*Erica carnea*), which the whole class of pine forests is named after (*Erico-Pinetea* Ht. 1959). *Erica carnea* has Illyrian geographical distribution, so the climate of Kopaonik (Serbia) does not suit it, hence this species was recorded in low numbers and coverage in this locality. In the area of B&H in 4 phytocoenological relevés typical Illyrian species alpine barrenwort (*Epimedium alpinum*) was recorded, with its presence decreasing going from the west towards the east, so it was not recorded in relevés in Serbia. Regular satelite of pine forests of Kopaonik (Serbia) is prickly juniper (*Juniperus oxycedrus*), representative of sub-Mediterranean flora, which was not recorded in stands of B&H, as another evidence of xerophillity of studied stands. Although these pine forests are on ultrabasic bedrock, in the floristic composition, two noticably acidophilous species stand out with their abundance and coverage: *Vaccinium myrtillus* in Serbia and common heather (*Calluna vulgaris*) in B&H. This phenomenon is a result of bases from the soil having been washed out due to the high amount of precipitation that led to acidification. This applies in particular to the species *Calluna vulgaris*, which belongs to the Atlantic areal type and its presence is, as expected, greatest in western and northern Europe, and decreases going towards the east. In the area of ex Yugoslavia, this species has the largest presence in Slovenia and Croatia, somewhat less in the B&H, and it is recorded at only four locations in Serbia (Cvjetićanin et al., 2014). Serpentine bedrock has low number of species compared to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_49995010

limestone (Ritter-Studnička, 1963; Brković et al., 2015), but is rich in endemic and relic species. Following species were recorded in studied stands as relic: *Pinus nigra,* European hop-hornbeam (*Ostrya carpinifolia*), mahaleb cherry (*Cerasus mahaleb*), *Cardamine glauca* and spurge (*Euphorbia glabriflora*). According to Stevanović et al. (2003), following endemics within studied forests of black pine in Serbia were recorded: *Allysum markgrafii, Sesleria serbica, Crocus veluchensis, Stachys scardica, Euphorbia glabriflora* and *Melampyrum hoermannianum*; while on the territory of B&H *Thymus jankae* is present as an endemic species, and *Scabiosa leucophylla* as a sub-endemic species. Black pine stands in Serbia are poorer in floristic composition in comparison to stands in B&H. The explanation might be that in terms of the continental climate on Pešter (Serbia), where winters are long and cold and vegetation period is short, only those species within the black pine forest that had adapted to extreme temperature conditions have survived. On Kopaonik (Serbia) there is a strong influence of the Mediterranean, so stands of black pine contain largest number of sub-Mediterranean species and chamaephytes, because these species are able to withstand the harsh life conditions. Clyster analysis of beech forests of SE Europe also showed that there was a significant increase in the proportion of Stenomediterranean, Eurymediterranean, Mediterranean-Montane, and Eurasian species, while Boreal species, decreased toward the southeast (Marinšek et al., 2013). Ritter-Studnička (1963) came to conclusions about the presence of individual life forms studying the serpentine complex in Bosnia, where decreasing presence of chamaephytes with increasing mesophilous conditions is observed, while geophytes are equally present on both bare substrate and in mesophilic conditions. Slopes are generally steeper than at other sites, soils are more skeletal and shallower, exposures are warmer, mainly west and southwest, all of which have an effect on poorer floristic composition. On the other hand, stands of black pine in B&H grow in more humid conditions, have developed soils, mild slopes, lower altitudes, and therefore living conditions are more favorable. The study of transition from warm to mesic forest vegetation showed that the model based on all variables has the best explanatory power and it is followed by models based on groups of variables, as: ecology, chorotypes, geomorphology, structure and function and soil properties (Čarni et al., 2016).

Conclusion

Comparison of floristic characteristics of Black pine forests on the territories of Serbia and B&H was conducted. Stands in B&H are floristically richer with 152 taxa recorded, while stands in Serbia had 82 taxa recorded. In the spectrum of floral elements, mesophilic floral elements (Central and Sub-Atlantic) were dominant on the territory of B&H, while stands in Serbia were richer in xerophilous floral elements (Mediterranean, Balkan, Balkan-Apennine). Results indicate the need for further research of flora and vegetation of the aforementioned localities. Multidisciplinary research, especially monitoring microclimate characteristics of these territories, could provide explanation for the distribution of certain plant species, as well as forest phytocenoses of researched territories.

Abstract. Territorial planning plays a fundamental role in preservation of areas for ecological conservation and environmental management as well as in providing adequate spaces for visitation and research and prioritizing sustainable relationships between man and nature. The present work exhibits a methodological proposal that allows the standardization of territorial classifications in preservation areas. Based on fuzzy logic, the proposed model observes the particularities of a preservation area; hence, the decision generated in the classification of zones represents the work that is currently being developed in the areas of biology, geography, environmental engineering, among other research groups. The modeling combines the evaluation of the data collected in the field (variables: quantitative and qualitative) with vegetation indices obtained from satellite imagery. Combining this information enables each sampling point to be categorized, thereby generating preservation area zones. The results showed that the methodology can distinguish border areas as transition zones, allowing appropriate management to offer detailed information of the study area. The case study, in which the methodology was applied in a preservation area in southern Brazil, showed that the methodology assists in territorial planning, with a clear indication of what actions have been performed and simple data collection.
Keywords: *environmental preservation, southern Brazil, standardized classification, territorial planning, zone of transition*

Introduction

The recent decades have seen a growing discussion by political authorities and scholars regarding the need to delimit natural areas for conservation and increased coverage and effectiveness of protected areas (Watson et al., 2014). The meaning of sustainability is often debated, which can be conceptualized as the management of resources such that their contribution to human welfare is conserved or improved for the next generations (Kennedy, 2007). Brazil, with its vast territory of more than 8.5 million km² (IBGE, 2019), is responsible for protecting its natural environment, which is a difficult task when facing pressures for the expansion of land use for economic purposes, such as agriculture, pasture, and mining (IBGE, 2015). From 2003 to 2009, Brazil stood out in relation to the expansion of the network of preservation areas (PA). Brazil accounts for 73% of world expansion out of the entire legally protected area of the planet that was established in 2003 (Jenkins and Joppa, 2009).

In Brazil, PAs are called conservation units; hence, the designation to the National System of Nature Conservation Units (SNUC in Portuguese) established in 2000 by federal law aims to ensure that all conservation units represented significant ecological samples from different populations, safeguarding the existing biological patrimony

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50115027

(Ministério do Meio Ambiente, 2011; Bernard et al., 2014). In 2002, the Brazilian government established several procedures and criteria for the creation of each PA, establishing its management plan, protection, and supervision actions that must be formalized and implemented. The management plan is a document that works as the identification of the area of preservation, having the zoning definition of a PA observing the particularity of each zone as a fundamental part with adequate management to the territorial ordering, such that the administration of the entire of the area reaches objectives with consistency and effectiveness. Although the legislation deals with zoning, the distinction between legislation and scientific knowledge is still quite high (Azevedo-Santos et al., 2017). The process of how to do this territorial division is guided by documents with a methodological superficial purpose; however, when we looked for this information in the management plans, we observed that zoning occurs in different ways because no methodology standardizes this classification.

In terms of the effectiveness of classification, many questions can still be asked regarding zoning in preservation areas. Liu and Li (2008) highlighted several known problems with the implementation of zoning schemes in China and elsewhere, including the lack of clear regulations on how to structure the spatial arrangement of zones and the lack of guidelines that determine the factors that should be considered since the creation of the PAs (Fendrich et al., 2019).

In study by Lima and Ranieri (2018), zoning can be approached in many ways. Land use planning is done with respect to only one type of zone. The study was done through a documentary analysis using the management plans. Zhang et al. (2013) used the methodology of combining interviews with geographic information systems (GIS) using a multi-criteria decision analysis based on the GIS method to formulate the zoning areas in the national park, with a wise process used to identify the priorities and prior knowledge of the area. Interviews were then conducted for the case study. The study of Vardarman et al. (2018) observed that the invasion of exotic species generated a zoning according to the degree of invasion by making field observations and performing statistical analyses. The main source of data for spatial delimitation of maps was provided by a nature conservation agency in the Czech Republic.

A natural phenomenon related to sustainability can be described in many ways, including visualization, physical models based on the creation or recreation of ecosystems, and conceptual and quantitative models. The last method, where the fuzzy logic theory can be applied, is the most informative for decision makers (Todorov and Marinova, 2011). An eminent factor of the fuzzy logic theory is the ability to capture intuitive concepts in addition to considering the psychological aspects used by humans in their usual reasoning; this has not been represented in traditional models (Zadeh, 1965; Oliveira, 1999; Zimmermann, 2001).

Multi-criteria analyses are examples of techniques that consider several perspectives and can integrate several actions in the decision process in a certain complex situation. From the operational point of view, multi-criteria methods have the ability to adapt to problems on several fronts, which can be described as conflicting interests. Although the multi-criteria evaluation technique does not solve the problem, it can help detail the problem, making the complex situation more transparent for decision makers (Munda et al., 1994; Hsueh and Cheng, 2017).

The objective of this study was to develop a quantitative model based on fuzzy logic to delineate the management zones in PA in Brazil. For this purpose, the possible variables (i.e., quantitative and qualitative) must be combined such that the map of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50115027

area emphasizes its relationship with the surrounding areas. A case study was performed in a PA in southern Brazil to test the efficiency of the model.

Materials and Methods

Preservation area establishment

The establishment of all possible zones for a Brazilian PA covers the following: zone intangible, natural, extensive use, intensive use, historical-cultural, recovery, special use, conflicting use, temporary occupation, indigenous superposition, experimental interference, buffer, and presented in the Methodological Guideline according to the national legislation (IBAMA, 2002; Mazza et al., 2016; Simardi and Souza, 2018).

A PA can be classified in two ways. Some PAs need only a specific element for their classification (e.g., in the case where buildings are identified, the PA is automatically classified as a "zone of special use"). These zones in PAs include zones of special use, zones of conflicting use, zones of temporary occupation, indigenous superposition, and zones where historical/cultural heritage is found (*Fig. 1*).

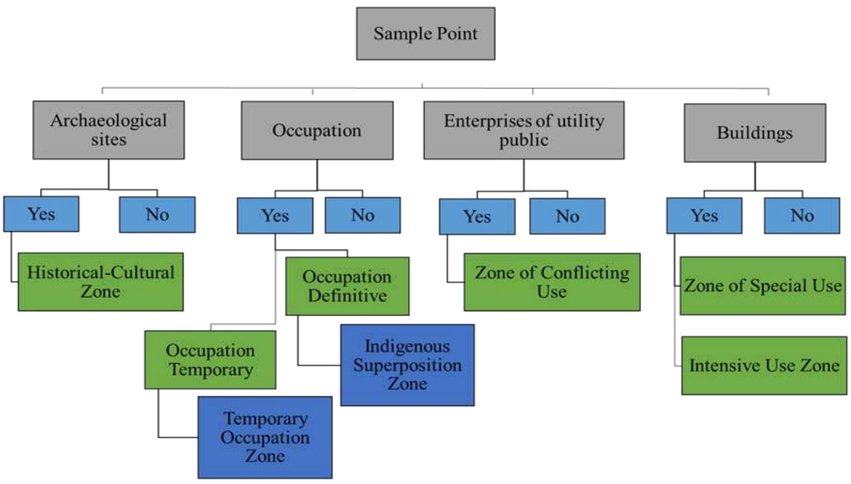

***Figure 1.** Scheme for the classification of areas with specific characteristics*

However, such specific elements will not always appear to generate the classification, which makes it necessary to seek the criteria for classifying intangible zone (IZ), natural zone (NZ), extensive use zone (EUZ), and recovery zone (RZ). The classification of this second group of PAs is much more complex and relies on the criteria not always clear for a decision maker.

Study area and data

The study area is the Santa Helena Relevant Ecological Interest Area (ARIE-SH), a 1.515 ha preservation area in the phytogeographic domain of the Atlantic Forest, which, in ecology, is considered a hotspot (Myers et al., 2000). According to the Brazilian legislation, this PA is classified as a Relevant Ecological Interest Area, a permanent category to sustainable use, with characteristics of possessing small areas with little or no human occupation and a singular natural feature with the purpose of protecting local ecosystems.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50115027

ARIE-SH is located in the southern region of Brazil in the municipality of Santa Helena, state of Paraná (*Fig. 2*). It was officially established in 1984 on the banks of the Paraná River at the border between Brazil and Paraguay after the construction of the hydroelectric power plant of Itaipu (Management Plan, 2010).

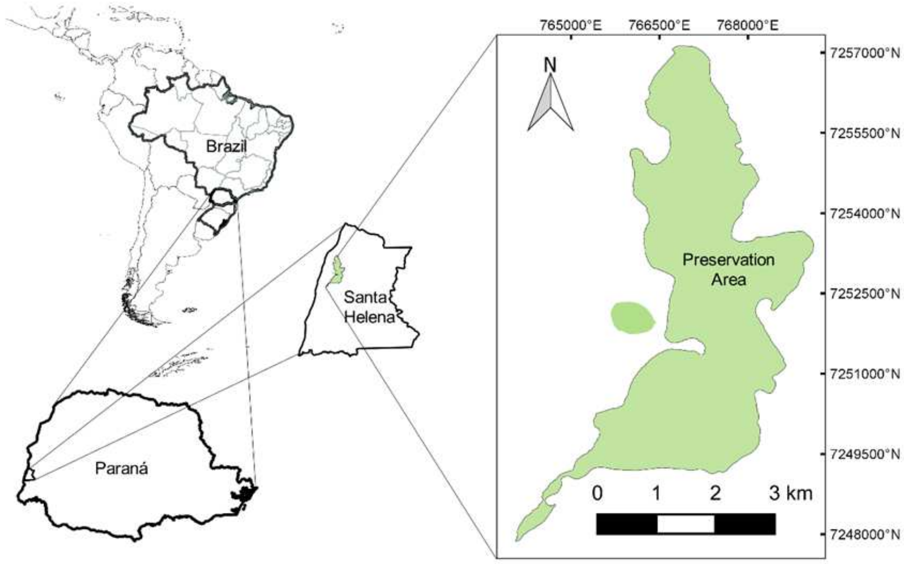

Figure 2. *Location of the Santa Helena Relevant Ecological Interest Area (images projected in the Universal Transverse Mercator (UTM) projection zone 21S and WGS 84 (World Geodetic System 84) ellipsoid)*

At this time, many areas along the river were expropriated, and reforestation with exotic and native trees species took place. Nowadays, the ARIE-SH is covered by a semi-deciduous seasonal forest according to the Brazilian classification of vegetation provided by IBGE (2012) in different stages of ecological succession. The main exotic species present include mango (*Mangifera indica* L.), jambolão or Java plum (*Syzygium cumini* (L.) Skeels), and Japanese raisin tree (*Hovenia dulcis* Thunb.). Meanwhile, the areas, where native species were planted, show a high diversity with several native herbaceous and shrub species, including ferns, growing in the shade sub-forest. The areas, where native species were planted, such as pitanga or Surinam cherry (*Eugenia uniflora* L.) and gabiroba (*Campomanesia xanthocarpa* Mart. ex O. Berg), are the richest in the number of trees species and present an intermediate successional stage.

Fieldwork was performed between March 2018 and June 2018. A total of 87 plots measuring 5 × 10 m² were sampled using the method proposed by Muller–Dombois and Ellenberg (1974). The location of the plots was selected with a distance of approximately 400 m. During the survey, the circumference at breast height (CBH) parameter was used in reference to the circumference of the trunk at 1.30 m height. Each plot was georeferenced at its center point using a global navigation satellite system (GNSS) (Etrex 30, Garmin, Garmin International, Inc., Kansas City, USA) receiver with a positional accuracy of approximately 5 m. The vegetation data collected in each plot consisted of (a) the number of trees with a CBH greater than or equal to 0.30 m, (b) the diversity of species, that is, how many species have a CBH greater than or equal to 0.30 m, and (c) the regeneration level registered by photography.

Model structure

The interpretability of the classification systems refers to their ability to express their behavior in a manner that is easily understood by a user (Jim and Mart, 2019). Based on this indication and to find means of facilitating the systematization of the process, a model was developed to propose to classify the sampled areas. The chosen variables were based on vegetation because "the lower degree of degradation of vegetation generally leads to the lower degree of degradation of fauna and soils" (IBAMA, 2002).

The input variables for the study are as follows: vegetation density index, diversity of species, and regeneration index. The expected output variable refers to "zoning," where each investigated point will be associated with a zone. The general approach is to first quantify the linguistic statement then retransmit the quantized logical input and output ratios using mathematical operators (Chen and Pham, 2000).

The fuzzy sets for the input and output variables considering the working hypothesis can be represented in several ways by pertinence functions, the most common being the triangular, trapezoidal, Gaussian, bell-shaped, Z-shaped, and S-shaped functions (Ibrahim, 2004). The pertinence functions chosen to describe the variables in this work exclude the triangular and trapezoidal functions considering that in nature, the behavior changes are not abrupt.

The membership function in the "Z" form is presented as follows:

$$f(x,a,b)=\begin{cases}1, & x<a\\ 1-2\left(\dfrac{x-a}{b-a}\right)^2, & a\le x<\dfrac{a+b}{2}\\ 2\left(\dfrac{b-x}{b-a}\right)^2, & \dfrac{a+b}{2}\le x<b\\ 0, & x\ge b\end{cases} \quad \text{(Eq.1)}$$

The membership function in a bell shape is:

$$f(x,a,b,c)=\frac{1}{1+\left|\dfrac{x-c}{a}\right|^{2b}} \quad \text{(Eq.2)}$$

The membership function in the "S" form is presented as:

$$f(x,a,b)=\begin{cases}0, & x<a\\ 2\left(\dfrac{x-a}{b-a}\right)^2, & a\le x<\dfrac{a+b}{2}\\ 1-2\left(\dfrac{x-b}{b-a}\right)^2, & \dfrac{a+b}{2}\le x<b\\ 1, & x\ge b\end{cases} \quad \text{(Eq.3)}$$

Input variable: "Vegetation density index"

The vegetation density index (VDI) is described by the membership function considered in the range of 0 to 10, with the low, medium, and high linguistic denominations (*Fig. 3*). It could have been chosen from 0 to 1 or from 0 to 5 provided that the membership functions were allocated at intervals consistent with its name.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50115027

The membership function with a "low" denomination is a Z-shaped function (*Eq. 1*) with $f(x,1.5,5)$. The term "medium" is described by a bell-shaped function (*Eq. 2*) with $f(x,1.5,3,5)$. Finally, the membership function described by the linguistic term "high" vegetation concentration has an S form (*Eq. 3*) with $f(x,5,8.5)$.

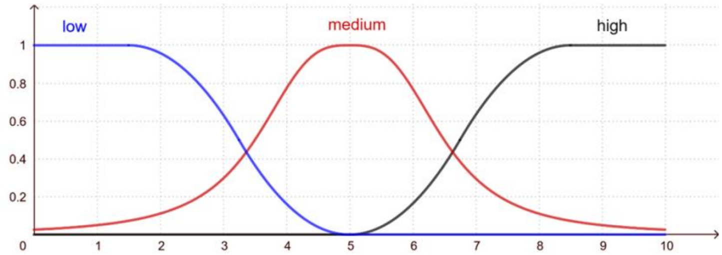

Figure 3. *Membership functions describing the vegetation concentration*

The VDI of the *i*th sampling plot is calculated as follows (*Eq. 4*):

$$VDI_i = \left[\frac{(EVI_i + NT_i)}{\max\limits_{1\le j\le n}\{EVI_j\} + \max\limits_{1\le k\le n}\{NT_k\}} \right] \cdot 10 \qquad \text{(Eq.4)}$$

where EVI_i is the result obtained by the index of vegetation between -1 and 1, which can be searched for in the software by georeferenced points; NT_i is the number of trees in the *i*th sampling plot; $\max\limits_{1\le k\le n}\{NT_k\}$ is the maximum number of trees observed among all the sampling plots (k = 1, 2, 3, …, 87); and $\max\limits_{1\le j\le n}\{EVI_j\}$ is the maximum enhanced vegetation index (EVI) observed and calculated for each point sampled in the study area (*j*=1, 2, 3, …, 87).

With regard to remotely mapping disturbances and land use/land cover (LULC), the data from the satellite-based sensors have proven useful for large-area characterization (Atzberger, 2013). The EVI will be used as input in the fuzzy system. The EVI is an "optimized" vegetation index designed to improve the vegetation signal with better sensitivity in regions of high biomass and vegetation monitoring (*Eq. 5*) (Jensen, 2009).

$$EVI = G\frac{\rho_{nir} - \rho_{red}}{(\rho_{nir} + C_1\rho_{red} + C_2\rho_{blue} + L)}, \qquad \text{(Eq.5)}$$

where, ρ_{nir} is the reflectance in the near infrared band (0.73 µm); ρ_{red} is the reflectance in the red band (0.66 µm); L is a soil adjustment factor; and C_1 and C_2 are the coefficients describing the use of the blue band for the correction of the red band for atmospheric scattering by aerosols. These coefficients were empirically determined as L = 1, C_1 = 6, C_2 = 7.5, and G (gain factor) = 2.5 (USGS, 2017). The Landsat 8 images used in this work were accessed by the United States Geological Survey (USGS) search platform in March 8, 2018.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50115027

Input variable: "Diversity of species"

Data collection was designed to survey the variety and quantity of the plant species present on the site. The methodological guideline states that areas with the greatest number of species found should integrate the zones of greater degree of protection, such as the intangible and natural zones. For the variable "diversity of species," the membership function with a "low" qualification is a function in Z form with $f(x,1.5,5)$. The linguistic term "medium" is described by the bell-shaped function $f(x,1.5,3,5)$, while the term "high" is described by the S-shaped function with $f(x,5,8.5)$.

The diversity of tree species at the *i*th sampling plot, DTE_i was calculated using the following formula:

$$DTE_i = \left(\frac{NE_i}{\max\limits_{1\le l\le n}\{NE_l\}}\right)\cdot 10 \qquad \text{(Eq.6)}$$

where NE_i is the number of tree species observed in the *i*th sampling plot, and $\max\limits_{1\le l\le n}\{NE_l\}$ is the maximum number of tree species found among all sampling plots. The output was multiplied by 10 to scale the values between 0 and 10.

Input variable: "Regeneration index"

The input variable "regeneration index (RI)" is the variable considered in the characterization of zoning because it is a reforestation area. The classification of regeneration provides information that will be considered in the model. The linguistic denominations in the variable regeneration were low, medium, and high (*Fig. 3*).

To distinguish between terms, an area with a mean vegetation that did not enter the sample was considered as high regeneration because it did not complete the 0.30 m diameter that was considered. The term linguistic medium regeneration considered areas with a low and sparse vegetation, among others. The term "low regeneration" was used in places without vegetation in the sub-forest layer.

The membership function with the "low" qualification is a function in Z form (*Eq. 1*) with $f(x,1,5)$. The function with the "medium" qualification is expressed by the bell-shaped function with $f(x,1.5,1.5,5)$. Meanwhile, the function with the "high" qualification is expressed by the function with an S form with $f(x,5,9)$.

Output variable: "Zoning"

The output variable "zoning" has four membership functions: IZ, NZ, EUZ, and RZ (*Fig. 4*).

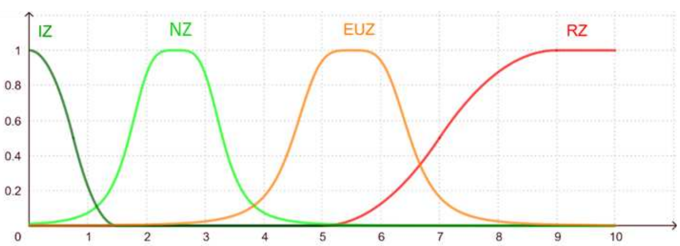

Figure 4. *Membership function of the output variable "zoning"*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50115027

The membership function that represents IZ is a function in the Z shape with $f(x,0,1.5)$. The membership function for NZ is associated with the bell-shaped function with $f(x,0.8,2,2.5)$. The EUZ is also associated with the bell-shaped function with $f(x,1,2,5.5)$. Finally, the membership function that describes RZ is a function in the S shape with $f(x,5,9)$.

Base rule

This phase is the construction of the base rule that directly interferes with the result, which is still subjective and handmade (Rezende, 2005). Many efforts have been made to systematize or even automate the process of acquiring knowledge. In fuzzy systems, the semantics formed by the operators play a deterministic role.

The base rule is a statement of fuzzy rules in the form of if–then. A general approach would be to first quantify the linguistic statement then retransmit the quantized logical input and output ratios using the mathematical operators (Chen and Pham, 2000). In this work, the operator "and" will be used with the Mamdani controller defined as $I_c(x,\mu(x)) = \min\{x,\mu(x)\}$ (Zimmermann, 2001). The operator "and" is used with Mamdani (*Fig. 5*) when listing the input variables.

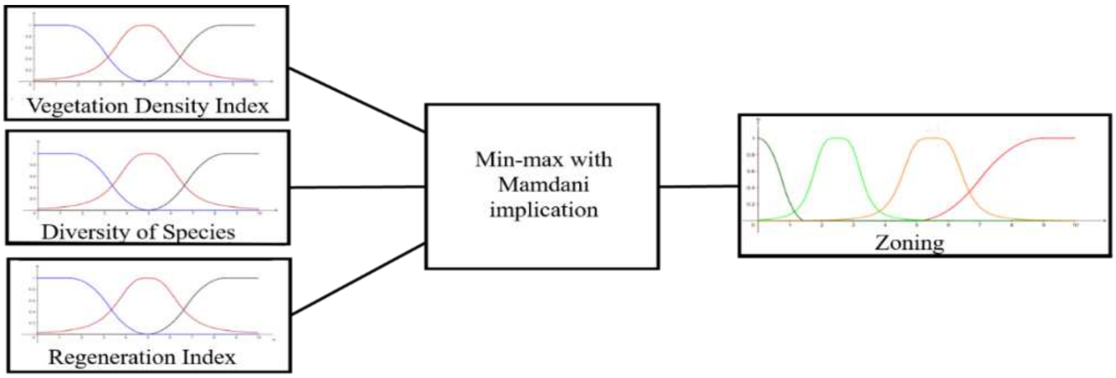

Figure 5. *Fuzzy system scheme for the proposed model*

The base rule in the proposed model will combine the input variables according to its attributes, thereby obtaining 27 rules (*Table 1*).

Table 1. *Rules for zoning delineation*

nº	*Input variables*					*Output variables*	
	If vegetation concentration	**and**	**if** species diversity	**and**	**if** regeneration	**then**	zoning
1	low	and	low	and	Low	then	RZ
2	medium	and	low	and	Low	then	RZ
…							
10	low	and	medium	and	Low	then	RZ
11	medium	and	medium	and	Low	then	EUZ
…							
26	medium	and	high	and	High	then	NZ
27	high	and	high	and	High	then	IZ

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50115027

Fuzzy inference

The information regarding the RI were observed for each sample point. VDI_i and DTE_i were also calculated according to (*Eq. 4*) and (*Eq. 6*), respectively. The input value in the fuzzy system will be a point with three coordinates, which generates a real number as a result, using the gravity center defuzzification method (GCD) (Gomide and Gudwin, 1994; Zimmermann, 2001) (*Eq. 7*):

$$GCD = \frac{\int_a^b x\mu(x)dx}{\int_a^b \mu(x)dx}. \tag{Eq.7}$$

In the GCD, [a, b] is the range of coverage of the membership functions, which in this case is [0,10]. Considering the area formed by the contribution of all the rules, (*Eq. 7*) considers the degree of pertinence (weight) of each point inserted in the model, consequently obtaining a real number as a result. This method returns the point representing the center of the area (or gravity) under the curve formed by the output membership function. The sampled point was classified according to the zone established depending on the GCD output value (*Table 2*).

Table 2. *Zoning classification according to the GCD range*

Zone	GCD range
Intangible	0 to 1.5
Natural	0 to 5.0
Extensive Use	2.0 to 9.0
Recovery	5.0 to 10.0

Each sampled point will be at the intersection of two fuzzy sets representing the zoning. The set for which the point has the highest degree of pertinence will be considered in their classification. If this point is exactly at the intersection point of the pertinence functions, this point will be classified in the most restrictive zone.

Interpolation

The inverse distance weighted (IDW) interpolation method (*Eq. 8*) (Shepard, 1968) was used to generate the thematic maps with the results of the case study applied to the model proposed in this work. Several powers were tested (i.e., 1, 2, 3, 4, 5, and 10). The one with the lowest mean error in the cross-validation was chosen.

$$X_p = \frac{\sum_{i=1}^{n} \frac{1}{d_i^p} \cdot X_i}{\sum_{i=1}^{n} \frac{1}{d_i^p}} \tag{Eq.8}$$

where, X_p is the interpolated variable; X_i is the value of the variable for the *i*th neighbor; d_i is the Euclidean distance between the *i*th neighborhood point and the sampled point; and p is the power of the distance.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50115027

Results

The model presented an efficacy in classification, coherence between the surrounding areas, and in describing the area as observed in the fieldwork in conformity to the area documents (Management Plan, 2010). The results obtained using the model for zoning delineation in ARIE-SH allows classifying the 87 sampled points in the area in accordance to the PA defined by IBAMA (2002). The samples were classified in the range of 0.51 to 8.29 in accordance with the proposed methodology with an average of 4.70 and a CV of 0.43. The average parameters permeated the area as an "Extensive Use Zone." The IDW (power 2) interpolated thematic map (*Fig. 6a*) represents the area divided in four zones (*Table 3*). The transition areas between the zones (i.e., IZ and NZ, NZ and EUZ, and EUZ and RZ) were created by observing the coverage range (*Table 2*) of each pertinence function for the output variable (zoning) (*Fig. 6b*). The values obtained in these intervals were considered as transition regions, which may belong to zones with different degrees of pertinence (*Table 4*).

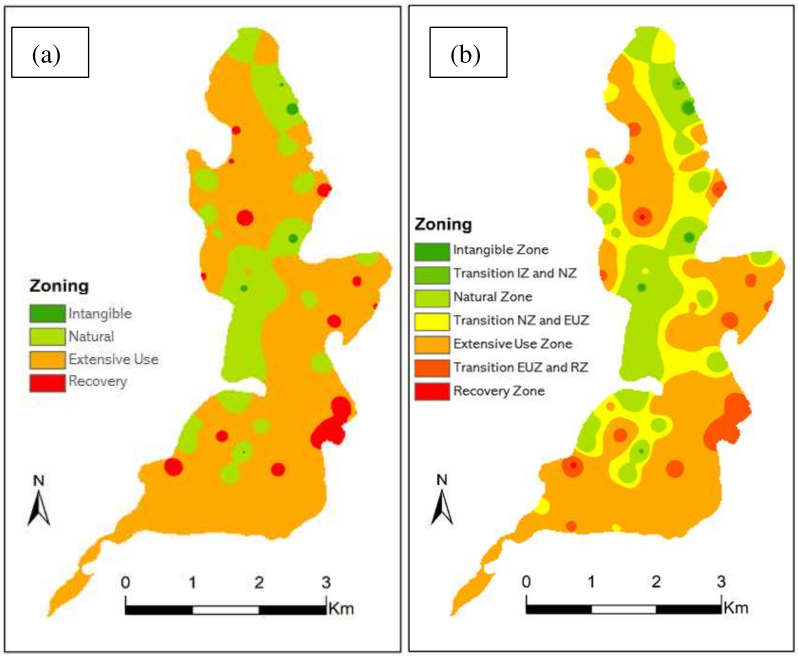

***Figure 6.** Zoning map of the area with the proposed methodology: (a) area divided in four zones and (b) area considering the regions of transition between one zone and another*

***Table 3.** Area of each zone considering the PA classification (IBAMA, 2002)*

Zone	Area (ha)	Area (%)
Intangible IZ	2.47	0.16
Natural NZ	339.63	22.41
Extensive Use EUZ	1123.2	74.09
Recovery RZ	50.60	3.34

The cross-validation performed for the PA classification produced a correlation coefficient of 0.2429, which was evaluated as poor (values under 0.5), moderate to good

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50115027

(values from 0.50 to 0.75), and excellent (values above 0.75). The root mean square error (RMSE) was 1.99. The mean error (ME) was 0.0136 (*Fig. 7*).

Approximately 74.09% of the area extension belonged to the Extensive Use Zone, 0.16% to the Intangible Zone, 22.41% to the Natural Zone, and 3.34% to the Recovery Zone (*Table 3*). When zoning was distributed, including the transition areas, a more detailed understanding of the area can be achieved (*Table 4*). The natural zone that occupied 22.41% of the original map was reduced to 21.91%, but allowed the observation of a larger area (19.25%) that can be classified as a transition area between NZ and EUZ. This result indicated that this area can receive an adequate management to integrate the Natural Zone in the future.

Table 4. *Area of each zone considering the transition zone for PA*

Zone	Area (ha)	Area (%)
Intangible IZ	2.47	0.16
Transition IZ and NZ	7.55	0.5
Natural NZ	332.07	21.91
Transition NZ and EUZ	291.87	19.25
Extensive Use EUZ	831.32	54.84

Discussion

The model presents allows decision makers to classify the PA in a reasonable zoning scheme and enables it to be adjusted to any biome by observing the input variables. This classification generates reliability to the process that becomes standardized. Our model was able to describe the study area using quantitative (i.e., VDI and diversity of tree species) and qualitative (regeneration) variables because of the fuzzy logic that allows us to describe the variable flexibility; hence, it has been used to model landscapes and in different ecological and environmental studies (Sheehan and Gough, 2016).

In the case of a complex system (e.g., natural reserves), we have a model generating several zones based on measurable variables that present ease in the field work, not

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50115027

generating great distortions according to the specialist who will reproduce the zoning. Moilanen et al. (2009) argued that a major limitation in land-use planning when made by software is the inability to consider different zone types.

Our work differed from that of Lima and Ranieri (2018) because it studied documentary based only on one type of zone with specific characteristics. Zhang et al. (2013) presented a similarity in the sense of combining methodologies (e.g., GIS and multi-criterion analysis), although they used previous knowledge, which is difficult for research in Brazil because many units do not have the minimum mandatory document that is the management plan. Vardarman et al. (2018) developed a method of zoning by observing biological factors like the invasion of exotic species resembling the variable regeneration treated in this model. It is difficult within the context of conservation to say which methodology is the best because each area has its particularity. The variables are chosen according to specificity of the area, making it difficult to compare approaches. Territorial zoning is undeniably difficult, even with its limitations, yet it reduces the external impact on the area (Bruggeman et al., 2015).

The high variation of the model classification occurred because during reforestation in the case study area, the natural distribution of the species was not observed. The area was divided in fields, where in some cases, a single species or a combination of two or three species were planted without criterion. Therefore, the interpolation method cannot understand the characteristic of the area that is extremely particular. In areas where the vegetation change is not as abrupt as natural areas, this variation tends to be very small because the neighborhood of the studied site will have similar characteristics.

The model proposed herein showed that zoning classification can be done in a standardized and simplified manner, as suggested by Lin and Li (2016), because traditional models are complex to use and interpret.

In the case of zoning, this classification may encounter different interests with different stakeholders perceiving different versions of the same problem. In this context, the implantation of an ecological park, for example, can have a double understanding. Those interested in installing the park may want to enter the natural areas, which contradicts the conservationist interests of maintaining the intangibility of a core area. In this sense, approaches that consider transition zones present more information for decision makers, and can be interpreted as a buffer for the possible damages on the intangible and natural areas, that is, work as attenuating human intervention, for example (Liu and Li, 2008).

Zoning is indispensable in decision making in a conservation area, and studies of possible reproduction and understanding are valued (Cook et al., 2012). The obtained results allowed for an adequate management of each class according to its peculiarity. When transition areas are included in the classification, the knowledge of their size and location can contribute to the management of the area, thereby allowing greater care with areas that already belong to a more restrictive level, but with a small degree of pertinence.

Many preservation areas in Brazil still do not have a management plan even with numerous documents and studies that confirm the importance of zoning. The management plan has been defined since 1979 and is a mandatory document since 2002, and an integral part of this document is zoning. The preservation areas that have this territorial order do not explain the methodology to generate the territorial classification (Ministério do Meio Ambiente, 2011).

Liu and Li (2008) argued that problems with the implementation of zoning schemes in China and elsewhere include the lack of clear regulations on how to structure the spatial arrangement of zones and the lack of guidelines that determine what factors should be

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50115027

considered. Many variables are treated and considered in Brazilian laws that define zoning in preservation areas; however, we chose to deal with vegetation because if vegetation is not in a favorable state, the fauna will also not find survival conditions. The choice permitted the use of classic vegetation indexes in the literature, such as EVI, which made the model very practical. Lin et al. (2018) compared the performance of some strategies used to evaluate areas that should be retained. The authors pointed out that unfortunately, selecting the most appropriate model is often difficult because of limited data and knowledge.

However, one of the advantages of the methodology proposed herein is the standardization in the territorial planning of preservation areas in the Atlantic Forest, and the particularity of each study area may be adequate. If an area has potential for visitation, a human intervention variable can be included. If the study area is another type, the rules of this model can be adapted to classify and describe the reality of that place.

Conclusions

The whole area under study can be covered during sampling. Moreover, with the experience acquired, the presented results can more adequately describe the studied area. We presented herein a new methodological proposal for PA zoning. The PA classification presents a systematization to the process of territorial planning with input variables having quantitative and qualitative parameters, which allows an approximation of the reasoning of specialists obtaining a numerical result easy to classify in the zones as established in the National System of Nature Conservation Units. The model provides methods of automating decisions based on fuzzy logic. This methodology is promising because it can be used automatically and independently. It also allows adaptation to any PA because it meets the law requirements. The intersections between the fuzzy set output will be areas of special attention because being in an intermediate stage, the management of this area can be improved for insertion into a category of greater preservation.

This model introduces a tool that can be used to review and monitor the zoning of protected areas that the legislation has defined to be periodically reviewed. In practice, the model offers zoning in which the spatial division presents no rigid limits, but rather flexible boundaries to the real objective of the area, thereby providing the manager with detailed spatial classification maps that can be used to plan impediments and permissions for the proper management of the area.

Future studies can work on the insertion of new variables. For example, in open areas to visitation, the variable "human intervention" can be inserted to verify the degree of impact of human action, qualifying factors as the presence of garbage, fires, tree cuttings, and signs of hunting, among others. For example, we can compare the model performance of areas with different characteristics including characteristics other than reforestation.

Abstract. The study was conducted at a greenhouse of the Graduate School of Biosphere Science in Hiroshima University, Japan under the ambient conditions to find out the effect of salinity stress on some physiological and biochemical characteristics of two bread wheat genotypes and also to elucidate the salt tolerance mechanism of these wheat genotypes. Two wheat genotypes namely 'Sakha 95' and 'Misr 2' were exposed to 50, 100 and 150 mM NaCl levels of salinity. Results showed that both genotypes were varied significantly for all traits under all levels of salt stress. Among the genotypes, growth of the genotype 'Misr 2' was found much better than the 'Sakha 95', with the maintaining a higher dry biomass. The genotype 'Misr 2' also maintained a high concentrations of soluble-sugars, proline, and various antioxidant enzymes activity such as glutathione reductase (GR), peroxidase (POD) and catalase (CAT) compared with genotype 'Sakha 95'; whereas, maintained a lower levels of lipid peroxidation represented by the malondialdehyde (MDA) concentration. Indicating that genotype 'Misr 2' has ability to survive under salinity stress than the genotype 'Sakha 95'. Similarly, salinity stress also significantly changed in Ca^{++} contents and Na^{+}/Ca^{++} ratio in both wheat genotypes. The relative reduction in Ca^{++} concentration and Na^{+}/Ca^{++} ratio was found higher in the genotype 'Sakha 95' than in 'Misr 2' and lead to showing the signs injury. Thus, the genotype 'Misr 2' would be useful to develop a salinity tolerant wheat varieties in the future breeding program.
Keywords: *antioxidant, salinity stress, wheat, physiological characteristics*

Introduction

Bread wheat (*Triticum aestivum* L.) is the leading widely grown food cereal around the globe, due to it wider adaptability as well as quality of nutritive values than other cereals. Similarly, in terms of production and acreage it is also stands first. It is as a strategic crop which has a significant role on the national economy of the third world countries (Barutcular et al., 2017; Yadav et al., 2018; Yildirim et al., 2018). Whereas, it demand is increasing day by day to meet the food security of increasing population (Hossain et al., 2012; Abdelaal et al., 2018; Jahan et al., 2019). At the same time the productivity of wheat across the globe is influenced by several abiotic stresses (i.e., heat, drought and salinity); among them soil salinity is the most important one, particularly in arid and semi-arid regions (Pitman and Läuchli, 2002; Rengasamy, 2010; Sommer et al., 2015; Out et al., 2018).

Soil salinity has considered as the foremost environmental difficulties that negatively influences the growth and development of plants by altering the physico-biochemical process (Allakhverdiev et al., 2000). Approximately a 60% crop productivity in the world is loss due to soil salinity stress (Xie et al., 2016). Study depicts that nearly 20% of the total cultivated land across the world is under salt stress (Oproi and Madosa, 2014). It is well-understood that under salt stress, plants uptake high concentrations of soluble salts that lead to limit the uptake of water through the roots system, due to higher osmotic stress. As a result, limited water in plant cells influences the turgor and also changes the membrane stability (Sairam et al., 2002), and absorbed the high concentration of ions in plant cells which compete with the uptake of essential nutrients lead to nutrient deficiency (Goudarzi and Pakniyat, 2008). The most predominant salt in saline soil such as NaCl increases the concentration of Na^+ and Cl^- level in the soil, which inhibits the uptake of nutrients like Ca^{++}, Mg^{++} and K^+ by the plants and subsequently increases the uptake of Na^+ and Cl^- in susceptible plants (Khan et al., 1999).

A group of antioxidants such as glutathione reductase (GR), peroxidase (POD) and catalase (CAT) are normally linked with the plant which tolerance to various stresses, including salinity stress (Munns and Tester, 2008). Plants which are capable to preserve a high levels of soluble-sugars, proline, and various antioxidant enzymes such as GR, POD and CAT to inhibit a lower levels of lipid peroxidation by representing a malondialdehyde (MDA) and efficient reactive oxygen species (ROS) concentration scavenger (Abogadallah, 2010; Gill and Tuteja, 2010); also can maintain a lower level of stress-induced injuries (Munns and Tester, 2008; Sharbatkhari et al., 2013). Sairam et al. (2002) revealed that the increasing level of SOD, GR and APX (ascorbate peroxidase) activity in wheat varieties under salinity stress showed the better level of tolerancey against salinity stress. They also found that antioxidants such as soluble sugars, proline, glycine betaine and abscisic acid contents were also increased of these tolerance wheat varieties under salinity stress. Other findings revealed that Na^+ and K^+ concentrations in the plants' cell, and their ratio, and dry biomass of salt-induced plants are also an appropriate indicator for the screening of wheat genotypes that are tolerant to salt stress (Goudarzi and Pakniyat, 2008). Sánchez-Rodríguez et al. (2010) reported that susceptible wheat genotypes showed a higher degree of lipid peroxidation represented by the MDA and ROS concentration than the tolerant genotypes. Therefore, a well thoughtful of wheat physiological responses under salinity stress may assistance to develop wheat varieties which will be suitable to grow under salt stress condition through improving growth

DOI: http://dx.doi.org/10.15666/aeer/1702_50295041

and yield. In the context, the current study was undertaken to know the effects of salinity stress on some physiological and biochemical characteristics of wheat and also to elucidate the salt tolerance mechanism of wheat genotypes.

Materials and Methods

Location

The study was undertaken in a greenhouse of the Graduate School of Biosphere Science in Hiroshima University, Japan under the ambient conditions

Plant growth and stress treatment

To fulfil the objectives of the present study, two Egyptian wheat genotypes namely 'Sakha 95' and 'Misr 2' were selected based on their agronomic performance. These two genotypes were collected from the Agriculture Research Center (ARC) in Egypt. For surface sterilization, seeds of two wheat genotypes were immersion in a 50% sodium hypochlorite solution for 30 minutes, and then carefully washed with distilled-water before sowing. Subsequently seeds were then soaked in tap-water for 24 hours at 28°C. Then germinated seeds were transferred to a 20 L half strength Hoagland solution. Ten days after germination, all seedlings were transferred to either Hoagland solution (as a control) or solution supplemented with NaCl (salinity treatment) for 12 days. Salt concentration such as 50, 100 and 150 mM (according to treatments) was applied gradually in 2 days' intermissions to avoid osmotic shock to the plants. The nutrient solution was continuously aerated with pumps and renewed every 2 days. The pH was adjusted at 5.0-6.0 daily. All treatments were arranged with a complete randomized design and were replicated in three times.

Growth measurements

Ten plants in all treatments were collected and separated into three parts (roots, stems and leaves) after 12 days of treatment imposition. Two sets of samples were prepared: one for recording dry weights (DW) for each plant after oven drying at 70°C for 3 days, and the other set was kept at -80°C for physiological analyses.

Measurement of lipid peroxidation (malondialdehyde; MDA) concentrations

The lipid peroxidation (such as MDA) concentration was determined through the reaction of thiobarbituric acid (TBA) (according to Fu and Hung, 2001), from frozen-samples (-80ºC). The lipid peroxidation concentration (MDA) was estimated by using a coefficient of absorbance (535 nm) of 155 mM^{-1} cm^{-1}.

Measurements of Na^+, K^+ and Ca^{++} concentrations

Dry biomass of root, stem, and leaves was ground finely in a sample mill separately (Model: Labo, Miser LM-Plus; Osaka Chemical Co., LTD, Japan). The fine powder was then used to determine the Na^+ and K^+ concentrations. For this, the powder was then digested with sulfuric acid (H_2SO_4) and hydrogen peroxide (H_2O_2) at 2:1 (v/v). The Na^+ and K^+ concentrations were measured using a flame photometer (Model: ANA 135; Tokyo Photoelectric, Tokyo, Japan). The Ca^{++} concentration was also determined by

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50295041

using an inductively coupled argon plasma method (Model: ICAP-575, Nippon Jarrel Ash, Kyoto, Japan).

Measurement of sugar concentrations

The dried ground sample of leaves was boiled with 80% (v/v) ethanol in a hot water (80ºC about 20 minutes; min). The mixture was then centrifuged at 2000 rpm for 5 min; after that the supernatant was collected, and the precipitate was exposed to two more times of the same extraction process. The sugar concentration was determined in the ethanol-soluble extract by anthrone reagent method with a spectrophotometer (Model: U-2001, Hitachi, Japan), using glucose solution as standard (according to Yemm and Willis, 1954).

Measurement of leaf water potential

The osmotic potential (ψ_π) of cell sap and osmotic potential ($\psi_{\pi(100)}$) at full turgor were measured by using a Wescor 5500 vapor pressure osmometer (Model: Wescor Inc., Logan, UT. USA), and was estimated by adjusting according to Wilson et al. (1979).

Measurement of proline

The proline was determined spectrophotometrically following the ninhydrin method as described by Bates et al. (1973), using L-proline as a standard and then determined using spectrophotometer (Model: U-3310, Hitachi, Ltd. Tokyo, Japan). For determination of proline, the dried ground samples were transferred to vials subjected to methanol extraction, and stored in the dark place at 4ºC.

Antioxidant enzyme activities

Protein Assay kit (Model: Bio-Rad DC, California, USA) and bovine serum albumin as a standard were used to estimate the activity of CAT (EC 1.11.1.6), POD and GR (EC 1.6.4.2). An amount of 0.5 g fresh sample was extracted according to the following method as described by Takagi and Yamada (2013). An aliquot of 1 ml of the CAT assay mixture was also used which was contained 50 mM potassium phosphate buffer (pH 7.0), 10 mM H_2O_2, and enzyme extract (5%). A decline in H_2O_2 was recorded at 240 nm to know the enzyme activity which is expressed as mmol H_2O_2 consumed per minute. 1 ml assay mixture containing 100 mM phosphate buffer (pH 7.5), 0.1 mM EDTA, 0.02 mM NADPH, 0.02 mM GSSG and 10% enzyme extract were used to know the GR activity. The concentration of oxidized NADPH was determined by using the extinction coefficient (6.22 mM^{-1} cm^{-1}) and 1-unit GR activity defined as μmol NADPH oxidized min^{-1}. For the measurement of POD activity, 1 ml reaction mixture contained 15 mM guaiacol, 73 mM phosphate buffer, 10 mM H_2O_2 and 2% enzyme extract. Increase in absorbance was monitored at 470 nm for 1 min and the enzyme activity calculated using the extinction coefficient (26.6 $mM^{-1}cm^{-1}$) for tetraguaiacol (Chance and Maehly, 1955). One-unit POD activity was defined as mmol tetraguaiacol formed per min.

Statistical analysis

Data were arranged and statically observed through one-way of analysis of variance (ANOVA) (Kao and Green, 2007). Treatments mean variation under different salinity treatments were observed by using Duncan's Multiple Range Test (DMRT) at the 0.05 level of significance (Duncan, 1955).

Results and Discussion

Plant growth

Both wheat genotypes exposed to 150 mM NaCl salt concentration showed that the salt stress highly influenced the leaf, stem & root dry weight (*Fig. 1*). As compared with control, leaf, stem, and root dry weight (DW) of both the genotypes were reduced significantly under salt stress treatments. While, DW reduction of genotype ‘Misr 2' was found a minimum than ‘Sakha 95'. Considering the visible signs injury, genotype ‘Sakha 95' showed the maximum signs injury than genotype ‘Misr 2' (*Fig. 1*). In the present study, plant biomass in both genotypes were decreased with the increase in the level of salinity, and it might be due to salinity stress altered the normal physiological and biochemical activities of the salinity exposed plants, which lead to decrease the DW. The assumption of the present study related to the adverse effect of salinity on plant biomass was also confirmed by Munns et al. (2006) and Rahman et al. (2017). Similarly, Dayiragije and Lutts (2006) also revealed that under salinity stress susceptible plants persist under-developed due to a decrease in cell division, elongation and also limit the synthesis of growth hormones (auxin) which lead to decrease the total biomass of the affected plant.

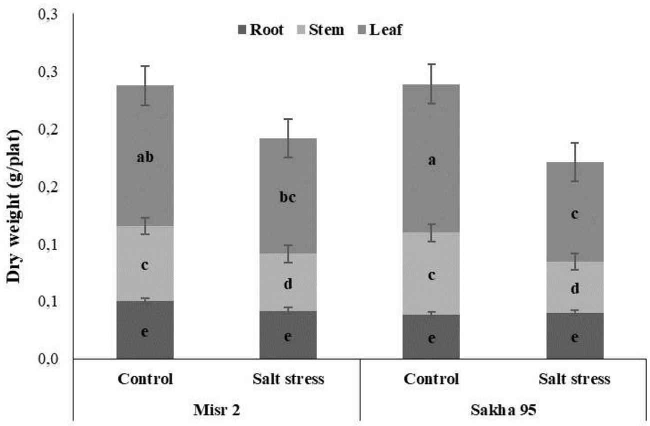

Figure 1. *Effects of salinity stress on the dry weight of the leaf, stem, and root of two wheat genotypes recorded at 12 days after germination. The values of standard error (± SE) in each bar were calculated for each treatment. The same letter indicates no significant difference (p≤0.05) between each other*

Na^+, K^+ concentrations and Na^+/K^+ ratio

Salinity treatments significantly influenced the Na^+, K^+ concentration as well as the ratio of K^+/Na^+ in all plant parts of both wheat genotypes. Under salt stress, accumulation of Na^+ increased in all of the organs of both genotypes; whereas the Na^+ concentrations significantly differed between the two genotypes (*Table 1*). As compared with control plants, the K^+ concentration in all parts of the plants was decreased significantly in both genotypes. The lower K^+ concentration was found in the genotype ‘Sakha 95' than the genotype ‘Misr 2' under stress condition. However, under the control condition, the leaf K^+ concentration was significantly higher in genotype ‘Sakha 95’ than that of genotype ‘Misr 2’. Our results revealed that the salt treatments remarkably reduced the leaf K^+ concentration in the genotype ‘Sakha 95’, whereas the

DOI: http://dx.doi.org/10.15666/aeer/1702_50295041

reduction of K^+ concentration in the leaf of 'Misr 2' was minor as compared with control plants (*Fig. 1*).

0	Misr 2	5.9±0.04c	6.1±0.04c	7.7±0.03c	69.6±1.3a	90.4±1.3b	54.5±2.7b	8.5±0.2ab	6.7±0.1c	14.2±0.7c
	Sakha 95	5.8±0.01c	6.3±0.10c	6.9±0.15c	68.5±0.7ab	97.4±0.6a	67.6±3.6a	8.5±0.1a	6.4±0.1c	10.3±0.4c
150	Misr 2	29.1±0.52b	37.1±1.09b	30.2±0.58b	64.8±0.5c	81.5±0.5c	38.7±1.1c	44.9±0.9c	45.6±1.5b	78.1±1.1b
	Sakha 95	34.7±1.03a	41.5±1.18a	36.1±1.72a	66.4±0.6bc	80.2±1.8c	42.2±1.2c	52.3±1.6bc	51.9±2.5a	85.45±3.1a

It is well-documented that lower Na^+ uptake and higher K^+ uptake are the key indicators of salinity tolerance in higher plants. In the present study, the Na^+/K^+ ratio in the leaves, roots and stems of the genotype 'Misr 2' was significantly lower than the genotype 'Sakha 95'. When exposed to salinity stress, K^+ concentration in the leaves, roots and stems of both genotypes was decreased significantly, whereas, Na^+ concentration was increased significantly, ultimately causing an increase in the ratio of Na^+/K^+, resulted in a serious deterioration of the ionic homeostasis in leaves, roots and stems of affected plants. Among the genotypes, K^+ concentration was not changed, but the Na^+ concentration and the Na^+/K^+ ratio was changed and higher changed was found in genotype 'Sakha 95' than the genotype 'Misr 2' (*Table 1*). It is indicated that the genotype 'Sakha 95' is sensitive to salinity stress as a result of more accumulation of Na^+ concentration and the Na^+/K^+ ratio, causing a serious visible injury signs in the leaves, roots and stems of affected plants, whereas genotype 'Misr 2' was found a tolerant genotype as the genotype did not show any signs injury under salinity stress. The results of the present study is agreement with the results of Benderradji et al. (2011), who noticed that salt sensitive wheat genotypes could exclude a lesser amount Na^+ effectively through the transpiration stream as a result of higher concentration of Na^+ entered in to the leaf blade, consequently a higher accumulation of Na^+, and causing a cell injury. Similarly, Assaha et al. (2015), EL Sabagh et al. (2015) and Mekawy et al. (2015, 2018) revealed that the salt tolerant crops accumulated lower amount of Na^+ concentration in the shoots and leaf blades. Although, the leaf K^+ content has been suggested as a weak index of salt tolerance as compared to Na^+ content under field conditions, due to most of the susceptible genotypes do not change K^+ under salinity stress (El-Hendawi et al., 2009).

Ca^{++} concentrations and Na^+/Ca^{++} ratio

Salinity stress significantly changed in Ca^{++} concentration and Na^+/Ca^{++} ratio in the leaves, roots and stems of both wheat genotypes. While, a significant decline of Ca^{++} concentration was observed in the leaves, stems and roots of salt treated wheat plants, which leads to a significant increase of Na^+, prompting an increment of the Na^+/Ca^{++} ratio, resulting in a serious deterioration of the ionic homeostasis (*Table 2*). The relative reduction in Ca^{++} concentration in the leaves, stems and roots of wheat plants was greater in the genotype 'Sakha 95' than in the 'Misr 2'. Similarly Na^+/Ca^{++} ratio in all

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50295041

plant parts of genotype ‘Sakha 95’ was found the higher than genotype ‘Misr 2’. The results of the present study indicated that Ca^{++} concentrations and Na^{+}/Ca^{++} ratio in the all plant parts was higher and lead to showing the signs injury under stress condition. The information of the present study is also confirmed by the earlier study as reported by Islam (2001) and Yusuf (2010), who revealed that accumulation of Ca^{++} in plant parts inhibit to uptake other nutrients as well as altering the physiological and biochemical process. Similarly, Islam et al. (2011) found that higher accumulation of Ca^{++} in the leaves under salt stress significantly inhibited the growth and development of foxtail-millet, whereas the inhibition of Ca^{++} was found insignificant in poroso-millet, indicated that proso-millet is tolerant to salinity stress than foxtail-millet.

Table 2. *Effects of salinity on Ca^{++} concentration (mg g^{-1} DW) in the leaves, stems and roots of both wheat genotypes. The values are the means (± S.E) of three replicates. Means followed by the same letter within each line are not significantly different ($p<0.05$)*

Effects of salinity on proline concentration in the leaf of the wheat genotypes

The increased levels of free proline in the leaf of both wheat genotypes under salinity stress conditions enhance the levels of antioxidant enzymes including proline activity which are natural responses of plants against stress. In the present study, the proline concentration in the leaves of both wheat genotypes was increased significantly under salt stress, whereas the accumulation level of proline varied remarkably between the genotypes. Among the genotypes, the genotype ‘Sakha 95’ showed a much higher level of proline accumulation than the genotype ‘Misr 2’ under salt treatment (*Fig. 2*). The results of the present study related to an accumulation of proline under salt stress also confirm by Szabados and Savouré (2010), who also noticed that the proline and total soluble carbohydrates synthesis influenced the growth and development of plant under stress conditions. To survive under stress, proline and soluble sugars could play a significant role in osmotic adjustment (Mafakheri et al., 2010). Similarly, Ueda et al. (2008) reported that proline accumulation under stress has been considered an adaptive character. They also found that higher proline synthesis during stress condition not only contribute to osmotic adjustment, but also improved the growth and development of the affected plants.

Effects of salinity on osmotic potential (ψ_π) of wheat genotypes under salinity stress

The osmotic potential (ψ_π) in both wheat genotypes was decreased significantly under saline condition (*Fig. 3*). Whereas, the genotype ‘Sakha 95’ exhibited a more negative potential than the cultivar ‘Misr 2’ under salinity treatment. Thus, the salinity-tolerant genotype ‘Misr 2’ would display a higher osmotic adjustment than the sensitive genotype ‘Sakha 95' under salinity stress conditions. The results of the present study indicated that water uptake of the plant under salinity stress was decreased due to changes in soil water potential. The information is also confirmed by Hussain et al.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50295041

(2008), who reported that under different levels of salinity, the ionic flux in plant cell was increased that affected water potential of the plant's cell, ultimately lead to damage the plant cellular membranes. Similarly, Parida and Dus (2005) found that increasing level of osmotic potential under salt stress is due to high ion absorption and compartmentation in vacuole or the production of osmolytes is responsible for the osmotic adjustment in the cell of the sensitive plant. They also revealed that the increase of osmotic potential in salinity sensitive plants is due to the reduction of turgor pressure.

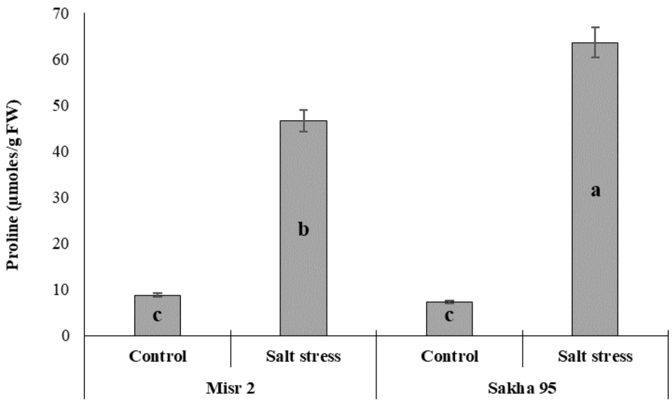

Figure 2. *Effects of salinity on proline ratio in the leaf of the wheat genotypes 'Sakha 95' and 'Misr 2' after 12 days of salinity stress (150 mM NaCl). The values of standard error (± SE) in each bar were calculated for each treatment for three replications. The same letter indicates no significant difference (p≤0.05) between each other*

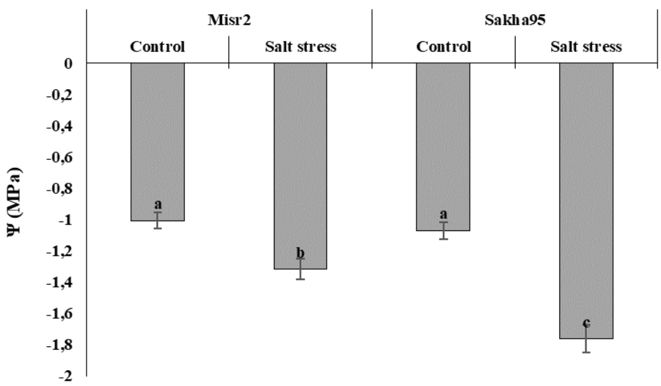

Figure 3. *Effects of soil salinity on osmotic potential (ψπ) in the leaf of the wheat genotypes 'Sakha 95' and 'Misr 2' after 12 days of salinity stress (150 mM NaCl). The values of standard error (± SE) in each bar were calculated for each treatment for three replications. The same letter indicates no significant difference (p≤0.05) between each other*

Effects of levels of salinity on Malondialdehyde concentration (MDA) of wheat genotypes

The MDA is a product of lipid peroxidation (Meloni et al., 2003), which is accumulated in plant parts under stress condition. High degree of MDA concentration in plant parts has a correlation with oxidative damage of plant cell membranes (Assaha et al., 2015). Therefore, it has been used to identify the grade of oxidative damage under

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50295041

stressful conditions including salt stress also (Gill and Tetuja, 2010). In the present study, MDA concentrations was increased significantly in the leaves of the genotype 'Sakha 95' than in 'Misr 2' under salinity treatment (*Fig. 4*). Whereas, in the roots of salinity-induced plants, the increment of MDA concentrations were insignificant in both the genotypes; however, numerically increment of MDA in genotype 'Sakha 95' was much higher than that in the roots of genotype 'Misr 2'. The results of the present study related to the oxidative damage of plant cells' membranes due to the higher production of MDA also confirmed by earlier studies (Demiral and Türkan, 2005; Koca et al., 2007), who found that a higher concentration of MDA in plant cells indicated that the plant/crop is susceptible to salinity, whereas a lower MDA concentration indicates protection of plants against oxidative stress. They also revealed that with a small concentration of MDA in plant cells is usually corresponding to an increase in antioxidant enzyme activities in plant tissues that lead to help the plant to survive under stress condition.

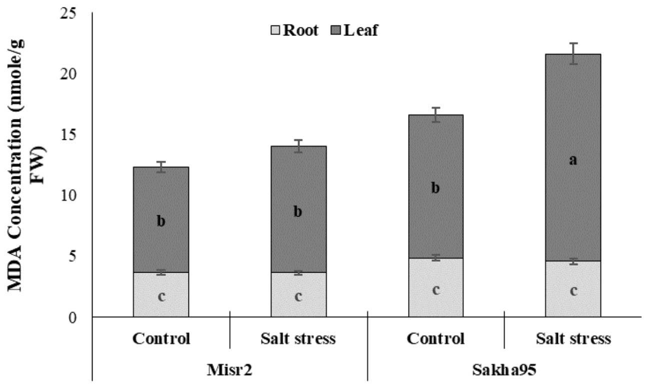

Figure 4. *Effects of soil salinity on MDA concentration in leaf and root of the wheat genotypes 'Sakha 95' and 'Misr 2' after 12 days of salinity stress (150 mM NaCl). The values of standard error (± SE) in each bar were calculated for each treatment for three replications. The same letter indicates no significant difference (p≤0.05) between each other*

Antioxidant enzymes activity under salinity stress in both genotypes

Antioxidants such as CAT, APX, POD and GR are excellent scavengers of stress-induced oxidative damage (ROS). Therefore, an increase of antioxidant enzymes activities in plant cells indicate the stress tolerant ability of the plant and have a correlation with the reduction of oxidative damage (Mittler, 2002). In our present study, the activity of all antioxidant enzymes such as CAT and POD were markedly increased in the leaf of the genotype 'Misr2' under salt stress (*Table 3*). The activities of the antioxidant enzymes CAT and POD were significantly elevated by salt treatment in the leaves of the genotype 'Misr 2', while reduced in leaves of the genotype 'Sakha 95' by salinity treatment. However, glutathione reductase (GR) activity did not alter in the leaf of 'Misr 2', while reduced in 'Sakha 95' by salinity treatment. The activities of all the enzymes (i.e., CAT, POD, and GR) were significantly reduced by salinity treatment in the roots of 'Sakha 95' than 'Misr 2' (*Table 3*). In the roots of 'Misr 2, salt stress significantly induced the activity of GR and CAT as compared to controls (*Table 3*). The results of the present study related to antioxidant enzymes activity during stress condition were also described by Apel and Hirt (2004), who noticed that there is a correlation between CAT, POD, and GR activity and salt tolerance. Mittler (2002), Meloni et al. (2003), Tammam et

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50295041

al. (2008) and Elsawy et al. (2018) reported that antioxidant enzymes such as CAT, APX, POD and GR are excellent scavengers against the oxidative damage (ROS) under stress condition including salt stress; who also revealed that an increased level of antioxidants enzyme activities in plant cells indicate the plant has the ability to reduce oxidative damage. Furthermore, during water-deficit, the enhancement of antioxidant enzymes activity is a response to the photosynthetic machinery against damage caused by ROS (Pirasteh Anosheh et al., 2012; Abdelaal et al., 2017).

Table 3. *Effects of salinity on POD (U/mg protein/min), CAT (U/mg protein/min) and GR (U/mg protein/min) in leaf and root of the wheat genotypes 'Sakha 95' and 'Misr 2' after 12 days of salinity stress (150 mM NaCl).The same letter indicates no significant difference ($p \leq 0.05$) between each other. Means followed by the same letter within each line are not significantly different ($p < 0.05$)*

Conclusion

From the results of the present study, it was found that both the genotypes were varied significantly for all traits under different levels of salinity, while the growth of the genotype 'Misr 2' was much better than that of 'Sakha 95', with the maintaining of higher dry biomass. The genotype 'Misr 2' also maintained a high concentrations of soluble-sugars and various antioxidant enzymes activity such as GR, POD and CAT compared with genotype 'Sakha 95'; whereas, maintained lower levels of lipid peroxidation represented by MDA concentration. Similarly, salinity stress also significantly changed in Ca^{++} concentration and Na^{+}/Ca^{++} ratio in both wheat genotypes. Among the genotypes, the relative reduction in Ca^{++} concentration and Na^{+}/Ca^{++} ratio was found the maximum in genotype 'Sakha 95' than in 'Misr 2' and lead to showing the signs injury. Thus, the genotype 'Misr 2' would be useful to develop a salinity tolerant wheat variety in the future breeding program. The above mentioned physiological and biochemical analyses may be useful as a model procedure for measuring the responses of other wheat genotypes to high-salinity in the field condition for development of salt tolerance genotypes in the future breeding program.

Abstract. This study consisted of the chemical treatment on three races of forager honey bee workers in Sulaimani-Kurdistan region. The races included, *Apis mellifera carnica*, *Apis mellifera ligustica* and *Apis mellifera Native*. The TITAN 48% herbicide affected *Apis mellifera carnica* the most by ingestion, leading to 83.67% mortality after 48 h at 1.00 ppm, which increased to 100% at 10.00 ppm. *Apis mellifera Native* was most affected by the insecticide Goldti5 through feeding, which led to 50.00% mortality after 48 h at 1.0 ppm and rose to 100% at 10.00 ppm. TITAN 48% herbicide had the most severe effect on *Apis mellifera ligustica* through feeding, leading to almost 100% mortality in all concentrations after 48 h. Laboratory test indicated that fat cells showed a series of changes in the cytoplasm when exposed to the recommended dose. The granulated cytoplasm developed a few droplets while the nucleus remained unchanged.
Keywords: *honey bee, foragers, fat body, insecticides, herbicides*

Introduction

Chemical insecticides are important in crop productivity in intensive farming systems, maintaining about one and a half crop yields (Oerke and Dehne, 2004). Bohnenblust et al. (2016) found that nearly 80% of all pesticides applied to row crops are herbicides, and these applications pose potentially significant ecotoxicological risks to nontarget plants and associated pollinators. When used, pesticides can cause unintentional damage by killing useful insects, such as pollinators and natural enemies of crop pests, both within the target field (Croft, 1990) and beyond by drifting (De Jong et al., 2008). Most pesticides are used as sprays, but such herbicides and fungicides are usually used directly on the soil before planting crops. Krupke et al. (2012) demonstrated that bees are exposed to these compounds and several other agricultural pesticides in several ways throughout the foraging period. During spring, extremely high levels of clothianidin and thiamethoxam were found in planter exhaust material produced during the planting of treated maize seed. Growing concern about the impact of pesticides on pollinators is reflected in the vast literature on the subject of the last few years (Osborne, 2012). The sublethal impacts of GLY on non-target organisms such as insect pollinators have so far been poorly evaluated. In this study, we used sublethal concentrations of GLY ranging from 2.5 to 10 mg l^{-1} (Herbert et al., 2014; Thompson et al., 2014). Sol Balbuena et al. (2015) demonstrated that glyphosate (GLY) is a herbicide

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50435057

that is widely used in agriculture for weed control. Although reports about the impact of GLY in snails, crustaceans and amphibians exist, few studies have investigated its sub-lethal effects in non-target organisms such as the honey bee *Apis mellifera*, the main pollen vector in commercial crops. Particular importance is the collapse of bee colonies (*Apis mellifera*) called Colony collapse disorder (CCD). Attempts to interpret the UNCCD have focused on biological diseases, including viruses (Cox-foster et al., 2007), nosema infection (Cameron et al., 2011), parasites such as mites (Thompson et al., 2003; Underwood and Engelsdrop, 2007) and beetles (Buczek (2009), including not only insecticides and corticosteroids but also fungicides and herbicides (Maini et al., 2010; Johnson et al., 2010).

Apart from pesticides used in agricultural production, honey bees are also exposed to the acaricides used to control varroa and other parasites. In this case, the bees interact with high residue levels on the waxy cells of the comb, which mainly affect the developing larvae, the adult honey bees and the queen (Martel et al., 2007; Zhu et al., 2014). Fat bodies are normally distributed throughout the body cavity of insects, especially in the abdomen, and appear as an irregular mass of a soft and usually white tissue composed of large loosely united cells. These cell masses are known collectively as fat body, because the cytoplasm of the cells contains small droplets of oily fat (Snodgrass and Erickson, 2003). The fat bodies can be irregularly distributed in the perivascular space of the abdomen and thorax, surrounding the organs (visceral fat body) or in the abdomen dorsal and ventral sinus, closed to the tegument (parietal fat body), in the head and even in the body appendixes (Chapman, 1978; Zanini and Caetano, 2003). Ayoub (2011) found that the average dimension of fat body cells in newly emerged workers is between 86.71-86.76 µm and in 10-days old workers the average dimension of fat body cells is between 89.15-89.95 µm while the average dimensions of fat body cells ranges between 67.33 and 69.05 µm. Fat body is the main storage agent of the metabolic device of insects and is responsible for the synthesis and supply of hemolymphs. Fat body is made up of cells of mesodermal origin, and sometimes contain epidermal cells (Oliveira and Cruz-Landim, 2003). Roma et al. (2010) demonstrated that fat body consists of a mass of cells under the epidermis, and in some insects, fat body also surrounds the digestive system and reproductive system.

The aim of this research was to shed light on the pesticides that were most commonly used in the study region to determine the sensitivity of the studied honey bee races (strains) to the lowest concentration of these pesticides, then determine the proportion of mortality and the histological properties of these strains under natural condition.

Materials and methods

Collection of forager honey bees was done at an apiary, and included three races of Honey bees: *Apis mellifera carnica*, *Apis mellifera ligustica*, *Apis mellifera* Native in April 2017. Ten foragers of each race were placed into an experimental box (30 X 30 X 30 cm) and fed with the sugar syrup that was treated with two types of insecticide and one type herbicide that are common used on the fields near the honey bee hives, with three replications. Four concentrations (1 ppm, 2.5 ppm, 5.00 ppm, 10.00 ppm) for the two types of insecticide were prepared as follows: 0.1 gm of insecticide was added to a volume of sucrose solution (10% W/V) which was then filled up to 1000 ml with the same solution to obtain 10 ppm of insecticides. Following this, the other three concentrations (5.00 ppm, 2.500 ppm and 1.00 ppm) of insecticides were directly

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50435057

prepared from stock solution with sucrose solution (10% W/V) dilution. Additionally, the four concentrations of the herbicide were prepared as follows: the same procedure was used as in the preparation of the insecticide solutions. The mortality of the foragers were measured after 1, 2, 4, 6 and 24 hours, and the mortality percentage ratio has been re-evaluated using Abbott's (1925) formula.

Insecticides

In this experiment the forager honey bees were exposed to three different insecticides:

Goldti 5EC

The active ingredient is Lambda-cyhalothrin, a quick-acting pyrethroid insecticide effective after contact or ingestion (Dalaly et al., 2012). Lambda-cyhalothrin is a synthetic pyrethroid based structurally on natural pyrithrins. Lambda-cyhalothrin affects both the peripheral and central nervous system of the insect. It initially stimulates nerve cells to produce repetitive discharges and eventually cause paralysis. These sympthoms are caused by their effect on the sodium channel, a tiny hole through which sodium ions are permitted to enter the axon to cause excitation (Ware and Whitacre, 2004).

Chemical structure of Lambdacyhalothrin/chemical name: [1α(S), 3α (Z)]-($_-^+$)-cyano-(3-phenoxyphenyl) methyl-3-(2-chloro-3, 3, 3-trifluoro-1propenyl)-2, 2-dimethylcyclopropanecarboxylate.

Delta ride

The active ingredient is Acetamiprid, a systemic pesticide used to control many sucking insects, which acquired immunity against other pesticides, used on vegetables, fruit trees and other plants. The effect appears after a few minutes of spraying. Used in a concentration of (50) gm /100 litter of water, it was sprayed on and consumed by the forager honey bee workers using a hand sprayer (Dalaly et al., 2012).

Chemical structure of Acetamiprid/chemical name: (E)-N^1-[(6-chloro-3pyridyl) methyl]-N^2-cyano-N^1-methyl acetamidine.

TITAN 48%

The active ingredient is Paraquat or N, N′-dimethyl-4,4′-bipyridinium dichloride, an organic compound with the chemical formula $[(C_6H_7N)_2]Cl_2$. It is classified as a viologen, a family of redox-active heterocycles of similar structure. Paraquat was manufactured by Chevron (Dalaly and et al., 2012).

Chemical structure/Chemical name: 1, 1^1-dimethyle-4, 4-bipyridinium.

Concentration: Four different concentrations were prepared from each insecticide (Lambdacyhalothrin, Acetamiprid, Paraquat). The concentrations were chosen by preliminary range-finding tests (OECD, 1998b; Maus, et al., 2003; Tornier, et al., 2003). The concentrations used were as follows:

1. 1.00 ppm, 2.50 ppm, 5.00 ppm, and 10.00 ppm for (Lambdacyhalothrin, Paraquat) the active ingredients. These four concentration of (TITAN 48%, Goldti 5EC) were prepared as follows:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50435057

a. 0.4 ml of TITAN 48%/Goldti 5EC was added to a volume of sucrose solution (50% w/v), which was then filled up to 1000 ml by the same solution to obtain 10.0 ppm Lambdacyhalothrin/Paraquat for the ingestion experiment.

b. The three other concentration (5.00 ppm, 2.50 ppm, and 1.00 ppm of Lambdacyhalothrin and Paraquat) were directly prepared from the previously prepared solution of step (a) or (b), diluted with a sucrose solution (50% w/v) or distilled water for the ingestion and contact experiments, respectively.

2. 1.00 ppm, 2.50 ppm, 5.00 ppm, and 10.00 ppm for the Acetamiprid active ingredient were prepared as follows:

0.1 gm of Delta Ride was added to a volume of sucrose solution (10% W/V) which was then filled up to 1000 ml by the same solution to obtain 10 ppm of Acetamiprid, then the other three concentration of (5, 2.5 and 1 ppm) of acetamiprid were directly prepared from the stock solution by diluting it with sucrose solution (10% W/V).

Samples collected

Ten workers of each stage were taken for the measurements such as the dimensions of fat bodies and, using binocular dissection and a digital microscope. The ages of worker were recorded (one day, one week, two weeks and three weeks old).

Dissection

The workers were fixed on the dissecting tray after the removal of legs and wings, then immersed in physiological solution. These units were transferred to the dissecting microscope and placed upside down on the tray and fixed with pins. Workers were dissected using a sharp scalpel to create two lateral longitudinal cleavages of the abdomen after mounting the specimens on the dissecting tray with fine stainless pins (Cook and Meola, 1983; Mahmoud, 1991, 1992; Shamdin, 2003). The workers were kept in Physiological saline of 0.9% NaCl and 0.9 gm per 100 ml distilled water (Pantin, 1964). The fixed workers were dissected under 2x and 4x magnification. After cutting the cuticle and removing the muscles, the fat bodies were picked up and placed on a clean slide and were either stained with methylene blue in normal quantities, or prepared with a wet smear. Then photographs and measurements were taken with the eyepiece graticule.

Climatic information data was acquired from Sulaimani General Directorate Meteorology and Seismology.

The results were analyzed statistically using factorial RCBD design with triple replicates and performed using the XLSTA program (2016). Duncan's multiple range Test was used to determine the differences between means at P = 0.05

Results and discussion

The effects of insecticides applied orally to Apis mellifera carnica

Table 1, among others, showed the relation among insecticides, insecticide concentrations and exposure time (ABC). The lowest mortality rate was 1.00 after 1 h of treatment with a concentration of 2.50 ppm of TITAN 48% for *A. mellifera carnica*. However, the highest mortality rate was 5.333 after 1 h of treatment with a concentration of 100% of Goldti5 for *A. mellifera carnica*. While the lowest mortality rate was 2.667 after 2 h of treatment with 1.00 ppm of TITAN 48% and Goldti5 for *A.*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50435057

mellifera carnica, the highest mortality rate was 8.667 after 2 h of treatment with 5.00 ppm of Goldti5 for adult *A. mellifera carnica*. The lowest mortality rate was 3.000 after 4 h of treatment with 1.00 ppm of Delta ride for the adult *A. mellifera carnica*. However, the highest mortality rate was 8.333 after 4 h of treatment with a concentration of 10.00 ppm of Delta ride for the adult *A. mellifera carnica*. Similarly, the lowest mortality rate of 3.333 was established after 6 h in the 1.00 ppm concentration. In addition, the highest mortality rate of 9.667 was observed in 10.00 ppm of Goldti5 after 6 h for adult *A. mellifera carnica*. The lowest mortality rate of 4.667 was established after 24 h in the 1.00 ppm for Delta ride, while the highest mortality rate of 10.00 was observed in 10.00 ppm of Delta Ride, Goldti5 and 2.50, 5.00, and 10.00 ppm concentrations of TITAN 48% after 24 h for adult *A. mellifera carnica*. As for the relation between insecticides and insecticide concentrations (AB), the lowest mortality rate was 2.466 at 1.00 ppm for Delta ride, the highest mortality rate was 8.200 at 10.00 ppm for Goldti5 in the case of adult *A. mellifera carnica*, in comparison with controls. Concerning the relation between insecticides and test periods (AC), the lowest mortality rate was 1.266 after 1 h for TITAN 48%, and the highest mortality rate was 7.000 after 24 h for TITAN 48% and Goldti5 in the case of adult *A. mellifera carnica*. As for the relation between insecticide concentrations and test periods (BC), the lowest mortality rate was 0.000 at a concentration of 1.00 ppm after 1 h, while the highest mortality rate was 10.000 at a concentration of 10.00 ppm after 24 h of testing, in comparison with controls. The relation between each insecticide (A) showed the lowest mortality rate to be 3.866 for Delta ride, while the highest mortality rate was 5.333 for Goldti5, at the significance level of $P < 0.05$ there was a significant difference among Delta ride, TITAN 48% and Goldti5. The relation between each insecticide concentration (B) showed the lowest mortality rate to be 3.511 at 1.00 ppm and the highest mortality rate was 7.510 at 10.00 ppm in the case of adult *A. mellifera carnica*, in comparison with control. As for the relation between each test period (C), the lowest mortality rate was 1.933 after 1 h, and the *A. mellifera carnica* mortality rate increased with time, up to 6.844 after 24 h.

Table 1. *Mean numbers of A. mellifera carnica mortality after being treated with various concentrations of insecticides through feeding*

Also *Figure 1* pointed out the toxicity regression related to the *A. mellifera* carnica mortality

Effect of insecticides applied orally to Apis mellifera Native

Table 2 showed, that concerning the relation among insecticides, insecticides concentration and exposure time (ABC) the lowest mortality rate was 0.00 after 1 h of treatment with 1.00 ppm of TITAN 48% for *A. mellifera* Native. However, the highest mortality rate was 6.333 after 1 h of treatment with 10.00 ppm of Delta ride and Goldti5 insecticides on *A. mellifera* Native. The lowest mortality rate was 1.333 after 2 h of treatment with 1.00 ppm of Delta ride and TITAN 48% for the forager honey bee of *A. mellifera* Native, while the highest mortality rate was 7.333 after a 2 h treatment of 10.00 ppm of TITAN 48%. The lowest mortality rate was 2.333 after 4 h of treatment with 1.00 ppm of Delta ride and TITAN 48% insecticide for *A. mellifera* Native foragers. However, the highest mortality rate was 8.333 after 4 h of treatment with 10.00 ppm of Delta ride insecticide for the forager of *A. mellifera* Native. The lowest mortality rate was 3.333 after 6 h of treatment with 1.00 ppm of Delta ride and TITAN 48% for *A. mellifera* Native foragers. The highest mortality rate of 9.333 was found after 6 h of 10.00 ppm TITAN 48% insecticide treatment. The minimum mortality rate was 4.333 after 24 h at 1.00 ppm of Delta ride and TITAN 48% for *A. mellifera* Native foragers. However, the highest mortality rate was 10.000 after 24 h of treatment with 10.00 ppm of Delta ride, TITAN 48% and Goldti5 for foragers of *A. mellifera* Native. The relation among insecticides and insecticides concentration (AB) showed the lowest mortality rate to be 2.266 at a concentration of 1.00 ppm of TITAN 48%, and the highest mortality rate to be 7.933 at a concentration of 10.00 ppm of Delta ride for *A. mellifera* Native foragers, in comparison with controls. The relation between insecticides and tested periods (AC) showed the lowest mortality rate to be 1.6666 after 1 h of TITAN 48% insecticide treatment, while the highest mortality rate was 6.066 after 24 h of Delta ride and Goldti5 treatments for the foragers of *A. mellifera* Native. As for the relation between insecticide concentrations and test periods (BC), the lowest mortality rate was 0.444 at 1.00 ppm after 1 h, while the highest mortality rate was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50435057

10.000 at 10.00 ppm after 24 h of testing, in comparison with controls. The relation between each insecticides (A) showed the lowest mortality rate to be 3.799 for TITAN 48%, while the highest mortality rate were 4.506 for Delta ride, and at the significance level of P < 0.05 there was significant difference between Delta ride, TITAN 48% and Goldti5. The relation between each insecticide concentration (B) showed the lowest mortality rate to be 2.532 at 1.00 ppm and the highest mortality rate to be 7.799 at 10.00 ppm, for the foragers of *A. mellifera* Native, in comparison with control. The relation between each tested period (C), showed the lowest mortality rate to be 2.466 after 1 h, and that the *A. mellifera* Native mortality rate increased with time, up to 5.955 after 24 h.

The effects of insecticides applied orally to A. mellifera ligustica

In *Table 3* we can see the relation among insecticides, insecticides concentration and exposure time (ABC) among others. The minimum mortality rate was shown to be 0.000 after 1 h of treatment with 1.00 ppm of Delta ride and TITAN 48% for *A. mellifera ligustica*. However, the highest mortality rate was 8.000 after 1 h of treatment with 10.00 ppm of Goldti5 insecticides for adult *A. mellifera ligustica*. The lowest mortality rate was 0.333 after 2 h of treatment with the 1.00 ppm of Delta ride for the foragers of *A. mellifera ligustica*, while the highest mortality rate was 9.333 after a 2 h treatment with 10.00 ppm of Goldti5 insecticide. The lowest mortality rate was 1.667 after 4 h of treatment with 1.00 ppm of Delta ride for *A. mellifera ligustica* foragers. However, the highest mortality rate was 9.667 after 4 h of treatment with 10.00 ppm of Goldti5 insecticide for the foragers of *A. mellifera ligustica*. The lowest mortality rate was 3.667 after 6 h of treatment with 1.00 ppm concentration Delta ride for *A. mellifera ligustica* foragers. The highest mortality rate of 10.000 after 6 h was found in the 10.00 ppm Goldti5 treatment. The lowest mortality rate was 5.333 after 24 h at 1.00 ppm of Delta ride insecticide, as determined for the foragers of *A. mellifera ligustica*. However, the highest mortality rate was 10.000 after 24 h of treatment with 10.00 ppm of Delta ride and Goldti5, and also with 1.000, 2.500, 5.000, and 10.00 ppm of TITAN 48%, in addition to 5.000 ppm of Goldti5 for *A. mellifera ligustica* foragers. The relation between insecticides and insecticides concentration (AB) showed the lowest mortality rate to be 2.200 at 1.00 ppm of Delta ride insecticide, while the highest mortality rate of 9.400 was found under 10.00 ppm of Goldti5 for *A. mellifera ligustca* foragers, in comparison with controls. The relation between insecticides and testing time (AC) showed the lowest mortality rate to be 0.466 after 1 h of TITAN 48% insecticide, and the highest mortality rate to be 5.613 after 24 h of Goldti5 for the foragers of *A. mellifera ligustica*. As for the relation between insecticide concentrations and test periods (BC), the lowest mortality rate was 0.222 at 1.00 ppm after 1 h, while the highest mortality rate was 7.777 at 10.00 ppm after 24 h of testing, in comparison with controls. As for the relation between each insecticide (A) the lowest mortality rate appeared to be 3.706 for Delta ride, while the highest mortality rate was 5.613 for Goldti5, and at the significance level of $P < 0.05$ there was a significant difference between Delta ride, TITAN 48% and Goldti5. The relation between each insecticide concentration (B) showed the lowest mortality rate to be 3.177 at 1.00 ppm and the highest mortality rate to be 7.777 at 10.00 ppm, for *A. mellifera ligustica* foragers, in comparison with controls. As for the relation between testing times (C), the lowest mortality rate was 1.755 after 1 h, and the adult *A. mellifera ligustica* mortality rate increased with time, up to 7.377 after 24 h. The increase in exposure time and concentration of pesticide caused increase in the mortality of honeybees. The exposure of *A. mellifera* Native to Delta Ride at a concentration of 2.5 ml /a gallon of water for 24 h after feeding caused a 23.00% mortality.

Figures 1, 2 and *3* illustrate the LC50 values, and the effect comparison of TITAN 40%, Delta ride and Goldti5 on *A. mellifera* Native. TITAN 40% had an LC50 value of 1.70 ml/gallon after 24 h of exposure after feeding. While Delta ride and Goldti5 had values of 1.45 and 1.37 respectively. In *Figures 4, 5* and *6* the result showed that, based on LC50 values, a Goldti5 insecticidal deposit was 1.75 times more effective than that of Delta ride after 24 h of exposure for *A. mellifera carnica*, and that Delta Ride insecticidal deposits were 1.63 times more effective than those of TITAN 48%. *Figures 7, 8, 9* show these effects on *A. mellifera ligustica*. Delta Ride insecticidal deposits were

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50435057

1.17 times more effective than those of TITAN 48% after 24 h of exposure, while TITAN 48% insecticidal deposits were 0.50 times more effective than those of Goldti5.

Table 3. *Mean numbers of A. mellifera ligustica mortality subsequently to being treated with different concentration of insecticides orally*

Propit line in *Figure 3* indicated to the toxicity of the pesticide used on *A. mellifera ligustica*

Fat bodies

Generally, the first change in the perivisceral fat cells was the development of small vacuoles in the cytoplasm. This occurred in all races of honey bee workers in the control experiment (*Fig. 10*). The fat cells showed a series of changes in the cytoplasm when exposed to the recommended dose. The granulated cytoplasm developed a few droplets while the nucleus remained unchanged. In a few cells the granulated cytoplasm accumulated around the central nucleus. Increasing the dose to 10 ppm caused more alterations in cell features. The round cells developed scattered inclusions and their nucleus disintegrated. The fat bodies showed a few changes in their features with droplets forming throughout the cytoplasm. The cytoplasm became slightly more granular than normal.

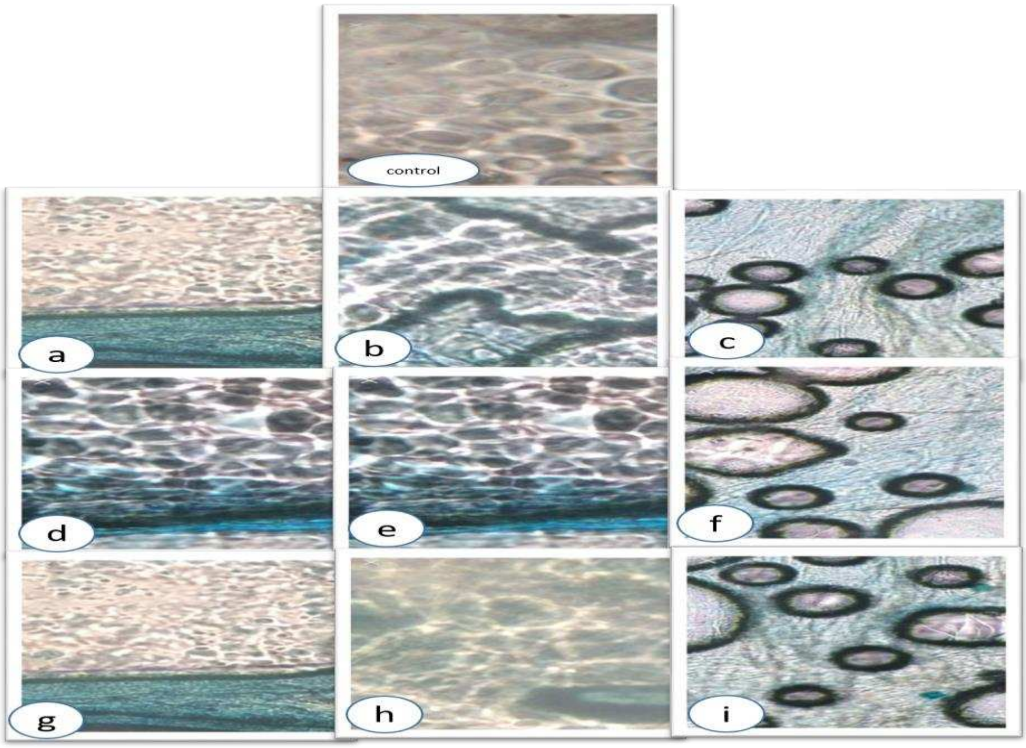

Figure 10. *Effect of pesticides on fat bodies of three races of honeybee workers: A. mellifera carnica, A. mellifera ligustica, A. mellifera Native*

The results are in agreement with Pham-Delègue et al. (2002), who found that the effect of insecticides on the direction sense of bees (reproductive ability), their communicative ability (bee dance language), and their foraging activity (olfactory learning performance) are affected by the LD50 of insecticides, and also agrees with EPPO (1993) and Thompson (2003) who found that the insecticides affect the bee larvae, division of labor, foraging, as well as the development of bee colonies while exposed to a lower lethal dose. The results are also in agreement with Bohnenblust et al. (2016), who found that nearly 80% of all pesticides applied to row crops are herbicides, and these applications pose potentially significant ecotoxicological risks to non-target plants and associated pollinators. The results similarly agree with Krupke et al. (2012), who found that bees are exposed to these compounds and several other agricultural

DOI: http://dx.doi.org/10.15666/aeer/1702_50435057

pesticides in several ways throughout the foraging period. During spring, extremely high levels of clothianidin and thiamethoxam were found in planter exhaust material produced during the planting of treated maize seeds.

Conclusion

Laboratory tests of oral ingestion application of different pesticides to susceptible honeybee foragers revealed that the most effective herbicide affecting *Apis mellifera carnica* was TITAN 48%, and that foragers are susceptible to toxicities of various pesticides (insecticides, herbicides) including pesticides not normally thought to affect them, generally having negative effects on fat bodes.

Abstract. Whereas groundwater numerical simulation is an essential part of groundwater environmental impact analysis, the authors propose a more accurate and suitable method for identifying and predicting the groundwater environment, laying a scientific basis for groundwater environmental impact evaluation. Targeted at the river and lake connection project in Jilin Province, this paper establishes a groundwater prediction model based on the groundwater modelling system (GMS), and considers the land salinization risk posed by the variation in groundwater level after the water diversion of the project. The results show that the depth of phreatic water in each area is greater than the upper limit of ecological water level after the implementation of the project plan, leaving a small chance for soil salinization.
Keywords: *groundwater modelling system, groundwater environmental, impact prediction, numerical simulation, soil salinization risk, water diversion project*

Introduction

The groundwater numerical simulation has been extensively applied to groundwater environmental impact analysis (Myles, 1970; Pradeep K., 2008; Li et al., 2014a). There are mainly two equivalently effective methods for numerical simulation of groundwater flow: the finite difference method (FDM) and the finite element method (FEM) (Liang, 2014). Featuring simpler method, faster speed and higher precision, the FDM, coupled with groundwater modeling system (GMS) (Environmental modelling research laboratory, 2005), was adopted to build up a model for ground water environment impact in this research.

As an enhancement of the hydraulic connection between different waterbodies, the river and lake connection system provides a strong guarantee to the smoothness of the water cycle (Li et al., 2014b). Taking the river and lake connection project in Jilin Province (Li et al., 2014c) as an example, the groundwater level was elevated to a certain extent through the diversion of groundwater to the study area. Therefore, the groundwater can be treated as an indicator in environmental impact assessment. With the aid of groundwater simulation technology, this paper predicts the variation in groundwater level before and after the leakage recharge, and analyzes the effect of the recharge on groundwater environment in light of the water level and quality, aiming to lay a scientific basis for preparation of groundwater environmental protection measures (Chao, 2008; Vishnu and Mukand, 2011).

The study area covers 9 cities and countries in western Jilin Province (*Fig. 1*). According to regional topographical and hydrogeological conditions, the western plains

DOI: http://dx.doi.org/10.15666/aeer/1702_50595066

region in the province was selected as the simulation area, and evaluated through the analytical method and analogy analysis (Martin, 1990).

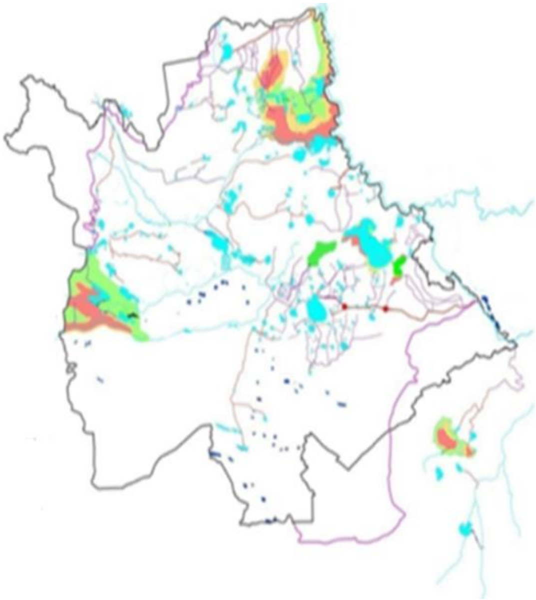

Figure 1. *Jilin Lakes connection scope of groundwater numerical simulation diagram*

Materials and methods

Conceptual hydro geological model

The lithology and thickness of the simulated area are different in the area, whether it is diving aquifer or confined aquifer. Therefore, the two computational aquifers are generalized as heterogeneous isotropic aquifers. The natural hydraulic gradient of the aquifer is very small and most of the areas are less than 1 ‰. The seepage is basically in accordance with the Darcy’s law. The groundwater flow is limited by the accuracy of the data and is treated as a planar two-dimensional flow. The elements change over time and are generalized as unsteady.

No matter the aquifer is confined or not, the lithology and thickness in the study area are subject to different degrees of changes. Hence, both confined and unconfined aquifers are generalized as heterogeneous but isotropic aquifers. In nature, the hydraulic gradient for groundwater flow in aquifer is extremely small, which is less than 1‰ in most areas. Thus, the seepage basically conforms to the Darcy’s law. Due to the limitations on data accuracy, the groundwater flow was treated as a 2D planar flow (Chao, 2011; Bai, 2006). Besides, it was treated as an unsteady flow because each element of the flow varies with time.

For the unconfined acquirer, the eastern rivers (the Nengjiang River and the Second Songhua River) were conceptualized as the river boundaries of groundwater in the simulation area. In southeastern and southern parts, the groundwater watershed of eastern upland plain was treated as the zero flow boundaries; the northwestern part of the simulation area was bordered by impermeable boundaries, for the bedrock of the surrounding hills were mainly volcanic rocks; In other sections in the western part of the simulation area, the boundaries were taken as the second flow boundaries; the roof

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50595066

was the water exchange boundary, and the floor was an impermeable boundary in single-layer aquifer area, and leakage boundary in double-layer aquifer area.

For the confined aquifer, in the southern part of the simulation area, the groundwater watershed was treated as the zero flow boundaries; the roof was a leakage boundary, as it was a layer of weak permeable soil, allowing the confined water to exchange with the upper phreatic water through the soil layer; the roof of the confined aquifer was generalized as an impermeable boundary, because the layer was formed up with extremely poor permeable tertiary mudstones.

Note: According to the characteristics of the regional groundwater flow field, zero flow boundaries refer to the boundaries perpendicular to water table contour lines.

Numerical simulation

Simulation context

The groundwater flow in the study area was simulated by a non-homogeneous, isotropic, quasi 3D model. The leakage amount was used to couple up the pore groundwater with porous confined water, upper pore-confined water and lower pore-confined water. The mathematical model was discretized by the GMS, the data interpolation was completed using the Kriging method, and the model was solved with the strongly implicit method. The 37,562 km^2 unconfined aquifer was divided into rectangles. In total, the area was split into 36,675 grid cells in 238 columns and 258 rows. Each cell was 1,000 m long, and 1,000 m wide, covering an area of 1 km^2. The meshing of the unconfined aquifer is depicted in *Figure 2a*. Total confined aquifer simulation area is 32,410 km^2, split it rectangle, it is divided into 238, 257 rows, altogether of grid cells, each cell is 1000 m long, 1000 m wide, with an area of 1 km^2. Confined aquifer model grid shown schematically in *Figure 2b*. The model was identified and verified based on the long observation data from Jan. to Dec. 2009 and from Jan. to Dec. 2012. The stress period was set to 1 month with a time step of 6 days. Consequently, the whole simulation period was divided into 36 stress periods, each of which was subdivided into 5 time periods.

DOI: http://dx.doi.org/10.15666/aeer/1702_50595066

According to the difference in topographical and hydrogeological conditions (e.g. aquifer lithology and thickness), the unconfined aquifer was classified into 21 parameter partitions, the leakage layer was divided into 5 parameter partitions, and the confined aquifer was split into 7 parameter partitions (*Fig. 3a-c*).

Model identification

The model was identified with the long observation data of groundwater from Jan. to Dec. 2009, which was provided by the water conservancy department of Jilin Province. The data were selected because the source sink terms of groundwater in 2009, a dry year, have little interference in model operation. Since the project is still in the planning phase, the information of the source sink terms is not accurate enough to fit the long-time series water levels at the observation points. Hence, groundwater flow field in the wet and dry periods was employed for data fitting in the simulation. The model was deemed as satisfying the accuracy requirements when the calculated flow field was in good agreement with the measured flow field.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50595066

The source sink terms include rainfall infiltration recharge, the side run-off recharge, irrigation infiltration recharge, evaporation discharge of phreatic water, artificial exploitation amount, and river course seepage and discharge. The initial groundwater level was identified through processing these terms. According to the water levels monitored in 129 phreatic water monitoring wells and 107 confined water level monitoring wells in and around the simulation area, the initial flow fields of confined water and phreatic water in the identification period were acquired through the interpolation via the Kriging method (Mazzia and Puttii, 2002) in the GMS software (*Fig. 4a* and *b*).

Figure 4. a *Identification phreatic groundwater the initial flow chart.* ***b*** *"Zero" forecast period phreatic groundwater the initial flow*

Results and discussion

After the source sink terms were inputted, the model was run to the end of the simulation period to get the calculated water level. With all things being considered, the groundwater level in the unconfined aquifer was basically stable or slightly declining under the Plan Zero, leaving little chance for soil salinization.

Based on the groundwater flow field prediction under the Plan Zero, the groundwater flow field was predicted considering the additional leakage recharge resulted from the implementation of the river and lake connection plan, and compared with the simulated results under the Plan Zero. The main source sink terms under the connection plan were consistent with those under the Plan Zero. Based on the mean annual calculated results, the additional leakage recharge was assigned to the model in light of the specific engineering plan. The simulation period lasted from Jan. to Dec. 2013. The stress period was set to 1 month with a time step of 6 days. Consequently, the whole simulation period was divided into 216 stress periods, each of which was subdivided into 3 time periods. As the model prediction plan was the same to the Plan Zero from 2013 to 2020, the authors mainly compared the variation in groundwater flow field in 2030 after the project implementation (*Fig. 5*). As shown in the prediction of groundwater flow field, the groundwater flow field under the project plan was basically the same with that under

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50595066

the Plan Zero; the piedmont in the western part and the groundwater shed in the southeastern part still had relatively high groundwater level and large hydraulic slope; the groundwater generally flew from the southwest to the northeast, mainly through the channels of the Nengjiang River and the Second Songhua River.

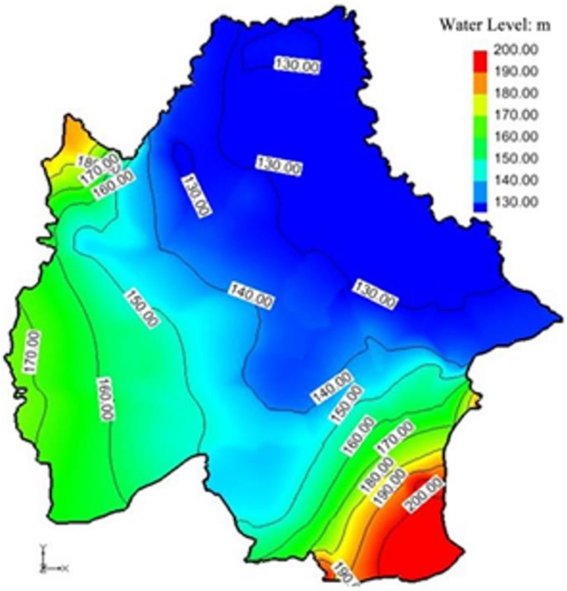

Figure 5. *Predicted flow field of unconfined groundwater*

According to the model prediction results under the connection plan, the regional groundwater level after the project implementation was higher than that in Plan Zero thanks to the increase in leakage recharge. Under the joint effect of growing groundwater exploitation and other factors, the phreatic water level continued to decline in 2013-2030 in core plate A; the groundwater level in core plate B kept falling in 2013-2020, but rebounded in 2021-2030 to a level lower than the initial level; the phreatic water level in core plate C and other edge plates remained stable in 2013-2030. *Table 1* displays the variation in phreatic water level of each area after implementing the connection plan, and compares the level with the ecological water level.

Table 1. *Plan after the implementation of the change of regional groundwater level and ecological water level of contrast*

Area	**2013-2030 Range of water level (m)**	**2013-2030 Fluctuation rate (m/a)**
A core plate (50, 136)	-1.8	-0.1
B core plate (113, 176)	-0.9	-0.05
C core plate (144, 31)	0.3	0.017
Others (211, 108)	0.1	0.006
Area	Water depth (m)	Ecological water level (m)
A core plate (50, 136)	5.8-7.8	1.88-5.17
B core plate (113, 176)	3.7-5.43	2.30-5.09
C core plate (144, 31)	2.39-3.96	2.35-4.87
Others (211, 108)	4.26-5.24	2.35-4.87

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50595066

As can be seen from the above table, the depth of phreatic water in each area is greater than the upper limit of ecological water level after the implementation of the project plan, leaving a small chance for soil salinization. However, dynamic monitoring should be applied in shallow groundwater areas to control the groundwater level within a reasonable range.

Conclusion

The river and lake connection project may bring changes to the groundwater level and quality (Mazzia and Puttii, 2007). Its influence on groundwater environment mainly attributes to the leakage recharge of the diversion water. Since the water is diverted from eastern rivers with much lower degree of mineralization than the groundwater, the leakage recharge will not increase the degree of mineralization of ground water, leaving no adverse effect on groundwater salinity variation.

With the groundwater numerical simulation technology, this paper simulates and analyzes the variation in groundwater flow field and water level of the simulation area. Only two conditions were taken into consideration: Plan Zero and the connection project plan. The prediction results show that, under the connection plan, the regional groundwater level after the project implementation was higher than that in Plan Zero thanks to the increase in leakage recharge. Under the joint effect of growing groundwater exploitation and other factors, the phreatic water level continued to decline slightly in core plates A and B, while that in core plate C and other edge plates remained stable; the depth of phreatic water in each area is greater than the upper limit of ecological water level after the implementation of the project plan, leaving a small chance for soil salinization.

Abstract. With the intensification of greenhouse effect, the global average temperature gradually increases, and the atmospheric CO_2 concentration has exceeded 400 ppm. It has been a global consensus to reduce carbon emissions and the impact of the greenhouse effect. However, researches are rare on how to develop a reasonable emission reduction target and distribute funds in maintaining sustainable development. Based on the system dynamics method in the environmental system, we took a macro approach to simulate the trends of CO_2 amount, CO_2 concentration and temperature change in the next 5 decades. Through sensitivity analysis, we found anthropogenic CO_2 emissions as the major factor influencing the above trends. The iteration result at the step size of -0.4% showed that the -3.2% CO_2 emission reduction rate can achieve the Paris Agreement goal. On this foundation, we calculated the future amount of global CO_2 emission reduction and its investment and depict the latter, which provides reference for relevant sectors to formulate CO_2 emission reduction policies.
Keywords: *global warming, CO_2, emission reduction, investment path, policies*

Introduction

Reducing carbon emissions and slowing down the greenhouse effect has become the consensus across the globe, as countries around the world have signed several climate agreements to mitigate the greenhouse effect. As early as 1992 (Tu, 2005), the United Nations Conference on Environment Development formulated a convention on climate change in Rio de Janeiro, Brazil. In 1997, 149 countries adopted the Kyoto Protocol, which set the goal of limiting the average temperature rise below 2 °C by the end of the 20th century (Meinshausen et al., 2009). The year of 2015 witnessed the signing of the Paris Agreement among representatives from more than 200 countries. According to it, the rise in global temperature should not exceed 2 °C or if it can be achieved 1.5 °C compared to the value before industrialization (Li, 2017; Ogle et al., 2018); the countries and regions around the world should achieve the peak carbon emissions as soon as possible and meet the goal of zero CO_2 emission in the second half of the 21st century (Chen and Chen, 2016; Marino et al., 2017).

To ensure that the temperature rise is not higher than 2 °C, the equivalent of anthropogenic CO_2 should not exceed 450 ppm (which used to be 280 ppm before industrialization) (Elzen and Höhne, 2008). IPCC experts concluded that the 2020 emission volume of developed countries should be reduced by 25-40% compared to the 1990 one, which is 15-30% for developing countries (Elzen and Höhne, 2010). The results of a variety of studies show with a higher than 66% probability, that if we want

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50675080

the total anthropogenic temperature rise at the end of the century not to exceed the temperature of the 1861-1880 period by more than 2 °C, countries should keep the amount of CO2 emissions accumulated since 1870 below 2,900 Gt, and yet it was already 1,900 Gt by 2011 (Magazzino, 2016). In June 30, 2015, our country submitted the document of Intended Nationally Determined Contribution (INDC), committing to reach the peak carbon emissions roughly by 2030, drop the carbon intensity by 60%-65% than 2005, and occupy around 20% accumulated carbon emissions quota of the total according to the equity requirements in the effort-sharing scheme (Cui et al., 2016). Most of the current researches are concentrated on total amount control, focusing little on the annual amount and allocation of investments on carbon dioxide emission reduction. The fragmented CO_2 emission goal-settings among countries are disadvantageous to unifying CO_2 emission reduction paths (Sikharulidze et al., 2016; Huang et al., 2016; Gotovsky et al., 2018). In this study, the system dynamics model was used to predict the temperature change trend and carbon dioxide emission trend in the next 50 years. By analyzing the influence of different emission strategies on the greenhouse effect, the optimal emission strategy was finally determined. The research can provide a reference for the country to formulate a reasonable carbon emissions policy.

Material and methods

Carbon cycle model and greenhouse effect

The land and sea on the surface of the earth will absorb the short-wave radiation from the sun and convert it into heat which returns to the outer space in the form of long-wave radiation. This circulation helps balance the terrestrial temperature. However, CO_2, CH_4 and other greenhouse gases are active in reflecting long-wave radiation off the atmosphere, causing the "greenhouse effect" as the temperature on the earth surface rises (Frolking et al., 2006; Köhler et al., 2017). Greenhouse effect is a natural phenomenon caused by the emission of large amounts of greenhouse gas due to the rapid economic development in recent years. In this scenario, the atmospheric and marine temperatures will ultimately increase, and the glacial sheet in the Polar Regions will melt down, causing the rise in sea levels and the change of climate patterns (Cloy, 2018; Perry et al., 2012; Shao et al., 2016).

The main measure to control the greenhouse effect are to control carbon emissions, mainly due to the recent high contribution of CO_2 84% to atmospheric radiation (Levin, 2012). Therefore, it is necessary to study on the global carbon cycle model. In doing so, there are mainly two approaches: dynamic simulation and statistics (Bayer et al., 2015). The latter method is simple but physically blurred. With the analysis of historical data, this method can directly establish the model of carbon cycle law to show the past and future development trend. However, it fails to illustrate the system dynamics behaviors of carbon cycle to climate change, and the source and integrity of known data limits the precision of the model. The statistical method can be combined with the dynamics model to achieve good effect (Isacs et al., 2016). The system dynamics method includes the radiation convection mode, energy balance mode, and atmospheric circulation mode (Li and Tan, 2000). They will be analyzed in the following part, so that we can choose the most suitable mode for this study.

Radiation convection: By studying the effect of greenhouse gas on the solar radiant energy and the terrestrial and atmospheric radiation, we can use this method to calculate

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50675080

the potential contributions of different green gases to global warming and the atmospheric contours when the radiations reach a balanced state. Also, by considering the atmosphere as a column, this mode allows the establishment of a greenhouse effect model with clear physical meanings and simple calculations (Inamdar and Ramanathan, 1994). Nevertheless, as the influence of atmospheric circulation is excluded, this method is insufficient for the biosphere analysis and the carbon cycle effect research in a large scale.

Atmospheric circulation: through the study of carbon cycle law of the ocean, the atmosphere and the terrestrial biosphere under global warming, this mode includes the marine factors of water content, heat and chemical effect and the terrestrial factors of plant photosynthesis and respiration in analyzing carbon cycle (Babič, 2017; Chen et al., 2015; Xu and Shang, 2016; Zhang et a., 2018). As the description of the physical process of carbon cycle in the atmosphere, this mode fits well for long-lasting, large-scale issues with highly precise outcomes. However, the error of research results can be high due to the large data pool and the complicated calculation procedures.

Energy balance: this mode is mainly based on the energy balance model established under the law of conservation of energy. The energy balance equation is *Equation 1*:

$$C\frac{dT}{dt} = R\downarrow - R\uparrow \qquad \text{(Eq.1)}$$

where:
C: the thermal inertia of land, ocean and the atmosphere,
R↓: incoming radiation,
R↑: outgoing radiation.
Equation 1 can be converted into *Equation 2*:

$$C\frac{\partial T}{\partial t} = Q(1-\alpha) - \Delta I - dvi(\mathrm{F}) \qquad \text{(Eq.2)}$$

where:
Q: solar radiation,
α: reflectivity,
ΔI: outgoing long-wave radiation,
dvi (F): net energy flux along the circle of latitude.

This method takes into account the carbon cycle system and the influence of biosphere on atmospheric temperature increased. It can reflect the physical processes and the sensitivity of different indicators to climate change in a clear and simple way (Pugh et al., 2016). In this study, the energy balance model will be used in line with the data obtained from the atmospheric circulation mode and the radiation convective mode to establish a system dynamics model of the greenhouse effect.

Relationship between CO_2 concentration and temperature increase

According to the present study, the atmospheric CO_2 concentration is correlated with the increase in atmospheric temperature. By collating the average terrestrial temperature data statistics from the NASA Goddard Institute for Space Research (*Fig. 1*), we find that the average temperature of the earth has increased annually since 1958, rising by 1 °C in 2015. Furthermore, we fit the equation of temperature increase (ΔT) at the R^2

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50675080

value of 0.8875, as shown in *Equation 3*. The reliability of these data should be high as they conform to the statistical principle.

$$\Delta T = 0.0001Y^2 + 0.0086Y - 0.0914 \quad \text{(Eq.3)}$$

where Y: the difference of temperature between the calculation year and the year of 1958.

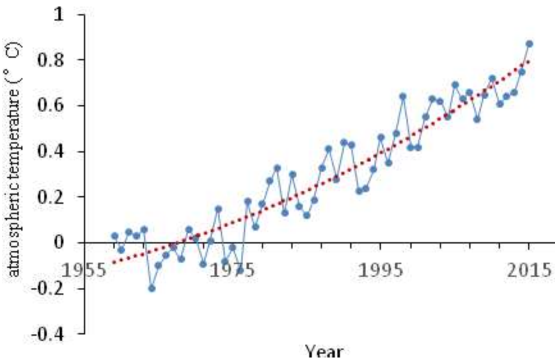

Figure 1. *The broken line of annual temperature increase since 1958*

According to *Equation 3*, it can be calculated that the temperature increase at the end of this century will reach 3.15 °C without considering the increase in CO_2 emissions from social development or human intervention. This value is far higher than the ideal value of the Kyoto Protocol. Actually, due to social development and economic boom, the CO_2 emissions will inevitably increase.

Figure 2 is the environmental monitoring data from the American Earth System Research Lab. The atmospheric CO_2 concentration has increased from 315 ppm in 1958 to the current 406 ppm, which is only 44 ppm lower than the threshold of 450 ppm. With these data, the CO_2 concentration equation can be obtained, as shown in *Equation 4*:

$$C_{CO2} = 0.0123Y^2 + 0.8119Y + 314.47 \quad \text{(Eq.4)}$$

where Y: the difference of CO_2 concentration between the calculation year and the year of 1958.

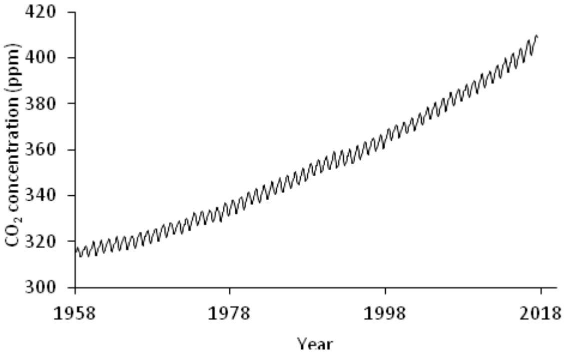

Figure 2. *Changes in atmospheric CO_2 concentration since 1958*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50675080

According to the average annual data, we obtain the average annual growth line of atmospheric CO_2 concentration after 1958. It can be seen from *Figure 3* that the average annual growth rate of CO_2 concentration increases from 0.75 ppm in 1958 to the current value of 2.98 ppm, indicating a fast speed of growth.

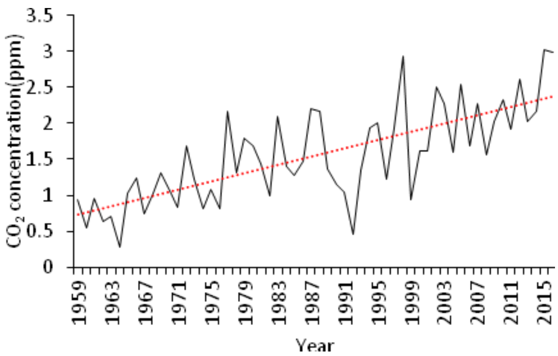

Figure 3. *The average annual growth line of CO_2 concentration since 1958*

The CO_2 concentration (C_{CO2}) and atmospheric temperature increase (ΔT) are fitted into a relationship line, as in *Figure 4*. With another fitting, we obtain the relationship formula between CO_2 concentration and atmospheric temperature increase (ΔT), as shown in *Equation 5*:

$$\Delta T = 8\times10^{-5} C_{CO2}{}^2 - 0.0472 C_{CO2} + 6.777 \quad \text{(Eq.5)}$$

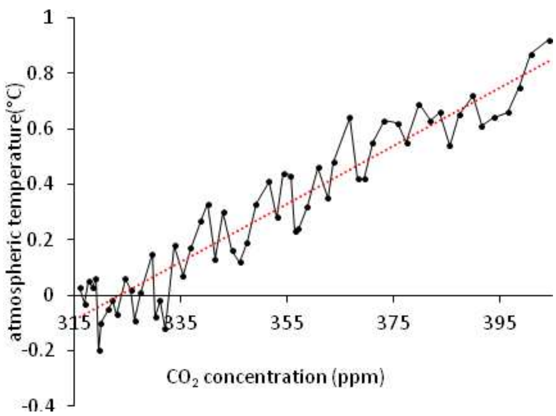

Figure 4. *The relationship line of CO_2 concentration and atmospheric temperature growth trend*

Establishment of the system dynamics model of greenhouse effect

Greenhouse effects in the global carbon cycle

The main source of greenhouse gases in the atmosphere are anthropogenic emissions, the respiration of plants and animals, and the release of dissolved permafrost. Greenhouse gases are adsorbed mainly by dissolving in ocean and plant photosynthesis (Albergel, et al., 2010; Stark et al., 2018), as shown in *Figure 5*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50675080

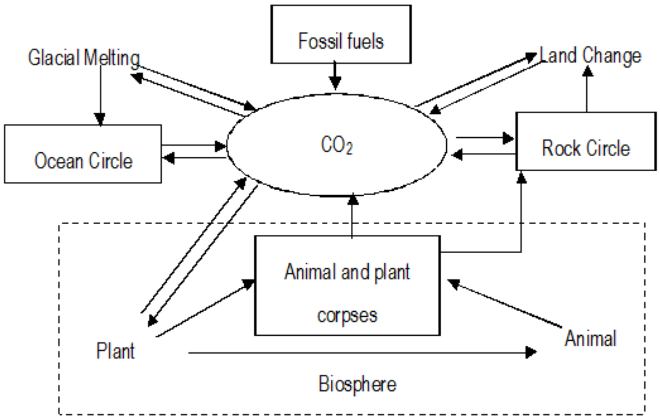

Figure 5. *Global carbon cycle flow char*

As can be seen from *Figure 5,* human production life needs to consume fossil fuels. The resultant large amount of CO_2 is discharged into the atmosphere and, through atmospheric circulation, partly dissolved into sea water and accumulated in the form of carbonate while partly absorbed by plants through photosynthesis. If plants are eaten by animals, some of the carbon will stay in the animal body and not released in the form of CO_2 until the animal is dead and the dead body is under microbial decomposition; the other carbons will exist in soil layers and turn into the carbon component of rock after a long time. In this process, those that cannot be fixed will circulate in the atmosphere and generate the greenhouse effect. As a result, the atmospheric temperature will rise, melting glaciers and thawing permafrosts. Consequently, the CO_2 that used to accumulate in glaciers and permafrosts will be released to the air, which intensifies the greenhouse effect. The atmospheric CO_2 equilibrium equation is as follows (*Eq. 6*) (Shi and Guo, 1997):

$$\frac{dn_a}{dt} = p_{fos} + p_{bio} + k_{ma}(\mathrm{N_m} + \xi_{\mathrm{nm}}) - \mathrm{k_{am}}(\mathrm{N_a} + \mathrm{n_a}) + \mathrm{F_{bi,a}} + \mathrm{F_{a,bi}} + \mathrm{F_{h,a}} \quad \text{(Eq.6)}$$

where:
P_{fos}: CO_2 release rate of fossil fuels,
P_{bio}: the rate of CO_2 release due to land use change,
K_{ma}: ocean atmosphere exchange coefficient,
K_{am}: atmosphere ocean exchange coefficient,
N_m: total carbon in the ocean,
N_a: total carbon in the atmosphere,
n_a: atmospheric carbon increment,
ξ_{nm}: ocean buffer factor,
$F_{bi,a}$: CO_2 exchange flux from land to the atmosphere,
$F_{a,bi}$: CO_2 exchange flux from the atmosphere to land,
$F_{h,a}$: CO_2 exchange flux from soil humus to the atmosphere.

System dynamics principles

System Dynamics (short for "SD") is an approach to understanding the dynamic behaviour of complex systems over time created by Professor Jay W. Forrester of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50675080

Massachusetts Institute of Technology (Alirezaei et al., 2017). It is based on the theory of feedback control and computer simulation technology in studying the relationship between the structure, function and dynamic behavior of complex systems. The system dynamics emphasizes the system as a whole, understand the composition of the system and the interaction of system components, and can carry on the dynamic system simulation experiment to examine the system dynamic change behavior and trend when the different parameters or strategic factors are inputted. In this way, decision-makers can take different measures and observe the simulation results in different scenarios.

The system dynamics model is a causal mechanism model. It emphasizes the decisive role of system inherent mechanism played in system behaviors, performing well in addressing long-term and periodic issues. In the case of insufficient data and unquantized parameters, feedback loops are also usable in some researches. The system dynamics model is good at handling high-order, non-linear, time-varying complex problems. Because of the unparalleled advantages of system dynamics in the study of complex nonlinear systems, it has been widely used in many fields such as society, economy, management, resources and environment.

System dynamics model in the global carbon cycle

The greenhouse effect model was established in Vensim according to the principle of the carbon cycle and the equations summarized above, as shown in *Figure 6*. Based on the 2015 report of the United Nations Environment Program, the CO_2 concentration reaches 400.21 ppm, the atmospheric CO_2 content is 1,965 Gt, and the global anthropogenic CO_2 emission is 36.3 Gt with the total atmospheric CO_2 amount as the variable of integration. By measuring World Bank statistics, the annual CO_2 emission in recent years grows at the rate of 0.82%. The CO_2 produced by the change in land used is about 9.47% of anthropogenic emission (Bergamaschi et al, 2013), while the CO_2 equivalent released annually from the global permafrost is about 1.84 GT. The ocean absorbs about 35% of anthropogenic CO_2 per year, and the proportion is 20% to the biosphere.

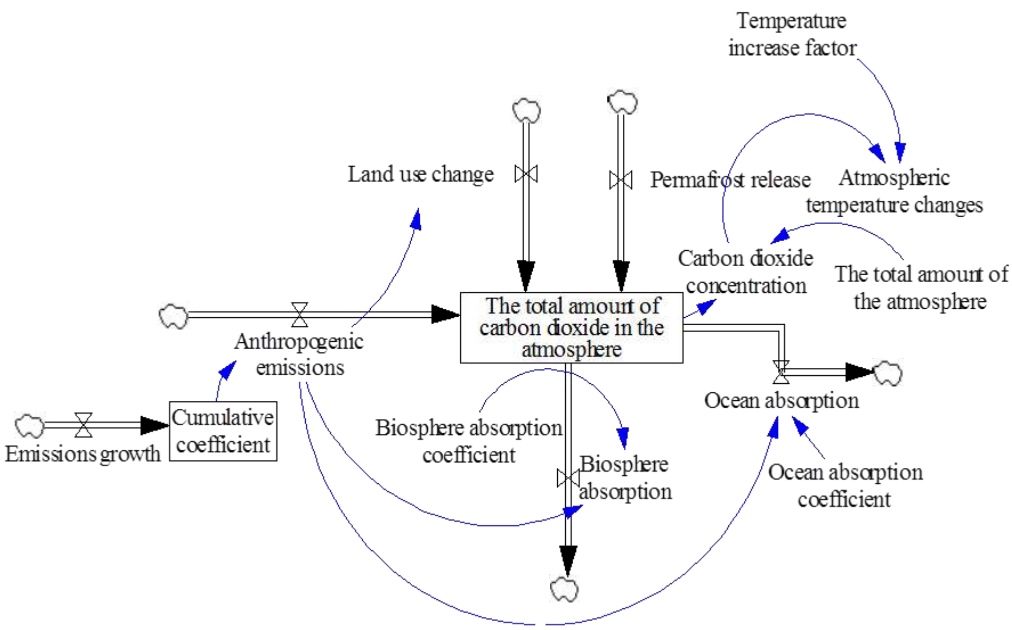

Figure 6. *Global carbon cycle and greenhouse effect model*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50675080

Results and discussion

With 50 years as the data boundary, these data are inputted into the model for simulation analysis without taking any carbon reduction measures.

The total amount of CO_2 in the atmosphere is analyzed and shown in *Figure 7*. The figure shows the constant increase in total atmospheric CO_2 amount from the 1,964 Gt in 2015 to the final 3,581.85 Gt, rising by 82.38%. The initial CO_2 concentration of 404 ppm grows to 736.92 ppm by the fifth decade, which far exceeds the warning line of 450 ppm.

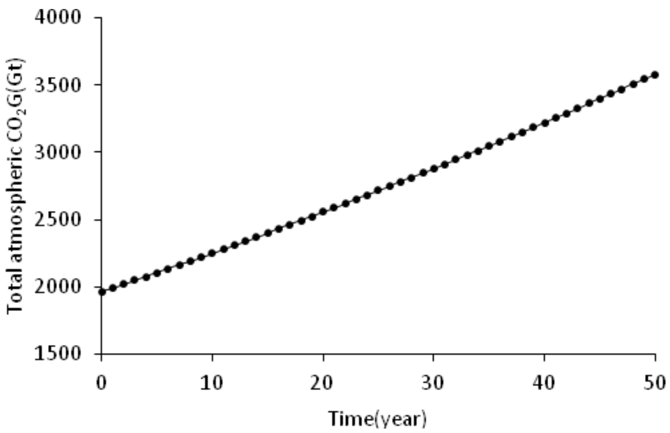

Figure 7. *Total atmospheric CO_2 amount*

The impact of anthropogenic emissions growth rate on key indicators

The anthropogenic emissions are mainly determined by the emission growth rate (Van den Bergh and Botzen, 2015). By adjusting the emission growth rate, the impact of the emission growth rate on the atmospheric index can be found, providing an intuitive way for determining the reasonable emission amount on which basis the goals of the upper limit and reduction amount of emitted CO_2 can be formulated.

The current annual emission growth rate is 0.82%, and we set the decline in growth rate to 0.4%, as shown in *Figure 8*. With the decrease of the CO_2 emission growth rate, the anthropogenic CO_2 emission line begins to tilt down. When the emission growth rate drops to -2%, the anthropogenic emissions will become zero in 50 years. As the emission growth rate continues to decrease, the time required for reaching zero carbon emissions will be shortened gradually. When the emission growth rate is -3.2%, the zero carbon emissions will be achieved in 28 years. However, the lower the emission growth rate is, the more challenges the technologies will be posed to. After a comprehensive thought, we will discuss what the reasonable decline amount of growth rate should be below.

To obtain the reasonable decline amount in growth rate, we re-simulate the model in terms of the CO_2 concentration in the atmosphere at different emission rates, as shown in *Figure 9*. The figure shows that the CO_2 concentration line becomes inverse parabolas with peaks. The peak value gradually decreases as the decline in growth rate is enlarged. When the growth rate becomes -3.2%, the sole peak will emerge in the 22th year at the value of 453.99 ppm. The calculated result complies with the result of INDC.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50675080

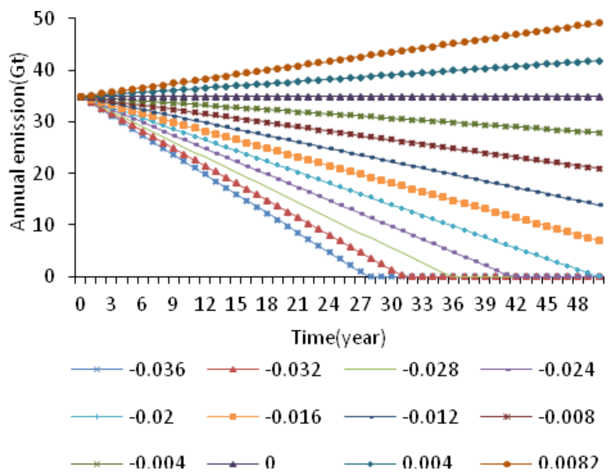

Figure 8. *Annual emission amounts at varying emission growth rates*

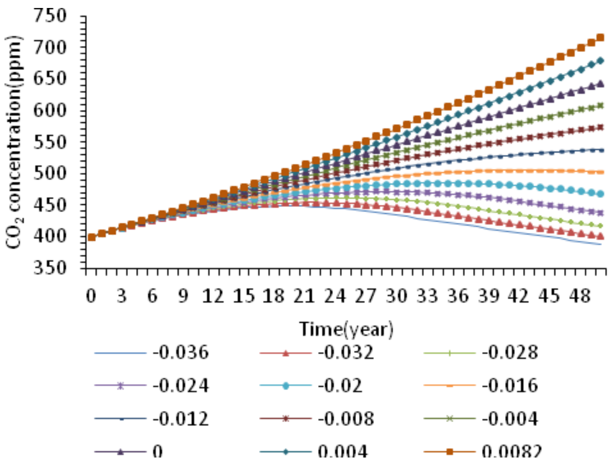

Figure 9. *CO_2 concentration in the atmosphere at different emission rates*

We continue to simulate the model to analyze the average atmospheric temperature changing with the CO_2 emission growth rate, as shown in *Figure 10*. As can be seen from the figure, if the emission growth rate remains unchanged, the atmospheric temperature change curve will go up exponentially, which will bring disastrous consequences to the environment. When the CO_2 emission growth rate declines to -0.8%, the average atmospheric heating curve will present the form of inverse parabola. When the CO_2 emission growth rate declines to -2.8%, the peak temperature becomes 2.029 °C. When the CO_2 emission growth rate declines to -3.2%, the peak temperature becomes 1.836 °C, which meets the requirements of CO_2 concentration. Therefore, -3.2% is the reasonable decline value of CO_2 emission growth rate in order to address the greenhouse effect.

Emission reductions and emission reduction investments

The emission reduction amounts are calculated according to the emission growth rate, and then we draw them in lines in *Figure 11*. It can be seen that there is an

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50675080

inflection point in the 31th year, indicating the realization of zero-emission. This result can be basically equated with the Paris Agreement goal of realizing zero-emission in the second half century. In the next 5 decades, the global carbon emissions reduction amount should increase from the initial 1.4 GT p.a. to the final value of 49.16 GT p.a., and the total emission reduction amount is 1,580 GT, China needs to bear 20% of the total emission reduction amount, which is about 316 GT.

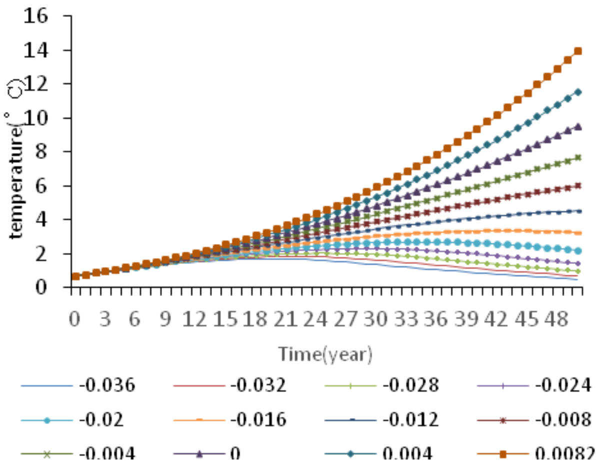

Figure 10. *The average atmospheric heating curves at different emission rates*

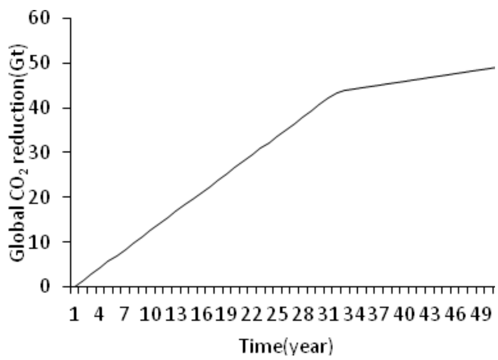

Figure 11. *Global CO_2 reduction line in the next 50 years*

Some scholars have measured the macroeconomic cost of CO_2 emission reduction, which ranges between US $456/t and US $592/t (Fan et al., 2010). We take the average of US $524/t to calculate the future global investment on carbon emissions (see *Fig. 12*). The figure shows that it is necessary to constantly increase investments on carbon emissions in the future 50 years until the annual investment value rise to US $2.57 trillion. The total sum of investments should reach US $82.81 trillion across the globe.

Taking China as an example, in formulating investment policies, the investment on CO_2 emission reduction in the next 50 years can be calculated on the premise that China bears the 20% of global carbon emissions reduction amount. And the related data is shown in *Figure 13*. To address climate change, China should continuously increase

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50675080

investments on carbon emissions reduction in the future 5 decades until the annual investment amount reaches US $0.514 trillion. The total sum of Chinese investments on carbon emissions reduction should be US $16.56 trillion and the total carbon emissions reduction amount should be 316 GT.

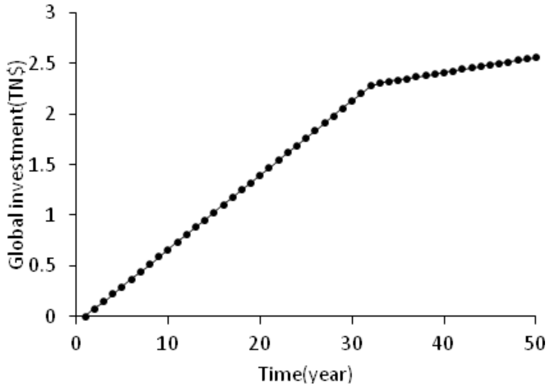

Figure 12. *Global investment line on CO_2 emission reduction in the next 50 years*

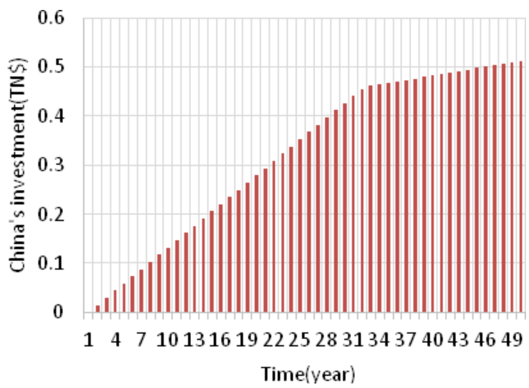

Figure 13. *China's investment on CO_2 emission reduction in the next 50 years*

Conclusion

The greenhouse effect is an environmental phenomenon that triggers global climate change and has attracted the attention of all countries in the world. Although countries are committed to reducing carbon emissions, related goals can only be realized by them setting emission reduction targets according to scientific calculations and investing a reasonable amount of funds on the targets. Reduce carbon emissions, and gradually weaken the impact of greenhouse effect. Through the macro-data based system dynamics analysis, we can see that the task of global CO_2 emission reduction is still arduous. Only by settling the CO_2 emission reduction funds can a country achieves the objectives specified in the Paris Agreement. With certain responsibilities, countries and regions need to make reasonable investments to help reduce global CO_2 concentrations, so as to avoid the unpredicted and uncontrollable consequences brought by the otherwise intensified greenhouse effects. In future research, it is necessary to strengthen the accumulation of basic data, study the relationship between different industrial development and carbon emissions, improve the accuracy of carbon emissions

DOI: http://dx.doi.org/10.15666/aeer/1702_50675080

prediction model, and timely adjust the carbon emissions strategy through more accurate model.

(Received 5th Feb 2019; accepted 6th Mar 2019)

Abstract. This paper evaluates the quality of drinking water sources of 9 villages in Nang County, Tibet Autonomous Region (TAR) of China using the water quality index (WQI) model of the Canadian Council of Ministers of the Environment (CCME), and verifies the evaluation results by the comprehensive pollutant index (CPI) method. The results show that CCME WQI and CPI have outputted similar rankings, and the results of the two methods have high Spearman's rank correlation coefficient. This means CCME WQI is a feasible way to evaluate the safety of rural drinking water sources. CCME WQI evaluation shows that the water qualities in the 9 villages satisfy the requirements on drinking water.
Keywords: *comprehensive pollution index (CPI), the CCME water quality index (WQI), drinking water safety, water quality protection, Spearman's rank correlation coefficient*

Introduction

The hygiene and safety of drinking water directly bears on the health of people. To ensure drinking water safety, it is necessary to implement a whole process control before, during and after consumption. This control strategy relies heavily on the safety evaluation of drinking water. To date, the safety of rural drinking water has been mainly evaluated by analytic hierarchy process (AHP) (Guo et al., 2018; Xu et al., 2016), fuzzy evaluation (Mohamed et al., 2018; Wang et al., 2018), entropy weight method (Li et al., 2018), principal component analysis (PCA) (Naz et al., 2016), Comprehensive Pollution Index (CPI) (Savio et al., 2018), etc. In most studies, only one of these methods is adopted to evaluate the safety of drinking water. However, the evaluation result on the same object may vary from method to method. This problem has not been fully recognized or rationally solved in the existing studies on safety evaluation of rural drinking water. Moreover, there is no report on the safety features or regional differences of drinking water (Hood et al., 2014).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50815091

Currently, Canadian Council of Ministers of the Environment (CCME) water quality index (WQI) (Hurley et al., 2012) is mainly applied in the management of surface water environment, while the comprehensive pollution index (CPI) (Sun et al., 2013) is mainly used to evaluate the drinking water sources. Targeting the quality evaluation of drinking water sources in 9 villages of Nang County, China's Tibet Autonomous Region (TAR), this paper explores the correlation and differences between CCME WQI and CPI, with the aim to assess the applicability of CCME WQI in the evaluation of drinking water sources. Specifically, CCME WQI was adopted to evaluate the safety of drinking water in the 9 villages, and results were verified by CPI method. The evaluation of drinking water safety in these villages can lay a solid basis for decisions on selecting and protecting drinking water sources.

Materials and methods

Based on the field monitoring data of drinking water in 9 villages of Nang County, TAR, two evaluation models were constructed by CCME WQI and CPI, respectively.

Overview of the study area

Nang County (28°40'~29°29'N; 92°28'~93°31'E) is a border county southwest of Nyingtri City and southeast of TAR. It covers an area of more than 4,200 km^2 on the northern foothills of the Himalayas and in the middle and lower reaches of the Yarlung Tsangpo River. With jurisdiction over 6 townships, the county is home to over 18,000 people living in 51 administrative villages and 1 neighborhood community. Most administrative villages are scarcely populated and scattered in remote areas, making it difficult to implement centralized water supply. Currently, the villagers mainly drink natural surface water, which fluctuates greatly by season due to the low vegetation coverage, and the drinking water sources are far from abundant (Tian et al., 2015). To rationalize the selection of rural drinking water sources, it is imperative to carry out targeted safety evaluation of rural drinking water and adopt rational remediation measures.

Data sources

As shown in *Figure 1,* a total of 9 monitoring points were arranged in light of the status of the drinking water sources. The monitoring was carried out in August, 2018. Four sampling points were selected at each monitoring point to measure 16 items, namely, zinc, copper, iron, manganese, total hardness, dissolved oxygen (DO), chemical oxygen demand (COD), total dissolved solids, arsenic, hexavalent chromium, fluoride, anionic synthetic detergent, cyanide, volatile phenols, lead and selenium. These items were selected according to relevant literature (Chang et al., 2017), and analyzed according to the *Environmental Quality Standards for Surface Water* (GB3838-2002) and the *Water and Wastewater Analysis Method*.

Analysis methods

In this paper, CCME WQI is employed to evaluate the drinking water sources at the 9 monitoring points, and CPI was selected to verify the evaluation results of CCME WQI.

DOI: http://dx.doi.org/10.15666/aeer/1702_50815091

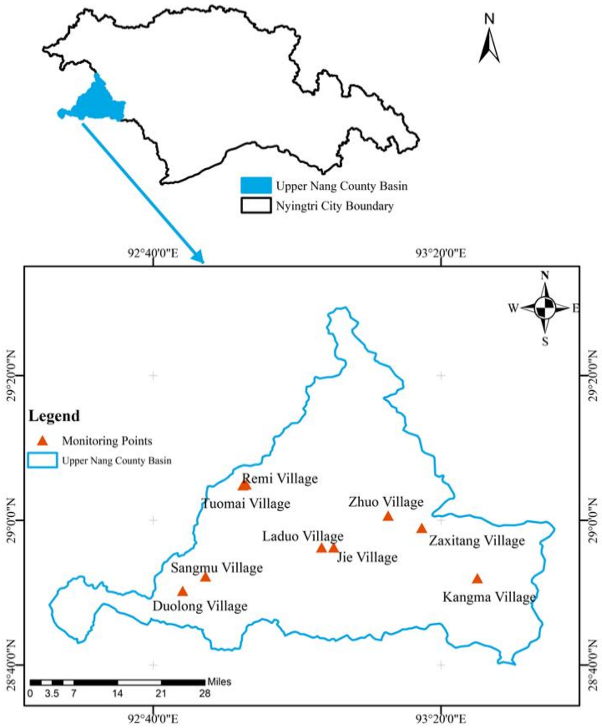

Figure 1. *Location map of monitoring points*

CPI

CPI (Meng et al., 2014), an indicator of the degree of water pollution, is the sum of the relative pollution indices of different pollution items. This method can determine the pollution degree of the water bodies in our research. CPI value can be derived from single pollution indices by the following equations:

$$P_{ij} = \frac{c_{ij} - c_{jok}}{c_{jok+1} - c_{jok}} + P_{jok} \quad \text{(Eq.1)}$$

where P_{ij} is the single pollution index of the j-th item of the i-th water sample (the serial number of water sample i = 1, 2, …, n; the serial number of pollution item j = 1, 2,…, m); c_{ij} is the measured content of the j-th item of the i-th water sample; c_{jok} is the standard content of level k of the j-th item; c_{jok+1} is the standard content of level k + 1 of the j-th item; P_{jok} is the standard index value of level k of the j-th item. The c_{ij} falls between c_{jok} and c_{jok+1}.

$$P_i = \frac{1}{m} \sum_{i=1}^{m} P_{ij} \quad \text{(Eq.2)}$$

where P_i is CPI of the i-th water sample; m is the total number of pollution items.

CCME WQI

CCME WQI is a water quality management tool that evaluates the water quality of the target water body against three aspects: the number of terms whose objectives are

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50815091

not met (Scope), the frequency with which the objectives are not met (Frequency) and the amount by which the objectives are not met (Amplitude). This method has been highly lauded for its flexibility in parameter selection and study area, intuitiveness in computing process and evaluation results, and tolerance of the missing values.

(1) Scope F_1

The percentage of items that do not meet their objectives during the evaluation period, relative to the total number of evaluation items of the i-th sampling point F_{1i} can be expressed as:

$$F_{1i} = \frac{m}{M} \times 100$$

where M is the total number of evaluation items of each sampling point in the evaluation period; N is the number of sampling points; m is the number of items failing to meet the objectives of water quality.

(2) Frequency F_2

The percentage of individual monitoring of the i-th sampling point that does not meet objectives F_{2i} can be expressed as:

$$F_{2i} = \frac{q}{M \times p} \times 100$$

where p is the number of times by which each item of a sampling point is monitored; q is the number of times by which a sampling point fails to meet the objectives of water quality.

(3) Amplitude F_3

Let C_j be the objective of water quality for the j-th item and a_{ij} be the monitored value of the j-th item of the i-th sampling point. Then, the amount by which failed items do not meet their objectives e_{ij} can be calculated as follows:

For items that must exceed the objective (e.g. DO), the amplitude e_{ij} can be calculated as:

$$e_{ij} = \begin{cases} \frac{C_j}{a_{ij}} - 1 & a_{ij} < C_j \\ 0 & a_{ij} \geq C_j \end{cases}$$

For items that must not exceed the objective (e.g. total hardness and COD), the amplitude e_{ij} can be calculated as:

$$e_{ij} = \begin{cases} \frac{a_{ij}}{C_j} - 1 & a_{ij} > C_j \\ 0 & a_{ij} \leq C_j \end{cases}$$

(4) Level classification

CCME WQI is defined in the interval [0, 100]. The greater the value of CCME WQI, the better the evaluation result. CCME WQI can be calculated as:

$$\text{CCME WQI} = 100 - \frac{\sqrt{F_1^2 + F_2^2 + F_3^2}}{1.732}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50815091

According to the value of CCME WQI, the quality of the target water bodies was divided into 5 levels (Alazawii et al., 2018; Feng et al., 2018) (*Table 1*).

Table 1. *Five levels of water quality*

Level	The value of the CCME WQI
Excellent	[94,100]
Good	[79,94)
Fair	[64,79)
Marginal	[44,64)
Poor	[0,44)

Results and discussion

Monitoring data and water quality objectives

As mentioned before, 16 water quality items, namely, zinc, copper, iron, manganese, total hardness, DO, COD, total dissolved solids, arsenic, hexavalent chromium, fluoride, anionic synthetic detergent, cyanide, volatile phenols, lead and selenium, were measured at the four sampling points of each monitoring point. The measured value of each item is recorded in *Table 2*.

According to the *Environmental Quality Standards for Surface Water* and the *Sanitary Standard for Drinking Water Quality*, the objectives of the 16 water quality items were determined (*Table 3*).

Table 3. *Objectives of the 16 water quality items*

Item	Objective	Unit	Item	Objective	Unit
Zinc	1	mg/L	Fluoride	1	mg/L
Copper	1	mg/L	Anionic synthetic detergent	0.2	mg/L
Iron	0.3	mg/L	Cyanide	0.05	mg/L
Manganese	0.1	mg/L	Volatile phenols	0.002	mg/L
Arsenic	0.05	mg/L	Selenium	0.01	mg/L
Lead	0.01	mg/L	DO	5	mg/L
Total hardness*($CaCO_3$)	450	mg/L	COD	4	mg/L
Hexavalent chromium	0.05	mg/L	Total dissolved solids*	1000	mg/L

*No objective is specified for the corresponding item in the *Environmental Quality Standards for Surface Water*. The objective was thus extracted from the *Sanitary Standard for Drinking Water Quality*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50815091

CPI evaluation results

According to the *Technical Rules for the Evaluation of the Safety Status of Drinking Water Sources in Urban Areas* (2005), two aspects of the water quality of river water sources should be evaluated, namely, the level of general pollutants and the level of toxic pollutants. Specifically, the water quality status index of river and underground water sources = 0.3 × the level of general pollutants + 0.7 × the level of toxic pollutants. The level of general pollutants measures by eight items, including zinc, copper, iron, manganese, total hardness, DO, COD and total dissolved solids (the total hardness and total dissolved solids, which are water quality evaluation items for underground water sources, are treated as those for surface water sources), while the level of toxic pollutants is measured by another eight items, including arsenic, hexavalent chromium, fluoride, anionic synthetic detergent, cyanide, volatile phenols, lead and selenium (the anionic synthetic detergent, which is a water quality evaluation item for underground water source, is treated as one for surface water sources). The specific calculated results are shown in *Table 4*.

Table 4. *CPI evaluation results*

Monitoring points	Level of general pollutants	Level of toxic pollutants	CPI	Ranking
Tuomai Village	1.193	2.700	2.248	5
Zhuo Village	1.173	2.700	2.242	3
Zaxitang Village	1.229	2.700	2.259	7
Remi Village	1.181	3.400	2.734	8
Sangmu Village	1.280	3.400	2.764	9
Duolong Village	1.209	2.700	2.253	6
Laduo Village	1.184	2.400	2.035	2
Jie Village	1.187	2.700	2.246	4
Kangma Village	1.109	2.400	2.013	1

In light of CPI evaluation results in *Table 4,* the villages in the study area were ranked in descending order by the quality of drinking water source: Kangma Village, Lado Village, Zhuo Village, Jie Village, Tuomai Village, Duolong Village, Zhaxitang Village, Remi Village and Sangmu Village. The water qualities in all villages belong to Level III. On the level of general pollutants, the water quality belongs to Level II; On the elvel of toxic pollutants, the water quality belongs to Level III at 9 monitoring points and Level IV at 2 monitoring points. CPI evaluation results demonstrate that the drinking water sources at 9 monitoring points meet the requirements on Level II water source protection zone for centralized supply of drinking water (Sun et al., 2014; Wang et al., 2017), and can provide drinking water to the local areas. These water sources mainly face high content of toxic pollutants, which should be controlled in future water treatment.

CCME WQI evaluation

CCME WQI evaluation results of the 9 villages in Nang County were computed according to the equations in the section “Analysis methods – CCME WQI” and recorded in *Table 5*.

Item	Tuomai Village	Zhuo Village	Zaxitang Village	Remi Village	Sangmu Village	Duolong Village	Laduo Village	Jie Village	Kangma Village
F_1(%)	12.5	12.5	12.5	18.75	18.75	12.5	12.5	12.5	6.25
F_2(%)	3.125	6.25	7.8125	9.375	10.9375	6.25	6.25	7.8125	4.6875
F_3(%)	2.4836	3.0841	2.3596	3.5515	3.6032	2.7043	2.5397	2.5265	2.1806
CCME WQI	91.3967	91.7369	91.3809	87.7241	87.2956	91.7814	91.7989	91.3652	95.3169
Ranking	5	4	6	8	9	3	2	7	1

According to CCME WQI evaluation results, the villages can be ranked in descending order of drinking water source quality as: Kangma Village, Laduo Village, Duolong Village, Zhuo Village, Tuomai Village, Zhaxitang Village, Jie Village, Remi Village and Sangmu Village. Comparing CCME WQIs with *Table 1,* it can be seen that only one monitoring point belongs to the excellent level, while all the other points belong to the good level. All monitoring points are under limited or no threat, and low or extremely low risk. To sum up, the monitoring points can serve as reliable and safe water sources for centralized supply of drinking water (Venkatramanan et al., 2016).

Results and analysis

The evaluation results of CPI were compared with those of CCME WQI to find their correlations (*Fig. 2*).

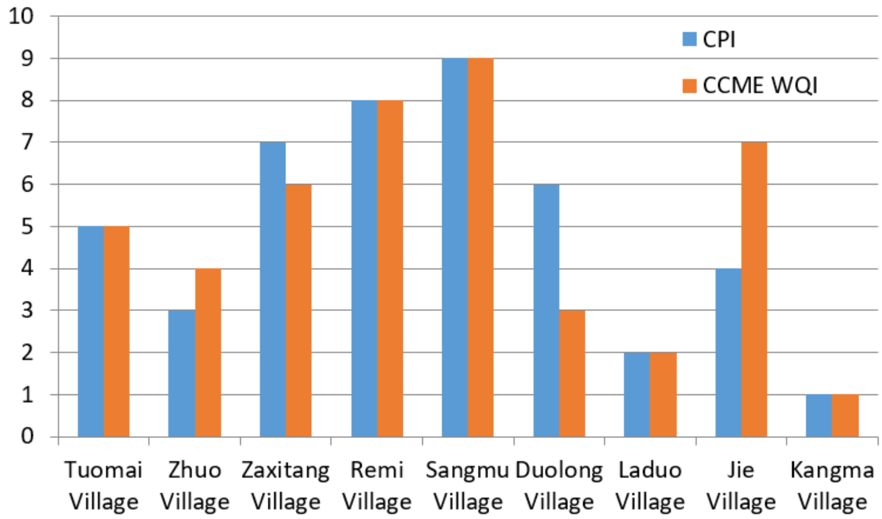

Figure 2. *Comparison between evaluation results of CPI and those of CCME WQI*

As shown in *Figure 2,* the water quality ranking of the villages of CCME WQI differs from that of CPI in the following areas: the ranking of two monitoring points (Duolong Village and Jie Village) change by three places; the ranking of no monitoring point change by two places; the ranking of two monitoring points (Zhuo Village and Zhaxitang Village) change by one place; the ranking of the other five monitoring points remains the same. To verify the reliability of CMME WQI method, the research results were tested by the Spearman's rank correlation coefficient.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50815091

The Spearman rank correlation coefficient (Dikbas, 2018) is a nonparametric measure of statistical dependence between two variables. Here, this measure is adopted to check the consistency between the evaluation results of CPI and those of CCME WQI. The calculation formula is as follows:

$$r = 1 - \frac{6\sum_{i=1}^{n} d_i^2}{n(n^2-1)}$$

Where d_i is the rank difference of each item; n is the number of evaluation items. The Spearman's rank correlation coefficient falls in the interval of [0, 1]. The closer the value is to 1, the better the correlation.

The Spearman's rank correlation coefficient between the evaluation results of CPI and those of CCME WQI is 0.8333, revealing a close positive correlation. In other words, the two evaluation methods have outputted highly consistent evaluation results.

The comparison between *Tables 4* and *5* shows that CPI and CCME WQI have different emphases in calculation. CPI consists of the level of general pollutants and that of toxic pollutants. The former is about the mean value, while the latter only considers the peak value (without considering the data size or data volume). As a result, the level of toxic pollutants may be exaggerated when a few toxic pollutant items exceed the objectives and differ in the amount by which the objectives are not met, which pushes up the CPI value. The opposite situation will occur when many toxic pollutant items exceed the objectives but agree in the amount by which the objectives are not met.

CCME WQI is made up of three parts: Scope, Frequency and Amplitude. Among them, only the Amplitude is related to the mean value, while the Scope and Frequency are about the number of terms whose objectives are not met and the frequency with which the objectives are not met, respectively. When the mean value does not change much, CCME WQI is negatively correlated with the Scope and Frequency. The opposite situation will occur if only a few terms exceed the objectives and differ in the amount by which the objectives are not met. In summary, CPI and CCME WQI both increase with the growth in the amount by which the objectives are not met and with the reduction of the number of terms failing to meet the objectives. However, the results of the two methods exhibit as the deterioration and improvement of water quality, respectively (Jie Village vs. Zhuo Village). The inverse is also true, as evidenced by Zhaxitang Village vs. Duolong Village.

Conclusions

This paper evaluates the quality of drinking water sources of 9 villages in the Yarlung Tsangpo River Basin using CCME WQI model, and verifies the evaluation results by CPI method. The subjective weighting of the CPI method may affect the evaluation results, while CCME WQI, free of subjective factors, can output relatively stable results. To ensure the reliability of CCME WQI, the evaluation results were subjected to reliability test by the Spearman's rank correlation coefficient. The following conclusions were drawn from the drinking water source qualities evaluated by CCME WQI.

(1) According to the evaluation results and ranking of monitoring points, CCME WQI and CPI have outputted similar rankings, and the results of the two methods have high Spearman's rank correlation coefficient. This means CCME WQI is a feasible way

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50815091

to evaluate the safety of rural drinking water sources. However, CCME WQI also has certain limitations as CPI.

(2) Through CCME WQI evaluation, the 9 villages can be ranked in descending order of drinking water source safety as Kangma Village, Laduo Village, Duolong Village, Zhuo Village, Tuomai Village, Zhaxitang Village, Jie Village, Remi Village and Sangmu Village. Besides, the water qualities at these monitoring points satisfy the requirements on drinking water.

In the future, CCME WQI can be applied to rural drinking water sources after the operation is mature and simplified. And then the safety evaluation of rural drinking water sources will be completed quickly.

(Received 10th Jan 2019; accepted 8th Mar 2019)

Abstract. Forest resources in Turkey, according to the principles of ecosystem-based, multiple-use management approach, forest management chief/planning units are governed by forest management plans. Forest management planning process involves taking inventory, preparing the database with Geographic Information Systems (GIS), determining the forest management units and silvicultural treatments, and the preparation phase. After its completion begins the process of preparing silvicultural plans. First, in the regeneration areas, ecological conditions are evaluated and tree seeds are measured. Then regeneration methods are applied in this area and a detailed spatial and temporal planning is performed. Three different silvicultural plan tables are prepared by the forestry legislation. Beside the preparation of silvicultural plans, its enforcement has put an additional workload on forest management chief officers. Selected as a pilot region, the preparing of a silvicultural plan and monitoring its application with geographic database was undertaken at Oltu Forest Planning Unit. First of all, afforestation, regeneration and tending areas according to forest management plan were measured and evaluated. Then, the existing geographic database was updated to prepare the silvicultural plan. Then, in order to prepare and perform silvicultural prescriptions, spatial and temporal arrangements were added to the geodatabase. In the next step, the allowable cut was calculated. Finally, silvicultural treatments were applied at regeneration and tending areas, and illustrated with tables, graphs and maps. The paper is a case study for Oltu Forest Planning Unit, consisting mostly of *Pinus sylvestris*, while other tree species should be supported by a similar study in Turkey, particularly for mixed stands.
Keywords: *silvicultural recipe, Pinus sylvestris L., geographic information systems, forest management plan, allowable cut*

Introduction

Forest areas around the world are either decreasing or degrading structurally due to clearings for agriculture and residential development, road and energy line constructions, illegal logging and harmful forestry practices. Numerous plant and animal species living in these areas either become extinct or are under risk of extinction. Human population and demands are continuously increasing and becoming more varied. According to the Food and Agricultural Organization (FAO, 2015) data, global forest areas are 3.99 billion hectares (ha) in size and make up 30.6% of terrestrial lands. There has been a decrease of approximately six times the total forest area of Turkey (129 million ha) in global forest areas since 1990. As a result of the aforementioned reasons, utilization of forest resources is handled internationally and assessed globally with many conventions, primarily the Convention on Biodiversity. Sustainable management of forest resources takes form according to the criteria and indicators determined by the forestry philosophy of each country. Every country has made the required legal legislations and the technical and administrative infrastructure according to its own culture and economic structure (Yolasığmaz, 2013). 148 countries have

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50935108

policies that support sustainable forest management and 145 of them prepared forestry legislations based on these policies. 39% of forest areas (2.1 billion ha) are managed by forest management plans (FAO, 2010; FAO, 2015; GDF, 2014a).

In Turkey, forest areas are administrated by the Ministry of Agriculture and Forestry. Forests are treated in two categories as protected and managed. Protected areas like national parks, nature reserve areas and nature parks are managed by Nature Conservation and National Parks General Directorate using long-term development plans and management plans. Management forest are managed by the General Directorate of Forestry at the scale of the administration chief offices/forest planning units, which are the smallest planning and administration units, using forest management plans prepared according to the principles of the ecosystem based multiple use forest management. Planning process consists of a) the inventory of forest ecosystem, b) setup of a geographic database using geographic information systems (GIS) technology, c) the generation of associated digital and baseline maps (stand map, forest function map, forest management units map etc.), d) the determination of management goals and conservation targets with a participatory approach by preparing forest management units map, e) the arrangement of utilization (i.e., determination of the location, time, quantity and the silvicultural treatments for the allowable cut), f) the presentation in plan format, (i.e., the preparation of cutting map and the associated tables, which are the final outputs) (GDF, 2017; Asan, 1999; Yolasığmaz, 2013; Başkent et al., 2008a, b, 2005; Asan, 1999).

The forestry philosophy in Turkey, in particular the planning approach and the basic principles need to be explained briefly to understand the topic better. 300 m × 300 m plots are established within the planning unit using a systematic random sampling approach during forest inventory, which is the first phase of forest management plan preparation. The main goal of sampling is the generation of the baseline stand map. This map contains stands, compartments and sub-compartments. Compartments are those areas defined by natural lines like streams and artificial lines like roads and whose borders do not change. Sub-compartments are the sections of stands enclosed by compartments. Stand is a forest fragment that is greater than one hectare in size and differs from the adjacent forest areas by species, mixture, canopy closure and development stage. The main goal of forest area inventory and tree volume and increment inventory is to decide on stand symbols and to determine the stand borders and parameters. A stand symbol contains information like tree species, mixture, stand development stage and closure. Tree species are displayed by symbols. For example, species found at the study area including *Pinus sylvestris*, oak, poplar and juniper are displayed by the symbols Çs, M, Kv and Ar, respectively. The number of trees in the stand and stand volume are considered together to determine the tree species mixture type. The species that exceeds 10% of the stand values for these parameters are included in the stand symbol. The species that has the greatest number or volume by proportion is written first in the stand symbol. Stand development stages are symbolized by the letters *a* (young stands: < 8 cm dbh), *b* (pole pine stands: 8 -19.9 cm dbh), *c* (pre-mature stands: 20-35.9 cm dbh), *d* (mature stands: 36-51.9 cm dbh) and *e* (old stands: >52 cm dbh). Crown closure, or canopy closure (B (degraded); 1-10% crown cover, 1; 11-40% crown cover, 2; 41-70% crown cover, 3; 71-100% crown cover) is defined as the sheltering or shadowing of the ground by tree crowns (GDF, 2017). Development stages and crown closure are two important parameters because the former one is used to determine the method of silvicultural treatment to be applied in the stand and the latter is used to decide on the quantity and the intensity of the allowable cut.

Silvicultural treatments are grouped under four headings including afforestation, tending, regeneration and rehabilitation (Saatçioğlu, 1971; Genc, 2017; GDF, 2017, 2014b). The type and method of the silvicultural treatment and the allowable cut are decided based on factors like ecological and growth conditions of the forest area, biological requirements of tree species, road network, transport and management opportunities, technical capacities of forest enterprises, management goals, conservation targets, forest types and stand parameters. While the silvicultural treatment is applied to the entire sub-compartment, the sub-compartment is/can be partitioned at fields where only afforestation is carried out (Eraslan, 1982). Afforestation areas are the gaps in the forest regime that are to be planted with trees within the plan period. Regeneration areas are those fields which are either done or about to be finished with their management periods and either will be regenerated or their regeneration has begun in the previous period and is still going on. Tending areas are the forested areas except afforestation and regeneration areas. These fields undergo silvicultural treatments in accordance with management goals and conservation targets according to primarily species and then stand canopy closure, development stage, and whether it's a pure or mixed stand. Tending treatments including weeding, release cutting and weeding and thinning are proposed for young, pole pine and pre-mature and old stands, respectively. The silvicultural method used in thinning is low cutting and it is considered heavy and moderate based on the dose or the amount of the treatment. In regeneration areas, final yield allowable cut is taken while in tending areas, intermediate yield allowable cut is taken. Afforestation, regeneration and tending areas are shown by different colors according to the pertinent legislation in harvest maps, which are the final output of forest management plans (Saatçioğlu, 1971; Genç, 2001; GDF, 2017, 2014b; Yolasığmaz and Güner, 2016).

The dominant species at the study is the *Pinus sylvestris*, which is a light tree. It is not damaged by frost. It has tap root system and grows fast in youth stage. Therefore, the weeding period in *Pinus sylvestris* forests is either one or two years. Pole pine stand stage lasts about eight to ten years. The initial thinnings in premature stand stage are heavy low cuttings. The subsequent thinnings that take place every ten years are moderate low cuttings. Tending treatments like the weak low thinnings are performed towards the end of management period past 70 years of stand age. Regeneration is carried out in closed stands with gaps where there are no sufficient seed trees based on slope. Uniform clear cutting method is performed in areas where there is no danger of erosion whereas planting under the forest canopy method is employed in the areas where there is risk of erosion. Uniform shelterwood method, which is based on natural regeneration, is preferred in *Pinus sylvestris* stands where there is sufficient quantity of seed trees. Preparation cuts generally are not needed in the regeneration practices performed using the uniform shelterwood method. Abundant seed years occur every two to four years. Difficulty in determining the abundant seed year of *Pinus sylvestris* is not encountered because its seeds mature over three years. A light cutting after two to three years following the seed cutting done in the abundant seed year and a subsequent removal cutting two to three years later must be performed as the seedlings grow fast. Weeding must be carried out at least once after the removal cutting to reduce the competition of seedlings with the dense live cover present at the areas.

In Turkey, preparation of silvicultural plans, which are the application bases of forest management plans, has been incorporated in the planning process as a legal necessity within the last decade. However, standards for the preparation and application stages of the silvicultural plans could not be established completely. Moreover, silvicultural plans are prepared by conducting a series of field and office work in addition to the ones done for forest management plans with the technical support of administration of chief officers and other administrators.

The type of the silvicultural treatments, the decided functional allowable cut and the sub-compartments in which the silvicultural treatment will take place are identified in two different tables for the regeneration/afforestation and tending areas in the forest management plans. The silvicultural treatment times to be carried out in these areas involve ten or twenty year periods depending on the plan execution schedule. However, the exact location of treatment in each year and the types of regeneration and tending methods to be applied are not clearly stated (GDF, 2017, 2014b).

Three additional tables are prepared as part of the silvicultural plan preparation according to the pertinent legal notice. The first of these tables indicates the field studies that need to be carried out during the preparation of the silvicultural plan, the second one identifies the treatment methods to be applied to the regeneration and tending areas and the third one provides information on the years of the silvicultural treatments and the allowable cut (GDF, 2014b).

Besides, spatial databases generated using GIS technology are designed to prepare forest management plans and maps and thus they are not suited for preparing silvicultural plans and associated maps. The monitoring of structural changes in the forest also is not suited to the monitoring and control of the silvicultural treatments (Yolasığmaz and Keleş, 2009).

The main aim of this study is to prepare a silviculture plan of Oltu Forest Planning Unit dominated by Pinus sylvestris. In addition, the database prepared using GIS is to measure the success of silvicultural treatments and to monitor forests.

Materials and methods

Materials

The main materials used in the study are the forest management plan attribute and digital data of the Oltu Forest Planning Unit and the geographic database. The measurements and examinations in the study area especially were focused on afforestation and regeneration areas where soil analyses data, ecological conditions, current stand structures and abundant seed years were assessed and determined.

Study area

The study area is enclosed by 714000-777000 (30° 41’ 08” 42” – 40° 39’ 45”) east longitudes and 4470000-4510000 (40° 32’ 46” – 40° 46’ 51”) north latitudes in zone 37 according to UTM coordinate system and ED 50 datum (*Fig. 1* and *2*). The planning unit is bordered by Narman Forest Planning Unit to the southeast, Tortum Forest Planning Unit to the southwest, Hisar Forest Planning Unit to the northeast Kılıçkaya Forest Forest Planning Unit in the Yusufeli Forest Enterprise to the northwest. Oltu Forest Planning Unit is within the boundary of Oltu Forest Enterprise with a distance of 100 to 180 km to Erzurum province. Elevation ranges from 1105 to 3045 m. Average

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50935108

temperature is 9.8 °C and the annual precipitation is 393.3 mm according to meteorological data. High slope topography and harsh winter conditions render living conditions difficult resulting in accelerating migration from the area to urban regions (GDF, 2015a).

Figure 1. *Images of the study area*

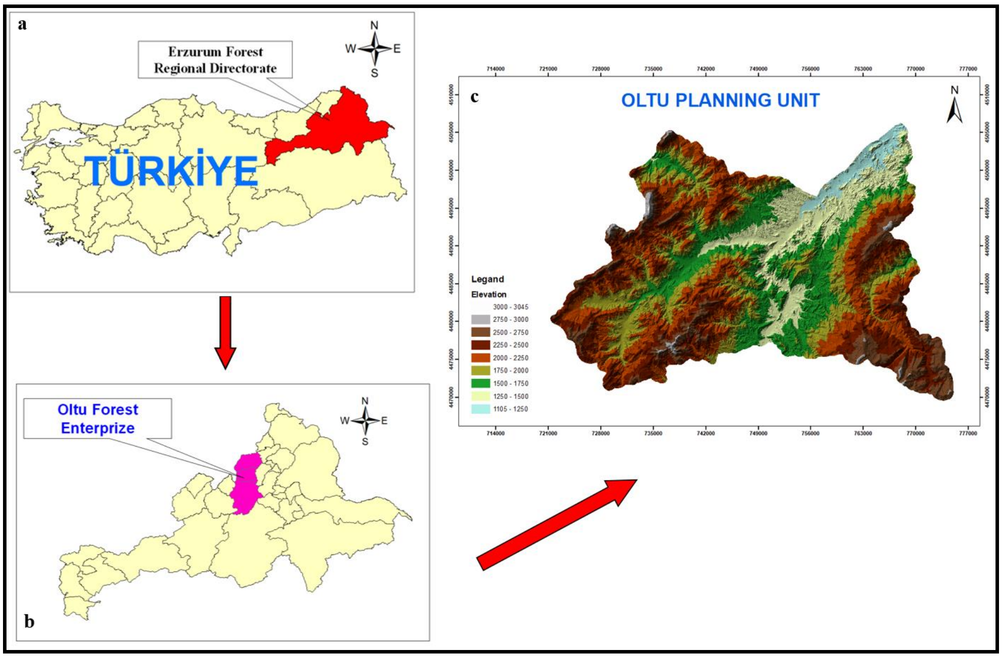

Figure 2. *Location of the study area according to the administrative organization of Turkish forests. a) Location of Erzurum Forest Regional Directorate within Turkey, b) location of Oltu Forest Enterprise within Erzurum Forest Regional Directorate, and c) elevation map of Oltu Forest Planning Unit*

The total area of the study area is 105108.707 ha of which 28788.303 ha is forested and 13755.785 ha is non-forest area. The planning unit is comprised of 586 compartments and 2679 sub-compartments with 43 different stand types identified (GDF, 2015a).

The dominant species of the flora include *Pinus sylvestris* (L.), *Juniperus* sp., *Qercus* sp. and *Populus tremula* (L.). Even though a comprehensive plant sociology study is not conducted at the study area, four different tree species (*Platanus orientalis*, *Acer* sp., *Pyruselae agnifoliave*, *Sorbus torminalis*) that do not form stands by themselves but are part of the mixture either individually or in groups were recorded in the forest management plan. Additionally, four different small trees and shrub forms and nine plant species were identified and also recorded in the forest management plan. The management units used for wood production are dominated by *Pinus sylvestris* (L.). There are also poplar (*Populus tremula* (L.)) stands with normal canopy closure. Forest areas where *Pinus sylvestris*, juniper and poplar codominated and formed mixtures together were identified in degraded areas.

Oltu Forest Planning Unit is grouped into eight different forest management units according to the forest management plan (*Table 1*). 17.455% of the study area is planned to be utilized for economic purposes while 53.061% is planned for ecological use and the remaining 29.485% is planned for socio-cultural use.

Methods

Field measurements and assessments

Investigations were done in afforestation and regeneration areas in the summer months of 2015. Data related to ecological conditions (slope, aspect, elevation, soil

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50935108

type, soil depth and stoniness, etc.) were collected and current stand structure was inspected in area. Abundant seed years and presence or absence of seed trees were determined in order to decide on the regeneration method.

Table 1. *Area distribution of the forest management unit in Oltu Planning Unit (GDF, 2015a)*

Forest management units	Area (ha)	%
A-Wood Production	18346.336	17.455
B-Nature Conservation	37767.906	35.932
C-Wildlife Development Areas	5353.919	5.094
D- High Mountain Forest Ecosystem	11244.117	10.698
E- Forest Ecosystem Monitoring Areas	43.090	0.041
F- Erosion Control - Soil Conservation	1362.304	1.296
G- Conservation of Water Sources	30748.068	29.254
H- Recreation	242.969	0.231
Total	**105108.707**	**100.000**

Design and configuration of database

The baseline map used for the preparation of silvicultural plans is the forest management plan geographic database. The primary dataset within the database associated with compartments, sub-compartments, stand parameters like stand type information, age class and site quality class and forest management units and harvest map were used directly. Data including the volume of trees per hectare (m^3/ha), annual tree volume increment (m^3/ha/year), types of silvicultural treatments as defined in the plan (afforestation, regeneration and tending) and the decided functional allowable cuts/tending allowable cuts (m^3) were entered in the geographic database of the silvicultural plan in addition to the forest management plan data. Also, data titles displaying the fundamental components of a silvicultural plan like the silvicultural treatment method, five different types of silvicultural treatments, five different silvicultural treatment times, the quantity of the allowable cuts decided for each treatment, the number of treatments and the realized allowable cut were added as columns to the database.

Preparation of silvicultural recipes

Afforestation areas are gaps in the forest and degraded forest areas that are suitable for afforestation. Silvicultural recipe to be applied to the gaps and degraded forest areas (*Tables 2* and *3*).

Table 2. *The silvicultural recipe to be applied to gaps*

Silvicultural treatment number	Silvicultural recipe
Silvicultural Treatment_1	Planting
Silvicultural Treatment _2	Weeding (1 year after planting)
Silvicultural Treatment _3	Weeding (2 years after planting)
Silvicultural Treatment _4	Release cutting (10 years after second weeding)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50935108

Table 3. *The silvicultural recipe to be applied to degraded forest areas*

Silvicultural treatment number	Silvicultural recipe
Silvicultural Treatment_1	Clear cutting+Planting
Silvicultural Treatment _2	Weeding (1 year after planting)
Silvicultural Treatment _3	Weeding (2 years after planting)
Silvicultural Treatment _4	Release cutting (10 years after second weeding)

Regeneration areas are those stands in which regeneration treatments started in the previous plan period and are ongoing or they either completed their management plan cycle or are in the process of completion. Factors like the technical capacity of the forest enterprise, workforce and road condition beside growth environment characteristics like elevation, slope, soil properties (soil type, stoniness, soil depth, etc.) and stand parameters such as the biological requirements of the tree species, canopy closure and mixture patterns were considered during the silvicultural treatments to be applied to these areas. Regeneration areas were divided into three groups as follows "areas currently undergoing regeneration", "*Pinus sylvestris* stands with canopy closure level 1" and "*Pinus sylvestris* stands with canopy closure levels 2 and 3" (*Tables 4, 5* and *6*).

Table 4. *Silvicultural recipe to be applied to stands that currently are undergoing regeneration (Çsd1/Çsa0)*

Silvicultural treatment number	Silvicultural recipe
Silvicultural Treatment_1	Removal cutting (in 2015 or 2016 years)
Silvicultural Treatment_2	Weeding (1 year after removal cutting)
Silvicultural Treatment_3	Release cutting (10 years after second weeding)

DOI: http://dx.doi.org/10.15666/aeer/1702_50935108

Tending is proposed to all forest areas except afforestation and regeneration areas. Factors like the technical capacity of the forest enterprise, sociocultural and socioeconomic structure of the villages within and adjacent to the forest, workforce potentials of these villages, social problems and disputes and road condition were considered during the spatial arrangement of the tending areas. Tending cuts every ten years are proposed during a management period of twenty years due to the biological requirements of *Pinus sylvestris* species. Low cutting method is used in *Pinus sylvestris* forests primarily even though the silvicultural treatment method varies based on the development stages of stands. Allowable cut during tending is calculated following the inventory conducted in the field and it is determined based on the forest function that the area provides, management goals and conservation targets. The current characteristics of the stands, (i.e., stand parameters including canopy closure and stand development stage) affect the dose and method of the silvicultural treatment to be applied to these areas. The silvicultural treatment methods to be applied to each stand type in tending areas are shown in *Table 7*.

Table 7. *Silvicultural treatment methods to be applied to tending areas*

</table>

Tending areas are divided into ten tending blocks in traditional planning. Here, each tending block was further grouped into ten separate sub-tending blocks, which is different from the traditional approach. Since the legislation requires that the harvest jobs be given to the local residents in the nearest settlement, spatial planning was carried out to provide employment to each village every year.

Calculation of the allowable cuts

Intermediate yield allowable cut (the allowable cut taken from tending areas)

Ten separate tending blocks were established and each tending block was further grouped into ten separate sub-tending blocks and numbered. The treatment years for the sub-blocks within each tending block were determined according to their ordinal hierarchy such that the first set of treatments would be completed between 2015 and

2024 and the second set of treatments would be completed between 2025 and 2034 across the tending blocks.

Final yield allowable cut (the allowable cut taken from regeneration areas)

The entire volume within regeneration areas will be harvested during the 20 year plan period but in different years. Once the youth is established healthily, the trees in the canopy will be harvested by removal cutting. The remaining trees will increase their volume during the period between seed cutting and removal cutting. Therefore, half of the tree volume increment was added to the current tree volume in calculations of the allowable cut in regeneration areas. The allowable cuts that will take place in these areas based on the silvicultural treatment method and the cutting technique were calculated/determined as follows:

- In degraded *Pinus sylvestris* stands (BÇs), the entire volume will be harvested by clear cutting in the first treatment and seedlings will be planted.
- In *Pinus sylvestris* stands with level 1 canopy closure (Çscd1) where planting under the forest canopy will take place, it is assumed that 20% of the current tree volume will be harvested during the initial treatment, 50% of the remaining tree volume will be harvested during the second treatment, i.e., the light cutting, and that 97% of the remaining tree volume will be harvested by the next treatment, which is the removal cutting.
- In *Pinus sylvestris* stands with level 1 canopy closure (Çscd1) where uniform clear cutting will take place, it is assumed that 97% of the tree volume will be clear cut during the initial treatment and the area will be replaced by seedlings.
- In *Pinus sylvestris* stands with level 2 canopy closure (Çscd2) where uniform shelterwood method will be applied, it is proposed that 20% of the current tree volume will be harvested during seed cutting, which is the initial treatment, 50% of the remaining tree volume will be taken during light cutting, which is the second treatment and that 96% of the remaining tree volume will be taken during removal cutting.
- In *Pinus sylvestris* stands with level 2 canopy closure (Çscd2) where uniform clear cutting will take place, it is assumed that 97% of the tree volume will be clear cut during the initial treatment and the area will be replaced by seedlings.
- In *Pinus sylvestris* stands with level 2 canopy closure (Çscd2) where planting under the forest canopy will take place, it is assumed that 20% of the current tree volume will be harvested during the initial treatment, 50% of the remaining tree volume will be harvested during the second treatment, i.e., the light cutting, and that 97% of the remaining tree volume will be harvested by the next treatment, which is the removal cutting.
- In *Pinus sylvestris* stands with level 3 canopy closure (Çscd3), it is assumed that uniform shelterwood method will be applied and 40% of the current tree volume will be harvested during initial treatment, 50% of the remaining tree volume will be taken during light cutting, which is the second treatment and that 96% of the remaining tree volume will be taken during removal cutting.
- In stands currently undergoing regeneration where light cutting is recommended, it is proposed that 50% of the current tree volume will be harvested and that 96% of the remaining tree volume will be taken during removal cutting. If light cutting is not recommended at these areas, than it is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50935108

proposed that 96% of the tree volume at the area will be harvested by removal cutting.
- It is proposed that 3-4% of tree volume will be left at regeneration stands as value trees for ecological and biological balance.

Results and discussion

According to the forest management plan data, the total tree volume at the planning unit is 1415343.798 m^3, annual tree volume increment is 44214.787 m^3/year and the amount of agreed allowable cut during the plan period of 20 years is 1121891.449 m^3 (*Table 8; Fig. 3*).

In the silvicultural plan, thinning and release cutting are proposed as the first treatments at tending areas. Thinning and release cutting are planned for 81.262% and 17.685% of the tending areas, respectively (*Table 9; Fig. 4*).

Table 9. *The distribution of the area and allowable cut by silvicultural treatment method in silvicultural plan*

was abandoned, which consisted of the value trees left at the area to allow for the sustenance of wildlife.

Abundant seed year occurs every two years and the first abundant seed year was 2015. Therefore, regeneration started in the abundant seed year of 2017. The focus was on completing the ongoing regeneration practices in the planning unit.

We tried to keep the size of the tending areas even across the years, where the average annual size and the average tending allowable cut quantity were 1186.702 ha/year and 4898.721 m^3/year, respectively. The total quantity of the allowable cut of the tending areas is 97974.418 m^3 and makes up 87.671% of the total allowable cut whereas the allowable cut that will be harvested from the regeneration areas constitutes 12.329% of the total allowable cut. We aimed to keep the annual treatment area size and the quantity of the annual allowable cut equal during the treatments to be applied to the regeneration areas.

The average annual treatment area size and the average quantity of the annual allowable cut to be conducted in the regeneration areas were planned as 21.774 ha/year and 688.874 m^3/year, respectively. The average annual treatment area size and the average annual allowable cut quantity were 1186.702 ha and 5587.595 m^3/year, respectively when the allowable cut and treatment area size were examined across the years and regeneration and afforestation areas were combined (*Table 10; Fig. 5*).

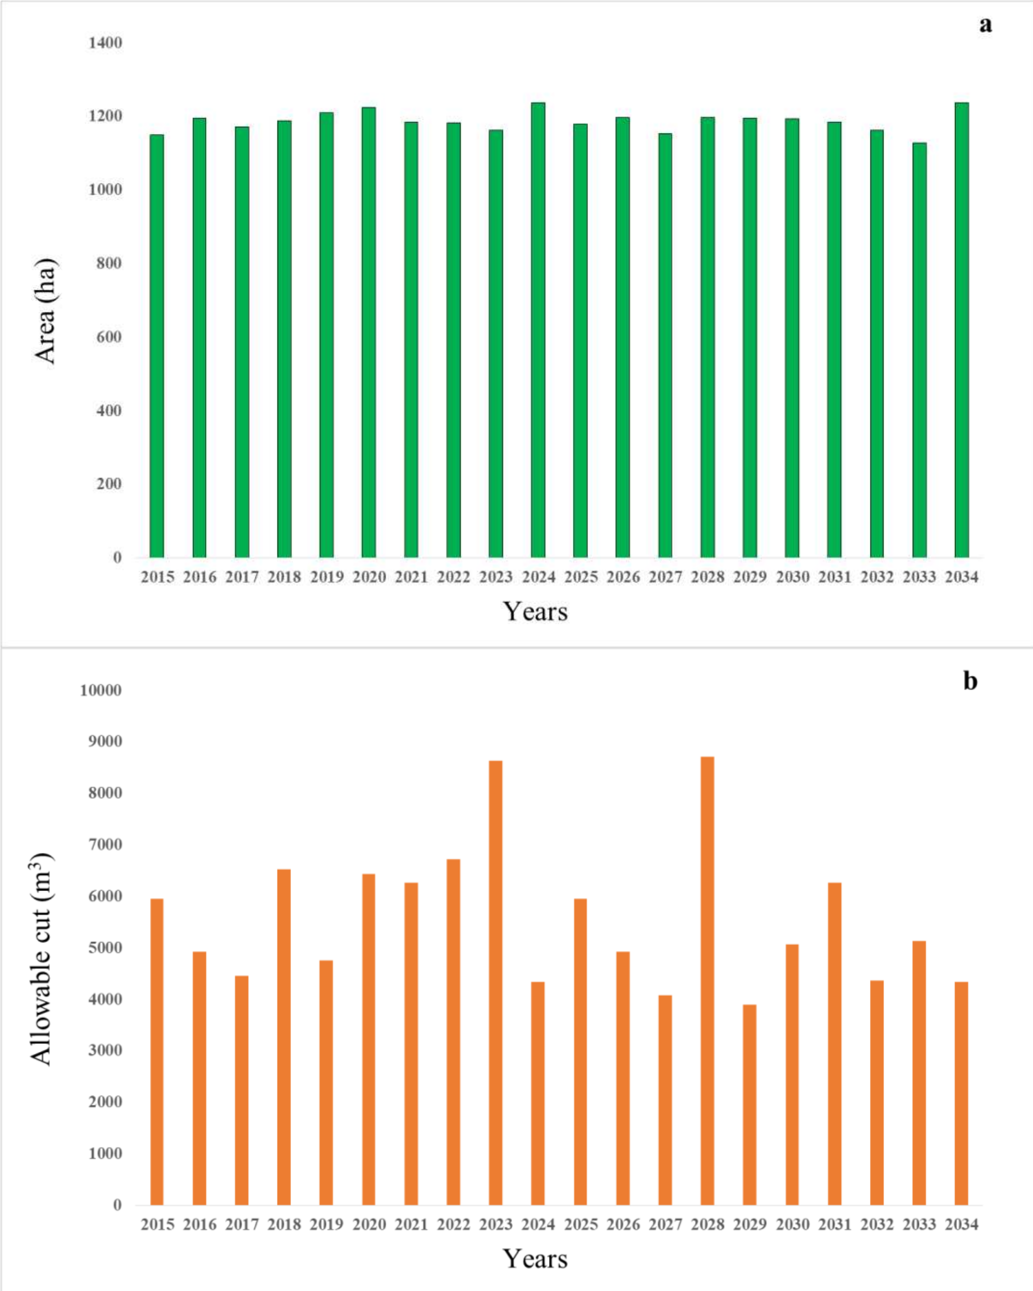

Figure 5. *The distribution of total treatment area (a) and allowable cut (b) according to treatment years*

Conclusion

The silvicultural plan of Oltu Forest Planning Unit was prepared using the joint approaches of forest management and silviculture disciplines. A new spatial database was designed in the silvicultural plan by using the treatment areas in the forest management plan and the associated geographic database as the base. Silvicultural recipes were prepared according to the silvicultural treatment type (afforestation, regeneration and tending) for each sub-compartment. Final outputs in the form of harvest maps or in other words, silvicultural plan map was produced and provided to the users.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_50935108

General assessments like the silvicultural treatment methods to be applied at the study area, their distribution across the years and the number of treatments were performed and provided as outputs of this study using the analysis, query and presentation capabilities of GIS. In addition to these outputs, other outputs including detailed silvicultural plan tables, numerous analyses on stand parameters like development stage, age and site quality classes as well as the treatment areas and the application years for the five separate treatment types can be generated and provided.

Overall, 1.98 ha area was agreed to be afforested, 11646.306 ha was decided to undergo tending cuts and 121.933 ha area was decided to be regenerated in the forest management plan of Oltu Forest Planning Unit. The forest management plan was adhered to in the silvicultural plan and thus there was no change in these areas. Total of 111751.901 m^3 allowable cut was planned at the study area during the 20 year plan period, comprised of 97974.418 m^3 intermediate yield allowable cut and 13777.483 m^3 final yield allowable cut.

The annual tree volume increment is 44214.786 m^3/year and approximately 12.64% of the annual increment will be harvested as the allowable cut every year. This is much lower than the national average annual allowable cut to annual tree volume increment ratio of 39.87% (GDF, 2015b). As stated earlier quantitatively, large portion of Oltu Forest Planning Unit is utilized for ecologic and social goals. Similarly, the demand for wood production in the US decreased, as opposed to increasing demand for ecological and social services (D'Amato et al., 2017). As a result, silvicultural practices and planning approaches in Turkey are developing within the framework of ecological and social objectives.

The silvicultural plan was prepared for Oltu region forests, which are composed of pure *Pinus sylvestris* stands generally dominated by one species and specifically for Oltu Forest Planning Unit. Different tree species, different species compositions and different forestry problems exist in different regions of Turkey because of the geographic diversity of the country. The number of silvicultural treatments, their years and the quantity of the allowable cut also will differ in these regions. Therefore, similar studies need to be conducted in different forest regions of Turkey, in which silvicultural plans and digital baselines should be generated for each forest planning unit.

Acknowledgements. This study was carried out as part of the project 2016. F10.02.02 supported by the Scientific Research Projects Coordinatorship of Artvin Çoruh University (AÇÜBAP). Foremost, we thank (AÇÜBAP) for the support they provided. Also, we extend our thanks to the Anatolia Environment Forestry Mapping Inc. Company (ANÇEO), the General Directorate of Forestry and the Faculty of Forestry of Artvin Çoruh University for all the support and help they provided during the preparation of the silvicultural plan and the forest management plan and for the acquisition of the data.

WHAT'S GOING ON AT THE UNIVERSITIES? HOW MUCH HAS THE RESEARCH REVEALED UNIVERSITY STUDENTS' ATTITUDES TOWARDS THE ENVIRONMENT? A CASE STUDY OF BURSA, TURKEY

GURBUZ, I. B.* – OZKAN, G.

Department of Agricultural Economics, Faculty of Agriculture, Bursa Uludag University Bursa, Turkey

(Received 11th Jan 2019; accepted 20th Feb 2019)

Abstract. The aim of this research is to reveal the environmental consciousness levels of university students determine how they evaluate the society and the University at this level of consciousness and analyse the attitudes and behaviour they exert. For this purpose, a structured survey was conducted at nine faculty students at Bursa Uludag University in Turkey. Students' attitudes and behaviour were examined through their gender, family income level, parental education and professions and the field of the study variables. In this research, the questionnaire consisting of open and close–end questions was used; SPSS 23 program was used to evaluate the data. The research revealed that variables other than gender and the fathers education have a significant effect on the environmental awareness of the students. Furthermore, the students stated that universities did not take an active role in environmental protection. They attributed the lack of environmental awareness to the lack of adequate environmental protection laws and penalties. They wanted society to be more active in protecting the environment and universities to include students in environmental decisions and practices. The results show that students have inadequate environmental knowledge, therefore, display lower levels of environmental attitude and do not exert highly favourable behaviour.

Introduction

The environment can be defined as the surroundings or conditions in which a person, animal, or plant coexists and interacts. The environment is in a state of integrity and equilibrium with its living and non-living beings and is an ordered system capable of tolerating its own adversities within a certain degree. It can also be defined as all the factors that affect the lives of people and society in all aspects physically, psychologically and culturally (Baki and Cengiz, 2002). *Environmental awareness* is the understanding of the consequences of environmental damage and its sustainable level of use (Kollmuss and Agyeman, 2002). Environmental awareness requires a willingness to take positive actions against environmental problems.

Problems encountered in the natural and cultural environment in forms of population growth, urbanisation and improper land use have soared tremendously as a result of industrialisation and technological developments (Gayford, 2002; Mazi and Demirci, 2004; Palabiyik and Altunbas, 2004; Withgott and Brennan, 2007). As the environmental problems expanded and penetrated, the unrestrained nature of the problems has been realised. Thus, national and international efforts have been intercalated to solve them (Najam and Cleveland, 2003). Since destroying natural and cultural resources in the world is not a new phenomenon, the measures taken to protect nature are not new either.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51095138

Nonetheless, the emergence of legal measures, the increase in environmental awareness, the systematic conservation of nature that requires the segregation of protected areas and the emergence of international organisations coincide in the nineteenth and twentieth centuries. Aforementioned developments accelerated, especially after the 1960s.

Individuals with sufficient environmental sensitivity are vital to solve environmental problems permanently. The intensity of societal perception about nature and the environment's known and unknown problems, the response and the discomfort displayed by individuals and society are the indicators of environmental awareness. The level of awareness may vary depending on a number of factors such as one's life experiences, beliefs, socioeconomic level, interactions with the natural environment and educational levels (Aydin and Cepni, 2010).

The major cause of many environmental problems is the irresponsible behaviour of the individuals and along with negative attitudes towards the environment. Therefore, it is necessary to re-establish those behavioural patterns and attitudes to eliminate the existing environmental problems, to prevent new problems and to achieve a more sustainable future (Lehman and Geller, 2004).

Environmental attitudes are the sum of all the positive and negative attitudes and thoughts of individuals, who exhibit environmentally beneficial behaviour, environmental value judgments and readiness to solve them. *Environmentally friendly* behaviour refers to a behaviour that harms the environment as little as possible and is influenced by various factors. The most important of these factors is environmental attitude.

While environmental attitudes are seen as strong determinants of environment-friendly behaviour, there is a subtle difference between the two. From primary to university, students' attitudes and behaviour about the environment have been frequently examined in the literature, especially in developing countries.

Bowonder (1987) argues that environmental problems in developing countries are growing and becoming more difficult to resolve as a consequence of the combined effect of population growth, urbanisation, poverty and industrialisation. Progress is slower than developed countries (OECD Green Growth Indicators, 2017) and enforcement are mostly driven by pressure from more developed countries and international institutions such as United Nations Environmental Programme (UNEP) Global Environment Facility (GEP), Food and Agriculture Organisation of the United Nations (FAO), United Nations Educational, Scientific and Cultural Organisation (UNESCO), United Nations Industrial Development Organisation (UNIDO) and World Health Organisation (WHO) Intergovernmental Panel on Climate Change (IPCC) (Stephan and Zelli, 2009).

The population in developing countries is younger; hence young people need to shoulder the responsibility to solve them. Turkey's number of students exceeded the population of 143 countries. In the 2018-2019 academic year in Turkey, 17 749 876 students receive primary and secondary education in state and private schools affiliated by the Ministry of National Education. There are 7 560 000 students in higher education and a total of 25 309 876 students in Turkey (National Education Statistics, 2018). Compared to Finland and Denmark with a population of 5.5 million, Bulgaria with a population of 7 million, Azerbaijan with a population of 10 million, the Netherlands with a population of 17 million, Australia with a population of 25 million, Chile with a population of 18 million and Cameroon with a population of 25 million are behind the student population in Turkey (World Population Prospects, 2017). This explains the importance of research on students at varying levels of educational stages (Anonymous, 2018).

Universities bear certain responsibilities in increasing knowledge, awareness and inventing technology. They educate young generations to perform important social roles effectively; thus they have a critical role in enhancing human behaviour and promote pro-environmental behaviour (Corcoran and Wals, 2004; Frank and Meyer, 2007). In consequence, university students are regarded as decision makers, opinion shapers and the community leaders of the future in a given society (Lee, 2008; Lozano, 2006; Waas et al., 2010; Wright, 2007; Zilahy and Huisingh, 2009).

Environmental awareness, environmental conservation and sustainability have become frequently discussed issues in universities in the last twenty years. University students are equipped with more diversified and exclusive resources such as several means of media, research projects, conferences, and workshops to learn about the environment (Morigi and Krebs, 2012; Silveira and Cruz, 2012). Despite this rich resources, whether they exert sufficient environmental knowledge and awareness or reflect this knowledge to their behaviour are still questionable (Hartmann and Apaolaza–Ibazez, 2012; Levine and Strube, 2012; Markowitz et al., 2012).

Berberoglu and Tosunoglu (1995) and Oguz et al. (2010) reported that university students did not have sufficient awareness and participation in environmental issues. Arunkumar (2012) reported an average level of environmental awareness. Many studies have shown that the majority of university students are aware of environmental problems and believe sustainability is an important goal to be achieved. Some research confirms that students environmental knowledge influence their environmental behaviour (Huang and Shih, 2009; Thapa et al., 2005), remaining research is inconclusive. Environmental awareness and knowledge may well influence the individual's environmental behaviour. Environmental sensitivity could intensify environmental behaviour and increase participation (Sivek and Hungerford, 1990). Environmental knowledge affects behavioural intentions positively (Wang et al., 2014). As Abbas and Singh (2014) reported, a higher proportion of university students possess a high level of environmental knowledge but a low level of participation. They show interest in global problems such as climate change, acknowledge that environmental problems are serious and take a positive attitude towards it; however, the students inclined to exert minimum environmentally friendly behaviour in their everyday activities (Elder, 2003; Heyl et al., 2013; Kollmuss and Agyeman, 2002; Kormos and Gifford, 2014; Muderrisoglu and Altanlar, 2011; Schultz et al., 2005; Sharma, 2014). Hadlock and Beckwith (2002) in their study found that people did not try to understand the reasons or were not willing to participate in environmental issues that were not directly related to them. In addition, the availability of options and infrastructure, the degree of sacrifice students have to make (Arbuthnott, 2009; Kagawa, 2007; Stern, 2000) determines their environmental behaviour. Consequently, habitat or natural species become trivial to them unless there is a situation directly related or harmful. In short, there is always no linear relationship between environmental attitudes and environmentally friendly behaviour.

As stated earlier university students are more likely to access the information about the environment and achieve positions to take meaningful action and to build a more sustainable world (Sharon and Wright, 2006). For this reason, it is crucial to identify the factors affecting students' environmental behaviour. Undeniable number of research focuses on students from various countries e.g. United States (Levine and Strube, 2012; Meyer, 2016), China (Chuanhui and Hanwei, 2011), Taiwan (Chen and Tsai, 2015; Pan

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51095138

et al., 2018), Philippines (Ejem and Bello, 2013), Rwanda (Kabera, 2017), Malaysia (Elsawahli and Mohit, 2010; Hassan et al., 2011), Mexico, Brazil, Portuguese (Córtes et al., 2016), Spain (Vicente–Molina et al., 2013), India (Panth et al., 2015), Israel (Yavetz et al., 2009), Bangladesh (Ullah et al., 2013), United Arab Emirates (UAE) (AlMenhali et al., 2018), Yemen (Abdulrab, 2015), Poland (Demeskhant, 2013), Serbia (Major et al., 2017), Romania (Crumpei et al., 2014), Hungary (Zsóka et al., 2013), Ireland (Nicolaou and Conlon, 2013) aimed at determining the environmental attitudes, awareness and behaviour of university students.

Researchers claim that students' behaviour is affected and formed by their existing environment (Asunta, 2004; Lukman et al., 2013); some of which are namely: family, friends, neighbours, and cultural values. Different research revealed contradictive results for above-mentioned factors. Also, other variables such as educational background, the field of study, family income, parental education, parental occupations and where they live revealed a similar contradiction. Following this, some of this research specifically concentrated on demographic factors (Meyer, 2016; Sharma, 2014; Vicente–Molina et al., 2018), others focused on cultural factors (Córtes et al., 2016; Kaplowitz and Levine, 2005; Kilbourne and Polonsky, 2005; Major et al., 2017; Vicente–Molina et al., 2013). Researchers also wanted to reveal whether the major student study could be an influencing factor (Budak et al., 2005; Chen and Tsai, 2016; Demeskhant, 2013; Duman–Yuksel and Ozkazanc, 2015; Kiper, 2014; Nicolaou and Conlon, 2013; Pan et al., 2018). While the majority of the research was conducted on university students in general, there is substantial research on the teacher candidate students (Goldman et al., 2006; Ozden, 2008; Pe'er et al., 2007; Tuncer et al., 2009; Yavetz et al., 2009).

The purpose of this study is to explore undergraduate students' awareness and behavioural patterns towards the environmental problems at Bursa Uludag University in Turkey. The city of Bursa is founded in one of the most fertile plains of Turkey (Eisenlohr et al., 1995). It is believed that this research in Bursa with three million residents (TurkStat, 2017) and about 75 thousand students (Bursa Uludag University, 2018) will provide significant results for the field. It will allow researchers to compare the results of the current research and shed light on the issues raised in previous researchers.

Materials and methods

The universe and the sampling

This study was carried out at Bursa Uludag University, Turkey. Bursa Uludag University is the seventh largest university in Turkey (Higher Education Council, 2018). It accommodates 74 822 students 42 917 of whom undergraduate, in 14 faculties, 4 institutes, and 15 vocational schools. 10 of the 14 faculties are located on the central campus, Gorukle. The number of students here was 47 138 in the 2017-2018 academic year (Bursa Uludag University, 2018). Other faculties and vocational high schools are distributed in various districts of the province. However, this research is limited to Gorukle campus and 9 faculties, taking the student distribution rates of the faculties into consideration and the transportation restrictions of the campuses in the districts.

For this research, a structured questionnaire was prepared by carefully scanning the existing literature and reviewing the previous work. At the beginning of the lecture, the students were asked to fill in this questionnaire under the supervision of the trained interviewers with the permission of the lecturer. The age of the students varies between

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51095138

18 and 24 in 4-year faculties, while the rate of the Medical School varies between 18-26, 18-21 in vocational schools, and 18-26 in Art School. The research was carried out from March to May 2018.

The sample size was determined by estimating a proportion formula used by Thompson (2012). To obtain an estimator p having probability at least 1 - α of being no farther than d from the population proportion, the sample size formula based on the normal approximation gives

$$n = \frac{Np(1-p)}{(N-1)\left(\frac{d^2}{z^2}\right) + p(1-p)} \quad \text{(Eq.1)}$$

Hence, the minimum sample size was found to be 680 (32 questionnaires were discarded because they were incomplete, resulting in a valid sample of 648 individuals).

Data collection

The survey questionnaire consisted of 32 questions in three parts: The first part contained items to measure the socio-demographic and economic characteristics of the students such as gender, family income; parental education and parental occupation (see *Appendix*). In the second part, students were asked to describe 'environment' and 'environmental pollution' with their own words in two open-ended questions. Open-ended questions allow participants to express their views without being affected by the researcher (Foddy, 1993). However, open-ended questions also have drawbacks in comparison to close-ended questions. They require extensive coding and often result in significantly larger nonresponse rate (including 'Don't know', 'Prefer not to answer' and blanks) (Dohrenwend, 1965). Further, four multiple choice and one 'yes' and 'no' questions were asked. The third part included 14 items to measure the students' environmental behaviour and attitude. They were asked to indicate what extent they participate in the statements in the questionnaire on a 5 point Likert type scale. (1 = Strongly Disagree; 2 = Disagree; 3 = No opinion, 4 = Agree, 5 = Strongly Agree).

SPSS 23.00 package was used to analyse the data. The Independent Sample T-test and the One-way ANOVA were performed to reveal the relationships between the variables.

The Cronbach Alpha reliability coefficient of the survey was found to be $\alpha = 0.731$. A Shapiro-Wilk test was used to test for normality assumption. The analysis showed that [D (648) $p < 0.001$] the data does not show normal distribution. Therefore, the skewness and kurtosis values are further used and skewness of 0.132 (SE = 0.096) and kurtosis of -0.329 (SE = 0.192) was found. As the Skewness and kurtosis values are between +1.5 and -1.5, recommended by Tabachnick and Fidell (2013), the normality assumption is accepted.

Results and discussion

General characteristics of participants

Of the 648 respondents, 47.2% were female and 52.8% were male. Around 33.3% were from the Faculty of Economic and Administrative Sciences, 12.42% were from the Faculty of Education. Detailed respondent distribution of faculties is given in *Table 1*.

Agriculture	54	8.3	100.0
TOTAL	648	100.0	

*The results of the Faculty of Architecture and Engineering are combined

30.6% of participants' family income fell between $588–640. This means both parents work in the family but they earn minimum wage. Almost a quarter of students family income (24.1%) is around legal salary, meaning only one of the parents contribute to the family budget at the minimum wage level. 22.2% of the students reported to have a family income less then minimum level meaning none of the parents actively work, they are either unemployed or retired. Half of the students' mothers had only compulsory basic education (50.9%) while 21.3% of their fathers had a university degree. As the income of the family and education of the household reflects, a large majority (80%) of the participants' mothers are housewives. *Table 2* shows that only 16.7% of the mothers found to be working and providing income for the family. 21.3% of fathers was retired and 3.7% were unemployed, therefore, a quarter of participants' fathers were actively employed.

Demographic findings

Gender

In order to assess the gender effect on student environmental awareness and attitude, an independent samples *t*-test was conducted. The result indicated that there was *no significant difference* in gender effect between males and females, $t(646) = -0.528$, $p = 0.598$ (*Table 3*).

Many studies examining the effects of gender on environmental attitudes and behaviour stated that there is no meaningful and consistent relationship between gender and environmental attitudes (Isildar and Yildirim, 2008; Kanbak, 2015; McDaniel and Alley, 2005; Robinson and Crowther, 2001; Sadik and Sadik, 2014; Stern et al., 1995; Zelezny et al., 2000). Artun et al. (2013) and Timur and Yilmaz (2011) show that gender is not influential at the levels of environmental literacy of teacher candidates. The participants' gender has not been prevalent in their environmental judgments either (Ozdemir et al., 2004; Sever and Yalcinkaya, 2012; Sungur, 2017). Genc and Genc (2013) and Gercek (2016) concluded that students' perception of environmental ethics did not differ significantly according to their gender. Stated examples underline the outcome of this research.

Family income

Many research reviled middle and lower middle–class families display lower level attitudes toward the environment than more affluent families (Altin et al., 2002; Sama, 2003; Tekin and Gunes, 2018; Yilmaz and Erkal, 2016). de la Vega (2006) in his study on students and parents in Southwest Florida, showed parental income did not make any significant difference for awareness or knowledge. However, he observed a significant difference in their attitudes. Parent with an annual income of >$15,000 scored considerably lower in attitude compared to parent with an income of $15,000-29,000.

A one–way ANOVA was conducted to reveal whether family income affects students' environmental attitudes (*Table 4*). An analysis of variance showed that family income on the level of their environmental attitude was *significant* [$F(4,643) = 15.09$, $p < 0.001$]. In order to find out which income levels differ on the environmental attitude, post hoc comparisons using the Tamhane's T2 test was performed. Results indicate that only children of families with the lowest income group (2.06 ± 0.43) differ in terms of their environmental attitudes from children of families with all other income groups (please refer to *Table 2* for means scores).

Table 4. *Analysis of variance (ANOVA) between demographic variables and university students' environmental attitude*

	df	*MS*	*F*	*p*
Family income	4	3.21	15.09	0.000*
Fathers education	3	3.52	16.34	0.000*
Mothers education	3	0.59	2.57	0.053
Mothers occupation	4	2.06	9.40	0.000*
Fathers occupation	5	1.96	9.01	0.000*
Field of study	7	1.877	8.811	0.000*

*p < 0.001

University students belong to the lowest income level ($ < 294; 2.06 ± 0.43) differ from all other income levels in their awareness levels. Students from other income levels do not exhibit any statistically meaningful difference in their awareness. This result partially supports to the findings of Altin et al. (2002), Sama (2003), Tekin and Gunes (2018) and Yilmaz and Erkal (2016) that lowest level income groups displayed lower levels of environmental awareness means. On the other hand, students from families of all other income levels scoring very close means, suggest that parental income only significant at a point but not as a whole. This fact is in line with the findings of de la Vega (2006). It suggests that parental income is only of the utmost importance in the lowest income group and not meaningful for all other income groups

Parental educational and occupational analysis

Whether parents' educational levels and their occupation affect students' attitude and behaviour has been investigated thoroughly in the literature. Children learn by observing and imitating their parents, therefore, what goes on within the family may affect the formation of children's' environmental attitude and consequently their behaviour. Students raised by highly educated parents especially by educated mothers are expected to demonstrate a higher level of environmental awareness and attitude. The substantial number of research found a positive significant relation between parents' occupation and educational level and students' behaviour. Especially 'mothers' levels of education claimed to have a more positive effect on students' behaviour (Altin et al,. 2002; Bozoglu et al., 2016; Erol and Gezer, 2006; Goldman et al., 2006; Kanbak, 2015; Kayali, 2010; Kose et al., 2011; Ozden, 2008; Ozmen et al., 2005; Pe'er et al., 2007; Sam et al., 2010; Sama, 2003; Tekin and Gunes, 2018; Timur and Yilmaz, 2011; Yilmaz and Erkal, 2016; Vaizoglu et al., 2005; Zuzovsky, 2001).

A one–way ANOVA was conducted to reveal whether parental educational level affects students' environmental attitudes (*Table 4*). Statistically significant difference was found between mothers' educational level and students' environmental attitude [F (3, 644) = 16.34, p < 0.001]. Tukey post-hoc comparison reveals that children with

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51095138

literate mothers (2.05 ± 0.45), and mothers with primary (2.32 ± 0.46) and secondary (2.45 ± 0.40) education differ significantly between their environmental attitudes. Interestingly, no statistically significance found between the children of literate mothers and those having mothers with university education (2.11 ± 0.40).

Result confirms that as mothers' education levels increases, the environmental awareness of their children increases.

A one-way ANOVA was conducted to reveal whether mothers' occupation affects students' environmental attitudes. A statistically significant difference found between mothers' occupation and students' environmental attitude [F (4,643) = 9.40, $p < 0.001$]. Tukey post–hoc comparison reveals that children's of white collar (2.60 ± 0.54) mothers significantly differ from the ones with blue-collar (2.25 ± 0.45) and housewife mothers (2.31 ± 0.47). No statistical significance observed between housewife and blue-collar mothers children environmental attitude. Therefore, it can be said that mothers's occupation has a positive impact on their children's environmental attitudes.

Another one–way ANOVA analysis was performed to analyse whether fathers' education affects their children's environmental attitudes. No statistically significant difference observed between fathers education and students' environmental attitude [F (3,644) = 2.57, $p = 0.053$].

Despite the fact that the education level of fathers does not significantly affect the environmental awareness of children, their professional status found to be highly influential [F (5,642)= 9.01, $p < 0.001$]. This effect is much more significant than the mothers' professional status. Post hoc comparisons using the Tamhane's T2 test indicated the children of working fathers (white-collar (2.40 ± 0.44), self-employed (2.42 ± 0.44) and blue-collar (2.40 ± 0.44) have a higher environmental awareness. There was no statistically significant difference between the non-working (retired (2.20 ± 0.57); unemployed (2.09 ± 0.48)) and farmer (2.03 ± 0.29) fathers' children. Participants who have farmers father have shown the least environmental awareness. It is thought that the fact that farmers work under very difficult conditions and have very little income has an important effect on this finding.

Field of study

The study field and environmental attitudes that students exhibited was one of the variables included in almost every research conducted in the field. The aim is to see whether the environmental attitudes and behaviour of the students have an impact on the selection of the subject they attend at the university and to examine whether the subject they choose and faculty they attend have impacted on their environmental attitudes and behaviour.

Research on the universities reveals many contradictions. For example, a study by Ozmen et al. (2005) found that the Medical School and Health Science Vocational School Students 'Environmental Attitude Scale' results are higher 'Health Services Vocational School.' Similarly, Kolomuc et al. (2013), Oguz et al. (2011) and Talay et al. (2004) found that Heath Sciences students were more knowledgeable in subjects such as air pollution, organic farming and environmental problems. In contrast, Tekin and Gunes (2018) found the students of the Faculty of Dentistry scored the lowest level of environmental behaviour. Kaplowitz and Levine (2005) stated the five highest scoring colleges are the Colleges of Osteopathic Medicine, Human Medicine, Agriculture and Natural Resources, Veterinary Medicine and Natural Science. Tekin and Gunes (2018), Kose et al. (2011), Ek et al. (2009) and Ozmen et al. (2005) found that Economic and Administrative Sciences students displayed more positive environmental attitudes than Engineering students. Yazici and Babalik (2016) found students of social sciences consider recycling important more than others. In contrast, Benton and Funkhouser (1994) and Benton (1994) consistently found business students lag behind their peers.

Goldman et al. (2006) reveal that students who study in environmentally affiliated subject achieved a higher overall mean score for environmental behaviour than non-environmentally affiliated fields. In the same line, Tikka et al. (2000) found biology and forestry student displayed the highest levels of environmentally related activities. Vicente–Molina (2013, 2018) in the US and Spain found that science and engineering students are more likely to behave pro-environmentally than social science students.

One-way ANOVA using post hoc Tamhane's T2 test was undertaken to see if the field of study affects students' environmental attitudes. Statistically significant difference observed between the students' field of study and their environmental attitude [F (7, 640) = 8.81, $p < 0.001$]. Medical School students (2.48 ± 0.34) displayed the highest level of environmental awareness followed by Business School (2.41 ± 0.49) and Veterinary School (2.40 ± 0.53). In contrast to Kaplowitz and Levine (2005), agriculture students achieved the lowest mean scores (2.05 ± 0.36, 95%) along with the Science and Life Sciences (2.07 ± 0.51) students.

This research outcome confirms the findings of Oguz et al. (2011), Ozmen et al. (2005) and Talay et al. (2004). Kolomuc et al. (2013) underline Medical students have the highest environmental awareness (M = 2.48). Benton (1994) and Benton and Funkhouser (1994) consistently confirmed that business students lagged behind their peers. In contrast, this research revealed the opposite. While this research did not analyse particular branches, the School of Education where prospect teachers are educated achieved a medium level of awareness (2.39 ± 0.45). Students' scoring average to lower level in the science faculties can be interpreted as not a failure of the curriculum but of the poor performance of the university itself. Students of agriculture may be expected to score the much higher because they are supposed to be more knowledgeable about the causes and consequences of environmental problems. This is particularly important for Turkish content because while Turkey has been making efforts to expand its industry, agriculture still maintains its importance.

Faculty distribution of the environmental problems perceived by students may reveal a more fruitful picture (*Table 5*).

Table 5. *Faculty distribution of the most important problems perceived by students*

CC: climate change, GW: global warming, UU: unplanned urbanisation

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51095138

The medical student stated air pollution as a serious environmental problem by 50%. This may be that respiratory illnesses once were frequent in winter times are spreading over all seasons and increasing its intensity. Therefore, air pollution-related illnesses are becoming more visible. On the other hand, arts and science students thought water pollution is an environmental threat (36.4%). As expected, third of agriculture students were concerned with soil pollution. On the other hand, climate change, global warming and urbanisation were a common concern across faculties. Veterinary schools concern with urbanisation is striking (37.5%). Perhaps unlike agricultural student whom urbanisation obliterates their work field, urbanisation creates additional problems to a veterinary specialist such as strayed and starved animals.

Fundamentals of environmental awareness

The second part of the questionnaire aimed to analyse students' environmental knowledge. They were given two open-ended questions and asked to describe 'environment' and 'pollution' with their own words in 'one sentence'. Two–thirds of students left these two questions blank and other students only written unrelated single words. Stated words did not provide sufficient data to make a meaningful content analysis which is often the problem with open-ended questions. Students also did not give reasoning when they have chosen 'other' option on the 'multiple choice' questions.

When students were asked to state 'the most important environmental problem of Turkey', almost a third of them declared this as 'unplanned urbanisations'. Turkey is a developing country. 23.4% of citizens are between 15–29 years old (19 183 261; TurkStat, 2018a). Unemployment rate is 10.9% and non–agricultural unemployment rate is 13.0% (TurkStat, 2018b). Domestic immigration is over 20% in some cities (Tekirdag 20.8%, Yalova 20.2%). This figure is 14.7% in another industrial city Kocaeli, 7.2% in Bursa. High young population and unemployment rate lead to a high labour migration, which lays the ground for unplanned urbanisation. In fact, this cause new environmental problems such as traffic, air, water and noise pollution, loss of fertile land and deterioration of the natural environment and also accelerate existing problems. Therefore, for students in Bursa, the fourth most populous and seventh largest industrial city of Turkey, this finding is not surprising. Air pollution ranked second and water pollution ranked third equality with climate change and global warming. Interestingly soil pollution ranked the least important problem.

There found no significant differences between women and men in the answers given according to gender. In males, unplanned urbanisation (35.1%) and air pollution (19.3%) were higher than females, whereas, in females, water pollution and global warming (19.6%) were higher than males (*Table 6*).

Ullah et al. (2013) in their study in Bangladesh cited unplanned urbanisation (32%) as the major problem followed by air pollution (17%) and soil pollution and loss of farmland (13.5%). Sadik and Sadik (2014) research on the teacher candidate students of social sciences in Adana revealed similar result: urbanisation was found the most serious problem (28.5%) and population growth (10.8%) ranked second. Kulozu (2016) in Ataturk University also identified unplanned urbanisation (27.3%) highest followed by air pollution (20.9%) and environmental pollution (18.5%). In the same line, male students in Hatay ranked urbanisation as the most serious problem (Bozdogan et al., 2016). Gulgun et al. (2008) research similarly ranked the very same problem second (18.5%) after air pollution (24.22%).

TOTAL	306	100	345	100	648	100

Other research highlighted Ozdemir et al. (2004) stated that the problems of the Faculty of Medicine students in the first three ranks were air pollution with 37.5%, waste disposal with 36.2% and deforestation with 30.6%. The most important problems stated by the students of the Faculty of Health Education of Ankara University were air pollution with 49.5%, environmental pollution with 26.6% and wastes with 25.7% (Celen et al., 2002). As for students of Landscape Architecture, Environmental Engineering and City and Regional Planning in Ankara, the most important environmental problem in Turkey is air pollution (17.1%). It follows water pollution (14.9%), urbanisation (14.3%) and depletion of natural resources (14.3%) (Oguz et al., 2011). Erdal et al. (2013) reveal similar findings: students consider air pollution (73.91%) Turkey's most important environmental problem, followed by water (60.87%), soil (33.99%) and noise pollution (54.15%). Kanbak (2015) reveals air pollution as first, water second and solid waste third-ranked problem for Physical Sciences at Kocaeli University. For Health and Social Sciences, air pollution comes first, forest destruction lands come second and solid waste problem comes third. According to students at Suleyman Demirel University, the most important environmental problems in Turkey are air pollution, forest loss and solid waste treatment (Yazici and Babalik, 2016). Bozdogan et al. (2016) cited air pollution is the most worried problems in females. Ozen and Ozen (2017) state the ranking of the Faculty of Veterinary Faculty of Firat University as air pollution, waste and water pollution.

Artun et al. (2013) indicated that 54% of social studies teacher candidates chose global warming, 33% air pollution, 10% greenhouse gas, 10% distorted urbanisation, and 4% ozone layer perforation. Yadav and Pathak (2013) research of female university students in Jharkhand India, reviled that 33% of respondents consider global warming as the main problem, 41.67% consider pollution followed by 33.33% air pollution, 33.33% ozone depletion, 25% water pollution, and 25% soil pollution. Ermolaeva (2010) in Fort Collins, Colorado illustrates that students are most worried about the destruction of wilderness and forests (9.4%), air pollution (9.3%), people's consumption habits (8.9%), water pollution (8.8%), growing waste/not enough recycling (8.7%) and urban problems (8.2%). Amongst the various environmental problems of China, students ranked water pollution as the most urgent (Wong, 2003). They ranked deforestation and soil erosion problems as the second and urban air pollution was as the third most urgent environmental problem. In the study conducted on medical students in Finland, more than half of the participants stated that the most important environmental risk was water pollution (Kasma–Ronkainen and Virokannas, 1996).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51095138

The different answers given by the above studies show that the geographic and socio-economic situation of the country and or the region affected the students' responses and the issues they prioritised changed. For example, surveys, where unplanned urbanisation is the highest, are usually developing countries like India and Turkey. Students who indicate priority problems as air and water pollution are seen to live in regions or countries they are overpopulated or naturally depleted of such resources.

Students were asked whether their university sensitive to environmental problems. An overwhelming number of students have disagreed (*Table 7*).

Table 7. *Are universities susceptible to environmental problems?*

	Frequency	%	Cumulative %
Yes	162	25.0	25.0
No	486	75.0	100.0
TOTAL	648	100.0	

This finding is in line with Erdal et al. (2013) who revealed very similar result in Gazi Osman Pasa University in Tokat where 75.49% of students declared no and 24.1% declared yes. Oguz et al. (2011) also examined Landscape Architecture (Ankara University, Bilkent University), Environmental Engineering (Middle East Technical University) and City and Regional Planning (Middle East Technical University, Gazi University) in Ankara. Their score was 69% 'no' and 31% 'yes' to the same question. Similar results were revealed in Yazici and Babalik (2016) research at Suleyman Demirel University.

Students have given a unanimous reply to this statement. Such high numbers indicate that universities fail to achieve their part in protecting the environment. Since universities should be the forerunners of environmental protection, the reason why students have such low perceptions of their universities environmental sensitivity should be urgently and thoroughly analysed.

When students were asked the reason why there is no sensitivity to environmental problems in society (*Table 8*), the most striking answer was the lack of deterrent sanctions against environmental offenders (40.7%). In the second statement, respondents admitted that although they were aware of environmental problems, they were reluctant to reflect this behaviour to their lives (26.9%) and the consequences of environmental problems were not obvious to people (18.2%). Only 4.6% claimed that institutions and organisations that are in charge of protecting the environment are not effective and 2.8% highlighted the need for training and education. On the other hand, Oguz et al. (2011) indicated highest ranked outcome with 32.9% that people are aware of the problems but do not act to protect it while Erdal et al. (2013) research achieved 21.99% to the very same statement. Being indifferent to the consequences of environmental problems scored 20.7% in Erdal et al. (2013) and 12.9% in Oguz et al.'s (2011) research. Oppositely, inadequate education and not to witness implementation are regarded main reasons for lacking environmental sensitivity (Oguz et al., 2011, 31.4%; Erdal et al., 2013, 24.3%).

Another striking result of the survey was that non-governmental organisations (NGOs) (47.2%) stood out in the evaluation of the organisation that made the most important contribution in the fight against environmental problems. Despite this finding, Korkmaz (2018) points out that NGO's activities in the environment in particular

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51095138

climate change are inadequate despite raising activities of civil society organisations. Universities (2.8%) were considered the least contributing organisations (*Table 9*). The ministries (19.4%) and public service announcements (18.5%) ranked lower than NOGs. This research is in the same line with Erdal et al.'s (2013) research. There, student ranked NGOs work first with 38.74% but universities scored 16.21% unlike 2.8% that Bursa Uludag University scored. Related ministries scored 20.95% and charitable foundations achieved 24.11%.

Table 8. *What's the reason for not having sensitivity towards environmental problems?*

Table 9. *Which organisation makes the most important contribution to prevent environmental problems?*

	F	%	Cumulative %
Activities of non–governmental organisations	306	47.2	47.2
Public service announcements	120	18.5	65.7
Research and educational activities of universities	18	2.8	68.5
Works of the Ministry of Environment and Urbanism	126	19.4	88.0
Works of the municipalities	78	12.0	100.0
TOTAL	648	100.0	

The students of the Faculty of Health Education stated that they rely on voluntary organisations at the highest rate (92.5%) in solving environmental problems (Celen et al., 2002). 54.9% of the students in the Faculty of Education at the Hacettepe University stated that the written and visual media were the most important agenda determinants and the least contributing group was the politicians (Yilmaz et al., 2002).

When students were asked the role of society in protecting the environment they stressed that people should take an active part in protecting the environment (36.1%) (*Table 10*). As earlier question already pointed out, students believe that people are aware of the problems but they did not reflect this awareness into their behaviour. Despite students' statement of the most important environmental problem as urbanisation in the earlier question, preventing unplanned urbanisation was given the least importance (3.7%). This finding must be investigated further. It had already been revealed that the work of related ministries and municipalities were considered unsatisfactory. Preparing city plans and deciding the way in which the city will expand is their work but citizens also play a pivotal role. It will not be realistic to expect from ministries or municipalities to prevent urbanisation problems or at least alleviate them. Society must be proactive preventing urbanisation problems.

DOI: http://dx.doi.org/10.15666/aeer/1702_51095138

34% of the students of Hacettepe University responded cared not to pollute the environment. This rate was 27.8% for Bursa Uludag University students. Moreover, 20% of the students in Hacettepe stated that people should use 'recycled materials' (Yilmaz et al., 2002). The same statement is marked by 17.6% in Uludag University.

Table 10. *What is the role of society in protecting the environment?*

	F	**%**	**Cumulative %**
To take care not to pollute the environment	180	27.8	27.8
To prevent unplanned urbanisation	24	3.7	31.5
To use environmentally friendly products	114	17.6	49.1
To actively take part in preserving the environment	234	36.1	85.2

TOTAL	648	100.0	

Bursa Uludag University students strongly emphasized (47.2%), wanting to involve in the decision-making process. They also want to be able to monitor and evaluate the outcome of those decisions (*Table 11*). They stressed that environmental education should be compulsory throughout the university education. Only a handful of departments include environment related lectures in the curriculum. In fact, the majority of departments of social sciences, medicine and economics do not cover environmental issues in any way.

Table 11. *What is the role of universities in protecting the environment?*

	F	**%**	**Cumulative %**
Environmental education should be compulsory	90	13.9	13.9
Students should take part in the decision making and application process	306	47.2	61.1

Experimental waste should not be randomly disposed	78	12.0	98.1
Other	12	1.9	100.0
TOTAL	648	100.0	

Various research highlights that they are in favour of mandatory environmental education (Ek et al., 2009, 84.1%; Oguz et al., 2010, 93.4%). Some stated that compulsory courses should be included in the curriculum at all educational stages (Ek et al., 2009, 33%; Oguz et al., 2011, 74.4%). Various researchers have specifically emphasized that a course on the environment at the university must be compulsory (Erdal et al., 2013, 65%; Grodzinska–Jurczak and Trabula, 2001; Ozdemir et al., 2004, 61.7%; Ozmen et al., 2005, 44.9%).

The equal number of students also stressed that more research and development activities should be organized by the university. The substantial number of science students have witnessed the random disposal of experimental waste and raised their concern. Last but not the least, students expressed the need for more research and development but ranked working with the industry least important.

University students' attitudes and behavioural patterns towards environmental problems

In the third part of the questionnaire, statements aimed to understand the students' awareness levels about environmental issues and to determine their attitudes at this awareness level. It is hoped that the answers to these questions will show the extent to which university students reflect their environmental attitudes to their behaviour. The questions and answers given in this section are given in *Table 12*.

Table 12. *Questionnaire statements and responses (n = 648)*

	1	2	3	4	5	M	SD
I have taken enough education on the environment at school before the University.	30.6%	26.9%	14.8%	23.1%	4.6%	3.56	1.27
I donate money or become a member of environment-related organisations.	13.9%	27.8%	24.1%	30.6%	3.7%	3.18	1.12
When purchase. I prefer products with a recycle sign.	17.6%	12.0%	33.3%	26.9%	10.2%	3.00	1.23
I prefer to read in a digital environment instead of printing to avoid paper waste.	11.1%	29.6%	14.8%	31.5%	13.0%	2.94	1.25
I take an active part in protecting the environment.	7.4%	17.6%	36.1%	32.4%	6.5%	2.87	1.02
I take care not to use consumer goods that can damage the ozone layer.	3.7%	18.5%	30.6%	32.4%	14.8%	2.64	1.06
When I see someone polluting the environment. I don't remain unresponsive and I warn them.	5.6%	10.2%	34.3%	31.5%	18.5%	2.53	1.08
I dispose of materials such as plastic, glass, paper, battery etc. separately and help them to be recycled.	2.8%	7.4%	18.5%	39.8%	31.5%	2.10	1.02
When I need to use paper. I use them double-sided.	0.9%	9.3%	11.1%	42.6%	36.1%	1.96	0.96
I prefer to use public transport when I'm travelling.	3.7%	6.5%	10.2%	31.5%	48.1%	1.86	1.08
I try to use resources such as electricity, water etc. as efficient as possible.	0.9%	3.7%	7.4%	41.7%	46.3%	1.71	0.83
I make sure that my rubbish goes into the garbage bin.	0.9%	1.9%	6.5%	13.9%	76.9%	1.36	0.76
Our sensitivity to the environment is also our responsibility to society.	0.0%	0.9%	5.6%	17.6%	75.9%	1.31	0.62
I'm aware that environmental pollution is a problem for future generations.	1.9%	0.0%	3.7%	14.8%	79.6%	1.30	0.71

1: strongly disagree, 2: disagree, 3: no opinion, 4: agree, 5: strongly agree

Attitudes towards environmental problems

Researchers in the field agree that students have not been able to convey the level of consciousness to their behaviour. According to Ullah et al. (2013) in Bangladesh, only 12% of students took part in environmental activism and only 35% of them are interested in joining any environmental organisation. Hassan et al. (2011) found that UKM students in Malaysia had a high level of knowledge, awareness and attitudes about the environment, but low prevalence of participation in environmental activities. This view is supported by Wahida et al. (2004) (cited in Hassan et al., 2011). They say that awareness towards environmental issues and awareness about the need to protect the environment has increased among society, but the level of individual participation in protection activities still remains low. Azizan's (2008) (cited in Hassan et al., 2011) findings also support Wahida et al. (2004) (cited in Hassan et al., 2011). He underlines

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51095138

that the students have a good awareness of environmental problems but have not yet taken this awareness into action.

In support of the above argument, the result of this research indicates that the students who are actively involved in protecting the environment remain at 38.9%. Comparison to other research, Oguz et al. (2011) revealed similar results: 39% of the students actively involved in activities related to environmental issues. Gulgun et al. (2008) showed a more optimistic figure: more than half of the students (56.4%) actively involved in these activities. Kiper (2014) found 72.1% of the students were 'sometimes' active. The most worrying response came from Ozmen et al. (2005); 84.9% of the students did not participate in any environmental activities.

It is not surprising that the ratio of students who actively participate in the events related to environmental issues, and the ratio of those who are members or donate to the environment–related organisations are close (34.3%). The findings of the previous research similarly reveal low participation rates. Wong (2003) found that 6% of the students, Budak et al. (2005), 12.9% and Timur and Yilmaz (2011), 17.4% of student were members of the mentioned organisations. Wong (2003) in China further showed only 1.7% of the students was active members of such organisations.

It may be assumed that the income level of the students participating in the study is at the lower and middle class; hence affects their ability to pay their membership fees or to donate to such institutions. However, the general finding in the literature is that students do not participate in studies and activities on environmental issues regardless of income level. For example, Cabuk and Karacaoglu (2003) asked students whether they participate in volunteer organisations working on the environment and the reply was 52.2% 'sometimes', and 38.7% 'never.' Isildar and Yildirim (2008) showed a more negative result: 21.7% of the students said 'sometimes', 65.2% said 'never'. In the Kanbak (2015) survey, 62.6% of the respondents said that they did not participate in the activities of any environmental organisation.

What is important here is that although more than half of the students (57.5%) state that they have not received any education about the environment before the university, they are still reluctant to participate in such events and improve their knowledge of the environment. One of the outcomes of this low educational level is the inability to define the concepts of *environment* and *pollution* in their own words in the previous section of the questionnaire. The previous research in the field gives contradictory results to this statement as well. For example, Ozdemir et al. (2004) reported 94.4% of the students received environmental education at any time during their education. 75.9% of the participants in Ozmen et al. (2005), 44% of the participants in Erdal et al. (2013), and 47.2% of the participants in Kiper (2014)'s research reported receiving environmental education before the university. Paksoy and Paksoy (2015) stated that 35% of the students received environmental education at primary and 23% at the secondary education.

Despite the inadequate education, knowledge base and lack of willingness to participate in environmental problems, an overwhelming percentage of the students (94.4%) agree that environmental pollution will pose a problem for future generations. They also realise that sensitivity towards environmental problems means also a responsibility to society (93.5%). Students are once again in contradiction with themselves, while they are reluctant to join environmental organisations and participate in their activities, they are almost unanimous in agreeing that it is a social duty to protect the environment.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51095138

The other contradiction posed by the students is that, although they think it is a social duty to protect the environment, when it comes to 'warning' someone polluting the environment they remain 'indifferent.' Only 10.2% 'agreed' that they warn people and 5.6% strongly agreed, 34.3% was 'unresponsive' and 31.5% 'disagreed.' In fact, this ratio coincides with the rates of participation in environmental activities and membership to related organisations.

These results bring the following question to mind. If a student really believes that environmental protection is a social duty and pollution is a threat to the future, why do they not play an active role in protecting the environment? The fact that students expect others to display 'behaviour' that they do not do 'themselves' can be interpreted in two ways: One of them is social desirability bias. Social desirability is the tendency to respond to question in a manner that will be viewed favourably by others. They do this to exhibit a positive image of themselves to avoid receiving an unfavourable opinion. This could lead to either over-reporting 'right' behaviour' or under-reporting 'bad' or 'undesirable' behaviour (Fisher, 1993). Or they really feel the need to protect the environment and warn those who do not fulfil their environmental responsibilities. However, they are unable to put their intentions into action for various reasons such as being condemned by people, judged as disrespectful and not knowing the legal sanctions.

Although other researchers in the field have reported higher figures, they have shown that students, in general, are reluctant to warn the polluters. Ullah et al. (2013) in Bangladesh reported 56.5% of those to warn them. This ratio is 47% in Paksoy and Paksoy's (2015) and 44.2% in Kiper's (2014) work.

Purchasing and disposing behaviour

In the introduction section of the article, it was stated that having knowledge about the environment affects the attitudes of the individual in a positive way (Sivek and Hungerford, 1990) and that the positive attitude leads to positive behaviour (Wang et al., 2014).

The statements that measured the students' attitudes did not display a very revealing picture. It was observed that the students were not knowledgeable about the environment and did not have a positive attitude towards the environmental problems.

The survey included eight statements aimed at determining students' environmental behaviour. The extent to which students' responses reflect their attitudes to their behaviour is examined below.

When the university students behavioural patterns were examined, the lowest mean ($M = 1.30$) was obtained from the statement indicating that 'they make sure their rubbish goes into the garbage bin'. 90.8% of the participants state that they pay attention. It is expected that young people with university education will reflect this sensitivity. To see the actual behavioural patterns, it is necessary to evaluate other statements.

When examined in into more depth, it is observed that the ratio of the students who sorted their garbage as plastic, glass, paper, battery and disposed of separately, decreased to 71.3%. It is also noteworthy that the ratio of those who say they have 'no opinion' is close to 20%. Kiper's (2014) research has also yielded more concerning results; while 24.4% of those who say they always sort household waste out, 19.8% said that they never do it.

Recyclable packaging has been on the market for more than two decades. The benefit of recycling to the environment and the country's economy is often emphasized in the written and visual media, and publications that attempt to raise public awareness about the use of recyclable products are widely available. Perhaps, due to this emphasis, young people may have had the illusion that all products are sold in recycled packages or that each product is recyclable. Likewise, when purchasing a product, the ratio of those agreed that they make sure that the product is in recycled packaging, dropped to 37.1%. The ratio of those who said they absolutely agreed with the statement, further dropped to 20.2%. The ratio of those who strongly disagreed being 17.6%, is concerning. Present results despite not being promising, are not far from other studies undertaken. Kiper (2014) studied the environmental attitudes of Landscape Architecture students and he observed that 40.7% of those claimed 'always' paid attention. Erdal et al.'s (2013) study showed a similar outcome with the current research results. In his study, those who absolutely agreed were 26.48% partially agreed were 28.46%.

On the other hand, the rate of those who participated in the statement that they chose products that would not harm the ozone layer increased to 47.2%. The findings of the present research are consistent with previous research. Paksoy and Paksoy (2015) research states 43% of the participants, Gulgun et al.'s (2008) research states 39.23% of them do not use the products that damaged the ozone layer. However, it is striking that in both statements, a third of the students said "they had no idea".

As in the previous statement, the students indicating that they use natural resources such as electricity, water and natural gas sparingly reached to 90%. Especially in developing countries, utility bills amount higher than in developed countries and constitute a significant portion of the household budget. Therefore, the careful use of these resources may reflect the environmental consciousness of the students and or may have acquired as a result of a necessity imposed by their parents because participating students are usually from families belonging to the lower and middle-income groups

Above findings may be interpreted as the fact that the participant students are generally in low and middle-income families, therefore they rather pay more attention to the price of the product rather than its eco-friendly properties.

As a result of technological developments in recent years, people especially young people use digital environments increasingly. Consequently, various studies are carried out to monitor their digital literacy development. Many businesses have adopted paperless office principles for over a decade. Bookstores have extended their e-book range, and universities have started to broadcast lectures online and moved lecture material to the virtual environment. Students were asked a special question about whether they read in digital media to save paper. Research findings showed that students do not prefer to read in digital media, contrary to common assumption. Only half of the students (44.5%) read on screen. 40.7% still prints the lecture notes and they do seem to concern with paper saving.

Despite not reading from the screen, students were sensitive about paper use. 48.1% was 'strongly agreed' and 35.1% 'agreed'. 78.7% of the respondent stated that they used both sides of papers. Nevertheless, the rate of those who said that they would definitely use double-sided paper is behind the findings of other studies. Cabuk and Karacaoglu (2003) came up with the figures of 'always' 63.8%, and 'sometimes' 30.1%. Whereas Erdal et al. (2013) found those who 'absolutely agree' with were 51.38%, and those who 'agree with' were 33.20%

Car ownership is regarded as a symbol of economic welfare and social status in many countries. Nonetheless, the public transport usage rate depends on the availability of alternatives. Bicycle usage is a new phenomenon in Turkey. Urban metro is also available only in a few major cities and suburban train network is almost negligent. In addition, universities can develop a variety of approaches depending on whether they are in rural or urban areas. In small cities, students can have easier access by foot or by bicycle. This present research reveals 79.6% of the students' prefer public transport. Bursa Uludag University's distance from the city centre makes it difficult to reach the campus by bicycle. Furthermore, the starting of the city metro line from campus helps to explain the height of this number. It should also be remembered that the majority of the participants come from the middle and lower-middle income families. There is often one car in these families and the cost of driving can reach the amounts that students cannot afford with their allowance. The ratio of the students who indicate their preferred transportation as public transport varies from 64% to 87% (Isildar and Yildirim, 2008; Muderrisoglu and Altanlar, 2011; Oguz et al., 2011) in the literature.

The statements of the questionnaire that examined the students' behavioural patterns shown that their environmental behaviour was changed depending on the situation they are in.; Their economic situation and the existing opportunities could also affect how they behave. It is possible to claim that their overall behaviour is on the positive side considering the level of knowledge they have and the attitudes they maintain.

Conclusions

Increasing environmental problems have resulted in an increase in the research carried out on the subject matter. The aim of the research was to identify the causes of these problems and to solve them. Literature is dominated by the studies that examine students' attitudes and behaviour towards environmental issues and environmental problems at almost every level, ranging from primary school to university.

While research in developed countries focuses on how to solve them and how to prevent future problems, research in developing countries is more about understanding the causes of problems. Especially, studies toward university students have a significant share in the current research. This interest emphasizes that university students are leaders who will manage the future. Studies examining the environmental attitudes and behaviour of university students have exposed many contradictions and have laid the foundation for new research. This research, while analysing survey questions, attempted to include findings and contrasts revealed in the previous research in the context of Bursa Uludag University.

It has been observed that gender is not significant on students' environmental awareness. The research found that students belong to the lowest income level ($<294) differ from all other income levels in their awareness and display lower level environmental awareness. Other income levels did not appear to be a predictive factor of environmental behaviour. As the level of education of the mother increased, the students' environmental awareness increased, but when the mother's education reached the university level, the difference was not significant. Mother occupation too was significant on the student's environmental attitude; students whose mothers were a white collar and self–employed showed higher environmental awareness. In contrast, students who had blue–collars and self–employed fathers achieved higher environmental awareness. Students with farmer fathers scored the lowest awareness.

Fathers' education not reveals any significance. Finally, Medical and Business School students displayed higher levels of awareness while the School of Agriculture students scored the lowest means.

Most of the students in the research were unable to describe the environment and environmental pollution. This may be the result of them not receiving adequate environmental education up until the university. The students stated that the country's biggest problem was urbanisation. This was followed by air and water pollution. Faculty of Agriculture students do not consider soil pollution as an important problem is one of the remarkable findings of the research.

Another important finding was that the students find a lack of punishment and sanction the most important reason for the lack of sensitivity to the environment in society. On the one hand, it is striking that education about the environment students receive before they come to university is not sufficient. While on the other hand, the ratio of those who stated that the cause of environmental insensitivity in society is lack of education remains at 2.8%. Although students emphasize the lack of knowledge, they want to increase penal sanctions instead of making environmental education more accessible and effective.

As in other studies, Bursa Uludag University students stated that those who make the most contributions to the environment are voluntary organisations. The 2.8% share of 'education and research of universities' in the environment protection rate is directly proportional to the 75% 'no' answer to the statement of whether universities are doing their part about the environment. These findings should be very concern rising for the university. Students indicate that they want to take part in the environmental decision–making mechanisms of the University. They claim that society should play a more effective role in environmental protection. Another important finding of the study is that students did not see the problem of urbanisation as one of the tasks of society although they ranked this as the most important problem for the country.

In the section that examines the attitudes and behaviours' of the students. it was seen that students adopted the highest behaviour in the society, such as preferring public transportation, using the papers in two sides, separating the garbage on disposal. However, it was observed that one of every three students abstained in behaviour such as using recycled packaging, buying products that do not damage the ozone layer, taking active duties as members of the related institutions and warning the environment polluters. Therefore, the answers that are given suggest that students are inclined to social desirability bias. Or as this result has been underlined by other researchers, it can be interpreted that students do not reflect this to their behaviour even though they have a positive attitude towards the environment.

Acknowledgements. We would like to thank Emeritus Professor Derek J. Clements-Croome for his proofreading, suggestions and feedback during the preparation of the manuscript.

Please describe the environment in one sentence.
....
What pollution means to you?
....
What is the most important environmental problem in Turkey?
Air pollution ( ) Water Pollution ( ) Soil Pollution ( ) Noise Pollution ( )
Climate Change /Global Warming ( ) Urbanisation ( ) Other: ....

Are universities susceptible to environmental problems?
Yes ( ) No ( )
What's the reason for not having sensitivity towards environmental problems?
( ) The consequences of environmental problems are not known.
( ) Deterrent punishment/sanctions not issued.
( ) People are aware of environmental problems but they do not act to protect it.
( ) Not enough education and implementation.
( ) Shortage of relevant institutions.

Which organization makes the most important contribution to prevent environmental problems?
( ) Activities of non–governmental organizations. ( ) Works of the municipalities.
( ) Works of the Ministry of Environment and Urbanism. ( ) Public Service Announcements.
( ) Research and educational activities of universities.
What is the role of society in protecting the environment?
( ) To take care not to pollute the environment ( ) To prevent unplanned urbanization
( ) To use environmentally friendly products ( ) To actively take part in preserving the environment
Other:...
What is the role of universities in protecting the environment?
( ) Environmental education should be compulsory
( ) Students should take part in decision making and application process
( ) More R & D and training activities should be organized
( ) Should work in cooperation with the industry
( ) Experimental waste should not be randomly disposed
( ) Other:...

(Received 14th Jan 2019; accepted 26th Feb 2019)

Abstract. The present study was designed to study the effects of the pesticide chlorpyrifos (CPF) on the physiology of the economically important fish species common carp (*Cyprinus carpio* Linnaeus, 1785) by applying a biomarker approach. This pesticide is considered as a priority substance in surface waters according to Directive 2013/39/EU of the European Parliament and of the Council. The fish were treated with decreasing concentrations of CPF for 72 hours (acute exposure) and the histological structure of gills and respiration rate were examined. In sum, we found pronounced alterations in the gill structure and changes in the respiration rate index, regardless of the applied pesticide concentrations which indicates its negative effects on non-target aquatic species such as common carp. The results from such studies could be incorporated in the legislation to prevent water contamination in areas with intensive agricultural practices by applying biomarkers, and an update could also be initiated on the maximum permissible concentrations of CPF in surface waters.
Keywords: *biomarkers, fish, gills, histology, pesticides*

Introduction

The increasing use of pesticides in agricultural activities for controlling pests and diseases attacking agricultural crops is considered a major problem worldwide. However, after their application, these compounds migrate to the aquatic environment mainly by drift and transportation via air, and runoff from agricultural set ups (Marino and Ronco, 2005). Currently, pesticides are also commonly used in several other areas such as livestock and households (Fevery et al., 2016). In addition, according to Katsumata et al. (2006) in recent years, more than 10,000 chemicals have been used for industrial and agricultural purposes. After prohibiting the use of organochlorine (OCs) insecticides, the organophosphorus insecticides (OPs) have become the most commonly used compounds worldwide.

Chlorpyrifos (O, O-diethyl O-(3, 5, 6-trichloro-2-pyridyl) phosphorothioate; CPF) is a moderately toxic broad-spectrum lipophilic OP insecticide (Kow of 4.7) (Mugni et al., 2016) and one of the several OP compounds developed in the 1960s to replace persistent OC pesticides (Kumar et al., 2017). Today it is the most intensively used OP pesticide in agriculture. CPF is commonly used to control foliage and soil-borne insect pests on a variety of crops including rice, cotton, fruit, vegetable crops, lawns and ornamental plants, as well as subterranean termites (Rao et al., 2005; Fang et al., 2008). The urban uses of CPF include landscape maintenance, structural pest control,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51395157

dormant sprays and pet products (Solomon et al., 2014). However, according to Humphrey et al. (2004) its usage is restricted in inhabited areas. The highest amount of CPF produced globally (3.64–4.99 million kg) was recorded in 2007 (Grube et al., 2011). In India, it was reported that CPF was the second most used agricultural insecticide (9540 tons) in 2013–2014 (Kumar et al., 2017). In addition, this pesticide is one of the most widely used OPs in Argentina (Asselborn et al., 2015). As other OP insecticides, the primary site of action of CPF in animals is the acetylcholinesterase enzyme which is inactivated by phosphorylation, thereby interfering with normal cholinergic nerve transmissions (USEPA, 1986). Moreover, acetylcholinesterase plays an important role in neurotransmission at cholinergic synapses by rapid hydrolysis of neurotransmitter acetylcholine to choline and acetate (Kwong, 2002).

Aquatic species can be exposed to various OP pesticide concentrations which range from lethal to sublethal (Streit and Kuhn, 1994). Few reports are available on the effects of CPF on non-target aquatic organisms and some authors demonstrated its adverse effects on aquatic invertebrates and fish. Varó et al. (1998) pointed out EC_{50} values ranging from 0.95 to 18 mg l^{-1} of CPF in several *Artemia* species. Earlier reports also revealed fish kill incidents in association with CPF in water reaching several hundred parts per billion (Abdel-Halim et al., 2006). According to Varó et al. (1998) CPF passes via air-drift or surface runoff into natural waters, where it is accumulated in different aquatic organisms, especially in fish, making it vulnerable to several discernible effects. Thus, it is found that CPF is estrogenic and alters embryonic hatching, cell proliferation and apoptosis in Zebra fish (Yu et al., 2015); it affects the sex steroid production and thyroid follicular development in adult and larval lake sturgeon (Brandt et al., 2015); as well as the acetylcholinesterase activity in climbing perch and Zebra fish (Nguyen et al., 2015) and the activity of glucose-6-phosphate dehydrogenase in rainbow trout (Topal et al., 2014); it causes oxidative stress in common carp and Zebra fish (Chen et al., 2015); it impacts the protein synthesis in Zebra fish (Liu et al., 2015) and DNA and RNA synthesis in common carp (Wang et al., 2014), and causes histopathological alterations in common carp (Xing et al., 2012). Moreover, CPF is known to change the lysosomal membrane stability in other aquatic species such as Zebra mussel (Yancheva et al., 2017a,b).

A biomarker is known to be a change in a biological response, either at molecular, cellular, histological, physiological or behavioral level that can be related with the exposure to toxic environmental elements (Colin et al., 2016). One advantage of biomarkers relative to bioindicators is that the former allow examining specific target organs and cells, including gills, kidney and liver which are affected by exposure to environmental chemicals and are responsible for vital functions such as respiration, excretion and the accumulation and biotransformation of xenobiotics (Van der Oost et al., 2003).

According to Varó (1998) the histopathological effects produced in different tissues of non-target organisms are usually used to biomonitor polluted areas and environmental conditions in aquaculture systems, and the use of histopathological biomarkers in biomonitoring has many advantages. As stated by Hinton and Laurén (1990) the histological effects are consequences of biochemical mechanics that provide interpretative power about damage effects to individuals done at the molecular level. These biomarkers can be used as an early warning system for potential effects at the level of the individual. In addition, the histopathological lesions are easily recognizable alterations that ideally indicate alone a pathological condition,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51395157

also reflecting the severity and duration of pollution events. Although they cannot reveal toxic identity, the histological biomarkers can identify the pollution type through its mode of action, further supporting the use of histopathological biomarkers as faithful indicators of environmental pollution (Colin et al., 2016).

The gills of aquatic animals are usually used to assess pollution effects, as they are the first organ which comes in contact with the aquatic pollution. They are also highly vulnerable to toxic chemicals, mainly because their large surface area facilitates the interaction and their absorption. The toxicant absorption through gills is rapid and therefore, the toxic response in gills is also rapid (Pandey et al., 2008; Topal et al., 2015). Moreover, the histological lesions of gills are frequently the consequence of exposure to various contaminants (Fonseca et al., 2016) with the severity being dependent on the pollutant concentration and exposure time span (Tchounwou et al., 2012). Last but not least, the gill histopathological changes were previously recognized as valuable biomarkers of water ecosystem stressors (Pereira et al., 2013; Cruz et al., 2015).

According to Chen and Yang (2007), Dobreva et al. (2008), and Nishida (2011) the toxic effects of different pollutants may be linked to changes in the respiration rate and may also be used as an indicator of polluted waters. These changes are associated with insufficient amount of oxygen in the water, causing stress to the aquatic organisms. In addition, the rate of respiration reflects the metabolic activities of organisms and the responses due to changes in the surrounding environment could also serve as an indicator of adjustment capacity (Kumar et al., 2012).

The fish communities are key elements to evaluate the ecological condition of different water bodies based on biomarkers (Hermoso and Clavero, 2013), while histopathology is the standard method for assessing both short- and long-term xenobiotic effects on fish (Hinton and Lauren, 1990). What is more, to face environmental problems Water Framework Directive (WFD, Directive 2000/60/EC) has driven the need to assess the ecological status of water bodies through an integrative ecosystem approach using elements of biotic quality such as bioindicators. Along with diatoms, macroinvertebrates and macrophytes, the fish are key elements to assess the ecological status of water aquatic ecosystems (Fonseca et al., 2017).

Since 2000, aquaculture has been growing 6% per year and now has become a major food industry in the world market, as well as an important source of meat in the human diet (FAO, 2016). Common carp (*Cyprinus carpio*, Cyprinidae) which belongs to the omnivorous fish is one of the most important commercial species in aquaculture with a successful spread all over the world, and it is also highly valued in many different areas of biology (Kong et al., 2018). According to Zoral et al. (2017) common carp is a major cultured fish species, accounting for 10% of freshwater aquaculture production worldwide. Furthermore, common carp is introduced as one of the most suitable fish models for toxicological studies (OECD, 1992). The dominance of common carp in the aquatic systems and the fact that it has a better capacity for resistance against pollutants rather than other laboratory fish, such as Zebra fish and Japanese medaka are common reasons for choosing this exact species in toxicological tests (Lee et al., 2012; Pirsaheb et al., 2019).

Based on the above, in terms of aquatic toxicology it is essential to study the effects of CPF which is considered as a priority substance in surface waters according to Directive 2013/39/EC of the European parliament and the Council on non-target organisms, such as fish. Hence, the main objective on the present work was to study

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51395157

the possible negative effects of a short-term exposure (72 hours) of decreasing and environmentally relevant concentrations of CPF on the physiology of common carp by applying a biomarker approach as we hypothesized that we would also observe changes in the fish at lower concentrations than the permitted annual average concentrations in surface waters. Thus, we aimed to semi-quantitatively assess the gill histology through a histology-based fish health protocol and to measure the respiration rate.

Materials and methods

Experimental set up

Common carps with no external lesions were obtained from the Institute of Fisheries and Aquaculture, located in the city of Plovdiv, Bulgaria where fish are reared under strict and controlled conditions. They were weighed (g; total weight including viscera) and the total length (cm) were recorded (22.5 g ± 3.5; 13.5 cm ± 2.5). The fish were transported in plastic tanks equipped with air pumps to the laboratory of Faculty of Biology, Plovdiv University, Bulgaria. After transportation they were moved in glass tanks with 100 l chlorine free tap water (by evaporation) to acclimatize for a week. All tanks were equipped with air pumps for permanent aeration and the water was kept oxygen saturated. The fish were kept under a natural light/dark cycle (12:12) and they were not fed prior to the experiment. The fish were divided into four test groups (n=15), including the control. Thereafter, they were treated with different and decreasing (environmentally relevant) soluble concentrations of CPF, dissolved in cyclohexane for 72 hours (acute, short-term experiment). According to the national and EU legislation the annual average concentrations (AA-EQS) of CPF in inland surface waters and other surface waters is 0.03 µg l^{-1}. The tested concentrations were prepared as 50 and 30% of the AA-EQS. The reason for this selection is that the natural waters are usually contaminated with organic substances in low concentrations which subsequently lead to chronic exposure effects for the aquatic organisms. Therefore, in the current experiment for 100 l tanks, 3 µg (AA-EQS), 100%, 0.03 µg l^{-1}), 1.5 µg (50% from AA-EQS, 0.015 µg l^{-1}) and 0.9 µg (30% from AA-EQS, 0.009 µg l^{-1}) were applied. No fish mortality was observed. The basic physical characteristics of the water such as: pH, temperature, oxygen level and conductivity were followed strictly three times on the 24^{th}, 48^{th} and 72^{nd} hour according to a standard procedure (APHA, 2005) with a combined field-meter (WTW, Germany). All experiments were conducted in accordance with the national and international guidelines of the European Parliament and the Council on the protection of animals used for scientific purposes according to Directive 2010/63/EU.

Histological techniques

Fish dissection was performed according to the international standard procedures given in the EMERGE Protocol (Rosseland et al., 2003). All histological were prepared according to a standard procedure for light microscopy analysis (Gautier, 2011). For each fish, the gills were sampled and preserved in 10% neutrally buffered formaldehyde for 24 hours. The preserved samples were washed in tap water, dehydrated in a series of increasing ethanol concentrations (70% – 80% – 85% – 96% – 100%), cleared in xylene, infiltrated with liquid paraffin with a melting point of 54–56°C and finally embedded in paraffin wax. They were then sectioned (5 µm thick) on a rotary

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51395157

microtome (Leica RM2125 RTS, Germany) according to Humason (1962). The sections were stained with hematoxylin-eosin (H&E) and observed with a light microscope (Leica DM 500, Germany). The glass slides were labelled and were examined "blind". Firstly, the histological lesions were assessed according to the semi-quantitative system proposed by Bernet et al. (1999). Briefly, according to this method the histological lesions were classified into three reaction patterns – circulatory, regressive and progressive changes. Each reaction pattern includes several alterations which concern either functional units of the organ or the entire organ (see Bernet et al., 1999). As we did not find any inflammatory or neoplastic (tumor) alterations, these reaction patterns were excluded. Secondly, a six degree (0–6) severity gradation scale (SGS) which represents the severity of each alteration was defined according to Saraiva et al. (2015). Each grade represents specific histological characteristics and is categorized as follows: (0) – no histological alterations which represented normal gill histological structure; (1) – mild histological alterations; (2) – moderate histological alterations; (3) – pronounced histological alterations; (4) – severe histological alterations and (5) – very severe histological alterations. The relevance of a lesion depends on its pathological importance, i.e. how it affects the organ function and the ability of the fish to survive. Therefore, the pathological extent of each lesion was defined with an importance factor according to Bernet et al. (1999) as follows: (1) – minimal pathological importance, the lesion is easily reversible as toxicant exposure ends; (2) – moderate pathological importance, the lesion is reversible in most cases if the stressor is neutralized and (3) – marked pathological importance, the lesion is generally irreversible, leading to partial or total loss of the organ function. The final value for each alteration results from the multiplication of the score value with the importance factor. Summing up these final values for one reaction pattern or organ gives the index for the respective reaction pattern i.e. index for circulatory disturbance (IC), index for regressive changes (IR), index for progressive changes (IP) for the gills or organ index (OI). Organ index values were used to classify the severity of histological response using classes based in the scoring scheme proposed by Zimmerli et al. (2007): Class I (index ≤ 10) – normal tissue structure with slight histological alterations; Class II (index 11–20) – normal tissue structure with moderate histological alterations; Class III (index 21–30) – moderate modifications of normal tissue; Class IV (index 31–40) – pronounced histological alterations of the organ; Class V (index N 40) – severe histological alterations of the organ. The sum of the multiplied score values and importance factors of all diagnosed changes for each specimen resulting in different indices were statistically analyzed. The results were presented as averages. Besides the indices calculated by extent (score value) and pathological importance (importance factor) of lesions, a further point of interest to us was the prevalence of histological changes. Histological lesions were observed in each individual from the tested concentrations (15 individuals in concentration, 3 tested concentrations). From each individual 10 slides were prepared (10 slides x 15 individuals = 150 slides per concentration). From each slide approximately 100 lamellae were observed and the specific lesions were recorded. The prevalence was presented as average for all studied specimens for each concentration (n=15). We proposed the following classification: (10-30%) – alterations which occurred rarely; (30-50%) – alterations which occurred frequently; (50-70%) – alterations which occurred more frequently, and (>70%) – alterations which prevailed in the gill histological structure.

Respiration rate measurements

The respiration rate was measured along with the histological analysis on the 72nd hour. At the given time 5 fish were transferred in 30 l glass aquaria filled with water from the test tanks. The oxygen levels were measured using an oximeter (WTW, Germany). The tanks were filled with water until the edge and covered with plastic foil in order to prevent oxygen access from the air. The tanks were left for one hour and thereafter, the oxygen level was again measured. The respiration rate was determined by calculating the difference in the dissolved oxygen levels before and after one hour following Tsekov (1989): $I = Q_2/G$ where I – respiration rate index; G – weight of the fish, Q_2 – oxygen consumed by the fish between the two measurements (the difference between the oxygen levels before and after one hour Q_2=Q-Q_1 hour). Q was calculated by the following formula: $Q = V \times q$, where: Q – total oxygen level in the tank; V – volume of the water in the tank; q – level of dissolved oxygen in one liter of water (mg l^{-1}).

Statistical analysis

For the statistical processing of the data the software package Graph Pad Prism 7 for Windows (USA) was used, as well as the software package Past v. 3.0 (Hammer et al., 2001). The histological index results were presented as average values per tested group. The number of fish affected by a specific histological lesion was presented as percentage prevalence. The normal distribution was tested with the D'Agostino-Pearson normality test. T-test was applied to see if there is a significant difference between the histological alterations in the exposed groups and the control, as well as between the different lesions. Pearson’s correlation index (r) was applied, using normalized data (square root transformation) when the data were not normally distributed (Fowler et al., 1998) in order to determine if there is correlation between the respiration rate and the pesticide concentrations. The index of determination (r^2) was also given. A level of probability $p < 0.05$ was considered as statistically significant.

Results

Water quality

The basic physical water quality parameters measured at the three tested concentrations are presented in *Table 1*. They did not differ significantly ($p > 0.05$) compared to the control and were also within the acceptable water quality guideline ranges for aquatic ecosystems (DWAF, 1996).

Table 1. *Basic water physical properties measured in the three CPF test tanks, including control*

Test tank	pH	T (°C)	Conductivity (µS cm-1)	Dissolved oxygen (mg L-1)
0.9 µg CPF	8.3±0.5	16.5±1.5	370 ±5.5	8.5±1.5
1.5 µg CPF	8±0.5	17.3±2	365 ±3.5	8.3±0.3
3 µg CPF	7.5±1.5	18.5±0.5	410 ±0.5	7±0.5
Control	8.5±0.5	19±0.5	353.3±0.3	9.1±1

Gill histology

No external abnormalities were identified on any of the common carps, both control and tested fish. The general gill structure of control carps was typical for teleostean (Evans et al., 2005). In addition, our results for the control carps corresponded to Rajeshkumar et al. (2017). The gills of the control group were characterized with normal morphology including primary and secondary lamellae. The gills had four gill arches on each side of the buccal cavity. Each arch was composed of numerous gill filaments which had two rows of secondary lamellae which ran perpendicular to each filament. Each lamellae was made up of two sheets of epithelium delimited by many pillar cells which were contractile and separate the capillary channels. The single-cell thick lamellar epithelia contained goblet and chloride cells. One to two erythrocytes were usually recognized within each capillary lumen. Therefore, based on the proposed scale we determined the gill histology of control common carp as relatively normal (0) (*Fig. 1, Tables 2 and 3*). However, the macroscopic examination of the common carp gills exposed to different CPF concentrations for 72 hours showed alterations which differed in type, severity and prevalence. These lesions are presented in *Tables 2 and 3*, and respectively in *Figures 2, 3 and 4*.

Overall, from the conducted study on the negative effects of CPF on the histological structure of common carp gills alterations which we categorized overall in three groups – proliferative (progressive) changes, degenerative (regressive) changes in the gill epithelium and changes in the circulatory system (circulatory disturbances) were observed. We found that the proliferative alterations among the three groups were with the most severe degree of expression at all three tested concentrations, and these were lamellar lifting, edema, epithelial proliferation covering the primary and secondary lamellae, glandular cell proliferation (*Table 2*). Furthermore, these alterations showed an increase in the degree of expression in line with the increase in the pesticide concentration, except the proliferation of filament epithelium and fusion. These changes were expressed in a higher degree at the CPF concentration of 1.5 µg. We observed the most severe proliferative alteration, fusion, in the area of the secondary lamellae which completely altered the structure of the studied organ. Proliferation of epithelial tissue covering the filament reached the tip of the lamellae, whereby the individual secondary lamellae were not distinguishable. In general, fusion was presented at all tested concentrations, but its most severe degree of expression was detected at the CPF concentration of 1.5 µg (*Table 2*). This in turn, probably demonstrates the inclusion of active cell division processes associated with compensatory-adaptive mechanisms against the entry of the toxicant at this concentration.

The observed degenerative changes also showed an increase in the degree of expression along with the increase in the CPF concentration. However, degeneration of epithelial cells in the filament and secondary lamellae was not found at the lowest applied concentration (0.9 µg). On the other hand, at the same CPF concentration we observed a more active manifestation of proliferative changes in the gill epithelium which was also confirmed by the presence of fusion expressed in a mild degree of expression. At a CPF concentration of 1.5 µg the proliferative changes prevailed over the degenerative ones, with a severe degree of fusion which covered the majority of the secondary lamellae. In contrast, the degenerative changes were found to a mild extent (*Table 2*). This in turn, also shows a more active inclusion of compensatory-adaptive responses expressed through cell division processes compared to the lesser expression of necrotic processes in the common carp gills. At the highest applied concentration which equals AA-EQS of CPF in surface waters (3 µg), unlike the previous ones, we found predominant degenerative changes associated with more active involvement of necrotic processes in the gill epithelium. There was also a gradual substitution of the degenerative over the proliferative lesions associated with necrotic processes which showed a more severe degree of damage at the highest concentration, most likely due to the higher toxicity of CPF.

The changes found in the gill circulatory system consisted of vasodilatation in the main sinus and the blood vessels in the secondary lamellae. Similarly to the proliferative and degenerative changes in the gill epithelium these alterations also showed a certain tendency to increase the degree of expression with increasing the CPF concentration. At the lower applied concentrations (0.9 µg) vasodilatation of the secondary lamellae was found in their basal part, with a mild degree of expression (*Table 2*). Basal sinus vasodilation was observed in a severe degree of expression at the highest CPF concentration, probably indicating an increase in the internal blood vessel volume associated with red blood cell influx.

Overall, the occurred changes limited to the severe degree of expression which we linked with the particular exposure time of 72 hours. As for the very severe degree of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51395157

histological alterations, we consider that a longer exposure period is required which in turn is associated with further thorough studies.

The statistical analysis showed a significant difference ($p < 0.05$) between the score value for the control and the three groups of alterations (circulatory disturbances, progressive and regressive lesions) observed in the fish gills exposed to the highest CPF concentration. No significant differences were found for the reaction patterns between the different tested CPF concentrations.

The mean gill index (I_G) showed variation comparing the different CPF concentrations (*Table 2*). It was highest ($I_G = 46$) for the common carps exposed to 1.5 µg CPF, followed by the one calculated for the fish treated with 3 µg CPF ($I_G = 44$), but they were not significantly different ($p > 0.05$). Significantly different were the gill indexes (I_G) for the common carps exposed to the control and the lowest CPF concentrations compared to the other two ($p < 0.05$). Evaluating these results in terms of the severity of the histological response, the gill index (I_G) results of common carp were classified as Class II – normal tissue structure with moderate histological alterations for the lowest concentration and Class IV – pronounced histological alterations of the organ for the mean and highest concentration, respectively.

As for the percentage prevalence the gills were most affected in terms of the progressive alterations at all tested CPF concentrations (respectively 0.9, 1.5 and 3 µg) compared to the regressive and circulatory lesions (*Table 3*). In addition, the t-test proved significant differences ($p < 0.05$) between the percentage prevalence of the progressive lesions compared to the other two gill histological patterns at all applied CPF concentrations. Significant differences were also found between the circulatory disturbances and progressive lesions at 0.9, 1.5 and 3 µg. In the control group we found only lamellar lifting which was presented in 16% of the observed samples.

Respiration rate measurements

The results from the respiration rate measurements are presented in *Table 4*.

Table 4. *Index of respiration rate of common carp exposed to CPF concentrations at the 72nd hour (n=5 fish for each 30 l tank)*

CPF concentrations	Fish weight. g (G)	Oxygen content (mg l^{-1})					Index of respiration rate (I)
		Start		End		Total	
		q	Q	q_{1h}	Q_{1h}	(Q_2)	
72 hour							
Control	71.3	6.4	192.00	6.1	183.00	9.00	0.126
0.9 µg	64.7	6.2	186.00	5.9	177.00	9.00	0.139
1.5 µg	54.5	5.9	177.00	5.6	168.00	9.00	0.165
3 µg	59.5	5.9	177.00	5.5	165.00	12.00	0.202

Overall, we determined that the fish increased its respiration rate most likely because CPF disrupted the gill histological structure and thus, destabilized the respiration process. At the end of the acute experiment (72^{nd} hour) we recorded a 1.6 times increase in the respiration rate of the fish exposed to the highest CPF concentration, compared to the control. We also registered a strong correlation between the pesticide concentrations and the respiration rate index, although it was statistically insignificant ($r = 0.92$, $p = 0.08$). Furthermore, the index of determination showed that 84.64% of the observed correlation was probably caused by the CPF concentration.

Discussion

Water quality

The results on the basic physical water properties showed a good agreement with the control. Therefore, we consider that the lesions in the gill histological structure and respiration rate measurements were not due to changes in the abiotic factors.

Gill histology

As described by Bernet et al. (1999) in some publications lesions were described only morphologically and in these studies the effects of water pollution correlated with the abundance of lesions found in the studied organ. However, other studies concentrated on a few alterations in the organ and assessed their extent by using a scale. With the quantification of the alterations, statistical evaluation becomes practicable. The corresponding indices can be compared more easily than the morphological descriptions of pathological changes. We agree with Bernet et al. (1999) that histology is a descriptive science and the assessment of morphological changes will always depend on the investigator's experience, but such a tool that we also used allows more reliable interpretation of the results and comparisons with others. Furthermore, to properly interpret results from histopathological evaluations, it is essential to realize that a healthy control condition is not characterized by the complete absence of any histological lesions, but may display moderate alterations such as minor structural disorders or mild inflammatory reactions (Bernet et al., 2004). In our study we only observed lamellar lifting in the gills of control common carp which was categorized as a mild lesion. We also share the opinion of Zimmerli et al. (2007) that a technical disadvantage of histology is its qualitative nature. For this reason, in the present study we applied the approach of Bernet et al. (1999) and Zimmerli et al. (2007) that developed an evaluation scheme to transform qualitative histological observations into a semi-quantitative index.

The gills are among the most delicate structures of the teleost body and are very sensitive to environmental conditions (Saraiva et al., 2015). We support the statement of Camargo and Martinez (2007) that by assessing the degree of expression of gill alterations, the extent of exposure to toxicants can be traced, given that the gills are involved in respiration, osmoregulation and excretion. They are an effective tool in biomonitoring studies also because of their large surface area that comes into contact with water, as well as their permeability (Evans et al., 2005; Vigliano et al., 2006). Therefore, the importance of gills in the respiration and ionic regulation of fish has led to many studies on the changes in this organ under the exposure of various environmental pollutants, including pesticides.

In the present experiment the degree of expression of lamellar lifting and edema was found to be mainly severe in the common carp gills. In addition, there was a clear proportional relationship found between the CPF concentrations and the degree of expression of these changes, and at the highest concentration they were severely expressed. Similarly to Jiang et al. (2011) we also consider that the most commonly found changes in gills under the action of toxicants are edema and lifting of the lamellar epithelium. However, they can serve as a protective mechanism because the separation of the epithelium from the lamellae increases the distance through which the pollutants in the water have to pass before they reach the bloodstream (Arellano et al., 2004). Lifting of the lamellar epithelium and edema were also found by other authors

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51395157

such as Girija et al. (2014) Babatunde et al. (2014) and Saraiva et al. (2015). Furthermore, Schmidt et al. (1999) and Bernet et al. (2004) also consider alterations such as branching of the secondary lamellae as an adaptation to low oxygen concentrations as it increased the surface area in brown trout after exposure to untreated sewage.

Proliferation of the epithelial tissue in the filament and in the secondary lamellae, as well as the glandular cells showed a difference in the degree of expression. We agree with Mallatt (1985) according to who epithelial tissue proliferation is one of the major alterations observed in fish gills in contaminated aquatic ecosystems. Similarly to Hassan (2011) we also consider that epithelial cell proliferation, partial fusion of secondary lamellae and lamellar lifting are protective mechanisms which increase the distance between the external environment and the blood, and this serves as a barrier to the entry of toxicants. Similar lesions in freshwater fish after pesticide contamination were found by Gabet et al. (2014). As for the most severe proliferative alteration, along with Butchiram et al. (2009) and Karthigayani et al. (2014), we also observed fusion as a result of activating epithelial cell division processes and hyperplasia of epithelial cells after exposure to pesticides leading to significant proliferative changes. We agree with Bentivegna et al. (2015) and Fonseca et al. (2017) that cell proliferation probably occurs as defense mechanisms, leading not only to increased epithelial thickness, but also in, extreme cases, to lamellar fusion. Indeed, the increased thickness of epithelium prevents further toxicant absorption, but on the other hand, this causes the adverse effect of compromising gas and ion exchange mechanisms (Fonseca et al., 2017).

In addition, along with hyperplastic epithelial areas reaching fusion, we also found such with thinning of the lamellae due to degenerative processes. The identified higher degree of observed degenerative changes at higher tested concentration confirmed the reduction and probably subsequent exclusion of compensatory-adaptive processes. However, we consider that the toxicant could act by simultaneously involving two processes – active cell division and degenerative-necrotic destruction. It is noteworthy that there was an inverse relationship between these lesions i.e when fusion was expressed in a more severe degree; the degenerative changes were in a lower one and vice versa. Furthermore, at the highest CPF concentration (0.03 μg = AA-EQS) the degenerative processes were intensified and gradually shifted the proliferating ones. We consider that this would eventually affect the functioning of the organ, and could therefore inevitably cause oxidative stress and destabilize the health of the overallfish health. Our results confirmed the results of Theurkar et al. (2014) who found similar histological lesions, such as degeneration and necrosis of epithelial cells covering the filament, but at sublethal concentrations of insecticide monocrotophos. Together with the activation of compensatory-adaptive mechanisms associated with proliferative changes, we also found changes in the blood vessels of the gills of the experimental fish. At the lower concentrations, the histological changes were mild and with the increasing concentration, they shifted to moderate and severe.

The observed alterations, such as vasodilatation in the secondary lamellae and the main sinus were presented in varying degrees of expression, but we found a clear relationship between the impact and CPF concentration. The changes were found more frequently in the area of the venous sinus than in the secondary lamellae. Our results corresponded to those of Shubat et al. (1982) according to who vasodilation is observed mostly in the main sinus. In addition, we agree with Schwaiger et al. (2004) who suggested that the circulatory system alterations lead to a higher degree of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51395157

stress-induced damage in the organism. On the other hand, according to McHugh et al. (2011) the circulatory disturbances and regressive alterations are generally regarded as reversible when the toxicant exposure stops.

Respiration rate

In terms of the other biomarker which we measured, the fish reacted by increasing their respiration rate with the increase of the pesticide concentrations after the 72nd hour of exposure. We agree with Kumar et al. (2012) who suggested that in most cases the respiration rate increases with the increase of the pollutant concentration and level of toxicity. As stated by Stoyanova et al. (2017) and Yancheva et al. (2017b) the reason for this is that the organism tries to deliver more oxygen to all tissues and organs triggered by the oxidative stress due to the toxic exposure. Overall, our respiration rate measurements were in line with the histological lesions in the gills which confirmed that CPF affects negatively the respiration process and thus, physiology of common carp.

Conclusions

In sum, we can point out that the present study is a contribution in the field of pesticide contamination, especially for the short-term exposure effects of CPF on the physiology of commercially important fish species, such as common carp. Based on our results we can conclude that the gill changes which were identified were CPF related and CPF also affected the histology of carp gills by activating compensatory-adaptive and degenerative mechanisms leading to pathological alterations. In addition, the extent and prevalence of the proliferative alterations were predominant over the degenerative alterations, and those in the circulatory system. These changes subsequently changed the physiology of common carp by disrupting the gill function. Regardless of the applied concentrations the negative effects of CPF were also confirmed by the respiration intensity measurements. Moreover, the negative effect of CPF was observed at all three decreasing concentrations based on the permitted annual average concentrations (AA-EQS) in Directive 2013/39/EU which confirmed its toxicity on common carp. Overall, the results from the present study enhanced the importance of multi-biomarker approach in biomonitoring programs to assess the impact of organophosphorus pesticides on freshwater ecosystems. Thus, we strongly suggest that further studies in this particular area are continued.

CONVERSION FROM GRASSLAND TO CROPLAND AND LENGTH OF CROPPING HISTORY DRIVING SOIL METHANE UPTAKE IN CHINA

Abstract. The change of land use from grassland to cropland in Northern China has raised serious concern about regional carbon (C) cycle and greenhouse gas balance. We measured soil methane (CH_4) uptake using manual static chambers in grassland and cropland soils in the agro-pastoral ecotone of Inner Mongolia over three growing seasons (2010-2012). The primary aims were to assess the effect of undisturbed grassland and croplands from converted grassland with different land use histories on gas fluxes and systematically compare the site-specific CH_4 uptake factor. We found a significant difference ($P < 0.001$) in CH_4 uptake between grassland and croplands from reclaimed grassland for 5, 10 and 50 years old, and cropland soils in 5 and 10 years old were a significant sink of CH_4. Compared with cropland soils, the grassland had the lowest cumulative CH_4 uptake, with 141.4, 210.0 and 236.0 mg/m^2 during growing seasons of 2010, 2011 and 2012, respectively. Over the 3 growing seasons, the cumulative CH_4 uptake of croplands aged 5, 10 and 50 was 544.5, 361.7 and 266.1 mg/m^2. With the increase of farming time, the methane accumulation and absorption of C5, C10 and C50 decreased. Differences in CH_4 uptake of grassland and cropland with different length of cropping history can be explained by the amount of soil ammonium nitrogen (NH_4^+-N) and soil moisture. We conclude that (i) croplands for 5 and 10 years old from reclaimed grassland are the best approach considered here for optimizing the land use as a sink for atmospheric CH_4, and (ii) the practice that croplands from grassland reclaimed for more than 10 years old should be planted into grasslands is recommended for managing CH_4 uptake and soil carbon sink in the agro-pastoral ecotone of Inner Mongolia, China.
Keywords: *land-use change, greenhouse gases, soil physical and chemical properties, carbon sink*

Introduction

Methane (CH_4) is the second most important greenhouse gas in the atmosphere after carbon dioxide (CO_2). The atmospheric concentration of CH_4 has been increasing by 0.3%/yr (Liu et al., 2007). Although the main sink for atmospheric CH_4 is its oxidation in the troposphere by hydroxyl(-OH) (Khalil, 2000), aerobic soils are the only biological sinks for atmospheric CH_4 with an estimated global sink of 20-45 Tg CH_4/yr^2 (IPCC, 2007). Methane uptake is influenced by several factors including land use change, temperature, precipitation, N input and soil properties (e.g., moisture, temperature, texture, pH and C/N ratio) (Liu et al., 2009; Mou et al., 2014). Among these factors, land use change and soil properties are considered to be important drivers of the magnitude of methane uptake (Dörr et al., 1993; Ojima et al., 1993; Steudler et al., 1995). Changes in land use or intensification of land management directly affect the

DOI: http://dx.doi.org/10.15666/aeer/1702_51595172

CH_4 uptake and the atmospheric CH_4 budget (Smith et al., 2000; Verchot et al., 2000; Merino et al., 2004).

Inner Mongolia steppes account for approximately 80% of grassland in China. Land use conversions from grassland to cropland have occurred in the arid and semi-arid lands of Asia (ASAL) during the 20th century. The agro-pastoral ecotone of Inner Mongolia is included in the ASAL of Asia. The transition from livestock grazing to farming causes changes in land use practice. The grassland in Inner Mongolia is a typical *Leymus chinensis* temperate steppe, where land use types are often diverse with frequent changes. Wang et al. (2005) and Liu et al. (2007) found that CH_4 uptake rates and soil moisture were negatively correlated, while other soil properties were not discussed in these studies (Wang et al., 2005; Liu et al., 2007). How these changes have altered or will alter the CH_4 uptake remains unknown. Moreover, although much is known regarding CH_4 uptake, few data specific to soils of agro-pastoral ecotone is available, and few studies have been conducted on the effect of length of cropping history or soil properties on CH_4 uptake in this region. The effects of the conversion of grassland to cropland on CH_4 uptake are uncertain. The determining factors that mediate the influence of land use change on CH_4 uptake have not been elucidated.

Therefore, we conducted a study in the agro-pastoral ecotone of Inner Mongolia to investigate the effects of land use change on CH_4 uptake. The objectives were to understand the impact of cropping history and soil properties on CH_4 uptake from the conversion of grassland to cropland. This study investigated CH_4 uptake throughout 3 years in an agro-pastoral ecotone in Inner Mongolia, China. We compared cropland soils with different length of cropping history and adjacent grassland that were derived from the same parent material of soil under the same climate.

Materials and methods

Description of the study site

The study was conducted in Taipusi County, Inner Mongolia (China), located 41º49′52″north latitude and 115°13′26″east longitude, at an elevation of 1400 m above sea level (*Fig. 1*).

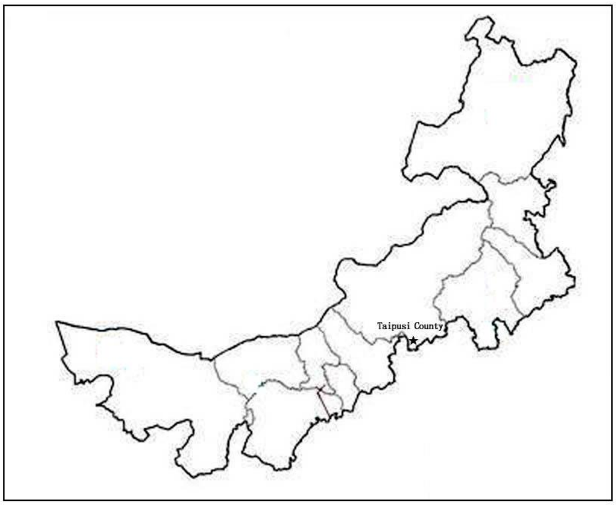

Figure 1. *Location of study area in Inner Mongolia, China*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

Located in the south of the Xilin River and characterized by scattered farms in the steppe, the study area is very representative of both the Eurasian temperate grasslands (Wang et al., 2007) and the steppe region of Inner Mongolia (Tong et al., 2004). The grassland is dominated by *L. chinensis* which is the typical vegetation of the region's grassland (Geng et al., 2010). The grassland in the study site was a natural clearing of native vegetation, without grazing or additional treatments such as fertilization or grass seeding. This region falls in the semi-arid temperate climatic zone. The mean annual temperature is approximately 1.6ºC, ranging from a mean monthly temperature of -17.6ºC in January and 17.8ºC in July. The region receives an average of 400 mm of precipitation annually. The growing season is from late April to early October.

Four sites were selected for the study, including an area of grassland (reference site) and croplands (farmer-managed fields) for 5, 10, and 50 years old from reclaimed grassland (*Table 1*). The length of cropping history was determined according to a field inventory and Taipusi County records. Hereafter, the four sites are referred to G (grassland), C5 (5 y old cropland), C10 (10 y old cropland) and C50 (50 y old cropland). The 4 sites presented similar slope and soil type within the adjacent ecosystems including flat areas of grassland soil and cropland soil. N, P and K compound fertilizers were applied before planting. Agriculture management in C5, C10 and C50 soil after conversion was carried out similarly.

Table 1. *Site characteristics of the agro-pastoral ecotone on Taipusi County, Inner Mongolia*

Site†	**Coordinates**		**Land use history**
	Latitude N	Longitude E	
G	41º49′52″	115°13′26″	Natural grassland
C5	41º50′29″	115°13′19″	Cropland reclaimed for 5 years old
C10	41º50′49″	115°13′43″	Cropland reclaimed for 10 years old
C50	41º50′53″	115°13′23″	Cropland reclaimed for 50 years old

There were three replicates plots for every natural grassland (G) and cropland from reclaimed grassland with different length of cropping history (C5, C10, and C50), respectively, and the area of each plot is 100 m × 100 m. Grassland vegetation was *L. chinensis* and *Stipa capillata.* Potatoes (*KexinNO.1*) and oats (*Avena sativa L.*) were grown in the three cropland sites in 2010, 2011 and 2012. Potatoes and Oats were alternatively planted in 2010, 2011 and 2012, respectively. Cropland was plowed once a year before planting. The plowing depth was 30-35 cm via machine plow. N, P and K compound fertilizer ($N:P_2O_5:K_2O$ = 15:10:10)(450 kg/ha) was incorporated into the soil before planting once a year. The crops were planted in May and were harvested in September, and the soil was bare from October to the following April. The croplands were irrigated in spring and autumn.

Measurement of methane flux

Field measurements of CH_4 flux were conducted in the four soils from April 2010 to October 2012. Measurements were taken every 15 days between June and August and once a month in April, May, September and October.

Three square chambers (n = 3) were randomly placed in each plot replicate and were in the same location for the duration of the measurements. All the chambers were fixed to the ground, reaching approximately 10 cm down into the soil. Aluminum flux collars

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51595172

were permanently installed to ensure reproducible placement of the gas collection chambers for successive CH_4 flux measurements throughout the growing season. The top edge of the collar had a groove that could be filled with water to seal the rim of the chamber. The chamber was equipped with a circulating fan to ensure complete gas mixing and was wrapped with a layer of sponge and aluminum foil to minimize air temperature changes inside the chamber during the period of the measurement. Cross-section of the chamber was 0.25 m^2 (0.5 m × 0.5 m). The height of chamber (or H) was 0.5 m. Samples were collected over a 30-min period (0, 10, 20 and 30 min) after closing the chambers at 8:00-11:00 am. Gas samples were taken using 25 mL gas-tight plastic syringes which were closed with stopcocks. The air temperature inside the chamber was recorded by thermometer for each measurement. Soil temperature (0-5 cm depth) was continuously recorded using temperature sensors interfaced with data loggers (HSY-TL881). During the CH_4 flux measurement period, soil water content was monitored using a TDR instrument (MP-406 Kits for moisture measurement). Five temperatures and five soil moisture data were measured on each plot. The aboveground biomass of the potatoes and oats under the sampling chamber (0.25 m^2) were determined by harvesting followed by oven-drying at 105ºC to constant weight.

Air samples were analyzed for CH_4 using a modified gas chromatograph (Agilent 6820D, Agilent Corporation) equipped with a flame ionization detector (FID) (Wang and Wang, 2003). Nitrogen was used as the carrier gas (30 mL/min). The oven was operated at 55ºC and the FID was operated at 200ºC. Flux was determined from the slope of the mixing ratio change in four samples taken 0, 10, 20 and 30 min after chamber closure. The gas samples were rejected if they did not yield an R^2 greater than 0.90 over the 30 min period. If the detected mixing ratio in the samples is decreased with the prolonging of time, it is a negative value, representing uptake. Carbon sinks into soil. Otherwise, it represents emissions.

Flux calculation

The CH_4 flux was calculated with *Eq. 1* (Yang et al., 2018):

$$F = 1000 \cdot S \cdot H \cdot M \cdot \left(Pa/Ps \right) \cdot \left(Ts/Ta \right) / 22.4 \qquad \text{(Eq.1)}$$

where F refers to CH_4 flux (μg/(m^2 min)), S is the linear slope of the concentration change with time over the measurement period (μL/(L min)), H is the valid height of the sampling chamber (m) and M is the molar mass of CH_4 (16 g/mol). Pa and Ta are the actual measured atmospheric pressure and temperature inside the chamber, respectively. Ps and Ts are the standard conditions (760 mm Hg, 273.15K). The standard molar volume of CH_4 (L/mol) is 22.4. Seasonal (7 month values) amounts of CH_4 uptakes were sequentially accumulated from the uptakes between every two adjacent intervals of the measurements.

Soil property measurements

Soil samples were collected for chemical analysis during the CH_4 flux measurements. The measurements were taken once every 15 days from June to August and once a month in April, May, September and October. Three replicates were collected from each site (G, C5, C10 and C50), with 10 sampling locations for each composite replicate. The samples were air-dried and sifted through 2 mm for

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51595172

physicochemical analysis. The sample of soil bulk density was collected using a steel cylinder (5 cm of diameter, 5 cm of height). Soil organic carbon (SOC), total nitrogen (TN), NH_4^+-N and NO_3^--N were determined following procedures. SOC was determined using a TOC (Total Organic Carbon) analyzer (Sievers 5310 C, GE Analytical Instruments, USA) (Lim and Choi, 2014), and TN was measured via the dry combustion method using a C/N Analyzer (Vario Macro, Elementar, Germany) (Yan et al., 2012). Soil ammonium nitrogen (NH_4^+-N) and nitrate nitrogen (NO_3^--N) were measured using a micro-Kjeldahl procedure (Aulakh et al., 2000). Soil microbial biomass C (MBC) and microbial biomass N (MBN) were determined using the chloroform ($CHCl_3$) fumigation–incubation method (Nunan et al., 1997). The pH value was measured in 1:2.5 soil/H_2O (w/w) suspension with a Titrino pH meter (Metrohm Ltd. CH.-901, Herisau, Switzerland) fitted with a glass electrode (Godsey et al., 2007).

Data analysis

Data were analyzed using ANOVAs and General Linear Mixed Model to assess the effect of the study site. Pearson's correlation analysis was performed to investigate the relationship between CH_4 uptake and soil properties (i.e., soil temperature, soil moisture and soil NH_4^+-N content etc.). The R^2 (square of Pearson correlation coefficient) values were used to determine the fitness of regression functions. For all analysis, statistical significance was determined at $P < 0.05$. All statistical analyses were performed using SPSS 11.5 (SPSS Inc., Chicago, IL, USA).

Results

Seasonal change on CH_4 uptake flux from the soils of grassland and croplands with different ages reclaimed

The CH_4 uptake flux in the grassland, C5, C10, and C50 soils showed obvious seasonal variability from 2010 to 2012 in the study (*Fig. 2*). During the first month of the growing season, CH_4 uptake increased rapidly in C5 soil. However, the seasonal uptake of CH_4 in G and C50 soils increased moderately, and there was no significant uptake peak. Throughout the testing stage, CH_4 uptake was lower in grassland and C50 soil than that in C5 and C10 soils. The maximum uptake flux of CH_4 in the grassland soil was 0.06, 0.12 and 0.11 mg/(m^2 hr), and was 0.09, 0.13 and 0.20 mg/(m^2 hr) in the C50 soil during the growing seasons in 2010, 2011 and 2012, respectively (*Fig. 2*). CH_4 uptake flux was the highest in C5 and C10 soils during the experimental period. The peak of CH_4 uptake flux in C5 and C10 soils was detected between June and July. The maximum CH_4 uptake flux of C5 soil was 0.27, 0.23 and 0.29 mg/(m^2 hr), and was 0.22, 0.20 and 0.29 mg/(m^2 hr) in C10 soil in 2010, 2011 and 2012, respectively. CH_4 uptake declined in all of the study sites at the end of the growing season (*Fig. 2*).

Cumulative methane uptake in the soils of grassland and croplands with different land use history

There were significant differences for cumulative CH_4 uptake in the grassland soil, C5, C10, and C50 cropland soils in 2010 (F=273.7, $P < 0.0001$), 2011 (F=264.8, $P < 0.0001$) and 2012 (F= 362.4, $P < 0.0001$). The land use conversion in more recently-established croplands (5 and 10 years old) from grassland to cropland promoted greater atmospheric CH_4 uptake compared to C50 and grassland type.

DOI: http://dx.doi.org/10.15666/aeer/1702_51595172

The grassland and C50 soils exhibited lower cumulative CH_4 uptake with 141.4 and 224.0 mg/m^2 than that of the C10 and C50 soils in 2010, 2011 and 2012, respectively (*Fig. 3*). Cumulative CH_4 uptake during the growing season was 544(±103) and 361(±47) mg/m^2 in C5 and C10 soils, respectively. The cumulative uptake flux in C5, C10, and C50 soils was 190%, 90% and 38% higher than that of the grassland soil. As the cropping history increased, the cumulative CH_4 uptake decreased in C5, C10, and C50 soils.

The changing relationship between CH_4 uptake and moisture or temperature of soil from different land use types

A significantly negative correlation in grassland, C5, C10, and C50 soils (r = 0.52, 0.75, 0.63, 0.62; P < 0.01) was detected between CH_4 uptake flux and soil volumetric

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51595172

moisture (% v/v) when soil temperature was above 5ºC (*Fig. 4a-d*). Soil moisture was a major factor affecting CH_4 uptake flux in the soils. The correlation between temperature and CH_4 uptake flux was not observed in the soils ($P > 0.05$) (*Fig. 5*). Soil moisture was the important controlling factor for CH_4 uptake flux when the temperature was not the limiting factor.

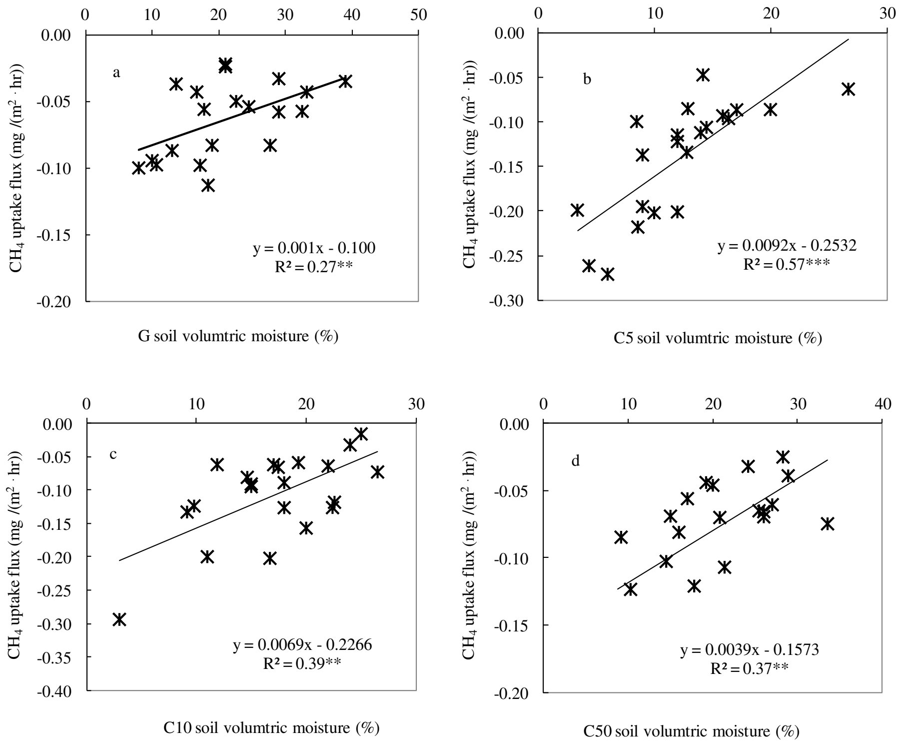

***Figure 4.** Correlation between CH_4 uptake flux and soil moisture from grassland and cropland soils; The soil volumetric moisture was simultaneously measured when gas sample were collected from 2010 to 2012; C5, C10, and C50: cropland for 5, 10, and 50 years old from reclaimed grassland, respectively*

Potential links between cumulative methane uptake and soil NH_4^+-N

A negative relationship (r = -0.86; P < 0.01) was found between cumulative CH_4 uptake and soil NH_4^+-N in the soils (*Fig. 6*). Soil NH_4^+-N and NO_3^-–N were greater in the cropland soils than that in the grassland soil in our study (*Table 2*). The soils with a high NH_4^+-N content showed lower cumulative CH_4 uptake. However, no correlation was observed between cumulative CH_4 uptake and soil NO_3^-–N in the growing season. The regression analysis indicated that a linear combination of soil NH_4^+-N explained more than 73% of the variability in the cumulative CH_4 uptake, and may account for the difference of the cumulative CH_4 uptake in the soils (*Fig. 6*).

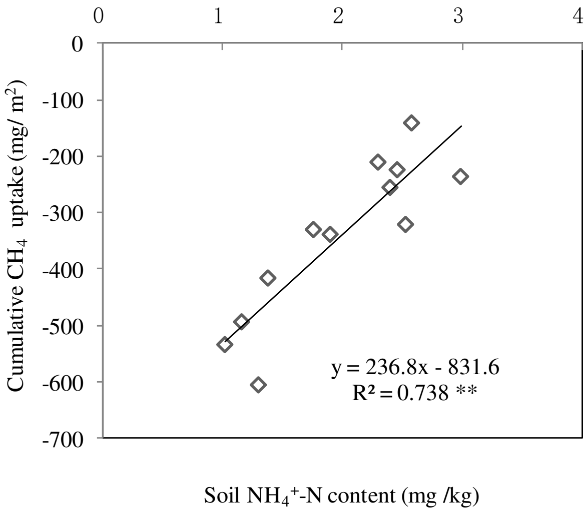

Figure 6. *Correlation between cumulative CH_4 uptake and soil NH_4^+-N in grassland and cropland soils; NH_4^+-N content was seasonal mean value from 2010 to 2012*

Discussion

Cropland soils from reclaimed grassland increasing methane uptake

The CH_4 uptake flux in the grassland soil was 0.001-0.120 mg/(m^2 hr) from 2010 to 2012 in our study. This falls in the range of a study conducted by Wang et al. (2015) (0.017-0.162 mg/(m^2 hr)) in a typical steppe dominated by *Leymus chinensis* (Trin.) Tzvel at Guyuan State Key Monitoring and Research Station of Grassland Ecosystem (Wang et al., 2015). In our study, the cropland soil after conversion from grassland to cropland increased the CH_4 uptake from 2010 to 2012 (141-235 mg/m^2 in G, 534-737 mg/m^2 in C5, 210-605 mg/m^2 in C10, and 235-493 mg/m^2 in C50). We found that the croplands from reclaimed grassland accelerated the CH_4 uptake. Compared to natural grasslands, agricultural soils from reclaimed grassland experience more physical disturbance due to fertilizer application as well as plowing, planting and harvesting with heavy agricultural equipment, which increases the aeration and porosity of the soils, affects mineralizable carbon and the other biochemical attributes (Rong et al., 2015), and creates favorable conditions for CH_4 oxidation. The oxidation of atmospheric CH_4 in upland soils is a biological process governed by CH_4-oxidizing bacteria and is dependent on the availability of both CH_4 and oxygen (O_2) in the soil profile (Yang et al., 2018). Boeckx et al. (1997) also reported that grassland had a lower methane uptake capacity than arable land in a study conducted in Belgium.

Decreasing methane uptake in cropland soils with the increase of cropping history from reclaimed grassland

CH_4 uptake rule on a temporal trend of cropping history was discovered in the agro-pastoral ecotone of Inner Mongolia. CH_4 uptake in cropland soil decreased with the increase of cropping history from 5 to 50 years after the grassland was converted into cropland (*Fig. 3*). Higher CH_4 uptake in the cropland soils from C5 and C10 was found in more recently-established croplands. The CH_4 uptake of C50 soil is close to that of grassland soil. Changes in soil carbon and soil properties after long-term fertilizer application affect methane oxidative bacteria community structure and soil methane oxidation rate (Hütsch et al., 1993). To reduce CH_4 uptake was proved on a period (7 years) of inorganic nitrogen application (Mosier et al., 1998).This study showed that enhancing or reducing CH_4 uptake by soil cultivation depends partly on the time elapsed from the conversion of grassland to cropland. In the field experiment, none of the CH_4 uptake was correlated with potatoes and oats biomass production ($P > 0.05$).

Methane uptake driven by the soil physicochemical properties of different land use type

Our study showed that the conversion of natural grassland to cultivated land can temporarily increase the uptake of CH_4 from the atmosphere depending on soil moisture level and soil NH_4^+-N. Soil moisture ranged from 6%-26% in C5, 3%-25% in C10, and 9%-34% in C50. Soil moisture in grassland is the highest (8%-39%) from 2010 to 2012. CH_4 uptake decreased as soil moisture level increased, which is consistent with previous studies (Price et al., 2004). There was negative correlation between CH_4 uptake and soil moisture in a semi-arid steppe. Moisture content is an important factor on regulating the transport process of methane from soil macro pores to methane oxidizing bacteria and the diffusion of methane into the soil (Wang et al., 2005; IPCC, 2007). Quantity and activity of methanotrophs significantly reduce on higher moisture levels in the soil

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51595172

(Castro et al., 1992; Sitaula et al., 1995). As soil moisture increases, the soil microbial community is covered by a thick water film which reduces the microorganisms activity and hinders the spread of CH_4 oxidation. CH_4 in soil water diffuses at a slower rate compared to soil air.

The effect of temperature on CH_4 uptake capacity in our study was not pronounced between 10ºC and 26ºC in grassland soil and cropland soils (*Fig. 5*). Castro et al. (1995) found that soil temperature was not an important controller of CH_4 uptake when temperature ranged between 10°C and 20°C (Castro et al., 1995). Warming (4.5°C) increased the average seasonal CH_4 uptake by 65.9% in the permafrost region of an alpine meadow (Chen et al., 2017). Soil moisture on CH_4 uptake was more important than temperature when the temperature was not the limiting factor. Irrigation and management in cropland create an optimum temperature for soil methanotrophs. The seasonality of CH_4 uptake exhibited a strong dependency on the seasonal variation of soil moisture in a typical semi-arid steppe in Inner Mongolia (Chen et al., 2010).

The negative correlation between CH_4 uptake and soil NH_4^+-N is detected over the whole testing stage (r=0.86, n=12). This result was consistent with previous findings in an incubation experiment under ambient CH_4 levels (Chan and Parkin, 2001). Soil NH_4^+-N is a key determinant on CH_4 oxidation capacity due to the significant competitive inhibition of CH_4 uptake by NH_4^+-N in recently cultivated soils (Jacinthe and Lal, 2005).

There were no significant correlations between CH_4 uptake and soil properties such as SOC content, MBN concentration, MBC, TN, soil sand content, pH, soil clay content and soil bulk density in all of the soils ($P > 0.05$) (*Table 2*, *Fig. 3*). As there was no significant difference for SOC, TN, soil bulk density and pH between the four types of land use in 2010. In addition, they change more slowly than other physicochemical properties such as NH_4^+-N, NO_3^-N, MBN, and MBC. Therefore, these data were not measured in 2011 and 2012. Variation in soil moisture and soil NH_4^+-N may have concealed the changes in soil bulk density, SOC, TN, soil MBN content, MBC, soil clay content and soil pH from land use change, although CH_4 uptake is affected by various factors. In our study, soil moisture (*Fig. 4*) and soil NH_4^+-N content (*Fig. 6*) were the major factors determining the difference on CH_4 uptake between grassland and cultivated land.

This study was designed to address how land use change affects CH_4 uptake and what soil parameters are the most important for assessing CH_4 uptake from the conversion of grassland to cropland in the agro-pastoral ecotone of Inner Mongolia. These efforts will improve our understanding of land use change on the CH_4 uptake in the agro-pastoral ecotone. The observed effects of physical and chemical properties of soil on CH_4 uptake in this study will support to estimate CH_4 fluxes based on soil properties from different land use types using model and simulation method. However, in our study, we examined the effects of land conversion on soil methane uptake in Inner Mongolia. The effects of nitrogen fertilizer application on methane uptake in croplands and grassland need to be further studied in the future.

Conclusions

The four land-use types (G, C5, C10 and C50) that we studied in the semi-arid steppe of the agro-pastoral region of northern China were sinks for atmospheric CH_4 with an average uptake flux of 0.06-0.29 mg m^{-2} hr^{-1}. Cropping history of the conversion from

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51595172

grassland to cropland affects CH_4 uptake. Land-use types exhibited different soil CH_4 fluxes with the maximum CH_4 uptake occurring in the C5 land-use type, and CH_4 uptake was higher for C10 compared to C50 type. The CH_4 uptake of C50 soil was approximately equal to that of grassland soil. Soil moisture and soil NH_4^+-N content are the key driving factor on CH_4 uptake of the observed differences between grassland and arable lands with different reclaimed history and may provide a possible approach for estimating soil CH_4 fluxes. Our results contribute to understanding soil uptake levels of atmospheric CH_4 in four important land-use types in northern China. The cropland reclaimed more than 10 years old should be planted into grasslands to facilitate CH_4 uptake and soil carbon sequestration in the agro-pastoral ecotone of Inner Mongolia. However, how long will the cultivated grassland be grazed and reclaimed into cropland be conducive to carbon sink? These tasks need to be studied in the future.

(Received 17th Oct 2018; accepted 2nd Jan 2019)

Abstract. Many human activities in the margin of Choghakhor wetland, (Iran) causes evaluation of the phytoplankton status in relation to the physico-chemical parameters in different seasons of 2011 in 5 marginal stations of the wetland. Water samples prepared in triplicate and temperature, pH, dissolved oxygen, nitrate and phosphate concentration were measured using APHA methods. The phytoplankton identified, counted and Shannon diversity index (H′). Phytoplankton community included 59 genera, 43 families and 6 divisions, among which Bacillariophyta was the most common (46.6%) followed by Chlorophyta (32.0%), Cyanophyta (13.3%), Dinophyta (4.4%), Euglenophyta (3.0%) and Chrysophyta (0.8%). Phytoplankton density, nitrate, and phosphate concentration were different in different stations and seasons ($P < 0.05$). The highest density was recorded for *Nitzschia* followed by *Cosmarium*, *Microcystis*, *Peridinium*, *Euglenaria* and *Dinobryon*. Also, *Microcystis* density was maximum in station 5 [S5]. There were significant correlations between the phytoplankton density and nitrate concentration ($r = 0.6$, $P < 0.01$), Chlorophyta and phosphate concentration ($r = 0.3$, $P < 0.01$), Cyanophyta and phosphate concentration ($r = 0.2$, $P < 0.05$). Although wetland water was still clean ($H' > 3$), high density of *Nitzschia* and *Microcystis* as eutrophication bio-indicators showed starting of eutrophication. *Microcystis* as the most abundant genus of *Cyanophyta* must be seriously controlled to avoid blooms in the wetland.
Keywords: *phytoplankton composition, physico-chemical parameters, Choghakhor wetland, nitrate, phosphate*

Introduction

The enrichment and pollution due to human activities are one of the most important environmental problems in wetlands that cause serious risks and may damage their fauna and flora (Rosińska et al., 2017). Land use and human activities lead to entry of chemicals from various resources including residential and industrial wastewater as well as agricultural runoffs to aquatic environments, especially wetlands (Chang, 1995; Khan and Ansari, 2005; Bressler and Paul, 2018). These compounds mainly contain high concentrations of nitrogen and phosphorus (Fonge et al., 2012) and could affect

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51735192

physicochemical characteristics and quality of water as well as the bio-communities of the wetlands. These effects vary in different ecosystems. For example, different studies have shown that increase of agricultural and residential wastewater inputs to wetlands causes changing water quality, variation in growth of phytoplankton communities, decrease water dissolved oxygen and ultimately an eutrophication status and elimination of the wetlands (Paludan et al., 2002; Sakset and Chankaew, 2013; Stević et al., 2018; Zhang, 2018). Hence, it is necessary to evaluate the growth of phytoplankton bio-communities in the wetlands exposed to agricultural and residential pollutants to control the effects of the pollutants and to preserve and maintain their life (Khan and Ansari, 2005).

Phytoplankton as photosynthetic organisms are the major producer especially in deep water as well as are the base of food chain in aquatic ecosystems (Muhammad et al., 2005). Other aquatic organisms are dependent on the phytoplankton directly and indirectly (Kelly, 1998; Moss, 2009; Jones et al., 1996). The production levels of phytoplankton maximizes when the water physicochemical characteristics are at optimum levels (Sinha and Srivastava, 1991; Muhammad et al., 2005; Sahu et al., 2012). Therefore, the composition of phytoplankton communities is a bio-indicator for the quality of lake water (Peerapornpisal et al., 2004; Wu et al., 2014; Sakset and Chankaew, 2013; Bellinger and Sigee, 2015).

The communities of the phytoplankton in freshwater ecosystems such as wetlands and lakes are mainly composed of Chlorophyta (green algae), Cyanophyta (blue-green algae), Bacillariophyta (diatoms) and Dinophyta (Rosén, 1981; Eloranta, 1986; Sorayya et al., 2011). Also, growth, ecological distribution, presence and abundance of the phytoplanktonic communities are affected by numerous environmental factors especially changes in water quality or mineral nutrients (Stević et al., 2018; Zhang, 2018). Algal blooms, especially in Cyanophyta and Dinophyta, is the main problems due to the excessive inputs of organic and inorganic compounds -such as agricultural fertilizers and pesticides- to aquatic environments (Rosińska et al., 2017). It causes to unfavorable taste and odor of water as well as destruction of organisms due to toxic substances produced by this phytoplankton (Fonge et al., 2012).

International wetland of Choghakhor is one of the most important water bodies in Iran, have different capabilities as valuable habitat for birds as written by Ramsar convention (Ebrahimi and Moshari, 2006). Nowadays, this wetland is affected by human activities especially agriculture runoffs and residential wastewaters (Nadushan and Fatemi, 2008; Samadi, 2016). Due to the obvious effects of human activity on the excessive phytoplankton abundance and its deleterious effects on biology of aquatic ecosystems (Chang, 1995; Khan and Ansari, 2005; Bressler and Paul, 2018), in this study the phytoplankton status involving density, composition, diversity as well as spatial / temporal distribution in relation to physico-chemical changes were evaluated in different seasons of 2011 as well as different stations designated in the margin of Choghakhor wetland.

Materials and methods

Description of study area

Choghakhor wetland is located on the Gondman district, Boroojen city in the province of Chahar-Mahal-Bakhtiari, Iran. This province is located on the southwest part of Iran which is near Zagros Mountains. This area extended 1500 ha between 31°

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51735192

54′ 32″ N to 31° 56′ 32″ N and 50° 53′ 58″ E to 50° 56′ 09″ E, with an average altitude of 2400 m above sea level (Ebrahimi and Moshari, 2006). Choghakhor is a permanent shallow lake by an average depth of 2 m. Rainfall occurs at spring (mid-March) and fall (mid-October) with the mean annual rainfall of 380 mm.

In the southern part of the wetland, the villages of Sangchin, Avorgan, Sibak, Dastgerd, Khaniabad, Sakiabad, Khedrabad and Galugerd are located from east to west, respectively. Recent human activities in the vicinity of the Choghakhor wetland have caused to increase agricultural runoffs and residential wastewaters, especially at its southern and western parts (Samadi, 2016).

Determination of sampling stations

The location of sampling stations was selected on topographic map considering the aim of the study in the margin of the wetland at different coordinates (*Table 1; Fig. 1*). Although Chaghakhor is a uniform lake with a steady slope (Ebrahimi and Moshari, 2006), entire environment of the lake was evaluated during the sampling period and 5 stations were selected, eventually. It was assumed that the selected station represented the surrounding area (*Table 1*).

Table 1. *Coordinates of sampling stations (S1 - S5) in Choghakhor wetland*

Station	Coordinate (degree -minute -second)
S1	50° 52′ 51.49″ E, 31° 55′ 49.27″ N
S2	50° 54′ 12.20″ E, 31° 56′ 11.14″ N
S3	50° 52′ 58.36″ E, 31° 45′ 51.88″ N
S4	50° 55′ 54.52″ E, 31° 55′ 07.84″ N
S5	50° 56′ 05.69″ E, 31° 55′ 17.24″ N

Sample collection

Sampling was done in 1 liter Teflon bottles at a depth of 50 cm at five stations with 3 biological replicates in spring (May), summer (August), fall (October) and winter (December) seasons in 2011.

First, the sampling containers were washed with the wetland water (three times) to accurate measurement of physicochemical properties of water. Then, the one set of the collected samples were transferred to the laboratory under standard conditions to evaluate some physicochemical properties of water using American Public Health Association [APHA] standard methods (Amy et al., 1992) (*Fig. 2*). The water temperature (thermometer; HANNA, PHep 4 HI98127, USA), pH (pH-meter; JENWAY3330, Canada), dissolved oxygen (DO-meter; Pro20 Dissolved Oxygen Instrument, Xylem, Japan) as well as the nitrate and phosphate concentration (spectrophotometer; Hach- DR 2400, USA) were measured based on the instruments manual.

Other set of the collected samples were used for phytoplankton assessment. These samples were fixed with three drops of Lugol's solution (0.007 v/v) in polyethylene containers (250 ml) to easy identification and then were transferred to laboratory in a cooler packed with ice blocks.

Identification, count and diversity of phytoplankton

The genera of phytoplankton were identified using binocular optical microscope (Olympus CH20i, Japan) with a magnification of 1000x (with emersion oil) and the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51735192

related text books and papers (Krammer and Lange-Bertalot, 1986; Bellinger and Sigee, 2015). To count and measure the phytoplankton density, 1 ml from each sample were evaluated using Sedgwick rafter slides (Wildco 1801-A10, JA Whitlock & Co, Australia) with three technical replicates.

The Shannon diversity index (H′) was calculated (Eq. 1):

$$H' = \sum P_i * \ln P_i \qquad \text{(Eq.1)}$$

Where P_i is proportion of total sample belonging to i^{th} genus and i is the number of genera (Magurran, 1988).

Statistical analysis

Data analysis were done using One-way ANOVA (SPSS21) and the mean values were compared using Duncan῾s multiple range tests at 95% confidence interval ($P < 0.05$). Pearson correlation coefficient was used to evaluate the correlations between physicochemical parameters of water and phytoplankton density and diversity.

Results

Physico-chemical parameters

Physicochemical characteristics of Choghakhor wetland are given in *Figure 2*.

Nitrate

In average, nitrate concentration (mg/L) were different ($P < 0.05$) in different seasons and stations (*Fig. 2A*). High amount of nitrate was observed in S5 and then in S4, S3, S1 and S2 respectively. Nitrate concentration in S2 and S1 decreased from the spring to winter. However, maximum concentration of nitrate was measured in S4 and S5 in the fall as well as the minimum in S2 in the spring (*Fig. 2A*).

Phosphate

Phosphate concentrations (mg/L) average in different season and stations were significantly different ($P < 0.05$) (*Fig. 2B*). Phosphate in different stations varied as: S3 > S5 > S4 > S2 ≈ S1. In S3, phosphate was highest in the fall and then varies as: spring > winter ≈ summer. In S5, phosphate was respectively highest in the fall followed by the spring or winter and lastly summer. Also, phosphate in S2 was maximum in the summer, afterward it was higher in the winter, fall and spring, respectively. The maximum concentration of phosphate was measured in S3 in the spring and fall (0.155 and 0.145, respectively) and the minimum ones (0.050) in S2 in the spring (*Fig. 2B*).

pH

Different stations had the same pH but, the seasons showed different pH ($P < 0.05$). pH was 9.55 in the summer and 8.12 in the winter by an average pH of 8.78. The wetland water is completely alkaline throughout the year (*Fig. 2C*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51735192

Water temperature

The results showed that the annual water temperature was 14 °C in average. Water temperature in different season was significantly different (P < 0.05) but there were no significant difference between the studied stations. The maximum and minimum temperatures were measured in the summer and winter, respectively (*Fig. 2D*).

Dissolved oxygen

The concentration of water dissolved oxygen varies from 7 to 10.9 mg/L. Only, dissolved oxygen was different in different stations in the winter, as S1, S2 and S3 were different from S4 and S5. Also, different seasons had different dissolved oxygen (except for spring and fall) as it was maximum in the winter and minimum in the summer. There were observed a reverse trend for temperature and dissolved oxygen variations (-0.7, P < 0.01) (*Fig. 2E*).

Identification of the phytoplankton

In this study, 59 genera belonging to 43 families and 6 divisions were identified (*Table 2*). Bacillariophyta was the most common phylum (46.6%) with the most abundant number of genera followed by Chlorophyta (32.0%), Cyanophyta (13.3%), Dinophyta (4.4%), Euglenophyta (3.0%) and Chrysophyta (0.8%) (*Table 2*). The most abundant genus was *Nitzschia* (14.8%) belonging to Bacillariaceae family and Bacillariophyta phylum. The density and abundance of the genera in each division are given in *Tables 3-6*.

The genus *Nitzschia* with the density of 6054 ± 1915 cell/L (32% abundance) was the most common in Bacillariophyta (*Table 5*). Also, *Cosmarium* (2869 ± 1855 cell/L, 22%), *Microcystis* (1969 ± 714 cell/L, 36%), *Peridinium* (1293 ± 1310 cell/L, 73%), *Euglenaria* (717 ± 605 cell/L, 59%) were the most common genera in Chlorophyta, Cyanophyta, Dinophyta and Euglenophyta, respectively (*Tables 3, 4* and *6*). It was found only one genus from Chrysophyta named as *Dinobryon* with the density of 314 ± 337 cell/L (*Table 6*).

Phytoplankton density

The total phytoplankton density was seasonally and spatially different (P < 0.05) (*Fig. 3A*). The density was highest in S5 in the fall (55563 cell/L) followed by spring (53788 cell/L) while it was the lowest in S2 in the spring (31922 cell/L) followed by S1 in the fall (31952 cell/L).

The phytoplankton community showed highest divergence in S4 and S5 in the summer and winter as well as in S4 in the spring and fall. The less diversity of the phytoplankton community was observed in the spring in S1 (*Fig. 3B*).

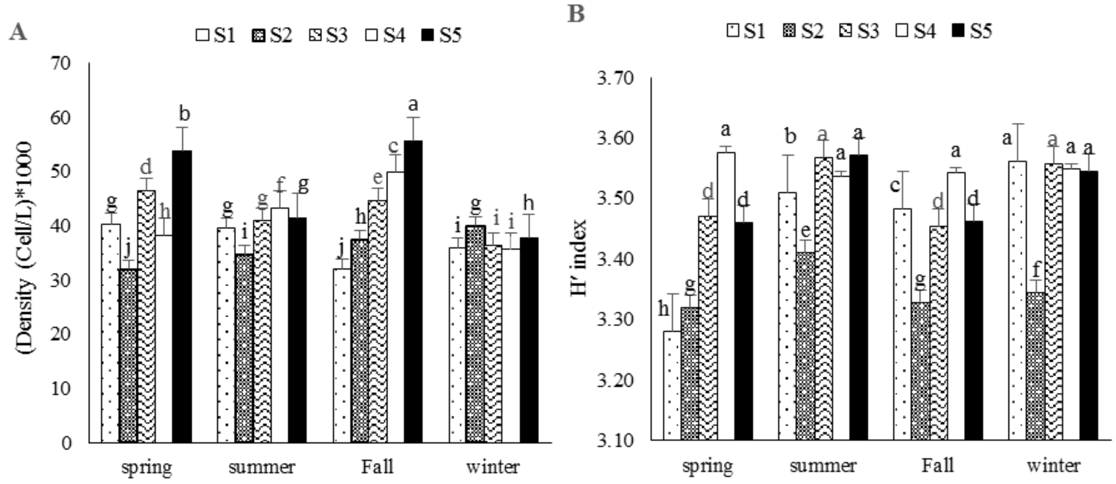

Figure 3. *Total phytoplankton density (A) and diversity (H' index: Shannon diversity index) (B) in different seasons and stations (S1-S5) in the Choghakhor wetland. Different letters in the mean values indicated difference between the means based on Duncan's multiple range tests, P < 0.05*

The density of Chlorophyta, Cyanophyta, Bacillariophyta, Dinophyta, Euglenophyta and Chrysophyta were different in different seasons and stations (S1 - S5) in the wetland (P < 0.05) (*Fig. 4*). The density of Chlorophyta in S5 was highest (7756 Cell/L) followed by S3, S4, S1 and S2 (5655 Cell/L), in the fall. Also, the density of Chlorophyta in S2 in the winter was highest followed by the summer, fall and spring while in S5 it was highest in the fall followed by spring, winter and lastly in the summer. The highest density of Cyanophyta was observed in S5 followed by S4, S3, S1 and S2, in the fall. In S5, Cyanophyta showed the maximum density in the fall and afterwards in the spring. Cyanophyta density in S2 in the fall was maximum and different from other seasons. Bacillariophyta density in S2 was more than the other stations (S2 > S1 > S3 ≈ S4 > S5) and in it was highest in the spring (P < 0.05). In S2, Bacillariophyta had the highest density in the fall and winter afterwards in the spring and summer. Bacillariophyta density in S3 and S5, in the summer and spring was greater than winter and fall.

In average, the highest and lowest density of Dinophyta was observed in S5 and S3, respectively. Dinophyta in the summer were most frequent than other seasons and they were not found in the winter in any stations. In the summer, the density of Dinophyta in S4 was highest and in S2 was at least. In the spring and fall, Dionophyta was found at maximum density in S5 and greater than S2 (*Fig. 4*). Euglenophyta and Chrysophyta in

DOI: http://dx.doi.org/10.15666/aeer/1702_51735192

S5 and in the winter were more abundant than other stations (*Fig. 4*). The lowest density of Euglenophyta was observed in S2 and did not change during the year. Also, Chrysophyta in S2 and S1 were not found in any of the seasons.

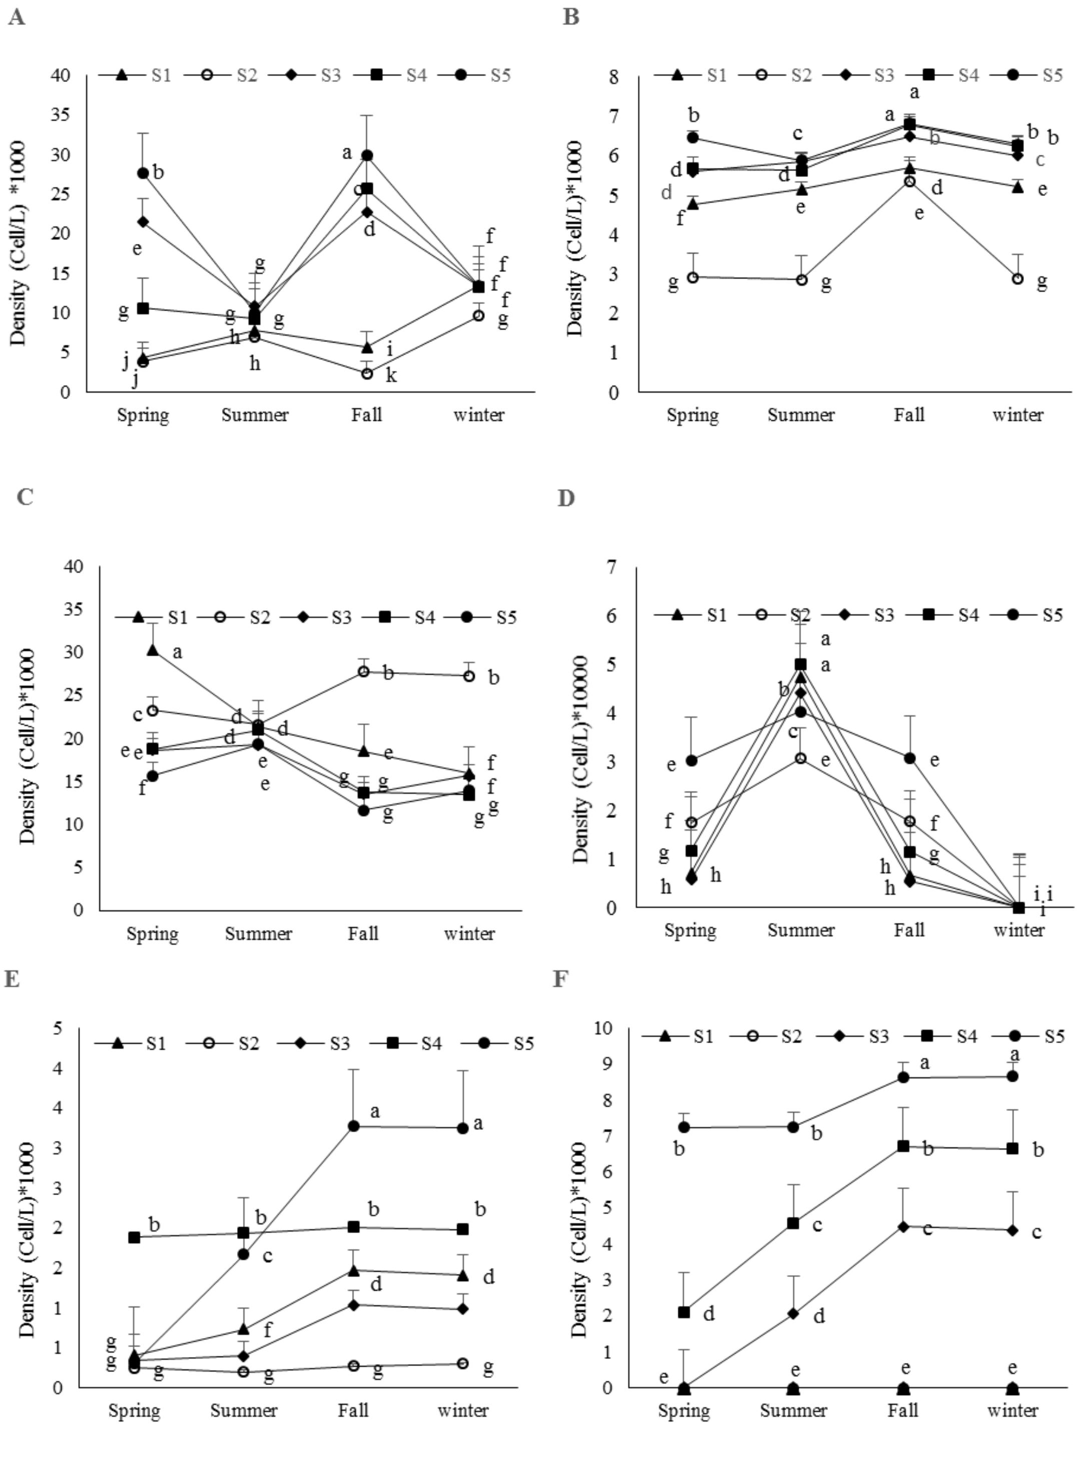

***Figure 4.** Density of different divisions: Chlorophyta (A), Cyanophyta (B), Bacillariophyta (C), Dinophyta (D), Euglenophyta (E) and Chrysophyta (F) in different seasons and stations (S1 - S5) in the Choghakhor wetland. Phytoplankton diversity

The phytoplankton diversity index (H′) in different stations and seasons was different and was more than 3 ($P < 0.05$) (*Fig. 3*). S4, S3 and S5 had highest diversity (3.55, 3.51 and 3.50, respectively). The diversity index of S1 was 3.46 while in S2 was least (3.35). Also, phytoplankton diversity was highest in the summer (3.52) followed by winter (3.51), fall (3.45) and spring (3.414).

In S5, S3 and S2, H′ was changed similarly as it was highest in the summer followed by winter, fall and spring. In S1, H′ in the winter was maximum followed by the summer, fall and spring. H′ in S4 did not change during the year.

Pearson correlation coefficient was shown in *Table 7* to compare the correlations between physicochemical parameters of water and phytoplankton density and diversity.

Table 7. *Pearson correlation coefficient between the total density and diversity (H') of phytoplankton, density of Chlorophyta (Chl.), Cyanophyta (Cya.), Bacillariophyta (Bac.), Dinophyta (Din.), Euglenophyta (Eug.) and Chrysophyta (Chr.) with physico-chemical parameters (T: temperature, DO: dissolved oxygen, pH, N: nitrate concentration and P: phosphate concentration) of water in the Choghakhor wetland*

Discussion

Variations in the physico-chemical parameters of water

The results showed that S5 had highest nitrate concentration followed by S4, S3, S1 and S2 (*Fig. 2A*). Other studies on Choghakhor wetland has been shown that this wetland is affected by human activities including agricultural runoffs containing chemical fertilizers and residential wastewaters mostly in the southern and western parts (Ebrahimi and Moshari, 2006; Nadushan and Fatemi, 2008; Samadi, 2016). The residential wastewaters containing high nitrate concentration and phosphate (Khan and Ansari, 2005) has been caused to Choghakhor wetland pollution in south east and North West parts (Ebrahimi and Moshari, 2006; Nadushan and Fatemi, 2008; Samadi, 2016). It seems that the higher nitrate concentration in S5 and S4 may be due to the residential wastewaters leakage from Avorgan (28387 m^3) and Sibak (23433 m^3) villages into the stations. S3 and S1, are also received residential wastewaters from adjacent villages

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51735192

especially from Galugerd with the lower volume (13208 m^3). S2 is located in the north of the wetland in the vicinity of the unutilized lands and so received minimum residential wastewater or agricultural runoff (Samadi, 2016). In fact, S2 can be considered as a control site to compare the effect of vicinity of the stations to residential and agricultural land uses on water quality and phytoplankton status. However, nitrate concentration in S2 was at least. Also, nitrate concentration in S5 and S4 in the fall and spring were more than the winter and summer. It may be due to the start of rainfall in the spring as well as fall, which causes leakage of residential wastewater flow from the adjacent regions to the wetland. The vicinity of S2 to unutilized lands was the reason for its lowest nitrate concentration than other stations in the spring and fall, in spite of rainfall. Accumulation of nitrate in the winter in S2, is likely related to less biochemical activities of macrophytes and less consumption of nitrate by them (Moss and Balls, 1989; Rana et al., 1995). Also, nitrate concentration was high in S2 in the summer due to less rainfall, rise of temperature which enhances decomposition followed by evaporation (Santhanam and Perumal, 2003). However, maximum concentration of nitrate was measured in S5 in the fall as well as the minimum in S2 in the spring (*Fig. 2A*).

Phosphate concentration was the highest in S3 followed by S5 and S4 and it was the lowest in S1 and S2. There are evidences supports that the Choghakhor wetland has been polluted by chemical farming fertilizers mainly containing high amounts of phosphate and to some extent nitrate in southwest (Ebrahimi and Moshari, 2006; Nadushan and Fatemi, 2008; Samadi, 2016) similar to other wetlands (Nassar and Gharib, 2014), especially. The vicinity of S3 to the farming lands leads to entry of agricultural runoffs containing much phosphate. Although S5 and S4 may receive less agricultural runoffs than S3, their phosphate content was remarkable (*Fig. 2B*). In S3 and S5, phosphate was highest in the fall and spring than other seasons due to more rainfall in theses seasons and consequently more leakage of the runoffs to this stations. Also in S1 and S2, maximum phosphate was measured in the summer followed by the winter as well as it was minimum in the spring followed by fall (*Fig. 2B*). It seems that raining in the fall and spring caused to dilution of the wetland water and low nutrient status. Also, highest phosphate in the summer in S2 may related to less rainfall, increase in temperature, decomposition enhancement followed by evaporation (Santhanam and Perumal, 2003). Also, phosphate concentration in S2 in the winter likely is because of less growth of macrophytes and less consumption of the phosphate due to higher share of macrophytes for phosphate absorption than phytoplankton (Rana et al., 1995; Moss, 2009).

The wetland water is completely alkaline throughout the year (pH ~ 8.78) as its pH was 9.55 in the summer and 8.12 in the winter and it was the same in different stations (*Fig. 2C*). Water temperature in different stations was similar and it was maximum in the summer and minimum in the winter (*Fig. 2D*). Dissolved oxygen of S4 and S5 was more than S1, S2 and S3 only in the winter. Also, dissolved oxygen was maximum in the winter and minimum in the summer (Watson et al., 1997). In fact, there were significant correlations between water physicochemical parameters (*Table 7*) (Peerapornpisal et al., 2004). There was a negative correlation between dissolved oxygen and temperature (-0.7, $P < 0.01$) (Moss and Balls, 1989). Similarly, there was a negative correlation between pH and temperature (-0.9, $P < 0.01$). Nitrate and phosphate concentration were negatively correlated with the pH (-0.3, $P < 0.05$ and -0.4, $P < 0.01$, respectively).

Phytoplankton density

Although different concentrations of nitrate and phosphate were measured in different stations (*Fig. 2A, B*), the total density of phytoplankton seems to be affected by variations in nitrate concentration, alone (*Fig. 2A*) because total phytoplankton density was positively correlated with nitrate concentration (0.6, $P < 0.01$) and not correlated with phosphate concentration (*Table 7*) and also there was the highest total density in S5 in the fall or spring and the lowest in S2 in spring and in S1 in fall (*Fig. 3*). As previously mentioned, S2 was considered as control because of its more distance to residential and farming land uses as well as any leakage of the polluted runoffs, unlike the S5. In fact, the vicinity of S5 by the residential regions caused to increase nitrate content especially in rainfall seasons and consequently to increased total density of the phytoplankton.

The result also showed that the Chlorophyta density (*Fig. 4*), nitrate and phosphate concentration (*Fig. 2A* and *B*) in S2 was less than S5. Also, there was correlations between Chlorophyta density and dissolved oxygen ($r = 0.4$, $P < 0.01$), pH ($r = -0.2$, $P < 0.05$), nitrate ($r = 0.7$, $P < 0.01$) and phosphate concentration ($r = 0.3$, $P < 0.01$). Perhaps, high phosphate and nitrate concentrations in S5 may be the reason for high density of Chlorophyta in this station. Similarly, other studies has been shown that physico-chemical factors such as phosphate, nitrate, temperature and dissolved oxygen support the growth of Chlorophyta (Rana and Nirmal Kumar, 1992; Hegde and Sujata, 1997; Nirmal Kumar et al., 2005).

Also, the density of Chlorophyta, in S2 - as control station- in the winter and summer was higher than fall and spring while in S3, S4 and S5 - as polluted stations by nitrate and phosphate- it was higher in the fall and spring than winter and summer (*Fig. 4*). This difference may be related to the accumulation of the nutrients in S2, in the winter due to less biochemical activity and in the summer due to evaporation and less rainfall in these seasons. These results were similar to a previous work (Kumar and Oommen, 2011).

Accumulation of nitrate and phosphate in S5 in the fall and spring was due to rainfall in these seasons and leakage of the nutrients from adjacent polluted lands to these stations which caused to increase the density of Chlorophyta. In this study, an increase in the frequency of Chlorophyta at station 5 corresponds to the results obtained by Zębek and Szymańska (Zębek and Szymańska, 2017)

According to the correlation coefficients were observed between Cyanophyta density and dissolved oxygen content ($r = 0.4$, $P < 0.01$), pH ($r = -0.2$, $P < 0.05$), nitrate ($r = 0.6$, $P < 0.01$) and phosphate concentration ($r = 0.2$, $P < 0.01$), the highest density of Cyanophyta which was observed in S5 may be related to the pollution of S5 by nitrate and phosphate especially in the rainy seasons of fall and spring. Inversely, the Cyanophyta density was at least in S2 (as control station) due to S2 vicinity to un-utilized regions and lack of pollution by nitrate and phosphate (*Fig. 4*). Williams and Tonnessen stated that increased concentration of nitrate and phosphate caused to increase in phytoplankton density in water due to the essential role of nitrogen and phosphorous for phytoplankton activity (Williams and Tonnessen, 2000). The main consequence for enrichment of surface waters by nitrate and phosphorus is eutrification (Stoddard, 1994; Khan and Ansari, 2005). One of the indications for eutrification is the growth of Cyanophyta or green-blue algae which causes to water appears greenish. They assimilate phosphate at a faster rate than green algae (Lam and Silvester, 1979).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51735192

Bacillariophyta density in S2 was more than S5 (*Fig. 4*) which is likely due to the lower concentration of nitrate in S2. There was a negative correlation between Bacillariophyta density and nitrate concentration (r = -0.5, P < 0.01, (*Table 7*). Due to dominance of Bacillariophyta in the lakes with less pollution (Song et al., 2007), so the lowest abundance of Bacillariophyta in S5 represents highest pollution of the wetland in this station. Also, Bacillariophyta is the most algal taxonomic group represented in mesotrophic systems (Rosén, 1981) such as S2 in our work.

The highest density of Dinophyta was observed in S5 followed by S3 (*Fig. 4*) while phosphate concentration was highest in S3 followed by S5 (*Fig. 2A*). Higher concentration of phosphate in S3 than S5 was related to agricultural runoffs entry to the station due to it vicinity to farming lands. So, considering negative correlation between the Dinophyta density and phosphate (r = -0.7, P < 0.01) (*Table 7*), the vicinity of S3 to farming lands may be a main factor to receive more phosphate and less growth of Dinophyta. Watson and colleague (1997) believe that in eutrophic regions (such as S3 and S5 in our work) Dinophyta generally decline (Watson et al., 1997).

Also, Dinophyta in the summer were most frequent than other seasons and they were not found in the winter in any stations (*Fig. 4*). This is because of highest temperature (r = 0.8, P < 0.01) and pH (r = 0.8, P < 0.01) as well as lowest dissolved oxygen (r = -0.7, P < 0.05) in the summer (*Fig. 2C, D* and *E*) (*Table 7*) which caused to more growth of Dinophyta.

Euglenophyta and Chrysophyta in S5 were more abundant than other stations (*Fig. 4*). In S2, Euglenophyta was at least and Chrysophyta was absent in all seasons. There were positive correlations between the nitrate concentration and density of Euglenophyta as well as Chrysophyta (r = 0.4, P < 0.01) (*Table 7*). Higher content of nitrate in S5 -due to the vicinity to residential regions- may be main factor to increase Euglenophyta and Chrysophyta in S5. Due to negative correlation between Euglenophyta density and pH (-0.2, P < 0.05) (*Table 7*) it seems that higher density of Euglenophytain in the winter (*Fig. 4*) is related to the lower pH in this season (*Fig. 2C*).

Phytoplankton diversity

The diversity indices (H′) in S4, S3 and S5 (3.55, 3.51 and 3.50, respectively) were not significantly different (P < 0.05) (*Fig. 3*) and were more than S1 and S2 (3.46 and 3.35, respectively). *Table 7* showed a positive correlation between total diversity of phytoplankton and phosphate concentration (r = 0.4, P < 0.01). Therefore, higher phosphate concentration in polluted stations (S3, S4 and S5) may be the cause of greater diversity of phytoplankton than S1 and S2. Also, Diversity was highest in the summer (3.52) followed by winter (3.51), fall (3.45) and spring (3.414) which is due to the change in diversity of different divisions during the seasons. For example, Dinophyta in the summer were most frequent than other seasons and they were not found in the winter in any stations. Chrysophyta in S1 and S2 was absent.

The normal range of H′ is from 0 to` 4 and indicated the diversity value and pollution status of a water body. The values > 3, 1-3 and < 1 indicate clean water, moderate pollution and heavily polluted, respectively (Williams and Tonnessen, 2000). In this study, Shannon diversity index (H′) ranged from 3.28 up to 3.57 and it was clear that the wetland water was still clean. Higher concentration of phosphate causes more diversity of individual taxonomic groups (Watson et al., 1997) which is similarly observed in S5.

DOI: http://dx.doi.org/10.15666/aeer/1702_51735192

Phytoplankton composition

In this study, 59 genera and 43 families belonging to 6 divisions were identified which Bacillariophyta phylum and *Nitzschia* genus were the most common ones by the abundances of 46.6% and 14.8%, respectively (*Table 2* and *3-6*). Similar result has been obtained by Arimoro et al. (2008). In each division, the highest density was recorded in the genus *Nitzschia* (Bacillariophyta, 6054 ± 1915 cell/L) as a bio-indicator for eutrophic status of the water, followed by *Cosmarium* (Chlorophyta, 2869 ± 1855 cell/L) as an oligotrophic status bio-indicator, *Microcystis* (Cyanophyta, 1969 ± 714 cell/L) as an eutrophic status bio-indicator, *Peridinium* (Dinophyta, 1293 ± 1310 cell/L), *Euglenaria* (Euglenophyta, 717 ± 605 cell/L) and *Dinobryon* (Chrysophyta, 314 ± 337 cell/L) (*Tables 3, 4* and *6*) (Wu, 1984; Sakset and Chankaew, 2013; Bellinger and Sigee, 2015). Also, the genus *Pinnularia* (Bacillariophta, 743 ± 237) is indicated an oligotrophic status while *Cyclotella* (Bacillariophyta, 2544 ± 967 cell/L), *Anacystis* (Cyanophyta, 925 ± 405 cell/L) and *Surirella* (Bacillariophyta, 557 ± 178 cell/L) indicating mesotrophic status of the wetland (Song et al., 2007; Fonge et al., 2012). Considering the highest density of the genus *Microcystis* indicating eutrophication in S5, S4 and S3 (*Fig. 5*) and due to the variations of nitrate and phosphate concentration in these stations (*Fig. 2A* and *B*), it seems that the high nutrient content in the stations especially nitrate and phosphate caused to initiate eutrophic status in the wetland. In fact, the vicinity of these stations to the residential and agricultural land uses caused to the high nutrient concentrations specially in the raining seasons of the fall and spring.

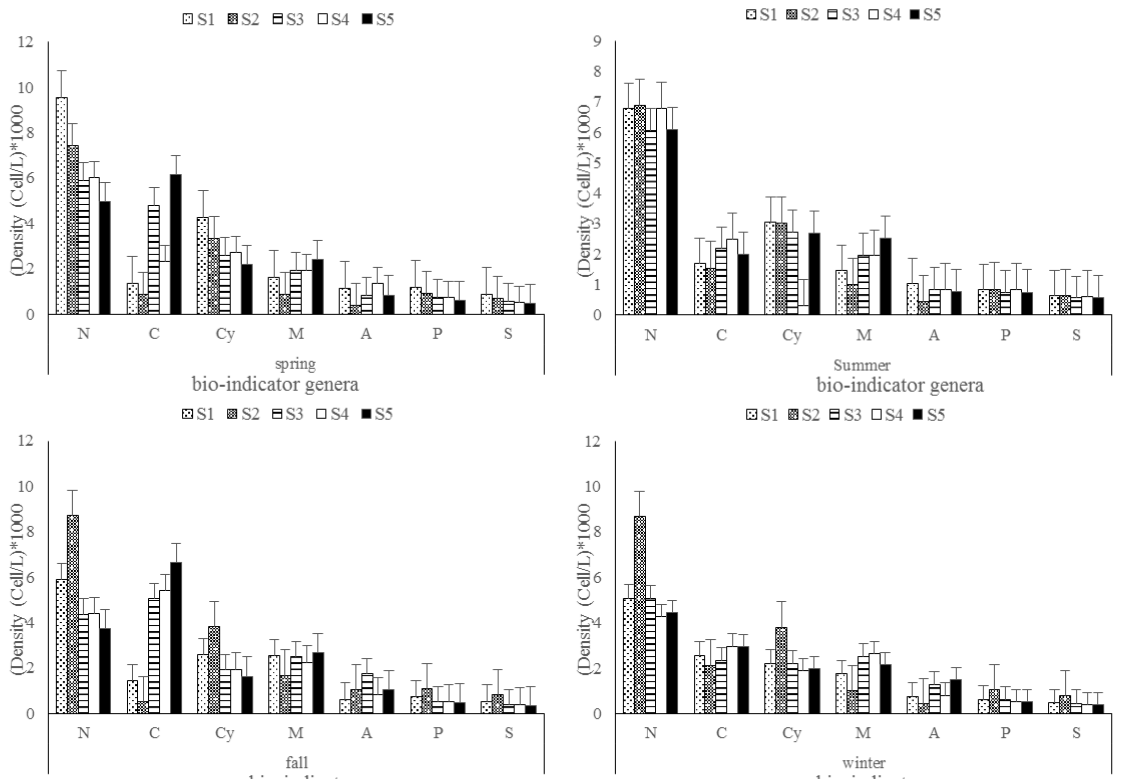

Figure 5. *Composition of the bio-indicator genera (N: Nitzschia, C: Cosmarium, Cy: Cyclotella, M: Microcystis, A: Anacystis, P: Pinnularia, S: Surirella) for water trophic status in different stations and seasons in Choghakhor wetland*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51735192

Considering a positive correlation between the Cyanophyta density and nitrate (0.6, $P < 0.01$) as well as phosphate concentration (0.2, $P < 0.05$) (*Table 7*) the *Microcystis* as the most abundant genus of *Cyanophyta* must be seriously controlled due to its ability to develop bloom in the wetland and to produce toxic compounds which threat the life of the organism living in the wetland (Lam and Silvester, 1979).

The total density of bio-indicator genera for eutrophic, oligotrophic and mesotrophic status were 8023 ± 2888, 3612 ± 1503 and 4026 ± 1057 cell/L, respectively. Although, H′ index was greater than 3 and so indicating the wetland water is clean, but according to the greater density of bio-indicator genera for eutrophic status, it seems that the wetland moves from mesotrophic and oligotrophic to the eutrophic status. It may be caused by the human activity mainly residential wastewaters and farming runoffs which makes entry of nitrate and phosphate to the adjacent parts of the wetland through the rainfall.

Conclusion

The phytoplankton status in relation to physico-chemical changes were evaluated in different seasons of 2011 as well as different stations in the margin of Choghakhor wetland. The stations were: S1 in north west affected by residential wastewaters; S2 in the north was adjacent to un-utilized regions (control); S3 in southwest was receiving agricultural runoffs; S4 and S5 in south east get residential wastewaters.

Phytoplankton community was included 59 genera, 43 families and 6 divisions which Bacillariophyta was the most common (46.6%) with 25 genera followed by Chlorophyta (32.0%), Cyanophyta (13.3%), Dinophyta (4.4%), Euglenophyta (3.0%) and Chrysophyta (0.8%). The most abundant genus was *Nitzschia* (14.8%) from Bacillariaceae.

Phytoplankton density (S5 > S4 > S3 > S1 > S2), as well as nitrate (S5 > S4 > S3 > S1 > S2) and phosphate (S3 > S5 > S4 > S1 ≈ S2) were different in different stations and seasons ($P < 0.05$). Also, there were correlations between phytoplankton density and nitrate ($r = 0.6$, $P < 0.01$), Chlorophyta density and phosphate ($r = 0.3$, $P < 0.01$), Cyanophyta density and phosphate ($r = 0.2$, $P < 0.05$) which supports the nitrate and phosphate role to increase the density of the phytoplankton in the stations with high nutrient contents (S5, S4 and S3). Chlorophyta and Cyanophyta abundance were maximum in S5 and minimum in S2. Inversely, Bacillariophyta density was highest in S2 and lowest in S5. The highest and lowest density of Dinophyta was observed in S5 and S3, respectively. In S5, It was greater than S2. Dinophyta in the summer were most frequent than other seasons. Euglenophyta was most abundant in S5 and least abundant in S2. Chrysophyta in S5 was most abundant and in S2 was absent.

The composition of the genera within the divisions showed that the highest density was recorded in the genus *Nitzschia* (Bacillariophyta, eutrophic status bio-indicator), followed by *Cosmarium* (Chlorophyta, oligotrophic status bio-indicator), *Microcystis* (Cyanophyta, eutrophic status bio-indicator), *Peridinium*, *Euglenaria* and *Dinobryo*. Also, *Microcystis* was maximum in S5 followed by S4 and S3. Generally, the total density of bio-indicator genera for eutrophic, oligotrophic and mesotrophic status were 8023 ± 2888, 3612 ± 1503 and 4026 ± 1057 cell/L, respectively.

Mean diversity index was varied as: S4 ≈ S3 ≈ S5 > S1 ≈ S2 ($P < 0.05$) and represented that the wetland water is still clean (H′ > 3). Although, H′ index was greater than 3 and so indicating the wetland water is clean, but according to the greater density

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51735192

of bio-indicator genera for eutrophic status, it seems that the wetland moves from mesotrophic and oligotrophic to the eutrophic status. It may be caused by the human activity mainly residential wastewaters and farming runoffs which makes entry of nitrate and phosphate to the adjacent parts of the wetland through the rainfall.

Abstract. Cassava (*Manihot esculenta* Crantz) is a versatile crop that plays a vital role in sustaining smallholders' livelihoods, and in increasing farmers' income. This research assessed the cassava value chain in Dak Lak province, Vietnam. It demonstrated the need for enhanced efficiency in the production of cassava thus enhancing the cassava value chain. Value chain analysis was conducted through a questionnaire-based survey of 300 household farmers, in-depth interviews with key informants, and focus group discussions in seven communes in three districts. The aim was to explore how to improve and develop the value chain, increase stakeholders' incomes and particularly, to ensure sustainable household livelihoods. The findings relating to the sharing of value added among the stakeholders showed that farmers create the highest value added but that intermediaries derive the most profit. In addition, relationships exist amongst different stakeholder ranging from input providers to the final users which are overwhelmingly starch and ethanol factories. There is a local linkage between input suppliers and farmers, both spot-market and persistent relationships which exist between farmers and intermediaries. Furthermore, the distribution of both gross and net profits overwhelmingly favors the traders and processors. However, intermediaries play an important role and the farmers would not secure full benefits without their support.
Keywords: *gross profit, household, intermediaries, stakeholders relationship, value added*

Introduction

Cassava (*Manihot esculenta* Crantz) is a perennial drought-resistant crop cultivated mainly in dry areas, which contributes significantly to the nutrition and livelihood of many farmers (Sewando, 2012). This crop is a versatile plant that is used in the production of a large number of products ranging from traditional food products to livestock feeds as well as having uses in the industrial sector as a raw material for ethanol and starch and its numerous derivatives (Pingmuanglek et al., 2017). The Vietnamese cassava value chain is characterized by numerous intermediaries due to inadequate commercial infrastructure as well as a fragmented pattern of land use for cassava production (Thao et al., 2013). As a result, cassava has a lower value compared to other crops in the same region. Dak Lak province is in the middle of the Central Highlands where four other provinces, Gia Lai, Kon Tum, Lam Dong, and Dak Nong are also located (Dak Lak, 2018). In Dak Lak, cassava is grown as a cash crop by rural

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51935217

households and the income earned from cassava plays a vital and increasing role in farmers' livelihoods (Son et al., 2016). The area cassava plantations in Dak Lak province has grown from 30,732 ha in 2014 to 36,300 ha in 2017 (GSO, 2018a), and the yield of cassava during that period fluctuated only slightly from 18.3 to 18.8 tonnes per hectare (GSO, 2018b). Cassava farmers also face various challenges stemming from a lack of access to modern inputs and improved varieties, as well as the problems relating to the local infrastructure and a lack of access to credit (Njukwe et al., 2014). Hence, improvements in the productivity of cassava, the processes used, their products, in the means of distribution in the value chain would lead to an improvement in output (Masamha et al., 2017).

This would in turn contribute to an increase in household income which would lead to increased spending in areas such as education and health services as well as other aspects of daily life (Rutherford et al., 2016). Nevertheless, unpredictable cassava prices in developing countries have tended to increase the vulnerability of farming household incomes (Ouma and Jagwe, 2010). In addition, the farmers have limited to connection with the market as well as a lack of comprehensive information. Consequently, building relationships among stakeholders in the cassava value chain and increasing cassava productivity is necessary in this region. The aim of the study is to improve and develop the cassava value chain, increase stakeholders' income and particularly, to find out the appropriate strategies to ensure sustainable household livelihoods.

Review of literature

Cassava is a crucial source of food in Africa because it can be planted in unfertile soil and is also able to resist severe weather (McNulty and Oparinde, 2015; Meridian Institute, 2012), and it is, for instance, a vital staple crop in Liberia (Coulibaly et al., 2014a). Africa is one of the leading cassava producing regions contributing over 56% of the total global supply (FAO, 2018). It has been proposed that labour, transportation systems and novel technologies, as well as the coordination of agents, are all factors by which the efficiency of the cassava value chain could be improved (Trienekens, 2011). The cassava market is primarily based on the cassava tuber and products made from it. However, cassava leaves also offer an additional source of nutrition although there have been few studies to date of their benefits or of how they are consumed and whether there is a wider market for them (Andersson et al., 2016). The utilization of locally available resources such as cassava, not only creates value-added products but also brings benefits to the local society, with benefits accruing to all stakeholders within the cassava value chain in the region (Mcnulty and Adewale, 2015). Olukunle (2013) found that income and employment for farmers in Nigeria could be created from the cassava value chain as well as other actors in the value chain with over one million jobs being created in rural areas of Nigeria and an increase of approximately US$450 per year in the income of 1.8 million participating farm families. However, although a strong long-standing market has been established in the cassava sector it was found that the farmers gained a smaller percentage of the total profits, compared to traders who received the largest part of the profit. Naziri et al. (2014) studied the cassava value chain and the diversity of post-harvest losses arising in four countries on two continents, Thailand and Vietnam in Southeast Asia, Nigeria and Ghana in sub-Saharan African. They found that post-harvest losses at different stages of the cassava value chain were due to cassava cultivation, processing and consumption methods and the relationships and linkages

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51935217

among the value-chain stakeholders. However, they suggested that there was no "one-size-fits-all" solution for dealing with post-harvest losses but those solutions depended on the specific characteristics of different value chains. They estimated that in Ghana, economic losses due to partial spoilage of cassava root were be between 16 and 28% caused by the long distance between the production site and the place of final consumption. Similarly, in Nigeria, economic losses suffered by cassava root due to breakage and deterioration during harvesting and distribution were estimated to be between 10 and 30%. Daniels et al. (2011) were able to provide a complete picture of the value chain in Nigeria including farmers, processors, traders, input suppliers and other stakeholders

In Cambodia, the yield of cassava is from 8 to 10 tonnes per ha with the average area under cassava being 0.2 to 1 ha/household. A study of the cassava value chain was conducted by the IBC (Inclusive Business for promoting sustainable Cassava smallholders) project in Tboung Khmum province and the study particularly examined government policy (SNV Cambodia, 2015) as well as examining gender-related aspects of the value chain. The linkages among stakeholders were analyzed with the aim of improving knowledge as well as proposing appropriate measures for further strengthening the cassava value chain. In recent years, the productivity and yield of cassava in Vietnam has increased and it now ranks third in terms of agricultural production after rice and corn. The area planted to cassava has reached 560,000 ha, with an average yield of 17.63 tonnes/ha and a production of 9.87 million tonnes annually (Hieu, 2016). This is because the area in which cassava is grown has been widened and hybrid varieties have been applied with farmers now cultivating 70% hybrid varieties including KM94 and 30% local varieties (Phuc, 2015). The average yield of cassava in 2016 was approximately 19 tonnes/ha (FAO, 2018), which was more than double that in 2000 (8.4 tonnes/ha). Nguyen et al. (2005) presented a complete picture of the cassava value chain and also the relationship among the stakeholders in the chain. The study also examined the role of the government as well as their operations and the sharing of benefits between stakeholders in the value chain, finding that as (Olukunle, 2013) noted in Nigeria, the farmer received unfairly small share of the benefits while intermediaries obtained most of the profit in the cassava value chain. According to (Naziri et al., 2014) study of postharvest losses there were differences between the northern and southern parts of Vietnam. In the north, production was mostly by small-scale farmers while in the south, it was characterized by both larger scale production and processing units normally consisting of from 20 to 30 hectares. That study found that post-harvest losses mainly occurred on large sized and small-sized plots because the local people lack of knowledge as well as in harvested. The kind of losses experienced were breakage and deterioration of roots as were found in other areas studied. Vietnam is a tropical country and it is unsurprising that cassava has become one of its most vital crops (GSO, 2018c). In Dak Lak the area planted with cassava increased from 32,000 ha to over 36,300 ha between 2011 and 2017, with the average cassava yield fluctuating around 19 tonnes/ha and the total production reaching a peak of 703,300 (*Fig. 1*) tonnes in 2017. The province is, therefore, a region where cassava is one of the most prominent crops. The study reported discusses the major aspects of the cassava value chain in Dak Lak province. Firstly, it systematically identifies and maps the stakeholders participating in the distribution channel and marketing of cassava and details the profit and cost structures. Secondly, it identifies the sharing of benefits between the various actors and analyzes the gross and net profits within the chain. It also examines how and by whom

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51935217

benefits could be gained from enhancing the relationships among the actors and organizations involved. Thirdly, it examines ways in which the cassava value chain could be upgraded by improvements in cassava productivity (Naziri et al., 2014). Finally, it highlights the role of relationships and coordination mechanisms in improving farming-related policies in order to enhance the cassava value chain and to increase the earnings of farmers.

Materials and methods

Study area

Dak Lak province is located in the Central Highlands between longitude 107°28'57" and 108°59'37" east, and between latitude 12°9'45" and 13°25'06" north (*Fig. 2*). It occupies an area of 13,125.37 km^2 (Dak Lak, 2018). Currently, the population is over 1.8 million people with a provincial population density of over 137 people per square kilometre. There are 47 ethnic groups living in the province, the largest; of which, the Kinh account for about 70% of the people, with other ethnic minority communities including Ede, Thai, Tay, M'nong, and Nung people representing the remaining approximately 30%. The climate of the province is separated into two sub-regions with the North West being quite hot and dry in the dry season, while the climate in the south east is cool and pleasant.

The Krong Bong district is located in the south east and the centre of the district is 55 km from Buon Ma Thuot city in the north west of the province (Krong Bong, 2018). Krong Bong has an area of 1,257.49 km^2 and a population of 90,126 people. It is affected by the tropical monsoon, and it's climate, which has two distinct seasons, rainy and hot, is not only impacted by the generally high altitude but is also influenced by the Cu Yang Sin mountain, which rises to over 2,400 m.

Ea Kar district was established on 13th September 1986 under decision No. 108/1986/QĐ-HĐBT of the Vietnamese government. It is 52 km from Buon Ma Thuot city, along the No. 26 National Highway. It is located to the north of Dak Lak province

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51935217

and has a land area of 1,037.47 km^2 and the population density is over 138 inhabitants per square kilometre. Cassava is one of the staple crops produced to meet the material needs of local industry and it is the largest producer among agricultural crops in Dak Lak province (Ea Kar, 2017).

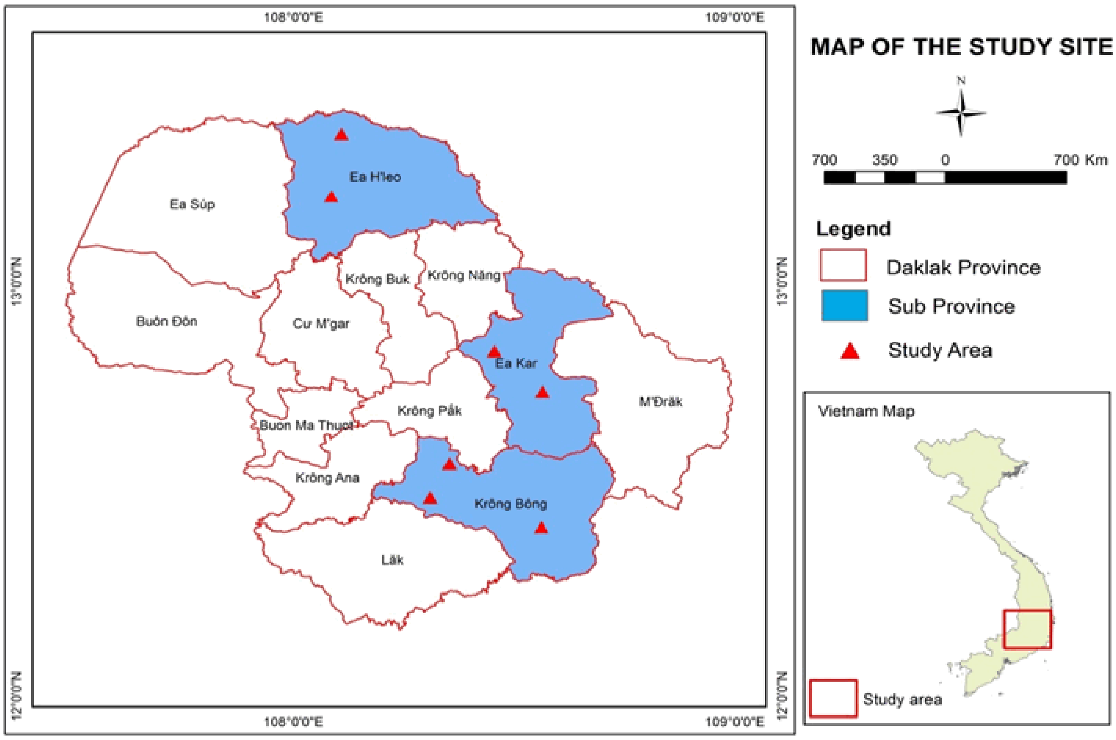

Figure 2. *The location of the study area*

Ea H'Leo district is the northern gateway of Dak Lak province. The district is approximately 80 km from Buon Ma Thuot city and was separated from Krong Buk district on 8th April 1980 under government decision No.110/QĐ-HĐBT. It has an area of 1,335.12 km^2 and a population of 125,123 people. Cassava is a prominent crop in the region (Ea H'leo, 2018). The study reported was conducted by surveys in three districts, Ea Kar, Krong Bong and Ea H'leo which are prominent areas of cassava production in Dak Lak. The major source of household income is from cassava, other cash crops and cattle husbandry. The average area planted to cassava by households is from 0.5 ha to 3.5 ha and the average yield is approximately 20 tonnes/ha. Most of the households growing cassava consist of northern ethnic minorities such as the Ede, Dao, Tay and Nung.

Data collection and analyses

Data collection

The study was conducted using a case study approach, which is one of several methods of conducting social science research (Yin et al., 2009). Data collection was conducted with the aid of structured questionnaires (Fonji et al., 2017). Data relating to household characteristics (Mukete et al., 2018) came from a household survey, interviews with key informants and focus-group discussions with heads of household

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51935217

and actors in the cassava value chain. The cross-sectional design enabled the researchers to address the study objectives and this method was adopted in order to save time during the data collection process (Kothari, 2004; Masamha et al., 2017). This method has been employed in a number of previous studies of the cassava value chain and related issues (Komen et al., 2010; Masamha et al., 2017; Son et al., 2016). The researchers selected seven communes from the three districts, Krong Bong, Ea Kar and Ea H'leo, using the multi-stage sampling method. In each commune, a questionnaire-based survey was conducted to collect relevant data from stakeholders in the cassava value chain based on visits to households. In this study, the interviews covered at least 70% of the households in each commune, where the farmers grow cassava. The questionnaire employed consisted of a mixture of open and closed ended questions. It was written in English then translated into Vietnamese before being used to interview the indigenous people (Echato and Echato, 2018). To complement the survey data, both primary and secondary data were collected from stakeholders who directly participate in the value chain, including from input providers, traders and processors (Masamha et al., 2018). Both in-depth interviews using a semi-structured questionnaire and direct observation in the field were also applied in this study (Coulibaly et al., 2014b). The in-depth interviews were conducted with key informants, including directors of local cassava starch factories (Son et al., 2016), input suppliers, cassava growers, collectors, traders, in Cu Kty, Hoa Son and Cu Pui (Krong Bong district), Ea Sar and Ea Pal (Ea Kar district), and Ea Tir and Ea H'leo (Ea H'leo district). These key informants were surveyed using a different questionnaire, which covered core processes (Naziri et al., 2014) traded quantities and prices of inputs as well as the selling price of cassava in the local market compared to other areas. Focus group discussions with cassava farmers were conducted during 2018 in the seven different communes included in the study. Field trips were used to gather primary as well as secondary data. The basic unit for this research was the *household farmer* which was defined as a group of people living together in the same house and taking part in the same daily activities (Mukete et al., 2018). The populations of the study were the cassava growing household farmers in Dak Lak province. Goal-directed sampling, a commonly used sampling approach was adopted, with the sample of participants being selected based on preselected criteria appropriate to a specific research question (Mack et al., 2005). The total sample size was 300 households across the seven communes, and 20 both collectors and traders, and key informants were interviewed as well as the owner of a cassava starch factory in the area.

Statistical analyses

Both qualitative and quantitative methods of analysis were applied in this study to understand the roles and actions of the major's actors (Apata, 2013). The analysis of the data from the questionnaire-based survey involved coding, data entry and analysis using the SPSS Version 20 statistical program (Masamha et al., 2017; Mukete et al., 2018) and Microsoft Excel. Frequencies and means for socio-economic and demographic data were described based on descriptive statistics (Masamha et al., 2017).

The qualitative data from the in-depth interviews with stakeholders and focus group discussions were analyzed by specific content analysis in order to identify and examine the most important topics (Masamha et al., 2018). A value chain details the many activities that are required to take a product or service through the different phases of production and delivery to the final consumers, and its disposal after use (Kaplinsky and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51935217

Morris, 2000). The analysis of the cassava value chain was based on the value-chain analysis method (VCA) (Naziri et al., 2014) and value-chain upgrade solutions were computed in this study using a quantitative method. The VCAs were designed using techniques to determine specific relationships and linkages at different stages among actors who participate in the cassava value chain. Analyzing supply stages, marketing and trading relationships between actors in chain analysis has become a key tool since it can enable an understanding of the whole chain (Meaton et al., 2015).

This study identified major aspects of the cassava value chain in Dak Lak province. The production cost, intermediate input (II) value added (VA) and other economic parameters, including gross profit (GPr), net profit (NPr). These were evaluated based on specific actors' perspectives. Revenues were calculated according to the following equation:

$$\text{Revenues} = (Q \times P) + \text{income from by-products}$$

where Q = quantity sold and P = price paid by buyer (Purcell et al., 2008).

Components of total value generated by the value chain such as output value (Y) and product value were also calculated using the Q × P formula, based on analytical frameworks for value chain analysis proposed by international organizations such as Deutsche Gesellschaft für Internationale Zusammenarbeit (GIZ, 2007).

Value added (VA) was calculated to measure the new wealth created by a productive activity and thus the creation of wealth and the contribution of the production process to the growth of the economy. VA was calculated according to the following equation:

$$VA = Y - II$$

where Y = total sales (output) value and II = intermediate input such as fertilizer, pesticide and seedlings.

Profit elements were calculated as follows:

$$GPr = VA - (\text{wages and salaries} + \text{interest charges} + \text{taxes})$$

$$NPr = GPr - \text{depreciation}$$

GPr expresses the economic gain, or loss, to an actor once all current production costs have been met. NPr indicates the economic gain or loss taking into account the predictable costs of actual investment.

Results

Description of stakeholders in the cassava value chain

Input provider

The study found that there were both backward and forward linkages in the cassava value chain. Input providers were backward-linked from the farmer. Thus, input providers were important actors who supply agricultural products to meet farmer demands for items such as seedlings, fertilizer and pesticide as well as being a source of informal credit for agricultural activities. A good relationship between providers and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51935217

farmers has the potential to improve the value chain by giving farmers access to informal credit without them needing to resort to the banking system or other sources of credit, and can help small-scale household farmers to pool their resources to deal with activities which cannot be done by individual farmers.

Farmer/producer

This is the first actor in the chain and they are mostly located in rural areas where an inequitable infrastructure has developed, with the farmer being at a disadvantage by needing to supply fresh cassava to the buyer (Njukwe et al., 2014). *Table 1* shows the socio-economic characteristics of household farmers across the study sites. The average age of the respondents is one of the major factors that affect the chain with 82.33% being over 35 years of age and 71.67% having received at least secondary formal education. Furthermore, it was notable that males represented almost 90% of the respondents suggesting that cassava production is overwhelmingly dominated by men. In addition, most of the farmers (92.32%) had more than 5 years' experience of cassava cultivation. The fresh cassava produced by farmers is mostly sold locally to large traders or factories as well as to other collectors at both the village market and the farm gate. However, this spot linkage only exists during the harvest period. The seedlings for the cassava varieties cultivated in the region are derived from multiple sources such as producers' own farms or those of neighbours, local seeding centres or from donations by international organisations conducting research about cassava cultivation. The land is generally prepared with a machete, hoe or dibble and the cassava plant cutting is inserted vertically, horizontally or at an angle (El Bassam et al., 2010). Some farmers who own larger areas prepare their land using tractors.

Transportation of the harvested cassava from the field may be by truck, motorbike or bicycle, but is mostly accomplished by a tractor-pulled trailer known locally as a *xe cay* (*Fig. 3*). Cassava is widely grown as a mono-crop by small-scale farmers on fragmented land (0.1 to 4.5 hectares) for food purposes and for use in the industrial sector. Nevertheless, larger scale inter-cropping models are also practiced by a small number of household farmers who sell their produce to processing factories. Cassava production is labour intensive (Masamha et al., 2017) so it is one of the best options to improve a farmer's livelihood in a rural area where there is an excess of labour available.

Collectors and traders

Collectors can be grouped based on the quantity of cassava which they buy, namely local, small and large and they include local people as well as those who come from a different region. They play a vital role in the linkage between the cultivation and consumption of fresh and dried-chip cassava. Depending on the buying capacity of the collector, the cassava is collected by different means. Local collectors usually gather directly from both small-scale cassava farmers and from indigents who collect the cassava residue from the harvested fields in or near the village. Larger collectors are able to buy fresh cassava from previous actors in the value chain as well as providing information to those other actors. Most of the product is then sold to starch or ethanol factories with a small volume being delivered to the Tay Ninh province cassava factory.

Figure 3. *Transportation in the cassava value chain. (Photo by author)*

Processors

Most of the cassava produced in Dak Lak is bought by starch or ethanol factories in each district. There are seven starch factories in Dak Lak province with capacities ranging from 150 to 250 tonnes of cassava starch per day, all of which are owned by the Dak Lak Starch Cassava Company. In addition, cassava is used as a raw material by Dai Viet, which was established in 2010, and is one of the biggest ethanol factories in Vietnam with an installed capacity of 54,000 tonnes of ethanol per year. The factories buy cassava in the form of dried chip or fresh root from small collectors as well as from traders and farmers who have large cultivation areas. Thus, most of the cassava tubers are transported to factories by collectors or traders (Son et al., 2016). In addition to its industrial use, fresh cassava is also processed into cassava chips by small-scale chip producers for use both in household animal husbandry and by animal feed companies. There is also a small amount of cassava root used for human consumption including in the form of local traditional cakes known as *Banh Trang* or *Bot Loc*.

Cassava value chain distribution channel in Dak Lak province

Currently, there are a number of distribution channels for cassava derived from cultivation by farmers to the final customer. However, there are only two major channels and these have an effect on the income of the households surveyed in this study. Firstly, the cassava is supplied to starch companies in order to produce starch (Son et al., 2016) for the export market (85%) with the rest (15%) for the domestic market. The second channel is to the ethanol factory which uses cassava as its feedstock to produce ethanol for a diverse range of domestic consumers (*Fig. 4*).

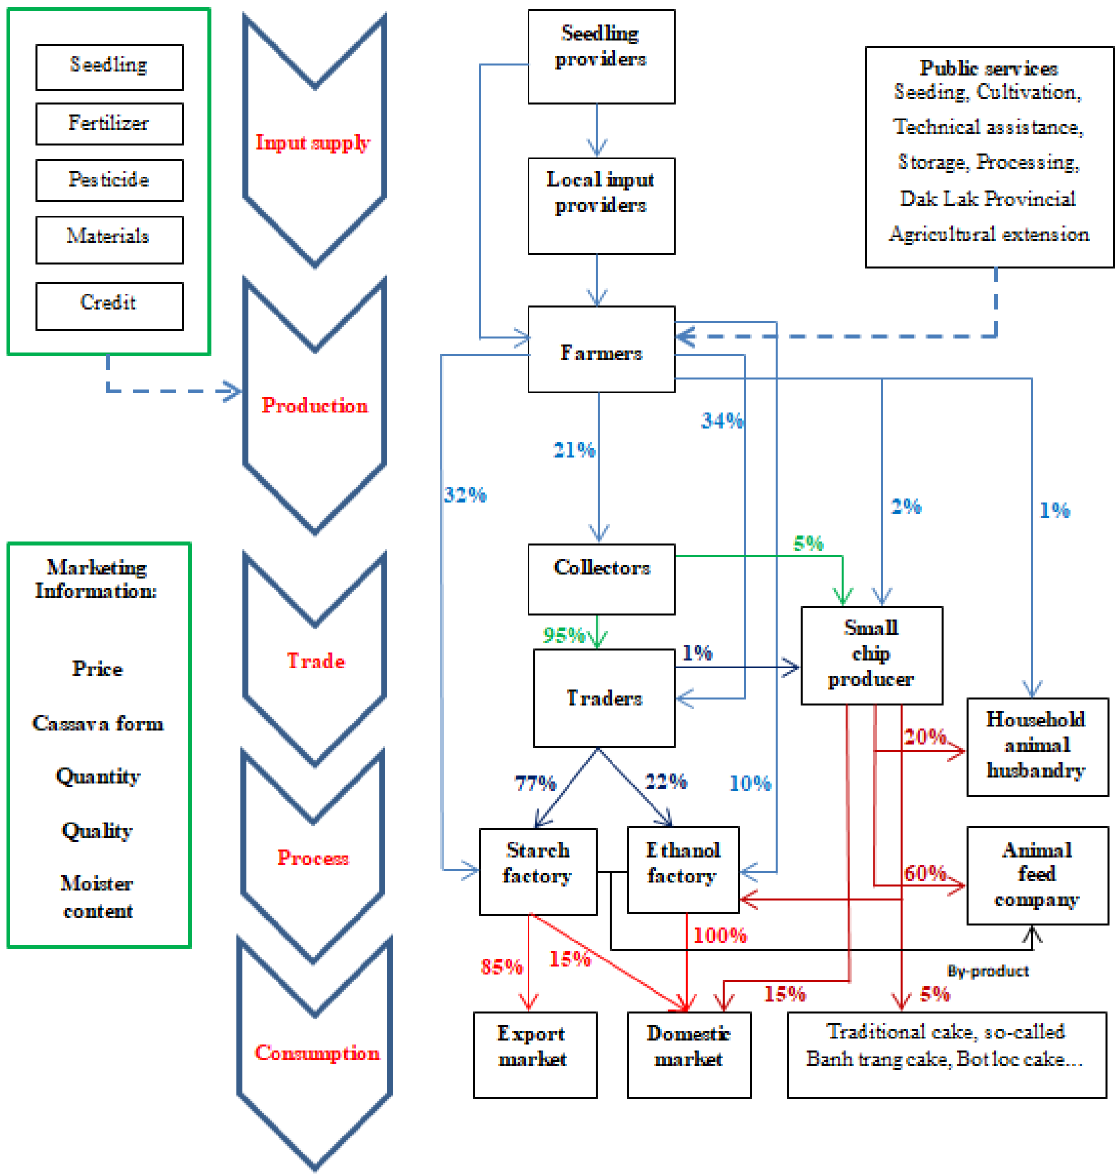

Figure 4. *Dak Lak cassava value chain map*

Based on our findings, it was estimated that 97% of the total cassava production is sold in fresh-root or dry chip form for industrial use with the rest being used to meet household requirements. In the first distribution channel, the fresh cassava tubers are

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51935217

either sold by the farmer to intermediaries (collectors, 21% and traders, 34%) and then sold to a starch factory, or are supplied directly by the farmer to the factory (32% - all percentages based on total production) to produce starch. In the second distribution channel, the farmers sell either directly to the ethanol factory (10% of total production) or through traders (22%) (*Fig. 4*). In addition, small chip producers and household animal husbandry account for 2% and 1% of total production respectively.

Financial analysis of stakeholders in the cassava value chain

Cassava growers

The yield of cassava production in the study site fluctuated in a range of 20 to 25 fresh root tonnes/ha. However, in exceptional cases, the yield was as low as 5.5 tons per hectare. This is because some households make an inadequate investment in growing cassava. Moreover, the low fertility of the land and the use of poor quality varieties also contribute to low productivity. The average yield was approximately 20 tons of cassava tubers per hectare. The conversion rate was 50%, and the farmer can thus obtain around 10 tons of dried chip cassava from the fresh quantity harvested. The producers had various options to sell their products to buyers. Depending on individual farmer's targets and market price information, the cassava growers sold 21%, 34%, 32% and 10% of their produce respectively to collectors, traders, starch factories and the ethanol factory. In terms of the price obtained for cassava, there is great variability depending on the price of exported starch (Son et al., 2016). In this study, the total farmer's income was VND47.895 million or US$2,048 per hectare (US$1 = VND23,390). The price of cassava was approximately VND2 million per tonne and the average yield was around 23.64 ton ha^{-1}. In the value chain analysis of cassava, the cost of intermediate inputs represented 8.52% of the total income of the producers, of which the highest percentage (over 50%) related to seedlings (VND4.081 million) (*Table 2*).

Table 2. *Major indicator analysis of fresh cassava value chain per hectare*

Item	Value (VND1,000)	Value USD	Proportion %
Output	**47,895**	**2,048**	**100.00**
Intermediate input	**4,081**	**174**	**8.52**

Interest	122	5	0.25
Gross profit (GPr = NPr)	**28,618**	**1,224**	**59.75**

Exchange rate: 1 US$ = 23,390 Vietnamese dong (VND) (HSBC, 2018)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51935217

The value added was calculated to be VND43.814 million (US$1,873) which accounted for 91.48% of the total production and this confirms that cassava is a favourable crop, which contributes to household farmer income with high economic efficiency, producing a GPr of VND28.618 million per hectare with low intermediate input costs.

In the case of chip cassava, the value added and the NPr accounted for 92.33% of the total production and 55.64% per hectare, respectively (*Fig. 5*). Although the total cost incurred also involved incurring an additional VND4.320 million (US$67) per hectare for peeling and drying the fresh cassava. However, both the income and profit received by the producers was higher for chip cassava than for fresh cassava since chips attract a higher price than fresh cassava, selling for VND4,500 per kg compared to VND2,026 per kg respectively. Furthermore, processing cassava into dried chips at the farm level provides employment for the indigenous people and thus helps to deal with rural employment, which is a growing problem in the region, and also helps to diversify the farmers' income. Finally, the farmer is able to negotiate the selling price with other actors in the value chain because they can store their product in dried chip form for a longer period in order to wait for the optimal market price (Viet et al., 2013).

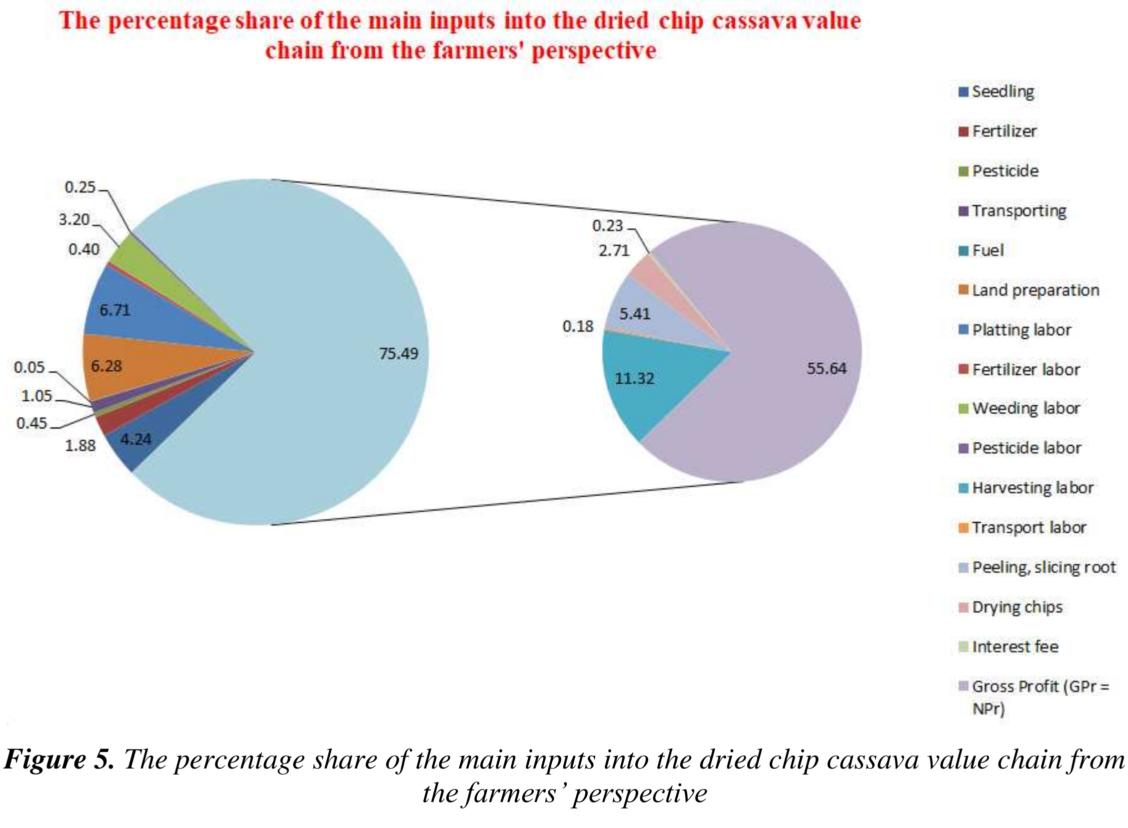

Figure 5. *The percentage share of the main inputs into the dried chip cassava value chain from the farmers' perspective*

The study found that based on different market price and productivity scenarios, the producer can always gain profit from their production. This is an advantageous situation and one that is attractive to household farmers who participate in the cassava value chain. In the worst-case scenario with both a low selling price and productivity, the farmers GPr was VND215 per kg, while the producer's GPr was VND1,729 per kg (*Fig. 6*) for the best scenario with a lucrative market and high productivity coinciding.

High productivity	729	1,229	1,729

Figure 6. *The sensitivity analysis of farmers' income based on the price and yield of cassava*

The collector perspective

The analysis of the financial situation from the collectors perspective shown in, *Table 3* indicates that, the amount expended by collectors for fresh cassava was approximately VND2,338/kg of which, the cost of fresh cassava accounted for the highest proportion of approximately 85%, followed by transport costs accounting for 9.42%. At this stage, the value added was created less than farmer with 6.15% compared to mostly over 90% in dried chip cassavas. However, a large quantity of produce was purchased by the collectors and the GPr and NPr of VND62,650 and VND61,530 per ton respectively were both higher than those earned by the farmer. According to Viet et al. (2013), it is normal for an amount to be deducted from the price paid by collectors to cover impurities in the cassava supplied by the farmer. This ranges from 7 to 10% of the purchase price depending on the time after harvesting as well as the moisture content and this finding was supported by our study. The quality of cassava tubers deteriorates depending on the harvesting season, the length of cultivation and the time to storage. Moreover, the collector is usually faced with having to provide finance due to delays in payment by the starch factories and this will also affect the purchase price paid to the farmer. The business pattern is also similar for the sale of dried chips by farmers to traders, and starch and ethanol factories. The GPr and NPr are actually little different from the fresh root model at VND62,550 (US$2.67) and VND57,550 (US$2.46) per tonne, respectively. However, in the case of dried chips, the collectors have more opportunity to locate the best market for their produce. The quality of cassava tubers depends on the harvesting time and length of storage. Generally, the percentage of starch reduces proportionally based on the length of storage by as much as 10% after a matter of days. In addition, the processing factories often postpone payments to collectors for several weeks because the factories face short-term financial constraints. The collectors do not have any other options although their business activities are affected by this problem. One of the reasons is that the purchasing system in this area has not yet developed and the local market for cassava is excessively dependent on demand from the processing factories (*Fig. 7*).

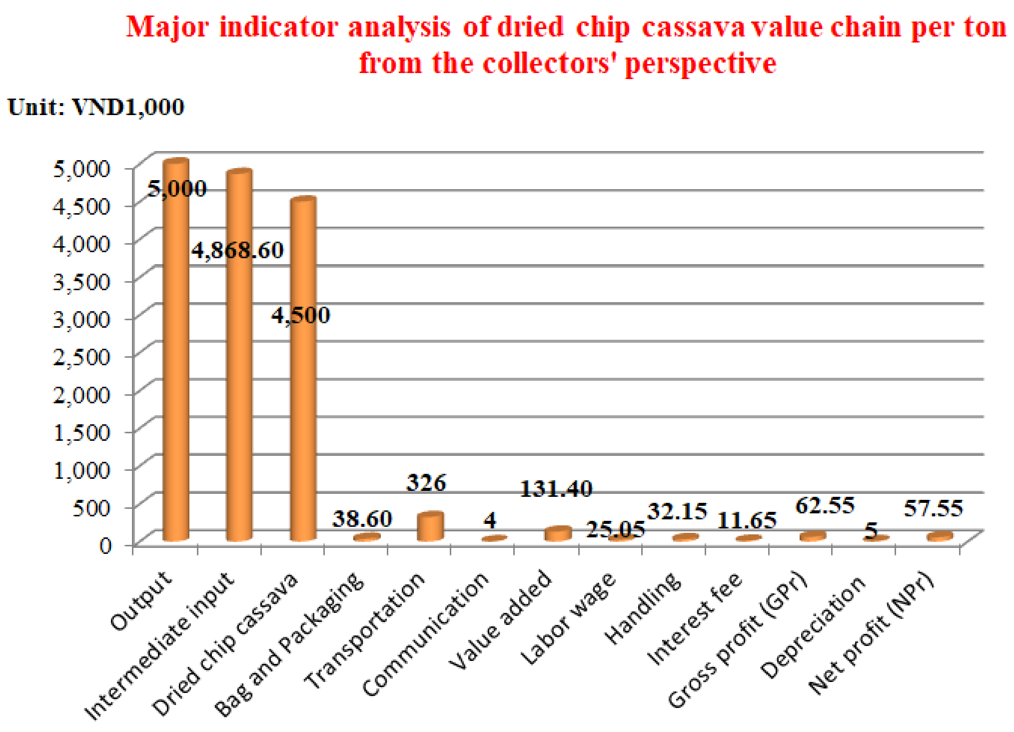

Figure 7. *The major indicators analysis of dried chip cassava per ton from the collectors' perspective*

The trader perspective

The traders' business pattern is similar to that of collectors, with traders buying some fresh cassava as well as dried chip from producers in February and March but also obtaining most (95%) of their cassava from collectors in both root and chip forms (*Fig. 4*). The quantity purchased ranges between 20 and 25 tons per day with this figure reaching a peak of 40 to 50 tons per day during the harvesting season. It is notable that

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51935217

the purchase price paid by traders is very similar to that paid by collectors who buy cassava directly from farmers.

Furthermore, traders usually negotiate with farmers in order to fix the price of cassava before it is harvested. However, changes in the market can affect this practice and, for instance, if the market price is greater than the price fixed before harvesting, then the purchase of the cassava will be concluded based on the market price. In contrast, if the market price is lower, the sale will be concluded based on the price fixed which represents a fair trading relationship between these actors in the cassava value chain. The average selling price of fresh and dried chip cassava were VND2.85 million (US$121.85) and VND5.5 million (US$235.14) per ton, respectively, and the gross profit gained was VND75,930 (US$3.25) (*Table 4*) per ton for cassava root and VND75,040 (US$3.21) per ton for dried chip cassava (*Fig. 8*). Nevertheless, traders play a vital role through their relationship with the farmer because they usually facilitate the supply of intermediate inputs, such as fertilizer, pesticide and herbicide, as well as financing the living costs of household farmers. The farmers can borrow money from the traders in order to deal with day-to-day demands which they have to face, including the cost of food, education and health care.

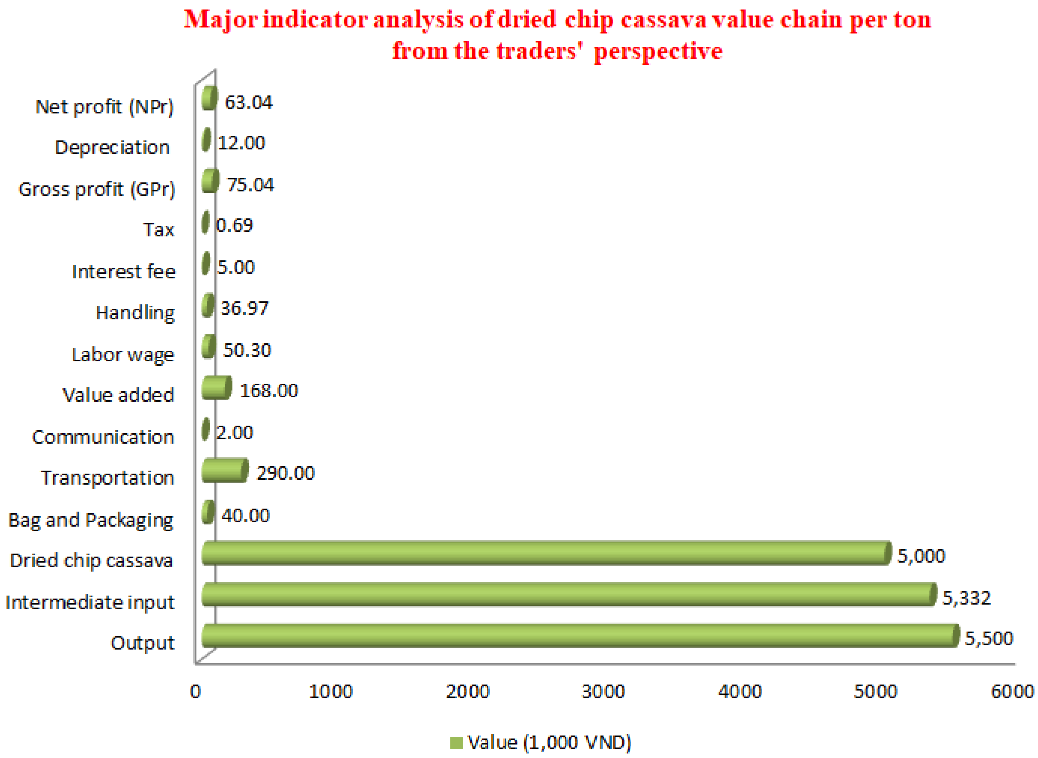

Figure 8. *The major indicators analysis of dried chip cassava per ton from the trader' perspective*

The starch factory perspective

The feedstock used by starch factories is mostly derived from traders (77%) as well as directly from producers (32% their production). The intermediate cost to produce 1 ton of cassava starch is approximately VND11.2 million (US$479.5) (*Fig. 9*). The conversion rate for fresh cassava is approximately 3.5 tons of cassava to produce 1 ton

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51935217

of cassava starch (Viet et al., 2013) and the factory is also left with a pulp residue for which there is a market after processing. Hence, the gross profit derived by the factory was found to be approximately VND1.14 million per ton (US$48.57) including the revenue from both cassava starch and pulp residue. However, there is great variability in the price of cassava starch depending on the export price of starch (Son et al., 2016). Thus, the total cost and profit have been unstable over the years. This is a difficulty that most cassava starch factories are currently facing.

Table 4. *Major indicator analysis of fresh cassava value chain per ton from the traders' perspective*

Item	Value (VND1,000)	Value USD	Proportion %
Output	**2,850.00**	**121.85**	**100.00**

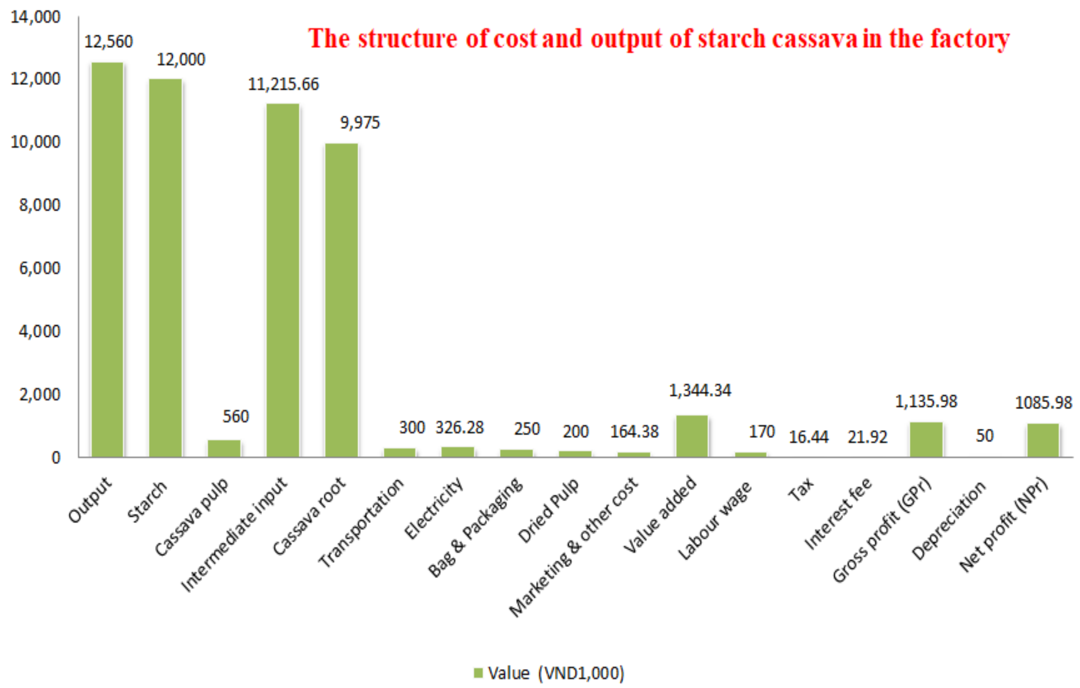

Figure 9. *The structure of cost and output of starch cassava per ton from starch factory perspective*

The ethanol factory perspective

The production capacity of the ethanol factory in this area is approximately 54,000 tons per year or around 4,500 tons per month based on market demand. The ethanol produced is used for numerous purposes in industries including food, cosmetics, and pharmaceuticals as well as others. There is a large quantity of cassava available to the factory and there is the potential to export its product to the Chinese market as well as to other overseas markets. However, currently, the total production of the ethanol factory is used domestically since its current processing costs are not competitive with that of similar products from other countries, particularly with those in Brazil which dominates world ethanol processing. *Table 5* shows that the production cost in the Dak Lak ethanol factory is around VND15.74 million (approximately US$673) per ton while the price of ethanol processed in Brazil is currently US$600 per ton at Ho Chi Minh City port in Vietnam. Therefore while the factory currently earns a GPr of nearly US$29 per ton based on current production costs, according to Mr. Dao Trong Tuan (personal communication), who is the Chairman of the board of directors of the Dak Lak ethanol factory, it will be very difficult to be competitive with prices in the global market in the near future without government support.

***Table 5**. Financial analysis of the operation of the Dak Lak ethanol factory per ton*

Item	Value (VND1,000)	Value (USD)	Proportion %

The ethanol products produced in the ethanol factory are therefore at a disadvantage compared to ethanol at the global market scale, largely because of the small scale farming by which the raw material is produced, a lack of advance cultivation technology, and the provision of short-term subsidies from the Vietnamese government. *Table 5* indicates how the value added is shared among the stakeholders comprising the farmers, the ethanol and starch factories, and the collectors and traders who obtain approximately 38%, 28%, 27%, 4% and 3% respectively. From these figures, it can be

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51935217

seen that the greatest value-added is created by the farmers which is fair based on their contribution to the value chain among the stakeholders. Shifting to cassava cultivation from other crops is considered as an appropriate strategy in poverty alleviation for household farmers in rural areas. In the cultivation phase, it is the farmers who as the producers commit almost all the resources required to produce fresh and dried chip cassava. In addition, the farmers are also the stakeholders who gain the highest percentage of the NPr (48%). However, the absolute value of both their GPr and NPr was the lowest among the stakeholders in the chain due to the volume of cassava that is provided by each farmer. In contrast, while the value added by collectors and traders accounted for less than 5% of the cassava value chain their absolute profit was higher than that of the farmers since they are undertaking cassava transactions representing from 30 to 40 tons per day while most household farmers harvest less than 30 tons per hectare per year (*Figs. 10* and *11*).

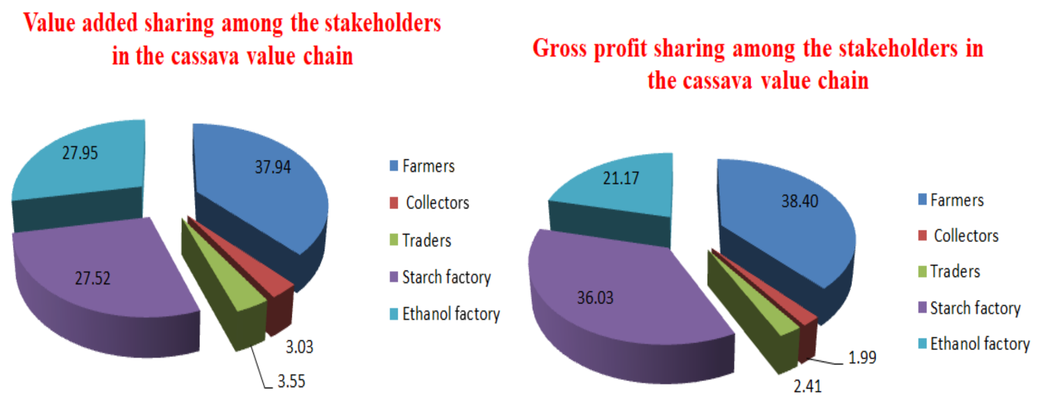

Figure 10. *Value added and gross profit sharing among the stakeholder in cassava value chain*

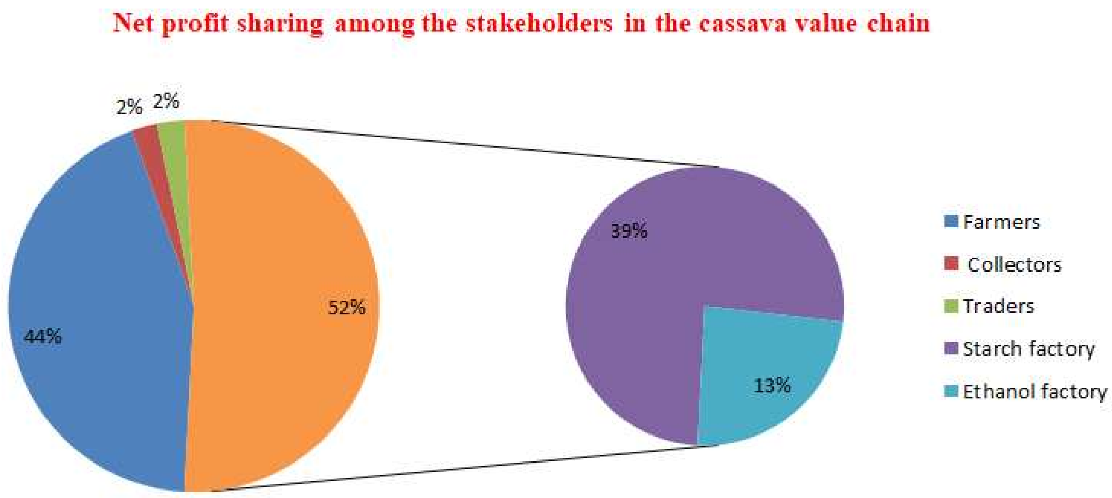

Figure 11. *The net profit sharing among stakeholder in cassava value chain*

With regard to the starch and ethanol processing factories, it is undeniable that they obtain the greatest absolute benefit from the cassava value chain since they are responsible for processing the largest volumes of cassava into products which they can

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51935217

sell. Moreover, they must meet the market demands of consumers and the value of the cassava will be increased through processing it as a raw material into starch, ethanol and other products. Hence, in order to increase the value of cassava, appropriate strategies involving linkages and collaboration among these actors is vital.

The relationships and linkages among cassava value chain stakeholders

Relationships exist amongst actors at different process stages in the cassava value chain by which input providers are connected with producers (farmers), farmers are connected with intermediaries and finally by which farmers and processors in the guise of both starch and ethanol factories are linked. Further, each of the actors has indirect relationships at each stage of the chain. The findings, of this study, identify a local relationship between input suppliers and farmers, which manifests its importance in the cassava planting season. However, this relationship does not solidify linkages since farmers generally prefer to change the location of their purchases every year. In addition, poor farmers cannot afford to buy input materials such as fertilizer and pesticide which might improve cassava productivity. Linkages between farmers and intermediaries are manifested as both spot-market and persistent relationships. On the one hand, the farmers can sell their products to any collector or trader who will pay the highest price. However, there is a potential risk in cassava value chain transactions that the selling price may be unstable over time. Buyers will always try to find any reason to reduce the purchasing price and sellers are under pressure to sell since the quality of cassava deteriorates rapidly and fresh cassava can only be preserved for two days after harvesting (El Bassam et al., 2010). This is a disadvantage for farmers who live far from the market particularly if the local infrastructure in their area is poor. On the other hand, the intermediaries can assist farmers not only by providing necessary input materials but also by extending informal credit to them. This, therefore, creates a persistent linkage; and generally, the buyer and seller meet, come to an agreement which is confirmed in a contract. In this relationship, therefore, there is a higher level of trust and some level of interdependence. Hence, the farmer and collector or trader are responsible for agreeing both the quantity of cassava and the price to be paid which is formalized by a contract agreed for each succeeding season. This linkage, therefore, tends to ensure a sufficient volume of cassava for forward actors in the value chain (i.e. end users). Moreover, the farmers will be assured of a sufficient volume of production from which they can support their occupation and that of their families. Thus, both actors gain benefit from persistent relationships.

Discussion

Our results concurred with the finding of Naziri and Bennett (2014) in both African and Southeast Asia that Cassava is mostly cultivated as a mono-crop by household farmers in small plots but was somewhat at variance with, the findings of Njukwe et al., 2014 that in Cameroon, cassava is cultivated by over 90% of the farming population, mostly as an intercrop in small plots of between 0.4 to 12 hectares. Further, the study reported herein revealed that the education status of the respondents was different from those studied by Njukwe et al. who found that 21% of the farmers had only primary education while the present study found that the majority of the participants (76.67%) had received at least secondary school education which may represent an advantage when cultivating cassava. Further, some previous studies found that not only were

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51935217

cassava tubers consumed but the leaves of the cassava planted were also used as a foodstuff constituting a part in the daily food intake of some African people (Andersson et al., 2016). However, in our study, the cassava leaves were left in the field after harvesting. Son et al. (2016) found that the percentage of cassava converted to dried chip in Quang Binh province was 50% of the fresh cassava harvested. However, this rate depended on various factors such as the variety grown as well as the period that the cassava was kept post-harvest. This finding is in accord with the findings of our research. Additionally, our findings suggest that in order to improve the value chain the first priority is to ensure that the products meet the needs of the market, which was also suggested by (Thanh et al., 2017) as a means of enhancing the value chain for exported agricultural products. These researchers also suggested that particular solutions need to be adopted to overcome individual problems to ensure that exported agricultural products meet the needs of the export market in order to create a sustainable value chain. The present study also reveals that low productivity and competitiveness in the cassava value chain may be due to various factors such as poor infrastructure, lack of farmer skills and limited capital resources, as well as a lack of synchronized mechanisms amongst competent authorities (Fonji et al., 2017). Our results agreed with those of Fonji et al. (2017) relating to cassava cultivation in the central region of Cameroon. Moreover, the results of the present study were in agreement with those reported by Leo (2015) with regard to the effect of growing cassava on the income of small-scale farmers in Abia State, Nigeria which suggested that in order to increases the income level of farmers, they should apply advanced technologies and enhance the capacity of buildings (Leo, 2015). Further, as some previous studies have noted, in order to be successful, all partnerships should be formalized by appropriate contracts which clearly state the roles and responsibilities of the actors across the value chain (Njukwe et al., 2014). Our findings also determined that improving the cassava value chain can be achieved by cooperation among the stakeholders. Other scholars have emphasized farmers' participation in profitable stages of the cassava value chain by strengthening coordination, growing new cassava varieties and applying novel processing technologies (Sewando, 2012). Most previous studies have observed that the most common means by which farmers transport cassava involves the farmer carrying the cassava from the field to their home, and Njukwe et al. (2014) found that transportation from the growing area in Cameroon was dominated by head or back-loads, and that 32.5% of the cassava grown was consumed in fresh form due to inadequate infrastructure. This agrees with research by Tshiunza et al. (1997) in six major African cassava producing countries where transportation from field to home was accomplished by various means but most (70%) was by head-load or back-load and that women accounted for over 80% of that form of transport. In our study, it was found that currently, more than 90% of the cassava is sold as cassava root and that most of the farmers bring their products home as well as supply it to their market using the local vehicle known as the xe cay (*Fig. 3*). In addition, our study also found that almost all (97%) of the cassava tubers are consumed as raw material for starch and ethanol production, either based on direct sales or sales facilitated through collectors or traders, with only 3% processed for other purposes. This is important and quite different from some previous studies, for instance that of Nweke (1994) who found that an average of 40% of the cassava in South and Centre, West and North West and East regions in Cameroon as provided for sale in the market while Tshiunza et al. (1997) discovered that 85% of the farm production in six major African cassava producing countries was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51935217

consumed in households while 10% was sold directly in markets with only 5% being used for processing purposes (Njukwe et al., 2014).

Conclusion

This research used structured and semi-structured interviews with numerous cassava value chain actors, focus group discussions with farmers (Andersson et al., 2016), and in-depth interviews with key informants to construct a comprehensive overview of the cassava value chain which was also supplemented by direct participant observations in Krong Bong, Ea Kar and Ea H'leo districts in Dak Lak province. Our findings revealed that activities in the cassava value chain are dominated by males and that it is the farmers who create the highest value added while the role of intermediaries is the most profitable. It was also found that the household farmers from among the ethnic minority groups suffered most physical losses at the stage of selling their products because they tend to keep the fresh cassava for some days after harvesting it and then sell it to a collector or trader. Additionally, most of the farmers lack sufficient capital for investment in technologies etc. to improve cassava productivity and they, therefore, obtain less profit than other groups who trade in or process cassava. In the light of the foregoing result, improving the profitability of household farmers is a major challenge that will require critical and specialized budgetary and political support at national and global levels (Sattar et al., 2017). In particular, the household farmers in the Dak Lak cassava production areas have limited resources although the household farmers' incomes are improving because of the currently increasing cassava price. The study found that intermediaries play an important role in the relationship between the cultivation and consumption step and they not only provide input material but also supply informal credit that can help farmers conduct good cassava cultivation. However, these intermediaries purchase cassava at low prices from household farmers depending on the contracts they sign with them. Depending on their financial capacity, cassava is collected either as fresh cassava or as dried chips. In either case, however, most of the profits from the cassava value chain accrue to the intermediaries.

With regard to the processors, the factories who were the end users of 97% of the cassava currently grown specialize in the production of starch and ethanol. It would be beneficial for them to diversify into other cassava products to meet different market demands in the future. Our findings suggest that these actors currently receive less profit than before because of increasing input-material costs. It is undeniable that the demand from factories makes the cassava market more competitive and it is also leading to the price of the fresh cassava produced by Vietnamese farmers becoming dependent on the Chinese market, which is a very volatile and risky market. Therefore, processing factories play a vital role in the cassava value chain and their demand has led to the enhancement of the value of cassava root, which in turn has mitigated hazards inherent in the traditional market by diversifying the uses to which cassava is put to include products such as starch, flour and ethanol. On the other hand, this study revealed that although there are various distribution channels, there are, in fact, two major channels which dominate the cassava value chain. Therefore, addressing the emerging opportunities and challenges in the cassava market requires cross-sectorial participation from the full range of stakeholders in the value chain notably the government through the Ministry of Agriculture and rural development which can supply credit in the form of soft loans for fertilizer or pesticide. This would probably represent a cheaper form of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_51935217

capital financing that is currently available through intermediaries. Once interdisciplinary cooperation is committed from all sides, this will improve the operation of the cassava value chain in this region.

Finally, this finding has just focused on value added and financial cost as gross and net profit of stakeholders in the cassava value chain. It has not yet referred to the role of gender in the household such as females' decision to participate and level of participation cassava production as well as market participants. In addition, this study has not clearly analysed the role of government policy in reducing the risk of cassava market (such as price subsidy, rural credit policy). Thus, it is highly recommended for further researches regarding inequality gender and, or improving females' role in the cassava value chain as well as policy reform in order to give a boost to cassava value chain for both farmer and the rest of stakeholders.

Acknowledgements. The authors would like to thank Thailand's Education Hub for the Southern Region of ASEAN Countries (TEH-AC) and the Faculty of Environmental Management at Prince of Songkla University, Thailand for funding while conducting this research. We are grateful to the directors of the starch factory in Dak Lak as well as the Director of the ethanol factory in Dak Nong province who kindly contributed to this research by sharing their experiences in in-depth interviews. We would like to acknowledge the contribution of all the respondents as well as the local authorities in the three districts. They all give us valuable information during the field research and farmer group discussions and interviews. Finally we would also like to say thank you to both Mr. Le Khac Dong who given us valuable recommendations relating to environmental aspects and to Mrs. Vu Trinh Vuong who made a valuable contribution associated with economics aspects of the research.

Conflict of interests. The authors confirm that there is no conflict of interests related to the content of this article.

Abstract. The development of stable and adaptable new cultivars are based only on positive results obtained from the interaction between the genotype and the environment. Therefore, the study aimed to test the stability and general adaptability of promising barley lines in terms of grain yield and traits in multi-environments. For this purpose, twelve barley genotypes were used in the study. The trials were carried out with four replications in a random design at seven environments in years 2012-13 and 2013-14. The superior and stable genotypes were identified with GGE biplot and AMMI (Additive main effects and multiplicative interaction) models. The AMMI analysis showed that the major treatment sum of squares was affected by environments (80.6%), GE (14.0%) and genotypes (5.4%), respectively. On the other hand, the first two principal component axes (PCA 1 and PCA 2) contributed to the complete interaction with 88.1%, whereas, PCA 3 and PCA 4 axes only with 12.0%. The GGE biplot indicated that G4 is adaptable for all environments, while Altikat, G2 and G3 showed specific adaptation to E1, E3 and E5, G6, G7 and G8 to E6, respectively. According to both techniques, G2, G3, G6, G7, G8 and Altikat were the best genotypes with high yield, whereas G4 was the best with high yield, and stable and general adaptation. The results of biplot indicated that G4 (ARUPO /K8755//MORA/3/CERISE/SHYRI//ALEL I/4/CANELA/5/HART-BAR) was recommended for release and it was released as HEVSEL in 2017. On the other hand; G7 and G6 were protected as genetic material to use as parent in breeding programs for yield stability and quality respectively.

Introduction

Barley (*Hordeum vulgare* L.) is the fourth most commonly used crop after wheat, rice and corn worldwide and this crop is more durable than other grains for stress conditions (drought, salinity, temperature stress), which is important in arid and semi-arid regions based on rainfall grows (Vaezi et al., 2017). The grains of barley are used as animal feed, food and biodiesel as well as raw material in malt industries to obtain

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52195233

malt. Approximately 65-70% of the produced barley in the world is used as animal feed, 33-35% as malt in beer, whiskey and biodiesel production and 2-3% as human food in food production. The consumption of barley in Turkey 90-92% is used as animal feed and the rest of it as malting in brewing and food industry (Anonymous, 2019).

The potential of a genotype in any environment is determined by the effect of environmental (E), genotype (G) or interaction (GE or GEI) factors. Because the breeders need quite stable cultivars in different environmental conditions and main some traits for agronomic, new varieties must have reliable results in a wide range of environments (Solonechnyi et al., 2015). The reason for the basic differences in the performance of genotypes in wide environments is due to the interaction of the genotype with the environment (Kendal and Aktas, 2016; Neisse et al., 2018). Genotype environmental interaction (GEI) analysis is of primary importance, as is the case for other crops inn barley breeding and many other intermediate studies (Kilic, 2014).

The most effective method to predict G, GE and GEI effects is multiple environmental trials (METs). METs are the most appropriate method to select the best genotypes for any environment and to identify genotypes that keep their genetic potential in many different environments (Farshadfar et al., 2012). Since the data obtained from METs are quite high, it is difficult to interpret these data without graphs. Therefore, different models have been used recently by many investigators to evaluate the data obtained from studies conducted in different environments. At the beginning of these methods, AMMI and GGE biplot methods are used and the shapes obtained from these methods visually provide the breeders with very important facilities in terms of the performance of the genotypes (Mortazavian et al., 2014; Solonechnyi et al., 2018). The AMMI model provides more information to researchers about the stability of genotypes in terms of grain yield, while GGE biplot on the relationships between genotypes and properties (Mohammadi et al., 2016).

The aim of this study was to evaluate the multiple traits data obtained from the studies conducted with advanced barley lines in multiple environmental conditions with AMMI and GGE biplot models and to determine the most stable genotypes as registration candidates and to present the benefits of these models to the breeders.

Materials and methods

Material

Ten spring barley promising lines and two checks were evaluated in seven locations across 2012-2013 and 2013-2014 years. The introductory information of genotypes presented in *Table 1* and the introductory information about locations presented in *Table 2*. **Altıkat** cultivar used in the study as control; because this cultivar was released in 2011in research area. So, it is very stable among cultivars which used in research on grain yield. Because it is regional and majority barley growers prefer the 6 rows cultivar in this area. **Şahin 91** cultivar used in the study as control; because this cultivar is national a cultivar, and it is facultative type and used in common in north part of region, because it is resistant to cold damage which is sometime happening in spring time. Therefore the genotypes compared with this cultivars for grain yield and other properties of traits).

DOI: http://dx.doi.org/10.15666/aeer/1702_52195233

Method

The trials was carry out in a randomized block design with four replications and planting density was used 450 seeds in per m^{-2}. Plot size was 7.2 m^{-2} in sowing time (6 m long × 1.2 m wide) planted at 20 cm spaced and composed of a total of 6 rows. Sowing of trials were done in October month and Harvest were done in June in both of season and across locations. The sowing dates and harvest dates in all locations are not very effective, because the harvesting time is dry usually and sowing were done after rainfall. The fertilizing percentages were used 60 kg N ha^{-1} and 60 kg P ha^{-1} with planting and 60 kg N ha^{-1} was used to each plots at tillering time for all plots. The chemical struggle was done against weeds in the period of 2-4 leaves in all locations and seasons. Harvesting was done using a Hege 140 harvester in an area of 6 m^2 in each plot.

The described growing seasons 2012-2013

After exiting the plants, the barley was developed with the cool weather and cold damage occurred in extreme winter days. Seasonal conditions were favorable for barley cultivation in the development period, but in March and April, partly due to arid history, the expected high yield was not obtained. Adiyaman location during the spring period to partially heat stress, Hazro location was exposed to frost damage in late spring. In Diyarbakir location, conditions were more favorable than other locations.

The described growing seasons 2013-2014

Seasonal conditions were negative in terms of barley cultivation in the development period and snowfall occurred on March 31, 2014, especially when the barley was in the period of stalking. Genotypes were exposed to drought in Ceylanpınar location. In the Adiyaman location, it was partially exposed to temperature stress and cold damage. In the Hazro location, frost damage occurred during the period of erasing. In Diyarbakır, cold stress were effective in March and heat stress after heading period. Therefore the grain yield of 2012-2013 season was suitable than 2013-14 growing season. The conditions of Ceylanpınar location is usually hard than other location, because the the total of rainfall of seasons usually is low (*Table 2*).

The protein content was measured in the NIT (Near-infrared transmittance) instrument.

Statistical analysis

The AMMI analysis was used to ranking of the genotypes based on grain yield and GGE biplot was used to see the relation hip between genotypes and tarits across seven environment and two years The AMMI model used as recommended by Verma et al. (2016), and GGE biplot were used as recommended by Yan and Thinker (2005), to identify the mega- environments and superior genotypes. Statistical analyzes of data were performed using JMP and GenStat 12 analysis programs.

The graph (1) introduced by AMMI analysis based on grain yield of across years, and other graphs (2-6) generated by GGE biplot, (2) the ranks genotypes based on stability in aceoss environments, (3) which-won-where/what of GT biplot based on across years, (4) the ranks genotypes based on ideal genotype, (5) the relationship between genotype by trait, (6) the relationship between environment by trait.

Results

The AMMI analysis showed that the major treatment sum of squares were effected by environments (80.6%), GE (14.0%) and genotypes (5.4%), respectively (*Tables 3* and *4*). The major variation of yield explained by the circles showed that the environments varied and the majority of the variation in yield was due to environmental changes. On the other hand, the first two principal component axes (PCA 1 and PCA 2) distributed to the complete interaction 88.1%, whereas, PCA 3 and PCA 4 axes only 12.0% (*Table 5*). The majority percent of multiplicative variance of the sum of the squares based interaction influenced by the first two PCA scores.

The AMMI model showing Genotype x Environment means

The AMMI method is interpreted as bi-directional, the genotypes and environment main effect indicate by *x* axis and the effects of interaction indicate by *y* axis (*Fig. 1*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52195233

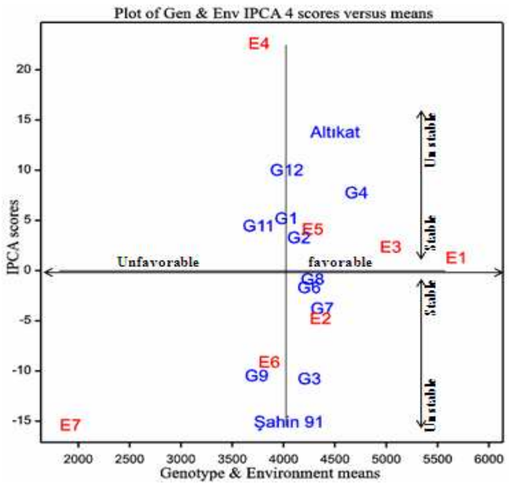

Figure 1. *The AMMI model based on grain yield (kg/ha^{-1}) of genotypes(G) in 7 environments(E)*

The main effects of genotype and environment are seen along the x-axis while the interaction effects are seen along the y-axis. On this figure; genotypes and environments are evaluated according to the mean (y axis) with stability (x axis). If the genotypes are close to the x axis, they are interpreted as stable, ıf they located the far from x axis it means that they are unstable. According to the AMMI analysis model, the genotypes showed a high variation and were found in different regions on the graph and the performance of the circles could be clearly seen. According to AMMI, E1, E2, E3 and E5 looking as high yielding environments, because these environments located upper on y axis, while E4, E6 and E7 looking as low yielding environments, because they located below of y axis. On the other hand, G2, G3, G4, G6, G7,G8 and G5 (Altikat variety) showed good performance, because of they located above on y axis (mean yield axis). It is believed that these genotypes were high yielding. But, G1, G9, G11, G12, G10 (Sahin 91) showed low performance, due to they located under on y axis (mean yield axis). Moreover, G4 is looking as high yielding genotype, but moderate stable because it was locate the far from x axis (stable line), while G8 is looking as stable, but this genotype is looking low yield potential than G4 genotype. The IPCA scores indicated that E1 could be recommended to tested genotypes, because of high yield potential of it (*Table 5*). According to Mirosavlievic et al (2014), the genotypes have small IPCA1 values are more stable, and similar outputs were recorded by Mohammadi et al (2013), in barley.

The recommendation of genotype for environment

The average grain yield of spring barley genotypes ranged from 3600 kg/ha to 4593 kg/ha in seven environments (*Table 6*). The genotype G4 was existence in the top of four environments. On the other hand, some genotypes estimated for special environments. For example; the genotype G6 dawn in the top genotype for E6, Altikat for E1, E3 and E5. Also, G4 can advise in the first to E1, E4 and the second to E5 and E7. The results of *Table 5* and *Table 6*, showed that AMMI is an effective method to evaluate the perfect genotype for all environments or specific genotype for desirable environments. Moreover, the AMMI analysis is describe recommendations of correct genotype for special environment (Bantayehu, 2013).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52195233

The recommendation of environment

The average yield of seven environments was changed from 1818 kg/ha to 5577 kg/ha of spring barley genotypes (*Table 5*). The AMMI analysis indicated that E1 is the best among test environments, followed E3 and E2.On the other hand, E7 is looking very poor among test environments, because the rainfall of this environment is very low. According to results of AMMI analysis showed that we can recommend the E1 to describe the top yield of genotypes, while E7 for describe the genotypes on drought conditions (*Figure 1*). Xu et al. (2014) reported that the GGE biplot is the best way to determine the best environment to tested genotypes.

Table 6. *The traits value of average for twelve genotypes*

Genotypes	Heading time (date)	Plant Height (cm)	Thousand grain weight(g)	Hectoliter weight(g/l)	Protein content (%)
G1	98	83	38.1	74.2	13.2
G2	96	89	33.7	71.4	11.1
G3	97	83	40.1	72.2	12.1

Ranking genotypes based on stability and environment

The ranking genotypes indicate the ideal and stable genotype in across environments, as showed in *Figure 2*.

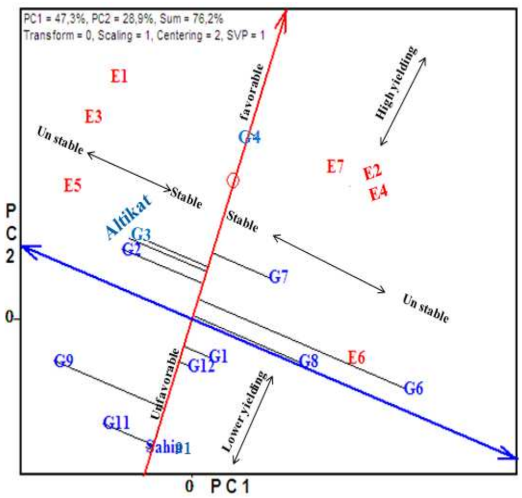

Figure 2. *The rank genotypes based on stability*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52195233

The horizontal line with double arrow pointed the average of environment the upper of arrow points to higher mean yield through the environments, the vertical line with one arrow is ordinate the points the stability of genotypes across environments (Yan and Tinker, 2006). Thus, the genotype G4 with short genotype vector had both the highest mean yield and stability values, while Sahin 91 had low mean yield through across environment, but stable. On the other hand, G6 had above average yield, but unstable because of long genotype vector. The genotypes have large PC1 values mean that this genotype is high yielding and stable. The results of this study showed that G4 had wide adaptability for across environments, while G1, G9, G11, G12 and Sahin 91 for none environments. Some genotypes (G2, G3 and Altikat) showed special adaptability to special environments (E1, E3 and E5), G6, G7 and G8 to E6 (*Fig. 2*). Therefore, the ranking of genotypes are depend on their stability performance in across environments. Taheripourfard et al. (2017) reported that the GGE is good method to tested genotypes for multi-environment.

Which-won-where/what of GE biplot based on across environments

The GE biplot based on across season data is visualize the polygon of which-won-where/what. The figure divided by thick axis from center figure, and each zone separated by two thick lines is referred to as the "sector" and is indicated by numbers 1, 2, 3 etc., starting from the lower right part of the graph, and if the genotypes and traits located in the same sector it means that are closely related each other (Yan and Tinker, 2006; Dogan et al., 2016). Considering the *Fig. 3* with this prediction; thick axis from center figure divide the biplot into five sectors. The environments (E1, E2, E5, E6, E7) with G4 down in the sector 2; G2 and Altikat with E3 in sector3; G1, G6 and G8 with E6 in sector1; while other genotypes did not relation with any environment. Consequently, G4 had high yielding at five environments (E1, E2, E5, E6 and E7), while G6 at E6. Therefore, the best genotype is definete by the best performance in mega-environments.

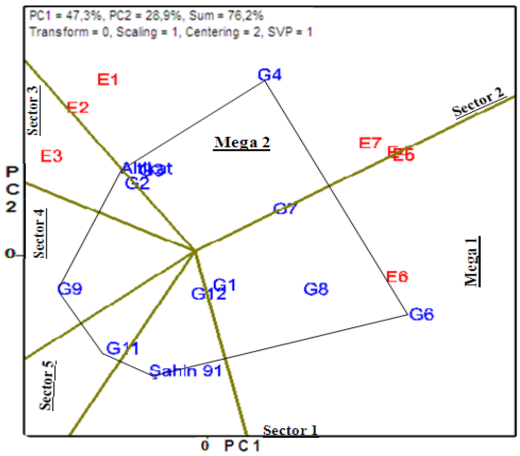

Figure 3. *Which-won-where/what of GE biplot based on across season data*

The ranks genotypes based on ideal genotype

The discriminating and representativeness of genotypes based traits are visualize the "ideal center" over the mean values of the environments and offers the opportunity to evaluate genotypes according to their proximity or distance to this center(Yan and Tinker, 2005; Oral, 2018). If the genotypes are located in the center, they are the most ideal, if they

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52195233

are located above the average vertical axis, but far from the center, it means that they are ideal, if they are located below vertical axis, it means that they are undesirable. Considering on this prediction the *Fig. 4* explained that the G4 located center of AEA, and so, it is more desirable than other genotypes, while Sahin 91 is the poorest genotype, because it is located under mean axis. The term "ideal genotype" is meaningful only when associated with mean performance. According to *Fig. 4*, the G4 is highly "ideal", other genotypes (G2, G3, G7 G6, G8 and G5 (Altikat)) are desirable genotypes, and because of G4 took places in center of AEA and other genotypes took places on above averages yield axis, and so it means that they are just yielding for specific environments. On the other hand, G1, G9, G11, G12 and Sahin 91 are very poorest for average yield, so they are undesirable genotypes across environment. From this example, we can say that the ideal genotype (G4) is the best among genotypes for across environments.

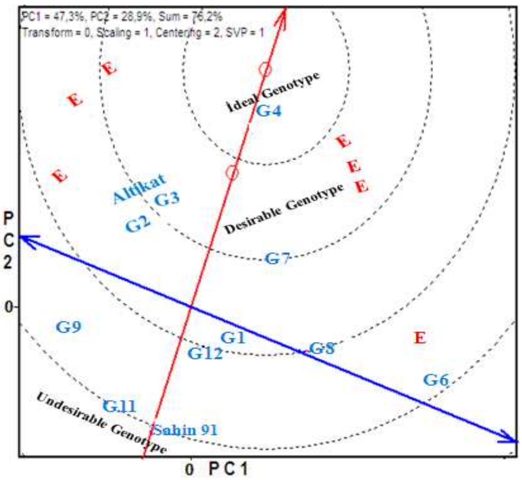

***Figure 4.** The ranks genotypes based on ideal genotype*

The relationship genotype by trait (quality) in seven environments

The relationships between genotype by trait visualize the performance each genotype on traits (*Fig. 5*).

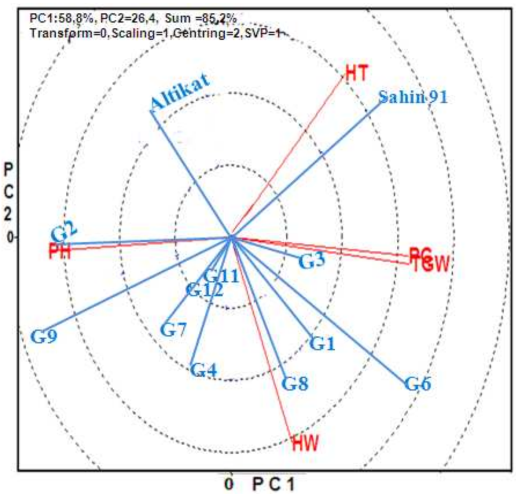

***Figure 5.** The relationship between genotype by trait*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52195233

A biplot such a graph to be interpreted bi-directionally has the following comments (Yan et al., 2000; Yan and Tinker, 2006; Kendal and Dogan, 2015). 1) The cosine of the angle between the vectors of the two properties approaches the Pearson correlation between them. Therefore, an angle of less than 90° shows a positive correlation, an angle greater than 90° shows a negative correlation and an angle of 90° shows zero correlation. 2) If the vector of a trait is longer than other vectors, the variation of this trait on genotypes is higher than the other traits, ıf the vector length of any trait is very short than other traits vector then the variation of this trait is very low. 3) The angle between the vector of any genotype and any trait gives information about the state of the genotypes. If the angle is quite sharp and narrow indicates that the genotype is below of average for that trait if the angle is too large then the genotype is under. 4) The length of the vector of a genotype indicates the strength or weakness of the genotype for all trait profiles. Depend on these principles described in the GT biplot technique, the following observations can be made about *Fig. 3*. Considering the observations on this figure showed that there was positive correlation (the angel of vectors <90°) among protein content (PC), thousand grain weight (TGW) and hectoliter weight (HW), whereas negative correlation (the angel of vectors >90°) with plant height (PH) and these three traits. Also, the relationship between genotypes and traits were observed. Therefore, G6 associated with PC, TGW and HW, while G3 with PC and TGW G2 with PH, Şahin 91 with heading time (HT). Because of the genotypes were positioned on these traits. Consequently, the biplot showed excellent discriminating to select special genotypes with special trait and results confirmed that barley parameters were affected by G, GE, and GEI as reported by (Dogan et al., 2016).

The relationship between environments by trait (quality) of four genotypes

The relationship between environment-trait showed in *Figure 6* and *Table 7*. The information and explanations related to the identification of *Figure 6* are already given in the upper section (3.5). The biplot showed that there was positive correlation between TGW and HW, between PH and HT, whereas negative correlation among PC and other traits except PH.

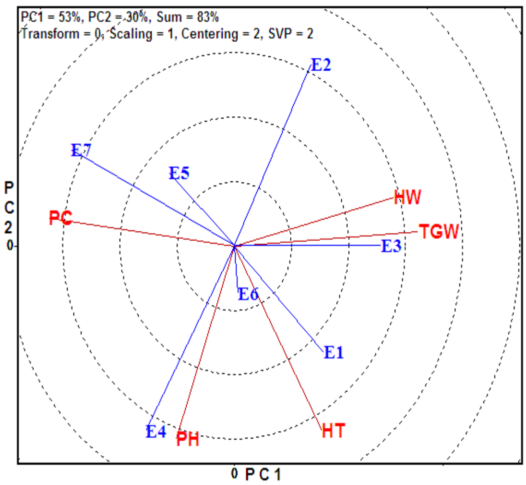

Figure 6. *The relationship between environments by trait*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52195233

Also, the relationship between environments and traits were observed. Therefore, E3 associated with TGW, HW, while E1 with HT and E4 with PH and E5, E7 with PC. Because of these environments were positioned on definite traits. Consequently, the biplot showed excellent discriminating to select special environment with special traits and to work environments for recommendation special traits.

***Table 7.** The traits value of average over environments*

Environments	Heading time (date)	Plant Height (cm)	Thousand Grain weight(g)	Hectoliter weight(g/l)	Protein content(%)
E1	105	98	38.1	71.8	12.0
E2	97	60	40.1	70.5	13.4
E3	105	80	38.4	73.1	11.1
E4	109	98	33.6	67.1	15.5
E5	93	85	31.9	69.8	13.8
E6	101	95	35.8	71.1	14.4
E7	92	85	30.6	69.4	18.3
Mean	100	86	35.5	70.4	14.1

Discussion

The methodology of AMMI biplot approach have been reported to be a comprehensive and effective method since it classifies genotypes according to their levels in combination with target environments and graphically rank the genotypes with their strengths and weaknesses in different environments (Yan and Tinker, 2006). On the other, GGE biplot method allows breeders to establish an relations between genotype by traits or environment by traits (Dehghani et al., 2006; Stanisavlievic et al., 2013; Karami et al., 2018; Oral, 2018). The selection genotype by AMMI and GGE biplot method helps breeders to evaluate genotype on grain yield, and to seen the relations between genotype by traits or environment by traits (Sayar and Han, 2015; Dogan et al., 2016).

The AMMI analysis showed that the main effects of genotype (G), environment (E) and GE interaction are very important (*Fig. 1* and *Table 4*). The results of AMMI showed that a large variation explained by environments (80.6%), while a little variation by genotype effect (5.4%). Therefore, the effect of the environment on the fluctuation and variation of the grain yield was found to be higher than the genotype effect and interaction. Many researchers have reported that they have achieved similar results in their AMMI studies (Bantayehu, 2013; Shukla et al., 2015; Kendal and Tekdal, 2016). According to Stanisavlievic et al (2013), majority percent of treatment variation explained by environment, while genotype and interaction effect is very low. On the other hand, the majority percent of multiplicative variance of the sum of the squares based interaction influnced by the first two PCA scores. Vaezi et al. (2017) reported that in the AMMI model in different parameters, because of stability analysis was performed using multiple IPCA numbers, and so it is better than stability analysis using the first IPCA score. Hense, the study showed that G4 is looking as high yielding genotype, but moderate stable, while G8 is looking as stable, but this genotype is looking low yield potential than G4 genotype. According to these explanations, it is possible to determine the best registration candidate for the Southeastern Anatolia Region of Turkey with AMMI method and this study can be used successfully for other regions, countries in different plants as well as.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52195233

GGE biplot analysis establishes a framework for classifying target test environments that differ between genotypes which are stable and yielding (*Fig. 2*).The study showed that G4 is stable for all environment, while G6 is unstable for majoirty environments. If the effect of genotype in the variation (G) is quite large (47.3%), PC1 scores will be highly correlated with G and PC2 (28.9%) is controlled by GE interaction (Yan and Tinker, 2005; Kendal and Aktas, 2016; Kendal et al., 2016; Vaezi et al., 2017; Oral et al., 2018). GGE biplot gives an idea to evaluate the relationships between all circles (*Fig. 3*). The GGE biplot defines the relationships between all circles based on the general model of MET data, whereas the simple correlation coefficients define only the relations between the two environments (Farshadfar et al., 2013). In the study, there was positive and significant correlation among E1, E2, E3 and also E4, E5, E7 in which-won-where graphical pattern. In fact, the GGE biplot polygon image is the best method used to determine the best genotype in every mega environment (Elakhdar et al., 2017). The study indicated that G4 is the best genotype for two mega-environment (*Fig. 3*), while G6 only for mega 1. The genotypes which are favorable discriminating and representative of across environments (Dehghani et al., 2006; Jalata, 2011; Kendal and Sayar, 2016).The study indicated that G4 is favorable genotype on discriminating and representative across test environments (*Fig. 4*). According to these explanations, it is possible to determine the best registration candidate for the Southeastern Anatolia Region of Turkey with GGE biplot method and this study can be used successfully for other regions, countries in different plants as well as. On the other hand, the results of the study showed that it was possible to make environmental-genotype relations, the stability of genotypes in all circles, the most ideal genotypes and mega environment in all circles with the figures formed by GGE biplot method.

Conclusion

The results of the study evaluated with AMMI and GGE biplot; the genotype (G), environmental (E) main effects and the and GE interaction effect was significant for tested advanced barley genotypes warm and warm-half environments of Turkey and other similar countries. The genotype (G4) showed best performance on grain yield among genotypes across environments, therefore this genotype was desirable in terms of high mean yield and stability. On the other hand; specific genotypes were appropriate for specific environments (G2-E5, G7-E2, G9-E6) and E1 was the best yielding. The result of study indicated that G4 is suitable to recommend for release and G7 desirable origin for yield stability and G6 valuable source for quality to use in barley breeding program. These three lines were obtained from ARUPO /K8755//MORA/3/CERISE/ SHYRI//ALELI/4/CAN ELA/5/HART-BAR hybrid. Depend on the results G4 was released as **HEVSEL** in 2017. On the other hand; G7 and G6 protected as genetic material to use as parent in breeding program for improve grain yield and quality, respectively. The multiple environment data can be evaluated by AMMI and GGE biplot analysis, because these two analysis methods allow a meaningful and useful summary of genotype performance across test environments.

(Received 19th Jan 2019; accepted 27th Feb 2019)

Abstract. The present study was conducted to evaluate the association between residues of α-endosulfan, β-endosulfan, endosulfan sulfate and total endosulfan (Σ endosulfan) with serum cholesterol, alkaline phosphatase (ALP) and total proteins (TP) in diagnosed cancer patients and healthy subjects of Karachi, Pakistan. Donors provided fasting blood samples with informed consent and serum was separated within two hours of blood collection through centrifugation at 2500 rpm. Levels of serum cholesterol, ALP and TP were quantified on Roche/Hitachi spectrophotometers while gas chromatograph (GC-17A) coupled with 63Ni electron capture detector was used for the quantification of endosulfan residues. Detected mean concentrations of α-endosulfan, β-endosulfan and endosulfan sulfate were higher in the cases compared with controls *($p > 0.05$)*. Mean levels of serum cholesterol and TP were found significantly reduced in the cancer cases *($p < 0.05$)* while ALP activity was found significantly elevated in the cancer cases compared with controls *($p < 0.05$)*. An association between endosulfan sulfate and cholesterol levels ($r = 0.333$) and between Σ endosulfan and cholesterol ($r = 0.245$) was detected in the cancer cases but no such association was found in the control group. The presence of higher serum concentrations of α-endosulfan, β-endosulfan, endosulfan sulfate and Σ endosulfan associated with abnormal serum biochemical parameters may be a risk factor of various malignancies in humans.
Keywords: *insecticide, cholesterol, ALP, total proteins, environmental pollutants*

Introduction

Endosulfan is a broad spectrum organochlorine insecticide used around the globe in household and agriculture to control insect pests (Dilna et al., 2018). Endosulfan has been reported in human tissues, milk and serum samples (Latif et al., 2012; Khawaja et al., 2012; Khwaja et al., 2013; Saeed et al., 2017; Attaullah et al., 2018). Endosulfan consists of α and β isomers in the ratio of 7:3 (Wan et al., 2005). The main endosulfan metabolite is endosulfan sulfate which is liphophilic and mainly accumulated in the adipose tissues (Cerrillo et al., 2005). Endosulfan causes a variety of disorders in humans including testicular cancer, prostate cancer and breast cancers (Soto et al., 1994; Romeo and Quijano, 2000; Saiyed, 2003; Ibarluzea et al., 2004), teratogenicity (Grumfeld and Bonefeld-Jorgensen, 2004; Singh et al., 2007; Silva and Beauvais, 2010), DNA damage (Bhalli et al., 2009) and neurotoxicity (ATSDR, 2015). Endosulfan damages human RBCs at concentrations ranging from 1ppb to 1ppm (Daniel et al., 1986).

Serum cholesterol is a useful biomarker of several metabolic disorders. Levels of serum cholesterol are mostly found diminished in the cancer patients compared

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52355244

with the healthy subjects (Ding and Hu, 2008). There is a potential association between serum concentrations of chlorinated pesticides and serum cholesterol levels (Aminov et al., 2013; Singh and Chan, 2018). Alkaline Phosphatase (ALP) is found almost in all tissues and is comparatively stable in serum. ALP levels are found elevated in the cancer cases compared with controls as reported in colorectal carcinoma (Saif et al., 2005), breast cancer (Prabasheela et al., 2012) and osteosarcoma (Kim et al., 2017; Sahran et al., 2018).

Serum total protein contents is a good indicator for the assessment of various malignancies and stage of the disease as reported in squamous cell carcinoma (Nayyar et al., 2012). Several studies have shown a correlation between persistent organochlorine pesticide residues and alterations in enzyme levels (Azmi et al., 2006; Arshad et al., 2007; Dyk and Pletschke, 2011), serum proteins and ALP (Khan et al., 2008) and serum cholesterol, TP contents and ALP levels (Paccagnella et al., 1971).

Endosulfan is banned in Pakistan but is sold and used illegally on vegetables, fruits, crops and for other miscellaneous purposes as confirmed in recent studies across the country (Anwar et al., 2011; Randhawa et al., 2016; Ahmad et al., 2018; Hayat et al., 2018). It was therefore necessary to evaluate endosulfan residues with respect to health risk in humans. The present study was aimed to comparatively evaluate the concentrations of α-endosulfan, β-endosulfan and endosulfan sulfate in the cancer cases and healthy subjects and to find out any potential association between endosulfan concentrations with serum cholesterol, ALP and TP contents.

Materials and Methods

Analysis of endosulfan isomers (α and β) and endosulfan sulfate, cholesterol, ALP and Total Proteins was carried out in sera of the diagnosed cancer cases (n= 51) and healthy control subjects (n = 30) at Karachi, Pakistan. Mean ages and male to female ratio was (39.5 years, 47:53) in the cancer cases and (33.3 years, 90:10) in the controls respectively. The study was conducted in general population of Karachi, Pakistan with no past history of occupational exposure of the subjects to endosulfan. The study subjects were indirectly exposed to endosulfan due to intake of contaminated vegetables, food, water, fruit and milk. This shows exposure of the general population to endosulfan indirectly through food chain. Blood samples (8 ml each) were collected randomly from the cancer patients and healthy subjects with informed consent at various hospitals of Karachi. Serum was separated from the blood within two hours of collection through centrifugation and was stored at – 20 ºC at the Toxicology Laboratory, Department of Zoology, University of Karachi. Extraction, purification and quantification of endosulfan in the serum samples was carried out according to the previously described methods (Dale et al., 1970; Atuma and Aune, 1999; Moreno Frias et al., 2001). The detailed protocol for the extraction of endosulfan residues, clean-up with florisil column and quantification through Gas Chromatography coupled with Electron Capture Detector (GC-ECD) has been described elsewhere (Attaullah et al., 2018).

Cholesterol analysis was carried out according to (Allain and Roeschlau, 1974) with Cholesterol Kit catalogue no. (CHOL 12016630 122), COBAS Registered was used for this purpose. About 3.0 µl of the sample was mixed with 250 µl of R1 reagent. A photometric determination of the color intensity produced by hydrogen peroxide was made on Roche/Hitachi 902 analyzer.

ALP in the serum samples was processed according to (Bowers and McComb, 1975) with the help of ALP Kit catalogue no. (AP 7927) and quantification was carried out on HITACHI 717 Spectrophotometer, Randox Laboratories Ltd., UK. About 0.025 ml (25 µl) of serum sample was mixed with 1.0 ml of reagent and heated up to 37 °C for 5 min. A yellow colored p-nitrophenol was produced at 405 nm. The color intensity is a measure of the level of ALP in the sample.

Total Proteins in the serum were determined according to (Weichselbaum, 1946) with Kit catalogue no. (TP-11553836 316), COBAS Registered. Serum sample (5 µl each) was mixed with 90 µl of R1 reagent, then R2 reagent (90 µl) was added which formed a purple colored biuret complex. The color intensity of the biuret complex was quantified with Roche/Hitachi 902 Spectrophotometer at 546 nm.

Statistical evaluation of the data was carried out using MS Excel Office Version 365 by calculating the mean values of endosulfan concentrations, cholesterol, ALP and Total Protein contents in the cancer cases and controls. The calculated mean values of the studied parameters were compared in the cases and controls through independent t Test (two samples assuming unequal variances) with *p* values less than 0.05 showing statistically significant difference between the cancer cases and controls. Values of Pearson correlation coefficient (r) between endosulfan and serum biochemical parameters were calculated in MS Excel and were confirmed statistically through regression analysis.

Results

Elevated mean concentrations of endosulfan isomers and endosulfan sulfate (mg/kg wet weight serum) were detected in the cancer cases compared with controls. Mean levels of endosulfan in the cases versus control subjects were: α-endosulfan (0.043 *vs.* 0.03, $p = 0.56$), β-endosulfan (0.041 *vs.* 0.021, $p = 0.42$), endosulfan sulfate (0.104 *vs.* 0.1, $p = 0.62$) and Σ endosulfan (0.189 *vs.* 0.153, $p = 0.37$) (*Table 1*).

Table 1. *Mean levels ± SD of the studied parameters in the cancer cases and controls*

Studied Parameters	Cases			Controls			*P values*
	Mean	SD	Range	Mean	SD	Range	
α-endosulfan (mg/kg)	0.043	0.124	0 – 0.712	0.03	0.06	0-0.231	*0.56*
β-endosulfan (mg/kg)	0.041	0.161	0 – 1.118	0.021	0.044	0-0.183	*0.42*
Endosulfan Sulfate (mg/kg)	0.104	0.236	0 – 1.422	0.1	0.183	0-0.771	*0.62*
Σ Endosulfan (mg/kg)	0.189	0.364	0 – 2.134	0.153	0.178	0-0.771	*0.37*
Chol. (mg/dl)	116	22.7	78 – 165	157	34.9	82 – 225	*<0.05*
ALP (U/L)	128	49.5	60 – 419	109	28.6	71 – 223	*0.03*
TP (g/dl)	6.2	0.57	4.5 – 7.3	7.2	1.06	4.6 – 9.1	*<0.05*

Legend: Σ endosulfan = Sum of the endosulfan isomers (α, β) and endosulfan sulfate, SD = Standard Deviation. Normal ranges in an average adult human for cholesterol: < 200 mg/dl; ALP: 30-120 U/L; Total Proteins: 6.0 – 8.0 g/dl

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52355244

Cholesterol levels were found significantly diminished in the cancer cases compared with controls. The detected mean levels of cholesterol in the cancer cases versus controls were (116 ± 22.7 mg/dl *vs.* 157 ± 34.9 mg/dl; $p < 0.05$) (*Table 1*). ALP activity was found elevated in the cancer cases compared with controls. Mean ALP levels in cases versus controls were detected as 128 ± 49.5 U/L *vs.* 109 ± 28.6 U/L; $p < 0.05$) (*Table 1*). Total Proteins in cases were found significantly reduced (6.2 g/dl) compared with controls (7.2 g/dl; $p < 0.05$) (*Table 1*).

In the cancer cases, Pearson correlation coefficient between endosulfan sulphate and cholesterol (r = 0.333; $p = 0.02$) and between Σ endosulfan and cholesterol (r = 0.245; $p = 0.08$) indicate a positive association between endosulfan and cholesterol levels as shown in *Fig. 1*. Correlation between endosulfan and ALP was found very weak in the studied cohort (*Fig. 1*). Statistical significance was not achieved between endosulfan residues and the studied parameters because significance level obtained was higher than 0.05 in all of the cases except between endosulfan sulphate and cholesterol (r = 0.333; $p = 0.02$) and between α-endosulfan and TP (r = - 0.303; $p = 0.03$) in the cancer cases (*Fig. 1*).

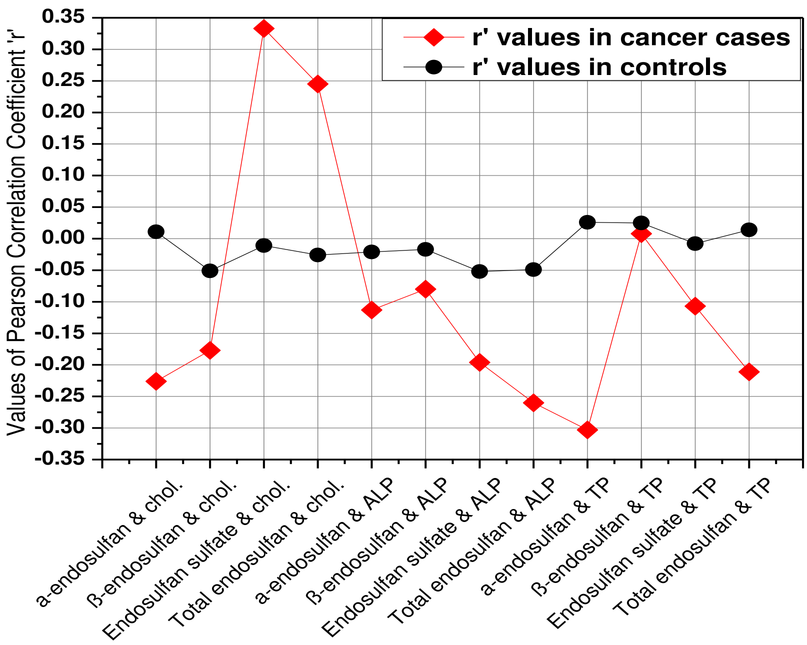

Figure 1. *Correlation between endosulfan residues with serum Cholesterol (chol.), alkaline phosphatase (ALP) and total protein (TP) contents in the cancer cases and controls*

In the major cancer sites, the Lymphatic system showed the lowest mean cholesterol level (99.6 mg/dl) with a higher concentration of endosulfan sulfate (0.107 ± 0.152 mg/kg), reduced mean ALP level (99 ± 4.2 U/L) and reduced mean TP level (5.6 ± 0.1 g/dl) (*Table 2*). Highest ALP activity was detected in the blood cancer cases (148 ± 30.7 U/L) with reduced mean cholesterol level (102 ± 19.1 mg/dl) and a mean Σ endosulfan level of 0.131 ± 0.244 mg/dl (*Table 2*).

In the sub sites of cancer cases, lowest mean level of cholesterol was detected in Hodgkin's Lymphoma (HL) as 83 mg/dl with mean level of endosulfan sulfate as 0.215 mg/kg and lowest mean level of TP (5.5 g/dl) (*Table 2*). Highest mean cholesterol level

was detected in the ovarian carcinoma (151 mg/dl) with significantly reduced level of α-endosulfan (0.007 mg/kg) (*Table 3*).

Discussion

Endosulfan is a widely used insecticide worldwide and has been associated with various malignancies in human and animal studies. The present study was conducted to evaluate the potential association of endosulfan residues with serum biochemical parameters and to ascertain the possible role of endosulfan residues in causing various malignancies in humans. Findings of the present study are consistent with the previous cases-control studies on the association of endosulfan with various cancers in humans (Kumar et al., 2010; Arrebola et al., 2015; Shah et al., 2018). Serum mean cholesterol levels and Total Proteins were found significantly reduced in the cancer cases compared with controls ($P < 0.05$) while serum ALP levels were found elevated in the cancer cases than controls ($P < 0.05$) (*Table 1*). Similar findings in cancer cases versus controls have been detected in previous studies for cholesterol levels (Mufti and Baseer, 1996; Memon et al., 2007; Chawda et al., 2011; Ahmad et al., 2012), for Total Protein levels (Nayyar et al., 2012) and for ALP levels (Saif et al., 2005; Prabasheela et al., 2012).

Variations in levels of serum cholesterol, ALP and TP from the normal levels indicate the severity of disease in various cancers and can be utilized as diagnostic and prognostic biomarkers.

An association between endosulfan sulfate and cholesterol ($r = 0.333$) and between Σ endosulfan and cholesterol ($r = 0.245$) has been detected in the cancer cases. A very weak association between α-endosulfan and cholesterol ($r = 0.011$) has been detected in the control subjects (*Fig. 1*). This indicates that endosulfan concentrations are associated with cholesterol levels and support the previous literature on the subject (Aminov et al., 2013; Singh and Chan, 2018; Fadaeipuor et al., 2016). Endosulfan and organochlorine pesticides residues increases with increasing levels of serum cholesterol and declines with decreasing levels of cholesterol. In the present study, although levels of cholesterol were significantly lower in the cancer cases but the residues of endosulfan were higher in the cancer cases in comparison with controls (*Table 1*). Apparently, reduction in cholesterol level may be an immune mechanism for decreasing the lipid pool in serum and thus reducing the storage reservoirs for lipophilic toxic chemicals in the body. Another reason for the reduced cholesterol levels in the cancer cases may be due to the adverse effects of higher endosulfan

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52355244

residues in the cancer cases. A weaker association was found between endosulfan and ALP in the cases compared with controls (*Fig. 1*).

Serum endosulfan concentrations detected in the present study may not be capable to affect ALP activity as indicated by the weak association from the Pearson correlation coefficient (*Fig. 1*). Highest ALP activity (148 U/L) was found in the blood cancer cases while lowest was found in cases of the lymphatic system (99 U/L) (*Table 2*). In the blood cancer cases, detected mean levels of endosulfan were: α-endosulfan (0.056 mg/kg), β-endosulfan (0.032 mg/kg), endosulfan sulfate (0.042 mg/kg), Σ endosulfan (0.131 mg/kg) with reduced mean level of cholesterol (102 mg/dl) and elevated level of ALP (148 U/L) (*Table 2*). This indicates that the altered levels of cholesterol and ALP might be due to the presence of high endosulfan concentrations. Lowest cholesterol level (99.5 mg/dl), lowest ALP level (99 U/L) and lowest TP level (5.6 g/dl) were detected in cases of the lymphatic system with detected mean conecentration of endosulfan sulfate as 0.107 mg/kg (*Table 2*). The altered parameters in lymphatic system is indicative of the role of endosulfan sulfate in cases of the lymphatic system. A similar pattern was also detected in cases of AML, Neck and Appendicular Carcinoma (*Table 3*).

In cases of Hodgkin's Lymphoma, reduced mean TP level (5.5 g/dl), lowest mean cholesterol level amongst sub sites (83 mg/dl) and significantly elevated mean level of endosulfan sulfate (0.215 mg/kg) were detected (*Table 3*). This indicates a possible role of endosulfan sulfate in the risk of HL and an association with cholesterol and TP levels.

In the sub sites of cancer cases, highest ALP activity was found in cases of the rectal carcinoma and CML while lowest was detected in cases of NHL (*Table 3*).

The overall results indicate that cancer cases are having higher residues of endosulfan compared with controls. Serum cholesterol and total proteins are significantly lower in the cancer cases compared with controls while ALP activity was higher in the cancer cases compared with controls. There was a positive association between endosulfan residues and serum cholesterol levels in the cancer cases, but no such association was detected in the controls. Presence of lower cholesterol levels and higher endosulfan residues simultaneously may act as risk factors of various malignancies in humans. The overall results indicate that the cancer cases are having higher serum concentrations of endosulfan associated with abnormal levels of serum biochemical parameters compared with the control group.

Conclusion

The presence of higher serum concentrations of α-endosulfan, β-endosulfan, endosulfan sulfate and Σ endosulfan associated with abnormal serum biochemical parameters may be a risk factor of various malignancies in humans. Further work is recommended to ascertain the actual causes of endosulfan toxicity focusing on the mechanisms underlying alterations of serum biochemical parameters and associated health risks in humans and experimental animals.

(Received 23rd Jan 2019; accepted 8th Mar 2019)

Abstract. In the South East Anatolia region of Turkey as well as in many parts of world, soil planker is used to level and firm the soil prior to planting of cotton (*Gossypium hirsutum* L.) at least four times. However, excessive soil compaction due to using of planker can increase soil strength and hamper root growth. This study aimed to investigate the effects of soil planking on soil physical properties, the root growth of cotton and the density of weed species. In this purpose, a field experiment was carried out at different pass numbers of a planker by using a randomized block design with three replications in 2018. The results showed that penetration resistance was increased by the pass number of the planker at 0-15 cm soil depths. While soil planking increased the soil moisture content at 15 cm soil depth, it reduced the soil temperature. Multiple passes of planker decreased the root length and dry root weight of cotton. Soil planking levels differently influenced the density of weed species. Consequently, it can be said that the planking of soil before cotton seeding may influence the root growth and the density of weed species due to changing the physical properties of soil.
Keywords: *soil packing, penetration resistance, moisture content, root length, root weight, weed density*

Introduction

The main condition for a successful cotton production is early stand of uniform seedlings that are rapidly emerging and developing. One of the key factors to accomplish this goal is a well-prepared, smoothened and firmed seedbed. The smoothening of seedbed is required for proper operation of sowing machines. Also, a firm seedbed is considered desirable for increasing emergence and seedling growth of cotton because the close contact between the soil particles and between soil and seed results in faster germination and allow more effective use of existing soil moisture (Berti et al., 2008; Tong et al., 2015). Therefore, planker are commonly used before seeding in cotton production in the South East Anatolia region of Turkey as well as in many parts of world because the using of planker can create appropriate soil condition for planted seeds by compacting soil particles to a suitable density, providing better soil-seed contact and encouraging capillary rise of water from subsoil (Tong et al., 2015; Zuo et al., 2017). However, excessive soil compaction due to using of planker can hamper root growth and decrease soil aeration, and consequently affect yield of crops. Also, it decreases infiltration rate and hydraulic conductivity by increasing bulk density and penetration resistance of soil (Nawaz et al., 2013; Singh et al., 2015).

There have been contradictory findings reported in the literature about the effects of the change of soil physical properties due to compaction on plant root growth and yield.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52455258

The effect of the same compaction degree on root growth and plant yield depends on the crop grown, soil type, and weather conditions (Dias et al., 2015). Baker (2014) reported that the effect of soil compaction was different under dry and wet conditions. He stated that although slight compaction is beneficial but too much is detrimental to yield under dry conditions, any amount of compaction can decrease yields as a result of inhibiting root respiration due to reduced soil aeration under wet conditions.

Using of a planker before seeding results in important changes in the movement and content of heat, air, water and nutrients in the seedbed. These changes within soil significantly affect plant root growth, which has an important role in the nutrient uptake and plant growth. Although several researchers (e.g. Lipiec and Hatano, 2003; Botta et al., 2010; Sivarajan et al., 2018) determined the axle load on some soil properties and yield, most of them did not investigate the correlation between the soil physical properties caused by compaction and plant growth. Also, there is little research on using of the planker before seeding in the literature. It is important to know how much the amount of packing is necessary for smoothening of seed bed and allowing more effective use of soil moisture without hampering root growth. The work by Johnston et al. (2003) showed that a packing force of 333 N per press wheel provided adequate emergence and grain yield across varied environmental conditions. They found that the higher packing force influenced emergence in canola, and not yield. Planking level of a particular soil is affected by many factors such as moisture content, type of soil, contact pressure, number of planker passes, and working speed of planker. In South-East Anatolia region of Turkey, farmers usually pass the planker at least four times before cotton seeding. An understanding of how the planking pressure and the passes number of a planker before seeding influence the soil properties and root growth would help producers apply the optimum number of passes for given type of planker in their farm and soil conditions.

The objective of this study is to investigate the effects of different pass numbers of a planker on soil physical properties (moisture content, temperature, penetration resistance), the root growth of cotton (root length, root thickness, root dry weight) and the density of weed species. Also, the relationship between the soil physical properties caused by compaction, and soil physical properties and root growth parameters will be evaluated by correlation analysis.

Materials and methods

Experiment site description and experimental design

An experiment was conducted in a farmer's field in Diyarbakır, Turkey during cotton growing season in 2018. Experimental field (latitude: 37°55’36”N, longitude: 40°13’49’E, altitude: 630 m above sea level) is located at South-East Anatolia region of Turkey. The region is characterized by a semi-arid climate (humid winters and dry summers). The annual rainfall, based on the long-term average (1929-2017) is 483.5 mm, about 80% of which occurs from November to May. Monthly rainfalls and temperature records during the experimental year and over the long term are shown in *Figure 1*. The rainfall at experimental growing season was significantly higher than long-term average at May after cotton planting. There was no much difference between mean monthly air temperatures of long-term years and 2018. Post-planting rainfall and air temperature may be expected to influence seedling emergence and plant growth by affecting the oxygen content and temperature of soil (Berti et al., 2008).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52455258

The soil (0-20 cm) of the experimental field was clay loam with pH of 8.03, organic matter content of 15.8 g kg^{-1}, total salt of 0.08% and $CaCO_3$ of 60.8 g kg^{-1}. Average values of soil moisture content, temperature, penetration resistance at different soil depths before the application of treatments are listed in *Table 1*. The moisture content (dry basis) of soil at 10 cm depth was 10.87%. This moisture content is suitable for planking operations on a clay loam soil. The values of soil temperature and penetration resistance were within the appropriate limits for cotton emergence and seedling root growth.

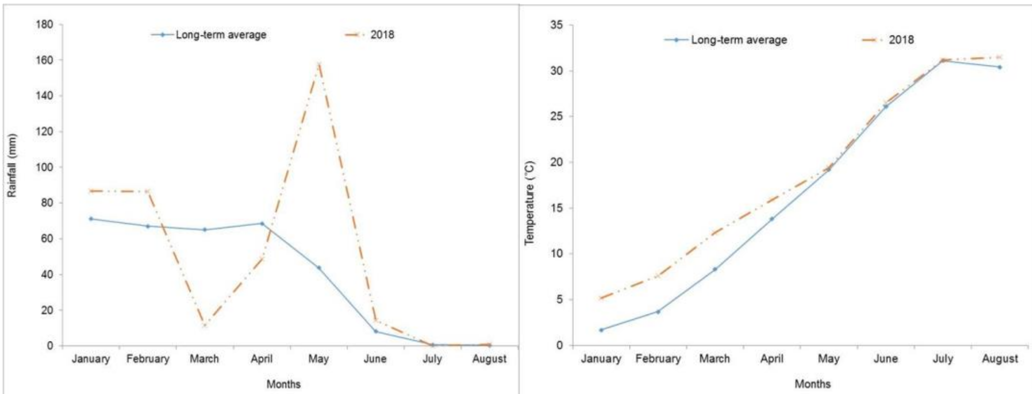

Figure 1. *Total monthly rainfall and mean temperature during experiment year*

Table 1. *Initial soil physical properties at 0-30 cm soil depths before the application of the treatments*

Soil parameters	10 cm		20 cm		30 cm	
	Mean	SD	Mean	SD	Mean	SD
Moisture content (%)	10.87	2.96	44.96	2.42	74.53	10.18
Temperature (°C)	21.30	0.8	20.85	0.45	20.40	0.20
Penetration resistance (kPa)	76.33	44.64	510.60	204.60	1007.20	146.84

The previous crop at the experimental site was cotton. The seed bed preparation included chopping the post-harvest cotton stalk, an autumn moldboard plowing (20 cm) followed by cultivator to 10 cm in April after broadcasting the fertilizer (20-20-0%, N-P_2O_5-K_2O for supplying 60 kg N plus 60 kg P_2O_5 ha^{-1}). The different pass numbers of a planker (200 kg m^{-1}) were tested by using a randomized block design with three replications. Treatments included the pass numbers of planker as untreated control (planking0), soil planking by planker in one (planking1), two (planking2), three (planking3) and four (planking4) passes. Plot size was 84 m^2 (30 m x 2.8 m). The first passing of planker was applied on 15 April 2018, and other passing was applied two days after the first passing of planker. DP-499, standard cotton cultivar for the region, was planted at seed rate of 20 seeds m^{-2} by using a pneumatic precision seed drill on 18 April 2018. The sowing depth of drill was adjusted as approximately 5 cm. First hoeing was done at about 15-20 days after sowing (DAS), second and third hoeings were done at about 30 and 45 DAS to loose, aerate the soil and control the weeds two times. Also, a lister was used to apply the top-dress fertilizer (100 kg ha^{-1} ammonium nitrate) and make the furrow before the first irrigation. The first irrigation was applied by furrow

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52455258

irrigation methods 60 days DAS. The latter furrow irrigations were applied by 7 times at approximately 11-13 days intervals during growing season, with nearly 150 mm at each irrigation. For a given irrigation, all plots received the same amount of water.

Description of planker

The planker tested was a metal rectangular with length of 600 cm and width of 20 cm, attached to a carriage frame (*Fig. 2*). Total weight of the planker was 1200 kg, calculating the weight per meter as 200 kg m^{-1}. The calculated contact pressure of the planker was 9.81 kPa. The tractor, New Holland T6600 with 4-wheel-drive developing 119 kW, was operated at 5.4 km h^{-1} for pulling the planker.

Figure 2. *The packer tested in the experiment*

Measurements

Soil moisture content and temperature was measured by Aquaterr - Model T300 - Moisture Measurement Instrument (*Fig. 3a*). The measuring range of this Instrument was 0% d.b.–100% d.b., and the precision was ±1.5 F.S. Measurements was taken at 15 cm soil depth before the application of treatments and 5 days DAS. Soil penetration resistance were measured using a digital cone penetrometer FieldScout SC 900 (Spectrum Technologies, Aurora, IL) recording the pressure applied in Pascals every 2.5 cm, to a depth of 45 cm at the same time when soil moisture content and temperatures were measured (*Fig. 3b*). All the measurements were conducted at three random locations in each plot and the average value was taken as the result.

Figure 3. *Soil moisture and temperature measurement instrument (a) and soil penetrometer (b)*

Root samples were obtained by digging out plant roots to a depth of 30 cm at the early flowering period. A cylindrical soil corer with a 130 mm inner diameter was used to dig out the roots (*Fig. 4a*). Five plants were randomly selected in each plot to determine the root length, root thickness and root dry weight. Root thickness was recorded with a digital vernier caliper (Mitutoyo UK Ltd., Hampshire, UK) on the collar

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52455258

and root length was measured with a meter ruler (*Fig. 4b*). To determine dry root weight, roots was cut on collar from plant and thoroughly washed with water for devoid of soil particles. Then, roots samples were oven-dried to a constant weight at 65 °C for 72 h and weighed to determine the root weight (g).

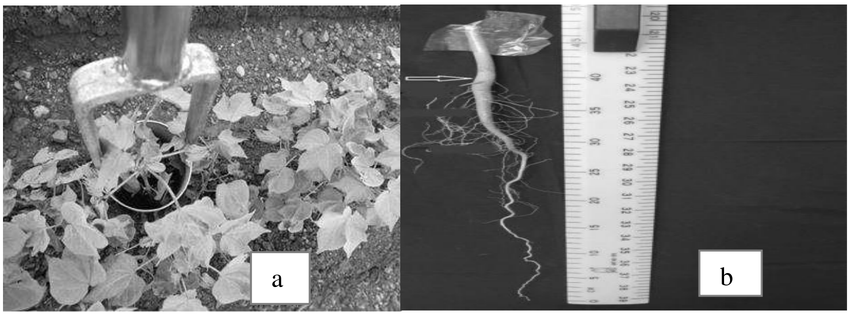

Figure 4. *The soil corer for taking root sample (a) and measurement of root length and the measurement point of root thickness (b)*

Weed species and their densities were determined by counting their numbers in 1 m^2 quadrats which were located randomly in each plot before cotton harvest. The density of weed species was calculated by taking the arithmetical mean of plots for each treatment and classified according to A-E scale used by Uremis (2005). In this scale,
a represents weed density ≥ 3 weeds m^{-2}
b represents 2 weeds m^{-2}≤ weed density < 3 weeds m^{-2}
c represents 1 weeds m^{-2} ≤ weed density < 2 weeds m^{-2}
d represents 0.1 weeds m^{-2} ≤ weed density < 1 weeds m^{-2}
e represents weed density < 0.1 weeds m^{-2}.

Statistical analysis

Analysis of variance (ANOVA) was performed on all the measured soil properties and root growth variables using the JMP statistical software package (SAS, 2002, Cary, NC, USA). The means between treatments were compared using LSD’s multiple range tests at the significance level of 0.05. Simple correlation coefficients between the soil properties and root growth in the study were calculated using correlation analysis.

Results and discussion

Soil physical properties

Soil moisture content and temperature

Figure 5 shows that the soil moisture content was affected by the passing numbers of planker five DAS. Using the planker significantly increased the soil moisture content at 15 cm soil depth. However, there was no significant difference among the pass numbers of planker. Unlike the soil moisture content, the soil temperature was the highest in the untreated plots that planker was not used. As their effects on soil moisture content, the difference among the pass numbers of planker was not statistically significant (*Fig. 5*). Soil moisture and temperature are two important soil parameters which have significantly influenced crop growth by affecting many physical and biological

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52455258

processes such as soil N-mineralization within the soil (Wang et al., 2006). Therefore, it is very important to know how planking practices affected the soil moisture content and temperature. Soil planking decreases air pockets in which evaporation occurs. Therefore, soil drying and heating slow down as the result of soil compaction. Also, soil compaction encourage capillary rise of water from subsoil to topsoil (Tong et al., 2015).

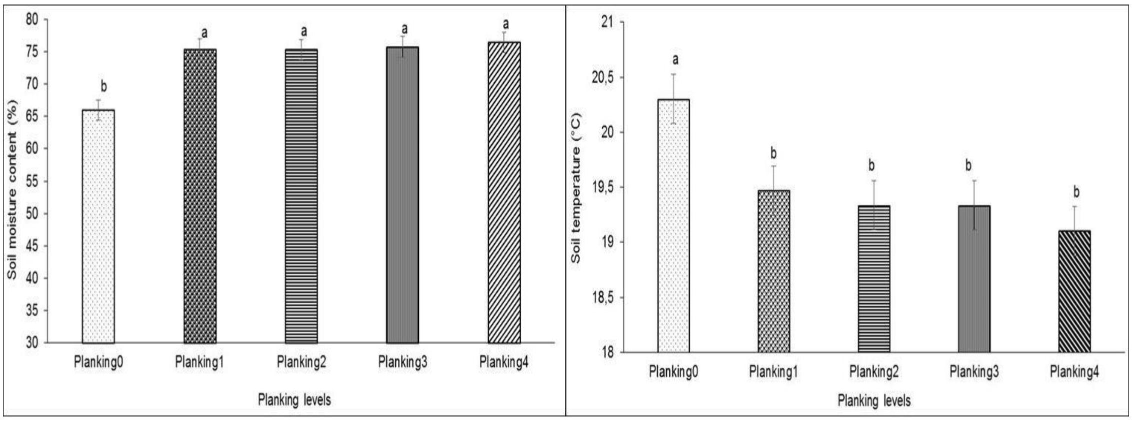

Figure 5. *The effect of different pass numbers of planker on soil moisture content and temperature at 15 cm depth. Means followed by different letters are significantly different according to LSD's multiple range test at the significance level of 0.05. Planking0: untreated control; Planking1: soil planking by planker in one pass; Planking2: soil planking by planker in two passes; Planking3: soil planking by planker in three passes; Planking4: soil planking by planker in four passes*

Soil penetration resistance

Mean values of penetration resistance at different planking levels and different soil depths are presented in *Figure 6*. While the pass number of planker significantly influenced the penetration resistance at the soil surface (~0 to 15 cm depth), there was no significant difference between treatments at subsurface layers (20-30 cm soil depths). Using the planker significantly increased the penetration resistance at the soil layers of 0-15 cm depth. The soil planking by planker in four passes (Planking4) resulted in a significantly higher soil penetration resistance which was the highest (1356.67 kPa) at 5 cm depth. There was no significant different between planking3 and planking4 at 0-10 cm soil depth. In general, it can be said that penetration resistance was linearly increased by the pass number of the planker at all soil depths of surface layer (~0 to 15 cm). However, the peak values of penetration resistance for all the pass numbers of planker were commonly obtained at 5 cm soil depth. In all treatments, the values of the penetration resistance at all soil depths were below critical compaction (2000 kPa) reported by Hamza and Anderson (2005).

Root growth parameters

Root growth is a critical component in overall plant performance during production. Main root growth parameters include: root length, root thickness, root weight, root volume, root:shoot ratio, specific root length, branching pattern, horizontal distribution, root hair density, root uptake ability, root hydraulic conductance, and root viability

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52455258

(Judd et al., 2015). In this study, we could determine only root length, root thickness and root dry weight at the early flowering period.

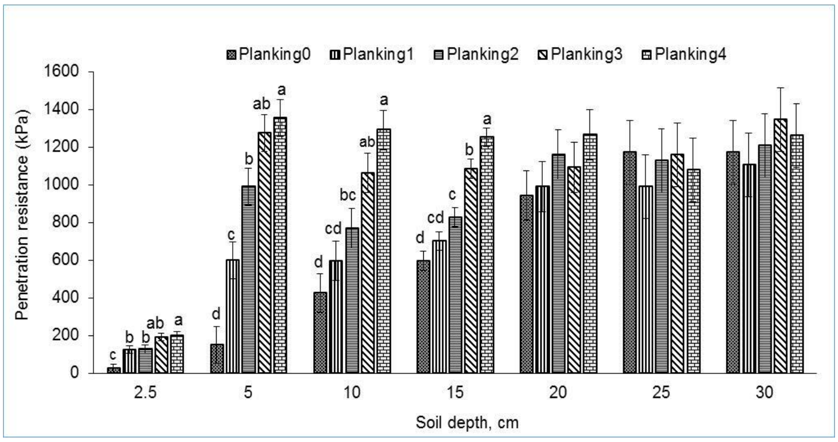

Figure 6. *The effect of different pass numbers of planker on soil penetrometer resistance at different depths. Means followed by different letters are significantly different according to LSD's multiple range test at the significance level of 0.05. Planking0: untreated control; Planking1: soil planking by planker in one pass; Planking2: soil planking by planker in two passes; Planking3: soil planking by planker in three passes; Planking4: soil planking by planker in four passes*

Figure 7 shows a picture of the characteristic growth patterns of individual roots under different soil planking levels. As seen in picture, the direction of the root growth change from vertical to horizontal immediately above the restricting layer with increasing the pass number of the planking because roots are physically restricted by a dense layer containing few pores suitable for root penetration. Several researchers (e.g. Goss and Russell, 1980; Tsegaye and Mullins, 1994) reported that soil compaction cause the root tip exert a force to deform the soil due to pores much smaller than the root diameter. They stated that this process may considerably decrease root elongation rates, increase the root diameter and change the pattern of lateral root initiation.

The root length was the highest in the Planking0 (untreated control) treatment and the difference between the Planking0 and Planking1 was not statistically significant. Increasing the pass number of planker from one to two significantly decreased cotton root length and there was no significant difference among Planking2, Planking3, Planking4 treatments (*Fig. 8*). Our results are consistent with general results from the previous researches. For example, in a recent review, Bengough et al. (2011) reported that root elongation significantly slowed in soils with penetrometer resistances in the range 800-2000 kPa. Similarly, Logsdon et al. (1987) determined that the root length of corn (Zea mays L.) seedlings decreased with increased mechanical impedance in a fine-textured soil. In our study, multiple passes of the planker significantly increased the penetration resistance at 0-15 cm soil depths as seen in *Figure 6*. This increase in penetration might decrease the root elongation. Geisler-Lee et al. (2010) reported that the higher ethylene production in roots due to a lack of oxygen in compacted soils is associated with the inhibition of elongation. Also, the decreased root elongation in compacted soil might be resulted from a decreased rate of cell division in the meristem together with a decrease in cell elongation (Bengough and Mullins, 1990).

Soil compaction can increase root thickness in order to reduce the risk of root buckling and the mechanical stress acting on the root during penetration (Kirby and Bengough, 2002; Colombi et al., 2017). Hettiaratchi et al. (1990) reported that a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52455258

variable apex geometry's cyclic growth routine enabled plant roots to penetrate compact soil and this growth mode resulted in thickened roots. Also, Bengough and Mullins (1990) reported that soil mechanical impedance caused the increased root thickness due to increased thickness of the cortex and increases in the diameters of the outer cells as well as increases in the number of cells per unit length of root. *Figure 8* shows that the pass number of the planker did not statistically influence the root thickness. In this study, root thickness was determined on the root base near the soil surface not on root cap. No difference among treatments in terms of their effect on root thickness might be resulted from the measurement point of root thickness. Additionally, in our experiment, the highest soil penetration resistance was 1345 kPa. This resistance value might be apparently not high enough to modify root diameter. Rosolem and Foloni (2002) reported that the effect of soil compaction on root diameter depends largely on the level of penetration resistance.

The dry root weight was significantly reduced with the increased pass number of planker (*Fig. 8*). While untreated control treatment had the highest dry root biomass, the four passes of the planker resulted in the lowest dry root weight. There was significantly no difference among the other treatments. As seen in *Figure 6*, four passes of the planker significantly increased soil penetration resistance. This increase in soil penetration decreased the root length, consequently root dry weight (*Fig. 8*). Similarly to our results, several researchers found that the root dry weight was significantly reduced by soil compaction during growing of other crops including wheat (Rahman et al., 1999; Wu et al., 2018), alfalfa (Hakl et al., 2007), sugar beet and cotton (Gemtos and Lellis, 1997), soybean and common bean (Buttery et al., 1998). However, Sarto et al. (2018) determined that the root dry matter of safflower genotypes decreased as penetration resistance levels were increased from 200 to 1770 kPa. They stated that the effect of increased penetration resistance on root growth can change according to each plant species or genotype.

Correlations between soil properties and root growth parameters evaluated

The relation between the soil properties, and soil properties, seed cotton yield per plant and root growth parameters measured in the study was evaluated by Pairwise Correlation analysis. The results are shown in *Table 2*. The soil moisture content was positively correlated with the penetration resistance at 0-15 cm soil depths. This indicate that the increase in the penetration resistance due to planking significantly increase moisture content at 0-15 cm soil depth. However, these findings are contrary to the previous studies reported by several researches (e.g. Veronese et al., 2006; Van Quang et al., 2012; Lomeling and Möri Lasu, 2015) that show that penetration resistance is negatively correlated to soil moisture content. In this study, positive correlation between soil penetration resistance and moisture content can be attributed to the change in bulk density and macro pores caused by soil planking, prevention of the loss of soil moisture content and the capillary rise of water from subsoil to topsoil. The soil temperature was negatively correlated with both penetration resistance and moisture content. This indicates that the increase in soil moisture content and penetration resistance decreased the soil temperature. Lakshmi et al. (2003) reported that the changes in soil temperature affect soil moisture and vice versa. While the root thickness was positively correlated with penetration resistance at 10 cm soil depth, no significant correlations were found between the root thickness and penetration resistance at other soil depths. This indicates that increase in penetration resistance at 10 cm soil depth increased the root thickness.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52455258

Root length was positively correlated with soil temperature whereas it was negatively correlated with penetration resistances at 2.5, 5.0, 10, 15 cm soil depths and moisture content. This means that the increase in penetration resistance decreased the root length. Bengough and Mullins (1990) reported that mechanical impedance decreased the rate of root elongation because of both the decrease in the rate of cell division in the meristem, and the decrease in cell length. Negative correlation between soil moisture content and root length indicates that root length was increased with decrease in soil moisture content at 15 cm soil depth. This can be resulted from physiologically increasing root elongation to uptake available water in deeper soil zone (Serraj and Sinclair, 2002). Similarly, Malik et al. (1979) reported that the initial rate of root elongation after emergence was faster in the soil at low water content compared with that at high water content. There was no significant correlation between root length and thickness. While the root dry weight was positively correlated with soil temperature, it was not correlated with soil penetration resistance and moisture content. Besides, the root dry weight was positively correlated with the root length whereas no significant correlation was found between root dry weight and root thickness. This shows that while the root dry weight was affected by root length, effect of root thickness on root weight was not significant.

The density of main weed species affected by planking levels

Soil firming by planker significantly affects the species richness, composition, and diversity of weed phytocenoses because it may change soil properties and weed seed emergence. The weed community in this experiment area was composed of 13 species including Cultivated licorice (*Glycyrrhiza glabra* L.), Common mallow (*Malva neglecta* Wallr.), Field bindweed (*Convolvulus arvensis* L.), Field Mallow (*Malvella sherardiana* (L.) Jaub. & Spach), Mexican Ground-cherry (*Physalis philadelphica* Lam.), Black nightshade (*Solanum nigrum* L.), Cocklebur (*Xanthium strumarium* L.), Redroot amaranth (*Amaranthus retroflexus* L.), Johnsongrass (*Sorghum halepense* (L.) Pers.), Giradol (*Chrozophora tinctoria* (L.) Raf.), Purple nutsedge (*Cyperus rotundus* L.), Common reed (*Phragmites australis* (Cav.) Trin. ex Steud.), Bermudagrass (*Cynodon dactylon* (L.) Pers.). The weed species observed in quadrats was Black nighshade (*Solanum nigrum* L.), Bermudagrass (*Cynodon dactylon* (L) Pers.), Mexican Groundcherry (*Physalis philadelphica* Lam.), Common reed

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52455258

(*Phragmites australis* (Cav.) Trin ex. Steud), Purple nutsedge (*Cyperus rotundus* L.) and Field bindweed (*Convolvulus arvensis* L.).

Figure 9 shows the effect of soil planking levels on the density of those weed species. Considering the total density of weed species, while the highest weed density was observed in untreated control (17.21 weeds m^{-2}) and the four passes of the planker (16.99 weeds m^{-2}), planking1 treatment had the lowest (4.54 weeds m^{-2}). Total weed density was 10.32 weeds m^{-2} in Planking2 and Planking3 treatments. As seen in *Figure 9*, while the increase in the pass number of planker decreased the density of the Bermudagrass and Field bindweed species, it increased density of Common reed and Purple nutsedge. Planking1 treatment had the highest density of Black Nighshade among all treatments. While the density of the Bermudagrass was > 3 plant m^{-2} at untreated control plots, no plant was observed in in quadrats at other treatments (*Fig. 9*). The two passes of planker resulted in the highest density of Mexican Ground-cherry. Density of Common reed and Purple nutsedge was observed to be more than 3 plants m^{-2} when planker was passed four times. However, the density of Purple nutsedge was the highest at the Planking2 treatment as seen in *Figure 9*. The untreated control plots had the highest density of Field bindweed.

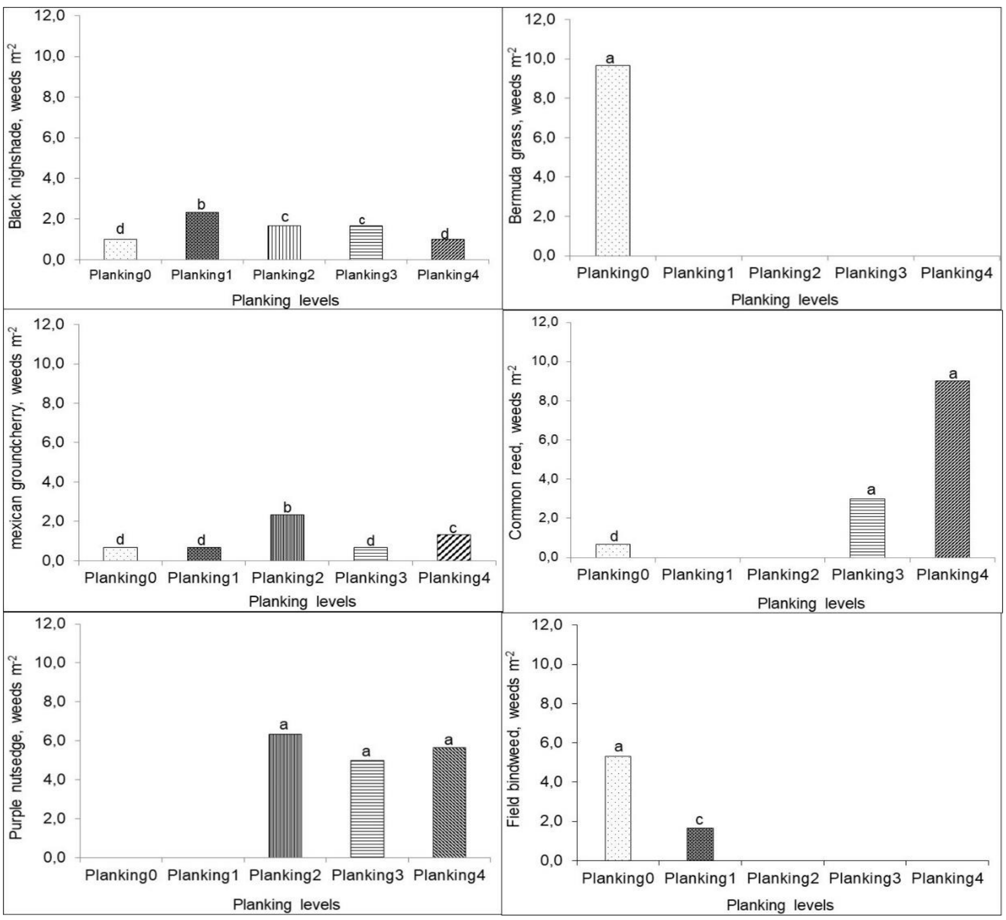

Figure 9. *The effect of different pass numbers of planker on the density of some weeds species. a:> 3 weeds m^{-2}; b: 2-3 weeds m^{-2}; c: 1-2 weeds m^{-2}; d: 0.1-1 weeds m^{-2}; e: <0.1 weeds m^{-2}. Planking0: untreated control; Planking1: soil planking by planker in one pass; Planking2: soil planking by planker in two passes; Planking3: soil planking by planker in three passes; Planking4: soil planking by planker in four passes*

The seedling emergence and growth of weed species can change in different soil conditions because of their genetic characteristics (Whitely and Dexter, 1984; Materachera et al., 1991). Therefore, the changes in soil physical and chemical properties due to soil planking may differently influence the seedling emergence and growth of weed species. Similarly, Lenssen (2009) determined that land rolling differently affected weed species after crop emergence and at harvest. Reintam and Kuht (2012) reported that the soil physical and chemical properties, and the position of weed seeds within the soil matrix play an important role in seedling emergence and seed survival.

Conclusions

In this study, the effects of soil planking levels on soil physical properties, the root growth of cotton and density of weed species was determined. The results of study revealed that the soil planking had an important effect on the root length and dry root weight of cotton for significantly changing the penetration resistance, moisture content and temperature of soil. Soil planking significantly increased the soil moisture content at 15 cm soil depth although there was no significant difference among the pass numbers of planker. Unlike moisture content, the soil temperature was the highest in the untreated plots and there was no significant difference among the pass numbers of planker. The penetration resistance was increased by the increased pass number of the planker at all soil depths of surface layer (0 to 15 cm) although soil planking had no significant effect on the penetration resistance at 20-30 cm soil depths. Multiple passes of planker significantly decreased cotton root length. Also, the dry root weight was significantly reduced with the increased pass number of planker. Correlation results indicated that while the increase in the penetration resistance due to planking significantly increased moisture content at 15 cm soil depth, it reduced soil temperature and root length. There was positive correlation between root thickness and penetration resistance at 10 cm soil depth but not other depths. Also, the density of weed species was affected by the pass number of planker. While the increase in the pass number of planker decreased the density of the Bermudagrass and Field bindweed species, it increased the density of Common reed and Purple nutsedge.

Abstract. This research aims to enhance the biodegradation efficiency of waste activated sludge co-digested with olive mill wastewater in a batch system at a laboratory scale in (600 ml) digester. The potential biomethane production was investigated. Different concentration ratios were tested out at a thermophilic temperature (55°C) for a retention period of 32 days. The results showed an increase in methane amount in the case of co-digestion. A height methane yield was obtained (71% of CH_4) at a mixing ratio: 87.5/12.5 of waste activated sludge/olive mill wastewater. The kinetic modelling was done to analyze the digestion performance with two models: the modified Gompertz equation and the modified logistic equation. The kinetic data and the concentration ratio give a peak correlation, whose the Gauss amplitude equation is convenient to predict the optimum mixing ratio and the limited concentration to avoid the inhibition of process. The synergistic effect is limited if olive mill wastewater mixing ratio exceeds the limited ration (22%).
Keywords: *anaerobic co-digestion, waste activated sludge, olive mill wastewater, kinetic study, synergistic effect*

Introduction

Anaerobic digestion is a waste management method aimed at the reduction of harmful effects on the environment (Manyi-Loh et al., 2013; Ali Shah et al., 2014). Anaerobic digestion (AD) has been recognized as an efficient bioprocess for the management of waste activated sludge (WAS) (Kardos et al., 2011), by offering many environmental and economic benefits (Mulat and Horn, 2018). In this method, microorganisms play a crucial role in treating organic matter and returning the chemical elements into the active cycle. Thus, they are effective in mineralization of the complex organic matter through a sequential breakdown and release of chemically stabilized compounds, mainly methane (CH_4) and carbon dioxide (CO_2) (Gopinath et al., 2014; Ali Shah et al., 2014; Zeng et al., 2017). However, WAS is known for its low biodegradability mainly due to its low carbon to nitrogen (C/N) ratio. This limits its digestion under traditional mesophilic conditions (Coelho et al., 2011; Mahanty et al., 2014). Therefore, the co-digestion of sludge with other organic wastes can offer numerous potential benefits for the AD process, such as: dilution of the potentially toxic compounds eventually existing in any treated materials, augmenting the organic matter biodegradability, better biogas yield due to synergistic effects, tuning of the moisture content and pH, strengthening the essential buffer capacity to the mixture and the enlarging of bacterial range strains taking part in the process (Anjum et al., 2017; Kashi et al., 2017; Xu et al., 2018).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52595274

Therefore, notable issues have been performed by digesting simultaneously the WAS with different biological wastes (Heo et al., 2004; Bolzonella et al., 2006; Carrere et al., 2008; De Vrieze et al., 2013; Sun et al., 2013; Qiao et al., 2015; Mulat and Horn, 2018).

Olive Mill Wastewater (OMW) is a very attractive co-substrate option for the anaerobic co-digestion of municipal sludge because, carbon source addition like OMW as a substrate, enhanced the total VS and therefore the biogas yield (Ma et al., 2008). OMW is becoming a serious environmental problem, especially for its high chemical oxygen demand (COD). It is generally acknowledged that the high toxicity of OMW is entirely ascribable to phenols (Perez et al., 1992).

This article focuses on the anaerobic co-treatment of two typical wastes in Algeria, which are totally unexploited and in some cases harmful to the environment. WAS (production period whole year) and OMW (production period October–March) and as two representative types of biomass wastes produced in Boumerdes (Algeria) and other mediterranean countries. The precise aim of the present research was to investigate biochemical methane potential assays for raw WAS alone and mixed with varying amounts of OMW.

Material and methods

Waste sampling

The sampling of WAS was carried out in a municipal wastewater treatment plants in Boumerdes (Geographical coordinates are 36°45'0"N and 3°40'0"E in DMS), Algeria. When the sludge age, is 12 days in the extended aeration. The OMW used in this study was taken from a three-phase olive mill processing plant located at the Issers city (Geographical coordinates are 36°43'0"N and 3°40'0"E in DMS) in Boumerdes during the harvesting season. The biochemical compositions of wastes are revealed in *Table1*.

Table 1. *Characteristics of substrate*

Parameters	Waste activated sludge	Olive Mill Wastewater
pH	7.8 ± 0.15	4.8 ± 0.1
CODt (g l^{-1})	90.7 ± 1.8	128.1 ± 5.4
CODs (g l^{-1})	35.0 ± 0.6	64.7 ± 1.4
TS (g l^{-1})	150 ± 0.8	69.5 ± 3.1
VS (g l^{-1})	71.7 ± 0.5	57.4 ± 4.5

Cu(mg l^{-1})	1116	0.33

CODt total chemical oxygen demand , CODs: Soluble chemical oxygen demand
TS :total solids, VS: Volatile solids , TN:total nitrogen / TP total phosphorus
TPc: total phenolic compounds

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52595274

Digester and operation

A 600 ml digester used for producing biogas from biomass through AD (*Figure 1*). The functioning volume of each digester was maintained at 450 ml and run under uncontrolled pH. For these experiments, the inoculum was an anaerobic sludge treating WAS which was diluted to 0.64 g/l of volatile solids (15 ml /for each digester). When the mixtures were prepared at different weight ratios (WAS % / OMW %): (87.5 / 12.5, 75 / 25, 50 / 50, 25 / 75, 12.5 / 87.5) and the mono- digestion of both wastes (100/0, 0/100), the bioreactor was purged with helium gas to eliminate air from the reactor. Experiments were carried out at a thermophilic temperature of 55°C by incubation in Marie-bath. Biogas volume generated was measured by liquid displacement (NaOH 2%) (Esposito et al., 2012). The chemical compositions of each mixture ratio are revealed in *Table 2*.

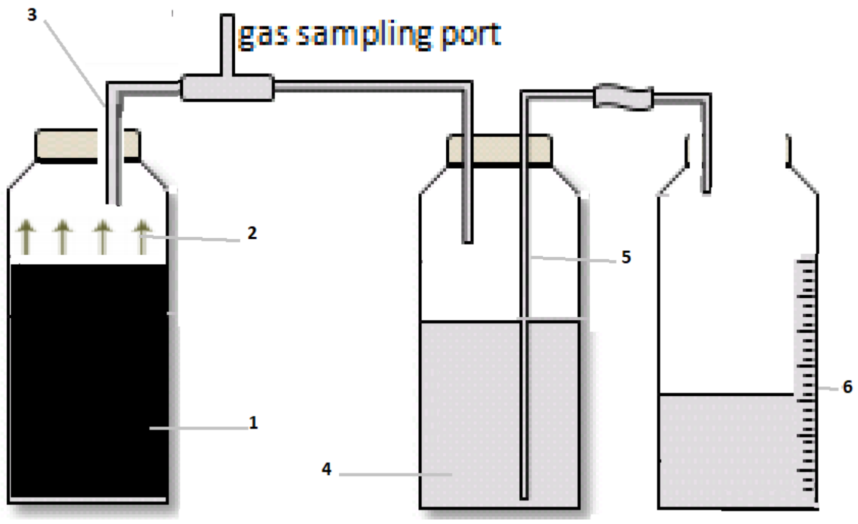

Figure 1. *Anaerobic digestion system: From each digester placed in a water bath (1) a silicone tube (2) led the generated gas (3) out. This tube was led to the top of another glass bottle which contained NaOH 2% solution (4). There was another tube (5) from the bottom of that bottle, through which the gas pumped the solution to the graduated bottle meter (6). This way, it was possible to measure the volume of the generated gas accurately, on a daily basis*

Analytical method

Soluble and total chemical oxygen demand (CODt and CODs) total nitrogen (TN) and total phosphorus (TP), Total solids (TS) and Volatile solids (VS) were quantified according to Standard Methods (Apha, 1998). The pH of the wastes measured according to NF ISO 10390 by a portatif pH-Metre (HANNA HI8424, France) (Rodier et al., 2009). Total phenolic compounds (TPc) were extracted and purified in ethyl acetate using the method of Macheix et al. (1990). The concentration of TP compounds was determined spectrophotometrically (according to the Folin–Ciocalteu method (Singleton and Rossi, 1965)) Heavy metals were determined by the atomic absorption spectrophotometer (Perkin Elmer, Optima8000) according to the Method cited by Liu et al. (2001). The biogas composition (CH_4 + CO_2) was measured using a gas chromatograph (GC-HP 5890) coupled with a thermal conductivity detector (*TCD*) and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52595274

stainless steel column that was 2 m long with a 5 mm OD and 2 mm ID and contained Porapak Q 100 that had a mesh range from 80 to100. The carrier gas was N_2, and the analysis was carried out at a carrier gas flow rate of 30 ml min^{-1} with the injector, column, and detector temperatures at 120, 90, and 120ºC, respectively.

GC-MS analysis of ethyl acetate extract of OMW was performed on a BRUKER SCION 365 GC System (NS-GC 1409S312), Gas chromatography (GC) coupled to a triple quadruple mass spectrometer fitted with an Rtx-5MS capillary column (30 m X 0.25 mm inner diameter, X 0.25 µm film thickness; maximum temperature, 350°C). Ultra-high purity helium (99.99%) was used as a carrier gas at a constant flow rate of 1.0 ml min^{-1} using the condition cited by Al Owaisi et al. (2014). The percentage composition of the ethyl acetate extract components was expressed as a peak area percentage. The identification and characterization of chemical compounds was based on GC retention time. The mass spectra were computer matched with those of standards available in mass spectrum libraries.

Table 2. *Characteristics of the mixture prepared with different waste activated sludge/Olive Mill Wastewater mixing ratios*

WAS /OMW ratios	TS (g l^{-1})	VS (g l^{-1})	CODt/TN	pH

Ratio WAS /OMW: mixing ratio of waste activated sludge /Olive Mill Wastewater
TS: Total solids ,VS: Volatile solids
CODt/TN: the ratio of total chemical oxygen demand /total nitrogen

Methanogenic activity test

To control the biomass composition of anaerobic co-digested waste the methane production potential of the test biomass is measured under an unlimited substrate. The acetoclastic methanogenic activity of each biomass was evaluated in shaken batch assays on the end of each kinetic. All assays were carried out in glass serum bottles (250 ml), and each biomass sample was washed with 25 mM phosphate buffer to remove any extra substrate and was dispersed by a homogenizer. The bottles containing 230 ml of 25 mM phosphate buffer were inoculated with the washed anaerobic biomass directly to a final concentration of 2 g VSS l^{-1}. The test substrates used were acetate, COD strength was set at 2000 mg COD•l^{-1}. Nutrients were not added in order to limit the biomass growth during the test period. The medium and the headspace were filled with N_2 gas at 1 atm (101 k Pa). The bottles were incubated in the dark at 55ºC. All measures other than specifically described here are given elsewhere by Pat-Espadas et al. (2015). Methane gas production was determined through the liquid (11.2% w/v KOH Solution + Thymol Blue Indicator) displacement method according to Jawed and Tare (1999) and Esposito et al. (2012). The maximum specific methanogenic acetoclastic activity (SMAA) (ml CH_4/VSS /h) was calculated from the slope of the cumulative CH_4 versus time graph.

DOI: http://dx.doi.org/10.15666/aeer/1702_52595274

Kinetic models

Tow models to estimate performance parameters were used. The cumulative methane production data from the experiments were fitted to the modified Gompertz equation (MGE) given by (*Eq. 1*), so this equation plot the cumulative methane production according to the time (Maamri and Amrani, 2014).

$$M = \mathrm{P.exp} \quad \text{- exp } [\frac{R_m.e}{P}(\lambda \text{ - t}) + 1] \qquad \text{(Eq.1)}$$

where M is the cumulative methane production (l), P the methane production potential (l), R_m the maximum methane production rate (l d^{-1}), λ the duration of lag phase (d) and t is the duration of the assay (time) at which cumulative methane production M is calculated (d).

The Logistic equation (LGE) a model which has been used for anaerobic fermentation, as well as, for estimate the methane generated from sewage sludge (Donoso-Bravo et al., 2010). In this case, a modified version of the logistic function was used (*Eq. 2*).

$$M = \frac{P}{1 + \exp(4\mathrm{R}_m(\lambda \text{ - t})/\mathrm{P} + 2)} \qquad \text{(Eq.2)}$$

The parameters P, R_m, and λ were estimated for each of the digesters using the OriginPro8 software.

Statistical analysis

All assays were conducted in triplicate. The data on characteristics of the substrate with different mixing ratios were expressed as mean ± standard deviation. The data on performances of each digester were expressed as mean ± standard deviation during the operation period. A one-sample t-test was used to test the significance of the results and $p < 0.05$ was considered statistically significant. The statistical analysis of regression was qualified by an analysis of variance (ANOVA) and Akaike’s test by OriginPro8.

Results

Identification of phenolic compounds extracted from OMW

The identification of phenolic compounds was performed by relevant molecular mass data from GC-MS. GC provided the separation of the major biophenols in the OMW extracts as illustrated in *Figure 2*. The phenolic composition of the OMW ethyl acetate extract is summarized in *Table 3*.

Anaerobic digestion

The cumulative methane production (ml) during the codigestion of WAS/OMW is shown in *Figure 3*. As was the case for different ratios of a mixture for a retention time of 32 days. Methane production started immediately from the first day of digestion in all the digesters.

DOI: http://dx.doi.org/10.15666/aeer/1702_52595274

The cumulative methane is better in case of codigestion than monodigestion (WAS /OMW =100/0 and 0/100), especially at the ratio 87.5 / 12.5 of WAS/OMW with the highest specific methane yield value (*Figure 3*) comparatively. The kinetic parameters of the AD process are constantly used to analyze the performance of digesters and design appropriate digesters, which are also useful to considerate inhibitory mechanisms of degradation (Kabouris et al., 2009). With an assumption that methane produced is a function of bacterial growth in batch digesters, to quantify analytically parameters of the batch growth curve, the MGF and LGF were selected to fit the cumulative methane production data. Values of parameters obtained are summarized in *Tables 4 and 5*.

It has been observed that the cumulative methane produced is well fitted with the two models as is evident from the correlation coefficient R^2 (0.9) between the experimental and predicted values along with the parameter estimated.

Ratio WAS /OMW: mixing ratio of waste activated sludge /Olive Mill Wastewater
P: the methane production potential
R_m: the maximum methane production rate
λ: the duration of the lag phase

The Akaike test (*Table 6*) confirms that the model of the MGF has lower AIC value and so is more likely to be correct. This model is 6139.83 times more likely to be correct.

Performance data (*Table 7)* shows that the WAS/OMW ratio of 87.5 / 12.5 favored the degradation of the organic matter, considering the best VS reduction (69.91 ±1.72). The methane yield increases slightly with the addition of OMW and remains stable until the WAS/OMW ratio of 75/25.

We can easily observe that the increase in the amount of OMW in the mixture gives a peak correlation (*Figure 4*) in the methane production parameters. Then the SMAA also gives a peak profile.

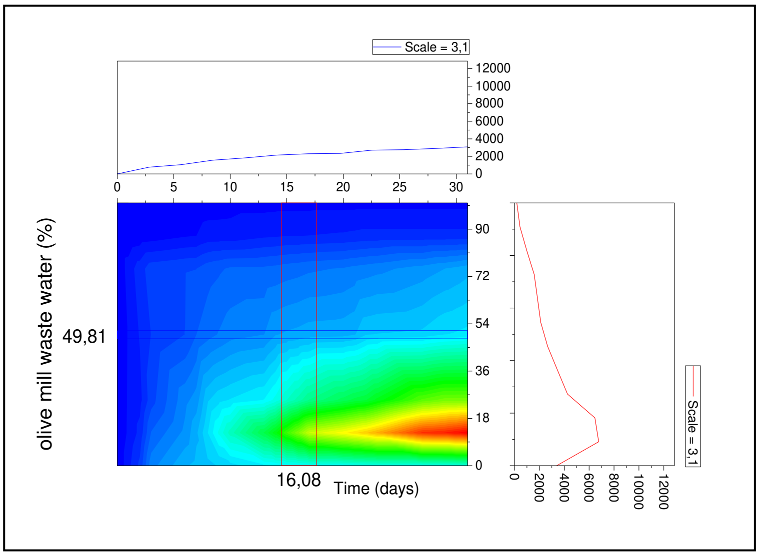

***Figure 4.** Correlation between cumulative methane production and Olive Mill Wastewater amount and retention time*

In light of these results, the investigate the WAS/ OMW optimum mixture ratio by the modelling of these correlations (*Figure 5*) via the Gauss amplitude equation (*Eq. 3*) has given a good statistical significance (*Tables 8 and 9*).

$$Y = Y_0 + Ae^{-\frac{(X-Xc)^2}{2W^2}} \quad \text{(Eq.3)}$$

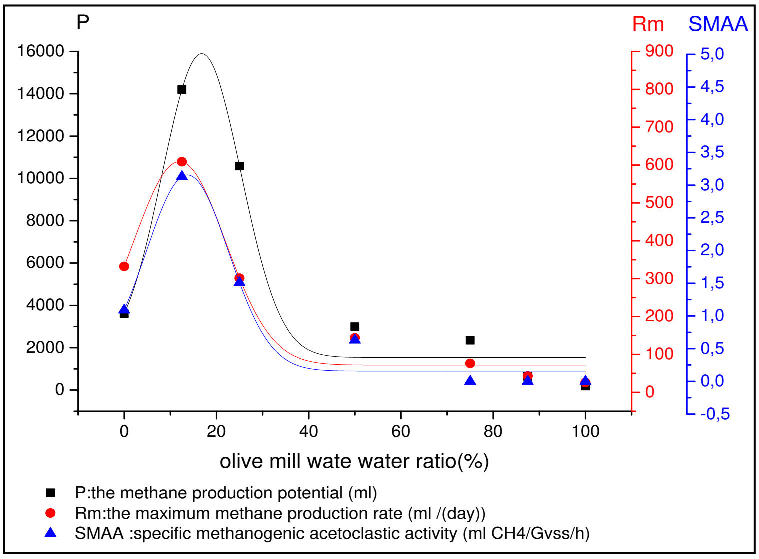

***Figure 5.** Gauss amplitude correlation between Olive Mill Wastewater ratio and the methane production potential, the maximum methane production rate, and specific methanogenic acetoclastic activity*

Table 9. *ANOVA analysis of regression*

	DF	Sum of Squares	MeanSquare	F Value	Prob>F
P	4	3.36048E8	8.4012E7	46.64	0.005
R_m	4	592609.95	148152.48	54.76	0.004
SMAA	4	13.36	3.341	33.76	0.008

P: the methane production potential
R_m: the maximum methane production rate
SMAA: specific methanogenic acetoclastic activity

Based on the adjusted correlation coefficient (R^2 > 0.9), we can approve a good agreement and advocates greater significance of the model.(Niladevi et al., 2009). ANOVA of the fitted model for the P, R_m, and SMAA (*Table 9*) demonstrates that the model is significant due to the F-value of 46.64, 54.76, 33.76 respectively and the low probability P-value ($p \leq 00$). Generally, an F-value with a low probability P-value suggests a significant regression model (Rene et al., 2007). The maximum value of P, R_m and SMAA are obtained from the (x,y) coordinates of amplitude, and that the Limit of synergistic effect is calculated from the addition of Xc to the W value, *Table 10* summarizes these results.

Table 10. *Optimization parameters*

Parametres	Maximum value	Olive mill wastewater ratio %	
		Optimum ratio	Limit of the synergistic effect
P (ml)	15897.39	16.79	25.33
R_m (ml /d)	609.1	12	21.98
SMAA (ml CH_4/VSS/h)	3.14	13.69	22.65

P: the methane production potential
R_m: the maximum methane production rate
SMAA: specific methanogenic acetoclastic activity

To verify the limited mixing ratio, by considering the waste activate sludge (WAS) as the main compound and the olive mill wastewater (OMW) as the additional mixing compound in this study, the calculation of the relative fraction "*f*" from the specific production of the co-digestion dived to the WAS mono-digestion alone was done. This

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52595274

factor give an exponential correlation (*Figure 6*) with good R^2 (0.962) and statistical significance (p = 0.016). Logically to obtain synergistic effect the "*f* "must be upper than1 (*f* > *1*).This condition is verified when the Olive mill wastewater ratio is lower than 22 (%).This result validate the result presumed by the Gauss amplitude model 21.98 and 22.65 (%) predicted by R_m and *SMAA* data, respectively.

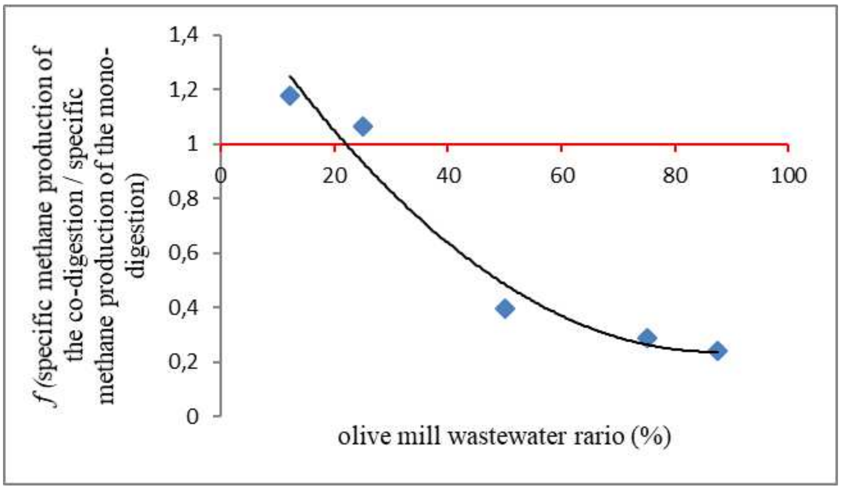

Figure 6. *Exponential correlation between Olive mill wastewater ratio and factor "f" of increase in the specific methane production*

Discussion

The GC-MS identification of phenolic compounds present in olive mill wastewater showed qualitative differences amongst the different research paper according to cultivars and their geographical origin (La Cara et al., 2012; Leouifoudi et al., 2014).

The best cumulative methane production was done at WAS/OMW ratio of 87.5/12.5 (12000 ml) without adjusted pH (neutral), this result is comparable to the result of codigestion of olive mill wastewater and swine manure established by Azaizeh and Jadoun (2010) with a 14000 ml of biogas under adjusted pH (neutral), at 38 ± 2°C for 11 days using Gadot sludge (25 g) or Prigat sludge (25 g) added to 250 ml of olive will waste water (Azaizeh and Jadoun, 2010). In our study the addition of OMW (WAS/OMW: 87.5/12.5) up to 72.34% in the cumulative production, this result is better comparativly to the codigestion of pig manure and OMW at pig/OMW ration equal to 60/40 which up to 40% the production of both substrates (Kougias et al., 2010).

The synergistic effect for co-digestion of waste activated sludge and olive mill wastewater at 87.5/12.5 mixture ratio was mostly attributed to a greater extent of volatile solids reduction and higher specific methane yield. This is a result of a supplementary requirement of nutrients and micro/trace elements from co-substrates, as the catalytic centers of the involved enzymes in methanogenic pathways (Pagés-Díaz et al., 2014; Xie et al., 2017). The olive mill wastewater is an additional source of Ni metal which is implicated in three recognized pathways of methanogenesis. This last one is regularly metal-rich enzymatic pathways when Fe is the most abundant metal, followed by Ni and Co, and smaller amounts of Mo (and/or W) and Zn. Fe is primarily present as Fe–S clusters used for electron transport and/or catalysis. Ni is either bound to Fe–S

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52595274

clusters or in the center of a porphyrin unique to methanogens, cofactor F430. Zn occurs as a single structural atom in several enzymes (Glass and Orphan, 2012). However, other origins of synergisms must additionally be considered, such as the optimization of the C/N ratio (Xie et al., 2017).

However, OMW alone and other mixtures have acidic pH and low biogas yield because the methanogenic bacteria are most efficient at pH 6.5–8 (Mao et al., 2017). Based on the pH value at the end of digestion (*Table.7*) the WAS/OMW ratios: 75/25 and 50/50 reinforce the system buffer capacity.

The obtained results show clearly that SMAA and the lag phase λ values are moderately varied with initial condition COD/ N, pH, TS, VS, and waste type. This can be done in the dynamic of biomass composition and to the selective synergistic effect of bacterial communities. Li et al. (2015) in their study of AD system, of cattle and/or swine manure by metagenomics assays, noted that the substrate type, the ratio of co-substrate, play major roles in the COD/N ratio of substrate and free ammonia which play a central factors in the development and structuring of the bacterial communities in AD systems.

This peak profile of correlation can be explained by the limitation of the AD at high amounts of OMW % in the medium of fermentation. Though the WAS microorganisms have a limited capacity to degrade the high molecular-mass polyphenols in OMW biotreatment (Sayadi et al., 2000) and the inhibition of AD of OMW imply polyphenolic compound and the long chain fatty acids, which are considered as a toxic compound in the system of the AD (Hamdi, 1996; Hernandez and Edyvean, 2008; Saha et al., 2011; Oz and Uzun, 2015; Al-Mallahi et al., 2016). According to Borja et al. (1997) the cinnamic, benzoic, caffeic and protocatechuic acids are an inhibitor of acetoclastic methanogenesis at a limit concentration.

The long-chain fatty acids present in OMW are also responsible for its toxicity to methanogenic bacteria (Hamdi, 1992). The oleic acid is present in high concentration in OMW (Sayadi et al., 2000; Visioli and Galli, 2002; Elkacmi et al., 2017) which gives a high concentration of oleates. Comparatively to Sousa et al. (2009) an oleate added have given a stoichiometric value considering complete oleate oxidation. This indicates that acetoclastic activity was affected by oleate, so methane production in these cultures could be justified just by hydrogenotrophic activity or a limited acetoclastic activity (Sousa et al., 2013). Referring to Wu et al. (2017) the improvement in methane production rate was limited to the oleic acid concentration.

Conclusion

These results are consistent with the batch conducted tests, where the best performance was observed through a clear peak correlation which describe that the optimum settings for the maximum value of methane yield and acetoclastic activity are delimited by OMW components. The lower performance degrees achieved for a high OMW amount in codigestion. Gauss amplitude function is a good model to predict the area limits of the microbial communities synergistic effect which are not able to avoid inhibitory effects associated with the inhibitors present in OMW. Further research studies are needed to determine the microbial and biochemical properties of substrates. In addition, a follow-up study on the effects of individually isolated inhibitors on process performance.

Abstract. In Azerbaijani part of the Greater Caucasus, which has been intensively developed in recent years in order to exploit recreational resources. Based on the interpretation of the ASP within the Azerbaijani part of the Greater Caucasus based on the derived from the effect of mudflow processes (the amount of material taken out, the erosive effect of the flow on the valley, the accounting of the mudflows and the basin as a whole, and the prevailing types and classes of mudflows, the geomorphological conditions of formation and passage mudflows, and statistical data on past mudflows) on the actual and possible damage affecting the population from mudflows a map-scheme was drawn up according to five-point scale. On the scale there are zones with a high (once in two-three years, one strong mudflow is possible) - V, with an average (possibility for one strong mudflow every three-five years) - IV, with a weak (every five-ten years is possible 1 strong mudflow) - III, with potential mudflow hazard - II and where no mudflow processes are observed - I. The synoptic-climatic conditions of mudflow formation have been studied, the mudflow links with macro forms of circulation over Europe and Siberia have been revealed.
Keywords: *modern dangerous geomorphological processes, recreation, precipitation, meteorological conditions, types of circulation, anthropogenic impact*

Introduction

Occurrence of catastrophic mudflows is one of the most serious problems, faced when developing mountain areas. Mudflow streams destroy various buildings, disrupt the functioning of infrastructure facilities, and may even lead to human casualties. Some recent mudflows that occurred in the world can be noted. On the night of April 1, 2017, the rivers of Mokoa, Sangoyako and Mulatos caused mudflow in Colombia, passing through 17 districts of the Mokoa city with 45 thousand dwellers. Eventually 254 people were killed, 400 people were injured, and 220 were missing [https://ria.ru/20170401/1491281111.html]. On August 8, 2017 a mudflow was responsible for killing of 23 people in the Sichuan province of China, destroying more than 70 buildings as well [https://ria.ru/20170808/1499983623.html]. On December 23, 2017, the mudflow and floods caused the death of about 90 people in the Philippines. Several dozens went missing [https://ria.ru/20171223/1511564592.html]. On the same day, 15 people were killed in the Los Lagos region of Chile as a result of the mudflow. About 200 houses were destroyed as well. The disaster disrupted supply of water and electricity [https://ria.ru/20171223/1511563855.html]. Many similar examples more can be noted. The above mentioned facts serve as an evidence for the topicality of studying mudflow hazard in the regions.

Mudflows are observable in almost all mountain and foothill regions of Azerbaijan. The mountain areas occupy about 60% of the territory of Azerbaijan, where over 17% of the population lives (Chernomorets, 2005). However, in some cases, the mudflow-resistant installations are ineffective and may aggravate the consequences of mudflow processes, since they were built without sufficient scientific justification. Development of scientifically grounded methods of protection of settlements, industrial enterprises, agricultural regions, etc. from mudflows is the most urgent problems of further development in the mountainous regions of Azerbaijan.

In May-June of 2018 heavy rains in the mountainous areas of the Greater Caucasus caused mudflows to occur that left serious problems in Zagatala, Balakan, Agsu, Gabala, Guba, Shamakhi, Ismayilli and other districts. The mudflows on Agsu River flooded the sown areas of the villages of Basgal, Kohne Dahar, Sulut and Zarnava of the Ismayilli region, and destroyed the Basgal-Sulut Bridge. The mudflow, observed on the Goychay River in Goychay district damaged two two-storey residential buildings and also several private houses. 45 families were evacuated. In the Mashadganly village of Agsu district, the Agsu River washed off the road that connects the village with a population of 1500 people with the district center. The poles installed for power transmission and telecommunications were destroyed, water- and gas supply of the village was disrupted, and irrigation channels became useless completely. In the village of Madrasa, the Shamakhi district, a road connecting the village with the district center was damaged. Relatedly, the bridge was broken down, and communal facilities were heavily affected. In the villages of Buynuz and Diyalli of the Ismayilli district, the mudflows on Pirsaat River resulted in destruction of the telephone- and electricity lines. Mudflow on Dalichay River nearby the Katekh village of Balakan district affected more than 50 houses, leaving livestock and poultry killed and 8 small bridges destroyed as well. Electricity facilities and sources of drinking water were also damaged. The territory area of flooded areas made up 150 ha in total, including 10 ha of tobacco, and 140 ha of wheat, barley and corn plantations. The village roads, as well as part of the road of Yevlakh–Zagatala–Lagodekhi were damaged. Mudflow on Bum River (tributary of the Kishchay river) destructed the bridge connecting the Tikanly village with the city of Gabala. Residents of the village received assistance (*Fig. 1*). Similar processes on a smaller scale were recorded in the adjacent territories as well.

Figure 1. *Bridge demolished by the mudflow in the valley of the Bum River (tributary of the Kishchay River)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52755291

Mudflows do not occur accidentally. Typically, they are preceded by a long period (stage) of pre-catastrophic changes (Alizade, et al., 2015). At present, there is no unambiguous answer to the question of the mechanisms of the occurrence of mudflows. In most cases even in the presence of all the necessary conditions, origination of this natural disaster is hardly possible without some additional impulse, whether it is the impact of one process (abundant snowmelt, rainstorm and others) or the total effect of many factors. Some territories in this regards, despite all the prerequisites, may remain stable for years. Others, on the contrast, quite unexpectedly become the place of the formation of catastrophic mudflows. However, “unexpectedly” does not mean “illogically” (Barinov, 2010).

In Azerbaijan, the most hazardous region in terms of debris mudflows is the territory of the Greater Caucasus (41°55’ n.l.-39°56’ n.l.; 46°46’ e.l.-50°33’ e.l.), the region that has become increasingly popular among tourists in recent years (*Table 1*).

Here, practically the whole spectrum of contemporary hazardous geomorphological processes (CHGP) such as high seismic activity, avalanches, rockfalls, landslides, screes, mudflows, etc. are observable.

Recreational and tourism nature of the development in the Greater Caucasus includes also the use of the territories in remote and inaccessible places where construction of various facilities is already underway. Relatedly, it is necessary to develop principles for forecasting, protecting and managing the CHGP.

In the Greater Caucasus, the duration of mudflows is different by various regions. On the southern slope, 45.5% of the mudslides typically last up to 6 hours. Short-time mudslides are observed in the basins of the rivers of Goychay, Girdiman and Agsu. To the west of the Goychay basin, the duration increases. The most continuous mudflows are observed in the western part of Greater Caucasus. The duration of mudflows in the northeastern Greater Caucasus and also Gobustan is 1 to 4 h as usual (80% of the total mudflows). On the southern slope of the Greater Caucasus, the maximum of mudflow is observed between 20.00 and 22.00, whereas on the northeast slope and Gobustan in 16.00-18.00 hours. Falling rainfall and passing mudflows in the evening hours are conditioned by convective processes, since invading cold air masses are heated above the plains. This heating leads to the development of convective ascending currents and the formation of cumulonimbus clouds and mudflow-forming rainfall.

The purpose of this study is to research the conditions of the formation of mudflows, to identify the main geomorphological factors that play a large role in the formation of mudflows, as well as to establish the connection of the passage of mudflows with circulation types with the identification of primary features.

Materials and methods

The issues of exploring distribution and differentiation of mudflow foci by different altitudinal belts, as well as the study of synoptic and climatic conditions of mudflow formation and the identification of primary mudflow hazard features are the important problems, solution of which can allow develop specific measures on reducing the formation of mudflow foci and the passage of mudflows.

The materials of satellite imagery (SRTM) were used as the initial data for creating the map-scheme of mudflow hazard of the studied region.

Table 1. *Dates of passage of the dangerous mudflow processes in the Azerbaycan part of the Greater Caucasus for 2016-2018. (Compiled by Tarikhazer, 2018)*

№	River	Date of passage of mudflow	Duration of mudflow (hours)	The causes of beginnings of mudflow	Consequences of mudflow
1.	Gudialchay	17.04.2016	2	Shower	The bridge in Guba district is destroyed
2.	Pirsaatchay	18.04.2016	2	Shower	The material damage was caused to the villages of Ranjbar and Navai of the Shamakhi district
3.	Pirsaatchay	09.05.2016	2	Shower	The crop areas were destroyed and perished livestock in the villages of Archiman and Chagan of Shamakhi district
4.	Gusarchay	19.05.2016	2	Shower	The road in the village of Guzun of the Gusar district is destroyed
5.	Gudialchay	20.05.2016	2	Shower	The bridge in the village of Tuler of the Guba district was destroyed
6.	Kurmukhchay	12.06.2016	2	Shower	The material damage was caused to the houses of the villages of Gakhbash and Ibakhly of the Gakh district
7.	Pirsaatchay	12.06.2016	5	Shower	The damage was caused to Kurdmashy, Gushendzhe, Garakollug, Balik, Enishdibi, Talysh, Yenikend, Shukurchyu and Ashygbayramli villages of the Ismayilli district. The mudflows destroyed, orchards, grains and grape fields, and livestock perished. Part of the road of Garamyaryam-Ismayilli was destroyed. In the village of Gushendzhe mudflows destroyed one house, whose resident was seriously wounded
8.	Gusarchay	25.06.2016	2	Shower	Damage was caused to more than 20 houses, crop areas of the village of Guzun of the Gusar district. The livestock perished. Ruined bridge
9.	Kishchay	03.07.2016	2	Shower	The bridge connecting the village of Kish of Sheki district with the district center is damaged. 35 villagers were evacuated
10.	Lazachay	01.09.2016	3	Shower	53 people of village of Laza of Gusar district evacuated. Partially destroyed the Guba-Khinalig road and the bridge for 29 km this route. The traffic was interrupted. The mudflows also caused damage to residential buildings in the village of Utug in the same district, electricity was not delivered to this settlement
11.	Gudialchay	01.02.09.2016	5	Shower	About 10 villages of the Guba region were damaged. The mudflow destroyed the supports of power lines in the village of Krasnaya Sloboda. The section of the road Guba-Khinalig was destroyed. The mudflow destroyed almost 30 pillar of telecommunications, as a result, communication with 20 settlements of the district was interrupted. The greatest damage was caused to the automatic telephone exchange, functioning in the villages in the directions of Gonagkent-Sokhub, Kupchal-Gechresh, Zargova-Chichi and Khinalig
12.	Damiraparanchay	02.09.2016	2	Shower	The mudflows made traffic difficult on the central roads of the Gabala district. The mudflow washed away the car (VAZ-21015 model)
13.	Geychay	02.09.2016	4	Shower	In the villages of Istisu, Chaygovushan, Galynjag and Sumagallli of Ismayilli district, damage was caused to crop areas and gardens. The poultry has perished

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52755291

14.	Agsuchay	20.10.2016	3	Shower	Mudflows destroyed the coastal dams near the villages of Mashadganly and Agalarbeyli of Agsu district, as well as in the city of Agsu. The mudflows flooded the mountain village of Kyalva, interrupting the communication with the rest of the district
15.	Turyanchay	17.05.2017	2	Shower	Damage to crop areas and gardens of Gabala district is damaged
16.	Agsuchay	25.05.2017	2	Shower	The material damage was caused to the villages of Kechmaddin, Archiman and Talishnuru of the Shamakhi district. Power poles are destroyed
17.	Shinchay	29.05.2017	3	Shower	Roads were destroyed in the village of Kichik Dehne in the Sheki district
18.	Jeyrankechmez	02.07.2017	2	Shower	76 km of the Baku-Shamakhi road is damaged
19.	Delichay (tributary of the river Talachay)	14.04.2018	5	Shower	In the village of Mazikh of Zagatala district homestead land of 200 houses flooded, 15 houses are damaged, poultry has perished. The mudflows were washed away the a private car of the “VAZ 2106” model. Damage to power lines and material damage was causedto houses and household lands of the villages of Mamrukh, Hoytala, Yolayryj, Mago
20.	Agsuchay	11.05.2018	2	Shower	The crop areas in the villages of Basgal, Kekhni Dahar, Sulut and Zarnava of the Ismayilli district, were flooded, and the Basgal-Sulut bridge was destroyed
21.	Talachay	14.05.2018	4	Shower	In the village of Mazikh of Zagatala district the crop areas are flooded. 4 people injured
22.	Damarchin (the tributary of the Kishchay river)	02.06.2018	4	Rains	A pedestrian bridge has been destroyed in the city of Sheki on the road to the fortress Naryngala and Shambagy
23.	Geychay	03.06.2018	3	Rains	Damaged two two-story residential buildings and several private houses. 45 families were evacuated
24.	Agsuchay	03.06.2018	2	Rains	In the village of Mashadganly in the Agsu district, the mudflow was washed away the road that connects the village (with a population of 1500 people) with the district center. The supports of power lines and telephone communications were destroyed, water and gas supply to the village was disrupted, irrigation channels were completely destroyed
25.	Pirsaatchay	04.06.2018	2	Shower	In the villages of Buynuz and Diyalli of the Ismailli district, telephone and power transmission lines were destroyed
26.	Dalichay	12.06.2018	4	Shower	In the village of Katekh of the Balakan district, more than 50 houses were flooded, livestock and poultry were perished, 8 small bridges were destroyed. Power lines, sources of drinking watere was damaged corp areas of a total area of 150 hectares, including 10 hectares of tobacco, 140 hectares of wheat, barley and corn was flooded. The village roads and part of the road Yevlakh-Zagatala-Georgia are damaged
27.	Agsuchay	12.06.2018	2	Shower	In the village of Madrasa of the Shamakhi district a road has been damaged that connects the village with the district center. The bridge was destroyed, livestock was perished
28.	Bumchay	13.06.2018	3	Shower	The mudflow destroyed the bridge connecting the Tikanly village of the Gabala district with the district center. Residents of the village received assistance
29.	Agsuchay	17.06.2018	2	Shower	The road and power lines in the Machachy village of Ismayilli district have been destroyed. Residents were left without light, water supply was disrupted. The cultivated areas and orchards are blurred

Data SRTM represent the processed results of a radar topographic survey of the surface of the globe, made by the method of radar interferometry, produced from the American ship “Shuttle” in February 2000.

The result of the survey was a digital model of relief of 85% of the Earth’s surface. For data processing SRTM we used a software ArcGIS package.

The main operations were performed in ArcGIS Spatial Analyst, 3D Analyst and Geostatistical Analyst applications.

In this work, the materials about overpast mudflows (1891–2016), rainfall ≥20 mm/day for the mudflow period (1964–2014), and about types of circulation according to B. D. Dzerdzeevsky (1899-2015) and G. Ya. Wangenheim (1891-2002) were used.

Results

In the territory of Azerbaijan, mudflow processes are observed more often and on larger scale in the Greater Caucasus. Formation, development and geographical spread of these processes are considerably driven by geological and tectonic conditions (which, combined with other contemporary exogeomorphological processes, contribute to the formation of scress, rockfalls, landslides, etc.), lithological conditions (sedimentary deposits of the Jurassic, Cretaceous and partly Paleogene-Neogene systems such as clay shales, sandstones, limestones, marls, which, in connection with the intensive weathering, create huge loose and detrital materials), tectonic structure of the mountains (the latest tectonic movements and discontinuous infractions with a large amplitude), seismicity of the territory (7-8 and higher seismicity points), the amount of precipitation (on the southern slope, within the heights of 1500-2700 m it falls at 900-1600 mm), etc. (Alizade, et al., 2015). The CHGP data in the conditions of high anthropogenic load reflects the base for hazard posed to infrastructure of Sheki-Zagatala, Shamakhi-Ismayilli, Guba-Khachmaz and other territories. In these regions, cities, significant number of settlements, tourism complexes, highways, and electricity and communication lines that contribute to the demographic and industrial potential, are typically located on the cones of the rivers of mountain areas, as well as terraces (*Fig. 2*) and seismogenic-gravitational blocks that are linked to risk zones.

Contemporary and latest tectonic movements. Endogenous processes

The Greater Caucasus was formed as an alpine orogenic structure between the Scythian and Transcaucasian epihercine plates (Alizade, 2004). This is a megantiklinorium that covers a narrow strip of the Caucasian geosyncline and the adjacent parts of the Scythian and Transcaucasian epihercine plates.

Longitudinal faults of the north-western stretching play an important role in the development of the Greater Caucasus, since they contributes to high seismicity of the region. Transverse (Transcaucasian) deep faults play an important role in the structure of the Greater Caucasus as well (*Fig. 3*).

The Greater Caucasus is characterized by the most intense manifestation of the latest tectonic movements. In the late Sarmatians, most of the territory (with the exception of the Watershed Range) was below sea level, and the mountain peaks had a height of 600-800 m. The total sweep of the newest uplifts of the Greater Caucasus at the tops of mounts of Bazarduzu, Shahdag and Tufandag during the Pliocene-Quaternary period exceeded 3600 m (Budagov, 1993).

The existence of a system of longitudinal faults separating the zones of uplifts from the descending zones in the region indicates the folded-block character of the development of the latest tectonic movements and the block structure of the morphostructures of the Greater Caucasus (Alizade, et al., 2016).

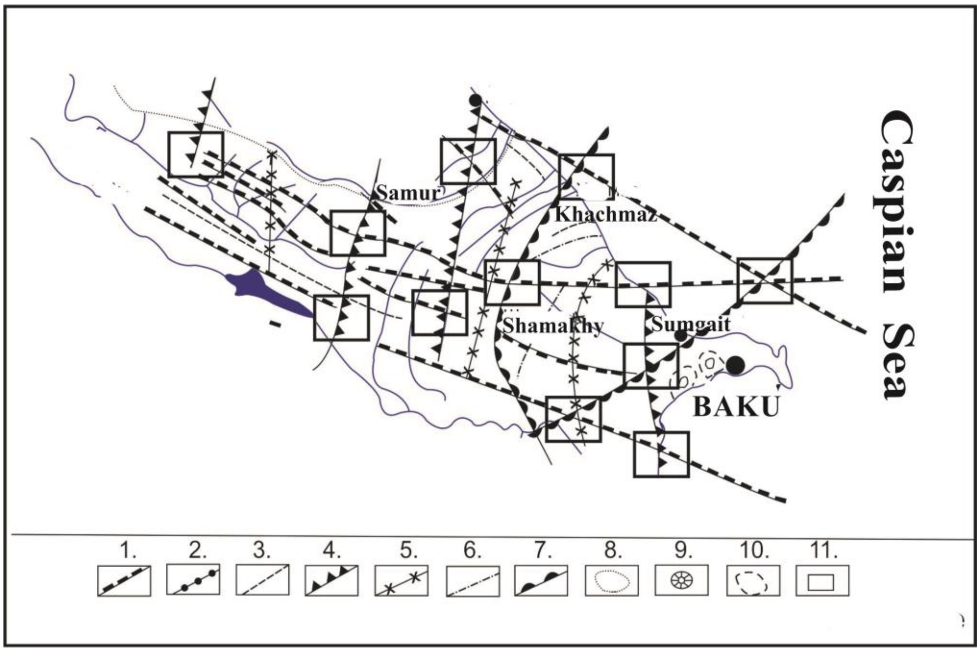

Figure 3. *Map of transverse (Transcaucasian) deep faults of the Greater Caucasus (Compiled by E. K. Alizade)*

Lineaments corresponding to faults (thrusts and reverse faults) of the longitudinal (general Caucasian) direction:

1. Regional deep faults, which limit large longitudinal fold-block stages
2. Local faults corresponding to the boundaries of longitudinal fold-block morphostructures
3. Discontinuous violations that determine the details of morphostructures

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52755291

Lineaments corresponding to faults (fault-shifts) of the transverse (anti-Caucasian) direction:

1. Regional deep faults, limiting transverse megablocks
2. Local faults corresponding to the boundaries of transverse block segments
3. Breaking violations
4. Large interregional diagonal disjunctive zones
5. The contour of the Samur ring object
6. Large volcanic centers
7. Ring structures (tectono-volcanogenic)
8. "Geodynamically tensional fields"

The morphostructures of the Greater Caucasus are characterized by the alternation of longitudinal (general Caucasian) and transverse steps. Their development is due to differentiated neotectonic uplifts along longitudinal and transverse deep faults with an amplitude of uplift at +3–3.5 km. Features of the neotectonic regime have determined the formation of high-altitude morphographic steps in the Greater Caucasus and the corresponding spectra of high-altitude landscape belts, as well as the specifics of the manifestation of CHGP within their boundaries. Seismic phenomena are confined to areas of contrasting relief and active modern tectonic movements as well as to zones of active deep faults and places of their intersection, i.e. morphostructural nodes.

The seismotectonic factor defines the development of avalanches, mudflows, landslides, screes and rockfalls. Intensive gravitational displacements of detrital masses are observed particularly in the earthquake foci. On the tectonically tense slopes with high relief energy, the regime and intensity of the gravitational processes are sensitive in regard to earthquakes of 3-4 points. The talus and scree processes become activated on the slopes of 40° or more steepness, where conditions for the formation of mudflow foci are shaped. Landslides are activated on slopes of 15° of steepness. Among all factors of mudflow development, the seismotectonic factor serves as the basis for the formation of foci of the solid phase of mudflows and the unpredictability of the hazard level (Laperdin et al., 2011).

Exogenous processes

The development and intensity of exogenous processes are significantly influenced by two factors of fracturing:

1) The conditions of rocks and the grade of fissuring of rocks. In the high mountains of the Greater Caucasus, sandstones, sandy, clayey and calcareous shales, limestones and other rocks are widely spread. The rocks are easily destroyed under the influence of physical weathering. In the mid-mountain and low-mountain belts clay rocks are most common, and are subject to intense erosion;

2) Climatic conditions (regime, amount, annual distribution and formation conditions of mudflow-forming precipitation; air temperature, etc.). The highest precipitation falls in the middle belt of Greater Caucasus region (up to 1600 mm), whereas the lowest amount is recorded on the southern coast of the Absheron Peninsula (up to 200 mm). The average annual air temperature is also unevenly distributed: in the highland belt it is from below 0 to +2 °C; in the mid-mountain belt it is from 6 to 10 °C; and in the lowland belt and lowland zones from 11 to 14.5 °C. The diurnal amplitudes of air temperature in the zone of formation of mudflow foci, as an indicator of physical weathering, fluctuate within 8-12° (Ayyubov, 1962).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52755291

It should be noted that climatic factors are involved in the pre-formation of loose mud material, while other factors, including heavy rainfalls are directly involved in the process of mudflow formation. As analysis of data on mud-forming precipitation shows, mudflows in the territory of Azerbaijan are formed if diurnal precipitation is 20 mm and higher per day (Nabiyev, 1985).

Extreme values of mudflow-forming rains in different mudflow-prone areas vary within different limits. For example, on the southern slope of the Greater Caucasus the amount makes up 20-188 mm, while in the northeastern Greater Caucasus and Gobustan it is 20-132 mm. The maximum amount of mudflows in the main mudflow areas is observed during the period of the greatest frequency of abundant precipitation. The number of days with a daily rainfall of ≥20 mm on the southern slope of the Greater Caucasus increases towards an altitude of 2200-2400 m, whereas on the northeastern slope precipitation increases towards 3000-3200 m. It is defined that the main amount of precipitation with a daily amount of ≥20 mm falls out at relatively short intervals, during which the average intensity was very high.

According to the analysis, the share of the storm (duration and amount of precipitation) in the overall abundant precipitation of ≥20 mm is various by mudflow-prone areas, since on the southern slope of the Greater Caucasus, they constitute 20.1 and 58.2% respectively, whereas on the northeastern slope of the Greater Caucasus and Gobustan 15.2% and 50%. It was revealed that mudflows occur during continuous rains that last for several hours, accompanied by short showers, with high intensity.

Quantitative and qualitative data of macrocirculation were determined to analyze large-scale processes leading to downpour precipitations and at their high intensity also to mudflows in the study area. Meantime, to quantify the types of circulation, the criteria of the general index, proposed by Katz (1973) were used. The study showed that in days of mudflows, mainly meridional processes predominated, but in some cases the main role was played by zonal processes. It should be noted that, as a rule, zonal processes in the territory of the South Caucasus, including Azerbaijan, do not result in heavy rainfall and mudflows. Typically, the fall of intense downpours and the formation of mudflows can be observed only in the conditions of invasion of cold, moist and unstable-stratified air masses, which occurs only in meridionally-developing processes. A study of mudflows affected by zonal processes showed that a few days before the beginning of mudflows over Western Europe, a meridional conversion of circulation occurred, as a result of which cold air masses in the rear part of the high-rise hollow trough invade the southern regions of Western Europe across the British Isles, where the upper-level frontal zone (ULFZ) and cyclogenesis occur.

Further, the high-rise hollow and the cyclone gradually shift to the east – towards the territory of Asia Minor and the South Caucasus. In other words, the formation of mudflows occurred in condition of interaction of cold air masses, entering the ULFZ system during the meridional transformation period. While meridional transformations happen, anticyclones are formed under the high-level crest in the lower troposphere over the north of Europe. In the days of mudflow formation they shift to the central regions of the European part of Russia. The stationing of these anticyclones takes place when the cyclone is blocked over Asia Minor – the east of the Mediterranean Sea. It should be noted that the division of atmospheric processes in a quantitative way into zonal and meridional processes gives a general idea of the directions of air currents at certain period of time, but this is not always sufficient for a detailed description of the processes entailing abundant downpours and mudflows. Therefore, we preferred the use

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52755291

of qualitative methods for determining the nature of the circulation as the more expedient way. To identify the relationship between atmospheric circulation and mudflows in Azerbaijan, circulation types were used in accordance with the classification of Wangenheim (1935) and Dzerdzeevskij (1975). The simpler form of typing of atmospheric processes was considered by Wangenheim (1935), who proposed three types or forms of basic atmospheric processes: western (W), meridional (C) and eastern (E). In the case of type W, the western conveyance of air masses prevails; in the case of C, transportation occurs from the north-west and the north, whereas for E the direction is from northeast. The study found that there is a direct connection between the mudflows occurring in Azerbaijan and the E processes, namely, the intensification of these processes makes mudflows more active in the research area. Conversely, during the W processes, mudflow formation is enfeebled. The obtained results are justified not only in the Caucasus, but also in the regions of Central Asia (Dzerdzeevskij, 1975), since on the rivers of these territories the activation of mudflow phenomena is observed when E processes prevail, whereas it weakens during W processes. When macroforms E prevail, then precipitation falls out above the norm in Central Asia, Kazakhstan and also the Caucasus, which leads to an increase in the likelihood of mudflow formation. When W processes dominate, precipitation is low in those regions, and mudflow activity is weakened. In the case of western transportation, the high-pressure axis is not indifferent at what latitude it is.

Therefore, the processes W can be divided into two subtypes (W_1 and W_2). This division shows that the weather conditions in the territory of the South Caucasus, as well as along its latitudes are different. In the first case (W1), the high-pressure region covers the southern regions of Europe and consequently, while this subtype is present, as in Southern Europe, dry weather prevails.

In the case of subtype W_2, on the contrary, the anticyclone area is located at latitudes north of 50° northern latitude, while cyclonic weather with sufficient moisture prevails over the southern regions of Europe, including the South Caucasus (Sheкo, 1980).

To estimate the synoptic situations responsible for the formation of mudflows, the classification of atmospheric circulation types, proposed by Dzerdzeevskij (1975), was used as well.

It was established that the mudflows in Azerbaijan are mainly formed under the subtype 12a (the subtype of the northern meridional circulation) and 13l (the subtype of the southern meridional circulation that prevails in the summer). These subtypes were observed during the all months with high probability of occurrence of mudflows in the period of 1960-2014. They led mudflow-forming precipitation. In certain years, some types were more intense than others, and differed in terms of the increase in frequency. For example, during the decrease in the frequency of subtype 12a (1980-1992 years), an increase in the subtype 13l was observed, whereas in 2008-2014, the contrary was observed. In the period of 1899-2014, the participation of macroprocesses of the subtype 12a was always noticeable in the mudflow formation. However, the subtype 13l processes became intensified since the beginning of the 1960s, and their frequency increased from year to year (*Figs. 4* and *5*).

Under the subtype 13l, the exit of southern cyclones to the territory of the Northern and Southern Caucasus was observed. These cyclones are characterized by high speed of movement and significant temperature contrasts. Relatedly, within the short time, they entail rainfall leading to activation of mudflows. In the case of subtype 12a a blocked anticyclone is formed over the Siberia and stretched to the southern regions of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52755291

Western Siberia. At this time, the cyclones formed over the Mediterranean Sea, move to the territory of the South Caucasus, and farther to the north-east. When warm and moist masses formed over the Mediterranean Sea meet cold arctic air masses, the atmospheric fronts become activated, as a result of which precipitation falls out above the norm in the study area that causes the mudflow activity of the rivers to increase.

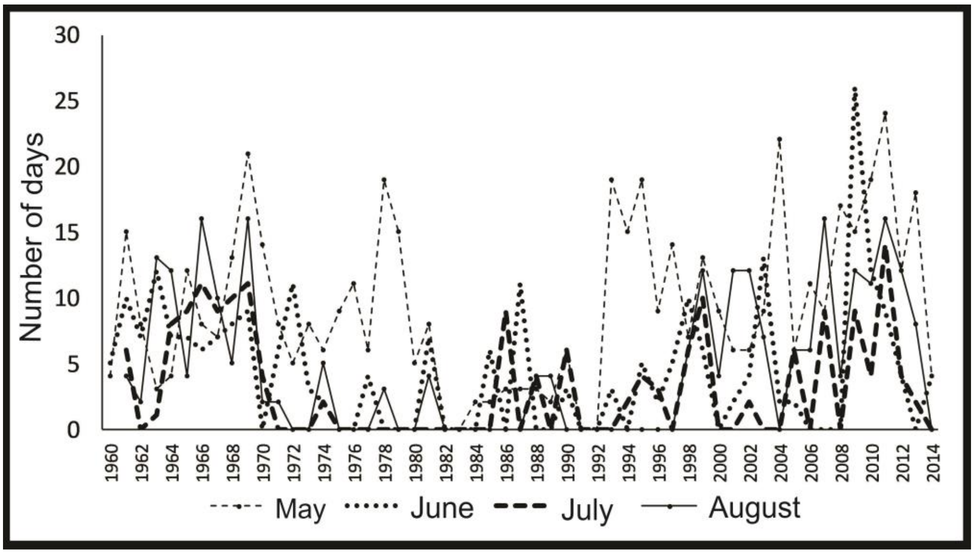

Figure 4. *Repeatability of the circulation type 12a in the mudflow dangerous months*

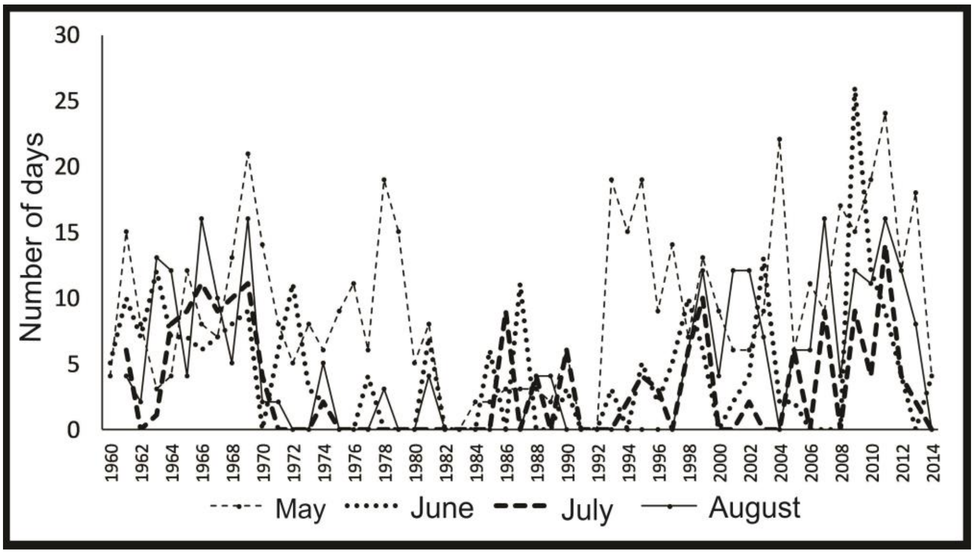

Figure 5. *Repeatability of the circulation type of 13l in the mudflow dangerous months*

3) Relief (depth of dismemberment, change of absolute heights, exposure of slopes, direction of watersheds, etc.). A significant part of the territory of Greater Caucasus consists of slopes, the steepness of which exceeds 10-15°. This feature left an imprint on the nature of the relief-forming processes. Steep slopes cover significant (upper and middle) parts of river basins. Within the high mountains, intensively dissected by erosion, denudation and nival processes, they are characterized by the development of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52755291

glacial and gravitational exogenous processes. The energy of the relief and the slopes are the determining conditions for the speed, nature and massive motion of the soils on the slopes. The slopes of the mountains and ridges of the Greater Caucasus, composed of clayey shales, sandstones, marls and limestones, are distinguished by the development of planar and linear flushing, different rates of drift and accumulation intensity. For example, in the headwaters of the Gusarchay, Velvelichay and Gudialchay rivers, the steepness of slopes of river valleys is more than 45° (Alizade, et al., 2015; Tarikhazer, et al., 2017).

Here, the movement of detrital masses occurs at a high speed, and the removal of the weathered material predominates over the speed of accumulation of debris. Consequently, the slope factor here is the main condition for the mass movement of detrital material, regardless of the physical and mechanical properties of the soils. However, such types of mass movements as landslides in most cases do not depend on the slope of the slopes, rather being a result of the breaking of stability in relationship with the lithological differences. In the highlands, where the energy of the relief is more than 1000 m, and the steepness of slopes is more than 30-40°, the flushing intensity exceeds 1 mm/year, while in the low mountains it is 0.10–0.5 mm/year.

The largest washout from the surface is observed in the mid-mountain zone, which is apparently due to the denudation features of the bedrocks and the destructive influence of the climatic factor. In general, the speed of denudation is 0.5 mm/year in the Greater Caucasus, while in the highland and in part the middle part, it is 1 mm/year.

4) Density of the river network has a great influence on the depth of the relief fragmentation. In the high-mountain and mid-mountain zones of the Greater Caucasus, the density of the river network is 0.4-0.7 km/km^2, and in the low-mountain and plain zones, it makes up 0.1-0.2 km/km^2. Eventually, the mudflow-forming factors, depending on their combination, serve as the basis for the development of mudflow streams which poses the level of risk in this territory.

The flows are typical for all the high-altitude belts of the Greater Caucasus, and the most typical are the mud flows, the mud- and stone flows, and also the debris (stone) flows which are typical for the southern slope of the Major Caucasus Ridge. The rivers of the southern slope of the Greater Caucasus are typical mudflow rivers, which are different in terms of frequency, strength and type of mudflow. The most powerful mudflows are typical for Kurmukhchay, Shinchay, Kishchay, Balakanchay, Demiraparanchay, Tikanlychay and other rivers. Flows of mud composition are typical for rivers, the basins of which are composed of clays and shales (tributaries of Talachay, Mukhakhchay, Jeyrankechmaz, Sumgaitchay and other rivers). Mudstone and stone flows (debris flows) are developed in river basins, the upper parts of which are composed of shales, sandstones, limestones and other rocks (Gamidova, 2011).

Within boundaries of the basin of the Kish River, the most powerful mudflow tributary river is Damarjig, the territory area of basin of which is 66 km^2. It lies from north to south for a distance of 12 km (*Fig. 6a* and *b*). Forests are developed only in the lower parts of the valley up to 2000 m of elevation. Above this altitude, steep rocky slopes, devoid of vegetation are found. The thickness and spatial distribution of slope deposits are in relationship with the nature of the relief and the lithology of the rocks, as well as the impact of mudflow-forming torrential rains.

In the basin of Kurmuk River, the main mudflow-sensitive tributary is Bulanigsu (with total area at 18 km^2). This river originates at an altitude of 3200 m. In its lower

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52755291

part, there is a forest with an area of 4 km^2, and the rest of the territory is devoid of vegetation because of the steep slopes. The natural conditions of the basin determine the intensive co-development of subnival and gravitational, as well as gravitational and denudation processes. The main tributary of Shin River with high prone to mudflow process is Shikhgaflan (with total area at 12 km^2). Its waters are formed on the slope of the Garagaya Mount (3460 m). In the lower part of the river there is a forest with an area of 2 km^2, while the rest of the basin consists of rocky slopes with a small area of mountain meadow landscapes. Babachay is another tributary of Shin River characterized by occurrence of mudflows. Mudflows are observable also in the basins of the rivers Katekhchay, Talachay, Mukhakhchay, Dashagylchay (*Fig. 7a* and *b*), Kungutchay, Filfilichay, Tikanylychay, Dyamiraparanchay, Gumbashchay, Lyakitchay, Zayzitchay, Gashgachay, Gamzalichay and others flowing on the southern slope of the Greater Caucasus (Tarikhazer, et al., 2013, 2014).

In this research, the hearts feeding the mudflows are grouped morphologically as follows: screes (the feeding areas of Shinchay, Kishchay, Damiraparanchay, Mazymchay and other rivers); rockfalls (high-mountain areas in the basins of Kurmukhchay, Tikanylychay and other rivers); moraines (Kishchay, Kurmukhchay, Vandamchay and other rivers); landslides (the upper parts of Kishchay, Balakanchay, Filfilichay, Khalkhalchay, Mukhakhchay, Gabalachay, Dashagylchay and other rivers) (Tarikhazer, et al., 2013, 2014, 2015).

On the northeastern slope of the Greater Caucasus, mudflows are observed mostly in the basins of Gilgilchay, Atachay, Shabranchay, Devechichay, etc. rivers. Traces of mud-stone mudflows in the form of mud-shafts and mud masses are well seen in the wide floodplains of the rivers Gilgilchay and Atachay. Origination of flows of mud and stone composition in these river basins is obviously associated with the widespread development of landslides as well as the co-development of landslides and mudflows in the catchment areas of these rivers (Tarikhazer, 2018).

In the arid-lowland zone, typically the formation and stream of mud as well as the related flat and diffuse forms of hardened debris are observed. Often solidification of muddy mass can be observed at the bottom of ravines and girders due to their "enrichment" with silt and clay inclusions in conditions of the short-term downpours, the waters of which are one of the main driving factors (Khain, 1984).

a b

Figure 7. ***a*** *Upper detrital cone of the Dashaghlachay River.* ***b*** *The detrital cone of the Dashaglychay River on 1.5-2 km below the village of Bash-Dashagyl*

Hearts of mudflow formation are confined mainly to extensive erosion catchments and massifs of landslide- and mudflow origin. Foci of mudflow of such types as erosion funnels are typical for high-mountainous parts of the basins of the rivers Gudialchay, Jimichay, Babachay and Gusarchay. The mudflow foci of basins of such rivers as Gilgilchay, Atachay, Tugchay, Shabranchay and Takhtakorpuchay are associated with flows of landslide, as well as flows of landslide and mudflow origin. In this regard, Atachay River can be shown as the most typical case. Here, the landslide massif of Bakhyshly serves as the foci of the mudflow formation in general related to watercourse stretched from Bakhishly village to Halanj village at a distance of 6-8 km. Such similar hearts are available in the valley of the Velvelechay River between the settlements of Gonagkend and Afurja. In the southeastern Greater Caucasus, Jeyrankechmaz, Sumgaitchay, Pirsaatchay, etc. can be shown as examples for mudflow rivers (flows of mud composition) as well (Alizade, et al., 2015 Tarikhazer, 2018).

Proceeding from the above, it follows that in the process of mudflow formation the considerable role is played by the high-mountainous (rocky) belt (2200-3000 m of altitude and more), since here, contemporary exogenous processes (especially physical weathering) are active. In the mid-mountain belt at 1200-2200 m of altitude, the slopes are densely covered with forest vegetation, which protects the surface from intensive erosion and weathering. In the low-mountain belt (from 400-800 m to 1200 m), the vegetation cover, the decrease in the energy of relief, the moderate contrast of the daily temperature variation and other factors prevent erosion and weathering (Alizade, et al., 2016)

Based on the interpretation of the aerospace images within the Azerbaijani part of the Greater Caucasus, a map-scheme reflecting hazard rate of mudflow processes (in terms of the volume of transported materials; the erosive effect of the flow on the valley; occurrence of mudflows in the tributaries and the basin as a whole; types of the prevailing types and classes of mudflows; the geomorphological conditions of origination, formation and passage of mudflows; statistical data on the happening mudflows), as well as actual and possible damage posed on the population, was drawn up (*Fig. 8*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52755291

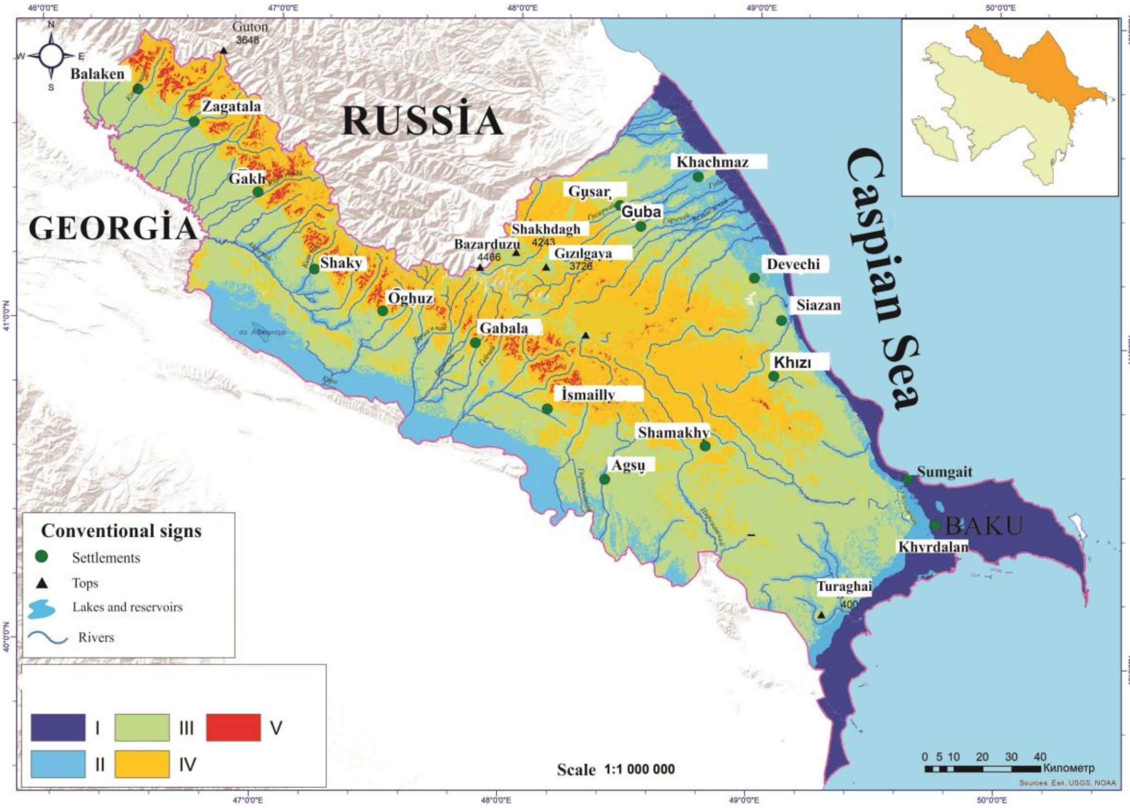

Figure 8. Map-scheme of mudflow hazard in the Azerbaijani part of the Greater Caucasus (compiled by Tarikhazer, 2018). Territories, where there are no mudflow processes - I point. Territories with potential mudflow hazard - II points. Territories with a weak mudflow hazard (once in 5-10 years is possible 1 strong mudflow) - III points. Territories with an average mudflow hazard (once in 3-5 years is possible 1 strong mudflow) - IV points. Territories with high mudflow hazard (once in 2-3 years is possible 1 strong mudflow) - V points

As follows from the map-scheme, the areas with high mudflow hazard include the basins of the rivers Mazymchay, Balakanchay, Katekhchay, Talachay, Mukhakhchay, Gashgachay, Kungutchay, Dashagylchay, Filfilichay, Vandamchay, Goychay (mudflows of water- and stone composition); the basins of the rivers Kurmukhchay, Shinchay, Tikanlychay, Bumchay, Demiraparanchay, the upper parts of the Girdimanchay, Pirsaatchay, Sumgaitchay, Tugchay, Gilgilchay, Velvelichay and Atachay (flows of mud- and stone composition); and the basins of the rivers Devechichay and Shabranchay (mud flows).

The areas with medium mudflow hazard include the basins of Garachay, Gudialchay, Gusarchay, Agchay, Jagajugchay and other rivers.

The areas with low mudflow hazards are the arid valleys and gulches of the Ajinohur foothills, the Gobustan, the southeastern extremity of northeastern Azerbaijan, and the eastern extremity of the Gusar inclined plain. Here mudflows occur in ravines and gulches, being a muddy and stony in their nature.

Intra-mountain hollows, valleys and plains are included by us in the areas of attenuation of mudflows and deposition of their outflows. Absheron Peninsula, the coastal zones of the Caspian Sea are the areas where mudflow processes are not seen.

Conclusion

1. It was defined that in the territory of the studied region the mudflows are formed in conditions of abundant precipitation with high intensity, and cannot be formed without the invasion of cold and transformed air masses from the northern regions of the Europe.

In the conditions of all circulation processes, such air masses penetrate the territory of the Greater Caucasus beyond the cold fronts under the impact of meridional transformations of the tropospheric altitudinal deformation fields. In this case, the altitude frontal zone becomes more powerful, while the value of the specific and relative humidity of air, as well as the instability of stratification, which leads to mudflow-forming torrential rains, grows. It was established that when the E process is available, the mudflow activity increases in this mudflow-prone region, whereas in the case of W, it decreases. In the process of mudflow formation, active role is played by the subtypes of circulation 12a and 13l in accordance with the classification of Dzerdzeevskij.

2. From the above mentioned it follows that mudflow processes are one of the most significant risk factors fixed within the Azerbaijani part of the Greater Caucasus. They intensify ecological tension and cause huge damage to the economy of the country and human settlements. The most important issues are:

- The detailed study of the dynamics of the development of mudflow foci, as well as the features of the accumulation of mudflow materials and their readiness for demolition
- The study of the nature of changes in river beds, the state of coasts and protective structures (currently, one of the main measures is the construction of mudflow dams)
- The study of potential mudflow routes and, on this basis, carrying out ecological and geomorphological measures to stabilize the ecological situation

3. Timely informing about the threat of development of such hazardous phenomena as mudflows would significantly reduce the risk and amount of damage, posed from these processes.

Abstract. The objective of this study was to examine the effects of management and environmental effects on first lactation milk yield by means of regression tree method. Regression tree method is useful to determine the effects of several factors on specified depended variables. The independent variables used in the model were factors such as farm, breed, year of calving, season of calving, age at calving and days in milk. Data used in this study were obtained from three state farms. The resulting data set consisted of 754 records from 1st farm, 1120 records from 2nd farm and 324 records from 3rd farm. The average total milk yield and days in milk were 5413.11 ± 2033.18 kg and 324 ± 64 days, respectively. Year of calving and days in milk were important variables affecting first lactation milk yield of dairy cattle, followed by farm and breed ($p < 0.01$). The determination coefficient of the prediction was found as 78.9%. As a result of the study 14 distinct paths from the root node to the leaves were presented.
Keywords: *multiple linear regression, farm, breed, year of calving, days in milk, cow*

Introduction

First lactation milk yield is a very important characteristic in all dairy cattle. Factors affecting this trait can be divided into genetical (breed) and environmental, such as farm, year of calving, season of calving, age at calving and days in milk. Understanding the factors that change the environment of the dairy cattle can be used to take advantage of some improvement in milk yield that occur in normal lactation. During first lactation at an average age of 2.5 years cow produces approximately 76% of the milk produced by a mature cow (Nirish, 2010). Milk production is usually less during the summer because of the higher environmental temperatures and the prevalence of green-forage scarcity. Thus the season of calving has got a marked effect on the total production. Cows freshening shortly before winter months produce more total yield than those calving at other times of the year. The increase is probably due to more favorable temperature and more digestible feeds available during the winter. The farmer has no effect on the physiological factors of the cow, but has some effects on environmental factors affecting the cow. Factors that alter the environment of dairy cattle can be used to take advantage of some changes in milk composition and the yield during the lactation (Irshad, 2015).

An alternative approach to nonlinear regression is to sub-divide the space into smaller regions, where the interactions are more manageable. The general model consists of two parts: one is only a recursive section, and the other is a simple model for each cell of the section. The regression trees use the tree to represent the recursive part.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52935303

Each terminal node or leaf of the tree represents a cell of the section and has just added a simple pattern applied to it in this cell. This is due to CART's desirable properties as, automatic handling of the variable selection, variable interaction modeling, local effect modeling, nonlinear relationship modeling. CART also is more robust in the presence of outliers and not affected by monotonic transformations of variables. Not all variables have to be in the same type; some of them can be continuous, some can be discrete, etc. Regression trees have several advantages: there are no complicated calculations and hence the estimation is fast: it is easy to understand what variables are important when estimating. In practice, it is possible to build CART models with dirty data (i.e. missing values, lots of variables, nonlinear relationships, outliers, and numerous local effects).

Many studies have been carried out in the application of regression trees in animal husbandry. Lots of them concerning determination of factors effecting milk yield (Mirtagioglu et al., 2008; Bakır et al., 2010; Topal et al., 2010; Cak et al., 2013; Eyduran et al., 2013) and body weight (Topal et al., 2010) of animals. But also there are some researches concerning the application of regression trees to the different data from animal science (Eyduran et al., 2008, 2016; Koç et al., 2017; Takma et al., 2017)

In the present study we are interested in examining the management and environmental effects affecting cows at first lactation by means of regression tree analysis.

Materials and methods

Materials

Data on total lactation milk production were obtained from Tahirova, Konuklar and Malya farms. These farms are the state enterprises belonged to General Directorate of Agricultural Enterprises (*Fig. 1*). Konuklar Farm is located in the 57 km from Konya. The climate is a typical continental climate of Central Anatolia; summers are hot and dry, winters are cold and rainy (GDA, 2016). The average annual rainfall is 322.4 mm, and the altitude is 1050 m. The average annual temperature is 11.6 °C (GDM, 2017). Malya Farm is located 27 km north east of Kırşehir. This farm is located in the Central Anatolia Region, at an altitude of 985 m. Again, the climate is the typical continental climate of Central Anatolia, summers are hot and dry and winters are cold and rainy (GDA, 2016). The average annual rainfall is 378.4 mm. The average annual temperature is 11.4 °C (GDM, 2017). Tahirova Farm is located in Balıkesir province; the farm is situated at an altitude of 166 m. Summers are hot, winters are rainy. The average annual rainfall is 583.7 mm. The average annual temperature is 14.6 °C (GDM, 2017).

At all three farms the cows were grazed and winter supplement was also provided. In the current paper, 2198 first lactation records were assessed for 1874 Brown-Swiss dairy cattle reared at Konuklar and Malya State Farms, and 324 Holstein dairy cattle reared at Tahirova State Farm. Records covered the period of calving from 1987 to 2007.

Methods

Regression tree method

Multiple linear regression (*Eq. 1*) is a way of making quantitative predictions with multiple independent variables $X_i \equiv \{X_1, X_2, . . . Xn\}$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52935303

$$Y = \beta_0 + \beta^T X + \varepsilon, \qquad \text{(Eq.1)}$$

Independent variables have an additive effect on Y, also an interaction (*Eq. 2*),

$$Y = \beta_0 + \beta^T X + \gamma X X^T + \varepsilon \qquad \text{(Eq.2)}$$

Prediction trees use the tree to represent the recursive partition. Each of the terminal nodes, or leaves, of the tree represents a cell of the partition, and has attached to it a simple model which applies in that cell only (*Fig. 2*).

Figure 1. *Locations of investigated farms (Google Earth, 2019)*

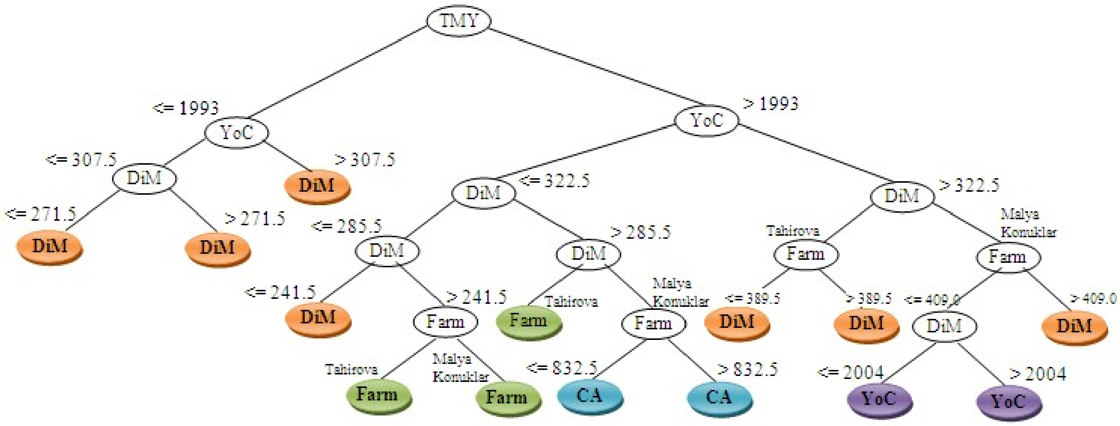

***Figure** 2. Scheme of CART of present work. TMY - total milk yield, YoC - year of calving, DiM - days in milk, CA - calving age*

Classification and Regression Tree splits the data into segments that are as homogeneous as possible with respect to the dependent variable (*Fig. 3*) (Lahmann and Kottner, 2011).

A regression tree can be seen as a kind of additive model (Hastie and Tibshirani, 1990) of the form:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52935303

$$m(x) = \sum_{i=1}^{n} k_i \times I(x \in D_i) \quad \text{(Eq.3)}$$

where k_i are constants; I(.) is an indicator function returning 1 if its argument is true and 0 otherwise; D_i are disjoint partitions of the training data D such that $\bigcup_{i=1}^{n} D_i = D$ and $\bigcap_{i=1}^{n} D_i = \emptyset$.

A terminal node in which all cases have the same value for the dependent variable is a homogeneous, "pure" node. Regression trees (RT) is a method, where the target variable is continuous and tree is used to predict its value.

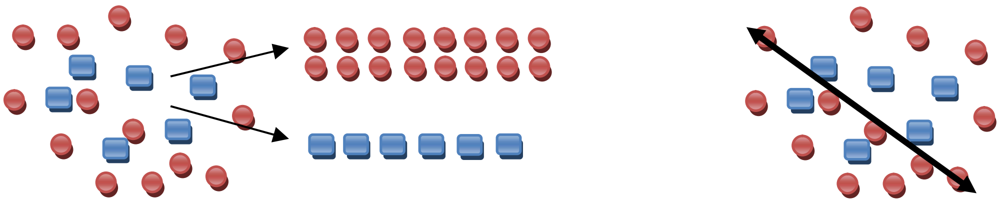

Figure 3. *Classification (left) and regression tree structure (right) for a model with 2 classes*

Each path from the root of the tree to a leaf corresponds to a region. Each inner node of the tree is a logical test on a predictor variable. In the particular case of binary trees, there are two possible outcomes of the test, true or false. This means that associated to each partition D_i we have a path p_i consisting of a conjunction of a logical tests on the predictor variables. This symbolic representation of the regression function is an important issue when one wants to have a better understanding of the regression surface (Soman et al., 2006).

For all analysis handled in this study IBM SPSS Statistics version 20 was used.

Goodness of fit

The coefficient of determination (*Eq. 4*) was used for determination of goodness of fit of the regression tree model.

$$R^2 = 1 - \sum_{i=1}^{n} (y_i - \tilde{y}_i)^2 / \sum_{i=1}^{n} (y_i - \bar{y})^2 \quad \text{(Eq.4)}$$

Results and discussion

There are 2 continuous (days in milk (DIM), calving age (CA) and 4 categorical (farm, breed, season of calving and year of calving) variables used to predict total milk yield (TMY). *Table 1* shows descriptive statistics of continuous variables. *Table 2* represents the frequency and percentage of categorical variables.

Table 1. *Descriptive statistics for the continuous variables*

Traits	N	Mean	SD	Min.	Max.	CV (%)
Total milk yield (kg)	2198	5413.11	2033.178	1098	12032	37.56%
Days in milk (days)	2198	324.19	63.899	137	675	19.7%
Calving age (days)	2198	858.46	90.160	702	1194	10.5%

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52935303

Table 1 shows that the most variation is in the total milk yield. At the same time, the lowest number of days in milk is 137 days and the lowest calving age is 702 days.

Table 2. *Frequency and percentage values for several categorical variables*

Farm	Frequency	Rate	Season	Frequency	Rate	Breed	Frequency	Rate
Konuklar	754	34.3%	Winter	522	23.7%	BS	1874	85.3%

**$p < 0.01$, $R^2 = 78.9\%$

At the top of regression tree diagram, Node 0, which gave general descriptive statistics of TMY, was divided into new two child nodes, with respect to YoC factor. The TMY averages of the cows were born in 1994 and early on (Node 1) was estimated as 3238.79 kg and the TMY average of the other cows (Node 2) was estimated as 5957.31 kg. Right side nodes always show high level mean. With an average of 5957.31 kg, Node 2 gave the highest TMY. Numbers (proportions) of lactation records were 440 (20%) for Node 1 and 1758 (80%) for Node 2. The YoC factor yielded a significant influence on TMY of cows whose lactation records were included in Node 1 ($F = 55.548$, df1 = 21, df2 = 2176, $P < 0.01$). This shows the increase in total milk yield over the years. Afterwards Node 1 was divided into two child nodes (Nodes 3 and 4), depending on DiM factor. Corresponding average values for these two new child nodes were 2693.45 kg and 3799.21 kg, respectively. Numbers of lactation records were established as 223 (10.1%) and 217 (9.9%). While TMY values of cattle with DiM of 307.5 days and less were 2693.45 kg and TMY values of cattle with DiM more than 307.5 days, were found as 3799.21 kg. On the other hand, Node 3 is divided into 2 branches according to DiM factor. While TMY value of 76 cows with DiM 271.5 days and less was found to be 2246.47 kg, TMY value of 147 cows with DiM more than 271.5 days was found as 2924.54 kg. DiM is the first criterion in the TMY classification of records from 1993 and after (Node 2). DiM factor remarkably influenced the TMY of cows whose lactation records were consisted of DiM less than 322.5 days in the Node 2. The TMY averages for these two nodes (Node 5 and Node 6) were found as: 5172.333 kg and 7049.87 kg, respectively. Numbers (proportions) of lactation records were established as 1023 (46.5%) and 735 (33.4%), respectively. According to DiM factor these records are also divided into animal classes which are less than 285.5 days (Node 9) and more than 285.5 days (Node 10). Node 9 is divided into classes with DiM less than 241.5 days (Node 13) and more than 241.5 days (Node 14). The Node 13 consists of 54 records and the average TMY value is 3427.19 kg. The Node 14 was divided into two child nodes: the Tahirova farm with an average TMY of 6138.00 kg and the Malya and Konuklar farms with an average TMY of 4612.06 kg. The records with DiM over 285.5 (Node 10) was divided into two groups. 81 animals with an average TMY value of 6883.35 kg were belonged to Tahirova (Node 15) farm and 467 animals with an average TMY value of 5419.06 kg belonged to the Konuklar and Malya farms (Node 16). The Node 16 was then further classified (Node 23 and Node 24) according to the CA factor that was not statistically significant. Animals with DiM of 322.5 days and more were divided into two child nodes on the basis of farm (Node 11

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52935303

and Node 12). 182 animals with an average TMY value of 8391.31 kg were belonged to the Tahirova (Node 11) and 553 animals with an average TMY of 6608.38 kg were belonged to the Malya and Konuklar farms (Node 12). 182 animals (Node 11) in the Tahirova farm were divided into 2 homogeneous classes according to the DiM criteria: 104 animals with an average of 7750.57 kg milk and less than 389.5 DiM (Node 17) and 78 animals with an average of 9245.63 kg of milk and 389.5 and higher DiM (Node 18). The animals in the Malya and Konuklar farms (Node 12) were classified according to the DiM factor. Accordingly, the average TMY value of the 430 animals (Node 19) with a DiM of less than 409.5 days was 6311.57 kg, and the 123 animals (Node 20) with a DiM of more than 409.5 days were 7646.02 kg. Then, Node 19 was divided into two child nodes according to the YoC factor as before 2005 (Node 25) and after 2005 (Node 26).

On account of the fact that Nodes 4, 7, 8, 13, 15, 17, 18, 20, 21, 22, 23, 24, 25 and 26 are terminal nodes, there is not any separation for providing homogeneity in those nodes.

The following algorithms were used for the estimation of the TMY in the regression tree method we applied:

$P_1 = (\boldsymbol{YoC \leq 1994}) \cap (\boldsymbol{DiM > 307.5})$	$k_1 = 3799.2$ kg
$P_2 = (YoC \leq 1994) \cap (DiM \leq 307.5) \cap (DiM \leq 271.5) = (\boldsymbol{YoC \leq 1994}) \cap (\boldsymbol{DiM \leq 271.5})$	$k_2 = 2246.5$ kg
$P_3 = (YoC \leq 1994) \cap (DiM \leq 307.5) \cap (DiM > 271.5) = (\boldsymbol{YoC \leq 1994}) \cap (\boldsymbol{271.5} < DiM \leq 307.5)$	$k_3 = 2924.5$ kg
$P_4 = (YoC > 1994) \cap (DiM \leq 322.5) \cap (DiM \leq 285.5) \cap (DiM \leq 241.5) = (\boldsymbol{YoC} > 1994) \cap (\boldsymbol{DiM \leq 241.5})$	$k_4 = 3427.2$ kg
$P_5 = (YoC > 1994) \cap (DiM \leq 322.5) \cap (DiM \leq 285.5) \cap (DiM > 241.5) \cap (Farm = Tahirova) = (\boldsymbol{YoC} > 1994) \cap (\boldsymbol{241.5} < DiM \leq 285.5) \cap (\boldsymbol{Farm = Tahirova})$	$k_5 = 6138.0$ kg
$P_6 = (YoC > 1994) \cap (DiM < 322.5) \cap (DiM < 285.5) \cap (DiM > 241.5) \cap (Farm = Malya \cup Konuklar) = (\boldsymbol{YoC} > 1994) \cap (\boldsymbol{241.5} < DiM \leq 285.5) \cap (\boldsymbol{Farm = Malya \cup Konuklar})$	$k_6 = 4612.1$ kg
$P_7 = (YoC > 1994) \cap (DiM \leq 322.5) \cap (DiM > 285.5) \cap (Farm = Tahirova) = (\boldsymbol{YoC} > 1994) \cap (\boldsymbol{285.5} < DiM \leq 322.5) \cap (\boldsymbol{Farm = Tahirova})$	$k_7 = 6883.4$ kg
$P_8 = (YoC > 1994) \cap (DiM \leq 322.5) \cap (DiM > 285.5) \cap (Farm = Malya \cup Konuklar) \cap (CA \leq 832.5) = (\boldsymbol{YoC} > 1994) \cap (\boldsymbol{285.5} < DiM \leq 322.5) \cap (\boldsymbol{Farm = Malya \cup Konuklar}) \cap (\boldsymbol{CA \leq 832.5})$	$k_8 = 5157.6$ kg
$P_9 = (YoC > 1994) \cap (DiM \leq 322.5) \cap (DiM > 285.5) \cap (Farm = Malya \cup Konuklar) \cap (CA > 832.5) = (\boldsymbol{YoC} > 1994) \cap (\boldsymbol{285.5} < DiM \leq \boldsymbol{322.5}) \cap (\boldsymbol{Farm = Malya \cup Konuklar}) \cap (\boldsymbol{CA} > 832.5)$	$k_9 = 5652.0$ kg
$P_{10} = (YoC > 1994) \cap (DiM > 322.5) \cap (Farm = Tahirova) \cap (DiM \leq 389.5) = (\boldsymbol{YoC} > 1994) \cap (\boldsymbol{322.5} < DiM \leq 389.5) \cap (\boldsymbol{Farm = Tahirova})$	$k_{10} = 7750.6$ kg
$P_{11} = (YoC > 1994) \cap (DiM > 322.5) \cap (Farm = Tahirova) \cap (DiM > 389.5) = (\boldsymbol{YoC} > 1994) \cap (\boldsymbol{DiM} > 389.5) \cap (\boldsymbol{Farm = Tahirova})$	$k_{11} = 9245.6$ kg
$P_{12} = (YoC > 1994) \cap (DiM > 322.5) \cap (Farm = Malya \cup Konuklar) \cap (DiM > 409.5) = (\boldsymbol{YoC} > 1994) \cap (\boldsymbol{DiM} > 409.5) \cap (\boldsymbol{Farm = Malya \cup Konuklar})$	$k_{12} = 7646.0$ kg
$P_{13} = (YoC > 1994) \cap (DiM > 322.5) \cap (Farm = Malya \cup Konuklar) \cap (DiM \leq 409.5) \cap (YoC \leq 2005) = (\boldsymbol{1994} < YoC \leq 2005) \cap (\boldsymbol{322.5} < DiM \leq 409.5) \cap (\boldsymbol{Farm = Malya \cup Konuklar})$	$k_{13} = 6134.8$ kg
$P_{14} = (YoC > 1994) \cap (DiM > 322.5) \cap (Farm = Malya \cup Konuklar) \cap (DiM \leq 409.5) \cap (YoC > 2005) = (\boldsymbol{YoC} > 2005) \cap (\boldsymbol{322.5} < DiM \leq 409.5) \cap (\boldsymbol{Farm = Malya \cup Konuklar})$	$k_{14} = 7039.6$ kg

where, P_i shows the algorithm to the terminal Node. TMY obtained from each algorithm is shown with the variable k_i.

There are 14 distinct paths from the root node to the leaves. This three divides the input data in 14 different regions. Using the (*Eq. 3*), we obtain:

$$m(x) = \sum_{i=1}^{14} k_i \times I(P_i)$$

Figure 6 shows importance level of the independent variables. According to *Figure 6,* YoC was significantly identified as the most important factor influencing TMY.

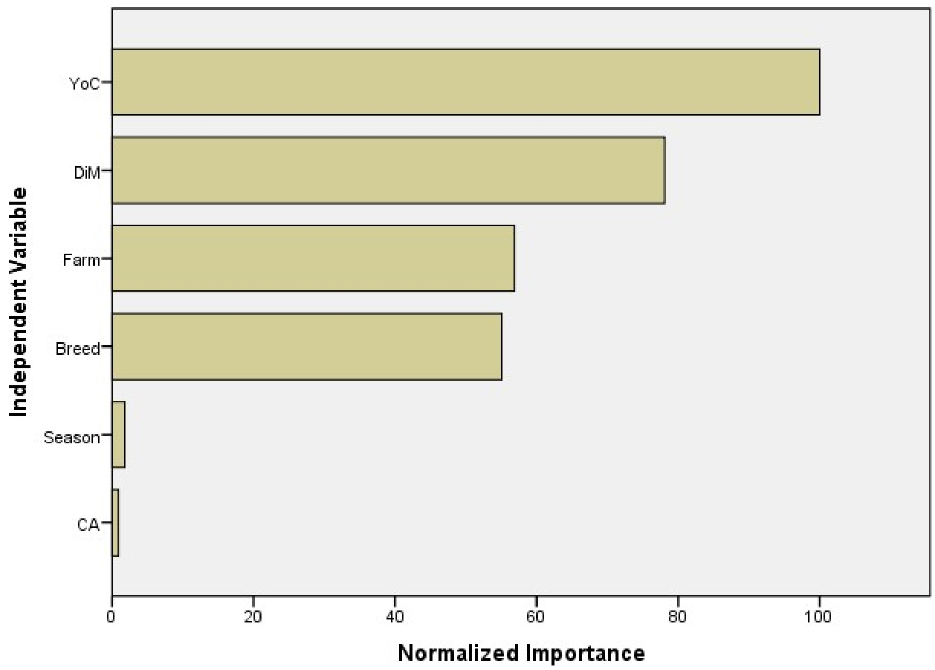

Figure 6. *Importance level of independent variables affecting TMY*

Their importance rate was given in *Table 4*.

Table 4. *Importance level of independent variables affecting TMY*

Independent Variable	Importance	Normalized importance (%)
Year of Calving	1299236.915	100.0
Days in Milk	1052872.027	81.0
Farm	765055.898	58.9
Breed	741247.200	57.1
Season	29218.096	2.2
Calving Age	24202.305	1.9

The R^2 of the tree is 78.9%, which is significantly higher than that of a multiple linear regression fit to the same data (R^2 = 59.1%). In current YoC was found most

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_52935303

important factor affecting total milk yield followed by days in milk (81%). Teke and Akdağ (2010); Bayril and Yılmaz (2010) in their study indicated that the effect of calving year on lactation milk yield were significant in Holstein cows. The categorical variable farm, as we expected, is grouped separately Malya and Konuklar (close to each other geographically) and Tahirova. The other common characteristics of Konuklar and Malya farms are that they have the same breed animal (Holstein). As a result of the analysis, it is expected that the importance rate of both farm and breed characteristics are close (58.9% and 57.1%, respectively). Gürses and Bayraktar (2012) reported that effects of enterprise, calving year were found significant on 305 days milk yield. Season and age at calving was not found so important in the total milk yield prediction (2.2% and 1.9%, respectively). In the study of Topal et al. (2010) season of calving of Swedish Red cattle also was found the least important factor (5.9%) affecting actual milk yield. But there are some other works were claiming the opposite (Bakır and Çetin, 2003; Özçakır and Bakır, 2003; Sehar and Özbeyaz, 2005; Erdem et al., 2007; Akçay et al., 2007; Çilek, 2009).

Conclusion

Due to the fact that CART is not a parametric method, the data used here is not required be belonged to a particular type of distribution. Also, this method can easy determine effects of both continuous and categorical variables on dependent continuous variable.

In regression tree diagram, the year of calving trait was determined to be the most affective factor for total milk yield prediction, followed by days in milk, farm and breed ($P < 0.01$). Thus, while the average total milk yield in the first lactation was 3238.79 ± 1130.83 until 1993, this yield increased in years and reached 6134.81 ± 1313.56 kg in 2005. This yield has increased to 7039.63 ± 1445.52 kg in Malya and Konuklar farms after 2005. In the Tahirova farm, we can say from the P_{11} path that the total milk yield increased after 1994 and reached the average of 9245.63 ± 1580.26 kg. Insignificant input variables such as season and age at calving were excluded from the regression tree.

As a result, the routing of the algorithms leading to the terminal node will help to determine the criteria for the classification in the regression tree and the application of the test data to this algorithm.

Abstract. In order to explore the effects of biomass carbon on the basic properties of black soil and bacterial diversity, in this study, the combination of indoor culture and high-throughput sequencing was used to analyze the nutrient changes and bacterial communities of black soil after adding biochar. The results showed that compared with CK, soil pH, organic matter and available potassium increased significantly after adding biochar ($P < 0.05$), and catalase, invertase, urease, and phosphatase increased substantially, while polyphenol oxidase decreased. A total of 17 phyla, 51 known genera were detected by high-throughput sequencing, among which *Proteobacteria* was the dominant phyla. The dominant genera including *Sphingomonas, Mizugakiibacter, Bacillus, Marmoricola, Rhodanobacter*, and *Streptomyces*. From the analysis of bacterial diversity, it can be concluded that the bacteria ace, chao1, Shannon and Simpson index of black soil increased after adding biochar, compared with CK in redundancy analysis (RDA), AN, NO_3^--N, NH_4^+-N had a greater impact on microbial communities. The microbial functional bacteria AOA and cbbl were significantly correlated with pH, SOM, AN, NH_4^+-N, and NO_3^--N ($p < 0.05$). Therefore, the addition of biochar can not only improve soil nutrients but also plays an important role in maintaining the diversity of soil bacterial communities.
Keywords: *biochar, enzyme activity, high-throughput sequencing, bacterial diversity, microbial functional genes*

Introduction

As a good soil improver, biochar could not only improve soil pH and base saturation but also reduce soil aluminum saturation (Cantrell et al., 2012; Zwieten et al., 2010; Liang et al., 2006). Zhou et al. (2017) found that biochar can also increase soil respiration in temperate forests. In recent years, more and more scholars have found that biochar could reduce greenhouse gas emissions (Weber et al., 2018). Biomass carbon can promote nutrient availability and increase carbon sequestration and soil fertility (Tian et al., 2016). The restoration of heavy metal pollution in soils and sediments by biochar is also considered by more and more scholars (Oleszczuk et al., 2012). So many characteristics of biochar are applied to the improvement of soil. As a big agricultural country, China's black soil is one of the three black soils in the world. Because of the unscientific fertilization and other factors in recent years, black soil is also facing environmental pollution. Therefore, the material charcoal is of great significance to the improvement of soil. However, the research on the microbial community of black soil by biochar is relatively scarce. The diversity of the microbial community is different when different biochars are added to different soils. Castaldi et al. (2011) found that the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_53055319

addition of wood biomass charcoal had little effect on soil microbial communities, while the addition of cotton biomass charcoal increased microbial activity. Some scholars have shown that biochar can provide suitable habitat for microorganisms due to its high porosity and cation exchange capacity (Cui et al., 2013). Some scholars have also shown that adding biomass charcoal to fine textured soil reduces microbial activity (Wang et al., 2017). The effect of biochar on soil enzyme activity is also the focus of current scholars. According to recent research, the addition of biomass carbon increases the enzyme activity associated with the N and P cycles, while at the same time reducing the enzyme activity associated with the C cycle (Bailey et al., 2011). Anyway, some studies have the opposite result.

The relationship between physical and chemical properties of black soil, enzymatic activity, microbial community diversity, and functional bacteria and environmental factors can help to further understand the improvement mechanism of biochar on black soil, and explore the influence of environmental factors on microbial community. Good use of biomass carbon in black soil, and the relationship between environmental factors and functional bacteria can more clearly understand the mechanism of action of biomass carbon, enzyme activity plays an indispensable role in soil activity, through A series of detailed studies on black soil by biochar can clearly identify the types and amounts of biomass carbon that are beneficial to soil improvement. This experiment mainly used three kinds of biomass charcoal to explore the improvement effect of black soil. In order to provide theoretical basis to the application of charcoal in Agriculture.

Materials and methods

Test soil and biochar

Test soil

The test soil was a typical black soil and was collected from the long-term location test points (43°47'42" N, 123°20'45"E) of the Jilin Agricultural University. Corn is the major crop mostly cultivated on this soil. The fertilizer mostly applied during corn production are N 180 kg hm^{-2}, P 39.3 kg hm^{-2}, K 75 kg hm^{-2}, soil bulk density of 1.15 g cm^{-3}. The soil sample was collected from 0-20 cm plow layer soil, and after air drying, it was sieved by 2 mm. The basic physicochemical traits are shown in *Table 1*.

Table 1. *Physicochemical characteristics of the test soil*

pH	**SOM (g kg^{-1})**	**AN (mg kg^{-1})**	**AP (mg kg^{-1})**	**AK (mg kg^{-1})**	**clay (%)**	**silt (%)**	**sand (%)**

SOM: Soil organic matter; AN: alkali-hydrolyzable nitrogen; AP: available phosphorus; AK: available potassium

Test biochar

Three kinds of biomass carbon were provided by Dalian Xinglongxi Development Co., Ltd. These included corn stover, rice husk, and pine wood pyrolyzed at 350-550 °C. The basic physical and chemical properties of biomass carbon are shown in *Table 2*.

Training test design

Bio-char-soil preparation: black soil over 2 mm sieve and biomass charcoal over 20 mesh sieve were initially obtained. The air-dried black soil sample was mixed with certain quantities of each biomass charcoal to obtain 1000 g for each treatment. A total of 7 treatments were included in the trial (*Table 3*). Treatments were put in plastic bowls and randomly placed in an incubator at constant temperature and humidity (*Fig. 1*). Samples were incubated at 25 °C for 6 months and moisture was always adjusted to 70% of field capacity. We had three repeats per treatment (Note: 1.2% is 1.2% of total weight; 6.0% is 6.0% of total weight).

Research methods

The sampling of mixed culture soil

After the biomass carbon-black soil mixed treatments were cultured for six months, two soil samples were taken from each treatment. One for DNA extraction and the other for basic data determination. The soil was passed over 2 mm sieve for the removal of impurities. The same treatment was mixed three times in parallel. Samples for DNA extraction was stored at -80 °C and samples for basic data determination was air dried.

Determination of basic data

Soil pH was measured on a 1:2.5 (w/v) ratio in distilled water using a pH meter, Soil organic matter (SOM) was determined after dichromate oxidation and titration with ferrous ammonium sulphate, alkali-hydrolyzable nitrogen (AN) was determined alkaline solution diffusion method, available phosphorus (AP) was determined colorimetrically using the molybdate method, and available potassium (AK) was extracted by incubation with 1.0 mol L^{-1} ammonium acetate for 0.5 h, followed by filtration, available potassium content was determined using a flame photometer (Brookes et al., 1985). Ammonium nitrogen and Nitrate nitrogen (NH_4^+-N and NO_3^--N) was extracted with 2 M KCl and determined by flow injection analysis (TRAACA-2000, Germany). Polyphenol oxidase and Catalase were measured calorimetrically in a clear 96-well microplate according to Ai et al. (2015). Urease activity was determined according to Kandeler and Gerber (1988) and was expressed as mmole NH_4^+ g^{-1} dry soil h^{-1}. Invertase activity was determined by using sucrose solution as the substrate as described by Chen et al. (2013). The activity of Phosphatase was measured by the transformation of disodium phenyl phosphate to phenol as described by Jin et al. (2016).

Extraction and detection of total soil DNA

Soil microbial DNA extraction was performed using the Power Soil DNA Isolation Kit from MOBIO, USA. 0.5 g of soil samples were weighed and stored in a refrigerator at -80 °C to extract total DNA and purify soil genomic DNA (TIAN quick Midi Purification Kit, TIANGEN) according to the kit manual procedure; Detected by ultra-micro spectrophotometer (Nanodrop 2000) DNA concentration ≥ 20 ng.μL^{-1}, $OD_{260/280}$ between 1.8 and 2.0, and $OD_{260/230}$ between 1.8 and 2.0. The extracted DNA was stored at -20 °C for subsequent measurement.

High-throughput sequencing of the Illumina MiSeq platform

The construction of a high-throughput sequencing library was completed by GENEWIZ Corporation (Shanghai, China). The V3–V4 hypervariable regions of the Bacteria 16S rRNA was amplified by PCR using 5 to 50 mg of DNA as a template. The end of the PCR product of the 16S rRNA genes were amplified using the primer set U341F (ACTCCTACGGGAGGCAGCAG) and U806R (GGACTA CHVGGGTWTCTAAT). The library quality was detected using an Agilent 2100 Bioanalyzer (Agilent Technologies, Palo Alto, CA, USA) and the library concentration was detected by Qubit and real-time quantitative PCR (Applied Biosystems, Carlsbad, CA, USA). After the DNA library was mixed, double-ended sequencing (PE) was performed using the Illumina MiSeq (Illumina, San Diego, CA, USA) instrument instruction manual. Image analysis and base calling were performed using the MiSeq Control Software (MCS) in the MiSeq tool. Finally, an initial classification analysis was performed on the Illumina base space cloud computing platform.

All sequences were deposited in the NCBI sequence read Archive (SRA) database (Accession numbers: SRR7275367-SRR7275373).

Real-time PCR amplification

The abundances of genes (nifH, archaeal amoA (AOA), bacterial amoA (AOB), nosZ, *cbbl* and *gdh3*) encoding the key enzymes for biological N, P cycling were quantified by real-time PCR (IBA7500) for all soil samples. These methods were modified from their original descriptions (references following primers) (*Table A1* in the *Appendix*). Gel-purified PCR producgts from a common DNA mixture (equal amounts of DNA from all samples) were used to prepare sample-derived quantification standards (YU et al., 2005). The copy number of genes in each standard was calculated by DNA concentration (ng•μL^{-1}, measured by Qubit) divided by average molecular weight (PCR product length and GC content was obtained from barcoded-pyrosequencing results) of the amplified gene fragment (Mao et al., 2012).

Data processing

OTU analysis uses V-SEARCH (1.9.6) for sequence clustering (sequence similarity is set to 97%), and the aligned 16S rRNA reference database is UNITE ITS database (https://unite.ut.ee/), then RDP is used. Classifier (Ribosomal Database Program) Bayesian algorithm performs species taxonomy analysis on representative sequences of OTUs and gives statistics on the community composition of each sample at different species classification levels. The analytic diversity software Qiime (1.9.1) was used to calculate the alpha diversity indices such as Shannon, Chao1, Ace, Simpson, goods-coverage. The (Un) Weighted Unifrac analysis was used to compare whether there was a significant difference in microbial communities between samples. Based on the (Un) Weighted Unifrac sample distance matrix information, non-metric multi-scale (NMDS) analysis was used to demonstrate β diversity. Correlation analysis between species and environment (RDA) was performed using Canoco 5.0 software. We use Excel 2010, SPSS19.0 for data statistics and analysis.

Results

Effect of biomass carbon addition on physical and chemical properties and enzyme activity of black soil

The basic physical and chemical properties of the soil after adding biochar are shown in *Table 4*. After adding biochar, the pH, organic matter and available potassium of black soil increased compared with CK treatment, and the effect of 6.0% CB treatment was the most significant. After adding biochar, the available phosphorus content of soil increased significantly with 1.2% RB, 6.0% RB, and 6.0% CB, while 1.2% CB, 1.2% PB, and 6.0% PB treatment decreased compared with CK treatment. After adding biochar, the alkaline nitrogen, ammonium nitrogen and nitrate nitrogen in the soil showed a decreasing trend, and their values were the highest compared with CK treatment.

The changes in soil respiration intensity and enzyme activity after adding biochar are shown in *Table 5*. After the addition of biomass charcoal, the respiration intensity of the soil was significantly enhanced by the addition of corn stover charcoal, while the addition of rice husk biomass charcoal was significantly enhanced by 1.2% RB, and 6.0% RB treatment was lower than CK treatment. The treatment of adding pine biomass charcoal significantly reduced its respiratory intensity compared to CK. After adding biochar, the catalase was increased compared with CK treatment, and the effect of 6.0% CB was the most significant. The addition of rice husk with 6.0% RB increased the effect significantly, and the addition of pine charcoal increased the effect when 6.0% PB was added. The invertase activity of the soil had the best effect when corn straw charcoal was added and decreased with rice husk and pine charcoal as compared with CK. The urease activity of soil also had the best effect when corn straw charcoal was added, and the effect of treatment with 6.0% CB was the most significant. Adding biomass carbon has little effect on phosphatase, and treatment with 1.2% CB was the most significant. Polyphenol oxidase is inversely proportional to the degree of humification of the soil, with 6.0% CB being the best.

Effect of biomass carbon addition on the abundance of bacteria in black soil

As seen from *Figure 2,* a total of 17 known bacterial phylum were detected in the black soil supplemented with biochar, of which *Proteobacteria* was the dominant flora, and the *Proteobacteria* gate was occupied by 1.2% RB treatment compared with CK treatment. The proportion was up to 41.46%, and the proportion in the 6.0% CB treatment was relatively small at 40.56%. The *Bacteroidetes* and *Actinobacteria* gates

DOI: http://dx.doi.org/10.15666/aeer/1702_53055319

accounted for a large proportion in the CK treatment, which was 30.02% and 17.68%, respectively. The *Acidobacteria* gate was at 1.2% CB. The proportion of 6.0% CB treatment was 12.73% and 11.64%, respectively. *Firmicutes* accounted for a large proportion of 1.2% RB and 1.2% PB at 7.24% and 7.55% respectively.

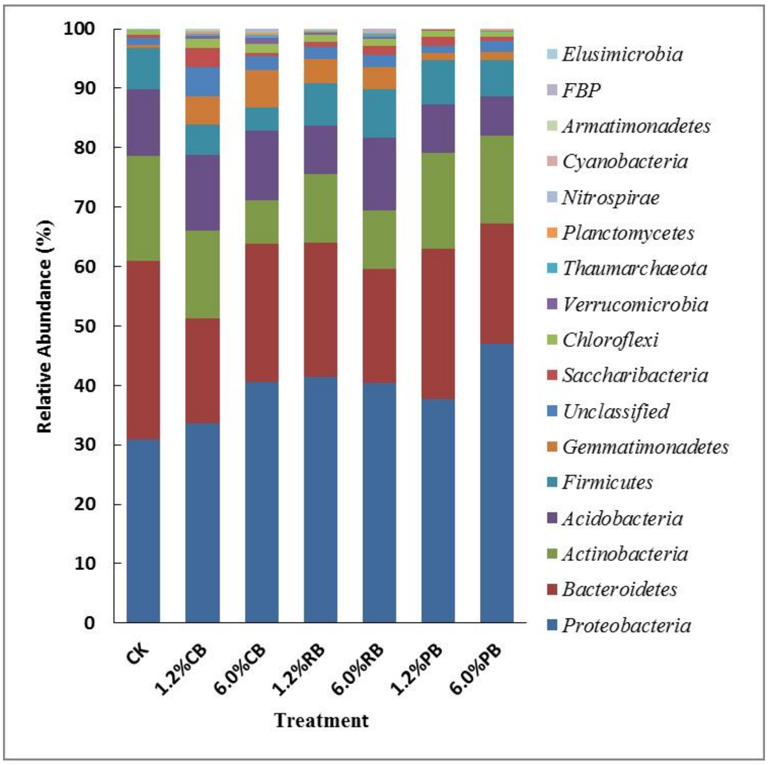

***Figure 2.** Relative abundance of bacterial community at phyla level. (CK: only black soil; CB: black soil +corn stover biomass carbon; RB: black soil + rice husk biomass charcoal; PB: black soil + pine biomass carbon)*

According to the abundance data of OTU, the heat map can cluster different OTUs at the genus level, and the heat map can reflect the relationship between the similarity, difference, and species clustering relationship of different treatments according to the color gradient. A total of 51 bacterial genera were detected from 7 samples in this sequencing. In this study, the top 30 bacterial genera with higher abundance were selected and the heat map was drawn using R language (*Fig. 3*). The dominant species

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_53055319

included *Sphingomonas, Mizugakiibacter, Bacillus, Marmoricola, Rhodanobacter*, and *Streptomyces*, which accounted for 19.77%, 6.86%, 4.74%, 2.49%, 1.69%, and 1.37, respectively. It can be seen from the figure that, *Sphingomonas* is the lightest color in CK treatment, the darkest in 6.0% PB treatment and the darkest in *Mizugakiibacter* in CK treatment. The *bacillus* is the darkest in 6.0% treatment, at 6.0%. The color is the lightest in CB treatment, the darkest color in the treatment of 1.2% PB of *Marmoricola*, the lightest in 6.0% CB treatment; the darkest color of *Rhodanobacter* in CK treatment, the lightest in 6.0% PB, *Streptomyces* The color is the deepest in the process, and the lightest in the 1.2% CB process. In addition to the above-mentioned several abundance genus species that are significantly concentrated in different treatments, the other genus species also have branching aggregation similarities in different treatments.

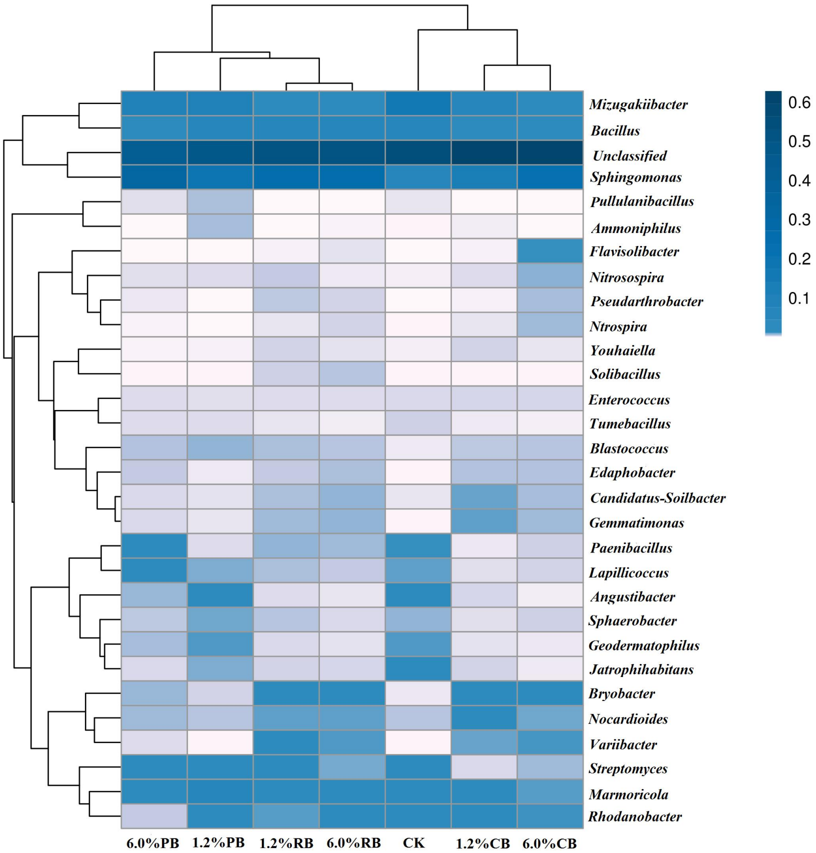

Figure 3. *Heat map of black soil bacterial community level. (CK: only black soil; CB: black soil +corn stover biomass carbon; RB: black soil + rice husk biomass charcoal; PB: black soil + pine biomass carbon)*

The diversity of the bacterial community after adding biochar

It can be seen from *Table 6* that compared with CK treatment, after adding different kinds of biochar, the ace, chao1, Shannon and Simpson indices of black soil increased significantly, which shows that after adding biochar to black soil, the uniformity and richness of the soil have increased. Between the additions of different biochars, the ace and chao1 indices of 1.2% CB and 1.2% RB increased significantly, while the Shannon and Simpson indices of 1.2% CB and 6.0% CB increased most significantly. After

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_53055319

adding different amounts of biochar, thus, after adding corn stover biomass charcoal, ace, chao1, Shannon, Simpson index of 1.2% CB treatment were greater than 6.0% CB treatment; after adding rice husk biomass charcoal, the ace and chao1 indices of 1.2% RB treatment were greater than 6.0% RB treatment, while the Shannon and Simpson indices were less than 6.0% RB treatment; after adding pine biomass carbon, the ace, chao1, and Shannon indices of 1.2% PB treatment were less than 6.0% PB treatment, only the Simpson index was greater than 6.0% PB processing.

Table 6. *Statistical table of α diversity index of black soil bacteria*

Sample	Ace	Chao1	Shannon	Simpson	Goods_coverage
CK	239.61	239.05	5.09	0.94	1.00
1.2%CB	275.83	277.14	6.42	0.98	1.00
6.0%CB	271.58	271.14	6.34	0.97	1.00
1.2%RB	277.48	277.11	6.07	0.96	1.00
6.0%RB	273.40	273.50	6.24	0.97	1.00
1.2%PB	260.28	257.13	5.27	0.95	1.00
6.0%PB	266.11	270.50	5.39	0.94	1.00

The dilution curve uses a random sampling method for sequencing sequences to determine whether the sample size is sufficient and predicts the species richness. It can be seen from *Figure 4* that when the sample Reads < 10000, the number of OTUs increases rapidly with the increase of the sequencing depth. When 10000 < Reads < 20000, the number of OTUs increases slowly as the depth increases, when Reads > 20000, as the depth of sequencing increases, the number of OTUs tends to be flat, indicating that the sequencing data at this time is more reasonable. The number of bacteria was higher when treated with 1.2% RB and lower with CK.

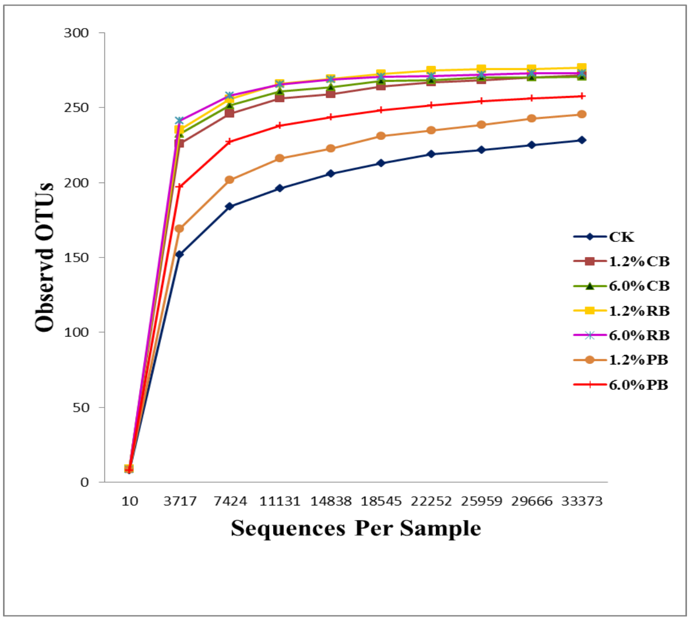

Figure 4. *Dilution curve of soil bacterial in black soil. (CK: only black soil; CB: black soil +corn stover biomass carbon; RB: black soil + rice husk biomass charcoal; PB: black soil + pine biomass carbon)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

Effects of environmental factors on bacterial community structure of black soil treated by different biomass carbon

In order to analyze the effects of different biomass charcoal on black soil bacterial community, typical correspondence analysis was carried out in this study. The results are shown in *Figure 5*. As can be seen from the figure, the angle between the pH, SOM, AP, and AK vector arrows is an acute angle, indicating that there is a synergistic effect between the four physical and chemical factors. The 6.0% CB of the sample had the highest correlation with pH and SOM, and the correlation between 6.0% RB and AP was the highest. CK and 1.2% CB had the highest correlation with AN, NO_3^--N and NH_4^+-N. The bacterial *Variibacter* belongs to the AP vector arrow with the smallest acute angle, indicating the highest correlation with AP. The correlation between *Bryobacter* and AK was the highest, the correlation between *Nitrosospira* and pH was the highest, the correlation between *Sphingomonas* and SOM was the highest, and the correlation between *Rhodanobacter* and *Streptomyces* was the highest with AN, NO_3^--N and NH_4^+-N, while AN, NO_3^--N and NH_4^+-N have an acute angle with most species, so AN, NO_3^--N and NH_4^+-N have a greater impact on microbial communities.

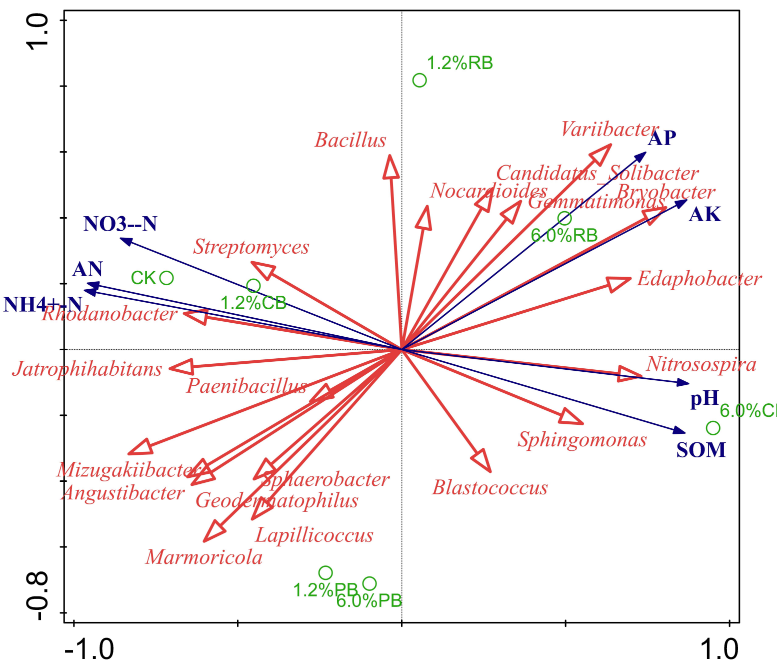

***Figure 5.** RDA analysis between environmental factors and bacterial genera levels (CK: only black soil; CB: black soil +corn stover biomass carbon; RB: black soil + rice husk biomass charcoal; PB: black soil + pine biomass carbon; SOM: Soil organic matter; AN: Alkaline nitrogen; AP: Available phosphorus; AK: Available potassium; NH_4^+-N: Ammonium nitrogen; NO_3^--N: Nitrate nitrogen)*

Correlation analysis between soil functional microorganisms and environmental parameters

Pearson correlation analysis was used to add a correlation between soil nutrient cycling functional genes and soil environmental parameters. It can be seen from *Table 7* that the relative abundance of AOA is significantly positively correlated with pH

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_53055319

($r = 0.811$, $p < 0.05$) and SOM ($r = 0.852$, $p < 0.05$), and the relative abundance of AOA is related to AN ($r = -0.823$, $p < 0.005$), NO_3^--N ($R = -0.857$, $P < 0.05$) showed a significant negative correlation, cbbl relative abundance with AN ($r = -0.860$, $p < 0.05$), NH_4^+-N ($r = -0.844$, $p < 0.05$) showed a significant negative correlation.

Table 7. *Correlation analysis between soil functional microorganisms and environmental parameters*

Discussion

Khadem et al. (2017) added scorch and unburned biomass charcoal to the soil. The results showed that the addition of both biochars significantly increased the enzyme activity of the soil. Huang et al. (2017) found that urease activity remained stable when the amount of biomass carbon added was 1% by adding exogenous carbon. When the amount of biomass carbon increased to 5%, urease activity increased significantly, while phosphoric acid. The activity of the enzyme temporarily decreased at the beginning, but eventually increased when the precipitate was treated with 1% biochar. When the concentration of biochar was as high as 5%, the activity of alkaline phosphatase decreased to 0.75 times that of the control. Luo et al. (2016) found that peroxidase activity decreased with the increase of biomass carbon by adding different amounts of biomass charcoal, and the biomass carbon content was significantly negatively correlated with peroxidase activity. Wang et al. (2015) found that by adding biochar, biochar can increase soil pH and CEC. With the addition of biochar, NH_4^+-N in soil gradually decreases peroxidase and fractional oxidation. The activity of the enzyme decreases with the addition of biomass carbon, and the activity of urease increases with the increase of biomass carbon. This study is similar to the results of Wang et al. (2015). After adding biochar, the pH of the soil increased, and the NH_4^+-N, NO_3^--N, and AN in the soil decreased compared with CK, and the polyphenol oxidase in the soil gradually decreased. Because the activity of polyphenol oxidase is negatively correlated with the degree of soil humification, as shown in *Table 5*, the polyphenol oxidase values of 6.0% CB, 6.0% PB, and 6.0% RB are significantly less than CK, indicating that the degree of humification is the best. Catalase is related to soil respiration intensity and microbial activity. In this study, the highest catalase activity was treated with 6.0% CB, the value was 1.12 mL g^{-1}, and the soil respiration intensity of 6.0% CB treatment was 119.27 ml kg^{-1}. Both are higher than other treatments, which also indicates that the catalase activity is proportional to the soil respiration intensity. After adding three different biomass charcoal, the catalase activity was treated with 6.0% activity higher than 1.2%,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_53055319

and 1.2% treatment was higher than CK treatment. Urease activity was also highest in 6.0% CB. Most of the urease activity was proportional to the organic matter content, and the organic matter content of 6.0% CB treatment was 114.52 g kg^{-1}, which was higher than other treatments. The urease activity of the other rice husks and pine biomass carbon was treated with 1.2% treatment above 6.0%.

Zhang et al. (2018) found that after adding biochar, the bacterial abundance of bacteria at the bacterial level increased correspondingly, and the effect of *Chloroflexi* gate abundance was significant. In this study, after adding biochar, *Proteobacteria* is the dominant population at the gate level, accounting for 47% of the 6.0% PB treatment, and 41.46% of the 1.2% RB, and the proportion in the CK treatment. Only 30.85%, so adding biochar can increase the abundance of bacterial phylum levels. Taking *Sphingomonas*, a dominant genus of bacteria, as an example, the proportion in the 6.0% PB treatment was 31.22%, the treatment in the 1.2% RB was 24.58%, and the proportion in the CK treatment was 4.74%. The dominant genus *Mizugakiibacter* had the opposite result, accounting for 14.83% of the CK treatment, and the proportion of other treatments is smaller than the proportion of CK treatment. Therefore, the addition of biochar does not necessarily increase the bacterial abundance. Nguyen et al. (2018) found that soils supplemented with biochar had higher bacterial alpha diversity and OTU richness compared to CK. Li et al. (2018) found that by applying biochar, the application of biochar increased the Shannon index of the bacteria compared to the control. This study is the same as the above two studies. After adding biochar, ace, chao1, Shannon, Simpson, CK treatment increased, and the ace index increased significantly with 1.2% RB treatment, both chao1, Shannon, Simpson were significantly increased by 1.2% CB treatment. Du et al. (2018) found that the addition of different doses of biomass charcoal, will change the bacterial community during the composting process, but the composition of the bacterial community did not change much, and they found that the addition of biochar can also change the function such as sexual bacterial community. The smallest acute angle between the genus *Variibacte*r and the AP vector arrow indicates the highest correlation with AP. The correlation between *Bryobacter* and AK was the highest, the correlation between *Nitrosospira* and pH was the highest, the correlation between *Sphingomonas* and SOM was the highest, and the correlation between *Rhodanobacter* and *Streptomyces* was the highest with AN, NO_3^--N and NH_4^+-N, while AN, NO_3^--N and NH_4^+-N had a great influence on the genus. The angle between the pH, SOM, AP, and AK vector arrows is an acute angle, indicating a synergistic effect between the four physical and chemical factors. Fluorescence quantitative PCR was used to detect the abundance of functional genes in soil. Compared with CK, the application of biochar could significantly increase the abundance of functional genes in the soil, and the correlation between environmental factors and functional genes was analyzed by Pearson correlation. As seen from *Table 7*, the relative abundance of AOA is significantly positively correlated with pH ($r = 0.811$, $p < 0.05$) and SOM ($r = 0.852$, $p < 0.05$), and the relative abundance of AOA is related to AN ($r = -0.823$, $p < 0.005$), NO_3^--N ($R = -0.857$, $P < 0.05$) showed a significant negative correlation, cbbl relative abundance with AN ($r = -0.860$, $p < 0.05$), NH_4^+-N ($r = -0.844$, $p < 0.05$) showed a significant negative correlation, which also indicated that the relative abundance of AOA in soil had significant correlation with pH, SOM, AN, NO_3^--N, and cbbl had significant correlation with AN and NH_4^+-N. Therefore, the application of biochar has a relatively large effect on the functional bacteria AOA and cbbl in the soil.

DOI: http://dx.doi.org/10.15666/aeer/1702_53055319

Conclusion

Adding biochar can increase the pH, SOM and AK of black soil, and the increase of AP value is not significant, but the content of AN, NH_4^+-N and NO_3^--N in the soil after adding biochar is less than that of CK. The addition of biochar can increase the enzyme activity in soil. The activity of polyphenol oxidase is negatively correlated with the degree of humification. The lower the value, the higher the degree of humification and was best at 6.0% CB. Adding biomass charcoal can also affect the microbial community diversity of black soil. After adding biochar, the α diversity index of black soil was increased compared with CK, and environmental factors also have an effect on the microbial community. Microbial functional bacteria AOA, cbbl and pH, SOM, AN, NH_4^+-N, NO_3^--N had a significant correlation. Based on the above basic properties and changes in microbial communities, in the various treatments of this experiment, the best effect was to add corn stover charcoal, and the best amount to add was 6.0% CB.

Abstract. *Tomato spotted wilt virus* (TSWV) is an economically important disease causing significant yield and quality loss in tomato. The most efficient method of disease control relied on the use of the *Sw-5* resistant gene. The new resistance-breaking Tswv isolates have severely infected greenhouses grown tomatoes Eastern Mediterranean area, including Antalya, Turkey. The objective of the study was to identify the cause of the resistance-breaking genetic mutations on the virus genome. The plant materials included resistant *Solanum peruvianum* PI126944 and four commercial hybrids, and a susceptible control. The six resistance-breaking strains (RBS) of the virus were collected from greenhouse-grown tomato plants throughout Antalya, Turkey. Beginning at the seedling stage, five consecutive inoculations were carried out at five-day intervals, using both the resistant and susceptible genotypes. The Medium segment of the virus includes the cell-to-cell movement protein (NSm) and a precursor of the surface glycoproteins (GN/GC) that were sequenced with different primer combination. The medium segment of the RBS genomes was amplified and 4825 bp sequence aligned and blasted using NCBI database. On-structural movement (NSM) domain of the M segment consistently carried C118Y mutation in all RBS analyzed. The multiple mutations on Gc-Gn domain were not associated with resistance break down. Phylogenetic analysis indicated that RB strain identified in Turkey was closely related to Spanish RB strains. The C118Ymutation overcame the resistance conferred by the Sw-5 gene. Hence, a new resistance source is needed to protect the tomato from new RB strains.
Keywords: *orthotospoviruses, NSm protein, avrirulence determinant, hypersensitive response, Sw-5b gene*

Introduction

Tomato production is under threat from viral diseases causing significant yield and quality loss all over the world (Pappu et al., 2009). One of the most common viral diseases occurs with *Tomato spotted wilt virus* (TSWV) on tomato. The TSWV is a member of genus *Orthotospovirus,* family Bunyaviridae (Adams, 2017), limits tomato production especially in greenhouses. The TSWV virus is transmitted by thrips (Thysanoptera, *Thripidae),* the most common vector being *Frankliniella occidentalis*in a persistent and circulative manner (Todd et al., 1995; Mandal et al., 2001).

Orthotospoviruses are enveloped viruses including additional protein package on their RNA genomes. The virus genome contains three RNA segments known as a tripartite RNA genome structure (Cortez et al., 2001). The TSWV has similarly three RNA parts described as small (S), medium (M), and large (L) RNAs (de Haan et al., 1991). The whole genome of TSWV codes six proteins via five different open reading frames (ORFs). The M and S RNAs have special structures where genomes are ambisense The ambisense viruses include both parts of positive and part of negative polarities in their genome (Kormelink et al., 1994; Lewandowskia and Adkins, 2005).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_53215339

The genome size of TSWV is 16.6 kbp where small, medium and large segments are 2.9 kb, 4.8 kb, and 8.9 kb, respectively (de Haanet al., 1990). The S segment has two ORFs encoding non-structural RNA silencing suppressor (NSS) and nucleocapsid (NC) proteins (Takeda et al., 2002). The M segment produces both non-structural movement protein (NSm) and envelope glycoproteins Gn-Gc (Kormelink et al., 1994). The last L segment encodes putative RNA-dependent RNA polymerases (RdRp), such as replicase, transcriptase, nuclease, helicase, cap-binding and NTPase proteins responsible for several enzymatic functions of TSWV (de Haan et al., 1991).

TSWV is the second most destructive viral pathogen in the list of economic damage causing plant viruses (Scholthof et al., 2011). The prevention and control of the spread of TSWV is very difficult due to its vectors. For TSWV management, resistant tomato varieties carrying *Sw-5* resistance gene derived from *Solanum peruvianum* have extensively been used (Pappu et al., 2009). In recent years, the resistant tomato plants have been infected with TSWV in Spain (Debreczeni, 2011). Similarly, resistant-breaking TSWV isolates have been reported on genetically resistant pepper plants since 2014 in Samsun, Turkey (Deligöz, 2014). Likely, severe TSWV infections are obtained on resistant gene containing tomato varieties indicating TSWV changed its genetic structure in 2016 in Turkey (Fidan et al., 2016; Batuman et al. 2017). In order to understand the genetic cause of virulence, the study has been conducted. Hence, whole genome structure of avirulent non-resistant breaking isolates and virulent resistance-breaking TSWV isolates are compared in nucleotide sequences and possible functional mutation site(s) have been investigated.

Materials and methods

Determination of the Sw-5 gene containing TSWV resistant plants

Total genomic DNAs were extracted by DNA extraction kit (Thermo Scientific, Germany,) from the resistant *Solanum peruvianum* PI126944, a susceptible commercial tomato hybrid variety (Hazera 5656 (Hazera Seed), and four resistant commercial hybrids, namely Torry F1 (Syngenta), Matatu F1 (RijkZwan), TayfunF1 (De Ruiter), Swanson F1 (Seminis). The DNA samples were PCR amplified using Sw5-2 primers F-AATTAGGTTCTTGAAGCCCATCT, and R-TTCCGCATCAGCCAATAGTGT as reported by Dianese et al. (2010) where the 574 bp and 500 bp amplicons representing resistant and susceptible Sw-5 alleles, respectively.

Inoculations of susceptible and resistant tomato plants with TSWVAntRB isolate

The six resistance-breaking isolates (RBS) were collected throughout Antalya, Turkey, from tomato plants grown in greenhouses. Because sequence analysis indicated the presence of single haplotype, all six RBS were mixed to inoculate the resistant and susceptible tomato samples. The resistant and susceptible samples, five plants in each replicate, were inoculated with RBS and a mock inoculation with phosphate buffer was used as a control. The inoculations were repeated five times at 5 intervals. At 15 days' post inoculations (dpi) when susceptible plant showed virus symptoms, leaf tissue was collected from mock and RBS inoculated plants. Systemic viral infection was subsequently determined by RT-PCR analysis as described previously (Dianese et al., 2010).

Genome analysis of TSWV isolates

The TSWV isolates were collected from greenhouse-grown tomato plants in Antalya province, Turkey. The TSWV isolates originated from tomato hybrids reported to carry resistance against TSWV in 2016. The TSWV isolates were kept in -20 °C as infected leaf material at Virology Laboratory, Plant Protection Department, Akdeniz University, Antalya, Turkey. Total RNAs were extracted from the samples using an RNA extraction Kit (K0731**,** Thermo-Scientific, Germany). The cDNAs of TSWV were obtained with high capacity cDNA Reverse Transcription Kit (Thermo Scientific, Germany) according to the manufacturer's instructions. The M segment specific primers (Hallwass et al., 2014 and Zhong et al., 2011) presented in *Table 1* were paired (*Table 2*) to amplify TSWV isolates by RT-PCR analyses.

Table 1. *Primer sequences representing M segment of tomato spotted wilt virus (TSWV) used in RT-PCR studies (Hallwass et al., 2014)*

TSWV-M-5F	CTTATCCAAGAAAAATTGATGC	1051 bps
TSWV-M-5R	AGAGCAATCAGTGCAAACAAAA	

The amplified RT-PCR products were both run on a 1.5% agarose gel, and stained with ethidium bromide and then visualized under UV (Integrated Biometra Gel Imager, Goettingen/(Germany)), and sequenced from both ends at HibriGen

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_53215339

(Biotechnology Research, Development Industry and Trade Co. Ltd, Turkey). The M Segment were divided into smaller sequences (700 bp to 1200 bp) using primers (*Tables 1* and *2*) to yield overlapping sequences for alignments. The sequence analysis and multiple sequence alignment were carried out using Chromas (Technelsium DNA Sequencing Software Australia) and CodonCode Corporation (Florida) software. The complete M segment sequences were analyzed in National Center for Biotechnology Information (NCBI) using nucleotide BLAST. The agarose gel electrophoresis of M segment amplifications is shown in *Figure 3*.

Results

The plant materials used in this study were tested using Sw-5 specific molecular marker (Dianese et al., 2010). The codominant SCAR *Sw5-2* marker confirmed the resistant vs susceptible status of the plant materials. The resistant *Solanum peruvianum* was homozygous resistant (574 bp), the four commercial hybrids were heterozygous (574 and 500 bp), and the susceptible one was homozygous (500 bp) as expected (*Fig. 1*).

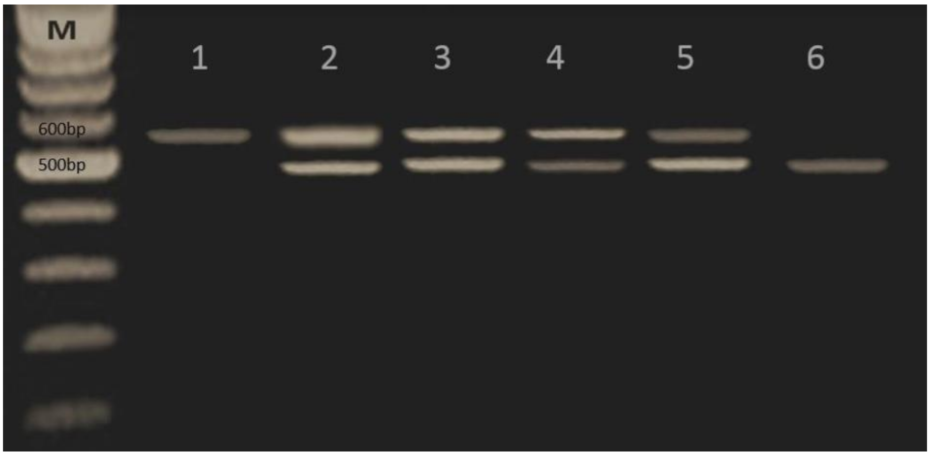

Figure 1. *Agarose gel electrophoresis of Sw-5 primers. M: 100 bpDNA ladder; Lane 1 resistant Solanum peruvianum, is a source of resistance with homozygous alleles (574 bp); Lanes 2 Torry F1 (Syngenta), 3 Matatu F1 (RijkZwan), 4 Tayfun F1 (De Ruiter), and 5 Swanson F1(Seminis). heterozygous resistant alleles known as resistant tomato varieties (574-500 bp); Lane 6 sensitive negative control. Tomato variety (Hazera 5656 (Hazera Seed)) without Sw-5 allele (500 bp)*

Antalya resistance-breaking (AntRB) TSWV isolates are confirmed in mechanical inoculations

After the TSWV mechanical inoculation (Hull, 2014), first typical virus symptoms were observed at 7 dpi on susceptible tomato variety. In resistant *Solanum peruvianum* and 4 commercial tomato varieties, the symptoms were barely evident at 15 dpi, similar in both homozygous and heterozygous plants.

RT-PCRs were performed at 21 dpi for 12 different tomato viruses (*Alfalfa Mosaic Virus* (AMV) (Saleh and Amer, 2013), *Cucumber mosaic virus* (CMV) (Paradies et al., 2000), *Potato virus X* (PVX) (Fidan et al., 2011), *Potato virus Y* (PVY) (Fidan et al., 2011), *Tabaco Etch Virus* (TEV) (Lee et al., 2011), *Tobacco Mosaic Virus* (TMV)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_53215339

(Kumar et al., 2011), *Tomato mosaic virus* (ToMV) (Kumar et al., 2011), *Tomato yellow leaf curl virus* TYLCV (Anfoka et al., 2008), *Tomato Chlorosis Virus* (ToCV) (Tiberini et al., 2010), *Tomato ringspot virus* (ToRSV) (Fuchs et al., 2009), *Pepino Mosaic Virus* (PePMV) (Ge et al., 2013) and TSWV (Adkins et al., 2005) (*Fig. 2*) it was confirmed that the samples were infected with only TSWV.

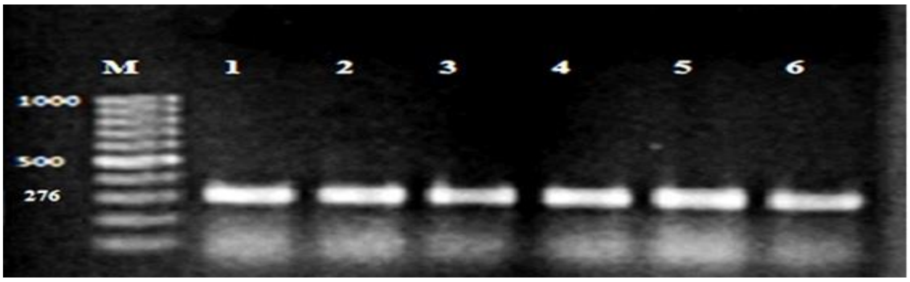

Figure 2. *Agarose gel electrophoresis of PCR products obtained using L1TSWVR and L1TSWVF primers specific to TSWV. The TSWV coat protein specific primers have produced 276 bp amplicon in PCR analyses. Lanes: M: 100 bp Standard Marker; Lane 1 resistant source 'Solanum peruvianum', Lanes 2 'Torry F1' (Syngenta), 3'Matatu F1' (RijkZwan), 4 'TayfunF1' (De Ruiter), and 5 'Swanson F1' (Seminis). Resistant varieties, Lane 6 ('Hazera 5656' (Hazera Seed)) sensitive varieties*

After confirming that the samples got infected with TSWV (*Fig. 2*), the M domain (Medium segment) were sequenced using different primer combinations. The 4825 bp M segment was amplified at five overlapping pieces (*Fig. 3*). The sequence of M Segment parts was aligned and the consensus sequence was subjected to haplotype analysis, using DnaSP 5 program (DNA Sequence Polymorphism. Universidad de Barcelona). Both sequence and haplotype analysis showed that RBS of TSWV collected in Antalya had a single haplotype (Additional file A4), which was named and deposited into NCBI as TSWVAntRB.

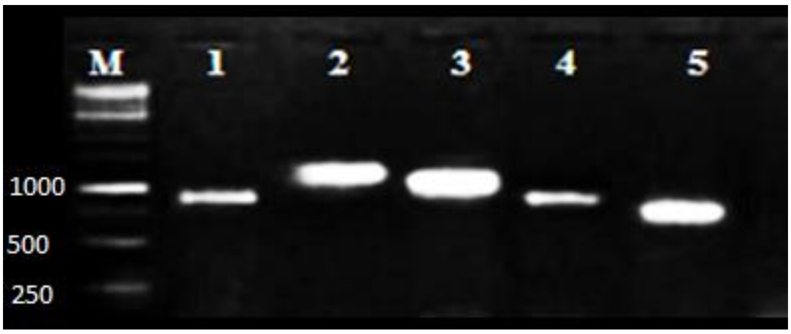

Figure 3. *TSWVAntRB Medium site is belonging to agarose gel electrophoresis. M: marker, Lane 1: M1-M3 primers (759 bp), Lane 2: M2-M5 (1269 bp), Lane 3: M4-M7 primers (1230 bp), Lane 4 primers: M6-M9 primers (1082 bp), Lane 5: M-5F/M-5R- primers (1051 bp)*

Phylogenetic analysis of complete nucleotide sequences of the M segment

The complete nucleotide M segment sequence obtained after assembly was recorded at NCBI database (MH367503). For phylogenetic analyses, the M segment sequences of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_53215339

both resistance breaking and non-breaking isolates originating from different parts of the world were retrieved from NCBI to trace the possible origin of resistance-breaking TSWVAntRB isolate. The nucleotide comparison was made in the NCBI BLAST system and the isolates with the highest similarity were selected (*Table 3*). Five of these isolates were RB (Resistance-breaking) and 13 of them were NRB (Non-Resistance-breaking).

Table 3. *The table is nucleotide comparison made in the NCBI BLAST system and the TSWVAntRB (MH367503) with the highest similarity was selected. The first five rows are RB (Resistance-breaking) and 13 of them are NRB (Non-Resistance-breaking) isolates*

NRB: non-resistance-breaking

The phylogenetic analysis of the isolates selected from NCBI according to the Neighboring method was carried out using the Mega 7 program. The phylogenetic trees showed that the isolate TSWVAntRB is originated from Europe (*Fig. 4*). The genome analysis placed the virus with HM15520.1, Spanish Resistance-breaking isolate.

Of the 17 TSWV isolates with the highest similarity to the RB isolate (TSWVAntRB), five belonged to RB isolates originating from tomato reported in Spain, Italy, USA, and Australia (*Table 3*). The RB isolate TSWVAntRB located on the same branch with one of the Spanish RB isolates. The result indicates that the RB isolate TSWVAntRB identified in Antalya, Turkey most probably originates from Spain. TSWV isolates worldwide have been divided into two roots, Asian and European isolates (Lian et al., 2013). It was determined that the isolates divided into two separate groups and TSWVAntRB isolate was found in group II (*Fig. 4*). The Group II consisted of European resistance-breaking isolates. The most of Group I isolates of Asian origin.

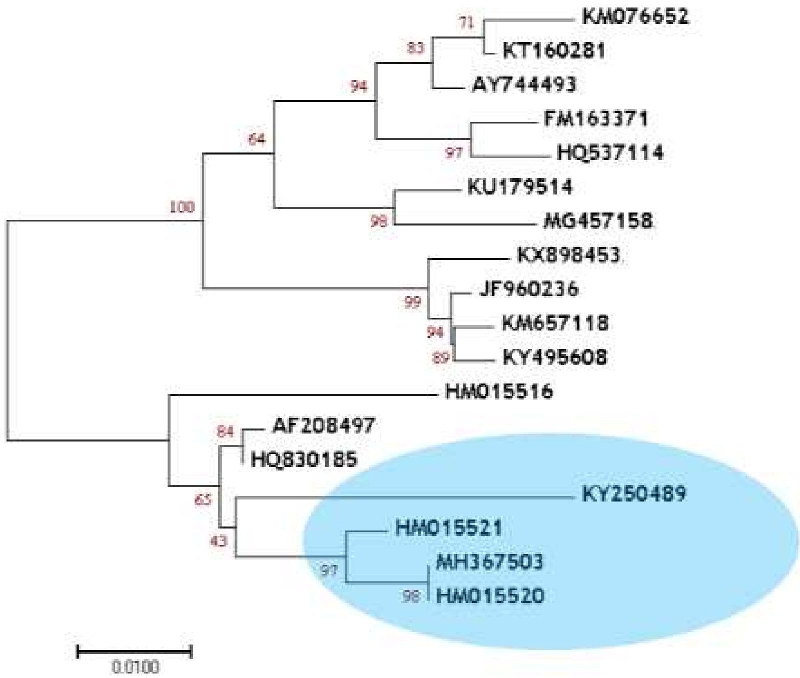

Figure 4. *Phylogenetic analysis showing the relationship between TSWVAntRB (MH367503) isolates with world isolates. The phylogenetic tree MEGA7 program was created using the Neighbor-Joining method. It was determined that the 18 isolates that were taken into consideration were formed by two groups and were calculated using the maximum composite likelihood method, which is the same root as the Spanish isolate (HM015520.1) that breaks down on the same branch with European isolates*

Protein-based comparisons on medium segmentation

Worldwide studies of TSWV indicate that resistance-breaking isolates arise due to a mutation in the NSm protein responsible from cell to cell movement on the Medium segment (Lopez et al., 2011).

The Bioedit and CodonCode Aligner programs were used to process sequence data and ExPASY Tool to obtain the predicted protein sequences of the M segment (*Figs. 5* and *6*). The predicted protein sequences of the TSWVAntRB isolate and the 17 isolates were aligned on which C118Y mutation was highlighted (*Fig. 5*) (Additional files 1, 2). The predicted protein alignment of the M segment further confirmed that a single point mutation on the movement protein located on M segment causes the resistance to break (KY973680.1; KY973679.1, KY973677.1, KT192625.1, KT192624.1, KT192623.1, KM379142.1, KM379141.1, MH367502.1, KX618636.1, KX618635.1, KM407603).

The remaining M segment sequence was also analyzed. The 40 different mutations detected throughout glycoproteins Gn and Gc (1135 aa) were not meaningful for resistance (Additional files 3).

It was previously reported that C118Y point mutation prevents the formation of HR response, causing systemic disease establishment on infected plants (Lopez et al., 2011).

The NSm protein domain on the TSWV's Medium region is the region that allows the virus to move from cell to cell. The resistance provided by the Sw-5 gene on the old isolate both causes rapid deaths in the contaminated tissues through HR reactions and there is no possibility of virus infection and contamination of new tissues in these tissues. However, it is shown that the TSWV resistance-breaking isolates related to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_53215339

NSm protein, a point mutation on the cell to cell movement gene, caused resistance breaking on TSWV resistant tomato.

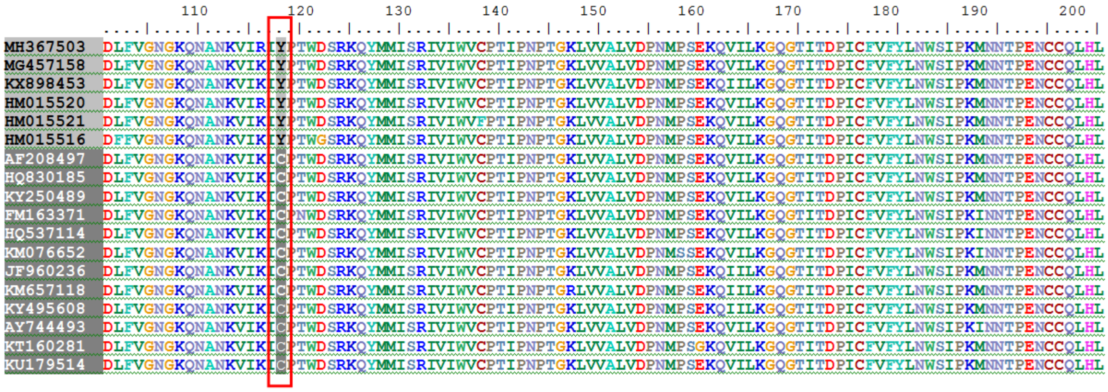

Figure 5. *Sequence alignment of the NSm proteins derived from the six resistance-breaking (RB) and 12 non-resistant-breaking (NRB) strains. The C118Y mutation on predicted amino acids derived from RB and NRB is indicated. The MH367503 (TSWVAntRB Antalya-Turkey RT tomato) line 2 to 6 are resistance-breaking (R.B). Lines 7 to 19 are non-resistance-breaking (N.R.B)*

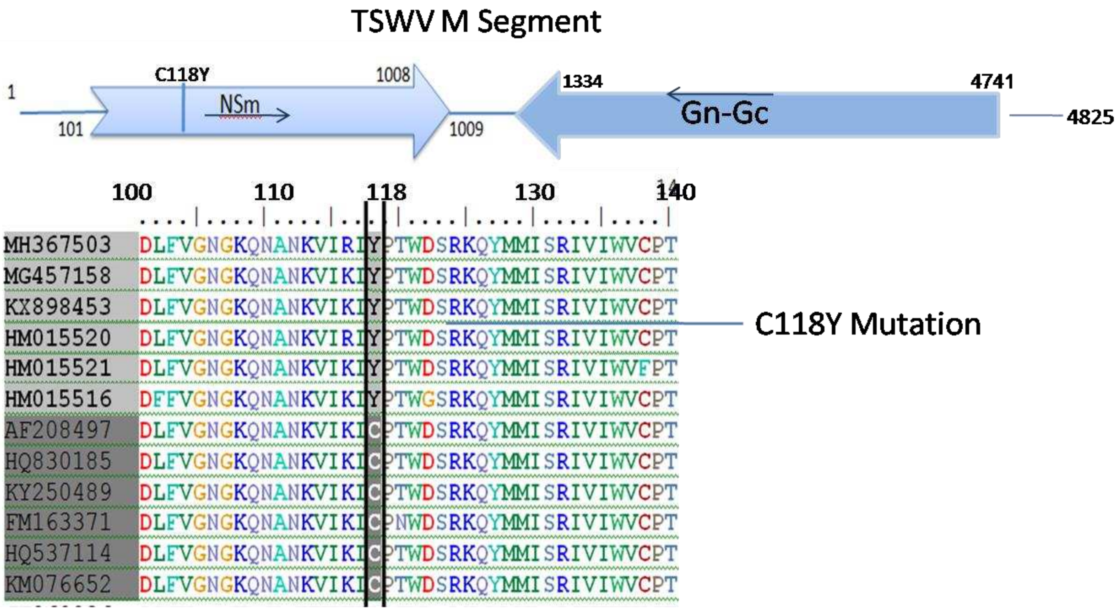

Figure 6. *The mutation site in the NSm protein domain (ORF-open reading frame) of the medium segment of the TSWVAntRB isolate*

Recombination events for single-stranded RNA viruses are thought to be involved in a major evolutionary process. Genetic alterations that occur due to recombination events can be very important for RNA viruses with ambisense character, which has a multi-segmented structure such as TSWV. Earlier studies emphasized the emergence of new isolates due to changes in the form of point mutations on viruses with multi-segmented structures such as TSWV.

Discussion

Comparison of NCBI isolates and evaluation of the phylogenetic analysis

The TSWV isolates were divided into two origins, namely Asia and Europe (Lian et al., 2013). The sequence comparison of M segment of TSWVAntRB isolates with that of isolates in NCBI returned a similarity ratio of 93-98%, confirming previous reports for two distinct origins (Lopez et al., 2011; Tsompana et al., 2005). However, origins of RB isolates are independent of sequence diversity where the same single point mutation results with resistance break. The extensive use of Sw-5 allele may have caused positive selection, leading to the occurrence of RB isolate (de Ronde et al., 2014). The Sw-5 gene is known to provide resistance to *Orthotospovirus*es through HR response. When infection occurs in plants, cell death occurs rapidly via the Sw-5 gene and the virus is trapped within the dead cells. Recent studies have informed that C118Y mutation on the NSm proteins of *Orthotospovirus*es fails Sw-5 protein to initiate the HR, leading to systemic virus infections in plants (Leastro et al., 2015). The NSm protein is a non-structural protein (Kormelink et al., 1994; Storms et al., 1995) that promotes the generation of *Orthotospovirus*es through plasmodesmata into envelope-free nucleocapsids. Hence, the NSm protein is able to spread to neighboring healthy cells through plasmodesmata at the absence of a functional Sw-5 gene or C118Y mutation that make Sw-5 protein fail to trigger HR.

Lopez et al. (2011) reported that C118Y mutation on the NSm protein in the medium segment is a very important for adaptation on new hosts. This mutation, which is likely to occur on the cysteine, is considered to be a fundamental point in the adaptation of TSWV to the new hosts during the evolutionary process.

The TSWVAntRB may have been transported from Spain via thrips vectors. Persistent propagative transmission of the virus with thrips may explain the long-distance transmission. However, it has been noted that there is no association in the breakdown of the resistance of the TSWV isolate accumulated in thrips body (Debreczeni et al., 2014). It has been argued that the phylogenetic relationship of isolates obtained from different continent may be effective in transporting vector thrips with long-distance migration capability (Lopez et al., 2011). Knowing the factors involved in the evolution of viruses is essential to understanding the processes involved in molecular biology and epidemiology (including the emergence of new viruses), to develop more effective and strong control strategies (Garcia et al., 2001; Moya et al., 2004).

The entire genomic sequences of the Gn-Gc domain in the medium segment were also obtained and compared against the database. The result showed that although this domain carries multiple mutations, none of which plays a role in the breakdown of resistance.
