(Received 6th Oct 2018; accepted 28th Nov 2018)

Abstract. A problem of rationalizing industrial wastewater treatment is considered. It issues from that industrial enterprises may violate conventions about water treatment, so then they are fined. Those fines are directed to control water pollution by measuring it and treating wastewater additionally, if necessary. Under threat of heavy fines, however, an enterprise may reduce or stop its manufacturing resulting in a budget cut for water resources conservation and recirculation. Therefore, fining for under-treating industrial wastewater is balanced using an environmental protection model in the form of a dyadic 3-person game. According to this game, in which three subjects of water pollution (industrial enterprises) are obliged to treat industrial wastewater, the ecologically healthy water balance of the reservoir does not worsen if just one subject does not apply the treatment. Such model implies that about one third of the polluted water recovers without treatment. If none of the subjects applies a water treatment system, they are fined (with a 3-fine for each). If only two subjects do not treat wastewater, all the three subjects are fined (with a 2-fine for each) due to impossibility of finding those two violators. Application of a water treatment system costs a conventional unit for each subject per a period of time (a day, a week, or a month). The game solution is searched on the regular finite lattice of situations, which is obtained by sampling the continuous set of those situations. Dealing with either non-symmetric or non-profitable situations, an approximate solution is found using concessions in the equilibrium. By this solution, the water treatment system is turned off for 3 periods of 10, and the 2-fine is optimally set at 0.34 units, whereas the 3-fine is set at 1.394 units. Under threat of the heavy 3-fine, the subjects will definitely come to a convention of scheduling the water treatment systems. Switching from "clean" to "polluting" manufacturing and backwards is to be controlled exactly once per those 10 periods. Eventually, the cost of 8.018 units for a subject is just the expected spending, whereas the least cost in 7 units is still possible under the corresponding water treatment schedule.
Keywords: *industrial wastewater, water treatment, fining, dyadic game, equilibrium situations*

Introduction

Water resources are intensively used in industries. For their conservation and recirculation, subjects of water pollution are obliged to treat industrial wastewater. The treatment should be executed as much as needed for maintaining the ecologically healthy water balance. A part of polluted water recovers without treatment (Beiras, 2018; Parimal, 2017).

Some industrial enterprises may violate conventions about water treatment. Then the government fines them for under-treating wastewater. Those fines are directed to control water pollution by measuring it and treating additionally, if necessary (Jiménez et al., 2018; Rey et al., 2018). In a certain sense, fining for under-treating is a way for strengthening the state treasury. However, an enterprise may reduce or stop its activity (manufacturing) under threat of heavy fines. The treasury subsequently will receive less. Then a budget for water resources conservation and recirculation will be cut. Therefore, fining for under-treating industrial wastewater should be balanced (Arguedas, 2013; Heyes, 2000; Regens et al., 1997).

Currently an imbalance in a water treatment convention is a common phenomenon. Primarily, this is about the absence of compelling factors which would force parties to comply with a convention. For instance, the Convention on the Protection and Use of Transboundary Watercourses and International Lakes, also known as the Water Convention, has a joint ad hoc expert group on water and industrial accidents (see [unece.org/env/water.html]). This group deals with the prevention of the accidental pollution of transboundary waters. There is a Protocol on civil liability for damage and compensation caused by transboundary effects of industrial accidents on transboundary waters. Its aim is to give individuals affected by the transboundary impact of industrial accidents on international watercourses a legal claim for adequate and prompt compensation. The financial limits of liability as well as the minimum amount of financial securities have been agreed by all the actors of the Protocol negotiation, including the insurance sector. Despite this, the Protocol has been ratified only by Hungary and it is not in force. The Protocol will enter into force once 16 states have ratified it. This is a partial but demonstrative evidence of the force lack in a convention. But it is obvious that such conventions can be reinforced by financial influence. Therefore, the role of budgeting to achieve a balance in a water treatment convention is principal (Heyes, 2000; James, 2017; Wolf, 2009).

An environmental protection model in the form of a dyadic 3-person game

A lot of economical factors influence how the budget for water resources conservation and recirculation is formed (Sgroi et al., 2018; Cui et al., 2018; Zikos and Hagedorn, 2017). So, no exact formulae exist for counting the fines. Only simple and rough models can be economically reliable and practically executable (Zomorodian et al., 2018; Regens et al., 1997; Arguedas, 2013). One of such models is a 3-person dyadic game firstly considered by Vorob'yov (1984). According to this game model, three enterprises manufacturing roughly the same production use similar water resources of a reservoir. The used water is polluted through the manufacturing process (e.g. it is shown by Skouteris et al., 2018; Hussain and Wahab, 2018; Mousavi et al., 2015). Sometimes an enterprise is called an environmental pollution subject. Application of a water treatment system costs a conventional unit for each subject per a period of time (a day, a week, or a month). If just a one subject does not apply the treatment, it does not worsen the ecologically healthy water balance of the reservoir owing to recovering. Such model implies that about one third of the polluted water recovers without treatment. If two or three subjects do not apply the treatment, then the polluted water cannot recover and all the three subjects are fined. Along with the fundamental research by Vorob'yov (1984), the fine set at 3 units was also researched by Romanuke (2009, 2010a) continued trying the equilibrium approach, which recently has been intensively developed for improving resource management policies (Xu et all, 2018; Guo, 2018; James, 2017). With fining the subjects in such a way, the corresponding dyadic game has four equilibrium situations in pure strategies and five equilibrium situations in mixed strategies (Romanuke, 2010a). However, no one of these situations is simultaneously symmetric and profitable. An equilibrium situation at which the subjects work without treating wastewater (a symmetric situation) is totally senseless, because the subsequent fines in 3 units are far worse than just applying three water treatment systems. Another symmetric equilibrium situation is in mixed strategies, at which a cost for every environmental pollution subject is equal to $2-\sqrt{3}/2$, i.e. this cost is about 13.4% higher than applying three water treatment

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14511474

systems. At this situation, about 21.13% of the water-for-manufacturing is discharged back into the reservoir without treatment. A promising situation, though neither equilibrium nor very profitable, is a case when only 5.9% of wastewater is not treated whereas it costs 0.971 units for every subject. Despite these costs are very close to costs for applying the water treatment system, there are no any other symmetric situation at which the costs would be less.

A generalization of fining was researched by Romanuke (2010b). The article considered the fine greater than the unit. If the fine is less than 2 units then the corresponding dyadic game does not have equilibrium situations. For the fine equal exactly 2 units, there is a single symmetric equilibrium situation at which every environmental pollution subject treats just a half of the discharged wastewater. Obviously, this situation is unprofitable as the reservoir is polluted irreversibly whereas it costs 1.5 units for every subject. For fines greater than 2 units, the game has a single symmetric equilibrium situation at which the cost for a subject decreases down to 1 unit as the fine increases. Theoretically, threat of heavy fines may force the environmental pollution subjects to totally convert their manufacturing to treating wastewater as every subject will pay 1 unit anyway. Although such “clean” situation is not a Nash equilibrium, its equilibration is forced by the threat of heavy fines. On the other hand, those heavy fines threaten with that some subjects may reduce their manufacturing because of the cost in 1 unit may be initially unprofitable or economically irrational.

Goal of the article and tasks to be performed

Inasmuch as heavy fines may ruin an economical balance among those three environmental pollution subjects and government, subsequently leading to cutting a budget for water resources conservation and recirculation, economically more reasonable fines should be substantiated. Thus, fining for when all subjects do not apply treatment must be heavier than fining when only two subjects do simultaneously not treat wastewater. Along with that, no less than two thirds of the polluted water is to be treated. To find a solution to such a problem, there are six tasks to be performed:

1. To state costs in the game explicitly.
2. To substantiate a range of the fine for when only two subjects do simultaneously not treat wastewater (let it be called a 2-fine).
3. To substantiate a range of the fine for when no one treats wastewater (let it be called a 3-fine).
4. In order to find an applicable solution, to sample the continuous set of situations in mixed strategies.
5. To find symmetric equilibria (over the sampled set), at which the cost for every subject is less than 1 unit.
6. For the found equilibria, to select those fines by which no less than two thirds of the polluted water is treated costing the least.

Materials and methods

Costs of wastewater treatment in the dyadic 3-person game with generalized fines

Denote a pure strategy of the k-th subject by x_k, where $x_k \in \{0, 1\}$. Strategy $x_k = 0$ implies that the k-th subject totally applies its water treatment system, whereas $x_k = 1$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14511474

implies that all wastewater is discharged without treatment. Henceforward, a mixed strategy of the k-th subject can be represented as a probability $d_k \in [0;1]$ of choosing pure strategy $x_k = 1$. This is why strategies $x_k = 1$ and $d_k = 1$ coincide (implying the same action or decision), and strategies $x_k = 0$ and $d_k = 0$ coincide also.

There are eight situations in pure strategies written as $\{x_1, x_2, x_3\}$ in the dyadic 3-person game. A cost for the k-th subject in situation $\{x_1, x_2, x_3\}$ is $c_k(x_1, x_2, x_3)$ or, shortly, $c_k^{\langle x_1 x_2 x_3 \rangle}$. If the 2-fine is a and the 3-fine is b, then (see the cube of situations and costs in *Fig. 1*):

$$\begin{gathered}
c_1^{\langle 000 \rangle} = c_2^{\langle 000 \rangle} = c_3^{\langle 000 \rangle} = 1, \\
c_1^{\langle 010 \rangle} = c_3^{\langle 010 \rangle} = 1,\ c_2^{\langle 010 \rangle} = 0, \\
c_1^{\langle 010 \rangle} = c_3^{\langle 010 \rangle} = 1,\ c_2^{\langle 010 \rangle} = 0, \\
c_2^{\langle 100 \rangle} = c_3^{\langle 100 \rangle} = 1,\ c_1^{\langle 100 \rangle} = 0, \\
c_1^{\langle 011 \rangle} = 1 + a,\ c_2^{\langle 011 \rangle} = c_3^{\langle 011 \rangle} = a, \\
c_2^{\langle 101 \rangle} = 1 + a,\ c_1^{\langle 101 \rangle} = c_3^{\langle 101 \rangle} = a, \\
c_3^{\langle 110 \rangle} = 1 + a,\ c_1^{\langle 110 \rangle} = c_2^{\langle 110 \rangle} = a, \\
c_1^{\langle 111 \rangle} = c_2^{\langle 111 \rangle} = c_3^{\langle 111 \rangle} = b.
\end{gathered} \quad \text{(Eq.1)}$$

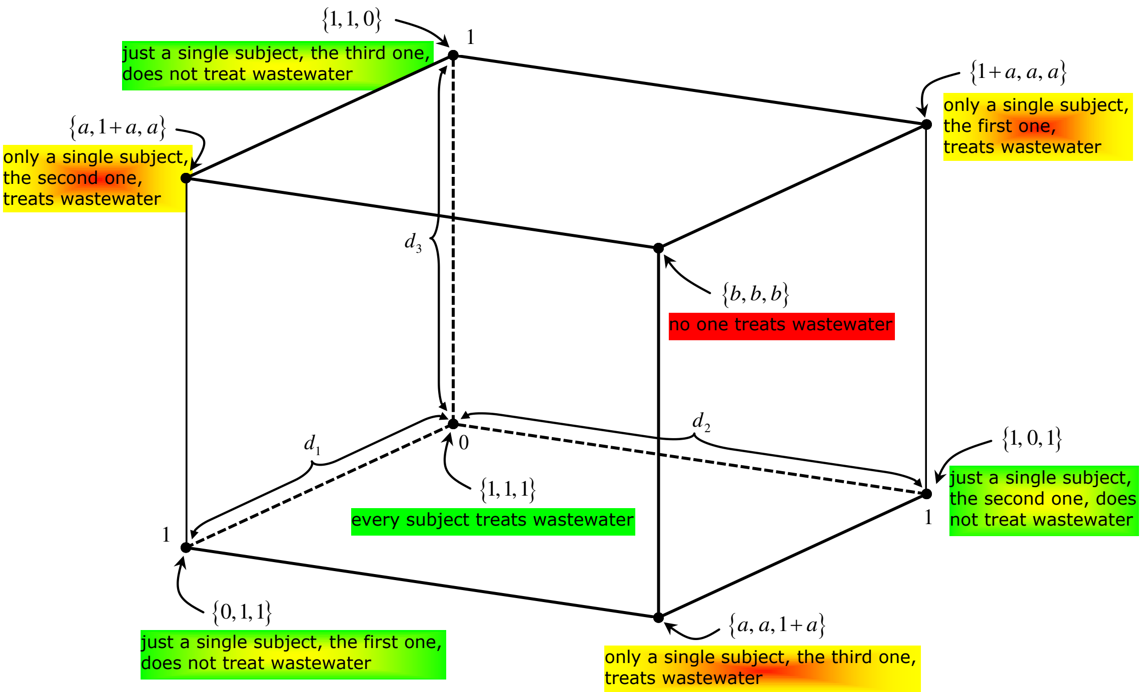

***Figure 1.** The cube of situations and costs in the dyadic 3-person game with generalized fines (see Romanuke, 2010b)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14511474

A cost for the k-th subject in mixed strategies situation $\{d_1, d_2, d_3\}$ is:

$$\begin{gathered} c_k(d_1, d_2, d_3) = \\ = (1-d_1)(1-d_2)(1-d_3)c_k^{\langle 000\rangle} + \\ +(1-d_1)(1-d_2)d_3 c_k^{\langle 001\rangle} + \\ +(1-d_1)d_2(1-d_3)c_k^{\langle 010\rangle} + \\ +(1-d_1)d_2 d_3 c_k^{\langle 011\rangle} + \\ +d_1(1-d_2)(1-d_3)c_k^{\langle 100\rangle} + \\ +d_1(1-d_2)d_3 c_k^{\langle 101\rangle} + \\ +d_1 d_2(1-d_3)c_k^{\langle 110\rangle} + \\ +d_1 d_2 d_3 c_k^{\langle 111\rangle},\ k = \overline{1, 3}. \end{gathered} \quad \text{(Eq.2)}$$

Plugging costs *Equation 1* into *Equation 2* gives:

$$c_1(d_1, d_2, d_3) = 1 + a(d_1 d_2 + d_2 d_3 + d_1 d_3) + (b - 3a) d_1 d_2 d_3 - d_1, \quad \text{(Eq.3)}$$

$$c_2(d_1, d_2, d_3) = 1 + a(d_1 d_2 + d_2 d_3 + d_1 d_3) + (b - 3a) d_1 d_2 d_3 - d_2, \quad \text{(Eq.4)}$$

$$c_3(d_1, d_2, d_3) = 1 + a(d_1 d_2 + d_2 d_3 + d_1 d_3) + (b - 3a) d_1 d_2 d_3 - d_3. \quad \text{(Eq.5)}$$

Every subject struggles to minimize its cost by adjusting the probability of discharging without treatment. If in situation $\{d_1^*, d_2^*, d_3^*\}$ costs (*Eqs. 3–5*) are such that

$$c_1(d_1^*, d_2, d_3) \leqslant c_1(d_1, d_2, d_3) \text{ by } d_k \in [0; 1] \ \forall k = \overline{1, 3}, \quad \text{(Eq.6)}$$

$$c_2(d_1, d_2^*, d_3) \leqslant c_2(d_1, d_2, d_3) \text{ by } d_k \in [0; 1] \ \forall k = \overline{1, 3}, \quad \text{(Eq.7)}$$

$$c_3(d_1, d_2, d_3^*) \leqslant c_3(d_1, d_2, d_3) \text{ by } d_k \in [0; 1] \ \forall k = \overline{1, 3}, \quad \text{(Eq.8)}$$

then situation $\{d_1^*, d_2^*, d_3^*\}$ is an equilibrium (by Nash). The equilibrium situation is explicitly determined by inequalities (*Eqs. 6–8*) represented in the form of inequalities

$$\begin{gathered} 1 + a(d_1^* d_2 + d_2 d_3 + d_1^* d_3) + (b - 3a) d_1^* d_2 d_3 - d_1^* \leqslant \\ \leqslant 1 + a(d_1 d_2 + d_2 d_3 + d_1 d_3) + (b - 3a) d_1 d_2 d_3 - d_1 \text{ by } d_k \in [0; 1] \ \forall k = \overline{1, 3}, \end{gathered} \quad \text{(Eq.9)}$$

$$\begin{gathered} 1 + a(d_1 d_2^* + d_2^* d_3 + d_1 d_3) + (b - 3a) d_1 d_2^* d_3 - d_2^* \leqslant \\ \leqslant 1 + a(d_1 d_2 + d_2 d_3 + d_1 d_3) + (b - 3a) d_1 d_2 d_3 - d_2 \text{ by } d_k \in [0; 1] \ \forall k = \overline{1, 3}, \end{gathered} \quad \text{(Eq.10)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14511474

$$1+a\left(d_1d_2+d_2d_3^*+d_1d_3^*\right)+\left(b-3a\right)d_1d_2d_3^*-d_3^*\leqslant \leqslant 1+a\left(d_1d_2+d_2d_3+d_1d_3\right)+\left(b-3a\right)d_1d_2d_3-d_3 \text{ by } d_k\in\left[0;1\right]\ \forall k=\overline{1,3}. \quad \text{(Eq.11)}$$

Inequalities (*Eq. 9–11*) are subsequently simplified:

$$d_1^*\left(a\left(d_2+d_3\right)+\left(b-3a\right)d_2d_3-1\right)\leqslant \leqslant d_1\left(a\left(d_2+d_3\right)+\left(b-3a\right)d_2d_3-1\right) \text{ by } d_k\in\left[0;1\right]\ \forall k=\overline{1,3}, \quad \text{(Eq.12)}$$

$$d_2^*\left(a\left(d_1+d_3\right)+\left(b-3a\right)d_1d_3-1\right)\leqslant \leqslant d_2\left(a\left(d_1+d_3\right)+\left(b-3a\right)d_1d_3-1\right) \text{ by } d_k\in\left[0;1\right]\ \forall k=\overline{1,3}, \quad \text{(Eq.13)}$$

$$d_3^*\left(a\left(d_1+d_2\right)+\left(b-3a\right)d_1d_2-1\right)\leqslant \leqslant d_3\left(a\left(d_1+d_2\right)+\left(b-3a\right)d_1d_2-1\right) \text{ by } d_k\in\left[0;1\right]\ \forall k=\overline{1,3}. \quad \text{(Eq.14)}$$

So, a situation with probabilities d_1^*, d_2^*, d_3^* becomes a Nash equilibrium if inequalities (*Eqs. 12–14*) hold. In such a situation, an environmental pollution subject cannot pay less acting on its own. If two or three subjects start searching for decreasing their costs, the equilibrium is ruined as subsequent costs for at least one party will be greater than previously. Obviously, equilibration is strongly dependent on what 2-fine and 3-fine are and how much they differ. The best situation is such that

$$d_1^*=d_2^*=d_3^*=d^*\leqslant 1/3 \quad \text{(Eq.15)}$$

for the stated problem.

A range of the 2-fine

The model claims that the polluted water recovers without treating it by investing 2 units. This is a situation when two of three environmental pollution subjects apply their water treatment systems. When only a single subject applies, a unit is lacked. Measurement of a water pollution rate cannot reveal which subject is "clean" and which subjects work "polluted". Therefore, every subject is fined. The sum of three 2-fines should be equal to 1 unit or greater. So, a minimally possible 2-fine is one third of the unit.

Now, a maximal 2-fine should be considered. As it is mentioned above, setting $a>1$ is unfavorable. In the case of $a=1$ or close to that, the "clean" subject potentially pays a doubled cost. This is a kind of demotivation for conscientious subjects. Besides, this may be a (negative) motivation for violators. The case of $a=0.75$ is more attractive but nonetheless the "clean" subject may eventually pay too much. In the case of $a=0.5$ the investment into the reservoir is 2.5 units, which is sufficient for maintaining the ecologically healthy water balance. Hence, the 2-fine can be studied within range $\left[0.34; 0.5\right]$ by a step of 0.01 (instead of unsuitable 0.33, the marginal endpoint 0.34 is included for closing the range). However, if no solution is found, the range must be widened.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14511474

A range of the 3-fine

When no one treats wastewater, the sum of 3-fines should be far greater than that (2 units), which is sufficient for the ecologically healthy water balance. A reason is that worse pollution may require more investment for recovering. This is so because of a water recover function is probably not linear. Another reason is to demotivate violators. Such demotivation must be stronger than a minimal 2-fine. Hence, a suitable range for the 3-fine is from a up to $5a$. The step can be set at $a/10$, rougher than for the 2-fine as the latter is more influential. Note that such a range implies inequality $b \geqslant a$ although inequality $b \leqslant 1+a$ is possible. This means that the case with the totally senseless equilibrium of a situation, when no one treats wastewater, here is not excluded.

Sampling the continuous set of situations in mixed strategies

It is apparent that the dyadic 3-person game (see *Fig. 1*), by fixing some a and b from their ranges, will not have profitable symmetric equilibria in pure strategies. So, the best solution will be sought in mixed strategies. But, even if a profitable symmetric equilibrium in mixed strategies exists, it is likely to contain probabilities which are either irrational numbers or irreducible fractions with great denominators. Practical realization of such probabilities is impossible: relative frequencies (of both pure strategies) tend to be represented as much simpler fractions like $1/2$, $n/3$ by $n \in \{1, 2\}$, $n/4$ by $n \in \{\overline{1, 3}\}$, and so on, because switches from “clean” to “polluting” manufacturing and backwards cannot be too frequent. An exception could be if the work of those environmental pollution subjects was observed and controlled for a few years without any corrections by inflation, development, implementation of new technologies, etc. In other words, such exception is hardly plausible.

Therefore, the continuous set of situations in mixed strategies is sampled to obtain a finite lattice of situations. The lattice is

$$\mathscr{L} = \bigtimes_{k=1}^{3} \left\{ d_k^{\langle j \rangle} \right\}_{j=0}^{M} \text{ by } M \in \mathbb{N} \setminus \{1\}, \tag{Eq.16}$$

where $d_k^{\langle j \rangle} = j/M$ is a mixed strategy (being factually a probability) of the k-th subject. Lattice (*Eq. 16*) is regular as its step $1/M$ is a constant (*Fig. 2*).

Nevertheless, the game may not have a symmetric profitable equilibrium even over the sampled set of situations in mixed strategies. Thus, concessions in costs will be considered.

Results

Approximate equilibria by cost concessions

When an exact equilibrium does not exist, or condition (*Eq. 15*) does not hold, an approximate equilibrium is found by a concession β (for more detailed analysis, see it in Romanuke, 2016). Instead of inequalities (*Eq. 12–14*), if inequalities

$$d_1^{\langle\beta\rangle}\left(a\left(d_2+d_3\right)+\left(b-3a\right)d_2 d_3-1\right)-\beta \leqslant$$
$$\leqslant d_1\left(a\left(d_2+d_3\right)+\left(b-3a\right)d_2 d_3-1\right) \text{ by } d_k \in [0; 1] \;\; \forall\, k=\overline{1, 3},$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14511474

$$d_2^{\langle\beta\rangle}\left(a\left(d_1+d_3\right)+\left(b-3a\right)d_1d_3-1\right)-\beta\leqslant$$
$$\leqslant d_2\left(a\left(d_1+d_3\right)+\left(b-3a\right)d_1d_3-1\right) \text{ by } d_k\in\left[0;\,1\right]\ \forall\,k=\overline{1,\,3},$$

$$d_3^{\langle\beta\rangle}\left(a\left(d_1+d_2\right)+\left(b-3a\right)d_1d_2-1\right)-\beta\leqslant$$
$$\leqslant d_3\left(a\left(d_1+d_2\right)+\left(b-3a\right)d_1d_2-1\right) \text{ by } d_k\in\left[0;\,1\right]\ \forall\,k=\overline{1,\,3}$$

hold for some $\beta>0$, then $\left\{d_1^{\langle\beta\rangle},\, d_2^{\langle\beta\rangle},\, d_3^{\langle\beta\rangle}\right\}$ is the approximate equilibrium. The concession is a kind of re-achieving an equilibrium at a situation by small losses when the situation is not in equilibrium (by Nash). By an appropriate concession β, condition

$$d_1^{\langle\beta\rangle}=d_2^{\langle\beta\rangle}=d_3^{\langle\beta\rangle}=d^{\langle\beta\rangle}\leqslant 1/3 \tag{Eq.17}$$

defines the best approximate equilibrium. Clearly, the greater the concession is, the less stable the respective approximate equilibrium becomes.

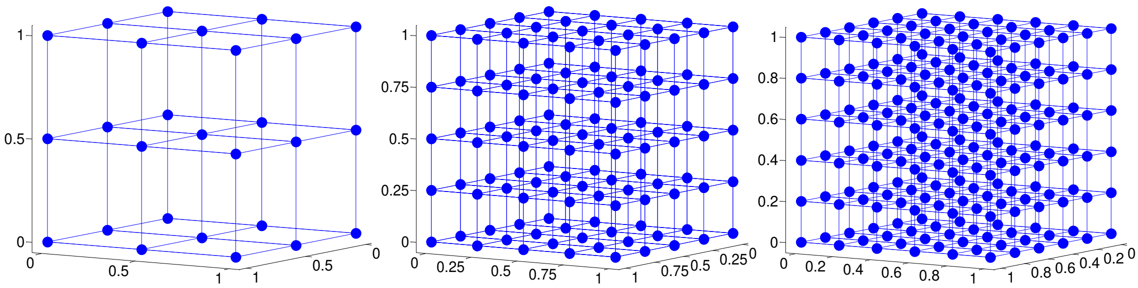

Figure 2. *The regular finite lattice of situations in the dyadic 3-person game by decreasing the sampling step (from the left to the right)*

In the game being considered, an initial concession can be set at between 0.01 and 0.11 with a step of 0.01 (the marginal endpoint 0.11 is included for closing the range). However, condition (*Eq. 17*) does not hold for $\beta\in\left[0.01;\,0.11\right]$ (see it by 2-fines along with concessions in *Fig. 3* and by 3-fines along with costs in *Fig. 4*). Subsequently, let the range of 2-fines be widened to $\left[0.34;\,1\right]$ and the range of concessions be widened to $\left[0.01;\,0.5\right]$. For these widened ranges, condition (*Eq. 17*) holds for $\beta\geqslant 0.21$ (*Fig. 5*), but sampling with a step of $1/16$ is canceled as it is practically unrealizable (although it is promising in bringing minimal and maximal fines, costs, and concessions closer).

The symmetric “cleanest” situation (see it in *Fig. 5* at $M=9$)

$$\left\{d_1^{\langle 0.5\rangle},\, d_2^{\langle 0.5\rangle},\, d_3^{\langle 0.5\rangle}\right\}=\left\{1/9,\, 1/9,\, 1/9\right\} \tag{Eq.18}$$

has pretty narrow gaps for 2-fines and costs (*Fig. 6*). The corresponding gap for 3-fines is the narrowest (*Fig. 7*). Nonetheless, situation (*Eq. 18*) considered as an approximate equilibrium is risky to be too unstable because of very great concessions (which are greater than maximal 2-fines). This is why situation (*Eq. 18*) is excluded from further consideration. On the other hand, this sampling has another two, less “clean”, situations

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14511474

$$\left\{d_1^{\langle\beta\rangle}, d_2^{\langle\beta\rangle}, d_3^{\langle\beta\rangle}\right\} = \{2/9, 2/9, 2/9\}$$

and

$$\left\{d_1^{\langle\beta\rangle}, d_2^{\langle\beta\rangle}, d_3^{\langle\beta\rangle}\right\} = \{1/3, 1/3, 1/3\} \quad \text{(Eq.19)}$$

which satisfy condition (*Eq. 17*). The concession for approximate equilibrium

$$\left\{d_1^{\langle 0.19\rangle}, d_2^{\langle 0.19\rangle}, d_3^{\langle 0.19\rangle}\right\} = \{1/3, 1/3, 1/3\} \quad \text{(Eq.20)}$$

is just 0.19, but the costs are higher than 0.9966 units.

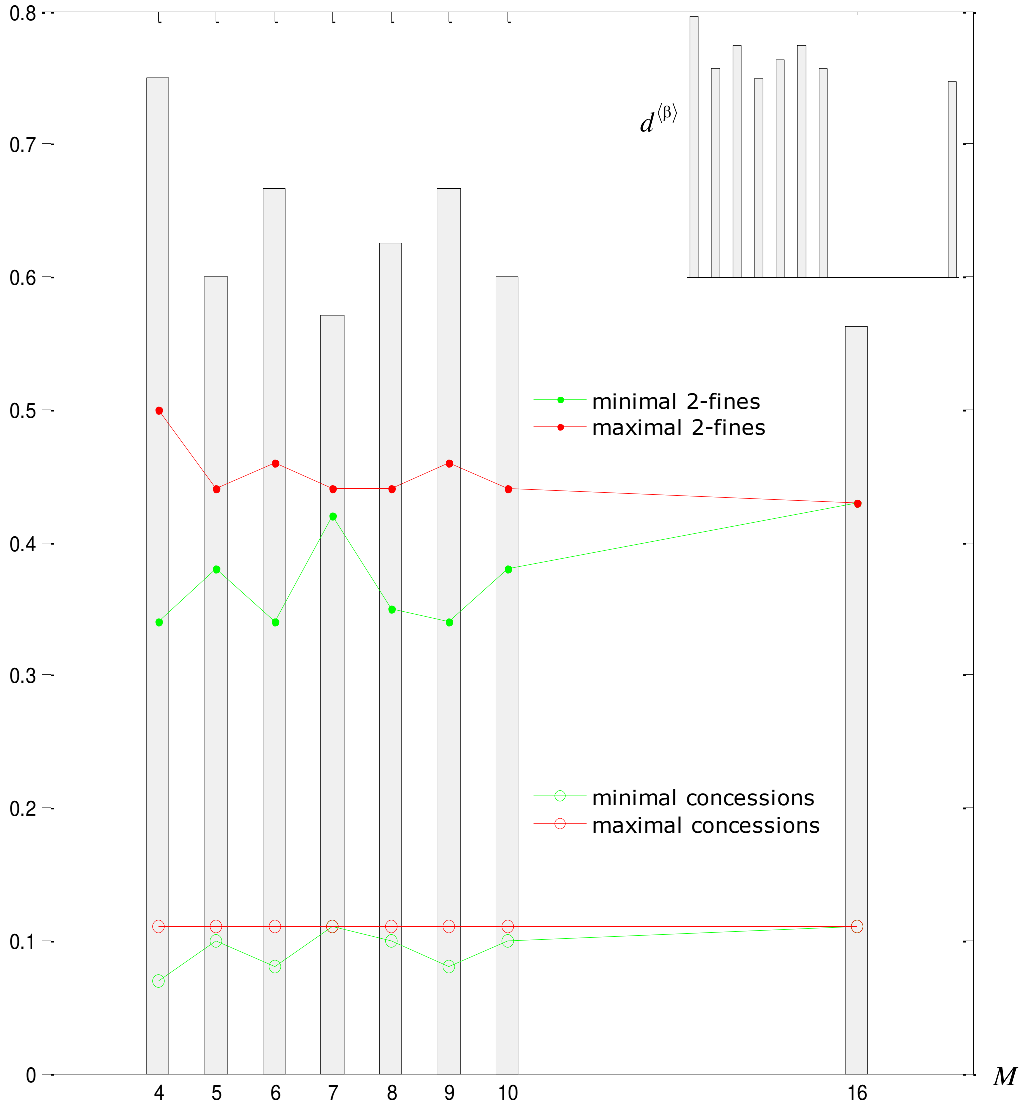

Figure 3. *The slowly decreasing minimal probability of discharging without treatment by the corresponding gap of 2-fines along with the corresponding gap of concessions for* $\beta \in [0.01; 0.11]$ *and* $a \in [0.34; 0.5]$

DOI: http://dx.doi.org/10.15666/aeer/1702_14511474

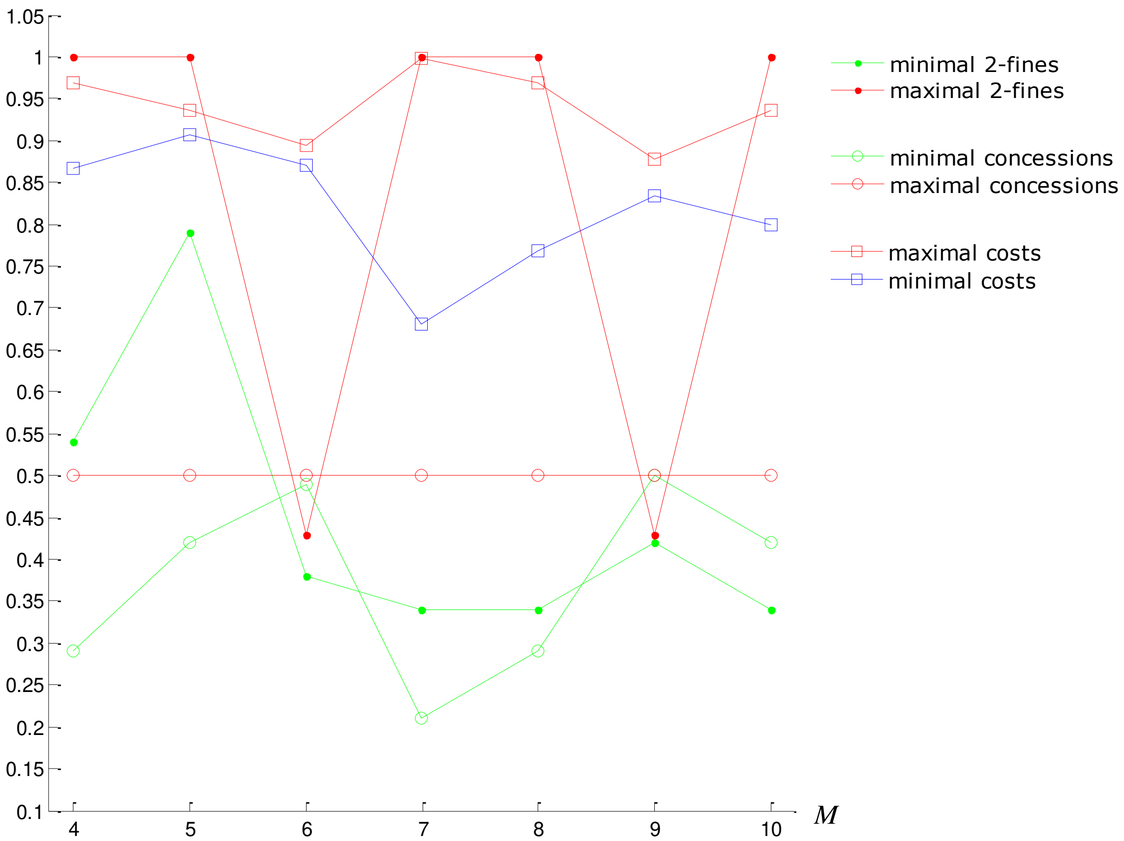

Figure 6. *The corresponding gaps of 2-fines, concessions, and costs for* $\beta \in [0.01; 0.5]$ *and* $a \in [0.34; 1]$*, at which the ecologically healthy water balance of the reservoir is maintained owing to recovering*

Sampling with a step of $1/4$ has wider gaps than those for $M = 5$. In its turn, sampling with a step of $1/5$ has wider gaps than those for $M = 6$. The widest gaps are at $M = 7$ but approximate equilibria

$$\left\{ d_1^{\langle\beta\rangle}, d_2^{\langle\beta\rangle}, d_3^{\langle\beta\rangle} \right\} = \{2/7, 2/7, 2/7\} \quad \text{(Eq.21)}$$

by such sampling are achieved by

$$0.21 \leqslant \beta \leqslant 0.5,$$
$$0.34 \leqslant a \leqslant 1,$$

and

$$0.62 \leqslant b \leqslant 4.85$$

which are very promising. In fact, situation (*Eq. 21*) is achievable at the smallest concession $\beta = 0.21$ (see the minimum in *Fig. 6*).

Despite "clean" situation (*Eq. 21*) implies the heaviest discharge without treatment, it is the most stable approximate equilibrium owing to the smallest concession. Thus, approximate equilibrium

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14511474

$$\left\{d_1^{\langle 0.21\rangle}, d_2^{\langle 0.21\rangle}, d_3^{\langle 0.21\rangle}\right\} = \{2/7, 2/7, 2/7\} \qquad \text{(Eq.22)}$$

is exactly achieved at $a = 0.97$ and $b = 4.85$. Eventually, however, situation (*Eq. 22*) forces every environmental pollution subject to pay about 0.9971 units. That makes this situation almost senseless under those fines. Besides, those fines are heavy and they seem discouraging.

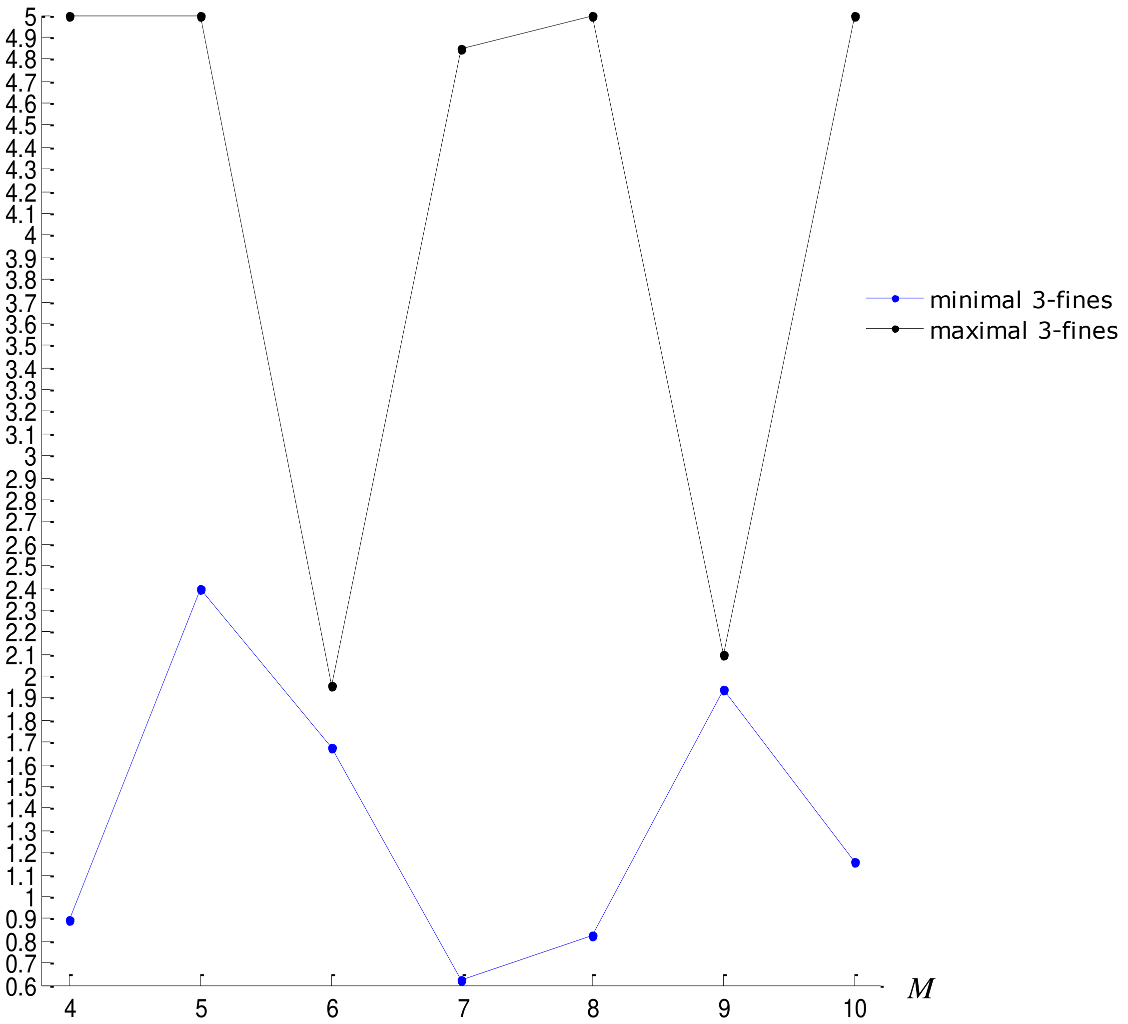

Figure 7. *The corresponding gaps of 3-fines for* $\beta \in [0.01; 0.5]$ *and* $a \in [0.34; 1]$*, at which the ecologically healthy water balance of the reservoir is maintained owing to recovering*

Approximate equilibrium

$$\left\{d_1^{\langle 0.29\rangle}, d_2^{\langle 0.29\rangle}, d_3^{\langle 0.29\rangle}\right\} = \{1/4, 1/4, 1/4\}$$

exactly achieved at $a = 0.99$ and $b = 4.95$ is rejected by similar reasoning: every subject will eventually pay 0.9666 units. Another relatively acceptable concession, possible at $M = 8$, does not seem better: approximate equilibrium

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14511474

$$\left\{d_1^{\langle 0.29\rangle}, d_2^{\langle 0.29\rangle}, d_3^{\langle 0.29\rangle}\right\} = \{1/8, 1/8, 1/8\}$$

is achieved at the same fines (plausibly, due to the doubled sampling) forcing the same cost. Meanwhile, a hardly acceptable concession, possible at $M = 6$, allows to achieve approximate equilibrium

$$\left\{d_1^{\langle 0.49\rangle}, d_2^{\langle 0.49\rangle}, d_3^{\langle 0.49\rangle}\right\} = \{1/6, 1/6, 1/6\} \qquad \text{(Eq.23)}$$

at $a = 0.4$ and $b = 1.92$, being quite acceptable fines, which costs only 0.89 units. Another dubious concession, possible at $M = 10$, will cost 0.8227 units if the subjects hold at approximate equilibrium

$$\left\{d_1^{\langle 0.42\rangle}, d_2^{\langle 0.42\rangle}, d_3^{\langle 0.42\rangle}\right\} = \{1/5, 1/5, 1/5\} \qquad \text{(Eq.24)}$$

by $a = 0.4$ and $b = 1.68$ (even more acceptable 3-fines for the subjects). Samplings at $M = 6$ and $M = 10$ have their second possible approximate equilibria: less "clean" situation (*Eq. 19*) at $M = 6$ and

$$\left\{d_1^{\langle \beta\rangle}, d_2^{\langle \beta\rangle}, d_3^{\langle \beta\rangle}\right\} = \{3/10, 3/10, 3/10\}$$

at $M = 10$. And again, the relatively small concession in approximate equilibrium (*Eq. 20*) stands against the same high cost as it has been in the case of $M = 9$. A relative stability of approximate equilibrium

$$\left\{d_1^{\langle 0.2\rangle}, d_2^{\langle 0.2\rangle}, d_3^{\langle 0.2\rangle}\right\} = \{3/10, 3/10, 3/10\}$$

at $M = 10$ is expensive: the costs are higher than 0.998 units.

So, it is apparent that struggling to minimize concessions within those gaps in *Figure 6* leads to increasing costs. Apart from democratizing fines, the next stage is to balance costs with concessions, starting off minimal concessions for each $M = \overline{4, 10}$. At that, concessions close to 0.5 (see *Fig. 6*) are unacceptable. For example, both approximate equilibria (*Eq. 23*) and (*Eq. 24*) are unstable, losing thus their practicability (in spite of their lower costs compared to more stable approximate equilibria).

Fines producing symmetric "clean" situations whose costs are the least

Henceforward, both costs and concessions are to be minimized. In order to do this, denote by $\gamma_i(M)$ the subject's cost at the i-th set of fines

$$\{a_i(M), b_i(M)\}$$

and the concession

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14511474

$$\beta_i(M) \text{ for } M=\overline{4,\,10} \text{ and } i=\overline{1,\,I_M}$$

for I_M sequences

$$\left\{\gamma_i(M),\beta_i(M),a_i(M),b_i(M)\right\}_{i=1}^{I_M}$$

at which $\gamma_i(M)<1$ and condition (*Eq. 17*) holds, i.e.

$$d_1^{\langle\beta_i(M)\rangle}=d_2^{\langle\beta_i(M)\rangle}=d_3^{\langle\beta_i(M)\rangle}=d^{\langle\beta_i(M)\rangle}\leqslant 1/3\,.$$

Having

$$\gamma_{\min}(M)=\min_{i=\overline{1,\,I_M}}\gamma_i(M)$$

and

$$\beta_{\min}(M)=\min_{i=\overline{1,\,I_M}}\beta_i(M),$$

the best couple of the cost and concession can be found by its index

$$i^*\in\arg\min_{i=\overline{1,\,I_M}}\sqrt{\left(\gamma_i(M)-\gamma_{\min}(M)\right)^2+\left(\beta_i(M)-\beta_{\min}(M)\right)^2} \qquad \text{(Eq.25)}$$

for the given M. With distance

$$\rho_i(M)=\sqrt{\left(\gamma_i(M)-\gamma_{\min}(M)\right)^2+\left(\beta_i(M)-\beta_{\min}(M)\right)^2} \qquad \text{(Eq.26)}$$

used in (*Eq. 25*), it is admissible to loose its minimum by 2%. Thus, a set of indices

$$L_*(M)=\left\{i\in\left\{\overline{1,\,I_M}\right\}:\rho_i(M)\leqslant 1.02\cdot\rho_{i^*}(M)\right\}\subset\left\{\overline{1,\,I_M}\right\}$$

will give the best couples

$$\left\{\gamma_{i^{**}}^*(M),\beta_{i^{**}}^*(M)\right\}_{i^{**}=1}^{|L_*(M)|}\subset\left\{\left\{\gamma_i(M),\beta_i(M)\right\}_{i=1}^{I_M}\right\}_{M=4}^{10} \qquad \text{(Eq.27)}$$

for the given M, where the superscript asterisk refers to re-indexation started from 1 again in the subscript. Couples

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14511474

$$\left\{\left\{\gamma_i(M), \beta_i(M)\right\}_{i=1}^{I_M}\right\}_{M=4}^{10}$$

are specifically shown in *Figures 8 — 14*, where thicker dots correspond to lower 2-fines, black dots correspond to that $b_i(M) < 2$, light dots correspond to that $b_i(M) \geqslant 3.5$, and dots are moderately darkened if

$$2 \leqslant b_i(M) < 3.5 .$$

Lines in those graphs link best couples (*Eq. 27*) to couple (drawn as a circled dot)

$$\left\{\gamma_{\min}(M), \beta_{\min}(M)\right\} \quad \text{(Eq.28)}$$

for every $M = \overline{4, 10}$. The thickest line in every graph links couple (*Eq. 28*) to couple

$$\left\{\gamma_{i^*}(M), \beta_{i^*}(M)\right\} \in \left\{\gamma^*_{i^{**}}(M), \beta^*_{i^{**}}(M)\right\}_{i^{**}=1}^{|L_*(M)|} \quad \text{(Eq.29)}$$

for the given M , which is the shortest in the graph.

Further below is a table (*Table 1*) with a list of subsets

$$\left\{\left\{\gamma^*_{i^{**}}(M), \beta^*_{i^{**}}(M), a^*_{i^{**}}(M), b^*_{i^{**}}(M)\right\}_{i^{**}=1}^{|L_*(M)|} \subset \right.$$
$$\left. \subset \left\{\gamma_i(M), \beta_i(M), a_i(M), b_i(M)\right\}_{i=1}^{I_M}\right\}_{M=4}^{10} \quad \text{(Eq.30)}$$

along with distances

$$\left\{\left\{\rho^*_{i^{**}}(M)\right\}_{i^{**}=1}^{|L_*(M)|}\right\}_{M=4}^{10} \quad \text{(Eq.31)}$$

by (*Eq. 26*), where the superscript asterisk refers to re-indexation started from 1 again in the subscript. Note that any two distances for different samplings are incomparable due couple (*Eq. 28*) changes as M increases (that is, sampling becomes more compact). Therefore, a generalized distance is introduced to a couple of the minimal cost

$$\gamma^*_{\min} = \min_{M=\overline{4,10}} \left(\min_{i=\overline{1,I_M}} \gamma_i(M) \right) \approx 0.6042$$

and the minimal concession

$$\beta^*_{\min} = \min_{M=\overline{4,10}} \left(\min_{i=\overline{1,I_M}} \beta_i(M) \right) = 0.19 .$$

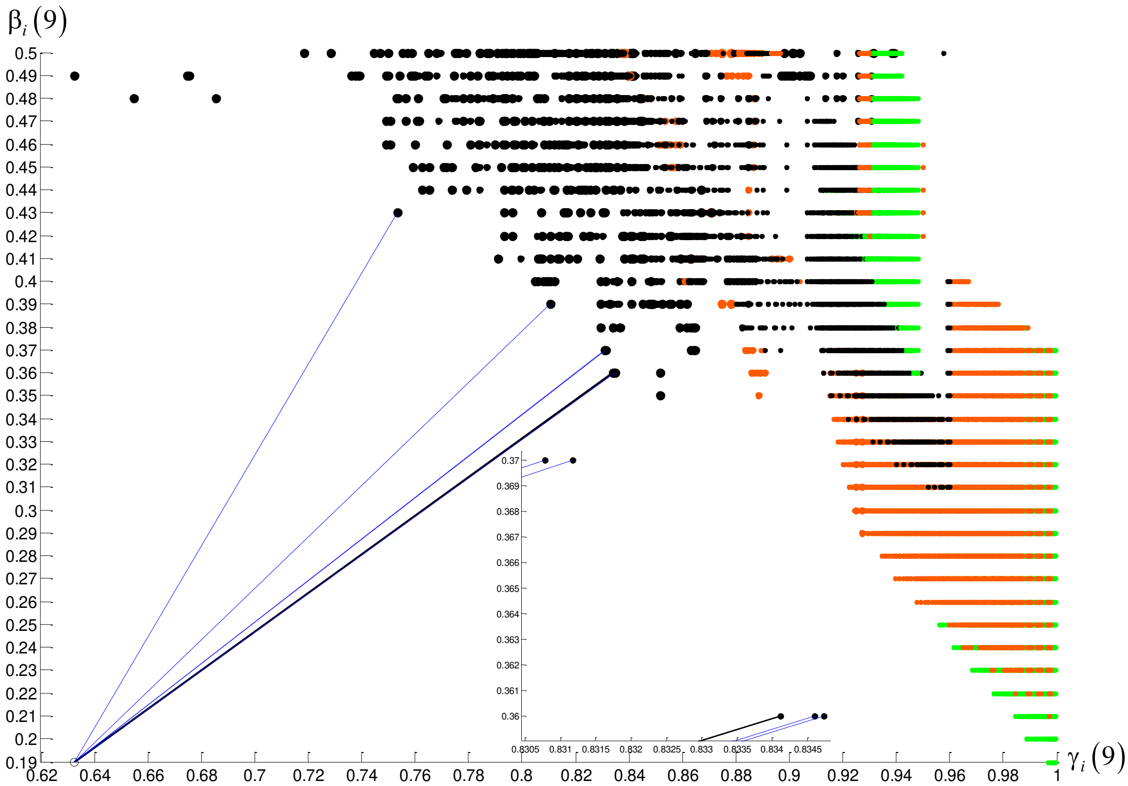

***Figure 13.** Acceptable costs and concessions among these 7 versions of best couples (Eq. 27), where just 2 versions (the 2 lines above) are excluded; the corresponding fines are light (there is a version wherein the 2-fine is 0.34 and the 3-fine is 0.986, i.e. even lesser than the cost of application of a water treatment system)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14511474

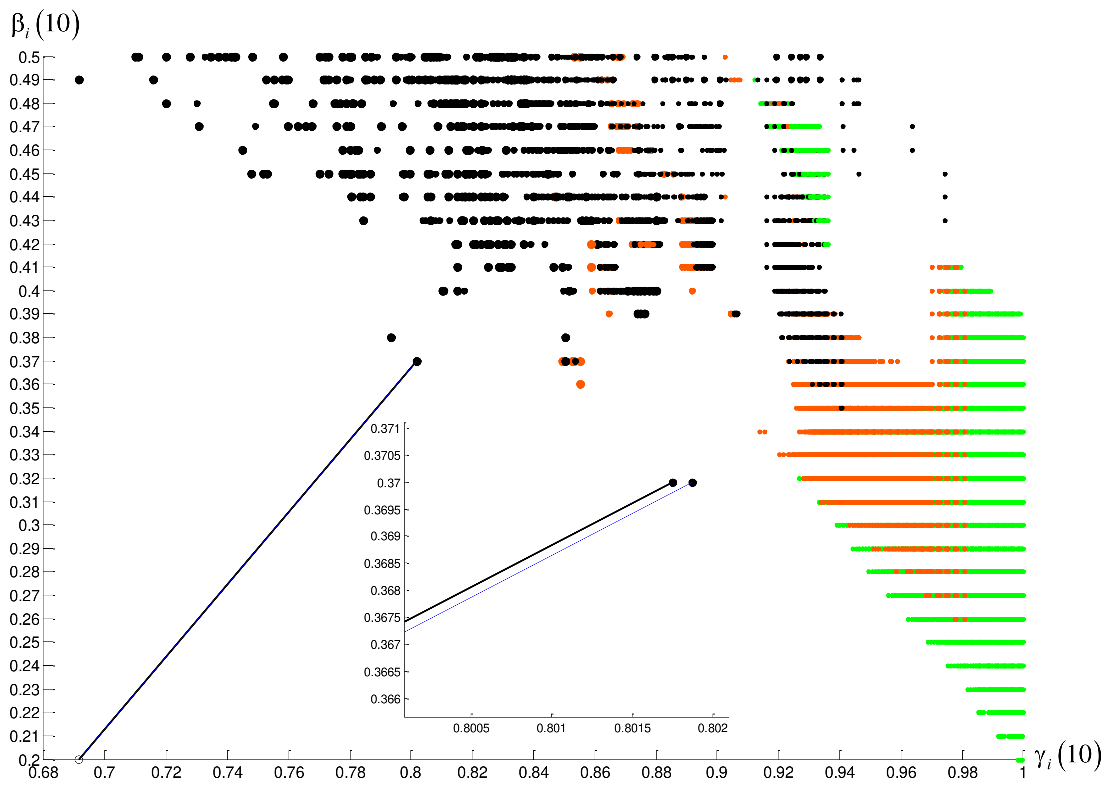

Figure 14. *After the tightest sampling, here are only 2 versions of best couples (Eq. 27) including couple (Eq. 29) by both acceptable costs and concessions; the corresponding fines are close to the relatively lightest*

The best couple of the cost and concession can be found by its index (a subset number in *Table 1*)

$$i^{***} \in \arg \min_{\left\{ i^{**} = \overline{1, \left| L_{*}(M) \right|} \right\}_{M=4}^{10}} \sqrt{\left(\gamma_{i^{**}}^{*}(M) - \gamma_{\min}^{*} \right)^2 + \left(\beta_{i^{**}}^{*}(M) - \beta_{\min}^{*} \right)^2}$$

independently of M, where distance

$$\rho_{i^{**}}^{\langle \min \rangle}(M) = \sqrt{\left(\gamma_{i^{**}}^{*}(M) - \gamma_{\min}^{*} \right)^2 + \left(\beta_{i^{**}}^{*}(M) - \beta_{\min}^{*} \right)^2} \tag{Eq.32}$$

similarly to (*Eq. 26*), for $i^{**} = \overline{1, \left| L_{*}(M) \right|}$ and $M = \overline{4, 10}$.

Distances (*Eq. 32*) are shown against the subset number (rows in *Table 1*) in *Figure 15*. It is roughly seen that as sampling becomes more compact (being tightened) both cost and concession tend to decrease. The best couple of the cost and concession has index $i^{**} = 1$ for $M = 10$ (row #30 in *Table 1*) whereas

$$\rho_{1}^{\langle \min \rangle}(10) \approx 0.2373 \tag{Eq.33}$$

but

http://www.aloki.hu • ISSN 1589 1623 (Print) • ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14511474

$$\rho_2^{\langle \min \rangle}(10) \approx 0.2374$$

for row #31 in *Table 1*. Therefore, the corresponding fines are $a_1^*(10) = 0.34$ and $b_1^*(10) = 1.394$, which allow every subject paying 0.8018 units by conceding 0.37 units to make situation

$$\left\{ d_1^{\langle 0.37 \rangle}, d_2^{\langle 0.37 \rangle}, d_3^{\langle 0.37 \rangle} \right\} = \{3/10, 3/10, 3/10\} \quad \text{(Eq.34)}$$

at $M = 10$ the best approximate equilibrium.

Table 1. *The list of subsets (Eq. 30) along with distances (Eq. 31) by (Eq. 26), where rows with best distances for its sampling are highlighted bold (all 31 rows correspond to the linking lines in Figs. 8–14)*

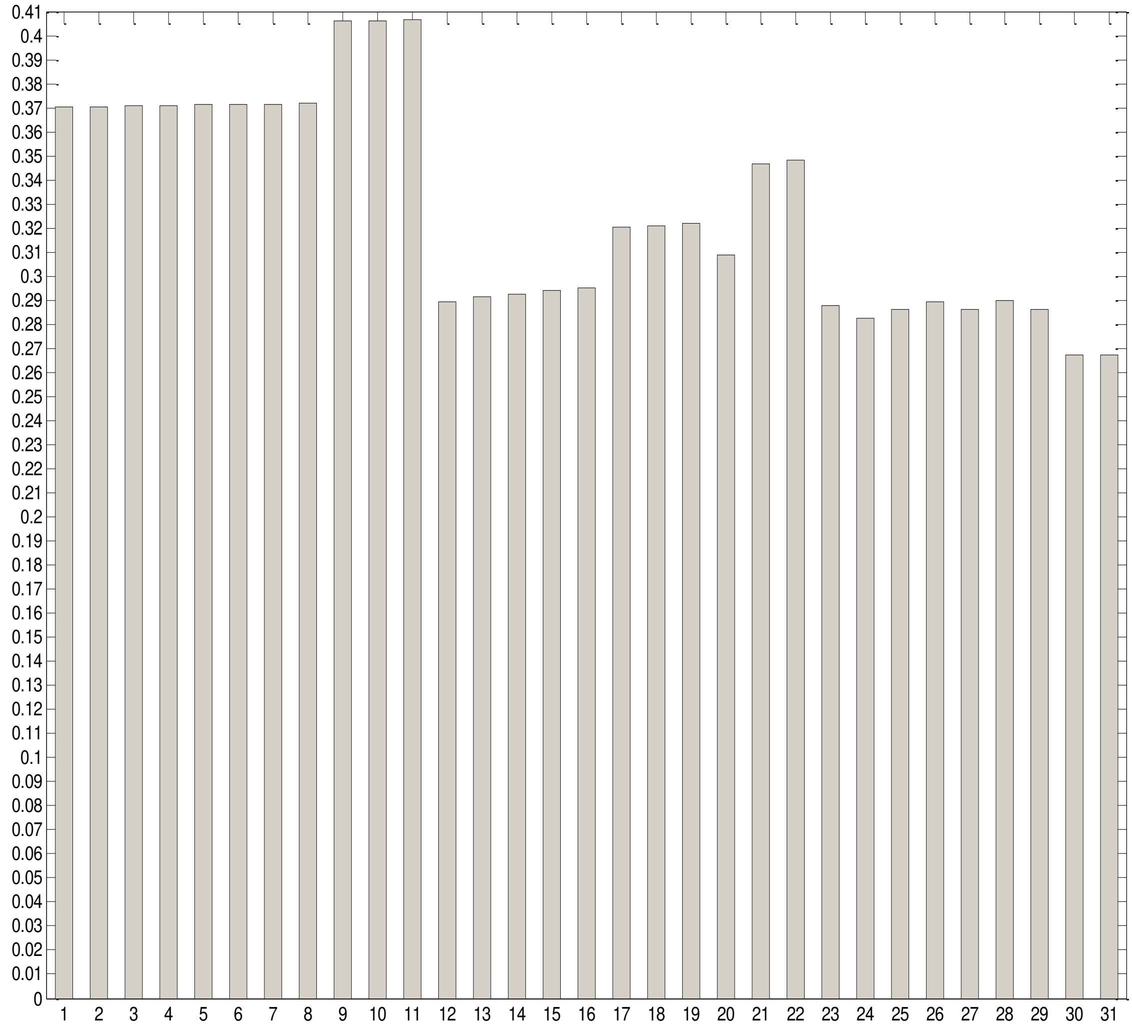

Figure 15. *Distances (Eq. 32) against the subset number (row) in Table 1*

Row #31 corresponds to approximate equilibrium (*Eq. 33*) also. The only difference is a slightly greater cost (0.8019 units). This is caused by a slight increment of the 2-fine (by 0.01 units). Amazingly enough, the 3-fine here is decreased more (by 0.029 units, which is 2.1%).

Discussion

First of all, it must be mentioned that subjects are not tied to any sampling, or to concessions. Moreover, the subjects may do not "know" the probability 0.3, not speaking about situation (*Eq. 34*). Hence, the sampling at $M = 10$, which has appeared to be the best according with distance (*Eq. 33*), should be imposed on the subjects. This implies that some conditions are to be established by which switching from "clean" to "polluting" manufacturing and backwards will be controlled exactly once per those 10 periods of time (10 days, weeks, or months), where the fastest switch is possible only after one period. Such controlling will allow seeing how many times each of the subjects switches per every 10 times. Once a recommendation of holding to the probability 0.3 is given (by which the water treatment system is turned off for 3 periods

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14511474

of 10), the environmental pollution subject is able to control it itself. Prior to that, the 2-fine is set at 0.34 units. This is the lowest rate of fining when only two subjects do simultaneously not treat wastewater. The 3-fine is set at 1.394 units, which is 4.1 times greater than the 2-fine, but it is not as heavy as it could have been. Nevertheless, this is enough preventive from bad pollution. Under threat of the heavy 3-fine, the subjects will definitely come to a convention of scheduling the water treatment systems. After every 10 periods of time, the grand total of 2-fines is 3.4 units per subject, and the grand total of 3-fines is 13.94 units per subject. Eventually, the cost of 8.018 units for a subject is just the expected spendings, whereas the least cost in 7 units is still possible. For instance, if a permanent schedule of water treatment is approved and followed (*Table 2*), then it costs the least for all.

Table 2. *An example of scheduled water treatment (1 – water treatment system is applied, 0 – water treatment system is turned off, * – obligatory control and fining, if there are violations)*

The suggested model along with approximate equilibrium (*Eq. 34*) can be useful especially for triples of industrial enterprises which are not situated in one country but use the same river water (such as the Danube, Tisza, Rhine, etc.). It is easy to implement this model across countries of the European Union using the same currency (the euro is the official currency in 19 of 28 member states of the European Union, as well as in some of the territories of the Union) and thus sharing the analogous background (Guo, 2018). Countries with different currencies are neighbors anyway, so discrepancies in exchange rate are not dramatic, and standardization to the conventional units is realizable (Wolf, 2009). Although a source of pollution could be determined easier for this case, it will always take additional costs from governments. Even if measurements of a water pollution rate along with some complex investigations could reveal which subject is "clean" and which subjects work "polluted", the process of eventual compensation might be badly lingered after suing (e.g. see the undecided tri-state water dispute described by Jordan and Wolf, 2006).

From the other side, a single enterprise may have its capacities allocated in various sites of the same reservoir. In such a case, those capacities can be grouped into three clusters, similar to each other, and the suggested model becomes applicable.

Conclusion

Generally, the environmental protection model in the form of the considered dyadic 3-person game is a basis for two balances. The first novelty is the ecologically healthy water balance maintained via a policy of approximate equilibrium (*Eq. 34*). The second novelty, but it is not less important, is that rationally substantiated fines allow environmental pollution subjects to function stably. Although concessions in (*Eq. 34*) may be thought as a destabilizing factor, they eventually mean that a seductive

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14511474

possibility to pay 3.7 units less (after the next 10 periods) will disappear as quickly as other subjects start violating. Therefore, the concessions are a deterrent factor rather than a seduction to decrease costs. Conceding is just a primary advantage, which will be destroyed once a control is executed. Thus, approximate equilibrium (*Eq. 34*) becomes really stable. This is realized by the balanced (economically more reasonable) fines, which also merge stable functioning of environmental pollution subjects with the ecologically healthy water balance.

In terms of legal theory, the suggested model is an environmental law based on rigorous inferences from stability, rationality, and non-biased profitability. It may serve as a substantiation as for small environmental conventions (within one country), as well as for international conventions (e.g. like the Kyoto Protocol and the mentioned Water Convention). This is quite tractable owing to that the model-based decisions are not only prescriptive and constraining but also are motivating to environmental protection.

(Received 9th Oct 2018; accepted 5th Dec 2018)

Abstract. The main source of botanical information of a particular area is its floristic checklists. Floristic study of any given area helps to evaluate the plant wealth and its potential values. To assess floristic diversity of an unexplored remote valley (Manoor Valley), frequent field visits were arranged in different growing seasons during 2015 to 2018. The life form classes and leaf spectra of all plant species were determined and further classified according to the Raunkiaer classification. Plant species were identified and deposited to the Herbarium at Hazara University, Mansehra. The floristic diversity consisted of 354 plant species belonging to 93 families. Herbaceous was the most representative growth form, with 259 species, followed by shrubs with 52 species, trees with 42 species and parasitic plant with one species. Asteraceae was the leading family with 36 species, followed by Lamiaceae species. Furthermore, results indicated the dominancy of Therophytic plants and Nanophyllous and Microphyllous leaves. July marked the peak of flowering period and September the peak of fruiting period. This study provided the first insight of the floristic inventory in relation to multivariate approaches in this unexplored area. This regional novel launched list may serve as a vital resource for all future endeavors in the field of phytosociological, pharmacological and conservational studies of natural resources.
Keywords: *floristic checklist, Asteraceae, principal components analysis, species response curve*

Introduction

Vegetation is an umbrella term that indicates plant life of a region (Rahman et al., 2018a) or, in other words, a group of plants growing together in a particular area and may be characterized by its component species (Malik, 1990). Flora is a priceless donation of nature upon which the mankind always relies (Khan et al., 2013). Flora comprises the total plant species of any specific geographic region, which are characteristic of a geological period or in habit a particular ecosystem (Durrani et al., 2005). According to the report of Walter and Hamiston (1993), approximately 422,000 flowering plants have been reported globally (Rahman et al., 2016a). Pakistan is blessed with diverse flora due to variability in climate (Rahman et al., 2018b) and presents about 6000 flowering plant species (Rahman et al., 2016a).

The main source of botanical information of a particular area is its floristic checklists (Safidkon et al., 2003). Floristic study of any given area helps to evaluate the plant wealth and its potential values (Shaheen et al., 2016). Local plant species documentation is very necessary to introduce specific floral species of the local area, their occurrence and finding new species (Ali, 2008). Many workers have contributed comprehensive floristic checklists of local flora in different regions (Qureshi, and Bhatti, 2008; Jabeen et al., 2009; Shaheen et al., 2011).

In these studies of floristic checklist, besides evaluating the species richness, it is also necessary to observe the plant life form, leaf size and phenology over the year (Rahman et al., 2018a). Life form is the indicator of micro and macroclimate and it is characterized by plant adaptation to certain ecological conditions (Shimwell, 1971). As the plants arranged by the Raunkiaer (1934) in order to form classes on the basis of their life form, five major classes were formed (Hussain and Perveen, 2009) which includes: Phanerophytes, Hemicryptophytes, Cryptophytes, Chamaephytes, and Therophytes. Plants are also classified on the basis of leaf sizes and this has been exceptionally helpful for association mapping of vegetation. The leaf size knowledge helps in understanding physiological processes of plants (Oosting, 1956). For instance, biotic agencies are the chief causes for changing the biological spectrum in a given floristic zone (Amjad, 2012).

Phenology demonstrates the relationship of plant development to seasonal variations as well as photoperiod to program their developmental stages and natural exercises appropriated with the normal seasonal conditions (Manske, 2006). Essentially, timings and interim of the intermittent natural occasions (biological events) among stages of plant species give a foundation of gathering and synthesizing quantitative data of plant communities, which are directly linked with phenology (Singh and Singh, 1992). There is a synchronization of phenological behavior of the plant species and the various elements of the environmental conditions that plants are discussed, the organic tickers (biological clocks). These are habitually controlled by external environmental stimuli (Zhang et al., 2006, Vilela et al., 2017). Leaf growth, leaf fall, flowering and fruiting of species occur in specific seasons of the year and the phenology of life forms varies and is associated with day length/ temperature (Rahman et al., 2018a). As reported by Ahmed (2017), the blossoming and fruiting could be connected with the climatic conditions for posterity survival. Cornejo-Tenoria and Ibarra-Manriquez (2007) recorded blossoming and fruiting behavior on month-to-month premise. Bhat and Muralli (2001) depicted the climatic factors, for example, precipitation, water accessibility, change in day length and temperature additionally triggers the phonological occasions and because of temperature contrast, there is huge variety among species in various climatic zones.

In this way, the unexplored remote valley Manoor Valley, Pakistan, has great potential for flourishing a rich plant biodiversity due to the presence of diverse microhabitats and topographic features. Since biodiversity is greatly affected by different environmental factors (Khan, 2012) and is facing serious challenges due to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14751498

anthropogenic activities like deforestation and over grazing (Ijaz, 2014), it is fundamental to develop floristic checklist studies. Hence, the current study was designed to explore the biodiversity and document the floristic checklist of Manoor Valley. This study provides the updated insights into the floristic diversity of the area and it might also be very helpful for the future plant ecological, conservational and ecophysiological studies.

Materials and methods

Study area (Manoor Valley)

There are two sub-valleys in Kaghan Valley, i.e. Naran Valley and Manoor Valley. Naran Valley is located in upper Kaghan Valley, while Manoor Valley is reached from the main Kaghan Valley road at the junction 'Mahandri' (*Fig. 1*) and is about 50 Km north of Balakot (Rahman et al., 2016a, b). Floristically, the valley is very rich, diverse and unexplored. To date, very few references are available on floral studies of the area including few reports of medicinal studies (Rahman et al., 2016a, b, c; 2018c) and preliminary checklist (Rahman et al., 2018a).

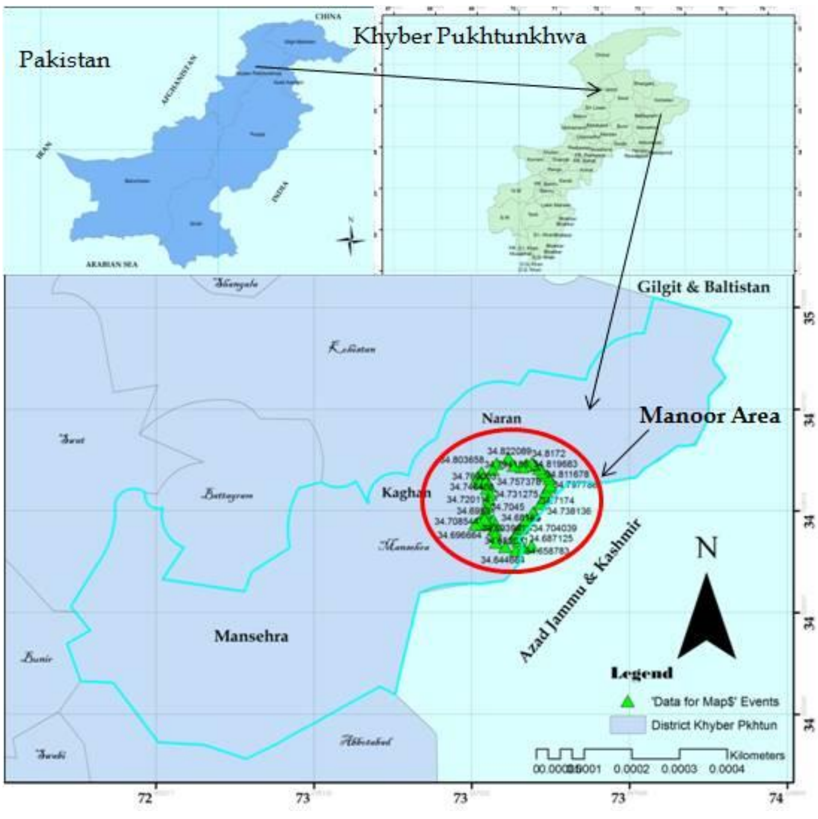

Figure 1. *Map of Mansehra area showing the Manoor Valley, Pakistan*

Field work, equipments, identification and preservation

From 2015 to 2018, field surveys were conducted to cover the understory area for collection of data regarding plant species. For this purpose, the study area was divided into 133 sampling sites or stations, where they were classified into life form and leaf

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14751498

sizes classes following Raunkiær (1934); Oosting (1956); Hussain (1989). Field notebook, pen, pencil, polythene bags, tags, trowel, scissors, camera, newspaper, plants presser and twig cutter were used during survey (Ijaz, 2014). The collected plants were properly dried and pressed by using newspaper for about 2-4 weeks at normal temperature. Then plants were treated or poisoned with chemical solution for preservation and mounted on standard herbarium sheets. Then data were shifted from field notebook on herbarium label of standard herbarium sheets. This herbarium label was pasted on right side of herbarium sheets (Ijaz, 2014; Ahmed, 2017). The size of herbarium sheet was standardized (11.5 x 16.5) (Ijaz, 2014). The specimens were identified by using the Flora of Pakistan (Nasir and Ali, 1971-1989; Ali and Nasir, 1989-1991; Ali and Qaiser, 1995-2017) and the identified specimens were deposited in the Herbarium of Hazara University, Mansehra, Pakistan (HUP).

Multivariate approaches

Recorded plant species data was analyzed through various multivariate approaches by using different statistical packages. CANOCO 5 version was used (Rokaya et al., 2012) for multivariate ordination analyses like 'dominance curve' (DC), 'principal components analysis' (PCA) (Rokaya et al., 2012, 1992) and species response curve (SRC). PCA was determined to examine the correlation between 354 plant species and 4 growth form categories. PC-ORD 5 was used for correlation and regression coefficient (Rahman et al., 2018c). The correlation and regression coefficient evaluates the variables behavior on different axes. Chord Diagram was made through R software using package 'circlize' (Gu et al., 2014).

Results

Floristic diversity

Flora of the study area consisted of 354 plant species belonging to 93 families. In this total, the leading plant habit was herbaceous having 259 spp., followed by shrubs with 52 spp., trees with 42 spp., and parasitic plant with one species, respectively (*Fig. 2*). Asteraceae was the leading families with 36 species, followed by Lamiaceae with 24 species, Rosaceae with 22 species. For a complete inventory see *Appendix*.

Based on biological spectrum, the flora was dominated by Therophytes (116 spp.) followed by Hemicryptophytes (90 spp.), Nanophanerophytes (48 spp.) and Chamaephytes (29 spp.) (*Fig. 3*). On the basis of leaf spectra, the study area was dominated by Nanophyll and Microphyll with 105 spp. and 100 spp., respectively, followed by Mesophyll (64 spp.), Leptophyll (58 spp.), and Megaphyll (23 spp.) (*Fig. 4*). Further, four species (*Cuscuta reflexa, Ephedra girardiana, Equisetum arvense* and *Periploca aphylla*) were found as Aphyllous. For a complete inventory of biological spectrum and leaf size see *Appendix*.

The flowering data showed that July marked the peak of flowering season where 90 plant species had flowers, followed by June with 80 species. In May, flowering was observed in 68 species, followed by April with 42 species. The fruiting data showed that September was the peak fruiting season for 82 plant species, followed by August for 79 species.

DOI: http://dx.doi.org/10.15666/aeer/1702_14751498

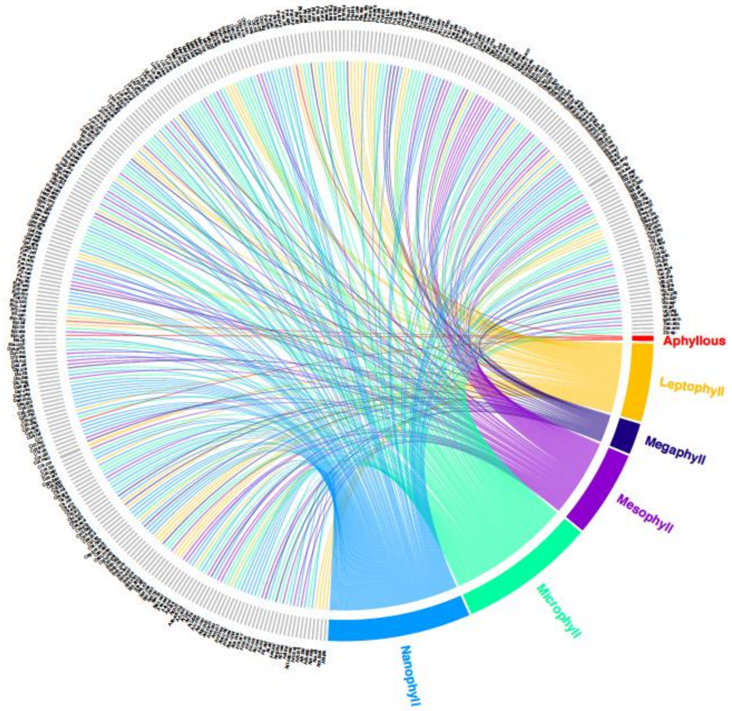

Figure 4. *Distribution of the 354 species found in Manoor Valley, Pakistan, among the leaf size classes. The full name of species is in Appendix*

Correlation and regression coefficient

The correlation and regression coefficient variables behaved differently on different axes. On axis 1, highly positive correlation (1.000) and highest positive tau value (0.957) was recorded for herbaceous plant habit, while on axis 2, positive correlation value was recorded (0.24) but negative tau value (-0.095) was logged for herbaceous growth form in comparison with all other growth forms (*Fig. 5A*). Moreover, on axis 1, highly negative correlation (-0.705) and highly negative tau value (-0.766) was recorded for shrubby plant habit, while on axis 2, highly positive correlation value (0.706) and highest positive tau value (0.766) was logged (*Fig. 5B*).

The correlation and regression results of tree growth form showed negative correlation (-0.586) and positive tau value (-0.464) on axis 1 and highly negative correlation value (-0.807) and highest negative tau value (-0.696) was logged on axis 2 (*Fig. 5C*). Further, the parasitic growth form on axis 1 showed minimum negative correlation (-0.74) and minimum negative tau value (-0.055) and similarly, minimum negative correlation value (-0.014) and minimum positive tau value (-0.089) was logged on axis 2 in comparison with all other growth forms (*Fig. 5D*). Axis 1 was dominated by herbaceous growth form, while axis 2 by shrubby plant habit (*Fig. 5A-D*).

Principle components analysis (PCA)

The PCA results revealed that 259 plant species were most frequently cited positively and significantly correlated with herbaceous growth form (*Fig. 6*). Fifty-two plant species indicates positive influence towards the direction of shrubby growth form. Tree growth habit was most frequently cited and positively correlated with 40 plant

DOI: http://dx.doi.org/10.15666/aeer/1702_14751498

species. *Cuscuta reflexa* was the only species assigned to parasitic growth form category (*Fig. 6*).

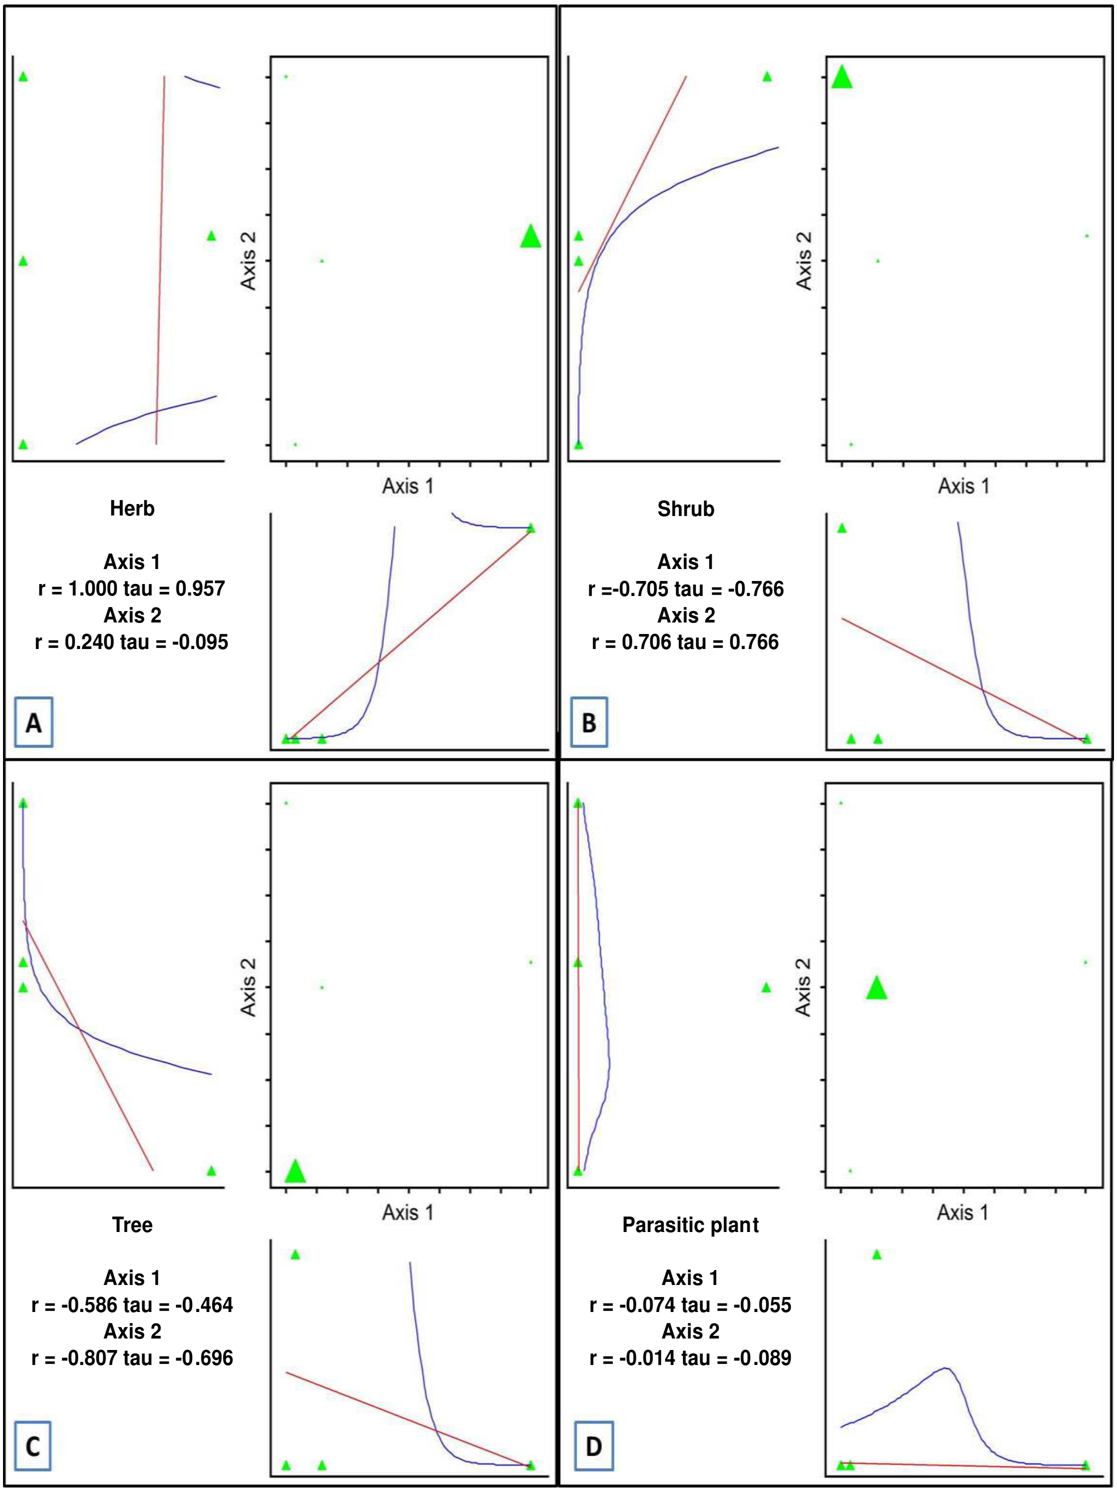

***Figure 5.** Correlation and regression coefficient of growth form on different axis: A) Herb, B) Shrub, C) Tree and D) Parasitic plant*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14751498

Species response curve (SRC)

The analysis clearly indicates highly significant differences (F = 451, p < 0.00001; *Fig. 7*) for herb category in comparison with all other growth form categories due to maximum number of species (*Fig. 7A*). This growth form category also revealed highest response (99.3%). Nonetheless, shrub growth form also showed highly significance (F = 415, p < 0.00001) due to its number of species in comparison with tree and parasitic plant habit and presented a response percentage of 55.1%. Also tree growth form presented significant differences (F = 142, p < 0.00001) and response percentage (29.6%) in comparison with parasitic plant habit category. Parasitic plant showed non-significant differences (F = 0.81, p = 0.63206) and response percentage (0.2%) as given in the *Table 1*. Additionally, *Figure 7B* illustrates the flow of species cited within each growth form category from top to bottom as enlisted in *Table 1*.

Table 1. *Summary of fitted generalized linear models four response variables*

Response	Type	R^2[%]	F	p
Herb	linear	99.3	451	<0.00001
Shrub	linear	55.1	415	<0.00001
Tree	linear	29.6	142	<0.00001
Parasitic plant	linear	0.2	0.81	0.63347

Discussion

The results of this study showed that Manoor Valley, Pakistan, it is an area rich in plant species, presenting 354 species, being the herb habit most representative. Furthermore, it can be observed that the multivariate approaches showed significant differences, which supports the prediction and assertion that the herb habit is the principal plant habitat in this area.

Floristic structure is the main reflection of vegetation of any area (Rahman et al., 2018a). Plant species has its own ecological amplitude and interaction with its environment and also with other species (Giustiet al., 1995). The flora of Pakistan is diverse due to different ecological zones, diverse climatic and soil condition. In the present study, flora consisted of 354 species, where the dominating growth form was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14751498

herbaceous with 259 species. In Pakistan, many researchers from different areas also mentioned herbaceous growth form as the leading one from their study areas (Ijaz et al., 2015; Khan et al., 2015a; Ijaz et al., 2016), which shows a predominance of herbaceous growth form in Pakistan.

Asteraceae was the leading familly with 36 species, followed by Lamiaceae with 24 species and Rosaceae with 22 species. Due to wide ecological amplitude, Asteraceae family are very diverse in habitat (Badshah et al., 2013). Khattak et al. (2015) found similar results in Karak, Pakistan and in addition Iqbal et al. (2015) also reported Asteraceae as the most predominant group in Malakand, Pakistan. On the other hand, Khan et al. (2015b) showed in a study made in Kabal (Swat), Pakistan, that Lamiaceae was the dominant family. Regardless of the family, Asteraceae and Lamiaceae appear to be the main plant families present in Pakistan's vegetation.

The flora of Manoor Valley was dominated by Therophytes, followed by Hemicryptophytes. Similarly, Badshah et al. (2013) observed Therophytes as the leading life form in Tank region, Pakistan. For various physiological processes of plants and plant communities leaf size plays a vital role (Oosting, 1956). On the basis of leaf spectra, Nanophyll and Microphyll were the most representatives. The species with Microphyllous leaves are rich due to ecological variation, which shows the percentage of different leaf form classes varied with rising altitudes and according to Cain and Castro (1959) Microphyllous species are the indication of steeps. Similar findings were observed by Saxina et al. (1987) who stated that the percentage of Microphyllous species was completely associated with the rising altitude.

Results showed that July had the flowering peak with 80 plant species, followed by June with 77 species (*Fig. 8*). These results are in agreement with those of Shrestha et al. (1998), where the authors noticed the blooming period from May to August in Kavrepalanchok, Nepal. As indicated by Marques et al. (2004), phenological period and atmosphere are associated with each other in terms of temperature, day length and precipitation or rainfall. Fruiting phase had peak in September and August (*Fig. 9*). Similar phenological scenario was reported by Morellato (1995) who reported that the blooming period begins toward the end of the dry season and at the starting of the wet season, thus fruiting takes place in dry season and that the next rainy period will offer appropriate conditions for seed germination (Morellato et al., 1989).

Conclusion

The present study indicated that the study area has rich plant biodiversity. Flora of Manoor Valley area consisted of 354 plant species, where the leading plant habit was herbaceous with 249 species and family was Asteraceae with 36 species. We can use these inventory lists as a vital resource for all future endeavors in the field of phytosociological, phytochemical, pharmacological and conservational studies of natural resources. Regarding the multivariate approaches, we can observe that these analyzes are extremely useful to show us significant differences in certain floristic survey studies, providing support and veracity in the discussions and conclusions found. Studies like this present are necessary to evaluate the plant richness and its potential value.

Author's Contributions. IUR conducted the fieldwork, collected data and plant species, and designed the map, FI helped in the herbarium work. IUR drafted the manuscript and ESC helped in analysis of the data, NA helped in organizing the data. AA and ZI supervised the work. EFA, AA and ZI critically reviewed the manuscript. IUR, ESC, EFA and NA revised the manuscript, AAA, MSA, RK, MS and MI helped in revision. All the authors have read and approved the final manuscript.

Acknowledgements. First author would like to thank Higher Education Commission (HEC), Pakistan for granting scholarship under International Research Support Initiative Program (IRSIP) to conduct a research work at Missouri Botanical Garden, USA). The authors would like to extend their sincere appreciation to the Deanship of Scientific Research at King Saud University for its funding to the Research Group number (RG-1435-014).

APPENDIX

Floristic composition, biological and leaf spectra, and phenological behaviour of the plant species of Manoor Valley, Pakistan

S. No	**Family name/** Scientific name	Habit	Biological spectrum		Phenology	
			Life form	**Leaf size**	**Flowering**	**Fruiting**
	Acanthaceae					
1	*Dicliptera bupleuroides* Nees	H	Th	N	Sept	Feb
2	*Justicia adhatoda* L.	S	NanP	Me	March	May
	Adiantaceae					
3	*Adiantum capillus-veneris* L.	H	G	N	July	Sept
4	*Adiantum indicum* J. Ghatak	H	G	Me	July	Aug
5	*Adiantum venustum* D. Don	H	G	N	June	Aug
6	*Asplenium adiantum-nigrum* L.	H	HemC	N	July	Sept
	Adoxaceae					
7	*Viburnum cotinifolium* D. Don	S	NanP	Ma	March	May
8	*Viburnum grandiflorum* Wall. ex DC.	S	NanP	Ma	March	May
	Amaranthaceae					
9	*Achyranthes aspera* L.	H	Th	N	May	July
10	*Achyranthes bidentata* Blume	H	Th	Mi	Aug	Sept
11	*Amaranthus viridis* L.	H	Th	Mi	Aug	Sept
12	*Celosia argentea* L.	H	Th	N	Aug	Sept
	Apiaceae					
13	*Aegopodium burttii* Nasir	H	HemC	Mi	June	July
14	*Anthriscus nemorosa* (M.Bieb.) Spreng.	H	Th	Mi	April	Aug
15	*Bupleurum nigrescens* E. Nasir	H	Th	N	June	Sept
16	*Bupleurum gracillimum* Klotzsch	H	Th	N	June	Sept
17	*Bupleurum longicaule* Wall. ex DC.	H	Th	N	June	Sept
18	*Foeniculum vulgare* Mill.	H	Th	N	July	Sept
19	*Heracleum candicans* Wall. ex DC.	H	HemC	L	April	June
20	*Pimpinella stewartii* (Dunn) Nasir	H	Th	N	July	Sept
21	*Pleurospermum brunonis* Benth. ex C.B.Clarke	H	HemC	L	June	Aug

Abstract. In the last decade, the question of the current disproportion of quality of life and economic progress of global proportions is often raised, in contemporary socio-economic and political-economic conditions. We are witnessing a constant tendency toward targeted well-being that can be seen through human, economic and environmental benefits. The first two dimensions are goals that imply the complete sustainability of social protection of people and the protection of the environment. They are in a strong correlation with each other, since they can not be regarded as separate goals, but mutually equal because they depend on each other. On the other hand, in order to achieve sustainability of economic well-being, it is necessary to include multidimensional aspects of innovation, which will provide tools, through which adjustments of policies to promote long-term growth of production and increase of productivity, ie decrease of unemployment rate, will be adapted. Therefore, as part of the globalization process, it is necessary to review the possibilities and capacities of efficient sustainability of people's quality of life and environmental protection, with constant and balanced economic prosperity, not only countries in transition, but all factors in the world economy.
Keywords: *quality, continuial, novelty, worldwide, guide*

Introduction

If the "sustainability index" can be taken as a genetic term, then it would include two of the most important aspects of quality of life, or a sustainability indicator. These indicators are:

- Sustainable Society Index (SSI) and
- Environmental Performance Index (EPI).

Twenty-four indicators are taken into account when determining the index of a sustainable society. They are divided into seven categories, and those in three dimensions (living standard of the population, environmental protection and economic well-being). By summing up the data obtained through these dimensions, the SSI is calculated. This index is used to monitor the prosperity of the country's determination, the establishment and determination of sustainability priorities, the comparison of achieved results at the level of countries and regions, and for further research and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14991516

development. What is characteristic of this type of indicator, and based on previous research, is that high-income countries per capita at an annual level have a high standard of living but do not achieve such good results when it comes to environmental protection. There is a trend of improving living standards and economic well-being on a global level, while environmental protection is accompanied by a negative index, despite all plans and signed interstate agreements (Van de Kerk et al., 2008).

Although it can be said that, in general, progress has been made, it is disturbing that it is not balanced between the three dimensions of society's sustainability, and that there are differences in development between high and low income countries. Particularly disappointing are the still low results of organic agriculture, renewable energy and energy savings.

With the UN's sustainable development goals in 2018, the emphasis on the actions of the governments of countries that are subject to this type of indexing is on explaining the achieved results through a series of pollution control and challenges to natural resource management in relation to quantitative indicators. Precisely obtained data and empirical approach to environmental issues provide the possibility for a certain type of security in identifying problems, monitoring trends, highlighting the results of the current policy action, identifying best practices, and optimizing the benefits of environmental investments (Yale Univeristy, 2018).

The aforementioned empirical approach to environmental issues works through several instruments, and one of them is the environmental efficiency index. The EPI is a joint project developed by the Yale Center for Environmental Law & Policy (YCELP) and the Center for International Earth Science Information Network (CIESIN) at Columbia University, in collaboration with the Samuel Family Foundation and the World Economic Forum (Hsu et al., 2014).

Based on the index value obtained, countries are ranked, and an assessment is made of the success of meeting the set objectives for the improvement of environmental protection for each of them. In this way, the best applied approach to problem-solving is considered, and guidance is provided to countries with a tendency towards further progress.

The EPI offers the possibility of bridging the two opposing sides - environmental health, which increases economic growth and prosperity, and the vitality of the ecosystem, under the pressure of industrialization and urbanization. Strategic management is a critical and essential factor necessary to establish a balance between these two dimensions of sustainability.

With the aim of a comprehensive approach to innovation in the economy and the provision of instruments that help achieve the desired economic goals, the Global Innovation Index contributes to the creation of an environment in which innovative factors are continually valued.

The core of the GII report consists of ranking innovative capabilities and innovation results in the economies of indexing countries. Over the last ten years, this index has been established in practice as a leading innovation reference. A more fundamental analysis of the human factor, which is behind innovation, is essential for the development of development policies. Recognizing the key role of innovation, as a driver of economic growth and prosperity, and the need for a broad horizontal vision of innovation, the Global Innovation Index includes indicators that go beyond traditional innovation measures, such as the level of research and development (Cornell University, 2017).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14991516

In order to determine the GII, as the type of output required by the state-level leadership for decision-making, there is a range of inputs that need to be processed in this regard:

1. Institutions.
2. Human capital and research.
3. Infrastructure.
4. Market sophistication and
5. Complexity of business.

The main characteristic for computing the GII is that the overall result is a simple average of the input and output subindices. Also, the Global Innovation Index collects data from more than 30 sources, covering a large spectrum of drivers of innovation and results. The standard framework of the resource is reviewed every year, in transparent workshops, to improve the way innovation is measured.

The primary goal of this research is to develop a tool that can serve as a parametar for underdeveloped countries and countries in transition when directing and implementing state policy, by presenting the correlation coefficients between the SSI, EPI and GII in the countries of the region that are in the transition process. That refers to improving the sustainability of the society and the ecological effects efficiency, where the development of innovations, the overall well-being and the balance of modern systems imposes itself as the ultimate goals.

Review of literature

Inclusive green economy or ’green growth’ primarily refers to environmentally susatainable economic production and consumption that also embrace equity in distribution of resources. Green growth is defined as – ’improved human wellbeing and social equity, while significantly reducing environmental risks and ecological scarcities’ (Kumar, 2017).

According to Zugic (2014), countries in the transition process are continually addressing two basic economic issues: macroeconomic stability and structural transformation of the market environment. Macroeconomic stabilization should contribute to the establishment of a distorted economic balance, and solving the problem of structural transformation should enable these countries to efficiently and rationally engage. This requires the formulation of a macroeconomic policy with more efficient measures, mechanisms and instruments for the realization of the chosen objectives and tasks.

The more the economy of a country is integrated into the globalized world economy, the more it has to compete with other countries by simultaneously transforming its economic structure towards a green economy. This competition pressure has the advantage that industry does not look towards the domestic market for customers for its new products but also tries to find new customers for its new green products on the world market. The country is not just reliant on the shielded home market and can initiate a co-evolution process of technological, organizational and institutional changes (Schlor, 2017).

Climate change is a global concern. Growth in energy-related CO_2 emissions has been identified as the main cause of climate change. The growing trend will persist if no sustantial efforts on constraining emissions are made (Wang et al., 2018).

Based on Vaninsky’s research (2018), data combined on energy consumption from nuclear, hydroelectric, and other renewable sources, are refered to as clean energy since

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14991516

CO_2 emissions are zero, or very small as compared to fossil fuels. As follows from the data, there are three main GDP producers in the world: OECD (The Organization for Economic Co-operation and Development is a forum of 35 democracies comprising ecnomomies - website http://www.oecd.org provides details) Europe, China and USA, with their GDP shares equal to 18.88%, 16.43% and 15.94%, respectively. They are also the greatest polluters, contributing 12.08%, 27.08% and 16.42% of the world's CO_2 emissions, respectively. It should be mentioned that while Chinese and US economies' CO_2 emissions exceed their GDP shares, the emissions are much less in the OECD Europe's economies. The energy from clean sources is mostly consumed in OECD Europe (34.74%) and the US (30.61%), comprising 65.35% of the total.

At the very begining of their research, Djekic et al. (2018) state that in line with the increased global attention of environmental and sustainable impact of the food chain, transportation environmental impacts became polemic tools in various environmental and food policies, and from an enviromental point of view, some authors assume that transportation of trade goods enhances over 20% of total global CO_2 emissions.

Barnhart's et al. (2016) approach offers several advantages for informing conservation targeting decisions. Constructed from multi-input/multi-output productions models, the EPI can accommodate multiple agricultural outputs and types of pollution. The distance functions used to construct the EPI allow for empirical estimation of the production technology without imposing a functional form on the relationship between inputs, outputs and environmental effects. This is particulary useful for identifying and ranking low-performing sites for targeting decisions.

Frank et al. (2016) propose a new methodological framework which allows companies to preform their own benchmark analysis to understand how they are positioned regarding environmental performance in comparison with their competitors. They suggested framework that can help to improve environmental competitiveness within the industry and thereby contribute to environmental sustainbility of the sector.

Also, Zuo et al. (2017) use the environmental performance index to indicate the environmental scores of China's 30 provincial administrative regions, which were developed from the pilot Environmental Performance Index that was published in 2002. Their studies provide useful environmental sugestions for local government.

Sustainable development measuring initiatives have reached such volume that perhaps a sustainable development index revolution is now warranted. As with all rapidly growing academic and professional topics, theoretical and applied research can become so focused on improving accuracy of current practices that they often lose sight of practical application. In this regard, measuring progress toward sustainbility now resembles true cost accounting rather than rapidly employable tools useful for the developed and developing world alike (Shaker, 2018).

The SSI covers sustainability in its broadest sense, including social, environmental, ecological and institutional aspects, while most other indexes do so only partly. One of the main objections to the SSI is the aggregation of all indicators into one single figure for the index. Should one only consider this figure in isolation, the results may be misleading and can easily be misused (Van de Kerk et al., 2008).

Many rapidly growing economies reveal similar findings, with some exceptions. According to the Dual Citizen LLC (2016), India, Bangladesh and Senegal had GDP growth between 6-8% in 2016. On the other hand, these countries perform poorly on the new global green economy index, raising the question of what kind of growth these nations are realizing and how sustainable it is. Interestingly, Cambodia realized the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14991516

highest improvement on the global green economy index in 2016 compared to 2014. Given that Cambodia is projected to grow at 7% in 2016, it represents a possible model for how green growth can be integrated in similar developing countries. These overall findings are just the beginning of the snapshot that provides on the state of the global green economy today and the progress countries are making within it.

Dasic (2014) in his research states that the energy security is essential for sustainable economic development and the stability of the country. The inability to access energy resources causes serious economic disturbances and political instability. In the conditions of the global economy, disruptions are easily transmitted and it is, therefore, essential to permanently provide energy resources and make an effort to reduce the so-called energy poverty most affecting countries in transition (the countries of Southeastern Europe) and third world countries. The problem can be solved by the introduction of alternative or renewable energy sources. This greatly alleviates the problem, with the positive effects of helping local economic development and reducing the greenhouse gas emissions. However, for a successful solution, there is a need for awareness of the existence of problems, political will and the ability to implement the solution. South-East European countries are characterized by a good geostrategic position, which should be used in the field of energy in order to achieve the strategic goals of regional development.

By looking at the previous research, the results of the correlation between the index of sustainability, green economy, innovations, etc. were tested, both in the economies in the transition process, and in the developed economies, which significantly helped this research process, on the question of knowledge, on the one hand, and on the other hand, the systematization of the information provided.

For instance, the results of Van de Kerk et al. (2008) research show that one of the main objections to the SSI is the aggregation of all indicators into one single figure for the index. Should one only consider this figure in isolation, the results may be misleading and can easily be misused. This objection is inextricably bound up with aggregation into one final figure. It stresses the importance of presenting all the results of the SSI - values of all indicators and categories - in a transparent and easily understandable way. Since the ultimate goal is to achieve a score of 10 - expressing full sustainability for each indicator - there can be no trade-off between the indicators or categories.

A study of 30 Western Hemisphere nations was presented in Shaker (2018) research shows that, its overall goal was to create the first mega-index of sustainable development (MISD), with the aim to improve humanity’s ability to calculate progress toward sustainability through an inductive approach. In doing so, 31 known indices were reduced into seven underlying dimensions of sustainable development, then normalized 0–100, and aggregated by their geometric mean. The seven orthogonal axes (latent dimensions) were subjectively articulated as: (1) socioeconomic well-being synergies; (2) economic freedom and democracy; (3) environmentally efficient happiness; (4) ecosystem well-being; (5) peace to economic vulnerability tradeoff; (6) natural resources protection; and (7) environmental stewardship and risk resilience. Overall, this study found that the underlying socioeconomic themes of sustainability dwarfed environmental themes, signifying a greater need for more simple, accurate, and scaleless (spatial and temporal) biogeophysical indicators. Using Pearson’s correlation and bivariate ordinary least squares (OLS) regression, 11 common development indicators were then explored regarding collinearity and explanatory power of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14991516

sustainable development dimensions and MISD. In sum, winning countries were characterized by low population density, increased forestland, decreased urban, and larger country area. The presented evidence is sufficient to suggest that just a few common and freely available indicators could eventually capture all present dimensions of sustainable development.

The aim of Latif et al. (2017) research as to develop an interactive model to develop the sustainability index for small and medium scale manufacturing industry.

In addition, Almeida et al. (2016) claim that Composite Index of Environmental Performance and Environtmental Performance Index models have initial objectives that guide all following steps, and there are many available variables that can be used to construct an ecological composite index. Some methodological techniques are used in each phase and the choices of the best methods were made based on theoretical background. Based on the three cited factors, the Composite Index of Environmental Performance and Environtmental Performance Index models are decomposed and analyzed in order to determine possible differences and similarities. The Composite Index of Environmental Performance and Environtmental Performance Index indicators have similar essential goals, which are to measure and rank environmental performance by country, although the focuses are different due the methods used to aggregate single variables. The first tool focuses on five dimensions, and the second focuses on nine environmental policy categories and two objectives ecological issues. In other words, the information provided by one, can be expanded by the other index. On the other hand, it is only possible to compare both indexes at the final stage when they are finished, and it is not possible to compare within subcategories. For example: it is impossible observe pressure on the ecosystem using the EPI, and it is impossible to assess ecosystem vitality using the CIEP, because they are aggregated through different categories. Both composite indexes analyzed use a positive approach because they measure performance, and thus the higher the value, the better are the results.

Also, Zuo et al. (2017) use EPI to evaluate China's environmental performance at the provincial level and then identifies weaknesses inenvironmental management for the purpose of improving government efficiency and solving severe environmental problems.

Crespo et al. (2016) explain the use of GII in their research. Their study should stimulate new research projects that compare the performance of innovation systems that distinguish between different levels of economic development. For instance, an extension might keep the sample together or might split the country sample into more disaggregated groups in order to understand the alternative recipes that could lead countries to high innovation performance. Another possible development deals with asymmetric causality. This approach might lead to better understanding of the causal conditions that lead countries to low innovation performance.

Materials and methods

The methodology of this article is based on the implementation of the sustainability index, which consists of the SSI and the EPI, and their connection with the GII, or the establishment of mutual correlation.

The subject of correlation analysis is to examine the mutual strength of the relationship and the dependence between sustainability and innovation. The selected variables are the SSI, the EPI and the GII. The examination of the direction and strength

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14991516

of the interaction of these three indexes is carried out on the basis of correlation analysis. It is also implemented on a sample of ten countries: Albania, Bosnia & Herzegovina (B&H), Bulgaria, Croatia, Hungary, Macedonia, Montenegro, Romania, Serbia and Slovenia (see *Figure 1*).

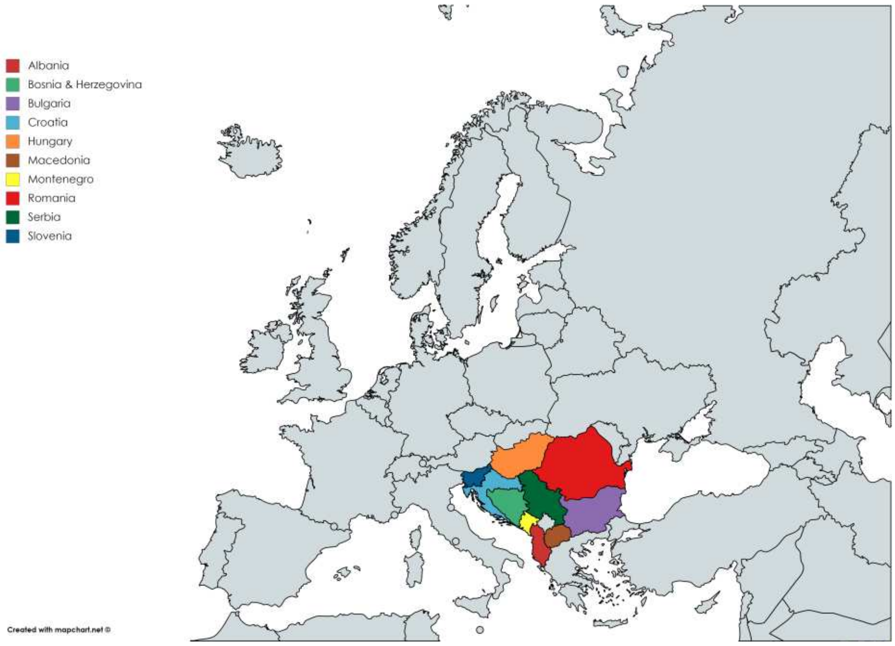

Figure 1. *The location of the countries involved in the presented study*

Classification (systematization) is the process of organizing information into categories or classes so that data can be more clearly analyzed or understood. Therefore, this research carried out the classification of the countries of Central and Eastern Europe, which are the subject of research, according to the following (*Table 1*).

Table 1. *Country classification according to two different criteria*

Country	Criterion	
	EU Membership Status	**Economy Development Status[a]**
Albania	Candidate	Economy in transition
Bosnia & Herzegovina	Potential candidate	Economy in transition
Bulgaria	Member	Developed economy
Croatia	Member	Developed economy
Hungary	Member	Developed economy
Macedonia	Candidate	Economy in transition
Montenegro	Candidate	Economy in transition
Romania	Member	Developed economy
Serbia	Candidate	Economy in transition
Slovenia	Member	Developed economy

[a] Information Source: Development Policy and Analysis Division of the Department of Economics and Social Affairs of the United Nations Secreteriat

Thus, the classification of countries in this survey will be based on the status of membership in the European Union, on the one hand, or on the basis of economic development, on the other.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14991516

The time interval to be tested is from 2010 to 2016. Testing the direction and strength of the interconnection will be expressed by the coefficient, using the Pearson linear method. It is a covariance of standardized variables X and Y. It is calculated using the following formula:

$$r = \frac{\sum_{i=1}^{n} x_i y_i - n\overline{x}\overline{y}}{n\sigma_x \sigma_y} \quad \text{(Eq.1)}$$

Or alternatively:

$$r = \frac{\sum_{i=1}^{n} x_i y_i - n\overline{x}\overline{y}}{\sqrt{\left(\sum_{i=1}^{n} x_i^2 - n\overline{x}^2\right)\left(\sum_{i=1}^{n} y_i^2 - n\overline{y}^2\right)}} \quad \text{(Eq.2)}$$

where:

- n is the sample size.
- X_i, Y_i are the sample points indexed with i.
- σ_x is standard deviation of X.
- σ_y is standard deviation of Y.

and the sample mean calculation would be

$$\overline{x} = \frac{1}{n}\sum_{i=1}^{n} x_i \;, \quad \overline{y} = \frac{1}{n}\sum_{i=1}^{n} y_i \quad \text{(Eq.3)}$$

The coefficient takes values from a closed interval between -1 and 1. The zero value indicates that there is no linear correlation; the value plus one denotes a perfect positive fit, and minus one shows a perfect negative fit. The value of the coefficient is closer to 1, the linear bond is stronger. The lower value of the coefficient does not necessarily indicate a weak link between the variables, since there may be a very strong correlation between the variables, but the curvilinear, so the application of the linear coefficient of correlation is not appropriate in this case (Buturac and Ignjatijević, 2017).

Data from the Global Innovation Index Report (2010-2016), the Environmental Performance Index Report (2010-2016) and the results of the Sustainable Society Foundation research (2010-2016), are taken as information source, based on which this research was conducted.

Sustainable Society Index (SSI)

In the SSI, the parameters of human well-being and environmental performance are integrated. These are the goals that each country should strive for, since economic well-being, without the previous two, can not be sustainable.

For the SSI only public data sources that are current and available are used. However, data reliability still leaves room for arbitrariness. Especially in the production

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14991516

of time series, processors are faced with many irregularities and obstacles in the creation of data. This problem can be reduced over time, as the significance of statistical data is now generally recognized.

Aggregation is an abstraction in which the connection between two objects or more object types is treated as an object at a higher level of abstraction. Because at the same time it is an object and a connection, aggregation is often referred to as a mixed type of object-connections. Aggregation objects are called aggregation components. For the aggregation of parameters of the SSI, a geometric average is used. The arithmetic average offers the possibility of compensation, where the low value of one indicator can be compensated by the high value of the other indicator. Since sustainability does not allow for compensation, it is best to use geometric compensation.

Van de Kerk et al. (2008) in their research demonstrated that the SSI is a simple instrument for assessing a country's sustainbility. The SSI, based on a solid definition, shows at a glance the present level of sustainability of a country and the distance to full sustainability. The SSI offers a country a practical tool for defining targets on its way to sustainability and for monitoring the progress over time.

The SSI calculation methodology

For lack of a scientific basis for the attribution of different weights to the indicators, every indicator has recieved the same weight for the aggregation into dimensions. In the data tables it is presented the averages per country. Thus one can notice the impact of weighting per person or per country. For each indicator the formula is shown, in which F(x) is the indicator score and X the value of the raw data (*Table 2*). In addition the range of validity is indicated.

Because of all of the above, the values of the three parameters are not aggregated into the total index, so that the researcher, could decide either for individual data, or for a summary result. Taking previously into consideration, the Sustainable Society Index data are trusted data, not the calculation of the authors, except the fact that we decided on the aggregate score of the index, which is presented in *Table 3*.

In the period from 2010 to 2016, the highest progress, according to the results of the conducted measurements (see *Table 3*), was achieved by Romania with a coefficient of 1.5, while the smallest progress was achieved by Albania with a coefficient of 0. The negative trend was achieved by the two countries, Montenegro and Slovenia (-0.4 and -0.2), however, this data should be taken with reserve, given that, according to the latest measurements from 2016, Slovenia is the second country in the region (coefficient of the Sustainable Society Index: 6.2), immediately behind the leading Romania (6.8).

Environmental Performance Index (EPI)

According to Almeida and Garcia-Sanchez (2016), EPI is one of the most known indexes, and it is used in several studies and frequently receives innovations and improvements. The EPI has published an annual report that ranks 180 countries, according to ecological performance comprised of twenty two four variables, combined into ten policy issue that are aggregated in two different groups (health of the environment and vitality of ecosystems).

These measures enable the quantitative expression of the effectiveness of the implementation of environmental performance policies at the national level. These results highlight advanced countries and those lagging behind in this segment, giving insights into best practices, and providing guidance for countries that are striving to be

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14991516

leaders in environmental sustainability. The innovations in EPI data from 2018 and the methodology generated a new ranking based on modern approaches in natural science and analysis.

According to research of Yale University presented in EPI Report (2018), this index draws attention to the issues on which policy makers need to take further initiative. Although the EPI provides an analytical framework suitable for a more rigorous creation of an environmental policy, it also reveals and points to more serious failures through data. According to the Foundation for Environmental Protection, EPI projects that data collection, reporting and verification is necessary, through a series of ecological problems. Existing deficiencies are particularly evident in the areas of sustainable agriculture, water resources and waste management. Therefore, data systems are exceptional support for better management of sustainable development challenges.

Table 2. *Calculation formulas of the SSI*

Indicator number	Indicator Name	Formula
1	Sufficient food	F(X)=(100-X)/10 if 5≤X≤100 F(X)=10 if X<5
2	Sufficient to drink	F(X)=X/10 0≤X≤100
3	Safe Sanitation	F(X)=X/10 0≤X≤100
4	Education	F(X)=X/10 if 0≤X≤100 F(X)=10 if X>100
5	Healthy Life	F(X)=((X-20)/60)*10 20≤X≤80
6	Gender Equality	F(X)=X*10 0≤X≤1
7	Income Distribution	F(X)=EXP(-0,1*(X-4,5))*10 If 4,5≤X≤168, F(X)=0 if X>168
8	Population Growth	F(X)=-0,0067*X^2 -0,4333*X+8 if -5<X<15 F(X)=0 if X≥15, F(X)=10 if X<-5
9	Good Governance	F(X)=((X+15)/30)*10 -15≤X≤15
10	Biodiversity	F(X)=(F(X1)+F(X2))/2
11	Renewable Water Resources	F(X)=(100-X)/10 if 0≤X≤90 F(X)=0 if X>90
12	Consumption	F(X)=10-3*X*2/1,8 if 0≤X≤2,7 F(X)=0 if X>2,7
13	Energy Use	F(X)=-2*X+10 if X≤5 F(X)=0 if X>5
14	Energy Savings	F(X)=25*X+5 if -0,2≤X≤0,2 F(X)=0 if X<-0,2, F(X)=10 if X>0,2
15	Greenhouse Gases	F(X)=10-X if 0≤X≤10 F(X)=0 if X>10
16	Renewable Energy	F(X)=X/10 if 0≤X≤100 F(X)=10 if X>100
17	Oganic Farming	F(X)=9*(1-EXP(-0,25*X))+1
18	Genuine Savings	F(X)=10*ARCTAN(0,2*X)/π+5
19	Gross Domestic Product	F(X)=10*(1,01-EXP(-0,000065*X)) if 0≤X≤70000 F(X)=10 if X>70000
20	Employment	F(X)=EXP(-0,1*X)*10 if 0≤X≤60 F(X)=1 if X>60
21	Public Debt	F(X)=-3,8*ARCTAN(0,06*X-3,5)+5 if 2,5≤X≤117 F(X)=0 if X≥117, F(X)=10 if X<2,5

The EPI calculation methodology

To create the EPI, raw datasets is transformed into comparable performance indicators, which requires standardizing raw values according to population, land area, gross domestic product, and other common units of measurement. Then statistical transformations are performed to normalize data distributions and ensure weights assigned in the aggregation phase affect data as intended.

The transformed data are used to calculate performance indicators. EPI indicators are developed using a 'proximity-to-target' methodology, which assesses how close each country is to an identified policy target. The targets are high performance benchmarks defined primarily by international or nation policy goals or established scientific thresholds.

A high performance benchmark can be determined through an analysis of the best-performing countries. Scores are then converted to a scale of 0 to 100 by simple arithmetic calculation, with 0 being the farthest from the target and 100 being the closest. In this way, scores convey analogous meaning across indicators, policy issues, and throught the EPI.

Each indicator is weighted within the issue categories to create a single issue category score. These weightings are generally set according to the quality of the underlying data, as well as an indicator's relevance or fit for assessing a given policy issue. If the underlying data for a particular indicator is less reliable or relevant than others in the same issue category, the indicator will be weighted less. Policy issues are weighted approximately equally within their objective. Contigent on the data strength in each category, slight adjustments to this weighting can be made (Yale University, 2018).

Countries only receive scores for issues that are 'material' or relevant to their environmental performance. The exclusion of certain issues for some countries proportionally increases the weight on other indicators within a policy issue and objective. The two objectives, Environmental Health and Ecosystem Vitality, are weighted equally to achieve a single value, the EPI score, for each country.

$$EPI = \sum_{i=1}^{n}(WiXi) \quad \text{(Eq.4)}$$

where

- i is total number of the indicator.
- n is total number of all indicators.
- Wi is weight of the i_{th} indicator.
- Xi is standard value of the i_{th} indicator (Zuo et al., 2017).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14991516

It is interesting to compare the EPI trend in the countries of the region, taken as a sample in this survey. If we take into consideration the indicators from 2016, it can be established that most of the countries in the region are in front of Serbia, when index indices are considered (see *Table 4*). The three countries have an unfavorable outcome compared to the Republic of Serbia, which are Albania, B&H and Macedonia.

Table 4. *Environmental Performance Index of the selected countries in transition*

Country / Yr	2010	2012[a]	2014	2016	Country / Yr	2010	2012[b]	2014	2016
Albania	71.14	65.85	54.73	74.38	Macedonia	60.60	46.96	50.41	78.02
B&H	55.90	36.76	45.79	63.28	Montenegro[c]	/	/	78.89	78.89

Source: Environmental Performance Index Report (2010-2016). Publisher: Yale University: Center for Environmental Law & Policy
[a] Scores and rankings for the 2012 EPI cannot be compared with scores and rankings from eralier releases of the EPI owing to changes in data and methodology
[b] Ibid.
[c] No data available for Montenegro in the specified years

As it is presented in *Table 4*, between the countries of the region, which are highly ranked on the world ranking list, the difference in the index coefficient is negligible (88.98 - 83.24). According to these results, Slovenia is ahead, followed by Croatia, Hungary, Bulgaria and Romania.

A more sensitive difference in the value of the measured index was recorded in Montenegro (78.89), Serbia (78.67) and Macedonia (78.02). The following countries are followed by Albania (74.38) and B&H (63.28).

Data source for the EPI come from international organizations, research institutions, academia, and government agencies. These sources use a variety of techniques, including (Yale University, 2018):

- Remote sensing data collected and analyzed by research partners.
- Observations from monitoring stations.
- Surveys and questionnaires.
- Academic research.
- Estimates derived from both on-the-ground measurements and statistical models.
- Industry reports; and
- Government statistics, reported either individually or through international organizations, that may or may not be independently verified.

Taking this into consideration, the Environmental Performance Index data are trusted data, not the calculation of the authors.

The Global Innovation Index (GII)

The Global Innovation Index is important for achieving economic progress and competitiveness in the market, both in developed countries and in countries in transition. Many countries, when implementing their economic policies, include this index in the center of state strategies.

Also, one of the reasons for introducing this kind of measurement of the achieved results in terms of innovation in the economy of a particular country is to provide timely

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14991516

and accurate data to the state leadership, which is an important prerequisite for decision-making and improvement of innovation policies. This does not mean that the GII is merely the ranking of the economies of countries that are subject to indexing, based on certain parameters, but also in this way to assess the conditions that incite the potent trend of innovation, that is, to assess the outcome of the introduction of concrete improvements (Cornell University, 2017).

Although the final results are presented in several forms, in order to provide a better comparison of indicators, the GII is more focused on understanding and analyzing innovations, that is, identifying targeted policies, good practices and instruments that help improve innovation. Previously, comprehensive indexing is used at the level of the index, subindex or at the level of individual data used to monitor the performance over a specific time period, as well as to develop in relation to countries in the region.

According to the Cornell University's Global Innovation Index Report (2017) an innovation is the implementation of a new or significantly improved product (good or service), a new process, a new marketing method, or a new organizational method in business practices, workplace organization or external relations. The Global Innovation Index is not meant to be the ultimate and definitive ranking of economies with respect to innovation. Measuring innovation outputs and impacts remains difficult, hence great emphasis is placed on measuring the climate and infrastructure for innovation and on assessing related outcomes. Today innovation capability is seen more as the ability to exploit new technological combinations; it embraces the notion of incremental innovation and 'innovation without research.

The GII calculation methodology

The Global Innovation Index is an evolving project that builds on its previous editions while incorporating newly available data and that is inspired by the lateset research on the measurement of innovation. The GII relies on two sub-indicies – the Innovation Input Sub-Index, and the Innovation Output Sub-Index – each built around key pillars (*Figure 2*).

Five input pillars capture elements of the national economy that enable innovative activities: (1) Institutions, (2) Human capital and research, (3) Infrastructure, (4) Market sophistication and (5) Business sophistication. Two output pillars capture actual evidence of innovation outputs: (6) Knowledge and technology outputs and (7) Creative outputs (Cornell University, 2017).

Each pillar is divided into sub-pillars and each sub-pillar is composed of individual indicators (80 in total). Sub-pillar scores are calculated as the weighted average of individual indicators; pillar scores are calculated as the weighted average of sub-pillar scores. Four measures are then calculated:

- Innovation Input Sub-Index: is the simple average of the first five pillar scores.
- Innovation Output Sub-Index: is the simple average of the last two pillar scores.
- The overall GII score is the simple average of the Input and Output Sub-Indicies.
- The innovation Efficiency Ratio is the ratio of the Output Sub-Index over the Input Sub-Index.

Taking previously into consideration, the Global Innovation Index data are trusted data, not the calculation of the authors.

Expectedly, the values presented in the *Table 5* show that innovation in the EU Member States is more prevalent. The largest coefficient in 2016, from the countries that are the subject of consideration, has Slovenia (45.97) as a strong innovator, while the lowest coefficient is Albania (28.38). The countries who scored coefficient values among this range (28.38 - 45.97) also have their innovation status – moderate and modest innovators. It is interesting that in the period from 2010 to 2016, the GII registered a negative trend (Hungary, Serbia, Montenegro, B&H, and Albania), while in the period after this year, there was an increase. The status of innovators, in fact, follows the status of development and membership status in the European Union, which are previously set criteria for the classification of countries that are the subject of this research.

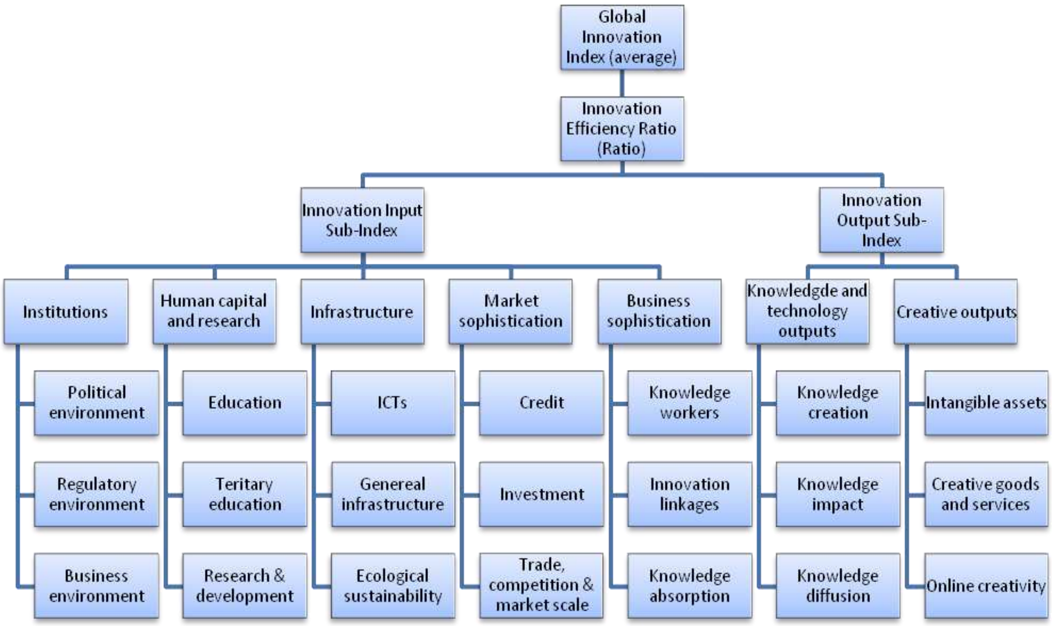

Figure 2. *The Global Innovation Index Framework*

Table 5. *Global Innovation Index of the selected countries in transition*

Country / Yr	2010[a]	2012	2014	2016	Country / Yr	2010[b]	2012	2014	2016
Albania	2.86	30.40	30.47	28.38	Macedonia	2.89	36.20	36.90	35.40
B&H	2.58	34.20	32.43	29.62	Montenegro	3.08	40.10	37.01	37.36
Bulgaria	3.26	40.70	40.74	41.42	Romania	3.22	37.80	38.08	37.90
Croatia	3.28	40.70	40.75	38.29	Serbia	2.68	40.00	35.89	33.75
Hungary	3.54	46.50	44.61	44.71	Slovenia	3.80	49.90	47.23	45.97

Results

Based on previously explained indicators of sustainable society, environmental performance and global innovations, in the first part of the research, the center was moved to determine and describe the coefficient of mutual correlation between the SSI and the GII.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14991516

Since this is parametric statistics, where the coefficient of variation is less than 30 (in the concrete case SSI = 10.1100775091025, GII = 15.5680187865172), the Pearson method of correlation was applied, thus calculating the correlation coefficient of these two indices.

The correlation coefficient of the SSI and the GII is 0.749413095249505, that is, 0.75, which means that the correlation of these two parameters is above all: positive (> 0.50) and then strong.

In *Figure 3*, the correlation of these two indices is shown, along with the variation coefficients, also mentioned. Based on this, we conclude that a low SSI value (living standard of the population, environmental protection and economic well-being) also contributes to a low GII value. Thus, the underdevelopment of innovation is a result of low living standards and underdeveloped economies. This group of countries includes Albania and B&H.

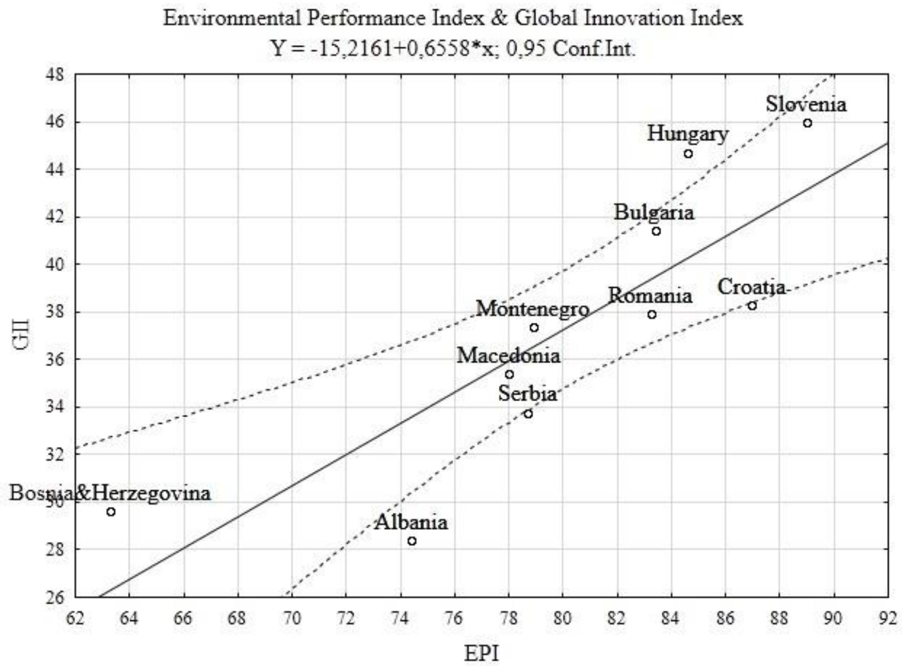

Figure 3. *Correlation between EPI & GII of the selected countries in transition*

The group of non-EU countries is led by Montenegro, followed by Macedonia and Serbia. Also, on the basis of an analysis of the mutual correlation of the index, we conclude that the countries of the regions that are members of the EU, have significantly better results than the rest of the considered sample. This group is led by Slovenia and Hungary, followed by Bulgaria, Croatia and Romania. The results of this group confirm that economic prosperity and high living standards of the population directly influence the level of innovation in the domestic economy.

Smilarly, comparing the Environmental Performance Index to the Global Innovation Index, we arrive at the results, and interpretations of the results close to the previous one.

Since in this case the coefficient of variation <30 (EPI = 9.22410037158007, GII = 15.5680187865172), the Pearson method of correlation was used. Correlation

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14991516

coefficient of the Environmental Performance Index and Global Innovation Index is 0.834337304281034. The correlation between these two parameters is positive, and more pronounced, than in the previous case.

The division of countries by groups is identical to the previous interpretation of the results. Furthermore, the low efficiency of environmental protection, that is, the low level of people's awareness of the need for environmental protection, directly affects the low level of innovation in the economies of these countries that are in transition.

In this index clash, the results are even more dramatically determined (see *Figure 4*). The worst results are recorded by Albania and B&H, which still have the status of underdeveloped transition countries. A group of non-EU countries that are on the right path to achieving the goals of the set strategies and policies is led by Montenegro, followed by Macedonia and Serbia. Far ahead are the EU Member States, led by Slovenia and Hungary, followed by Bulgaria, Croatia and Romania.

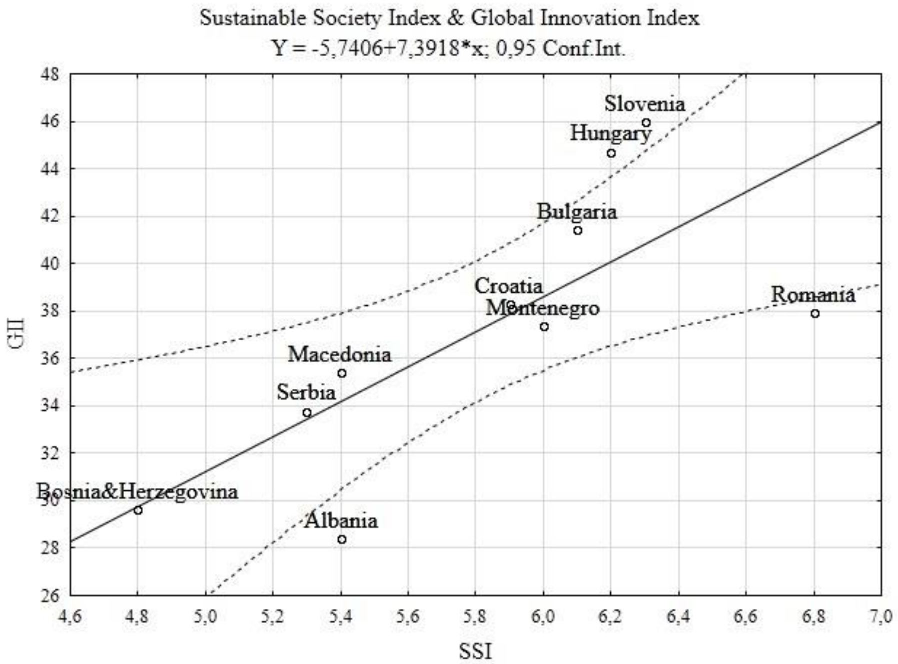

Figure 4. *Correlation between SSI & GII of the selected countries in transition*

The example of Slovenia, perhaps, is the best presentation of what each country in transition is tending to. The achieved high, desired results in the field of environmental protection directly influence the higher financial allocations and investments in innovations in the field of economy.

Discussion

Taking into account all the results obtained, the conclusion is that the paramteres in the subject of the conducted research are interconnected, as evidenced by the high coefficient of correlation. Looking at the individual results of countries in the region, they can be grouped according to the status of countries for EU membership.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_14991516

On a sample of ten countries in the region, which are related to a common transition, there is still a certain grouping, which is noticed in the graphic representation of the obtained results. Namely, the first group of countries are the countries that are in the status of a potential candidate for EU membership. This group belongs to B&H. However, according to unfavorable results in the considered areas of social activity, although in the status of EU candidate country, Albania joins B&H on the ranking list of the Sustainability and Innovation Index.

The next group of countries is a group of countries that are in the process of joining the EU. This group is led by Montenegro, followed by Serbia and Macedonia (although the country with the candidate status).

Expectedly, at the top of the list of countries in the region, Slovenia is the most developed country with the largest investments in innovation, which is the result of a favorable economic situation in the economy of this country, as well as high awareness of the need for environmental protection. Other EU member states are: Hungary, Bulgaria, Romania and Croatia.

On the other hand, a high degree of correlation of parameters, whose interdependence is researched, indicates interaction, and encouraging positive trends in the growth of innovation and improving the quality of life and living standards of the inhabitants of these countries. In order for the less developed countries in transition to reach the targeted level of sustainability of the society and the efficiency of environmental performance, it is necessary for the state leadership to direct and lead a more efficient policy towards the improvement of these areas. In this way, inevitably, as a consequence of this action, the development of innovations in the economies of these countries will be imposed, which, as the ultimate goal, represents the overall well-being and balance of modern systems.

(Received 21st Oct 2018; accepted 7th Jan 2019)

Abstract. The present study dealt with the removal of Reactive Red 45 (RR45) azo dye material through Fenton and Fenton-like oxidation processes. The effects of pH, Fe^{2+} and Fe^{3+} dosages, hydrogen peroxide (H_2O_2), concentration of colorant and temperature were evaluated. Removal of the colorant RR45 was monitored by considering color and Chemical Oxygen Demand (COD). Results showed that Fenton process is more efficient than Fenton-like processes in terms of color and COD removal efficiency. A removal efficiency of 91.1% of COD and 99.90% of color was obtained under optimum experimental conditions where initial solution pH was 3, the concentration of RR45 colorant was 200 mg L^{-1}, rates of Fe^{2+} and H_2O_2 were 75 mg L^{-1} and 400 mg L^{-1}, respectively, reaction temperature was 50°C and experiment time was 30 min. In addition, the first order, second order and Behnajady-Modirshahla-Ghanbery (BMG) models were applied and the best results were obtained by BMG model.

Introduction

Today, industrialization is developing in line with the demand of increasing human population and consumption and several new industries are added to the existing industrial facilities depending on this increasing demand. Pollution parameters may vary depending on the types of industries and wastewater is produced with different characteristics.

The textile industry exhibits higher polluting characteristics in terms of wastewater volume and composition than other industrial sectors (Vandevivere et al., 1998). Water consumption in the textile industry ranges from 25 to 250 m^3 per ton of product (Chacón et al., 2006). Numerous different types of dyes are used in different industries for different purposes. Dyes contain different chemical structures. However, they are generally composed of two components, chromophore and function group. Chromophore is an important compound for the color of the dye. The functional group, on the other hand, allows dye to bind to cotton or wool yarn. Different types of functional groups are used for dyeing different types of textile materials (Kayıkooğlu and Debik, 2006). They are characterized in terms of their chemical structures as azo, triaryl methane, anthraquinone, heterocyclic and phthalocyanine dyes. They are also catagorised into six groups for their application methods as watt, reactive, direct, acidic, disperse and cationic dyes (Xu et al., 2004). In recent years, advanced wastewater treatment methods, known to be environmentally friendly in wastewater treatment, have been used since they can oxidize wastewaters which are hard to biodegrade to a more harmless form (e.g. carbon dioxide, water and inorganic salts) (Neyens and Baeyens,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15171529

2003; Primo et al., 2008). Fenton process is one of these methods. In Fenton reaction, the hydroxyl radical ($OH^{\bullet}$) was shown to form after a series of reactions consisting of iron and iron salts and catalytic cracking of hydrogen peroxide (Harber and Weiss, 1934). This process is based on the formation of ($OH^{\bullet}$) under acidic conditions as a homogeneous catalytic oxidation process.

Fenton oxidation involves chemical mechanisms expressed by the following equations (*Eqs. 1-5*) (Sun et al., 2009a).

$$Fe^{2+} + H_2O_2 \rightarrow Fe^{3+} + OH^{\bullet} + OH^{-} \quad \text{(Eq.1)}$$

$$Fe^{2+} + OH^{\bullet} \rightarrow Fe^{3+} + OH^{-} \quad \text{(Eq.2)}$$

$$Fe^{3+} + H_2O_2 \rightarrow Fe^{2+} + HO_2^{-} + H^{+} \quad \text{(Eq.3)}$$

$$Fe^{3+} + HO_2^{\bullet} \rightarrow Fe^{2+} + O_2 + H^{+} \quad \text{(Eq.4)}$$

$$H_2O_2 + OH^{\bullet} \rightarrow HO_2^{\bullet} + H_2O \quad \text{(Eq.5)}$$

As an overview, the Fenton process consists of four steps; pH adjustment, oxidation reaction, neutralization and precipitation reaction through coagulation. In this way, the organic materials are removed in two steps, oxidation and coagulation (Kang and Hwang, 2000). According to the studies conducted in literature, Fenton process is widely used in removing organic materials (Fan et al., 2013), reducing toxicity (Zhang et al., 2014), phenol removal (Mofrad et al., 2015), textile wastewater treatment (Latif et al., 2015), color removal (Bouasla et al., 2010; Ertugay and Acar, 2017) and removal of organic matter from cosmetic waste water (Bayhan and Değermenci, 2017). In this study, Fenton and Fenton-like process studies were evaluated for color and COD removal of wastewaters from synthetic textile products prepared with colorant called commercially Reactive Red 45 and used in textile dyeing. In the experimental studies carried out, the effects of pH, rate of Fe^{2+} or Fe^{3+} salts and H_2O_2, initial dye concentration and temperature parameters on removal efficiency were investigated. Obtained data of kinetic studies were applied to the kinetic models, first-order, second-order and BMG models.

Materials and Methods

RR45 colorant was obtained from a commercial company, Duraner Boya A.Ş. The molecular weight of azo colorant (RR45) 802.1 g mol^{-1}, whose molecular is $C_{27}H_{19}ClN_7Na_3O_{10}S_3$. RR45 exhibits a complex structure together with azo aromatic groups and is used commonly in textile industry (Swarnkar et al., 2015). As the result of spectrum scanning of colorant, maximum absorbance was found to be 243 nm, 283 nm and 541 nm. Molecular structure of RR45 colorant is given in *Fig. 1*.

The experimental device was constituted of a perfectly agitated reactor in which a volume (600 ml) of solution was studied. In experiments, pH adjustment of the dye prepared in the desired concentration was performed first by adding diluted H_2SO_4 and NaOH. Following this stage, $FeSO_4.7H_2O$ or $FeCl_3.6H_2O$ and H_2O_2 were added and stirred fast for 3 min at 150 rpm and then slowly for 27 min at 50 rpm and the resultant

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15171529

mixture was filtered through 0.45 μm membrane filter. Color and COD measurements were then performed. Both experiments and analysis were repeated twice at the same conditions to ensure the accuracy of data and the averages values were given. Color measurements were conducted and values were registered at 541 nm wave-length spectrophotometrically. COD analyses were also conducted spectrophotometrically at 600 nm, 148°C and Merck Spectroquant TR320 according to Standard Methods (APHA 1998). *Table 1* gives the average COD values for the initial colorant concentration. In Fenton and Fenton-like processes; the investigated parameters and ranges are given in *Table 2*.

Results and discussion

Effect of iron dosage

The dosage of the Fenton reactive in the Fenton and Fenton-like oxidation process plays a very important role in the degradation of organic substances and the determination of the total cost of the process. In general, as the dosage of Fe^{2+} and Fe^{3+} increases, degradation rate of organic materials increases. However, a very large increase in the Fe^{2+} and Fe^{3+} ions leads to an increase in the amount of total dissolved iron ions. Therefore, it is necessary to avoid the formation of excessive amount of sludge (Saini et al., 2017). Fe^{2+} and Fe^{3+} experiments were first carried out in the determination of color and COD removals in the Fenton and Fenton-like oxidation of RR45. For this aim, experiments were conducted by fixing samples prepared at a dye concentration of 200 mg L^{-1} to 500 mg L^{-1} H_2O_2 and adding Fe^{2+} and Fe^{3+} at the concentrations of 25, 50, 75, 100, 125, 150, 200 mg L^{-1}.

As the result of the experiments (*Fig. 2*), the largest removal yields were obtained at 100 mg L^{-1} Fe^{2+} concentration for Fenton oxidation and at 75 mg L^{-1} Fe^{3+} concentration for Fenton-like oxidation. In the Fenton process, when Fe $^{2+}$ concentration increased from 25 mg L^{-1} to 100 mg L^{-1} color removal yield continued at 98% level while COD removal yield increased from 55.2% to 80.31%. When Fe^{2+} concentration increases from 100 mg L^{-1} to 200 mg L^{-1}, COD removal yield decreases from 80.31% to 76.72% while color removal decreases from 98.69% to 82.13%. In the case of the Fenton-like oxidation, in all Fe^{3+} dosage experiments, color removal yield was obtained to be nearly 99% while in the same Fe^{3+} dosage range (25 mg L^{-1} to 75 mg L^{-1}) COD removal yield was between 63.80% and 74.10% and at 200 mg L^{-1} it decreased to 52.12%. Since no main factor is present to produce hydroxyl radicals in the absence of iron ion, an effective oxidation based on Fenton reaction cannot be achieved. As the Fe^{2+} and Fe^{3+} concentration increases, theoretically higher rate of $OH^{\bullet}$ radicals will be produced.

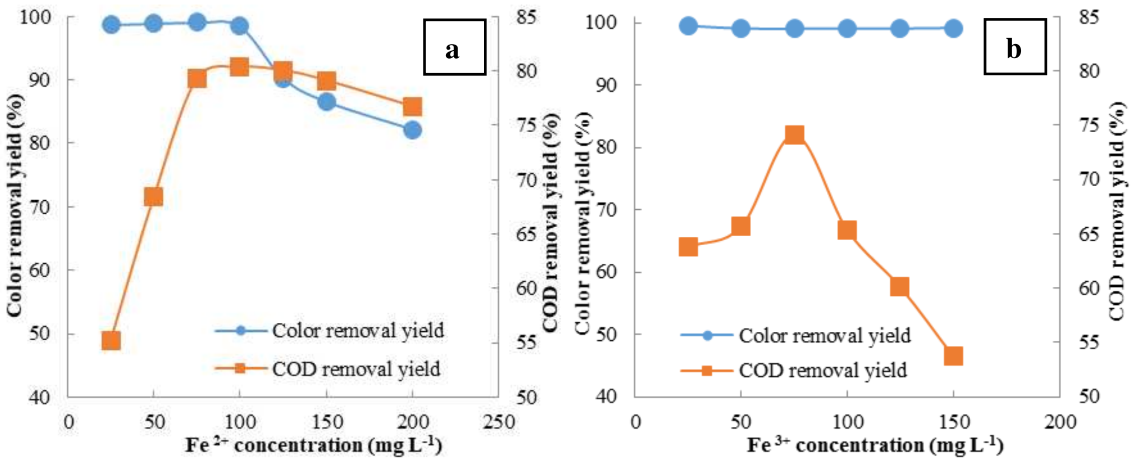

Figure 2. *Effect of iron doses on color and COD removal (a) Fenton and (b) Fenton-like processes (C_0=200 mg L^{-1}, H_2O_2=500 mg L^{-1}, pH=3, T=20°C, t=30 min)*

Such a situation is thought to affect unfavorably oxidation capacity of excessive Fe^{2+} concentration. It is known that in accordance with *Eq. 2*, higher concentrations of Fe^{2+}, can cause the consumption of $OH^{\bullet}$ radicals (radical scavenger effect) and thus

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15171529

decreasing removal yield (Tang and Chen, 1996; Lunar et al., 2000; Ntampegliotis et al., 2006; Pérez-Moya et al., 2007).

In addition, when solution media is acidic, higher Fe^{2+} concentrations can cause based on *Eq. 6*, and additional reaction resulting in the transformation of H_2O_2 into water (Tarr, 2003).

$$Fe^{2+} + H_2O_2 + 2H^+ \rightarrow 2Fe^{3+} + H_2O \quad \text{(Eq.6)}$$

In Fenton process, as the result of experiments, at the concentrations of 75 mg L^{-1} and 100 mg L^{-1}, color and COD removal yields are nearly the same and therefore, optimum Fe^{2+} dosage was determined to be 75 mg L^{-1} for cost effectiveness. In a condition of fenton-like process, optimum Fe^{3+} dosage was determined to be 75 mg L^{-1} for the highest removal yields.

Effect of H_2O_2 concentration

H_2O_2 concentration is an important parameter in Fenton processes. Determination of the optimum H_2O_2 concentration value in Fenton processes is important for removal yield of the process and for its applicability based on the cost of H_2O_2. In Fenton reactions, hydrogen peroxide plays very important roles as the production source of hydroxyl radicals (Sun et al., 2009a).

In order to determine the most suitable H_2O_2 rate in fenton and Fenton-like process, doses were adjusted to 100 mg L^{-1} to 600 mg L^{-1} of H_2O_2 concentrations by fixing C_0= 200 mg L^{-1}, Fe^{2+} and Fe^{3+}= 75 mg L^{-1}, pH= 3 and T= 20°C. Experimental results are given in *Fig. 3*.

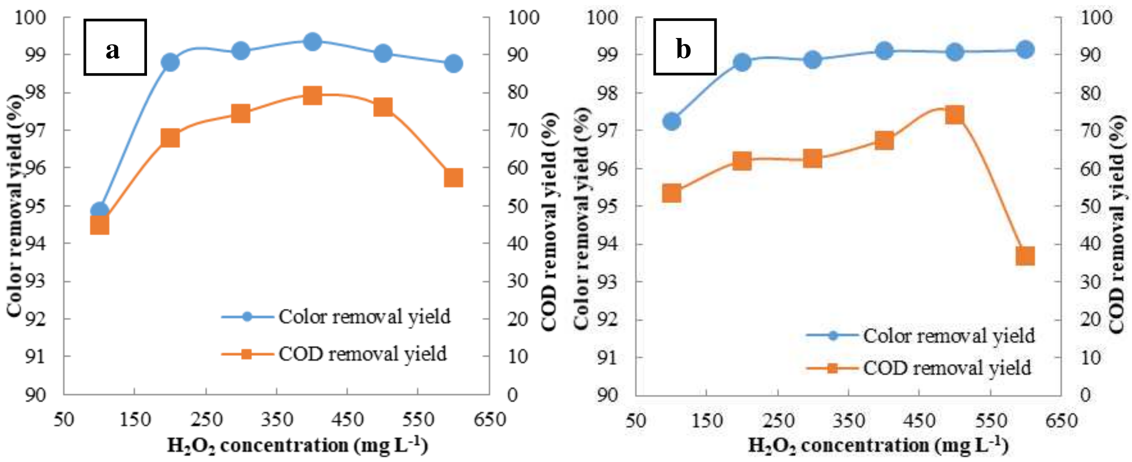

Figure 3. *Effect of H_2O_2 doses on color and COD removal (a) Fenton and (b) Fenton-like processes (C_0=200 mg L^{-1}, Fe^{2+} and Fe^{3+} =75mg L^{-1}, pH=3, T=20°C, t=30 min)*

When considered (*Fig. 3*), it is seen that at the end of a 30 – min reaction time, increase of H_2O_2 concentration from 100 mg L^{-1} to 400 mg L^{-1} causes increases in both color and COD removal yields. When H_2O_2 concentration increases from 100 mg L^{-1} to 400 mg L^{-1}, color removal yield rises from 94.87% to 99.35% while COD removal yield rises up from 44.66% to 79.25%. At the concentrations above 400 mg L^{-1}, H_2O_2 dosing

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15171529

causes decreases in color and COD removal yields. In case H_2O_2 concentration rises from 400 mg L^{-1} to 600 mg L^{-1}, color and COD removals were 98.77% and 57.38%. In the case of the Fenton-like oxidation, in all H_2O_2 concentration experiments, color removal yield was obtained to be nearly 98% while in the same H_2O_2 concentration range (100 mg L^{-1} to 500 mg L^{-1}) COD removal yield was between 53.40% and 74.10% and at 600 mg L^{-1} it decreased to 36.67%.

In general, increase in H_2O_2 dosage increases the degradation rates of pollutants (Lin and Lo, 1997; Lin et al., 1999; Kang and Hwang, 2000; Babuponnusami and Muthukumar, 2014). However, great care should be taken when deciding on H_2O_2 dosage in the studies. Unused part of H_2O_2 may cause COD in Fenton processes to increase and so at excessive concentration, H_2O_2 is not advisable (Lin and Lo, 1997). In the same way, H_2O_2 is harmful for several living organisms. Another unfavorable effect of H_2O_2 is the radical scavenger effect of ($OH^{\bullet}$) radicals (*Eq. 5*). Such a condition is seen at excessive concentrations and H_2O_2 (Tang and Chen, 1996; Kitis et al., 1999; Ntampegliotis et al., 2006; Sun et al., 2007). At the end of the experiments, optimum H_2O_2 concentration was found to be 400 mg L^{-1} for Fenton process and 500 mg L^{-1} for the Fenton-like process by considering both removal yield and the cost of H_2O_2.

Effect of pH

pH is a higly important parameter for producing $OH^{\bullet}$ radicals in Fenton and Fenton-like process (Singh and Tang, 2013; Mofrad et al., 2015). In the experiments in order to determine optimum pH in the treatment of RR45 colorant through Fenton and Fenton-like process, beakers were filled first with RR45 with the concentration of C_0= 200 mg L^{-1} taken from stocked solution and then, 75 mg L^{-1}'lik Fe^{2+} or Fe^{3+}, H_2O_2 is 400 mg L^{-1} (for Fenton process) or 500 mg L^{-1} (for Fenton-like process) found to be optimum were added and experiments were conducted between pH 2.5 and 5.0. Results obtained are showed graphically in *Fig. 4*. In the experiments, at the end of 30 – min experiment time, the highest color and COD removal yield for both fenton and Fenton-like processes were achieved at pH 3. In the experiments conducted with pH above and below 3, color and COD removal yields decreased.

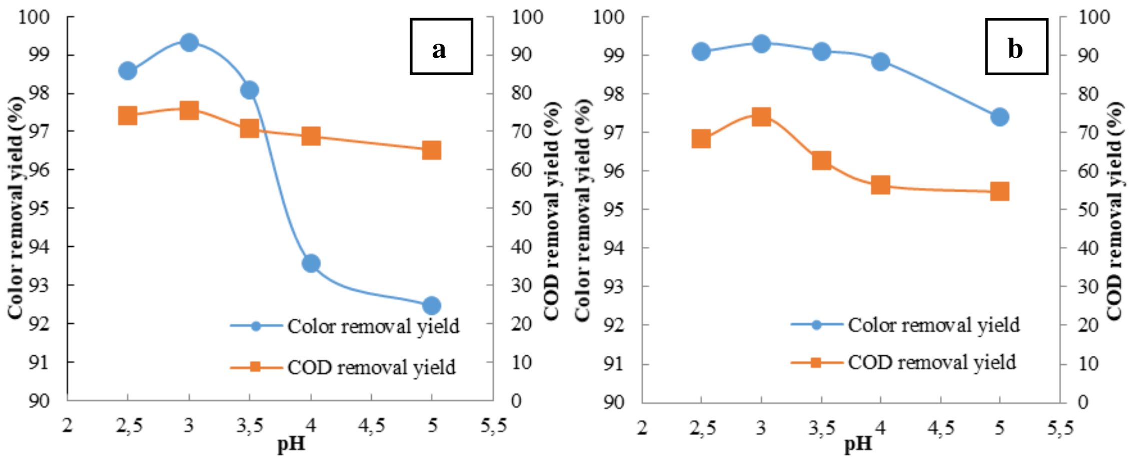

Figure 4. *Effect of pH on color and COD removal (a) Fenton and (b) Fenton-like processes (C_0=200 mg L^{-1}, Fe^{2+} and Fe^{3+} =75 mg L^{-1}, H_2O_2 is 400 mg L^{-1} (for Fenton process) or 500 mg L^{-1} (for Fenton-like process), T=20°C, t=30 min)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15171529

When pH is below 3, since complex iron types $[Fe(H_2O)_6]^{2+}$, $[Fe(H_2O)_6]^{3+}$, $[Fe(H_2O)_5OH]^{2+}$ reacting with H_2O_2 slower are formed, *reactions 2* and *7* also slow down and in that case oxidation removals also decrease.

$$Fe^{2+} + H_2O_2 + H^+ \rightarrow Fe^{3+} + OH^\bullet + H_2O \qquad \text{(Eq.7)}$$

In addition, under low pH conditions (pH<3), formation of oxonium ion $[H_3O_2]^+$ which increases the stability of H_2O_2 and limits the production of $OH^\bullet$ radical may cause the *reactions 3* and *8* to slow down (Bouasla et al., 2010; Singh and Tang, 2013).

$$R^\bullet + H_2O_2 \rightarrow ROH + OH^\bullet \qquad \text{(Eq.8)}$$

At pHs lower than 3, reason for the decrease in color and COD removal yields is that excessive amount of H^+ ions reacts with H_2O_2 and forms stable oxonium ion ($H_3O_2^+$) (*Eq. 9*).

$$H_2O_2 + H^+ \rightarrow H_3O_2 \qquad \text{(Eq.9)}$$

Production of $OH^\bullet$ radical decreases since precipitating $Fe(OH)_3$ is formed when pH is above 3 (*Eq. 10*).

$$Fe^{3+} + 3OH^- \rightarrow Fe(OH)_3 \qquad \text{(Eq.10)}$$

Following this precipitation, production of Fe^{2+} from Fe^{3+} stops and then the production of $OH^\bullet$ radical decreases (Chen and Pignatello, 1997; Bouasla et al., 2010). In addition, as pH increases, rate of self – degradation of H_2O_2 increases (*Eq. 11*).

$$H_2O_2 \rightarrow 2H_2O + O_2 \qquad \text{(Eq.11)}$$

The effect of initial colorant concentration

The effect of initial RR45 concentration on the removal yield in the Fenton and Fenton-like oxidation process was studied with dye concentrations of 150, 200, 250, 300, 350 and 500 mg L^{-1}. Experiments were conducted under the conditions, where pH is 3, H_2O_2 is 400 mg L^{-1} (for Fenton process) or 500 mg L^{-1} (for Fenton-like process), T is 30 min and Fe^{2+} is 75 mg L^{-1} or Fe^{3+} is 75 mg L^{-1}. Experimental results are shown graphically in *Fig. 5* and *Fig. 6*. As can be seen from *Fig. 5* and *Fig. 6*, as the initial colorant concentration increases both color and COD removal yields decreased. With the increase in initial colorant concentration from 150 mg L^{-1} to 500 mg L^{-1}, color removal yield decreased from 99.91% to 98.83% while COD removal yield from 77.93% to 55.13% in the Fenton oxidation and 73.80% to 46.70% in the Fenton-like oxidation process, respectively. Reason for this is that as the initial colorant concentration increases the number of dye molecules also increases. In this case, there was no change in the number of $OH^\bullet$ radicals since the concentrations of Fe^{2+} and H_2O_2 did not change in the medium. Reduced removal yields were observed since there would be less $OH^\bullet$ radicals matching with increasing number of dye molecules. Similar

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15171529

trend is seen in several studies in literature (Malik and Saha, 2003; Lucas and Peres, 2006; Sun et al., 2007; Bouasla et al., 2010; Harichandran and Prasad, 2016).

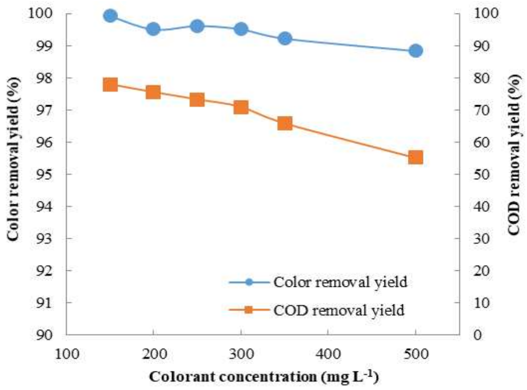

Figure 5. *Effect of initial colorant concentration in Fenton oxidation on color and COD removal (Fe^{2+}= 75 mg L^{-1}; H_2O_2= 400 mg L^{-1}; pH= 3; T= 20^0C; t= 30 min)*

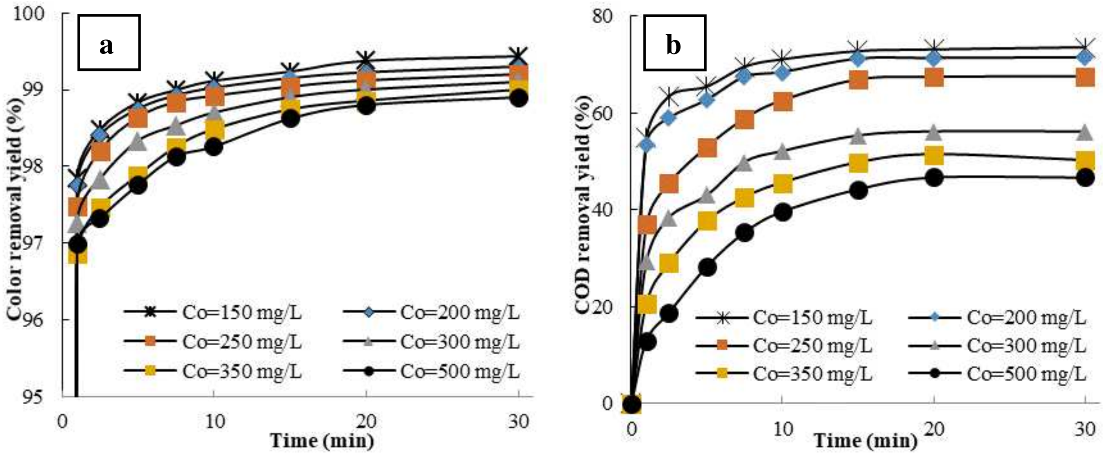

Figure 6. *Effect of initial colorant concentration in Fenton-like oxidation on (a) color and (b) COD removal (Fe^{3+}=75 mg L^{-1}; H_2O_2=500 mg L^{-1}; pH= 3; T= 20°C; t= 30 min)*

The Effect of Temperature

Temperature may have effects on the reactions between H_2O_2, Fe^{2+} and Fe^{3+}. Experiments were conducted at initial RR45 concentration of 200 mg L^{-1}, H_2O_2 concentration of 400 mg L^{-1} for fenton or 500 mg L^{-1} for fenton-like process, Fe^{2+} and Fe^{3+} concentration of 75 mg L^{-1}, pH=3, t=30 min and temperature between 20°C and 60°C in order to investigate the effect of RR45 on the temperature in the Fenton reactions.

Experiments were conducted in order to investigate the effect of temperature in the Fenton reactions of RR45. Results obtained are given graphically in *Fig. 7*. As can be seen from *Fig. 7*, in all temperature experiments, color removal yield was obtained to be nearly 100% while in the same temperature range (20°C to 50°C) COD removal yield was between 75.50% and 91.11% and at 60°C it decreased to 84.17% for Fenton process and COD removal yield was between 71.42% and 87.80% and at 60°C it decreased to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15171529

75.09% for Fenton-like oxidation process. The reason for the increasing removal yield with increasing temperatures may be that the high temperatures can cause both higher Fenton, Fenton-like reaction rates and the formation of larger amount of $OH^{\bullet}$ radicals (Sun et al., 2009b). The reason for the decrease at 60°C may be the degradation of H_2O_2 at higher temperatures (Bouasla et al., 2010) and evaporation (Bayhan and Değermenci, 2017).

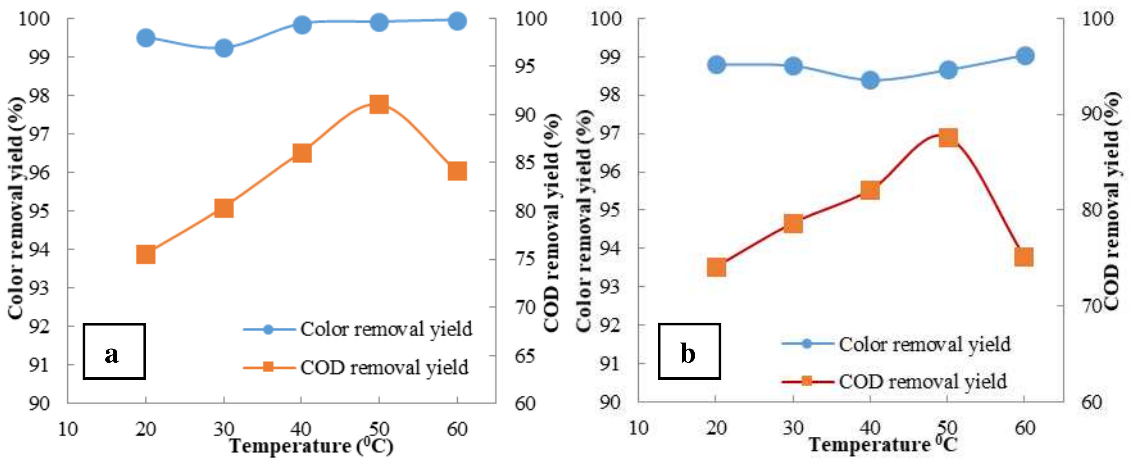

Figure 7. *Effect of temperature on color and COD removal (a) Fenton and (b) Fenton-like processes (C_0=200 mg L^{-1}; Fe^{2+} and Fe^{3+} =75 mg L^{-1}; H_2O_2 is 400 mg L^{-1} (for Fenton process) or 500 mg L^{-1} (for Fenton-like process); t=30 min)*

Kinetic experiments

In the present study, first-order, second-order and BMG reaction kinetics were used to study the removal COD kinetics of RR45 by the Fenton-like oxidation process. Kinetic studies were not performed in the Fenton process because color and COD removal yield have been obtained very fast. The kinetic parameters calculated for each reaction kinetics using the data obtained from experiments at different initial dye concentrations are given in *Table 3*. The results of kinetic analysis were shown in *Table 4*. The fitness of kinetic data to the first-order, second-order and BMG reaction kinetics model were given in *Figs. 8-9 and 10*.

Table 3. *The equations of kinetic models*

500	0.0200	0.7555	0.00009	0.8047	0.185	0.512	0.9840

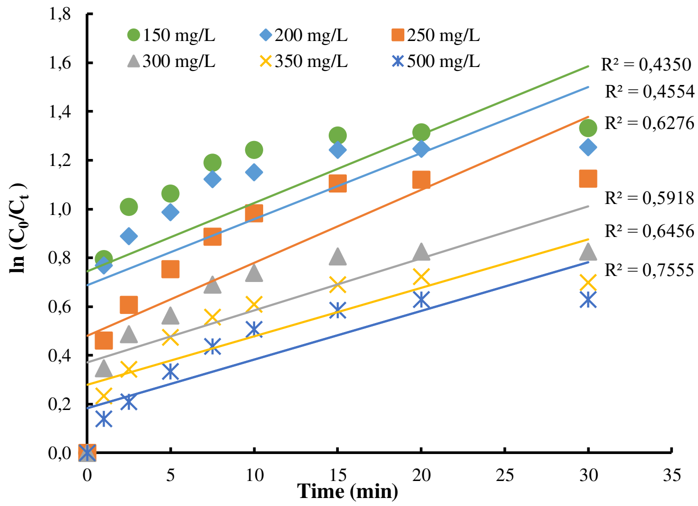

Figure 8. *First-order reaction kinetic for the COD removal of RR45 by Fenton-like oxidation (Fe^{3+} = 75 mg L^{-1}; H_2O_2 = 500 mg L^{-1}; pH= 3; T = 20°C; t = 30 min)*

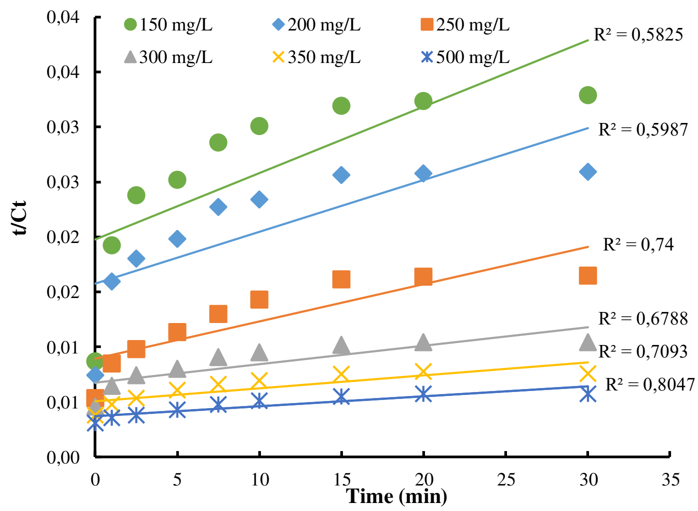

Figure 9. *Second-order reaction kinetic for the COD removal of RR45 by Fenton-like oxidation (Fe^{3+} = 75 mg L^{-1}; H_2O_2 = 500 mg L^{-1}; pH= 3; T = 20°C; t = 30 min)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15171529

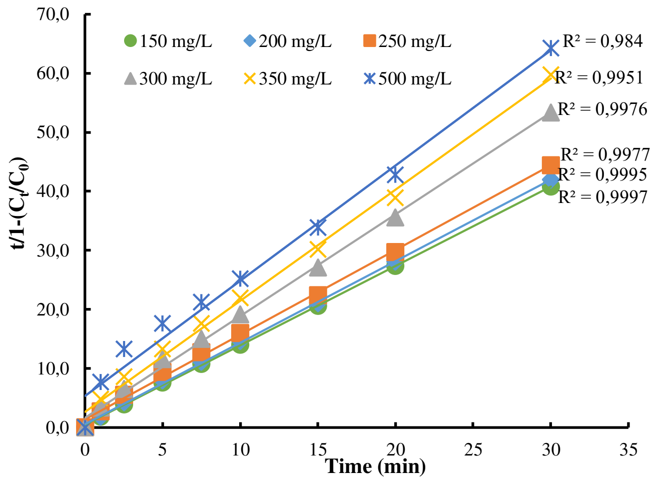

Figure 10. *BMG kinetic for the COD removal of RR45 by Fenton-like oxidation (Fe^{3+}= 75 mg L^{-1}; H_2O_2= 500 mg L^{-1}; pH= 3; T= 20°C; t= 30 min)*

As seen in *Table 4*, correlation coefficient for BMG model are higher than the first-order and the second-order models. The correlation coefficients for the the first order reaction kinetic equation have changed in the range of 0.435–0.755 for the second order reaction kinetic have changed in the range of 0.549–0.913 and for the BMG kinetic model have changed in the range of 0.9840–0.9995. These results have shown that the experimental data did not fit the first-order and second-order kinetic model.

Conclusion

The degradability of the reactive red 45 dye from azo colorants group through the fenton and fenton-like oxidation processes, was investigated in the present study. Degradability of RR45 was evaluated by considering color and COD parameters. Experiments were carried out for 30 minutes.

Effect of the rates of Fe^{2+} or Fe^{3+} (25, 50, 75, 100, 125, 150 and 200 mg L^{-1}), H_2O_2 (100, 200, 300, 400, 500 and 600 mg L^{-1}), pH (2.5; 3; 3.5; 4 and 5), the concentration of the dye (150, 200, 250, 300, 350 and 500 mg L^{-1}) and the temperature (20, 30, 40, 50 and 60°C) were investigated in the studies conducted on the degradation of RR45 colorant belonging to azo group through fenton and fenton-like oxidation processes. A removal efficiency of 91.1% of COD and 99.90% of color was obtained under optimum experimental conditions where initial solution pH is 3, the concentration of RR45 colorant is 200 mg L^{-1}, rates of Fe^{2+} and H_2O_2 are 75 mg L^{-1} and 400 mg L^{-1}, reaction temperature is 50°C and experiment time is 30 min. The experimental results obtained indicate clearly that the oxidation of RR45 by the Fenton and Fenton-like process is effective with a low concentration of H_2O_2, Fe^{2+} or Fe^{3+} and pH. High concentrations of iron and H_2O_2 concentrations cause consumption of hydroxyl radicals (radical scavenger effect). In addition, the increase in temperature from 20 to 50 increased the efficiency of removal in both processes. Kinetic studies were not performed in the fenton process because color and COD removal yield have been obtained very fast. In Fenton-like process, the BMG kinetic model provided the best correlation of the used experimental data compared to the pseudo-first and second-order kinetic models.

(Received 17th Oct 2018; accepted 7th Jan 2019)

Abstract. The aquaculture industry is increasing worldwide. However, many negative impacts have been associated with aquaculture effluent especially in the form of water pollution to the receiving water body. Hence, the aim of this study was to determine the effects of aquaculture effluents mainly from *Clarias gariepinus* (African Catfish) pond farm on the water quality of Kesang River in Malacca. Three sampling stations were selected at the fish farm. The parameters involved in the monitoring are dissolved oxygen (DO), pH, total dissolved solids (TDS), conductivity, biochemical oxygen demand (BOD), chemical oxygen demand (COD), total suspended solid (TSS), ammonia-nitrogen (NH_3-N), nitrite, nitrate, total nitrogen and phosphate. The water quality index was calculated to monitor the quality of the river. Results showed that there were slight effects of aquaculture effluent to the river. It is suggested that the effects of aquaculture effluents are studied according to seasons and the variables are monitored continuously to determine the actual effects of the effluents.
Keywords: *aquaculture, sharptooth catfish, wastewater, surface water, physicochemical parameters*

Introduction

Aquaculture has been considered as an alternative to assist the world food security issue (Kobayashi et al., 2015) due to the increasing demand for seafood (Nadarajah and Flaaten, 2017). In 2014, the total global aquaculture production was 101.1 million tons, which was valued at US$ 165.8 billion where Asia dominates this production as much as 88.91% in volume (Nadarajah and Flaaten, 2017). Malaysia is also promoting aquaculture as an important engine in growing the national economy. Malaysia's aquaculture industry has been developed since 1920's involving three practices, which are freshwater, brackish-water and marine aquaculture (Hamdan et al., 2015).

Aquaculture in Malaysia includes freshwater and marine fishes, aquatic plants, mollusks and crustaceans (Dauda et al., 2018). This industry has increased consistently with the sum production at the end of 2015 was at 506,465.25 tonnes, which valued about RM 3,296,463 ($US 756,937) (Dauda et al., 2018). In Malaysian production, more than 30 finfish species are farmed, dominated by the African catfish and followed by red (hybrid) tilapia, sea bass, *Pangasius* sp., and red snapper (Department of Fisheries, 2016). African catfish, *Clarias gariepinus* is an exotic fish species in Malaysia. It was introduced from Thailand between 1986 and 1989 through aquaculture

DOI: http://dx.doi.org/10.15666/aeer/1702_15311545

sector (Dauda et al., 2018). This non-native catfish is a fast grower fish, highly disease resistant and favored by the local people (Adan, 2000).

However, there are studies that report the aquaculture industry displays a variety of adverse impacts on the environment such as ecosystem degradation, land erosion, food chain pollution and water pollution (Ottinger et al., 2016). The adverse effects of aquaculture effluents are one of the significant impacts due to lack of enforcement on effluent discharge from aquaculture to the receiving river. According to Cao et al. (2007), effluents discharge without treatment into the receiving water is due to poor management of shrimp and fish farms, thus lead to environmental deterioration.

Rivers are the main source for raw water supply in Malaysia, supplying more than 90% of the country's water requirements (Hassan et al., 2018). The increasing population and expanding urban areas in Melaka State has caused a gradual rise in demand for water consumption (Daneshmand et al., 2011; Hazmi and Hanafiah, 2018). Melaka State is the third smallest state in Malaysia. Three dams and three reservoirs are the main water resources in Melaka (Tengku Azzlan et al., 2016). The Kesang River and Malacca River provide a total of 80 - 90% of the water supply in Melaka. The remaining 10 - 20% is imported from the Gerisik River of Johor (Malaysian Water Association, 2008). Kesang River is one of the main raw water supplies in Melaka State. There is a semi-commercial catfish pond farm located nearby the river, where the effluent is directly discharged to the Kesang River. The effluent discharged from fish ponds has a great impact on effective water treatment, which is due to the amount of organic material load, nutrients like nitrogen and phosphorus released to surface water (Teodorowicz, 2013). Water treatment in Malaysia mostly uses conventional water treatments which can only treat raw water that does not violate the National Water Quality Standards (NWQS). Raw water treatment at most water treatment plants is limited to coagulation, sedimentation, filtration and disinfection, which do not include treating the organic materials (Tengku Azzlan et al., 2016).

In 2010, a total of 1,055 water quality monitoring stations were monitored in Malaysia and it was found that 10% of these stations are polluted (Amneera et al., 2013). The water resource available may not be adequate to supply water to all consumers due to river pollution (Ashraf and Hanafiah, 2018; Harun and Hanafiah, 2018). Therefore, water quality monitoring is vital in Malaysia to identify the existing problem or emerging issues in the future. Monitoring the aquaculture effluents can be a valuable tool for guiding management actions to improve river conditions. Hence, this study was conducted to determine the impact of *Clarias gariepinus* pond farm effluent on physicochemical parameters of Kesang River in Malacca.

Materials and methods

Study area

The study was conducted in Sungai Kesang, Jasin, Malacca which is located in the west coast of Peninsular Malaysia between the latitude of 2°19'45.1"N and longitude of 102°23'54.7"E. Kesang River supplies 54 million liters of raw water daily to the state (Tengku Azzlan et al., 2016). The average annual runoff depth is about 500 - 600 mm (Shirazi et al., 2013). The length of the Kesang River is about 35 km, running through Jasin Town as a dividing line and a border between the southern states of Malacca and the state of Johor. Kesang River also passes through palm oil plantations. A large proportion of the land near the river is used for growing palm oil trees. Industrialization

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15311545

is restricted to around Jasin Town because Kesang River is gazetted as a catchment area. In this study, three sampling stations were selected along the river, first at the river before the farm, the second at the outlet of the farm, and finally is at the river after the farm. The sampling station is shown in *Figure 1*.

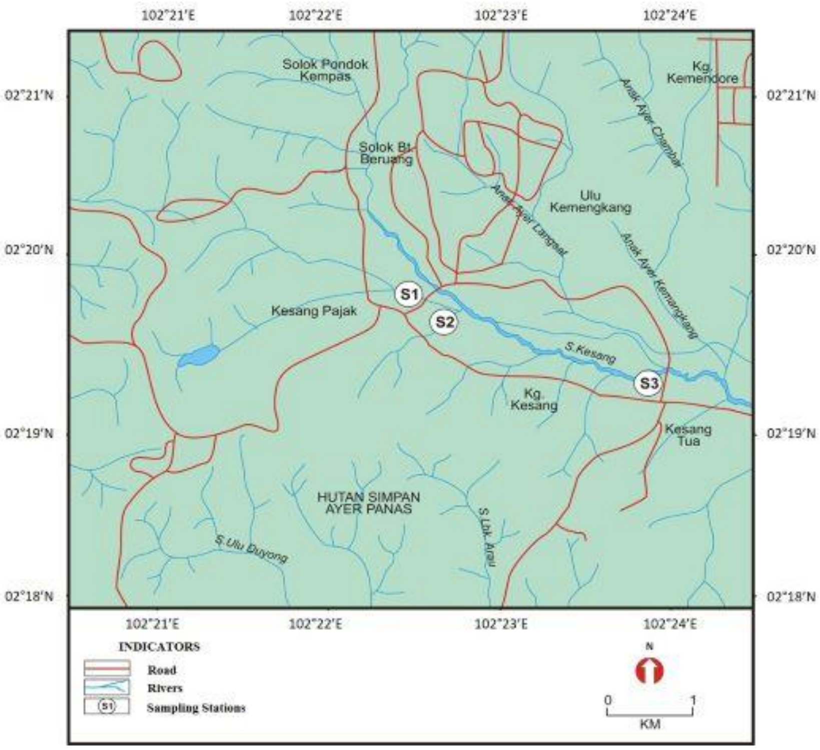

***Figure 1.** Sampling station map where S1 is Station 1, S2 is Station 2 and S3 is Station 3*

Physicochemical analysis

The data were obtained through sampling and laboratory work. The data obtained were collected six times from December 2017 to June 2018. The selected sampling stations were upstream of the river before the farm (Station 1), catfish pond farm effluent outlet (Station 2) and downstream of the river after the effluent outlet (Station 3). The selected water quality parameters used in this study include dissolved oxygen (DO), pH, total dissolved solids (TDS), conductivity, biochemical oxygen demand (BOD), chemical oxygen demand (COD), total suspended solid (TSS), ammonia-nitrogen (NH_3-N), nitrite, nitrate, total nitrogen and phosphate. The WQI formula (Department of Environment, 2011) used to determine of the water quality at Kesang River is as follows (*Eq. 1*):

$$WQI = 0.22 \times SIDO + 0.19 \times SIBOD + 0.16 \times SICOD + 0.15 \times SIAN + 0.16 \times SISS + 0.12 \times SIpH \quad \text{(Eq.1)}$$

where WQI is water quality index, SIDO is dissolved oxygen subindex, SIBOD is biological oxygen demand subindex, SICOD is chemical oxygen demand subindex, SIAN is ammonia-nitrogen subindex, SISS is suspended solid subindex, and SIpH is pH value subindex. WQI classification is illustrated in *Table 1*. The method used for each parameter is summarized in *Table 2*.

DOI: http://dx.doi.org/10.15666/aeer/1702_15311545

The water samples were kept in 1L polyethylene bottles and preserved with 65% nitric acid until the pH of the samples reached pH 2. Then, the water samples were kept in 4^{o}C until further analysis. The analysis was conducted within 24 hours after sampling.

All data were expressed in average ± standard deviation. Data were analyzed using Statistical Package for Social Science (SPSS, version 22) software. One-way ANOVA was conducted for comparing water quality parameter at different sampling stations. Tukey's HSD test was conducted for post hoc test. The significant value for the data analyzed was set at $p < 0.05$.

Table 1. *WQI classification*

Class	Uses
I	• Conservation of natural environment.
	• Water supply I: Practically no treatment required (except
	• by disinfection or boiling only).
	• Fishery I: Very sensitive aquatic species.
II A	• Water supply II – Conventional treatment required.
	• Fishery II - Sensitive aquatic species.
II B	• Recreational use with body contact.
III	• Extensive treatment required.
	• Fishery III: common of economic value and tolerant species; livestock drinking.
IV	• Irrigation.
V	• None of the above.

Results

All monitored physicochemical parameters were not diverse throughout the whole investigation period at all locations. The mean values of all studied parameters have been compared to the acceptable value of the Recommended Raw Water Quality Criteria which has been developed by the Ministry of Health Malaysia (Ministry of Health Malaysia, 2010). The classifications of water quality according to the Water Quality Index (WQI) were at class III for both river sampling stations, indicating that these stations need to be extensively treated but are suitable for irrigation and agriculture. The results of the study indicated that the effluent from the catfish pond farm have no significant impacts on water quality variations.

As shown in *Figure 2a*, the range of DO concentrations was from 32.5% at sampling Station 2 to 75.6% at sampling Station 1. The Ministry of Health Malaysia (2010) has no specific guide on DO. However, based on the National Water Quality Standards (NWQS) for Malaysia, DO values on sampling Station 1 and 3 are in class II, while DO values at sampling Station 2 is in class IV (EPA, 2008). ANOVA test showed that there was significant difference ($p < 0.05$) of DO concentrations between sampling stations. A post hoc Tukey's HSD test showed that Stations 1, 2 and 3 differed significantly at $p < 0.05$. However, there were no significant difference ($p > 0.05$) in the mean of DO levels between Station 1 and Station 3.

This study showed that the pH value ranged from 6.44 at sampling Station 3 to 7.02 at sampling Station 2 as shown in *Figure 2b*. The one-way analysis of variance (ANOVA) test showed that there was no significant difference ($p > 0.05$) for the pH values between all the sampling stations.

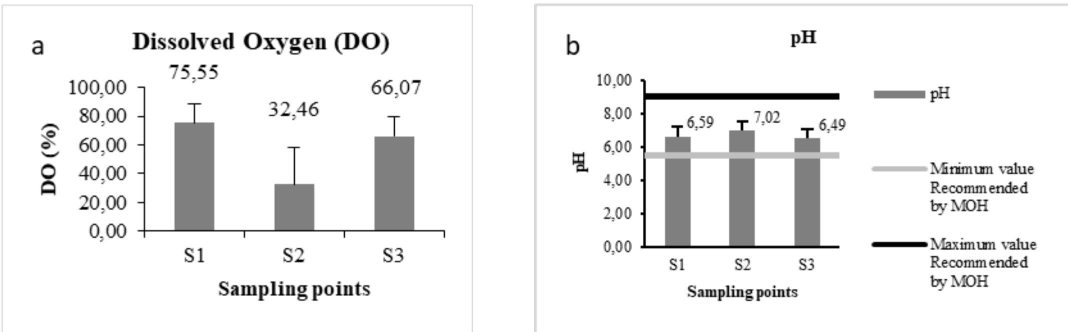

Figure 2. *(a) Average of DO concentrations for three sampling stations;(b) pH values for three sampling stations, where; the upstream before African Catfish pond farm outlet (S1), African Catfish pond farm outlet (S2) and the downstream after African Catfish pond farm outlet (S3) Values in average ± standard deviation (n = 6) Standard from MOH is not available for DO parameter*

Figure 3a shows the mean value of temperature for all three sampling stations. The range of temperature value was from 27.1°C to 28.5°C. The highest value was recorded at Station 1 and the lowest value was found at Station 2. However, ANOVA test showed that there were no significant differences ($p > 0.05$) between each sampling station.

The results also showed that conductivity ranged from 87.41 μS/cm to 243.34 μS/cm (*Figure 3b*). The lowest value was recorded at Station 1, while the highest value has recorded at Station 2. The conductivity level lies within the acceptable value of the

DOI: http://dx.doi.org/10.15666/aeer/1702_15311545

Recommended Raw Water Quality Criteria. The ANOVA test showed that there were no significant differences ($p > 0.05$) between each sampling station.

It was found that TDS values were ranged from 43.84 mg/L to 121.44 mg/L as shown in *Figure 4a*. The highest concentration of TDS was observed at Station 2, while the lowest concentration was obtained at Station 1. All the concentrations were still below the maximum value of the Recommended Raw Water Quality Criteria. The ANOVA test showed that there were no significant differences ($p > 0.05$) between all sampling stations.

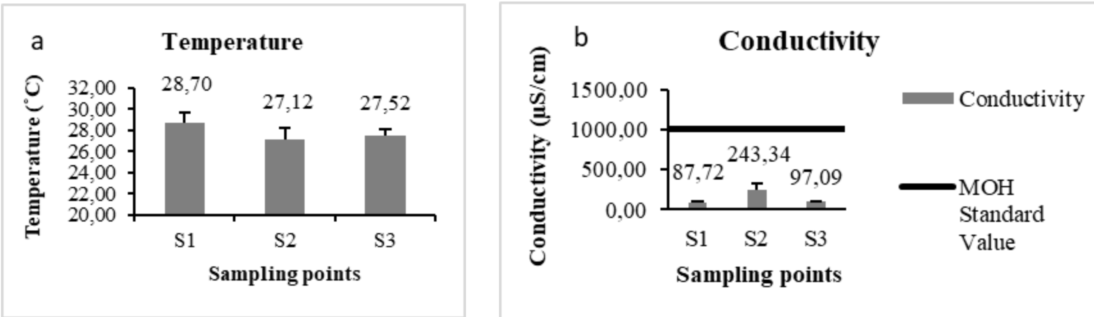

Figure 3. *(a) Temperature values for three sampling stations; (b) Conductivity values for three sampling stations, where; the upstream before African Catfish pond farm outlet (S1), African Catfish pond farm outlet (S2) and the downstream after African Catfish pond farm outlet (S3) Values in average ± standard deviation (n = 6)*
Standard from MOH is not available for temperature parameter

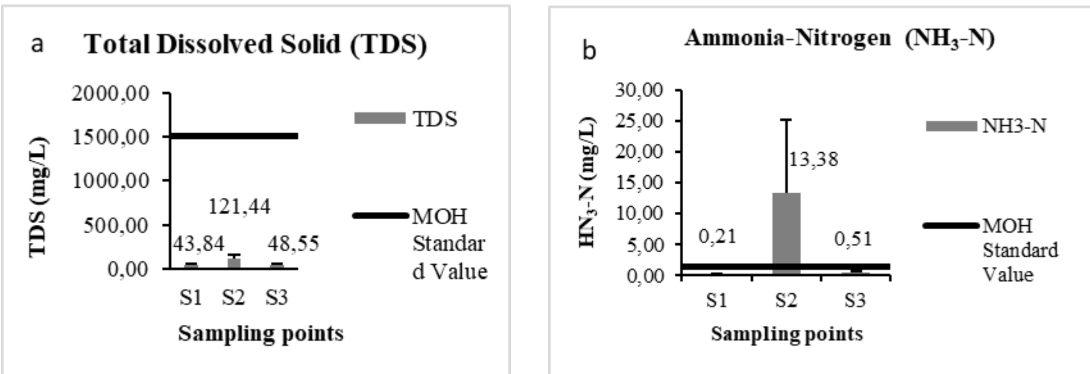

Figure 4. *(a) TDS concentrations for three sampling stations; (b) NH_3-N concentrations for three sampling stations, where; the upstream before African Catfish pond farm outlet (S1), African Catfish pond farm outlet (S2) and the downstream after African Catfish pond farm outlet (S3), Values in average ± standard deviation (n = 6)*

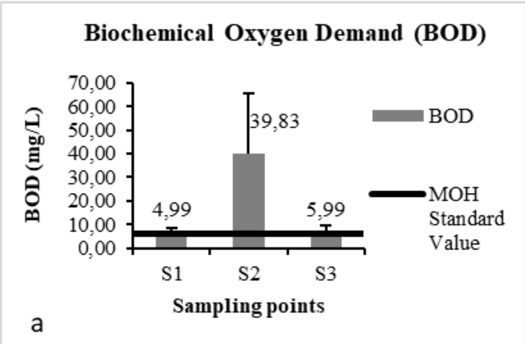
The highest ammonia-nitrogen (NH_3-N) concentration was observed at 13.38 mg/L at Station 2. The lowest NH_3-N concentration was found at 0.32 mg/L at Station 1. *Figure 4b* showed that only Station 2 violates the Recommended Raw Water Quality Criteria acceptable value. The ANOVA test showed there were no significant differences ($p > 0.05$) between each sampling station.

This study also showed that the highest amount of BOD at 39.83 mg/L was observed at Station 2. The lowest BOD amount at 4.99 mg/L was recorded at Station 1. ANOVA

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15311545

test showed that there was significant difference ($p < 0.05$) of BOD concentrations between sampling stations. A post hoc Tukey's HSD test showed that Stations 1, 2 and 3 differed significantly at $p < 0.05$. *Figure 5a* showed that only Station 2 had abused the acceptable value of the Recommended Raw Water Quality Criteria. BOD amount at Station 3 was on the border line of the Recommended Raw Water Quality Criteria maximum value.

COD ranged from 91.28 mg/L to 397.39 mg/L as shown in *Figure 5b*. The highest level of COD was recorded at Station 2 and the lowest at Station 1. All three sampling stations violated the Recommended Raw Water Quality Criteria acceptable value. ANOVA test showed that there were no significant differences ($p > 0.05$) between each sampling station.



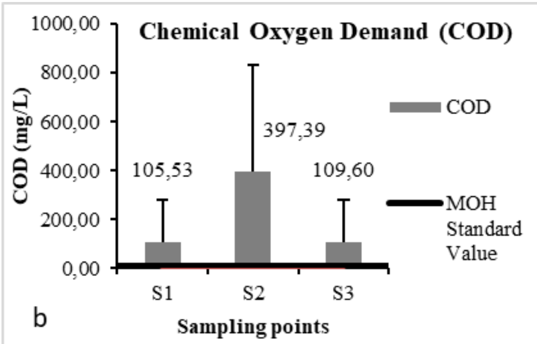


Figure 5. *(a) BOD concentrations for three sampling stations; (b) COD concentrations for three sampling stations, where; the upstream before African Catfish pond farm outlet (S1), African Catfish pond farm outlet (S2) and the downstream after African Catfish pond farm outlet (S3), Values in average ± standard deviation (n = 6)*

This study observed that the range of TSS were between 37.44 mg/L to 468.17 mg/L. The highest concentration of TSS was recorded at Station 2, while the lowest concentration was recorded at Station 1 as shown in *Figure 6a*. Analysis using ANOVA test showed there were no significant differences ($p > 0.05$) between each sampling station. The Ministry of Health Malaysia (2010) has no specific guideline on TSS.

Figure 6b shows the mean value of phosphate for all three sampling stations. The range of phosphate concentrations were from 0.33 mg/L to 5.38 mg/L. The highest value was recorded at Station 2 and the lowest value was recorded at Station 1. Station 3 recorded a higher phosphate concentration than Station 1. ANOVA test showed that there was significant difference ($p < 0.05$) of phosphate concentrations between sampling stations. A post hoc Tukey's HSD test showed that Stations 1, 2 and 3 differed significantly at $p < 0.05$. There is no guideline set by the Ministry of Health Malaysia (2010) on maximum concentration of phosphate as well.

This study showed that the highest nitrite concentration was at 0.24 mg/L at Station 2. Meanwhile, the lowest concentration of nitrite was at 0.015 mg/L at Station 1. There were no significant differences ($p > 0.05$) between each sampling point based on ANOVA test. As seen in *Figure 7a*, even though the concentration of nitrite at Station 3 was higher than Station 1, the increase was very minimal. However, there is no guideline set by the Ministry of Health Malaysia (2010) on maximum nitrite concentration.

DOI: http://dx.doi.org/10.15666/aeer/1702_15311545

Nitrate concentrations ranged from 90.76 mg/L to 142.89 mg/L. The highest and lowest concentrations have been observed at Station 2 and Station 1, respectively. The concentration of nitrate at Station 3 was slightly increased after passing through the fish pond farm. However, there were no significant differences (p > 0.05) between each sampling station using ANOVA test. *Figure 7b* shows that all three sampling points violated the Recommended Raw Water Quality Criteria acceptable value.

DOI: http://dx.doi.org/10.15666/aeer/1702_15311545

This study showed that the highest concentration of total nitrogen was at 512.95 mg/L at Station 2, while the lowest concentration at 60.29 mg/L at Station 1 as shown in *Figure 7c*. ANOVA test showed that there was significant difference ($p < 0.05$) of phosphate concentrations between sampling stations. A post hoc Tukey's HSD test showed that all sampling stations differed significantly at $p < 0.05$. There is no guideline set by the Ministry of Health Malaysia (2010) on maximum concentration of total nitrogen.

The WQI calculation of the water classification for Station 1 and Station 3 were reported to be in Class III. Class III is defined as moderately polluted where the water needs to be treated extensively.

Discussion

Dissolved oxygen (DO) is of uttermost importance in water quality, because it is essential for aerobic respiration (Boyde, 2015). Low DO concentrations at sampling Station 2 was due to the presence of high organic materials resulting from overfeeding of fish (US Environmental Protection Agency, 1974). DO concentration at sampling Station 3 was lower Station 1 due to the release of organic and inorganic pollutants as of biological matters from Station 2. However, the result of this research showed that the pollutants released from the fish farm had slightly decreased the DO levels of water that passed through it.

The pH of aquatic systems is an important criterion of the water quality in the watershed areas (Yisa and Jimoh, 2010). The value is used to determine the level of alkalinity or acidity of water (Hanafiah et al., 2018). The results were within the pH range of the Recommended Raw Water Quality Criteria (Ministry of Health Malaysia, 2010). The results in this study were in agreement to the study conducted by Teodorowicz (2013) where pH value had dropped after the water passed through the studied catfish pond farm. It was reported that the pH decreased due to the increase of feeding fish respiration rates, which increased the content of free CO_2. However, the pH values were still in the normal range of natural water pH that is 6 – 9 (Boyde, 2015) and is considered safe to aquatic organism (Teodorowicz, 2013). The extreme values of pH can cause destruction to the sensitive aquatic organism (Hassan et al., 2018).

The temperature of river water is an important characteristic for aquatic system because it could affect dissolved oxygen levels, species composition, chemical and biological activities (Shuhaimi-Othman et al., 2007; Hanafiah et al., 2018). This study showed that the temperature at the upstream sampling point is higher than downstream sampling point. This was not in line with the study conducted by Al-Badaii et al. (2013) in which the study found that temperature values increased from upstream to downstream. The concentrations of temperature recorded in this study were approximately comparable to the study reported for Malacca River (range 26°C–32°C) by Hua (2017). In general, weather conditions, sampling time and location are the factors that could give impact on the increase or reduction of temperature values (Al-Badaii et al., 2013). The weather conditions during the sampling time is shown in *Table 3*.

Conductivity is a substance's capability to carry an electrical current (Boyde, 2015). Conductivity in water was conveyed by inorganic dissolved solids such as calcium, chloride, aluminum cations, nitrate, sulfate, iron, magnesium and sodium (Al-Badaii, 2011; Boyde, 2015). It is also influenced by temperature and organic compounds such

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15311545

as oil, alcohol, phenol and sugar (Al-Badaii, 2011). According to Al-Badaii et al. (2013) and Laila et al. (2018), most freshwater conductivity ranges from 10 to 1000 μS/cm. Kesang River showed that the level of conductivity was lower than the study conducted in Malacca River (Hua, 2017) where the conductivity levels had ranged from 109.60 μS/cm to 1950.72 μS/cm. Harun et al. (2010) stated that the conductivity level in the water that receives pollution can exceed 1000 μS/cm.

Table 3. *Weather conditions during the sampling time*

Sampling months	Rainfal (mm)	Temperature (°C)
December 2017	0.0	26.4

Source: Meteorology Department of Malaysia, 2018

Dissolved solids are tiny particles considered to be in true solution. Dissolved solids contain largely inorganic and some organic compounds (Boyde, 2015). A slight increase of TDS concentration was observed in Station 3 after the water had passed through the fish pond farm. TDS concentration in the river was due to the human activities along the river and suspended matter from overflow water (Al-Badaii et al., 2013). The TDS concentrations in Kesang River were much lower compared to TDS level observed in Malacca River (Hua, 2017) where the study reported that the TDS had ranged from 77.22 mg/L to 10444.61 mg/L. TDS concentration of less than 1000 mg/L in water can be used for drinking and irrigation (Oyem et al., 2014).

The presence of ammonia is due to the presence of decomposing urea, feces and organic matter since that is the initial product of the decomposition of nitrogenous organic wastes and respiration (Zweig, 1999). High NH_3-N concentration can be toxic to aquatic organisms, but it could provide nutrients for growth of algae in small quantities (Corwin et al., 1999). However, the ammonia toxicity is influenced by the increase in temperature, pH and decrease of DO (Zweig, 1999).

Biochemical oxygen demand (BOD) concentrations show the amount of dissolved oxygen used for the decomposition of organic matter by microorganisms (Boyd and Tucker, 2014). Typical BOD amount at pond aquaculture effluent is 10 – 30 mg/L (Suratman et al., 2015). BOD amount at Station 2 slightly exceeded the typical amount of BOD at pond aquaculture effluents. This is because there are many organic materials that can be broken down by microorganisms and this process requires dissolved oxygen (Asman et al., 2017). The sources of the organic matters are fertilizer, animal farm waste and septic system (Al-Badaii et al., 2013).

Chemical oxygen demand (COD) is the amount of dissolved oxygen required by the oxidizing agent of all the organic matter found in the body of water that produces CO_2 and ammonia as a product (Din et al., 2012). COD readings will be compared directly with the BOD reading to distinguish between the value of oxidized material in terms of biological and chemical oxidizing substances (Suratman et al., 2005). Usually, COD reading value is higher than BOD value. This is because it will go through the oxidation process and almost all organic matter will be oxidized (Vesilind et al., 1988). The concentration of COD in unpolluted water is usually less than 20 mg/L (Hassan et al.,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15311545

2018). Thus, the high level of COD indicates the high level of water pollution in the study area (Waziri and Ogugbuaja, 2010) where there were occurrences of organic and inorganic matter oxidation (Hassan et al., 2018).

Total suspended solid (TSS) is defined as the total amount of organic and inorganic particles scattered in water (United States Environmental Protection Agency, 2003). According to Rosli et al. (2010), TSS level of less than 30.0 mg/L was considered low and TSS level of more than 50.0 mg/L was considered high value. The Department of Environment, Malaysia (2006) sets the maximum value of TSS in rivers as 150 mg/L. The river sampling points in this study did not violate the guideline set by Department of Environment (2006). High suspended solids concentrations can lower water quality by absorbing light and increasing the water temperature, making the ability of the water to hold oxygen needed for aquatic life to be reduced (Vesilind et al., 1988). TSS was also linked to nutrients, metals and chemicals transported by the river from anthropogenic activities (Rosli et al., 2010).

Phosphate in aquaculture effluents was continuously supplied by the decomposition of uneaten feed and feces (Boyd, 1998; Jegatheesan et al., 2011). Lin et al. (2002) reported that the range of phosphate concentrations in aquaculture effluent were 3.1 mg/L – 17.7 mg/L. The phosphate concentration at Station 2 was in line with the study reported by Lin et al. (2002). The high level of phosphate in water body is associated with the occurrence of eutrophication (WHO, 1998).

Nitrite is formed through a nitrification process primarily as an intermediary in converting ammonia to nitrate (Zweig, 1999). According to Boyd (2015) and Zweig (1999), high concentration of nitrite is uncommon in aquatic system because nitrite is quickly oxidized to nitrate. Usually, the presence of nitrite is below 0.05 mg/L in oxygenated water. However, the nitrite concentration at Station 2 was above 0.05 mg/L which might be due to low DO concentration (Boyd, 2015). Nitrite is toxic to aquatic animals when the concentration reaches 1 mg/L and above.

Nitrate is the final oxidation product of nitrogen which is very mobile in water (Al-Badaii et al., 2013; Hassan et al., 2018). Nitrate is much less toxic than other major inorganic nitrogen compounds (Zweig, 1999). However, nitrate concentration of 50 mg/L and above in ground and drinking water is considered as Nitrate Vulnerable Zone (Giammarino and Quatto, 2015). High concentration of nitrate in river water is potentially harmful to human and animal health. According to Ling et al. (2007), aquaculture is the main contributor of ecosystem pollution due to the discharging of aquaculture waste into the receiving water. The high concentration of nutrients in a fish pond farm is due to the accumulation of feed residue and fish excreta (Lin et al., 2002).

Total nitrogen is a combination of ammonia, ammonium, nitrite and nitrate (Boyd, 2015; Chen and Kang, 2016). Nitrogen can be found majorly as organic matter in bottom sediments, but small amounts of nitrogen can be found in the water to include nitrogen gas, nitrate, nitrite, ammonia, and nitrogen in dissolved and particulate organic matter (Boyd, 2015). The concentration of total nitrogen at Station 3 was slightly higher than Station 1. Jegatheesan et al. (2011) reported that 22% nitrogen still remains in the water of the catfish pond. About 7% – 32% of total nitrogen in the water was carried by suspended solid (Turcios and Papenbrock, 2014). Generally, the high concentration of nitrogen in rivers is due to the use of nitrogen-containing fertilizers, animal waste, septic system, industrial processes, atmospheric deposition from nitrogen oxide emission, irrigation and storm runoffs from farmlands which can affect the drinking water quality and aquatic ecosystem (Liu et al., 2018).

Conclusion

In conclusion, we found the physicochemical characteristics of African Catfish, *Clarias gariepinus* pond farm's effluent affect the quality of water for certain parameters such as COD and nitrate that exceed the permissible limit of the Recommended Raw Water Quality Criteria. High concentration of COD and nitrate need to be further treated to reduce the accumulation of the pollutants to the receiving water body. Some parameters such as nitrate cannot be treated by conventional treatments. So, high concentration of nitrate could have an impact on human health if not treated properly. A regular monitoring is vital to determine the effects of catfish pond farm effluents to river.

Acknowledgements. The researchers wish to extend their appreciation to Universiti Kebangsaan Malaysia for funding this research through a research grant GUP-2017-044 and researchers also would like to express their gratitude to Malacca Water Regulatory Board (Badan Kawal Selia Air Melaka) for partial funding of this study.

INFLUENCE OF PLUVIO-THERMAL CONDITIONS, GROWTH BIOSTIMULATORS AND HERBICIDE ON DRY MATTER CONTENT AND STARCH IN EDIBLE POTATO TUBERS

BARANOWSKA, A.

Department of Agriculture, Pope John II State School of Higher Education in Biala Podlaska
Sidorska 95/98, 21-500 Biała Podlaska, Poland
(e-mail: alabar@tlen.pl;phone: +48-83-344-99-08)

(Received 22nd Oct 2018; accepted 7th Jan 2019)

Abstract. In the changing climate conditions, the knowledge of the impact of weather factors on the quality of crop plant yield is of great significance. The field research was conducted in 2015-2017 in the area of eastern Poland in Biała Podlaska commune, in Lublin Voivodship, on light, acidic soil. The purpose of the study was to assess the impact of meteorological conditions and cultivation methods with the application of growth biostimulators and herbicide on dry matter and starch content in tubers of three edible potato cultivars. The examined factors were: I. cultivars of edible potato – Bellarosa, Owacja, Vineta, II. methods of using growth biostimulators: GreenOk-Uniwersal Pro and Asahi SL, as well as their combination with herbicide Avatar 293 ZC. A close relationship between pluvio-thermal conditions, cultivation methods and the percentage content of dry matter and starch in edible potato tubers was proven as a result of the conducted study. The highest concentration of the discussed components was obtained in 2015, in which there was a shortages of precipitation. The methods of cultivation employed in the experiment had a positive impact on the rise in dry matter and starch content in potato tubers in comparison with the control object. The highest dry matter (on average 23.31%) and starch content on average 16.31% in potato tubers was obtained after the application of biostimulator GreenOk-Universal Pro and herbicide Avatar 293 ZC (object 4).
Keywords: *Solanum tuberosum L., weather conditions, Asahi SL, GreenOk-Universal, Avatar 293 ZC, nutrients*

Introduction

In the XXI century farming limitation of use of mineral fertilizers and chemical agents for plant protection, is strived for and more and more often preparations of natural origin are used (Sawicka et al., 2016). In plant production, pro-ecological cultivation methods are being researched. These trends are also visible in potato cultivation. Potato (*Solanum tuberosum* L.) is one of the main cultivated plants not only in Poland, but also worldwide. It is cultivated in over 130 countries and consumed every day by more than a billion people (Ezekiel et al., 2013; Bishwoyog and Swarnima, 2016).

Dry matter and starch content is one of the most important features determining the nutritional and technological value of potato tubers (Ramezani and Aminlari, 2004; Storey, 2007; Murnice et al., 2011).

Edible potato tubers contain about 75% of water and 17-25% of dry matter after harvest. Dry matter content is of great significance, as it determines nutritional value, taste value, consistency of raw and processed tubers, as well as resistance to mechanical damage (Wierzbicka, 2011). Depending on dry matter content, potato cultivars can be divided into 3 groups: with low <20%, medium 20-23% and high content >23% (Wierzbicka, 2012).

The main component of potato tubers' dry matter is starch, its content in dry matter equals from 60 to 80% (Lutaladio and Castaldi, 2009). Starch is a natural polymer

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15471557

found in all plant organisms, further to being an indirect product of photosynthesis, hence it is called a renewable and biodegradable material. It more and more often replaces polymers of petrochemical origin in biotechnological processes and the chemical industry. Potato starch is found mainly in the form of grains with a diameter of 20 to 60 μm. Large grains are very useful in the processing of starch into glucose and dextrins, while small grains – in the production of starch-polyethylene concentrate (Leszczyński, 2004; Kołodziejczyk et al., 2013). Depending on the cultivar, edible potato tubers contain on average from 11.0 to 16.0% of starch, while starch potato tubers from 18.0 to 27.0%, respectively. Starch content is very significant on account of the usefulness of tubers in gastronomy and processing (Pobereżny and Wszelaczyńska, 2011). The impact of starch on the consistency of boiled tubers is connected with its swelling, which causes the destruction of cell structures (Lamberti et al., 2004). The caloric value of starch is the result of it being converted to glucose under the influence of enzymes, thus being quickly digested in the human organism (Leszczyński, 2012).

Dry matter and starch content in *Solanum touberosum L.* tubers is determined by the genetic features of cultivars which are the result of biological progress, the level of agrotechnology and habitat conditions, especially the course of pluvio-thermal conditions during plant growth. Currently, in climate change conditions, the knowledge of the impact of weather factors on the growth and development of crop plants and the quality of yield is of great significance. According to Tosheva and Alexandrova (2004), Shahbazi et al. (2009), Usowicz et al. (2014), Radzka and Rymuza (2015) agro-climatic factors, further to topographical and soil factors, define the kind of agricultural production and its efficiency. Meteorological factors can determine the yielding variability of potato in 40%, and with unfavourable weather conditions even in 50% (Kołodziejczyk, 2013, 2014b). Potato's water requirements in conditions of proper technology depend mainly on the duration of the growing season, the area of cultivation and the kind of soil (Kolbarczyk and Kolbarczyk, 2009). In Polish early potato cultivars have the highest yield with the precipitation of 250-300 mm (Nowak, 1989; Dzielżyc et al., 2012). The rise in air temperature of only 1-2°C increases crop plants' water requirements in Polish conditions on average by 6.3-14.5 mm on a monthly basis (Ziernicka, 2004).

Agriculture in the 21st century still needs modern means of production that will allow moderating the unfavourable effect of meteorological conditions on plant yielding and thus, stimulate plants to grow and develop more effectively (Matysiak et al., 2011; Sawicka et al., 2011). A solution can be the introduction of natural or synthetic preparations, classified as biostimulators or growth stimulators to plant production, (Paradikovic et al., 2011; Kołodziejczyk, 2014a). Growth biostimulators are defined as preparations supporting the natural vital processes of plants and increasing the resistance of plants to stressful conditions, are preparations friendly for the environment and consumer's (Sawicka et al., 2016; Pszczółkowski and Sawicka, 2018). However, the possibility of using these preparations in practice is not fully examined yet and the results of the research are often ambiguous and fragmentary.

Therefore, the purpose of the study was to assess the impact of pluvio-thermal conditions and cultivation methods with the application of growth biostimulators and herbicide on dry matter and starch content in tubers of three early edible potato cultivars.

Materials and methods

Location of the experiment

The field experiment was conducted in 2015-2017 in eastern Poland, in the Biała Podlaska Commune (52°02'N; 23°07'E), located in the Lublin Voivodeship, on acidic light soil (*Figure 1*).

Figure 1. *Location of the experiment*

Experiment and plant material

A three-year experiment was performed in the split-plot system, in three replications. Two factors were examined in the experiment:

I. Factor – three early edible potato cultivars: Bellarosa, Owacja, Vineta.

II. Factor – methods of application of biostimulators and herbicide:

1. Standard object – mechanical treatment (without biostimulators and herbicide).
2. From sprouting of potato plants – mechanical treatment and after sprouting – GreenOK Universal–PRO bioactivator, three times to leaves: at a dose of 0.10 dm^3 ha^{-1} – peak–end of sprouting (phase BBCH 13-19) + 0.15 dm^3 ha^{-1} – covering of interrows (phase BBCH 31-35) + 0.15 dm^3 ha^{-1} – flower bud break (phase BBCH 51-55).
3. From sprouting of potato plants – mechanical treatment, and after sprouting – Asahi SL bioactivator, three times to leaves at a dose of 0.50 dm^3 ha^{-1} – peak–end of sprouting (phase BBCH 13-19) + 0.50 dm^3 ha^{-1} – covering of interrows (phase BBCH 31-35) + 0.50 dm^3 ha^{-1} – flower bud break (phase BBCH 51-55).
4. From sprouting – mechanical treatment, and after the final shaping of ridges and just before sprouting Avatar 293 ZC herbicide at a dose of 1.5 dm^3 ha^{-1} (phase BBCH 00-05). After sprouting – three applications of GreenOK Universal–PRO bioactivator at a dose of 0.10 dm^3 ha^{-1} – peak–end of sprouting (phase BBCH 13-19) + 0.15 dm^3 ha^{-1} – covering of interrows (phase BBCH 31-35) + 0.15 dm^3 ha^{-1} – flower bud break (phase BBCH 51-55).
5. From sprouting – mechanical treatment, and after the final shaping of ridges before sprouting of potato plants – Avatar 293 ZC herbicide at a dose of 1.5 dm^3 ha^{-1} (phase BBCH 00-05).

The biostimulator Asahi SL contains three active ingredients from the nitrophenol group: sodium para-nitrophenol – 0.3%, sodium ortho-nitrophenol – 0.2% and sodium

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15471557

5-nitroguaiacol – 0.1%. These substances occur naturally in plant cells and participate in many metabolic processes. The preparation is known in the USA by its trade name as Chaperone, and in Europe as Atonik (Babuška, 2004). The preparation GreenOK Universal-PRO, according to the producer's information (Latvian Institute of Humic Substances), is a liquid organic fertilizer with biostimulating effect, consisting of humic substance concentrate (20 g dm^3) and elements NPK (0.13-0.09-0.7%). The herbicide Avatar 293 ZC applied in the experiment is a preparation in the form of capsule suspension. It is applied to soil, before sprouting of plants on moist soil. It contains clomazone (a substance from the isoxazolidinone group) – 60 g dm^3 (5.13%) and metribuzin (a substance from the triazinone group) – 233 g dm^3 (20.64%).

Each year in autumn, before establishment of the experiment, natural fertilization was used at a dose of 25 t ha^{-1}, as well as mineral fertilization with phosphorus 44.0 kg P ha^{-1} (triple superphosphate 46%) and potassium 124.5 kg K ha^{-1} (potassium salt 60%), and during spring – nitrogen fertilization (ammonium nitrate 34%) at a dose of 100 kg N per 1 ha. Potato tubers were planted in the second decade of April (in 2015 and 2016) and in the third decade of April (in 2017). Protection treatment against diseases and pests was used according to needs, in accordance with the plant protection recommendations. Harvest was performed in the phase of full technological maturity of tubers.

The content of dry matter in fresh tuber mass was determined by means of the oven-dry method, that of starch on Reimann's balance.

Data analysis

The results of the study were subjected to the statistical analysis by means of StatSoft Inc. STATISTICA v.10 using the method of the analysis of variance. Significance of variability sources was tested by means of the Fisher-Snedecor F test, and the assessment of significance of differences at the significance level $p = 0.05$ between the compared means using Tukey's range test was performed. In order to determine the relationship between pluvio-thermal conditions and dry matter and starch content in potato tubers, Pearson's r correlation coefficients were measured, and the significance at the confidence level 0.05 was tested with Student's *t* test. Statistical calculations were performed on the basis of average values from three years and means for three potato cultivars.

Weather conditions

Weather conditions in the growing seasons of 2015-2017 (years of research conduct) were characterized against the background of the years 1981-2010 on the basis of deviations of average monthly air temperature (°C) and the sum of precipitation (mm). The values of hydrothermal Sielianinov coefficient were measured (*Equation 1*), (*Table 1*) (Chereszkowicz, 1979; Skowera and Puła, 2004; Skowera et al., 2014).

$$K = \frac{P}{0.1\sum t} \qquad \text{(Eq.1)}$$

K – value of hydrothermal coefficient,
P – sum of monthly precipitation,
$\sum t$ – monthly sum of average daily air temperature >0°C.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15471557

Values of air temperature and precipitation sum from the growing period of 2015-2017 years and the years between 1981-2010 came from Meteorological Station in Cicibór Duży (51°19'N; 22°16'E), located at a distance of 6 km from Biała Podlaska and belonging to the Experimental Station of the Central Research Facility of Varieties of Cultivated Plants (COBORU) in Słupia Wielka.

During the conduct of research diverse pluvio-thermal conditions occurred (*Table 1-2, Figures 2-3*). Growing season of 2015 was characterized by a high shortage of precipitation in the period from June to August (that is during flowering, growth of tubers and crop accumulation), and the month of August 2015 was extremely dry, deviations from the average multi-year air temperature in that month amounted to +3.7°C, while precipitation in comparison to the years 1981-2010 was lower by 60 mm, these months in 2017 were similar but the drought turned out to be milder. In 2016, in the period of the largest demand of potato for precipitation, thermal-precipitation conditions were more beneficial when compared to the remaining years of research (*Table 1-2, Figures 2-3*).

Table 1. *Hydrothermal conditions in potato's growing season (mean for years 2015-2017)*

Month/ Year	***Sielianinov hydrothermal coefficient *(K)***					
	2015		**2016**		**2017**	
IV	1.43	optimal	1.19	quite dry	2.68	very humid
V	2.28	humid	0.47	very dry	0.93	dry
VI	0.59	very dry	1.53	optimal	1.97	quite humid
VII	0.80	dry	1.97	quite humid	1.24	quite dry
VIII	0.11	extremely dry	0.48	very dry	0.66	very dry
IX	1.66	quite humid	0.26	extremely dry	2.37	extremely humid

*Sielianinov hydrothermal coefficient *(K)* – formula as in research methodology;
**Month's classification: extremely dry $K \leq 0.4$, very dry $0.4 < K \leq 0.7$, dry $0.7 < K \leq 1.0$, quite dry $1.0 < K \leq 1.3$, optimal $1.3 < K \leq 1.6$, quite humid $1.6 < K \leq 2.0$, humid $2.0 < K \leq 2.5$, very humid $2.5 < K \leq 3.0$, extremely humid
$K > 3.0$ (Chereszkowicz, 1979; Skowera and Puła, 2004; Skowera et al., 2014)

Table 2. *Mean air temperature (°C) and precipitation sum (mm) (in the years 1981-2010)*

Meteorological factor	**Months**					
	IV	**V**	**VI**	**VII**	**VIII**	**IX**

Results and discussion

The results of the study proved that there is a close relationship between pluvio-thermal conditions, cultivation methods and the percentage content of dry matter and starch in edible potato tubers.

The calculated Pearson's *r* correlation coefficients proved that there are significant negative relationships between the precipitation sum, Sielianinov hydrothermal coefficient, and dry matter and starch content in potato tubers (*Table 3*). A significant negative relationship between average precipitation sum in the years when the study was carried out and average dry matter and starch content in potato tubers was confirmed. In the case of dry matter content, the correlation coefficient was: r = -0.62 (strong correlation, substantial relationship), and in the case of starch content: r = -0.56 (moderate correlation, significant relationship). It means that the rise in precipitation sum had a significant impact on the drop in the percentage content of dry matter and starch in edible potato tubers.

Table 3. *The values of Pearson's r correlation coefficients between the percentage content of dry matter and starch in potato tubers and pluvio-thermal conditions (mean from three years and cultivars)*

Variable *X*	Variable *Y*	*r (X. Y)***	r^2	*t*	*p*
dry matter content (%)	air temperature (ºC)	0.20	0.04	1.37	0.1775
	precipitation (mm)	-0.62	0.39	-5.22	0.0000*
	Sielianinov hydrothermal coefficient *(K)*	-0.59	0.35	-4.78	0.0000*
starch content (%)	air temperature (ºC)	0.24	0.06	1.61	0.1154
	precipitation (mm)	-0.56	0.31	-4.42	0.0001*
	Sielianinov hydrothermal coefficient *(K)*	-0.54	0.29	-4.16	0.0002*

R (X. Y) – Pearson's *r* correlation coefficient, r^2 – coefficient of determination, *t* – the value of Student's t test, *p* – significance level, *significant differences at p<0.05, **the ranges of correlation according to Sobczyk (2011): below 0.2 – very weak correlation (no relationship), 0.2-0.4 – weak correlation (clear relationship) 0.4-0.6 – moderate correlation (significant relationship), 0.6-0.8 strong correlation (substantial relationship), 0.8-0.9 – very strong correlation (very substantial relationship), 0.9-1.0 – full relationship

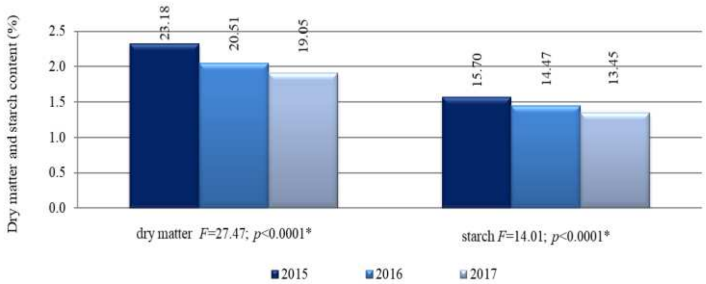
A significant negative relationship between Sielianinov hydrothermal coefficient (K) and dry matter and starch content in tubers was proven as well (*Table 3*). In the case of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15471557

these features, a linear negative correlation in the range of moderate correlation (significant relationship) was obtained.

Analysing the impact of air temperature on dry matter and starch content, no significant statistical differences were proven, but instead, weak linear positive correlation (clear relationship) was found (*Table 3*). Other authors' studies also confirm the significant impact of pluvio-thermal conditions in particular periods of the growing season on dry matter and starch content in potato tubers. According to Skowera and Puła (2004), Wierzbicka (2011), Kołodziejczyk (2014b) substantial amounts of precipitation were a factor that significantly limited the storage of dry matter and starch in tubers. However, in the research conducted by Pszczółkowski et al. (2016) meteorological conditions with very humid May, June, July and dry August created favourable conditions for obtaining higher starch content in tubers. Wierzbicka (2012) and Kołodziejczyk (2014b) stated that air temperature, beside moisture conditions, has a significant impact on the storage of dry matter and starch in tubers, and especially warm and dry months late in the growing season create favourable conditions for the storage of dry matter and starch. Kalbarczyk and Kalbarczyk (2009) proved that the optimal air temperature allowing potato plants to grow and develop should be at the level of 15.2ºC.

Within own research significantly larger contents of dry matter and starch in edible potato tubers in dry growing season of 2015 than in the remaining years of research in which greater volumes of precipitation were recorded (*Figures 4-5*).



F - the value of *F* test in the analysis of variance, *– significant differences at $p<0.05$

* – labelling as in research methodology

Figure 5. *Average dry matter and starch content (%) in potato tubers depending on cultivation methods and research years*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15471557

This study proved that the cultivation methods applied in the experiment with the use of growth biostimulators and herbicide had a significant impact on dry matter and starch content in potato tubers (objects 2.-5.) in comparison with only mechanical treatment (objects 1.) (*Figure 6*).

The highest content of dry matter as well as starch was found in the tubers harvested from objects 4. where mechanical treatment was used from sprouting of plants and Avatar 293 ZC herbicide at a dose of 1.5 dm^3 ha^{-1} just before sprouting, and GreenOK Universal–PRO bioactivator at a dose of 0.10 dm^3 ha^{-1} + 0.15 dm^3 ha^{-1} + 0.15 dm^3 ha^{-1} three times after sprouting; and from objects 5. where mechanical treatment was used and then Avatar 293 ZC herbicide at a dose of 1.5 dm^3 ha^{-1} (*Figure 6*). The research of Sawicka (2003), Czeczko and Mikos-Bielak (2004), Sawicka and Krochmal-Marczak (2009), Kołodziejczyka (2016) also confirms the rise in dry matter and starch content in potato tubers in the conditions of using growth biostimulators. However, according to Maciejewski et al. (2007), the applied biostimulators Asahi SL and Atonik, did not have any impact on dry matter and starch content in potato tubers. The research of Gugała and Zarzecka (2010) indicated a positive impact of herbicides on the rise in dry matter and starch content in potato tubers. The mechanical and chemical treatment applied by these authors had a positive impact on the rise in dry matter and starch content in potato tubers in comparison with only mechanical treatment. However, in the study of Barabaś and Sawicka (2016), dry matter and starch content did not depend on potato cultivation method.

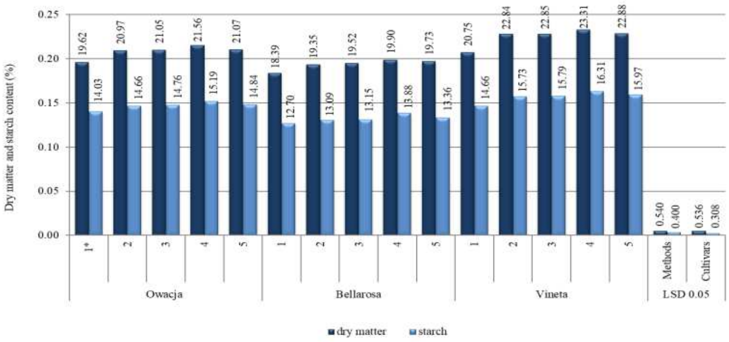

Figure 6. *Average Dry matter and starch content (%) in potato tubers depending on cultivation methods and planted potato cultivars (mean for years 2015-2017)*

The study proved that the cultivars' genetic features had a significant impact on dry matter and starch content in tubers (*Figure 6*). The highest average dry matter and starch content was stored in the Vineta cultivar (from 20.75% to 23.31% dry matter content and from 14.66% to 16.31% starch content), and the lowest in the Bellarosa cultivar (from 18.39% to 19.90% dry matter content and from 12.70% to 13.88% starch content) (*Figure 6*). According to other authors as well, the content of nutrients in potato tubers depended mainly on the cultivars' genetic features (Zarzyńska and Goliszewski, 2006; Abong et al., 2010; Krzysztofik and Skonieczny, 2010). However, Bombik et al. (2003) indicated that not only the genotype (cultivar) but also the environment and the genotype-environment interaction had a significant impact on most of the analysed quality features of potato tubers. Rytel (2004) and Lisińska (2006) stated that 20-22% content of dry matter and 15-17% content of starch determine the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15471557

usefulness of cultivars to being processed into chips, and in the case of crisps, the values should be: 21-25% of dry matter and 16-20% of starch, respectively. The high content of dry matter in tubers causes lower fat absorption during technological processes, which makes the final product healthier for the consumer.

Conclusions

The content of dry mass and starch in edible potato tubers was determined by thermal-precipitation conditions. In the years characterized by a larger sum of precipitation in the growing period, potatoes gathered less dry mass and starch in comparison to the warm and dry growing season of 2015. Application in the experiment of the treatment methods with the use of GreenOk-Uniwersal Pro and Asahi SL biostimulators and their combination with Avatar 293 ZC herbicide positively impacted the increase of content of dry mass and starch in potato tubers in comparison to the tubers gathered from the control object. Moreover, genetic features of the cultivars had a significant impact on the content of dry mass and starch. The largest concentration of the discussed components was found in Vineta cultivar.

Abstract. The aim of this study was to determine the most suitable irrigation schedules and sources of manure for maize under Mardin ecological conditions. For this purpose, four sources of fertilizer and three irrigation schedules were applied in hybrid maize cultivar to find out their effects on the yield and yield factors in the years of 2014 and 2015. The study used a randomized complete block with split block design with 3 replications. In the study, significant differences were determined on traits at the level of 1% and 5%. The plant height, first cob height, cob length, number of seeds per cob, cob yield, 1000 seed weight, seed yield per unit, hectoliter, protein and oil ratio in seed, Mg, K, Fe, Ni, Cu, Zn, Mn, Na, Ca content of seeds were significantly influenced by irrigation schedules and sources of fertilizer for two years. The highest values were obtained from chicken manure with 9646 kg ha^{-1} in the first year and 11019 kg ha^{-1} in the second year, whereas the lowest values were obtained from control with 6363 and 6662 kg ha^{-1} for the first year and the second, respectively. But the difference between 180-80 kg N-P_2O_5-ha^{-1} and chicken manure was not statistically significant in the second year. According to the irrigation schedules, the grain yield ranged between 6386-10678 kg/ha in the first year and 7575-12133 kg ha^{-1} in the second year. The lowest grain yield per area was from the four-irrigation application, whereas the highest values were obtained from the six-irrigation application. The results of the study showed that grain yield and nutrient level of corn seeds increased, depending on irrigation time and number.

Introduction

Maize is a widely cultivated grain cereal for food consumption on the global scale with 183 million hectares and 1.031 million tons of worldwide production. The area sown in Turkey is 6.390.000 hectares and it produces 5.900.000 tons. Average global yield per year is 563 kg ha^{-1}, 9230 kg ha^{-1} for Turkey (FAO, 2017). Maize is a major crop for both direct and indirect human consumption as it forms a major energy feed for livestock. It is a cheap source of raw material for various agricultural industries and extensively used for preparation of corn starch.

Appropriate development and growth of maize need favorable moisture in root zone. The amount of moisture in the soil decreases in time during dry seasons. Limited water supply during the growing season results in soil and plant water deficits, causing a decrease in maize yields (Gordon et al., 1995; Patel et al., 2006). Timing and supplemental irrigation is important in irrigation scheduling for the most effective use of available water in optimizing maize production. Water deficit affects timing of emergence, number of leaves per plant but delays tasseling initiation and silking,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15591570

reduces plant height and vegetation growth of maize (Abrecht and Carberry, 1993; Singh et al., 2007).

The constant use of chemical fertilizers leads to hazards concerning health and environment (Pimentel et al., 1996). The importance of the use of organic manures under low input agricultural systems has been the subject of many studies. Majority of these studies aim at improving the quality and fertility of soil (DeJager et al., 2001; Palm et al., 2001). Manure can serve as a source of significant nutrient element which includes P and N (Gilley and Eghball, 2002). The application of manure to land give rise to similar results to those obtained when inorganic fertilizers are applied (Eghball and Power, 1999). The amount of organic matter in manure can significantly increase soil aggregation, structure and water holding capacity, infiltration, microbial activity, and can reduce erosion and soil compaction (Haynes and Naidu, 1998; Gilley and Risse, 2000). Poultry manure is relatively a cheap source of macro and micro nutrients (N, P, K, Ca, Mg, S, Cu, Fe, Mn, B). It has the potential to increase soil carbon and N content, soil porosity and enhance microbial activity. The hazards of chemical fertilizers, which occurred in heavy and unbalanced ways, led to the use of organic manures in intensively growing areas for sustainable production system. Therefore, in order to sustain the land and achieve potential crop production, careful use of organic manures has become important scientifically. It must be stressed that the importance of farm yard manure, vermicompost, chicken manure and green leaf manure in soil improvement depends on their nutrient content. It helps the improvement of soil structure and water holding capacity (Kale and Bano, 1986; Srivastava, 1998).

The aim of this research is to determine the effects of irrigation scheduling and different manure sources on yield and nutrition content in maize cultivation.

Materials and Methods

This trial was conducted to determine the most suitable irrigation schedules and sources of manure in a well-adapted maize (*Zea mays* L.) Farw. cultivar Limagrain Helen, in 2014 and 2015 in the fields of Kiziltepe Vocational High School of Mardin Artuklu University (longitude 40º57´59.01"E, latitude 37º07´34.74"N, and altitude 494.0 m) (*Figure 1*). Cultivar Limagrain Helen is intensively grown as a kind of grain maize in the region.

Figure 1. *The research was conducted in Kiziltepe/Mardin of Turkey*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15591570

In 2014 and 2015, precipitation throughout the season was 158.6 mm and 133.6 mm respectively, and the average over the long-term for the same period was 111.1 mm (*Table 1*).

Table 1. *Meteorological data for the growing seasons of 2014, 2015 and long-term averages in Mardin, Turkey (TSMS, 2016)*

	Precipitation (mm)			Average temperature (°C)				Relative humidity (%)	
Months	**2014**	**2015**	**LTA***	**2014**	**2015**	**LTA***	**2014**	**2015**	**LTA***
June	1.4	2.9	4.1	25.9	25.9	25.7	22.5	29.0	32.3
July	1.0	0.2	1.1	30.4	31.6	29.9	20.0	19.6	27.7
August	7.0	0.4	0.5	31.3	30.5	29.6	17.1	25.8	28.4
September	10.8	9.9	1.9	24.3	28.4	25.1	31.2	23.0	32.6

Total	158.6	133.6	111.1						
Average				23.4	24.6	23.3	31.9	32.9	37.2

*LTA = Long-term average (1960-2015)

Average temperature was 23.54°C in 2014 and 24.6°C in 2015. There was an increase in average temperature when it is compared to long term average of 23.3°C. Average relative humidity was 31.9% in the first and 32.9% in the second vegetation periods (TSMS, 2016) and 37.2% for the long term. The soil, in which this study carried out, is classified as entisols according to soil taxonomy (Soil Survey Staff, 1999). The results of calcareous soil analysis are as follows: sandy loam texture, very low organic matter and moderate in available phosphorus (*Table 2*).

The experiment was laid out in a randomized complete block design (RCBD) with split-plot arrangement keeping the irrigation schedules in main plots and integrated manure sources in sub plots. The experiment was replicated three times. The net plot size was 5m x 2.8m.

[A]1:2.5 soil:water, [B]Bouyoucos (1951), [C]lime by calcimetric methods, [D]Olsen et al. (1954), [E]Richard (1954), [F]Jackson (1962)

The treatments were three irrigation schedules i.e. I1: four irrigations (1st at three leaf stage, 2nd at ninth-leaf stage, 3rd at tasseling stage, 4th at milking stage), I2: five irrigations (1st at fourth leaf stage, 2nd at ninth leaf stage, 3rd at tasseling, 4th at milking stage, 5th at dough stage) and I3: six irrigations (1st at third leaf stage, 2nd at ninth leaf stage, 3rd at tasseling, 4th at blister stage, 5th at milking stage, 6th at dough stage) and four manure (M0: control, M1: 180-80 kg N-P_2O_5- ha^{-1}, M2: Chicken manure 15 t ha^{-1} and M3: Farmyard manure 15 t ha^{-1}). Manure and irrigation were applied

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15591570

according to the treatments. All other agronomic practices were kept normal and uniform for all treatments. Observations on growth and yield parameters were recorded using standard procedures. All fertilization and irrigation applications were conducted as (Sharif et al., 2004; Hussaini et al., 2008; Rezvantalab et al., 2008). The concentrations of Zn, Fe, Mn and Cu in the digested solutions were determined by inductively coupled plasma atomic emission spectroscopy (ICP-AES, OPTIMA 3300 DV, Perkin-Elmer, USA). IPE556 grain and IPE883 straw (Wageningen University, The Netherlands) were used as reference materials (Hussaini et al., 2008).

Three different irrigation methods were applied in the research, and the irrigation was the same in the both seasons of 2015 and 2016. Details of irrigation applications are given below (*Table 3*).

Table 3. *Details of different irrigation application have been shown*

Years	1.st irrigation application		2nd irrigation application		3rd irrigation application	
2015* 2016	1st at three leaf stage	125 mm	1st at three leaf stage	125 mm	1st at three leaf stage	125 mm
	2nd at ninth-leaf stage	125 mm	2nd at ninth-leaf stage	125 mm	2nd at ninth-leaf stage	125 mm
	3rd at tasseling stage	125 mm	3rd at tasseling stage	125 mm	3rd at tasseling stage	125 mm
	4th at milking stage	125 mm	4th at milking stage	125 mm	4th at milking stage	125 mm
			5th at dough stage	125 mm	5th at dough stage	125 mm
					6th at dough stage	125 mm
Total	500 mm		625 mm		750 mm	

* Irrıgation was used the same for both (2015 and 2016) seasons

The sowing was made 5 cm depth, the eight seeds counted for per square meter and the separate of between two rows calculated 70 cm and between two plant on bed 20 cm. The first-year sowing was down on 15th of June 2014 with trial plantation and harvest was made on 5 November 2014. The second-year sowing was made on 13 June 2015; the harvest was made on 10 November 2015. On the other hand, chemical application and hoeing were made against weeds during the growing season in the trial plots. Any chemical drugs were not used during these two years, because there was no shown disease in the trials.

Observations and measurements in each plot were calculated by taking the mean of 10 randomly selected plants. Observations and measurements were obtained as suggested by Turgut (2003).

The effect of treatments (Irrigation schedules and sources of manure) on maize were analyzed using the analysis of variance procedures for a randomized complete block design with the SAS (1998) statistical package. When the F-value of the ANOVA was significant at the $P<0.05$ level of probability. The means related with nutrient content, yield and yield components in maize were evaluated with Duncan's Multiple Range Test statistical analysis.

Results

Regarding maize grown under different fertilizer and irrigation treatments, results in *Table 4* indicated that all the studied characteristics were significantly affected by irrigation treatments over the two growing seasons.

The highest plant height, according to the sources of manure, were obtained from M1 with 226.9 cm and 215.7 cm for 2014 and 2015, respectively. But the difference with

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15591570

M2 (chicken manure) was not statistically significant in both years. The lowest plant heights were obtained from control plots with 205.4 cm and 200.3 cm in 2014 and 2015, respectively. According to the irrigation schedules, the plant height ranged between 199.4 and 239.7 cm in the first year, and 190.5 and 239.9 cm in the second.

In terms of first cob height, the highest values were obtained from M1 with 89.7 cm and 91.8 cm for both years, whereas the lowest first cob height was obtained control plots (M0). On the other hand, the difference among M, M2 and M3 was found to be statistically insignificant in the first year. According to the irrigation schedules the first cob height ranged between 83.2 and 90.7 cm in 2014, and 80.2 and 90.4 cm in 2015. The lowest first cob heights were observed in the I1 application, whereas the highest values were obtained from the I3 application (*Table 4*).

I1: Four irrigations (1st at three leaf stage, 2nd at ninth-leaf stage, 3rd at tasseling stage, 4th at milking stage), **I2:** Five irrigations (1st at fourth leaf stage, 2nd at ninth leaf stage, 3rd at tasseling, 4th at milking stage, 5th at dough stage) and **I3:**Six irrigations (1st at third leaf stage, 2nd at ninth leaf stage, 3rd at tasseling, 4th at blister stage, 5th at milking stage, 6th at dough stage) and four manure (**M0:**control, **M1:** 180-80 kg N-P_2O_5- ha^{-1}, **M2**: Chicken manure 15 t ha^{-1} and **M3:** Farmyard manure 15 t ha^{-1})

The highest cob lengths according to the sources of manure were obtained from M2 with 20.9 cm and 21.3 cm for the first and second years, respectively. The lowest cob lengths were obtained from control plots (M0) with 17.7 and 18.1 cm for 2014 and 2015, respectively. The highest cob lengths for irrigation were obtained from I3 with 22.1 and 22.6 cm in the first year and the second, respectively, while the lowest values were obtained from I1 for both years.

The highest number of grains/cob, according to the sources of manure, was obtained from M3 with 431.3 grains/cob in 2015. The highest number of grains/cob was obtained from M2 with 468.7 grains/cob in 2015. The lowest grains/cob were obtained from

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15591570

control plots in both years but the difference between M0 and M1 was not statistically significant in the second year. In terms of irrigation schedule, the number of grains/cob ranged between 289.3 and 546.1 grains/cob in the first year, and 371.7 and 490.2 grains/cob in the second year.

In terms of grain yield of cob, while the highest value was collected from M2 with 36.1g, the lowest value was obtained from 24.4 g for the first year. Whereas, the highest value was obtained from M1 with 38.7 g but the difference among M1, M2 and M3 was found to be statistically insignificant in the second year. According to the irrigation schedules, grain yield of cob ranged between 24.5 and 39.7 g in 2014, and 29.4 and 43.7 g in 2015. The lowest values were collected from the I1 application, whereas the highest values were obtained from the I3 application (*Table 4*).

Significant results of both factors under study during both years of experimentation were found. According to the source of manure, the highest 1000 seed weight was obtained from M2 with 134.8 g in the first year, while the highest 1000 seed weight was collected M3 with 145.1 g in the second year. The lowest values were obtained from control plots in both years. In terms of irrigation schedule, the highest 1000 seed weights were obtained from I3 with 138.7 and 148.9 g for years, whereas the lowest values were obtained from the I1 application with 118.9 and 135.5 g for the first year and the second, respectively.

In terms of grain yield, the highest values were obtained from M2 with 9646 and 11019 kg ha^{-1} for 2014 and 2015, while the lowest values were obtained from M0 with 6363 and 6662 kg ha^{-1} for both years, respectively. But the difference between M1 and M2 was not statistically significant in the second year. These finding are also supported by (Seker and Ersoy, 2005). According to the irrigation schedules, the grain yield ranged from 6386 to 10678 hg/ha in the first year, and from 7575 to 12133 kg ha^{-1} in 2015. The lowest seed yield was collected from the I1 application, whereas the highest values were obtained from the I3 application (*Table 3*).

The highest hectoliter weight was obtained from M2 with 73.9 and 72.8 kg for the first year and the second, whereas the lowest hectoliter weight were observed from control plots both years. In terms of irrigation schedule, the highest hectoliter weights were obtained from I2 with 73.1 kg in the first year, I3 with 72.7 kg in 2015, the lowest values were obtained from I1 application with 69.4 and 70.4 kg for the first year and the second, respectively. But the difference between I2 and I3 was statistically insignificant in 2014.

The highest grain oil contents were reached from M1 with 4.05-4.32%, the lowest values were obtained from M0 application with 3.50-3.57% for 2014 and 2015, respectively. According to the irrigation schedules the seed oil content ranged between 3.60 and 4.13% in 2014, and 3.58 and 4.17% in 2015. The lowest seed oil contents were obtained from the I1 application, whereas the highest values were obtained from the I3 application (*Table 5*). In terms of seed protein ratio, the highest values were obtained from M2 with 10.9 and 10.6% for the first and the second years, the lowest values were obtained from control plots with 8.9 and 9.01% for both years, respectively. The highest seed protein ratio for irrigation schedule were obtained from I3 with 10.8 and 10.51% in 2014 and 2015, respectively, while the lowest values were obtained from I1 but the difference between I1 and I2 was statistically insignificant for both of the years.

The results on the nutrient contents of maize, based on the application of different manures and irrigation schedules, are showed in *Table 4*. When the effect of irrigation schedules and sources of manure on nutrient contents of maize seed, the highest K

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15591570

values were obtained from the M2 application in both of the years but there among M1, M2 and M3 was not statistically significant in the first year. When potassium is examined in terms of irrigation schedule while the highest values obtained from I3, the lowest values obtained from I1, but the difference between I2 and I3 was statistically insignificant in the second year.

The highest Na, Mg and Ca values were obtained from M2 application, while the lowest values were obtained from M0 application in 2014 and 2015. According to the irrigation schedule, the I1application gave the lowest value while the I3 gave the highest value (*Table 5*).

I1: Four irrigations (1st at three leaf stage, 2nd at ninth-leaf stage, 3rd at tasseling stage, 4th at milking stage), **I2:** Five irrigations (1st at fourth leaf stage, 2nd at ninth leaf stage, 3rd at tasseling, 4th at milking stage, 5th at dough stage) and **I3:** Six irrigations (1st at third leaf stage, 2nd at ninth leaf stage, 3rd at tasseling, 4th at blister stage, 5th at milking stage, 6th at dough stage) and four manure (**M0:** control, **M1:**180-80 kg N-P_2O_5- ha^{-1}, **M2:**Chicken manure 15 t ha^{-1} and **M3:**Farmyard manure 15 t ha^{-1})

In terms of Fe contents, the highest values were obtained from M2 application, the lowest values were obtained from the M0 application in both of the years. When Fe is examined in terms of irrigation schedule, the highest values obtained from I3, while the lowest values obtained from I1, but the difference between I2 and I3 was statistically insignificant in the second year.

When evaluated in terms of copper contents, the highest Cu content was obtained from M2 in the first year, M1 in the second. The lowest values were obtained from M0 in both years. In addition, the I3 application has the highest Cu content, whereas the I1 application has the lowest content both years. But the difference between I1 and I2 in 2014 and among I1, I2 and I3 in 2015 was not statistically significant.

The highest Zn, Mn, and Ni contents were obtained from M2 application, whereas the lowest values were obtained from the M0 application in 2014 and 2015. But the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15591570

difference between M2 and M3 was statistically insignificant for Ni content in the first year. According to the irrigation schedule the highest values were obtained from I3, the lowest values were obtained from I1 except Ni content both years. Ni content was found to be insignificant in 2014.

According to the source of manure, Pb content was found to be insignificant in the first year, while the highest value was obtained from M2, the lowest value was obtained from M0 in the second year. In terms of irrigation schedule the highest values were obtained from the I3 application, the lowest values were obtained from the I1 application. But the difference between I1 and I2 was not statistically significant.

There was a significant interaction between irrigation schedules and different manure sources during both years. In *Table 6* I3 M2 (the first year: six irrigations and chicken manure) and I3 M1 (the second year: six irrigations and farmyard manure) interaction produced maximum grain yield (1348 kg ha^{-1} in 2014 and 1495 kg ha^{-1} in 2015).

Table 6. *Interaction between irrigation schedules and different manure sources affecting grain yield (kg ha^{-1}) during 2014 and 2015*

	Irrigation schedules	Sources of manure			
		M0	M1	M2	M3

Discussion

Each year was separately evaluated since there were significant differences between both years, as found from combined analysis. Maize yield and its components tend to be higher in 2015 growing season, compared with 2014 growing season. This could be attributed to favorable climatic conditions that were prevailing during the 2015 growing season. The lowest plant heights were obtained from the I1 application, whereas the highest values were obtained from the I3 application (*Table 4*). These results are similar to the findings of Randhawa et al. (2012), and El-Gizawi and Nasser (2005), who found taller plants by increasing irrigation interval. While the minimum plant height was obtained in control treatment. These results are inline as the results of Qasim et al. (2001), who reported an increase in plant height with farmyard manure application due to more availability and uptake of nutrients. Increasing scarcity and greater competition for use of freshwater resources will force irrigated agriculture to be more efficient in use of available supplies. Significant difference was found among the irrigation treatments and different manure sources on the production of first cob height and cob length. The highest values were obtained for the I3 irrigation application and the M2 fertilization. Similar effects were observed by Abera et al. (2013) and Majid et al. (2017). Rezvantalab et al. (2008) also reported higher number of grains cob-1 with application of farmyard manure and mineral fertilizers. While the highest values were obtained from I3, the lowest values were obtained from I1. Confirmatory results regarding number of grains cob-1 were given by El-Tantawy et al. (2007), who reported significant differences among different irrigation schedules. According to the irrigation schedules, grain yield of cob ranged between 24.5 and 39.7 g in 2014, and 29.4 and 43.7

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15591570

g in 2015. The lowest values were collected from the I1 application, whereas the highest values were obtained from the I3 application (*Table 4*). These data confirm that of El-Tantawy et al. (2007) and Majid et al. (2017), who reported significant response of supplementary irrigation on grain weight cob-1. The highest 1000 grain weight was produced with the I3 irrigation treatment whereas the minimum weight of 1000-grain was produced by the control treatment. Significant results of both factors under the study during both years of experimentation were found. In case of plant nutrition treatments, the highest 1000-grain weight was noted in treatment chicken manure 15 t ha^{-1} (M2) as compared to all other integrated plant nutrition treatments in 2014. The same trend was observed during 2015. The increase in 1000-grain weight might be due to integrated use of farmyard manure and I3. Reports supporting the present results have appeared in the literature by Sharif et al. (2004) and Kashiani et al. (2011). The levels of irrigation and different manure sources remarkably influenced the grain yield in cultivar Limagrain Helen. Minimum grain yield counted from the treatment I1 M0, and it differed statistically from other treatments applications. The water stress (deficit water) remarkably influenced productivity and quality in maize (Barutcular et al., 2016; El Sabagh et al., 2017). However, water availability is usually the most important crop production factor limiting yield and yield traits of maize. These facts are comparable with the study of (Zhang et al., 2007) who obtained higher yield with the increase in number of irrigations. These results are similar to the findings of (Randhawa et al., 2012). The highest grain oil contents were reached from M1 with 4.05-4.32%, the lowest values were obtained from the M0 application with 3.50-3.57% for 2014 and 2015, respectively. According to the irrigation schedules, the seed oil content ranged between 3.60-4.13% in 2014 and 3.58-4.17% in the second year. The lowest seed oil contents were obtained from the I1 application, whereas the highest values were obtained from the I3 application. These results were in agreement with what was obtained by Yalçın et al. (2006). Grain analysis has been used to reveal the deficiency, adequacy or excessiveness status of various nutrient elements in a soil-plant system. Chicken manure application significantly increased the concentrations of K, Ca, Cu, Fe, Mn, Zn, Ni and Mg in maize seed. Application of chicken dunk organic fertilizer not only capable to increase sweet corn production, but also had positive impacts in term of improvement of soil physical, chemical and biological properties. Improvement of soil physical properties is achieved because organic matter (organic fertilizer) functions as adhesive of loose soil particles or aggregate stabilizer compound (Gonzales et al., 2002; Margaretha et al., 2014). The highest Na, Mg and Ca values were obtained from the M2 application. The lowest values were obtained from the M0 application in the first year and the second. According to the irrigation schedule, the I1 application gave the lowest value while I3 gave the highest. Similar effects were observed by Hussaini et al. (2008).

Conclusions

The effects on all the characteristics researched for different sources of manure and irrigation schedules were statistically significant for 2014 and 2015. The results of our work indicated that the highest plant yield for maize planted in both growing seasons of 2014 and 2015 was obtained when the plants were irrigated six times. On the basis of this two-year study, it is concluded that in order to obtain higher grain yield of hybrid maize under agro ecological conditions of Mardin/Turkey, the crop should be irrigated six times and fertilized with organic manures (15 t chicken manure ha^{-1}). While the

DOI: http://dx.doi.org/10.15666/aeer/1702_15591570

highest grain yield per area was obtained from the third irrigation schedule and chicken manure in 2014, the highest value was obtained from the third irrigation schedule and standard fertilizer with 14959 kg ha^{-1} and the third irrigation schedule and chicken manure with 13463 kg ha^{-1} in 2015. Chicken manure application significantly increased the concentrations of K, Ca, Cu, Fe, Mn, Zn, Ni and Mg in maize seed. The results revealed that increase in soil moisture and mineral contents leads to increase in plant growth promotion and biomass production.

Abstract. A novel, rapid low-density solvent based dispersive liquid-liquid microextraction combined with magnetic nanoparticles has been developed for extraction and preconcentration of Cr^{2+}, Ni^{+}, Co^{2+}, Hg^{+} in environmental samples prior to liquid chromatography with UV analysis. In the proposed method, the Schiff base was used as a complexing agent and the environmental samples were treated with acetonitrile/water (60:40, v/v) which was then utilized as disperser solvent in the dispersive liquid-liquid microextraction process along with using 1-octanol as extractant. In magnetic solid phase extraction approach, hydrophobic magnetic nanoparticles were used to retrieve and separate the 1-octanol in the dispersive liquid-liquid microextraction step. In fact the target of magnetic solid phase extraction was the 1-octanol rather than the metal ions directly. Several parameters including the volume of extractant, the pH of the sample, the concentration of complexing agent, the volume of magnetic nanoparticles were optimized. Under the optimized conditions, there coveries obtained for each metal ion ranged from 86 to 106% with relative standard deviations lower than 5.6%. The limit of detection were 0.05 μg L^{-1} for Cr^{2+}, 0.05 μg L^{-1} for Ni^{+}, 0.06 μg L^{-1} for Co^{2+}, 0.05 μg L^{-1} for Hg^{+}, respectively. The preconcentration factors were 205, 200, 195 and 190 for Cr^{2+}, Ni^{+}, Co^{2+} and Hg^{+}, respectively. The presented method has been successfully used for the determination of metal ions in real water samples.
Keywords: *preconcentration, 1-octanol, DLLME, hydrophobic magnetic nanoparticles, LC-UV*

Introduction

Heavy and transition metal ions are distributed widely in biological systems and the environment, and play important roles in many biological and environmental processes (Trautwein, 1997). Excess amount of these ions is, however, toxic. Lead poisoning can cause a variety of diseases, such as muscle paralysis, memory loss, irritability, and anemia (Strużyńska et al., 1997; Rifai et al., 1993; Rezende et al., 2011). The World Health Organization (WHO) has released the guide-lines for drinking water quality containing the guide line value of 10 μg L^{-1} for lead (WHO, 2006). Cadmium is not regarded as essential to human life and is known to damage organs including the kidneys, liver and lungs (Pourreza et al., 2010; Zhang et al., 2010). Methods for detecting the presence of one or several of these ions are thus urgently needed, and if the detection method could identify different component of the analytes, it would be an excellent improvement compared with other sensing methods. Although many methods for their analysis have been well developed, existing methods require complex equipments and sophisticated operations.

In many cases the determination of trace metal ions in various samples such as natural and waste water, biological and alloy samples, the direct determination with various instrumental methods is not possible owing to matrix effect and low concentration of metal ions in a sample (Andruch et al., 2012a). Thus separation and preconcentration procedures are required for elimination or minimization of matrix effects and concomitants, lowering the detection limit of many metals with different techniques and enhancing the delectability for many metals. A variety of procedures for preconcentration of metals, such as solid phase extraction (SPE) (Andruch et al., 2012b; Baig et al., 2009), liquid–liquid extraction (LLE) (Duran et al., 2007; Karami et al., 2008; Fritz et al., 2000), coprecipitation, ion-exchange (Kocúrová et al., 2011), flotation (Li et al., 2009), and cloud point extraction (CPE) have been developed (Mohammad et al., 2013; Nascentes et al., 2003; Parham et al., 2009; Rezende et al., 2011; Tuzen et al., 2006). SPE is one of the most frequently employed methods, as it is surface-dependent processes and their efficiency directly depends on the particle size and the surface area of the sorbent (Taylor et al., 1996; Tang et al., 2004). Dispersive liquid-liquid microextraction (DLLME) has been brought up as an exciting microextraction technique in 2006 (Yuet al., 2014; El-Shahawi et al., 2013; Rezaee et al., 2006).

In this procedure, a mixture of high density organic solvent (serving as extraction solvent) and water miscible polar dispersive solvent (dispersive solvent) is rapidly injected into an aqueous sample to form an emulsion consisting of fine droplets of the extraction solvent, dispersive solvent, and water. Due to the extraction solvent being highly dispersed in the aqueous phase, the surface area between extraction solvent and sample solution is infinitely large, thus speeding up the extraction. While, the main disadvantage of DLLME is that the extraction solvent is generally limited to solvents with higher density than water in order to be sedimented by centrifugation, typically chlorinated solvents such as chlorobenzene, chloroform, and tetrachloromethane, all of them are potentially toxic to humans and the environment.

Then, another microextraction technique based on magnetic nanoparticles (MNPs) has gained research interest since the MNPs can be easily isolated from matrix by using an external magnetic field without retaining residual magnetization after its removal (Giannoulis et al., 2013; Shih et al., 2014; Gómez-Pastora et al., 2014; Zou et al., 2013). Also MNPs offer a significantly higher surface area-to-volume ratio and a shorter diffusion route than conventional sorbents, resulting in high extraction capacity, rapid extraction dynamics and high extraction efficiencies (Faraji et al., 2010; Chen et al., 2011; Román et al., 2011).

By combining the merits of the dispersive liquid-liquid microextraction (DLLME) and magnetic solid phase extraction (MSPE) techniques, a new sample preparation method was proposed to trace metal ions of environmental samples. The applications of magnetic nanoparticles in biotechnology and environmental, and so on, has attracted considerable attention in recent years, because of their rapid adsorption ability, surface modification, easy to separation and good biocompatibility etc. The quick separation and excellent adsorption performance of magnetic nanoparticles have gained increasing application in sample pretreatment. The magnetic nanoparticles with suitable surface modification are capable of binding molecules selectively. Magnetic nanoparticles and the magnetic separations, magnetic detections have advantages of rapidity, convenience and high selectivity.

This is the first report regarding preconcentration of Cr^{2+}, Ni^{2+}, Co^{2+}, Hg^{+} by DLLME-MSPE prior to liquid chromatography-UV analysis. A novel, rapid low-

density solvent based dispersive liquid-liquid microextraction combined with magnetic nanoparticles has been developed for extraction and preconcentration of Cr^{2+}, Ni^{+}, Co^{2+}, Hg^{+} in environmental samples prior to liquid chromatography with UV analysis.

Materials and methods

Chemicals and materials

The standards of Cr^{2+}, Ni^{+}, Co^{2+}, Hg^{+} (1000 mg L^{-1}) were purchased from National standard material network (Beijing, China). Working standard solutions were freshly prepared by diluting the stock solutions with high-purity water. 1-hexanol, 1-heptanol, 1-octanol, 1-nonanol, 1-decanol and decanoic acid were obtained from the Aladdin Reagent Corporation (Shanghai, China). As a complexing agent, the Schiff base was from our own laboratory. $FeCl_3 \cdot 6H_2O$, $FeCl_2 \cdot 4H_2O$, ammonium nitrate and the other used chemicals were supplied by Tianjinzhiyuan (Tianjin, China).

Instrumentation

High-purity deionized and doubly distilled water (UPS-I40L, Ulupure, Shanghai) was used during this study. A pH-meter (PHS-3E, China) was used for pH measurements. An ultrasonic homogenizer (LTB-300, China) equipped was used as a dispersing agent. A centrifuge (TDZ4-WS, China), with a centrifugation speed in the range from 500 to 6000 rpm, was used for phases separation after the microextraction procedure. A High performance liquid chromatography system (Agileng 1260, Agilent, USA), which consisted of an UV detector, was used for the analysis.

Real sample preparation

Environmental water samples were from local river water and lake water and were analysed by DLLME-MSPE/LC-UV procedure. All water samples were stored at 4 °C.

Synthesis of magnetite nanoparticles (MNPs)

Preparation of magnetic nano materials Fe_3O_4 by hydrothermal reduction method. The $FeCl_3$ was reduced to Fe_3O_4 by using ethylene glycol. The addition of anhydrous sodium acetate and surfactant polyethylene glycol was added to prevent the agglomeration of particles. The specific reaction condition, 1.35g$FeCl_3.6H_2O$ dissolved in 40ml of glycol, adding 3.6g anhydrous sodium acetate and 1.0g polyethylene glycol under magnetic stirring, at 60°C under vigorous stirring until completely dissolved, then the mixed solution into the reaction kettle in a 50mL, under 200°C reacted 12h and then cooled to room temperature. The synthesis of Fe_3O_4 nano particles with water and ethanol alternate cleaning, vacuum drying at 80°C.

Extraction procedure

DLLME step

A 15 mL aliquot of the sample solution containing Cr^{2+}, Ni^{+}, Co^{2+}, Hg^{+} was transferred into a 50 mL glass test tube. The pH of the sample was adjusted to 5.0 with the acetate buffer. Then 500 μL 10% w/v Schiff base (complexing agent) and 80 μL of 1-octanol (as extraction solvent of DLLME) and the acetonitrile/water (80:20, v/v)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15711584

extract (used as disperser solvent) were added and the mixture was diluted to 40 mL by deionized water. Then, the tube was sealed and swirled on a vortex agitator at 2000 rpm for 30 s to accelerate the formation of the fine droplets of the extraction solvent and to enhance the transfer of the analytes.

MSPE step

50 mg of the synthetic magnetic nanoparticles were quickly added into the upper tube and the mixture was vigorously blended using a vortex agitator for 60s at 5000 rpm. The Cr^{2+}, Ni^{+}, Co^{2+}, Hg^{+} (complexes of Schiff base)-containing 1-octanol was successfully partitioned on the surface of MNPs. Subsequently, a magnet was held next to the outer wall of the test tube to attract and isolate the MNPs, and the sample solution was discarded by decanting it. After then, an aliquot of water was added into the vial to rinse the residue. Ultimately, 200 µL of methanol was used to desorb the 1-octanol as well as the Cr^{2+}, Ni^{+}, Co^{2+}, Hg^{+} from the MNPs by swirling for 30 s and 10 µL of the eluent was used for LC-UV analysis.

Liquid chromatography

A 10 µL aliquot of the extractant phase was injected into the liquid chromatography with UV detector. An Agilent C18-AR column (250 × 4.6 mm, 5 µm particle size) was used as the analytical column. The mobile phase consisted of methanol/water at a ratio of 65/35 (v/v). The flow rate of the mobile phase was at 1.0 mL min^{-1} and the detection wavelength was set at 256 nm.

Results and discussion

Characterization of decanoic acid@Fe_3O_4 nanoparticles

The size and morphological features of decanoic acid@Fe_3O_4 (DA@Fe_3O_4) MNPs were visualized with Transmission electron microscope (TEM). As can be seen in *Figure 1,* the MNPs have an average size of about 10 nm. The prepared DA@Fe_3O_4 NPs were stabilized against agglomeration by a monolayer of decanoic acid. And the edge morphology of DA@Fe_3O_4 NPs became blurred because the particles' surface was encapsulated with 10 carbons of acid.

The functional groups of DA-MNPs were identified by Fourier Transform Infrared Spectrometer (FT-IR). The FT-IR spectra of DA-MNPs and 1-octanol-DA-MNPs are shown in *Figure 2*. The spectrum of DA-NMPs exhibited strong bands at 621 and 3434 cm^{-1} due to Fe-O-Fe and O-H stretching vibrations of magnetic nanoparticles. The peaks at 2924 and 2849 cm^{-1} were attributed to the C-H stretching vibrations of decanoic acid and the peak at 1599 cm^{-1} contributed to the C=O stretch band of the carboxyl group. All these adsorption peaks confirmed the successful coating of Fe_3O_4 nanoparticles by DA.

Optimization of the DLLME-MSPE method

During the two-step extraction procedure, several parameters affect the extraction performance and the recoveries. Several parameters, including sample pH, the concentration of complexing agent, the type and volume of extraction solvent, equilibration time, amount of MNPs were optimized by investigation a single parameter when the other parameters remained unchanged.

Selection of the disperser solvent

The applicability of several organic solvents including MeOH, MeCN, EtOH, MeOH 80% and MeCN 80% was investigated in the preliminary experiments taking into

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15711584

account that it should used to primary extract of the analytes from real water samples must then act as disperser solvent in DLLME process. *Figure 3* shows the recoveries of the whole procedure (extraction + DLLME + MSPE) of all extraction solvents tested. The results revealed that the maximum extraction efficiency was achieved by MeCN/water (80:20 v/v).

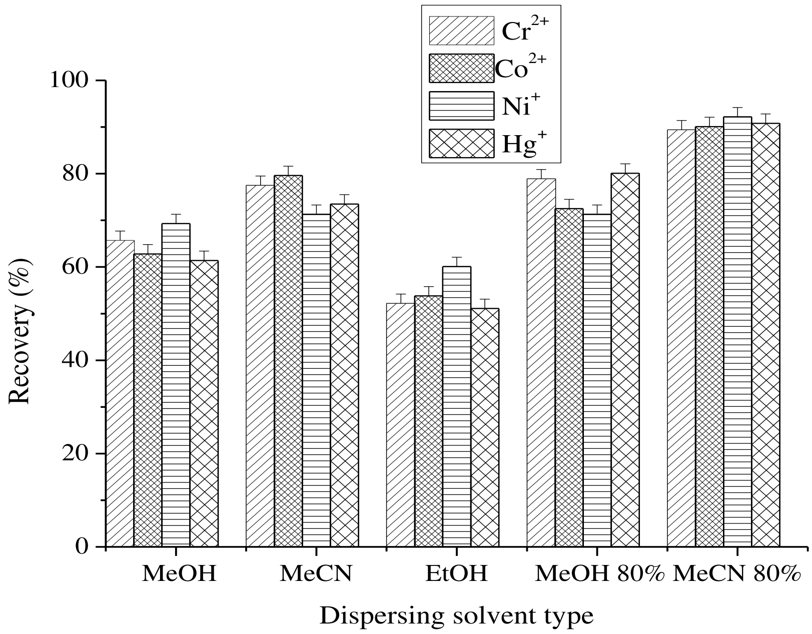

Figure 3. *Effect of dispersing solvent*

To study the volume effect of disperser solvent, it was varied from 4 to12 mL in the interval of 2 mL while extraction solvent was kept at 80 µL. The obtained results showed that the extraction efficiency increased with increasing the volume of MeCN 80% up to 10 mL and then dropped down slightly above 10 mL due to decreasing the distribution ratio.

Therefore 10 mL MeCN 80% was selected as both the extraction solvent of Cr^{2+}, Ni^{+}, Co^{2+}, Hg^{+} from water samples and as disperser solvent in DLLME for subsequent experiments.

Effect of solution pH

The effect of sample pH was investigated in the range of 2.0–9.0. Adjustment was done using hydrochloric acid, sodium hydroxide and acetate buffer. The achieved areas of the liquid chromatographic peaks were the highest at pH = 5.0 and these conditions were used for further experiments.

Selection of extraction solvent

Selection of appropriate extraction solvent is of great importance in microextraction technique in order to obtain efficient extraction. For the DLLME, the extraction solvent should meet the following requirements: (1) be immiscible with aqueous solution (2) able to extract the analytes, and (3) possess low toxicity. To avoid the use of more highly toxic solvents such as trichloromethane, tetrachloromethane, tetrachloroethylene,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15711584

chlorobenzene etc., five low density organic alcohol including 1-hexanol (density, d = 0.819 g mL^{-1}), 1-heptanol (d = 0.820 g mL^{-1}), 1-octanol (d = 0.821 g mL^{-1}), 1-nonanol (d = 0.827 g mL^{-1}), and 1-decanol (d = 0.828 g mL^{-1}) were evaluated as extractants. Among them a stable cloudy solution and good extraction recovery were observed with 1-octanol. The fine droplets of 1-octanol afford larger surface area to contact with the water sample and can be completely absorbed by MNPs after magnetic separation, so that higher extraction performance can be attained. As can be seen in *Figure 4*, 1-octanol has higher extraction recovery than those obtained by other extraction solvents for the Cr^{2+}, Ni^{+}, Co^{2+}, Hg^{+}. The volume of 80 µL of 1-octanol was selected as an optimum solvent volume for further studies.

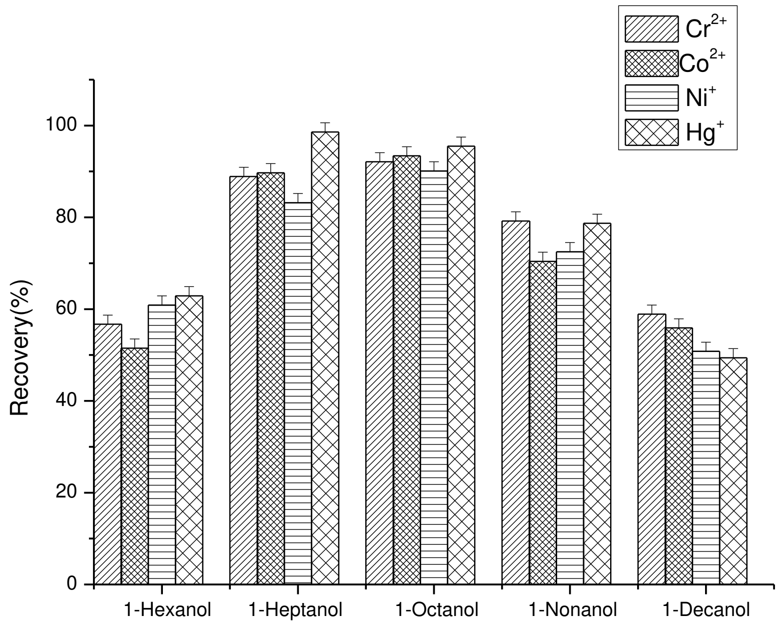

Figure 4. *Selection of extraction solvent*

Influence of sonication time

In DLLME extraction, sonication time is defined as an interval time from the occurrence of cloudy solution and before addition of magnetic adsorbents. The effect of extraction time on the adsorption was investigated for 0-120 s. The result showed that sonication time has no influence on extraction efficiency. It is well-known that vortex process is an effective way to enhance mass transfer from aqueous phase to the extraction phase. Consequently, short time was required for extraction. Generally, 30 s of extraction time was enough to achieve high extraction recovery, and prolonged extraction time did not contribute significantly to an increase in extraction recovery. Therefore, vortex time of 30 s was selected.

Influence of concentration of Schiff base

Schiff base has the ability to form metal-ligand complexes (1:2) with divalent metal ions. The effect of Schiff base concentration on the formation of metal complexes was studied in the range from 0.05 to 0.50 (%, w/v). The results show that the extraction

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15711584

efficiency of metal ions enhances up to 0.20 (%, w/v). Hence, 0.30 (%, w/v) of Schiff base was selected for preconcentration of the metal ions for further experiments.

Influence of amount of MNPs

After the DLLME procedure, the magnetic sorbents were dispersed in sample solution to rebind 1-octanol. In order to guarantees the quantitative separation of metals-containing1-octanol from DLLME step, the effect of the amount of DA@Fe_3O_4 MNPs in the solution was investigated in the range from 20 to 80 mg. As shown in *Figure 5,* the extraction recovery for the analytes increased rapidly when the DA@Fe_3O_4 MNPs amount was increased from 20 to 60 mg and then remained almost constant when the amount of the adsorbent was above 60 mg. High surface to volume ratio of nanoparticles causes the quantitative extraction could perform using very low amount of adsorbent. Based on the above results, the addition of 60 mg DA@Fe_3O_4 MNPs to samples was optimal for magnetic retrieval.

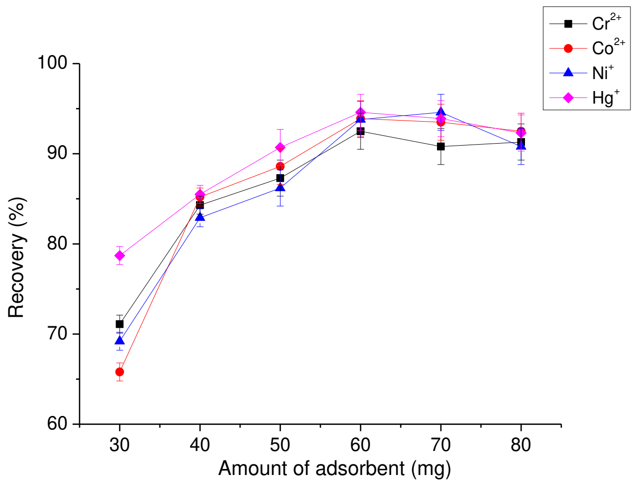

Figure 5. *Effect of amount of magnetic nanoparticles*

Analytical figures of merit of the DLLME-MSPE method

The linearity ranges, correlation coefficients, limits of detection and enrichment factors of the Cr^{2+}, Ni^{+}, Co^{2+}, Hg^{+} were evaluated under the optimized DLLME-MSPE-LC/UV conditions. As listed in *Table 1*, the linearity of the method was examined using a mixed working solution of Cr^{2+}, Ni^{+}, Co^{2+}, Hg^{+} with a concentration range of 0.2-100 μg L^{-1} in environmental water sample solutions. All of the analytes exhibited good linearity, with coefficients that ranged from 0.9985 to 0.9990. The limit of detection (LOD) was calculated on the basis of signal to noise (S/N) ratio. The S/N = 5 was used for calculation of LOD. The LODs were 0.05 μg L^{-1} for Cr^{2+}, 0.05 μg L^{-1} for Ni^{+}, 0.06 μg L^{-1} for Co^{2+}, 0.05 μg L^{-1} for Hg^{+}, respectively. The relative standard deviation (RSD) for five replicate measurements of 1.0 μg L^{-1} in standard solution was 5%. Preconcentration factors calculated as the ratio of the calibration curves slopes for analytes before and after the preconcentration step, were 205, 200, 195 and 190 for Cr^{2+}, Ni^{+}, Co^{2+} and Hg^{+}, respectively. The precision study was carried out in five parallel experiments and provided relative standard deviations below 5.6%.

Real sample analysis

To test the applicability of the proposed method, it was applied to the determination of Cr^{2+}, Ni^{+}, Co^{2+} and Hg^{+} in river and lake water samples. The river water samples were obtained from Liucangqiao River (Bijie, China), the lake water samples from the Jinhai lake wetland park (Bijie, China). Under the recommended experimental conditions, the developed method is employed to determine Cr^{2+}, Ni^{+}, Co^{2+} and Hg^{+} in water samples. And all the water samples are spiked with Cr^{2+}, Ni^{+}, Co^{2+} and Hg^{+} standard solutions at different concentration levels to assess the matrix effects. Non-spiked samples are also analyzed. The results are shown in *Table 2*. It shows the developed method applied to the determination of Cr^{2+}, Ni^{+}, Co^{2+} and Hg^{+} in water samples. Also, *Figure 6A* shows the typical chromatogram of Cr^{2+}, Ni^{+}, Co^{2+} and Hg^{+} at 100 μg L^{-1} without preconcentration, and *Figure 6B* shows the chromatogram from water sample solution spiked at 100 μg L^{-1} of Cr^{2+}, Ni^{+}, Co^{2+} and Hg^{+} after DLLME-MSPE. Comparison of the chromatograms and acceptable recoveries demonstrated that the interferences from the substances in the real sample had no effects on the performance of the presented method and this method had higher sensitivity for determination of Cr^{2+}, Ni^{+}, Co^{2+} and Hg^{+}.

Comparison with other methods reported

Comparisons of the mentioned method with other methods reported for extraction and determination of target metal Cr, Ni, Co and Hg ions were summarized in *Table 3* in details. According to the comparison results obtained, the proposed method showed the recovery comparable with most of the previously reported methods, whereas the detection limit (LOD) for the proposed method were obviously lower than those of the reported methods. Moreover, the extraction time was also shorter than for the other methods. It demonstrated that the developed technique was a powerful alternative for rapidly analyzing target metal Cr, Ni, Co and Hg ions in water samples.

Conclusion

In the present study, a new two-step microextraction technique, based on dispersive liquid-liquid microextraction (DLLME) and magnetic solid phase extraction (MSPE), was developed for determining Cr^{2+}, Ni^{+}, Co^{2+} and Hg^{+} in water samples. A low density solvent (1-octanol) was successfully used in conjunction with magnetic nanoparticles (MNPs) that allowed convenient operation of the procedure. The extraction could be achieved within 2 min and good extraction efficiencies were obtained. Such facile separation is essential to improve the operation efficiency which avoiding time-consuming centrifugation or freezing or manual collection of extractant. Coupled with LC-UV analysis, the proposed method exhibited good linearity and acceptable repeatability, and the limits of detection were as low as in the nanogram per milliliter range for Cr^{2+}, Ni^{+}, Co^{2+} and Hg^{+}. In general, this methodology can be considered as a promising procedure for environmental samples or other samples.

Abstract. Quetta, the capital city of Baluchistan province which was once called as “little London” has been affected by severe drought since 1998. This situation led to fresh water shortage which compelled the local population to irrigate their crops by waste water. In this way, heavy metals started to accumulate in the soil and as well as in our food chain. The main objectives of this research were to elucidate the effect of waste water on leafy vegetables growth. For this purpose, three leafy vegetables were selected i.e. Coriander (*Coriandrum sativum),* Purslane *(Portulaca oleracea)* and Lettuce (*Lectuca sativa).* The research is also aimed to know the influence of waste water treated plants on human health. The experiments were performed in the botanical garden, Botany Department, University of Baluchistan. Waste water was collected from waste water channels of the Quetta city. From March 2016-14 June, 2016, after an extensive survey, different sites of the municipal were selected for the collection of waste water used as sample collected from the Agriculture Department of Quetta city. Vegetative growth parameters such as height, number of leaves, weight of fresh, dry leaves and rate of germination of seed were measured to know the impact of waste water treatment. Waste water treatment had found a significant effect on the growth of leafy plants. All the growth parameters were measured in the three selected leafy vegetable plant species i.e. Coriander (*Corianderum sativum),* Purslane *(Portulaca oleracae)* and Lactuca *(Lactuca sativa).* Comparatively, better results were found by treating the plant with waste water rather than fresh water. The usage of municipal wastewater for irrigation can be an abundant resource of the nutrients essential for plant’s growth. However, keeping in view the health hazards, edible crops irrigated with this untreated waste water should not be grown in spite of its positive impact on the physical parameters of some plants.
Keywords: *wastewater utilization, land irrigation, leafy vegetables plants growth, nutrients, human health*

Introduction

The use of waste water in the agricultural sector to overcome the severe drought is becoming a substitute throughout the world, particularly in China. In developing countries, wastewater is used in 70% of irrigations. Approximately, 20 million ha areas in the world is cultivated by using waste water. Waste water is composed of several minerals which are essential for plants growth. Similarly, using clean water for irrigation has itself some drawbacks. Its increases mainly the scarcity of drinking water. For that

DOI: http://dx.doi.org/10.15666/aeer/1702_15851597

reason, in Mexico, peasants using dirty water can let their land at three times the price of those who use clean water, but these waters also contain risks of disease and pollution. Research studies revealed that Mexican children under four years old living in areas where wastewater is being used for irrigation of plants, have found sixteen times more intestinal problems than the other areas (Achakzai et al., 2011; Adenle et al., 2011).

The World Health Organization (WHO) reveals in one of its laboratory manuals titled "Analysis of waste water for use in agriculture" that the use of waste water for crop irrigation is becoming more common. As wastewaters contain mineral nutrients which are good for the development of plants growth, the yield is superior. However, there is a risk that irrigation with waste water facilitates may enable the transmission of diseases related to intestinal nematodes and fecal bacteria to consumers and farmers (WHO, 2006; ATSDR, 1993; Chang et al., 2002; Mushtaq et al., 2018).

Like in many other counties, untreated waste water is used for irrigation in over 80% of all Pakistan societies with a population of over 10,000 inhabitants. More specifically, considering the case of Quetta, which is the capital city of Baluchistan, with an area of 2,653 km^2, surrounded by the Takato and Murdaar mountains, it has been seen that in Quetta, people have started to fulfil the food requirement by growing the daily use vegetation and vegetables using the waste water of the city (Khalil et al., 2011; Saidi, 2010; Shah, 2014; Ahmad et al., 2004; Amerasinghe, 2004; Siraj et al., 2018).

In Pakistan, there are predominantly agricultural societies, most of the fresh water is used for irrigation purpose and with increased competition for water by rapidly renewed interest the total estimated area directly irrigated by waste water is 32,500 ha, with 19,250 households depending on direct waste water use for their livings. Quetta is the capital city of Baluchistan. Its population is approximately 3 million. It has a rocky landscape. Mostly, its climate is semi-arid with a great variation in the summer and winter temperature (Ensink, 2004; Amerasinghe, 2004; Nidaa et al., 2017; Siraj et al., 2018).

The Quetta city was once very famous for its scenic beauty but has now turned into probably the most polluted city in the country, especially with respect to sanitation and hygiene conditions. The workers reported herewith that due to overpopulation, the basic needs of life have become inadequate for the people. Therefore, the people have started to fulfil the food requirement by irrigating their crops with the wastewater in the areas of Sabzal Road, Spini Road, Saryab Road and Hazar Gangi. Polluted water is composed of hospital, domestic and industrial waste. The pH of sewage water range from 7.24-9.21. The concentration of essential nutrients (macro+ micro) and poisonous metals varied greatly in samples between two selected locations (Kakar et al., 2010; Amerasinghe, 2004' Shah, 2014; Bazai et al., 2005; Zahid et al., 2011; Siraj et al., 2018).

The concentration of P and K^+ was high (1.18 ppm) in Habib nala than Ispini and Subzal road sewage drain. The concentration of micro nutrients (Fe^{++}, Mn, Zn, Cu) were within acceptable limits. In relation with toxic metals, Pb was generally greater (0.12 ppm) in Ispini road drain wastewater as compared with (0.05-0.08 ppm) other sewage drains. According to Kakar et al. (2006), the minimum and maximum (0.09 and 0.18 ppm) Ni was found in Ispini and Subzal road drain. Wastewater has a drastic impact on the seed germination also. The results revealed that the germination of seed, and roots, shoot elongation was significantly affected by two types of waste water (Kakar et al., 2010; Shah, 2014; Bazai et al., 2005; Abdul et al., 2013).

Black Niger *(Nigella sativa)* plant was highly affected in domestic waste water treatment and pharmaceutical waste water treatment followed by Coriander (*Coriandrum sativum).* Germination percentages of Mustered (*Brassica juncea)* in domestic and pharmaceutical

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15851597

waste water usage were 18% and 22%, respectively. Fenugreek (*Trigonella foenum-graecum)* germination percentage was less affected by wastewaters as only 20% and 17% reduction was observed in the domestic and pharmaceutical industry waste water. Germination reduction in Barley (*Hordeumv ulgare)* showed 23% under domestic polluted water condition while its reduction under industrial waste water treatment was near to 35%. It has been determined that the germination and growth of seeds and seedlings of various species of plants are significantly affected by domestic and industrial waste water (Herpin, et al., 2012; Al-Jamal et al., 2002; Blumenthal et al., 2000).

The hospital waste of the city which comprises the awash of patient suffering from typhoid fever, malaria, hepatitis causes food borne illnesses. As the contaminants of waste water flow through the food chain of an ecosystem and affect each trophic level and disseminate the diseases in each level of food chain. The farmers of the developing countries prefer the use of waste water for irrigation just because it is economical and does not need organic fertilizers, but, the people are unaware of the consequences of using these vegetables. Waste water is a significant source of water and nutrients for irrigation in developing countries, particularly but not restricted to those located in arid and semi-arid areas. The use of waste water is extensive and represents around 10 percent of the total irrigated surface worldwide, although varying widely at local levels. While, the farmer gets benefits using the waste water, mainly related to their income level, but it has adverse effects on human health and the environment (Jimenez, 2006; Disciglio et al., 2015; Fonseca et al., 2007).

Materials and methods

Experimental research approach was chosen to conduct this research. As the experimental research approach is all about using manipulation and testing in a controlled manner to understand the casual processes, so, this is the reason this approach was best-suited considering the nature of the research. The study was based on mixed method approach; both descriptive and calculation analysis was done to describe the findings in an understanding way.

Geographical position of sampled plant species

Three types of leafy green vegetable plants i.e. Coriander (*Coriandrum Sativum)*, Lactuca (*Lactuca sativa)*, Purslane (*Portulaca oleracea)*, belonging to the family of Apiaceae, Asteraceae and Portulacaceae, respectively were selected for the experiments to assess the impact of waste water on their growth and phenotypic parameters and to examine the impact of plants irrigated with untreated wastewater on the health of the people. In Quetta city, the practice of growing these edible plants through municipal wastewater is common. Therefore, these types of plant seeds were selected for the investigation of impact of wastewater on these plants.

Seed sample collection

Fresh Certified Seeds of Coriander (*Coriandrum sativum),* Lactuca *(Lactuca sativa)*, and Purslane (*Portulaca oleracae)* were collected from the Federal Certification Department, Quetta, Balochistan, Pakistan.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15851597

Soil sample collection

Soil samples were collected from the water and soil testing center Quetta field through random selection method by digging out the soil inside the ring. Then this soil was air dried and sieved through a 2 mm sieve.

Particle size determination

Particle size distribution is a vital parameter in soil classification. The texture of the soil was determined by calculating the percentage of clay, silt and sand present in the soil sample. The standard size of soil particles are presented in *Table 1* (Glendon, 2002; Lado et al., 2012; Keller et al., 2002; Zafar et al., 2010).

Experimental procedure

The experiments were conducted in the Botanical Garden, Botany Department, University of Baluchistan, Quetta, Pakistan. Waste water was collected from waste water channels of the known Quetta city. Various concentrations of waste water i.e. T_0 (containing 100% pure or distilled water), T_1 (containing 20% waste water), T_2 (having 40% waste water), T_3 (containing 60% waste water), T_4 (containing 80% waste water), T_5 (containing 100% waste water) were employed in the experiment to check their effect on the growth of the selected plant species using tap water as control. The selected plant species were grown in 54 pots, 18 pots for each type of plant. Each plant in a pot was irrigated with a specific prepared concentration of waste water. After irrigating, the three types of plants with different percentage of waste water, the effect of waste water on the germination rate of seed and phenotypic parameters of these selected plant species were recorded.

Data collection

Different sites of the municipal wastewater were selected for the collection of waste water after an extensive survey from March 2016 to Jun 2016. After selection of sewage effluent sites, waste water was taken for the various experiments of the study. From the recommended cultivars, the seeds of Coriander (*Coriandrum sativum),* Purslane *(Portulaca oleracea)* and Lactuca (*Lectuca sativa)* were screened for germination potential in the laboratory.

Detailed experiments were held in the Botanical Garden of Baluchistan University. In the meanwhile, the resources used in this research were many including books and scientific journals, periodicals, research articles, digital media and the materials of Human Resource Department (HRD), University of Balochistan, Pakistan.

Results and discussion

Wastewater utilization

The scarcity of water increasingly makes agriculture dependent on the reuse of water, which has led to a search of alternative sources of irrigation that justify the yield potential of crops and can also be used as a substitute to fresh water in plants. It has been forecasted that by 2050, due to the population explosion, a severe water crisis would occur for irrigation of these crops. Waste water irrigation is becoming an attractive practice for agriculture as its use not only supplies nitrogen and phosphorus

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15851597

but also nitrogen to the plants and helps to recycle nutrients in wastewater to reduce and minimize the direct use of fertilizers. It is thus reducing significantly the pollution of receiving water bodies (Connor et al., 2017; Tarantino et al., 2009; Hein et al., 1992; Connor, 2015; Ensink et al., 2004).

The waste water of any city is mainly used for irrigating vegetables near the cities. Leafy vegetable plants such as cauliflower, cabbage, spinach, etc. grow by irrigating with waste water, while some vegetables such as radishes growth does not give positive response to wastewater. Vegetables irrigated with waste water contain many heavy metals that pose serious health risks for the community and animals. This problem is of particular importance, since untreated sewage is used for a long time for vegetable growing in urban areas (Mensah et al., 2002; Kakar et al., 2006; Borkin et al., 2000).

Soil management

Managing the productivity of soil is another problem that farmers face. The ability of soil to produce useful crops is called soil productivity. It produces valuable amounts of crop and is related to the physical and chemical properties of the soil as well as hydrological and atmospheric factors of the systems in which it is located. The loss of soil productivity has been a persistent problem worldwide. With regard to the application of waste water, its use increases the production of leafy vegetable plants in the short term. However, further use has serious consequences for the productivity of soil. The optimum parameters for soil management is given in the proposed *Table 1* (Gupta, 2008; Herpin et al., 2007; Leila et al., 2007).

Table 1. *Soil/particle parameters*

S/No.	Name particle diameter	Soil particle size
1	Clay below	0.002 mm
2	Silt	0.002 to 0.05 mm
3	Very fine sand	0.05 to 0.10 mm
4	Fine sand	0.10 to 0.25 mm
5	Medium sand	0.25 to 0.5 mm
6	Coarse sand	0.5 to 1.0 mm
7	Very coarse sand	1.0 to 2.0 mm
8	Grave	1 2.0 to 75.0 mm
9	Rock greater than	75.0 m (~2 inches)

Leafy vegetable plants

Vegetables have a significant role in meeting the food requirements of people in the world and are also a good source of various essential ingredients i.e. minerals, fibers and vitamins. Vegetables are also a rich source of essential nutrients like proteins, iron and calcium that have important health benefits. Beet is a great source of vitamins like vitamins A, vitamins B_6, vitamins C, vitamins E and folate, dietary fiber of copper, calcium and its consumption is very effective for preventing a wide range of health problems (Olaniran et al., 2013; Muchuweti et al., 2006; Adhikari et al., 1998; Hernandez et al., 1991).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15851597

Radish has also many benefits for health point of views and used to treat various diseases, including pertussis, stomach problems, cancer, cough, constipation, dyspepsia, liver disorders, arthritis, gallbladder problems, gallstones, intestinal parasites and kidney stones. If leafy vegetable plants are irrigated with wastewater containing toxic heavy metals such as nickel, chromium, copper, lead, arsenic, cadmium and zinc etc., it has an adverse impact on human health (Ahmad et al., 2013; Ehmann et al., 1996; Henry et al., 2013).

Aluminum and chromium often occur concurrently in agricultural soils and causes enormous damage to plant productivity. The interactive effects of aluminum and chromium emphasize the absorption of nutrients and metals in barley. In such a situation, vegetable plant species accumulate increased amounts of heavy metals as compared to the soil not affected. This is because they absorb nickel, chromium, copper, lead, arsenic, cadmium and zinc through their leaves (Amoah et al., 2005; Joseph et al., 2002; Latare et al., 2014).

In general, urban waste water is a potential source of metals but it is still used to grow vegetables in cities. Irrigating of vegetable plants by these waste water containing toxic metals can cause various physiological and biochemical disorders (Ahmad et al., 2013; Alia et al., 2013).

This waste water is a rich source of organic matter as well as other plant nutrients. Waste water from industries of textile and paper is released into the water body or directly on the surface of agricultural land. This waste water is usually used for the irrigation of vegetables and fodder plant species due to fresh water scarcity. For increasing the soil productivity of soil mainly for leafy vegetable plants, use of untreated waste water can lead to the accumulation of metals in plants in phytotoxic amounts. The consumption of these toxic metals in vegetable plants cause diseases such as typhoid, cholera, leukemia, brain damage, diarrhea, vomiting, gastroenteritis, lung cancer, high blood pressure, pregnancy toxicity, pigmentation of the fingers nails, impairment of growth, heart failure, low blood pressure, liver neurosis, skeletal abnormalities, myocardial infarction, dermatitis, alcopia tumor, hair loss, depression and parkinsonism etc. (Ahmad et al., 1994; Husain et al., 2010).

Effect on seeds germination

Many researchers predict that the high pressure of textiles, paper, marble, dairy and brewery as well as strong osmotic pressure decreased seeds germination. Mohammad and Khan (1985) found that beans and ladyfingers plant species in the presence of industrial effluents reduced the percentage of seeds germination. However, there was no hazardous effect in the presence of treated waste water. Strong reduction in germs and early growth of radish, turnip and brassica occurred due to the use of untreated textile waste water. It was more pronounced in turnip, than in radish and brassica. Panasker and his co-workers studied the effect of textile mill effluent on the seeds germination and growth of black grams. Yousaf et al., found that with a lower concentration of sewage, seeds germination and seedling growth were higher than the control, but at higher concentrations, seeds germination and growth decreased gradually (Norton et al., 2007; Pathak et al., 1999; Saruhan et al., 2012).

The best growth of seeds germination and seedlings were observed at 25% concentration. They concluded that textile waste water is present and can be used safely for irrigation after proper treatment and recommended the 25% dilution, accordingly. Dayama (1987) reports that even in the presence of highly diluted industrial waste (5%),

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15851597

the germination of the seeds of Gram (*Cicer arietinum*) is diminished, whereas, Swaminanthan et al., found seed germination and chlorophyll improvement in the peanut plant (*Arachis hypogaea*) at 50% diluted waste. Mohammad et al., reported that 75-100% of concentrated waste water in the textile industry has harmful effects on seeds germination of Mung bean (*Phaseolus aureus)* and Okra (*Abelmoscus esculentus)*, whereas, a concentration up to 50% of the same effluent did not have any consequences (Dayama, 1987; Moreno et al., 2015).

Many researchers have documented that there are different concentrations of textile waste water and papers helping in the improvement of seedling lengths in various crops. However, it has been found that high levels of heavy metals in soils hinder the growth, metabolic processes and nutrient assimilation in plants. As per the given schedule, the rate of seeds germination were analyzed for all the plants species and checked proportionally by the waste water (Akbar et al., 2007; Dhanam, 2009).

It was clearly evident that increasing the percentage of waste water, the seeds germination were increased except in the Lactuca plant species. For clearer demonstration, the graphical representation rate of seed germination for every plant with every proportion of waste water is given in *Figure 1*. Lactuca is the plant with high effect on the growth of seed by the waste water. Increasing the waste water, its rate increased but in the other two plant species, the rate was partial. However, there is a decrease in germination of seed with waste water irrigation for coriander and purslane.

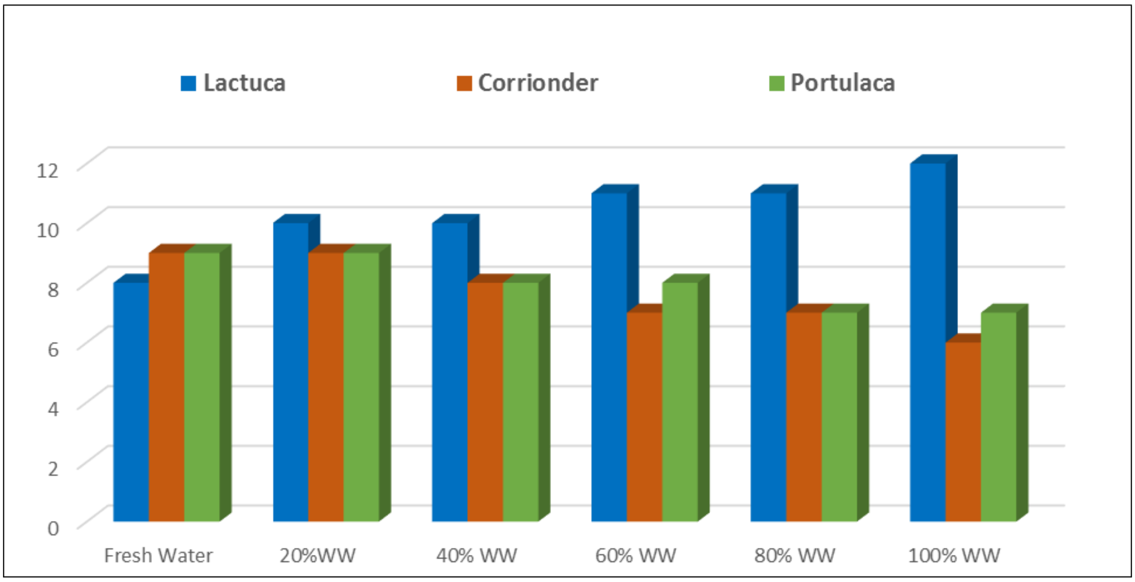

Figure 1. *Rate of seeds germination in different plant species*

It can be said that the rate of seed germination may or may not be influenced by the waste water irrigation depending on the environmental conditions. The next measuring parameter that was observed was height; the impact of waste water on the height of plants is shown in *Figure 2*. It is observed that with an increase in percentage of waste water, the height of plants was increased. An increase in height was measured in all the three plants but Purslane (*Portulaca oleracea)* has shown quicker response as compared to the other two plants.

DOI: http://dx.doi.org/10.15666/aeer/1702_15851597

Effect on green leaves elongation

Examining the increase in number of green leaves, it was observed that the numbers of green leaves were increased with higher proportion in Purslane (*Portulaca oleracea)* and Coriander (*Corianderum sativum)* as compared to Lactuca (*Lactuca sativa).* The significant impact of waste water on the number of green leaves of the plants was reported as shown in *Figure 3*.

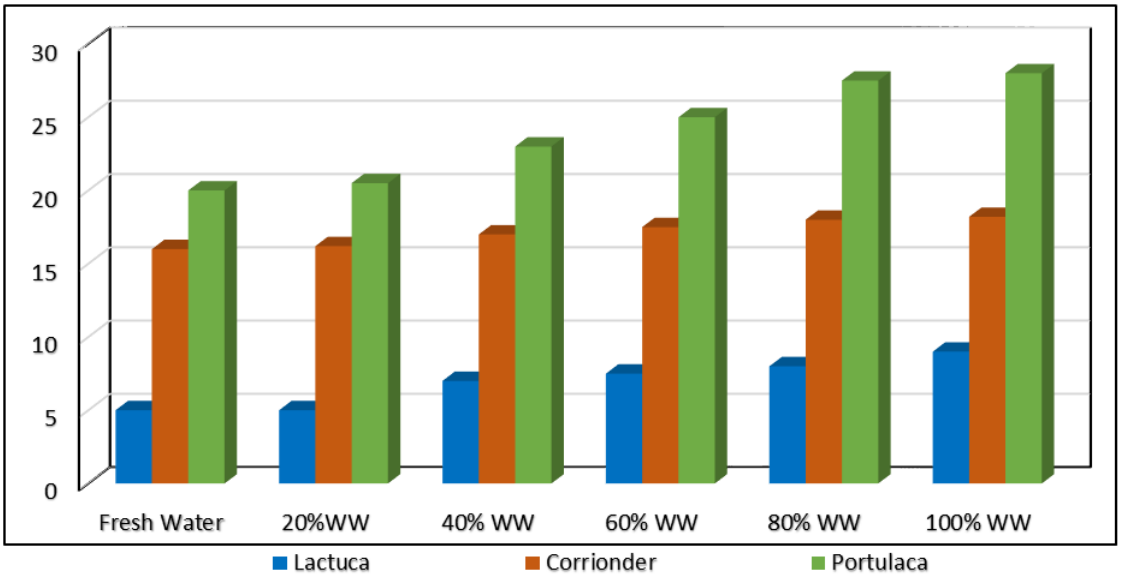

Figure 2. *Height status of different plants species (in cms)*

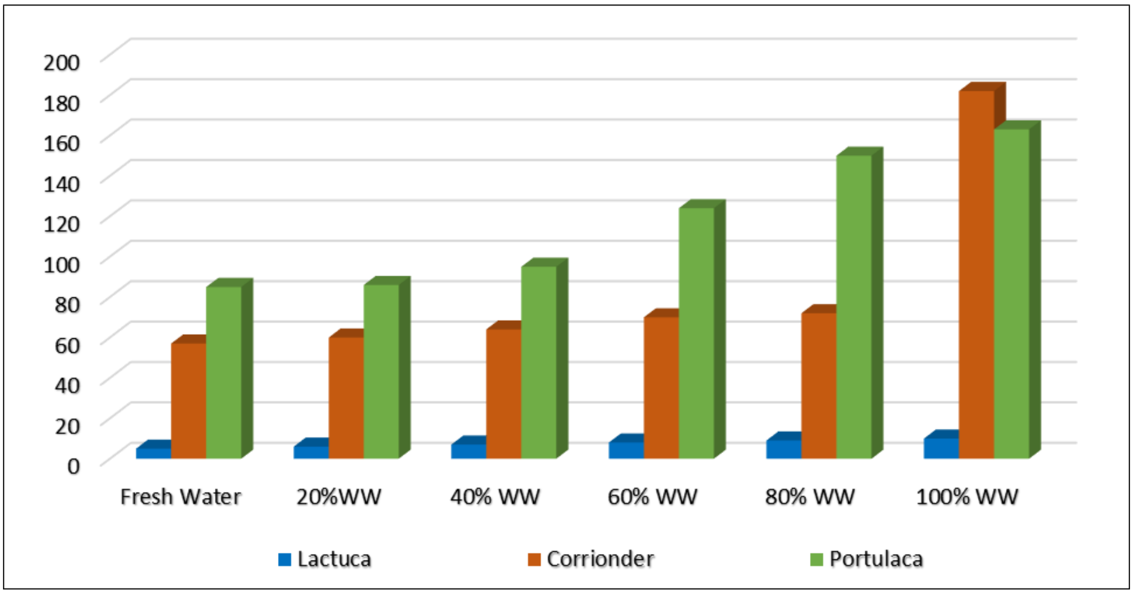

Figure 3. *Number of leaves per species in different plants*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15851597

Effect on biomass growth

By increasing the concentration of waste water, the vegetative growth of plants were increased as previously reported by other researchers (Khalil et al., 2011; Emongor et al., 2004). Waste water containing sludge increases the root length. Coriander stem length also increases with increasing waste water concentration. The sludge present in waste water also raises the biomass of coriander plant. By adding sludge to the soil a positive impact may be reached on the soil porosity, water retention by root, water-holding capacity of the soil mixture. By application of sludge to the soil, moisture content modified but the number of seed in each type of plants reduced by increasing the waste water concentration. Significant reduction in the number of seed by increasing the concentration of waste water was also reported.

Examining the increase in weight of leaves per plant, it was observed that the weight of both fresh and dry leaves were increased in Purslane (*Portulaca oleracea),* Coriander *(Corianderm sativum),* and Lactuca *(Lactuca sativa)*. It should be noted that the rate of increase in every attribute is dependent on the nature and characteristics of the plant itself. However, the increase in rate was measured for every plant but one of the plants showed much more increase in values as compared to the other two. Overall, the significant impact of waste water on the weight on fresh and dry leaves per plant was reported as shown in *Figure 4*.

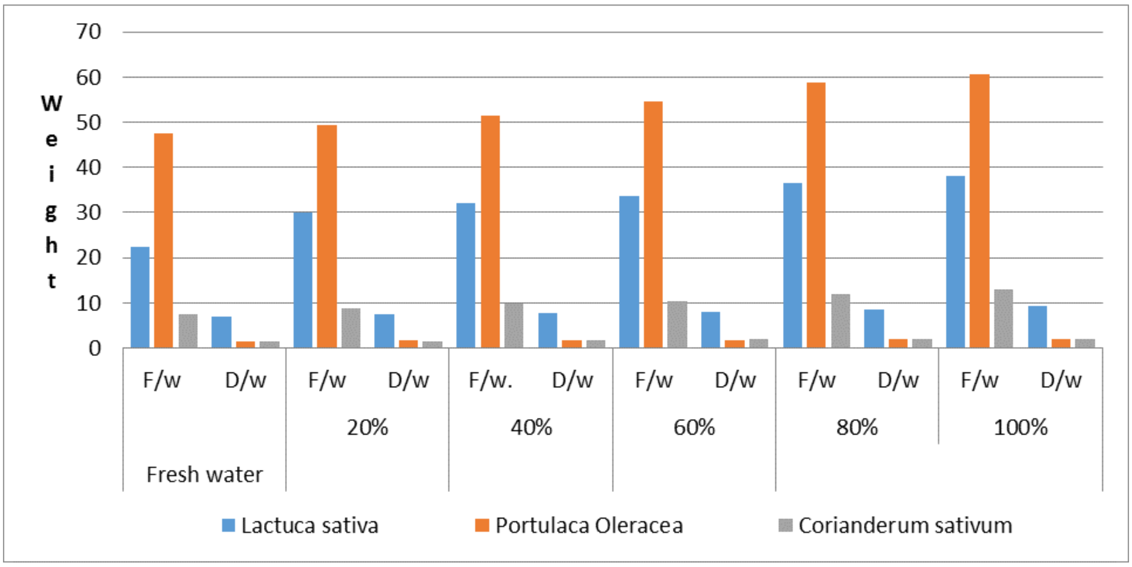

Figure 4. *Comparative weight of fresh and dry leaves in different plants species*

Conclusion

The sludge present in waste water showed a very positive impact on the growth of plants in general. By increasing the concentration of waste water, the concentration of sludge also increased and healthy vegetative growth had been observed in the waste water treated plant species. It is reported that application of sludge to the soil, moisture content was modified due to additional pores which are able to hold more water. Pore surface roughness, which enhance the water retention and reduction of micro-cracking of soil pores. Soils that hold water support more plant growth and are less susceptible to nutrient loss.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15851597

Our study revealed that all growth parameters measured in the three selected leafy vegetable plants, i.e. Coriander *(Corianderum sativum),* Purslane *(Portulaca oleracae),* Lactuca *(Lactuca sativa)* were statistically greater in waste water irrigated plant species than in fresh water plants. The usage of municipal waste water for irrigation may be an abundant resource of nutrients and essential elements for plant's growth. In fact, waste water has high concentration of organic matter and nutrients as compared to fresh water. Therefore, the nutrient accumulation occurring in the soil and this high concentration of nutrients will make the plants easy to access these nutrients.

Acknowledgements. Authors would like to express their gratitude to the technical facilities provided by Botany Department, University of Baluchistan, Quetta and COMSTAS University Islamabad, Pakistan.

Author contributions. Fahmeda Ali and Niaz Muhammad Tareen, Tahira Bibi participated in the research project, experimental findings, data compilation and participated in the preparation of manuscript draft. Kifayat Ullah, Anwar Ullah and Sadullah Laghari participated in sample collection, identification, systematic studies and the species feasibility recommendation, taxonomic studies for the proposed project, and helped to draft the manuscript. Saeed Ur Rehman supervised the overall techniques and participated in the article preparation to draft the manuscript.

Conflict of interests. All the authors listed above in the article authorship line have contributed equally to the proposed research project, and all those authors who are qualified accordingly the proposal preparation, laboratory work and report compilation are listed. To the best of our knowledge, no conflict of interests here in this research work exists.

(Received 18th Jul 2018; accepted 5th Dec 2018)

Abstract. The reduction of the size and range of populations, and the destruction of their breeding sites has led to situations in which the existence of a population depends on breeding performed by humans in controlled conditions. Such conservation and restoration work should be based on maintaining the ability of protected populations to adapt to environmental conditions. This ability is determined by genetic variation within populations as well as individual genetic characteristics specific to a given population. Managing and preserving the genetic variation of a conserved population is one of most important factors that determine the success of a conservation program. This paper reviews a method based on DNA microsatellite polymorphism and its associated techniques for detection, management and conservation of genetic variation. It covers the use of this method in detecting and monitoring changes in intrapopulation genetic variability. It also covers the usefulness of this technique in assembling breeding pairs based on their genetic profiles, evaluating genetic differences between populations, optimizing and managing genetic variation resources deposited in banks of cryopreserved gametes, and evaluating the effectiveness of programs for conservation and restoration of species. Finally, suggestions for further development of the method are included.
Keywords: *biodiversity, bioinformatic tools, conservation of endangered species, genetic variation, human dependent populations, molecular techniques*

Introduction

The rate of extinction of populations has been accelerating since the end of the 19th century, especially that of populations susceptible to environmental changes caused by human activity. Reduction of population ranges, destruction of breeding sites and reduction of population sizes have led to populations that depend on breeding performed by humans in controlled conditions (Koljonen et al., 2002). After being reared in controlled conditions, individuals are released into existing populations to extend the existence of those populations (Brown and Day, 2002).

Large numbers of progeny can be obtained from a few parents by using cryoconservation techniques and artificial breeding, but this method does not take into consideration the genetic differences between parents and their impact on population fitness. Although this method can be effective if environmental conditions are optimal, it leads to gradual reduction in the genetic variation of populations, which progresses with each succeeding generation (Fraser, 2008). This decrease in variation reduces the potential of the population to adapt and makes it vulnerable to changes in environmental conditions and invasion of pathogens, and thus could pose a threat to the existence of that population (Pastor et al., 2004; Zemanová et al., 2015).

Therefore, maintaining the ability of protected populations to adapt to environmental conditions should be the basis of conservation and restoration works. This ability is determined by genetic variation, which can be estimated with molecular techniques.

This paper reviews a method of estimating genetic variability based on DNA microsatellite polymorphism and its associated techniques, which can be used to help conserve species endangered by extinction and to solve problems in conservation biology.

The paper should serve as useful compilation of up-to-date information about this method and its applications, as well as a source of suggestions for future developments of the method.

Microsatellite DNA

Microsatellite fragments of DNA constitute a substantial part of the genome of eukaryotic organisms (Charlesworth et al., 1994; Sawera et al., 2001). They are commonly used as a marker of genetic diversity in protected populations (Nielsen and Sage, 2001; Kim et al., 2004; Jurczyk, 2006; Zemanová et al., 2015). Microsatellite DNA is also used in monitoring the genetic fitness of conserved populations and in tracking their interaction with other populations (Wąs and Wenne, 2002).

Microsatellite DNA has a number of characteristics that make it useful for these purposes. First, changes within microsatellite sequences are inherited according to Mendel's laws. Second, because changes in microsatellite fragments are not subject to natural selection, it is likely that the individuals that are heterozygous in many of the microsatellite loci may also be heterozygous in loci encoding proteins responsible for their adaptability. Thus, the degree of polymorphism of microsatellite loci is a measure of the level of genetic variability in a stock or natural population (Guichoux et al., 2011). Third, microsatellite fragments can be used as universal markers and will not be affected by chromosomal mutations, because they are evenly distributed within chromosomes (Sawera et al., 2001). Fourth, these fragments are adjacent to evolutionally preserved flanking sequences (Santana et al., 2009). The presence of these flanking sequences enables the design of short oligonucleotides (primers) and the replication of mini-microsatellite sequences using the Polymerase Chain Reaction (PCR) (Sztuba-Solińska, 2005). Finally, microsatellite DNA can be used to detect very small genetic differences between organisms. This is because microsatellite fragments are some of the most polymorphic fragments of DNA, due to the presence alleles differing in length in a given chromosomal locus. The differences in length result from variations in the number of the repeat motifs that make up a microsatellite DNA fragment (O'Conell and Wright, 1997; Kelkar et al., 2010).

Advantages of Microsatellite DNA for Estimating Genetic Variability

Although the various techniques for estimating genetic variability have their advantages, the use of microsatellite DNA for this purpose has a number of advantages that make it a method of choice in a wide range of applications. For example, single nucleotide polymorphisms (SNP) can be used in studies on genetic variation as well. The SNP technique requires the analysis of many sites of point mutations, and therefore also requires detailed knowledge of the genome of the investigated species (Fernández et al., 2005). This can be a limitation of the SNP method because the genomes of many endangered species are mostly unknown. In contrast, the region flanking a microsatellite marker is evolutionary conserved, which allows these markers to be amplified when they are present in closely-related species and genomic knowledge about one of the species is lacking. Methods based on microsatellite DNA also offer other advantages over methods based on anonymous multilocus genomic markers (RFLP, AFLP, ISSR)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15991615

and on SNPs: the microsatellite technique is easily transferable between laboratories; it requires only limited equipment and computational facilities; it provides a high polymorphism information content (PIC) per locus; and it is highly cost efficient when only a small number of loci are needed (Bezault et al., 2012). For these reasons, microsatellites markers are likely to remain the optimal choice for a wide range of ecological and evolutionary studies (e.g., relatedness and parentage analysis, population diversity and demography assessment, noninvasive genetic analysis, and conservation) (Bezault et al., 2012).

Methodological Considerations

To properly assess genetic differences on the basis microsatellite DNA polymorphism, samples must be taken from an appropriate number of individuals (Ruzante, 1998; O'Connell and Wright, 1997). These samples need to be properly acquired and preserved. PCR primers and the PCR reaction must be properly designed, and the lengths of DNA fragments need to be measured.

Typically, the sample size for inferring the amount of genetic variation in the population is a few dozen individuals (Hart et al., 2014). The number of individuals in a sample is usually difficult to determine because it depends on the number of genetic markers used and their polymorphism (O'Connell and Wright, 1997). As the number of individuals and the number of microsatellite markers that are examined increase, the precision of the estimates of genetic differences within and between populations also increases (O'Connell and Wright, 1997). However, it can be difficult to increase the number of individuals in a study due to limited availability and increased costs. As a guideline, if at least 5 markers are used and their polymorphism varies between 5 to 10 alleles, a sample size of about 50 individuals should be used (O'Connell and Wright, 1997). In studies based on 10 polymorphic microsatellite markers, increasing the number of individuals from 50 to 100 had no significant effect in the level of genetic diversity estimated in the population (Ruzzante, 1998).

Samples for analysis of microsatellite DNA polymorphism can be collected from live individuals (Powell et al., 1996). This enables studies on commercially valuable individuals and endangered species, such as marine vertebrates (Thorpe et al., 2000) and many fish species (Kumar et al., 2007; Naik et al., 2018). If the results are used for optimizing the assemblage of individuals into breeding pairs, the individuals should be marked before sample collection, which can be done with microchip tags (Kaczmarczyk and Fopp-Bayat, 2012).

After sample collection, the tissue should be preserved until DNA extraction. Unfortunately, using 70% ethanol and then storing the tissue at 4°C does not always successfully preserve the DNA. A much more reliable method is drying samples in a laboratory drier, placing them in paper envelopes and storing them at about 20°C until DNA is isolated (Kaczor, 2013).

DNA can be extracted with a phenol/chloroform extraction protocol (Sambrook et al., 1989) or DNA extraction kits, which are designed for extracting DNA from tissues like blood, muscles, etc. (Żuchowska, 2011; Kaczor, 2013; Ocampo et al., 2018), allowing various tissues to be used as a source of DNA.

To amplify microsatellite fragments with the PCR technique, primers that are complementary to the regions of DNA that flank the microsatellite are needed. The primers’ sequences can be obtained from published reports on the genetic variation of a species, and from the National Center for Biotechnology Information database at

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15991615

www.ncbi.nlm.nih.gov. When studying a species with a little known genome, like the lake minnow, DNA sequencing is useful for identifying microsatellite loci (Furukawa et al., 2004; Grover and Sharma, 2016). Furthermore, because the sequences surrounding microsatellite DNA are often conserved, it is often possible to use a set of primers that have been developed for another species that is not too phylogenetically distant. For example, primer sets that were designed for use with the zebra fish (*Danio rerio*) or with other species of cyprinid fish such as *Campostoma anomallum* can be used in studies of the lake minnow (*Eupalasella percnurus*) (Kaczmarczyk and Żuchowska, 2011; Kaczmarczyk, 2013; Gadomski, 2013).

Microsatellites can be amplified separately, via singleplex PCR, or together in a single multiplex PCR reaction (Edwards and Gibs, 1994; Migliaro et al., 2013), which allows up to 21 genetic markers to be amplified in a single PCR reaction (Shewale et al., 2013). Multiplex PCR not only accelerates research and reduces the costs of analyses (Guichoux et al., 2011; Migliaro et al., 2013; Liu et al., 2017), but also combines well with the use of an automatic capillary DNA sequencer for detection of microsatellite DNA polymorphism. To assemble a group of genetic markers into a multiplex set, the primers need to be labelled with phosphoramide dyes at the 5' end so that the product of amplification of one locus can be distinguished from the product of another. Either the forward or the reverse primer should be marked in each set. If the PCR products of two or more microsatellites have a similar size range, each primer pair should be marked with a different type of phosphoramid dye (Liu et al., 2017).

Automated capillary electrophoresis is the primary method of detection of microsatellite DNA polymorphism. It can detect single nucleotide differences in DNA lengths (Butler et al., 2001), and it allows greater accuracy, speed, and reproducibility than previous methods of detecting polymorphism of microsatellite loci. Automatic capillary electrophoresis is carried out in a polyacrylamide gel that is optimized for use in a specific type of automatic DNA sequencer and for a specific method of measuring DNA fragment length (Mansor et al., 2015). It is combined with software that detects differences in the length of DNA fragments, stores the results, and can perform further analyses, such as genotyping (Dennis et al., 2010).

To meet the objectives of conservation biology, the genotyping results from the investigation of microsatellite DNA polymorphism can be subjected to mathematical and statistical analyses using various software packages. These packages can be divided into four groups. The first group comprises software that calculates indicators of genetic variation within populations and the genetic distance between populations, and compares those indicators across populations to track phylogenetic relationships. This group includes software such as ARLEQUIN (Excoffier et al., 2005; Excoffier and Lischer, 2010), MSA (Dieringer and Schlötterer, 2003), STRUCTURE (Pritchard et al., 2000; Falush et al., 2003, 2007; Hubisz et al., 2009), GENEPOP (Rousset, 2007) and others. There is some overlap between the first group and the second, which comprises programs that can estimate the likelihood of events that affect genetic variation, such as migrations, and bottleneck and founder effects; these programs include ARLEQUIN (Excoffier et al., 2005; Excoffier and Lischer, 2010), BOTTLENECK (Piry et al., 1999), STRUCTURE (Pritchard et al., 2000; Falush et al., 2003, 2007; Hubisz et al., 2009). The third group comprises software for optimal assemblage of individuals into breeding pairs, based on their genetic profiles and indicators of the genetic variation expected in their progeny, such as GENEASSEMBLAGE 1.0 (Kaczmarczyk, 2015). The fourth group comprises programs that combine the use databases and genetic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15991615

profiling to determine the origin of individuals or commercial products, for example SPAGeDi software (Hardy and Vekemans, 2002) and COLONY (JoneS and Wang, 2009).

Microsatellite DNA polymorphism for conservation of endangered populations

The uses of the analysis of DNA microsatellite polymorphism can be divided into two categories. First, genetic variation can be assessed at the intra- and interpopulation levels. This assists in identifying processes affecting genetic variation and assessing methods for maintaining and managing genetic resources, including the genetic variability of populations created in conservation programs and the restitution of extinct populations (Kim, et al., 2004; Hart et al., 2014). Second, the genetic profiles of individuals can serve a variety of other ends. For example, the survival of individuals obtained under controlled conditions can be compared to that of individuals produced via natural reproduction (ICES WGBAST, 2017). Individual genetic profiles can also be used to manage cryopreserved gamete banks, to optimize assemblage of individuals for breeding (Abdul-Muneer, 2014), and to identify interspecies hybrids (Cruz et al., 2014).

Detection and monitoring of changes in intrapopulation genetic variability

Breeding individuals from local populations under controlled conditions can increase the likelihood of breeding closely related individuals, and thus reducing the genetic variability of the population. When a small number of individuals whose relationship is unknown are used for breeding, the risk of inbreeding increases (Bentsen and Olesen, 2002). Inbreeding usually increases homozygosity (Yi et al., 2015), which may decrease allelic diversity, which may affect the adaptive ability of the population (Charlesworth and Charlesworth, 1987; Saccheri et al., 1996; Crnokrak and Roff, 1999; Hedrick and Kalinowski, 2000; Chapman et al., 2009; Nielsen et al., 2012) and may lead to expression of genetic defects encoded by recessive alleles (Charlesworth and Willis, 2009; Gao et al., 2015).

The harmful effect of inbreeding on viability and population fitness is more evident in populations than in commercial stocks (Crnokrak and Roff, 1999; Whitlock, 2004; Harrison et al., 2011) and may cause programs for conservation of endangered species to fail (FAO/UNEP, 1981; Olech, 2003; Hallerman, 2003). Estimating genetic variability based on microsatellite DNA polymorphism is thus a useful tool that can be used to determine the level of genetic diversity in a protected population. It can be used for comparisons with stable populations that do not show inbreeding depression (Kaczmarczyk and Żuchowska, 2011; Gadomski, 2013), and for detection of differences between populations that are important for their survival in their respective environments (Gadomski, 2013; Abdul-Muneer, 2014).

Based on the length of DNA fragments and genotyping results, indicators of genetic variation can be calculated. These indicators are the observed (H_o) and expected heterozygosity (H_e), genotypic and phenotypic diversity, the percentage of polymorphic loci (P), the average number of alleles in a locus (A) and allelic richness (R) (Min et al., 2015; Long et al., 2017). For assessing genetic variation and tracking its changes, the most important of these indicators are heterozygosity and allelic diversity (Hoban et al., 2014). Low values of (H_o), (H_e) and (A) indicate low genetic variation in the population (Szczecińska et al., 2016), and a statistically significant difference between (H_o) and (H_e) indicates a departure from Hardy-Weinberg equilibrium. This departure can reflect a disturbance in the genetic balance of the population, possibly connected with changes

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15991615

in population size or with non-random assemblage of individuals in reproductive pairs (Hansen et al., 2008). By comparing these indicators of genetic variation with historical data and data from other populations, the genetic diversity in a population can be assessed, and actions can be taken to counter diversity loss, if necessary (Kim et al., 2004). These indicators can be calculated with software packages such those mentioned above.

Detection of the consequences of reduction of genetic variability resulting from founder and bottleneck effects

A founder effect occurs when only a few individuals start a new population, causing the genetic variation of the new population to be only a fraction of that of the parent population (Whitlock and McCauley, 1990; Kusza et al., 2013; Rochet and Lise, 2016). A bottleneck effect might be caused by environmental changes or human activity, such as overfishing (Rochet and Lise, 2016). This temporary reduction in population size reduces the genetic variation in the population. A bottleneck effect may also result from reproduction under controlled conditions. Populations whose existence depends on reproduction in controlled conditions where a small number of parental individuals are used are especially vulnerable to genetic bottlenecks (Price and Hadfield, 2014).

The polymorphism of microsatellite DNA can be used to estimate the probability that a founder or bottleneck effect occurred, and the size of those effects (Knapen et al., 2003). To this end, microsatellite DNA fragments are used to track changes in the number of alleles, allelic frequencies and heterozygosity. Based on this data, the Garza-Williamson (G-W index) can be calculated. This index provides information about the size of the founder or genetic bottleneck effect that probably occurred in the history of the population. It is calculated on the basis of two numbers. The first is the number of alleles of a given microsatellite, and the second is the allelic range. This range is the difference in length between the longest and the shortest fragments that contain that microsatellite. The G-W index is based on the observation that, when population size decreases, the number of alleles at a microssatelite locus is more likely to be reduced than the allelic range. Thus, the index is calculated for polymorphic loci by dividing the number of alleles of a given microsatellite in a population by its allelic range plus one. In a population that did not experience a genetic bottleneck, the G-W index ranges from 0.8 to 1. Values below 0.8 indicate the possibility of reduction of genetic variability, while those below 0.6 indicate a significant reduction in genetic variability due to a genetic bottleneck effect (Garza and Williamson, 2001).

As an alternative, the expected heterozygosity (H_e) and the heterozygosity resulting from genetic drift and mutation (H_{eq}) can be compared, and the distribution of allelic frequency at microsatellite loci can be determined (Cristescu et al., 2010). In this procedure, one of three models can be used: the infinite alleles model (IAM), the stepwise mutation model (SMM), or a combination of these two hypotheses, the two phase model (TPM) (Di Rienzo et al., 1994). The two phase model is based on the observation that heterozygosity and allelic frequency reflect changes in population size (Rosa de Oliveira et al., 2009). If H_e is significantly higher than H_{eq} (typically at $p \leq 0.05$) and the distribution of alleles has changed from an L-shape to shifted, then the population is likely to have been affected by a bottleneck or founder effect in the recent past (Hart et al., 2014). These calculations can be performed with BOTTLENECK software (Piry et al., 1999; Cristescu et al., 2010).

Assemblage of breeding pairs based on their genetic profiles

Using individuals for captive breeding without knowing their genetic characteristics can lead to a progressive decline in genetic variation, because the probability of breeding individuals that are genetically similar to each other is higher than that of breeding those that differ substantially (Kaczmarczyk, 2016; Aguiar et al., 2018). The resulting offspring will have lower heterozygosity and allelic diversity than their parents, and this process is likely to progress with each successive generation (Bentsen and Olsen, 2002; Fraser, 2008). For this reason, techniques for genetic management of broodstock should be applied (Blackie et al., 2011) genetic profiles should be prepared before individuals are selected for breeding and assembled into pairs. These profiles should include information such as the individual's sex, the population it came from, and a list of the alleles of microsatellite DNA that were detected across the investigated microsatellite loci (Kaczmarczyk, 2015). These profiles can be used to produce progeny that are as genetically diverse as possible because only the individuals that genetically differ the most will be selected and assembled into breeding pairs. To find the best pairs out of many possible combinations, software like Geneassemblage 1.0 (Kaczmarczyk, 2015) can be used, which is appropriate not only for diploid organisms but also for tetraploid or partially tetraploid organisms because it calculates the expected percentage of offspring with three alleles that are the same and a fourth that differs, i.e. "weak heterozygotes" (Fopp-Bayat et al., 2015).

Evaluation of genetic differences between populations

Allelic frequency can change in response to environmental conditions. These changes cause and maintain genetic differences between populations (Higgs and Derrida, 1992) that can be essential for their survival (Barraclough and Nee, 2001). Thus, preservation of genetic diversity is important for the success of conservation programs: for example, the maintenance of the unique genetic characteristics of cheetah, lion, panther and humpback whale populations is closely related to the success of conservation programs (O'Brien, 1994; Hedrick and Fredrickson, 2010).

Genetic distance is a measure of the difference in genetic characteristics between populations and species. Interpopulation genetic differences are manifested by the occurrence of private alleles and differences in allele frequencies (Avise, 2004). Private alleles are variants of microsatellite DNA fragments specific to a given species, population or group of populations. Identification of the private alleles in an individual's genotype enables determination of the population it came from and whether it is an interspecies hybrid (Van Dongen et al., 2012). In contrast to private alleles, common alleles are detected in all studied populations (Slatkin, 1981). As the phylogenetic distance between populations increases, the number of private alleles increases, the number of common alleles decreases, and the frequencies of alleles in the respective populations differ to a greater extent (Rosenberg, 2011).

To estimate genetic distance, gene flow between populations and interrelations between species, methods based on microsatellite polymorphism can be used (McManus et al., 2015). Although a description of all of these methods is beyond the scope of this paper, more than one method should be used, and their results should be compared (Balloux and Lugon-Moulin, 2002; Haris et al., 2013). Two methods are given below as examples.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15991615

One of the most commonly used methods is based on the fixation index (F_{ST}). To determine the statistical significance of F_{ST}, a permutation test is done, and the *P*-value indicates the proportion of the permutations that give an F_{ST} greater than or equal to the observed F_{ST} (Reynolds et al., 1983; Slatkin, 1995). F_{ST} is proportional to the genetic differences between populations. Its value ranges from 0 to 1, where 0 indicates no genetic distance, and 1, the largest possible difference between populations. Typically, a value of 0.05 or less indicates a very small genetic difference; 0.05-0.1 a moderate; 0.1-0.25, a large; and above 0.25, a very large genetic distance (Balloux and Lugon-Moulin, 2002).

As an alternative to F_{ST}, the difference in mean size of alleles ($\delta\mu^2$) can be calculated, which compares the mean allele sizes of microsatellite segments in terms of repeat number (Goldstein et al., 1995). The method is largely unaffected by differences in sample sizes, although it shows bias with small sample sizes (Ruzzante, 1998). Unlike F_{ST}, there is no upper limit to the value indicating genetic distance that is calculated by this method. A value of $\delta\mu^2$ above 10 indicates a very large genetic distance between populations (Goldstein et al., 1995; Harris et al., 2013). $\delta\mu^2$ can be estimated using MSA 4.05 (Dieringer and Schlötterer, 2003).

The genetic distance between pairs of populations and the intrapopulation genetic diversity can be represented graphically (Waser and Strobeck, 1998). The graph is based on a genetic assignment test, which determines the probability of occurrence an individual with a specific genotype in its native population versus the probability of its occurrence in another population (Larson et al., 2014; Kaczmarczyk and Wolnicki 2016). Those calculations are performed by Arlequin software (Excoffier et al 2005; Excoffier and Lischer, 2010), and can be imported into an Excel spreadsheet (Microsoft, USA) and scaled as co-ordinates in an X–Y coordinate system. If a point representing an individual lies on the diagonal between the X and Y axes, the probability of its occurrence in its native population is the same as the probability of its occurrence in the alternative population. Points that are closer to one axis than to another have a greater probability of occurring in the population that corresponds to the nearer axis than in the other population, and the further the points are from the diagonal, the greater the probability of that individual occurring in the population that corresponds to the nearer axis. The spread of points within a cloud of points representing a group of individuals shows the degree of intrapopulational differences, and the distance between the points indicates the genetic differences between the individuals in that population (Kaczmarczyk and Wolnicki, 2016).

Optimization and management of genetic variation resources deposited in banks of cryopreserved gametes

Cryopreservation of gametes is a method for protecting the genetic resources of a population (FAO, 2012), and is used to safeguard the level of genetic variability (Yang and Tiersch, 2009) in the event of a catastrophe resulting in the extinction of the population. It is used for both endangered species and economically valuable breeds and breeding lines (Zhang, 2004; Cabrita et al., 2010).

The potential usefulness of cryopreserved gametes in protecting the genetic variability of a population depends on the genetic diversity of the individuals from which the gametes were collected (FAO, 2012). If gametes from a group of individuals are cryopreserved without taking into account the genetic differences between them, only a small part of the genetic variation in that population may be preserved. This

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15991615

could lead to a strong founder effect, resulting in a restored population with too little genetic variation to ensure its survival. Increasing the size of the group from which gametes are collected is not an ideal solution because it not only increases the cost of creating a gamete bank, but also does not always safeguard the genetic diversity of the population. This is particularly a concern for species such as the lake minnow, whose populations are characterized by low levels of genetic diversity (Kaczmarczyk and Żuchowska, 2011; Kaczmarczyk and Wolnicki, 2016).

To address the potential problem of a lack of genetic diversity in preserved gametes, genetic profiles of gamete donors can be developed using microsatellite DNA polymorphism to indicate which individuals differ the most and are especially valuable for conservation of genetic diversity in that population. This technique can be used with genomes that are relatively little investigated, and it enables maximum conservation of genetic diversity with the minimum number of samples. The resulting information can be used to assemble breeding pairs (Danchin-Burge et al., 2009) and maintain the genetic diversity of the population (Fernández et al., 2005).

The polymorphism of microsatellite DNA as a tool for evaluation of the effectiveness programs for conservation and restoration of species

Maintaining the level of genetic diversity of protected populations is one of the criteria for assessing the effectiveness of conservation programs (Stem et al., 2005), and investigations of the polymorphism of the microsatellite DNA can be used for this purpose. The results of investigations of microsatellite DNA that are obtained from samples taken from the current population can be compared with those from archival material (Abdul-Muneer, 2014), which can be formalin or paraffin-treated tissues (Shi et al., 2004; Wu, 2005) and scales (Kumar et al., 2007), or bones (Piglionica et al., 2012). Alternatively, the genetic diversity of a conserved population can be compared with that of stable populations in which there is no decrease in viability (Gadomski, 2013). It is possible to check whether the genetic variability of the newly created population of conserved species is close to that of a population that has existed for many years (Kashiri et al., 2018). It is also possible to estimate the size the founder effect involved in the creation of a new population (Gadomski, 2013).

In human-dependent species, the survival rate of individuals obtained in controlled conditions and released into the environment also indicates the effectiveness of conservation programs. In this context, microsatellite markers are used to determine whether an individual was produced by natural reproduction or human-controlled reproduction (Martínez and Fernández, 2008). A database with the genetic profiles of individuals used in reproduction and the use of SPAGeDi (Hardy and Vekemans, 2002) or COLONY software (Jones and Wang, 2009) enable estimation of the probability that an individual was produced by artificial or natural reproduction. Estimating the relative amounts of individuals produced by natural reproduction and those produced in controlled conditions indicates the relative effectiveness of natural breeding and conservation or restoration programs. This technique has been used for example in evaluation of the effect of the release of brown trout (*Salmo trutta* L.) obtained under hatchery conditions on the genetic characteristics of the Danish population of this species (Hansen et al., 2000) and in monitoring the effectiveness of programs for the conservation of sea trout (*Salmo trutta morpha trutta)* and salmon (*Salmo salar*) (Bartel, 2000; Wąs and Wenne, 2002; Nilsson et al., 2008; Jones et al., 2010; ICES WGBAST, 2017).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15991615

One approach that is used in conservation programs is limited translocation, in which endangered populations are relocated to safer habitats. This method is currently used in the conservation of many species including the lake minnow (Kusznierz et al., 2006; Kaczmarczyk and Wolnicki, 2016). Because the effectiveness of this strategy depends on the degree of genetic diversity achieved by the population in the target location, the factors that decrease genetic variability, such as the founder effect, should be limited (Fraser, 2008). When the genetic characteristics of the source population and the genetic profiles of individuals are known, it is possible to minimize the size of the founder effect by choosing the optimal size and composition of the group that will be transferred (Gadomski, 2013). Furthermore, the information obtained about the source population will allow comparison of the genetic diversity of the source population with that of the newly established population, and estimation of the influence of the founder effect on the new population, which in turn allows assessment of the effectiveness of this method of species conservation.

To counteract changes in the environment due to human activities, species restoration can be employed. The main objective of these programs is to ensure that the genetic characteristics and functionality of the restored population are as close as possible to those of the original (extinct) population. To this end, individuals are selected from the available populations whose genetic characteristics are as similar as possible to those of the extinct population (Falk et al., 2001). The accuracy of this selection depends on the use of techniques such as the evaluation of genetic differences based on the polymorphism of the microsatellite DNA (Cibrian-Jaramillo et al., 2013). This technique was used, for example, in the program for restitution of Baltic salmon in Pomeranian rivers, in which evaluation of microsatellite polymorphism showed that the most similar existing population, and thus the most appropriate for use as stocking material, was the population spawning in the Daugava river (Bartel, 2001).

Future directions

Future developments in the application of microsatellites should include studies of the correlation between levels of genetic variation determined on basis of microsatellite DNA polymorphism and population fitnes. If we find that decreased genetic variation, as determined by this technique, correlates with reduced population fitness, then we will be able to use microsatellite DNA polymorphism to indicate which conservation projects should be given priority. This task will require genetic analysis of many individuals and populations, so the developement of multiplex PCR techniques for all relevant species is yet another task that should be undertaken. Finally, the future of investigations of microssatelite loci in conservation biology should involve combinations of the results of studies on intra- and interpopulation variation and genetic profiling with bioinformatic tools designed to manage genetic variation on both local and worldwide scales. Tools such as databases of genetic profiles of individuals and donors of gametes deposited in cryoconservation banks, combined with software designed to evaluate genetic similarity between individuals will be the future of conservation/restoration programs based on progeny produced in controlled conditions.

Summary

This paper has reviewed a molecular method based on analysis of the polymorphism of microsatellite DNA for use in the conservation and restoration of endangered

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_15991615

populations. This method is particularly useful when the conservation or restoration work involves supporting populations with individuals obtained in controlled breeding programs. Analysis of microsatellite DNA polymorphism can be used to estimate and monitor genetic variability, and to select individuals for breeding or transfer that will maintain a safe level of genetic variation in a population. Furthermore, this method can also be used to optimize the selection of gametes for cryopreservation. The analysis of microsatellite DNA polymorphism can help not only to ensure the lasting success of conservation and restoration projects, but also to reduce costs by indicating how many individuals should be included in a project.

(Received 4th Oct 2018; accepted 2nd Jan 2019)

Abstract. In contemporary agricultural based economies, smallholder farmers are encouraged to organize and reunite themselves into different forms of association, for overcoming major challenges and obstacles imposed by the market functionality and barriers, land grabbing and land fragmentations, ownership rights or reducing transaction costs. But farmers are often resistant to associate, due to the way in which cooperation was made in the previous regime in Romania. The objectives of this paper are to identify both the farmers' willingness to associate in any associative form, considering the current economic context in which cooperatives are established on voluntary bases, and also to highlight the determinants of their willingness to join an associative form from the broad perspective of a short supply chain. The research is specific targeted to for vegetables and fruits producers. The results provide an overview of the intensions of the farmers' willingness to associate and create better comprehension of this situation in the Romanian agriculture. Consequently, the paper points out, that the probability of farmers' willingness to adhere to a associative form or in a short supply chain environmental responsible is often hampering by factors as: age, education level, cultivated area, activity type, year of establishment, opportunities to access financial support which confirms the gap between economic necessity to associate and the traditional restrictions.
Keywords: *supply chain, environmental farming, ecologic products, agricultural policy, holdings*

Introduction

Emergent countries as Romania, with a significant share of the agricultural sector in the national economy provide a unique opportunity to study farmers' willingness to associate in any associative form and to adhere in environmental responsible short supply chain as land reforms have redistributed the land ownership rights and liberalized land exchange restrictions imposing the free market economy rules. While much studies has been written on land reforms (Cartwright, 2017), land ownership (Sabates-Wheeler, 2001; Vidican, 2009), land fragmentation (Thomas, 2006; Kuemmerle, 2009; Sikor, 2009) importance of agriculture in domestic economies (Aligica, 2003; Davidova et al., 2003; Mănescu et al., 2016; Aničić et al., 2018; Hu et al., 2018), farm restructuring and land grabbing (Van der Ploeg, 2015; Constantin,

DOI: http://dx.doi.org/10.15666/aeer/1702_16171639

2017) in transition countries, still few researches have concentrated on providing formal conceptual and economic analysis of the farmers' willingness to associate and their determinants to form agricultural cooperatives and other forms of joint exploitation of agricultural potential.

The central goal of stimulating the process of associating agricultural producers in agricultural cooperatives or other forms of specific agricultural association is to establish viable agricultural production structures in private farming sector. However, in Romanian agricultural sector, land privatization and numerous land reforms has led to a more problematic economic and social situation by dividing large land properties, previously existing and economically efficient, into numerous small privately and less economic viability holdings. The excessive land ownership fragmentation has caused significant problems in valuing agricultural potential and in creating agriculture that fulfills the demands of the market economy by increasing competitiveness and living standards in rural areas.

The evolution of the farmers' willingness to associate in any associative form has a long history in Romanian agriculture. The Romanian agricultural sector has experienced numerous and often unfinished land reforms during the process of implementing and achieveing a well and functional market economy imperatives. As (Dale and Baldwin, 2000; Hartvigsen, 2014) argues in their studies, numerous farm structures and holdings have emerged during the reforms which are now, incompatible with modern agricultural practice and tendencies. The contradictory evolution of farmers' willingness to associate is often due to the historical background of land ownership situation triggered by collectivization process and sharing agricultural benefits among members. From this perspective, achieving a competitive and highly functional agricultural sector impose agricultural cooperation as a functional and potential instrument in stimulating the capitalization of the national agricultural potential and developing the short supply chains. Taking into account the evolution of national agricultural sector, the term "cooperation" raises many contradictions and emotional reactions to Romanian farmers, since it is linked to the forced cooperation during the communist period. At that time, the cooperatives were not established on the traditional cooperative principles and values: voluntary and open membership, democratic member control, autonomy and independence (ICA, 2018), and this is the reason why farmers are still resistant to cooperation. Despite the fact, that nowadays, cooperation is made on voluntary membership and farmers' willingness to associate and has a more comprehensive approach which is centered on the principles of efficiency and competitiveness and less on considerations of social nature, belonging to a social community or social group in rural area.

As in literature (Nosenzo and Tufano, 2017), voluntary participation has a strong, positive effect on cooperation, as reported by Nosenzo and Tufano (2017). Thereby, the main objectives of the research are to find whether the farmers want to join an associative form, in the current economic context in which cooperatives are established on voluntary bases, and to identify the determinants of farmers' willingness to join a short supply chain and an associative form. In this context, a need to explore the determinants and economic impacts of membership in farmer cooperatives and food supply chains in Romania is necessary in explaining the reasons of farmers' willingness or resistance to membership.

The relevance of the topic emerged from the low level of farm efficiency in Romania, attributed to the small size of farms. There are 3,342,185 holdings and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_16171639

12,502,535.5 ha of cultivated land, resulting an average farm size of 3.74 ha, as National Institute of Statistic of Romania reported for 2016 (NIS, 2018). Also, as it is reviled in some national studies (CRPE, 2016), in 2015, there were 743 agricultural cooperatives in Romania, most of them being found in the North-East region of the country, as reported by the National Trade Register Office. The Ministry of Agriculture and Rural Development presented that less than 1% of Romanian agricultural producers are part of associative structures, as compared to 34%, the European Union average.

For overcoming this problem, some authors (Narrod et al., 2009, Bernard et al., 2010) consider that the solutions could be either farmers' association in different forms (marketing, selling or processing cooperatives, producers' organizations or agricultural associations), known in literature as horizontal integration (Malassis, 1992), or farmers' integration into a supply chain, known in literature as vertical integration. Both horizontal and vertical forms of integration lead to higher performance in carrying out the agricultural activities (Ion, 2005).

The term supply chain is defined by Malassis et al. (1992: p. 94) as the itinerary of a product or group of products within the agro-food system and comprising all agents and operations that contribute to the formation and transfer of products to the final stage of use. In some cases, the chains are long and complex, as reported by Manole et al. (2005), implying numerous agents and operations. Since every agent within the chain asks for a certain profit considering the activities performed, increasing, finally, the prices that the consumer pays for products, the need to shorten the chain has emerged.

The attempts to shorten the supply chains are encouraged and financed by the Ministry of Agriculture and Rural Development of Romania, through the National Program for Rural Development. Short supply chain is defined as the configuration of the food chain that does not involve more than one intermediary between producers and consumers (MARD, 2016: p. 43). A short supply chain implies fewer agents, but the same number of operations, meaning that the activities of the chain are performed by the remaining two agents – farmer and retailer (Marin et al., 2017).

Since the solution agreed to overcome the low level of farm's efficiency seems to be the producers' association, the public agricultural policy in Romania aims to encourage farmers to associate, using subsidies, financial support or preferential financial leverage for associative forms. If referring to fruits and vegetables branch, the public policy grants financial support to producers' organizations (Romanian Government Decision no.740/2017). Integration, including association, is also stimulated through the National Program for Rural Development in Romania, where one specific measure (16.4) refers to financial support for horizontal and vertical cooperation between the actors in the supply chain (MARD, 2017).

Understanding farmers' motivations for cooperation, and the tension associated, is important for the expectation management and funding efficiency (Wynne-Jones, 2017), at a time when great funding and support is being channelled through the European Union Common Agricultural Policy to encourage cooperative and collaborative practices (Prager, 2015).

In this context, the research of the farmers' willingness to join a short supply chain or an associative form environmental responsible is needed for justifying the state's financial efforts to fund the farmers' projects aiming to create short supply chains and to encourage the establishment of cooperatives.

DOI: http://dx.doi.org/10.15666/aeer/1702_16171639

The questions arising are whether farmers want to join a supply chain or a cooperative or not, and what are the determinants of their membership. The answers to these issues are searched in this research.

Other additional objectives are considered within the study. Thus, research aims to find out the farmers' perceptions on different issues: the level of the state subsidies and other financial support, the public taxation in agriculture, the short supply chain functionality, and the association role within the short supply chain.

In achieving these issues, a survey of farmers across fifteen (15) counties in Romania has been conducted. The method used for data collection was the interview. The data were analyzed using SPSS. The hi2 test and coefficient of contingence were used to analyze the correlations between variables. The sample contains one hundred and forty (140) valid observations. Besides asking the farmers' willingness to join a short supply chain environmental responsible or a cooperative, the survey also asked the follow-up questions about the reasons why farmers do not want to join a short supply chain environmental responsible or an associative form of organization.

The relevance of the research lies in the economic, social and environmental benefits brought by collective actions in agro-food system. Short supply chains (vertical integration) and collective actions of farmers (horizontal integration) are studied in the light of multi-stakeholder cooperatives. When the two forms of integration are combined, they form multi-stakeholder cooperatives which bring together producers, processors and/or retailers, and consumers under one single enterprise. It has been demonstrated by Gonzales (2017) that multi-stakeholder cooperatives create more sustainable food flows between rural and urban areas and they overcome the limitations of conventional producers' cooperatives focused more on economic than social and environmental benefits.

The paper outcomes are expected to provide a specific framework for policy makers on economic, demographic and psychological factors that influence the farmers' willingness to join a short supply chain environmental responsible and an associative form of organization. Also, the main findings may contribute to develop policy initiatives to finance collective actions in food supply chains.

Following the introduction, the paper is structured into six parts, as follows. In Section 2, a holistic approach is taken to review the literature in the field of supply chains, integration and cooperation, with the final goal to establish the study hypotheses, in Section 3. The paper then proceeds to present the database and methodology, in Section 4, whereas, in Section 5, the main findings are discussed. Finally, the implications of the findings are considered and concluding remarks are drawn, in Section 6.

Literature review

There is abundant literature and numerous case studies and field research referring to agricultural integration, supply chains and farmers' associations. With respect to integration, Poole and Frece (2010: p. 7) recognized that it is a means of tackling poverty in rural areas, and that increasing vertically coordinated supply chains plays a significant role in linking smallholder farmers to more dynamic markets. Williamson (1985) showed that integration aim is to minimize transaction costs. Other authors (Neven and Reardon, 2004) argued that the supply chains need to be redesigned, advocating the development of new, smaller farmer markets closed to local residential

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_16171639

areas that are able to facilitate an effective procurement system. This idea, linked to shortening the supply chain, meaning fewer agents, is sustained by Poole and Frece (2010: p. 100), as well. They found that one approach to the fair-trade sector consists on creating links between farmers and traders, importers or even retailers, thereby cutting out middlemen and maximizing profit margins for farmers.

Supply chains, described as all steps involved in production, manufacturing and distribution of food until its final consumption (Stone and Rahimifard, 2018), face vulnerabilities due to the limited shelf life of food, and variability in quality and availability of raw materials as organic products (Dani and Deep, 2010).

In respect to the process of collective collaboration in agriculture, many papers studied both its benefits and failure. The term "smallholder farmers' association" is referring to diverse types of groups who act collectively in order to benefit either as individuals or as a group (Poole and Frece, 2010: p. 17). The terminology used in the literature varies from terms such as cooperatives, farmer collectives, farmer associations, rural community enterprises, rural producer associations, community enterprises, and farmer organizations (Donovan et al., 2008). A cooperative is defined as "an autonomous association of persons united voluntarily to meet their common economic, social, and cultural needs and aspirations through a jointly owned and democratically-controlled enterprise" (ICA, 2018). Cooperatives are considered to play significant economic roles by reducing transaction costs and improving the bargaining power of individuals (Bonin et al., 1993), as a consequence, they are recognized to fight poverty in rural areas (FAO, 2005).

Some studies highlighted the socio-economic benefits of cooperatives. Fischer and Qaim (2012) reported the positive impact of cooperative membership on production and productivity in Ethiopia. Abate et al. (2014) claimed that improved technical efficiency of member of agricultural cooperatives is obtained due to better access to productive inputs and services, as compared to non-members. Marketing cooperatives allow small farmers to get better price by overcoming the powerful oligopolistic firms (Bontems and Fulton, 2009). Moreover, grace to marketing cooperatives, farmers have a better position for price negotiation and gain access to markets that they cannot access individually (Camanzi et al., 2011).

But cooperatives cannot be simply generalized as benefiting all their members and all locations (Mojo et al., 2017). Studies show that their performance varies across countries, regions and even sector (Bernard et al., 2010), and the skills of the managers and the administrative organization determine their success. Cooperative management seems to be the weak point of associative forms in Romania. Also, farmers' resistance to association is a characteristic of the Romanian agricultural system, as many authors observed in their works (Marin et al., 2016).

There are both practical and theoretical explanations of the failures of collective organization. Sound financial management, good organizational governance and the potential for free riding, remain problems for the more complex cooperatives (Poole and Frece, 2010: p. 46). But at the same time, there are fundamental reasons for collaborating: the potential for exploiting production and managerial economies of scale, overcoming market entry barriers, reducing transaction costs and cultivating supply chain relationships.

The term "new cooperative" has emerged (Cook and Chaddad, 2004) referring to the market-oriented producer organizations, and extending this commercial orientation further by linking ownership rights, investment and governance. Whereas traditional

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_16171639

cooperative forms are described as being defensive, aiming to protect farmers and minimize risk, new generation cooperatives can be seen as 'offensive', able to cope with falling profit and income risks.

Not only horizontal integration creates new cooperatives, but also vertical integration advocates fundamental changes in supply chains in the advanced economies. A shift from competitive vertical relations towards the cooperative organization of the supply chain, or supply chain management has been identified by Poole and Frece (2010: p. 21).

Table 1 summarizes the main findings in the field of farmers' cooperation, supply chains and their economic implications, relevant for our research.

The links between supply chains and collective actions are also discussed in many papers. Lund (2012) studied the place of the modern multi-stakeholders' cooperatives in food and farming in the context of the emerging concept of value chains, which implies approaches beyond economics. The activities along value chains involve many cultural and social aspects such as taste, identity, connection with nature and community (Baggini, 2014). Bauwens and Kostakis (2014) go beyond multi-stakeholder cooperatives and value chains and call for "open coops", which combines multi-stakeholder ship and the co-production of the value chain by everyone affected by a provisioning service. The cooperatives are described as potential leading actors in shortened food chains, since they make possible economies of scope or synergy, versus simplistic economies of scale (Marsden et al., 2002).

Table 1. *Main findings in the field of farmers' cooperation, supply chains and their economic implications*

Issue	Explanation	Relevant studies
Vertical integration of activities within supply chains increases performance	Reduced transactions costs, smallholder farmers are closer to more dynamic markets, overcoming market entry barriers, increasing equity	Ion (2005), Lund (2012), Marin et al. (2016), Marin et al. (2017), New (1997: p. 19), Poole and Frece (2010), Williamson (1985)
Horizontal integration of activities within supply chains increases performance	Collective actions include greater accessibility of finance, technology and market information; improve farmer returns by lowering production costs, counterbalancing the negative economic impacts of market power and reducing producer income risks	Abate et al. (2014), Bonin et al. (1993), Bontems and Fulton (2009), Camanzi et al. (2011), Cook and Chaddad (2004), Markelova et al. (2009), Wynne-Jones (2017)
The length of the supply chain must be reduced	In longer chains, too many agents ask for profit, increasing, as such, the prices that the final consumer pays for food. In shorter chains, there are direct links, cutting out middlemen and maximizing profit margins for farmers	Chirwa et al. (2005), Manole et al. (2005), Marin et al. (2016), Poole and Frece (2010)
Multi-stakeholder cooperatives combine supply chains and collective actions (they bring together producers, processors and/or retailers, and consumers under one single enterprise)	Multi-stakeholder cooperatives create more sustainable food flows between rural and urban areas. Multi-stakeholder cooperatives have the potential to generate a diverse range of more-than-economic benefits: sectorial, legal, cultural, policy and public procurement, academic	Baggini (2014), Bauwens and Kostakis (2014), Gray and Stevenson (2008), Gonzales (2017), Lang et al. (2009), Lund (2012), Mooney (2004)

Although there is abundant literature in the field of farmers' cooperation, supply chains environmental responsible and their economic implications, the need of analysing these phenomena in Romania arises from the agriculture's particularities in this country, especially by the existence of numerous and small agricultural holdings. The land reforms have determined extreme forms of land use fragmentation which has generated and maintained for a long time a small peasant property with a low degree of efficiency and poorly technically endowed. An opposite situation is drafted in Bulgaria, where according to (Lerman et al., 2004) more than 40% of land is being farmed in associations. Still, for Romania, the high fragmentation of agriculture structures creates premises for farmers' association as viable solution for overcoming market entry barriers, and increasing equity along the chain.

Romanian agriculture is facing a long and difficult process of land aggregation, marked often by the resistance of farmers to reunite in holdings. Despite the fact that, domestic agriculture is trying to diminish the contradictory effects of the dominance of the subsistence farming imposed by the peasant property, there are successful attempts in determining the farmers' association and achieving a comparative convergence level with the European agricultural model. The need for farmers' association and cooperation emerge as a stringent necessity imposed by real and determinant factors as, low productivity in agriculture, poor access to markets, low investment capacity, technical and technological capital shortage, and low levels of competitiveness.

This study conducted a survey to investigate the factors influencing the Romanian farmers' willingness to join a short supply chain environmental responsible and an associative form of organization. Surveys and behavioural approaches in agricultural studies are not new. They cover a broad range of studies that employ quantitative methodologies to the investigation of decision-making and farmers' willingness to adopt new technologies, instruments, services etc. Folorunso and Ogunseye (2008) explored the farmers' acceptance of a knowledge management system in agricultural extension services. Heyder et al. (2010) examined the major factors influencing the investment behaviour of agribusiness firms. Pappa et al. (2018) identified the drivers that determine the acceptance and use of electronic traceability systems in agro-food supply chains. Survey has been used before to understand consumers' preferences for vegetables and fruits (Ion, 2015), using as dependent variables consumer preferences for preserved vegetables and fruits and as independent variables gender, age, income. Adrian et al. (2005) investigated the perception and attitudinal characteristics of farmers who plan to adopt precision agriculture, using a survey to measure constructs of perception and attitudes. As such, our intention in this paper is to explore the changes in food chains and cooperation phenomenon in Romania, considering the financial efforts of the public agricultural policy to fund the creation of short supply chains environmental responsible and the establishment of associative forms of organization. Our main contribution is to add to the discussions and enrich the evidence supporting different factors which determine farmers' willingness to join short supply chains environmental responsible and cooperatives, including demographic and economic variables, economic impacts of membership, and farmers' perceptions on financial and fiscal issues in agriculture.

Research hypotheses

Considering the results of the previous studies described in Section 2, four hypotheses (H1 to H4) emerged and need to be studied subsequently, as:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_16171639

H1: Socioeconomic and demographic factors influence the farmers' willingness to join a short supply chain or an associative form of organization.

This hypothesis is based on the results of other studies (Marin et al., 2016; Marin et al., 2017), showing that membership in an associative form varies with the farmer's age and the date of establishment of the holding. Mojo et al. (2017) found that the probability of farmers' membership decision increases with age, education level, family size, social networks, land property and accessibility to cooperatives. Adrian et al. (2005) argued that perceptions of net benefit, farm size and farmer educational levels positively influenced the intention to adopt precision agriculture technologies.

H2: Membership in a collective form of organization and a short supply chain has a positive impact on farm income and assets.

This hypothesis is based on the assumptions mentioned in *Table 1* and it is sustained by many other studies (Abate et al., 2014, Bonin et al., 1993, Chirwa et al., 2005, Cook and Chaddad, 2004, Manole et al., 2005, Markelova et al., 2009, Marin et al., 2016). They show that both vertical and horizontal integration of chain activities increases performance.

H3: Farmers are resistant to join a short supply chain or an associative form.

This presumption is based on emotional connotations related to the communist period when association was not established on voluntary bases. One study regarding the problems encountered by the Romanian farmers reported that 62% of subjects do not intent to associate in the future (Marin et al., 2016: p. 19). The longstanding question raised in the literature – whether farmers are inherently disposed towards self-reliance and independent actions rather than collective and collaborative working (Wynne-Jones, 2017).

H4: Farmers' reasons for not joining short supply chains and associative forms of organizations are linked to the lack of trust in other members, the lack of legislation and to bureaucracy.

The assumption is made on people resistance to cooperation as experienced in the previous period and on the results of other research (Marin, 2017) showing that farmers do not want to associate because they do not trust other people, and that there are no legal support and preferences or incentives for cooperatives.

Poole and Frece (2010), Turek et al. (2007), Ion (2005) found that farmers act collectively to get accessibility of finance, technology and market information and to enter the final consumer market. By fostering long-term relationships rather than punctual commercial transactions, Lund (2012) argued that membership in a collective form can overcome the higher transactional costs that traditional economic theory would expect from the involvement of separate parts. Economic motivation is a determinant of the choice to become a cooperative member, as Wynne-Jones (2017) found in the research studying farmer cooperation drivers and effects.

Experimental section

The survey data were collected from randomly chosen farmers across 15 counties in Romania, from January to April 2018. The response rate is 92% and there are 140 valid observations out of 152 responses. The sampling method is based on voluntary selection of units, which is a non-probabilistic method, considering rational choices (Porojan, 1993: p. 205). Sample inclusion is based on the voluntary option of individuals to participate in the sample. The survey questions include farmers' willingness to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_16171639

participate in short supply chains and cooperatives, farms' characteristics, and farmers' socio-demographic characteristics.

In the questionnaire, the key questions involve two parts. The first question is phrased "If you are not part of an associative form, do you consider to associate in the near future?" (Q5). The respondents could answer yes, showing their willingness to associate, or no, showing their resistance to association. If no, the respondent is asked to provide reasons (Q6: What are the reasons why you did not associate?).

The second key question is phrased "Do you intend to integrate your exploitation into a short supply chain of vegetables/fruits?" (Q14). The respondents could answer yes, showing their willingness to join a short value chain, or no, showing their resistance to join a short value chain. Explanatory factors considered in this piece of research are: the year of farmer's establishment, the form of farmer's organization, holding surface, crops' structure, farm's revenues, the type and level of farmer's financial resources, occupation, education, studies in agriculture/horticulture, age, gender and nationality (*Table 2*).

Table 2. *Dependent variables used in the model and other studies which considered them relevant*

Variable	Explanation	Relevant studies
Farmer's characteristics: age, gender, nationality, residence, civil status, education, studies in agriculture/horticulture occupation	Demographic characteristic of the subjects may influence their decision to join a short supply chain or an associative form of organization. The age of the household head is positively correlated with participation in cooperatives. It is assumed that the farmers who have studies in the field of agriculture or horticulture make informed choices and decisions	Bernard (et al., 2013), Burton (2004), Hansson et al. (2012), Knowler and Bradshaw (2007), Marin et al. (2016), Montefrio (2016), Nosenzo and Tufano (2017), Prokopy et al. (2008), Zhong (2016)
Farm's characteristics: year of establishment (farming experience), type of activity, farm size, structure of crops, financial resources	It is assumed that farmer's experience influences its process of decision making, including the decision of joining a short supply chain or a cooperative. The level of financial resources influence the farmers' decisional autonomy and, as such, their willingness to make the decisions on joining short supply chains and collective forms of organization	Bernard (et al., 2013), Gonzales (2017), Knowler and Bradshaw (2007), Marin et al. (2016), Pappa et al. (2018), Prokopy et al. (2008), Zhong (2016)

Edited by the authors

Findings

The key questions of the research are: Are you part of an associative form in agriculture? (Q3), Are you part of a short value chain for vegetables and fruits? (Q4), If you are not part of an associative form, do you consider association in the near future? (Q5), What are the reasons why you did not associate? (Q6) and Do you intend to integrate your exploitation into a short supply chain of vegetables/fruits? (Q14). The answers to these questions show that 81.4% of the respondents are not part of an associative form and 78.6% are not part of a short value chain for vegetables and fruits. 82.1% of the respondents want to join an associative form and 67.1% of the respondents want to integrate their business into a short supply chain, in the near

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_16171639

future. The main reason why farmers do not cooperate is the lack of legislation to support small and medium-sized producers, since 34.3% of the farmers have chosen this answer. Another significant reason is the high level of taxation (29%).

To achieve the research goals, the determinants of association are analysed, based on the correlations between variables. The results of the survey have been analysed using the values of the hi^2 test and the values of the contingency coefficient calculated with SPSS (Analyse-Descriptive Statistics-Crosstabs-Statistics-Chi-square/Contingency coefficient). Correlations between variables exist when the value of the hi^2 test do not exceed .05. Depending on the value of the contingency coefficient, this link may be of weak, medium or strong intensity.

The first assumption is that the socioeconomic and demographic factors influence the farmers' willingness to join a short supply chain or an associative form of organization (H1). To test this hypothesis, the correlations between variables are analysed. The dependent variable is the farmers' affiliation to an associative form of organization (Q3), and the independent variables are the farm's characteristics: the year of starting the activity (Q1), the activity type (Q2), the holding surface (Q7), the structure of crops (Q8.1), the exploitation's dimension (Q8.2), the estimated revenues (Q11), the subsidies (Q22), the accessing of European funds (Q25), and the farmer's characteristics: occupation (Qa), education (Qb), studies in the field of agriculture (Qc), age (Qd), gender (Qe), nationality (Qf), marital status (Qg).

Table 3 and *Figures 1, 2* and *3* illustrate the results of the analysis. Medium correlations have been found between the farmers' affiliation to an associative form of organization and the holding surface, because the value of hi^2 test is .005, lower than .05, and the value of the contingent coefficient is .308, over .300. It was noticed that farmers holding agricultural areas ranging from 1 to 5 ha are not part of an associative form.

Weak correlations were found between the farmers' affiliation to an associative form of organization and the activity type, the estimated revenues, the subsidies, the farmer's occupation and education level, where the values of hi^2 test are lower than .05, and the value of the contingent coefficient are below .300. Most of the farmers who act as physical persons do not belong to an associative form of organization, but some of the farmers who act as legal persons do belong to associative forms. Farmers with high income are part of associative forms, compared to farmers with lower income. Persons who graduated higher education are likely to associate, as compared to people who graduated only secondary schools.

There are no significant correlations between farmers' affiliation to an associative form of organization and the year of starting the activity, the structure of crops, the exploitation's dimension, the accessing of European funds, studies in the field of agriculture, age, gender, nationality, marital status.

Linear and positive relationships have been found between associative membership and holding surface (*Fig. 1*), supply chain membership and activity type (*Fig. 2*) and supply chain membership and holding surface (*Fig. 3*).

Medium correlations were found between the farmers' affiliation to a short supply chain environmental responsible and the activity type and the size of the farm, because the values of the hi^2 test are lower than .05, and the values of the contingent coefficients are .319, respectively .308 (*Table 3*). Farmers who act as physical persons and who hold small agricultural areas belong to a short supply chain environmental responsible.

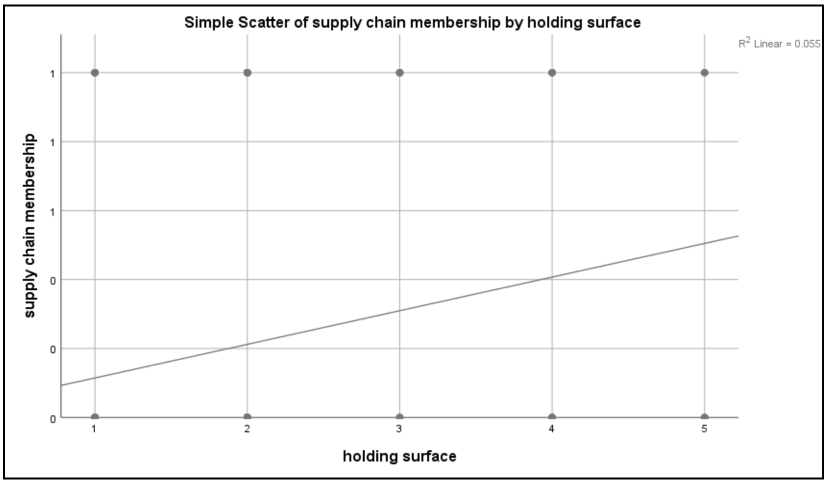

Figure 3. *Correlations between the variables supply chain membership and holding surface. (Source: results of the model. The charts are built only for those variables in Table 3 for which the values of the hi² test are lower than .05 and the values of the contingent coefficients are higher than .300)*

Weak correlation is found between the farmers' affiliation to a short supply chain and the farmer's education level, because the value of the contingent coefficient is .285. Persons who graduated higher education are likely to belong to a short supply chain environmental responsible, as compared to people who graduated only secondary schools. There are no significant correlations between farmers' affiliation to a short supply chain environmental responsible and the year of starting the activity, the structure of crops, the exploitation's dimension, estimated revenues, subsidies, the accessing of European funds, occupation, studies in the field of agriculture, age, gender, nationality, marital status. The second assumption is that "Membership in a collective form of organization and a short supply chain has a positive impact on farm income and assets" (H2). The dependent variable is farm's income and assets (Q11) and the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_16171639

independent ones are the affiliation to an associative form of organization (Q3) and the affiliation to a short supply chain (Q4). The results are presented in *Table 4*.

Table 4. *The model estimated results for the hypothesis "Membership in a collective form of organization and a short supply chain has a positive impact on farm income and assets" (H2)*

Independent variable	**Dependent variable** **Q11: Farm's income and assets**
Q3: Affiliation to an associative form of organization	.009 .252*
Q4: Affiliation to a short value chain	.594

Source: results of the model. The results show the values of hi^2 test. The value symbolized with * represents the value of the contingent coefficient, calculated only for those variables for which the values of hi^2 test are lower than .05

Weak correlation has been found between farm's income and assets and farmers' affiliation to an associative form of organization, because the value of the hi^2 test is below .05 and the contingent coefficient is .252, lower than .300. Farmers with higher levels of income are likely to belong to an associative form of organization. There are no significant correlations between the farm's income and assets and the farmers' affiliation to a short supply chain environmental responsible, because the value of the hi^2 test is over .05.

The third assumption is that "Farmers are resistant to join a short supply chain or an associative form" (H3). The answers to the questions: If you are not part of an associative form, do you consider association in the near future? (Q5) and Do you intend to integrate your exploitation into a short supply chain of vegetables/fruits? (Q14) show that most of the farmers (82.1%) want to join an associative form of organization and 67.1% of the respondents want to integrate their business into a short supply chain environmental responsible. The hypothesis is not validated.

For analysing the reasons why some farmers are resistant to association and integration, the determinants of this resistant are studied. The dependent variables are the farmers' willingness to associate (Q5) and their willingness to join a short supply chain (Q14). The independent variables are the farm's characteristics: the year of starting the activity (Q1), the activity type (Q2), holding surface (Q7), the structure of crops (Q8.1), the exploitation's dimension (Q8.2), the estimated revenues (Q11), the subsidies (Q22), the accessing of European funds (Q25), and the farmer's characteristics: occupation (Qa), education (Qb), studies in the field of agriculture (Qc), age (Qd), gender (Qe), nationality (Qf), marital status (Qg) (*Table 5*).

Linear and positive relationships have been found between the variables willingness to associate and year of starting the activity (*Fig. 4*), willingness to associate and holding surface (*Fig. 5*), willingness to join a short supply chain and year of starting the activity (*Fig. 6*).

Medium correlations have been found between the farmers' willingness to associate and the year of starting the activity and the surface of the farm, because the values of the hi^2 test are below .05 and the values of the contingent coefficients are over .300. Respondents who recently started the activity and who exploit smaller areas of land are willing to join an associative form of organization, as compared to others.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_16171639

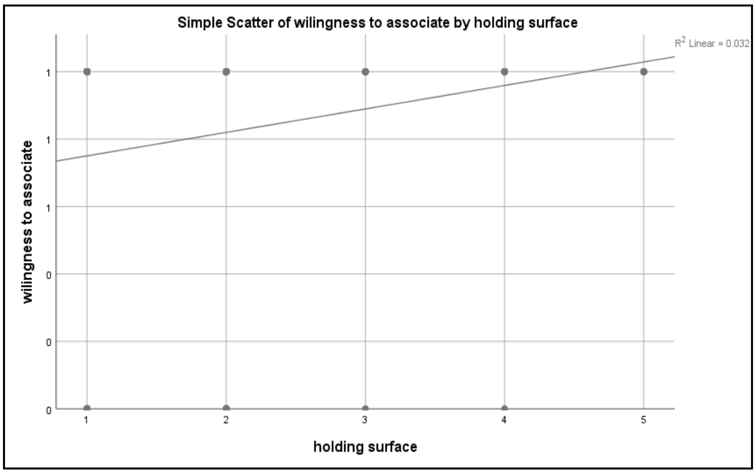

Figure 5. *Correlations between the variables willingness to associate and holding surface. (Source: results of the model. The charts are built only for those variables in Table 5 for which the values of the* hi^2 *test are lower than .05 and the values of the contingent coefficients are higher than .300)*

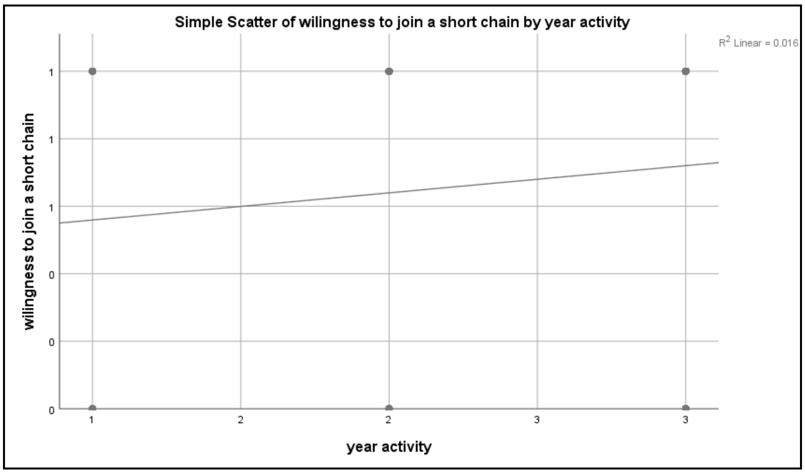

Figure 6. *Correlations between the variables willingness to join a short supply chain and year of starting the activity. (Source: results of the model. The charts are built only for those variables in Table 5 for which the values of the* hi^2 *test are lower than .05 and the values of the contingent coefficients are higher than .300)*

Weak correlations have been found between farmers' willingness to associate and the activity type, the access to subsidies and the farmer's education, because the values of the hi^2 test are below .05, but the values of the contingent coefficients are lower than .300. Physical persons who never accessed subsidies before and who have graduated higher education are more likely to associate, as compared to others.

No significant correlations have been found between the farmers' willingness to associate and the crops' structure, the farm's size, the estimated revenues, the access to European funds, occupation, specialized studies in agriculture, age, gender, nationality, and marital status.

Medium correlations are found between farmers' willingness to join a short supply chain and the year of starting the activity, because the value of the hi^2 test is below .05

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_16171639

and the value of the contingent coefficient is .313, higher than .300. People who started an agricultural business after 2017 want to be part of a short chain more than others.

Weak correlations have been found between farmers' willingness to join a short supply chain and the possibility to access European funds, because the value of the hi^2 test is below .05, but the values of the contingent coefficient is .203, lower than .300. People wishing to access European funds want more than others to integrate into a short supply chain.

No significant correlations have been found between the farmers' willingness to join a short supply chain and the activity type, the holding surface, the structure of crops, the exploitation's dimension, the estimated revenues, the subsidies, and the farmer's characteristics: occupation, education, studies in the field of agriculture, age, gender, and nationality.

The fourth assumption is that "Farmers' reasons for not joining short supply chains environmental responsible and associative forms of organizations are linked to the lack of trust in other members, the lack of legislation and to bureaucracy" (H4). To test this hypothesis, the answers to the question "What are the reasons why you did not associate?" are presented in *Figure 7*.

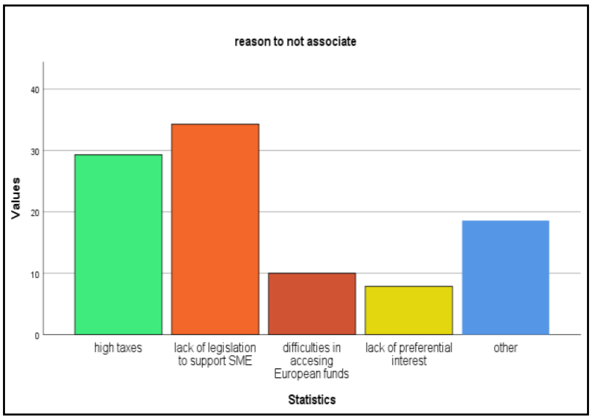

Figure 7. *Reasons why farmer do not want to associate. (Source: authors' own computations)*

Thus, the main reasons why the respondents did not associate are related to the legislation in force which is not supporting enough the associative forms, and the high level of taxes. For other reasons, the respondents mentioned the complex bureaucracy and the fact that they had no one to associate with, as well as the lack of trust. Hypothesis 4 is confirmed. Other objectives of the paper are to identify farmers' perceptions on the benefits of the short supply chain, and on the level of the state subsidies and taxes. The farmers' perceptions on the benefits of the short supply chain environmental responsible and association are presented in *Figures 8* and *9*.

Most people considered the short supply chain functional, since the average score is 3.08, on a scale from 1 to 5. Farmers consider that the association has a beneficial role in shortening the chain, since the most of the respondents (42.1) answered that farmers benefit from the association and 31.4 of them answered that the role of the association is very beneficial (*Fig. 9*). Moreover, high correlation has been found between the farmers' age and their perceptions on the role of the association in shortening the supply chain. People aged at first intervals (18-25 years old and 26-40 years old) consider that this role is beneficial to very beneficial.

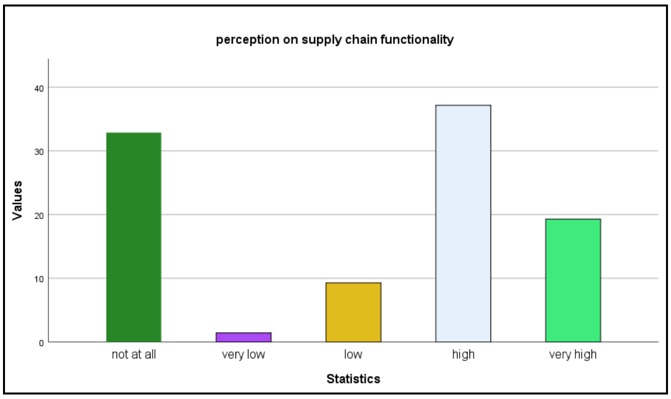

Figure 8. *Farmers' perceptions on supply chain functionality. (Source: authors' own computations)*

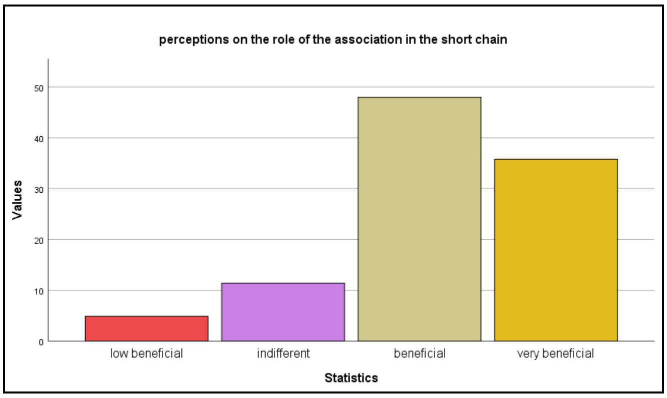

Figure 9. *Farmers' perceptions on the role of the association in the supply chain shortening. (Source: authors' own computations)*

The farmers' perceptions of the level of the state subsidies and taxation are presented in *Figures 10* and *11*. Over 70% of the respondents who answered the question "How do you appreciate state's financial support?" (128 out of 140) considered that the support provided by the state is insignificant and insufficient. Over 60% of farmers considered that the taxes and fees they owe the state are high and 32% consider them moderate.

Conclusions

Farmers' willingness to associate and join in environmental responsible short supply chain in Romania is a complex and challenging research topic in Romanian agricultural economics, taking into consideration the impact of association on shaping agricultural production in modern agriculture. During the research it has been found that cooperation plays a significant role in shortened food chains and that association goes beyond simple farmers' cooperation to multi-stakeholder cooperatives. They become leading and powerful actors in food chains, since they generate a diverse range of benefits, besides economic ones: sectorial, legal, cultural, policy, academic.

The hi2 test and the contingent coefficients are used to analyze the correlations between variables. Findings indicate that the probability of farmers' membership in an associative form or in a short supply chain environmental responsible is determined by age, education level, cultivated area, activity type, year of establishment, opportunities to access financial support.

A final answer to the research question is that farmers want to involve their businesses into collective actions, since 67.1% of the farmers answered that they want to join a short supply chain, and 82.1% of them answered that they want to join an associative form of organization, in the near future. This result is opposite to those found in other research showing that 62% of subjects do not intent to associate in the future (Marin et al., 2016: p. 19).

But the association is poorly developed in Romania's agriculture, namely in the sector of vegetables and fruits, as long as only 18.6% of farmers declared that are part of an associative form of organization. Moreover, statistics show that only 1% of the Romanian agricultural producers are part of an associative form of organization.

The determinants of the farmers' affiliation to an associative form are: the type of activity, the size of the holding, the estimated revenues, access to state subsidies and farmers' occupation and education. The affiliation of farmers to a short supply chain is determined by the type of activity, the size of the holding and the level of education. As such, the hypothesis H1 is confirmed in the sense that socio-economic factors influence the farmers' willingness to join an associative form or a short supply chain with a weak to medium intensity. These results are similar to those found in the literature by Adrian et al. (2005), Marin et al. (2016), Marin et al. (2017) and Mojo et al. (2017).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_16171639

The hypothesis "Membership in a collective form of organization and a short supply chain has a positive impact on farm income and assets" (H2) is partly confirmed. The fact that farmers are part of an associative form influences their income, but not that they are part of a short supply chain.

The assumption that farmers are resistant to join a short supply chain or an associative form (H3) is not confirmed, since 82.1% of respondents want to join an associative and 67.1% of respondents want to integrate their business into a short supply chain.

The assumption that farmers' reasons for not joining short supply chains and associative forms of organizations are linked to the lack of trust in other members, the lack of legislation and to bureaucracy is confirmed (H4), and consistent to other findings (Marin, 2017).

Regarding the reasons for joining the short supply chains environmental responsible and associative forms of organizations, the determinants of the farmers' willingness to associate are: the year of starting the activity, the type of activity, the size of the holding, the access to subsidies and the level of education. The farmers' willingness to join a short supply chain is determined by the year of starting the activity and the opportunity to access European funds, with intensity from weak to moderate.

Most of the farmers considered the short supply chain functional and the association as positive in shortening the chain. Over 70% of the farmers who answered the question related to the perceptions on the level of the state subsidies considered that the support provided by the state is insignificant and insufficient.

To conclude, the profile of farmers who want to associate and/or to integrate the activity into a short supply chain can be drawn. The farmers willing to associate are young, under 40 years old, with higher education, legally organized as physical persons, exploiting smaller agricultural areas. They recently started their activity and they never accessed subsidies before. The farmers willing to join a short supply chain are organized as physical persons. They have higher education and exploit smaller agricultural areas. They recently started their activity and intend to access European funds for developing their businesses. The results may be used to develop policy initiatives to finance collective actions in food supply chains environmental responsible, because they provide insights into the socio-economic factors that influence the farmers' membership in short supply chains and associative forms of organization. The current study contributes to the literature by analyzing the determinants of association and short supply chain membership using the survey data of farms gathered from vegetables and fruits producers in Romania.

Abstract. The objective of this study was to evaluate the effects of mineral fertilizer (NP) and thirty-five N_2-fixing and/or P-solubilizing and different carbon sources utilizing-bacterial strains (7 isolates each of *Bacillıs megaterium, Bacillus subtilis*, *Paenibacillus polymyxa*, *Pseudomonas putida* and *Pseudomonas fluorescens*) isolated from the acidic rhizospheric soil of native tea, grapevine and wild red raspberries, as bio-fertilizers on growth, yield and quality characteristics of the plant, on chlorophyll content, on macro- and micronutrient concentrations, on essential oil content and on major component of the essential of Turkish oregano (*Origanum onites* L.). The isolates were identified based on whole-cell fatty acid methyl ester (FAMEs) analysis using the MIDI system and BIOLOG assays. The study contains both applications NP-fertilizer and a control application without inoculation of bacteria and fertilizer application. This study was carried out in Greenhouse at Atatürk University, Faculty of Agriculture and Department of Agronomy in 2011-2012 growing season. As an average of years the treatments showed that the plant has 35.3-48.5 cm of length, 34.29-48.30 cm of canopy diameter, 36.56-47.19 SPAD units of chlorophyll concentration, 41.88-74.64 g/plant of green herb yield, 11.52-15.52 g/plant of drug herb yield, 6.53-12.18 g/plant of drug leaf yield and 1.85-2.78% of essential oil content rate. Increasing carbon source utilization rates significantly increased plant height, canopy diameter, green herb, drug herb and drug leaf yield. The main components of the oil were carvacrol (58.19-70.08%), followed by thymol (17.85-26.27%), linalool (1.64-8.13%), borneol (1.36-2.39%) and p-cymene (0.37-3.21%) which were the most abundant components. In addition, with PGPR inoculation, macronutrient concentrations (N, P and K,) of oregano leaves increased, main component of the essential oil also changed. In terms of growth, yield and quality criteria of Turkish oregano, in particular, the most effective N_2-fixing and P-solubilizing strains *P. fluorescens* (8/2, 58/3, 9/7, 53/6 and 51/2), *B. subtilis* (52/1, 6/3 and R 3/3), *B. megaterium* (21/3, K5E and 35/6), *P. polymyxa* (R2/2), and *P. putida* (55/2, 3/10 and 53/5) may be used instead of mineral fertilizer as bio-fertilizers in sustainable organic oregano cultivation.
Keywords: *medicinal and aromatic plants, Origanum onites, carvacrol, main component, nutrient uptake*

Introduction

Turkish oregano (*Origanum onites* L.), distributed in Western and Southern Anatolia is widely used as a spice and herbal tea in Turkey. In Turkey, *O. onites* is on the top of the list in case of its commercial *origanum* species which has a dominant position in the worldwide trade (Başer, 2002). Dried oregano is obtained both from wild populations in nature and from cultivated plants, its vegetative parts and biochemical essence are quite used in the food and spice industrial area, and also as a condiment herb for flavouring fish, soups, salads, olives, chicken, meat, vegetables, salad dressing, and wine (Tonk et al., 2010). As food preservation, natural antimicrobial and antioxidant, *O. onites* becoming increasingly popular (Stefanakis et al., 2013). Carvacrol, thymol, p-cymene, gamma-terpinene, borneol, linalool, and alpha-terpinene is main component of essential oil of *O. onites* (Bokov et al., 2015). Carvacrol is main component of essential oils of this species (Avcı and Bayram, 2013), which is an oxygenated monoterpene with multiple pharmacological actions (Baser, 2008), and an important impact compound of oregano aroma (Bansleben et al., 2009). It is also known for its antibacterial, antifungal, antioxidant, insecticidal, anti-angiogenic and anticarcinogenic activities, antispasmodic effects, lipid peroxidase inhibition, radical scavenging effect and cardiac depressant activity (Kotan et al., 2014).

In recent years, oregano cultivation has expanded rapidly because of its conservation of natural resources and production with high standard and quality. Consumed without further processing in medicinal and aromatic plant species is important because its components have not synthetic compounds in the harvested crop. Undoubtedly, excessive use of chemical fertilizer has adverse effects on plant and soil health. In view of environmental pollution and high costs of the production due to excessive use of fertilizers; plant growth- promoting rhizobacteria (PGPR) may be used in sustainable agricultural production (Cakmakçi et al., 2006). Plant growth with excrete of vitamins and phytohormones, decline of plant ethylene level, resistance to stress, contribution to food intake, solubilisation of inorganic phosphate, fixing N_2, and mineralization of organic phosphate can provide with applications of PGPR. As a new concept and alternative strategy emerging in plant growth and yield increase, PGPR can provide increase in agricultural productivity, decline in product cost and environmental protection against pollution. It is evident that rhizobacteria could possibly serve as eco-friendly, safe and sustainable alternative to the harmful synthetic fertilizers used for the nutrient management and sustainable production in medicinal and aromatic crops.

Knowledge of about the monoterpene accumulation and biosynthesis of secondary metabolites can provide new procedure for medical plant cultivation and other agricultural application without chemical input (Cappellari et al., 2015). Similarly to bio-fertilization, optimal and balanced mineral fertilization of aromatic plants, adjusted to their nutritional requirements and growing conditions, is an important cultivation factor determining the quantity and quality of essential oil (Nurzynska-Wierdak, 2013). Bacteria and plant related studies are usually focused on cereals and grassy plants and studies on medical plants are very few. In medicinal and aromatic plants, experiments with PGPR indicated yield and essential oil increases in Italian oregano and *Origanum majorana* L. (Banchio et al., 2008, 2010), rosemary (Leithy et al., 2006), *Pelargonium graveolens* (Mishra et al., 2010), sweet fennel (Rezvani Moghaddam et al., 2011), dill plant (Hellal et al., 2011), common basil (Ordookhani et al., 2011), coriander (Hassan et al., 2012), Mexican marigold (Cappellari et al., 2013), *Thymus daenensis* (Bahadori et al., 2013), summer savoury (Farahani et al., 2015). Although some experiments have addressed the role of PGPR added in medicinal plants (Santoro et al., 2011), the impact of PGPR on production of secondary metabolites is poorly known (Banchio et al., 2008). In general, physiological and morphological property of medicinal plants connected with rhizobacteria leftovers restricted and piecemeal (Cappellari et al., 2015).

In particular, the possibilities of medicinal and aromatic plants development, yield, volatile oil content and components to be increased or replaced have not been extensively investigated using multi-traits bacteria. However, there is no study on

DOI: http://dx.doi.org/10.15666/aeer/1702_16411653

agronomic factors such as application of bio-fertilizers as well as plant growth promoting rhizobacteria on biological soil properties, yield and essential oils of Oregano. In addition, there is a trend towards biological fertilizer applications and sustainable agricultural systems in the production of medical plants due to environmental impacts, which are caused by over application of chemical fertilizers, energies and expenses. Therefore, a study was conducted in order to investigate the effect of plant-associated beneficial multi-traits 35 bacteria on growth, yield and content and composition of essential oils of Turkish oregano.

Materials and methods

Bacterial strains

In this study, thirty-five different isolates of PGPR were selected from stock of 460 rizobacterial isolates obtained from the native grapevine, wild red raspberries and tea rhizosphere Selection criteria of these bacteria was made according to whether 1-aminocyclopropane-1-carboxylate (ACC) deaminase-containing, IAA-producing, N_2-fixing, P-solubilizing, and different carbon sources using ability. In the study, gram-positive *Bacillus megaterium*, *Bacillus subtilis* and *Paenibacillus polymyxa*, gram-negative *P. fluorescens* and *P. putida* species were used for at least seven different isolates from each species to be used in *Origanum onites*. The isolates were identified based on whole-cell fatty acid methyl ester (FAMEs) analysis using the Sherlock Microbial Identification System (Version 4.5) and Biolog microplate assays (Biolog Inc., Hayward, CA, USA). Also, characterized by using BIOLOG GN2 and GP2 MicroPlates, were used to determine the ability of bacterial strains to utilize 95 different carbon sources (Çakmakçı et al., 2010).

Acetylene reduction assay and phosphate solubilisation

Nitrogen fixation of the isolates was determined in a nitrogen free medium by the acetylene reduction assay (Hardy et al., 1968). Using a Hewlett Packard gas chromatograph, Ethylene production was measured (Model 6890, USA). Entire of the bacteria were tried in threefold for their phosphate solvent talent in sucrose-tricalcium phosphate agar media (Pikovskaya, 1948) by added 1 ml of 6-day-old culture (density 4×10^9) in 250-ml Erlenmeyer flasks containing 500-μg ml^{-1} of P as rock phosphate at 29-31°C (Çakmakçı et al., 2010).

Greenhouse experiment and growth conditions

This study was carried out in the Department of Agronomy at Atatürk University under greenhouse conditions in Erzurum, Turkey, in 2011-2012 growing season under two trial sets. Flowerpot were sterilized by 20% NaClO and replete with a sandy clay-loam which is virgin field soil with an organic matter content of 3.2 and 0.17% nitrogen, an available Olsen-P and changeable potassium calcium and magnesium content of 16.2, 448, 3420, and 472 mg kg^{-1}, respectively. Iron, manganese, zinc and copper contents were 5.9, 9.6, 1.2, and 1.8 ppm. Two set of experiment was conducted with the same treatments. The experiment was conducted in a completely randomized design with five replicates (each having five pots), having 37 treatments as 35 high N_2-fixing and/or P-solubilizing and different carbon sources utilizing-bacteria, NP fertilizer (200 mg N $plant^{-1}$ + 200 mg P $plant^{-1}$) applications as well as a control

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_16411653

treatment without inoculation and any fertilizer application. In our study, bacteria were developed in fifty percent tryptic soy broth. Bacteria in Rotary shaker was stayed three days (120 rpm; 25°C). Control applications were stayed 5 ml of diluted SPB without bacteria. Oregano seeds were germinated in a seed trays containing garden soil/peat/sandy (2:1:1 [v/v]). Our plants were grown conditions which 16 h day, and 8 h night conditions, at 19-29°C with about sixty percent humidity in greenhouse. Seedlings were removed from seed trays after one month. Uniform oregano seedlings were dipped and kept in bacteria solution for an hour, later three uniform 30-day-old inoculated seedlings were transferred into each pots containing virgin garden soil, and seedlings were thinned to one after two weeks. In all plants, irrigation was done every 4 days, keeping 70% water holding capacity. Weed control was done by hand when required. In the second year of bacterial inoculation, 5 ml bacterial suspension was injected into rhizosphere of each oregano plant. About three months after planting, the oregano plants were harvested twice approximately in mid-July and September in each year.

Essential oil extraction and GC–MS analysis

Plants were harvested at full flowering stage, were cut 5-6 cm above ground level and weighed to determine fresh herbage yield. Then, harvested the oregano herb was dried under natural conditions, in a dry, airy and shaded place. Essential oil of plants was obtained with using Clevenger apparatus. Dry herb was made hidrodistilation for 3 h v/w and essential oil of these plant was obtained. The essential oil' analyses was performed (Kordali et al., 2008). Oil components and RI (relative retention times) values detected according to Adams (1997).

Plant analysis

Before 2 g of leaf samples was grinded to be 1 mm, oven-dried at 68°C for 48 h. For determine total N the oregano leaves were used Kjeldahl method and a Vapodest 10 Rapid Kjeldahl Distillation Unit (Gerhardt, Konigswinter, Germany). After determined P and K with an inductively Coupled Plasma spectrophotometer (Perkin-Elmer, Optima 2100 DV, ICP/OES, Perkin-Elmer, Waltham MA, USA), extraction was made. For measuring chlorophyll contents of leaves which top fourth and fifth was used chlorophyll meter (SPAD-502, Minolta, Japan) which is used to measure leaf greenness of the plants. Firstly, it was measured at four locations on each leaf for each plant. After, this numbers were received for average.

Statistical analysis

The experiment was performed in a completely randomized design with five replicates. Each replicate consisted of five plants. The experiment was repeated twice. Our data were analyzed by SPSS 20 and the means were separated according to Duncan's Multiple Range Test.

Results

Plant growth parameters

Different rhizobacteria had variable effects (both negative and positive) on the measured plant growth parameters, the essential oil content and yield of *Origanum onites* (*Table 1*). In terms of fresh herbage yield in oregano, all application except *B.*

megaterium 44, *B. megaterium* R2C, *B. subtilis* 36/10, *P. putida* 48/2, *P. fluorescens* 22B and *P. fluorescens* 8/6 were detected to be higher according to control. The maximum fresh herbage yield in oregano was obtained with the mineral NP fertilizer application, followed by *P. fluorescens* 8/2 inoculation. The maximum dry herbage yield in oregano was found after *P. polymyxa* R2/2 and *P. fluorescens* 58/3 inoculation, followed by *B. megaterium* 21/3, *B. subtilis* 52/1, and *P. fluorescens* 8/2, whereas the highest levels of dry leaf yield per plants were determined in treatments with *P. fluorescens* 58/3, followed by *B. subtilis* 52/1, *B. subtilis* 6/3, and *P. polymyxa* R2/2 (*Table 1*).

DOI: http://dx.doi.org/10.15666/aeer/1702_16411653

In terms of dry herbage yield, 31 applications were found to be effective according to control. In terms of plant height, 5 applications were detected as taller according to mineral fertilizer. The maximum plant height in oregano was found after *B. megaterium* 21/3 (48.3 cm) inoculation, followed by *P. fluorescens* 8/2, whereas the highest levels of canopy diameter per plants were measured in treatments with mineral NP fertilizer and *P. putida* 3/10 (46.01 cm), followed by *B. subtilis* 52/1 and *P. fluorescens* 8/2. In terms of chlorophyll content (SPAD value), applications except *B. megaterium* 66/5, *B. megaterium* R2C and *B. subtilis* 36/10 were found as effective according to control. The maximum chlorophyll content measured as *P. fluorescens* 8/2 (*Table 1*). Control plants gave the lowest water content of air drying (71.4%) while NP application gave the highest water content (74.8%), bacterial inoculations having values generally higher than control but lower than NP applied plants.

Oil yield, content and chemoarray

According to two years results, in terms of essential oil yield, only 4 applications were found as less than control. All of *P. fluorescens* and *P. putida* applications were increased yield of essential oil when compared to control. The maximum essential oil yield in oregano was found as *B. subtilis* 6/3 inoculation, followed by *B. subtilis* 52/1, *P. fluorescens* 53/6, and mineral fertilizer (NP). Essential oil yields ranged from 1.85 to 2.78%. The main components of the oil were carvacrol (58.19-70.08%), followed by thymol (17.85-26.27%), linalool (1.64-8.13%), borneol (1.38-2.39%), and p-cymene (0.37-3.21%). Highest p-cymene (3.21%) in oil was determined in control application. Other components were changed with bacteria inoculations. The maximum linalool content of oregano oil was obtained with the inoculation of *P. polymyxa* 2/5 (8.13%), followed *P. polymyxa* 11/4 and *P. polymyxa* R2/2 (*Table 2*). Of the 37 treatments, the maximum borneol and thymol components of oregano oil were seen in *P. fluorescens* 51/2, *P. fluorescens* 9/7, *P. fluorescens* 53/6 and *P. fluorescens* 58/3 inoculations. Borneol and thymol components in all four applications were detected respectively as % 2.39 and 26.27. The maximum carvacrol content essential oil in oregano was obtained with the *P. putida* 20C and *P. putida* 3/10 inoculations, followed by *P. putida* 27/3 and *B. subtilis* 52/1 (*Table 2*).

Nutrient uptake

All applications were found to be higher according to control in leaf nitrogen content. Twenty-four, ten and eleven of the 35 PGPR strains test selectively increased nitrogen, phosphorus and potassium content leaf, and most of them improved the plant growth parameters and yield in oregano plants. In terms of leaf phosphorus and potassium content, all applications except *B. magaterium* 22D inoculation was detected more effective than control. While the highest leaf nitrogen contents were determined on *P. putida* 3/10 inoculated oregano leaves, followed by *P. putida* 53/5, 55/2 and 48/2; *P. polymyxa* 43/5 and *P. polymyxa* R2/2 inoculations (*Table 3*). The leaf nitrogen content of inoculated *P. putida* 3/10 was higher (16.3%) than mineral fertilization. In terms of leaf phosphorus content, *P. polymyxa* 43/5, *P. polymyxa* 31/5, *P. polymyxa* R2/2, *B. subtilis* 52/1 and *P. polymyxa* 24/3 applications were found effective. As in terms of leaf phosphorus content, *P. polymyxa* 43/5, *P. polymyxa* 31/5, *P. polymyxa* R2/2, *B. subtilis* 52/1 and *P. polymyxa* 24/3 applications were found effective, in terms of leaf potassium content, *B. subtilis* 6/3, *B. subtilis* 52/1 and *P. polymyxa* R2/2 applications were detected as effective (*Table 3*).

Discussion

Inoculation with multi-traits bacteria increased fresh and dry herbage yield, dry leaf yield, plant height, canopy diameter, chlorophyll content (SPAD) and essential oil yield in oregano compared with the control. The responses to inoculation, compared to uninoculated control plants, were: -13.7% to +34.8% for dry herbage yield per plant, -13.4% to +49.2% for dry leaf yield, -0.4% to +30.3% for plant height, -0.6% to +24.2% for chlorophyll content, and -4.1% to +43.3% for essential oil yield. Plant growth responses were variable and dependent on the inoculant strain used, as well as on the growth parameter being evaluated. Increased plant dry weight and the oil content and biosynthesis of terpenes provided the increases in total essential oil yield by PGPRs inoculation. Using PGPR in the study was promoted the growth, yields and essential oil

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_16411653

content of oregano and chemical fertilizer application was equal or lower according to bacterial inoculations. Several authors have indicated that PGPR inoculation increased in shoot and root biomass, leaf area, and stomatal density, and marked qualitative and quantitative changes in monoterpene content in different medicinal and aromatic crops (Banchio et al., 2009; Banchio et al., 2010; Cappellari et al., 2013; Çakmakçı, 2016).

According to our data, aromatic structure, content and essential composition of oregano oil changed positively with multi-traits PGPR inoculation. In our study, major components of oregano oil have been carvacrol, thymol and borneol. Turkish oregano' essential oil was described as high content of phenolic compounds enclosed thymol and carvacrol (Bokov et al., 2015) and they have various biologic and pharmacological role (Dundar et al., 2008), antioxidant activity and they are important effect for component of oregano aroma (Bansleben et al., 2009). In addition, essential oil content and its composition are the most significant of quality criterion for oregano in all purposes (Baydar et al., 2004; Yaldiz et al., 2005; Baser, 2008; Bansleben et al., 2009; Ekren et al., 2013). Total essential oil yield, chemical composition and biosynthesis of major essential oil components of medicinal and aromatic plants were significantly affected by inoculation with PGPR (Banchio et al., 2008, 2009, 2010; Santoro et al., 2011, 2015; Prasad et al., 2012; Bahadori et al., 2013; Cappellari et al., 2013). However, there are not enough studies on the effect of inoculation with PGPR on plant growth or on production of secondary metabolites in important aromatic plants.

Effective multi-traits PGPR species, such as *P. polymyxa* R2/2, *P. putida* 3/10, *P. fluorescens* 8/2 and *P. fluorescens* 58/3 improved the N, P and K, nutrition in oregano, and therefore encouraged plant growth, essential oil quantity and quality. When particularly effective strains are used, it is possible that without using of chemical fertilizers to grow Turkish oregano organically without any loss in yield and quality. Beneficial role of these PGPR in growth, yield, oil content and compositions of oregano plants can have related to IAA-production, N_2-fixation, P-solubilisation, ACC deaminase activity utilization of variety and high rate of carbon sources and metabolize root exudates by the effective strains may be possible to afford a competitive advantage and play an important role in adapting to plants and soil. Previous studies suggested that carbon sources which were differentially utilized by the strains tested and many carbon sources were preferred by PGPR strain, which was one of the best bio fertilizers strains (Çakmakçı et al., 2010). Nutrients such as N, P, K, S, Ca, Mg and microelements can change of essential oil yield and composition according to reported similar studies (Nurzynska-Wierdak, 2013). In addition, for essential oils synthesized by plants, phosphorus is an important source. Therefore, PGPR can stimulate essential oil synthesis in medicinal plants when increased P uptake (Lichtenthaler, 2009). Moreover, according to researchers, leaves of PGPR inoculated plants are more contain to N, P and K than un-inoculated plants. Therefore, PGPR can provide increase in growth characters of medicinal plants (Saharan and Nehra, 2011). According to result of this study, versatile PGPR can be effective for improving growth and nutrient uptake of aromatic oregano crop. Also, more uptakes of nutrients that involved in chlorophyll formation can provide increasing for total chlorophyll due to beneficial effect of PGPR uptake of mineral elements in tea plants by application of PGPR was provide increased the chlorophyll content in leaves (Çakmakçı, 2016).

The better nutrient status were positively correlated with growth rates and yield of essential oils (Trivino and Johnson, 2000) and resulted in increased assimilation and translocation of photosynthates (Singh et al., 2016). While, N strongly affected not only

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_16411653

herb yield, but also its essential oil content and major oil constituents (Ozguven et al., 2006), an increase in the amount of phosphorous of the plants resulted in the enhanced accumulation of essential oil (Khalid, 2014) and affects the primary and secondary metabolites (Pal et al., 2016). While an adequate nutrient supply results in larger biomass production and consequently higher oil yield, changes in the essential oil composition may be related to better nutrition. On the other hand, mineral element composition of medicinal and aromatic plants has gained an interest and essential macronutrients may have nutritive, preventive and curative role in human.

Rate of carbon assimilation and photosynthetic activity can have provided by higher chlorophyll content in inoculated plants and for evaluation of plant photosynthetic efficiency, chlorophyll is an important parameter (Cappellari et al., 2015). For replace the use of chemical fertilizers, Microbial strategy is an attractive way for herbal plants, but little is known about their potential effect and ability of PGPR to increase plant secondary metabolites. At this point, limited knowledge is available in respect to effects of inoculation with PGPR in aromatic and medicinal plants (Banchio et al., 2008). For investigate the possible mechanisms by which bacteria increase phytochemical constituents in medicinal plants at the tissue, cell, or molecular level are need with more studies (Egamberdieva and da Silva, 2015).

Conclusion

PGPR have clear potential for improving the productivity of aromatic plants, and may significantly increase plant growth and reduce the amount of fertilizers required for economically sustainable crop production. Bacterial inoculants may be an efficient biotechnological tool for stimulating secondary metabolism in oregano plants, and studies of their activities will increase our understanding of processes that affect the accumulation of monoterpenes and phenolic compounds for a variety of applications in food and cosmetic industries, and poorly understood at present. In particular, *P. fluorescens* (8/2, 58/3, 9/7, 53/6 and 51/2), *B. subtilis* (52/1, 6/3 and R3/3), *B. megaterium* (21/3, K5E and 35/6), *P. polymyxa* (R2/2), and *P. putida* (55/2, 3/10 and 53/5) stimulated overall plant growth, including plant height, canopy diameter, fresh and dry herbage and leaf yield; improving macro- and micronutrient uptake, chlorophyll and essential oil content, and oil yield of oregano. Responses were variable and dependent on the inoculants strain and parameter evaluated. In addition, these bacteria can be used instead of mineral fertilizer as bio-fertilizer in sustainable organic oregano cultivation. Beneficial plant-associated bacteria exhibiting plant growth promoting traits can play a key role in supporting and/or enhancing plant growth, dry herb yield, and essential oil content, yield and its components. The action of PGPR on the essential oil and their components in medicinal aromatic plants remains a focus area for future research. Additional field trials are required to confirm the effects of PGPR strains on the growth characters, yield, essential oil and its constituents and nutrient contents, in this and so on plant species under different conditions. Future researches will also need to focus on elucidating the exact mechanisms by which PGPR have their growth-promoting effect and biosynthesis of secondary metabolites and monoterpene accumulation in medicinal and aromatic plants.

(Received 19th Oct 2018; accepted 2nd Jan 2019)

Abstract. A high concentration of arsenic in groundwater is a worldwide problem, high concentration of arsenic in groundwater has been documented as a major health issue around the globe. According to WHO standard, the maximum contamination level for total arsenic in water is 10 μg/L. China is one of the most affected country facing health issues because of arsenic contamination in groundwater that is often greater than established limits for human health. Although arsenic is present in several geographical regions in mainland China, Northern China has been identified as high-risk area. It has been estimated that 19.6 million people are at risk of being exposed to arsenic contaminated groundwater — especially rural areas, as those communities use groundwater for drinking water and household chores. To overcome the aforementioned problem, it is important to know the actual concentration level of arsenic in China and introduce a strategy to remove arsenic contamination. This paper provides a comprehensive overview on arsenic contamination status, sources and exposure pathways in China. It also aims to review the arsenic removal technologies which are easily available. Furthermore, it can be a useful resource for researchers as well as policy makers to identify and investigate useful treatment options.
Keywords: *water pollution, arsenic poisoning, human health, water treatment, remedy, China*

Introduction

The term water pollution usually refers to the introduction of physical, chemical, or biological materials in a body of water which affects its usage in the future. Water pollution has different types of contaminants, from which arsenic is a more poisonous and harmful one. Arsenic is the 12th most common element in nature and it usually appears in three allotropic forms including black, yellow and gray. If heated, it rapidly oxidizes to arsenic trioxide (As_2O_3) and has a garlic odor (Fendorf et al., 2010a). Arsenic is also known as the "King of Poisons". It is classified as carcinogen, mutagens and teratogen. Generally, in groundwater, natural occurrences of high arsenic levels were reported in aquifers — especially unconsolidated sediment aquifers throughout the world and have been connected to several adverse health effects. Arsenic content in water can harm the immune system, kidney, lungs and liver. In addition to this, it causes bladder cancers. Due to these major health risks, World Health Organization (WHO, 2004) has established a standard value (10 μg/L) which states that the maximum arsenic contaminant level in water for drinking water should not exceed 10 μg/L. Arsenic originates from different sources particularly geological surroundings such as a polluted environment, polluted bodies containing manganese oxides, irons, and arsenic-rich

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_16551683

minerals. There are extensive scientific research-based investigations in high arsenic level in groundwater all over the world (Sanjrani et al., 2017).

Arsenic contamination has been found in more than 70 countries but, the countries which are at the top of list for arsenic poisoning in groundwater are: India, Cambodia, Vietnam, Chile, Argentina, America and China. In other parts of the world, high concentration of arsenic has also been found in the bodies of water, including parts of the USA, Chile, Mexico, Argentina, Hungary, Japan, Canada, Poland, Ghana, Bangladesh, India, China, Afghanistan, Pakistan, Myanmar, Taiwan, are also reported to have arsenic contaminated water (WHO, 1999; Nickson et al., 2000; Niedzielski et al., 2001; Smedley and Kinniburgh, 2002; Guo and Wang, 2005; Marchiset-Ferlay et al., 2012; Ahmad et al., 2013; Horner and Beauchemin, 2013; Oguri et al., 2014; Qurat-ul-Ain et al., 2017; Sanjrani et al., 2018; Zheng, 2018). In 2004, World health organization (WHO, 2004) issued a list of countries with arsenic issues in water. The list is shown in *Table 1*.

Table 1. *List of countries affected by arsenic contamination*

Americas	United States of America, Alaska, Chile, Peru, Dominica, Honduras, Nicaragua, Argentina, El Salvador, Mexico
Africa	South Africa, Ghana, Zimbabwe
Asia	India, Bangladesh, Japan, China, Cambodia, Iran, Pakistan, Myanmar, Vietnam, Nepal, Thailand
Europe	United Kingdom, Austria, Finland, Romania, France, Greece, Italy, Hungary, Russia, Croatia, Serbia, Germany
Pacific	New Zealand, Australia

Among the countries that produce arsenic, China is the top producer of white-arsenic who produces almost 50% world-share, followed by other countries such as Peru, Chile and Morocco. Studies have identified some areas of high-risk for arsenic contamination belong to northern areas of China, including the Xinjiang province, the Shanxi province, the Inner-Mongolia province, the Henan province, the Shandong province and the Jiangsu province. All of the provinces contain naturally occurring arsenic with a concentration exceeding 10 μg/L (Nickson et al., 1998; Smith et al., 2000; Sun et al., 2003; Li, 2005; Xie et al., 2008; He and Charlet, 2013). In recent decades, it estimated that more than 19.6 million people are likely to be at risk of waterborne diseases. Moreover their lives are in danger due to arsenic contamination in groundwater (Rodríguez-Lado et al., 2013). There is collaboration between Switzerland and China, a special team is conducting research on ground-breaking studies, using geological maps and geological data to pin-point areas more likely to be put at high-risk due to the poison (SWI, 2012). The conducted study shows the increasing health-threat in China, including those areas which were not previously at risk. Each year, approximately 19.0 million Chinese people get sick because of polluted water from either industrial or agricultural activities, which cause approximately 60,000 premature deaths (Sun et al., 2011; IWR, 2011). There is a particular health threat in northern China because communities who belong to this area mostly depend on groundwater for their lives. China is a big country with more than 10 million drinking wells which are difficult to screen. It is expected that recent advanced research will help policy makers and authorities in China manage their well-screening programs as contaminated wells need to be treated. (Chan and Griffiths, 2010; WHO, 2011; CR, 2013). The situation needs be

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_16551683

quickly placed under control and there is an urgent need to arrange drinking water free of arsenic to communities who belongs to rural areas. In this regard, many different approaches may be applied for different bodies of water. Treatment options are available for arsenic contaminated water. These treatment options include pond water, surface water and harvesting rainwater. There are also other treatment possibilities such as to create a safe environment while also providing low-cost and small level fitted systems for removal of arsenic from groundwater for removal of arsenic from groundwater. In rural areas, it may not be feasible to install such a system for many families; however with the government supports rainwater harvesting could be possible option to acquire safe water for more households (Cheng et al., 2004; Sarkar et al., 2010).

Around the world, arsenic is being removed in many areas. With the introduction of many arsenic removal technologies, it is easy to treat the water. These technologies helps in arsenic remediation, including activated alumina, ion exchange, membrane filtration, reverse osmosis, modified coagulation-filtration, and also enhanced lime-softening. However, affected rural areas or developing areas need ideal and effective technology that should be versatile, low-cost, transferable and adoptable for both community application and household units (USEPA, 2000; Berg et al., 2006; Visoottiviseth and Ahmed, 2008).

While considering the serious issues of arsenic pollution in groundwater of several regions of China and it treatment technologies, this paper aims to review recent status of arsenic contamination in several regions of China which are highly affected exceeding WHO standard level 10 ug/L. This paper also aims to review about its sources and reasons for mobilization, exposure pathways as well as suitable technologies for arsenic removal which can be applied for treatment. This paper will prove to be a helpful and useful resource for readers and researchers or policy makers in regards to the identification and investigation for the better solutions.

Contamination level of arsenic and affected areas in China

The distribution of arsenic concentration drawn (as shown by contour lines) in groundwater of different provinces in China and is presented in *Figure 1*. Investigations have identified several basin areas around China where groundwater frequently contains >10μg/L arsenic, which exceeds the current drinking water standard established by the Chinese Environmental Protection Agency for Public Water Supply. Every province has different arsenic range; after reviewing several studies, a map has been drawn to this review paper to help one understand the situation of arsenic in every province clearly. In the map, the most affected regions with arsenic contaminated aquifers indicated by the color red. Arsenic pollution occurs in many provinces (Beijing, Guangdng, Gansu, Henan, Hunan, Heilongjiang, Inner Mongolia, Jilin, Jiangsu, Liaoning, Ningxia, Qinghai, Sichuan, Shandong, Shanxi, Taiwan, Xinjiang, Yunnan and Zhejiang) (*Table 2*). It is important to take note of the method in which arsenic contamination has been detected in water samples. Many different organizations (government and non-government groups) have employed both field-kits and in-laboratory research to identify arsenic contaminated waters. These studies have yielded accurate results. These findings are based on the data from (Tseng et al., 1968; Huang et al., 1985; Wang et al., 1993; Luo, 1993; Jin et al., 2003; Chen et al., 2003; Pang et al., 2003; Liu et al., 2003; Deng et al., 2004; Guo and Wang, 2005; Pei et al., 2005; Shen et al., 2005; Li et al., 2006; Luo et al., 2006; Yu et al., 2007; Yang et al., 2008; Guo et al., 2008; Xie et al.,

DOI: http://dx.doi.org/10.15666/aeer/1702_16551683

2008; Han et al., 2009; Zhu et al., 2009; Liu et al., 2009; Qin and Xu, 2010; Huang et al., 2010; Li et al., 2010; Jiang et al., 2010; Hao and Xing, 2010; Bo and Luo, 2010; He et al., 2010; Shi et al., 2010; Tang et al., 2010; Zhang et al., 2010; Han et al., 2010; Wang et al., 2010; Yang et al., 2011; Xie et al., 2011al., 2011b; Bian et al., 2012; Chen et al., 2012; Wen et al., 2013; Gao et al., 2013; Guo, 2013; Guo, 2014) previously published literatures. Most affected areas to date, rounded about 3998 individuals with arsenicosis, including children most who have been identified living in rural areas of the Shanxi province, in Northern, China (Wang et al., 2007; Sun et al., 2011).

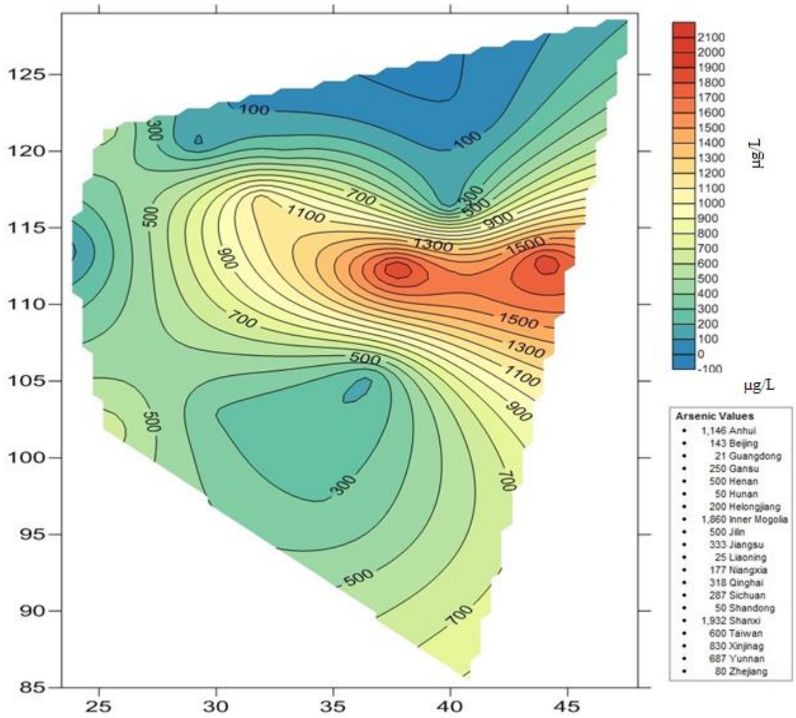

Figure 1. *Contamination level of arsenic*

The arsenic problem in China was first documented in the late 1970's and early 1980's; arsenic-specific changes were diagnosed in the Kuitun area of the Xinjiang province. Later in 1989, Inner Mongolia was reported as another serious arsenicosis area, followed by Shanxi province around 1994 (SWI, 2012, Unicef). Researchers are still interested in some areas because the arsenic value may vary every year especially in Shanxi province of China. Moreover, the Shanxi province has been recognized as a famous area with significant exposure in terms of high arsenic concentration (up to 1932 µg/L) level (*Figure 2*). According to new recent research the area of China with the highest arsenic content is Datong Basin. Its maximum arsenic content (2610.9 µg/L) was detected at the depth of 26.8 m (Sun, 2004; Xie et al., 2013). The Shanxi province —especially Datong Basin — has a high level of arsenic in groundwater, which many use as drinking water. Datong Basin is one of the most water-stressed regions (Xie et al., 2011c), in the world. In this water stressed region, surface water supply is usually very limited; therefore, alternative sources for portable, drinking water and house hold and irrigation water is mostly groundwater. The nexus of population growth and climate change in the region has exacerbated the use of groundwater resources with dramatic

DOI: http://dx.doi.org/10.15666/aeer/1702_16551683

impact both on its quality and quantity (Wang et al., 2009). The current challenge is to understand the process and also focus on how to decontaminate the widely occurring geogenic arsenic in groundwater in this region of China so the water supply meets the required WHO standards (Xie et al., 2012).

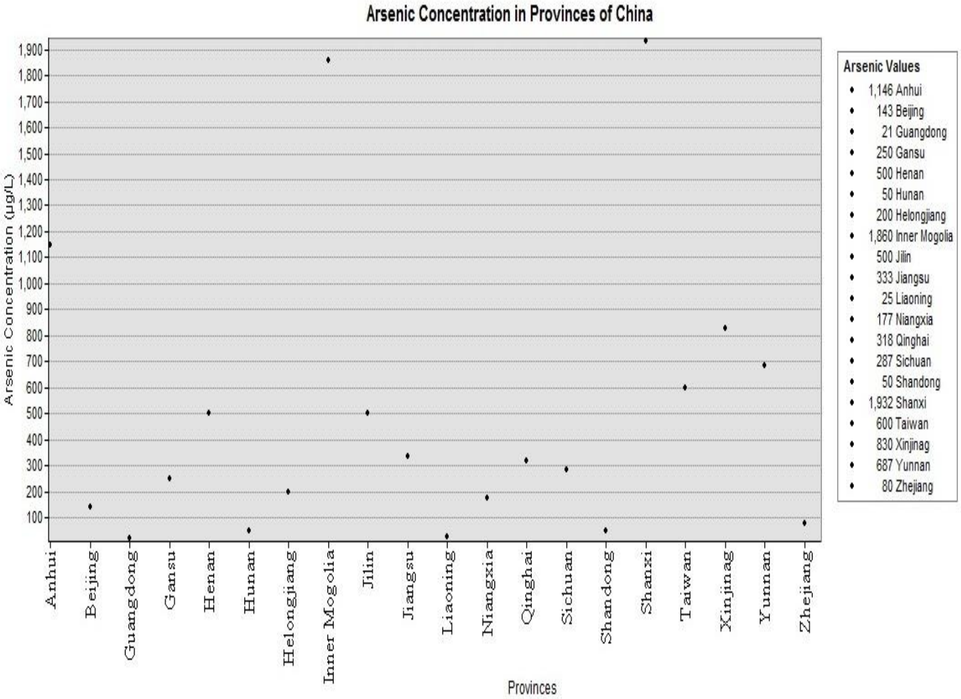

Figure 2. *Arsenic contamination level in different provinces of China*

Sources and Mobility of Arsenic

Natural occurrences of arsenic-contaminated groundwater have brought severe associated health risks. Arsenic may enter water bodies, air and land by transportation through water runoffs and wind-blown dust etc. Arsenic in the atmosphere comes from geological activities such as volcanoes, and organisms — especially microorganisms— and industrial activity in as the burning of fossil fuels as well as other activities. It has been previously accepted that the major sources of arsenic contamination in the groundwater of China are geological deposits, which is present in 200 minerals. Except geo and mining environments, other two main environmental conditions are known to be linked to natural arsenic in groundwater systems (Deng et al., 2009) (i) aerobic alkaline environments in closed basins in semiarid and in arid regions, where pH is high and leads to alkaline desorption of arsenic from mineral oxides, and (ii) aquifers are in under reducing conditions, where the release of arsenic is closely related to reductive dissolution of arsenic-bearing iron (hydro)oxides in sediments. In groundwater, there are two common types of forms of arsenic including Arsenite and Arsenate. Arsenite is always present under more reducing conditions whereas arsenate almost always present under oxidizing conditions. Several related studies in China have indicated the arsenic-enriched groundwater to be classified as reducing conditions (Smedley et al., 2003; Guo and Wang, 2005; Zhang and Guo, 2007; Guo et al., 2010; Hagiwara et al., 2011; Xie et al., 2013), particularly in the arid regions, where such conditions in alluvial and lacustrine aquifer sediments are often concomitant with high salinity and/or alkalinity. In some areas, mostly Taiwan, arsenic release has also been associated with anoxic aquifers (Lee et al., 2009).

As stated earlier, previous studies indicate that the sediment–water interactions cause geogenic enrichment of arsenic in groundwater. Furthermore, arsenic content ranging

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_16551683

from 1 to 10 mg/kg can cause enrichment of dissolved arsenic in groundwater may exceed 1000 μg/L (Smedley and Kinniburgh, 2002). It is critical to document the source of arsenic in sedimentary aquifers to improve our understanding of arsenic enrichment mechanism. Efforts have been made by different organizations to document the potential sources of arsenic in aquifers and it has been indicated that the sources of arsenic in sedimentary aquifers are related to chemical weathering of the minerals, which contain arsenic within it (Saunders et al., 2004; Zheng, 2007). Studies have reviewed and explained the link between natural arsenic contaminated aquifers and weathering. Several minerals related to arsenic and occurrences are documented in detail in *Table 3*.

Table 3. *Arsenic minerals occurring in nature*

S. No	Mineral	Composition	Occurrence
1	Native arsenic	As	Hydrothermal veins and deposits that contain other arsenic minerals
2	Niccolite	NiAs	A minor-component of Ni-Cu ores in high-temperaturehydrothermal veins
3	Safflorite	$(Co,Fe)As_2$	Hydrothermal veins
4	Realgar	AsS	Vein deposits often associated with orpiment clays, and lime stones, deposits from hot springs
5	Orpiment	As_2S_3	`Hydrothermal veins, hot springs, volcanic sublimation products
6	Cobaltite	CoAsS	Medium-temperature hydrothermal deposits, metamorphic rocks
7	Arsenopyrite	FeAsS	The most abundant arsenic mineral, dominantly in vein sofhydrothermal origin, found in pegmatites, high-temperature gold, quartz and tin veins, in contact metamorphic sulfide deposits, also in gneisses, schist sand other metamorphic rocks
8	Arsenianpyrite	$Fe(As,S)_2$	Hydrothermal veins, accessory mineral in igneous rocks, pegmatites and contact metamorphic deposits
9	Lollingite	$FeAs_2$	Mesothermal deposits associated with other sulfides and calcite gaunge
10	Tennantite	$(Cu,Fe)_{12}As_4S_{13}$	Hydrothermal veins and contact metamorphic deposits
11	Enargite	Cu_3AsS_4	Hydrothermal vein deposits formed at medium temperatures
12	Arsenolite	As_2O_3	Secondary mineral formed by oxidation of FeAsS, native arsenic and other arsenic minerals
13	Scorodite	$FeAsO_4 \cdot 2H_2O$	Secondary mineral formed by oxidation of arsenic-bearing sulfides
14	Annabergite	$(Ni,Co)_3(AsO_4)_2 \cdot 8H_2O$	Secondary mineral formed by the alteration of Co-Ni-bearing arsenides and sulfides, in the oxidized zone of hydrothermal mineral deposits
15	Hoernesite	$Mg_3(AsO_4)_2 \cdot H_2O$	Secondary mineral, in limestone blocks and volcanic tuff
16	Symplesite	$Fe^{2+}{}_3(AsO_4)_2.8H_2O$	Secondary mineral in the oxidized zone of some arsenic rich Hydrothermal mineral
17	Conichalcite	$CaCu(AsO_4)OH$	Secondary mineral in the oxidized zone of Cu deposits, and alteration product of enargite

Source: Modified from (Smedley and Kinniburgh, 2002; Anthony et al., 1990; Anthony et al., 2000)

Although large areas such as the Tarim basin (Xinjiang), the Ejina basin (Inner Mongolia), the Heihe basin (Gansu), the Qaidam basin (Qinghai), the Northeastern plain (Inner Mongolia, Jilin, and Liaoning), and the North China plain (Henan and Shandong) are known as being potentially affected, the worst situation of arsenic problems in China has been documented in Inner Mongolia and the Datong Basin, where several studies have been conducted. More recently, the controlling factors

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_16551683

(Saunders et al., 2004; Xie et al., 2008, 2009a, 2009b) have been documented to understand the arsenic mobilization in aquifers system at the Datong basin. Fe-hydroxides/oxides were the major causes for arsenic in aquifer systems at Datong (Xie et al., 2008, 2009a, 2009b). However, the source of the geogenic arsenic in some areas is a controversial issue and has yet to be determined. Although results of the preliminary geochemical survey have indicated that the bedrocks around the basin were the potential sources for arsenic in the aquifer system (Xie et al., 2013), more detailed work is still needed to answer this open question.

It is already generally accepted that the reduction of arsenic-bearing Fe oxides/hydroxides through organic carbon oxidation can be said to promote the mobilization of arsenic. However, the mechanisms involved are still not fully understood. Studies are being conducted to understand the processes controlling the mobilization of arsenic. Therefore, it is important to understand the transformation of Fe minerals within the aquifer system in order to elucidate the mechanisms involved in the release of arsenic into groundwater. Studies (Jiang, 2001; Xie et al., 2008, 2013) have shed a light on arsenic mobilization and the associated dissolution/precipitation and transformation of Fe minerals. Studies have presented Fe isotope compositions of Fe leached from aquifer sediments which were collected from a well-known arsenic-contaminated site in China at the Datong Basin; the results demonstrate that in various Fe pools, the Fe isotopic composition may be produced through microbial Fe(III) reduction and the secondary Fe(II) phases formation. The Fe isotope compositions and the distinct arsenic concentrations in HCl extracted poor-crystalline Fe phases and crystalline Fe(III) provide a framework to interpret arsenic mobilization in aquifers in the Datong Basin, China (Jiang, 2001, Xie et al., 2008, 2013; Zhu et al., 2009; Lee et al., 2009).

Generally, Arsenic pyrites/ferrous hydroxides are arsenic-rich minerals which are stable in reducing environment under water-table and are mostly concentrated in organic deposits. However, the different anthropogenic activities accelerate the oxidation process and arsenic release from the minerals. Absorption onto iron hydroxide is not a problem,while adsorption of arsenic onto iron hydroxide returns to the reduced-environment under the water-table and mixes with water and ultimately poisons the water. The hypothesis elaborates the recent phenomenon that the origin of arsenic-rich groundwater is human-made. Moreover, the different geological processes such as weathering, erosion, sedimentation, and use of irrigation and fertilizers accelerate the processes (Xie et al., 2008, 2009b, 2012; Hagiwara et al., 2011; Maity et al., 2012; Jiang, 2001).

Exposure pathways and toxic effects of arsenic to human health

Several studies have been conducted to document the toxicity of arsenic and its effects on human health in various arsenic-contaminated regions around the globe (Engel and Smith, 2004; Raven, 2009). Usually arsenic enters human-beings through two pathways; first, direct consumption of drinking water that contains arsenic and second, for populations not exposed to elevated arsenic in drinking water to have indirect contact through food intake and the cultivation of crops. Undetectable in its early stages, arsenic poisoning takes between 8 and 14 years to impact health, depending on the amount of arsenic ingested, nutritional status, and immune response of the individual (Raven, 2009; Fontcuberta et al., 2011). Toxicity depends on the amount of arsenic intake, which can be classified into acute, sub-acute and chronic toxicity

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_16551683

respectively. Arsenic contamination in drinking-water threatens health around the world and affects an estimated amount of more than 150 million people. While around 110 millions belong to highly affected ten countries in South and South-east Asia including Bangladesh, Vietnam, China, Taiwan, Laos, Cambodia, Myanmar, India, Pakistan, and Nepal (WHO, 1999; Hsueh et al., 1995; Brammer, 2008; Raven, 2009; Fontcuberta et al., 2011). Recent studies have also documented that human intakes of arsenic, especially inorganic in a range of 0.05 mgL^{-1} leads to arsenicosis. Arsenic is associated with a several non-neoplastic diseases, such as cerebrovascular disease, cardiac disease, leuco-melanosis and hyperker- atosis, diabetes mellitus, pulmonary disease and diseases of the capillaries, arteries and arterioles (Fontcuberta et al., 2011). Chronic arsenic ingestion from drinking water is known to cause skin cancer affected by arsenite and arsenate. Chronic exposure to inorganic As causes several disorders upon different biological systems such as the digestive system, respiratory system, cardiovascular system, hematopoietic system, endocrine system, renal system, neurological system, and reproductive system. These diseases ultimately increase the risk for bladder, kidney, liver, lung cancer, and diseases of the blood-vessels of the legs and feet, and possibly high blood pressure which is shown in *Figure 3* (Mandal et al., 1996; Maharjan et al., 2005; Saha, 2009; Shukla et al., 2010; Fendorf et al., 2010b; Chakraborti et al., 2010; WHO, 2011).

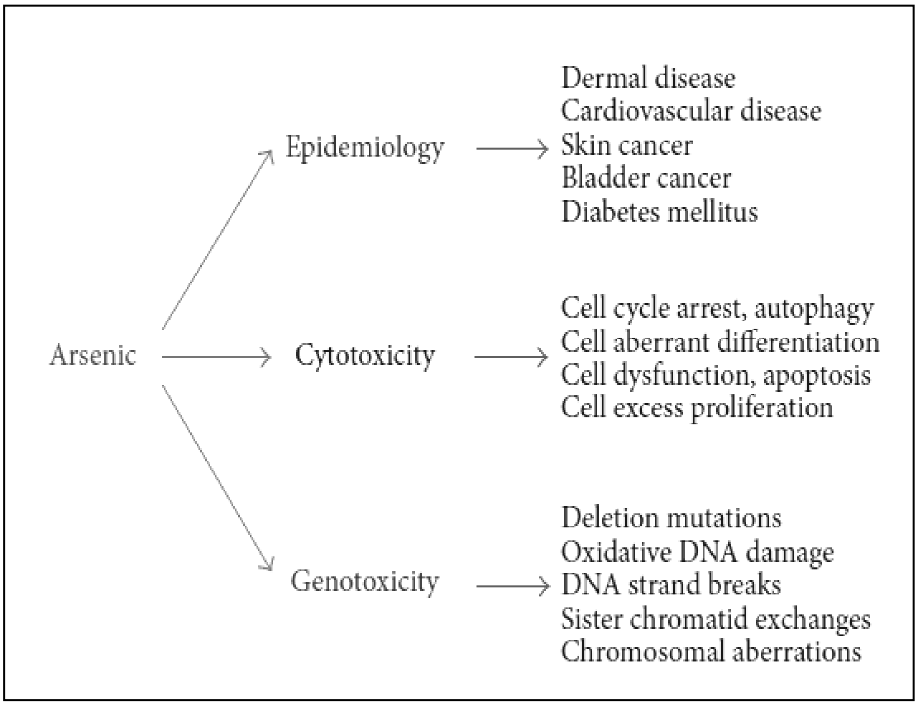

Figure 3. *Arsenic toxicity in human (Saha, 2009; Shukla et al., 2010)*

The major arsenicosis regions are presently documented in large deltas and along the largest rivers merging from the Himalayas (Fendorf et al., 2010a) such as in the Bengal delta (Chakraborti et al., 2010), other parts of India (Saha, 2009; Shukla et al., 2010), Nepal (Thakur et al., 2011), Pakistan (Malik et al., 2009), Myanmar, Vietnam, Cambodia (Berg et al., 2007; Polya et al., 2008) and China (He and Charlet, 2013). Therefore, arsenic free water is urgently needed to mitigate arsenic toxicity and protect

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_16551683

the health and well being of people living in acute arsenic problem areas — especially in rural areas where the groundwater is the only source for drinking water. The populations exposed to to arsenic around the world are shown in the *Table 4*. It was first realized in the late 1970s and early 1908s that there were arsenic issues in China; firstly patients from Kuitun area of Xinjiang province were diagnosed to have arsenicosis. Later Inner Mongolia was documented as another areawith the worst arsenicosis in 1989, followed by the Shanxi province around 1994, and recently the Datong Basin has the worst arseni ccontamination levels, which has brought health risks communities belonging to rural areas (Sun, 2004; Kongkea et al., 2010, Xie et al., 2013, He and Charlet, 2013).

Table 4. *Estimated Number of people exposed to arsenic contamination in selected countries*

Countries	Population exposed to As	Reference
India	102585	WHO 1999, UNICEF 2013
China	31385	
Bangladesh	30969	
Pakistan	23202	
Vietnam	15603	
USA	6225	
Italy	5210	
Mexico	5041	
Japan	4910	
Taiwan	4133	
Argentina	2551	
Cambodia	2422	
Nepal	1465	
Hungary	1422	
Canada	1404	
Chile	1046	

In China, several provinces have arsenic contamination in its groundwater, which crosses the standard range of 10 ug/ml. However, epidemiological studies on the effects of arsenic exposure from drinking water on public health indicated a carcinogenic effect. As arsenic bring cancers of the skin, liver, lung, bladder and kidney, and probability, experts indicated that a concentration level of 50 µg As/L could lead to cancer in 1 in 100 individuals. In the case of chronic poisoning, this deadly element accumulates in skin, hair and nails, resulting in strong pigmentation of hand and foot, also known as keratosis, and problems in other body system such as respiratory, neurological, high blood pressure, endocrine, cardiovascular and metabolic dysfunctions/disorders (Yunus et al., 2011; McClintock et al., 2012; Ferlay et al., 2015).

Treatment options for remediation of arsenic contaminated water

Several methods are available for the determination of arsenic in water by WHO and several studies have been conducted for arsenic removal (Kartinen and Martin, 1995; Joshi and Chaudhury, 1996; Gates, 1998; Leupin et al., 2005; Mondal et al., 2013; Sharma et al., 2005a; Sharma, 2007a, 2007b). The most common of these methods include:

(i) Atomic absorption spectroscopic method – (a) hydride generation atomic absorption (AAS – HG) and (b) electrothermal atomic absorption (AAS – GF).

(ii) Silver diethyldithiocarbamate method (SDDC).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_16551683

(iii) Inductively coupled plasma (ICP) method – (a) mass spectrometry (ICP-MS) and (b) atomic emission spectrometry (ICP-AES).
(iv) Anodic stripping voltammetry (ASV).

There are also several available options suited for arranging drinking water with low arsenic content such as:

(i) Explore alternative source of water with low arsenic content.
(ii) Treatment/removal of arsenic from the water source.

It is accepted that arsenic is found in shallow groundwater, while deep groundwater is either free of arsenic content or have low content. However, the depth to arsenic free aquifers differs between the locations so a detailed server is needed. The second option is to use surface water i.e lakes, rivers and ponds which are arsenic free or have a low arsenic content. The third option is to harvest rainwater, historically it is a way to utilize rainwater for domestic water supply and it has been used around the globe (BGS, 2004; Ahmed et al., 2005; WHO, 2011).

The aim of this section is to review and update the recent advances made in the technological development in arsenic removal technologies and to explore the potential of those advances so we can document the problem of arsenic contamination. There will be a special focus on the efficiency, applicability and social acceptability of the various technologies. In the 1990s, several methods were introduced for the removal of arsenic from water through large conventional treatment plants. The most commonly used technologies include adsorption onto sportive media, ion exchange resin and membrane processes, oxidation (biological and chemical), co-precipitation and adsorption onto coagulated flocs, lime treatment, and bacterial treatment, which can be applied for arsenic removal (Gates, 1998; Leupin et al., 2005; Sharma et al., 2005a; Sharma, 2007a, 2007b; Mondal et al., 2013) These techniques are still being used all around the world, several techniques are defined below.

Arsenic removal by Oxidation

Arsenic [As(III) and As(V)] is present in groundwater so oxidation is a pretreatment process which is conducted for converting arsenite to arsenate/AsIII, then to AsV and finally AsV precipitation is takes place. This process is important for anoxic/anaerobic groundwater because AsIII is the pre-dominant form of arsenic at aneutral pH (Sharma et al., 2007). Free chlorine, chlorine dioxide, hypochlorite, chloroamine, ferrate, ozone, oxygen, hydrogen peroxide, permanganate, and fulton's reagent are used for the oxidation of AsIII into AsV (Sharma et al., 2005b; Sharma and Sohn, 2009), but in developing countries, hypochloride, atmospheric oxygen and permanganate are being used. During the process of oxidation — which can take up to a couple of weeks hydrogen peroxide and chloroamine are slower than permanganate, chlorine and ozone (Islam, 2005, 2007). It is accepted that free Chlorine or hypochlorite is very effective for the oxidation of AsII, while theoxidation of AsIII is well achieved by ozone. However, chlorine dioxide is prohibited to use for surface water, American environmental agencies paymuch attention to this factor (Sarker, 2010). About the removalof arsenic, Utilizing FeO42- forpurifying water is recommended HFO (hydrous ferric oxide) appears to be the most important phase responsible for removing the arsenic from ground water around the world. It is well documented that High arsenic came into contact with iron oxides in the shallow aquifer, which could possibly lead to arsenic removal (Young, 1996; BGS, 2004; Ahmed et al., 2005; Lena et al., 2014; Shankar et al., 2014; Wegelin et al., 2000). Thus, for the removal of arsenic from water,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_16551683

oxidation/precipitation technology is very effective (Yoon and Lee, 2005; Sharma et al., 2005b).

Arsenic removal by In-situ Oxidation

DPHE Danida Arsenic Mitigation Pilot Project is applied for In-situ oxidation of iron and arsenic in the aquifer. Stored aerated tube-well water is released back into the aquifer. The dissolved oxygen in water oxidizes arsenite to arsenate (less mobile) and the ferrous iron in the aquifer is oxidized to ferric iron which leads to a reduction in arsenic content in tube-well water. Results of the experiment in-situ oxidation show that arsenic in tube-well water is reduced to about half due to underground-precipitation and adsorption on ferric iron. In-situ oxidation has also been achieved by pumping the oxygenated water into the groundwater aquifer to reduce the arsenic content in the pumped groundwater. While its potential for the removal of arsenic is only little, the results indicate that arsenic concentrations can be reduced in the groundwater zone before water extraction (Dutta et al., 2004; Sharma et al., 2007).

Arsenic removal by Photochemical, Solar photo-catalytic Oxidation

Photochemical and photo-catalytic oxidation of AsIII have been used in many studies for arsenic removal. The most widely tested chemical oxidant in presence of naturally occurring iron in the field is UV-light assisted oxidation of AsIII (Miller et al., 2011) because FeIII - hydr-oxide and chloride species can absorb photons to provide highly oxidizing hydr-oxyl and di-chloro radicals which converts AsIII to AsV (Ryu et al., 2013), as SORAS is a simple technique of solar oxidation for arsenic in transparent bottles to reduce arsenic content of drinking water (Emett and Khoe, 2001). It is also indicated that the efficient oxidation of AsIII to AsV can be achieved by photo-catalytic oxidation (PCO) (Bissen et al., 2001). Here ultraviolet radiations speedup the oxidation of AsIII in presence of other oxidants or oxygen. Ultraviolet radiation/solar light help to create/generate the hydroxyl-radicals via the the process of photolysis of Fe(III) i.e (FeOH2+) and both oxygen and hydroxyle radicals accelerate the rate of oxidation.

It has also been investigated that adsorption of arsenic on TiO2 takes place while the oxidation process of AsIII to AsV is through photo-catalytic oxidation and TiO2. This can provide safe water; we know this because from experiments formentioned, it shows that it reduced arsenic levels to less than the standard limit given by WHO for drinking-water (Anthony et al., 1990, 2000; McNeill and Edwards, 1995; Dutta et al., 2004, 2005; Choong et al., 2007; Ravenscroft, 2009). This experiment is still being used in Bangladesh and indicated that this process averagely can reduce one-third of arsenic content from water.

Arsenic removal by Biological oxidation

Study (Pallier et al., 2010) documented that some micro-organisms such as Gallionella ferruginea and Leptothrixochracea support and accelerate biotic-oxidation of iron. The study (Pallier et al., 2010) was conducted in the laboratory where iron-oxides and micro-organisms (Gallionella ferruginea and Leptothrixochracea) were deposited in a filter-medium, which has a favorable environment for the adsorption of arsenic, as AsIII cannot be efficiently absorbed onto iron-oxides. These micro-organisms are assigned to oxidize AsIII to AsV, which got adsorbed in FeIII. This leads to up-to 95% removal of arsenic. Kinetics of bacterial oxidation of AsIII and oever all removal of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_16551683

AsV by sorption onto bio-genic manganese-oxides during ground-water treatment was also studied (Sharma et al., 2007; Pallier et al., 2010; Hu et al., 2012). Biological oxidation is a new technique of the oxidation of iron and manganese as a treatment technique for arsenic removal. These biological treatment techniques are the natural biological processes, and it takes a couple of days for remediation of metals in soil and groundwater by certain plants and micro-organisms. During treatment, the following sequences of reactions have taken place in the treatment system:

a. FeII to FeIII and MnII to MnIV (oxidation).
b. AsIII to AsV (oxidation).
c. MnO_2 (Precipitation).
d. Abiotic-oxidation of AsIII by MnO_2.
e. AsV sorption via MnO_2.

Whereas steps (a) and (b) are biotic steps (c) to (e) are abiotic. This natural process for treatment has been found excellent as it can lead to up-to 95% of the removal of arsenic (Pallier et al., 2010).

Arsenic removal by Coagulation–flocculation

Coagulation-flocculation has got attention for the removal of arsenic from water, it is most commonly used for larger-capacity facilities and it requires the formation of a floc used to remove arsenic from groundwater. Coagulation-flocculation usually requires Fe and Al based coagulants among other various chemical coagulants i.e ferric chloride, or ferric sulfate or aluminium sulfate, need to be added and dissolved in water under efficient stirring for 1-10 minutes. Positive-charged cat-ionic coagulants have to decrease the negative charge of colloids. In this process, aggregation of particles forms larger particles. It is described that this technique obtained enough amount for removal, which roundedout to more than 90% of AsV and 77% of AsIII. While using 9.2 ppm of Fe3+ aluminium or when ferric hydroxide micro-flocs are formed, As trivalent arsenic occurs in non-ionized form. For efficient removal, oxidation of As(III) to As(V) is thus required as a pretreatment. This surely can be achieved with the addition of bleaching powder (chlorine) or potassium permanganate. It has been documented that this technique is good for removal of arsenic below standard drinking water and also Fe based coagulants have also been investigated by several authors (Cheng et al., 1994; Appelo et al., 1999; Song et al., 2006; Sharma et al., 2007; Andrianisa et al., 2008; Gupta et al., 2009; Baskan and Pala, 2010; Lakshmanan et al., 2010; Van Halem et al., 2010; Lacasa et al., 2011). Recently, Hu et al. (2012) has used it and found the same.

Some of chemical coagulants are being used, whereas Fe based coagulants have been documented to be most efficient in water treatment than others e.g Al based coagulants (D.P.H.E, 2001; Katsoyiannis et al., 2004). For efficient removal of arsenic from water, the arsenic needs to be adsorbed on amorphous metal hydr-oxides formed from coagulant. There is critical limitation in the process of coagulation/flocculation, it produces a large amount of sludge along with a big concentration of arsenic (Hering et al., 1996; Appelo et al., 1999; D.P.H.E, 2001; Song et al., 2006; Sharma et al., 2007; Andrianisa et al., 2008; Gupta et al., 2009; Baskan and Pala, 2010; Lakshmanan et al., 2010; Van Halem et al., 2010; Lacasa et al., 2011). Real management of the contaminated sludge is needed for safeguarding the environment from secondary pollution and thus reduces the applicability of this method in field conditions.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_16551683

Arsenic removal by Electro-coagulation

Coagulation/flocculation has an alternative way known to be electro-coagulation which has a different the process, instead of adding a chemical reagent as ferric-chloride; metallic cat-ions are directly generated in the effluent to be treated while applying current between iron electrodes for dissolving soluble anodes. Generally, Electrolytic-oxidation of a sacrificial iron anode creates FeIII oxy-hydroxides / precipitates in the arsenic contaminated water in electro-coagulation. While with FeIII precipitated arsenic produces bi-nuclear inner-sphere complexes and it further aggregates to form a floc. Then metallic cat-ions and hydroxides are formed and colloids neutralize negatively charged which allow them to coagulate and finally create helpful results (Ghurye et al., 2004; Katsoyiannis and Zouboulis, 2006a, 2006b).

Arsenic removal by Electro-Chemical

In this method, a small amount of electricity is needed to create rust in arsenic contaminated water. The rust binds to arsenic, settling and/or filtering. The rust can then remove from the water (Jain and Singh, 2012).

Arsenic removal by Adsorption

This is one of the processes of adsorption, in which, solid particles are used for removing substances from solutions such as gas or liquid. Removal of arsenic by this technique onto activated/coated surfaces has been famous and used the most in many countries. Some of its benefits are its low cost, high removal efficiency, easy operation and handling and also its sludge-free day-to-day operations. There is an extra advantage of this technology a number of the adsorbents can be reused and regenerated. Several studies have addressed the arsenic-removal by adsorption via many adsorbents (Wilkie and Hering, 1996; Mohan and Pittman, 2007), including commercial activated carbon, activated alumina, layered double hydroxide, natural/modified clays and zeolites. Mohan and Pittman (2007) and Wilkie and Hering (1996) have reviewed and addressed approximately 40 different types of adsorbents using published literature, with more than 500 references. Recently, gaps in exploration and improvement in new adsorbents are being found. A few years back adsorption based on zeolites (Raven et al., 1998), iron oxides (Grafe et al., 2001; Zhu et al., 2013), alumina (Kanematsu et al., 2013), clays (Swarnkar and Tomar, 2012), etc. to adsorb arsenic from water and the removal of arsenic by adsorption processes/techniques probably depended on pH and the speciation of arsenic with better AsV removals as compared to AsIII at a pH level lower than 7 (Giménez et al., 2010; Anjum et al., 2011; Sun et al., 2013; Han et al., 2013; Zhu et al., 2013). Several other studies such as Kanematsu et al. (2013) reviewed that the general rate of arsenic adsorption and capacity adsorbents further depend on the presence of other ions such as: silicate, phosphate, $HCO^{-}3$, and Ca2+. These ions compete for the adsorption sites; some other studies (Lin and Wu, 2001; Singh and Pant, 2004) also substantiated this fact. It is documented that the most widely tested aluminium-oxide is activated alumina (AA) (Giles et al., 2011; Genuchten et al., 2012; Kanematsu et al., 2013). There are some other adsorption methods used for removal of arsenic from water, which are discussed in the section below.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_16551683

Arsenic removal by Bucket Treatment Unit

The Techniques of Bucket Treatment Unit (B.T.U) is an extremely effective and affordable treatment technique for the removal of arsenic within the household. Locally available materials can be used to build the treatment unit and if operated properly and smoothly, it is effective for removing of arsenic from water. These technology units units are generally based on chemical doses of 2 mg/L of potassium permanganate and 200 mg/L aluminum sulfate in a crushed powder form. In both lab and field conditions, these units were documented to provide good performances in removing arsenic.

Bucket Treatment Unit (B.T.U) was proposed by the DPHE-Danida Project which is based on the principles of co- precipitation, coagulation and adsorption techniques/processes. In this technique, there are two buckets, each one has a 20 liter capacity, and are placed one above the other. The further the process is conducted; chemicals are put manually with arsenic contaminated water in the upper red bucket. Mixing of chemicals is done by vigorous stirring with a wooden stick for about 30 to 60 seconds, followed by the flocculation process by gentle stirring for about 90 second. It takes 1-2 hours to settle. Once the water is settles, the water from the top red bucket is further allowed to flow via plastic pipe into the lower the green bucket, where a filter is already installed. In the lower bucket, which should have sand filter and a valve sludge does not build up in the upper bucket. This is how practically a treated water container (EPA, 2000a, 2000b; Giles et al., 2011).

Arsenic removal by Membrane technology (MT)

Membrane technologies, i.e RO, have been documented as reliable and efficient for arsenic removal. RO has proven to be the best practiced technology which can completely purify water. It is generally accepted that RO is superior in both pilot-scale and lab experiments; results have shown more than 95% As(V) and 74% As(III) removal efficiencies (BAMWSP, 2001; Tripathy and Raichur, 2008). Membrane processes get rid of arsenic through electric repulsion, filtration, and adsorption of arsenic containing compounds. With the help of poly-sulfone thin film and nano-filtration membrane (BQ01), the distinction between the removal of As(III) and As(V) was explored (Sarkar et al., 2000). It has been observed that the elimination of As(V) was much higher than that of As(III). Furthermore, another study (Kohnhorst and Paul, 2000) was conducted on the nano-filtration operating conditions, it was concluded that there is no effect on arsenic removal by the trans-membrane pressure, temperature or cross-flow velocity (Kohnhorst and Paul, 2000). This technique is proven to be the best and results shows that up to 99% of the arsenic can be removed (Sheng et al., 2006; Xi et al., 2014) through the conducted studies.

Arsenic removal by nano-filtration Technology

Arsenic is being removed from groundwater by nano-filtration (NF) membrane configuration. It has played a key role in controlling operation performances and membrane fouling. The nano-filtration (NF) membrane surface puts negatively charged above its iso-electric point (approximately at pH 5.9–6.4). Generally, alkaline/neutral pH is adjusted for raw groundwater so it brings up the effect of electrical charge repulsion and ion removal efficiencies, which is improved by nano-filtration (NF). This nano-filtration (NF) system has an efficiency of up to 92˜94% for arsenic removal (Xie et al., 2015; Song et al., 2015).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_16551683

Arsenic removal by Activated alumina (AA)

Activated alumina (AA) successfully removed arsenal from water supply systems and it was the first adsorptive medium for water supplies (Xie et al., 2008). Activated alumina is defined as a physical/chemical process, which is used particularly for the removal of arsenic and other ions. In this process, ions in feed water are sorbed to the oxidized Activated alumina (AA) surface. It is the widely tested aluminum oxide. It is prepared at high temperature, generally by the thermal de-hydration of aluminium hydroxide Al(OH)3. It has diameter approximately 0.3–0.6 mm; in addition, it has a high surface area for impressive sorption properties as it is a porous, granular material. The AA is used in the contaminants such as fluoride, arsenic NOM, silica and selenium. (Holl, 2010). It has been reported that, alum-impregnated AA can be adsorbent for AsV rather than untreated AA at a pH range of 2.8–11.5. When employed in batch mode, AsV concentration could be decreased down from $10mgL^{-1}$ (10,000 ppb) to 40 ppb (Katsoyiannis and Zouboulis, 2006a, 2006b).

Arsenic removal by Stevens Institute Technology

In this technology, the process resembles the previously mentioned B.T.U as Bucket Treatment Unit (B.T.U) proposed by DPHE-Danida Project which is mostly based on the principles of co-precipitation, coagulation and adsorption techniques/processes. This technology is also involved in two buckets, the first bucket is to mix chemicals (such as calcium hypo-chloride and iron sulphate) then supply in packets. The other bucket is used to separate flocs, where two processes have taken place (a) sedimentation and (b) filtration. The second bucket has a second inner bucket with slits on the sides to help sedimentation and to keep the filter sand bed in place (EPA, 2000a). This technology has been mostly used in Bangladesh and has been effective. The results of tested samples show that 80 to 95% of the samples reduce arsenic concentration to less than 0.05 mg/L (EPA, 2000a, 2000b).

Arsenic removal by iron coating

An experimental study has been conducted (Seidel et al., 2001), where an iron coating method is used as a simple groundwater remediation technology, which has great potential. Moreover, it is affordable, especially in villages and rural areas where groundwater is used by communities for drinking purposes. Under different conditions, coated iron oxide/hydroxide was investigated for the arsenic removal mechanism using an electron probe microanalysis, scanning-electron microscopy(SEM)/X-ray absorption spectroscopy, and fourier transformation infrared spectroscopy. It has proven to be an effective method for arsenic removal. Generally, the 4-step develop aquifer iron coating method, alternating injection of oxidant, iron salt and oxygen-free water. In situ the removal of arsenic from ground water in an aquifer was achieved by simultaneous injections of As(V) and Fe(II) reagents. The technique of adsorption or co-precipitation brings arsenic fixation with fine particles of goethite by way of bi-dentate bi-nuclear complexes. Therefore, the study documents that the technology results in high arsenic removal efficiency by the situ aquifer iron coating technique. This is likely resulted by the expanded particular surface area of the small goethite particles, which enhanced arsenic sorption capability and/or from coprecipitation of arsenic on the surface of goethite particles.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_16551683

Arsenic removal by hollow fiber nano-filtration membranes with a sulfo-nated poly ether ether ketone coating

In 2015, this technique got high attention when experimental studies were done (Saitua et al., 2005). The overall performance of this technique for arsenic removal from drinking water was tested. The membrane works well and does not allow above 95% of As(V) to contaminate the water. Furthermore, the membrane properties were studied, and rejects arsenic in the presence of interfering ions. Results indicated that di-electric exclusion might be able to rationally explain the rejection deviation from the Donnan exclusion effect. The valence of the ions played a major role, where there was a presence of interfering ions. Finally, cost estimation was conducted at 1000 m3 h^{-1}, which is about 0.15 US$ per 3 m when using the proposed SPEEK coated hollow fiber membrane for a plant. Results from different sources indicate that a SPEEK composite nano-filtration membrane is mostly suitable and efficient for removing arsenic from groundwater (Pinon-Miramontes et al., 2003; Saitua et al., 2005; Shih, 2005; Harisha et al., 2010).

Arsenic removal by Naturally Occurring Iron

This method has been found effective in Asian countries, where naturally occurring iron is used to precipitate the ground water and for removing arsenic by adsorption (Ahmed, 2001).

Concluding Remarks and future perspective

Arsenic is worldwide problem; arsenic has been documented in the Americas, Africa, Asia, Europe and Pacific countries. Arsenic in groundwater can found in several geographical regions in mainland China. Studies identify areas of high-risk arsenic contamination in the north of China, including Xinjiang, Shanxi, Inner Mongolia, Henan, Shandong and Jiangsu. The most affected areas to date, rounded about 3998 individuals with arsenicosis, including children, with most living in rural areas of the Shanxi province, in northern China.

Arsenic has created health problems around the world. The major arsenicosis regions are presently documented in large deltas and along biggest rivers merging from the Himalayas, such as in the Bengal delta, other parts of India, Nepal, Pakistan, Myanmar, Vietnam, Cambodia and China. Usually, arsenic enters human-beings through two pathways; first, direct consumption of drinking water contaminated by arsenic and second, for populations not exposed to elevated arsenic in drinking water, the indirect intake through foods and crops cultivated using arsenic-contaminated water represent the main sources of arsenic intake for humans.

Several available options suited for arranging drinking water with low arsenic content such as: (i) Explore alternative source of water with low arsenic content and (ii) Treatment/removal of arsenic from the water source. The most commonly used technologies include adsorption onto sorptive media, ion exchange resin and membrane processes, oxidation (biological and chemical), co-precipitation and adsorption onto coagulated flocs, lime treatment, and bacterial treatment, which can all be applied for arsenic removal.

Aeration/Fe precipitation/filtration is developed to remove arsenic; this technology has been accepted in China. The modification of commercial adsorbents (e.g., activated

DOI: http://dx.doi.org/10.15666/aeer/1702_16551683

carbon and activated alumina) and modification of natural mineral materials (e.g., zeolites) seem to be an approach to lower the operating cost and improve arsenic removal efficiency. Recently, several technologies to remove arsenic from drinking water have been introduced. Many of them are described in this review; each have their own advantages and disadvantages. Most of these technologies for removal of arsenic involve the direct removal of AsV or converting AsIII to AsV followed by removal of AsV.

While talking about future perspective, the government should monitor and document industrial and agricultural activities as they brought the arsenic pollution issue to the bodies of water in the first place.

Mining or chemical plants should be documented to deal with sewage, sludge storage and waste treatment. Sub departments should be developed and should be supervised by well-known persons; there should also be sampling and analysis of the discharge from industrial plants, which aim to supply safe drinking water to people in rural areas, including arsenic control. The government should take additional should take steps and put restrictions, if there is a not safe water source. Investment should be employed on the great engineering system for water transportation and water quality should be well documented. Small treatment facilities installations should be recommended in rural areas.

Abstract. The process of breeding to enhance nutrients, such as vitamins and minerals, in food crops through biofortification is a sustainable, eco-friendly and powerful strategy to overcome micronutrient deficiency. Therefore, the aim of the present investigation was to increase selenium content in edible parts of garlic (*Allium sativum* L.) supplied with either 20g/ha or 50g/ha aqueous solution of anhydrous sodium selenate. This was done either through foliar spray or soil flood application under open-field conditions. Results indicated that the 50g/ha concentration of sodium selenate application in the form of foliar spray significantly enhanced the selenium content in garlic bulb (3.23±0.16mgSe/Kg) and vegetative part (15.46±0.71mgSe/Kg) that is, a 12.52 and 7.8 fold increase was observed respectively, as compared to control. A significant increase in total phenolic content (4.72±1.79GAE/100g), total flavonoid content (18.50±1.82 mgQE/100g) and total antioxidant capacity (IC_{50} of 0.81mg/ml determined through DPPH radical scavenging assay) was also observed in the bulbous part of garlic. The results suggested that the consumption of 16g of dried garlic bulb, biofortified with 50g Se/ha, could cover the daily recommended dose of selenium for human beings. Selenium biofortified garlic crop can hold a market value as selenium functional food and can be used as an alternative to synthetic selenium supplements to overcome selenium deficiency.
Keywords: *Allium sativum; antioxidant activity; flavonoid content; malnutrition; polyphenols*

Introduction

Many people, particularly those living in developing countries are facing a silent crisis of malnutrition or hidden hunger (Swaminathan, 2012, Muthayya et al., 2013). About half of the world's inhabitants suffer in macronutrients and micronutrients deficiency which is responsible for 20 million adult deaths and more than five million childhood mortalities annually (Zhao and McGrath, 2009, Bouis and Welch, 2010) . In developing countries many food systems cannot provide adequate micronutrients to meet the demands of their citizens, especially families having fewer income resources (Bouis and Welch, 2010, El-Ramady et al., 2015). It is reported that among the six billion people in the world more than 15% are suffering from selenium deficiency (Fordyce, 2013). A range of chronic diseases have been associated with selenium deficiency including Keshan (an endemic congestive cardiomyopathy in China, with high rate of fatality) (Yang et al., 2008), cardiovascular diseases (Kardinaal et al., 1997, Oropeza-Moe et al., 2015), cancer, viral diseases (Clark et al., 1996, Beck et al., 2003), inflammatory conditions, diabetes mellitus, hepatopathies and HIV infection (Holben and Smith, 1999, Burk et al., 2015). Under this scenario, boifortification offers a cost

DOI: http://dx.doi.org/10.15666/aeer/1702_16851704

effective and sustainable strategy in modern agriculture to allow the access of more nutritious and healthy food to large population (Bouis et al., 2011, Carvalho and Vasconcelos, 2013).

Biofortification is the process of increasing the bioavailable micronutrient density of staple crops through conventional plant breeding and modern biotechnology to achieve a measureable and positive impact on human health (Pfeiffer and McClafferty, 2007). Such an intervention can be used to enhance the uptake and accumulation of specific nutrients in edible part of plants (Rouached, 2013). It is attained through genetic engineering, conventional breeding and manipulation of agricultural practices such as rhizosphere fertilization, soil and crop management strategies (Zuo and Zhang, 2011) etc. Selenium is a vital micronutrient for human beings and animals (Hartikainen, 2005, Lobanov et al., 2008). Plant based foods are significant nutritional sources of selenium (Se) supply for both human beings and livestock to meet their daily requirement for selenium. For adults, daily consumption of 40 to 50µg selenium for women to 75 µg for men and 8.7-10 µg for infants is recommended and an intake exceeding 400µg/day is assumed to be toxic (Burk, 2002, Fordyce, 2013). Selenium poisoning, referred to as selenosis is related to dietary intake of approximately 5 mg of selenium per day. In 1960, an outbreak of endemic human selenosis was reported in China, associated with the consumption of food containing more than 300mg/Kg selenium (Fordyce, 2013). In almost all European countries, the selenium fortified foods and the use of dietary selenium supplements are quite popular to overcome the Se deficiency (Yadav et al., 2007).

To overcome the animal Se deficiency, different practices are commonly employed, e.g., the use of dietary supplements, injections, salt licks and drenches (Yadav et al., 2007). Alternatively, consumption of selenium enriched plants and their products is beneficial because selenium present in organic form is more bioavailable than in inorganic form (Terry et al., 2000, Li et al., 2017). The process of selenium accumulation in agricultural plants varies according to the plant species, soil properties and the chemical nature of selenium (Mikkelsen et al., 1989).Vegetable crops belonging to the Allium family (*Allium sativum, Allium cepa,* etc) are important part of the human daily diet. Biofortification of the vegetables, known as seleniferous plants, can contribute to the alleviation of selenium deficiency. Among these alliaceous species, garlic is one of the most popular vegetables around the globe (Ghasemi et al., 2015). In 2007 according to FAO (United Nations Food and Agriculture Organization), approximately 1.01million hectare of land was used to produce about 10 million metric tons of garlic annually in the world. China is the largest producer of garlic, accounting more than 75% of the global production (Chen et al., 2013). *Allium sativum* has the ability to uptake the inorganic Se from the soil through the roots and is able to convert it into organic forms that are accumulated in its edible parts (Yadav et al., 2007). The chemistry of selenium in seleniferous plants simply relates to sulfur chemistry because selenium share great likeness in its chemical properties with sulfur and exists in oxidation states as elemental selenium (Se^0), selenide (Se^{2-}), selenite (Se^{4+}) and selenate (Se^{6+}). Within biological systems, selenium is incorporated as a constituent of selenocysteine (SeCys) and selenomethionine (SeMet) amino acids during translation of primary structure that comprise selenoprotiens. They are stored in the form of selenium methylselenocysteine (SeMSC) in seleniferous plants including garlic, Indian mustard (*Brassica juncea* L.), onion *(Allium cepa*), broccoli (*Brassica oleraceae* L.), sugar beet (*Beta vulgaris* L.)etc (Zayed et al., 1998, Fordyce, 2013). The main available form of

DOI: http://dx.doi.org/10.15666/aeer/1702_16851704

selenium to plants is sodium selenate which is actively taken up by seleniferous plants through sulfate transporter and assimilated as organic form (SeMet and SeCys) with the help of enzymes, including ATP reductase, ATP sulfurylase, SeCys-lyase and O-acetyl serine transferase (*Figure 1A*) (Adhikari, 2012).

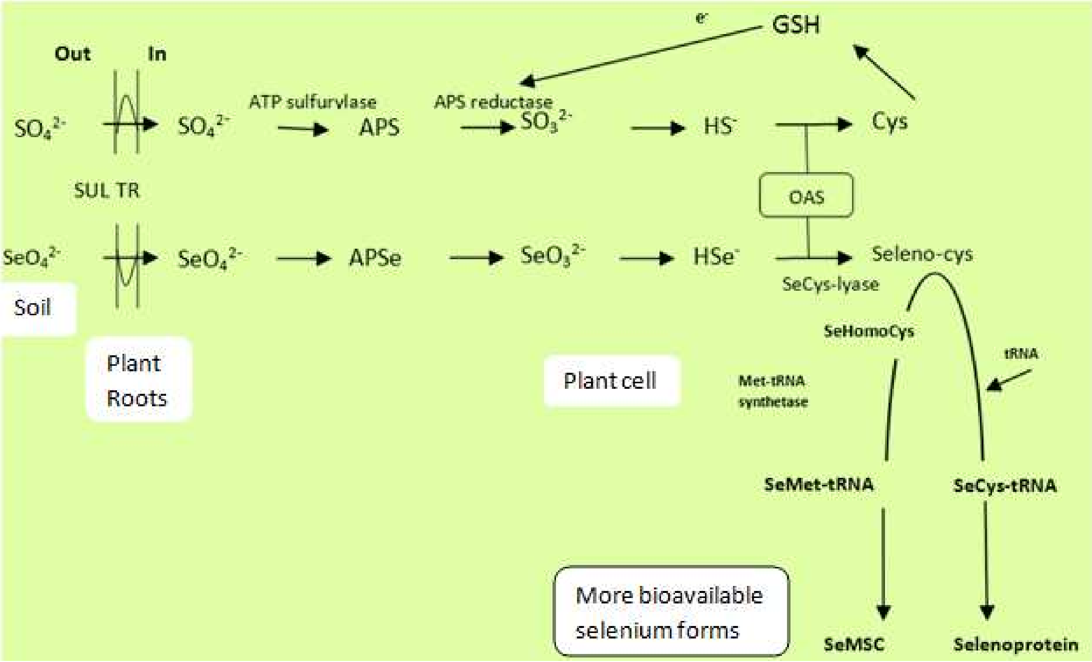

Figure 1A. *Flow diagram showing sulfur and selenate uptake and assimilation pathway in seleniferous plants. SeCys-lyase is the enzyme that is highly specific to selenium substrate. Sulfate transporter (SULTR), 5' adenylylsulfate (APS), 5' adenylylselenate (APS), O-acetylserine (Rehse et al., 2016)*

In the past few decades, interest of scientists in naturally occurring compounds that act as antioxidants and regarding particularly dietary selenoenzymes has been increasing. Selenoenzymes play a vital role in protecting the body from oxidative damage/harmful effects of reactive oxygen species (ROS) and contain one or more unpaired electrons (Birringer et al., 2002). ROS are produced either from external sources, such as chemicals/pollution, or from internal sources e.g. aerobic respiration. They react quickly with other compounds and a chain reaction starts as the other molecule loses electrons and becomes a free radical. The result is the oxidation of vital cellular parts like DNA and proteins, the disintegration of cell membrane that lead to diseases (Kaur and Kapoor, 2002). In human beings, important selenoproteins(also known as selenoenzymes) are catalase, glutathione peroxidase (GPx) and superoxide dismutase which act as antioxidant and protect cells from ROS (Steinbrenner and Sies, 2009). *Allium sativum* is a natural source of various bioactive phytomolecules, including selenoproteins, allyl thiosulfinates, flavonoids, organosulfur compounds, phenolic acids and vitamins (Choi et al., 2014). Previous studies have reported on the health-promoting benefits of garlic because of its biologically active phenolic compounds with interesting medicinal properties (González-Morales et al., 2017). The extract of garlic has a remarkable antioxidant capacity and provides protection from oxidative DNA damage (Park et al., 2009), decreases the risk of chronic diseases,

DOI: http://dx.doi.org/10.15666/aeer/1702_16851704

mitigates atherosclerosis and cancer (Morihara et al., 2010) etc. The objective of this study is to enrich garlic with selenium through biofortification, to analyze its impact on garlic quality parameters including phytochemical content and biological potential as free radical scavenging property. Additionally, there is possibility to introduce the selected garlic species for selenium phytoextraction in to selenium laden soils of Punjab Pakistan.

Materials and Methods

Site description and Experimental design

A field experiment was conducted at botanical garden of PCSIR Labs Complex, Lahore, Pakistan. Local garlic variety was sown season in January 2016 and harvested in May 2016. The experimental site is situated between 31.52° North latitude, 74.33° East longitude at the altitude of 217 m above sea level. A randomized complete block (RCB) design with three replicates was used with two factors (conc. of selenium salt applied and way of applications). Garlic sets were planted in the field divided into five plots. Treatments were control (no selenium application), selenium foliar spray and selenium soil flooding and two selenium salt concentrations (20g/ha and 50g/ha). Standard agronomic practices were used. The size of each individual plot was 2 m length x 3.66m width= 29.28 m^2, with a density of 15 plants per square meter. Each plot was consisted of 11 rows, with 6 plants in each row and the distance between rows was 0.65 m. A basal dose of N-P-K in ratio of 11-5-18 kg/ha was applied prior to planting. Melathion was sprayed as a herbicide after 8 weeks of sowing.

Chemicals

All chemicals were analytical grade. sodium selenate, Folin Ciocaltaeu reagent, ascorbic acid, butylated hydroxyl Toluene (BHT), sodium carbonate, aluminium chloride potassium acetate, quercetin and gallic acid were purchased from sigma aldrich chemical Co (St.Louis, MO, USA). DPPH dye was purchased from Alfa Aesar, Germany. Ethanol, hydrochloric acid, dimethylsulphoxide (DMSO), methanol were obtained from Merck (Darmstadt, Germany).

Selenium treatments

Selenium was applied as sodium selenate (Na_2SeO_4) in the experimental field. Aqueous sodium selenate solution (1.0 g/Liter) was applied at the concentration of 20g/ha) and 50g/ha in two ways i.e. by foliar spray and through water flooding in selected plots. First application was carried out on day 9 and afterward 30 days interval from sowing, during whole growing season (*Figure 1B*). Garlic crop was harvested in May after120 ± 2 days of growth.

Preparation of sample

Finely ground sample 0.5 g was accurately weighed in a china crucible. The sample was kept in the muffle furnace at 500°C for 4-6 hours or until white ash is formed. The ash was dissolved in 5 ml of 6 N HCl by heating on a hot plate, filtered through Whatman no.1 filter paper and the final volume was made up to 100 ml with double distilled water (AOAC, 1990).

Determination of selenium by inductively coupled plasma-mass spectrometer using dynamic reaction cell

Shimadzu Sequential type plasma Emission Spectrometer model ICPS-1000 111 and JY 24 spectroanalyzer (ICP-MS) was used for the determination of Se. A glass Meinhard nebulizer and a glass cyclonic spray chamber were used to introduce the sample. Experimental Instrument Conditions were RF Power 1200 watts, plasma gas flow 15 L min^{-1},auxiliary gas flow 1.2 Lmin^{-1}, RPq 0.5, cell gas (O_2)flow rate(DRC) 0.4 Lmin^{-1}. A series of standards containing selenium (0.01 -0.5 mg/L) were prepared from standard stock solution of Se (1000 ± 2mg/L, Merck, Darmstadt, Germany), and used to calibrate instrument. Standard solutions of Selenium with 1.0 to 50 mg L^{-1} were used for quantification. Method validation was performed by analyzing three replicates of artificially spiked garlic powder with a final concentration of 5mg/kg of selenium. A standard deviation of 0.05 mg/kg and coefficient of variation of 2.71% was obtained with a recovery of 97%. The limit of detection (LOD=3SD) as calculated by the Eurachem Guide (Guide, 1998) was 0.15mg/kg. Measurement of uncertainty of the method (K=2) was 0.03.

Phytochemical analysis

An appropriate amount (20g) of garlic foliar mass and bulb powder were separately extracted in 80% ethanol by stirring at 25℃ for 24h in closed vessel system, according to the method described by Peschel et al. (2006) with minor modification. After solvent evaporation under vacuum, extracts were resuspended in DMSO and stored at 4 °C.

Estimation of total phenolic content (TPC)

Total phenolic content of each treatment (garlic bulb & foliar mass) were determined by using Folin Ciocalteu reagent for color development along with sodium carbonate, by following the method with slight modifications reported by Singleton and Rossi (1965). Absorbance of developed blue coloured complex was taken at 755 nm with a spectrophotometer (Nicolet, Evlution-300, Germany). TPC of extracts was quantified through the standard curve of gallic acid (r^2 = 0.9972). The results are given in mg gallic acid equivalent (GAE)/ 100 g of dry wt.

Estimation of total flavonoid content (TFC)

Total flavonoid content was estimated by using aluminum chloride colorimetric method (Chang et al., 2002). Appropriate quantity (100µl) of each sample extract was taken and mixed with suitable amount of methanol, 10% aluminum chloride and 1 M potassium acetate for development of coloured complex. After 30 minutes of incubation period, absorbance of the developed colour was taken at 415 nm with a spectrophotometer. Quercetin standard curve (r^2 = 0.9985) was used for the quantification of TFC of experimental samples and expressed in mg quercetin equivalent (QE) /100g of dry wt.

In vitro 2, 2-diphenyl-1-picrylhydrazyl radical scavenging activity

In current study the hydrogen atoms donating capacity of garlic leaves and bulb extracts were determined through DPPH free radical assay (Brand-Williams et al., 1995). Ethanolic solutions of each extract were prepared in the range of 0.02 mg/ml to 0.1 mg/ml, following the mixing of ethanolic dilutions of extract (100 µl each) with DPPH (0.1mM) solution. BHT (Butylated hydroxytoluene) and Ascorbic Acid were used as positive controls. After an incubation period of 30 minutes in the dark at ambient temperature, absorbance of reaction mixtures were taken at 517 nm through UV-spectrophotometer. Finally, duplicate measurements were taken and percentage DPPH radical scavenging ability was calculated by using *Equation 1*.

$$DPPH\ scavenging\ activity(\%) = \left\{(Abs._{(control)} - Abs._{(sample)} / Abs._{(control)}\right\} \times 100 \quad \text{(Eq. 1)}$$

where Abs. (control) was absorbance of DPPH radical + ethanol and Abs. (sample) was absorbance of DPPH radical + sample.

Statistical analysis

All data are presented as mean ± SD. The calculated mean values were based on the data obtained from at least three independent experiments. Two ways Analysis of Variance (Webb et al., 2012) was performed by Graph pad Prism 5 at a confidence interval of 95% to see the significant difference among results (GraphPad Software). Results showing probability value of < 0.05 were considered to be statistically significant.

Results

Fresh weight yield m^{-2}, dry matter and climatic conditions

Observations were taken for the fresh weight of plantlets both in the case of control set as well as those treated after harvest, which showed that maximum fresh wt. yield of garlic plants was obtained in treatment III (1723 ± 32.12 g/m^2) and minimum in treatment II (1653 ± 25.86 g/m^2) in comparison to control plants (1650 ± 33.82 g/m^2). Present results were non significantly different (P > 0.05) in total fresh weight yield per square meter as shown in *Figure 2*. Dry matter of garlic plants enhanced as the concentration of selenium salt was increased. The highest amount of dry matter was obtained in treatment III (13.49 ± 0.71%) and treatment I (13.01 ± 2.46%) which were non significantly different (P > 0.05) from control (12.12 ± 1.57%) (*Figure 3* and *Table 1*).

Selenium content

Total selenium content of plant samples was determined by ICP-MS. Current results depicted that Se concentration was enhanced with increasing fertilization for all treatments. However, foliar application was found to be most effective in garlic selenium enrichment as compared to soil application (*Figure 5*). The highest average selenium concentration 3.23±0.16mgSeKg^{-1} in bulbs and 15.46±0.71 mgSeKg-^{1} in garlic vegetative part were observed in treatment III in comparison to control plant exhibiting 0.369±0.078 mgSeKg^{-1} in bulbous part and 4.96±0.49 mgSeKg^{-1} in vegetative part, respectively (*Table 2*).

Total phenolic content (TPC)

Total phenolic content of all treated and control garlic samples exhibited significant results (*Figure 6*). The results showed that higher phenolic content are present in treatment III vegetative part (23.46±2.12 mg GAE/100g dry wt) followed by treatment IV (21.71±0.51mg GAE/100g dry wt), treatment I (19.24±0.35mgGAE/100g dry wt) and treatment II (18.82±1.17 mgGAE/100g dry wt) vegetative part, respectively. Treatment III was more effective for enhancing TPC of garlic bulbs i.e. 4.72±1.79 mgGAE/100g dry wt (1.82 fold increase) in comparison to control containing total phenolic content of 2.59±0.707mgGAE/100g dry wt which are significantly different from each other (*Table 3*).

Total flavonoid content (TFC)

Significantly (P > 0.05) elevated amount of total flavonoid content were observed in *Allium sativum* leaves and bulb (*Figure 7*). Current results depicted that total Flavonoid content of treated *A. sativum* bulbs and leaves were in the range of 18.19 ± 1.21 to 18.50 ± 1.82 mgQE/100g dry wt and 34.13 ± 1.36 to 34.99 ± 1.54 mgQE/100g dry wt, respectively in comparison to control bulb (11.32 ± 0.95 mgQE/100g dry) and leaves (13.53 ± 0.76 mgQE/100g dry wt. as in *Table 4*).

In vitro antioxidant activity

The percentage DPPH radical scavenging capacity of garlic extracts with different treatments as well as controls is depicted in *Figure 8*. The IC_{50} values (sample concentration needed to scavenge 50% of DPPH dye) of all garlic extracts as well as both standards (Vitamin C and BHT) were calculated by linear regression of plots. The lowest IC_{50} indicates the higher antiradical activity of extract. Garlic extract of treatment III had an IC_{50} of 0.81 mg/ml, followed by treatment IV (0.82 mg/ml), treatment I (0.84 mg/ml) and treatment II (0.898 mg/ml). The IC_{50} value of non treated (control) garlic extract was 0.97 mg/ml. Of the two positive controls, BHT had the lowest IC_{50} (0.50 mg/ml) than vitamin C (0.51 mg/ml) but both showed significantly (P< 0.05) higher DPPH scavenging activity than treated garlic extracts (*Table 5*).

Discussion

Micronutrients malnutrition is the insufficient availability of essential dietary microminerals to the population that will negatively impact the health of people and increase the risk of diseases (El-Ramady et al., 2015). Improvement of selected nutrients such as selenium in plants edible part through the process of biofortification will increase the nutritional value of food (Hirschi, 2008) which is proved through findings of current results that selenium concentration and polyphenolic content of selected garlic cultivar was enhanced through biofortification. Present results indicated that there is no considerable difference in fresh wt yield of treated and control sets of garlic plants. These results are in consistent with the findings of Põldma et al. (2013), who reported that effects of selenium treatment on yield of onion bulb (*Allium cepa* L.) was not significant and at Se50 (50µg/ml) there was no reduction in bulb size as compared to Se100 (100µg/ml). However, these observations are contradictory to Yadav et al. (2007) who reported that leaves and bulbs of *Allium cepa* were reduced in size at high concentration of 50µg/g Se spiked soil. High concentration of selenium (50g/ha) foliar application enhances the dry matter content of the whole plant. Current findings showed that on increasing the concentration of available selenium salt (Na_2SeO_4), accumulation of selenium content was increased in garlic plants. Foliar application of 20mgSem^{-2} and 50mgSem^{-2} to garlic plants resulted in 7.8 and 12.52 fold increase of selenium content in garlic bulbs as compared to control. Similarly, 3.52 fold increase of selenium content was observed in vegetative part of garlic plants on 50mgSem^{-2} foliar spray (*Figure 5*), which could be used as fodder for animals to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_16851704

improve their nutritional value regarding selenium content.Hegedűsová et al. (2017) reported that foliar application of selenium salt to Ambassdor pea variety at two concentrations i.e. 5mgSe/m^2 and 10mgSe/m^2 resulted in 25.4 and 49.1 fold enhancement of selenium content, depending on applied doses. Similar observations were reported by Yadav et al. (2007) that selenium accumulation in tissues of *Allium cepa* was improved from 278 to 1248.8 µg/g along with increasing Se concentration from 25µg/g to 50µg/g of soil, respectively. Whanger et al. (2000) was also reported that selenium uptake of *Allium tricoccum* was enhanced with increasing concentration of available Selenium, despite the nature of experimental media including peatmoss (I), vermiculite and hydroponics (III). Seleniferous plants has the potential to mobilize inorganic form of selenium from soil, and to accumulate it in the biomass in organic form making it more bioavailable to animals and human beings, which is proved by the study of Yan and Johnson (2011). Due to this inherited ability of the crop plants belonging to Allium family, they can be grown in those geographical areas that naturally enriched with selenium loaded soil, to do the work of phytoremediation. Hasanuzzaman et al. (2010) reported that selenium accumulators have the ability to accumulate 4000mg/kg selenium without exhibiting signs of toxicity in comparison to non seleniferous plants like rice, which showed 10% yield reduction on selenium threshold level of 2mg/kg in shoot tissues. Thus biofortification can be indirectly linked with phytoremediation (Yadav et al., 2007). These selenium biofortified garlic can be exported as food commodity in those specific areas of the world such as China (Tan et al., 2002) that naturally deficient for selenium. Daily intake portion (80g) of selenium biofortified rice for 20days can significantly increase the serum selenium level, which is confirmed by Giacosa et al. (2014). Based on the results shown in *Figure 5*, it can be assumed that daily intake of 16g of dried garlic bulb procured in treatment III can cover the daily recommended dose (40ug to 50ug for adults) of selenium (Burk et al., 2003).

Food enriched with polyphenolic compounds such as phenolics, flavonols and flavonoids have been reported to exhibit strong antioxidant activities which protects the cells from damaging effects of free radicals and reduces the risk of chronic diseases (Otunola and Afolayan, 2013).In this study, selenium accumulation in garlic biomass enhances the nutritional value and antioxidant capacity of garlic plant. Significant value of phenolic content that is 4.72 mgGAE/100 g dry wt of garlic was observed in the present study. Beato et al. (2011) had reported that the total phenolic content in four garlic cultivars varied from 3.4 mg GAE/100 g dry wt to 10.8 mg GAE/100 g dry wt with a mean value of 6.5 mg GAE/100 g dry wt grown at Andalusia, Spain. They reported ferulic acid and caffeic acid were the major polyphenols present in garlic with mean values of 2.6 and 2.9 mg/kg of dry matter, respectively. In the present study, considerable amount of total flavonoid content (TFC) were observed in garlic extracts of all treatments depending on the amount of available selenium in comparison to control plant. Higher value of TFC of garlic extract (18.50 ± 1.82 mgQE/100 g dry wt) in treatment III could be related to increased concentration of available selenium salt (50g/ha). Stable DPPH free radical scavenging assay is a commonly used method for the estimation of free radical scavenging ability of various compounds (Ghasemi et al., 2015). In the current study, results showed that there was a significant ($P< 0.05$) increase in the scavenging ability of DPPH-radical as dose of garlic extract increased (*Figure 8*). This trend is similar to results of Park et al. (2009) who accounted that garlic extracts exhibited remarkable scavenging properties by reducing stable radical DPPH to yellow colored diphenyl picrylhydrazine. This could be due to the hydrogen donating

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_16851704

ability of various vegetable extracts from their phenolic hydroxyl groups. Previously, Velioglu et al. (1998) reported a considerable association between phenolic content and antioxidant activity of various fruits, cereals and vegetable extracts. Kavalcová et al. (2014) reported statistically considerable value of antioxidant activity (4.05% to 5.07%) in association with polyphenolic content (260 t0 279 mg/Kg) in garlic samples collected from Pruzina, Strazov. Similarly, experimental garlic bulb obtained in treatment III exhibited a significant relation between higher value of polyphenolic content (2.59 to 4.72mg/100g) and total antioxidant capacity (93.75±1.54%).

Conclusion

The present study revealed that garlic selenium content was increased through biofortification process in field conditions. The process of selenium fertilization through foliar spray was more effective than soil irrigation and positive for all biochemical parameters analyzed. High polyphenolic content and antioxidant properties were observed in biofortified garlic in concordant with high selenium content which could be used as a powerful source of natural antioxidants along with selenium to combat hidden hunger of micronutrient. Further field experiments conducted in the present study will shade a new light to improve selenium content in other seleniferous crops which could be valuable considering agronomic and human health benefits.

Abstract. Short term monitoring of soil and vegetation recovery following alien plant removal is required to reveal how ecological restoration is progressing. This study examined the recovery of soil physical properties and vegetation following *Acacia mearnsii* removal at Zvakanaka farm in Limpopo Province, South Africa. Soil and vegetation measurements were conducted in paired cleared, invaded and natural sites on 10 x 10 m plots. Results of the study show significantly ($P < 0.001$) higher soil moisture content in invaded and natural compared to cleared sites. Soil penetration was significantly ($P < 0.001$) higher in cleared than invaded and natural sites. Both infiltration rate and hydraulic conductivity showed no significant ($P > 0.05$) difference between the three sites. Strongly repellent soils were recorded in cleared sites only. Results showed a significant ($P < 0.05$) increase in measured diversity indices (species richness, Shannon-Wiener, Simpson's and evenness index) in cleared and natural than in invaded sites. However, most secondary woody invasive alien plants were recorded in cleared sites. The study concludes that *A. mearnsii* clearing triggers varying changes in soil physical properties. Although native plants are present in cleared sites, recovery may be hampered by the growth of secondary woody invasive alien plants.
Keywords: *post-clearing monitoring, invasive plants, ecosystem repair, revegetation, secondary invaders*

Introduction

Invasion by Australian *Acacia* species in South Africa has resulted in biodiversity loss (Werner et al., 2010; Gaertner et al., 2011), altered ecosystem functioning and service provisioning (Kull et al., 2008; Le Maitre et al., 2011). *Acacias* are known to stimulate changes in soil communities (Yelenik et al., 2004; Gaertner et al., 2011) which enables them to dominate native species, resulting in native species displacement (Le Maitre et al., 2011). Negative impacts of *Acacia* invasion on biodiversity and ecosystems ultimately affect human well-being (Le Maitre et al., 2011). For example, stands of *A. mearnsii* invasion in South Africa have been shown to utilize more water compared to fynbos biome native vegetation (Dye et al., 2001; Dye and Jarmain, 2004), this resulting in water reduction for agriculture, industry, recreation, conservation and domestic use (Görgens and van Wilgen, 2004). Also, the high biomass of *Acacia* species has been known to increase fire severity (van Wilgen and Richardson, 1985), thus not only affecting re-sprouting native plants but also housing properties.

Management interventions to address the impacts of *Acacia* invasions, and may other invasive plants, are underway in South Africa (Le Maitre et al., 2011). The Working for

Water (WfW) programme, a government initiative to manage and control invasives, has adopted a passive restoration approach which aims to remove the invader as well as limit and prevent their regeneration (Le Maitre et al., 2002; Esler et al., 2008; van Wilgen et al., 2012). However, the passive restoration approach by WfW has yielded mixed results when it comes to soil and vegetation recovery (Galatowitsch and Richardson, 2005; Blanchard and Holmes, 2008; Pretorius et al., 2008; Ruwanza et al., 2013a; Nsikani et al., 2017; Fill et al., 2018). As a result, there is a need to improve understanding of factors that hinder or facilitate soil and vegetation recovery after alien plant clearing.

For ecological restoration to be successful, periodic monitoring of cleared areas is required to reveal how restoration is progressing and were management interventions are required (Ruiz-Jaen and Aide, 2005; Fill et al., 2018). However, a complicating factor in monitoring ecological restoration projects is the defining of appropriate variables to be measured (Ruiz-Jaen and Aide, 2005). In cases were the restoration goal is to return natural vegetation structure, function and processes to reference condition, monitoring native vegetation diversity and soil processes e.g. physical (soil structure), chemical (soil nutrients) and biological (soil bacteria) becomes important (Ruiz-Jaen and Aide, 2005; Wortley et al., 2013). Unfortunately, both short and long-term monitoring in most WfW alien clearing projects is rarely done (Fill et al., 2018).

Methodological constraints associated with monitoring biological invasions have been reported in the past (Stricker et al., 2015). Although most observational studies compare differences between invaded, uninvaded and cleared areas (Fill et al., 2018), a more appropriate method is to observe changes before and after invasion (Stricker et al., 2015). The challenges associated with before and after observational experiments is time, given that invasion could have occurred several years ago, and observations prior-invasion might not have been done. Observing changes between invaded, uninvaded and cleared areas does not allow deduction on causation to be made, because observed differences may be driven by other ecosystem processes and not necessarily by invasive plants (MacDougall and Turkington, 2005; Guido and Pillar, 2015; Guido and Pillar, 2017). Despite these methodological limitations, observing invaded, natural and cleared areas can assist in generalizing recovery patterns that can be used to inform recovery trajectories. This study present findings on soil and vegetation recovery post *A. mearnsii* removal. The goal is to assess changes in both soil physical properties and native vegetation diversity after *A. mearnsii* clearing, to provide a picture of ecological recovery. Results will guide future ecological restoration initiatives following *A. mearnsii* removal.

Materials and methods

Study area and site identification

The study area was Zvakanaka farm (22°97'72.23"S and 29°95'30.90"E; *Fig. 1*), some 10 km outside Louis Trichardt in Limpopo Province, South Africa. The farm is used for tourism purposes, with a few guest houses and camp sites. Vegetation in the farm is classified as both Soutpansberg Summit Sourveld and Soutpansberg Mountain Bushveld by Mucina and Rutherford (2006). Soils in the study area are derived from shale and siltstones of the Soutpansberg group (Mucina and Rutherford, 2006). They are generally shallow and drain quickly leading to leached and acidic soils. Average annual rainfall is between 450 and 900 mm, with most rain falling in summer between October

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17051716

and March. Temperature ranges from approximately 5°C in winter to 35°C in summer (Mucina and Rutherford, 2006).

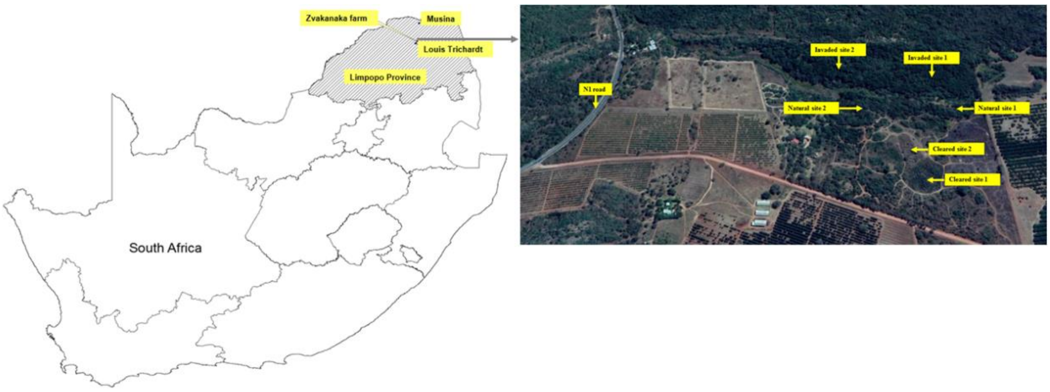

Figure 1. *The location of the study area in Zvakanaka farm located outside Louis Trichardt in the Limpopo province of South Africa*

Within Zvakanaka farm three invasion conditions (approximately 2 km apart), namely cleared, natural and invaded were identified (*Table 1*). Two sites were setup at each of the above-mentioned invasion condition (paired sites were approximately 50 m apart). Due to the small size of the cleared area, only two sites were possible in the cleared area, therefore the experimental design was limited to site pairing per each of the above-mentioned invasion condition.

Table 1. *Characteristics of the study area showing the three invasion conditions namely cleared, invaded, and natural sites. Each site's Universal Transverse Mercator coordinate location is shown*

Invasion condition	Site name	Coordinates	Site characteristics
Cleared site	CS 1	22°58'47.02"S, 29°57'25.77"E	- Cleared of *A. mearnsii* and other woody invasive in early 2016 - Follow-up clearing treatment in progress
	CS 2	22°58'46.86"S, 29°57'21.37"E	
Natural site	NS 1	22°58'38.59"S, 29°57'21.70"E	- Dominated by stands of native species - Canopy cover > 60%
	NS 2	22°58'38.32"S, 29°57'17.36"E	
Invaded site	IS 1	22°58'32.64"S, 29°57'26.08"E	- Invaded by huge stands of *A. mearnsii* with little underground vegetation - Canopy cover > 60%
	IS 2	22°58'32.43"S, 29°57'20.54"E	

Cleared sites had *A. mearnsii* (and any other existing woody invasives) removed by WfW in early 2016 (Maytham, 2017, personal communication). Clearing by WfW involved the felling of alien trees and herbicide application on cut stumps to prevent re-growth. Cleared plant material were stack burnt on site. The cleared area had received only one follow-up treatment (meant to remove all alien plant saplings) since the initial clearing was conducted. No soil or vegetation surveys were conducted before WfW clearing, therefore, the condition of the cleared areas prior both invasion and clearing is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17051716

unknown. Close to the cleared site is a mature stand of *A. mearnsii* that is yet to be cleared. The stand which is dominated by *A. mearnsii* represented the invaded site. In-between the cleared and invaded sites, dense stands of native species exist, and these acted as the natural reference sites. Therefore, the three invasion conditions comprised two cleared sites where *A. mearnsii* was removed in 2016, two invaded sites where *A. mearnsii* dominate (canopy cover above 60%), and two natural sites where stands of native species dominate (canopy cover above 60%).

Survey design and field sampling

In winter 2017, five randomly distributed replicated plots, each measures 10 m x 10 m, were set-up on each of the above-mentioned site. A total of 30 plots were setup (5 plots x 2 sites x 3 invasion conditions). Within each plot soil and vegetation surveys were conducted. Soil cores (30 in total) measuring 10 cm in diameter and 10 cm depth were collected from the center of each plot for gravimetric soil moisture and soil water repellency measurements which were conducted under laboratory conditions at the University of Venda. Before the above-mentioned laboratory measurements were conducted, soils were first sieved using a 2-mm sieve to remove debris. Gravimetric soil moisture (expressed as a percentage) was assessed by weighing wet soils, dry them in an oven at 105°C for 72 hours, then re-weighing them to obtain the water content (Black, 1965). The Water Droplet Penetration Time (WDPT) method was used to measure soil water repellency (Doerr and Thomas, 2000). Sieved soils were air dried for seven days under laboratory conditions (temperature 18±2°C which is the average Thohoyandou winter temperatures) before being set into petri dishes and levelled. The WDPT test was conducted by placing five water droplets on the soil surface and record the time taken for the water droplet to penetrate the soil (Doerr and Thomas, 2000). The penetration time was averaged to represent the WDPT for each soil sample. Soils were classified based on repellecy classes suggested by Bisdom et al. (1993) (see *Table 2*).

Table 2. *Classification of soil water repellency based on the The Water Droplet Penetration Time (WDPT) method*

Classification	The Water Droplet Penetration Time (in seconds)
Non-repellent	< 5
Slightly water repellent	6 - 60
Strongly water repellent	61 - 600
Severely water repellent	601 - 3600
Extremely water repellent	> 3 601

Soil penetration resistance levels and infiltration rates were measured under field conditions 30 cm away from soil collection points at the center of each plot. Soil penetration resistance levels were measured using a pocket penetrometer (SOILTEST, Inc., Evanston, Illinois, USA). To take measurements, the penetrometer is pushed into the soil and a metal ring is pushed up to mark the resistance value in kg cm^{-2} (Leung and Meyer, 2003). Infiltration rate and hydraulic conductivity in the soil were measured with a mini disk infiltrometer (Decagon Devices, Pullman, WA, USA). The infiltrometer is an acrylic tube with a semipermeable plastic disk, a suction tube inside, and a rubber stopper (Latorre et al., 2013). Suction rate was set at 2.0 cm in this study. Both the upper and lower chambers were filled with water before taking measurements

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17051716

on flat soil surfaces following the hand removal of litter. The water infiltration rate was measured from the drop of water level in the lower chamber in mL after every 30-s interval for 5 minutes. The cumulative infiltration rate over time was determined using the method suggested by Zhang (1997). Similarly, hydraulic conductivity was calculated from the infiltration data using the van Genuchten-Zhang method (Zhang, 1997, 1998). For more information see the mini disk infiltrometer manual which can be found at Decagon Devices (2014).

A detailed vegetation survey was conducted in all plots. Richness of trees and shrubs was determined from counts of the total individual plant species in the plot. Richness of herbs and graminoids was determined from counts of all the individuals in a 1 m^2 quadrat placed at the center of the plot. All recognized plant species in the plot were collected for identification at University of Venda herbarium in the Department of Botany. Plant species were assigned to four broad growth form classes based on morphology and height. The four-growth form used in this study are trees, shrubs, forbs and grasses, as described by Goldblatt and Manning (2000).

Data analysis

To avoid pseudo-replication, soil and vegetation results from the ten plots per invasion condition (two sites x five plot replicates) were averaged. Gravimetric soil moisture, soil penetration resistance levels, infiltration rates**,** and hydraulic conductivity for the different sites, were analysed using one-way ANOVA in Statistica version 13.1 (Statsoft Inc, 2016). For each site, species richness, Shannon-Wiener diversity index (H'), Simpson's index of diversity and Evenness index (J) using Pielou's 'J' (Zar, 1996) were calculated per plot and used to examine the effects of alien plant clearing on species diversity. The effects of the above-mentioned diversity indices on invesion conditions were compared using one-way ANOVA in Statistica. Proof of normality and homogeneity of varience were tested using Kolmogorov-Smirnov tests and Levene test respectively. Data was normally distributed and where ANOVAs were significant, Tukey's HSD unequal n test was used to determine differences between sites. Soil water repellency classes were analyzed using the Chi-squared test. Plant species occupancy frequencies, which is the number of species occupying different plots per site independent of their abundance, were calculated as a percentage for all the identified species at each site (presented as *Appendix*).

Results

Comparisons between the three sites showed significant ($P < 0.001$) differences in gravimetric soil moisture levels (*Fig. 2A*). Soil moisture levels were higher in invaded and natural sites than in cleared sites. Contrary, soil penetration resistance levels were significantly ($P < 0.001$) higher in cleared sites than in the invaded and natural sites (*Fig. 2B*). The average infiltration rate in the cleared and natural sites was 3.2 ± 0.58 cm and 3.2 ± 1.11 cm respectively after 5 minutes, compared to 2.0 ± 1.26 cm in the invaded sites. However, the above-mentioned results on infiltration rates showed no significant ($P > 0.05$) differences between the three sites (*Fig. 2C*). Similarly, soil hydraulic conductivity showed no significant differences between the three sites (*Fig. 2D*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17051716

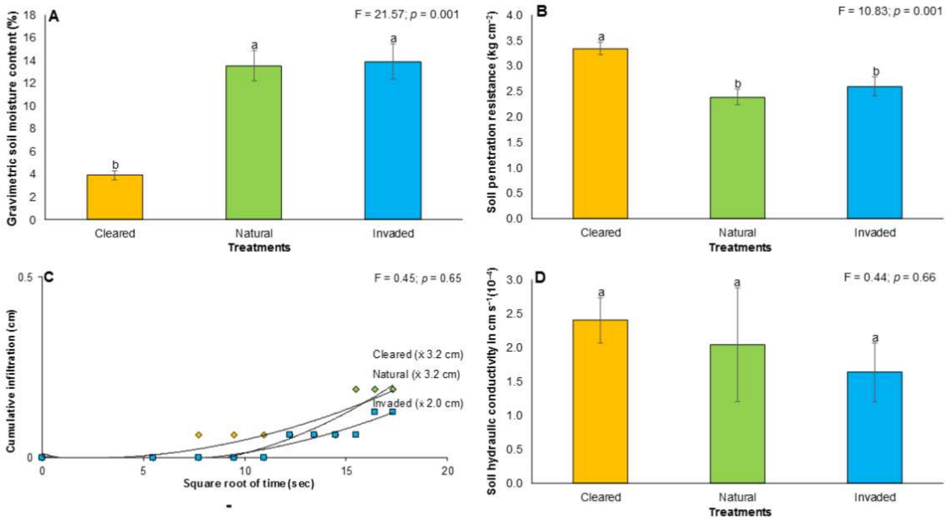

Figure 2. *Results show (A) gravimetric soil moisture content (%), (B) soil penetration resistance levels (C) cumulative infiltration and (D) hydraulic conductivity in soil samples taken from cleared, natural and invaded sites. Bars represent mean ± se and ANOVA results are shown. Bars with different superscripts are significantly different at p < 0.05*

The chi-squared analysis of WDPT classes showed no significant (*P > 0.05*) differences between the three sites (*Fig. 3*). The above-mentioned result is because a greater percentage (80%) of soils in all the three sites were slightly repellent. The remaining 20% in cleared sites were strongly repellent, whereas in the natural and invaded sites the remaining 20% of collected soils were wettable (*Fig. 3*).

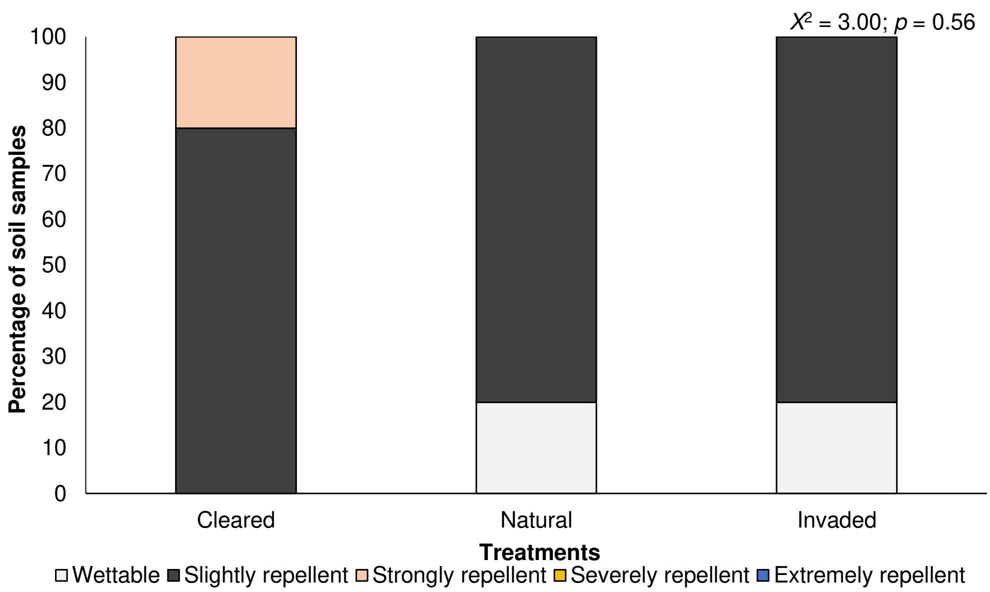

Figure 3. *Distribution of water repellency classes (based on the Water Droplet Penetration Time (WDPT) method) in soil samples taken from cleared, natural and invaded sites. Chi-squared analysis results are shown*

A total of 42 plant species were identified of which 27 were trees and shrubs, six were herbs and nine were grasses (*Appendix*). Cleared sites recorded a higher occurrences of woody alien invasive plants compared to natural and invaded sites. The most commonly occurring woody invasive alien plants in the cleared sites were *A. mearnsii*, *Lantana camara*, *Psidium guajava*, *Solanum mauritianum*, *Eucalyptus spp.* and *Rubus rigidus*. Species richness showed significant ($P < 0.001$) differences between all the three sites (*Table 3*). Higher species richness was recorded in cleared sites compared to natural and invaded sites. Comparisons on species richness per growth form showed significant ($P < 0.05$) differences between all three sites for all the growth forms (*Table 3*). Trees, shrubs and herbs were higher in cleared and natural sites compared to invaded sites, whereas grasses were higher in cleared sites than in natural and invaded sites. Both Shannon-Wiener and Simpson's index of diversity were significantly ($P < 0.01$) higher in cleared and natural sites compared to invaded sites (*Table 3*). Evenness index showed no significant ($P > 0.05$) differences between all the three sites.

Table 3. *Comparison of indices of diversity between cleared, natural and invaded sites. Data are means ± se and One-ANOVA results are shown*

Discussion

The removal of *A. mearnsii* has triggered varied changes in soil physical properties, decreased soil moisture content, increased soil compaction, and intensifying soil water repellency. Soils underneath both *A. mearnsii* and natural areas exhibited higher soil moisture content compared to soils were *A. mearnsii* was removed. The above findings agree with previous findings by Ruwanza et al. (2013b) who showed that soils in cleared areas have lower moisture content than soils in natural and invaded areas, though the above study was conducted in *Eucalyptus* cleared sites. The reasons for higher soil moisture content underneath natural and *A. mearnsii* invaded areas could be linked to higher stand densities compared to the cleared areas. Generally, soils underneath vegetated areas have higher water holding capacity than soils in areas where vegetation has been removed (Wang et al., 2013; Schoonover and Crim, 2015). High water holding capacity in vegetated areas could be a result of hydraulic redistribution, thus the transportation of water via plant roots from wet to drier parts of the soil profile (Leffler et al., 2005). Orwa et al. (2009) indicated that *A. mearnsii* develop a superficial lateral root system whose taproot development is largely depends upon the depth of the soil, thus allowing the plant access to water from the water table. Besides hydraulic redistribution as a factor contributing to the observed soil moisture content differences

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17051716

between sites, increased litter content cover underneath both natural and invaded areas could explain the higher soil moisture under these areas compared to cleared areas. Litter is known to provide soil cover, which facilitates the capture of rainwater and avoid evaporation (Dormaar and Carefoot, 1996). Besides, the canopy of both natural and *Acacia* species has the potential to provide shelter for soil moisture thus making it high upon being captured by litter (Mugunga and Mugumo, 2013).

The removal of *A. mearnsii* is expected to cause soils to become less repellent given that some studies have shown that invasion by *A. mearnsii* causes soils to be repellent (Ruwanza, 2017). Contrary, results of this study showed that soils in cleared areas were strongly repellent with the bulk being slightly repellent. The reason why some soils in the cleared areas were strongly repellent compared to the natural and invaded areas could be linked to reduced soil moisture content and soil compaction that was reported in the cleared areas. Soil with low moisture content, which are generally compact, are known to be repellent (Diehl, 2013). Soil compaction on cleared areas could be linked to the clearing method used to remove the invasive trees, especially were mechanical harvesting is used. Mechanical harvesting of plants has been found to trigger soil compaction and repellency, which can persist for years after clearing (Titshall et al., 2013).

The removal of alien plants by WfW assumes that natural vegetation will recover unassisted (Esler et al., 2008; Fill et al., 2018). Although results of this study indicate that the clearing of *A. mearnsii* facilitates an increase in native vegetation diversity, the presents of woody invasive alien plants may hinder this recovery process. Previous studies have reported that removal of *Acacias* facilitates native species recovery (Pretorius et al., 2008; Ndou and Ruwanza, 2016; Fill et al., 2018). However, rapid secondary invasion by invasion alien grasses and herbs was observed in all the above-mentioned studies. However, this study observed the dominance of woody invasive alien plants in cleared areas. The reason for the dominance of these recruiting woody invasives could be that the removal of *Acacias* facilitated soil stored seed bank of other invasives to germinate. Also, the clearing of *Acacias* is known to facilitate the recruitment of woody invasive alien plants due to the increased availability of soil nutrient resources (Pretorius et al., 2008). The recruitment of woody invasive alien plants can negatively affect native species recovery and slow down the native vegetation recovery process. This is because the fast-growing recruiting woody invasive alien plants have the potential to outcompete recruiting native species for resources (e.g. soil nutrients) thus negatively affecting the recovery process.

Conclusions and recommendations

Although native vegetation recovery is improving in cleared sites, it can be slowed down by the recruitment of secondary woody invasive alien plants. The above results point to the need for effective follow-up and monitoring of cleared areas so that recruiting secondary invaders are removed. Effective monitoring may include increasing the follow-up interval to facilitate continues removal of any recruiting invasive plants. Besides, removing recruiting invasive alien plants during follow-up, effective monitoring should include developing appropriate interventions to improve both soil and vegetation recovery. Such interventions during follow-up can include, soil nutrient manipulation and native plant species introduction in cleared areas. However, the efficacy of these interventions will need to be tested.

Our comparison of cleared, invaded and natural sites has revealed some changes in measured soil and vegetation variables. However, the study results cannot infer that the observed changes were a result of clearing alone, since knowldge on pre-invasion and pre-clearing condition is limited. Given that previous studies have showed that *A. mearnsii* invasion trigger changes in soil properties and vegetation diversity (see Le Maitre et al., 2011; van der Waal et al., 2012), the reported changes in soil and vegetation diversity in this study's cleared sites can be a consequence of *A. mearnsii* removal. The above explanation is further supported by the fact that plant composition in invaded and natural sites were significantly different, this pointing to the notion that invasion cause changes to plant composition, so does removal of the invader in this case *A. mearnsii* (Kumschick et al., 2015; Guido and Pillar, 2017).

Abstract. This study was aimed at evaluating allelopathic activity of various solvent extracts of *Pinus roxburghii* (Pine tree) against some important weeds viz. *Phalaris minor* (bunchgrass), *Avena fatua* (wild oat), *Chenopodium album* (pigweed), *Euphorbia helioscopia* (sun spurge) and *Rumex dentatus* (toothed dock) of bread wheat (*Triticum aestivum*) by employing sandwich method (powdered needles) on filter paper, soil and agar. The data attained from statistical analysis revealed that methanolic needle extract possessed the highest germination percentage inhibition for *T. aestivum*, followed by *C. album* and *A. fatua* applied in soil. Similarly, maximum radical length suppression was observed for *R. dentatus*, followed by *C. album*. The plumule length retardation was noted best in *R. dentatus*, followed by *A. fatua.* The application of methanolic *P. roxburghii* extract was responsible for reduction in seed germination, radical and plumule length of wheat. Based on results, it can be concluded that methanolic *Pinus* needles extract possesses potential inhibitory effects that required for further detailed analysis to establish allelopathic potential and onward application to be used as phytoherbicide.
Keywords: *Allelopathic potential, Bread wheat, Pinus needles, Growth retardation, Methanol extract, Weed management*

Introduction

Allelopathy is the negative effects of one plant on the germination, growth, and/or development of other plants. The chemicals which execute allelopathy are commonly known as allelochemicals. Plant release chemical into the environment and these chemicals affect physiological functions of other plants in immediate vicinity, such as seed germination, photosynthesis, respiration, transpiration, stomatal behavior and ion uptake (Anwar et al., 2017a). Allelochemicals come from the class of secondary metabolites that are produced as by-products in the primary metabolic pathways of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17171739

plants. Like many other natural compounds, these chemicals have the capacity to cause a wide array of biological effects and can be quite useful for agriculture systems as well as weed control practices (Anwar et al., 2013). Allelochemicals include alkaloids, flavonoids phenoloids, and glucosionates. These are produced by the plants during their growth and developmental processes (Ahmed et al., 2014). Allelochemicals have been found to act as agent in the formation and disintegration of plant hormones, for instance they play role in the activation of Abscisic acid (ABA) synthesis via the action of ferulic acid (Zafar et al., 2010; Zhou et al., 2004).

Pinus roxburghii Sarg. (Family: Pinaceae) commonly known as “chir pine” is native to Himalaya, the region extends from northern Pakistan, across northern India and Nepal to Bhutan. Dried needles of Pine trees forms a dense carpet on the forest floor, which are gathered by the locals in large bundles to serve as bedding for their cattle, for the year round. Still a large quantity of these needles is left on the forest floor and with the rain water these needles are weathered and the leachates from them are mixed with the surrounding soil environment. Needles and bark of *P. roxburghii* is reported to possess secondary metabolites such as alkaloids, glycosides, flavonoids, saponins, tannins and triterpines which may have potential aliphatic actions (Baroniya and Baroniya, 2014). It is concept that Wheat in the high mountain areas, do not reach to maturity in most cases and as such the crop is harvested premature and used as fodder. However, past temperature trends in the high mountain areas (Chitral district) have led to shortening of the growing season length which certainly has helped in increasing wheat yield as well as crop area in high mountain areas (Hussain et al., 2005). In this context, a study was carried out to evaluate allelopathic activity of *Pinus roxburghii* (Pine tree) against some important weeds viz. *Phalaris minor* (bunchgrass), *Avena fatua* (wild oat), *Chenopodium album* (pigweed), *Euphorbia helioscopia* (sun spurge) and *Rumex dentatus* (toothed dock) of wheat crop.

Materials and methods

Collection and mechanical processing of P. roxburghii needles

Mature needles (500 g) of *P. roxburghii* were collected from district Rawalpindi (73° 02’ E longitude and 33° 36’ N latitude, 508 m above sea level) Punjab, Pakistan during November, 2017 and washed for several times under running tap water. The needles were dried for 4 weeks in shade at 30°C. The dried needles were crushed using heavy duty blender to make fine powder by passing through mesh size 2mm and kept in air tight plastic zip lock bags at 4 °C (Anwar et al., 2013).

Procurement and surface sterilization of test species seeds

Seeds of major weeds of *T. aestivum* viz. *P. minor, A. fatua, C. album, E.helioscopia* and *R. dentatus* were procured from Barani Agricultural Research Institute (BARI), Chakwal, District Rawalpindi, Punjab, Pakistan. Seeds (15g) of each test species were surface sterilized with 2% (w/v) solution of Sodium hypochlorite (NaOCl) for 1-2 min. After disinfection seeds were washed with distilled water (Anwar et al., 2016; Biljana and Kragujevac, 2015).

Filter paper and soil bioassay with P. roxburghii needles solvent extracts

Dried needles powder was extracted in distilled water, hexane and methanol separately at 30°C for 24h on an orbital shaker (160rpm). The extract was filtered through Whatman filter paper No.1. The stock solution was diluted to prepare different concentration i.e. T_1 (100%), T_2 (75%), T_3 (50%) and T_4 (control) (Sahu and Devkota, 2013; Anwar et al., 2017a).

An aliquot of 15 ml extract was added on 25g soil and 5 ml extract was added on filter paper per Petri dish. Distilled water, blank hexane and methanol was used as control in respective solvent extract bioassay. Ten seeds of selected test species were used per Petri dish. Each treatment was replicated for three times. The Petri dishes were wrapped with aluminium foil and incubated in growth chamber (NTS Model MI-25S) at 28°C for 15 days. The germination percentages, lengths of radical and plumule were calculated for each test species by comparing with respective control (Khan et al., 2008).

Filter paper and soil bioassay with P. roxburghii needles dried powder

Dried powder (10mg) of *P. roxburghii* needles was added on filter paper along with 5ml distilled water per Petri dish. Similarly, 50mg powder was added on 25g soil along with 15ml distilled water per Petri dish (Raana et al., 2012). Ten surface sterilized seeds of each test species were placed in sterilized Petri dishes. The Petri dishes were wrapped with aluminium foil and incubated in growth chamber (NTS Model MI-25S) at 25°C for 15 days. The germination percentages, lengths of radical and plumule were calculated for each test species (Anwar et al., 2017b).

Sandwich method

Five ml of 0.75% (w/v) agar (Nalge Nunc Intl., Roskilde, Denmark) was poured in each of the six-well ($10cm^2$ area/well) into multi-dish plastic plate. The agar solution was left for solidification. The powder of *P. roxburghii* needles was placed @ 10 and 50 mg in wells of plate and roofed by a thin layer of 0.75% (w/v) agar. After solidification, 10 seeds of each test species were placed on agar gel in each well of the plate (Fujii et al., 2003, 2004). The multi-well plastic plates were incubated in growth chamber (NTS Model MI-25S) at 25°C for 15 days. Each treatment was replicated three times. The germination percentages, lengths of radical and plumule for each test species were calculated.

A completely randomized design (CRD) was used for experiment analysis. The statistical analysis was done using STATISTIX 9. Means were separated by Fisher's protected LSD test (Nekonam et al., 2014).

Results

Allelopathic potential of P. roxburghii aqueous extract

Germination percentage

The results revealed that aqueous extract inhibited 54%, 48% and 43% germination percentage of *T. aestivum, C. album* and *A. fatua*, respectively on filter paper (*Table 1*), whereas, no significant inhibitory effect on the germination of *R. dentatus*, *P. minor* and *E. helioscopia* was observed supposed to be resistance against *P. roxburghii* extract.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17171739

Similarly, *P. roxburghii* aqueous extract on soil significantly inhibited 59%, 50% and 44% seed germination of *T. aestivum*, *C. album* and *A. fatua*, respectively compared to the control (*Table 2*). It has been observed that maximum (98%) germination was observed for *R. dentatus*, *P. minor* and *E. helioscopia*. During the experimentation, minimum germination was noted for *T. aestivum* (i.e. 46% and 41%) on filter paper and soil, respectively. The results revealed that germination percentage reduction of the *T. aestivum, C. album* and *A. fatua* were concentration dependent, with the increase of concentration, the suppression potential was gradually enhanced (*Fig. 1a*).

Radical length

The aqueous extract of *P. roxburghii* exhibited radical length inhibition of *C. album* (40%) followed by *R. dentatus* (39%) on filter paper (*Table 3*), whereas, no significant effect was noted for *T. aestivum*, *P. minor, E. helioscopia* and *A. fatua* showing resistance against extract. Similarly, the applications of extract into soil significantly suppressed radical length of *C. album* and *R. dentatus* with 46% and 41% respectively as compared to control (*Table 4*). The maximum (98%) radical length was observed for *T. aestivum*, *P. minor, E. helioscopia* and *A. fatua.* The final data concluded that minimum radical length was noted for *C. album* i.e. 60% and 64% on filter paper and soil, respectively (*Fig. 1b*).

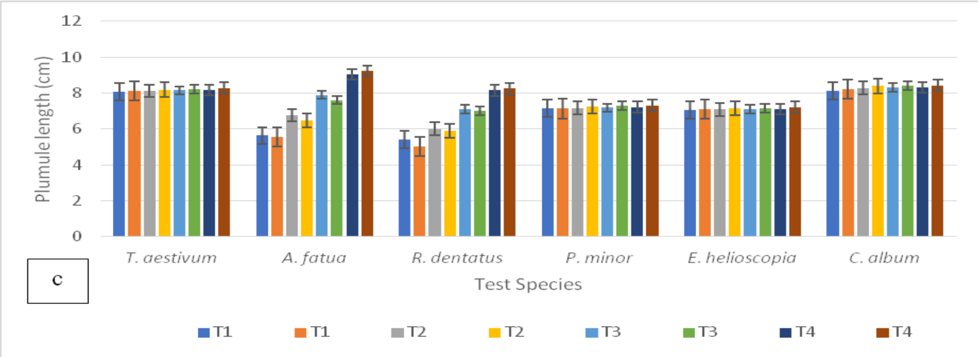

Figure 1. *Allelopathic potential of P. roxburghii aqueous extract against test species on filter paper (FP) and soil (S) on: (a) germination percentage (b) radical length (c) plumule length (T_1 = 100%, T_2 = 75%, T_3 = 50% and T_4 = control)*

Plumule length

The aqueous extract of *P. roxburghii* significantly inhibited the plumule length of *A. fatua* (38%) and *R. dentatus* (34%) as compared control on filter paper (*Table 5*). Remarkably, there was no momentous effect on plumule elongation of *T. aestivum, P. minor, E. helioscopia* and *C. album*. Likewise, *P. roxburghii* aqueous extract significantly inhibited plumule length of *A. fatua* (40%) and *R. dentatus* (39%) as compared to control in soil (*Table 6*). The statistical figures also proposed that maximum plumule length (98%) was noted for *T. aestivum, P. minor, E. helioscopia* and *C. album*. The statistical data concluded that minimum plumule length was noted for *A. fatua* showing 62% and 60% on filter paper and soil, respectively (*Fig. 1c*).

Allelopathic potential of P. roxburghii hexane extract

Germination percentage

It has been observed from the results that there was significant reduction of germination of *T. aestivum, C. album* and *A. fatua* showing 54%, 48% and 43% respectively as compared to their respective control on filter paper (*Table 7*), whereas, no significant effect on the germination of *R. dentatus*, *P. minor* and *E. helioscopia,* showing resistance to the allelopathic *P. roxburghii* hexane extract. Similarly, *P. roxburghii* hexane extract applied into soil showed the highest degree of inhibition of seed germination of *T. aestivum, C. album* and *A. fatua* with 62%, 52% and 49% respectively as compared to their respective control (*Table 8*). The maximum (98%) germination was noted for *R. dentatus*, *P. minor* and *E. helioscopia*. In the present study it was noted that minimum germination was noted for *T. aestivum* i.e. 46% and 38% on filter paper and soil. The statistics also recommended that allelopathic inhibitory effect was concentration dependent for *T. aestivum, C. album* and *A. fatua* with concentration increase, suppression potential was gradually enhanced (*Fig. 2a*).

Radical length

It is also clear from the result that *C. album* (40%) followed by *R. dentatus* (39%) exhibited radical length inhibition in *P. roxburghii* hexane extract on filter paper (*Table 9*), whereas, no noteworthy effect on radical length of *T. aestivum*, *P. minor, E. helioscopia* and *A. fatua* showing resistance to extract. Likewise, *P. roxburghii* hexane extract on soil cause significant radical length reduction of *R. dentatus* (50%) and *C. album* (48%) as compared to control (*Table 10*).

The maximum (98%) radical length was observed for *T. aestivum*, *P. minor, E. helioscopia* and *A. fatua*. The final data concluded that minimum radical length was noted for *C. album* (60%) and *R. dentatus* (50%) on filter paper and soil, respectively (*Fig. 2b*).

Plumule length

P. roxburghii hexane extract significantly retarded the plumule length of *A. fatua* (38%) followed by *R. dentatus* (34%) as compared to control on filter paper (*Table 11*), whereas, no momentous effect on plumule length of *T. aestivum, P. minor, E. helioscopia* and *C. album*. Likewise, the plumule length of *R. dentatus* (49%) and *A. fatua* (45%) was suppressed significantly as compared to control in extract applied into soil (*Table 12*).

*Significant at $P < 1\%$

The maximum plumule length (98%) was noted for *T. aestivum, P. minor, E. helioscopia* and *C. album*. The statistical data concluded that minimum plumule length was noted for *A. fatua* (62%) and *R. dentatus* (61%) on filter paper and soil, respectively (*Fig. 2c*).

Allelopathic potential of P. roxburghii methanolic extract

Germination percentage

P. roxburghii methanolic extract on filter paper showed significant inhibitory activity on seed germination of *T. aestivum* (57%), *C. album* (49%), and *A. fatua* (46%), respectively as compared to control (*Table 13*). Likewise, *P. roxburghii* methanolic extract on soil exhibited the highest degree of inhibition germination for *T. aestivum*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17171739

(62%), *C. album* (52%), and *A. fatua* (49%) respectively as compared to control (*Table 14*). The statistical data also suggested that the there was no significant effect on germination %age of *P. minor*, *R. dentatus* and *E. helioscopia*. The maximum (98%) germination was observed for *P. minor*, *R. dentatus* and *E. helioscopia*. The statistical results recommended that minimum germination was noted for *T. aestivum* showing 43% and 38% on filter paper and soil, respectively. The statistics also recommended that allelopathic inhibitory effect was concentration dependent for *T. aestivum, C. album* and *A. fatua* (*Fig. 3a*).

Radical length

The data revealed that the highest radical length inhibition activity exhibited by *R. dentatus* (47%) followed by *C. album* (43%), measuring 47% and 43% in *P. roxburghii* methanolic extract on filter paper (*Table 15*). Likewise, methanolic extract on soil caused significant radical length reduction of *R. dentatus* and *C. album* measuring 50% and 48%, respectively as compared to control, while *T. aestivum P. minor, E. helioscopia* and *A. fatua* remained unaffected (*Table 16*). The maximum radical length was noted for *T. aestivum, P. minor, E. helioscopia* and *A. fatua* (98%). The results also

Plumule length

P. roxburghii methanolic extract on filter paper significantly inhibited plumule length of *R. dentatus* (46%) and *A. fatua* (42%) as compared to the control (*Table 17*). Likewise, the highest degree of inhibition in plumule length was measured for *R. dentatus* (49%) and *A. fatua* (45%) in methanolic extract applied into soil (*Table 18*). The data further suggested that there was no significant effect on germination of *T. aestivum, P. minor, E. helioscopia* and *C. album*. The statistical results recommended that highest plumule length (98%) was exhibited by *T. aestivum, P. minor, E. helioscopia* and *C. album*. The results further indicated that minimum plumule length noticed for *R. dentatus* i.e. 68% and 61% on filter paper and soil, respectively (*Fig. 3c*).

Allelopathic potential of P. roxburghii in sandwich method

Germination percentage

The data revealed that *T. aestivum, C. album* and *A. fatua* showing 52%, 47% and 44% germination inhibition respectively as compared to control in *P. roxburghii* needles powder on filter paper, whereas, no significant effect on germination of *R. dentatus, P. minor* and *E. helioscopia* showing resistance to dry powder. The results also declared that maximum (97%) germination was noted for *R. dentatus, P. minor* and *E. helioscopia.* In the present study, it was demonstrated that minimum germination was noted for *T. aestivum* i.e. 48% and 45% on filter paper and soil, respectively. The experimental results of the current study indicated on agar the highest germination reduction was noted for *T. aestivum* (51%), followed by *C. album* (36%) and *A. fatua* (35%) at 10 mg conc. Similarly, the highest germination reduction was noted for *T. aestivum* (56%), followed by *C. album* (48%) and *A. fatua* (43%) at 50 mg conc (*Table 19*). The statistical data concluded that minimum germination was noted for *T. aestivum* measuring 49% and 44% at 10 mg and at 50 mg conc., respectively. The statistics also recommended that with the increase of concentration, the inhibitory effect was progressively increased for *T. aestivum, C. album* and *A. fatua*. The statistical

Radical length

The data revealed that *C. album* and *R. dentatus* showing 35% and 32% radical length inhibition respectively as compared to control in *P. roxburghii* needles powder on filter paper, whereas, no significant effect on radical length of *T. aestivum*, *A. fatua, P. minor* and *E. helioscopia* showing resistance to dry powder. It is also clear from the result that *C. album* and *R. dentatus* showed 45% and 42% radical length inhibition respectively as compared to control in powder applied into soil. The results also declared that maximum (96%) radical length was noted for *T. aestivum*, *A. fatua, P. minor* and *E. helioscopia.* In the present study, it was demonstrated that minimum radical length was noted for *C. album* i.e. 65% and 55% on filter paper and soil, respectively (*Table 20*). The experimental results of the current study indicated on agar the highest radical length reduction was noted for *R. dentatus* (35%), followed by *C. album* (34%) at 10 mg conc. Similarly, the highest radical length reduction was noted for *R. dentatus* (41%), followed by *C. album* (36%) at 50 mg conc. The statistical data concluded that minimum radical length was noted for *R. dentatus* i.e. 65% and 69% at 10 mg and at 50 mg conc., respectively (*Fig. 4b*).

Plumule length

The data revealed that *A. fatua* (39%) and *R. dentatus* (37%) showing plumule length inhibition respectively as compared to control in *P. roxburghii* needles powder on filter paper, whereas, no significant effect on plumule length of *T. aestivum*, *C. album*, *E. helioscopia* and *P. minor* showing resistance to dry powder. It is also clear from the result that *R. dentatus* (49%) and *A. fatua* (46%) showed and plumule length inhibition respectively as compared to control in powder applied into soil. The results also declared that maximum (95%) plumule length was noted for *T. aestivum*, *C. album*, *E.*

Discussion

Aqueous extracts of *Pinus albicaulis, P. contorta, P sabiniana* and *P. ponderosa* needles inhibited radical length of *Hordeum vulgare* and *Bromus mollis* (Heisey and Delwiche, 1983). *P. densiflora* needles water extract inhibited seed germination and seedling growth in *Clematis apiifolia, Ledebouriella seseloides, Melandrium firmum, Bidens pinnata,* and *Platanus orientalis* (Kil and Yim, 1983). Aqueous extracts of *Pinus divaricata* and *P. resinosa* fresh needles and litter reduced seed germination, root elongation and growth of *Poa pratense, Epilobium angustifolium, Agropyron repens* and *Phleum pratense* (Jobidon, 1986). *P. koraiensis* water extracts from leaves affected the seed germination and seedling elongation of selected weeds of wheat crops (Kil et

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17171739

al., 1991). *P. sylvestris* water soluble root secretions exerted negative biochemical effect on *Picea excela* (Kolesnichenko and Andryushchenko, 1978) and inhibited germination and early seedling growth of *Betula pendula. Betula pubescens* and *Pinus sylvestris* (Hytonen, 1992). Aqueous extracts of *P. thunbergii* needles inhibited seed germination and seedling length of *Lactuca sativa*, Carpesium *abrotanoides* and *Oenothera odorata* (Kil, 1989). The allelopathic potential is due to the presence of 9α, 13β-epidioxyabeit-8(14)en-18-oic acid reported from the aqueous methanolic extract of red pine needles that inhibited the growth of *Lepidium sativum*, *Lactuca sativa*, *Medicago sativa*, *Lolium multiflorum* and *Digitaria sanguinalis* (Kato-Noguchi et al., 2009). Another compound abscisic acid-β-D-glucopyranosyl ester (ABA-GE) was also isolated and found to have allelopathic activity (Kato-Noguchi et al., 2011). The needle extract from *P. nigra* inhibited seed germination of rye grass (Terzi, 2013). Similarly, aqueous extract of *P. roxburghii* needles suppressed the growth of mustard and wheat seedlings (Baroniya and Baroniya, 2014), while that of *P. brutia* needles suppressed the growth of *Lolium multiflorum* and *Poa pratensis* seedlings (Aliloo et al., 2012).

The current study was in accordance with Singh et al. (2001), who determined that seedling growth and seed germination of *Capsicum annuum, Pisum sativum* and *Oryza sativa* was significantly retarded by *Pinus* needles and the inhibitory effect was concentration dependent. Likewise, *Amaranthus paniculatus* and *Trifolium pratense* seeds treated with leaf extract of *P. roxburghii* and *Rhododendron arboreum* that resulted momentous consequence on germination of tested species (Madgil and Kapil, 1990). Poisonous compounds produced by *P. densiflora* checked growth and seed germination of adjacent species (Kil and Yim, 1983). The phenolic composites of *P. rigida* exhibited both retardation and development effect on *Cassia mimosoides* revealing concentration dependent. Fresh, senesced and decaying needles from *P. halepensis* exhibited potent inhibitory potential on *Festuca arundinacea*, *Cyanodon dactylon*, *Avena sativa* and *Lemna minor* (Nektarios et al., 2005).

Different species of *Pinus* had exhibited allelopathic potential against other plant species (Kato-Noguchi et al., 2009). *P. roxburghii* extract possessed significant inhibitory potential on different plants (Melkania, 1984). Allelopathic effects of *P. halepensis* possessed herbicidal activities (Hamrouni et al., 2015; Anwar et al., 2019). A significant herbicidal activity of *P. halepensis* against common weeds of cereal crops (Amri et al., 2013). The inhibitory effect of the *Pinus* needles, being more pronounced in the fresh, moderate in the senesced, and low in the decaying conditions (Monnier et al., 2011). Allelopathic potential of *P. halepensis* had been broadly calculated from various plant parts, which can be autotoxic and thus prevent the germination of seeds in a forest plants as was observed for inhibition of *Stipa tenacissima* grasslands (Fernandez et al., 2013; Navarro-Cano et al., 2009). Allelochemicals are reported to be present in stems, roots, leaves and fruit of *P. halepensis* (Baroniya and Baroniya, 2014), which exhibited allelopathic effects (Hamrouni et al., 2015) and strong herbicidal activity of essential oil was reported against common weeds of cereal crops (Fujii et al., 2004). *P. halepensis* extracts inhibited germination and growth of *Lactuca sativa* and *Linum strictum*. The strong allelophatic potential of *P. halepensis* could be attributed to the presence of numerous phenolic compounds such as benzeneacetic, 4-hydroxybenzoic, vanillic, veratric, syringic and p-coumaric acids, and non-phenolic acids such as lactic, succinic, palmitic acids in *P. halepensis* (Fernandez et al., 2006). Green needles are found to have higher amounts of phenolic compounds and condensed tannins (Refifa et al., 2016). Reduced germination and suppressed growth in different

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17171739

plants could be a result of damage in the membrane integrity. It has been observed that seeds supplemented with Pinus needle extract showed enhance electrolyte leakage which reveals higher damage to membranes (Baroniya and Baroniya, 2014).

The black pine showed to inhibit the growth of *Phalaris canariensis*, *Trifolium campestre* and *Sinapis arvensis* seeds (Amri et al., 2013; Anwar et al., 2018c). Different pinene isomers exhibited allelopathic potential against *Zea mays* seed germination (Areco et al., 2014). The leaf methanolic extract from *P. nigra suppressed* the seed germination of perennial ryegrass and tall fescue (Robert, 1986; Terzi et al., 2013). Valera-Burgos et al. (2012) noticed inhibitory potential of *Pinus pinea* needles extract on seedling growth and seed germination 3 Mediterranean shrub species. Allelopatic substance was isolated from the exudates of Japanese red pine trees the substance was identified as phenylacetic acid which inhibited shoot and radical elongation of *Cryptantha crassipes* I. M. Johnst (Khan et al., 2008; Anwar et al., 2018d). *P. densiflora* needles contain toxic substances that inhibit seed germination and growth of plants (Fernandez et al., 2013), these inhibitory effects can be attributed to direct molecular alteration (Hamrouni et al., 2015). The main inhibitory substance from methanol extract of the pine needles was identified as 9alpha, 13beta-epidioxyabeit-8(14) en-18-oic acid, this substance is responsible for the inhibition of root and shoot growth of *Echinochloa crus-galli* (Baroniya and Baroniya, 2014).

Powdered *P. roxburghii* needles reduce germination and, root and shoot growth of *Achyranthes aspera* L. (Khosla et al., 1981; Anwar et al., 2018a). Plants growing at higher altitudes are observed to accumulate phenolic compounds in higher concentrations consequently inhibit plant growth (Baroniya and Baroniya, 2014). Gymnosperm trees showed strong allelopathic effect on the germination, growth, and development of other plant species in the forest community (Silva et al., 2015) due to presence of allelochemicals, mostly phenolic compounds and terpenoids (Rice, 1984). *P. halepensis* had strong inhibitory effect on seedling establishment of various species suggesting allelopathic effects of litter or root exudates (Maestre, et al., 2003). Needle essential oil identified components are (*E*)-caryophyllene, terpinen-4-ol, α-humulene, and α-terpineol (Satyal et al., 2013; Anwar et al., 2018b), it was reported that (*E*)-caryophyllene inhibited the germination and seedling growth of *Brassica campestris* and *Raphanus sativus* (Wang et al., 2009). Application of *α*-pinene inhibited the growth of *Cassia occidentalis, Amaranthus viridis, Triticum aestivum, Pisum sativum and Cicer arietinum* seedlings due to the oxidative damage in root tissues (Singh et al., 2006). Allelochemicals in chir pine needles suppressed the growth of radical and plumule length of canary grass (Refifa et al., 2016). Blum (1998) observed that *P. divaricata* and *P. resinosa* needles leachates suggestively checked seedling growth and germination of *Epilobium angustifolium, Agropyron repens and Phleum pretense. The* seedling growth of *Lepidium virginicum* was significantly checked by *P. roxburghii* needles (Williams and Hoagland, 1982). The mechanism of retardation on the seedling growth produced by phytochemicals checked cell elongation and division (Node et al., 2003). Similarly, *P. densiflora* cones have high biological activity against select plant species (Lee and Monsi, 1963).

Conclusions

Present results indicated that pine needles extract and dried powder at higher concentrations reduced the seed germination, radical and plumule length of weeds

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17171739

associated with the wheat crop. *P. roxburghii* is located in the mountain region of Pakistan and in every season, the fallen needles form a bed on the forest floor. During the rainy season, pine needles get dissolved with water and mixed into the soil and resultantly caused in crop reduction. Further work is needed to appraise the potential inhibitory effects of allelochemicals from the pine needles.

Abstract. One of the most important functions of forests is providing raw material for wood. Timber extraction is among the most technically demanding, expensive and time consuming activities for wood raw material production. The analysis of timber extraction activities is complex and it is quite difficult to model them. Therefore, Artificial Neural Networks (ANN) frequently used as a modelling tool in the analysis of complex problems have been used to solve this issue. The aim of this study is to investigate the feasibility of ANN's including Multilayer Perceptron (MLP), Cascade Forward Back Propagation (CFBP) and compare the predictions for total time during log skidding operations stations in Eastern Black sea region (Giresun Forest District Directorates) of Turkey with those of the Multiple Regression Analysis (MRA). Moreover, standard times are calculated, and affective factors are determined, after which the effectiveness levels are evaluated at each working stage by way of timing determinations when skidder is used for timber extraction. The comparison of models were carried out by using the correlation coefficient, mean squared error, root mean square errors and mean absolute error. The comparison results indicate that MLP and CFBP models are better at predicting the total time during log skidding operations in comparison with the MRA model. These results have put forth that artificial neural networks have a greater prediction in comparison with multiple regression analysis for predicting the skidding time in timber extraction operations and that less erroneous results are obtained. It is observed that artificial neural networks can be preferred in cases for which the multiple regression analysis predictions have not been met and the analysis cannot be performed.
Keywords: *timber extraction, log skidding, multilayer perceptron, cascade forward back propagation, Turkey*

Introduction

Turkey has a total of 22.7 million hectares of forest area, which makes up 27% of its total land area. Almost 46% of the total area is on steep land with slopes greater than 40%. Thus, harvesting in mountainous regions has always played a significant role (GDF, 2017). Forestry operations in Turkey are carried out under different conditions on a forest area of approximately 22.7 million hectares, located at different parts of the country (Çalışkan et al., 2017).

Timber harvesting, as a succession of interrelated and interdependent operations in timber production, felling, processing and timber transport. Timber transport consists of two sub phases: timber extraction and further transport that are mutually dependent (Bayoğlu, 1962; Seçkin, 1978; FAO, 1982; Erdaş, 1986; Haarlaa and Jurvelius, 1987; Acar, 1994; Dykstra and Heinrich, 1996; Heinimann, 1999; Karaman, 2001; Heinimann and Stampfer, 2003; Pentek, 2008; Çalışkan et al., 2017).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17411756

Different tools and methods are used according to technical, economic and environmental factors for timber extraction operations which is one of the stages of wood raw material production. Skidding the wood raw material on skid trails via forest tractors or agricultural tractors to place on temporary stacking locations (ramp) is one of these methods. Land topography is among the most distinctive factors in skidding work. Timber extraction methods are generally determined according to ground slope classes. The slope groups taken as basis for determining production type are as follows: using agricultural tractor and animals for skidding 0-33% ground slope, using skidder (MB Trac 900) for cable drawing 34-50% ground slope and cable timber extraction 50%< ground slope (Erdas et al., 1986; Heinimann, 1999). Timber extraction is the most difficult and expensive stages of producing wood raw material and also has the highest environmental damage. A planned approach is required for shortening this process, making the work easier, improving efficiency and thus attaining an economical process (Marchi et al., 2014).

When wood raw material skidding activities are taken into consideration with a system approach, there is a necessity for determining the standard times for different conditions that can be used while planning, applying and inspecting skidding activities which will also form a basis to ensure that skidding workers receive equal pay under equal conditions. Effectiveness of operating conditions while calculating standard time is quite high especially for mountainous forests. Determining the wages according to these factors is of vital importance for ensuring wage justice among employees and for the cost effectiveness of forest management for employers. There are various studies on timber extraction operations in which time studies have been carried out for cable drawing via agricultural tractors and forest tractors (Acar, 1995, 1997; Karaman, 1997; Öztürk, 2005; Tunay et al., 2002; Öztürk, 2010; Çağlar, 2016).

ANN is used as a popular method in different engineering applications by many researchers. ANNs are software designed for simulating the operation of simple biological neural systems (Yurtoğlu, 2006). The main reason why a human being may develop solutions for issues that require thinking and observation skills is his/her ability to learn through experience (Sağıroğlu et al., 2003). Therefore, ANN may be a beneficial tool in engineering applications (Topçu and Sarıdemir, 2008). ANN is a strong tool especially for data models with low regression coefficients (Esteban et al., 2009). ANN's are used for modelling complex operations in many engineering fields ranging from aeronautics, electronic, production, robotics, communication, construction, forest etc.

ANN's was successfully implemented in the field of forest modelling. Particularly, ANN approach has been used for many objectives modeling individual tree survival probabilities (Guan and Gertner, 1991), forest age using TM images (Jensen et al., 1999), tree mortality (Hasenauer et al., 2001; Castro et al., 2013), forecasting of industrial wood demand (Güngör et al., 2004), pine bark volume (Diamantopoulou, 2005), tree volume (Diamantopoulou, 2005a; Diamantopoulou and Milios, 2010; Özçelik et al., 2008, 2010), tree stem diameters (Diamantopoulou, 2005b; Leite et al., 2011), tree felling times (Karaman and Çalışkan, 2009), tree heights (Diamantopoulou and Özçelik, 2012; Özçelik et al., 2013), diameter distributions (Cai et al., 2012) predict of skidding time (Naghdi and Ghajar, 2012), trunk volume estimates (Bayati and Najafi, 2013), prediction of cable drawing time (Bayati and Najafi, 2015), tree diameter increments (Ercanlı et al., 2016), describing diameter distribution (Bolat et al., 2016), bark volume estimation (Çatal et al., 2018).

The use of artificial neural networks in timber extraction is at a starting stage in Turkey. Hence, there are a few studies in forestry literature which compare the performance of artificial neural networks with other models. For this reason, the aim of this study was to investigate the feasibility of two different reputed types of ANN's and compare the results with those of MRA for predicting the total time during log skidding operations stations. Thus, the network architecture, training algorithm and transfer function that yielded the best result were determined. The data set was separated into three sets as training, test and validation. The training data set used for the training of ANN which makes up the majority of the input data set is used to maximize the ability of the network to predict the correct results and the minimize the error. Test data set is not considered during learning and is used to test the success rate for the prediction of the network after the learning stage. Control data set used during the training of the network. If the performance of the trained data set is very low, but the performance of the control set is high; this raises a suspicion that the network has memorized. In such cases, the network has to be trained again (Çelik, 2004).

Material and Methods

Study Area

This study was carried out at the Anbardağ forest planning unit covering an area of approximately 5975.0 ha in the Giresun province in the north-eastern Black Sea region of Turkey. The area is located between 40° 42' 47" – 40° 30' 13" North, and 38° 01' 49" – 38° 13' 16" East. The average terrain gradient is 30%, and altitudes range from 1.100 m to 1.500 m above sea level. Dominant tree species used for production purposes are natural oriental spruce (*Picea orientalis* Link.) and oriental beech (*Fagus orientalis* Lipsky). Felling and delimbing operations were carried out via chainsaws. Agricultural and skidder (MB Trac 900) are mostly represented as off-road machines and have been widely used (Çalışkan et al., 2017.

Field Data Collection

Timber extraction was done by skidder with cable drawing and on-road skidding system. Measured data for the timber operations have been recorded in study forms. Time values for each stage have been measured as 1/100 minute (PM) using a chronometer, the amount of work done has been determined in units and as m^3, factors that have an impact on the work done (tree type, diameter, height, ground slope, cable drawing distance, number of logs, log volume, skidding distance) have also been recorded in the work form. No intervention was made on the workers regarding issues such as starting and stopping of work, breaks, pauses, dealing with other operations.

Variables that were considered to have an impact on the work time for skidder timber extraction operations have been evaluated as $X_{ii}\left(X_{11}-X_{17}\right)$ and expressed in numerical values. These variables have been briefly explained in *Table 1*.

Continuous time measurement method was used for time measurements and the work phases, total turn time and waiting times were determined using a digital chronometer. The measured time values were for a two person working group with units of 1/100 minute. Work phases and related time values have been expressed as $y_{ii}\left(y_{11}-y_{21}\right)$ for tractor timber extraction operations and related time values have been briefly explained in *Table 1*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17411756

Measurements and observations have been carried out related with the timber extraction operations for spruce trees using skidder (preparation time on skidder, pulling time to empty cable, hooking time, time to take the load, wait time to obstacle, waiting time to cable dissolution, waiting time, skidding time, unhooking time, stacking time).

Table 1. *Work phases and their descriptive statistics*

Work phases	*Aver.*	*Std. Dev.*	*min.*	*max.*	Work phases	*Aver.*	*Std. Dev.*	*min.*	*max.*
y_{11} : Preparation time on Tractor	72.00	49.74	0.00	205.0	y_{fa} : Total activity(skidding) time	936.0	462.3	250.0	2800
y_{12} : Pulling time to empty cable	143.0	88.28	10.00	420.0	y_{tr} : The tractor is actively operating time	327.0	157.1	60.00	730
y_{13} : Hooking time	160.0	201.8	10.00	980.0	y_{ge} : For cable drawing, actual skidding time	609.0	357.9	130.0	2080
y_{14} : Time to take the load	146.0	88.55	20.00	470.0	X_{11} : Cable haulage distance	26.92	15.45	2.00	90.00
y_{15} : Wait time to obstacle	60.00	12.88	0.00	550.0	X_{12} : Land slope	57.08	12.48	25.00	85.00
y_{16} : Waiting time to cable dissolution	9.00	36.65	0.00	210.0	X_{13} : Diameter of logs	51.48	19.70	17.00	100.00
y_{17} : Load take-off time	34.00	64.83	0.00	300.0	X_{14} : Length of logs	6.61	3.90	1.00	24.00
y_{18} : Waiting time	192.0	731.8	0.00	6340	X_{15} : Number of log	3.15	3.09	1.00	15.00
y_{19} : Skidding time	40.00	46.90	0.00	210.0	X_{16} : Log volume	0.96	0.72	0.09	3.74
y_{20} : Unhooking time	92.00	50.35	0.00	230.0	X_{17} : Skidding distance on the road	9.67	11.13	0.00	50.00
y_{21} : Stacking time	36.00	68.21	0.00	250.0					

In addition, times for work groups have been determined as such by combining certain work phases:
Active operating time for the tractor(skidder):

$$y_{tr} = y_{11} + y_{14} + y_{17} + y_{19} + y_{21} \quad \text{(Eq.1)}$$

Real skidding time required for cable drawing:

$$y_{ge} = y_{12} + y_{13} + y_{14} + y_{15} + y_{16} + y_{20} \quad \text{(Eq.2)}$$

Total activity time:

$$y_{fa} = y_{tr} + y_{ge} \quad \text{(Eq.3)}$$

The definitions of all the y parameters mentioned in the equations are shown in *Table 1*. The ANN models were generated using Matlab software. Statistical analyses were carried out via “SPSS 21.0” software.

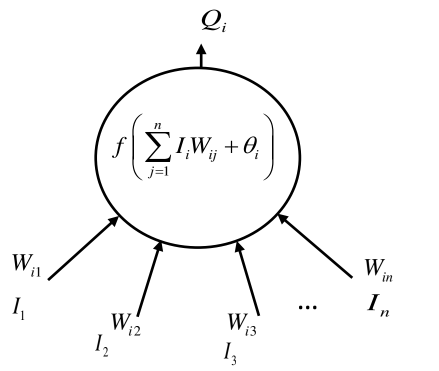
Artificial Neural Network (ANN) modelling approach

General background

ANN is a methodology developed based on the biological operating principle of the human brain which is applied on complex problems. An artificial neural network has three main elements: neurons, connections, and training rules (*Figure 1*) (Dağlı, 1994; Fausett, 1994; Haykin, 1994). In addition, an ANN is comprised of three layers with interconnected neurons which are input layer, output layer and hidden layer. The hidden layer just receive signals from the input layer and send signals to the output layer and their number is determined by way of trials (Benli, 2002).



Here;
I_j : input signal from the jth neuron
W_{ij} : connection weight for the connection from the jth neuron to the ith neuron
θ_i : initial value of the ith neuron
O_i : output signal of the ith neuron
f (..) : activation function

Figure 1. *Topology of a Neuron*

One of the most important aspects of an ANN is the connections that enable the neurons to transfer data to each other with weight values (w_{ji}). The weight values have an impact on each input of every operating element (Yıldız, 2001). Training of an ANN is defined as making changes in the weights matrix. It can be classified in two groups as supervised and unsupervised learning (Dağlı, 1994; Karaman and Çalışkan, 2009): MLP and CFBP methods have been used in this study for the prediction of the total time during log skidding operations.

Multiple Layer Perceptron (MLP)

Back propagation (BP) algorithm is used for training MLP networks in this study since it is easy to understand and prove mathematically. The BP artificial neural network models have already been described and are used widely (Rumelhart et al., 1986; Fausett, 1994; Haykin, 1994; Özçelik et al., 2010).

BP algorithm uses two parameters that control the speed at which training takes place. The learning coefficient determines the amount of change in the weights. It is observed that generally values between 0.2 and 0.4 are used and that the value of 0.6 yields the most successful results (Öztemel, 2003). The momentum coefficient plays a role on training performance. It is observed that selecting a value ranging between 0.6 and 0.8 would be best (Öztemel, 2003). Levenberg-Marquardt is highly recommended for neural networks since it is one of the most efficient algorithms (Yu et al., 2011). Levenberg–Marquardt (LM) algorithm has been developed by Kenneth Levenberg and Donald Marquardt (Yu et al., 2011). Considering the features of the problem in this

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17411756

study, LM (trainlm) was chosen as the training function. Network architecture, training rate and momentum factor have been determined in our study after examining different combinations. The general structure of MLP is shown in *Figure 2*.

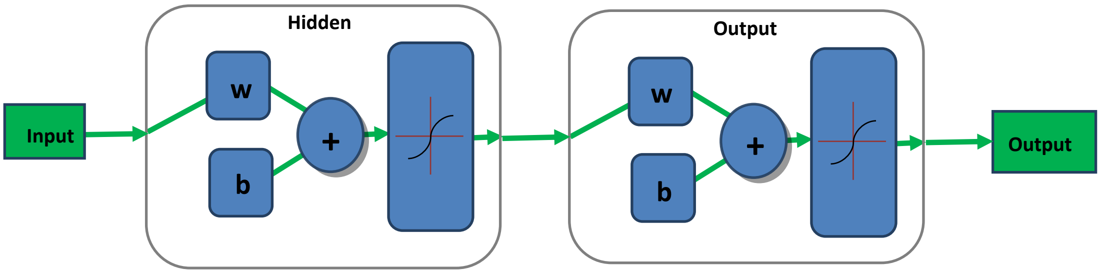


Figure 2. *Multilayer Perceptron (MLP) network architecture*

Cascade Forward Back Propagation (CFBP)

Different than MLP, the input values in CFBP are connected with all layers. CFBP has a learning property just like MLP (*Figure 3*) (Demuth et al., 2009). Considering the features of the problem in this study, LM (trainlm) was chosen as the training function. Network architecture, learning rate and momentum factor were determined in the study after examining different combinations. The general structure of CFBP is shown in *Figure 3*.

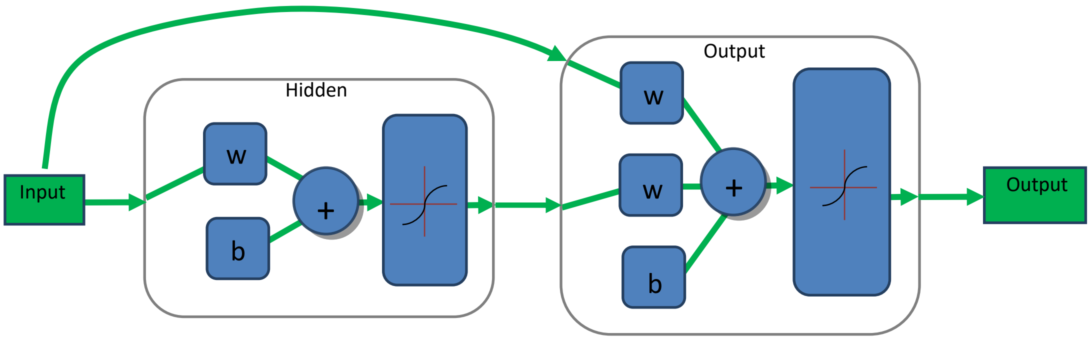

Figure 3. *Cascade Forward Back Propagation (CFBP) network architecture*

Multiple Regression Analysis (MRA)

Regression is one of the methods used for testing whether there is a relationship between two or more variables and to express the relationship between the variables by way of linear or curvilinear equations (Öztürkcan, 2009). Regression analysis using more than one independent variable is called multiple regression analysis.

The general structure of the equation in cases when there is more than one independent variable (such as $x_1, x_2, x_3, \ldots$);

$$Y = \beta_o + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_3 + \ldots + \beta_n x_n \pm \varepsilon \qquad \text{(Eq.4)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17411756

where Y: Dependent variable, X_i: Independent variable ($i=1,2,3\ldots n$) β_i: Regression parameters ($i=1,2,3\ldots n$), ε: Random error and n: number of unknown parameters.

Statistical calculations on variables that are independent from (x_{ii}) and dependent on (y_{ii}) measurement results have been carried out as;

- Calculation of the average and deviations.
- Examination of the variables that are effective on the actual time spent for each work phase or the unit time value.
- Examination of the relations between variables.
- And determination of the impact of independent variables on the total time spent for work phases (multiple regression analysis).

Model evaluation criteria

In this study, the corrected determination coefficient (R), Mean Squared Error (MSE), Root Mean Square Error (RMSE) and mean absolute error (MAE) were used as criteria for comparing artificial neural networks (MLP, CFBP) and multiple regression analysis (MRA). Accordingly, high R and low MSE, RMSE and MAE values indicate the best model. MAE and MSE values were close to 0 and the R value was close to 1, thereby indicating that the predicted value strongly converges to the right (Hocking, 1986; Law, 1999; Cho, 2003; Arıkan Kargı, 2014).

a) The Correlation coefficient (R)

$$R = \frac{\sum\left(X_i - \bar{X}\right)\left(Y_i - \bar{Y}\right)}{\sqrt{\sum\left(X_i - \bar{X}\right)^2\left(Y_i - \bar{Y}\right)^2}} \qquad \text{(Eq.5)}$$

b) Mean Squared Error (MSE)

$$MSE = \frac{1}{n}\sum_{i=1}^{n}\left(y_i - \hat{y}_i\right)^2 \qquad \text{(Eq.6)}$$

c) Root Mean Square Error (RMSE)

$$RMSE = \sqrt{\frac{\sum_{i=1}^{n}\left(x_i - y_i\right)^2}{n}} \qquad \text{(Eq.7)}$$

d) Mean absolute error (MAE)

$$MAE = \frac{\sum_{i=1}^{n}\left(x_i - y_i\right)}{n} \qquad \text{(Eq.8)}$$

where X_i and Y_i are the observed and predicted data, respectively; $\bar{X}$ and $\bar{Y}$ are the mean of the observed and predicted and n the number of observations in the dataset.

Results and Discussion

The arithmetic average, standard deviation, max and min values for the actual time values measured with a unit of 1/100 minutes as the variables of observed values regarding the work phases of cable drawing by forest tractor have been calculated and presented in *Table 1*.

Single input variance analysis was used to examine whether the impact of the correlation matrix indicating the relationship between the variables and X_{ii} groups on the values of y_{ii} was statistically significant or not.

The developed ANN models (both MLP and CFBP models) used Cable haulage distance (X_{11}), Land slope (X_{12}), Diameter of logs (X_{13}), Length of logs (X_{14}), Number of logs (X_{15}), Log volume (X_{16}) and Skidding distance on the road (X_{17}), as input variables and the Total activity time (Skidder, y_{fa}) as the output variable.

In this study, all data were first normalized (0-1) and training, validation and testing data sets that are randomly partitioned into training (65% of all data). The validation (10%) and test data sets (the remaining 25%) were used for conquering general patterns between input and output variable while building the ANN model. The training set adjusts the connection weights and the parameters of the model; the validation set checks the performance of the model through the training process and stops the training to avoid overfitting; while the testing set evaluates the trained ANN performance and generalization power (Ghajar et al., 2012a,b; Ghorbani et al., 2016).

A typical MLP model with a BP algorithm is constructed for predicting the total activity time for skidder. The most important characteristic of multi-layered artificial neural networks is that they can be designed to contain more than one hidden layer. However, it has been determined that networks designed with one or two hidden layers display a good performance, whereas networks with more than one or two hidden layers do not have any advantage (Yeşilnaçar et al., 2005; Rumelhart, 1986). The number of neurons in the hidden layer is also an effective element in network performance. In some cases, networks with two hidden layers with a smaller number of neurons may have a better performance in comparison with networks that contain many neurons in one hidden layer (Yılmaz, 2009).

In this study, the number of neurons in the hidden layer was determined by trial and error. In this context, one hidden layer with 30 neurons was included in the model. Neurons ranging between 1 to 40 were given to each layer for determining the number of neurons included in the hidden layer. Each model was tested 15 times to determine the best model for our study. Therefore, the most suitable model was identified as the model with a 7-30-1 network structure. This study, the hyperbolic tansig transfer function was used between the input and hidden layers, and a pureline transfer function was used between the hidden and output layers. The Levenberg-Marquardt (LM) method was used for the optimization of the algorithms.

In this model, each combination of learning rates and momentum factors were tested for different numbers of hidden neurons. The network was trained in 930 epochs using the LM learning algorithm with a learning rate of 0.001 and a momentum coefficient of 0.3. This was the best combination that conducts to the smaller values of R, MSE, RMSE and MAE in *Table 2*. Regression values for the data used in the training, validation and testing of the MLP have been given in *Figure 4*.

Figure 4 shows the R values graph for the training, test and validation stages of the studied model. The values determined were R= 0.9027 for the learning stage, R= 0.7767

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17411756

for the test stage, R= 0.7427 for the validity testing of the model and R=0.8536 in total. *Figures 5 and 6* show the graphs comparing the model predictions and observed values for the MLP model. It can be observed from *Figures 5-6* that the values of the total time during log skidding operations were usually predicted near the observed value.

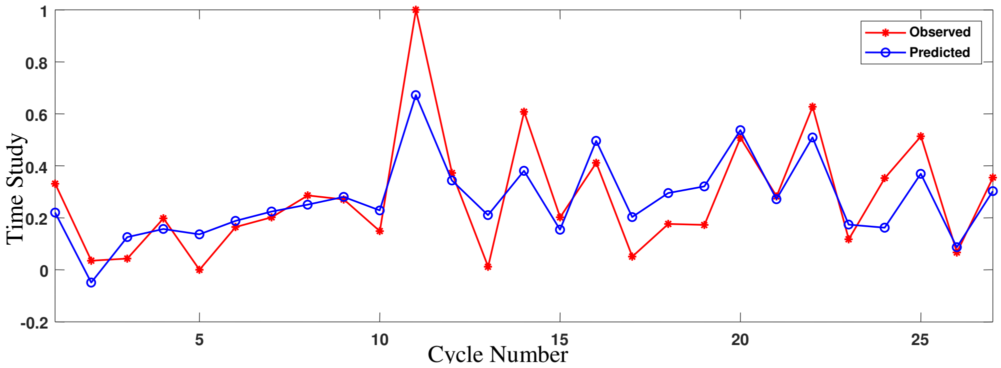

Figure 6. *Comparison of predicted (blue line) and observed (red line) values for test sets using MLP*

The hyperbolic tansig transfer function was used between the input and hidden layers, and a pureline transfer function was used between the hidden and output layers in CFBP model which gave the best results. The LM method was used for the optimization of the algorithms. CFBP model had a single hidden layer with 16 neurons. According to results, the most suitable model for CFBP is 7-16-1 network structure. In this model, the network was trained in 900 epochs using the LM learning algorithm with a learning rate of 0.001 and a momentum coefficient of 0.3. This was the best combination that conducts to the smaller values of R, MSE, RMSE and MAE in *Table 2*. Regression values for the data used for the training, validity and testing of the CFBP model have been given in *Figure 7*.

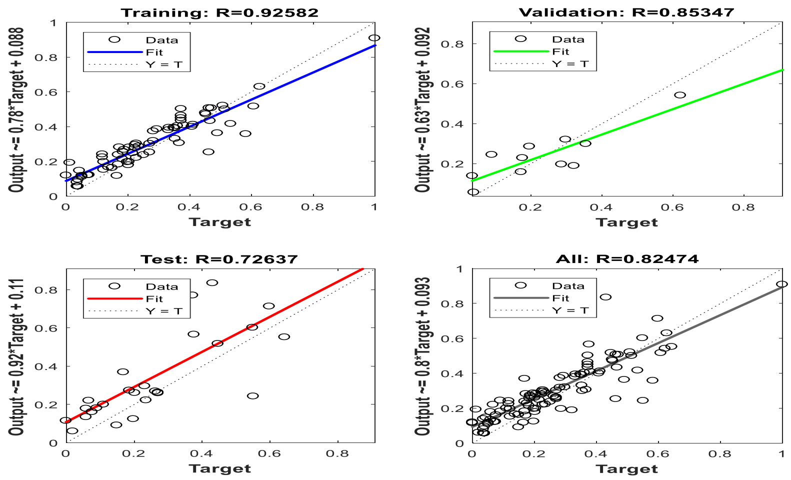

Figure 7. *Training, test, validation distribution graphs for the CFBP prediction model*

Figure 7 shows the R value graphs for the training, test and validation t stages for the studied model. The values determined were R= 0.9258 for the learning stage, R= 0.7263 for the test stage, R= 0.8534 for the validity testing of the model and R= 0.8247 in total. *Figures 8 and 9* show the graphs comparing the model predictions and observed values for the CFBP model.

It can be observed from *Figure 8-9* that the values of the total time during log skidding operations are usually predicted near the observed value.

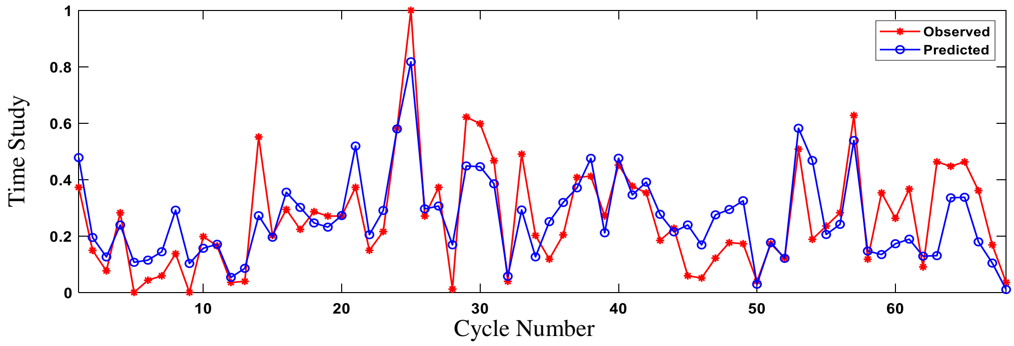

Figure 8. *Comparison of predicted and observed values for training sets using CFBP*

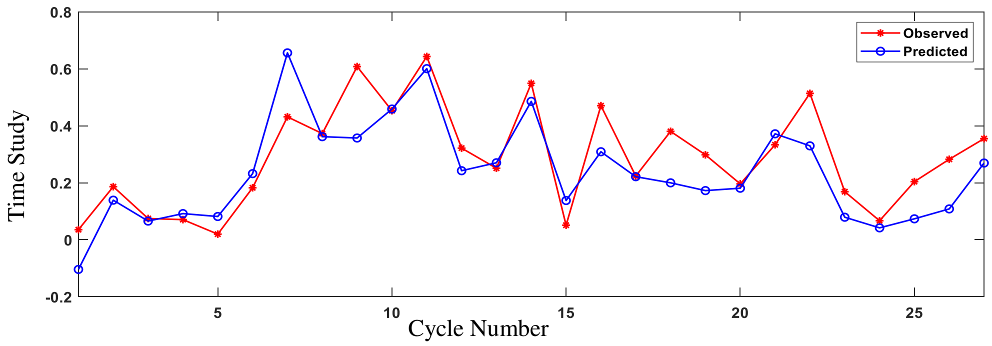

Figure 9. *Comparison of predicted and observed values for test sets using CFBP*

Alternative equalities have been generated via multiple regression analysis. Operations carried out for the timber extraction total activity time with forest tractor (y_{fa}) have been given in detail.

Regression equalities based on the $y_{fa} = f\left(X_{11}, X_{12}, X_{13}, X_{14}, X_{15}, X_{16}, X_{17}\right)$ relationship have been given in *Table 3*. Consistency of the equation was tested using the coefficients obtained from the regression equation and test data. Graphs that compare the model predictions obtained from the MRA model and the observed values have been given in *Figure 10*.

Table 3. *A Comparison of the MLP, CFBF and MRA Models*

Model	*Topology*	*R*	*MSE*	*RMSE*	*MAE*
MLP	7-30-1	0.85	0.0098	0.0991	0.0760
CFBP	7-16-1	0.82	0.0125	0.1120	0.0784
MRA	7-1	0.77	0.0127	0.1126	0.0877

It can be observed from *Figure 10* that the values of the total time during log skidding operations usually predicted near the observed value.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17411756

The performances for predicting total activity time for skidder are compared using three techniques of MLP, CFBP and MRA. The values of performance measures are given in *Table 3*.

Values of R, MSE, RMSE and MAE were compared at the end of the study for determining the algorithm with the best performance. MLP had the best performance in the study followed by CFBP and finally MRA with the lowest performance.

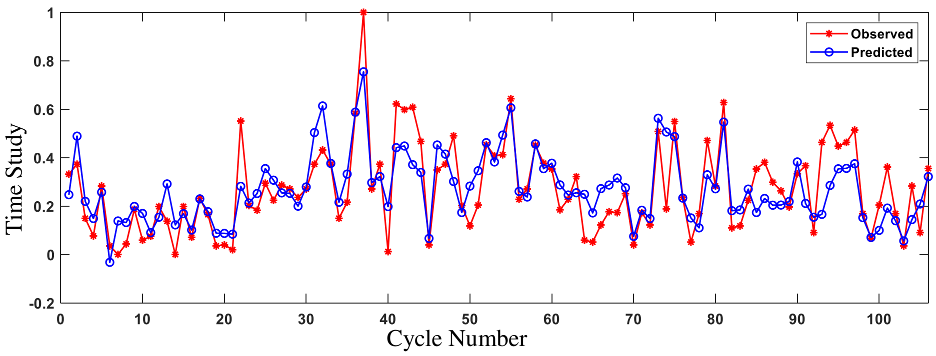

Figure 10. *Comparison of predicted and observed values using MRA*

Conclusion

The aim of this study was to investigate the feasibility of two different reputed types of ANNs including MLP, CFBP and compare them with the MRA model with regard to predicting the total time during log skidding operations stations in Eastern Blacksea region (Giresun Forest District Directorates) of Turkey.

Determination coefficient (R) and the expressions that indicate the error variance (MSE, RMSE and MAE) have been taken into consideration for determining the model with the best results. Accordingly, the model with high R and low MSE, RMSE and MAE values was taken into consideration as the best model. The R values obtained in the study were determined to vary between 0.85 and 0.82 for MLP and CFBP and as 0.77 when multiple regression was used.

Thus, it can be observed that artificial neural networks have higher prediction accuracy in comparison with multiple regression analysis and yield results with lower error values. In this case, it can be predicted that artificial neural networks may be preferred in cases when regression analysis predictions are not met and the analysis cannot be carried out.

MLP yielded better results in comparison with CFBP when ANN methods are compared among themselves for the prediction of total time during log skidding operations stations. The results of this study can be used for preparing and inspecting machine operating programs and for calculating production cost. MLP models can be used reliably for calculating the operating time of different land and operating conditions.

The results of this study can be used for determining the time dependent machinery demand to be used in timber extraction operations by private companies, for cost calculation and for putting forth the alternatives to carry out the work at minimum cost.

(Received 28th Oct 2018; accepted 11th Jan 2019)

Abstract. Determinations of success of semi-arid plantations are very important. This paper was handled to evaluate the success of Calabrian pine plantations established in the semi-arid Harran Plain of Turkey between 1996 and 1999 regarding technical and economic aspects. The data were obtained from both 12 sample plots at different aspects in 2015 and from the Şanlıurfa Forest Enterprise Directorate's records. Also data of the yield tables of plantation areas and natural stands, and the product range table of Calabrian pine were used. Variance analysis was administered to control the growth performance of Calabrian pine plantations. The differences of diameter and height growths and the number of trees per hectare were determined. The criteria of net present value, internal rate of return and benefit cost ratio were used for economic evaluation. In conclusion, diameter and height growth and success rate were found higher in eastern, northern and western aspects, the mean survival percentage ranged from 18.60-57.13%, and the high percentage of survival was found in the north aspect. Economic return of Calabrian pine plantations in semi-arid areas in terms of wood production was found to be lower than that of the natural stands and of the plantations in other areas. However, it was concluded that the plantations in semi-arid regions are crucial because of the benefits such as the biological diversity, the protection of natural balance, prevention of erosion and carbon sequestration, and incorporation of the wastelands to the production. It was suggested that the plantations in semi-arid area should be improved and maintained for sustainable environmental management.
Keywords: *benefit cost ratio, internal rate of return, net present value, Pinus brutia, plantation growth performance, semi-arid region, sustainable environmental management*

Introduction

As one of the countermeasures against global warming, afforestation in arid and semi-arid lands had been proposed and has been tested from 1999. In this areas, harsh environmental condition constrains plant growth and survival, and then biomass productivity is usually quite low (Suganuma et al., 2014). As plantations become increasingly important sources of wood and fiber in arid and semi-arid places, they have also become increasingly criticized for their hydrological impacts (Sadeghi et al., 2016). In arid and semi-arid regions, where rainfall is not sufficient to sustain a good seedling/tree growth, water harvesting for afforestation is applied (Prinz, 2001). On the other hand, in combating desertification and erosion, the most significant issue is to conduct successful plantation activities. With this aim, it needs well-designed plantation projects, a consideration of all details and accurate implementation of the projects

(Niskanen, 1997; Ürgenç, 1998; Turna et al., 2007; Tunçtaner, 2007; Yılmaz and Tonguç, 2010). Hence, the destruction of ecological balance brings the environmental problems that threaten the community life such as drought, erosion and flood, and such catastrophes led many people to say that forest sources are of significant functions in protecting community health care (Koçer et al., 2009; Oğuz et al., 2009). Other biological and mechanical measures should be taken into consideration alternatively in case of the lack of convenient conditions for plantations (Anonymous, 1999).

Afforestation area has grown rapidly over the last few decades in the semi-arid grasslands in the world in an effort to restore mountain vegetation. The reasons for this land-use change included an increasing demand for timber production (Chen et al., 2016). Hence, analyses of the rationale of forest plantations in many developing countries have often been focused on efficient wood production and financial return on invested capital (Niskanen, 1997). Afforestation is a key technique for the control of desertification and environmental deterioration in arid and semiarid regions. Therefore, it is important to quantify the influence of the succession that results from afforestation on biodiversity conservation and ecological environment (Liu et al., 2015). The most common afforestation efforts in the arid and semi-arid regions of Asia include planting plantations of *Pinus eldarica, Cupressus arizonica, Robinia pseudoacacia*, and *Fraxinus rotundifolia* (Harrington et al., 1989; Michelozzi et al., 2008; Motahari et al., 2013; Sadeghi et al., 2016). These species are frequently preferred because they are drought resistant and grow fast. For this aim, *Pinus halepensis, Pinus brutia* and *Eucalyptus camaldulensis* are also used with success in some countries.

Although the slumping hills or the ones prone to slump in erosion areas were temporarily stabilized through technical facilities with alluvial cones, avalanche corridors, sand and gravel deposits, the most effective and permanent measures are taken through plantations in the basin (Ürgenç, 1998). In order for a successful plantation in the areas with shallow and poor soil, little and irregular rainfall, high evaporation, insufficient organic materials and stony surface, it is important to provide funds for plantation activities without industrial concerns as well as recruiting knowledgeable and experienced technical staff. In arid and semi-arid planting lands, it is essential for a successful plantation to use local species and local races among these species which are compatible with the existent ecological conditions. Also, deep-rooted tree species should be used in these areas (Turna et al., 2006). Besides, it will also achieve success in terms of combating erosion by using advanced nursery techniques and certain methods reducing crop water stress (mulching, soil improver materials, seedling shelter etc.).

In Turkey, combating desertification and erosion began in 1955 and the activities continued in a more planned way after the foundation of General Directorate of Afforestation and Erosion Control. According to the data of the General Directorate of Forestry, 2.2 million ha of Turkey's forest area, which is 22.3 million ha, are subject to afforestation from ecological, technical and social aspects. The areas to be afforested in Turkey will reach to a total of 4.8 million ha when a million hectare public lands to be afforested and the areas, which are in 0.11-0.40 canopy and afforested with difficulty in terms of technical aspect since it has lost its natural regeneration conditions. And, this has added to 2.2 million ha (Ürgenç et al., 1993; Anonymous, 2001).

There is a report that 40% of Turkey's total area is suffering from drought and desertification is indispensable unless satisfactory measures are taken (Ürgenç, 1998). Furthermore, the most important issues as a result of global warming causing serious

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17571772

changes in climate systems are drought, desertification and erosion (Koçer et al., 2009). In this respect, it was stated that drought and desertification directly threatened more than 4 billion ha of area and a population of 1.2 billion people in 110 countries in "the United Nations Convention to Combat Desertification" which was accepted by the Intergovernmental Negotiating Committee in the United Nations Conference on Environment and Development on 17 June 1994 and was adopted by Turkey since 16 May 1998 (Anonymous, 2013). That is, desertification will result in erosion and, therefore, lead to yield loss, hunger and poverty in arable lands, pastures and woodlands (Turna et al., 2007). Only successful regeneration and plantation activities will make it possible to prevent this situation (Saatçioğlu, 1976; Atay, 1987; Ata, 1995).

Arid and semi-arid regions are fragile ecosystems. Sustainable management of arid and semi-arid areas requires good planning and careful implementation, as they have ecological, biological, technical and socio-economic constraints. Decisions related to the species and provenance selection, site preparation, spacing and other techniques and details should be made by paying attention to the specific conditions of these areas (Boydak and Çalışkan, 2015). In semi-arid area afforestation, it is the front plan to offer various benefits such as biodiversity service, protection of natural balance, prevention of erosion, etc., which often do not have a price in the market, rather than wood production. By estimating indirectly the economic values of such benefits and services, it is possible to add them in plantation incomes. In this case, it is obvious that the benefits will be very high. Although wood production is not for the purpose of production, there is also time to time wood production in these fields. Therefore, it is necessary to make economic evaluations in terms of wood production and compare with the natural stands in the same conditions.

This study was carried out in the plantation fields in the semi-arid and arid Şanlıurfa-Harran Plain in Turkey. These plantations established in the region between 1996 and 1999 years are arid/semi-arid plantations in the scope of combating erosion. Despite some studies related to technical and economical evaluations of plantations in general (Türker, 1986; Niskanen, 1997; Ahtikoski and Pulkkinen, 2003; Daşdemir and Şahin, 2006; Turna et al., 2007; Tuçtaner et al., 2012; Suganuma et al., 2014; Kulik et al., 2015; Wu et al., 2015), there are not many regarding particularly the economic evaluation of plantation activities in semi-arid areas. In this study, technical and economical evaluations were carried out in the plantation area in the Şanlıurfa-Harran Plain by making measurements in the field in 2015 after 16-18 years of field installation. So, this research was conducted in order to investigate the success rate of plantations with Calabrian pine in semi-arid areas, determine the diameter and height growth as a result of half of the rotation age, and make economic evaluations based on wood production.

Materials and methods

Study area

The study was carried out in the Calabrian pine (*Pinus brutia* Ten.) plantation area established as Tofaş Memorial Forest in the period 1996-1999 in the Eyyübiye district of Şanlıurfa (Harran Plain) of Turkey (*Fig. 1*). Calabrian pine is also known as Turkish pine, East Mediterranean pine and brutia pine. According to data of the Şanlıurfa Meteorological Station (TSMS, 2015), the average annual temperature in the region was 18.4°C. While the maximum temperature was 46.8 °C in July and the minimum was -

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17571772

11.4 °C in February. The mean annual precipitation amount was 382 mm and the precipitation was 223 mm in the vegetation period. Since the places which receive a rainfall of 300 mm and below are considered to be arid and those which receive a rainfall between 300-600 mm are semi-arid, Şanlıurfa is understood to be semi-arid. The general acreage of the plantation area is 77.33 ha and 64.40 ha of the total area were planted. Through this plantation was aimed to prevent moderate and heavy sheet erosion and gully erosion (Anonymous, 1997). The average height of the field is 423 m and soil structure is clay loam. In the plantations, 0 + 1 aged, potted and Hatay originated Turkish pine seedlings were used. The planting distance was 3 × 3 m. The tilth was made with tractor + ripper plough in the plantation area and planting was made with labor force.

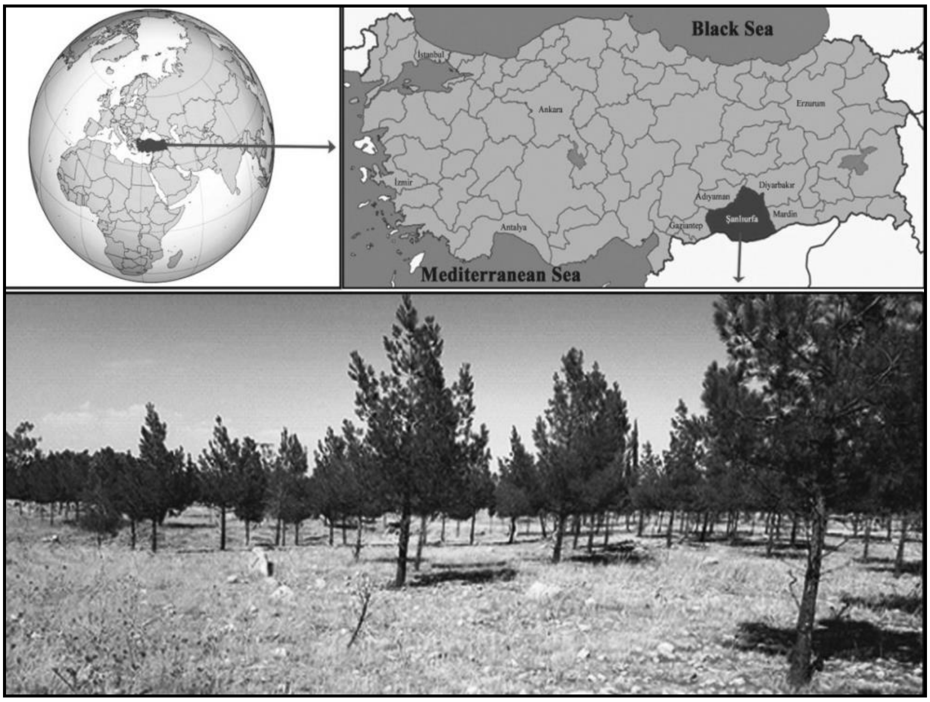

Figure 1. *The location and a general view of the study area (up left: URL-1 2016, up right: URL-2 2016)*

Data and evaluation

The materials for the study are as follows: the data obtained from the diameter, height measurements and the number of trees and their ages in the sample plots from different aspects in the plantation areas in 2015 was used for technical evaluations, the data from the Şanlıurfa Forest Enterprise Directorate (plantation expenses, wood production costs, sale prices of wood, etc.). The yield table for Turkish pine plantation areas (Usta, 1991), the yield table for Turkish pine natural stands (Erkan, 1996) and barked volume ratios in the product range table of Turkish pine (Sun et al., 1977) was used for economical evaluations.

A total of 12 sample plots at 4 different aspects and heights, each measuring 20 × 20 m square sized with 3 repetitions, were taken in 2015 (*Table 1*). The number of trees, the heights and their 1.30 m diameters, and ages of five predominant (the tallest) trees were determined in each sample plot.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17571772

Table 1. *The features of sample plots*

Research area	Species	Sample plots			
		Aspect	Altitude (m)	Size (m^2)	Number (piece)
Harran Plain-Tofaş Land	Calabrian pine	North	400	400	3
		South	425	400	3
		East	431	400	3
		West	457	400	3

The planting distance at the beginning (3 × 3 m) was taken as a reference in order to find out the success rate in the plantation areas after 16-18 years. Thus, the success rate was measured by converting the current number of trees in the sample plots into hectare and proportioning them to the required seedling number (1,111 pcs/ha) in the plantations with the distance at the beginning. Moreover, the mean diameter and height was determined at the sample plot level by calculating the arithmetic mean of diameters and heights. The mean success rate, diameter and height values were obtained from the sample plots according to different aspects. In this study one way variance analysis (ANOVA) were administered and the differences between the mean rates were determined by Duncan Range Test. For this purpose, SPSS 22.0 package program was used.

The economic evaluations of the plantation areas were made in relation to income and expense accounts of wood production (ŞFED, 2015). Firstly, the site index of the plantation area was determined. For this, the heights and ages of five predominant trees were measured. By taking the top height and age means of five predominant trees as a reference, the top mean height and age of sample plots at each aspect were measured. The site class of the sample plots, rotation age (u), and the highest mean increment in that site class were determined based on the top mean height, age and 3 × 3 m potential growth area by using the yield table for Turkish pine plantation areas (Usta, 1991). The intermediate yields (D_1, D_2, …) during the rotation age benefiting from the yield table and final yield amounts (A_u) were determined. As the plantation areas were bare at the beginning, the yield from the area was taken as null before the application. Likewise, the site index and yield table made by Erkan (1996) for Turkish pine natural stands, the rotation age for the related site index, intermediate and final wood production volumes were determined. The intermediate and final yield sizes were classified into product ranges using barked volume ratios in the product range table for Turkish pine by Sun et al. (1977).

The production costs (stumpage price + loading + transportation + stacking-sorting + storage) and auction sale prices according to product range were taken from the Production Cost Sheet and General Sale Sheet in the 2015 balance sheet of the Şanlıurfa Forest Enterprise Directorate (ŞFED, 2015). The net selling prices were calculated by extracting production costs from selling prices of the products. The net incomes were found by multiplying the net selling prices by the intermediate and final yields in terms of product ranges for both plantation areas and natural stands. Also, Calabrian pine plantation costs (establishment, maintenance, sapling cost and other expenses) were taken from the records of the Directorate for the machine + labor force production technology with 2015 prices (US$/ha) and were added into the economic analyses.

DOI: http://dx.doi.org/10.15666/aeer/1702_17571772

Taking into consideration of the determined incomes and expenses, economical analyses were made by the use of the following criteria as Net Present Value (NPV) (*Eq. 1*), Internal Rate of Return (IRR) (*Eq. 2*) and Benefit Cost Ratio (BCR) (*Eq. 3*) (Geray, 1986; Türker, 1986; Erkan, 2002; Daşdemir and Şahin, 2006; Tunçtaner et al., 2012; Daşdemir, 2012, 2015; Bijarpas et al., 2015):

$$NPV = \sum_{t=0}^{n} \frac{B_t}{(1+i)^t} - \sum_{t=0}^{n} \frac{C_t}{(1+i)^t} \quad \text{(Eq.1)}$$

$$IRR\ (i_r) \rightarrow NPV = 0 = \sum_{t=0}^{n} \frac{B_t - C_t}{(1+i_r)^t} \quad \text{(Eq.2)}$$

$$BCR = \frac{\sum_{t=0}^{n} \frac{B_t}{(1+i)^t}}{\sum_{t=0}^{n} \frac{C_t}{(1+i)^t}} \quad \text{(Eq.3)}$$

In the formulas, B_t shows revenues in the t year, C_t shows costs in the t year, n is rotation age, i is interest rate and i_r is internal rate of return (IRR). In the research, P = 3% forestry little interest rate was used in NPV and BCR calculations. IRR is calculated by iteration method using different interest rates in the Excel software. The current prices of 2017 have been used in the calculations.

In this study, the economic analyses were made only in terms of wood production without considering the advantages such as biodiversity service of semi-arid regional plantations, the protection of natural balance, prevention of erosion, etc., and they were compared with the economic returns of natural brutia pine stands under the same conditions.

Results

Results related to the technical analysis of plantations

According to the results of the variance analysis, the survival percentage, height and breast height diameter ($d_{1.30}$) of the young saplings were found to vary according to the aspects (*Table 2*).

When examined the results of the variance analysis related to the variables such as diameter, height and survival percent in *Table 2,* it was found that there is a significant difference among the aspects of three variables at a confidence level of $P < 0.01$. Therefore, a Duncan test was conducted in order to determine homogenous groups in terms of the examined variables (diameter, height, survival percentage). The Duncan test results related to the variables of diameter, height and survival percent, which are important in terms of growth and adaptation in the evaluation of plantation activities, were shown in *Table 3*.

From the mean values examined in *Table 3,* it is understood that breast height diameter growth ranges from 13.49 to 15.20 cm. According to the Duncan test, three different groups were emerged in terms of breast diameter growth at a confidence level of $P < 0.01$. When taking into consideration age difference in the Calabrian pine

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17571772

plantations at different aspects, it was ascertained that on the northern aspects growth was better than other aspects in terms of mean diameter growth, and it decreased especially among those towards the south aspects despite the age difference. The height was found to range 3.66-6.25 m according to the aspects. In the result of the Duncan test at a confidence level of $P < 0.01$, three different homogenous groups were determined among the aspects in terms of the variable of height (*Table 3*). One of the significant variables in determining the adaptability of plantations is the mean survival percentage. It was found out that the mean survival percentage ranges from 18.60 to 57.13%. According to Duncan test results; the survival percentage at a confidence level of $P < 0.01$ forms three different homogenous groups in terms of the aspects (*Table 3*). These results show that the high percentage of survival is seen in the north aspect while the lowest one is in the south aspect. Despite the age difference, the mean survival percentage is seen to be higher in north and eastern (shady) aspects rather than southern and western (sunny) aspects.

Results related to the economic analysis of plantations

Site index, rotation age, thinning age and intensity, volume results

Based on the top age and height values from the sample plots, the top height and age averages were measured at the aspects. From the yield table produced for Turkish pine plantation areas by Usta (1991), it was found out that all the sample plots were in the third (bad) site class based on the top height, age and 3 × 3 m (9 m^2; 1,111 trees in per

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17571772

hectare) potential growth area (*Table 4*). According to this table, the top height in partially shady (northern, eastern and western) aspects is higher than that in the south. This shows that water-humidity is the minimum factor limiting the growth in semi-arid areas.

Table 4. *The top height, age and site index at the aspects of Calabrian pine plantation area*

Sample plot		**Top height (m)**	**Age (year)**	**Site index (Third class = III = bad site)**
Aspect	**Number (piece)**			
North	3	6.26	18	III
South	3	3.80	16	III
East	3	6.53	18	III
West	3	6.06	17	III
Mean		5.66	17	III

By using the yield table prepared by Usta (1991), the 33rd age with the highest average volume increment was identified as rotation age for the 3 × 3 m (9 m^2) potential growth area in the third site index. Likewise, the only thinning age was taken as the 25^{th} age determined by Usta (1991), and it was assumed that the thinning treatments was applied at 35% intensity. Also, 35% (21.35 $m^{3)}$ of 61 m^3 volume given by Usta (1991) for the 25^{th} age was taken as the intermediate yield (D_{25}). Assuming that a thinning treatment of 35% intensity applied at the 25^{th} age increased the gap-distance by 35%, the volume of the final yield (A_{33}) at the 35^{th} age was taken as 95.5 m^3 corresponding to 12 m^2 potential growth area.

For natural Turkish pine stands the yield table and site index prepared by Erkan (1996) were used. The site class which is close to the top height (5.66 m) and age (17 years old) values in the sample areas in the triple site classification table of Erkan (1996) belong to third class. The yield table of 13.3 site index which is close to 12.5 as the average of this class was used. The rotation age in this table was 45 years, and it was supposed that first thinning was at the age of 25 (D_{25} = 15.68 m^3), second thinning was at the age of 35 (D_{35} = 20.67 m^3) and the final yield was at the age of 45 (A_{45} = 138.23 + 19.25 = 157.48 m^3).

Income and cost findings

The intermediate and final yield volumes determined for both natural Calabrian pine stands and plantation areas were distinguished into product ranges based on the medium diameter values that corresponded to these volumes in the related yield table and using the barked volume ratios in the product range table prepared by Sun et al. (1977). The net selling prices were calculated by extracting production costs from the auction sale prices in terms of production range of the Şanlıurfa Forest Enterprise Directorate (*Table 5*). The net incomes were calculated by multiplying the number of production range by net selling prices.

On the other hand, the cost of 1 ha plantation area (establishment, maintenance, sapling cost and other expenses) was determined as 2,467.17 US$/ha at 2015 prices based on unit prices of the General Directorate of Forestry for the option of machine + labor production technology.

Table 5. *Production costs and sale prices according to product types of Calabrian pine (as of 2015)*

Tree species	Product types	Production cost (US$)	Sale price (US$)	Net sale price (US$)
Calabrian pine	Log (m^3)	21.87	78.57	56.69
	Mine pole (m^3)	21.87	65.06	43.19
	Industrial wood (m^3)	15.31	61.89	46.58
	Fuel wood (m^3)	17.19	28.10	10.91

Findings of net present value, internal rate of return and benefit cost ratio

The rotation age, thinning ages and third site class were determined in the way described above for brutia pine plantations and natural stands. The economic analyses were made using NPV, IRR and BCR criteria based on net selling prices, plantation costs, and the intermediate and final yield volumes determined by the help of the related yield tables and product range table. The calculations were made based on the 2015 prices (*Table 6*).

In order to eliminate the effect of rotation age, the annual mean NPVs were calculated by dividing NPVs (US$/ha) calculated for plantation areas and natural stands to rotation age. According to this, the annual NPVs are calculated as - 29.52 US$/ha/year for the option of *plantation area + bad site + 33 year rotation age* and - 15.64 US$/ha/year for the option of *natural stand + bad site + 45 year rotation age*. Therefore, it was found that natural brutia pine stands in the same site index had a higher NPV than that of brutia pine plantations in semi-arid regions in terms of wood production according to NPVs calculated for both the whole rotation age and annually.

In the above calculations, NPV, IRR and BCR values were calculated according to the assumption that success of plantation areas was 100% (optimal). However, since the success was determined to be 33.01% in the plantation areas because of several reasons (*Table 3*), the incomes from the fields were multiplied by these success rates and thus actual economic results were achieved and the results were shared in *Table 7*. Because the yield tables for the natural stands reflected the real situation of the areas, the optimal and actual situations of them were the same.

According to *Tables 6* and *7,* NPVs of both natural stands and plantation areas with 3% interest rate in the third site index areas were found negative. However, the NPV of plantation areas is smaller. Considering the actual success of plantation areas, the NPV is even smaller. Similarly, IRR and BCR values of plantation areas are smaller in natural stands. This most probably stems from the fact that the plantation area is in semi-arid regions and the success rate is low.

Discussion and conclusion

In this study, technical and economical evaluations were carried out by making measurements in the plantation area in the Şanlıurfa-Harran Plain of Turkey as a result of half of the rotation age in 2015 after 16-18 years from establishment of the area. In this research, it was determined that the top mean height value was 6.25 m for Calabrian pine in the plantation area of the Harran Plain, the top mean breast diameter value was 15.20 cm and the top mean survival percentage was 57.13% in northern and eastern

DOI: http://dx.doi.org/10.15666/aeer/1702_17571772

(shady) aspects (*Table 3*). According to the variance analysis, significant differences were estimated at a confidence level of $P < 0.01$ in spite of the age differences in the aspects (*Table 2*). The mean values of such variables were determined to decrease from the shady aspects towards sunny (southern and western) aspects by Duncan test (*Table 3*).

NPV: net present value, IRR: internal rate of return, BCR: benefit cost ratio

The mean height, mean diameter and mean survival percentage of the research area are generally at a low rate. But, when considered that the general ecological structure of the research area falls under the domain of a semi-arid climate zone, the stated diameter and height growth and survival percentage in this plantation area can be said to be at a

http://www.aloki.hu • ISSN 1589 1623 (Print) • ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17571772

satisfactory level and value in terms of prevention of erosion in the region and soil conservation. In a research study that was conducted in the black pine plantation areas of the Konya-Karapınar region which had similar ecological conditions to those of this research (Özel, 2010); its growth and survival percentage were found to be low. The function of black pine in order to protect especially agricultural areas against endemic wind erosion and the consequential soil erosion was of crucial importance. Similarly *Eucalyptus camaldulensis* was considered as the most suitable tree species for arid land afforestation of Western Australia, by comparing biomass growth and survival ratio of planted trees (Suganuma et al., 2014). Along with this, the variable of survival percentage is a significant one in order to determine adaptability of the species used in the plantation activities (Ürgenç, 1998; Tunçtaner, 2007). That this variable reaches up to 57.13% at the northern aspects in a poor plantation circumstances under semi-arid climate conditions like the study area will be useful in terms of the implementation and sustainability of protective forest functions such as erosion control, carbon sequestration and recreation. A study made in the semiarid desert steppe of China showed that afforestation greatly affected the community and habitat characteristics, and promoted the formation of the crust on the soil surface with the succession of vegetation (Liu et al., 2015). In this regard, it is important to establish new forest areas in different plantation conditions and to manage them functionally against catastrophic disasters such as erosion, flood and avalanche as a result of the destructions of Turkey's forest resources, irregular urbanization and industrialization.

Table 7. *Net present value, internal rate of return and benefit cost ratio values for Calabrian pine according to optimal and actual situation*

Stand type	Site index	Rotation period (year)	According to optimal situation			According to actual situation		
			NPV (US$/ha)	IRR (%)	BCR	NPV (US$/ha)	IRR (%)	BCR
Afforestation	Bad	33	- 974	1.46	0.61	- 1,974	1.25	0.20
Natural forest stand	Bad	45	- 704	2.19	0.71	- 704	2.19	0.71

NPV: net present value, IRR: internal rate of return, BCR: benefit cost ratio

In Turkey, a total of 57.17 million ha are exposed to moderate and severe erosion. The amount of soil loss due to erosion eliminates the primary sources for agricultural production, cultivated for nutrition in semi-arid and arid regions especially of the countries whose forests have been destroyed. While a total of 585.6 ton/km^2 topsoil is lost because of floods in Turkey, this rate is 31.3 ton/km^2 in Europe (Çepel, 1992; Dağdaş, 2007). The places which experience erosion are mostly arid and semi-arid areas in Turkey and the world (Fidan, 2006). In the plantation of such areas where there is poor and shallow soil and of erosion risk, some applications should be used such as the selection of appropriate species and origins, the use of potted seedlings which are of quality root-shoot balance and mycorrhizal vaccines as well as some cultural rehabilitation activities (Ürgenç, 1998; Boydak and Çalıkoğlu, 2006). Especially the use of quality seedlings has a special importance in terms of the plantation success. The quality seedling should be of a balanced root-shoot rate and sufficient capillary root density (Turna et al., 2007). What is more, by protecting the existent vegetation where there is a risk of drought, desertification and severe erosion, it will make the plantations successful to make use of natural species and local races which have adaptability. In this regard, the successful samples of erosion control, dune and arid area plantations that need special techniques can be found in Turkey (Boydak and Çalıkoğlu, 2006; Ayan et al., 2007).

Arid and semi-arid afforestations have many environmental and protector impacts. Afforestation decreases percent cover and aboveground biomass, and increase plant diversity of herbaceous community. Afforestation also decreases soil bulk density and pH, and increased soil water content (Chen et al., 2016). Moreover, afforestation increases soil organic carbon and nitrogen storage in semi-arid grass lands, which has important implications for C sequestration. In the arid and semi-arid regions, water supply is the main factor limiting sustainable development of planted forests (Wang et al., 2011; Chen et al., 2016).

On the other hand, a thorough plantation in semi-arid areas reduces seedling survival percentage significantly. It is thought to be an important factor on the low survival percentage of brutia pine seedlings in the study area. In this regard, it is necessary first to protect the area and provide soil stability by placing endemic and existent annual and perennial plant species in order to reduce earth movement. Since greening which is also called as temporary and pre-stabilization activity enables to improve physical soil properties and increase organic ingredients in soil, it boosts significantly the achievement of the main plantation activity or the adaptation success of permanent stabilization activity. In this issue, similar outcomes are achieved in the research studies aimed at controlling erosion in the Eastern Anatolia Region and it is recommended that the natural vegetation should be protected and prohibited for pasturage before plantations (Daşdemir et al., 1996; Daşdemir, 2006). Besides, it is observed that the research areas are anthropogenic steppe areas where the black pine and oak forests are cleared in order to grow crops and consequently they are faced with a moderate and severe risk as a result of denudation. Hence, it is more convenient that the plantation is maintained with the drought-tolerant origins of a local species, black pine, in such plantation areas. Also, leaved species should be partly utilized where local climatic factors are suitable. Therefore, it will enable plantation activities to be carried out swiftly and genetic diversity to be protected.

Economic analyses were made by taking third class (IIIth =bad) site, 33 and 45 year rotation age and machine + labor force production technology into consideration in terms of only wood production for the natural Calabrian pine stands and the Calabrian pine plantations in the Şanlıurfa-Harran Plain (*Table 6*). The NPV, IRR and BCR values of each option were calculated according to optimal and actual situation. According to the both situations, the NPV, IRR and BCR values of natural stands are greater than those of plantation areas (*Table 7*). According to this, NPV = - 974 US$/ha, IRR = 1.46% and BCR = 0.61 for the option of *plantation area + bad site + 33 years rotation age*; NPV = - 704 US$/ha, IRR = 2.19% and BCR = 0.71 for the option of *natural stand + bad site + 45 years rotation age*.

In this issue, in a research study carried out on the Turkish pine plantations of the Bartın region (Daşdemir and Şahin, 2005), the lowest NPV and IRR values were found to be as follows: NPV = 217.45 US$/ha and IRR = 4.28% for the option of *bad site + 33 years rotation age + labor force*. On the other hand, in another study carried out in the Antalya region by Erkan et al. (2002), the lowest NPV = - 23.845 US$/ha and IRR = 4.48% in 40 years rotation age for brutia pine without the exception of production techniques. Economical profitability with 10% discount rate was found as a value

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17571772

chancing between 311 and 3,863 US$/ha according to different afforestation options in afforestation with fast-growing eucalyptus species in Northeast Thailand (Niskanen, 1997). Hence, NPV and IRR values of the Calabrian pine plantations in the Şanlıurfa-Harran Plain are lower than those of both natural and planted Calabrian pine stands in other regions in the same site index. It mainly stems from that the plantation areas are in semi-arid regions, the growth-increment is limited, the success rate is low and plantation expenses are high.

Even if Calabrian pine plantations in semi-arid areas are of low income in terms of wood production, they play an important role because they bear significant benefits and services such as the services of biological diversity, the production of natural balance, prevention of erosion, carbon sequestration, recreation, employment in addition to wood production. Among the studied environmental impacts of afforestation, carbon sequestration and transpiration are most important in economic terms (Niskanen, 1997). As a result of taking into consideration these benefits and services, which are priceless but is estimated indirectly, it will be seen that semi-arid area plantations are of high benefit. In this regard, in a study of erosion control by Daşdemir et al. (1996) in the Erzincan region, the price of such benefits and services was estimated as 4.50 US$/ha with 1994 prices and BCR = 1.37. Similarly, in a research study in the Bartın region (Daşdemir and Seğmen, 2009), such benefits and services were estimated to be 33.58 US$/ha at 2004 prices. Provided that these benefits and services are taken into consideration, it is obvious that the plantations in semi-arid areas will be of high income. Therefore, the potential semi-arid plantations should be accelerated as well as industrial plantations for wood production in good site areas. In addition, economic efficiency and cost minimization principles should be obeyed as much as required in semi-arid plantations and the highest success should be targeted with a minimum cost.

(Received 29th Oct 2018; accepted 5th Dec 2018)

Abstract. In recent years, tanning industries have been proved to be among the major contributors of heavy metals. Different convectional and biological method has been used to remove these heavy metals from tannery wastewater but most of these technologies are costly and not easily accessible. This research is aimed at determining the efficiency of combining the waste rind of *Citrulus lanatus* and waste peel of *Citrus sinensis* as a low cost biosorbent for the removal of Cr^{3+} and Pb^{2+} pollutants present in tannery wastewater. The selected biosorbents where surface characterized and point of zero (pH_{PZC}) was determine with pH adjusted using NaOH solution to be between 2-12. The adsorption process of Cr^{3+} and Pb^{2+} by the selected biosorbent was determined under factors such as contact time, pollutants dosage, absorbent dosage, and particle size. The Lagmuir equation and Freundlich isothermal were used to determined adsorption equilibrium while pseudo first order and pseudo second order were used to determine the adsorption kinetics. The result obtained shows that *Citrulus lanatus* has better adsorption of Pb^{3+} (86%) while the combined fruit better adsorption of Cr^{3+} (85%) under the all factors. The Lagmuir equation and Freundlich shows suitability of indicating equilibrium sorption for Cr^{3+} and Pb^{2+}. The adsorption kinetic study shows that pseudo-second order obeys kinetics model signifying that absorption occurs by chemisorptions. The combination of the waste rind of *Citrulus lanatus* and waste peel of *Citrus sinensis* is an effective low cost biosorbent for the removal of Cr^{+3} and Pb^{+2} pollutants present in tannery wastewater.
Keywords: *adsorption isotherm, heavy metal pollution, adsorption kinetics, Citrus sinensis, Citrulus lanatus*

Introduction

Heavy metal pollution resulting from anthropogenic activities is a serious problem to man and his environment due to the persistence nature and ability of heavy metals to accumulate in the food chain (Dudgeon et al., 2006; Lintern et al., 2016; Liu et al., 2018). In developing countries, industries channel wastewater into nearby water bodies either untreated or not properly treated due to their proximity to these water bodies (Desrosiers et al., 2019).The wastewater produce by most of these industries are rich in heavy metals which pose serious toxicity at low level exposure (Hughes et al., 2015). In recent years, tanning industries have been proved to be among the major contributors of heavy metals (Cr, Pb, Zn, Cu, Cd, As and Se) in to water bodies (Aravindhan et al., 2004; Di Iaconi et al., 2003; Panizza and Cerisola, 2004). These heavy metals release into water bodies have been shown by many researchers to be associated with chronic and acute effects to man and detrimental to other organisms such as algae, plants, other animals, microorganisms etc (Costa-Boeddeker et al., 2018; Wang et al., 2018; Xun et al., 2018). It is thereby paramount to treat wastewater before discharge (Tong and Elimelech, 2016; Zhang and Anadon, 2013).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17731787

A lot of technology is available for the treatment of wastewater before discharging into water bodies, many of which have contributed in minimizing pollution resulting from chemical industries but biosorption is gaining acceptance owing to the fact that most researchers have reveal the potentiality of some bio sorbents to effectively remediate wastewater with high heavy metal pollutants removal if match up to other biological and conventional technologies (Nahar et al., 2018). Biosorption is a remediation technology that depends on the mechanism of heavy metal accumulation by agricultural or biological adsorbents from an aqueous solution as a result of binding site present on this bio sorbents (He and Chen, 2014; Ileri et al., 2014).

Several research have been conducted showing the efficiency of different biosorbent removing Cr^{3+} from wastewater among which include egg-shell, sawdust, rice husk and lemon peel (Nahar et al., 2018), phosphate treated sawdust (Ajmal et al., 1996), cotton hull and soybean (Marshall and Champagne, 1995), sawdust carbon (Selvi et al., 2001), egg-shell (Park et al., 2007; Mashangwa et al., 2017), Litchi peel (Manikandan et al., 2016), modified groundnut hull (Owalude and Tella, 2016), Powdered potatoes peel (Mutongo et al., 2014), *Citrus limetta* (Saha et al., 2013) etc.

Nevertheless, Pb^{2+} has also attracted researchers for use in the biosorption of wastewater. This curiosity have led to the success of the used of different agricultural waste as low-cost biosorbents, among which include banana peel (Anwar et al., 2010), different cortex fruits (Al-Qahtani, 2016), Agare bagasses (Velazquez-Jimenez et al., 2013), Garden grass (Hossain et al., 2012), modified orange peel (Guo et al., 2011), modified lentic husk (Basu et al., 2015), olive stone raw (Fiol et al., 2006), ponkan peel (Pavan et al., 2008) etc.

A lot of success has been recorded for the biosorption of different pollutants by *Citrus sinensis* (Feng et al., 2011; Guiza, 2017; Pérez-Marín et al., 2008) and *Citrulus lanatus* (Reddy et al., 2014; Liu et al., 2012; Jawad et al., 2018), however more research is needed to investigate how those agricultural wastes can be improved for effective pollutants removal from waste water. The current research is aimed at determining the efficiency of combining the waste rind of *Citrulus lanatus* and waste peel of *Citrus sinensis* as a low cost biosorbent for removal of Cr^{3+} and Pb^{2+} pollutants present in tannery wastewater.

Material and Method

Sample Collection and Preparation

The waste peel of C*itrus sinensis* peel and *Citrulus lanatus* rind were collected from road side fruit sellers at kasuwan mata, Kaduna South Local Government, Kaduna State, Nigeria. Both bio-wastes were cut into small pieces, washed several times with borehole water then distilled water. *Citrus sinensis* peel was dried at 40°C in the oven as described by Kelly-Vargas et al. (2012). *Citrulus lanatus* rind was first dried in sunlight for 48 hours then oven dried at 80°C. The fruit wastes were grounded using a mechanical blender (Greenis, FGR-8840) and then sieved through standard sieve to obtain various size of C*itrus sinensis* peel and *Citrulus lanatus* rind. The fruit waste powders were stored separately in an airtight container before use. To obtain a combined fruit waste of the two peels, an equal amount of dried, grounded peels were weighed and mixed together. Tannery effluent samples were collected from the main discharge point/network pipeline of Unique Leather Industry located at Sharada industrial area, Kano. Standard sample bottles were used in collecting the wastewater

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17731787

sample. Using distilled water, the bottles were washed thoroughly. The samples were placed in an storage box containing ice packs in order to preserve and maintain their composition thus preventing degradation by microbes. In this regard, each sample bottle is added with 5 ml 2.0 M nitric acid per litre (Lugo-Lugo et al., 2012). Digestion of samples was carried out according to the Standard method by Ahuja (2012). Samples were filtered using Whatman filter paper of pore size 0.45µm and analysed using AAS for heavy metal content as described by Lugo-Lugo et al. (2012). pH was measured using Toledo pH meter of model FE20/EL 20.

Characterization of Biosorbents

Citrus sinensis peel, *Citrulus lanatus* rind and Combine fruit waste were pre-treated using H_2O_2 according to Shen et al. (2011). Surface characterization was done using the method of Boehm (1966) in which 0.4g of *Citrus sinensis* peel, *Citrulus lanatus* rind and Combine fruit waste was were neutralize separately using 50ml of Cr^{+3} and Pb^{+2} solution by using acid based titration techniques for 5 days. Point of zero (pH_{PZC}) of *Citrus sinensis* peel, *Citrulus lanatus* rind and Combine fruit wastewater determined by adjusting the pH value using 50ml 0.01 NaCl solution to between 2-12. The samples were agitated and stored for 24 hours at 12rpm at room temperature. The P_{PZC} was then calculated graphically according to Banerjee et al. (2017). Scanning electron microscope (JEOL JSM-6100) was used to observe how the surface of *Citrus sinensis* peel, *Citrulus lanatus* rind and Combine fruit waste is affected by the adsorption process.

Effect of Particle Size and Contact Time on Cr and Pb Adsorption

The effect of contact time and particle size was studied together by placing 5g of *Citrus sinensis* peel, *Citrulus lanatus* rind and Combine fruit waste of two particle sizes (40mm (coarse) and 60 mm (fine)) in separate conical flasks containing 100 ml effluent sample and agitated at 150 rpm in a shaker. Each set of flasks were agitated for 20, 40, 60, 80, 100, and 120 minutes, respectively. The samples were filtered using Whatman No 41 filter paper after each interval. Residual heavy metal concentration of the sample was measured, using AAS.

Biosorption was calculated using the mass balance formula below:

$$q = \frac{v(C_l - C_e)}{m} \quad \text{(Eq.1)}$$

where, q (mg/g) is the adsorption capacity, C_l and C_e are the initial and final concentrations (mg/l) of sample, V(l) is the volume of effluent sample and m is the weight (mass) of adsorbent (g).

Percentage removal: it was calculated using the formula:

$$q\%\ uptake = \frac{(C_o - C_e)}{Co} \times 100 \quad \text{(Eq.2)}$$

where C_0 and C_e are the initial and final concentrations (mg/l) of metals in sample before and after shaking.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17731787

Effect of Cr^{3+} and Pb^{2+} dosage on Adsorption Process

To the 250 m/l of solution containing 15 mg/l, 20 mg/l, 25 mg/l, 30 mg/l and 35 mg/l Cr and 10 mg/l, 15 mg/l, 20 mg/l, 25 mg/l and 30 mg/l of Pb 5g of dried *Citrus sinensis* waste peel, *Citrulus lanatus* waste rind and combined fruit waste was added separately and shaked at room temperature at 150 rpm for 12 hours. Cr and Pb percentage reduction was thus calculated using the method employed by Kumar et al. (2018).

Percentage removal: it was calculated using the *Equation 2*.

Effect of pH on Cr and Pb adsorption Process

The absorption ability of the solvent was compared at a pH of 2, 4, 6, 7, 8 by placing 1g of *Citrus sinensis* waste peel, *Citrulus lanatus* waste rind and combined fruit waste in 100 ml each of the solution of Cr and Pb at 15 mg/l and 10 mg/l, respectively. The samples were filtered using Whatman No 41 filter paper after each interval. Residual heavy metal concentration of the sample was measured, using AAS. The pH of the solution was adjusted using diluted sodium hydroxide and Nitric acid as adopted from Salim et al. (2016).

Effect of Particle Size and Dosage

The effect of absorbent dosage was study by dissolving a fixed mass of 15mg/l of Cr^{3+} and a fixed mass of Pb^{2+} 10 mg/l in 100 ml of solution. 1 g, 2 g, 3 g, 4 g and 5 g each of *Citrus sinensis* peel, *Citrulus lanatus* rind, and combined fruit waste where placed in each solution. The samples were filtered using Whatman No. 41 filter paper after each interval. Residual heavy metal concentration of the sample was measured by using AAS as described above.

Adsorption Equilibrium Study

Adsorption equilibruim study for Cr and Pb using *Citrus sinensis* peel, *Citrulus lanatus* rind and hybrid fruit waste powder was performed by suspending 1g, 2g, 3g, 4g and 5g of *Citrus sinensis* peel, *Citrulus lanatus* rind and combined fruit waste powder in 15mg/l, 20mg/l, 25mg/l, 30mg/l and 35mg/l Cr^{+2} and 10mg/l, 15mg/l, 20mg/l, 25mg/l and 30mg/l of Pb^{+2} and shaked at room temperature at 150 rpm for 12 hours. Langmuir and Freudlich isotherm models were thus tested according to the method adopted by Manikandan et al. (2016).

Langmuir equation is represented below:

$$\frac{1}{q_x} = \frac{1}{b_i q_f} T_e + \frac{1}{q_f} \qquad \text{(Eq.3)}$$

The equation was adopted from Kumar et al. (2018), where T_e = Equilibrium Cr^{3+} and Pb^{2+} concentration in solution (mg/l), q_f is maximum Cr^{3+} and Pb^{2+} absorbed per unit weight of *Citrus sinensis* peel, *Citrulus lanatus* rind and combined fruit waste powder (mg/g), b_i is affinity adsorbate – biosorbent (l/mg), = is the amount of Cr^{3+} and Pb^{2+} adsorbed by the adsorbent at equilibrium (mg/g) the value of q_f and b_i is determined from the slope and intercept of. Z is the separation factor and is calculated using the formula below:

$$Z = \frac{1}{1 + b_I T_a} \qquad \text{(Eq.4)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17731787

where T_g = initial concentration of Cr^{+3} and Pb^{+2} in the solution.

Freundlich Isotherm is represented below:

$$Log\, qx = Log\, Kf + \frac{1}{r \log T_e} \quad \text{(Eq.5)}$$

The equation was adopted from Wang et al. (2010), where K_f is Freudlich Constant *r* is Freudlich Coefficient, and K_f and *r* are determine by plotting a graph of q_x against T.

Adsorption Kinetics

Adsorption kinetics is fundamental in describing the characteristic of an absorbent. To ascertain the mechanism involve in the adsorption of Cr^{3+} and Pb^{2+} by *Citrus sinensis* peel, *Citrulus lanatus* rind and combined fruit. Pseudo first order and pseudo second order reaction was used according to the procedure of Ho and McKay (1998).

The pseudo first order is represented below:

$$Log\ (q_i - q_t) = log\ (q_i) - \frac{K_i T}{2{,}303} \quad \text{(Eq.6)}$$

The equation was adopted from Poonam et al. (2018), where q_i and q_t = Amount of Cr^{3+} and Pb^{2+} (mg/g^{-1}) absorbed at equilibrium and time *T*, respectively, *K* is the pseudo-first order rate constant (min^{-1}).

The pseudo second order is represented below:

$$\frac{T}{q_t} = \frac{1}{K_2 q_2} + \frac{T}{q_2} \quad \text{(Eq.7)}$$

$$\frac{1}{q_t} = \frac{1}{K_2 q_2 T} + \frac{1}{q_2} \quad \text{(Eq.8)}$$

The equation was adopted from Poonam et al. (2018), where q_i and q_t = Amount of Cr^{3+} and Pb^{2+} (mg/g^{-1}) absorbed at equilibrium and time *T*, respectively, K_2 is the pseudo second order rate constant ($g\ mg^{-1}\ min^{-1}$).

Desorption Study

Desorption of Cr^{3+} and Pb^{2+} was from *Citrus sinensis* peel, *Citrulus lanatus* rind and combined fruit waste powder was studied for 0.1 N HCl, 0.1 N HNO_3, 0.1 N H_2SO_4 and 0.1 N NaOH. The dried *Citrus sinensis* peel, *Citrulus lanatus* rind and combined fruit waste powder with absorbed Cr^{3+} and Pb^{2+} in the solvents and shake for 150 rpm at room temperature for 12 hours adopted from Rosales et al. (2016). In order to determine the mechanism involve in adsorption of Cr^{3+} and Pb^{2+} by *Citrus sinensis* peel, *Citrulus lanatus* rind and hybrid fruit waste.

Statistical Analysis

Experimental was conducted in triplicate and data were analyzed statistically using standard deviation to find significance difference at 5% level. The Residual Sum of Squares (RSS) was determined for both adsorption kinetic and isotherm models to check error in model fittings. All analysis was done using BM SPSS statistics version 23.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

Result and Discussion

Effect of Contact Time on Cr^{+3} and Pb^{+2} Adsorption

Figure 1 shows the uptake of the two metal ions, Cr^{3+} and Pb^{2+} the waste peels (C*itrus sinensis* waste peel, *Citrulus lanatus* waste rind and combine fruits waste) was effective and continued progressively at the various time intervals set for the experiment. However, at 80 min the uptake of both metals stopped.

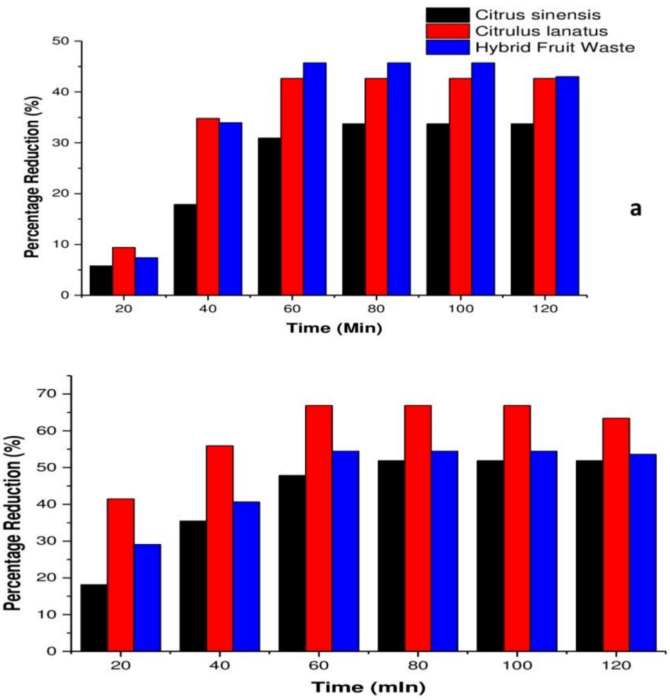

Figure 1. *Effect of Contact Time on Adsorption Cr^{+3} (a) and Pb^{+2} (b)*

The situation remained same from 100 min to 120 min. In other words, there was no net uptake of the metals after 80 min. The reason why the uptake of both Cr^{3+} and Pb^{2+} stopped from 80 min could be attributed to the fact that the particles of C*itrulus lanatus* waste rind, *Citrus sinensis* and the combined fruit waste peel posses selective potential for retaining of some heavy metals over a period of time (Ahad et al., 2017). With respect to contact time it is ascertain that Combined fruit waste was best in Cr^{3+} removal and *Citrulus lanatus* best in Pb^{2+} removal at all time interval used for the studies. This could be attributed to their surface areas. *Citrulus lanatus* waste rind and the combine waste fruit particles have a high surface area compare to *Citrus sinensis* waste peel thus providing more binding sites for metal ions. In contrast, *Citrus sinensis* has lesser surface area as such fewer sites for attachment by metal ions are available. Although, there was loss of metals at 120 min from the combine waste materials, it is likely that there was a synergistic effect by *Citrulus lanatus* and combine fruit waste (Gupta and Garg, 2015). The uptake of Cr^{3+} and Pb^{2+} also varied with size of the absorbent as higher uptake was noticed by fine absorbent (40mm) compare to coarse absorbent (60mm). The result obtained attribute high Pb^{2+} adsorption to fine particle of *Citrulus*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17731787

lanatus if compare to coarse particle of *Citrulus lanatus*. The adsorption of Cr^{3+} by fine particles of combine fruit waste peel also follow the same trend as *Citrulus lanatus* if compare to coarse particle of combine fruit waste peel. The reason for the differences of pattern of adsorption of Pb^{2+} and Cr^{2+} by the absorbents based on size could be attributed to the fact that as the particle size increase so do the binding site increase resulting in the enhancement of metal absorption by the biosorbents (Al-Ghouti et al., 2003). Although, Senthil Kumar et al. (2012) shows that decrease of absorbent to a diameter of 240µm can cause reduction in adsorption ability of the adsorptive sites due to agglomeration of the particles that is not the case here because the lowest size used was 40mm.

Characterization of Biosorbents

Active site and surface area increase was recorded for *Citrus sinensis, Citrulus lanatus* and combined waste fruit waste peel although no significant differences (P = 0.05) exist between the increase of active sites and surface area of *Citrulus lanatus* rind compare to combine fruit waste but significant difference exist (0.05) between the increase of binding site and surface aarea of *Citrulus lanatus* rind and combined fruit waste compare to *Citrus sinesis* with both *Citrulus lanatus* and Combine fruit waste having more binding site and larger surface area. The pH (pH_{ZPC}) *Citrus sinensis, Citrulus lanatus* and combined waste fruit waste peel were 3, 4 and 7, respectively for Cr^{3+} but 2, 5, 4 for Pb^{3+}. The increase in active site and surface area is attributed to the collapsing of the adsorbent wall resulting to the modification of the adsorbent structure into porous structure. Result of scanning electron microscopic shows smooth surfaces for all the absorbent before adsorption study but rough surfaces after adsorption. The rough surface after adsorption signifies enhancement in adsorption capacity of the adsorbents and also the reason for the increase surface area.

Effect of Adsorbent Dosage on Cr^{+3} and Pb^{+2} Adsorption

Variation in dosage of *Citrus sinensis, Citrulus lanatus* and combined waste fruit waste peel affected the percentage uptake of Cr and Pb. Increase in dose of the test material from 1 – 5 g, was signified by an increase in percentage uptake of both metal ions (*Figure 2*). This could have resulted from the availability of more binding sites with each addition of waste materials. The difference in percentage uptake of Cr^{3+} by *Citrus sinensis* waste peel, *Citrulus lanatus* waste rind and combine waste rind was significant ($P < 0.05$) with combine waste fruit waste performing better than *Citrus sinensis* and *Citrulus lanatus.* The difference was also significant between *Citrus sinensis* waste peel, Citrulus lanatus and combines fruit waste for Pb^{2+} uptakes with *Citrulus lanatus* performing better than combined fruit and *Citus sinensis*. The reason could be similar to the same reason why both test material display the pattern of metal uptake under different duration.

Effect of pH on Adsorption Process

The adsorption process for Cu^{3+} and Pb^{2+} follow the decreasing pattern from pH of 2-12 with combine fruit waste material having higher adsorption for Cr^{2+} at the pH of 2 and *Citrulus lanatus* having higher adsorption for Pb^{2+} at pH of 2, pH was determined for these studies owing to the fact that Wang and Chen (2009) reported that the reason why biosorption occur is due to exchange of ion of which pH is the determinant factor

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17731787

for which proton compete with cation for binding sites (*Figure 3*). The higher adsorption recorded at the pH of 2 by all the materials used could be attributed to the fact that at lower pH (acidic medium), the removal of H^+ lead to availability of free binding sites for Cr^{3+} and Pb^{2+} (Poonam et al., 2018). Elhafez et al. (2017) had earlier reported that the removal of heavy metal by biosorption increases with increasing pH and decreases after pH of 4. This increasing pH tend to facilitate the precipitation of heavy metals thereby contributing to it removal.

Effect of Cr^{3+} and Pb^{2+} Dosages on Adsorption Efficiency

The test for the effect of Cr^{3+} and Pb^{2+} on adsorption efficiency was carried out taking into consideration the concentration of both heavy metals in the wastewater for effective treatment. The result obtain shows decreasing trend of adsorption efficiency with increase in mass of Cr^{3+} and Pb^{2+} ion concentration (*Figure 4*). This trend could be attributed to the fact that the increases in the concentration of Cr^{3+} and Pb^{2+} lead to decrease in the availability of free binding site on the solvent until the binding sites are completely saturated (Poonam et al., 2018; Zhang et al., 2018; Zhao et al., 2018). The difference in adsorption capacity of Cr^{3+} by *Citrus sinensis* waste peel, *Citrulus lanatus* waste rind and combine waste rind was significant at the different Cr^{3+} and Pb^{2+} concentration ($P < 0.05$) with combine waste fruit waste performing better than Citrus sinensis and Citrulus lanatus in Cr^{3+} adsorption and Citrulus lanatus performing better in Pb^{2+} adsorption.

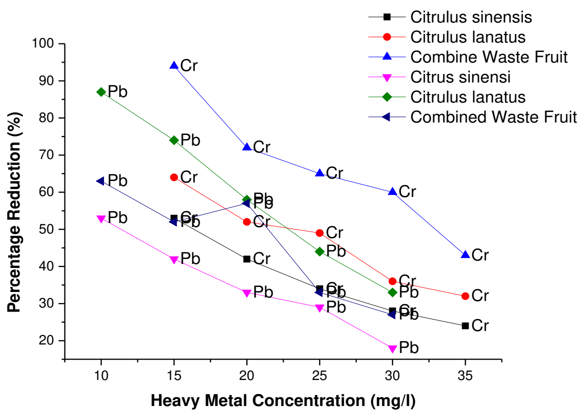

Figure 4. *Effect of Cr^{3+} and Pb^{2+} on Absorption efficiency*

Desorption Study

All the solution used for the desorption process recorded a high recovery of Cr^{3+} and Pb^{2+} from the biosorbent and are also non-polluting and non-damaging. This research is in agreement with the research available in literature (Zhang et al., 2018; Yang and Cui, 2013). This high efficiency recovery supports the fact that exchange ion depends on desorption. The recovered absorbents (*Citrus sinensis* waste peel, *Citrulus lanatus* waste rind and combine waste rind) still show high Cr^{3+} and Pb^{2+} removal even after triplicating the process indicating its high reuses capacity for commercial application (*Figure 5*).

Comparison of the Removal Efficiency of Combined Fruit Waste and Other Biosorbents

Comparative study of the removal efficiency of the combination of *Citrus sinensis* peel and *Citrulus lanatus* rind with and other Biosorbents shows high removal efficiency by the combination of *Citrus sinensis* peel and *Citrulus lanatus* rind (*Table 1*). The difference in uptake by the Biosorbents could be attributed to difference in surface area, binding sites and experimental conditions.

Adsorption Isotherms

Langmuirs and *Freundlich* isotherms for Cr^{3+} and Pb^{2+} is approximately 1 signify the suitability of *Langmuir* and *Freundlich* isotherms in indicating equilibrium sorption (*Table 2*). The separation factor (Z) for *Langmuir* isotherms was found to be between the ranges of 0-2 signifying that the adsorption of Cr^{3+} and Pb^{2+} by the surfaces of the peels were favourable (Mallampati et al., 2015).

Adsorption Kinetics

The correlation coefficient value (r) obtained follow pseudo-second order kinetics model and pseudo-first order kinetic model indicating that absorption occurs due to chemical and physical reaction between the surface of *Citrus sinensis* waste peel, *Citrulus lanatus* waste rind and combines wastes and Cr^{3+} and Pb^{2+} (Elhafez et al., 2017; Salmani et al., 2017; Xu et al., 2013). Since the adsorption of Cr^{3+} and Pb^{2+} by the waste fruit favour second order model, it signifies that the valence electron of the heavy metal binded with the negative charged surface site of the waste fruit in order to attain equilibrium (Elhafez et al., 2017) (*Table 3*).

Conclusion

Based on the findings of the current work, it could be concluded that *Citrus sinensis* peel and *Citrulus lanatus* rind as well as combination of the two fruit wastes can be used to reduce or control heavy metals from industrial effluent. Although, *Citrulus lanatus* is best for Pb^{2+} removal while combination of the two fruit wastes is best in Cr^{3+} removal. Further investigations involving the use of the agricultural wastes could lead to the discovery of more effective materials or compound materials for control of heavy metal pollutants in waste waters. Further research is needed on how to strengthen the uptake efficiency by such natural materials (the combination of *Citrus sinensis* peel and *Citrulus lanatus* rind) so as to enhance their effectiveness.

Abstract. The possible role of reducing effects of nano-Fe_3O_4 and hydrogen sulfide on alleviating heavy metal toxicity in germinating cucumber seedling was investigated. The toxic effects of Fe_3O_4 nanoparticles (NPs) (6, 50, 100 nm), and bulk were evaluated in cucumber plants. Among the synthesized nano-Fe_3O_4, only the small size (6 nm) had significant inhibit effect on fresh and dry biomass of cucumber seedlings. cucumber seedlings grown under lowest concentrations of 50 mg/L nano-Fe_3O_4 (6 nm) were affected by a decrease in biomass and enzyme activities compared to control. However, at higher concentration of nano-Fe_3O_4 dosage (2000 mg/L), there was significant increase in biomass and enzymatic activities of superoxide dismutase (SOD) and peroxidase (POD), respectively. The toxicity effects of the different sizes of nano-Fe_3O_4 particles and bulk-Fe_3O_4 might depend on the chemical composition, the structure properties/ particle sizes, the concentration in the tested medium, the time of incubation, as well as the plant species.
Keywords: *heavy metal toxicity, toxic mechanism, magneto dipole interaction, nano-Fe_3O_4, cucumber seedling*

Introduction

Due to the anticipated high-volume production and widespread use in coming years, engineered nano-materials will inevitably be released into the environment and interact with plants during manufacture, use, and disposal. Magnetic (Fe_3O_4) nanoparticles have been widely investigated for their scientific interests but also their technological application in many fields (ferrofluids, biomedicines, magnetic records, catalysts and electronic technique) due to their biological compatibility and magnetic properties (Shen et al., 2013). Iron oxide nanoparticles are among the primary nano-materials used in biomedical fields due to their magnetic property and high chemical stability (Xiao et al., 2011). Co-precipitation method and high-temperature decomposition are the two methods commonly used to prepare iron oxide nanoparticles. However, reactions of co-precipitation do not furnish excellent control of size distribution and crystallinity of the resulting particles; they are also thermodynamically driven (Laurent et al., 2008; Vinod et al., 2012; Jain et al., 2008). On the other hand, the use of FeOx NPs produced with high-temperature decomposition reactions of metal-organic compounds is limited because they are soluble only in organic solvents. The preparation of water-dispersible iron oxide nanoparticles with suitable surface coatings provides a major challenge in nanotechnology. In the present study, we synthesized water-soluble small iron oxide nanoparticles by the chemical reduction method using vitamin C as the reducing agent by oxidizing its C=C double bond. It has been reported that the magnetic property of magnetic (Fe_3O_4) nanoparticles could depend on their particle sizes (Roca et al., 2007). The polyol-mediated method is a versatile chemical system to prepare excellent-quality

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17891797

water-stable Fe_3O_4 nanoparticles (Shen et al., 2013). In this synthesis approach, polyols (ethylene glycol (EG), diethylene glycol (DEG), triethylene glycol or poly-ethylene glycol) are usually used as solvent and reductant and play a stabilizer role to control the growth of particles and prevent inter-particle aggregation (Liu et al., 2009; Miguel-Sancho et al., 2011). Magnetic (Fe_3O_4) nanoparticles synthesized with this method can exhibit some water dispersibility, compared to the thermal decomposition method. This might be dependent on the hydrophilic coating (Liu et al., 2009). In the present work, the polyol-mediated method was used as the second method to prepare magnetic (Fe_3O_4) nanoparticles: 50 nm and 100 nm, using ethylene glycol (EG) as the solvent and reductant. The TEM images, XRD, vibrating sample magnetometer (VSM), Fourier transform infrared (FTIR) spectroscopy and thereto gravimetric analyses (TGA) were used in this study to characterize the synthesized nanoparticles and bulk. The aim of this paper is to research on the effects of nano-Fe_3O_4 and hydrogen sulfide on alleviating heavy metal toxicity in germinating cucumber seedling.

Materials and Methods

Photosynthesis of cucumber can be best accumulated at 25~32 °C. During the morning, the temperature should be maintained at around 25 °C, and the temperature will be slightly reduced in the afternoon. Carbon dioxide fertilized in the morning. In order to promote nutrient transport and reduce plant consumption, the temperature should be controlled in the first half of the night at 16-18 °C and in the second half of the night at 10-14 °C. The optimum temperature for root growth is 20~23 °C, the lowest temperature is 8~12 °C, and the highest temperature is 32~38 °C. The temperature of root growth is no less than 15 °C.

Chemicals

Different chemicals were used to synthesize different sizes of magnetic (Fe_3O_4) nanoparticles. In general, ferric chloride hexahydrate ($FeCl_3.6H_2O$), sodium hydrogen carbonate ($NaHCO_3$), ascorbic acid or vitamin C ($C_6H_8O_6$), ethylene glycol $C_2H_6O_2$, 1,6-Hexanediamine ($C_6H_{16}N_2$), and sodium acetate (CH_3COONa), also abbreviated NaOAc were used as shown in the *Table 1* to synthesize nanoparticles of 6, 50 and 100 nm sizes.

Table 1. *Chemicals used to synthesis nano-Fe_3O_4 (6 nm, 50 nm, and 100 nm)*

N	Chemical composition				Autoclave		
					Temperature (°C)	Time (min)	Size (nm)
I	$FeCl_3.6H_2O$(0.54g)	$NaHCO_3$(1.52g)	VC(0.06g)	H_2O(35ml)	150	240	6
II		NaOAc(2g)	1,6-Hexa(6.7ml)		198		50
	$FeCl_3.6H_2O$(1g)			EG(30ml)		360	
III		NaOAc(1g)	1,6-Hexa(7ml)		205		100

The mini-Q quality water was used for all reactions and preparation procedures. All glassware used in the synthesis processes of magnetic (Fe_3O_4) nanoparticles were

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17891797

thoroughly cleaned several times in aqua regia (HCl: 3 parts and HNO_3: 1 part); then rinsed with water mini-Q and dried at 60 °C before being used (Burman et al., 2004; Garg et al., 2006).

The Magnetic (Fe_3O_4) Nanoparticles

Magnetic (Fe_3O_4) nanoparticles (6 nm) were synthesized following the procedure from Xiao et al. (2011), with some modification (*Figure 1*). In a typical Fe_3O_4 nanoparticles, a 15 mL of 0.54 g ($FeCl_3$. $6H_2O$) aqueous solution was first vigorously mixed with 20 mL of 1.52 g $NaHCO_3$ aqueous solution, then the mixture solution was stirred for 30 min to form a yellow solution. About 0.06 g of vitamin C was added into the first solution and the mixture stirred for 10 min before being transferred into an autoclave that was kept at 150 °C for 4h. After being allowed to cool at a room temperature, the black products were collected by magnetic separation and washed three times with water (Millipore, resistivity>18.2 MΩ.cm^{-1}) and ethanol. The residue obtained was dried at 60 °C before being analyzed and used.

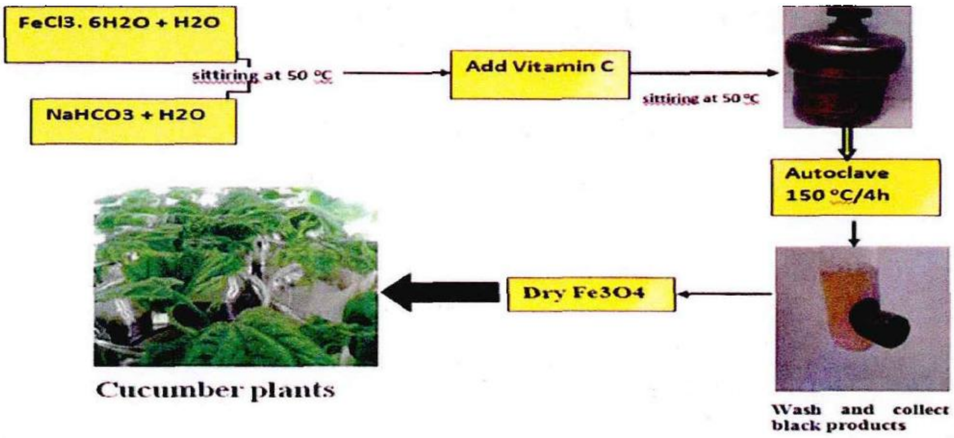

Figure 1. *Synthesis procedures of magnetic (Fe_3O_4) nanoparticles (6 nm)*

Magnetic (Fe_3O_4) nanoparticles (50 nm and 100 nm) were synthesized following some modification of the procedures from Yin et al. (2013). For Fe_3O_4 (50 nm), 1 g ($FeCl_3$. $6H_2O$) and 2 g (NOAc) were first vigorously mixed with 30 mL of EG (Ethylene glycol). Then 6.5 mL of 1,6-hexanediamine was added into the first solution and the mixture stirred for another 10 min before being transferred into an autoclave that was kept at 198 °C for 6 h. The synthesis procedure of 50 nm and 100 nm were similar. The only difference was in the addition of 1 g NOAc), 7 mL of 1,6-hexanediamine and boiled at 205 °C for 6 h in the synthesis of nano-Fe_3O_4 (100 nm). All procedures after autoclaving were similar to those of Fe_3O_4 (6 nm).

The morphology, particle shape and structure of Fe_3O_4 NPs were determined by Scanning Electron Microscopy (SEM, S-4800, HITACHI, Japan) and Transmission Electron Microscope TEM (JEM 200CX, Japan), respectively. For TEM analysis, the Fe_3O_4 NPs or bulk-Fe_3O_4 were dispersed in deionized water and sonicated for 40 min. Then, some suspension liquid was dropped on a copper grip for Transmission Electron Microscopy (TEM) observation (Zhang et al., 2011). The TEM pictures were obtained from Tecnai G2 20 S-Twin transmission electron microscope 119 (FEI company, Japan)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17891797

operating at 200 kV. The mean size, size distribution, and Zeta potential of 50 mg/L magnetic (Fe_3O_4) nanoparticles or bulk-Fej04 were measured by Dynamic Light Scattering (DLS) equipment (ZETA SIZER 90, Nano series, Malvern, UK) in deionized water and nutrient solution (pH 5.5). FT-IR spectra were obtained using Fourier transform infrared spectroscopy (FTIR Tensor 27, Broker, Germany) analysis. The magnetic property was determined using the vibrating sample magnetometer (VSM, 7410, Lake Shore, USA). The crystal structure of the synthesized nanoparticles or bulk was obtained by X-ray diffraction, XRD (XRD, X'pert PRO MPD, Holland) measurement. To collect 20 data from about 10 °C to 90 °C, we used a continuous scanning mode. Thermo gravimetric analysis (TGA) was carried out for powder samples using a NETZSCH STA 449C thermo gravimetric analyzer.

To combat against adverse environmental heavy metal toxicity, plants have developed potential mechanisms such as enzymatic activities (SOD and POD) and the production of low molecular weight thiols. Naturally, plants show differences in their capacity of heavy metals tolerance. Some plants can grow in metal-contaminated soils with high level, while other groups could not grow even at low concentration. The fresh roots or shoots (0.2 g) from each treatment were homogenized with 1.8 mL of 0.05M sodium phosphate buffer (PH 7.8) under ice bath to make 10% sample compound liquid. The homogenate was centrifuged at 10.000 mg and 4 °C for 15 min. Then, the supernatant was used for superoxide dismutase (SOD) and MDA contents. The SOD activity was analyzed by determining the ability to inhibit the photochemical reduction of nitroblue tetrazolium at 550 nm.

Results

Figure 2 shows the XRD patterns of the synthesized magnetic (Fe_3O_4) nanoparticles with different sizes and bulk-Fe_3O_4.

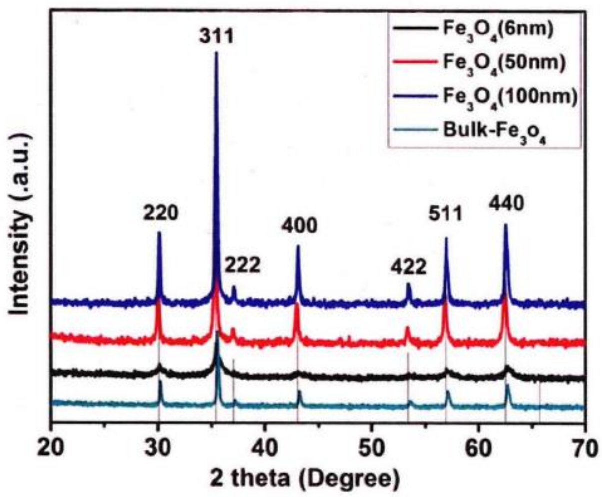

Figure 2. *XRD patterns of Fe_3O_4 nanoparticles (6 nm, 50 nm, and l00 nm), and Bulk-Fe_3O_4*

In this study, the characteristic peaks observed in the XRD pattern at 2θ of 30.09, 35.42, 37.05, 43.05, 53.39, 56.94, 62.51 were corresponding to the diffractions of 220, 311, 222.400, 422, 511 and 440 lattice planes of inverse cubic spinet structure of Fe_3O_4

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17891797

NPs and Fe_3O_4-Bulk. As shown in *Figure 2*, all XRD patterns had a diffraction peak at 2θ=35.42 °C corresponding to the spinet phase of the synthesized (Fe_3O_4) nanoparticles or bulk. The decrease in the intensity after the diffraction peaks at 2θ=35.42 °C could be attributed to the formulation of more crystalline phase particles in all annealed magnetic (Fe_3O_4) nanoparticles and the bulk-Fe_3O_4. The results show that the spinet structures are in good agreement with the XRD standard for the magnetic nanoparticles and no peaks of impurities were observed in the XRD pattern, indicating that the synthesized particles powders are magnetic (Fe_3O_4) nano-particles.

The properties of nanomaterial strongly depend upon the dimension of nanoparticles. Hence, the control of particle size is very important in nanotechnology study or nanoparticles application. In order to analyze the morphology and particles size of the synthesized magnetic (Fe_3O_4) nanoparticles and bulk-Fe_3O_4, SEM images of particles were taken. The results are presented in the *Figure 3*.

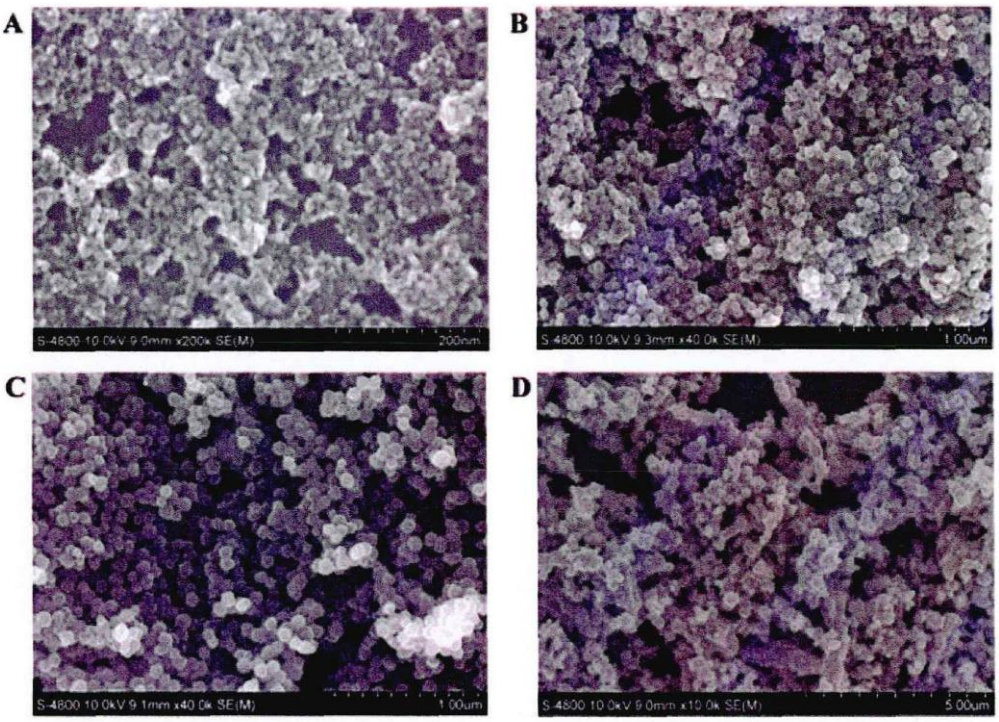

Figure 3. *SEM images of Fe_3O_4 nanoparticles 6 nm (A), 50 nm (B), 100 nm (C) and bulk-Fe_3O_4 (D)*

The SEM images showed that spherical magnetic (Fe_3O_4) nanoparticles (*Figure 3A,B and C*) were obtained from all methods of synthesis used in this study. The SEM images of the synthesized Fe_3O_4 nanoparticles (*Figure 3A*) showed that the materials obtained were made of small particles. As showed in *Figure 3*, Fe_3O_4 nanoparticles (small size) are found to be interconnected with least agglomeration which might be due to their high surface charge and the magneto dipole interaction.

Discussion

The *Figure 4* shows representative TEM images of the synthesized magnetic (Fe_3O_4) nanoparticles with diameters of 6.82±1.38 nm; 52.56±8.01 nm; 100.66±15.62 nm,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17891797

respectively. We observed that the sizes of all synthesized nanoparticles were smaller compared to bulk-Fe_3O_4 (144.27±28.95 nm). The size histograms of the synthesized nanoparticles and bulk based on statistical analysis of over 90 particles are shown in the *Figure 4a-d*. The measurement of the particle diameters of all synthesized magnetic (Fe_3O_4) nanoparticles showed a normal distribution curve after ultra-sonication dispersal as compared to bulk (*Figure 4a-d*). Similar observation has been reported by Shen in 2013 (Shen et al., 2013), who synthesized and characterized water-soluble ultra-small Fe_3O_4, nanoparticles for potential bio-application.

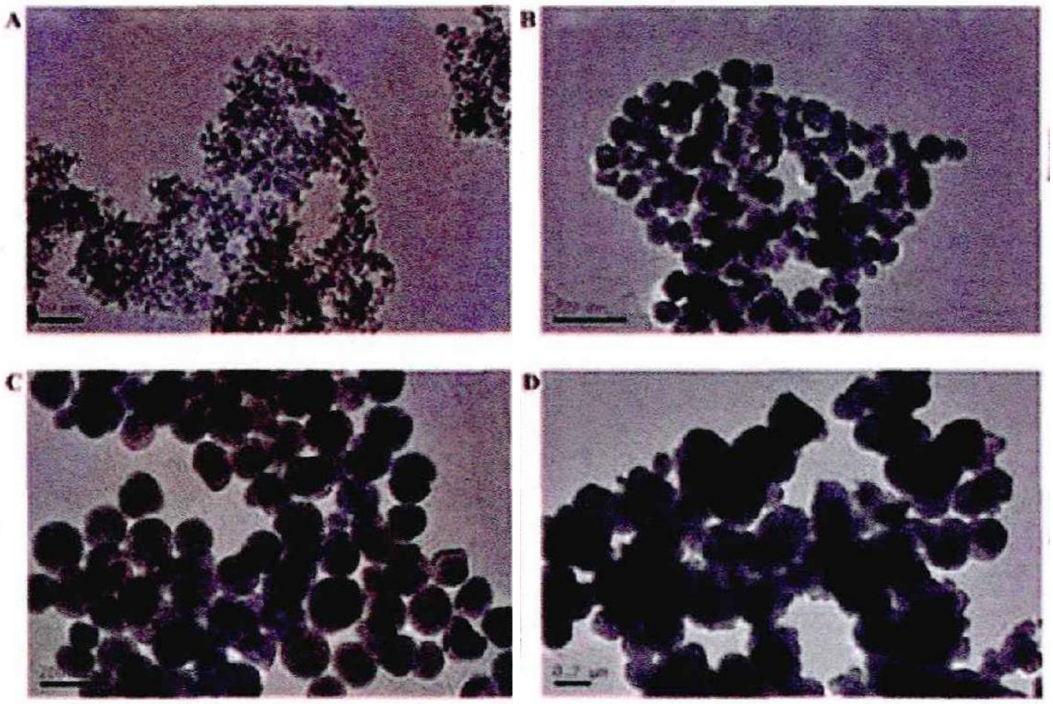

Figure 4. *TEM images and size distribution histogram of Fe_3O_4 NPs: 6 nm (A-a), 50 nm (B-b), 100 nm (C-c) and Bulk-Fe_3O_4, (D-d)*

When suspended in water or nutrient solution, the hydrodynamic diameters of the 50 mg/L of all sizes of the synthesized nanoparticles and bulk-Fe_3O_4 were larger than the results measured by their corresponding TEM images. This is due to their agglomeration. The *Table 2* shows that nano-Fe_3O_4 particles were largely aggregated.

Table 2. *Size distribution and zeta potentials of nano- and bulk- Fe_3O_4*

Nanoparticles or bulk	Water		Nutrient solution	
	<DH>nm	ξ-potential (mV)	<DH>nm	ξ-potential (mV)
Fe_3O_4 (6nm)	255±9.1	-12.66±0.4	433.3±42.2	-15.9±0.2
Fe_3O_4 (10nm)	242.2±0.6	27.9±0.4	741.1±39.6	-16.6±1.3
Fe_3O_4 (100nm)	184.7±4.1	29±0.1	911.5±35.3	-13.5±1.1
bulk- Fe_3O_4	1041±150.8	9.8±0.6	1402±118.9	-18.8±0.1

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17891797

In water, the aggregation level appeared in the order of 6 nm>50 nm>100 nm with the particles averaging 255±9.1 nm, 242.2±6.6 nm and 184:7±4.1 nm, respectively. The practical averages in nutrient solution were 433±42.2 nm, 741±39.6 nm, 911±35.3 nm, and 1402±118.9 nm respectively for 6 nm, 50 nm, and 100 nm. The change in the order of the aggregation level (100 nm>50 nm>6 nm) in the nutrient solution could be due to the presence of additional chemicals in the nutrient solution. We observed that the hydrodynamic diameters of all nanoparticles were smaller in water and nutrient solution compared to bulk-Fe_3O_4, (1041±150.8 nm in water and 1402±118.9 nm in nutrient solution).

The modification of the synthesized magnetic (Fe_3O_4) nanoparticles with different sizes (6 nm, 50 nm, and 100 nm) and bulk-Fe_3O_4 surfaces for their stabilization were analyzed and confirmed by Fourier Transform Infrared Spectroscopy (FTIR) as shown in the *Figure 5*.

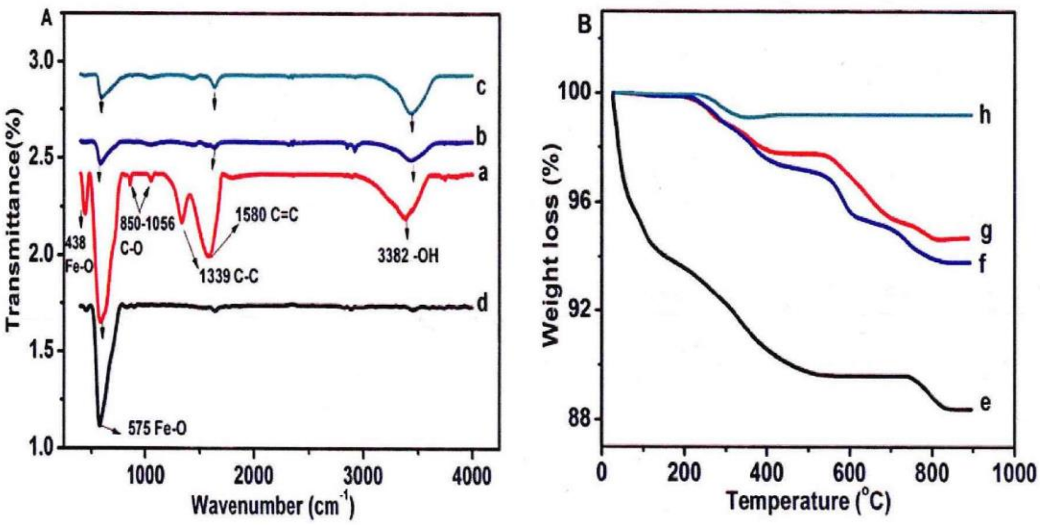

Figure 5. *FTIR Analysis of Fe_3O_4, nanoparticles (Aa-c) and Bulk- Fe_3O_4, (Ad), TGA curves of Fe_3O_4, nanoparticles (Be-f) of bulk- Fe_3O_4 (Bh)*

In general, the stretching absorption peaks of Fe-O at 575 cm^{-1} appeared in the FTIR spectra of all the synthesized nanoparticles and bulk (*Figure 2-SAa-d*). In addition, the peaks in the region numbers 438-575 cm^{-1} are also attributed to the Fe-O vibration (*Figure 5*). In the FTIR spectra of the nano-Fe_3O_4 (6 nm), the peaks around 850-1056 cm^{-1}, 1342 cm^{-1} and 1580 cm^{-1} were related to the group C-O, C-C and C=C respectively (*Figure 5*). The double bonds of C=C were due to the additional compounds, mainly the Vitamin C in using chemicals for the synthesis of nano-Fe_3O_4 (6 nm). The peak observed in the region number 3382 cm^{-1} was related to the vibration of -OH. This peak (around 3382 cm^{-1}) was found in the FTIR spectra of all synthesized nanoparticles (6 nm, 50 nm, and 100 nm). However, it was not observed in the bulk spectra (*Figure 5*). The FTIR spectra analysis suggests that the characteristic stretching absorption peaks at 575 cm^{-1} corresponding to the Fe-O was related to the magnetite phase. *Figure 5 (Be-h)* shows the weight loss curves of magnetic (Fe_3O_4) nanoparticles (6 nm, 50 nm, and 100 nm) and bulk-Fe_3O_4 at different stages of surface modification. It appeared that below 200 °C, the weight loss was insignificant for nano-Fe_3O_4 (50 nm,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17891797

100 nm) and bulk, which probably; presents a relative good thermal stability. The weight loss of 1.93%, 2.29% and 0.84% for 50 nm, 100 nm, and bulk, respectively (*Figure 5 B-f, g, and h*), in the region of 200-400 °C, may be attributed to the release of crystal water. On the other hand, the TGA curve of the small size (6 nm) was very complex as shown in the *Figure 5*. The weight loss in the temperature range of 26-100 °C is about 4.85% corresponding to the release of physically absorbed water and the residual solvent in the sample. In the temperature range 100-450 °C there still exists a gradual weight loss of 5% which is due to the organic surface modification. There was another stage of weight loss of 1.2% observed in the temperature range of 730-830 °C, which may be due to the deoxidation of FeO. The total weight loss from the graph of synthesized nanoparticles (*Figure 5*) was 11.33%, 5.31% and 6.2%, respectively for 6 nm, 50 nm, and 100 nm indicating the transition phase from Fe_3O_4 to FeO. The experiment result shows the toxicity effects of the different sizes of nano-Fe_3O_4 particles and bulk-Fe_3O_4 might depend on the chemical composition, the structure properties/ particle sizes, the concentration in the tested medium, the time of incubation, as well as the plant species.

The phytoxicity effects of Fe_3O_4 NPs (6 nm, 50 nm, 100 nm), and bulk were evaluated in cucumber (Cucumis sativus L) plants grown in hydroponic conditions in terms of growth parameters, biomass production, TEM observation, antioxidant enzyme activities and MDA content. The results show that among the synthesized nano-Fe_3O_4 (6 nm, 50 nm and 100 nm), only the small size (6 nm) was observed to have significant inhibition on fresh and dry biomass of cucumber plants. Nano-and bulk-$Fe_3O_4$4 treatments (21days) caused more oxidative stress in cucumber plants. Cucumber plants grown under lowest concentrations of 50 mg/L nano-Fe_3O_4 (6 nm) were affected by a decrease in biomass and enzyme activities compared to the control. However, at higher concentration of nano-Fe_3O_4 dosage (2000 mg/L), there was significant increase in biomass and enzymatic activities (SOD and POD) respectively. The phytotoxicity effects of the different sizes of nano-Fe_3O_4 particles and bulk-Fe_3O_4 might depend on the chemical composition, the structure properties/particle sizes, the concentration in the tested medium, the time of incubation, as well as the plant species.

Conclusion

The results showed that,nano-Fe_3O_4 (2000 mg/L) did not change the toxicity of the tested heavy metals at high concentration (10 mM) in the seedlings of cucumber. Addition of magnetic (Fe_3O_4) nanoparticles (2000 mg/L) in each metal solution (1 mM), significantly decreased the growth inhibition and activated protective mechanisms to alleviate oxidative stress induced by heavy metals in the cucumber seedlings. The reducing effects of nano-Fe_3O_4 against heavy metals stress could be dependent on the increase in the enzyme activity (SOD and POD), but also their adsorption capacity of heavy metals.

Abstract. In China, rapid urbanization has profoundly transformed the spatial pattern of urban land use, including urban green spaces. The government plans to optimize green spaces to integrate them with urban development; this requires an understanding of the process of green space change. Quantifying landscape pattern and its change is essential for monitoring and assessing ecological consequences of urbanization. In this study, the moving window method and gradient analysis were used to analyze high-resolution satellite images and interpret Shanghai urban green space distribution data. A window of 5 km was found to be a rational size that can reflect urban green space patterns via changes in landscape metrics. Green space patterns can be quantified through gradient analysis and landscape metrics. Different types of green space exhibit obvious "spatial characteristics" along the landscape pattern gradient. Urban green space distribution patterns can be used to verify the urban space development mode. The 'concentric circle' development theory was applicable to the urban development of Shanghai. The research provides significant guidance for further study on the interrelations of urban green space pattern processes, for examination and assessment of urbanization processes and for urban planners and decision makers.
Keywords: *landscape pattern, spatial extents, gradient analysis, landscape index, urban green space*

Introduction

With the accelerated progress of globalization and urbanization, urban issues (such as urban shape and evolution) have become very topical issues across the world (Breuste et al., 1998; Pickett et al., 2001; Whitford et al., 2001). In 1940, only 8% of the global population lived in downtown areas. By the year 1980, more than one third of the population was living in urban areas (World Commission on Environment and Development, 1987). Experts predict that by the year 2025, 60% of the world population will be living in cities (Schell and Ulijaszek, 1999). With the rapid growth of population, downtown areas within cities develop quickly and the urban areas increase tremendously as well; this growth results in various modes of city development. The morphology and evolution of cities have been extensively studied by geographers, economists, and social scientists for centuries (von Thünen, 1825; Christaller, 1933; Hoyt, 1939; Harris and Ullman, 1945; Lösch, 1954; Wilson, 1976; Allen and Sanglier, 1979; Tobler, 1979; Wilson, 1981; Couclelis, 1985; Batty et al., 1989; Wong and Fotheringham, 1990; White and Engelen, 1993; Batty, 1997; Schweitzer, 1997; Portugali, 2000). The changes in urban morphology will have a profound and far-reaching influence in the urban environment, especially the transformation of urban green landscapes (Gordon, 1990). Furthermore, green land plays a critical role in urban

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17991815

development. Thus, the rationality and scientific validity of urban green land distribution is a criterion for judging a city's sustainable development (Chiesura, 2004). At the same time, governments are beginning to recognize the importance of healing the rift between humans and nature. Planners, designers and researchers are in need of valid tools for making quantitative assessments and analyses of reasonable development models with the aim of giving a stronger scientific basis for decisions about urban development.

In previous research on urban shape and evolution, landscape pattern analysis has increasingly been applied to examine urban issues (Kong and Nobukazu, 2006). The window movement method and the gradient analysis method, both based on FRAGSTATS software (http://www.umass.edu/landeco/research/fragstats/fragstats.html) are especially widely used. A landscape index has been widely applied to analyze the urban landscape pattern quantitatively (Pickett et al., 1997, 2001; Whitford et al., 2001; Kong and Nobukazu, 2006). Gradient analysis is now repeatedly adopted in research aimed to investigate the influence of urbanization on urban morphology development (Whittaker, 1975; Kowarik, 1990; Pouyat and McDonnell, 1991; Pouyat et al., 1995; Frohn, 1998; Sukopp, 1998; Zhu and Carreiro, 1999; Wu, 2000; McGarigal and Cushman, 2008). For instance, Luck and Wu (2002) found that the spatial pattern of urbanization can be studied quantitatively by combining gradient analysis and a landscape index. Kong and Nobukazu (2006) utilized these methods of gradient analysis and landscape index to show that the urbanization had changed greatly Jinan's land use types. Li et al. (2004) utilized the landscape pattern index and gradient analysis method to research the landscape structure of Shanghai and the effects of its spatial characteristics on urbanization gradient; results showed that the farmland was the dominant landscape, accounting for about 60% of the landscape. Zhang et al. (2008) also combined the two methods to analyze changes in the landscape index under different extents in Huizhou city of Guangdong Province. However, these studies examined the range of a whole city region and different land types (Luck and Wu, 2002; Zhu et al., 2006). Research using the gradient analysis method and landscape index to study urban green space patterns is limited. Therefore, the use of these two methods to study the pattern of urban green space has a very important significance.

Shanghai, as a megalopolis in China, is undergoing rapid urbanization. A series of problems (such as short-term high-density investment, population explosion, industrial concentration, rapid urbanization of suburbs, and high-strength development features of increased building density and plot ratio) arising from urbanization are being developed at the sacrifice of urban green space and agricultural land and could endanger the sustainable development of Shanghai. One of the urgent issues to be solved by Shanghai is how to optimize the land utilization pattern to meet the land demand for residential, industrial and urban greening purposes. This must be accomplished while also addressing the impact of unlimited expansion of urban space on the urban ecological system and its ecological result during the process of urbanization. The landscape pattern index is an important tool for quantitative analysis of landscape space dynamics and has played an important role in urban ecology and urban landscape research in recent years (Luck and Wu, 2002; Zhang et al., 2004).

In the current study, high resolution remote sensing images were used to interpret urban green space vector diagrams. With the help of a geographic information system (GIS), a gradient analysis was conducted of the landscape belt transect across

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17991815

downtown Shanghai, China. The objectives were to illustrate the space pattern characteristics of Shanghai's urban green space landscape, examine the extent of change in various green space landscapes using gradient analyses, and study the changes of landscape metrics in landscape stratification along the belt transect under different extents. Three main questions were studied. (1) What is the rational extent for the gradient analysis of Shanghai urban green space landscape pattern? (2) Do different urban green spaces have unique spatial characteristics? (3) What is the development pattern of Shanghai urban space? The research was intended to provide a scientific basis for further optimization of the landscape pattern and construction of an urban green space landscape system with a rational structure, scientific layout and ecological benefit.

Materials and Methods

The Shanghai metropolitan region (30°23′–31°37′ N, 120°50′–121°45′ E) is located on the eastern coast of China, with the Yangtze River estuary to the north, the East Sea to the east and Hangzhou Bay to the south (*Fig. 1a*). The region has an area of 6,340 km^2 and a population of 24.1527 million. Shanghai has a northern subtropical monsoon climate, with an average annual temperature of 16°C; however, summer temperatures average 28°C, while the winters are cold with an average temperature of 4°C. Average annual precipitation is approximately 1,200 mm, with 60% of the annual rainfall occurring during May–September.

The research area was mainly located within the outer ring road of Shanghai and had an area of 660 km^2. Included in the study area were Yangpu District, Hongkou District, Zhabei District, Jing'an District, Huangpu District and Luwan District, and partial areas of Putuo District, Changning District, Minhang District, Xuhui District, Baoshan District and Pudong New Area (*Fig. 1b*).

Shanghai has proposed a strategy of building a forested city, with the focus on constructing urbanized areas and public green space at various levels to form a greening network described as "surrounded by forest, internal greening network". The strategy is intended to realize the purpose of urban area greening through a large cycle of "ring, wedge, corridor, garden and forest". The network will situate the city in a forest to surround people with green area so as to lay a foundation for "Shanghai in forest" and "green Shanghai". Therefore, research on Shanghai's urban green space pattern is of great importance for urban greening construction in the city.

Primary data sources used in the study included: (1) 2015 Landsat-8 images (resolution 30 m; bands 6, 5 and 4); (2) Shanghai city image atlas in 2015 and 1:28,000 greater Shanghai map in 2015; and (3) urban planning data obtained from the Shanghai Planning Bureau and the Statistics Bureau (auxiliary information).

Green land information for Shanghai in 2015 was obtained using ArcInfo software (Version 8.2, ESRI, Redlands, CA, USA) as well as visual interpretation to classify green land. In addition, a field survey and data adjustment helped to define the urban green type vector diagram with attribute data and the corresponding spatial data. At various spatial scales (3 km, 4 km, 5 km, 6 km and 7 km), 160 belt transects were established in the directions from north to south and east to west; 320 sampling points were identified as well (*Fig. 1c*). The classification of urban green space types was determined using the Standard for Classification of Urban Green Spaces (CJJ/T85-2002) of the Ministry of Housing and Urban-Rural Development. The specific urban

DOI: http://dx.doi.org/10.15666/aeer/1702_17991815

green land function and characteristics were determined, as well as the types of land use, ownership, and physical factors (colors, tones, location, size and texture) (*Fig. 1c*). The accuracy of grading different urban green land samples was 97.5%, which was considered acceptable. ArcMap (Version 8.2, ESRI) was used for spatial analysis and for transforming the vector data of green land types into the raster format in 2 × 2 m pixel areas.

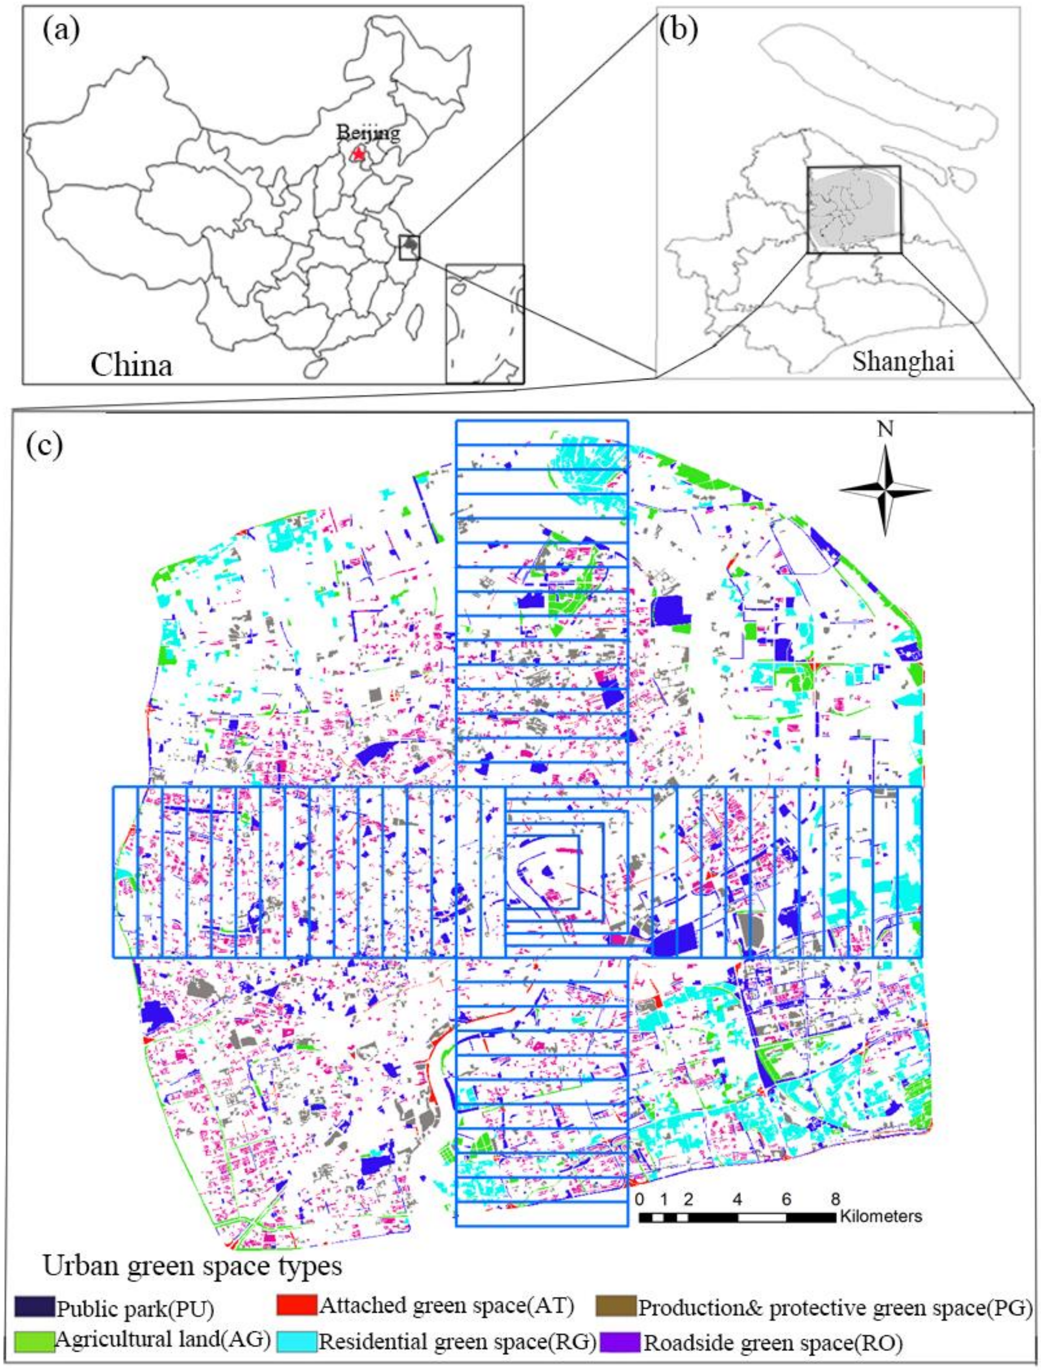

***Figure 1.** The study area showing: (a) location of Shanghai city in China; (b) regional location of Shanghai City; (c) urban green space map of Shanghai City and transects of windows used to sample green space*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17991815

Based on the Standard for Classification of Urban Green Spaces (CJJ/T85-2002) of the Ministry of Housing and Urban-Rural Development, and in combination with Shanghai's urban green space characteristics, Shanghai's urban green spaces were divided into six categories, as follows:

- Public park (PU) - this type of green space included comprehensive parks, citywide parks, regional parks, community parks, parks in residential areas, gardens and parks in residential quarters, theme parks, children's parks, zoos, botanic gardens, historical gardens and parks, scenic spots, amusement parks, other theme parks, and belt-shaped parks.
- Residential green space (RG) - this type of green space included residential quarters and communities.
- Attached green space (AT) - this type of green space included public facilities, industrial green space, green space for warehousing, green space for external traffic, green space for municipal facilities, and special green space.
- Roadside green space (RO) - this type of green space included roadside verges and similar green fields.
- Production and protective green space (PG) - this type of green space included green space for production and protection.
- Agricultural land (AG) - this type of green space included cultivated land, garden plots, forest land, grassplots, agricultural land for facilities, field ridges, and country roads.

Identification of each green space type was determined (in combination with the comprehensive analysis of the specific situation of Shanghai) based on the features of the spaces that were visible on the remote sensing image including color, tone, shape, position, size and texture.

The combined method of gradient analysis and landscape metrics was used in the study. "Windows" of various sizes (3 km, 4 km, 5 km, 6 km and 7 km) were used to move along a selected belt transect and analyzes the landscape pattern changes so as to identify the urban green space landscape pattern and its gradient change. The Lujiazui central green space was the central window. The spatial step of each window along a transect was 1 km and windows moved from west to east and from south to north, obtaining a series of land pattern samples of various sizes. The central window location was the origin (0 km). Movements toward the east and north were designated positive values and toward the south and west were negative values. Land pattern characteristics were calculated using a 1-km sliding step to correct for noise caused by small scale and local variations, a technique similar to the analysis of time series data (*Fig. 1c*). ArcMap software (ESRI) was used to digitally cut the sample belts from the Shanghai green space vector diagram and convert them into 2-m × 2-m grid (raster) data for visual presentation.

The FRAGSTATS 4.2 software (McGarigal, 2002) was used to determine the correlation pattern characteristic index of green space landscape (McGarigal and Marks, 1995). The redundancy and overlap among landscape metrics have been investigated previously (e.g., O'Neill et al., 1999). Not all the available landscape metrics were needed to capture the changes in the composition and configuration of the landscape. A small set of metrics (13 in total) were chosen to be both sensitive to changes and numerically reliable (i.e., showing consistent trends) for depicting landscape patterns (*Table 1*). As in most cases in the existing literature, the term "landscape pattern" in this study included both the non-spatial composition (e.g., the number and relative

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17991815

abundance of patch types, patch size, and other related non-spatial measures) and spatial configuration (e.g., patch shape, juxtaposition, contrast, and boundary characteristics). Li and Reynolds (1994) defined spatial heterogeneity in a similar way.

Specifically, 10 indices were used as compositional measures: percentage of landscape (PLAND), patch density (PD), edge density (ED), patch richness (Hobbs, 1988) (PR), Shannon diversity index (SHDI), largest patch index (LPI), mean patch size (MPS), aggregation index (AI), patch size standard deviation (PSSD) and patch size coefficient of variation (PSCV). The remaining three indices were used as configurational measures: landscape shape index (LSI), area-weighted mean shape index (AWMSI) and area-weighted mean fractal dimension (AWMFD) (O'Neill, 1988). This dichotomy of compositional versus configurational indices is apparently an oversimplification, and many of these indices reflect both aspects of landscape pattern to varying degrees (McGarigal and Marks, 1995). However, this simple classification scheme was adopted so as to facilitate the organization of results and their interpretation.

Table 1. *Landscape metrics used to quantify the spatial pattern of urbanization in metropolitan Shanghai, China (based on McGarigal and Marks, 1995)*

Landscape metrics	Abbreviation	Description
Compositional measures		
Percentage of landscape (%)	PLAND	The proportion of total area occupied by a particular patch type; a measure of dominance of patch types
Patch density	PD	The number of patches of per 100 ha
Edge density (m ha^{-1})	ED	The total length of all edge segments per hectare for the class or landscape of consideration
Patch richness	PR	The number of patch types in the landscape; a measure of diversity of patch types
Shannon diversity index	SHDI	A measure of patch diversity in a landscape, which is determined by both the number of different patch types and the proportional distribution of area among patch types
Largest patch index (%)	LPI	The ratio of the area of the largest patch to the total area of the landscape
Mean patch size (ha)	MPS	The average area of all patches in the landscape
Aggregation Index	AI	The aggregation index reflects the patches in the landscape and the index of the decentralized state
Patch size standard deviation (ha)	PSSD	The standard deviation of patch size in the entire landscape
Patch size coefficient of variation (%)	PSCV	The standard deviation of patch size divided by mean patch size for the entire landscape
Configurational measures		
Landscape shape index	LSI	The total length of patch edges within the landscape divided by the total area, adjusted by a constant for a square standard
Area-weighted mean shape index	AWMSI	Mean patch shape index weighted by relative patch size
Area-weighted mean fractal dimension	AWMFD	The patch fractal dimension weighted by relative patch area

Results

Synoptic characteristics of the Shanghai area landscape

Data in *Table 2* show the six categories used to distinguish green space in Shanghai. PU had the largest PLAND (up to 30.32%), and its PSCV value (278.15%) was also relevantly large, indicating that PU was the dominant green space type in the belt

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17991815

transects. AT had the second largest PLAND (26.46%) and the proportions of RG, AG, PG and RO decreased (in that order) such that RO occupied the smallest proportion (2.46%) of the sampled area. PD (the number of patches per unit area) reflects the degree of landscape breakage; i.e., the larger is PD, the smaller are the patches and the higher is the degree of fragmentation. The PD of RG was the largest and far higher than that of other green space types; AT had the most scattered distribution and highest degree of fragmentation among the belt transects. AG had the largest LPI (1.25%) and the largest AI (87.25%), indicating that AG green space was concentrated with a low degree of fragmentation.

The PD and LSI of the entire landscape were relevantly large, indicating that the overall degree of breakage of Shanghai urban green space was relevantly large and Shanghai was comprised of complex green space patch shapes. The AI of RO was the smallest of all green space types, and RO consisted of small areas and scattered distribution. The Shannon diversity index of the entire belt transect was 1.65, indicating a low level of diversity.

Table 2. *Class and landscape-level metrics of the land use transects*

Landscape metrics	Types						Landscape level
	PU	RO	RG	AT	PG	AG	
Percentage of landscape (%)	30.32	2.46	18.08	26.46	6.94	15.74	—
Patch density (No/100hm^2)	8.34	3.20	13.55	6.87	1.63	0.93	37.77
Largest patch index (%)	2.54	0.18	1.40	0.36	0.6235	1.25	4.34
Edge density (m/ha)	3.23	0.77	1.60	2.27	1.12	0.50	4.75
Landscape shape index	36.53	22.37	31.59	59.13	17.84	15.54	77.43
Patch size coefficient of variation (%)	278.15	176.615	236.06	146.54	231.16	269.14	365.74
Area-weighted mean shape index	2.017	1.99	1.937	2.18	2.52	4.15	2.41
Aggregation Index (%)	77.53	51.85	74.92	74.18	60.63	87.25	74.30
Shannon diversity index	—	—	—	—	—	—	1.65

Gradient analysis with landscape-level metrics at different spatial extents

Although there is a large amount of literature about the use of landscape gradients, the study area does not conform entirely to previously used methodology. Therefore, a rational spatial extent had to be chosen for analyzing the land use pattern in Shanghai. Based on the literature, five spatial extents were selected (3 × 3 km, 4 × 4 km, 5 × 5 km, 6 × 6 km and 7 × 7 km) to study the gradient distribution characteristics of Shanghai urban green space landscape pattern in an attempt to find the window size that was most appropriate.

Based on the landscape metrics at various spatial extents, PD, MPS, LSI and AWMSI exhibited obvious gradient change trends (*Figs. 2b, 2c, 2e and 2f*). Among these indices, PD gradually decreased from west to east and the highest value occurred at −8 km to −2 km from the origin. This area was the old city of Shanghai with small and scattered landscape green spaces indicating a high degree of breakage in the landscape (*Fig. 2b*). MPS gradually increased from west to east along the belt transect and displayed a J-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17991815

shaped distribution; this distribution indicated that the areal extent of a single patch from west to east of the city gradually increased and was highly concentrated at the urban suburbs. Furthermore, there was a concentration of either of two types of green space based mainly on large patch green space (such as AG) with low breakage degree (*Fig. 2c*).

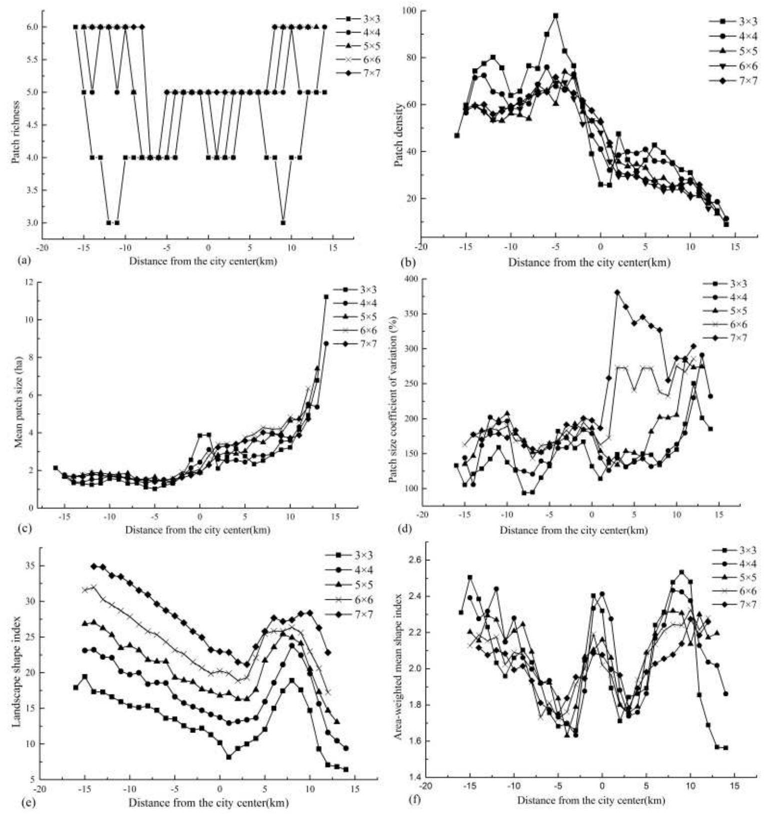

Figure 2. *Variation of landscape metrics along the east-west direction land use transect at different spatial extents: (a) patch richness, (b) patch density, (c) mean patch size, (d) patch size coefficient of variation, (e) landscape shape index, and (f) area-weighted mean shape index. To examine the effect of changing scale of analysis, five window sizes were used: 3 × 3 km, 4 × 4 km, 5 ×5 km, 6 × 6 km and 7 × 7 km blocks. See text for details*

LSI gradually decreased from west to east along the belt transect with the valley at −2 to +4 km from the center and peaked at +9 km; this occurred because at a distance of −16 to −4 km, there was a gradual transition from urban suburbs to the old city. The proportion of RG in the living area of the urban suburbs was large and, the larger the LSI value, the more dispersed were the green space patches. The peak occurred at +9 km this was the location of the Pudong New Area of Shanghai, which had a large RG area and therefore large LSI value (*Fig. 2e*).

The large values of AWMSI mainly occurred at −16 to −10 km, −3 to +2 km and +8 to +12 km because urbanization and government planning policy had resulted in patch shapes having greater complexity (*Fig. 2f*). Although PR and PSCV did not exhibit obvious gradient characteristics along the east-west belt transect gradient (*Figs. 2a and 2d*), they both showed increased fluctuation (and a zigzag trend) as the spatial extent of the analytical windows decreased (*Fig. 2b*). LSI progressively decreased, then

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17991815

progressive increased and finally progressively decreased again from west to east along the belt transect (*Fig. 2e*). The highest value of LSI occurred at −16 km from the city center and another peak occurred at +8 km because these were the locations of residential estates with large greening area and relevantly large dispersion.

Based on the change of spatial extent of the analytical windows and comprehensive analysis, PR, PD, MPS, PSCV, LSI and AWMSI fluctuated irregularly (with both increases and decreases of spatial extent) along the belt transect. Generally, when the window was large (≥ 5 km), the changes in landscape metrics were gradual along the belt transect and exhibited smooth trend lines. When the window was small (≤ 4 km), the landscape metrics fluctuated dramatically. Therefore, a spatial extent of 5 km was deemed to be an appropriate scale for the gradient analysis of Shanghai green space landscape pattern. This size of analytical window not only avoided large fluctuations in the landscape metrics, but also comprehensively reflected the pattern of change of the urban green space landscape gradient.

Variation of urban green space types percent coverage along the land use transect at different spatial extents

There was almost no distribution of AG along the belt transect gradient in the city and the percentage of AG in the landscape increased sharply at +10 km east of the origin, i.e. near the junction between the second ring road and third ring road (*Fig. 3a*).

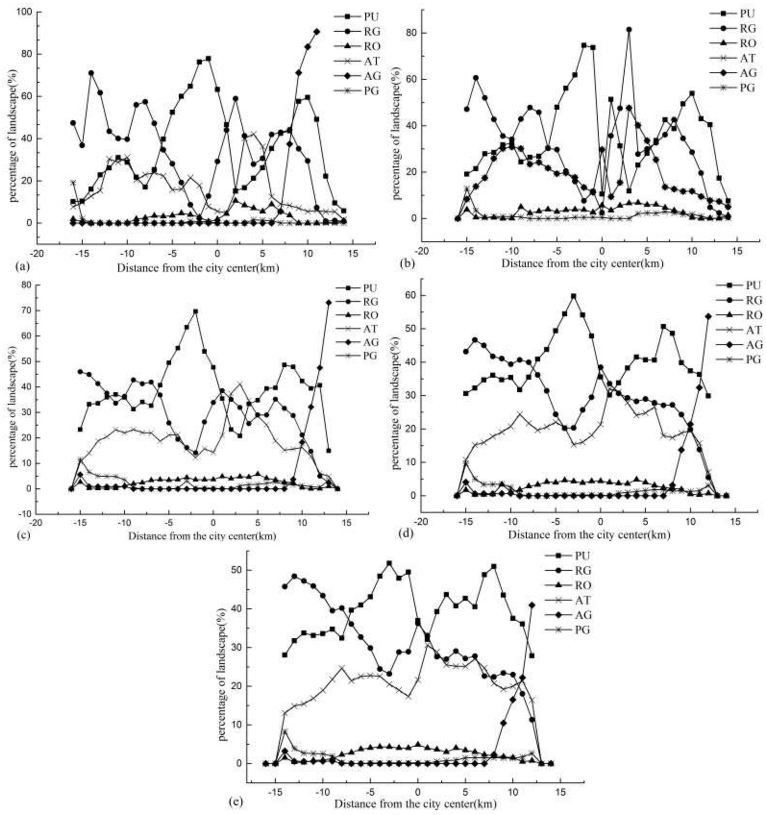

Figure 3. *Variation in the proportions of Shanghai urban green space types along the east-west direction transect at different spatial extents: (a) 3 km extent, (b) 4 km extent, (c) 5 km extent, (d) 6 km extent, (e) 7 km extent. RO: roadside green space; PU: public park; RG: residential green space; AT: attached green space; AG: agricultural land; PG: production and protective green space*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17991815

The distribution of RG progressively decreased from west to east of the city with a low value within the range −4 km to −1 km. PU progressively increased from the suburbs to the central urban area with the highest value at the central urban area; this type of green space exhibited an M-shaped distribution with peaks at −4 km and +11 km, and a valley at +1 km to +3 km (*Figs. 3a, 3b, 3c, 3d and 3e*). PG reached its highest peak between −13 km and −14 km from the center, and its proportion in the landscape was small between −10 km to +14 km from the center with sporadic distribution and a value close to 0. AT generally exhibited an M-shaped distribution (*Figs. 3a, 3b, 3c, 3d and 3e*) and reached peak values at −10 km to −13 km and +1 km to +5 km, with a sharp decrease to a valley at −1 km to +5 km. RO changed in an irregular pattern, with a small proportion at both sides of the city and a large amount at −10 km to +8 km.

Changes in the proportion of the landscape occupied by various green space types were closely related to the land utilization space pattern of Shanghai. The downtown area within the second ring is the political and business center of Shanghai; due to its early construction it mostly consisted of AT and PU with a small percentage of RO, and the green space types were not fragmented (*Figs. 3a, 3b, 3c, 3d and 3e*). When the spatial extent of the windows along the transect was 6 km and 7 km, changes in the proportions of green space in the landscape along the belt transect exhibited a smooth trend line. However, when the extent was reduced to 3 km and 4 km, the changes exhibited erratic fluctuations, indicating that the landscape metrics used in this research were sensitive to pattern changes when the spatial extent of windows used to identify them was small. Therefore, we concluded that the window size of 5 km was a proper extent for studying Shanghai's urban green space landscape pattern.

Transect analysis using landscape-level metrics

Figures 4 and 5 portray the variations in landscape metrics in the study area. The cross-section analysis from east to west and from south to north using a 5-km window showed that variations in the six major types of green space exhibited the same pattern. As a proportion of the landscape (PLAND), PU and AT exhibited an M-shaped distribution and the largest proportions of PU occurred at the city center and at +9 km from the city center. The largest proportions of AT occurred at +4 km and +8 km from the city center, and PU mainly occurred between these two locations. The trends in the proportions of other categories of green space at the same distance from the city center were the same (*Figs. 4a and 4b*). The patch density (PD) of the six major categories of urban green space was basically the same from east to west and from south to north (*Figs. 4c and 4d*), and there was only some difference between PU and RO at −5 km to -16 km. However, at the landscape level, the overall PD trend of the six major categories of urban green space was the same (*Fig. 5a*).

The overall trend of the largest patch index (LPI) was also the same in the six major categories of urban green space, although there was some difference for PU at −7 km to −16 km, and for AT at +6 km to +16km. However, at the landscape level, the distribution trend of LPI from east to west and from south to north was the same (*Figs. 4e, 4f and 5b*). The overall trend for LSI was the same in all green space types, but there was some small difference between PU and the other types at −5 km to −16 km. At the landscape level, the distribution trend of LSI for the six major categories of urban green space was the same (*Figs. 4f, 4g and 5c*).

At the landscape level, the distribution trends of MPS and PSSD for the six major categories of urban green space from east to west and from south to north were the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17991815

same, exhibiting exponential growth (*Figs. 5d and 5e*). Furthermore, the distribution trends of AWMSI, AWMFD and SHDI were also the same (*Figs. 5f, 5g and 5h*). To sum up, the distribution trends of the six major categories of urban green space in Shanghai were basically the same for both cross-sections and at the landscape level, which is characteristic of a "concentric circle" development pattern. Thus, these results provide further evidence that Shanghai's urban development can be described by the "concentric circle" urban development theory.

Discussion

The reasonable extent for landscape pattern analysis

The spatial resolution of remote sensing images and data processing accuracy have an effect on the identification of green space types and on research about landscape pattern changes (Turner, 1989; O'Neill et al., 1996; Baldwin et al., 2004; Wu, 2004; Buyantuyev and Wu, 2007; Weng, 2007; Castilla et al., 2009). Therefore, the selection of high spatial resolution images and reasonable study amplitudes is vital to quantitative research of urban green land distribution patterns (Buyantuyev et al., 2010). In this study, we examined a range of reasonable spatial extents (3, 4, 5, 6 and 7 km) by which

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17991815

to analyze Shanghai's urban green land landscape pattern. The results showed that 5 km was the most suitable size of window, which corroborates the research findings of Shenyang (Tang, 2008).

Moreover, the spatial resolution of remote sensing images that suits the research on urban green land landscape pattern amplitude is determined by characteristics of the research area, by researchers' caution and by the analytical methods applied. According to our research, the spatial resolution of Landsat images (30 meters) was sufficient to determine the key information about urban green land needed in the research. For instance, LPS, AWMFD and SHDI (*Figs. 5c, 5g and 5h*) indicated that the green land area from the suburban district inward to the downtown area of Shanghai was increasing while the patch density was decreasing. This pattern reflects the fact that the government has put emphasis on the provision of urban green land and has made a reasonable plan for the city. The method that combines the use of FRAGSTATS, GIS analysis and landscape indices provides significant guidance for further research about urban landscape patterns and town planning.

However, some uncertainty and a use of subjective factors is involved when considering the impact of the "background" land uses and edge effects during execution of the moving window procedure, sampling methods, and the selection of landscape metrics at different periods. Yet, little thought is given to the combination of the moving window procedure, landscape metrics and transfer matrix method of quantification. Therefore, classification training, revision of parameters and mathematical modeling should be conducted according to the characteristics of different research areas so as to increase the analysis accuracy and the degree to which research methods are integrated.

The theories of urban development

Dietzel et al. (2005) proposed a "concentric" model to describe urban development. Under this model, urban growth starts with the expansion of urban core areas and diffuses from these core areas outward. Urbanization in the Shanghai metropolitan region has resulted in dramatic increases in patch density, edge density, and patch and landscape shape complexity, as well as sharp decreases in both the largest and mean patch sizes, agricultural area, and landscape connectivity (*Figs. 4 and 5*). The general pattern of urbanization revealed in this study was that the increasingly urbanized landscape became compositionally more diverse, geometrically more complex, and ecologically more fragmented. This pattern is consistent with those in Phoenix and Las Vegas, USA as reported by Wu et al. (2011). First, both 32-km long and 7-km wide west–east and south–north transects in this study provided an excellent opportunity for characterizing broad-scale landscape pattern change along a rural–urban–rural environmental gradient; this has not been reported previously in any Chinese city. The urbanization gradient revealed by our transect analysis seemed to suggest that the different types of urban green space that are located different distances away from the downtown center can reflect different types of land-use. Therefore, land-use regularly ranges from the suburban agricultural land to public land to residential land, and then again to public land and residential land (*Figs. 4a and 4b*). The classic concentric zone urban development theory seems to account adequately for the land use pattern of the Shanghai metropolitan region up to the year 2015, and this is partly because classic theories of urban morphology such as the "concentric circle" theory were developed based primarily on studies of old and well-established cities (i.e., Chicago, San Francisco and Boston in the USA).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_17991815

Shanghai was growing rapidly in the beginning of the 21st century, which may be indicative of a fast-growing city, or urban development among Chinese coastal cities. Perhaps a new urban development theory will be proposed in the near future that is more suitable for understanding the metropolitan area of Shanghai urbanization development.

In particular, combining gradient analysis with landscape metrics, as illustrated in this study, can help to quantitatively identify and characterize the gradients and complex spatial pattern of urbanization, which can subsequently be related to ecological and socioeconomic processes (McDonnell et al., 1997). The expansion of this study to understand the mechanism of urban landscape pattern formation requires a more comprehensive study. (e.g., Luck et al., 2001).

Conclusions

The method that combines the use of FRAGSTATS software, GIS analysis and landscape indices provides a completely new way of thinking and methodology for the analyzing the gradient of urban green landscape from an urban area to a suburban area. Meanwhile, this technique also promotes the analysis and quantitative research of landscape ecology (Herold et al., 2003; Sawaya et al., 2003; Garrigues et al., 2006).

“Windows” of different spatial extents were applied in this study to determine the one most reasonable for analyzing Shanghai’s urban green space. Results confirm that the range of 5 km is the most suitable for research on Shanghai green landscape gradient analysis. Analysis at this scale not only avoids erratic changes in landscape indices, but also accurately identifies how urban green land types vary as the gradient changes. At the same time, a window of 5 km shows the significant “spatial characteristics” of urban green land changes with the different gradients.

Urban green landscape pattern can corroborate spatial development patterns, confirming that Shanghai urban development represents a mode of concentric circles. This conclusion relates closely to the leading urban development policies, and the coherence of urban land space and urban sustainable development.

Abstract. The present study was aimed to evaluate the effect of naphthyl acetic acid (NAA) on chlorophyll, protein, proline, sugar and carotenoid contents along with certain enzymatic activities, namely peroxidase (POD), superoxide dismutase (SOD), catalase (CAT), and ascorbate peroxidase (APOX) in two selected varieties i.e. Iqbal and Pahari of maize crop induced under salt stress of different concentrations (100mM, 80mM, 60mM, 40mm and 20mM). The experiment was conducted at the Department of Botany, Bacha Khan University Charsadda, Pakistan during maize growing season, 10-09- 2015. The result of the study revealed that different concentrations of NaCl affect the physiological and biochemical parameters. The anti-oxidative enzymes, such as peroxidase (POD), superoxide dismutase (SOD), catalase (CAT) and ascorbate peroxidase (APOX), and sugar, proline, and proteins were found maximum in treatment T2, T4, T10 and T12 in the Pahari variety which on physiological basis was found more tolerant to the saline condition and regarding the response to exogenous application of naphthyl acetic acid (NAA) the variety Iqbal was more sensitive to salt stresses.
Keywords: *nephthyl acetic acid, selective growth, antioxidant enzymes, action, salt stress tolerance*

Introduction

Maize (*Zea mays* L.) is one of the most important crops which are used as breakfast and the oil of maize for diabetic patient all over the world. Maize is also used as food

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18171834

for animals (Hussain et al., 2010). It is important measure salt stress tolerance of plants because up- or down-regulation of salt changes physiological mechanisms in the plants (Tas and Basar, 2009). The salt was effect resolute at seed earlier stage of wheat from a decrease in germination percentage, fresh and dry weight of shoots and roots due to the translocation of several nutrient ions (Afzal et al., 2005). The presence of salt in the soil of marshlands or when salt is already a part of the soil is called primary or main salinization, but some plants are growing and adapted to saline soil. Minor or secondary salinization occurs in the soil where salt concentration is low and sometimes soil becomes saltier because of poor and low irrigation (Zhu, 2007). Soil salinization is one of the major factors of soil squalor or soil salinity. Soil salinization reached about 19.5% of the irrigation land and 2.1% of the dryland agriculture current in the world (FAO, 2000). In Pakistan, after wheat, cotton, and rice, maize is the fourth largest grown crop. In Pakistan one million hectares of maize production produce about 3.5 million metric tons. Punjab contributes 39% of the total area under maize and 30% of total production, Khyber Pakhtunkhwa contributes 56% of the total area production, Sindh contributes 63% of the production and Baluchistan 5% of the total area (PARC, 2010*).* Salt stress creates both ionic as well as osmotic stress on plants (Parvaiz and Satyawati, 2008). Salt stress is a major abiotic stress that can affect plant morphology and physiology, in this way the fresh and dry parts of shoots and roots are decreased perhaps due to the high concentration of salt ions or water-related qualities (Hajer et al., 2006). The leaf chlorophyll imbalance due to salt stress (abiotic stress) reduces photosynthesis (Turan et al., 2007). Salt stress is caused by high concentration of Na^+ and Cl^- in the environment that reduce the fertility of the soil so plant roots can't grow in the saline soil (Rasool et al., 2013). When maize, wheat, and rice etc. seeds are sown in saline soils, salt (Na^+ and Cl) cause many adverse symptoms on seed germination, as result less number of seeds germinate, plant growth is stunted, height of the plant becomes short, leaves are smaller and thicker than in normal size of plants and the color is dark green and bluish. When plants grow in saline soils, the various plant parts e.g. leaves, fruits, roots, stems etc. are very small and so they affect quality and quantity of fruits, vegetables, and agricultural products e.g. high concentration of Na^+ also decrease sugar production in sugar crops (Storey et al., 1977). Salinity causes two major effects osmotic stress and ionic toxicity in plants, these two major effects osmotic stress, and ionic toxicity affect the various processes in the plant (Yadav et al., 2011).

To use growth-stimulating chemicals (Naphthalene acetic acid) for the increase of plant production and also stimulate plant physiologists the world (Ahmad et al., 2010). To study the upward transport of nutrients due to growth regulator chemical Naphthalene acetic acid (NAA), these growth regulator chemical Naphthalene acetic acid (NAA), ameliorate growth of the physiological and proteins, carbohydrate, sugar etc. the of plants (Iqbal et al., 2009; Tůmová et al., 2018). Growth regulators or hormones stimulate and promote growth in plants. Naphthalene acetic acid (NAA) is a growth controller and also increases the production and yield of plants. Naphthaleneacetic acids (NAA) are synthetic growth regulator hormones which ameliorate the potential of plants with suitable concentration. Naphthaleneacetic acid (NAA) also affects the growth, yield, and production of tomatoes plants. (Jahan and Fattah, 1991). Keeping in view all the above information, the present study will be conducted to screen maize (Pahari and Iqbal) accessions for salt stress tolerance. In addition, physiological and biochemical variations are also assessed for some physiological traits that could be used as selection criteria for future breeding programs.

Aims of the study

The present study was aimed at assessing the physiological mechanism of adaptation to salt tolerance in maize at the vegetative stage with variable levels of salt stress (20, 40, 60, 80, and 100mM of salt, accompanied by the application of naphthyl acetic acid (NAA) foliar spray). The reactions of maize to salt stress were assessed on the basis of selectivity of growth responses, osmoregulation, and antioxidant enzyme actions.

Materials and methods

Experimental design

The experiment was conducted during the 10- 09- 2015 corn growing season in the greenhouse of the Botanical Department of Bacha Khan University Charsadda (latitude 34.1509', east longitude 71.735'E, 908 feet above sea level). Seeds of two seed selections, Iqbal and Pahari, are from the Crop Research Institute Pirsabaq Nowshehra (CCRI). Seeds were sterilized with 5% oxychloride and 95% ethanol before planting and then rinsed three times with distilled water. After soaking, the seeds were sown in plastic pots (14 cm below the inner diameter, inner diameter 18.5 cm, height 15.6 cm, thickness 0.5 cm), filled with 3 kg of air-dried soil and sand (3:1), and placed in triplicate. The plants were exposed to 20, 40, 60, 80 and 100 mM salts for about 15 (26- 09- 2015) days after germination in an incubator with an average day and night temperature of 25°C (10 hours) and 16°C (14 hours), respectively. In the group experiments, all treatments were sprayed with NAA for 1 week; control plants were usually irrigated with distilled water. After 15 days, leaf samples were collected for analysis.

Chemical analysis of rhizospheric soil

Soil pH and electrical conductivity (EC)

The pH of the rhizospheric soil was measured by preparing a 1:1 (soil: water) suspension (McKeague, 1978; McLean, 1982). Air-dried soil samples (10 g) were mixed in 10 ml of distilled water and stirred for 1 hour in a magnetic stirrer for uniform mixing, and then the suspension was filtered through Whatman No. 42 filter paper. The pH of the filtrate was measured with an Electrical pH meter while the EC was recorded using an electrical conductivity (EC) instrument. The readings were measured in micro-siemens per centimeter (µS/cm). Soil Moisture (10 g) was taken from a uniform depth, 6 inches from the surface of the pot. The dry weight was determined by drying the soil in an oven at 70°C for 72 hours to constant weight.

Soil moisture content

The soil (10 g) was removed from the same depth, i.e. 6 inches from the surface of the pot. The dry weight was determined by drying the soil in an oven at 70°C for 72 hours to constant weight. The soil moisture content is calculated by the following formula:

$$\text{Parentage moisture content} = \frac{(\text{Fresh weight of soil - the Dry weight of soil}) \times 100}{\text{Fresh weight of soil}} \qquad \text{(Eq.1)}$$

Field capacity of the rhizospheric soil

The field capacity of rhizospheric soil was determined by the following method:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18171834

$$\text{Parentage Field Capacity} = \frac{(\text{Weight of wet soil (g) - Weight of dry soil (g)}) \times 100}{\text{Weight of dry soil}} \quad \text{(Eq.2)}$$

The agronomic character of maize under drought stress

Detailed agronomic characterization of maize under drought stress was performed, including:

- Root length
- Root fresh weight
- Root dry weight
- Root moisture content
- Shoot length
- Shoot fresh weight
- Shoot dry weight
- Shoot moisture content
- Number of leaves
- Leaf fresh weight
- Leaf dry weight
- Leaf moisture content
- Germination
- Leaf area
- Root/shoot ratio
- Vigorous index

Physiological and biochemical analysis

- The protein content of leaves was determined following the method of Lowry et al. (1951) using BSA as standard.
- Sugar estimation of fresh leaves was done following the method of Dubois et al. (1956).
- Chlorophyll content of leaves was determined by the method of Arnon (1949).
- The proline content of leaves was measured by the method of Bates et al. (1973).
- Peroxidase (POD) activity was determined by the method of Vetter et al. (1958) as modified by Gorin and Heidema (1976).
- Superoxide dismutase (SOD) activity was determined by measuring the inhibition of the photochemical reduction of nitro-blue tetrazolium (NBT) using the method of Beauchamp and Fridovich (1971).
- Ascorbate peroxidase (APX) activity was determined according to Asada and Takahashi (1987).
- Catalase (CAT) was measured according to Asada and Takahashi (1987), with modification.

Statistical analysis

The data were analyzed statistically by the Analysis of Variance technique (Steel and Torrie, 1980) and comparison among treatment means was made by Duncan's Multiple Range Test (DMRT) (Duncan, 1955).

Results

Physicochemical characteristics of rhizospheric soil

The effect in *Table 1*, *Equations 1 and 2* shows that the extreme pH of the treatment for T6 (60 mM) was recorded in Iqbal and Pahari compared to the control (untreated). A decrease in the pH and EC of the soil collected from Iqbal and Pahari was noted in T10 (100 mM + NAA), reflecting the positive role of NAA in maintaining EC and pH under induced salt stress. In Iqbal and Pahari, the maximum moisture content percentage and field capacity percentage for T8 (80 mM + NAA) treatment were reported; T6 reported the minimum for both varieties.

Agronomic characteristics

The results in *Table 2* show that the maximum germination rate, leaf area, root activity and leaf area index (LAI) had been measured or calculated of (LAI = leaf area / ground area, m^2/ m^2) were recorded in the two varieties treated T12 (control + NAA), while the minimum germination rate was reported of T4 (80 mM + NAA). The results in *Table 3* indicate that the T12 treatment of the two varieties reported maximum shoot length, shoot fresh and dry weight, and moisture content, while T5 (60 mM) reported the minimum shoot length, indicating that NAA increased the shoot length under salt stress. The results in *Table 4* indicate that the maximum root length and root fresh and dry weight were recorded of T3 (40 mM) treatment in Iqbal, while the minimum values were reported in T5 and T6 (60 mM + NAA). The data in *Table 5* shows that treatment of T12 in both varieties reported maximum leaf number and leaf fresh and dry weight, and reported the smallest in T3 (60 mM) and T4. A detailed physiological and biochemical evaluation of these varieties revealed significant differences in these varieties under salt stress.

Chlorophyll a/b ratio

The chlorophyll a/b ratio (mg/g) of the selected maize varieties Iqbal and Pahari during the vegetative phase was evaluated (*Figure 1*). The results showed that the maximum chlorophyll a/b ratio was found for T6 (60 mM + NAA) in Iqbal and T12 (control + NAA) in Pahari. In Iqbal, the chlorophyll a/b ratio content of the vegetative phase of T12 was statistically similar to T9 (100 mM), T10 (100 mM + NAA) and T11

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18171834

(control), at P < 0.05. The chlorophyll a/b ratios of the two varieties were the lowest, T1 (20 mM), T3 (40 mM), T4 (40 mM + NAA) and T8 (80 mM + NAA), at P < 0.05, indicating that NAA did not have a role in induction. The positive effect of improving chlorophyll a content under salt stress.

Total chlorophyll content

The results in *Figure 2* show that the total chlorophyll content (mg/g) is the largest of the T11 treated (control) out of the two varieties, while in Pahari, the value of T12 (control + NAA) is significantly higher than that of T9 (100 mM) and T10 (T10). Similarly, (100 mM + NAA) at P < 0.05 at the nutritional stage. The minimum total chlorophyll content in two varieties of T1 (20 mM), T2 (20 mM + NAA), T5 (40 mM) and T6 (40 mM + NAA) was reported, at P < 0.05.

Carotenoid

A comparative study of carotenoid content (μg/g) was carried out at the nutrient stage (*Figure 3*). The results showed that the maximum carotenoid content of the two varieties was reported in the T12 (control + NAA) treatment. In Iqbal, the carotenoid content of T12 (control + NAA) was significantly similar to the T11 (control) of the vegetative phase, at P < 0.05. The lowest carotenoid content in the two varieties was T1 (20 mM), T2 (20 mM + NAA), T3 (40 mM) and T5 (60 mM), at P < 0.05, indicating that NAA did not have a role in carotenoid content. The positive role enhanced and influence the content is induced under salt stress.

Sugar

The sugar content (μg/g) was evaluated at the nutrition stage (*Figure 4*). The results showed that the maximum sugar content was reported for both T12 (control + NAA) treatments, while in Iqbal, the carotenoid content of T12 was significantly similar to T5 (20 mM), T7 (80 mM) and T11, at P < 0.05 nutritional stage. The lowest sugar content of the two varieties was reported as T1 (20 mM), T2 (20 mM + NAA) and T3 (40 mM), at P < 0.05.

Proline

A comparison of proline content (μg/g) was carried out at the nutrient stage (*Figure 5*). The results showed that the maximum proline content was detected of T10 treatment in both varieties, while the carotenoid content of T10 (100 mM + NAA) was reported in Pahari. In the vegetative phase, it was significantly similar to T4 (40 mM + NAA), T5 (60 mM) and T9 (100 mM), at P < 0.05. The lowest proline levels of T3 (40 mM), T4 (40 mM + NAA), T6 (60 mM + NAA) and T8 (80 mM + NAA) were reported, at P < 0.05, indicating that NAA is active in the enhancing effect of induction of sugar content changes under salt stress

Protein

Protein content (μg/g) was assessed during the nutrition phase (*Figure 6*). The results showed that the maximum protein content was reported in T10 (100 mM + NAA) treated Pahari and Iqbal. Pahari protein content T10 (100 mM + NAA) Iqbal is significantly similar to T2 (20 mM + NAA), T4 (60 mM + NAA), T7 (80 mM) and T12 (control + NAA) cultivars with the same vegetative phase at P < 0.05. The lowest protein content of T7 (80 mM), T3 (40 mM), T5 (60 mM) and T6 (60 mM + NAA) was reported, at P < 0.05, both of which indicated that NAA did not induce protein content under salt stress influences.

Anti-oxidant enzymes

Various biological processes in organisms result in reactive oxygen species (ROS) which cause oxidative stress. In response to such oxidative stress, organisms can deploy superoxide dismutase (SOD) and catalase (CAT) to scavenge ROS so as to protect the cellular homeostasis (Balaban et al., 2005). Plants have enzymatic and non-enzymatic antioxidant mechanisms that counteract the adverse effects of salinity. The former includes enzymes such as superoxide dismutase (SOD), catalase (CAT), guaiacol peroxidase (GPX), ascorbate peroxidase (APX) and glutathione reductase (GR). The latter includes compounds such as ascorbate, glutathione, flavonoids, and vitamins C and E (Noctor and Foyer, 1998). Thus, an imbalance between the production of free radical species and the cellular antioxidant defence system will produce an appearance of oxidative stress. Cell damage caused by excess free oxygen free radicals has been explained as a result of changes in the cell membrane produced by acid oxidation of the lipid bilayer, a process known as lipid peroxidation. This produces changes in chemical composition and deterioration of cell membrane ultrastructure, reduces their fluidity, alters their permeability, and inactivates enzyme and membrane channel receptors (Mansour and Salama, 2004).

Peroxidase

Comparison of POD (OD/mint/g) in the selected maize varieties including Iqbal and Pahari at the vegetative stage was made from the plant samples collected from the designed experiment (*Figures 7,8*). The results showed that the T12 (control + NAA) treatment of both varieties reported the maximum POD, while the POD activity of Pahari, T12 (control + NAA) was significantly similar to T2 (20 mM + NAA) and T4 (40 mM + NAA). T6 (60 mM + NAA) and T8 (80 mM + NAA) at P < 0.05 at the vegetative stage. The lowest POD activity among the two varieties was T1 (20 mM), T7

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18171834

(80 mM) and T9 (100 mM + NAA), at P < 0.05, indicating that NAA has a positive role in the improvement of POD activity under salt stress induction.

Superoxide dismutase

The SOD activity (OD/min/g fw) in the selected maize varieties including Iqbal and Pahari at the vegetative stage was made for the plant samples collected from the designed experiment (*Figure 9*). The results showed that the maximum SOD was reported for both T12 (control + NAA) treatments, while in Iqbal, the SOD activity of T12 (control + NAA) was significantly similar to T2 (20 mM + NAA) and T4 (40 mM + NAA) and T6 (60 mM + NAA) in the vegetative phase at P < 0.05. It was reported that T9 (100 mM + NAA), T7 (80 mM), T10 (100 mM + NAA) and T11 (100 mM + NAA) had the lowest POD activity in two varieties, at P < 0.05, indicating that NAA acts to induce SOD activity under salt stress.

Discussion

Effect of nephthyl acetic acid foliar spray on the physiological character of maize under salt stress

The importance of this study shows significant changes in all physiological indicators of all maize genotypes. For both genotypes, all treatments showed significant changes in chlorophyll content under control and salinity conditions. During the vegetative growth phase, an increase in salt stress resulted in an increase in Pahari's chlorophyll "a", chlorophyll "b", chlorophyll "a/b" ratio and total chlorophyll content, and a decrease in registered Iqbal (*Figure 1*). The application of nephtyl acetic acid (NAA) showed a significant increase in both Iqbal and Pahari in both conditions (saline and control). Current surveys show a significant increase in the levels of chlorophyll "a"

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18171834

(*Figure 1*) and chlorophyll "b" (*Figure 2*) as the salinity of the two germplasm stages decreases. These results are consistent with the views of Jamil et al. (2012). They believe that the content of chlorophyll a (Chl a), chlorophyll b (Chl b) and total carotenoids in salt-stressed plants are significantly reduced, depending on the NaCl concentration. Salinity has a greater effect on chlorophyll "a" than chlorophyll "b". In Basmati 385, chlorophyll "a" is disturbed by salinity. In the current study, chlorophyll content was significantly reduced under salt stress because chlorophyll content was sensitive to salt experience, and salt stress caused a decrease in chlorophyll content (Ashraf et al., 2004; Elgamaal and Maswada, 2013).

Current studies indicate that chlorophyll content "a" (*Figure 1*), chlorophyll "b" (*Figure 2*), chlorophyll a/b ratio (*Figure 3*) and total chlorophyll content (*Figure 2*) are significant ($P < 0.05$) with all consent. The increase in duration of salt stress during the somatic cell phase. In all treatments, GAs (gibberellin 5 mM) showed the best result with increased chlorophyll content, and GA (gibberellic acid 10 mM) also showed a significant increase with increased chlorophyll content. These results are similar to those of Aldesuquy and Gaber (1993), who reported the use of gibberellic acid to increase plant growth and pigment content. Carotenoids act as unique pigments and activate the defense system, but the effects of SA are not significant under stress-free conditions. Current studies have shown a significant increase in carotenoid content (*Figure 5*) in both materials (*Figure 5*) ($P < 0.05$), increased salinity in the vegetative growth phase and decreased carotenoid content as saline conditions decrease. At the somatic stage, the extreme increase in carotenoid content is a consideration when added Iqbal variety in (*Figure 5*) initially increased but decreased at the minimum NaCl treatment, while the maximum increase in carotenoid content observed when Pahari was added (*Figure 5*). Increasing carotenoid levels under salt stress can express a tolerant genotype because it may be a mechanism to escape stress (*Figure 5*). Carotenoids successfully eliminated singlet oxygen from primary photochemical reactions, so there is a close relationship between leaf carotenoid content and leaf genotype production of tomato genotypes under salt stress (Juan et al., 2005; Sami et al., 2016).

The current results show that under salt stress, most of the treatments increased significantly, while under salt stress, the increase of Iqbal variety increased significantly, while Pahari increased significantly under the maximum and minimum salt stress. Under salinity and control conditions, all treatments showed the lowest proline content in Iqbal, but the greatest increase in proline content under minimal saline conditions (*Figure 7*). NAA foliar application in Iqbal showed its effect in both conditions, whereas, in foliar sprays, no effect on Pahari was observed under both conditions of vegetative phase ($P < 0.05$). These results are consistent (Cha-um et al., 2009; Tůmová et al., 2018). Salt-tolerant plant species may survive salt stress conditions using other defense mechanisms such as ionic homeostasis, anti-oxidation and hormonal systems (Sami et al., 2016; Zhang et al., 2006). Therefore, the evaluation of many parameters in salt-stressed plants will lead to the identification of some valid criteria for the classification of plants for salt tolerance.

Sugars are compatible solutes which accumulate in plant tissues that are exposed to abiotic stresses, such as water deficit, or dangerous salt stress. Addition of solutes especially proline, glycine-betaine, and sugar is a common observation under stress condition (Al-Temimi et al., 2013; Qasim et al., 2003; Tůmová et al., 2018). All treatments showed a significant increase in sugar content under both salinity and control conditions in all two genotypes Iqbal and Pahari, but initially sugar content was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18171834

increased. Present investigation revealed that sugar content (*Figure 6*) significantly (P< 0.05) decreased but increased with the increase in the duration of water stress at vegetative stages in all accessions. At vegetative stage maximum increase in sugar content was observed in Pahari (*Figure 6*). Our result is similar to the work of those (Al-Temimi et al., 2013; Shah and Bano, 2012; Kareem et al., 2017), who suggested that salinity increased sugar contents, protein, proline and superoxide dismutase (SOD), peroxidase (POD), catalase (CAT) and ascorbate peroxidase (APOX) activities. Gemes et al. (2008) have described that SA application increased the soluble sugar content of tomato plants exposed to salt stress. Sugars are compatible solutes which accumulate in plant tissues that are exposed to abiotic stresses, such as water deficit, or dangerous salt stress (Morsy et al., 2007; Kareem et al., 2017).

The effect of the current examination showed that all treatments of Iqbal increased significantly under saline conditions, while Pahari was added, some treatments began decrease significantly, under minimal saline conditions and then increased (*Figure 8*). All treatments resulted in a significant increase in sugar content of Iqbal and Pahari under salinity compared to the control. Application of NAA foliar spray in Pahari did not show its effect in both conditions (salinity and control), whereas, in Iqbal, the foliar spray was significant for both conditions of the plant growth period (salinity and control) (P < (0.05). Our results are compared with Jamil et al., 2012. By increasing the salt concentration, a significant decrease in the protein content of rice plants under stress was observed. Khan and Srivastava (1998) and Shanker et al. (2014) also reported a decrease in chlorophyll and protein content with increasing NaCl.

The current analysis showed that all treatments of the Iqbal population were significantly increased under saline conditions, while some treatments initially decreased significantly and then decreased under minimal saline conditions when Pahari was added (*Figure 9*). All treatments resulted in a significant increase in peroxidase (POD) (*Figure 8*), superoxide dismutase (SOD), catalase (CAT) and ascorbate peroxidase (APOX), levels of Iqbal and Pahari under saline conditions compared to the control. Application of NAA foliar application in Iqbal did not affect both conditions (salinity and control), while foliar application in Pahari had significant effects on both vegetative conditions (salinity and control) (P < 05). According to Garratt et al. (2002) plants containing high concentrations of antioxidants showed considerable resistance to oxidative damage caused by reactive oxygen species.

Conclusion

The study was meant to evaluate the outcome of nephthyl acetic acid on chlorophyll content, protein, proline, sugar, and carotenoid along with certain enzyme activates (POD, SOD, CAT, and APOX). It was concluded that both varieties namely Iqbal and Pahari showed a different level of salt tolerance. All of the antioxidative enzyme activities (POD, SOD, CAT, and APOX), sugar, proline and protein contents reached maximum values in treatment T2, T4, T10, and T12 under saline condition Pahari. On physiological basis variety Pahari was found the most tolerant to the saline condition and responsive to the exogenous supply of NNA while variety Iqbal was more sensitive to salt stress. However, further studies into the best method of application of the bio-regulator to achieve optimum effect should be encouraged and the possiblity to combine treatment of bio-regulators to improve plant productivity should also be considered.

Recommendations

The salinity stress is a major salt stress limiting factor affecting crop yield, much research has been conducted to develop plants with improved salt tolerance. Salinity stress affects many aspects of plant physiology, making it difficult to conduct comprehensive research. Instead, the plant's response is broken down into a trait that is assumed to be involved in the overall tolerance of the plant to salinity.

Abstract. Information about land covers is essential for a variety of purposes, such as environmental studies, sustainable development, and regional managements. This study aims to use a novel combination model to generate a land cover map in a part of the Cameron Highlands, Malaysia, where there are different kind of land covers, including tea plantation, florification and forest. Because of the high similarity in land covers of the study area, only through satellite imageries with a high spatial and spectral resolution the land covers can be differentiated. We have combined satellite imageries of Sentinel-1 (S1A, GRD, IW) and Landsat-8 (Operational land imager) for the year 2017 as well as different algorithms of Maximum Likelihood (ML), Minimum Distance (MD), Support Vector Machine (SVM), Spectral Angle Mapper (SAM) and Artificial Neural Network (ANN). The results showed that the combination model is an applicable technique for extracting land covers in areas with high similarities in land covers. The overall accuracy of the confusion matrix and the Kappa Coefficient are 98.1984% and 0.9579, respectively, which indicate that it is a robust model for extracting land covers in areas like the Cameron Highlands. The obtained results can be useful for different purposes, including urban and environmental management, change detection, agriculture and many more purposes.
Keywords: *land use, satellite data, remote sensing, geographic information system, Cameron Highlands*

Introduction

Information about Land Covers (LC) and changes affecting them is essential for many purposes, including urban planning, vegetation and environmental issues (Shahabi et al., 2012; Chen et al., 2015; Gómez et al., 2016). Combination model refers to the ability of using two or more satellite imageries, in which we can improve the spectral resolution to detect the land covers more precisely. In recent years, database and methodology for creating a land cover map have undergone considerable changes (Tehrany et al., 2014; Megahed et al., 2015). Advancements in Remote Sensing (RS) technology and also a demand for using them for different issues have made it a the most used technology for gaining information about earth surface objects since 2 decades ago (Walker and Blaschke, 2008; Belward and Skøien, 2015; Ma et al., 2017).

Land cover has been undergoing considerable changes in either local or global scales (Megahed et al., 2015; Miettinen et al., 2016). Land cover mapping is not an easy issue and needs considerable attention regarding both data collection and model selection (Megahed et al., 2015; Khatami et al., 2016). Selecting data sets should be based on the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18351848

study area and the kinds, shapes and color of the land covers, which help us to select appropriate satellite imagery (Moser et al., 2013; Tehrany et al., 2014; Hasmadi et al., 2017). Since the study area is one of the touristic destinations for both locals and foreigners, so its preservation for Malaysian government is vital.

One of the highlighted issues when generating a land cover map from satellite imagery is the spectral and the spatial resolutions (Griffiths et al., 2013; Poursanidis et al., 2015). However, the precise information about land cover is highly essential. Until about 15 years ago land cover data bases were in form of pre-existing maps, gathered from field survey and previous maps (Griffiths et al., 2013). From two decades ago onwards, RS and Geographical Information System (GIS) have drawn researcher’s attention toward using satellite imagery and machine learning algorithms (Loveland et al., 2000; Tehrany et al., 2014).

Many studies have been conducted with the land cover mapping using different models, techniques and satellite imageries, including global land cover map using Landsat satellite imageries and SVM algorithm (Gong et al., 2013); object-based and pixel-based approaches using SPOT-5 satellite imagery (Tehrany et al., 2014); airborne LiDAR data (Yan et al., 2015); different algorithms of Savitzky-Golay, asymmetric Gaussian, double-logistic, Whittaker smoother and discrete Fourier using MODIS imagery for Great Lake, USA (Shao et al., 2016); supervised and unsupervised algorithms using SPOT-5 satellite imagery (Hasmadi et al., 2017); hyperion data using SVMs classifier (Lamine et al., 2018).

The main objective of the current study was to use a novel combination model for extracting land covers in a part of the Cameron Highlands, Pahang, Malaysia. However, this study dealt with two significant combinations of satellite imageries (Landsat-8 and Sentinel-1), and also combination of different algorithms of ML, MD, SVM, SAM, and ANN by using a Decision Tree (DT) model.

Materials and methods

Description of the study area

The study area is a part of the Cameron Highlands, Pahang, Malaysia between longitudes 101° 20’ 00” E to 101° 27’ 10” E and latitudes 4° 23’ 30” N to 4° 31’ 10” N (*Fig. 1*). This scope with an area of 81.249 km^2 is located approximately in the south-western part of the Cameron Highlands (Tien Bui et al., 2018). The lowest and the highest area of the study area is 912 and 1960 m above the sea level, respectively. However, the average rainfall fluctuates between 1800 mm to 3000 mm annually (Jebur et al., 2015; Tien Bui et al., 2018).

Data collection

Sentinel-1 is a part of the Copernicus Programme conducted by the European Space Agency (ESA). This product consists of the two satellite platforms of 1A and 1B. It has four sensor modes (Strip Map (SM), Interferometric Wide Swath (IW), Wave (WV), and Extra Wide Swath (EW)), and three product types namely, Ground Range Detected (GRD), Single Look Complex (SLC), and Ocean (OCN) (Potin et al., 2012). In this research, we have acquired Landsat-8 and Sentinel-1 satellite imageries for the year 2017 online for free from www.earthexplorer.usgs.gov and www.scihub.copernicus.eu,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18351848

respectively. *Table 1* and *Figure 2* illustrate the technical characteristics of satellite data and geographical position of the study area on the satellite imageries, respectively.

Research methodology

Using Sentinel Application Platform (SNAP) software and Environment for Visualizing Image (ENVI) software, either images radiometrically, spectrally and geometrically were corrected, co-registered and stacked. Using pan-sharpening command in ENVI software, the spatial resolution of Landsat-8 improved to 15 m by its panchromatic band, then via co-registration process the spatial resolution of Landsat-8 (Slave image) enhanced to 10 m by Sentinel-1 as the master image.

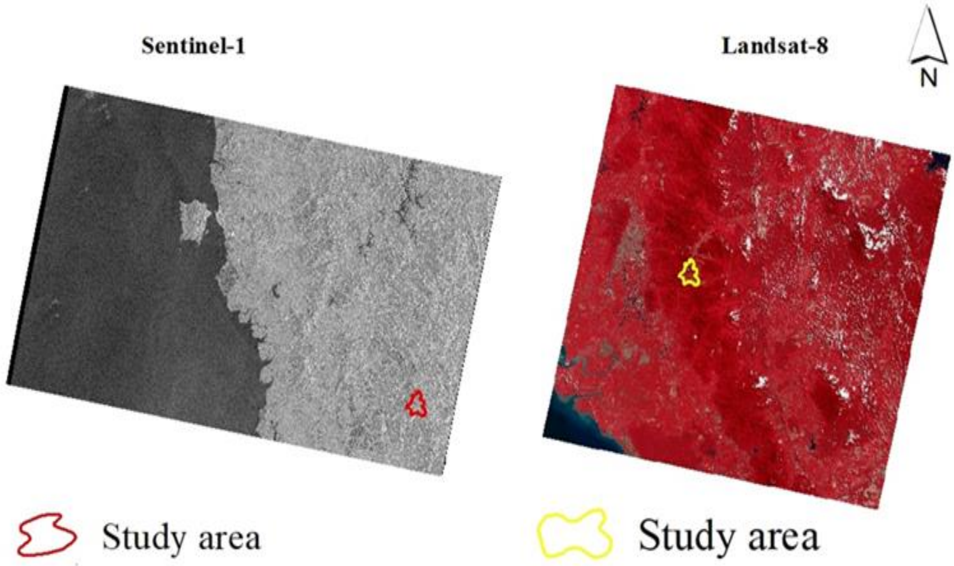

Figure 2. *Shows scope of the study on the satellite data*

After picking up the Region of Interests (ROIs) from co-registered image, different algorithms of maximum likelihood, minimum distance, support vector machine, spectral angle mapper and artificial neural network, were applied for classification. Each algorithm has shown a 1 or 2 land covers better, therefore in order to use the information of all algorithms, the DT method was used. Finally, after the post classification process, to evaluate the overall accuracy some Ground Control Points (GCPs) were extracted using Google Earth (For water body) and field checks for the other land covers (*Fig. 3*). Using ArcGIS the raster map was converted into a vector file and then was dissolved as the number of land covers. Moreover, after calculating the area for each land cover, the attribute table was imported into Microsoft Excel for calculating the total area and creating the final output table.

Description of the used algorithms

Maximum likelihood (ML)

Maximum likelihood model assumes that the statistics for each class are normally distributed and measures the probability that a given-pixel belongs to a certain class (Stamatakis, 2006). Each pixel is assigned to a class, which has the highest probability (Richards and Richards, 1999; Stamatakis, 2006). Once the highest probability has been smaller than the threshold, then the pixel remained unclassified (Richards and Richards, 1999).

Minimum distance (MD)

The minimum distance classification utilize the mean vector of every endmember and measures the Euclidean distance from unknown pixels to the mean vector for each class (Abtan et al., 2017; Kolesár, 2018). Based on the specified standard deviation, number of classes and a distance threshold, all pixels will be classified to the nearest class, however, some pixels may remain unclassified if they do not meet the selected criteria.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18351848

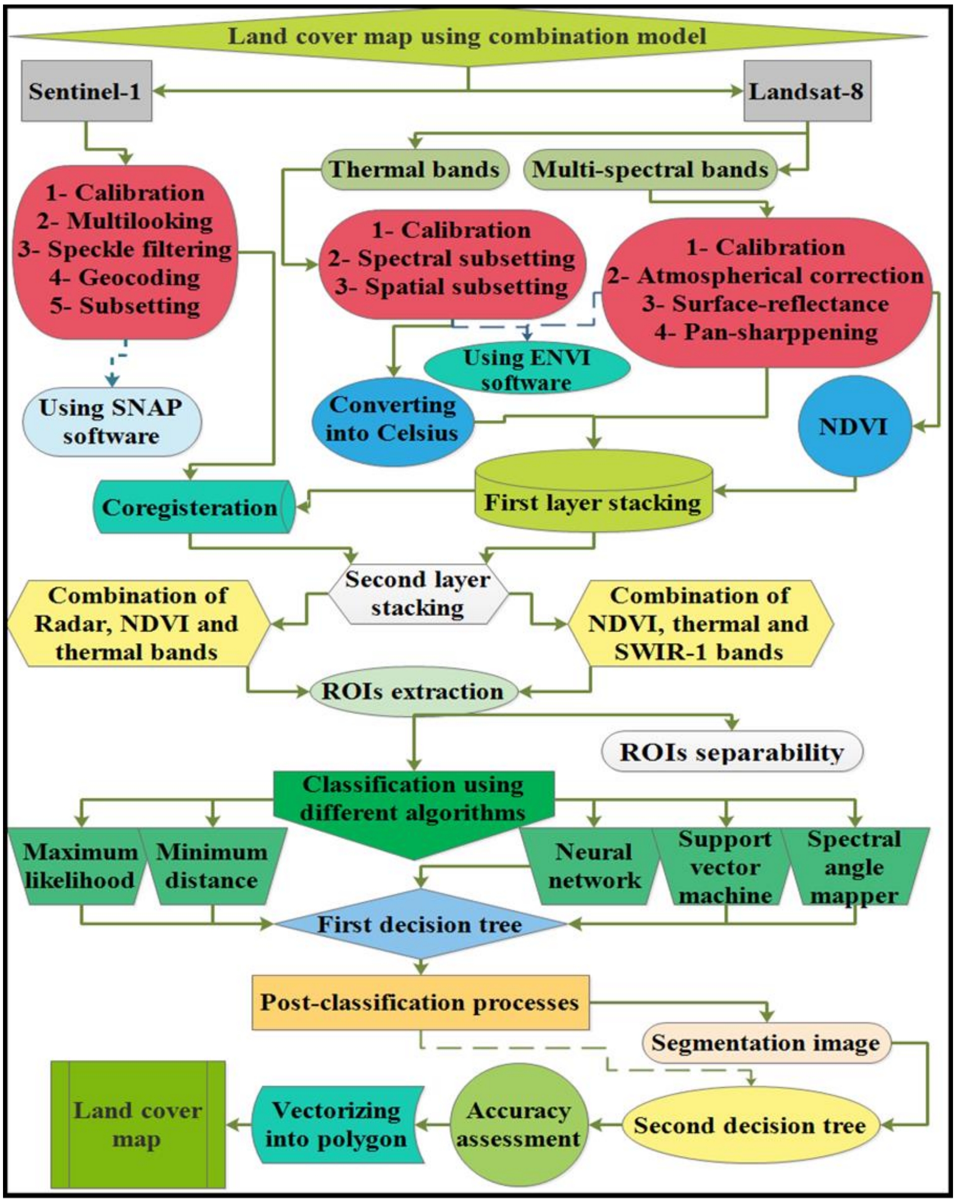

Figure 3. *Methodology of the study*

Neural network (NN)

The neural network technique implies standard back-propagation for a supervised learning (Yoshida and Omatu, 1994). You can choose a number of hidden layers to use and also you can select between hyperbolic or logistic activation functions (Zhang and Foody, 2001). The NN algorithm can be used to perform non-linear classification (Scott et al., 2017). In this model, the error is back-propagated through the network and weight adjustment is made by using a recursive method (Scott et al., 2017; Chakraborty and Roy, 2018).

Support vector machine (SVM)

The SVM is a fast and accurate model for the land cover/ land use studies (Sukawattanavijit et al., 2017). This model provides a good result from noisy and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18351848

complex data (Gu and Sheng, 2017). It tries to separate the created classes with a decision surface, which maximizes the margin between the selected classes (Mohammadi et al., 2018). Despite this fact that the SVM is a binary classifier, it works as a multiclass classifier as well, provided that several binary SVM classifiers are combined (Gu and Sheng, 2017; Mohammadi et al., 2018). The classifier performs training at a lower resolution level, because retraining at each level provides higher accuracy for the resampled image, however, it considers the rule image values to identify those that exceed the probability threshold (Sukawattanavijit et al., 2017; Mohammadi et al., 2018).

Spectral angle mapper (SAM)

The SAM classifier is a physically-based classification that utilize an n-D angle to match pixels to reference spectra (Renza et al., 2017). The model determines the spectral similarity between two different spectra by calculating the angle among the spectra (Kumar et al., 2015). End-member spectra used by SAM model can come from ASCII files, spectral libraries, and you can extract them from Region of Interests (ROIs) (Renza et al., 2017; Yan and Roy, 2018). SAM compares the angles between the end-member spectrum vector and each pixel vector in n-D space (Yan and Roy, 2018). However, smaller angles represent a closer match to the reference spectrum.

Decision tree (DT)

A DT is a type of multistage classifier, which can be applied to a single imagery or a stack of images (Chasmer et al., 2014). It comprises of a series of binary decisions, which are applied to determine the correct group for each pixel (Hua et al., 2017). It can be based on the available characteristics of the dataset (Lu et al., 2014). As an example, you may have an elevation dataset and two multispectral imageries that collected at different times, and any of those images can contribute to decision within the same tree.

Validation

The confusion matrix is important to validate statistical classification (Stehman, 1997). Overall accuracy is calculated by measuring the number of corrected classified pixels then dividing them by the total number of pixels (*Eq. 1*) (Jensen and Lulla, 1987). Kappa coefficient is measured through multiplying the total pixel classes by the sum of the confusion matrix, then subtracting the sum of ground truth pixels in a class times the sum of classified pixels in that class summed over all classes (*Eq. 2*).

$$OA = \frac{1}{N}\sum P_{ii} \quad \text{(Eq.1)}$$

where: OA = total accuracy, N = total number of test pixels, and $\sum P_{ii}$ = total pixels that are correctly classified.

Equation for the Kappa coefficient is written as below:

$$K = (OA - \frac{1}{q})(1 - \frac{1}{q}) \quad \text{(Eq.2)}$$

where: K = kappa coefficient and q = unclassified pixels.

Results and discussion

One of the most important steps in extracting ROIs is the separability assessment of them (Laurin et al., 2013; Megahed et al., 2015; Levin, 2016). However, the value for measuring the ROIs separability is between 1 and 2, the values less than 1.8 are not acceptable (Laurin et al., 2013). The higher the value the more precise the ROIs are (Levin, 2016). *Table 2* illustrates the least to most separability values of extracted ROIs for this study.

Table 2. *Pair separation of ROIs (least to most)*

Vegetation/florification and township = 1.99	Water body and cleared forest = 1.99
Vegetation/florification and tea plantation = 1.99	Township and tea plantation = 1.99
Road network & vegetation/florification = 1.99	Cleared forest & vegetation/florification = 2
Road network and township = 1.99	Forest and water body = 2
Forest and township = 1.99	Forest and road network = 2
Cleared forest and township = 1.99	Forest and cleared forest = 2
Water body and township = 1.99	Water body and tea plantation = 2
Water body and road network = 1.99	Cleared forest and tea plantation = 2
Forest and vegetation/florification = 1.99	Forest and tea plantation = 2
Water body & vegetation/florification = 1.99	Cleared forest and road network = 2
	Road network and tea plantation = 2

It is worth mentioning that the pair separation of the extracted ROIs from the combination of Sentinel-1 and Landsat-8 satellite imageries showed that this model is a robust way in extracting ROIs for generating land cover maps (*Fig. 4*).

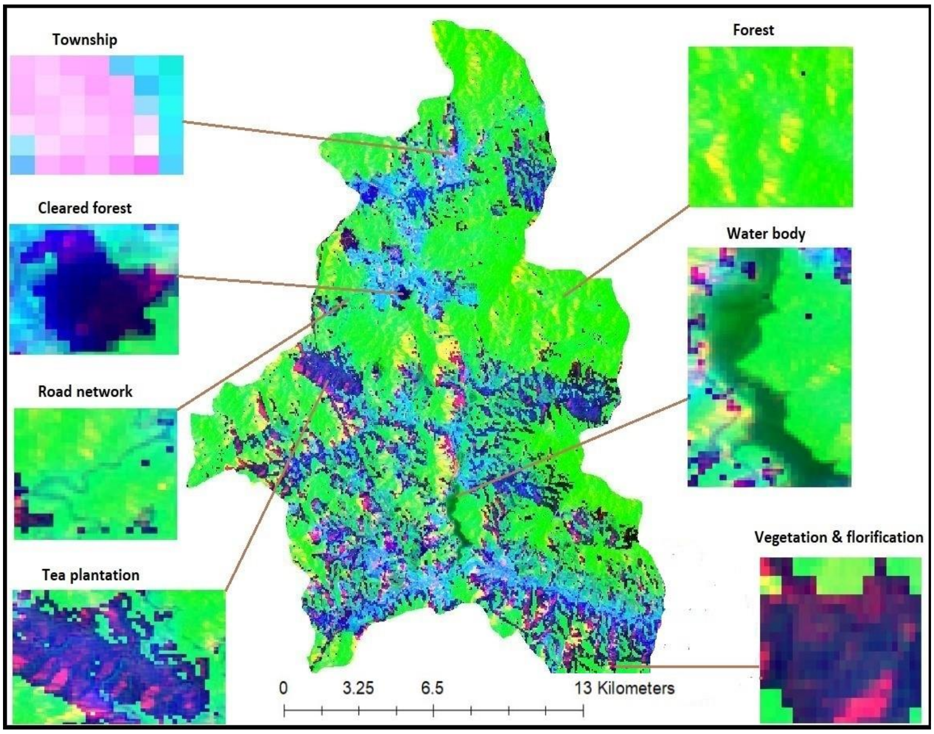

Figure 4. *Different land cover's tones using combination model*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18351848

As a matter of fact, the land covers were extracted based on the ROIs extraction, where every land cover has its own reflection in the satellite imagery. If we do not extract the ROIs for one single land cover with a different reflection, it will remain unclassified. In this study, because of the different reflection in the satellite imagery, the tea plantation fields are separated from the vegetation coverage, spatially and statistically. Overall, a total number of 6 land covers were extracted for the study area (*Table 3* and *Fig. 5*). Using ArcGIS and Microsoft Excel the area of extracted land covers were calculated and finalized. The vegetation and florification fields as well as the forest areas have the biggest area among all of 39.13176 km^2 and 33.90341 km^2, respectively. However, water body has the smallest area of only 0.364556 km^2.

Table 3. *The area of extracted land covers*

No	Name	Area km^2
1	Forest	33.90341
2	Water body	0.364556
3	Tea plantation	3.024364
4	Township	4.139532
5	Vegetation and florification	39.13176
6	Cleared forest	0.436157

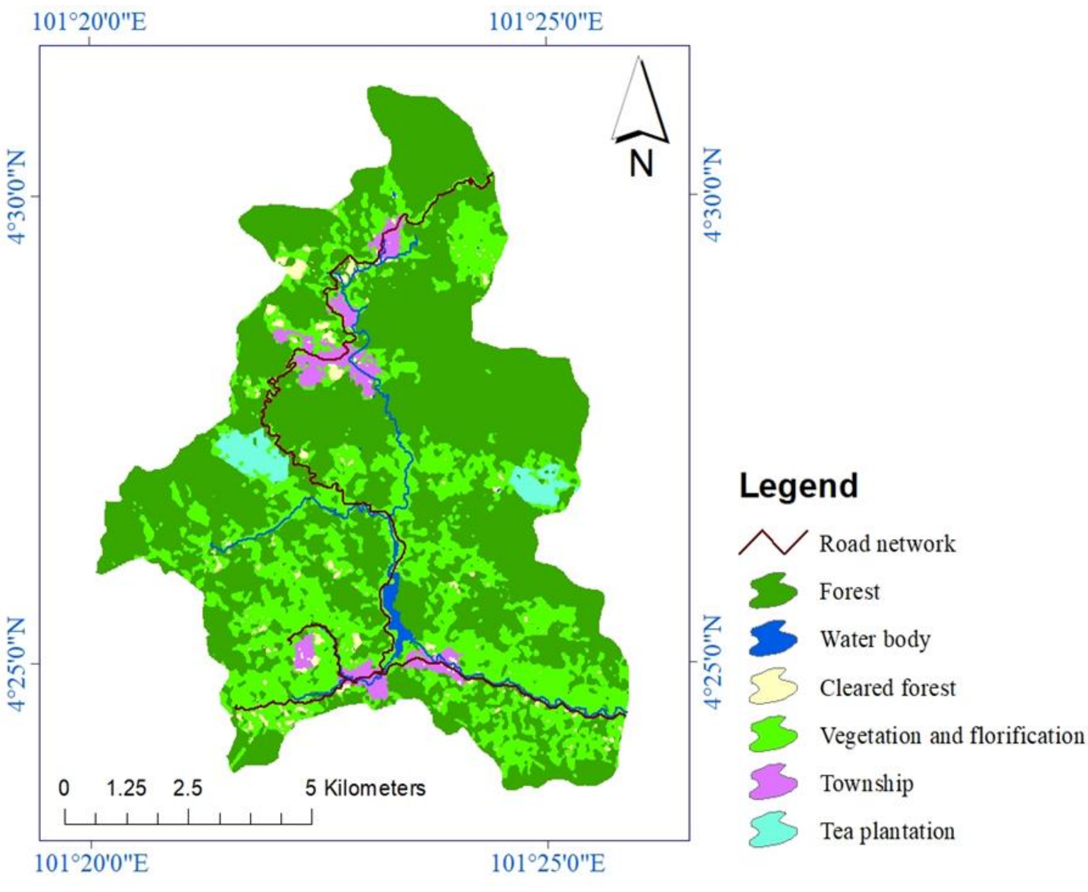

Figure 5. *Land cover map of the study area*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18351848

Validation

Validation of land cover map is important to show the quality of used methods and techniques (Chen et al., 2017; Ma et al., 2017). Using a handheld Geographic Positioning System (GPS), a total number of 20 Ground Control Points (GCPs) were picked up for each land cover (Except the water body, where the Google Earth was employed for extracting GCPs for) by Ayub Mohammadi on Thursday 19 July, 2018 (*Fig. 6*). Because of the hilly situation of the Cameron Highlands, the GCPs were extracted near the main road and the accessible areas only. However, these GCPs were applied for validation purposes using the overall accuracy and Kappa statistic. *Table 4* lists the result of the validation.

Comparison of the combination model with a single model

Using Enhanced Thematic Mapper plus (ETM+) satellite imagery for the date 06/09/2017 and Support Vector Machine (SVM) model, the land covers of the study area were extracted to compare with the combination model. Based on the results there are not too much differences between the two models statistically. The most considerable change has occurred inside the tea plantation area, where in the single model about 0.600 km^2 was added to the tea fields. At the same time, roughly 1.80 km^2 was decreased from the vegetation and florification areas (*Table 5*).

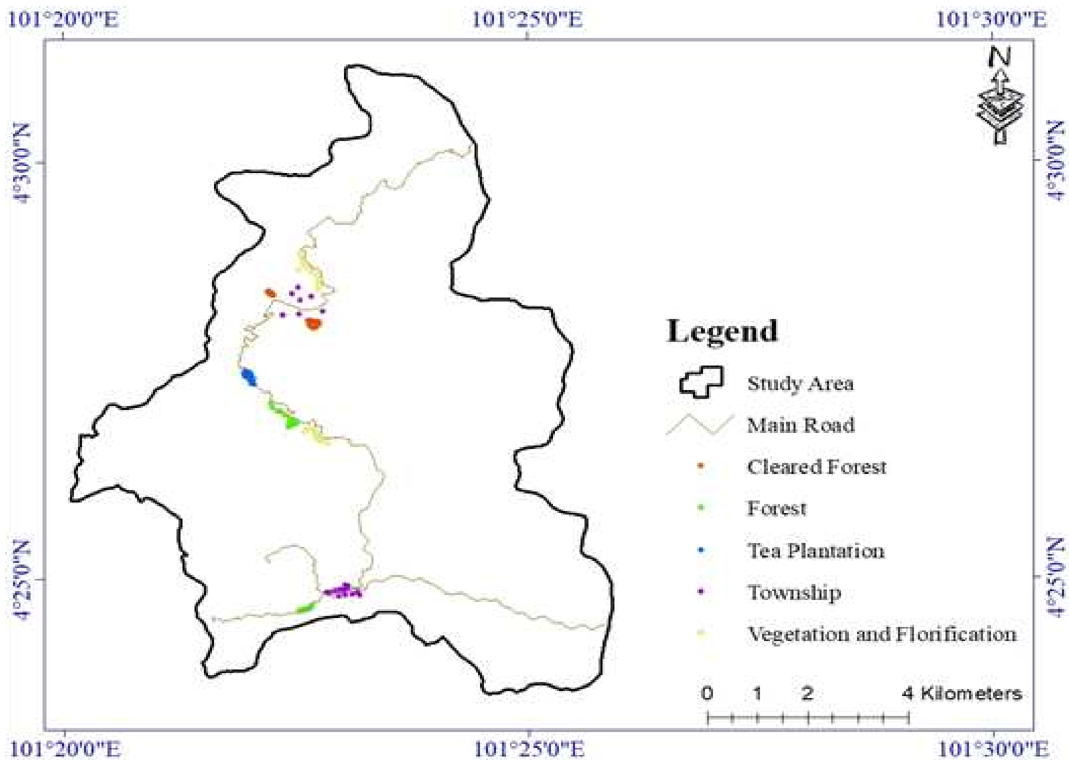

Figure 6. *Shows the geographical positions of the extracted GPS points*

Table 4. *Highlights the confusion matrix for this study*

Overall accuracy	**Kappa coefficient**
98.1984%	0.9579

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18351848

***Table 5.** Represents the area for extracted land covers from ETM+ and SVM model*

No.	Name	Area km^2
1	Cleared forest	0.429154
2	Forest	34.1433
3	Tea plantation	3.623
4	Township	4.63918
5	Vegetation and florification	38.0521
6	Water body	0.364556

As a matter of fact, compared to the Google Earth images (*Fig. 7*), the combination model has shown the final map more realistic. In the output map of the single model the land covers are seen more unrealistic (especially for the vegetation and florification fields; *Fig. 8*).

Conclusion

Information about land covers is essential for environmental issues. Combination model refers to using the ability of two or more satellite imagery or even different algorithms, in which we can improve the spectral resolution of them to detect the land covers more precisely. In this study, a novel combination model of satellite imageries of Sentinel-1 and Landsat-8 as well as the combination of different algorithms namely: maximum likelihood, minimum distance, support vector machine, spectral angle mapper, and artificial neural network were used for extracting land covers in a part of the Cameron Highlands, Pahang, Malaysia.

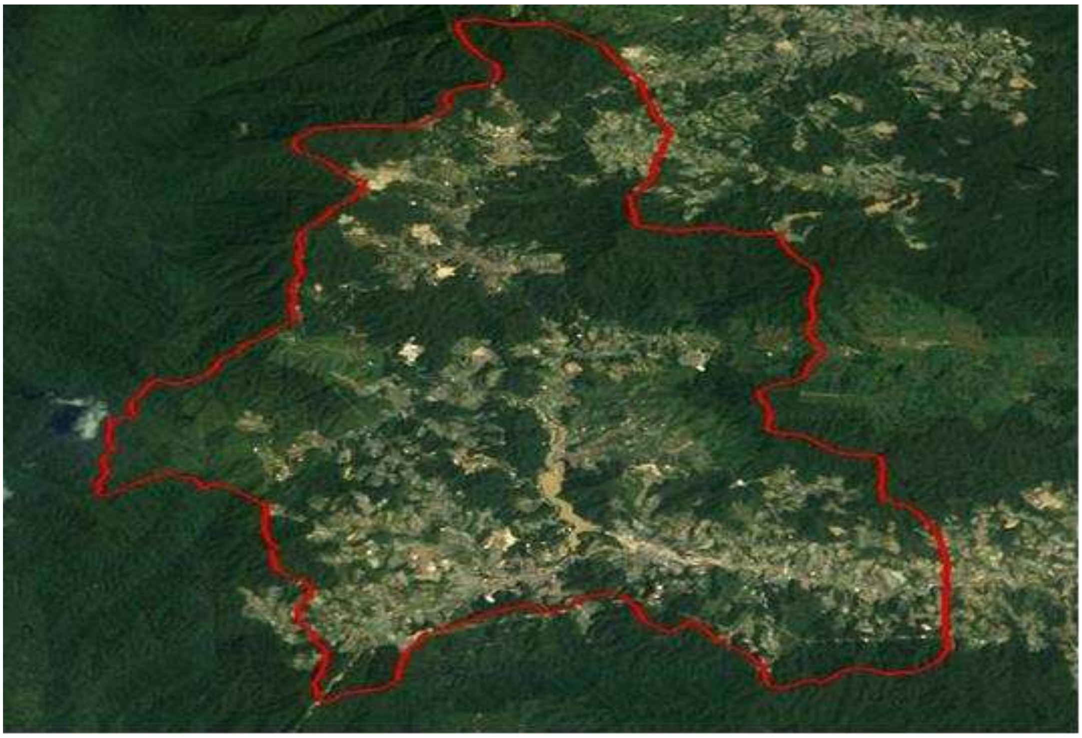

***Figure 7.** Shows the study area on the Google Earth image*

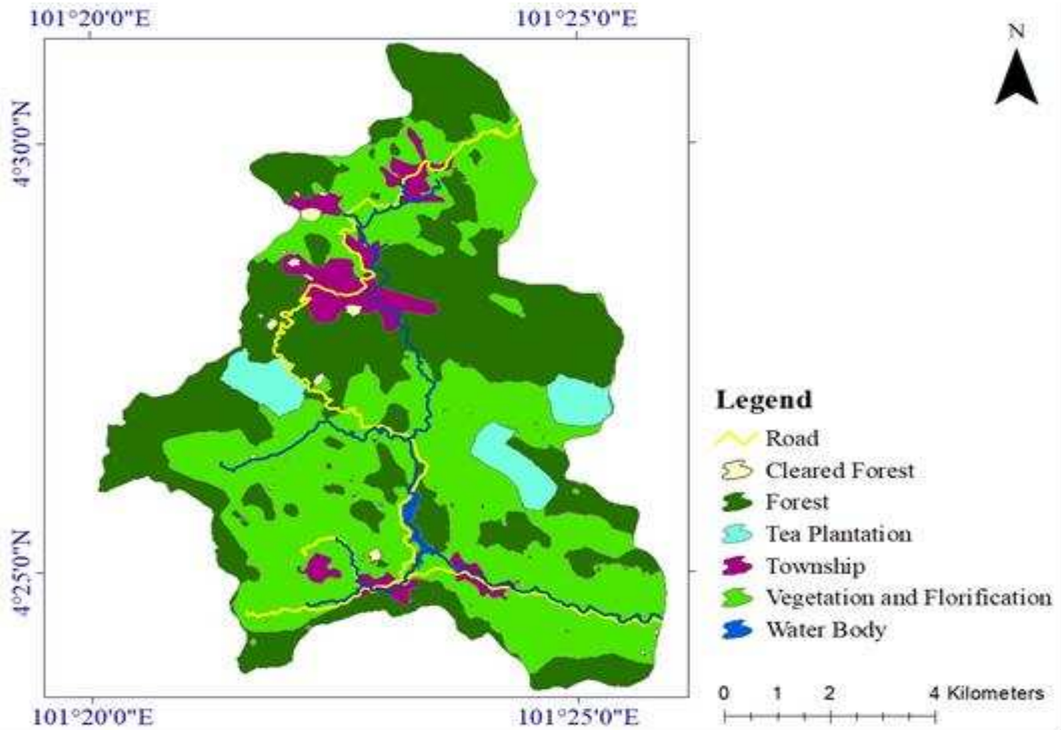

Figure 8. *Illustrations of the extracted land covers using ETM+ and SVM model*

However, a total number of 6 land covers were mapped, which using the Google earth and field survey all land covers were validated. Eventually, by a set of ground control points (GCPs), overall accuracy and Kappa statistic were measured of 98.1984% and 0.9579, respectively. It is noticed that the outputs of this study have promising results for multi-temporal monitoring of land covers in the Cameron Highlands for long term analysis. The obtained results showed that dual Sentinel-1 (S1A, GRD, IW) and Landsat-8 Operational Land Imager (OLI) are suitable satellite imagers for rapid land cover extraction in the geographical situation with high similarity in land covers.

(Received 22nd Oct 2018; accepted 7th Jan 2019)

Abstract. During the planning and design stages of visual resource management and landscape utilization, it is necessary to evaluate the visual quality of landscape elements, determining the requirement for their preservation, restoration, enhancement, and concealment. Turkey has the advantage of offering a wide range of visual resources to its visitors, shaped by its climatic and geographical features. The Van Lake Basin located in the Eastern Anatolia Region is of particular significance as it is one of the rare locations offering numerous visual resources to the visitors. Sustainable management of these resources is very important in terms of their contributions to the economic development of the region and its local population. Coastsal areas provide resources with limited landscape elements, that are hard to be reproduced. These elements play a critical role in recreation and tourism sectors. In respect of landscape architecture, coastal areas represent a combination of land and water, providing the visitors with the opportunity to enjoy the beauty of nature. The coastal areas around Van Lake have a high potential for recreation activities due to their richness of landscape resources. This study, therefore, aims to evaluate the landscape quality of Van Lake Basin by conducting a biophysical investigation of its coastal areas, containing considerable amount of landscape elements. The study determines the areas that should be prioritized for preservation or restoration, and reveals the most suitable precautions for their sustainability, taking into account their nature and identity.
Keywords: *visual resource, landscape quality, recreation activities, coastal area, Van Lake Basin (Turkey)*

Introduction

According to the European Landscape Convention, every country is obliged to identify, plan, preserve, and restore the landscape elements within their borders (Anonymous, 2000). Thus, it is necessary to evaluate the cultural and natural landscape properties of different regions in a country. The determination of human-environment interactions through the method known as “visual impact analysis” offers a solution for the challenge of improving a given environment in terms of its basic social and physical potential, and utilization of modern habitable areas in these areas (Bozhüyük, 2007). The coastal areas have been the most important habitable locations for numerous civilizations during history. The importance attributed to water as a visual landscape element dates back to the gardens of Mesopotamia and Egypt (Burmil et al., 1999). Many studies (Arriaza et al., 2004; Özhancı and Yılmaz, 2011) report that water aesthetically increases the quality of a given landscape.

Coşkun and Kaplan (2001) maintain that visual problems arising from changes in the urban landscapes lead to loss of prestige for the habitat and reduce the natural-cultural value of the location. Consequently, the studies evaluating the impact of such changes on the cultural properties, physical development, and loss of social life become extremely important (Hepcan, 2003). The cities with coastal areas suffer from certain limits due to interventions to the landscape. Generally, shorelines can provide a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18491864

valuable opportunity for recreational activities and tourism sector; the coastal line of the Van Lake and nearby regions are quite rich in this respect.

Review of Literature

Coastal Landscape

Coastal areas are landscape resources with limited landscape elements that are hard to reproduce, and they can provide the opportunity to enjoy the beauty of nature to their visitors as they represent the combination of land and water.

The strips of land that lie beside seas, lakes, and rives are called “coastal areas”. Coasts are some of the most rapidly evolving geographical formations on the face of the earth (Karabey, 1978; Duru, 2001). Coastal areas and shores are important resources that can meet the ever-increasing recreational needs of urban dwellers. While deciding on the physical planning of shorelines, it is important to balance the needs of the society with the natural potential, and to underline the identity and culture of the shoreline while preserving the integration of the settlement (Clark, 1996; Duru, 2001; Kaya, 2006; Gülez et al., 2007; Yazici, 2018). The populations of the coastal regions keep increasing all around the world. As a result of this phenomenon, the utilization of the landscape elements for recreational and tourism demands has been rising. Resultantly, coastal areas suffer from environmental problems that are very difficult -and sometimes outright impossible- to fix (Yılmaz, 2006).

The interest of humans on water resources have not been limited to seas, but have also been directed towards lakes and rivers. Activities like swimming, fishing, bird-watching, kayaking, sailing, windsurfing, and canoeing are conducted not only on seas but on the lakes as well (Soykan, 2000). Van Lake is the largest lake in Turkey, the largest alkaline lake in the world, and represents one of the most significant visual landscape resources of the region. As the lake is located over the migration routes of birds, it also provides for an ornithological and recreational potential as an ecosystem.

Visual Landscape Quality

Evaluation of a visual landscape is an inquiry for the location with the aesthetical criteria and elements determined beforehand in mind (Parsons and Danial, 2000; Palmer, 2003). In that regard, a visual landscape consists of a series of interactions between abiotic, biotic, visual, and cultural elements (Kane, 1981; Bulut and Yılmaz, 2007; Gruehn and Roth, 2008; Yazici, 2018). Visual landscape evaluation is a method utilized while comparing the aesthetical values of study areas, determining priorities during preservation efforts, and identifying the changes in the landscape character. During the planning and design stages of visual resource management and landscape utilization, it is necessary to evaluate the quality of visual landscape elements of the study area to prioritize their preservation, restoration, enhancement, and concealment (Kane, 1981; Palmer and Hoffman, 2001).

There are three approaches used in the determination of the visual quality of a given piece of landscape. These are the physical (topographical aesthetics), psychological, and psychophysical approaches (Daniel and Boster, 1976; Lothian, 1999; Daniel, 2001; Kaptanoğlu, 2006; Çakcı, 2007). In the perception-based evaluation method, a group of observers are asked to quantify the quality of the landscape they are observing or seeing through pictures (Daniel, 2001). Making use of photographs is a valid approach when

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18491864

determining the visual status of a landscape (Hall, 2001; Clay and Smidt, 2004; Çakcı, 2007; Dupont et al., 2017; Palmer, 2019).

As the visual quality of the landscape is naturally an extension and result of its physical properties, the evaluation in this method is based on the objective or physical approaches. According to Palmer (2019), bio-physical influences of a landscape should always be considered in the evaluations. The morphological-aesthetic approach where the landscape qualities and elements that are believed to have influence over the beauty of the sight -and have been analyzed in terms of their contents- shall be conducted by experts only. Since the evaluations of a single expert might be questionable, it is reasonable to conduct evaluations with at least five experts (Wherrett, 1996; Çakcı, 2007; SNH, 2013; Palmer, 2019). According to literature (BCMF, 1997; Clay and Daniel, 2000; Wu et al., 2006; Arriaza et al., 2004; Sevenant and Antrop, 2009; Uzun and Müderrisoğlu, 2011; Jahany et al., 2012; SNH, 2013; Huang, 2014; BLM, 2016) the biophysical parameters are the angle of visibility, the configuration and silhouette of visible borders, the silhouette of the land, the expanse, inclination, impression, land formations, surface relief, land cover, neighboring vistas, cultural properties, vegetation, richness in terms of species, and the presence of water.

Various studies have been conducted on the evaluation of visual qualities of landscapes. Smardon (1979) have counted color, texture, line, shape, and proportion properties with influence levels of low, medium, high, and irrelevant; and further quantized each element and created a numerical system. He grouped landscape elements as vegetation, water surface, and structure, and evaluated them numerically.

Ayad (2005) has researched the potential of GIS and distant perception methods in a coastal region in Egypt. He transferred the landscape properties of the study area into a GIS environment with numerical values and determined the utilization of land, distance to coast strip, cover, and topographical variations in the digital environment.

Huang (2014) has analyzed the landscape elements of Washtenaw County, Michigan, and evaluated the visual quality. In his study, Huang presented the participants with 50 photographs of various vistas from the study area, and asked them to sort the locations out based on their preferences and intuitions. He also conducted map-making analyses and visual quality evaluations. He found out that participants were inclined towards the vistas with natural properties.

Naspetti et al. (2016) used a selection of landscape images containing photovoltaic elements and conducted a Q-sort study. 34 participants, some of which were landscape and lighting experts, were presented with 54 landscape images. They were asked to sort them in three different categories to determine the best way of integrating photovoltaic systems into the urban and rural landscapes.

Keleş et al (2018) studied Edirne / Turkey, representing one of the most interesting cities of the region in terms of tangible and intangible cultural landscape elements. They presented a questionnaire and photographs of the landscape elements to a group of experts and asked them to evaluate the structures, textures, and characters. The results of the study were used in rational planning and preservation of the cultural resources by various authorities.

The Van Lake Basin, rich in physical geographical formations, contains various types of geomorphic elements. It also contains ancient settlements developed by numerous civilizations in its long history. Thus, the area contains various population and settlement types that are quite different from each other. As it is a closed basin, the area contains idiosyncratic elements and properties each of which should be inspected

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18491864

from different perspectives. This is a novel study since the evaluation of visual landscape qualities of settlements in the coastal lines of the Van Lake has never been carried out before. In the present study, significant settlement areas in the coastal lines of the cities of Van and Bitlis are inspected in terms of their visual landscape qualities using Q-Sort analysis. Q- sort analysis is a relatively new tool not only as approach but particularly following the quite recent rediscovery of its usefulness in those fields where psychometric knowledge of individuals have thorough implications (Kramer et al., 2003). Various biophysical parameters (general interest, naturalness, the presence of water, vegetation, topographic variation, natural and cultural elements, and color variety) are also investigated. The aim of the study is to present a reference point for future studies and efforts to remove the negative impact of various factors on the natural and visual landscape elements and to act as a guide for visual resource management, decision making/strategy, and restoration studies.

Materials and Methods

Material

The coastal strips of significant settlements on the shorelines of Van Lake Basin form the material of the study (*Figure 1*). These settlements belong to district of Erciş, Adilcevaz, Ahlat, Tatvan, Gevaş and Edremit, the most significant district in the region.

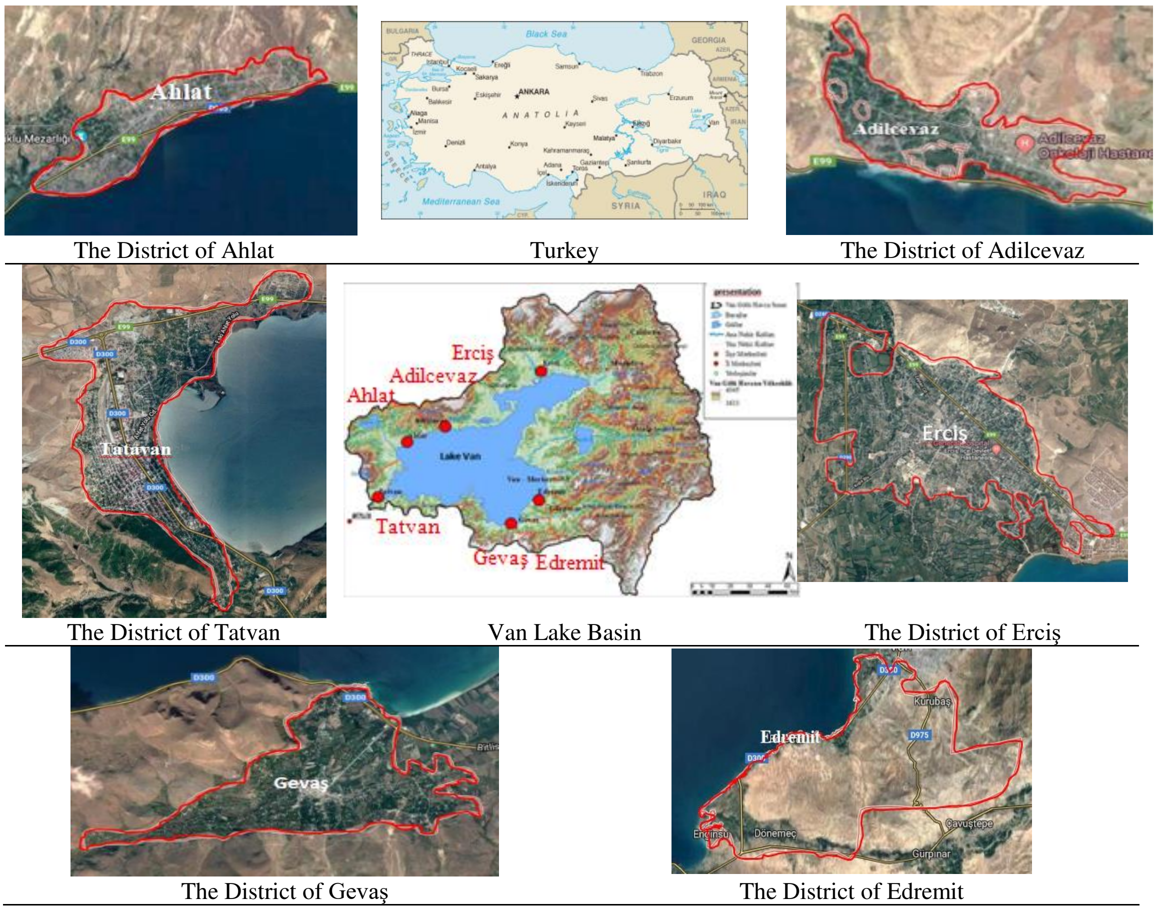

Figure 1. *Satellite images of settlements on the coastal regions of the Van Lake Basin*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18491864

The photographs of the coastal locations were taken between 09.00 and 17.00 in summer months using a digital camera. Areas open to the public were preferred, taking into consideration the active recreational use of the locations by the community. A total of 186 photographs were taken in 6 different coastal locations, 24 of them selected (4 from each location) for the final inquiry. The experts were then asked to specify a preference ratio for each location (*Table 1*), and each individual picture.

Van Lake is believed to have formed as a result of water gathering inside a crater formed by the explosion of the Nemrut volcanic mountain. The surface area of the lake is 3,713 km^2, and the lake contains numerous bays. It represents an aquatic ecosystem, different from both the fresh and saltwater ecosystems. With an elevation of 1646 meters, it is surrounded by volcanic mountain masses to the west and north, mountain ranges with steep slopes to the south, and a relatively lower morphological field towards east and northeast, creating a closed basin. The shores are grainy and pebbly, and contain numerous rocky or cliffy areas, presenting various areas of interest in terms of views and vistas.

The district of Erciş is approximately 100 km to the Van city center and is built over the Erciş plains. The district has an elevation of 1690 meters, influenced positively by the well-watered terrain, large number of streams and watercourses, and its coastal position. The area has numerous natural catchment areas. Many landscape design studies were conducted on the shorelines by municipalities in 2017 to provide recreational opportunities for the public (Anonymous, 2018a).

The district of Adilcevaz is positioned inside a valley surrounded by the skirts of the Süphan Mountain, positioned 71 km distance to the city center of Bitlis towards the northwest of the lake with an elevation of 1690 meters. Most of the district lacks a soil ground cover; thus, it is weak in vegetation. Local authorities have conducted various coastal landscape studies in order to increase the recreational use of the landscapes (Anonymous, 2018b).

The district of Ahlat is within the borders of Bitlis, with an elevation of 1545 meters, 44 km north of Tatvan district. The district is built over a plateau between Süphan and Nemrut Mountains and East Anatolia Region. Ahlat is located in the northwest shores of the Van Lake, and the coastal landscapes are actively used by the community, especially during summer (Anonymous, 2018b).

The district of Tatvan is also within the borders of Bitlis, approximately 25 km to the city center. With an elevation of 1671 meters and its position on a high elevation location towards the southwest of Van Lake, most of the district area is covered with mountains. Tatvan also has a historical importance as it is positioned over the Silk Road (Anonymous, 2018b).

The district of Gevaş is 35 km distant to the Van city center, built at an elevation of 1750 meters on the shorelines of the Van Lake. The district is quite rich in historical artworks and natural vistas. Gevaş is the favorite location of many tourists and local populations, particularly during the summer. Tatvan is located in the skirts of the Artos Mountain, the highest of the Kavuşahap Mountain range and the extension of the Southeastern Toros Mountains (Anonymous, 2018a).

Finally, the district of Edremit is only 15 km to the city center of Van within elevation of 1846 meters. With a south-southeastern orientation, the district is quite rich in natural and cultural landscape elements. Edremit has always been popular due to its beautiful shoreline, having a high value in terms of visual landscape (Anonymous, 2018a).

The touristic data regarding the provinces of Bitlis and Van where these settlements are located are as follows: According to Bitlis Province Directorate of Culture and Tourism 2018 data, the native and foreign tourist count that visited touristic facilities of Bitlis in 2017 is 179,639, of which 176,073 were natives and 3,566 were foreigners. According to Van Province Directorate of Culture and Tourism 2018 data, the native and foreign tourist count that visited touristic facilities of Bitlis in 2017 is 1,070.260, of which 584,040 were natives and 486,220 were foreigners.

Method

The method chosen for the evaluation of the visual landscape quality was a combination of methods in the literature by BCMF (1997), Wu et al. (2006), Çakcı (2007), Uzun and Müderrisoğlu (2011), Jahany et al. (2012), SNH (2013), BLM (2016), and Huang (2014), developed by Aşur (2017) (*Table 2*). The main criteria evaluated by the experts by looking at the photographs were their personal opinion of the general view, naturalness, presence (and clarity) of water, vegetation, topographical variation, man-made constructs with a positive contribution, and color variety.

Table 2. *The evaluation chart according to visual landscape biophysical parameters that developed by Aşur (2017)*

Landscape qualifications	Points				
	+2(Very beautiful n1)	+1(Beautiful n2)	0(Ordinary n3)	-1(Ugly n4)	-2(Very Ugly n5)
General view	I liked it very much	I like	normal	I do not like	I did not like at all
Degree of naturalness	Natural elements are very dominant	Natural elements less dominant	Natural elements half dominant	Natural elements are not dominant	Non-natural elements dominant
Vegetation presence	%80-100	%60-80	%40-60	%20-40	%0-20
Water view	Very dominant and clear water surface	Water surface is very visible but non-clear water	Water surface obvious	Water surface is obvious and dirty	appearance of the water is very bad, dirty
Topographic diversity	Very clear	Clear	Little clear	Not clear	Not at all clear
Presence of human-made positive elements / historical buildings and typical houses	%80-100	%60-80	%40-60	%20-40	%0-20
Variety of colors	Color variety is very and compatible	Color diversity less and compatible	Color variety less	Very little variety of colors	No variety of colors

In this study, because of the biophysical evaluation of visual landscape quality, expert opinions were consulted. Biophysical properties of the visual landscapes were quantized numerically (very beautiful as +2, beautiful as +1, ordinary as 0, ugly as -1, and very ugly as -2). 35 experts, all of whom had previously seen the locations in person, were presented with the 24 photographs from the 6 locations (4 from each location) with an online questionnaire. All the evaluations were recorded. Each of the 4 pictures for a given location was given a preference ratio by the experts. The value of a given piece of the landscape was calculated based on the scores given to them by the experts. A high score indicates a potentially desirable view and a high preference rate

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18491864

by the community. The results are listed in *Tables 3 to 8*. The Likert-scale scores explained above were then Q-sorted, revealing the meaningfully preferred locations over the others. In order to compute achieved points for each photo, the formula below is used (Kramer et al., 2003; Golchin et al., 2012).

$$N = \sum_{i=1}^{5} n_i (3 - i) \qquad \text{(Eq.1)}$$

N = Total points for each photo.
n1 = Number of users which choose very beautiful quality photo.
n2 = Number of users which choose beautiful quality photo.
n3 = Number of users which choose normal quality photo.
n4 = Number of users which choose ugly quality photo.
n5 = Number of users which choose very ugly quality photo.

Results and Discussion

As can be seen from the results (*Tables 3 to 8*), the image 2 E.C.L. was the most liked location in the Erciş coast (50.5% ratio), while the 1 Ad.C.L from the Adilcevaz coast (49.7%), the image 3 A.C.L from the Ahlat (56.6%), the image 3 T.C.L from the Tatvan (58.3%), image 3 G.C.L from the Gevaş coast (60.7%), and image 1 Ed.C.L. from the Edremit (59.8%) were the ones for every location earning the highest ratios. One common theme detected in these selections was the inclination towards natural beauties of shores, while the artificial landscape elements were mostly avoided. The assessment of study outcomes according to the 7 parameters of visual landscape quality; Q-Sort analysis of the expert opinions revealed that the coastal of the Gevaş district was the most preferred one amongst all the locations in terms of the beauty of the general view. Edremit and Tatvan coastal area follow closely.

As can be observed from *Table 9*, half of the 6 coastal locations have received higher view scores compared to the other 3. Adilcevaz shores were given the lowest score.

The standard deviation for the general view property of the expert evaluations of visual landscape value of Erciş, Adilcevaz, Ahlat, Tatvan, Gevaş and Edremit coastal areas are given in *Figures 2, 3, and 4*.

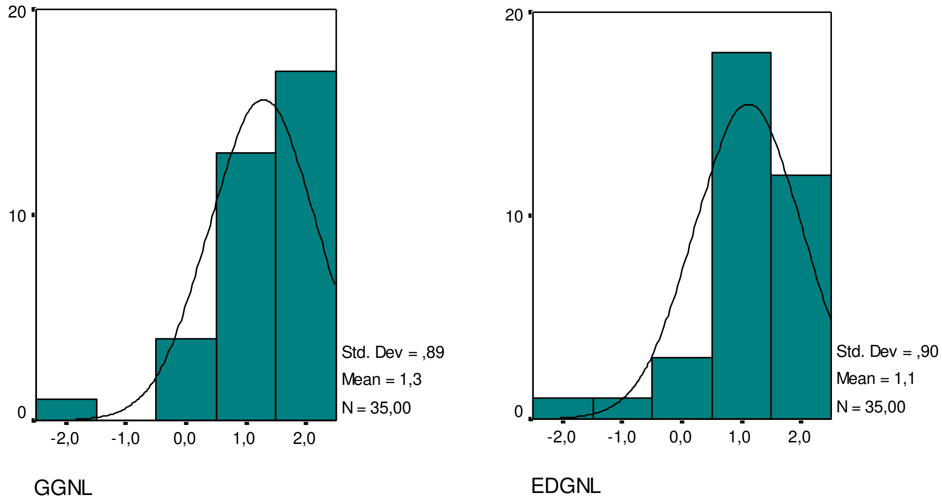

Figure 4. *Standard deviation values of general opinion evaluation by experts of visual landscape value of Gevaş and Edremit Coastal areas*

When the evaluation results of the Erciş's coastal area is investigated (the one with high level of flat topography) according to the visual landscape biophysical parameters it is found that: the lack of man-made elements contribute to the attraction of the locations in the coastal areas of the Erciş based on inspection of positive artificial structures parameter for the landscape elements. The results are in accordance with the actual vegetation levels of the districts.

Coastal area of the Erciş has received low scores in terms of protection of naturalness. In terms of water presence, the district of Erciş achieved the highest score for its waterscape beauty, as can be seen in *Table 3*.

As can be observed from *Table 4*, Adilcevaz's coastal area received the lowest score in terms of vegetation presence, presence of human-made positive elements, and variety of colors. The results also parallel the vegetation presence of the district.

When the assessment results of the Ahlat's coastal area is analysed against the biophysical parameters of the visual Ahlat's coastal area received the lowest score in terms of vegetation presence and presence of human-made positive elements. On the other hand, as can be seen from *Table 5*, Ahlat's coastal area received the highest score in terms of water view.

When the assessment results of the Edermi's coastal area according to visual landscape biophysical parameters as can be observed from *Table 6*, the interpretation of this result indicates that positive artificial structures parameter for the landscape elements reveals the lack of man-made elements contributing to the attraction of the locations in the coastal areas of the Tatvan. While as can be seen from *Table 6*, Tatvan's coastal area received the highest score in terms of water view and variety of colors.

When the biophysical property of naturalness parameter is inspected, the Q-sort analysis supports the fact that Gevaş's coastal area has a lower amount of settlements. When the parameter of vegetation presence is inspected, it can be realized that although being quite small in size, the coastal area of the Gevaş district were given the highest scores. This is probably due to the presence of the only forest in the region. The outcomes of the Q-sort analysis also parallel the vegetation presence of the district. In terms of water presence, the district of Gevaş achieved the highest score for its

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18491864

waterscape beauty, as can be seen in *Table 7.* Since this coastal area is farther than the city center compared to other locations’ shorelines, it has a clearer water overall, also reflected in the results of the questionnaire.

When the assessment results of the Edermi’s coastal area according to visual landscape biophysical parameters is inspected, it is found that: Edremit’s coastal area received a high score in terms of water view and variety of colors. Being called the “Green Edremit” in the region, Edremit is rich in terms of vegetation presence. The results are in accordance with the actual vegetation levels of the districts (*Table 8*).

Towards the north and west of the Van Lake lie the volcanic mountain masses, while its southern side is dotted with high-slope mountain ranges; the east and northeast are relatively lower in terms of morphological formations. This configuration has also influenced the results of the questionnaire. When the topographical variety parameter of the study area is inspected, it can be understood that the presence of formations of various heights contributing to the vistas was reflected into the results of the questionnaire as higher scores. Results of the analysis reveal that the Gevaş coastal area received the first position in terms of morphological variation, while Edremit coasts were placed second with a close score.

These results show that the balance between natural and man-made elements was lost for all the locations. Since the region lacks the understanding of sustainable landscaping, suitable for the nature and identity of its elements, the problematic urbanization of the coastals seems inevitable. This is also reflected in the result of the questionnaire.

Displays the results for the color variation biophysical parameter where Edremit coastal landscape earns the highest score. The interpretation of this result indicates that while the coastal of Gevaş district had indeed preserved its naturalness, it is somewhat lacking in color variety, while the coastal landscaping conducted by local authorities in the Edremit district had indeed increased the color variety and attractiveness of the location. Adilcevaz coastal landscaping, on the other hand, was given the lowest score in terms of color variety.

Conclusion and Suggestions

As a result of the ongoing population increase, it becomes inevitable that humankind disturbs the nature more and more every day. Presenting a source for beautiful visual resources, coastal areas are being repurposed through landscaping so they can provide for the physical and recreational/touristic requirements of the population. When carried out improperly, such landscaping results in serious environmental problems in these coastal regions. Evaluation of these areas in terms of their visual landscaping impact enables the decision makers to determine the priority for preservation and restoration studies, offering solutions for improving and preserving modern settlement areas in terms of sustainable landscaping.

In the present study, the coastal areas of 6 significant locations commonly visited by the local population in the Van Lake Basin, namely Erciş, Adilcevaz, Ahlat, Tatvan, Gevaş, and Edremit districts, are evaluated in terms of their visual landscape qualities. These locations are very popular recreational areas for visitors, especially during summer months and weekends. Considering the fact that visual landscape quality has a strong influence on the recreational attraction, the landscaping of these locations are conducted, heeding some of the most important criteria. The outcomes of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18491864

evaluations revealed that the highest scores were achieved by Gevaş, Edremit, and Tatvan districts' coastal regions, respectively (*Figure 5*). The general view of the coastal areas, their naturalness, and the presence of vegetation were determined to be the most influential parameters.

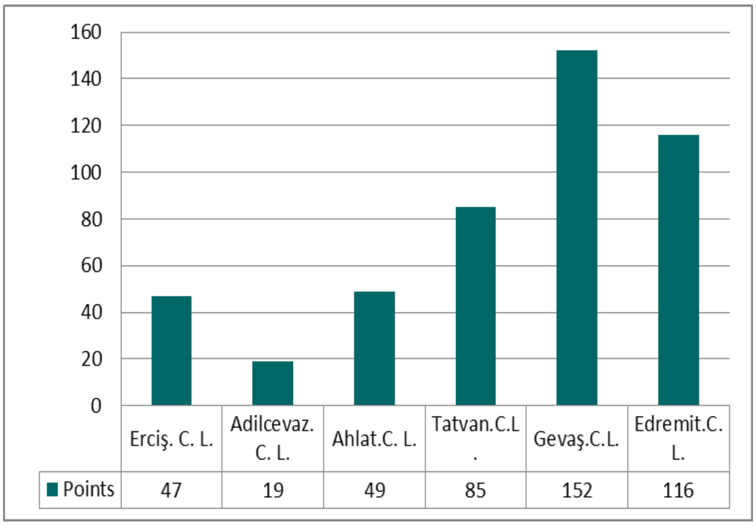

Figure 5. *Results of the visual landscape quality evaluation of the coastal area*

The analysis conducted in this study reveals that the highest score in terms of general attractiveness was achieved by the coastal area of the Gevaş district, followed closely by the coastal strips of Edremit district. Among all the locations under study, the Gevaş coastal area maintained its naturalness to the highest level; thus, it received the best score in terms of biophysical parameters of the visual landscape. While these two locations achieved high scores due to their vegetation presence, dominating water presence and beauty, and topographical variety, they received no scores for the man-made positive landscape elements. This shows that the landscaping conducted in the region by the authorities was not approved by the experts. Similar results were also achieved for Ahlat, Erciş, Tatvan and particularly for Adilcevaz coastal areas, as the landscape designs applied in these locations are unrelated to the identities of the locations, looking like ordinary parks.

The lowest scores for the visual landscape evaluation were obtained by the coastal areas of Adilcevaz district, presenting an urgency and priority for restoration and improvement studies for the location. To achieve this, the weak vegetation presence in the coastal areas of Adilcevaz could be initially enhanced, using ample amounts of plants appropriate for the ecological conditions of the region. Meanwhile, prevention of the waste being dumped into the lake should be sufficient to improve the visual quality of the water itself. All of the coastal areas included in the study suffered from the lack of positive contribution of man-made landscape elements, receiving low scores for this particular parameter. Considering this, future artificial landscape elements should be designed considering the history of the locations. A strategy should also be employed to choose appropriate construction materials, accessories, and local plants.

The coastal areas of Gevaş and Edremit districts were highly praised by the experts in the study; thus, they can be the focus of future preservation efforts and utilization of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18491864

sustainable landscape strategies. These strategies should be developed based on most influential biophysical parameters discussed in this study.

The coastal areas of the Van Lake are subject to the Shore Protection Law (no 3621) (Anonymous, 2018c). Implementation and execution of preservation and protection laws is essential for prevention of constructions breaching the Construction Zoning Law and the damages caused by solid and liquid wastes. Construction of facilities that aid community life by focusing on recreation, entertainment, culture, sports, and social aspects are of paramount importance, but they should also adhere to determined constructions of the selected strategy and preserve natural habitats and vistas. The landscaping studies should be reinforced by the contribution of decision makers, communities, and their engagement in consciousness-raising efforts, taking into consideration the vistas and views into the plans. Cooperation between the institutions in various scales is also necessary to properly manage the visual resources in the preservation and restoration of coastal landscape regions.

(Received 25th Oct 2018; accepted 7th Jan 2019)

Abstract. In this study, the effects of gyttja on some soil properties in two different nickel-contaminated soils (Inceptisol and Entisol) were investigated. This study was conducted with the application of three levels of gyttja (0, 5 and 10%) in two different soils (Inceptisol and Entisol) contaminated with Ni at three levels of concentration (0, 40 and 80 mg kg^{-1}) in a factorial experimental design with three replications. Some soil properties showed differences in different nickel and gyttja applications. Soil nickel content significantly ($P < 0.01$) increased in nickel-contaminated soils. Soil organic matter and phosphorus contents in gyttja applicated soils were found to reach higher levels compared to those without gyttja application.
Keywords: *organic material, heavy metal, soil properties, Inceptisol, Entisol*

Introduction

Heavy metals natural components of the Earth's crust, the concentration of several heavy metals can reach toxic levels due to consequence of anthropogenic activities. Heavy metals are recognized as important environmental contaminants in industrialized societies. Heavy metal contamination is originated from local sources, mostly industry, agriculture, waste incineration, combustion of fossil fuels and road traffic (Farid et al., 2015). Fifty three elements are in the heavy metal category and defined as the group of elements whose densities are higher than 5 g cm^3 (Özbolat and Tuli, 2016).

Nickel is one of the most important heavy metal in terms of its potential toxicity to plants and animals (Kabata-Pendias and Pendias, 2001). Although nickel has been recognized as essential micronutrient in plant cells (Ankel-Fuchs and Thaver, 1988), its excess has destructive effect on plant growth, causing disturbances in photosynthesis, destruction of cell membranes and damages of cells (Pandolfini et al., 1992). Baranowska-Morek (2003) reported that the presence of heavy metals can induce deficiency of the elements necessary for proper plant development similarly. It was reported that high concentrations of heavy metals cause an imbalance of nutrients and have an adverse effect on the synthesis and functioning of many enzymes, vitamins and hormones (Luo and Rimmer, 1995).

It was reported that mobility and availability of heavy metals are controlled by adsorption and desorption characteristics of soils (Krishnamurti et al., 1999). The soil properties including pH, cation exchange capacity, organic matter content, clay minerals contents, lime and Fe and Mn oxides play important role in adsorption and desorption of heavy metals (Antoniadis et al., 2008; Usman et al., 2008).

Organic matter has been implicated for alleviating bioavailability of heavy metals in soils recently soil organic matter has been of particular interest in researches of heavy metal sorption by soils, because of transformation of metal cations to stable complexes

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18651873

form with organic ligands (Elliott et al., 1986). Organic matter makes strong complexes with heavy metals (Bloom, 1981). Khan et al. (2000) reported that amendment of contaminated soils with organic matter decreased bioavailability of heavy metals.

The humic substances, the major component of soil organic matter, have effects on various biochemical outcomes in plant tissue and soil properties such as aggregation, aeration, permeability, water holding capacity, micronutrient transport and availability (Tan, 2003). Among the deposits of humic substances, gyttja, which is a semi-formed lignite coal cover layer and its content of organic matter, can change from 6 to 40% by weight (Demirkıran et al., 2008). In the other researchers reported that gyttja which low-cost and locally available natural materials is a mixture organic and inorganic materials as calcareous and clay, its content of organic matter generally varied from 40 to 50% by weight, and located on lignite deposits. The gyttja which is not used in the coal-fired power plant due to its low quality must be removed for the lignite layer can be taken for mining (Saltalı et al., 2015).

In this study, the effects of gyttja on some soil properties and nickel content in nickel-contaminated two different soils (Inceptisol and Entisol) were investigated.

Material and methods

This study was conducted with the pots having 2 kg different soils (Inceptisol and Entisol) in a plant growth room. Experimental soils were taken from depth of 0-20 cm in Van province, east of Turkey. The Inceptisol soil used in this study had a clay loam texture, non saline, and neutral, limely, insufficient in organic matter (OM), sufficient in phosphorus (P) and potassium (K) contents. The Entisol soil used in this study had a silty loam texture, non saline, slightly alkaline, limely, insufficient in organic matter and P contents and sufficient in K content (*Table 1*).

Table 1. *Some properties of Inceptisol and Entisol soil*

Analyses		Soil types	
		Inceptisol	**Entisol**
pH		7.41	7.64
Texture		Clay loamy	Silt loamy
Lime	%	2.03	2.27
Organic matter	%	1.03	1.70
Salinity	µS cm^{-1}	120	118
Phosphorus (P)	mg kg^{-1}	7.20	4.40
Potassium (K)	mg kg^{-1}	35	35
Calcium (Ca)	mg kg^{-1}	696	594
Magnesium (Mg)	mg kg^{-1}	70	24
Iron (Fe)	mg kg^{-1}	1.96	1.05
Manganese (Mn)	mg kg^{-1}	3.53	4.64
Zinc (Zn)	mg kg^{-1}	0.15	0.16
Copper (Cu)	mg kg^{-1}	0.42	0.33

After filling each pot without drainage holes with two different soils, 54 pots were autoclaved. Three levels of gyttja (0, 5, 10%) were applied into pots including two

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18651873

different soils contaminated with three levels of nickel (Ni) (0, 40 and 80 mg kg^{-1}) in factorial experimental design with three replications. The planned doses of gyttja were directly mixed the each pot. Nickel doses were applied as their solutions prepared by using distilled water. Yedikule lettuce cultivar was used as experimental plant. The lettuce seedling having three leaves planted to each pot. This experiment was carried out within 65 days. At the end of experiment firstly it was determined that increasing gyttja doses had the positive effects on plant growth criteria of lettuce in Ni contaminated soils. Conversely, Ni applications decreased the means of plant growth criteria (Gülser et al., 2017). Secondly effects of gyttja on some soil properties in nickel-contaminated soils were determined by using following soil analyses methods.

The gyttja used in this study had neutral pH (7.28), 0.71 dS m^{-1} in salinity, 51.3% in organic matter (OM) content, 1.88% in nitrogen (N), 0.11% total P content and 55.12% in humic acids.

Some soil physical and chemical properties of soil were determined as follows; pH in 1:1 soil water suspension by pH meter (Jenway, 3310), salt content in the same suspension by EC meter (YSI 3100), organic matter by modified Walkey-Black, lime content by Scheibler calcimeter, phosphorus with Olsen bicarbonate method by spectrophotometer (Shimadzu UV mini 1240), potassium (K), calcium (Ca) and magnesium (Mg) by the extraction with 1 N neutral ammonium acetate and heavy metal by extraction with a mixture of nitric acid and perchloric acid in 2:1 ratio by using atomic absorption spectrophotometer (Thermo 1CE 3000 series) according to Kacar and İnal (2008).

Statistical analyses was done using SAS package program (SAS Institute, 1989) to show difference among the mean values of some soil properties and some nutrient contents from the different applications.

Result and discussion

The results of variance analyses for the some soil properties are given in *Table 2*.

Table 2. *F values of the variance analyses for the some soil properties*

*significant at 0.05 level, **significant at 0.01 level, ns: non significant

Soil types had significant (P < 0.01) effects on pH, Ca, Mg, Ni contents. Lime, OM contents were also significantly (P < 0.05) influenced by the soil types. Gyttja treatments significantly affected pH, lime, OM, Ca, Ni contents (P < 0.01), EC (P < 0.05) contents. Ni applications had no effects soil properties expect Ni contents (P < 0.01). Interactions of soil type and gyttja had significantly (P < 0.01) effects on OM, K and (P < 0.05) Ni contents. The effects of soil type and Ni interactions were found significant at 5% level in P and Mg contents; Ni and gyttja interactions had

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18651873

significantly ($P < 0.05$) effects on K and Ni contents. The effects of soil type, gyttja and Ni had significantly ($P < 0.05$) effects on pH level and P contents (*Table 2*).

EC, OM, Ca and Ni contents increased by increasing gyttja doses though pH and lime decreased. These increases were significant statistically. The highest means of EC, OM, Ca, Mg and Ni contents were obtained as 1607.63 µS cm^{-1}, 6.49%, 8618 mg kg^{-1}, 541.38 mg kg^{-1}, 63.59 mg kg^{-1} in 10% gyttja treatment respectively (*Figs. 1–6*). Gyttja used in this study had lower pH value than those in experimental soils. Therefore gyttja applications may be decrease pH value of soils of growing media.

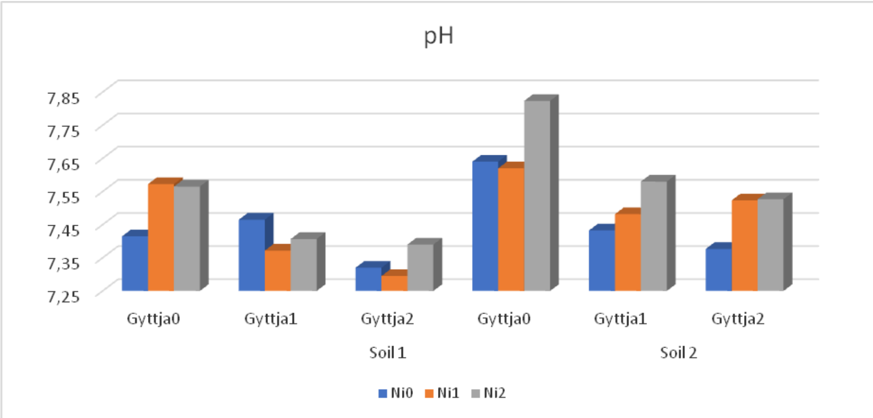

***Figure 1.** Effects of different gyttja level ($P < 0.01$) and nickel doses (ns) on pH. Gyttja0: 0%, Gyttja1: 5%, Gyttja2: 10%, Ni0: 0 mg Ni kg^{-1}, Ni1: 40 mg Ni kg^{-1}, Ni2: 80 mg Ni kg^{-1}, LSDsoil ($P < 0.05$): 0.05, LSDgyttja ($P < 0.05$): 0.05 LSDnickel ($P < 0.05$): 0.04*

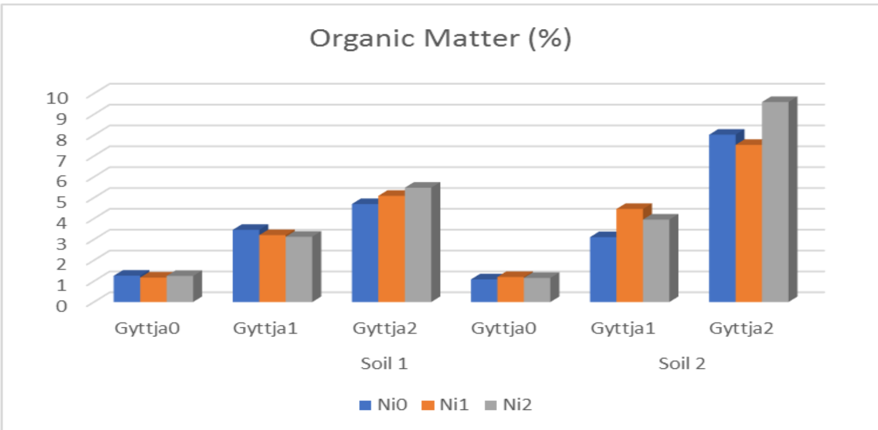

***Figure 2.** Effects of different gyttja level ($P < 0.01$) and nickel doses (ns) on organic matter. Gyttja0: 0%, Gyttja1: 5%, Gyttja2: 10%, Soil1: Inceptisol, Soil2: Entisol, Ni0: 0 mg Ni kg^{-1}, Ni1: 40 mg Ni kg^{-1}, Ni2: 80 mg Ni kg^{-1}, LSDsoil ($P < 0.05$): 0.38, LSDgyttja ($P < 0.05$): 0.38, LSDnickel ($P < 0.05$): 0.31*

The means of some soil properties determined in Entisol soil were significantly higher than those in Inceptisol soil (*Figs. 1–6*). Ni contents means obtained in Entisol soil were also higher than those in Inceptisol soil in ratio of 22.67%. It was thought that differences in Ni contents among two soil types caused by differences in soil properties. The pH value and OM content of Entisol soil were in higher level than those in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18651873

Inceptisol soils. Zhao et al. (2010), reported that soil pH was found to play the most important role in determining metal speciation, solubility from mineral surfaces, movement and bioavailability of metals in the soil solution. The Entisol soil used in this study had higher pH and OM content according to Inceptisol soil. Ramachandran and D'Souza (2013) determinate that Ni adsorption capacity of the soil increased with an increase in pH of the soil. On the other hand OM is a major factor to the availability of soils for retaining heavy metals in exchangeable form (Mc Cauley et al., 2009).

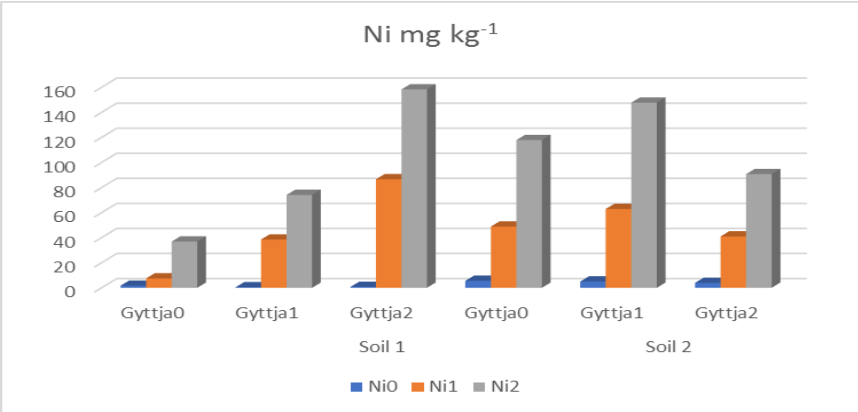

***Figure 3.** Effects of different gyttja level (P < 0.01) and nickel doses (P < 0.01) on nickel content. Gyttja0: 0%, Gyttja1: 5%, Gyttja2: 10%, Soil1: Inceptisol, Soil2: Entisol, Ni0: 0 mg Ni kg^{-1}, Ni1: 40 mg Ni kg^{-1}, Ni2: 80 mg Ni kg^{-1}, LSDsoil (P < 0.05): 7.85 LSDgyttja (P < 0.05): 7.85, LSDnickel (P < 0.05): 6.41*

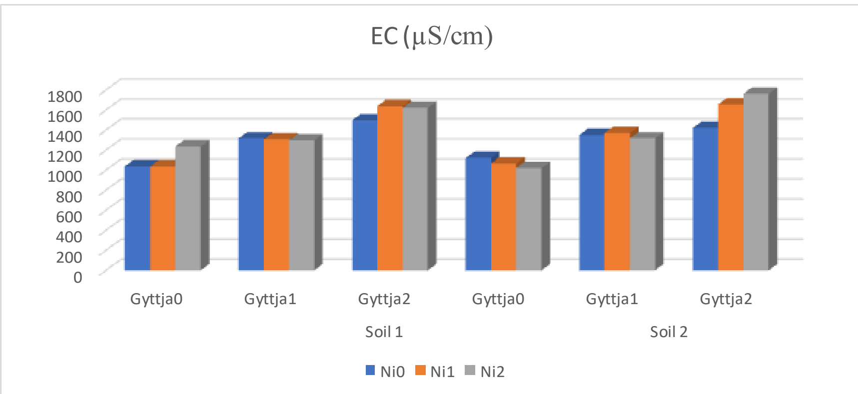

***Figure 4.** Effects of different gyttja level (P < 0.05) and nickel doses (ns) on EC. Gyttja0: 0%, Gyttja1: 5%, Gyttja2: 10%, Soil1: Inceptisol, Soil2: Entisol, Ni0: 0 mg Ni kg^{-1}, Ni1: 40 mg Ni kg^{-1}, Ni2: 80 mg Ni kg^{-1}, LSDsoil (P < 0.05): 0.6, LSDgyttja (P < 0.05): 0.6, LSDnickel (P < 0.05): 0.5*

Similarly, high EC level of Gyttja used in this study may be lead to increase in EC levels of growing media. Numerous studies demonstrated that humic substances such as gyttja and leonardite increased soil organic matter content. Ece et al. (2007) reported that leonardit applications did not changed pH, lime content and EC significantly while OM content of growth media soils added leonardit increased significantly. Similarly, it was also reported that gyttja applications to soil significantly increased soil organic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18651873

matter content (Karaca et al., 2006; Turgay et al., 2011; Gülser et al., 2014; Saltalı and Eryiğit, 2015). Turgay et al. (2011) reported that gyttja as humic substances added to the soil did not affected soil parameters and macro nutrient contents. Applying of organic materials (barnyard manure, poultry manure, sewage sludge, leonardite, gyttja etc.) is a commend practice to increase OM content (Stevenson, 1994). Decomposition of such organic materials added to soil enhance energy source and this stimulate soil microbial activity (Flieβbach and Mäder, 2000) which finally accelerates the conversions of added organic materials to the background soil organic matter. It was known that humic substances play a critical role in increasing soil organic matter content having useful effects on soil structure, water-holding capacity, adsorption and retention complexes and are responsible for increasing stable carbon levels in soil (Paulin and Q'Malley, 2008).

Generally, nickel contents of soil were higher than critical level (50 mg kg^{-1}) reported by Bergman (1992) in 80 mg kg^{-1} gyttja applications in both soil types. It was thought that high organic matter contents gyttja applied soils caused retention of Ni.

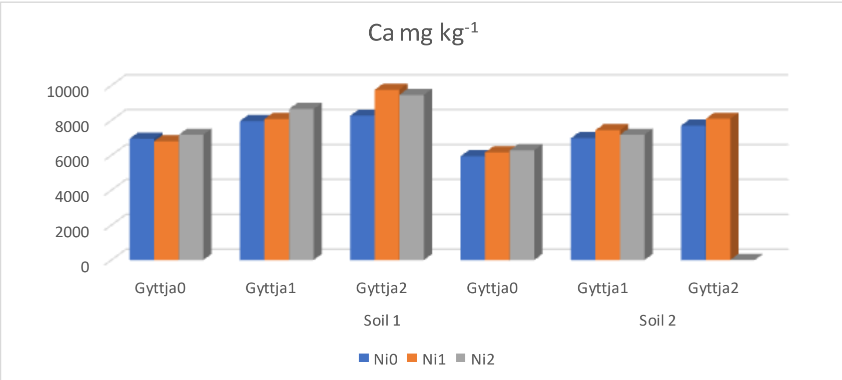

Figure 5. *Effects of different gyttja level (P < 0.01) and nickel doses (ns) on Ca. Gyttja0: 0%, Gyttja1: 5%, Gyttja2: 10%, Soil1: Inceptisol, Soil2: Entisol, Ni0: 0 mg Ni kg*$^{-1}$*, Ni1: 40 mg Ni kg*$^{-1}$*, Ni2: 80 mg Ni kg*$^{-1}$*, LSDsoil (P < 0.05): 220, LSDgyttja (P < 0.05): 220, LSDnickel (P < 0.05): 179*

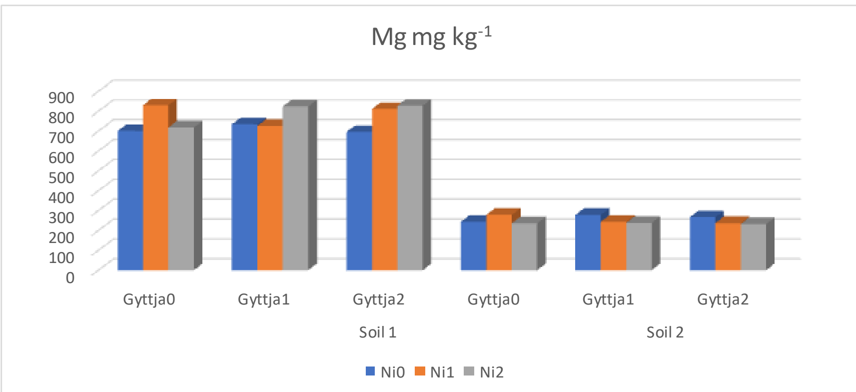

Figure 6. *Effects of different gyttja level (ns) and nickel doses (ns) on Mg. http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18651873

The Ni applications increased significantly Ni contents of soils. Nickel contents of control soils were determined at low levels in both soil types. The doses of gytjja 10% had more positive effect to prevent nickel contamination in Entisol soil according to those in Inceptisol soil (*Fig. 3*). Apart from soil pH, organic matter content in soils is also one of the most important soil properties affecting heavy metal availability (Mc Cauley et al., 2009).

Antoniadis et al. (2008) and Mc'Cauley et al. (2009), Bai et al. (2008), reported that organic matter is a major factor to the ability of soils for retaining heavy metals in exchangeable form. They also determined that heavy metal adsorption onto soil constituents declined while soil organic matter content decreased. Organic matter supplies organic chemicals to the soil solution. These organic chemicals can serve as chelate and increase metal availability to plants.

The lowest and highest Ni means of Inceptisol soil were obtained as 2.92 mg kg^{-1} and 158 mg kg^{-1} control and G2, in while the lowest and highest Ni means of Entisol soil were in control and G1 application as 8 mg kg^{-1} and 142 mg kg^{-1}, respectively (*Fig. 3*).

In this study, increasing gyttja doses decreased Ni contents according to control in Entisol soil with 10% gyttja applications in Inceptisol soils. Karaca et al. (2006) reported that gyttja application decreased Ni concentrations of soil among 90th-180th day following applying time. In this regard, applying gyttja to soil contaminated with Ni can decrease the availability of nickel.

Conclusion

As a result, 10% gyttja application decreased Ni contents according to control in Inceptisol and Entisol soils. The organic matter contents of experimental soils increased by increasing gyttja doses. These increases were found at higher level in Entisol soils than those in Inceptisol soils. Similarly increasing gyttja doses increased EC values in both soil types without causing of salinity problem. According to results of this study 10% gyttja application was suggested to increase the soil matter contents and to decrease damages of heavy metals in plants growing nickel polluted soils. On the other hand it was thought that gyttja doses using to prevent heavy metal damages may be show the changes according to soil type, plant variety and kind of heavy metal and degree of heavy metal pollution in soil. So, determination of the beneficial effects of gyttja in heavy metal contaminated soils needs the more researches in long-term experiments.

(Received 27th Oct 2018; accepted 11th Jan 2019)

Abstract. The use of saffron dates back to ancient times. It is commonly used in medicine, as well as the function of dye and spice in the food industry. The oldest documents about the edible use of saffron are recorded by Polyen (in the 2nd century BC), a Greek military writer who, in his graduation thesis entitled “Stratagemes” reports a list of foods consumed by the court of the Persian Achemenide dynasty (550-330 BC), which had been carved on a bronze column in front of the kitchen (Abrishami, 2004). Its cost is variable according to the production vintage and drying methodologies, it can reach up to 20,000 euros per kilo. The reason for the very limited genetic diversity in cultivated saffron is explained by its asexual mode of reproduction. The AFLP technique could be a good choice to investigate the genetic diversity because of its high-multiplex-ratio which allows detecting differences even between samples sharing most of the genetic material, and it is still one of the most used tools for the molecular characterization of genetic variability in cultivated plants. The aim of this study was to assess the variability of morpho-physiological traits and to evaluate the genetic differences among different proveniences of *C. sativus* with AFLP. The results of this paper in part confirm those obtained by previous studies. Despite morphological differences found between the accessions, molecular markers have revealed limited genetic differences for samples with different origin.
Keywords: *AFLP, Crocus sativus L., morphology characterization, genetic diversity, molecular markers, genetic pool*

Introduction

Saffron (*Crocus sativus* L.), with a basic chromosome number of x = 8, is a triploid and sterile plant, is propagated exclusively by vegetative means (Petersen et al., 2008; Agayev et al., 2009) via its corms which undergo a period of dormancy (Fernandez, 2004).

Saffron is one of the most expensive spices in the world because of the high demand and the different uses, but also for the high costs of cultivation and production. Saffron consists of the dried dark red “stigmas” of the *Crocus sativus,* flower (Chryssanthi et al., 2007), which on average weighs about 6 mg. Therefore, approximately 150,000 to 200,000 flowers are required to yield 1 kg of saffron spice. It is worth nothing that its high price reflects the time required for its cultivation, harvesting and handling (separation of stigma from other parts of the flower parts). In order to gather the saffron, the stigmas of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18751887

the saffron flower must be handpicked. This becomes very time consuming, considering that in order to produce just 1 g of saffron, need to collect an average of 150 flowers (Hosseinzadeh Gonabad, 2013).

In addition to its culinary uses, saffron has a long history as a potent component of traditional medical systems (Gutheil et al., 2012; Premkumar et al., 2006; Abdullaev, 2002; Kim et al., 2014).

Like most plant derivatives, saffron contains a multitude of bioactive molecules. Chief among these molecules are *crocin*, *crocetin*, and *safranal*, members of the carotenoid family of molecules that also includes forms of vitamin A (Aung et al., 2007).

Commercial saffron (dried stigmata of Crocus sativus L.) contains: crocin and crocetin (colors) Crocin is the principle coloring pigment, at nearly 10% (Pfander and Wittwer, 1975; Tsimidou and Tsatsaroni, 1993), picrocrocin (bitter principle), the glycoside picrocrocin which is a precursor of safranal and responsible for its distinctly bitter flavour safranal (flavor), safranal, is the deglycosylated form of picrocrocin and the major organoleptic principle of the stigmas.

Its cultivation has long been concentrated on a broad belt of Eurasia, bounded by the Mediterranean Sea in the Southwest, to Kashmir and China in the northeast. Iran is the main producer of saffron, accounting for more than 90% of world production (about 300 tonnes in the year 2017), followed by India (5%) and countries of the Mediterranean basin (Greece, Morocco, Spain, Italy and Turkey) (Gresta et al., 2008a). However, the Mediterranean region is recognized worldwide as producing the best quality of saffron, which is attributed to many factors (Gresta et al., 2008b; Lage and Cantrell, 2009).

About crocus cultivation in Europe one theory states that Moors reintroduced saffron corms to the region around Poitiers in AD 732 (Pearce, 2005). Two centuries after their conquest of Spain, Moors planted saffron throughout the southern provinces of Andalucía, Castile, La Mancha, and Valencia. Later the proliferation of saffron began to spread throughout Europe (Abrishami, 1987, 2004). Today Spain is the biggest exporter of saffron in the world. Every year, a saffron festival (Fiesta de la Rosa del Azafran) takes place in Spain, consisting of competition for the best saffron dish and saffron picking contest. In Spain there are many dishes which need saffron; the most important one is Paella (Abrishami, 1987; Winterhalter and Straubinger, 2000; Dadkhah et al., 2003).

Archaeological records indicate that saffron was cultivated and used as a spice or medicinal plant in the Mediterranean basin as early as the late Bronze Age. However, there is no consensus on where the first saffron plants were domesticated and grown (Grilli Caiola and Canini, 2010; Molina et al., 2015).

Saffron is one of the oldest crops, which, despite its long history of cultivation compared to conventional crops, is still mainly grown in marginal lands and in low-input farming systems. Therefore, it can be considered an alternative crop in sustainable agricultural systems and marginal land with low efficiency. Several years of studies have demonstrated that differences in saffron quality can be due to environmental effects, post-harvest processing the stigmas, and any genetic variation (Agayev et al., 2006; Nehvi et al., 2007; Ghaffari and Bagheri, 2009; Fluch et al., 2010; Siracusa et al., 2013; Babaei et al., 2014).

Recent studies carried out with molecular techniques have demonstrated that genotype could also play a very important role. The high price of saffron makes it frequent subject of adulteration of various types, i.e. including the mixing authentic Saffron stigmas with other plants flowers colored with natural or artificial dyers. Therefore, the development of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18751887

molecular tools could be fundamental not only to control the purity of saffron products, avoiding adulteration but also for tracing the origin of pure saffron products.

DNA markers have been used in Crocus spp. to characterize germplasm collections, inform breeding programs, and facilitate genetic diversity studies and taxonomic analysis. Over the last decade some technological advances in DNA marker techniques were made. The methods include: random amplified polymorphic DNA (RAPD) (Grilli Caiola et al., 2004; Beiki et al., 2010; Rubio Moraga et al., 2010); ii) inter-retrotransposon amplified polymorphism (IRAP) (Alavi Kia et al., 2008); iii) amplified fragment length polymorphism (AFLP) (Zubor et al., 2004; Erol et al., 2011; Nazzal et al., 2011; Siracusa et al., 2013); iv) intersimple sequence repeat (ISSR) (Rubio Moraga et al., 2010); v) simple sequence repeat (SSR) (Rubio Moraga et al., 2010; Nemati et al., 2012); and vi) single-nucleotide polymorphism (SNP) (Syvanen, 2001; Singh et al., 2010).

Among these molecular markers, AFLPs, based on the selective PCR amplification of restricted total DNA fragments (Vos et al., 1995; Powell et al., 1996) were found to show high levels of polymorphisms per primer combination and yielded high resolution and reproducibility (Meudt and Clarke, 2007; Erol et al., 2014). AFLPs could then be a good choice for investigating genetic variability among saffron accessions because of its high-multiplex-ratio which allows detecting differences even between samples sharing most of the genetic material (Vos et al., 1995). In recent years we successfully have applied AFLP for dissecting genetic variability in faba bean (Gresta et al., 2010), in lentil, (Torricelli et al., 2012), celery (Torricelli et al., 2013), olive (Albertini et al., 2011) and saffron (Siracusa et al., 2013).

The aim of this study was to assess the variability of morpho-physiological traits in *C. sativus* populations coming from Iran and Italy and to evaluate the genetic differences among different origins (Iran, Italy and Spain) with AFLP markers. here are many advantages to AFLP when compared to other marker technologies including RAPD, RFLP, SSRs and SNPs. AFLP not only has higher reproducibility, resolution, and sensitivity at the whole genome level compared to other techniques, but it also has the capability to amplify between 50 and 100 fragments at one time. In addition, no prior sequence information is needed for amplification (Meudt and Clarke, 2007).

Materials and methods

Morphological analysis

Corms coming from Iran (6 accessions) and from Italy (2 accessions) (*Table 1*) were planted in September 2012 on a sandy-clay soil in Umbria, Central Italy (220 m a.s.l.). Sowing was executed in raised beds at 20 cm depth 50 cm between rows and 20 cm between corms in rows. A complete randomized block design with two replications was adopted. Fifteen corms per accession per replication were used; no fertilizer and no irrigation were applied. Weeds were managed by hand. Seventeen morpho-physiological traits were recorded per single plant; detailed information about the recorded traits is reported in *Table 2*.

DNA extraction and AFLP analysis

About eighty days after transplant, leaf tissues were collected for DNA extraction, which was carried out on a single plant basis using the DNeasy 96 Plant Kit and an MM300 Mixer Mill (Qiagen GmbH, Hilden, Germany). In addition to the saffron

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18751887

accessions used for the morphological characterization, two Italian populations (Cascia – PG and S. Anatolia di Narco – PG) and one population coming from Spain (Mancha) for molecular analysis were used (*Table 1*). For each population 3 plants were used as biological replicas. DNA was concentrated and quality was assessed using a Thermo Scientific NanoDrop 1000 ultraviolet spectrophotometer and confirmed by agarose gel electrophoresis.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18751887

All amplifications were performed on Gene Amp PCR System 9600 (Perkin Elmer, USA). One microliter of each sample was combined with 10 µl of Hi-Di formamide, 0.25 µl size standard Liz 500 (Applied Biosystems), denaturated and fractionated on an ABI 3130xl capillary sequencer (Applied Biosystems).

AFLP analysis was carried out according to (Vos et al., 1995) with minor modification as reported by (Albertini et al., 2011). Genomic DNA (300 ng) was restricted with EcoRI /MseI enzyme combination and double-strand adaptors were ligated to fragment ends. Pre-amplification of the diluted (10-fold) ligated DNA was performed using primers carrying one selective nucleotide (EcoRI + C, MseI + A). The pre-amplification products were diluted 10-fold and used as a template for the selective amplification. Selective amplifications were performed by using fluorescent-labeled EcoRI+3 primer and unlabeled MseI+3 primer (*Table 6*).

Statistical data analysis (morpho-physiological data)

For the morpho-physiological data, ANOVA (Analysis of variance) was carried out using PROC GLM of SAS (SAS, 2008). Means were compared using Duncan's multiple range test. Finally, Pearson's correlation between each couple of morpho-physiological was also calculated. In order to summarize all the information from the collected data, a Principal Component Analysis (PCA) was performed.

Molecular data

5 AFLP fragments were scored dominantly and recorded in a 0/1-matrix for the peak absence/presence along with their sizes using the Genemapper 4.0 software (Applied Biosystems). Molecular data were arranged in a data matrix. The number and percentage of polymorphic loci were calculated for each marker and in total on the entire data set. Number of private bands within an accession (i.e. bands belonging only to a certain farmer population or variety) were also counted. AFLP fragments were scored as 1 or 0 for presence or absence of the band, respectively, using the Genescan software (Applied biosystem). Genetic similarity (GS) was estimated using the similarity coefficient of Jaccard (1908): $SGij = a / (a + b + c)$, where GSij is the genetic similarity between individual i and j; a is the number of polymorphic bands that are shared by i and j, b is the number of bands present in i and absent in j, and c is the number of bands present in j and absent in i. Genetic similarities among samples were clustered by the unweighted pair-group method of arithmetic average (UPGMA; Sneath and Sokal, 1973). The statistical analyses were worked out using the SAS Institute Inc. (SAS, 2008) and NTSYS-PC Version Q 2.11 (Rohlf, 1993) software.

Results

Morpho-physiological analysis

Based on results of ANOVA the accessions of *C. sativus* differed in most characteristics. The average values of the evaluated traits, compared by using the Duncan's multiple range test, are shown in *Table 3*. There were no significant differences for following traits: sheath height (SHE), main leaf length (MLW), tepals length (TEL), tepals width (TEW) and corms number produced per plant (CORN). Significant difference was detected among accessions for all other traits (value $P < 0.05$). In particular regarding days to emergence (DEME), Barisciano and Torbat

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18751887

Market were the earliest populations, while Ghaien and Rahn were the latest. Città della Pieve accession shows the highest buds number in vegetation (BUNU) per plant (5.27) while Rahn has the lowest buds number (2.36). Barisciano and Città della Pieve have the highest number leaves per bud (LENU), 10.00 and 9.54 respectively. Barisciano and Città della Pieve populations highlighted the highest corms diameter (CORD), 31.35 and 23.34. Regards the flowers production (per plot and per plant), the Italian saffron populations were the most yielded. The correlation matrix between morphological traits was summarized in *Table 4*. Pearson's coefficients were calculated, significant differences were found and will be taken into account only those traits related to the spice and corms production. Days to emergence (DEME) is negatively correlated with flower number per plot (FNPLO) (r= -0.54) and flower number per plant (FNPLA) (r = -0.59). Buds number in vegetation (BUNU) is positively correlated with corms number per plant (CORN) and flower number per plot (FNPLO) (r = 0.70). Leaves number per bud (LENU) is positively correlated with dry weight of stigmas (DWS), corms diameter (CORD) and flower number per plant (FNPLA) (r = 0.65, 0.75 and 0.94, respectively). Stigma length (STIL) is positively correlated with dry flower weight (DFW), dry weight of stigmas (DWS), corms diameter (CORD) and flower number per plant (FNPLA) (r = 0.80, 0.88, 0.65 and 0.78 respectively). Anther length (ANTL) is positively correlated with flower number per plant (FNPLA) (r = 0.83). Corms diameter (CORD) is highly correlated with flower number per plot (FNPLO) (r = 0.72) and flower number per plant (FNPLA) (r = 0.80). Finally, dry weight of stigmas (DWS) is positively correlated with anther length (ANTL), corms diameter (CORD) and flower number per plant (FNPLA) (r = 0.76, 0.66 and 0.74 respectively). To summarize all the variability among the saffron accessions a principal component analysis (PCA) was worked out by using averages of data recorded per accession. The first three components (PC1, PC2 and PC3) of the PCA accounted for 46.15%, 26.82% and 12.03% of the total variation, respectively (85.00% of total variation) (*Table 5*). Eigenvectors (*Table 5*) showed that: i) PC1 was highly correlated with flowers number produced per plot (FNPLO) (0.35), flowers number produced per plant (FNPLA) (0.34), leaves number per bud (LENU) (0.34), anther length (ANTL) (0.33) and stigma length (STIL) (0.32); ii) PC2 was highly correlated with main leaf length (MLL) (0.45), leaf area (LEA) 0.44), main leaf width MLW (0.35) and tepals length (TEL) (0.34); iii) PC3 was highly correlated with tepals width (TEW) (0.53) and Dry flower weight DFW (0.47). The plot of PC 1 and PC2 is shown in *Figure 1*. From the scatter plot it is clear that the Italian saffron populations are separated clearly from the Iranian accessions. This separation is mainly due to PC1. The saffron accession which comes from the market (Torbat Market) is separated from all other Iranian accessions especially thanks to the second main component (PC2). The cultivated saffron populations coming from Iran are subdivided into two main groups, the first group comprises Rhan and Ghaien; the second group includes Ghassabeh, Tapehrigh and Torbat. With regard to the morpho-physiological traits the Iranian accessions highlight among them some phenotypic diversity.

Molecular analysis

A total of 22 samples (2 samples per accession) were genotyped using 8 AFLP primer combinations and a total of 318 amplification products were scored (*Table 6*). Detected polymorphisms range from 0% (Eco-CCA/Mse-ATC and Eco-CCA/Mse-AGC) to 8.51% (Eco-CCA/Mse-AGC) depending on the primer combination, with an

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18751887

average of 4.13%. The molecular weight of the amplification products ranged from 51 to 389 bp. and the average number of bands scored per reaction was 39.75 with a variation from 24 (Eco-CAA/Mse-ACA) to 61 (Eco-CCA/Mse-AGC).

A graphic representation of saffron accession genetic similarity level, based on a cluster analysis, is showed in *Figure 2*. With the exception of the saffron population coming from Spain, which showed to be well differentiated from all others, all the accessions are grouped into two main clusters (A and B). Cluster A consists of two sub-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18751887

groups: the first includes all Umbrian accessions (Cascia, Città della Pieve, and S. Anatolia di Narco). In particular, with the primer combinations used, accessions from Città della Pieve and S. Anatolia di Narco showed no molecular differences. The second sub-group consists of two Iranian populations (Rahn and Ghaien) and the population belonging to Abruzzo Region (Barisciano). Cluster B grouped all the remaining Iranian populations (Ghassabbeh, Torbat, Tapehrig, and Torbat_Market). However, in cluster B it is also possible to distinguish two sub-clusters: the first includes the accession collected both in Tapehrigh and in the market (Torbat Market), the second sub-cluster gathers one accession from Torbat and one from Ghassabeh.

Discussion

In this study, a morpho-physiological and molecular characterization was developed for investigating the existing diversity among different populations of *C. sativus* L. Analysis of variance of the morpho-physiological data shows that the Italian accessions of saffron yielded a greater number of flowers than the Iranian accessions. Regarding to the diameter of the corms, highly correlated with the production of flowers, the Italian accessions (in particular Barisciano) showed higher values than those collected in Iran. This is probably due to the traditional practice of the annual selection of bigger corms carried out in Abruzzo (Gresta et al., 2008a), and the increased availability of water and nutrients. Barisciano accession was also characterized by the earliest emergence of leaves and by the highest length of the stigmas. In the present work, the morpho-physiological characteristics of the leaves, flower and corms allowed to discriminate saffron populations. This result highlights the usefulness of the morphological characterization of local germplasm, especially in the early stages of the genetic characterization. Indeed, the morpho-physiological traits have allowed a clear discrimination of the Italian accessions from those collected in Iran and in the Torbat market.

For the genetic characterization the AFLP markers were chosen among other classes of molecular markers because they do not require a priori knowledge of the genome of the species, further more they are highly informative and reproducible. The eight AFLP primer combinations discriminated the Spanish accession from all other saffron populations. In addition, this study showed that populations belonging to Umbria (Cascia, Città della Pieve, S. Anatolia di Narco) may have the same genetic origin, as they show no or very little molecular differences. Probably the original saffron was spread through Umbria by exchange of corms between farmers and this is particularly true for saffron belonging to Città della Pieve and S. Anatolia di Narco. The Abruzzo population (Barisciano), although belonging to the same cluster (cluster A) of other Italian populations, seems to be genetically closer to two Iranian populations (Rhan and Ghaien). The other four Iranian populations were grouped apart from other accessions in a separate cluster (cluster B) (*Fig. 2*).

Conclusion

The results of this study partially confirm obtained in previous studies carried out in saffron (Grilli Caiola and Canini, 2004). However, according to (Fernandez, 2007) it is possible to find different saffron products on the market. This may be due to the growing environment, to the collection and processing of spice, but probably also to genetic differences between the different clonal populations. For instance in Navelli (Abruzzo Region – Italy) the selection of corms carried out each year has produced a significant “genetic pool” with respect to corm dimensions and disease resistance (Gresta et al., 2008a). The same results eas shown in comparison the results of this study, with other saffron research’s (Yousefi Javan and Gharari, 2018), using the other molecular markers for prove genetic diversity. The main difference between the two studies is use of different markers and different regions.

Particularly in this study, despite several morphological differences found between accessions, molecular markers (AFLP) have revealed limited genetic differences in particular for Italy and Iran (Genetic Similarity = 0.985) samples. Also in another research with the different markers, *C. sativus* demonstrated minimal genetic variation,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18751887

in contrast to the intraspecific variability seen in other *Crocus* species, and it is concluded that the triploid hybrid species has most probably happened only once. The data show that saffron is an allotriploid species, with the IRAP analysis indicating that the most likely ancestors are *C. cartwrightianus* and *C. pallasii* subsp. *Pallasii* (or close relatives). The results may facilitate resynthesizing saffron with improved characteristics, and show the need for conservation and collection of wild *Crocus*.

The vegetative multiplication limits for this crop the application of conventional breeding approaches for its further improvement. The selection of the best lines among natural or cultivated populations is restricted to searching for a quote of variability deriving from some rare mutations.

Therefore greater efforts must be made to investigate the genetic variability in this crop that is having an increasing economic value. Looking for saffron populations, that have retained some level of sexual reproduction, with the aim of crossing and selecting new types, could be a further challenge.

Abstract. Fertilizer application is an important part in super rice production. In order to investigate the effect of fertilizer amounts on the antioxidant performance of the super rice, three super hybrid rice cultivars, *YLiangyou-1173*, *YLiangyou-911* and *Chaoyou-1000*, were used in the experiment. The fertilizer amounts were set as: (F1)1050 kg N ha^{-1}; (F2) 1200 kg N ha^{-1}; (F3) 1350 kg N ha^{-1}; (F4) 1500 kg N ha^{-1}; (F5) 1650 kg N ha^{-1}. The results showed that the activities of antioxidant enzymes were decreased when excessive fertilizers such as F4 and F5 were applied. Compared with F1, F4 and F5 significantly reduced the activity of superoxide (SOD, EC 1.15.1.1), guaiacol type peroxidase (POD EC1.11.1.7) and catalase (CAT, EC1.11.1.6). Furthermore, there was no remarkable significant difference related to the yield among F2, F3, F4 and F5.
Keywords: *rice, superoxide, catalase, peroxidase, yield, fertilizer*

Introduction

Rice (*Oryza sativa* L.) has been cultivated in China for a very long time and its production has played an important role in Chinese food security (Ren et al., 2017). Many experts had done many researches in different fields to improve to improve rice yield and quality (Wang and Zhang, 2017; Wu et al., 2018; Jiang et al., 2018). Generating rice varieties with high yield potential is a main method to improve rice yield. In 1996, China's ministry of agriculture proposed the super hybrid rice cultivation program which was led by Yuan Longping, the "father of hybrid rice", in 2000, the super hybrid rice varieties reached the first-stage single rice yield standard, that is, the yield per hectare exceeded 10.5 tons and in 2004, the output of super hybrid rice reached the second stage (Schmalzer, 2017). Normally, in order to improve the potential of yield and increase the final yield of super rice, researchers and farmers would apply as much fertilizer as possible and try to found the correlation between rice yield and fertilizing amount. However, there was no much report about the effect of fertilizer amount on rice physiological property especially antioxidant property.

The antioxidant system is very important when rice faces the environment stress such as heat stress, chilling, heavy metal stress and it also has relationship with rice yield and quality. When rice faces the environmental stress including UV stress and pathogen invasion, the reactive oxygen species (ROS) will be produced and accumulated while oxidative stress is induced. Then, a lot of cellular reactions will be produced in by various enzymes such as superoxide dismutase (SOD), catalase (CAT) and peroxidase (POD). The formation of ROS is prevented and decreased by an antioxidant system which including ROS-interacting enzymes such as SOD, CAT and POD (Blokhina, 2003). The study of Kong (Kong et al., 2017) showed that the malondialdehyde (MDA) content would increase when rice suffered from high temperature stress at filling stage and the soluble protein, POD, SOD, CAT and free proline would work together to quench the ROS and decrease the MDA concentration. Pan (Pan et al., 2013) demonstrated that spraying paclobutrazol (PBZ) and 6-Benzylaminopurine (6-BA) at heading stage could not only increase POD and SOD activities but also improve the rice yield and grain quality.

Many researches had proved that fertilizer application is a key part in rice production (Shakoor et al., 2018; Liu et al., 2018). The study of Li et al. (2016) showed that manganese (Mn) fertilizer could enhance enzyme activity involved in 2-acetyl-1-pyrroline (2-AP) biosynthesis in fragrant rice while regulating the grain yield. The investigation of Pan et al. (2017) revealed that mechanized deep placement of nitrogen fertilizer in direct-seeded rice improved rice yield by promoting the fertilizer uptake of rice and increasing the utilization rate. Fertilizer application is the other source of rice nutrition beside photosynthesis and it also could affect the rice growth environment such as soil properties (Sun et al., 2018; Ghaley et al., 2018). However, the relationship between fertilizer amount and rice antioxidant property is still unknown to us.

Therefore, the study was conducted in Guangzhou, Guangdong (major rice producing province in South China) in early season in 2018 in order to investigate the effect of different amount of fertilizer on antioxidant performance of three super rice cultivars.

Materials and methods

Plant materials and growing condition

Three super hybrid rice cultivars, *YLiangyou-1173*, *YLiangyou-911* and *Chaoyou-1000*, well-known and widely grown in South China, were in planted in the early season in Guangzhou (23°16’ N, 113°23’ E) during 2018. Before sowing, the seeds were soaked in water for 24 h, germinated in manual climatic box for the next 24 h, shade dried and the germinated seeds were sown in PVC trays for nursery raising. 20-day-old seedlings were transplanted to the field at the planting distance (30 cm × 12 cm). The experimental soil in Guangzhou was sandy loam with of 24.65% organic matter content, 1.560% total N, 0.956% total P, and 18.460% total K.

Treatments and plant sampling

Five amounts of commercial compound fertilizer were applied at the experiment and set as below:

F1: 1050 kg ha^{-1} commercial compound fertilizer (pure nitrogen 131.25 kg ha^{-1}, pure phosphate 63 kg ha^{-1}, pure potassium 105 kg ha^{-1}, organic fertilizer 210 kg ha^{-1});
F2: 1200 kg ha^{-1} commercial compound fertilizer (pure nitrogen 150 kg ha^{-1}, pure phosphate 72 kg ha^{-1}, pure potassium 120 kg ha^{-1}, organic fertilizer 240 kg ha^{-1});
F3: 1350 kg ha^{-1} commercial compound fertilizer (pure nitrogen 168.75 kg ha^{-1}, pure phosphate 81 kg ha^{-1}, pure potassium 135 kg ha^{-1}, organic fertilizer 270 kg ha^{-1});

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18891898

F4: 1500 kg ha^{-1} commercial compound fertilizer (pure nitrogen 187.50 kg ha^{-1}, pure phosphate 90 kg ha^{-1}, pure potassium 150 kg ha^{-1}, organic fertilizer 300 kg ha^{-1});
F5: 1650 kg ha^{-1} commercial compound fertilizer (pure nitrogen 206.25 kg ha^{-1}, pure phosphate 99 kg ha^{-1}, pure potassium 165 kg ha^{-1}, organic fertilizer 330 kg ha^{-1}).

The fertilizer was invented by Tang Xiangru (CN 101955394 A). The special fertilizer is a mixture of nitrogen (N) fertilizer, phosphate (P) fertilizer, potassium (K) fertilizer and biological organic fertilizer (12.50% N, 6.00% P, 10.00% K and 20.00% organic matter content). Normally, the local farmers in Guangdong were used to applied 1500 kg ha^{-1}. The treatments were arranged in randomized complete block design (RCBD) in triplicate in each year with net plot size of 20 m^2.

The fresh flag leaves were separated and collected from the rice plants at tillering stage, heading stage and maturity stage, respectively. The sample was washed with double distilled water and stored at -80 °C for physio-biochemical analysis.

Measurement of malondialdehyde (MDA) and anti-oxidants responses

The MDA content and activities of POD, SOD and CAT were determined according to the methods described by Kong et al. (2017). MDA reacted with thiobarbituric acid (TBA) and the absorbance was read at the 532 nm, 600 nm, and 450 nm. The content of the reaction solution was calculated as: MDA content (μmol/L) = 6.45(OD532 −OD600) − 0.56OD450, while the final result was expressed as μmol/g FW.

Guaiacol type peroxidase (POD EC1.11.1.7) activity was estimated after the reaction which the solution was including enzyme extract (50 μl), 1 ml of 0.3% H2O2, 0.95 ml of 0.2% guaiacol, and 1 ml of 50 mM l−1 sodium phosphate buffer (pH 7.0) while One POD unit of enzyme activity was expressed as the absorbance increase because of guaiacol oxidation by 0.01 (U/g FW). The superoxide (SOD, EC 1.15.1.1) activity was measured by using nitro blue tetrazolium (NBT). 0.05 ml of enzyme extract was added into the reaction mixture which contained 1.75 ml of sodium phosphatebuffer (pH 7.8), 0.3 ml of 130 mM methionine buffer, 0.3 ml of 750 μmol L^{-1} NBT buffer, 0.3 ml of 100 μmol L^{-1} EDTA-Na 2 buffer and 0.3 ml of 20 μmol L^{-1} lactoflavin. After reaction, the absorbance was recorded at 560 nm. One unit of SOD activity is equal to the volume of extract needed to cause 50% inhibition of the color reaction. Catalase (CAT, EC1.11.1.6) activity was estimated by adding an aliquot of enzyme extract (50 μl) to the reaction solution containing 1 ml of 0.3% H2O2 and 1.95 ml of sodium phosphate buffer and then the absorbance was read at 240 nm. One CAT unit of enzyme activity was defined as the absorbance decrease by 0.01 (U/g FW).

Estimation of rice yield

At maturity stage, the rice grains were harvested from ten unit sampling area (1.00 m^2) in each plot and then threshed by machine. The harvested grains were sundried and weighed in order to determinate the grain yield.

Statistical analysis

Data were analyzed using statistical software ‘Statistix 8.1’(Analytical Software, Tallahassee, FL, USA) while differences amongst means were separated by using least significant difference (LSD) test at 5% probability level. Graphical representation was conducted via Sigma Plot 14.0 (Systat Software Inc., California, USA).

Results

SOD activity

As shown in *Figure 1,* there were some differences on SOD activity among different fertilizer amounts. For *YLiangyou-1173*, there was no remarkable difference between F1 and F2. However, F4 and F5 had lower SOD activity than F1 at tillering stage, heading stage and maturity stage. The trend of SOD activity at tillering stage and maturity stage was recorded as: F1 = F2 > F3 > F4 > F5. For *YLiangyou-911*, the activity decreased with the increase of fertilizer amount. The lowest activity was recorded in F5 while the highest was recorded in F1 at tillering stage and heading stage. The trend at maturity was recorded as: F1 > F2 = F3 > F4 = F5. For *Chaoyou-1000*, at tillering stage, the trend of SOD activity was recorded as: F1 = F2 > F3 > F4 = F5, at heading stage, highest activity was recorded in F1 and the lowest was observed in F5 while in maturity stage, there was no significant difference among F1, F2 and F3 while F4 and F5 were significantly lower than F1.

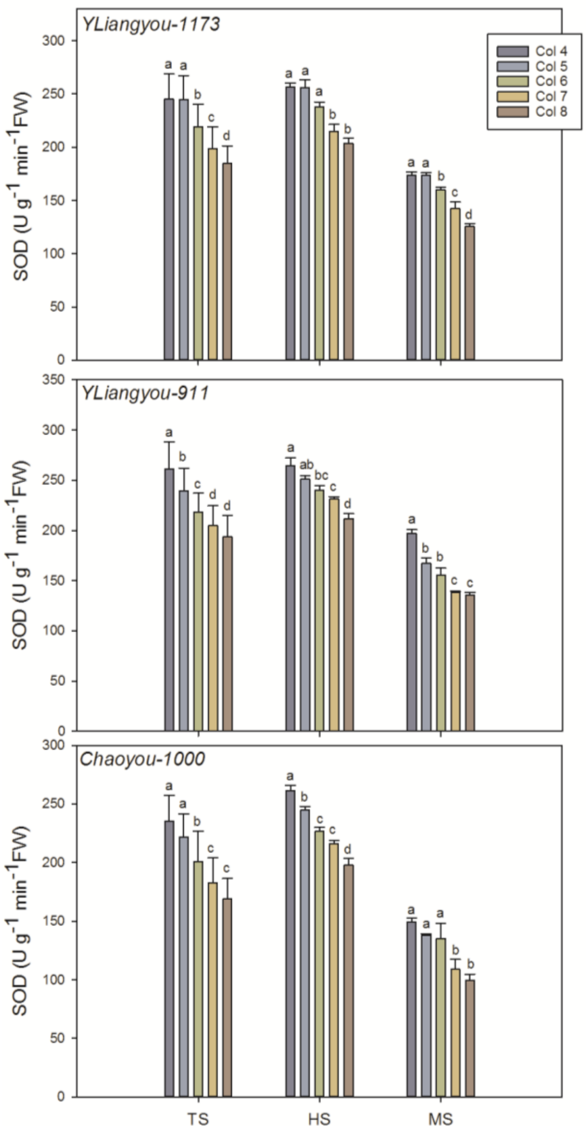

***Figure 1.** Effect of fertilizer amounts on SOD activity. TS: tillering stage; HS: heading stage; MS: maturity stage. Means sharing a common letter do not differ significantly (at P < 0.05) according to least significant difference (LSD) test for both the seasons*

CAT activity

As shown in *Figure 2,* fertilizer amounts affected CAT activity significantly. For *YLiangyou-1173*, the trends of CAT activity at tillering stage, heading stage and maturity stage were recorded as: F1 = F2 > F3 > F4 = F5, F1 = F2 ≥ F3 ≥ F4 = F5, F1 = F2 = F3 ≥ F4 ≥ F5, respectively. For *YLiangyou-911*, at tillering stage, the highest CAT activity was recorded in F1 and there was no remarkable difference among F3, F4 and F5. At heading stage, there was no significant difference among F1, F2, F3 and F4 while F5 had lower activity than F1. At maturity stage, compared with F1, F2, F3, F4 and F5 all significantly reduced the CAT activity while there was no remarkable difference among F2, F3, F4 and F5. For *Chaoyou-1000*, F3, F4 and F5 all had lower activity than F1 at tillering stage and heading stage, however, at maturity, there was no significant difference among all fertilizer treatments.

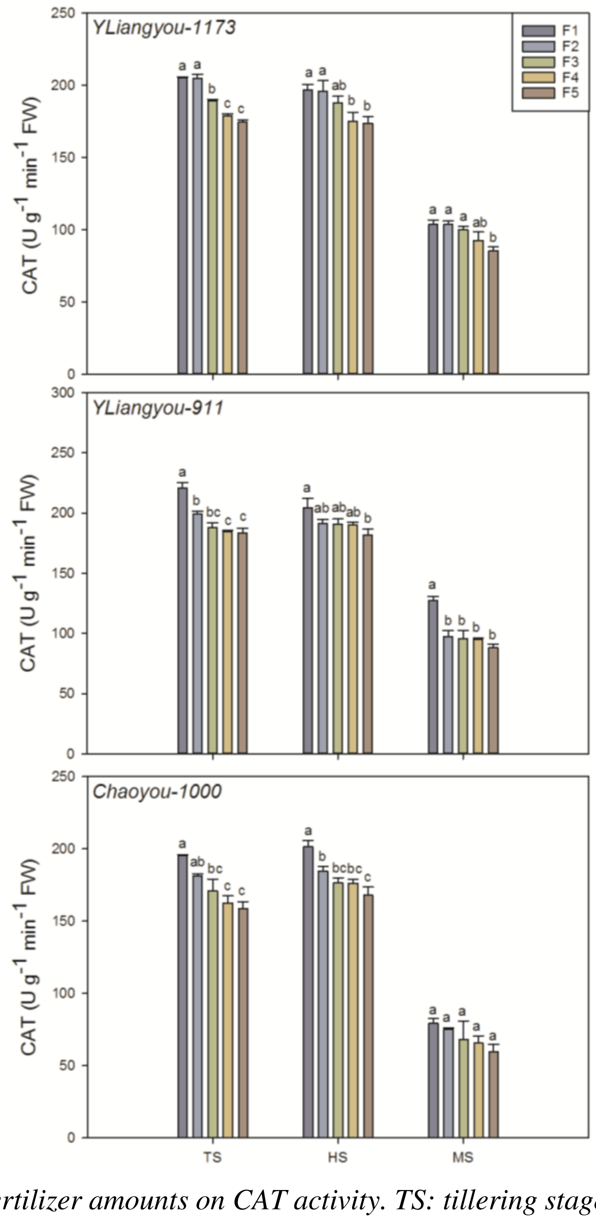

Figure 2. *Effect of fertilizer amounts on CAT activity. TS: tillering stage; HS: heading stage; MS: maturity stage. Means sharing a common letter do not differ significantly (at P < 0.05) according to least significant difference (LSD) test for both the seasons*

DOI: http://dx.doi.org/10.15666/aeer/1702_18891898

POD activity

As shown in *Figure 3,* fertilizer amounts affected POD activity significantly. For *YLiangyou-1173*, compared with F1, F4 and F5 reduced the POD activity significantly and there was no significant difference between F2 and F1 at heading stage and maturity stage. For *YLiangyou-911*, there was no remarkable difference between F1 and F2 at all three growth stage. However, F3, F4, F5 had lower activity than F1 at all three growth stage. For *Chaoyou-1000*, compared with F1, F4 and F5 significantly decreased the CAT activity at all growth stage. Furthermore, there was no remarkable difference among F1, F2 and F3 at maturity stage.

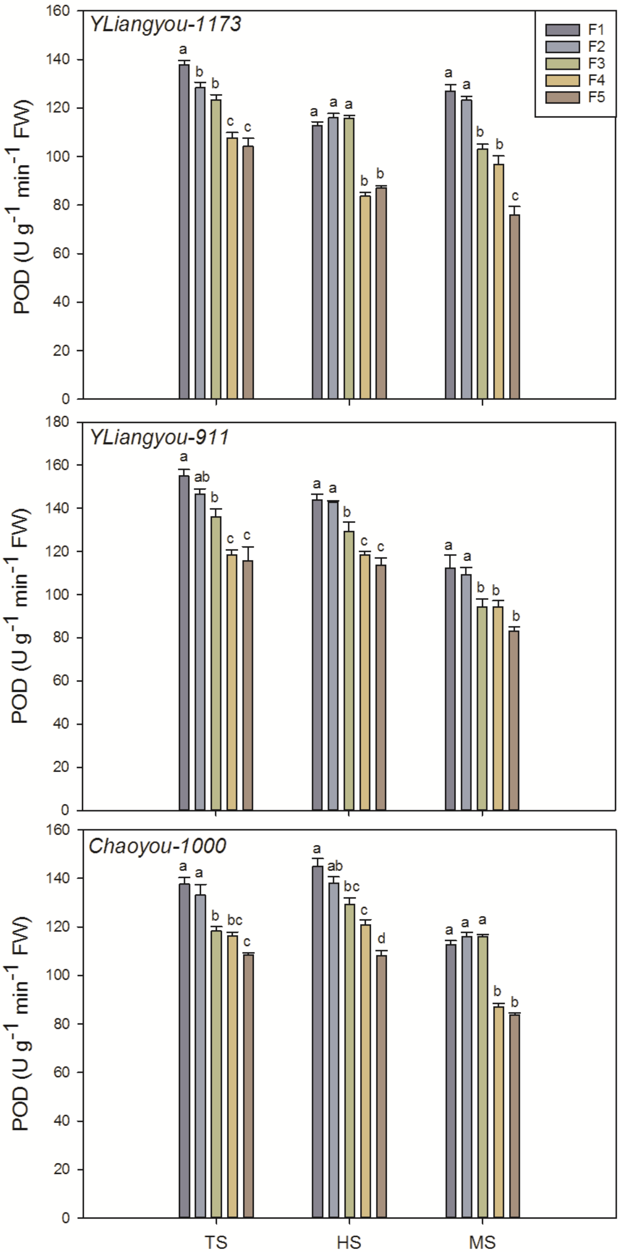

Figure 3. *Effect of fertilizer amounts on POD activity. TS: tillering stage; HS: heading stage; MS: maturity stage. Means sharing a common letter do not differ significantly (at P < 0.05) according to least significant difference (LSD) test for both the seasons*

DOI: http://dx.doi.org/10.15666/aeer/1702_18891898

MDA content

As shown in *Figure 4,* fertilizer amounts affected MDA concentration significantly. For *YLiangyou-1173*, the highest MDA content was recorded in F5 and the lowest was recorded in F2. For *YLiangyou-911*, at tillering stage, there was no significant difference among F1, F2, F3 and F4, at heading stage, the highest content was recorded in F5 while there was no remarkable difference among F1, F2 and F3, at maturity stage, there was no significant difference among all fertilizer treatments. For *Chaoyou-1000*, the trend of MDA content was recorded as: F5 > F1 > F4 > F3 > F2 at tillering stage, at heading stage, the highest content was recorded in F5 while the lowest was recorded in F2 and F3. At maturity, the highest concentration was recorded in both F5 and F4 while the lowest was recorded in F1.

DOI: http://dx.doi.org/10.15666/aeer/1702_18891898

Yield

As shown in *Figure 5,* fertilizer amounts affected grain yield significantly. For *YLiangyou-1173*, F2, F3, F4 and F5 had higher yield than F1 but there was no remarkable difference among F2, F3, F4 and F5. For *YLiangyou-911*, with the increase of fertilizer application, the yield increased first and then decreased but there was no significant difference between two adjacent fertilizer gradients. For *Chaoyou-1000*, the trend of was recorded as: F5 = F4 = F3 ≥ F2 ≥ F1.

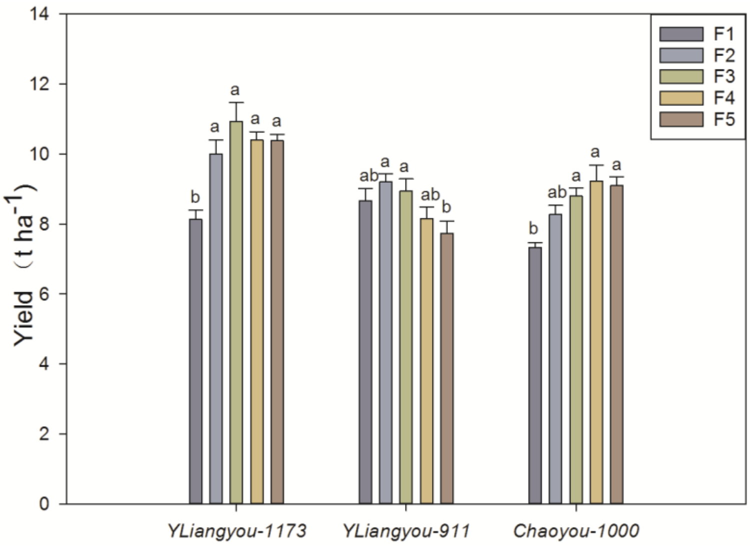

Figure 5. *Effect of fertilizer amounts on yield. Means sharing a common letter do not differ significantly (at P < 0.05) according to least significant difference (LSD) test for both the seasons*

Discussion

The effect of fertilizer on rice had been reported by many researchers. Mo et al. (2017) demonstrated that Silicon (Si) fertilizer had ability to regulate the fragrant rice yield and the content of 2-AP. The research of Sikar et al. (2008) showed that 80 kg hm^{-2} nitrogen improved grain quality significantly and the nitrogen utilization efficiency is connected to the locations and rice genotypes. Previous study (Mahajan et al., 2010) also revealed that high nitrogen application could cause the lodging in rice. In our study, we observed that different amounts of fertilizer influenced the super rice antioxidant system in terms of POD, SOD, CAT and MDA. The result showed that F4 and F5 treatments reduced the enzymes activity significantly which indicated excessive fertilization might improve rice growth, but would reduce the antioxidant capacity.

Antioxidant capacity which involves antioxidant enzymes such as POD, SOD and CAT is a key indicator to measure the ability of rice to resist environmental stress (Almeselmani et al., 2006). Normally, when rice faces environmental stress such as heat damage, chilling, heavy metal stress or extreme weather, the reactive oxygen species (ROS) concentration would increase quickly and cause a number of reactions (ZhangWei and Peng, 2018). For example, the peroxidation of unsaturated fatty acid in plant membranes induced by ROS, resulting in a decrease in the content of unsaturated fatty acid, an increase in MDA concentration and a decreased in membrane fluidity (El-Shintinawy, 2000), then, POD, SOD and CAT would play an important part in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18891898

quenching the ROS and lowering the MDA content. In our study, the results showed that the activity of antioxidant enzymes including SOD, CAT and POD would decrease if too much fertilizer was applied in super rice production. The decrease in antioxidant enzymes activity meant that the reduction of rice ability to quench the ROS and decreased MDA. Then, the risk of environmental stress and disease would be increased.

The harm of excessive fertilization had been reported in previous studies. For example, the study of Zhong and Zu (1997) revealed that supplying with excessive phosphate (P) fertilizer in early stage could not increase yield more than that applied with adequate P, due to the reduction in the valid grain percentage and weight per thousand grains. Similar phenomenon also was found in present study by showing that both F4 and F5 did not have a higher yield than F3. The investigation of Peng et al. (2010) showed that excessive nitrogen application to rice in China could cause environmental pollution, increase the cost of rice farming, reduce grain yield and contribute to global warming. From the perspective of antioxidant performance of rice, this experiment proved again that the importance of moderate fertilization and the harm of excessive fertilization.

Conclusion

Excessive fertilization could cause the decrement of activity of antioxidant enzymes such as SOD, POD and CAT, thus reduced antioxidant capacity of super rice. In rice production, people should pay more attention on rational application of fertilizer and for revealing the mechanism of how fertilizer amounts affecting rice antioxidant system, much work should be done at molecular and physiological level.

Abstract. Quinoa (*Chenopodium quinoa* Willd.) is a nutritionally important plant with a good protein quality and a high concentration of vitamins and minerals. It has been cultured for several thousand years in South America. In this study, we investigated the use of inter-primer binding site (iPBS) for the molecular characterization of 17 quinoa genotypes (*Chenopodium quinoa* Willd.) cultivated in Turkey. For this purpose, 25 iPBS markers were employed, and six primers provided sufficient polymorphic data generating a total of 19 alleles with an average of 2.83 bands/primer. The number of iPBS bands per individual was calculated as 1.12. The rate of polymorphism information content ranged from 0.02 to 0.49 with an average of 0.20. Genetic associations were assessed using the Dice dissimilarity coefficient between different pairs of accessions and revealed an average value of 0.84 for the French population and Q-52 genotypes. Cluster analysis on the unweighted pair-group mean average divided the 17 quinoa genotypes into two major clusters. The results of the principal component analysis were in agreement with those of the cluster analysis. The highest number of alleles, Nei's genetic diversity, and Shannon's information index were obtained from the French Vanilla genotype at 1.99, 0.50 and 0.69, respectively, whereas the lowest values were observed in the Q–52 genotype at 1.10, 0.09 and 0.20, respectively. The expected heterozygosity ranged from 0.398 in the first sub-population to 0.140 in the second sub-population with an average of 0.269. The mean population differentiation measurement (F_{st}) values of the sub-populations were 0.048 and 0.676 for the first and second sub-populations, respectively. The results of this study provide useful information for the management of the quinoa germplasm and contribute to the improvement of existing breeding approaches. They also presented the iPBS marker system as a suitable tool for identification and genetic diversity analysis of quinoa genotypes.

Introduction

In the region of Andean-South America, quinoa (*Chenopodium quinoa* Willd.) is considered to be one of the essential food crops. It is known as a member of the amaranth family (formerly *Chenopodiaceae*), which also contains other frugally essential species, such as spinach (*Spinacea oleracea* L.) and sugar beet (*Beta vulgaris* L.). Quinoa usually grows in saline and arid soils, frequent forests, and high altitudes of the Altiplano (Prado et al., 2000). Quinoa is traditionally widely consumed as a food crop by the people of the Altiplano region as part of their daily diet. Quinoa contains a perfect balance of lipids, protein, and carbohydrates, as well as amino acids essential for human nutrition (Chauhan et al., 1999). It is an allotetraploid (2n = 4x = 36) which has a domestic inheritance of most quality characters (Ward, 2000).

To simplify the application of molecular tools and enhance basic knowledge concerning quinoa, Fairbanks et al. (1990) and Ruas et al. (1999) reported DNA-based markers for this species based on the random amplified polymorphic DNA (RAPD) method. Microsatellite markers (SSR) have been developed to characterize the quinoa germplasm by Mason et al. (2005), Christensen (2007), Fuentes et al. (2009), Costa

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18991911

(2012) and Lu et al. (2015). Ana-Cruz et al. (2017) and Al-Naggar et al. (2017) also attempted to characterize the genetic diversity of a collection of quinoa using inter-simple sequence repeats. Employing markers, such as amplified fragment length polymorphism (AFLP), RAPD, and SSR, a genetic linkage map was established for quinoa (*C. quinoa*) (Maughan et al., 2004); furthermore, single nucleotide polymorphism (SNP) markers were developed (Coles et al., 2005; Maughan et al., 2012). Anabalon-Rodriguez and Thomet-Isla (2009) detected the level of polymorphism and the genetic relationships using the AFLP technique in quinoa (*C. quinoa*).

The fundamentally predominant existence of the tRNA complement as a converse transcriptase primer binding site (PBS) in LTR retrotransposons is a source of polymerase chain reaction (PCR)-based iPBS amplification (inter-primer binding site - iPBS). Specifically, the iPBS amplification technique was developed as a remarkable DNA fingerprinting technology that does not require any primary sequence data. Therefore, for controlling the changes in the DNA profile of plants, the iPBS marker system is an easy and fast process. This technique has been successfully used in flax (Smykal et al., 2011), apricot (Baránek et al., 2012), latvia (*Saussurea esthonica* L.) (Gailite and Rungis, 2012), chickpea (Andeden et al., 2013), guava (Mehmood et al., 2016), grape (Guo et al., 2014), okra (Yildiz et al., 2015), rice (Comertpay et al., 2015), lentil and pea (Baloch et al., 2015), tea (Phong et al., 2016), saffron (Gedik et al., 2017) and motherwort (*Leonurus cardiaca* L.) (Borna et al., 2017). In this study, to simplify the application of molecular tools and offer a better understanding of the genetic diversity of quinoa genotypes, we utilized iPBS molecular markers for these species for the first time in the literature.

The purpose of this experiment was to investigate the genetic diversity of 17 quinoas genotypes using the iPBS marker system, to evaluate the structure of the diversity in the germplasm, and to generate useful information for future breeding programs on quinoa.

Materials and methods

Genetic material

The quinoa (*C. quinoa* Willd.) genotypes were collected from different countries as a work package of a project supported by The Scientific and Technological Research Council of Turkey (TUBITAK) (TOVAG 214 O 232). A total of 17 quinoas genotypes were used in the experiment (*Table 1*).

Genomic DNA isolation

Total genomic DNA from the quinoa genotypes was isolated from 300 mg young leaf tissue using the method described by Zeinalzadeh-Tabrizi et al. (2015). For determination of the concentration and quality of genomic DNA, a spectrophotometer (Thermo Fisher Scientific) was used and electrophoresis was performed in 0.8% (w/v) agarose gel.

iPBS-PCR amplification

Twenty-five primers were used in iPBS-PCR reactions (*Table 2*). The PCR amplifications were carried out in a thermal cycler (Labcycler). The PCR mixture consisted of 10x buffer, 2 µM (20 pmol) primer, 2 mM $MgCl_2$, 0.25 mM of each dNTP, 0.5 U *Taq* polymerase, and 50 ng/µl DNA template in a total volume of 20 µl. The

DOI: http://dx.doi.org/10.15666/aeer/1702_18991911

amplification conditions were; an initial denaturation step of five min at 95 °C, 38 cycles of 60 s at 95 °C, 60 s at 44-60 °C and 60 s at 72 °C, and a final extension step of 10 min at 72 °C. The amplification products were resolved in 1.5% agarose gel in 1X SB buffer at 100 V/cm for 120 min, stained with ethidium bromide (0.2 ug/ml), and visualized under a UV light in a Universal Hood II (Bio-Rad, Hercules, CA, USA). The sizes of the base pairs were determined based on a DNA ladder between 50 and 1000 bp (Vivantis Product No: NM2421).

Data analysis

For each primer, the presence and absence of a strong and sharp polymorphic band were scored as 1 and 0, respectively using TotalLab TL120 software package (Germany). The association between the genetic dissimilarity was evaluated with the Numerical Taxonomy and Multiware Analysis System (NTSYSpc version 2.0) according to the Dice similarity matrix (Dice, 1945). Using the same software, an unweighted pair-group mean average (UPGMA) tree was constructed and a principle component analysis (PCA) was undertaken (Rohlf, 1998). The diversity of each iPBS marker was calculated using polymorphism information content (PIC) according to the following equation: $PIC = 1 - \Sigma pi2$, where P_{ij} is the frequency of the patterns (j) for each marker (i) (Anderson et al., 1993). To determine the genetic parameters, the number of alleles (ne), Nei's genetic diversity (h), and Shannon's information index (I) were calculated by POPGEN 1.32 (Yeh et al., 1997).

The genetic structure datasets were formed to be determined by a model-based cluster analysis using STRUCTURE software version 2.2 (Pritchard et al., 2000a, b). The number of populations (K) was presented for a run of ten times for each population, which varied from 2 to 10, characterized by a set of distinctive allele frequencies at each locus, and individuals were situated in K clusters. In this process, the posterior

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18991911

probabilities were estimated using the Markov Chain Monte Carlo (MCMC) method. The MCMC chains were run with a 100,000-iteration burn-in period, followed by 100.000 iterations using a model allowing for admixture and correlated allele frequencies. The most expected value for K was predicted using Evanno's ΔK method (Evanno et al., 2005) using STRUCTURE HARVESTER. Furthermore, the expected heterozygosity (gene diversity) and population differentiation (Fst) between the individuals in a sub-population were determined using STRUCTURE (Earl, 2012).

Results and discussion

Polymorphism revealed by iPBS primers

In this experiment, 25 iPBS primers were used to evaluate 17 quinoa genotypes, and only six primers generated a sufficient number of polymorphisms (*Fig. 1*) with four primers providing more than one polymorphic band. The average of polymorphic bands was calculated as 2.83, and that of monomorphic bands was 0.33. Based on these values, the number of iPBS bands per individual was calculated as 1.12 (*Table 3*).

Table 3. *Diversity statistics for Quinoa (Chenopodium quinoa Willd.) with iPBS*

Primer name	**Allele number**	**Percentage of polymorphism**	**PIC value**
iPBS-2080	7	100.00%	0.49
iPBS-2270	1	100.00%	0.03
iPBS-2279	3	66.66%	0.14
iPBS-2390	1	100.00%	0.02
iPBS-2391	4	75.00%	0.23
iPBS-2392	3	100.00%	0.18

Similar to our results, Mehmood et al. (2013) selected 6 primers out of 83 iPBS primer set in guava genotypes and Guo et al. (2014) selected 15 primers out of 41 iPBS primers in grape varieties, for further analysis. This is also in agreement with reports on other plants, such as grape (Guo et al., 2014), guava (Mehmood et al., 2016), and those investigated by Kalendar et al. (2010). The total number of polymorphic bands was 19 for iPBS markers, of which 17 were polymorphic and the remainder were considered as monomorphic. In this research, the number of alleles/polymorphic loci ranged from one to seven with an average of 3.16 for the iPBS analysis. Furthermore, the highest number of polymorphisms was obtained from iPBS-2080 with seven bands. In a study that aimed to develop molecular markers for the Fusarium wilt resistance gene in eggplant, Mutlu et al. (2008) found an average number of 1.5 bands per primer. The PIC value varied between 0.02 (iPBS 2390) and 0.49 (iPBS 2080), with an average of 0.20 (*Table 3*). These results are in agreement with earlier research into different plants, such as guava (*Psidium guajava* L.) cultivars with an average PIC of 0.28 (Mehmood et al., 2016) and tea (*Camellia sinensis*) cultivars with an average PIC of 0.30 (Phong et al., 2016). The percentage of polymorphism (%) value ranged from 66% (iPBS 2279) to 100% (iPBS 2080, 2390 and 2392) with an average of 90.27% (*Table 3*).

Genetic diversity in quinoa

Table 4 presents a summary of the statistical results for each of the 17 quinoa genotypes. The highest number of alleles (ne), Nei's genetic diversity (h), and Shannon's information index (I) were obtained from the French Vanilla genotype at 1.99, 0.50 and 0.69, respectively, whereas the lowest values were observed in the Q–52 genotype at 1.10, 0.09 and 0.20, respectively. In addition, the total average number of alleles (ne), Nei's genetic diversity (h), and Shannon's information index (I) were 1.52, 0.032 and 0.49, respectively. Fuentes et al. (2009) used 20 SSR loci and calculated

DOI: http://dx.doi.org/10.15666/aeer/1702_18991911

Shannon's index as 2.582 for the Highland genotype and 3.714 for the coastal genotypes Furthermore, the average value of Shannon's information index was reported as 0.12 in the Turkish okra germplasm (Yildiz et al., 2015), 0.29 for the *Crocus sativus* genotypes (Gedik et al., 2017), and 0.27 for guava (Mehmood et al., 2013) using iPBS-retrotransposon markers.

Cluster analysis and principal component analysis for iPBS-retrotransposon markers

The Dice genetic similarity coefficient was used for the diversity estimation of the genotypes. This coefficient is commonly utilized to estimate genetic distances. The genetic similarity between the accessions based on the iPBS markers ranged from 11% to 100% with an average value of 55.5%. In this study, the 100% similarity value was found between the two most closely related accessions, Titicaca and UK6, and Q haslala Blanca and Red (*Table 5*). Nemli et al. (2014) reported similar findings in a study that explored the genetic similarity between the accessions of common bean (*Phaseolus vulgaris* L.) by peroxidase gene-based markers. The authors found the similarity coefficients to vary between 0.7 and 1.

The UPGMA tree constructed using the Jaccard genetic distance coefficient is presented in *Figure 2*. The analysis divided the quinoa genotypes into two main groups: Group A containing three genotypes (17.65%) and group B containing 14 genotypes (82.35%). Group A had two sub-groups: the first containing French Population and the second comprising the genotypes Chinese Population and Mint Valle. Similar to group A, group B had two sub-groups; the first containing Rainbow, Moqu Arochilla, and Red Head and the second comprising French Vanilla, USA 4, Red Population, Q Blanca, Sandoval Mix, Q-52, Chery Vanilla, Oro de Volle, UK6, Titicaca, and Ikwadur 7 (*Fig. 2*).

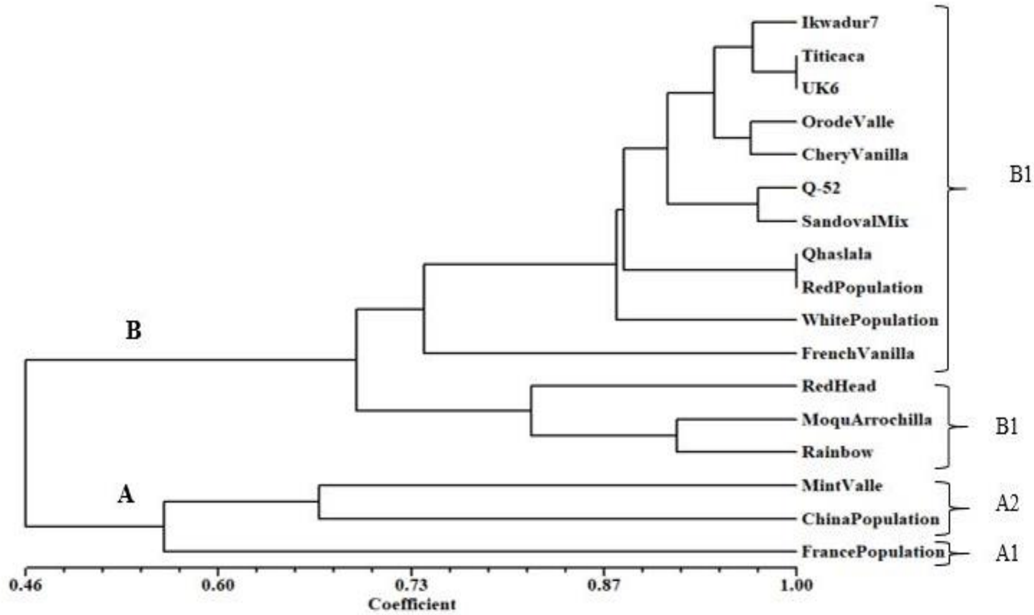

Figure 2. *Dendrogram of 17 Quinoa genotypes based on iPBS markers according to UPGMA with the Dice similarity index*

As a one-dimensional reduction technique, PCA can be used to review molecular marker profiles into some uncorrelated components (Hotelling, 1933). The pattern of cluster analysis was further confirmed by PCA because this method provides a better-defined structure than a dendrogram. In the current study, PCA was used to determine the variations between the two populations (*Fig. 3*). The clustering of varieties based on a dendrogram and a PCA plot was similar with no discrepancy being observed. This result is supported by Belaj et al. (2002) and Zargar et al. (2014), who reported similar

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18991911

findings using RAPD and SSR markers obtained similar findings related to the diversity of 32 olive cultivars based on the dendrogram topologies.

Christensen et al. (2007) evaluated the hereditary mutation in the USDA and CIP-FAO international nursery collections of quinoa (*Chenopodium quinoa* Willd.) by means of microsatellite markers and found that both UPGMA and PCA analyses divided the quinoa accessions into two key groups. Fuentes et al. (2009) investigated the genetic variety patterns in the Chilean quinoa (*Chenopodium quinoa* Willd.) germplasm using multiplex fluorescent microsatellite markers and reported that PCA divided PC1 into two major branches, conforming the clusters and groups of the highland and coastal quinoa accessions of the UPGMA analysis.

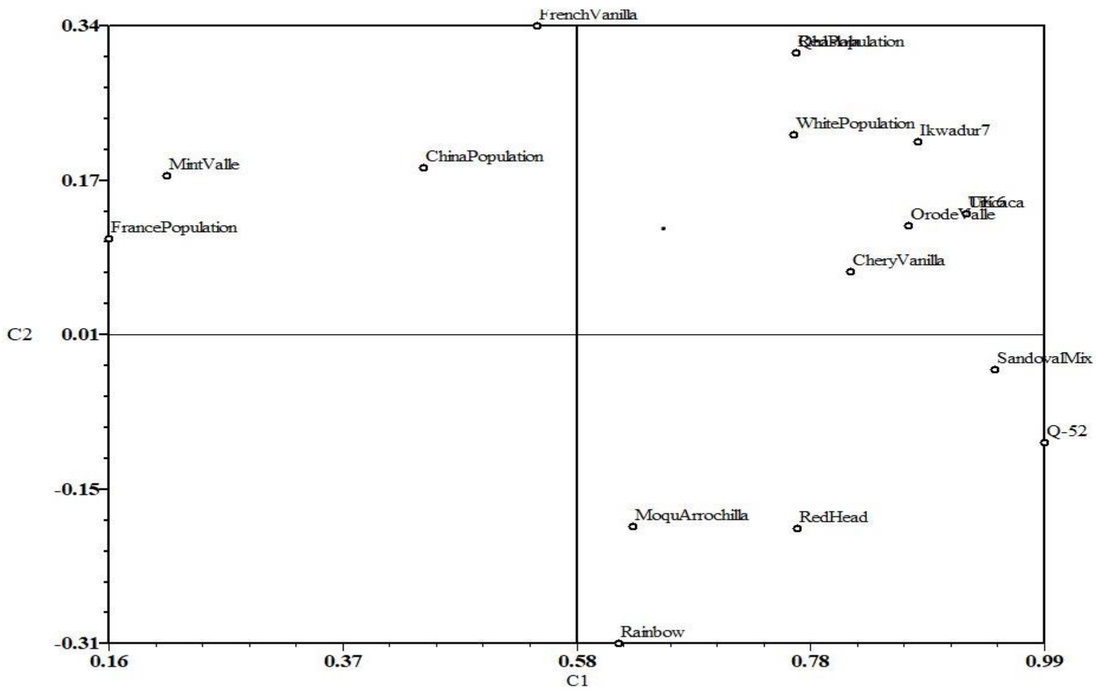

Figure 3. *PCA of 17 Quinoa genotypes based on 10 iPBS markers*

Population genetic structure analysis for iPBS-retrotransposon markers

Crop improvement is based on the understanding of the population assembly of germplasm collections. Before performing an association mapping study, it is crucial to first set the population structure within the germplasm to avoid spurious associations (Flint-Garcia et al., 2005). In this research, the population structure of the 17 quinoa accessions was categorized according to the iPBS data using STRUCTURE version 2.2 (*Fig. 4*) and two sub populations were found. Population 1 (POP 1) contained three accessions (French Population, Chinese Population and Mint Valle) and Population 2 (POP 2) consisted of the following 14 accessions (82.35% with membership probability of <0.7): Rainbow, Moqu Arochilla, Red Head, French Vanilla, USA 4, Red Population, Q Blanca, Sandoval Mix, Q-52, Chery Vanilla, Oro de Volle, UK6, Titicaca, and Ikwadur 7). The membership coefficient of the genotypes to specific sub-populations was very high and no possible admixture was detected in a reduced number of landraces. This may be due to the high rate of self-pollination of quinoa. Similar results were reported by Zhang et al. (2017) investigating the development of novel InDel

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_18991911

markers and genetic diversity in *Chenopodium quinoa* through whole-genome re-sequencing. The authors found that according to both L (K) and △K values, the two groups presented the optimal classification for these quinoa accessions. Parallel results were reported with high degrees of genetic variation as detected by AFLP in *Sideritis tmolea* by Nemli et al. (2014), who revealed the presence of a model-based structural analysis of two populations. Yoon et al. (2012) reported genetic diversity and population structure analysis of two populations of strawberry (Fragaria x ananassa Duch.) using SSR markers.

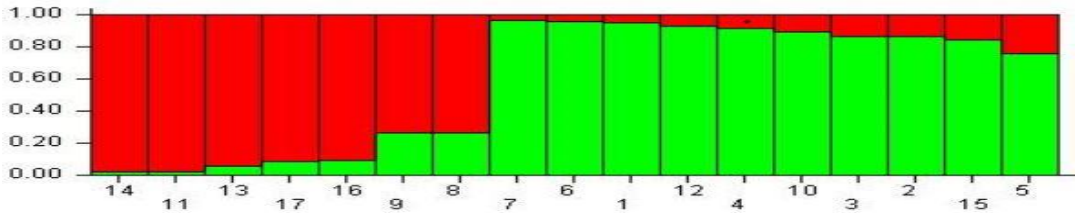

Figure 4. *Genetic structure of 17 quinoas genotypes as inferred by STRUCTURE software with 10 iPBS marker data sets. Single vertical line represents an individual accession and different colors represent genetic stocks/gene pools. Segments of each vertical line show extent of admixture in an individual*

In the current study, the population structure analysis confirmed the grouping of the genotypes, as observed by PCA and UPGMA clustering analyses. Similarly, Chen et al. (2015), who developed SSR markers to assess the genetic diversity of adzuki bean in the Chinese germplasm collection, showed that the structure and cluster analyses were usually consistent.

These results support the idea that dissimilar elevations in a topographical area might result in various levels of selection pressure for modification and could increase the differences within a population (Lopez-Gartner et al., 2009). The variation between gene pools suggests that cross breeding among these diverse areas will accelerate the process of diversifying germplasm creation and widen germplasm resources of quinoa. Meanwhile, efforts are being made to gather samples from different regions and produce the most effective markers to clarify the genetic diversity, population structure, and other details of population changeability in this ergonomically important genotype.

The expected heterozygosity which measures the probability of two randomly chosen individuals being different (heterozygous) in a given locus ranged from 0.398 in population 1 to 0.140 in the population 2 with an average of 0.269. The mean population differentiation measurement (F_{st}) values of the sub-populations were 0.048 and 0.676 (*Table 6*) for the first and second sub-populations, which was relatively high confirming the separation of the two sub-populations and their diversity in iPBS alleles. Similar results were reported by Zargar et al. (2016) who found that according to the population differentiation measurements (Fst), there were two distinct clusters or populations with an average Fst of 0.3301, indicating a clear separation of the sub-populations and their diversity in RAPD and SSR alleles. Blair et al. (2012) analyzed 108 common bean genotypes using 36 fluorescently labeled SSRs and also observed a high Fst value (0.203) for the genetic differentiation between all the five populations. In the current study, we obtained an even higher Fst value as a result of using the iPBS marker system.

Table 6. *Heterozygosity and Fst value calculated for 2 quinoas sub-populations*

Sub-population (K)	Expected heterozygosity	Fst value
1	0.398	0.048
2	0.140	0.676
Average	0.269	0.362

Conclusion

Molecular markers are effectively used to explore genetic variation to enhance breeding efficiency. This study was undertaken using iPBS molecular markers for quinoa genotypes to simplify the application of this method and provide essential data on these genotypes. We also effectively categorized the population structure of 17 quinoa genotypes cultivated in Turkey using iPBS markers and model-based clustering. Moreover, the data obtained from the population structure analysis is valuable to perform association mapping on quinoa genotypes for various traits. The results obtained during the study can assist in the decision-making process concerning the selecting of markers for future experiments, as well as further characterization, breeding and management of the quinoa germplasm.

Abstract. In this study, conducted between 2015 and 2017, 49 different volatile components were identified from *Phlomis rigida* Labill that was reaped from Gölcük highland located on Konya Seydişehir-Bozkır road and *Phlomis monocephala* P.H.Davis that was reaped from Mersin Silifke Bahçederesi Village in Turkey at three different periods (pre-flowering, flowering and post-flowering) through gas chromatography mass spectroscopy (GC-MS) after solid phase micro extraction (SPME). The main components of *Phlomis rigida* were found to be (E)-2-Hexenal (9.21%), β-Caryophyllene (60.23%) and Germacrene D (9.76%). The main components of *Phlomis monocephala* were found to be α-Pinene (15.59%), (E)-β-Farnesene (17.69%) and Germacrene D (18.92%). It was concluded that reaping *P. rigida* and *P. monocephala* species during the flowering period was important for the yield of volatile components.
Keywords: *Phlomis, GC-MS, Germacrene D, α-Pinene, Turkey*

Introduction

Turkey has a rich diversity of plant and animal species thanks to its geographical location, geological, geomorphological and climatic features. Turkey is a bridge between Asia and Europe; therefore, it has three different flora zones. For that reason, several species of Asian and European origin are distributed in Turkey (Durmuşkahya, 2005). Located at the intersection of three phytogeographical zones, Turkey has a high species endemism due to the high species richness and endemism by ecological and phytogeographical differentiation as a result of several factors such as its function as a bridge between the floras of South Europe and Southeast Asia, and since Anatolia is the hub of origin and differentiation for several genera and sections (Tan, 1992). Flora of Turkey has around 11,466 plant taxa, whereas European continent has around 12,000 plant taxa. Almost 3649 plant taxa out of those that are naturally distributed in Turkey are endemic (Güner et al., 2012). Hundreds of plant species naturally distributed in Turkey including the endemic species have a very high medical and aromatic value (Baydar, 2009).

Volatile oils have been used as therapeutic medicine since ancient times (Kubecka, 1973). Volatile oils are volatile lipoid mixtures with strong smell that are derived from plants or herbal drugs through water or steam distillation, and that are liquid under normal conditions but sometimes can be frozen (Tanker and Tanker, 1990). In particular, those medical and aromatic plants with a rich content of volatile oil are especially important. Volatile oils (extracts, etheric oils) and their aromatic extracts are

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_19231928

commonly used in the fragrance and flavour industries as the source for perfumes, food additives, cleaning substances, cosmetic and medicine preparations, aroma-chemicals or initial material for synthesis of nature-identical and semi-synthetic beneficial aroma chemicals. Particularly, there has been a tremendous increase in the demand for volatile oils to be used in aromatherapy practices that have become popular in recent years (Weiss, 1997).

Across the world, Lamiaceae family that can grow nearly everywhere regardless of habitat type and elevation is one of the largest families considering the number of its members (Watson and Dallwitz, 1978). Its widest distribution area is located in the Mediterranean Basin, while the taxa in this family are mainly the open field plants except some of the genera growing in the tropical rain forests (Watson and Dallwitz, 1978; Morgaris et al., 1982; Davis, 1988). With 200 genera and around 3200 species, Lamiaceae family has 45 genera and 546 species in Turkey (Davis, 1982; Baytop, 1997).

Phlomis that is one of the genera of Lamiaceae family has around 100 species around the world. It is represented by a total of 52 taxa including 39 taxa and 13 hybrids in The checklist of the Flora of Turkey (Güner et al., 2012). Its appetising leaves and flowers are used as anti-allergic, diuretic, anti-diarrheal, gas relieving, stomach relieving, pain-killing, antidiabetic herbal tea and tonic. Furthermore, it s known to be commonly used by people for respiratory diseases and haemorrhoid (Harput et al., 2006).

In the last decade, there have been important developments with respect to the discovery of pharmacological mechanisms of *Phlomis* species and associated different components. The phytochemical studies on *Phlomis* showed that the species contained iridoid, flavonoid, phenylpropanoid, phenylethanoid, lignan, neolignan, diterpenoid, alkoloid and volatile oils (Kamel et al., 2000; Zhang and Wan, 2008).

Phlomis rigida Labill. is a perennial herbaceous plant that can grow as high as 125 cm with glandular hairs. Its leaves are large, oblong, elliptic or cuneate and have a size of 5-30 x 2-10 cm with pale greenish colour and tomentose hairs. It is verticillate, has 5-8- 18 flowers, numerous bracteoles, subulate 20-25 mm, calyx is 15-23 mm and dense hispid stellate-tomentose hairs, corolla is pink-purple. On the other hand, *Phlomis monocephala* P.H.Davis is a bush species that can grow as high as 150 cm with glandular hairs. Its leaves are ovate-lanceolate or ovate-oblong, cuneate or truncate, under leaf surface is yellowish and densely stellate-tomentose, upper hairs are greenish stellate-tomentose, and its size is around 2-6,5 x 1-3,5 cm. It is verticillate with 6-12 flowers, bracteole lanceolate is 5-8x1,5-2 mm long, calyx is 10-14 mm and has stellate-tomentose-lanate hairs, corolla is yellow (Davis, 1982). The purpose of this study was to identify the impact of different reaping times of *Phlomis rigida* and *P. monocephala* taxa on volatile oil components and determine the appropriate reaping time.

Materials and Methods

This study was conducted between 2015 and 2017. The research materials that were *Phlomis rigida* Labill. and *Phlomis monocephala* P.H.Davis were reaped from Gölcük Highland located on Konya Seydişehir-Bozkır road at an elevation of 1732 m (37°13′21′′N, 32°00′28′′E) and Mersin Silifke Bahçederesi Village in Turkey at an elevation of 527 m (36°21′17′′N, 33°48′28′′E), respectively (*Figure 1*). The samples were collected from the pre-determined sampling plots in 3 different periods, which were pre-flowering, flowering and post-flowering periods.

DOI: http://dx.doi.org/10.15666/aeer/1702_19231928

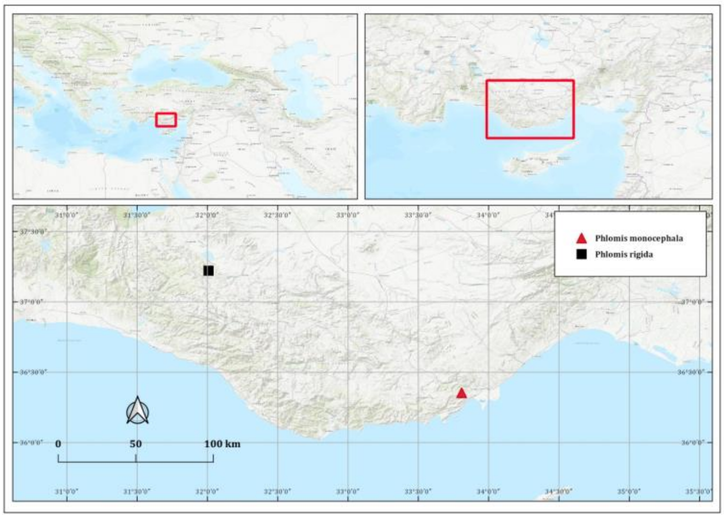

Figure 1. *Stands of collecting samples*

The leaf and flower samples of *Phlomis rigida* and *P. monocephala* collected from the sampling plots were placed in paper packages and transported to the laboratory without delay and avoiding their exposure to sunlight by private car in same day.

Flower and leaf samples were dried in room temperature (25ºC) and processed for solid phase microextraction (SPME). Samples were put into 10 mL vials from each after incubation at 60°C during 30 min. Then, GC-MS (Shimadzu 2010 Plus) process were applied at a temperature of 250°C for desorption (5 min) of the adsorbed volatile compounds for analysis. Constituents were identified by using libraries.

Results

The volatile components in the leaves and flowers of *Phlomis rigida* Labill. and *P. monocephala* P.H.Davis collected from the sampling plots were identified through gas chromatography mass spectroscopy (GC-MS) after solid phase micro extraction (SPME).

SPME analysis revealed 49 different volatile components *Phlomis r*igida and *P. monocephala*. The results of these samples are presented in *Table 1*.

(E)-2-Hexenal, β-Caryophyllene and Germacrene D were found to be the main components in *Phlomis rigida*. The rates in the pre-flowering period were as follows: (E)-2-Hexenal (8.23%), β-Caryophyllene (46.65%) and Germacrene D (8.74%); while the rates during the flowering period were as follows: (E)-2-Hexenal (9.21%), β-Caryophyllene (60.23%) and Germacrene D (9.76%); and the rates in the post-flowering period were as follows: (E)-2-Hexenal (8.85%), β-Caryophyllene (56.01%) and Germacrene D (9.29%) (*Table 1*).

α-Pinene, (E)-β-Farnesene and Germacrene D were found to be the main components of *Phlomis monocephala*. The rates in the pre-flowering period were as follows: α-Pinene (14.90%), (E)-β-Farnesene (16.47%) and Germacrene D (17.78%); while the rates during the flowering period were as follows: α-Pinene (15.59%), (E)-β-Farnesene (17.69%) and Germacrene D (18.92%); and the rates in the post-flowering period were as follows: α-Pinene (14.63%), (E)-β-Farnesene (15.69%) and Germacrene D (16.16%) (*Table 1*).

Discussion and Conclusions

SPME analysis revealed that *Phlomis rigida* Labill. and *P. monocephala* P.H.Davis had 49 different volatile components. Main components of *Phlomis rigida* were (E)-2-Hexenal (9.21%), β-Caryophyllene (60.23%) and Germacrene D (9.76%). Demirci et al. (2006) found through GC-MS analysis that the main components of *Phlomis rigida* Labill. were β-Caryophyllene (31.2% - 38.7%) and β-selinene (13.1% - 15.1%). β-Caryophyllene was found to be the dominant component in that study. This finding is consistent with our result. Contrary to the abovementioned study, (E)-2-Hexenal and Germacrene D were also identified as dominant components in our study.

α-Pinene (15.59%), (E)-β-Farnesene (17.69%) and Germacrene D (18.92%) were found to be the main components of *Phlomis monocephala*. In a study conducted by Demirci et al. (2009), they aimed at exploring the antimicrobial effects and phytochemical profile of *Phlomis lunariifolia* Sm., *Phlomis amanica* Vierh., *Phlomis monocephala* P.H. Davis, *Phlomis sieheana* Rech. fil., *Phlomis armeniaca* Willd. species in Turkey. They applied GC and MS for the analysis of the volatile oils that they derived through hydrodistillation. They identified 143 components in the volatile oils of *Phlomis amanica* Vierh. and *Phlomis monocephala* P.H.Davis. They found that 8(14), 15-Isopimaradien-11α-ol (1) were the main components in the volatile oils of *Phlomis monocephala* P.H.Davis. This finding is different from our result. Contrary to that study, Germacrene D, (E)-β-Farnesene and α-Pinene were identified as the dominant components in our study.

In conclusion, the volatile components β-Caryophyllene, (E)-2-Hexenal, Germacrene D, (E)-β-Farnesene and α-Pinene obtained in this study may be considered as potential sources and materials for the pharmacology and cosmetic industry thanks to their antimicrobial activities. It was found that reaping *P. rigida* and *P. monocephala* species, which were collected from the field in the form of leaves and flowers, during the flowering period was important with respect to the yield of volatile components. These findings are considered to help preventing the haphazard collection of plants by traders and local people and economic losses that may arise due to misinformation and raise awareness for the collection of the plants. Although *Phlomis* taxa are used in many areas, there are limited numbers of studies conducted on *Phlomis* taxa in Turkey. There is a need for further studies in this field.

Abstract. The greatest failure rate of reforestation programs in Algeria is related to the water deficit especially at young plant stage. Hence, the objective of this paper is to study the responses to drought stress generated by three different water regimes 100% (control), 60% (moderate stress) and 40% (severe stress) of field capacity (FC) on 3 young populations of *Ceratonia siliqua* L. in Algeria with different eco-geographical origins (*Zeralda, Tissemsilt* and *Ain Sefra*). The germination seeds of these populations were conducted in February 2013. The results exhibit a significant decrease in stomata conductance (cs) and in relative water content (RWC) with the increase in the intensity of drought stress. Negative and significant correlations were recorded between the RWC and the intensity of drought stress in the studied plants compared to the control plants. A considerable increase of proline and soluble sugar was positively correlated with drought stress severity for the three ecotypes of *Ceratonia siliqua* L. Significant differences in the chlorophyll and carotenoid content were detected among the three ecotypes in three water regimes. According to the canonical discriminant analysis of our data, the three ecotypes were separated by the physiological and biochemical parameters studied. It is clear that the ability of drought tolerance in the three studied contrasting ecotypes is different. We suggest the following order with respect to the ability of drought tolerance: *Ain Sefra - Tissmesilt - Zeralda.*
Keywords: *water regimes, proline, soluble sugar, young plant, relative water content*

Introduction

Most of Mediterranean natural plants are exposed to persistent and severe drought stress (Nogués and Baker, 2000). Drought, the most important abiotic stress, affects the physiological and biochemical process in plants leading to a reduction of growth and productivity (Yoon et al., 2014; Lambers et al., 2008).

Drought significantly reduces germination mainly due to low water absorption during the imbibition phase of germination, to the low energy supply and to the decreased enzyme activity (Okcu et al., 2005; Taiz and Zeiger, 2010). It also reduces leaf size, stem elongation and root proliferation, and disturbed stomata variations, plant water and nutrient relations with diminished crop productivity (Li et al., 2009).

Responses of plants to drought stress in the arid and semi-arid areas are complex and different mechanisms (morpho-anatomical, physiological, biochemical and molecular) involve allowing the plant to survive (Rodziewicz et al., 2014). There are often the main mechanisms of tolerance to water deficit (Tardieu, 2005); (i) maintenance of leaf water

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_19291945

potential (RWC, stomatal conductance), (ii) the biosynthesis and accumulation of various osmolytes (proline, soluble sugars), (iii) and the activation of different resistant genes (Chaves et al., 2003; Reddy et al., 2004).

In Algeria, a gradual rise in aridity towards the north was observed over the past thirty years. This aridity is marked by a pronounced increase in the degradation of all components of the ecosystem (Ait Chitt et al., 2007).

This desertification, which reaches the most advanced stage of land degradation resulted in the reduction of biological potential, the breakdown of ecological and socio-economic equilibrium, and a remarkable regression of plant genetic resources (Le Houérou, 1985). Central and north-western regions of Algeria are characterized by rare and irregular rainfall, and long dry summer periods (Batlle and Tous, 1997). Forests are in a perpetual decline due to anthropogenic activities such as forest fires, overgrazing, and uncontrolled urbanization (Batlle and Tous, 1997). As a result, several forest development programs have been implemented in many areas of Algeria. To that end, the government uses the multipurpose tree and drought resistant species that exhibit morpho- physiological traits and genetic adaptation to climatic variation (Ait Chitt et al., 2007). Among these species is *Ceratonia siliqua* L. which is a perennial evergreen tree. It is an agro-sylvo-pastoral species with enormous socio-economic and ecological interests (Batlle and Tous, 1997; Gharnit et al., 2001). Carob tree is considered one of the most interesting forest trees since all its parts (leaves, flowers, fruits, wood, bark, and roots) are exploited (Aafi, 1996).

Although carob tree is a non-nodulable species, endophytic associative bacteria can be observed in their root systems (Nautiyal et al., 2000; Reva et al., 2002).

The presence of these bacteria inside vegetative tissues would probably contribute significantly to the palliation of nutritional deficiencies of carob, which settles favorably on poor soils. They have a great ability to solubilize and release certain mineral or organic elements such as phosphorus and iron origins essential for plant nutrition (Konate, 2007).

The carob tree is mainly concentrated in coastal, semi-arid and arid zones, owing to its great ability to develop adaptation strategies by reducing its leaf area, leaf curling (Rejeb, 1995; Batlle and Tous, 1997) and enhancing the growth of its root system. Often, the response of a plant with a water deficit results in a preferential allocation of biomass to the roots expressed by an increase in the dry matter ratio between the underground part and the aerial part (Gales, 1979; Benbelkacem et al., 2000; Albouchi et al., 2003).

The greatest failure rate of revegetation programs faced by carob trees is at the seedling stage. The installation of the seedling root system requires adequate soil hydration and will be more difficult in heavy areas characterized by a high saturation deficit (Letreuch, 1991). Vegetation with weak rooting can disappear; also, we propose the study of physiological mechanisms of resistance to drought stress on three ecotypes of *Ceratonia siliqua* L. aged 18 months, from three different bioclimatic regions of Algeria.

Materials and methods

Plant material

Populations of *Ceratonia siliqua* L. were collected from three different bioclimatic stages in the Centre and North-Western of Algeria respectively in Zeralda (wet

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_19291945

bioclimatic stage), Tissemsilt (upper semi-arid bioclimatic stage) and Ain Sefra (arid bioclimatic stage). Climatic, geographical and hydrological conditions of these three regions are markedly different (*Table 1*). Sapling locations are illustrated in (*Fig. 1*).

Table 1. *Geographical and climatic characteristics of the different sites of Ceratonia siliqua L. ecotypes. (ANAT, 2004)*

Ecotype	Latitude	Longitude	Altitude (m)	Pluviométrie	T min (°C)	T max (°C)
Zeralda	36.7040 N	2.8672 W	30	600-900	0-9	28-31
Tissemsilt	35.9049 N	1.5248 W	866	400-600	2-4	33-38
Ain Sefra	32.7439 N	-0.8801 W	1078	100-300	-10	35-42

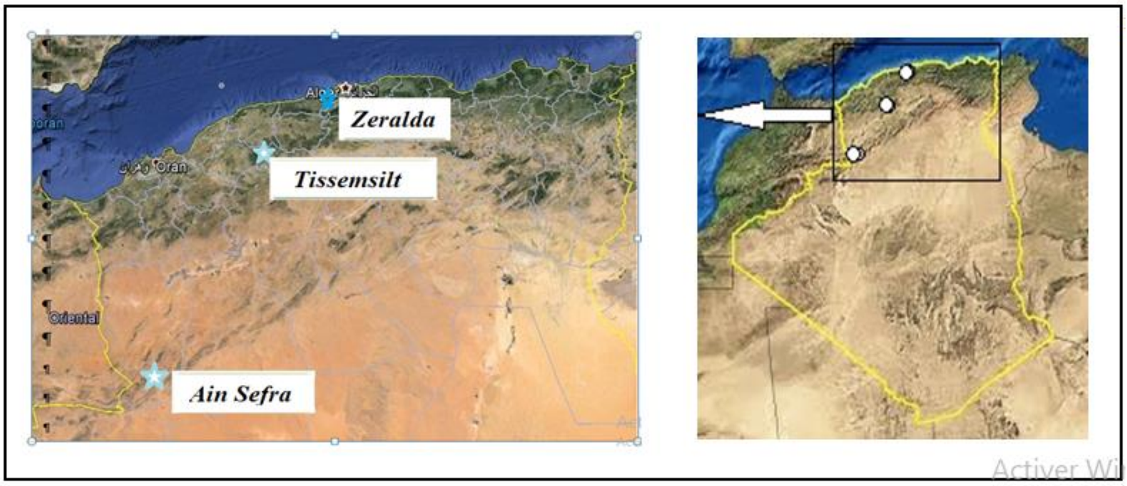

Figure 1. *Repartition map of the different sites of Ceratonia siliqua L. ecotypes of Algerian carob populations*

Culture conditions

After being scarred with a sharp instrument at the opposite side of the embryo, seeds were disinfected using bleach diluted for 10 min and finally rinsed twice with distilled water and deposited in Petri dishes on filter paper a reason of 10 seeds per petri dish. Petri dishes were put in an oven 48 h at 27 °C in the dark. Germination rate are 54.5%, 100%and 74.4%for *Zeralda, Tissemsilt* and *Ain Sefra,* respectively.

Plants were transferred into pots (15 × 27 cm) filled with a mixture of peat and soil 2/3 (v/v) with one seedling per pot and watered daily with tap water. The experiment was conducted at 28 ± 1°C and the range of relative humidity is 60% to 70% over 18 months.

The experiments were performed during July 2015, on plants at the same stage of development. 162 young plants of *Ceratonia siliqua* L., 18 months old have been divided into three groups which undergo three different water regimes:100% (control), 60% (moderate stress) and 40% (severe stress) of field capacity (FC).

The treatments were applied during two months and each treatment included eighteen plants for each ecotype. Leaves were collected after seventeen days of treatment. Three plants per treatment were used for each experiment.

Physiological parameters

Relative water content

The water status of the plants is measured by the Relative Water Content (RWC) according to Ladiges (1975), used by Clarke et al. (1982) and Rascio et al. (1988). RWC calculations were made according to *Equation 1*:

$$RWC (\%) = [(FW - DW) / (TW - DW)] \times 100, \qquad (Eq.1)$$

where FW, TW and DW refer to fresh weight, Turgid weight (after 24 h rehydration on distilled water), and dry weight after oven drying for 48 h at 70 °C respectively.

Stomata conductance

Stomata conductance (CS) was measured using a porometer (AP4DELTA-T Devices, Cambridge, UK) and on 18 month old plants. Measurements were made on fully exposed leaves between 10 h and 12 h on the lower face of three young leaves per plant. Stomata conductance has been expressed in mmol $H_2O/m^2\ s^{-1}$.

Biochemical parameters

Proline content

The determination of the proline content is carried out according to the colorimetric method of Troll and Lindsley (1955) later developed by Magné and Larher (1992).

The determination of the proline content is carried out according to the colorimetric method of Troll and Lindsley (1955) later developed by Magné and Larher (1992). Leaf samples (150 mg) are extracted by using 3 mL of methanol placed in batch at 90 ° C for 1 h. After cooling, extract (1 mL) was treated with 2 mL of ninhydrin solution (1% in glacial acetic acid). After addition of 2 mL toluene, the mixture is stirred vigorously and the upper phase is removed. The optical density is read at 520 nm with a spectrophotometer (U.V/visible Shimadzu Modèle V630). The results are referred to a standard curve made of increasing quantities of proline solution. The results are expressed in µg. g-1 MS. Three repetitions are planned by treatment between 08 h and 10 h (one plant per replicate).

Soluble sugar

The soluble sugar content (SS) was measured according to Schields and Burnet (1960). 5.25 ml of 80% ethanol was added to leaf tissues (100 mg) in a test tube at room temperature in the dark. After 20-h extraction, ethanol was evaporated in a water bath at 70 °C. Then, 2 mL of this solution previously diluted 10 times with ethanol 80% was transferred into another tube, adding 4 ml of reagent (prepared 4 h before the test) composed of 2 mg pure anthrone added to 100 mL of sulfuric acid and vortexing to homogenize the solution. After 10 min, tubes were placed again in the water bath for 08 min at 92 °C. The absorbance is read at the spectrophotometer (U.V/visible Modèle V630) at a wave length of 585 nm. The results are referred to a standard curve made of increasing quantities of a solution of glucose and the concentration is expressed in $\mu g.g^{-1}$ of MS. Three repetitions are planned by treatment (one plant per replicate).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_19291945

Chlorophyll pigments

The levels of chlorophyll (a + b) and carotenoids are determined according to Lichtenthaler (1987). The extraction is performed through cold acetone. A measure of the absorbance is made of 470, 662 and 645 nm using a spectrophotometer Shimadzu (UV-1605). The levels in pigments, expressed in $\mu g.ml^{-1}$ of MS, are calculated in *Equations 2* and *3:*

$$C\ (a + b) = 7.05\ A662 - 18.09\ A645 \quad \text{(Eq.2)}$$

$$C\ (x + c) = (1000\ A470 - 1.90Ca - 63.14Cb)\ 214 \quad \text{(Eq.3)}$$

where C(a + b) is total chlorophyll concentration of and C(x + c) is caroténoid concentration.

Statistical analysis

All statistical analyses are performed using SAS 9. On 162 observations, the ANOVA procedure of SAS was used to adjust the generalized linear model (GLM). The fixed factors are the accessions and the different water regimes. The variable factors chosen for this analysis are the various physiological and biochemical parameters.

The signification is chosen for a value of $p = 0.05$. In the declaration of the model, the options of Statistics Type 1 and Type 3 are used.

To differentiate between groups of accessions and water regimes which are homogeneous on the statistical plan, we used the test of Waller-Duncan. The meaning $\chi = 0.05$ in ANOVA was chosen, with the selection of the ANOVA model means of SAS 9.

All statistical analyses were performed using the Database Software SAS, version 9 for Windows, Version 7. The graphical extrapolation of the results was performed with Microsoft Excel software.

Results

Physiological parameters

The relative water content (RWC) of control seedlings of Zeralda ecotype (87.08%±5.16) was higher than Tissemsilt and Ain Sefra ecotypes with 83.22%±1.23 and 72.32%±7.92 respectively (*Fig. 2A*).

Moderate and severe drought stresses cause a decrease in RWC proportional to the severity of stress. However, Zeralda ecotype still has the largest RWC and Ain Sefra ecotype has the lowest regardless of water regime (*Fig. 2A*).

Highly significant differences between the three water regimes in Tissemsilt (ddl = 2; value $F = 9.38$; $P = 0.0035$) and Zeralda ecotypes (ddl = 2; Value $F = 20.25$; $P < 0.0001$) with $R2 = 60.99\%$, and no significant difference between the three water regimes of Ain Sefra ecotype were observed for RWC.

In control plants, the highest values of stomata conductance were noted in *Ain Sefra* ecotype with 11.16 ± 1.12 mmol $H_2O/m^2/s$. Moderate and severe water stress cause a slight decrease in stomata conductance in *Zeralda* and *Tissemsilt* ecotypes. The most significant decrease was, however, recorded in *Ain Sefra* ecotype (*Fig. 2B*). We have noted that drought stress (moderate and severe stress) significantly reduced ($P < 0.001$)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_19291945

stomata conductance of *Ain Sefra* ecotype (ddl = 2; F = 76.74; P < 0.0001). There is no significant variation in stomatal conductance in moderate and severe stress of *Zeralda* and *Tissemsilt* ecotypes.

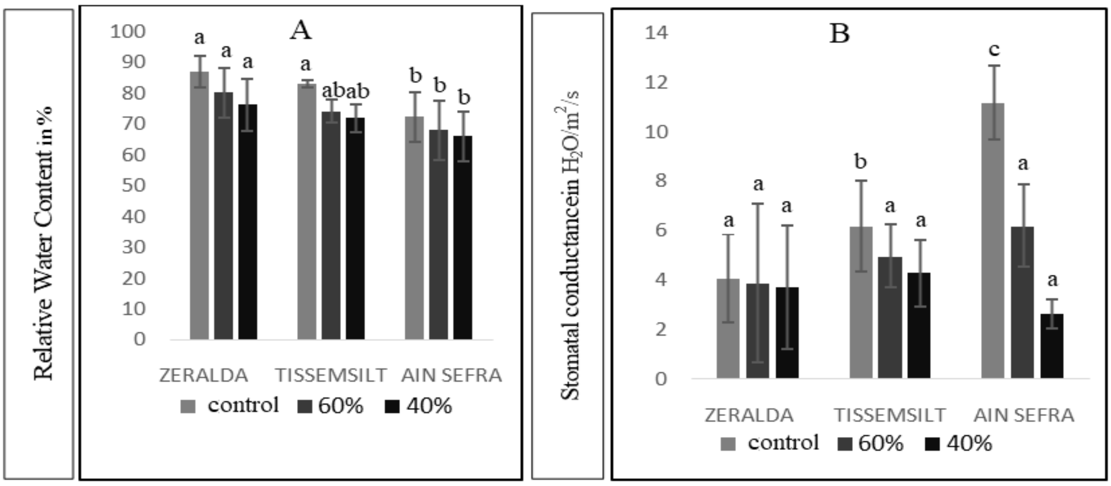

Figure 2. *Effect of drought stress on leaf water content (A) and stomatal conductance (B) of three Ceratonia siliqua L. ecotypes. Eighteen-month-old young plants were exposed to three water regimes (control, 60 and 40% of field capacity (FC)) during 17 days. Mean ± SE (n = 3) with distinct letters are significantly different at 5% (Waller-Duncan test)*

The statistical analysis shows that RWC and CS are strongly influenced by ecotype and water regimes (p < 0.05). The water regime (WR) has a significant effect on the expression of RWC (p < 0.0001) and a significant variation (p < 0.05) on CS. The interaction of the two factors (type of ecotype and water regime) also exerts significant variations on RWC and CS (p < 0.05). Therefore, the ecotypes tested reaction distinctly with respect to the intensity of drought stress.

This study shows also that RWC is the first parameter affected by the progression of water stress severity of *Zeralda* and *Tissemsilt* ecotypes (P < 0.001). Under drought stress, especially in severe water stress (40% of field capacity), we noticed a significant decrease in RWC compared to the control (P < 0.001). However, we did not observe a significant difference in the different water regimes *of Ain Sefra* ecotype (*Table 2*).

Table 2. *Statistical analysis of the variance of water regime (WR), ecotype (ECO) and ECO×WR interactions in Ceratonia siliqua L.*

	ECO		**WR**		**ECO×WR**	
RWC	29.88	<.0001	18.82	<.0001	2.72	0.0319
CS	16.8	<.0001	7.12	0.0011	5.48	0.0004

Biochemical parameters

Stressed plants showed significantly higher concentrations of soluble sugars (*Fig. 3A)* and proline than control plants (*Fig. 3B*). An increase in the level of proline and soluble sugar, which is a function of the severity of stress in the studied ecotypes, is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_19291945

observed. In severe drought stress, the highest concentrations of proline and soluble sugars were found in the *Ain Sefra* ecotype (*Fig. 3*).

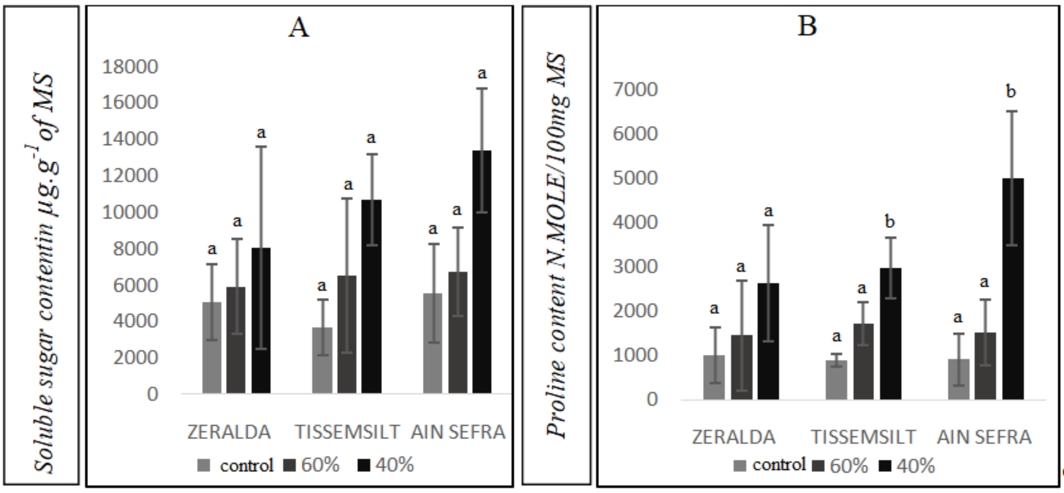

***Figure 3.** Effect of drought stress on prolin content and soluble sugar of three Ceratonia siliqua L. ecotypes. Eighteen-month-old young plants were exposed to three water regimes (control, 60 and 40% of field capacity (FC)). Mean ± SE (n = 3) with distinct letters are significantly different at 5% (Waller-Duncan test)*

A very high significant difference was detected in the concentration of the proline between the different water regime of *Zeralda*, *Tissemsilt* and *Ain Sefra* (*Table 3*).

Water Regime has a tremendous effect on proline and soluble sugar accumulation ($p < .0001$). The interaction of the two factors exerts also significant variations ($p < 0.05$) while the ecotype factor has no significant effect (*Table 4*).

***Table 3.** Analysis of variance of the proline and soluble sugars of the plants of Ceratonia siliqua Lunder three water regimes (control, 60 and 40% of field capacity (FC))*

	Zeralda		Tissemsilt		Ain Sefra	
	F	**P**	**F**	**P**	**F**	**P**
Proline	22.33	<0.0001	16.76	0.0003	45.34	<0.0001
Soluble sugars	6.33	0.0025	5.33	0.0221	17.12	<0.0001

The relationship between the accumulation of proline and the water regime was studied using the regression procedure of SAS 9. We have found a strong positive correlation between the accumulation of proline and the water regime (ddl = 1; value of the test t = 8.87; $p < 0.0001$).

DOI: http://dx.doi.org/10.15666/aeer/1702_19291945

Our results show a notable difference in soluble sugars of *Ain Sefra's* ecotype. In contrast, there has been a significant difference between *Zeralda* and *Tissemsilt* (*Table 3*).

In control plants, the highest values of total chlorophyll were observed in *Zeralda*'s ecotype with 4.70 ± 2.23 µg.mL^{-1}. For the three ecotypes, total chlorophyll contents are lower in stressed plants compared to control plants (*Fig. 4A*).

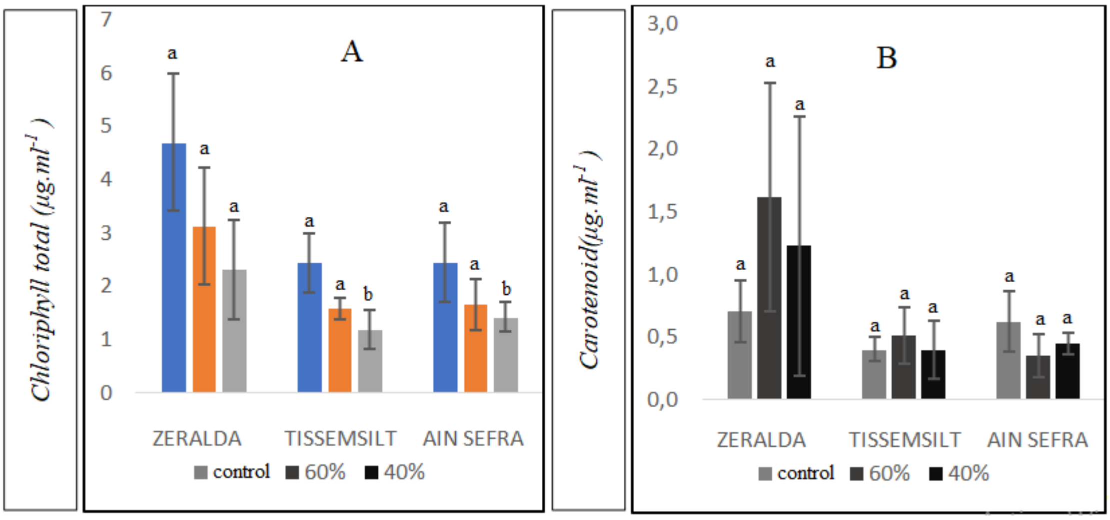

Figure 4. *Effect of drought stress on chl T and carotenoids of three Ceratonia siliqua L. ecotypes. Eighteen-month-old young plants were exposed to three water regimes (control, 60 and 40% of field capacity). Mean ± SE (n = 3) with distinct letters are significantly different at 5% (Waller-Duncan test)*

Significant differences in the total chlorophyll content between the three water regimes (F = 4.60, P = 0.0119), (F = 12.64, P = 0.0011) and (F = 8.71, P = 0.0012) are recorded in *Zeralda, Tissemsilt* and *Ain Sefra* ecotypes respectively (*Table 5*).

Table5. *Statistical analysis of the variance of water regime (WR), ecotype (ECO) and ECOxWR interactions in Ceratonia siliqua L.*

	Zeralda		***Tissemsilt***		***Ain Sefra***	
	F	**Pr>F**	**F**	**Pr>F**	**F**	**Pr>F**
Chlorophyll	4.60	0.0119	12.64	0.0011	8.71	0.0012
Caroténoid	4.62	0.0118	0.51	0.6138	6.08	0.0066
Raportchl a/b	3.90	0.0230	1.11	0.3637	13.21	0.0001

Water regimes altered the content of carotenoids among the ecotypes of *Ain Sefra* (F = 6.08; P = 0.0066) and *Zeralda* (F = 4.62; P = 0.0118), but not for the ecotype of *Tissemsilt.* The greatest value of the carotenoid has been recorded in the ecotype of *Zeralda* under moderate stress with 1.65 ± 0.92 *µg.ml*$^{-1}$ (*Fig. 4B*).

The highest Chl a/b ratio for the control plants was noted in *Ain Sefra's* ecotype. It significantly decreased in stressed plants of *Ain Sefra* (F = 13.21, P = 0.0001) and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_19291945

Zeralda (F = 3.90, P = 0.023) ecotypes (*Table 6*). Conversely, WR has no significant effect on the Chl a/b ratio Tissemsilt's ecotype (p < .0001) (*Table 5*).

Table 6. *Effect of drought stress on ratio Chlorophyll a/b of three Ceratonia siliqua L. ecotypes. Eighteen-month-old young plants were exposed to three water regimes (100, 60 and 40% of FC) during 17 days. Mean ± SE (n = 3)*

Canonical analysis

The analysis of principal components (APC) of osmolytes shows two separate groups (*Fig. 5*; *Tables 7* and *8*). The first group includes the stands in the region of *Zeralda*. In the second group, there are still two sub-groups; one constituted of the whole samples of *Tissemsilt* and the other formed by the samples of *Ain Sefra.*

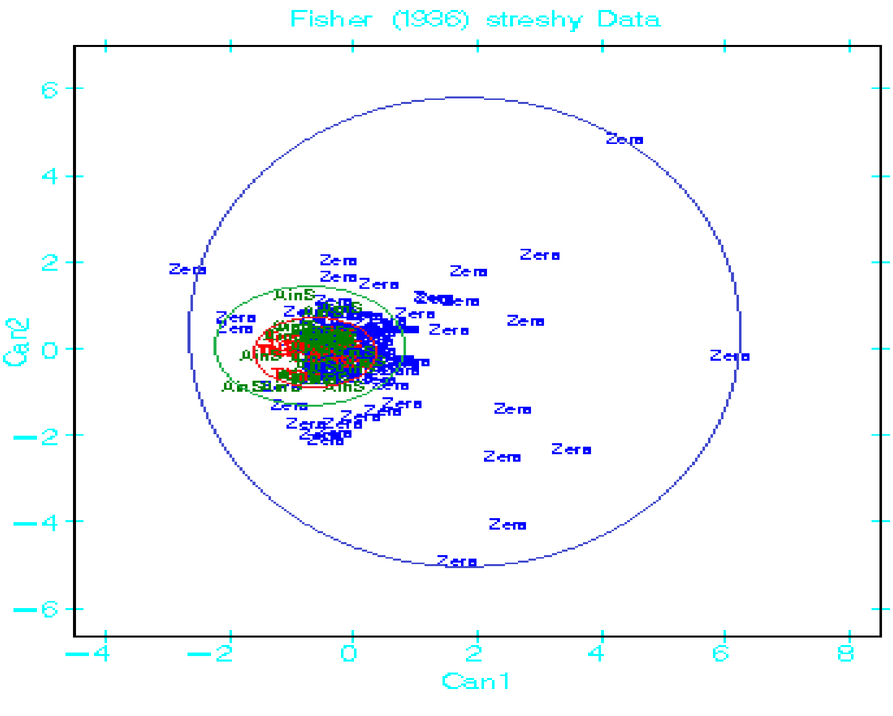

Figure 5. *Projection of points means of the regions studied on the first plan factorial of a principal component analysis*

Table 7 shows the point's means of the regions on the canonical variables. Group one is represented by *Zeralda* ecotype (means points (0.22/-0.0007)) and the group two is represented by ecotypes of *Tissemsilt* (means points (−0.63/0.061)) and *Ain Sefra* (means points (-0.55/0.033)) ecotypes.

DOI: http://dx.doi.org/10.15666/aeer/1702_19291945

Table 7. *Medium of classes on the canonical variables*

Class meanings on canonical variables		
Ecotype	Can1	Can2
Ain Sefra	-0.5528	0.0338
Tissemsilt	-0.6304	-0.0616
Zeralda	0.2225	-0.0007

This interpretation is performed according to the plan 1-2 because it provides the maximum of information with 100% contribution to the total variation (99.56% of contribution for the axis 1 and 0.44% for the axis 2).

The values of squared distance, estimated between ecotypes studied two by two, do not exceed 3.002, indicating an overlap between the ecotypes (*Table 8*).

The first group includes the ecotypes of the locality of *Zeralda*. The second group brings together the stands of the locality of *Tissemsilt*. Finally, the third group is represented by the stands from the locality of *Ain Sefra*.

According to *Table 8*, squared distance between ecotype is less than 50 (maximum value 35 between *Zeralda* and *Ain Sefra* ecotype), which shows an overlap between the three studied ecotypes.

Table 8. *Distance square, value of F for the distance square and value of the probability of square distance between the different ecotypes*

Squared distance to ecotype			
	Ain Sefra	*Tissemsilt*	*Zeralda*
Ain Sefra	0	0.01513	0.60256

Tissemsilt	0.0071	1.0000	0.0246
Zeralda	<,0001	0.0246	1.0000

Table 10 shows the points means of the regions on the canonical variables *Zeralda* (0.38/0.011), *Tissemsilt* (−0.348/−0.160) and *Ain Sefra* (−1.343/0.034).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_19291945

Table 10. *Medium of classes on the canonical variables*

Class meanings on canonical variables		
Ecotype	Can1	Can2
Ain Sefra	-1.3433	0.0342
Tissemsilt	-0.3486	-0.1608
Zeralda	0.3891	0.0118

According to the canonical analysis, the ecotypes *Ain Sefra* and *Zeralda* are well differentiated for all parameters studied. But *Tissemsilt* is getting closer to *Zeralda* for proline and soluble sugar parameters and form a different group for rwc and cs parameters.

Discussion

Drought stress is the key factor influencing plant growth and development in arid and semi-arid areas (Passioura, 2007). The assessment of the impact of the drought on the behaviour of plants includes mainly the estimate of their level of hydration. Thus, the RWC is a physiological indicator that is often used to assess the water status of the plant (Teulat et al., 1997). It has also been proposed as an important physiological indicator of the state of hydration in the function of the water regime (Lawlorand Cornic, 2002; Mefti et al., 2002).

Our results show that the water deficit is accompanied with a net decrease in the relative water content and stomata conductance in relationship with the intensity of water stress. The decrease of relative water content and stomata conductance documented in our study was in accordance with previous data (Maamar et al., 2015; Lassouane et al., 2013; Chakhchar et al., 2015b). The decrease in RWC is greater in *Ain Sefra's* ecotype. These two parameters are considered as the main responses against stress which is expressed by the stomata closure to minimize the water loss (Pita et al., 2005). This agrees with the results of some studies in a wide variety of plants (Nayyar and Gupta, 2006; Shultz, 2003). Under drought stress, the stomata closure with the decrease of their conductance constitutes one factor of plants drought tolerance (Yamaguchi-Shinozaki and Shinozaki, 2006).

A significant relationship between RWC increase and low stomata conductance was observed among the three contrasted ecotypes with a very significant stomata closure, which plays a very effective role in the prevention of the water loss (Medrano et al., 2002; Flexas et al., 2004).

The water deficit tolerance of plants is realized also through the maintenance of a low water potential (Blum, 2005). This strategy is mainly based on the osmotic adjustment, provided by the accumulation of a large diversity of osmolytes (Jalil et al., 2007; Sankar et al., 2007). Proline was considered as an osmolyte compatible which protects subcellular structures and macromolecule under osmotic stress (Kavi-Kishor et al., 2005). It may, also, increase the activity of many enzymes and stabilize protein integrity (Szabo and Savoure, 2010; Lipiec et al., 2013). In another context, the accumulation of the proline plays a very important role in the absorption of water (Ashraf and Foolad, 2007; Miller et al., 2010) to ensure osmotic adjustment which is the main physiological characteristics of tolerance (Manivannan et al., 2008).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_19291945

Our study results show a significant accumulation of proline and soluble sugars at the three studied ecotypes, with different degrees under water deficit. Hence, the ecotype *Ain Sefra* has the highest accumulation of proline and soluble sugars. We suggest that this ecotype is associated with a high tolerance to drought compared to other ecotypes. A significant increase of proline content in drought stress has been recorded in several species such as Olive (Sofo et al., 2005; Boughallleb and Mhamdi, 2011), poplar (Yin et al., 2005), and rice (Mostajeran and Rahimi-Eichi, 2009). The accumulation of proline in dehydrated seedlings is the consequence of the activation of the proline biosynthesis and inhibition of its degradation (Nakashima et al., 1998). Furthermore, the accumulation of soluble sugars allows to protect the membranes and proteins in cells exposed to a water deficit and reduce the aggregation of denatured proteins (Ashraf and Harris, 2003). The involvement of these two osmoticumin the osmotic adjustment allows the maintenance of cell turgorat the highest level possible for low water potentials, thus maintaining the photosynthetic activity, membranes structure and growth (Lawlor and Cornic, 2002; Farooq et al., 2008).

The chlorophyll pigment content in the leaves is a good indicator to the detection of stress and the tolerance of the plants subjected to stress (Chakhchar et al., 2015a). Our results have shown that water deficit induced a significant decrease in the concentration of chlorophyll and carotenoids in the leaves of *Ceratonia siliqua* L., which is in agreement with the results of Smirnoff (1993). The decrease of chlorophylls documented in our study was in accordance with previous data (Cui et al., 2004; Lei et al., 2006). This diminution may be due to a low chlorophyll biosynthesis or their degradation (Bacelar et al., 2006). The stress response varies considerably between species, genotypes and even between the parts of the same plants (Kozlowski et Pallardy, 2002). There were clear intraspecific differences in stomatal sensitivity, proline content, RWC, soluble sugars and chlorophylls, suggesting different adaptations to drought related to the ecotype effect and significant genetic variability in carob populations in Algeria. The same results were obtained by (Chakhchar, 2015b; Maamar, 2015).

According to the APC (analysis of principal component), all three ecotypes separated into three different groups. Thus, we find that the ecotype of the arid zone (*AinSefra*) was the most tolerant ecotype; it can be used in future reforestation programs in the semi-arid area of Algeria.

Conclusions

An integrated study combining of physiological and biochemical analysis has been adopted to study the reactions and behavior of *Ceratonia siliqua* toward the water stress. Significant differences between ecotypes were recorded in leaves water status, the content of photosynthetic pigments, and the accumulation of osmoregulators.

This study shows that the water deficit is accompanied with a net decrease in the relative water content, stomata conductance, and a significant increase in the accumulation of proline and soluble sugars of the three studied ecotypes.

The canonical analysis classified of *Ain Sefra* ecotype as the most tolerant one from the arid zone and suggested the following order of the ecotypes with respect to the drought tolerance: the *Ain Sefra* (arid zone) - the *Tissemsilt* (semi-arid zone) - the *Zeralda* (sub-humid zone).

According to the analysis of principal components, the three ecotypes were distinguished on the basis of the RWC, CS, proline accumulation and soluble sugar. *Ain Sefra* ecotype is more likely to be the most droughts tolerant and very promising to the regeneration of carob tree cultivation in Algeria in arid and semi-arid areas.

(Received 10th Oct 2018; accepted 29th Nov 2018)

Abstract. Nowadays, the demand for forecasting techniques has increased due to conservation management of water resources. In this study, an artificial neural network model (ANN) was followed for determining the water quality index parameters. By the use of computer program, we can get a set of coefficients for a linear model in the calibration of ANN model. The Palayar River is one of the oldest rivers in Tamil Nadu originating from Western Ghats and flowing through Suchinthram area and Parakai Lake. Seven water quality parameters of Parakai Lake were chosen at four monitoring stations in the time period between December 2016 and March 2018. It is clear from the results that the water quality index (WQI) predicted with ANN model brings better output (correlation coefficient R = 0.9907) when compared with the Multiple regression model having R = 0.7908.
Keywords: *comprehensive pollution index (CPI), multiple linear regression, performance evaluation, water quality*

Introduction

Water is the vital resource for the existence of life. The ultimate use of water for various purposes such as drinking, irrigation and industrial needs has put forth an entire failure in the water quality standards. The excessive use of natural resources has developed a reduction in the water table apart from the significant increase in the concentration of pollutants (Yada et al., 2018). Because of disagreeable conservation management and expansion of population, the water resource has declined and existence of man has become threatened. Water quality indices (WQIs) are widely used to predict the eutrophication levels of lake waters by creating the data interpretation and gathering several parameters of water quality data into one single index. The parameter of all variables of this study is to observe the laboratory analysis and to calculate the pollutants of water body in place of the WQI.

Nowadays, a wide variety of applications of ANN is used to forecast the water quality (Kumar and Sharma, 2015) and to determine the water quality index by the use of independent variables such as DO, COD, BOD, SS, N-NO3 - and pH. By the use of customary water samples, the assessment of water quality and its laboratory analyses is exact, but very costly and more time utilization (Gorashi and Abdullah, 2012). Comprehensive pollution Index for the samples is also calculated. The pollution index method can give an assessable description of water quality which is low, heavy or extremely heavy but it cannot discriminate functional categories of water (Xing, 2011).

The total dissolved solids, dissolved oxygen and biochemical oxygen demands are forecasted using pH, TS, T-Hard, T-Alk, K+, Cl-, PO_4 -, Na+, N-NO_3 -, N-NH_4 +, and COD was done by means of a multi-layer perceptron neural network (Maier and Graeme Dandy, 1996). Similarly, Abyaneh (2014) employed the ANN model to forecast DO and BOD. Since the beginning of the 1990s, the applications of ANNs report was created by the areas of environmental sciences, ecological sciences and water engineering (Zali et al., 2011). The proposed model employed artificial neural networks (ANNs) with the back-propagation algorithm which can obtain a highly nonlinear relationship (Chine et al., 2009). The ANN model is constructed for fast calculation and predicting the selected water quality variables at any location. At other locations, particular remaining variables are used as the input parameters such are salinity, temperature, dissolved oxygen, and chlorophyll-alpha (Najah et al., 2013). The application of artificial neural network (ANN) models to simulate water quality parameters is cost-effective, quick, and reliable. This study provides two methods of mathematical and ANN modeling to simulate and forecast five important river water quality indicators (DO, TDS, SAR, BOD_5, HCO_3) correlated with variables such as EC, temperature, and pH which can be measured easily and almost with no cost (Salami et al., 2016; Spitz et al., 1999). The WQI is predicted by a simulative model using an ANN. This model has been developed for the assessment of the WQI and compared with the conventionally determined values of WQI. A Multilayer-Perceptron (MLP) network with a single hidden layer was used along with back-propagation algorithm. The results were found to be quite impressive. Thus, the ANN proved to be an efficient tool to assess the WQI of any sample (Hore et al., 2008). The most ordinarily used feed forward error back propagation neural network technique has been utilized. Monthly data sets on turbidity, total hardness, total dissolved solids, and electrical conductivity have been employed for the analysis. The results present the ability of suitable ANN models to predict the water quality parameters (Dawood et al., 2016). The Karoon River in Iran is selected to evaluate the capability of ANNs for water quality simulation. Several water quality variables including CO_3, HCO_3, SO_4, Cl, Na, Ca, Mg, K, EC, TDS and SAR has been simulated. Qnet 2000 ANN is selected for modeling purposes in the present research. Results show that Qnet 2000 is able to predict the water quality variables of the Karoon River very successfully with more than 90% accuracy (Musavi-Jahromi et al., 2008). The multiple regression models and artificial neural network models are used to predict the value of hardness with respect to the corresponding values of chloride, fluoride, and calcium contents of the groundwater sample based on the specific data. Novel techniques such as Artificial Neural Networks (ANNs) can be used to predict the output from the data set with better accuracy than that using Regression technique. This study will trigger DOE to use ANNs in order to predict WQI rather than using conventional method (WQI equation) that is currently being used by DOE. In addition, the ANNs managed to show remarkable prediction performance to predict the WQI in Juru River (Zali et al., 2011).

Many researchers have activated the artificial neural network technique in the satellite data in order to assess the water quality because of the limitations of linear regression methods. So, that the effort and computational time requirement can be reduced to develop the ANN water quality model. The main objective of this study is the variation of temporal and spatial surface water quality in the Parakai Lake is predicted by the use of multiple regression analysis and ANN model.

Materials and methods

Study area

The study area, Parakai Lake is Located at 8°09'46.2"N 77°26'59.9"E (*Fig. 1*). Parakai Lake is one of the lakes which fed water to irrigation field in southern parts of Kanyakumari district. The lake is fed by canals derived from Pazhayar River. The bound length of the lake extends to 4 m and water spread area of 1.684 km^2 and has an average storage depth of 3.2 m with holding capacity of 2.351 m^3. Kanyakumari district has four distinct seasons such as southwest monsoon (Jun. to Sep.), the northeast monsoon (Oct. to Dec.), the winter (Jan. and Feb.) and the hot weather (Mar. to May). Parakai Lake is located near the southern tip of India in Kanyakumari district in the state of Tamil Nadu, just to the north of Parakai village and west of the town Suchindram. According to the census, the total population of seven villages and two urban habitations along this river bank was 4, 76, 018. Calculation of water supply based on the 135 LPCD, the total quantity of water consuming in above area was 4, 55, 72, 200 l/day, and its sewage generation (80% of the consuming water) was 3, 64, 57, 832 l/day. The sewage has been discharged into the Parakai Lake without any treatment. The current study focuses the importance on the environmental and health risks subordinate with the use of lake water mixed with sewage fed from open sewerage in the system tank of Parakai Lake. The coordinates of sampling location are shown in *Table 1*.

Sample collection and analysis

The samples are collected from four locations such as 1) Pazhayar river inlet, 2) sewage water inlet, 3) irrigation channel (sluice gate no.2, outlet) and 4) irrigation channel (sluice gate no.5, outlet) (*Fig. 1*). The monthly water samples are collected from the four nodes by following the water sampling procedure IS 3025 (Part I) 1987. Totally 64 water samples are tested and analysed for the level of concentration of various parameters which are taken from IS 11624 (1986).

Comprehensive pollution index (CPI)

Based on the assessment of single factor index and considering the combined effect of all factors evaluated, CPI was calculated through different mathematical models and determines the pollution degrees by the appropriate method (*Eqs. 1* and *2*).

$$CPI = \frac{1}{n}\sum_{i=1}^{n} \text{PI} \quad \text{(Eq.1)}$$

$$PI = \frac{measured\ value\ of\ individual\ parameter}{standard\ permissible\ value\ of\ parameter} \quad \text{(Eq.2)}$$

The CPI values of each sample are calculated and are analyzed by the use of limits stated in *Table 3*.

DOI: http://dx.doi.org/10.15666/aeer/1702_19471958

Table 3. *CPI limits for water quality*

Sl.No	CPI Limits	Category
1	< 0.2	Clean water
2	0.2 - 0.4	Moderately polluted
3	0.4 - 0.6	Severely polluted
4	> 0.6	Purely sewage water

Modeling method

Multiple linear regressions

Multiple linear regressions (MLR) were functional as well in this work to validate the relationship between the water quality parameters and their impact on WQI. An MLR model takes the form (*Eq. 3*):

$$Y = \beta_p + \beta_1 x_1 + \beta_2 x_2 + \ldots + \beta_{p-1} x_{p-1} + \varepsilon \quad \text{(Eq.3)}$$

where Y is the response variable, and there are $p - 1$ explanatory variable $x_1, x_2, \ldots, x_{p-1}$, with p parameters (regression coefficients) $\beta_0, \beta_1, \beta_2, \ldots, \beta_{p-1}$

In this study the adjusted R^2 value was calculated. This adjusted value indicates the loss of predictive power or shrinkage. While R^2 explains how much of the variance in Y is accounted for by the regression model, the adjusted value tells us how much variance in Y would be accounted for if the model is derived from the population from which the sample was taken. One version of R^2 that explains how well the models cross-validates is the Stein's formula below (*Eq. 4*):

$$adjusted\ R^2 = 1 - \left[\left(\frac{n-1}{n-k-1}\right)\left(\frac{n-2}{n-k-2}\right)\left(\frac{n+1}{n}\right)\right]\left(1 - R^2\right) \quad \text{(Eq.4)}$$

In Stein's equation, R^2 is the adjusted value, n is the number of subjects and k is the number of predictors in the model. It is useful to use the equation to cross validate a regression model.

Artificial neural network as WQI prediction model

In the Artificial Neural Network model, an output layer is water quality index and it is used according to the Indian standard. Here, the input variables are collected based on the correlation analysis. Based on the priority target, the forecaster variables are selected and separated where parameters can be analyzed in the field. The initial predictors contained seven parameters of water quality.

Pre-processing of data

The original testing sample data are collected and these data are converted into 64 segments such as 40 data are used for training and remaining 24 are used for testing. The net architecture for WQI comprises of input nodes and output node. The desired

http://www.aloki.hu • ISSN 1589 1623 (Print) • ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_19471958

output delivered by the choices of input parameters used. In the present study, the input variables are sodium, soluble sodium percentage, sodium adsorption ratio, total salt concentration, total dissolved solids, residual sodium carbonate, and boron. The non-linear mapping structure comprises of natural networks of biological neurons in brain. It also contains simple calculated units called neurons. These are highly interrelated.

Progress of ANN model

This model is a multilayer ANNs and assembled with layers of units. The first layer is called as input units and the last layer is known as output units. In the statistical nomenclature the units are known as dependent variables or response variables and the arithmetical input units are called as independent variables remaining other units are called as hidden units and it having hidden layers. There are three basic layers or levels of data processing units viz., the input layer, the hidden layer and the output layer. Each of these layers consists of processing units called nodes of the neural network. The interconnections between the nodes of different layers are called weights of the neural network. These weights are updated or modified iteratively using the generalized delta rule or the steepest gradient descent principle (ASCE Task Committee, 2000). In the present study; the feed forward error back propagation algorithm (Rumelhart et al., 1986) is used for ANN training. Among most of the ANN applications studied in the literature, the feed forward error back propagation neural network is the most popular and widely used ANN architecture. The ANN network used for the present study is shown in *Figure 2*.

Training of ANN

An ANN stores the knowledge about the problem in terms of weights of inter-connections. The process of determining ANN weight is called learning or training. At the beginning of training, the initial value of weights can be assigned randomly or based on experience. The weights are systematically changed by the learning algorithm such that for a given input, the difference between the ANN output and the actual output is small. Many learning examples are repeatedly presented to the network, and the process is terminated when this difference is less than a specified value. At this stage, the ANN is considered trained. An ANN is better trained as more input data are used.

Performance evaluation

A large number of statistical criteria are available to compare the goodness/adequacy of any given model. The performance evaluation statistics used for ANN training in the present work are root mean square error (RMSE) and coefficient of correlation (R).

Some statistical analysis techniques are used to validate the result of prediction models. The root mean square error is used to measure the difference between actual value of water quality index and the value from prediction model (*Eq. 5*).

$$\boldsymbol{RMSE} = \sqrt{\frac{\sum_{i=1}^{n}(WQI_{act} - WQI_{Pre})_i^{2}}{n}} \quad \text{(Eq.5)}$$

where WQI_{act} = actual value of water quality index
WQI_{Pre} = predicted value of water quality index
n = number of monitoring data

Results and discussion

Correlation between the water quality parameters

From the measured water quality parameters the Pearson's correlation matrix was drawn to find the possible causes of water pollution (Tyagi et al., 2013). The correlation coefficient of seven water quality parameters are categorized by choosing the bivariate significance level 0.05 and 0.01 (*Table 4)*. EC has significant positive correlation with TDS (r = 0.6952), sodium (r = 0.8373), SSP (r = 0.6733), SAR (r = 0.6991), RSR (r = 0.5765) and Boron (0.3379). It is observed that with increase or decrease in values of EC; TDS, Na, SSP, SAR, boron also exhibit decrease or increase in their values. It has been expressed that the increasing EC appear to be associated with the increasing use of alkaline detergents in residential areas effluent. TDS has significant positive correlation with sodium (r = 0.8498), SSP (r = 0.8215), SAR (r = 0.7916), RSR (r = 0.5621) and Boron (0.6519). This also shows that with increase or decrease in the values of TDS; Na, SSP, SAR, boron also show decrease or increase in their values. A significant positive correlation was found between Na and SSP (r = 0.9269), SAR (r = 0.9291), RSR (r = 0.7742) and boron (r = 0.7142). Further, study of boron (r = 0.7817) showed a positive correlation with sodium and therefore it can be assumed that B and Na originates from the same minerals, most likely from clay.

Table 4. *Correlation coefficient of water quality parameters*

	Total salt concentration	**Total dissolved solids**	**Sodium**	**Sodium soluble percentage**	**Sodium absorption ratio**	**Residual sodium ratio**	**Boron**
Total salt concentration	1						
Total dissolved solids	0.6952	1					
Sodium	0.8373	0.8498	1				
Sodium soluble percentage	0.6733	0.8215	0.9269	1			
Sodium absorption ratio	0.6991	0.7916	0.9291	0.9905	1		
Residual sodium carbonate	0.5765	0.5621	0.7742	0.8348	0.8642	1	
Boron	0.3379	0.6519	0.7142	0.7817	0.7803	0.7444	1

Summary of regression model

The main objective of this work is to reduce the number of parameters needed to carry out the water quality prediction without much loss of information. To meet this objective, MLR is engaged to investigate the connection between the water quality parameters and the dependent variables (WQI). In *Equation 3,* four variables are meet the entry requirement and which is accounted for approximately 71% of the variance in WQI. Two variables did not meet the entry requirement, namely the EC and SSP, which is contributed only 8% and 2%, respectively. The multiple regression coefficient R is determined between the independent variables and the dependent variables.

The difference between the adjusted R^2 from the R^2 was only 7.5% (0.625–0.550) and the value of regression coefficient R = 0.7908. This shrinkage means that if the models were derived from December 2016 rather than a sample it would account for approximately 0.7% less variance in the outcome.

To gain clearer evidence, Stein's formula was applied to R^2 (*Eq. 4*) and it can be applied by replacing *n* with the sample size and *k* with the number of predictors. An adjusted R^2 is calculated and the value is equal to 0.6084 indicate that the cross-validity of this model is very good (*Table 5*).

Table 5. *Consequences of establishing prediction models*

Model	R	R-square	Adjusted R-square	Standard error	Observations	Intercept nodes	*t Stat*	*P-value*
1	0.428398	0.183525	0.02023	18.01	7	S1	2.335601574	0.066744
2	0.790836	0.625421	0.550506	11.4	7	S2	-0.541583643	0.611356
3	0.662754	0.439243	0.327092	5.01	7	S3	2.775151086	0.039126
4	0.583011	0.339902	0.207883	4.85	7	S4	2.099131502	0.089852

The model can be written in the following form (*Eq. 6*):

$$WQI = -338.127 + 1.50764\,\text{EC} + 0.741\,\text{TDS} + 7.082\,\text{Na} + 6.678\,\text{SSP} - 41.474\,\text{SAR} + 1.698\,\text{RSC} - 36.759\,\text{B} \quad \text{(Eq.6)}$$

A positive value indicates that, there is a positive relationship between predictor and the outcome whereas a negative coefficient represents a negative relationship. In this study two out of four predictors have negative β values. It is clear that when WQI decreases, the pollutant concentration in S1 and S4 decreases. Positive β values in S2 and S3 shows an increase of WQI values which is followed by the increase of pollution.

Predicting models for water quality index

In the neural network prediction model, 40 set of data are used for training and remaining 24 set of data are used for testing. Initially, the model was trained with the selected input and output variables under 8 numbers of neurons. After that the testing was performed by the use of remaining dataset. In order to obtain the accuracy of this model, the length of data sets and number of neurons are changed. The numbers of trials were performed when the value of correlation coefficient is high. This model stimulated the water quality index with great accuracy and the coefficient of correlation R is 0.9907 (*Fig. 3*). Numbers of observing data were used in *Equation 5* and received the

DOI: http://dx.doi.org/10.15666/aeer/1702_19471958

root mean square value (RMSE) as 0.00617. The variations of original and predicted value of pollution index for all locations were identified.

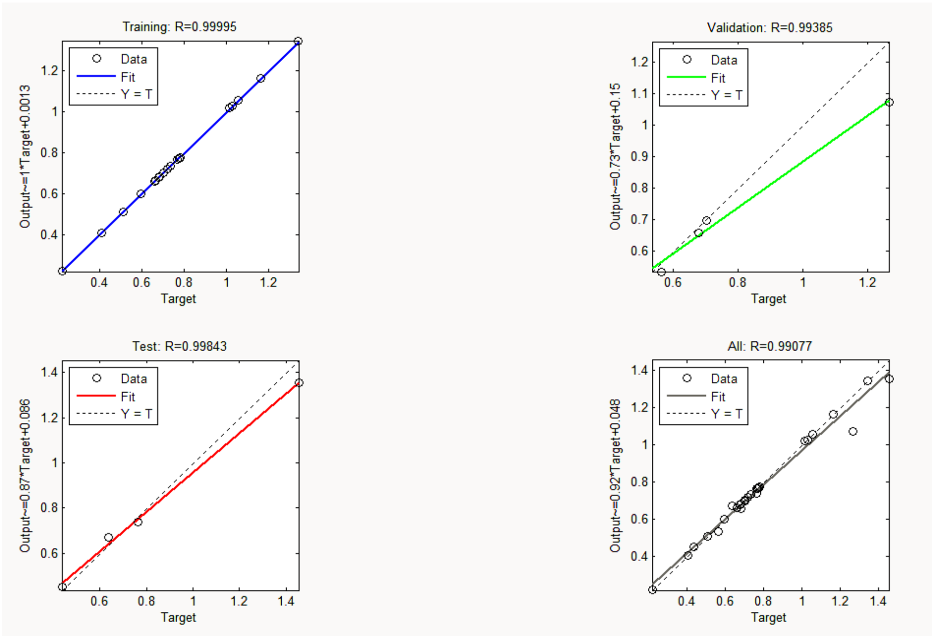

Figure 3. *Evaluation models for WQI for recurrent neural network*

It was detected (*Fig. 4*) that the range of CPI for inlet river water is under qualified category (CPI < 0.2) during December 2016 – March 2018. In the same way, the inlet river waste water, the parameters such as residual sodium carbonate and boron fall under severely polluted condition (CPI > 2) due to the flooding of waste water from the surroundings (*Fig. 5*). For outlet river waters S3 and S4, the parameters EC, TDS, Na and boron fall under qualified category (CPI < 0.8), the parameters such as SSP, SAR and RSC are affected moderately (*Figs. 6* and *7)*. The CPI value of each samples are calculated and are analyzed by the use of limits from *Table 3*. Based on these limits, we can identify the CPI value of sample 1 as 0.3126 indicates moderately polluted, sample 2 is 0.8789 indicates purely sewage water and sample 3 and 4 is 0.5468 and 0.5428 respectively indicates moderately polluted.

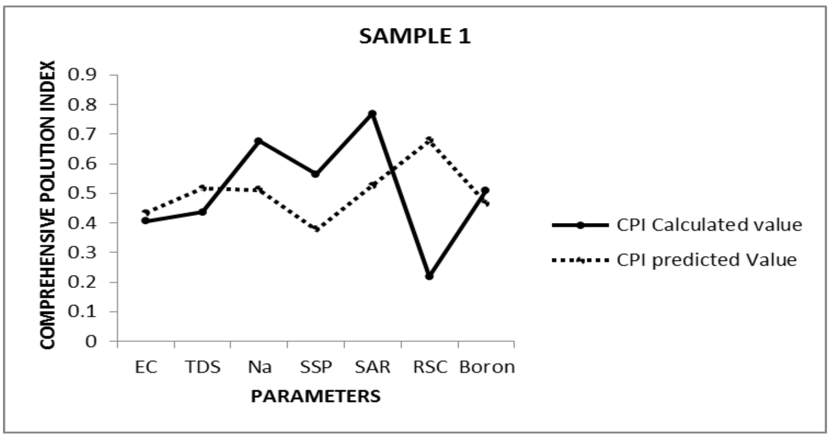

Figure 4. *Deviations in comprehensive pollution index for inlet river water*

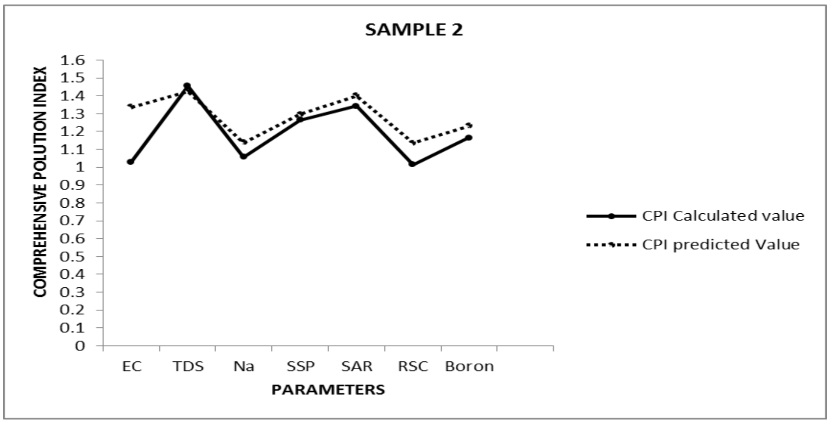

Figure 5. *Deviations in comprehensive pollution index for inlet waste water*

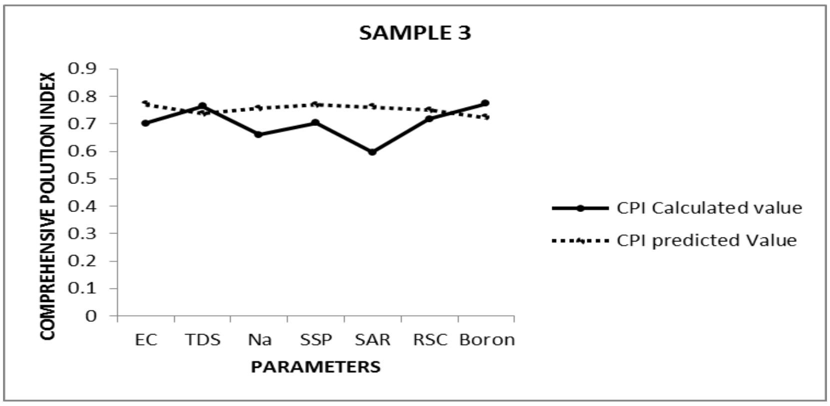

Figure 6. *Deviations of comprehensive pollution index for outlet river water*

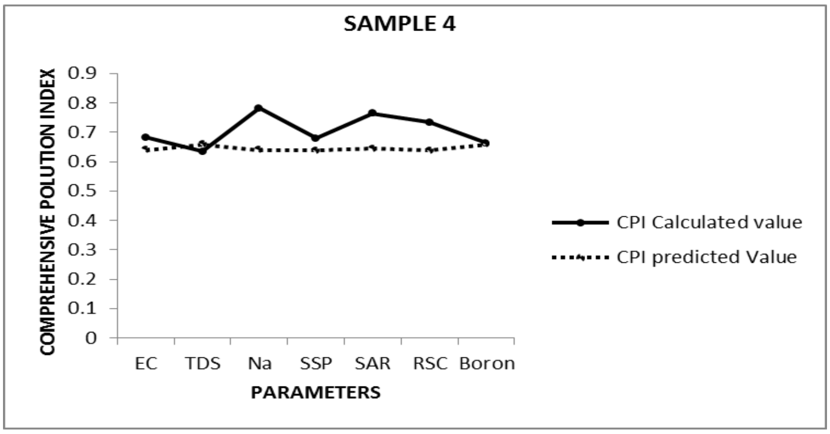

Figure 7. *Deviations of comprehensive pollution index for outlet river water*

The study proves that, in the ANN model, the coefficient of correlation (R = 0.9907) value is higher than the MLR model (R = 0.7908). Also, the MLR models are statistically significant; they contains higher errors than the ANN models. The results indicate that the ANN model is the wonderful prediction model compared with MLR model.

Conclusions

The lake water outlet during the study period revealed that the water is suitable for Irrigation purpose. The measured water quality values are compared with the IS water quality standards of drinking water and it is found that the water is moderately polluted i.e. not suitable for drinking and other life supporting activities, but can be used for irrigation purposes. It is also clear that the increased concentration of sodium may be the root cause for the increase in pollution. Hence, it is summarized that the control of point source and non-point source pollution directly discharged into the lake and are vital to clean the Parakai Lake. From the study, it is understood that the ANN model predicts the water quality indices more accurately than the MLR and also ANN model is a wonderful realistic and forecasting tool. The ANN models explained outstandingly data as long span patterns and as long as good forecasting results.

Abstract. $PM_{0.1}$ (ultrafine particles) emitted by motorcycles have been known as the major contributors to air pollution, and have a harmful impact on human health. Therefore, there is a need to decrease the concentration in the ambient air. In this study, we developed an ultrafine particle filter that was made of banana leaf powder (F_b) and water hyacinth powder (*Eichhornia crassipes,* F_{wh}). The powder was mixed to glutinous rice glue in the ratio of 80%:20%. The filter was characterized by the efficiency. The efficiency of the filter in reducing the ultrafine particles was determined by measuring the ultrafine particle concentration before and after passing through the filter. The ultrafine particle concentration was measured using the TSI P-Trak Ultrafine Particle Counter (Model 8525) for an hour with the sampling time interval of 5 min. The microstructure and the element contents of the filter were analyzed by an SEM and EDAX to determine the filter porosity and the filter element compound. The results show that the porosities were found 33% (F_b) and 21% (F_{wh}) and the filter contained organic and inorganic compounds. The filter efficiency was in the range of 55% to 64% for F_b and 35% to 59% for F_{wh}, respectively.
Keywords: *ultrafine particle filter, motorcycle emission, banana leaf, water hyacinth, efficiency*

Introduction

The usage of motorcycles has been increasing from year to year (Burke et al., 2017; Guerra, 2017). As a consequence, they produce more emissions that are classified into gas and particulate matter (PM) emissions (Grieshop et al., 2006). In terms of particulate matter with the diameter less than 0.1 μm (known as $PM_{0.1}$ or ultrafine particle), $PM_{0.1}$ deposits deeper into the lung (Clifford et al., 2018) and kidney (Wardoyo et al., 2018). Previous studies have showed the correlation between $PM_{0.1}$ and human health (Chen et al., 2016; Li et al., 2016; Liu et al., 2018; Solaimani et al., 2017). Therefore, there is a need to develop a particulate filtration technology in reducing the $PM_{0.1}$ concentration generated by motor vehicles.

The particulate filtration system has been developed, such as radiation based filter, electrostatic based filter, and porosity based filter (Barone et al., 2010; Budianto and Wardoyo, 2016; Wardoyo et al., 2016, 2017a). Meanwhile, the resulted filtration technology is not sufficient due to the high cost of the filter production. In this study, we developed low-cost $PM_{0.1}$ filters that were made of water hyacinth (F_{wh}) and banana leaf (F_b). Those two filter ingredients can be easily found in Indonesia. They also have a high cellulose content (25-39%) (Istirokhatun et al., 2015; Nada et al., 2010) that can adsorb ultrafine particles. Filter porosity can determine the level of adsorption (Ma et al., 2016). The aim of this study was to develop an ultrafine particle filter made of water hyacinth and banana leaf and to characterize the efficiency and the influence factors in terms of the porosity and the element compounds.

Materials and methods

Motorcycle samples

Three motorcycles were used as $PM_{0.1}$ source. They were classified into M1 (model year: 2015), M2 (model year: 2011), and M3 (model year: 2013). All of them had automatic transmission engines with the same engine capacity (108 cm^3). They were chosen due to their prevalence in Indonesia.

$PM_{0.1}$ filter

Water hyacinth and banana leaves were collected from the rivers and farms of Sengonagung village, Pasuruan, Indonesia. They were cut into small pieces, blended (diameter ± 70 mesh) and dried in an oven for seven hours (controlled temperature: 100 °C). After that, the resulted powder (16 grams) was mixed with water (190 ml) and a tapioca glue containing glutinous rice (4 grams) which was heated with water (100 ml). The filter dough was printed into a layer.

Particle measurement

Each filter was installed on a filter frame (diameter = 50 mm) and mounted on the tip of the motorcycle exhaust. The $PM_{0.1}$ concentrations emitted by the motorcycle samples before (C_o) and after being equipped with the filters (C_i) were measured using a P-Trak Ultrafine Particle Counter (Model 8525) for an hour in an idle condition (sampling time = 5 min). All measurements were repeated three times (Wardoyo et al., 2015).

Filter characterization

The filter was characterized by the porosity and the element compounds. The porosity was analyzed by using a scanning electron microscope analyzer INSPECT S50 SEM EDAX to determine the filterability in capturing $PM_{0.1}$ emission and the structure of the morphological surface (Van der Zande et al., 2014). The element compounds were analyzed using an EDAX (Kedar et al., 2018).

Statistical analysis

Values are expressed as the means ± SD (standard deviation). The differences between the groups were evaluated using a Student's *t*-test. The relationship between $PM_{0.1}$ concentrations and time series was determined using R-square value (Wardoyo et al., 2017b). The filter efficiency (*%F*) was calculated using *Equation 1* (Mondal et al., 2015):

$$\%F = [(C_o - C_i) / C_o] \times 100\% \qquad \text{(Eq.1)}$$

Results and discussion

Emission measurement

Figure 1 represents the comparison of the $PM_{0.1}$ concentration measurement of all motorcycles without a filter and using a filter (F_{wh} and F_b). According to *Figure 1,* the $PM_{0.1}$ concentrations without being filtered are 19,020 ± 2,958 to 62,362 ± 3,664 particle/cm^3. These concentrations are higher than the $PM_{0.1}$ concentrations obtained from F_b and F_{wh}.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_19591965

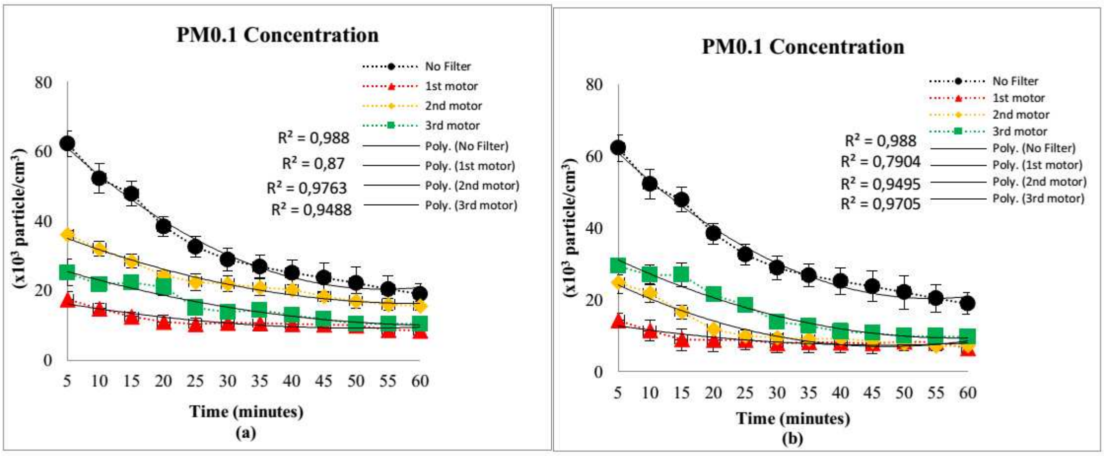

Figure 1. *The $PM_{0.1}$ concentrations of (a) F_{wh} and (b) F_b*

In contrast, the $PM_{0.1}$ concentrations obtained from using F_{wh} are 8,554 ± 389 to 36,136 ± 1,218 particles/cm^3. F_b has the lowest $PM_{0.1}$ concentration (6,565 ± 1,125 to 29,448 ± 2,307 particles/cm^3). The decreasing trend of the particle concentrations measured in all motorcycles is a polynomial trend with the order of 2. The R-square values of all motors using the filters are in the range of 0.79 to 0.98. If the R-square value is higher than 0.75 it presents a good relationship between the two variables on the graph (Duarte et al., 2014). *Figure 2* shows the average efficiency of F_{wh} and F_b on M1 and M2. According to *Figure 2,* the efficiency of F_b (55% to 63%) is higher than F_{wh} (35% to 59%) ($p < 0.05$).

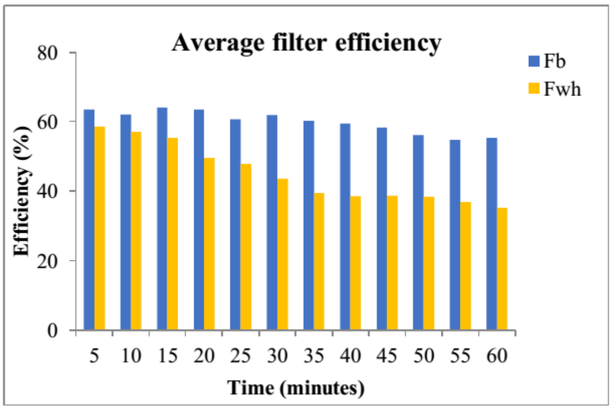

Figure 2. *Average efficiencies of F_{wh} and F_b*

The filter efficiencies were influenced by the content of cellulose in water hyacinth and banana leaf. Cellulose content in banana leaf is 39.2% (Nada et al., 2010) higher than cellulose content that is found in water hyacinth (25%) (Istirokhatun et al., 2015). Cellulose can bind the organic PAHs (Polycyclic Aromatic Hydrocarbons) and VOCs (Volatile Organic Compounds)) and inorganic content of $PM_{0.1}$ (Hokkanen et al., 2016; Liu et al., 2016). This is shown by the overall values of the weight percent of detected elements in F_{wh} and F_b after emission exposure as listed in *Table 1*. The most detected elements in *Table 1* are oxygen (O) and carbon (C). The spherical carbon was indicated

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_19591965

as one of the elements of the particles emitted by a gasoline operated vehicle (Ritovski et al., 1999). Carbon and oxygen are also the part of VOC and PAH content in $PM_{0.1}$ (Charron and Harrison, 2003; Hong-li et al., 2017). VOC contains aldehydes, alkenes, and aromatic rings (Zhang et al., 2018). The aldehydes occur as C=O stretching vibration, alkenes and aromatic rings occur as C=C stretching vibration. While one of the PAH content in $PM_{0.1}$ is perylene ($C_{20}H_{12}$) (Charron and Harrison, 2003). So, thus elements C and O in *Table 1* may be a part of the VOC and PAH in $PM_{0.1}$.

Table 1. *Elemental analysis of F_{wh} and F_b after emission exposure*

Element	Weight (%)	
	F_{wh}	F_b
C	28.62	54.30
O	29.35	33.65
Mg	0.67	0.57
Si	0.42	0.63
Pb	2.44	1.22
K	20.22	5.17
Ca	1.40	-
Fe	0.76	0.73
Co	-	0.23

The SEM EDAX results also showed the presence of several inorganic elements, e.g. Ca (only detected on F_b), and Co (only detected in F_w). Other elements (Ca, Fe, and K) are related to the crustal matter (Zhang et al., 2014). Inorganic elements that have the highest weight percent are K then Pb.

In addition, the filter efficiency is also influenced by the filter porosity. Filter porosity can be known from the micrographic structure of the filter. *Figure 3* shows the micrographic structure of SEM result from the processing ImageJ software (Igathinathane et al., 2008) on F_{wh} and F_b before emissions exposure. *Figure 3* shows the surface pores of the filter (black). According to the figure, F_{wh} has pores sizes in the range of 1.019 μm^2 to 1.499 mm^2, with a total porosity of 21%. Meanwhile, F_b has pore sizes in the range of 1.038 μm^2 to 1.613 mm^2, with a total porosity of 33%. With the size area porosity, the filter has a potential to trap the particulate matters with a diameter of 0.1 μm.

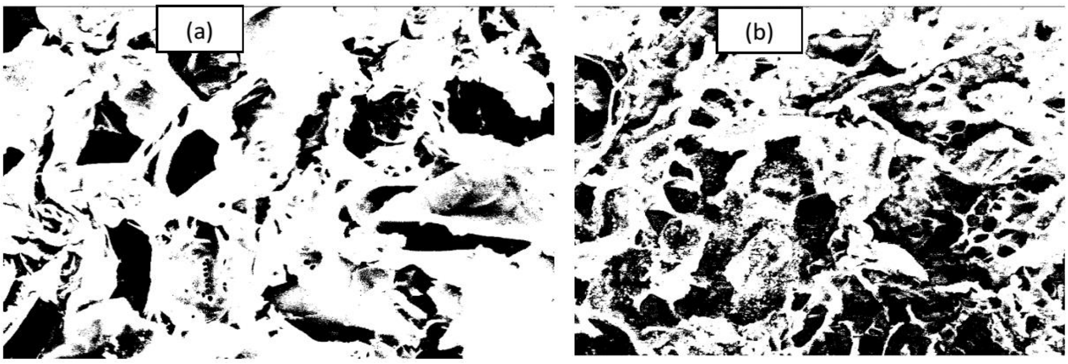

Figure 3. *Micrographic SEM of imageJ processing results of the filters before being tested: (a) F_{wh} and (b) F_b*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_19591965

The particles can be trapped in the filter pores with several mechanisms, i.e. inertial impaction, interception, and diffusion. Inertial impaction occurs when the particles pass through the filter with micrometer range and the particles hit the filter materials, so the particles trapped in the filter. Interception mechanism occurs when the center of the particle is shorter than the radius of the filter so the particle center does not touch the surface of the filter material to be deposited. Particles that move in the nanometer range generate Brownian motion, which causes the particles to collide with inertial or interception particles and diffuse on the surface and deposit during the time when they are passing the side of the filter (Liu et al., 2016).

Figure 4 shows the results of the water hyacinth filters before and after emissions exposure and banana leaf filters before and after emissions exposure. *Figure 4a* and *c* shows the cavities on the surface of the filters. Meanwhile, *Figure 4b* and *d* shows the invisible cavities and trapped particles on the surface of the filter. These results are similar to the results obtained in the Van der Zande et al. (2014).

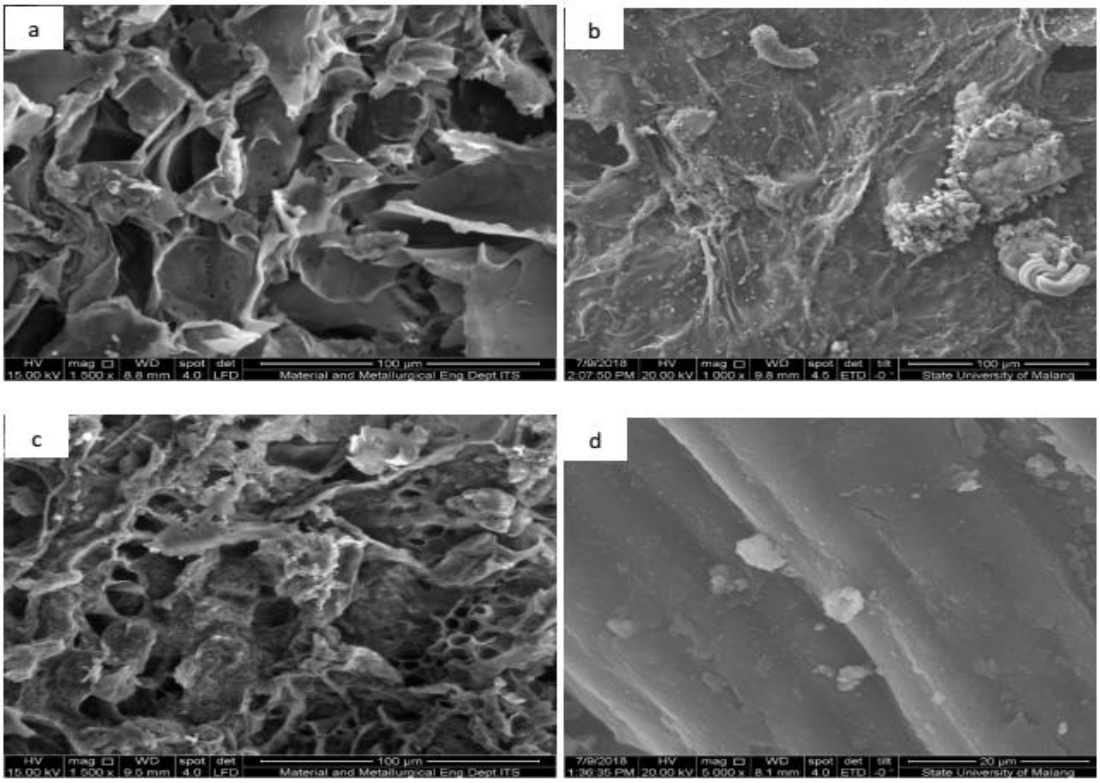

Figure 4. *SEM image of F_{wh} before (a) and after (b) being tested, and F_b before (c) and after (d) being tested*

Conclusion

In conclusion, the filters based on water hyacinth and banana leaf have a character to reduce the $PM_{0.1}$ concentrations with the efficiency of up to 59% and 64%, respectively. The filter efficiency is influenced by the cellulose content which can adsorb the organic and inorganic content of $PM_{0.1}$, which is proven by the presence of several $PM_{0.1}$ elements in the filter. Efficiency is also influenced by the filter porosity. F_b porosity is 33% higher than F_{wh} (21%), so the efficiency of F_b is also higher than F_{wh}.

(Received 18th Oct 2018; accepted 2nd Jan 2019)

Abstract. Ten *Bacillus thuringiensis* strains (Bt) isolated from Moroccan habitats were screened for their acaricidal proprieties against the Citrus brown mite, *Eutetranychus orientalis* Klein (Acarina: Tetranychidae) under laboratory conditions. Results of bioassay indicated that larvae are more susceptible to the tested Bt strains than adult females at different concentrations (0.5, 1, 2, 4 and 8 mg/ml). Among the Bt strains examined, Bt 26.4 (LC_{50} = 1.533 mg/ml) and *Bt* 13.4 (LC_{50} = 1.385 mg/ml) showed respectively the highest mortalities to adults and larvae when compared with others and with the commercial product of Bt. Concerning fecundity, the effect of all tested strains showed highly significant reduction within adult females, whereas no significant effect was observed in eggs hatching for all strains.
Keywords: *Bacillus thuringiensis, spore-crystal mixtures, Moroccan habitats, biological control, Eutetranychus orientalis, citrus*

Introduction

The Citrus brown mite, *Eutetranychus orientalis* (Klein), is principally a pest of citrus (Jeppson et al., 1975) that attacks a wide range of agricultural, ornamental, and medicinal plants (Rasmy, 1978). It has been found on about 70 host plants of important economic value (Jeppson et al., 1975; Smith-Meyer, 1987; EPPO, 1990). The damage engendered by *E. orientalis* can cause from one side direct effects, including change of leaves' color that become yellowish-brown following chlorophyll depletion, little webbing, leaf fall and branches dieback leading to trees defoliation. From another side, it set off indirect effects such as a decreased photosynthesis process and a retarded grow of plants (Yousef et al., 2006). Actually, the application of synthetic acaricides is commonly applied in a wide agricultural range to manage this invasive mite. Consequently, the use of these acaricides cause negative effects to human health and environment (Cavalcanti et al., 2010; Kumral et al., 2010). However, to achieve a sustainable management, alternative controls are necessary to reduce the use of conventional pesticides (Isman, 2001; Choi et al., 2003), one of which an

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_19671977

entomopathogenic bacterial toxins, *Bacillus thuringiensis,* may have interesting substitutive managerial effect.

Bacillus thuringiensis (Bt) preparations are one of the successful biological control products (van Frankenhuyzen, 2009) that can be used as alternative to achieve integrated pest management (IPM) program. Several forms of Bt preparations such as liquid and solid are now available on the market for application as biological control agents against many pests (George and Crickmore, 2012). Currently, over than 400 Bt preparations are used as bio-insecticide product which represents approximately 2% of the total insecticidal sold (Bravo et al., 2011).

The insecticidal activity characteristic of Bt is mainly due to its crystalline proteins (δ-endotoxins) produced concomitantly with endospore at the stationary phase of its growth cycle (Schnepf et al., 1998). Though δ-endotoxins are highly specific to their target, they are safe to humans, plants and vertebrates, and are completely biodegradable (IPSC-WHO, 1999). They are indeed toxic to several insects belonging to dipteran, lepidopeteran, and coleopeteran insects, as well as pests from other orders such as fluke, protozoa, nematodes, and mites (Jisha et al., 2013). To our knowledge, few studies have demonstrated the efficacy of Bt against mites, among which Hall et al. (1971) found that thuringiensin could be used to control the citrus red mite, *Pananychus citri* (McGregor). Similarly, the efficiency of thuringiensin was revealed on the adults of *T. urticae* (Royalty et al., 1990; Payne et al., 1993; Chapman and Hoy, 2009). Furthermore, some recent studies have suggested also that Bt preparations are effective to control *Tetranychus macfarlanei* (Neethu et al., 2015), *Aceria guerreronis* (Smitha et al., 2015) and *E. orientalis* (Jisha et al., 2017).

To our knowledge, no study has investigated the acaricidal effects of native Bt strains isolated from Moroccan habitats. Therefore, in the present study, we evaluate the biological activity of ten Bt strains isolated from Marrakech region and Argan field in Morocco. In addition, we test the effects of those Bt strains against eggs, larvae and adult females of *E. orientalis.*

Materials and methods

Rearing of E. orientalis

The Citrus brown mite, *E. orientalis*, was collected from citrus orchards of Agafay, latitude 31°30'01.6"N, longitude 8°14'55.4"W in May 2018. Collected mites were reared continuously on bean plants (*Phaseolus vulgaris* L.) at Laboratory of Molecular and Ecophysiology Modeling, Faculty of Sciences Semlalia, University Cadi Ayyad, Marrakech (Morocco). The rearing conditions used were 29 ± 2 °C and 70 ± 5% R.H. The photoperiod was 16 L: 8 D using fluorescent lamps.

Bacterial strains

10 Bt strains were selected from 83 Bt strains previously isolated from Moroccan habitats (Aboussaid et al., 2010, 2011). The selection of strains was based on the morphological, biochemical and genetic characters (*Table 1*).

Production of spore-crystal biomass

A loopful of bacterial from a colony of each selected strain grown in CCY agar medium were used to inoculate a small tube containing 4.5 ml of liquid CCY medium

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_19671977

(pre-culture), then the pre-culture was left to grow for 48 h at 28°C and agitated at 200 rpm (Edmund Bühler GmbH KS-15, Shakers). An aliquot was taken from the pre-culture to verify the formation of spore and crystal (over 90% sporulation is optimum). To eliminate vegetative cells, the pre-culture was heating at 70°C for 20 min (synchronization). 40 ml of main culture was inoculated with 1/1000 volumes of synchronized pre-culture and incubated as mentioned above (Aboussaid et al., 2011). From this culture, serial dilutions10-fold (10^{-1} to 10^{-5}) has been realized to determine the total number of cells by plating 0.1 ml of each dilution on CCY plates. Then the whole culture was centrifuged for 10 min at 9 000 × g (Universal 320R, centrifuge Hettich).

Table 1. *Morphological characterization (phase-contrast microscopy), biochemical (SDS-PAGE) and genetic (SDS-PAGE and PCR) of the selected Bt Moroccan strains (Aboussaid et al., 2010, 2011)*

N°	Strains	Sampling site	Habitat	Crystal form	Gene *cry* (PCR)

8	Bt 32.3			Crystal > 1	*cry 4*
9	Bt 13.4			Irregular	*cry 4*
10	Bt B9	Beni-mellal	Bean-cultivated soil	Spherical	*cry 4*

The supernatant was discarded and the pellet was washed one time with ice-cold 1 mol/l NaCl, 10 mmol/l EDTA solutions (Ethylenediaminetetraacetic acid). Then the pellet was concentrated by lyophilisation to express the mixtures spore and crystal in mg. Finally, the pellet lyophilized was suspended in 1 ml of 10 mmol/l KCl (Aboussaid et al., 2011). Optical Density (OD) was measured by spectrophotometry at 600 nm (Spectrophotometer “VR-2000”, P-Selecta) and the suspensions were stored at -20 °C until bioassay. To limit proteolysis after centrifugation, all steps were done on ice.

Doses preparation

Doses of spore-crystal of each Bt strain were prepared by mixing 10 microliters of Triton-X100 (G-Labrogos), with 80 mg of each Bt strain, then 10 ml of distillate water was added to obtain 8 mg/ml. A series of dilution were prepared from the stock solution (8 mg/ml) using distillate water.

Distillate water and Triton-X100 at a rate 0.01% were used as absolute control, and Bt commercial product (DELFIN®, *Bacillus thuringiensis* sp. *Kurstaki*) and Triton-X100 were used as positive control (Bt. sp. *Kurstaki,* 2 mg/ml + 0.01% Triton-X100).

Acaricidal activities of Bt strains against E. orientalis

Acaricidal effect of Bt strains on adult females and larvae

Toxicity of spore-crystal mixture of Bt strains to *E. orientalis* was evaluated following the method of Royalty et al. (1990) with slight modifications. Bean plant leaf discs were immersed during seven seconds in five concentrations 0.5, 1, 2, 4 and 8 mg/ml of each selected Bt strains. We have followed the same method to prepare the absolute control and the positive control. Treated leaf discs were placed on the lower surface in a petri dish surrounded with moist cotton wool and then allowed to completely dry at ambient temperature. Twenty *E. orientalis* adult females were introduced by using fine brush into the center of each leaf discs. Five replicates were made for each concentration. The same protocol was conducted for the larvae; eggs were placed on treated leaf discs, then the newly emerged larvae were used for the bioassay.

For all assays, after being exposed to leaf discs treated with *B. thuringiensis*, the larval and the adult females' mortalities were daily evaluated within the 96 h following the treatment. Furthermore, the number of oviposited eggs on the leaf was recorded at the 96th post-treatment hour.

Ovicidal effects of Bt strains

To determine an ovicidal activity of spore-crystal mixture of Bt strains, 20 adult females of *E. orientalis* were introduced on bean plant discs for oviposition and kept overnight. These discs were placed, the lower surface in petri-dish lined with moist cotton wool. After 24 h, the adult females were removed and the leaf discs were kept with 20 eggs on it; the excess of eggs was removed using a fine brush. Eggs laid on leaf discs were sprayed with five concentrations of spore-crystal mixture of each Bt strains. The leaf discs of absolute control and positive control were also prepared. Hatchability was determined 9 days after treatment and the eggs that did not hatch after this time was considered dead.

Statistical analysis

Mortality observations were subjected to one-way ANOVA by using SPSS program, version 11.5. Tukey's test was used for comparisons of means mortality. Probit analysis was used to determine lethal concentrations (LC_{50}) and the control mortalities were corrected by using Abbott's formula (*Eq. 1*).

$$\text{Corrected mortality } \% = \frac{1 - \text{n in T after treatment}}{\text{n in Co after treatment}} \times 100 \qquad \text{(Eq.1)}$$

where: n = Insect population, T = treated, Co = control.

Results

Effect of spore-crystal mixture of Bt strains on adult females of E. orientalis

Acaricidal activity of spore-crystal mixture of 10 selected Bt strains in female adults of *E. orientalis*, is shown in *Table 2*. There were significant differences between the corrected mortality of *E. orientalis* adults treated with five concentrations of each Bt

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_19671977

strains ($p < 0.05$). Furthermore, a positive correlation was observed revealing an increase of the corrected mortality with the increase of toxins concentrations.

The corrected mortality values varied significantly between strains and the acaricidal rates were ranging from 6.43 to 28.73% (df: 10, F = 17.96, p < 0.0001) at 0.5 mg/ml, from 21.84 to 43.67% (df: 10, F = 5.49, p < 0.0001) at 1 mg/ml, from 40.23 to 62.07% (df: 10, F = 4.23, p < 0.0001) at 2 mg/ml, from 45.97 to 71.26% (df: 10, F = 3.02, p < 0.005) at 4 mg/ml and from 56.32 to 83.91% (df: 10, F = 2.45, p < 0.020) at 8 mg/ml.

At 96 h after treatment within the screened strains, Bt 26.4 was found to be the most toxic with a caused mortality reaching 83.91% for the highest dose (LC_{50} = 1.533 mg/ml). The effect of Bt 13.4 was significantly lower compared to the others in every tested concentration (LC_{50} = 4.228 mg/ml). Moreover, significant difference was noted between corrected mortality caused by positive control (71.01%) and those caused by our strains with the concentrations 0.5, 1 and 2 mg/ml, whereas in higher concentrations, 4 and 8 mg/ml, no significant difference was observed (*Table 2*).

Effect of spore-crystal mixture of Bt strains on larvae of E. orientalis

Results of larvicidal effectiveness of 10 Bt strains are presented in *Table 3*. The difference of mite's corrected mortalities was significantly higher between those exposed to the lower concentrations of spore-crystal mixtures and those exposed to higher concentrations. The corrected mortality was dose dependent and varied significantly within all strains. Larvicidal rates were ranging from 17.01 to 35.10% (df: 10, F = 13.22, p < 0.0001) at 0.5 mg/ml, from 20.21 to 44.68% (df: 10, F = 8.29, p < 0.0001) at 1 mg/ml, from 39.36 to 67.02% (df: 10, F = 3.53, p < 0.002) at 2 mg/ml, from 57.45 to 71.27% (df: 10, F = 3.02, p < 0.842) at 4 mg/ml and from 72.34 to 85.11% (df: 10, F = 2.90, p < 0.007) at 8 mg/ml.

The lethal concentrations to kill 50% of larvae (LC_{50}) were determined after 96 h following treatment and summarized in *Table 2*. Results showed that Bt 13.4 at 8 mg/ml

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_19671977

cause maximum mortality (LC_{50} = 1.385 mg/ml) followed by Bt A-Mg Mg2.7 (LC_{50} = 1.472 mg/ml), Bt A10 (LC_{50} = 1.473 mg/ml), Bt 26.4 (LC_{50} = 2.191 mg/ml) and Bt A1 (LC_{50} = 2.263 mg/ml). Significant difference was noted between corrected mortality caused by positive control and those caused by our strains at lower concentrations 0.5 and 1 mg/ml, whereas no significant difference is revealed at the higher concentrations 2, 4 and 8 mg/ml (*Table 3*).

The bioassay has shown a decrease of oviposition within the treated females with increasing concentrations of selected Bt strains. In the absolute control, the mean of oviposited eggs reached 9.63 per female, a fecundity which is highly significantly superior to others of every Bt treated females ($p < 0.0001$). Whereas, the comparison between fecundities of females treated with the positive control and those treated with Bt strains has shown no significant difference at low doses (0.5 and 1 mg/ml), while at high doses, the fecundity values of Bt treated females decreased significantly.

Effects of spore-crystal mixture of Bt strains on eggs hatching

The observed hatch rates at 9 days after treatment are presented in *Table 5*. No concentration of all the ten Bt strains was able to avoid eggs hatching. There was no significant difference in eggs hatchability within tested Bt strains, absolute control and positive control ($P < 0.05$).

Discussion

Bacillus thuringiensis is an entomopathogen able to product two proteins inclusions during sporulation. The parasporal crystalline inclusion containing Cry and Cyt (also known as δ-endotoxins) are toxic to different insect orders (Schnepf et al., 1998; Tsuchiya et al., 2002; Aboussaid et al., 2010). Many formulations of Bt toxins revealed high toxicity to mite (Vargas et al., 2001; Jisha et al., 2017). For instance, these toxins have been reported to have different influences on *Tetranychus urticae,* such as antifeedant effect and reduction of fecundity (Royalty et al., 1990, 1991). Such toxicity of Bts is principally due to the primary action of Cry toxins consisting of the lysis of the midgut epithelial cells in the target insect so that it forms pores in the apical microvilli membrane of the cells (Aronson and Shai, 2001; de Maagd et al., 2001; Bravo et al., 2007).

Our results showed a significant acaricidal effect of ten Bt strains spore-crystal mixtures against adult females and larvae of *E. orientalis.* For adult females, 100% of

DOI: http://dx.doi.org/10.15666/aeer/1702_19671977

tested Bt are toxic and at the higher concentration (8 mg/ml) the mortality ranged between 65.51% and 83.91% after four days. These are corresponding with the data of Neethu et al. (2015) who studied the Bt activity against adults of *Tetranychus macfarlanei* and have reported that the culture pellet, mixtures of δ-endotoxin and crystals, (1-10 mg/ml) mixed with artificial diet caused mortality ranged from 40% to 80% four days after the treatment. Moreover, Jisha et al. (2017) have demonstrated the efficacy of the crude pellet of Bt var. *Kurstaki* (Btk) to combat *E. orientalis*. The results of this study revealed that the crude Btk-toxin eliminate completely the mite of infested plants after 12 days of direct spraying, an effect that has been established without supplementing any adhesive or surfactant. For larvae, all tested Bt strains are highly toxic and the mortality exceeds 80% for some strains. Similar results were reported by Vargas et al. (2001) in a study where the larvae of *Tetranychus urticae* and *Pananychus ulmi* have been highly susceptible to thuringiensin (β- exotoxin). Nevertheless, the results found by Alper et al. (2013) are in disagreement with our data. These authors have studied the effects of spore-crystal mixtures of 31 native *B. thuringiensis* isolates against *T. urticae* nymphs where they have found that 42% of the isolates caused mortality ranged between 16% and 30%. In addition to this, the same study has reported that 58% of the isolates resulted in less than 15% mortality. The difference observed between our results and those of Alper et al. (2013) on the larvicidal effect of the mixture may be linked to variability on the genes coding the Cry proteins.

The larvae of *E. orientalis* are more susceptible to spore-crystal mixtures of our Bt strains than adult females. However, the mortality of both stages increased with increasing concentration of Bt strains. These results agreed with the findings of Royalty et al. (1990) and Vargas et al. (2001) who reported that the application of thuringiensin affect more the immature stages than adults of *Tetranychus urticae* and *Pananychus ulmi,* with an observed dose dependent mortality for the both stages. Therefore, the adult mortality might be a result of the disruption of a diverse biochemical mechanism to that in immature stages (Beebee and Bond, 1973a, b).

Furthermore, the results presented in *Table 4* indicate that the spore-crystal mixtures of our Bt strains caused a reduction in the fecundity of adult female of *E. orientalis.* These are consistent with the results found by Royalty et al. (1990) and Vargas et al. (2001) who noted that the number of eggs laid by treated females of *Tetranychus urticae* is lesser than untreated ones.

Moreover, our finding indicates that spore-crystal mixtures of our strains did not show any ovicidal effect to eggs of *E. orientalis,* which is in agreement with Reza et al. (2011) who postulated that all concentration of thuringiensin did not revealed significant difference in the percentage of eggs hatching of *Tetranychus urticae*.

Conclusions

Based on the present research, Moroccan Bt strains provide the evidence for their acaricidal properties. The most Bt strains tested revealed a great activity against adult females and especially towards larvae and adults, also they reduced greatly the fecundity of female adults. All these results confirm that most of our Bt strains can be used as a good alternative to conventional pesticides harmful to consumers and environment.

(Received 20th Oct 2018; accepted 21st Dec 2018)

Abstract. An understanding of physiological and agronomical traits associated with high grain yield and efficiency of phosphorus use is important to the improvement of genotypes under dryland conditions. An experiment was conducted to evaluate the influence of differentiated phosphorus fertilization rate on the yield and quality of wheat at the experimental farm, University of Dicle, Diyarbakir, Turkey during 2013-2014 and 2014-2015 growing seasons. The experiment was consisted of five treatments comprising of five phosphorus (P_2O_5) levels (0 kg ha^{-1}, 30 kg ha^{-1}, 60 kg ha^{-1}, 90 kg ha^{-1} and 120 kg ha^{-1}). It was observed that phosphorus levels exhibited significant differences to the grain numbers per m^2, grain weight and grain yield ha^{-1}, as well as to starch content and protein content in the first season. There was no significant effect of phosphorus on all studied grain yield and quality characters in the second season. The improvement in grain yield was significantly associated with the increase in the values of grain number, accordingly, the coefficients of grain number and grain yield showed that grain number had a positive and direct effect on grain yield suggesting a criteria trait to enhance yield. It was concluded that the highest grain yield of wheat crop was obtained with 120 kg ha^{-1} P_2O_5 and it showed comparatively better performance than another treatment under investigation.
Keywords: *wheat, grain yield and quality, protein yield, starch content, water use efficiency*

Introduction

Wheat (*Triticum aestivum* L.) is one of the main essential food and a vital source of energy in human diet. It is one of the major significant and widely cultivated crop of the entire world and it is a major source of nourishment (Aktas, 2016; Kizilgeci et al., 2017; Khaled et al., 2018; Hossain et al., 2018). It is a principal food for more than 35% of the world's population, and a source of food and livelihood for over one billion people in developing countries (Metwali et al., 2011). Wheat grains used in the making of flour, breads, biscuits, cakes, cookies, pasta, noodles and also for beer, and other alcoholic beverages or biofuel. Presently, wheat is grown on more than 200 million hectares of the world's cultivated land and is the most important agricultural commodity in international trade (FAO, 2010). The worldwide requirements of wheat production by 2020 reached about 950 million tons to achieve food needs imposed by the increase of population and further, this could be reached, if global wheat productivity is enriched by 2.5% yearly. (Singh et al., 2011; Barutcular et al., 2017; Yildirim et al., 2018). Consequently, to feed the rapidly growing population of the world, food production should be heightened.

Phosphorus is a necessary nutrient for the normal development of the plant (Kaleem et al., 2009). The quality and productivity of wheat crop may be affected by the management of primary fertilizers (NPK) but, it is also physiologically dependent on the different micronutrients along major nutrient management (Wiatrak et al., 2006). It plays an important role and has a number of functions in the growth of plant. It utilizes

DOI: http://dx.doi.org/10.15666/aeer/1702_19791987

sugar and starch and involved in transfer of energy (Mumtaz et al., 2014). Balanced fertilization not only enhanced the yield of wheat, but also had a good influence on phosphorus uptake by plants (Rehman et al., 2006). While, deficiency of phosphorus is one of the factor of abiotic stresses that determine the productivity of cereal crops (Yu et al., 2013). Deficiencies regarding soil phosphorus (P) and zinc (Zn) noticed widely in numerous regions across the globe (Marschner, 1995). Keeping in view the importance of phosphorus in crop productivity, the aim of the field study was to evaluate the response of bread wheat in terms of growth, yield and quality properties to different rates of phosphorus fertilization.

Materials and methods

Plant material and growing conditions

Two field experiments were conducted under rainfed conditions at the experimental farm, University of Dicle, Diyarbakir (latitude 37°88′N, longitude 40°27′E, altitude 680 m above sea level), Turkey (*Figure 1*).

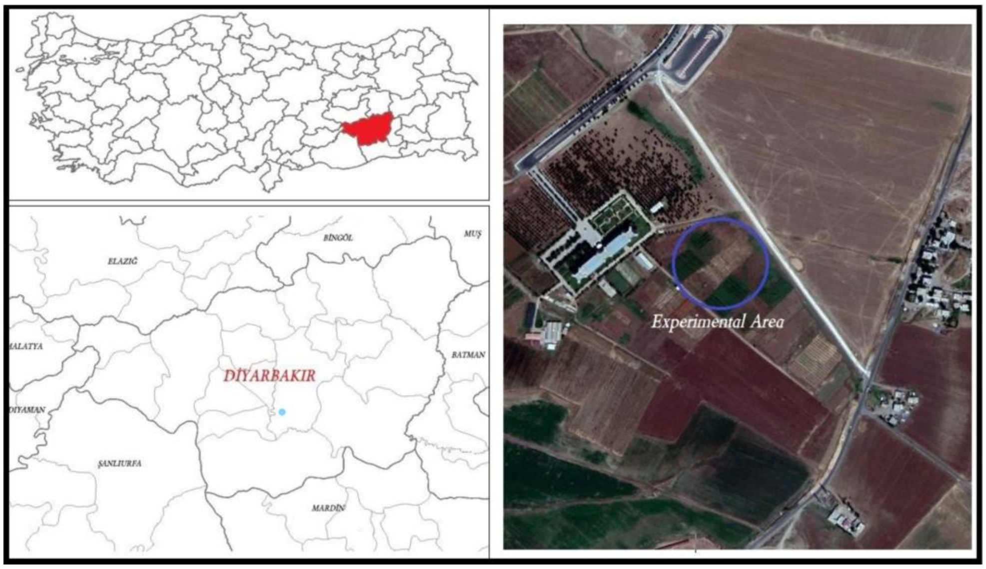

Figure 1. *Map of the experimental area*

Seeds of wheat cv: Pehlivan were sown on 12.12.2013 in the 1st year and on 26.12.2014 in the 2nd year. Pehlivan is one of the most important winter bread wheat variety registered in 1998. It has a medium early growth cycle. The spike is white, smooth, awnless and compact, and the plant height is 95-100 cm. The variety has high productive tillering with high winter hardiness to be grown in winter wheat areas of the Central Anatolian Plateau with a medium tolerance to drought. Pehlivan also has medium opposition to lodging. It is suitable for growing on fertile and poor fertile soils, and is grown in most wheat producing regions of Turkey. The grain is oval, hard-red, very large, and has good milling and baking qualities.

The physical and chemical properties of the soil used in the experiment were as follows: clay soil (71.6% clay), organic matter 1.25%, available phosphoros 16.3 kg ha^{-1}, salt 0.01%, calcareous 13.02%, pH 7.73. Meteorological data were given in *Table*

1. The experiment was arranged in randomized complete block design with four replications. The plots were arranged in six rows with 4 m long, 0.2 m intra-row using an experimental sowing machine. Five phosphorus (P_2O_5) levels (0, 30, 60, 90 and 120 kg P_2O_5 ha^{-1}) were established in the form of triple super phosphate. The trial was conducted under rainfed conditions. Genotype were sown at a seed rate of 450 seed m^{-2}. Nitrogen fertilization was carried out 2 times in the form of ammonium nitrate (33%N). 60 kg ha^{-1} was applied at the sowing (basal dose) and tillering stage, in accordance with recommendations.

Data collection and measurements

The chlorophyll content (SPAD) at the midpoint of the flag leaves of 10 randomly selected plants in each plot was measured by using a portable chlorophyll meter (Minolta SPAD-502, Osaka, Japan). Grain yield (kg ha^{-1}) was calculated in harvest plots. Grain yield in kilogram per hectare was calculated from the yield harvested from each plot, the plants collected with a harvester from the area were used for assessments of grain yield. The grain weight included a moisture content of 12%. The sampling and determination of grain quality traits were described according to AACC (2000).

Water use efficiency (WUE)

Water-use efficiency is normally described as the ratio of crop yield to the amount of water needed to achieve the yield according to total consumed water through wheat life circle, WUE was measured by referring to Gao (2000) and Gao et al. (2004).

Statistical analysis

The obtained data were subjected to analysis of variance as described by Gomez and Gomez (1984). The data were statistically analyzed by using MSTAT-C package program. The Least Significant Differences (LSD) test was used to compare the treatments at 0.05 levels.

Results and discussion

The statistical analysis of variance (*Table 2*) illustrated the influence of phosphorus on the yield and quality traits of wheat. It is evident from the table that the number of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_19791987

grains per m^2, thousand grain weight and grain yield were influenced significantly by the application of P fertilizer treatment in the first season. The analysis data showed that the analysis of variance of quality properties resulted in significant difference for phosphorus levels applications. Phosphorus fertilizer application also significantly infulenced the starch and protein content only in the 2014 growing season (*Table 3*). However, the maximum number of grains m^{-2} was observed with the application of 120 kg P_2O_5 ha^{-1}. While, the minimum value for number of grains was observed in control treatment. The results are in agreement with the findings of Ravnskov et al. (1995) and Reuter et al. (1995) who found that the application of phosphatic fertilizer significantly enhanced the number of grains per hill or per m^2 area.

Data regarding thousand grain weight influenced by various phosphorus rates are presented in (*Table 2*). Data after statistical analysis showed significant ($p \leq 0.05$) effect of various phosphorus rates on thousand grain weight. Data after statistical analysis revealed that in wheat crop thousand grain weight were significantly ($p \leq 0.05$) affected by phosphorus levels and maximum weight of thousand grains was recorded from plots applied with 120 kg P_2O_5 ha^{-1}, while the minimum thousand grain weight was observed from the control plot. Rahmatullah et al. (1994) found 90 kg P_2O_5 ha^{-1} the optimum rate for the greatest growth, development thousand grain weight of wheat. Similarly, Brennan (1992) found a progressive improvement in thousand grains weight with the increase in phosphorus dose from 60 to 120 kg P_2O_5 ha^{-1}, gradually.

It was intensively observed that, the data after statistical analysis showed significant ($p \leq 0.05$) effect of different levels of phosphorus on grain yield. Mean values for different phosphorus levels revealed that maximum grain yield were produced by the plots that received 120 kg P_2O_5 ha^{-1}, while less grain yield were produced by the control plots. The plot treated 120 kg P_2O_5 ha^{-1} achieved maximum yield (4510 kg ha^{-1}) which was statistically significant only in the first season, while the minimum grain yield (3100 kg ha^{-1}) was achieved in control plots in the first season. The main reason for the increase in grain yield with various rates of phosphatic fertilizer could be the higher thousand grain weight which might be due to higher rate of photosynthesis and better crop health which ultimately enhanced the final grain yield (Iqbal et al., 2003; Mehdi et al., 2003). Alam et al. (2003) has observed that the application of phosphorus fertilizer (SSP) to wheat has significantly improved the plant height, number of tillers $plant^{-1}$, straw and grain yield as well as P-uptake in grain over control. Regardless of the second year crop, phosphorus fertilizers shown no significant effect on the grain yield and attributes. This results are in agreement with the findings of Mihoub and Deraoui (2014), who observed that phosphorus fertilizer application did not effect significantly the P content in grain yield. The relationship of high grain yield, due to P fertilizer application with number of seed/plant have been reported elsewhere (Singh et al., 2012).

The analysis results of Protein yield (g m^{-2}) and Starch yield, (g m^{-2}) of wheat are presented in (*Table 3*), results showed the effect of phosphorus levels, the statistical analysis of variance indicated that the mean Protein yield (g m^{-2}) and Starch yield, (g m^{-2}) were significantly different. Among various factors, plant nutrition circumstances - usage of fertilizers, soil supply conditions - suit best to modify, and to enhance certain parameters (Sarkadi, 1981). According to views of several investigation variations in quality properties depend on fertilizing application (Tabl and Kiss, 1983). The yield traits and quality properties of wheat are usually affected by genotypes, environmental factors and their interactions (Barutcular et al., 2016).

Correlation analysis

Correlation coefficients between all traits are illustrated in *Table 4* and grain yield of wheat crop show positive association with correlation coefficient values of grain number. Grain number was significant to high grain yield for both years. Under the low rainfall year (2014); Grain yield was positively and significantly influenced by 1000-grain weight. The SPAD value was positively and significantly associated with the grain yield in the 2nd year of 2015, which was a year with high rainfall. The extent of association of different traits also revealed the significant relationship with grain yield of the crop and this result was supported by Shah et al. (2003). In general, it is believed that grain quality improved with the increament of phosphorus rates, and phosphorus caused remarkable improvement in protein yield. The protein content was negatively associated with grain yield. The unit increase in grain yield was positively associated with the increased values of observed crop parameters by various yield attributes, grains spike^{-1}, seed index and harvest index (Noonari et al., 2016).

Water use efficiency

Increasing phosphorus levels were positively and significantly improved water use efficiency (WUE) under low rainfall conditions (*Figure 2*). The WUE values are regulated, and the relationship is stronger. However, as reported by Gerloff (1977), when the performance of cultivars to P supply and their yield potential at low P supply. There are various considerations of P use efficiency in previous investigations of wheat, which have resulted in various definitions, such as agronomic efficiency (Alam et al., 2003).While, the non-significant inffluence of P application on crop water use might be that 90 kg P ha^{-1} was too high to influence root growth for superior water extraction (Lusiba et al., 2018). However, there is a deficiency of information on the interactive influence of phosphorus fertilizer on water use efficiency of wheat under dry conditions.

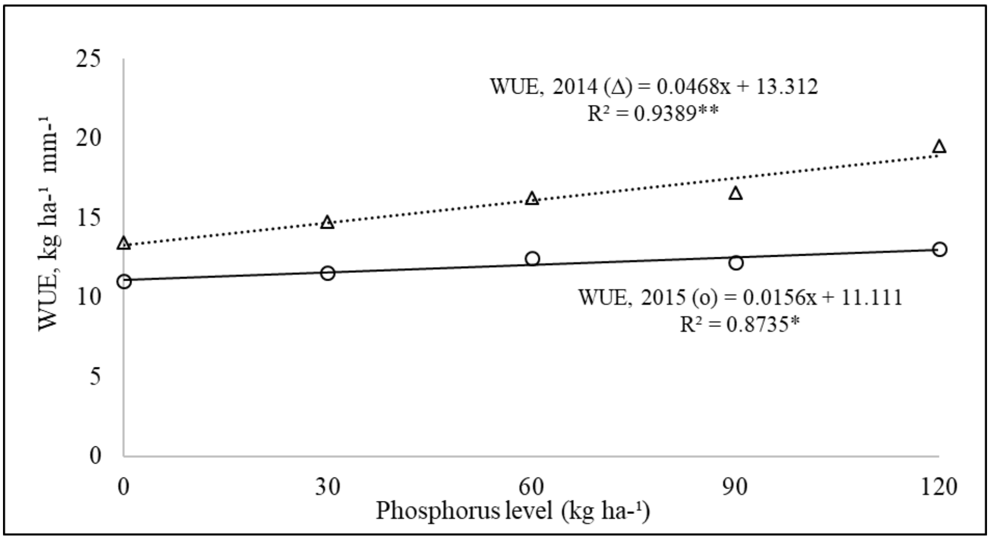

Figure 2. *Relationship between water use efficiency (WUE) and phosphorus level*

Conclusion

All these results indicate that phosphorus levels exhibited significant differences to the grain number per m^2, grain weight and grain yield ha^{-1}, as well as, for starch content and protein content in the first season. Evaluation of agronomical and quality traits in wheat showed that phosphurus application has significant effect on relationship between grain yield and quality. The grain yield increase was significantly associated with the improved values of noted plant traits like grain number and thousand grain weight. Accordingly, 120 kg P_2O_5 ha^{-1} was better rate of phosphorus for achieving reasonable productivity of wheat under investigation conditions.

Abstract. This study was designed to detect the anti-oxidant and anti-inflammatory effects of phenolic compounds in grape leaves Algerian variety (GLAV) on endothelial damage. The phenolics were identified by using HPLC/DAD/ESI-MS analysis. The research of the anti-oxidant and anti-inflammatory effects was conducted on mice through 15 days. Results showed high levels of phenols, anthocyanins, flavonols and *trans*-caftaric acid in GLAV. The plasma hs-CRP and homocysteine levels were elevated significantly ($p < 0.05$) however the glutathione reduced significantly ($p < 0.05$) after the administration of L-methionine in high doses to mice. This was associated with the desquamation of endothelium and muscular lysis with transformation of spindle nuclei to oval nuclei; this is due to the angiotoxic action of homocysteine on the aorta. These changes were not observed in mice treated with L-methionine plus the antioxidant and anti-inflammatory extract of GLAV. So, the study proved the antioxidant and anti-inflammatory effects of the GLAV on hyperhomocysteinemia induced inflammatory endothelial damage in cardiovascular diseases.
Keywords: *grape leaves, phenols, total Hyc, hs-CRP, GSH, endothelial damage*

Introduction

Hyperhomocysteinemia is defined as an abnormally high plasma homocysteine (Hcy) concentration after an oral Methionine load (Van Den Berg et al., 1995). It is a factor of risk for premature cardiovascular disease (Williams et al., 2002). Hence, it is one of the major pathogenic factors of atherosclerosis (Boldyrev et al., 2009). Besides its detection in all inflammatory diseases, hyperhomocysteinemia has been reported in other sicknesses like: type 2 diabetes, chronic kidney disease and cancer (Wu, 2008; Falvoa, 2007), and Alzheimer (Morris et al., 2001). It should be mentioned that hyperhomocysteinemia is not produced only by inflammation, but also by oxidative stress generated by high plasma homocysteine, which can cause a hyperhomocysteinemia induced inflammation (Jacobsen, 2000).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_19892003

The relationship between hyperhomocysteinemia and cardiovascular disease is highlighted by the deficiency of the cystathionine beta-synthase (CβS) enzyme, which is deficient during homocysteinuria (Flemming et al., 2010). In most cases, hyperhomocysteinemia is a result of deficiency of the vitamins B6, B12, folate, or a combination of them (Chiang et al., 2005). These vitamins are essential co-factors of the key enzymes of the Homoysteine's metabolism. Moreover, some drugs such as fibrates, antiepileptic, methotrexate, theophylline, metformin, and other substances like nicotinic acid can also cause hyperhomocysteinemia (Stalder et al., 2010). Homocysteine acts directly on endothelial and damaged vessel wall through generating an oxidative stress, and stimulating a pro-coagulant and pro-inflammatory state of blood components (Bernardo et al., 2004) is the most accepted hypothesis about Hcy's action in cardiovascular disease.

Several studies have demonstrated that correcting the plasma deficiency of folic acid and vitamin B12 decreases or makes hyperhomocysteinemia disappear (Rigaud, 1999). But in this study, the focus is on natural antioxidants, especially plants traditionally used in folk medicine and precisely GLAV (*Vitis vinifera* L leaves).

Vitis vinifera L. is a widespread crop in Algeria. In 2000, following the Algerian agriculture ministry, vineyards occupied an area close to 56,500 ha. *Vitis vinifera* leaves have been traditionally used as food or as medications all over the world. The leaves are used to treat hypertension, diarrhea, hemorrhage and varicose veins, inflammatory disorders, and reduce blood glucose levels in diabetics (Dani et al., 2010).

The aims of the study is identifying the phenolic compounds (Anthocyanins and non anthocyanins) by using HPLC-DAD/ESI-MS, and measuring the total Hyc, the plasma hs-CRP and the concentration of the GSH to estimate the antioxidant and anti-inflammatory effect of the GLAV on the inflammation induced by Hyperhomocysteinemia. By the end, the aorta histology had been examined in order to confirm the angiotoxic action of homocysteine and the effect of GLAV on the aorta.

Materials

Plant material

The plant material was collected from the leaves of fully matured grape (*Vitis vinifera* L.) in August, from Media Algeria. Leaves were rinsed in tap water and freeze-dried. Afterwards, they were crushed with a blender for 5 min and the resulting powder was collected and stored in the dark at 20 °C until needed.

Chemicals

All the used solvents and the formic acid of HPLC-grade (from Merck, Darmstadt, Germany). The water was purified by a milli-Qplus system from Millipore (Milford, MA, USA). All the employed Reagents were of analytical grade, purchased from Carlo Erba (Milan, Italy). The standards of HPLC-grade[malvidin-3-glucoside (n° 04288)], the 5,5′-dithiobis-(2 nitrobenzoic acid) DTNB and all the rest of chemicals were purchased from Sigma-Aldrich, Inc. 0.45 µm Polytetrafluoroethylene (PTFE) syringe membrane filters was purchased From Waters Co. - Milford, MA, USA.

Methods

Analysis of anthocyanins and non-anthocyanin phenolic compounds of GLAV by reverse phase liquid chromatography-diode array detection/electrospray mass spectrometry (RPLC-DAD/ESI-MS)

Sample preparation

Three grams of powdered leaves were extracted three times at 1:2 (weight/volume) (w/v) ratio with cold methanol: HCl (1000:1 (volume/volume) (v/v) by using an ultra turrax (Ultra Turrax-Tube Drive, BM-G-ball-mill tube, IKA, Germany) with 10/CS glass balls, for 3 min of each sample. After the extraction, centrifugation took place (1600 *g*, 15 min, 4 °C), the supernatant was collected and stored on ice. The pellet was re-subjected to subsequent extraction, and a final volume of 14.5 ml was collected. The methanol/HCl extract was first filtered through the 0.45 µm membrane PTFE, and then it was exposed to Speed Vac concentration (SC250P1-250, Thermo Fisher Scientific Inc, Waltham, MA, USA) at 20 °C until dryness. Next, the residue was brought to a final volume of 10 ml by adding formic-acidified (pH 3.2) MQ water and kept at -20 °C until analysis. Discarding the pellets, the extraction was performed in triplicate (Kammerer et al., 2004).

HPLC-DAD-ESI-MS characteristics and protocols

HPLC-DAD and HPLC-MS apparatus

The reverse phase liquid chromatography (RPLC) was performed according to Villiers et al. (2004) and Kammerer et al. (2004) with slight changes using a High Performance Liquid Chromatography system consisting of Hewlett-Packard series 1100 L equipped with a Diode Array Detector (DAD) operated by a HP 9000 workstation (Agilent Technologies, Palo Alto, CA, USA). The HPLC-MS system was equiped with HPLC-DAD instrument coupled to a quadripole mass spectrometer HP 1100 MSD electrospray interface (ESI) (Agilent Technologies, Palo Alto, CA, USA). The Separation had been occurred on a reverse-phase Waters Nova-Pak C_{18} column [150 mm × 3.9 mm, 4 µm] for anthocyanins analysis and a reverse-phase Waters Nova-Pak C_{18} column [300 mm × 3.9 mm, 4 µm] for non-anthocyanin phenols, and both had been kept at 26 °C with a pre-column of the same phase.

DAD and ESI-MS parameters

The non-anthocyanin phenols DAD was performed according to Dobes et al. (2013) with slight changes from 220 to 380 nm and ESI-MS parameters were: drying gas (N_2) at 350 °C with a 10 L/min flow, nebulizer pressure at 380 Pa (55 psi), and capillary voltage of 4000 V. The ESI scanned the mass from *m*/*z* 100 to 3000, employing a fragmentator voltage gradient of 100 V from 0 to 200 *m*/*z* and 200 V from 200 to 3000 min.

On the other hand, The anthocyanins DAD was performed from 260 to 600 nm, and ESI-MS parameters were: drying gas (N_2) at 350 °C with a 10 L/min flow, nebulizer pressure at 380 Pa (55 psi), and capillary voltage of 4000 V. The ESI scanned the mass from *m*/*z* 100 to 1500, employing a fragmentator voltage gradient of 100 V from 0 to 17 *m*/*z* and 120 V from 17 to 55 min.

DOI: http://dx.doi.org/10.15666/aeer/1702_19892003

Elution parameters

Whereas, the elution of non-anthocyanin phenols was performed at a 0.7 mL/min gradient flow of solvent 'A' and 'B'. The former was a combination of water/acetic acid (98:2, v/v), and the latter constituted of water/acetonitrile/acetic acid (78:20:2, v/v/v). A linear gradient started with 0% of 'B' and 100% of 'A', and then reached 80% of 'B' and 20% of 'A' after 55 min. After that, slight linear increase of 'B', from 80 to 90%, between 55 to 57 min, was observed, then it remained isocratic at 90% of 'B' and 10% of 'A'. Next, the process increased linearly from 90 to 95% of 'B' during 10 min. Finally, and still in a linear way, it reached 100% of 'B' at 90 min. The column was washed with Methanoland re-equilibrated from 90 to 120 min. The volume of the injected leaves extract was 15 μL.

Eluent of anthocyanins was performed at a 0.8 mL/min gradient flow of solvent 'A' and 'B'. The former was a combination of water/formic acid (90:10, v/v), and the latter constituted of water/methanol/formic acid (45:45:10, v/v/v). A linear gradient started with 15% of 'B' and 85% of 'A', then it reached 80% of 'B' and 20% of 'A' after 30 min.

After that, the process continued in an isocratic way, from 30 to 45 min, with 80% of 'B'. The column was then rinsed with methanol and re-equilibrated from 43 to 75 min. The injected volume of leaves extract was150 μL, and formic acid was employed as a pH modulating agent in order to optimise the anthocyanins detection by maximizing the absorption in the λ 520 nm region.

HPLC/DAD/ESI-MS identification of anthocyanins

The identification of malvidin 3-glucoside and cyanidin 3-glucoside was performed by comparing the results of commercial standards (Sigma-Aldrich) with the positive ion mass spectra achieved from the ESI-MS (retention time (t_R), UV λ_{max}, and MS^n) of the leaves extract, while other anthocyanins were identified by comparing the ESI-MS attained results against the ones available in the literature (*Table 1*). The flavonols were identified (glucose/galactose and glucuronide derivatives) under ESI-MS. This latter was achieved according to the molecular and fragment ions $[M\text{-H-}162]^-$ (quercetin-3-galactoside/glucoside) and $[M\text{-H-}176]^-$ (quercetin-3-glucuronide) (*Figs. 1* and *2*). In addition, the identity of all other constituents was validated by comparing the attained retention times (t_R), UV λ_{max}, and MS^n of peaks from the leaves extract with those reported in the literature (*Table 1*).

Compound quantitative analysis by HPLC/DAD

The quantification of anthocyanins in the leaves extract was obtained by measuring peak areas at 530 nm and taking into account the external standard calibration curve of malvidin-3-glucoside, which was measured at 524 nm. The concentrations were expressed as 'µg malvidin-3-glucoside equivalents/g of freeze-dried leaves'. The contribution of single anthocyanins was calculated and expressed in % of the total anthocyanins content.

The quantification of flavonols was performed according to the peaks attained at 340 nm and calculating the concentrations as 'µg quercetin or kaempherol equivalents/g of freeze-dried leaves' according to external standard calibration curve of quercetin and kaempherol. The contribution of single flavonols was calculated and expressed as % of the total flavonol content.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_19892003

Quantification of *trans*-caftaric acid was based on an external standard calibration curve carried out at 340 nm and expressed as 'µg *trans*-caftaric acid/g of freeze-dried leaves'.

The external standard calibration curves for malvidin-3-glucoside, quercetin, kaempherol and *trans*-caftaric acid, which were performed in duplicate by using five dilutions within linearity and an R^2 values, were 0.98, 0.97, 0.98 and 0.99 respectively.

Effect of GLAV on the inflammation induced by hyperhomocysteinemia

We are following the same protocol (the same conditions and diet) used by Benmbarek et al. (2013) but with a change in concentration of methionine and treatment period.

Animals and diets

Twenty eight Albino *Mus musculus* mice, 2 to 2.5 months old, weighed between 18 and 27 g, were used in this experiment. They were provided by the central pharmacy Constantine (Algeria). The mice were separated into four groups in four cages according to their body weight. The planned diet was given in the form of balls prepared with 0.5 mg of white flour and distilled water for 15 days. The first group (F) was fed with white flour (0.5 mg/kg/day), second group (M) was administered with with L-methionine (1 g/kg/day), third group (MP) was administerd with L-methionine and *Vitis vinifera* (1 g/kg + 500 mg/kg/day). The fourth group (P) was treated only with *Vitis vinifera* (500 mg/kg/day). Mice were housed at normal conditions of the animal house throughout the treatment period.

Blood biochemistry

At the end of experiment, mice were fasted overnight, and the blood samples were collected from the retro orbital vein into EDTA tubes by using glass capillaries. They were centrifuged immediately, and the plasma was stored at -30 °C. The values of plasma hs-CRP were measured by the immunoturbidimetric method on a Cobas integra 400 plus analyzer (Roche). Total homocysteine (t-Hcy) was estimated by competitive solid phase chemiluminescence immunoassay.

GSH glutathione assay (GSH)

We are following the same protocol mentioned by Houssem Eddine et al. (2014). After sacrificing the animals, the liver was dissected and washed with NaCl 0.9%. Then, the homogenate had been prepared with 0.5 g of the liver homogenized in 2 ml of TBS (Tris50 mM, NaCl 150 mM, pH 7.4). Next, it was centrifuged at 9000 g for 15 min at 4 °C. After that, the supernatant used for the determination of glutathione reduced (GSH), then it was measured spectrophotometrically by using 5,5′-dithiobis-(2 nitrobenzoic acid) (DTNB) as a coloring reagent, following the method of Rahman et al. (2006).

Histology

The animals were sacrificed and the aorta was removed for histological analysis. The tissues were then embedded in paraffin and cut in 5 µm thick sections and colored using heamatoxylineosin staining method.

Statistical analysis

Statistical analysis was carried out by one–way analysis of variance (ANOVA) followed by Tukey’s multiple comparison tests using statistics software package (SPSS for Windows, V. 20.0, Chicago, USA). P values < 0.05 were considered as statistically significant (common letter are not significantly different).

Results

Phenolic composition of extract GLAV (Vitis vinifera)

The HPLC/DAD/ESI-MS analysis was used to identify all compounds directly, or by comparing the results to literature, and the analysis of leaf ingredients were permitted the identification of cyanidin-3-glucosides, -3-(6-acetyl)glucosides, and -3-(6-p-coumaroyl)glucosides (*Table 1; Fig. 1*). Nonanthocyanin phenolic compounds identified in leaf ingredients included the flavonols quercetin-3-O-galactoside, quercetin-3-O-glucuronide, quercetin-3-O-glucoside, kaempherol-3-O-galactoside, kaempherol- 3-O-glucuronide, kaempherol-3-O-glucoside, and quercetin (*Table 1; Fig. 2*).

$^{x}t_R$Mean retention time of 3 runs

Among the extracted polyphenols from the Algerian *Vitis vinifera* L. leaves, the anthocyanins are the main chemical group, about 80.34 µg in each 1 g of freeze-dried

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_19892003

sample (*Table 2*). In this extract, 12 compounds were identified by HPLC-DAD as follows: the peonidins, as the main chemical group, with about half (46.50%) of the total anthocynins with 37.35 µg/g freeze-dried sample in each g of the predominant compound was peonidin 3-glucoside, the second abundant group was the cyanidins, with cyanidin-3-glucoside, of 78% per the total of cyanidins tailed by cyanidin-3-(6-acetyl)-glucoside (13%) and cyanidin-3-(6-*p*-coumaroyl)-glucoside (9%). The malvidins represented the third abundant group with 12.98 µg/g of sample and 2 compounds (malvidin 3-glucoside and malvidin 3-(6-*p*-coumaroyl) glucoside), the glucoside forms were the most abundant; the two remaining chemical classes, delphinidins and petunidins were contributed to total anthocyanins for 6.30% and 2.63%, respectively. Concerning the non-anthocyanins it is interesting to note the high concentrations of trans-caftaric acid and quercetin 3-*0*-glucuronide. Quercetins were the most abundant flavonols and were represented by quercetin (5.2%) and the glucuronide (76.5%), galactoside (8.3%) and glucoside (10%) forms. Kaempferols were presented 11.40% of flavons and the most abundant form was the galatoside (82.2%) one. For these compounds it is interesting to note the very high concentration of the glucuronide form and the notable concentration of quercetin.

Effect of Vitis vinifera extract on homocysteine induced inflammatory endothelial damage in cardio vascular diseases.

In this study, we have taken only 3 values from each group because some are outliers.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_19892003

As shown in *Figure 3,* the total Hcy levels in groups F (7.56 ± 0.21 µmol/l), M(12.20 ± 0.78 µmol/l), MP(9.06 ± 0.34 µmol/l) and P(7.24 ± 0.40 µmol/l) were showed a significant difference between groups in mice during 15 days of treatment $P \leq 0.05$. The Tukey test was showed that the homocysteine concentration in mice administered with L-methionine was increased highly significantly in group M when it was compared to the control group $P \leq 0.05$. However the homocysteine concentration was decreased significantly in the group of mice administered with L-methionine and treated with *Vitis vinifera L* when it was compared to the group (M) $P \leq 0.05$. Exceptionally, no significant changes were observed between the group treated only by *Vitis vinifera* leaves and the control group ($P > 0.05$).

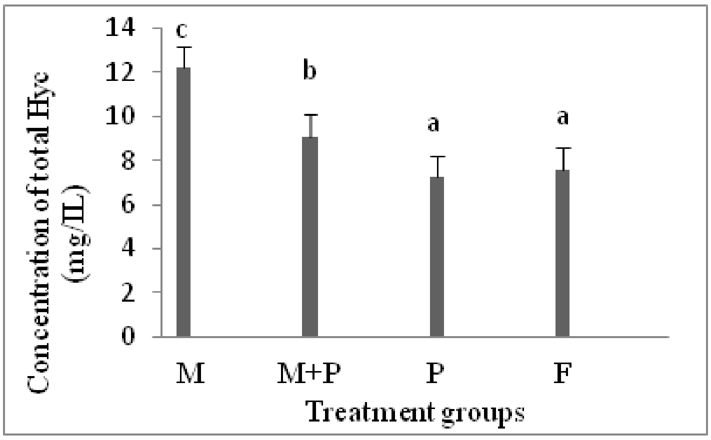

Figure 3. *Total Hcy level in the groups treated during 15 days. Values are the means ± SEM (n)*

The concentrations of hs-CRP in groups F (0.14 ± 0.017 mg/l), M (0, 28 ± 0,012 mg/l), MP (0.18 ± mg/l) and P (0.14 ± 0,012) were showed a significant difference between groups $P \leq 0.05$ (*Fig. 4*). The Tukey test was revealed that the hs-CRP concentration in the group (M) was increased highly significantly when it was compared to the groups (F) and (P) $P \leq 0.01$. However the concentration of hs-CRP was decreased significantly in the group (MP) when it is compared to the group (M).

Results demonstrated that the concentration of the glutathione reduced in groups F(29.28 ± 1.48 nmol/mg), M (19.38 ± 1.21 nmol/mg), MP(26.74 ± 1.06 nmol/mg) and group P(30.17 ± 1.37 were showed a significant difference between groups $P \leq 0.05$ (*Fig. 5*). The Tukey test showed that the concentration of the glutathione reduced in group M was decreased highly significantly when it is compared to the control group $P \leq 0.01$. However the concentration of GSH was increased in the groups treated with *Vitis vinifera L.*

Aorta histological

The results of the histological investigation showed a clear modification in the aorta. The group (M) which was fed with 1 g/kg of L-methionine appeared with oval nuclei of muscular fiber, desquamation of endothelial cells. However, in the control group (F), the aortic sections were showed an intact endothelium. The group (MP) which was fed with leaves extracts of the *Vitis vinifera* and 1 g/kg of L-methionine was showed only slight modifications including some oval nuclei of muscular cells (*Figs. 6*, *7* and *8*).

Discussion

In this study, the High-performance liquid chromatography (HPLC) was used for the separation and quantification of polyphenols in leaves of *Vitis vinifera. L* species, the Algerian variety. The results showed that high levels of phenols; anthocyanins, flavonols and trans-caftaric acid. The results is agrees with the work of (Monagas et al., 2006) who reported that HPLC-DAD/ESI-MS analysis of *V. Vinifera* spp. leaves ingredient allowed the identification of anthocyanidin-3-glucosides,-3-(6-acetyl)glucosides, and -3-(6-p-coumaroyl) glucosides and the flavonols quercetin-3-O-glucoronide, quercetin-3-O-glucuronide, quercetin-3-O-glucoside, kaempherol-3-O-galactoside, kaempherol-3-O-glucuronide, kaempherol-3-O-glucoside, and quercetin like non-anthocyanin content. The chromatograph pattern and the compounds identified agree with other paper on the same subject (Monagas et al., 2006). Trans-Caffeoyltartaric acid (trans-caftaric acid) was the only hydroxycinnamic acid derivative identified in the studied leaf ingredients and results obtained were in agreement also with (Monagas et al., 2006). According of the results obtained, GLAV contain much higher concentration of peonidins, Trans-Caffeoyltartaric acid (trans-caftaric acid) and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_19892003

Quercetins but the concentration of Kaempherols is found inferior than values mentioned by the results of Monagas et al. (2006). The differences observed between the results may be attributed to the period of the plant growth cycle, variety, cultivar conditions, weather and finally to the processing and preparation because leaves used by Monagas et al. (2006) were cultivated using the commercial dietary technology.

Homocystein (Hyc) is considered as a risk marker and can be used for screening patients of high menace for cardiovascular events (Refsum et al., 1998). In this study, the oral administration of high dose of L-methionine 1 g/kg/day during 15 days showed a significant increase in the level of plasma tHyc compared to the control group. These results are in agreement with those found by (Zerizer, 2006), who showed that the high oral methionine load is the direct cause of the elevation of the total homocysteine (tHcy), the sum of all homocysteine forms that exist in plasma or serum, therefore having hyperhomocysteinemia means the elevation of total homocysteine (Bernardo et al., 2004). Two hypotheses were formulated to explain the atherogenicity of hyperhomocysteinemia. The lipid hypothesis stipulates that the alteration of lipoprotein metabolism secondarily induces an involvement of the vascular wall, and the inflammatory hypothesis is dominated by the direct aggression of the cells and vascular connective tissue (Demuth et al., 2000).

The levels of hs-CRP and GSH have been exploited to monitor the effects of GLAV on the inflammatory and oxidative effect caused by hyperhomocystemia.

Currently and in several scientific researches, the CRP is used as a marker of cardiovascular risk (Folsom et al., 2002). The group (M) showed significant high level of hs-CRP compared with the control one. Benmbarek et al. (2013) confirmed that methionine at dose of 200 mg/kg/day administered to mice, during the 21 days period, increased significantly the levels of plasma hs-CRP. This result was considered as an initiative of the inflammatory process, which was confirmed by the histological investigation of the aorta. Results are in agreement with the previous experimental studies of Benmbarek et al. (2013) who found that Hyperhomocysteinemia as angiotoxic and toxic activity explained by the loss and degeneration of the endothelium, formation of foam cells in the different sections of the aorta, change in the smooth muscle cells nuclei forms from a fusiform aspect to a rounded appearance, and the alteration of the cardiac muscle and liver necrosis. In addition, Zerizer and Naimi (2004) reported the structural alterations in the aorta, heart and liver caused by the administration of high doses of methionine.

Substantially reduced (GSH) involved in maintaining the redox potential of the cell cytoplasm and in a number of detoxification reactions and scavenging reactive oxygen species (Haleng et al., 2007). Result demonstrated that the group (M) showed a significant decrease in the level of GSH compared to the control group (F). These results confirmed an oxidative stress generated by the reactive sulfhydryl group (-SH) in the homocysteine (Jacobsen, 2000), which is quickly oxidized, leading to the formation of Hcy, mixed disulfides and Homocysteinethiolactone. The oxidation of the -SH group generates superoxide anion O2-, hydrogen peroxide H_2O_2 and hydroxyl radicals OH- (Zitoun, 1998). Zeng et al. (2004) confirmed that the Hcy induced the production of MCP1 and IL-8. Additionally, a recent study suggested that Hcy induced the production of O2- in vascular smooth muscle cells (Wang et al., 2001). Yalçinkaya et al. (2009) demonstrated that a high methionine diet induced oxidative stress in serum, heart, and aorta in rabbits.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_19892003

The group (MP) treated by leaf of *Vitis vinifera* and L-methionine (500 mg/kg and 1 g/kg) noted a significant decrease in the levels of tHyc compared to group (M). The same group rectified significantly the level of hs CRP compared with the control group and group (M). At the same time, the group (MP) re-established significantly the level of GSH compared to the group (M).

These significant relationships between the parameters can be explained as the effect of the existed phenols in the GLAV. Exactly, the group (MP) treated by the GLAV was able to restore the level of the hs- CRP and GSH and maintain the correlation between the three parameters and could correct the damaged cells in aorta.

The results confirmed that GLAV (500 mg/kg/day) has an antioxidant and anti-inflammatory effects induced by Hyperhomocysteinemia in mice fed by a high dose of L-methionine 1 g/1 kg/day during 15 days. Benmbarek et al. (2013) asserted that S. mialhesi extract lowered the plasma hs-CRP and corrected the damaged cells.

In addition, the phenols, which are ubiquitous in almost all plant foods could decrease the risk of the occurrence of considerable number of diseases, particularly those related to aging and oxidative injury (cancer, cardiovascular diseases and neurodegenerative) (Hennebelle et al., 2014). While, low circulating levels of polyphenols (maximum, few µmol/L) compared to those of other endogenous antioxidants (GSH and acid uric) or exogenous (vit E as well as vit C) do not allow to envisage a direct antioxidant action of polyphenols in the body. This, however, with the exception of the gastrointestinal tract where the polyphenols present in large quantities can act as scavengers of free radicals. Today at the level of organism, polyphenols are perceived as molecules "Signal" (Mornad et Milenkovic, 2014), that could stimulate multi-target modes of action. Many in-vitro studies showed that flavonoids could affect their biological targets by modulating some enzymatic activities, gene expression or cell signaling, interacting with membrane or cell receptors, or via epigenetic regulations (Farga et al., 2010). The diversity of these potential mechanisms of action explains the broad spectrum of activities flavonoids observed *in-vivo*, including anti-inflammatory activities, antioxidant, anti-angiogenic, anti-proliferative or pseudo-estrogenic (Mornad and Milenkovic, 2014).

Conclusion

The grape leaves have a good antioxidant and anti-inflammatory activities. Where, it could be directly related to the high content of active compounds like peonidins, Trans-Caffeoyl tartaric acid (trans-caftaric acid) and Quercetins. More studies in this area are required further to find new ways and new efficient molecules from *Vitis vinifera* leaves to treat degenerative diseases and to slow the aging process induced by oxidative intermediate products and other pro-inflammatory components.

(Received 23rd Oct 2018; accepted 7th Jan 2019)

Abstract. Nowadays the environmental pollution caused by heavy metals is spreading all over the world, especially where the industry is developing rapidly, and soils are polluted very dramatically and hazardously at a high level. In this study, cocklebur-(*Xanthium strumarium* L.) plants were grown in nickel (Ni) contaminated soil (0, 50, 100, 200 and 400 mg Ni kg^{-1}) under greenhouse conditions for 6 weeks to study the ability of Ni uptake and accumulation of the plants. The Ni treated plants were compared with the control (0 mg Ni kg^{-1}) plant. As a result of that comparison, chlorophyll levels of old and young leaves, dry weights, reduced glutathione (GSH), macronutrient concentrations, such as nitrogen (N), phosphor (P), potassium (K), calcium (Ca) and magnesium (Mg)) and micronutrient concentrations, such as iron (Fe), zinc (Zn), and manganese (Mn) nutrient concentrations of the plants were decreased, whilst the concentrations of Ni and of copper (Cu) increased with increasing dose of Ni application. The results show that the studied plant (*Xanthium strumarium* L.) can be used for the cleaning up of Ni-contaminated soils and is suitable for phytoremediation.
Keywords: *chlorophyll, heavy metal, mineral element, phytoremediation, pollution*

Introduction

Soil pollution is one of the most important environmental problems nowadays. As stated in the previous studies, major soil pollutants, such as heavy metals, excessive use of fertilizers, pesticides, hormones, organic compounds, industrial wastes and accumulation of dangerous substances in the soil, etc. have become a rising problem as a consequence of human activities (Rahman et al., 2005; Daghan, 2007; Karaca and Turgay, 2012; Daghan and Ozturk, 2015).

Environmental pollution, especially caused by heavy metals such as Ni, lead (Pb), cadmium (Cd), mercury (Hg), chromium (Cr), arsenic (As), zinc (Zn), copper (Cu), has been a research topic and attracted attention of many countries in the world.

Nickel is one of the most commonly found elements in the earth's crust and is located in the 22^{nd} order among the other elements (Kaviani et al., 2017). This element is an essential element for plant growth and development in small doses (Marschner, 1995; Yang et al., 1996; Gheibi et al., 2009). Nickel is a functional component of some enzymes, especially urease (urea amidohydrolase, EC 3.5.1.5) enzyme in the plant. Urease is a metalloenzyme and plays an important role together with nitrogen being the enzyme that catalyzes the hydrolysis of ammonia and carbon dioxide (Dos Reis et al., 2017). Urea is accumulating in the plant tissue under Ni deficiency condition and it causes the toxic effect (Gheibi et al., 2009). Nickel has also function to catalyze enzymes for nitrogen fixation in legumes plants and increased tolerance to plant disease (Gerendás et al., 1999). However, at high concentrations Ni exhibits a toxic effect, negatively affects photosynthesis and membrane functions, and also prevents seed germination, plant growth and development (Parlak, 2016).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20052013

Many researchers have focused on the effects of heavy metals on human health and the environment, on the detection of contaminated areas, on cleaning methods and facilities to minimize the damage that these areas have on human health and the environment (Chaney, 1988; Ebbs et al., 1997; Gupta and Gupta, 1998; Karenlampi et al., 2000; Yankov et al., 2000; Lombi et al., 2002; Prasad and Freitas, 2003; Murakami and Ae, 2009; Daghan et al., 2012; Syam et al., 2016; Rehman et al., 2018). Remediation of polluted soil is usually done by excavating the contaminated area and renewing the soil that has been cleaned. However, in recent years, technologies applied directly *in-situ* without digging the earth has gained more attention (Kocaer and Baskaya, 2003).

Phytoextraction is the removal of soil contaminants by plant roots, accumulation in the organs above the soil, and subsequent harvesting of the plants, respectively. This method is especially used on plants to clean up active elements, such as Zn and Cu, or metals not in the nutrient group like Ni, lead (Pb) and cadmium (Cd) (Hamutoglu et al., 2012).

In the literature, many plants such as *Helianthus annuus* L. (Ahmad et al., 2011), *Nicotiana tabacum* L. (Daghan et al., 2012), *Oryza sativa* L., *Zea mays* L., (Murakami and Ae, 2009), *Sebertia acuminate* (Jaffré et al., 2013), *Glycine max* L. (Syam et al., 2016), *Salicornia iranica* (Kaviani et al., 2017) have been tested and used for the phytoremediation of heavy metals from the contaminated soil. Likewise, the success of phytoextraction depends on the detection of suitable plant species that can tolerate and accumulate heavy metals and to produce large biomass using conventional agricultural techniques (Syam et al., 2016).

A plant that is selected to be used in phytoremediation methods, should have a great amount of metal accumulation in its shoots and harvested parts, be able to tolerate heavy metal that has accumulated, also has to be deep-rooted and fast growing (Daghan et al., 2012).

The aim of this study is to investigate the potential use of *Xanthium strumarium* L., which can grow very easily in nature, has a high amount of roots and shoots, also can be grown in Ni contaminated soil, for heavy metals accumulation and phytoextraction method.

Materials and methods

In this study, *Xanthium strumarium* L., which belongs to the *Asteraceae* family and the Xanthium species was used as plant material. *Xanthium strumarium* L. is an annual plant which has the ability of self-pollinating. Additionally, it can grow even in the most adverse conditions up to 1 m and having advanced pile roots and can be found in almost all regions in Turkey (Cesur and Senkal, 2016).

The Pasakoy soil series of Amik Plain was used in experiments as a soil material (Kılıc et al., 2008). Some physical and chemical properties of the soil were given in *Table 1*.

The air-dried soil sample was sieved from a 4 mm sieve and then 2 kg of soil was filled into each pot. In order to obtain a homogeneous distribution in the soil, increasing doses of (0, 50, 100, 200 and 400 mg kg^{-1}) Ni were applied in the form of $NiSO_4.6H_2O$ prior to planting, and incubated for 3 weeks. Before planting, each pot was fertilizer with the solutions of 200 mg kg^{-1} nitrogen (N) in the form of NH_4SO_4, 100 mg kg^{-1} phosphorus (P) in the form of KH_2PO_4 and 125 mg kg^{-1} potassium (K) with 2.5 mg kg^{-1} iron (Fe) in the form of Fe-EDTA. During the experiment (6 weeks) the pots were

DOI: http://dx.doi.org/10.15666/aeer/1702_20052013

irrigated with pure water in soil field capacity of 60-80%. The experimental design used was completely randomized design with 3 replications in a factorial arrangement.

Before harvesting the leaf chlorophyll contents were measured in 3 replicates by a chlorophyll meter (Konica-Minolta SPAD-502). At the end of the experiment, the plants were harvested about 1 cm above the soil surface and washed with pure water, and then dried in an oven until they reached a constant weight at 65 °C. Afterward, dry weights of the plants were taken and grounded in a grinding mill (Retsch RM 200) for analysis. Test results were evaluated for the whole plant.

The concentrations of Ni, P, K, Ca, Mg, Fe, Zn, Cu and Mn were measured by the inductively coupled plasma atomic emission spectroscopy (ICP-AES Varian Liberty Series II) instrument by dissolving the grounded plant samples in a microwave (MarsXpress CEM) with nitric acid (HNO_3). Nitrogen (N) analysis of plant samples was carried out according to the Kjeldahl method (Bremmer and Mulvaney, 1982).

Nickel content (uptake) of *Xanthium strumarium* L. was calculated as follows (*Eq. 1*):

$$\text{Ni content } (\mu g \text{ plant}^{-1}) = [\text{DW } (g \text{ plant}^{-1}) \times \text{Ni concentration } (\mu g\ g^{-1})] \quad (\text{Eq.1})$$

Reduced glutathione (GSH) analysis was performed according to Cakmak and Marschner (1992). The experimental data were evaluated according to the factorial design pattern using the SPSS 22.0 statistical analysis program to determine the significance of levels and grouped by Duncan test according to Bek (1986).

Results and discussion

The results of Ni applications effects on the chlorophyll contents of leaves, dry weight, reduced glutathione (GSH) and Ni concentration of *Xanthium strumarium* L. plant were given in *Table 2*.

As can be seen on *Table 2,* the Ni applications cause a reduction in dry weights of *Xanthium strumarium* L. plant and likewise, chlorophyll contents were also decreased with those applications ($p \leq 0.01$).

*$p \leq 0.05$ statistically significant within error bounds

The chlorophyll content showed a decrease in the old and young leaves of *Xanthium strumarium* L. plant. The lowest chlorophyll contents were measured at 400 mg kg^{-1} Ni application dose of old and young leaves (respectively 22.4 and 32.4 SPAD unit). On the contrary, a decrease was observed with increasing Ni doses according to control groups. The dry weights of the plant were varied between 6.61-5.25 g plant^{-1}. Nickel applications were decreased plant dry weights compared to the control plant ($p \leq 0.01$). Similar results were reported by Parlak (2016). The researcher has investigated the effect of Ni treatment (0, 25 and 50 µM) on the growth and biochemical properties of wheat *(Triticum aestivum* L.). He found that the chlorophyll content of plants decreased with Ni applications. Rahman et al. (2005) were investigated the effect of increased doses of Ni (0, 1.0, 10 and 100 µM) on the growth and composition of barley plants. They reported that the barley plant was generally adversely affected Ni application and the lowest chlorophyll content was measured at 100 µM Ni treatment.

The increased application doses of Ni on the plant resulted with the lowest GSH concentration in the control group as 266 µg mL^{-1} and the highest as 336 µg mL^{-1} at 200 mg Ni kg^{-1} dose in the plant (*Table 2*). The GSH concentrations were decreased with Ni applications (*Table 2*). The lowest GSH concentration (266 µg mL^{-1}) was obtained at the control group while the highest GSH concentration (336 µg mL^{-1}) was obtained at 200 mg Ni kg^{-1} application. Daghan et al. (2012) reported an enhancement of glutathione concentrations in transgenic and non-transgenic tobacco plants, which different Ni doses were applied to the soil.

The Ni concentration of the *Xanthium strumarium* L. plant increased (5.03-101 mg kg^{-1}) with increasing Ni doses (*Table 2*). According to Alloway (1995), the critical concentration of Ni was obtained in tissues of the plant in the range of 10-100 mg kg^{-1}. As Kaviani (2017) stated in a previous research by using *Salicornia iranica* plant, augmented Ni (0, 50, 250, and 500 mg Ni kg^{-1}) doses in the soil resulted in increased Ni concentration in the plants.

The Ni contents were increased with Ni application ($p \leq 0.01$) and the highest Ni content (530 µg plant^{-1}) was obtained at 400 mg Ni kg^{-1} application (*Fig. 1*). Khan and Khan (2010) studying the effects of increased Ni application (0, 10, 50, 100, 200 and 400 mg kg^{-1}) on growth and yield of chickpea plant. They found that the Ni content of the root, stem, and leaf of plants was increased with Ni applications.

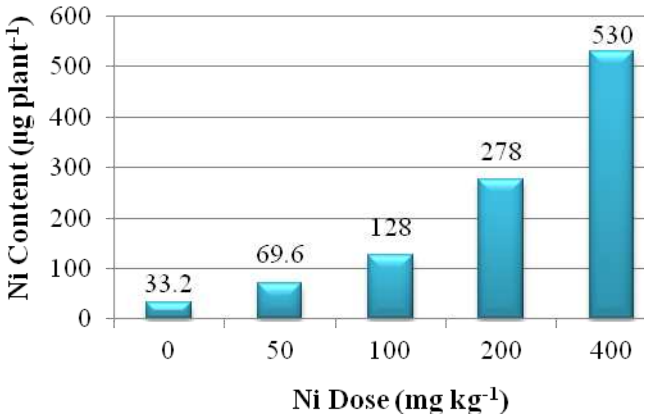

***Figure 1.** The effect of increasing Ni application on plant Ni content (n = 3)*

The effects of increasing doses of Ni on N, K, Ca and Mg concentrations of the plant were found statistically significant ($p \leq 0.01$). Compared to the control application the macro (N, P, K, Ca and Mg) element concentrations of plants were reduced with Ni applications (*Table 3*).

Ahmad et al. (2011), investigated the phytotoxic effect of macro and micronutrients on the yield and macro and microelement concentration of *Helianthus annuus* L. plants with Ni applications (0, 10, 20, 30 and 40 mg L^{-1}). They observed a decrease in concentrations of N, P, K, Ca, Fe, Zn, Cu and Mn elements by the increase of Ni doses, on the other hand Ahmad et al. (2009), reported that increased Ni (10, 20, 30, 40, 50 and 60 mg L^{-1}) applications have been associated with the effect of 5 different sunflowers (*Helianthus annuus* L.) seeds, indicating a decrease in Mg and K contents due to increased Ni dose.

It was observed that the effects of Ni applications on microelement concentrations of *Xanthium strumarium* L. plant were statistically significant ($p \leq 0.01$) (*Table 4*).

When the rise in Ni doses was compared with the control group on the microelements (Fe, Zn, and Mn) of the plants, it was found that the concentration of these elements was decreased, while the Cu element concentration was increased (*Table 4*). Previous studies have shown that high amount of Ni applications can reduce the

DOI: http://dx.doi.org/10.15666/aeer/1702_20052013

amount of Fe (Chen et al., 2009; Pandey and Sharme, 2002). Rahman et al. (2005) reported that microelements (Fe, Zn and Mn) reduced in other applications except for 1.0 μM Ni, whilst investigating the effect of Ni doses (0, 1.0, 10 and 100 μM) on the growth and composition of barley plants.

Conclusion

Increasing doses of Ni used in this study induced a decrease in chlorophyll content and dry weight of plants. The main causes of this decrease are thought to be the accumulation of the Ni element in plant tissues at toxic levels and the negative effects of metabolisms that allow the plant to grow and develop.

The effect of Ni applications on GSH concentration according to the control group was varied between 225-336 μg mL^{-1}, which was exhibited the highest at 200 mg Ni kg^{-1} application, while the lowest Ni content was at 33.2 μg plant^{-1} and the highest 530 μg plant^{-1} with 400 mg Ni kg^{-1}.

The content of Ni has increased with varying dose applications, and no chlorosis or necrosis has been observed in the plant. *Xanthium strumarium* L. plant is found to be an important step for investigating the biochemical and physiological responses of plants against Ni toxicity and suitable for increasing the phytoremediation efficiency.

In addition, *Xanthium strumarium* is a native and aggressive weed in many countries. Although the species can be used in phytoremediation, it absolutely should be grown on controlled conditions.

Abstract. Natural compounds produced in plant metabolism can offer an alternative method to the chemical control of weeds. The aim of this study was to evaluate the effects of *Salvia sclarea* L. and *Clinopodium menthifolium* Host on the bromus (*Bromush mollish* L.) antioxidant properties to explore the potential of these aromatic plants in weed control. The impact of bioherbicides on the growth of beneficial microorganism present in the soil is less known. Consequently, the second aim was to evaluate the effects of *S. sclarea* and *C. menthifolium* on the growth of beneficial microorganism so as to assess theirs possible side effects when applied as bioherbicides. Two different concentrations (0.1% and 0.2%) of the aqueous extract of *S. sclarea* and *C. menthifolium* were assayed. Both tested extracts caused a change in peroxidase (POD) activity in leaves and roots of the bromus plants. Furthermore, both extracts induced lipid peroxidation in bromus leaves. In addition, tested extracts showed positive effects on the growth of some beneficial bacteria. The results indicate that *S. sclarea* and *C. menthifolium* aqueous extracts have negative effects on the antioxidant system in bromus plants with no inhibitory effects on the growth of the beneficial mycorrhizal bacteria and fungi.
Keywords: *allelochemicals, beneficial bacteria, bioherbicides, Bromush mollish L., enzyme activity*

Introduction

Throughout the years, the separation, characterization and production of natural products have been used as pesticides against insects, weeds, plant pathogens, and nematodes in the field. In the context of green chemistry (Abd El-Gawad, 2016), there is an urgent need for development of natural products called biopesticides as an alternative for maintaining high production with low ecological impact (Hermosa et al., 2012). Weeds have been documented as serious plant pests which constantly compete with crops for light and nutrients which cause considerable losses in their productivity (Jabran et al., 2015). Therefore, nitrogen (N), phosphorus (P), and potassium (K) uptake is reduced (Gonzalez Ponce et al., 1996). One of the highly resistant weed species in our crops is bromus.

With the constant implementation of synthetic herbicides in crop protection systems weeds have developed resistance. Herbicide resistance demands a new solution to cope with economic losses generated by weeds (Abd El-Gawad, 2016). Allelopathy is an ecological phenomenon where plants produce a great variety of secondary metabolites, called allelochemicals (Abd El-Gawad, 2016; Céspedes et al., 2014). These compounds belong to numerous chemical groups including: phenolic acids, flavonoids, triketones, terpenes, benzoquinones, coumarins, terpenoids, tannins lignin, fatty acids and non-protein amino acids (Soltys et al., 2013). They are important in mediating interactions

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20152031

between plants and their biotic environment (Céspedes et al., 2014). Allelochemicals either have an inhibitory or stimulatory effect on plants, and they are considered to be a natural defense mechanism of plants (Abd El-Gawad, 2016).

Allelochemicals may be synthesised in all plant organs like leaves, stems, flowers, fruits, seeds and roots (Farooq et al., 2011). One of the main invisible effects of allelochemicals on the target plant is uncontrolled production of reactive oxygen species (ROS) (Bogatek et al., 2006). Under stress conditions, the generation of ROS is greatly increased (Soares et al., 2016). ROS are highly reactive and in the absence of any protective mechanism, they can seriously damage vital biomolecules such as lipids, proteins and nucleic acids (Meloni and Martinez, 2009). To mitigate the oxidative damage induced by ROS, plants have developed antioxidant defense systems, enzymatic and non-enzymatic (Azevedo Neto et al., 2006). During oxidative stress, plants produce hydrogen peroxide which is considered harmful to plant cells (Šimonovičová et al., 2004). Peroxidases are one of the major H_2O_2-scavenging enzymes. The cellular level of H_2O_2 could be toxic enough to inhibit the enzymes' activity, leaving the plant vulnerable to oxidative damage (Mandal et al., 2013). Allelopathic interactions between plants may become an alternative to pesticides for weed control (Khalid et al., 2002).

Salvia sclarea, commonly called clary sage, and *Clinopodium menthifolium* belong to Lamiaceae. *S. sclarea* is an important medicinal herb (Kumar and Sharma, 2012). The major phytochemicals of the sage plant are phenols and terpenoids. Different bioassays of plant extracts have shown biological activities such as antimicrobial, antioxidant, cytotoxic, antiprotozoal, antidiabetic (Mahmood et al., 2012). The aqueous extract of aromatic plants, which is rich in phenols, is easily used for foliar application due to their rich water solubility and their ability to create a uniform spray mixture.

The major objective of this study was to evaluate the allelopathic effects of the aqueous extract of two aromatic plants, *Salvia sclarea* L. and *Clinopodium menthifolium* Host, on bromus (*Bromush mollish* L.) antioxidant properties to explore the potential of this species in weed control. The effect of the two concentrations (0.1 and 0.2%) of *S. sclarea* and *C. menthifolium* aqueous extracts on the lipid peroxidation process (LP), as well as the activity of peroxidase (POD) antioxidant enzymes (pyrogallol and guaiacol peroxidases) in leaves and roots of bromus seedlings were examined 24, 72 and 120 h after the treatment. Due to strong antimicrobial activity of aromatic plants, the impact of tested aqueous extracts on the growth of beneficial microorganism present in the soil was additionally investigated.

Materials and methods

Plant materials and preparation of the aqueous extracts

Salvia sclarea L. was collected in the south of Serbia, around Vranje town (longitude: 21°53'09.23" E, latitude: 42°22'40.44" N, altitude: 494 m), in July of 2012. *Clinopodium menthifolium* (Host) was collected at localities near the Adriatic coast in Montenegro, around Sutomore town and Čanj town (longitude: 19°00'30.10" E, latitude: 42°09'52.19" N, altitude: 31 m), in May of 2012. Voucher specimens *Salvia sclarea* L. Nº 2-1545 and *Clinopodium menthifolium* (Host) Nº 2-1543 were confirmed and deposited at the Herbarium of The Department of Biology and Ecology, Faculty of Science, University of Novi Sad (Holmgren and Holmgren, 2003).

The plants were dried at 30 ºC for two weeks, and the dried plants were then ground into powder. The powdery material (10 g) was spilled with 100 mL of boiling distilled

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20152031

water (10%, w/v) and left for 24 h. After 24 h, the extracts were filtered through Whatman No. 4 filter paper and kept at 4°C in the fridge until application.

Seedling growth

The experiment was performed at the Laboratory of Biochemistry, Faculty of Agriculture, Novi Sad and conducted under controlled conditions (28 °C, 60% relative humidity, a photoperiod of 18 h, and a light intensity of 10.000 lx). The bromus (*Bromus mollish* L.) seeds were surface-sterilized with 3% H_2O_2 (v/v), washed with deionised water, placed in plastic pots containing sterile sand and maintained under dark conditions. Thirty-day-old seedlings were transplanted in plastic pots containing 700 mL of Hoagland's solution prepared according to Hoagland and Arnon (1950), and 7 or 14 mL of 10% *S. sclarea* and *C. menthifolium* aqueous extract, separately, while pots of control contained the same volume of nutrient solution. When 7 mL of the plant extract was added to the solution, the final concentration of the extract was 0.1%. When 14 mL of the plant extract was added to the solution, the final concentration of the extract was 0.2%. The bromus plants were harvested for determining the investigated biochemical parameters 24, 72 and 120 h after the treatments with the plant aqueous extracts.

Analysis of the POD antioxidant enzymes and MDA content

For the determination of the peroxidase (POD) activity and malondialdehyde (MDA) content, 2 g of fresh plant material (bromus leaves and roots from each growth condition: control, 0.1 and 0.2% plant aqueous extracts) was homogenized in 10 mL of phosphate buffer (0.1 M, pH 7.0) prepared in-house. After centrifugation, supernatants (bromus extracts) were used for protein quantification and POD activity assays. Biochemical analyses were carried out spectrophotometrically using an UV/VIS spectrophotometer (Thermo Scientific Evolution 220 (USA)). A measurement of protein levels in the supernatants was performed according to the method of Bradford (Sedmark and Grossberg, 1977; Spector, 1978). The activity of the POD (EC 1.11.1.7) was measured using guaiacol and pyrogallol as substrates according to Morkunas and Gmerek (2007). The absorbance was recorded at 436 nm. The activity of the POD was expressed in U/mg of proteins. The MDA content, an end product of lipid peroxidation process, was measured at 532 nm using the thiobarbituric acid (TBA) test (Mandal et al., 2008). The total amount of TBA-reactive substances was given in nmol of MDA equivalents/mg of proteins.

Bacteria culture

The test microorganism used in this study were as follows: Azotobacter–isolates 1 and 2; Pseudomonas–isolates 1, 2, and Marker; Bacillus–Bacillus subtilis marker 44, Bacillus subtilis and Bacillus megaterium; Rhizobium–isolate D_1, Bradyrhizobium japonicum isolate S511, Rhizobium trifolii 1; fungi–Penicillium sp., Alternarium sp. and Trichoderma asperellum. The collection of microbial soil isolates is from the Laboratory of Microbiology, Faculty of Agriculture, University of Novi Sad, Serbia).

Microorganism cultivation

Azotobacter isolates were grown on mannitol selective nutrient medium (mannitol 20.0 g, $K_2 HPO_4$ 0.3 g, $CaHPO_4$ 0.2 g, $MgSO_4$ 0.3 g, NaCl 0.5 g, $FeCl_3$ 0.1 g, $CaCO_3$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20152031

2.5 g, microelements solution 1.0 mL, distilled H_2O 1000.0 mL, pH 8.2) for 48 h on 150 rpm at 28 °C in shaker incubator (Aquilanti et al., 2004). After OD determination on 600 nm all inocula were adjusted at 10^8 cell mL^{-1}. *Pseudomonas* isolates were grown on King – B nutritet medium (pepton 10.0 g, trypton 10.0 g, K_2HPO_4 1.5 g, $MgSO_4$ 1.5 g, glycerol 10.0 mL, distilled H_2O 1000.0 mL, pH 7.2) for 48 h on 150 rpm at 28 °C in shaker incubator (Valls et al., 1999). After OD determination on 600 nm all inocula were adjusted at 10^8 cell mL^{-1}. *Bacillus subtils* and *Bacillus megaterium* strains were grown on the L – agar, selective liqud nutrient medium (distilled H_2O 1000 mL, tripton 10.0 g, yeast extract 5.0 g, NaCl 5.0 g,) for 48 h on 150 rpm at 28 °C in shaker incubator (Valls et al., 1999). After OD determination on 600 nm all inocula were adjusted at 10^8 cell mL^{-1}. *Bradyrhizobium japonicum* isolate S511 and *Rhizobium* isolates were grown on YMB selective liqude medium (mannitol 10.0 g, yeast extract 0.5 g, K_2HPO_4 0.5 g, KH_2PO_4 0.5 g, $MgSO_4$ 0.2 g, NaCl 0.1 g distilled H_2O 1000.0 mL, pH 7.2), *B japonicum* for 5 days and *Rhizobium* sp. for 3 days on 150 rpm at 28 °C in shaker incubator. After OD determination on 600 nm all inocula were adjusted at 10^8 cell mL^{-1}.

Pure cultures of fungi - *Trichoderma asperellum*, *Penicillium* sp., and *Alternarium* sp. were isolated from serial dilutions and grown on potato dextrose agar (PDA, Difco®) at 25 ± 1 °C for at least 7 days. Single colonies were purified by re-isolation on PDA and a single hyphal tip was isolated and grown on PDA. The sporulated colony arising from this hyphal tip was used to make inocula with 10^6 spore mL^{-1} for each fungi.

Disc diffusion method

The evaluation of the *S. sclarea* and *C. menthifolium* aqueous extracts on the growth of microorganism was carried out by the disc diffusion method described by Prabuseenivasan et al. (2006). Sterilized Petri dishes with agar were inoculated with microorganism cultures. The paper discs impregnated with plant aqueous extracts were placed on the agar surface. The plates were incubated at 28°C. After incubation (72 h and 120 h), the plates were examined for the stimulation/inhibition zone (*Fig. 1*). The test was repeated three times to ensure reliability.

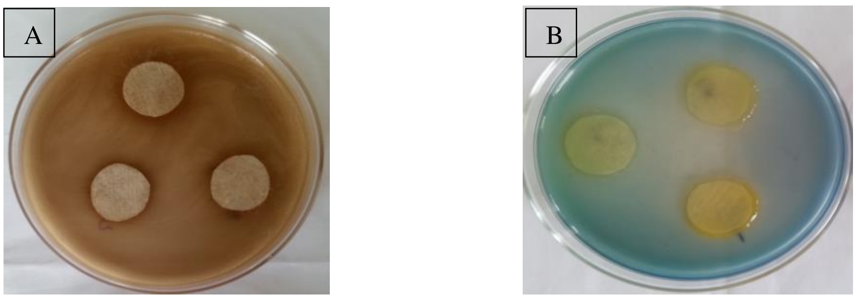

Figure 1. *The bacterial strain growth stimulator zone Azotobacter isolate 1 (A) and Bradyrhizobium japonicum isolate S511 (B) under the influence of the S. sclarea aqueous extract*

Statistical analysis

All measurements were performed in triplicates. Values of the biochemical parameters were expressed as mean ± standard error of mean and tested by ANOVA followed by comparison of the means by Duncan's multiple range test ($P < 0.05$). Data were analyzed

using STATISTICA for Windows version 11.0. Comparable percentage was done by *Equation 1*.

$$\Delta(\%) = (100 \text{ x sample / control}) - 100 \quad \text{(Eq.1)}$$

Results

POD activity and MDA content in bromus leaves and roots

In leaves of the bromus plants, a significant decrease in activity of POD was detected 72 h after the treatment with 0.1% *S. sclarea* aqueous extract (*Fig 2*). The activity of pyrogallol peroxidase showed a 30% decrease, while the activity of guaiacol peroxidase showed a 36% decrease (*Table 1*). In the treatment with a higher concentration of the *S. sclarea* aqueous extract (0.2%), there were no significant differences in the activity of POD in the leaves of treated bromus plants compared to plants from the control group. On the other hand, in the roots of bromus, a lower tested concentration of *S. sclarea* aqueous extract (0.1%) significantly increased the activity of POD 120 h after the treatment. The activity of pyrogallol and guaiacol peroxidases was increased by 117% and 248%, respectively. In the treatment with a higher concentration (0.2%) a significant increase in the activity of pyrogallol peroxidase was detected 72 h after the treatment (98%).

In the treatment with 0.1% *C. menthifolium* aqueous extract, there were no significant differences in the activity of pyrogallol peroxidase in the leaves of bromus between the plants from the control group and the treatments (*Table 2*). In the treatment with a higher concentration of the *C. menthifolium* aqueous extract (0.2%), a significant increase in the activity of pyrogallol peroxidase was detected 120 h after the treatment (26%). A significant increase in the activity of guaiacol peroxidase was detected in the leaves of bromus 72 h after the treatment. The activity of guaiacol peroxidase showed an increase of 88% in the treatment with 0.1% *C. menthifolium* aqueous extract and an increase of 85% in the treatment with 0.2% *C. menthifolium* aqueous extract. In the roots of bromus plants, both tested concentrations of *C. menthifolium* aqueous extract decreased the activity of pyrogallol and guaiacol peroxidases. In the treatment with a higher concentration (0.2%), a significant decrease in the activity of guaiacol peroxidase was detected (71% 24 h after the treatment, 75% 72 h after the treatment, and 55% 120 h after the treatment). In the treatment with 0.1% *C. menthifolium* aqueous extract, a significant decrease in the activity of guaiacol peroxidase was detected as well (52% 24 h after the treatment, 67% 72 h after the treatment, and 51% 120 h after the treatment). The activity of pyrogallol peroxidase showed a decrease of 48% in the treatment with 0.1% and a decrease of 68.5% in the treatment with 0.2% *C. menthifolium* aqueous extract 120 h after the treatment.

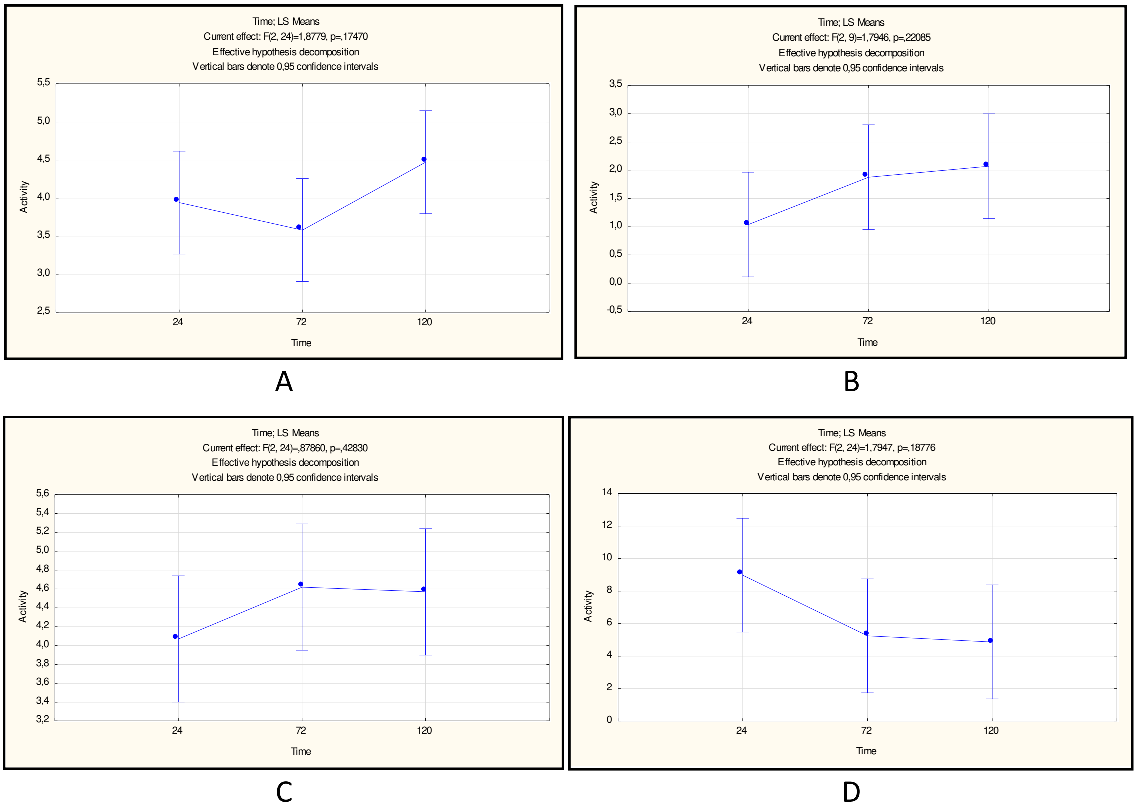

Figure 2. *The relationship between the period of time and the activities of the antioxidant enzymes in leaves of the bromus treated with S. sclarea aqueous extract (A), roots of the bromus treated with S. sclarea aqueous extract (B), leaves of the bromus treated with C. menthifolium aqueous extract (C), roots of the bromus treated with C. menthifolium aqueous extract (D)*

The accumulation of malondialdehyde (MDA), an end product of the lipid peroxidation process, was significantly higher in leaves of bromus plants 120 h after the treatment with *S. sclarea* extract and 72 h after the treatment with *C. menthifolium* extract (*Fig. 3*). In the treatment with 0.2% *S. sclarea* aqueous extract, the accumulation of MDA was 29% (*Table 1*). In the treatment with 0.1% and 0.2% *C. menthifolium* aqueous extract the accumulation of MDA was 46% and 48%, respectively (*Table 2*). Furthermore, the accumulation of MDA was higher in leaves of bromus plants after the treatment with *C. menthifolium* aqueous extract compared to *S. sclarea* aqueous extract. This observation could indicate that *C. menthifolium* possesses a higher phytotoxic effect than *S. sclarea*. On the other hand, in the roots of bromus plants, there was no significant increase in the lipid peroxidation intensity.

Disc diffusion method

In the treatment with both concentrations (0.1% and 0.2%) of *S. sclarea* and *C. menthofolium* aqueous extracts, separately, there were no stimulatory or inhibitory effects on the growth of the bacteria *Pseudomonas* – isolates 1, 2, and Marker; *Bacillus* – *Bacillus subtilis* and *Bacillus megaterium*; *Rhizobium trifolii 1*; and fungi – *Penicillium* sp., *Alternarium* sp. and *Trichoderma asperellum.*

Discussion

The activity of antioxidant enzymes is frequently used as an indicator of oxidative stress in plants caused by pro-oxidants (Li et al., 2013). For various plant species under oxidative stress, oxidative damage of cell membranes is observed. In this research, the phytotoxic effect of extracts was different between two examined plant tissues. Even though plant aqueous extracts affected the activity of the antioxidant enzymes in leaves and roots of the bromus seedlings, a significantly higher accumulation of MDA was detected only in leaves of bromus plants. The accumulation of MDA indicates that allelochemicals presented in plant extracts caused oxidative damage of membranes. No differences in MDA content in roots of bromus plants treated with extracts compared to untreated roots confirmed that leaves of bromus were more affected than roots. This is in accordance with the results reported in a study by Mahdavikia and Saharkhiz (2016) who reported that peppermint allelochemicals caused oxidative stress in the aerial parts of tomato seedlings. On the other hand, Chon et al. (2002) reported that even though phenolic compounds are involved in the inhibition of shoot growth, root length is a better indicator of phytotoxic effects of allelochemicals than shoot length. It is very important to know the mode of action of toxic compounds of plants. Non-protein amino acids produced by plants, such as *meta*-tyrosine (*m*-Tyr), modify the activity of non-enzymatic antioxidants while cell membranes are not primary cellular targets (Andrzejczak et al., 2018). Contrarily, plant phenolic compounds, such as p-cymene and cinnamic acid increase lipid peroxidation in tested plants and stimulate total SOD activity (Zhang et al., 2012; Ding et al., 2007).

In this study, changes in enzymatic activity were the highest 72 h after the treatment. This was accompanied by the accumulation of MDA in bromus leaves. This observation could indicate that plant extracts exhibit a toxic effect in the first 72 h. In the treatment with *C. menthifolium* aqueous extract both tested concentrations decreased the activity of antioxidant enzymes in roots of bromus plants. In spite of the increased activity of the enzymes, there were no significant changes in the lipid peroxidation intensity in roots of bromus between the plants from the control group and the treatments at the end of the experiment (120 h after the treatment). This could indicate that the allelopathy-provoked stress was not strong enough and scavenging effects of antioxidant enzymes could still prevent an oxidative burst and the induction of lipid peroxidation. In the leaves and roots of black nightshade, due to the exposure to *C. menthifolium* aqueous extract, an increase in the lipid peroxidation process was

DOI: http://dx.doi.org/10.15666/aeer/1702_20152031

observed (Šućur et al., 2017), which points to the different responses of species when facing allelochemicals. Chemical compounds produced by plants could be allelopathic agents with an inhibitory effect on plant growth. Phenolic compounds are identified as the most common allelochemicals produced by plants. Some phenolic compounds can either promote or inhibit plant growth according to their concentration (Li et al., 2010). Nandakumar and Rangaswamy (1985) reported that some flavonoids had promotive effects on plant growth while in contrast to the flavonoids some phenolic acids suppressed plant growth and inhibited seed germinations. The allelopathic effects of plant extracts were investigated in a number of studies. For example, Islam et al. (2013) found that aqueous methanol extracts of *Leucas aspera* L. and *Hyptis suaveolens* L. possess strong allelopathic potential against barnyard grass. Franco et al. (2016) observed that *Copaifera langsdorffii* leaf extract had an inhibitory action on seed germination and root growth in sorghum. Furthermore, *Thymus kotschyanus* (Lamiaceae) exhibited dose-dependent allelopathic effects on *Bromus tomentellus* seed germination and seedling growth (Safari et al., 2010). *Salvia officinalis* (Lamiaceae) aqueous extract showed a strong inhibitory effect on *Amaranthus retroflexus* seed germination (Bajalan et al., 2013).

It is very important that herbicides or bioherbicides used for weed control have no inhibitory effect on the growth of beneficial mycorrhizal bacteria and fungi. *Bacillus*, *Pseudomonas*, *Azotobacter* and *Rhizobium* species are well known as plant growth-promoting rhizobacteria (PGPR). They play an important role in increasing soil fertility, promoting plant growth, and suppressing phytopathogens for the development of ecofriendly sustainable agriculture (Gupta et al., 2015). Plant growth-promoting fungi (PGPFs), such as species of the genera *Trichoderma* and *Penicillium*, also have the ability to stimulate the plant immune response upon enemy attack and growth promotion in crop plants (Jogaiah et al., 2013). It is a useful finding that the tested plant extracts showed a stimulatory effect on the growth of some beneficial bacteria.

Conclusions

Based on our current results, it can be concluded that *S. sclarea* and *C. menthifolium* aqueous extracts possess a negative effect against bromus, inducing oxidative stress accompanied by the induction of the lipid peroxidation process. *C. menthifolium* possesses a higher phytotoxic effect than *S. sclarea* whereas the accumulation of MDA was higher in leaves of bromus plants after the treatment with *C. menthifolium* aqueous extract compared to *S. sclarea* aqueous extract. In addition, negative effects are dependent on the plant tissues and the sensitivity of the plant is dependent on the concentration of applied extracts. Since the present investigation suggests that *S. sclarea* and *C. menthifolium* aqueous extracts possess a negative effect against the antioxidant system in weeds, and a stimulatory effect on the growth of some beneficial bacteria, it would be good to explore the aromatic plants in the development of natural pesticides.

Abstract. The effectiveness of the predatory mite, *Phytoseiulus persimilis* Athias-Henriot (Acari: Phytoseiidae), as a suppressive agent of the two-spotted spider mite, *Tetranychus urticae* Koch (Acari: Tetranychidae), was evaluated on greenhouse cucumber at predator:prey release ratios of 1:5, 1:15, and 1:30. Releases at each predator:prey ratio were made at 30 *T. urticae* densities per leaf. Evaluation was initiated 4 days after the release. On the under side of the leaves which were selected randomly from the lower, middle, and upper parts of the plants, the eggs and active forms of *T. urticae* and *P. persimilis* were counted using 10X hand magnifier for each treatment. In control treatments without predatory mite and acaricide application, population of *T. urticae* was constantly increased and reached 140 active forms/leaf in August. Subsequently the population decreased when the plants died. At ratios of 1:5, *P. persimilis* reached 8 active forms/leaf while *T. urticae* populations reached 11 active forms/leaf. At ratios of 1:15 *P. persimilis* population increased (3.4 active form per leaf) and *T. urticae* population decreased (1.6 active forms per leaf) in September and the latter one was kept by *P. persimilis* at low levels thereafter. Plant damage also was significantly reduced at these densities. *P. persimilis* population decreased when prey (*T. urticae*) population decreased. Our work demonstrates the potential of *P. persimilis* to provide effective control of *T. urticae* on a greenhouse-grown cucumber at a moderately low predator:prey ratio (1:15) in Tokat Province, Turkey.
Keywords: *predatory mites, biocontrol, cucumber pests, spider mites*

Introduction

Spider mites of the Tetranychidae are major pests of greenhouse cucumber and other agricultural crops worldwide. Foliar damage caused by spider mite feeding causes significant yield loss. To protect these plants from spider mite damage, farmers have traditionally relied on synthetic pesticides to suppress population outbreaks. However, due to resistance of spider mites to pesticides, negative effects of pesticides on natural enemies, and environmental concerns, other control tactics besides pesticides are needed.

An alternative to pesticides for suppression of spider mites is the inoculative release of predatory mites from the family Phytoseiidae. Predatory mites are important biological control agents of spider mites in many agricultural systems. Phytoseiids (*Typhlodromus* spp., *Amblyseius* spp., *Phytoseiulus* spp.) are effective at suppressing two-spotted spider mites in vegetables grown in greenhouse. Predatory mites have a shorter development

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20332041

periods and active feeding in each period, therefore they are very important biocontrol agents. In recent years, especially greenhouse vegetables and floriculture, as well as the control of the red spider species in the open field, primarily *Phytoseiulus persimilis* and other phytoseiid species have been used (Loginova et al., 1987; Jarasik, 1990; Jarasik and Pliva, 1990; Easterbrook, 1992; Zang and Sanderson, 1995; Boom et al., 2002; Lanzoni et al., 2017). Kim and Park (2006) reported that *Tetranychus urticae* was effectively controlled by the release of predatory mites at a rate of 3 predator/m^2. Limited studies were conducted in mass production of *P. persimilis* and it use in control of *Tetranychus cinnabarinus* on greenhouse growing strawberries (Kılınçer et al., 1992; Kazak et al., 1992; Öncüer et al., 1994; Kısmalı et al., 1999; Kazak et al., 2002; Çakmak et al., 2005; Çakmak et al., 2007) and cucumber (Kazak et al., 2000) in Turkey. In the study, conducted by Çakmak et al. (2005) reported that when the *T. cinnabarinus* population level reached 2-3 individuals per leaflet in strawberry plants, *P. persimilis* was released once at the rate of 1 predator to 20 prey, the predatory mites provided an effective control 15-20 days after release, and no additional release was needed during the rest of the growing season. At present, mass rearing of predator mite *P. persimilis* is not continued in Turkey. Commercial companies are exporting predator mites from abroad.

Aims of the present study is assess the effectiveness of the predatory mite *Phytoseiulus persimilis* at controlling two-spotted spider mite (*Tetranychus urticae*) when released into greenhouse growing cucumber plants in Tokat-Turkey.

Materials and methods

Rearing predatory mites

The stock cultures of *Phytoseiulus persimilis* were purchased from private company (Koppert Biological Systems, Netherland) and reared on the bean plants grown at 25°C and 60% ± 5% relative humidity at 16h:8h (L:D).

Screenhouse trial

The experiment was conducted in Plant Protection Department screenhouse at the Tokat Gaziosmanpasa University, Tokat. The screenhouse received natural light during the course of the treatment with no artificial light source or climate controls. Coco peat is used for growing cucumber plants (*Figure 1*). Necessary plant essentials were given by water dripplet system. The average temperature and relative humidity were 26±2°C and 60±5% during the course of the experiment in the screenhouse. Five treatments were evaluated in an randomized complete block design with three blocks and nine plants per replicates. A predator:prey ratio of 1:5, 1:15; 1:30 was calculated for each release. In addition to this, there is a control and acaricide treatment with classical acaricide (Spiromesifen 240 g/l (Oberon SC 240) 50 ml/da) application. Thirty *Tetranychus urticae* young female were placed on individual plants with the aid of a fine-tipped saber brush. Two days after *T. urticae* release, at 1:5, 1:15, and 1:30 ratios 6, 2, and 1 mated young *P. persimilis* female individuals were released (Kazakoğlu et al., 2000). Acaricide was applied at recommended concentration.

Evaluation was performed 4 days after the predatory mite release. Plants were evaluated every four days. In each plot lower, middle and upper parts of randomly selected plants 25 leaves were visually assessed and the number of *T. urticae* and *P.*

persimilis motiles and eggs counted with hand-held 10X magnifier to quantify the effect of *P. persimilis* releases on *T. urticae* populations.

Figure 1. *A view from experiment unit*

Statistical analysis

The data were analyzed by the SPSS 17 statistical program (SPSS Inc., 2008) using general linear model to compare the effects of relase rates of predatory mites and time on controlling *Tetranychus urticae* at screenhouse conditions. ANOVA was used to compare means and Tukey's test was used to separate means.

Results

When *Phytoseiulus persimilis* was not released and without acaricide application, the population of *Tetranychus urticae* was constantly increased, and reached a peak of 141.11 motiles per leaf at week 5 and then decreased due to death of the infested cucumber plants ($F = 3.42$; $df = 4, 64$; $P < 0.05$) (*Figures 2, 3b*).

Two weeks after the predatory mite release, no *P. persimilis* motiles were recorded in the 1/5 predator:prey ratio treatment. However, at week 3 there were an average of 0.96 motiles per leaf ($F = 29.16$; $df = 4$; $P < 0.001$).

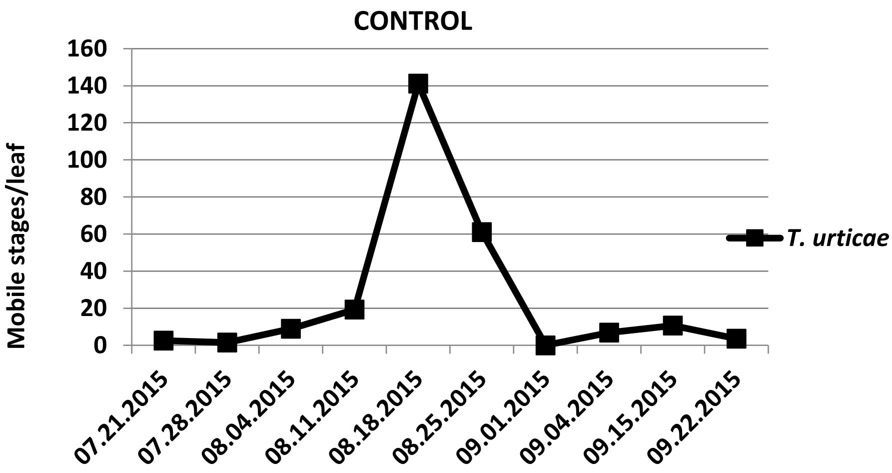

Figure 2. *Tetranychus urticae two-spotted spider mite density in untreated control*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20332041

This increased to 8.07 motiles per leaf at week 4 (F = 10.33; df = 4; P < 0.001) and declined to 4 and 2 motiles per leaf at week 5 and 6 respectively and then remained at this level for the remaining 2 weeks (*Figure 4*). The parasitic mite *T. urticae* population was followed the same trend with the predator mite. It's population reached at peak of 10.66 motile per leaf at week 4 (F = 22.25; df = 4; P < 0.001) and declined to 3.33 and 2.04 motile per leaf at week 7 and 8, respectively (F = 9.92; df = 4; P < 0.001) (*Figure 4*).

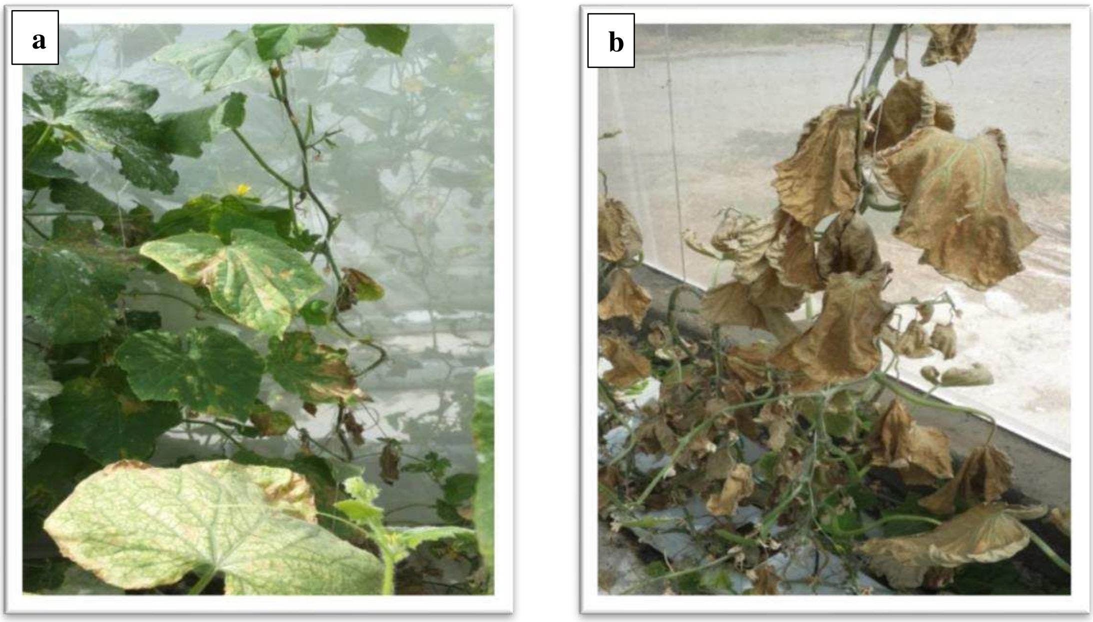

***Figure 3**. **a**. Cucumber plants in Phytoseiulus persimilis released plots **b.** Damages caused by Tetranychus urticae in untreated control plants*

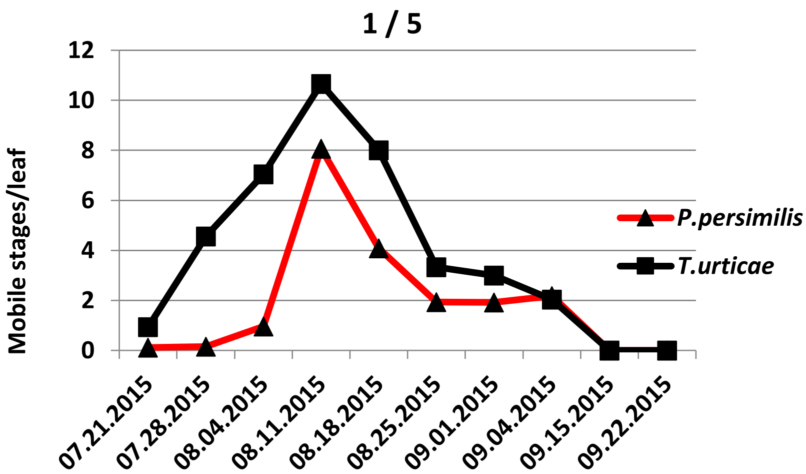

***Figure 4.** Tetranychus urticae two-spotted spider mite and Phytoseiulus persimilis density at 1/5 predator:prey ratio*

P. persimilis population density increased with increase in *T. urticae* population and decreased with decrease in prey density. The data demonstrated that releases of *P.*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20332041

persimilis at a 1:15 predator:prey ratio maintained low *T. urticae* populations (*Figure 4*). Two weeks after the predatory mite release, no *P. persimilis* motiles were recorded in the 1/15 predator:prey ratio treatment. However, at week 3 there were an average of 1.0 motiles per leaf (F = 29.16; df = 4; P < 0.001). This increased to about 3.5 motiles per leaf at week 7 and declined to 3 and 0.5 motiles per leaf at week 8 and 9, respectively (F = 4.88; df = 4; P < 0.01) (*Figure 5*).

The parasitic mite *T. urticae* population was followed the parallel trend with the predator mite It's population reached at peak of 4.25 motile per leaf at week 2 (F = 22.11; df = 4; P < 0.001) and declined to 3.25 (F = 6.52; df = 4; P < 0.01), 1.75 (F = 22.11; df = 4; P < 0.001), 1.0 (F = 3.41; df = 4; P < 0.05) and 0.75 (F = 8.59; df = 4; P < 0.001) motile per leaf at week 3, 4, 5 and 6, respectively. *T. urticae* population reached average of 1.75 motile per leaf at week 7 and declined to 1.41 and 0.0 motile per leaf at week 8 (F = 9.91; df = 4; P < 0.002) and 9, respectively (*Figure 5*).

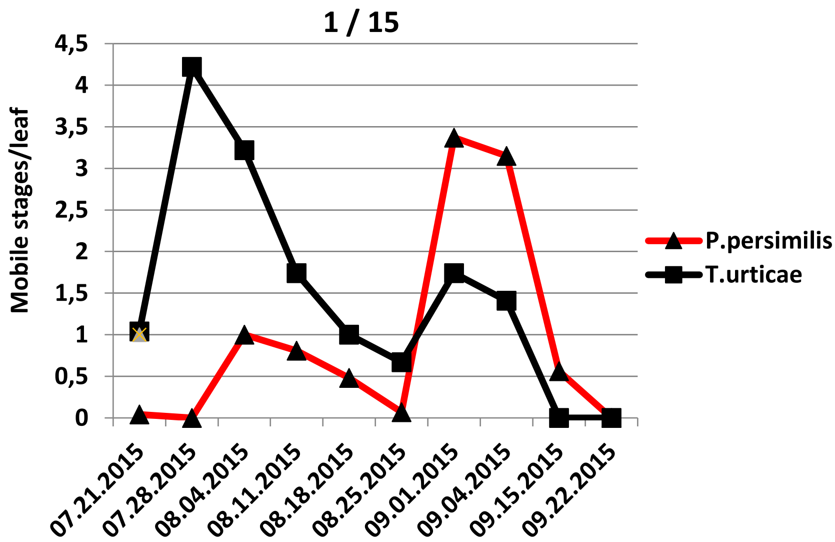

Figure 5. *Tetranychus urticae two-spotted spider mite and Phytoseiulus persimilis density at 1/15 predator:prey ratio*

At 1/30 predator:pery ratio treatment, despite the predator population reached peak of 22.0 motiles per leaf at week 4 (F = 10.30; df = 4; P < 0.001) it did not suppress the population of *T. urticae* which reached average of 40 motiles per leaf at week 4 (F = 22.25; df = 4; P < 0.001) (*Figure 6*). One week after predatory mite release, no *P. persimilis* motiles were recorded in the *P. persimilis* treatment. However, constant increase of *P. persimilis* observed after first week of release *P. persimilis* did not suppress *T. urticae* population effectively until week 5 (12.37 motiles/leaf) (F = 3.42; df = 4; P < 0.05). *Tetranychus urticae* population declined to average of 7.55 motile per leaf at week 6 (F = 8.59; df = 4; P < 0.003) then continued to decline constantly to 6.9 (F = 9.92; df = 4; P < 0.002), 2.2 (F = 6.28; df = 4; P < 0.01) and 0 motiles per leaf at week 7.8 and 9 respectively (*Figure 6*).

In the acaricide treatment, *T. urticae* population reached the peak of 2.8 motile per leaf at week 3 (F = 6.53; df = 4; P < 0.01) and declined to average of 0.8 motile per leaf at week 4 (F = 22.25; df = 4; P < 0.001) than increased up to average of 1.95 motile per leaf

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20332041

at week 5 (F = 3.42; df = 4; P < 0.05). Again the population of *T. urticae* started to decline at week 6 (F = 8.59; df = 4; P < 0.003) (*Figure 7*).

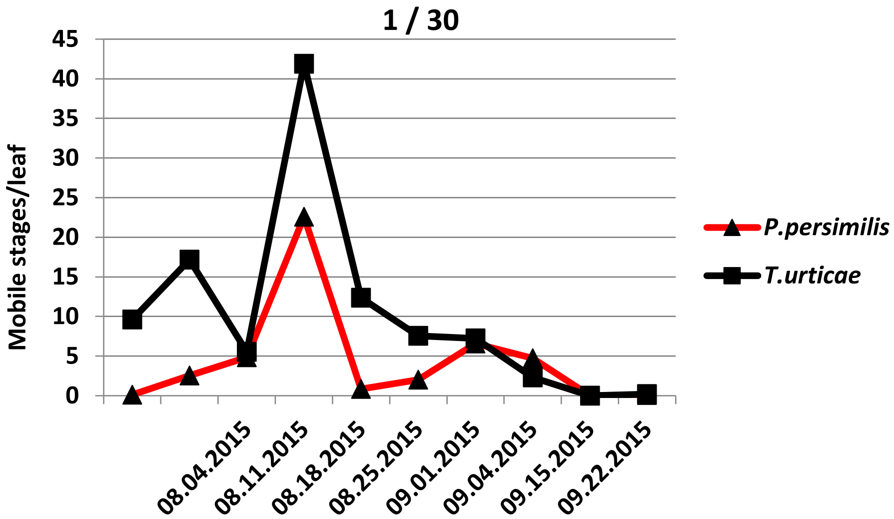

Figure 6. *Tetranychus urticae two-spotted spider mite and Phytoseiulus persimilis density at 1/30 predator:prey ratio*

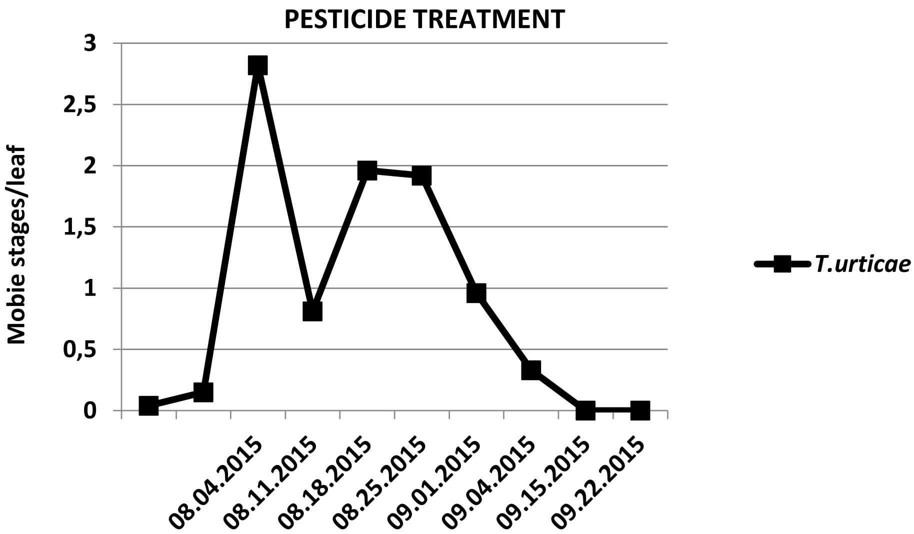

Figure 7. *Tetranychus urticae two-spotted spider density in acaricide treatment*

Discussion

The natural predator of two-spotted spider mites *Phytoseiulus persimilis* is the most widely used commercial predators for controlling mites. Having shorter development period from one generation to the next provides advantage to *P. persimilis* over the preys. However, the faster development potential of *P. persimilis* is an important factor in its success as a predator, it was reported that the initial ratio of pest to predator determines the outcome of a control program (Griffits, 2000; Lanzoni et al., 2017). Based on the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20332041

results of the present study, population of *Tetranychus urticae* increased rapidly in control treatment after week 4. The rapid population growth of *T. urticae* in the control treatment was expected, given the high biotic potential of *T. urticae*. Indeed prevailing conditions in protected cultivation such as greenhouse often favor the development of *T. urticae* (Kim and Park, 2006). The present study indicated that the potential of the predator to reduce the population of *T. urticae* determined by the predator:prey ratios at the time of predator release. At the 1/5 and 1/30 predator:prey ratios, population of *T. urticae* increased, and reached the peak of 10.5 and 40.0 motiles per leaf respectively at week 4. At these two ratios tested *P. persimilis* population increased constantly up to 4th week of release and then began to suppress *T. urticae* population significantly ($p \leq 0.05$). On the other hand, population of *T. urticae* reached at peak of 4.25 motile per leaf at week 2 and declined to 3.25, 1.75, 1.0 and 0.75 motile per leaf at week 3, 4, 5 and 6, respectively. *Phytoseiulus persimilis* took to reach control over *T. urticae* was 14 days when the pest:predator ratio is 1/15. The finding of the present study demonstrated that predator:prey ratio was a determinative factor for the effective control of *T. urticae*. This finding is supported by another greenhouse study showed that Predator mite *Anthoseius recki* (Wainstein) (Mesostigmata: Phytoseiidae) suppressed the population of *Tetranychus cinnabarinus* at 1/30 and 1/15 predator:prey ratios effectively. However, at 1/60 predator:prey ratio the predator failed to provide effective control of the prey on strawberry plants (Şekeroğlu, 1984). Scopes (1985) reported that *P. persimilis* took to reach control over *T. urticae* was 16 days when the pest:predator ratio was 1:200, 13 days when it was 1:100, and 11 days when it is 1:50. This clearly demonstrates that early application is more efficient. *P. persimilis* gave effective control of *T. urticae* when it was released onto strawberry with low levels of *T. urticae* infestation in southeast Queensland, Australia (Waite, 1998). Bonomo et al. (1991) also reported that releases of *P. persimilis* gave effective control of *T. urticae* at lower density of it. Similarly Kim (2001) evaluated the effectiveness of *P. persimilis* against *T. urticae* on strawberry in five commercial greenhouses and got an excellent result by releasing the predator at a rate of 3/m^2 in Korea. Spicciarelli et al. (1992) and Boom et al. (2002) recommended that phytoseiid mites give good control of *T. urticae*, if one mite is released per plant when the infestation of *T. urticae* has reached two individuals per leaf, and about 30% of the leaves are infested.

Conclusion

This study was conducted to see controlling two-spotted spider mites using *P. persimilis* at cucumber plants in screenhouse conditions in Tokat. Our results indicate that when released at 1:15 predator:prey and when *T. urticae* population are low per leaf, *P. persimilis* is able to maintain populations of *T. urticae* below damaging levels throughout a growing season (*Figure 3a*). It would appear that *P. persimilis* can give good control of two-spotted spider mite on cucumber plants, particularly if the predator is introduced when numbers of *T. urticae* are fairly low. What we do for growers, we arrange field days in the light of experiences and the results are shared with our producers and the stakeholders.

(Received 30th Oct 2018; accepted 11th Jan 2019)

Abstract. The factorial experiment was set up in a randomized complete block design as a split-plot arrangement with three replications. Irrigation as main-plot consisted of four levels: stopping of irrigation after 60, 75, and 90 days from planting, and full irrigation. The sub-plot encompassed three sunflower genotypes (Barolo RO, Velko, and Local) used under a semiarid condition in Sulaimani, Kurdistan Region of Iraq. Velko genotype under full irrigation produced the highest seed yield of 5716.685, and 5190.545 kg ha^{-1} at Kanipanka and Qlyasan locations respectively. Overall, 60 days of irrigation, and full irrigation showed the highest and lowest WUE or IWUE, respectively. All the genotypes offered a crop response factor of less than one at both locations indicating that the grown crop is more tolerant to water deficit, and recovers partially from stress. The result of this study concluded that the Barolo RO genotype has the highest performance under deficit irrigation. Therefore, this genotype is the most proper one for the study area as a part of drought-prone environments. Furthermore, the results obtained from this study indicated that the early stage of growth was more effective to increase the seed yield of sunflowers than irrigation in the middle and later stages.
Keywords: *sunflower water productivity, seed yield, deficit irrigation, and yield response factor*

Introduction

An estimated 70% of the world fresh water is used for agricultural productions, and this percentage could reach above 90% in some developing countries (WWP, 2017). The application of efficient water management strategies is a key element to increase water productivity (Mancosu et al., 2015). Further, water availability is one of the primary factors in sunflower seed production by irrigation depths (Gomes et al., 2012). The applied irrigation depths must be adequately quantified; otherwise, they may negatively affect the crop through water deficit or excess. Water deficit compromises photosynthesis, stomatal conductance, and transpiration, reducing plant biomass (Duarte et al., 2012). Water is decreasing day by day due to unavailability of natural rainfall, excessive withdrawal of groundwater, population growth, and increased use of irrigation water (Vörösmarty et al., 2000; Rosegrant et al., 2002; Rockström et al., 2009; Sarkar and Ali, 2009; Asraf et al., 2015). To deal with this situation, the lowest water usage with the highest yield has to be utilized in order to achieve maximum water productivity instead of highest yield, this method called, deficit irrigation and efficient use of water. Also, this technique can save irrigation cost with a negligible yield reduction consequently net farm income increase (Ali et al., 2007). This method shows a quantitative relationship between relative evaporation deficit and relative yield

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20432057

decrease. Therefore, to accept this theory, higher crop production and water productivity can be achieved with better water management planning (Ali, 2009). The sunflower plant is categorized as one of the low to medium drought-sensitive crop. Many researchers found that both quantity and distribution of water have a significant impact on achene and oil yield in sunflower (Fereres et al., 1986; Andrich et al., 1996; Krizmanic et al., 2003; Reddy et al., 2003; Iqbal et al., 2005). Deficit irrigation causes a yield reduction to some extent which depends on both the severity and timing of the water deficits (Orgaz et al., 1992). In water deficit condition (when it occurs during the life cycle) plant can achieve maximum water productivity (Ali, 2009). Ayas and Korukcu (2010) reported the k_y factor of 0.909 in potato during growth period in Yenisehir, Bursa. Demir et al. (2006) estimated yield response factor k_y of sunflower to deficit irrigation in a sub-humid climate (Bursa, Turkey). They found k_y of 0.8382 for the total growth period of sunflower. However, by using furrow irrigation method (Karaata, 1991) found a k_y value of 0.91 for the whole growing season and 0.83 for the vegetative + yielding stage. Hence, it is understandable that response factor differs from location to location depending on weather conditions, soil types, variety, crop, season and also for individual growth stage to the total growing season (Ali, 2009). Therefore, it is utmost essential, to consider location-specific response factor for efficient management of water. A hybrid yield was conditioned by its capacity to use the environmental variables efficiently in different phenophases (Gonzáles et al., 2013). Thus, the genetic potential of the sunflower hybrid was reduced by the action of the growth factors, either environmental or technological ones. Agronomic practices in addition to high yielding varieties are the two most important items for higher productivity of the sunflower crop (Beg et al., 2007). Productivity per unit area of sunflower was determined by many factors, including plant population and variety (Ibrahim, 2012). The objective of this study was to determine the effect of different deficit irrigation levels on the yield, irrigation water use efficiency (IWUE), water use efficiency (WUE), and yield response factor k_y of some sunflower genotypes (*Helianthus annuus L.*) in the semi-arid conditions of Sulaimani region.

Material and methods

Study area and soil sampling

This experiment was conducted during the summer season of 2016 between July and October at two locations surrounding Sulaimani city. The first location was the Kanipanka Agricultural Research Station (latitude: 35° 22’ 22” N, Longitude: 045° 43’ 22” E, altitude: 548 masL) in Sharazoor valley. While the second location was Qlyasan, the farm of Crop Science Department, College of Agricultural Sciences, the University of Sulaimani, located at (latitude: 35° 34’ 17” N, Longitude: 045° 22’ 00” E, altitude: 757 masL) “Garmin, GPSmap60 Cx.” (*Fig. 1*). The total available water at these two locations is 151 and 147 mm m^{-1}.

At each location of the experiment, a composite soil sample of about 5 kg was obtained by mixing subsamples from 6 sites using a shovel. Each composite soil sample was freed from plant roots and other debris. Collected soil samples were placed in the open to be air dried at room temperature for about a week, then gently crushed and sieved at 2 mm with a stainless-steel sieve to avoid any contamination and then stored for subsequent analyses.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20432057

Each experiment was set up in a randomized complete block design (RCBD) as a split-plot factorial arrangement with three replications with the deficit and full irrigation treatments as the main plot. Four levels were used: I_1 irrigation treatment (stopping of irrigation after 60 days from planting), I_2 irrigation treatment (stopping of irrigation after 75 days from planting), I_3 irrigation treatment (stopping of irrigation after 90 days from planting), and I_4 nonstop irrigation treatment (full irrigation), while the sub-plot factors encompassed three sunflower genotypes (Barolo RO, Velko, and Local). These genotypes were selected because of different responses to water stress.

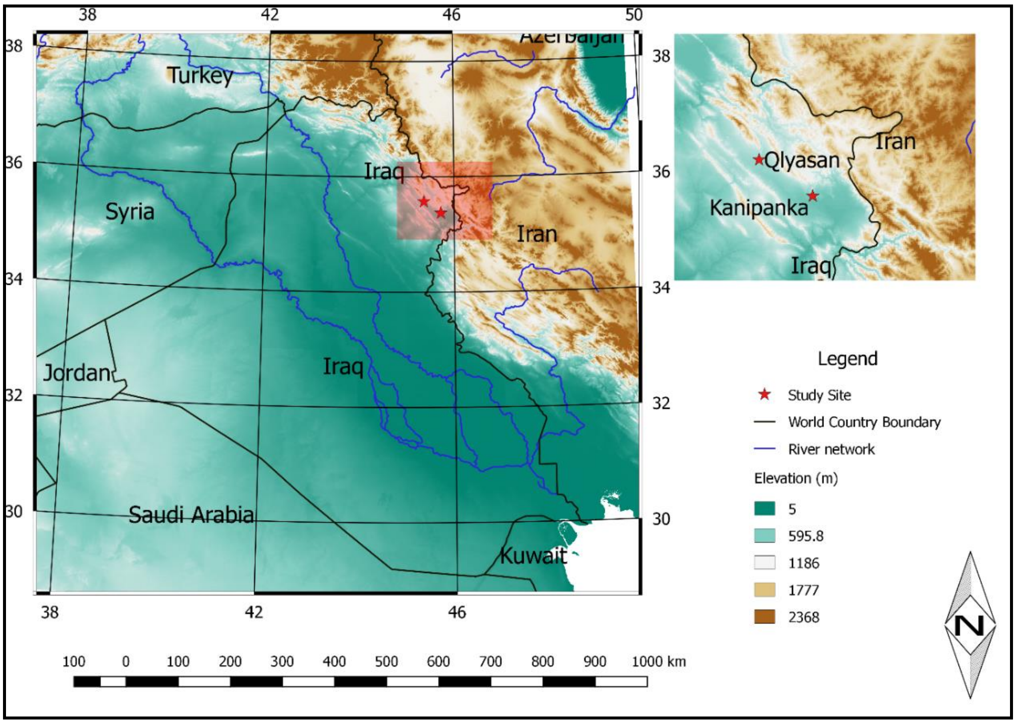

Figure 1. *Map of the study site in Sulaimani-Kurdistan Region, Iraq*

The sub-plots were 3 m by 1.8 m in size, and each consisted of three rows, spaced at 0.60 m with a plant distance of 0.30 m. The seeds were planted during July 11th, and July 15th at Kanipanka and Qlyasan location respectively. Three seeds hole^{-1} were placed at a depth of 2-4 cm. Two weeks after planting, the seedlings were thinned out to one plant hole^{-1}. Urea, as a source of nitrogen fertilizer, was applied to all plots in two equal split doses before the second irrigation and prior to flowering at a rate of 43 kg ha^{-1} as recommended. Hand weeding practiced as needed.

Climate conditions of Sulaimani Governorate

The climate of Sulaimani governorate is semi-arid environment: hot and dry in summer; cold and wet in winter. During July and August, the average temperature is between 39-43 °C, and often reaching nearly 50 °C. Autumn means high temperatures are 24-29 °C in October, cooling slightly in November. Precipitation is limited to winter and spring months, and the overall average annual rainfall of 666.8 mm was at Sulaimani city in 2016 (Kurdistan Regional Government, 2018). An overview of experimental conditions is given in *Table 1*.

	October	14.95	32.01	29.42	1.44	0

Watering schedule and restrictions

Irrigation timing method was based on an allowable root zone available water depletion (45%) during full and no deficit irrigation (Allen et al., 1998). The amount of irrigation water was measured with water flow meter devices (SOTERA digital display meter) (*Fig. 2*). The soil water content was monitored gravimetrically (Lorenz and Maynard, 1980), using a small auger 5 cm in diameter. The net water requirement (crop consumptive use) was calculated from soil moisture. When the available soil moisture was depleted by 45%, the soil moisture was brought to filed capacity. The sum of the crop consumptive use during the growing season was comparable well with that computed by Penman-Monteith equation

At each location, the matured plants from the central rows in each plot were harvested manually and then yield and yield components for each treatment at each replicate were determined. The yield data was taken at about 10% seed moisture level. The harvesting dates were on October 19th, 2016 for the deficit irrigation treatments, and October 24th for the full irrigation treatment at Kanipanka location, while October 25th were the harvesting dates for all the treatments at Qlyasan location respectively.

Figure 2. *SOTERA digital display meter*

The below-stated equation was used to estimate water use efficiency (WUE, *Eq. 1*), and irrigation water use efficiency (IWUE, *Eq. 2*), as the ratio of crop yield per unit of water applied (Kang et al., 2000):

$$WUE = \frac{Y}{ETc} \qquad \text{(Eq.1)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20432057

$$IWUE = \frac{Y}{I} \quad \text{(Eq.2)}$$

where:
Y = The total sunflower seed yield (kg ha^{-1})
ETc = The seasonal evapotranspiration (m^3 ha^{-1})
I = The total volume of applied irrigation water (m^3 ha^{-1})

While the irrigation application efficiencies for the locations under study based on average land slop and basic infiltration rate was calculated according to Karim and Karim (2001) and the results are revealed in *Table 2*.

Table 2. *Irrigation application efficiencies for the locations under study based on average land slope and basic infiltration rate*

Locations	Average land slope (%)	Basic infiltration rate, Ib (mmhr^{-1})	Irrigation application efficiency, Ea
Kanipanka	Nearly level	44	0.70
Qlyasan	1.16	80	0.65

The crop response factor *Ky* is the relationship between relative yield decrease and relative evapotranspiration deficit which was determined by the procedure given by Doorenbos and Kassam (1979) (*Eq. 3*).

$$\left(1 - \frac{Ya}{Ym}\right) = Ky\left(1 - \frac{ETa}{ETmax}\right) \quad \text{(Eq.3)}$$

where:
Ya = Actual crop yield (kg ha^{-1})
Ym = Maximum crop yield (kg ha^{-1})
Eta = Actual evapotranspiration (mm)
ETm = Maximum evapotranspiration (mm)
Ky = Yield response factor (dimensionless)

The k_y factor for the entire season determined by linear regression, adjusted through the origin, between the reduction in relative yield and deficit of relative evapotranspiration.

The uniformity coefficient (UC, *Eq. 4*) for some selected parameters was determined according to Devitt et al. (1992):

$$UC = 1 - (standard\ deviation/mean) \quad \text{(Eq.4)}$$

Analytical methods and laboratory analysis

The results of the studied soil parameters are shown in *Table 3*. Particle size fractionation and distribution were conducted by international pipette method as recommended by Black et al. (1965). EC and acidity (pH) of soil sample were measured in 1:10, soil to H_2O ratio suspension according to Thomas (1996) by using these models of instruments; pH-meter (model WTW 330i/ Germany); EC-meter (model WTW 330i/Germany). The percent of organic carbon (o.m%) in soil samples were determined by the Walkley-Black method (wet oxidation by potassium dichromate $K_2Cr_2O_7$ and concentrated H_2SO_4) as described by Black et al. (1965). Then the content of organic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20432057

matter (OM) was calculated as follows: % Organic matter = % organic carbon × 1.724 (factor). The percent of the total ($CaCO_3$%) was determined by the acid-neutralization method according to the method 23c of U.S. Salinity Laboratory Staff, 1954 (Black et al., 1965).

Table 3. *Some physicochemical properties of the soil samples for locations of the experiment*

Physicochemical properties		Locations	
		Kanipanka	**Qlyasan**
Particles size distribution (kg^{-1})	Sand	36	87
	Silt	529	435
	Clay	435	458
	Texture	SiC	SiC
PH		7.70	7.59
ECe (micro siemens cm^{-1}) or ($\mu S\ cm^{-1}$)		218	490
O.M. ($g\ kg^{-1}$)		14.8	22.4
CaCO3 ($g\ kg^{-1}$)		208.3	304.3

Statistical analysis

Statistical analysis for all measured variable was performed using the XLSTAT software (XLSTAT, 2017). For direct comparison of treatments, least significant difference tests (LSD) at levels of 0.05 and 0.01 levels were used. For testing the main effects of deficit irrigation on sunflower genotypes in a semi-arid region, the data were subjected to analysis of variance (ANOVA).

Results

Table 4 shows the seed yields, for irrigation water use efficiency (IWUE) and water use efficiency (WUE) for all three genotypes of sunflower at Kanipanka and Qlyasan locations under different deficit irrigation treatments during the summer season of 2016.

As seen in *Table 4,* highly significant differences among genotypes were recorded (see *Appendix*). The highest value of seed yield recorded with the Velko genotype under I_4 (full irrigation) at first location was 5716.685 kg ha^{-1} which predominated all combinations significantly while the lowest value was 2915.600 kg ha^{-1} recorded with the Local genotype under I_1 (stopping of irrigation after 60 days) at the same locations. The irrigation water use efficiency varied from as low as 4.511 kg ha^{-1} mm^{-1} for the Local genotype under I_3 (stopping of irrigation after 90 days) at the second location to as high as 9.382 kg ha^{-1} mm^{-1} for the Velko genotype under I_1 (stopping of irrigation after 60 days) at the same location, in which exceeded other combinations significantly. On the other hand, it was reported that the water use efficiency varied from a minimum of 6.754 kg ha^{-1} mm^{-1} for the Barolo RO genotype under I_4 (full irrigation) at the first location to a maximum of 14.437 kg ha^{-1} mm^{-1} for the Velko genotype under I_1 (stopping of irrigation after 60 days) at the second location.

Based on the average values of IWUE, and WUE for the two locations, the order of performance of the genotypes is as follows: Velko > Barolo RO > Local. Our study showed that the Velko and Local genotypes offered the highest and lowest performance respectively.

As expected the percent yield reduction decreased progressively with an increase in the amount of applied water. Further, the Velko genotype offered the maximum percent of the reduction in yield (27.08%) under I_1 (stopping of irrigation after 60 days) at the first location. *Table 5* revealed that water stress imposed at the later stage of growth influence yield the least, and offered water saving of about 40% compared with the full irrigation treatment. The percent of the reduction under limited irrigation was less than 20% in most cases (*Table 5*).

As shown in *Table 6* and *Figures 3* and *4,* the crop yield response factor was estimated for sunflower at the study locations were calculated according to Doorenbos and Kassam (1979). The k_y values ranged from the minimum of 0.337 for the Barolo RO genotype at the second location to a maximum of 0.827 for the Velko genotype at the first location.

Table 6. *Crop response factor for different sunflower genotypes to limited irrigation*

Locations	**Genotypes**	**Seed yield (kg ha^{-1})**	**ETa (m^3 ha^{-1})**	**Ky**

DOI: http://dx.doi.org/10.15666/aeer/1702_20432057

The result displayed in *Table 6* revealed that among the genotypes, Barolo RO exhibited the least value of k_y at both locations. The lower result indicates that this genotype is the most proper one for the study area as a part of drought-prone environments. Further examination of *Table 6,* revealed that the k_y values for both locations exhibited similar trends. The Barolo RO and Velko offered the minimum and maximum values for k_y respectively at both locations.

Based on the k_y values listed in *Table 7,* deficit irrigation may be needed at different stages for water limiting areas. Also, it was noticed that the uniformity coefficient values were below 0.86. The Velko genotype showed a uniformity coefficient of 0.55. Therefore, statistical differences between genotype and locations can exist.

Table 7. *Yield response factor (Ky) of sunflower genotypes under different irrigation treatments*

Genotypes	ETa (m^3 ha^{-1})		Ky value		Mean	Standard deviation (SD)	Uniformity coefficient (UC)	Coefficient of variance (CV) %

Discussion

The results of the study indicated that the highest seed yield was obtained from the control treatment (full irrigation) and drought stress statistically decreased seed yield compared to no stress. These results collaborate (Tabatabaei et al., 2012; Dehkhoda et al., 2013; and Hussain et al., 2013). Unger (1982) found that limited irrigation water resulted in higher water use efficiency than full irrigation.

The higher IWUE and WUE values were due to limited irrigation treatments. Therefore, the increase of seed yields depends on genotypes and irrigation interval. Further, it can be reported, that with one exception, there is a steady decrease in both IWUE and WUE with an increase in the amount of applied water or plant evaporation. These changes may be due to a minimum water use efficiency of 6.754 kg ha^{-1} mm^{-1} under I_4 (full irrigation) for Barolo RO genotype, and maximum water use efficiency 14.437 kg ha^{-1} mm^{-1} under I_1 (stopping of irrigation after 60 days) for Velko genotype. However, Langeroodi et al. (2014) found that the highest water use efficiency achieved under several limited irrigation treatments for sunflower in the Islamic Republic of Iran was 7.1 kg ha^{-1} mm^{-1}. Also, Demir et al. (2006) found that the highest value was 10.19 kg ha^{-1} mm^{-1} under (full irrigation) at Bursa, Turkey. These findings support the results of Mahender et al. (2000) and Kakar and Soomro (2001) who pointed out that the increase in seed yield of sunflower depended on genotypes and irrigation intervals. Therefore, further studies are needed to investigate the important of water use efficiency on sunflower seed yields.

In regard to the genotypes, at the second and third stages, i.e., stopping of irrigation after 75 and 90 days was the critical stages for deficit irrigation. It was proved that stopping of irrigation after these periods can minimize crop yield to a great extent. Stopping of irrigation after 60 days should be preferred due to higher IWUE and WUE

if water resources are limited and irrigation water cost is high. Sunflower genotypes showed different responses to irrigation treatments under the conditions of the experiments.

It is interesting to note that the obtained values of the crop response factor were within the range of values documented for sunflower found in the literatures. There are numerous research reports exist on yield response of sunflower to water, a host of researchers found that the k_y values were in the range of 0.80–0.95 for sunflower (Doorenbos and Kassam, 1979; Moutonnet, 2002; Demir et al., 2006). Apart from this, Mila and Ali (2016) found that the k_y values were in the range of 0.25 to 0.64 for the entire growing season of sunflower. The factor k_y captures the essence of the complex linkages between production and water use by sunflower in this study. With no exception, all the genotypes yielded crop response factors were of less than 1.0. The decrease k_y value indicates that the grown crops are more tolerant to water deficit, and recovers partially from stress, exhibiting less than proportional reductions in yield with reduced water use. Based on the k_y values deficit irrigation may be needed at different stages for water limiting area. Our result collaborates with the FAO standard as reported by Steduto et al. (2012).

The Velko genotype showed a uniformity coefficient of 0.55. Therefore, statistical differences between genotype and locations can exist. These values vary depending on season, location and intensity of water deficit (Mila and Ali, 2016).

It is apparent from obtained results that the growth stage is most responsive to irrigation was early stage (the first 60 days), compared with other stages. Therefore irrigation during this period would ensure the least yield reduction of sunflower. These results implied that irrigation at an earlier stage was much useful to increase seed yield of sunflower genotypes rather than the middle and later irrigation. Enough root penetration without water deficit during the early stage may be responsible for the crop tolerance to drought at later stages of growth. Additionally, plant stress due to the increased production of antioxidant enzymes may also contribute to plant resistance to drought (Langeroodi et al., 2014). Therefore, tolerance of sunflower plants to drought makes sunflower more valuable under the prevailing climatic condition of the study area where the climate is characterized as semiarid due to irregular and insufficient rainfall and hot weather during vegetation period for sunflower production (Flagella et al., 2002; Reddy et al., 2003).

Conclusion

The results of this study indicated that Barolo RO genotype is the most proper one for the study area as a part of drought-prone environments. Additionally, the results indicated that full irrigation at the early stage of growth was more effective to increase the seed yield of sunflower genotypes rather than the middle and later stages of its growth. Thus some water must be ensured at this stage. Also, higher response factor indicates greater water stress. Therefore, the water supply must be applied at the vegetative and pre-flowering stage. However, this will vary with location, the intensity of water deficit, and growth stages. In view of the obtained values of water efficiency, it is recommended to give high priority to Velko genotype coupled with stopping irrigation after 60 days.

Abstract. Major effect of climate change can be seen in developing countries like Pakistan that make them food insecure. Grain yield of wheat (*Triticum aestivum* L.) is low as it is affected by erratic weather conditions. Latest development of wheat genotypes applicable for late planting is one of the prime objectives of wheat breeders. Keeping in view the climatic conditions of Pakistan, current investigations were conducted to figure out the inheritance pattern and extent of variations using generation mean analysis. For the aforementioned study the two genotypes Miraj 2008 and Punjab 2011 were evaluated along with following generations i.e. F_1, F_2, BC_1 and BC_2 in normal and late sowing trial in Faisalabad, Pakistan. The highest reduction percentage was observed in grain weight per spike (-33.6%). The inheritance of all traits revealed complex inheritance due to the involvement of non-allelic interactions. The traits like days to heading and days to maturity had both additive, additive × additive i.e. fixable and additive × dominant non fixable genetic effects. So, selection in later generation would be fruitful for these traits when combinations are fixed. Heritability estimates for narrow sense was also determined. Low to moderate heritability was depicted under late sowing conditions.
Keywords: *late planting, generation mean, reduction percentage, grain weight, heritability*

Introduction

Crop yield is reducing due to adverse weather conditions whereas, supplies are becoming scarce, and the price is rising ultimately leads to food insecurity. Global mean temperature has risen at a rate of 0.3°C per decade during the twentieth-century (IFPRI, 2009) and is expected to reach 1 and 3°C above the current value by 2025 and 2100 respectively, resulting in more severe global climatic changes in near future. Heat stress (late sowing) at grain filling stage of wheat causes physiological and biochemical processes abort (Gupta et al., 2013). Therefore, selection of genotypes tolerant to high temperature with proper sowing time is a priority to manage the adverse effects of environments (Alghabari et al., 2014). Time of planting is one of the most important non-monetary input for optimizing the growth according to prevailing agro-climatic conditions and genotypes (Jena et al., 2017). It is an ultimate truth that crop yield is the inter-play of crop genetics, environment and management practices (Mirshekarnezhad et al., 2018). It is impossible to control the environment, but we can develop genotypes that can cope with changing environment. Among many other factors, late sowing is one of the major causes of lower wheat yield in Pakistan. Many cropping patterns prevailing in Pakistan have rotation like wheat; cotton, rice, maize, vegetables, fodders and sugarcane. This inertia in crop rotation cannot allow wheat to have an optimum

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20592071

time of plantation resulting in a large spectrum of sowing dates. About 80% of the wheat crop is grown after cotton, sugarcane and rice which exposes the crop to high temperature during the gain filling time that is the terminal heat stress which leads to drastic loss in grain yield and ultimately shortage of food (Prasad et al., 2011). High temperature is found to be accompanied with drought stress because of the rise in evapotranspiration. Terminal heat stress has drastic impacts on reproductive development such as flower initiation, ovary and pollen development, fertilization leading to reduction in sink potential which further results in yield loss (Barnabas et al., 2008). Selection of appropriate variety with respect to date of sowing is important to cope with the expected temperature rise at reproductive stage without compromising yield. Thus improvement in the crop genetic is the only inexpensive, effective and targeted approach available for wheat breeders in developing countries like Pakistan (Saxena and Toole, 2002). It is really important to know about genetic components as well as their interactions to achieve a workable breeding program. Generation mean analysis is a unique biometrical technique based on phenotypic performance of traits under study (Mather and Jinks, 1982). Generation mean analysis is most trusted biometric technique to investigate the genetic and epistatic effects. The present study was designed to achieve the information regarding the extent of variation and inheritance patterns in wheat genotypes under two different sowing windows.

Materials and Methods

Plant material

The current study was carried out in the research area of Department of Pant Breeding and Genetics University of Agriculture Faisalabad, Pakistan. The investigational material comprised of two bread wheat cultivars Miraj-2008 and Punjab-2011 (*Table 1*) as parents and their generation's i.e. F_1, F_2, BC_1, and BC_2 were established from two contrasting cultivars selected based on their planting time and commercial importance.

Table 1. *Name and pedigree of parental bread wheat cultivars (spring type)*

Parent	Name	Pedigree
1	Miraj-2008	SPARROW/INIA//V7394/WL711/13/BAUS
2	Punjab-2011	AMSEL/ATTILA//INQ-91/PEW'S'

All six generations of cross were sown on November 15, 2015 under normal (optimum) sowing conditions. The research trial was conducted in randomized complete block design (RCBD) with three replicates (P×P=15 cm; R×R= 30 cm). Dibbler method was used for sowing. To attain a single vigorous seedling per hole thinning was done after germination. To abate the border effect lines of non-experimental material was sown at the border of the experiment. Total four irrigations were applied. First irrigation was applied at tillering stage, second at booting stage, third at anthesis stage, fourth at milking stage. Fertilizer were applied at the rate of 46 kg nitrogen, 34 kg phosphorus and 25 kg potash per acre. Twenty well-guarded plants from P_1, P_2 and F_1 was tagged. Fifty plants from each back cross (BC_1 and BC_2) and two hundred plants from F_2 generation per replication were tagged prior to flowering. Similar activities were

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20592071

performed for the late sowing experiment on December 20, 2015. Harvesting was done 8-15 April, 2016. Data were recorded for the following traits: Plant height, tillers number per plant, Days taken to heading, days taken to maturity, grain filling duration (*Eq. 1*), grain filling rate (*Eq. 2*), harvest index (*Eq. 3*) and grain weight per spike.

$$\text{Grain filling duration} = \text{Days to maturity} - \text{days to heading} \quad \text{(Eq.1)}$$

Grain filling rate was estimated using following formulae (*Eq. 2*):

$$\text{Grain filling rate} = \frac{\text{Grain yield}}{\text{Grain filling period}} \times 100 \quad \text{(Eq.2)}$$

$$\text{Harvest index} = \frac{\text{Grain yield}}{\text{Biological yield}} \times 100 \quad \text{(Eq.3)}$$

Statistical analysis

Analysis of variance was done following Steel et al. (1997) and generation mean analysis (*Eq. 4*) was performed according to the method given by Mather and Jinks (1982). A computer program provided by Dr. H.S. Pooni, School of Biological Sciences, University of Birmingham UK was used for generation mean analysis by the method of Mather and Jinks (1982). The narrow sense heritability (h^2ns) was estimated by the method shown by Mather and Jinks (1982) and Saleem et al. (2016).

$$Y=m+\alpha[d]+\beta[h]+\alpha^2[i]+2\alpha\beta[j]+\beta^2[l] \quad \text{(Eq.4)}$$

where Y = mean of one generation, m = mean of all the generations, d = sum of additive effects, h = sum of dominance effects, i = sum of additive × additive gene interaction i.e. complementary, j = sum of additive × dominance α^2, $2\alpha\beta$ and β^2 were the coefficient of genetic parameters, l = sum of dominance × dominance interaction i.e. duplicate.

Results and discussion

Understanding the genetic makeup of any crop plants is dire to batten the crop performance in the current scenario of climate change. Analysis of variance revealed significant genotypic difference for each generation (P_1, P_2, F_1, F_2, BC_1 and BC_2) for all traits under study. Under both sowing conditions parents and generations exhibited significant differences (*Table 2*). The presence of genetic diversity in breeding material is basic criterion for success in any breeding program. Under different sowing conditions changed behavior of breeding material is an indication of significant environment into genotypes interaction (Akram, 2011; Saleem et al., 2016).

Comparison of two treatment means of six generations of cross Miraj 2008 × Punjab 2011 under normal and late sowing conditions

Expression of genes in any stress become restricted. Under late sowing trial the overall performance of all the traits decreased. The magnitude of sensitivity was different for the different traits. Most sensitive traits grains weight per spike with a reduction of 33.6% succeeded by tillers number per plant 28.3% and harvest index

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20592071

27.1%. In contrast the lowest reduction was shown by days to heading 12.3% followed by grain filing rate 13.4% and grain filling duration 17.0% (*Table 3*). Scientists have also exhibited that under stressed environment, traits do not fully express themselves (Tahir et al., 2009; Sohail et al., 2014).

Grain Filling Rate	94.535	81.857	-13.4
Grain weight per plant	2.2550	1.4978	-33.6

Phenological traits

Days to heading

Heading time is phenological stage as it determines the pattern of yield potential and stability. When overall reduction percentage was exhibited from pooled means (*Table 3*) of both parents (P_1 and P_2) and their generations (F_1, F_2, BC_1 and BC_2) the results depicted that growth span reduction percentage maximum in BC_2 (15.81%) and minimum in F_2 (10.28%), and when individual performance of parents and generation was investigated for mean values the response was different in both normal and late sowing conditions (*Figure 1*). In late sowing condition F_2 depicted maximum mean value for days to heading (117.35) which revealed more variation in the segregating generation. Those observation were in line with the finding of Kilic and Yagbasanlar (2010). The study of controlling days to flowering is really pivotal as per genetic needs because genetic potentials would show negative indicators with the onset of erratic weather conditions. The genotypes with more days to heading in delayed planting

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20592071

conditions produce more grain yield because these genotypes assimilate nutrient from stem to kernels very precisely and grains enjoyed large size ultimately increased grain weight.

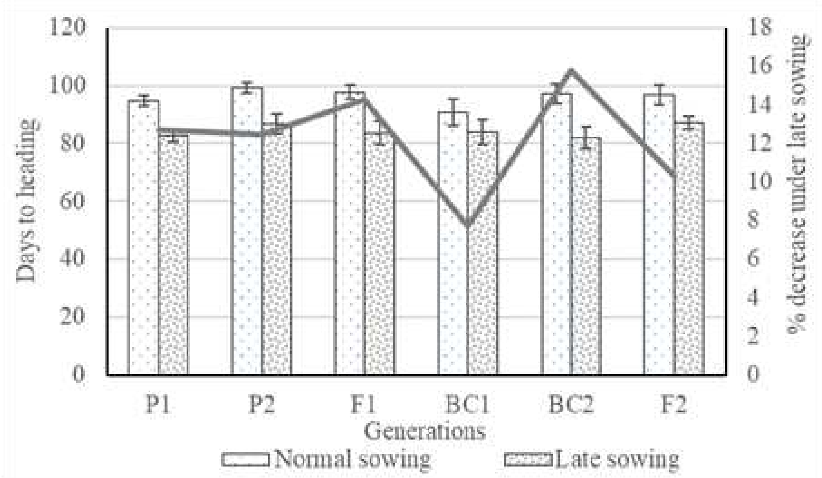

Figure 1. *Days to heading of six generations of cross Miraj 2008 × Punjab 2011 under normal and late sowing conditions along with % increase or decrease. Error bar represents standard errors and overlapping bars are statistically at par with each other*

Days to maturity

The stress environment forced early maturity and abridged the life cycle of the genotypes and their generation. P_1 exhibited uppermost reduction percentage (16.5%) for maturity days and lowermost (11.52%) was revealed by F_2 (*Table 3*). It means P_1 was more sensitive to environmental stress. While in late sowing date F_2 depicted highest days to maturity (117.3) and lowest magnitude (112.2) were documented for BC_1 (*Figure 2*). Those statement were also analogous with the finding of Kilic and Yagbasanlar (2010).

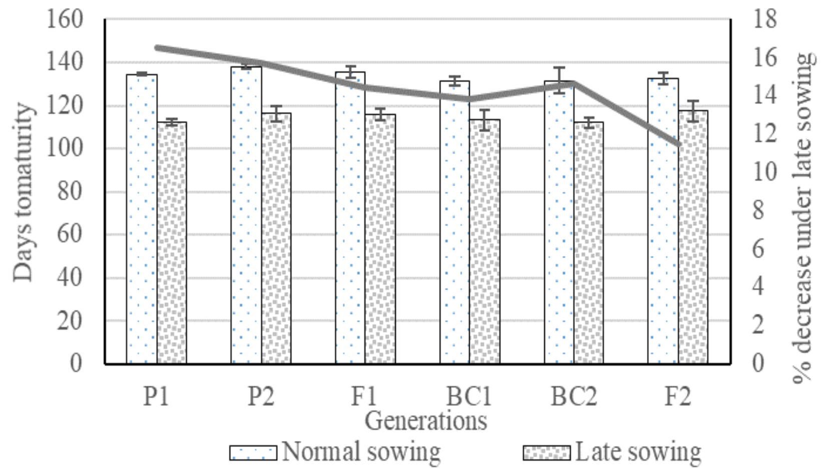

Figure 2. *Days to maturity of six generations of cross Miraj 2008 × Punjab 2011 under normal and late sowing conditions along with % increase or decrease. Error bar represents standard errors and overlapping bars are statistically at par with each other*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20592071

Grain filling duration

When genotypes were sown in normal dates more grain filling days were produced comparative to late sowing (*Table 3*). For grain filling duration in pooled mean values of both parents and generations back cross 1 attained highest reduction (27.9%) percentage while lowest value (13.59%) was noted in F_2 depicted in *Figure 3*. The losses percentage was out of parents range. In late planting conditions P_2 (33.86) illustrated maximum grain filling days and P_1 (28.60) showed lowest value when separate performance of parents and generations was observed. Delayed sowing shortens the duration of each development phase which ultimately reduces grain filling period resulting in lower grain weight (Kaur, 2017). It additionally shows that the optimum planted genotype relished a prolonged development stage and favorable pre-heading environments, which have had a persist impact on grain weight via stem reserves mobilization (Baloch et al., 2012).

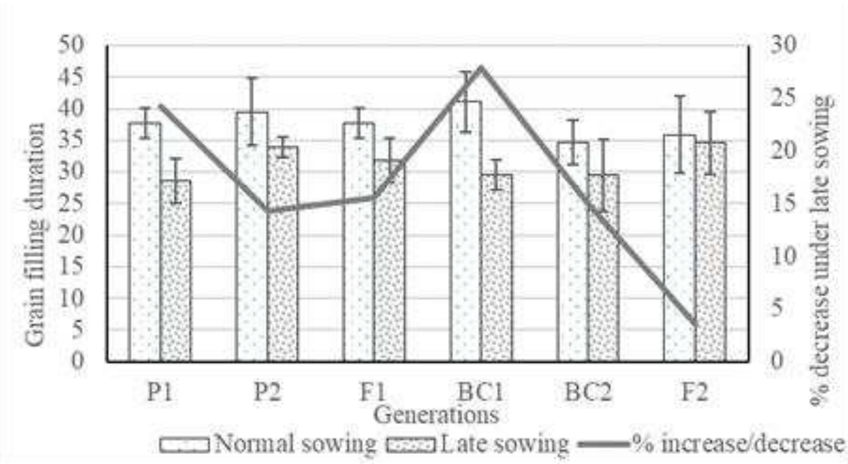

Figure 3. *Grain filling duration of six generations of cross Miraj 2008 × Punjab 2011 under normal and late sowing conditions along with % increase or decrease. Error bar represents standard errors and overlapping bars are statistically at par with each other*

Grain filling rate

It is also an important penolohgiacal trait. In pooled mean values for both parents and their generations P_1 showed maximum reduction percentage magnitude (14.96%) and minimum value showed by F_2 that was (11.52%). For observing individual performance in all generation and parents under both normal and late sowing trial the uppermost mean magnitude revealed by F_2, while the lowermost value was perceived by BC_1 (93.41) in normal and P_1 (80.05) scored minimum in late planting experiment (*Figure 4*). Similar results were presented by Tahir et al. (2009), Laghari et al. (2012) and Golparvar (2012). Grain filling rate is critical growth phase where hostile environmental circumstances leads to harmful effect on grain yield and quality. Delay planting face high temperature at the time of maturity and reduced grain filling duration. It has been noted in the recent studies high temperature stress increase rate of stem reservoir mobilization towards grain filling but not reimburse for short grain filling days (Farooq et al., 2011). Due to this reason grain could not reach maximum size ultimately decline in grain yield occured.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20592071

Harvest index

It may be explained as translocation of nutrients from vegetative part to reproductive part. In pooled mean value of both parents and generations, highest reduction percentage was noted in F_2 segregating generation (32.89%) while the lowest percentage was revealed by F_1 (23.62%) of cross Miraj 2008 × Punjab 2011. while in detecting individual performance of parents and generations under normal planting trial F_2 represented (44.10%) highest mean value and BC_2 showed (38.59%) the lowest value, whereas in late planting trial P_2 obtained (32.23%) highest mean value (*Figure 5*). Harvest index deliver fruitful information regarding selection of genotypes in late sowing conditions. It has been noted in literature the genotypes with more harvest index attained more biomass and performed well in delay sowing conditions (Akram, 2011; Mushtaq et al., 2011).

Morphological and yield related traits

The yield associated traits like Plant height (*Figure 6*), tillers number per plant (*Figure 7*) and grain weight per spike (*Figure 8*) were advisedly affected under late sowing conditions. Grain weight per spike revealed maximum decline, as all other yield related traits add up to decrease grain yield in delay planting condition. To select genotypes with optimum plant height with vigorous vegetative growth is painstaking criteria. Tillering in wheat crop help to compensate the yield even though plant population is not met adequately. Number of tillers per plant is reportedly decreased with the onset of late planting due to less growing degree days. Grain weight per spike is more sensitive trait under late sowing conditions.

Gene action

Generation mean analysis was employed to assess the mean [m], additive [d], dominance [h], additive × additive [i], additive × dominance [j] and dominance × dominance [l] gene actions and magnitudes. The best efficacy of model was selected using two things i.e. lowest standard error and non-significant value of chi square χ^2 test for all traits under observation. For the detection of inheritance array in normal conditions for plant height five parameter model was best and vastly presence of additive [d] genetic effect than dominance [h], while the adequacy of three parameter model in late sowing conditions observed best fitted. Additive × additive [i] gene effects were significant. This suggests that selection should be carried out in later generations and the interaction should be fixed by selection under selfing conditions. These results are agreed with the observation of Farshadfar et al. (2001). Ojaghi and Akhundova (2010) noted additive, while conflicting results were depicted by Saleem et al. (2016). For tillers number per plant significant additive genetic effects with epistatic effects were also recorded. Additive × additive [i] interaction is more valuable for genetic improvement of characters through selection. In normal planting condition five [mdhij] and four [mdhi] parameter models in late planting conditions were observed best tailored to explain the genetic variation existed in breeding material for number of tiller per plant. Such type of findings were documented via Badran and Moustafa (2014) and conflicting conclusion were publicized by Ullah et al. (2010) and Rashid et al. (2012). Generation mean analysis revealed that days to heading was governed by polygenes i.e., complex genetic inheritance. The negative magnitude of [i] additive × additive epistatic effect showed in late sowing conditions gene expression not fully expressed in stressed condition and nature of epistasis was duplicate as main additive effect [d] were also reported. Five parameters [mdhij] in late and four [mdhi] parameter models obtained best fit to examine the variation in inheritance pattern (*Table 4*). Zara-Kohan and Heidari (2012) witnessed similar results. They revealed both fixable and non-fixable gene action. According to the nature of treatments in cross for days taken to maturity five parameter model [mdhij] was investigated fit for detection of gene action under both planting conditions. Hybrid breeding is fruitful for selection of trait because

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20592071

prominent dominant [h] effect was paving. In normal planting non fixable gene action somewhat more percentage than fixable gene action.

Additive type of gene action was prominent in grain filling period in normal planting conditions with [i] and [j] epistatic effects but under late planting conditions change in gene action was witnessed (*Table 4*). It viewed under the effect of environment and duplicate type of epistasis was found because of main dominance effect [h] and epistatic dominance × dominant [l] effect had opposite sign under late planting time. The similar situation was examined by Nazeer et al. (2004). Zara-Kohan and Heidari (2012) reported selection in stable generation would be fruitful due to governing of non-fixable type of gene action for this parameter. For the inheritance of grain filing rate under late planting conditions four parameter model [mdhl] was found best fit (*Table 4*).

Table 4. *Estimates of the best fit model for generation means parameters (±, standard error) by weighted least squares analysis in cross Miraj 2008 × Punjab 2011 under normal and late sowing conditions*

N = normal sowing, L= late sowing conditions

Due to presence of non-allelic interaction this attribute was governed by multiple genes. Hybrid breeding is done for the improvement of grain filling rate due to presence of dominance component [*h*]. To obtain maximum grain filing rate selection could be done in succeeded generations. These results are lined with Nazeer et al. (2010) and clashing conclusions obtained by Ullah et al. (2010). For harvest index five parameters models i.e. [mdhij] and [mdhil] were found best fit under both normal and late planting environments. In late sowing condition [i] epistatic gene action showed negative sign which exhibited that gene interacting with one another (*Table 4*). Due to presence of main dominance effect [h] and dominant × dominant [l] selection can also performed in later generation and also hybrid breeding for harvest index would be fruitful. Farshadfar

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20592071

et al. (2001) displayed same type of conclusion while. Grain weight per spike five parameter model [mdhjl] was adequate to elucidate the gene inheritance in late planting environment (*Table 4*). In order to attain higher grain weight per spike selection in succeeded generation could be helpful. Parallel results are confirmation with Amin (2006) and El-Rahman (2013).

Heritability studies

Estimation of heritability is another important estimate in order to understand the potential of characters to be improved through selection and also tells about the possibility of accumulation of favorable gene in the successive generation after selection. It also indicates the amount of genetic variability relative to environmental affects and is considered a good index of transmission of characters from parents to their offspring. Under normal sowing conditions range of narrow sense heritability was from 0.35 to 0.90 (*Table 5*). Most of the examined traits revealed moderate to high heritability except grain filling rate and grain weight per spike. The range (0.23 to 0.71) was observed under late sowing conditions (*Table 5*). Low to medium narrow-sense heritability can be attributed to the reduction of genetic variability in the late sowing environment. The higher heritability value will make the selection process effective, which will result in higher response. Selection of traits with high heritability in early generation is more fruitful. Abinasa et al. (2011) and Saleem et al. (2016) found high heritability for plant height, days to heading and days to maturity. While moderate type of heritability was observed by Nazeer et al. (2010). Zara-Kohan and Heidari (2012) and Khan and Naqvi (2011) have also noted high heritability for grain filling period. The reduction in heritability value under late sowing conditions indicated that gene responsible for the heritability of trait do not expressed themselves strongly in late sowing. Usually late sowing produce early senescence hence decrease in grain filling period causing reduction in yield. Therefore the genotypes which have longer grain filling period under stress conditions would be better yielder.

Table 5. *Estimation of narrow sense heritability of different traits under studied*

Traits	Normal sowing	Late sowing
Plant height	0.90	0.67
Tiller number per plant	0.76	0.23
Days to heading	0.89	0.71
Days to maturity	0.78	0.55
Grain filling duration	0.64	0.26
Harvest index	0.62	0.65
Grain filling rate	0.35	0.33
Grain weight per spike	0.47	0.41

Conclusion

Optimum sowing date for any cultivar is very crucial to accumulate ample dry matter and grain weight per spike yet to elude potential yield losses form high temperature stress during critical time mainly flowering initiation to grain filling stage. Genetic analysis showed that all traits under study were under the control of complex inheritance due to presence of epistasis. So, selection for these traits would be done in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20592071

later generations when combinations fixed. The phenological traits grain filling rate, grain filling duration and harvest index considered pivotal for the development of genotypes in late sowing conditions. So, for efficient breeding utilization of these phenological traits like grain filling rate, grain filling duration and harvest index are necessary to improve crop yield for late sowing wheat areas.

(Received 7th Nov 2018; accepted 11th Jan 2019)

Abstract. In this study, in order to investigate the diversity of fungi in the roots of *Machilus pauhoi* in different age, we investigated the fungi diversity and community structure in the roots of *Machilus pauhoi* in the age of 2-year-old, 5-year-old, 8-year-old and 20-year-old by Illumina Hiseq sequencing platform. 424 fungi operational taxonomic units (OTU) were obtained. There was no significant difference in fungi abundance and diversity index between the age of 2-year-old, 5-year-old and 20-year-old, but they were higher than those in the age of 8-year-old. On phylum level, *Ascomycota*, *Basidiomycota* and *Glomeromycota* were the dominant species with a relative abundance of more than 1%. Besides, with the increase of age, the fungi community in the roots of *Machilus pauhoi* showed a certain degree of change while then decreased to the equivalent level in the young age. On genus level, *Clitocybula*, *Chaetosphaeria*, *Phylchara* and *Ochroconis* were the dominant species, accounting for more than 10% of the investigated species. The specific species of *Phyllachora* appeared in the highest proportion in 8-year-old roots. Abundance heat map analysis showed that the fungi communities in the 2-year-old and 20-year-old roots were clustered into one category and those in the 5-year-old and 8-year-old were classified as another group. These results indicated that the fungi community in the roots of *Machilus pauhoi* was greatly affected by the growth age.
Keywords: *endophytic fungi, high throughput sequencing, relative abundance, Venn diagram, phylogenetic tree analysis*

Introduction

Soil microbes are the basis for the recycling and utilization of materials in ecosystems and are also a guarantee for the stability and normal functions of ecosystems (Chapin et al., 1997). Soil, as a site for soil microbial activity, has an important impact on microbial community and activity (Jeanbille et al., 2016; Kuramae et al., 2011). Fungi in soils play a huge role in improving the plant stress resistance and maintaining normal plant growth (Mukerji et al., 1996; Smith et al., 1999). Endophytic fungi in roots mainly results from soil microorganisms infection when contacting with soil. Soil fungi are closely related to plant growth and can affect the health and productivity of plants. As an important part of the whole plant, the endophytic fungi play a very important role in plant growth, development, accumulation of secondary metabolites and adaptation to the environment (Vandenkoornhuyse et al., 2015). Some species can enhance the resistance and daptability of the host (Kaushik et al., 2013; Iranshahi et al., 2016; Zhao et al., 2013; Kumar et al., 2013) and promote the uptake of nitrogen, phosphorus and other elements (Rodrigue et al., 2004; Azevedo et al., 2000). Some have no significant effect on plants, neither attacking plants nor promoting plant growth (Rout, 2014). And some are latent in plant tissues and remain dormant. When plants suffer from physiological and biochemical dysfunction caused by changes in the external environment, they become active to attack plants (Petrini, 1991). Endophytic fungi are

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20732083

ubiquitous in a variety of plants. However, in over ten thousand kinds of plants on the earth, only hundreds of endophytic fungi have been studied (Stone et al., 2000). In addition, the distribution of endophytic fungi in the host is often affected by various factors such as the forest age, season, altitude, and sampling number (Schmit et al., 2004).

Machilus pauhoi belongs to Lauraceae, Machilus Nees, which is a large evergreen tree with rapid growth and adaptability. It is a national second-class protected plant with high economic value in both wood and seeds (Guo et al., 2017). Because of its important ecological and economical value, *Machilus pauhoi* has been listed as a key tree species by Guangxi Forestry Department. It is worthy of vigorous promotion in depth (Wei et al., 2011). At present, there are few studies on *Machilus pauhoi* at home and abroad, and most of articles only briefly describe the cultivation techniques, ecological characteristics and basic measures for afforestation (Zhong et al., 2009). However, the effects of growth age on the diversity and community of fungi in the roots of *Machilus pauhoi* have not been reported. In addition, through field investigations, after 5 to 6 years of growth, yellow, brown to black irregular shape lesions appear in large areas of leaves, stems and other parts above ground, and sometimes the whole leaves are even covered by black spots, which form a black-colored convex stroma, seriously inhibiting the photosynthesis of the plant. As a result, a significant part of the plant would die, greatly reducing the survival rate of the *Machilus pauhoi*. Whether this phenomenon is related to some pathogens in the roots of the *Machilus pauhoi* is worth exploring.

At present, many researchers at home and abroad are committed to the restoration and reconstruction of fragile or degraded ecosystems, and plantations have become a better means of repair (Rappaport et al., 2014). It is necessary to restore the plants on the ground and the functional microorganisms underground that are symbiotic with plants. Given to the universal distribution of endophytic fungi in terrestrial ecosystems, the diversity of ecological functions and their important roles in the restoration and reconstruction of degraded ecosystems, and taking into account the development potential and economic value of *Machilus pauhoi*, this research studied the cultivated *Machilus pauhoi* in different age groups in Yangshan County, Qingyuan City, Guangdong Province, China for the first time. The high-throughput sequencing technology was used to reveal the diversity of fungi in the roots of *Machilus pauhoi* in different developmental stages. This study helped to screen the mycorrhizal fungi which could promote the growth of *Machilus pauhoi.* Besides, it can effectively guide the introduction and cultivation application of *Machilus pauhoi*. At the same time, it is necessary to explore whether the scabs formed in *Machilus pauhoi* are related to certain pathogens. The results of this study not only help to understand the role and status of soil microbes in the different growth years of *Machilus pauhoi*, but also provide a theoretical basis for the sustainable management of *Machilus pauhoi*.

Materials and methods

Overview of the study area

The plantation forest of *Machilus pauhoi* is located in Yangshan County, Qingyuan City, Guangdong Province, China (N24°26’, E112°36’), which belongs to the monsoon climate zone with transition from south subtropical to mid-subtropical. The annual

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20732083

average temperature is 20.3 °C, and the average annual rainfall is about 1850 mm. The altitude is in the range of 10 to 270 m, and the soil type is mainly red soil.

The original study area is mainly mountain rain forest. However, it has been damaged by human activities for a long time, resulting in secondary forests and extremely irregular physiognomy. Since 1995, the artificial test plantation of *Machilus pauhoi* has been constructed with similar site conditions. At present, there are four different developmental stages of *Machilus pauhoi* plantation with forest ages of 2 years, 5 years, 8 years and 20 years respectively. The site conditions of the plots of the test plantation were basically the same, and the row spacing was 3×3 m. A map indicating the location of sampling site was given (see *Fig. 1,* which was generated by Google earth). Some photos about the habitat of experimental sites are also given in *Figure 2*.

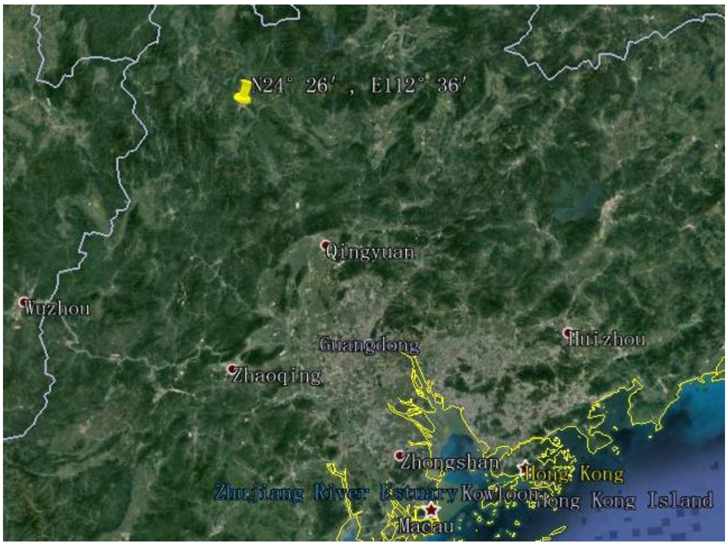

Figure 1. *GPS coordinates of the sampling site*

Figure 2. *Habitat of the experimental sites*

Sampling method

In October 2017, root samples at 4 different stages of development, i.e., 2a, 5a, 8a and 20a, were selected as the research objects from the test plantation. In order to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20732083

reduce the error, each sample was selected in random and three parallel samples were selected. The samples of the 2a *Machilus pauhoi* were numbered as 2YR.1, 2YR.2, 2YR.3, and the 5a *Machilus pauhoi* were numbered as 5YR.1, 5YR.2, 5YR.3, 8a *Machilus pauhoi* were numbered as 8YR.1, 8YR.2, 8YR.3, and the 20a *Machilus pauhoi* were numbered as 20YR.1, 20YR.2, and 20YR.3, respectively. When selecting samples, the end part of taproots with low lignification degree were collected. Root samples were cut into 2-3 cm long segments first, then rinsed with tap water, then rinsed with distilled water, then soaked in 0.1% mercury bichloride for 5-10 min, then rinsed with distilled water, then soaked in 75% alcohol for about 20 s, then rinsed with distilled water, then dried with silica gel in aseptic self-sealing bags and marked, and then stored in a refrigerator at 4 °C. A total of 12 *Machilus pauhoi* samples were collected.

High-throughput sequencing methods

In this study, high-throughput sequencing technology was used. DNA samples were extracted from root samples with the kit (Plant Genomic DNA Kit, Tiangen, China) using the modified Cetyl Trimethyl Ammonium Ammonium Bromide (CTAB) method (Guo et al., 2000). The concentration and purity of the extracted DNA were measured by spectrophotometer (Thermoelectric Corporation, USA). The integrity of the DNA sample was measured by 0.8% agarose gel electrophoresis at a voltage of 120 V and an electrophoresis time of about 20 mins.

30 μL PCR reaction system: 15 μL of Phusion Master Mix (2×), 3 μL of Primer (2 μmol/L), 10 μL of gDNA (1 ng/μL), and 2 μL of H_2O. The amplification procedure: pre-denaturation at 98 °C for 1 min; 30 cycles including denaturation at 98 °C for 10 s; annealing at 50 °C for 30 s; extension at 72 °C for 30 s; and extension at 72 °C for 5 min. Library preparation, homogenization, detection, computer sequencing and data quality control were all completed by Guangzhou Meg Biotechnology Co., Ltd.

The phylum and genus level was identified based on the alignments of majorizing sequence and reference sequence in the database. The uclust del method (Caron et al., 2009) was used to cluster OTUs with high-quality sequences with a similarity ≥ 97%. According to the results of cluster analysis, alpha diversity analysis was carried out. The Observed species index and the Chao1 index reflect the richness of the community in the sample, that is, simply refer to the number of species in the community (the number of OTUs); the Shannon index and the Simpson index reflect the diversity of the community, and are affected by species richness and species uniformity in the sample community. The results were processed and bioinformatics analysis was carried out using Microsoft Excel 2013 and R 3.4.2 software (Knezevic et al., 2007).

Results and analysis

Sequencing depth evaluation

12 fungi samples were sequenced and a total of 557,906 sequences were obtained after sequence optimization. The sequences were randomly selected. Curves of the number of selected sequences versus the number of OTUs they represent were drawn. The OTU was clustered at 97% similarity level and the rarefaction curves of each sample was prepared (*Fig. 3*). The curves gradually flatten indicating a reasonable number of sequencing.

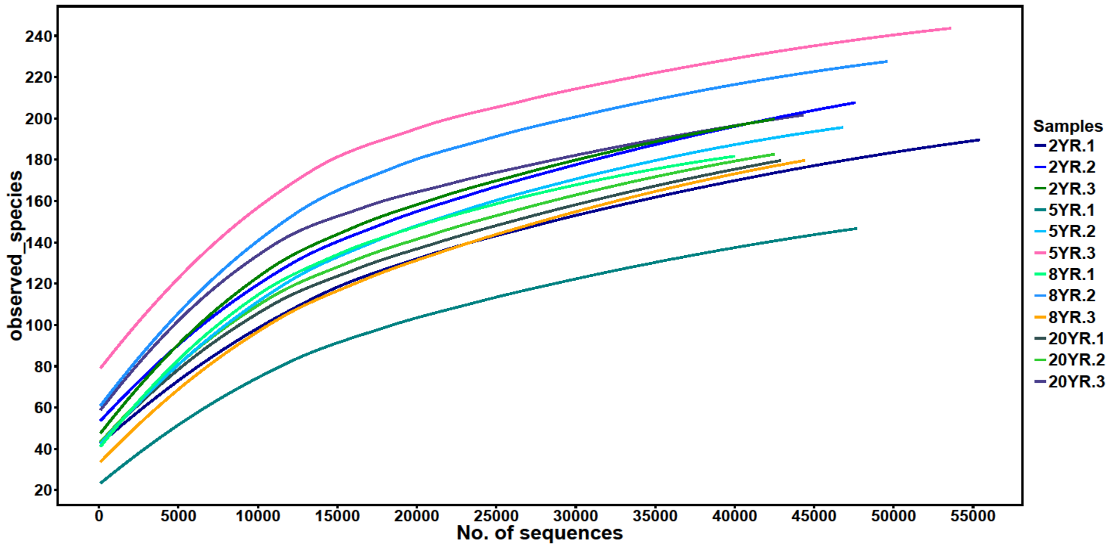

Figure 3. *Rarefaction curves of roots of Machilus pauhoi*

Fungi diversity and OTUs in roots of Machilus pauhoi in different age groups

It can be seen from *Table 1* that the fungi richness and diversity index in the roots of 8a *Machilus pauhoi* are significantly lower than the other three ages. However, there is no significant difference in the abundance and diversity index of fungi communities in the roots of the 2a, 5a and 20a *Machilus pauhoi*.

Table 1. *Diversity indexes of fungi in roots of Machilus pauhoi in different age groups*

Treatment	Observed species index	Chao1 index	Shannon index	Simpson index
2a	183.67±11.72a	270.9±14.11a	3.16±0.04a	0.78±0.04a
5a	187.00±15.59a	269.02±31.96a	3.17±0.3a	0.77±0.09a
8a	165.33±16.06b	223.32±19.3b	2.11±1.91b	0.40±0.38b
20a	190.33±22.68a	251.65±24.47a	3.31±0.58a	0.82±0.05a

According to the Venn diagram (*Fig. 4*), which represents the relationship between the number of OTUs in the roots of *Machilus pauhoi* in different age, 424 fungi OTUs were obtained from all samples in 4 age groups, including 223 in the second year, 233 in fifth year, 216 in eighth year and 220 in twentieth year. The unique OTUs in the roots of 2a, 5a, 8a and 20a *Machilus pauhoi* are: 53, 47, 50 and 51, accounting for 12.50%, 11.08%, 11.79% and 12.03% of the total OTU, respectively. There are 106 OTUs shared by samples in different age groups, accounting for 25.0% of the total number of OTUs. The common OTU in the roots of *Machilus pauhoi* in fifth year and eighth year is the most, up to 151. And the common OTUs in the roots of *Machilus pauhoi* in second year and twentieth year is the least as 135. The common OTUs shared by other age groups are: 141 OTUs for the second and fifth year, 143 OTUs for the second and eighth year, 147 OTUs for the twentieth and fifth year, and 135 OTUs for the twentieth and eighth year.

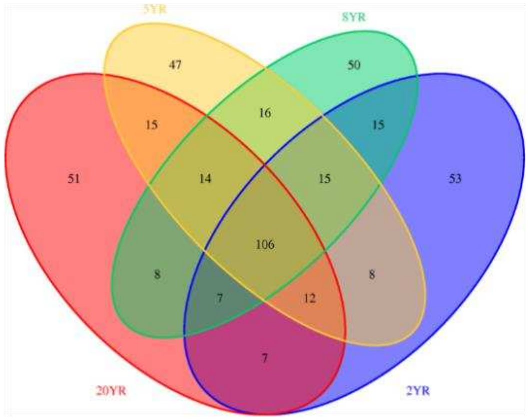

***Figure 4.** OTU Venn diagram of root samples in various age groups of stand*

Analysis of fungi community in roots of Machilus pauhoi in different age groups

At the phylum level, there are 3 species with relative abundance more than 1%. *Ascomycota* fungi accounts for the highest proportion (60.98%), followed by *Basidiomycota* fungi (33.62%), and *Glomeromycota* fungi accounts for the smallest proportion (2.74%). According to the analysis of the proportion of all kinds of fungi, the fungi community in roots of *Machilus pauhoi* in different age groups presents a significant change (*Fig. 5*). From the interannual variation, in the roots of 5a *Machilus pauhoi*, the relative abundance of *Basidiomycota* is the highest while that of *Ascomycota* is the lowest. However, in the case of the roots of 8a *Machilus pauhoi* is the exact opposite. The relative abundance of *Glomeromycota* increases first and then decreases with the growth age. Compared with the 20a *Machilus pauhoi*, the fungi community in the roots of the 2a *Machilus pauhoi* has little change. On the whole, with the increase of growth age, the fungi community in the roots of *Machilus pauhoi* shows a certain degree of change and then returns to the similar structure in the young age (2a) at the phylum level.

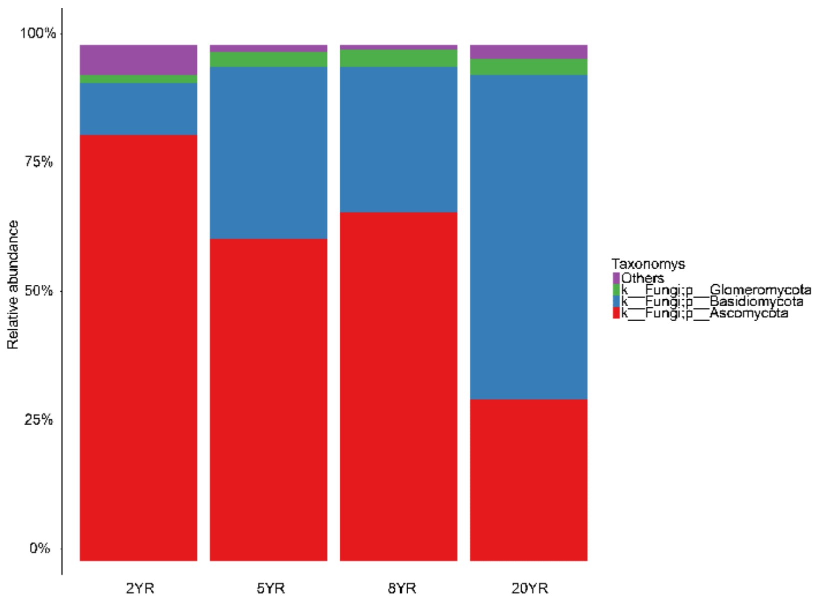

***Figure 5.** Composition of fungi community at a phylum level*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20732083

At the genus level, in each community, there were 8 genera with the relative abundance more than 1% in the roots of *Machilus pauhoi* (*Fig. 6*): *Archaehorhizomyces*, *Chaetosphaeria*, *Clitocybula*, *Capronia*, *Muyocopron*, *Ochroconis*, *Parascutellinia* and *Phylchara*. Among them, *Clitocybula*, *Chaetosphaeria*, *Phylchara* and *Ochroconis* were dominant species, accounting for 36.16%, 21.54%, 11.31% and 19.11%, respectively. From the perspective of interannual variation, the composition of fungi communities in roots of *Machilus pauhoi* in different age groups also changes significantly (*Fig. 4*). The relative abundance of Clitocybula first increases and then decreases and further increases to the peak level at 20a. The relative abundance of *Ochroconis* decreases first, then increases and then decreases. The relative abundance of *Chaetosphaeria* increases with the extension of the growth age. The relative abundance of *Parascutellinia* does not change much with the increase of growth age. The relative abundance of *Capronia* is small, which appears to decrease first and then increase with the increase of growth age. *Archaeorhizomyces* has a relatively low abundance at young age, and reaches the maximum value after 20 years. It is worth noting that *Phylchara* only appears in the roots of 8a *Machilus pauhoi*, and ranks the largest proportion of each species.

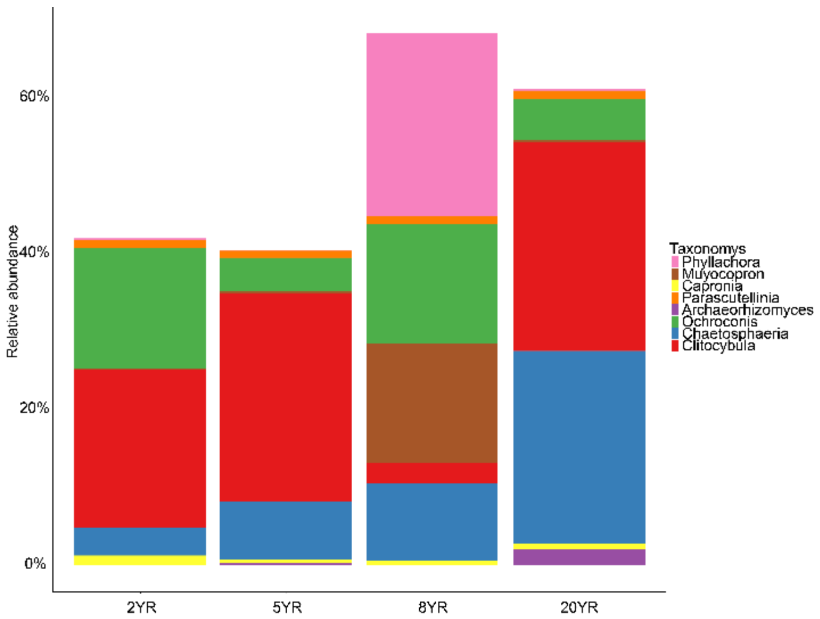

Figure 6. *Composition of fungi community at a genus level*

The relative abundance distribution of fungi in roots of Machilus pauhoi in different age groups

In terms of their abundance, the top 30 species are selected (all species are selected if there are less than 30 species). The relative abundance of fungi in the roots of *Machilus pauhoi* of different age groups are clustered based on their average abundance of different growth age at both the phylum and genus level, and the heatmap is obtained (*Fig. 7*). At phylum level, *Blastocladiomycota* and *Annelida* are most abundant in the roots of 20a *Machilus pauhoi*; *Basidiomycota* and *Chytridiomycota* are most abundant in the roots of 5a *Machilus pauhoi*; *Arthropoda* is most abundant in the roots of 2a *Machilus pauhoi* and *Kickxellomycotina* and *Zoopagomycotina* are most abundant in the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20732083

roots of 20a *Machilus pauhoi*. The genera with high relatively abundances in each sample are also different: *Chaetosphaeria*, *Capnobotryella*, *Phomopsis*, *Archaehorhizomyces*, *Henningsomyces* and *Heleiosa* are most abundant in the roots of 20a *Machilus pauhoi*; *Capronia*, *Phaeococcomyces* and *Pyxidiophora* are most abundant in the roots of 2a *Machilus pauhoi Camarophyllopsis*, *Cladochytrium* and *Boudiera* are most abundant in the roots of 5a *Machilus pauhoi* and *Conioscyphascus*, *Papulosa*, *Atractiella*, *Muyocopron*, *Phylchara* and *Galactomyces* are most abundant in the roots of 8a *Machilus pauhoi*, which indicates a difference in the abundance of fungi in the roots of *Machilus pauhoi* in different age groups. Due to the high similarity between the 2a and the 20 samples, they are grouped together. For the same reason, 5a and 8a samples are clustered as one group.

Discussion

High-throughput sequencing accurately reflects the composition and proportion of the fungi with different abundance in the roots of *Machilus pauhoi*, especially the species with low abundance, and objectively and comprehensively reveals the fungi structure in the roots in different age groups, making contributions to enriching plant endophytic resources and giving full play to high-throughput sequencing.

In this study, based on the Illumina Miseq sequencing platform, the diversity of fungi in the roots of *Machilus pauhoi* has been successfully detected, and a large amount of comprehensive and in-depth information on the fungi communities has been obtained. A total of 557,906 optimized sequences and 424 OTUs were obtained. A total of 10 fungi phyla and 32 genera were separated from the samples in different age groups. The rarefaction curves analyzed the sampling depth of root samples of different age groups. The number of OTUs in each sample presented the same or similar variation trend, that was, with the increase of sequencing depth, the increase of OTU number tended to slow down and eventually, reached basic saturation.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20732083

The *Machilus pauhoi* in this study were in the same plantation but in different age groups, so the environmental difference was very small. The air humidity, climate, temperature, latitude and longitude, altitude, soil pH and concentrations of N, P, K and other soils in the same area were basically the same. During the experiment, a unified experimental method and data analysis method were employed. Therefore, the growth age became the dominant factor in the diversity of fungi in the roots of *Machilus pauhoi*.

A total of 424 fungi OTUs were obtained from *Machilus pauhoi* in 4 different age groups. According to the Venn diagram (*Fig. 4*), in the second and eighth year, the number of OTU is large, but it is small in fifth and twentieth year. With the increase of growth age, the fungi abundance and diversity index decreases first and then increases, reaching minimum value in the eighth year. In the analysis of community structure, with the increase of the age, the community structure of endophytic fungi in the roots of *Machilus pauhoi* changes dramatically. In the cluster analysis of relative abundance in different age groups, the fungi in 2a and 20a samples are clustered as one group and fungi in 5a and 8a samples are grouped together, indicating that the composition of endophytic fungi in second and twentieth year is more similar but is different from that in the fifth and eighth year. The results indicate that, with the increase of age, the fungi community in the roots of *Machilus pauhoi* changes to a certain degree and then goes back to the young age.

Through the above results, it can be clearly seen that there are a large number of endophytic fungi colonization with great diversity in the roots of *Machilus pauhoi* in the plantation. However, with the growth and development of *Machilus pauhoi*, endophytic fungi colonized in its roots have undergone certain changes, which might be related to the regulation of plants themselves in the process of adapting to the environment. When the plant was initially planted in the plantation field, there were lots of endophytic fungi in the roots. However, as the growth and development of plant and adaption to the environment, the number of competitive relationships among endophytic fungi colonized in the roots decreases. Then, after the plants slowly adapt to the surrounding environment, some fungi have established stable parasitic relationships with plants. Therefore, the number of fungi colonized in the roots of the plants increases.

It is worth noting that the characteristic genus, *Phylchara*, appears in the roots of 8a *Machilus pauhoi*, and its relative abundance is the highest among all species. This might be related to the decline in quality and productivity in forest land soil. *Ascomycotina*, *Ascomycetes*, *Phyllachorales*, and *Phyllachoraceae* are a class of obligate parasitic vegetative fungi (Mccoy et al., 2018; Denman et al., 1999). The *Phyllachora* fungi are widely distributed in plants in tropical and subtropical regions. *Phyllachora graminis* is a main kind of plant disease for precious tropical native species in Hainan Province, such as *Dalbergia odorifera*, *Pterocarpus macrocarpus*, and *Pterocarpus santalinus* (Liu et al., 2016). Combined with the symptoms of *Phyllachora graminis* (Levente et al., 2018; Reddell et al., 1999; Egham et al., 1992), it can speculate that the scabs formed on *Machilus pauhoi* might be related to these species, but further experimental verification is needed. Moreover, the reduction of fungal community diversity in eighth year might be related to the dominant position of phytopathogenic fungi.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20732083

Conclusions

This study, for the first time, used high-throughput sequencing method to study the fungi community structure in the roots of *Machilus pauhoi*, a secondary protected plant, in the experimental forest in Yangshan County, Qingyuan City, Guangdong Province. The results show that endophytic fungi in the roots have a great diversity and great research value. The dominant species are *Ascomycota* and *Basidiomycota* at phylum level and *Clitocybula*. *Ochroconis* and *Chaetosphaeria* at genus level. With the increase of the age, the fungi abundance and diversity index decreases first and then increases. *Phylchara*, might be related to scabs formed on *Machilus pauhoi*, appears in the roots of 8a *Machilus pauhoi.* These conclusions can provide a theoretical basis for the protection of the community of *Machilus pauhoi*. Personally, the experiment only focused on the change of fungal community structure, ignoring the effect of other factors such as bacteria. Future researches should carry out multiple factors analysis and comparative experiments to explore the regulatory relationship between other factors such as microorganisms, insects and human activities destruction and the structure and function of the fungal.

Abstract. Responses of trophic structure to reservoir regulation are important to manage and conserve the river ecosystem influenced by dams. We used stable isotope-derived community-wide metrics to describe spatiotemporal variation in trophic niches and trophic structures of fish assemblages in a tributary of the Three Gorges Reservoir (TGR) in China where water level regulation is put into operation annually. A longitudinally increasing trophic space was discovered in this tributary especially when the water level was low. Trophic diversity declined and trophic redundancy increased from the non-flood period to flood season at the upper backwater region. However, trophic space was more stable in the estuarine site. The site differences were associated with availability of food resource and pathway of consumers, as specifically, disturbance derived from flow pulse at the end of backwater site altered diet composition of the fish consumers, while immense water body in the lower confluence area limited the flood influences as well as promoted exploitation of diverse available sources. Moreover, the declined water level control facilitated the contraction of the trophic niche size at the tail backwater site because of remarkable riverine morphology alternation leading to decreasing water body whereas the rising water level regulation homogenized trophic structure along the downstream river. Our study revealed that there was different response of fish assemblages along longitudinal fluvial gradient to the water level regulation in the reservoir and targeted management and conservation measures are needed for the different sections of the tributary.

Keywords: *reservoir regulation, stable isotope, community metrics, pathway, food resource*

Introduction

For purposes of flood control, power generation and/or navigation, dams have been constructed on the majority of large rivers globally since the last century (Avakyan and Iakovleva, 1998) and these river systems have been affected spatiotemporally to varying

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20852104

extent (Nilsson et al., 2005). By altering thermal and flow regimes as well as sediment transport (Kondolf, 1997; Graf, 2006), the presence of dams leads to subsequent changes in biotic assemblages (Cumming, 2004; Freedman et al., 2014) and contributions of allochthonous and autochthonous nutrients (Doi et al., 2008; Sabo et al., 2018). As a result, a variety of trophic shifts may occur resulting in alteration for trophic diversity and food web structure (Mercado-Silva et al., 2009; Growns et al., 2014; Kaymak et al., 2018), which ultimately affect river ecosystems function. Although numerous studies have been devoted to understanding how dams influence biodiversity and food-web interactions (Holmquist et al., 1998; Bunn and Arthington, 2002; Cross et al., 2011), responses of rivers and river ecosystems to dams are intricately varied and usually show contrasting results (Growns et al., 2014), as they depend on local geomorphic, hydrological and biologic attributes (Power et al., 1996).

Tributaries could promote the function of large river ecosystems, such as enhancing the overall biodiversity of large rivers (Fernandes et al., 2004), resetting the ecological continuum of the mainstem (Kiffney et al., 2006), and maintaining fish reproductive success with retained natural flow regime (Pracheil et al., 2009). Certain tributaries can sometimes serve as a sanctuary for many indigenous species after the mainstem has been altered by dams (Park et al., 2003; Pracheil et al., 2013). Hence, tributaries, by virtue of lower degree of alteration could provide underappreciated opportunities for conserving biodiversity (Pracheil et al., 2013) especially in the impounded reaches where lotic species are more susceptible to environmental changes. However, much research focuses on downstream effects (Cross et al., 2011; Sabo et al., 2018) or on longitudinal patterns of the river continuum (Mercado-Silva et al., 2009; Cross et al., 2013; Growns et al., 2014) from the dam. There is a paucity of information pertaining to variation in trophic diversity in the upper tributaries which are also influenced by the regulated reservoir.

The Three Gorges Dam (TGD) is built in the middle of the Yangtze River, the largest river in China, and has created a reservoir 600 km long with a total storage capacity approaching 40 billion m^3. The dam has been put into operation in 2003 and filled initially up to 175 m, the normal pool level, in 2010. Since then, the reservoir would be drawn down to 145 m water level during the flood season (May-September) for flood control, and impounded to 175 m water level after the flood season and maintained until the next year for power generation and navigation. In the Three Gorges Reservoir (TGR) region, six tributaries with the watershed area larger than 3000 km^2 (ten tributaries more than 1000 km^2) flow into the Yangtze River. These tributaries have supported the mainstream biodiversity and possess the potential to be suitable refuges for the affected biota (Park et al., 2003). However, the same water fluctuation cycle as the mainstream occur at the lower reaches influencing the fish assemblages (Yang et al., 2013; Zhao et al., 2015) and thus would likely impact the energy flow and trophic structure as well. The Daning River is one of these important tributaries with less damaged natural landscape in particular in the pristine upper reaches. Previous study has analyzed whether the impoundment affected assimilation of carbon sources by fish consumers in this tributary (Deng et al., 2018). Isotope mixing model results indicated that riparian C_3

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20852104

plants are the consistently major energy source for fish consumers irrespective of reaches or feeding strategies because of abundant standing stock of riparian vegetation and hydrologic regimes in this river (Deng et al., 2018). This tributary suffers the same hydrological regulation in the backwater accompanied by seasonal flood flows from the uppers as other tributaries in TGR. However, trophic structure shifts on account of spatiotemporal variation in environmental conditions are still unknown. The present study extends previous research on the Daning River to explore the effects of water level regulation on food web structure of local fish assemblages.

Stable isotopes, providing a concrete quantitative measure of niche width and trophic diversity (Bearhop et al., 2004; Layman et al., 2007a; Schmidt et al., 2007; Jackson et al., 2011), are widely used to examine structural features and variations of food webs influenced by species invasion (Jackson et al., 2012), overexploitation recovery (Hamilton et al., 2014), land use (de Carvalho et al., 2017), river fragmentation (Freedman et al., 2014; Kaymak et al., 2018). In this study, we employed stable isotope-derived community metrics to describe and compare trophic diversity of fish assemblages among sites and between periods. The purpose of this study was to examine the spatiotemporal variation in trophic niches and trophic structures of fish assemblages and further how local food webs responded to changes in the environmental conditions enhanced by hydrological regulation. We hypothesized that trophic niches size of fish assemblage increased along longitudinal gradient within the tributary due to the enlarged water body and the effects of flood flow on structure diversity would mitigate by water level conditions. The study on spatiotemporal variation of food web structure in association with flood flows and water level fluctuation in this important tributary could help provide the necessary references for understanding how reservoir regulation could affect overall river systems in the region. Further, this information could be benefit to ongoing management and conservation efforts in the tributaries alike.

Materials and Methods

Study sites and sampling design

This study was conducted in the Daning River, a tributary of the Yangtze River, located in the central part of the Three Gorges Reservoir (*Fig. S1*) in China. The tributary watershed covers an area of 4426 km^2, and is 200 km long with 47-60 km backwater channel due to the impoundment of TGR. The backwater area vary in length and depth according to the hydrologic regulation of the TGR. The river is canyon bound scattering several open sections with less steep slopes where both C_3 and C_4 vegetation dominate the riparian areas. The valley has subtropical humid monsoon climate with mean average temperature of 16.6°C and an annual mean precipitation of 1124.5 mm, about 80% of which falls in May-October. As a result, the maximum flow in the river is generally observed from June to September (*Fig. 1*).

DOI: http://dx.doi.org/10.15666/aeer/1702_20852104

Three sites representing the estuary area (Wushan), the end of the backwater water region (Dachang) and the natural fluvial site (Wuxi) were selected for sampling (*Fig. S1*, *Table 1*). The Wushan site is located in the confluence to the reservoir, 123 km upstream of the Three Gorges Dam. This site is characterized by steep littoral zones with little vegetation cover because of the populated areas. The estuary water area is nearly 1.2 km wide and 55 m deep at the lowest water level and 1.3 km wide, 68 deep when the water level rises to 175 m (*Table 1*). The Dachang site is located 45 km above the estuary, near the end of the backwater water. In this zone, the channel is wider with less steep slopes, which forms 9 km^2 lacustrine environment with the depth of 33 m at the highest water level (*Table 1*).

During the lower water levels, however, large lateral habitats characterized by muddy substrates expose out of the water and dense macrophyte mats would appear along the littoral zone. The Wuxi site is an upstream site where riverine system has not yet affected by the TGR. The section is characterized by lotic and shallow habitats with the substrate dominated by rock and cobble. Due to pronounced seasonality in rainfall, highest annual river discharges typically occur from June to September with an average

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20852104

of 122 m^3/s and the average discharge drops to 34 m^3/s between October to May (*Fig. 1*). According to the water-level regulation in the TGR as well as river monthly discharges from Wuxi hydrologic gauge station, two sampling periods that reflected strong seasonal patterns in precipitation, water-level and thus, the potential for observing changes in trophic structure of fish assemblages were chosen (*Fig. 1*). In order to detect temporal differences in trophic structure based on consumer stable isotope composition, enough time need for muscle tissue to reflect any new diet (Abrantes et al., 2014). At each period, consumers were living for more than two or three months under that condition before sampling (Boecklen et al., 2011; Abrantes et al., 2014). Therefore, in the Daning River, fishes collected in September-October were referred as samples from the flood period and in December-May were referred as from the non-flood period (*Fig. 1*). All the data we used were collected from 2011 to 2013 and were classified into two periods.

Sample collection and analysis

Fish were collected from the river using 2 m by 50 m gillnets with different mesh sizes (30, 60, 80 and 120 mm). After captured, the number and weight of fish species collected were recorded. Fish were classified into five trophic groups based on available literature in Daning river (The Fish Laboratory, 1976; Zeng, 1990; Ding, 1994), which included planktivores, herbivores, benthivores, omnivores and piscivores (*Table S1*). A total of 68 fish species in this tributary were captured in our several surveys. However, the most dominant species from the different trophic groups were selected for isotopic analysis based on the abundance and frequency of capture in the surveys (Yang et al., 2013) so that the species analysed at each site during each period represented well their trophic groups. For each species, only large adult individuals were selected in case of the influence of ontogenetic diet shifts on isotopic value. For selected individuals, fish were weighed (g), measured (mm), and dissected to extract approximately 5–10 g of dorsal muscle tissue for isotopic analysis. Samples of basal carbon sources were also collected and detailed information are described in Deng et al. (2018).

All fish samples were dried at 60 °C for at least 48 h and ground into a fine powder and stored in glass vials. Carbon and nitrogen stable isotopic analysis was done at the Stable Isotope Laboratory, Chinese Academy of Forestry, Beijing, China, using a Flash EA1112 HT Elemental Analyzer coupled to a DELTA V Advantage Isotope Ratio Mass Spectrometer. Stable isotope ratios are expressed as delta (δ) and defined as parts per thousand (‰) relative to the laboratory standard material. The ratios is calculated by *Equation 1*:

$$\delta X = (R_{\mathrm{sample}} - R_{standard})/R_{standard} \times 10^3‰ \quad \text{(Eq.1)}$$

where X is ^{13}C and ^{15}N and R is the corresponding ratio $^{13}C/^{12}C$ or $^{15}N/^{14}N$. R is the molar ratio of the heavy to light isotope of the sample and standard (‰). The standard

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20852104

material used for carbon and nitrogen are Pee Dee Belemnite (PDB) limestone and atmospheric nitrogen. Precision of the isotopic analysis was 0.1‰ for carbon and 0.2‰ for nitrogen.

Data analysis

Five quantitative community-wide metrics derived from stable isotope data (Layman et al., 2007a) were used to describe variation in trophic structure of fish assemblages at each site during each period. Because not all species occurred at all sites, analyses were based on fish trophic guilds. Three of these metrics are community-wide measures of trophic diversity, including $\delta^{13}C$ range (CR), which depicts basal source diversity, $\delta^{15}N$ range (NR), which gives information on trophic length, and mean distance to centroid (CD), which is calculated as the mean Euclidean distance of each assemblage component to the centroid and a measure of the average degree of trophic diversity within the assemblage (Layman et al., 2007a). Two additional metrics reflect the extent of trophic redundancy, namely mean nearest neighbour distance (NND) and standard deviation of the nearest neighbor distance (SDNND). MNND is an estimate of density and clustering of species within the community and SDNND measures the evenness of the groups' spacing in the bi-plot space (Masese et al., 2018). Smaller NND and SDNND indicate greater trophic redundancy, which means, groups have more similar trophic niches (Abrantes et al., 2014; Masese et al., 2018). Because riparian plants are the major carbon source to fishes and widespread along the river channel (Deng et al., 2018), the range in potential source $\delta^{13}C$ was similar for all sites, meaning that the community-wide metrics are comparable among sites and periods (Layman et al., 2007a). In order to provide more robust metrics that are unbiased with respect to variations in the number of groups and allow for statistical comparisons among sites and periods, Bayesian methodology was implemented to generate a posterior distribution of estimates of these metrics, thus providing a measure of uncertainty of these metrics for the fish communities at each site and period (Jackson et al., 2011). Then the comparison was conducted graphically based on the visual analysis of the credibility intervals and the degree of overlap between the Bayesian distributions was used as an indication of similarities or dissimilarities between sites and periods (Abrantes et al., 2014; Masese et al., 2018).

The area of $\delta^{13}C$- $\delta^{15}N$ space occupied by all consumers generally represents a measure of trophic niche size and thus a proxy for the total extent of trophic diversity (Layman et al., 2007a). Instead of total area, which is highly sensitive to sample size, standard ellipse area (SEA) was used to quantify the trophic niche space of fish assemblages (Jackson et al., 2011). SEA is equivalent to bivariate standard deviations and robust to variation in sample size or the number of groups (Jackson et al., 2011). Two versions of SEA, Bayesian standard ellipse area (SEA_b), which estimate via Bayesian approach taking account of sampling error and returning probability distributions, and size-corrected standard ellipse area (SEA_c), which correct bias towards underestimation of the SEA when sample sizes are small, were calculated for

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20852104

niche space comparisons of different fish assemblages. All metrics were calculated using the R statistical computing package, "Stable Isotope Analysis in R"(SIAR) and "Stable Isotope Bayesian Ellipses in R" (SIBER) (R Development Core Team, 2007; Parnell et al., 2008, 2010; Jackson et al., 2011).

T-test and ANOVA were used to compare $\delta^{13}C$ and $\delta^{15}N$ isotopic signatures data from different periods or sites. Pairwise differences were tested using Dunnett T3's post hoc test. Statistical analyses were conducted using IBM SPSS Statistics (16.0). Statistical significance was determined at $p = 0.05$.

Results

Spatiotemporal differences in $\delta^{13}C$ and $\delta^{15}N$ values of fish assemblages

At Wushan, a total of 42 fish species were found. Each 22 dominant fish species were sampled during the non-flood and flood period (*Table S1*). The $\delta^{13}C$ and $\delta^{15}N$ values of fish assemblages ranged from -29.74‰ to -17.60‰ and 4.54‰ to 17.51‰, with an average of -23.52‰ and 9.37‰ in the non-flood period and an average of -22.02‰ and 10.94‰ in the flood period, respectively. There are also 42 fish species captured at Dachang site. The 27 and 23 dominant species were sampled in the non-flood and flood period (*Table S1*). Fish $\delta^{13}C$ values varied from -28.57‰ to -16.61‰, with an average of -23.70‰ in the non-flood period and -23.51‰ in the flood period. Fish $\delta^{15}N$ values varied from 4.91‰ to 14.15‰ and the average $\delta^{15}N$ values of fish assemblages were 9.10‰ and 9.78‰ in the non-flood and flood period, respectively. At Wuxi, 35 fish species were captured during the surveys. The 13 and 15 dominant fish species were sampled in the non-flood and flood period (*Table S1*). The range of $\delta^{13}C$ and $\delta^{15}N$ signatures was from -25.31‰ to -21.56‰ and 2.25‰ to 10.81‰.

There were significant differences in fish $\delta^{13}C$ between the non-flood and flood period at Wushan site (t-test, $t = 2.855$, $p < 0.01$) and no significant differences at Dachang (t-test, $t = 0.382$, $p = 0.703$) and Wuxi site (t-test, $t = 1.297$, $p = 0.201$). During the non-flood period, there are no significant differences in $\delta^{13}C$ among sites (ANOVA, $F = 0.096$, $p = 0.908$). However, the average fish $\delta^{13}C$ value displayed significant differences among sites (ANOVA, $F = 4.577$, $p < 0.05$) during the flood period. Fish assemblages at Wushan were more enriched in $\delta^{13}C$ than that at Dachang (Dunnett T3's method, $p < 0.05$) and Wuxi (Dunnett T3's method, $p < 0.05$) in the flood period. Similarly, differences in fish $\delta^{15}N$ signature between the non-flood and flood period were significant at Wushan (t-test, $t = 2.497$, $p < 0.05$) but not significant at Dachang (t-test, $t = 1.916$, $p = 0.058$) and Wuxi site (t-test, $t = 0.947$, $p = 0.349$). There are significant differences in $\delta^{15}N$ values among sites within each period (non-flood: ANOVA, $F = 14.129$, $p < 0.01$; flood: ANOVA, $F = 18.158$, $p < 0.01$) and only $\delta^{15}N$ values at Wushan and Dachang did not differ significantly (Dunnett T3's method, $p = 0.07$) during the non-flood period. Overall, average $\delta^{15}N$ value of fish assemblages increased from upstream site to the downstream site.

Spatial differences in trophic diversity and structure

SEAs of fish communities differed in size, shape and position in the bi-plots (*Fig. 2*). Generally, standard ellipse areas sizes declined with sites upstream from the confluence. In the flood period, the SEA of the Wushan site was larger than that of Dachang site, of which was sequentially greater than the SEA of the Wuxi site. SIBER indicated that the SEA_b at the downstream sites had more than 97% probability of being larger than the SEA_b at the upstream sites for the flood period in each two-sites comparison (*Table 2*). In the non-flood period, however, the SEA sizes were more similar between at the Wushan and Dachang sites, which were both larger than at the Wuxi (*Table 2*). The probability that the SEA_b of the Wushan was larger than that of the Dachang in the non-flood period was only 56% (*Table 2*) and this lack of differences was also demonstrated by the high overlaps in the SEA_b 50% CIs between these two sites (*Fig. 3*). Besides, there was more overlap between the different SEA in the non-flood period than in the flood period (*Fig. 2*, *Table 2*). SEAs of the Wushan site showed larger overlap with the Dachang site during non-flood period than in the flood period (14.41‰^{2} in the non-flood period and 4.02‰^{2} in the flood periods) (*Table 2*) and the distributions of Bayesian results (SEA_b) showed that the probability was 100%.

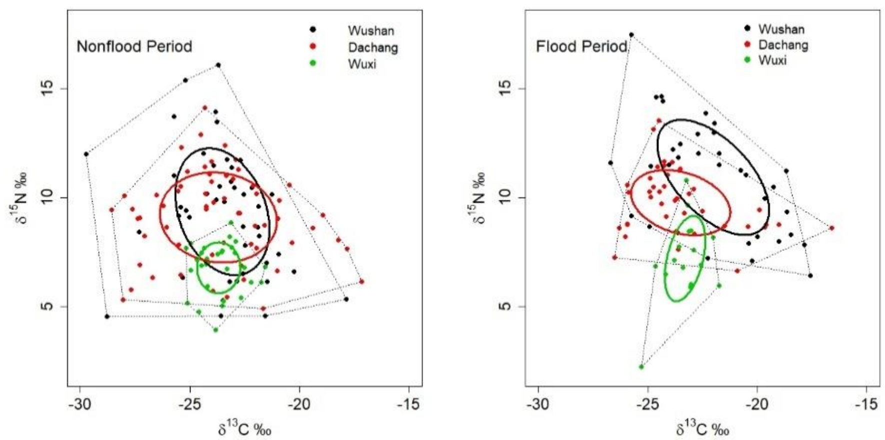

Figure 2. *Mean stable isotope composition of the different fish species from the three study sites for the non-flood and flood period. Solid lines represent the standard ellipses area, and dotted lines are the convex hull areas of fish assemblages for each site*

Five Layman's community metrics also varied among sites in each period (*Figs. 4*, *5*). In the flood period, all the metrics at the Wushan were the largest than the other two sites except SDNND, whereas the metrics at the Wuxi showed the widest range of values (*Figs. 4*, *5*). In the non-flood period, the five metrics were more similar between Wushan and Dachang, with a large overlap of the 50% CIs for each metrics in these two sites (*Figs. 4*, *5*). However, the Wuxi site showed the smallest mode value for all the metrics compared to the two downstream sites in the non-flood period.

Table 2. *Small size-corrected standard ellipse areas (SEAc), probability that the SEA in the flood period is larger than the SEA at the non-flood period, overlap in SEA between periods for the same site and overlap in SEA between pairs of sites*

	SEA_c (‰^{2})	p Value SEA flood > non-flood	Overlap in SEA_c (SEA_b) between periods (‰^{2})	SEA overlap between pairs of sites (‰^{2})		
				Wushan	Dachang	Wuxi
flood period						
Wushan	17.42	0.720	**5.80** (3.69-10.64)		**4.02** (1.98-6.65)	**0.00** (-0.06-0.89)
Dachang	10.18	0.001	**9.89** (5.88-10.99)	1.00		**0.83** (-0.18-1.96)
Wuxi	5.15	0.861	**2.87** (1.15-3.77)	0.97	1.00	
non-flood period						
Wushan	18.87				**14.41** (9.76-15.67)	**1.92** (0.54-3.43)
Dachang	17.30			0.56		**1.24** (0.04-2.20)
Wuxi	3.62			1.00	1.00	

Note: The top halves of the matrices show the SEA overlap between sites, in ‰^{2}. The bottom halves of the matrices with grey shading show the Bayesian probability (in %) that the SEA of group 1 (sites from the first column) is smaller than that of group two (sites from the first row). Values in brackets are 95% Bayesian credibility intervals estimates by models. Values in bold are calculated by SEA_c

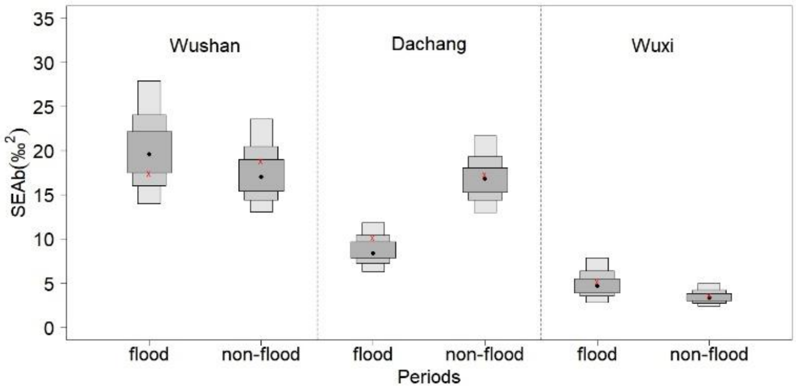

Figure 3. *Density plots of the credibility intervals of the standard ellipse areas (SEA). Black dots are the mode SEA, and boxes indicate the 50%, 75% and 95% credible intervals. Red crosses are the small sample size-corrected SEA (SEA_c)*

Temporal variation in trophic diversity and structure

For Wushan site, there was a temporal change in SEA position with higher $\delta^{13}C$ and $\delta^{15}N$ values in the flood period (*Fig. 2*). However, SEA did not differ in size between periods at this site (*Table 2*, *Fig. 3*). The overlap in SEA between periods was relatively low (5.85‰^{2}, corresponding to 33.32% and 30.77% of the total SEA for the flood and non-flood period, respectively; *Table 2*). CR, NR, CD and NND were wider in flood period than in non-flood period with the slight overlap in the 75% or 95% CIs of the distributions of Bayesian results (*Figs. 4*, *5*), suggesting that the fluctuation of water-levels and the discharge during the flood period increases isotopic trophic diversity and decreases trophic redundancy at the Wushan site.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20852104

Conversely, fish groups from the Dachang site showed no evidence of temporal changes in SEA position but increased in size in the non-flood period when 99.9% of the SEA_b was larger than that in the flood period (*Table 2, Figs. 2, 3*). The area overlap between the two periods' standard ellipses was 9.89‰^{2}, corresponding to 97.21% and 57.21% of the total SEA of the flood and non-flood period, respectively (*Table 2*). NR, CD and NND were significantly narrower in flood period (*Figs. 4, 5*) which confirmed by Bayesian results that 98.40%, 97.15% and 97.93% of the metrics in flood period were smaller than in the flood period, respectively. However, CR was similar for both periods and there was high overlap in the 95% CIs for SDNND (*Fig. 5*).

As for Wuxi site, there was slight seasonal differences in SEA size (*Fig. 3*). The SEA_b in the non-flood period had 89.8% probabilities of being larger than the SEA_b in the flood period and the SEA overlap between periods was 2.87 ‰^{2} (*Table 2*), which accounted for 55.81% and 79.36% of the whole SEA in the flood and non-flood period, accordingly. As well, for the five Layman's metrics, there was little evidence of temporal differences, which were mostly a result of the large overlap in the 95% CIs between periods, due to the wide range of every value in the flood period (*Figs. 4, 5*).

Discussion

Longitudinal patterns of trophic diversity in fish assemblages

The lowest site, Wushan, displayed the largest SEA while the upper site showed the lower values (*Fig. 3*) suggesting the greater niche space in the downstream, which was also supported by higher CR and CD values implying higher trophic diversity in Wushan (*Fig. 4*). This longitudinally increasing tendency, which is also discovered in other impounded river (Kaymak et al., 2018), is much more evident in the flood season (*Fig. 3*) when the water level is relatively low and the discharge varies. It is reported that there are 42 and 35 fish species recorded at downstream and upstream respectively after the impoundment of TGR (Yang et al., 2013). Increased fish species richness in the downstream gives the opportunities for consumers to exploit more food resources and occupy new niches (Roach et al., 2009). Nevertheless, the opposite was the case in the upstream, Wuxi site, where fish community revealed a lack of planktivorous group and preponderance of omnivorous group (*Table S1*) (Ding, 1994). Besides, several fish species, such as *Coreius heterodon*, distributed mainly in the mainstream, was only found in the estuary in this tributary. These fish species could integrate the food carbon source from the mainstream. On the other hand, although the former study has verified that riparian C_3 plants are the main basal food source irrespective of reaches or feeding groups (Deng et al., 2018), the CRs, which are indicative of food source diversity in the backwater area are significantly larger than those in the upper lotic reaches (*Fig. 4*). This is likely explained by the massive backwater area as well as large periodic inundated zone in the downstream that boost diverse fish species assemblage and alternative food resource presence (Deng et al., 2018).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20852104

Temporal variation in trophic structure of fish assemblages

Seasonal differences in food web structure were observed at the downstream sites. At Wushan, the slight overlap of the SEA (*Table 2*) suggested that the position of the fish community had change substantially between two periods although the area occupied was similar. This position alternation is attributed to the change in both the base and the vertical structure of the food web influenced during the flood period (*Figs. 2, 4*). A widening of food source (larger CR) in flood season when the water level is low and fluctuant probably results from the carbon subsidies in the estuary from the mainstream where terrestrial C_4 plants is important to fish species (Wang et al., 2014). Therefore, the fish community had significantly higher $\delta^{13}C$ values in flood season (*Fig. 2*). The increase in trophic length (NR) is also likely attributed to enlarged optional food resource. There is strong evidence that food web length increases with productivity or resource availability (Pimm and Kitching, 1987; Sabo et al., 2009; Takimoto and Post, 2013). Previous reports have confirmed that planktonic algae, of which biomass in the estuary peaked in June and August during the flood season (*Table 1*) (also see Zhu et al., 2013), is an important secondary carbon source in the downstream (Deng et al., 2018). Exploitation of diverse available sources, both abundant from terrestrial and aquatic, as well as tributary and mainstream, leads to a higher trophic diversity (larger CD) and lower trophic redundancy (higher NND) at the lower water level (*Figs. 4, 5*).

In the tail of backwater region (Dachang site), there was a decrease in niche area and trophic diversity during the flood season. In general, an increased range of available food sources during the flood season, e.g. increased input of terrestrial organic matter by surface run-off, leads to a higher consumer trophic diversity and expanded niche sizes (Junk et al., 1989). However, the considerably overlapping in CR between two periods suggested that fishes exploited similar food sources, which could be consolidated by the importance of C_3 plants as the major and consistent carbon source supporting fish species because of the predominance of nutritious riparian C_3 plants in vast periodic inundated area at Dachang (Deng et al., 2018). Consequently, the decrease of niche sizes was associated with the shorter trophic length in the flood season (*Figs. 2, 4*), perhaps as a function of fluctuant water level and discharge resulting in limiting intermediate predators as prey for fish (McHugh et al., 2010). Environmental disturbance such as hydrologic variability can influence food web length in many ecosystems (Post, 2002; Sabo et al., 2009) and some argue that flood disturbance with more unpredictable flow regimes generally reduce food web length in temperate stream systems (Marty et al., 2009; Sabo et al., 2010; McHugh et al., 2010). In flood season, an effect of drastic perturbation on the backwater ecosystem in Daning River derives from dramatically descending water level and stochastic discharges from the upstream (*Fig. 1*). As a result, trophic length at Dachang would be shorten through disturbance-induced change in diet strategies according to relative accessibility of a prey (McHugh et al., 2010; Ruhí et al., 2016). In addition, the flood disturbance could further enhance fish consumers to prefer abundant C_3 plants than diverse food sources resulting in increased trophic redundancy (lower NNR) during the flood season.

The effect of hydrological regulation on the trophic structure

The larger overlap of SEA with the similar trophic metrics between Wushan and Dachang sites during non-flood period (*Table 2*) inferred that trophic structure were becoming more homogenous after the impoundment. This could be explained by expanding backward mixing processes of the whole backwater zone increasing longitudinal connectivity during the higher-water-level period (Ran et al., 2010; Zhao et al., 2015). Due to extended water retention time, it is reported that uniformity of environmental conditions (*Table 1*) (Zhu et al., 2013) and fish community (Yang et al., 2013) among different sections occur in the backwater area when the water level rises.

The hydrological regulation also could adjust response of fish assemblages from different sites to flood. After the water level declines, the significant alternation of fluvial morphology and riverside zone appears in the tail of the backwater zone but seems much less in the estuary area. The depth of water drops remarkably from an average of 33 m to 19 m at Dachang section in the flood period, which would produce a large area of inundated riparian rocky and muddy substrates outcrops and thereby compress overall ecosystem size. However, the estuary area characterized by an incised channel with steep slopes has a mean depth of more than 50 m even at the lowest water level. Accordingly, fish assemblages at Dachang site is likely more susceptible to the unpredictable flow pulse in the flood period considering comparatively smaller water body in the tail of the backwater zone than the estuary area. On the contrary, the vast water storage in the estuarine confluence zone that dampens the effect of unregulated flow pulse but likely subjects to the mixing processes with the mainstream (Ran et al., 2010). Consequently, owing to the constant contribution from C_3 source within this tributary (Deng et al., 2018), the shrinkage of ecosystem size interacting with drastic flow pulse from the upper contribute directly to contraction of the niche size and trophic diversity in Dachang region by reductions in prey diversity (Layman et al., 2007b), that is, preference of more easily accessible resources which are at lower trophic levels (Roach et al., 2009; Ruhí et al., 2016). Nevertheless, the subsidies from the mainstream and autochthonous production due to relatively stable ambient at Wushan site facilitate trophic diversity increase and maintain ecological stability.

Conclusion

Overall, river impoundment have altered the hydrology at locations in the downstream and hence the food web structure throughout the Daning River. The lower sites with larger water storage had broader trophic niches and higher trophic diversity for fish assemblages reside. The temporal variation in trophic structure changed differently according to their distinct habitats. The trophic diversity shift in the estuarine area is caused mainly by availability of basal food sources either from the mainstream or aquatic algae. However, the variation of niche diversity in the end of backwater site results from disturbance on the vertical structure of the fish food web, specifically, disturbance-induced change in diet composition based on changeless food resource

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_20852104

choice because nutritious vegetation contribution prevail within this tributary. The water level control promote disparate response for trophic structure of fish assemblages at different sites to the flood. The descending water level concomitant with unpredictable flow would shrunken the trophic niche size for fish assemblages in the end of backwater where considerable riverine morphology alternation resulted in water body decrease, whereas the stability of trophic size in the estuarine area were due to less perturbation mitigated by immense water body. In addition, the rising water level regulation could homogenize trophic structure along the river. The findings supplement the information of trophic ecology in the impound rivers and have important implications for development plans in this tributary.

(Received 12th Nov 2018; accepted 16th Jan 2019)

Abstract. The objective of the study was to define the impact of nursing methods with the application of growth biostimulators and herbicide on the content of ascorbic acid in edible potato tubers. A series of field experiments were carried out in the years 2015-2017 in the region of eastern Poland (52°02'N; 23°07'E). The examined factors included: factor I – three early cultivars of edible potato (Owacja, Bellarosa, Vineta), factor II – five methods of nursing with the application of growth biostimulators: GreenOK-Universal Pro and Asahi SL as well as their combination with the Avatar 293 ZC herbicide. The treatment methods applied in the experiment with the use of growth biostimulators and herbicide had a significant impact on the rise of the content of ascorbic acid in edible potato tubers in comparison with only mechanical treatment. The highest concentration of ascorbic acid (on average 193.88 mg kg^{-1}) was marked in the tubers gathered from object 4., in case of which mechanical treatment has been made. Then the Avatar 293 ZC herbicide and the GreenOK Universal-PRO biostimulator were applied. The content of ascorbic acid in potato tubers was also significantly impacted by genetic characteristics of individual cultivars and weather conditions during the conduct of tests.

Introduction

Experiment background

Conventional, intensive methods of plant production have a significant impact on the natural environment and such impact is most frequently a negative one. In particular, the „high-tech-agriculture" model may constitute a threat not only for the health of consumers but also for natural resources on which we are entirely dependent (Scherr and McNeely, 2008; Głodowska and Gałązka, 2018).

Presently, within plant production, including potato (*Solanum tuberosum* L.) cultivation an increasing level of attention is drawn not only to the size of crops but also to the health-related qualities, while agricultural practice continues to evolve towards ecological, balanced cultivation systems, which are at the same time environment friendly (Bulgari et al., 2015).

In modern agriculture various types of agroecosystem friendly preparations have become commonly applied which are classified as growth biostimulators. They limit the application of agro-chemicals and thus, contribute to the development of balanced methods of plant production (Radkowski and Radkowska, 2013; Calvo et al., 2014; Du Jardin, 2015).

Growth biostimulators

According to the definition of The European Biostimulant Industry Council (EBIC), growth biostimulators are preparations which are applied on a plant, seeds or a root zone in order to stimulate the natural processes, increasing the effectiveness of use of nutrients, tolerance to abiotic stress and/or quality of crops. Their activity does not depend on the content of nutrition elements. Biostimulators do not directly counteract pests, therefore they are not classified as pesticides (European Biostimulants Industry Council, 2012; Matyjaszczyk, 2015). These preparations do not also act as fertilisers, while their main role is to control and accelerate the life processes of plants and to increase their resistance to abiotic stress (Matyjaszczyk, 2015). In the opinion of Calvo et al. (2014), interest in the use of biostimulators in agricultural practice continues to increase and the global market of these preparations may in 2018 reach the level above 2 241 million dollars.

Growth biostimulators constitute preparations of natural or synthetic origin the chemical content of which is characterized by a number of bioactive organic and non-organic components such as: effective micro-organisms, humus substances, extracts from seaweed and fruits, enzymes, phytohormones, chitin, chitosan, poli-oligosaccharides and chemical elements, inorganic salts (including phosphonates), phenolic compounds, antitranspirants and other substances of stimulating properties (Hamza and Suggars, 2001; Kauffman et al., 2007; Khan et al., 2009; Du Jardin, 2012; Przybysz et al., 2014).

Biostimulators contribute to an increase and growth of plants for their entire life cycle: They improve some physicochemical properties of soil and support the growth of useful soil microorganisms, stimulating germination and plant growth (Vernieri et al., 2002; Yildirim et al., 2002). They impact bio-chemical processes, facilitate assimilation, translocation and the use of nutrients (Kauffman et al., 2007; Kunicki et al., 2010; Du Jardin, 2012; Calvo et al., 2014). They may increase tolerance of plants towards biotic and abiotic stress as well as accelerate their regeneration (Ziosi et al., 2013).

Growth biostimulators may also impact the nutritional value of arable crops, including also the content of ascorbic acid (Dudaš et al., 2016; Mikos-Bielak et al., 1999a, b).

Ascorbic acid – Albert Szent-Györgyi

In 1928, Albert Szent-Györgyi – Hungarian scientist, biochemist, laureate of the Nobel prize (1937) extracted and identified vitamin C from pepper plant (ascorbic acid ($C_6H_8O_6$) – Latin: *acidum ascorbicum*). This compound was named ascorbic acid since its shortage or lack in nourishment leads to the development of scurvy (Latin: *scorbutus*). Five years later the first synthetic ascorbic acid was obtained (Gábor, 1982; Szarka and Lőrincz, 2013; Szendrei and Háznagy-Radnai, 2013).

Ascorbic acid is an organic chemical compound from the group of unsaturated polyols; it is essential for the functioning of living organisms. Vitamin C belongs to the most commonly known vitamins with multidirectional functions. It is an activator of various enzymes, performing a key role in cellular respiration. It also plays a role in the course of many metabolic processes. It participates in production of collagen and the basic proteins in the whole organism (bones, cartilages, tendons, ligaments). It helps the wounds, breaks to heal, inhibits the healing of bruises, occurrence of haemorrhage and gum bleeding, activates our immunological system stimulating the growth and

effectiveness of T and B type immunological cells as well as other white blood cells (Moszczyński and Pyć, 1999; Huang et al., 2002; Nowak, 2004; Janda et al., 2015; Carr and Maggini, 2017). It participates in the synthesis of hormones and transmitters (Moszczyński and Pyć, 1999). Ascorbic acid is one of the strongest water-soluble antioxidants which performs the protective function against cancer diseases (Asensi-Fabado and Munné-Bosch, 2010). It is necessary in prevention of circulatory system diseases – it regulates the production of cholesterol in liver and its transformation into bile acids (it decreases the general level of "bad" LDH cholesterol in blood, increasing the volume of "good" HDL cholesterol) (Nowak, 2004; Janda et al., 2015).

Human beings do not possess metabolic pathways leading to the synthesis of C vitamin, therefore it must be provided on an ongoing basis by means of nourishment (Tabatabaei-Malazy et al., 2014). Vitamin C appears in the greatest volumes in fresh vegetables and fruits, thus it is extremely important to enrich our diet in these products.

Within our everyday diet, the cheapest and most widespread source of vitamin C are the edible potato tubers. This stems from the fact that edible potato is cultivated in approx. 160 countries worldwide and it is consumed on a daily basis by over a billion of persons (Bishwoyog et Swarnima, 2016; Baranowska, 2018). Content of vitamin C in potato tubers amounts to from 11.5 to 27.8 mg 100 g^{-1} (Grzesińska and Kierebiński, 1990; Kris-Etherton et al., 2002; Love and Pavek, 2008).

One must underline that in the course of preparation of meals and potato preserves, losses in the content of ascorbic acid occur, caused mainly by the operations of high temperature, enzymes, oxygen and light. Already the peeling process of potatoes causes a 6% loss of ascorbic acid. Once we chop the peeled potatoes before boiling, losses of vitamin C will be even more substantial. The largest losses occur as a result of slicing or dicing the tubers (15-16%), whilst the smallest – as a result of cutting into poles (9%). Losses of vitamin C during technological processes may range between: 27 and 33% - blanching process, up to 50% boiling in water, up to 83% - frying of crisps. However, the greatest losses of ascorbic acid (up to 93%) occur in the course of production of dry potato cubes. In order to minimize the losses of vitamin C it is most beneficial not to peel or cut the tubers, but rather wash them thoroughly prior to boiling (boiling with an addition of a small amount of hot water and kitchen salt in accuthermal dishes, pressure cookers, microwaves or steaming is recommended). One ought to further limit to the minimum the time of operations of destructive factors impacting the content of vitamin C, such as high temperature (Rytel and Lisińska, 2007; Janda et al., 2015). Despite the losses of ascorbic acid in the course of preparation of meals or potato preserves, potato is one of the main sources of vitamin C in human diet due to the significant volumes in which it is consumed. Consumption of 200 g of potatoes covers daily demand for vitamin C in approx 50% (Leszczyński, 2000).

Purpose of the experiment

Sparse and ambiguous so far empirical results of studies on the impact of growth biostimulators on the chemical composition of edible potato tubers, including also the content of ascorbic acid incline to carrying out further studies.

The purpose of the experiment was to specify the impact of five methods of treatment with the application of growth biostimulators and herbicide on the content of ascorbic acid in tubers of three cultivars of edible potato. Research hypothesis assumes that plant-care procedures with the use of growth biostimulators and herbicide will impact the content of ascorbic acid in edible potato tubers.

Materials and methods

Location of the experiment

The field experiment was conducted in the years 2015-2017 in the region of eastern Poland (*Fig. 1*), in the Biała Podlaska Commune (52°02'N; 23°07'E) in the Lublin Voivodship, on acidic light soil.

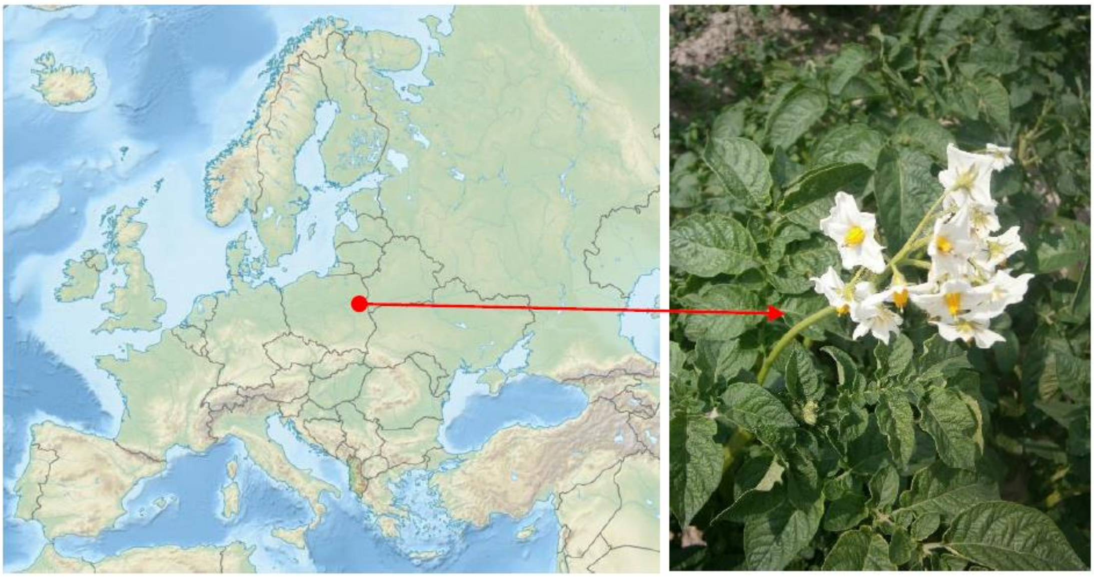

Figure 1. *Location of the experiment*

Experiment and plant material

The experiment was performed in the split-plot system, as two-factor in three replications. The influence of two factors was tested:

I. Factor – three early edible potato cultivars: Bellarosa, Owacja, Vineta,

II. Factor – five methods of treatment with the application of growth biostimulators and herbicide:

1. Standard object – mechanical treatment (without biostimulators and herbicide),
2. From sprouting of potato plants – mechanical treatment and after sprouting – GreenOK Universal–PRO bioactivator, three times to leaves: at a dose of 0.10 dm^3 ha^{-1} – peak–end of sprouting (phase BBCH 13-19) + 0.15 dm^3 ha^{-1} – covering of interrows (phase BBCH 31-35) + 0.15 dm^3 ha^{-1} – flower bud break (phase BBCH 51-55),
3. From sprouting of potato plants – mechanical treatment, and after sprouting – Asahi SL bioactivator, three times to leaves at a dose of 0.50 dm^3 ha^{-1} – peak–end of sprouting (phase BBCH 13-19) + 0.50 dm^3 ha^{-1} – covering of interrows (phase BBCH 31-35) + 0.50 dm^3 ha^{-1} – flower bud break (phase BBCH 51-55),
4. From sprouting – mechanical treatment, and after the final shaping of ridges and just before sprouting Avatar 293 ZC herbicide at a dose of 1.5 dm^3 ha^{-1} (phase BBCH 00-05). After sprouting – three applications of GreenOK Universal–PRO bioactivator at a dose of 0.10 dm^3 ha^{-1} – peak–end of sprouting

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_21052118

(phase BBCH 13-19) + 0.15 dm^3 ha^{-1} – covering of interrows (phase BBCH 31-35) + 0.15 dm^3 ha^{-1} – flower bud break (phase BBCH 51-55),

5. From sprouting – mechanical treatment, and after the final shaping of ridges before sprouting of potato plants – Avatar 293 ZC herbicide at a dose of 1.5 dm^3 ha^{-1} (phase BBCH 00-05).

The characteristics of the potato varieties and preparations used in the experiment are presented in *Tables 1* and *2*.

Table 1. *Characteristics of varieties of potatoes grown in the experiment. (Source: Plant Breeding and Acclimatization Institute – National Research Institute)*

Variety	Year of inscription to variety register	Breeder of variety	Yield t ha^{-1}	Colour of skin	Colour of pulp
Bellarosa	2006	Europlant, Pflz. GmbH Germany	38.3	Red	Yellow
Owacja	2006	PMHZ Strzekęcin Poland	41.4	Yellow	Light yellow
Vineta	1999	Europlant, Pflz. GmbH, Germany	39.1	Yellow	Yellow

Table 2. *Characteristics of biostimulators and herbicide applied in the experiment. (Source: information disclosed by agents' manufacturers)*

Name of preparation	Holder of the authorization	Content of active substances
GreenOK Universal-PRO – natural fertilizer with biostimmulating effect	Latvian Institute of humic substances Brivibas Street 144, Riga, Latvia, LV–1012	Humus substances ≤ 20 g dm^3 (NPK 0.13-0.09-0.7), dry mass 22 g dm^3, humidity 96%, organic substances 3%, pH 7-9
Asahi SL – growth regulator (known under the name of Atonik in Poland)	Asahi Chemical Europe s.r.o., Lužná 591/4 – Vokovice, 160 00 Praha 6, The Czech Republic	Sodium para-nitrophenolate (substance of nitrophenoles group) – 3 g dm^3 (0.3%) sodium orto-nitrophenolate (substance of nitrophenolates group) – 2 g dm^3 (0.2%) sodium 5-nitroguaiacolate (substance of nitrophenolates group derivatives) – 1 g dm^3 (0.1%)
Avatar 293 ZC – herbicide	FMC Chemical sprl, Boulevard de la Plaine 9/3, B–1050 Brussels, The Kingdom of Belgium	Clomazone (substance of isoxalodine group) – 60 g dm^3 (5.13%) metribuzin (substance of triazinones group) – 233 g dm^3 (20.64%)

In autumn, before the experiments, natural manure fertilization was used at a dose of 25 t ha^{-1}, as well as mineral fertilization with phosphorus 44.0 kg P ha^{-1} (triple superphosphate 46%) and potassium 124.5 kg K ha^{-1}(potassium salt 60%), and during spring – nitrogen fertilization (ammonium nitrate 34%) at a dose of 100 kg N per 1 ha. Potato tubers were planted in the second decade of April (in 2015 and 2016) and in the third decade of April (in 2017). Protection treatment against diseases and pests was used in accordance with the plant protection recommendations. In the period of vegetation, potato crops were protected by means of insecticides: Actara 25 WG (thiamethoxam 250 g kg^{-1}) at a dose of 0.08 kg ha^{-1}, Calypso 480 SC (tiachlopryd 480 g dm^{-3}) at a dose

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_21052118

of 0.1 dm^{-3} ha^{-1} and fungicides: Copper Max New 50 WP (copper 500 g kg^{-1}) at a dose of 2.0 kg ha^{-1} Dithane Neo Tec 75 WG (mancozeb 750 kg ha^{-1}) at a dose of 2.0 kg ha^{-1}. Harvest was performed in the phase of full technological maturity of tubers.

Chemical analysis methods

The content of ascorbic acid was marked in fresh mass of tubers via Tillmans method modified by Pijanowski which consists of reducing the colour solution of 2.6-dichlorphenolindophenol to colourless leuco compound by acid solution of ascorbic acid (Pijanowski et al., 1964; Rutkowska, 1981).

Statistical analysis

The obtained results of research regarding the content of ascorbic acid of have been developed statistically by means of the analysis of variance method. Significance of variability sources was tested with the Fischler-Snedecor *F* test, and the assessment of significance of variance at the significance level $p = 0.05$ between the compared averages using Tukey's range test.

Weather conditions

Meteorological conditions in potato growing season have been presented in *Figures 2–5* and *Table 3*. The data come from the Meteorological Station of the Research Centre for Cultivar Testing (COBORU) in Słupia Wielka and they were compiled for the Cultivar Assessment Experimental Station situated near Biała Podlaska.

Meteorological conditions were characterized on the basis of monthly precipitation sums (*Figs. 2* and *3*), average air temperatures (*Figs. 4* and *5*), and hydrothermal coefficient of Sielianinov (*K*) (*Table 3*) (*Eq. 1*):

$$\mathbf{K} = \frac{\mathbf{P}}{\mathbf{0.1} \sum \mathbf{t}} \quad \text{(Eq.1)}$$

K – value of hydrothermal coefficient, *P* – sum of monthly rainfall, *t* – sum of daily air temperatures from a given month, where: *P* – signifies the monthly sum of rainfall, $\sum t$ – monthly sum of air temperatures >0 °C.

Extremely dry and extremely humid conditions were distinguished, performing a division of values of Sielianinov coefficient (*K*) into nine classes. The following divisions of values were applied: borderline dry $K \geq 0.4$, very dry $0.4 < K \geq 1.0$, dry $0.7 < K \geq 1.0$, rather dry $1.0 < K \geq 1.3$, optimal $1.3 < K \geq 1.6$, rather humid $1.6 < K \geq 2.0$, humid $2.0 < K \geq 2.5$, very humid $2.5 < K \geq 3.0$, borderline humid $K > 3.0$ (Chereszkowicz, 1979; Skowera and Puła, 2004; Skowera et al., 2014)

During the conduct of tests diverse meteorological conditions occurred (*Figs. 2–5* and *Table 3*). The lowest precipitation sum (288 mm) was recorded in 2015 with mean air temperature of 15.7 °C. In this season, precipitation shortage occurred from June to August, while August was extremely dry with precipitation sum of 7 mm and high atmospheric air temperatures. This season was defined as dry ($0.7 < K \geq 1.0$). Whilst, the highest precipitation sum was recorded in the growing season of 2017 (425 mm) in which the average air temperature was 15.4 °C; it was the coldest year in comparison with other years covered by the research. Within the growing season of 2016 the most humid months were: July with a sum of rainfall of 121 mm and high air temperatures

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_21052118

(on average: 19.8 °C) and June with a sum of rainfall 84 mm and average air temperature of 18.4 °C. This season was specified as rather dry (1.0 < $K \geq 1.3$) (*Figs. 2–5* and *Table 3*).

Table 3. *Sielianinov's hydrothermic coefficient (K)*

*Sielianinov's hydrothermic coefficients *(K)*							
Month/Year	**IV**	**V**	**VI**	**VII**	**VIII**	**IX**	**Mean IV–IX**
2015	1.43	2.28	0.59	0.80	0.11	1.66	0.99
2016	1.19	0.47	1.53	1.97	0.48	0.26	1.00
2017	2.68	0.93	1.97	1.24	0.66	2.37	1.50

*Sielianinov hydrothermal coefficient (K) – formula as in research methodology: Month's classification according to (Chereszkowicz, 1979; Skowera and Puła, 2004; Skowera et al., 2014): extremely dry K ≥ 0.4, very dry 0.4 < K ≥ 0.7, dry 0.7 < K ≥ 1.0, quite dry 1.0 < K ≥ 1.3, optimal 1.3 < K ≥ 1.6, quite humid 1.6 < K ≥ 2.0, humid 2.0 < K ≥ 2.5, very humid 2.5 < K ≥ 3.0, extremely humid K > 3.0

Results and discussion

As a result of the carried out research, it was proved that both applied cultivation methods ($F(4;120) = 4.23$; $p = 0.0031$), potato cultivars cultivated in the experiment ($F(2;79.06) = 12.93$; $p < 0.0001$), as well as meteorological conditions ($F(2;120) = 170.99$; $p < 0.0001$) that prevailed in particular research years had a significant impact on the content of ascorbic acid (*Tables 4* and *5*).

The cultivation methods applied in the experiment with the use of growth biostimulators and herbicide had a significant impact on the rise of content of ascorbic acid within potato tubers (object 2.-5.) in comparison with only mechanical treatment (object 1.) Statistically significant differences occurred also between object 3. and 4. ($p = 0.0164$) (*Table 4*). The largest concentration of vitamin C was reported in tubers gathered from object 4., (on which mechanical treatment was applied from sprouting, followed by application of Avatar 293 ZC at a dose of 1.5 $dm^3\ ha^{-1}$, and after sprouting, triple application of bioactivator GreenOK Universal-PRO at a dose of 0.10 $dm^3\ ha^{-1}$ +

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_21052118

0.15 dm^3 ha^{-1} + 0.15 dm^3 ha^{-1} (on average 190.06 mg kg^{-1}). Positive impact of herbicides on the content of ascorbic acid was observed also in the research carried out by Zarzecka and Gugała (2003), Rymuza et al. (2013). Barabaś and Sawicka (2015) who noted a greater tendency to accumulate vitamin C after application of a mixture of herbicides Sencor 70 WG and Titus 25 WG, applied after sprouting of potato plants.

Mikos-Bielak et al. (1999a, b) applying growth regulator Mival (1 chloromethylosilatran) and Potejtin (mixture of sodium N oxide 2, 6 lutidine and succinic acid) noted an increased content of vitamin C in potato tubers (24 out of 37 tested cultivars). Trawczyński and Prokop (2017) post applying biostimulators obtained from marine algae: Fertiliser Gold and Fertiliser Axis obtained significantly larger content of vitamin C in tubers in comparison to the standard object. Similar results were obtained also by Dudaš et al. (2016) who applied preparation Bio-algeen S-90.

Whilst, according to the research carried out by Rudzińska-Mękal (2000) application of Moddus 250 ME regulator (ethyl trinexapac) and Atonik (polish name Asahi SL) – decreases the content of ascorbic acid in tubers regardless of the term and method of application. According to Mikos-Bielak (2005) one may assume that Atonik biostimulator not so much hinders biosynthesis of vitamin C but rather its transport to floral organs and spare organs.

***Table 4.** Content of ascorbic acid in fresh mass of edible potato tubers depending on the treatment methods and cultivars (average from the years 2015-2017) (mg kg^{-1})*

Methods*	Cultivars			Mean
	Owacja	Bellarosa	Vineta	
1.	170.00	188.30	176.33	$178.20^{a,b,c,d}$
2.	176.33	195.60	183.33	185.08^{a}
3.	174.66	192.73	181.36	$182.92^{b,e}$
4.	183.66	199.83	186.70	$190.06^{c,e}$
5.	177.00	192.96	184.33	184.76^{d}
Mean	176.33^{f}	$193.88^{f,g}$	182.41^{g}	184.20
**$LSD_{0.05}$ for: cultivars – 4.620; methods – 2.634; methods x cultivars – n.s.				

*As in the experiment's methodology:
1. Standard object (without biostimulators and herbicide)
2. GreenOK Universal-PRO 0.10 dm^3 ha^{-1} + 0.15 dm^3 ha^{-1} + 0.15 dm^3 ha^{-1}
3. Asahi SL 0.50 dm^3 ha^{-1} + 0.50 dm^3 ha^{-1} + 0.50 dm^3 ha^{-1}
4. Avatar 293 ZC 1.5 dm^3 ha^{-1} + GreenOK Universal-PRO 0.10 dm^3 ha^{-1} + 0.15 dm^3 ha^{-1} + 0.15 dm^3 ha^{-1}
5. Avatar 293 ZC 1.5 dm^3 ha^{-1}

**$LSD_{0.05}$: Least significant difference, n.s. – not significant
[a, b, c,…]Values marked with the same letter differ significantly

It was noted that the content of vitamin C in potato tubers significantly depended on genetic conditions of the cultivars. Bellarosa cultivar gathered the greatest level of vitamin C (on average 193.88 mg kg^{-1}), while Owacja gathered the smallest amount of it (on average 176.33 mg kg^{-1}) (*Fig. 6*). Content of Vitamin C within Bellarosa tubers was substantially higher than in the tubers of the remaining cultivars (Bellarosa-Owacja $p < 0.0001$; Bellarosa-Vineta $p = 0.0054$). In case of the discussed feature no significant differences between Owacja and Vineta cultivars were observed ($p = 0.1363$) (*Table 4*).

DOI: http://dx.doi.org/10.15666/aeer/1702_21052118

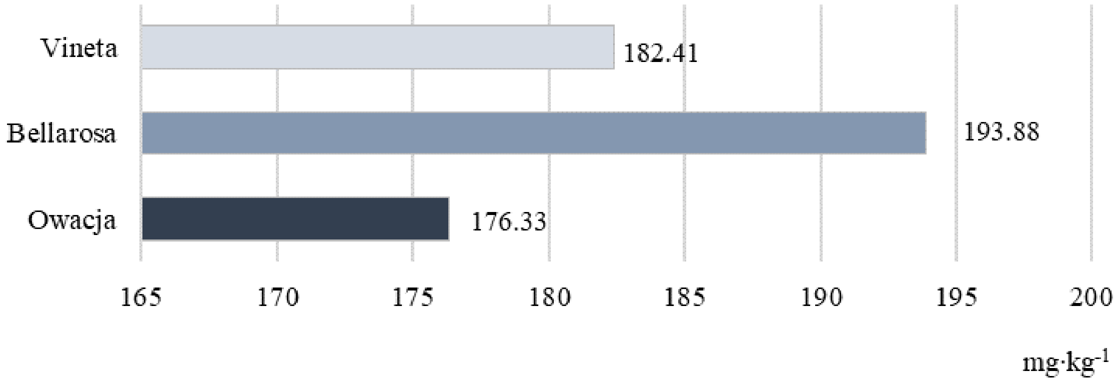

Figure 6. *Average content of ascorbic acid in the wet weight of edible potato tubers depending on the variety (averages from 2015-2017) (mg·kg^{-1})*

These results are compliant with the tests performed by Weber and Putz (1999), who carried out the tests with 26 German potato cultivars and noted that the content of vitamin Ca in tubers is determined by genetic factor. Also within the research by Wichrowska and Pobereżny (2008), Gugała and Zarzecka (2012) the content of vitamin C in tubers depended to a great degree on the genetic conditions of the analysed cultivars. In the opinion of Sowicka et al. (2014) differences in the content of vitamin C, in potato tubers are conditioned by phenotypic switching of cultivars which is a joint effect of genetic and environmental volatility.

A significant impact on the content of vitamin C in edible potato tubers was also assigned to atmospheric conditions in the years of research conduct (*Table 5* and *Fig. 7*).

Table 5. *Content of ascorbic acid in fresh mass of edible potato tubers depending on the treatment method and years of conduct of tests (average from years 2015-2017) (mg kg^{-1})*

Methods*	Year			Mean
	2015	2016	2017	
1.	195.56	184.03	155.03	178.20^{a,b,c,d}
2.	203.53	191.03	160.70	185.08^{a}
3.	200.33	189.73	158.70	182.92^{b,e}

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_21052118

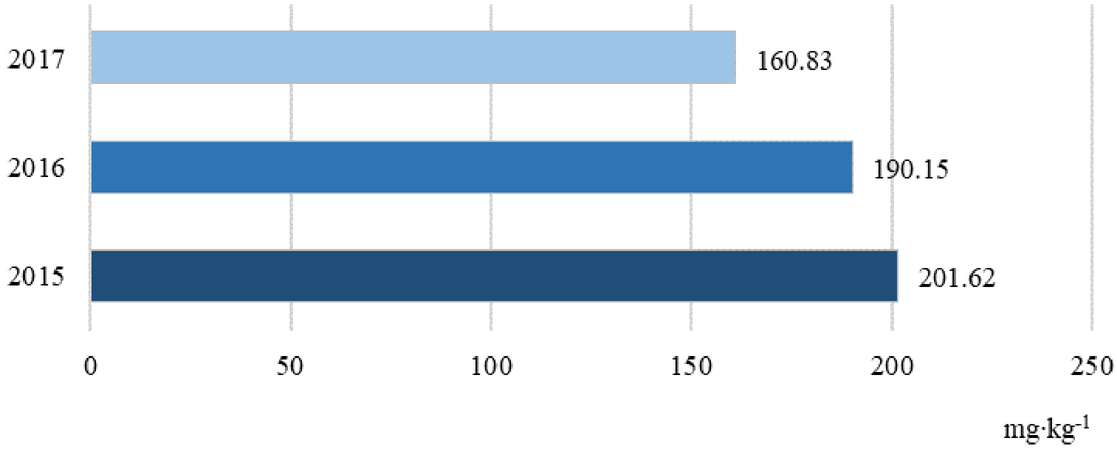

Figure 7. *Average content of ascorbic acid in the wet weight of edible potato tubers in the years 2015-2017 (mg·kg^{-1})*

The largest concentration of this component was noted in the growing season of 2015 (on average 201.62 mg kg^{-1}), which was warm and characterized by the smallest volume of rainfall (288 mm) in comparison to the other tests. Whilst, the smallest concentration of ascorbic acid was noted in humid and cool season of 2017 (on average 160.83 mg kg^{-1}). Statistically significant differences were observed in all medium pairs, that is between 2015 and 2016 ($p < 0.0001$), between 2016 and 2017 ($p < 0.0001$) and between 2015 and 2017 ($p < 0.0001$) (*Table 5*). Similar results of tests were obtained by Mazurczyk and Lis (2001), Love and Pavek (2008). According to Trawczyński and Prokop (2016) years with moderate volume of rainfall and close to approximate with multiple year air temperature positively impact the content of vitamin Ca in potato tubers. Sawicka et al. (2014) they proved that the content of vitamin C is decided by the content of chlorophyll in leaves and the intensity of the photosynthesis process.

Conclusions

Growth biostimulators continue to trigger an increasing interest both in science and agricultural practice. However, the impact of these preparations on the more crucial quality features of arable crops, including also on the content of ascorbic acid, has not yet been fully discovered and requires carrying out further scientific researches. Obtaining the results of own elaborations has allowed to note that treatment methods using growth biostimulators and herbicide significantly impacted the growth of content of ascorbic acid in potato tubers in comparison to the control object subjected to purely mechanical treatment. The content of ascorbic acid was substantially influenced also by genetic features of varieties as well as atmospheric conditions occurring in the subsequent years of conducting research. The greatest concentration of the discussed component was observed in Bellarosa variety of tubers whilst the smallest – in case of Owacja variety. Significantly higher content of ascorbic acid in the tubers of potato was noted in the growing season of 2015, which was characterized by the smallest sum of precipitation in comparison to the other years of research conduct.

(Received 14th Nov 2018; accepted 16th Jan 2019)

Abstract. The study investigates the effect of water deficit conditions on blossom-end rot (BER) in tomato. Drip irrigation was used in irrigation. Therefore, experiment was conducted as a randomized complete block design (three replicates), in a 2 × 5 factorial arrangement, corresponding to two different water resources [treated wastewater (TWW) and freshwater (FW)] and five different irrigation practices. The irrigation strategies comprised full irrigation (100%), deficit irrigation, which involves the use of 75% and 50% of the water used in full irrigation, and partial root drying (PRD). According to the study results, in the full irrigation applications, blossom-end rot according to the fruit number values were 10.85% in fresh water irrigation while it was the lowest with 8.57% for treated wastewater. Also, in full irrigation applications, blossom-end rot values according to fruit weight were found to be lower compared to those in other applications. It was determined that there was a negative relation between blossom-end rot and Ca value. The lowest blossom-end rot incidence was observed in the full irrigation applications, while it was lower in the PRD applications than in the D applications. In the production of marketable tomato, the PRD applications can be more advantageous than the D applications under water shortage conditions.
Keywords: *BER, wastewater, tomato, PRD, deficit irrigation*

Introduction

The gap between water supply and demand is growing with the increasing global population and has reached life-threatening levels in certain regions of the world (Hussain et al., 2002). Moreover, although water of higher quality is suitable for household use, lower-quality waters are used in agricultural irrigation due to increasing demand for water in arid and semi-arid regions (Kızıloğlu et al., 2008). Thus, the need for the re-use of treated wastewaters is increasing. Today, according to recent estimates, 20 million hectares of agricultural land are irrigated with raw, processed or partially-diluted wastewaters worldwide (Drechsel et al., 2010). In agricultural irrigation, water saving-oriented applications are also used in addition to the use of wastewaters to protect surface and underground water resources. Deficit irrigation and partial root drying methods are examples of these applications. The studies have shown that deficit irrigation and partial root drying yielded positive results in the reduction of agricultural water use (Doğan Demir, 2016). Partial root drying and deficit irrigation are fundamentally similar to each other but in the partial root drying method, a portion of the root remains dry while the rest is wetted depending on alternating wetting (Stikic et al., 2003).

Various plant species are irrigated using wastewater with partial root drying and deficit irrigation. High yields can be achieved with the irrigation of tomato plants with partial root drying and deficit irrigation either using clean water or wastewater and there are various studies investigating this subject (Al-Lahham et al., 2007; Li et al., 2007; Ekici, 2002; Alrajhi et al., 2015; Zegbe et al., 2007), but certain diseases may develop and cause yield losses due to applications. In tomatoes, blossom-end rot is the most common issue with these applications. Blossom-end rot in tomato has been described as a physical disorder for more than a century (Selby, 1896; Spurr, 1959; Saure, 2001; Ho and White, 2005; Taylor and Locascio, 2004). Although low calcium content has generally been reported to be the cause of blossom-end rot in tomato, various factors including acidic growing media, high N content, high soil salinity, low soil moisture and soil dryness have also been reported to affect the development of blossom-end rot (Selby, 1896; Shaykewich et al., 1971; Pill and Lambeth, 1980; Winsor and Adams, 1987; Ikeda and Osawa, 1988; Ho et al., 1999; Saure, 2001; Taylor and Locascio, 2004; Zhai et al., 2015).

There is limited information about the effects of water deficit and water stress on plant nutrition. In general, the nitrogen concentration in plant tissues increases with water stress. On the other hand, the phosphorus concentration in plants has been reported to decrease with decreasing water (Reichman and Grunes, 1966; Greenway et al., 1966; Thorup, 1969). The relationship between moisture deficit in soils and plant nutrition affects blossom-end rot development in tomatoes (Shaykewich et al., 1971; Bost, 2010). Tan and Dhanvantari (1985) reported that blossom-end rot development in tomatoes was reduced with irrigation. The water stress in plants increases under water deficit conditions, which results in blossom-end rot (Shaykewich et al., 1971; Ward, 1973).

Although partial root drying is a variation of deficit irrigation, deficit irrigation has been reported to aggravate blossom-end rot development in tomatoes (Adams and Ho, 1992; Obreza et al., 1996; Taylor et al., 2004; Sun, 2013). The irrigation method also affects the development of blossom-end rot (Carrijo et al., 1983).

For the detection of blossom-end rot (BER), total fruit number and rotten fruit number were determined. The number of the fruits with a rotten blossom-end were divided by the total fruit number and the blossom-end rot was given in percentages in the calculations. Furthermore, blossom-end rot value was also determined in percentages with respect to fruit weight. For this purpose, the weights of the fruits with a rotten blossom-end were measured and divided by the total weight of the fruits (Koral, 2006).

Studies have reported that the ratio of K/Ca was a more deterministic indicator of blossom-end rot in tomato than Ca content and the ratio between K and Ca and Ca content were related with each other (Gerard and Hipp, 1968; DeKock et al., 1982; Nukaya et al., 1994). Thus, this study also investigates the relationships between the Ca, K/Ca and K+Mg/Ca contents of the leaves and upper 30 cm of the soil and blossom-end rot. Moreover, the study examines the relationship between blossom-end rot and nitrogen and salinity values, which are thought to affect blossom-end rot.

The study investigates the effects of partial root drying (PRD) and deficit irrigation (D) on blossom-end rot (BER) in the tomato plants irrigated with treated wastewater.

The Joker-F_1 (*Lycopersicon esculentum*) variety was used in the study. In the trials, Joker F1 tomato variety was chosen due to the fact that it is a very strong variety that can cover the fruit, it is more resistant to diseases, it has can highly adapt to the region, it yields a hard fruit with a long shelf-life and it is suitable for temporary and long-term harvest. The seedlings were planted in the field on May 20. Prior to planting, plough cultivation was applied, large clods were crushed and field surface was smoothed to prepare the conditions for planting. The plants were planted in 5 rows with an inter-row spacing of 100 cm and intra-row spacing of 50 cm. Weeding was carried out manually through hoeing three times until the first harvest. Nitrogenous, phosphorous and potassium fertilizers were used in fertilization. Prior to planting, compound Diammonium Phosphate (DAP) (20:20:0) was applied in the dose of 50 kg per decare. Equal fertilization to each plant was carried out until reaching a cover level of 30% and irrigation conditions were met; after planting, in each irrigation, the NPK 15:15:15 and potassium nitrate 13-0-46 fertilizers were applied in the amount of 10 kg (50 kg in total) using a drip irrigation system. To control the more cricket population, the Korban-4 insecticide was used after planting. The experiments were carried out using waters of two different qualities in the applications, i.e. freshwater (FW) and treated wastewater (TWW). The quality result of each parameter in the *Table 3* shows the three sampling periods (June, July, and August). The clean water was obtained from the open irrigation channel at the entrance of the field and the wastewater was obtained from the exit of the wastewater treatment plant of Bingöl. *Table 3* shows the properties of the irrigation waters.

no. 2-4-6 lateral pipes in even-number irrigations]. The amount of irrigation water were equal in wastewater and clean water applications and adjusted in accordance with the control application in which 100% full irrigation was applied. The irrigations were commenced immediately after planting and finalized on September 29, when the growing season ended. *Table 4* shows the total and monthly irrigation water amounts in different applications. A total of 640.2 mm irrigation water was used in the 100% full irrigation application to tomato plants. The lowest irrigation water amount was 338.3 mm and applied in the 50% D and 50% PRD applications (*Table 4*).

Table 4. *The amounts of monthly and seasonal irrigation water applications to tomato plants in different irrigation applications (mm)*

Application	Months					
	May	June	July	August	September	Total
% 100	10.6	37.0	219	207.6	166.1	640.2
% 75 D	10.6	34.2	164.3	155.7	124.6	489.3
% 50 D	10.6	31.4	109.5	103.8	83.1	338.3
% 75 PRD	10.6	34.2	164.3	155.7	124.6	489.3
% 50 PRD	10.6	31.4	109.5	103.8	83.1	338.3

%100 full irrigation, *75D* and *50D* 75 and 50% deficit irrigation, *75PRD* and *50PRD* 75 and 50% deficit irrigation with PRD

Irrigation quantities in the scheduled irrigation period were corrected using a coefficient of 0.50 for the 50D and 50 PRD treatments and using a coefficient of 0.75 for the 75D and 75PRD treatments (*Table 4*).

BER were calculated using the below equations (*Eqs. 1–2;* Koral, 2006):

$$BER = \frac{Nf}{Ntf} x100 \quad \text{(Eq.1)}$$

where *BER* is the blossom-end rot (%), *Nf* number of rotten fruits, *Ntf* total number of fruits.

$$BER = \frac{Mf}{Mtf} x100 \quad \text{(Eq.2)}$$

where *BER* is the blossom-end rot (%), *Mf* rotten fruits weight (kg), *Mtf* total fruit weight (kg).

The changes in soil moisture were measured before the irrigations and showed that moisture did not drop to the wilting point in any of the applications throughout the growing season and the available water was reduced about 40% in the full irrigation application. A growing period of minumum 30% was provided and water was given equal to each plant until irrigation issues started. In general, the soil moisture values in the 75% PRD and 50% PRD applications were the closest values to the wilting point according to the soil moisture values. The changes in soil moisture during the growing season were close to each other in all applications (*Table 5*.)

FW freshwater, *TWW* treated wastewater, *%100* full irrigation, *75D* and *50D* 75 and 50% deficit irrigation, *75PRD* and *50PRD* 75 and 50% deficit irrigation with PRD

The variance analyses were carried out using the SAS software (SAS, 2000) and the Duncan multiple comparison test of the Minitab software was used to compare the significant averages (Kesici and Kocabaş, 2007).

Results and discussion

Tables 6 and *7* show the effects of PRD and D applications on the blossom-end rot in tomato. According to *Table 6*, blossom-end rot incidences with respect to fruit number varied between 8.57% and 33.22%. The highest blossom-end rot incidence was obtained in the 50% D freshwater applications. The differences between the averages obtained for water resources were statistically not significant, while the differences between the applications were significant. The lowest blossom-end rot incidence was obtained in the 100% full irrigation applications, while the highest blossom-end rot incidence was obtained in the 50% D applications. The PRD applications had less effect

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_21352147

on blossom-end rot than the deficit irrigation applications. In their study, Zegbe et al. (2007) reported that the highest blossom-end rot was obtained in the D (37%) and PRD (22%) applications and determined that blossom-end rot was higher in the deficit irrigation application than in the partial root drying application. Obreza et al. (1996) found that blossom-end rot was five times higher in the 30% deficit irrigation application than in the full irrigation application. In the same vein, Dorji et al. (2005) determined that the highest blossom-end rot incidences were obtained in the deficit irrigation and partial root drying applications. The increased blossom-end rot incidences in deficit irrigation and partial root drying applications are attributable to the water deficit-induced decrease in the calcium content of the fruits (Adams and Ho, 1992).

FW freshwater, *TWW* treated wastewater, *%100* full irrigation, *75D* and *50D* 75 and 50% deficit irrigation, *75PRD* and *50PRD* 75 and 50% deficit irrigation with PRD

According to *Table 7*, the blossom-end rot values with respect to fruit weight varied between 16.96 and 30.96%. The differences between the applications in the ratios of the weight of fruits with blossom-end rot to total fruit weight were not statistically significant.

The higher incidences of blossom-end rot in the deficit irrigation applications is attributable to the activation of the self-defense mechanisms of the plants in response to water stress. Moreover, irregular irrigation and saline water conditions have been reported to be the most common causes of blossom-end rot (Cuartero and Fernandez-Munoz, 1999; Franco et al., 1999; Zhai et al., 2015). The decrease in the soil moisture in the D and PRD applications can contribute to the increase in blossom-end rot incidences. According to *Table 6*, the highest incidence of blossom-end rot was observed in the deficit irrigation applications due to decreased soil moisture (*Tables 4* and *5*). In their study, Shaykewich et al. (1971) reported that blossom-end rot increased in soils with decreased moisture content. Pill and Mambeth (1980) observed that hardness and blossom-end rot increased in tomatoes under conditions of low NH_4 fertilization and soil water potential. It has also been reported that low Ca content in the fruit and deficit irrigation application affected the development of blossom-end rot (Adams and Ho, 1993; Taylor et al., 2004; Ho and White, 2005). Researchers have

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_21352147

noted that the PRD method is a variation of the deficit irrigation applications and one of its negative effects on the tomato plants is blossom-end rot development (Obreza et al., 1996; Zegbe et al., 2004). In their study in which the effects of PRD and D applications on tomato were investigated, Sun et al. (2013) reported that the PRD applications had a lesser effect on the development of blossom-end rot than the D applications and associated it with the increase in the abscisic acid concentration and the subsequent increase in stomatal conductivity leading to increased calcium uptake and, thus, decreased blossom-end rot development.

There was a statistically significant relationship between blossom-end rot and Ca contents of the fruit and leaves (*Table 8*). The first studies about the issue generally reported that blossom-end rot occurred under conditions of Ca deficiency (Hamner et al., 1942; Ward, 1973; Bradfield and Guttridge, 1984; Adams and Ho, 1992). However, blossom-end rot is not only affected by Ca deficiency but also affected by high Mg, Na, K and NH_4 concentrations, rapid growth, irrigation amount, low Ca content in soil and high or low transpiration (Geraldson, 1955; Kirby and Pilbeam, 1984; De Kreij, 1996; Paiva et al., 1998; Marcelis and Ho, 1999; Franco et al., 1999; Saure, 2001; Taylor and Locascio, 2004). The K and N contents of the fruits were also determined to have statistically significant effects on blossom-end rot while in soil, only the effects of K+Mg/Ca and EC on blossom-end rot were statistically significant. The results indicated that various factors affected blossom-end rot in addition to Ca deficiency.

Table 8. *The linear correlation between BER and Ca, K, N, K/Ca K+Mg/Ca and EC*

	Fruit	**Leaf**	**Soil**
Ca	-0.557**	-0.691**	-0.055
K	-0.407*	-0.280	-0.480
N	-0.399*	-0.300	-0.160
K/Ca	-0.264	0.380*	-0.040
K+Mg/Ca	-0.290	0.465**	0.396*
EC	-0.002	-	-0.535**

**p < 0.01, *p < 0.05

There was a significant negative relationship between blossom-end rot and the potassium content of the fruits, while the relationship between blossom-end rot and the potassium contents of leaves and soil was not statistically significant. Moreover, there was a significant negative relationship between the nitrogen content of the fruits and BER. There was a significant positive relationship between the K/Ca and K+Mg/Ca ratios in leaves and BER. BER had a significant positive relationship with the K+Mg/Ca ratio in soil, while it had a significant negative relationship with EC (*Table 8*). DeKock et al. (1982) reported that the ratio of K/Ca was a better determinant of blossom-end rot than the Ca content. However, Wada et al. (1996) and Bar-Tal and Pressman (1996) argued that the relationship between K/Ca and blossom-end rot did not have a predictive value. Albahou (1999) reported that high salinity contributed to the decrease in the blossom-end rot incidences. However, various researchers are of the opinion that blossom-end rot increases with increasing salinity and NH_4 content (Pill and Lambeth, 1980; Nonami et al., 1995; Saure, 2014).

Conclusion

In the study in which the effects of the D and PRD methods on blossom-end rot were investigated, the lowest blossom end-rot incidence was observed in the 100% full irrigation applications. The D application had the highest effect on blossom-end rot development. The PRD method had a lower effect than the deficit irrigation application. The lower incidence of blossom-end rot in the PRD applications compared with the D applications was associated with increased abscisic acid concentration in the xylem, decreased stomatal conductivity and the more effective use of water leading to increased Ca uptake and reduced blossom-end rot development. Therefore, the PRD can be a promising method for water saving under water deficit conditions and reduction of blossom-end rot development in tomatoes.

The results indicated that blossom-end rot was affected by various factors in addition to Ca deficiency. Furthermore, the results showed that in the production of marketable tomato, the PRD method is more advantageous than the D method under water shortage conditions where full irrigation is limited.

Abstract. This study set out to determine which seeding rate produces the maximum grain yield through the monocropping and intercropping of maize and soybeans using different seeding rates on the research and land of the Faculty of Agriculture, Ordu University, in 2016. To this end, the study used a randomized block experimental design with three replications. The treatments included a sole crop of maize, a sole crop of soybean, one row of soybean intercropped with one row of maize, two rows of soybeans intercropped with one row of maize, three rows of soybeans intercropped with one row of maize, one row of soybean intercropped with two rows of maize, and one row of maize intercropped with three rows of soybean. According to the results on maize, the chlorophyll concentration index ranged from 45.50 to 50.93, leaf area from 360.51 to 510.19 cm^2, ash content from 5.76 to 9.30%, protein content from 9.26 to 10.77%, crude fat content from 3.35 to 4.85%, palmitic acid content from 12.17 to 13.12%, stearic acid content from 1.98 to 2.44%, oleic acid content from 23.86 to 24.95%, linoleic acid content from 58.97 to 60.90%, linolenic acid content from 0.91 to 1.13%, unsaturated fatty acid content from 84.62 to 85.84%, saturated fatty acid content from 14.15 to 15.37%, unsaturated to saturated fatty acid ratio from 5.50 to 6.08%, and grain yield from 32.01 to 89.512 kg ha^{-1}. According to the results on soybean, the chlorophyll concentration index ranged from 42.33 to 44.43, leaf area from 32.41 to 41.38 cm^2, ash content from 9.67 to 10.82%, protein content from 42.92 to 45.38%, crude fat content from 19.65 to 20.77%, palmitic acid content from 10.39 to 10.77%, stearic acid content from 3.81 to 4.28%, oleic acid content from 19.86 to 20.29%, linoleic acid content from 58.01 to 58.98%, linolenic acid content from 6.58 to 7.07%, unsaturated fatty acid content from 84.92 to 85.54%, saturated fatty acid content from 14.45 to 14.99%, unsaturated to saturated fatty acid ratio from 5.66 to 5.91%, grain yield from 10.36 to 61.11 kg ha^{-1}, and the Land Equivalent Ratio (LER) from 1.03 to 1.21. Considering all the properties investigated and LER together, three rows of soybean intercropped with one row of maize were found to be the most appropriate intercropping system.
Keywords: *crude fat content, fatty acids, leaf area, LER, protein content*

Introduction

Maize or corn occupies an important place both in Turkey and throughout the world because it has greater adaptability and the highest yield among cereals. 35% of the maize produced in Turkey is used in human nutrition, 30% in animal nutrition, 20% in the feed industry, and 15% in other areas (Gençtan et al., 1995). Maize is also a good source of energy because the majority of maize (corn grains) is composed of starch. Not only is corn starch obtained from maize, but also corn gluten meal and bran are manufactured from maize embryos for use in the oil and feed industry (Hallauer, 2001). The widespread use of oil and starch as bioenergy and the high yield of the maize plant have led to maize manufacture in every region where climatic conditions allow (Abbasi and Abbasi, 2010).

Soybean plants consist of 18 to 26% fat and 40% protein. The quality of soybean oil is increased by the high amount of oleic and linoleic fatty acids and the low amount of linolenic fatty acids. By-products obtained from soybean (flour, lecithin, protein, and fat) are used as raw materials in the industry (Cole and Erdahl, 2018). A wide range of products are manufactured from soybeans, including coffee cream, cooking oil, margarine, mayonnaise, medication, pharmaceuticals, salad dressing, anti-corrosion agents, anti-static agents, construction materials, ink printing materials, epoxies, fungicides, soap, detergents, bread, confectionery, biscuits, soya coffee, packaging foils, antibiotics, textiles, cat and dog foods, and fish feed (Endres, 2001).

In the world and in Turkey, the limited possibility of increasing the number of cultivable agricultural areas and the rapid increase in population have caused to agricultural workers to seek ways to exploit the maximum amount of agricultural land. Intercropping is one of these ways. Intercropping is recommended in order to produce greater and more balanced yield from unit area and to bolster defence against weeds (Acar et al., 2006).

Intercropping is an effective alternative for the prevention of loss within a complete growing season. The objective of intercropping is to create beneficial biological interactions between plants. Using legumes, it improves soil fertility through biological nitrogen fixation and ensures better soil conservation than monocropping. Ecological resources can be used better and far superior efficiency can be achieved in intercropping compared to monocropping. Having said that, there is a competition between intercropped inter- and intra-species for water, light, and nutrients. Therefore, it is of utmost importance to determine appropriate species and the ratio of crop mixtures in order to gain the expected benefit from intercropping (Lithourgidis et al., 2011).

Against this background, the purpose of the present study is to identify the effects of sole-cropped and intercropped maize and soybeans on a set of technological and physiological properties, which are manufactured to obtain material in primarily human nutrition and secondly animal nutrition.

Material and method

The trial was conducted on the research and land of the Faculty of Agriculture, Ordu University, in 2016. The land is located at 40°58′13.4″N latitude and 37°56′16.6″E longitude at an altitude of three meters (*Fig. 1*).

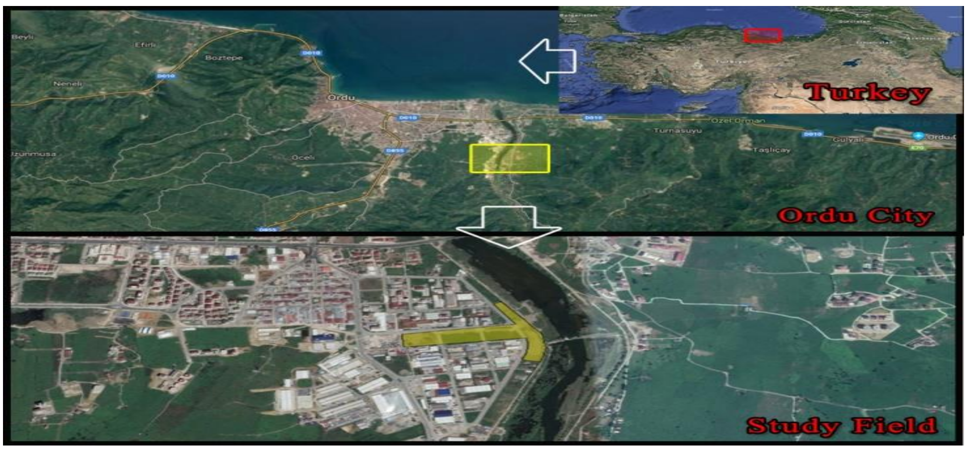

Figure 1. *Location of the study field*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_21492165

During the vegetation period of maize and soybean, the total precipitation at the trial site is 474.7 mm, the average temperature is 19.7ºC, and the average humidity is 74.3%. During the vegetation period of maize and soybean in 2016, the total precipitation at the trial site was 624 mm, the average temperature was 22.1ºC, and the average humidity was 68.3%. The total precipitation and average temperature recorded in the year of trial 2016 are above the average of long years (1965-2015) and the average humidity is below the average of long years (1965-2015). According to the results of soil analysis, the soil sampled from the trial site is clayey and neutral in terms of soil reaction and has a moderate amount of organic matter. Its less chalky soil is also less chalky and more saline.

The present study used Arısoy soybean seed variety supplied from the Black Sea Agricultural Research Institute, and SY Inove maize seed supplied from a private seed company. The trial was established in Ordu on June 13, 2016, under ecological conditions of the main crop. The study used a randomized block experimental design with three replications. The plots at the trial site were seeded with sole crops of maize and soybean, intercropped maize and soybean. *Table 1* shows the patterns of seeding. Prior to seeding, soybean seeds were inoculated using Rhizobium japonicum L. bacteria supplied from the Soil, Fertilizer and Water Resources Central Research Institute. Each plot was designed to have a length of 4 meters, a width of 7.7 meters, and 12 rows of seeding (30.8 m^2). An inter-row spacing of 70 cm was maintained for all row arrangements. An intra-row spacing of 20 cm was maintained for both the distinct row intercrops and the sole crop of maize. An intra-row spacing of 5 cm was maintained for both the distinct row intercrops and the sole crop of soybean.

Table 1. *Row Arrangements of Intercropping*

Crop Rows	Intercropping
Maize	Sole Crop
Soybean	Sole Crop
1 row of soybean + 1 row of maize	Distinct-row
2 rows of soybean + 1 row of maize	Distinct-row
3 rows of soybean + 1 row of maize	Distinct-row
1 row of soybean + 2 rows of maize	Distinct-row
1 row of soybean + 3 rows of maize	Distinct-row

Fertilization was carried out on the basis of the three periods of the growing cycle of maize and soybean. Diammonium phosphate (DAP, 18.46.0) was used as the bottom fertilizer and calcium ammonium nitrate (CAN, 46%). *Table 2* describes the time and amount of fertilizers applied to the plots.

Table 2. *Time and Amount of Fertilizers Applied on the Plots*

Time of Fertilizer Application	Fertilized Plot	Amount of Fertilizer
Pre-seeding	Sole Maize Soybean– Maize	Pure 0.7 kg ha^{-1} N/, 0.7 kg ha^{-1} P_2O_5
	Sole Soybean	Pure 0.3 kg ha^{-1} N 0.7 kg ha^{-1} P_2O_5
Bolting Time	Sole Maize Soybean – Maize	Pure 0.7 kg ha^{-1} N
Maize Dent Stage	Sole Maize Soybean – Maize	Pure 0.7 kg ha^{-1} N

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_21492165

Hoeing and weeding were done, when necessary, to control weeds and air the soil on all sole-cropping and intercropping plots. According to crop water needs, crops were irrigated four times using springer irrigation system: the time when crops attain a height of 20 cm, at maize tasseling and soybean flowering stages, at pollination stage, and at maize dent and soybean seed-filling stages.

Technological and physiological measurements made in the experiment are given in *Table 3*.

Table 3. *List of technological and physiological traits measured*

Trait	Maize	Soybean
Chlorophyll Concentration Index	Chlorophyll concentration index of 10 plants randomly selected from each plot chlorophyll concentration index was determined by measuring chlorophyll in sunny and cloudy days in the leaves of corn plant by using Apogee tool.	Chlorophyll concentration index of 10 plants randomly selected from each plot chlorophyll concentration index was determined by measuring chlorophyll in sunny and cloudy days in the leaves of soybean plant by using Apogee tool.
Leaf area	$LA=\left[\begin{array}{c}-5.87+(2.76xW)+(1.11xL)+(0.04X\ L^2) \\ +[0.05x(LxW^2)]\end{array}\right]$ LA: Leaf Area, L: Leaf length, W: Leaf width	Digimizer is determined using the package program.
Ash Content	The grains of 10 plants were randomly harvested from each parcel and ground to a 1 mm sieve. Calculation of ash ratio calculated using the formula given below $Ash\% = \frac{\text{Weight of burnt sample x 100}}{\text{Weight of unburned sample}}$	
Protein content, Crude fat content	The grains of 10 plants taken from each parcel were randomly blended and identified in non-grinded samples using the IC-1020WE maize calibration kit in the "Near Infrared Reflection" (NIRS) device.	The grains of 10 plants were randomly harvested from each plot and were determined in the non-grinded samples using the IC-0923FE soybean calibration set in the Near Infrared Reflecting" (NIRS) device.
Fatty acids	The grains of 10 plants randomly collected from each plot were blended and the amount of fatty acids was determined as % in Gas Chromatography.	
Grain Yield	In 10 plants randomly collected from each plot, the grains are blended and the grain moisture is arranged according to 14%. 10 plant yield per hectare multiplied by the number of plants and yield per hectare	
Land Equivalent Ratio (LER)	The land equivalent ratio (LER) was calculated as the sum of the relative yields of maize and soybean in the intercropping plots to the monocropping plots using the following equation: $LER=\left[\frac{Yint\text{-}soy}{Ymono\text{-}soy}\right]+\left[\frac{Yint\text{-}maize}{Ymono\text{-}maize)}\right]$ LER = LERsoy+LERmaize =Yint–soy +Yint–maize Ymono–soy Ymono–maize where Yint–soy, Ymono–soy, Yint–maize, and Ymono–maize are the grain yields (kg ha^{-1}) of intercropped soybean, monocropped soybean, intercropped maize, and monocropped maize, respectively.	

After crops attained full maturity, they were harvested October 25, 2016 (*Fig. 2*). After edges of 50 cm were cut to avoid edge effect during harvesting, technological properties were analyzed on 10 crops randomly selected among maize and soybeans. LER values were calculated for the seeding plots to determine the efficiency of the land use by dividing the intercrop yields of maize and soybean to the sole yields of maize and soybean and then adding two values. SAS-JMP 10.0 statistical software was used to run an analysis variance on the values based on a randomized block experimental design. The Least Significant Difference (LSD) test was used to measure significant differences between means.

Figure 2. *Some views from experimental plots*

Results and discussion

Chlorophyll Concentration Index (CCI) of Maize

Considering the effect of intercropping on the chlorophyll concentration content of the maize plant, no significant difference was found. The CCI varied from 45.50 to 50.93. The lowest CCI was observed in the sole-cropped maize, while the highest CCI was observed in two rows of soybean intercropped with one row of maize. The mean CCI of the intercropped maize was found to be 47.91 (*Table 4*).

Our results on the maize chlorophyll concentration index are reported 35.17 - 47.03 in Choudrary et al. (2014), 17.89 - 29.53 in Sabancı (2015).

Table 4. *The Values of CCI, Leaf Area, Ash Content, Protein Content, and Crude Fat Content for the Intercropped Maize*

Intercropping	CCI	Leaf Area (cm^2)	Ash Content (%)	Protein Content (%)	Crude Fat Content (%)

CCI of Soybean

Considering the effect of intercropping on the chlorophyll concentration content of the soybean plant, no significant difference was found. The CCI varied from 42.33 to 44.43. The lowest CCI was observed in the sole-cropped soybean, while the highest CCI was observed in three rows of soybeans intercropped with one row of maize. The mean CCI of the intercropped soybean was 43.30 (*Table 5*).

Sole cropping of corn had the least chlorophyll content, while in all intercropping treatments especially when corn was in neighboring of soybean, chlorophyll content of corn significantly increased (Amini et al., 2013).

CCI: Chlorophyll Content Index, SM: Sole Soybean, S: Soybean, and M: Maize

Maize Leaf Area (cm^2)

Considering the effect of intercropping on the leaf area of the maize plant, no significant difference was found. The leaf area of maize varied from 360.51 cm^2 to 510.19 cm^2. The smallest leaf area was observed in one row of soybean intercropped with two rows of maize, while the largest leaf area was observed in three rows of soybean intercropped with one row of maize. The mean leaf area of the intercropped maize was 433.08 cm^2 (*Table 4*).

Our results on the maize leaf area are above those reported to be 305.96 - 325.62 cm^2 in Subedi and Ma (2005) but below those reported to be 877.3 - 626 cm^2 in He et al. (2011). A positive significant relationship has been reported between the number of leaves per plant and the leaf area of maize (Öner et al., 2012).

Soybean Leaf Area (cm^2)

Considering the effect of intercropping on the leaf area of the soybean plant, no significant difference was found. The leaf area of soybean varied from 32.41 cm^2 to 41.38 cm^2. The smallest leaf area was observed in the sole-cropped soybean, while the largest leaf area was observed in two rows of soybean intercropped with one row of maize. The mean leaf area of the intercropped soybean was 37.16 cm^2 (*Table 5*).

Our results on the soybean leaf area are below those reported to be 68.70 - 35.50 cm^2 in Ngalamu et al. (2012).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_21492165

Maize Ash Content (%)

The effect of intercropping on the ash content of the maize plant was found to be statistically significant (P<0.05). The ash content of maize varied from 5.76 to 9.30%. The lowest ash content was observed in one row of soybean intercropped with one row of maize, while the highest ash content was observed in two rows of soybean intercropped with one row of maize. The mean ash content of the intercropped maize was 7.96% (*Table 4*).

Our results on the maize ash content are above those reported to be 1.46 - 1.81% in Lucchin et al. (2003), and those reported to be 1.08 - 2.22% in Moreno et al. (2015).

Soybean Ash Content (%)

The effect of intercropping on the ash content of the soybean plant was statistically insignificant. The ash content of soybean varied from 9.67 to 10.82%. The lowest ash content was observed in three rows of soybean intercropped with one row of maize, while the highest ash content was observed in one row of soybean intercropped with one row of maize. The mean ash content of the intercropped soybean was 10.36% (*Table 5*). Our results on the maize ash content are above those reported to be 1.99 - 18.74% in Ahmad et al. (2016).

Maize Protein Content (%)

The effect of intercropping on the protein content of the maize plant was statistically insignificant. The protein content of maize varied from 9.26 to 10.77%. The lowest protein content was observed in the sole-cropped maize, while the highest protein content was observed in two rows of soybean intercropped with one rows of maize. The mean protein content of the intercropped maize was 10.20% (*Table 4*).

Our results on the maize protein content are consistent with those reported to be 7.94 - 10.61% in Bekele and Rao (2014), while they are below those reported to be 11.02 - 12.73% in Öner et al. (2011) but above those reported to be 6.21 - 8.65% in Vartanlı and Emeklier (2007).

Soybean Protein Content (%)

The effect of intercropping on the protein content of the soybean plant was statistically significant (P<0.05). The protein content of soybean varied from 42.92 to 45.38%. The lowest protein content was observed in three rows of soybean intercropped with one row of maize, while the highest protein content was observed in one row of soybean intercropped with one row of maize. The mean protein content of the intercropped soybean was 44.08% (*Table 5*).

Our results on the soybean protein content are consistent with those reported to be 44.30 - 47.20% in Şenyiğit et al. (2015), while they are above those reported to be 32.27 - 33.87% in Aydemir and Kızılşimşek (2018).

Maize Crude Fat Content (%)

Considering the effect of intercropping on the crude fat content of the maize plant, no significant difference was found. The crude fat content of maize varied from 3.35 to 4.85%. The lowest crude fat content was observed in one row of soybean intercropped with two rows of maize, while the highest crude fat content was observed in one row of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_21492165

soybean intercropped with three rows of maize. The mean crude fat content of the intercropped maize was 3.95% (*Table 4*).

Our results on the maize crude fat content are consistent with those reported to be 3.50 - 8.30% in Hartings et al. (2008), while they are below those reported to be 11 - 6.28% in Akıncı et al. (2011) but above those reported to be 2.71 - 3.24% in Sabancı (2016).

Soybean Crude Fat Content (%)

The effect of intercropping on the crude fat content of the soybean plant was statistically significant (P<0.05). The crude fat content of soybean varied from 19.65 to 20.77%. The lowest crude fat content was observed in one row of soybean intercropped with one row of maize, while the highest crude fat content was observed in three rows of soybean intercropped with one row of maize. The mean crude fat content of the intercropped soybean was 20.10% (*Table 5*).

Our results on the soybean crude fat content are consistent with those reported to be 17.54 - 19.90% in Kan et al. (2011), while they are below those reported to be 22.06 - 24.67% in Dolapçı (2012) but above those reported to be 12.00 - 14.00% in Karagül et al. (2011).

Maize Palmitic Acid Content (%)

Palmitic acid is the second most common saturated fatty acids, following oleic acid. Palmitic acid composes 15 - 50% of fatty acids found in most fats (Kale et al., 2017). The effect of intercropping on the palmitic acid content of the maize plant was statistically insignificant. The palmitic acid content of maize varied 12.17 to 13.12%. The lowest palmitic acid content was observed in one row of soybean intercropped with three rows of maize, while the highest palmitic acid content was observed in the sole-cropped maize. The mean palmitic acid content of the intercropped maize was 12.45% (*Table 6*).

Our results on the maize palmitic acid content are consistent with those reported to be 12.79 - 15.55% in Akıncı et al. (2011), while they are above that reported to be 11.20% in Kan et al. (2011).

Table 6. *The Values of Palmitic Acid (%), Stearic Acid (%), Oleic Acid (%), Linoleic Acid (%) and Linolenic Acid (%) for the Intercropped*

DOI: http://dx.doi.org/10.15666/aeer/1702_21492165

Maize Stearic Acid Content (%)

The effect of intercropping on the stearic acid content of the maize plant was also statistically insignificant. The stearic acid content of maize varied from 1.98 to 2.44%. The lowest stearic acid content was observed in one row of soybean intercropped with three rows of maize, while the highest stearic acid content was observed in one row of soybean intercropped with one row of maize. The mean stearic acid content of the intercropped maize was 2.15% (*Table 6*).

Our results on the maize stearic acid content are consistent with that reported to be 1.88 - 2.13% in Kaplan et al. (2017), while they are below those reported to be 2.87 - 3.50% in Akıncı et al. (2011).

Maize Oleic Acid Content (%)

Oleic acid is the most common fatty acid in nature. More than half of the fatty acids in most fats is oleic acid. It is quite rare that oils have less than 10% oleic acid. All natural oils and phospholipids known to date have oleic acid (Kaplan et al., 2017).

The effect of intercropping on the oleic acid content of the maize plant was also statistically insignificant. The oleic acid content of maize varied from 23.86 to 24.95%. The lowest oleic acid content was observed in one row of soybean intercropped with three rows of maize, while the highest oleic acid content was observed in two rows of soybean intercropped with one row of maize. The mean oleic acid content of the intercropped maize was 24.61% (*Table 6*).

Our results on the maize oleic acid content are consistent with that reported to be 24% in Lambert (2000), while they are below that reported to be 20 - 50% in Olmos et al. (2018).

Maize Linoleic Acid Content (%)

The effect of intercropping on the linoleic acid content of the maize plant was also statistically insignificant. The linoleic acid content of maize varied from 58.97 to 60.90%. The lowest linoleic acid content was observed in the sole-cropped maize, while the highest linoleic acid content was observed in one row of soybean intercropped with three rows of maize. The mean linoleic acid content of the intercropped maize was 59.72% (*Table 6*).

Our results on the maize linoleic acid content are above those reported to be 41.84 - 50.70% in Betancourt et al. (2017).

Maize Linolenic Acid Content (%)

The effect of intercropping on the linolenic acid content of the maize plant was also statistically insignificant. The linolenic acid content of maize varied from 0.91 to 1.13%. The lowest linolenic acid content was observed in one row of soybean intercropped with one row of maize, while the highest linolenic acid content was observed in the sole-cropped maize. The mean linolenic acid content of the intercropped maize was 1.01% (*Table 6*).

Our results on the maize linolenic acid content are consistent with that reported to be 0.65-0.95% in Betancourt et al. (2017), while they are below those reported to be 1.31 - 2.02% in Akıncı et al. (2011).

DOI: http://dx.doi.org/10.15666/aeer/1702_21492165

Maize Unsaturated Fatty Acid Content (%)

Unsaturated fatty acids have double bonds (Ramos et al., 2009). The effect of intercropping on the unsaturated fatty acid content of the maize plant was also statistically insignificant. The unsaturated fatty acid content of maize varied from 84.62 to 85.84%. The lowest unsaturated fatty acid content was observed in the sole-cropped maize, while the highest unsaturated fatty acid content was observed in one row of soybean intercropped with three rows of maize. The mean unsaturated fatty acid content of the intercropped maize was 85.37% (*Table 7*).

Maize Saturated Fatty Acid Content (%)

Saturated fatty acids have no double (Ramos et al., 2009). The effect of intercropping on the saturated fatty acid content of the maize plant was also statistically insignificant. The saturated fatty acid content of maize varied from 14.15 to 15.37%. The lowest saturated fatty acid content was observed in one row of soybean intercropped with three rows of maize, while the highest saturated fatty acid content was observed in the sole-cropped soybean. The mean saturated fatty acid content of the intercropped maize was 14.61% (*Table 7*).

Table 7. *The Values of Unsaturated Fat Acid Content, Saturated Fat Acid Content, and Unsaturated to Saturated Fat Acid Ratio for the Intercropped Maize*

* Unsaturated fat acid content (%) = oleic acid + linoleic acid + linolenic acid
* * Saturated fat acid content (%) = palmitic acid + stearic acid

Maize Unsaturated to Saturated Fatty Acid Ratio (%)

The most important property that determines the quality of vegetable fats is the ratio of the total amount of unsaturated fatty acids to the total amount of saturated fatty acids. The effect of intercropping on the unsaturated to saturated fatty acid ratio of the maize plant was also statistically insignificant. The unsaturated to saturated fatty acid ratio of maize varied from 5.50 to 6.08%. The lowest ratio was observed in the sole-cropped maize, while the highest ratio was observed in one row of soybean intercropped with three rows of maize. The mean unsaturated to saturated fatty acid ratio of the intercropped maize was 5.84% (*Table 7*).

Soybean Palmitic Acid Content (%)

The effect of intercropping on the palmitic acid content of the soybean plant was statistically insignificant. The palmitic acid content of soybean varied 10.39 to 10.77%. The lowest palmitic acid content was observed in one row of soybean intercropped with

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_21492165

two rows of maize, while the highest palmitic acid content was observed in the sole-cropped maize and in one row of soybean intercropped with one row of maize. The mean palmitic acid content of the intercropped soybean was 10.64% (*Table 8*).

Our results on the soybean palmitic acid content are consistent with those reported to be 2.7 - 11.2% in Bilyeu et al. (2018), while they are below those reported to be 10.98 - 12.88% in Arıoğlu et al. (2012) but above those reported to be 8.80 - 10.30% in Arıoğlu et al. (2012).

Soybean Stearic Acid Content (%)

The effect of intercropping on the stearic acid content of the soybean plant was also statistically insignificant. The stearic acid content of soybean varied from 3.81 to 4.28%. The lowest stearic acid content was observed in the sole-cropped soybean, while the highest stearic acid content was observed in three rows of soybean intercropped with one row of maize. The mean stearic acid content of the intercropped soybean was 3.99 % (*Table 8*).

Our results on the soybean stearic acid content are consistent with those reported to be 3.60 - 4.70% in Kan et al. (2011), while they are below those reported to be 4 - 12.1% in Carrero et al. (2014) but above those reported to be 1.15 - 2.02% in Sultan et al. (2015).

Table 8. *The Values of Palmitic Acid, Stearic Acid, Oleic Acid, Linoleic Acid, and Linolenic Acid for the Intercropped Soybean*

Intercropping	Stearic Acid (%)	Palmitic Acid (%)	Oleic Acid (%)	Linoleic Acid (%)	Linolenic Acid (%)

LSD	-	-	-	-	-

Soybean Oleic Acid Content (%)

The effect of intercropping on the oleic acid content of the soybean plant was also statistically insignificant. The oleic acid content of soybean varied from 19.86 to 20.29%. The lowest oleic acid content was observed in one row of soybean intercropped with one row of maize, while the highest oleic acid content was observed in three rows of soybean intercropped with one row of maize. The mean oleic acid content of the intercropped soybean was 19.98% (*Table 8*).

Our results on the maize oleic acid content are consistent with that reported to be 20.09 - 20.88% in Sultan et al. (2015), while they are below those reported to be 22.20 - 25.90% in Kan (2011).

Soybean Linoleic Acid Content (%)

The effect of intercropping on the linoleic acid content of the soybean plant was also statistically insignificant. The linoleic acid content of soybean varied from 58.01 to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_21492165

58.98%. The lowest linoleic acid content was observed in three rows of soybean intercropped with one row of maize, while the highest linoleic acid content was observed in two rows of soybean intercropped with one row of maize. The mean linoleic acid content of the intercropped soybean was 58.50% (*Table 8*).

Our results on the maize linoleic acid content are below those reported to be 50.30 - 54.30% in Kan (2011).

Soybean Linolenic Acid Content (%)

The effect of intercropping on the linolenic acid content of the soybean plant was also statistically insignificant. The linolenic acid content of soybean varied from 6.58 to 7.07%. The lowest linolenic acid content was observed in two rows of soybean intercropped with one row of maize, while the highest linolenic acid content was observed in the sole-cropped soybean. The mean linolenic acid content of the intercropped soybean was 6.83% (*Table 8*).

Our results on the soybean linolenic acid content are consistent with those reported to be 6.30 - 7.62% in Arıoğlu et al. (2012), while they are below those reported to be 7 - 10 % in Kim et al. (2015).

Soybean Unsaturated Fatty Acid Content (%)

The effect of intercropping on the unsaturated fatty acid content of the soybean plant was also statistically insignificant. The unsaturated fatty acid content of soybean varied from 84.92 to 85.54%. The lowest unsaturated fatty acid content was observed three rows of soybean intercropped with one row of maize, while the highest unsaturated fatty acid content was observed in two rows of soybean intercropped with one rows of maize. The mean unsaturated fatty acid content of the intercropped soybean was 85.33% (*Table 9*).

Our results on the soybean unsaturated fatty acid content are consistent with those reported to be 82.02 - 84.93% in Arıoğlu et al. (2012), while they are below those reported to be 88.12 - 88.58% in Sultan et al. (2015).

Soybean Saturated Fatty Acid Content (%)

The effect of intercropping on the saturated fatty acid content of the soybean plant was also statistically insignificant. The saturated fatty acid content of soybean varied from 14.45 to 14.99%. The lowest saturated fatty acid content was observed in two rows of soybean intercropped with one row of maize, while the highest saturated fatty acid content was observed in three rows of soybean intercropped with one row of maize. The mean saturated fatty acid content of the intercropped soybean was 14.64% (*Table 9*).

Our results on the soybean saturated fatty acid content are consistent with those reported to be 13.59 - 16.88% in Arıoğlu et al. (2012), while they are below those reported to be 17.60 - 20.36% in Barış (2016) but above those reported to be 11.42 - 11.80% in Sultan et al. (2015).

Soybean Unsaturated to Saturated Fatty Acid Ratio (%)

The effect of intercropping on the unsaturated to saturated fatty acid ratio of the soybean plant was also statistically insignificant. The unsaturated to saturated fatty acid ratio of soybean varied from 5.66 to 5.91%. The lowest ratio was observed in three rows of soybean intercropped with one row of maize, while the highest ratio was observed in one row of soybean intercropped with two rows of maize. The mean unsaturated to saturated fatty acid ratio of the intercropped soybean was 5.83% (*Table 9*).

Our results on the soybean unsaturated fatty acid content are consistent with those reported to be 6.25 - 4.90% in Arıoğlu et al. (2012), while they are above those reported to be 3.92 - 4.69% in Barış (2016).

Table 9. *The Values of Unsaturated Fat Acid Content, Saturated Fat Acid Content, and Unsaturated to Saturated Fat Acid Ratio for the Intercropped Soybean*

Maize Grain Yield (kg ha^{-1})

The effect of intercropping on the grain yield of the maize plant was found to be statistically very significant (P<0.01). The grain yield of maize varied from 32.01 kg ha^{-1} to 89.52 kg ha^{-1}. The lowest grain yield was observed in three rows of soybean intercropped with one row of maize, while the highest grain yield was observed in the sole-cropped maize. The mean grain yield of the intercropped maize was 63.20 kg ha^{-1} (*Table 10*).

Our results on the maize grain yield are consistent with those reported to be 37.00 - 51.00 kg ha^{-1} in Ijoyah and Fanen (2012) and 67.50 kg ha^{-1} in Alı et al. (2015), while they are above that reported to be 17.70 kg ha^{-1} in Rajı (2007).

Soybean Grain Yield (kg ha^{-1})

The effect of intercropping on the grain yield of the soybean plant was also found to be statistically very significant (P<0.01). The grain yield of soybean varied from 10.36 kg ha^{-1} to 61.11 kg ha^{-1}. The lowest grain yield was observed in one row of soybean intercropped with two rows of maize, while the highest grain yield was observed in the sole-cropped soybean. The mean grain yield of the intercropped soybean was 33.59 kg ha^{-1} (*Table 10*).

Our results on the soybean grain yield are consistent with those reported to be 10.20 kg ha^{-1} in Adeniyan and Ayoola (2007), 10.2 kg ha^{-1} in Raji (2007), 7.80 - 12.10 kg ha^{-1} in Ijoyah and Fanen (2012), and 10.88 kg ha^{-1} in Ali et al. (2015).

Land Equivalent Ratio (LER)

LER refers to the land amount needed by sole-cropping to produce the equivalent yield obtained from intercropped maize and soybean. The LER value varied from 1.03 to 1.21. The highest LER was observed in three rows of soybean intercropped with one

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_21492165

row of maize, while the lowest LER was observed in one row of soybean intercropped with two rows of maize (*Table 10*).

Our results on the LER value are consistent with those reported to be 1.27 in Wekesa et al. (2015) and 1.27 in Zhang et al. (2015), while they are below those reported to be 1.30 in Jamkhanh et al. (2012), 1.29 in Osang et al. (2014), and 1.44 in Alı et al. (2015).

Table 10. *The Values of Grain Yield and LER for the Intercropped Maize and Soybean*

Conclusions and Suggestions

The study has found significant differences between the applied cropping systems in terms of the maize ash content, soybean protein content, and soybean crude fat content but not in terms of the grain yields of maize and soybean. Considering the analysis results and LER values together, three rows of soybean intercropped with one row of maize were found to be the most appropriate intercropping system. However, this study needs to be carried out for 1 to 2 years for a more precise recommendation. In line with the findings of the study, further work could assess different systems of cropping and focus on the fodder and silage capacity of intercropped maize and soybean rather than grain yield.

EVALUATION OF THREE CANOLA (*BRASSICA NAPUS* L.) CULTIVARS FOR YIELD AND SOME QUALITY PARAMETERS UNDER THE ENVIRONMENTAL CONDITION OF SOUTHEASTERN ANATOLIA, TURKEY

OZTURK, F.

Department of Field Crops, Faculty of Agriculture, University of Sırnak, 73300 Şırnak, Turkey
(e-mail: fozturk@sirnak.edu.tr; phone: +90-532-254-0197; fax: +90-486-551-3031)

(Received 20th Nov 2018; accepted 11th Jan 2019)

Abstract. Canola is a significant alternate oilseed crop in Southeastern Anatolia, Turkey. While, there is no evidence for good yield potential canola cultivars are available in this area. Therefore, the study was conducted with three canola cultivars in consecutive two seasons (2013-14 and 2014-15) to find out the appropriate canola cultivars which are suitable to grow under the environmental condition of South-eastern Anatolia, Turkey. The experiment was carried out in a randomized complete block design with three replications. After two years of observation, it was found that plant height and branches plant^{-1} of all cultivars were varied significantly in both years. Considering the growing season, the maximum seed yield (2593.7 kg ha-1) was recorded in the first season (2014-15), while the minimum was recorded in the second season (2015-16). Among the cultivars, seed yield varied significantly and the maximum seed yield (2617.1 kg ha-1) was achieved in the variety 'Licrown'. The variety, 'Licord' was produced the highest oil content (37.92%) and protein (22.48%), while, variety 'Express' achieved the lowest oil content (37.43%). The greatest palmitic acid (4.67%), stearic acid (2.06%) and oleic acid (65.5%) content were produced by the variety 'Express'. While the variety 'Licord' produced the smallest value of stearic acid (1.86%), linoleic acid (17.17%). The variety 'Express' produced the lowest saturated fatty acid content (12.63%), while, the variety 'Licrown' achieved the highest (12.97%), although, the variety 'Licrown' produced the lowest (85.14%), and variety 'Express' produced the highest (85.47%) unsaturated fatty acid content. It is concluded that all cultivars have a good potential for the winter season of Southeastern Anatolia of Turkey. Accordingly, in the future the cultivar 'Express' could be used as a cultivar with high oleic and linoleic acid content and high yield under investigation conditions.
Keywords: *canola, genotypes, oil composition, saturated fatty acid, unsaturated fatty acids, yield*

Introduction

Canola (*Brassica napus* L.) is an essential oil seed crop in the world. Its oil is used as biofuel, human consumption (edible oil), feeding animals, and used in chemical and pharmaceutical industries (Friedt and Snowdon, 2009). It belongs to the family of Brassicaceae, which is becoming one of the major sources of the vegetable oil in the world (Baghdadi et al., 2013). It is the second largest oil seed after soybean worldwide, producing high-protein meal used for animal feed during processing (FAO, 2018). Presently, over 50% of vegetable oil, consumed in Turkey, is imported from abroad (İkiel and Kaymaz, 2005). To reduce the gap between oil consumption and the production of oilseed in Turkey, it is essential to grow alternate oilseed crops such as canola in crop rotation system in this region. Thus, the supplementary production of oilseed can meet up vegetable oil, increase biodiesel production, and decrease the import of vegetable oil (Öztürk, 2010; Cosgun and Öztürk, 2014).

Canola is a specific type of rapeseed correlated with high quality oil and meal. It is a special type of rapeseed that have less than 2% erucic acid in the oil and less than 30 micromoles per gram of glucosinolates in the oil-free meal (Anonymous, 2002). Moreover, canola contains 40-45% oil and 39% protein, and oil contains a desirable

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_21672177

profile of saturated fatty acids (~7%), high level of unsaturated fatty acids like oleic acids (61%) and medium level of linoleic acid (21%) and linolenic acid (11%) (Molazem et al., 2013; El Sabagh et al., 2017; El Sabagh et al., 2018; Joughi et al., 2018). Hence, it represents a healthy edible oil. Oil seed of canola provide over 13.2% of edible oil in the world (Eskandari and Kazemi, 2012; Joughi et al., 2018). Gheorghe et al. (2013) found that grain yields significantly differences among fifty rapeseed cultivars grown under Romanian conditions. The agronomic management factors influenced the yield of the crop (Anonymous, 1992) and the cultivars with high yield potential play an important role in the increase of the yield per unit area (Sana et al., 2003). However, winter canola is a relatively new crop for Turkey, but the suitable cultivars for winter canola have not yet been established for this region of study (Coşgun and Öztürk, 2014). Therefore, in this study we considered three cultivars to evaluate the varietal performance of these cultivars, considering agronomic characteristics, oil quantity and quality parameters in Southeastern Anatolia of Turkey.

Materials and methods

Location, duration, edaphic and climatic conditions

Two field experiments were conducted during 2013/14 and 2014/15 growing seasons at the research area of Dicle University to evaluate the yield and quality properties of some canola cultivars in the Southeastern Anatolia region of Turkey. Soil samples at sowing were analyzed and was observed the soil was classified as clay (71.6%), 1.25% organic matter, Available Phosphorus 1.63 kg/da, 13.02% alkaline, 0.01-0.02% salt and 7.73 pH. The average, and minimum temperatures, monthly rainfall and relative air humidity data for 2013/2014-2014/2015 during the canola vegetation period are presented in (*Fig. 1*).

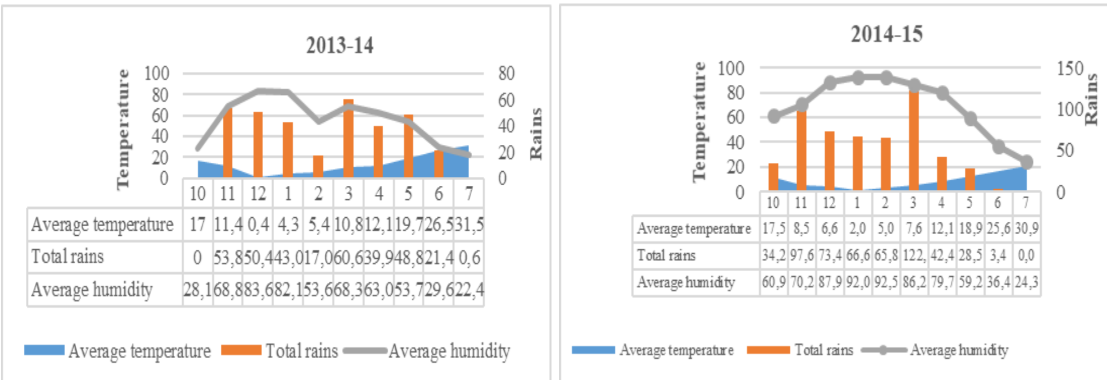

***Figure 1.** Monthly average air temperatures °C, totally rains (mm) and humidity (percentage), respectively during the growing seasons*

The monthly rainfall, humidity and average temperatures for 2013-14 and 2014-15 within the growing period of canola (October-May) are presented in *Figure 1*.

The average temperature was around 14.5 °C. The average rainfall was 42.07 mm. The highest rainfall was observed in March in 2013-14 as 60.6 mm and in March in 2014-15 as 122.2 mm. Air temperatures and humidity were close to the long term averages during the two growing seasons and but annual rainfall is different in the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_21672177

experimental years. 2013-14 growing season was a relatively dry year and monthly rainfall during the growing season (October–May) were lower than 2014-15 and long-term averages. Frost damage was not seen in 2014 and 2015 years.

Experimental design, plant materials, treatments and experimentation

The experimental area is located (37°532588 N, 40°162356 E) at 670 m above sea level. The field experiments were arranged in a randomized complete block design with three replications. Three canola (*Brassica napus* L.) cultivars i) Express, ii) Licord, and iii) Licrown were used as material in this study, which these cultivars are consider the most preferred are variants in Turkey. It has been used to determine the most suitable cultivars in southeastern of Anatolia. The area of each plot was including 6 rows with 0.7 m row distance, 5 m row length, plants in the row were 5 cm apart from each other and seed rate of 60 seed m^{-2}. All plots were received at 36 kg N ha^{-1} and 92 kg P_2O_5 ha^{-1} (18-16-00) before the sowing of crop and 80 kg N ha^{-1} was added as top dressing during stem elongation. The source of N was ammonium nitrate (33%N). The crop was sown on October 20 in both years (2013/14 and 2014/2015). The crop was harvest on June 20 in both years (2013/14 and 2014/15).

Data collection

Yield attributes: Randomize selected 10 plants each plot. Plant height, branch number, pod number and seed number. 1000-seed weight, and seed yield were examined. Plants were harvested 11.2 m^2. Seed yield (kg ha^{-1}) was calculated from the plants of the four ridges in each plot and the yield per hectare was measured.

Quality properties

Oil content, protein content and Fatty acid content: Protein content (%) was measured by Kjeldahl method (AOAC, 2000). Oil content (%) was measured by Soxhlet instrument with n-hexane (60 °C) as organic solvent. Fatty acid compositions of seeds were measured with a gas chromatography and the analyses were performed at the central laboratories of Tubitak–Mam (*Marmara Research Center*) according to the method described by Slover and Lanza (1979).

Statistical analysis

Data for the experiment was analysed by JMP 5.0 software program for comparison of data was analyzed by JMP package program Mean tested by Tukey at the 1% level.

Results and discussion

Agronomic traits

The results of ANOVA for agronomic traits are presented in *Table 1*. Statistical analysis for the yield attributes, the analysis of variance, year, and year x cultivar interactions were found significant on the plant height, and the number of branches per plant except for pod number, seed number, 1000-seed weight and seed yield. Moreover, the cultivars were insignificant for all parameters. According to the mean of two years were revealed that, the highest number of pod (122.5) was produced from Licrown and the lowest value (112.2) was produced from Express. These findings showed that, the

DOI: http://dx.doi.org/10.15666/aeer/1702_21672177

highest value of seed number was achieved from Expres with 25.9, while the lowest value was produced from Licrown with 24.5 (*Table 2*).

Considering the average two years yield, the greatest seed yield was achieved from second (2014-15) growing season with 2593.7 kg ha^{-1} and the minimum seed yield was achieved in first (2013-14) growing season. Regarding the averages, the difference between cultivars were statistically non-significant in terms of seed yield and the highest seed yields were produced from cultivar ‘Licrown’ (2617.1 kg ha^{-1}) in *Table 2*. Several factors affect the seed yield and yield attributes in crop, including cultivar, seasonal variation, location, planting date, soil nutrient, moisture availability, growing conditions in different crops (Abdelaal et al., 2017; Barutçular et al., 2017; Gormus et al., 2017a, b). Zhang et al. (2011) who pointed out the seed yield of different canola cultivars was significantly varied among them. Also, El Habbasha and El salam (2009) observed that there are significant differences among canola cultivars on the seed yield. It was assessed several genotypes of *Brassica napus* L. and found significant differences for some yield attributes. Likewise, various investigators studied for various mustard and canola cultivars, and observed the seed yield differences among the cultivars were significantly (Khehra and Singh, 1988; Stingram et al., 2002).

Quality traits

The statistical analysis (ANOVA) of data of quality traits are presented in (*Table 3*). It was observed that, the cultivars differed significantly and various cultivars non-significant in in oil quality traits. The means of some of quality properties of canola cultivars are given (*Table 4)*. As it can be seen from (*Table 4*), the oil and protein content among peanut varieties was significant, the cultivar Licord was recorded the highest oil content (37.92%) and protein (22.48%), while, the cultivar Express was produced the lowest oil content (37.43%). Oil content of canola depends on several factors such as variety, growth environment, agrotechnics and fertilization (Laaniste et al., 2004; Coşgun and Öztürk, 2014). It was found that the oil and protein percentage in various crops depending on genotype and growing conditions, and influenced by genotype, climatic conditions, geographical location, growing season and growing conditions (Yıldırım et al., 2018; Akdeniz et al., 2018a,b). Oil content is negatively related with protein content (Gül et al., 2005). Although, protein content may be affected by environments, they differ due to the genetic properties (Atakişi, 1977).

Generally, more work required to enhance oil quality among canola cultivars under investigation conditions. The main aims in canola breeding to reduction the long chain and saturated fatty acids in canola cultivars. Statistically significant differences among cultivars were found for fatty acids. The saturated fatty acids content in canola oil were affected by cultivars, the greatest value of palmitic acid (4.67%), stearic acid (2.06%) and oleic acid (65.5%) were produced from the variety Express. On the other hand, the cultivar Licord achieved the smallest value of stearic acid (1.86%) followed Licrown it statically group. According to Hassan et al. (2005) observed that significant differences for saturated fatty acids were due to the variances of the genotypes. However, the saturated fatty acids content in oil were affected by genotype (Isleib et al., 2008).

In each column, means followed by the same letter within columns are not significantly different (P < 0.01) according to Tukey test, ns: not significant

Generally, in case of average values of both years, the variety Express achieved the smallest value (12.63%), while, the cultivar Licrown generated the greatest (12.97%) saturated fatty acid. In contrary, the maximum value (85.47%) and the minimum values (85.14%) of unsaturated fatty acid were observed in the variety Express and Licrown, respectively. Accordingly, the variety ‘Express’ achieved the highest rate for saturated fatty acids/unsaturated fatty acids (6.75%) and oleic/linoleic (3.82%). The potential impact of seed maturity is dependent on genotype, climatic conditions, and genotype/climate interactions was reported by (Onat et al., 2017). Lower temperature during the seed development normally is associated with more unsaturated oil due to the increased activity of oleatedesaturase, which promotes the synthesis of linoleic acid (Bovi, 1982). The increase in oleic acid with seed maturity is normally accompanied by a decrease in palmitic, linoleic, arachidic, eicosenic, behenic and lignoceric acid (Holaday and Pearson, 1974).

Concerning, the Erucic concentration, Erucic acid is one of the most essential fatty acids within Brassica genus. Low or zero erucic acid contents are desirable in edible oil. Data in *Table 5* revealed that the amount of Erucic percentage in all canola cultivars used ranged from the lowest (0.182) in Express to the highest (0.252 and 0.243) in Licord and Licrown. These results were supported by another investigations finding, who reported that, the safe limits for these compounds have been described as less than 2% of erucic acid in oil (Grombachr and Nelson, 1992; El sabah et al., 2016).

In each column, means followed by the same letter within columns are not significantly different ($P < 0.01$) according to Tukey test, ns: not significant

The differences in the fatty acids among cultivars are due to differential growth habit, environmental factors and genetic variations. The statistically analysis of data indicated that cultivars differed significantly for oil content among cultivars, locations and their interactions in present study was confirmed the earlier by (Pritchard et al., 2000). Oil content of canola depends on several factors such as variety, growth conditions and fertilization (Laaniste et al., 2004). Bengtsson (1988) recorded 9% difference between two cultivars of winter canola, while, it was reported less difference of 2.3% between different *Brassica carinata* lines for seed oil content (Gentent et al., 1966). The protein contents of cultivar examined in the study varied between 21.98 to 23.48%. The protein content may be affected by environmental conditions (Barszczak et al., 1993), and Sargın (2012) noted that the variation largely depends on the genetic properties of variety.

The various cultivars of canola crop are differed to fatty acid under the current environments. It was observed that the most important fatty acid in rapeseed is oleic acid with 70-80% (Schierholt, 2000). Although the low level of palmitic acid and other saturated fatty acids (less than 5%) in canola oil is considered to be nutritionally desirable (Kay, 1988). In this concern McCartney et al. (2004) found that the major of the variation in the palmitic (C16:0) due to the impact of genotypic. The oil composition in peanut is affected by different factors involving environmental factors, genetic factors, and interaction between environmental and genetic factors (Mzimbiri et al., 2014; Gulluoglu et al., 2016). Fatty acid composition is the function of genotype, climate conditions, morphology and physiology as well as crop management (Arsalan, 2007).

Conclusion

The results of the study suggested that, that all cultivars have a good potential for the winter season of Southeastern Anatolia of Turkey. Regarding the production, all cultivars were surpassed in yield as well as, others quality parameters such as high oleic, linoleic (Express) as well as high content in unsaturated Fatty Acids SFA/UFA. All cultivars produced low erucic acids, while the cultivar 'Licord' produced low linolenic acid content. The cultivar, 'Express' was produced a high oleic and linoleic acid content and these findings could be useful in maintaining the required yield and quality attributes of canola cultivars under investigation condition for future breeding programs.

HABITAT UTILIZATION AND WINTER TIME-ACTIVITY BUDGETS OF THE WHOOPER SWAN *CYGNUS CYGNUS* (LINNAEUS, 1758) POPULATION WINTERING AT THE VAN LAKE BASIN, TURKEY

NERGIZ, H.

Bitlis Eren University, Faculty of Arts and Sciences, Department of Biology, Bitlis, Turkey (e-mail: humeyranergiz@gmail.com)

(Received 23rd Nov 2018; accepted 16th Jan 2019)

Abstract. In this study, daily behaviour patterns of whooper swans (*Cygnus cygnus*) were studied at the Van Lake Basin, which is one of the most important wintering areas of the species in Turkey. Winter-time activities of the swans were monitored from sunrise to sunset in 6 different categories: resting, feeding, preening, walking on land, swimming and flying. The most common daytime activity was resting (55%). Feeding (12.48%) and preening (10.98%) were the two other main diurnal activities of whooper swans during the present study. Resting peaked in midday period (08:30-13:30) while feeding was observed frequently in early morning hours (06:00-8:30) and late afternoon (13:30-17:00). At the beginning of severe winter period (December and January) whooper swans clearly reduced feeding time in all parts of the day, probably because they still met metabolic demands. A significant increase in feeding behaviour was observed in January and February when they were preparing to migrate. While open water surface was the most preferred area for resting, shallow coastal areas and reeds were the most utilized foraging habitats.
Keywords: *waterfowl, behaviour, diurnal period, movements, waterbirds, wetlands*

Introduction

Behaviour patterns of waterbirds vary with weather conditions, food availability, threat factors and the physiological status of the species (Weathers and Sullivan, 1993; Meissner and Markowska, 2009). These behaviours that birds show under different environmental conditions offer important tips in understanding their ecological requirements. Furthermore, changes in waterbird activity may provide an earlier indication of an impact than numbers of birds (Weathers and Sullivan, 1993; Hamilton et al., 2002).
