To demonstrate the model performance, *Table 3* shows the evaluation indexes of the SWAT model driven by CFSR weather data in calibration and validation at Cuntan, Yichang, Hankou, and Datong hydrological gauge stations. The R^2 and E_{NS} are larger than 0.70 in both calibration and validation periods, which are superior to the simulated result based on NCEP (National Centers for Environmental Prediction of United States) data in upper reach of Yangtze River basin by the study (Yang et al., 2014). In addition, the model tended to overestimate the streamflow, except at Datong gauge station in calibration period, and it underestimated the streamflow in validation except slightly overestimated

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36153632

at Yichang station. According to performance ratings (Moriasi et al., 2007, 2015), the calibration results at all of the hydrological stations can be rated as "good" because E_{NS} and R^2 are larger than 0.75.

Comparing *Table 2* and *Table 3* for the model performances of the GMS- and CFSR-driven SWAT model calibrated and validated separately alone, the performance of the model driven by GMS weather data is better than that of the CFSR data for calibration, as well as for validation. The comparison shows the GMS-driven SWAT model is more robust than the CFSR model. However, the CFSR-driven model can also generate rather satisfactory results.

Table 3. *Performance evaluation for the SWAT model driven by the Climate Forecast System Reanalysis (CFSR) weather data in calibration and validation period at different hydrological gauge stations*

	Calibration			Validation		
	R^2	E_{NS}	PBias/%	R^2	E_{NS}	PBias/%
Cuntan	0.75	0.75	-1.91	0.71	0.70	14.9
Yichang	0.83	0.71	-23.6	0.76	0.72	-0.14
Hankou	0.88	0.84	-4.8	0.89	0.80	15.34
Datong	0.88	0.79	0.00	0.91	0.74	21.05

Although the R^2 of the precipitation validation was approximately 0.6 between from CFSR and GMS weather data, the CFSR-driven SWAT model produced a streamflow with R^2 and E_{NS} greater than 0.70 in both calibration and validation periods. The established SWAT model provides parameter adjustment to improve the accuracy of hydrology prediction through parameter sensitivity analysis and model calibration. The streamflow simulated with GMS weather data is better than that simulated with CFSR weather data, and the results simulated with CFSR weather data are reasonable.

From the perspective of the whole large-scale watershed, the Datong gauge station records the discharge for the whole basin. The simulation with the CFSR weather data produced better results for the watershed scale than the simulation with the GMS data based on the indexes of E_{NS} and R^2 during validation period at Hankou and Datong station. From the perspective of the sub-watershed-scale, the discharge recorded at Cuntan, Yichang and Hankou gauge stations represented the hydrological regimes of different sub-watersheds. Comparing the results in *Table 2* and *Table 3*, the GMS weather data simulation generated better results than the simulation with CFSR weather data at Cuntan and Yichang stations during both calibration and validation periods. Therefore, the GMS weather data are superior to the CFSR weather data for predicting hydrology at Cuntan and Yichang gauge stations at the sub-watershed-scale. In addition, a group of parameters calibrated in the GMS-driven model in future years with the scarce data for the Cuntan and Yichang gauge stations were proposed because the E_{NS}, R^2 and PBias in these simulations are all superior to the simulation with parameters calibrated with the CFSR model.

Comparison of the monthly average streamflow hydrograph (1981-2002) among the observed data, simulated results by CFSR- and GMS-driven model

Hydrological regime of the monthly average streamflow from 1981 to 2002 were simulated to investigate the performance of the GMS- and CFSR-driven SWAT model which were calibrated and validated separately, respectively (*Figure 7*). For Cuntan gauge

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36153632

station, the simulation with GMS underestimated the streamflow during March to July, and it was a better match to the observations than the CFSR weather simulation at the recession curve from August to December. The results from the CFSR weather-driven model more closely matched the observations during January to June, whereas the GMS data simulation more closely matched the peaks than the CFSR simulation in July and better replicated the recession curve during September to December at Yichang gauge station. The GMS weather model generated better results and replicated the observations better than the CFSR model throughout the year at Hankou and Datong gauge stations.

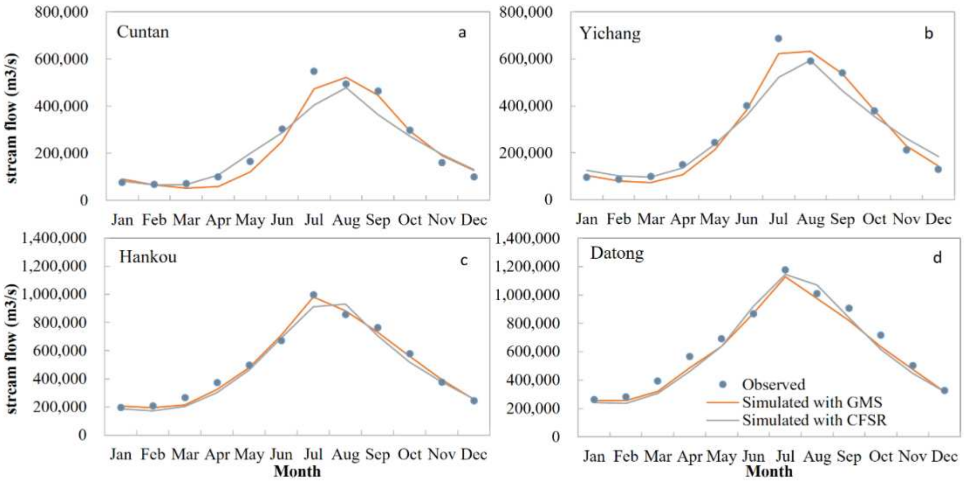

Figure 7. *Average monthly streamflow hydrograph (1981-2002) for observed and simulated results from the SWAT model driven by the Climate Forecast System Reanalysis (CFSR) and the ground-based meteorological station (GMS) weather data at (a) Cuntan, (b) Yichang, (c) Datong and (d) Hankou gauge stations*

From these four hydrological gauge stations, there were two patterns in the comparison curves. Firstly, there was a distinct difference in the lower streamflow between the results from the GMS and CFSR simulations, and there was less discrepancy for the peak streamflow with the GMS simulation. Secondly, the results from the GMS weather simulation more closely matched the peaks and the recession period than the CFSR weather model. From the perspective of gauge station distribution in the basin, the results from the GMS and CFSR simulations in the upper reaches of the Yangtze River are characterized as distinct difference in the lower streamflow and less discrepancy for the peak streamflow, such as the patterns at Cuntan and Yichang gauge stations, whereas the results are characterized as close match the peaks and the recession period in the middle and lower reaches of the Yangtze River, such as the patterns at Hankou and Datong gauge stations.

Discussion

From the investigation of the CFSR-driven SWAT model with Calibrated parameters of GMS model (CSWCG), although, the R^2 and E_{NS} were greater than 0.80 in both the calibration and validation periods except Cuntan station, The CSWCG resulted in acceptable results. It proves that it is feasible to apply the CFSR global data to the establishment of a SWAT model in a large-scale watershed. In addition, the CFSR and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36153632

GMS data driven SWAT model can share the same hydrological parameters to a certain extent for hydrology prediction in the YRB. That is to say, the CFSR dataset can be used to quickly established hydrology model for real time flood prediction when conventional weather data are absent in urgently, as well as the former calibrated hydrological parameters is also applicative.

Performance of the CFSR data using as hydrological model driven data is reasonable accepted, which is in agreement with the findings of Dile et al. (2014), Fuka et al. (2014), and Yang et al. (2014). However, the results found here conflict with the findings of Tan et al. (2017), who report that the original CFSR weather data is not suitable to apply for streamflow simulations in Malaysia. Differences in climate and geographical conditions are the most likely explanation for such differences between different studies. In any case, data accuracy and representativeness is more important (Yang et al., 2014). Therefore, It is important to validate the data representativeness of the weather occurred in study area before hydrological prediction.

The input weather data density is an influence, and alters the hydrologic model results. the GMSs and CFSR grids is show in *Figure 1*, in which the spatial distribution patterns of GMSs, CFSR grids and used CFSR were clearly demonstrated. The gridded data usually contain weather data of high density for hydrology simulation in the large-scale basins. Although, the density of CFSR grids is superior to the GMSs available in this study, the performances of the hydrologic simulations in this study strongly suggest the spatial density has no major influence on model simulations of this study area. Because of the automatically selected by SWAT model, the number of used CFSR data grids happened to be the same of GMS data in this study. The advantage of intensive distributions of the CFSR grids will be take effects in many large-scale and data-scarce regions.

Conclusions

In this study, the performance of CFSR global data for quickly building a hydrological model was investigated for the Yangtze River, the largest river basin in China. The study demonstrated that the CFSR weather data could modestly replicate weather conditions occurring in the YRB to a certain degree. In addition, the accuracy of the CFSR meteorological data was stronger at low elevation conditions versus high altitude. With reasonable accuracy of CFSR data validated by GMS observed weather data, it is feasible to predict hydrology with the CFSR weather datasets to drive the hydrological model of the YRB.

The R^2 and E_{NS} were larger than 0.8 in both the calibration and validation periods for the GMS weather data driven SWAT model in the YRB. However, the model showed a tendency to underestimate streamflow at all four gauge stations. Because of the reasonable accuracy of the CFSR-driven SWAT model without calibration, the CFSR- and GMS driven SWAT models can share the same hydrological parameters for hydrology prediction in the YRB, and the prediction results were better in the middle and lower reaches than in the upper reaches of the Yangtze River. Using only the CFSR global weather data, the SWAT model R^2 and E_{NS} are larger than 0.70 in both calibration and validation periods. Although the R^2 of the precipitation validation is only 0.6 between the CFSR and GMS weather data, the established SWAT model provides parameter adjustment to improve the accuracy of hydrology prediction through parameter sensitivity analysis and model calibration. Comparing the monthly average streamflow hydrograph,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36153632

the results from the GMS and CFSR simulations are characterized by two patterns in the upper, middle, and lower reaches.

This paper presented the performance of the CFSR driven hydrological model in the Yangtze River basin during 1981-2002. As we know, the Three Gorges Dam commenced impoundment since 2003, which would influence hydrology regimes of the Yangtze River. It will be an interesting topic for the further research based on CFSR driven hydrological model. Although, the CFSR-driven hydrological model generated results are less accurate than that of GMS-driven model, the CFSR global data are an alternative data source for quickly building a SWAT model for hydrology prediction in such a large-scale river basin. We can conclude that the CFSR weather data provides new opportunities to meet the challenges of driving the hydrological model in data-unavailable river basin. The CFSR weather data can be a viable option for simulating the hydrology where traditional GMS networks do not satisfied the given spatiotemporal resolution, or the GMS weather data are unavailable.

(Received 14th Dec 2018; accepted 22nd Feb 2019)

Abstract. This paper analyses the effect of titanium foliar application on the Fe, Zn, Mn and Ti content in early crop potato tubers. The titanium source was the plant growth stimulant Tytanit® (8.5 g Ti per litre). Tytanit® was applied once at the leaf development stage (BBCH 14-16) or at the tuber formation stage (BBCH 41-43) and twice at the leaf development and tuber formation stages, at the dose of 0.2 L ha^{-1} or 0.4 L ha^{-1} in each treatment. Potatoes were harvested 75 days after planting (the end of June). Following Tytanit® application, the content of Fe was higher by 6.150 mg kg^{-1} and Mn by 0.409 mg kg^{-1} of dry matter. Titanium foliar application did not affect the content of Zn, whereas the content of Ti was higher by 0.364 mg kg^{-1} of dry matter. The dose and date of Tytanit® application slightly affected the content of Fe. The content of Mn was greatest with a single Tytanit® application at the tuber formation stage at the dose of 0.2 L ha^{-1}, whereas the Ti content was greatest with a double Tytanit® application, at the leaf development and tuber formation stages, at the dose of 0.2 L ha^{-1}.
Keywords: *early potatoes, plant growth stimulant, Tytanit®, nutritional value*

Introduction

Although micronutrients are used in relatively small amounts, they play an important role in plant metabolism and in the human body assisting in the prevention of many diseases and the maintenance of good health. On the other hand, an excessive amount of some micronutrients can be toxic to a human (Welch, 2002; Martinez-Ballesta et al., 2010; Soetan et al., 2010; Al-Fartusie and Mohssan, 2017; Nieder et al., 2018). The Recommended Dietary Allowance (RDA) of Fe for men and postmenopausal women is 8 mg and for premenopausal women 18 mg per day. The RDA of Zn is 11 mg per day for men and 8 mg for women, and the RDA of Mn for men and woman is 2.3 mg and 1.8 mg per day, respectively (Institute of Medicine US, 2001). Micronutrient deficiency in humans occurs in all regions of the world (Martinez-Ballesta et al., 2010; Nieder et al., 2018). Plant based food provide most of the micronutrients required for a healthy human diet. Soil is the main source of micronutrients for plants. The micronutrient availability to plants depends on their chemical form, soil properties, particularly pH and organic matter content, and environmental conditions. Abiotic stresses such as drought or extreme temperatures affect the mineral element content in the field growing crops (Tack, 2014). Micronutrient deficiencies in plants not only limit crop productivity but also affect crop quality as a human food. In sustainable agriculture, the most environmentally-friendly way to increase the amount of essential human micronutrient in plant based food is breeding of genotypes that have a naturally higher micronutrient content and proper agronomic practices (Frossard et al., 2000; Khoshgoftarmanesh et al., 2010; Haynes et al., 2012).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36333643

In modern plant production focusing on high quality of plant based food, biostimulants have been gaining increasing importance (Calvo et al., 2014; Bulgari et al., 2015). Titanium is categorized as a plant growth stimulant. Water-soluble chelate forms of titanium, such as ascorbate, citrate or malate applied via roots or leaves in low concentrations have a beneficial effect on various plant physiological processes and increase the crop yield, and can improve the crop quality. The beneficial effect of titanium is a result, among others, of its interaction with other elements, primarily with Fe (Du et al., 2010; Bacilieri et al., 2017; Lyu et al., 2017). Titanium foliar application resulted in an increase in Fe, Cu and Zn contents in bean (Ram et al., 1983), Fe in red pepper and in barley grain (Carvajal and Alcaraz, 1995; Tlustoš et al., 2005) and Zn in wheat grain (Tlustoš et al., 2005). To date, few studies have been focused on the effect of titanium on micronutrient contents in root and tuber plants. Titanium foliar application resulted in an increase in Zn content and a decrease in Fe and Mn contents in potato tuber (Tlustoš et al., 2005; Mystkowska, 2018).

Potato (*Solanum tuberosum* L.) is a one of the most important crops ensuring food security in the world and a valuable source of nutritional compounds in the human diet. Potatoes do not contain a large amount of micronutrients, with the exception of Fe, however, due to the amount consumed per capitata, they can make up a significant source of micronutrients in the human diet (Burgos et al., 2007; Haynes et al., 2012; Tack, 2014). Consumption of 100 g potatoes can provide 12-15% of the Recommended Dietary Allowence (RDA) of iron, 6-8% of manganese and 2-3% of zinc (Leszczyński, 2012; Wierzbicka, 2012). Micronutrient contents in potato tubers are affected by a cultivar, environmental conditions and agronomical practices (Rivero et al., 2003; Martinez-Ballesta et al., 2010; Wierzbicka, 2012; Lombardo et al., 2014; Tack, 2014; Wierzbowska et al., 2018). In the our study it was hypothesised that the stimulation of potato plant growth by titanium foliar application would contribute to an increase in essential human micronutrient content in tubers. It was assumed that the potato response to titanium depend on the dose and date of titanium application and that the results of titanium application depends on the potato cultivar and environment in which the potato grow. The aim of the study was to determine the effect of the dose and date of titanium foliar application on essential human micronutrient contents in early crop potato tubers.

Materials and Methods

Plant material and experimental design

The study material included tubers of two very early potato cultivars ‘Lord’ and ‘Miłek’ (Polish cultivars which are registered on the Common Catalogue of Varieties of Agricultural Plant Species CCV) obtained from a field experiment carried out in central eastern Poland (52°03'N; 22°33'E) during three growing seasons (2009, 2010 and 2012) with a varied the weather conditions (*Table 1*). Over the three-year period of the study, the mean air temperatures in the beginning period of potato growth were above the long-term average. In 2009 total precipitation in potato growing season was above and in 2010 and 2012 similar to long-term average, however, unevently distributed during potato growth period (Wadas and Kalinowski, 2018). The field experiment was carried out on Luvisol with an acidic-to-slightly-acid reaction, with a low content of available Zn, a medium content of Mn as well as a high content of Fe (*Table 2*).

The titanium (Ti) source was the mineral plant growth stimulant Tytanit® (8.5 g Ti per litre, 0.8% m/m, in the form of Ti-ascorbate) produced by INTERMAG Ltd., Poland. The

effect of dose (0.2 L ha^{-1} and 0.4 L ha^{-1}) and date of Tytanit® application (a single foliar application at the leaf development stage – BBCH 14-16 or at the tuber formation stage – BBCH 41-43, and a double foliar application at the leaf development and tuber formation stages – BBCH 14-16 and BBCH 41-43) on the essential human micronutrient and titanium contents in early crop potato tubers was investigated. The field experiment was established in a split-block-split-plot design with a control object without Tytanit® in three replications. Potato cultivation was carried out according to common agronomical practice. In successive years, 6-week pre-sprouted seed potatoes were planted on 15th, 13th and 12th April. Potatoes were harvested 75 days after planting (the end of June). For laboratory studies 50 different-sized tubers of each treatment were taken.

Chemical analysis

The contents of Fe, Zn, Mn and Ti were determining by atomic emission spectroscopy with the inductively-coupled plasma method (ICP-AES) following previous mineralization of potato tuber samples. One gram of the oven-dried potato sample was oxidized dry at 450-550°C in a muffle furnace, and the ash was dissolved in a 10% HCl. The total contents of Fe, Zn, Mn and Ti were determined on an atomic emission spectrometer with inductively-coupled plasma Optima 3200 RL produced by Perkin-Elmer. All assays were performed in duplicate and the mean results were expressed in milligrams per kilogram of potato tuber dry matter (DM).

Statistical analysis

The results of the study were analysed statistically by means of analysis of variance (ANOVA) for the split-block-split-plot design. The analysis of the results was conducted using orthogonal contrast to compare the control object without Tytanit® with the remaining objects. The significance of differences was verified using Tukey's test at $p \leq 0.05$.

Results

Tytanit® application caused an increase in the content of Fe, Mn and Ti in potato tuber but did not affect the content of Zn (*Table 3*). Over the three-year period of the study, the Fe content in tubers was higher, on average, by 6.150 mg kg^{-1} of DM, Mn by 0.409 mg kg^{-1} of DM and Ti by 0.364 mg kg^{-1} of DM compared to the cultivation without the growth stimulant. Tytanium foliar application had a greatest effect on the Mn content in tubers in 2012 with the lowest content of available Mn in soil (data not presented). In that year, with the Tytanit® application, the Mn content in tubers was higher by 0.939 mg kg^{-1} of DM, on average, compared to the control object without the growth stimulant.

Table 3. *Effect of Tytanit® on micronutrient contents in potato tubers (mg kg^{-1} of DM); mean for years and cultivars*

Treatment	Fe	Zn	Mn	Ti
Without Tytanit®	73.33b	24.72a	6.774b	1.803b
With Tytanit®	79.48a	24.64a	7.183a	2.167a

Means within columns followed by the same letters do not differ significantly at p≤0.05

The Tytanit® dose did not affect the content of Fe in tubers of either tested potato cultivars (*Table 4*). The study demonstrated a significant interaction effect of the potato cultivar and the dose of Tytanit® on the Mn content in tubers. The dose of Tytanit® application had a significant effect on the Mn content only in the 'Lord' cultivar tubers (*Table 4*).

Table 4. *Effect of Tytanit® dose on Fe, Mn and Ti contents in potato tubers in relation to cultivar (mg kg^{-1} of DM); mean for years and date of Tytanit® application*

Tytanit® dose	Fe		Mn		Ti

Means within columns followed by the same letters do not differ significantly at p≤0.05

Following the application of 0.2 L ha^{-1} of Tytanit®, the Mn content in tubers of 'Lord' was higher, on average, by 0.485 mg kg^{-1} of DM compared to the dose of 0.4 L ha^{-1}. The Tytanit® dose had the greatest effect on the Mn content in tubers of 'Lord' in 2012 with the lowest content of available manganese in soil (data not presented). In that year, following the application of 0.2 L ha^{-1} of Tytanit®, the manganese content in tubers of this cultivar was higher, on average, by 1.338 mg kg^{-1} of DM compared to the dose of 0.4 L ha^{-1}. The dose of Tytanit® application had a significant effect on the Ti content in tubers of both tested potato cultivars (*Table 4*). After the application of 0.2 L ha^{-1} of Tytanit®, the Ti content in tubers was higher, on average, by 0.198 mg kg^{-1} of DM compared to the dose of 0.4 L ha^{-1}. The difference was greatest in the warm and moderately wet growing season of 2012 (*Table 5*). In that year, after the application of 0.2 L ha^{-1} of Tytanit®, the Ti content in tubers was higher, on average, by 0.455 mg kg^{-1} of DM.

In that year, with the single Tytanit® application in the leaf development stage the Mn content in tubers was lower, on average, by 0.959 mg kg^{-1} of DM as compared with the single application in the tuber formation stage. With double Tytanit® application, in the leaf development stage and with a repeated treatment in the tuber formation stage, the Mn content in tuber was similar to the single treatment in the tuber formation stage. The Ti content in tuber was greatest with double Tytanit® application (*Table 6*). With double Tytanit® application, the Ti content in tuber was higher, on average, by 0.535 mg kg^{-1} of DM compared to the single treatment in the leaf development stage and by 0.325 mg kg^{-1} of DM compared to the treatment in the tuber formation stage. The differences were greatest in 2010 with heavy rainfall in May and the periodically water shortage in June, 0.940 mg kg^{-1} and 0.963 mg kg^{-1} of DM, respectively (*Table 7*). The performed study demonstrated a significant interaction effect of the dose and date of Tytanit® application

Means within columns followed by the same letters do not differ significantly at $p \leq 0.05$

The content of examined micronutrients in the potato tuber depended to a great extent on the cultivar and environment conditions during the potato growing season (*Table 9*). Regardless of the treatment, 'Lord' tubers contained more Fe, on average, by 3.20 mg kg^{-1} of DM and Zn by 2.50 mg kg^{-1} of DM and less Mn by 0.30 mg kg^{-1} of DM than tubers of 'Miłek'. The content of Ti in tubers of both cultivars was similar. The most Zn and Mn were accumulated by potato tubers in the cool and very moist growing season of 2009, whereas the most Fe and Ti were accumulated in tubers in 2010, with havy rainfall in May and the periodically water shortage in June.

Table 9. *Micronutrient contents in potato tubers in relation to cultivar and year (mg kg^{-1} of DM); mean for objects with and without Tytanit®*

Results presented in this study demonstrate that a typical meal with 200 g of boiled potatoes (at least three medium-sized tubers) from the cultivation without Tytanit® provided up to 32% of the Recommended Dietary Allowance (RDA) of Fe for men and postmenopausal women and up to 14% of the RDA for premenopausal women, and up to 10% of the RDA of Mn for men and 13% for woman. Potatoes derived from the cultivation with Tytanit® provided up to 35% of the RDA of Fe for men and postmenopausal women and up to 16% of the RDA for premenopausal women, and up to 11% of the RDA of Mn for men and 14% for woman. Potatoes from the cultivation with or without Tytanit® provided up to 8% of RDA of Zn for men and 11% for woman.

Discussion

The beneficial effect of titanium on plant metabolism include, among others, an increase in the uptake of other elements (Du et al., 2010; Lyu et al., 2017; Bacilieri et al., 2017). A foliar application of Ti during potato growth increases the activity of peroxidase, however, during tuberization the activity of superoxide dismutase and peroxidase. Tytanit® did not affect the content of dry matter and nitrogen, phosphorus, potassium, calcium, magnesium or sulphur in potato tubers. Following Tytanit® application, there was only an increase in sodium content (Wadas and Kalinowski, 2018). The application of Ti favored Fe uptake (Bacilieri et al., 2017), which was confirmed in the present study. A single or a double Tytanit® (Ti-ascorbate) application during potato grown on Luvisol with an acidic-to-slightly-acid reaction at the dose of 0.2 L ha^{-1} or 0.4 L ha^{-1} in each treatment caused an increase in the contents of Fe, Mn and Ti in early crop tubers of very early 'Lord' and 'Miłek' cultivars. Titanium foliar application did not affect the content of Zn. A study carried out in the Czech Republic showed that titanium foliar applied three times in the form of Ti-citrate during potato grown on Chernozem with an alcaline reaction (at the beginning of June with a plant height of 30 cm and repeated treatment in two-week intervals) in the dose of 10 g Ti ha^{-1} in each treatment resulted in a slight decrease in Fe and an increase in the Zn in mature tubers of 'Cordoba' cultivar (Tlustoš et al., 2005). A study carried out in Poland showed that three times Tytanit® application during potato grown on the soil with a slightly-acid or alcaline reaction (beginning of plant flowering, full flowering and after plant flowering) in the dose of 0.2 L ha^{-1} in each treatment resulted in a decrease of Mn and Fe content in mature tubers of three medium-early ('Honorata', 'Jelly', 'Tajfun') potato cultivars (Mystkowska, 2018), which was not confirmed in the present study. Titanium application up to a dose of 25.5 g Ti ha^{-1} is not toxic for the potato crop (Bacilieri et al., 2017). A negative correlation was revealed between soil pH and iron and manganese concentration in potato tubers (Rogóż, 2009; Tack, 2014), which was confirmed in the present study. Fe and Ti have sinergistic and antagonistic relationships (Lyu et al., 2017). In the presented studies titanium was applied in the chelate forms as Ti-citrate or Ti-ascorbate. Leaf ability to uptake chelated nutrients is related to various properties of a chelate, such as the molecular weight of the complex, dissociation constant and stability of the complex at various pH (Wójcik, 2004). The effect of titanium depends on the plant age and the tissue concentration of other minerals (Lyu et al., 2014; Bacilieri et al., 2017). Potato plants uptake mineral elements primarily from the soil solution through their roots. Direct uptake of minerals into the developing tubers across the periderm is also possible, however in a mature tuber it will be limited due to the suberized nature of the periderm (Subramanian et al., 2011). The dose and date of Tytanit® application slightly affected the content of Fe in tubers of both tested potato cultivars and the content of Mn in the 'Miłek' tuber. The Mn content in the 'Lord' tuber was greater with Tytanit® application at the dose of 0.2 L ha^{-1}. The results showed a differential response of the examined very early potato cultivars to titanium foliar application. The response of crop plants to a foliar supply of nutrients differed between crop species as well as cultivars within the same species (Kannan, 2010), which was confirmed in the present study. The age of the leaf is important for nutrients foliar absorption. The young leaves absorbed more nutrients than the older ones (Wójcik, 2004). This study demonstrated a significant effect of the interaction of the dose and date of Tytanit® application on the Mn and Ti contents in potato tubers. Regardless of the potato cultivar, the content of Mn was greatest with the single Tytanit® application in the tuber formation stage at the dose of 0.2 L ha^{-1}, whereas the Ti content was greatest with a double

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36333643

Tytanit® application during potato grown at the leaf development stage and at the tuber formation stage at a dose of 0.2 L ha^{-1} in each treatment. Leaf-absorbed Ti is distributed approximately equally between the leaves and roots (Kelemen et al., 1993; Lyu et al., 2017). The study carried out by other authors, showed a trace amounts of Ti in potato tuber after foliar application of titanium-containing fertilizers (Ti-ascorbate). The content of Ti in sugar beet roots was considerably higher. The content of Ti in the green parts of a plant (leaves, stems) was greater than in the roots or tuber (Świerczewska and Sztuder, 2004). A positive correlation was found between the Fe and Mn content in potato tubers (Wierzbicka, 2012), which was confirmed in the present study. Tytanit® caused an increase in the content of both Fe and Mn in early crop potato tubers. An opposite correlation between the Fe and Mn are in human body; Fe deficiency can increase in Mn availability (Jędrzejczak, 2004). Following Tytanit® application, the Fe/Mn ratio in the early crop potato tubers (11.1/1) was similar to that for potatoes with the cultivation without the growth stimulant (10.8/1), and was on the same level or broader than those reported for mature tubers of early and medium-early potato cultivars (Lombardo et al., 2014; Wierzbowska et al., 2015; Mystkowska, 2018).

The content of Fe, Zn or Mn in potato tubers depended to a great extent on the cultivar and environmental conditions, which was confirmed by other authors (Rivero et al., 2003; Burgos et al., 2007; Haynes et al., 2012; Lombardo et al., 2014; Rivadeneira et al., 2016; Sharma et al., 2017; Wierzbowska et al., 2018). In the present study, 'Lord' tubers contained more Fe and Zn and less Mn than 'Miłek' tubers grown under the same conditions, although the content of Ti in tubers of both tested cultivars did not differ significantly. Genotype variation in nutrient uptake from soil is associated with the size of the root system and root morphology (Trehan and Singh, 2013). Nutrient uptake by plants depends on their levels in the soil and phytoavailability. The most significant environmental factors affecting the nutrient uptake by plant are soil moisture and pH. The availability of micronutrients present in a soil solution as cations (e.g. Fe^{2+}, Zn^{2+} and Mn^{2+}) increases with increasing soil acidity. The potential of roots to uptake mineral elements generally declines in water-stressed plants (Martinez-Ballesta et al., 2010; Trehan and Singh, 2013; Rivadeneira et al., 2016), which was confirmed in the present study. Under drought conditions, the greater presence of oxygen in the soil induces a decrease in the Fe^{2+}/Fe^{3+} ratio, leading to a decrease in Fe available for plants (Silva et al., 2011). Under a limited plant supply with Fe, the application of an appropriate concentration of Ti may induce the expression of genes related to iron acquisition, enhancing iron uptake (Lyu et al., 2017), which was confirmed in the present study. The most Ti was contained in potato tubers in the year with the highest air temperature and a heavy rainfall in the leaf development and tuber formation stages. Generally, it is believed that high light intensity and high air temperatures during rapid leaf expansion favours the absorption of mineral nutrients by the leaves. High air humidity also stimulates the absorption of leaf-applied nutrients (Wójcik, 2004), which was confirmed in the present study.

Titanium foliar application may be one approach to increasing the amount of essential human micronutrients in potato tubers. It has been estimated that human body take in about 0.8 mg Ti per day (Kabata-Pendias and Pendias, 1999). The amount of Ti provided with the examined potatoes does not exceed 10% of the estimated daily intake.

Conclusions

This study showed that it is be possible to increase Fe and Mn content in early crop potato tubers by foliar application of an appropriate dose of titanium, particularly under abiotic stress conditions. Following Tytanit® application, the content of Fe was higher, on average, by 6.150 mg kg^{-1} of DM and Mn by 0.409 mg kg^{-1} of DM compared to the cultivation without the growth stimulant. Titanium foliar application did not affect the content of Zn, whereas the content of Ti in tuber was higher, on average, by 0.364 mg kg^{-1} of DM. The dose and date of Tytanit® application slightly affected the content of Fe in potato tuber. The content of Mn was greatest with a single Tytanit® application at the tuber formation stage at the dose of 0.2 L ha^{-1}, whereas the Ti content in tuber was greatest with a double Tytanit® application during potato growth, at the leaf development stage and with a repeated treatment in the tuber formation stage at the dose of 0.2 L ha^{-1} in each treatment. This study showed a differential response of very early potato cultivars to titanium foliar application. So, determination of the possibility of increasing micronutrient contents in potato tubers with foliar application of titanium needs the more researches. Determining of optimal dose and date of titanium application for various potato cultivars is very important in the optimisation of potato production.

(Received 16th Dec 2018; accepted 12th Feb 2019)

Abstract. Water is one of the most important resources in the universe. This is due to the fact that all life processes require the use of water. The rate at which petrochemical refineries release wastewater is alarming, and needs to be stoped. Many attempts to improve the efficiency of treatment methods of petrochemical refining wastewater have been made, among which bioremediation is considered an emerging advancement. Bioremediation incentivized the identification and characterization of most bacteria responsible for the breakdown of petrochemical refinery wastewater pollutants. The use of genomic approach (DNA and RNA sequence) in the identification of these bacteria is widely accepted. However, proteins and metabolites as functional entities in a cell are gaining less attention but could still be used to give an accurate insight into how Bacteria respond to pollutants in refinery wastewater. This review aims to find out the present trend and predicting the future prospect of the concept of a molecular genetics approach to uncover the function of bacteria present in refinery wastewater. The review presents literature that identified and characterized bacteria responsible for the degradation of pollutants in petrochemical refining wastewater using culture methods and molecular methods, such as the genomic, metabolomic and proteomic approach. The research hereby recommends the need for further research on a molecular approach to uncover the function of bacteria in petrochemical refinery wastewater using metaproteomic and metabolomic approach.
Keywords: *biostimulation, bioremediation, metabolites, metaproteomic, metagenomic, adsorption*

Introduction

Water is the most important asset in the universe. This is based on the fact that all life procedures require the utilization of water (Long et al., 2019; Longyang, 2019). The ever expanding world population and adoption of industrial lifestyle have inevitably lead to an increase in water shortage and water-borne diseases (Jimena Zambrano et al., 2018). Petrochemical refineries produce enormous amounts of wastewater consisting of both organic and inorganic pollutants, due to its refining process which involves cracking, resulting in the formation of simpler organic substances including benzene, toluene, biphenyl, cresol, cumene, ethylbenzene, hexane and methyl-butyl, etc. (Serio et al., 2018). The wastewater created contains oxygen depleting organisms and can lead to the production of toxic compounds e.g. heavy metals, phenol, oil and grease, bicarbonate etc. which, if not properly treated, could be discharged into the environment (Jimena Zambrano et al., 2018). These pollutants are created in an effort to increase the standard of living for man, but ironically the unplanned intrusion of these pollutants can reverse the same standard and affect the environment in a negatively way (Zhao et al.,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36453665

2018). These pollutants have the capacity to pollute underground water, or where it is released without proper treatment it affects Biochemical Oxygen Demand (BOD) and Chemical Oxygen Demand (COD) of surface water.

Refinery wastewater contains microbial world which has the ability to withstand the pollutants of petrochemical wastewater (Gunawardena et al., 2018; Karbassi et al., 2018; Liu et al., 2018). Bioremediation is rising in importance owing to the way that the technique is has been efficiently used for remediation of the polluted site over other biological and conventional methods (Pettit et al., 2018; Ribeiro et al., 2018; Singh et al., 2018; Zhang et al., 2018). There is an increasing trend in the quantification of a molecular cellular component such as Deoxyribonucleic acid (DNA), Ribonucleic acid (RNA), Protein and metabolites of an organism (Vendramel et al., 2015; Asl et al., 2018; Dalman et al., 2018). The use of DNA and RNA sequence has been dominantly used. However, proteins and metabolites are functional entities in cell and therefore could be used to give an accurate insight into how Bacteria respond to pollutants in refinery wastewater (Rafat et al., 2018; Al-Namnam et al., 2019; Megarajan et al., 2019). This review is aimed at knowing the present trend and predicting the future prospect of the concept of a molecular genetics approach to uncover the function of bacteria present in refinery wastewater.

Petrochemical refinery pollutants

The water consumption rate of petrochemical refining industries is worrisome owing to the fact that large volumes of water are used in the refining of petroleum thus leading to the creation of wastewater (Licht and Isebrands, 2005). Factors such as crude oil composition and extraction mechanisms play a great role in the determination of the properties of wastewater resulting from crude oil refining attributing to the reason why was petrochemical refining wastewater varies from one refinery to the other (Colborne et al., 2019). Research worldwide has shown that refinery wastewater contains diverse pollutants that are either organic or inorganic (Donner et al., 2019). Organic pollutants can be subdivided into aliphatic or aromatic pollutants (Ghazouani et al., 2019). These pollutants influence the production of the aquatic environment by facilitating the process of oxygen depletion which leads to increased chemical oxygen demand (COD) and biological oxygen demand (BOD) (Mkhinini et al., 2019; Sancho et al., 2019; Sousa et al., 2019; Williams et al., 2019). Many studies have associated carcinogenic and mutagenic effect caused to microorganisms, macro-organism, and even human beings to be due to exposure to organic pollutants particularly BTEX benzene (toluene, ethylbenzene, and xylene) (Colborne et al., 2019), PAH (polycyclic aromatic hydrocarbon) (Chen et al., 2019), MTBE (methyl tert-butyl ether) (Krizman-Matasic et al., 2019; Nie et al., 2019; Zhang et al., 2019). Some organic pollutants that are likely found in petrochemical refining wastewater and the possible environmental effects associated with them are summarized in *Table 1*.

Inorganic pollutants in petrochemical refinery wastewater range from heavy metals to phosphorus. Heavy metals are one of the major problems associated with petrochemical refining wastewater owing to their non-biodegradable ability (Chen et al., 2019; Derakhshan et al., 2019). Though most times these metals are in minute concentration measured in microgram, they tend to accumulate till they get to toxic level. Research has demonstrated that heavy metals are harmful in both elemental and soluble form. The most reported toxic metals include Cd, Pb, Hg, Ag, Cr and As

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36453665

(Derakhshan et al., 2019). Heavy metals such as Cr, Cd, and Pb are highly toxic to plants because they are needed by plants in either minute quantity or not needed, whereas heavy metals such as Cu and Zn are used by plants but can be highly toxic to plants also at higher concentration (Ioannou-Ttofa et al., 2019). Iron which is a vital mineral needed by the body becomes toxic at a higher concentration of above 1.6 mg/l leading to hemorrhagic and sloughing of the stomach particularly the mucosa area. Some heavy metals needed for plants growth are carcinogenic to human e.g. Ni (Kolecka et al., 2019). Another pollutant present in petrochemical refining wastewater is a nitrogen compound which is sometimes in combine state with hydrogen forming ammonia (Long et al., 2019). Phosphorus is also another pollutant present in petrochemical refining wastewater (Tahtouh et al., 2019). The worrisome situation associated with the presences of phosphorus and nitrogen compound in petrochemical refinery wastewater is the fact that both contribute immensely to eutrophication, a process that encourages the growth of algae leading to a scenario refers to as algae blooms. Algae blooms tend to deplete oxygen and some of the algae are directly poisonous to fishes and other aquatic organisms. The situation thereby leads to a drastic reduction in aquatic productivity (Costa et al., 2019; Tahtouh et al., 2019; Tang et al., 2019). It is thereby of paramount importance to remove Nitrogen and phosphorus from petrochemical refining wastewater (Costa et al., 2019).

Table 1. *Organic pollutants and environmental impacts*

S/N	Pollutant	Environmental impact	References
1	Benzene	It hinders the growth of plants and other terrestrial animals and could lead to their death through extended exposure. The presence in the aquatic environment leads to behavioral changes, health instability of the organisms and low reproductive rate	Cuo et al. (2018), Staehelin et al. (2018)
2	Toluene	Causes mutagenic and carcinogenic effects to micro organisms and other macro organisms	Lagoviyer et al. (2018)
3	Biphenyl	In humans, exposure to biphenyl leads to eye and skin irritation, toxic effect on liver, kidney and nervous system. In the aquatic environment, exposure to biphenyl leads to behavioral changes and low reproductive rate	Lauren Hayashi (2014), Li Z (2016)
4	Cresol	Exposure can lead to severe gastrointestinal damage which could eventually lead to the death of an organism	Shi et al. (2019)
5	Cumene	No observable effect has been recorded in a mammal and some larger vertebrates but exposure to cumene inhibits photosynthetic activities in some algae and also shows positive effects on some invertebrates	Junqueira et al. (2018)
6	Ethylbenzene	Long time exposure causes the damage of the kidney can lead to an irreversible damage to the inner ear	El-Hashemy and Ali (2018)
7	Hexane	Exposure causes body weight lost, neurological, reproductive and developmental defects in exposed organisms	El-Hashemy and Ali (2018)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36453665

8	Methyl-butyl ether	Causes leukemia and lymphoma (blood cancer), cancer of the kidney and nerve dysfunction. In an aquatic environment, it rapidly leads to the depletion of dissolved oxygen	El-Hashemy and Ali (2018)
9	Xylene	Causes the dysfunctions of the liver, kidney and nervous system. A lot of neurological effects have also been reported	El-Hashemy and Ali (018)
10	Phenol	Causes muscles tremor resulting into walking difficulty and gastrointestinal damage and even death	Wang et al. (2018)
11	Styrene	Exposure could lead to impaired learning and reproductive defects particularly damage in sperm. Possible carcinogenic effects have been reported to result as a result of exposure to styrene	Arabjafari et al. (2017)
12	Nepthalene	Causes mutagenic and carcinogenic effects to micro organisms and other macro organisms and also associated with damage of red blood cells	Wang et al. (2018)
13	1,2,3 Trimethylbenzene	No normal background level adverse effect to human have been reported but on a high exposure lead to Vomiting, tension, wheezing and may be injurious to the blood	Kostrzewski et al. (1997)

Remediation of petrochemical refining wastewater by bacteria

The use of Bacteria for bioremediation can be dated to 1972 when soil pollution resulting from the bursting of Ambler pipeline was bioremediation (Raymond, 1976). Bioremediation technology in the remediation of petroleum wastewater holds a promising start owing to the fact that its earliest research has shown high pollutants removal efficiency compared to other biological and conventional methods (Bako et al., 2008; Peng et al., 2017; Panasia and Philipp, 2018).

Bioremediation of organic pollutants in refinery wastewater can occur naturally by the degradation of the pollutants to a minimum concentration to exert toxicity except for persistence organic compound such as polycyclic aromatic hydrocarbon (PAHs) and benzene, toluene, ethylbenzene and xylene (BTEX) (Horemans et al., 2017; Buryska et al., 2018; Nikolaivits et al., 2018). Although, the rate at which organic pollutants degrade naturally is very slow hence the reason why bacteria are used to engineer the process (Wang et al., 2017).

Petrochemical refining wastewater treatment using bioremediation techniques is less energy, pressure, and temperature consuming if compare with another convectional method (Silva et al., 2012; Ojha et al., 2013; Banerjee and Ghoshal, 2016). Bioremediation potential of bacteria to degrade refinery wastewater depend on its metabolic activities (Eberlein et al., 2013; Boll et al., 2014; Nikel et al., 2016) which involves the ability of the bacteria to introduce molecular oxygen into the wastewater to catabolize the hydrocarbon present in the wastewater utilizing it as a source of energy and carbon (Moghadam et al., 2016; Banerjee and Ghoshal, 2017; Iqbal et al., 2018). Thapa et al. (2012) stated that the bacteria with the potentiality to degrade petroleum pollutants includes *Pseudomonas sp, Beijerinckia sp, Chlorobacteria sp, Antinetobacter sp, Nocardia sp, Lavobacteria sp, Streptomyces sp, Cyanobacteria sp, Baccilus sp,*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36453665

Moraxella sp, Corynecbacteria sp, Aeromonas sp, Mycobactena sp etc. Although, in the treatment of petrochemical refining wastewater these bacteria must not be indigenous bacteria inhabiting the wastewater because nonindigenous bacteria isolated from other sources can be used to treat this wastewater (Chaudhary and Borah, 2011; Singh et al., 2013; Rodriguez-Mateus et al., 2016). Remediation of petrochemical refining wastewater using bacteria is associated with little or no adverse effect to the ecosystem on like in the case of phytoremediation where the disposal of the plants use for remediation becomes another problem to the ecosystem (Boroujeni et al., 2014; Bahobail et al.,, 2016; Duniya, 2016). Many researchers have used indigenous and non-indigenous bacteria in the treatment of refinery petrochemical wastewater as summarized in *Table 2*.

It will be noticed from the *Table 2* that despite the fact that benzene, toluene, biphenyl, cresol, cumene, ethylbenzene, hexane, and methyl-butyl ether are very poisonous pollutants present in petrochemical refining wastewater, there is still scanty literature with respect to the bioremediation of these pollutants in refining wastewater

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36453665

using bacteria. Instead, a significant number of researches on bioremediation of petrochemical wastewater centered the research on total petroleum hydrocarbon which encompasses all. Quite a number of researches have shown the potentiality of some bacteria to bioremediate total petroleum hydrocarbon in petrochemical refining wastewater but it is of paramount importance to be case specific with respect to the potentiality of bacteria that can bioremediate benzene, toluene, biphenyl, cresol, cumene, ethylbenzene, hexane and methyl-butyl ether in the free state because these pollutants varied in state and testing site and so also do their ecological effects. *Table 2* also shows that scanty literature exists for the bioremediation of heavy metals from petrochemical refining wastewater. The poor literature in the bioremediation of heavy metals from petrochemical refining wastewater could be attributed to the non-biodegradable behavior of heavy metals. Although the literature has shown the potentiality of bacteria to remove heavy metal from a polluted site by biosorption and enzymatic degradation, the process of biosorption is illustrated by *Figure 2*. The poor literature in the bioremediation of phosphorus and nitrogenous compound in petrochemical, refinery wastewater is also worrisome because degradation catalyst by bacteria is dependable on environmental conditions.

Biodegradation of pollutants in petrochemical refining wastewater

Petrochemical and refining wastewater contains pollutants that are either organic or inorganic as shown in *Table 2*. The degradation of organic pollutants depends on the aerobic and anaerobic pathway as shown in *Figure 1* while in the case of inorganic pollutants it occurs by adsorption, absorption or the action of enzyme release by the bacteria as shown in *Figure 1* (Fuchs et al., 2011).

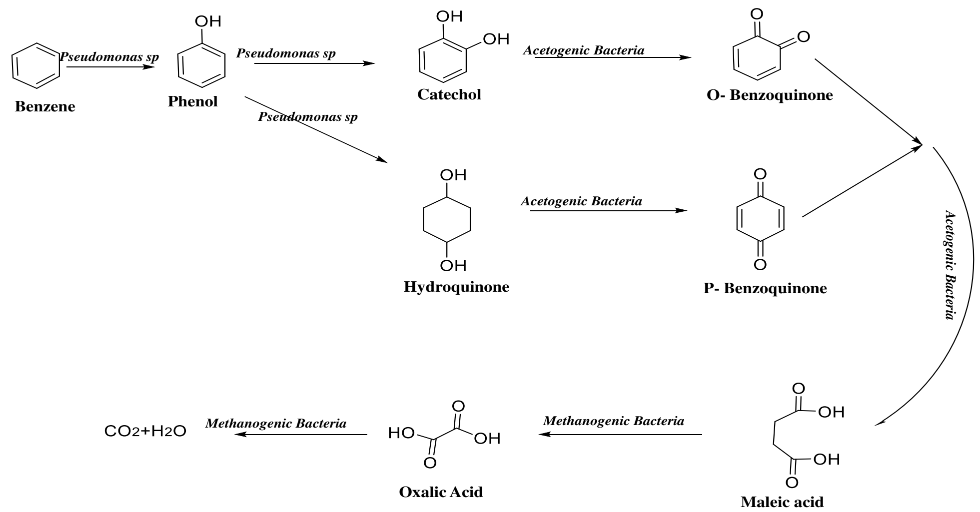

***Figure 1.** Proposed process of biodegradation of benzene by bacteria*

Bacteria possess high potentiality in the biodegradation of hazardous petrochemical wastewater as shown in *Figure 1*. To further enhance the Biodegradation by bacteria particularly in a contaminated site, there is the need to study the condition in which bacteria best perform it functions and the enzymes involved in this process. The role of enzymes in the degradation of petrochemical pollutants particularly organic compounds

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36453665

was reported by Scoma et al. (2017) to be due to Rieske non-heme iron oxygenases, flavoprotein, Monooxgenases or soluble di iron monooxygenases.

Heavy metal present in petrochemical wastewater is nonbiodegradable due to their persistence nature as such this persistence pollutants are removed from petrochemical wastewater by adsorption as shown in *Figure 2*. Researchers such as Gutnick and Bach (2000), Feng et al. (2012) and Oves et al. (2013) have used the dead and live culture of bacteria for heavy metal removal by adsorption. The efficiency of heavy metal adsorption by bacteria depends on the speciation, behavior, transportation mechanism and the fate of heavy metal in binding with the functional group of the bacteria as shown in *Figure 2*. To understand the mechanism involved in adsorption of heavy metals by bacteria, studies on cell surface characterization, functional group identification, acidic and basic active site identification etc have been performed by researchers such as Vecchio et al. (1998), Banerjee et al. (2018).

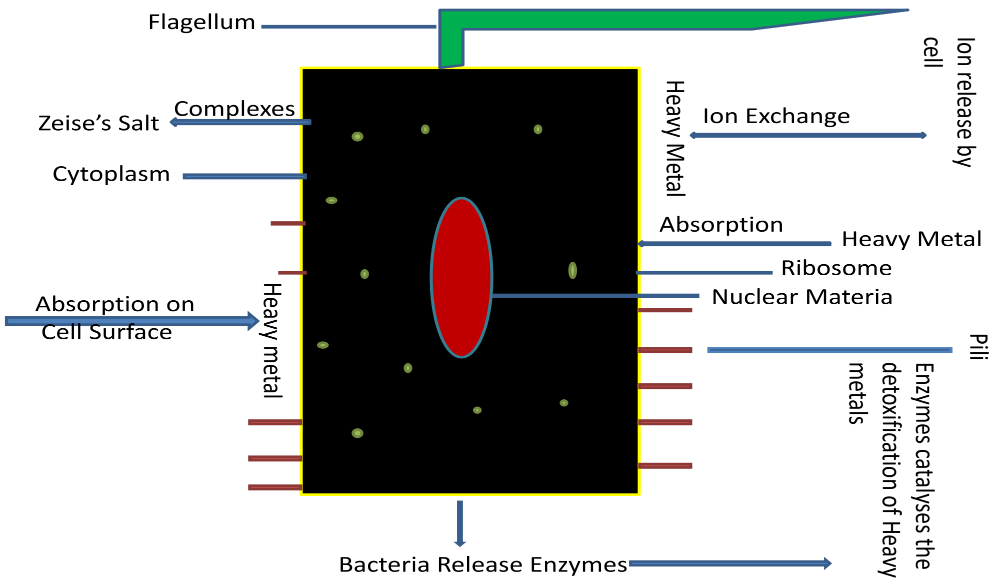

***Figure 2.** Process of heavy metal removal by bacteria (Jin et al., 2018)*

Petrochemical refining wastewater remediation strategies and principles

The strategies used in the bioremediation of petrochemical refining wastewater include biostimulation, bioaugmentation, bioattenuation and the use of genetically modified bacteria.

Biostimulation

This is a strategy that involves the use of indigenous bacteria for the treatment of petrochemical refining wastewater. The indigenous bacteria used for biostimulation are supported by nutrients which maybe inform of cations or anions to enhance the biodegrading capability of the bacteria (Jemli et al., 2017). The addition of nutrient supports the metabolic process of the bacteria thereby facilitating the degradation of pollutants present in refinery wastewater. Sarkar et al. (2016) reported high total petroleum hydrocarbon degradation of about 80% after the retention time of 90 days after bio stimulating indigenous bacteria by enhancing the nitrate constituent of the wastewater (Lin et al., 2012).

DOI: http://dx.doi.org/10.15666/aeer/1702_36453665

Bioaugmentation

This is a strategy employ in the treatment of petrochemical wastewater in which foreign bacteria is introduced into petrochemical refining wastewater to enhance the biodegradation ability of the indigenous bacteria (Yan et al., 2014). To have a successful bioaugmentation of petrochemical refining wastewater, the adaptability of the foreign bacteria must be considered owing to competition that may exist between indigenous and foreign bacteria, another problem that the foreign bacteria may face include predation by protozoa. Dueholm et al. (2014) recorded high removal efficiency of methyl ethyl ketone remediation using bioaugmentation assisted bioremediation using Rhodococcus pyridinivorans. Yan et al. (2013) also recorded high cresol removal efficiency using Pseudomonas sp supported by bioaugmentation.

Bioattenuation

Bioattenuation is a type of strategy which employs natural biodegradation mechanism of bacteria to treat petrochemical wastewater (Huling et al., 2002). The presence of other refinery wastewater pollutants such as phosphate, sulfate, nitrate etc stimulates the process of bioattenuation leading to the degradation of BTEX and PAHs as shown in *Figure 1*. Bioattenuation is the process that occurs when wastewater is stored in stabilization pond. The bioattenuation process is achieved either aerobically or anaerobically by acetogenic bacteria and methanogenic bacteria (Nijenhuis et al., 2004).

The use of genetically modified bacteria

Genetic modification of bacteria genome was among the earliest contribution in the field of genetic engineering owing to their simple structures. The use of the genetically modified bacteria in the degradation of hydrocarbons and chlorinated hydrocarbon is a cost-effective an emerging trend in bioremediation. The degradation pathway of organic compounds as shown in *Figure 1* have been reported by researchers such as Scoma et al. (2017). Also Duarte et al. (2014) reported that enzymes such as dioxygenase, flavoprotein monooxygenase, catechol 2-3 dioxygenases, protocatechuate, gentisate dioxygenase etc are responsible for the degradation organic compound as shown in *Figure 1*. The used of genetically modified bacteria in degradation of petrochemical wastewater is beyond just the use of the natural biodegrading potential of bacteria. genes are introduced into bacteria by recombinant DNA technology to enhances the bioremediation of both organic and inorganic Pollutant.

Molecular characterization of bacteria present in petrochemical refinery wastewater

Molecular characterization of bacteria present in petrochemical refinery wastewater involves the investigation of the chemical functional groups or constituent in bacteria cell that allow the bacteria to be able to survive in petrochemical refinery wastewater and even bring about the bioremediation by degradation of both organic and inorganic pollutants presents in the wastewater (Chaudhary and Borah, 2011; Singh et al., 2013). The technique used in the molecular characterization of bacteria present in petrochemical refinery wastewater includes the following approaches:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36453665

- Genomic approach
- Proteomic approach
- Metabolomic approach (Bahobail et al., 2016; Duniya, 2016; Rodriguez-Mateus et al., 2016)

The methods stated above are changing the understanding of bacteria functions in petrochemical refinery wastewater from a simple study of the sequences of gene, protein or metabolites to a more complex and detailed approach showing the role of bacterial in petrochemical wastewater environment (Hobert, 2010). The molecular approach to petrochemical wastewater bacteria characterization is achieved at the microbial community rather than a single bacteria species due to the fact that biodegradation activities of bacteria depend on consortia (Santisi et al., 2015).

Genomic approach in the uncovering of bacteria function in petrochemical refining wastewater

Bacteria genome simply refers to as the total sets of DNA found in bacteria. Genomic investigation of bacteria genome is centered towards the study of the bacteria genomic structure, bacteria genomic evolution, bacteria genomic mapping, and editing of a bacterial genome (Gilbert and Scott, 2017).

This technique has been helpful in the determination of how bacteria cell is able to successfully leave in petrochemical refinery wastewater and the function they play in this wastewater. This has also helped in the determination of the most efficient bacteria to be used in the remediation of petrochemical wastewater (Larsen et al., 2012).

The aspect of genomic, that is the concern with the study of environmental samples such as petrochemical refining wastewater, is referred to as metagenomic or ecogenomic. This technique employs the use of 16S rRNA gene (16S rDNA) sequences analysis method for the identification of bacteria strain. These methods have shown a better advantage over the culture method of the function of bacteria in petrochemical refinery wastewater. The major sequential method employed includes extraction of DNA, PCR amplification of the 16S rRNA gene, nucleotide sequence determination (sequencing) and sequences comparison with available data (Fuks et al., 2018). The sequencing and analysis of bacteria genome by the use of DNA sequencing, RNA sequencing, and bioinformatics techniques have been utilized in the assembling and analysis of the function and structure of the entire organism genome of bacteria presents in petrochemical refinery wastewater (Toshchakov et al., 2017).

Metabolomic approach in the uncovering of bacteria function in petrochemical refining wastewater

The metabolomic approach of studying the function of a living organism in an environment is highly complex because it tends to give more detail or complex cellular pathways and biological mechanisms in organisms (Vinaixa et al., 2016; Beale et al., 2018a; Beale et al., 2018b). This approach employs the use of small bacteria metabolites including metabolic intermediates hormones, signaling molecules and secondary metabolites to uncover the function play by bacteria (Bonifay et al., 2017).

This approach is used as a basic tool used in functional genomics studies to ascertain the function of the gene (Tang, 2011). This approach holds a promising future towards the ascertaining the function play by bacteria in petrochemical wastewater owing to the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36453665

fact that they are involved in normal growth and development of bacteria as such could provide important detail to why the organism was able to survive and develop fully in the presence of petrochemical wastewater pollutants (Foght, 2008). Metabolites are also involved in activities carried out by antibodies and pigments which is also an important tool for the determination of the reaction pathway in the degradation of organic and inorganic pollutants in petrochemical refining wastewater and biosorption of heavy metals by the bacterial cell (Tang, 2011).

Table 2 summarized some recent contribution done by researchers in the uncovering the function of bacteria in the degradation of petrochemical wastewater making references to metabolomics.

Proteomics approach in the uncovering of bacteria function in petrochemical refining wastewater

This approach involves the use of proteins to uncover the function of bacteria in petrochemical wastewater. The use of this technique has made possible to know the function of bacterial consortia. The proteomic study that a deal with the study of protein for the particular environmental function is refers to as metaproteomic. The use of metaproteomics approach in the characterization of bacterial consortia has given a better insight to which bacteria consortia is best to be used in the wastewater treatment.

Recent findings on molecular identification and characterization of refinery wastewater

Genomic DNA extraction from bacteria isolate was performed by Chaudhary and Borah (2011) who shows that *Bacillus* and *Pseudomonas* species have the maximum capacity to degrade oil but gave upper hand advantage to *Bacillus species*. Singh (2013) shows the presence of *Alcaligens odorans, Bacillus subtilis, Corynebacterium propinquum* and *Pseudomonas aeruginosa* in petrochemical refinery wastewater. The researcher positively collated high pollutant reduction efficiency to lipolytic activities of the bacteria. Rodriguez-Mateus et al. (2016) using wizard genomic DNA purification Kit (Promega, USA) identified bacterial isolates using amplification and sequencing. Rodriguez-Mateus et al. (2016) detected the present of 10 species of bacterial isolate stating that the bacteria isolates belong to the genus *Candida* and *Bacillus*. Rodriguez-Mateus et al. (2016) also show that the bacterial isolates show visible lipolytic activity evidenced by the reduction of in the pollutants of the palm oil refining wastewater. Iqbal et al. (2018) performed molecular characterization by 16S rRNA gene sequencing and find out that phenol was degraded completely by *Achromobacter species, Pseudomonas specie*, and *Alcaligenes species*. The researcher also reported the significant degradation of benzene by *Bacillus species, Enterobacter sp,* and *Acinetobacter sp*. This study is supported by the previous work performed by Bahobail et al. (2016) who shows that *Pantoea agglomerans, Acinetobacter iwoffi* and *Bacillus thuringiensis* where fully characterized to be lipolytic to hydrocarbons. Duniya (2016) shows the presences of the gene for hydrocarbon enzymes catechol 2,3 dioxygenase in *Enterobacter hormaechei*, *Escherichia coli*, and *Shigella flexneni*. Boroujeni et al. (2014) reported that the sequences of the gene bank and the highest homology were identified for bacteria belonging to the *Nitratireductor aquamarinus* and *Pseudomonas stutzeri* were identified. Igwaran et al. (2018) shows the molecular characterization and antimicrobial resistance pattern by 31 genes of *Escherichia coli*. Chikkanna et al. (2018) using

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36453665

polyphasic taxonomy approach identify bacterial strain including Halomonas *Mauramaura, Halomonas nitoreduceus, Halomonas ventose, Halomonas trenophila* and *Halomonas methanobrevibacter*. Azadi et al. (2017) screen and characterized Mycobacteria from the diverse range of Iranian aquatic and terrestrial ecosystem with a harsh and unfavorable environmental condition that can be used in biodegradation of refinery product. The presences of *Mycobacterium fortuitum, Mycobacterium flavescens, Mycobacterium paragordonae, Mycobacterium monacense, Mycobacterium fredriksbergense, Mycobacterium aurum, Mycobacterium conceptionense, Mycobacterium porcinum, Mycobacterium aurum, Mycobacterium celeriflavum, Mycobacterium novocastrense, Mycobacterium obuense* and 12 isolates belonging to an unknown potentially novel bacterium species. Obi et al. (2016) performed molecular characterization using rRNA gene to indicate the presence of bacteria belonging the genera *Stenotrophmonas, Bordetella, Pseudomonas, Brucella, Bacillus, Achromobacter, Ochrobactrum, Advenella, Mycobacterium, Mesorhizobium, Klebsiella, Pusillimonas* and *Raultella sp* with potential to degrade polycyclic aromatic hydrocarbons (PAHs) from oil sludges. Abo-State et al. (2018) was able to isolate Naphthalene tolerance bacteria belonging to *Bordetta avium* including *MAM-P14, MAM-P22, MAM-P25, MAM-P26, MAM-P9*. Nascimento et al. (2018) was able to characterize microbial diversity in sewage sludges from Sao Paulo, Brazil. The presence of high bacterial diversity was noticed with proteobacteria as dominant phylum then Bacteroidetes and Firmicutes, Clostridium were the dominant genus followed by Treponema, Propionibacteria, Syntrophus, and Desulfobulbus. Ma et al. (2015) isolated Strain DN002 from petroleum-contaminated soil which was identified as *Achromobacter xylosoxidans.* The research shows that during fluoranthene biodegradation, catechol 2, 3 dioxygenases (C23O) activity was augmented 1.5 times more than catechol 1,2 dioxygenase (C12O), which indicated that C23O played a major role in fluoranthene degradation by DN002. The dominant general was *Propionibacterium, Comamonas, Brevundimonas, Methylobactenum, Stenotrophomona*s, and *Cloacibacterium.* Jamal and Pugazhendi (2018) identify the halophilic bacteria trains present in the consortium to include *Ochrobacterium halosaudis, Stenotrophomonas maltophilia, Achromobacter xylosoxidans* and *Mesorhizobium halosaudis*. Katyal and Kaur (2018) were able to isolate chromate tolerance bacteria from a treatment plant. The isolates belonging to the *Micrococcus luteus* include HM 16, *HM, 2, HM 3, HM 15*. Ibarbalz et al. (2016) used function encoded in metagenome to establish a link between microbial community structure and function in activated sludge. The bacteria detected include Actinobacter, Planctomycetes, Verrucomicrobia, and Chlorobi. Rosso et al. (2016) also use a proteomic approach to investigate the changes of bacteria community overtime, Cyanobacteria, Bacteriodetes, and Proteobacteria were the bacteria that express extracellular hydrolases. Navarro-Locsin and Lim-Jurado (2018) use geno-wide transcriptome and proteome data to confirm most highly expressed organohalide respiration (OHR) rate. He concluded that hydrogenase (HUPL) transcript is the most robust activity biomarker across multiple Dehalcoccoides mccartyi (DMC) strain and in mixed communities including DMC co-culture such as bioaugmentation culture (KB1^{TM}). Cernava (2017) used multi-omics approach to characterize functional guilds in an unconventional model system. The community structure of the microbiota was found to be highly similar irrespective of the omics approach. The abundant bacterial orders include Sphingomonadales, Rhodospirillales, Myxococcales, Chthoniobacterales, and Sphingobacteriales. The function played by these Bacterias identified is the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36453665

provision of vitamins and cofactors to the degradation of phenolic compounds like phenylpropanoid, xylenols, and cresols. Matilda and Shanti (2017) isolated trivalent chromium resistant bacterium and identify it by 16S rRNA gene sequencing and designated as *Alcaligenes faecalis* VITSIM2. The organism also showed resistance to copper, cadmium, and certain antibiotics and also shows changes in cell wall content.

Nzila (2018) Isolated and characterized a bacterial strain capable of metabolizing the four fused aromatic ring polycyclic aromatic hydrocarbons (PAH). The analysis of 16S rRNA gene revealed that the bacterium is called Achromobacter xylosoxidans. The proteins involved in the degradation of PAH are 4-hydroxyphenylpyruvate dioxygenase and homogentisate 1,2-dioxygenase. Otzen et al. (2018) isolated a caprolactam-degrading strain of Pseudomonas jessenii from soil and identified proteins and genes putatively involved in caprolactam metabolism using quantitative mass spectrometry-based proteomics. He demonstrated that caprolactamase consist of two subunits and demonstrated high sequence identity to the 5-oxoprolinases. Escherichia coli cells expressing this caprolactamase did not convert 5-oxoproline but were able to hydrolyze caprolactam to form 6-aminocaproic acid in an ATP-dependent manner. The research concluded that the presence of a caprolactam catabolism gene cluster comprising a set of genes involved in the conversion of caprolactam to adipate.

Conclusion

Molecular characterizations of bacteria responsible for the bioremediation of petrochemical refining wastewater have a promising future for the control of petrochemical engineered pollution. Bacteria consortia consisting of bacteria which have shown bioremediation capacity for phenol, benzene and other constitutes of petrochemical refining wastewater should be properly utilized as an advantage to properly degrade these pollutants completely from the wastewater before discharge. Molecular characterization will help in the proper identification of the bacteria and enzyme released by the bacteria responsible for the pollutant degradation. The technique will also lead to the identification of the mechanism involved in the ecological adaptation of the bacteria to polluted environment and the role of antibiotic, antimicrobial compound (metabolite and proteins) and bacteria gene in the degradation of petrochemical refining wastewater.

Abstract. Water is an essential natural resource and is even known to be the cause of many wars of history. While people depend on it to survive, they also use it for everyday activities and several other purposes. As for plants, water is an essential factor, one they need for growth. Although irrigation is really important for certain agricultural plants, many criticise its water consumption especially on scientific platforms and media. This naturally pushes the world to find alternative ways to decrease the water consumption where possible. Greywater (GW) use is one of these alternative ways. This study aims to focus on two different but ecologically useful recent phenomena; GW use and green roofs. GW use makes it possible to decrease water consumption by replacing irrigation water, while green roofs (GRs) are known to increase biodiversity in urban areas and to decrease heat island effect and as a result reduce the costs of air conditioning. Since the main purposes of this study are to evaluate the use of GW on GRs to examine if there might be an ecologically and economically more beneficial way to keep the roof green, we used a prepared greywater simulation (PGWS) to measure green roof plants' responses to it. Two different greywater models, non-diluted prepared greywater simulation (N-D.PGSW) and 50% diluted prepared greywater simulation (%50-D.PGWS), were used for irrigation; while tap water (TW) irrigation and no irrigation (N-I) were the other two conditions to make the study more reliable.
Keywords: *Sedum irrigation, urban landscape, water management, environmental management, sustainable water use*

Introduction

Water is a life-sustaining natural resource and has been regarded as inexhaustible until quite recently, but the accelerating population growth and development of industrial activities have led to its depletion, especially in areas facing drought (Illan, 2011). After the recognition of water as an exhaustible resource, innovative technological and agronomic practices such as storage and regulation methods for water, installation of irrigation automation systems, and reuse of wastewater were adopted. Despite these innovations and cultural practices, cities currently suffer from water deficit. Water deficit is defined as the exceedance of the currently-available renewable sources by the sum of the water use requirement of different fields (urban, agricultural, industrial, and environmental uses) (Zavala and Estrada, 2016).

GW is defined as the urban wastewater consisting of the waters used for domestic purposes except for the toilet water (water from bathroom sink, shower, lavatory, dishwasher, washing machine, and kitchen) (Mohamed et al., 2013; Li et al., 2009; Ottoson and Stenströn, 2003; Eriksson, 2002; Jefferson et al., 1999). GW constitutes 50-80% of the total wastewater use of a household (Antonopoulou, 2013; Friedler and Hadari, 2006; Eriksson et al., 2003). Previous studies reported that depending on the population structure, tradition and habits, structure of the plumbing system, and water abundance, the use of GW vary between 90-120 l/p/d (liter/person/day) in developed countries, whereas in low-income and water-scarce countries the rate drops to 20-30 l/p/d (Morel and Diener, 2006).

In addition to avoiding river pollution, the use of GW as a valuable fertilizer and for irrigation purposes in landscape and agricultural areas in Rome, Greece, China, England, and Germany dates back to ancient times. The use of wastewaters in irrigation has emerged as an effective mechanism to regulate water resources in water-scarce areas since the 16th century (Zavala, 2016; Negahban-Azar et al., 2012).

One of the main factors adding to the importance of GW is undoubtfully the expanding place of its generators in everyday use. In addition, since GW do not contain fecal waters, they can be easily treated and potentially reused (Yalçınalp et al., 2018). Moreover, GW is increasingly used due to the lower polluting effects of pathogens and nitrogen (Li et al., 2009; Li et al, 2003). The use of GW in gardens, car washing, laundries, and toilet flushes has been a long-employed practice in various regions of the world. The use of treated GW also greatly contribute to the protection of high-quality water resources. Depending on the popularization of these practices, this contribution brings along a great cumulative potential as well (Li et al., 2003).

It is clear that the reuse of waste water poses a health risk both for the public and system employees due to the high exposure rate to pathogenic microorganisms and toxic materials. The health concerns regarding the increases in these activities generally involve the extent of human exposure to treated wastewater, the type and quality of the treated wastewater, and the safety of the treatment processes (Zavala and Estrada, 2016; Benami et al., 2013). Nonetheless, in the case of landscape plants, since they are not edible and thus, the water used in their irrigation can have a lower microbiological quality, the use of wastewaters is advantageous in the irrigation of landscape plants.

The great amounts of the GW generated by the recent large-scale urban development in Trabzon have led to its emergence as a new recyclable water resource. GW will be an important resource to partially mitigate the water deficiency and prevent the pollution of environment by these waters.

Despite its huge popularity in recent years due to its great potential and the environmentally destructive course of the world, pessimistic and refraining voices have been raised against the use of GW. The most prominent concern is the doubts about its possible use in the irrigation of edible plants. Furthermore, the possibility and rapidity of bacterial growth during the storage of GW, which contains bacterial growth-facilitating organic wastes, have long been among the underlying causes of the reluctance towards its use. However, scientific studies evaluating it within the limits of universal standards have indicated that GW was a safe and sustainable resource.

Analysis of the detailed information gleaned in this study helps (1) to evaluate green roof plants' response to GW irrigation, (2) to make a contribution to green roof phenomena by decreasing the estimated irrigation costs in the long term as GW has a huge potential to take tap water place for irrigation and maybe the most importantly (3)

DOI: http://dx.doi.org/10.15666/aeer/1702_36673680

to create a more sustainable green roof approach to prevent water waste while green roof is already considered as an ecological way to make urban areas healthier and more livable.

Material and Method

Study area

The roof of the Landscape Architecture Department of the Karadeniz Technical University (40°59'27.02"N, 39°46'30.80"E) was selected as the study area (*Figure 1*). After obtaining the necessary permissions, the materials were transferred to the roof using a crane installed on the rooftop and the irrigation equipment were prepared for use. The city covers an area of approximately 4.685 km2 and has a population of about 758.237 inhabitants, making it the second largest principal city in the region (Anonymous, 2013a). The city is within the A8 of the grid system created by Davis 1965 and Davis 1985 and the annual mean rainfall is about 760 mm, while the mean temperature is about 14.6 °C. The monthly mean temperature ranges from 7.3 °C in January and from 13 to 23.1 °C in August.

Figure 1. *Study area*

The Installation of the Experiment

A review of the relevant literature revealed that Sedum species were used in various studies on GRs. *Sedum album* and *Sedum sediforme*, as two species from one of the genera that first come to mind when GRs are considered, were used as the plant materials in this study as well. *Sedum album* and *Sedum sediforme* plants that were brought to the study area, derived from the same origin, and as identical as possible were planted in 60cmx40cm pots and on 10cm blockage for drainage and 20cm soil. To obtain data for the comparisons, experiments were installed in a total of 80 pots comprising 10 pots for each *Sedum* species and each irrigation type (N-I, TW, 50%-D.PGWS, N-D.PGWS). The irrigation rate was planned to be 1 L/w (Liter/Week) for each pot. The plants were planted

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36673680

in the middle of the pots in an area of 24 cm2 (about 10% of the total area) to achieve the adequate examination of the plant propagation. According to the monthly precipitation reports of the Trabzon General Directorate of Meteorology for 2016-2017, during the experiment, the plants were exposed to a monthly precipitation ranging from 6.3mm to 160.2mm and corresponding to an annual precipitation of 88.37mm.

The plant and soil samples were prepared for analyses at the end of the experiment in December 2017 by collecting and blending the samples from each pot that contain plants from the 8 groups examined using different irrigation systems. Soil samples were randomly taken in a depth of approximately 0–15 cm from an open-air field in a nursery. Then the samples were dried at 110 °C and transferred to polyethylene bags until the installation. To make sure that each pot will have the same amount of soil, a bascule was used just before putting the soil into the pots. Trying to pick similar in size, plant samples in 2 different *Sedum* species were also taken from the same nursery and kept on the roof top for the last 3 days to the installation.

Because one of the main aims of the study is to make a practical, sustainable and significant contribution to the green roof existence apart from the evaluating of the plants' responses to greywater, periodic watering was chosen as the irrigation method just like how it is done in the traditional gardening in the area to simulate the conditions on the roof top as close as possible to the daily life.

The Preparation of the Greywater Simulation

The daily water use in Turkey is 216 L/p/d (liter/person/day), whereas the daily water use in Trabzon, Turkey, was determined to be 333 L/p/d (Anonymous, 2013b). No reliable data concerning the average consumption of the chemicals involved in the formation of GW in Turkey were found. Thus, developing an average model for GW has emerged as one of the most important steps of the study. For the simulation of average GW, a "Household greywater scenario" (HGWS) that can provide an insight into the average consumption levels was constructed by combining statistical data such as the average number of individuals in a household and empirical data such as hand washing, teeth brushing, shaving, etc. By grouping the activities such as bathing, cleaning, and personal care, etc. according to the scenario, we were able to derive estimates about the weekly frequency of the activities and by whom the activities were performed, the amount of shampoo, detergent, and cleaning product use, and the contents of the greywater generated by water use. According to the simulation, the amounts of the materials in 1 L GW generated within the scope of the study are given below (*Table 1*).

The cleaning products were randomly procured from a grocery at the city center and during the study, same products were used in the same amounts. The storage of GW is one of the most important issues in industrial GW use, the main reason being the emergence of a bacterial growth-facilitating habitat during the storage due to the organic wastes in its content. To evade this problem, GW was not stored in the study and instead, a new HGWS was created using measuring cups before each irrigation. Attention was given to the complete dissolution of each material added to the HGWS and continuous stirring was applied; then, the GW was rested for an hour, followed by it use for irrigation. Although not using storage for the GW used in irrigation may seem like a disadvantage in terms of the accurate representation of the standard case, this concern is minimized by the currently present measures taken against the bacterial growth in the GW generated by the use of industrial products.

Detergent	0,750 g/l	0,375 g/l

In the study, a group of plants was not irrigated and left by themselves after installation, while the other groups were irrigated for two years from March 2015 to March 2017 in every Saturday when no rainfall had occurred. For irrigation, 1 L water was used for each case containing the plants and drip irrigation was preferred. The HGWS was directly applied to one plant group, while the other group received 50%-D.PGWS and the final group directly received TW.

In addition to the irrigation with the GW, all samples were exposed to natural rainwater. Although this may raise a doubt about the accurate uncovering of the relationship between GW and the two Sedum species examined in the GR, since the main concern of the study is the performance of GW in GRs and GRs are already exposed to rainwater, this issue is believed to enhance the ability of the study to reflect the realities of practice. In addition, as all cases containing the plants were exposed to rainfall, the effect of precipitation on GW-plant relationship, if there is any, most certainly takes place under the same conditions as each plant.

The Analyses of Soil, Water and Plants

To determine the plant propagation rate at the end of the two-year experiment in the pots, separate photographs of each pot from each group were taken 1m above the intersection of the diagonals and prepared for examination in an office setting. Each photograph was divided into 5cmx5cm grids in the computer environment and the *Sedum* cover for each pot was established by determining the frames containing the *Sedum* species. The growth of wild weeds both through the soil in which the experiment was installed and through pollination was also observed in the experimental areas during the vegetation period. Weeding was not carried out to observe the competition between the *Sedum* species and wild weeds.

Then, the plant samples were pressed and dried between blotting papers and prepared for identification. The dried and identified plants were then ground in a plant grinding mill and the wet digestion method was employed using HNO_3 to prepare the samples for analysis. The soil samples were laid and dried on blotting papers for one week and the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36673680

blotting papers were replaced three times during this period. Upon drying, the soil was prepared for analysis after sieving with a 2mm sieve.

The heavy metal ratios in the plant, soil, and water samples prepared for analyses were determined and entered in the database using the atomic absorption device of the Research and Application Center of the Central Laboratory of Bingol University. As the same water samples were used for N-D.PGWS and 50%-D.PGWS, water analysis was not separately performed for the each group.

All parameters (soil particle size; pH; EC; organic matter; $CaCO_3$, Fe, Zn, Cu, Mn, Cr, Ni, and Pb contents) were determined by common methods used in practice. The particle size analysis was done using standard hydrometer method described by Gee and Bauder (Gee and Bauder, 1986). The pH and EC of soil samples was measured in the saturation extract by a pH and EC meter (McLean, 1982; Rhoades, 1996). In addition, pH and EC of water samples was measured directly by a pH and EC meter (Tüzüner, 1990). Organic matter was determined by using Walkley– Black method (Nelson and Sommers, 1982). The $CaCO_3$ content was measured with a Scheibler calcimeter after addition of dilute acid to the samples (Nelson and Sommers, 1982). The contents of Fe, Zn, Cu, Mn, Ni and Cr extractable by DTPA in the soil were determined as described by Lindsay and Norwel 1987. In addition, the Pb content was determined by the ammonium acetate method. The total Fe, Cu, Zn Mn, Ni, Cr and Pb contents of plant samples were measured as described by Kaçar and inal (Kaçar nad İnal, 2010).

Results

There is no doubt that evaluating ecological conditions that affect plants on a GR and in a pot on a conventional roof is not exactly the same thing as the conventional one can could warm up faster and more intensively, which probably makes the conditions a bit more challenging. However, because all the plants in the research area was in the same conditions and because performances of the plants in harder conditions are important while rooftops are knowns as tough habitats, this micro climatic situation was ignored. The propagation rates of the *Sedum* species and the chemical content of the plants are the two most important parameters in the evaluation of the effect of the use of GW as the irrigation water on herbal life in GRs, which was the starting point of this study as well. Thus, the analyses for each pot was carried out by considering these two parameters and the results are given below (*Table 2*).

According to the field measurements, the highest coverage (67.622%) was observed in the trial with N-DPGWS irrigation, while the lowest coverage (34.376%) was observed in the N-I trial. As for the case of *Sedum* species-specific coverage, the *Sedum album* species irrigated with N-D.PGWS had the highest cover rate (60.922%), while the lowest cover rate (12.830%) was observed in the *Sedum sediforme* species irrigated with TW (*Figure 2*).

Wild weed coverage ratio was calculated by comparing it with the whole plant coverage within the 5cm-5cm grids on each pot. The comparison of the total cover rates with the differences between the cover rates of the *Sedum* species revealed that the trial with the TW irrigated *Sedum sediforme* species had the highest wild weed content (47.786%), while the trial with the N-D.PGWS irrigated *Sedum album* species had the lowest wild weed content (6.7%) (*Figure 3*).

Conclusion and Recommendations

Making a classification according to the irrigation types, non-irrigated plants were coded as ‘N-I’, the plants irrigated with tap water were codes as ‘TW’, the plants irrigated with 50 % diluted water were coded as ‘50%-D.PGWS’, and the plants irrigated with non-diluted water were coded as ‘N-D.PGWS’ while, in terms of *Sedum* species, *Sedum album* was coded as ‘*S. Al.*’and *Sedum sediforme* as *‘S. Sed.’* and recorded into the database.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36673680

In *Table 3*, in a comparison between the irrigation type and the cover density of *Sedum* species, it is seen that the highest average value was obtained in N-D.PGWS *(S. al.)* group (x=60,400). This rate was followed by 50%-D. PGWS *(S. al.)* (x=38,000), N-I *(S. al.)* (x=36,600), N-I *(S. sed.)* (x=34,000), 50%-D. PGWS *(S. sed.)* (x=33,000), N-D.PGWS *(S. sed.)* (x=23,800) and TW *(S. al.)* (x=18,600). The irrigation type that *Sedum* species exhibited the lowest propagation was determined to be TW *(S. sed.)* (x=12,400).

Table 3. *Results of the One-way Analysis of Variance performed to determine the differences between the coverage area of Sedum species according to the irrigation variable*

	Irrigation Type	N	X	SE	F	Sig.

	N-D.PGWS *(S. al.)*	10	60,400	7,325		

To determine if different irrigation types have a significant effect on the propagation types of *Sedum* species, the statistical analysis One-Way Anova test was utilized. As a result of the statistical analysis, a statistically significant difference was determined F=6.767, ($p<0.05$). To determine the source of the difference, the Tukey test of the Post Hoc tests was utilized. The direction of the difference was determined to be N-D.PGWS *(S. sed.)*-TW *(S. sed.).*

To examine whether different irrigation types significantly affect the overall propagation rates, One-Way Anova test was used *(Table 4).* As a result of the statistical analysis, no statistically significant differences were found. In the study, for the *Sedum* species used to determine the performance of GW in GRs, it was determined that irrigation with GW had a positive effect on the coverage area.

Table 4. *One-way ANOVA results to determine the differences between total coverage area according to irrigation variables*

	Irrigation Type	N	X	SE	F	Sig.

	N-D.PGWS *(S. al.)*	10	67,622	7,361		

When the same analysis was performed for the wild weeds in the pots and all the areas covered green, it was seen that the irrigation type had no effect on the propagation area. GRs are known as surfaces where living conditions are not so easy due to many conditions including solar energy and intense winds that they are exposed to. Therefore, certain

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36673680

species with high resistance to these challenging conditions are very popular in both scientific researches and practice studies in this field. *Sedum album* and *Sedum sediforme* are two of the most known species of these species and are selected as the materials in this research. Numerous wild weeds that came to the area after these species were brought to the area, since they can easily adapt to and tolerate these difficult conditions, were found abundantly even in the N-I trial and, therefore, inhibited the effect of the green area associated with irrigation. At the point, the best answers to the question "So, why are *Sedum* species primarily preferred for the GRs?" are that they are always green compared to these wild species, they cover the area in a more compact way and they form a more aesthetic and successful layer in terms of thermal insulation. In addition, the contribution of these natural *Sedum* species to the biological diversity and the effect of feeding the wild life is inherently higher.

Examining the correlation tests, it was determined that the propagation of *Sedum* species is inversely proportional to Fe (Fe **) and Pb (Pb **) elements in the plant *(Table 5).*

Table 5. *Sedum cover density correlation analysis*

Iron has an important feature since it can easily form clay with organic complexes in soil and plants. Therefore, iron can become soluble in the upper layers of the overly washed and low-drainage soils, and it adheres to the lower soil layer (Karaman, 2012). In the nutrient environments such as the roof gardens where the depth of the soil is low, Fe can be transported to the plant via the plant roots even if it adheres to the lower soil.

Excessive Fe intake forms a toxic effect in plants. Tanning is the most important example of this toxic effect in plant leaves. This is observed when Fe content in leaves is 700mg/kg (Anonymous, 2005; Yamauchi, 1989). Tanning in iron toxicity results from oxidized polyphenols (Peng and Yamauchi, 1993). K application can be carried out to eliminate iron toxicity. In this case, K both reduces the Fe^{2+} uptake and increases oxidative potential of roots (Güneş et al., 2000).

Lead is not absolutely required for plants, but it is found in the soil at a dose of 15-40 ppm. It is potentially dangerous for human health when it exceeds 300 ppm (Özkan, 2017; Kaçar et al., 2013; Dürüst et al., 2004). Lead affects the plant water regime due to its negative effects on cell turgor and cell wall stability, and its reducing effect on stoma movements and leaf area. Also, it reduces the uptake of cations and anions since it is held by the roots and it reduces root development, affecting nutrient uptake (Tao et al., 2007; Sharma, 2005).

Examining the propagation of the species in total, it was determined that the cover density was directly proportional to Cr (Cr *) in the soil and pH value (pH ***) of the irrigation water and inversely proportional to Cu (Cu **) in the plant *(Table 6).*

Chrome is naturally found in soils in amounts ranging between 5-100 mg/kg (Asri and Sönmez, 2006; Özbek et al., 1995). The first physiological process affected by the toxic chrome levels in plants is seed germination (Knezevic et al., 2009; Jain et al. 2000). Although chrome reportedly inhibits the development of roots through obstructing cellular division in roots and root growth and thus reduces plant growth and development through decreased water and nutrient intake from soils (Khan et al., 2000), the statistical analysis of the results obtained with the experiment installed in this study showed that the total cover density increased with increased chrome levels in soils.

The toxicity level of copper differ among plants (Knezevic, 2009; Robson and Reuter 1981; Hodenberg and Finck, 1975). The first symptoms of copper toxicity in copper-sensitive plants include decreased root growth, damaged plasms and membranes, and release of potassium (K) ions (De Vos et al., 1991; Baker and Walker, 1989). The decreases in the indole-3-acetic acid (IAA) oxidase activity in plants due to exposure to high Cu concentrations lead to certain changes such as reduced root growth and lateral root formation (Karaman, 2012).

The pH of the irrigation waters directly or indirectly affects various physical, chemical, and biological phenomena that occur in soils. There is a close relationship between soil reactions and soil biota; for example, fungi are more active at pH 4-5, while bacteria are more active at pH 6-8. Moreover, pH levels also play an important role in the availability of the nutrients found in soils to vegetables. The most suitable pH range for nitrogen, phosphorus, and potassium intake by vegetables is between 6.5 and 7.5. At pH levels below 6.0, phosphorus bonds with Al and at pH levels above 7.5, phosphorus bonds with Ca, which obstructs its intake by plants. Al and Mn have toxic effects on plants at pH levels below 5.0, while at pH levels below 7.5, microelements such as Fe, Cu, Zn, Mn convert to a non-soluble form and their availability to plants significantly decreases (Url 1; 2018). As a result of the statistical analyses, it was seen that the Cu taken from the soil was inversely proportional to the plant growth. It is expected that the pH of the irrigation water will increase the plant propagation since the pH of the water makes the element of Cu insoluble and decrease its intake by the plants, preventing the toxic effect of Cu.

Evaluating the study as a whole, it was seen that there was a significant difference between irrigation and non-irrigation of *Sedum*, one of the most popular GR plants, in terms of the roof surfaces they cover. In addition, since clean water is one of the most valuable items in the world, considering GW as an alternative irrigation method, it was seen that this usable waste water can decrease, even eliminate, the use of important and expensive TW. It was also seen that the use of GW provides more positive effects on the plant growth compared to that of the TW. In this sense, by using GW in GRs, it would be possible to achieve both economical and ecologically more favorable results, by both reducing water consumption and providing positive effects on plant growth. Moreover, it is also clear that utilizing this waste water will reduce the irrigation costs of the GR systems and consider the GR as a more sustainable and economic alternative in the long run, thus becoming more widespread and having an impact on urban sustainability. Yalçınalp at al. (2018) has stated that the use of the industrial system required for GW use would prove to meet the GR cost in the long run and that greywater should be used as irrigation water. Despite its ecological and economic benefits, the incentives and scientific studies on using GW in the irrigation for the widespread use of GR systems, which are still not widespread as it should be, will greatly contribute to making the world a more sustainable place.

Acknowledgements. This research was designed as a part of a master thesis of which the title is "Performance of Greywater Irrigation on Two *Sedum* Species", which was supervised by Emrah Yalçınalp.

(Received 21st Dec 2018; accepted 20th Feb 2019)

Abstract. The study was conducted to compare the levels of bioactive compounds and antioxidant activities of (*Solanum lycopersicum* var. cerasiforme) fruits cultivated on different soil amendments (cow dung, chicken droppings and ([40 g/kg N: 60 g/kg N: 40 g/kg N] Nitrogen-Phosphorus-Potassium) in a shaded house. Tomato seedlings were transplanted into pre-treated soils and watered daily in the afternoon for a period of five months. The general growth and yield performances were in the order of NPK > Chicken droppings > Cow dung. The fruits were harvested at maturity (red-ripened stage) and subjected to bioactive compounds analysis using High Performance Liquid Chromatography (HPLC). The results of the study showed strong relationship between the level of macronutrients like nitrogen, phosphorus and potassium in the soil and the level phenolics, flavonoids, beta-carotene and lycopene contents in tomato. The level of beta-carotene was significantly higher ($p < 0.05$) in the fruits cultivated in the NPK amended soil which was totally different to the result of other bioactive compounds like phenolics, flavonoids, and lycopene which recorded their highest concentrations in the fruits harvested from control and cow dung amended soil. Antioxidant activity was determined by adding 2,2-diphenyl-1-picrylhydrazyl to an aliquot of methanolic extract. The ability to scavenge radical was measured by reading the decrease in purple coloration of the solution using Ultraviolet-Visible (UV) Spectrophotometer. The tomato fruit from cow dung showed highest percentage of radical scavenging activities.

Introduction

The use of chemical fertilizer has been a popular and widespread practice in the effort to address global food security challenge resulting from low fertile agricultural soil. The dependence on these chemical fertilizers, particularly nitrogen fertilizer has become necessary to replenish soil nutrients and invariably improve the quantity and quality of agricultural produce. High crop yield and high biomass of plant from N-fertilizer application are responsible for increasing dependent on N-fertilizer (Camara et al., 2003; Guo et al., 2010). However, intensive usage of N-fertilizer has been reported to cause accumulation of nitrogen residues, nutrient toxicity, metal pollution, greenhouse gas emission, groundwater contamination and soil acidification (Han and Zhao, 2009; Sierra et al., 2015). Furthermore, research has shown that increase in applied nitrogen leads to increase in the soil electrical conductivity, available nitrogen, distortion of C/N ratio, distorting soil microbial community and reduction in nutritional quality of agricultural produce (Stuart et al., 2014; Sierra et al., 2015; Norman and Dazzo, 2016; Wei et al., 2018). It has been established that crops only take up 30-50%

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36813694

of chemical fertilizers and the remaining percentage are lost to the environment (Norse, 2005; Mózner et al., 2012).

Conversely, the use of organic manure, has been reported to improve biological, chemical and physical properties of the soil and invariably increase plant growth and yield because of its high organic matter content due to high microbial activity (Stephen et al., 2014; Mitran et al., 2017). Organic manure, as opposed to inorganic fertilizer has also been reported to increase the level of secondary metabolites like phenolic, flavonoid, and antioxidant activity in plant (Zeinab et al., 2013; Fließbach et al., 2007). For example, Wiebel et al. (2000) reported a 19% higher phenolic content for organically produced apples compared to the inorganically produced ones. Higher level of phenolic content was also recorded for organically grown strawberries compared to inorganically cultivated ones (Hakkinen and Tomonen, 2000). All these reported cases have led to growing preference by consumers for organic agricultural produce (Hughner et al., 2007; Mie, et al., 2016). All over the world, attention has now shifted towards the use of organic manures because of the perceived health benefits and higher nutritional contents believed to be derived from products from these types of farming (Worthington, 2001; Magkos et al., 2001; Tarozzi et al., 2006). This submission is supported by the studies which reported that the positive attitude of the consumers towards organic food is based on their perception of higher nutritional contents and better tasting of organic food compared to the conventional or inorganic foods (Hunter et al., 2011; Smith-Springer et al., 2012). Organic manures are said to enhance antioxidant activity and bioactive compounds like phenol, flavonoid, beta-carotene and lycopene contents of fruits and vegetables (Dumas et al., 2003; Mohd et al., 2013). The beneficial effects of these plant bioactive compounds range from giving fruits their quality tastes and distinct colors in the case of phenolic and lycopene compounds, to their nutraceutical properties such as prevention of degenerative and carcinogenic diseases (Johnson et al., 2014; Canene-Adams et al., 2005). These reported reasons and benefits of organic farming have prompted scientists and farmers to embark on the use of organic manures in the cultivation of agricultural crops, fruits and vegetables.

However, there are a lot of reports which contradicts the suggestion of superior nutritional quality of organic produce over conventional ones. This study was therefore setup to investigate the effects of these different nutrient sources on the nutritional quality of *Solanum lycopersicum* var. Cerasiforme commonly known as tomato.

Tomato is a fruit bearing herbaceous plant grown annually for its many nutritional contents. It is an important fruit with a wide range of reported health benefits and cultivated in all continents except Antarctica (Ilahy et al., 2011; Pinela et al., 2012). It is one of the cheapest and most readily available sources of proteins, minerals, vitamins and essential amino acids (Stephen et al., 2014), and is said to be rich in antioxidants and bioactive compounds such as phenolics, flavonoids, beta-carotene and lycopene contents which are reported to serve as endogenous defense mechanisms produced in response to pathogens (Pinela et al., 2012; Bhowong et al., 2009; Simova-Stoilova et al., 2008). The concentration level of these bioactive compounds has been linked with the system of production. The effort to reduce the negative impacts of mineral fertilizers on the environment and the increasing demands of consumers for tomato fruit due to its nutritional and health benefits have caused scientists and growers to device means of meeting the demand for quality produce. This study was therefore conducted to compare the effect of organic manures and chemical fertilizer on the growth rate and the levels of bioactive compounds in tomato.

Methodology

A farming experiment was set up at the production unit of Sefako Makgatho Health Sciences University located in the northern part of Pretoria (Tshwane metropolitan) South Africa, on a coordinate (25°37’8” and 28°1’22” E). The study area experiences a climate of long hot, rainy summer and a short cool and dry winter with an average annual temperature of 18 °C (65.7 °F).

Experimental design and planting

The farming experiment was carried out in the summer period of September 2015 – March 2016. The study was conducted on red beefsteak tomato with a globe shape fruit, smooth and glabrous skin and weighs between 0.12 – 0.18 kg. The design comprised three different soil amendments (cow dung, chicken droppings and Nitrogen-Phosphorus-Potassium (NPK) fertilizer with a control experiment of soil with without any amendment. The experimental design consisted of comparable amounts of 0.15 kg of inorganic amendment (NPK fertilizer) manufactured by Omina Fertilizers Johannesburg, South Africa was purchased from a registered marketer, Plantland Kwikery Akasia Pretoria North, South Africa. The dry organic amendments (cow dung and chicken droppings) were collected from a registered livestock farm De-Wildt Brits Road North west South Africa. The 0.15 kg weight of the $N_{40}P_{60}K_{40}$, i.e. N_{40} is 40% Nitrogen, P_{60} is 60% phosphorus and K_{40} is 40% potassium used as the basis for the comparison of the organic amendments falls within the recommended doses of NPK fertilizer for the cultivation of tomato (Hebbar et al., 2004). The experiment was a randomized block design which contained 32 pots, each with a 22 cm diameter (Alain et al., 2013) divided into four groups which were each filled with 5 kg of sandy-loam soil mixed with 0.15 kg of the amendment. The first group were each filled with an equal quantity of soil mixed with dry 0.15 kg of cow dung; the second group contained equal quantity of soil thoroughly mixed with dry 0.15 kg of chicken droppings; the third group were filled with the same quantity of soil thoroughly mixed with 0.15 kg of pellet $N_{40}P_{60}K_{40}$ fertilizer and the last group contained pot plants each filled with equal quantity of soil without any treatment which served as the control. The soils were continuously watered and turned over at two weeks interval with garden forks and left for over a month after the addition of the treatments for proper mineralization of the amendments to take place (Ayeni, 2014). The Pot plant saucers/ trays were placed under the perforated bottom pots to prevent nutrient loss by runoff during irrigation. The seedlings of tomato at two weeks old purchased from a registered nursery, Plantland Kwikery Nursery Akasia Pretoria North were transplanted into each pot plant and watered daily using a measuring cylinder with each plant receiving the same volume of water enough to moist the soil and the plants and preventing runoff.

Soil nutrients

The soil is a sandy loamy with 71% sand, 15% silt and 14% clay. The control and cow dung amended soils were low in total N, available P and exchangeable K compared to NPK and chicken droppings treated soils (*Table 1*).

Data collection

Parameters such as plant height, stem girth and leaf area index were recorded for the determination of growth performance of tomato plants from different amendments and the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36813694

control following the procedure of (Stephen et al., 2014). The Plant height was measured using a meter rule. Stem girth was recorded by using a vernier caliper and the leaf area index was measured by determining the average of the distances between the two longest and the two shortest branches using a meter rule (Witness et al., 2016).

Table 1. *Composition of soil nutrients*

Treatments	Total N (%)	Available P (µg/g)	Exchangeable K (µg/g)
Cow dung	0.8	552	535
Chicken droppings	1.2	647	443
NPK	1.8	670	456
Control	0.6	518	376

Preparation of tomato fruit for phytochemical and antioxidant activity analyses

Tomato fruits from soil treated with different amendments and that of the control were harvested after ripening. Visually selected injury free, ripened fruits were picked and immediately transferred to the laboratory where they were cut into small pieces and homogenized. The homogenates were then frozen in a -80 °C refrigerator and freeze-dried for the phytochemical and antioxidant activity analyses.

Extraction and determination of free radical scavenging activity

The methanolic extraction was carried out by sonicating the mixture of 100 ml of 50% methanol into an Erlenmeyer flask containing 6 g of freeze-dried powdery sample for 60 min. The resulting solution was thereafter filtered through a Whatman No. 1 filter paper and the filtrate (extract) placed in fume cupboard for 24 h for a complete evaporation of methanol. The determination of free radical scavenging activity was done by following the procedure described by (Biehler et al., 2010). An aliquot (10 mg) of methanolic extract was dissolved in 1 ml of 50% methanol from which 30 µl of the solution was pipetted into an Eppendorf tube. This was made up to 750 µl volume to which 750 µl of 2,2-diphenyl-1-picrylhydrazyl (DPPH) was added. The solution was incubated for 40 min in the dark at room temperature. The decrease in the purple coloration of the reaction mixtures was read at 517 nm using an Ultraviolet-Visible Spectrophotometer (SPECORD 210 PLUS). Ascorbic acid was used as the standard and methanol used for extraction served as a negative control. The assay was performed in triplicate and the radical scavenging activity (RSA) was calculated using *Equation 1:*

$$RSA(\%) = A_0 - \frac{A_1}{A_0} \cdot 100 \quad \text{(Eq.1)}$$

where A_0 is the absorbance of the control and A_1 is the absorbance of the sample.

Beta-carotene and lycopene contents

Extraction and quantification of β-carotene were done using the method described by (Moyo et al., 2017). Samples were extracted with ice-cold hexane: acetone (1:1, v/v). The mixture was vortexed before centrifuging at 2000 rpm for 2 min and the organic phase decanted into another test tube containing 5 ml sodium chloride solution. The

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36813694

residue was similarly re-extracted and was combined in the saturated sodium chloride solution each time until the extract was colorless. The separated organic phase was injected into a High-Performance Liquid Chromatography (HPLC) equipped with a Photodiode Array Detector (PDA) and a mobile phase consisted of (7:2:1) acetonitrile-dichloromethane-methanol with an injection volume of 20 µl and detection at 450 nm. Peak identification and quantification were achieved with comparison to authentic β-carotene standard which was used for the plotting of the calibration curve (Moyo, et al., 2017).

Total phenolic

The method described by Singleton et al. (1999) was used for the extraction and the determination of the total phenolic content. An aliquot (10 ml) of 50% methanol was added into an Erlenmeyer flask containing 0.2 g of the freeze-dried tomato sample and the mixture sonicated for 30 min. The resulting solution was subsequently centrifuged in a HERMLE Z513 at 2000 rpm for 2 min. About 50 µl of the supernatant was pipetted into a new test tube and 450 µl of distilled water, 450 µl of 1N folin ciocalteu reagent, 125 µl of sodium carbonate solution were added. The solution was vortexed and incubated for 40 min at room temperature. Different aliquots of gallic acid (0.1 mg/ml) was used as the standard for plotting the calibration curve and total phenolic content was expressed in mg gallic acid equivalents (GAE) per g dry weight.

Flavonoid content

The flavonoid content was quantified using aluminum chloride colorimetric method as described by (Zhisten et al., 1999). An aliquot (0.2 g) of the freeze-dried tomato sample was weighed into an Erlenmeyer flask into which 10 ml of 50% methanol was added and the mixture sonicated for 30 min. The solution was then vortexed and centrifuged at 2000 rpm for 2 min and the supernatant pipetted into a new test tube. About 250 µl of the supernatant was pipetted into a new test tube and 1 ml of distilled water, 75 µl of 5% $NaNO_2$ were added. After 5 min, 75 µl of 10% $AlCl_3$, 500 µl of 1 M NaOH and 600 µl of distilled water were added and the solution vortexed. Different aliquots of gallic acid (1 mg/ml) catechin was used as standard for the calibration curve and flavonoid content was expressed in mg catechin equivalents (CE) per g DW.

Statistical analysis

All statistical analyses were performed using SPSS 24.0 by carrying out analysis of variance to determine the statistical significance and post hoc test using Tukey for the separation of the means of growth performance, bioactive compounds and scavenging activity from the different treatments.

Results

Effect of different soil amendments on the growth and yield performances

The results of the growth and yield performances were presented in *Tables 1* and *2* (Aina et al., 2018). Although, plants from control soil and cow dung amended soil recorded higher plant height and canopy size at the early stage after transplanting. This observation according to literature, may be due to the physiological adjustment of plant

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36813694

to the new environment (Ayeni et al., 2014). Overall, the tomato cultivated in inorganic fertilizer (NPK) recorded the best growth rate which was determined by recording the height, canopy size and stem girth of the plant. Similarly, the yield results showed that NPK produced the highest number of tomato fruits, followed by chicken droppings and with a yield pattern of NPK > chicken droppings > cow dung > control. This yield result is also consistent with other study which suggested that it may be a result of deficiency and or slow mineralization of nutrient of organic manure during the plant growing and developmental stages (de Ponti et al., 2012).

Effect of different soil amendments on the level of bioactive compound concentrations

The varied level of bioactive compounds of the tomato fruits as influenced by different soil amendments are presented in *Table 2*. The results showed that the level of phenolics, flavonoids, and lycopene were lower in the fruits harvested from inorganic NPK fertilizer compared to their counterparts from the control and cow dung amended soil. The difference in the level of phenolics flavonoids and lycopene in the fruits cow dung manures, NPK and control soil were statistically significant, the difference in the lycopene across different treatments was statistically significant. However, in reverse pattern, beta-carotene (*Fig. 1*) was significantly higher in fruit harvested from the soil treated with NPK fertilizer compared to the ones from the rest of the amendments and control. Finally, although the tomato fruit from cow dung amended soil recorded the highest concentration of potential radical scavenging activity, there was however no significant difference in the radical scavenging activity of the fruits across the group (*Fig. 2*).

Discussion

It has been suggested that nitrogen stimulates more roots production which in turn enhance plant growth and yield performance (Sultana et al., 2012; Rai et al., 2013). The study done by Mani et al. (2002) reported higher plant height and yield in plant cultivated with NPK fertilizer and attributed this observation to higher N and P contents. Chemical fertilizer like NPK has been reported to increase plant biomass and crop yield due to its richness in N and P contents which are reported to promote growth in plant (Ekbic et al., 2010; Zeng et al., 2011; Stephen et al., 2014; Mishra and Singh, 2006). The growth result of the current study is consistent with all these previous observations. In this study, application of NPK fertilizer enhances plant height, stem girth and leaf area index considered to be key factors in determining growth vigor. The higher growth response of tomato may be due to the higher nitrogen (N) and phosphorus (P) contents in the NPK compared to other treatments (*Table 1*).

This observation corroborates previous findings that NPK and poultry manure recorded better yield compared to control and cow dung (Znidarcic et al., 2007; Hague, 2012). The better growth rate and yield performance of NPK and chicken droppings compared to the cow dung and control could be due to the high content of essential nutrients like N and P in poultry manure which have been reported to enhance photosynthetic activity capable of promoting root development, vegetative growth and crop yield (John et al., 2004; Lima et al., 2012; Isah et al., 2014; Nafiu et al., 2011; Meysam et al., 2017).

On the other hand, organic manures are reportedly less concentrated nutrient sources compared to mineral or chemical fertilizers and are noted to be very slow in mineralization rates, leading to lower nutrient bioavailability during growth and development nutrients demanding stages (Zhao, et al., 2009; Lester and Saftner, 2011;

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36813694

Seufert et al., 2012). This condition causes organically cultivated tomato to experience; 1. oxidative stress from superoxide dismutase which is a key enzyme in plant defense and development (Chang et al., 2008), and 2. abiotic stress which causes accumulation of Reactive Oxygen Species (ROS) that inhibits enzymatic activity, disturbs cellular homeostasis and ruptures membrane with deleterious effects on plant growth (Luis, 2015; Baxter et al., 2014). Consequently, organically grown vegetables react to this condition by activating their own defense mechanisms which leads to the synthesizing of more bioactive and antioxidant compounds (Vallverdu-Queralt et al., 2011). They activate signaling pathway for the detoxification of ROS by synthesizing antioxidant that scavenges on ROS (Sharma et al., 2012).

It is therefore conceivable that the result of this study which showed the tomato fruits cultivated in control and organic cow dung amended soils producing higher phenolic, flavonoid and lycopene contents in comparison to their counterparts from chicken droppings and especially inorganic NPK fertilizer amended soil corroborates these reports. The cow dung amended soil as well as the control were low in essential nutrients like N and P in comparison to the soil treated with chemical (NPK) fertilizer (*Table 1*). Several literatures have linked the accumulation of phenolics, flavonoids and lycopene to the level of available N in the soil. For instance, Oliveira et al. (2013) and Mitchell et al. (2007) in their separate studies which investigated the effects of organic and inorganic fertilizers on plant secondary metabolites, reported that organically produced tomatoes accumulated higher concentrations of bioactive compounds like total phenolics and flavonoids compared to inorganically grown ones. These compounds have been reported to accumulate more in plants cultivated on organic manures due to low level of N (Mittler, 2002; Abd El-Moniem et al., 2012; Mohd et al., 2013). Numerous studies have explained that plants tend to produce more or higher level of bioactive compounds and antioxidant as a preventive or protective measure against oxidative and abiotic stress which may result from low level or slow release of macronutrient like N (Caris-Veyrat et al., 2004; Toor et al., 2006; Wang et al., 2008; Vallverdu-Queralt et al., 2012; Oliveira et al., 2013). This conclusion is backed up by several other studies on the nutritional quality of fruits and vegetables, which reported that organically produce have approximately three times less nitrate in comparison to conventional crops due to lower availability of nitrogen in organic farming systems (Worthington, 2001; Williams, 2002; Tuomisto et al., 2012).

The result of the current study is consistent with the above submissions as evident in the concentrations of phenolics, flavonoids and lycopene in the tomato fruits from control and cow dung amended soils, both growing media with lower level of available N compared to NPK fertilizer and chicken droppings. Whereas lower concentrations of total phenolic, flavonoid and lycopene were detected in the fruits harvested from soils amended with chicken droppings and NPK fertilizer, both growing media with higher level of available N. It was therefore assumed that there is an inverse relationship between the concentration of bioactive compounds like phenolics, flavonoids, lycopene and the level of available N in the soil.

Other studies concluded that organic manures have stimulatory effect on the accumulation of bioactive compounds by inducing acetate shikimate pathway in biosynthesis, resulting in higher production of secondary metabolites like flavonoids and phenolics (Sousa et al., 2008; Yoldas et al., 2008). It must be noted that although the results of this study showed a significantly higher lycopene content in both the control and the organic cow dung amended soils, some studies have argued that, types

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36813694

of soil fertilization have no effect on lycopene content of fruits. It was explained that lycopene content is accumulated more in the deep ripen stage (Toor et al., 2006; Ilahy et al., 2011). The current study therefore identified this area for further studies in future research.

This study however showed a result of opposite pattern for beta-carotene which was significantly higher in the fruit cultivated in the soil treated with NPK fertilizer and closely followed by that from chicken droppings. This could be due to the higher content of available P in the NPK fertilizer and chicken droppings manure which has been reported to increase beta-carotene contents in fruits and vegetables (George and Zhou, 2002; Abd El-Baky, 2010). Furthermore, the action of phosphorus on enzymes like phosphofructokinase, pyruvate kinase and precursors of pyruvate has been linked with the biosynthesis of carotenoid (Bramely, 2002; Black et al., 2008). The study by Meysam et al. (2017) also reported that increased level of P application led to increase level of carotenoid production.

Although, there was no statistical significance in the potential ability to inhibit and retard oxidation processes, also known as radical scavenging activity of the fruits, it was however slightly higher in the fruits from the soil treated with cow dung. There is no conclusive report on what is responsible for higher production or stimulation antioxidant activity in plant. While some reports have suggested that organic production increases plant antioxidant activity (Janzantti et al., 2012; Vinha et al., 2014), other studies with similar observation to the current study have reported no significant difference in the antioxidant activity of plants from organic and conventional system of production (Fischer et al., 2007; Reche et al., 2019).

Conclusion

In general, this study demonstrated the responsiveness of bioactive compounds in tomato to the level of soil macronutrients which are relatively low or slowly released in organic amendments. It was observed that nitrogen content in the soil has a significant effect on the level of certain bioactive compound synthesis. Although, inorganic NPK fertilizer produced highest growth, yield and beta-carotene, control and organic cow dung amended soils had a higher stimulatory effect on the bioactive compounds like phenolic, flavonoid, lycopene and antioxidant activity. This study therefore concludes that in the effort to reduce environmental degradation through minimum dependence on chemical fertilizer, more usage of free and readily available organic manures as a source of soil fertility management should be recommended. The study also identifies that the link between method of farming system and other secondary metabolites as well as radical scavenging activity requires extensive and detailed study in future research.

(Received 21st Dec 2018; accepted 20th Feb 2019)

Abstract. The decomposition and nutrient release of maize (*Zea mays* L.) straw under the four returning amounts of 10.0 g (CR1), 30.0 g (CR3), 50.0 g (CR5), and 70.0 g (CR7) were studied by nylon mesh bag method, exploring the decomposition characteristics and nutrient releases rules of maize straw, and providing a theoretical basis of rational use of straw resources and nutrient resources management. The results showed that decomposition and the nutrients release of straw are fast in the early stage (0-20 days) and slow in the late stage (20-100 days). In the first 20 days, the C/N ratio of the straw decreased the fastest, and the decomposition and nutrient release was the fastest. At the end of the experiment, the C/N ratio is relatively stable, the characteristics of decomposition rate and P and K releases rules was CR3 > CR5 = CR7 > CR1, the C and N release rate rules were CR3 = CR5 > CR7 > CR1; the release order of the different nutrients was K > P > N > C; the decomposition and nutrient release of CR3 was the fastest. In summary, a reasonable amount of returning promotes straw decomposition and nutrient release, which are conducive to the rational use of straw resources, and put forward measures of nutrient resource management.
Keywords: *straw returning, maize planting, decomposition stage, nutrients, C/N ratio, rational use, nutrient resources management*

Introduction

In recent years, the extensive application of chemical fertilizers has led to agricultural non-point source pollution, soil ecosystem damage and other issues. The crop straw is an important biological in crop production and contains rich plant nutrients and organic carbon. Straw returning is of great significance for improving soil fertility, reducing fertilizer application, reducing agricultural non-point source pollution and improving soil ecosystem (Jin and Zhou, 2018). Many studies have shown the straw returning to the field reduces the use of chemical fertilizers by releasing nutrients from crop straw decomposing, which is an important technology for green agriculture, ecological agriculture and environmental agriculture (Chen et al., 2018; Streets, 2006; Shibu et al., 2006). Straw returning is of great significance for improving soil nutrient, increasing resource use, reducing environmental pollution and improving ecological environment (Jin and Xing, 2018; Witt et al., 2000; Lal, 2010; Hu et al., 2012), so, it is an important way to the rational use of straw resources and sustainable development of agriculture.

To speed up the development and promotion of straw returning technology, some research on straw decomposition is increasing. Studies have shown the crop straw requires the combined action of microorganisms and enzymes to decompose (Becker et al., 2014; Ji et al., 2014). When the straw enters the soil, the decomposition rate of straw increases gradually with time, and the speed of straw decomposition decreases

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36953707

gradually, which is faster in the early stage and slower in the latter stage (Dai et al., 2010; Huang et al., 2016; Ji et al., 2013). The study found the different crops have different speeds of decomposition, for example, maize straw is faster than wheat (Zheng et al., 2004). Some studies have shown the amount of straw returning is negatively correlated with the rate of decomposition, and the application of decomposition agents can significantly speed up the decomposition and mineralization rate of straw (Jusoh et al., 2013; Chen et al., 2011). However, the application of chemical fertilizers in the soil can also promote to decompose of straw (Zheng et al., 2004). Soil fertility affects the decomposition rate of maize straw and high fertility promotes decomposition (Wang et al., 2009). The decomposition rate of crop straw mainly depends on the C/N ratio, and the decomposition is obviously accelerated after the C/N ratio is lowered (Zhang et al., 1994). About nutrient release rate of straw, studies have shown that characteristic is P > K > N > C (Dai et al., 2010; Ji et al., 2013), but some studies have found that is K > P > C > N (Zhong et al., 2017). The depth of straw application also influences on the release of nutrients, the release rate of N, P and K in the deep application of straw is faster than the surface application (Douglas et al., 1980). It can be seen that are many studies on straw decomposition, but a few studies on the amount of straw returning. Thus, it is of great significance to study the straw decomposition at different returning amounts.

Most studies on straw decomposing use the nylon mesh bag method (Olson and Krawczyk, 1963; Dai et al., 2010; Nakajima et al., 2016). Our study was carried out in the arid area using the nylon mesh bag method, because it has little effect on soil water transport, it is close to the actual situation in the field, and is more suitable for studying the decomposition of crop straw in arid and semi-arid areas (Lin et al., 1992). Yining County is the major maize producing area in Xinjiang, China. It has a large planting area, excessive use of chemical fertilizers in production, rich maize straw resources but low use rate; therefore, straw returning has enormous potential. Exploring the decomposition characteristics and nutrient (C, N, P, and K) releases rules of maize straw under different returning amounts of maize planting, and providing a theoretical basis of rational use of straw resources and nutrient resource management.

Materials and methods

Experimental site description

This experimental site was located in Yining County Modern Agricultural Technology Demonstration Park in Xinjiang, China (43°55'N, 81°33'E; altitude is 843 m). The county is temperate desert climate, which is mild and humid in the winter and spring, and warm and dry in the summer and autumn. The annual average temperature is 10.6 °C, and the annual maximum temperature is 35.8 °C. Annual precipitation is from 250 mm to 550 mm, the frost-free period is 154 days to 184 days, the annual average sunshine hours are 2792.7 h, and the effective accumulated temperature ≥10 °C is 3621.2 °C (10 years of data). Air temperature, precipitation and soil temperature during the experimental period in 2018 (*Fig. 1*).

The curve represents air temperature (°C) and soil temperature (°C), and the bar represents 20 days of accumulative precipitation (mm). Air temperature (°C) and daily average soil temperature (°C) are recorded once a week and recorded 20 days of accumulative precipitation (mm) every 20 days. The meteorological data are from local meteorological departments.

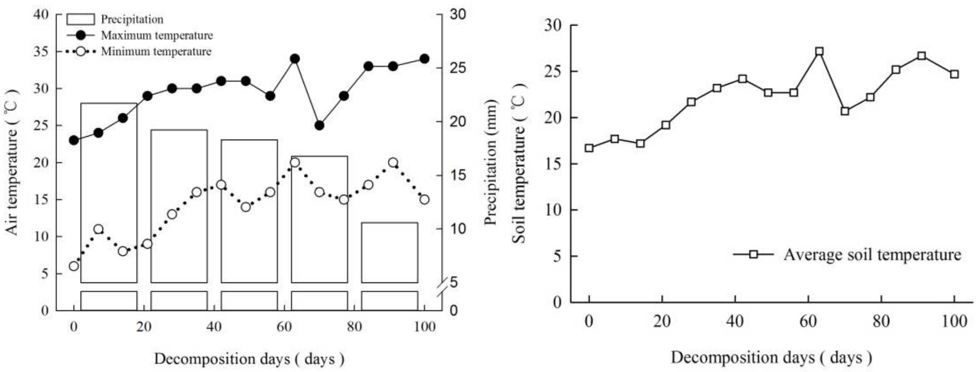

Figure 1. *Temperature and precipitation during the experimental period*

Experimental materials

The soil type of the experiment area is the *irrigated sierozem*, and the basic physical and chemical properties of the ploughed soil (0-20 cm): pH of 7.71 (1:2.5 soil/water ratio), soil organic matter (SOM) of 12.73 g kg^{-1}, total nitrogen (TN) of 0.96 g kg^{-1}, alkali-hydrolyzable nitrogen (AN) of 85.95 mg kg^{-1}, available phosphorus (AP) of 23.94 mg kg^{-1}, and available potassium (AK) of 229.24 mg kg^{-1}, soil C/N ratio of 13.26.

The experimental straw was maize (*Zea mays* L.) straw (comprised the stems and leaves) preserved after harvest in 2017, and its initial nutrient contents were as follows: C/N ratio of 28.13, organic C (C) of 413.50 g kg^{-1}, total N (N) of 19.47 g kg^{-1}, total P (P) of 3.09 g kg^{-1}, total K (K) of 17.53 g kg^{-1}. Fertilizers used included urea (46.0% N), diammonium phosphate (18.0% N, 48.0% P_2O_5), potassium sulfate (51.0% K_2O), and organic fertilizer (1.77% N, 1.95% P_2O_5, 0.53% K_2O).

Experimental design

The plot experiment was conducted from May 8, 2018, to August 16, 2018. There were three plots with a plot area of 33.2 m^2 (4 m × 8.3 m). Maize (*Zea mays* cv. Xinyu 50) was planted with the plot, the row spacing was 50 cm (8 rows), the plant spacing was 21.5 cm, and the planting density was 9.3 × 10^4 plants ha^{-1}. 469.5 kg urea ha^{-1}, 333.0 kg diammonium phosphate ha^{-1}, 103.5 kg potassium sulfate ha^{-1} and 1350.0 kg organic fertilizer ha^{-1} were applied to the soil (total fertilization amounts: 300.0 kg N ha^{-1}, 180.0 kg P_2O ha^{-1}, 60.0 kg K_2O ha^{-1}). Each plot had four different straw returning amount treatments: 10.0 g (CR1), 30.0 g (CR3), 50.0 g (CR5) and 70.0 g (CR7), with 5 repetitions. Maize straw (comprised the stems and leaves) is dried and pulverized into 3 cm to 5 cm, mixed and weighed (10.0 g, 30.0 g, 50.0 g, and 70.0 g, respectively), and placed them in a nylon mesh bag (length × width is 30 cm × 20 cm, pore diameter 0.125 mm) and tightened the bag mouth, and the net bag is about 2 cm high when leveled. Each returning amount is 15 bags, a total of 60 bags (3 plots × 4 treatment × 5 repetitions).

The specific operation steps of the buried bag: at the center of each plot, between the 2-6 rows (5 rows × 4 treatment), the nylon mesh bags of each treatment is completely randomly buried below the plough layer for 10 cm (*Fig. 2A*). When landfilling, the soil 10 cm depth between rows of maize is taken out, the soil deep in the 2 cm is dug out (no landfill), then the nylon mesh bag is laid horizontally (the distance between the two

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36953707

rows of maize is 15 cm), and then the soil is filled back and compacted to the level with the ground (*Fig. 2B*).

The experimental period was 100 days, and 12 nylon mesh bags were taken every 20 days (4 bags were randomly taken out from each plot). To avoid interference from topdressing on determines the nutrient content of maize straw residue; no topdressing was carried out in the area where straw was buried.

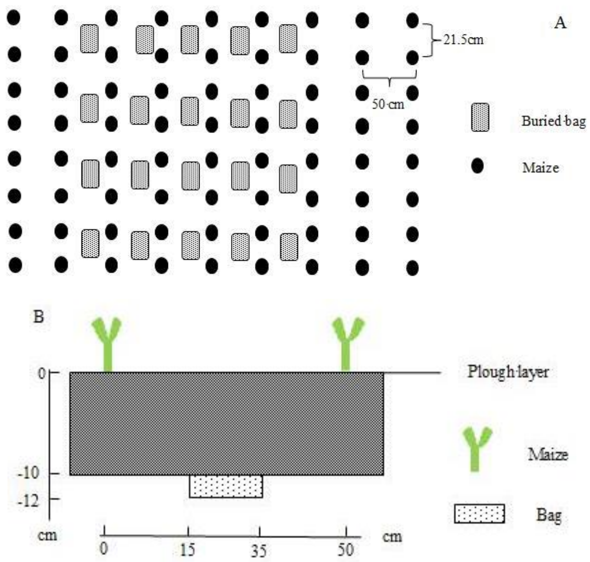

Figure 2. *Schematic diagram of the buried bag of maize straw in the plot. A and B are schematic diagrams of buried mesh bags in the plot and vertical cross-sections of the buried mesh bags, respectively*

Sampling and chemical analysis

Sampling began on May 28, 2018, and ended on August 16, 2018, the sampling is 5 times (20, 40, 60, 80, and 100 days of decomposition days). After each sampling, remove the floating soil and root debris on the surface of the nylon mesh bag, rinse the nylon mesh bag and dry it in an oven (65 °C) (KJ-DY02, Kejie Company, China) to constant weight. The straw was removed, weighed, pulverized and sieved (pore size of 1 mm) to determine the contents of C, P, N and K.

Determination of organic C (C) by $K_2Cr_2O_7$ dichromate-external heating method (133 mmol L^{-1} $K_2Cr_2O_7$ at 170-180 °C), The straw samples (0.25 g) were digested by the H_2SO_4-H_2O_2 method, the total N in the digestate was measured with an automatic Kjeldahl nitrogen determiner (K9840, Hanon Company, China), the total P (P) in the digestate determined by vanadium molybdate yellow-visible spectrophotometric (722N, JKI Company, China), the total K (K) in the digestate was measured with automatic digital flame photometer (FP640N, OEM Company, China). All methods have been described by Bao (2000).

Calculation and statistical analysis

Calculate the decomposition rate, decomposition speed, nutrient release rate, and C/N ratio methods (Dai et al., 2010; Yue et al., 2016) (*Eqs. 1-4*):

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36953707

$$\text{Decomposition rate (\%)} = \frac{M_0 - M_t}{M_0} \times 100\% \qquad \text{(Eq.1)}$$

$$\text{Decomposition speed (g day}^{-1}) = \frac{M_0 - M_t}{t} \qquad \text{(Eq.2)}$$

$$\text{Nutrient release rate (\%)} = \frac{M_0 \cdot C_0 - M_t \cdot C_t}{M_0 \cdot C_0} \times 100\% \qquad \text{(Eq.3)}$$

$$\text{C/N ratio} = \frac{C_t\ (\text{C})}{C_t\ (\text{N})} \qquad \text{(Eq.4)}$$

where M_0 (g) is the initial dry weight of the straw; t (day) is the decomposition day; M_t (g) is the dry weight of straw at t; C_0 (g kg^{-1}) is the initial nutrient (C N, P, and K) content of the straw; C_t (g kg^{-1}) is the nutrient (C N, P, and K) content of the straw at t.

All analyses were carried out on the replicates. Statistical analysis was completed using the SPSS 17.0 software. Statistically significant differences were identified using analysis of variance (one-way ANOVA) and Duncan's multiple range tests. Differences were considered significant at $P < 0.05$.

Results

Decomposition characteristics of maize straw

With the increase of decomposition days, the decomposition rate of maize straw gradually increases, and the decomposition speed gradually decreases, it is fast in the early stage (0-20 days) and slows in the late stage (20-100 days) (*Table 1*). In the first 20 days, the decomposition speed was the highest and the decomposition rate was higher. The decomposition rates increased to the increase in returning amounts, ranging from 17.07% to 27.55%, accounting for 36.97% to 58.20% of the total decomposition rate, and the characteristics of decomposition rate were CR7 = CR5 = CR3 > CR1. At the 40th days, there was no significant ($P > 0.05$) difference in the decomposition rate of each treatment, range from 28.43% to 36.68%. The decomposition speed gradually decreased, CR7 and CR5 decreased faster than CR1 and CR3. After 100 days of decomposition, CR3 was the fastest, the decomposition rate reached 53.94%, CR1 was the slowest, and the decomposition rate was 46.17%, and CR3 decomposition rate was 7.77%, 3.79%, and 6.60% higher than CR1, CR5, and CR7, respectively, and the characteristics of the decomposition rate was CR3 > CR5 = CR7 > CR1. The entire decomposition process, when the same decomposition days, the decomposition speed increases significantly ($P < 0.05$) with the increase in returning amounts, and the characteristics of decomposition speed were CR7 > CR5 > CR3 > CR1.

Nutrient releases rules of maize straw

With the increase of decomposition days, the nutrient releases rate of the straw increased, and the C, N, P and K release rate was fast in the early stage (0-20 days) and slow in the later stage (20-100 days) (*Fig. 3*), which was similar to the characteristics of decomposition (*Table 1*). In the first 20 days, the nutrient releases rate increased from the increase in the returning amount. The C, N, P and K released 16.95% to 29.16%, 17.35% to 29.87%, 23.55% to 33.93%, and 46.04% to 53.13%, respectively, accounting for 36.18% to 59.26%, 34.76% to 57.11%, 42.45% to 59.97%, and 51.43% to 58.85%

http://www.aloki.hu • ISSN 1589 1623 (Print) • ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36953707

of the total release rate, respectively, the rules of C, N and P releases rate were CR7 = CR5 = CR3 > CR1, the K release rate was not significant ($P > 0.05$). As the decomposition progresses, the releases speed decreased slowly, at 40th days, the nutrient releases speed of CR7 and CR5 decreased faster than CR3, and was gradually lower than CR3, and at 60th days, and the nutrient release rate of CR3 was higher than CR1, CR5, and CR7. After 100 days of decomposition, the C, N, P, and K release rates reached 46.85% to 56.51%, 49.92% to 59.69%, 55.48% to 63.23%, and 86.64% to 100.00%, respectively. Among them, the nutrient release rate of CR3 was the highest, and the release rates of C, N, P, and K of CR3 were 3.61% to 9.66%, 3.73% to 9.77%, 3.76% to 7.75%, and 6.58% to 13.36% higher than CR1, CR5, and CR7, respectively. The rules of C and N release rate were CR3 = CR5 > CR7 > CR1 (*Fig. 3A-B*), and the rules of P and K release rate were CR3 > CR5 = CR7 > CR1 (*Fig. 3C-D*).

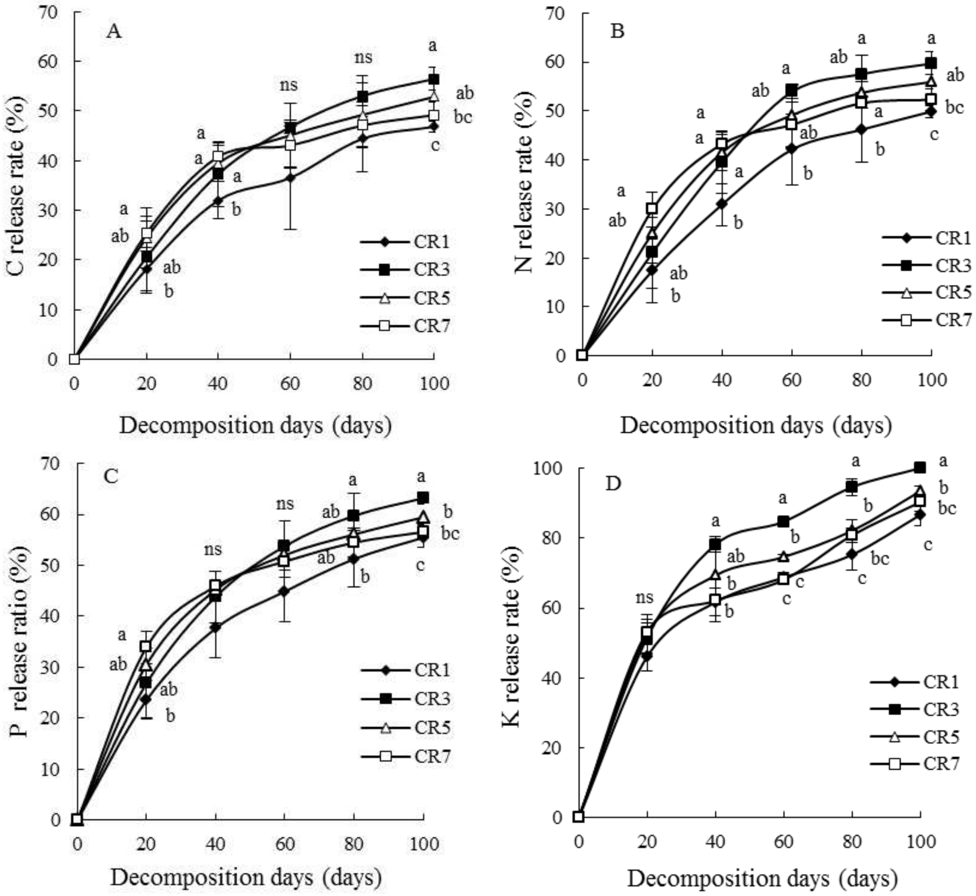

Figure 3. *Nutrient releases rate of maize straw under different straw returning amounts. A, B, C, and D is the nutrient release rate of C, N, P, and K, respectively. The data represent the mean values of three replicate ± SD (n = 3), and different lowercase letters next to the mean value show a significant difference at P < 0.05, ns = not significant. Error bars show the SD (n = 3)*

In the whole decomposition, according to the nutrient release rules of different treatments (*Fig. 3*) and comparing the nutrient release rates of different treatments, we can be found the release order of different nutrients was K > P > N > C (*Table 2*).

Table 2. *The order of nutrient release at different decomposition days*

Decomposition day	The ranking order of nutrient release			
	1st	2nd	3rd	4th
20th days	K (46.04%-53.13%)	P (23.55%-33.93%)	N (17.35%-29.87%)	C (16.95%-29.16%)
40th days	K (61.65%-78.11%)	P (37.65%-45.93%)	N (30.91%-43.27%)	C (28.76%-40.86%)
60th days	K (68.74%-84.70%)	P (44.88%-53.80%)	N (42.14%-53.92%)	C (38.26%-49.77%)
80th days	K (75.25%-94.55%)	P (51.26%-59.75%)	N (46.22%-57.56%)	C (44.42%-53.06%)
100th days	K (86.64%-100.00%)	P (55.48%-63.23%)	N (49.92%-59.69%)	C (46.85%-56.54%)

The values in parentheses show the range of nutrient (C, N, P, and K) content in different treatments

Dynamic change of C/N ratio of maize straw

In the first 20 days, the C/N ratio decreased rapidly with the increase of decomposition days and the decomposition and nutrient releases of straw were the fastest, the C/N ratio ranged from 21.15 to 22.72, and it is 5.41 to 6.98 lower than the initial value (*Table 1; Fig. 3*). After 40 days, the C/N ratio of CR5 and CR7 increased first and then gradually stabilized, ranging from 22.71 to 22.81, CR1 and CR3 increased first and then decreased, and gradually stabilized after 80 days. At the end of the decomposition, the C/N ratio ranging from 22.64 to 23.02, among them, the C/N ratio of CR3 is higher than CR1, CR5 and CR7 by 0.38, 0.21 and 0.31, respectively (*Fig. 4*). Similar to the decomposition and nutrient release of CR3 was higher than other treatments at the end of decomposition (*Table 1; Fig. 3*).

Discussion

Decomposition characteristics of maize straw

With the increase of decomposition days, the decomposition rate increased, and the decomposition speed decreased, and the decomposition characteristics of straw were fast in the early stage (0-20 days) and slow in the late stage (20-100 days), which was

DOI: http://dx.doi.org/10.15666/aeer/1702_36953707

consistent with some researches (Dai et al., 2010; Ji et al., 2013; Zheng et al., 2004; Che et al., 2013; Chen et al., 2011). The reasons may be: on the one hand, maize straw contains a large amount of easily decomposed organic substances in the early stage, such as polysaccharides, amino acids, organic acids. It provides plentiful energy and nutrients for the life activities of soil microorganisms, and improves the activity and quantity of soil microorganisms, thus promoting the decomposition of maize straw. As the straw is decomposed, the remaining major organic substances are difficult to decompose, such as lignin and cellulose, which are difficult to be used by soil microorganisms, resulting in a decrease in microbial activity and a slow decomposition of straw in the later stage (Summerell and Burgess, 1989; Li et al., 2009). On the other hand, the experiment began in May, because of the climate characteristics of the experimental site *(Fig. 1)*, the air temperature and soil temperature gradually increased, and the average precipitation was high, which improved microbial activity, promoted the decomposition of straw. With the increase of decomposition days, the temperature and soil temperature was too high, the precipitation decreases, which weaken microbial activity and metabolic activity, inhibiting the decomposition of straw (Summerell and Burgess, 1989; Nakajima et al., 2016; Azam et al., 1991). Besides, it applied organic fertilizer and chemical fertilizer in maize planting in the plot, which improved soil nutrients. In the early stage of decomposition, maize grew slowly. With the increase of decomposition days, maize grows rapidly and reduces the content of available nutrients, thus inhibiting microbial activity and slowing decomposition. We can see that the decomposition of maize straw is affected by the climate such as temperature, precipitation, and field management, which is consistent with research by Wang et al. (2016). Some studies have shown that pre-decomposition speed is fast, it too slows the medium-term decomposition speed down, and the late decomposition is stagnant (Kuang et al., 2012; Li et al., 2001).

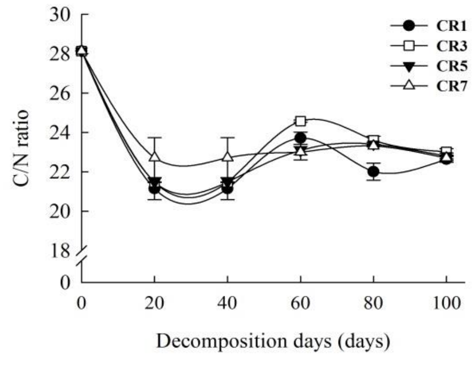

Figure 4. *Variation characteristics of the C/N ratio of maize straw under different straw returning amounts. The data represent the mean values of three replicate ± SD (n = 3). Error bars show the SD (n = 3)*

Nutrient releases rules of maize straw

This study found the release rules of nutrients (C, N, P, and K) of different treatments were fast in the early stage (0-20 days) and slow in the late stage (20-100 days), which is similar to the characteristics of decomposition. In the first 20 days, the decomposition rate, decomposition speed and nutrient release rate of different treatments increased with the increase of the amounts of returning, which is consistent

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36953707

with Yue et al. (2016) research on the decomposition experiment of maize straw and wheat (*Triticum aestivum* L.) straw. At the end of the experiment, the nutrient release rate of the treatments with higher decomposition rate was also higher, which is the same result as some studies have found a positive correlation between decomposition rate and nutrients release rate (Dai et al., 2010; Ji et al., 2013; Zheng et al., 2004). We found that when the returning amounts were greater than 30.0 g, the decomposition rate was negatively correlated with the returning amounts, some studies have also shown this result (Zheng et al., 2004). We found the returning amounts were 30.0 g, and its decomposition and nutrient release was the fastest, which is similar to Yue et al. (2016) result of the decomposition and nutrient release of maize straw was the fastest when the amount of maize straw returned was 26.3 g. Therefore, the proper amount of returning is conducive to the decomposition and nutrient release of straw.

This study showed the release of nutrients under different returning amount was K > P > N > C, which is consistent with some studies (Dai et al., 2010; Xu et al., 2010; Gong et al., 2018). In addition, Ji et al. (2013) studies showed that nutrient release of rapeseed (*Brassica napus* L.) and wheat (*Triticum aestivum* L.) straw was K > P > N ≈ C. Some studies have also found the release rate of maize straw by different decomposers was K > P > C > N (Zhong et al., 2017; Yang et al., 2016). Therefore, nutrient release rules of different crop straw are different. The release rate of nutrients depends mainly on the morphology of the elements in the straw. Among them, the K is mainly in the ionic state in cells or plant tissues and is easily soluble in water, so the release rate is the fastest, final cumulative release rate is also the highest; The content of P is less than K, which is mainly in the insoluble organic state, so the rate of K release is slower than P (Wang et al., 2013; Dai et al., 2017); The N mainly comprises insoluble organic matter, which is decomposed faster in the early stage, and is more difficult to decompose in the later stage, resulting in a decrease in decomposition rate (Murayama et al., 2010); The C mainly exists in various organic compounds, the decomposition rate is different (Tang et al., 2016). The C and N are the main ingredients of straw, the degree of cementation is high, and it is difficult to decompose, resulting in the slower release (Ji et al., 2013; Devêvre et al., 2000). Therefore, there are differences in the nutrient release. This study shows the rule of nutrient release was K > P > N > C.

Dynamic change of C/N ratio of maize straw

The speed of decomposition of straw mainly depends on C/N ratio, and the decrease of C/N ratio has a certain promoting effect on decomposition (Zhang, 1994), when C/N ratio is large, it affects the rapid growth and metabolism of microorganisms, so the process of straw decomposition is inhibited (Ding et al., 2008). The initial C/N ratio of maize straw is 28.13, and the best C/N ratio of microbial activity ranges from 25 to 30 (Devêvre et al., 2000). In addition, fertilization and proper temperature and precipitation also promote microbial activity, which promotes the decomposition of straw and rapid release of C and N; therefore, the C/N ratio decreases rapidly (Summerell and Burgess, 1989; Zhou et al., 2015; Nakajima et al., 2016). As decomposition progresses, the C/N ratio rise first and then are relatively stable, which because of the same as the reason for straw decomposition and nutrients release. Although the C/N ratio is close to the proper range of microbial growth, the C and N in the straw are mainly organic substances that are difficult to be used by microorganisms, and the N content needed for microbial metabolism in the soil is not enough, which reduces the microbial activity, leading to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_36953707

slower decomposition and nutrient release (Summerell and Burgess, 1989; Li et al., 2009; Rao et al., 1976). At the end of the decomposition, the decomposition and nutrients release was faster when the C/N ratio was higher. The dynamic change of C/N ratio in the process of decomposition cannot only reflect the characteristics of straw decomposition and the rules of nutrient releases, but also the speed of decomposition and nutrient release of different treatments.

Rational use of straw resources and nutrient resource management

The proper amount of returning is conducive to the decomposition and the nutrients release of straw and promotes the rational use of straw resources. According to this study found the characteristics of decomposition and the rules of nutrients release of straw are fast in the early stage (0-20 days) and slow in the late stage (20-100 days), which can properly reduce the use of base fertilizer, and carry out topdressing during the period when maize needs fertilizer, and effectively use fertilizers. According to the rule of nutrient release (K > P > N > C), the release of P and K are faster, P and K fertilizer can reduce the K fertilizer or delay the application period of P and K fertilizers; Because of the slow release of N and the decrease of soil N content in the later stage, N fertilizers should be applied in time for maize growth and to promote the decomposition of straw.

Conclusions

Our study concludes that, at the end of the decomposition, the decomposition and nutrient release of CR3 (30.0 g) are the fastest under different returning amounts, therefore, the proper amount of returning is conducive to the decomposition and the nutrients release of maize straw; In the whole decomposition, the characteristics of decomposition and the rules of nutrients (C, N, P, and K) release of straw under different returning amount are fast in the early stage (0-20 days) and slow in the late stage (20-100 days), and the release order of the different nutrients was K > P > N > C; Proposed that proper amount of returning in maize planting can reduce the amount of base fertilizer used, and the nutrients resource management measures to reduce or delay the application of P and K fertilizers and timely applied N fertilizers.

Prospect

According to the characteristics of decomposition and the nutrient release rules of straw, guiding scientific straw returning is conducive to the rational use of straw resources and to reduce fertilizer uses. In agricultural production, the characteristics of crops needed for fertilizer should be fully considered, and a reasonable amount of straw returning and nutrient resources management measures should be planned. Therefore, we will conduct a comprehensive study on the characteristics of crop fertilizer need and reasonable straw returning, to further guide the rational use of resources in agricultural production.

Abstract. Changes in land use affect the living environment of humans, considering even the survival and development of human beings. Study on the driving mechanism of land use plays a vital role in the accurate prediction of the changing trends of land use, and sustainable development of land. In this study, the Landsat images in Nanping City from 1995, 2010 and 2015 were obtained and processed using ENVI 5.2 and Arcgis 10.1. Object-oriented classification was used as the land use classification in this study. Transition matrix was used to study the characteristics, directions and structures of land use changes. The driving factors that led to the land use changes were studied using qualitative analysis and quantitative analysis (principal component analysis). The results showed that the forestland increased greatly and the cultivated land decreased significantly over the 20 years. Population, economy, urban development, policy, spending power, and technical factors were the drivers of the land use changes. The impact of comprehensive factors on the land use changes gradually increased with time.

Introduction

Land is an indispensable resource for humans because of food supplies. Land use changes are the process that human beings constantly change land surface for surviving and developing (Aklile and Beyene, 2014; Bestelmeyer et al., 2016; Maimaitijiang et al., 2015). Human behavior changes the coverings of land surface and affects the natural ecosystems on the earth's surface, such as the cycles of energy, water, biochemistry, and atmospheric circulation (Allan et al., 1997; Liu et al., 2010). Therefore, Land Use and Land Cover Change (LUCC) proposed by the International Geosphere-Bisphere Program (IGBP) and the International Human Dimensions Program (IHDP) in the 1990s has become the frontier of global environmental change research (Turner, 1997). Land use changes are one of the three important issues of LUCC research (Alexander et al., 2015). It has a profound impact on the global sustainable development (García-Ruiz et al., 1996; Lovell, 2010; Young et al., 2005). Therefore, the studies of land use changes and its impact on the surrounding environment have become an extremely important research field in sustainable development (Renetzeder et al., 2008).

Studies of the driving mechanism of land use changes are also the core of land use changes research. The shortage of land resources and the deterioration of ecological environment caused by irrational land use are increasingly serious with the continuous development of industrialization and urbanization, and the increase of population, and the continuous expansion of human activities (Meyfroidt et al., 2013; Chaudhary et al., 2015; Song et al., 2015). Examining the driving factors have a highlighted practical

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37093721

significance in accurately predicting the trends of land use changes, the rational planning of regional land, and the protection of ecological environment (Liu et al., 2016; Zhang et al., 2015). Driving factors of land use changes can be divided into natural and socio-economic factors (Maimaitijiang et al., 2015). The impact of the natural factors, such as topographic gradient, elevation, climate, etc., on land use was not obvious during a short period of time. However, the impact of socio-economic factors covering population, economic status, policies, on land use was significant during a period of the 20 years (Girma et al., 2014). Therefore, we focused on the socio-economic driver of the land use in this study.

The Economic Zone on the West Side of the Taiwan Straits is a regional economic complex. Its purpose is to cooperate with Taiwan in economy and is to drive the growth of economy in China. Nanping, the study area, is located in the central region of the Economic Zone. Consequently, studies of the driving factors in Nanping provided an important basis for the sustainable development, ecological protection, and the formulation of relevant policies and regulations in the Economic Zone.

Materials and methods

Study area

Nanping, the study area, is located in the southeast coast of China and the west side of the Taiwan Straits (*Fig. 1*). The climate belongs to the subtropical humid monsoon with an average annual temperature of 17-19 °C, an average winter temperature of 6-9 °C, an average summer temperature of 28-29 °C, and an average annual rainfall of 1684-1780 mm.

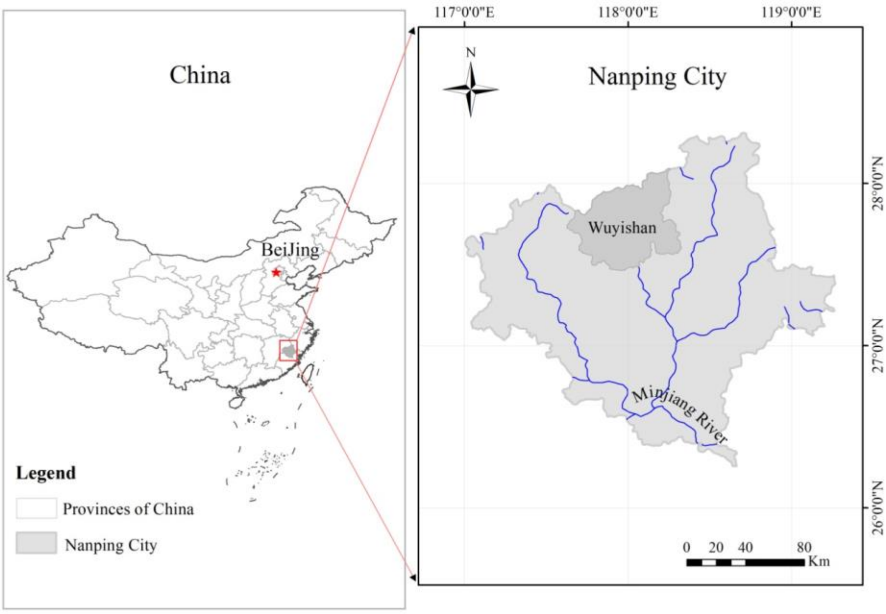

Figure 1. *Map of study area*

It has a history of more than 4000 years, a population of 3.19 million, and an area of 26,300 km^2. The area of the bamboo forest accounts for one-tenth of that of China. In

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37093721

2015, the gross domestic product (GDP) achieved 20.933 billion USD, amd the forest coverage was 74.75%. It ranks first in the reserves of niobium and tantalum in Asia. It not only is the birthplace of Minjiang River that is the mother river of Fujian Province but also is one of the best ecological regions in the world at the same latitude. Wuyishan under the jurisdiction of Nanping is one of the four World Natural and Cultural Heritage in China.

Acquisition and processing of the remote sensing data

The remote sensing images from Landsat-5 TM (1995 and 2010) and Landsat-7 ETM (2015) were derived from Chinese geospatial data cloud (*http://www.gscloud.cn/*). The images from Landsat-7 were processed using strip treatment. Cloud coverage of these images is less than 10%. The track numbers were respectively 120/40, 119/40, 119/41, 119/42, 120/42, 121/41, 120/41. Other study materials include the statistical yearbook from 1995 to 2015(NSB, 1995; NSB, 2005; NSB, 2015), the topographic maps of 1: 50000 and the administrative zoning maps obtained by Geographical information monitoring cloud platform (http://www.dsac.cn/).

These remote sensing images had undergone the correction of ground control point geometry and DEM terrain before downloaded. Therefore, the processing of remote sensing data in this study was to do color synthesis, mosaic, clip and object-oriented classification using ENVI 5.2. Types of the land use were divided into six categories: forestland, grassland, cultivated land, construction land, water and unused land. Band 5, 4, and 3 (RGB) was used for object-oriented classification. 250 samples for each type of land use were selected to achieve better classification results. The field investigation and interactive verification using Google Earth were carried out. After field verification, the classification accuracy of the remote sensing images from the three periods was 88.30%, 90.70%, and 92.10%, respectively, which can meet the requirements of this study.

Transition matrix of land use

Transfer matrix is used commonly to study the characteristics, directions and structures of land use changes. It not only can express the structural characteristics of land use, but also indicate the source and composition of each type of land use during study period. In addition, transition matrix can also generate a transition probability matrix that can be sorted by percentage. The major and secondary land use types that causing the changes of land use can be found by the sequence and the reason of the changes can be analyzed.

The mathematical equation of transfer matrix is as follows:

$$P_{ij} = \begin{bmatrix} P_{11} & P_{12} & \cdots & P_{1n} \\ P_{21} & P_{22} & \cdots & P_{2n} \\ \vdots & \vdots & \vdots & \vdots \\ P_{n1} & P_{n2} & & P_{nn} \end{bmatrix} \quad \text{(Eq.1)}$$

where P represents the area; and i and j expresses the land use type at the early and late stages of study period respectively; and n indicates the number of land use types.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37093721

The transfer probability matrix in this study was calculated using post-classification images of the land use and Change Detection Statistics tool of Spatial Analysis Module from ENVI classic 5.1 according to *Equation 1*.

Principal component analysis

Principal component analysis is to recombine variables that have a certain correlation with each other into those with non-correlation. It extracts some new variables from original variables, and represents the information of the original variables as many as possible with minimum amount of the variables.

The mathematical model of principal component analysis is as follows:

$$\begin{cases} F_1 = a_{11}ZX_1 + a_{21}ZX_2 + \cdots + a_{P1}ZX_P \\ F_2 = a_{12}ZX_1 + a_{22}ZX_2 + \cdots + a_{P2}ZX_P \\ \vdots \\ F_i = a_{1i}ZX_1 + a_{2i}ZX_2 + \cdots + a_{Pi}ZX_P \end{cases} \quad \text{(Eq.2)}$$

where $a_{1i} + a_{2i} + \cdots (i = 1, \cdots, m)$ indicates the eigenvector corresponding to X covariance matrix; and $ZX_1 + ZX_2 + \cdots$ donates the value after normalized original variable.

Principal component analysis was used to examine the impact of socio-economic driving factors on the land use changes according to *Equation 2*. However, the selection rules of socio-economic factors needed to be determined at first. The rules and the operation steps are as follows:

1. Review the statistical yearbook of Nanping to ensure that the factors are easy to be quantified and have a significant relationship with the land use changes.
2. Review the two statistical yearbooks of 1995 and 2015 to make sure the data of the chosen factors are complete.
3. The units of the chosen factors are different. Hence, these data need to be processed in a non-dimensional manner for subsequent calculation using SPSS.
4. Confirm the data are suitable for principal component analysis. If appropriate, correlation coefficient among the data is calculated, and Bartlett and KMO are tested. Finally, principal components are extracted using SPSS.
5. Comprehensive score of the driving factors of land use changes is obtained by multiplying the obtained eigenvectors and normalized data.

Results

Areal changes of the land use

The area of various land use types was achieved using ArcGIS 10.1 during the 20 years (*Table 1*). As shown in *Table 1*, the land use types were dominated by forestland, cultivated land and grassland, accounting for over 89% of the total area in Nanping City. The forestland increased rapidly with a total increase of 2075.90 km^2. The construction land had a significant rise with an increase of 329.99 km^2. In contrast, the cultivated land declined with a reduction of 1198.70 km^2. The water, unused land, and grassland also decreased with a reduction of 32.65 km^2, 545.10 km^2, and 528.03 km^2 respectively.

Table 1. *Areal changes of different land use types during the 20 years (km^2)*

Land use types	1995	2010	2015	Changing value (km^2)
Construction land	771.64	1350.44	1101.63	329.99
Forestland	19304.79	19258.94	21380.69	2075.90
Water area	657.49	645.76	624.84	-32.65
Cultivated land	2305.14	2452.60	1106.44	-1198.70
Unused land	955.46	770.43	410.36	-545.10
Grassland	2172.78	1796.45	1644.75	-528.03

Transfer matrix of the land use

As shown in *Table 2* that the value of outflow of the forestland was the lowest with a value of 16.64%. In contrast, unused land had a highest value (99.5%) in outflow. The order of the outflow of these land use types was unused land (99.5%) > cultivated land (91.86%) > water (84.14%) > construction land (77.64%) > grassland (76.91%) > forestland (16.64%). The main transition directions of all the land use types were forestland, which caused the continuous increase in forestland over the 20 years. In addition, grassland was also one of the transition directions of the unused land. The construction land and grassland were the main outflow types of cultivated land.

Table 2. *Transfer matrix of land use in the study area from 1995 to 2015 (%)*

2015 \ 1995	Construction land	Forestland	Water	Cultivated land	Unused land	Grassland
Construction land	22.36	6.05	10.83	20.60	11.04	7.08
Forestland	57.68	83.36	64.96	47.55	53.74	65.35
Water	11.60	2.55	15.86	3.10	1.85	1.52
Cultivated land	3.36	1.15	1.95	8.14	4.43	2.68
Unused land	0.20	0.10	0.16	0.53	0.50	0.28
Grassland	4.80	6.79	6.24	20.08	28.44	23.09

Driving factors of the land use

Comprehensive driving factors of the society and economy

From *Table 3*, 12 factors were selected in this study. Owing to the greater number of these factors, they were reduced dimensionally in order that most information was expressed with the least number of the factors. The correlation coefficient matrixes were obtained using these dimensionless factors (*Table 4*). As shown in *Table 4*, the correlation coefficients were all higher except GDP and natural population growth rate, which indicated the greater repetitiveness of information expressed by these factors. Accordingly, principal component analysis, and Bartlett and KMO tests were implemented. The value (Sig.) of Bartlett's concomitant probability was 0.000, less than the significance level (0.05), and the KMO value was 0.865, which showed these factors were linearly correlated and principal component analysis were adopted compatibly.

As shown in *Table 5*, one principal component was achieved according to the principle of specifying eigenvalue >1 and initial eigenvalue >80%. The initial eigenvalue of the first principal component was 83.75%, which indicated that it

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37093721

reflected 83.75% of the overall factors. Hence, it could explain the reason of the land use changes.

Table 5. *Eigenvalue and cumulative rate of driving factors*

Principal component	Initial eigenvalue			Rotation square sum loading		
	Total	Variance (%)	Accumulative total (%)	Total	Variance (%)	Accumulative total (%)
1	10.05	83.75	83.75	10.05	83.75	83.75

As shown in *Table 6*, the loads values of the factors exceed 0.9 except for the total population and the natural population growth rate. From *Table 6*, the values exceed 0.9 that represented economic factors, spending power and technical factors. Consequently,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37093721

the three types of the factors were the dominating ones for the land use changes in Nanping during the study period.

Table 6. *List of factors loading matrix*

Index of factors	Factors	Component 1
ZX_1	Total population	-.197
ZX_2	GDP	.997
ZX_3	Primary industry	.993
ZX_4	Secondary industry	.997
ZX_5	Tertiary industry	.994
ZX_6	Local fiscal revenue	.996
ZX_7	Local financial expenditure	.991
ZX_8	The total retail sales of social consumer goods	.999
ZX_9	Resident deposits end of the year	.997
ZX_{10}	Natural population growth rate	.329
ZX_{11}	The total social investment in fixed assets	.989
ZX_{12}	Per capita net income of farmers	.997

A principal component expression was obtained using the principal component load matrix and the result of the eigenvectors multiplying with the normalized data.

$$\begin{aligned}F = &-0.0621ZX_1 + 0.3145ZX_2 + 0.3132ZX_3 + 0.3145ZX_4 \\ &+ 0.3136ZX_5 + 0.3142ZX_6 + 0.3126ZX_7 + 0.3151ZX_8 + \\ &0.3145ZX_9 + 0.1038ZX_{10} + 0.3120ZX_{11} + 0.3145ZX_{12}\end{aligned} \quad \text{(Eq.3)}$$

The comprehensive score of the factors of the land use changes was calculated using *Equation 3.* As can be seen from *Figure 2,* the impact of the factors on the land use changes showed a sharp increase over time. Specifically, the comprehensive score of the factors had increased slowly before 2008, which indicated that economic factors, spending power and technical factors had little effect on the land use changes. However, the score of driving factors had demonstrated an exponential growth after 2008. This was mainly due to the rapid increase in GDP, the continuous development of high-tech industries, the integration of geographical advantages and the adjustment of industrial layout in Nanping after 2008.

Discussion

Population

Population is one of the most active drivers of land use changes (Shoshany and Goldshleger, 2002). The increase of population directly changes spatial distribution of land use. According to the statistical yearbook of Nanping City from 1995 and 2015, it was found that the population in Nanping City was continuously increasing from 2,939,904 in 1995 to 3,198,600 in 2015 with an increase of 258,700 over the 20 years. This phenomenon was bound to cause changes in the land use (Bilsborrow et al., 1992; Miao et al., 2016; Rufino et al., 2017). The large-scale facilities, such as water,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37093721

electricity, early warning facilities, and the daily facilities, such as landfill, recreational facilities, water supply system, resident health information system and school informatization, and other convenient service facilities were constructed during this time in order to deal with the increase of population (Liu et al., 2006; Sun et al., 2013). The construction of these facilities profoundly affected the spatial distribution of the land use in Nanping.

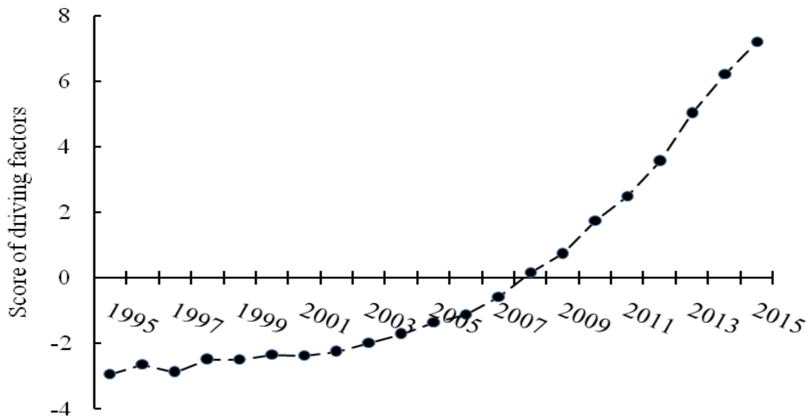

Figure 2. *Comprehensive score of socio-economic driving factor of the land use change*

The growth in the population led to a marked increase in the construction land and a significant decrease in the cultivated land over the 20 years. The construction land and cultivated land increased and decreased by 329.99 km^2 and 1198.7 km^2 respectively. It was found that the construction land was one of the main transfer directions of the cultivated land, which indicated that population growth inevitably increased the construction of large-scale convenient services facilities, resulting in more the cultivated land being transferred to the construction land. However, cultivated land is the main source of food for human beings. The rapid population growth led to the conversion of more cultivated land into the construction land, which inevitably led to insufficient food supply. Therefore, it is crucial to solve the contradiction between population and cultivated land. In summarize, population was one of the main factors causing the changes in the land use.

Economy

GDP refers to the status of regional economy. The growth of GDP represents the improvement of people's living level, which is the prevalent aspiration and struggle target of people. The activities of human beings for living affect changes in land use types. Hence, economic development inevitably leads to changes in land use (Weber et al., 2001). GDP in Nanping was continuously increasing from 2.28 billion USD in 1995 to 20.94 billion USD in 2015 (*Fig. 3*). The citizens began to seek spiritual enjoyment after satisfying their food and clothing needs. For raising the living quality and meeting spiritual needs of the citizens, the municipal government accelerated the construction of infrastructure buildings, which led to the significant changes of the land use in Nanping (Liu et al., 2015).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37093721

According to the Classification of Chinese Economic Industries, agriculture, forestry, animal husbandry, and fishery were classified as the primary industry, and the supply and construction industries such as mining, manufacturing, electricity, and gas were classified as secondary industry, and service industry as the tertiary industry.

As shown in *Figure 3,* the rankings of the three industries in Nanping City significantly changed during the 20 years. The proportion of the primary industry decreased from 34.44% in 1995 to 21.59% in 2015, the secondary industry increased from 35.82% in 1995 to 43.16% in 2015 and the tertiary industry only increased by 5.52% over the 20 years, which showed that the agriculture, forestry, animal husbandry and fishery gradually turned to service industry and manufacturing industry.

In this study, the decrease in the proportion of the primary industry (agriculture, forestry, animal husbandry and fishery) indicated the decline in the cultivated land and grassland. With the increase in the proportion of the secondary and tertiary industry, more land resources were occupied by the facilities, which means that the increase in the construction land and the decrease in the unused land. In summarize, the changes of the economy undoubtedly affect the spatial distribution of the land use (Fan et al., 2017). Economy is one of the driving factors of the land use changes in Nanping.

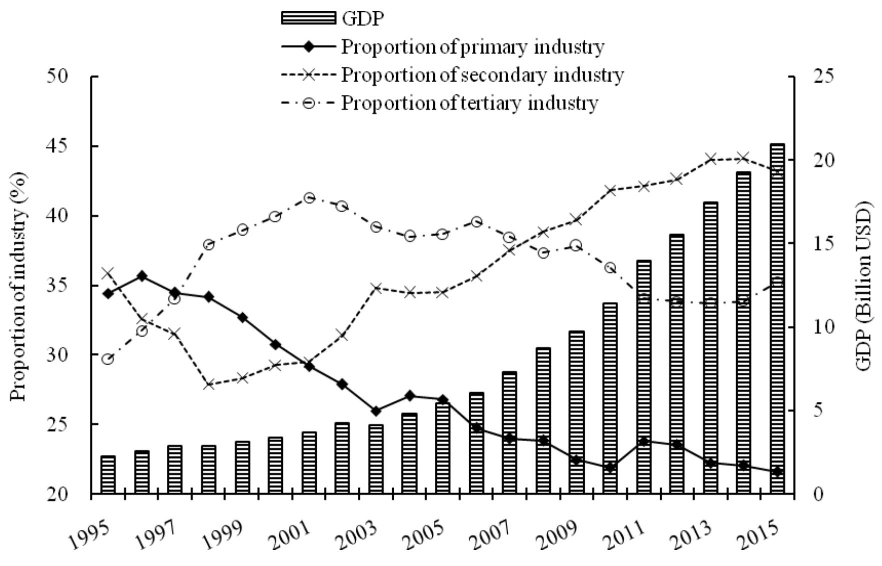

Figure 3. *The proportion of GDP and three major industries in the study area*

Urbanization and transportation

Urbanization is a symbol of the improvement of people’s living level (Sigel, 1978). It is a kind of development trends to shift from simple agricultural life to multiple city life for human beings. However, a series of environments problems, such as biodiversity loss, heat island effect, environmental pollution, and water and soil loss, have arisen due to the rapid urbanization and irrational use of land resources (Wang et al., 2012). The urban construction in Nanping continued to expand outward over the 20 years. The urbanization rate in Nanping increased from 29.0% in 1995 to 54.0% in 2015 with an increase of 27.0% (NSB, 1995; NSB, 2015), which led to the changes of the land use.

Accordingly, the staggered road networks resulted in the serious destruction of the landscape (Mo et al., 2017). In 2015, the total mileage of the roads was 15554.24 km

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37093721

and mileage of freeway was 929.67 km, and the pavement with asphalt and cement concrete were 877.48 km and 10846.19, respectively (NSB, 2015). The intensity of the fragmentation in the landscape was obviously enhanced, which led to the decrease in the types of the landscape such as cultivated land, water and grassland (Jaeger et al., 2007). In short, the development of the urbanization and transportation led to the dramatic changes of the land use.

Policy

The main pillars of the development plan of the Economic Zone issued by the state council were as follows.

1. Strengthen exchanges and cooperation between mainland China and Taiwan by virtue of the construction of Pingtan Experimental Zone which is a nearest island in mainland China to Taiwan.
2. Accelerate infrastructure construction and improve sustainability in economic development in the Economic Zone.
3. Accelerate optimization in industrial layout and improve innovation capability in order to build a modern industrial system of the Economic Zone.
4. Realize the coordinated development of the urban and rural areas.
5. Focus on improving people’s livelihood and build a harmonious atmosphere in the Economic Zone.
6. Improve ecological environment of the Economic Zone and strive to build a sustainable development area with beautiful living environment.

According to these pillars, it is necessary to construct the economic zone into a beautiful, ecological, and friendly region, and focus on the coordinated development of the economy and the ecological environment. It is therefore indispensable to increase the forestland so as to maintain the stability of the ecosystem and improve the ecological environment (Wang et al., 2017). In this study, the forestland had decreased by 45.85 km^2 from 1995 to 2010 before the “Plan” was promulgated. However, from 2010 to 2015, the forestland had increased by 2121.75 km^2 after the “Plan” was issued, which further illustrated the decisive role of policies in the land use changes.

The Development Plan for Wuyishan was promulgated in 2010, which is of great significance to further improve the economy in Nanping. Accordingly, new land policies were introduced by the government. The forestry reform was executed and inappropriate cultivated land was retreated. As a result, the forestland continued to increase after 2010. Especially, the cultivated land had increased before 2010. In contrast, it had decreased sharply after 2010. Consequently, the promulgation and implementation of the policies had a profound impact on the spatial distribution of the land use (Dempsey et al., 2017).

Conclusion

The main conclusions are as follows:

The percentage of forestland in overall study region increased significantly from 73.77% in 1995 to 81.39% in 2015 with an increase of 2075.90 km^2 over the 20 years. The cultivated land decreased sharply from 8.81% in 1995 to 4.21% in 2015 with a decline of 1198.70 km^2.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37093721

The unused land, cultivated land, and water had a higher outflow over the 20 years. The forestland was the main outflow types for the land use types. Hence, the forest coverage rate remarkably increased.

The study found that the growth of population and economy, and urban expansion resulted in the sharp increase of construction land, and the decline of cultivated land, grassland and unused land. National and local policies led to a notable increase in the forestland and the decline in the cultivated land over the study period. In a word, the comprehensive impact of population, economy, urban development and policies was the main reason for the land use changes in Nanping during the study period.

Economic factors, spending power and technical factors were the driving factors of the land use changes. The impact of the three drivers on land use changes demonstrated an exponential rise after the year of 2008.

In summary, population, economy, urban development, policy, spending power, and technical factors were the driving factors of the land use changes in Nanping over the 20 years.

(Received 24th Dec 2018; accepted 14th Feb 2019)

Abstract. The production of dye is usually associated with several intermediate products and waste which are usually toxic and bio-hazardous and often disturb the environmental equilibrium. The present study is aimed at selecting macrophytes with the highest efficiency in the remediation of wastewater generated from dyeing activities. The test macrophytes were introduce into three different troughs for each plant containing 100% wastewater, 50% wastewater and control (100% borehole water). After 21 days the macrophytes were removed for further analysis. The reduction efficiency, Heavy metal bioconcentration and bio translocation factor of the macrophytes was determined. The result obtained shows that the test macrophytes improved the pH but were not able to improve the color of the wastewater. *Lemna minor* have the highest reduction efficiency for BOD, COD, Oil, and Grease while *Pistia stratiotes* have the highest reduction efficiency for TDS and TSS, *Eicchornia crassipes* have the highest reduction efficiency for Cl^- and *Salvinia molesta* have the highest reduction efficiency for phenol and ammonical Nitrogen. All macrophytes recorded high reduction efficiency for heavy metal removal but *Pistia stratiotes* and *Eicchornia crassipes* had the highest bioconcentration and translocation. These macrophytes should be introduced to the local dye users as a costless and environmentally friendly way of treating wastewater resulting from dyeing activity.
Keywords: *Azolla pinnata, Lemna minor L., Eicchornia crassipes, Pistia stratiotes, Salvinia molesta*

Introduction

The world ever increasing population and adoption of industrial based lifestyle have led to an increasing in anthropogenic activities which has lots of effects on the biotic community. The availability of water, both in quality and quantity, is one of the prime factors in deciding the growth of towns and cities as well as industries (Amare et al., 2018a; Costa et al., 2018; Fernandes et al., 2018). It is thereby in the best interest of the world if water is properly treated for the purpose of reuse. In Northern Nigeria, different communities and ethnic groups use numerous plants as dyeing agents. This has greatly influenced cultural acceptability and easy method of survival. The synthesis of organic dye was introduced in 1871 and was practiced in Egypt, Persia, China and India thousands of years ago using natural materials derived from insects, plants, shellfish etc. as dyestuff. Dyes are generally fast as they retain their color in the fiber throughout the textile making process and under exposure to normal wear including sunlight, water, and detergent washing. Dye is a soluble compound that can either be absorbed or retained by the fiber. The production of dye is usually associated with several intermediate products and waste which are usually toxic and bio-hazardous and often disturb the environmental equilibrium. Local dye users of Faskari road (*Fig. 1*) who use dye in the dyeing of cloths and other garments create a large quantity of wastewater which contains different pollutants. The wastewater generated during dying activities is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37233735

characterized by high BOD, COD, Acidity, Deep color of Different Shades, levels of chlorides etc (Haddad et al., 2018; Lyu et al., 2018; Pandian et al., 2018). These pollutants are produced in an effort to improve the looks of the inhabitants of Kaduna south local government but ironically the lack of treatment facilities reverse the same standard by impacting negatively on the environment (Amare et al., 2018b; Carvalho et al., 2018).

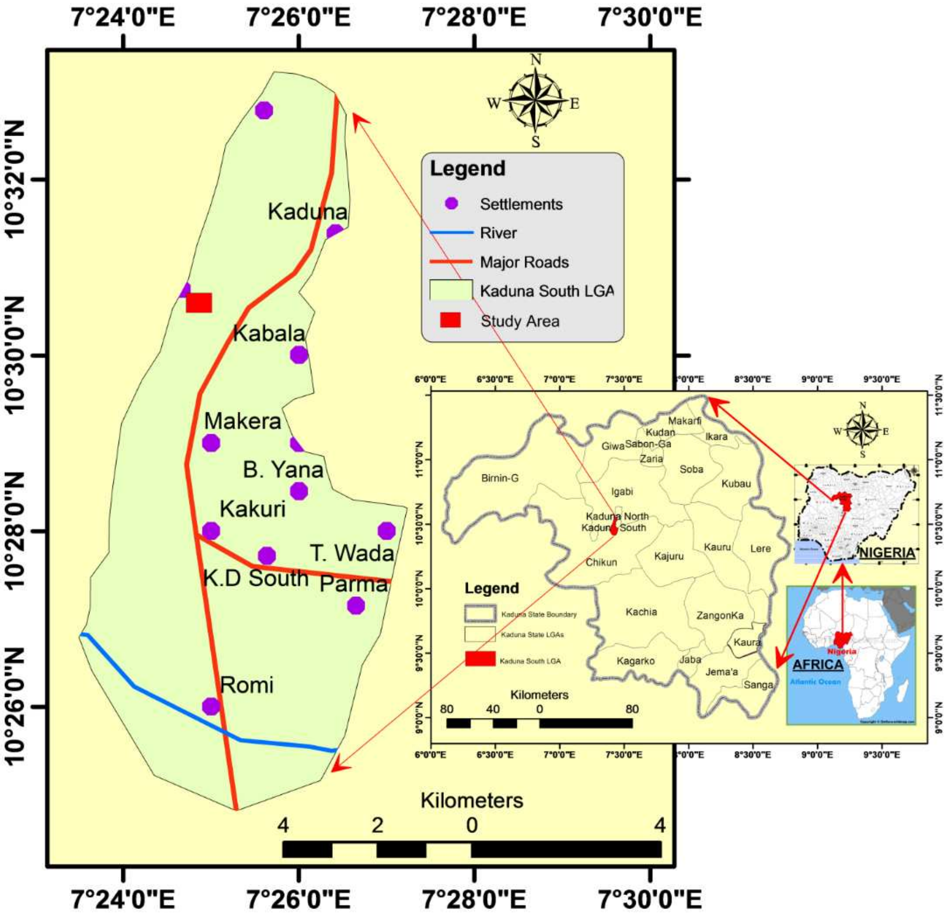

Figure 1. Map showing Study Area

The wastewater is released into drainage system without treatment, eventually, this toxic wastewater makes it way into River Kaduna which is the nearby water body (Bununu et al., 2015; Ogwueleka, 2014, 2015). Some of the wastewater can seep into aquifers and pollute underground water since they cannot be confined within specific boundaries (Braun et al., 2018; Demarco et al., 2018; Fernandez San Juan et al., 2018). The untreated wastewater tends to have an ecological impact on the nearby water bodies which is river Kaduna leading to increased nutrient load leading to eutrophication, which is open water can progressively lead to oxygen deficiency, algae blooms, and death of aquatic life. Several technologies are available to remediate this wastewater before discharge. However, many of these technologies are costly, so not easily accessible (Jiang et al., 2018; Osti et al., 2018; Zhao et al., 2018). Phytoremediation can provide a long lasting, cost effective, long lasting and aesthetic solution to the remediation of this wastewater, since macrophytes such as *Lemna minor* L., *Azolla*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37233735

pinnata, Pistia stratiotes, Eicchornia crassipes and Salvinia molesta which are easily accessible have been proof to have phytoremediation potentials by researchers such as (Saraswat and Rai, 2018; Ting et al., 2018; Vanhoudt et al., 2018) etc. The present study is aimed at selecting macrophytes with the highest efficiency in the remediation of wastewater generated from dyeing activities.

Materials and Methods

Plant Sampling and Identification

Young macrophytes of *Lemna minor* L., *Azolla pinnata, Pistia stratiotes, Eicchornia crassipes, and Salvinia molesta* were collected from different pond located at Kaduna, Kaduna State, Nigeria and identity using relevant guide. The young plants were selected for these studies due to their ability to double their size in 3 weeks. The plants were authenticated at the herbarium of the department of botany (*Table 1*), Ahmadu Bello University Zaria, Kaduna State, Nigeria.

Table 1. *Test Macrophytes Used for Phytoremediation*

SN	Plants	Common Name	Accession Number
1	*Lemna minor* L.	Duckweed	L.6935
2	*Eichhornia crassipes*	WaterHyacinth	3268
3	*Pistia stratiotes*	WaterLettuce	1977
4	*Azolla pinnata*	WaterVelvet	0678
5	*Salvinia molesta*	Kariba Weed	01689

Water Sampling

Wastewater was collected from dyeing point of Faskari road located in TudunWada of Kaduna South Local Government, Kaduna State, Nigeria from March 2017-March, 2018 (*Fig. 1*). The collection, storage, transportation and analysis of the sample for the parameters such as BOD_5, COD, pH, electrical conductivity, Chlorides, Ammonical Nitrogen, phenol, phosphate, total suspended solids, total dissolved solids, oil and grease before treatment was done according to (AFNOR, 2001).

Phytoremediation Setup

To access the phytoremediation efficiency of these macrophytes in the improvement of dyeing wastewater, an offsite culture experiment was performed in the general biology laboratory of Kaduna State University. The test plants were thoroughly washed using borehole water and distilled water then kept on a filter paper to remove excess water before transferring into fifteen different troughs having a capacity of five liters. The experiments were grouped into 5 groups with each group consisting of three troughs as shown below:

Group 1: *Lemna minor* L. was inoculated in wastewater of different concentration below:

- 100% of wastewater.
- 50% of wastewater.
- 0% wastewater (control).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37233735

Group 2: *Eicchornia crassipes* was inoculated in wastewater of different concentration below:

- 100% of wastewater.
- 50% of wastewater.
- 0% wastewater (control).

Group 3: *Pistia stratiotes* was inoculated in wastewater of different concentration below:

- 100% of wastewater.
- 50% of wastewater.
- 0% wastewater (control).

Group 4: *Azolla pinnata* was inoculated in wastewater of different concentration below:

- 100% of wastewater.
- 50% of wastewater.
- 0% wastewater (control).

Group 5: *Salvinia molesta* was inoculated in wastewater of different concentration below:

- 100% of wastewater.
- 50% of wastewater.
- 0% wastewater (control) (Qin et al., 2016, Qu et al., 2017)

After 21 days the plants were removed from the treated water, the treated water was thus filtered before the re-determination of BOD_5, COD, pH, electrical conductivity, Chlorides, Ammonical Nitrogen, phenol, phosphate, total suspended solids, total dissolved solids, oil and grease by using standard method as described by (AFNOR, 2001), the color change before and after treatment of the wastewater was also observed. The removal efficiency of each of the macrophyte was thus calculated according to the method employed by Ugya (2015) as represented below:

$$x = \frac{B-A}{B} X \ \frac{100}{1} \quad \text{(Eq.1)}$$

where:
B = Final Concentration.
A = Initial concentration.
X = ReductionEfficiency.

The experiment was repeated for nine months to enable the determination of the mean removal efficiency of each of the macrophyte (Akhtar et al., 2016; Bokhari et al., 2016; Zhao et al., 2016).

Heavy Metal Bioconcentration and BiotranslocationFactor

After remediation macrophytes were removed and separated into leaves, stems, and roots. These parts were washed using tap water, ionized water then oven dried at 70^0C before grounding. The grounded plant materials were then subjected to acid digestion using HNO_3 and $HClO_4$. After digestion, the sample was then analyzed using Atomic Absorption Spectrophotometer for the concentration of heavy metals (Ni^{2+}, Cr^{3+}, Cd^{2+}, and Pb^{2+}) present in theroot and shoot (leave and stem) of the macrophyte. These were then used in the determination of Bioconcentration and biotranslocation factor using *Equations (2)* and *(3)* below:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37233735

$$\text{Bioconcentration Factor} = \frac{a}{b} \quad \text{(Eq.2)}$$

$$\text{Biotranslocation Factor} = \frac{c}{d} \quad \text{(Eq.3)}$$

where:
a = metal concentration in root.
b = metal concentration in wastewater.
c = metal concentration in shoot.
d = metal concentration in root.

The concentration of heavy metals present in the wastewater was also determined before and after the treatment process for the determination of heavy metal reduction efficiency using *Equation (1)*.

Data Analysis

With the objective of determining the macrophyte with the highest reduction efficiency, biotranslocation factor and bioaccumulation factor, Data were analysed using IBM SPSS statistics version 23 for two-way analysis of variance (ANOVA).

Result and Discussion

Wastewater Colour and pH Reduction Efficiency

The result obtained shows that all the test plants were not able to improve the color of the wastewater from dark brown although *Lemna minor* L and *Pistia stratiotes* were able to change the color of the wastewater to pale yellow after treatment. The pH of the wastewater was improved by all the test plants as the pH was not reduced but increase. On the mean scale, the macrophytes were able to increase the pH of the water from 4.2 to 7.3 (i.e from acidic to neutral pH). The pH of the dyeing wastewater was increased from high acidity to neutral by all the aquatic macrophytes, this increase in pH could be attributed to the utilization of CO_2 by the test plants for photosynthesis (Irawati et al., 2017; Singh and Rai, 2016; Victor et al., 2016). Some recent studies of the success of increase in pH resulting from the use of macrophytes include workdone by researchers such as Galal et al. (2017), Klink (2017), Maleva et al. (2016), Zhao et al. (2017) with references to different wastewater. The color removal efficiency of *Pistia stratiotes* could be attributed to the property of proper particle sedimentation by *Pistia stratiotes* or the ability of the root of *Pistia stratiotes* to retain both coarse and fine particle (Kaminski et al., 2014; Neagu et al., 2014).

The efficiency of Macrophytes in BOD, COD and EC Reduction

The BOD and COD reduction by the macrophytes is in the trend of Lemna minor, Pistia stratiotes, *Eicchornia crassipes, Salvinia molesta,* and *Azolla pinata* according to decreasing efficiency. *Lemna minor* was able to reduce BOD and COD from 645 mg/l to 75 mg/l and 1604 mg/l to 352 mg/l, respectively (*Fig. 2a*). The pattern for EC reduction is different that of COD and BOD because *Pistia stratiotes* show a maximum EC reduction compare to other macrophytes (*Fig. 2a*). Similar pattern of COD, BOD and EC reduction by the macrophyte recorded in 100% wastewater was followed by the macrophytes in 50% wastewater and control (0% wastewater) (*Figs. 2b, 2c*) signifying

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37233735

that *Lemna minor* has the highest reduction efficiency for COD and BOD while *Pistia stratiotes* is a has the hieghest reduction efficiency for EC. The high BOD and COD removal by macrophytes could be linked to the increase in pH. Ng and Chan (2017) and Qin et al. (2016) reported an increase in pH by macrophyte and concluded that the macrophytes can be used to increase low pH. This pH increase canalso be linked to COD and BOD reduction since studies by Qu et al. (2017) and Riaz et al. (2017) has shown that the presence of plants in water contributes to the growth of microbes which in turn causes the degradation of organic compounds. The reduction of EC is attributed to the growth of the macrophytes. Higher EC, COD and BOD removal has been reported by Augustynowicz et al. (2014), Di Luca et al. (2014), Török et al. (2015) using different macrophytes to remediate various wastewaters. The reduction of EC is attributed to the growth of the macrophytes (Haddad et al., 2018).

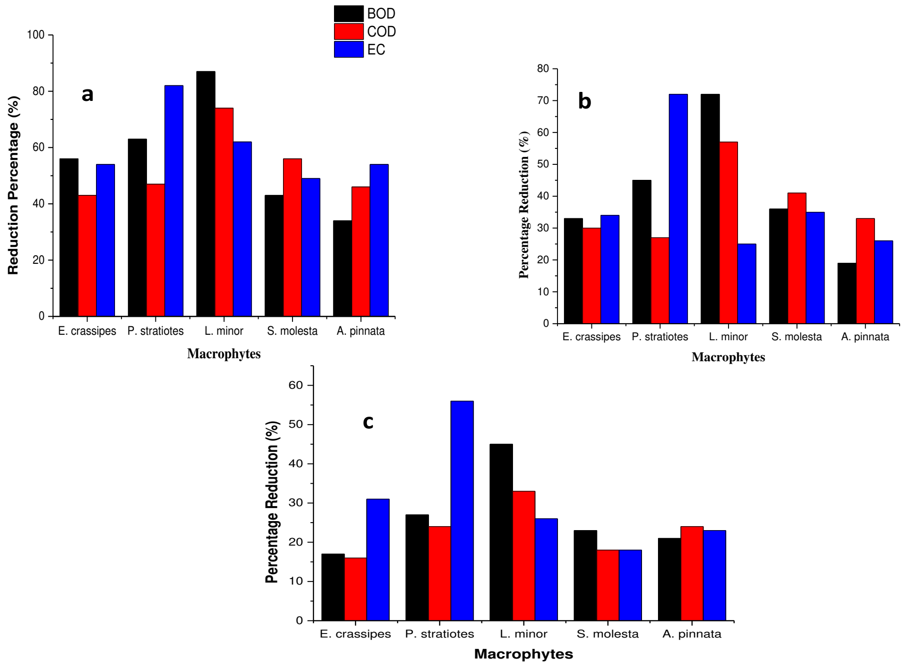

Figure 2. *Efficiency of Macrophytes in BOD, COD and EC Reduction from (a) 100% Wastewater (b) 50% Wastewater (c) Control*

The efficiency of Macrophytes in Oil and grease, Total Dissolved Solids and Total Suspended Solid Reduction

The pattern of TDS and TSS removal was heighest in the control than 100% wastewater and 50% wastewater, it was also noticed that the performances of all the plants were without any significant differences (*Fig. 3c*). *Pistia stratiotes* and *Eicchornia crassipes* have no significant differences in term of their reduction efficiency of TDS and TSS but both have a high significant difference to the removal efficiency of *Lemna minor, Salvinia molesta* and *Azolla pinnata* for TDS and TSS removal from both 75% wastewater and 100% wastewater (*Figs. 3a, 3b*). The removalefficiency of *Lemna minor* was found to be higher for oil and grease removal from 100% wastewater and 50% wastewater. Little significant differences exist between

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37233735

the removal efficiency of *Lemna minor, Pistia stratiotes* and *Eichhornia crassipes* in oil and grease removal if compare to oil and grease removal efficiency of *Salvinia molesta* and *Azolla pinnata*. The ability of the macrophytes to reduce TDS and TSS have been reported to be due to the particle sedimentation ability of the macrophytes which is due to there taining of the particle by the roots of macrophytes hence the reason why *Pistia stratiotes* and *Eicchornia crassipes* have higher TDS and TSS reduction efficiency than other macrophytes (da Silva et al., 2018; Osti et al., 2018). The reduction of oil and grease by the macrophytes is attributed to the enhancement of microbial growth caused by the presences of themacrophyteswhich in turncausesthedegradation of oil and greases (Amare et al., 2018b; Liu et al., 2010).

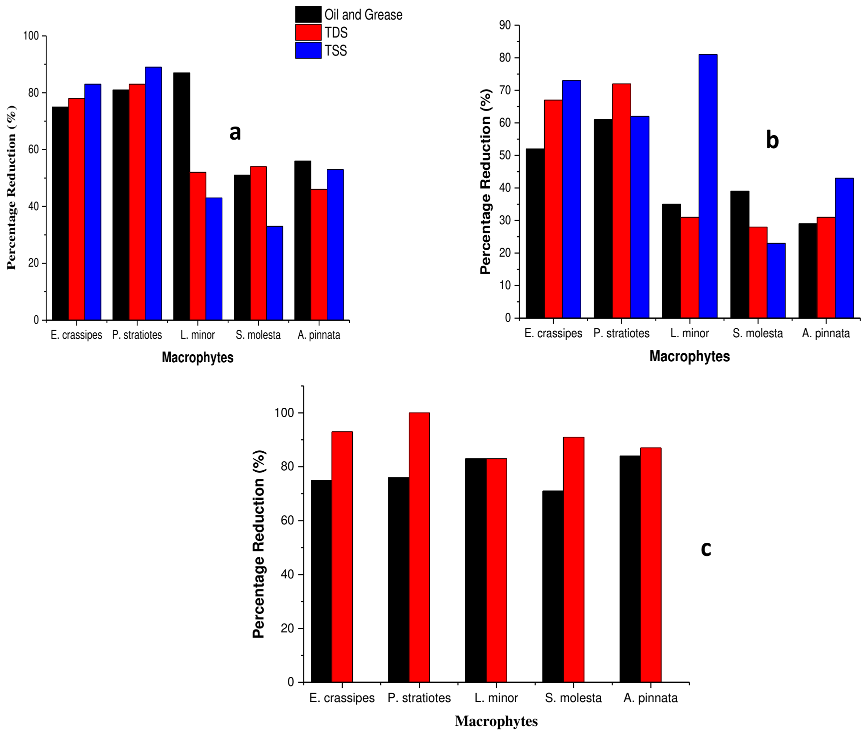

Figure 3. *Efficiency of Macrophytes in Oil and grease, Total Dissolved Solids and Total Suspended Solid Reduction (a) 100% Wastewater (b) 50% Wastewater (C) Control*

The efficiency of Macrophytes in Chloride, Phenol, and Ammonical Nitrogen Reduction

The result obtained shows a similar pattern for the removal of chloride, phenol and ammonical nitrogen present in 100% wastewater and 50% wastewater (*Figs. 4a, 4b*) by the macrophytes, with *Eicchornia crassipes* having the highest efficiency for chloride removal (780 mg/l to 107 mg/l) and *Salvinia molesta* having the highest efficiency for phenol and ammonical nitrogen removal (13 mg/l to 3 mg/l and 87 mg/l to 14 mg/l, respectively). The high phenol removal efficiency could be attributed to the fact that the presences of the macrophytes favor the growth of some microorganisms which help in the degradation of phenol (Mustapha et al., 2018; Suyamud et al., 2018). The high

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37233735

ammonical nitrogen and chloride % reduction by the macrophytes is attributed to the fact that but nitrogen and chloride are needed for plant growth although chloride are needed in minute quantity, so there as on for the high chloride removal efficiency could be due to the fact that the concentration of chloride in the wastewater was minute (Han et al., 2018).

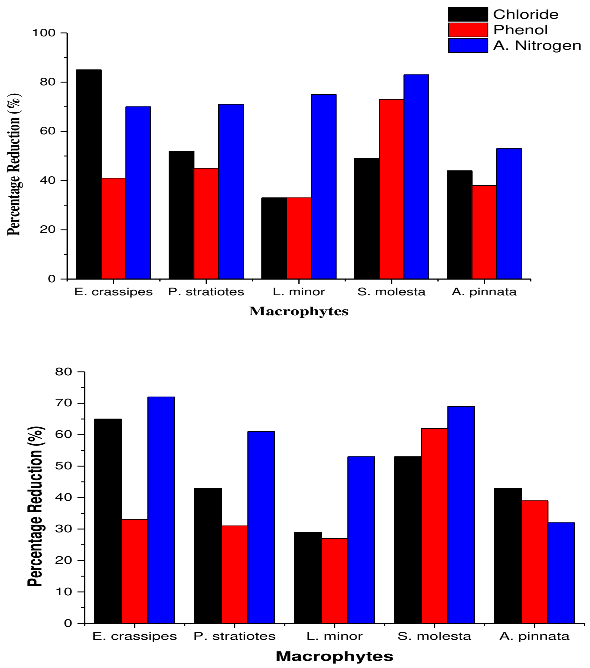

Figure 4. *Efficiency of Macrophytes in Chloride, Phenol and Ammonical Nitrogen Reduction (a) 100% Wastewater (b) 50% Wastewater*

Heavy Metal Removal Efficiency, Bioconcentration and BiotranslocationFactor

The result obtained shows high heavy metal removal efficiency by the entire test macrophytes (*Fig. 5*). This result obtained could be due to the fact that the heavy metal present in the wastewater was in low concentration with the highest been 10 ug/l. Several researchers such as Malar et al. (2014) have show that most macrophytes have the ability to effectively utilized heavy metal to a concentration of within 10 mg/l-15 mg/l (Sharma et al., 2015; Teles Gomes et al., 2014; Török et al., 2015). The BTF and BTC factor obtained in *Tables 2 and 3* respectively show that *Eicchornia crassipes* have the highest bioconcentration and biotranslocation factorfor Cd^{2+} and Ni^{3+} signifying that the plant can effectively absorb Cd^{2+} and Ni^{2+} from the wastewater and successfully transport the heavy metal totheshoot (stem and leaves) for utilization. *Pistia stratiotes* effectively absorbed and translocated Cr^{3+} and Pb^{2+} due to the high biotranslocation and bioconcentration factor recorded in *Tables 2 and 3*, respectively. This also shows that the plants were able to properly utilize the absorbed heavy metals. *Lemna minor, Azolla pinnata,* and *Salvinia molesta* were found to have accumulated the heavy metals, they still are not better accumulators if compared to *Eicchornia crassipes* and *Pistia stratiotes* (Amare et al., 2018b).

Conclusion

Although, all the test plants show the ability of removal of pollutants from wastewater resulting from dying activities when compare to the control and 50% dilution, *Eicchornia crassipes*, *Lemna minor* L., and *Pistia stratiotes* proof to be more efficient in the the remediation of wastewater resulting from dying and can be used in dyeing wastewater sedimentation and treatment before discharge into drainage system to prevent effects on aquatic flora and fauna.

Abstract. As spatial occupants, humans expect the space to be designed to meet their needs and satisfy their goals. Thus, designers should identify the changing spatial uses and preferences of several different groups. The present study aimed to determine intergenerational differences among generations x, y, z in their preferences in open space occupation and activities and their well-being levels based on occupation types. The study was conducted in Trabzon province in Turkey. It aimed to determine the occupation types for different generational groups in urban open spaces. For this purpose, a survey was conducted with 70 individuals from each generation (x, y, z), a total of 210 individuals in urban open spaces and their well-being levels were determined based on their occupational objectives and usage. The analyzes and tests conducted on the collected data demonstrated that the generations x, y, and z had different objectives and conducted different activities in open urban spaces. It was determined that generation x used the urban open spaces for sitting, resting, chatting, reading newspapers, etc. activities, generation y used the urban open spaces for meeting their peers, socialization, shopping, eating-drinking, etc. activities, while generation z occupied the urban open spaces for activities such as entertainment, sports, spending time with friends, meeting, etc. It was found that when they spent time in spaces that offer adequate activities, the level of well-being improved. It was concluded that different generations occupied outdoor spaces for different purposes, performed different activities in these spaces and their well-being improved when they spend time in adequate spaces.
Keywords: *age groups, activities, preferences, outdoor spaces*

Introduction

The group of individuals that were born in a particular period of time is called a generation. Generation is defined as a group of people who were born during the same period, sharing similar age, experiencing similar problems, fate and responsibilities. Sociological definitions of generation describe the concept as group of individuals who were born in certain period, affected by similar social, political and economic factors in the socialization process, assumed similar responsibilities due to similar conditions, and thus share common values, beliefs, expectations and behavior (Kon, 2017; Alpak et al., 2018; Glass, 2007; Inglehart, 1997). Nowadays, the term generation is generally used to emphasize the social or cultural structure of a period. Differences between generations are evident in every century, every period, and every époque. Intergenerational conflicts led to important social problems, the attempt of older generations to understand the new ones is very important for the society to live together and occupy a common space.

Auguste Comte initiated the scientific research on generation studies between 1830 and 1840. Comte suggested that generational deviations are forces that evolve in the historical process and social progress is possible only with the knowledge that one generation would transfer to the next (Comte, 1974). As the generations age, the behavioral characteristics of individuals differ. This is called the ageing effect and explains the different behavior of different generations within the same timeframe. Each generation has its own history and knowledge that distinguishes it from other generations. This difference stems from the socio-cultural and political legacy of previous generations (Toruntay, 2011; Dereli and Toruntay, 2015).

Strauss and Howe (1991), who conducted generation studies based on the work by John Stuart Mill, August Comte and Karl Manheim, used the following criteria to describe the concept of generations:

- There should be a common historical period shared by the members of a generation. These individuals experience similar historical events and social trends when living the same periods of their lives.
- Generation members tend to share behavior and common beliefs, including attitudes such as taking risks, culture, values, professional and domestic life that were shaped by their experiences in childhood or adulthood.
- They are aware of the experiences and skills they share with their peers and share this belonging with the members of the same generation. Several studies demonstrated that individuals in different generations define the traits of their generation as original and unique, although these traits are not observed as such by others. Known and frequently used generations in recent history are classified as follows:
  - Traditionalists1925-1945 (Lehto vd, 2006).
  - Baby boomers 1946-1964 (Pekala, 2001), 1944-1960 (Arsenault, 2004) and 1943-1960 (Families & Work Institute, 2002), 1945-1965(Roberts and Manolis, 2000; O'Bannon, 2001; Smola and Sutton, 2002; Wallace, 2006).
  - Generation X 1966-1979 (Alwin, 2002; Roberts and Manolis, 2000; Smola and Sutton, 2002; Wallace, 2006).
  - Generation Y (Millennials) 1980-2001 (Lower, 2008), 1980-1995 (Cogin, 2012).
  - Generation Z (Millennial/Internet Generation) 2000-2020 (Haeberle et al., 2009; Kuran, 2010).

The classification of the generations in the 21st century included traditionalists, baby boomers, generations X, Y and Z. Individuals' perceptions, expectations, priorities, perspectives on life, and ultimately their behavior vary based on time. The fact that individuals born on similar timeframe have similar characteristics and each generation have distinct characteristics led to the studies on the concept of generation and the characteristics of generations (Davis et al., 2006; Adıgüzel et al., 2014). Currently, there are at least 3 generations that must spend time together and occupy the urban spaces as peers. The conflicts between these generations are undoubtedly an important social issue. As spatial occupants, humans expect the space to be designed to meet their needs and satisfy their goals. Thus, designers should identify the changing spatial uses and preferences of several different groups. Children, young individuals and adults, i.e., generations x, y, and z are groups of occupants with different ages whose needs should be identified.

Ultimately, different generations have different demands, requirements and preferences. It is important to determine the differences between the generations to construct suitable designs for the occupants and create open spaces that the occupants could use, heal the occupants and increase their prosperity (Zhang et al., 2018). The present study aimed to determine the different needs of the generations x, y and z and the differences in outdoor

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37373751

space use among these generations. Determination of the different uses and activities by different generations in urban open spaces was also aimed in the present study. Thus, design criteria for the open space occupancy by different generations were determined to design therapeutic and prosperous spaces for the occupants in order for the spaces to attract individuals of all current generations.

Generation X and its attributes

The generation x was defined as the generation born between 1965 and 1978 (Okay, 2001) in certain resources and between 1961 and 1980 (Arsenault, 2004) and between 1965 and 1979 (Families and Work Institute: 2002) in others. This generation was raised in a world where the economy was in decline and a completely different value system was constructed (Acar, 2010). The decisive events for this generation were the Challenger Disaster in the US, divorces, AIDS, Sesame Street, MTV, Game Boy, and the first personal computers (Pekala, 2001). X generation possess a lower level of communication skills and technology knowledge when compared to younger generations (Elmore, 2011; Jianrui, 2011). Their technology knowledge is generally limited to general skills such as e-mailing and online job search. They are usually children of working parents and are defined as "latchkey kids" in various studies since they grew up with house keys hanging on their necks (FWI, 2002). They learned to grow up on their own and going home from school alone (Toruntay, 2011).

In this period, oil crisis, economic shocks, the generation of '68, university revolts, political conflicts and television were the most important events in Turkey. Women began to participate in the labor activities in this period in Turkey. Parents started to have fewer children for a better life. They focused more on finance and individualism gained importance (Mengi, 2011).

Generation x is often described as indifferent and aimless. Researchers argued that this may be due to a phenomenon derived from a collective cynicism among Generation X, a generation who witnessed more violent and negative events with the introduction of television into homes (Wolburg, 2001; Smola and Sutton, 2002).). They tend to take more risks and question authorities such as common rituals and traditions when compared to previous generations, as well as being family-oriented, self-confident, open-minded and fun-loving (Zhang and Bonk, 2010; Etlican, 2012). Generation X is defined as a generation that is compliant with the rules, with a strong sense of belonging, respect for authority, loyal and hardworking. this age range, they experienced a feeling of alienation as a result of being the first generation to witness the divorce of their parents (Montana and Petit, 2008). According to Elmore (2011), members of Generation X do not endeavor to understand other generations. They usually work to live. Furthermore, this generation witnessed a number of inventions and discoveries. The members of the generation X, who opened their eyes to the world with washing machines with a roller press, transistor radios, cassette players and turntables, experienced several transformations. Specifically, they tried to adapt to the transformation to computer systems and the changing business processes due to technological advances. Today, they are 22% of the population in Turkey (URL 2).

Generation Y and its attributes

The generation y was defined as the generation born between 1981 and 2000 in certain resources (Arsenault, 2004), between 1980 and the present (Families and Work Institute, 2002), between 1979 and 2001 (Pekala, 2001), and between 1982 and 2004 (Strauss and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37373751

Howe, 1997) in others. This generation has different names such as Millennials, Generation Next, Digital Generation, Echo Boomers and Nexters (Morgan and Ribbens, 2006).

The principal events of the period that affected the generation y in Turkey included increasing terrorist acts, the Gulf War, Iraq War, the Internet, globalization and mobile phones (Aktan, 2011). Similar to generation x, generation y had working parents. However, the age of parenthood increased to 27. This generation, which had quite different parents when compared to previous generations, had more active parents who had a more active role in raising their children under better conditions, their education and safety. Members of Generation Y are the children of parents who regularly check the children's grades, question bad grades, meet their teachers, and visit the school frequently. The generation y, who had to defend themselves against their parents constantly on issues they failed, learned how to deal with the system at an early age (Wendover, 2001; Zempke et al., 2013).).

Generation Y, the busiest generation ever, were raised with micro programs by their overprotective parents and grew up within close relationships, however they are still the most stressed generation ever (Raines, 2002). In the literature, the parents who monitor this generation closely and are constantly around are called "Helicopter Parents" (Howe and Strauss, 2007). Globalization also had a great impact on this generation. This generation is the first generation to be born to Internet with the highest daily interaction with different ethnicities and cultures, and its members possess more cultural richness when compared to previous generations. They grew up under the media and commercial influences since their birth, and thus possess higher brand awareness when compared to their parents. When the economic conditions of the members of this generation are compared, it is observed that the difference between the members with high and low purchase power is the greatest among the studied generations (Toruntay, 2011). Sheahan (2005) defined the generation y as the generation that could easily express their thoughts and emotions, who love social relationships and with high emotional intelligence.

This generation in Turkey that includes young adults who are free-spirited, adaptable, fickle, well-educated, technology-oriented and like to defy the authority live in a period where the impact of globalization are felt intensely and economic and intercultural interaction is at a maximum due to the facilities available (Türk, 2013). It was claimed that this generation is approximately three times larger than the Generation X (Schroder and Warren, 2005). 35% of the population living in Turkey currently are the members of this generation (TUDK). In Turkey, there are more Generation Y members when compared to the total population in several European countries (Toruntay, 2011).

Generation Z and its attributes

This generation is believed to include individuals who are born between 2000 and 2020 and will join the labor force within the next 5 years (Kuran, 2010).

Generation Z children live in a society where novel technological means of communication and transportation are in abundance. They could communicate with each other via verbal or even visual communication using digital tools even when they live far away. The members of this generation play with tablet computers instead of toys, are fast-consuming, and have the ability to multitask. Unlike previous generations, although they are considered as 'network' youth, they are estimated to be physically alone and tend to live alone since they could communicate in long distance. Since their multitasking skills are extremely developed, they are considered as the generation with the highest motor skill synchronization such as manual, sight and auditory skills (Toruntay, 2011). According to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37373751

Senbir (2004), this generation would be open to technology, and will not consider technology as a tool, but as a natural part of life.

However, it is considered that these advantages could turn into disadvantages due to attention and concentration difficulties. They like creative activities. Their long-term memory could be activated through games, storytelling and imagination rather than memorization. They are result oriented. Since the members of this generation are unsatisfied, unstable and innate consumers, it is considered that the concept of authority is not important in their lives. The networks they live in since their birth would play a major role in their identity.

This generation that includes the children born after 2000 in Turkey is also called the 'Crystal Generation'. Experts consider this generation as 'deeply emotional' and it includes 17% of the Turkish population (Adıgüzel et al., 2014). It is estimated that the share of generation z in the Turkish population reached 18.000.000 in 2015. Since they dislike hierarchy and are open to communications, it is considered that they would alter the organizational structures of the spaces they live in and work. Children who are the members of this generation expect everything to be personalized (Toruntay, 2011). The fact that their high education level, their independence and individuality would increase their creativity, their immediate honesty could lead to a motivated environment, the decrease in intergenerational differences, their social character and openness to communications, leading to a good understanding of each other, destruction of geographical borders due to the Internet, their higher self-expression levels could be considered among the positive attributes of this generation. Similarly, the disloyal, nondriven and unambitious, and fickle characteristics of the generation z and their desire to personalize everything could be considered among the negative attributes of this generation (Toruntay, 2011). It is also expected that they would have several diplomas and become experts, and would be innovative, malcontent and indecisive.

As a result, previous study findings demonstrated that there are different personality development, requirements and perceptions of these three generations. Thus, are the outdoor activities that these 3 generation occupants with different attributes conduct or desire to conduct different? The present study aimed to answer this question. Whether the well-being levels of the occupants increase when they spend time in spaces adequate for different activity requirements was another question that the present study aimed to respond.

Materials and methods

The study area included the outdoor spaces in the Eastern Black Sea Region and Trabzon province. Trabzon was established in early 2000's BC at the beginning of the historic Silk Road, which passes through Erzurum and reaches the Iranian border, connecting Europe and Asia. Trabzon, which is an important historical city, possesses several cultural assets due to its location. This led to the privileged position of Trabzon province among Eastern Black Sea Region provinces (*Fig. 1*).

Application

A survey was conducted with 210 Trabzon residents from the generations x, y, and z (70 individuals from each generation) in urban open spaces. The survey form included two sections. In the first section, different generation occupants were provided a list of activities

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37373751

and they were asked to mark the most frequent activity they conduct in open spaces. The second section was designed to determine the correlation between space occupancy and well-being of the occupants. In this section, the following statements were tested with 5-point Likert attitude scale (5 = very frequently, 1 = never):

- I feel happy when I can conduct different activities that suit my needs in spaces.
- I feel happy when the spaces provide facilities for the activities I desire to conduct.
- I feel better in spaces that allow me to conduct active activities.
- I feel better in spaces that allow me to conduct passive activities.
- The activities I conduct in urban spaces make me happy.

Snowball sampling was used to select the survey participants. This method starts with the selection of a subject based on the research criteria and the other subjects are accessed using the initially selected subject. The subject is asked to recommend someone or some people with the same characteristics (Lawrence, 2016). Thus, individuals in the adequate generation were accessed and 210 individuals (70 in each generation) were interviewed. Initially, demographic data about the 210 participants were obtained, then the activity preference rates for the generations were determined and One-way ANOVA was conducted to determine the differences between the distribution of activity levels of the generations in urban open spaces. In the second stage, the questions asked to determine the correlation between the activities in open spaces and occupant well-being was analyzed separately for each generation and percentage and mean values are presented. Then, t-test statistics were applied to determine the distribution of well-being level for each generation (x, y, z).

Figure 1. *Study area*

Findings and discussion

Demographic findings

The survey form included the age of the participants to determine their generation (*Table 1*).

	30-26	11,0	23	
	25-19	11,9	25	
Generation Z	18-16	12,4	26	70
	16-14	10,5	22	
	14-12	10,5	22	

Activity findings

Gehl (1987, 2010) categorized the activities conducted in open spaces in three categories: compulsory activities, optional-selective activities and social activities:

- The compulsory activities include more or less obligatory and non-selective activities such as going to work, transportation, and waiting for someone. Since the activities in this group are mandatory, they occur under all conditions throughout the year. The participant has no right to choose.
- Optional activities are voluntary activities conducted when the time and space is suitable. The activities in this group take place only in favorable external conditions, when suitable whether and space are available. There is no obligation to conduct these activities and an individual conducts these activities compleyelt voluntarily such as taking a walk.
- Social activities take place based on the other two types of activities and are also called "eventual activities." Social activities are scrutinized in two categories: passive and active activities. Passive activities include short-lived and single superficial activities such as watching and listening to other people that one is not familiar with, watching the environment, reading newspapers or books, playing games such as backgammon, etc. (Gehl, 1987) These passive relations are important. Because the weak relationships established via the passive relations could be used as a first step in establishing a strong structural interaction (Peters et al., 2010). Active activities include activities where individuals interact with each other such as chatting, playing games, eating and drinking, sports, socializing, shopping and meeting.

In studies conducted to determine human behavior, attitudes and behavior, the optional and social activities that people conduct on their own without any requirement are investigated rather than the mandatory activities conducted without any choice. Various studies reported these activities conducted by occupants of various age groups in public open spaces (Bäckman and Rundqvist, 2005; Whtye, 1980; Mehta, 2007, 2009; Yuen and Chor, 1998; Kärrholm, 2008; Lofland, 1998). These activities included passive or active activities such as watching and listening to other people, talking, sitting with friends, chatting, reading newspapers, playing games, listening to street performers, etc. In the present study, behavior and attitudes of different generations, in other words age groups, were investigated. Thus, the present study scrutinized social and optional activities conducted in open spaces. The activities determined based on this

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37373751

criteria included 15 activities (going out with friends, spending time with peers, sitting-resting, eating-drinking, spending time with family members, to breath the fresh air, shopping, walking, meeting with peers, viewing, reading books and newspapers, playing backgammon, playing games, socializing, having fun, playing sports, chatting) is provided in the question posed to determine the activities that the occupants from different generations conducted in urban open spaces and they were asked to mark the activity they conducted most. The highest value was observed for sitting-resting activity for generation x (22.9%). The highest value was observed for being with peers activity for generation y (28.6%). The highest value was observed for sports activities for generation z (24.3%) (*Fig. 2*).

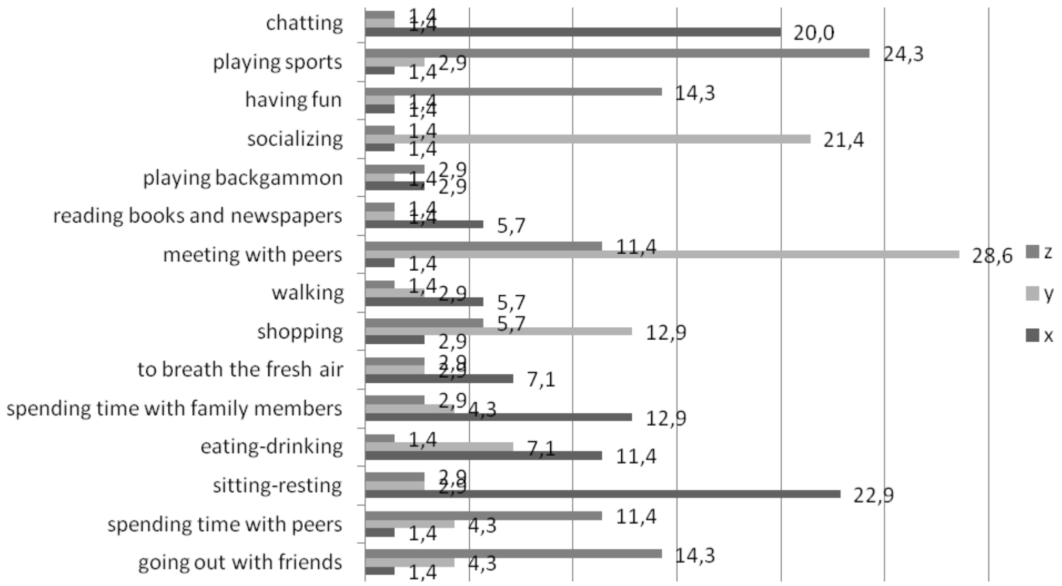

Figure 2. *Activity distribution for generations x, y, and z*

Since the age range of generation x includes adults who are more serene when compared to the new generations, the preference for passive activities such as sitting-resting was higher among these individuals. According to Elmore (2011), members of the Generation X do not endeavor to understand generations other their own. The fact that they are inclined to conduct activities alone increases the possibility that they would be challenged in crowded activities. This could explain why they preferred passive activities in the study. It was observed that the generation y members preferred to be among peers the most, since they are between the ages of youth and adulthood and due to the social attributes of the generation. It could be suggested that the fact that their lives are generally fast, versatile and extremely intense (Zhang and Bonk, 2010) could be due to their environment of growth where these rapid changes occurred. Thus, they live in fast, active and crowded environments to meet their expectations. This explains the fact that they preferred social activities conducted with their peers in the study. Finally, generation z preferred active activities the most since this group includes the youngest individuals between childhood and youth and the sportive activities were the most preferred activities. Because this generation has high self-esteem, and the fact that their parents cherished them and considered them different increase their self-esteem.

They are independent and free, there is nothing impossible for them (Haeberle et al., 2009). Thus, it was expected that they would prefer active activities in the study.

The One-Way ANOVA test conducted with SPSS (v. 17.0) software demonstrated that the distribution of the activity levels among different generations in urban open spaces was significant (*Table 2*).

Table 2. *Distribution of urban open space activities based on generations*

	Sum of squares	df	Mean square	F	Sig.
Between groups	138.867	2	69.433	3.383	.000
Within groups	4248.657	207	20.525		
Total	4387.524	209			

Occupant well-being findings

In order to determine the correlation between the open space activities and occupant well-being, the answers provided to 5 questions by each generation were analyzed separately.

The generation x preferred to conduct passive activities with an average of 3.94, they were satisfied with the activities they conducted in urban outdoor spaces with an average of 3.80, they were satisfied with conducting various suitable activities with an average of 3.61, they stated that they were satisfied when the spaces allowed them to conduct the activities they desired with an average of 3.39, however their preference on conducting active activities was low with an average of 2.93. Since individualism and competitiveness are more important in this generation that prioritizes materialism (Reynolds et al., 2009), it was determined that they conducted more passive individual activities and their open space satisfaction was also high. The percentage graph for the answers of generation x members is presented in *Figure 3*.

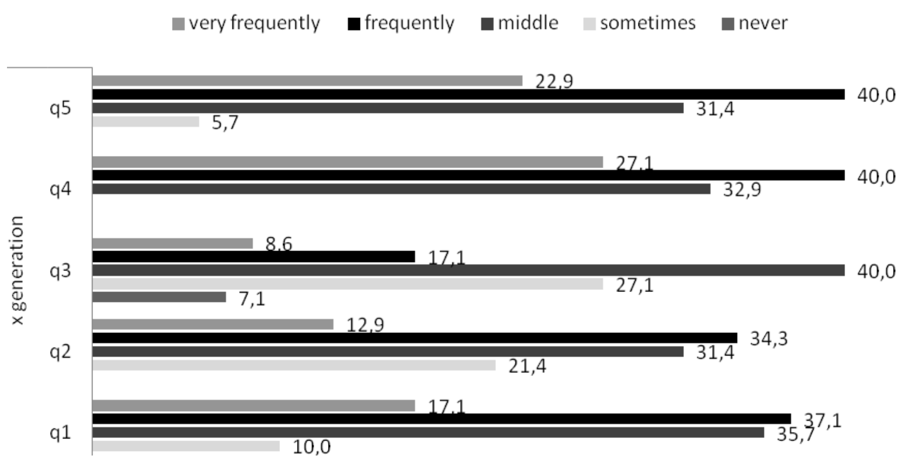

Figure 3. *Percentages of the generation x responses*

Then, it was determined that the above-presented distribution of the generation x responses was significant based on the t-test results conducted with SPSS (v. 17.0) (*Table 3*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37373751

Table 3. *Distribution of the generation x responses*

	t	df	Sig. (2-tailed)	Mean difference	95% confidence interval of the difference	
					Lower	Upper
s1	33.998	69	.000	3.614	3.40	3.83
s2	29.279	69	.000	3.386	3.16	3.62
s3	23.558	69	.000	2.929	2.68	3.18
s4	42.398	69	.000	3.943	3.76	4.13
s5	36.908	69	.000	3.800	3.59	4.01

It was determined that generation y was satisfied with the activities they conducted in urban outdoor spaces with an average of 3.96, preferred to conduct passive activities with an average of 3.56, they were satisfied with conducting various suitable activities with an average of 3.51, they preferred to conduct active activities with an average of 3.31, that is, the answers to all questions were at higher levels. As demonstrated with the literature review, peers and families are very important for Generation Y. They can come together very quickly due to their peer acceptance traits. This is the generation where the difference between the generations is felt the most. This is a technology-friendly, individualist, entrepreneurial, comfortable and globalized generation. Changes in living conditions introduced different preferences for this generation (Zempke et al., 2013). In the present study, it was determined that urban outdoor spaces have positive effects on their preferences and increase their well-being levels. The percentage graph for the answers of generation y members is presented in *Figure 4*.

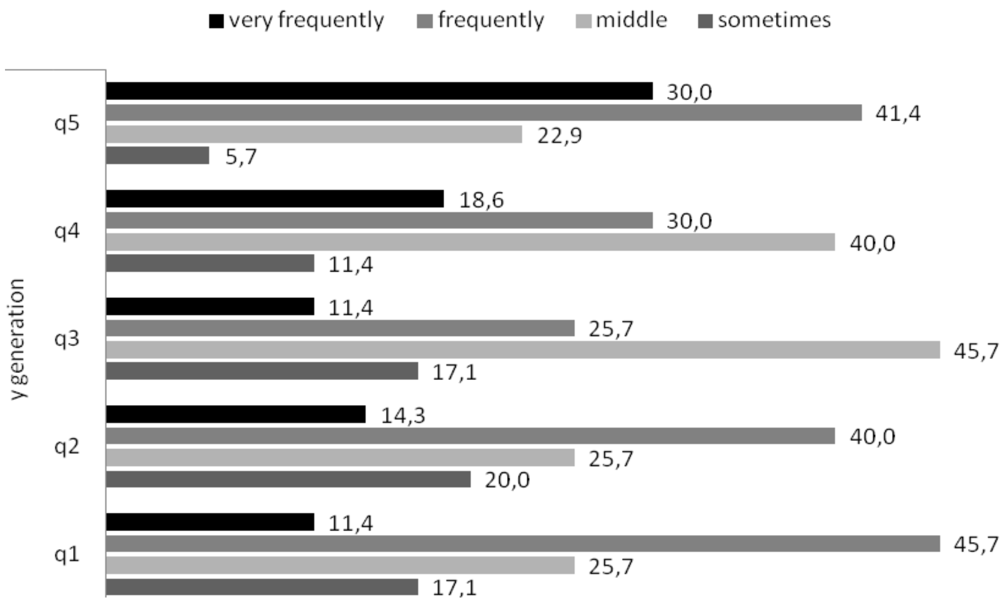

Figure 4. *Percentages of the generation y responses*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37373751

Then, it was determined that the above-presented distribution of the generation y responses was significant based on the t-test results conducted with SPSS (v. 17.0) (*Table 4*).

Table 4. *Distribution of the generation y responses*

	t	df	Sig. (2-tailed)	Mean difference	95% confidence interval of the difference	
					Lower	Upper
s1	32.213	69	.000	3.514	3.30	3.73
s2	29.936	69	.000	3.486	3.25	3.72
s3	31.034	69	.000	3.314	3.10	3.53
s4	32.111	69	.000	3.557	3.34	3.78
s5	37.822	69	.000	3.957	3.75	4.17

It was determined that generation z preferred to conduct active activities with an average of 4.26, they were satisfied with conducting various suitable activities with an average of 4.06, satisfied with the activities they conducted in urban outdoor spaces with an average of 4.03, they stated that they were satisfied when the spaces allowed them to conduct the activities they desired with an average of 4.00, and the responses to all questions were close to very high level, however their preference for passive activities was low with an average of 2.31. This was due to the fact that this generation is still very young and with active-mobile attributes. This generation is a fast-consuming generation. However, since they are familiar with the Internet, they are expected to develop the ability to deal with more than one subject at the same time (Senbir, 2004). The present study findings demonstrated that this generation preferred active activities due to their age group and they were happy when they conducted different activities and open spaces were effective on their well-being levels. The percentage graph for the answers of generation z members is presented in *Figure 5*.

Conclusion and recommendations

In conclusion, the present study conducted to determine open space occupancies of three generations with different desires, requirements and preferences revealed the following results:

- The generation x predominantly preferred passive outdoor activities such as sitting-resting,
- The generation y predominantly preferred social activities such as being with their peers,
- The generation z predominantly preferred more active activities such as sports.
- It was determined that all three generation members were happy when they conducted activities that were adequate for their needs and when the spaces allowed activities that were adequate for their desires.
- It was observed that urban open space activities were satisfactory for the members of all three generations and increased their well-being.
- Generation x felt better when they conducted passive activities, generation y felt better when they conducted both passive and active activities, and generation z felt better when they conducted active activities.

The different preferences and occupations determined based on the generations should be used to develop user-friendly designs and to create functional outdoor spaces that are therapeutic and increase the well-being of the occupants. The study investigated the different requirements of generations x, y and z and to determine the differences between these generations in outdoor occupancy. The study also aimed to guide future designs by determining the outdoor occupancy types suitable for different generational groups and the activities preferred by these groups. The study findings are quite important to design open spaces that needs to be renewed, renovated or built and would appeal to all generations, thus would enable creation of adequate spaces to improve the health and well-being of the occupants.

EFFECTS OF GLYCINE BETAINE CONCENTRATIONS ON THE AGRONOMIC CHARACTERISTICS OF STRAWBERRY GROWN UNDER DEFICIT IRRIGATION CONDITIONS

ADAK, N.

Akdeniz University, Faculty of Agriculture, Department of Horticulture, 07058 Antalya, Turkey (e-mail: nafiyeadak@gmail.com; phone: +90-242-3102469; fax: +90-242-2274564)

(Received 29th Dec 2018; accepted 14th Feb 2019)

Abstract. Glycine betaine (GB) is a quaternary ammonium compound that can be found in a wide range of bacterial, plant and animal species. The exogenous application of GB is a convenient method for the induction of crop tolerance to various abiotic stresses. We examined the effects of different exogenous GB concentrations to deficit irrigation conditions (15% drainage) under soilless condition in terms of morpho-physiological, yield, quality and biochemical features. The different GB concentrations (0, 10 and 20 mM) were used in Fortuna and Albion strawberry cultivars. As a result of the research, GB treatments increased plant growth and yield under deficit irrigation conditions. Fruit weight inclined by 26.29-49.50% and fruit yield by 17.17-39.59% at GB treatments as compared to control. Regarding biochemical content, increasing GB concentrations from 0 mM to 20 mM caused total anthocyanin to decrease, whereas the ascorbic acid increased. Furthermore, the highest yield, fruit firmness, chroma and total anthocyanin were determined in the Fortuna; the highest total soluble solid and ascorbic acid content in the Albion cultivar. Our results showed that the increase in yield and quality was due to exogenous GB applications. Indeed, water stress tolerance varied depending on cultivars.
Keywords: *water stress, ascorbic acid, colour, total anthocyanins, yield*

Introduction

Many strategies aimed at saving water are practiced in horticulture (Tunc et al., 2019). Drip irrigation method increases the efficiency of water use while decreasing the applied amount (Tunc et al., 2019). Mulch usage is a very important cultural practice to decrease evapotranspiration in conventional agriculture. Recent years, soilless culture techniques have expanded to increase the efficiency of water use in many agriculture countries. In addition, soilless culture enables lower water usage, lower fertilizer and higher yield per unit area than conventional method. Therefore this technique is known as a sustainable agricultural method. In fact, in Turkey, while 390 tons of water/decare is used under soil conditions with clay soil in the Mediterrenean region, in soilless systems much less water is used.

Turkey, with a strawberry production of 415150 tons in a production area of 15431 ha, was ranked fifth in 2016 in global production according to the FAOSTAT statistics (FAO, 2018). The strawberry protected production quantity increased by 40.51% (168,191 tons) in total production (TURKSTAT, 2017). Under protected conditions, there is a remarkable increase in general soilless production areas and the total soilless strawberry production area has reached 70 ha (Adak et al., 2018a). In soilless cultivation about 1.5–2 L of growing media/plant is used and even short time water stress causes loss of turgor (Adak, 2009). Thus, abiotic stress experiments, for example water stress, salinity stress, are conducted easier, faster in soilless culture technique as compared to conventional agriculture technique.

Recently, the most important environmental and agricultural problems are global warming and water shortage (Cramer et al., 2007; Fereres and Soriano, 2007; Osakabe

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37533767

et al., 2014; Bakhsh and Hussain, 2015; Zhu, 2016). In particular, salinity and drought are two major constraints that limit agricultural production worldwide. Mainly drought stress causes to decrease yield and quality and affects biochemical features in arid or semi-arid climate, for example Mediterrenean conditions (Souza et al., 2004; Zlatev and Lidon, 2012; Adak et al., 2018b; Tunc et al., 2019). Adak et al. (2018b) stated that some of the fruit's physical features were affected negatively by stress conditions whereas many of the biochemical features such as total anthocyanin content, total phenolic content and antioxidant activity were positively modulated in strawberries. Barreales et al. (2019) stated that deficit irrigation applications drastically affect the phytochemical composition and antioxidant activity of grapevine leaves. Controversaly, Centofanti et al. (2017) indicated that the deficit irrigation strategies did not affect the yield, fruit color, pH, concentration of soluble solids, total phenolic compounds, anthocyanin and non- anthocyanin compounds, and mineral elements in pomegranate fruit.

Plants have evolved various protective mechanisms that allow them to acclimate to unfavourable environments for continued survival and growth (Wani et al., 2013). Osmotic adjustment is an adaptive mechanism involved in drought or salinity tolerance, which permits the maintenance of turgor under water deficit conditions (Wani et al., 2013). Different strategies have been improved for management of these stresses (Wani et al., 2013). Recently, some exogenous agent applications, such as aminoacids, plant nutrients, hormone-like compounds, have been tried in terms of practical usage for producer (Ahmad et al., 2007; Shi et al., 2014; Osman and Salim, 2016). In this regard, osmoprotectants or compatible solutes are small molecules that act as osmolytes and help organisms survive extreme osmotic stress (Lang, 2007).

Glycine betaine, an amino acid derivate from sugar beet (*Beta Vulgaris L. v. altissima*), is purified, enriched and crystallised (Makela et al., 1998; Rajashekar et al., 1999). The known role of GB is maintaining water content in plant cells by lowering solute potential under osmotic stress in osmotic adjustment (Makela, 2004; Dutta et al., 2018). Both the exogenous application of GB and the genetically engineered biosynthesis of GB in such crops is a promising strategy to increase stress tolerance (Wani et al., 2013). As a matter of fact, it ameliorated the harmful effects to various abiotic stress conditions, such as drought (Makela et al., 1998; Rajashekar et al., 1999; Rezaei et al., 2012; Zamani et al., 2014; Dawood, 2016; Rady et al., 2018), high salinity (YingYun et al., 2012; Yildirim et al., 2015), low temperature (Rajashekar et al., 1999; Zhang et al., 2008) and heat stresses (Oukarroum et al., 2012) in many crops. In addition, exogenous application of GB in non-accumulator plants may be a possible alternative approach for tolerance improvement against multiple abiotic stresses (Harinasut et al., 1996; Diaz-Zorita et al., 2001; Yang and Lu, 2005). In fact, tomato plants (*Lycopersicon esculentum* Mill.) do not naturally accumulate GB (Wyn Jones and Storey, 1981). However, Park et al. (2006) stated that exogenous application of glycine betaine increases chilling tolerance in tomato plants.

Glycine betaine can be phytotoxic, when applied either at higher concentration or by increasing the number of applications. The species such as bean, tomato, and grape are more sensitive to high concentrations of GB than grass species/cereals. Therefore, it is important to determine optimal concentration of GB, number of applications, and time of application for each crop species (Muhammad et al., 2006). In this regard, Rajashekar et al. (1999) determined exogenous application of glycine betaine (2 mM) to strawberry plants increased the cold tolerance of leaves within 72 h of application. Likewise, Armin and Reza Miri (2014) examined different application types of glycine betaine

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37533767

(seed-treating, seed-treating+foliage spraying, spraying at flowering and non-application of glycine betaine) under rain-fed and irrigated conditions. 100 mM GB concentration was used in both seed treating and spraying. The result of this study, the seed application+spraying of glycine betaine was superior to other application methods in terms of yield and yield components increasing in cumin plants. Yildirim et al. (2015) observed that exogenous GB treatments at 10 and 25 $mmol \cdot l^{-1}$ elevated the concentrations of gibberellic acid, salicylic acid and indole acetic acid levels and it could ameliorate the harmful effects of salt stress in lettuce. Shams et al. (2016) suggested that exogenous GB treatments could ameliorate the tolerance of lettuce to salt stress by increasing the total antioxidants and total phenolics. Likewise, Youssef et al. (2018) foliar GB at 10 mM to cucumber plants ameliorated the harmful effects of NaCl stress on the vegetative growth and yield through enhancing both leaf relative water content and leaf membrane stability. In additon, Denaxa et al. (2012) stated GB and kaolin clay particles treatments increased CO_2 assimilation rates drought stress as compared to control in olive (*Olea europaea* L.) plants.

In this regard, a little is known about the effects of exogenously applied glycinebetaine concentrations on quantitative and qualititative characteristics in different strawberry cultivars and deficit irrigation conditions with soilless cultivation. As a matter of fact, in strawberries, the degree of water stress tolerance varies according to plant growth stage, stress duration, growing system, growing medium and cultivars (Adak et al., 2018b). Therefore, optimal GB concentrations and number of application and time of application should be determined in strawberry as well. The aim of the study were to assess the effectiveness of GB concentrations in different strawberry cultivars in terms of morpho-physiological, yield, quality and biochemical characteristics. Thus, the most suitable GB concentrations will be determined for drought conditions and it will be recommended to producers working under water stress conditions.

Materials and Methods

Plant Materials, Growing Conditions and Treatments

Experiments were conducted between October 2015-February 2016 in high plastic greenhouse owned by the private research center located in Serik-Antalya (36° 50' 37" N; 30° 50' 31" E; at an altitude of 50 m). Climatic data during the experiment are given in *Table 1*.

Table 1. *Monthly averages of temperature (°C) and relative humidity (%) inside the experimental greenhouse*

	October	November	December	January	February
Temperature (°C)	25.9	22.5	17.9	16.8	18.2
Relative humidity (%)	72.23	68.54	69.65	65.30	69.30

Treatments consisted of two strawberry cultivars (Fortuna and Albion) and three glycine betaine concentrations with control (0, 10 and 20 mM GB) under deficit irrigation condition (15% dranaige fraction). Seedlings were planted in grow bags containing cocopeat (100 cm in length × 15 cm in width × 7 cm in height) on the gutter at the height of 75 cm on 20 October 2015 (14.2 $seedlings \cdot m^{-2}$). A control irrigation regime (30% drainage) was applied to the plant for the first 2 weeks. Later, deficit

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37533767

irrigation (DI) regime (15% dranaige) was followed from 03 November 2015 to 05 February 2016. In the system, a separate irrigation programme was implemented by using separate irrigation valves. Three different concentrations (0, 10, 20 mM) of glycine betaine (GB) (Sigma-Aldrich, 98%). were applied twice (during planting and 30 days after planting) through spraying the foliar part of plants. Ionized pure water was used in control treatment (0 mM GB).

The nutrient concentrations in the nutrient solution named as Starter Solution (from October to December) were in all treatments as follows: 4.50 mM K^+, 4.00 mM Ca^{2+}, 1.25 mM Mg^{2+}, 0.50 mM NH_4^+, 11.50 mM NO_3^-, 1.00 mM $H_2PO_4^-$, 1.50 mM SO_4^{2-}, 20 µM Fe, 10.0 µM Mn, 7.0 µM Zn, 0.75 µM Cu, 25.0 µM B, and 0.50 µM Mo. The EC and pH in the above NS were 1.55 $dS \cdot m^{-1}$ and 5.6, respectively. On reproductive stage, fertigation solution was replenished with different nutrient concentrations than in the initial nutrient solution. In this stage, the ion concentrations in the reproductive solution applied (from December to February) in all treatments were as follows: 5.50 mM K^+, 3.50 mM Ca^{2+}, 1.50 mM Mg^{2+}, 11.00 mM NO_3^-, 1.50 mM $H_2PO_4^-$, 1.50 mM SO_4^{2-}, 20 µM Fe, 10.0 µM Mn, 7.0 µM Zn, 0.75 µM Cu, 25.0 µM B, and 0.50 µM Mo. The EC and pH in the above NS were 1.70 $dS \cdot m^{-1}$ and 5.6, respectively. In the experiment, irrigation schedule was programmed depending on solar radition (3-8 irrigation/day with 3 min/irrigation) and irrigation programmes were done by automatic fertilising system (INTA Crop Technology S.L, Murcia, Spain).

Data Collection and Statistical Analysis

In the experiment, the morpho-physiological features of plants (crown diameter, chlorophyll index), pomological features in fruits (fruit weight, total soluble solid, titratable acid, firmness, colour) and biochemical features (ascorbic acid, total monometric anthocyanin) were examined. While morpho-physiological observations were carried out from November to February, all pomological and biochemical analysis were done from samples taken at the end of January. The yield per plant was determined from the total yield values obtained during the whole season.

Determination of crown diameter and chlorophyll index

In plants, crown diameter and chlorophyll indexes were measured monthly with digital calipers, and with chlorophyll meter (Field Scoot CM1000), respectively. Results were expressed as average monthly taken datas from November to February.

Determination of fruit weight and yield

Fruit weight and fruit yield were determined throughout the growing season (2 December 2015 to 05 February 2016). Fruit weight was presented as grams (g), and yield as yield per plant.

Determination of total soluble solids, titratable acidity and firmness

Total soluble solids content (TSS) were measured by a digital refractometer (REF121; Atago, Guangzhou, China) and expressed as %. The titratable acidity (TA) was determined by juice titration with 0.1 N NaOH up to 8.1 pH and expressed in % of citric acid per 100 mL juice (AOAC 1980). Firmness was determined by the equatorial region of fruit, using a texture analyser (FT-011, with 7 mm probe, Effegi, Italy) and expressed as $kg \cdot cm^{-2}$.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37533767

Colour measurements

Fruit skin colour were measured by a Minolta CR-200 (MINOLTA Camera Co, LTD Ramsey, NJ) chromameter in terms of L* (whiteness = darkness), a* (redness) and b* (yellowness) values. Hue angle (colour shade) was calculated from arc tan (b*/a*) and chroma (colour saturation) was from square root ($a^{*2}+b^{*2}$). High values of hue angle indicate more red–orange and low values more red–bluish colour. Chroma shows transition from grey (low values) to pure colour (high values) (Selcuk and Erkan, 2005).

Determination of ascorbic acid (AA) and total monomeric anthocyanins (TMA)

Ascorbic acid (AA) content of strawberry samples was analyzed according to Bozan et al. (1996) with HPLC method. Results were expressed as mg/100 g fresh weight basis (FW). Total monomeric anthocyanins (TMA) were determined by the pH-differential method. After 30 min incubation at room temperature extracts were diluted with buffers (pH 1 or 4.5), the absorbance was measured at 520 and 700 nm (Agilent 8453 spectrophotometer, Agilent Technologies). The anthocyanins were quantified as mg Pg-3 glk/kg fresh weight (FW) basis (Giusti and Wrolstad, 2001).

Statistical analysis

The treatments were arranged in randomised block design (RBD) using a 2 × 3 factorial arrangement with three replications and 26 plants per treatment. The data were analysed using the Statistical Analysis System software programme, version 9.0 (SAS Institute, Cary, NC, USA) by ANOVA and treatment means were statistically compared using LSD test 5% of error probability.

Results and Discussion

Crown diameter and chlorophyll index

The determined data on crown diameter and chlorophyll index are given in *Table 2*. As can be seen in *Table 2*, the effects of the GB concentrations, cultivar and GB concentrations x cultivar interactions on crown diameter were found to be statistically insignificant. Crown diameter values, depending on the treatments, ranged from 2.30 mm to 2.58 mm.

In the case of chlorophyll index, there were statistical differences among the GB treatments and the highest chlorophyll index was observed at 10 mM GB concentrations (341.83). In the experiment, while cultivars insignificantly influenced the chlorophyll index, interactions were determined to be significant (*Table 2*). As a matter of fact, the highest chlorophyll index was indicated at 10 mM GB concentration x Albion cultivar interaction (346.00), while the lowest was at 20 mM GB x Fortuna cultivar interaction (254.33) (*Table 2).*

Consequently, according to our results, 10 mM GB concentration was the best concentration determined in terms of chlorophlly index. As for crown diameter, although statistical differences are insignificant, the highest values were founded at 10 mM application. In this concern, no literature was found regarding the effect of different exogenous glycine betaine concentrations under deficit irrigation conditions on morpho-physiological features in soilless strawberry cultivation. However, regarding cold stress conditions, Aras and Esitken (2013) stated that GB applications in strawberries affected leaf-relative water content, chlorophyll index, membrane

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37533767

permeability criteria. In addition, the same researchers have also reported that concentration of 10 g/L GB has a protective effect on strawberries under cold stress. Likewise, Rajashejar et al. (1999) determined that exogenous application of glycine betaine (2 mM) to strawberry plants increased the cold tolerance of leaves within 72 h of application.

** $n = 26$

Other experiments examining different abiotic stress conditions and species indicated similar results. As a matter of fact, Mickelbart et al. (2006) stated application of GB (50, 100, 200 mM) increased the average number of days to maximum leaf area, and specific leaf weight on grapevine. However, leaf water potential and leaf relative water content were unaffected by GB. In addition, while 100 or 200 mM GB concentrations were determined as toxic concentrations, the research studies recommend concentrations below 50 mM for further applications to increase stress tolerance of grapevine. Rezaei et al. (2012) investigated effects of exogenous GB concentrations (0, 5 and 10 mM) in three stages with 10 days interval on some morpho-physiological characteristics of tomato plants at different levels of drought stress (weekly, bi-weekly and tri-weekly watering). Results showed vegetative growth parameters inclined as compared to control, that is shoot height by 70%, root length by 73%, leaf number by 187%, leaf area by 193%, total shoot fresh weight by 168%, total shoot dry weight by 9%, relative water content by 72% and stress tolerance index by 122%. Zamani et al. (20131) examined effects of proline (10 mM) and GB (15 mM) were sprayed on the grapevines at four growth stages (before flowering, flowering, sour cluster and veraison) under drought stress. Results showed that GB significantly affected leaf relative water content, canopy temperature, chlorophyll content, leaf area in all the treated cultivars. Shams et al. (2016) examined four concentrations of GB (0, 5, 10, and 25 mM) and two levels of salinity (0 and 100 mM of NaCl) in lettuce plants. Results showed the 25 mM GB treatment increased the dry matter by 44% as compared to control. Youssef et al. (2018) applied foliar GB at 10 mM to cucumber plants which improved both chlorophyll

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37533767

contents and nutrient content under salt stress condition. Similarly, YingYun et al. (2012) reported that exogenous betaine significantly increased the photosynthetic pigments. Likewise, Rady et al. (2018) investigated the effects of different GB concentrations (0, 25 and 50 mM) under 4.80 dS m^{-1} salt stress on onion. GB treatment significantly increased shoot length, leaves area of plant, shoot fresh and dry weights, bulb yields, leaf chlorophyll contents, leaf relative water content and membrane stability index. Research studies determined that a level of 50 mM GB was more effective under moderate salt stress.

Figure 1. *General view from experimental area (left), 20 mM GB application (middle), 10 mM GB application (right)*

Fruit weight and yield

The effects of GB concentrations, cultivars, GB concentration x cultivar interactions on fruit weight and yield under deficit irrigation condition are given in *Table 3*. As seen in Table 3, increasing GB concentrations from 0 mM to 20 mM induced fruit weight to increase. The highest fruit weight was determined at 20 mM GB application (13.49 g). In the case of fruit weight, there were no statistical differences between cultivars. Regarding interactions, the highest fruit weight was found at 20 mM GB concentrations (13.81 g and 13.17 g), the lowest values were determined in control applications (9.74 g and 8.31 g) in all the tried cultivars.

In the case of fruit yield per plant, all tried GB treatments increased yield as compared to the control under deficit irrigation condition. Among the treatments, the highest fruit yield per plant was founded in 10 mM GB (359.00 g·$plant^{-1}$), followed by 20 mM GB concentrations (301.33 g·$plant^{-1}$). Fruit yield were found statistically different according to cultivars. The highest yield per plant was determined in Fortuna cultivar with 351.00 g·$plant^{-1}$ under deficit irrigation conditions (*Table 3*). Regarding interaction between GB concentrations and cultivars, the highest fruit yield was founded in 10 mM GB X Fortuna cultivar (430.67 g·$plant^{-1}$) (*Table 3*).

Consequently, all tried GB concentrations increased fruit weight and yield as compared to control. In fact, fruit weight inclined by 26.29-49.50% and fruit yield by 17.17-39.59% at GB treatments as compared to control. These results were similar to the values reported by other authors (Makela et al., 1998; Rezaei et al., 2012; Rady et al., 2018). Makela et al. (1998) emphasized that 3.36 kg·ha^{-1} GB during mid flowering

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37533767

period increased fruit yield by 36 and 39%, as compared to control in tomato plants under salt and heat stress conditions. Furthermore, Rezaei et al. (2012) reported that the 10 mM exogenous glycinebetaine was the best treatment in terms of reproductive growth parameters on tomato plant grown under drought conditions. Rady et al. (2018) reported that GB treatments remarkably increased bulb yields of onion under 4.80 $dS{\cdot}m^{-1}$ salt stress. However, our results were in contrast to the findings of Meek et al. (2003), who pointed out that the yield components were not affected in drought stress in cotton plants by foliar GB applications. It can be said that differences on determined GB concentrations may be caused by differences in species, cultivar and application.

Table 3. *Effects of different glycine betaine concentrations on fruit weight and yield at different strawberry cultivars grown under deficit irrigations*

** $n = 26$

Total soluble solid (TSS), titratable acidity (TA) and firmness

The effects of GB concentrations, cultivars, GB concentration x cultivar interactions on total soluble solid (TSS), titratable acidity (TA), and firmness under deficit irrigation condition are given in *Table 4*. As seen in *Table 4*, while the effects of strawberry cultivars on TSS, TA and firmness were found statistically different, GB concentrations was insignificant differences. As a matter of fact, the highest TSS value was determined in the Albion (7.39%) and the highest TA was in the Fortuna (0.78%) and the highest firmness was in the Fortuna cultivar (0.57 $kg{\cdot}cm^{-2}$) under deficit irrigation condition. Regarding the interaction between GB concentrations and cultivars, the highest TSS was founded in the Albion x Control (7.56%) and Albion x 10 mM GB (7.36%). In addition the highest TA value was determined in the Albion x 10 mM GB interaction (0.80%) (*Table 4*).

Consequently, exogenous GB applications did not affect to total soluble solid, titratable acidity, firmness whereas cultivars significantly affected these criteria. Between the cultivars, TSS was higher in the Albion, whereas TA and firmness were in the Fortuna under deficit irrigation condition. However, our results differed from those of YingYun et al. (2012) who reported that exogenous betaine significantly increased

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37533767

the photosynthetic pigments and soluble sugar content. This difference is thought to be caused by species, cultivar and growing conditions.

** $n = 26$

Colour

The effects of GB concentrations, cultivars, GB concentration x cultivar interactions on L*, chroma, and hue (h°) under deficit irrigation condition are given in *Table 5*. As seen in *Table 5*, statistical analysis showed that there were insignificant differences in terms of lightness (L*) values according to cultivars and treatments. Regarding interactions, the highest lightness (L*) value was founded in Fortuna x 10 mM GB (34.38) (more brighter); the lowest L* value was Albion x 10 mM GB (29.57) (less brighter). In terms of chroma value, while the highest value was determined in 10 mM GB (34.32), the lowest was in control treatment (32.21). In *Table 5*, on the basis of cultivars, the highest color intensity (chroma) value was found in the Fortuna cultivar (34.56) and the highest h° values were at 10 and 20 mM GB concentrations. Indeed, the highest chroma and h° values were determined in the Fortuna and 10-20 mM GB treatments (light-colored).

Consequently, GB applications negatively affected fruit colour in terms of chroma and h° values as compared to control. In this concern, no literature was found regarding the effect of GB treatments on fruit colour in any horticultural plant.

Ascorbic acid (AA) and total monomeric anthocyanins (TMA)

The data on ascorbic acid and total monomeric anthocyanin (TMA) content determined were given in *Table 6*. As seen in *Table 6*, increasing GB concentrations from 0 mM to 20 mM caused ascorbic acid contents to increase. As a matter of fact, the highest ascorbic acid (AA) content was founded at 20 mM GB application (35.29 mg·100 g^{-1} FW), the lowest was in control (24.79 mg/100 g FW). Furthermore, on the basis of cultivars, Albion strawberry cultivar (34.17 mg·100 g^{-1} FW) was determined higher than the Fortuna strawberry cultivar (27.91 mg·100 g^{-1} FW) in terms of AA. Interactions between cultivar and GB concentrations showed significant effects on AA. In general, Albion x 10-20 mM GB interactions gave the highest values (39.91 and 37.53 mg·100 g^{-1} FW) (*Table 6*).

As seen in *Table 6*, statistical analysis showed that there were significant differences in terms of TMA contents according to cultivars and GB treatments. As a matter of fact, increasing GB concentrations from 0 mM to 20 mM caused TMA to decrease. While the highest TMA content was founded in control with 511.97 mg Pg-3 glk·kg^{-1} FW; the lowest was at 20 mM GB treatment with 480.70 mg Pg-3 glk·kg^{-1} FW. On the basis of cultivars examined for the TMA content the highest value was determined in the Fortuna cultivar (517.66 mg Pg-3 glk·kg^{-1} FW). Interactions between cultivar and GB treatments showed significant effects on TMA. In general, the highest TMA values were obtained in control x Fortuna cultivar (544.23 mg Pg-3 glk·kg^{-1} FW) (*Table 6*).

Consequently, increasing GB concentrations from 0 mM to 20 mM caused total anthocyanin content to decrease, whereas the ascorbic acid content increased. Similar results were obtained in previous studies (Karjalainen et al., 2002; Shams et al., 2016). In

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37533767

this regard, Karjalainen et al. (2002) indicated that foliar-applied glycine betaine (50 mM) and benzothiadiazole (60 g/ha) at the young-seedling stage (3-4 leaf stage) enhanced the levels of several phenolic compounds in strawberry leaves under field condition. Remarkable increases were detected in the levels of ellagitannin, ellagic acid and gallic acid derivates, quercetin and kaempferol konjugates. Briefly, the authors suggest that exogenously applied BTH and glycine betaine may be used to increase the levels of protective and health-promoting compounds in strawberries. Likewise, Shams et al. (2016) tried four concentrations of GB (0, 5, 10, and 25 mM) and two levels of salinity (0 and 100 mM of NaCl) in lettuce plants. Results showed that the 25 mM GB treatment increased dry matter and the content of total phenolics compared to the non-GB-treated plants under salt stress. Briefly, the authors suggested that exogenous GB treatments could ameliorate the tolerance of lettuce to salt stress by increasing the total antioxidants and total phenolics. Also, Khadouri (2015) noted the beneficial effects of GB application on biochemical and mineral content on cowpea plant.

Table 6. *Effects of different glycine betaine concentrations on ascorbic acid (AA) and total monomeric anthocyanin content (TMA) at different strawberry cultivars grown under deficit irrigations*

Glycine Betaine Con. (mM)	Cultivars		Treatments
	Fortuna	Albion	
	AA ($mg{\cdot}100\ g^{-1}$ FW)		
0	24.54 C*	25.05 C	**24.79 b***
10	26.13 C	39.91 A	**33.02 a**
20	33.06 B	37.53 AB	**35.29 a**
Cultivars	**27.91 b**	**34.17 a**	
$LSD_{\%5\ treatment}$: 4.75; $LSD_{\%5\ cultivar}$: 3.87; $LSD_{\%5\ treatmentx\ cultivar}$:6.711			
	TMA ($mg{\cdot}Pg\text{-}3\ glk{\cdot}kg^{-1}$ FW)		
0	544.23 A	479.70 C	**511.97 a**
10	520.15 AB	465.16 C	**492.65 ab**
20	488.62 BC	472.78 C	**480.70 b**
Cultivars	**517.66 a**	**472.54 b**	
$LSD_{\%5\ treatment}$:23.58; $LSD_{\%5\ cultivar}$: 19.25; $LSD_{\%5\ treatmentx\ cultivar}$:33.348			

Ascorbic acid content (AA) was determined by HPLC method of Bozan et al.(1997). Values were expressed as mg/100 g fresh weight basis (FW).
Total anthocyanin content (TAC) was determined by the pH-differential method of Giusti and Wrolstad (2001). Values were expressed in $mg{\cdot}Pg\text{-}3\ glk{\cdot}kg^{-1}$ by spectrophotometer.
*The comparison of the means of the cultivars is done within the same row and means of treatment in the same column and the interaction between all the values are significantly different ($P \leq 0.05$) using LSD comparison test. The mean of treatment and cultivar are shown in lowercase letters while interactions are in uppercase.
**The results based on wet basis for fresh fruit.
*** $n = 26$

Conclusion

Considering the rise in global warming, environmental changes and water shortage will affect sustainable agriculture. Therefore, identification of resistant and tolerant cultivars to stress conditions are crucial for future breeding programs. Furthermore, it is very important to determine suitable agents and application concentrations of these agents under drought stress conditions. In this regard, glycine betaine is environmentally safe, non-toxic and water-soluble and can be practically applied on plants.

In this study, we examined the various effects of glycine betaine concentrations on plant morpho-physiological features, fruit physical and some biochemical features in two different soilless grown strawberry cultivars under deficit irrigation conditions. Our results showed that exogenous GB treatments induced plant growth and development, fruit yield as compared to untreated GB under stress condition. The best GB concentration was 10 mM in terms of fruit weight and yield. Fruit colour was affected negatively by GB concentrations. It can be said that the most important result was that increasing GB concentrations from 0 mM to 20 mM caused total anthocyanin content to decrease, whereas the ascorbic acid content increased. Furthermore, regarding cultivars, Fortuna was the best cultivar in terms of yield, titratable acidity, firmness and total anthocyanin, whereas Albion was the best cultivar in terms of total soluble solid and ascorbic acid content under deficit irrigation condions in soilless strawberry cultivation.

Abstract. The theory of sponge city has been attracting extensive attention in addressing urban water-related issues especially in China. We discussed on the emergy-GIS method of selecting areas for sponge-like urban reconstruction in Shenzhen, with four main concerns including data source, neglecting the issue of urban waterlogging, potential inaccuracies in emergy calculations and indices in selecting key areas. The corresponding suggestions and solutions are developed including the rational selection of precipitation and anthropogenic heat, consideration of land use types in assumption of the first 50% of stormwater runoff, incorporation of areas with high risk of waterlogging, methods for emergy calculations of runoff and runoff pollution, scientific choice of indices and integration of local planning and actions. This study could help improve the emergy method integrated with GIS in the application of sponge city studies.
Keywords: *sponge city, emergy, GIS, urban waterlogging, anthropogenic heat, runoff pollution*

Introduction

The theory of Sponge City which is related to low impact development (LID) and green infrastructure (GI) has been attracting extensive attention in addressing water-related issues due to rapid urbanization (Jia et al., 2017; Xia et al., 2017; Jiang et al., 2018; Tang et al., 2018; Wang et al., 2018). Both its practice and theoretical research have become exciting topics across interdisciplinary fields for achieving urban sustainability especially in China (Li et al., 2017, 2018; Xu et al., 2018). Recently an important study was published with the title of an emergy-GIS method of selecting areas for sponge-like urban (Zhao et al., 2018). A comprehensive framework composed of stormwater indices and anthropogenic heat was employed to facilitate selection of key areas for sponge-like urban reconstruction based on the integration of emergy analysis and GIS models with a case study in Shenzhen. Zhao et al. (2018) also claimed that the proposed emergy–GIS framework could bridge the gap between empirical studies and standardize research to ensure that the results of the green infrastructure plan. Emergy evaluation integrated with GIS can certainly help the spatial analysis of sponge city planning (Odum, 1996; Pulselli, 2010; Chang and Huang, 2015; Chen et al., 2016; Wang et al., 2016). However, after extensive analysis of the modeling approach, we found four main issues with the study: (1) selection of time scale of data source; (2) neglecting the issue of urban waterlogging; (3) potential inaccuracies in emergy calculations of runoff and runoff pollution; and (4) choice of indices in selecting key

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37693780

areas. Therefore, we investigated these issues and provided the suggestions and solutions correspondingly. It will help develop the emergy method integrated with GIS in the application of sponge city studies.

Main issues and solutions

Time scale of the data source

Zhao et al. (2018) used the precipitation data from 2010 to assess the stormwater indices (stormwater runoff and runoff pollution). The year 2010 can be hydrologically characterized as an average to dry year. For reference, the annual precipitation data with the deviation from the long-time (1958-2017) average of 1935.8 mm is showed in *Figure 1* (WRBS, 2018). Since precipitation is the dominant variable that determines runoff, and stormwater storage and runoff control are main tasks for sponge city construction, comparative analysis on the data from different typical hydrological years (wet, normal and dry) can help good understanding of the performance of sponge city construction (Jia et al., 2017; Jiang et al., 2018; Wang et al., 2018). Thus, it might be not sufficient to only use one year data from 2010, when is even a normal to dry year. It is recommended that the data from a wet year can be selected to enhance the analysis, such as 2013, 2014 or 2016 in *Figure 1*. Moreover, since Zhao et al. (2018) only used one precipitation value from the 2011 Shenzhen statistical yearbook, the temporal and spatial variability of precipitation was neglected (Tao et al., 2010; Ma et al., 2017; Luo et al., 2018). For reference, the monthly precipitation and the distribution of annual precipitation are showed in *Figure 2* (MBSZM, 2011b). The annual precipitation data at typical hydrometric stations are presented in *Figure 3* (WRBS, 2011), which can help improve the calculation of stormwater runoff on the use of one precipitation value by Zhao et al. (2018).

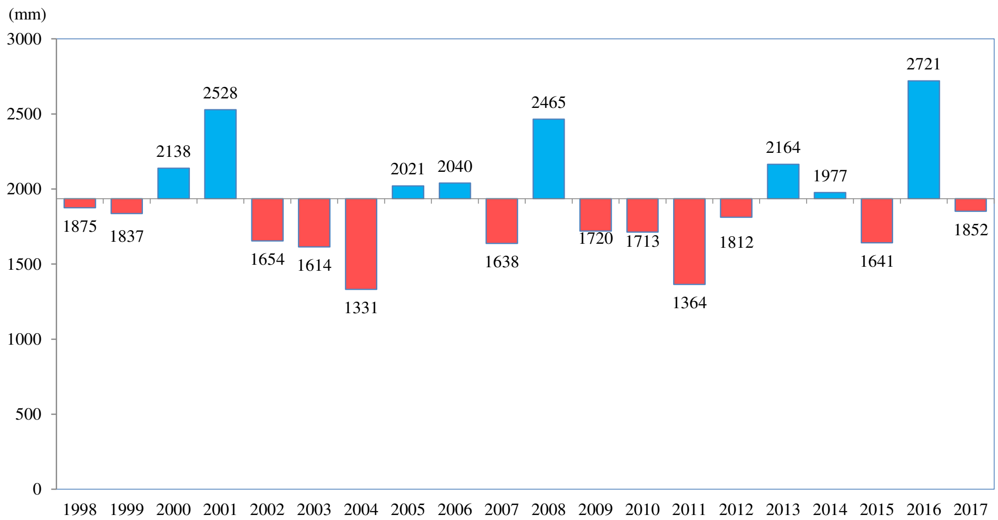

Figure 1. *Annual precipitation data in Shenzhen (1998-2017) (WRBS, 2018)*

Regarding the runoff pollution as the second indicator, Zhao et al. (2018) estimated the pollutant loadings using the first 50% of the stormwater runoff volume, which referred to a study by Qin et al. (2010) in Shenzhen. Yet, Qin et al. (2010) reported that

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37693780

impervious land use contributed significantly to first flush (the first proportion of the runoff volume containing the main proportion of the related pollutant load), whereas pervious land use had low or even zero first flush (Qin et al., 2010). Zhao et al. (2018) applied this assumption of the first 50% of stormwater runoff to all the land use types, which might cause overestimate of the runoff pollution. Thus, it is recommended that only impervious land use types can be considered into the estimation.

Figure 2. *Temporal and spatial variability of precipitation in Shenzhen (2010) (MBSZM, 2011b). (a) Monthly precipitation in Shenzhen (2010). (b) Distribution of annual precipitation in Shenzhen (2010)*

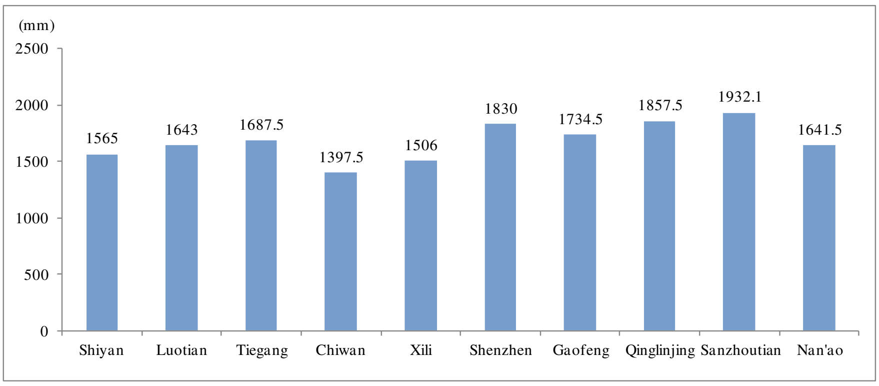

Figure 3. *Annual precipitation data at typical hydrometric stations in Shenzhen (2010) (WRBS, 2011)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37693780

Concerning the anthropogenic heat as the third indicator, Landsat-5 TM images and meteorological data (temperature) on December 23, 2010 were used by Zhao et al. (2018). The one-day data might be inconsistent with the whole year data for the precipitation and runoff analysis. Moreover, Zhao et al. (2018) did not interpret the representativeness of this day for the anthropogenic heat calculations. Yet, season-specific diurnal profiles of anthropogenic heating for cities had morning and evening peaks in summer and winter (Sailor and Lu, 2004). There are also typical characteristics of the temporal and spatial variation of anthropogenic heat flux in South China (Zhu et al., 2017). Anthropogenic heat has great impacts on the formation of urban heat island (UHI) effect, especially from June to August in Shenzhen (MBSZM, 2011a). Mitigation of the UHI effect has been considered as a major aim for sponge city construction, which was also a key indicator for the performance assessment of China's sponge city construction, issued by the Ministry of Housing and Urban-Rural Development of the People's Republic of China (MHURD) (MHURD, 2015a, 2018). The MHURD also claimed that the average daily data of temperature from June to September should be used to assess the mitigation of the UHI effect (MHURDa, 2015, 2018). However, the day of December 23 was not in this period. The maximum (28 °C), minimum (20.9 °C) and average (24.5 °C) temperatures on December 23 were different from the mean values from June to September (35.3 °C, 22.1 °C and 28.6 °C, respectively). For reference, the monthly mean temperatures in 2010 are shown in *Figure 4* (MBSZM, 2011b). Therefore, the proper date for the anthropogenic heat calculations can be a certain day from June to September, when has the same average temperature with that in this period, rather than December 23.

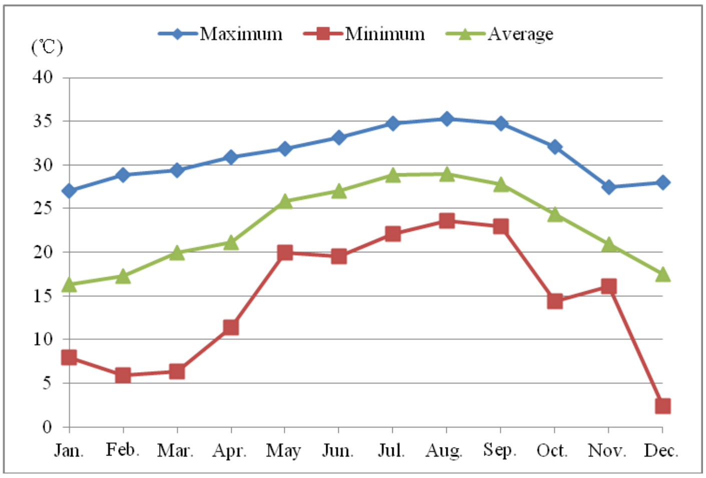

Figure 4. *Monthly mean temperature in Shenzhen (2010) (MBSZM, 2011b)*

Neglect in the situation of urban waterlogging

Mitigation and control of urban waterlogging and flooding is one of the foremost aims for China's Sponge City Construction pilot project programs. For instance, on September 30, 2015 the Chinese government has officially declared to build sponge cities to address urban waterlogging (Wang et al., 2018). It showed that China has been trying to turn its cities into "sponges" to better absorb rain following several fatal bouts of urban inundation in recent years. This target has also been written into two important official documents issued by the MHURD, which are *the Performance Evaluation*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37693780

Indicators of China's Sponge City Demonstration (Pilot version) in 2015 (MHURD, 2015b) and *the Assessment Standard for Sponge City (Discussion version) in 2018* (MHURD, 2018). In the past 60 years, Shenzhen has suffered as much as 111 times from flooding, water lodging and storm surge (Cai, 2017). As for the selection of key areas for sponge-like urban reconstruction, the situation of urban waterlogging in Shenzhen should be firstly incorporated into the evaluation system, including the spatio-temporal distribution, magnitude and frequency of waterlogging events. Investigation of urban waterlogging generally involves several factors, such as the extreme values of rainstorms, rainfall frequency of occurrence, land cover, drainage and runoff, urban drainage system capacity, and location of control structures (Xue et al., 2016; Ma et al., 2017; Sang and Yang, 2017; Lin et al., 2018). Neglecting urban waterlogging and solely using the 2010 precipitation data reduce the applicability of the selected areas for sponge city practices, as these regions could not reveal the extent of urban waterlogging events. In addition, the development of flood and waterlogging risk maps can help in improving the understanding of selecting key areas for sponge-like urban reconstruction (Zhang et al., 2005; Pandey et al., 2010). The Water Resources Bureau of Shenzhen Municipality has identified 446 areas with high risk of waterlogging in Shenzhen in 2015 (*Fig. 5*) (Cai, 2017). It is obvious that these waterlogging concerns have not been incorporated into the study of Zhao et al. (2018).

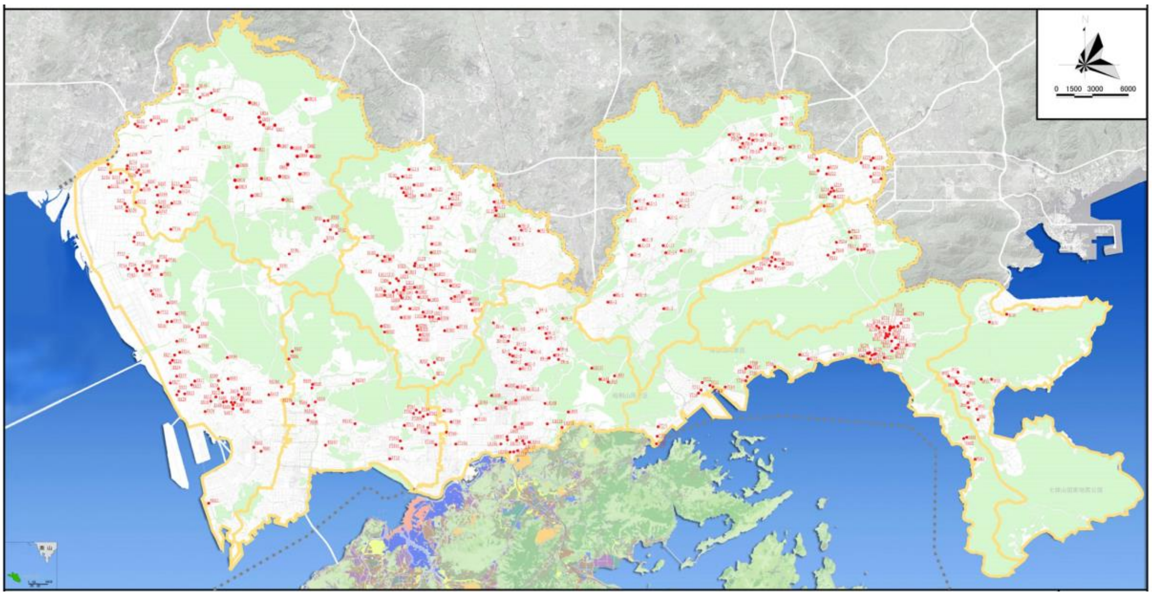

Figure 5. *Locations with high-risk waterlogging in Shenzhen (Cai, 2017)*

Potential implications of the methods used for emergy calculations of runoff and runoff pollution

Since Zhao et al. (2018) calculated the energy of runoff using the volume of runoff water, the water density and the Gibbs free energy, this energy was identified as the chemical potential energy. It appears like there is a misunderstanding in the underlying theory of chemical potential energy and geopotential energy (Kangas, 2002). As per the emergy theory, contributions of inland precipitation can be broken down into physical (runoff) and chemical (evapotranspiration) effects due to its gravitational and diffusive

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37693780

chemical potential energy relative to seawater (Odum, 1996; Buenfil, 2001; Chen et al., 2009; Mellino et al., 2014). Runoff represents a kind of elevated potential energy, rather than the chemical potential energy used by Zhao et al. (2018). The available energy associated with runoff can be a product of the mass flow rate, the gravitational constant, the elevation drop or head and the transformity of runoff geopotential (Kangas, 2002; Mellino et al., 2014). Since this geopotential is closely related to the elevation, the Digital Elevation Model (DEM) could be used (Wang et al., 2016). Thus, the equation of runoff energy can be used as *Equation 1* (Mellino et al., 2014):

$$En_{runoff} = A \times \rho_{water} \times R \times g \times h \qquad \text{(Eq.1)}$$

where A is the area in m^2, ρ_{water} is the water density (1E + 6 g/m^3), R is the runoff in meters, g is the gravitational constant (9.81 m/s^2) and h is the vertical distance from the water level.

In addition, Zhao et al. (2018) claimed that the runoff analysis was based on the yearly precipitation data obtained from the 2011 Shenzhen Statistical Yearbook. Since this yearbook (Page 372) only presented a single dataset of the 2010 annual precipitation (1634.0 mm), it showed that Zhao et al. (2018) did not consider spatial and temporal variability in the distribution of precipitation in the runoff analysis. Moreover, according to the data from 1981 to 2010, the Meteorological Bureau of Shenzhen Municipality reported that the average annual evapotranspiration in Shenzhen was 1433 mm, compared to the average annual precipitation of 1935.8 mm. The evapotranspiration should not be ignored in the runoff calculation in the common water budget equation, as annual data was used by Zhao et al. (2018). Evapotranspiration map can be gained implementing Turc equation in GIS, which is an empirical equation with good results estimating evapotranspiration values for areas with annual mean temperatures. Thus, the runoff map can also be generated by the difference between precipitation map and evapotranspiration map (Mellino et al., 2014). Concerning the emergy calculation of runoff pollution, Zhao et al. (2018) obtained the emergy of Chemical Oxygen Demand (COD) by multiplying the energy of COD by the transformity of wastewater as adapted from Bjorklund et al. (2001). Yet, this transformity was based on an emergy analysis of household wastewater in a Swedish town, which was considered to be a by-product of the summation of all activities in terms of water used and food consumed including transport, processing and food storage (Björklund et al., 2001). Therefore, it is possible that the emergy might be orders of magnitude larger than the transformity of COD in natural runoff required by Zhao et al. (2018). Therefore, this potential overestimation of runoff pollution with differences in orders of magnitude can potentially change the integration of the three indices, which can further affect the selection of suitable areas. Due to lack of the proper transformity of COD, a potential solution can be direct calculation of the emergy of runoff pollution in terms of the emergy associated with dilution of COD pollutant to its environmental safety concentration, using *Equations 2* and *3* (Li et al., 2013; Shao et al., 2017).

$$En_{runoff\ pollution} = \rho_{water} \times (M_{COD} / C_{COD}) - M_{runoff\ pollution} \qquad \text{(Eq.2)}$$

$$Em_{runoff\ pollution} = En_{runoff\ pollution} \times G \times UEV_{water} \qquad \text{(Eq.3)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37693780

where M_{COD} is the quantity of COD in grams, C_{COD} is the environmental safety concentration of COD in g/m^3, $M_{runoff\ pollution}$ is the total quantity of the runoff pollution in grams, G is the Gibbs free energy (4.82 J/g), UEV_{water} is the transformity of surface water (4.48 × 10^4 sej/J). According to China's environmental quality standard for surface water (GB 3838-2002), the environmental safety concentration of COD is 15 mg/L (EPB, 2002).

Choice of indices in selecting key areas

In order to select key areas for sponge-like urban reconstruction, Zhao et al. (2018) adopted three indices including stormwater runoff, runoff pollution and anthropogenic heat on the emergy-GIS method. In addition to the incorporation of water logging discussed in the previous section, techno-economic and institutional factors should also be considered in addition to the existing indices. From a practical perspective, the degree of demand, reconstruction costs, demonstration effects and importance of a certain region could have great impacts on whether this region can be selected as a priority area. These concerns have also been written into several official documents about China's sponge city construction plan. For instance, in January 2015, the MHRUD in conjunction with the Ministry of Finances and the Ministry of Water Resources issued a notice on selecting national-level pilot cities for sponge city construction with campaigning rules (Liu et al., 2017). These rules involved the positivity of local government, the rationality of construction demand and targets, the feasibility of construction projects, the innovation of investment and financing mode, and the integrity of supporting measures and infrastructure conditions (MHRUD, 2015). Therefore the three indices proposed by Zhao et al. (2018) might be incomplete for practical application in Shenzhen.

Based on the three indices, Zhao et al. (2018) presented emergy distribution maps and selection results with nine sub-districts. However, the validity of the results presented is questionable due to the aforementioned issues with data source, emergy calculation methods, and indices selection. Moreover, in November 2016 the Planning, Land and Resources Commission of Shenzhen Municipality (PLRCS) released two key planning documents on the sponge city construction in Shenzhen based on abundant data and materials (PLRCS, 2016a, b). The reports included several planning maps involving the spatial patterns, functional divisions and suitable areas (*Figs. 6-8*) (PLRCS, 2016a, b). *Figure 6* presents main urban green spaces, wetland patches, major rivers, ecological corridors and ecological matrix spatial patterns, which can help identify the green cover spatial patterns of the sponge city construction in Shenzhen. *Figure 7* presents the development and protection directions in different functional divisions. The suitable areas for the sponge city construction are shown in *Figure 8,* by identifying uncompleted urbanization areas and unsuitable areas (Karst distribution and slumping area, debris flow distribution area and landslide and slumping area). The Shenzhen Municipal Government selected 24 key areas with a total of 250.12 km^2 for promoting the sponge city pilot construction (PLRCS, 2016b). Therefore, local policies and planning can have a significant influence on future sponge city construction in Shenzhen, however, the implications of these decisions have not been considered in Zhao et al. (2018). These figures and aforementioned information can be incorporated into the discussion section by Zhao et al. (2018), which help assess the validity of emergy distribution maps and improve the areas selection results for sponge-like urban reconstruction.

Conclusions

The theory and practice of sponge city has been attracting extensive attention in addressing urban water-related issues especially in China. This paper focused on a study of the emergy-GIS method of selecting areas for sponge-like urban reconstruction in Shenzhen, with four main concerns including data source, neglecting the issue of urban waterlogging, potential inaccuracies in emergy calculations and indices in selecting key areas. As per the detailed discussion provided in the previous sections, there are four main conclusions that can help improve the analysis further and develop the emergy method integrated with GIS in the application of sponge city studies. These are summarized below:

(1) The analysis of selecting areas for sponge-like urban reconstruction based on an emergy-GIS method needs to be modified due to the improper time scale of data source and inconsistencies in the data itself. The main solutions include the rational selection of precipitation data, consideration of land use types in assumption of the first 50% of stormwater runoff and date selection for the anthropogenic heat calculations.

(2) Since mitigating urban waterlogging is the primary objective for sponge city construction, the spatio-temporal distribution, magnitude, and frequency of waterlogging events in Shenzhen should not be neglected and need to be revaluated while considering these parameters. Incorporation of areas with high risk of waterlogging is needed for the selection of key areas for sponge city construction.

(3) The methods used for emergy calculations of runoff and runoff pollution ignore runoff geopotential, spatio-temporal rainfall distribution, and evapotranspiration, which can potentially weaken the reliability of the emergy distribution maps. The theory and equations which we presened above can improve the methods for emergy calculations of runoff and runoff pollution.

(4) The existing indices for selecting key areas for sponge city construction should also consider techno-economic and institutional factors such as local planning and actions. This can help in providing a more robust spatial-discretization of key areas.

Abstract. Environmental protection requires adopting and implementing legal, economic, and societal procedures to limit the side effects of the massive real-estate and economic development in today's world. The purpose of this research was to investigate the implementation level of the eight main environmental laws affecting the construction industry in Saudi Arabia, and to identify the difficulties faced by practitioners to implement these laws. Using the descriptive analytical approach, this research described and analyzed the level of implementation of environmental laws using a Likert scale questionnaire distributed to 1000 organizations that work in 29 construction industry fields, in 13 Saudi Arabian regions. These questionnaires were filled out by engineers and professionals, authorized contractors, unauthorized contractors, individuals, and officials and owners. The one-way ANalysis Of VAriance (ANOVA) was applied to the data collected (at <0.05 level of significance), using SPSS Version 23.0 software. The overall environmental legitimacy implementation level in Saudi Arabia was found to be 2.95 out of 5.00 and a standard deviation of 1.13 indicating difficulties in defining the level for environmental legitimacy implementation in the construction industry. Results indicated that more attention was given to regulations related to the handling and disposal of radioactive materials, hazardous waste management, wastewater discharges, hazardous and dangerous substance compliance programs, environmental noise, general environmental requirements, air quality emissions, and external emergency planning with mean values of 3.23, 3.12, 3.10, 3.06, 3.05, 2.95, 2.80, and 2.75, respectively. Further investigation is required to evaluate internal auditing, accounting, and the availability of review teams regarding the environment in the industrial organizations in Saudi Arabia.
Keywords: *environmental laws implementation, statistical analysis, construction industry*

Introduction

Interest in environmental issues is widespread, with climate change and other environmental concerns receiving significant media attention and among the greatest threats facing the world today (White and Hunter, 2009). Today's, economic growth is based on the use of depleted energy resources leads to environmental pollution and stress. One the same time, it works to increase the development of individuals and society. Defining the equilibrium point between economic growth, societal development, and environmental pollution is one of the main points of concern to the world community in general and Saudi Arabia in particular. To coordinate the effort among the countries of the world, several international environmental agreements are

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37813802

signed concerning climate protection, Ozone layer, climate change, marine/water and environmental protection, availability of information and participation, waste management, prevention of environmental damage caused by chemicals, environmental impact assessment, protection of flora and fauna and biological diversity, and landscape besides the bilateral agreements. Moreover, the international effort seeks to include intergovernmental organization involvement as United Nations and World Trade Organization (Millimet and Roy, 2015; Eckersley, 2016; Barrett, 2005; Horn and Mavroidis, 2014; Kellenberg and Levinson, 2014).

Consequently, organizations are heavily implicated in these environmental issues. With greater awareness, the public is now demanding that organizations should take responsibility for voluntarily integrating social and environmental concerns into their operations and into their interactions with stakeholders. Organizations have responded to this call in a variety of ways, complying with regulatory requirements such as ISO 14001 certification and environmental responsibility (To and Lee, 2014). This synthesis of the literature delineates these three important concepts of corporate environmental performance and behavior, explains the causal links between the concepts, and depicts the concepts and causal links diagrammatically in a framework. Jordan et al. (2010) presented a model of environmental accountability and an outline of a process for achieving it and concluded that achieving and maintaining a sustainable environment requires more than accounting. They mention that actions, including legislation, regulation, mitigation, resource management, enforcement, education, and social responses to environmental challenges are the dynamic forces that produce results. Findings are environmental accounting can only tell us what those results are the ecosystem services paradigm, worthiness, and service to humanity. Environmental performance is the most important central concept in the framework. Improvements in environmental performance will eventually lead to the goal, namely sustainability. The general system of environmental protection and its executive regulation aims to protect the environment and prevent pollution, protect public health against the dangers of activities and actions harmful to the environment, conservation, development and rational use of natural resources, and make environmental planning an integral part of comprehensive planning for development in all industrial, agricultural, urban, and other fields (The General Authority of Meteorology and Environmental Protection, 2001).

In this context, an extensive body of literature has emerged recently on environmental legitimacy. The construction industry consumes a large portion of natural resources (Paudel et al., 2014), which has enormous side-effects, such as air and water pollution, deforestation, stratospheric ozone depletion, and increased threat of global warming (Hallett, 2002; Field, 2014). The government and public are setting an increasing number of legislative restrictions on businesses to implement more ecofriendly alternatives. The construction sector in Saudi Arabia includes a variety of activities such as construction, water piping, electrical connections, maintenance activities, and cleaning activities. Under these activities, there are multiple and interrelated sub-activities, which are classified into three basic groups: engineering design and consultancy; project execution, operation, and maintenance; and contracting activities. The fields of activity in this sector include building, roads, water and sanitation works, electrical work, mechanical work, industrial activities, marine works, dams, landscaping, afforestation, slaughterhouses, and building maintenance and operation (Contractor Classification Agency, Ministry of Municipal and Rural Affairs, 2018). The research work done in the field of environmental assessment of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37813802

construction industry has focused on measuring their environmental performance. The researchers noticed that, no research work has been done to assess the implementation of various environmental laws in any industrial sector. The main objective of this article is to present the results from analysis of the environmental legitimacy implementation in the Saudi Arabian construction industry.

Literature review

Legitimacy, as defined by Suchman (1995), is "a generalized perception or assumption that the actions of an entity are desirable, proper, or appropriate within some socially constructed system of norms, values, beliefs, and definitions". Expanding Suchman's (1995) definition of legitimacy into the environmental arena, Bansal and Clelland (2004) define environmental legitimacy as "the generalized perception or assumption that a firm's environmental performance is desirable, proper, or appropriate". Legitimacy is a complex concept, it is generally accepted that organizations have social responsibility towards society. On the other hand, legitimacy is temporally and culturally defined (Deegan, 2002), thus creating an immense challenge for organizations to secure legitimacy. Hutchins et al. (2019) utilized a stakeholder perspective to make the case that firms should focus on multiple constituents in order to be successful specifically with regard to building sustainability programs. They proposed a conceptual model and research propositions that can serve as a foundation for future research to empirically investigate the role of legitimacy in reducing skepticism of a comprehensive sustainability program. Building legitimacy, therefore, can serve as a foundation for operational and competitive success. The conditions of the social contract include granting of legal standing to organizations and offering support to an organization by supplying resources and labor.

A legitimacy gap can arise because of changing organizational performance, changing societal expectations, or a combination of both (Deegan, 2002). Furthermore, legitimacy can be both factual and perceptual. An example of factual legitimacy could be an environmental event (e.g., a catastrophic oil spill, or a fine for non-compliance), which is visible to stakeholders either by their own observation or through widespread media publicity. However, often external stakeholders cannot easily discern environmental performance (Hunter and Bansal, 2007), explaining the importance of perceptions. Legitimacy, as described above and adopted in the framework of this study, is concerned with a status or condition. Hence, it is essential to clarify, from the beginning, the difference between legitimacy (a status or condition) and legitimizing (an act or process aiming at legitimacy. Depending on whether the strategy is to gain, maintain, or repair legitimacy, an organization may engage stakeholders in the decision-making process, redefine its corporate mission statement, establish a separate department dealing with sustainability issues and/or obtain external certifications, contribute to charity, associate itself with other 'legitimate' institutions, and comply with legislation to appear legitimate in the eyes of its relevant publics (Bansal and Roth, 2000). While gaining legitimacy is proactive in nature, repairing legitimacy is generally a reaction to an unforeseen crisis (Suchman, 1995). Moreover, for any legitimizing strategy to be effective, communication between organizations and society is very important (Villiers and van Staden, 2006; Hasseldine et al., 2005; Toms, 2002).

Palazzo and Scherer (2006) proposed a fundamental shift to moral legitimacy, from an output and power-oriented approach to an input related and discursive concept of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37813802

legitimacy. This shift creates a new basis of legitimacy and involves organizations in processes of active justification vis-a-vis society rather than simply responding to the demands of powerful groups. They consider this a step towards the politicization of the corporation and attempt to re-embed the debate on corporate legitimacy into its broader context of political theory, while reflecting the recent turn from a liberal to a deliberative concept of democracy (see also Aerts and Cormier, 2009; Brønn and Vidaver-Cohen, 2009). For such organizations, a symbolic response may only intensify the threat to legitimacy, and consequently, society would be more likely to demand more substantive change in organizational performance (see further Burchell and Cook, 2008). It is argued that a symbolic legitimacy strategy, due to its rhetoric and often manipulative nature, would not give the same positive impact and could possibly further detriment the organizational legitimacy. As a final note, it is important to emphasize that by setting environmental legitimacy as a desired goal, the framework does not simplify the overly complex reality by nullifying other possible motives. Organizations embrace social and environmental responsibility for numerous reasons (e.g., (Okereke, 2007; Solomon and Lewis, 2002; Williamson et al., 2006).

At the global level, researchers were interested in studying the relation between environmental laws and the application of these laws on the real world. They recommended concentrating on environmental protection through public awareness programs. For example, Fernandes Rei (2018) highlighted the southern approaches brought to international governance gets mixed with the addressing of the challenges facing the legal science in harmony with the others sciences to handle with the complex environmental issues of the 21st century and concluded the southern influences suggest a more pragmatic, finalistic international law concerned about the results, the attainment of the targets suggested. Pavoni and Piselli (2016) introduced the implications for global environmental legislation of the maintenance of the continuous development goals, which occurred at the 2015 United Nations Sustainable Development Summit. Kelemen and Knievel (2015) pointed out the United States has lagged the European Union in its approval and implementation of significant multilateral environmental agreements. They argued varying levels of responsibility to substantive environmental management goals at the national level, rather than varying levels of commitment to international law, may best explain US and EU positions concerning international environmental policy.

Wang (2013) reviewed bureaucrats took positive efforts on environmental protection, making major investments in pollution control infrastructure in China. They seek to offer insight into several broader ongoing debates - about environmental regulation in developing countries, accountability and regime survival in authoritarian states, and legal development in China. Sand (2012) recommended a recent focus on techniques for support by the national community in the work and implementation of transnational environmental law. Van Kempen (2012) highlighted European environmental law has become progressively complex and needs the clarity to allow for adequate implementation and therefore effective environmental protection. Howarth (2011) focused the National Audit Office Report, Tackling Diffuse Water Pollution in England, addresses three issues: the Environment Agency’s recognition of the causes of diffuse pollution; whether attention of diffuse pollution is being raised; and whether the Agency is well using its legal the latter because of diffuse pollution.

Yang and Percival (2009) addressed the global growth of public concern about environmental issues over the lost several decades, environmental legal norms have

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37813802

become increasingly internationalized called “global environmental law” for the implementation, practice, and development of environmental law worldwide. Fine and Owen (2005) explored the origins of legal requirements for both public participation and modeling and then considers how models fit within planning processes. They highlighted how planning depends upon models and how model use impedes the public role because of limitations inherent in modeling. Freeman and Farber (2005) proposed framed the enterprise of environmental regulation and resource management as an exercise in designing governance institutions capable of managing multiple and incompatible demands over the long term. This approach departs from the traditional legal framing of such environmental conflicts as shorter-term and zero-sum questions of jurisdiction, authority, entitlement, and prohibition.

The aim of this research was to evaluate the Saudi environmental laws implementation in the construction industry by category. In the next section the methodology will be explained.

Methodology

The methodology involved the data collection regarding Saudi Arabian environmental legislation, population and sample size of respondents, questionnaire, and statistical analysis along with questionnaire analysis using SPSS (Statistical Package for Social Sciences) Version 23.0. *Table 1* highlights Saudi Arabian environmental legislation chronologically by promulgation date.

Table 1. *Saudi Arabian environmental legislation chronologically by promulgation date*

Saudi Arabian environmental legislation

The first comprehensive Saudi Arabian national environmental legislation was enacted on September 24, 2001 in the form of the General Environmental Regulation, Council of Ministers Resolution No. 193. It entered into force on October 31, 2002, and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37813802

its Implementing Rules were published on September 30, 2003. Under the Regulation, the Presidency of Meteorology and Environment (PME), an agency of the Ministry of Defense, is charged with the general supervision of environmental affairs in Saudi Arabia. The legislation sets out wide-ranging prohibitions of pollution and contamination of air, land, and water, with reference to all parties involved in services, industry, or other economic activities. Owners of 'projects' that might influence the environment, are required to comply with existing and future environmental specifications, standards, measurements, and guidelines as promulgated by the PME and set out in the appendices of the Implementing Rules. Moreover, prior to the setting up of a project, an environmental evaluation study must be completed and approved by the PME.

The detail of the legislation is contained in the appendices of the Implementing Rules, as Environmental Protection Standards, Procedures for the Assessment of Environmental Effects of Industrial and Development Projects, Manual of Environmental Qualification Procedures, Rules and Procedures for the Control of Hazardous Waste, National Contingency Plan for Combatting Pollution by Oil and other Harmful Substances of the Marine Environment in Emergency Cases, and Violations and Fines. Apart from the above national environmental legislation, the following specific regulations are also applicable in certain areas of Saudi Arabia:

- The Royal Commission for the industrial cities of Jubail and Yanbu has issued detailed local environmental regulations applicable to facilities located within the Royal Commission areas and contractors operating therein, of which the Jubail Industrial City Royal Commission Environmental Regulations of September 1999 are the most recent.
- Pollution and contamination incidents within ports under the administration of the Saudi Arabian Seaports Authority are governed by the Rules and Regulations for Seaports of the Co-operation Council for the Arab States of the Gulf of 1985, as revised in 2006.
- Saudi Aramco, which administers the oil loading terminals at Ras Tanura, Ju'aymah, and several smaller terminals independently of the of the Seaports Authority, has its own set of rules entitled "Saudi Aramco, Oil Ports & Terminals, Rules, Regulations and General Information."
- Saudi Arabia has ratified the International Convention for the Prevention of Pollution of the Sea by Oil of 1954 (OILPOL 1954, 1958) and its Amendments of 1962, 1969, and 1971, and the International Convention on Civil Liability for Oil Pollution Damage of 1969 (CLC, 1969) and its Protocols of 1976 and 1992.

Table 1 lists the Saudi Arabian environmental legislation chronologically by promulgation date that adopted in this research. *Table 2* lists the questions for the designed questionnaire.

Population and sample size

A survey of construction industry fields was conducted in which the respondent categories included engineers and professionals, authorized contractors, unauthorized contractors, individuals, and officials and owners, along various Saudi Arabian regions. Of the total construction industries (18,573) only 1,000 were incorporated into the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37813802

survey analysis. From the respondent category of engineers and professionals, a greater number of respondents were from the categories individual, maintenance and operation for electrical works, and city cleaning and waste disposal from a total of 202 construction industries. Authorized contractors showed more response from building maintenance, from the total of 29 industries. From unauthorized contractors, a greater number of responses were received from buildings, and from maintenance and operation of electrical works, from a total of 29 industries. The category ‘individual’ got more responses from city cleaning and waste disposal, from among 196. Officials and owners had more responses from catering for medical centers, among 189.

When Saudi regions were compared with construction industries, the eastern region got more responses for water and sanitation, and maintenance roads among 453 districts, regarding 114 industrial fields. The Al Baha region had almost no responses among nine fields, as did the Al-Jouf region among 13 fields and the northern border region among six fields. The Riyadh region responded better in all fields when compared to all other regions as it showed more response towards city cleaning and waste disposal among 443 fields. The remaining regions, like Qassim (62 fields), Madinah (35 fields), Tabuk (12 fields), Jazan (10 fields), Hail (17 fields), Asir (62 fields), and Najran (44 fields) showed less response. The Makkah region responded for catering by individuals from among 173 fields. The details for the sampling plan are shown in *Table 3*.

Questionnaire

After extensive review of the literature and studies related to environmental assessment, it was decided that the questionnaire was the most suitable method for data collection. For this purpose, a questionnaire was designed to meet the objectives of the research and the requirements for answering its questions. These questions consisted of eight sections as general requirements, air quality/emissions, waste water discharges, hazardous waste management, radioactive materials handling and disposal, hazardous/dangerous substance compliance programs, environmental noise, and external emergency planning. The sections include 7, 6, 6, 7, 2, 6, 3, and 12 questions, respectively, as shown in *Table 2*.

Table 2. *Environmental questionnaire questions*

Environmental requirements		Environmental requirements	
F1. General requirments		F4.7	Hazardous wastes spill prevention systems in accordance with any applicable regulations
F1.1	Up-to-date operating license	F5. Radioactive materials handling and disposal	
F1.2	Environmental violations relating to environmental matters approved or signed?	F5.1	Handle the final disposal of radioactive materials, with the procedures the Rules
F1.3	Environmental impact assessment done during the project feasibility stage	F5.2	Storage, treatment, recycling, and transportation of radioactive wastes, in accordance to regulations
F1.4	Making modifications to an existing project, using technologies with lowest level of pollution to the environment	F6. Hazardous/dangerous substance compliance programs	
F1.5	Use of natural resources and apply recycling technologies and reuse of resources	F6.1	Records maintained of dangerous chemicals used and stored
F1.6	Planning for projects and programs, with developing environmental aspects	F6.2	Handling of final disposal of poisonous, hazardous materials, with the procedures
F1.7	Regulations and standards when designing or operating any project or activity	F6.3	Treatment, recycling, and transportation of hazardous waste as per regulation

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37813802

F2. Air quality/emissions		F6.4	License and approval to perform disposal of hazardous waste as per regulation
F2.1	Stationary sources of air emissions and recording of sources	F6.5	Responsibility for any incidents of environmental pollution and reporting of any incident
F2.2	Air emission limit details	F6.6	Training programs for the handling, transportation, storage, recycling, disposal of toxic, hazardous, waste
F2.3	Emission frequency and methodology for monitoring, and evaluation	F7. Environmental noise	
F2.4	Emission within allowable limits permitted in the environmental standards	F7.1	Prevention of noise pollution when operating machinery or other equipment or using horns or loudspeakers
F2.5	No leaking or emission of air pollutants into the work place beyond the allowable limits	F7.2	Check noise levels do not exceed allowable environmental standard limits
F2.6	Adequate ventilation system	F7.3	Upgrade technologies and equipment used in existing activities to attain allowable noise levels
F3. Waste water discharges		F8. External emergency planning	
F3.1	Prevention of contamination of surface and ground waters	F8.1	Emergency plans to prevent or alleviate the hazards of such impacts
F3.2	Prohibition of discharge of harmful pollutants	F8.2	Importance to environmental aspects while planning for projects and programs
F3.3	Wastewater discharge to treatment plant or Municipal zone	F8.3	Facility to cope Environmental disaster management plans
F3.4	Discharge of waste water to natural environment with permission	F8.4	Environmental protection from pollution resulting from conducted projects
F3.5	Discharge of wastewater; are any of the compounds, exceeded?	F8.5	Training given with technical emergency environmental protection plans
F3.6	Limitation level in Mixing Zone, exceeded?	F8.6	Emergency plans in case of a pollution emergency incident
F4. Hazardous waste management		F8.7	Coordination to safe employees from environmental damage resulting from emergency pollution incidents
F4.1	License or permit for the handling of hazardous wastes	F8.8	Emergency plans to handle hazards situation
F4.2	Hazardous waste disposal standards (1413-03)?	F8.9	Emergency plans with qualified work force and equipment
F4.3	Permit for transport and/ disposal of hazardous wastes?	F8.10	Emergency plans for projects conducted and prevent or alleviate the risks of potential adverse environmental impacts
F4.4	Record of hazardous wastes and disposal in accordance to regulations?	F8.11	Periodically review of emergency plans that protect the environment from pollution or prevent adverse impacts on the environment
F4.5	Check hazardous wastes are not mixed with other types of waste	F8.12	Conduct periodical trial drills regarding the implementation of emergency plans
F4.6	Hazardous wastes labeled during storage in accordance with regulations		

**Correlation is significant at the 0.01 level (2-tailed)

A Likert scale (*Table 4*) was used to measure the responses of participants to the questionnaire elements. The questions were discussed with 30 reviewers in concerned governmental agencies, and then modified according to reviewer feedback to evaluate their validity. Cronbach’s alpha was used to measure the questionnaire’s internal consistency, which was found to be 0.71 by SPSS, indicating a high level of consistency. *Table 5* shows the Pearson correlation coefficient (ρ) between each questionnaire item and the corresponding dimension. All coefficients were positive

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37813802

except F1.2 was negative, as a higher item's score represented a good correlation for the dimension. It shows the significance of items to the corresponding dimension.

**Correlation is significant at the 0.01 level (2-tailed)

Statistical analysis

For this work, the Statistical Package for the Social Sciences (IBM SPSS Statistics, 2015) was used for data description and analysis. The following techniques were used:

- Descriptive statistics measures to describe the collected data in terms of frequencies, mean, and standard deviation.
- Cronbach's alpha was used to measure the questionnaire’s internal consistency.
- Pearson correlation coefficient (ρ) was used to measure the correlation of each subfactor with the related factor.
- One-way ANOVA was used to evaluate whether the mean of data from one group was different from the others.
- Levene’s test was used to measure homogeneities between sample groups.

The statistical analysis and test results at the 0.05 level of significance are described in the next section. Also, the performance of the law implementation score in addition to the performance for each construction industry category is estimated based on the collected data.

Results and discussion

Table 6 reflects the overall average and average environmental performance of each factor for of the 13 regions. The table highlights that the overall average Likert scale value for Asir, Riyadh, Madinah, Makkah, Eastern, Najran, Al Baha, and Qassim regions are 3.03, 3.03, 3.04, 3.09, 3.01, 3.10, 3.02, and 3.08 respectively. This indicates that the environmental laws implementation is seen more in the southern part of the KSA. The remaining regions perform less than 2.99. Also, the table shows that industry categories get a mean Likert scale value of 3.23, 3.12, 3.10, 3.06, 3.05, 2.95, 2.80, and 2.75 for radioactive materials handling and disposal (F5), hazardous waste management (F4), wastewater discharges (F3), hazardous dangerous substance compliance programs

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37813802

(F6), environmental noise (F7), general environmental requirements (F1), air quality emissions (F2), and external emergency planning (F8). These factors have high exposure of harmful effects on the environment which should be controlled.

Table 7 shows the overall average and average environmental performance of each factor of the 29 construction industry categories KSA. It highlights the average Likert scale score for slaughterhouses, catering for individuals, landscaping, maintenance buildings, maintenance and operation of slaughterhouses, maintenance and operation of communication technology, maintenance and operation of electrical works, city cleaning & wastes disposal, roads, marine works, maintenance and operation of electronic works, maintenance and operation of mechanical works, electrical works, catering for medical centers, buildings, maintenance health centers, industrial works, dams, maintenance roads, and maintenance and operation of marine works are 3.21, 3.20, 3.19, 3.14, 3.13, 3.11, 3.09, 3.09, 3.08, 3.08, 3.07, 3.07, 3.06, 3.06, 3.04, 3.02, 3.01, 3.01, 3.01, and 3.00 respectively highlighted in the table by a green color. Twenty construction industry categories achieve a score greater than 3.00. This indicating that these industries follows to some extend the Saudi environmental laws.

These industries are imposed by strict rules of Saudi government and continuous monitoring done to protect the environments and heavy penalties imposed if disposed in a wrong manner. The environmental monitoring system and procedures in Saudi Arabia is done with perfection to save the environment and maintain the society.

The remaining industries as electronic works, mechanical works, water & sanitation works, maintenance of landscaping, maintenance and operation of industrial works, communication technology, maintenance and operation of water & sanitation works, well drilling, and maintenance and operation dams achieve a total score between 2.80-2.99 with average Likert scores of 2.95, 2.94, 2.93, 2.90, 2.89, 2.86, 2.86, 2.81, and 2.80 respectively, as these construction industries are far away from city dominated areas and does not affect the environment. Also, the performance of the factors is similar to data in *Table 6*.

Table 6. *The overall average and average environmental performance of each factor for of the 13 regions*

Region	Environmental law category (mean Likert scale value)								Overall average	Rank
	F1	F2	F3	F4	F5	F6	F7	F8		
Jazan region	2.66	2.43	2.85	2.89	3.05	3.05	3.07	2.48	2.83	12

Tables 8–15 shows the count and percentage of respondents in terms of the Likert scale, mean, standard deviation in terms of "mean±standard deviation", priority, and response for all subfactors. The tables show the counts (Count) of all respondents with respect to opinions "strongly disagree, disagree, neither, agree, strongly agree) in the third to seventh columns and respondent percentages (N%). Column 7 calculates the mean while column 8 determine the standard deviation and column 9 highlights priority and finally column 10 attributes the responses.

Table 16 shows the corresponding values for the overall performance for implementation. *Table 8* demonstrates that the mean overall performance in implementing the general requirements of Saudi environmental laws by the construction industry is equal to 2.97 ± 1.31. This indicates that the implementation level of the general requirements is difficult to be defined by practitioners and that the environmental protection concepts were not clear to respondents. The respondents agree with F1.1 that the facility has an up-to-date operating license from the government and agree with F1.2 related to the question "Has the facility been cited for any

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37813802

environmental violations or been issued any notifications relating to environmental matters, and if so, have the conditions or violations been addressed and subsequently approved or signed off by the appropriate authorities”. The response for F1.7 was “Disagree” with a mean 2.36 ± 1.46, indicating that the facility did not comply with all applicable regulations and standards when designing or operating any project or activity. The remaining sub-factors performance was “Neither”, as shown in the tables.

Table 8. *General environmental requirements implementation descriptive statistics*

Sub-factor		Strongly disagree	Disagree	Neither	Agree	Strongly agree	Mean	Std. deviation	Priority	Response
F1.1	Count	193	208	242	197	160	2.92	1.34	4	Neither

	N %	16.7%	22.9%	23.1%	21.7%	15.6%				

Table 9 shows the performance of the construction industry in implementing environmental laws, regarding air quality/emissions. The overall performance level was 2.85 ± 1.35, indicating that the response was “Neither”. The performance for all sub-factors was also “Neither”, indicating that the respondents could not decide on the level of implementation. The lowest performance level for F2.4, related to “Does the facility ensure that emission of smoke, gases, vapors, and solid or liquid residues resulting from the burning of any kind of fuel or a similar action are within allowable limits permitted in the environmental standards listed under Attachment A of this document?” was a 2.70 ± 1.37. F2.5 is related to “Does the facility ensure that there is no leaking or emission of air pollutants into the work place beyond the allowable limits of the environmental standards?”. This analysis has priority level of 5 and response result as neither, with a mean of 2.74 ± 1.42 which confirms that the company has no proven records about the leakage of emission and air pollutants beyond allowable standard limits.

The overall performance for implementing regulations related to wastewater discharges from the point of view of respondents is “Neither” with a mean of 3.11 ± 1.30, as shown in *Table 10*. The lowest performance was for F3.1, related to whether the various facilities take the necessary precautions to ensure prevention of direct or indirect contamination of surface, ground, and coastal waters that might be caused by solid or liquid residues; and take actions to ensure that the soil and land were preserved and its deterioration and/or contamination was curbed. “Neither” was the

Table 11 summarizes the performance of hazardous waste management regulation implementation. It indicates that the overall mean is 3.12 ± 1.26, and that the implementation scale is “Neither”. As shown in the table, the implementing of environmental regulations for this factor ranges from 3.27 for F4.3 to 3.01 ± 0.26 for F4.4 indicates the extreme keenness of the Kingdom’s institutions in the construction industry that deal with hazardous materials.

The performance regarding radioactive materials handling and disposal (shown in *Table 12*) indicates an implementation level mean of 3.23 ± 1.35, and a small range of 0.02 between F5.1 and F5.2, due to the nature of materials that may cause severe chronic diseases and affect the health of individuals and workers. The main reason for the increased percentage of disagree in F5.2 “storage, treatment, recycling, and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37813802

transportation of radioactive waste in accordance to regulations" is due to the nature of the radioactive waste in Saudi Arabia resulting from water treatment with the acceptable levels and controlled completely with the Saudi governmental specialized agencies. The inspection team totally ignore, because used in lower levels and it is within the radioactive acceptable limits zone of disposal standards, but the engineers in and around the company feel that it is disposed with not following the standards.

	N %	13.1%	20.0%	20.7%	23.2%	23.1%				

Table 13 shows the implementation level of hazardous or dangerous substance compliance-program implementation. The performance of implementation had a mean of 3.07 ± 1.30, and the overall performance is "Neither". The lowest implementation level is for F6.1, related to the existence of a listing of all dangerous chemical substances used at the facility on-site (2.75 ± 1.05 and a "Neither" response).

Table 14 demonstrates the extent to which the companies apply environmental noise laws and whether they take the necessary precautions to ensure that noise levels do not exceed permissible/standard environmental limits. The overall average performance measure for this factor was 3.05 ± 1.

Table 15 shows the implementation level of Saudi companies for the emergency planning factor. It shows that the average overall performance is 2.78 ± 1.28. Sub-factor F8.1 represents the opinion of the participants in the field study whether the facility has the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_37813802

potential to cause adverse impacts on the environment, and if so, whether the facility has prepared emergency plans to prevent or alleviate the hazards of such impacts, and finally whether the facility has enough means to implement these plans. The average opinion of the participants was 2.80 ± 1.28, representing a "Neither" response. The reason for this evaluation might be explained by the fact that the responsibility to deal with emergency cases was assigned to the Saudi General Directorate of Civil Defense and thus, that the emergency work was not assigned to the industrial organization itself. The lowest performance was assigned to F8.4 (2.59 ± 1.18) with a "Disagree" response in relation to "Has the facility verified plans required for environmental protection from pollution resulting from conducted projects, and periodically reviewed these plans to coordinate efforts for their implementation?"

Table 17 shows the one-way ANOVA for the for environmental law implementation by field of construction industry. It shows the mean, standard deviation, standard error, 95% confidence interval for the mean, test of homogeneity of variances, ANOVA'F and significance, and the statistical significance for each factor. From this table, we conclude that there is no homogeneity between samples of the implementation levels for F1.3, F1.4, F1.6, F1.7, F2.1, F2.2, F2.4, F2.5, F3.1, F4.2, F4.3, F4.4, F4.5, F4.7, F5.1, F6.1, F6.3, F6.4, F6.5, F6.6, F7.2, F7.3, F8.1, F8.3, F8.4, F8.5, F8.6, F8.8, F8.9, F8.10, F8.11, and F8.12, wherein the values of F < 0.05; therefore, the ANOVA test cannot be completed. However, the ANOVA can be completed for the remaining factors. Judgment for non-homogeneity is based on calculating the Levene's test and corresponding significance level of <0.05.

Moreover, the one-way ANOVA test for F3.2, F3.3, and F8.2 demonstrates that homogeneity of samples does exist and consequently, there is a difference between the implementation levels of the environmental laws in all 29 construction industry fields with mean levels of 3.18, 3.12, and 3.06.

The significance value for ANOVA regarding F1.1, F1.2, F1.5, F2.3, F2.6, F3.4, F3.5, F3.6, F4.1, F4.6, F5.2, F6.2, F7.1, and F8.7 was >0.05, indicating that there is no statistical evidence that there is a difference between the implementation levels for the corresponding factors. The main results obtained from this research are supporting the work done in China by Wang (2013) and van Zeben (2014) as they highlighted the importance of monitoring the environmental laws implementation not by enforcement but by societal involvement.

Conclusions

The aim of this research was to investigate the environmental legitimacy implementation in the Saudi Arabian construction industry. To do this, eight regulation categories, each including a set of sub-laws, were defined: general environmental requirements, radioactive materials handling and disposal, hazardous/dangerous substance compliance programs, air quality/emissions, environmental noise, wastewater discharges, external emergency planning, and hazardous waste management. An analytical statistical approach was used to describe and analyze the data set collected in a newly designed Likert 5-scale questionnaire distributed to 1000 organizations that work in the construction industry in 13 regions in Saudi Arabia. These were filled out (through direct meeting with via email) by engineers and professionals, authorized contractors, unauthorized contractors, individuals, and officials and owners. The analysis was done using measures of descriptive statistics, Cronbach's alpha, Pearson correlation coefficient, ANOVA, and the Levene's test (which was used to measure homogeneities between sample groups). The main purpose was to answer the following questions: "Does the construction facility applies the set of environmental regulations or not?" and "Does the construction facility applies the regulations for each law or not?" The levels of implementation were also indicated.

The main finding of this research was that the mean implementation performance was 2.95, indicating a Likert scale of "Neither". This indicates that the participants had difficulty defining accurate answers regarding environmental legitimacy implementation in the Saudi Arabian construction industry. The implementation levels for all eight sub-regulations were defined as "Neither". The one-way ANOVA test for F3.2, F3.3, and F8.2 demonstrates that homogeneity of samples existed and, consequently, that there was a difference between the implementation levels of the environmental laws in all 29 construction industry fields (mean levels of 3.18, 3.12, and 3.06). The significance value (>0.05) for ANOVA regarding F1.1, F1.2, F1.5, F2.3, F2.6, F3.4, F3.5, F3.6, F4.1, F4.6, F5.2, F6.2, F7.1, and F8.7 indicated that there is no statistical evidence that there is a difference between the implementation levels for the corresponding factors. The remaining sub-regulations do not appear to exhibit sample homogeneities according to the Levene's test, so ANOVA could not be conducted. The means for the eight regulation categories (arranged from highest to lowest) for radioactive materials handling and disposal, hazardous waste management, wastewater discharges, hazardous and dangerous substance compliance programs, environmental noise, general environmental requirements, air quality emissions, and external emergency planning were 3.23, 3.12, 3.10, 3.06, 3.05, 2.95, 2.80, and 2.75, respectively. This performance level could be explained by the existence of multiple systems related to the environment, the conflict of competencies between the government agencies concerned with the environment, and the failure to activate the current environmental legislation to the appropriate extent. The results of this research are in consistence with the work done by Wang (2013) and van Zeben (2014) in China.

The natural expansion of this research would be to evaluate the implementation of environmental accounting audits and to measure the environmental awareness at different levels of employers in the construction industry. Moreover, an investigation is required to evaluate the existence of internal environmental audit teams in industrial organizations.

Abstract. Biochar is used for water treatment as a low-cost adsorbent with high efficiency. It has a large pore volume and is environmentally friendly. Recently, biochar has been a popular topic in the field of environmental management and wastewater treatment. There has been a rising interest in biochar due to its low-cost production, environmental stability and potential effects on several ecosystem functions. A high number of studies have shed light on the potential use of biochar as a sorbent as well as the application of biochar to adsorb pollutants in wastewater and enhance the efficiency of constructed wetlands. The removal of heavy metals from aqueous solutions was examined and biochar was found to efficiently remove more heavy metal ions from these solutions than activated carbon. This study has shed light on the role of biochar in water treatments and provided an updated review to produce biochar from different biomass feedstock around the world.
Keywords: *biochar, biomass feedstock, biochar preparation, water treatment, constructed wetlands, potentially toxic elements*

Introduction

A basic necessity of life is clean and safe drinking water. It is documented that water contamination with potentially toxic elements (PTEs) has been a critical problem since the last few decades, which risks the lives of humans, plants, and animals around the globe. Due to increasing amounts of waste and lack of waste management, water bodies have become polluted. In the 1990's, a huge percentage of the world's population was suffering from water scarcity. In 1990, it was reported that more than 2.7 billion people around the world lacked access to improved sanitation services such as garbage collection and wastewater disposal. Raising awareness for common people and waste management authorities brought a mere 7% improvement. In 2015, the number of people who lacked access to sanitation facilities decreased to 2.4 billion (WHO, 2015; Sanjrani et al., 2018). Waste management is a big issue. It is estimated that more than 80% of wastewater in developing countries is released into the environment without treatment. Most problems in regards to wastewater are faced by urban populations. Currently, 54% of the world's population are living in urban areas and the percentage is expected to increase to 66% by 2050 (WHO, 2015). Thus, providing good quality sanitation and wastewater treatment facilities is required. Mining or chemical plants should be documented to deal with sewage, sludge storage and waste treatment, as an attampt to supply safe drinking water to people in affected areas. Several studies are being conducted for solid waste management plans (Sanjrani et al., 2019; WHO, 2015).

DOI: http://dx.doi.org/10.15666/aeer/1702_38033818

A report has been issued by the United Nations World Water Assessment Programme (UNWWAP, 2017) which stated that in some developing countries, around 80% of sewage effluent and more than 70% of the industrial wastes are being discharged into surface water without proper treatments. This means water bodies contain several potentially toxic elements (PTEs) and the quantities of these pollutants have risen to over the year. These toxic elements include arsenic (As), chromium (Cr), cadmium (Cd), copper (Cu), nickel (Ni), mercury (Hg), lead (Pb), vanadium (V), selenium (Se), and zinc (Zn) (Sanjrani et al., 2018; Rakotondrabe et al., 2018). Recent studies have recommended that easy and low-cost water treatment techniques should be introduced to the public; especially in the affected areas where health is threatened due to water pollution. Alternative water supply options should be introduced and should consider the social, and economic status of the local population. Several options have been implemented for treatment, but wetlands technology has been found more efficient and low-cost. One of the best and valuable services given by wetlands is that they generally create a system where everything occurs naturally. Constructed wetlands are complex systems with large number of active chemical, physical, and biological processes that mutually influence each other and treat the water properly (Varga and Oirschot, 2017; Sanjrani et al., 2017).

Recently, the use of wetland media “biochar” to increase constructed wetland efficiency for treating wastewater has been demonstrated in several studies. Results from those studies have been highly appreciated by the organizations who work for the improvement of water quality. Biochar was first mainly studied as an amendment of soil but further studies found out it can also acts as a well-adsorbent; later, it was proved to be an easily available option for low-cost wastewater treatment. In addition, after activated carbon, biochars got more attraction for their new techniques as an effective low-cost alternative. Biochar is a generally carbon-rich solid material generated by the pyrolysis of bio-organic things at middle to low temperature approximately (<700_C) under anoxic conditions. The formation methods of biochar are: pyrolysis, hydrothermal carbonization, gasification, and so on. Moreover, some studies concluded that different bio-organic materials, modification methods, and pyrolysis temperatures may show different performances. In addition, many studies also demonstrated that biochar stimulates N transformation, due to its highly porous structure and DOM release (Gupta et al., 2015; Lehmann and Joseph, 2015). The present paper attempts to provide an overview on the role of Biochar in wetlands systems and its effect on removal efficiency. It also provides review about the materials from which biochar is being generated as well as its preparation methods.

Biochar production around the world

The interest in biochar firstly grew in USA, nearly 17 million tons of organic waste was identified in Washington State. This waste mostly came from wood and straw, a situation where pyrolysis is an attractive option to recover energy and produce stable carbon, which can then benefit the soils and climate (Bio, 2018). The Center for Sustaining Agriculture and Natural Resources (CSANR) and the Washington Department of Ecology at Washington State University has produced a series of in-depth reports on biochar production, use, and economics. Later, it was innovated by Australia, China and Japan. Water treatment by biochar and constructed wetlands has been widely studied in temperate countries such as Canada, Belgium (Lesage et al., 2007), the Republic of Czech

DOI: http://dx.doi.org/10.15666/aeer/1702_38033818

(Vymazal, 2014), the United States of America (Kadlec et al., 2010) and the United Kingdom (Shutes, 2001). It has also been studied in tropical countries such as Thailand (Kantawanichkul et al., 2009), Kenya (Mburu et al., 2012), Malaysia (Sim et al., 2008) and in subtropical countries such as Australia (Greenway, 2005). Up-to-now, it is being used all around the world, especially; addition of biochar in constructed wetlands is an innovation and adopted by several countries. Recently, For biochar, different materials have been used in different countries, some of them are shown in *Table 2*.

Biochar preparation methods

Recently, the preparation of biochar requires some methods including the cleaning and drying of material, pyrolysis, hydrothermal-carbonization, gasification, as well as some other methods. The preparation of Biochar is not complicated; the basic process is known as pyrolysis. Pyrolysis releases gas as the material is broken down, a process (heating rate up to 1000 °C/s) of a decomposition reaction under high temperature and anoxic-conditions. Before material transferred into high temperature resistance furnace for pre-oxidation, carbonization and activation treatment, the material (mostly less than <2 cm in size) is washed with HCL plus water solution for a few hours and then is baked in a vacuum oven at about 65-105 °C for 12 h depending on the type of material (Li et al., 2018). After pyrolysis, major changes can be found in the material. Finally, the obtained product is immersed in a 1 M hydrochloric acid solution for 2 h to remove impurities, such as ash, from the product, it is washed with deionized water until at a considerable pH level, and then it is baked in an oven (105 °C) for 1-2 h, until the product is ready. It can be further divided into slow-pyrolysis, rapid-pyrolysis, and flash-pyrolysis which are based on temperature, time, and the heating rate of pyrolysis process. Slow-pyrolysis is considered as a main preparation of biochar (Shaheen et al, 2018; Li et al., 2018; Patra et al., 2017; Kambo and Dutta, 2015).

Another method for the preparation of biochar is hydrothermal-carbonization. From studies (Berge et al., 2015; Tan et al., 2015; Kambo and Dutta, 2015) the hydrothermal-carbonization is a process under heating conditions and high pressure, which uses water as the reaction medium. In addition, the reaction of biomass is undertaken in a system (an underwater stagnant system), which has a relatively low temperature (<350 °C) and pressure of 2–6 MPa for 5 min to 16 h. It was concluded in the study (Breulmann et al., 2017), that pyrolysis is more effective than hydrothermal-carbonization. The capacity of cat-ion exchange for sewage sludge was successfully reduced by hydrothermal-carbonization but stayed on a higher-level than after pyrolysis, because it failed to increase the chars' resin-extractable phosphorus contents. In addition, slow pyrolysis is recommended as the comparison was studied, chars were made from same feedstock material (corn, C4) while using hydrothermal-carbonization and slow pyrolysis. Results showed differed chemical properties and decomposition behavior, even different physical appearance. Although both chars were produced from the same feedstock, results by pyrolysis had a higher potential for carbon sequestration than hydrothermal-carbonization. In addition, this method is limited by the preparation conditions; there is a high preparation cost, and a high need for high pressure and high temperature of the expensive reactor (Berge, 2015; Tan et al., 2015; Kambo and Dutta, 2015; Malghani et al., 2013).

Other methods are mainly used to generate gaseous materials or bio-oil, such as gasification, drying, rapid pyrolysis, and "flash" pyrolysis (Tan et al., 2015). Different techniques to prepare biochar require different temperature and time, it is shown in *Table 1.*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38033818

Table 1. *Different techniques to make biochar. (Modified from Tan et al., 2015; Oliveira et al., 2013; Deng et al., 2017)*

Main products	Material size	Mode	Temp °C	Heating rate	Residence time
Oil, gas, char ~1/3 each	1-200 mm	Slow pyrolysis	400-650	Slow 1-20 °C/m	Minutes to days
Bio-oil, 75% Char, 10-20%	<1 mm	Fast pyrolysis	700	Very fast >300 °C/s	Second
Gas, 80% Char, 10-20%	5-20 mm	Gasification	>800	2-100 °C/m	5-30 ins

Characterization of media

Biochar prepared from different biomass, has different physic-chemical properties: the size of particle of the feedstock, the temperature and pyrolysis, the time of pyrolysis, and the conditions of modification. It is recommended to know the characterization of media so one can recognize if it is prepared well or not. Characterizing the biochar is mostly done by scanning electron microscopy/energy dispersive X-ray spectroscopy (SEM/EDX) (Li et al., 2018; Tan et al., 2015). Many factors affect the structure of biochar; in addition, biochar has an abundant surface of functional groups (carbonyl, carboxyl, hydroxyl and methyl). In addition, the high specific surface area, the natural and developed pore structures, and the stable molecular structure, allowbiochar to have good adsorption performance. Hence several studies have concluded that biochar is favorable for waste water treatment (Tan et al., 2015; Li et al., 2018; Berge, 2015; Tan et al., 2015; Kambo and Dutta, 2015; Malghani et al., 2013).

Biochar from different sorbent materials

Different types of sorbent materials were studied and used in the previous studies because media influences numerous processes. Media controls the retention time, rate of water infiltration, provides surface biofilms, provides sorption surfaces so nutrients can absorb heavy metals, filters sediments and particulates, and provides a nutrient source for macrophytes and microbes (bacteria, fungi, protozoan, algae) (Greenway, 2008). Recently, the following sorbent materials are being used: hydrous zirconium oxide (Kumar et al., 2018), clay minerals (Uddin, 2017), brick dust (Allahdin et al., 2017), activated alumina (Millar et al., 2017), nano-materials (Yazdani et al., 2017; Gunti et al., 2018), hematite and feldspar (Yazdani et al., 2017), Zeolite (Visa, 2016), activated carbon (Saleh et al., 2017; Shaheen et al., 2015), and limestone (Iakovleva et al., 2015). Five to ten years ago, coal fly ash (Hizal et al., 2013), Zeolite (Shaheen et al., 2012), and red mud (Gupta and Sharma, 2002) were used in removal of PTEs from waste-water. Though they are effective for water treatment, the most of these sorbents keep some demerits, such as low stability, production of waste products, difficulties in recyclability, high operational cost, use of hazardous chemicals in the synthesis of some sorbents and high operational cost (Gunti et al., 2018; Barakat, 2010). Several studies around the world have different media commonly used in constructed wetlands, which are given in *Table 2*. In addition, studies found that wood-based biochar is more effective with no demerits or less demerits.

Wood-based biochar

Up-to-now, Wood-based biochar has been recommended for the removal of potentially toxic elements in water and wastewater such as such as bioenergy crops (willows, miscanthus, and switchgrass) and forest residues (sawdust, grain crops, and nut shells). Biochar is generally produced from the pyrolysis of different low-cost starting materials. In recent studies (Shaheen et al., 2018; Li et al., 2018; Patra et al., 2017), biochars were originated from different wood feed-stock, i.e. luffa, water-melon, saw dust, pine cone, softwood, hardwood, and bark as they have major chemical and physical properties and their efficiency in removing potentially toxic elements in water. Studies (Shaheen et al., 2018; Li et al., 2018; Patra et al., 2017) demonstrated the biochar and discussed the (i) preparation, characterization and removal efficiency of wood-based biochar; as well as removal mechanisms of potentially toxic elements by wood-based biochar; therefore, it was concluded that wood-based biochar is effective for enhancement of wetlands systems. This particular study (Li et al., 2018) concluded that by-products from forests and agriculture may not be easily available. Furthermore, most of them are seasonal, but the “arundodonax” is a wetland plant which can be easily accessible anytime from many parts of the world. A study from Malaysia (Jong and Tang, 2015) used palm kernel shell and got promising results. Further studies are being conducted to find out the material for biochar which is easily available and effective.

Use of biochar in constructed wetlands for waste water treatment

Use of biochar and wetlands technology has received great interest because they are helpful to treat wastewater at low-cost. The untreated wastewater released in the environment increases the concentrations of suspended solids, nitrogen (N), phosphorus

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38033818

(P), and organic matter (Biochemical Oxygen Demand (BOD) and Chemical Oxygen Demand (COD)) in water bodies. These chemicals are easily treated by the combination of wetlands and its media (biochar).

Up to now, only a few studies have focused on integrating biochar into constructed wetlands when treating wastewaters. Combining both of these technologies can play a vital role in pollutant removal performance; when compared in the studies as shown in *Figure 1* (Li et al., 2018; Gupta et al., 2015), it was concluded that the wetlands with biochar were more efficient as compared to the wetland with gravels alone (Li et al., 2018; Gupta et al., 2015). Constructed wetlands (CWs) are an effective option to be applied around the world due to their lower cost. Plants and media are the main factors; they determine the effectiveness of the CWs in removing pollutants. Biochar is a potential media amendment for pollutant removal, which can be used in subsurface CWs (De Rozari, 2017).

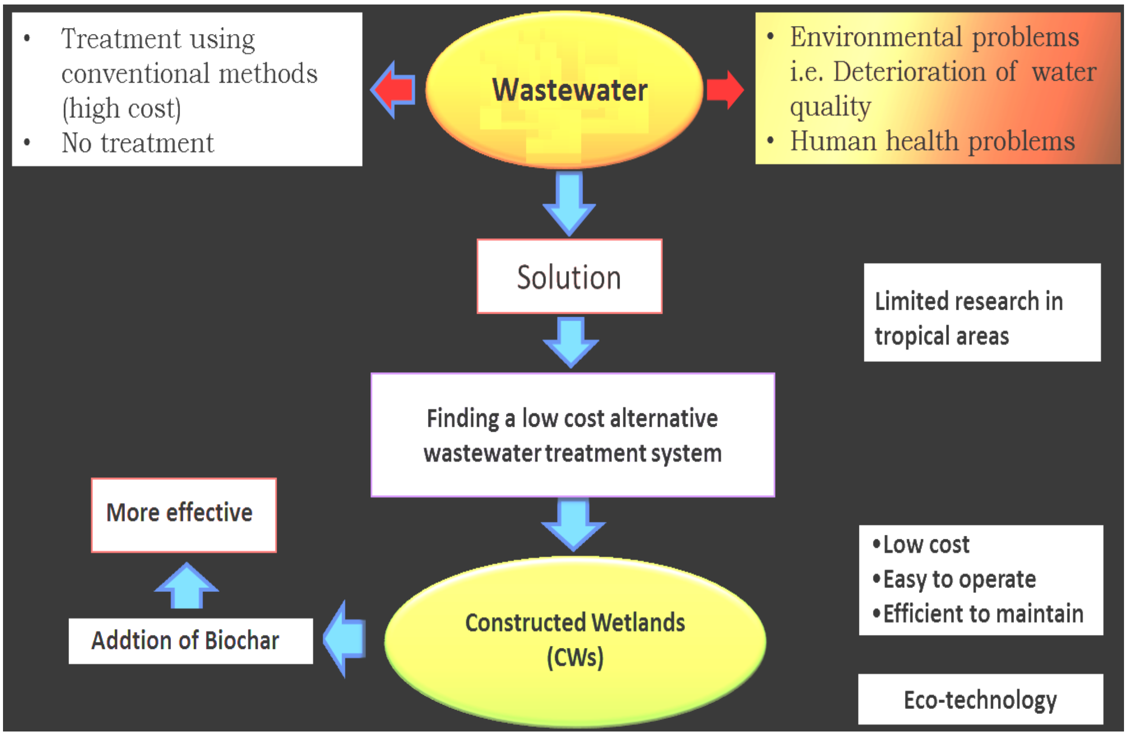

Figure 1. *Combination of constructed wetlands and biochar as an alternative and low-cost technology for wastewater treatment. (Modified from De Rozari, 2017)*

Effect of biochar on contaminants produced from different feedstocks

The removal of the pollutants by biochar depends on various factors such as adsorption, precipitation, filtration, sedimentation, microbial degradation, and plant uptake. The application of biochar produced from different feedstocks and techniques in aqueous solutions has been studied and it has been concluded that biochar isa more effective and better option. For Chromium, the biomass feedstock from Coconut coir goes under slow pyrolysis; the pyrolytic temperature ranges from 250 to 600 °C and has been effective (Shen et al., 2012). For Copper and zinc, the biomass feedstock from Corn straw under slow pyrolysis the pyrolytic temperature 600 °C has been effective (Chen and Chen, 2009; Chen et al., 2007). Comparison of rice husk-and dairy manure-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38033818

derived biochars for simultaneously removing heavy metals (Pb, Cu, Zn, and Cd) from aqueous solutions was studied; biochar was formed from from rice husk and dairy manure under slow pyrolysis the pyrolytic temperature 350 °C (Xu et al., 2013). The biomass feedstock from Sugarcane bagasse was studied for removal of Sulfamethoxazole. Biochar was formed under slow pyrolysis; the pyrolytic temperature (°C) ranges 450 (Subhashini et al., 2013).

Recently, Arundo donax, a wetland plant was used to prepare biochar; biochar was prepared for enhancing the performance in SFCWs nitrogen removal. Studies demonstrated that biochar significantly promoted plant growth in SFCWs (Li et al., 2018). Gupta et al.'s study (2015) was conducted for the removal of phosphorus, nitrogen and organic matter. An oak tree (Quercus sp) was used as a porous media to enhance constructed wetland performances in wastewater reclamation. This study reveals that the wetlands with biochar were more efficient as compared to the wetland with gravels alone with average removal rate of 58.3% TN, 79.5% TP, 91.3% COD, 58.3% NH_3, 92% NO_3-N, and 67.7% PO_4 (Gupta et al., 2015). In SFCWs with 20% (v/v) biochar addition enhanced the average removal efficiencies of TN and NO_3^--N as 85.62% and 81.16%. In the study (Li et al., 2018), it was concluded that the introduction of biochar has played an effective role to strengthen N removal efficiency in SFCWs. As comparisons were made, higher TN removal efficiency was offered by biochar added in SFCWs (Li et al., 2018).

In addition, a study was conducted to examine the treatment of wastewater; an evaluation of the efficiency of twotypes of pyrolysis chars (rice husk biochar and refuse derived fuel char) was done. Results of the study show that the efficiency of biochar in treating wastewater is much better compared to char. Hence, biochar could be the best option as a sorbent for wastewater remediation; moreover, biochar has a strong adsorption effect for organic pollutants such as antibiotics, phenols, herbicides, etc. (Rasheed et al., 2017; Deng et al., 2017). Biochar also has an adsorption effect for pollutants in liquid phase. Tan's (2015) study summarized the applications of biochar for water pollutants adsorption, it was concluded that 39% adsorption of organic-pollutants, 46% adsorption treatment for heavy metal, 13% for the adsorption of phosphorus and nitrogen (Tan et al., 2015). Studies (Zheng et al., 2013) were conducted for biochar preparation from donax to adsorb sulfamethoxazole (hazardous material), an antibiotic which is used for curing acute and chronic urinary tract diseases caused by proteus escherichia coli. Furthermore, the raw material has some inorganic components, which weaken the adsorption capacity of sulfamethoxazole in the high-temperature pyrolysis biochar and enhanced the adsorption capacity of sulfamethoxazolein low-temperature pyrolysis bochar. It varies from material to material; De Rozari et al.'s (2016) was conducted for the preparation of the sand media amended with biochar to develop its effectiveness. Two plant species (Cymbopogoncitratus and Melaleuca quinquenervia) were planted to remove phosphorus from sewage effluent in CWs. Removal efficiencies of TP in the mesocosms loaded with SCW, and septage ranged from 42 to 91%; 30 to 83% were recorded. The results revealed that the sand media performed better than the biochar-amended media (De Rozari et al., 2016). Overall, the application of biochar to enhance water treatment has concluded that biochar produced from different feedstocks and techniques is a more effective and better option.

Conclusion and recommendation

This review has focused on the effect of biochar in water treatment. A literature survey is conducted on the biochars production from the different feedstocks and pyrolyzed by different processes to reduce water pollution. Several researches confirmed that biochar is a good adsorbent with high efficiency and it has enhanced the efficiency of constructed wetlands for water treatment.

Biochar is efficient, but after the adsorption of heavy metal or organic pollutants, it may lead to secondary pollution if it is not properly treated. There is little research done on biochar recycling or regeneration after adsorption of pollutants. However, more research is needed to understand feedstock material for biochar, preparation parameters, biochar pore structures and the relationship between biochar adsorption performances. Studies for preparation biochar from different materials are recommended as future avenues for research. Experimental and modeling studies need to explore further in depth, especially on heavy metals, nitrogen and phosphorus adsorption, and whether biochar can be used as bio-fertilizers or soil conditioners after adsorption of nitrogen and phosphorus.

Abstract. One of the major concerns in Flood Frequency Analysis (FFA) is to predict floods of high magnitude for larger return periods. Magnitudes of smaller floods behave as nuisance in the estimation of larger floods. In this study, to avoid the unnecessary effect due to smaller observations, we implemented the technique of left censoring. The primary objective of this study is to see the efficacy of censoring, by comparing Regional Flood Frequency Analysis (RFFA) using Partial Linear Moments (PLM) for censored samples with RFFA using Linear Moments (LM) for uncensored samples of annual peak flows observed at ten stations of Indus Basin in Pakistan. After fulfillment of fundamental assumptions of randomness, independence, homogeneity, and stationarity, a Grubbs-Beck (GB) test for outlier detection is applied to the samples from all stations. For further analysis, Discordancy measure shows that none of the site is discordant and all ten stations would be retained for further investigation. On the basis of geographical closeness, stream hydrology and morphology of Indus basin, a single homogenous region is proposed and testified by the heterogeneity standards. The best fit distribution is selected by implying the Z-statistic (goodness of fit test base on LM) and L-Moments Ratio Diagram (LMRD). Generalized Pareto Distribution (GPA) distribution under PLM while Generalized Normal Distribution (GNO) under LM is selected as the reasonable choice for design flood estimation. Monte Carlo simulation experiment is performed to check the efficacy of PLM over LM through Root Means Square Error (RMSE) and bias. These accuracy measures indicated the outperformance of censored samples under PLM to uncensored samples under LM.
Keywords: *discordancy, heterogeneity, design flood estimation, censored samples, uncensored samples*

Introduction

Changing climate around the globe is the major challenge of today's world. Global warming leads to many changes in climatic conditions, which ultimately induce to changes in the intensity, spatial extent, frequency, duration and timing of extreme weather and climate events such as bolstering heat waves, lengthening droughts and causing more precipitation and flooding. In Pakistan, climate change has also resulted in extreme

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38193836

weather conditions such as torrential rainfalls, irregular floods, droughts, glacier melting, sea-level rising, etc. (Rasul et al., 2012). Currently, Pakistan is among the top ten countries that are vulnerable to the adverse effects of climate change. Pakistan Meteorological Department (PMD) reported that due to an abrupt change in climate during the past three decades a 100 kilometres spatial shift towards the west as well as the seasonal shift in the overall monsoon distribution pattern is observed in Pakistan. For example, the summer monsoon has moved towards the end of the season, and the winter rains have also driven towards late February and March (Ali, 2013).

In Pakistan, monsoon season is one of the major causes of heavy floods. Monsoon rains and floods usually create havoc in different parts of the country leaving thousands of families affected, a large number of houses destroyed, thousands of acres of ready to harvest crops and fruits orchards damaged, link roads and bridges destroyed. The resulting consequences of floods could be mitigated by improving water resources management. This goal could be achieved by collecting accurate information about the estimation of floods magnitude and frequency of occurrence, which ultimately would be helpful in designing, planning, and management of different hydrological structures such as water reservoirs, spillways, headworks, dams, culverts, bridges and other hydrological related structures. Water resources management could be strengthened by exploring flood frequency analysis and making headworks and stations attuned to water flows (Zin et al., 2009).

To improve above mentioned perspectives, there are two approaches of frequency analysis commonly used in hydrology. First one refers to at-site flood frequency analysis while the second one as regional flood frequency analysis. In at-site frequency analysis, we analyze the results of each site or station individually instead of grouping the information from all sites (Zin et al., 2009; Seckin et al., 2011; Ahmad et al., 2015, 2016a; Afreen and Muhammad, 2012; Rahman et al., 2013; Asikoglu, 2018). At-site frequency analysis is not a promising technique in the presence of small data and non-availability of data at ungauged stations. Due to data scarcity and sampling variability, RFFA is considered as more reliable technique providing information by using multiple sites and grouping them on the basis of similarity of their hydrological and geographical characteristics. RFFA based on Index Flood Procedure (IFP) is more helping and practical technique in providing design flood estimates for different sites especially in the presence of small data or no data at some sites in the region (Yue and Wang, 2014).

This method, with probability weighted moments (PWM) scheme has shown more promising results in the homogeneous regions. PWM was initially introduced by (Greenwood et al., 1979) and further, the L-moments technique was proposed by Hosking (1990). In design flood estimation, our primary goal is the evaluation of larger events on right tail of the frequency distribution. In this situation, practically small flood events are of little relevance and sometimes put unnecessary influence in design flood estimation of larger events. This problem can be tackled with the help of left censoring. We can discard the smaller flood events using some criterion to get rid of the unnecessary effects which they put on the estimation of larger flood events.

Under this motivation, we employed PLM method for censored samples (the samples in which some small values have been discarded) in characterizing the larger events for better water resources management. PLM is an extension of LM and is based on Partial Probability Weighted Moments (PPWM). With the help of PLM, we could mitigate the undesirable influences of small events which they leave on the estimation of higher return period events. RFFA based on method of LM had been successfully applied in many

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38193836

countries across the world, For example: in South Africa (Kjeldsen et al., 2002), Malaysia (Mohd Baki et al., 2015), Turkey (Saf, 2009, 2010), Australia (Zaman et al., 2012; Eslamian, 2014), China (Zhang et al., 2015; Du et al., 2014; Yang et al., 2010a, b), Italy (Noto and La Loggia, 2009; Caporlai et al., 2018), Pakistan (Hussain, 2011; Ahmad et al., 2017, 2016b), Tunisia (Abida and Ellouze, 2007), Canada (Glaves and Waylen, 1997); UK (Fowler and Kilsby, 2003), India (Ngongondo et al., 2011; Bora and Borah, 2017), Iran (Khanmohammadi et al., 2018) and Korea (Sung et al., 2018; Kar et al., 2017).

The initial work on PPWM was proposed by Wang (1996) on censored flood samples by fitting Generalized Extreme Value (GEV) distribution. The idea of PPWM is based on the extension of PWM as by Wang (1990, 1996) and Hosking (1990). Partial L-moments could be derived from PPWM on the same lines as L-moments from PWM. Bhattarai (2004), discussed the matter of various censoring levels and revealed that Partial L moments and L-moments show similar properties up to 30% censoring of the flood samples. Moisello (2007) compared PPWM and PWM and found that in case of unknown parent distribution, PPWM is better than PWM. Kochanek et al. (2008) used PPWM for log Gumble distribution censoring the largest observation in the sample. In Malaysia, some work has been conducted on PLM; see for example (Zakaria et al., 2011, 2012, 2017; Zakaria and Shabri, 2013). In recent years, Khan et al. (2017) used the method of LM and PLM for quantile estimation of extreme precipitation in Pakistan. In this study, we analyzed and compared the performance of the PLM method for censored with method of LM for uncensored samples implementing RFFA of annual peak flows of ten stations on Indus basin in Pakistan. The primary objectives of the study is to see the efficacy of censoring and to compare RFFA under PLM and LM using data of annual peak flows observed at ten stations of Indus Basin in Pakistan. Secondary objective of the study is to estimate the quantiles of upper tail of the distribution and get knowledge about the larger return periods, which would be helpful in designing, planning, and management of different hydrological structures such as water reservoirs, spillways, headworks, dams, culverts, bridges and other hydrological related structures.

Materials and methods

Study area

Irrigation and hydrological structure of Pakistan is world's remarkable irrigation system. Pakistan’s hydrological structure is mainly stretched under the umbrella of Indus basin that comprises of three main reservoirs namely Chashma, Mangla, and Tarbela, 19 stations, 12 linking canals, about 56,000 km of canals, and 110,000 km of watercourses. The climate of the Indus Basin plains varies from semi-arid to arid with temperature ranges from 2 to 49 °C. The Indus River is one of the main transboundary rivers in Asia with nine tributaries (rivers). Among these five tributaries lie on its left bank that are Beas, Chenab, Jhelum, Ravi, and Sutlej rivers. Among these five tributaries, three tributaries as Beas, Ravi, and Sutlej are also transboundary rivers having upper catchments in India. On the other side, right bank tributaries are the Gomal, Kabul, Swat and Kurram rivers. According to the Indus Water Treaty (1960) between Pakistan and India, the water from three rivers (Beas, Sutlej and Ravi) has been allocated to India while of other three rivers (Jhelum, Chenab and Indus) to Pakistan. Based on its morphology and stream hydrology, the Indus River can be divided into three segments: (i) the upstream segment (ii) the midstream segment, (iii) and the downstream segment. The upstream segment ranges from the Singi Khahad spring down to Jinnah Barrage being a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38193836

hilly catchment area. The midstream segment, prolongs from Jinnah to Guddu stations being an upper floodplains area dominated by an intervening pattern of channels and river inflows. The last one, the downstream segment, ranges from Guddu Barrage to the Arabian Sea, is a lower flood plains area and has a flat topography, a meandering channel pattern and deltas (Ali, 2013). These ten stations are located on the three rivers, the Jhelum, Chenab and Ravi (mid segment) and Indus River/Sindh (lower segment). Stations Location, latitude, longitude, elevation, length and drainage area are given in *Table 1* and geographical locations are depicted in *Figure 1*.

Basic assumptions of the data

First of all, we will check the basic assumptions important for a hydrological analysis such as, homogeneity, randomness/independence and stationarity for the data from all stations.

Assumption of homogeneity

The term homogeneity refers to the notion that all elements of a sample belonging to a single common population. Because the sample of flood data may arise in the result of ordinary rainfall or extraordinary rainfall with high intensities and volumes resulting from extreme hydrometeorological conditions. In these scenarios, we may face non-homogeneous sample of flood data. To check the assumption of homogeneity we apply Mann and Whitney test.

Assumption of independence and randomness

In frequency analysis, the idea of independence postulates that none of the peak flow in the sample will affect the occurrence or non-occurrence of any other value in the same sample. Randomness implies that each element of the sample is independently drawn at random from the population with equal probability. In this study we apply, Wald and Wolfowitz test to check the independence and randomness assumption for the observed data from all stations. The same test has been used in different studies for the same purpose see for example Naghettini (2017) and Hussain (2011).

Table 1. *Basic information of different stations in the study*

Rivers names	Site name	Latitude (degrees north)	Longitude (degrees east)	Altitude	Length of the basin (feet)	Drainage area (km^2)
Jhelum	Mangla	33.15	73.65	774	10,300	20712
	Rasul	32.68	73.5	699	3209	24069
Chenab	Marala	32.68	74.43	702	4472	31148
	Khanki	32.4	73.2	666	4000	29732

Figure 1. *Geographical location of different stations in the study*

Assumption of stationarity

In general, stationarity of hydrological variable implies the invariance over time of some statistical properties of a hydrological variable such as its probability distribution and related parameters (Naghettini, 2017). Usually, we face monotonic trend in hydrology. For measurement of this kind of trend, we can use Spearman's rank correlation coefficient test. It is a nonparametric procedure to test the statistical dependence between two variables. Statistical dependence is not restricted to be linear as in case of simple correlation coefficient test. The basic notion behind this test is that the trend hidden in a flood data evolving over time can be measured with the help degree of association or correlation between ranking orders "m_t" of original series and corresponding time indices T_t.

Outliers detection and Grubbs-Beck (GB) test

In frequency analysis of extreme events like droughts, floods and others, it is very common to have some observation below some threshold value. These values are of little interest, especially, when your interest is in modeling the right tail of the distribution, i.e. estimating the higher return periods of extreme events. In a given sample, a value is treated as an outlier if it shows a significant departure from the overall tendency of other sample values due to any reason. The reason might be measurement error or processing or some other. In any case, these outliers may severely influence parameters and quantiles

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38193836

estimation and in general fitting process of the probability distribution. Once an outlier is detected in the sample, the decision of its removal or not removal needs further investigation. If its removal is conclusive, then it must be censored or removed from the sample. These observations are nuisance in the frequency analysis and problematic for the validity of the end results. In such situation, it is good practice to censor these observations in order to understand the process in a better way. In frequency analysis of annual peak flows or rainfall, the removal of an outlier from the lower side (left censoring) is justified because our main concern is an estimation of upper tail quantile or high return period's events. However, if some outlier is detected from the upper side, it should not be expunged from the sample because it might be due to some natural causes or extraordinary hydrometeorological conditions and helpful in estimating larger return periods events (Naghettini, 2017). Among other tests for outlier detection in statistical hydrology, the Grubbs- Beck (GB) test is the most frequently used test. This test defines two bounds, X_U upper bound and X_L lower bound, as given in *Equations 1* and *2*. Any value below or above these bounds would be treated as an outlier in the ranked sample values, where

$$X_U = \exp\left(\overline{x^*} + K_{n,\alpha} S_X^*\right) \quad \text{(Eq.1)}$$

$$X_L = \exp\left(\overline{x^*} - K_{n,\alpha} S_X^*\right), \quad \text{(Eq.2)}$$

where, $\overline{x^*}$ and S_X^* are the mean and standard deviation of logarithms of original data of annual peak flows. In *Equations 1* and *2,* $K_{n,\alpha}$ shows the critical values of the GB test statistics. The critical values for GB test statistic at 5% level of significance with sample size (n), ranges from 10 to 120, could be found as in *Equation 3*.

$$K_{n,\alpha=0.05} = -5.2269 + 8.768n^{0.025} - 3.8063n^{0.5} + 0.8011\,n^{0.75} - 0.0656n, \quad \text{(Eq.3)}$$

Methods of estimation

Method of linear moments (L-moments)

PWM primarily was defined by Greenwood et al. (1979), and later LM (linear moments) by Hosking (1990). The PWM of order r was defined by Greenwood et al. (1979) as *Equation 4:*

$$\beta_r = \int_0^1 x(F) F^r \, dF, \quad \text{(Eq.4)}$$

where $x(F)$ is quantile function and $F = F(\mathrm{x})$ is the cumulative distribution function. The first four L moments as a linear combination of PWM's are described below:

$\lambda_1 = \beta_0$ (First L-moment as measure of central tendency)

$\lambda_2 = 2\beta_1 - \beta_0$ (Second L-moment as measure of dispersion)

$\lambda_3 = 6\beta_2 - 6\beta_1 + \beta_0$ (Third L-moment as measure of skewness)

$\lambda_4 = 20\beta_3 - 30\beta_2 + 12\beta_1 - \beta_0$ (Fourth L-moment as measure of kurtosis)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38193836

$\tau_2 = \frac{\lambda_2}{\lambda_1}$ (Measure of coefficient of variation based on L-moments)

$\tau_3 = \frac{\lambda_3}{\lambda_2}$ (Measure of coefficient of skewness based on L-moments)

$\tau_4 = \frac{\lambda_4}{\lambda_2}$ (Measure of coefficient of kurtosis based on L-moments)

In practice, for $r = 0,1,2,3\ldots.n,$ LM could be estimated from sample PWMs by *Equation 5:*

$$b_r = \frac{1}{n}\sum_{i=r+1}^{n}\frac{(i-1)(i-2)\ldots\ldots(i-r)}{(n-1)(n-2)\ldots\ldots(n-r)}x_{i:n} \quad \text{(Eq.5)}$$

The relationship of both sample LM and PWM is determined by *Equation 6:*

$$l_{r+1} = \sum_{k=0}^{r} p_{r,k}^{*} b_k \, r = 0,1,2,\ldots\ldots\ldots(n-1). \quad \text{(Eq. 6)}$$

For $r = 0,1,2,3\ldots.n,$ we obtain:

$$l_1 = b_0$$

$$l_2 = 2b_1 - b_0$$

$$l_3 = 6b_2 - 6b_1 + b_0$$

$$l_4 = 20b_3 - 30b_2 + 12b_1 - b_0$$

Sample version of coefficient of variation, skewness and kurtosis based on LM can be defined by replacing the population values with sample estimates of LM; denoted by $t, t_3, and\ t_4$ respectively.

Method of partial linear moments (PLM)

Wang (1996) extended the idea of probability weighted moments (PWM) and defined PPWM for censored samples as *Equation 7:*

$$\beta_r' = \frac{1}{1-F_0^{r+1}}\int_{F_0}^{1} x(F)F^r\,dF, \quad \text{(Eq.7)}$$

where F_0 is varying point and could be 10%, 20% or 30%; it is also called censoring threshold. Note that, if $F_0 = 0$, the partial L moments becomes simple L moments. The unbiased estimates of β_r' can be defined as *Equation 8:*

$$b_r' = \frac{1}{(1-F_0^{r+1})n}\sum_{i=1}^{n}\frac{(i-1)(i-2)\ldots\ldots\ldots(i-r+1)(i-r)}{(n-1)(n-2)\ldots\ldots(n-r+1)(n-r)}x_{(i)}^{*}, \quad \text{(Eq.8)}$$

where:

$$x_{(i)}^{*} = 0 \quad \text{for}\ x_{(i)} \le x_0$$

and

$$x_{(i)}^{*} = x_{(i)} \quad for\ x_{(i)} > x_0$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38193836

The censoring level tells about the number of sample values to be censored as $F_0 = \frac{n_0}{n}$; where n_0 and n are the number of censored values determined through GB test) and the length of the complete sample respectively. The first four PLM are parallel to first four LMs by replacing PWM by PPWM. In this study, they are denoted by $\xi_1, \xi_2, \xi_3, \xi_4$.

The relationships for "ς_2" (Coefficient of variation based on partial L moments), "ς_3" (Coefficient of skewness based on partial L moments) and "ς_4" (Coefficient of kurtosis based on partial L moments) are defined as *Equation 9:*

$$\varsigma_2 = \frac{\xi_2}{\xi_1},\ \varsigma_3 = \frac{\xi_3}{\xi_2} \text{ and } \varsigma_4 = \frac{\xi_4}{\xi_2} \quad \text{(Eq.9)}$$

Sample version of coefficient of variation, skewness and kurtosis based on PLM can be defined by replacing the population values of PPWMs by their sample counterparts and denoted by $t^{/}, t_3^{/}, and\ t_4^{/}$.

Regional flood frequency analysis (RFFA) using LM and PLM

Hosking and Wallis (1997) provided a comprehensive RFFA procedure using linear moments theory. It consists of mainly four steps.

Data screening

For RFFA, the first step is the initial screening of data. The sites with a trend and showing some gross error are excluded from the rest of sites. Hosking and Wallis (2005) suggested a discordancy measure D_i using LM to distinguish those sites which are discordant from other sites. For $i = 1, \ldots, n$, D_i is given by

$$D_i = \frac{1}{3}(u_i - \bar{u})^T S^{-1}(u_i - \bar{u}), \quad \text{(Eq.10)}$$

where $S = \frac{1}{N-1}\sum_{i=1}^{N}(u_i - \bar{u})(u_i - \bar{u})^T$ is a matrix of sum of squares and cross products. Note that $u_i = [t^{(i)}, t_3^{(i)}, t_4^{(i)}]$ is a vector consisting sample LM ratios, $\bar{u} = N^{-1}\sum_{i=1}^{N} u_i$, and N is the total number of sites

Hosking and Wallis (2005) provided threshold values for D_i. A site is treated as discordant site if calculated value of D_i exceeds the corresponding critical value. Critical values for a different number of sites are given in *Table 2*. We used the same criterion for detection of discordant sites for censored sample under PLM followed by Zakaria and Shabri (2013).

Table 2. *Critical values of discordancy measure for different number of sites*

Number of sites in the region	5	6	7	8	9	10
Critical values	1.333	1.648	1.917	2.140	2.329	2.491

Formation of homogeneous regions

A homogenous region can be formed using geographical convenience strategy, subjective approach, objective approach and cluster analysis for partitioning, e.g. K-means clusters etc. However, the formed region should be confirmed later by the heterogeneity tests. The latter test has been explained by Zakaria and Shabri (2013). In

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38193836

our study, we fit four parameter kappa distributions to $1, t, t_3^R, t_4^R$ and estimate the parameters of this distribution analytically. After 500 realizations of artificial regions considering ten sites, each site with the same number of values as real data, we calculate mean and standard deviation denoted by μ_V and σ_V respectively and calculate the heterogeneity statistic given by

$$\boldsymbol{H} = \frac{(V-\mu_V)}{\sigma_V}. \quad \text{(Eq.11)}$$

According to the heterogeneity criterion mentioned in *Equation 11,* if H< 1 the region is acceptably homogeneous. If H is in between 1 and 2, it can be possibly heterogeneous. However, when $H \geq 2$, the region is definitely heterogeneous.

Selection of regional frequency distribution

Selection of the best distribution is possible through different statistical tests and graphical inspections. In this study, we use Z-statistic based on LM and LMRD as suggested by (Zakaria and Shabri, 2013). Regional frequency studies showed that more than one distribution could be marked as best fit. However, the most suitable distribution will be that which also provide robust results. Hosking (1990) marked LMRD as the powerful tool to identify the distribution by the depicting ratio of sample regional skewness and kurtosis. In Z-statistic we assess the quality of fit by evaluating the difference between the L-kurtosis of fitted distribution τ_4^{Dist} and the regional average L-kurtosis τ_4^{R}. To know the significance of this difference, we compare the difference with the sampling variability of t_4^{R}. The statistics is calculated by using

$$Z^{Dist} = \frac{(\tau_4^{Dist} - t_4^R)}{\sigma_4}, \quad \text{(Eq.12)}$$

where σ_4, *is* the standard deviation of t_4^{R} obtained by repeated simulations of the homogeneous region fitted by Kappa distribution and using same record length of the sites as the observed data. More than one distribution can be selected using the criterion given in *Equation 12*. Best fit is claimed on the basis of the lowest value of Z^{Dist}. In literature, $|Z^{Dist}| \leq 1.64$ is the criterion at 90% confidence level. In case of more than one candidature fulfill this criterion, best fit will be declared that one with Z^{Dist} near to zero or equal to zero.

Estimation of selected frequency distribution

In this step, we will estimate the parameters of best fit frequency distribution and regional quantiles (regional growth curve) corresponding to different probabilities of non-exceedance useful in water resources management. Index Flood Procedure (IFP) is a prevailing method to estimate at site quantiles (quantile of every site in the homogeneous region). For a given station, the quantile estimates could be obtained by multiplying the sample estimate of index flood estimate/scaling factor μ_i (which may be an estimate of central tendency of the specific site) with regional quantile function $q(.)$. The latter being a dimensionless quantity is common to all sites in the homogeneous region. The relationship can be defined by *Equation 13:*

$$\hat{Q}_i(F) = l_1^{(i)} \hat{q}(F),\ i = 1,2,3, \dots, N, \quad \text{(Eq.13)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38193836

where $\hat{Q}_i(F)$ refers to at-site quantile function and $l_1^{(i)}$ is the estimate of μ_i. Results obtained from the statistical analysis may contain some inherent errors and hence are uncertain. To make these results more practical and useful, we must assess the uncertainty of these estimates. One of the reasonable choices to assess this uncertainty is Monte Carlo simulation. A simulation algorithm used in this study is known as Regional L-moments algorithm proposed by Hosking and Wallis (2005). For an i^{th} site at m^{th} replication, $\hat{Q}_i^{[m]}(F)$ is quantile estimate for that site while $Q_i(F)$ is the simulated value and F be the probability of non-exceedance. The relative error can be estimated by $\frac{\{\hat{Q}_i^{[m]}(F)-Q_i(F)\}}{Q_i(F)}$. Further, this quantity could be averaged on the total number of M repetitions to derive relative BIAS and relative RMSE respectively given by

$$B_i(F) = \frac{1}{M}\sum_{m=1}^{M}\frac{\{\hat{Q}_i^{[m]}(F)-Q_i(F)\}}{Q_i(F)}, \quad \text{(Eq. 14)}$$

and

$$R_i(F) = [\frac{1}{M}\sum_{m=1}^{M}\{\frac{\{\hat{Q}_i^{[m]}(F)-Q_i(F)\}}{Q_i(F)}\}^2]^{\frac{1}{2}}. \quad \text{(Eq.15)}$$

A summary statistic for accuracy assessment of all sites in the homogeneous region is calculated by regional average relative BIAS and RMSE respectively given by *Equation 16:*

$$B^R(F) = \frac{1}{N}\sum_{i=1}^{N}B_i(F), \quad \text{(Eq.16)}$$

and *Equation 17:*

$$R^R(F) = \frac{1}{N}\sum_{i=1}^{N}R_i(F). \quad \text{(Eq.17)}$$

It is worth noting that the above assessment measures as given in *Equations 14* and *15* deal with the accuracy of quantile estimates of different sites in the region. When our concern is to get the accurate assessment of regional quantile estimates/ growth curve, the quantities $\hat{Q}_i^{[m]}(F)$ *and* $Q_i(F)$ could be replaced with $\hat{q}(F)$ and $q(F)$, respectively.

Results and discussion

Data characteristics

Taking into account the basin's geophysical and hydroclimatic characteristics, the central segment and downstream segments seem more important to assess the severity of floods. We have used Annual peak flows/Annual maximum flows data measured in cusecs (the single maximum value recorded in 24 hours for everyday of the year). This value is the maximum value among 365 values of a year. For every year we have only one value in the sample. In this study, ten stations are selected for RFFA, namely, Mangla (with record length of 87 years), Rasul (with record length of 93 years), Marala (with record length of 90 years), Khanki (with record length of 90 years), Qadirabad (with record length of 45 years), Balloki (with record length of 93 years), Sidhnai (with record length of 90 years), Kotri (with record length of 48 years), Guddu (with record

DOI: http://dx.doi.org/10.15666/aeer/1702_38193836

length of 30 years) and Sukhur (with record length of 30 years). The required data has been retrieved from Federal Flood Commission of Pakistan for research purpose. The smallest record length of 30 values for 30 years belongs to Guddu and Sukhur stations while the largest record length of 93 values for 93 years belongs to Balloki and Rasul stations. Some basic characteristics of the original sample without censoring are presented in *Table 3*.

Table 3. *Samples statistics with discordancy measure for uncensored (original) samples*

Site name	n record length of original sample (years)	Mean of original sample (Cusecs)	t (coefficient of variation)	t_3 (coefficient of skewness)	t_4 (coefficient of kurtosis)	D_i (discordancy measure)
Mangla	87	194352	0.4226	0.4544	0.3467	0.77
Rasul	93	202372	0.4551	0.4412	0.2920	1.75
Marala	90	317614	0.3576	0.3659	0.1581	0.79

Guddu	30	542060	0.3272	0.2522	0.0284	0.87
Sukkur	30	491594	0.3389	0.2596	0.0743	0.67

Table 3 shows that the value of mean peak flows for Guddu station is maximum as compared to other stations. Coefficient of variation tells us about the relative variation in a data sets. Using the information provided in *Table 3,* it is obvious that there is more variation in the sample values of Rasul station. The station Guddu carries less variation in all of the ten stations. The most skewed and sharp peak sample belongs to Mangla station. On the other side, sample belongs to station Gudu is less skewed and carries small peak among all stations.

Results of the fundamental assumptions show that annual peak series from all sites fulfill the criteria of randomness, independence, homogeneity, and stationarity. All the probability values (P-Values) are less than 5% (level of significance), which implies that the hypotheses of randomness, independence and homogeneity are not rejected, and data are suitable for frequency analysis. Further, using Grubbs-Beck test, we determined the number of outliers need to discard from the lower side as well as from upper side. These numbers of observations are discarded from the original sample in order to avoid their unnecessary influence on design flood estimates for higher return periods using PLM. *Table 4* shows that none of the observation is declared as outlier from upper side. Different number of observation are discarded from lower side for different stations from the original sample in order to avoid their unnecessary influence on design flood estimates for higher return periods using PLM. The Grubbs-Beck test shows that the maximum number of observation discarded from Rasul station are nine (10%) while no observation is discarded from Sukhur sample. Numbers of observations smaller than lower limit given by Grubbs-Beck test are treated as censored observations. Although in our study, the numbers of censored values are not too large, but their presence may pertain an unnecessary effect on design flood estimation. To retain larger observations

in the sample is also justified because it might be due to natural causes or extraordinary hydrometeorological conditions and are also helpful in estimating high return periods (Naghettini, 2017). Results are given in *Table 4*.

Regional flood frequency analysis

To know about the discordant site from the group of ten sites, we calculated discordancy measure given in *Equation 10.* Record length, mean, the coefficient of skewness, the coefficient of kurtosis along with discordancy measure for each station are presented for uncensored and censored samples. Results are presented in *Tables 3* and *5* respectively.

The maximum value of D_i is 1.75 for Rasul station, while for all other nine sites, D_i value is comparatively less. According to the criterion of *Table 1*, if the D_i value for a site is greater than 2.491, then that site will be declared as discordant. In present study, none of the sites is exceeding 2.491, none of the site is treated as discordant. Thus, all sites are considered suitable for further procedure. *Table 5* describes the results of discordancy measure and other basic statistics using PLM theory for censored data. *C* denotes discarded values from lower side while *n** is sample size after censoring.

A reduction in discordancy measure using the censored sample is obvious as compared original samples. The reason for this change is censoring of data. Our main focus is on the upper tail of the fitted distribution, so these discarded observations might be the nuisance for further analysis. Initially, a single homogenous region is formed and verified by the heterogeneity standards. Seven stations are located in Punjab province while the three in Sindh province. The stations named Sukhur, Guddu and Kotri constitute the lower segment of Indus River. Under morphology and stream hydrology of the Indus basin, it is justified to make one homogenous region from these ten sites. To verify the homogeneity of the region, the heterogeneity is calculated using LM and PLM (see *Table 6*).

Table 6. *Heterogeneity measure for censored and uncensored samples.*

Heterogeneity measure	H
Uncensored samples	0.98
Censored samples	0.72

As *H* is based on the coefficient of variation and explicates more variation as compared to the coefficient of skewness and coefficient of Kurtosis. For uncensored sample using LM the value of $H = 0.98$ and for the censored sample using PLM the value of $H = 0.72$. Both measures present similar results but heterogeneity measure based on PLM is smaller showing some edge over LM method. It also implies that after discarding some observation from some sites, the heterogeneity measure of the region is likely to decrease. Hosking and Wallis (2005) preferred to use three parameters distributions like generalize Pareto (GPA), generalize logistic (GLO), generalize extreme value (GEV), generalize normal (GNO) and generalize Pearson 3 type (PE-III) based on L-moments. For PLM only GEV, GLO, and GPA are the distributions whose partial L moments are available (Zakaria and Shabri, 2013). The selection of the distribution is made by Z- statistic. According to the criterion, if the absolute value of Z-statistic is less than 1.64, the distribution will be declared as best one. But in case of more than one distribution satisfying this criterion, the closer the absolute value of Z-statistic to zero, better will be the distribution. The simulation procedure for the calculation of Z-statistic is explained in the previous section.

GNO, GPA, PE-III show that the Z-statistic for these distributions is less than the critical value. But the value of this statistic for GNO = 0.71 meets the criterion of the most appropriate distribution for uncensored samples while for GPA = -0.53 for censored samples. Results are presented in *Table 7*. The second best fit distributions using LM and PLM are GPA and GEV respectively.

PLMRD is comparable to LMRD. LMRD and PLMRD are delineated for the described region. Sample regional coefficients of L-skewness/PL-skewness and L-kurtosis/PL-kurtosis are used for LMRD/PLMRD. The ratio of regional sample coefficients of skewness and kurtosis based on LM fall contiguous to the GNO (*Fig. 2a*)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38193836

while using PLM the ratio falls near to GPA (see *Fig. 2b*). The results found with Z-statistic and ratio diagrams are similar.

Table 7. *Z-Statistic for best fit distribution for censored and uncensored samples*

Z-Statistic Value					
Method	**GNO**	**PE-III**	**GEV**	**GLO**	**GPA**
Uncensored sample	0.71	-1.76	2.14	3.04	-0.83
Censored sample	----	-----	2.29	3.15	-0.53

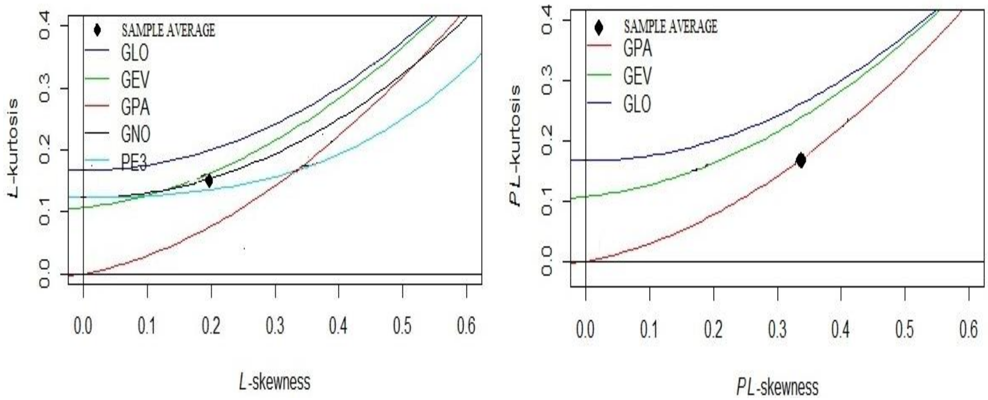

Figure 2. a *L-moments ratio diagram for uncensored data;* ***b*** *partial L-moments ratio diagram for censored samples*

The regional design flood estimates for the prescribed region corresponding to 2, 5, 10, 20, 50, 100 and 500 return periods (average recurrence period of flood events) using LM and PLM are illustrated in *Table 8*.

Table 8*. Quantile estimation for homogenous region for censored and uncensored samples*

Distribution	**Parameters**	**Quantile Estimates**
	b a k	Q_{10} Q_{20} Q_{50} Q_{100} Q_{200} Q_{500} Q_{800} Q_{900}
GNO (uncensored sample)	0.7540 0.5207 -0.8013	0.205 0.230 0.278 0.337 0.435 0.754 1.380
GPA (censored sample)	0.2894 0.6337 -0.1083	0.256 0.302 0.392 0.457 0.541 0.946 1.804

The Monte Carlo simulation procedure based on Regional L-moment algorithm (Hosking and Wallis, 2005) determines the accuracy of estimated quantiles/ growth curves. The repetitions in this process must be larger enough so that the RMSE and bias values are contiguous to the actual RMSE and bias. Therefore, 10000 repetitions are performed (see *Table 9*). Using PLM, Regional Average Relative RMSE and Bias values, i.e. $R^R(F)$ and $B^R(F)$ delivered by GPA under PLM are smaller than GNO under LM for all return periods. But the difference is more pronounced at larger return period events for example 100 years and 500 years.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38193836

The at most decrease in R^R using PLM as compared to LM up to 20 years return period is 0.9%. Similarly, at most decrease in R^R using PLM as compared to LM up to 500 years return period is 4.6%. The at most decrease in B^R using LM as compared to LM up to 20 years return period is 0.12%. Similarly, at most decrease in B^R using PLM as compared to LM upto 500 years return period is 0.22%. This decrease is more rapid and pronounced at higher return periods. It shows that PLM comparatively outperforms than LM especially at larger events. PLM is useful when our concern is higher return period's events and our target is long-term planning in water resources management. Unnecessary bias and errors due to smaller values of flows could be avoided using PLM. As the main objective of the RFFA is to estimate the quantiles for upper tail of the distribution and get knowledge about the larger return periods, PLM would be a more reasonable and effective choice for such type of design flood estimation. This study reinforces the use of PLM using censored samples. Our results support the outcomes of earlier studies (e.g., Bhattarai, 2004; Zakaria et al., 2011, 2012; Zakaria and Shabri, 2013; Khan et al., 2017) where PLM technique using censored samples outperformed than LM for large return periods estimations.

Conclusions and recommendations

PLM and LM estimation methods were applied to annual peak flows data of ten stations located at Indus Basin, Pakistan. No station was appeared to be discordant. On the basis of geographical closeness, stream hydrology and basin morphology one homogenous region is formed and verified through the heterogeneity measure. Z-statistics and ratio diagrams depicted the best fit distributions for both methods. Using LM, GNO was more appropriate choice for the homogenous region while GPA under PLM. The accuracy of the estimated design flood estimates (regional quantiles/growth curves estimates) was assessed through, regional average RRMSE and bias, i.e. $R^R(F)$ *and* $B^R(F)$. The decrease in these measures was relatively more at higher return periods under PLM method. Our results support the outcomes of earlier studies (e.g., Bhattarai, 2004; Zakaria et al., 2011, 2012; Zakaria and Shabri, 2013; Khan et al., 2017), where PLM technique using censored samples outperformed than LM for large return periods estimations. During flood frequency analysis, in comparison with LM, PLM describe the data samples in a better way and improve the accuracy of design flood estimates. With the help of PLM, we can mitigate the undesirable influences of small events which they leave on large return period events. Therefore, it is a reasonable and effective method for flood frequency analysis. These estimates would be of great help for designing, planning, and management of different hydrological structures in the

DOI: http://dx.doi.org/10.15666/aeer/1702_38193836

form of water reservoirs, spillways, headworks, dams, culverts, bridges and other water related structures.

The present study can be extended to other sites of the Indus basin Pakistan, which will help the researchers to make policy implications related to water resources management for the whole country.

Abstract. The aim of this study is to determine the germination ability and biochemical properties of seedlings of two taxa (*Ajuga chamaepitys* subsp. *chia* var. *chia*, *Ajuga orientalis*) belonging to the *Lamiaceae* family which is naturally distributed in Lakes District-Turkey and cultivated in the Botanic Garden of Süleyman Demirel University in Isparta. These two taxa, which have usage potential as ornamental, medicinal and aromatic plants, were cultivated in 2015 vegetation period and seeds were collected at the end of 2016 vegetation period. During the same vegetation period, seeds were also collected from the areas where these two species were naturally grown. Seed germination tests were performed in 2017 vegetation period on the plants. Seed germination tests and seedling raising tests were carried out in the seedling and phenological properties (plant height, plant diameter, leaf width, leaf length) and SPAD values were also measured. Some macro and micro elements (Total N, P, K, Ca, Mg, Fe, Cu, Mn and Zn) and volatile oil compounds were analysed in the samples taken. As a result of the study, germination was not observed in *Ajuga chamaepitys* subsp. *chia* var. *chia*; however, seedling raising rate was between 33% and 40%. Seedling raising speed was 33.7% in the trial area and 36.41% in the seeds collected from the natural habitat. The germination rate of *Ajuga orientalis* was found to be 18% in the seeds taken from the natural habitat and 21.33% in the seeds taken from cultivars. Seedling raising rate was 43.33% in the seeds taken from the natural habitat and 60% in the seeds obtained from the trial area. Although the germination ability of the seeds from both origins (natural habitat and cultivars) were low, the phenological properties measurements and the biochemical analysis results were in a close relation with each samples.
Keywords: *Lamiaceae, Ajuga sp., cultivated plant, seed, volatile components*

Introduction

Today, the basic material of all designs is nature itself. In the creation and development of design, the use of various structural and plant materials inspired by nature is an indispensable approach. The selection of naturally propagated species from the area or region in which the design will be put, is an important factor both for sustainable design and for lowering costs such as irrigation and maintenance (Bassuk, 2017). In the world, especially in urban areas where water scarcity is felt more prominently in recent years, alternatives to wide grass surfaces are sought, and more sensitive to nature and less water consuming designs come to the fore. In order to put into practice these designs, studies were carried out on the cultivated and development of the natural species belonging to these regions (Çakır and Dönmez, 2018; Gül et al., 2012). However, in order to use natural species in planted design studies, it is necessary to know the breeding and production properties of plant materials. Although successful

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38373848

results can be obtained in some cases in terms of visual characteristics in the cultivation studies, the genetic continuity of the plants can not be achieved and successful results can not be obtained. The most remarkable and critical stages during the life cycle of plants are seed germination and seedling establishment (Copete et al., 2015). Besides, it is necessary to know the germination time and their growth properties in order to be produced both as industrial usage and as ornamental plant.

Lamiaceae family is represented by 400 genera and 3200 species in the world (Kahraman et al., 2009; Bazarragchaa et al., 2012). Members of these families are concentrated mainly in the Mediterranean countries, Australia, South West Asia and South America. Almost in all habitat types and at all heights, *Lamiaceae* family members can grow and there are very few regions in which they can not be seen. *Lamiaceae* family in Turkey is one of the important gene centers. About 546 species are represented in 45 genus. The rate of endemism in Turkey is approximately 44.5%. Most of the members of the *Lamiaceae* family are rich in ornamental leaves, flowers, angular bodies and volatile oil; for this reason, they are very important in landscape architecture, pharmacy, food and cosmetic industries (Castro et al., 2011; Kahraman et al., 2009; Guo et al., 2011). It is known by previous studies that the volatile oil of *Ajuga* species have antibacterial properties thus it can be used as medicinal and aromatic plant (Turkoğlu et al., 2010; Yaldiz, 2012; Delezar et al., 2012; Göder et al., 2015).

"*Ajuga chamaepitys* subsp. *chia* var. *chia*" also known as Ground Pine can be occured in Greece, Crimea, Palestine, North West and West Iran, Northern Iraq. In Turkey; it can be seen in almost all regions, up to 2000 m above sea level (Davis, 1982; Coll and Tandron, 2008). This taxa, which can be sized up to 30 cm in diameter and 10 cm in length, is yellow in color and can be flowered during the vegetation period (*Fig. 1*). This suffrutescent plant can be used either as ground covering or as an element of emphasis (Israili and Lyoussi, 2009; Dönmez et al., 2017; Jakovljević et al., 2015).

Figure 1. *Ajuga chamaepitys subsp. chia var. chia*

"*Ajuga orientalis*" can be grown in Crimea, Sicily, West Syria, Cyprus, Caucasus and North West Iran. In Turkey, it is seen in Mediterranean, Aegean, Black Sea and Central Anatolia regions up to 2500 m above sea level (Davis, 1982). It is a suffrutescent perennial herbaceous plant that can be grown up to 40 cm (Dönmez et al., 2017). The flowers are violet-blue and cream-colored. *Ajuga orientalis* stands out with its dense green texture (*Fig. 2*). It is suitable for use as a background in plant design. It is thought that its use in waterfronts and humid areas will increase the visual appeal.

Figure 2. *Ajuga orientalis*

These taxas were cultivated for the first time (Dönmez et al., 2018). To the best our knowledge, there are no papers on the germination and seedling growth of these taxas. From this point of view, the aim of the study was to determine the germination abilitiy of *Ajuga chamaepitys* subsp. *chia* var. *chia* and *Ajuga orientalis* taxa belonging to *Lamiaceae* family, which is naturally grown in Lakes District, Turkey and cultivated in Isparta Süleyman Demirel University (SDU) Botanic Garden.

Materials and methods

The plants were cultivated in "SDU Botanic Garden" during the 2015 vegetation period. *Ajuga chamaepitys* subsp. *chia* var. *chia*'s natural habitat plant samples were collected from Asağıgökdere, Isparta (GÜL HERBARIUM No: 14340). *Ajuga orientalis* plants were collected from Kemer, Antalya (GÜL HERBARIUM No: 14341). In May 2015, trial parcels were created in SDU Botanic Garden. A total of 6 parcels were established, three of which with replicates, and each parcel consisting of 25 plants. As the physiographic and climatic factors were considered the same in the trial area where the experimental areas were established, the parceling was done in accordance with the Randomized Complete Block Design. Irrigation and drip was made by irrigation system. It was observed that 55 and 40 plants adapted in trial area, respectively, for *Ajuga chamaepitys* subsp. *chia* var. *chia* and *Ajuga orientalis.* At the end of 2016 (July) vegetation period, seeds were collected from natural habitat and trial area plants. Seeds were stored at 4 °C until germination experiments. Germination experiments were carried out after nine months. At the start of the 2017 (April) vegetation period, they were sowed, measurements and analyzes were carried out on the seedlings.

Germination and seedling raising test

The germination test was carried out in petri dishes (9 cm in diameter) with 3 replicates and 50 seeds were put into each dishes (*Fig. 3*). Sufficient amount (about 5 ml) of pure water was added and seeds were allowed to germinate at 25 °C in the dark. 1 mm length of rootlet is decided to be adequate for germination and germinated seeds were counted every day. This process was continued until the number of germinated seeds is fixed. Germination rate (GR, %) was calculated as percentage of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38373848

ratio of germinated seeds to total sown seeds. Average Germination Speed (AGS, day) were calculated according to *Equation 1* (Pedersen et al., 1993).

$$AGS = (A_1.D_1 + A_2.D_2 + \ldots\ldots A_n.D_n) / (A_1 + A_2 + \ldots\ldots A_n) \qquad (Eq.1)$$

A: The number of seeds germinated every day,
D: The day required for germination of the seed,
n: Number of the days until the last count.

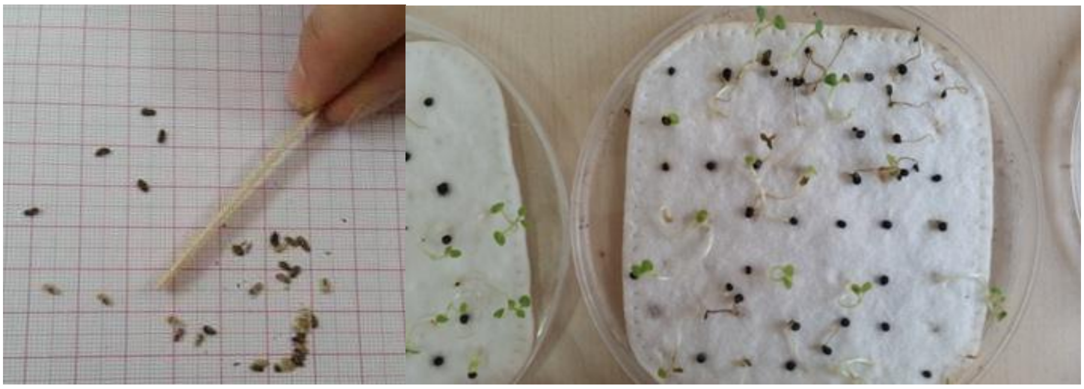

Figure 3. *A view from germination test*

Seeds obtained from the natural habitat and trial area were planted in a viol (4 cm × 4 cm × 6 cm) which includes peat soil and perlite and placed in greenhouse. In 3 replicated experiments, 30 seeds were planted in each replicate for the seedling tests. Appearance of cotyledon leaves was considered as seedling (*Fig. 4*). Each day the seedling was recorded and this process was continued until the number of seedlings was fixed. Seedling raising rate (SRR, %) was calculated as percentage of the ratio of seedlings to total sown seeds. Average Seedling Raising Speed (days, ASRS) were calculated according to *Equation 2*.

$$ASRS = (A_1.D_1 + A_2.D_2 + \ldots\ldots A_n.D_n) / (A_1+A_2 + \ldots\ldots A_n) \qquad (Eq.2)$$

A: The number of seeds raising every day,
D: The day required for germination,
n: Number of the days until the last count.

Determination of phenological properties and chlorophyll (SPAD) value

After germinating, seedlings reached a certain size (65 days after seed sowing), 10 of them were selected and transferred to viols. Flowering was not seen in seedlings. 2017 vegetation period phenological properties such as plant height, plant diameter, leaf width and leaf length were measured. SPAD value of the plants was also determined on the plants (*Fig. 4*). SPAD-502 (Minolta Ltd, Osaka Japan) is hand-held chlorophyll meter equipment based on the measurement of leaf chlorophyll content. It measures the leaf transmittance in red light at 650 nm (at which chlorophyll absorbs) and in near-infrared light at 940 nm (for the correction of leaf thickness). The ratio of these two transmission values is referred to as SPAD reading or SPAD value (Monostori, 2016).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38373848

SPSS (Statistical Programs for Social Science) 13.0 program was used for statistical analyses. The mean values and standard deviation values of the data were given.

Figure 4. *Seedlings on the experimental plots and determination of chlorophyll value*

Biochemical analysis

It is important to ensure the continuity of their biochemical properties as well as their phenological properties especially in medicinal aromatic plants. Biochemical analyzes were performed in the seedlings in 2017 vegetation period and their average values were given. Randomly selected five plants from each plot were cut from the base at each stage and separated into leaf+stem and head. They were oven dried at 65 °C until constant weight was obtained. The oven dried weight of leaf, stem and head were recorded. Total N determination was made according to the Regular Kjeldahl Method (Boț et al., 2017) and Phosphorus (P) amount was determined by Vanadomolybdophosphoric Yellow Color Method (Spectrophotometric) (Rajkumar et al., 2017). Determination of Potassium (K), Calcium (Ca), Magnesium (Mg), Iron (Fe), Copper (Cu), Manganese (Mn) and Zinc (Zn) were determined by wet decomposition-AAS (Atomic Absorption Spectroscopy) method (Tariq et al., 2017).

Besides, after the plant materials collected, flower and leaf samples were subjected to solid phase microextraction (SPME) by GC-MS system. 2 g of samples were placed into a 10 ml vial. After incubation for 30 min at 60 °C, SPME fibre was pushed through the headspace of a sample vial to absorb the volatiles and then inserted directly into the injection port of the GC-MS (Shimadzu 2010 Plus GC-MS with the capillary column, Restek Rxi®-5Sil MS 30 m × 0.25 mm, 0.25 µm) at a temperature of 250 °C for desorption (5 min) of the adsorbed volatile compounds. The constituents were identified using retention times of standard substances by aligning mass spectra with the data given in the Wiley, NIST Tutor, FFNSC library (Özderin et al., 2016).

Results and discussions

Germination ability and seedling raising rate of plant

Seed dormancy varies depending on the temperature and species among *Lamiaceae* family (Copete et al., 2015). Although there is no study in these taxas, the different species belonging to the *Lamiaceae* family are mentioned as non-dormant (Panuccio et al., 2017). In germination experiments, no germination was observed in *Ajuga chamaepitys* subsp. *chia* var. *chia* plants. The germination rate of *Ajuga orientalis* was 18% in the seeds taken from the natural habitat and 21.33% in the seeds taken from the trial area. Although there was no germination for *Ajuga chamaepitys* subsp. *chia* var. *chia* in petri dishes, it was determined that seedlings emerged in peat soil experiments.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38373848

Seedling rising rate increased in seedling trials for both taxa (*Table 1*). In germination experiments in soil, herbal seeds have adaptation advantages, since seeds are protected from environmet (Adams et al., 2005). Avarage seedling raising speed for *Ajuga chamaepitys* subsp. *chia* var. *chia* was 23.67 days. It was observed that germination was seen between the days of 20-30. Avarage seedling raising speed for *Ajuga orientalis* was 20.67 days and germination of these seeds was mostly seen between the days of 20-35 (*Fig. 5*). In different species of the *Lamiaceae* family, the percentage of germination varies from 20 to 50%, while the average germination time can be as long as 30 days (Mattana et al., 2016).

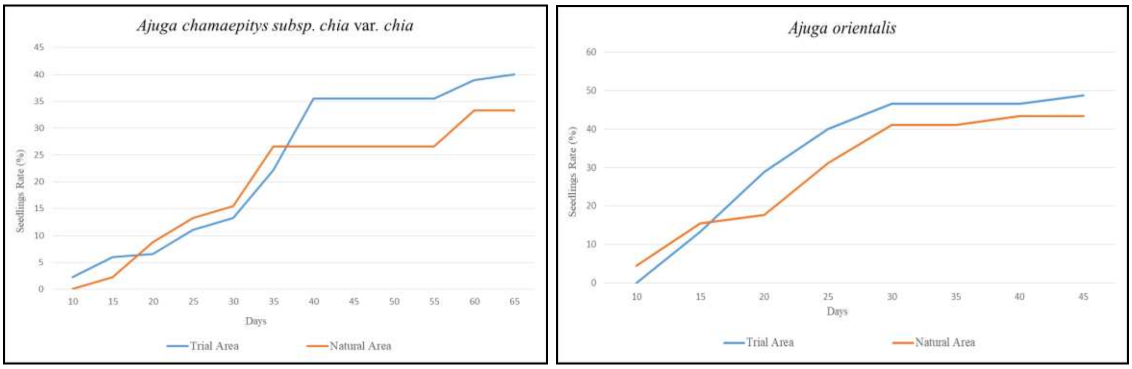

Figure 5. *Distribution of seedling rate by day*

Phenological properties and chlorophyll (SPAD value)

These *Ajuga* taxas are horizantally growing plants and height and diameter values are directly related to each other (Dönmez et al., 2017). According to the data in *Table 2*, no change was observed in plant height and diameter values in the seedlings obtained from seeds taken from natural habitat and trial area.

Chlorophyll is a necessery pigment for photosynthesis. The content of chlorophyll is one of main sources reflecting leaf photosynthesis ability and plant health condition (Jiang et al., 2017). The connection between leaf chlorophyll content determined in vitro and SPAD meter readings (SPAD values) were extensively analysed and usually parameterised by linear relationship (Monostori, 2016). Chlorophyll was measured almost 50.00 SPAD value in both plant species. This rate corresponds to the rate in which the seeds are collected from rootstock plants (Dönmez, 2018). When the phenological properties were compared, no statistically significant difference was found between the seeds collected from natural habitat and trial area. Although studies on

DOI: http://dx.doi.org/10.15666/aeer/1702_38373848

phenological properties of *Ajuga* seedlings is out of our knowledge, results are compatible with some of the species belonging to *Lamiaceae* family (Rather et al., 2016; Mandal et al., 2008).

Biochemical properties

As a result of biochemical analyzes, the nitrogen amount of *Ajuga chamaepitys* subsp. c*hia* var. *chia* was found to be 2.15% in the seedlings obtained from natural habitat seeds and 2.23% from trial area seeds. There were seen little differences between the other macro and micro-element analyzes, the seedlings of the seeds obtained from the trial area have higher calcium, copper and manganese ratios (*Table 3*). The nitrogen amount of *Ajuga orientalis* was 2.94% in the seedlings obtained from the natural habitat seeds and 3.42% in the seedlings obtained from trial area seeds. In the other macro and micro-element analyzes, the phosphorus, potassium and copper ratios of the seedlings obtained from the trial area seeds were found to be higher. In the literature, there is no study on the macro and micro element content of these plants.

48 different volatile components of *A. chamaepitys* subsp. *chia* var. *chia*, collected from both area, were determined by GC-MS after solid phase micro extraction (SPME). Limonene, which is the highest component, was determined as 28.17% in the natural plants seedlings and 29.24% in the cultivated plant seedlings. The second highest component, β-pinene was found to be 17.71% in the natural plants seedlings and 18.26% in the cultivated plant seedlings (*Table 4*). These results coincide with the studies done by Azizan et al. (2002) and Delezar et al. (2012). In addition, the same components were also seen to be the highest in rootstocks where seeds were collected (Dönmez, 2018). In *A. orientalis* seedligs volatile oil, 41 components were identified from both area samples. 1-Octen-3-ol, which is the highest component, was determined as 23.48% in the natural plants seedlings and 22.89% in the cultivated plant seedlings (*Table 5*). However, germacrene-D and β-cubebene, was previously identified as the highest compounds in this plant (Saijadi and Ghannadi, 2004; Yaldiz, 2012).

Conclusion

It was seen that the seedling rising rate in production of *Ajuga chamaepitys* subsp. *chia* var. *chia* with seed was about 35% and the rising speed was found to be between 33 and 36 days. Seed experiments were carried out in seeds collected from plants randomly and no improving nursing material was given to the seeds. The phenological properties and biochemical structures of the seedlings had the same characteristics. The seedling rate in production of *Ajuga orientalis* with seed was about 45% and the rising speed was 23 days. There were no differences in germination and seedling characteristics of the seeds. Although germination ratio was seen to be low, the trial area seedlings had the same germination ability with natural plants.

(Received 16th Jan 2019; accepted 20th Feb 2019)

Abstract. Germination, emergence and seedling growth are considerably restricted by salinity. The study aimed to compare safflower with sunflower during germination and seedling growth for tolerance to salinity. Four safflower cultivars (Asol, Balcı, Linas and Olas) and sunflower hybrids (Esbella, Oliva, Cartago and C-180) were subjected to various NaCl levels (control, 5, 10 and 15 dS m^{-1}) and their seedling growth and ion concentration were investigated. Classification for salinity tolerance was performed by a combination of Principal Component (PCA) and Cluster Analysis considering germination percentage (GP), mean germination time (MGT), vigor index (VI), Na^+ and Na:K ratio in seedlings. The results elicited that genotypes exhibited varying responses to salinity, MGT significantly prolonged and a dramatic reduction in seedling growth of sunflower was observed. The highest seedling fresh weight was observed in Esbella among sunflower and Asol among safflower and, Na^+ concentration of seedlings increased with increasing salinity levels. The safflower seedlings absorbed a higher Na^+ than that of sunflower. Safflower cv. Balcı had the highest Na^+ concentration in seedling and it maintains its ion balance (Na:K ratio) at all levels of NaCl. Cluster analysis revealed that there were two groups for salinity tolerance, and the safflower cultivars were apparently more salt-tolerant than sunflower hybrids.

Introduction

Sunflower (*Helianthus annuus* L.) and safflower (*Carthamus tinctorius* L.) are the most important oil seed crops from *Asteraceae* family. These plants are usually preferred in arid and semi-arid regions under rain-fed conditions, where low rainfall and high evapotranspiration during vegetation periods restricts the growth of crop plants (Kaya et al., 2003). Under these conditions, drought and salinity are the major abiotic stresses that severely inhibit germination, seedling establishment and plant growth; consequently, seed yield decreases (Hussain et al., 2016). The restrictive effects of salinity on plant life are mainly osmotic effect of salts and toxic effects of Na^+, Cl^- and SO_4^{-2} ions (Ashraf and Fatima, 1994; Chinnusamy et al., 2005; Muhammad and Hussain, 2010), but some crop plants or varieties in a species have been more tolerant than the others.

Sunflower and safflower are classified as moderately salt tolerant based on seed yield (Grieve et al., 2012). When the plants were to be classified according to salinity tolerance, they were compared under saline and non-saline conditions with each other in terms of plant growth parameters, yield and quality performance. For the classification, the controlled conditions are commonly preferred because the environmental changes are discarded. A lot of researches on the comparison of genotypes, varieties or species for tolerance to salt stress have been conducted and tried to find a valid selection criteria for the tolerance mechanism (Hussain et al., 2016). Plant biomass and photosynthetic activity by Munns and Tester (2008), Siddiqi et al. (2009) and Farooq et al. (2015), reduced chlorophyll content by Ashraf (2004), leaf water and osmotic potential by Gadallah (1996) and Munns (2002), ion toxicity by Munns et al. (2006) and Rejili et al. (2007) and reduction in seed yield by Francois (1996) and Natarajan et al. (2005) have been considered the suitable parameters for ranking the genotypes for salinity tolerance. On the other hand, these parameters to be used for selection criteria have not been easily investigated and heritable. Recently, several indices have been commonly developed for grouping plants under salt stresses (Nikbakht et al., 2010; Zafar et al., 2015; Krishnamurthy et al., 2016). Saboora and Kiarostami (2006) and Kaya et al. (2012) classified the genotypes using all the parameters they measured by using a combination of Cluster and Principal component analysis (PCA) instead of searching a parameter, and lastly Aslam et al. (2017) ranked lentil germplasm for salinity tolerance using multiple traits by PCA based Biplot. Multivariate analysis has the superiority for genotypic classification because accuracy is considerably increased using multiple traits, and gives a general tolerance level based over mean values derived from each stress level (Zeng et al., 2002). For these reasons, this research focused on determining more tolerant plant to salinity between sunflower and safflower considering germination and seedling growth traits, sodium concentration and sodium / potassium ratio in seedling.

Materials and Methods

This study was conducted at Seed Science Laboratory of Department of Field Crops, Eskişehir Osmangazi University, Turkey. Four native safflower cultivars Asol, Balcı, Linas and Olas registered in Turkey, and four sunflower hybrids Esbella, Oliva, Cartago and Pioneer C-180 were used in the study. The seeds of the respective varieties were subjected to three levels of the electrical conductivity of 5, 10 and 15 dS m^{-1} constituted by NaCl along with distilled water as a control treatment.

Two hundred (4×50) seeds of each genotype were inserted into three layer filter papers irrigated with 7 mL of the saline solutions for each paper. After filter papers with seeds were rolled, they were replaced into a sealed plastic bag to prevent moisture evaporation. Each rolled paper was renewed every 2 days after incubation to avoid the salt accumulation. Germination tests were conducted at 25 ± 1 °C in the dark condition and a seed with 2 mm radicle was counted every 24 h for 10 d as germinated. The speed of germination was evaluated by means of mean germination time (MGT) which was represented by the ISTA (2003) rules. MGT= $\Sigma(Dn)/\Sigma n$, where, n is the seed number germinated on day D, and D is the number of days from the beginning of germination test. Ten seedlings selected from each treatment at the 10^{th} day were sampled for determination of seedling growth traits such as root length (RL), shoot length (SL) and seedling fresh weight (SFW). Vigor index (VI) is calculated by multiplying germination percentage (GP) (%) and seedling length (cm) and the genotypes with the higher vigor index are considered to be more vigorous (Abdul-Baki and Anderson, 1973). Also, percent reduction in shoot length and seedling fresh weight between control and 15 dS m^{-1} were calculated as (control plants-stressed plants / control plants) × 100 described by Shirani Rad and Abbasian (2011). The index didn't give in Tables because they used only for statistical evaluation. To determine Na^+ and K^+ concentration in seedlings, all the seedlings from each treatment were used. After the seedlings were firstly washed with

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38493857

distilled water three times, excessive water on seedling surface water was dried with paper towel. The weighed seedlings were dried in an oven at 70°C for 48 hours and then they were grounded. Plant samples were acid digested in microwave oven, and Na^+ and K^+ concentrations were measured using a flame photometric method described by Kacar and Inal (2008).

The experiment was established as two-factor factorial (salinity × genotype) arranged in a completely randomized design (CRD) with 4 replications. Data were statistically analyzed by MSTAT-C program (Michigan State University). The differences between the means were tested by the Least Significant Differences at $P < 0.05$ level. For ranking the varieties for salinity tolerance, Principle Component (PCA) and Cluster Analysis were done by SPSS.

Results and Discussion

A two-way interaction was significant for all characters of safflower varieties ($P < 0.05$; *Table 1*). Similar germination percentages from safflower cultivars were observed while Balcı gave the highest germination percentage at all levels of NaCl. MGT was clearly prolonged by increasing NaCl levels, and NaCl level of 15 dS m^{-1} led to retardation in germination more dramatically compared to lower levels of NaCl. The most rapid time to germination at 15 dS m^{-1} was calculated in Linas (1.96 days). Compared to control, the root length was remarkably depressed at 15 dS m^{-1} and Balcı gave the longest root under NaCl stresses. The shoot length of safflower was the most sensitive parameter adversely affected by salinity. It was drastically diminished and the longest shoot at 15 dS m^{-1} was measured in Asol with 7.00 cm. Similarly, the seedling fresh weight was reduced under salt stresses and Asol exhibited a heavier seedling than the others did. In terms of seedling growth and germination percentage together under salinity, the highest vigor index was obtained from Balcı under all levels of NaCl.

The responses of the investigated sunflower hybrids to salinity stresses are illustrated in *Table 2*. A significant difference was determined for germination percentage of sunflower as affected by the interaction of hybrids × NaCl levels. In general, sunflower hybrids gave similar germination percentage under NaCl levels, but lower germination percentage was observed in C-108 and Cartego at 5 dS m^{-1}. MGTs of sunflower hybrids also showed similarity to each other while it was prominently extended by an increase in NaCl level. Also, an apparent reduction in root length was detected by increasing salinity; however, the root growth of Esbella was not adversely influenced. Esbella and Oliva gave the highest root and shoot length under NaCl stresses. Seedling fresh weight of sunflower hybrids was gradually declined depending on changes in root and shoot growth, but Esbella showed the superiority to other hybrids for seedling growth under salinity. The highest vigor index was observed in Oliva under NaCl levels except for 10 dS m^{-1}.

*: Means followed by the same letter(s) are not significantly different at $p<0.05$. GP: germination percentage, MGT: mean germination time, RL: root length, SL: shoot length, SFW: seedling fresh weight, VI: vigor index

Seedling of safflower cultivars accumulated much more Na^+ than did the sunflower hybrids, and the amount of Na^+ was the highest in Balcı at all levels of NaCl (*Figure 1*). Moreover, NaCl level of 15 dS m^{-1}, Asol seedlings absorbed more Na^+ from the medium. Na:K ratio represented that Balcı maintained the ionic balance under salt stresses while Asol become unbalanced at 15 dS m^{-1} (*Figure 2*).

PCA and Cluster Analysis performed by mean values of germination percentage, MGT, vigor index, percent reduction in seedling length and fresh weight, ion concentration in seedlings and Na:K ratio emerged that two main groups were constituted (*Figure 3*). The safflower varieties were found more tolerant than sunflower varieties to NaCl stresses. Among safflower varieties, the superiority of Balcı and Asol appeared under NaCl stresses.

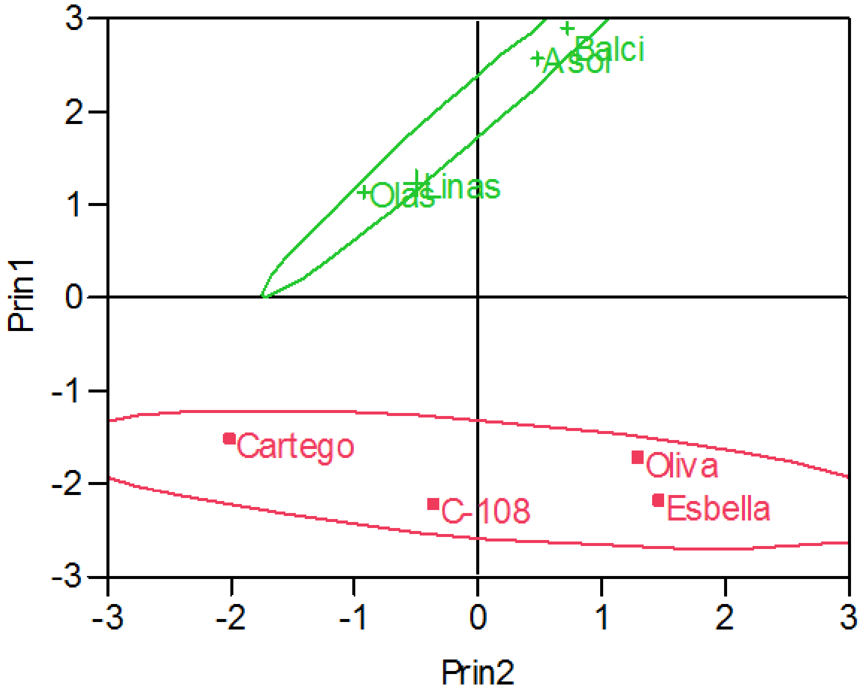

***Figure 3.** Classification of sunflower and safflower genotypes for salinity tolerance using germination percentage, MGT, vigor index, Na^+ and K^+ concentrations of seedling, Na:K ratio, percent reduction in seedling length and fresh weight measured at 10 d old seedlings*

Salt concentration between control and 15 dS m^{-1} didn't lead to a clear increase or decrease in germination percentage of safflower and sunflower genotypes while the statistical differences were determined. Similar findings were reported by Kaya et al. (2006) who found no significant changes in germination with increasing salinity stresses in sunflower. Genotypic variation at 15 dS m^{-1} was significantly appeared and the most rapid germination was recorded in Asol and Oliva. Generally, NaCl levels slightly affected germination of both species, indicating that it should not be used for selection criteria for salinity tolerance. The findings are confirmed by the results of Muhammad and Hussain (2010), who reported that NaCl levels up to 15 dS m^{-1} didn't severely influence germination in flax. Salts constitute osmotic stress or specific ion toxicity, especially Na, responsible for retarding and inhibiting germination of several plants as declared by Chinnusamy et al. (2005), Okcu et al. (2005) in pea, and Atak et al. (2006) in triticale. Nevertheless, seedling growth of both species was severely depressed while sunflower seedling was more sensitive to increasing salinity. The greatest reduction was observed in shoot length of sunflower compared to safflower. Depending on root and shoot growth depletion, seedling fresh weight was severely reduced and this reduction was obvious at 15 dS m^{-1}. These findings have supported the results of previous researches in sunflower by Ashraf and O'Leary (1997), Mohammed et al. (2002), Kaya et al. (2006), Day et al. (2008) and in safflower by Kaya et al. (2003), Siddiqi et al. (2007) and Farhoudi and Motamedi (2010).

Seedling of safflower cultivars accumulated much more Na^+ than did the sunflower hybrids, and the amount of Na^+ was the highest in Balcı at all levels of NaCl (Figure 1).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38493857

Moreover, Na^+ concentration in Asol seedlings clearly improved at 15 dS m^{-1}. This means that Balcı could keep up with higher Na^+ concentration in cells without any significant depression or vitality in seedlings (Chinnusamy et al., 2005). Conversely, NaCl depressed the seedling growth of sunflower hybrids, although they absorbed less Na^+ from the germination medium. It seems that K^+ in the seeds was leaked into the medium and the seedling uptook Na^+ from the medium. Chinnusamy et al. (2005) and Hussain et al. (2016) represented that increasing NaCl levels caused an increase in K^+ leakage from seeds. Atak et al. (2006) found Na^+ concentration in seeds was increased by increasing NaCl levels regardless of K^+ level. In terms of ion balance, Na:K ratio, Balcı was the most stable genotype against increasing NaCl levels, although Asol showed an extraordinary behavior at 15 dS m^{-1} (Figure 2). It is argued that Asol could not maintain the ion balance and ultimately Na^+ was surprisingly peaked at 15 dS m^{-1}.

Principle component analysis (PCA) has been effectively implemented with sorting the genotypes under different environmental conditions, especially drought and salinity stresses (Kaya et al., 2012; Aslam et al., 2017). Cluster analysis and PCA analysis were made on mean data obtained from each genotype subjected to various salinity stresses. Our results showed that two main groups were discovered by Cluster analysis, and PCA1 (67.2%) and PCA2 (13.8%) represented 81.0% of data variability. It is strongly declared that safflower varieties were more tolerant to salinity than sunflower hybrids along with differences among genotypes.

Conclusion

This experimental preliminary study shows that significant differences between safflower and sunflower for salinity tolerance apparently existed at germination and early seedling growth. The superiority of safflower under saline condition was clearly identified, while there were genotypic variations within the species; eliciting that Balcı and Asol among safflower, Oliva and Esbella among sunflower were more tolerant to NaCl stresses. However, the further study is required to evaluate salt tolerance subsequent growth stages of safflower and sunflower under field conditions to confirm their tolerance levels.

VOLATILE OIL COMPOSITION OF *AJUGA* SPECIES OF NATURAL AND CULTIVATED ORIGIN IN THE LAKE DISTRICT OF TURKEY

DÖNMEZ, Ş.

Department of Landscape Architecture, Faculty of Architecture, Süleyman Demirel University 32100 Isparta, Turkey
(e-mail: sirindonmez@sdu.edu.tr; phone: +90-246-211-3985; fax: +90-246-211-8231)

(Received 21st Jan 2019;accepted 20th Feb 2019)

Abstract. Leaves and flowers of *Ajuga chamaepitys* subsp. *chia* var. *chia* and *Ajuga orientalis*, which were taken from both their natural habitat and cultivars, were analyzed by SPME and GC-MS. The amount and the composition of volatile oil of cultivated plants were compared with natural area plants. β-pinene was detected as major component in *A. chamaepitys* in both natural habitat and cultivars. It was seen that its amount was between 17.86-25.21%. Moreover, germacrene-D was determined in significant amount (15.40-21.13%) in both samples of *A. chamaepitys*. 2-hexen-1-al was the most abundant component in the natural area (30.89%) and cultivated plants (23.12%) in the first vegetation period of *A. orientalis* but a decrease of almost 80% was determined in the second vegetation period. The amount of 1-octen-3-ol was found as one of the dominant components in *A. orientalis* and no significant difference was observed in both natural habitat and cultivars, during the vegetation periods. In addition, the amount of limonene in *A. orientalis* volatile oil increased in the second vegetation period compared to the first.
Keywords: *Lamiaceae, SPME, GC-MS, pinene, germacrene, Turkey*

Introduction

Volatile oil mainly consists of volatile components. It is fragrant, naturally occurring, colorless or light yellow and it is obtained from plants, leaves, fruits, bark and root parts, which are liquid and easily crystallizable (Ceylan, 1983). It is known that volatile oil contains a large amount of terpenes and a small amount of alcohols, aldehydes, esters and phenolics (Linskens and Jackson, 1997). There are many ways to reveal the volatile oil components of plants. Although distillation and extraction are quite well-known methods, SPME (Solid Phase Micro Extraction) is used as it is new and easily applicable. It is suitable for both combining the sample preparation, extraction and concentration sections in a single step and for providing significant gains in processing time and cost. SPME is used to identify volatile organic compounds in the samples by combining with GC or GC-MS (Vas and Vekey, 2004).

Research on the volatile oil components of medicinal and aromatic plants has gained a significant place both scientifically and economically. In recent years, the use of volatile oil has also increased with the increase of interest in aromatherapy and phytotherapy, which is a branch of the alternative medicine (Rangahau, 2001).

Ajuga chamaepitys subsp. *chia* var. *chia* and *Ajuga orientalis* are species which belong to the *Lamiaceae* family. The *Lamiaceae* family grows almost everywhere in the Mediterranean climate without considering the plant type and height. *Lamiaceae* family has 400 genus and 3200 species around the world and it is represented by 45 genus and more than 546 species in Turkey. Among the species belonging to the *Lamiaceae* family, *Thymus* and *Origanum* have an important position in food industry, *Pogestamon* and *Lavandula* are considered in the perfume industry, and particularly the volatile oil

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38593866

of the species of *Ajuga* and *Teucrium* is used for therapeutic purposes (Watson and Dallwitz, 1978; Clive and Stace, 1980; Davis, 1982; Baytop, 1991; Ozkan, 2007).

Ajuga chamaepitys subsp. *chia* var. *chia* can grow up to 2000 m altitudes in Turkey, Crimea, Greece, Palestine, Iran and Northern Iraq (Davis, 1982). It is a herbaceous plant with a 20 cm length, yellow flowering and pleasant fragrant perennial suffrutescens (Baytop, 1999). The length of the shoots is 5-30 cm. The whole plant is covered with white feathers and the flowers are yellow and the flowering time is between April and July (Akcan et al., 2006; Jakovljević et al., 2015; Dönmez et al., 2017).

Ajuga orientalis extends from Crimea to Sicily, West Syria, Cyprus, Caucasus and North West Iran. It can grow up to 2500 m from sea level in Mediterranean, Agean, Black Sea and Central Anatolia Regions in Turkey (Tekin, 2007). It is a perennial herbaceous plant with violet-blue and cream-colored flowers that can be sized up to 140 cm (Yazgın, 2010). The leaves are crossed on the trunk and rich in the lower part of the trunk. The flowering time is between April and May (Dönmez et al., 2017).

In this study, it was aimed to determine the composition and the amount of volatile oil and the yield of the same plant species in both natural habitat of the plants and their cultivars after the cultivation of *A. chamaepitys* subsp. *chia* var. *chia* and *A. orientalis*.

Material and method

Material

A. chamaepitys subsp. *chia* var. *chia* and *A. orientalis*, which belong to *Lamiaceae* family, were used for determining volatile oil yield and components. In the vegetation period of 2015, *A. chamaepitys* subsp. *chia* var. *chia* was taken from Aşağıgökdere, Isparta, where the altitude was 324 m (37º32´42´´ N, 30º46´42´´ E) and *A. orientalis* was removed from Kemer, Antalya, from an altitude of 413 m. (36º36´26´´ N, 30º27´53´´ E), with their roots. They were cultivated at Süleyman Demirel University (SDU), Botanical Garden by sowing. Plants, found in natural habitat and cultivars can be seen in *Figure 1*. In the vegetation period of 2016 and 2017, leaves and flowers of these plants, which were taken both from their natural habitat and cultivars at SDU, were used in the analyses of volatile oil production. The study area is located in the transition zone between the Mediterranean and terrestrial climate. According to data of Isparta Meteorological Station, the average annual temperature in the region was 12ºC. While the maximum temperature was 38.7ºC in July, and the minimum was -21ºC in January. The mean annual precipitation amount was 508.3 mm.

Volatile Oil Yield

In order to determine volatile oil yield, hydrodistillation with Clevenger apparatus was used. The material is directly immersed in water and it has direct contact with hot water and heat. For determining volatile oil yield of each species, 100 g ground samples were submitted to hydrodistillation for 5 h using a Clevenger apparatus. Volatile oil yield was calculated as ml/100 g samples.

SPME and GC-MS analyses

The leaves and flower samples that were collected from both natural habitat and cultivars were put into paper packages and transferred to the laboratory in the same day to avoid exposure to sunlight and samples were subjected to solid phase microextraction

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38593866

(SPME). 2 g of samples were placed into a 10 ml vial. After incubation for 30 min at 60°C, SPME fibre was pushed through the headspace of a sample vial to absorb the volatiles and then inserted directly into the injection port of the GC-MS (Shimadzu 2010 Plus GC-MS with the capillary column, Restek Rxi®-5Sil MS 30 m x 0.25 mm, 0.25 µm) at a temperature of 250°C for desorption (5 min) of the adsorbed volatile compounds. The constituents were identified using retention times of standard substances by aligning mass spectra with the data given in the Wiley, NIST Tutor, FFNSC library.

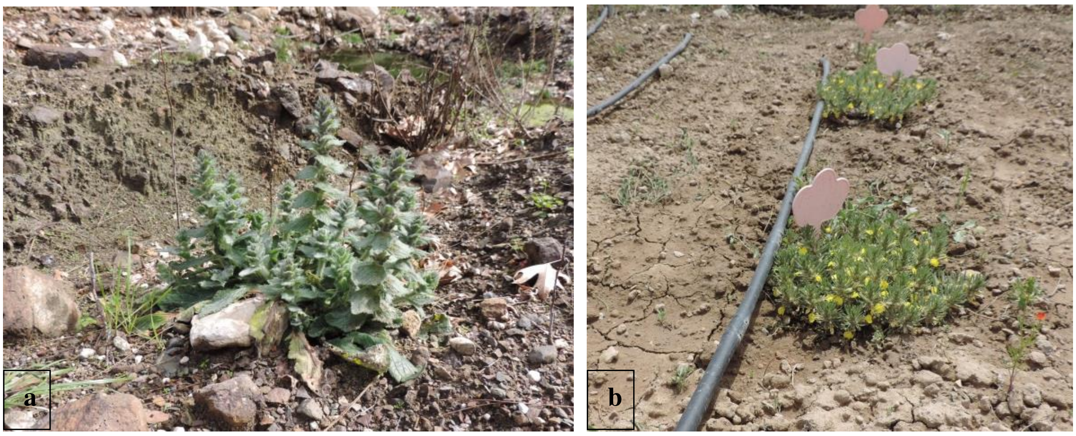

Figure 1. *A view from both natural habitat (a) of A. orientalis and cultivation (b) of A. chamaepitys subsp. chia var. chia*

Results and discussion

Analyses for getting volatile oil and determining volatile oil yield of both *Ajuga* species was performed in two vegetation periods (2016 and 2017) on the samples gathered from their natural habitat and cultivars at the same time. Volatile oil yield of both *Ajuga* species was determined after hydrodistillation. It was found that volatile oil yield of *A. chamaepitys* subsp. *chia* var. *chia* was determined very close in both samples during two vegetation periods. It was determined as 0.10 ml/100 g in natural area plants and 0.15 ml/100 g in field area plants in the first vegetation period. Moreover, it was 0.10 ml/100 g in both samples in the second vegetation period.

The volatile components in the leaves and flowers of *Ajuga* species collected from the sampling plots were identified through gas chromatography mass spectroscopy (GC-MS) after solid phase micro extraction (SPME).

The amount and the composition of volatile oil of *A. chamaepitys* subsp. *chia* var. *chia* can be seen in *Table 1*. 41 components in the samples from natural habitat and 39 components in the samples from cultivars of the first vegetation period were determined. However, 50 and 49 components, respectively, were identified in the second vegetation period. β-pinene was determined as the dominant component in all samples in both vegetation period of *A. chamaepitys* subsp. *chia* var. *chia*. While its amount was 19.15% in natural habitat and 17.86% in the samples from cultivars in the first vegetation period, it was found 22.25% in in natural habitat and 25.21 % in the samples from cultivars in the second vegetation period. Germacrene-D was the second component having highest amount. It was seen that its amount increased in the second vegetation period compared to the first vegetation period.

The amount of germacrene-D was 19.04% in the samples from natural habitat and 15.40% in the samples from cultivars in the first vegetation period. However, it was detected 19.63% and 21.13%, respectively, in the second vegetation period.

Although β-myrcene was determined only in the first vegetation period in both sampling areas, myrcene was seen only in the second vegetation period samples. Besides, caryophyllene was detected only in natural habitat samples with the amount of 12.17% in the first vegetation period. In the second vegetation period, the amount of caryophyllene decreased almost 50% compared to the first vegetation period samples. It was found 5.82% in the samples from natural habitat whereas it was 5.99% in the samples from cultivars.

Volatile oil of *Ajuga* species were determined by several researches. Azizan et al (2002) determined volatile oil components of *A. chamaepitys* subsp. *chia* var. *chia* by hydrodistillation. Totally 25 components were identified and α-pinene (16.1%), β-pinene (34.38%) and germacrene-D (5.6%) were found as the dominant components. Saijadi and Ghanhadi (2004) found germacrene-D (24.2%), β-cubebene (18.3%), β-caryophyllene (16.9%) and α-cubebene (5.3%) as the highest in *A. chamaepitys* subsp. *chia* var. *chia* volatile oil. It was another study done by Delazar et al (2012) in which α-pinene (23.66%), β-pinene (9.33%), β-phellandrene (8.70%) and germacrene-D (7.92%) were the dominant components of Iranian *A. chamaepitys* subsp. *chia* var. *chia* volatile oil.

Volatile oil yield of *A. orientalis* was 0.10 ml/100 g in the samples from natural habitat and 0.05 ml/100 g in the samples from cultivars in the first vegetation period. In the second vegetation period, volatile oil yield of natural habitat samples was 0.15 ml/100 g while it was the same as the former in the samples from cultivars. The amount and the composition of *A. orientalis* volatile oil determined by SPME and GC-MS can be seen in *Table 2*. In both samples of the first vegetation period, 44 components were identified. However, the identified components were 40 in the samples from natural habitat and 53 in the samples from cultivars in the second vegetation period.

While 2-hexen-1-al had the maximum amount in the first vegetation period in the samples from natural habitat, 1-octen-3-ol was determined as the highest amount component in the samples from cultivars.

Moreover, 1-octen-3-ol was also dominant component of the second vegetation period samples with 28.16% in natural habitat and 26.79% in cultivars. Volatile oil composition and antimicrobial activity of *Ajuga orientalis* was presented by Yaldiz (2012). It was seen that germacrene-D, cubebene and caryophyllene were the major components of *A. orientalis* volatile oil.

Conclusions

A. chamaepitys subsp. *chia* var. *chia* and *Ajuga orientalis*, which grow naturally in Lake District in Turkey, were cultivated in 2015. Volatile oil analyses were carried out in 2016 and 2017 by using leaves and flowers of these plant species from both natural habitat and cultivars. It was seen that there were same components and the amount of components were close to each other in both sampling areas. It was concluded that these plants were cultivated without losing their chemical structure. This is a particularly important result for these two plant species belonging to the *Lamiaceae* family, which are known to be used as medicinal and aromatic plants. In this direction, it is thought that these plants can be produced in industrial sense and can also be used in different industries such as pharmaceuticals and cosmetics due to their chemical composition.

Abstract. Cultivation is an important part in rice production which could affect rice growth and development significantly. In order to study the effect of different cultivation methods on rice performance, two land preparation ways (plough and rotary) and two rice growing techniques (direct-seed and transplanted rice) were used in present study and four cultivation methods were set as: (PD) the land was puddle twice with plough cultivator and pre-germinated seeds were hill-seeded with direct seeding machine; (RD) the land was puddle twice with rotary cultivator and pre-germinated seeds were hill-seeded with direct seeding machine; (PT) the land was puddle twice with plough cultivator and 15-day-old seedlings were hill-transplanted with transplant machine; (RT) the land was puddle twice with rotary cultivator and 15-day-old seedlings were hill-transplanted with transplant machine. The results showed that the highest yield was recorded in both PT and RT and the lowest yield was recorded in RD. There was no difference among different cultivation methods on net photosynthetic rate but different cultivation affected the transpiration rate and water use efficiency at different stage differently. Furthermore, the highest head rice rate and grain protein and the lowest chalky rice rate was all recorded in PD treatment. Overall, higher yield was recorded in transplanted rice cultivation than direct-seed cultivation and the greatest grain quality was observed under direct seeding rice cultivation and plough tillage conditions.
Keywords: *rice, tillage, cultivation methods, photosynthesis, yield, grain quality*

Introduction

Rice (*Oryza sativa.* L) is one of the main crops in Asia and the rice production system has become the backbone of Chinese food security system for many years (Xing et al., 2019; Wang et al., 2019). In 2017, China's rice planting area was 6.795 billion hectares (Han et al., 2019). However, the availability of arable land has been decreased in recent years and the increasing population has intensified the conflict for land planning between fiber and cereal crops (Fang et al., 2019). Therefore, experts are inevitably striving to find more ways to improve crop productivity.

Normally, land preparation is an important part in rice production because puddling is required to decrease the loss of water and nutrients through excessive percolation and it also is able to reduce weeds and enhance nutrient availability (Hazra et al., 2014; Alam et al., 2018). Previous studies already showed that soil puddling in paddy field benefits rice yield (Datta and Kerim, 1974; Kukal and Aggarwal, 2003). However, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38673875

effect of puddling is still not clear regarding rice growth and development despite the benefits.

Normally, mechanical puddling is performed twice in Chinese paddy field, ploughing and rotary tillage. There also are two rice system which including direct seeding rice and transplanted-flooded rice in China. Those managements all had their own impacts on rice growth and development. For example, the study of Pan et al. (2017) indicated that direct seeding rice could be a more substitutive rice growing technique to transplanted-flooded rice with less production costs, labor and extra efforts for nursery raising, seedling uprooting, and transplanting. SUN (2017) demonstrated that ploughing tillage could help to improve the soil temperature, improve the environment of soil and promote the root activity and improve the production of tobacco leaf. But there was no much report about the effect of different puddling or growing technique on rice growth, development, yield and quality.

Thus, in order to study the effect of different cultivation methods on rice growth and development, present study was conducted in Guangdong Province, China with two mechanical puddling and two rice growing techniques.

Material and Methods

Plant materials and growing conditions

A fragrant rice cultivar, *Meixiangzhan-2*, which having a growth period of 111-114 days and widely planted in South China, was used in the experiment and planted at late season of 2017 in Zengcheng (23°13’ N, 113°81’ E, altitude 11 m), Guangdong. The experimental site enjoyed a subtropical monsoon climate with mean annual air temperatures of 21.3ºC and mean annual precipitation of 2660.9 mm. Before sowing, the seeds were soaked in water for 24 h, germinated in manual climatic boxes for another 12 h and shade-dried. Some of the germinated seeds were sown in polyvinyl chloride trays for nursery raising. The experimental soil in Zengcheng was sandy loam containing organic matter 10.04 g kg^{-1}, total N 0.50 g kg^{-1}, total P 0.26 g kg^{-1}, and total K 15.10 g kg^{-1}.

Treatment description and plant sampling

Two land preparations, ploughing(P) and rotary(R) were adopted with two growing techniques. The treatment description is as below:

- PD: Before planting, the land was puddle twice with plough cultivator. Pre-germinated seeds were hill-seeded with direct seeding machine at a space of 25×15 cm while each hill was planted with 4–6 seeds.
- RD: Before planting, the land was puddle twice with rotary cultivator. Pre-germinated seeds were hill-seeded with direct seeding machine at a space of 25×15 cm while each hill was planted with 4–6 seeds.
- PT: Before planting, the land was puddle twice with plough cultivator. 15-day-old seedlings were hill-transplanted with transplant machine at a space of 25 × 15 cm while each hill was transplanted with 4–6 seedlings.
- RT: Before planting, the land was puddle twice with rotary cultivator. 15-day-old seedlings were hill-transplanted with transplant machine at a space of 25 × 15 cm while each hill was transplanted with 4–6 seedlings.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38673875

The treatments were arranged in randomized complete block design (RCBD) in triplicate in each year with net plot size of 120 m^2. At tillering stage, heading stage and maturity, ten random rice plants were collected from each plot, for estimation of dry matter accumulation.

Photosynthesis

Portable photosynthesis system (CIRAS 2; PP systems, Amesbury, MA, USA) was used to determine net photosynthetic rate and gas exchange attribute i.e., stomatal conductance, intercellular carbon dioxide concentration, transpiration rate, water use efficiency and vapor pressure deficit at 09:00–10:30 a.m.

Grain quality

After sun drying, grains were stored at room temperature for at least a month to determine grain quality components. About 1.0 kg rice grains from each treatment was taken from storage and brown rice rate was estimated using a rice huller (Jiangsu, China) while milled rice and head rice recovery rates were calculated by using a Jingmi testing rice grader (Zhejiang, China). Grains with chalkiness and chalkiness degree were estimated by using an SDE-A light box (Guangzhou, China) while an Infratec-1241 grain analyzer (FOSS-TECATOR) was used to determine the grain amylose and protein contents.

Yield and yield related traits

At maturity stage, the rice grains were harvested from seven-unit sampling area (1 m^2) in each plot and then threshed by machine. The harvested grains were sun-dried and weighted in order to determinate the grain yield. Twenty hills of rice from different locations in each plot were sampled for estimate the average effective panicles number per hill. Then, eight hills representative plants were taken for estimation of the yield related traits.

Statistical analysis

Data were analyzed on Statistix 8.1 (Analytical Software, Tallahassee, FL, USA) while differences among means were separated by using least significant difference (LSD) test at 5% probability level. Graphical representation was conducted via Sigma Plot 14.0 (Systat Software Inc., California, USA).

Result

Yield and yield related trails

As shown in *Table 1*, different cultivation methods affected rice yield and its related trails significantly. The highest yield was recorded in both PT and RT while there was no significant difference between RT and PT. The lowest yield was recorded in RD. The difference in rice yield among different cultivation could be explained by the yield related trails. For panicle number, the panicle number per hill in RT and PT was significantly higher than PD and RD; For grains number per panicle, the highest grains number was recorded in PD and grains number in RD and PT was remarkably number

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38673875

than PD; For seed-setting rate, the highest rate was recorded in PT; For grain weight, the 1000-grain weight in PD was significantly higher than RD, PT and RT.

Table 1. *The effect of different cultivation methods on rice yield and its related trails*

Treatment	Panicle number per hill	Grains number per panicle	Seed-setting rate (%)	1000-grain weight (g)	Yield (t ha^{-2})
PD	328.74±2.37b	117.87±4.22a	74.29±1.77b	22.08±0.31a	6.63±0.14b
RD	329.38±1.01b	107.33±4.15b	74.05±4.15b	20.74±0.27b	5.61±0.38c
PT	385.06±4.65a	106.80±6.99b	82.41±6.99a	20.84±0.05b	7.11±0.29ab
RT	395.73±18.51a	111.87±3.25ab	77.77±3.23ab	21.16±0.28b	7.43±0.29a

Values sharing a common letter within a column don’t differ significantly at (P≤ 0.05) according to least significant difference (LSD) test for both the years. The same as below

Grain quality

As shown in *Table 2*, different cultivation methods affected grain quality significantly. There was no remarkable difference among different cultivation methods in both brown rice rate and milled rice rate. However, the head rice rate in PD and RD was significantly higher than PT and RT. The moisture in PD and RD was significantly higher than PT and RT. The trend of crude protein content was recorded as: PD > RD > RT > PT. The lowest amylose content was recorded in RT while there was no significant difference among PD, RD and PT. Moreover, there was no remarkable difference among Akali and chalkiness whilst the trend of chalky rice rate was recorded as: RT > PT > RD = PD.

Table 2. *The effect of different cultivation methods on grain quality*

Plant height

As shown in *Figure 1*, the plant height of rice under different cultivation methods increased with the growth until 70 days after the sowing and then it gradually stabilized and remained unchanged. The trend of plant height was recorded as: PT = RT > PD > RD since 42 days after the sowing.

Photosynthesis and gas exchange

As shown in *Figure 2*, there was no remarkable difference in net photosynthetic rate among different cultivation methods at tillering stage, heading stage and maturity. Similar conditions were also observed in both intercellular carbon dioxide concentration and stomatal conductance. However, at tillering stage, the transpiration rate in RT was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38673875

significantly higher than PD while the both the lowest vapor pressure deficit and water use efficiency were recorded in RT. Moreover, at maturity, both the highest transpiration rate and the lowest vapor pressure deficit were recorded in RD treatment.

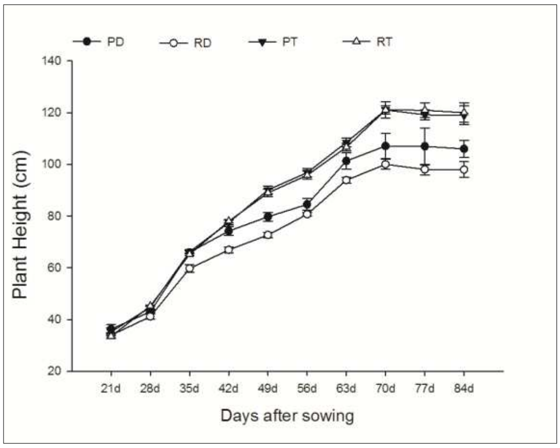

Figure 1. *The effect of different cultivation methods on rice plant height*

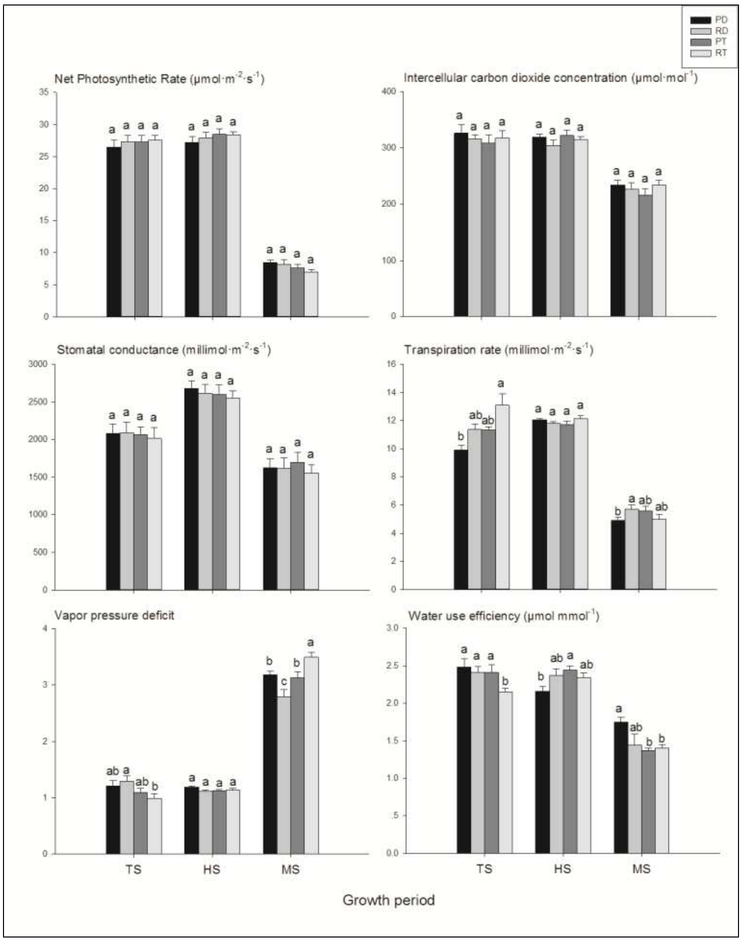

Figure 2. *The effect of different cultivation methods on rice photosynthesis and gas exchange. Means sharing a common letter don't differ significantly at (P≤ 0.05) according to least significant difference (LSD) test*

Dry matter accumulation

Different cultivation methods affected dry matter weight differently (*Figure 3*). At heading stage, the dry matter weight in PT and RT were significantly higher than PD and RD. At maturity, the trend of dry matter weight was recorded as: PT = RT > PD > RD.

Discussion

Cultivation is a very important part in rice production. Some researchers already investigated the effects of some cultivation methods on rice performance and paddy fields. For example, Zhang et al. (2008) indicated that non-flooded mulching cultivation not only could increase root oxidation activity and photosynthesis, but also enhanced the activities of key enzymes in sucrose-to-starch conversion at filling stage. The study of Bouwman (1991) revealed that different cultivation methods could affect the methane emissions in paddy field by influencing the oxido-reduction capacity of the soil. Moreover, the study of Qin et al. (2006) showed that non-flooded rice cultivation was able to mediate rice growth, decrease the evapotranspiration and increase water use efficiency. In our study, there were also some differences among different cultivation methods in rice yield and yield related trails. The highest yield was recorded in both PT and RT while the rice yield in PT was significantly higher than PD just like RT was higher than RD. This discovery indicated that the transplanted-flooded rice cultivation had higher yield compared to direct seeding rice. The increment of yield in transplanted-flooded rice cultivation could be explained by the higher panicle number and seed-setting rate. The further reason might be the transplanted rice cultivation had the nursery raising part for seedling growth which direct seeding rice culitivation didn't. This result was consistant with previous studies which showed that nursery practice was benefit to early establishment for rice and could improve the rice yield potential (Sarangi et al., 2015; Zhang et al., 2017). Moreover, there was no signifcant difference in yield between PT and RT whilst the grain number, grain weight and yield in PD were signifcantly higher than RD. This discovery might indicated that the land prepation of plough tillage would be more suitable for direct seeding rice system.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38673875

Present study also showed that different cultivation methods also affected the grain quality significantly. Compared to PT and RT, PD and RD had higher head rice rates and crude protein contents. The lower chalky rice rates were also recorded in PD and RD than PT and RT. Grain quality is the main factor which depends the rice price in market (Ahmad et al., 2017; Norton et al., 2017). In our study, the result showed that the grain quality in direct seeding rice was higher than transplanted-flooded rice. Moreover, the highest grain protein content was recorded in PD and it might indicate that the environment of direct seeding rice cultivation and plough tillage would be the most suitable for protein content biosynthesis in grains. The reasons could be PD condition enhanced the activity of key enzymes involved in protein biosynthesis or improved the nitrogen absorption, utilization and transportation in rice (TsukaguchiNitta and Matsuno, 2016; Luo et al., 2018; Wang et al., 2018).

In our study, there was no significant difference among different cultivation methods in net photosynthetic rate. But interestingly, we found that different cultivation methods could alter the vapor pressure deficit in paddy field by affecting the transpiration rate of rice. The values of water use efficiency were also different under different cultivation methods. Those differences might be caused by plant-soil systems which were different because of the different land preparations and rice growing techniques (Pan et al., 2017; Wang et al., 2017).

Conclusion

Different cultivation methods affected rice yield and quality differently. Present study showed that the higher yield was recorded in transplanted rice cultivation than direct-seed cultivation and the greatest grain quality was observed under direct seeding rice cultivation and plough tillage conditions. In order to reveal the mechanism of how cultivation affected rice performance, more investigation should be couducted at the field trials or at molecular level before the real application.

Abstract. This study was carried out with 3 replications and 24 parcels according to randomized complete blocks trial design between 2017 and 2018 as two separate experiments. The study was planned to determine the effects of previously identified *Stenotrophomonas maltophilia* TV14B (phosphate solubilizing), *Bacillus atrophaeus* TV83D (nitrogen fixation), *Bacillus*-GC group TV119E (phosphate solubilizing), *Cellulomonas turbata* TV54A (nitrogen fixation) and combined effects of *Bacillus atrophaeus* TV83D and *Bacillus*-GC group TV119E on the development of Ceyhan-99 and Fırat-93 bread wheat cultivars. According to the results, the highest grain yield for Fırat-93 durum wheat cultivar was obtained under full dose chemical fertilizer application (288.89 kg/da); while the highest grain yield (283.33 kg/da) in the case of bacteria applications was observed with *Bacillus atrophaeus* TV83D, nitrogen-fixation bacteria. The difference between these two was not significant, and these bacteria can be seen as an alternative to chemical fertilization. The highest yield among bacterial applications was obtained under treatment with *Bacillus atrophaeus* TV83D, a nitrogen-fixation bacterium with 319.45 kg/da, and the difference between them was statistically significant. At the end of the study it was concluded that *Bacillus atrophaeus* TV83D bacterial strain can be used as a microbial fertilizer because of its ability to increase grain yield significantly in both genotypes.

Introduction

Cereals is a large group consisting of economically important species like the *Graminea* (wheats = corbels) family, cool climate cereals like wheat (*Triticum*), barley (*Hordeum*), oats (*Avena*), rye (*Secale*) and triticale, and warm climate cereals like corn (*Zea*), paddy (*Oryza*), maize (*Sorghum*), flint corn (*Panicum*) and avian (*Phalaris*) (Elçi et al., 1994). Wheat, corn and rice generate 85% of the world's grain production. Wheat is the most cultivated grain among these agricultural products providing high energy with grains containing plenty of starch. Wheat (*Triticum* sp.) is the most highly composite among cereals. Wheat is an indispensable plant used as a source of carbohydrates, providing basic input to livestock and industry. It is also the main food source of most countries with the largest cultivation area in the world.

Wheat constitutes approximately 29-30% of the world total grain production and is the most important plant-based protein source of humankind (Gustafson et al., 2009). Scientists consider its genetic complexity as a miracle, and which blends perfectly with changing environmental conditions. Wheat cultivars are the more superior in comparison with other grains and their nutritive values (Zohary and Hopf, 2000).

Global efforts to increase wheat production in parallel with population growth have been partially successful. Although this has also increased the yield of wheat, it is not sufficient to meet the needs of the growing population.

As the aim in crop production is to increase the dry matter yield per unit area, intensive input use increases in parallel. Fertilizer is one of the most important items among these inputs. It is determined that approximately 15% of the total chemical fertilizer used in the world is in wheat farming. There is an increasing trend towards the use of organic fertilizers worldwide to avoid the negative effects of chemical fertilizer use. In these organic fertilizers, Plant Growth-Promoting Bacteria (PGPB) is an alternative source of microbial fertilizers. In researches, especially *Pseudomonas* ssp., *Azospirillum* sp. and *Pantoea* sp. bacteria groups were found to increase plant growth and nitrogen intake in wheat and maize grown in temperate climates (Meena and Rai, 2017).

In recent years, the commercial formulations of these bacteria have been used in the cultivation of many plants such as corn, wheat, potatoes and tomatoes and it has been determined that these bacteria have a significant effect on plant height, root development and increase in dry matter. In addition, the use of these bacteria is predicted to reduce the use, cost and environmental pollution of chemical fertilizers and pesticides (Mehnaz et al., 2001, 2010; Tozlu et al., 2014). It has been reported that bacterial activity varies according to soil properties, soil organic matter content, plant and bacteria variety and plant growing conditions (Çakmakçı et al., 2006). In this respect, further studies are needed on the effects of bacteria on plant growth. In this study, the effect of Plant Growth Inhibiting Bacteria on the development, yield and yield components of wheat were investigated. It has been determined that the effect of the bacteria, which are revealed by field and greenhouse studies especially on wheat, has not been investigated at an adequate level before. In this study, the bacteria, which are isolated from Van Lake Basin and known to promote plant growth, are inoculated in bread and durum wheat varieties. Afterwards, their effects on wheat yield, yield and yield components were investigated.

One of the aims of this study was to quantify the productivity of dryland farmed bread and durum wheat cultivars that was seed inoculated. In addition, the effect of these bacteria on reducing the use of inorganic fertilizers was also examined.

Literature research

In many countries, the effect of Plant Growth-Promoting Bacteria (PGPB) on durability against biotic and abiotic stress on yield increase in cereals has been extensively researched and will continue to be researched more. Studies conducted in different countries and ecologies show that PGPB significantly increased wheat yield parameters in single applications (Naveed et al., 2008; Zabihi et al., 2011; Hussain et al., 2016; Mukhtar et al., 2017; Sood et al., 2018; Tahir et al., 2018). In addition, it has been reported that biomass, grain yield, macro and micronutrient intake increased significantly compared to the control in studies where different bacteria were administered in multiple combination (Zabihi et al., 2011; Sood et al., 2018). In addition to the yield parameters of wheat, PGPB has been reported to increase the number of germination, increase in germination speed and germination rate (Rana et al., 2011; Laloo et al., 2017), increase the amount of capillary root (Dal Cortivo et al., 2017), increase the root length (Afzal and Bano, 2008; Abbasi et al., 2011; Dal Cortivo et al.,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38773896

2017), increase the height of the plant (Afzal and Bano, 2008; Abbasi et al., 2011; Mukhtar et al., 2017) and increase the root and body dry weight (Mukhtar et al., 2017). In addition, plant growth-promoting bacteria containing 1-Aminocyclopropane-1-Carboxylate Deaminase (ACCD), which provides resistance to plant stress conditions, contribute to the growth and development of plants normally by reducing plant ethylene levels under various environmental stress conditions (Çakmakçı, 2009). In the study conducted with Indol Acetic Acid (IAA), siderefor, Hydrocyanic Acid (HCN) and ACC deaminase producing bacteria, germination rate and speed of the bacterium producing siderophore (Rana et al., 2011) was observed to increase. In addition, it has been reported that the bacteria with ACC deaminase activity have a significant increase in the yield parameters (Naveed et al., 2008).

It is aimed to reduce the amount of chemical fertilizers by using PGPB since chemical fertilizers cause significant environmental problems during and after their application to agriculture areas and also due to the use of intensive fossil fuels in their production. For this purpose, it was revealed in the studies conducted on wheat that the use of chemical fertilizers could be reduced by 20% to 50% with the usage PGPBs (Naveed et al., 2008; Zabihi et al., 2011; Abbasi et al., 2011; Hussain et al., 2016; Sood et al., 2018). In a study, it has been reported that PGPBs increase the yield of grain by 30-40% according to chemical phosphorous fertilization (Afzal and Bano, 2008).

Materials and methods

Materials

Wheat species

In this study, Fırat-93 durum and Ceyhan-99 bread wheat varieties were used. Seeds were obtained from Seed Sales Office of General Directorate of Agricultural Enterprises. General characteristics of varieties are below.

Fırat-93: Medium plant height, very waxy and strong stems; narrow, long and steep leaf structure. Spike is medium length, white in color and has black stringiness. It has a fuller, hard and glassy grain and its thousand grain weight is between 45-50 g. It is suitable for summer, middle early and drought tolerant and has good tillering characteristics. It is recommended for rainy, irrigable areas and coastal areas of Southeastern Anatolia. It shows a tolerant reaction to yellow rust disease which can be seen from time to time in the region (Anonymous, 2018a).

Ceyhan-99: Plant height is between 90 and 100 cm. The spikes are white and lengths are medium, and they are upright. It is resistant to bending. Grain color is white, and it has a hard structure. The weight of thousand grains varies between 41 and 45 g. This wheat variety reacts well to fertilizers. Drought and winter resistances are moderate. It is resistant to yellow rust and *Septoria* diseases and it is half resistant to brown rust. Harvest-blending ability is high. The strings are not spilled at harvest time (Anonymous, 2018b).

Bacteria strains

The bacteria were isolated from the Van Lake basin with the TOVAG 108O147 TÜBİTAK project and their PGPB activity was detected (Erman et al., 2010). These bacteria were diagnosed with the microbial identification system (MIS) they were used as double combinations. These bacteria are: *Stenotrophomonas maltophilia* TV14B (phosphate solubilizing), *Bacillus atrophaeus* TV83D (nitrogen fixation), *Bacillus*-GC group TV119E (phosphate solubilizing), *Cellulomonas turbata* TV54A (nitrogen fixation) and *Bacillus atrophaeus* + *Bacillus*-GC group (TV83D + TV119E)

Methods

Climate and soil properties of the research site

The research was carried out in the laboratory of Field Crops Department of Agricultural Faculty of Siirt University in the period of 2017-2018 and in the trial area of Field Crops Department in dry agricultural conditions. The field trial was established at 37°58'2.18"K and 41°51'13.10"D coordinate point and 538 meters altitude.

In Siirt, terrestrial climate is dominant in general. Summers are hot and dry. The highest air temperature measured is 43.3 °C and the lowest air temperature is –19.5 °C. The average temperature, precipitation and relative humidity values of Siirt, where the research was conducted are presented in *Table 1*. These values cover the long years (1938-2017) as well as the period between October-June 2017-2018. As can be seen from *Table 1*, the 2017-2018 production season was generally dry and the rate of rainfall in March and April decreased. However, the rainfall in the month of May has been 84.6 mm higher than the average of many past years (Anonymous, 2018c). This situation affected the wheat yield negatively.

Table 1. *Average climate values of Siirt for long term averages in the past and for 2017-2018 October-June period*

Months	Temperature (°C)		Precipitation (mm)		Humidity (%)

Trial pattern

The trial consisted of 48 parcels in two separate trials consisting of 24 parcels of 1 × 5 m size with 3 replications, with bread and durum wheat according to the randomized block design.

Fertilizer application

Fertilization has been done to the bacteria untreated parcels as full fertilization with values of 9 kg N/da and 7 kg P_2O_5/da; half of these values were applied in 50% fertilization. In addition, 50% and 100% chemical fertilizers were applied without control and fertilization (0% fertilizer). No bacteria were applied to the parcels where the controls were located. The activity of the bacteria was determined according to the controls. All of the phosphorus and 1/3 of the nitrogen were given during planting and diammonium phosphate (18-46-0) was used. The remaining part of the nitrogen was given by urea fertilizer (46% N) during the period of tillering and stalking.

Bacteria application

In the experiment, within the scope of the TÜBİTAK project numbered TOVAG 108O147, nutrient agar (Merck-VM71680604), which was isolated from Van Lake basin and was previously diagnosed with MIS system, was used as a feed-lot for the multiplication of bacteria, PGPB activity of which was exposed to greenhouse and field conditions. 20 g of nutrient agar was added to one liter of distilled water, adjusted to pH 7.0, and the mixture was sterilized by autoclave for 15 min at 121 °C. After sterilization, the feed-lots were cooled to 50 °C, then transferred to petri plates and allowed to solidify. The stock cultures of the bacteria were planted in nutrient agar medium with the help of the needle and incubated at 26 ± 2 °C for 24 h (*Fig. 1*).

Figure 1. *Development of bacteria in nutrient agar and nutrient broth fed-lot*

The nutrient broth (Merck-VM775843711) was used as the liquid feed-lot. 8 g of nutrient broth feed-lot was added to one liter of distilled water and pH was adjusted to 7.0. The mixture was sterilized by autoclave for 15 min at 121 °C and then allowed to cool. A single colony was taken from the bacteria developed in nutrient agar feed-lot and was transferred to nutrient broth feed-lot in aseptic conditions. The bacteria transferred to the liquid feed-lot were incubated at 26 ± 2 °C for 24 h and at 120 rpm in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38773896

the horizontal shaker. After incubation, the bacteria concentrations were turbidimetrically adjusted to ~ 10^8 cfu/ml (*Fig. 1*). In the final stage, the bacteria were inoculated into the seed. Surface sterilization of the seeds was made with 5% (v/v) sodium hypochlorite for 20 min and washed 3 times with distilled water. Bacteria were applied to the surface sterilized seed for 3 h in order to allow the swelling of the seed (Clark, 1965). Seeds were laid on drying sheets and allowed to dry. Dried seeds were planted on the field one day later. Sterile nutrient broth feed-lot was used as control.

Planting, care, harvest and threshing

The experiment was established on the experimental area of Agricultural Faculty of Siirt University in the 2017-2018 production season with three replications according to the randomized block design (*Fig. 2*).

The size of the parcels is 5 m, the width is 1 m (5 rows and between each row there is 20 cm) and each parcel area is 5 m^2. Seeds were planted in parcels as 500 seeds per m^2. In each parcel, gloves were used to prevent the bacteria from smearing on the seed surface. Experiment was established on 21.11.2017, and the plants sprouted on 01.12.2017 (*Fig. 3*). Weed control was done by hand. No disease or harmful situation has been observed in the trial area which could cause economic damage.

Figure 2. *Land parcelling and planting*

Figure 3. *Trial and parcel views*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38773896

With the planting process, diammonium phosphate (DAP) was given as 7 kg phosphorus and 3 kg nitrogen per decare. According to the results of soil analysis, to meet the nutrients needed by plants; in the period of tillering and bolting, urea was applied in the form of upper fertilization with 3 kg of pure nitrogen. 9 kg pure nitrogen and 7 kg phosphorus were given to the plants during planting, tillering and bolting periods. One row on each side of the parcels and 50 cm of space at the beginning and end of the parcel were left and the remaining 2.4 m^2 area was harvested with the sickle on 01.07.2018. Then it was taken to the warehouse and blended with the machine.

Obtaining data

The experiment was continued during one growing season. Plant height (cm), spike length (cm), number of tillerings (pcs), number of spikes per square meter (pcs/m^2), number of spikelets per spike (number/spike), number of grains per spike (pieces/spike), weight of thousand grams (grams), grain yield (kg/da), biological yield (kg/da), hectoliter weight (kg/100 l), harvest index (%) values were determined based on the methods applied in the studies of Tosun et al. (1971) and Ünver (1995).

Statistical evaluation of the results

The mean values obtained from the data were analyzed using the Statix 10 package program. Grouping of means was done according to Tukey's HSD test.

Results

Plant height (cm)

In terms of applications, the highest plant height of Fırat-93 durum wheat was obtained from *Stenotrophomonas maltophilia* (TV14B) with 74.13 cm. and the lowest plant height was obtained from non-inoculated and non-fertilized control with 68.23 cm. Plant sizes in other applications are among these two values (*Table 3*).

Table 3. *Average values of plant height in Fırat-93 durum and Ceyhan-99 bread wheat varieties inoculated with different bacterial strains*

Application	Fırat-93 durum wheat	Ceyhan-99 bread wheat
Non-inoculated and non-fertilized control	68.23	71.67^b
50% fertilized control	70.76	78.20^a
100% fertilized control	72.43	77.33^a
Stenotrophomonas maltophilia (TV14B)	74.13	80.07^a
Bacillus atrophaeus (TV83D)	73.36	78.60^a
Bacillus-GC Group (TV119E)	73.71	79.47^a
Cellulomonas turbata (TV54A)	72.80	77.50^a
Bacillus atrophaeus + *Bacillus* -GC Group (TV83D+TV119E)	72.33	78.40^a
Average	72.22	77.65

Mean values in columns shown with different letters are significant at $p < 0.05$ level according to Tukey's HSD test

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38773896

The highest plant height of the Ceyhan-99 bread wheat was obtained from the application of *Stenotrophomonas maltophilia* (TV14B) with 80.07 cm. and the lowest plant height was obtained as 71.67 cm. from non-inoculated and non-fertilized control. Plant sizes in other applications are among these two values. Plant height in TV14B bacterial application was observed to be 11% higher than non-inoculated and non-fertilized control. However, in all bacterial applications, the height of the plant was observed to be higher than non-inoculated and non-fertilized control (*Table 3*).

Spike length

The highest spike length of the Fırat-93 durum wheat was obtained from *Bacillus*-GC Group (TV119E) bacteria with 5.92 cm. and the lowest spike length was obtained from non-inoculated and non-fertilized control as 5.23 cm. Spike length in other applications is among these two values. In addition, it was observed that other bacterial applications had a positive and significant effect on spike size compared to non-inoculated and non-fertilized control (*Table 4*).

Table 4. *Average values of spike size in Fırat-93 durum and Ceyhan-99 bread wheat varieties inoculated with different bacterial strains*

Application	Fırat-93 durum wheat	Ceyhan-99 bread wheat
Non-inoculated and non-fertilized control	5.23^{b}	6.45^{c}
50% fertilized control	5.38^{ab}	6.94^{bc}
100% fertilized control	5.42^{ab}	6.98^{bc}
Stenotrophomonas maltophilia (TV14B)	5.69^{ab}	7.90^{a}
Bacillus atrophaeus (TV83D)	5.84^{ab}	7.22^{ab}
Bacillus-GC Group (TV119E)	5.92^{a}	7.92^{a}
Cellulomonas turbata (TV54A)	5.86^{ab}	7.63^{ab}
Bacillus atrophaeus + *Bacillus* -GC Group (TV83D+TV119E)	5.77^{ab}	7.37^{ab}
Average	5.64	7.30
P	**0.0126**	**0.0001**
Tukey's HSD	0.6471	0.7668

Mean values in columns shown with different letters are significant at $p < 0.05$ level according to Tukey's HSD test

The highest spike length of the Ceyhan-99 bread wheat was obtained from the *Bacillus*-GC Group (TV119E) bacteria with 7.92 cm. The lowest spike length was obtained from non-inoculated and non-fertilized control with 6.45 cm. Spike length in other applications is among these two values. It has been observed that bacterial applications have a positive and statistically significant effect on the increase of spike length compared to all three controls (*Table 4*).

Tillering count

In terms of applications, the highest number of tillerings of Fırat-93 durum wheat was obtained from 2.93 to 50% fertilized control application, while the lowest number of tillerings was obtained by *Cellulomonas turbata* (TV54A) with 2.52. The number of tillerings in other applications was among these two values. Only *Bacillus atrophaeus*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38773896

(TV83D) (2.73 count) bacterial application increased in terms of the number of tillerings compared to non-inoculated and non-fertilized control (2.63 count) and other bacterial applications remained below this value (*Table 5*).

Table 5. *Average values of number of tillerings in Fırat-93 durum and Ceyhan-99 bread wheat varieties inoculated with different bacterial strains*

Application	**Fırat-93 durum wheat**	**Ceyhan-99 bread wheat**
Non-inoculated and non-fertilized control	2.63	2.07
50% fertilized control	2.93	2.30
100% fertilized control	2.76	3.27
Stenotrophomonas maltophilia (TV14B)	2.57	2.07
Bacillus atrophaeus (TV83D)	2.73	2.23
Bacillus-GC Group (TV119E)	2.60	2.50
Cellulomonas turbata (TV54A)	2.52	2.53
Bacillus atrophaeus + *Bacillus* -GC Group (TV83D+TV119E)	2.53	2.27
Average	2.66	2.40
P	**0.722**	**0.2748**
Tukey's HSD	0.8756	1.6299

The highest number of tillerings of Ceyhan-99 bread wheat was obtained from the application of 100% fertilized control with 3.7. The lowest number of tillerings was obtained with 2.07 from non-inoculated and non-fertilized control and *Stenotrophomonas maltophilia* application (TV14B). The number of tillerings in other applications was among these two values. With the exception of *Stenotrophomonas maltophilia* (TV14B), there were positive increases in other bacterial applications compared to non-inoculated and non-fertilized control (*Table 5*).

Number of spikes per square meter

In terms of applications, the highest number of spikes per square meter that belongs to Fırat-93 durum wheat was obtained as 450 from 50% fertilized control application. The lowest number of spike number for square meter was obtained from *Cellulomonas turbata* (TV54A) bacteria application with 291.67. In other applications, the number of spikes per square meter was between these two values. It has been found that bacterial applications generally do not contribute to the increase in the number of spikes per square meter compared to the controls, and that the number of spikes per square meter in all bacterial applications is lower than the general average (369.79) (*Table 6*).

The highest number of spikes per square meter of Ceyhan-99 bread wheat was obtained as 535.33 from 100% fertilized control application, while the lowest number of spikes were obtained as 370.00 from non-inoculated and non-fertilized control bacterial application. In other applications, the number of spikes per square meter was between these two values. It has been observed that bacterial applications have more spike numbers per square meters compared to non-inoculated and non-fertilized control. According to the results of the study, the highest number of spikes per square meter was obtained in chemical fertilizer applications (*Table 6*).

Spikelet count of the spike

In terms of applications, the highest number of spikelets that belong to Fırat-93 durum wheat was obtained from *Bacillus*-GC Group (TV119E) bacteria application with 18.10 and the lowest number of spikelets was obtained as 15.93% with 50% Fertilized Control application. In other applications, the number of spikelets was between these two values. However, it was observed that *Stenotrophomonas maltophilia* (TV14B) and *Bacillus atrophaeus* (TV83D) bacterial applications did not affect the increase in the number of spikelets (*Table 7*).

Table 7. *Average values of the number of spikelets per spike in Fırat-93 durum and Ceyhan-99 bread wheat varieties inoculated with different bacterial strains*

Application	Fırat-93 durum wheat	Ceyhan-99 bread wheat
Non-inoculated and non-fertilized control	16.90[ab]	14.43[b]
50% fertilized control	15.93[b]	15.70[ab]

DOI: http://dx.doi.org/10.15666/aeer/1702_38773896

In terms of applications, the highest number of spikelets of Ceyhan-99 bread wheat was obtained from *Cellulomonas turbata* (TV54A) as 17.57 and the lowest number of spikelets was obtained from non-inoculated and non-fertilized control as 14.43. In other applications, the number of spikelets in the spike was between these two values (*Table 7*).

Grain count of the spike

In terms of the applications, the highest number of grains per spike for Fırat-93 durum wheat is 36.40 with *Bacillus*-GC Group (TV119E) bacterial application, the lowest number of grains per spike obtained as 27.93 with 50% Fertilized Control application. The number of grains per spike in other applications was between these two values (*Table 8*).

Table 8. *Average values of the number of grains per spike in Fırat-93 durum and Ceyhan-99 bread wheat varieties inoculated with different bacterial strains*

Application	**Fırat-93 durum wheat**	**Ceyhan-99 bread wheat**

Tukey's HSD	7.2193	10.615

Mean values in columns shown with different letters are significant at $p < 0.05$ level according to Tukey's HSD test

The highest number of grains per spike of Ceyhan-99 bread wheat is observed to be 34.54 with *Bacillus atrophaeus* + *Bacillus*-GC Group (TV83D + TV119E) bacterial application and the lowest grain number per spike was obtained as 25.63 with non-inoculated and non-fertilized control. The number of grains per spike in other applications was between these two values. The data obtained from all bacterial applications were found to be higher on average than the non-fertilized and non-inoculated and 50% fertilized control applications (*Table 8*).

Thousand grain weight

In terms of applications, the highest thousand grain weight of Fırat-93 durum wheat is obtained from 100% fertilized control application as 47.99 g. while the lowest thousand grain weight is obtained from *Bacillus atrophaeus* (TV83D) application as 43.88 g. The weight of one thousand grain in other applications was between these two values (*Table 9*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38773896

Table 9. *Average values of thousand grain weight in Fırat-93 durum and Ceyhan-99 bread wheat varieties inoculated with different bacterial strains*

Application	Fırat-93 durum wheat	Ceyhan-99 bread wheat
Non-inoculated and non-fertilized control	46.30	38.45
50% fertilized control	46.17	38.81
100% fertilized control	47.99	38.45
Stenotrophomonas maltophilia (TV14B)	45.54	40.03

Average	46.13	39.00
P	**0.0706**	**0.0806**
Tukey's HSD	3.7015	2.268

The highest thousand grain weight of the Ceyhan-99 bread wheat was obtained from the application of *Stenotrophomonas maltophilia* (TV14B) application as 40.03 g. and the lowest thousand grain weight was obtained as 38.28 g. with *Bacillus atrophaeus* (TV83D) application. One thousand grain weight in other applications is among these two values (*Table 9*).

Grain yield

In terms of applications, the highest grain yield of Fırat-93 durum wheat was obtained from 100% fertilized control application as 288.89 kg/da. The lowest grain yield was obtained from *Bacillus atrophaeus* + *Bacillus*-GC Group (TV83D + TV119E) bacteria application as 218.75 kg/ha.

Table 10. *Average values of grain yield in Fırat-93 durum and Ceyhan-99 bread wheat varieties inoculated with different bacterial strains*

Application	Fırat-93 durum wheat	Ceyhan-99 bread wheat
Non-inoculated and non-fertilized control	243.06	256.95^{c}
50% fertilized control	256.25	354.17^{ab}
100% fertilized control	288.89	360.00^{a}
Stenotrophomonas maltophilia (TV14B)	275.69	304.08^{abc}
Bacillus atrophaeus (TV83D)	283.33	319.45^{abc}
Bacillus-GC Group (TV119E)	229.17	285.41^{abc}
Cellulomonas turbata (TV54A)	244.44	273.61^{bc}
Bacillus atrophaeus + *Bacillus* -GC Group (TV83D+TV119E)	218.75	274.30^{bc}
Average	254.95	303.50
P	**0.1174**	**0.0052**
Tukey's HSD	89.116	85.447

Mean values in columns shown with different letters are significant at $p < 0.05$ level according to Tukey's HSD test

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38773896

The grain yield in other applications was between these two values. In addition, *Bacillus atrophaeus* + *Bacillus*-GC Group (TV83D + TV119E) and *Bacillus*-GC Group (TV119E) bacterial applications were found to be scarcer and less effective on grain yield compared to the non-inoculated and non-fertilized control. However, yield in *Bacillus atrophaeus* (TV83D) (283.33 kg/da) and *Stenotrophomonas maltophilia* bacterial applications (TV14B) (275.69 kg/da) was found to be close to the full dose fertilizer application (288.89) (*Table 10*).

The highest grain yield of Ceyhan-99 bread wheat was obtained from 100% fertilized control as 360.00 kg/da and the lowest grain yield was obtained from non-inoculated and non-fertilized control application as 256.95 kg/da. The grain yield in other applications was between these two values. Bacterial applications were found to contribute to grain yield compared to non-inoculated and non-fertilized control, but the yield was 50% and 100% lower than fertilized control. It was observed that *Bacillus atrophaeus* (TV83D) bacterial application showed a 24% increase in yield compared to non-inoculated and non-fertilized control (*Table 10*).

Biological yield

In terms of applications, the highest biological yield of Fırat-93 durum wheat was obtained from *Stenotrophomonas maltophilia* (TV14B) bacteria as 756.95 kg/da. The lowest biological yield was obtained from *Bacillus atrophaeus* + *Bacillus* -GC Group (TV83D + TV119E) bacterial application as 565.97 kg/da. Biological yields in other applications are among these two values. *Bacillus*-GC Group (TV119E) and *Cellulomonas turbata* (TV54A) bacterial applications were found to have a negative effect on biological yield. It was observed that *Stenotrophomonas maltophilia* (TV14B) application had the highest biological yield (756.95 kg/da) and was found to be more efficient than the yield in full dose fertilizer application (752.78 kg/da) (*Table 11*).

Table 11. *Average values of biological yield in Fırat-93 durum and Ceyhan-99 bread wheat varieties inoculated with different bacterial strains*

Application	Fırat-93 durum wheat	Ceyhan-99 bread wheat
Non-inoculated and non-fertilized control	745.14^{a}	615.28^{c}
50% fertilized control	704.17^{ab}	850.00^{a}
100% fertilized control	752.78^{a}	794.00^{ab}

DOI: http://dx.doi.org/10.15666/aeer/1702_38773896

The highest biological yield of Ceyhan-99 bread wheat was determined as 850.00 kg/da from 50% fertilized control application and the lowest biological yield was observed as 615.28 kg/da from non-inoculated and non-fertilized control application. Biological yields in other applications are among these two values. Bacterial applications were found to contribute to the increase in biological yield compared to non-inoculated and non-fertilized control (*Table 11*).

Hectoliter weight

In terms of applications, the highest hectoliter weight of Fırat-93 durum wheat was obtained as 77.60 kg with 50% fertilized control application, the lowest hectoliter weight was obtained as 74.13 kg from *Bacillus atrophaeus* + *Bacillus* -GC Group (TV83D + TV119E) bacterial application, hectoliter weight in other applications were among these two values. At the same time, according to the full dose fertilizer application (76.13 kg), *Stenotrophomonas maltophilia* (TV14B) bacterial application (77.60 kg) was found to be higher but not statistically significant (*Table 12*).

Table 12. *Average values of hectoliter weight in Fırat-93 durum and Ceyhan-99 bread wheat varieties inoculated with different bacterial strains*

Application	**Fırat-93 durum wheat**	**Ceyhan-99 bread wheat**
Non-inoculated and NON-FERTILIZED CONTROL	76.80	75.33
50% fertilized control	76.00	77.47
100% fertilized control	76.13	74.73
Stenotrophomonas maltophilia (TV14B)	77.60	76.13
Bacillus atrophaeus (TV83D)	75.47	76.53
Bacillus-GC Group (TV119E)	74.13	76.00
Cellulomonas turbata (TV54A)	75.93	76.00
Bacillus atrophaeus + *Bacillus* -GC Group (TV83D+TV119E)	74.27	77.73
Average	75.79	76.24
P	**0.1276**	**0.2728**
Tukey's HSD	4.14	4.1987

The highest hectoliter weight of the Ceyhan-99 bread wheat was obtained as 77.73 g. with *Bacillus atrophaeus* + *Bacillus* -GC Group (TV83D + TV119E) bacterial application and the lowest hectoliter weight was obtained as 74.13 g. with *Stenotrophomonas maltophilia* (TV14B) bacterial application. The weight of hectoliter in other applications was between these two values. It was observed that the bacterial application with the highest values, *Bacillus atrophaeus* + *Bacillus* -GC Group (TV83D + TV119E) (77.73 kg), was higher than chemical fertilizer applications. In terms of hectoliter weight, which is an important quality parameter, *Bacillus atrophaeus* + *Bacillus*-GC Group (TV83D + TV119E) bacterial application having the highest value suggests that bacterial preparations may be an alternative to chemical fertilizer (*Table 12*).

Harvest index

In terms of applications, the highest harvest index of Fırat-93 durum wheat was obtained from *Bacillus atrophaeus* (TV83D) bacterial application as 40.16 and the lowest harvest index was obtained from non-inoculated and non-fertilized control application as 32.91. The harvest index in other applications is among these two values. In general, it was observed that all of the bacterial applications caused a statistically positive and significant increase in the harvest index compared to chemical fertilization (*Table 13*).

Table 13. *Average values of harvest index in Fırat-93 durum and Ceyhan-99 bread wheat varieties inoculated with different bacterial strains (%)*

Application	Fırat-93 durum wheat	Ceyhan-99 bread wheat
Non-inoculated and non-fertilized control	32.91	41.70
50% fertilized control	36.54	41.79
100% fertilized control	38.48	45.08
Stenotrophomonas maltophilia (TV14B)	36.60	45.02
Bacillus atrophaeus (TV83D)	40.16	45.34
Bacillus-GC Group (TV119E)	39.69	43.66
Cellulomonas turbata (TV54A)	39.25	41.94
Bacillus atrophaeus + *Bacillus* -GC Group (TV83D+TV119E)	38.71	41.95
Average	37.79	43.30
P	**0.1503**	**0.2919**
Tukey's HSD	8.65	7.0067

The highest harvest index of the Ceyhan-99 bread wheat was obtained from *Bacillus atrophaeus* (TV83D) bacterial application as 45.34% and the lowest harvest index was obtained from non-inoculated and non-fertilized control application as 41.70%. The harvest index in other applications is among these two values. The average of bacterial applications was generally higher than non-inoculated and non-fertilized control (*Table 13*).

Discussion

Considering the environmental hazards of chemical fertilizers, the fact that plant height values, which are known to increase with nitrogenous fertilizers, do not show a significant difference between the bacterial applications, indicates that the bacterial applications show promising effect. In addition to the fact that no bacterial application studies were performed on wheat before, it was stated that bacterial inoculation related to bacterial growth promotes the nitrogen content and vegetative development of the plant and this increases the plant height. (Şahin et al., 2004; Mukhtar et al., 2017; Kumar et al., 2014; Abbasi et al., 2011; Sultana et al., 2016; Arshadullah et al., 2017). Zafar-ul-Hye et al. (2017) reported that the bacterial applications increased the spike size.

In previous studies, it has been shown that inoculating the seeds in the form of double combination application results in significant increases in yield and yield

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38773896

components compared to control (Darmwal and Gaur, 1988; Rai and Gaur, 1988; Şahin et al., 2004). Sood et al. (2018) reported in their study that bacterial application increased the number of tillerings by 28.3%. As a result of our study, it is thought that differentiation of bacterial strains, wheat varieties, climate and soil characteristics may cause in obtaining different findings. According to the results of our research, the highest number of spikes per square meter was obtained in chemical fertilizer applications. It has also been reported by the researchers that nitrogen contributes to healthy plant and spike formation by increasing vegetative growth in the plant and therefore increases the number of spikes per square meter (Millet and Feldman, 1984; Davidson and Chevalier, 1990; Öztürk et al., 2003; Salantur, 2003). Öztürk et al. (2003) investigated the effect of plant growth-promoting bacteria inoculation on wheat and barley yield at various nitrogen fertilization levels. They found that inoculation with *Bacillus* sp. OSU-142 significantly affected the number of spikelets in wheat spikes but did not have a significant effect on other characters.

It has been reported by many researchers that bacterial inoculation increases the number of grains per spike compared to non-inoculated and non-fertilized control (Öztürk et al., 2003; Salantur, 2003; Sood et al., 2018). In addition, it is said that double and single bacterial inoculation increases the number of grains in the spike (Dokuyucu et al., 1997; Afzal and Bano, 2008; Nain et al., 2010). Bhattarai and Hess (1993) and Das and Saha (2005) reported in their field study that bacterial applications were effective in increasing the thousand grain weight and combined inoculation was more effective than single inoculants. Although there is no similarity between the findings of the cited studies and the findings of the durum wheat variety, some researchers have reported that bacterial applications have a positive effect on the thousand grain weight (Zahir et al., 2009; Mukhtar et al., 2017; Sood et al., 2018). It is thought that this situation is caused by working with different bacteria and varieties.

Many researchers have reported that bacterial inoculation increases grain yield (Barazani and Friedman, 1999; Şahin et al., 2004; Çakmakçı et al., 2005; Çakmakçı et al., 2007; Behera and Rautaray, 2010). In this respect, the results obtained are similar to the previous studies. In previous studies, it has been reported by many researchers that chemical fertilization and bacterial inoculation provide increases in biological yields according to control (Kumar and Ahlawat, 2006; Sultana et al., 2016; Dos Santos et al., 2017; MeCarty et al., 2017; Inwati et al., 2018; Sood et al., 2018). Çığ (2011) reported that bacterial applications do not affect hectoliter. The researcher also stated that the two-bacterial applications cause an increase in the harvest index, but the single bacterial application showed the lowest value.

In terms of the effect of bacteria on varieties; *Bacillus*-GC groupTV119E bacteria application in durum wheat on spike size, spikelet count, the grain count on the spike has been found to have a statistically significant positive effect. In bread wheat, it was observed that it has a significant positive effect on spike size. *Stenotrophomonas maltophilia* TV14B (phosphate solubilizing) bacterial application statistically significantly increased the biological yield of durum wheat and plant height in bread wheat varieties. *Bacillus atrophaeus* TV83D (nitrogen-fixation) bacterial application has been found to have a statistically significant effect on the increase of the biological yield of bread wheat. None of the bacterial applications had statistically significant effect on the number of tillerings, weight of thousand grains, hectoliter weight and harvest index in both varieties.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38773896

All bacterial applications in the bread wheat varieties increased the grain yield statistically significantly compared to the non-inoculated and non-fertilized control. In particular, bacterial application of *Bacillus atrophaeus* (TV83D) increased yield by 24% compared to non-inoculated and non-fertilized control. This bacterial strain also yielded an increase on yield in durum wheat, but it was not found to be statistically significant compared to other applications. The fact that durum wheat grain yield (283.33 kg/da) is close to 100% chemical fertilization (288.89 kg/da) shows that this bacterium significantly contributes to yield. In addition, the yield of durum wheat varieties in 100% chemical fertilizer (288.89 kg/da) was less than the bread wheat (360.00 kg/da). It is believed that this situation may be caused by the fact that the water demand for durum wheat is higher than that of bread wheat and the drought in 2018 spring months has a negative effect on the development of durum wheat.

As a result, bacterial applications significantly increased the yield in bread wheat compared to non-inoculated and non-fertilized control. In addition, it has been determined that bacterial applications show different reactions according to varieties and different bacteria have different effects on plant yield. The highest grain yield increase among microorganism applications was obtained from *Bacillus atrophaeus* (TV83D) bacterial application. In this respect, it is thought that this bacterial strain can be used as a bio-fertilizer material.

Conclusion

At the end of the study, mainly *Bacillus atrophaeus* (TV83D) which has a positive effect on all parameters, Bacillus-GC group TV119E and *Stenotrophomonas maltophilia* TV14B bacteria strains were found to be promising. However, in order to determine the effectiveness of the bacteria used in the study, it is thought that field trials should be established on different plant species and under different ecological conditions, at least for two years. In addition, in later studies, it is thought that testing of bacterial applications and other organic fertilizers (barn, worm etc.) will contribute to revealing the potential of these bacteria.

(Received 16th Apr 2018; accepted 26th Feb 2019)

Abstract. This research investigated the lead contents of the water, sediment and freshwater organisms around an abandoned mining area in Kanchanaburi province, western Thailand. Samples were collected in 2017 during the monsoon season from three zones (upstream or control, middle-stream or inferred source and downstream or impacted zone) of Khli Ti creek. We found that the lead concentration of the water was the highest (0.0549 mg/l) on average in the downstream zone, and slightly exceeded the national standard level. In the sediment, the lead content was the highest (31,937.30 mg/kg) in the middle-stream zone and was approximately 25 times higher than the national standard level. The means of other selected heavy metal concentrations in the sediment were the following in descending order: Fe>Zn>As>Cd>Hg. The results also revealed lead accumulation in freshwater flora and fauna (plankton, macroinvertebrates, fish and macrophytes). Macroinvertebrates, in the middle-stream zone in particular, had the highest lead contents. Our study also showed the potential biomagnification of lead through the food chain. High contents of lead in organisms may cause both acute and chronic effects on stream dwellers on which further detailed research is needed. Lastly, the consumption of freshwater organisms by the local community should be avoided to reduce any health risks.
Keywords: *environment, heavy metals, invertebrate, stream, water quality*

Introduction

Mining is important for the development of the country since minerals and metal ores such as lead, coal and potash can be used as valuable raw materials for various industries. However, mining operations such as mineral dressing and smelting processes can be a major cause of heavy metal contamination in freshwater bodies because heavy metals are non-biodegradable and can persist in the environment for a very long time (Horowitz et al., 1993; Mazej et al., 2010; Thorslund et al., 2012).

Long term accumulation of heavy metals such as lead, copper and cadmium can reach elevated toxic levels even after the mine has closed, thus creating negative environmental problems (Dudka and Adriano, 1995). Several studies have shown that the water and sediment in lakes and rivers are contaminated by heavy metals. For example, in India, downstream sites in the Yamuna River had high concentrations of cadmium, chromium, iron, nickel and these values exceeded the standard maximum permissible limits prescribed for drinking water (Kaushik et al., 2009). In the Tigris River, Turkey, contamination of arsenic, cadmium, chromium, copper, manganese, nickel and zinc derived from anthropogenic sources was found in sediments (Varol, 2011). In Thailand, manganese (40-382 µg/l) and arsenic (0.68-8.79 µg/l) concentrations in Phayao Lake, northern Thailand, were close to the maxima for

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38973908

minimum drinking water standards proposed by USEPA and WHO (Tupwongse et al., 2007).

Heavy metal contamination can also impact biotic components through bioaccumulation and biomagnification (Miller et al., 1992; Goodyear and McNeill, 1999; Mazej et al., 2010). Producers, consumers and predators can be contaminated by heavy metals (Nagayama et al., 2010) through 1) consumption of food and water and 2) from direct exposure via gills and tissue surfaces (Newman and McIntosh, 1991; Goodyear and McNeill, 1999; Lee et al., 2012). The study of Moiseenko and Kudryavtseva (2001) revealed that fish in Russian lakes were contaminated with high concentrations of nickel and copper and showed kidney pathologies. In Thailand, several species of fish (*Rasbora tornieri* and *Systomus rubripinnis*) and frog (*Kaloula pulvhra* and *Microhyla heymonsi*) have taken up metals such as copper and manganese from the environment around a gold mine area in Loei province (Intamat et al., 2016). Furthermore, heavy metals can biomagnify in aquatic food webs when the heavy metal concentration increases through the trophic levels (Chen et al., 2000; Barwick and Maher, 2003). For example, in the newly-formed wetlands of the Yellow River Delta of China, heavy metals such as cadmium and zinc increased with the trophic level (Cui et al., 2011).

In Thailand, it is known that Kanchanaburi province is a major important source of lead. Lead mining operations in Khli Ti village started in the mid 1960s and then in 1998 the mining was ordered to close due to leakages of toxicants from tailing ponds to Khli Ti creek and surrounding environment (Department of Pollution Control, 2009; Greenpeace Thailand, 2012). Lead and other associate heavy metals from mining are toxic and could cause adverse impacts to the environment and human health if present in large quantities. Therefore, the objectives of this study were to assess the present state of spatial distribution of lead contents in the water and sediment environment of Khli Ti creek and to determine any lead contamination in terms of bioaccumulation and biomagnification in freshwater flora and fauna. The results will be useful to understand lead accumulation in the environment and freshwater organisms and to evaluate potential lead transfer pathways from producers to consumers in a lotic food web.

Materials and methods

Study site

Khli Ti creek is located in Chalae sub-district, Thong Pha Phum district, Kanchanaburi province, western Thailand. Its total length is 22 km and the water flows from north to south ending in the Srinakharind Dam. Sampling locations were divided into three zones: 1) sampling point I in the upstream zone or reference site (14.962309, 98.909397); 2) sampling point II in the middle-stream zone or source of contamination in an old abandoned lead mining area (14.955716, 98.921583); and 3) sampling point III in the downstream zone or impacted site (14.878604, 98.948969) (*Figs. 1, 2*). There were five sub-sampling points in each zone and therefore in total there were 15 sub-sampling points along the creek. Data were collected only one time in the rainy season of 2017 due to high water level and suitable time for sampling.

Water and sediment sampling

At each sampling point, we used a multi-parameter analyzer (Consort 663) to measure the water temperature, pH, dissolved oxygen (mg/l), total dissolved solid (mg/l) and conductivity (µs/cm). Transparency was measured using a Secchi disk and 2 L of water were also collected in plastic bottles from each point and then nitric acid was added as preservative and the samples were kept in a cool container for further analysis of total nitrogen (mg/l) and total phosphorus (mg/l) at the Department of Soil Science, Kasetsart University, Bangkok, Thailand. Another 1 L water sample was taken and preserved with nitric acid for lead (mg/l) analysis at the Central Laboratory,

DOI: http://dx.doi.org/10.15666/aeer/1702_38973908

Bangkok using an in-house method TE-CH-126 based on standard methods for the examination of water and wastewater (APHA, AWWA, WEF 21st edition 2012 Part 3030E) (APHA, 2005) and AOAC (2016) using an inductively coupled plasma mass spectrometer (ICP-MS). Contents of chlorophyll a (mg/l) were determined using acetone attraction at the Department of Environmental Technology and Management, Faculty of Environment, Kasetsart University, Bangkok, Thailand. All analyses were done in triplicate.

Sediment sampling was conducted at the same water sampling points. Approx. 1 kg of sediment was collected and transferred to a plastic bag. Sediment samples were air dried, ground into fine powder and sieved through a 0.2-mm sieve. Prepared sediment samples were then analyzed for pH, electrical conductivity (EC, µs/cm) using an electrical conductivity meter, organic matter content (%) using Walkley and Black titration (Walkley and Black, 1934) and soil texture using the pipette method at the Department of Environmental Technology and Management. Sediment samples (20 g from each sampling point) were also sent to the Central Laboratory for analysis of heavy metals (lead (Pb), iron (Fe), arsenic (As), mercury (Hg), and zinc (Zn)) using in-house method TE-CH-329 based on the Environmental Protection Agency (EPA) 3052 standard.

Biotic sampling

We collected biotic samples and measured their lead contents. Plankton (both phytoplankton and zooplankton) were collected by pouring 50 L of water through a plankton net with a mesh size of 20 µm and 67 µm. Subsequently, the water was filtered again through Whatman GF/C and kept in a cool plastic container. Benthic macroinvertebrates (mainly shrimp, mollusc, dragonfly nymph and crab) were taken from the sediment using an Ekman grab and invertebrates associated with plants were collected using a hand net (1 min per sampling). Plant and other materials collected from sampling were separated and removed by hand and animals were sorted and kept in plastic bags in an ice box. Fish specimens were collected using gill nets left overnight in the creek and the following day fish samples were retrieved. Samples of fish were kept in an ice container. Freshwater plants present in the creek (mainly taro) were sampled from a 1×1 m quadrat and whole plant specimens were collected in plastic bags. Plants were identified to the Family level by the Forest Herbarium, Bangkok, Thailand. All biotic samples were sent to the Central Laboratory for analysis of lead contents using in-house method TE-CH-134 based on AOAC (2016) 999.10 and the ICP-MS. Then bioaccumulation factors (BAF) were calculated based on (USEPA, 2001) by using the lead content in aquatic animals (mg/kg) divided by the lead concentration in water (mg/l). In addition, biotransference factors (BTF) or biomagnification factors were obtained from the calculation of the lead content in selected consumers or predators divided by that of the selected producer or prey (mg/kg) according to Laskowski (1991).

Data analysis

Values were reported as mean±standard deviation (n=5) throughout. Data distribution was tested by using Test of Homogeneity of Variance and Robust Tests of Equality of Mean (Welch) and then Post Hoc Multiple Comparison (Turkey) was applied to analyze which parameters or variables have different statistical significance among the upstream, middle-stream and downstream zones.

Results

Water and sediment properties

The results of water quality analysis are shown in *Table 1*. The water temperature was rather low. Transparency was in the range 0.27-0.66 m and corresponded well with the total suspended solids. The pH values were neutral and tended to be higher in the downstream zone. The dissolved oxygen contents were relatively high from the upstream to downstream zones. The total nitrogen concentration was high in the upstream zone and gradually decreased toward the downstream zone whereas the total phosphorus concentration was comparable among zones. Significant differences in water quality parameters (temperature, transparency, pH, conductivity, TDS and TSS) were found among zones.

Table 1. *Water quality analysis in Khli Ti creek (n=5)*

Parameter	Upstream zone	Middle-stream zone	Downstream zone
Temperature (C)	$25.9±0.6^{a}$	$24.9±0.7^{b}$	$26.3±0.4^{a}$
Transparency (m)	$0.5±0.2^{a}$	$0.7±0.3^{a}$	$0.3±0.1^{ab}$
pH	$7.96±0.03^{a}$	$8.04±0.06^{b}$	$8.15±0.05^{c}$
Conductivity (µs/cm)	$378.2±10.8^{a}$	$409.0±9.7^{b}$	$428.8±3.3^{c}$
Dissolved oxygen (mg/l)	$12.28±0.65^{a}$	$12.72±0.62^{a}$	$12.32±0.38^{a}$
Total dissolved solid (mg/l)	$204.2±8.7^{a}$	$220.0±3.5^{b}$	$230.4±2.1^{c}$
Total suspended solid (mg/l)	$0.71±0.35^{a}$	$0.89±0.34^{a}$	$4.04±0.38^{b}$
Total nitrogen (mg/l)	$21.00±14.64^{a}$	$14.00±11.74^{a}$	$5.25±4.79^{a}$
Total phosphorus (mg/l)	$1.51±0.90^{a}$	$1.57±0.77^{a}$	$2.31±1.52^{a}$
Chlorophyll a (mg/l)	$0.51±0.46^{a}$	$0.40±0.06^{a}$	$0.33±0.0^{a}$

Mean values followed by different superscript letters are significantly different ($p < 0.05$)

Analysis of the sediment properties revealed that the pH values were neutral (6.9-7.2) (*Table 2*). Electrical conductivity was highest in the middle-stream zone and significantly different from that in the upstream and downstream zones. The organic contents of the upstream and middle-stream zones were significantly higher than in the downstream zone. The results of the sediment texture analysis disclosed that the bottom sediment was sandy loam. In particular, the sediment texture of the downstream zone had a lower percentage of sand and a higher percentage of clay and silt compared with the upstream and middle-stream zones.

Table 2. *Sediment quality analysis in Khli Ti creek (n=5)*

Parameter	Upstream zone	Middle-stream zone	Downstream zone
pH	$6.93±0.25^{a}$	$7.19±0.22^{a}$	$7.00±0.14^{a}$
EC (µs/cm)	$370.03±172.25^{a}$	$519.80±102.95^{ab}$	$259.33±55.55^{a}$

The result of the lead content in the water showed that they were significantly different among zones. The lead content was lowest in the upstream zone (0.0037-0.0075 mg/l) and increased in the middle-stream zone (0.0132-0.0184 mg/l) being highest in the downstream zone (0.0476-0.0549 mg/l). Furthermore, in the sediment, the lead content was also highest in the middle-stream zone (2,175.04-31,937.30 mg/kg) and lower in the upstream (92.76-184.97 mg/kg) and downstream (504.02-1,514.99 mg/kg) zones. *Figure 3* shows the lead contents in the sediment among zones. The contents of cadmium, mercury and zinc were highest in the middle-stream zone, whereas the arsenic content was highest in the downstream zone (*Table 3*). The iron contents were saturated in all zones.

Lead contents in biotic samples

We found lead contamination in biotic samples and the degree of contamination in organisms increased in the downstream zone. In contrast, the lowest values foe the lead content in organisms were detected in the upstream zone. The highest lead contents in plankton and plants were found in the downstream zone whereas the lead contents in macroinvertebrates and fish appeared to be high in the middle-stream zone (*Table 4*).

Bioaccumulation and biomagnification

Table 5 presents the bioaccumulation and biomagnification results for lead in freshwater organisms. It shows that the highest bioaccumulation values were found in the middle-stream zone. Furthermore, on average, macrophytes had the highest bioaccumulation value followed by macroinvertebrates, plankton and fish, respectively. The biomagnification values increased from the lower trophic to higher trophic levels. In particular, the highest biomagnification value was in the middle-stream zone.

Discussion

Overall, the water quality values met the standards for inland surface water set by the Department of Pollution Control. The water temperature was rather low due to shading from forest cover. Water was also turbid as indicated by the low transparency and high suspended solid contents. This was likely due to erosion from the high discharge during the rainy season. The nitrogen content was relatively high in the upstream zone compared to the other zones, suggesting fertilizer runoff from agricultural areas. In contrast, the phosphorus content was high in the downstream zone. The chlorophyll a content did not reflect nutrient concentrations in the Creek and this could have been the result of the fast flow and suspended solids that inhibited phytoplankton growth. This was similar to the assertion by Mayer and Likens (1987) that algal production had a small portion of energy input in a shaded headwater stream.

The lead content results in the water in the downstream zone exceeded the water quality standard level (0.05 mg/l) of Department of Pollution Control (1992). This was rather consistent with the lead contents in the stream sediment that were relatively lower in the upstream zone and below the standard level for soil quality. However, in the middle-stream and downstream zones, the lead contents in the water were exceptionally higher than the standard levels and increased along with the distance from the inferred source indicating its accumulation.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38973908

Contamination of lead in the water and environment reflects the impact from abandoned old mining at the inferred source (middle-stream) and in the downstream (impacted) area. Our study also revealed that the lead contents in the sediment were very high, similar to previous studies (Department of Pollution Control, 2009). In particular, the highest lead content was detected around the old abandoned mining area in the middle-stream zone, similar to Gomes Ribeiro et al. (2017). The detected level of lead in the middle-stream zone was approximately 25 times higher than the standard level (400 mg/kg) for soil quality set by Department of Pollution Control (2004) for Thailand and much higher than in other studies (Beane et al., 2016; Pavlowsky et al., 2017). The lead content in the sediment of the downstream zone also exceeded the standard level reflecting the fact that contaminated sediment can be carried downstream from the inferred source by stream flow. This is consistent with the results for the lead concentration in the water that was highest in the downstream zone as mentioned earlier. A similar case was reported for metal-polymetallic tin mining of the Potosí deposits in Southern Bolivia which began operation in 1945 and has led to severe contamination of the Pilcomayo River's water and sediments for at least 200 km downstream of the mines (Miller et al., 2004). The study of Pavlowsky et al. (2017) also showed that the lead concentrations in the channel and floodplain sediments were above the background levels from mine sources for up to 171 km downstream.

The analyzed sediment data also revealed other heavy metal contents which were high in the middle-stream and downstream zones. In particular, the arsenic and zinc contents were higher than for the other metals and this could have been due to these metal forms usually being associated with mining (Davies, 1987; Ferreira da Silva et al., 2004). Iron contents are usually abundant (>10 g/kg) in this area.

This study revealed the accumulation of lead in organisms from producers to consumers that were higher than in previous studies (*Table 6*). We found the lead content in plankton was relatively lower than in other organisms. However, it should be noted that the lead content from plankton could be a combination of plankton and suspended sediment since some sediment could not be separated through filtration.

Table 6. *Lead contamination ranges in the environment and freshwater organisms in Khli Ti creek from previous years*

Lead content	Year						
	1998	**1999**	**2000-2003**	**2004-2007**	**2008**	**2009**	**2017***
Water (mg/l)	0.005-0.55	0.003-0.08	0.001-0.256	0.005-0.287	0.005-0.06	0.007-0.896	0.0037-0.0549
Sediment (mg/kg)	402-65,771	228-68,920	152-118,872	115-143,097	145-105,943	141-117,000	92.76-31,937.30
Fish (mg/kg)	5.8-81.8	-	-	1.65-8.85	0.4-8.48	0.08-16.3	55.12-76.59

Source: Department of Pollution Control (2009) and data of 2017 are from this study

Freshwater macrophytes had also a high content of lead due to their assimilation through root uptake (Pourrut et al., 2011) from the contaminated sediment. Among freshwater organisms, macroinvertebrates appeared to be the most affected by lead

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_38973908

contamination (Beane et al., 2016) because they dwell in the benthic zone and thus have a greater chance of exposure to lead accumulation through feeding and direct contact (Yoo-iam et al., 2014). The highest lead content in macroinvertebrates was detected in the middle-stream zone. In a higher trophic level, fish had a much lower lead content than macroinvertebrates. Therefore, it could be stated that the contents of lead in the sediment were somewhat paralleled by their content in benthic macroinvertebrates as was also observed in water (Kiffney and Clements, 1993). The BAF values in macrophytes were high due to direct uptake through roots since the higher heavy metal concentration in the soil is, the higher will be the concentration in plants (Davies, 1987). In addition, lead accumulating in organisms is of concern, as all organisms had higher lead contents than the recommended standard levels for food set by Department of Public Health (1986) and by the World Health Organisation (WHO) of 1 mg/kg and 25 µg/g for fish, respectively. Therefore, it would be wise to avoid any consumption of freshwater flora and fauna from the affected area since lead is one the major threats for heavy metal contamination of food chain (Hezbullah et al., 2016).

The results of bioaccumulation identified the bioaccumulation potential of the organisms and the metal concentrations in the water. The BAF values of all organisms were higher than 100 meaning that the organisms had potential to accumulate heavy metals (Yu et al., 2012). Our results showed marked lead accumulation when compared to other studies. For example, in Loei province, Thailand, the BAF values of lead in fish around a gold mining area were in the range 44.30-133.90 mg/kg (Intamat et al., 2016). *Table 5* indicates the trophic transfer of lead in the stream food web as lead increased with the trophic level (from producer to primary consumer) in the middle-stream zone around the old mining area because biomagnification of heavy metals occurs when the values of the biotransference factors of heavy metals between prey and predator are greater than one (Gray, 2002; Misztal-Szkudlinska et al., 2011) and when an increase in trace metal concentration occurs through at least two trophic levels in a food chain (Barwick and Maher, 2003). On the contrary, biomagnification in the upstream zone did not occur due to lower concentrations of lead there in the environment and organisms.

Conclusion

This study highlighted the lead contamination from old mining activity and its effects on the water, sediment and freshwater organisms in Khli Ti creek, Kanchanaburi province, western Thailand. The middle-stream zone around the mine area had highest lead content in the sediment whereas the downstream zone had the highest concentrations of lead in the water. Lead accumulation in plankton, macroinvertebrates, fish and macrophytes was also detected. Furthermore, lead can be passed through the food web as indicated by the biomagnification factor from producers to consumers in the most contaminated zone around the mining area. Based on our results, the lead contents detected in the environment and the food web may pose a potential risk to human health and may also cause acute and chronic impacts on freshwater organisms.

Acknowledgements. This research was funded by the Kasetsart University Research and Development Institute (KURDI) during 2016-2017. We are also grateful to the staff of the Department of Pollution Control for useful information regarding sampling sites and field work planning. Lastly, we thank the Headman of Khli Ti village for background information, site navigation and fieldwork assistance.

(Received 8th Aug 2018; accepted 31st Oct 2018)

Abstract. Crop yield estimation prior to harvest is an important for planning and taking various policy decisions. The recent development in satellite remote sensing technologies with their increased spatial and temporal resolution enabled their enormous application for many users with low cost. The current study was planned based on time series Landsat 8 remote sensing data for real time estimation of wheat (*Triticum aestivum* L.) yield based on vegetation indices and ground-truthing wheat yield data for growing season 2015-16 in district Chakwal, Pakistan. Wheat yield data were collected from an area of 10 m × 10 m at 43 sites along with GPS positions at farmer's field from district Chakwal to develop regressional model. Different indices like, Green Normalized Difference Vegetation Index (GNDVI), Normalized Difference Vegetation Index (NDVI), Wide Dynamic Ratio Vegetation Index (WDRVI) and Enhanced Vegetation Index (EVI) were derived from time series Landsat 8 imagery throughout the growing season (2015-16). Linear regression models fitting were developed between all the indices and ground truthing wheat yield data were analyzed based on Coefficient of Determination (R^2) and Root Mean Square Error (RMSE). The results revealed that EVI index showed higher values for the month of March 2016, compared with other months. This showed that crop was at the booting and anthesis stage in these months. The EVI and GNDVI indices showed better accuracy and precision with coefficient of determination (R^2) 0.89 and 0.82 values with RMSE value of 203.83 and 224.67 respectively for the month of March-2016. This indicated that Landsat 8 imagery can be used for reliable estimation of wheat yield prior to harvest which can be useful for planning and maintaining national food security stock timely.
Keywords: *remote sensing, wheat yield, time series, Landsat 8, vegetation indices*

Introduction

Wheat (*Triticum aestivum* L.) is an important food cereal for more than 33% of the world population. Wheat yield was recorded as 754.1 million tons with production of 3.07 metric tons/ha globally which makes wheat the third most grown cereal after maize and rice (World Wheat Production, 2016). By 2050, to provide food for 900 million to 1 billion people seems to be a big challenge (Smith, 2013). Yield assessment before actual production helps in making numerous policies in agricultural production system due to high demand of food grain in the world (Sawasawa, 2003). In various countries, conventional techniques of data collection based on field visits and reports are used for crop inventory. All the rural development plans which are based on such unreliable crop acreage and production estimates become unrealistic leading to faulty decisions and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39093925

actions and subsequent uncertainties in agricultural sector (Al-Gaadi, 2010). Remote sensing is a key component of precision agricultural practices. It is used to examine the crop growth and production and in provision rapid and nondestructive estimation of plant biomass, leaf area index (LAI), nitrogen (N) content and grain yield (Aparicio et al., 2000; Tahir et al., 2013). Remote sensing provides a better option for precision agriculture like providing low cost data, high spectral, spatial and temporal resolution. Remote sensing works collectively with technologies of Geographic Information System (GIS), Global Positioning system (GPS) and through integration their strengths can be fully utilized (Tayari et al., 2015).

Landsat Multispectral Scanner System (MSS), Landsat Thematic Mapper (TM), and Satellite Pour l'Observation de la Terre (SPOT) are the major satellite systems. Other systems are National Oceanic and Atmospheric Administration (NOAA), Advanced Very High Resolution Radiometer (AVHRR). Early work with these satellite imagery used visual interpretation for classification (Ozesmi and Bauer, 2002). Landsat 8 Operational Land Imager (OLI) sensor has improved abilities to investigate land surface observations by adding new spectral bands of blue and cirrus cloud-detection spectrum, two improved thermal bands which includes narrower near-infrared waveband, higher signal-to-noise ratio (SNR), and better radiometric sensitivity (Roy et al., 2014; Ke et al., 2015). Spectral vegetation indices are numeric transformations of mathematical models by using different spectral bands which measures seasonal variations of vegetation, but across space as well. Hence, these are appropriate in detecting within-field spatial variations (Viña et al., 2011). However, most vegetation indices tend to be species specific. They can recognize and provide material on spatial variation and allow more proficiency and accuracy in field investigation (Schuler, 2002). Remote sensing data in the visible, near and thermal infrared spectral bands had been used in monitoring phenology and infer biophysical variables of canopy (Rodriguez et al., 2004).

Previous researches demonstrated the utility of remote sensing but there are many areas of possible application which are still unexplored. This system is quite reliable and comprehensive and also cost effectiveness. Improvements in the accuracy and timeliness of crop production statistics are still in business. There is still lack of accurate, rapid and need practical methodologies to estimate yield of ground area. Therefore, the current study was planned to evaluate different spectral vegetation indices for accurately estimation of yield based on time series LANDSAT8 imagery data in Chakwal district. The main objectives of study were to: 1) real time (non-destructive) estimation of wheat yield based on spectral vegetation indices derived for time series Landsat 8 imagery, 2) compare the vegetation indices derived from Landsat 8 imagery with ground truthing data for developing regressional model and validation to improve the prediction accuracy of wheat yield in district Chakwal.

Review of literature

Hooda et al. (2006) observed that increasing the sample segments and decreasing the size of segments improved the area and production estimates by gradually decreasing the size of various districts. From last 15 years, the satellite data's spatial resolution has gradually improved. Moreover, improvement in the spatial, spectral and temporal resolution has extremely enhanced the capabilities to discriminate of crop from other vegetation. Since all the era the accuracy and the precision of estimation enhanced its efficiency. However, better accuracy and precision has been shown in large areas of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39093925

crop as compared to the areas with numerous mixed cropping systems. Presently remote sensing technique with 95% efficiency and precision enabled the acreage and yield estimation at district level.

There are many other indices that could assist in vegetation sensitivity rather than frequently used VIs in archeological investigation i.e. NDVI, SR etc. Results proved the efficiency of hyperspectral VIs by maximizing differences among archaeological and non-archaeological areas. These differences can be maximized by using narrowband indices up to 20% than broadband indices. In this study SARVI, SR and PVI are reported as most auspicious vegetation indices of broadband. SR-MTCI, SR-SR and VOG are reported as narrowband indices. Each phenological stage has different vegetation index to enhance the archaeological area than non-archaeological area (Agapiou et al., 2012).

NDVI, SM, ST and RF reported as the key factors or variables that control normal crop production. This approach might be utilized for estimation the gaps in crop produce by bringing empirical equations in use. Factors such as pests, diseases and human activities observed as the main factors of subsistence variabilities of yield estimation, which act as limiting factor in estimation techniques. Though, if NDVI is added to model which may help in determining yield losses caused by diseases or pests. The model can be calibrated by gaining more historical data of growth for the better prediction (Prasad et al., 2006).

Dempewolf et al. (2014) in his experiment evaluated four different indices, among them more consistent and more accurate yield prediction was observed by WDRVI as compared to the NDVI, EVI2 and SANDVI. While using the six years' data at district level RMSE values were found to be very low (within 0.2% and 11.5%) among the forecast and the recorded yield. Results reported that deviations in wheat area and yield prediction were slightly higher than the previous year's moving average values. The reason behind is that 250-m MODIS data is not able to provide the sufficient spatial resolution for improved wheat area and the yield estimation.

Castaldi et al. (2015) in his introductory investigation reported vegetation variables which were gained from the SPOT data (LAI, Fcover, FAPAR, and Cab) had accurate simple and the spatial significance related to final yield of wheat on stem elongation stage. The model for the yield estimation expressed the maximum RMSE when CR models were used. Moreover, when wheat crop production mapped it aided farmers in obtaining the estimate for the crop yield and identifying variability in the field as well. This approach is best suitable to several crops as well as for several regions. It could also be observed a valued practice particularly in the conditions where limited mapping techniques of yield are present for farmers. These tools can also be utilized for the environmental changes and have ability to give the significant information for the ecological remote sensing.

Materials and methods

Study area and ground truthing data collection

The proposed study was carried out in the Chakwal district of Pakistan. District Chakwal lies at 33° 40' North and 72° 51' East with elevation range from 500 to 1200 m. Total area of Chakwal is 6,524 km^2. District Chakwal has population 1083725 and about 70% people's livelihood depends on agriculture directly and indirectly. The district Chakwal has temperate climate with semi-arid area and annual rainfall ranged

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39093925

from 400 mm to 600 mm. It has hot summer and cold winter season. Total area depends on rain fall for agriculture. No irrigation system is present in this Area. Wheat crop usually planted in mid-November to end of November in districts Chakwal and Rawalpindi. The wheat crop has main distinct growth stages, like tillering, jointing, booting, anthesis, grain filling and physiological maturity. The March was the peak growth month of wheat crop. Wheat crop is usually harvested in end of April to mid-May. Chakwal district comprises of four Tehsil and total 68 union councils. We collected the data from different locations in district Chakwal t (*Fig. 1*). We collected the information about crop history and then collected the wheat yield samples from farmer's field during 2015-16 growing season. Wheat yield data was collected manually from an area of 10 × 10 m in the farmer's field, then expressed this yield in Kg/ha. We also took the GPS data with the help of GPS meter from the same place of wheat yield samples collected at selected sites in district Chakwal.

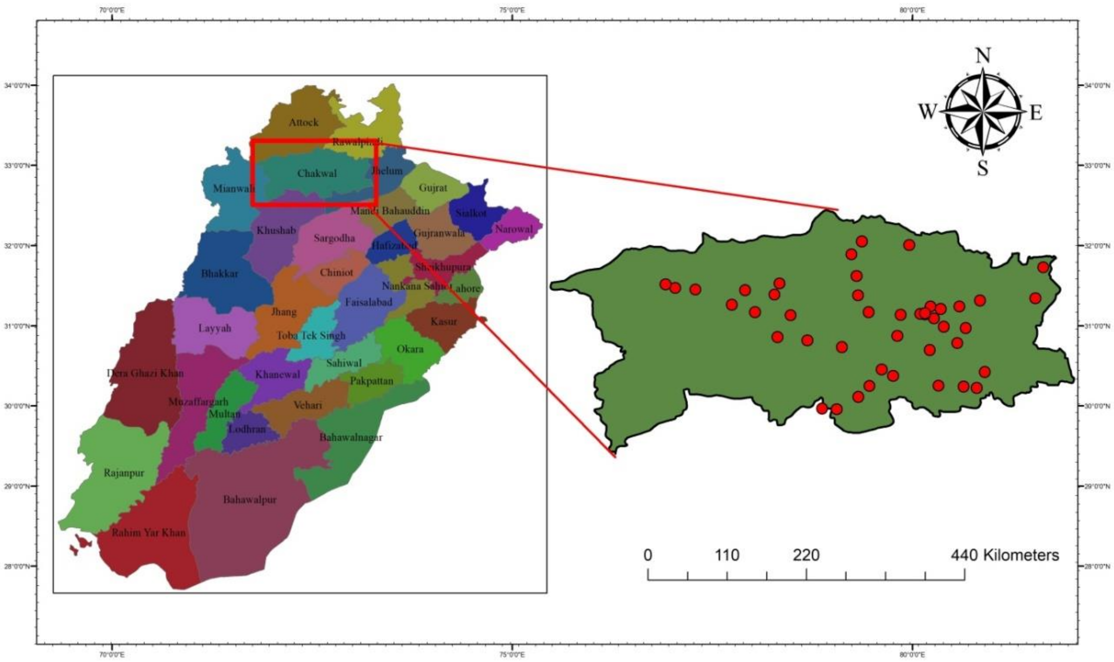

Figure 1. *Map of study area of Chakwal*

Remote sensing data and digital image processing and analysis

The remote sensing data was downloaded from USGS website (http://earthexplorer.usgs.gov/). We used the time series LANDSAT 8 satellite images for remote sensing data for the growing season 2015-16. Landsat 8 has 11 bands. Landsat 8 has operational land imager (OLI) and thermal infrared sensors (TIRS) with nine spectral bands with a spatial resolution of 30 m. The bands 1 to 7 having different wavelengths with red, green and blue sensors are combined to produce true-color image. The band 8 has 15-m resolution. The New band 9 (ultra-blue) is useful for cloud detection and also useful for costal and aerosol studies. Band 10 and 11 are thermal bands which are useful in providing more accurate surface temperature with resolution of 100 m.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39093925

After collecting time series images from available sources, the images were passed through different analysis processes. ERDAS IMAGINE (2014) and Arc GIS 10.2 software were used for processing and analysis of remote sensing data. The images of the study area pertaining to specific orbit, path and row were downloaded and opened into the viewer of ERDAS IMAGINE (2014). Later, geometric correction of the images was performed. Magnification of the original images was done to obtain the detailed information about the spectral reflectance of the area of interest. Images were atmospherically and geo-corrected using these ground control positions (GCPs). Stacking was performed by using Arc GIS 10.2 software. We performed the unsupervised classification by using ERDAS Imagine software. Following vegetation indices were performed on the processed images for the estimation of wheat yield by using ERDAS IMAGINE (2014) and Arc GIS 10.2 software (*Fig. 2*).

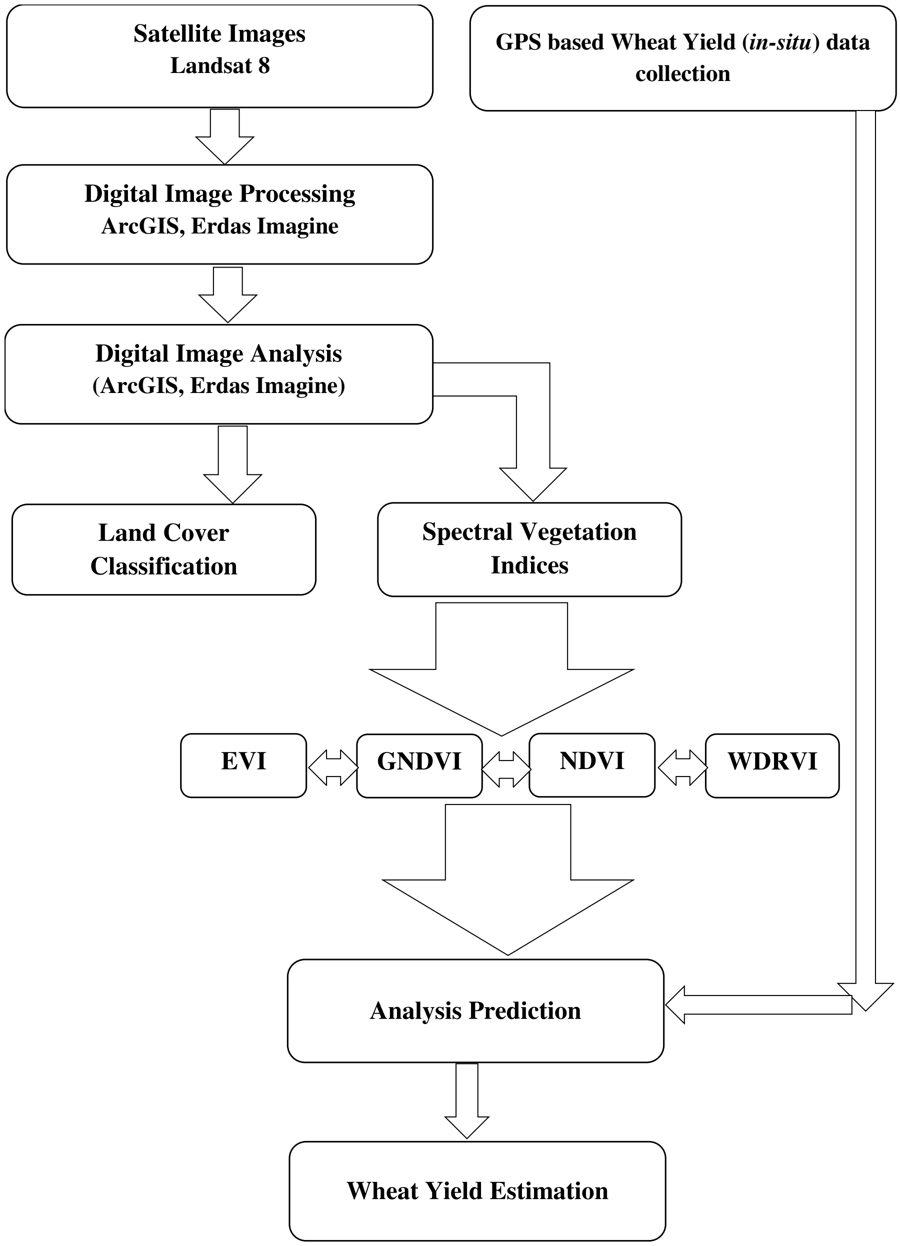

Figure 2. *Flow diagram of remote estimation of wheat yield*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39093925

Spectral vegetation indices

The spectral vegetation indices are presented in *Table 1.*

Table 1. *Spectral vegetation indices*

Sr.#	Vegetation indices	Formula	References
1	Green normalized difference vegetation index (GNDVI)	$GNDVI = \frac{(NIR - GREEN)}{(NIR + GREEN)}$	Huete et al. (2002), Wang et al. (2007)
2	Normalized difference vegetation index (NDVI)	$NDVI = \frac{NIR - R}{NIR + R}$	Ferencz et al. (2004)
3	Enhanced vegetation index (EVI)	$EVI=2.5\frac{NIR-RED}{(NIR+6RED-7.5BLUE)+1}$	Glenn et al. (2008)
4	Wide dynamic range vegetation index (WDRVI)	$WDRVI = \frac{0.1NIR-RED}{0.1NIR+RED}$	Henebry et al. (2004)

Statistical analysis

Regression was used to describe the effect of independent variables on dependent variable by representing the latter as a function of a former. Linear regression model were performed between satellite derived spectral vegetation indices and ground truthing yield data of wheat crop in Chakwal district. The performance of the model was estimated by comparing the differences in coefficient of determination (R^2) and root mean square error (RMSE) in prediction. The higher the R^2 and the lower the RMSE value and the higher will be the precision and accuracy of model for prediction. The RMSE was calculated using following equation:

$$RMSE = [\frac{1}{n}\sum_{i=1}^{n}(Si - Mi)^2]^{\frac{1}{2}}$$

Results

Vegetation indices

Following full processing of the LANDSAT 8 time series imagery for different vegetation indices were calculated using the mean values of the reflectance in green, red and NIR portion of the electromagnetic spectrum. The derived vegetation indices; GNDVI, NDVI, WDRVI and EVI proposed band ratios demonstrated the feasibility of estimating the wheat yield throughout the growing season of 2015-16. All vegetation indices for each month were used for the simple regression analysis which was performed on the field yield data to calculate equations for predicting wheat production.

GNDVI yield maps derived from time series data of Landsat 8 (2015-16)

Green normalized difference vegetation index is used for measurement of greenness in crops. The progressive increased in the GNDVI value was shown in the maps as the change in vegetation was occurred over time (*Fig. 3*). The GNDVI maps showed the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39093925

variations across the Chakwal district with minimum values (-0.1888–0.2154) in the month of November-2015 when crop was at early stage or in some areas at two to three leaf stage while the highest values (-0.0806–0.36672) were shown in the month of March-2016 (*Fig. 3*). Legends indicated in maps of GNDVI represented with low to high crop vegetation in these areas.

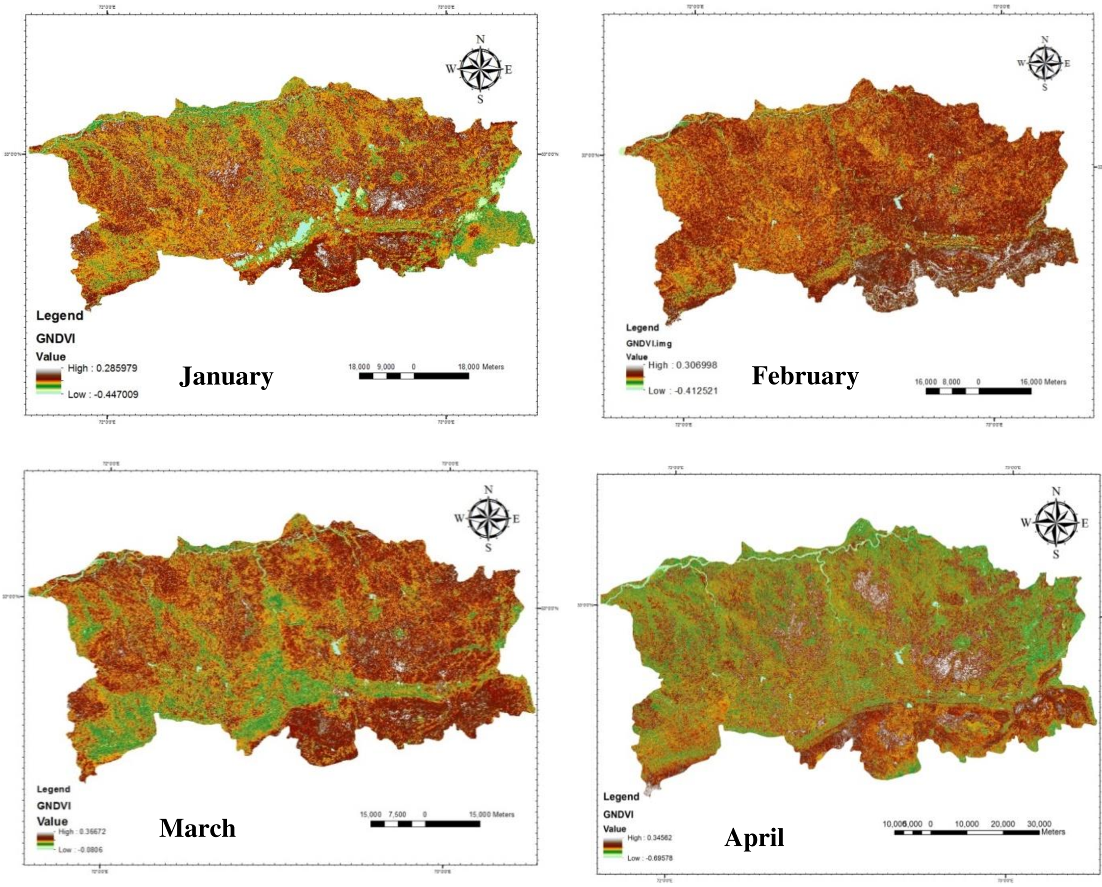

Figure 3. *GNDVI map of district Chakwal during wheat growing season of 2015-16*

Relationship between GNDVI derived from time series Landsat 8 with ground truthing wheat yield data

Figure 4 of wheat crop for growing season 2015-16 showed positive and strong relationship between GNDVI and wheat yield. The regressional model for each month expressed the relationship between GNDVI and wheat yield over time. A significant linear and positive relationship was observed between GNDVI and wheat yield for the month of March-2016 with coefficient of determination $R^2 = 0.82$ value as compared to other months throughout the growing season which showed the highest vegetation content/cover of the wheat crop in this month. GNDVI showed great variation from November-2015 to April-2016 with coefficient determination values (R^2) 0.37, 0.48, 0.61, 0.72, 0.82 and 0.55 respectively. GNDVI showed the higher accuracy for predicting wheat yield accurately with the value of $R^2 = 0.82$ and RMSE = 224.67 for the month of March-2016.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39093925

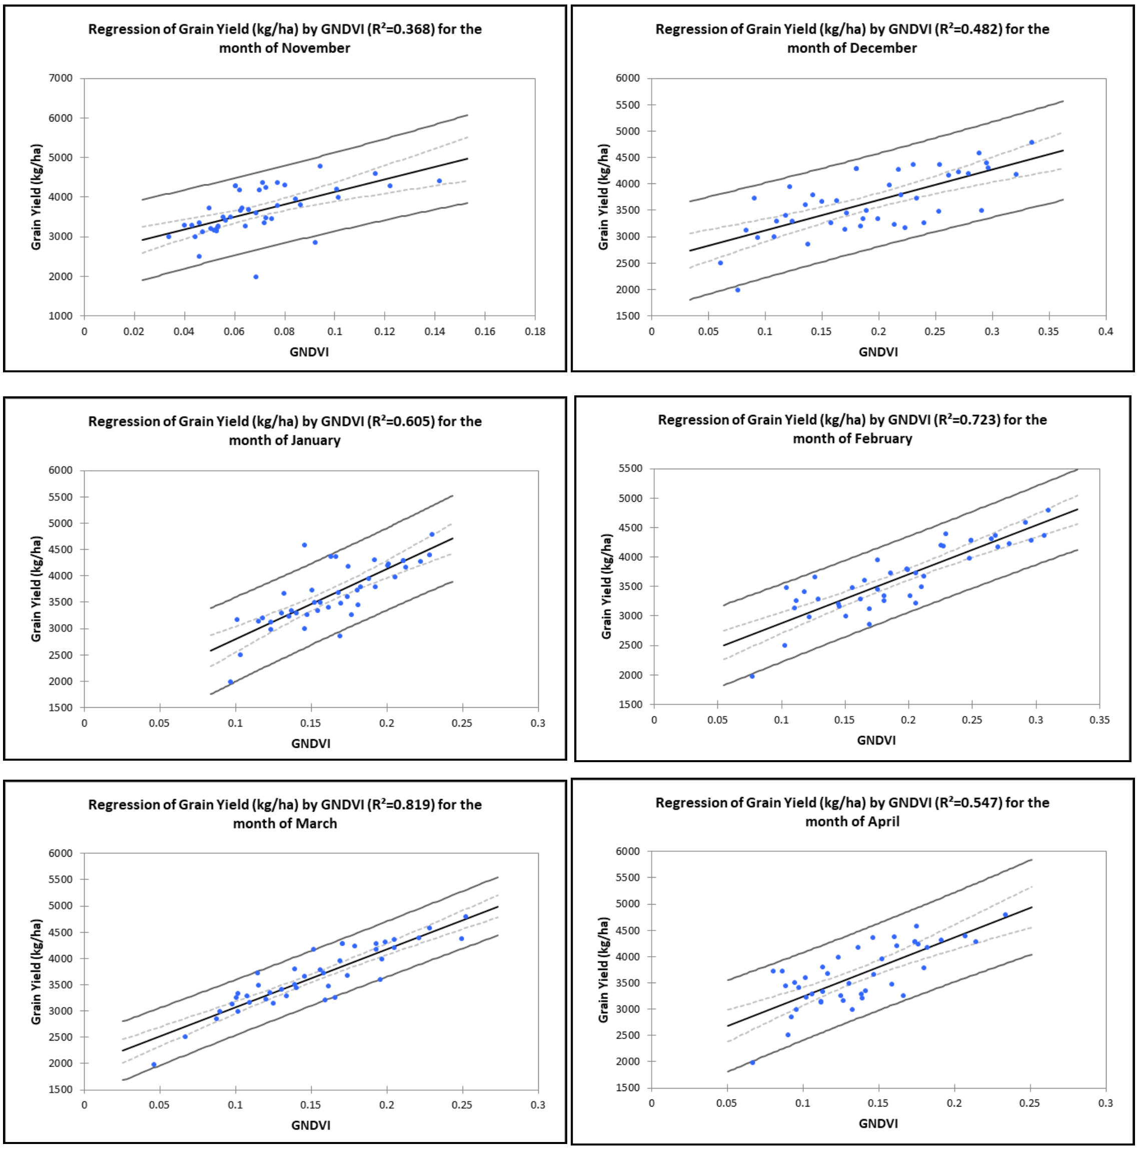

Figure 4. *Relationship between GNDVI and ground truthing wheat yield throughout the growing season*

NDVI yield maps derived from time series data of Landsat 8 (2015-16)

The NDVI map showed the status of whole growing season of wheat crop in district Chakwal. NDVI value ranged between -0.2538 to 0.40236 for the month of March-2016 while in the month of November-2015, NDVI value ranged between -0.1885 to 0.23224 (*Fig. 5*). This showed that highest crop vegetation was present in month of March-2016 and the lowest value was present in the month of November-2015. This showed that the vegetation was sparsely covered the ground during the month of November-2015. Water bodies and build area have negative value where as barren and rocks have zero value. Where as strong positive value represented only high dense green vegetative area.

DOI: http://dx.doi.org/10.15666/aeer/1702_39093925

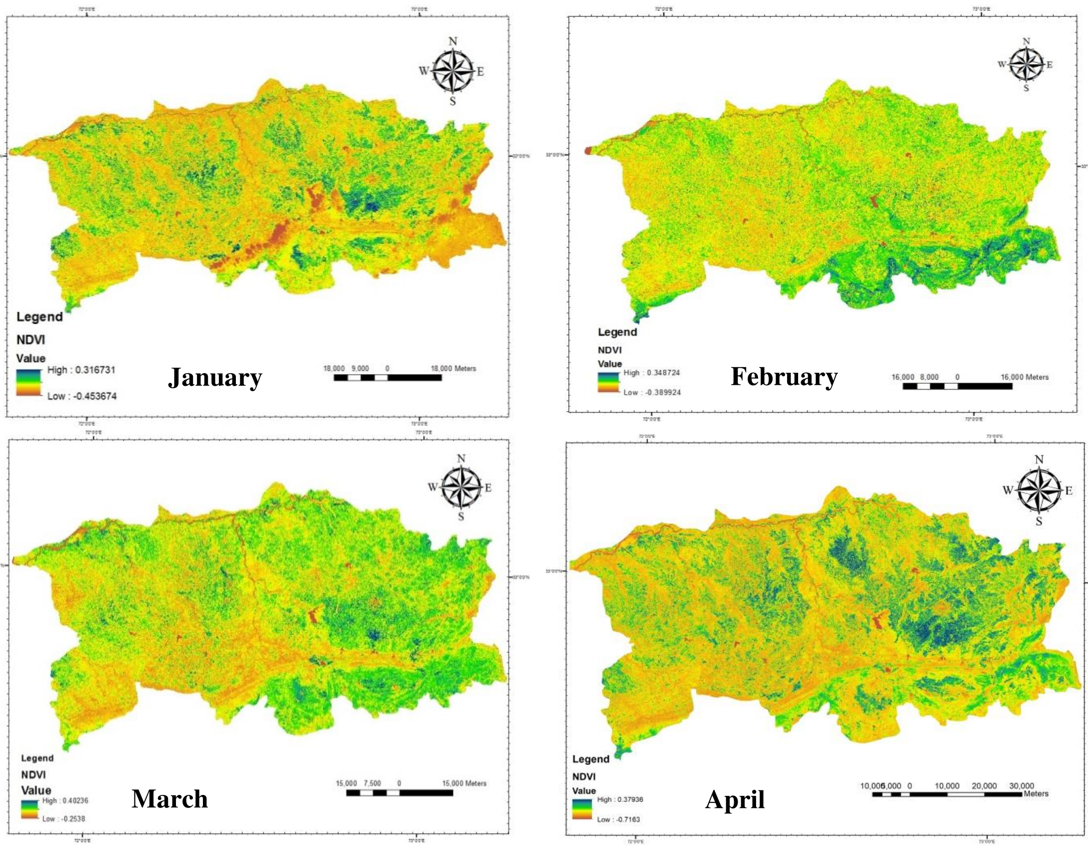

***Figure 5.** NDVI map of district Chakwal during wheat growing season of 2015-16*

Relationship between NDVI derived from time series Landsat 8 with ground truthing wheat yield data

Figure 6 showed the significant relationship between NDVI and wheat yield throughout the growing season 2015-16. There was positive and linear relationship between NDVI and wheat yield and the regression accounted for 75% of the variation in the data (R^2 = 0.75) for month of March-2016. The higher value of R^2 between the NDVI and wheat yield explained the vegetation conditions. *Figure 8* showed the relationship between NDVI and high vegetation.

If α = 1, then the WDRVI is equivalent to the NDVI. By calculating the value in current study α was also equal to 1. Maps of WDRVI are shown in *Figure 7*. The value of WDRVI was same as NDVI for all the months. So the NDVI and WDRVI produced exactly the same results for March-2016. WDRVI showed higher value of R^2 = 0.75 for month of March-2016, while November showed the weak relationship with R^2 = 0.36 (*Fig. 8*).

EVI yield maps derived from time series data of Landsat 8 (2015-16)

The EVI maps showed the variations across the district Chakwal. EVI wheat yield map showed great variations throughout the growing season. The highest value was shown in the month of March-2016 with the value ranged from -0.913381 to 0.903439 while the lowest value was shown in the month of November-2015 (-0.08294–0.27622). The highest value showed the highest greenness content of wheat crop (Booting and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39093925

anthesis stage) in this month. The lowest value showed that crop was at 2-3 leaves stage and ground cover was not fully covered with the crop at this stage (*Fig. 9*). Legends indicated in maps of EVI represented with low to high value of crop vegetation in these areas.

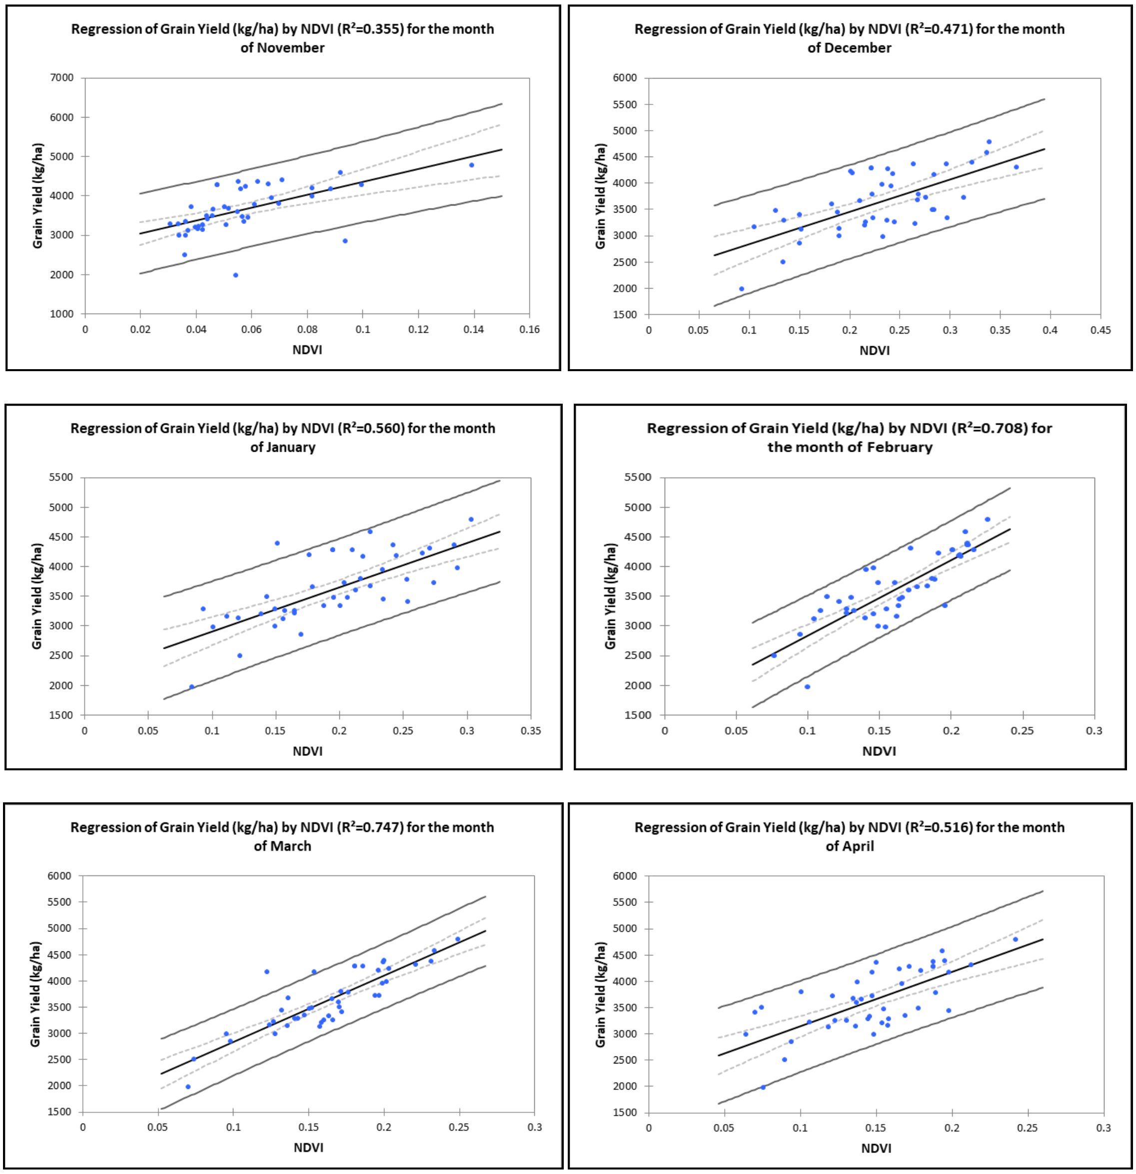

Figure 6. *Relationship between NDVI and ground truthing wheat yield throughout the growing season*

Relationship between EVI derived from time series Landsat 8 with ground truthing wheat yield data

Figure 10 showed very significant interactions between EVI and wheat yield. The regressional model for each month interprets the relationship between EVI and wheat yield production (*Fig. 10*). There was a positive and strong linear relationship between EVI and wheat yield in the month of March-2016 as compared to other months throughout the growing season of wheat crop. Minimum value of coefficient of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39093925

determination was R^2 = 0.39 in the month of November when crop was at emergence stage or in some areas at two or three leaf stage while the maximum value of R^2 = 0.89 was in the month of March where highest vegetation was present. As soon as the crop turned to yellow in most areas the EVI value also reduced to R^2 = 0.65 in the month of April-2016. The EVI showed the higher accuracy for predicting wheat yield for month of March-2016 with value of R^2 = 0.89 and RMSE 203.83. Results revealed that EVI has highest efficiency to predict wheat yield than other indices used in the current study.

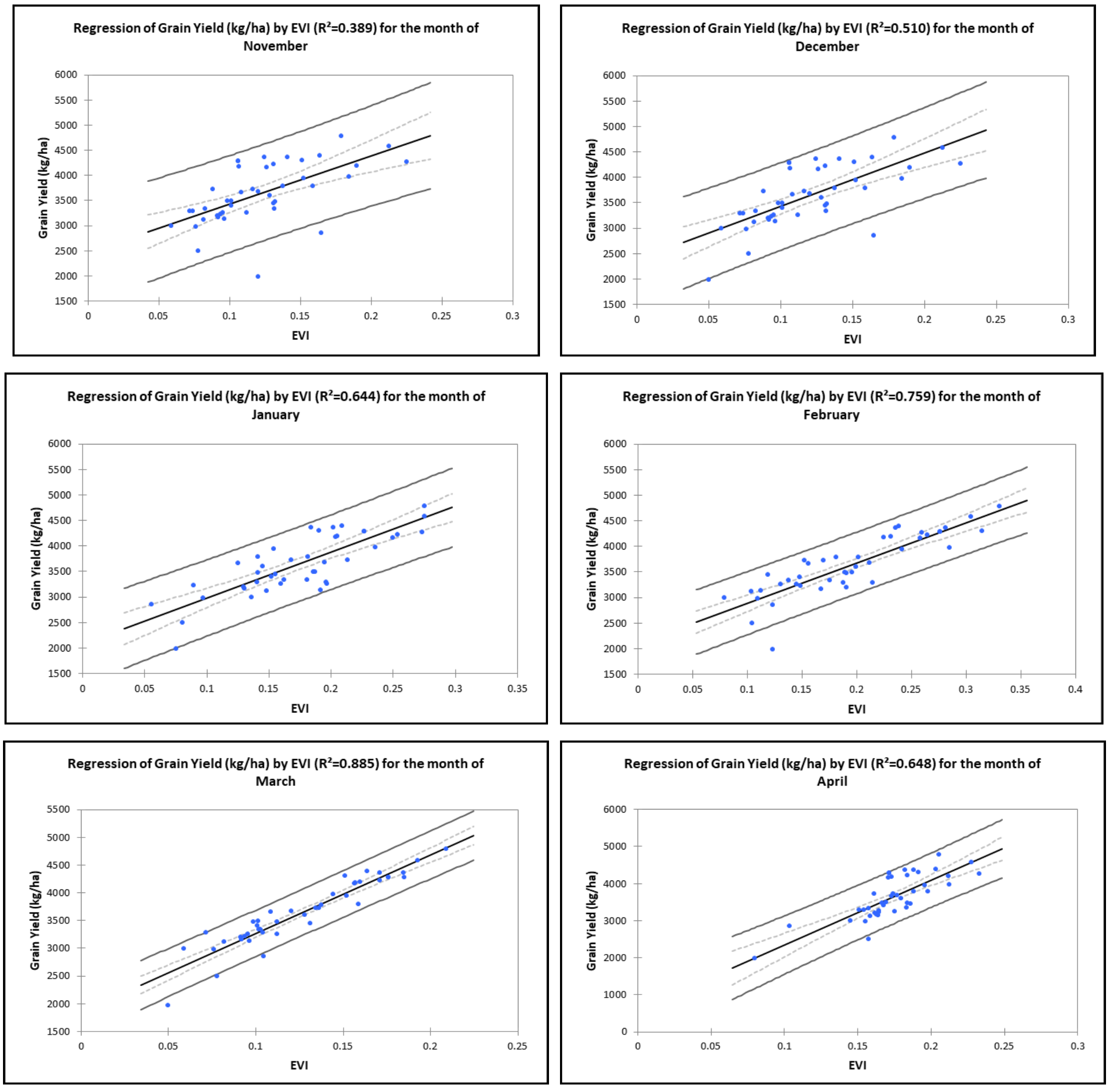

Figure 10. *Relationship between EVI and ground truthing wheat yield throughout the growing season*

Probability map of yield

The Probability Map of wheat yield showed the status of yield in the district Chakwal. The probability map of wheat yield was developed based on the satellite derived yield to predict the yield for the future year 2017-18. The values of probability map ranged from 1981 to 4778 Kg/ha. Some areas showed with white color in map had low wheat yield with the lower value of 1981 Kg/ha in district Chakwal. When more values lied near to 4778 Kg/ha showed higher wheat yield in that part of the map as represented in blue color in the map. From map, trend of future wheat yield is shown approximately from lower to high wheat yield (*Fig. 11*).

Discussion

Due to advancement in satellite remote sensing technologies reduced the cost of the imageries with improved temporal and spatial resolution which improved the crop area

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39093925

and yield estimation reliable. The study was planned based on Landsat 8 time series remote sensing data to derive vegetation indices and compared with observed wheat yield data using regressional model to estimate wheat yield accurately. All vegetation indices GNDVI, NDVI, WDRVI, and EVI were derived from November 2015 to April 2016 during the whole wheat growth season. Map of all indices developed using ERADAS 14.0. February and March 2016 months were the peak wheat growing months. The Map of all indices showed higher value for the month of February and March 2016 compared with other months. This explained that crop was at booting/anthesis stages. In district Chakwal, the weather remained mild and cold till the end of March. Therefore, all indices showed higher value for the month of March 2016. Lower values of all vegetation indices showed that wheat crop was at early stage or ground cover was not fully cover by the wheat crop (Viña et al., 2011). Wheat crop was harvested from selected sites in district Chakwal during mid-April to end of May 2016.

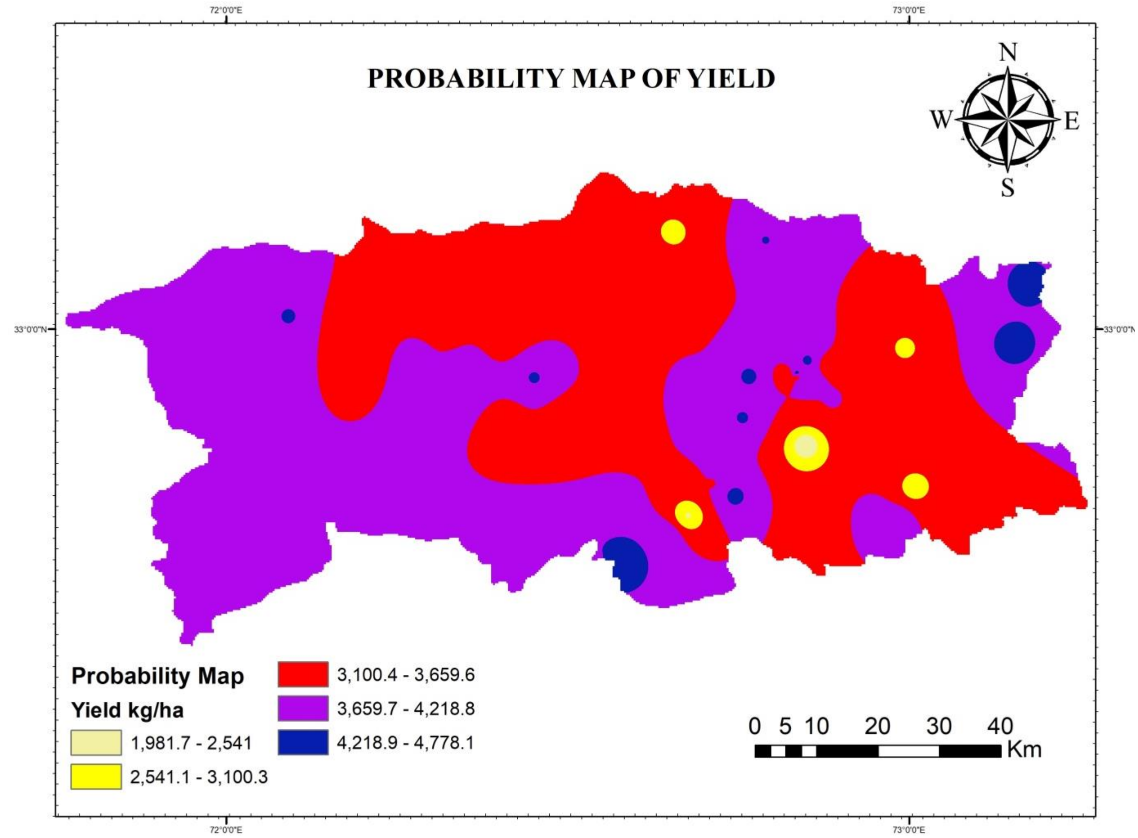

Figure 11. *Probability map of district Chakwal of wheat yield*

Regressional model were developed between Landsat 8 derived vegetation indices and observed wheat yield in district Chakwal for predicting wheat yield accurately. EVI and GNDVI proved more robust indices compared with NDVI and WDRVI. EVI showed positive and strong relationship with coefficient of determination value 0.89 for the month of March 2016. This is also explained that crop at booting /anthesis stage. This is the most important stage of wheat which directly related with increase of decrease crop production. The study proved that vegetation indices are robust in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39093925

estimating wheat yield accurately. Similar results were also reported by Agapiou et al. (2012) and Shen et al. (2009, 2010).

Future wheat crop prediction was developed based on the probability analysis in ArcGIS 10.2. Remote sensing derived wheat yield were plot in district Chakwal which showed the same trend as the observed yield data collected at different sites. Results showed the improved accuracy for estimating wheat yield compared with previous studies. The current study can be helpful in future prediction of wheat yield well before time which can be useful to managing food security issues and taking better decisions for policy making.

Conclusion

Wheat yield can be achieved in real time accurately by using remote sensing data prior harvesting. Different vegetation indices were evaluated derived from time series data of Landsat 8 imagery for the growing season 2015-16. Regressional model were developed between the vegetation indices and wheat yield data for predicting wheat yield accurately. Study results showed that EVI index showed higher value for the month of February-March 2016 compared with the month of November 2015. This showed that crop was at peak vegetation stages (booting/anthesis). EVI and GNDVI proved more robust indices and showed better accuracy compared with other indices. EVI showed the higher accuracy with $R^2 = 0.89$ value and RMSE value of 203.83 for determining wheat yield accurately. The current study can be helpful in future prediction of wheat yield well before time which can be useful to managing food security issues and taking better decisions for policy making.

(Received 14th Oct 2018; accepted 2nd Jan 2019)

Abstract. This study was aimed to identify the grape cultivars growing in Diyarbakır. A total of 45 genotypes were analyzed using 7 microsatellite loci. The numbers of alleles per locus ranged between 7 and 10, whereby VVS2 and VrZAG47 had the highest and VVMD7, VrZAG62, and VrZAG79 had the lowest number of alleles. The expected and observed heterozygosity were 0.77 and 0.73, respectively. Clustering analysis was performed using the UPGMA method (Unweighted Pair-Group Method using Arithmetic means). A dendrogram was constructed based on the genetic similarity among the genotypes, which indicated 5 distinct groups, with each group involving numerous subgroups. Two additional genotypes that are used as reference genotypes around the world, Cabernet Sauvignon and Merlot, were also analyzed and were classified into a separate subgroup and differentiated from the other 43 genotypes. In conclusion, synonyms and homonyms were detected among some of the genotypes analyzed in the study.
Keywords: *Vitis vinifera L., molecular analysis, genotype, similarity index, homonym, synonym*

Introduction

Grape (*Vitis vinifera* L.) is one of the most important fruit in the world. Turkey has a long history of grape cultivation. Diyarbakir province, located in the Southeastern Anatolian Region in Turkey, has an important position in Turkey with regard to its plant diversity. Grapevine, in particular, is a leading perennial garden plant well adapted to this region. The region also features various forms of grapes including table grapes, wine grapes, and grapes for drying. Kaplan (1994) conducted an ampelographic study using the classic method for naming the grapes growing in this region. The researcher demonstrated the rich genotypic diversity in the region and also noted that the naming of grapes is complicated mainly due to the complexity of the synonyms used for grapes. Accordingly, it is commonly known that the use of different names for plants based on regional variation leads to significant problems and confusion in terms of the correspondence of these names to those used in studies and to those mentioned in each phase of production. These problems can only be resolved by the use of molecular markers of polymorphism.

Microsatellite, a highly powerful type of DNA markers, provides a unique genetic profile for every cultivar, permitting unambiguous identification that is not affected by environment, disease, or farming methods (Meredith, 2001). Since the first grape microsatellites were reported by Thomas and Scott (1993), many more microsatellites have been developed for characterization of *Vitis* germplasm (Bowes et al., 1996, 1999; Sefc et al., 1999; Dı Gaspero et al., 2000; Scott et al., 2000; Dı Gaspero et al., 2005).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39273939

Microsatellite markers have been extensively used for genotyping and the determination of synonyms and homonyms of grape genotypes (Costantini et al., 2005; Karaağaç, 2006; Cipriani et al., 2010; Emanuelli et al., 2013; Alifragkis et al., 2015; Maletic et al., 2015 Maul et al., 2015; Li et al., 2017; Zequim Maia et al., 2018; Van Heerden et al., 2018) and for pedigree analysis and for investigating the parentage of cultivars and genome mapping (Meredith et al., 1996; Sefc et al., 1998; Grando et al., 2003; Vouıllamoz et al., 2004; Adam-Blondon et al., 2004; Akkak, 2007; Huber, 2016; Dong et al., 2018). These markers have also been used for the identification of chimaeras of grapes (Franks et al., 2002; Riaz et al., 2002; Hocquigny et al., 2004; Boz et al., 2011). Moreover, these SSR markers have recently been successfully used for the protection of the germplasms of wild grapevine (*Vitis vinifera* ssp. silvestris) and the elucidation of the historical development of grapevine (Schneider et al., 2015; Zdunić et al., 2017; Butorac et al., 2018).

The aim of this study was to identify the grape cultivars growing in Diyarbakır based on the DNA profiles of the grape cultivars transplanted to the Tekirdağ National Germplasm Repository Vineyard in order to protect the germplasms of these grapes and to provide an accurate genetic identification for these cultivars. With the aims stated above, we performed genetic identification of 43 grape cultivars growing in Diyarbakır Province, where gene potential is remarkably high.

Materials and methods

Materials

The study was conducted at Ankara University Agriculture Faculty Horticulture Department. The materials used in the study consisted of 36 genotype samples that were collected from Diyarbakir Province and its districts (D) and all the 7 genotype samples of the cultivars that had been transplanted to the Tekirdağ National Germplasm Repository Vineyard several years earlier (TD). One-year-old seedlings with 3-5 buds were obtained from each genotype and were planted in polyethylene tubes filled with a 2:2:1 mixture of perlite, turf, and powder and then germinated in greenhouse conditions until the buds were rooted. In addition to D and TD genotypes, two additional genotypes that are used as reference genotypes around the world, Cabernet Sauvignon and Merlot, were also analyzed.

Table 1 presents the microsatellites used for the characterization of the genotypes analyzed in the study.

Methods

DNA was extracted from the young leaves of cultivars collected during the summer season, using the method proposed by Lodhi et al. (1994). The DNA concentration was adjusted to 30 ng/µl for polymerase chain reaction (PCR) amplification.

A total of 7 SSR primers were used in the study including the 6 microsatellite loci, VVS2, VVMD5, VVMD7, VVMD27, VrZAG62 and VrZAG79, which were used in a previous GENRES 081 European Union (EU) research project and are currently accepted as minimum standards around the world, and another primer, VrZAG47, which was used in our previous studies and was proven to be a polymorphic primer. Forward primers of each primer pair were labeled with fluorescent dyes including Fam (blue), Vic (green), and Ned (yellow) (*Table 1*).

DNA amplification was performed using GeneAmp PCR System 9700 with EU-Applied Biossystems, and PCR optimization was achieved for each cultivar. PCR amplification was performed in a reaction volume of 20 µl containing 5 µl of DNA, 2 µl of 10X Buffer, 1.2 µl of $MgCl_2$, 0.6 µl of dNTP, 1 µl of primer 1, 1 µl of primer 2, 0.2 µl of GoldTaq (0.5 U), and 9 of µl distilled water. Touchdown PCR was performed using the following cycling conditions: 95 °C for 10 min, 94 °C for 30 s, and 52 °C for VVS2, VVMD5, and VVMD7, 58 °C for VVMD27, 55 °C for VrZAG47, and 62 °C for VrZAG62 and VrZAG79 for 30 s, depending on the rate of primer annealing, with a decrease of 0.2 °C/cycle. After 25 cycles, 15 additional cycles were performed with a reduction of 5 °C from the primer annealing temperature, finally followed by holding at 72 °C for 40 min.

To screen for amplification of the fragments in the loci analyzed, a minimum of 10 samples representing each locus were separated on agarose gel, and the amplified fragments were subjected to sequencing using ABI Prism 3730 automated DNA sequencer with GeneScan™ 500 LIZ™ dye Size Standard. The resulting data were analyzed, visualized, and processed using GeneMapper v 3.7 software. The allele size per locus was represented as peak levels.

A total of 45 grapevine genotypes were analyzed in 7 SSR loci and the genetic similarity between the genotypes was calculated using the Microsat software (Minch et al., 1995) and the genetic parameters (number of alleles per locus [n], allele frequency, expected heterozygosity [H_e], observed heterozygosity [H_o], parentage, null allele frequency (r), and probability of identity [PI]) were calculated using the IDENTITY 1.0 software (Wagner and Sefc, 1999). The dendrograms were constructed and visualized using the NTSys software (version 2.02g, Exeter Software, Setauket, NY). Clustering analysis was performed using the UPGMA method (Unweighted Pair-Group Method using Arithmetic means).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39273939

Genetic parameters of 45 genotypes (i.e. number of alleles per locus [n], allele frequency, expected heterozygosity [H_e], observed heterozygosity [H_o], parentage, null allele frequency (r), and PI) were calculated for each of the 7 loci using the IDENTITY 1.0 software (Wagner and Sefc, 1999). Genetic diversity was calculated based on the following formula: the expected heterozygosity (H_e) = $1-\Sigma p_i^2$, where p_i refers to the frequency of individual alleles (Nei, 1987). The observed heterozygosity was considered as the ratio of the number of heterozygous genotypes to the total number of genotypes analyzed. The frequency of null alleles was calculated based on the following formula: $(H_e - H_o)/(1 + H_e)$ (Brookfield, 1996). PI was defined as the probability that two randomly selected samples have the same SSR profile and was calculated based on the following formula: $\Sigma p_i^4 + \Sigma\ \Sigma(2p_ip_j)^2$, where p_i and p_j indicate the frequencies of alleles *i* and *j*, respectively (Paetkau et al., 1995).

In total, 59 alleles were identified in 7 loci, whereby the total number of alleles per locus ranged between 7 and 10 and the mean number of allele per locus was 8.43. The highest numbers of alleles were detected in VVS2 and VrZAG47 and the lowest were detected in VVMD7, VrZAG62, and VrZAG79. The expected and observed heterozygosity were 0.77 and 0.73, respectively. The PI value per locus was higher than 0.05, the value proposed by Sefc et al. (2001). The PI value detected in our study implicates that the microsatellite markers used in this study are highly polymorphic for genotypic analysis of grapevine.

Genetic similarity between the genotypes was calculated using the Microsat software based on the following formula: genetic distance (D), D = 1-(proportion of shared alleles) (dissimilarity). The resulting value was then converted to genetic similarity index. Genotypes with a value of 1.000 had the highest similarity index and were considered as synonym cultivars, some other genotypes had a value of 0.929 and were considered to be genetically similar, and the remaining samples genotypes that had no shared alleles or no genetic similarity in any locus were considered to be genetically dissimilar.

Dendrograms were constructed and visualized using the NTSys software (version 2.02g, Exeter Software, Setauket, NY). Clustering analysis was performed using the UPGMA method. The genotypes of the samples collected from Diyarbakır were grouped based on the proportion of shared alleles. The dendrogram of the 43 genotypes indicated 5 distinct groups, with each group involving numerous subgroups. The 2 reference genotypes were classified into a separate subgroup and were differentiated from the other 43 genotypes. Genotypes with a similarity index of 1.000 were classified as synonym cultivars on the dendrogram. Overall, the dendrogram indicated that the genotypes of the samples collected from Diyarbakır were not remarkably dissimilar and even showed close relationship with each other. Moreover, numerous synonyms and homonyms were detected among the accessions in the dendrogram (*Figure 1*).

Discussion

In the present study, a total of 59 alleles were identified in the 45 genotypes characterized by 7 loci, whereby the total number of alleles per locus ranged between 7 (VVMD5, VrZAG62, and VrZAG79) and 10 (VVS2 and VrZAG47) and the mean number of alleles per locus was 8.43. *Table 4* presents the number of alleles per locus reported by previous studies. In contrast, the studies by Crespan and Milani (2001), Dangl et al. (2001) and Hvarleva et al. (2004) were conducted with lower numbers of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39273939

genotypes and thus detected lower mean numbers of alleles compared to our study. In our study, the number of alleles per locus ranged between 7 and 10 (*Table 3*), which are higher than the numbers reported by Dong et al. (2018) and Zequim Maia et al. (2018). Dong et al. (2018) analyzed 34 grape genotypes using 15 SSR markers and found that the number of alleles per locus ranged between 1 and 8. Zequim Maia et al. (2018) analyzed 69 grape genotypes and reported that the number of alleles per locus ranged between 1.94 and 2. This difference is associated with the large number of low-frequency alleles in large-scale sample sets (Laiadi et al., 2009). However, our study was similar to those reported by Akkak et al. (2005), Costantini et al. (2005), Vouillamoz et al. (2006), and Li et al. (2017) with regard to the number of alleles per locus (*Table 4*).

34	15	1-8	3.6	Dong et al. (2018)

Of the loci used for the analysis of 43 genotypes in our study, VVS2 and VrZAG47 were detected with the highest number of alleles (n = 10 each). In previous studies, VVS2 has also been reported to have the highest number of alleles by Lopes et al. (1999), Borrego et al. (2001), Lefort and Roubelakis-Angelakis (2001), Fatahi et al. (2003), Martín et al. (2003) and Núñez et al. (2004). This marker was followed by VVMD5 and VVMD27 (n = 9) and VVMD7, VrZAG62, and VrZAG79 (n = 7).

The PI values varied from 0.62 to 0.83 with a mean value of 0.74 (*Table 3*). The mean PI value was similar to the value reported by Ramezani et al. (2009) (0.77). The most informative locus was VVS2 (0.83) (*Table 3*). This finding was consistent with the finding reported by Li et al. (2017) that indicated that VVS2 showed the highest level of polymorphism with a value of 0.815.

The PI value per locus in our study was higher than 0.05, the value proposed by Sefc et al. (2001). This finding implicates that the microsatellite markers used in this study are highly polymorphic for genotypic analysis of grapevine. With the highest PI values, VVMD5 (0.80) and VVS2 (0.83) were the most informative markers in our study, also revealing maximum differentiation among the genotypes. In other words, these two markers showed the highest level of differentiation compared to other markers. In other

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39273939

studies, the most informative markers have been shown to be VVMD5 (Lefort and Roubelakis-Angelakis, 2001; Ibáñez et al., 2003b; Martín et al., 2003) VVS5 (Borrego et al., 2001), and VVMD14, VVMD28, and VVMD36 (Crespan and Milani, 2001). Meaningfully, VVMD5 has been shown to be an informative marker in numerous studies, as seen in our study.

The expected and observed heterozygosity in our study were 0.77 and 0.73, respectively (*Table 3*). Accordingly, the observed heterozygosity was lower than the expected heterozygosity, which could be attributed to the existence of null alleles. However, the absence of a significant difference between these two rates further confirms that our cultivars were heterozygous. Moreover, the observed heterozygosity in our study was lower than those reported by other studies including Sefc et al. (2000), Dangl et al. (2001), Aradhya et al. (2003), Fatahi et al. (2003), Costantini et al. (2005) and Vouillamoz et al. (2006).

Based on the proportion of shared alleles among the 45 genotypes characterized by 7 microsatellite loci, 15 synonyms and 8 homonyms were detected among the genotypes (*Table 5*).

The reference genotypes used in our study, Cabernet Sauvignon and Merlot, have also been studies by other researchers (Bowers et al., 1999; This et al., 2004). The researchers found similar differences to those of our study, between the two alleles in a single loci for each of the 7 loci.

Conclusion

In conclusion, we obtained a very high allelic polymorphism among the genotypes that were expected to be different or between the genotypes that were supposed to have the same variety name. Moreover, 15 synonyms and 8 homonyms were detected among the 45 genotypes characterized by 7 microsatellite loci, based on the proportion of shared alleles among the genotypes. However, in the genotypes detected with homonyms, it was not clear as to which homonym represented the real name of each genotype. A total of 30 distinct cultivars were detected among the 45 genotypes characterized by 7 microsatellite markers, suggesting that Diyarbakır Province is rich in genetic diversity of grapevine and that the gene sources of these cultivars should be protected.

We consider that the differentiation in the names of homonymous cultivars could be attributed to erroneous naming of the cultivars or to the variations (e.g. clone, type) that

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39273939

have emerged within the same cultivar over time. Considering the naming of synonymous cultivars, it appears that a single genotype might have been erroneously given several different names.

Our results indicated that the microsatellite markers used in our study were highly suitable for the genetic identification of grape cultivars and the determination of synonyms and homonyms. Notably, VVS2 and VVMD5 were the most informative markers among the others and successfully differentiated the 45 genotypes.

Abstract. Our study demonstrates the use of the Walter–Elwood method in double-peak seasonal variation. The concept of the geometrical model for analysing cyclic variation is described. Monte Carlo simulation procedures are used to compare the performance of the Walter–Elwood and negative binomial regression methods with double-peak seasonality, in both a comparison between the two methods and a power analysis. The results of 10,000 independent Monte Carlo simulations showed that the Walter–Elwood method and the negative binomial regression analysis identified the same peak in 9,956 samples, indicating that the power of both methods is similar in analysing double-peak cyclic trends. Additionally, two epidemiological applications of double-peak seasonality are presented, which were analysed using the Walter–Elwood method. Further, this is the first study to describe the power of the Walter-Elwood method for double peak seasonality. In conclusion, double-peak seasonality could be investigated with the Walter–Elwood method in ecological studies when only the population at risk is available and there is no other variable.
Keywords: *environmental effect, geometrical model, cyclic variation, Monte-Carlo simulations, power analyses, population at risk, perinatal mortality, childhood leukaemia*

Introduction

Seasonal variation is a feature of many diseases with a potential infectious component and contributes to a better understanding of aetiology. There are a number of methods for analysing cyclic trends, and this type of patterning can be studied in several different ways (Hewitt et al., 1971; Roger, 1977; Marrero, 1983; Jones et al., 1988). In 1961, Edwards introduced a geometrical model, which only used the number of observations (Edwards, 1961). Walter and Elwood (1975) extended Edwards' idea by including the population at risk. Stolwijk et al. (1999) described an application of logistic regression. The methodology developed by Walter and Elwood is widely used in single-peak analyses but not in double-peak analyses. However, the method is entirely suited to analysing double-peak seasonal variation.

The most frequent numbers of deaths occur in infants aged under 1 year, and a relatively high proportion of children aged between 0 and 14 years die from cancer. Acute lymphoid leukaemia (ALL) is the most common type of cancer found in children.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39413948

Environmental hazards including infections around the time of birth have long been suspected as a possible factor in the aetiology of childhood ALL and in perinatal mortality (McNally and Eden, 2004).

The aim of our study was to demonstrate the use of the Walter–Elwood method in double-peak seasonal variation when the investigated event repeats in six-monthly cycles. Two datasets are used to illustrate the use of the Walter–Elwood method for analysing seasonality in the aetiology of ALL in children under 5 years of age and in perinatal mortality, respectively.

Methods

We describe the concept of the geometrical model for analysing cyclic variation. Seasonal fluctuations of an event (e.g. infant death) which occurs on a fixed date every year might be described using cyclic patterns over a period of time (e.g. two decades).

We suppose that within a certain time span (e.g. a year) there are k sectors (e.g. 12 months) and that in sector i there are n_i events from a population at risk of size m_i (e.g. total births during that month). The total number of events is $N=\sum n_i$ and the total size of the population at risk is $M=\sum m_i$.

H_0: The expected number of events in a sector is proportional to the population at risk in that sector, i.e. $E(n_i)=Nm_i/M$.

The basic idea of the Walter–Elwood method is that the monthly number of observed events and the population at risk are grouped by month over the study period yielding data for all 12 months for both events and population at risk. Then the weighted monthly numbers in the aggregated data are placed on the circumference of a circle with unit radius using the polar co-ordinate system. In the case of single-peak seasonality, this circle represents the year, and the sectors correspond to 12 months.

The data by weights $\sqrt{n_i}$ are placed around a unit circle at points corresponding to the sector midpoints at angles θ_i to an arbitrary diameter (e.g. the diameter through 1 January: January is $0°$).

Average observed frequencies are:

$$\bar{x}=\frac{\sum_{i=1}^{k}\sqrt{n_i}\cos\theta_i}{\sum_{i=1}^{k}\sqrt{n_i}} \quad \bar{y}=\frac{\sum_{i=1}^{k}\sqrt{n_i}\sin\theta_i}{\sum_{i=1}^{k}\sqrt{n_i}} \qquad \text{(Eq.1)}$$

From (*Eq. 1*) we calculate the expected values of x and y:

$$\mu_{\bar{x}}=\frac{\sum_{i=1}^{k}\sqrt{Nm_i/M}\cos\theta_i}{\sum_{i=1}^{k}\sqrt{Nm_i/M}}=\frac{\sum_{i=1}^{k}\sqrt{m_i}\cos\theta_i}{\sum_{i=1}^{k}\sqrt{m_i}} \quad \mu_{\bar{y}}=\frac{\sum_{i=1}^{k}\sqrt{m_i}\sin\theta_i}{\sum_{i=1}^{k}\sqrt{m_i}} \qquad \text{(Eq.2)}$$

The variances of the coordinates of the sample centre of gravity are:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39413948

$$\sigma^2_{\bar{x}} = \frac{\sum_{i=1}^{k} \frac{1}{4} \cos^2 \theta_i}{[\sum_{i=1}^{k} \sqrt{Nm_i / M}]^2} \quad \sigma^2_{\bar{y}} = \frac{\sum_{i=1}^{k} \frac{1}{4} \sin^2 \theta_i}{[\sum_{i=1}^{k} \sqrt{Nm_i / M}]^2} \tag{Eq.3}$$

The test statistic (*Eq. 4*) is distributed on the null hypothesis as χ^2 with 2 degrees of freedom:

$$\left(\frac{\bar{x} - \mu_{\bar{x}}}{\sigma_{\bar{x}}} \right)^2 + \left(\frac{\bar{y} - \mu_{\bar{y}}}{\sigma_{\bar{y}}} \right)^2 \tag{Eq.4}$$

The distance *d* of the sample centre of gravity from its null expectation is provided by

$$d^2 = (\bar{x} - \mu_{\bar{x}})^2 + (\bar{y} - \mu_{\bar{y}})^2 \tag{Eq.5}$$

If the null hypothesis is true (no seasonal trend or equal underlying rates in each month), then the centre of gravity has an expected value of zero on both the *x* and *y* axes. This hypothesis is tested using chi-square statistics with 2 degrees of freedom. If the test statistic is greater than 5.99, then a simple harmonic trend should be fit to the data (*Fig. 1*). We may suppose that the expected frequency in sector *i* is proportional to

$$c_i = m_i \left[1 + \alpha \cos(\theta_i - \theta^*) \right] \tag{Eq.6}$$

where amplitude $\alpha = 4d$ is a measure of the cyclic variation, which is calculated using the formula developed by Edwards (*Eq. 6*), and where θ^* (*Eq. 7*) provides the discretion of the maximum rate, which may be estimated as

$$\theta^* = Tan^{-1} \left(\frac{\bar{y} - \mu_{\bar{y}}}{\bar{x} - \mu_{\bar{x}}} \right) \tag{Eq.7}$$

The adequacy of the description of the data afforded by a simple harmonic curve may be evaluated by a goodness-of-fit test using a further χ^2 statistic. The expected frequencies n_i' are calculated by

$$n_i' = Nc_i / \sum_{i=1}^{k} c_i$$

and the goodness-of-fit test statistic (*Eq. 8*) is:

$$\sum_{i=1}^{k} \left(n_i - n_i' \right)^2 / n_i' \tag{Eq.8}$$

which has a χ^2 distribution with (*k-1*) degrees of freedom.

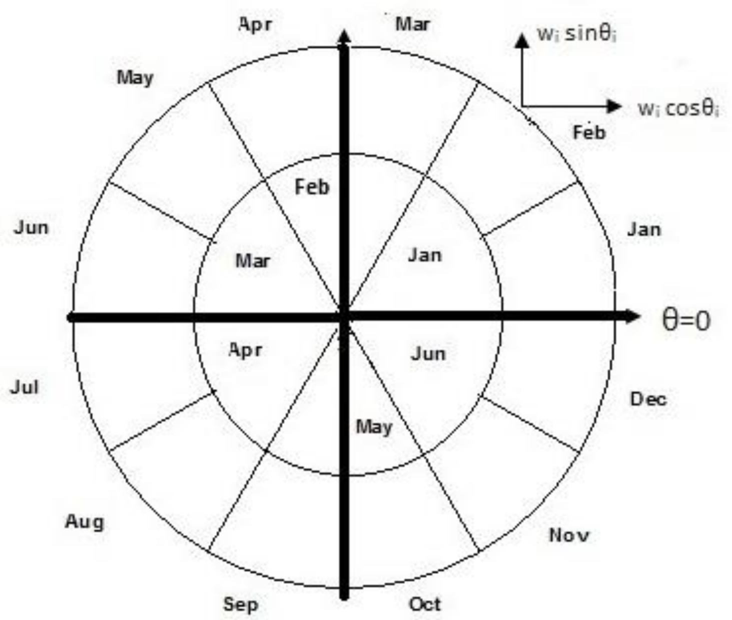

Figure 1. *Sectors for single-peak (outside circle) and double-peak (inside circle) analysis*

The use of the Walter–Elwood method to analyse double-peak seasonality with six sectors is based on the assumption that the observed events occur six months apart. Thus, the monthly data are aggregated using the months of the first half year and adding to them the corresponding data from six months later (e.g. January and July). Additionally, the first angle of maximum variation is detected by this test and the second maximum is at $\theta^*+\pi$ (*Fig. 1*). The test statistic remains unchanged, that is a chi-square statistic with 2 degrees of freedom. Similarly, the goodness-of-fit test remains the same for both single-peak and double-peak analyses. Nevertheless, Monte Carlo simulation procedures were used to compare the performance of the Walter–Elwood and negative binomial regression methods. 10,000 random samples from a Poisson distribution were generated with double-peak seasonality and used in both a comparison between the two methods and a power analysis. A p value of less than 0.05 was considered to indicate a significant effect.

Two datasets are used to illustrate the use of the Walter–Elwood method for analysing seasonality.

Acute lymphoblastic leukaemia study

We have investigated seasonal trends in the incidence of ALL around the time of birth in children aged 0-4 years. Children born between 1981 and 1997 in south-eastern Hungary were considered. The monthly number of cases and births in the 1981-1997 period are displayed in *Table 1*.

Perinatal mortality study

In this study, cyclic changes in early perinatal mortality rates were investigated during the 34-year interval between 1 January 1980 and 31 December 2014 in Hungary. The data on the cause of perinatal deaths were published annually by the Central Statistical Office (KSH, 1980-2014).

Results

Monte Carlo simulation

The results of the Monte Carlo simulations showed that out of 10,000 independent data sets, the Walter–Elwood method indicated significant double-peak seasonality in 8,416 cases, while the negative binomial regression analysis did so in 8,672 cases. Moreover, the two methods identified the same peaks in 9,956 samples, indicating that the power of the Walter–Elwood method is similar to the negative binomial regression in analysing double-peak cyclic trends.

Acute lymphoblastic leukaemia study

Table 1. *The monthly number of acute lymphoblastic leukaemia (ALL) cases and births in the period 1981-1997*

Month	Number of live births	Single peak		Double peak	
		Observed number of ALL	Expected number of ALL	Observed number of ALL	Expected number of ALL
1	23631	9	11.537	12	11.476
2	21894	10	9.721	16	14.808
3	23862	6	9.515	12	14.905
4	21922	3	8.038	12	9.945
5	22953	2	8.023	6	6.234
6	23274	3	8.204	6	6.632
7	25236	3	9.696		
8	24631	6	10.384		
9	23872	6	11.299		
10	22724	9	11.535		
11	21799	4	11.428		
12	22358	3	11.615		

The calculated expected frequencies in the analysis using a single-peak seasonal pattern are also shown in *Table 1*. The χ^2 test statistic is 2.45, which indicates no significant (p = 0.293) cyclic pattern. However, with the Walter–Elwood method using a double-peak seasonal pattern, the χ^2 test statistic is 6.11, which indicates a significant (p = 0.047) cyclic pattern. The amplitude and the angle of maximum rate were 0.43 and 116.5, respectively. Thus, peak rates occurred in children born in February and August. The goodness-of-fit test statistic was 1.18 (p = 0.946). These findings with the Walter–Elwood method are similar to our published results from southern Hungary (Nyári et al., 2008).

Perinatal mortality study

The monthly number of deaths and births in the study period are summarised in *Table 2*. The calculated expected frequencies in the analysis using a single-peak seasonal pattern are also shown in *Table 2*. The χ^2 test statistic is 1.114, which indicates no significant (p = 0.57) seasonality.

DOI: http://dx.doi.org/10.15666/aeer/1702_39413948

Table 2. *The monthly number of perinatal mortality and births in the period 1980-2014*

Month	Number of live births	Single peak		Double peak	
		Observed number of perinatal mortality	Expected number of perinatal mortality	Observed number of perinatal mortality	Expected number of perinatal mortality
1	164527	691	702.11	1404	1429.44
2	148237	569	627.27	1292	1266.50
3	159762	663	671.50	1315	1334.36
4	151516	680	634.84	1373	1362.08
5	156203	720	655.32	1399	1406.96
6	159247	711	671.70	1441	1424.63
7	175431	713	745.89		
8	169170	723	725.35		
9	169792	652	732.83		
10	163604	693	708.29		
11	153903	679	665.46		
12	158881	730	683.38		

If we employ the Walter–Elwood method using a double-peak seasonal pattern, the χ^2 test statistic is 18.74, which indicates a significant ($p < 0.001$) cyclic pattern. The amplitude and angle of maximum rate were 0.068 and -71.8, respectively. Maximum rates occurred in children born in May and November in the simple harmonic model for perinatal mortality. The goodness-of-fit test statistic was 1.567 ($p = 0.905$). These findings using the Walter–Elwood method confirm our published results that significant double-peak seasonality was found in children born in May and November for perinatal mortality (Nyári et al., 2015).

Discussion

We have presented detailed descriptions of the use of the Walter–Elwood method for double-peak seasonality and shown the power of this method using Monte Carlo simulations. These simulations have revealed that the power of the Walter–Elwood method is very close to the negative binomial regression method in analyses of double-peak seasonality.

Using the Walter–Elwood method seasonal variability for ALL related to date of birth of all children diagnosed under age five years was detected. We found evidence of seasonality related to month of birth with peaks in February and August. Both peaks correspond to previous findings and could reflect the seasonality of infectious diseases.

Significant double peak model was fitted to characterize the seasonal variation of perinatal mortality using the Walter-Elwood method. The peaks were observed in May and November and we might assume that perinatal mortality may have been related to respiratory infections (Borchers et al., 2013). Formerly, we have detected double peak of seasonality with generalized linear models. This study demonstrates that the application of the Walter -Elwood method for double peak of seasonality gives similar

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39413948

results with high power. Further, this is the first study to describe the power of the Walter-Elwood method for double peak seasonality.

Many health conditions and exposures (or risk factors) involve some seasonal element (Marrero, 1983; Jones et al., 1988). The harmonic model is one of the simplest. It may be adopted to represent oscillating rates. However, the main limitation of using a fitted sine curve is the inability to adjust for covariates. Furthermore, the fitted harmonic trend yields a poor goodness-of-fit test statistic when the variation of the observed data is high.

The choice among analytical approaches should ideally reflect the research question of interest, and simple methods are compelling in many cases. There is a free programmed spreadsheet known as Episheet to apply Edwards' geometrical model (Rothman, 2008). However, this program only detects single-peak seasonality. Our study demonstrates that the Walter–Elwood method is easy to calculate using a spreadsheet program for double-peak seasonality.

Walter (1977) published a power calculator for the Edwards method for a single-peak cyclic pattern but not for a double peak. Stolwijk and his colleagues (1999) criticized the Walter–Elwood method for analysing double-peak seasonality. Similarly, Barnett and Dobson (2010) described a poor power for the use of the Walter–Elwood method in analysing double-peak seasonality. In contrast, our findings have revealed a similar power for the Walter–Elwood method, which characterizes the negative binomial regression method in analyses for double-peak seasonality.

Christiansen and his colleagues (2012) reviewed methods for analysing seasonal variation. They suggested using the peak-to-trough ratio. Cave and Freedman (1975) presented a method for double-peak seasonality analysis of Crohn's disease using an extension of the Edwards test in methodology. Similarly, our study found that the Walter–Elwood method is a suitable method to analyse double-peak seasonal variation. Furthermore, this method allows the inclusion of the population at risk, and it is simple to calculate both for the test statistics and the fitted expected frequencies.

In conclusion, double-peak seasonality could be investigated with the Walter–Elwood method in ecological studies when only population at risk is available and there is no confounding variable. Since cyclic trends in the aetiology of a disease reveal some effect of environmental factors we might assume that both childhood acute lympoid leukaemia under age five years and perinatal mortality may have been related to respiratory infections. These findings could prove useful in preventive strategies, but further cohort studies need to investigate this hypothesis.

(Received 1st Nov 2018; accepted 25th Jan 2019)

Abstract. In order to study the adsorption property of straw biochar of methylene blue dye, five kinds of biochar (rice straw, corn straw, wheat straw, peanut straw and reed straw) were prepared at 500°C through the method of oxygen limiting and temperature control. The microstructure, functional group and elemental composition of biochar were characterized with a scanning electron microscope, Fourier transform infrared spectroscopy and X-ray diffraction. The adsorption experiments of the methylene blue solution by five kinds of straw biochar were carried out, and the properties of the biochars after the adsorption of the methylene blue solution were compared and analyzed. The result revealed that S500, X500 and L500 have round hole microporous structure, and Y500 and H500 have parallel wall microporous structure. The FTIR spectra of five kinds of straw biochar contained polar groups and aromatic structures. Their adsorptive capacities were as follows: X500 > S500 > L500 > Y500 > H500. Among the five kinds of straw biological charcoals, X500 had good surface characteristics and the ability to adsorb methylene blue. It is the preferred material for adsorbing organic contaminants. Moreover, the surface characteristics of the five kinds of straw biological charcoal also affected their ability to adsorb the methylene blue solution.
Keywords: *charcoal, surface features, adsorb-ability*

Introduction

Biochar is a carbon rich material (Warnock et al., 2007) cracking under both the presence of oxygen and oxygen free conditions, has rich surface functional groups, high carbon content and developed pore structure, and can be used as a new adsorbent of organic pollutants (Yang and Sheng, 2003). Methylene blue ($C_{16}H_{18}ClN_3S$) is widely used in the field of chemical indicators, dyes, biological dyestuffs, drugs and so on (Zhou, 2010). In the printing and dyeing industry, a large amount of organic dye wastewater is produced, which holds great environmental risks. Using a low-cost material to control environmental pollution has become a popular topic of researches (Yang et al., 2006; Warnock et al., 2007). A new technology of biomass carbonization and a resource for agricultural products has been gradually conceived (Jian et al., 2016). Therefore, biochar plays an important role in industrial waste treatment and the remediation of environmental pollution.

Through studying three kinds of improved corn straws, Ci and Chen (2016) discovered that the improved corn straw adsorption capacity of methylene blue increased. Huang et al. (2018) found that the adsorption of methylene blue on activated carbon from rice straw was mainly affected by pore size. Fragiskos et al. (2008) found that the untreated wheat straw had strong ability to adsorb methylene blue and could be used as a low-cost adsorbent. Hammes et al. (2008) explored the changes in the elemental composition of black carbon after pyrolysis, indicating that the hydrogen and oxygen elements in biochar continued to remove hydrophobicity with increasing temperature. Chen and Chen (2009) studied the surface functional groups of wood biochar and found that they were adsorbed by π-π conjugated structure and filled with pores. Lu et al. (2013) compared rice straw biochar and corn straw biomass, found that corn straw biochar degree of aromatization was higher, thus

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39493958

enhancing organic solution adsorption. Zhang et al. (2016) studies showed that the biochar adsorption capacity of reed straw pyrolyzed at 500°C was the strongest. Ji et al. (2016) found that the adsorption of methylene blue on cationic dyes by rice straw biochar was mainly mediated by ion exchange. From the above, the surface morphology, functional groups and chemical composition of straw biochar have great influence on the adsorption properties of methylene blue organic solution. The biological charcoal of different straw has different structures and components. It is of great significance to study the physicochemical characteristics and adsorb-ability of straw biological charcoal for the treatment of organic dyes.

In this paper, five kinds of straw biomass were selected at 500°C for slow oxygen slow thermal cracking and carbonization, the structure characterization of five kinds of biological charcoal and the adsorption experiment on methylene blue solution. The physical and chemical properties of five kinds of biological charcoal were characterized by electron microscope scanning, Fourier transform infrared spectrum analysis and modern analysis of X-ray diffraction. The physicochemical properties of five kinds of biological charcoal were compared.

Materials and Methods

Preparation of biological carbon from straw

Five kinds of straw biomass were selected as the raw materials for preparing biochar. Rice straw and corn straw were collected from farm field in Pu Kou District of Nanjing, China. Wheat straw and peanut straw were collected from a farm field in Yang Zhou, and reed straw was collected from Nanjing Bagua. Each straw was collected at 1 kg. The straw was washed, dried, cut in 1-2 cm pieces, put into a grinding machine, smashed in 60 mesh, and stored in 90°C drying oven.

The biological carbon was prepared by the slow speed hot cracking method. The straw treated with powder was placed in a quartz boat and placed in a muffle furnace and passed into nitrogen for 10 min to discharge the air in the tube. The heating rate was set at 5°C /min, and the temperature was raised to 300°C for 1 h. Then the temperature was kept at the highest temperature of 500°C for 2 h, and then cooled to room temperature after the pyrolysis was completed, and the biological charcoal was dried. The biochar samples of rice straw, wheat straw, corn straw, peanut straw and reed straw were signed as S500, X500, Y500, H500 and L500.

Properties and characterization of biological carbon

Carbon yield

The quality of five kinds of straw before and after pyrolysis was weighed. The carbon yield of biological charcoal was referred to "*Wood Charcoal and Charcoal Test Method (GB/T17664 - 1999)*" (Wood charcoal and test method of wood charcoal), and the mass ratio of straw before and after was the carbon yield. The carbon yield of different straw biochar was calculated according to *Formula (1)*.

$$\eta = \frac{m_2}{m_1} \times 100\% \qquad \text{(Eq.1)}$$

where η is carbon yield and m_1 and m_2 represent the mass /g before and after carbonization.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39493958

Microstructure of biological carbon from straw

Field emission scanning electron microscopy (SEM) (*US FEI Inspect F50*) was used to observe the microstructure of the straw bio carbon. The instrument voltage of the scanning electron microscope was 20 KV, and the magnification was 1000 and 3000, and their SEM images were recorded.

Fourier transform infrared spectroscopy

Five kinds of biological charcoal were called each 0.002 g, and the KBr particles of 0.2 g were mixed (1:100), lapped, pressed (Lu et al., 2013) via using *Nicolet 380 Fourier Transform Microscopic infrared spectrometer*, and the sample was scanned on the spectrometer sample frame.

X- ray diffraction

The crystal structure characteristics of biochar were analyzed by *Brook D8 ADVANCE*. 1.5 g biochar samples were collected and placed on the sample stage for equipment diffraction. CuK was used as the transmitter source, and the tube voltage and tube current were 40 kV and 30 mA, respectively. The scanning angle was 10-60°, the step length was 0.02°, and the scanning speed was 7° /min (Kim et al., 2012).

Adsorption test of methylene blue by biological carbon

Five kinds of biochar 0.8 g were added and standard methylene blue solution with 20 mL of $100\,mg \cdot L^{-1}$ (BZ) was added. Then it was put in constant temperature cradle for shocking at 25 ℃ and $150\,r \cdot \min^{-1}$ for 2 h, then is was placed statically for 24 h. The adsorbed methylene blue solution was filtered through the 0.45 μm polyethersulfone filter membrane through a needle filter, and the color image of the filtrate was recorded. The filtrate was used to measure the absorbance of the solution at 665 nm with the UV visible spectrophotometer, and compared with the 5 g/L$CuSO_4$ solution ($CuSO_4$).

The absorbance and concentration of methylene blue solution after adsorption were measured by ultraviolet visible spectrophotometer after absorption of methylene blue standard solution by five kinds of biochar. The adsorption rate of 5g/L$CuSO_4$ solution for standard methylene blue solution is 100%, and the setting value is 100, and the standard methylene blue solution corresponds to the standard methylene blue adsorption rate of 0% and the setting value of 0.

Results and discussion

Analysis of carbon yield

Five kinds of straw biochar were calculated by *Formula (1)*. *Figure 1* was pyrolytic carbon yield of five kinds of straw materials at 500°C. From the *Figure. 1*, the yield of H500 is 46.96% and the yield of Y500 is 37.01%. The yields of S500 and X500 are 38.83% and 38.93%, respectively, and their yields are similar. The yield of L500 is 39.93%. The decomposition of cellulose, hemicellulose and lignin in the straw component at 500℃ shows that the carbon yield will decrease slowly with the increase of pyrolysis temperature, so the biochar has a good thermal stability (Yang et al., 2017). The carbon yield of H500 is high. On the one hand, the ash content of H500 is high and the component of pyrolysis is not easily affected by high temperature. At 500℃, the heat stabilization

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39493958

ability of H500 is stronger than other straw. On the other hand, the lignin content in H500 is higher than that of other straw. Lignin is a kind of high aromatic substance. The temperature range of the molecular compound is broad and the thermal stability is strong. The yield of S500 is similar X500 (Yang et al., 2017; Wei, 2017). It is found that the composition of metal salts in Y500 is low, and the composition of metal salts can catalyze the pyrolysis of biomass (Raveendran et al., 1995), resulting in low carbon yield of Y500.

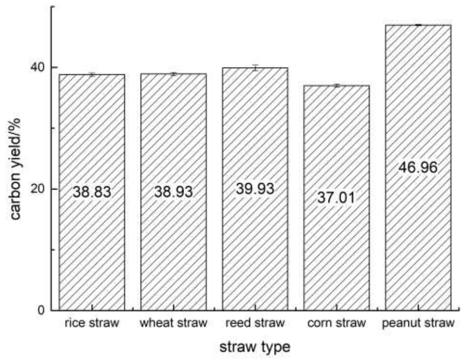

Figure 1. *Yield of biological coals*

Morphology analysis

Figure 2 is a scanning electron microscope (SEM) of five kinds of straw biomass at 500°C carbonization. *Figure 2* shows, there are pore structures on the surface of five kinds of straw biochar.

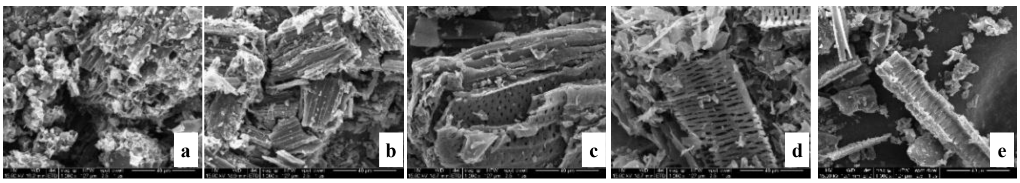

Figure 2.1 *×1000 SEM*

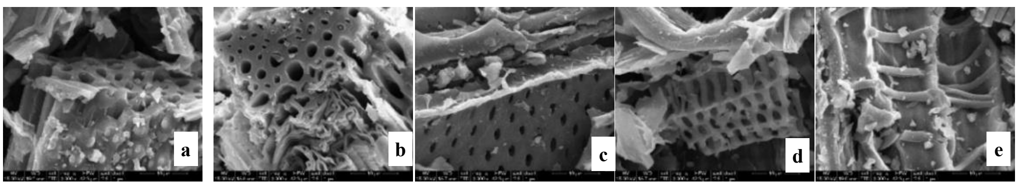

Figure 2.2 *×3000 SEM*

Figure 2. *SEM of biochar (a. S500; b. X500; c. L500; d. Y500; e. H500)*

The pore shape of S500, X500 and L500 show a circular pore shape, with smooth surface and different pore structure and specific shape. The pore distribution of S500 is uniform, the pore size is the same, the pore distribution of X500 is uneven, the pore size is gradually reduced, and the pore size of L500 is smaller. The space is large and the hole is evenly distributed. The pore shape of Y500 and H500 appear as parallel wall type, the surface is rough, the arrangement of pore structure and specific shape are different.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39493958

Compared with the first three kinds of pore size, the maize straw bio carbon hole arrangement is dense, H500 arrangement is compact, the pore distribution is uneven, and the aperture is not shaped. Under the same amplification conditions, the number of holes in S500, X500 and L500 is more than that in Y500 and H500. Although there is obvious pore structure on the surface of S500 and H500, there is no lamination structure of X500, L500 and Y500, which may be related to the temperature and time of carbonization, the structure breaking of pore structure as well as the surface structure of its own straw. The volatile components in biomass can be precipitated in large quantities and thus gradually form porous structures. The number of pores and pore size pores will affect the adsorption capacity of biological carbon. The pore structure of the straw bio carbon is rich in pore structure and the pore size is obvious. It can be used as an efficient adsorbent to remove methylene blue from the waste-water (Xu et al., 2012).

FTIR analysis

Figure 3 is a Fourier transform infrared spectrum analysis of straw biochar. The changes in the functional groups of the five kinds of biological carbon are basically the same.

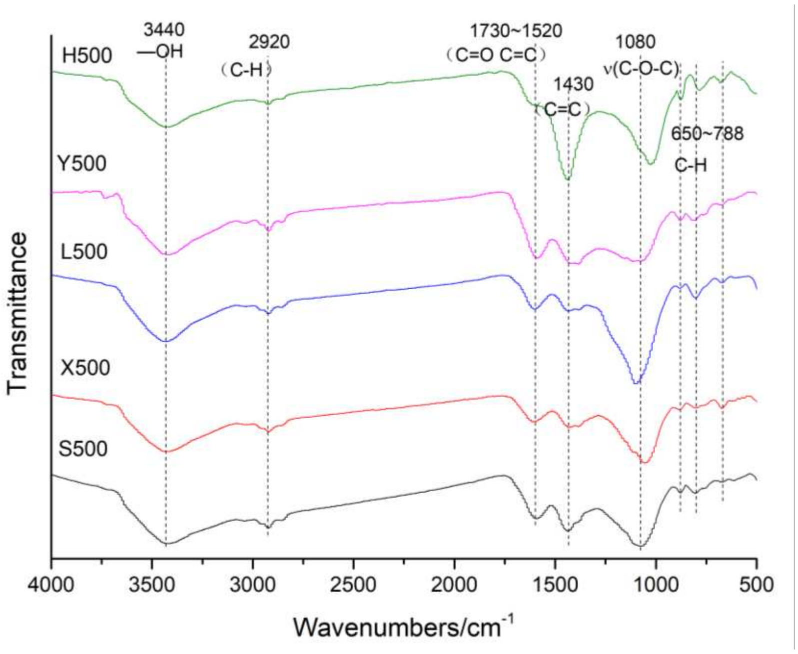

Figure 3. *FTIR of five types of straw biochar*

There is a peak of phenol hydroxyl absorption at 3440 cm^{-1}, and a higher methylene absorption peak of the aliphatic (C-H) is found at 2920 cm^{-1} (Zhang et al., 2016). Because of the bending vibration of aromatic ring C=O, the absorption peak appears between 1730~1520 cm^{-1}. 1080 cm^{-1} appeared C-O-C antisymmetric stretching vibration in Six-element dioxygen ring ether (Yang et al., 2010). The absorption peak at 1522 cm^{-1} and 1430 cm^{-1} is aromatic ring C=C, and there are many aromatic (C-H) flexural vibration peaks between 650~788 cm^{-1}. It shows that straw biochar contains hydroxyl, carboxyl, carbonyl, ester, aldehyde groups and other oxygen-containing functional groups. Therefore, five kinds of biochar mainly exist hydroxyl and other polar groups, and they

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39493958

have aromatic structure at the same time. It shows that the adsorption of methyl blue on methylene blue solution is due to the effect of polar group, and the aromatic structure of biological carbon and aromatic methylene blue can form π-π conjugated structure, and there is a kind of π-π interaction (Ji et al., 2016).

The content of surface functional groups on the surface of biochar affects its adsorption capacity. From *Figure 3*, in the vicinity of 1520~1730 cm^{-1} it can be seen that the expansion vibration intensity of aromatic ring functional groups on the surface of S500, X500 and L500 is greater than that of H500 and Y500, among which H500 is used. The vibration intensity of straw biochar is the weakest. It can be concluded that the content of π-π conjugated structure of H500 is the lowest in the process of adsorbing methylene blue.

XRD analysis

Figure 4 is a X- ray diffraction pattern of five kinds of straw biochar. It can be seen from the *Figure 4* that the main peaks of S500, X500 and Y500 appear in 2θ=23.5°, L500 has a wide peak of 22.5°, and H500 has no obvious main peak. This kind of peak corresponds to the diffraction peak of the amorphous structure. The diffraction peak of the amorphous structure on the surface is mainly related to the crystalline structure of cellulose in biomass (Keiluweit et al., 2010; Kim et al., 2012).

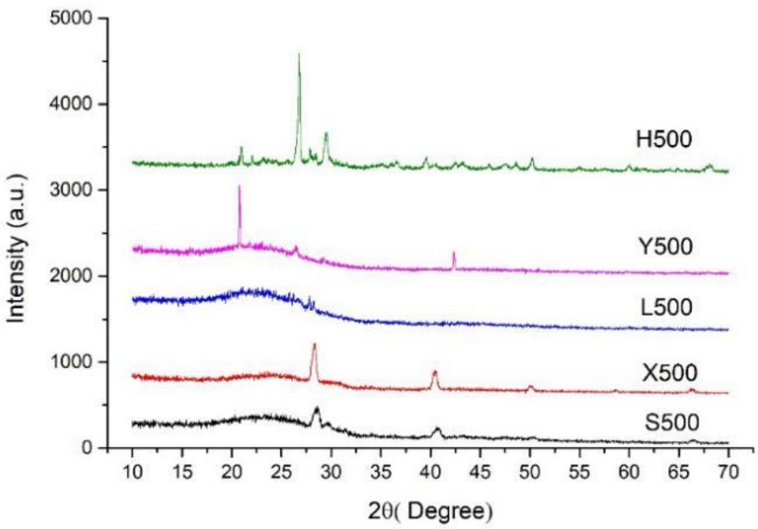

Figure 4. *XRD of five types of biochar*

The main peak is not found in H500. Most of the cellulose is completely pyrolyzed at 500℃. The other four kinds of biological carbon cellulose diffraction peak still exist at 500℃, which may have the good thermal stability of these crystalline cellulose. Without complete pyrolysis, it can be concluded that the crystallisation of H500 is not high, the high crystal stability is good, and the adsorption effect is good (Lin et al., 2016). In this experiment, there are potash mineral components in S500 and X500. The mineral diffraction peak of SiO_2, $CaCO_3$ is found in Y500 and H500. It is found that L500 has a amorphous structure but no mineral diffraction peak, but it is L500. The content of the components of the mineral salt is very small, and the content of K is only 0.22%, and the content of P is 0.16%. Compared with the C element with the content of 46.8%, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39493958

content is not obvious (Meng et al., 2015). On the other hand, it might be related to the source of L500 and the content of local environmental elements, which has a low impact.

Experimental analysis of adsorption of methylene blue standard solution by biochar

The absorbance and concentration of methylene blue solution after adsorption were measured by ultraviolet visible spectrophotometer after the absorption of methylene blue standard solution by five kinds of biochar. The adsorption rate of 5 g/L$CuSO_4$ solution for standard methylene blue solution is 100%, and the set value is 100, and the standard methylene blue solution corresponds to the standard methylene blue adsorption rate of 0% and the set value of 0. Absorbance and adsorption rate of biochar after adsorption of standard methylene blue solution are in *Figure 5*. The lower the absorbance value, the higher the transmittance of the solution (is) and the better its adsorption effect. With the absorbance 0.1068Abs of 5 g/L$CuSO_4$ solution as the transparent index of solution, the absorbance of X500 is lowest 0.0571Abs, less than the absorbance of $CuSO_4$ solution. It is considered that the adsorption rate reaches the maximum value of this experiment, which is 100% adsorption, and the absorbance of S500 is 0.1091Abs, its adsorption rate is 97.4%. The absorbance of L500 is 0.3356Abs, its adsorption rate is 94.6%. The absorbance of Y500 is 0.6865Abs, its adsorption rate is 83.9%, and the absorption rate of H500 is 2.1945Abs, and its adsorption rate is 51.5%. The biological charcoal with higher adsorption rate than 90% believes that the adsorption effect is good, and the adsorption efficiency is less than 50%. The adsorption effect of S500, X500 and L500 on methylene blue solution is better, the adsorption rate of H500 is near 50%, and the adsorption effect of H500 is not good (Fu et al., 2012).

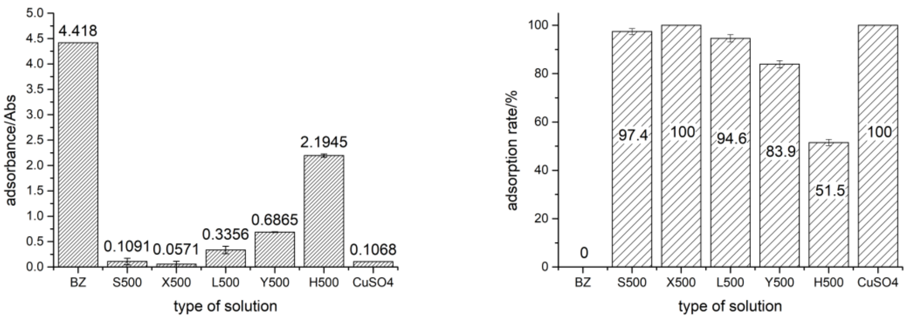

Figure 5. *Absorbance and adsorption rate of five kinds of straw biochar adsorption solution, methylene blue standard solution and 5g/L$CuSO_4$ solution*

Figure 6 is the effect of five kinds of biological carbon adsorbed on the standard methylene blue solution. The effect of the adsorbed solution is: X500 > S500 > L500 > Y500 > H500. Compared with the effect of five kinds of adsorbed methylene blue solution and standard methylene blue solution, the adsorption solution of X500 becomes transparent and clear due to the pore shape of the microstructure of X500. Besides that, it is also because the number of pores is more, the texture structure is obvious, the polar and aromatic structure content of X500 is more than that of X500, and it has an amorphous structure. The pore size of S500 and L500 is different, and the content of functional group is less than that of X500, so the adsorption effect of methylene blue solution is second only to that of X500, which can be determined as the main factor affecting the adsorption

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39493958

capacity of methylene blue solution. The pore shape of H500 microstructure is parallel wall shape. The pore structure is damaged by high temperature, large pore size, less pore number and is has no obvious bedding structure. Most of the cellulose pyrolysis after the carbonization of H500 has a large number of SiO_2, $CaCO_3$, and the peak expansion vibration peak of polar group is weak, and the number of aromatic structure is obviously less. In other biochar, the adsorption capacity of ion exchange and π-π interaction are weakened, which is the reason why the adsorption effect of H500 is not good. The biological charcoal of Y500 also has the shape of parallel wall, and its polar and aromatic structure content is less, it contains more SiO_2, $CaCO_3$ mineral diffraction peak, and the adsorption effect of Y500 to methylene blue solution is not good.

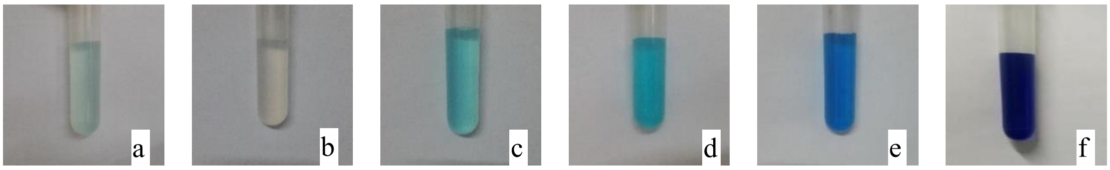

Figure 6. *Comparison of adsorption effect between five kinds of biochar and standard methylene blue solution (a. S500; b. X500; c. L500; d. Y500; e. H500)*

Conclusion

The microstructure, elements and functional groups of five kinds of straw biochar, also the adsorption properties of methylene blue solution were analyzed. The conclusions are as follows:

1) The pore shape of S500, X500 and L500 is round, and the hole shape of Y500 and H500 is parallel wall shape, and the number of pore number is more than that of the latter. Pore shape, pore number and pore size affect the adsorption capability of biochar to methylene.
2) There are mainly hydroxyl group and aromatic structure in the straw biological carbon. Additionally, the higher content of the polar and aromatic structural functional groups of the straw bio carbon, the better effect of the adsorption of methylene blue.
3) The adsorption capacity of five biochar to methylene blue: X500 > S500 > L500 > Y500 > H500. The adsorption rate of X500 reaches 100%. The results show that X500 has the best adsorption capacity for methylene blue and it is suitable for the application of organic dye pollution control.

(Received 2nd Nov 2018; accepted 28th Jan 2019)

Abstract. The groundwater of the Teboulba region in Tunisia suffers from overexploitation and from the degradation of its quality due to salt water intrusion from the Mediterranean sea as well as from the sebkha of Moknine. The actual groundwater quality was assessed using the *Vicia faba* root meristem micronucleus assay. The exposure of *V. faba* to irrigation water from 3 wells showed no spectacular changes in the root growth, fresh and dry matter and the membrane integrity compared to the control plants. However, the plants exhibited decreases in their mitotic index and high inductions of micronuclei and chromosomal aberrations including stickiness, bridges, fragments, vagrant chromosomes and laggards. Consequently, and despite the fact that the morphological parameters and the membrane integrity did not show noticeable variation, the micronucleus test has proved to be an early bioassay allowing the detection of the Teboulba groundwater genotoxicity, which may probably result from contamination of the groundwater by agricultural and industrial activities in/or surrounding the region.
Keywords: *aberrations, contamination, membrane integrity, micronucleus, mitotic index, morphological parameters, Teboulba groundwater*

Introduction

The groundwater is considered as the primary resource for water. It is widely used for agriculture and industry especially in regions with limited annual precipitation. However, shallow groundwater is vulnerable to various types of pollution. In fact, in coastal regions, the overuse of groundwater wells located near the shoreline is the major cause of the salt water intrusion in the groundwater (Bouri and Ben Dhia, 2010). This phenomenon is considered as the primary cause of the salinization of groundwater (Bear et al., 1999). Moreover, groundwater contamination with anthropogenic materials is possible, harming both the groundwater quality and quantity. Such materials dissolve in the liquid phase, and may penetrate into the soil and affect the groundwater quality via percolation (Bear and Cheng, 2010). The groundwater quality may also suffer from other contamination like septic tanks and wastewater effluents. There are different types of pollutants that can be found in the groundwater such as salt, nitrate, heavy metals and new contaminants like pharmaceuticals and personal care products (Zghibi et al., 2013; Ameur et al., 2016; Ouessar et al., 2017).

In Tunisia, numerous irrigation regions are located near the coast where extensive areas have evolved into an advanced agricultural production zone with considerable economic importance. However, the agricultural practices in these regions have already led to the overexploitation of the groundwater resources and an increased salinity by seawater or saline water intrusion. Additional groundwater contamination was caused

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39593971

by industrial activity, applications of artificial fertilizers, manures, pesticides and irrigation with treated wastewater in many Tunisian coastal regions (Saidi et al., 2013; Fries et al., 2016; Dahmouni et al., 2017). 750 sources of contamination of urban, industrial and agricultural origins were identified. They cause significant damage to the Tunisian water resources according to the national inventory established in 2004 by the Ministry of the Environment and Sustainable Development (Besbes et al., 2013). These sources include alimentary, textile and plastic industry sectors and domestic and industrial treated wastewater, the quality of which frequently exceeds the Tunisian standard.

Teboulba is a Tunisian coastal region with a long tradition of highly profitable irrigated agriculture. Like most coastal zones with shallow groundwater, the Teboulba region suffers from overexploitation caused by intensive pumping that led both to a decrease of the water level and to an increase of salinity. It caused salt water intrusion from the Mediterranean sea as well as from the sebkha of Moknine, an endorheic and salty depression resulting from Quaternary tectonic events (Chairi et al., 2010) which was used as a discharge site for many industrial activities (Wali et al., 2015). There is not much known about the current state of the groundwater, only measurements of water and salinity levels during and a few years after the artificial recharge from the overspill of the Nebhana dam and its injection into a limited number of wells (Bouri and Ben Dhia, 2010). Even if there is no recent information about the quality of the Teboulba groundwater, there are increasing complaints about the poor quality of the irrigation water. Therefore, a short-term laboratory study has been carried out with the root meristem of *Vicia faba* plants to evaluate the genotoxicity potential as an indicator of the groundwater quality. The *V. faba* test has widely been used to detect and evaluate toxic elements and has commonly been regarded as an excellent genetic model for toxicity monitoring since it offers a detection of the DNA damage and/or DNA abnormalities in cell division. The fast and sensitive *V. faba* test enables to assess the mitotic index, the micronucleus formation, and the chromosome and the nuclear aberrations. This test was used to assess the genotoxicity of waters collected from 3 wells used for irrigation when water from Nebhana dam is unavailable. The aim of this paper is therefore to evaluate the genotoxicity of the irrigation water and this get an overview of potential quality problems.

Materials and methods

Study area

The experiment was carried out in the Teboulba region situated in the Monastir governorate (Tunisia), some tens of kilometers southeast of the city of Monastir (*Fig. 1*). The Teboulba region belongs to the Nebhana irrigation district where water scarcity remains an important issue. This region has a semiarid to arid climate with mild, wet winters and dry, hot summers. The mean annual rainfall is approximately of 375 mm and the mean annual temperature is about 20°C. The coastal Teboulba aquifer is confined between the sea in the north and the salinized sebkha of Moknine in the south. It is threatened by overexploitation causing a decreasing water level and increasing salinization due to the seawater and/or sebkha intrusions. The aquifer basin of Teboulba covers approximately 35 km^2 and represents an average hydrological recharge potential of 0.65 $Mm^3\ y^{-1}$ with an exploited volume of 1 $Mm^3\ y^{-1}$. This heavy deficit of 0.35 $Mm^3\ y^{-1}$ is compensated not only by reserves but also by an inflow of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39593971

saltwater from the sea and/or the sebkha as well as by a return flow of the irrigation water from the neighboring regions (Beni-Akhy, 1998).

The total agricultural area in Teboulba is 1914 ha, of which 600 ha are irrigated. In the governorate of Monastir, 39% (572 ha) of the total land area are reserved for greenhouses, almost one third of this lies in the Teboulba region (CRDA, 2004). The agricultural sector is dominated by rain-fed olive plantations for olive oil production and horticulture in non-warmed greenhouses. The main water source for irrigation is the Nebhana dam. Each farm in the irrigation perimeter was equipped by a storage tank. Irrigation water prices in Teboulba are among the highest in Tunisia (Chebil et al., 2010). To minimize the water cost, farmers mixed the water from the dam with water pumped from their wells.

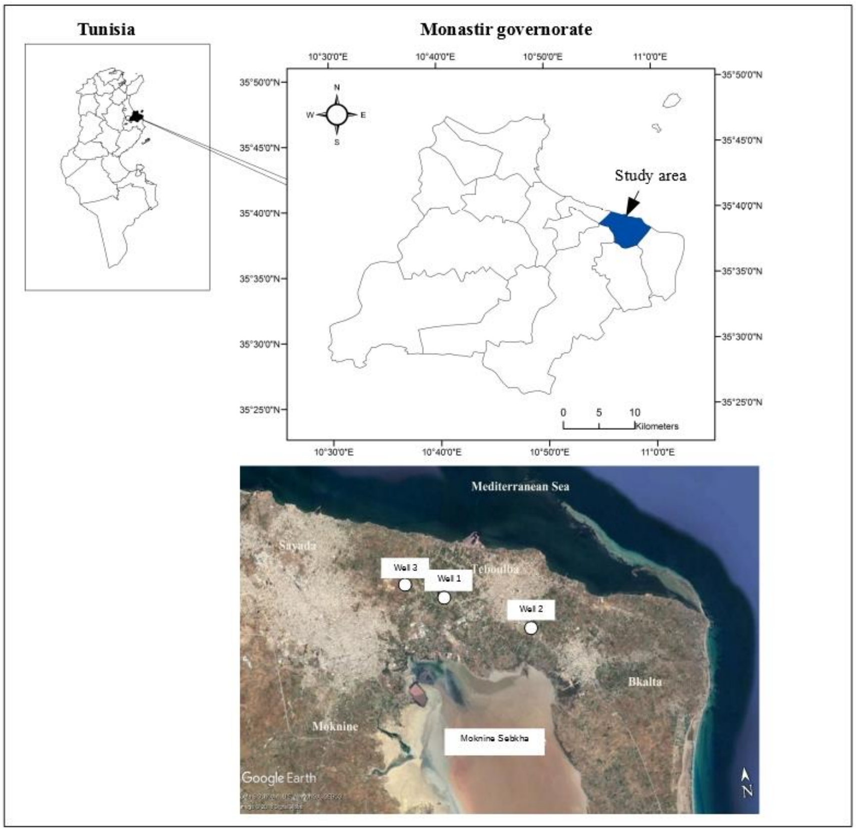

Figure 1. *Study area and location of the 3 sampling wells*

The present study was carried out in 2017 and with the most frequently used well of 3 farms from the irrigation perimeter with poor water quality in their wells (*Fig. 1*). The coordinates of the 3 wells (in Degrees Minutes Seconds) are: 35°38'49.94"N and 10°56'30.64"E for Well 1; 35°38'4.38"N and 10°58'35.72"E for Well 2, and 35°38'49.88"N and 10°55'37.52"E for Well 3. The well depths were measured and water samples were collected, pH and electrical conductivity (EC) were measured with a pH meter (Lutron pH-211) and a conductivity meter (Cond./TDS, AZ 8361), respectively. Mineral composition was determined using the following methods: sodium (Na^+) and potassium (K^+) with flame emission spectrophotometry (Jenway, PFP7), calcium (Ca^{2+}) and magnesium (Mg^{2+}) with complexometric titration using a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39593971

standardized solution of ethylenediaminetetraacetic acid (EDTA), chloride (Cl^-) and bicarbonate (HCO_3^-) by titrating with silver nitrate ($AgNO_3$) and sulfuric acid (H_2SO_4), respectively, and sulphate (SO_4^{2-}) with UV-Visible spectrophotometer (Up Lab, UV-Vis-Auto). The 3 wells extracted the shallow groundwater at depths ranging between 27.5 and 44 m (*Table 1*). The water used for irrigation had a pH between 7.93 and 8.01 and a considerable salt content. The highest salinity was 7.26 dS m^{-1}, found in Well 1 and the lowest salinity was 3.60 dS m^{-1}, recorded in Well 3. Cl^- and Na^+ were the dominating ions at all salinity levels.

Table 1. *Characterization of water collected from the 3 wells in the region of Teboulba*

Plant treatments

The *V. faba* seeds (Tunisian Chahbi variety) were surface sterilized with 10% sodium hypochlorite, rinsed several times with water and placed on moistened filter paper at 25°C for 3 to 4 days. Subsequently, the roots were introduced in both distilled water (control) and 3 samples of water collected from the 3 wells. For the genotoxicity assessment, a positive control was added. After 24 hours of exposure, the seedlings were rinsed a few times with distilled water and divided into three groups: the first was used for the growth measurement; the second to determine the membrane integrity and the third for the micronucleus test.

Growth parameters

Control and treated seedlings were separated into roots and epicotyls for root length, fresh and dry matter measurement. Root length was determined by measuring the length of the whole root after the treatments and dry matter was determined after drying the plant parts at 65°C. At least 6 seedlings were used for the measurement of the growth parameters.

Assessment of the plasma membrane integrity loss

The loss of plasma membrane integrity was evaluated with three root tips by a spectrophotometric test using Evans blue (an indicator for the measure of the plasma membrane integrity) as described by Souguir et al. (2011). The first centimeter of the roots was incubated in 0.025% Evans blue (m/v) for 30 min, rinsed for 15 min and squashed in a 800 µl solution of 50% of MeOH (v/v) and 1% of sodium dodecyl sulphate (SDS). The root extracts were then incubated for 15 min at 50°C. The homogenate was centrifuged at 14,000 rpm for 15 min. The optical density of the supernatant was determined spectrophotometrically at 600 nm.

DOI: http://dx.doi.org/10.15666/aeer/1702_39593971

Genotoxicity assessment

The genotoxicity of the water from the 3 wells and the control was assessed with the micronucleus test applied on the meristematic roots of *V. faba* plant. A positive control with the hydrazide maleic (HM, 4 10^{-3} M) was added since the HM is well-known for its induction of numerous and very easily observable micronuclei (Souguir et al., 2008; Cotelle et al., 2015). The root tips were cut, placed overnight in a Carnoy's fixation solution containing ethanol and glacial acetic acid (3/1), and stored in the dark in 70% of ethanol before being hydrolyzed with 1N HCl as described by Souguir et al. (2008). The root meristematic tissues were stained with orcein, squashed between a slide and a coverslip, and finally examined under a research microscope (Leica DM2500) with 40 or 100 times magnification.

Three slides were prepared for each of the three replicates and a total of 9,000 cells were observed. The mitotic index (MI) was expressed as the number of dividing cells in 100 observed cells. Micronuclei were observed in both the interphasic and the mitotic cells. Only micronuclei observed in interphases were counted and expressed in terms of micronuclei per 1,000 interphase cells.

Chromosomal abnormalities were photographed with a digital camera (Canon EOS 1100) attached to the microscope.

Statistical analysis

The results were presented as the mean ± standard deviation (SD) obtained from three replicates. Significant differences were determined by Tukey's test at the 0.05% confidence level with the SPSS software (IBM SPSS statistics, v20).

Results

Morphological parameters and membrane integrity

The morphological parameters, root growth and fresh and dry matters of the different *Vicia* organs (root and epicotyl), are illustrated in *Table 2*. In general, the plants exposed to the water from wells and control did not show any significant difference in terms of root length. The average length varied between 3.92 and 5.22 cm. Fresh and dry matter of the plants irrigated with the water from the wells did not differ from the control plants.

The root treatment with Evans blue indicator also did not show a change of membrane integrity loss between the control and the roots (*Fig. 2*).

Genotoxicity data

Figure 3 lists the genotoxicity data of the 3 wells. The MI related to the number of cells undergoing division was higher in the control cells (exposed to distilled water) and reached 37%, whereas the HM as a positive control decreased severely the mitotic activity. This decline also occurred in the roots exposed to all kinds of irrigation waters. Values oscillated between 7% in well 3 and 14% in Well 1. In addition, cells supporting a micronucleus were counted. Low micronucleus frequencies (0.2 micronucleated cells per 1,000 counted cells) were recorded in the root tips of the control plants. As expected, the HM treatment sharply increased the frequency of micronuclei (21.8 micronucleated cells per 1,000 counted cells) compared to the control. The well water significantly increased the frequency of micronucleus formation in the root cells

DOI: http://dx.doi.org/10.15666/aeer/1702_39593971

of *V. faba*. The highest frequency of micronucleus (7.15 micronucleated cells per 1,000 scored cells) was detected in Well 1, while the lowest level (5.75 micronucleated cells per 1,000 scored cells) was noticed in Well 3.

Chromosomal abnormalities

The root cells of *V. faba* treated with the 3 water qualities showed various types of chromosomal aberrations (*Fig. 4*). The cytological aberrations recorded in the bean root tips were stickiness at the prophase, bridges at the anaphase, fragments at the anaphase and the telophase, and finally vagrant chromosomes and laggards at the anaphase and the telophase.

Discussion

The water quality used to irrigate the Teboulba parcels was evaluated by analyzing root morphology, membrane integrity and by screening genotoxicity. *V. faba* showed no changes in their morphological parameters (root growth, fresh and dry matters) between control plants and those exposed to the tested well water. The same results were obtained for membrane integrity measured by the Evans blue uptake. However, several effects were observed in the *Vicia* meristematic root tips on genotoxic parameters, estimated by MI, a micronucleus induction band, and some chromosome abnormalities.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39593971

A significant retardation in the MI was remarked for all treatments compared to the control, which indicates the presence of cytotoxic substances in the irrigation water causing inhibition of the mitotic activity (Fernandes et al., 2007). The cell division inhibition could result from an arrest of the DNA synthesis or a blocking in the G2 phase of the cell cycle, preventing the cell from entering mitosis (Sudhakar et al., 2001). It could also be caused by an impaired nucleoprotein synthesis and a reduced level of ATP to provide energy for spindle assembly and chromosomal movements (Majewsk et al., 2003).

Micronuclei were considered as an indication of a true mutation effect (Auerbach, 1962). Thus, the high percentage of micronuclei induced may indicate the mutagenic effect of contaminants in the tested samples. Micronuclei detected in interphasic cells may originate from acentric chromosome fragments, acentric chromatid fragments or whole chromosomes that fail to be included in the daughter nuclei at the completion of the telophase during mitosis (Fenech, 2011). Micronuclei may also be generated by the elimination of exceeding genetic material from the main nucleus (Fernandes et al., 2007). In addition to micronucleus appearance, many chromosomal aberrations in different mitotic phases including bridges, fragments, stickiness, vagrants and laggards were noticed in cells exposed to the irrigation waters. The induction of such aberrations in the bean root tip meristems indicates that the well water probably contains genotoxic chemical constituents with clastogenic and aneugenic impacts: The clastogenic compounds may induce a disruption or a breakage of chromosomes, whereas the aneugenic ones may result in a tubule formation or a chromosome segregation errors (Parry et al., 2002; Bignold et al., 2009).

The high salinity in the well water (3.60 - 7.26 dS m^{-1}) may lead to such mutagenic/genotoxic effects. The effect of salt on micronucleus induction and on chromosome changes was recently assessed in the *Vicia* root tips treated with 25 dS m^{-1} of NaCl (Souguir et al., 2018). The salt treatment caused micronuclei and changed the organization and the morphology of chromosomes and nuclei. It was shown for salinity values close to those in the Teboulba wells (Teerarak et al., 2009) that the cytotoxicity could be attributed to salinity.

In addition to salt-induced DNA damages, the genotoxicity may be caused by contaminants released from the sebkha of Moknine into the Teboulba groundwater. The sebkha of Moknine, a salty coastal depression, is considered as a hotspot of the industrial activities in the region. One of the most significant sectors in the Monastir region is the textile industry with about 917 factories. This industry is considered to be the most polluting sector of all industries (Garg and Kaushik, 2007; Sarker et al., 2015). About 24 tanneries discharge their effluents on the open land of the sebkha of Moknine and into the surrounding water bodies. Other industries such as blue jeans dyeing, printing industries and washing companies, also release their sewage directly and/or indirectly into the sebkha (Wali et al., 2015). The extensive use of dyes in textile industries and the release of effluents containing toxic compounds can harm soil, water and the living systems including human beings (Minhaz et al., 2018; Vega-Negron et al., 2018). Using *Allium cepa,* known as sensitive as *V. faba*, Sudhakar et al. (2001) showed a marked lowering of the mitotic index (from 9 to 2.2%) when germinating onion bulbs were immersed in 25, 50, 75, 100% of silk industry dye effluents for 24 hours. Silk dyeing effluents were shown to be genotoxic due to presence of mitotic inhibitors like tannins and alkaloids (Rath and Sethi, 2017).

DOI: http://dx.doi.org/10.15666/aeer/1702_39593971

The contribution of the textile industries as well as that of the potteries and the brick industry to the high pollution of the sebkha of Moknine has been previously pointed out through a sebkha sediment analysis (Wali et al., 2015). Moreover, the sebkha receives treated wastewaters from the treatment plants of Moknine, which treat domestic (50%) and pretreated industrial (50%) wastewater using naturally aerated lagoons as secondary treatment process (Rafraf et al., 2016). Effluents from textile industries, brick kilns as well as industrial and household wastewater treatment plants contain a high amount of heavy metals (Achakzai et al., 2015). These contaminants were found in the sebkha of Moknine and lead to groundwater contamination (Malarkodi et al., 2007).

Soil leaching may also contribute to the contamination of groundwater with heavy metals through the overuse of fertilizers, which are usually not completely removed during the production. Being an agricultural region providing nearly a third of the Monastir governorate production (CRDA Monastir, 2004), the use of fertilizers in order to improve soil fertility and plant production is a common agricultural practice in Teboulba. For instance, the cadmium (Cd) contained in P fertilizers may cause high contents in the soil (McLaughlin et al., 1996). Like other metals, Cd might be either absorbed by plants or leached to the groundwater. Its behavior in the soil, accumulation by crops or groundwater leaching depend on numerous factors such as pH, organic matter, salinity, crop species and cultivar, etc. As a non-essential element, this metallic element is well-known for its genotoxic potential and many authors focused on its ability to decrease the MI value and to induce micronuclei and chromosomal aberrations. Souguir et al. (2011) investigated the cyto-mutagenic defects in *V. faba* root tip cells exposed to $CdCl_2$ (10, 100 and 200 μM) for 24 hours. They found increased micronucleus incidences in exposed root cells and with severe mitotic activity decreases. Such effects were also reported by Ünyayar et al. (2006) with $Cd(NO_3)_2$ but for much longer exposure (48 hours) and by Beraud et al. (2007) under lower concentrations of $CdCl_2$ (0.075 - 0.5 μM). Likewise, the genotoxic potential of many other heavy metals has been previously determined. *V. faba* has also been used to analyse mitotic activity decrease, micronuclei and chromosomal abnormality induction, which appeared when roots exposed to 0.5 - 1 mM of CrO_3 for 24 hours (Duan et al., 2013), 0.01 - 10 mM of $AlCl_3$ for 12 hours (Yi et al., 2009), and 0.005 - 0.01 mM of $(Pb(NO_3)_2$ for only 6 hours (Pourrut et al., 2011). Souguir et al. (2008) found that high concentrations of Cu (2.5 - 50 mM) were needed to increase significantly the micronuclei frequency in *V. faba* after 42 hours of exposure to $CuSO_4$, while Steinkellner et al. (1998) found that neither $CuSO_4$ nor $ZnCl_2$ induced any significant changes of genotoxic parameters in *V. faba* root tips. Heavy metals as well as salinity are usually associated with oxidative stress and generation of reactive oxygen species (ROS), which may also be behind the genotoxicity observed in the water collected from the tested wells. ROS production could increase DNA alterations and DNA-repair inhibition at the origin of micronucleus (Valverde et al., 2001).

Excessive fertilization may also cause the high levels of nitrate detected in the groundwater of Grombalia, Korba and Sminja in the North- East of Tunisia, Bekalta and Mahdia-Ksour Essaf in the Center-East of Tunisia, and Sidi-Aïch Gafsa oases and Djerba in the South of Tunisia (Wakida and Lerner, 2005; Einschlag, 2011; Zghibi et al., 2013; Hamed et al., 2013; Ameur et al., 2016; Souid et al., 2017). Nitrate concentrations can be caused by many factors such as the over use of nitrogen fertilizers in agriculture, the leaching of natural soil nitrate by the recharged water, nitrate-rich irrigation-return flow and septic tanks allowing the infiltration of the major part of the

DOI: http://dx.doi.org/10.15666/aeer/1702_39593971

liquid phase. The potential genotoxicity of nitrates in the drinking water was previously investigated in the peripheral blood lymphocytes of children exposed to nitrate concentrations exceeding 70.5 mg l^{-1} (Tsezou et al., 2010).

Groundwater may also be contaminated by pesticides reaching groundwater through runoff and leaching. They can be harmful for the environment and human health. Pesticides including a wide variety of compounds belonging to different chemical classes, have been considered as inciters of gene mutation and micronuclei and chromosomal alteration (Bolognesi and Morasso, 2000; Sta et al., 2012; Goujon et al., 2014).

The sensitivity of the biomass endpoint was less than cell division and micronucleus induction. The cyto-mutagenicity/genotoxicity was not accompanied by notable changes in morphological and physiological parameters. Such sensitivity was previously pointed out in the *Vicia* roots exposed to Cd stress (Souguir et al., 2011) where cell division inhibition and micronucleus induction occurred soon after Cd exposure (12 h), prior to plasma membrane integrity and lipid peroxidation. Other authors thought that contaminants may disrupt microtubule arrays at a concentration lower than that causing root growth inhibition (Eun et al., 2000).

Conclusion

The analysis of the Teboulba groundwater revealed signs of genotoxicity in terms of mitotic index inhibition, micronucleus and abnormality induction. The micronuleus test using *V. faba* can be recommended as a fast, practical and reliable genotoxic assay for groundwater assessments. Genotoxic effects appeared while no changes of growth parameters (root elongation and plant biomass) and membrane integrity were found in treated plants compared to control plants, thus confirming the early sensitivity of the *Vicia* test to toxicity. The micronucleus test gave an idea about the effect of the whole contaminants present in the Teboulba groundwater. A more detailed study based on physico-chemical analyses of waters collected from different wells in the region should be carried out. Such analyses would allow to identifiy the harmful contaminants and to locate the anthropogenic sources. This could help the regional environmental services, local authorities, communities and industries to act responsibly against Teboulba groundwater contamination and to avoid further pollution.

Acknowledgements. The work was carried out under the PRM-IRESA project «Gestion Intégrée et Durable des Systèmes de Cultures Légumières Protégées (CléProD)». We would like to thank the Regional Commissariat for Agricultural Development of Monastir for the information support and the ease of access to farmers.

Abstract. This study is intended to evaluate and segregate potential zones of groundwater quality over residential area of Lahore, Pakistan, where population growth and modernization of urban infrastructure are exerting pressure on finite groundwater resources. The study is based on the groundwater quality data of the year of 2016, with physicochemical quality parameters of total dissolved solids (TDS) potential hydrogen (pH), calcium (Ca), chlorine (Cl), magnesium (Mg) and bicarbonates (HCO_3). Optimal spatial interpolation methods are applied to generate continuous information of all quality parameters using geospatial techniques. Each thematic map of quality parameter has been classified using standard laid down by World Health Organization (WHO). A brief spatial analysis of given quality parameters has been made with reference to their possible source and underground movement. Then, all parameters are overlaid to generate a single indicator of water quality in form of water quality index (WQI) that has been used for segregation of groundwater quality zones. An insight analysis of the spatial pattern of WQI has shown that urban expansion in the southeastern region of study area that has been transformed from agricultural land to impervious surface is the reason behind increased concentration of contaminants in local groundwater. Other prominent zones of contaminated groundwater are found near regions of Anarkali and Gulberg.
Keywords: *groundwater quality, geographic information system, spatial interpolation, spatial analysis, water quality index*

Introduction

Water is one of the primary natural resources to all existing living bodies and ecological systems on earth. Today, preservation of pure water has become a serious issue to maintain healthy environment and economic growth on earth (Ojo et., 2007; Postel et al., 1996). Domestic water demand is increasing day by day with the evaluation in the modern living culture commonly in most of the densely populated urban regions of the world. Over 2.5 billion people in the world have no access to proper sanitation and quality drinking water that costs in deaths of over 1.8 million people, annually (Shrivastava et al., 2015; WHO and UNICEF, 2013a; WHO, 2002). In general, a challenging situation has been driven out due to uncertain atmospheric conditions and lack of decision making by the world leading powers (Interpress, 1999; Shrivastava et al., 2015). In developing countries, including Pakistan, decreasing precipitation rates are ultimately affecting the conservation of freshwater resources (Azizullah et al., 2011). United Nations International Children's Emergency (UNICEFF) and Environmental Protection Agency (EPA) have reported an alarming

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39733988

situation in the main cities of Punjab where high proportions of toxic arsenic have been observed in drinking water (WWF, 2007). In Lahore city, provincial capital of Punjab, aquifer recharge has been reduced due to high abstraction rates of groundwater (Muhammad and Zhonghua, 2014). Water is a good solvent, having strong hydrogen bonding and distinctive nature of polarization it can dissolve many bacterial and natural components. Therefore, naturally occurring water always get polluted through anthropogenic as well as biological activities over and under the surface (Chitmanat and Traichaiyaporn, 2010; Khattak et al., 2012; Mendie, 2005). Today most of the studies regarding groundwater quality assessment are being conducted to highlight sources of contamination behind groundwater pollution in a region. Usually, natural processes of rock-water interactions, precipitation rates and anthropogenic activities like extensive use of fertilizers, disposal of wastes and intrusion of salts are general causes of groundwater contamination (Kumar et al., 2011). Nature of groundwater pollution sources can be categorized in point sources and non-point sources. Point sources are such distinct spots which spread pollutants directly like septic container etc. Whereas non-point sources are diffused sources of contamination that could be in form of fertilizers used over a wide spread agricultural land. As, groundwater flows from recharged regions to discharge areas because of gravity. So, high rates of groundwater withdrawal from certain regions tends towards the aquifer depletion of whole of the area (Siebert et al., 2010). TDS is key standard of drinking water quality and it is used to determine saline properties of groundwater. Presence of salts and slight number of organic components in water can change the groundwater quality. Such constitutes of salts either organic or inorganic are soluble in water in form of magnesium, calcium, sodium, potassium cations and their carbonates (WHO, 2003). Weathering of rocks is another cause of rising concentration of bicarbonates in the groundwater that could be either physical, chemical or biological (Mohsin et al., 2013). Successive natural weathering of rocks, decomposition of multiple salt rocks and percolation through soil significantly rise the chlorine concentration level in groundwater (Sivakumar et al., 2000). Calcium is insoluble in water, but its high concentrations in the presence of magnesium can cause hardness of the water (WHO, 2009). Alkaline or acidic nature of groundwater can be computed by pH, which is one of common indicator to describe the pH level. Values ranges from 7–1 reflects acidic nature and alkaline nature of groundwater is taken more than 7 (WHO, 2007). Ultimately, intrusion of pollutants into the steadily flowing water generate a downslope plume. Such plume elongates through its point source up to the several kilometres and contaminate the water body or groundwater recharge source (Montgomery, 2011). A preview of studies suggests that multivariate spatial techniques are useful to interpret spatial variability of different environmental variables (Mahmood et al., 2011; Sharaf and Sabyani, 2011). Geographic Information System (GIS) offers a complete set of tools to identify the spatial extent of groundwater variability and interpretation of groundwater quality over concerned area. It also helps to evaluate potential regions through variety of operational tools to examine the consequences behind the variability (Mahmood et al., 2016). Spatial interpolation is an artistry tool commonly used to analyze the variability by creating a continuous surface of estimated values from limited known sample data values. Different models and complex mathematical functions are operated to generate optimal output surfaces under the GIS environment (Batool et al., 2015). It also helpful to generate water quality index (WQI) for an overall groundwater quality assessment by using single number or grade based upon locational data of different water quality

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39733988

parameters. WQI converts complex data values into the user-friendly information for the public awareness and policy makers to make better decisions regarding water resource management (Shabbir and Ahmad, 2015). Asadi et al. (2007) have concluded the use of GIS as effective toolset for calculating groundwater quality index (GWQI). Overall results show that most of the study area is in permissible limits for drinking water, as defined by WHO. Nas and Berktay (2010) investigated the groundwater conditions in the area of Konya city using the same handy toolset of GIS. In the study thematic maps of different physical and chemical water quality parameters were critically analyzed to elaborate the decreasing trend of groundwater quality from south to north of the city. Adnan and Iqbal (2014) have performed physicochemical analysis for groundwater quality assessment to explore the spatial distribution of water quality parameters over the region of Peshawar, Pakistan. They have obtained spatial surfaces using Inverse Distance Weighted (IDW), as the interpolating function without checking accuracy with other available options. A comparison of different deterministic and stochastic interpolation techniques was explained by Gunarathna et al. (2016), for mapping pH concentrations in the region of Malwathu Oya cascade-I, Sri Lanka. It was justified that stochastic methods give more precise results for the spatial analysis of pH values in groundwater of the study area (Gunarathna et al., 2016). It has highlighted the importance of exploring all the interpolation techniques to generate most reliable prediction surfaces. Current study is designed to analyze groundwater quality trends in the potential zones of Lahore with an emphasis that how rapid urbanization and growing economic development effect on groundwater quality and cause water pollution.

Materials and methods

Study area

Lahore is the most dynamic metropolitan of the province Punjab, Pakistan. Geographically it is extended 31°15′ to 31°45′ in north and 74°01′ to 74°39′ in east over Asian plate. Lahore is surrounded by district Sheikhupura in north and easterly bordered with India (Muhammad and Zhonghua, 2014). At northwest edge, a prominent river course exists named as River Ravi which acts like administrative boundary between Sheikhupura and Lahore district, as given in *Figure 1*. Fresh water demand has become a big concern of the study area due to overpopulation, modern urban infrastructure and accelerated economic transformation rate (Shah and Abbas, 2017). Latest Census-report of Pakistan has shown that population of Lahore district has been reached to 11.13 million with an average annual growth rate of 4.07% (Pakistan Bureau of Statistics, 2017). Seasonal variations in temperature patterns and precipitation rates have decreased rainfall in Lahore. In hot summer, temperature rises from 40 °C, whereas in winter it reaches up to 5 °C. Monsoon period contributes almost up to 40 mm in groundwater recharge with approximately 75% precipitation per year (Dogar, 2008; Muhammad and Zhonghua, 2014). Various studies have revealed that unconciliated alluvial deposits have made Lahore’s aquifer unconfined, highly permissible and more substantial (Kanwal et al., 2015). Although, River Ravi accomplishes the water demand of the whole city but its condition is going worse day by day. With decreasing rain water runoff, it receives approximately 47% of the total municipal and industrial waste of the city which have been voided into it without any treatment (Akhtar et al., 2014). Extensive digging for the construction of deep surface infrastructure like underground bus systems and pillar bases for overhead bridges has

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39733988

been observed to provide a temporarily increased groundwater recharge, showing importance of local recharge in sustainability of this precious source of drinking water (Mahmood and Tariq, 2017; Wateraid and BGS, 2009). Ultimately, degradation of groundwater quality has caused serious health related issues in nearby areas (Basharat and Rizvi, 2011). Domestic and industrial needs of water are being fulfilled by pumping out groundwater either by the private societies and industries or government authorities. More than 500 production wells have been installed by Water and Sanitation Agency (WASA), Lahore to supply water to 531,336 connections in the mega city. WASA, Lahore also monitors groundwater quality by examining its chemical, physical and bacterial properties to ensure the availability of pure water (Akram and Gabriel, 2007; Basharat and Rizvi, 2011).

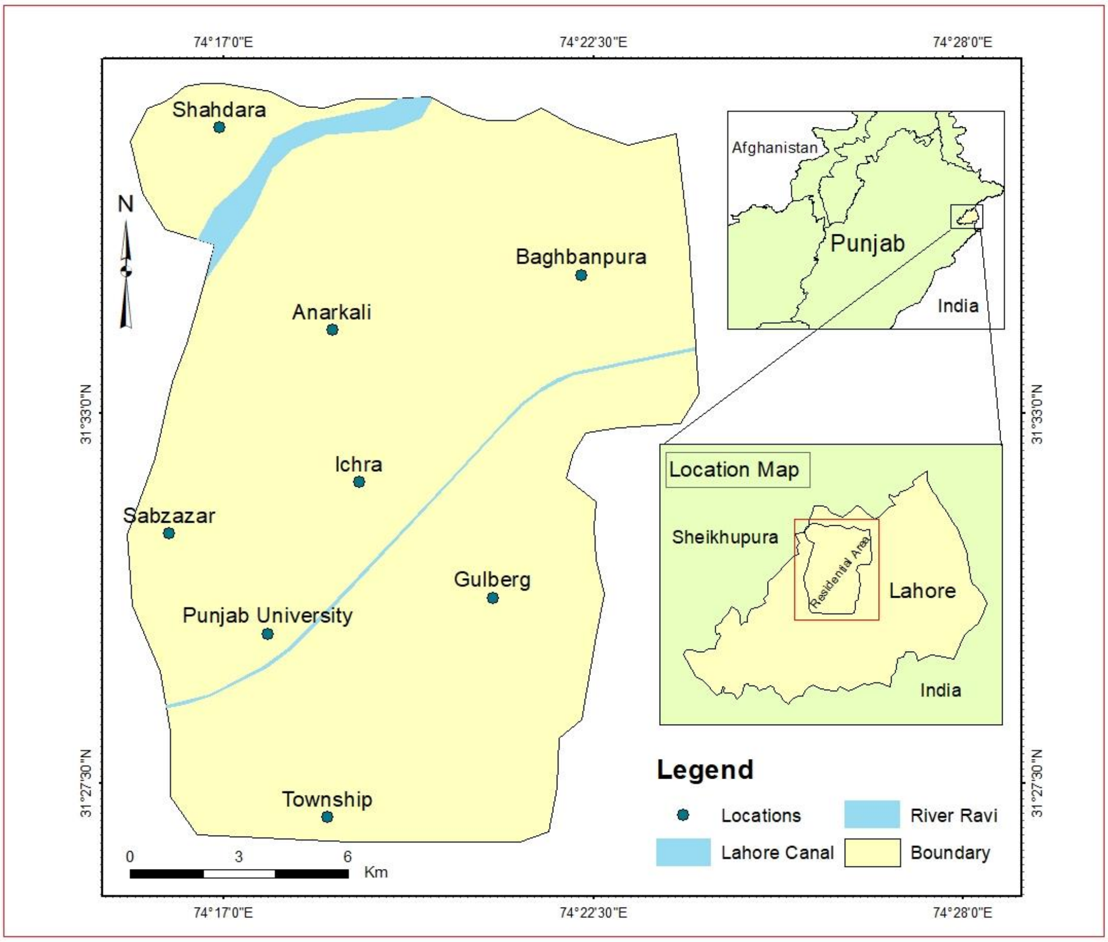

Figure 1. *Study area*

Data collection

Groundwater quality assessment of a region can be conducted by using multiple analytic approaches. In the present study, 200 water samples have been collected from installed tub wells by WASA in different regions of the district Lahore in the year of 2016, as presented in *Figure 2*. Sample data consists of limited quality parameters, Calcium (Ca), Chlorine (Cl), Bicarbonates (HCO_3), Magnesium (Mg), pH and Total

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39733988

Dissolved Solids (TDS) which were chemically analyzed in Water Quality Laboratory WASA, Lahore. All the collected samples have been chemically examined through different titration techniques recommended by American Public Health Association (APHA) and World Health Organization (WHO). pH values are calibrated through buffer solution of 7, 8 and 9 and alkalinity has been measured through acid-base titration method due to the presence of calcium and magnesium components. Geographic coordinate data of each sample location were collected through a GPSmap-76Sx, with an accuracy of approximately 3 m by field survey. All the sample data values and their location data have been combined in excel sheet. Further geographic coordinates have been assigned to assembled data and displayed in the ArcGIS 10.1 to generate a geographic layer. General statistical characteristics of each Groundwater quality parameters have been mentioned in *Table 1*. Different spatial interpolation techniques (Deterministic and Stochastic Methods) have been assessed to evaluate the spatial variability of water quality parameters over the study area.

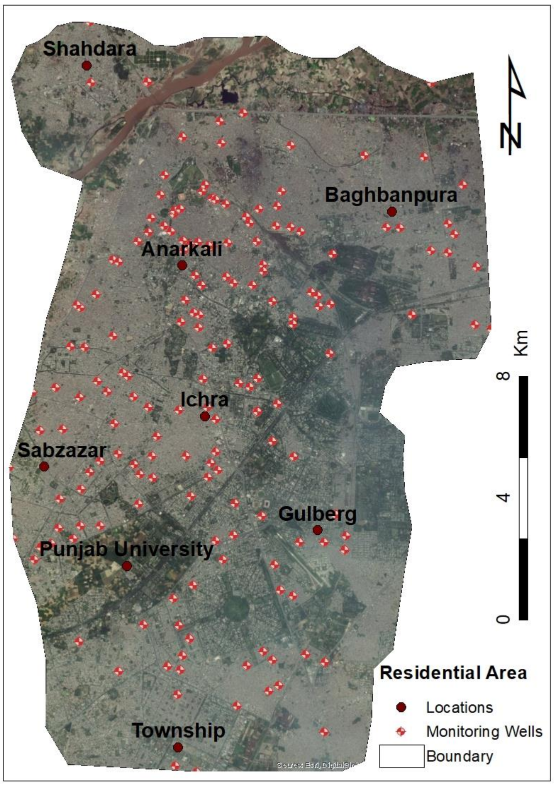

Figure 2. *Production wells in residential area of Lahore*

Table 1. *General statistics of selected groundwater quality parameters*

Water quality parameters	Mean	Median	Maximum	Minimum	Std.
Calcium (mg/L)	32.56	29.20	87.20	05	15.60
Chlorine (mg/L)	47.82	37	260	15	33.69
HCO3 (mg/L)	232.83	214	506	94	79.68
Magnesium (mg/L)	19.79	16.80	65.30	5.60	11.16
pH (Value)	7.87	7.80	8.30	7.80	0.11

Spatial interpolation

Geo-statistical techniques help to analyze spatial continuity and therefore have been used by most of groundwater studies, especially those which have used geographically unevenly distributed sample data. Spatial interpolation techniques are based on the first law of Geography which states that closer objects are more similar than those that are far apart (Batool et al., 2015). Inverse Distance Weighted (IDW) is being used since a long time in many studies which now has been replaced by advance methods of Kriging (Mahmood et al., 2016). IDW method interpolates through assigning weights, depending upon mutual distances between sample data values using a power function. Optimized power values define the influence of each quality parameters over the region in generating a continuous surface. On the other hand, kriging family get the real surfaces by using probabilistic function like semivariogram and its different models. Kriging have three main types, i.e. Ordinary Kriging, Simple Kriging and Universal Kriging that are based on the complex functions (Javari, 2017). Each spatial interpolation technique has its own significance; therefore, each of them has been applied to the current dataset to optimize the best predicted results. Accuracy of each method is measured and assessed using Root Mean Square Error (RMSE) which has been mentioned in *Table 2.*

Table 1. *Comparison of different interpolation methods by using RMSE values*

Water quality parameter optimal interpolation methods	Calcium (mg/L)	Chlorine (mg/L)	HCO_3 (mg/L)	Magnesium (mg/L)	pH	TDS (mg/L)
IDW	14.590	28.782	70.644	10.117	0.102	153.668
Global polynomial	14.877	32.392	65.464	10.058	0.105	169.060
Local polynomial	14.513	29.602	65.511	9.815	0.101	152.692
Radial basis function	14.430	28.627	68.883	9.982	0.102	151.286
Ordinary kriging	14.085	**27.609**	**64.779**	**9.545**	0.099	146.145
Simple kriging	**14.065**	27.703	65.167	9.555	**0.098**	146.474
Universal kriging	14.126	27.625	64.900	9.576	0.099	**145.245**

Calculation of water quality index (WQI)

Groundwater quality status is quite significant to evaluate the potential regions of good or poor water quality. Spatial distribution of each water quality parameter provides a pictorial view of measured and estimated sample data values. However, WQI indicates permissible limits of drinking water quality standards at a general scale for an absolute assessment of groundwater quality scenario in a region. Commonly weighted overlay analysis is being used to calculate water quality index in most of current studies (Acharya et al., 2018; Kumar et al., 2013; Mahmood et al., 2016). In weighted overlay method weights assign to each groundwater quality parameter as per their relative importance over each other. It is prerequisite that sum of weighted values of contributing groundwater quality parameters should be equal to 1 (in numbers) or 100 in percentage to generate WQI. According to the Mahmood et al. (2016), WQI for a certain region can be determined through a series of different steps. Input weights of each quality parameter have been computed by using the following expression given in *Equation 1:*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39733988

$$wi = \left\{ Wi / \sum_{i=1}^{n} Wi \right\} \times 100 \qquad \text{(Eq.1)}$$

where w_i and W_i are input and relative weights respectively, and n is the number of water quality parameters considered. Quality rate of each parameter was computed using *Equation 2,* by comparing measured and suitable values in the spatial analyst extension using raster calculator tool. The mathematical expression for the development of quality rating is:

$$Qi = \left(\frac{Ci}{Si} \right) \times 100 \qquad \text{(Eq.2)}$$

Since Qi stands for quality rating of ith parameter, Whereas C_i is concentration of ith parameter in an individual sample and S_i is the standard value of drinking water for ith parameter.

Further quality rates and weights of each water quality parameter have been taken into account according to *Table 3*, to calculate water quality index as follows:

$$WQI = \sum_{i=1}^{n} (wi \times Qi) \qquad \text{(Eq.3)}$$

Table 3. *Weight and standard values for selected groundwater quality parameters*

Water quality parameter	Ca (mg/L)	Cl (mg/L)	HCO_3 (mg/L)	Mg (mg/L)	pH	TDS (mg/L)
Relative weight (Wi)	2	3	3	2	4	6
Input weight (wi) %	10	15	15	10	20	30
WHO standard (Si)	75 mg/L	250 mg/L	120 mg/L	50 mg/L	8.5	500 mg/L

Results of calculated water quality index by using *Equation 3* represents a range from good to poor water quality status of Lahore district. The range is classified in five equal interval classes according to the standards defined by WHO, which are given below in the *Table 4.*

Table 4. *Recommended equal interval classes for each groundwater quality parameter*

No. of classes	Class-1	Class-2	Class-3	Class-4	Class-5
WQI Values	< 70	70–84	84–97	97–110	>110
Category	Good	Moderately good	Marginally good	Moderate	Poor

Results and discussion

Spatial analysis of water quality parameters

Continuous spatial surfaces of each groundwater quality parameter generated by different interpolation techniques, demonstrate some high and low potential areas. As per *Table 2*, kriging method with its different empirical models demonstrate optimized surfaces with least RMSE values. However, optimization of any method is completely depended on

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39733988

dataset in hand and may vary for a different set of sampling points. Final maps of each water quality parameters have been classified in five classes according to the drinking water quality standards provided by WHO. A brief analysis of measured and interpolated concentration levels of each groundwater quality parameters has been discussed below.

Calcium

Calcium is an essential component to regulate heart rhythms and control over blood clotting in human (WHO, 2009). In present scenario, the measured values of calcium ranges from 05 mg/L to 87.20 mg/L in the study area. Whereas the least values of less than 34 mg/L have been observed at garden town near Punjab University. A comparison of different spatial interpolation methods for Ca suggests that simple kriging is producing the most reliable prediction surface with RMSE of 14.065. Spatial distribution of Ca shows that most of the study area lies within permissible and safe limits of the element's concentration in drinking water, i.e. approximately less than 34 mg/L. However, a continuous central spot of values ranges from 45 to 57 mg/L can be observed near the Anarkali region as shown in *Figure 3*. This central spot has also been highlighted as a high concentration zone by previous studies done by Mahmood et al. (2016) and Mahmood and Tariq (2017). Maximum concentration values were measured at Napier road near Anarkali. A continuous spatial trend of estimated values ranges from 34 mg/L to 45 mg/L, is emerging from northeastern edge of study area. A set of past studies refers to this trend as an influence of landfill site existing in the region (Butt and Ghaffar, 2012; Mahmood et al., 2016). Presence of municipal solid waste near water body increases the rate of leachate production and percolation through underlying sediments that ultimately contaminates groundwater (Mahmood et al., 2013; Mahmood et al., 2017). Present discussions manifest that this trend may lead towards subsurface lateral flow of contamination from eastern side of the aquifer.

Chlorine

Natural water contains an excess amount of chloride ions due to its high polarizable nature. Highly chlorinated water causes different infections like asthma and other dermatitis infections and may increase the risk of bladder cancer (NHMRC, 2011). Comparison of deterministic and stochastic spatial interpolation methods suggests that ordinary kriging provides precise spatial distribution of Cl than radial basis function with RMSE value equals to 27.609. In present case, minimum values of Cl concentration level have been found at the upper region of Baghbanpura. Whereas high concentration of Cl (approximately 260 mg/L) found at Mozang nearer to Anarkali region. In general increase in concentrations of Cl in the region is due to increase of mineral content (Nas, 2009). Long distance lateral flow of groundwater towards the deepest aquifer near Anarkali allows subsurface materials to get mixed in the water and causes groundwater contamination (Mahmood et al., 2016). In general, spatial distribution of Cl shows that the concentration of Cl in the groundwater lies in acceptable range. A regular expansion towards north and south eastern domains of study area can be assessed through geographical representation of Cl as given in *Figure 3.*

Bicarbonates

Bicarbonates are water soluble in form of calcium and magnesium constituents, but their excessive quantities make water hard. Definite permissible guideline values have not been specified by WHO for bicarbonates but their concentrations more than 500 mg/l is usually

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39733988

not appreciated (Mohsin et al., 2013). In the study area the concentration level of bicarbonates has been observed from 94 mg/L to the maximum value 506 mg/L in 2016. The comparison of deterministic and stochastic spatial interpolation methods for HCO_3 suggests that ordinary kriging produces the more precise prediction surface with RMSE of 64.779. An overriding trend has been observed in the spatial distribution of bicarbonates over the study area. Spatial analysis of HCO_3 indicates a peculiar profile of descending order of concentration levels from south eastern region (Gulberg) to north western region (Shahdara). Maximum concentration levels are estimated at Gulberg that lies in the south eastern region of Lahore. However, least quality measures have been evaluated near the areas of river Ravi and Shahdara region. In current scenario, unusual spatial behaviour of bicarbonates tends towards high rate of underground weathering of rocks. As geological conditions explain that study area is composed of bicarbonates which dissolves in moving water. Due to longer path distance, ratio of dissolving sub-surface materials becomes greater causing alkalinity rise in the source.

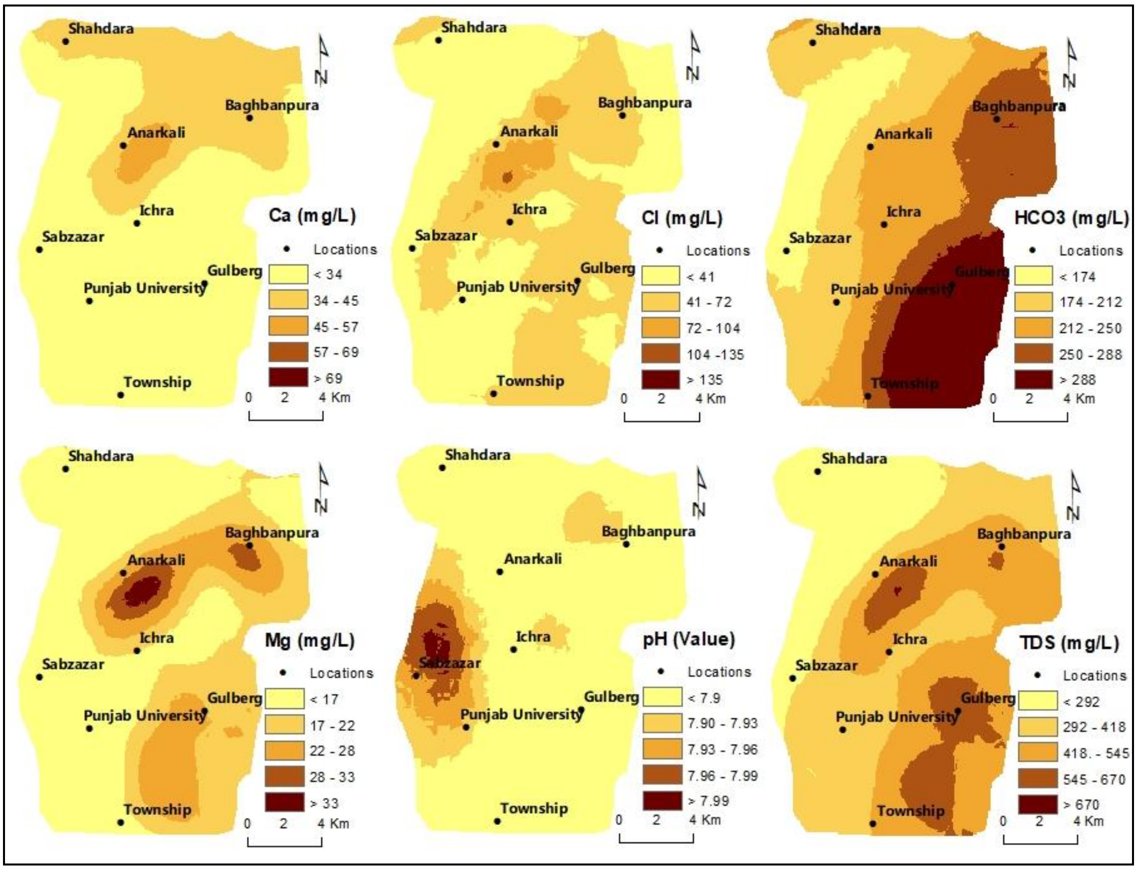

Figure 3. *Spatial analysis of considered water quality parameters*

Magnesium

Magnesium is most common component of natural water and usually exists in form of Mg^+ ion (WHO, 2009). Drinking water quality standards of Pakistan has specified approximate concentration of Mg in drinking water that should not exceeds from 50 mg/L. Quantitative measures show that the concentration of Mg over the study areas varies from 5.60 mg/L and 65.3 mg/L in the year of 2016. A comparison of different

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39733988

spatial interpolation methods for Mg suggests that ordinary kriging is producing the most reliable prediction surface with RMSE of 9.545. Least values were measured at Garhi Shahu, which located in the south of Baghbanpura, Lahore. However, spatial distribution of classified concentration data values shows that minimal values of Mg exist over the region near Shahdara. Again, a prominent central spot has been observed at Anarkali region with high concentration of Mg, approximately up to 65.30 mg/L. Mahmood et al. (2016) identified the same trend for Ca and Mg in temporal analysis of groundwater quality from 2010 to 2013. Moreover, Mahmood et al. (2016) and Mahmood and Tariq (2017) have also reported this spot near Anarkali region as a permanent source of contamination. The same lowering of water table at centre of the study area is responsible for high concentrations of Mg, Ca and HCO_3 (Mahmood and Asim, 2017; Mahmood et al., 2016). In case of Mg, a trend can be seen in the northeastern region near Baghbanpura, which illustrates a persistent range of concentration values from 22 to 28 mg/L. Local influencing parameters like least permeable surfaces causes weathering of rocks. Usually untreated waste from different industries is disposed of into the river without any purification, which consequently raises magnesium concentration in running river water. As most of the studies conclude that the presence of both Ca and Mg cause temporary and permanent hardness in water.

pH

It is one of physical parameter which controls the presence of hydrogen ion in water. Low values of pH make water soft and high values tends to make water hard (WHO, 2007). An evident trend of pH values exists in the given dataset that ranges from 7.80 to 8.30 respectively. Comparison of different spatial interpolators shows that simple kriging provides more reliable surface for pH with RMSE of 0.098. Classification of spatial data reveals that pH concentration values below 7.9 have covered a large portion of the study area. Whereas, a continuous convergence of high concentrations of pH, ranges from 7.99 to 8.30, towards the western centre of the study area, near Sabzazar has been observed, reflecting alkaline nature of groundwater as shown in *Figure 3*. This emerging spot is geographically located at the region where major drains (Babu Sabu and Gulshan-e-Ravi) of the city fall into the river Ravi. It has been asserted by Hamid et al. (2013) that inclusion of drain water into the river Ravi without any treatment is ultimately rising alkaline properties of river water. Baqar et al. (2014) has also investigated the impact of falling drains into river Ravi by using geospatial technologies with the conclusion that mean concentrations of total suspended solids were greater at the region closer Gulshan-e-Ravi outfall and region closer to it (Baqar et al., 2014). However, this impact is still at the closer regions of river Ravi. But in future it may expand towards the eastern areas of the study area. A range of 7.93 to 7.96 of pH levels have been observed near the regions of Baghbanpura and Ichra, reflecting presence of some temporary alkaline source across this region. Overall, pH values lie within their permissible limits suggested by WHO and PSQCA in the study area. But it should be noted that measured pH values range just below from the standard authorized values.

Total dissolved solids (TDS)

Natural water consists of different ionic constitutes in their specific amounts to made it saline (Atekwana et al., 2004). In Pakistan, the surface area is highly permissible, therefore concentrations of total dissolve solids in water is comparatively high.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39733988

Although all the samples have been found within the safe limit suggested by WHO for TDS but a considerable range of 173.2 mg/L to 988.40 mg/L exists in drinking water of the study area. A comparison of different spatial interpolation methods for TDS suggests that universal kriging is producing the most reliable prediction surface with RMSE of 14.065. A notable trend in variation of classified data values, especially in the southern part of the residential area. At Ravi road and Shahdara concentrations of TDS have been estimated below 292 mg/L. Whereas maximum concentration values have been found near Anarkali and Gulberg region, as can be identified through *Figure 3*. Total dissolve solids (TDS) is an important quality parameter which shows the measure of existing combinations of solid particles in accordance to lithology of examined groundwater samples. An emerging overriding trend in the current dataset of TDS shows a continuous spatial variation over the study area. It approves that Anarkali region and Gulberg have notable concentration levels of TDS. The prominent spatial affinity between Anarkali region and Baghbanpura also elevates a trend of contamination flow from north eastern side to south western edge. Gulberg has become the central commercial zone of residential area of Lahore due to the recent growth of modern infrastructure. Over extraction of groundwater has generated a depression zone in middle of city due to which degradation of water table is arising with the passage of time (Akhter and Tang, 2013; Kanwal et al., 2015; Mahmood et al., 2013). Usually, TDS rises in groundwater due to urban and rural runoff, desolation of natural sources, disposal of sewage and industrial waste into the rivers (Akhter et al., 2014).

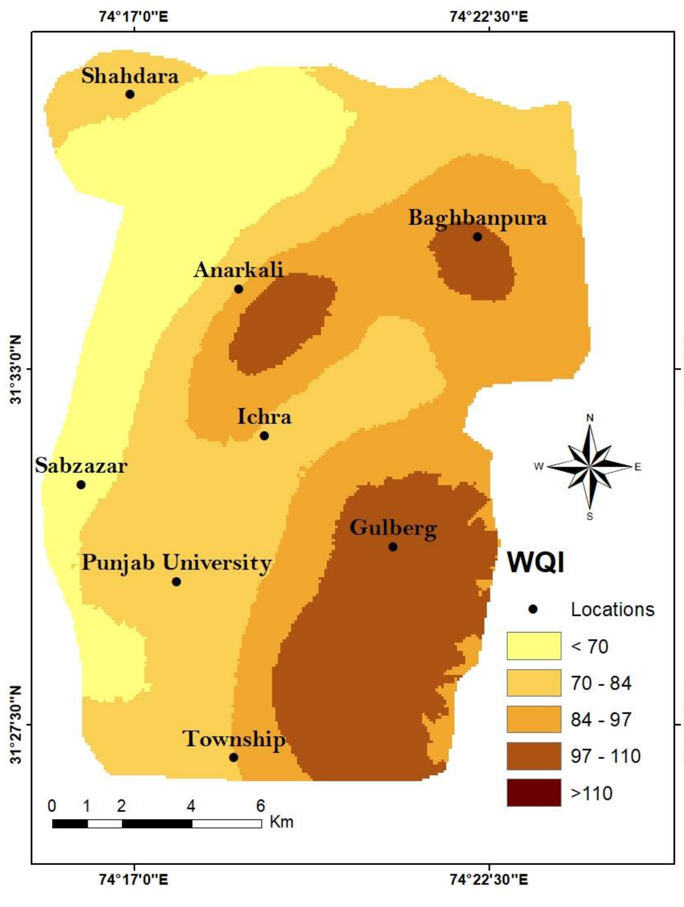

Figure 4. *Spatial distribution of water quality index, classified as per WHO standards*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39733988

Water quality index (WQI)

Thematic maps of selected physical (TDS, pH) and chemical (Mg, Ca, Cl, HCO_3) water quality parameters interpret spatial variability of their concentration levels at study area. Whereas, index map of groundwater quality shows current status of groundwater quality at any region, as given in *Figure 4*. Results of resampled interpolated rasters of current study have been classified in five equal number of classes. All the classes have been categorized as < 70 (good), 70–84 (moderately good), 84–97 (marginally good), 97–110 (moderate) and >110 as highly poor water quality. In present scenario, almost whole residential area lies with in the categories of marginally good, moderate and poor water quality. Spatial analysis of WQI map indicates that Anakali region is prominent and permanent source of highly poor groundwater quality. Since previous studies have also revealed the consistent growth of concentrated zone of contamination across this region. Low recharge and high abstraction rates are exerting high pressure on the aquifer, particularly near Anakali region. High concentration level of groundwater quality parameters can be caused by ground lithology that is composed of carbonates of magnesium and calcium. Upper northeastern region of study area at Baghbanpura shows an order of "moderate" water quality. A couple of studies show that the seepage of contaminants from Mehmood Booti landfill site are effectively deteriorating the groundwater quality of Lahore (Butt and Ghaffar, 2012; Mahmood et al., 2014). Leachate transfers through porous soil layer and flows towards local aquifer with the aid of groundwater. Mahmood et al. (2016) infers that lowering of water table tends water to take relatively longer path to travel. As longer will be the path, greater will be possibility of dissolution of minerals (soluble ions) in to water, which ultimately rise the alkaline characteristics in groundwater. Areas exits in the northern edge (Shahdara, Sabzazar and Punjab University) shows almost good and moderately good water quality due to the availability of high recharge zone, but comparatively low consumption rate. In south eastern edge, high proportions of contamination have been estimated which evaluate the expansion rate of urban area. Rapidly growing population and modern ways of civilization are degenerating the availability of permeable surfaces as given above.

Conclusion

This study illustrates current status of groundwater quality in the second largest metropolitan city of Pakistan, named Lahore. GIS based spatial analysis has been found very useful and effective in studying potential regions of groundwater contamination as well as their spatial distribution over study area. Along with having an insight analysis of the spatial distribution of considered water quality parameters, i.e. calcium, magnesium, chlorine, pH, bicarbonates and TDS, the WQI, as a sole representative of quality status, has been found very helpful in segregating water quality zones. Leaching through landfill sites (particularly Mahmood Booti) and disposal of industrial and municipal waste into river Ravi are major contributors of groundwater pollution in the area. WQI of 2016 along with previous similar studies of the region concludes that Anarkali region has become the permanent source of high contamination rate that is expanding towards the north eastern direction of study area. A directional impact of high concentrations from upper Baghbanpura region towards Anarkali region has been observed through TDS and WQI maps. High proportions of contaminants in groundwater under Anarkali could be due to dilution of calcium, magnesium and their

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39733988

carbonates that are abundant in underlying lithology. Deepest level of groundwater at Anarkali caused recharge water from outskirts of the area to flow towards it under gravity. As longer will be the travelling path for lateral flow of recharged water, more chances will be of soil-water interaction. Rapidly growing population and transforming of infrastructure in Lahore have lessened the availability of pervious land sites. Due to which south eastern region of study area explicitly shows high contamination ratios. Although, these factors generate temporary plumes in any concerned area but if unplanned infrastructure keep continues to develop, it will defiantly put long term effects on availability of safe groundwater. In general, groundwater quality of Lahore residential area is being deteriorating due to poor waste management system, involuntary developments in urban infrastructure, use of heavy pesticides in agricultural land surrounding the residential area and high-water extraction rates. Use of GIS based analysis in the study has highlighted potential regions of high concentrations of pollutants in the year of 2016, providing continuity of previous work done in this regard. Such a mapping of groundwater quality zones and their segregation can play a primary role in the decision-making process of local authorities for the sustainable solutions of drinking water in the region for which the only available source is the local groundwater. Therefore, this study concludes that an effective system for groundwater monitoring needs to be introduced by the local administrators and government authorities. Such issues are common in all over the developing world where lack of financial resources always hinder scientific knowledge-based solutions for sustainable development. Therefore, this study also concludes that the use of existing wells for sampling along with proper GIS can be an economical alternate in this regard.

(Received 11th Nov 2018; accepted 11th Jan 2019)

Abstract. The present factorial experiment was conducted based on completely randomized design (CRD) with three replications in order to determine the optimum time and concentration for *Catharanthus roseus* seed priming with salicylic acid. Treatments included five different levels of salicylic acid (0; 0.01; 0.1; 0.5 and 1 mM) as well as five different periods of time (0, 6, 12, 24, and 48 hours). Results indicated that the effects of concentration and time of priming were significant on all the studied traits. In addition, the effect of the interaction between concentration and priming time was significant on the mean time of germination, seedling length vigor index, chlorophyll content, and the activity of antioxidant enzymes. Further, the germination percentage increased by 24.1% and 22.3% in the treatment of 1 mM, and 48 hours, respectively, compared to the control. The highest germination speed was in 1 mM and 48-hour treatment, which had a 40% higher increase than the control. The interaction effect on the antioxidant activity indicated seed priming with 1 mM concentration in 24 hours, leading to 84% and 62.6% increment in the catalase (CAT) and peroxidase (POD) activities, respectively, compared to the control. Furthermore, 0.1 mM concentration in 24 hours led to 61.2% and 66.2% increment in chlorophyll a and total chlorophyll, respectively.
Keywords: *catalase and peroxidase enzymes; photosynthetic parameters; phytohormone; seed priming*

Introduction

Catharanthus is regarded as a medicinal ornamental plant. *Catharanthus roseus* is a perennial plant, semi-shrub or herbaceous and is related to the Apocynaceae family (Nejat et al., 2015). This plant is indigenous to Madagascar but is now widely distributed, and cultivated in China, India, Indonesia, Australia, North, and South America (Yang et al., 2011) (Verma et al., 2012). *Catharanthus* is known for its anti-cancer, anti-hypertensive, anti-diabetes, and antimicrobial properties. This plant contains about 130 bioactive Terpenoid Indole Alkaloids (TIAs), among which vinblastine and vincristine are regarded as the most important (Nejat et al., 2015). *Catharanthus* has a fairly long vegetative period due to its slow initial growth. It takes 180-200 days from cultivation to the maturity of the seed. (Omidbegi, 2006). The long growth period of the plant is considered as one of the limitations of its cultivation on a larger scale (Muthulakshmi and Pandiyarajan, 2013).

The process of germination of non-dormant seeds occurs in three phases including (I) imbibition, (II) lag phase, (III) the protrusion of the radicle through the testa (Bewley et al., 2013; Rosental et al., 2014). The duration of the third phase has great importance because the germination is completed and the embryo begins to develop concurrently during this period. Rapid seed germination and stand establishment are critical factors

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39894005

affecting crop production. After expanding our understanding of the processes involved in the germination methods used for changing the aforementioned factors, development of agriculturally applicable seeds began. The most frequently used method is known as "seed priming" (Bewley et al., 2013; Paparella et al., 2015). Seed priming is a controlled hydration technique which initiates the pre-germination metabolisms without actual germination (Hussain et al., 2015). In addition, it is considered as one of the most effective, pragmatic and short-term approaches to improve seed vigor (Batool et al., 2015), rate and percentage of seed germination (Santini and Martorell, 2013) synchronization of germination, crop establishment (Pouramir-Dashtmian et al., 2014; Paparella et al., 2015) and the seedling growth of many crops (Farooq et al., 2009) Further, it is associated with a wide range of metabolic and physiological improvements (Shehab et al., 2010) and cellular and molecular changes (Siri et al., 2013).

When the primed seeds are sown, the imbibition phase and lag phase of water absorption are shortened (Khan et al., 2009) to reduce growth time, in order to increase the productivity of agricultural land in such a way that the reported Indian farmers could harvest three products in one year (Harris et al., 2001).

The induced priming increase in the rate of seed germination was associated with the initiation of germination related processes, repair processes and increased levels of various free radical scavenging enzymes such as superoxide dismutase (SOD), CAT and POD (Vazirimehr et al., 2014). Furthermore, the positive effects of priming on seed germination in various species of plants are related to inducing biochemical mechanisms, repairing, and rebuilding cells (Di Girolamo and Barbanti, 2012) by activating the synthesis of many proteins and enzymes involved in cell metabolism (Varier et al., 2010). Salicylic acid (SA) is a phenolic compound, known as "phytohormone", which contributes to the regulation of the growth and development processes, especially seed germination, photosynthesis, respiration, flowering, and senescence (Rivas-San Vicente and Plasencia, 2011). Some studies indicated that priming strategies can enhance the activities of free radical scavenging enzymes such as CAT, POD, and SOD (Sharma et al., 2014). These enzymes reduce lipid peroxidation at the germination stage and increase the percentage and rate of germination (Baalbaki et al., 1999).

Recently, it has been reported that there are some encoding antioxidant enzymes such as CAT, SOD, and Ascorbate peroxidase (APX) preventing the overproduction of reactive oxygen species (ROS) among genes stimulated by SA (El-Esawi et al., 2017), Moreover, SA may act directly as an antioxidant, scavenging ROS (Popova et al., 2009). The utility of SA in inducing the plant defense mechanisms depends on its concentration and the method of its application (Huang et al., 2016). Hussein (2015) evaluated the effect of seed priming with SA (100 mg/L) for four hours at 25 °C on the germination of okra (*Abelmoschus esculentus* L.). The result indicated that seed priming with SA can induce the highest germination percentage and seed vigor index. Based on the results of previous studies, the effect of the interaction between time and different priming concentrations with gibberellic acid and SA was significant on germination rate (Azarniya et al., 2016).

There are many factors related to the effects of seed priming, which depend on the concentrations of priming solutions, the time and the temperature during priming (Khan, 1992). Thus, the optimization of the priming technique is important to achieve the best results (Maiti and Pramanik, 2013). Regarding the long growth period of this plant, the small size of the seed and poor establishment in the field with semi-heavy and heavy textured soils, the present study aimed to evaluate the effect of seed priming with SA in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39894005

different concentrations and periods of time on improving *Catharanthus roseus* seed germination indexes.

Materials and methods

Preparation, Priming of seeds and germination process

The present study was conducted in order to assess the priming effects of time and various concentrations of SA on germination parameters, *Catharanthus* seed (*Photo 1*), with a factorial experiment based on completely randomized design (CRD) with three replications at the Laboratory of Seed Science and Technology of Shahed University in Tehran. Treatments included five different concentrations of SA (0, 0.01, 0.1, 0.5 and 1 mM) and five periods of time (0, 6, 12, 24 and 48 hours). The seeds were purchased from the company named Green Farm, and were surface-sterilized using 70% ethanol for 30 seconds, washed with distilled water three times, transferred to a solution of 50% Clorox (containing 5.25% NaOCl) for 15 min, and were finally rinsed three times with sterile distilled water (Taha et al., 2009). The seeds were placed in SA solutions with different concentrations, and for different times (6, 12, 24, and 48 hours) at 25 °C in darkness (Pandey, 2017). After removing the priming solution with distilled water, seeds were re-dried to the initial moisture content (Ratikanta, 2011) at 25 ºC for 24 hours in the laboratory. In every sterilized Petri dish (90 mm diameter), 50 seeds were sowed with two-layer Whatman filter papers moistened with 5 ml appropriate solutions. Thus, untreated seeds were used as control. In order to prevent water evaporation, the Petri dishes were closed with parafilm and placed in a germinator at 25 ± 1 °C (Prabhu and Rajeswari, 2017) with a photoperiod of 12/12 h day/night light (Senbagalakshmi et al., 2017). The germinated seeds with a root length longer than 2mm were counted (Liopa-Tsakalidi et al., 2012).

Photo 1. *Catharanthus seed germination in a germinator at the laboratory*

Each day germinated seeds that had a root length over 2 mm were counted (Kaya et al., 2006). At the end of the experiment (10 days) (Barkat et al., 2017) five samples were randomly selected from each petri dish (Huang and Redmann, 1995) and seedling length, plumule length, radicle length, seedling dry weight (Panwar and Bhardwaj, 2005) (Liopa-Tsakalidi et al., 2012), mean germination time (Ranal and Santana, 2006), mean daily germination (Hunter et al., 1984), seedling length vigor index and seedling weight vigor

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39894005

index (Hu et al., 2005) were calculated according to the following equations (*Eq.1-5*) (Hunter et al., 1984):

$$Germination\ percentage(GP) = (N \times 100) / M \quad \text{(Eq.1)}$$

$$Mean\ germination\ time(MGT) = \sum(Ni\ Di) / \sum N \quad \text{(Eq.2)}$$

$$Mean\ daily\ germination(MDG) = GP / T \quad \text{(Eq.3)}$$

$$Seedling\ length\ vigor\ index = Germination\ percentage \times Seedling\ length \quad \text{(Eq.4)}$$

$$Seedlingweightvigor\ index = Germination\ percentage \times Seedling\ dry\ weight \quad \text{(Eq.5)}$$

N: the sum of germinated seeds at the end of the experiment, M: the total number of planted seeds, Di: The time from the start of the experiment to the i^{th} observation, Ni: the number of germinated seeds at time Di, ∑N: Total germinated seeds at the end of experiment, T: Period of germination.

Antioxidant enzymes assay

An enzyme extract was prepared by the method of Mukherjee and Choudhuri (1983). A 0.5 gr leaf sample was homogenized in 10 ml of 100 mM phosphate buffer (KH_2PO_4/K_2HPO_4) pH 7.0, containing 1% (w/v) insoluble polyvinylpyrrolidone (PVP). The homogenate was centrifuged at x 15,000 *g* for 10 min at 4 °C, and the resulting supernatant was collected and stored at 4 °C for CAT, POD assays.

Peroxidase assay

The POD activity was assayed following the method of Gueta-Dahan et al., (1997). The reaction mixture contained, 50 mM potassium phosphate buffer (pH 7.0), 1% guaiacol, 1% H_2O_2, and 0.3 ml enzyme extract. The change of absorption due to guaiacol oxidation were recorded at 470 nm for 3 min per 15 s with spectrophotometer**.** In the next procedure, the enzyme activity was calculated using the extinction coefficient of tetra-guaiacol (26.60 mM^{-1} cm^{-1} extinction coefficient).

Catalase assay

Catalase activity was determined using the method of Chaoui et al., (1997). The reaction mixture consisted of 125 mM potassium phosphate buffer (pH 7.0) and 100 mM H_2O_2, and 25 µL of the enzyme extract in a total volume of 3 mL. The absorbance at 240 nm for 1 min at 25 °C was recorded spectrophotometrically**.** The enzyme activity was expressed in ΔOD g^{-1} FW min^{-1}.

Chlorophylls and carotenoid content

0.5 g of fresh leaf tissues were ground in 5 ml of 80% (v/v) acetone using mortar and pestle. The suspension was centrifuged at 6,000 g for 10 min at 4°C. Absorbance of the solution was then measured at 645 and 663 for chlorophylls and at 470 for carotenoids.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39894005

The chlorophyll and carotenoid contents were determined using the formula given by Arnon (1967), and the following formulas (*Eq.6-9*):

$$Chlorophyll\ a\ (mg / gr\ fresh\ weight) = [19.3\ (A_{663}) - 0.86\ (A_{645})] v / 100w \quad (Eq.6)$$

$$Chlorophyll\ b\ (mg / gr\ fresh\ weight) = [19.3\ (A_{645}) - 3.6\ (A_{663})] v / 100w \quad (Eq.7)$$

$$Total\ chlorophyll\ (mg / gr\ fresh\ weight) = [20.8\ (A_{645}) + 8.02\ (A_{663})]\ v / 100w \quad (Eq.8)$$

$$Carotenoids = [(100\ (A_{470}) - 3.27\ (mgchl\ a) - 104\ (mgchl\ b)] / 227 \quad (Eq.9)$$

A= absorption of light at wavelengths of 663, 645 and 470 nm
V= the volume upper solution of centrifuges
W = weight of the sample in grams

Statistical analysis

After normalization test (Kolmogorov-Smirnov and ShapiroWilk test)**,** the data were analyzed with SAS 9.1 (SAS Institute, Cary, NC, USA). Means were compared with Duncan's multiple range tests in SAS at 5% statistical probability levels. The graphs were drawn with MS-Excel.

Results

Germination percentage

According to the analysis of variance (*Table 1*), the effect of duration and concentration of seed priming on germination percentage was significant at P≤0.01. However, the interaction between duration and concentration of seed priming failed to have a significant impact on germination percentage (*Table 1*). The comparison of the mean of results indicated that by increasing the duration of priming, germination percentage also becomes higher (*Table 3*). In addition, the highest germination percentage (83.2%) was shown in the 24 hour treatment, while the lowest germination percentage (64.6%) in control (*Table 3*). Further, the highest germination percentage was detected in 1 mM SA indicating a 24.1% increase, compared to the control, which allocated the lowest amount (control= nonprimed) (*Table 3*).

Mean germination time and mean of daily germination

Based on the results of ANOVA (*Table 1*), priming duration and concentration had a significant impact on mean germination time and mean of daily germination. Furthermore, the interaction effect between treatments has a significant influence on mean germination time at p≤0.05 (*Table 1*). The results of mean comparison showed that the highest mean germination time (4.5 days) was in the case of the control while treatment 0.01 mM SA+ 48 h hours with mean germination 2.7 days had the fastest germination (*Fig. 1*). The mean seed germination time is considered a very important trait in planting establishment and exploiting environmental conditions.

In each column, means sharing at least one letter, are not significantly different according to Duncan's multiple range test (p≤0.05)
*SA: Salicylic acid

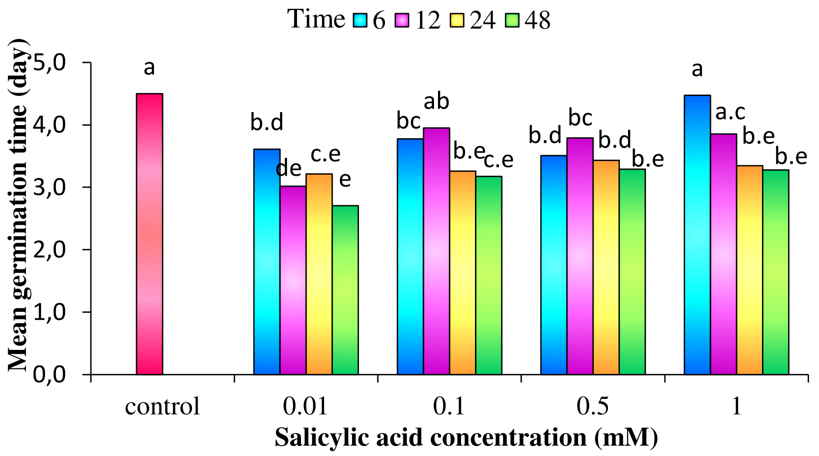

Figure 1. *Mean comparison of the effect of time and concentration on mean germination time*

The effect of different periods of time indicated that the highest and lowest required time for mean daily germination observed in the control and 24 hour long priming, were 9.2 and 7.1 days, respectively (*Table 3*). Furthermore, the speed of daily germination in the case of 24 hour treatment was 22.8% higher, compared to that of the control, although it was observed in the same statistical group with 12 and 48 hour treatments (*Table 3*). Results comparing the mean of the effect of different concentrations of SA showed, that increasing the concentration lead to a raise in mean daily germination and maximum mean daily germination achieved in 1 mM concentration SA which it did not has a meaningful difference with 0.5 mM concentration SA (*Table 3*).

DOI: http://dx.doi.org/10.15666/aeer/1702_39894005

Seedling length

The results indicated that the main effects of priming time and concentration of SA played a significant effect on seedling length (*Table 1*). The highest and shortest seedling lengths were observed in 6 hour and 12 hour treatments, respectively (*Table 3*). The results showed that the maximum seedling length (4.57 cm) occurred in the 0.5 mM SA treatment and the lowest seedling length (3.9 cm) was found in the 0.01 mM SA treatment (*Table 3*).

Plumule length and radicle length

The results of ANOVA revealed that priming at different times could significantly influence the plumule and radicle length at P ≤0.05, but the concentrations of SA had no significant effect on these characteristics (*Table 1*). In addition, 6 hour seed priming had the highest plumule length and a significant increase occurred in the control treatment (*Table 3*). The shortest radicle length (2cm) occurred in the12 hour treatment priming, and had a significant difference compared to other treatments (*Table 3*).

Seedling weight and length vigor index

The effect of concentration and time on seedling weight and length vigor index was significant at the significance level of p≤0.01 (*Table 1*). In addition, the interaction between concentration × time on the seedling length vigor index was also significant (*Table 1*). The highest seedling length vigor index was observed during 1 mM SA + 24 hour priming (*Fig. 2*). Among the main effects of concentration and time priming, 24 hour treatment and 1 mM SA concentration revealed the highest seedling weight vigor index (*Table 3*).

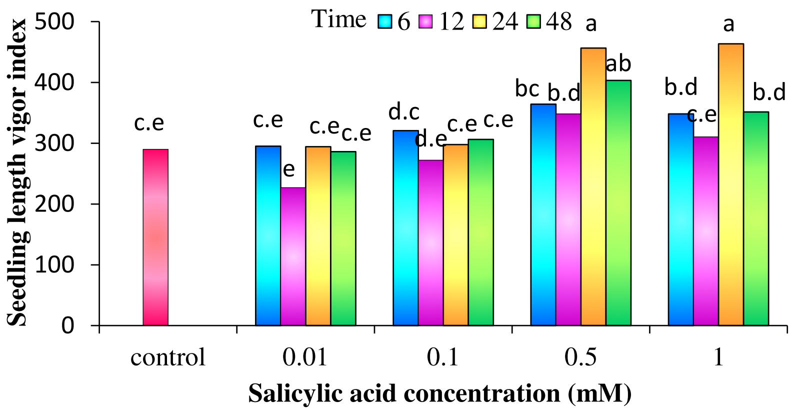

Figure 2. *Mean comparison of the effect of time and concentration on seedling length vigor index*

Chlorophyll content and carotenoids

According to the results, the effects of priming time and concentration, as well as interaction of concentration × time on chlorophyll a, b, total chlorophyll, and carotenoids were significant (p≤0.01) (*Table 2*). The highest chlorophyll a, b and total chlorophyll contents were related to the concentration of 0.1 mM SA, (*Fig. 3, 4, 5*) and higher carotenoid content was related to the treatment of 1 mM SA (*Fig. 6*). The results of this

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39894005

experiment showed that among the different levels of priming, 24 hours of treatment and control had the highest and lowest levels of chlorophyll a, total and carotenoids, respectively (*Figs. 3, 5, 6*).

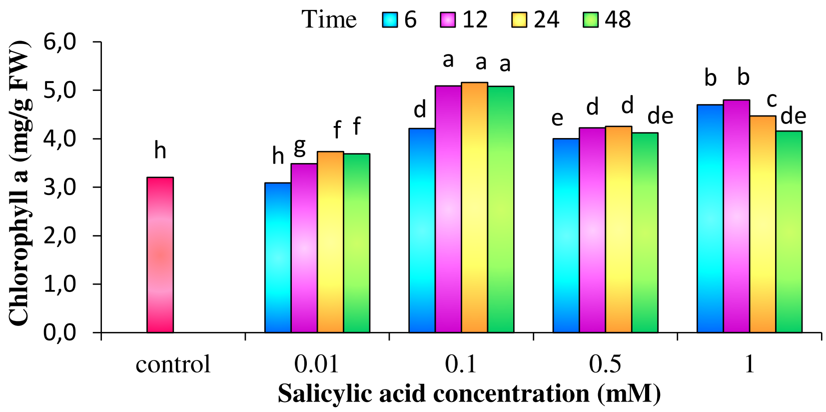

Figure 3. *Mean comparison of the effect of time and concentration on chlorophyll a*

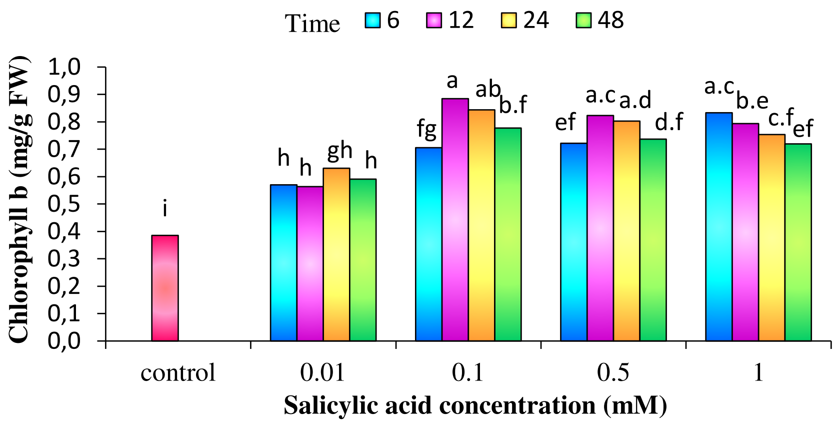

Figure 4. *Mean comparison of the effect of time and concentration on chlorophyll b*

DOI: http://dx.doi.org/10.15666/aeer/1702_39894005

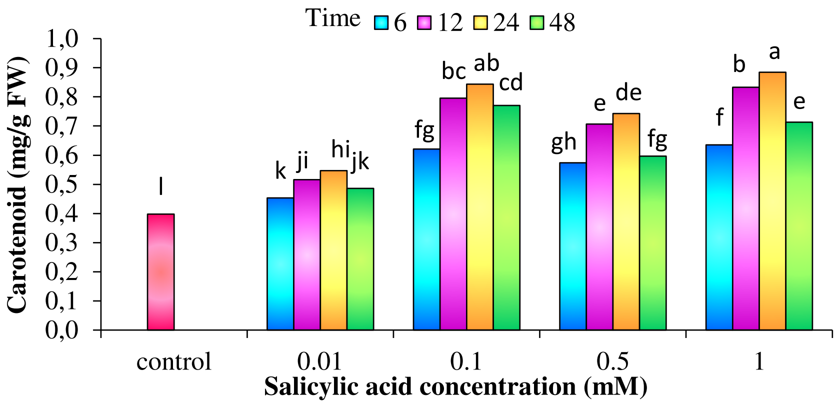

***Figure 6**. Mean comparison of the effect of time and concentration on carotenoid*

Furthermore, the highest and lowest levels of chlorophyll b were observed in the of 24 hour and control treatments (*Fig. 4*). In addition, interaction between concentration × time of priming indicated the highest concentration of chlorophyll a and total was at 0.1 mM SA + 24 hour seed priming (*Figs. 3, 5*) and the highest content of chlorophyll b and carotenoids was at 0.1 mM SA + 12 hour and 1 mM SA+ 48 hours of priming, respectively (*Figs. 4, 6*).

Antioxidant enzymes activities

The effects of time, concentration levels of priming, and the interaction between time × concentration on the activity of CAT and POD enzymes were significant at least at the significance level of 1% (*Table 2*). The highest activity of CAT enzyme was related to 1 mM SA treatment, which indicated a 84% higher activity than that of the control. Further, no significant difference was observed between the SA concentration of 0.1 and 1 mM (*Fig. 7*). Among the different priming times, 24-hour treatment and control had the highest and lowest activity of antioxidant enzymes, respectively. Furthermore, the interaction effects of 1 mM SA + 24 hours had the most significant effect on the activity of CAT enzyme (*Fig. 7*).

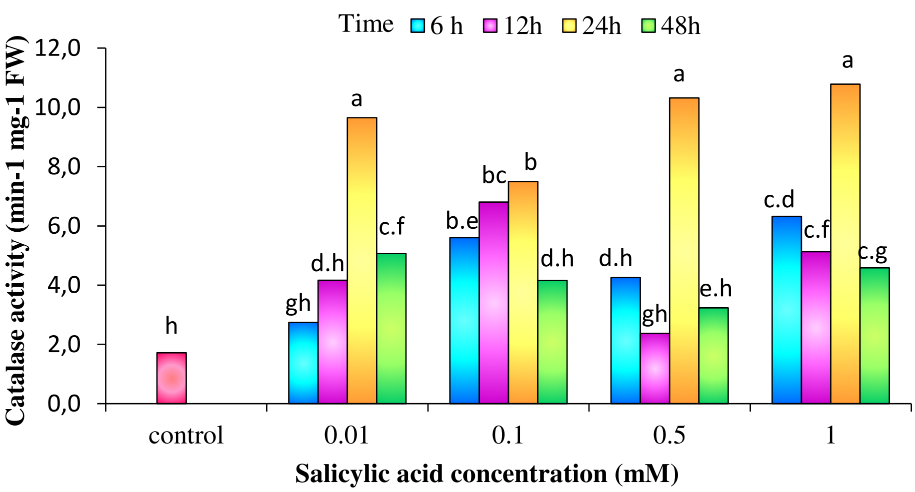

***Figure 7**. Mean comparison of the effect of time and concentration on catalase activity*

DOI: http://dx.doi.org/10.15666/aeer/1702_39894005

Based on ANOVA results, the highest POD enzyme activity was related to 1 mM SA concentration and 12 hours of treatment (*Fig. 8*). In addition, the means of the comparison of the interaction between SA concentrations × time indicated higher POD enzyme activity when the seeds primed with 1 mM SA + 24 hours (*Fig. 8*).

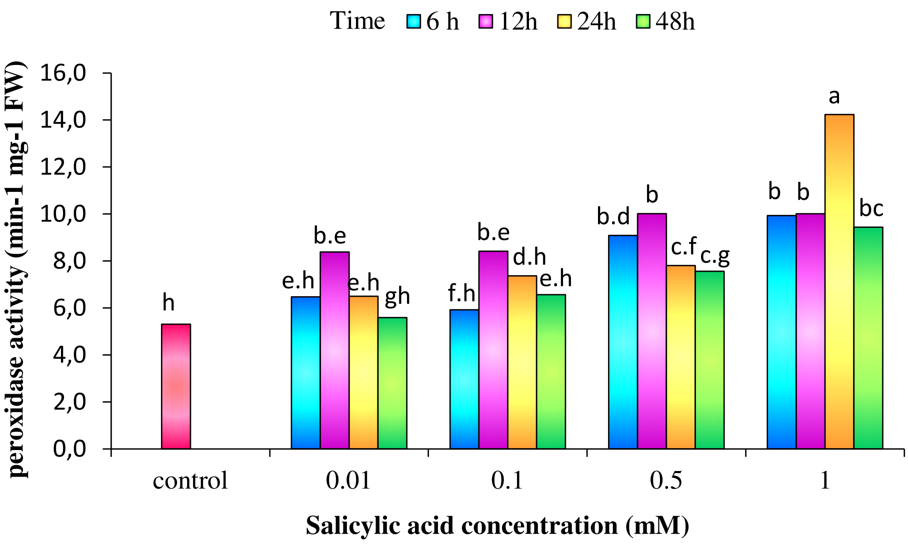

Figure 8. *Mean comparison of the effect of time and concentration on peroxidase activity*

Discussion

Several reports have been published demonstrating the role of SA in various physiological processes. Some of these reports demonstrated the protective or damaging effect of exogenous SA (Szalai et al., 2011). Priming pepper seeds in acetyl-SA improved the final germination percentage, and led to higher shoot and root dry weights (Korkmaz, 2005). However, it should also be noted that a dramatic inhibition of the germination process was reported above the concentration of 1 mM in maize (Guan and Scandalios, 1995).

Results indicated that by increasing the SA concentration germination percentage also becomes higher (*Table. 3*). Gorzi et al. (2017) reported that the seed priming with SA improved the germination parameters and seedling growth of stevia. Furthermore, SA may stimulate the seed germination via biosynthesis of gibberellic acid and induce thermogenesis (Shah, 2003). Previous studies reported that isocitrate lyase and malate synthase were found to be more abundant in seeds germinated in the presence of SA than in its absence. Isocitrate lyase and malate synthase are two key enzymes of the glyoxylate cycle, which play a crucial role in synthesizing carbohydrates from storage lipids during seed germination and seedling establishment (Eastmond and Graham, 2001).

Khoramdel et al. (2012) reported that an increase in SA concentration from 0.1 to 1 mM leads to an increase in germination percentage, and a reduction of the germination percentage occurred after increasing the concentration. It seems that different effects may be observed in different concentrations since SA is considered as a plant growth regulator. The time of contact with these substances is very important, along with the use of plant hormones. Thus, the amount or concentration of hormones should be lower in long time periods and it is better to consider the higher concentration of growth regulator

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39894005

substances in shorter periods of time. By increasing the duration of priming, hormones can better penetrate into seeds, leading to an increase in the activity of germination stimulating enzymes, as well as the percentage and speed of seed germination (Azarniya et al., 2016). Shahverdi et al. (2017) reported the highest germination percentage among the priming duration and different concentrations of boric acid were observed under 24 hours of priming. Application of 0.01 mM SA during a 48 hour priming showed the lowest mean seed germination time (*Fig 1*).

Reducing the mean germination time due to seed priming is related to an increase in the rate of cell division in primed seeds because the synthesis of RNA, DNA, and protein were completed in many physiological stages and the seed was placed at the threshold germination during seed priming (Foti et al., 2008; Brancalion et al., 2008). The results of the present study indicated that the 6 hour seed priming treatment had the highest seedling length and plumule (*Table. 3*). Compared to non-primed seeds, an important feature of primed seeds is that they quickly germinate and produce radicle and plumule in optimal conditions. Thus, the seedling length of primed seeds is considerably higher than that of non-primed seeds (Murungu et al., 2003). The maximum seedling length was assessed during the 0.5 mM SA treatment. The results of this study are in line with previous studies that indicated applying SA was more effective by soaking the seeds, and the best results were obtained using 0.5 mM SA solution (Baninasab, 2010). In addition, SA regulates elongation and cell division in collaboration with materials such as auxin. Furthermore, the exogenous application of SA causes cell division in the terminal meristem of the primary roots, which results in increasing longitudinal growth (Serraj and Sinclair, 2002).

Seedling length vigor index is derived from both multiplication germination percentage and seedling length. Therefore, every treatment increasing these two components leads to an increase in seed vigor. Thus, an increase in seed vigor using priming treatments can be related to increasing the activity of the enzymes involved in germination. Consequently, an increase in the consumption of seed reserves and length of seedling can be attributed to increased energy in primed seeds (Omid and Farzad, 2012). The results of our study indicated that 24 hours treatment and 1 mM, SA concentration resulted in the best seedling weight vigor index and seedling length vigor index (*Table. 3*).

Azarniya et al. (2016) reported that the effect of time and concentration of priming was significant on seed vigor and the most effective duration of priming was 12-hour priming. They also concluded that primed seeds have a more favorable germination vigor than non-primed seeds. Seed priming is considered as one of the strategies to improve the amount of chlorophyll a and b (Rehman and Ali, 2015). Furthermore, seed priming with SA has positively affected biochemical traits such as total chlorophyll (Singh et al., 2018).

Seed priming with the concentration of 0.1 mM SA indicated the highest chlorophyll a, b and total chlorophyll content (*Fig. 3.4.5*) and higher carotenoid content was related to higher a concentration of SA (1 mM) (*Fig. 6*). The results are consistent with the results of (Yanik et al., 2018), who reported that the total chlorophyll content increased under 10 μM SA. Higher concentration of SA resulted in decreasing total chlorophyll and increasing carotenoid contents. Moharekar et al. (2003) indicated that different concentrations of SA can activate the synthesis of carotenoids and xanthophylls while a total chlorophyll content reduction occurs in wheat. It seems that decreasing chlorophyll content due to the SA-induced excess leads to the accumulation of ROS and the inhibition of plant growth and development. (Ma et al., 2013). However, the results of other studies

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_39894005

indicated that the SA pretreatment leads to a significant increase in the chlorophyll and carotenoid content (Saidi et al., 2013), which is beneficial for improving photosynthesis (Zhang et al., 2015). Catalase is one of the most important antioxidant enzymes, which can be increased in plants using a seed priming technique (Fallah et al., 2018). The results of the present study indicated that treating seeds with 1 mM SA for 24 hours had the most significant effect on the activity of CAT and POD enzymes. Yang *et al* (2016) investigated that treating seeds with SA could enhance the defense mechanisms of *Helianthus annuus*, leading to an increase in germination indices by increasing the activity of antioxidant enzymes (Omid and Farzad, 2012).

Conclusion

The results indicated that the priming technique can improve the seed germination components of *Catharanthus roseus.* Furthermore, a significant difference was reported between different priming times. Additionally, seed priming time is regarded as one of the important factors in seed treatment and determining the appropriate priming time may prevent the negative effect of pretreatment on germination characteristics and seedling growth of primed seeds. In order to have a positive effect, the best time for pretreatment on improved germination and seedling growth indices should be determined for every plant. In the present study, the results indicated that an increase in the pre-treatment time results in improving most of the components related to germination. In this experiment, the most beneficial length of time was 24 hours for pre-treatment of *Catharanthus roseus* seeds. In addition, the best results were related to 0.5 and 1 mM SA concentrations. Therefore, determining the best concentration and time for seed priming is considered as a key factor to implement seed priming effects in the most beneficial way.

(Received 12th Nov 2018; accepted 14th Feb 2019)

Abstract. In this study, a wire kadayıf on a tray was fried at 175, 200 and 225 °C for 40, 50 and 60 min. The temperature levels affected hydroxymetylfurfural (HMF) content, color values (L, a, b), outward appearance, interior color, taste, texture, aftertaste and general acceptability values at significant levels ($p \leq 0.01$); as well as pH and aroma ($p \leq 0.05$). As the temperature increases the HMF content, color value a, outward appearance, interior color, taste, odor, aroma, texture, aftertaste and the general acceptability values have increased. Whereas the moisture, pH and L color values decreased. The frying time had an effect on moisture. The changes in the color brightness (L), red color (+a), and the yellow color (+b) values of the kadayıf were highly significant ($p \leq 0.01$); and the changeswere also significant ($p \leq 0.05$) on the HMF content, texture, aftertaste and general acceptability values. As the frying time increases HMF content, a color value, texture, aftertaste and the general acceptability values increased whereas the moisture, L and b color values decreased.
Keywords: *acrylamide, HMF, frying temperature, frying duration, tray kadayıf*

Introduction

Kadayıf is a delicious Turkish sweet pastry, consumed in different provinces of Turkey such as Mersin, Hatay, Erzurum, Diyarbakir, and Gaziantep. Tray kadayıf and creamy kadayıf can both be prepared with either whole hazelnut, walnut or pistachio (Anon, 2012). According to the “standard of tray kadayıf” (T.S-10344, 1992), it is a semi-processed product made by adding drinking water to sifted flour and baking it on a plate. However, tray kadayıf is offered in raw and fired varieties in markets. Flour for making Kadayıf should have the following properties: humidity 14.5% (max), protein 8-10% (F = 5.70), the essence of age 22% (max), water holding capacity 54% (max), stability 2 min (max), softening temperature 150 BU (max) and minimum value of the biscuits perchance show maximum level in kadayıf. In recent years, tray kadayıf has mostly been produced in small enterprises, but has also been manufactured in large quantities to a lower extent (Pekak, 2006).

Acrylamide was first prepared in 1893 by Moureu at 10 °C on a saturated solution of acrylic chloride in benzene, followed by adding dry ammonia and boiling for mean duration, then ammonium chloride was refluxed by filtrating, cooling, and precipitating acrylamide (Carpenter and Davis, 1957). Neurotoxic effects of acrylamide were detected in a laboratory with animal testing. In addition, genotoxic and carcinogenic effects of acrylamide have been identified in recent years, its presence in many processed foods has been a hazard to human health (Joint, 2005). Acrylamide as a chemical substance was synthesized in 1949, it is white, odorless, crystalline, solid and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40074017

soluble in water (255 g/L of water) (Thomas and Thomas, 2012), its melting and boiling point is 87.5 °C and 125 °C, respectively (Gölükçü and Tokgöz, 2005). It has no burn inducing or irritating properties, low acidity, and weak basic characters. It has a monomeric structure of two different functional groups; double bond and weak amid group as the electron, and these groups are joined through chemical reactions (Can, 2007). In food items, acrylamide has a simple structure which occurs as a result of reactions taking place among carbohydrates, proteins, amino acids, lipids, or other food components (Gölükçü and Tokgöz, 2005). It is usually formed during frying, baking, and roasting (Svensson et al., 2003). The content of acrylamide in the product can be identified by some factors, such as preparation methods, compositions, ambient temperature, and pH. Asparagine appears to be the primary amino acid involved in the production of acrylamide via the Millard reaction (LoPachin and Canady, 2004).

According to Zyzak et al. (2003), there is a linear relationship between free asparagine contents and forming of acrylamide in the product. Gölükçü and Tokgöz (2005) indicated that asparagine content of the product is the most important factor in the formation of acrylamide in cereals. The duration of heating initiates the Millard reaction, in which sugars (simple monosaccharides capable of carrying out reduction reactions) present in starchy foods are reduced with amino acids to produce acrylamide. Applying high temperature (more than 120 °C) caused a raise in the acrylamide contents above 1 mg/kg in food items with high contents of carbohydrates. Therefore, there is a relationship between acrylamide in the food and temperature. Controlling the temperature range can reduce the amount of acrylamide formation. Food which is prepared through boiling has a low content of this compound, thus it should be preferred to frying, baking, roasting, and grilling; using methods such as frying or roasting at elevated temperatures for a long duration should also be avoided (Gölükçü and Tokgöz, 2005).

Beside acrylamide, hydroxylmethylfurfural (HMF) is another harmful compound which occurs as a result of the Millard reaction in biscuits. HMF is formed from an aromatic alcohol, aromatic aldehyde, and furan ring, and as an intermediate product in the hydrolysis of hexose in an acidic medium or in the Millard reaction (Seyyed Cheraghi, 2014). The concentration of HMF varies significantly and in some food items it can even reach 1 g/Kg (Rada-Mendoza et al., 2004; Akkan et al., 2001). The formation and amount of HMF are affected by temperature and pH value, also the quality deterioration of a wide range of edibles is determined by Hydroxymethylfurfural (HMF) (Gökmen and Şenyuva, 2006). Beside the harmful compounds which are the result of Maillard reactions, antioxidant compounds are also formed (Yıldırım, 2010). Some researchers have stated that HMF has possibly genotoxic and mutagenic effects on human cells, possibly inducing liver and colon cancer (Svendsen et al., 2007; Monien et al., 2012; Zhang and An, 2017); so the objective of this study was to determine the effect of temperature and duration on acrylamide and hydroxymethylfurfural formation during the preparation of tray kadayıf.

Material

As the ingredients of tray kadayıf, butter and hazelnut were acquired in the markets (Erzurum, Turkey). The ratio of grout which has been used was 2:1 sugar mixed with water. After boiling, approximately (2.0 ml) lemon juice was added to prevent

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40074017

crystallization. The tray kadayıf had the following values: pH = 6.43, humidity = 20.53%, L (96.19), +a (0.53) and +b (16.89).

Method

Processing of tray kadayıf

200 g of butter was melted on a very low temperature and was then mixed with the kadayıf for a 4-5 min period; and about 500 g was laid with a homogeneous thickness. After seating on the tray, a special medium-density fiberboard (MDF) wood and an overall 10 kg heavy weight was placed on it. The tray kadayıf was fried at 175 °C, 200 °C and 225 °C for 40, 50, 60 min respectively. After that, the previously prepared syrup was poured onto it; then sliced and crushed nuts were placed on top, and was then presented to panelists. The analysis samples were prepared from the upper part of the fried tray kadayıf samples after grounding it into very small pieces.

The analyses performed on tray kadayıf samples

Measurement of the color intensity

In the above-mentioned samples, the color densities, which are brightness of kadayıf color (L; 0-100: dark-bright) red color (+a), yellow color (+b) were measured using three parallel Minolta Colorimeter device. Results were evaluated according to the International Commission on Illumination (CIE Lab, Commission Internationale de l'Eclairage; Anonymous, 2012).

Acrylamide analysis

The analysis of acrylamide was performed according to Robarge et al. (2003). During the preparation of the sample the following steps were taken.

The acrylamide standard solutions, used as the sample calibration solutions were 1000 ppb, 500 ppb, and 50 ppb 100 ppb, and were subjected to the same processes to obtain a calibration curve.

Extraction: very small particles of tray kadayıf samples (1 g) were put into 10 ml demineralized water in a 50 ml Erlenmeyer, then was magnetically stirred for 20 min, at 5500 rpm and centrifuged for about 10 min. After centrifuging the supernatant, it was filtrated through a 0.45 µm nylon filter, then 200-300 µL 0.1 normality (N) potassium bromate ($KBrO_3$) was slowly added to 3 ml of the filtrate, followed by stirring and 1 hour of rest in an ice bath. The ice bathing tubes received one drop of 1.0 N sodium thiosulfate ($Na_2O_3S_2$) and were mixed slowly with, followed by adding 2 ml of ethyl acetate ($C_4H_8O_2$). The tubes which had Ethyl acetate added were centrifuged at 5500 rpm for an additional 10 min, then the vials were transferred for supernatant analysis.

Sample extracts and the standard solution were measured using a Gas Chromatography-Mass Spectrometry (GC-MS, Agilent) analysis device. Positron effect was analyzed with imaging method of the GC-MS, DB-225 column (30 m × 0.25 mm × 0.25 µm) and helium gas. The oven temperature was increased from 40 to 200 °C and in this analysis set which increasing 30 °C in a minute split-less mode is used.

DOI: http://dx.doi.org/10.15666/aeer/1702_40074017

Sensory analysis

The sensory analysis of tray kadayıf was carried out at the laboratory of the Faculty of Agriculture, Food Engineering Department, Ataturk University, and panelists were selected from among the graduate and postgraduate students of the Food Engineering Department faculty. Slides which were cut from each tray kadayıf were served on coded plastic plates with drinking water to eight panelists, who were asked to evaluate them. The tray kadayıf was left waiting for 24 h at room temperature. Tray kadayıf samples' taste, aroma, color, texture and overall acceptability were subjected to evaluation. There was a 9-point hedonic scale for the evaluation of these parameters (1 = very bad, 9 = very good) for the panelists to rate each tray kadayıf (Kramer and Twigg, 1973).

Determination of hydroxymethylfurfural (HMF)

Hydroxymethylfurfural analysis was performed with a High-Performance Liquid Chromatography (HPLC) on samples prepared according to the method given by Rada-Mendoza et al. (2002). According to the aforementioned method, a 2 g sample was transferred to a 50 ml Erlenmeyer, to which 4 ml each of carrez I [15 g potassium hexacyanoferrate (II) trihydrate ($K_4[Fe(CN)_6] \times 3H_2O$) mixed with 100 ml ultra-pure water] and carrez II [30 g zinc sulfate heptahydrate ($ZnSO_4$ x $7H_2O$) mixed with 100 ml ultra-pure water] were added and flask was filled to 50 mL with deionized water. After stirring for 30 min, the contents of the Erlenmeyer were passed through a 0.45 µm filter. The samples were analyzed using the HPLC, Agilent 1100 system. UV-VIS detector and Nucleosil 5C18 (250 × 4,6 mm) column (Hichrom, Reading Berkshire, England) were used in this system. The samples were then placed at room temperature, and 10:90 (v/v) methanol-water was used with a flow rate of 1 ml/min to keep it mobile. Hydroxymethylfurfural concentration curve was measured using external calibration (55690-5-HMF, Fluka Chemika) at 280 nm.

Determination of pH

The homogenized 3 g tray kadayıf sample was placed into pure water and its pH was assessed. The sample's pH was previously measured to be pH 4.00 and pH 7.00 using an INOLAB pH 720 brand of Microprocessor (Torley et al., 2008).

Determination of dry matter

Homogenous samples of about 8-10 g were taken from the total samples of both acrylamide and HMF and then dried in a drying oven at 110 °C until a constant weight was achieved (Kotancılar, 2013).

Experimental plan

Trials were conducted with factorial arrangement by three different frying temperatures (175, 200 and 275 °C) and three different frying durations (40, 50 and 60 min) in complete randomized design (CRD) with two replicates (3 × 3 × 2).

Statistical analysis

The raw values received from trials were subjected to variance analysis in SPSS (SPSS1999), and the mean of the sources of the main variation has been found

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40074017

important, as compared with Duncan Multiple Comparison Test (Yıldız and Bircan, 2003).

Results and discussion

Acrylamide values in tray kadayıf

In the present study, variance analysis (*Table 1*) indicated that there were significant ($p \leq 0.01$) differences among different temperatures and different durations based on acrylamide values. As shown in *Table 2,* the temperature increase does not cause any significant changes on the acrylamide content, as the lowest amount of acrylamide was (130.5 μg/kg) at 200 °C, and the highest amount was (137.7 μg/kg) at 175 °C. Mottram et al. (2002) determinate that in the asparagine/glucose model systems the increase of temperature from 120 °C to 170 °C increases the amount of acrylamide and above 170 °C it is reduced. The acrylamide content increases with the frying duration. The lowest amount of acrylamide (132 μg/kg) was determined after 40 min and the highest amount (137 μg/kg) was obtained with 60 min of duration. Tuta (2009) stated that if the temperature rises above 100 °C and the duration of frying increases in parallel, then the acrylamide content decreases. The highest value was achieved with a high-temperature heat treatment of low duration.

*The average shown with the same letters are statistically indistinguishable from each other ($p < 0.05$)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40074017

Color parameter's values of the tray kadayıf

Variance analysis (*Table 1*) of the tray kadayıf L (Brightness), +a (Redness), and +b (Yellowness) color values influenced by the frying temperature, duration and C × S interactions was highly significant ($p \leq 0.01$). The important variables of the frying temperature and duration including L, +a, and +b color values can be found in *Table 2*. The lowest amount of L color value (45.05) was assessed at 225 °C and the maximum amount (66.67) was obtained at 175 °C temperature. By increasing the duration of frying, L color values decreased. The lowest L color value (51.36) was measured after the 60 min mark and the maximum amount (63.36) was obtained after 40 min of duration. The lowest amount of +a color value (2.72) was detected at 175 °C and the maximum amount (13.52) was obtained at 225 °C temperature. By increasing the frying duration, +a color value would increase. The lowest amount of +a color value (5.45) was assessed after 40 min and the highest amount (10.87) was obtained at the 60 min mark. The lowest amount of b color value (15. 81) was measured at 225 °C and the highest amount (26.77) was obtained at 200 °C temperature. By increasing the frying duration, b color values decreased. The lowest amount of b color value (19.01) was detected after 60 min and the maximum amount (25.44) was obtained during the 40 min duration. The interaction between C and S, and its effect on L, +a, and +b color values are given in *Table 1*.

The result showed that the reduction in the L color value as a result of the increased temperature caused the tray kadayıf to gain a dark color. In parallel, +a surface color value has increased and has become more of a reddish color, while in +b value there was an increase at first, followed by a serious decline. While o the dark and intense red color was obtained at 225 °C the brightest and least red surface color was obtained at 175 °C. Colored compounds formed as a result of Maillard reaction are high molecular weight macromolecules called Melanoidins and low molecular weight molecules which have two or three heterocyclic rings (Ames et al., 1998). Color formation, temperature, duration, increase with pH and moisture content in the medium ($aw = 0.3$ -0.7). As shown in *Table 2*, with the increase in temperature and duration caused a decrease in the L value of tray kadayıf, which means the surface color got darker. In parallel, the increase in a value was observed, which means that the intensity of red increased. The brightest and pinkish colors were obtained when the tray kadayıf was fried for 40 min and the darkest red was obtained by frying for 60 min. By increasing frying duration b color value decreased. A decrease was observed in yellow color as well. In a study by Özkaynak (2006) each of the three oil varieties developed darker colors depending on the frying duration as a result of variations in the formation of acrylamide, and L was found to decrease.

Sensory analysis values of tray kadayıf

Variance analysis values of appearance, interior color, taste, odor, flavor, texture, aftertaste and overall acceptability are shown in *Table 3*. The effect of frying temperature on appearance, interior color, taste, texture, aftertaste and the overall acceptability of tray kadayıf was statistically highly significant ($p \leq 0.01$) whereas that on the aroma and smell was significant at a different level ($p \leq 0.05$). The frying duration's effect on the overall acceptability was highly significant ($p \leq 0.01$); on the texture and aftertaste it was significant ($p \leq 0.05$) while on the appearance, interior color, test, smell and aroma it was not significant. The effect of the interaction between

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40074017

frying temperature and frying duration on the outward appearance of tray kadayıf, taste, texture, aftertaste and the general acceptability was highly significant ($p \leq 0.01$), while that on smell value was significant ($p \leq 0.05$) and was not significant on the interior color and the aroma. Significance values of frying temperature can be seen in *Table 3*, while the Duncan multiple comparison test results are shown in *Table 4*.

*The average shown with the same letter are statistically indistinguishable from each other ($p < 0.05$)

As shown in *Table 4*, increase in the temperature of tray kadayıf influenced the appearance, interior color, taste, odor, flavor, texture, and aftertaste positively and was also more appreciated by panelists. While the highest values of appearance, interior color, taste, odor, flavor, texture, aftertaste and general accessibility were obtained at 225 °C, the least admired was the tray kadayıf fried in 175 °C.

HMF, pH, and surface moisture values of tray kadayıf

Variance analysis of HMF, pH and the surface moisture under different frying temperatures and durations of tray can be seen in *Table 5*. As shown in *Table 5* the effect of frying temperature on HMF and humidity values was highly significant ($p \leq 0.01$), while on pH value was significant ($p \leq 0.05$). The effect of frying duration on humidity values was highly significant ($p \leq 0.01$) while on HMF values was significant

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40074017

($p \leq 0.05$). As shown in *Table 6*, the increase in the temperature caused an increase in HMF values (the lowest value of HMF was achieved at 175 °C, while the highest value was observed at 225 °C), and a decrease in pH and the amount of humidity on the surface. Depending on the increase in the temperature the moisture content decreased accordingly. Normal moisture content in particular decreased at temperatures above 50 °C and pH 4-7, while HMF formation rate increased (Borrelli et al., 2002; Oral, 2011).

*The averages shown with the same letters are statistically indistinguishable from each other ($p < 0.05$)

The increasing in frying duration lead to a pH decrease. However, this change was not statistically significant. The HMF value proved to be dependent on frying duration. The lowest HMF value was measured during the 40 min frying period, while the highest value was detected after the 60 min cooking (*Table 6*). Cooking duration in the production of dry fruit pulp is extremely important. The determination of HMF and acrylamide contents significantly increased with the increase in cooking duration (Boz, 2012). As a result of the increase of frying duration, moisture content decreased. Elmore et al. (2005) investigated how much the moisture content depends on frying duration of baked cakes of rye and wheat flour and potatoes. The moisture contents of potatoes and cakes made from rye and wheat flour in the first minute were 59.73, 41.60, and 39.60, respectively. With the 10 min duration, the ratio under 180° C decreased to 24.25, 3.86,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40074017

and 10.33. After 50 min, it decreased to 0.75, 0.70, and 0 (Elmore et al., 2005). The reduction was observed in the moisture content when the temperature of tray kadayıf was increasing.

As displayed in *Table 6*, with the increase of temperature, at the end of all three periods there was an increase in moisture content of tray kadayıfs. At 175 °C, 200 °C and 225 °C and with 40 min of frying duration the highest moisture content, but after 60 min it reached the lowest value. These properties were observed after the 50 and 60 min periods. When the temperature was raised from 175 °C to 200 °C, there was a rapid decrease in the moisture content. At 220 °C and 40 min of frying, there were not many changes to moisture content.

Conclusions

None of the factors has a statistically significant effect on the value of acrylamide. Increase in temperature does not cause any change on acrylamide content. While raising frying duration caused an increase. Increase in temperature levels of tray kadayıf reduced its *L* color value and a darker color was obtained.

The increase in temperature levels, caused an increase in HMF values, a decrease in pH and moisture content on the surface. Depending on the temperature rise a reduction in moisture content was observed. Increasing the frying duration caused an increase in pH values. Depending on higher temperature levels and longer frying duration, HMF values raised. With the increase of frying duration, the moisture content was reduced.

In this research, *a* color value of the surface increased and the kadayıf appeared much redder. In *b* color value there was an increase at first and then it had a serious decrease. Raising frying duration caused a decrease in *L* color value of tray kadayıf, which means that the surface color got darker. In parallel, an increase in the *a* color value was observed, which meant a more intensive red color. The *b* color value decreased by increasing frying duration. An increase in temperature levels had positively influenced the appearance, interior color, taste and smell and caused it to be appreciated by panelists. Increasing the duration of frying had no effect on the aroma of tray kadayıf and had a positive effect on texture, aftertaste and general acceptability.

Abstract. Oilseed crops are considered as one of the most essential dietary components in human consumption as well as animal feed. While drought is one of the most important abiotic stress that adversely effect on the yield and nutritional quality of major oilseed crops across the globe. Therefore, maintenance of nutritional quality in such crops under drought stress may offer good opportunities to

provide sufficient human food as well as animal feed. The current review is to quantify the adverse effects of drought on the qualitative and quantitative traits of oilseed crops, suggest strategies for enhancing drought tolerance in crops. Although drought stress-induced effects on seed oil quality vary with larger environments as well as crop species and their interactions. When short and long term drought occurs at the seed/grain filling stage of crops, it might negatively influence the grain yield as well as the quality of crops. In the present review, we highlight that there are two ways to mitigate the adverse effect of drought *viz.,* development of crop cultivars tolerant to drought and to follow improved management approaches including the exogenous application of osmoprotectants, essential macro and micronutrient management and using organic amendments (compost, green manures, cow manure and incorporation of crop residues) in soils in order to increase the yield and grain quality of oilseed crops.
Keywords: *abiotic stress, crop phenology, oil quality, osmotic stress, plant adaptation, protein content, stress resistance*

Introduction

The impacts of climate change are the foremost thought in many developing countries, due to greater vulnerabilities and limited ability to mitigate the adverse effect of climate change for sustainable crop production (Ali et al., 2017). The economy of most developing countries is based on agriculture, while agricultural sector is fully depend on nature (IPCC, 2012; Mendelsohn, 2014).

The major abiotic stresses such as drought, salinity, heat stress and water-logging are the main climatic factors for declining crop production in many developing countries (Hossain et al., 2013; Jahan et al., 2019; EL Sabagh et al., 2019b). Among them, drought stress is considered the most important one that adversely effect on the yield and quality of many field crops including oilseeds also (Alqudah et al., 2010), through altering the growth, physiology and metabolic activities of plants (Islam et al., 2011). Growing demand for food, feed and raw materials for industries has stressed upon the production of good quality of agricultural products. It is well established that drought has a directly affect the quality of agricultural crops, however, the severity of the drought on the crop production generally depends on the soil moisture status and nutrients availability (Gandah et al., 2003) as well as crop cultivars (Cooper et al., 1987).

Scientists have been trying to overcome the impacts of environmental stresses including drought by employing different strategies, such as improving stress tolerance in crops through foliar application of plant growth regulators, osmoprotectants (OSP), organic and inorganic nutrients which are efficient, economical and environmentally sound approaches (Ahanger et al., 2017; Yakhin et al., 2017). To counteract drought stress plants synthesize osmolytes and perform osmotic adjustment as a frontier in drought tolerance (Blum, 2016). Hence, the adverse effects of drought stress on the fatty acid composition in oilseed crops are not yet deeply elucidated. Therefore, the current

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40194043

review aims to understand the crop responses to drought stress in terms of important quality traits of oilseed crops, as well as to find the appropriate management approaches to enhance stress tolerance in these crops.

Effects of drought on quality of major oilseed crops

Drought stress leads to reduce the seed quality by producing small and medium-sized seeds; while deteriorating the seed vigour and rate of germination (Alqudah et al., 2010). Fahad et al. (2017) observed that under drought stress, the enzymatic activities of plants are diminished, that eventually lead to decrease the yield and quality of oilseed crops. The reduction in oil content has been observed under water deficient conditions of soybean seed also confirmed by Maclagan (1993). Serraj and Sinclair (2002) revealed that the increasing level of soluble carbohydrate and proline (Pro) content in many drought-induced plant species have been associated with the decrease in the protein content and the increase in proteolytic activation, resulting in an increase in the total soluble nitrogen.

Abiotic stresses such as drought might make changes in oil content and compositions in plants (Bagheri et al., 2012), due to water deficit condition often alters the composition and biosynthesis process of fatty acids leading to the reduction of oil yield and composition (Baldini et al., 2000). While, Amini et al. (2014) found a positive effect of water-deficit stress on seed quality (particularly protein) of oilseed crops. The greater seed quality was associated with the physiological process of the plants under water-deficit conditions. Similarly, Foroud et al. (1993) observed the significant increase of seed protein content in soybean under soil moisture stress. The increased protein and the reduced oil contents in plants were associated with the changes in the embryo, endosperm and testa of the seed (Henry and MacDonald, 1978).

Nevertheless, the underlying mechanisms and the extent of how drought stress affect fatty acids composition in different crop species are under research (Nazari et al., 2017). A details description of the effect of drought (soil moisture stress) on major oilseed crops is described below.

Soybean (Glycine max L.*)*

Soybean is considered as an essential oil seed legume crop in the globe, as it provides good quality oils, vegetable protein (Akande et al., 2009; El-Mohsen et al., 2013) and also extraordinary qualities suitable for humans and animals feeding, such as 40-42% good quality protein and 18-22% oil (Arshad et al., 2006). Drought is considered as the most important limiting factor reducing seed protein content of soybean (EL Sabagh et al., 2015) (*Fig.1*), through decreasing photosynthesis (Smiciklas et al., 1992). Drought also altered the composition of fatty acid in soybean, which affected oil content and oil composition (Bellaloui et al., 2013). The fatty acid composition differed when soybean plant was subjected to drought stress, along with a decrease in palmitic, linoleic and linolenic acids, with an increase of stearic and oleic acids were noticed by Gao et al. (2009). Further, drought affects the fatty acid composition, oil stability and oil processing (Gao et al., 2009). The increase of total oil and oleic acid concentrations and a decrease of linoleic and linolenic acid concentrations may be due to water deficit stress altering the rate of oil and fatty acids accumulation by possibly affecting fatty acid desaturations. The water deficit stress during seed filling stage is critical because of the inverse relationship between oil and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40194043

protein with temperature (Carrera et al., 2009). Drought also alters fatty acid composition (Gao et al., 2009) and affects oil stability (Brumm et al., 1990). The effect of drought on seed composition gives an opportunity to breeder and biotechnology researchers to develop drought-tolerant soybeans with stable desirable fatty acid traits.

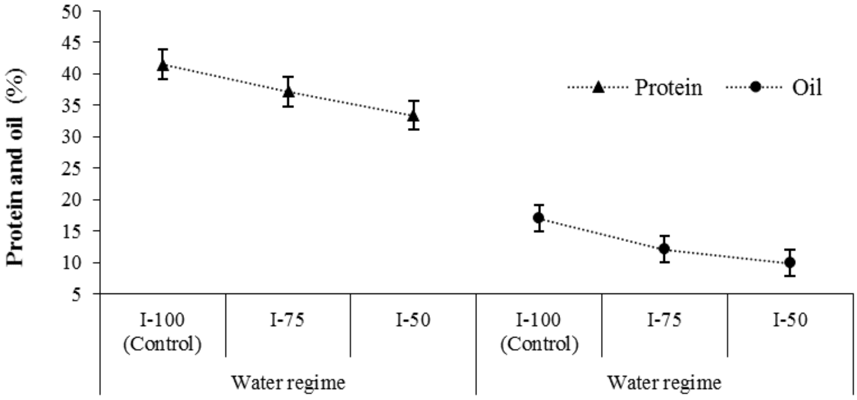

Figure 1. *Effects of proline, glycine betaine and compost application on yield traits and quality in soybean under water stress. Bars indicate standard errors. (Source: EL Sabagh et al., 2015)*

Protein content in seed depends on genetic and environmental factors, mainly drought through the grain filling stage (Tea et al., 2004). Drought stress during pod filling considerably reduced total protein and nitrogen content in seeds (Ghanbari et al., 2013). Drought stress occurs during critical periods of seed formation and seed filling stages reduced the oil content in seed. The reduction in the oil content under drought stress could be due to the oxidation of some of the polyunsaturated fatty acids (Singh and Sinha, 2005). Nonetheless, plants under drought stress increased protein contents by 2-23% as compared to unstressed plants (Rotundo and Westgate, 2010). The variations of the results among the investigations were due to the timing and intensity of the drought stress during the different stages (Carrera et al., 2009).

The decrease in oil content in soybean was also reported by Triboi-Blondel and Renard (1999). Whereas, the lowest oil percentage (20.8%) was obtained under drought stress at the grain filling stage (Smiciklas et al., 1992). Drought stress occurs during critical periods of seed formation and seed filling stages reduced the quantity and quality of seed oil (Maleki et al., 2013). A significant difference among soybean cultivars in terms of oil and protein percentage under drought stress was observed by Mohammadkhani and Heidari (2008). Franklin et al. (2010) also reported that the grain protein remarkably decreased with increasing water stress. The drought had little effect on the fatty acid composition of soybean seed (Dornbos and Mullen, 1992). The drought stress reduced the seed isoflavones in induced soybean plants (Al-Tawaha et al., 2007), while increased alfa-tocopherol concentration in seed (Britz and Kremer, 2002).

Under such situation, oil and protein percentages can be improved by external application of proline (EL Sabagh et al., 2016). Long-term interval of irrigation may build up water shortage in plants which generate organic acid contents in plants body. Boydak (2002) did not find any significant differences between 2-, 6- and 9-day irrigation intervals in the stearic acid content but an increase was observed with 12-day irrigation intervals in soybeans.

DOI: http://dx.doi.org/10.15666/aeer/1702_40194043

Canola (Brassica campestris* L.*)

The most prominent constituents of cell membrane lipids are fatty acids which play a central role in cell permeability under the harsh and normal environment (Sculer et al., 1991). The composition of fatty acids in canola seeds fully depends on polyamines, by controlling the activity of some enzymes synthesis, which play a vital role in fatty acids metabolism (Talaat and EL-Din, 2005). Ullah et al. (2012) found that the basic level of erucic acid was higher in the canola seed and the erucic acid level was increased under drought stress, while another fatty acid such as oleic and linoleic acids and their composition ratio was not altered by drought stress. EL Sabagh et al. (2015, 2016) found that drought is one of the limiting factors that significantly influenced the quality parameters of canola. The water deficit condition significantly influenced the oil content and oil yield as well as protein yield of canola seed (EL Sabagh et al., 2017) (*Fig. 2*).

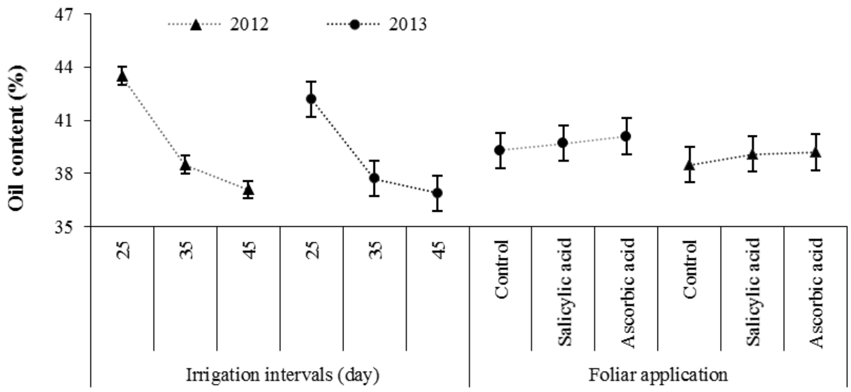

Figure 2. *Effect of irrigations intervals and antioxidants applications on the quality traits of canola during 2012 and 2013 seasons (Source: EL Sabagh et al., 2017)*

They also reported that irrigation at every 25 days intervals produced the highest values for these parameters followed by irrigation at every 35 days intervals. A similar type of reduction in oil content was also reported by Zhang et al. (2014) under-water deficient conditions, indicating that the reduction of oil contents is a common incident under drought stress. Zahedi et al. (2009) reported that drought stress caused a remarkable reduction in oil percentage, due to the reduction of the photosynthesis and the remobilization of assimilation.

Generally, the agronomic operations have an impact on the growth, yield and quality in different crops under different environmental conditions especially drought condition (Barutçular et al., 2016; Abdelaal et al., 2017; EL Sabagh et al., 2019a). Furthermore, optimum irrigation increases seed oil contents, whereas water deficit condition reduces the oil content of canola, due to the oxidation of some polyunsaturated fatty acids as a result of alteration in the physiological and biochemical activities of affected plants (Singh and Sinha, 2005). Similarly, a decrease in seed yield and deteriorating the seed oil quality of canola under drought conditions was also reported by Moghadam et al. (2011) and Rad and Zandi (2012). Reduction in linoleic acid and oleic content of canola under drought stress was also observed by Pritchard (2007).

Environmental stresses such as drought have significant effects on seed oil fatty acid composition of canola (Dawood and Sadak, 2014). Bouchereau et al. (1996) showed that water stress during the flowering stage affects the oil concentration as well as the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40194043

fatty acid composition of canola seeds. Drought stress increased the percentage of palmitic acid and reduced unsaturated fatty acids (Aslam et al., 2009). In addition, severe drought stress reduced the oleic acid content of canola by 3.8% in a Mediterranean-type environment (Qaderi et al., 2006). A reduction of 2.0% in the linoleic content of canola has also been reported in a Mediterranean-type environment under severe soil water stress. This effect on oil production could be due to the oxidation of some fatty acids under drought stress conditions (Singh and Sinha, 2005). Moderate and severe drought stress increased the total saturated fatty acids and decreased the unsaturated fatty acids relative to control plants (Dawood and Sadak, 2014). Tohidi-Moghadam et al. (2011) mentioned that water deficit condition decreased the canola oil and linoleic acid contents, but increased stearic, α-linolenic, and gadoleic acids contents. Ullah et al. (2012) stated that drought stress reduced the oil quality of canola by decreasing oleic acid content and increasing the erucic acid content. However, the maximum erucic acid content was observed in the treatment where 60% irrigation was applied while, the minimum was found at 100% irrigation level (Ali et al., 2014). The accumulation of glucosinolates in rapeseed under drought stress during flowering stage has been reported by Bouchereau et al. (1996). Drought stress augmented the seed glucosinolates and oil erucic acid (C22:1) content of canola also reported by Ullah et al. (2012). The decrease in total phenolic contents of canola seeds under drought stress is also reported by Dawood and Sadak (2014). While, Gecgel et al. (2007) revealed that the effect of oilseeds genotype on fatty acids was greater than that of the environment stresses.

Sunflower (Helianthus annuus **L.***)*

Since sunflower has the capability to survive under stress condition than other oilseed crops to some extent, but it is highly sensitive to drought stress from flowering to grain filling stage due to inadequate availability of soil moisture and high ambient temperature in the arid and semi-arid region (Hussain et al., 2018). They also noticed that low soil moisture (water deficit) in combination with high air temperature from flowering to grain filling stages significantly reduced the seed yield and seed oil quality of sunflower. Oraki and Aghaalikhana (2012) noticed that low precipitation (drought stress) in the arid and semi-arid regions in combination with high ambient temperature significantly reduced the oil quality of sunflower through shortening the germination, anthesis and achene filling period, and also suppressing the stem elongation and leaf area (Soleimanzadeh et al., 2010; Babaeian et al., 2011; Fulda et al., 2011). The environmental factors during the seed-filling period can widely affect the oil percentage and fatty acid composition of oil (Anastasi et al., 2010). Drought leads to an increase in the oleic acid content of high oleic acid of hybrids sunflower, but a decrease in ordinary hybrids (reported by Baldini et al., 2000). The increased of linoleic and palmitic acid and decreased of oleic acid and stearic acid contents in sunflower seeds under water stress were also reported by Petcu et al. (2001). Jasso de Rodriguez et al. (2002) stated that the oil content of sunflower seeds showed a slight decrease when drought was occurred during grain filling to harvest time. They also found that water stress caused a significant reduction of oleic acid (about 8-14%) in a standard hybrid. While Baldini et al. (2002) and Flagella et al. (2000) found that water stress increased the oleic acid content but decreased linoleic acid content in both standard and high oleic content genotypes. The findings of the previous studies related to the adverse effect of drought on the seed and oil quality of sunflower also confirmed by Rondanini et al. (2003) and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40194043

Lacombe et al. (2004), who noticed that under drought stress the composition of saturated fatty acids changed into unsaturated fatty acids. However, the linoleic acid (predominately unsaturated fatty acids) also changed through enzymatic processes governed by genes coding for oleoyl Δ-9 desaturase and oleoyl Δ-12 desaturase. Debaeke et al. (2017) and Hussain et al. (2018) confirmed that nitrogen (N) transport from root to shoot is restricted due to the weak absorbing capacity of the drought-affected crop which ultimately reduced the yield and oil quality of sunflower.

Flax (Linum usitatissimum **L.***)*

Flax is well known as linen flax or linseed around the World. It is grown in many countries for fibers as well as oilseeds. As linseeds' oil has been used as the basic component or additive of various paints and/or polymers industries (Shim et al., 2015). Likewise, seeds of flax contain about 36-40% oleic (omega-6), linoleic and linolenic acids (omega-3) (unsaturated fatty acids), which are very essential poly-unsaturated fatty acids for human beings and also for animals, because these acids cannot synthesize inside the body of both human and animals; thus it should ingest in human and animal diets (El-Beltagi et al., 2007).

However, under water deficit condition, flax plants produce less oil and fibre in comparison to irrigated condition (Bauer et al., 2015). Rashawn et al. (2016) observed a highly significant variation among the three tested flax cultivars of 'Sakha 1', 'Giza 9' and 'Giza 10' regarding protein and oil content under drought stress (*Fig. 3).* The highest oil yield was also reported at recommended (normal) irrigation, followed by limited irrigation at the stem elongation stage of flax also reported by Mirshekari et al. (2012). Considering on fiber-type flax, higher fiber contents along with the higher straw yield resulted in the high yielding fiber-type cultivars whose fiber yielding capacity is 60-70% higher than the seed-type cultivars (Bauer et al., 2015). The fiber quality (fineness and length), fiber percentage, overall yield and oil quality were adversely affected by drought (also reported by Abd El-Fatah, 2007; El-Refaey et al., 2010).

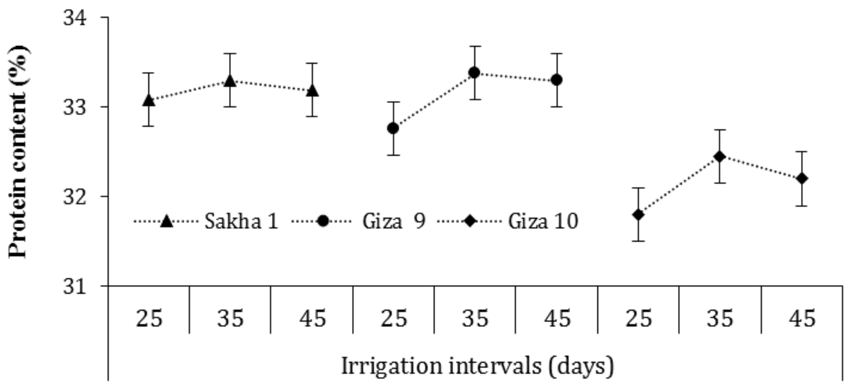

Figure 3. *Effects of irrigation intervals and flux cultivars on oil and protein content (Source: Rashawn et al., 2016)*

Safflower (Carthamus tinctorius **L.***)*

Safflower is an essential oilseed crop that can moderately tolerate against several environmental stresses including drought (Mohammadi et al., 2016). While, Amini et al. (2014) and Mohammadi et al. (2018) observed that the environmental conditions and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40194043

management practices affected the oil content of safflower cultivars. Among the environmental stresses, water deficient condition increase protein and decrease oil contents of safflower (Nabipour et al., 2007; Amini et al., 2014). Drought stress during seed filling has been referred to as the major reason for reduced oil content in safflower (Mohammadi et al., 2018).

Ashrafi and Razmjoo (2010) found that safflower oil content was highly affected by different irrigation levels. They also reported that the oil contents of safflower cultivars were significantly reduced under limited irrigation (drought). Similarly, Bagheri and SamDaliri (2011) found a significant reduction of oil content in safflower seeds' as a result of different irrigation regimes, especially with the lack of water during the seed-filling stage.

Generally, seeds' oil of safflower contains a large amount of saturated (palmitic and stearic) and unsaturated (oleic, linoleic and linolenic) fatty acids and composition, which may be affected by abiotic stresses particularly due to drought stress (Fernández-Cuesta et al., 2014). While, Ensiye and Khorshid (2010) found that drought stress reduced the content of oil and oil composition in the seeds of safflower cultivars, due to a dramatic decrease in saturated fatty acid contents. The oil contents, palmitic, stearic, oleic and linoleic acid contents were reduced under drought during the process of flowering and seed development (also reported by Boydak et al., 2010). Further, drought reduces the palmitic, stearic, oleic and linoleic acid contents (Ashrafi and Razmjoo, 2010). Petcu et al. (2001) also found that the stearic acid content was reduced as drought levels increased. Although the palmitic acid content was decreased, but linoleic acid content was increased up to 14% under drought stress (Petcu et al., 2001). Higher oleic and linoleic acids and lower stearic and palmitic acids under drought stress were reported by Arslan and Kucuk (2005). Under water-stress, the early maturity of plants get a shorter period of grain filling duration, as well as shorter time for conversion of oleic to linoleic acid. This could be the main reason for linoleic acid ratio reduction under drought-stress condition (Nazari et al., 2017).

Peanut (Arachis hypogaea **L.***)*

Major factors influencing oil and other composition profile of peanut includes variety/cultivars/species and environmental conditions such as light, temperature, water stress and atmospheric constituents (Pattee, 2005). Chaiyadee et al. (2013) and Gulluoglu et al. (2016) found that genotypes, seasonal variation, location, air and soil temperature, planting date, soil nutrient, moisture availability, growing conditions and maturity affect the fatty acid content in peanut oil. However, under stress conditions, the changes even in the fatty acid composition and the decreasing order of the main fatty acids was in oleic acid, linoleic acid and palmitic acid, respectively (Amir et al., 2005). Other reports indicate that mid-seasonal drought had no effect, while late season drought significantly reduced the total oil and linoleic acid contents, and increased the stearic and oleic acid contents of peanut seeds (Dwivedi et al., 1993). Under water stress conditions, a large reduction in oil and oleic acid content in peanut was observed by Hashim et al. (1993) and also, reduction in linoleic acid, but an increase in oleic acid (Dwivedi et al., 1996).

A reduction in oil content of soybean and groundnut under drought stress were also reported by Dornbos and Mullen (1992) and Dwivedi et al. (1993); while a significant increase in the stearic acid content of peanut seeds under drought stress has been reported by Dwivedi et al. (1993). A reduction of 4-14% in the oleic content of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40194043

sunflower but an increase in the oleic acid concentration of groundnut under drought stress have also been reported by Petcu et al. (2001). Reddy et al. (2003) observed the application of the different irrigation levels had different responses on the protein content of the seeds of groundnut; while the plants with adequate irrigation water not only gave more kernels but also produced the higher levels of total proteins and oil contents. Dwivedi et al. (1996) pointed out that the total oil and linoleic acid contents of peanuts decreased under water stress during the grain filling stage, but that total protein and stearic acid contents increased under this condition.

Management strategies of drought stress to improve the yield and quality of major oilseed crops

Plants induce stress tolerance mechanism by engineering/altering primary and secondary metabolites. Pant hormones and other compatible compounds such as carbohydrate, amino acid, polyamine, abscisic acid, phenolic compounds, glucosinolate, carotenoid and terpenoid derivatives , play a vital role to maintain the adaptation of plants through changing their membrane stabilization, osmoregulation, free radical scavenging, reduction of leaf area and leaf abscission, stimulation of root growth, electrolytic leakage etc. A details information related to crop-specific management and their survival mechanism is described under the following sub-headings.

Soybean (Glycine max **L.***)*

The most significant responses of plants to survive against drought stress are an accumulation of minerals and enhancement to OSP synthesis which are as a part of the metabolic activity of plants to enhance tolerance against drought stress (Samarah et al., 2004). The accumulation of OSP compounds such as Pro assists the stressed cells of plants through water preservation (Hare et al., 1998) and maintain the structure of cell membrane integrity (Conroy et al., 1988). Similarly, Ashraf and Iram (2005) reported that external application of OSP increased the osmotic adjustment in legumes (including soybean) for increasing the survival capacity against water stress. Metabolic changes in response to drought conditions play a significant role in the osmotic adjustment of metabolism and physiology of the soybean varieties to survive under drought stress (Silvente et al., 2012). One approach to increase oxidative stress tolerance in soybean plants on drought stress is the foliar application of exo-antioxidants through improving the total soluble protein, SOD, POD and H_2O_2 as compared to control (Hasanah et al., 2017). The increased seed oil and protein content were observed due to foliar application of Pro under water deficit conditions (EL Sabagh et al., 2016). Exogenous application of Pro in drought-affected plants ameliorated the adverse effect through maintaining the osmotic adjustment and altering the metabolic activity under water deficit conditions, thereby maintaining high photosynthetic efficiency and finally increased the quality of seeds (Ali et al., 2007). Ali and Ashraf (2011) stated that exo-GB improved the quality of oil by reducing the un-saponifiable matter and improving oil saponification and iodine values, the measure of oil unsaturation. In this concern, EL Sabagh et al. (2016) observed that foliar applied GB improved seed oil and protein content in soybean under water deficit conditions. Compatible solutes like GB or Pro improved the seed quality of soybean as a result of their protective effect on cellular structures during fatty oil biosynthesis and storage, which occurs in liposomes or oleosomes in seeds during the grain-filling stage of the plant (Ali et al., 2013;).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40194043

Similarly, EL Sabagh et al. (2015) also found that foliar application of GB, stimulated the protein content in stress affected plants by improving the osmoprotective impact on the photosynthetic machinery and regulation of ion homeostasis (Hussain et al., 2008). Under drought stress the OSP help to transport essential hormones like cytokinins for biosynthesis and also have a role in the transport of photo-assimilates (Taiz and Zeiger, 2006; EL Sabagh et al., 2015).

However, application of compost is more effective on seed oil content than applying mineral nitrogen. This might be due to the fact that nitrogen composes protoplasmic protein, which required for increasing the growth and then increasing the seed oil content and oil yield. The influence of organic manure by improving the physical structure of the soil and increasing available nitrogen, which reflects a good growth and, consequently, more absorption of nitrogen and more crude protein synthesis (El-Bana, 2000; El-Sadek, 2005). Compost application was more effective mineral nitrogen on seed protein content might be due to the fact that nitrogen composes protoplasmic protein, which required for increasing the growth and then increasing the seed protein content (Connor et al., 2011). Similarly, the relative increase in protein yield by the application of vermicompost as compare to mineral nutrients. Jaleel et al. (2009) indicated that application of vermicompost with inorganic fertilizers improved yield and protein of *Phaseolus vulgaris* (common bean) seeds.

Canola (Brassica campestris L.*)*

Application of antioxidants significantly influenced the protein percentage of canola seed; while non-significant variation was found in terms of the oil content. It was observed that the application of salicylic acid (SA) and ascorbic acid (AsA) in combination with irrigation intervals achieved superior yield of canola, as well as significant increase in protein and oil content of canola (*Fig. 4*).

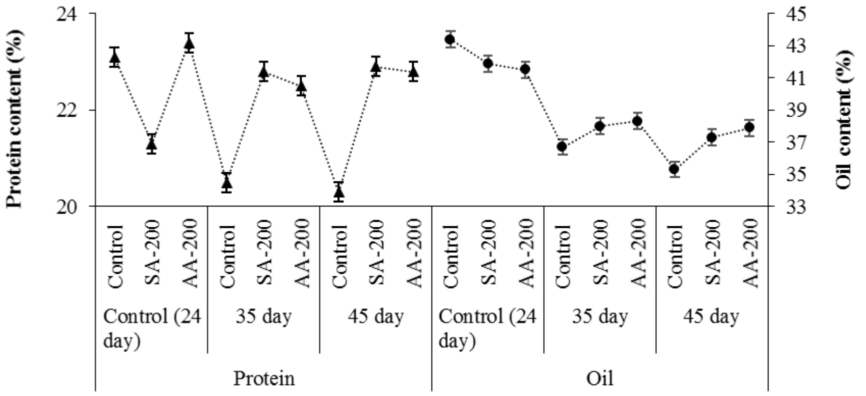

Figure 4. *Oil and protein content of canola as affected by the interaction of irrigation intervals and antioxidants applications during 2012 and 2013 seasons. SA, Salicylic acid; AA, Ascorbic acid (Source: EL Sabagh et al., 2017)*

Ahmadi et al. (2015) reported that spraying of 300 mg l^{-1} ascorbate peroxidase reduced the effect of drought-stressed on rape-seeds. Application of SA in an appreciative rate enhanced the antioxidant ability of cell and generated new protein synthesis in the photosynthetic apparatus (Tirani et al., 2013). According to EL-Tayeb (2005), SA application decreased the stress-induced loss in chlorophyll content and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40194043

photosynthetic rate. AsA can also decrease the harmful result of oxidative stress and enhancing the plant growth under stress environment (Dolatabadian et al., 2009). Application of SA decreased the erucic acid rates in rape oil (Ullah et al., 2012). Application of GB leads to higher carbohydrate contents, oil contents, Pro contents, total soluble sugars and lower concentration of MDA and H_2O_2 under drought stressed in rape plants (Dawood and Sadak, 2014).Similarly, Ali et al. (2013) reported that compatible solutes such as GB or Pro improved the oil quantity and quality, due to their protective effect on cellular structures during fatty oil biosynthesis and storage, which occurs in liposomes or oleosomes in seeds during seed filling stage. Ali (2011) stated that exogenous GB improved the quality of oil by decreasing the un-saponifiable matter and increasing oil saponification and iodine values, the measure of oil unsaturation. Plant growth regulators are important compounds for the rapeseed yield and quality (Huberman et al., 2014). Putrescine, a new plant growth regulator, belonging to polyamines, is reported for its beneficial effects on plant growth under environmental stresses (Perez-Adamor et al., 2002).

Sunflower (Helianthus annuus **L.***)*

Sunflower plays a vital role in providing a ridiculous source of edible oil and protein for human consumption. However, drought stress severely reduced the growth, development, and yield of sunflower. Therefore, under changing climate particularly in drought stress in arid and semi-arid regions, it is important for the development of drought tolerant genotypes and also adaptive management approaches that are suitable for sustainable sunflower production. There are two ways to mitigate heat stress in crops, either by developing and practising improved stress management practices or by developing and using drought-tolerant cultivars (Farooq et al., 2011; Hossain et al., 2013; Hussain et al., 2018). Since, researchers around the globe have been trying to find-out the adaptive technologies which are appropriate to alleviate the adverse effects of drought (Bowsher et al., 2016; Sourour et al., 2017). Nonetheless, development of drought-tolerant cultivars through breeding programs is highly important for improvement of global sunflower production mainly in dry regions where a major portion of sunflower is cultivated under limited water (Rauf and Sadaqat, 2007; Hussain et al., 2018). The first step for improvement of drought resistance of crops is to assess the genetic variation that exists in wild types. Therefore, evaluation of these target resources in combination with genotyping and phenotyping traits under field conditions are directly related to the improvement in drought tolerance of sunflower (Rauf, 2008; Hussain et al., 2018). Considering phenotyping criteria, leaf area index might be preferred as first priority to identify genotypes under drought stress as it is highly correlated with net assimilation rate (Hemmati and Soleymani, 2014).

On the other hand, several stress tolerance indices (STIs), including stress tolerance, mean productivity, geometric mean productivity and stress susceptibility index, and can be used for identification high-yielding varieties with improved tolerance to stress (Ramirez and Kelly, 1998). These are used to determine stress tolerance in terms of minimizing the reduction in production caused by unfavourable versus favourable environments. STIs are measuring stress tolerance in genotypes by comparing GY under stressed environments (Rauf and Sadaqat, 2007; Hussain et al., 2018).

In case of management approaches, exo-application of phytohormones and OSP such as ABA, potassium chloride, SA and $CaCl_2$, sodium nitroprusside (SNP) a nitric oxide (NO) donor, triazole compounds, Pro and GB positively improved oil quality of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40194043

sunflower through improving the physiological and biochemical processes of stress-induced plants (Babaeian et al., 2011). Zaidi et al. (2015) reported that foliar spray of SA significantly improved the Pro, sugars and proteins of sunflower under drought condition, indicating that exogenous SA plays an imperative role to survive plant under drought tolerance. Hussain et al. (2014) found that app of ABA at budding or flowering stages of sunflower helped to ameliorate the adverse effects of drought stress. Moreover, Narusaka et al. (2003) reported that ABA app regulates some stress reactive genes (*HaACCO*$_2$) and proteins in sunflower under drought stress. Similarly, Hussain et al. (2018) reported that exogenous ABA application induces the *HaACCO*$_2$ gene accumulated in leaves of sunflower, which is responsible for drought tolerant in sunflower. While, Rabert et al. (2013) found that triazole compounds like hexaconazole, tebuconazole and propiconazole when applied to sunflower under stress condition partially ameliorated the adverse effects of drought stress through improving the antioxidant enzymes i.e., SOD, APX and CAT activities. Filová (2014) reported that application of 28-homobrassinolide significantly improved the antioxidant enzymes and biochemical traits of sunflower to increase tolerance against drought stress. A sufficient nutrition of plants under stress conditions (including drought) improve tolerance against stress. Ashraf et al. (2015) observed that application of the major nutrients enhances the survival capacity against drought stress by improving protein synthesis, stomatal regulation, homeostasis and osmoregulation through reducing the ROS.

Application of micronutrients enhances sunflower performance against drought stress (Movahhedy-Dehnavy et al., 2009; Zafar et al., 2014) by improving the antioxidant defense, stay green, achenes weight and oil yield. Hussain et al. (2015) and Iqbal et al. (2015) found that exogenous application of $CaCl_2$ has a positive effect on relative leaf water content (RLWC), leaf pigments (such as chlorophyll a, chlorophyll b, carotenoids, anthocyanins, carotenoids), leaf minerals such as N, P, K and Ca, organic osmolytes (Pro and soluble sugars) and phenolic related enzymes such as phenylalanine ammonia lyase (PAL) and POD in sunflower against drought stress.

Similar to other management practices, organic manures have also played a positive role to improve the drought tolerance of sunflower when applied separately or in combination with chemical fertilizers or other OSP (Esmaeilian et al., 2012). Manures are the major source of many essential nutrients as well as enhance the nutrients availability by improving soil physicochemical properties (Hussain et al., 2018). Aowad and Mohamed (2009) and Esmaeilian et al. (2012) reported that when organic manure was applied either alone or in combination with synthetic fertilizers to drought-stressed sunflower, resulting in a significant improvement in drought tolerance.

Flax (Linum usitatissimum **L.***)*

Water deficit stress conditions (drought) is considered as one of the major harsh abiotic stresses that can inhibit the growth, development, yield and quality of flax. Some drought tolerant genotypes can abide stress by increasing the amount of secondary metabolites. It is reported that accumulation of secondary metabolites such as Pro, GB, sugars and some inorganic ions consider as a defense mechanism of plants to adapt the drought by altering their physiological and biochemical activities (El-Tayeb, 2006; Kiani et al., 2007). In addition, drought stress often leads to accumulating the excessive ROS that causes oxidative stress to the photosynthetic apparatus, which ultimately seriously damage the normal function of cells, finally reduced the total assimilation of plants (Niyogi, 1999; Fambrini et al., 1999). Bakry et al. (2012) found that application

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40194043

of SA @ 75 mg l^{-1} significantly increased the Pro and free amino acids content of two varieties of flax ('Olin' and 'Amon') under drought condition as compared to the corresponding control condition. Under drought stress, the significant increase in total carbohydrates in shoots of flax concurrently increased the growth rate of the flax that led to increase the photosynthetic efficiency in response to SA treatments and thus led to enhance biosynthesis of carbohydrates which are utilized in growth of flax plants under drought stress (El-Tayeb and Ahmed, 2010). Similarly, Kranner et al. (2002) demonstrated that SA is one of the antioxidant substances that concentrated in the chloroplast of the plant cell and protect the photosynthetic apparatus under drought stress, by reducing the excessively ROS species known as free radicals.

Accumulation Pro and free amino acids in plant tissues could be involved in the osmotic adjustment of plants under drought stress (Delavari et al., 2010) and could also be a protective agent of enzymes and cell membranes (El Tayeb and Ahmed, 2010). Harinasut et al. (2000) reported that when the plant is exposed to drought stress, they are maintaining their water content by the accumulation of compatible OSP, such as Pro, in their cytoplasm. Accumulation of Pro under drought stress produces hydroxyl radical scavenger for increasing stress tolerance in plant species under stress conditions (Hoque et al., 2007). Similarly, Arfan et al. (2007) found that SA is naturally produced in plants in very low amounts that acts as a potential non-enzymatic antioxidant as well as an endogenous plant growth regulator of phenolic nature. Exogenous application of SA helps in the activation of a range of plant defense genes for drought tolerance in plants (Sreenivasulu et al., 2007). Munns and Tester (2008) found that SA has a direct physiological effect through the alteration of antioxidant enzymatic activities by preventing oxidative damage in plants by detoxifying superoxide radicals, produced as a result of stress. The alleviation of oxidative damage and improve the tolerance to environmental stresses, at critical growth stages of the plant, are often correlated with an effectual antioxidative system, such systems may be induced or improved by SA application (He et al., 2005). This significant effect of SA could be attributed to improve in CO_2 assimilation and photosynthetic rate which improved mineral uptake by the plant (Noreen and Ashraf, 2008).

Safflower (Carthamus tinctorius **L.***)*

Plants adopt various strategic tactics to cope with water deficit conditions such as escape, avoidance and tolerance (Rasool et al., 2013). Among the above-mentioned cytosolutes, proline and glycine betaine constitute the most important organic solutes that have a multifunctional role in plants' defense for combating stresses (Hussain et al., 2015). Safflower has proved to be stress tolerant due to having more proline and GB application (Javadipour et al., 2013). Mona et al. (2012) is also in agreement with foliar application of SA during flowering in safflower that increased the production of oleic acid and linoleic acid.

The application of kinetin at 10-5 M as a foliar spray to safflower during flowering (140 days after sowing) was highly effective in increasing oil refractive index (Ullah and Bano, 2011), decreased oil acid value, free fatty acid content (% oleic acid) and specific gravity but increased oil pH. Kinetin was highly effective in increasing oleic acid (C18:1) but decreased the content of linoleic acid (C18:2) (Ullah and Bano, 2011). Foliar application in stem elongation stage obtained 6.02 percent more seed yield but in the flowering stage, fulvic acid spraying was achieved 35.5% more oil percent (Moradi et al., 2017). Boydak et al. (2002) reported that treating safflower plants by GA_3 had

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40194043

less oil content than the non-GA_3 treated plants. Spraying of Melagrow four times, at 60 or 40 ppm on safflower remarkably increased the oil yields, and percentages carthamin, carthamidin, oleic acid, and oleic/linoleic ratio (Hamza, 2015). Foliar application of zinc and manganese significantly improved the palmitic and oleic acids but these foliar applications reduced linoleic acid content. The palmitic acid content was increased and oleic acid content was decreased by drought stress (Dehnavi and Sanavy, 2008), while the foliar spray of potassium improved the oleic acid content of oil (Pandy et al., 2014).

Peanut (Arachis hypogaea L.*)*

Foliar application of LAA has a significant role in improving yield components, biochemical constituents and fatty acids composition in seeds of some groundnut cultivars (NC, Giza 6 and Gregory) grown in sandy soil (Mekki and Hussein, 2017). The addition of soaked poultry glaucoma as organic fertilizer gave the highest yield of peanut under drought stress, but the organic soaked pigeons' manure resulted in high percentage of oil (Abd El-Halim et al., 2016). The recommended dose of fertilizers (RDF) of P and K (100%) along with 50% of N basal and 50% of N as top dressing increased the yield attributes, yield and oil contents of groundnut as compared 100% RDF of N, P, and K to groundnut (Priya et al., 2009). Potassium was reported to play the main role on the oil content of groundnut (Charkaravarthy et al., 2002), and they also reported that potassium application during pod development stage increased the oil content in groundnut.

Phosphorus application in the form of single superphosphate has been shown to increase both oil and protein content of groundnut seed (Elsheikh and Mohamedzein, 1998). Rahman (2006) reported that oil and protein content of groundnut increased when calcium level was increased from 0-100 kg ha^{-1}. Recently, Vijayarengan et al. (2009) showed that cobalt at the rate of 50 mg kg^{-1} application in the soil had a beneficial effect on biochemical contents i.e., sugar, protein and amino acids of groundnut seeds compared with control plants. Applying P fertilizer obviously increased fat and protein content, applying N fertilizer mainly enhanced protein content, and applying K fertilizer mainly raised the content of soluble sugar. In addition, the application of NPK fertilizers also increased the contents of lysine and methionine which were inadequate in the protein fractions of peanut kernel, enhanced the contents of oleic acid and linoleic acid, raised the ratio of oleic acid to linoleic acid, improved nutritional quality of peanut, and pronged the shelf life of peanut products (Zhou et al., 2007).

Conclusion

Drought is the foremost abiotic stress that significantly influenced the qualitative and quantitative traits of major oilseed crops particularly in arid and semi-arid regions. Essential dietary components in human consumption, as well as animal feed, were significantly reduced as a consequence of drought stress through altering the physico-biochemical as well as enzymatic activities of crop plants. Hence, the negative effect of drought stress has been varied in almost all crops depending on crop species, genotypes, and their growth stages. The present review summarized that early growth stages followed by anthesis to grain filling stage of oilseeds crops are the most sensitive stages against drought. The review highlighted that there are different ways to mitigate the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40194043

adverse effect of drought *viz.,* development of crops cultivar tolerant against drought and to follow improved management approaches including exogenous application of osmoprotectants, essential macro and micronutrients management and using organic amendments (compost, green manures, cow dung and incorporation of crop residues) in soils which lead to increase the yield and grain quality of oilseed crop. The findings of the current review will be helpful to plant researchers to make research programs for resolving the consequences of drought stress for sustainable quality food production in the era of climate change.

Abstract. African elephants (*Loxodonta africana*) negatively influence woody vegetation, causing structural changes to ecosystems. Field-based survey methods used to monitor elephant impact, while valuable, are costly and time-consuming to execute. By applying distance-sampling techniques such as remote sensing technology, inaccessible areas can be surveyed. This overview provides insight into methods used by scientists to determine the impact of elephants on woody vegetation in sub-Saharan Africa. Data were sourced from a variety of research databases. Findings indicate that 87% (n = 92) of the reviewed studies used field-based methods and 13% (n = 14) used remote sensing-based methods. We explore the national affiliations of the lead and the last authors of the reviewed studies and the scientific journals that published them. Field-based is the dominant method used in the majority of published studies on elephant impact. The majority of these studies were published in European and American journals, instead of African journals, which are less represented. However, the majority of the lead and last authors' affiliations for both field-based and remote sensing based methods are affiliated with African institutions. We conclude that there is a need to improve the integration of remote sensing techniques into conservation and other ecological fields.
Keywords: *savanna, satellite imagery, national affiliation, accessibility, reviewed studies*

Introduction

African elephants (*Loxodonta africana*) are found in sub-Saharan Africa (Blanc et al., 2007), where they occupy savanna ecosystems, dense forests, Sahelian scrub and deserts (Nowak, 1999). Based on genetic information, taxonomists suggest that there are two sub-species of the African elephant namely, the forest elephant and the savanna elephant. Current literature indicates that there is no detailed knowledge available on the distribution of these sub-species or the presence of potential hybrid populations (Mondol et al., 2015). Savanna elephants are predominantly found in eastern and southern Africa, while the forest elephants are found mainly in the Congo Basin of Central Africa (Thouless et al., 2016). In this study, we considered African elephant as a single species found in sub-Saharan Africa (East, Central, West and Southern Africa).

Elephants, in general, utilize a wide range of landscape types when foraging. The distribution of resources across landscapes influences elephant home range use and size. Individual home ranges may include a variety of landscapes and ecosystems (Grainger et al., 2005). A home range is defined as an area traversed by an individual in its normal activities of food gathering, mating and caring for young (Burt, 1943). Elephant feeding

DOI: http://dx.doi.org/10.15666/aeer/1702_40454066

behavior, densities, interactions with other herbivores, associated ecological and environmental factors such as fire damage, rainfall patterns, and plant growth rates, all influence elephant impact on vegetation (Dublin et al., 1990; Ben-Shahar, 1996b; Ferguson, 2014).

Adverse impacts associated with African elephants on ecosystems include reducing tree heights and densities, which leads to structural changes in the woody layer (Ben-Shahar, 1998; de Boer and Kohi, 2008). Changes in overall vegetation composition lead to a decline in biodiversity (Kelly, 2000). Guldemond (2006) found that elephant impacts in closed woodlands create canopy gaps, leading to reduced recruitment of young trees. Elephants require a daily average fresh food intake of approximately 173 kg across both the wet and dry seasons (Ruggiero, 1992). Since they feed mainly on woody plants, tree mortalities are common in areas they frequent. Woody plant species composition, tree species distribution, tree size, tree age, feeding preferences and habitat availability influences the consumption of woody vegetation by elephants (Gadd, 2002; Van Staden et al., 2016).

Protected areas are representative of natural vegetation that previously occurred in the broader vicinity around the protected area. This includes woodland spatial distribution, composition, and structure without anthropogenic influences (Guy, 1976; Gandiwa et al., 2011). The vegetation type, rainfall (Gandiwa and Kativu, 2009), management and conservation strategies and interventions (Hamandawana, 2012), differ for each protected area. Smit and Ferreira (2010) state that the availability and distribution of water sources remain different from one area to another, influencing elephant movement patterns. Variability between areas and their sizes, coupled with different elephant densities leads to fluctuating distribution patterns and intensities of elephant impact. The numbers of elephants have been steadily increasing in many protected areas in the sub-Saharan region, raising concerns of their impacts to biodiversity (Van Aarde et al., 2006; Van Aarde and Jackson, 2007). The focus on elephant management in many protected areas has been on their numbers in relation to the size of the area they occupy. According to Van Aarde et al. (2006), this approach gave rise to the establishment of many artificial water points, which modify the movements and home ranges of elephants.

Available methods for managing elephant populations include culling, relocation, and the use of contraceptives (Pimm and Van Aarde, 2001; Rubio-Martínez et al., 2014). Elephant culling remains a highly debated and sensitive subject in the scientific community (Mackey et al., 2006; Balfour et al., 2008; Lotter et al., 2008). Relocation of elephants is not a permanent option, but a temporary solution that can present adverse effects on the breeding behavior of female elephants (Raath, 1999). Relocated animals that breed can often not be accommodated by the parks or reserves they are moved to (Rubio-Martínez et al., 2014). Laparoscopic vasectomy is a costly contraceptive technique applicable to free-ranging male elephants. The long-term effects of this type of contraception are yet to be studied to determine how the elephant population demographics and dynamics are influenced (Rubio-Martínez et al., 2014). Additional contraceptive techniques available to wildlife managers for free-ranging elephant cows include pregnancy termination, the use of estrogen implants and immunocontraception (Poole, 1993; Whyte and Grobler, 1998). While these contraceptive techniques reduce population growth rates, they are often impractical and expensive to implement (Whyte et al., 1998).

DOI: http://dx.doi.org/10.15666/aeer/1702_40454066

An increase in the number of studies that investigates the impact of elephants on vegetation structure and dynamics has been noticed over the three past decades (Ben-Shahar, 1996a, 1998; Shannon et al., 2011; Van Staden et al., 2016). Moreover, the impacts of elephants on vegetation has increasingly become one of the main concerns for environmental and protected area managers (Baxter and Getz, 2008; Wiseman, 2001). We identified two review papers on the impacts of elephants on vegetation in Africa (Guldemond and Van Aarde, 2008; Guldemond et al., 2017). Guldemond and Van Aarde (2008) reviewed 21 studies between 1961 and 2005 from 14 study sites in Africa. Although no opinion or broad generalizations were made on elephant management from the reviewed studies, there was no doubt that elephants have an effect on woody vegetation and that high elephant densities could result in adverse impacts. Guldemond and Van Aarde (2008) also highlighted the lack of published information on the effect of elephants on vegetation.

A current review paper by Guldemond et al. (2017) that looked at 51 peer-reviewed articles concluded that elephants have a significant influence on vegetation by changing tree structure and abundance. No overall adverse cascading effects for species that share space with elephants were reported. Both these reviews focus on the impact of elephants and not the methods applied. This makes it necessary to provide an overview of the studies and techniques that have been used to quantify the impacts of elephants on the environment. This would provide useful information for conservation managers, and would also identify opportunities for further research into practical and time-efficient methods for studying the impact of elephants on vegetation.

This paper aims to provide an insightful review of the types of methods used by different peer-reviewed studies to quantify and detect the impact of elephants on woody vegetation in sub-Saharan Africa from 1970 to 2017. For this paper, we grouped the studies into two different categories, a field-based (FB) approach and those that used a remote sensing-based (RS) approach. Field-based approaches involve the physical collection of detailed data using certain tools and techniques in the veld (Zimmerman, 2014). Remote sensing approaches provide a variety of imagery known for their different spectral, spatial, radioactive and temporal characteristics that are applicable for use in broad vegetation studies (Xie et al., 2008).

Our review provides information on the geographic location of each study (location of study area and spatial scale of research), the national affiliation of the lead and the last authors and whether the publication is local (within Africa) or international (outside the African continent). We further explore studies that use remotely sensed data in more detail and highlight the challenges and limitations of field-based and remote sensing-based methods.

Materials and methods

Database and literature search

For this review paper, we only included studies that related to the African elephant and made no distinction between forest and savanna elephants. We were interested in studies that explored the damage or impact of elephants on woody vegetation in conservation and protected areas. We have, therefore, excluded studies on immune-contraception, distribution, movement, population and densities of elephants. However, we sourced information on the densities of elephants in the sub-Saharan region from Thouless et al. (2016). Our review includes English; peer-reviewed articles containing

DOI: http://dx.doi.org/10.15666/aeer/1702_40454066

original research from 1970 to 2017. This review excludes thesis documents and dissertations. We considered all studies from the four sub-Saharan regions (west, east, south and central Africa).

Relevant articles were identified using different keywords in different databases. Data were sourced from the ISI Web of Science during May 2018. “African elephant” was the first keyword used to retrieve studies published on elephants from the database. Two thousand two hundred and fifty-three (n = 2 253) studies dating back to 1972 were retrieved. We refined our search using keywords such as “elephant damage”, “elephant impact” and “woody vegetation” which resulted in 26 studies that matched these criteria. Since the Web of science database only lists articles between 1972 and 2018, we decided to search other scientific databases.

An additional list of 507 studies was sourced from Nexus, SA e-Publications, EBSCOHost, ScienceDirect, Taylor & Francis, ProQuest, BioOne, and SpringerLink using the keywords “elephant damage, “elephant impact,” “woody vegetation” and “Africa.” Studies from these electronic databases, repositories and search engines dated back to 1970, which is two years earlier than the data retrieved from the Web of Science website. Eighty-one (n = 81) studies from this search were relevant and were included in this review. Based on all the retrieved studies (n = 2 253 from ISI Web of science + 507 from above listed additional databases = 2 760), a sample of 106 (n = 26 + 80 = 106) studies were used for this review paper. These studies matched our search criteria and were grouped according to which part of the sub-Saharan region they belong to (eastern, central, western or southern Africa).

From the 106 studies, we extracted the year of publication, authors, methods used, country and location of the study area, and publishing journal and its location. We broadly recognized two types of methods from these studies, field-based (FB) and remote sensing-based (RS). Field-based methods have been extensively used due to their robustness in providing a widely reliable dataset (Buchanan et al., 2013). According to Liverman et al. (1998), field-based studies are generally not sufficient to quantify and analyze patterns of spatiotemporal change at an aggregated level. On the other hand, remote sensing techniques provide useful data sources for quantitatively measuring the dynamics of change processes at the landscape scale by analyzing change trajectories (Mertens and Lambin, 2000). Since this paper intends to provide insight into the types of methods used by scientists to study the impact of elephants on woody vegetation in Africa, we further discuss the limitations of each of the two approaches (field-based and remote sensing-based).

Content analysis

We determined the number of studies using either field-based or remote sensing-based methods per African region. Based on Thouless et al. (2016) report that estimated densities of African elephants in sub-Saharan Africa, we compared the relationship between the number of studies and the estimated number of elephants per region. Information on the national affiliation of the lead and the last author (Bhattacharya, 2010) was extracted for each of the studies. We included the lead author on the basis that the first author is generally the person who did most of the work, while the last author was included on the basis that he or she may have contributed to the work as a supervisor affiliated to an academic institution (Bhattacharya, 2010). We further identified the scientific journals that published all the studies included in this review and whether these were local (within African) or international (outside Africa).

Results

For this review, we identified peer-reviewed studies on the impact of African elephants on vegetation in the sub-Sahara region, which is the natural distribution range for African elephants (Thouless et al., 2016) (*Fig. 1*). A total of (n = 106) papers was retrieved from different scientific databases (*Table 1*). Eighty-seven percent (87%) of the studies used field-based methods (n = 92) while 13% (n = 14) applied remote sensing-based methods for data collection. A list of all peer-reviewed studies, both field-based and remote sensing-based published between 1970 and 2017 is included as *Appendix A*. Field-based studies date back to 1970 and the oldest study that used remote sensing data to study elephant impact on vegetation was done in 1997, which is two decades after the field-based studies. A list of the estimated number of elephants (Thouless et al., 2016) for countries in Sub-Saharan Africa is included as *Appendix B*.

Field-based and remote sensing based methods

We determined countries with records of field-based and remote sensing-based studies and the number of elephants in each country (*Table 2*). Ninety-two (n = 92) of the field based studies are located in Africa, and one study was done in Gal Oya National Park, Sri Lanka (Ishwaran, 1983). This study is excluded in *Table 2* since it was not done in an African park or reserve. Another study area located in East Africa

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40454066

was not specific to a particular reserve or national park (Laws, 1970). Since we could not individually assign it to one specific study location, we have also excluded it from *Table 2*. Fourteen (n = 14) remote sensing-based studies were identified, and only one was located in Africa and not specific to a particular reserve or national park (Duffy and Pettorelli, 2012), and is therefore not included in the data represented in *Table 2*. There is a study that was done in Borgu game reserve, Guinea (Afolayan, 1976) on the impact of elephant activities on woody vegetation, and according to Thouless et al. (2016), there is no record of estimated elephant numbers for the country.

*Field-based studies, **Remote sensing-based studies

We compared the relationship between the top ten African countries with the highest number of elephants to the number of studies from each one of them (*Fig. 2*). We also summarised the type of data used in the remote sensing-based studies (*Table 3*).

Affiliation of the lead and the last author for FB and RS based methods

The majority of the articles' lead and last authors for both field-based and remote sensing-based methods are affiliated with institutions located in South Africa (26%). The United States of America follows South Africa with 17%, United Kingdom and Zimbabwe with 10%, and the rest of the other countries below 3% (*Fig. 3*). There is a relatively equal distribution of lead: last authors ratio affiliations in all the countries, except for Botswana, Netherlands and Uganda with higher numbers of last author affiliations: 3%: 2% for Botswana, 1%: 0% for the Netherlands and 3%: 1% for Uganda.

The highest percentage (6%) of lead and last authors affiliated with institutions in the United States of America were for studies that used remote sensing-based methods. This is followed by Botswana, South Africa and the United Kingdom with 2% each and the rest of the other countries at below one percent. Field-based methods were applied to 73% of the studies compared to 27% for the remote sensing-based methods (*Fig. 4*).

All studies, both field-based and remote sensing-based were published in 43 different journals. Eighty-four percent (n = 36) were in international journals, and 16% (n = 7) were published in local journals (*Table 4*).

Discussion

Southern Africa has the highest number of elephants on the African continent, with an estimated 71% (n = 293 447) of all the elephants on the continent. East Africa has 21%, Central Africa 6% and West Africa 3% (Thouless et al., 2016). The highest estimated elephant distribution range of 1 325 998 km² is in southern Africa, followed by 880 648 km² for East Africa, 783 085 km² for Central Africa and 142 500 km² for West Africa.

The top ten countries with the highest number of elephants include Botswana (131 626), Zimbabwe (82 630), Tanzania (50 433), Kenya (22 809), Namibia (22 754),

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40454066

Zambia (21 967), South Africa (18 841), Mozambique (10 884), South Sudan (7 103) and Gabon (7 058) (*Table 2* and *Appendix B*).

Our results indicate that South Africa produced the highest number of studies on the impact of elephants on woody vegetation and yet has a lower number of elephants compared to Botswana, Zimbabwe, and Tanzania. Botswana has the highest number of elephants but not as many research studies (15 studies) compared to South Africa (33) and Zimbabwe (22). According to Blanc et al. (2007), elephant numbers are increasing in Southern Africa, which may result in an irreversible impact on vegetation, especially in enclosed protected areas with high elephant densities.

South Africa's elephants are kept in fenced-off protected areas, which necessitates intensive management strategies. There are high levels of concern about how elephants influence vegetation and habitats. This explains the demand for increased research and resulting publications in South Africa. Another factor that could explain why South Africa has the highest number of studies could be that it is the most developed third world country on the continent, compared to for example Botswana. The presence and number of academic institutions, collaborative opportunities, and access to research funding, developed and maintained infrastructure, and a large number of protected areas and national parks all contribute towards the number of publications from the country.

Botswana has an estimated 131 626 number of elephants in an area covering approximately 228 073 km^2. South Africa is home to approximately 18 841 elephants in a 30 651 km^2 area (Thouless et al., 2016). The estimated density of elephants equates to 0.6 individual animals per square kilometer (0.6 /km^2) for both countries.

Field-based methods

Field-based methods have been used for many decades in ecological studies. Using field-based methods, information about the extent, spatial variation and resources species preferences by elephants can be studied in detail. Such information is essential for the development of effective management plans for conservation and protected areas. Although FB studies can be impractical and costly when applied in large areas and when large-scale datasets are required on a regular basis, they provide detailed ecological data at smaller scales and need to be simple enough to be widely applied in protected areas with limited capacity (Simms, 2009; Buchanan et al., 2013).

The highest number of studies on African elephants and their influence on vegetation using field-based methods emanated from southern Africa (*Table 2*). Almost half (48%) of the field-based studies are from South Africa, 32% from Zimbabwe and 16% from Botswana. Although Botswana and adjacent areas have the largest population of elephants in the world (Skarpe et al., 2004), only ten field-based studies on the impact of elephants on vegetation are from Botswana. South Africa and Zimbabwe are the most active countries regarding research on the interaction between elephants and plants, with 30 and 20 field-based studies, respectively (*Table 2*). The majority of reviewed studies located in South Africa were done in the Kruger National Park (43%, n = 13) and ten percent each (n = 3) were done for both Venetia-Limpopo Nature Reserve and Addo-Elephant National Park. All field-based studies in Botswana were conducted in the Northern-Botswana area along the Chobe River and Okavango Delta.

The lead and last authors for the field-based methods have affiliations with institutions in South Africa (26%), the US (17%) and the UK (10%). This shows that a significant proportion of field-based research on the impact of elephants is affiliated to Africa, while the US and UK researchers show active involvement.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40454066

Remote sensing-based methods

Remote sensing techniques are cost-effective for application in large areas for collecting large-scale datasets (Duro et al., 2007). Limitations relate to limited funding to acquire satellite images, facilities, accessibility to data and the skills required to manage such datasets.

Botswana applies remotely sensed data more actively than all other countries in the sub-Saharan region (*Table 2*). In southern Africa, five out of 13 studies (38%) who used remotely sensed data were from Botswana, three (23%) were from South Africa, two (15%) from Zimbabwe and one (8%) from Zambia. Only one study per country in East Africa (Kenya and Uganda) used remotely sensed data, while there were no such studies from central and West African countries. Thouless et al. (2016) highlight factors that contribute to the accuracy of elephant densities in different countries, which may also influence the probabilities of executing remote-sensing research studies. Some countries may not have the financial means and expertise to conduct systematic elephant censuses on a regular basis, while countries that have political conflicts may not have the time or finances to do these surveys, let alone research.

Multispectral images such as Landsat and SPOT images, Aerial photographs, MODIS and Normalised Difference Vegetation Index (NDVI) were used in 13 remote sensing-based studies. Three of these studies were done in South Africa and were based in the Kruger National Park. One of them used panchromatic aerial photographs and digital SPOT imagery (Munyati and Sinthumule, 2016), while the other two used state of the art hyperspectral satellite imagery to capture the three-dimensional (3D) structure of vegetation (Asner et al., 2009; Levick et al., 2009). Both of the studies used LiDAR imagery to study the large-scale impact of herbivory on the structural diversity of vegetation. Levick et al. (2009) also highlight the value of 3D remote sensing in the assessment of conservation management outcomes.

The lead and last authors for remote sensing-based methods are mostly affiliated with institutions in the USA (6%), followed by Botswana, South Africa and the UK with 2% each. The low number of lead and last authors with affiliations in Africa may suggest that foreign institutions have financed the research conducted in Africa. Alternatively, this could relate to a slow transfer pace of technology and skills by developed countries to developing countries.

Publishing scientific journals

From the 43 scientific journals (*Table 4*) that published the reviewed studies in this paper, 84% (*n* = 36) were from outside the African continent, and only 15% (*n* = 7) were in journals from within Africa. The 14 studies that used remote-sensing data were published in journals outside the African continent, while 22 of the field-based studies were in African journals and 70 in journals outside Africa. The Journal of Tropical Ecology (United States of America – USA) published the highest number of studies (*n* = 13) followed by the African Journal of Ecology (England) publishing eleven. Within Africa, 19 of the field-based studies were published in five South African journals (Koedoe, SA Journal of Botany, SA Journal of Science, SA Journal of Wildlife Research and the Transactions of the Royal Society of South Africa), two studies in a Kenyan journal, Pachyderm and one in a Zimbabwean journal, Kirkia. No remote sensing studies were published in any of the African journals. The South African

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40454066

Journal of Wildlife Research published the majority of the South African studies (n = 7) followed by Koedoe (n = 6).

Elephants are major agents of change to woody vegetation as observed in some studies (Anderson and Walker, 1974; Caughley, 1976; Guy, 1976). Despite elephants modifying woody vegetation, Thomson (1992) alluded that no protected area in Africa is big enough to maintain elephants in a healthy state indefinitely without population management manipulation. Culling elephants, as a means of preventing woody vegetation loss is unlikely to produce the desired effects (Ben-Shahar, 1996a) since there is adequate production of browse available for elephants in drought years. The use of contraceptives is impractical for elephant cows due to the requirement for frequent follow-up treatments. Contraceptives are expensive to administer for both elephant cows and bulls. As our protected areas become overpopulated with increasing numbers of elephants, three things are bound to happen: (i) destruction of woodlands that will be replaced by mixed scrubland/grassland or degraded savanna; (ii) a catastrophic crash of elephant populations; and (iii) loss of plants and animals (Thomson, 1992).

Collecting ecological data on a regular basis from large, inaccessible and often dangerous areas (due to the presence of lion, leopard, rhinoceros, buffalo and elephant) using field-based methods can be challenging. Limitations relate to accessing rugged terrain, large areas to traverse, time constraints and financial implications. Using remote sensing techniques integrated with traditional field-based approaches, we can identify the biophysical characteristics of landscapes, predict species distributions, determine spatial variability in species richness, and monitor the impact of species on their environment (Kerr and Ostrovsky, 2003; Kohi et al., 2010) with less time spent in the field. Limitations of remote sensing techniques include the need to be integrated with field-based observations to validate results (Reinke et al., 2006). Collecting remotely sensed data could be very costly, with limited access in some instances. It is crucial to identify appropriate imaging characteristics (such as spatial and spectral resolution) suitable for processing and extracting relevant and vital information (Adam et al., 2010). Garrity et al. (2013) identified a shortcoming in detecting trees that are in various stages of morbidity due to the limited availability of archived satellite imagery. Regardless of the recognized limitations to using remotely sensed data, it is still a valuable tool that continues to prove its potential for use in a wide range of vegetation studies providing timely, up-to-date and accurate information for sustainable and effective management of vegetation (Adam et al., 2010).

We have noted the lack of available published studies on the use of remotely sensed data to map the small-scale impact of African elephant on woody vegetation. Only two reviewed studies used hyperspectral images to determine the large-scale responses of vegetation and ecosystem structure to the presence/absence of herbivory (Asner et al., 2009) and to gain insight into the influence of fire and herbivory to the structure and heterogeneity of savanna vegetation (Levick et al., 2009). Northern Botswana is known to have the highest density of elephants in the world (Skarpe et al., 2004) and the majority of studies from Botswana reported that elephant damage to vegetation is not significant. As noted by Ben-Shahar (1996b), the impact of elephants is generally distributed randomly. Some authors used field-based methods to study the effects of elephants on woodland modification and the implications this has on the diversity of bird species (Herremans, 1995) and the nesting sites of Southern Ground Hornbill (Henley and Henley, 2005). The placement of artificial water points influences tree biomass (Ben-Shahar, 1996a) and structure (Kalwij et al., 2010). Tall tree densities are

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40454066

affected by elephants in mopane woodlands (Ben-Shahar, 1998). From these studies, the impact of elephants was not significant, and in other instances, woody biomass and densities remained unchanged, except for new damage to vegetation during the dry season, which was recorded by Ben Shahar (1996b).

Conclusion

Field-based methods have been extensively used in ecology since the 1960s and are still effectively used. From reviewed studies on the impact of elephants on woody vegetation that applied field-based methods, we have noticed a steady increase from an average of two studies per year before the 20th century, to an average of four studies after the 20th century. These methods provide detailed and reliable datasets. This is an indication that field-based methods are still relevant today, even with advancements in technology in the form of remote sensing techniques.

Remote sensing and GPS technology have also been utilized to track elephant movements (Kahumbu, 2002; Bohrer et al., 2014; Xu et al., 2017). Field-based methods are utilized in combination with remote sensing techniques for field observations. Although remote sensing techniques offer cost-effective and repeatable ways for regular data collection and monitoring for trends, there is also a fieldwork element associated with it. However, using remote sensing techniques, time and labour required for field surveys, especially on an annual basis, are drastically reduced (Jensen, 2005). The results of our reviews indicate that there is a limited amount of studies that used remote sensing-based methods for studying the impact of elephants on woody vegetation. Even the available studies are sparsely distributed between 1997 and 2017, with three studies published in 2009, two of which were done in the Kruger National Park, South Africa and one in Hwange National Park, Zimbabwe.

Guldemond et al. (2017) call for the management of habitats used by elephants to maintain the heterogeneity of Savanna, with particular attention to important tree species of conservation value. These can only be achieved with improved and efficient methods of data collection. Remote sensing techniques can be useful and practical and should be used in conjunction with field-based methods for improved data collection, analyses and interpretation. However, there is a need for the transfer of technology and skills, capacity building and increased support to Africa. Access to quality remotely sensed data needs to be improved to promote the use of this technology and its integration into nature conservation disciplines to address conservation research questions about vegetation trends and responses to impact. Collaborative projects between skilled remote-sensing and field-based researchers are recommended to increase research capacity and the use of technology.

Based on the studies we reviewed our conclusions suggest that the use of remote sensing techniques in studying the impact of elephants on woody vegetation are currently limited. The limited number of studies that applied remote sensing-based methods are in Africa. We therefore encourage the integration of data collected from both remote sensing technology and field-based methods for monitoring the influence of elephants on woody vegetation. Remote sensing techniques are continuously improving and incorporating data collected with the latest technology will enhance habitat management strategies in the future. It is important to highlight that most African countries are in a developmental stage with limited resources and capacity. We also recommend that researchers should take advantage of available novel tools such as

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40454066

remote sensing technology to explore its practical and cost-effective applications to managing environments containing elephants, especially in a world that is becoming tech-savvy.

We would like to thank Mrs L Adriaanse from UNISA Library Services for providing and sourcing the list of articles from Nexus, SA e-Publications, EBSCOHost, ScienceDirect, Taylor & Francis, ProQuest, BioOne, and SpringerLink databases. This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors. We applied the "sequence-determines-credit approach" (SDC) for authors in this paper.

(Received 1st Dec 2018; accepted 20th Feb 2019)

Abstract. In order to study the variation of solar activity and reveal its relationship with the intensity change of East Asian summer monsoon (EASM), the sunspot time series and EASM intensity index are calculated by using sunspot relative number (SRN) data and sea level barometric data respectively. Then, Morlet wavelet analysis and correlation analysis are used to reveal the interdecadal characteristics of solar activity and EASM changes with their relationship. The results show that after the 1940s, the SRN and the fluctuation amplitude of the EASM index increased gradually, and reached the maximum from the 1950s to the mid-1960s. The influence of solar activity on the interdecadal variations of EASM is significant, with the same 40-year and 11-year cycles. The correlation between them is relatively good on the centennial scale, showing a "- + -" correlation with time change.
Keywords: *sunspot relative number (SRN), wavelet analysis, monsoon index, periodic signal, interdecadal variation*

Introduction

Solar activity is one of the main driving factors of global climate and environmental change. The relationship between solar activity and medium-term and long-term climate changes larger than or equal to 10 years has become a research hotspot in climatology in recent years (Zhao et al., 2012; Gray et al., 2016). Solar activity may affect regional climate in two ways. On the one hand, the abnormal changes of solar radiation affect the weather, climate and ocean thermal state. On the other hand, by stimulating the anomaly of the earth's magnetic field which fills the whole space of the earth, the motion state of the ocean and atmosphere changes, resulting in climate changes including weather scale, interannual scale, interdecadal scale and century scale (Haigh, 1996; Li et al., 2013; Yin et al., 2017). Study results have shown that solar activity is the basic factor affecting the temperature change over 10 years (Hood and Soukharev, 2012; Antico and Torres, 2015), and temperature change can lead to the change of zonal temperature gradient and Hadley circulation, and then affect the long-term change of monsoon (Li et al., 2018a, b). There is a strong correlation between solar activity and Asian monsoon activity. Neff et al. (2001) found that there is a strong correlation between the summer monsoon precipitation and the solar activity in the past 3000 years. The intensity of Indian monsoon in the past 1200 years corresponds well with the intensity of solar activity, and they have the same 200-year and 100-year cycles (Agnihtri et al., 2002). The results of Wang et al. (2005) showed that the rotation speed of the earth and the length of sunspot cycle are the main factors that restrict the interdecadal variations of Asian monsoon. The high-frequency variations of the East Asian summer monsoon (EASM) climate are driven by solar activity, and the 10-100-year monsoon climate

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40674080

variations are basically consistent with the solar activity cycle (Wu et al., 2006). However, the relationship between solar activity and EASM intensity, which has a significant impact on climate, remains to be studied.

China is a typical monsoon region in the world. The temperature and precipitation of interannual, interdecadal and even intercenturial climate changes in China are affected by the EASM (Hsu et al., 2011; Sun et al., 2015; Ding et al., 2018). Therefore, it is of great importance to study the interdecadal variations of EASM for understanding the causes of interdecadal climate variations of China. In order to further and quantitatively study the multi-time scale changes of monsoon and to have a consistent understanding of the characteristics of strong and weak monsoon, many scholars have established various indices reflecting the strength of EASM based on different data and methods (Guo, 1983; Wang et al., 2001; Sun et al., 2002; Zhang et al., 2003). For example, Guo (1983) defined the EASM index by using the East-West sea-level atmospheric pressure difference, which to a certain extent reflects the difference of sea land thermal power determining the EASM through the difference of land-sea pressure system, and the index has a relatively good effect in reflecting precipitation. These studies show that the period from 1951 to the mid-1960s has strong summer monsoon, after which the summer monsoon weakens, and after 1976, the intensity of summer monsoon weakens again.

It can be seen from the above that due to the lack of data before 1948, the time range of the study was concentrated in the later period, and the time series was short, so the long-term variation trend and interdecadal variation characteristics of EASM intensity were not known. Since only the UK's sea level pressure (SLP) data can be dated back to 1850, this paper uses the monthly SLP data after 1850 released by the UK's Hadley center to form a long-term EASM index series and study its interdecadal variation characteristics. At the same time, the relationship between solar activity and EASM is still unknown from the above analysis. Therefore, this paper attempts to study the characteristics of solar activity and monsoon intensity change on a centennial scale, to find the relationship between them, and to reveal the possible interaction and influence ways, so as to provide indicative information for the EASM forecast.

Data and methods

Sea level atmospheric pressure data (HadSLP2) released by the Hadley Center. Time: 1850-2006, monthly average; Space: 5 *5 degree grid global coverage. The research scope selected in this paper is "20-50°N, 110-160°E". This set of data is the second edition released by Hadley Center. It is the longest SLP data at present, and is conducive to calculating the East Asian summer monsoon index for more than 100 years.

The annual average sunspot relative number (SRN) data, published by the Solar Activity Data Analysis Center (SIDC), Institute of solar physics, the Royal Observatory of Belgium, time: 1700-2006.

The main methods used are Morlet wavelet analysis, correlation analysis and Butterworth bandpass filtering.

Morlet wavelet analysis has the characteristics of multi-resolution analysis, and is able to characterize the local characteristics of signals in both time and frequency domains. Wavelet transform decomposes the time series into the time-frequency domain, and then obtains the significant fluctuation patterns of the time series, i.e., the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40674080

periodic change dynamics and the temporal pattern of the periodic change dynamics. In essence, the signal is decomposed by a function's wavelet sequence, which is obtained by scaling and translation of a basic wavelet (wavelet base) or mother wavelet. The scaling and translation are carried out simultaneously in the mother wavelet function. Mother wavelet plays a key role in scale selection and wavelet transform. The applicability of the wavelet function should be fully considered in the selection of the wavelet functions, because the wavelet function used in the wavelet analysis is not unique, i.e., the wavelet functions are diversified. Analyzing the same problem with different wavelet bases will produce different results. At present, the results of signal processing and theoretical results of wavelet analysis are mainly used to evaluate the quality of the wavelet bases, and then the wavelet bases are selected. Morlet wavelet is a complex form of wavelet. It can separate the modulus and phase of the wavelet transform coefficients, where modulus represents the number of components of a certain scale, and phase can be used to study the singularity and instantaneous frequency of signals (Wang et al., 2005).

Correlation analysis method is to calculate the correlation coefficient of any two meteorological elements. It is used to measure the statistical quantity of the relationship between two meteorological elements. The correlation coefficient r_{xy} is the correlation between n time series x_i and another time series y_i. The calculation method is *Equation 1*.

$$r_{xy} = \frac{\sum_{i=1}^{n}\left(x_i - \bar{x}\right)\left(y_i - \bar{y}\right)}{\sqrt{\sum_{i=1}^{n}\left(x_i - \bar{x}\right)^2 \sum_{i=1}^{n}\left(y_i - \bar{y}\right)^2}} \qquad \text{(Eq.1)}$$

Variation characteristics of SRN

Sunspot is considered as the main body of solar activity, and its variation is very regular. It is often used as an important indicator of the intensity of solar activity. In this paper, the interdecadal variations of solar activity are studied by using the SRN data published by the SIDC of the Royal Observatory of Belgium. As can be clearly seen from *Figure 1,* the SRN has a marked upward trend on the whole, and the fluctuation amplitude of sunspot number in the past three hundred years increased gradually after the 1940s.

Results

Interdecadal variations of sunspot activity

In order to study the periodic variation characteristics of solar activity, Morlet wavelet analysis is performed on the SRN series. From the wavelet transform (*Fig. 2a*), it can be seen that there are obvious quasi-periodic oscillations at the levels of 80, 100, 40-50 and 11 years in the variation of the intensity of sunspot activity. At the 50-year level, the SRN has weakened since the 1960s, and the wavelet values and amplitudes have decreased significantly. The changes of 50-year cycles gradually weakened and disappeared, and turn into 40-year cycles. At the 11-year level: from the 1940s to the end of the 1980s, solar activity changes most dramatically. From 1950s to mid-1960s,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40674080

the solar activity is the strongest in more than 300 years, which corresponded to the positive center of 180, 100, 40 and 11-year cycle changes. Secondly, from the 1970s to the 1990s, and from the 1930s to the 1950s, there are also two periods of strong solar activity. Since the solar cycle gradually changes from 50 years to 40 years around 1850, the wavelet variance series of 1700-1850 and 1851-2006 are analyzed respectively. From 1700 to 1850 (*Fig. 2b*), the most prominent period of solar activity is about 100 years, followed by 11 years and 50 years, and finally by 180 years. The 40-year cycle does not show up in this period. From 1851 to 2006 (*Fig. 2c*), the 11-year cycle becomes the most prominent cycle of solar activity, followed by the 100-year cycle, and then the 180-year cycle. The 50-year cycle no longer existed in this period, but a weaker cycle appeared in the 40-year scale. Han and Han (2001, 2002) pointed out that many periodic components of solar activity are not fixed, but have varying degrees of uncertainty and time-varying characteristics. That is, the period length, amplitude and phase change with time, which is consistent with the results of this paper.

Interdecadal variation characteristics of EASM

Intensity variation of EASM

In order to reveal the interdecadal variability of the EASM and its relationship with solar activity, the EASM index is selected and compared. Since the monsoon system is affected by the high and low latitudes systems at the same time, and there are interactions and constraints among various factors, each monsoon index can only describe one aspect of the characteristics of the monsoon better. At present, there is still no index that can describe the characteristics of monsoon variations in all aspects comprehensively. Considering the long-term nature of the time scale of the data, this paper chooses the method of calculating the EASM Index (EASMI) defined by Guo (1983), The strength of EASM is represented by the cumulative sum of △P ≤ -5 hPa at each 10 latitudes (∑△P) through the 110-160°E pressure difference (△P), between June and August 20-50°N. That is:

$$I_{\text{EASM}} = \sum \triangle P\left[SLP\left(20-50^{o}N,\ 110-160^{o}E\right)\right] \quad \text{(Eq.2)}$$

Figure 3 shows the East Asian summer monsoon index series calculated by *Equation 2* and normalized. As can be clearly seen from *Figure 3,* the EASM

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40674080

experienced four stages of strong-weak-strong-weak change in 1850-2006, which is non-linear and a long-time scale fluctuation. From the 1950s to the mid-1960s, the intensity of the EASM increased in general, and it reached its strongest stage in the 1950s and 1960s. This stage is also the strongest stage of solar activity analyzed in *Figure 2a,* which has been decreasing since the mid-1960s. The intensity of EASM changed abruptly in the mid-1960s and experienced a transition from the strongest to the weakest. Weak summer monsoon lasted until 2006, it reached its weakest stage after the mid-1970s. It is noteworthy that the fluctuation amplitude of the EASM increased gradually after the 1940s. Compared with the time series curve of SRN in *Figure 1,* it can be seen that the fluctuation amplitude of SRN has also increased gradually since 1940s. In conclusion, it can be concluded that the intensity of sunspot activity oscillation may be one of the reasons for the intensity oscillation of EASM.

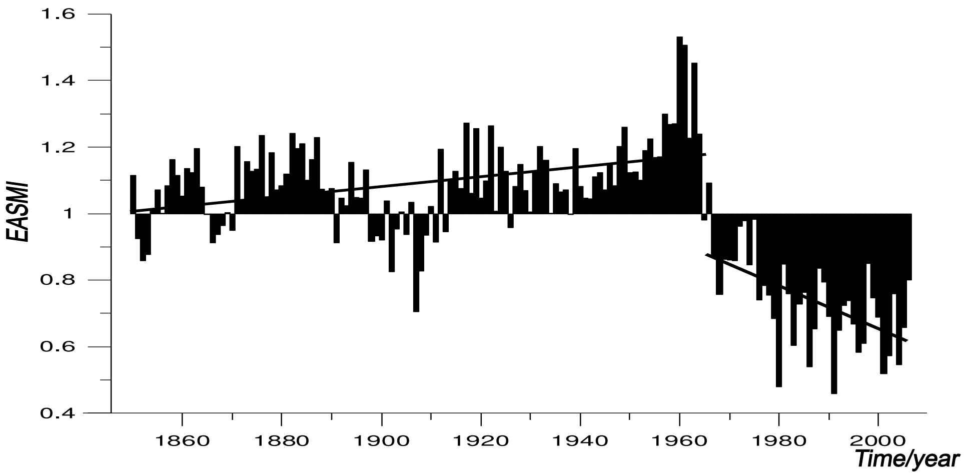

Figure 3. *EASM Index series (Dimensionless, oblique line is trend line)*

Interdecadal variation period analysis of EASM

From the previous analysis, we can see that the solar activity shows some interdecadal periodic changes. In order to study the possible relationship between solar activity and EASM, the wavelet transform and wavelet variance maps of the above-mentioned EASM indices are presented, and their periodic variation characteristics are analyzed.

As can be seen from *Figure 4a,* the EASM in 1850-2006 has obvious quasi-periodic oscillations in the levels of 80, 40, 20 and 10-13 years. The 40-year cycle has a decreasing trend since the 1950s; the 20-year cycle has increased since the 20th century, with an increasing trend of amplitude; and the 11-year cycle has also gradually increased since the 1950s. It can also be seen that the period from 1950s to mid-1960s was the strongest period of EASM. The density, numerical value and time level of the wavelet transform curve in this period was the largest in 157 years, and then followed by the weakest period of EASM, which is consistent with the previous analysis results. From the wavelet variance figure of *Figure 4b,* it can be seen that the main interdecadal period of the EASM is about 80 years, followed by about 40 years. In addition, there is a weak period of about 11 years. The period of about 20 years is not shown in the wavelet variance map because of the weak signal.

Relationship between EASM and solar activity

The above analysis shows that the solar activity has the same 40-year and 11-year cycle as the EASM intensity change. EASM and solar activity reached the strongest in all years from 1950s to mid-1960s. Therefore, the influence of solar activity on the interdecadal variation of the EASM intensity does exist. Comparing the EASM index and sunspot number series from 1850 to 2006, it is found that before the mid-1960s, both of them had an increasing trend, and then they changed in the opposite direction. In order to discuss the interdecadal correlation between the two, the 157 EASM index is averaged by a nine-year moving window, and the interannual variation information is filtered out. Then the sunspot number is averaged by an 11-year moving window, eliminating its inherent 11-year cycle. In this way, the interdecadal relationship between EASM intensity and solar activity can be better reflected. The smoothed values are shown in *Figure 5*. The variations of the EASM and sunspot activity are not always consistent. The EASM and sunspot number curves show obvious negative correlation changes before the 20th century, then positive correlation changes from the beginning of 20th century to the mid-1960s, and then negative.

Kilcik et al. (2007) studied the influence of solar activity on climate from 1940 to 1984, and concluded that there was a positive correlation between solar activity

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40674080

parameters and terrestrial atmospheric temperature before 1966, but a negative correlation after 1966, which is consistent with the results of this study. The correlation coefficients between the moving averaged EASM index and the SRN are calculated. The results show that the correlation coefficients are -0.845 before 1910, 0.723 between 1911 and 1965, and -0.489 after 1966, all exceeding the reliability test of 0.001. Based on the wavelet analysis of sunspot activity, it is found that the correlation between EASM and sunspot activity is affected by the 100-year cycle of solar activity. When the sunspots number decreases from the peak in 1850 to the valley in 1910 on a centennial scale (*Fig. 2a*), there is a negative correlation between the sunspots number and EASM index, i.e., EASM is strong in the year with weak solar activity, while it is weak in the year with strong solar activity. When the sunspot number transits from the valley value in 1910 to the peak value in 1965, EASM index is positively correlated with solar activity, i.e., EASM is strong when solar activity is strong, and is weak when solar activity is weak. Similarly, since 1965, solar activity has shifted from peak to valley on a centennial scale, and the relationship between them has changed again. It can be concluded that solar activity not only has a strong influence on the intensity change of EASM at interdecadal scale, but also is an important factor that can not be ignored in influencing the intensity change of summer monsoon at centennial scale.

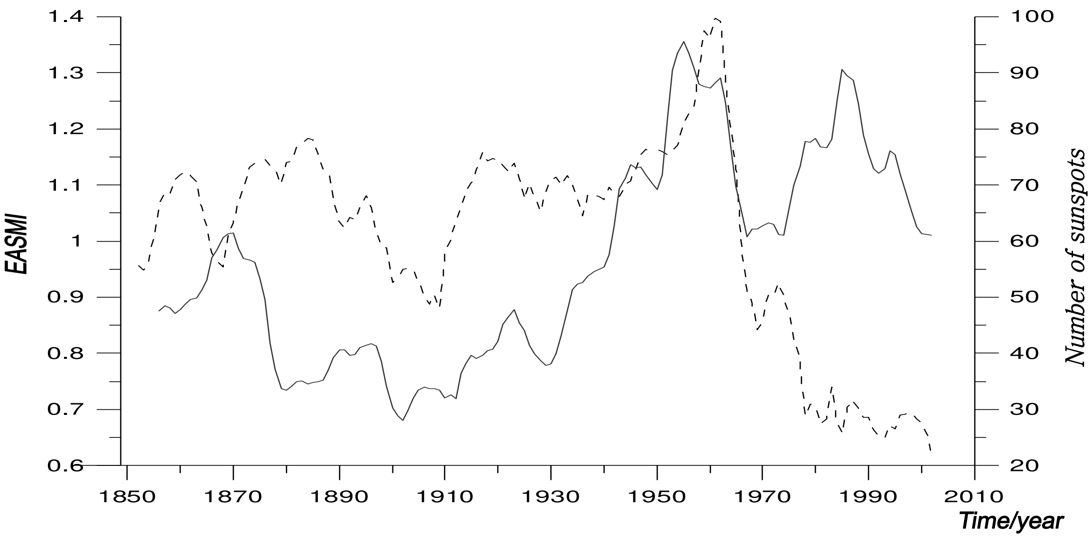

Figure 5. *Moving average curve of SRN (real line) and EASM index (dotted line)*

Analysis of solar activities affecting interdecadal variation of EASM intensity

The interdecadal variations of solar activity and EASM intensity are well correlated. Based on the previous analysis, the influence information of solar activity in the EASM index series is extracted and analyzed step by step in this section. When the information is separated from the concealed state, the relationship between them can be revealed, which provides a new basis for the interdecadal variation of the EASM.

The analysis of the EASM intensity index shows that in the mid-1960s, EASM changed dramatically. Before the mid-1960s, EASM generally strengthened. After reaching the strongest point in the mid-1960s, it suddenly changed and weakened, and then entered the period of weak summer monsoon. The trend line in *Figure 3* shows the trend changes before and after the sudden change of summer monsoon.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40674080

When $i = 1, 2, 3......117$, $l_1(i)$ represents the trend state before the sudden change;
When $i = 118, 119......157$, $l_2(i)$ represents the trend state after the sudden change;
The general trend changes:

$$l(i) = l_1(i) + l_2(i) \qquad i = 1, 2, 3......157 \tag{Eq.3}$$

By subtracting the climatic trend $l(i)$ in *Equation* 3 from the original summer monsoon index series $I_{sm}(i)$, the summer monsoon index series without climatic trend, $Y_{sm}(i)$, can be obtained.

$$Y_{sm}(i) = I_{sm}(i) - l(i) \tag{Eq.4}$$

The mean square deviation of the original summer monsoon index series $I_{sm}(i)$ is obtained.

$$S = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(I_{sm}(i) - \overline{I_{sm}})^2} = 0.204 \tag{Eq.5}$$

where $\overline{I_{sm}}$ is the average EASM index for 157 years during 1850-2006. Similarly, the mean square deviation of EASM index series after the trend change is filtered out according to *Equation 5:*

$$S_1 = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(Y_{sm}(i) - \overline{Y_{sm}})^2} = 0.129 \tag{Eq.6}$$

where $\overline{Y_{sm}}$ is the average of EASM index series $Y_{sm}(i)$ defined in *Equation 4* after filtering out trend change during 1850-2006. Then the variance contribution of trend change to the summer monsoon index series is as follows:

$$\begin{aligned} SS &= [(S - S_1)/S] \times 100\% \\ &= [(0.204 - 0.129)/0.204] \times 100\% = 37\% \end{aligned} \tag{Eq.7}$$

In the formula, *S* and S_1 are calculated by *Equations 5* and *6* respectively. The variance contribution of the trend is 37%, i.e., the increase of EASM intensity before the mid-1960s and the subsequent abrupt decrease are the basic characteristics of the change in the whole 157 years.

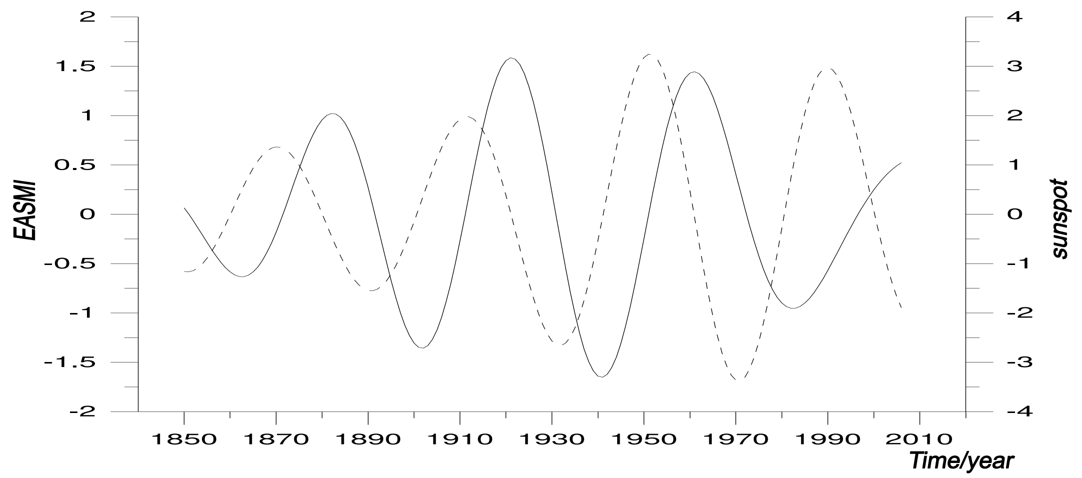
The wavelet analysis of EASM index and SRN shows that there exists the same 40-year and 11-year cycle between EASM and sunspot activity. The 40-year periodic component series of EASM $l_{40}(i)$ is obtained by band-pass filtering. By subtracting 40-year cycle components from the original summer monsoon index series, the index series without 40-year cycle $Y_{sm}(i)$ can be obtained. The mean square deviation of $Y_{sm}(i)$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40674080

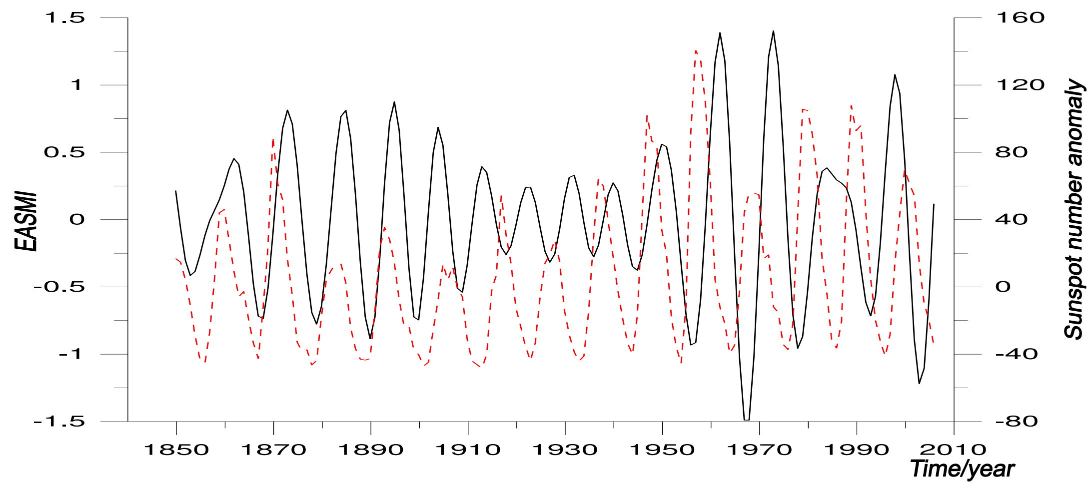
obtained from *Equation 5* is 0.159. According to *Equation 7,* the contribution of 40-year cycle change to the variance of summer monsoon variability is 22%.

It can be seen that the 40-year cycle is one of the main cycles of the EASM. Using the same method, the variance contribution rate of 11-year cycle is 14%, and that of 80-year cycle is 25%, which ranks only second to trend change.

The 11-year and 40-year cycles play an important role in interdecadal variations of the intensity of the East Asian summer monsoon. In order to further understand the influence of 11-year and 40-year cycles of solar activity on the variation of EASM, the wavelet component curves of the EASM index and SRN in the period of 40 and 11 years from 1850 to 2006 are plotted in *Figure 6*.



a



b

Figure 6. a *40-year wavelet periodic component curve of EASM index and SRN.* ***b*** *11-year wavelet periodic components of EASM index and anomaly values of SRN. (Real line and left coordinate are EASM index, while dotted line and right coordinate are SRN)*

As can be seen from the figure, there is a good positive correlation between the variation of EASM and the 40-year cycle of sunspot (*Fig. 6a*). The same is true for the magnitude. When the magnitude of sunspot variations increases, the magnitude of EASM variations also increases, and the sunspot number is about 10 years ahead of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40674080

summer monsoon. In the time scale of 11-year cycle (*Fig. 6b*), the variation curves of the two are generally similar. Before 1910, the variation of sunspot number is isotopic. The variation of sunspot number is 1-3 years ahead of that of EASM index. From 1910 to 1940, the two gradually changed into inverse phases, and the variation ranges were gentle. After 1940, the two phases gradually changed into the same phase. The magnitudes of the two increased obviously, but the magnitude of the EASM lagged behind the solar activity. The above analysis shows that the influence scale of sunspot activity on EASM variations is from 11 to 40 years, i.e., solar activity plays a decisive role in EASM variations on the “decadal” time scale.

Discussion

In this paper, the cycle analysis of the SRN and the EASM index variations shows that there is a close relationship between them: the fluctuation amplitude of the two shows a similar trend, with the same change period and strong correlation, and the variations of the EASM lag behind the changes of the SRN. The EASM seriously affects the weather and climate in China and East Asia. Therefore, it is of practical significance to analyze the solar activity to predict the intensity of the summer monsoon and then forecast the weather or climate conditions. At present, most studies focus on the characteristics of solar activity itself (Baldwin and Dunkerton, 2005; Frame and Gray, 2010) and the influence of solar activity on precipitation, temperature and other climatic factors (Maliniemi et al., 2014; Ge et al., 2016). Since some weather and climate systems, such as monsoons, directly influence precipitation. It is also beneficial to reveal the physical mechanisms of the sun affecting climate. Studies have yielded some useful results from this very point (Kerr, 2005; Verschuren et al., 2009), but there has been a lack of research on the East Asian monsoon. Because local climate systems vary from region to region, this paper is of certain value for the relevant research of EASM.

However, the effect of solar activity on interdecadal variations of EASM, and the law of solar activity affecting the variations of EASM are very complex, non-linear in different periods and time scales. Many problems still exist and need to be solved. Small changes in solar radiation over the 10-100-year scale can neither directly cause significant heating changes in the Qinghai-Tibet Plateau, nor affect the EASM. However, solar activity may affect the summer monsoon through atmospheric or oceanic circulation (Zhou and Chen, 2014). At present, the mechanism of solar activity changes affecting East Asian monsoon is not clear. More factors, such as sunspot magnetic field and total solar radiation (Qi et al., 2015), need to be considered to comprehensively study the ways and mechanisms of solar activities affecting EASM through atmospheric ocean circulation and ground radiation, etc.

Conclusion

In this paper, the main characteristics and main periodic variations of sunspot activity on a centennial scale are analyzed. The interdecadal variations of the EASM and their correlation with sunspot activity are discussed. Morlet wavelet technique is used to discuss them, revealing their common periods and analyzing them separately. The real change of climate factors is the combination of all effective signals and noise signals, i.e., the superposition of different periodic signals. Although the signal obtained by this

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40674080

method is only one of its “components”, the change of “original” information can be basically mastered by clarifying the change law of these basic periods. Therefore, it is significant to determine the interaction between these basic cycles for the analysis and prediction of interdecadal variations of EASM. The following conclusions can be drawn from this study:

From 1700 to 2006, SRN showed an obvious upward trend, and its fluctuation amplitude increased gradually after 1940s. On the centennial scale, before the 1960s, the sunspots number had significant 11-year, 50-year, 100-year and 180-year cycles, and then 50-year cycles changed to 40-year cycles.

There is a strong correlation between solar activity and EASM intensity variations on the centennial scale, showing a “- + -” correlation with time. The intensity of sunspot activity oscillation is one of the reasons for the intensity oscillation of EASM. Both of them reached their maximum from 1950s to mid-1960s, and they have the same 40-year and 11-year cycles.

The influence scale of sunspot activity on EASM variations ranges from 11 to 40 years. That is to say, solar activity plays a decisive role in EASM variations on the “decadal” time scale. The correlation between sunspot activity and EASM variations is regulated by solar activity on the centennial scale.

Abstract. The objective of this study was to perform the hierarchization procedure of habitat physical-chemical properties of peat bog waters in a five-year research cycle. The identification of important abiotic habitat properties in the context of the analyzed boreal plant relics' occurrence determines the mechanisms of their active protection, and in the case of useful plants with high medicinal values – the possibility of their ecological cultivation. The procedure covers desk studies involving source data analysis, field reconnaissance with selection of study sites, botanical-phytosociological analyses, and laboratory analyses of the abiotic properties of the habitat. The complex statistical analysis of the obtained data including descriptive statistics, non-parametric Kruskal-Wallis test, and multidimensional methods permitted the designation of range values for properties favoring the occurrence of the studied plant species. The procedure finds practical applications for both for the active protection of endangered plant species and other useful plants.
Keywords: *boreal relic, herbs, peat bog, habitat, physical-chemical factors, research method*

Introduction

Relevant literature quite frequently discusses the issue of conducting habitat research in the context of protection of rare plant species or importance of ecological conditions for proper growth and development of useful plants (e.g. Aleric and Kirkman, 2005; Zhang et al., 2002; Kostrakiewicz, 2008; Reckinger et al., 2010). Depending on the species, specificity of their biology and ecology, and the study objective, authors consider different environmental factors, from light conditions, temperature, and humidity (Matsumoto et al., 2000), through biogenic compounds (Wassen et al., 2005), to a combination of many largely varied environmental properties, which combined determine the quality of the habitat (Kumar and Stohlgren, 2009).

An example of a broad application of results of habitat research in reference to the key processes of the biology of a species threatened with extinction is the paper by Hroneš et al. (2018). The determination of the specificity of habitat conditions at the mountain sites of occurrence of the population of a rare relic species *Salix lapponum* in the Czech Karkonosze Mountains involved the application of results of research on both abiotic and biocoenotic environmental properties. First, floristic inventories performed in 207 study plots were analysed in terms of habitat preferences of all plant species,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40814096

based on the ecological index numbers of vascular plants (Ellenberg et al., 1991). The following factors were considered: temperature, light, continentality, moisture, soil reaction, nutrients. The co-occurrence of plant species in the studied communities was also analysed. The next stage was the analysis of 207 soil samples in terms of basic soil properties, i.e. pH, N ($g \cdot kg^{-1}$), P ($mg \cdot kg^{-1}$), Ca, and Mg ($mg \cdot kg^{-1}$). The study results were compared to data concerning blooming or lack of blooming of individuals of the studied species. The authors initially evidenced differences in conditions occurring in microhabitats in which individuals bloom more frequently.

Data concerning abiotic environmental factors are also used for the purpose of improvement of the state of preservation of endangered plant species. Adhikari et al. (2012) designated a potential area and habitat for the reintroduction of *Ilex khasiana* Purk by means of the algorithm of modelling maximum entropy distribution (MaxEnt). The model was developed with the application of 16 data on the location in native range and 16 environmental parameters.

The analysis of results of habitat research by Nicolè et al. (2011) among others permitted answering the question in what way the dynamics of the population of the endangered high mountain plant *Dracocephalum austriacum* depends on the local quality of the habitat and climatic variability.

The reconstruction of habitats does not always permit the reintroduction to the environment of rare plant species. According to Kleijn et al. (2008), it may partially result from the inability to reconstruct the specific biogeochemical conditions preferred by such species. Many variables concerning habitat conditions have been evidenced to affect the condition of plants – in this case rare species of heathers in Holland, but it remains unknown what their relative importance is and whether any biogeochemical variable acts as the key factor limiting their maintenance.

Habitat research is also used for the analysis of the possibility of future cultivation of useful plants. The objective of the study by Sugier et al. (2011) was the determination of the content of phenol glycosides in the bark of dark-leaved willow (*Salix myrsinifolia*). The bark of the species was determined to be a potential source of salicylates, hence the proposal of introducing the species to cultivation. The study involved among others the determination of habitat conditions of natural functioning of the species. Characteristics of plant communities with a contribution of the studied species, and selected abiotic properties of the habitat were determined through the analysis of soil samples in terms of content of organic matter, macro- and microelements, and reaction.

The objective of this study is to present a developed complex procedure of hierarchization of abiotic habitat properties related to groundwaters of peat bog ecosystems of the Łęczna-Włodawa Lake District (Polesie Podlaskie, East Poland). The procedure was developed in reference to research concerning the specificity of occurrence of protected relic species – *Salix lapponum*, *Salix myrtylloides*, and *Betula humilis* (Serafin et al., 2015a, b, 2018a); and species of plants with medicinal properties, namely *Menyanthes trifoliata* and *Oxycoccus palustris* (Serafin et al., 2017, 2018b) at sites representative of the region where the measurements were performed (subjective assessment).

The identification of abiotic properties of the habitat important for the occurrence of these groups of plants, related to groundwaters, can provide the basis for the selection of the right strategy of active protection of endangered plant species, e.g. in the case of their reintroduction. It also allows for the determination of the conditions of potential ecological cultivation of peat bog plants with high useful potential, e.g. medicinal, in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40814096

this case for naturotherapy – obtaining a natural composition of biologically active substances in cultivated herbal material (feature of natural medicine).

The popularisation of the procedure of hierarchization of abiotic habitat properties therefore seems to be a pragmatic measure.

Methodological concept and practical application

The developed procedure covers multiple-stage research: desk studies including the analysis of source texts; field reconnaissance for the selection of the right locations for conducting research, field research for botanical-habitat analyses at selected study sites, and laboratory analyses for the determination of the value of physical-chemical water parameters.

The applied statistical methods permit the interpretation of results and identification of factors important for the proper functioning of the studied plant species.

Study sites and procedures

Ecological analyses of different plant species require a complex approach to the selection of the study area. An optimal solution seems to be the determination of sites of occurrence of the studied species representative of a given region, characterised by the occurrence of its numerous populations in specific biocoenotic conditions, particularly in phytosociological terms. This is of particular importance in the case of research on natural conditions of occurrence of a given species. In nature, in spite of subjectively similar habitat conditions, largely undetermined factors exist that may affect the size of population of a given species in different ways. Subjective perception of the quality of habitats (including their apparent similarities) frequently does not consider factors determining the dynamics of the population of the studied species to a greater extent.

The variable size of population of the studied species at sites differing in terms of abiotic and biocoenotic factors in a given region permits the determination of the potential range of ecological tolerance of the species to the analysed environmental factors.

In the scope of the adopted assumptions and based on the conducted desk and field studies on peat bogs of the Łęczna-Włodawa Lake District, seven research locations representative of the region were selected (*Fig. 1*). They were lake-peat bog complexes – Bikcze (B), Karaśne (K), Moszne (M), Długie (D), Lubowierz (L), and ranges: Blizionki (BZ) and Dekowina (DK), covered by areal forms of nature protection – particularly the Poleski National Park and its buffer zone (*Fig. 1*).

Research on habitat properties at the selected sites was applied in different configurations during the determination of the range of ecological valency of different plant species.

The verification of the accuracy of selection of study sites in reference to the preferences of a given plant species and naturalness of the occurring phytocoenoses was based on *in situ* botanical and phytosociological analyses.

In the scope of the adopted methodology, plant species inventories in selected locations of the Łęczna-Włodawa Lake District were performed still before the designation of particular study sites. The size of the eventually designated research plots was optimised, depending on specific conditions. The analysis of the naturalness of habitats was performed, e.g. based on the assignation of a specific plant species to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40814096

historical-geographical and range groups, and determination of anthropogenic changes in the flora, articulated by the following ecological indices:

- total synanthropisation – ($\mathbf{W_{S\text{-}c}}$) = $\frac{Ap + A}{Sp + A} \times 100\%$; (Chmiel, 1993a)
- total anthropophytisation – ($\mathbf{W_{An\text{-}c}}$) = $\frac{A}{Sp + A} \times 100\%$; (Chmiel, 1993a)
- total apophytisation – ($\mathbf{W_{Ap\text{-}c}}$) = $\frac{Ap}{Sp + A} \times 100\%$; (Chmiel, 1993a)

where *Ap* - apophytes (taxa of synantropic plants of local origin, constituting part of the native flora, occurring in anthropogenic habitats developed as a result of human activity; *Sp* - spontaneophytes (taxa developed in a given area or imported, able to function with no human interference, existing of nature) + apophytes, *A* - anthropophytes (taxa developed in a given area as a result of human pressure, taxa imported to a given area by man, and species surviving at sites under constant human pressure) devised by Chmiel (1993a, b).

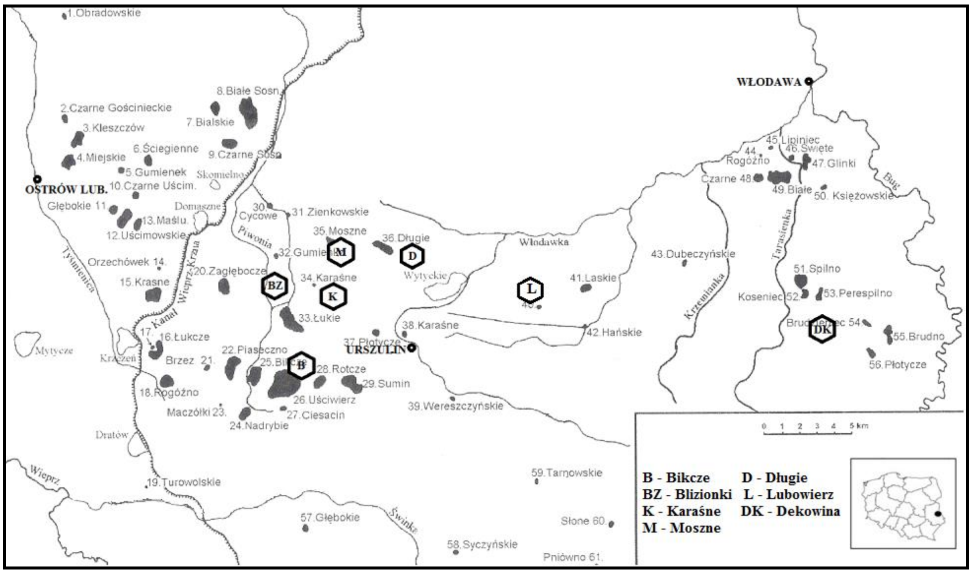

Figure 1. *Location of study sites related to the method of hierarchization of abiotic habitat factors in the Łęczna-Włodawa Lake District (Harasimiuk et al., 1998, changed)*

Low values of coefficients of anthropogenic changes in the flora suggest high biocoenotic naturalness of the selected locations, permitting the selection of specific study sites adjusted in terms of surface area to the local topographic and biocoenotic conditions, further described as subjectively representative (usually 100-625 m^2).

The selected study sites were characterised by a variable abundance of populations of the studied taxa, which allowed for grouping them in terms of contribution (%) of study objects in phytocoenoses.

Further analyses and presentation of results were performed for such designated groups. In the case of lack of considerable differences in the abundance of a given species in phytocoenoses of the selected sites, further analyses of all sites were performed for each site separately. Botanical research was supplemented with the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40814096

following analyses: index of species similarity of phytocoenoses according to Jaccard (Piernik, 2008), and hierarchical classification, both for the sites, and for the species composition, and presented particularly in the form of tables (*Table 1*), dendrograms (*Fig. 2*), or their combinations with heatmaps (*Fig. 3*).

The aforementioned methods permitted a more thorough verification of the accuracy of selection of study sites in the context of species composition and phytosociological connections of peat bog habitats of selected locations. The final effect was the designation of groups of species of plants classified by frequency of occurrence at different study sites.

The determination of phytosociological affiliation of plants the most frequently accompanying the analysed objects permitted the final verification of the accuracy of selection of study sites in the scope of the adopted representative regional locations.

The next stage of research involved analyses of physical-chemical properties of peat bog waters. The selected factors covered the most important physical properties of waters: reaction (pH), electrolytic conductivity (EC); biogenic chemical factors: phosphorus fractions – total phosphorus (TP), phosphates ($P\text{-}PO_4$), and nitrogen fractions – total nitrogen (TN), ammonia nitrogen ($N\text{-}NH_4$), nitrates ($N\text{-}NO_3$), nitrites ($N\text{-}NO_2$); content of dissolved organic carbon (DOC); sulphates ($S\text{-}SO_4$), and selected ions: Na, K, Ca, Mg.

In order to perform such research, ground piezometers were dug in the central part of each site. They were perforated PVC pipes with a diameter of 0.1 m and length of 1 m, ending in a cup closed with an adjusted lid.

Depending on the research schedule, water samples for further laboratory analyses, performed by means of certified methods, were collected from the peat bog piezometers with specified frequency.

Ranges of values of the analysed properties in comparison with the variable contribution of the studied species in phytocoenoses of selected sites determined the range of its ecological tolerance in reference to the analysed properties and region of its occurrence (*Table 1; Fig. 4*).

The study results were based on selected statistical methods and presented in graphic forms depicting the found patterns.

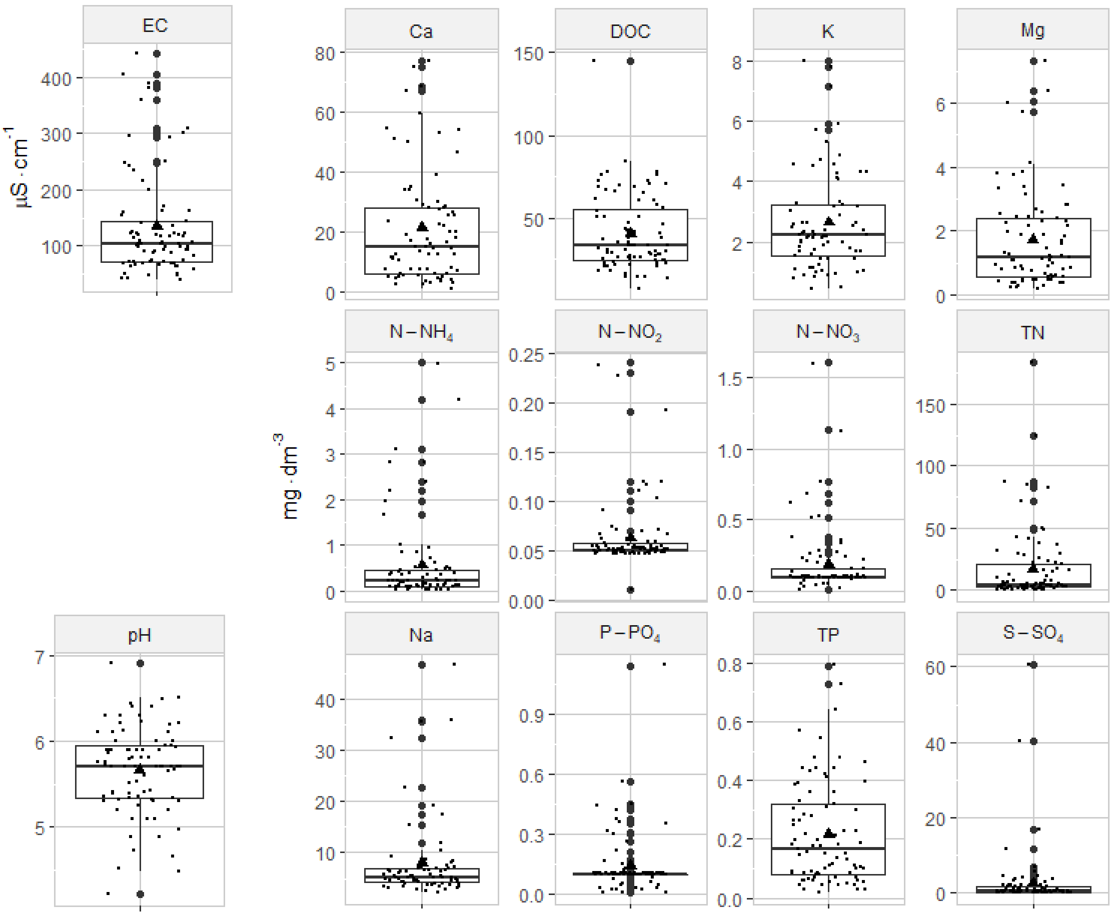

***Figure 4.** Distribution of values of the investigated physical-chemical properties of piezometric groundwater at the study sites in the period 2011-2014 for occurrence of Betula humilis on the Polesie Podlaskie peat bogs (Serafin et al., 2018a). (The box-and-whisker plots show the distribution of observations. In particular, the box represents the first and third quartiles. The horizontal line across the central region of the box represents the median. The mean value of the data is marked by a filled triangle. The whiskers are drawn to the most extreme observations that are located no more than 1.5 times the inter quartile range away from the box. Any observation not included between the whiskers is considered as an outlier and is plotted with an filled circle. When there are no outliers, the whiskers indicate the minimum and maximum values. The plot presents observed values of particular parameters, marked with small dots)*

Statistical methods

The statistical analysis of the species composition of the analysed phytocoenoses and values of physical-chemical properties of peat bog waters was divided into several stages.

The first stage concerning the analysis of the species composition of phytocoenoses at the study sites employed multidimensional methods, applied for distinguishing from the studied locations groups of objects uniform in terms of species composition (cluster analysis). Cluster analysis is a multidimensional technique permitting detecting similarities between analysed objects. Detection of similarities of sites in terms of species composition involved the application of the procedure of agglomerative hierarchical classification (Borcard et al., 2011). The practical and frequently applied in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40814096

similar analyses Jaccard coefficient (Piernik, 2008) was adopted as the measure of similarity. The key element of the analysis, affecting the results of grouping, is the choice of the grouping procedure. In spite of a high number of publications concerning the issues (among others Sneath and Sokal, 1973; Jongman et al., 1995; Legendre and Legendre, 1998; Digby and Kempton, 2014), no universal algorithm of selection of the method of grouping of data exists. The final selection is usually determined by obtaining interpretable clusters. In the case of research employing the hierarchization procedure, the algorithm of minimum variance (Ward clustering) proved the most efficient for the species composition, as well as the algorithm of complete linkage for habitats (Serafin et al., 2015a, 2018a, b). The obtained results of the classification were presented graphically in the form of a dendrogram (diagram of another connection of objects – sites or species – in clusters together with distances for the connections) or heatmaps (intensity of colour representing among others differences in the frequency of joint occurrence) – compare *Figure 3*.

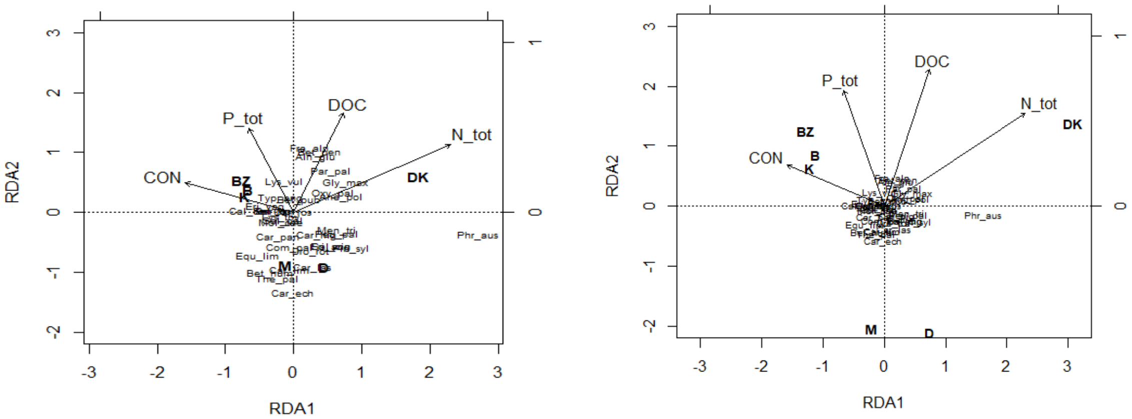
The next stage involved the statistical analysis of the structure of distribution of values of abiotic properties of a habitat for particular sites. Methods of descriptive statistics were applied for this purpose. Basic measures of distribution were determined for physical-chemical water properties. Additionally, the most important position statistics were presented in the form of boxplots – compare *Figure 4*. The analysis of the diagrams permitted the assessment of data distribution, identification of potential distribution skewness, and observations of untypical data or data suspected of untypical character. Then, the distribution of the analysed factors was performed for particular sites (or selected groups of sites with similarly higher and similarly lower % contribution of the analysed species). Due to the rejection of hypotheses on normality of distribution and homogeneity of variance, the comparison employed a non-parametric Kruskal-Wallis test.

A more thorough analysis of dependencies in the data set including the species composition of the analysed phytocoenoses (species composition) and physical-chemical properties of peat bog waters (environmental variables) at particular sites was possible with the application of the multidimensional direct ordination method (Jongman et al., 1995). The most popular methods of the type include redundancy analysis (RDA) and canonical correspondence analysis (CCA). The selection of the appropriate method was done based on the value of the length of the ecological gradient obtained by means of detrended correspondence analysis (DCA) (Gauch, 1982). DCA is indirect ordination method, and is performed based on data on species composition. In the discussed study, the length of the ecological gradient showed that the structure of the analysed data is of linear character (Jongman et al., 1995). Therefore, a method suitable for further research was the redundancy analysis (RDA). Before performing the analysis, for the purpose of meeting the assumption on normality, relevant transformation of data on environmental variables and their standardisation is required (Legendre and Legendre, 1998; Borcard et al., 2011). In the case of data on species, the necessity of their transformation was also considered (Legendre and Gallagher, 2001).

Prior to the analysis, redundant environmental variables (with linear correlation coefficient $|r| > 0.6$) were omitted to avoid collinear rite (Blanchet et al., 2008). The RDA output was presented graphically in the form of a triplot where sites and particular species are presented as points, and environmental variables as arrows. In the case of analyses performed with the application of the *vegan* package (Oksanen et al., 2018), in environment R (2017), depending on the used scaling method (scaling 1 or scaling 2), it

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40814096

was possible to obtain two types of triplots (compare *Fig. 5*). The selection of the scaling method determined the interpretation of the obtained triplot. The triplot obtained for scaling 1, also called a distance triplot, permitted the analysis of dependencies in the context of Euclidean distances among objects. In the case of scaling 2, it is the so-called correlation triplot, where the primary goal was the assessment of the occurring correlations for environmental variables. A detailed interpretation of triplots for both scaling types was performed based on Legendre and Legendre (1998).



(a) scaling = 1 (b) scaling = 2

Figure 5. *Triplot of RDA with fitted site scores, species and environmental variables as arrows connected with occurrence of Oxycoccus palustris in the Polesie Podlaskie Region (Serafin et al., 2018b)*

In the case of analysis aimed at the detection of the structure and general patterns between the analysed physical-chemical water parameters at specific sites, indirect ordination methods should be applied. The performance of this type of analyses employed one of the oldest and most frequently applied methods, namely principal component analysis (PCA). The method was indicated by the length of the ecological gradient as suitable for the investigation of mutual relations of environmental data of the study area, irrespective if the species composition of the analysed biocoenoses, in the case of analysis of occurrence of relic species of willows (Serafin et al., 2015a, b). The PCA output was presented as a biplot where objects (sites) are presented a points, and environmental variables as arrows (*Fig. 6*). Similarly as in the case of RDA, the interpretation of biplots also depends on the selected scaling method (Legendre and Legendre, 1998).

Possibilities of interpreting results

Based on the performed procedure, competent study results were obtained permitting the following for particular plant species: 1) identification of representative study sites related to the preferences of species, analysis of association of the accompanying plants, and degree of naturalness of habitats; 2) estimation of the range of ecological tolerance in reference to the analysed habitat properties and region of occurrence of study objects, and 3) determination of statistically significant abiotic factors favouring the occurrence of their populations, and sometimes also ranges of values of the factors.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40814096

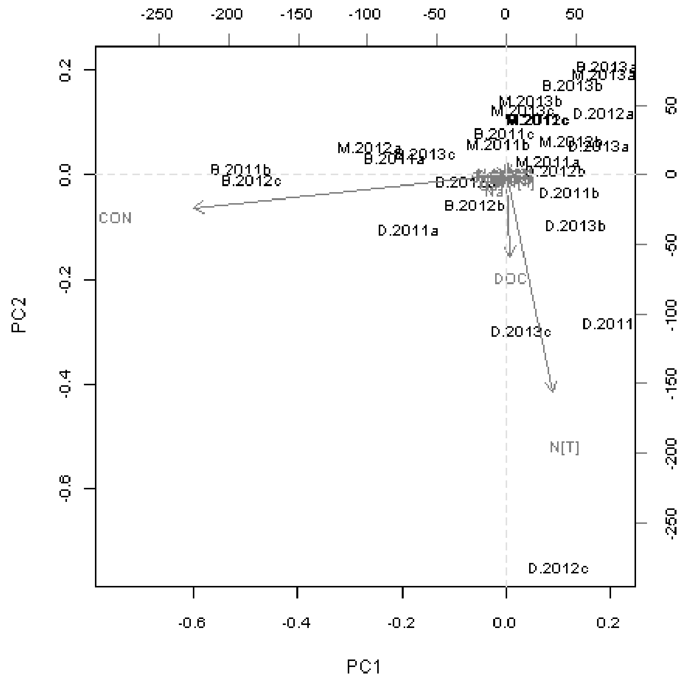


***Figure 6.** Projection of the original 14-dimensional scores onto the first two principal components for occurrence of Salix myrtilloides on the Polesie Podlaskie peat bogs (Serafin et al., 2015b). (The black labels indicate individual data items. Each variable (factor) is represented as a vector, while the direction and the length of the vector indicate how the corresponding variable contributes to a principal component)*

Study sites were designated for all plant species considered in the study in selected locations representative of the region. Their naturalness was evidenced by botanical-phytosociological analyses confirming the presence of plants from classes: *Scheuchzerio-Caricetea*, *Alnetea glutinosae*, and *Oxycocco-Sphagnetea* in the species composition of the analysed phytocoenoses strongly related to ombrogenic habitats of raised and transitional bogs, optimal in terms of occurrence of the analysed plant species (Serafin et al., 2017; Serafin et al., 2018a, b). Low values of anthropogenic coefficients of changes in the flora, high Jaccard coefficient indices, statistical hierarchical analysis of species similarity, as well as multidimensional analyses of the frequency of occurrence of characteristic species associations determined by preferences of the studied species additionally confirmed the accuracy of selection of natural study sites.

The specificity of occurrence of the studied species in reference to characteristic features of the peat bog environment in the region of Polesie Podlaskie (East Poland) permitted the determination that both boreal relics and medicinal plant species were characterised by a relatively broad amplitude of values of the majority of the studied physical-chemical properties of peat bog waters. This probably constitutes proof of the broad range of their ecological tolerance in reference to such factors and to such regional locations. The distribution of values of some of the analysed properties was favourable for the maintenance of the populations of the analysed species, whereas the distribution of the remaining ones should be considered as neutral or unfavourable. In the case of *Salix myrtilloides*, low level of values of nitrogen fractions, phosphorus fractions, studied cations, and DOC can be considered a group of conditions favouring

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40814096

the functioning of its population (Serafin et al., 2015b), whereas for the simultaneously studied *Salix lapponum*, such conditions were met by: low level of TN, phosphorus fractions and DOC, as well as a high level of Ca, pH, and EC (Serafin et al., 2015a).

For *Betula humilis*, values of statistically significant, favourable for its occurrence abiotic properties of groundwaters were provided in more detail also providing ranges of their values based on boxplots for which the upper and lower quartile referred to the Kruskal-Wallis test provide information on the range of values of physical-chemical water properties significant for the species. They included: TP: 0.08-0.32; P-PO_4: 0.1; TN: 2.2-21.2; N-NH_4: 0.1-0.46; DOC: 24.6-56.9 ($mg \cdot dm^{-3}$), as well as higher than average pH values, in a range of: 5.34-5.95; Ca: 5.67-28.1; Mg: 0.56-2.41 ($mg \cdot dm^{-3}$) m and EC in $\mu S \cdot cm^{-1}$: 72.1-142.3 (Serafin et al., 2018a).

For species of herbal plants with perspective possibility of ecological cultivation, additional research is necessary concerning the natural content of biologically active substances at natural sites of their occurrence (currently conducted). Nonetheless, also in their case, complexes of factors favouring their more abundant occurrence were determined.

For *Menyanthes trifoliata* they were - TN (N_{total}): from 4.16 to 27.4, TP (P_{total}) from 0.93 to 0.14 ($mg \cdot dm^{-3}$), EC (conductivity) from 70.4 to 112 $\mu S \cdot cm^{-1}$, and pH from 5.23 to 5.55 (compare *Fig. 7*).

Lower concentration values of important habitat parameters in the following ranges: TP = 0.17-0.36; P-PO_4 = 0.1, and DOC = 33.81-55.90 ($mg \cdot dm^{-3}$) can be considered as a state favouring proper functioning of *Oxycoccus palustris* individuals (Serafin et al., 2018b). Parameters important for the occurrence of a population of *Comarum palustre* in Polesie Podlaskie included: N-NH_4, Ca, Mg, DOC, EC, and pH (Serafin et al., in review).

The summary of the applied procedure of hierarchization of abiotic habitat properties in botanical research were PCA and RDA analyses supplementing the dependencies between groups of the studied elements: species composition of phytocoenoses, species similarity of study sites, and the values of physical-chemical properties of peat bog waters at the sites.

For example, in the case of *Salix lapponum*, the application of PCA analysis showed the highest correlations between chemical variables such as: P-PO_4-TP (0.9421), N-NH_4-TN (0.7607), and EC-pH (0.7533). It was also determined that EC, Ca, and pH were higher at site Karaśne (K) in comparison to sites Blizionki (BZ) and Lubowierz (L), and values of phosphorus fractions were higher for BZ in comparison to sites K and L, and that the separation of clusters K and L particularly results from the contribution of EC, Ca, pH, N-NH_4, TN, and DOC. Some data from sites B and L showed more uniform structure (Serafin et al., 2015a).

The analysis of data from research concerning *Oxycoccus palustris* based on the RDA method suggests that study sites located closer to each other (such as B, K, BZ, as well as D, M) have a similar species composition and similar values of habitat variables. Sites B, K, and BZ are characterised by high levels of EC and TP. Variable TN was related to the positive part of axis 1, and EC occupies the opposite part of the axis. The second axis is positively correlated with DOC and TP. The triplot suggests a positive correlation between TN and DOC, as well as a similar correlation of values between EC and TP, as well as between TP and DOC. In terms of species-habitat dependencies, the studied species was observed to be strongly positively correlated with TN (Serafin et al., 2018b).

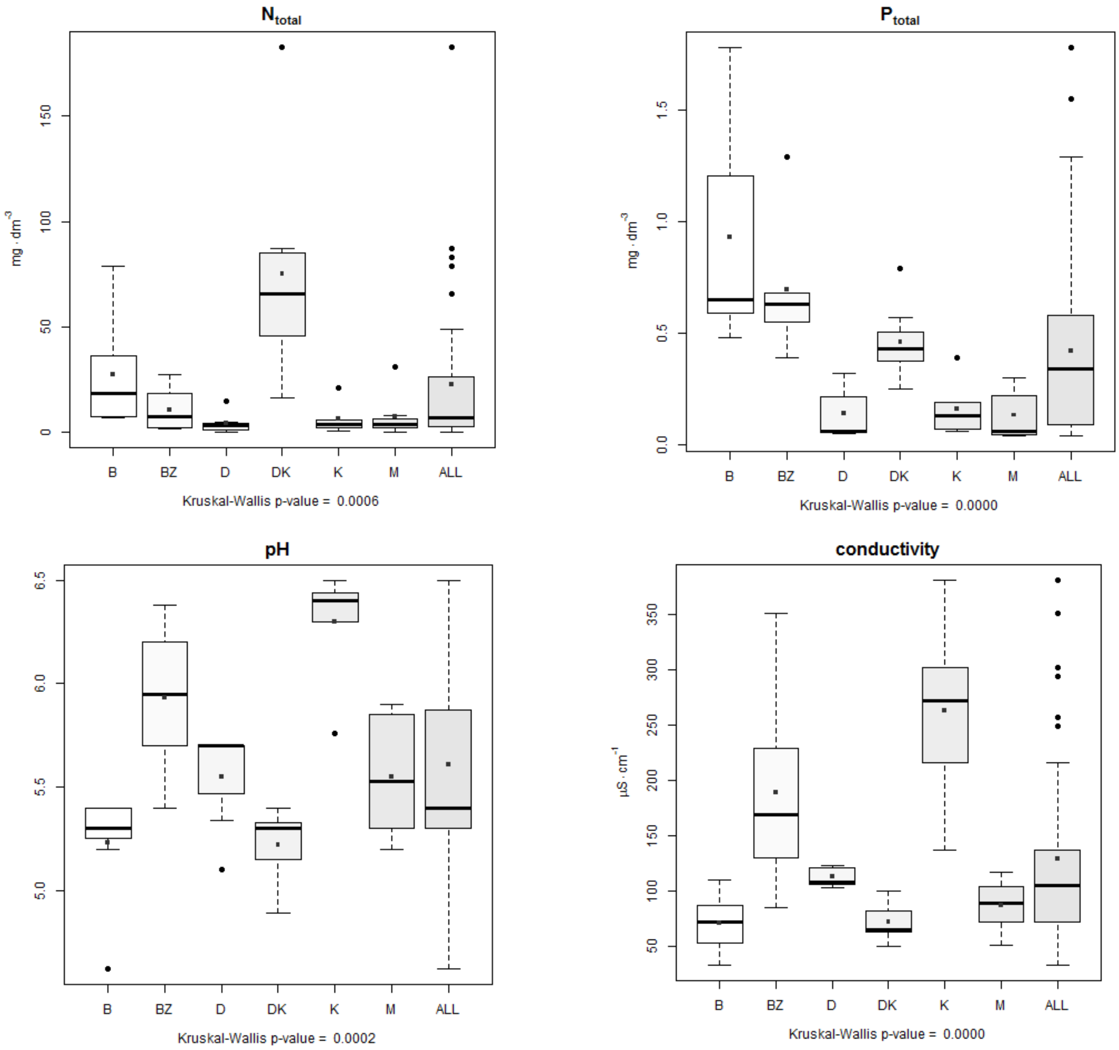

Figure 7. *Distribution of values of the investigated chemical factors of piezometric groundwater at the study sites in the period 2011-2013 (Serafin et al., 2017). (The box-and-whisker plots show the distribution of observations. The bottom and top of the box indicate the first and the third quartiles, respectively. The horizontal line across the central region of the box represents the median. The mean value of the data is marked by a filled square. The whiskers are drawn to the most extreme observations that are located no more than 1.5 times the inter quartile range away from the box. Any observation not included between the whiskers is plotted as an outlier with an circle. When there are no outliers, the whiskers indicate the minimum and maximum values. The abbreviations of the selected study sites are used to label tick marks on the x - horizontal axis. The x axis label provides the p-value derived from the Kruskal-Wallis test)*

Summary and conclusions

The modern dynamics of ecological patterns of different ecosystems require complex research methods accompanying the course of selected ecological phenomena and processes. Unlike in the case of comparative and reconstruction research, it is usually long-term, stationary research (in selected locations), also called process accompanying research. After a certain time, it provides material for many scientific fields, constituting the basis of essential source texts used in the planning and implementation of various research. In the case of the field of science based on botanical ecological analyses –

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40814096

dynamics of vegetation also called syndynamics – the basis for practical research methods was provided by among others Braun-Blanquet (1922); Collier et al. (1973, 1978); Faliński (1986); Burrows (1990); or Dierschke (1994). Irrespective of the character of the performed analyses, their success usually depends on three factors: consistency of interest, selection of the object, and continuity of financing (Faliński, 2001).

The procedure of hierarchization of abiotic habitat properties for botanical analyses in natural peat bog conditions meets all three conditions. It is based on constant interest in the study issue – particularly the occurrence of boreal relics in natural, although subject to increasing human pressure (global – climate change, and regional – impact of the Lublin Coal Basin, effect of the Melioration System if the Wieprz-Krzna Channel, as well as tourism and recreation in the Łęczna-Włodawa Lake District) habitats of Polesie Podlaskie (East Poland). Supplementary botanical research also focused on the conditions of occurrence of valuable species of herbal plants, and those with a perspective of ecological cultivation.

The selection of study objects resulted from conscious scientific interest of the authors particularly concerning boreal species of willows: *Salix lapponum* and *Salix myrtilloides*, subject to research already from the early 2000's (e.g. Pogorzelec, 2008, 2009). In the case of selected species of herbs: *Menyanthes trifoliata*, *Oxycoccus palustris*, and *Comarum palustre*, further research concerning the composition of biologically active substances in herbal material is currently conducted for different sites, and their occurrence in the aspect of performing an experiment of their ecological cultivation.

Eventually, financing of the said research was on the one hand related to resources available in the scope of project of NCN No. NN304385239: Population ecology and active protection of boreal relics from the *Salicaceae* (*Salix lapponum* and *Salix myrtylloides*) in Polesie Lubelskie Region, under the direction of D. Ph. Magdalena Pogorzelec, implemented in the years 2010-2014, and on the other hand to the statutory activity of the Department of General Ecology University of Life Science In Lublin (Poland), where Ph. D. Artur Serafin and Ph. D. Magdalena Pogorzelec were employed at the time.

The primary effect of the developed procedure are the possibilities of its practical application. In the scope of the restitution of the said species of willow in Polesie Podlaskie based on a project entitled: Active protection of particularly endangered species of relic plants from family Salicaceae in peat bog habitats (supervision Ph. D. Magdalena Pogorzelec), measures of their active protection have been implemented since 2018, involving their reintroduction. Places of introduction of new individuals of both species obtained from ex situ cultivation were optimised as habitats in terms of values of the analysed physical-chemical properties of peat bog waters in accordance with results of research based on the procedure described above.

In the case of the studied herbs, the perspective of their ecological cultivation depends on solving several issues. Firstly, in natural conditions of peat bogs, obtaining herbal material faces difficulties concerning the terrain conditions and safety of persons collecting plants. Secondly, part of herbal species are under species protection, and their collection is treated as an offence (*Menyanthes trifoliata*). Thirdly, the most natural habitats of occurrence of the plants are located in areas subject to different forms of areal protection (e.g. national park, landscape park, nature reserve, or ecological grounds), therefore sanctioning the possibility of collection of any plants in different

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40814096

ways. Finally, as a result of hydrotechnical economy, peat bog ecosystems are subject to shrinking in the territory of the majority of European countries (Ilnicki, 2002), resulting in a real threat of extinction of many species of plants related to this type of habitats. Ecological cultivation of medicinal species in optimal conditions of their natural occurrence provides a solution to the aforementioned problems. A very important issue in this aspect is the search for natural compositions of biologically active substances in herbal material for the purpose of development of a natural herbal medicine in accordance with the rules of the Good Manufacturing Practice (GMP) pursuant to the guidelines of the WHO (Borkowski, 1994; Drozd, 2012). It is particularly important in the times of search for different elements and measures limiting environmental impact and important for human health, especially in the context of naturotherapy, constituting a desirable alternative to synthetic pharmacology and dangerous polypharmacy (Oliveira et al., 2012; Senderski, 2015; Serafin et al., 2018b). Currently conducted research employing the procedure of hierarchization of abiotic properties of habitats for studied herb species preliminarily confirms higher values of biologically active substances from locations characterised by optimised natural values of the analysed physical-chemical water properties (Serafin, Dzida, unpublished data).

Due to the above, the developed procedure finds practical application both for active protection of endangered plant species and in the case of useful plants.

(Received 4th Dec 2018; accepted 27th Feb 2019)

Abstract. In recent years, the biosynthesis (green synthesis) of metal nanoparticles such as silver nanoparticles (AgNPs) have become one of the safest, most cost-effective and environmentally friendly approaches. In this study, AgNPs were synthesized using maize (*Zea mays L.*) leaves. For the characterization of synthesized AgNPs different techniques were used, such as X-ray diffraction spectroscopy (XRD), Ultraviolet visible (UV-Vis) spectroscopy, transmission electron microscopy (TEM), Energy dispersive X-ray spectroscopy (EDX), Fourier-transformed infrared spectroscopy (FT-IR) and Thermal gravimetric and Differential thermal analysis (TGA-DTA). The XRD results showed that AgNPs had a mean diameter of 12.63 nm and a crystal-like appearance. In addition, antimicrobial activities of synthesized AgNPs were evaluated using 3 different antibiotics against Gram-negative *Escherichia coli* and Gram-positive *Staphylococcus aureus* bacteria and *Candida albicans* yeast. Antifungal activity of AgNPs with antibiotics has been observed to be better than the antibiotics against Gram-positive and Gram-negative bacteria. The minimum inhibitory concentrations were found to be 0.084, 0.337 and 0.021 mg mL^{-1} for *Escherichia coli*, *Staphylococcus aureus*, and *Candida albicans*, respectively. The results revealed that AgNPs synthesized from maize leaf extract have antibacterial activity against Gram-negative *Escherichia coli*, Gram-positive *Staphylococcus aureus* and antifungal activity against *Candida albicans* yeast, and that the produced AgNPs could be used in the production of biomedical products and in the pharmaceutical industry.
Keywords: *antimicrobial activity, green AgNPs, Escherichia coli, Staphylococcus aureus, Candida albicans*

Introduction

Scientific research and applications of nanotechnology have increased rapidly in recent years. The properties of nanoparticles such as durability, high diffusion, and versatile chemical and biological activities have gained importance in technological applications (Nabila and Kannabiran, 2018). Metal nanoparticle synthesis researches have been increasing in number due to the potential applications in nanotechnology (Isaac et al., 2013). Nanoparticles are used in many industrial fields, especially in electrical, biomedical, automotive and chemical sectors due to their superior properties (Gürmen et al., 2008). Generally, nanoparticles are defined as particles smaller than 100 nanometers (nm) (Kreyling et al., 2006).

The green technology used in the production of metal nanoparticles has become popular in recent years because of its being rapid, easy, cheap, sustainable and eco-friendly. Green synthesis, as an alternative to physical and chemical synthesis studies

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40974105

for the production of AgNPs, is considered as an environmentally friendly and cost-effective method used by researchers from many different fields of science (Banerjee et al., 2014; Nartop, 2016; Majeed et al., 2018). In the biological synthesis of nanoparticles, organisms such as bacteria, fungi, seaweeds, plants, yeasts, and viruses are used (Khan et al., 2018). Among these organisms, plants are considered to be the most preferred organisms when they are evaluated in terms of cost and availability. In literature, antibacterial activity of metal or metal oxide such as zinc oxide nanoparticles (ZnO-NPs) has received significant interest worldwide (Gunalan et al., 2012). The most synthesized metal nanoparticles are copper (Cu), silver (Ag), gold (Au), zinc (Zn), nickel (Ni) and palladium (Pd). Edison and Sethuraman (2012) stated that the synthesized Ag and Au nanoparticles by *Magnolia kobus*, *Diospyros kaki*, *Ficus benghalensis* and *Citrus lemon* plant extracts are stable products. In studies with plants, the greatest phytochemicals, tannins, gallic acid, and gallate esters can be easily hydrolyzed (Swamy et al., 2015; Nabila and Kannabiran, 2018).

In this study, the plant extract obtained from maize plant leaves was used for the reduction of Ag^+ ions which are the basis of the synthesis of AgNPs to Ag^0 ions. Antimicrobial activity was evaluated by characterization of the obtained AgNPs. The green technology used in the synthesis of AgNPs in this study is cheaper, easier and faster than other applications.

Materials and Method

The plant extract used in the study was obtained from maize (*Zea mays* L.) plant. In the synthesis method, silver nitrate ($AgNO_3$, purity 99.8%) was used. The used antibiotics (Fluconazole, Vancomycin, and Colistin) were obtained commercially.

Preparation of plant extract

Collected maize leaves from Mardin region in Turkey were washed with deionized water, then dried under room conditions and afterward 50 grams of the ground samples were taken and boiled at 85°C with 500 mL of distilled water. After the formation of the extract, the sample was left to cool until reached the room temperature. Subsequently, filtration was performed using Whatman filter paper and the filtered extract was stored at 4°C.

Synthesis of nanoparticle

In general, the formation of AgNPs is determined by spectrophotometric measurements based on color change and time (Swamy et al., 2015; Jamdagni et al., 2016). A 1 mM $AgNO_3$ aqueous solution was used for the synthesis of AgNPs. In total, 125 mL of maize plant leaf extract and 500 mL of $AgNO_3$ solution were put into the reaction at room temperature in a 1000 mL flask. At the end of 40 minutes, the reduction of silver ions resulted in the change of light-colored Ag^+ ions to dark brown and the maximum absorbance value was determined at 461 nm wavelength by UV-Vis spectroscopy. The resulting dark solution was centrifuged at 6000 rpm for 20 min to remove the upper liquid phase and the remaining solid was washed seven times with distilled water. The obtained AgNPs were kept in a laboratory oven at 75°C for 24 hours and then left to dry and stored until the application of characterization tests.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40974105

Characterization techniques

Ultraviolet spectra of synthesized AgNPs were determined in the UV-1601 220V Shimadzu spectrophotometer in the wavelength range of 350-800 nm. Size and morphology of AgNPs were determined using EVO 40 LEQ scanning electron microscopy. The crystal structures of AgNPs were analyzed with RadB-DMAX II computer-controlled X-ray diffractometer in the $3^o \leq 2\theta \geq 79^o$ range. SEM-energy dispersive X-ray (SEM-EDX) spectroscopy was used to verify the presence of AgNPs in the elemental composition. FT-IR analysis was performed in the 4000-400 cm^{-1} range with the Perkin Elmer spectrum one-brand device to determine which functional groups were involved in the reduction of plant extracts. Decomposition temperatures of AgNPs were determined by thermal gravimetric analysis at a constant heating rate (Shimadzu TGA-50) at 25°C min^{-1} (25°C-900°C) under the nitrogen atmosphere.

The evaluation of XRD phase and crystal structure analysis of green synthesized AgNPs is shown in *Figure 1*. The reflections (111), (200), (220) and (311) of the spherical structures of the AgNPs were calculated in the XRD analysis by 2θ (38.01°, 45.83°, 64.29° and 77.34°) values. It was determined that AgNPs have elemental (Ag^o) and spherical crystalline structure. The mean crystal size was calculated as 12.63 nm with the following Debye-Scherrer equation (Kanipandian and Thirumurugan, 2014):

$$D = K\lambda / (\beta \cos\theta) \quad \text{(Eq.1)}$$

In the equation, D is particle size (nm), K is constant (0.90), λ is wavelength X-ray (1.5406 °A), β is half of the highest peak value (FWHM) and θ is the refractive angle.

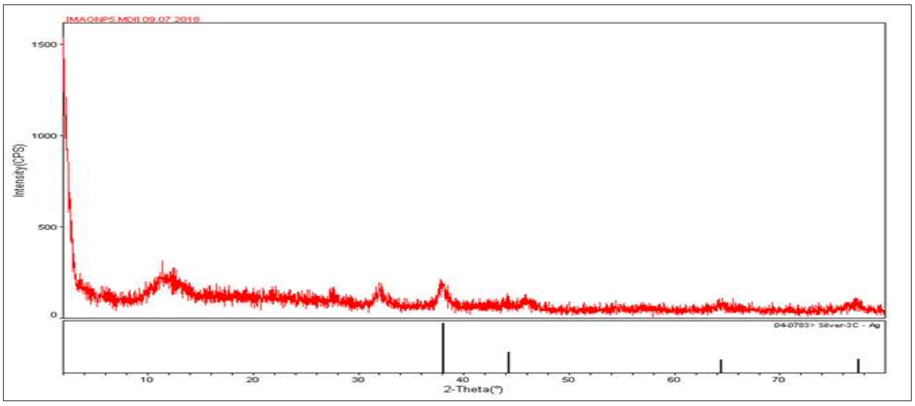

Figure 1. *XRD spectra of green method synthesized AgNPs*

Antimicrobial activity of silver nanoparticles

The antimicrobial assays were performed by the minimum inhibitory concentration (MIC) method (Wang et al., 2017). For this purpose, AgNPs were incubated overnight with Gram-positive (*S. aureus* ATCC 29213) and Gram-negative (*E. coli* ATCC 25922) bacterial and fungal (*C. albicans*) strains. Experiments were performed by the microdilution method and the predetermined medium was added to 96-well microplates. Following the preparation of a dilution series at adjusted concentrations, AgNP solutions were added on these dilutions.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40974105

Then, the solutions including a certain amount of microorganism were prepared according to 0.5 McFarland standard, added onto the samples and the samples were incubated at 37°C overnight. After incubation, the lowest concentration without growth was determined as MIC (Nadaroglu et al., 2017; Abinaya et al., 2018). All experiments were repeated with four replicates per treatment.

Results and discussion

Analysis of ultraviolet-visible spectroscopy

The formation of AgNPs with samples taken at 5, 10, 15, 20, 25, 30, 35 and 40 minutes was observed with UV-Vis spectroscopy analysis. The synthesized AgNPs showed a sharp plasmon resonance at a maximum of 461.25 nm (*Fig. 2*). Similarly, AlQahtani et al. (2017) determined the surface plasmon resonance of AgNPs at 468.5 nm. Furthermore, the absorption spectra of AgNPs in the reaction medium were indicated to be in the maximum absorption in the range of 425 to 475 nm due to surface plasmon resonance of AgNPs (Banerjee et al., 2014).

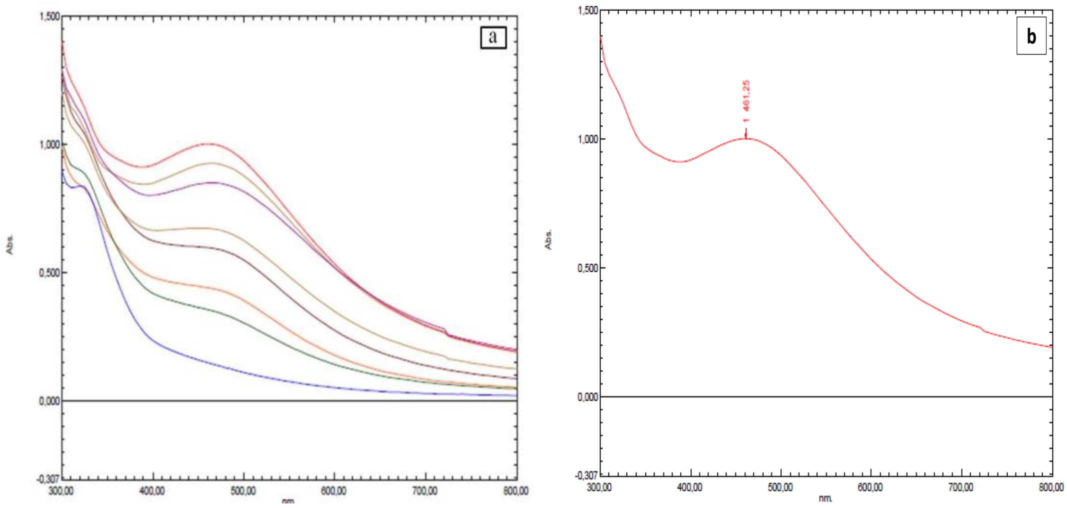

Figure 2. *a) Time-dependent formation of AgNPs in UV -Vis spectroscopy, b) Maximum absorbance value of synthesized AgNP in UV-Vis Spectrophotometer*

Fourier-transformed infrared spectroscopy analysis

The infrared spectrum in *Figure 3.* provides information about the functional groups of the synthesized AgNPs from maize leaf extract. The strong asymmetric flexural band of 3326.99-3321.54 cm^{-1} belongs to the -OH functional group on the leaf extract surface of the maize shifted due to the interaction between the extract and the silver metal. A frequency shifting of about 5 cm^{-1} occurred at the peaks around 3326.99 cm^{-1}. In the strong asymmetric stretch band at 2103-2106 cm^{-1}, a 3 cm^{-1} frequency shifting occurred between C≡C and C≡N groups. It was found that there was no considerable shifting in the 1636.29-1636.01 cm^{-1} band of the C-C groups belonging to the Amide I band and C-N functional groups and also the binding occurred on these three functional groups.

Shah et al. (2017) produced AgNPs by the interaction of $AgNO_3$ with an aqueous solution containing *Xanthorrhoea glauca* leaf extract and identified the peaks of carboxy

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40974105

and amide groups at 1642, 1556, 1536. They reported that the AgNPs demonstrated varying degrees of antibacterial activity against *Escherichia coli* and *Staphylococcus epidermis*, with *Staphylococcus epidermis* showing a larger zone of inhibition (11 mm).

The FT-IR spectrum measurements of AgNPs synthesized by Huang et al. (2007) showed the presence of five dense bands at 3422, 2922, 1629, 1381 and 651 cm^{-1}. It has also been stated that the maximum shifting was at 3422 cm^{-1}. In another study, it has been reported that the -OH stretch at 3430 cm^{-1} belongs to the functional groups of –C–N (peptide bone) at 2083 cm^{-1} and C-C at 1641 cm^{-1} and also the binding takes place on these two functional groups (Singh et al., 2017).

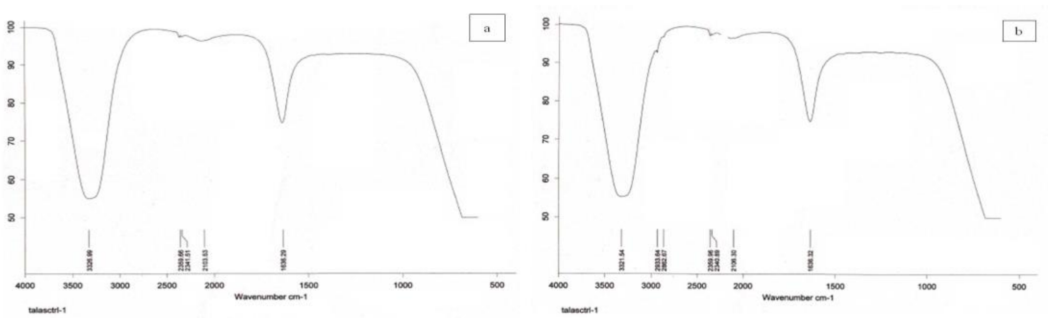

***Figure 3.** a) UV-Vis spectrum of plant extract, b) UV-Vis spectrum of synthesized AgNPs*

Scanning electron microscopy and energy dispersive X-ray spectroscopy analysis of silver nanoparticles

Morphological characteristics of AgNPs obtained from leaf extract of maize were investigated with scanning electron microscopy (SEM). The results clearly demonstrated the presence of spherically shaped AgNPs below 100 nm (*Fig. 4*).

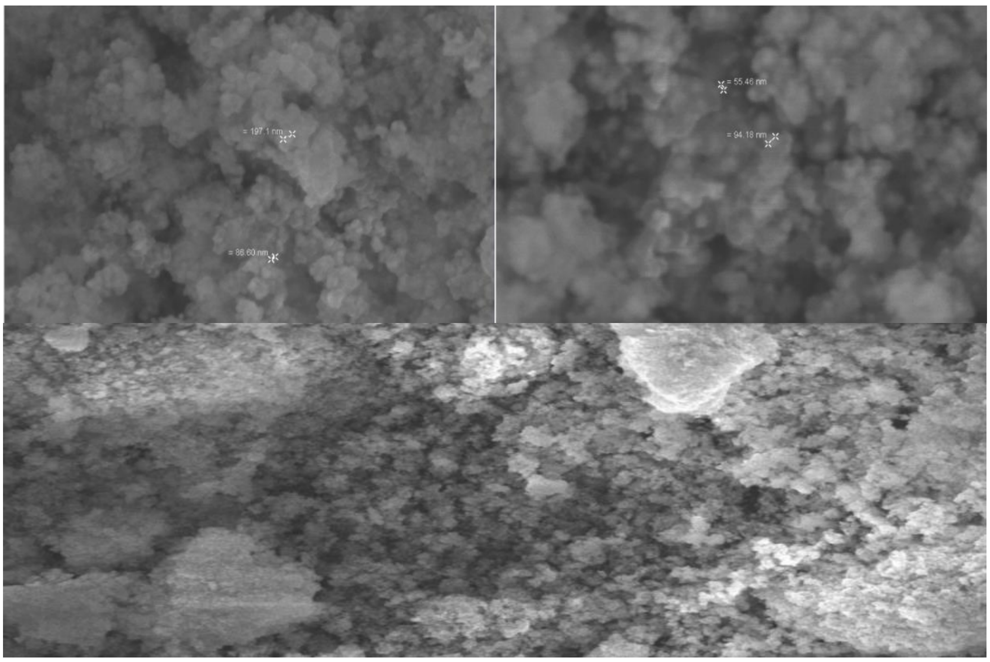

***Figure 4.** Images of SEM analysis of synthesized AgNPs*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40974105

Nanoparticles produced with green synthesis by Phanjom et al. (2012) from *Myrica esculenta* resulted with different morphologies ranging from 45 nm to 80 nm and the Ag nanoparticles obtained from *Ziziphus nummularia* plant leaves by Khan et al. (2016) had spherical and homogenous shapes with diameters ranging between 30 and 85 nm. In similar SEM analysis studies, the size and morphological characteristics of AgNP are consistent with the results of this study (Swamy et al., 2015).

When the obtained results of this study were compared to the results of the study belonging to Kotakadi et al. (2013), it was seen that AgNPs have a spherical shape and the diameters of AgNPs varied between 27 and 50 nm. As can be seen in *Figure 5*, the energy-dispersed spectra of AgNPs obtained from the SEM-EDX analysis revealed pure silver particles.

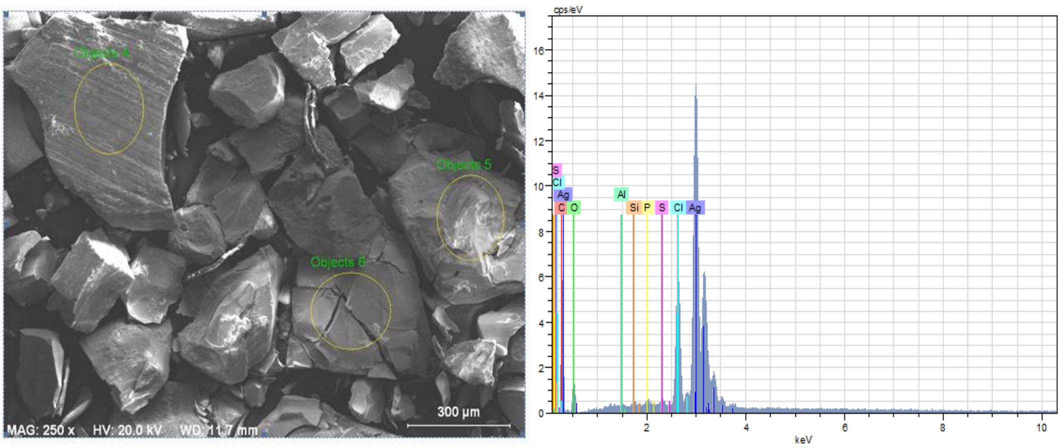

Figure 5. *SEM-EDX spectrum of AgNPs*

Thermal gravimetric and differential thermal analysis results

The TGA and DTA analyses of the nanoparticles prepared by green synthesis were evaluated between 25-900°C with a heating rate of 10°C min^{-1} and a flow rate of 20 mL min^{-1} in N_2 (g) atmosphere. The TGA curve indicates the mass loss due to thermal decomposition and the DTA curve shows the maximum decomposition temperature at each stage of the degradation (Baran, 2017).

As can be seen in *Figure 6*, the loss of mass at 37-100°C was caused by moisture, the loss of mass at 186-309°C was due to the cellulosic materials, and the loss of mass at 309-610°C was caused by phytochemicals from a plant extract. Finally, the substance was completely degraded at 610-900°C. The TGA data revealed that the mass loss of AgNPs synthesized in the study was between 50-800°C. In a similar study, when the TGA curve of AgNPs was examined, it was reported that there was a constant mass loss in the 50-800°C temperature range and this loss was due to the desorption of bioorganic compounds (Ali et al., 2015).

Antimicrobial assays of synthesized silver nanoparticles

In this study, the antimicrobial effect of AgNPs obtained from maize leaf was investigated by MIC method. The possible antibacterial effects of AgNPs on Gram-negative *E. coli* ATCC 25922 and Gram-positive *S. aureus* ATCC 29213 strains and antifungal activities on *C. albicans* were investigated. MIC values of AgNP and 1 mM

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40974105

silver nitrate were determined. The antimicrobial effect results of the produced AgNPs on *E. coli* ATCC 25922, *S. aureus* ATCC 29213 bacteria and *C. albicans* yeast were obtained as 0.084, 0.337 and 0.021 µg mL^{-1}, respectively (*Table 1*).

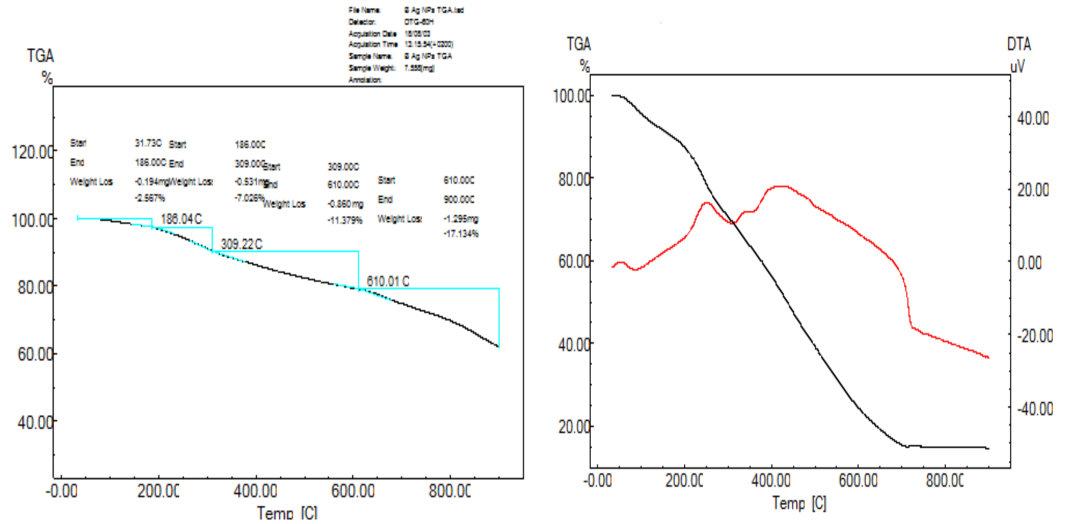

Figure 6. *TGA-DTA analysis result of the synthesized silver nanoparticle*

Table 1. *Minimum inhibitory concentration (MIC) values of AgNPs (µg mL^{-1})*

Organism	AgNP	Silver Nitrate	Antibiotic
***S. aureus* ATCC 29213**	0.337	0.500	0.500
C. albicans	0.021	0.500	0.500
***E. coli* ATCC25922**	0.084	1.000	0.125

Table 1 shows that AgNPs exhibit a more pronounced activity than silver nitrate. Wang et al. (2017) reported that AgNPs synthesized from green coffee grains showed excellent antibacterial activity against both Gram-negative and Gram-positive bacteria. Tippayawat et al. (2016) stated that the minimum inhibition concentration of AgNPs which they synthesized from *Aloe vera* plants was effective.

In another study, the nanoparticles synthesized with *S. potatorum* leaf extract were shown to be effective against on MDR human pathogenic bacteria namely, *S. aureus* and *K. pneumonia* (Kagithoju et al., 2015). Similar observations were reported on *Boswellia ovalifoliolata* and *Shorea tumbuggai* (Savithramma et al., 2011). Therefore, this study shows that the biosynthetic AgNPs have antimicrobial activity.

Conclusions and recommendations

Nowadays, different antimicrobial agents are being developed to be used on bacteria and yeasts which are resistant to antibiotics that still are in use in medicine and pharmacy. Therefore, many researchers have concentrated their studies on this field. In this study, the synthesis of AgNPs was performed by using maize plant extract. It has been determined that the synthesized AgNPs by maize leaf extract have a spherical structure. The synthesized AgNPs were characterized by UV, XRD, SEM-EDX, TGA-DTA and FT-IR methods. It is known that green synthesis is a cheap, simple and environmentally

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_40974105

friendly method and the biosynthesis of AgNPs is an alternative method to the chemical synthesis method. Furthermore, AgNPs produced by biosynthesis demonstrated a good antimicrobial effect on different strains.

Green-synthesized AgNPs will open up a new field for the production of pharmaceutical products, the biomedical and industrial products in the pharmaceutical industry.

(Received 15th Nov 2018; accepted 14th Feb 2019)

Abstract. The aim of this study is to demonstrate the effects of water shortage, which may occur in different periods, on wheat grain yield and quality. One of the most important factors limiting wheat yield in the Southeastern Anatolia Region of Turkey is drought, which is caused by inadequate precipitation and irregular distribution over the year. Four different bread and durum wheat cultivars (Sarıçanak-98, Fırat-93, Pehlivan, Ceyhan-99), which are widely cultivated in the region, were used as the material of the study. The experiment was carried out with 3 replications, according to the random blocks design. The research was carried out under greenhouse conditions. The effects of four different drought conditions on the wheat's development, yield and mineral content were investigated under irrigation (K0), early drought (K1), late drought (K2) and full drought (K3). According to the results, a 9.12% loss in chlorophyll content was observed under irrigated conditions (K0). 21.68% leaf area, 28.98% plant green area, and 52.09% plant height declines were recorded. The amount of potassium (K) was found to change between 2.86 mg (K3) and 34.77 mg (K2), while the amount of calcium (Ca) changed between 0.67 mg (K3) and 33.23 mg (K3) and the amount of sodium (Na) changed between 0.20 mg (K1) and 27.05 mg (K0) in the root and stem of plants.
Keywords: *wheat, drought, drought applications, drought parameters, chlorophyll content, agricultural and biochemical characteristics*

Introduction

Most of the agricultural areas in the world are affected by different stress factors. Drought stress affects these areas the most at a rate of 26%, mineral substance stress ranks the second, affecting them at a rate of 20%, and cold and frost stress rank the third with 15%. Aside from these, 29% are affected by other stress factors and 10% are not under any stress (Kalefetoglu and Ekmekçi, 2005). In areas where there is drought risk, the decrease in the water amount available in the soil primarily leads to a reduction in the water potential of the plant. It is well-known that turgor pressure drops, stomas are closed, and leaf development and photosynthesis is decreased in the following stages (Monti, 1986).

It was reported that 55% of the wheat cultivation areas throughout the world are affected by drought stress periodically (Richards et al., 2010). The wheat yield in affected areas less than between 50% to 90% of yield potential of irrigable conditions (Reynolds et al., 1999). It would be useful to develop new and multidisciplinary methods together with classical cultivation methods used for the development of drought-tolerant wheat cultivars.

In Turkey, in the development studies for the drought-tolerant wheat cultivars, generally the "earliness" feature of the plants was used. The height of the plant and leaf

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41074115

width are used as selection criteria. In later generations, drought-resistant cultivars are cultivated as a result of the yield level and "decisiveness". The severity of drought is a serious danger for the Southeastern Anatolian Region of Turkey. The reason of the danger varies depending on years, and it is not known how long the drought stress will last during the development of the wheat and how long its duration will be. In this case, the feature of "earliness" is not adequate for the yield in the conditions of the region, and genetic and some physiological properties are important in determining the resistance to drought. For this reason, it is desired that the cultivars that are developed have a yield potential which are capable of making use of the formation of optimum conditions meanwhile maintaining the yield at a certain rate compared to the sensitive plants when exposed to drought stress.

The yield of the cultivars that are not sensitive to drought stress stays the same even in the most suitable development conditions. The lack of photosynthesis area is shown as the reason for this. Due to this fact, in order to increase the yield, it is necessary to have high photosynthesis capacity as well as physiological durability. The efforts spent on developing a strong wheat variety require physiological tests which are inexpensive, simple, and repeatable and which may be considered as selection criteria with morphological parameters.

In Turkey, wheat plant is cultivated in conditions based on precipitation at a rate of 80%. The total rainfall is not adequate in dry agricultural areas where most of the total rain falls between November and April, and because of the irregular distribution, dry periods in different development stages cause the yield to be reduced.

The purpose of this research is to determine the endurance of bread and durum wheat cultivars produced in the Southeastern Anatolian Region of Turkey by using agricultural, quality and physicochemical parameters under different ecological conditions, which may be seen in different plant growth periods.

Materials and methods

This study was conducted in Dicle University, Agricultural Faculty, Field Plants Department, Medicinal and Aromatic Plants, Open Green House conditions in 2015-16 and 2016-17 cultivation periods. The greenhouse in which the study was performed was open in both sides and the top part was covered; and did not have any limiting factors that hindered air, light and wind. Two bread wheat (Pehlivan, Ceyhan-99) and 2 durum wheat cultivars (Sarıçanak-98, Fırat-93), which are cultivated widely in the region were used in the study as the study material. Fırat-93 and Pehlivan control cultivars have been produced in the region for many years, and have proven themselves to the drought and other negative conditions of the region. Ceyhan-99 and Sarıçanak-98 varieties are cultivated in large areas in the region. The cultivation of wheat in the province of Diyarbakır is made entirely in autumn. All cultivars used as materials were cultivated in autumn. Pehlivan is a kind of biological winter. The study was carried out according to the experimental design of random blocks with 3 replications.

In the Southeastern Anatolian Region of Turkey, precipitation is seldom in summer season. The relative humidity in the air is also quite low. The annual precipitation average of the region has been 485.7 mm and the relative humidity has been around 58% for many years. The trial soils in which the study was carried out is clayey and loamy; and the salt level is low. It is rich in potassium (0.42%), slightly alkaline (pH 7.77), normal limy (7.81% $CaCO_3$) and poor in organic matter (1.67%).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41074115

The pots which were used in the study were 0.085 square meters each (Diameter: 34 cm, height: 60 cm) and had 18 kg soil volume. The seeding process was done as 12 seeds per pot. After the seeding was done in mid-November as 450 seeds/m^2, the first irrigation for all of the pots was done for germination. In October, the pots were added 20 kg (DAP 18:46) and urea (46% N) as top-fertilizer.

Drought applications as follows: **Fully Irrigated Conditions (K0):** The plants were irrigated from the time of planting to maturity, when about 40% of the available water in the soil was consumed. **Early Drought (K1):** The plants were not irrigated and irrigation was avoided from the time when the second node appeared on the plant to the beginning of the *milking stage*. **Late Drought (K2):** The plants were grown in irrigated conditions until the beginning of the *milking stage*. Irrigation was avoided from the beginning of milking stage to the harvesting period and irrigation was not carried out. **Full Drought (K3):** Irrigation was avoided from the 2nd node on the plant base until the harvest time. No irrigation was made. Drought applications were determined based on "Feekes" development period scala values by using the gravimetric method (Zadoks et al., 1974; Cook and Veseth, 1991).

In this research, vegetative characters such as leaf area and index, plant green area, chlorophyll content, plant height, generative characters such as number of grain, grain weight and grain yield and some drought parameters were tried. Leaf area consists only of leaf (lamina) and leaf sheath (vagina), the plant green area consists of the sum of the fields of spike, leaf organs, node and internodes of stem.

In this study, the endurance to drought parameters like the yield, quality and mineral substance contents, Potassium, Calcium and Sodium Concentration in green parts and roots (mg/kg dry weight). Fresh leaf samples were washed with 0.1 % HCl and in pure water and then dried at 70°C for 48 hours. 200 milligrams of these samples were incinerated for 5 hours at 550°C in an ash furnace. The ash obtained was dissolved in 3.3% HCl and filtered using blue tape filter paper (Bremner, 1965). In the obtained filtrate, K, Ca, Na concentrations were determined by atomic absorption device (Atiunicam 929) in solution.

The chlorophyll content was measured in the 3rd and 4th leaves of plants by the SPAD meter device. the readings were made with the Minolta brand SPAD meter and, the chlorophyll content units were given as SPAD value.

With the data that were obtained as a result of the study, and by using the JUMP 7.0 Statistics Program, variance analysis was made, and the differences between the average scores were evaluated with the LSD Test.

Results and discussion

In this study, in terms of wheat cultivars, it was found that the highest leaf area average was in Ceyhan-99 variety with 28.70 cm^2; and the lowest leaf area average score was in Sarıçanak-98 variety with 25.18 cm^2. The highest leaf area in irrigated conditions (K0) was 31.36 cm^2, followed respectively by late drought application (K2) with a decrease of 13.23%; full drought application (K3) with a decrease of 16.77%; and early drought application with a decrease of 21.68% (*Table 1*).

In terms of the cultivars, the highest plant green area was determined in Pehlivan with 128.16 cm^2 and the lowest green area average was in Sarıçanak-98 with 110.85 cm^2. In terms of drought applications, the highest green area value was determined in irrigated conditions (K0: 138.7 cm^2), followed respectively by late

It was determined that the highest leaf area index average was in Pehlivan with 2.06 and the lowest leaf area index average was in Sarıçanak-98 with 1.57. In terms of drought applications, it was determined the highest leaf area index value was 3.05 in irrigated conditions, followed respectively by late drought application (2.15), early drought application (1.32) and full drought applications (0.88) (*Table 2*).

In terms of average values of the cultivars, it was determined that the highest chlorophyll content was in Fırat-93 with 61.05 SPAD and the lowest chlorophyll content was in Ceyhan-99 with 56.74 SPAD. In terms of drought applications, it was determined that the highest chlorophyll content value was 61.10 in irrigated conditions (K0), followed respectively by early drought application (K1: 60.88), late drought application (K2: 60.10) and full drought applications (K3: 55.53 SPAD) (*Table 2*).

In the present study, it was determined that leaf area, plant green area and chlorophyll content were affected by drought applications. The highest values obtained from the irrigated conditions showed that especially the early drought applications were

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41074115

affected more at a rate of approximately 50%. In fact, plants reduce the transpiration area to decrease water loss to a minimum level with their decreasing leaf surface area in stress conditions. Chlorophyll content is affected by drought stress and is decreased at a significant level when compared with normal irrigated conditions. Chlorophyll decomposition is increased towards the end of the development period due to drought stress (Aghanejad et al., 2015).

It was determined that the highest plant height average was 56.08 cm in Sarıçanak-98 and the lowest plant height average was 50.61 cm in Pehlivan. In terms of drought applications, it was determined that the highest plant height value in irrigated conditions (K0) was 69.93 cm, followed respectively by early drought application (K1) with a 3.07% decrease; late drought application (K2) with a 39.11% decrease; and full drought applications (K3) with a 52.09% decrease (*Table 3*).

The highest number of spike was determined in Pehlivan as 714 pieces/m^2 and the lowest number of ears value was determined in Fırat-93 variety as 611 pieces/m^2. In terms of drought applications, the highest number of ears in square meter in irrigated conditions was 967 pieces, followed respectively by late drought application (K2: 813), early drought application (K1: 506) and full drought applications (K3: 343) (*Table 3*).

The highest fertile stem ratio was determined in Ceyhan-99 with 68.89 % and the lowest fertile stem ratio average was determined in Fırat-93 with 45.16%. In terms of drought applications, the highest fertile stem ratio in irrigated conditions was found as 93.72%, followed respectively by late drought application (K2) and early drought application (K1). In full drought applications (K3), the fertile stem ratio was determined to be 0% (*Table 4*).

In the present study, when the average values of the cultivars were examined it was determined that the highest thousand grain weight was determined in Pehlivan with 26.72 g and the lowest thousand grain weight was determined in Fırat-93 with 19.21 g; and in terms of drought applications, it was determined that the average value varied between 19.49 g and 42.71 g. The highest thousand grain weight value in irrigated conditions (K0) was determined as 42.71 g followed respectively by late drought application (K2) with a decrease of 21.33%; and by early drought application (K1) with a decrease of 54.37%. No grains were obtained in the Full Drought Application (K3) (*Table 4*).

It was determined that the highest number of grains in the spike was in Ceyhan-99 with 24.86 and the lowest number of grains in the spike in average was in Fırat-93 variety with 14.01. In terms of drought applications, the highest number of grains in the spike in irrigated conditions (K0) was 35.01, followed respectively by early drought application (K1: 31.52) with a decrease of 9.97%; and late drought application (K2: 12.67) with a decrease of 63.81%. No grains were obtained in the Full Drought Application (K3) (*Table 5*).

The highest average grain yield was determined in Ceyhan-99 variety with 3057.4 kg/ha and the lowest grain yield average was determined in Fırat-93 with 2378.2 kg/ha; and in terms of drought applications, the average values varied between 949.1 kg/ha and 5605.9 kg/ha. The highest grain yield value in irrigated conditions (K0) was determined as 5605.9 kg/ha followed respectively by early drought application (K1) with a decrease of 17.72%; and late drought application (K2) with a decrease of 83.07%. No grains were obtained in the Full Drought Application (K3) (*Table 5*). Early drought applications were found to be effective on plant height, especially grain number per spike and indirectly on grain yield. Grain yield was taken but remained quite low.

In terms of drought applications, it was determined that the highest potassium amount in the plant root tissues was in early and late drought applications (K1: 18.71

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41074115

and K2: 18.20 mg), and the lowest potassium amount was 13.09 mg in full irrigated conditions. In the evaluation made in terms of variety-drought applications, the highest Potassium amount was determined in Sarıçanak-98 in the late drought application (K2: 18.23 mg), and the lowest Potassium amount value was found in Ceyhan-99 variety in late drought application (K2: 5.12 mg) (*Table 6*). In terms of the potassium (K) amount in the stem tissues of the wheat plants, when the average values of the cultivars were examined, it was determined that the highest Potassium amount was in Ceyhan-99 variety (24.47 mg) and the lowest Potassium amount was in Pehlivan variety (14.94 mg). In terms of drought levels, it was determined that the highest Potassium amount average was found in early drought application (K1: 18.71 mg), and the lowest Potassium average was found in irrigated conditions (K0: 13.09 mg) (*Table 6*).

Table 6. *The average values of potassium amounts in the plant roots and stems*

Potassium (K)

In the examinations on plant roots, it was determined that Fırat-93 variety had a value of 16.63 mg in terms of Calcium amount and Ceyhan-99 variety had an average of 6.15 mg. In terms of drought levels, the highest Calcium amount was determined in the late drought application (K2: 17.20 mg), the lowest Calcium average was determined in the full drought application (K3: 7.15 mg). In terms of variety-drought interaction, it was determined that the highest Calcium amount value was in Pehlivan variety in late drought application (K2: 29.40 mg), and the lowest Calcium amount value was in Fırat-93 variety in full drought application (K3: 0.670 mg) (*Table 7*).

In terms of the Calcium (Ca) amount found in the stem tissues of the wheat plants, when the average values were examined in terms of the average values of the cultivars, it was determined that the highest Calcium amount was in Ceyhan-99 variety (17.33 mg) and the lowest Calcium amount was in Sarıçanak-98 variety (9.27 mg). In terms of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41074115

drought levels, it was determined that the highest Calcium amount average was in full drought application (K3: 13.47 mg), and the lowest Calcium average was in late drought application (K2: 10.63 mg) (*Table 7*).

As a result of the analyses made on the plant root tissues it was found that the highest Sodium amount was in Ceyhan-99 variety (18.33 mg) and the lowest Sodium amount was in Pehlivan variety (2.22 mg). In terms of drought applications, the highest Sodium amount average was determined in irrigated conditions (K0: 14.51 mg), and the lowest Sodium average was found in late drought application (K2: 9.10 mg). In terms of variety-drought interaction, the highest Sodium amount was determined in Ceyhan-99 variety in early drought application (K1: 23.34 mg), and the lowest Sodium amount value was determined in Pehlivan variety in early drought application (K1: 0.20 mg). In terms of the Sodium (Na) in the stem tissues of the wheat plants, when the average values were examined, it was determined that the highest Sodium amount was in Ceyhan-99 variety (15.41 mg) and the lowest Sodium amount was in Pehlivan variety (0.69 mg). In terms of drought levels, the highest Sodium amount average was determined in full drought application (K3: 18.90 mg), and the lowest Sodium average was determined in early drought application (K1: 3.35 mg). In terms of variety-drought interaction, the highest Sodium amount was determined in Ceyhan-99 variety in irrigated conditions application (K0: 27.05 mg), and the lowest Sodium amount value was determined in Pehlivan variety in full drought application (K3: 0.21 mg) (*Table 8*).

Table 8. *The average values of Sodium amounts in the plant roots and stems*

Sodium (Na)

Conclusion

The effects of drought on the development and yield of the wheat depends on the developmental period in which drought occurs, on the severity, and on the time of the drought. The negative effect of drought on the leaf area after the heading and blooming is considered as the sole reason of the decrease in the yield. The drought occurring at the spike formation stage causes reductions in the number of grains in spike, and the one occurring after the blooming affects negatively the increase in the mass weight of the grains after a certain point.

The increase of Potassium concentration in plant tissues increases the durability of the plant to stress factors (Hsiao and Lauchli, 1986). It is known that the genotypes which have more K and Ca ions in green parts and roots have increased endurance to stress conditions, and in addition, this also causes increases in the enzyme activities in the genotypes during drought stress (Kusvuran, 2010). One of the basic elements that is necessary for growth and development is K and the other one is Ca ion. Abiotic stress affects the K and Ca intake negatively. In the present study, it was observed that

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41074115

drought stress increased the K and Ca levels in the plant however, it was also observed that this level changed according to different drought applications. It is possible to claim that especially in the late drought application, the substance coverage of both minerals increased. Again, it was also determined that the cultivars showed different K and Ca levels in different drought applications. It is known that the Sodium ion causes necrotic stains on the shoots and leaves starting from the old leaves in drought conditions (Aktas, 2002; Dasgan et al., 2006). As seen in the K/Na and Ca/Na rates in the green parts and roots, it was determined that the genotypes with higher Na and lower K and Ca contents were more susceptible to damage.

As a result, Ceyhan-99 cultivar which show the best average of 7 agricultural and biochemical characters, were superior to all other wheat cultivars in Southeast Anatolia conditions of Turkey. However, these drought studies should be continued for longer years and changing climate conditions, the drought resistance of the varieties, produced in the region should be determined.

(Received 5th Dec 2018; accepted 28th Feb 2019)

Abstract. Effective public participation is considered essential to making sound decisions for the protection and sustainable management of natural resources. This paper aims to analyze the preferences of forest villagers to protect state forests within the boundaries of villages and generate income for their livelyhoods. As a case study area in Turkey, forest villages of Rize-Ikizdere town were selected to carry out the research. In the study area, intensive forest protection activities are carried out under the administration of Trabzon Regional Directorate of Forestry. A questionnaire form was developed and applied to the villages of the town on a face-to-face basis. According to the survey results, while most of the participants preferred to hand over the forest protection responsibility from state to legal village administration, they indicated some concerns about taking over the responsibility of forest protection that would bring some risks under the proposed policy. In conclusion, most of the participants envisioned that the new policy was likely to develop mutual understanding of participation, thoughtfulness, worthiness and stewardship about forests rather than foreseeing it as a source of income generation, and help lessen the forest degradation to a certain extent.

Keywords: *public participation, natural resources, forest villagers, survey, conservation*

Introduction

One of the basic objectives of all national forest policies include conservation with a focus on protection, maintenance, sustainable utilization, restoration and enhancement of the forested lands (Alemagi et al., 2013); however, meeting the objectives set by these policies has rarely been fully achieved (Makarabhirom, 1999). One of the impediments has been the lack of public participation in processes and mechanisms which enable stakeholders to be part of decision-making in all aspects of forest resource management, including policy formulation processes. Effective public participation is thus considered essential to making sound and better quality decisions about sustainable forest management (Beierle and Cayford, 2002; Buchy and Hoverman, 2000; Diaw et al., 2009; Kozak et al., 2008; Mendoza and Prabhu, 2000; MPWG, 1999; UNCSD, 1992; WCFSD, 1999) through which the socio-economical, ecological, and cultural values of the public can fully be taken into consideration regarding forest use and management (Buchy and Hoverman, 2000; Duinker, 1998; Pretty and Smith, 2004; Shindler and Neburka, 1997). This can be achieved by ecologically acceptable and socio-economically feasible approaches involving processes and mechanisms that enable stakeholders in forest resources to be part of decision-making in all aspects of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41174132

forest management, including policy formulation (Cantiani, 2012; FAO, 2012 Kaskoyo et al., 2017).

Over the last several decades, public participation has become an important topic for environmental agencies throughout the world, and has been increasingly incorporated into forest management decision-making, with, in many cases, legal provisions for public input (Ahmed and Jana, 2017; Alemagi, 2007; Buchy and Hoverman, 2000; Cantiani, 2012; Coskun and Elvan, 2003; Duinker, 1998; Sinclair and Doelle, 2003). All these developments have been driven by pressures brought about by certain realities of ecology and economics and our increased demands for multiple use; expectations from and changing attitudes towards forests; and the need for the development of new policies and more effective management systems. The first examples of public participation in the management of forests were seen both in the developed and developing countries; however, objectives set and methodologies employed were different, due to the complex nature of the problems associated with the ownership of the lands and land use objectives.

In Canada and the US, for example, the onset of the participation process in as early as 1960 resulted in an increase in public awarenes of environmental issues among wider sections of the population (Cantiani, 2012; Germain et al., 2001; Grumbine, 1994; Tabbush, 2004; Vining and Tyler, 1999). Among other countries in Europe, Finland has been an important example in applying the effective and structured participation in forestry through establishing a number of working groups, represented by a wider range of people and the associated political parties to develop forest policies and prepare forestry related projects (Anonymus, 1995).

In some developing countries, public participation has been exercised in a more cohesive way and with more focus on the empowerment of local populations emphasising principles of equity and social justice (Cantiani, 2012). This approach assumes partial or full responsibility of local people in the management of resources within their jurisdictions. In this regard, a new concept of “Forest management by the village” in Tanzania (Warner, 1997), “Joint Forest management (JFM)” concept of India (Ahmed and Jana, 2017; SPMU, 2015), “Social Forestry Programme” of Nepal (Gimmour and Fisher, 1991) can be given as important examples.

Turkey also represents a similar and a unique example. Public participation is a major concern in the management of forest resources. With about seven million people living in about 20 thousand villages in and around forested lands, most forest villagers depend on forests for their livelihoods. Almost all forested lands (99.9%) in the country belong to the state and are managed and protected by the General Directorate of Forestry (GDF). State policies for the protection of forestlands and natural resources have been developed with little emphasis on the needs, demands and expectations of society and forest communities. Although many different protection measures have been taken and implemented, including “forest soldiers” (Bingöl, 1990) and “centralized protection centers” (Ayanoglu, 1981), success has been limited. In the search for a better alternative, a method/policy that empowers the legal village administration to protect the forests within the boundaries of villages with a certain amount of budget and a bilateral protocol has been explored for some two decades now. However, there have been no comprehensive research endeavors, aside from some theoretical studies, documenting the pros and cons of handing over forest protection activities to the village administration compared to the current practices. It is quite uncertain how much benefit the alternative methods may provide to the forest villagers and to the sustainable

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41174132

management of the forest resources. Besides, the expectations, demands and preferences of the forest villagers would be unknown when the new protection policy would be in effect.

The objective of this research is to analyze the attitudes and preferences of forest villagers regarding the transfer of forest protection activities, currently conducted by the forest protection unit of the state forest organizations, to the legal entity of villages. The study also focuses on revealing the probability of success of the newly proposed approach in the eyes of the forest villagers. The forest villages of Rize-Ikizdere town were selected as a case study area. Here, the forests are intermingled with both residential areas and agriculture lands creating complex and intense forest protection activities.

Material and methods

The case study area is located between 40°57'12"- 40°50'46" N latitudes and 40°24'15" - 40°55'07" E longitudes in the northeastern part of Turkey (*Fig. 1*). The total surface area of Ikizdere town within the province of Rize is about 89,800 ha, of which 29,698 ha (33%) is forested. The population of Ikizdere, which is the highest of all the towns in Rize, was nearly 5,600 in 2017. 68% of the population (3,814) lives in the villages and the outskirts of Ikizdere town (URL-1, 2018). According to article 31 of Turkish Forest Law 6831, 24 villages of Ikizdere Town are in the status of “forest villages” that have certain privileges and status over other ordinary villages.

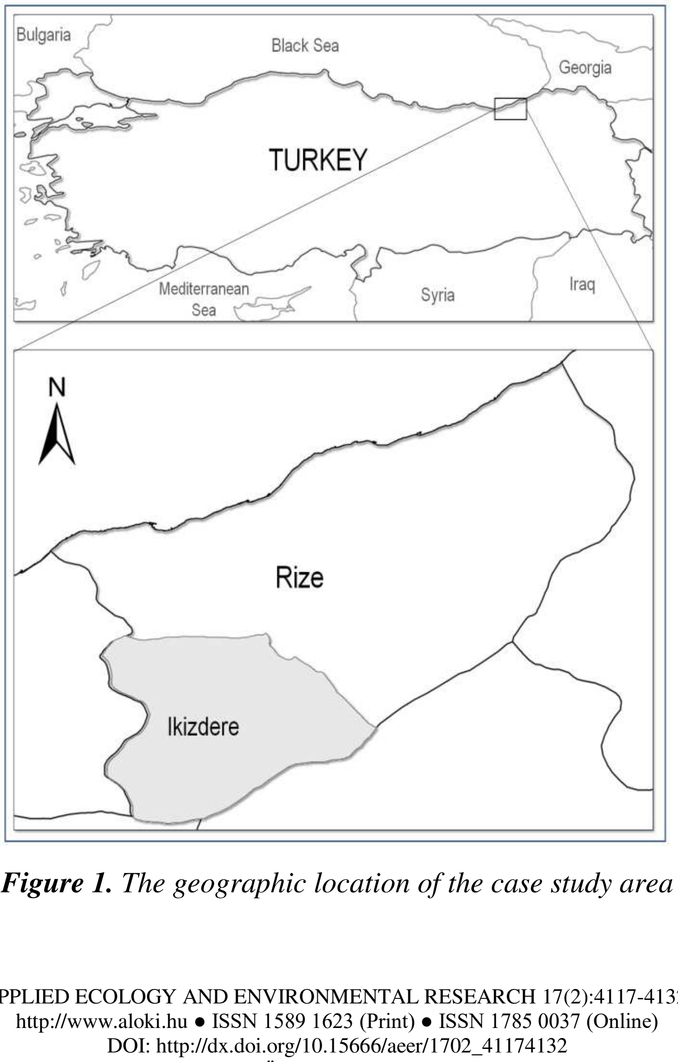

Figure 1. *The geographic location of the case study area*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41174132

The research method employed in this study entailed the use of structured questionnaires administered in the forest villages located within the study area. The questionnaire form consisting of 12 structured questions was tested with an initial pilot application in the study area prior to the implementation of the study. As a result, the number of questions were reduced to eight and revised accordingly in the process. The individuals interviewed were selected with a simple random sampling method. The survey was conducted by one researcher in the field on a face-to-face interview basis. A total of 104 households from 24 potential forest villages were contacted for the interview. Only one person per household (the household representative) was interviewed to avoid repetition and achieve some level of consistency in answers from respondents of the same household (Asante et al., 2017). Four to five household representatives from each village were included in the study. The number of respondents required (sample size) in this study was calculated to be 96 using the formula (*Eq.1*):

$$n = \frac{F \times t^2 \times P \times Q}{\left(F \times m^2 \right) + \left(t^2 \times P \times Q \right)} \quad \text{(Eq.1)}$$

where,
n: sample size
F: Population size
t: Confidence level (95%)
m: Margin of error (10%)
P and Q: Percentage value (0,5 × 0,5).

The questionnaire form was designed to acquire both personal information of forest villagers such as the number of individuals in the household, the age, education level of the respondents and the annual income of households, and other information in line with the objective of the study, such as the possibilities, advantages and disadvantages of transferring the rights of state forest protection activities to the forest villagers, as well as gathering the opinions of the villagers about the current status of forest protection. The questions of the survey were designed in the form of a series of closed-ended, single-choice questions. The respondents were asked to select one alternative among all alternatives provided within the survey form. In addition to the close-ended questions, the form also included an additional alternative under the heading of the “other” to allow the respondents to suggest different alternatives freely. The results of the survey were statistically analyzed using the Statistical Package for Social Scientists (SPSS version 16). The socio-economic and demographic characteristics of respondents were summarized and presented using simple descriptive statistics. Moreover, to see if there is a relationship between socio-economic and demographic characteristics of respondents and their choises, Chi-squared test was employed. In addition to the analysis of the questionnaire results, the qualitative data from the interviews was also evaluated to get the ideas and preferences of the respondents regarding the protection of the state forest resources.

Results

In this survey, two out of eight questions asked to the respondents were about the socio-economic and demographic structure of the villages. The rest of the questions were about the opinions and preferences of the respondents who were asked in order to select the method that people would see as appropriate.

[1]Worker: person working for a state organization as a worker; Officer: person employed by a state organization as a civil servant; Private sector: any person not employed by a state organization; Other: person retired or having no job.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41174132

According to *Table 1*, there are primarily 6-7 individuals in a household and the average age of the household representatives is over 50 years. The literacy rate of the household representatives is about 95%. This is almost the same as the average literacy rate of the country (96%) (URL-2, 2018).

The survey included questions regarding the employment and the income level of the households. The type of employment and the salaries of the respondents were directly asked in the household survey. Additionally, where agriculture is not the main source of income, it was thought that income from agricultural activities would also be valuable to determine the total income of the households more realistically. Thus, the amount of agricultural products produced were included in the questions asked, and the results were processed with the current unit prices in order to determine the income level of the households. *Table 2* shows the employment and the annual income level of the households. The US dollar currency of the date when the survey was conducted was used in the conversion.

About 54% of the households surveyed in this study has an annual income level under 1000$ per person, indicating a monthly income of less than 100$. The agricultural income is quite low due to the scarcity of agricultural land and the poor productivity of the land used for agricultural purpose. However, the presence of officers and workers in households helps increase the annual income level in the case study area. Some of the "private workers" are working only in agricultural activities and animal husbandry; the others are operators or small businesspersons in the town facilities or tourism facilities. The "other" category of occupation in *Table 2* refers to the persons who are either housewife or jobless.

Opinions of the household representatives about the forest and forestry

In this category of the survey, five closed-ended questions were asked to the representatives of the household and the results were analyzed in the following sub-headings.

Who should protect the state forests?

The appropriate choice among the possible alternatives for the protection of the state forests within their village boundaries was asked to the forest villagers. For that purpose, four alternative methods of forest protection were determined and placed into the survey. The first of the four alternatives in the questionnaire form refers to the current alternative of "continuation of the current method of forest protection (by the state forest sector)", the second alternative is about the "protection of forests by the civil authorities", the third one refers to the "forest protection by the squads of forest soldiers experienced in a certain period in the history of Turkish forestry" and the last one is the "protection of state forests by the villagers". The answers to these important questions are given in *Table 3*.

Table 3. *Alternative forest protection methods presented in the survey*

Alternative methods for better protection of forests	Number	Percent
Forests should be protected by the state forest organizations	47	45
Forests should be protected by the legal village entities	57	55
Total	104	100

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41174132

According to *Table 3*, the majority of the respondents (55%) preferred the choice of forest protection by the forest villages. The rest of the respondents (45%), however, favored the alternative of forest protection by the state forest organizations as currently practiced in Turkey. In fact, there was no significant difference between the two alternatives. Surprisingly, the other two alternatives (forest protection by the civilian authorities and forest protection by the squads of forest soldiers) developed in the survey form were not selected by the respondents at all. Aside from the four alternatives, no additional alternative was suggested by the respondents either.

Evaluating the pros and cons of forest protection by the villages

Table 4 presents the responses about the priority or degree of the possible consequences of transferring the state forest protection activities to the legal village entities.

Table 4. *Benefits of transferring forest protection to the forest villages; first option: "Development of desire to safeguard the forest and increased feeling of affection for them"; second: "A decrease in forest related crimes, due to resulting self-control"; third: "Less illegal forest utilisation"; fourth: "Generation of additional income for the villagers*

Benefits of forest protection by forest villages	Rank	Number	Percent
Develops the spirit for safeguarding and feeling of affection for the forests.	1	82	80
Decreases forest related crimes as it brings self-control	2	37	36
Lessens illegal forest utilization.	3	49	47
Helps generate additional income for the villagers.	4	75	72

Based on the interpretation of *Table 4*, the majority of the respondents (80%) believes that the principle benefit of forest protection by the forest villages would be the choice "develops the spirit for safeguarding and feeling of affection for the forests", that shows the level of forest stewardship. About 36% of the respondents indicated that forest protection by the forest villages will cause decreases in forest related crimes as it brings self-control. The third priority benefit of forest protection by the forest villages is indicated by 47% of the respondents to be the "lessens illegal forest utilization". At the bottom of the priority list, 72% of the respondents indicated that forest protection by the forest villages will help generate additional income for the villagers.

On the other hand, potential disadvantageous of forest protection by the forest villages were also questioned in the study. The opinions and the concerns of the villagers were gathered in the survey as well. The results are presented in *Table 5*.

Table 5. *Ranking the disadvantages of forest protection by the forest villages*

Disadvantages of forest protection by forest villages	Rank	Number	Percent
Inefficiency in forest protection by the villagers may arise due to the lack of knowledge about forest ecosystems in general.	1	35	34
Disputes with neighboring villages or villagers may be inevitable and this may fuel hostility, should village administrations take biased or prejudiced decisions.	2	64	62
Severe confrontations may be indispensable in the election of chiefs for the villages.	3	27	26
Illegal forest utilization may increase.	4	41	39

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41174132

According to *Table 5*, nearly 34% of the respondents indicated the most important concern about forest protection by the forest villages was “inefficiency in forest protection by the villagers may arise due to the lack of knowledge about forest ecosystems in general”. The second important concern indicated by the 62% of the respondents is the possible “disputes with neighboring villages or villagers may be inevitable and this may fuel hostility, should village administrations take biased or prejudiced decisions”. Of course, the chief or managers of forest village administration will become responsible and powerful with the initiation of forest protection by the villages. The candidates for the chief position may be confronted by serious challenges to get the rights and power of the village administration. Such situation may cause hostilities among the villagers. This concern is ranked third among the disadvantages of forest protection by the villages. Finally, 39% of the respondents believed that “illegal forest utilization may increase” as a forth concern when forest protection activities are transferred to the forest villages.

Forest villagers´ Expectations from the agreement between the state and the village administration upon the transfer of forest protection to forest villages

The opinions of the villagers were gathered in the survey in order to determine the conceivable expectations of forest villagers from the transfer of forest protection activities to forest villages. The results are summarized in *Table 6*.

Table 6. *Expectations of forest villagers from the agreement upon the transfer of forest protection to forest villages*

Expectations	Rank	Number	Percent
Social security coverage for the villagers working in forest protection activities.	1	95	91
Higher payments	2	62	60
Training of forest villagers who will work in forest protection activities about the rights and the responsibilities.	3	60	57
Provision of clothes, guns and other equipment to the forest villagers in charge of forest protection	4	57	55

Table 6 shows that the most important expectation is the “covering of the villagers working in forest protection activities under social security programme.” reflected by the 91% of the respondents in the survey. The second level of expectation is the high level of payment for the villagers who will work in forest protection activities. Training of forest villagers and provision of clothes, guns and other equipment to the forest villagers in charge of forest protection are among the latter expectations.

Evaluation of legal rights and responsibilities upon the transfer of forest protection to the forest villages

The villagers empowered with the rights to protect the forest resources need to know their legal rights and the responsibilities to carry out the activities effectively. The opinions and the concerns related to the legal rights and the responsibilities for the villagers are summarized in *Table 7*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41174132

Table 7. *Results related to the legal rights and responsibilities of forest villages entitled to protect forest resources*

Evaluations by the forest villagers	Number	Percent
Forest villages should be empowered with the same rights and responsibilities of the current forest rangers.	38	37
The duty of protection should exist, yet administrative and judicial penalty provisions for forest related crime and lawbreakers still need to be exercised by public officers.	31	30
Forest villages and the forest rangers need to cooperate in enforcing the penalties incurred for the incurred by lawbreakers.	42	40
No legal rights regarding the about the administrative and judicial penalty provisions should be granted to the forest villages	6	6

According to *Table 7*, forest villagers seem to abstain from undertaking legal rights and responsibilities for forest protection activities. Only 37% of the local people indicate their desire to empower the forest villages with the rights and responsibilities of the current forest rangers. Others either would like to cooperate with the public officers and do not want to get involved, as an intervener, in prescribing and enforcing the associated penalties for the lawbreakers.

Opinions about causes of committing forest crimes or misconducts

The fundamental causes of committing forest crimes in state forests in the eyes of forest villages are evaluated here. While four different questions were designed and asked to the forest villagers in the survey, only two of them were responded appropriately.

Table 8. *The results and the rates of the causes of committing forest crimes*

The causes of committing forest crimes	Number	Percent
Inadequacy of the recruited forest rangers	5	5
Poverty of forest villagers	99	95
Total	104	100

Table 8 clearly shows that the fundamental cause of forest related crimes or misconducts is apparently the poverty of the forest villagers (95%). The inadequacy of the recruited forest rangers is only represented by 5% of the respondents. However, the alternatives of “attitude to gain improper personal benefit” and “desire to proclaim forest land for agricultural activities” were not selected by the respondents at all. While there was the “other” alternative for the respondents to provide further causes of forest crime, it was left blank.

Discussion

This paper highlights the preferences of forest villagers to protect state forests within the boundaries of villages in the northeastern part of Turkey. It also outlines the perceptions of the local people in public participation and identifies challenges in forest protection in Turkey. The study is limited in terms of coherence and extent, but

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41174132

provides new perceptions in forest protection in state-owned forests. Almost all forests are owned by the state in Turkey, and General Directorate of Forestry (GDF is the primary state organization in the country responsible for both managing the forest resources including all forest related actions and patrolling the forest lands and protecting its properties against any illegal activities in all forests across the country. The forest protection activities have long been carried out by the forest rangers established by the state forest sector for over 60 years. While the forest crimes in the country have decreased for the last three decades, more than 120,000 forest misconducts have been registered over the last decade (2008-2017). The number of forest misconducts in 2016 alone constituted nearly 10,000 cases according to the official reports (GDF, 2016). Moreover, it is suspected that majority of forest misconducts have not been reported and registered in the official records, indicating an inadequacy in overall protection activities.

The questionnaire administered in the selected case study areas identified both demographic status of the respondents and the opinions and expectations of forest villagers about the transfer of the authority in forest protection to the villages as per an agreement between the state and the village administration. According to the survey results, the literacy level of the people and the size of the household in the case study area were found to be close to the country averages (URL-2, 2018). When the income is evaluated, nearly 55% of the people has an annual income of less than 1,000$ per individual. However, the annual income per individual is considerably higher in households having public officers and private job owners such as salesmen or small entrepreneurs.

People living in the forest villages consider that the primary reason for committing a forest crime in state forests around villages is the poverty in rural areas. Only the 5% of the respondents indicated that forest destruction is realized due to inadequacies or vicious attitudes of the forest rangers authorized in forest protection activities. These results are in agreement with poverty related forest crimes in the developing countries (ATIF). Forest management and protection programmes through participation have mostly been developed in response to both high number of forest crimes and the reality of the forest villagers being among the poorest people of the country (UNCSD, 1992; Duinker, 1998; WCFSD, 1999; MPWG, 1999; Buchy and Hoverman, 2000; Coskun and Elvan, 2003; Pretty and Smith 2004; Alemagi, 2007; Kozak et al., 2008; Cantiani, 2012). In this regard, public participation in forest management may be an important step towards the sustainable use and protection of forest resources (Alemagi, 2007; Kozak et al., 2008; Diaw et al., 2009; Cantiani, 2012; Ahmed and Jana, 2017). One of the practical alternatives seems to be the transfer of the forest protection activities to the forest villagers under certain provisions as suggested in this study. Such that, forests would be protected more effectively than previously and there would be a relative increase in the income of forest villagers.

Almost 45% of forest villagers involved in the survey favored the maintenance of current operation or method in forest protection. However, the majority preferred the transfer of forest protection authority to the villages. The contract of forest protection can be considered to be a source of income particularly for the unemployed villagers or the households involved in agriculture and animal husbandry. As a matter of fact, almost 70% of the respondents expects that the annual income of the forest villagers will considerably increase due to the contract of the forest protection taken by the villages. Several programmes implemented in many countries provided evidences to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41174132

support this conclusion (Kozak et al., 2008; Vergara-Asenjo and Potvin 2014; Kaskoyo et al., 2017; Ahmed and Jana, 2017). The results also indicate that additional sources of income may be generated for the common expenses of the villages such as roads, bridges, mosques and common village mansions. In addition to additional source of income for individuals and fund raising for common village expenses, it was understood with 80% of acceptance level that the protection of forest lands by forest villages would enhance the relationships between people and their forest, internalize the proposed forest management concept and help increase an interest in forests. Additionally, *Table 6* indicated that forest villagers authorized in forest protection activities would like to have payment and social security covered by the new alternative as they work in state forest management endeavors. These findings are in close agreements with other reports. In Panama, for example, it was reported that public participation and the provision of additional sources of income (Vergara-Asenjo and Potvin, 2014) and increased use of state forests by the villagers would increase the success in forest protection (Thang et al., 2010). Moreover, these provisions may foster and lead to the acceptance of new rights for the poor forest villagers (Scheba and Mustalahti, 2015).

Surprisingly, the assumption that the number of unaccounted and of reported forest crimes may be lowered as a result of transferring the forest protection activities to the forest villages due to self-control was not favored by the majority of the respondent forest villagers. Even, as seen in *Table 5*, almost 39% of the villagers showed a deep concern about the possible increase in illegal forest utilization. Besides, clothes, guns and other equipment was also requested for the forest villagers in charge of forest protection.

Forest villagers taking part in the survey are doubtful about fulfilling appropriately or enforcing the duty of forest protection given to them. Almost 57% of the forest villagers would like to be trained by the state forest organizations on the expected rights and the responsibilities. Trainings were reported to improve the succes of such programmes (Kaskoyo et al., 2017). In contrast to that, only 37% of the forest villagers thinks that they would be able to enforce the duty of forest protection if the related legal basis is established. The majority would like to cooperate with the public officers to conduct forest protection activities and indicated that administrative and judicial penalty provisions for the forest related crime and the lawbreakers still need to be exercised by the public officers.

The forest villagers show serious concerns about possible confrontations with neighboring villages as well as with their own during the prevention of forest crimes and struggle with lawbreakers. Furthermore, people worry about the fact that the challenge may spark off undesired confrontations among households during the elections for the village administration.

As for the relationship between socio-economic and demographic status of the respondents and protection alternatives, Chi-squared statistic did not reveal any significant relationships between the responses of villagers and the socio-economic and demographic variables. However, although not statistically significant, unlike expectations, results indicated that older people were more of the opinion that protection activities should be transferred to villages. This can be ascribed to the fact that young people have a tendency to move to metropolitan areas to find better job opportunities. The results also indicated a parallelism in the tendency of forest protection by the villagers as the number of households increase.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41174132

Conclusions

General conclusions reached can be summarised as:

- Villagers, in general, seem to be ambitious and prepared to use the rights and shoulder the responsibilities for the protection of forests within the boundaries of their villages with a certain amount of negotiated budget and a bilaterally agreed protocol.
- Most of the participants in the survey envisioned the new policy proposal to provide some opportunities to develop mutual impressions about participation, thoughtfulness, worthiness and stewardship in forest protection and, to a lesser extent, generate a source of income.
- Training is necessary for the successful implementation of the proposed program. In this regard, villagers who will take part in forest protection activities need to be trained systematically about the due rights and responsibilities. And,
- An effective administrative controlling process seems to be inevitable. State forest administration should continue to cooperate with the forest villagers in struggling with the forest lawbreakers as well as preventing any conceivable prejudiced decisions of the villagers and likely corruptions. It is also crucial and necessary that the state forest organizations enforce the duty of both administrative and judicial penalty provisions for the forest related crimes.
- Transferring the forest protection activities to the forest villages is considered timely and necessary in Turkish forestry provided that the required precautions are taken and some cases are designed and implemented in pilot areas to foresee any possible complications and problems, before the widespread implementation of the approach across the country.
- Given the area studied and issues contained in the study, this study can be considered extremely limited. Community involvement in any planning requires that local conditiones be also included in the overall planning process. Therefore, new studies are required for other regions before a wisespread implementation of the proposed program. The new studies should involve socio-economical, physical, ecological aspects of community involvement in future forest management plannings.

Questionnaire

1. The interviewee:

Age: …………………………………………………
Educational status:………………………………….
Occupation: …………………………………………
Number of population in the household: ……..…….

2. Total annual income of the household:

I. Salary: (for employees)……………...............……... $/year
ii. Agricultural income: ………………………………… $/year
iii. Livestock income:…………………………………… $/year
iv. Other incomes (self-employment):…………………... $/year

3. Alternative forest protection methods presented in the survey

a. Forests should be protected by the state forest organizations
b. Forests should be protected by local governors
c. Forests should be protected by troops
d. Forests should be protected by the legal village entities
e. other (please specify ....)

4. Benefits of forest protection by forest villages

a. Develops the spirit for safeguarding and feeling of affection for the forests
b. Decreases forest related crimes as it brings self-control
c. Lessens illegal forest utilization.
d. Helps generate additional income for the villagers.
e. other (please specify ....)

5. Disadvantages of forest protection by forest villages?

a. Inefficiency in forest protection by the villagers may arise due to the lack of knowledge about forest ecosystems in general.
b. Disputes with neighboring villages or villagers may be inevitable and this may fuel hostility, should village administrations take biased or prejudiced decisions.
c. Severe confrontations may be indispensable in the election of chiefs for the villages.
d. Illegal forest utilization may increase.
e. other (please specify ....)

6. Expectations of forest villagers from the agreement upon the transfer of forest protection to forest villages

a. Social security Coverage for the villagers working in forest protection activities.
b. Higher payments
c. Training of forest villagers who will work in forest protection activities about the rights and the responsibilities.
d. Provision of clothes, guns and other equipment to the forest villagers in charge of forest protection
e. other (please specify ....)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41174132

7. Results related to the legal rights and responsibilities of forest villages entitled to protect forest resources.

a. Forest villages should be empowered with the same rights and responsibilities of the current forest rangers.
b. The duty of protection should exist, yet administrative and judicial penalty provisions for forest related crime and lawbreakers still need to be exercised by public officers.
c. Forest villages and the forest rangers need to cooperate in enforcing the penalties incurred for the incurred by lawbreakers.
d. No legal rights regarding the about the administrative and judicial penalty provisions should be granted to the forest villages
e. other (please specify ....)

8. What are the main reasons for forest crimes?

a. Easy and unfair gain
b. Inadequacy of the recruited forest rangers
c. Efforts to provide new agricultural areas
d. Poverty of forest villagers
e. Other (Please specify…………………………………….)

Abstract. Many sites of the world are currently faced with the prospects of air pollution. It is well established that photocopying machines generally contribute to the indoor emissions of Volatile Organic Compounds (VOCs) and Ozone that strongly influence the health of individuals. The current study aimed to discern the spatiotemporal variations of indoor Total Volatile Organic Compounds (TVOCs) and Ozone using a real-time monitoring approach in photocopying centers over mega-city of Pakistan. The real-time monitoring transcribed the diurnal variability of TVOCs and Ozone in photocopying centers (n = 200) during working hours (8:00 AM to 8:00 PM). Spatially, a high degree fluctuation was observed in the indoor level concentrations of TVOCs and Ozone. A typical diurnal cycle with a minimum value in the morning and a maximum in the noon with a gradual decrease until night was observed for TVOCs and Ozone suggesting that the photocopying emissions were a major source of generation. A significantly strong positive correlation was found between TVOCs and Ozone ($r = 0.627$, $p < 0.001$). The findings were compared with the available standards indicating the potential of health hazards to workers.
Keywords: *air pollution, ozone, photocopying machines, indoor environment, total volatile organic compounds*

Introduction

In the current era of mechanization, photocopying machines are among the imperative accessories in the office setup. Globally, photocopying industry is a source of earning for millions of workers. A prominent modification with regards to the technical aspects, basic material, convenience, yield and skillfulness in the photocopying process has also encountered (Elango et al., 2013; Kasi et al., 2018).

In spite of commercial ease and viability, photocopiers are considerable initiators of air pollution. During functional mode, photocopiers release particles of toner, volatile and semi-volatile organic compounds, particulate matter, particles of paper, nano-particles, ammonia, ozone, oxides of nitrogen, metals including arsenic, iron, chromium, titanium, zinc, nickel, cadmium, elemental sulphur and silicon (Durga Ch and Gokhale, 2015; Lee et al., 2006; Bar-Sela and Shoenfeld, 2008; Barthel et al., 2011; Bello et al., 2013; Wensing et al., 2008; Morawska et al., 2009; Adetunji et al., 2009; Pirela et al., 2013; Kleinsorge et al., 2011).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41334146

The tracking of Volatile Organic Compounds is required to evaluate the air quality. Spatiotemporal fluctuation of VOCs with respect to source is crucial in alleviating photochemical pollution (Huang et al., 2014). The chemical deterioration of VOCs gives rise to secondary air pollutants including peroxyacetyl nitrate (PAN), secondary organic aerosols and aldehydes. Sunlight as an auxiliary component in the presence of nitrogen oxides and volatile organic compounds promotes the generation of ground level ozone. The profile of VOCs and ozone reveals that the generation of ozone is VOC restricted (Srivastava et al., 2005; Lee et al., 2002; Toro et al., 2006). The association between the atmospheric emissions in terms of Nitrogen oxides and VOCs couples with the generation of ozone (Xu et al., 2017).

Ozone is a predominant component of the atmosphere that is of crucial importance to global climatic variation and tropospheric chemistry (Reddy et al., 2012). The precursors and elevated ozone levels are of great concern owing to the deleterious effects on the human health, forests, plants, natural and anthropogenic materials (Mavroidis and Ilia, 2012; Fann and Risley, 2013; Szyszkowicz et al., 2012; Kheirbek et al., 2013; Kumar et al., 2014a, b; Singh et al., 2014).

The traditional methods for the detection of organic compounds can require weeks to systematize, execute, delineate and interpret results. Direct reading methods (DRMs) have been initiated in workplaces as a substitutive approach with the benefits of swift measurement of the concentration (Brown et al., 2016). Direct reading methods using a portable real-time monitor for the detection of VOCs is a convenient tool (Coy et al., 2000; Peng et al., 2007). For the measurement of Volatile Organic Compounds at workplace, commercially available PID has been used for several decades (Driscoll, 2013).

Various kinds of compact portable VOC monitors are available nowadays. A monitor employing photoionization detector (PID) is able to detect Total Volatile Organic Compounds (TVOCs) with the intervening time of few seconds. The sensitivity of the measurement was outlined to range from ppb to ppm (RAE Systems, 2005). The PID-supported VOC monitor is anticipated to be a beneficial tool for the accurate measurement of TVOC exposure (Mizukoshi et al., 2010). As a segment of an effort in comprehending the role of photocopying process in the generation of TVOC and Ozone, the current study aims to perform real-time monitoring of TVOC and Ozone in photocopying centers and to evaluate the temporal and spatial variation in different areas of Lahore, Pakistan.

Materials and methods

Sampling area

Lahore is a megacity of Pakistan with the inhabitants of about 10+ million people (Razi et al., 2017). It is situated between 30.25° N to 31.5° N and 73° E to 74.5° E and a provincial capital of Punjab covering an area of 1, 172 km^2 (ul-Haq et al., 2016). Lahore is characterized by the semi-arid climatic conditions with very hot and wet summer and ordinarily cool and dry winter. In the month of June, the recorded highest maximum temperature was 48 °C; whereas, the lowest temperature was recorded to be -2 °C in January. Lahore is documented with an annual rainfall of 489 mm (Ali et al., 2014). The photocopying centers (n = 200) in the vicinity of Lahore were selected randomly. For the convenience, the sampling areas were divided into two different zones. The

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41334146

sampling areas of the current study are outlined in *Figure 1*. For the collection of baseline data of photocopying centers, a self-structured questionnaire was designed.

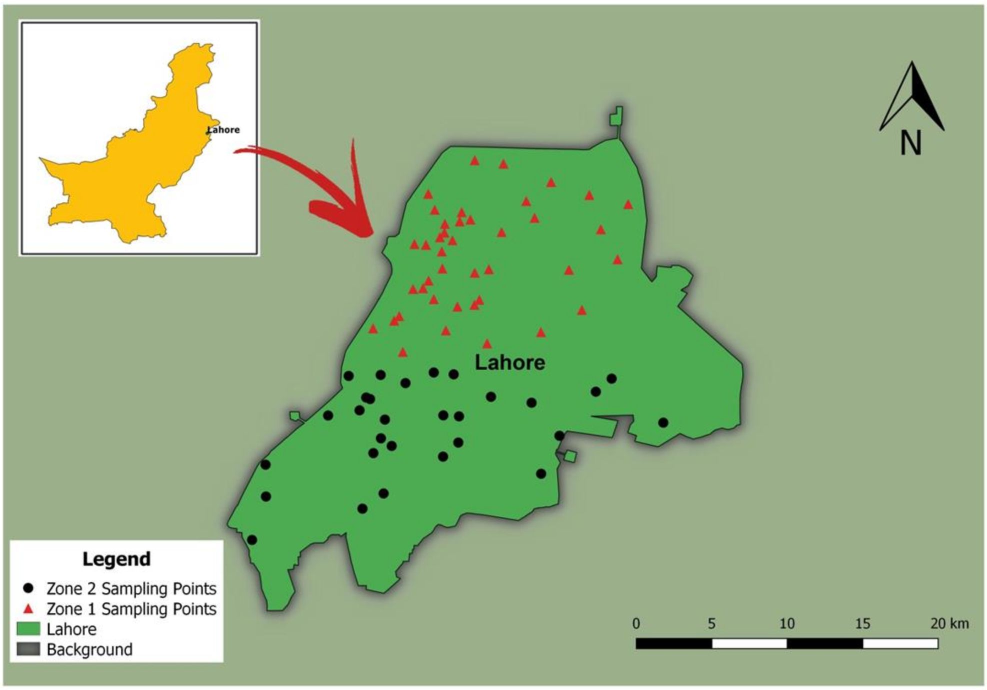

Figure 1. *Sampling areas of Lahore, Pakistan*

Monitoring instruments and technique

Monitoring was performed for the Total Volatile Organic Compounds (TVOCs) and Ozone (O_3) during the working hours in photocopying centers. A hand-held digital real-time VOC monitor with PID detector [ToxiRAE Pro PID (RAE Systems by Honeywell, 4.6” H X 2.4” W X 1.2” D, 235 g)] was employed as shown in *Figure 2a*. The monitor was characterized by the photoionization sensor with 10.6 eV lamp. The response time of the VOC monitor was <15 s. The monitor was turned on and the self-testing was performed by the instrument. Following the normal start-up process, the main measurement screen was displayed. The instrument specified the readings in parts per million (ppm). The documented values were converted to isobutylene equivalent concentrations in mg/m^3. Since Isobutylene is conventionally used for the calibration of PID detectors (RAE Systems, 2005).

For the monitoring of Ozone, portable single gas detector [BW Technologies GAXT-G-DL Gas Alert Ozone (1.1” X 2.0” X 3.75”, 82 g, by BW Technologies)] was employed with the concentration range of 0–1.00 ppm as shown in *Figure 2b*. The response time of Ozone monitor was 5 s. The self-testing was executed by the detector after being turned on. The normal start-up screen was displayed. The readings of Ozone were converted to µg/m^3. The TVOC and Ozone monitors can measure the concentrations every second. For the average concentration of TVOC and Ozone in an hour, the average concentration of 10-min interval derived from original 1-min interval reading was utilized. The TVOC and Ozone measuring instruments were placed inside the photocopying centers at the height of approximately 1.1–1.5 m above the ground

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41334146

(Meciarova et al., 2017). Meanwhile, it was ensured that the instruments are away from the direct pollutant sources and ventilation openings (Moreno-Rangel et al., 2018).

a b

Figure 2. *Monitoring instrument for* ***a*** *TVOC and* ***b*** *Ozone*

Data analysis

The mean TVOC and Ozone concentrations at a particular sampling point were shown in the maps. In order to analyze the spatial variability of TVOC and Ozone, the local interpolation method i.e., Inverse Distance Weighting (IDW) was employed using the QGIS Desktop 2.18.12.

Statistical analyses were executed by using SPSS [IBM SPSS Statistics Version 20 for Windows, SPSS Inc., Chicago, IL, USA]. The normal distribution of the data was determined by using Shapiro-Wilk Test. For categorical variables, Chi-square test was executed. For the data with no normal distribution, Mann Whitney U test was employed. Spearman's Rank correlation test was performed to quantify the correlation between testing variables. The Friedman Test was applied for assessing the difference in the concentrations of TVOC and Ozone with time of the day. The p-value < 0.05 was considered to be significant.

Results and discussion

The baseline attributes from photocopying centers were documented using a self-structured questionnaire as presented in *Table 1*. No significant difference was observed in terms of average working hours, number of machines and nature of area in photocopying centers located in both zones.

Spatial variability of total volatile organic compounds and ozone

The spatial variations of Total Volatile Organic Compounds (TVOCs) in mg/m^3 and Ozone in $\mu g/m^3$ are presented in *Figures 3a, b* and *4a, b.* A high degree fluctuation was observed in the concentrations of both variables.

Diurnal variability of total volatile organic compounds

The diurnal variation of Total Volatile Organic Compounds (TVOC) in mg/m^3 is presented in *Figure 5*. The average TVOC (mg/m^3) during working hours in photocopying center of Zone 1 and Zone 2 was found to be 0.674 ± 0.699 and 0.691 ± 0.786, respectively. The average TVOC concentration in photocopying centers located in Zone 1 was marginally lower than the centers in Zone 2. However, regarding the concentration of TVOCs, no significant difference was observed in the photocopying centers located in two different zones. In Zone 1, the diurnal variation revealed a similar pattern throughout the day with the lowest value observed at 8:00 am in the morning when the photocopying centers were opened. In case of Zone 2, the highest value of TVOC was observed at 12 Noon. Thereafter, it decreases gradually with the lower value during closing time of the photocopying centers. Several studies reported the generation of Volatile Organic Compounds in the photocopying centers (Stefaniak et al., 2000; Lu et al., 2015; Kowalska et al., 2015). A minimum TVOC concentration was observed during morning that gradually started increasing till noon. A progressive decline was found with the passage of time with the lower value at 8:00 pm.

***Figure 4. a** Spatial distribution of mean Ozone concentrations in photocopying centers of Lahore. **b** Spatial distribution of Ozone concentrations by IDW method*

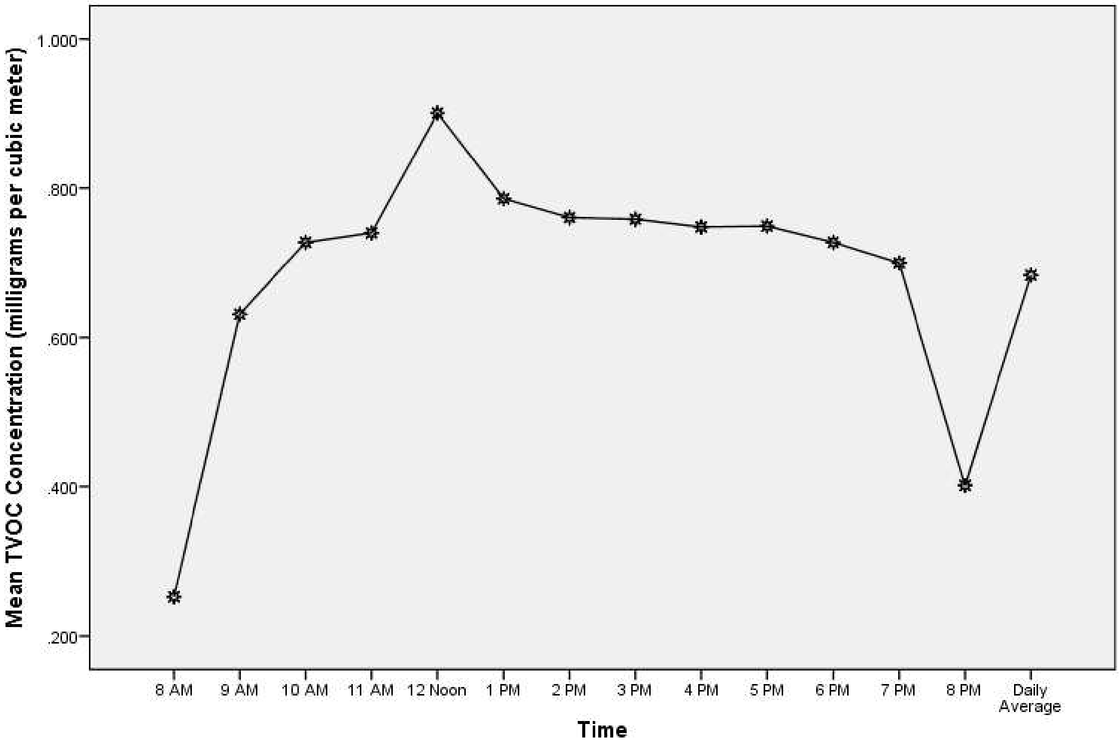

Figure 5. *Diurnal pattern of TVOC (mg/m^3) in photocopying centers*

Diurnal variability of Ozone

The observed diurnal variability of Ozone at different photocopying centers is shown in *Figure 6*. The average concentration of Ozone (µg/m^3) in Zone 1 and Zone 2 was found to be 187.50 $\pm$ 119.28 and 139.08 $\pm$ 83.56 respectively with the significant difference ($p < 0.05$) between both the zones. A relatively steep slope was recorded for the concentration of ozone. The diurnal variation of Ozone revealed that the minimum concentration was observed at 8:00 in the morning. It indicates that the maximum concentration was observed at 12 noon. Thereafter, it gradually declines and reaches the minimum value during the night. The similar diurnal variability was documented in other studies (Xue et al., 2017; Adame Carnero et al., 2010; Kumar et al., 2014b).

The Spearman's correlation was determined to evaluate the association between the TVOC and Ozone concentration (*Fig. 7*). A positive and highly significant correlation exists between the concentrations ($r = 0.627$, $p = 0.000$). The ozone precursors including oxides of nitrogen (NOx) and Volatile Organic Compounds (VOCs) vigorously affect the ozone profile (Filella and Penuelas, 2006).

In order to verify whether the time of the day makes any significant impact on the concentrations of TVOC and Ozone in photocopying centers, the Friedman test was employed. The significant results for both the concentrations indicated that the time of the day did have a significant impact on the concentrations of TVOC ($\chi^2 = 599.311$, Df = 13, Asym. Sig 0.000) and Ozone ($\chi^2 = 1357.799$, Df = 13, Asym. Sig 0.000).

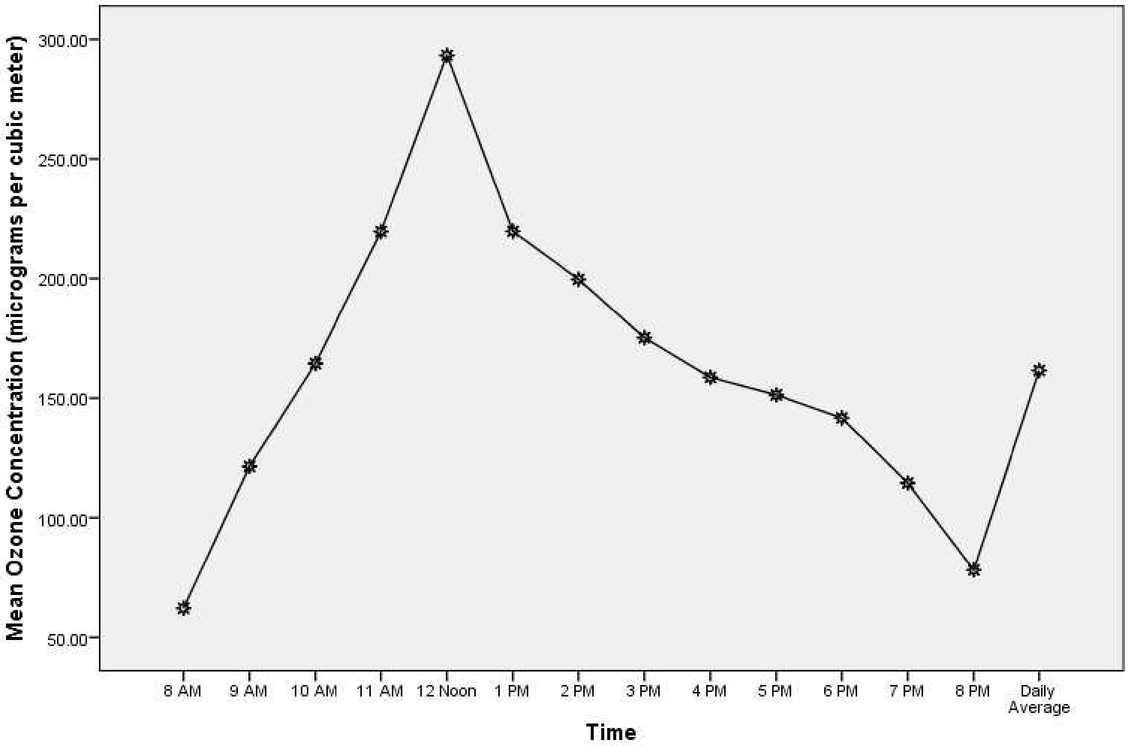

Figure 6. *Diurnal pattern of Ozone (µg/m^3) in photocopying centers*

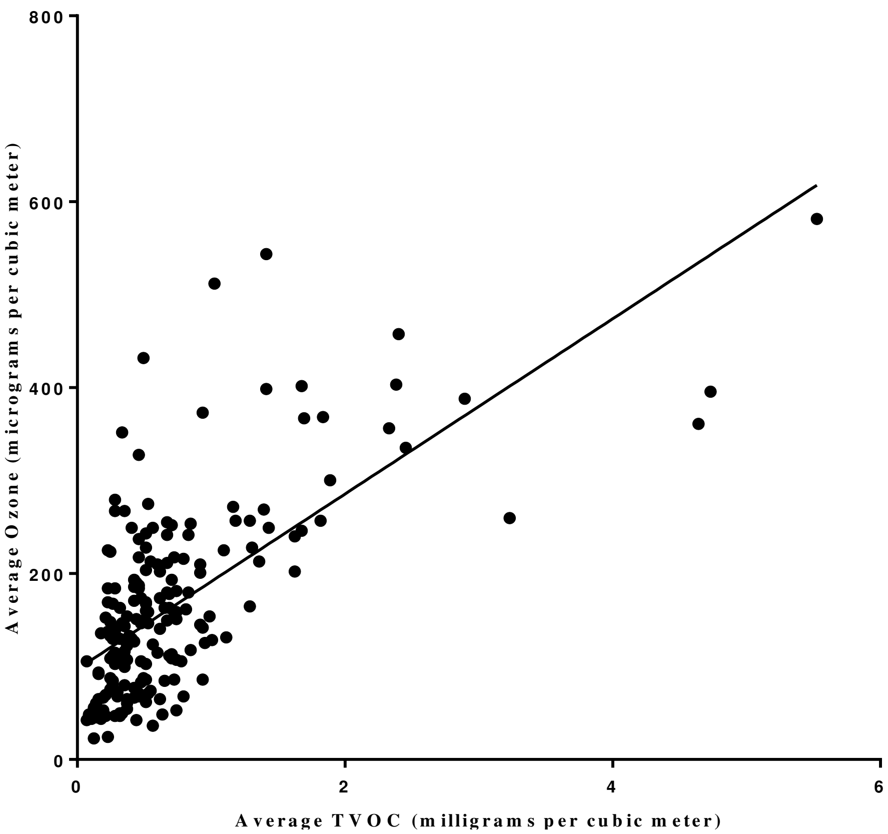

Figure 7. *Correlation between average TVOC (mg/m^3) and Ozone (µg/m^3)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41334146

The average number of copies made in each photocopying center per day was found to be positively correlated with the concentrations of TVOC and Ozone. A highly significant and positive association was found between the average number of copies per day and the concentration of TVOC ($r = 0.556$, $p = 0.000$). Likewise, the average number of copies per day was computed to be positively and significantly correlated with the Ozone concentrations ($r = 0.333$, $p = 0.000$).

Concentration of TVOC and Ozone with respect to nature of area

In order to compute the association between the concentration of the testing variable and the nature of the area, Kruskal-Wallis test was employed. Based on the observation, the nature of the area was divided into 5 main categories i.e., Well Ventilated, Ventilated, Congested, Dark and Congested, Dark and very Congested. A highly significant association ($p < 0.01$) was observed between the nature of area and the concentrations of TVOC and Ozone (*Figs. 8* and *9*).

The observations of the current study revealed the variation in TVOC concentration at photocopying centers with respect to the nature of area. The maximum concentrations of TVOCs and ozone were observed in dark and very congested photocopying centers representing the significant role of ventilation in the declined TVOC concentration. Hori et al. (2013) reported the reduced concentration of TVOCs with the elevated ventilation.

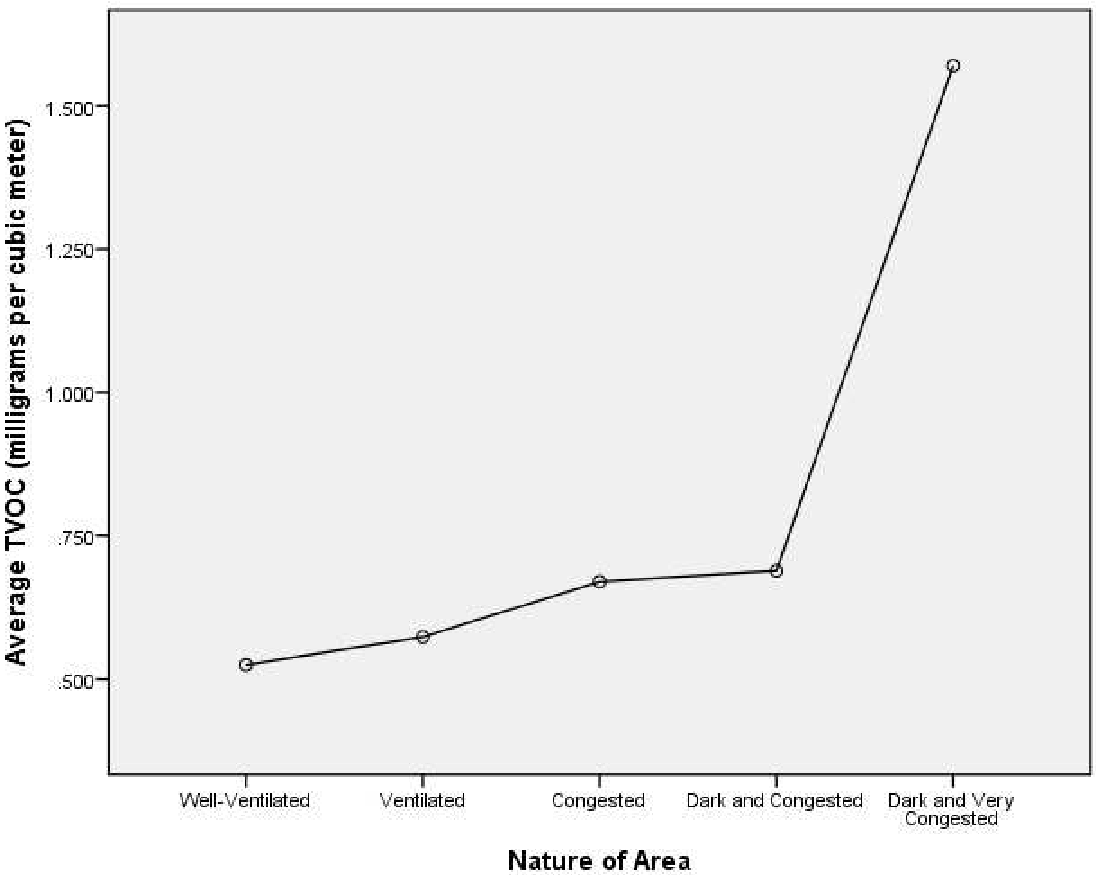

Figure 8. *Association between the nature of area and average TVOC (mg/m^3)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41334146

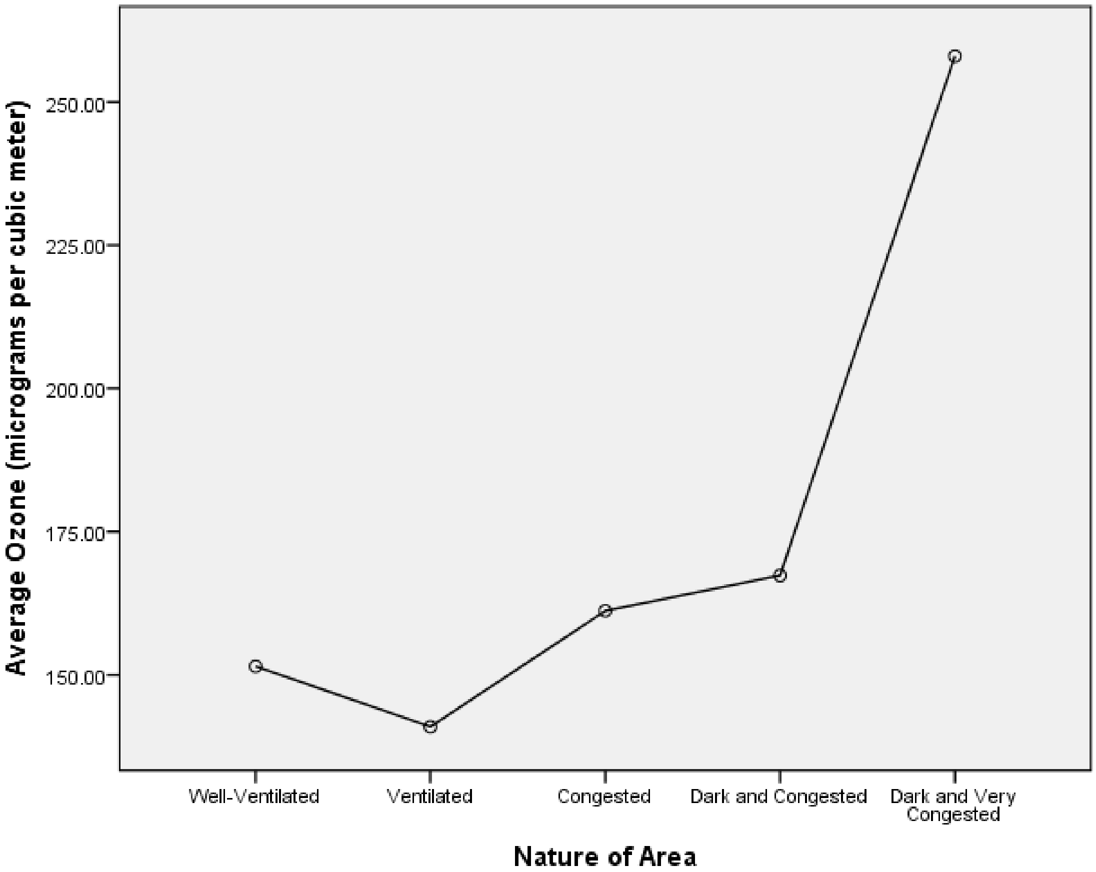

***Figure 9.** Association between the nature of area and average Ozone (µg/m^3)*

The concentration of ozone and its precursors may have a significant effect on the health of human beings (Kumar et al., 2014b). Keeping this in view, the results were compared with the available standards. In non-industrial indoor environment, discomfort and irritability ranges are defined by Molhave (1991). The concentration of VOCs below about 0.2 mg/m^3 is considered to be the comfort range. Between 0.2–3.0 mg/m^3, Irritation and discomfort is possible if other exposures are encountered. The results of the current study with reference to the concentration of TVOCs indicate that it lies within the range of multifactorial exposures i.e. 0.2–3.0 mg/m^3. As specified by the National Environmental Quality Standards for Ambient Air by Pak- EPA, the one hour average allowable concentration is 130 µg/m^3. However, in the current study, the average concentration exceeded this allowable limit that may result in ill-health of the workers.

Conclusion

In this research, the spatial and temporal variations of the total volatile organic compounds and ozone concentrations measured at photocopying centers in Lahore are presented. The variations in the concentrations of TVOC and Ozone between sampling sites indicated the role of photocopying emissions in generating indoor air pollution. The daily cycle presents variations with respect to the time of the day. The maximum

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41334146

concentrations of TVOC and Ozone was observed at 12:00 Noon. The daily minimum concentration was monitored at 8:00 am and 8:00 pm with fluctuating values throughout the day. The findings from this research highlight the importance of monitoring strategy to ultimately develop effective control measures. The present research can be used to find the association with the health impacts in the workers. Furthermore, it is recommended to perform comprehensive research using an appropriate risk assessment strategy.

(Received 8th Dec 2018; accepted 8th Feb 2019)

Abstract. Globally, fungi and fungi-like organisms, with over 8,000 species, cause more plant diseases than any other group of plant pests. Chitinases possess an anti-fungal role in disease resistance. They represent the pathogen-related protein group that cleaves β-1,4-glycoside bond of chitin present in the cell wall of filamentous fungi by catalysing the hydrolytic cleavage. In this study, we have amplified 672 base pair (bp) coding regions of the plant chitinase gene of *Hordeum vulgare*, over-expressed in *Eschercia coli* (*E. coli*) host BL21 DE3 strain by 0.5mM Isopropyl β-D-1-thiogalactopyranoside (IPTG) induction. In western blotting, the recombinant chitinase protein transferred on nitrocellulose membrane was detected at 26 kDa with histidine-tagged antibody reactions. By applying the nickel charged sepharose column affinity chromatography method, a single purified band of recombinant chitinase protein was found at 26 kDa in SDS-PAGE. The purified recombinant chitinase protein during the agar well diffusion method inhibited the growth of three phytopathogenic fungi in a significant way; *Alternaria alternate*, *Rhizoctonia solani* and *Fusarium oxysporum* in qualitative in-vitro antifungal assays. The purified recombinant chitinase protein showed up to 82.6% reduction in *A. alternate* hyphal growth; 77% reduction of hyphal growth in *Rhizoctonia solani* and 78% reduction of Fusarium's hyphal growth in in-vitro quantitative antifungal assays, thus depicting a strong antifungal potential. Conclusively, plant derived chitinase genes are superior in protecting the crops from phytopathogenic fungi if cloned in a suitable plant vector and expressed.
Keywords: *antifungal response, early blight, Fusarium oxysporum, Rhizoctonia solani*

Introduction

Fungal diseases have a deleterious impact on crops and consequently on the economy in direct, measurable terms. The extent of yield losses for major crops such as rice, wheat, maize, potatoes and soybean as the result of an epidemic outbreak vary, but a major threat to food security persists globally (Ramirez-Cabral et al., 2018). Oerke (2006) found that 26-30% of global yield losses of crops including sugar beet, cotton and wheat are due to fungal pathogens, while this number is 40% for potatoes and 37% for rice. Currently, fungal infections destroy approximately 125 million tons of crops including rice, wheat, maize, potatoes, and soybeans each year. Some of the world's greatest famines and the resulting human suffering can be blamed on plant pathogenic fungi and fungi-like organisms (FLOs). Fungicides are primarily used on fruit and vegetable crops and approximately 97% of potato crops are treated with fungicides

DOI: http://dx.doi.org/10.15666/aeer/1702_41474157

(Kaonga et al., 2018). The fungicides including Maneb, Mancozeb, cymoxanil, dimethomorph hexaconazole, iprodione, isoprothiolane and thia bendazole are sprayed on vegetables (Bentley et al., 2006; Stadlinger et al., 2018).

The most devastating among them include *Alternaria alternate*, *Rhizoctonia solani* and *Fusarium oxysporum*. *Alternaria alternate* causes early blight in tomato and potato, has a worldwide distribution and has been considered one of the most important foliage diseases in areas with warm wet conditions in the early crop season. The symptoms include tuber blight and leaf spot on potato; fruit rot and stem lesions on tomato. *Rhizoctonia solani* is a soil-borne fungus that causes economically important diseases in many crop species, such as sugar beet, potatoes, tomatoes, rice, rape, maize, soybean and others (van Lenteren et al., 2018). The disease caused by *Rhizoctonia solani* include stem canker and black scurf in potatoes, fruit rot in tomatoes, sheath blight in rice, Rhizoctonia crown and brace root rot in maize, root and stem rot in soybean crop and root rot in canola (Melzer et al., 2016). *Fusarium oxysporum* is a soil borne phytopathogen cause economical loss around the globe. It not only causes yield reduction but also accounts for dry rot on potato, sudden death syndrome in soybean, crown rot and head blight on the wheat and bakanae disease on rice (Bentley et al., 2006; Munkvold, 2017).

Various chemical fungicides and breeding methods for selection of natural resistant varieties are in practice to meet the fungal problem. But the selection of resistant variety is not up to mark to control fungi. The excessive use of chemical spray with about15-20 application per growing season, not only have a harmful effect on targeted pest but also on beneficial organisms in addition to hazardous environmental effects. The cell wall of the fungus is a complex structure, composed of chitin fiber and glucan held together by protein. Chitin is considered to be the second most abundant polysaccharide in the universe, composed of N-acetylglucosamine(Nakkeeran et al., 2016). The concentration of the chitin differs among fungi, as yeast cell wall composed of 1-2% chitin while Aspergillus contains 10-20% of chitin by dry weight. *F. oxysporum* contain 25-35% chitin in its cell wall (Becker et al., 2016). The primary role of chitin is to provide structural integrity but it also functions as linkage between cell wall and the capsule. Disruption of the fungal cell wall has severe effect on the morphology resulting in osmatic instability of the cell wall which leads to cell death (Cushion et al., 2018). It is, therefore, hypothesized that chitinase can have potential as an antifungal agent.

Chitinase an enzyme which cleaves β-1,4-glycoside bond of chitin by catalyzing its hydrolytic cleavage (Jitonnom et al., 2011). Chitinases belong to pathogen-related protein (PR) group in plants. Initially, when discovered, PR protein was considered as defense protein only as it was induced only in response to an infection but later it was revealed that PR protein has a potential role in abiotic stress also (Lincoln et al., 2018). The fact that plant chitinases act as a shield against plant fungi is well established (Fesel and Zuccaro, 2016). Plant chitinases are part of various groups of enzymes which differ with respect to their structure, enzymatic properties, and cellular localization. They are endo-chitinases and are present in stem, seed, tuber and flowers. Plant chitinases are categorized in 5-6 classes based on amino acid structure.

The aim of the present study was to isolate and over express barely chitinase II gene and evaluate its antifungal activity against major plant fungi including *Alternaria alternate*, *Rhizoctonia solani* and *Fusarium oxysporum* that cause yield loss to important crops.

Materials and methods

Isolation of chitinase gene from barley

Seeds of Barley (*Hordeum vulgare* L.) variety Haider-93 were kindly obtained from Ayub agriculture research center, Faisalabad, Pakistan and were grown in CEMB field, Lahore, Pakistan. Total RNA was isolated from the young, immature leaves using TriZol reagent (Invitrogen). cDNA was prepared by cDNA synthesis kit (Thermoscientific) according to the manufacturer instructions. Chitinase II gene specific forward (BLP-F) and reverse (BLP-R) primers were used to amplify 889 bp gene fragment (*Table 1*). For amplification, reaction mixture comprised of 1× PCR reaction buffer, 0.1 mM of dNTPs, 1 pmole each of forward and reverse primer, 1 unit of Taq DNA polymerase (Thermoscientific) and 50 ng of template cDNA. PCR reaction was carried out in a thermal cycler (GeneAmp PCR system 9700, ABI) with the following thermal cycling parameters: initial denaturation at 95 °C for 4 min followed by 35 cycles of 94 °C for 30 s, 60 °C for 30 s and 72 °C for 30 s and a final extension of 7 min at 72 °C. Amplified products were resolved on 1% agarose gel and visualized under UV transilluminator (Biotop, Pakistan). Amplified gene fragment was cloned into pCR2.1 TA cloning vector and transformed into *E. coli* DH5α competent cells. The cloning was confirmed by restriction digestion and sequencing. Further, the deduced gene sequence was submitted to GenBank database for accession number.

Cloning and over-expression of chitinase gene

For over-expression of chitinase II gene in *E. coli*, pET 30a vector (Novagen) was used. For directional cloning, *BglII* and *NcoI* restriction sites were added at 5’ in BLPetF and BLPetR primers (*Table 1*) to amplify 762 bp gene fragment. Cycling conditions were the same as above. Further, the amplified 762 bp chitinase gene fragment was codon optimized from IDT (Integrated DNA Technologies) and cloned in fusion with His tag in the pET30a vector. Further, the ligated product was transformed in chemically competent *E. coli* BL21 (D3) strain for expression studies.

Recombinant protein expression

Approximately, 22 different transformed colonies of BL21 (D3) were screened for over-expression of recombinant protein. Out of these, only three colonies were subjected to enhanced protein expression. Fast induction method opted for suboptimal yields of the recombinant protein by using a different concentration of IPTG (0.1 mM to 1.5 mM) and induction time.

Purification of His tag recombinant protein

The induced culture was pellet down and sonicated at 50% duty cycle with short pulses of 35 s each for 15 min. The tube was centrifuged and the pellet was resuspended in 20 mM Tris-HCl (pH-8) supplemented with 2 M Urea, 2%triton, 1 mM EDTA and 500 mM NaCl. After centrifugation, the pellet was washed with 1XPBS Buffer inclusion bodies were resuspended in 1 XPBS buffer containing 0.5% Triton X-100 and 2 M urea). This was kept at room temperature for 35 min. The detergent was removed by five times washing with sterilizing distilled water. Inclusion bodies were finally solubilized in buffer containing 6 M guanidine HCl, 20 mM Tris–HCl, pH 8.0 and 0.5 M NaCl stirred subsequently for 1 h at room temperature. Crude protein was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41474157

quantified by (Kruger, 2002). Finally, the protein was purified using Chelating Sepharose Fast Flow (Amersham) through Nickel. The column was equilibrated with 6 M guanidine HCl and protein was loaded on equilibrated column at the rate of 1ml/min. then washing was done with 1X PBS containing 0.5 M NaCl and 20 mM imidazole. The protein was eluted in 1X PBS containing 0.5 M NaCl and 200 mM imidazole. The eluted protein was Dialysed against 50 mM phosphate buffer pH 6.5 for 24 h at 4 °C and diluted in refolding buffer (100 mM Tris-HCl pH 8, 0.5 M L-arginine, 0.2 mM EDTA) with constant stirring.

Table 1. *Sequence of primers used to amplify the chitinase gene fragment from H. vulgare*

Name	Sequence (5'-3')
BLP-F	TAGTTAGCATGGCGCGGTA
BLP-R	TCATACGACACGATCAACTGG
BLPetF	GGCAGATCTGTCATCACGCAATCGGTGTA
BLPetR	GGCCCATGGGAAGTTTCGCTGGGTGTAGC

Western blot

After purification of the recombinant protein SDS-PAGE was run. The protein was transferred on nitrocellulose membrane using semidry Trans Blot (Bio Rad) transfer. The transfer was carried at 12 V for 40-50 min. The membrane was blocked in 5% skimmed milk overnight at 4 °C. Following day, membrane was removed from blocking solution and membrane was washed three times with 1X PBS buffer for 10 min each. The membrane was incubated with His tag anti rabbit primary antibody (1:500; Santa Cruz) in 1X PBS for 1 h with gentle shaking at room temperature. After washing the membrane with 1XPBST the Alkaline Phosphatase conjugated secondary antibody was added at 1:15000 and incubated at room temperature for 1 h with gentle shaking. After washing the membrane with 1XPBST the purple color was developed by NBT/BCIP tablet (Sigma). The reaction was stopped with autoclaved distilled water.

In-vitro antifungal assay

Qualitative assay

The phytopathogenic fungi *Rhizoctonia solani*, *Alternaria alternate* and *Fusarium oxysporum* were kindly obtained from USDA. For the antifungal assay, cylinder plate method of (Kirubakaran and Sakthivel, 2007; Toufiq et al., 2018) was adopted with some modifications. The 2 mm patch of the fungi to be tested was inoculated on potato dextrose agar (Oxoid) plate in the centre and kept at 28 °C for 72 h for growth. Three cylinders were made around the plate edges which refer to control, 70 µg and 100 µg of purified chitinase protein. In the control cylinder, sterilized water was poured. Resulting fungal growth retardation/inhibition of fungi was observed after 48 h of protein inoculation. The results were repeated in triplicate.

Quantitative assay

The inhibitory effect of recombinant chitinase protein on the hyphal growth of *A. alternata*, *R. solani* and *F. oxyporum* was evaluated as previously described by (Khan et al., 2017; Plascencia-Jatomea et al., 2003). Wells were made on potato dextrose agar

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41474157

(Oxoid) plate and filled with 40 µl of respective fungal spores suspension (10^4 spores per ml) followed by incubation at 28 °C for overnight. Further, in each well inoculated with respective fungi, 30 µg, 50 µg, 70 µg, 100 µg of the purified chitinase protein was added and incubation was continued at 25 °C for 5 days. The control well was contained only the fungal inoculum and instead of recombinant protein, protein extraction buffer was added. Subsequently, the radial growth of respective fungi was recorded every 24 h for 5 days. The distance between the control hyphal edge to the centre – the distance between the treated hyphal edge to the centre) / the distance between the hyphal edge to the centre in the control] × 100% (Plascencia-Jatomea et al., 2003). The results were replicated in triplicate.

Results

Over-expression of recombinant chitinase gene

Full-length Class II chitinase gene of 889 bp was successfully amplified from barley. Deduced sequences from recombinant TA clone were analyzed for the potential coding region through the CDD (Conserved Domain Database), and the sequence was submitted to NCBI Genbank and accession # KC899774 was obtained. *Figure 1* depicts the isolation of chitinase gene and restriction digestion of chitinase gene in pET30a vector.

Further, the amplified 762 bp gene fragment was directionally cloned in pET30a, under the control of T7 promoter by using *BglII* and *NcoI* restriction enzymes. Successful cloning was depicted by restriction digestion of the recombinant plasmid pET:ChiII. The appearance of the vector at ~ 5.4 kb and gene fragment at ~ 762 bp verified the construction of pET:ChiII (*Fig. 1*).

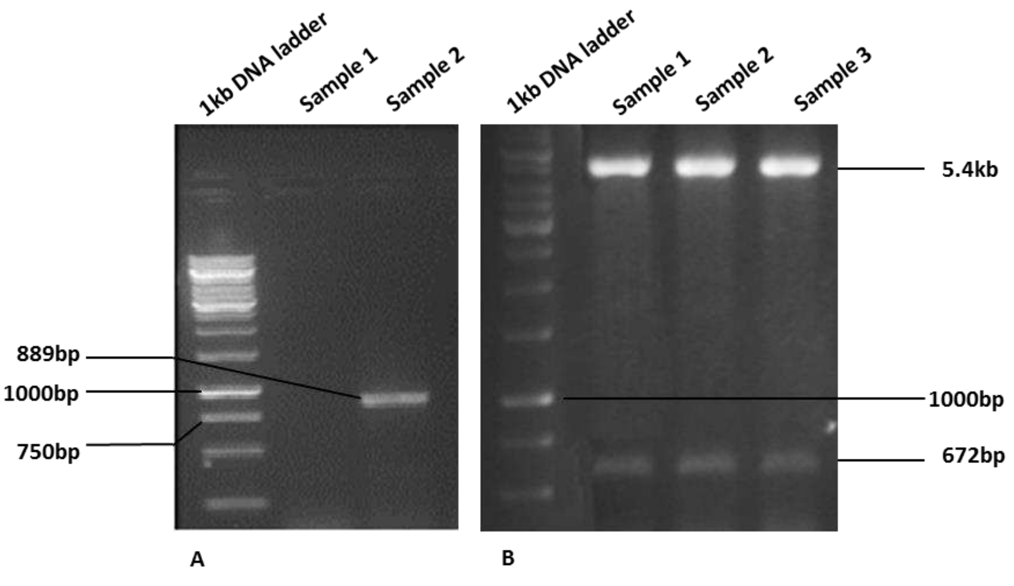

Figure 1. *Amplification and restriction digestion of chitinase gene. A) amplification of chitinase gene from barley, lane1 = 1 Kb ladder, lane2 = negative control, lane3 = amplification of 889 bp gene from barley. B) restriction digestion of chitinase gene into pET vector30a, lane1 = 1 Kb ladder, lane 2-4 = Restriction digestion of potential pET clones to verify the construct*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41474157

Several transformed colonies of BL21 strain were selected for recombinant protein expression onto SDS-PAGE. Out of total 22 colonies selected, only three were selected for further expression enhancement. Recombinant proteins over-expressed in bacteria often form insoluble proteins called inclusion bodies. It was found that recombinant chitinase protein was present inside the inclusion bodies while expressing in the *E. coli* host. Maximum expression of the recombinant chitinase protein was achieved when samples were induced with 0.5 mM IPTG while optimized induction time was 4 h. *Figure 3* depicts the expression patterns of all three selected colonies. A Clear difference in the expression pattern of induced versus uninduced sample can be seen (*Fig. 2*). For each treated colony, the recombinant protein expressed more as compared to the control, un-induced sample. However, maximum expression was achieved in colony # 2 where unwanted proteins did not express (*Fig. 2*). Subsequently, colony # 2 was selected for purification through column chromatography.

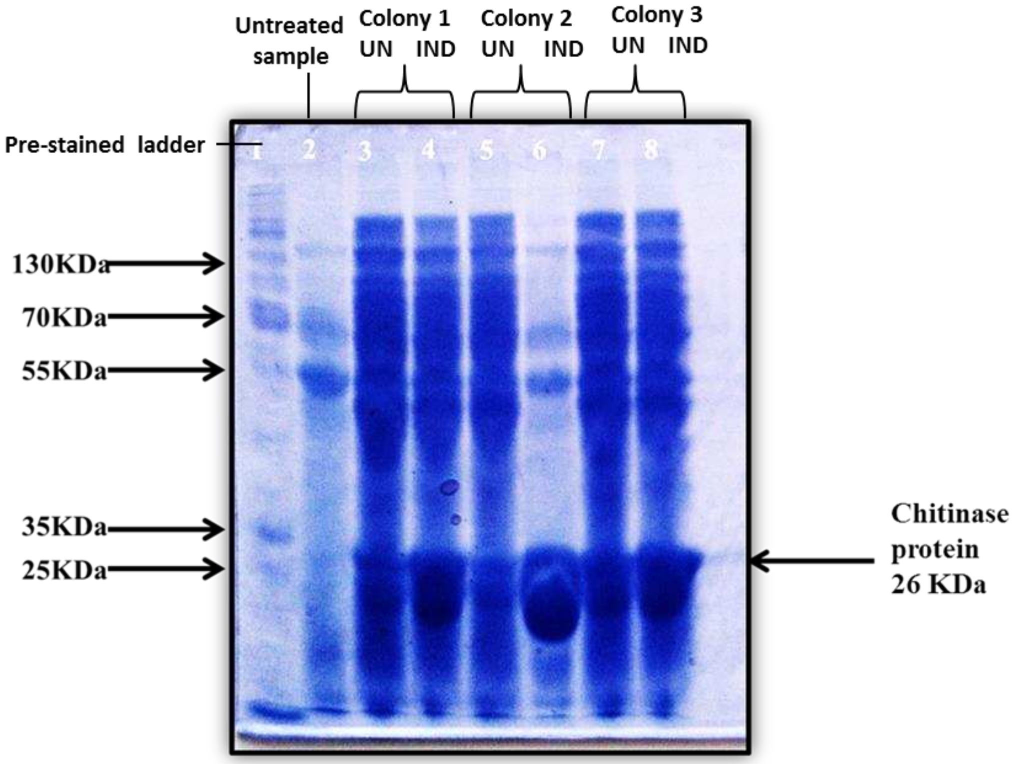

Figure 2. *SDS-PAGE of crude protein samples showing recombinant protein expression in different induced/uninduced colonies of BL21 strain. Un-induced cultures were also run in parallel. In each well, approximately 10 µg protein was loaded while pre-stained protein marker was used to define protein size. In the figure, UN refers to uninduced colony culture and IND refers to induced culture of the same colon while in total, three colonies were screened for expression of the recombinant protein*

As the recombinant protein was present in inclusion bodies, purification of the protein was convenient. The inclusion bodies were purified to avoid co-purification of contaminants. Solubilization was done by 6 M guanidine HCl and further subjected to refolding after elution using Ni-NTA IMAC purification system. The purified protein was resolved on 12% SDS-PAGE followed by western blotting using anti- His antibodies as shown in *Fig. 3A* and *B*.

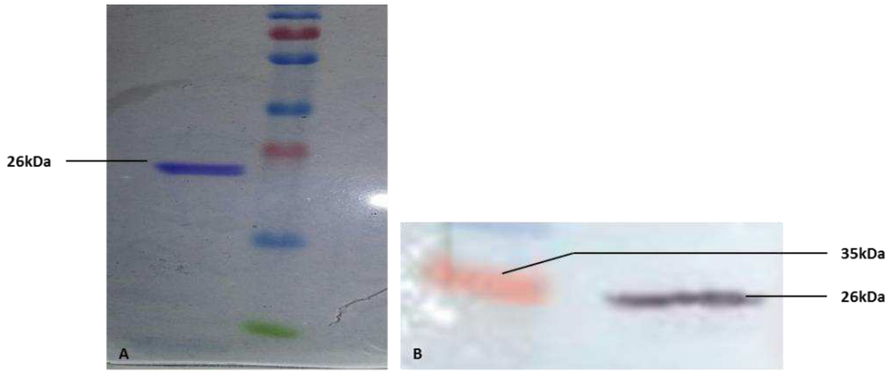

Figure 3. *A) Purification of the recombinant chitinase protein purified through IMAC fast flow affinity chromatography. A single purified protein fraction at 26 kDa was obtained. B) Western blot of chitinase protein over-expressed in BL 21 strains. The blot was developed through antigen antibody reaction where Histag anti-rabbit primary antibody and secondary goat anti-rabbit AP conjugated antibody were used*

Recombinant chitinase protein inhibited the hyphal growth to a significant extent

In *in vitro* qualitative assay, cylinder plate antifungal assay was performed where three phytopathogenic fungi; *Rhizoctonia solani*, *Alternaria alternate* and *Fusarium oxysporum* were tested against purified protein. Pathogen inhibition assay revealed that recombinant chitinase protein was effective in controlling the inoculated fungi. Growth retardation of *Rhizoctonia solani* was inhibited to a significant extent when treated with purified protein at 100 µg concentrations while fungus inhibition was more as compared to the 70 µg concentration of the protein where relatively less inhibition was observed. While in control sample, no inhibition was observed at all. Similar findings were met when *Alternaria alternate* and *Fusarium oxysporum* were inoculated and treated with purified recombinant protein. Maximum inhibition of the fungi growth was achieved at 100 µg protein concentration; less was in 70 µg concentration as compared to the control sample where no inhibition was observed (*Fig. 4A, B* and *C*). Conclusively, the fungus inhibition was found to be directly linked with increasing concentration of the recombinant protein, as, at maximum protein dose (100 µg), fungus inhibition was maximum.

In the *in-vitro* quantitative antifungal assay, percentage reduction of hyphal growth in *A. alternate* was 40% at a 30 µg concentration of the purified recombinant chitinase protein; 52% at 50 µg; 78% at 70 µg; 82.6% at 100 µg protein concentration (Fig. 5A). Similarly, purified recombinant chitinase protein inhibited the hyphal growth of *R. solani* maximally at a100 µg concentration where inhibition was 77% while the percentage inhibition was 42, 62 and 76 at 30 µg, 50 µg and 70 µg protein concentration (Fig. 5B). In parallel, chitinase protein reduced the hyphal growth of *Fusarium* to 78% at 70 µg and 100 µg concentrations while comparatively less reduction was observed at 30 µg and 50 µg protein concentration where inhibition was 52% and 66.6% (*Fig. 5C*). The findings of *in vitro* quantitative assay showed that there was a significant difference among control and different concentrations in standard value. ($P < 0.05$; $n = 3$). In summary, at 70 µg and above a concentration of the protein, fungal growth was inhibited maximally and the fungi were unable to grow across the well while at lower concentrations, the reduction was observed at a lesser extent. The control, untreated sample did not exhibit any inhibitory effect and the respective fungus grows maximally.

Discussion

The aim of the present study was to isolate a plant based chitinase gene, characterize it and express it into the *E. coli* BL21 strain. The full-length gene was successfully isolated from total RNA of barley. Roberts and Selitrennikoff (1988) proposed that bacterial chitinases are difficult to interact with fungal cell wall so they have less resistance against fungi, whereas plant chitinases show high antifungal activity. The plant chitinases are usually endochitinases and contain lysozyme activity (Islam and Datta, 2015). In contrast, the bacterial enzymes are exochitinases and hydrolysed the chromogenic trisaccharide analogue as a substrate (Horn et al., 2006; Roberts and Selitrennikoff, 1988; Toufiq et al., 2018). So plant chitinases are usually preferred for increasing antifungal activity in the host. For this purpose, a plant chitinase was selected in this study.

Subsequently, we over-expressed chitinase gene in *E. coli* host and after purification of recombinant protein, the inhibitory effect against the three most devastating pathogenic fungi was evaluated in-vitro. The purified recombinant protein was used for inhibition of *Rhizoctonia solani*, *Alternaria alternate* and *Fusarium oxysporum* Different studies showed the inhibitory effect of chitinases in-vitro against fungi containing chitin. Kirubakaran and Sakthivel (2007) used class 1 chitinase from barley to inhibit pathogenic fungi of broad range in-vitro. In another study, Eissa et al. (2017) showed protection of transgenic wheat by using class II chitinase from barley seeds, against powdery mildew. Similarly, Liu et al. (2013) expressed two chitinase genes, LbCHI31 and LbCHI32 from *Limonium bicolor* in *E. coli* and reported their antifungal activity against *Alternaria alternate*. While Shenoy et al. (2006) have reported a 29 kDa chitinase with antifungal activity in the bulbs of plant *Urginea indica*. Additionally, Garg and Gupta (2010) purified chitinase from moth bean having an inhibitory effect on *Macrophomina phaseolina* strain 2165. Tariq et al. (2018) transformed chitinase II gene to sugarcane and obtained significant resistance against *C. falcatum* compared to control. While Khan et al. (2018) expressed plant chitinase II gene and developed potato variety resistant to *A. solani*.

Conclusion

Conclusively, the potential inhibitory effect of barley derived chitinase II gene was exploited against phyto-pathogenic fungi which, in future, can be used to develop transgenic plants tolerant towards these devastating fungal pathogens.

(Received 16th Dec 2018; accepted 22nd Feb 2019)

Abstract. Water-borne epidemics caused by pathogenic microorganisms endanger public health especially in countries where access to clean water sources is difficult. Also, the conventional disinfection methods have various disadvantages on environmental health and they can be ineffective against some pathogenic microorganisms. For these reasons, the disinfection process applied in water has gained great importance and new alternative treatment technologies have to be developed to replace traditional methods used to protect public health. In this study, the effects of ultrasound (US) and hydrogen peroxide (H_2O_2), which have been used for water disinfection in recent years, have been examined whether or not they can remove *Klebsiella pneumoniae* from water. This study has concluded that the combination of US and H_2O_2 can effectively remove *Klebsiella pneumoniae* bacteria from water. When the application of ultrasound was performed with a H_2O_2 concentration of 5 mg l^{-1}, the disinfection efficiency of *Klebsiella pneumoniae* was 4.22 log after 60 min.
Keywords: *water disinfection, ultrasound, hydrogen peroxide, coliform*

Introduction

Water is significantly contaminated by human or other environmental factors. Water, which is required for the survival of living organisms, are polluted by anthropogenic sources, such as, chemical, physical and microbial contaminants. Especially, water storage tanks can be contaminated significant pollutants, such as leaks, mixing of sewage sludge from soil cracks, agricultural runoffs, unsuitable industrial applications, mining applications, underground injection of waste chemicals, and corrosive waters (WHO, 2004, 2011). The legal regulations to ensure clean and reliable drinking and potable water must be very strict in application and control, and so clear and easy to update in terms of compliance with scientific developments (WHO, 2004, 2011).

Pathogens that cause waterborne diseases include; bacteria, viruses, protozoa and algae (Ashbolt, 2004; Moe, 2007). Water-borne epidemics diseases have significantly reduced by chlorinating drinking water since 1900 (Akin et al., 1982) but can be ineffective against to some pathogenic microorganisms. *Klebsiella pneumoniae* is stationary, non-spore, short, rounded, 1-2 µm in length and 0.5-0.8 µm in with basil. *Klebsiella pneumoniae* is best grown at 12-43°C and at pH 7 using bloody agar, endo agar and EMB agar media in their analysis, which can show capsular, aerobic and facultative anaerobic character in Gram negative polysaccharide structure. Because it is a bacterium found in the upper respiratory tract and stool flora in humans, pathogenicity is released as an opportunistic pathogen in the face of inappropriate conditions (Dutka, 1973). The sources of pathogenic microorganisms in drinking water are surface waters and groundwater contaminated with fecal matter (Shiddamallayya and Pratima, 2008; Gray, 2014). Drinking water supplies are contaminated with fecal *Klebsiella pneumoniae* via domestic wastewater, meat treatment processes wastewater and the surface flow from farms (Percival, 2014). In addition, *Klebsiella pneumoniae* are responsible for hospital

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41594169

infections (Percival, 2014). *Klebsiella pneumoniae* is listed as total coliform in the international guidelines (Arbuckle et al., 1976). As for standard of WHO, the number of total coliform in 100 ml of untreated ground water is limited to less than 10 cells (WHO, 2004), and it is indicated in the guideline that there should be no fecal coliform in water samples (LeChevallier and Au, 2013).

Because of the various disadvantages of conventional disinfection methods on the environment and human health, the use of advanced treatment methods for disinfection have gained importance with effective inactivation of pathogenic microorganism to prevent disinfection by-product formation in conventional disinfection methods especially (Sirivedhin and Gray, 2005). At the beginning of advanced treatment methods are ultrasound, Fenton oxidation, UV, ozone, hydrogen peroxide applications. UV oxidation technologies; (titanium dioxide) in a homogeneous environment by the addition of a suitable oxidizing agent (hydrogen peroxide, ozone) (Stasinakis, 2008; Koparal, 2018). Homogeneous processes (UV / H_2O_2, UV / O_3) and heterogeneous processes (photolysis of semiconductor particles) as an advanced treatments methods also used for water disinfection but these alternative methods has some limits (Venkatadri and Peters, 1993). For examples, UV disinfection equipped with lamps producing 254 nm wave length UV rays is used to inactivate the microorganisms in the water, but it is difficult to obtain effective inactivation ratio in water with high turbidity (Qualls et al., 1983; Christensen and Linden, 2003; WHO, 2004). Also ozone application needs addition of chlorine after effective disinfection in order to supply residue protection (Langlais et al., 1991).

Hydrogen peroxide (H_2O_2) is a powerful chemical disinfection agent (Falagas et al., 2011). Disinfection efficacy of H_2O_2 depends on its concentration, contact time and microorganism (Alasri et al., 1992). H_2O_2 has wide-ranging activity against viruses, bacteria, yeast, bacteria spores. However, the effect of hydrogen peroxide is more effective against gram-positive, rather than gram-negative bacteria. Hydrogen peroxide is a powerful oxidizing agent because it produces free hydroxyl radicals. High-level disinfection can be obtained with hydrogen peroxide in the critical patient care units (Arrage et al., 1993).

Ultrasound or, in other words sonication, is one of the alternative advanced treatment technologies for water disinfection (Stasinakis, 2008). The inactivation of microorganisms depends on the time and power of the ultrasonic application. The ultrasound effect on bacteria is based on the destruction of the cytoplasmic membrane (Mason et al., 2003). When the ultrasonic wave passes through a liquid, very small bubbles are formed and this is called cavitation. The collapse of these cavitation bubbles creates high temperatures and pressures locally. These sudden changes in temperature and pressure cause the cell wall structure to deteriorate. When the US is combined with conventional chemical treatment, it increases the potency of the oxidizing chemical in the microbial cell membrane (Jatzwauk et al., 2001). Factors affecting ultrasound removal efficiency are temperature, wave frequency, wave amplitude, applied power, medium viscosity, contaminant type, surface tension of solution and solution vapor pressure (Mason and Peters, 2002).

In this study, the synergistic effects of ultrasound (US) and hydrogen peroxide (H_2O_2) have been examined on the removal of *Klebsiella pneumoniae* from water in order to eliminate the limited applications of these two methods. It has been shown that the combination of US and H_2O_2 can effectively remove *Klebsiella pneumoniae* bacteria from water.

Materials and Methods

This research was conducted in Department of Environmental Engineering, Faculty of Engineering, Eskisehir Technical University, and Eskisehir, Turkey. In this study, the disinfection efficiencies of ultrasound (US), hydrogen peroxide (H_2O_2) and hybrid application of these methods.

Microbiological studies

Klebsiella pneumoniae working solution of 100 ml and a concentration of 1×10^5 CFU ml^{-1} was disinfected at three ultrasonic frequencies and three H_2O_2 concentration. The disinfection studies were performed in a sterile cabinet (Heraeus KSP-18 Class II) at room temperature. The bacterial concentration was determined with a simple plate count method during all disinfection studies using serial dilution of the samples. All the samples were inoculated on plate count agar (PCA, Merck-Germany) solid media, and the plates were incubated at 37°C for 18-24 hours (Karel, 2016). The bacterial inactivation ratio was calculated as the difference between the initial bacterial concentration and final bacterial concentration for each disinfection study. The disinfection efficiencies of systems were determined with the average bacterial concentration of samples taking into account *Eq. 1* accounting to logarithmic term.

$$E\ (log)\ =\ log\ (Co - Ct) \qquad \text{(Eq.1)}$$

where:
E (log) = Disinfection efficiency in logarithmic term,
C_0 = Initial average bacterial concentration (CFU ml^{-1}),
C_t = Average bacterial concentration at t time (CFU ml^{-1}).

The results of microbiological studies were expressed as average of three independent experiments with error bar using standard deviation (SD). Each experiment was performed with three parallels. Statistical significance of the difference of the counted bacteria in in plate count agar among each trials was determined by analysis of variance (ANOVA) using two-way test. In order to show reliability of measurement, p value obtained from two-way ANOVA test was given for each disinfection study.

Ultrasonic disinfection studies

Disinfection studies were carried out in a W-113 Ultrasonic multi-cleaner (Honda Electronics Co., Ltd., Aichi, Japan) given in *Fig. 1* using batch flow condition. This batch type of ultrasonic reactor was operated at ultrasonic frequencies of 28, 45 and 100 kHz and at a power of 100 W. Ultrasonic disinfection studies were performed for a contact time of 60 minutes.

Disinfection with hydrogen peroxide

Hydrogen peroxide is a strong oxidizing agent and has a bacterial inactivation effect. The bacterial inactivation effect of hydrogen peroxide on *Klebsiella pneumoniae* was examined for concentrations of 5 mg l^{-1}, 10 mg l^{-1} and 20 mg l^{-1} in the working solution. Hydrogen peroxide stock solution of 500 mg l^{-1}, 1000 mg l^{-1} and 2000 mg l^{-1} were freshly prepared before the hydrogen peroxide disinfection studies. These working concentrations of hydrogen peroxide (5 mg l^{-1}, 10 mg l^{-1} and 20 mg l^{-1}) were set in the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41594169

working solution using 1 ml of suitable stock solution of each concentration. The disinfection studies were performed with three different concentrations of hydrogen peroxide, and the effect of bacterial inactivation was determined in the same working solution at similar flow conditions and contact time.

Figure 1. *Batch type of ultrasonic reactor was operated at ultrasonic frequencies of 28 kHz, 45 kHz and 100 kHz*

Disinfection with hydrogen peroxide and ultrasound

The hybrid disinfection studies of ultrasound and hydrogen peroxide were conducted in an ultrasonic reactor with H_2O_2 concentrations of 5 mg l^{-1}, 10 mg l^{-1} and 20 mg l^{-1} and applying a 28 kHz ultrasonic frequency. To determine the synergetic effect of H_2O_2, the US disinfection studies were repeated with similar conditions as the previous disinfection process.

Results and discussion

The effect of ultrasonic frequency on *Klebsiella pneumoniae* disinfection process at an average of 1×10^5 CFU ml^{-1} is shown in *Figure 2*.

When a 28 kHz ultrasonic frequency was used to inactivate *Klebsiella pneumoniae,* a 3.52-log disinfection efficiency was attained with a 60-min disinfection period. When a 45 kHz ultrasonic frequency was used to inactivate *Klebsiella pneumoniae,* a 1.52-log disinfection efficiency was attained with a 60 min disinfection period. When a 100 kHz ultrasonic frequency was used to inactivate *Klebsiella pneumoniae,* a 1.1-log disinfection efficiency was attained with a 60 min disinfection period. The results of ultrasonic disinfection studies showed that the maximum bacterial inactivation rate at an ultrasonic frequency of 28 kHz.

In the present study, the highest inactivation efficiency of *Klebsiella pneumoniae* was determined at an ultrasonic frequency application of 28 kHz after a 60-min disinfection

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41594169

period as the bacterial inactivation ratio is dependent on the mechanical disruption effect on the cell membrane from ultrasonic frequency. Gao et al. (2014b) studied *Enterobacter aerogenes*, *Bacillus subtilis, Staphylococcus epidermidis, S. epidermidis* and *Staphylococcus pseudintermedius* microorganisms at ultrasonic frequency 20 kHz and 100 kHz applying 13 W power. It was observed that the highest bacterial inactivation rate was determined to be 4.5-log after 20 min continuous sonication at 20 kHz ultrasonic frequency differing microorganisms(Gao et al., 2014a).

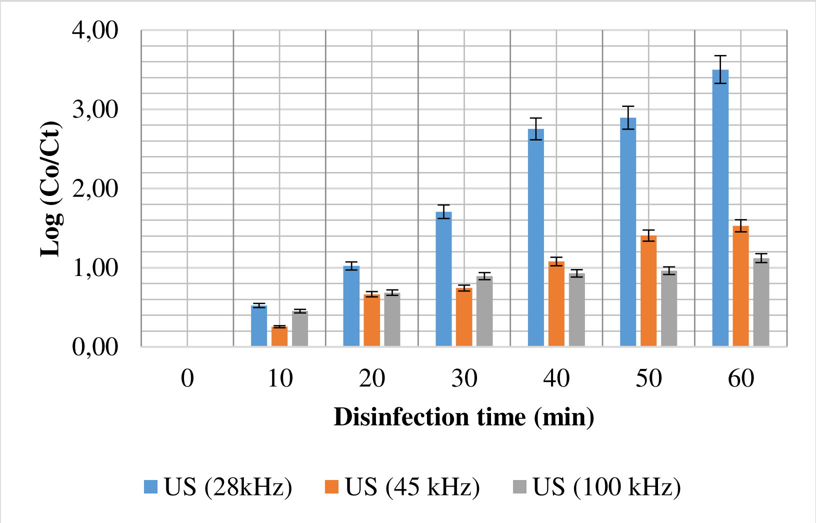

Figure 2. *Effect of ultrasonic frequency on the Klebsiella pneumoniae disinfection process at a concentration of 1 × 10^5 CFU ml^{-1} (p value was calculated as 0,334 using two-way ANOVA test. This value showed that there is no significant difference of each measurements among each three disinfection experiment because p>0.01)*

This ultrasonic frequency effect was disgusted in previous research(Gemici et al., 2014; Karel, 2016) by high-power ultrasound frequencies, which are described as using low ultrasonic frequencies between 16 kHz and 100 kHz because high-power ultrasound is more effective than high-frequency (500 kHz-1 MHz) ultrasound when performing bacterial inactivation(Joyce et al., 2003). The chemical effects of high-frequency ultrasound used in this study leading to thermal decomposition of water molecules into OH^- and H^+ radicals was probably insufficient for the inactivation of *Klebsiella pneumoniae,* although the physical effect of low-frequency ultrasound enhanced the efficiencies of bacterial inactivation(Mason et al., 2003).

The result of hydrogen peroxide disinfection studies is shown in *Fig. 3*. When a 5 mg l^{-1} $H_2O_2^+$ concentration was used to inactivate *Klebsiella pneumoniae*, a 0.04-log disinfection efficiency was attained with a 60-min disinfection period. When a 10 mg l^{-1} H_2O_2 concentration was used to inactivate *Klebsiella pneumoniae*, a 0.04-log disinfection efficiency was attained with a 60 min disinfection period. When a 20 mg l^{-1} $H_2O_2^+$ concentration was used to inactivate *Klebsiella pneumoniae*, a 0.08-log disinfection efficiency was attained with a 50 min disinfection period. These results showed that increasing the hydrogen peroxide concentration raises the bacterial inactivation ratio as expected (Loraine et al., 2012), however, the they indicated that obtained inactivation ratio of *Klebsiella pneumoniae* was not enough for effective disinfection.

When the application of ultrasound was performed with a H_2O_2 concentration of 5 mg l^{-1}, 10 mg l^{-1} and 20 mg l^{-1}, the disinfection efficiency of *Klebsiella pneumoniae* was 4.22 log after 60 min, 5 log after 60 min and 5 log after 50 min, respectively. This indicates that *Klebsiella pneumoniae* disinfection with hydrogen peroxide and ultrasound decreased the disinfection period and increased inactivation ratio according to a single hydrogen peroxide application. The physical effects of low-frequency ultrasound improved the bacterial inactivation ratio by enhancing the disinfection effect of hydrogen peroxide through synergistic effects of ultrasound. The results of microbiological studies were expressed as average of three independent experiments with error bar using standard deviation (SD) using three parallels studies of all disinfection process. The results of analysis of variance (ANOVA) using two-way test, p value was calculated 0,402524 within groups and p value was calculated 0,0000000178 between groups These value showed that there is no significant difference within groups of each three disinfection experiment because p value was greater than 0.01. To concluded, two-way ANOVA test indicated that US+ H_2O_2 hybrid applications gave reliable and repeatable results.

Image of *Klebsiella pneumoniae* on petri dish from disinfection with hydrogen peroxide and ultrasound studies was given in *Fig. 5* as initial bacteria concentration in *Fig. 5A*, 5 mg l^{-1} H_2O_2+ US 28 kHz in *Fig. 5B*, 10 mg l^{-1} H_2O_2+ US 28 kHz in *Fig. 5C* and, 20 mg l^{-1} H_2O_2+ US 28kHz in *Fig. 5D*. These results indicate that ultrasound and hydrogen peroxide reduced the hydrogen peroxide concentration to obtain an eligible bacterial inactivation efficiency in water because ultrasound accelerates the contact of OH^- and H^+ radicals, which are the decomposition products of H_2O_2, with bacteria.

Ultrasound can also facilitate breakage of microorganism agglomeration, thereby increasing the efficiency of other chemical disinfectants (Karel, 2018). This effect was clearly shown in literature. Gao et al. (2014a) was studied disinfection of *E. aerogenes*, *Bacillus subtilis*, *S. epidermidis* and *A. Pullulans* with hydrogen peroxide (30%) and t-butanol in 85 kHz ultrasonic reactor. As a result of their study, it was observed that the addition of H_2O_2 provided microorganism inactivation much shorter than ultrasound disinfection (Gao et al., 2014b). Lakeh et al. (2013), was disinfected *Anguillicola crassus*,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41594169

Paramecium sp. and *Artemia sp*. with low-frequency US and UV-C methods. They found that the mean size of suspended solids in the water culture with low frequency US decreased and therefore the UV-C inactivation rate increased by 0.6 log. Comparison of UV-C radiation with low-frequency US did not cause a decrease in the number of colonies in fresh water, but the antiseptic effect of UV-C in turbid water increased by 0.6 log. When colony count values were compared only with UV-C and low-frequency US with UV-C, pretreatment with low frequency US showed significant effect. The US sonication of 0.2-18.8 kJ/L low frequency dose range varies from 7% to 95% depending on the inactivation rate of paramecium (Lakeh et al., 2013). Ayyıldız et al. (2011) have demonstrated the effects on *E. coli* and total coliform inactivation when used in combination with chlorine dioxide (ClO_2, 2 mg /L) and US (150-300 W/L) in wastewater disinfection. Raw waste water and synthetic water are used. US (vibra cell 505) 500 W power and 20 kHz frequency were used. The log removal was 1.4-1.9 in single treatments and the combined use of consecutive US (150 or 300 W/L) and ClO_2 (2 mg/L) resulted in 3.2 - A 3.5-month fix was provided. Using the US and ClO_2 disinfection methods together, high concentrations of particles in the raw wastewater and their breakdown under shock noise waves have been achieved (Ayyildiz et al., 2011).

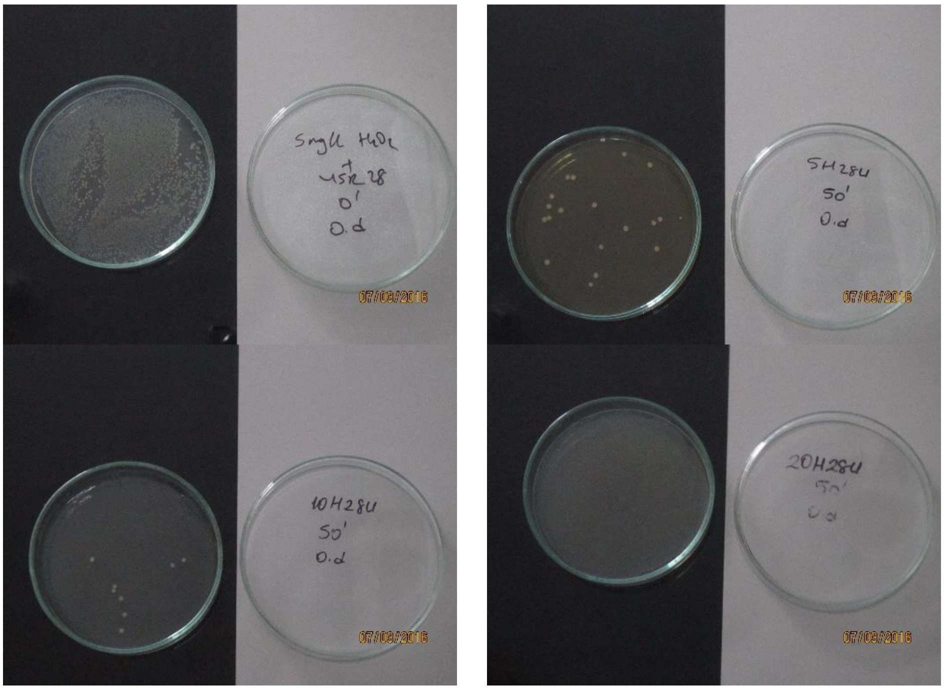

Figure 5. *Image of Klebsiella pneumoniae on petri dish from disinfection with hydrogen peroxide and ultrasound studies (A: initial bacteria concentration, B: 5 mg* l^{-1} H_2O_2*+ US 28 kHz, C: 10 mg* l^{-1} H_2O_2*+ US 28 kHz, D: 20 mg* l^{-1} H_2O_2*+ US 28kHz)*

Hydrogen peroxide, which has a significant effect on the disinfection performance of the ultrasound, can be generated simultaneously during the treatment of water and wastewater depending on the conditions under which the treatment takes place and the ultrasonic system parameters (frequency, power, amplitude, power density, etc.). This is most likely to be the production of OH-H radicals at ultrasonic frequencies in the range of 100 kHz to 1 mHz and the sonochemical process called H_2O_2 oxidation(Suslick, 1988), but it is seen in the literature that high power and retention times should be applied for

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41594169

the production of these radicals (Rae et al., 2005). In this study, H_2O_2 could not be produced by using effective sono-chemically at the 28 kHz ultrasonic frequency, US-H_2O_2 disinfection studies were also showed the effect of H_2O_2 addition to the ultrasonic system.

This study was showed that ultrasound and its hybrid application with hydrogen peroxide. It has been seen that, when US combined with H_2O_2 with the accelerator effect of ultrasound on mass transfer as seen in other oxidation methods, bacterial inactivation ratio increased with less chemical usage. Also, the disadvantages of ultrasound eliminated with H_2O_2 hybrid studies because it requires high energy density for high inactivation ratio by the use of ultrasound alone. Due to the catalysis effect of the ultrasound, a significant reduction in the amount of H_2O_2 required for the disinfection resulted in H_2O_2 disinfection for high bacterial removal efficiency. As a result of the study, it has been determined that the *Klebsiella pneumoniae* in water and other ecosystem effects on human health can be successfully treated with hybrid US- H_2O_2 process.

Conclusion

The effects of different frequencies and added H_2O_2 on microorganism removal performance in ultrasonic system were investigated in this paper. It is clearly stated that this study will be an important development in drinking and potable water disinfection to reduce limitation of these alternative methods. It was concluded that water could be microbiologically treated by ultrasound providing less energy consumption and less chemical usage. Microorganism inactivation can be recommended in higher yields by employing the ultrasonic system as a hybrid. The studies have been carried out in a small scale in the laboratory environment and this study can be given as a result of this study in pilot scale and larger systems. It can also be tested in the ultrasound system with separate studies for other microorganisms that can be found in the targeted water environment.

Abstract. In order to reveal the effects of lead stress on the chlorophyll content and fluorescence characteristics of *Vallisneria natans*, six Pb concentration levels were applied to a culture in clean river sand and water. The results showed that Pb could promote the synthesis of chlorophyll at a low concentration (Pb $\leq$ 10 mg·L^{-1}) in one day. *V. natans* had certain tolerance to the stress of low Pb concentration. With the prolongation of stress time and increasing Pb concentration, the leaves of *V. natans* gradually lost their green color. Chlorophyll a decreased more than chlorophyll b. It had the least effect on carotenoids. Fv/Fm, Fv/Fo, qP, Y(II) and ETR decreased significantly (Pb > 10mg·L^{-1}) in seven days. However, *qN*, *Y(NO)* and *Y(NPQ)* showed an upward trend. The efficiency of the leaves using light energy decreased noticeably, and the electron transport of PSII was blocked severely. It can be speculated that *V. natans* may be used in the phytoremediation of waters contaminated by a low concentration of lead.
Keywords: *Vallisneria natans, lead stress, photosynthetic pigment, fluorescence characteristics, rapid light curve*

Introduction

In recent years, heavy metal pollution has become prominent with mining, smelting, electroplating, and different types of wastewater, with solid wastes being discharged into water bodies (Ji et al., 2018). Due to the fact that these cannot degrade or be decomposed, heavy metals are accumulated in living organisms, impair the health of animals and humans with biological amplification through the food chain (Xu et al., 2003). As one of the “five poisonous” heavy metal elements, lead (Pb) is a non-essential element utilized during plant growth and metabolism, and otherwise has toxic effects (Sharma and Dubey, 2005; Bisht et al., 2013; Ansari et al., 2017; Shahid et al., 2016), inhibiting the progress of photosynthesis and reducing the activity of chlorophyllase.

Submerged macrophyte, as important primary producers in aquatic ecosystems, not only provide food, habitat and breeding sites for aquatic animals, but also can get rid of N, P and other nutrients (Song et al., 2011). It also has ability to adsorb and accumulate heavy metals (Pan et al., 2011; Chen et al., 2017), used to remove Pb from water (Li et al., 2011). The nutrient absorption, secondary metabolism and antioxidant response of *Vallisneria natans* (*V. natans*) under Pb stress were studied (Wang et al., 2011, 2012) Under Pb stress, malondialdehyde content increased and total chlorophyll and carotenoids decreased. *V. natans* had a certain resistance to Pb stress, and the key enzymes of nitrogen and phosphorus metabolism were more sensitive to the response of Pb stress (Yu et al., 2016). At present, the research focus on mainly the enrichment of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41714181

heavy metals (Liang et al., 2016; Xue et al., 2010), physiological and biochemical effects (Yu et al., 2016; Xu et al., 2006; Min et al., 2012), ultrastructure (Xu et al., 2004; Shi et al., 2000), etc. While the mechanisms of submerged macrophyte enduring heavy metals from photosynthetic and chlorophyll fluorescence are rarely reported.

V. natans is a perennial herbaceous plant perennial in China with high economic value (Wang et al., 2006), strong regeneration ability, used in water ecological restoration project widely (Gu et al., 2017; Wang et al., 2009). In 1980, professor Schreiber invented the pulse amplitude modulated. Due to the rapid, simple, sensitive, reliable and non-interference characteristics of the modulated fluorescence technology, it can reflect the "intrinsic" characteristics of the photosynthetic system (Hu et al., 2017), regarded as the effective probe in studying the relationship between plant photosynthesis and the degree of environmental stress (Janssen et al., 1992). The aims of this study were to investigate the intrinsic mechanism of photosynthetic system response under Pb stress, and provide some basic data and theoretical basis for the ecological restoration of Pb contaminated waters.

Materials and methods

Materials cultivation and treatment

Whole plants of *V. natans* were collecting from Nanjishan nature reserve of Poyang Lake, China, on June 5th in 2017. Plants (20 cm length) were planted in plastic buckets, adding 1/10 Hoagland nutrient solution, and acclimated for two weeks. Then, *V. natans*, healthy and consistent growth, were transplanted into eighteen transparent glass jars (50 cm × 40 cm × 40 cm) with 10 cm thick river sand paved at the bottom (*Fig. 1*). 50 L distilled water and Pb solution with different concentration levels were injected into the jars. Pb was added in the form of $Pb(NO_3)_2$ with a concentration level of 0, 1, 10, 20, 50 and 80 $mg \cdot L^{-1}$, 0 $mg \cdot L^{-1}$ was the control group (CK), three repetitions for each level.

***Figure 1**. Diagram of experimental device*

Determination of chlorophyll content

The determination of photosynthetic pigment was used by 95% ethanol extraction (Li, 2000). The value of absorbance was measured at 665, 649 and 470 nm, respectively. The concentrations of chlorophyll a (Ca), chlorophyll b (Cb), carotenoid (Cc) and total chlorophyll (Ct) in the extract were calculated respectively by *Equations 1-4*. The content of Ca, Cb, Cc and Ct ($mg \cdot g^{-1}$) was calculated by *Equation 5*.

DOI: http://dx.doi.org/10.15666/aeer/1702_41714181

$$C_a(mg \bullet L^{-1}) = 13.95A_{665} - 6.88A_{649} \quad \text{(Eq.1)}$$

$$C_b(mg \bullet L^{-1}) = 24.96A_{649} - 7.32A_{665} \quad \text{(Eq.2)}$$

$$C_c(mg \bullet L^{-1}) = \frac{1000A_{470} - 2.05C_a - 114.8C_b}{245} \quad \text{(Eq.3)}$$

$$C_t(mg \bullet L^{-1}) = C_a + C_b \quad \text{(Eq.4)}$$

$$Chlorophyl\ content(mg \bullet g^{-1}FW) = \frac{C_t(mg \bullet L^{-1}) \times total\ amount\ of\ extract(ml)}{sample\ fresh\ weight(g)} \quad \text{(Eq.5)}$$

Determination of fluorescence parameters

The chlorophyll fluorescence characteristics of *V. natans* leaves were determined by the underwater modulation fluorescence instrument (DIVING-PAM), produced by WALZ company in German. Before the measurement, the dark clips were clamped on the leaves of *V. natans* in situ. After dark adaptation for 20 min, the clips and detection light were opened. First, the induction curve was determined, the minimum fluorescence (Fo) and maximum fluorescence (Fm) were obtained. The biggest actinic light efficiency of PSII (Fv/Fm), effective quantum yield (Y(II)), photochemical quenching coefficient (qP), non-photochemical quenching coefficient (qN) and quantum yield of regulatory energy dissipation (Y(NPQ)) and quantum yield of non-regulatory energy dissipation (Y(NO)) were calculated automatically by the selected system mode. Fv/Fo = (Fm - Fo) / Fo. Then, the rapid light curve was measured. The gradients of photosynthetic active radiation (PAR) were 0, 100, 200, 300, 400, 600, 800, 1000 and 1200 $\mu mol \cdot m^{-2} \cdot s^{-1}$ respectively.

Statistical analysis

Excel 2017 was used to process the experimental data and draw graphics. SPSS19.0 was used for one-way analysis of variance. The Duncan method was used for multiple comparisons. $P < 0.05$ means significant difference.

Results

Effects on photosynthetic pigment under Pb stress

As shown in *Figure 2A,* Ct, Ca and Cb after one day under Pb stress of 1 $mg \cdot L^{-1}$ were increased significantly compared with the control group (CK). The increase of Ct, Ca and Cb under Pb stress of 10 $mg \cdot L^{-1}$ was not significant compared with the CK ($P > 0.05$). Ct, Ca, Cb, Cc and Ca/Cb were reduced significantly when Pb was over 20 $mg \cdot L^{-1}$.

As shown in *Figure 2B,* Ct, Ca and Cb were lower slightly after seven days under 1 $mg \cdot L^{-1}$ Pb. Above 10 $mg \cdot L^{-1}$ Pb stress, Ct, Ca, Cb and Cc decreased significantly ($P < 0.05$). It was respectively 45.89%, 39.20%, 58.01% of the CK under Pb stress of 80 $mg \cdot L^{-1}$. Ca/Cb appeared in overall downward trend. Ca was more sensitive than Cb under Pb stress, and decreased sharply. The damage of Pb stress on chlorophyll was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41714181

larger than carotenoids. The leaves of *V. natans* lost green color gradually with the increase of Pb concentration.

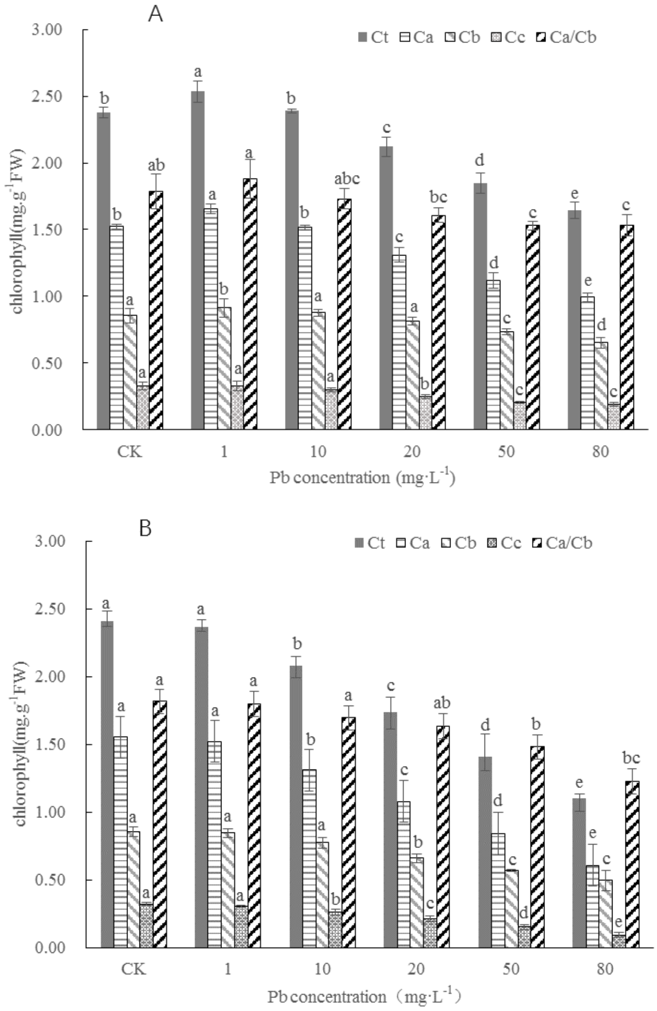

***Figure 2**. Varieties of Ct, Ca, Cb, Cc and Ca/Cb on V. natans under Pb stress. (Different lowercase letters represent the significant differences (P < 0.05) in different treatment groups, the same below. A represents one day stress, B represents seven days stress)*

Effect on Fo, Fm, Fv/Fm and Fv/Fo under Pb stress

As shown in *Figure 3,* Fo decreased with the increase of Pb compared with the CK after one day, but the difference was not significant. Fm was less than the CK. Fm had little difference at Pb stress of 20-80 mg·L^{-1}. Fv/Fm was lower than that of the CK except at Pb stress of 1 mg·L^{-1}. Fv/Fm had significant difference ($P < 0.05$) under Pb stress of 10-80 mg·L^{-1}. The change trend of Fv/Fo was similar with Fv/Fm.

After seven days, the increase of Fo was significant under the high Pb stress. Under Pb stress of 80 mg·L^{-1}, the increase of Fo was 28.32% compared with the CK. Fm was smaller than the CK, also smaller than that of the same Pb stress after one day. Fm was 39.58%, 37.23%, 31.47% of the CK at Pb stress of 20-80 mg·L^{-1}. Fv/Fm was lower than the CK. Conversion efficiency of PS II primary light energy decreased with the increase of Pb. Fv/Fo was also lower significantly than the CK ($P < 0.05$).

DOI: http://dx.doi.org/10.15666/aeer/1702_41714181

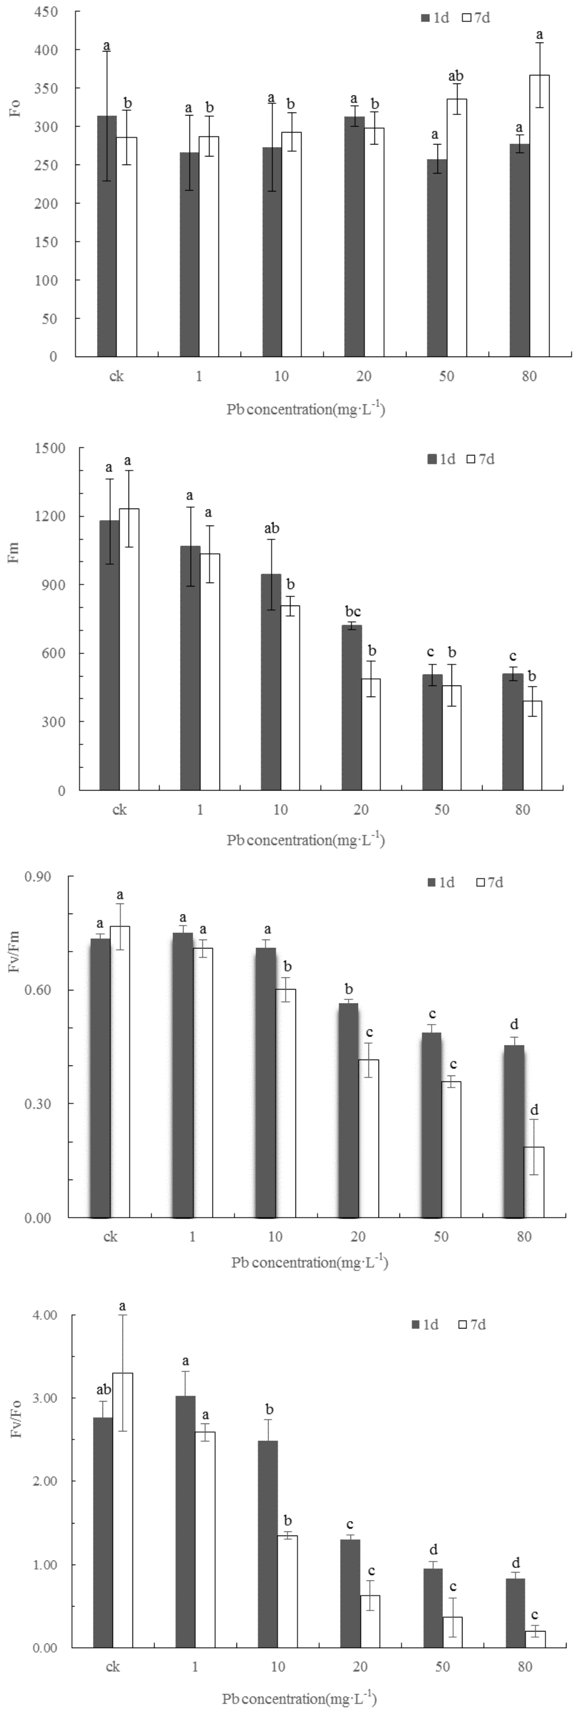

Figure 3. *Effects on Fo, Fm, Fv/Fm and Fv/Fo of V. natans*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41714181

Effects on qP, qN on leaves of V. natans under Pb stress

The value of qP was in a downward trend with the increase of stress intensity (*Fig. 4*). It had no significant difference under Pb stress of 0-10 mg·L^{-1} (P > 0.05) after one day. It decreased to 82.67% of the CK under Pb stress of 80 mg·L^{-1} after one day, and 37.36% after seven days. The trend of qN was opposite to qP. qN increased slowly with the increase of stress concentration. It peaked under Pb stress of 80 mg·L^{-1}, 141.3% higher than the CK.

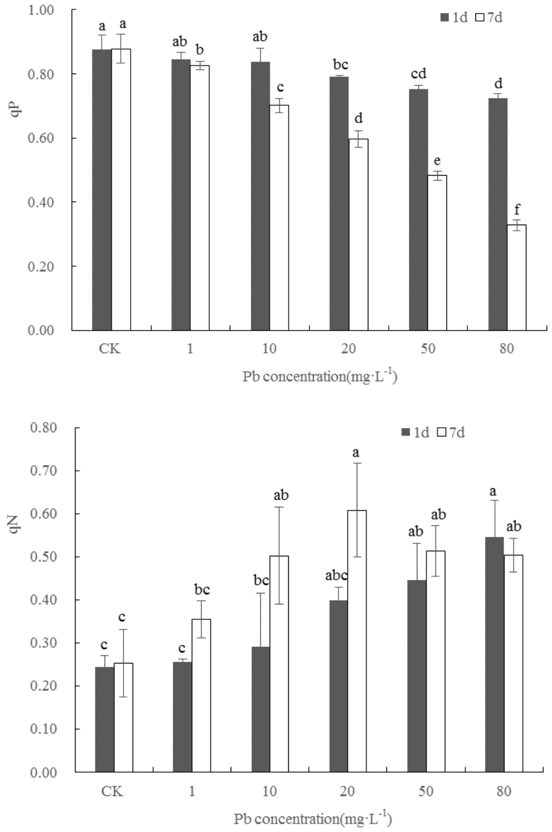

Figure 4. *Effects on qP and qN on V. natans under Pb stress*

Effect on Y(II), Y(NO), Y(NPQ) under Pb stress

Y(NO) increased slowly with the increase of stress concentration. The increase of Y(NO) was significant over 20 mg·L^{-1} Pb after one day. Under the same stress concentration, Y(NO) after seven days was higher than that after one day, which was 1.01, 1.01, 1.05, 1.08, 1.14 and 1.3 times respectively. Y(NPQ) showed an overall upward trend. Under Pb stress of 80 mg·L^{-1}, it peaked 4.05 times of the CK, then decreased significantly (P < 0.05) (*Fig. 5*).

Response of rapid light curves under Pb stress

The relative electron transfer rate (ETR) increased rapidly, then decreased and flattened. It behaved as light suppression. ETR increased compared with the CK under Pb stress of 1 mg·L^{-1} and 10 mg·L^{-1} after one day (*Fig. 6A*). It indicated low Pb could stimulate transmission of the electron. *V. natans* had certain resistance to low

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41714181

concentration. ETR was smaller than the CK under Pb stress of 20-80 $mg \cdot L^{-1}$. The maximum of ETR appeared when PAR was 300 $\mu mol \cdot m^{-2} \cdot s^{-1}$. ETR was 91.42%, 72.78%, 50.3% of the CK.

ETR in each treatment group was lower than the CK after seven days (*Fig. 6B*). ETR decreased significantly ($P < 0.05$) with the prolongation of stress duration. The change trend was similar to that of qP. The proportion of real electron transfer in light reaction center and absorbing light used in photochemical process reduced. Electron transfer in the leaves was significantly inhibited so photosynthetic efficiency weakened (Gan et al., 2017).

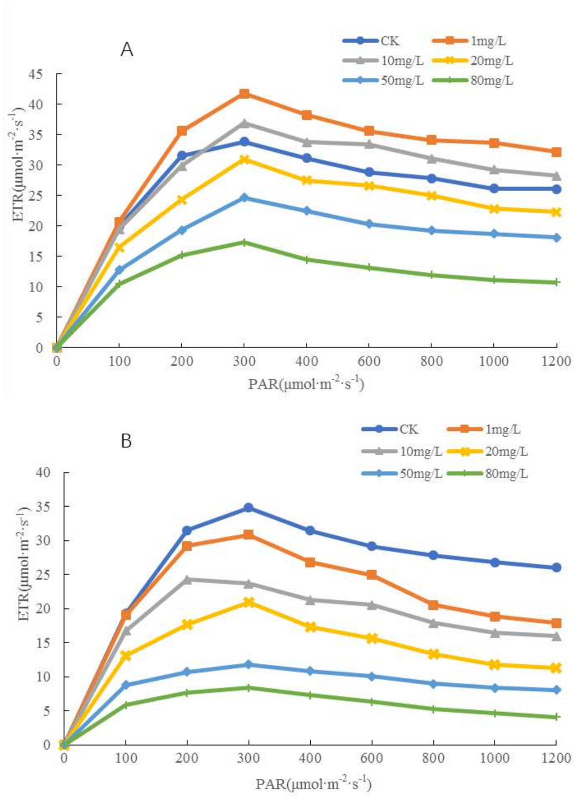

Figure 6. *Effects on ETR of V. natans under Pb stress. (A represents one day stress, B represents seven days stress)*

Discussion

Chlorophyll content is an important index to measure leaf senescence. The degree of reduction can also reflect the situation of Pb poisoning in plants. After one day under 1 mg·L^{-1} Pb, the synthesis of chlorophyll was enhanced because activated microorganisms in the water improved the supply condition of water nutrients (Yu et al., 2016), and Ca/Cb increased which may be a kind of resistance caused by Pb accumulation in *V. natans* to slow down the aging speed of the leaves.

After seven days, Ca decreased faster than Cb. Photosynthetic pigment decreased with the increase of Pb concentration. The main reason may be that Pb binds to the sulfhydryl of related enzyme in the chloroplast (Assche and Clijsters, 1990), destroyed the chloroplast structure. At the same time, with the accumulation of Pb, the combination of Pb and some enzyme (original chlorophyll reductase and porphobilinogen deaminase) that synthesize chlorophyll in cells (Asgharipour., 2011), make the enzyme activity blocked and chlorophyll synthesis inhibited.

The parameters of chlorophyll fluorescence kinetic have been widely recognized as one of the good indicators of plant resistance. The fluorescence parameters of plant growing under normal conditions were stable (Roháček, 2002). Fo was related with the activity of PS II light reaction center. In this research, Fo increased obviously when Pb concentration was over 20 mg·L^{-1}, which may be caused by the damage of the PS II reaction center of *V. natans* leaves (Gan et al., 2017). Fv/Fm indicated the light conversion efficiency of PS II reaction center. Fv/Fo indicated the potential activity of PS II. The change trend of Fv/Fo change trend is similar with and Fv/Fm. Fv/Fo is more

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41714181

sensitive to change of the photosynthetic efficiency. Conversion efficiency of PS II primary light energy decreased with the increase of Pb. The low Pb concentration had a weak effect on the potential maximum photosynthetic capacity of the leaves, and *V. natans* had a definite resistance to adversity. High Pb concentration hampered the light energy conversion efficiency of PS II reaction center, was unfavorable for the leaves to capture light energy into chemical energy.

After seven days, Fv/Fm, qP, Y(II) and ETR was 54.1%, 67.99%, 35.69% and 67.99% of the CK respectively under Pb stress of 20 $mg \cdot L^{-1}$, 24.25%, 37.36%, 15.3% and 24.14% of the CK respectively under Pb stress of 80 $mg \cdot L^{-1}$. This showed that with the prolongation of stress duration, the photosynthetic activity of PS II reaction center in *V. natans* leaves had been irreversibly damaged (Liu et al., 2017). It had basically lost photosynthetic capacity.

The decrease of qP indicated that the electron transportation from the oxidation side of PS II to the reaction center was blocked. The electrons used for photosynthesis decreased and the light energy dissipated in heat or other forms increased, which was consistent with the decrease of Y(II) (Zhang., 2016). qN reflects the plant's ability to dissipate excess light energy as heat and reflects the light protection ability of plants. The value of qN gradually increased with the increase of Pb level. *V. natans* would start self-protection mechanism, dissipate excess light energy absorbed by the antenna pigment as heat energy to reduce the damage of chloroplasts and other photosynthetic organs when it was threatened by the heavy metal (Qian et al., 2011; Wu et al., 2016; Janssen et al., 1992). With the prolongation of stress duration, the damage of leaves was severe under high Pb stress (>20 $mg \cdot L^{-1}$). Dead leaves appeared. It was beyond the scope of self-protection.

Light quantum of adsorbed by PS II reaction center transferred and dissipated in three ways (Kramer et al., 2004). The sum of all light quantum yield closed to 1, that is, Y(II)+Y(NO) +Y(NPQ)=1. The proportion of Y(II) was the smallest with the increase of Pb concentration. Excessive Pb directly inhibited the transportation of photosynthetic electron, thus reduce the percentage of energy conversion in photochemical way (Qian et al., 2011). Y(NO) is an important indicator of light damage. Its higher level indicates that the photochemical energy conversion and protective regulatory mechanisms (such as heat dissipation) are not sufficient to completely consume light energy absorbed by the plant. With the prolongation of stress time, it increased, indicating that *V. natans* had been damaged. Y(NPQ) is an important indicator of light protection. The higher of Y(NPQ) indicated that the light intensity accepted by the leaves was excess, the plant can adjust (such as the excess light energy dissipated into heat) in order to protect themselves. This research showed that Y(NPQ) after seven days was significantly higher than that after one day. It received excess light. The utilization of light energy by the plant was weakened under Pb stress. The plant consumed excessive heat to protect itself and adapt to the environment by increasing the quantum yield of regulatory energy dissipation (Li et al., 2005).

Conclusions

Vallisneria natans can carry out relatively normal physiological activities ($Pb \leq 10 mg \cdot L^{-1}$). It can be speculated that *V. natans* are used as repairing species in low concentration Pb contaminated waters. This study was conducted in the period of vigorous growth, the period of flowering and decay of *V. natans* should be studied in future.

Abstract.
The soil water movement under different biochar treatments of the black soil region in Northeast China was simulated by the Hydrus-1d software in this paper. The simulation errors were between -5.12% and 9.15%, within the ±10% range. with the increasing amount of biochar applied, the residual soil moisture content and the shape parameter were decreasing, while the saturated soil moisture content and the reciprocal of air inlet value were increasing. The difference between the saturated and residual water content was getting bigger with the increasing amount of biochar applied, which improved the available soil moisture content, a beneficial factor of crop growth. With increasing the amount of biochar applied, the moisture rate in the soil profile clearly increased, soil water redistribution curve right shifted significantly, which indicated that biochar can greatly improve the water retention ability of the soil. Furthermore, the soil moisture content increased when the soil depth was more than 50 cm. The effects of biochar on soil moisture diminished rapidly.
Keywords: *farmland, Northeast China, soil water distribution, simulation model application, biochar application*

Introduction

Hydrus-1d is a software for the simulation of water, energy and solute movements in saturated and unsaturated porous media, developed by US Salinity laboratory. It has been widely used in the analysis of the processes of water movement and solute migration in unsaturated and porous media. Simunek et al. (1999) and Simunek et al. (1996) used it to calculate the parameters of soil water movement and solute migration. Tang et al. (2011) simulated the soil water infiltration process of the snow melting in the desert region based on the Hydrus-1d, and the simulation deviation was small. Chi et al. (2014) used the modified Richards equation to simulate soil water infiltration and solute migration processes. Ma et al. (2011) studied field water cycle regularities in Huabei Plain by means of Hydrus-1d, and the simulation precision of the model was high. Liu et al. (2018) simulated the soil water infiltration process for different soils, and revealed the relationship between the soil water distribution, soil types, and amount and rate of irrigation water after 24 h of irrigation.

Biochar is a substance in the state of solid particles, which is produced from some wastes such as crop straw, animal manure, etc. under high-temperature and hypoxia (Wei et al., 2018b). Many studies showed that biochar application could both increase and decrease the bulk density and the total porosity of the soil separately, and these changes could affect its water capacity (Wei et al., 2018a). Furthermore, due to the higher moisture absorption ability of biochar, soil water capacity could be increased (Xiao et al., 2015; Qi et al., 2014), along with the improvement of plant growth (Oguntunde et al., 2008). In addition, it also could affect soil organic matter, aggregate, pH value, etc. to some extent. It would also be possible to influence soil water diffusivity, dispersion coefficient and unsaturated hydraulic conductivity significantly, which in turn would affect soil water storage and movement (Mukherjee et al., 2013; Mankasingh et al., 2011; Novak et al., 2012; Wei et al., 2016; George et al., 2012; Li et al., 2014). As a result of previous studies some researchers are turning their attention towards the effects of biochar on soil water movement. When biochar is applied to clay, the soil water contents, soil water infiltration rates and accumulated infiltration water amount could all be increased (Cen et al., 2016). By changing the amount of biochar soil water infiltration rate and the amount of accumulated infiltration water were influenced at varying rates under different salinization degrees (Liu et al., 2017). When the soil moisture content was lower than 0.4 cm^3/cm^3, biochar could lower the soil water diffusivity, and when it was higher than 0.4 cm^3/cm^3, the results were the opposite (Liu, 2017). Few researches have studied and simulated soil water movement in the black soil region of China, and this research could prove helpful for soil water management in the region.

The soil water movement simulation and analysis in this paper would provide a basis for the efficient utilization of soil and water resources, and the protection of the black soil region in northeastern part of China.

Materials and methods

The experimental area

The experiment area was located in a sloping farmland with a 3 degree slope gradient in the Hongxing state farm of Heilongjiang province, China (*Fig. 1*).

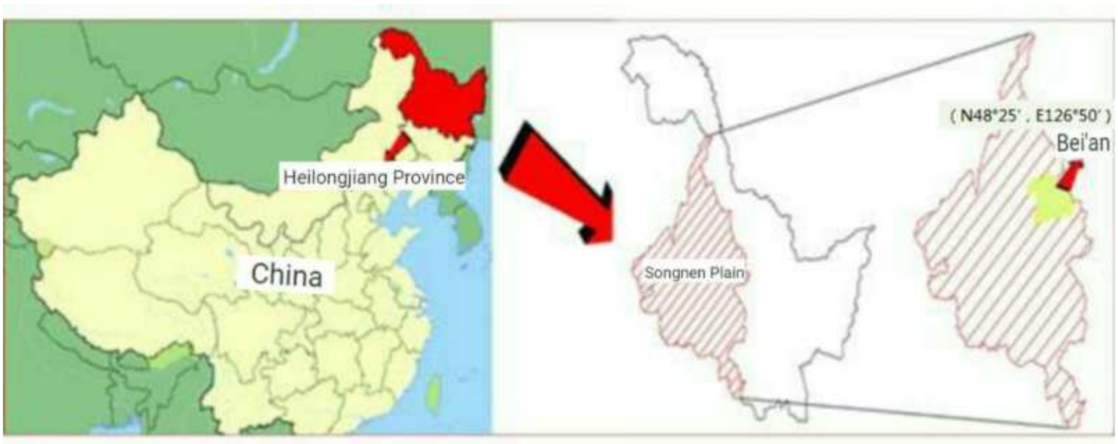

Figure 1. *Location of the experimental site*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41834192

The soil type was meadow black soil with 21.93% of sand (>0.02 mm), 44.21% of silt (0.02~0.002 mm) and 33.86% of clay (<0.002 mm) in mass fractions, 86.3 g/kg organic matter content, 18.5 mg/kg, 18.5 mg/kg of ammonium nitrogen, 58.5 mg/kg of available phosphorus, 151 mg/kg of available potassium, and the pH value was 6.3 (Wei et al., 2016). The raw material of the biochar was corn straw and was purchased from the Jinhefu agricultural development company of Liaoning province near the experimental site. It was formulated under 450 °C temperature and anaerobic conditions. The particle size of the biochar was 1.5~2.0 mm, the contents of total C, total N, total P and total K were 70.21%, 1.58%, 0.73% and 1.66% respectively, and the pH value was 9.36 (Wei et al., 2016).

Experimental design

Five different amounts of biochar were applied (0, 25, 50, 75 and 100 t/hm^2) in different field plots with 5 m of width and 20 m of length, named CK, C1, C2, C3 and C4 treatments respectively, among which CK was the control treatment.

Before seeding, the top 0-25 cm of the soil layer was loosened, followed by the artificial mixing of biochar into the soil, after which a waiting period took place until the seeding of the soybeans. The soybean variety used was Heihe number 3.

The fertilizer supply was as follows; NPK compound fertilizer with 13% of N, 25% of P_2O_5 and 10% of K_2O was supplied at the seeding stage, with a supply amount of 450 Kg/hm^2.

The items and methods of the observations

Soil matric potential was measured using tensionmeters installed in the soil layers at 10, 20, 40, 60, 80, 100, 120 and 140 cm below soil surface.

Meteorological data was measured using automatic weather station located in the experimental site.

Soil water content was measured using the TRIME-T3 Pipe Soil Moisture Measurement System made in Germany.

Simulation calculation

Brief introduction of Hydrus-1d

Hydrus-1d is a model annunciated by the international center of ground water simulation (Liu et al., 1998) with 5 modules used for different calculations, including water movement, solution migration, heat conduction, plant-root water uptake and plant-root growth. The water movement module can be specifically used for unsaturated soil water movement simulation, and not only does it take plant-root water uptake into consideration, but also modifies the lagging of soil water holding capacity. It's widely used in soil water movement simulation (Wang et al., 2005, 2012; Lai et al., 2015) and the results are more precise. The boundary conditions of the model are comprehensive, in which the upper boundary conditions include constant water head, constant water flow, atmospheric boundary, variable water head, variable water flow and atmospheric boundary condition surface with run-off; while the lower boundary conditions include constant water head, constant water flow, variable water head, variable water flow, freedom drainage, deep layer drainage, leached surface and horizontal drainage. Some boundary conditions are variable-boundaries and correspondent variable conditions should be imputed.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41834192

For the calculation of water movement the classical equation of Richards was used, taking the soil surface as the abscissa while the direction of the *Z* axis is downwards, then the basic equation of unsaturated soil water movement is as follows.

$$\frac{\partial \theta}{\partial t} = \frac{\partial}{\partial z}\left(D(\theta) \frac{\partial h}{\partial z} \right) + \frac{\partial k(\theta)}{\partial z} + S \qquad \text{(Eq.1)}$$

Where θ is soil water content; h is suction head; k is unsaturated soil water conductivity; S is plant-root water uptake, which would be 0 when no plants are present in the soil surface; and $D(\theta)$ is soil water diffusivity.

The model can be divided into a single pore model and a double pore model, and the Van Genuchten-Mualem model which was developed from the single models of Van Genuchten (1980) and Mualem (1975), its basic equation is as follows:

$$\theta(h) = \begin{cases} \theta_r + \dfrac{\theta_s - \theta_r}{\left(1 + |\alpha h|^n\right)^m}, h < 0 \\ \theta_s, h \geq 0 \end{cases} \qquad \text{(Eq.2)}$$

Where, θ_r is the residual soil moisture content; θ_s is saturated soil moisture content; h is pressure water head.

Considering the effect of suction head on plant-root water uptake, Feddes function was used to calculate the actual transpiration rate according to the potential transpiration rate. Its basic equation is as follows:

$$\alpha(h) = \begin{cases} 0, h \geq h_4, h \leq h_1; \\ \dfrac{h_1 - h}{h_1 - h_2}, h_2 \leq h \leq h_1; \\ 1, h_3 \leq h \leq h_2; \\ \dfrac{h - h_4}{h_3 - h_4}, h_4 \leq h \leq h_3; \end{cases} \qquad \text{(Eq.3)}$$

Where, h is soil water potential, *cm*; h_1 is the negative pressure value when the soil pores are full of water; h_2 is a negative value when the soil water reaches the water holding capacity; h_3 is a negative value when the capillary bond is disrupted due to plant consumption and evaporation from the soil surface; and h_4 is a negative pressure value when permanent wilting occurs.

Definite conditions

1) Initial conditions

The initial condition is the negative pressure value of every soil layer in the beginning.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41834192

$$h(z,0) = h_0(z), z \geq 0 \tag{Eq.4}$$

2) Boundary condition

The experimental plots were in a sloping farm land with a 3 degree gradient, thus the soil surface boundary condition was:

$$-K\frac{\partial h}{\partial z}\bigg|_{\Gamma 1} = q(z,t) \tag{Eq.5}$$

There should be no surface water when the rain intensity is lower than the infiltration intensity, which is:

$$-k(\theta)\left(\frac{\partial \theta}{\partial z} + 1\right) = R(t), z > 0 \tag{Eq.6}$$

And surface water will accumulate when the rain intensity is higher than the infiltration intensity, which is:

$$h(0,t) = H(t), t > 0, z = 0 \tag{Eq.7}$$

Where, $q(z,t)$ is the water flux density in the soil surface boundary; $R(t)$ is the rain intensity; and $H(t)$ is the depth of surface water.

The parameters to be measured are residual soil moisture content θ_r; saturated soil moisture content θ_s; reciprocal of air-entry value α and shape factor n; soil water content θ; pressure water head h; saturated water conductivity K_S; soil texture and soil layer thickness d; inclined degree of soil layer; times at which the simulation is started and finished, etc..

The above soil hydraulic parameters were obtained from soil water characteristic curves which were determined using a Hitachi CR-21G3 centrifuge manufactured in Japan. 8 levels of speed were set (500, 1000, 1500, 2000, 3000, 4000, 5000 and 6000 r/min), and the centrifugal time for each speed level was 100 min. Ks was measured with the double-rings method in the field plots, and the K_S value was calculated according to Daxi law, K_S=0.75 cm/h.

Unsaturated soil water conductivity was determined with the following equation:

$$K(\theta) = K_s\left(\frac{\theta - \theta_r}{\theta_s - \theta_r}\right)^{0.5}\left\{1 - \left[1 - \left(\frac{\theta - \theta_r}{\theta_s - \theta_r}\right)^{1/m}\right]^m\right\}^2 \tag{Eq.8}$$

The water diffusivity $D(\theta)$ was determined using an infiltration method of horizontal columns.

Results and analysis

Soil hydraulic characteristic parameters

Soil water holding capacity is reflected in the soil water characteristic curves. The Van Genuchten model in Hydrus-1d had good fitting effects for the experimental area (Liu, 2017; Wang, 2016), thus it was used to fit the soil water characteristic curve of every treatments. The fitting results of soil hydraulic characteristic parameters was shown in *Table 1*. The VG model was more effective, the fitting precision was higher than 0.995, the values of RMSE for every treatment ranged from 0.516 to 1.219, thus all the parameters can be used for soil water movement simulation.

With the increase of the amount of biochar applied, the residual soil moisture content and the shape parameter were decreasing, while the saturation moisture content and the reciprocal of air inlet value were increasing. The difference between the saturated and residual water content were getting higher with increasing the amount of biochar applied, which greatly improved the available soil moisture content, a beneficial factor for crop growth.

Model validation

The CK treatment and the rain with 26 mm of total rain-water and 2 h duration occurred on the 22nd of July 2015 were chosen for the model validation. Compare the actual soil water redistribution curves and their simulation results, and calculate their errors to check the model's reliability and accuracy. *Figure 2* shows the soil water redistribution at 20 min, 12 h, 24 h and 48 h after rain and their simulations. The actual value and simulation value were close.

The simulation errors were showed in *Table 2*. The simulation errors were between -5.12% and 9.15% which were within ±10%. The results showed that the simulation model was reliable and accurate, and that the model could be used for soil movement simulation.

Simulation results

The rainfall with 19 mm of total rain-water and 1 h duration occurred on the 22nd of July 2015 was chosen to simulate the soil water distribution at 48h after rain. The results was shown in *Figure 3*. The figure showed that with increasing the amount of biochar, the curves right shifted, especially in the case of the soil layer at a 0-50 cm depth, which means that the soil water content in the profile was increasing as well. However, below the soil depth of 50 cm, the soil water content changes were not significant, the reason for which is the fact that the biochar was applied to the upper layer of the soil, which made the soil porosity of the upper layer higher than that of the deeper layers. Thus with the depth increase, the soil water content reduced sharply, and with the increase of the amount of biochar applied, the soil water contents were also increasing by a small increment.

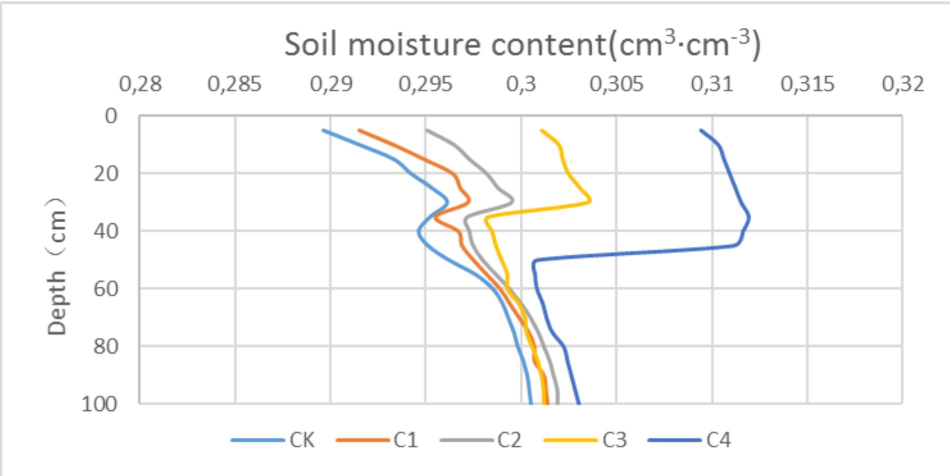

Figure 3. *Simulation results of water content in the soil profile for different treatments*

Conclusions

(1) With the increasing amount of biochar applied, the residual soil moisture content and the shape parameter were decreasing, and the saturated soil moisture content and the reciprocal of air inlet value were increasing. The difference between the saturated and residual water content increased with the amount of biochar, which greatly improved the available soil moisture content. Moreover, biochar treatment can improve soil water redistribution conditions, increasing the soil water holding capability in the cultivated layer, which should be beneficial to the growth of crops.

(2) The errors of soil water movement simulation based on the Hydrus-1d software were between -5.12% and 9.15% which is within ±10%. It could be used for soil water movement simulation under biochar application in the black soil region of Northeast China.

(3) The results above have a great significance for soil and water resources utilization and the protection of the black soil region of Northeast China. However, the research was limited to a farmland with a 3 degree slope gradient, thus it is necessary to do similar researches on lands with a 5 degree gradient, because 3 and 5 degree farmlands are the two main types of sloping farmlands in the region.

Abstract. Bamboo is an effective alternative material to alleviate the burden on wood supplies. Chemical components distributed in the gradient structure of bamboo culm are likely to be the determining factors in selecting the optimal application of bamboo. Bamboo culm exhibits a complicated chemical composition of in holocellulose, lignin, pentosan and extractives in the longitudinal direction of its culm cultivated for varying periods of time. In this study, the chemical constituents of moso bamboo were analyzed statistically at different heights cultivated for a minimum of 6 months to as long as 9 years. No significant impact on chemical components was found in the longitudinal direction of the bamboo culm. However, bamboo culm age should be taken into consideration in the trends of holocellulose, pentosan, lignin and extractives located in the inner, middle and outer layers. The moso bamboo cultivated from 3 to 5 years was optimal for industrial application. The yield percentage and difference between layers, in particular, are fundamentals for evaluating and improving the properties for bamboo products.
Keywords: *extractives, holocellulose, lignin, pentosan*

Introduction

Bamboo is mainly distributed in tropical and subtropical areas, the growing stock and yield of which in China is one of the highest worldwide (Mao et al., 2017; FAO, 2010). Bamboo is almost exclusively composed of cellulose, hemicellulose and lignin, which is quite similar to wood in chemical composition. As a fast-growing plant, bamboo is regarded as a huge renewable resource base to reduce stress on wood resources to some extent (Cao et al., 2014; Jiang et al., 2015; Cheng et al., 2015; Kaur et al., 2016). In traditional industries, bamboo utilization only occurs for primary products such as hand-plaited bamboo articles and daily necessities. In high-tech industries, bamboo charcoal fiber, pulp-making, bamboo-based composite lumber and bamboo vinegar present the outstanding value of bamboo (Sulaiman et al., 2005; Ahmad and Kamke, 2011; Sugesty et al., 2015; Han et al., 2017), which is intimately linked to the chemical details of bamboo.

Bamboo is a lignocellulosic biomass with a complicated network structure. Lignocellulosic cell walls in bamboo give it the majority of its properties. Due to the covalent linkages among cellulose, hemicellulose and lignin, the definitive structure of the three natural compositions is almost unfathomable (Guerra et al., 2006; Huang et al., 2016). The chemical constituents of bamboo are known to vary greatly depending on

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41934203

species, position within the culm and the age of the culm. The varieties, like *Bambusa arundinacea*, *Dendrocalamus asper, Gigantochloa apus,* and *Phyllostachys heterocycla*, are more common species of bamboo suited to large-scale comprehensive utilization (Jayanetti and Follett, 1998). In very general terms bamboo consists of 50-70% holocellulose and 20–25% lignin (Fengel and Shao, 1984; Liese, 1987). Lignin is a highly complex non-crystalline molecule comprising of a large number of phenyl-propane units. The structure of the lignin present in bamboo is unique, and undergoes changes during the elongation and ageing of the culm (Itoh, 1990). The lignin content is relatively high in the epidermal layer and at the top of bamboo (Jiang et al., 2006). Between 40 and 50 percent of the dry mass of bamboo is in the form of cellulose forming from the anhydrogluclose unit. Cellulose plays a main role in mechanical characteristics of bamboo culm, even for bamboo fiber. The lignification process of bamboo is from the epidermal layer to inner waxy layer, that is, there is less cellulose in the epidermal layer (Lin et al., 2002). Hemicelluloses, therefore, comprise mixtures of polysaccharides manufactured in bamboo from basic sugars such xylose, arabinose, glucomannan and galactose (Balakshin et al., 2011). 90% of the hemicellulose is xylan with a structure intermediate between hardwood and softwood xylans. The distribution of hemicellulose content is in a reversal of that of lignin content (Peng et al., 2012; Peng and She, 2014). Bamboo also has minor amounts of resins, waxes and tannins (Chung and Wang, 2017).

Bamboo industries on chemical components have different requirements. The higher cellulose content the better it is for pulping and papermaking. In general, cellulose is also closely related to the strength and deformation of bamboo-based panels. However, this relationship may be masked by the presence of amounts of extractives. Also, abnormally high lignin fractions in bamboo may influence structures and properties, at least in the longitudinal axis of bamboo (Richard and Harries, 2015; Huang et al., 2017). Therefore, thorough understanding of distributed chemical components in bamboo to optimize the further processing technology is required.

Materials and methods

Preparation

Moso bamboo (*Phyllostachys heterocycla* var. *pubscense*) was obtained from Sanming bamboo stands (27N, 117E) in Fujian province, China. After air drying, bamboo samples (inter node) were collected from 6-month-old to 9-year-old stem-sections at three different heights above ground level (1, 3, and 5 m), and also, on the basis of position which is outer, middle and inner layer of the bamboo stems. Outer layer is the epidermal layer, and inner layer is the waxy layer (*Fig. 1*). Dried samples were ground into powder with a particle size of 40-60 mesh for chemical analysis.

Determination of chemical components

The chemical characteristics of bamboo were determined according to the national standards outlined in GB test methods. Holocellulose content was determined based on GB/T 2677.10-1995 *Fibrous Raw Material* (or FRM for short) – *Determination of Holocellulose* (GB, 1995). The lignin content was determined following the GB/T 2677.8-1994 *FRM – Determination of Acid-insoluble Lignin* (GB, 1994b). Pentosan content was determined in accordance with GB/T 2677.9-1994 *FRM – Determination of*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41934203

Pentosan (GB, 1994c). The determination of extractives was carried out following GB/T 2677.6-1994 *FRM-Determination of solvent extractives* (GB, 1994a) and GB/T 2677.5-1993 *FRM – Determination of One Percent Sodium Hydroxide Solubility* (GB, 1993). The number of replicates was five, and the analyses of variance by Statistica 6 were used.

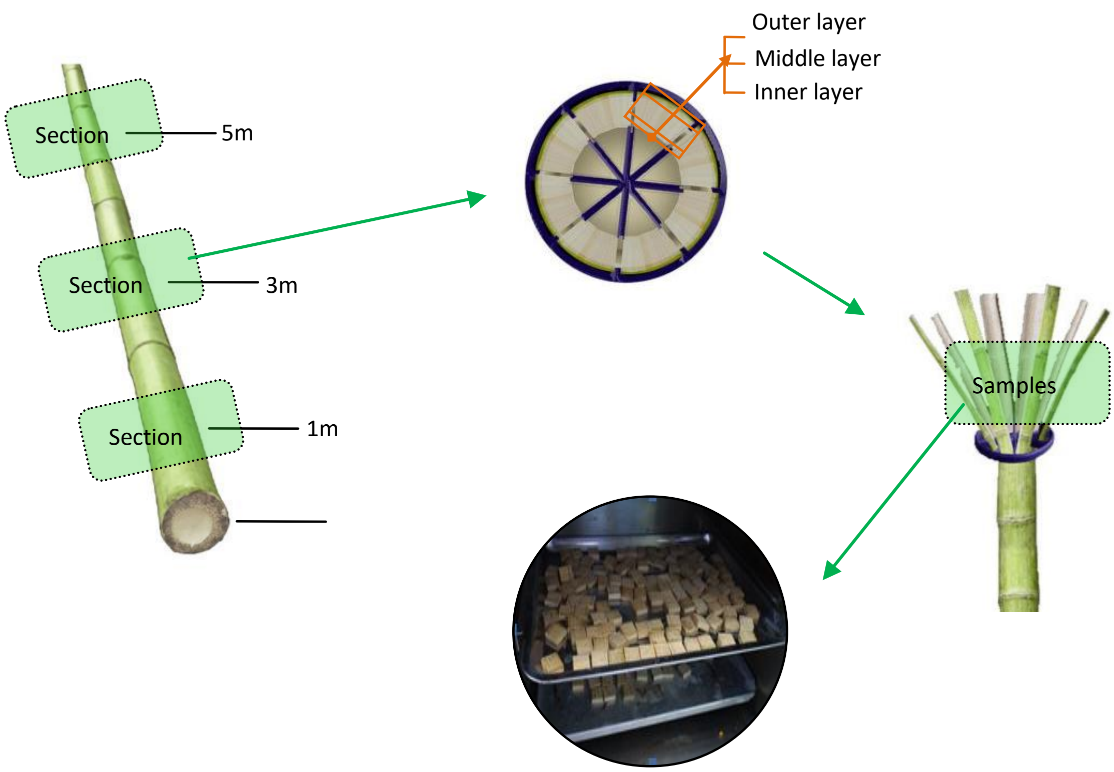

Figure 1. *Preparation of bamboo samples*

Results

Chemical characteristics at different heights

The chemical constitution of inner, middle and outer layer in the moso bamboo stems at different heights was determined respectively. The analysis of variance (ANOVA) on holocellulose, lignin, pentosan and extractives are showed in *Table 1*. There are no significant differences in chemical composition in the longitudinal direction of bamboo stems.

Table 1. *Summary result for analysis of variance for chemical components at different heights*

Position	P-value				
	Holocellulose	Lignin	Pentosan	1% sodium hydroxide extractives	Solvent extractives
Inner	0.750284	0.091319	0.991868	0.841184	0.697808
Middle	0.97058	0.24962	0.987907	0.403769	0.536052
Outer	0.843169	0.335781	0.863107	0.95569	0.509231

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41934203

Chemical characteristics at different ages

The chemical constitution of inner, middle and outer layer in the moso bamboo stems at different ages was determined respectively. The analysis of variance (ANOVA) on holocellulose, lignin, pentosan and extractives are showed in *Table 2*. Nearly all the chemical components for different layers shows significant differences among the culm age, except the lignin content in the inner and outer layer. Therefore, it is extremely valuable to perform trend analysis.

Table 2. *Summary result for analysis of variance for chemical components at different ages*

Position	P-value				
	Holocellulose	**Lignin**	**Pentosan**	**1% sodium hydroxide extractives**	**Solvent extractives**
Inner	0.00098	0.289121	0.002851	0.005266	0.004758
Middle	0.002666	0.028988	0.000192	0.017753	6.76E-05
Outer	0.021891	0.251166	0.020283	2.76E-07	0.000511

The yield trends of holocellulose in the inner, middle and outer layer are showed in *Figure 2* from 6-month-old to 9-year-old. The holocellulose content in middle layer is more than that in inner and outer layer in three years. However, holocellulose content in outer layer increases since 5-year-od, even more than that in middle layer. Meanwhile, there is a decreasing trend in percentage difference among the three layers. Considering there is no significance level along the height, the average of each layer at different height is carried out to determine the comparative benefit. The changing trends of holocellulose content for inner and outer layer are the similar, and peak at the fifth year.

The variation of lignin content in the three layers is shown respectively in *Figure 3* from 6-month-old to 9-year-old. Inner layer has a great similarity in lignin content compared to middle layer. However, only the middle layer shows a significant relativity for lignin content. In the middle layer, lignin content increases slightly from the sixth month to the third year, and then it is nearly at a constant level.

Here is that the pentosan content as a whole increases from the outer layer to the inner layer (*Fig. 4*). As such, there is much comparability between the inner layer and middle layer. Pentosan content reaches up to the maximum value in the fifth year and gets the minimum value in the seventh year. In the third year, however, the global minimal value of pentosan content appears in the outer layer.

The 1% sodium hydroxide extractive of bamboo is closely related to decay resistance, which is mainly composed of tannin, pigment, alkaloid, saccharine, starch, degraded hemicellulose and lignin, etc (Jiang et al., 2015). The variation trend in the inner layer is similar to that in the middle layer, but different from that in the outer layer (*Fig. 5*). The yield is ranging from 19.38% to 35.06%. The 1% sodium hydroxide extractive in the inner layer is more than that in other two layers except in the seventh year, and the tendency is almost smooth before the five year and changes suddenly in the seventh year.

The changing trend of solvent extractives in the inner layer is similar with that in the outer layer, and has a little difference from that in the middle layer (*Fig. 6*). The lowest content of solvent extractives is set in the 5-year-old bamboo stems for each layer. The

DOI: http://dx.doi.org/10.15666/aeer/1702_41934203

variation of solvent extractives is similar between each layer after the third year. In contrast, there is less extractives in the middle layer than that in other two layers.

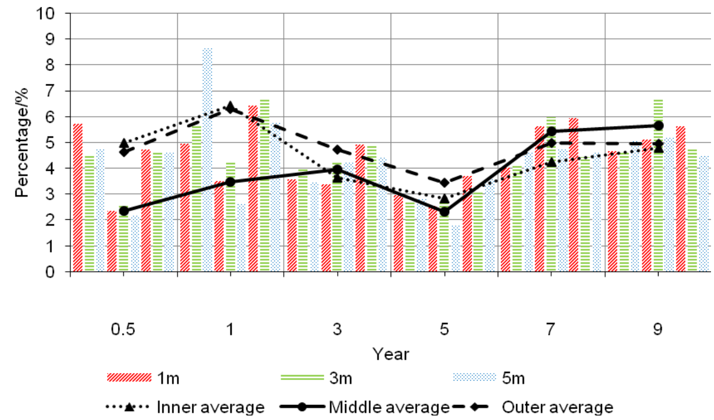

***Figure 6.** Variation of solvent extractives*

Discussion

It should be noted that the –OH groups of the cellulose molecules which give rise to hydrogen bonding are also highly attractive to moisture. Below the fiber saturation point, a subsequent dimensional change was occurred (Anokye et al., 2014). Bamboo strips are liable to distortion such as twist and bow, which has a strong influence with mechanical properties (Saito and Arima, 2002; Kamruzzaman et al., 2008). According to the findings, the distribution of chemical components in the longitudinal direction of bamboo stems should not be the reason to warping. That is, the distortion of bamboo strips may be due to the gradient fibrous structure (Chen et al., 2018).

However, the chemical constituents are fundamental to physical and mechanical properties of bamboo. The holocellulose content in middle layer reaches the maximum of all yield percentage at the third year, which has potential for use as dissolving pulp compared to softwoods (Lovell, 1945). As the panel practice, 3-year-old bamboo is optimum for tangential bamboo sliver, and 5-year-old bamboo is a good choice for radial bamboo sliver in regard of dimensional stability (Sinha and Miyamoto, 2014; Suthon, 2016; Li et al., 2018). A markedly higher proportion of lignin is in the outer layer, which is consistent with the outcome of lignification process (Lin et al., 2002; Tsuyama et al., 2017). For the 3-year-old and 5-year-old bamboo culm, there is obvious

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_41934203

difference in pentosan content among the three layers. The yield of pentosan in the outer layer is less than the inner layer and middle layer. Pentosan can not only lower moisture absorption of bamboo, it can also improve the toughness of bamboo (Das and Chakraborty, 2008; Banik et al., 2017). Therefore, failure region should be close to the outer layer when a force is applied perpendicular to grain. However, none of studies has been reported from this point at least for now. The extractive contents of moso bamboo are higher than that of softwood and hardwood. Therefore, it is more complicated for preservative treatment (Shah et al., 2018). The high yield percentage of 1% sodium hydroxide extractive indicates that there are more hemicellulose and lignin with lower molecular weight. The solvent extractives consist of wax, fatty acid, essential oil and so on. Higher percentage of solvent extractives has a negative effect on pulping process (Muhammad et al., 2013).

Conclusions

1. Heights have no significant impact on chemical constituents for the inner, middle and outer layer respectively. However, bamboo culm age is closely associated with holocellulose, pentosan, lignin and extractives.
2. The maximum yield of holocellulose is found in the middle layer of the 3-year-old bamboo culm. But it is obvious that the holocellulose contents in the three layers are similar at the fifth year. For lignin content, there is almost no difference in each layer between the third year and the fifth year. There is a clear distinction for percentage of pentosan in the three layers from the third year to the fifth year, which has a potential impact on strength. The lowest percentage of extractives presents in the fifth year. However, the percentage of 1% sodium hydroxide extractives changes hardly from the third year to the fifth year.
3. For the practical application, it is impossible to get a desired percentage of chemical components of moso bamboo in a particular culm age. However, the optimization of culm age could be accomplished in terms of the different performance requirements of bamboo products.

Abstract. Industrial development has led to the indisputable fact that high carbon emissions were brought into Anhui Province. This paper calculates the changes in Anhui's carbon emissions from 2000 to 2015 and analyzes the influencing factors. The results prove that carbon emissions show a stable upward trend, but the growth rate has declined after 2005. Carbon emissions produced by three major industrial sectors: mining industry, EGW (electricity, water and gas) and manufacturing industry, show a growing trend, but growth rates decrease successively. According to the STIRPAT model, five factors, including out-of-province investment, energy consumption structure, per capita income, proportion of output value in the secondary industry to GDP and actual use of foreign capital, are positively correlated with Anhui's carbon emissions, while there is a negative correlation between the proportions of the total volume of foreign trade and the industrial added value of enterprises above designated size (two factors) to total industrial output value. As the structure of energy consumption has long been fueled by coal, the transfer of external industry mainly focuses on projects concerning power plants, steel product processing and coal chemical industry, which are highly energy-consuming, which means these are the main factors driving the growth of carbon emissions.
Keywords: *industrial carbon emissions, overall change of carbon emission, STIRPAT model, influencing factors, external investment, economic development, energy structure*

Introduction

Greenhouse gases, especially carbon dioxide, are regarded as a major cause of global warming, thus becoming a widespread concern (Bamminger et al., 2018), while industries, as the main sources of carbon dioxide emissions, have been the focus of the academic scene (Ban et al., 2016; Rahman and Kashem, 2017; Griffin et al., 2018). As the largest developing country in the world, China has seen its economy maintain rapid development for 40 years since it began its reform and opening-up program in 1978 (Liu et al., 2013, 2014). By this time the country has become one of the world's biggest energy consumers (Deng et al., 2012) and the biggest carbon emitter (Zhang et al., 2015; Shao et al., 2016b). Recent academic researches focus on the following aspects:

Changes in carbon emissions and their spatial distribution during urbanization and industrialization

Jiang et al. (2018) have discussed the leading factors influencing carbon emissions of China and the U.S. and differences through comparison and analysis of the carbon emission processes between the two countries (Jiang et al., 2018). Tian et al. (2011) hold that economic growth, industrial sector and technological changes produce much more carbon dioxide than population, energy structure and other sectors after calculating carbon dioxide emissions of 31 provinces in mainland China and then dividing the 30 provinces (excluding Tibet) into seven groups (Tian et al., 2011). The study of Li et al. (2018) finds that from 2000 to 2013, China's carbon dioxide emissions have grown rapidly, with an average growth rate of 8.2% (Li et al., 2017). Olivier et al. (2015) believe that China accounts for 30% of total global emissions in 2014, up 80% from 2004.

In respect to studies on spatial distribution characteristics, Su and Ang (2014) have calculated the total transfer and flow characteristics of embodied carbon emissions in eight regions of China. Feng et al. (2013) find that 80% of China's carbon emissions come from economically developed coastal provinces, but since 2003, the carbon emissions have gradually shifted from eastern to western regions, especially in central ones with a huge increase (Meng et al., 2011). Wang et al. (2018c), based on the input-output data in 2007 and 2012, have established an input-output model, evaluate the characteristics of regional carbon flow in China and changes in carbon emissions of different industries and afterwards hold that carbon emissions see a decline from eastern to western regions; by employing a clustering method to evaluate the changes in the growth of carbon emissions in 30 provinces of China from 1996 to 2013, Jiang et al. (2017) hold that the expression of carbon emission intensity varies from province to province so the stages of development of different provinces should be fully considered when the government formulates emission reduction strategies. Zhou et al. (2018) use SDA model to analyze the characteristics of China's regional carbon emissions and transfer, and believe that China's regional carbon emission transfer is mainly completed through carbon-intensive manufacturing industry. Tian et al. (2018) calculate the periodic change of carbon dioxide emissions in China's manufacturing industry from 1992 to 2012 and conclude three main factors leading to the changes in carbon dioxide emissions: carbon emission intensity, input-output structure and final demand. Chen and Yang (2018), based on China's provincial-level panel data from 2006 to 2015, analyze the spatial-temporal evolutionary trend, spatial correlation and influencing factors of China's carbon emissions and find that the characteristics of carbon emission distribution are affected by various economic and social factors. Population pressure, affluence level, energy intensity, industrial structure, urbanization level and fixed asset investment have significant effects on promoting the growth of carbon emissions. Technological level and government environmental regulation play an obvious role in curbing carbon emissions while foreign direct investment (FDI) does not. Liu et al. (2018) analyze the carbon emission efficiency of ten typical urban clusters in China from 2008 to 2015 by setting up the ideal point cross efficiency (IPCE) model and then put forward four carbon emission effects brought by urbanization. Wang and Ma (2018a) study the influencing factors and regional difference of the emission efficiency of expandable industrial carbon dioxide of 13 cities in Jiangsu Province from 2000 to 2014; by analyzing the panel data of the Yangtze River Delta from 2000 to 2010 and the relationship between urbanization and carbon emissions, Li et al. (2018) believe that a u-shaped curvilinear relationship between carbon dioxide emission efficiency and urbanization indicates that carbon dioxide emission efficiency declines at the initial stage of urbanization and goes up when urbanization reaches a higher level.

Differences of China's regional carbon emissions and their influencing factors

During the "13th Five-Year Plan" period (2016-2020), China promises that the government will support provincial regions in taking the lead in reaching carbon emission peak value (Shao et al., 2016a). Since 2000, local governments have gradually replaced national ministries and commissions as the main force to implement energy conservation and emission reduction policy (Zhao et al., 2014). China's vast territory and imbalanced social and economic development produce obvious differences in energy consumption, carbon emissions and economic development level in different regions (Wang et al., 2014a; Zhang et al., 2014a), and many scholars begin to pay heed to regional (provincial-level) differences and transfer characteristics of carbon emissions among China's industries. For example, significant differences exist in China's provinces in respect to economic development, industrial structure, energy consumption patterns and other factors (Liu et al., 2013; Shan et al., 2016). Some provinces in eastern China have entered the post-industrial stage, while most of other provinces in central and western China are still at the accelerated stage of industrialization since industry is the main source of GDP for these provinces (Cai et al., 2016; Li et al., 2017; Jia et al., 2018); central and western regions are the major producer and exporter of fossil energy, while most eastern provinces are the main importer of it (Lindner et al., 2013) and in the meantime, some provinces still rely heavily on coal consumption (Wang et al., 2015a).

Consequently, the growth trend of carbon emissions and its driving factors demonstrate the marked features of the differences among provinces in China (Liu et al., 2012a; Guan et al., 2014; Xu et al., 2016). For instance, Su and Ang (2010) analyze the difference in carbon emissions between provinces in China. Meng et al. (2011) find that since 2003, the trend of embodied carbon emissions transfer based on energy products has gradually shifted from eastern to central and western regions, especially in central provinces. Feng et al. (2013) find that 57% of China's emissions is related to the consumption of goods outside the origin provinces. Western regions produce a large number of low value-added but high carbon-intensive products and export them to eastern regions, leading to a rapid increase in carbon emissions in western regions. Zhang et al. (2014b) analyze carbon dioxide emissions in different provinces of China from 1990 to 2011, and the cross-provincial transfer of carbon emissions in different regions and with different phase characteristics by comparing dioxide emission scale, emission growth rate and emission intensity of different provinces over the years. Sun et al. (2016a) also analyze the characteristics of carbon emission transfer in 30 provinces of China in 2007 and calculate the economic spillover effect and emission reduction effect of cross-provincial carbon emission transfer.

The influencing factors and driving forces of China's carbon emissions

At present, the research methods on the relationship between economic growth and carbon emissions mainly include Logarithmic Mean Divisia Index (LMDI) (Zhao et al., 2010; Song et al., 2015), panel models (Ren et al., 2014; Zhou et al., 2013), data envelopment analysis (DEA) (Sun et al., 2015b) and Input-Output models (Tian et al., 2014; Mi et al., 2015). Research scale stretches from regions (Lu et al., 2015; Tian et al., 2014) to cities (Mi et al., 2015; Zhao et al., 2010) and industry sectors (Lin and Moubarak, 2014; Lu et al., 2015).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42054227

For example, STIRPAT model is one of the mainstream means used to conduct research on influencing factors of carbon emissions (Waggoner et al., 2002; York et al., 2003). Ma et al. (2017) analyze the driving forces of carbon emissions in China's public construction industry from 2000 to 2015 based on the expanded STIRPAT model. Zhang et al. (2017) analyze the trend of carbon emissions and energy consumption in Henan Province from 1995 to 2014 with STIRPAT model and believe that energy consumption caused by population growth is the major contributor to carbon emissions in the province. Yang et al. (2018a) analyze the impact of the optimized economic structure of Shanghai City on carbon emissions by employing STIRPAT and NSGA-II models. Wang et al. (2018b) analyze the gross scale, structure and influencing factors of household carbon emissions in 30 provinces and regions in China based on the expanded STIRPAT model.

Two commonly used reverse synthesis methods are employed in existing literature (Liu et al., 2012; Xiao et al., 2016): index decomposition analysis (IDA) and structural decomposition analysis (SDA) (Malla, 2009). Both methods have their own advantages and disadvantages. Generally, SDA needs economic data shown in the form of IO table, while IDA only needs the summary data of each industry category (Cansino et al., 2016; Yang et al., 2016). SDA can only analyze changes between finite years, while IDA can usually analyze those between any year (Cellura et al., 2012). Or the study of the decoupling relationship between economic development and carbon emissions can also be conducted. Decoupling relationship analysis mainly adopts OECD decoupling index method (OECD, 2003) and Tapio elastic decoupling index method (Tapio, 2005). The objects of decoupling relationship analysis are diversified, which can be analyzed from a macro to micro perspective. For example, Yu et al. (2013) employ OECD decoupling model to study the decoupling relationship between carbon dioxide, sulfur dioxide, dust, sewage discharge and economic development in China from 1978 to 2010. Wang et al. (2015c), Zhang and Wang (2013) and Wang et al. (2015b) employ Tapio decoupling model to study the decoupling relationship between the economic development in Tianjin, Jiangsu Provinces and Beijing-Tianjin-Hebei region and pollutant emissions, featuring carbon dioxide. Wang et al. (2014b) combine Tapio decoupling model with LMDI decomposition model to analyze the decoupling situation between China's economic growth and energy consumption from 1991 to 2011.

Study on the impact of changes in industrial structure and industrial transfer on carbon emissions

Industrialization is the dominant driving force of China's economic growth and energy consumption growth. From 1985 to 2011, energy consumption in China's industrial sectors accounts for 70.3% of total energy consumption, showing an upward trend year by year. Energy conservation and emission reduction in China's industrial sectors are the key to China's emission reduction and successful low-carbon transition (Ouyang and Lin, 2015). Carbon emissions, industrial structure change and transfer of different industries in China have gradually become a research field with high attention (Auerbeck, 2001; Lebel et al., 2007). For example, Su et al. (2010) employ input-output analysis framework to analyze industrial agglomeration effect in China and estimate carbon dioxide emissions reflected in economic exports. Yan and Fang (2015) study the historical track, characteristics and influencing factors of carbon emissions in China's manufacturing industry from 1993 to 2011. Cheng et al. (2018) set up total-factor carbon emission efficiency index (TCEI) by employing improved NDDF model and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42054227

estimate the meta-frontier TCEI index of 30 provincial industrial sectors in China from 2005 to 2015. They hold that industrial meta-frontier TCEI in China is relatively low and many provinces still have large room for improving the industrial TCEI. Xian et al. (2018), taking China's electric power industry as an example, put forward a scenario analysis on whether China's electric power industry could achieve the goal of reducing national and provincial-level carbon dioxide emission intensity from 2016 to 2020 by analyzing changes in carbon productivity. Zhao et al. (2017) analyze the decoupling relationship of China's economic growth based on the carbon emissions in five economic sectors, including agriculture and industry.

Some scholars conduct studies on industrial carbon emissions through modeling. For example, Yang et al. (2018a) analyze the relationship between energy consumption and carbon emissions in different industrial sectors in Zhejiang Province from 1995 to 2014 by employing STIRPAT model. Zhang et al. (2017) analyze the influencing factors of carbon emissions in China's construction industry with factor analysis and STIRPAT model. Lindner et al. (2013) employ a bottom-up model to calculate the direct carbon embodied in China's power industry. Zhao et al. (2010) analyze the influencing factors of industrial carbon emissions of Shanghai with LMDI model.

On the other hand, with the development of China's economy, a large number of traditional industries are constantly shifting to central and western regions (Chen et al., 2011; Tian et al., 2014) and industrial transfer, mainly occurring in manufacturing sector, brings the transfer of carbon emissions (Yuan et al., 2009). These studies provide numerous useful information but limitations remain instead. For example, most studies focus on the overall and cross-provincial carbon transfer in China, but existing studies lack of consideration about the inter-industry carbon transfer and leading factors. In addition, most studies only center on short-term changes and lack long-term dynamic studies.

Anhui Province is an underdeveloped province in central China, but it is the main area carrying on industrial transfer in the Yangtze River Delta for being close to the Yangtze River Delta region which is the most economically developed in the country. Although a large number of studies have examined the rapid growth of Anhui's carbon emissions and its influencing factors (Zhang and Wang, 2013), existing studies rarely consider the specific impact of industrial transfer and structural change on Anhui's carbon emissions. Leading industries and technological capabilities vary from region to region, leading to different emission intensity in industrial sectors and there may be differences in the characteristics of carbon dioxide emissions (Tian et al., 2012). At the same time, if the decoupling relationship at the provincial level is not fully understood, the implementation effect of national policies or strategies will decline (Liu et al., 2015). Therefore, only the relationship between industrial transfer and carbon emissions can help to formulate an effective energy conservation and carbon emission reduction policy. Taking Anhui Province as a case study, this paper calculates Anhui's carbon emission model by collecting data of energy consumption and social development in Anhui Province from 2000 to 2015, and employs expanded STRIPAT model to reveal the changes in industrial carbon emissions and its influencing factors in the province in the context of industrial transformation. This study helps to understand the driving factors of industrial carbon emissions in Anhui Province and on that basis, provides reference for reducing industrial carbon emissions.

Materials and methods

Study area and data

Anhui Province is included in the case study hereof. Located in mid-eastern China, Anhui covers an area of 140,100 km^2 and has 14 prefecture-level cities under its jurisdiction, with a population of 70.27 million in 2016 and an urbanization rate of 52.0%. According to the date of Statistical Bureau of Anhui province (2017), Anhui is in the bottom half of national list of economic development as it ranks 13th among 31 Chinese provinces in GDP growth (from RMB 290.209 billion yuan in 2000 to RMB 2,411.789 billion yuan in 2016, growing by 14.15% annually), and ranks 25th in per capita GDP growth (from RMB 4,800 yuan in 2000 to RMB 39,100 yuan in 2016, growing by 14.04% annually). Anhui economy is dominated by the secondary industry, which accounted for 36.41% of the provincial GDP in 2000, and for about half (48.06%) in 2016, and its second industry is dominated by the Industry, which accounted for 30.04% of the output of second industry in 2000, and this increased to 40.82% in 2016. These indicate that Anhui is still at the mid stage of industrialization, where its economic development is mainly driven by the Industry. Anhui is a close neighbor of Yangtze River Delta (*Fig. 1*), the powerhouse for China's economy, and a critical base for implementation of the state strategy of rise of central China and industrial transference to Wanjiang City Belt, which is a contributor to carbon emission, therefore this study focuses on the carbon emission by Anhui's Industry that can be divided, according to *Industrial Classification for National Economic Activities* (GB/T 4754-2002), into mining, manufacturing and EGW (electricity, gas and water). End-use energy consumption, GDP, added value of industries above a designated scale, total industrial output, total external fund used (including investment from foreign countries, Hong Kong, Macao and Taiwan), output value of secondary industry, population and per capita income are all sourced from *China Energy Statistical Yearbook* and *Anhui Province Statistical Yearbook*, and the data of external investment are from the public data released by Anhui Development and Reform Commission (Anhui Statistical Bureau, http://www.ahpc.gov.cn/).

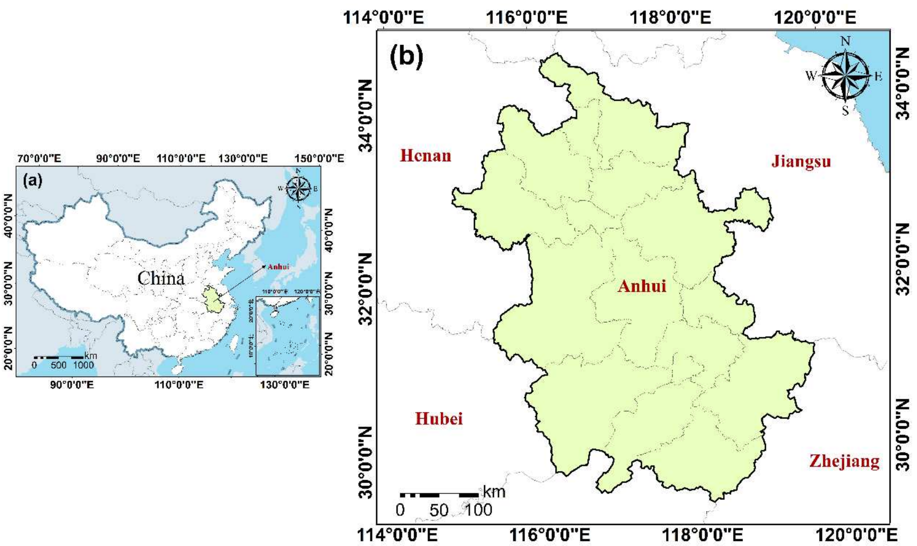

Figure 1. *Location of Anhui province*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42054227

Methods

Calculation of carbon emission

Given that no direct data of CO_2 emission is released by China's statistical organizations, scholars at home and abroad generally make estimation by multiplying the energy consumption with carbon emission coefficient, therefore the industrial carbon emission of Anhui 2000-2005 is calculated by the following model (Yang et al., 2018):

$$c = \sum E_j \times F_j \tag{Eq.1}$$

where, and signify the consumption and emission coefficient of j kinds of fossil fuels respectively. The standard coal conversion coefficient in *China Energy Statistical Yearbook* is adopted, while the emission coefficient is converted based on the statistics of Peng et al. (2013) (see *Table 1*).

Table 1. *Conversion coefficients (by Peng et al., 2013)*

Types of energy	Standard coal conversion coefficient	Carbon emission factor
Raw coal	0.7143 kg·kg^{-1}	0.7599
Washed coal	0.9 kg·kg^{-1}	0.7599
liquefied petroleum gas	1.7143 kg·kg^{-1}	0.5042
Crude oil	1.4286 kg·kg^{-1}	0.5847
Gasoline	1.4714 kg·kg^{-1}	0.5538
kerosene	1.4714 kg·kg^{-1}	0.5714
Diesel	1.4571 kg·kg^{-1}	0.5921
Fuel oil	1.4286 kg·kg^{-1}	0.6185
Coke	0.9714 kg·kg^{-1}	0.855
Gas field	1.2143 kg/m^3	0.4483
Oil field natural gas	1.33 kg/m^3	0.4483
Coke oven gas	0.5714 kg/m^3	0.3548

STIPRAT model

STIRPAT model was built by York et al. (2003) based on IPAT model, with the following formula:

$$\mathrm{I} = \mathrm{a}P^{b}A^{c}T^{d}e \tag{Eq.2}$$

where, I stands for environmental stress, P for population size, A for affluence, T for technical progress, a for the model efficient, b, c, d are the indexes of respective independent variables, and e is the model's error term. b, c and d are introduced to make up for the model's deficiency of I varies with all driving factors in proportion, and can be used for analysis of independent variables' non-proportional impact on environmental stress. After logarithm the model can be converted to:

$$\ln \mathrm{I} = \ln \mathrm{a} + \mathrm{b}\ln \mathrm{P} + \mathrm{c}\ln \mathrm{A} + \mathrm{d}\ln \mathrm{T} + \ln \mathrm{e} \tag{Eq.3}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42054227

where, b, c and d embody the elastic relation between independent and dependent variables. Every 1% change of P, A or T will result in b%, c% or d% change of environment impact.

As the regional industrial structure is changed and carbon emission affected by input of extern fund (Chen et al., 2017) during local industrial transference, to truthfully reflect such transference's impact on carbon emission, STIRPAT model for this study is hereby extended as:

$$\ln I = \ln B + \alpha_1 \ln X_1 + \alpha_2 \ln X_2 + \alpha_3 \ln X_3 + \alpha_4 \ln X_4 + \alpha_5 \ln X_5 + \alpha_6 \ln X_6 + \alpha_7 \ln X_7 + \ln e \quad \text{(Eq.4)}$$

where, I signifies the industrial emission, B is the model coefficient and e its error term. There are 7 variables in 5 categories: the factor that embodies the effect of industrial agglomeration, namely X1 – the ratio of the added value of industries above a designated scale to total industrial output value; the 2 factors that embody external capital scale in industrial transference, namely total external fund used X_2 and total external investment X_7; the 2 factors that indicate economic growth, namely X_3 – the proportion of secondary industry in GDP and X_4 – per capita income; X_5- proportion of coal consumption in total energy consumption, the factor that reflects the energy structure; X_6 – the proportion of total import-export volume in total industrial output value and α_i, the elastic coefficients of independent variables, which mean 1% variation of X_i can result in α_i% change of carbon emission.

Results

Anhui's industrial carbon emission

Overall change of carbon emission

Figure 2 shows that, from 2000 to 2015, the value of industrial output and carbon emission in Anhui grew annually by 15.26% and 10.50% respectively, but the 2010-2015 period saw such growths of 11.37% and 4.29% only. The change indicates that Anhui made some achievements in low-carbon transition and restructuring of its industries during the 12th five-year plan, and the rapid growth of carbon emission was more or less contained.

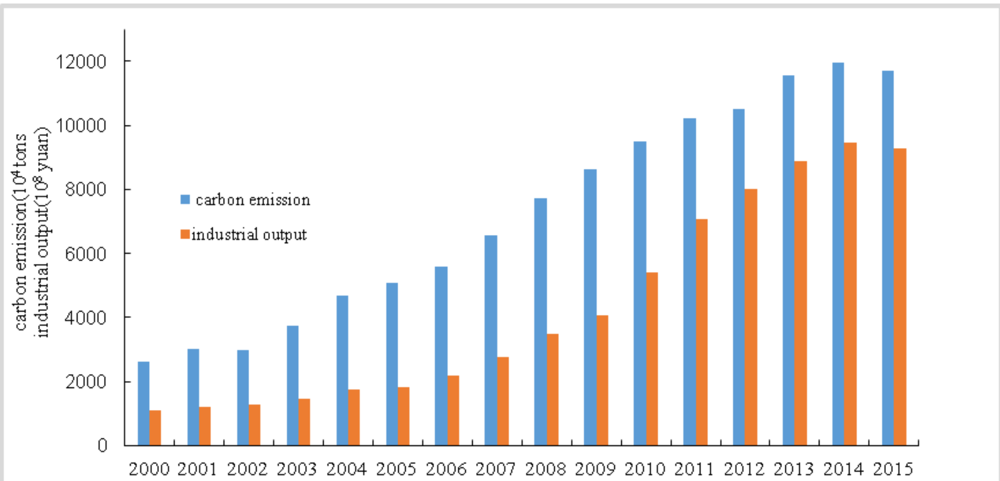

Figure 2. *Change of carbon emissions, industrial production of Anhui province (2000-2015)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42054227

Change of carbon emission for different industries

(1) In general, 2000-2015 saw increase of carbon emission in indusries of mining, manufacturing and EGW. In growth rate mining > EGW > manufacturing (slope: 217.35, 265.53 and 221.26) (*Fig. 3*), and the trend differs greatly among these three sectors: for manufacturing, the annual growth of carbon emission stood at 11.05% between 2000 and 2005, but by 7.43% only in the period 2005-2014, and this figure further deceased from 2014; For EGW, the carbon emission grew stably by 12.73% annually from 2000-2015, and only from 2015 this growth slowed down. Compared with EGW and manufacturing, mining is at a stage of relatively faster growth, for its growth of carbon emission reached a high level of 19.49% between 2000 and 2005, decreased somehow from 2005 to 2014, but the 12.78% growth rate was still high.

(2) As of proportions of these three industries, the proportion of manufacturing in carbon emission has been decreasing stably. Though EGW saw some narrow marked fluctuation, its proportion is considered stable in long term (about 30%). While the proportion of mining had been rising, its growth rate gradually dropped and reached a plateau after 2010. *Figure 4* shows that in general, the propotions of the three industries all tend to converge to the size of “one third”.

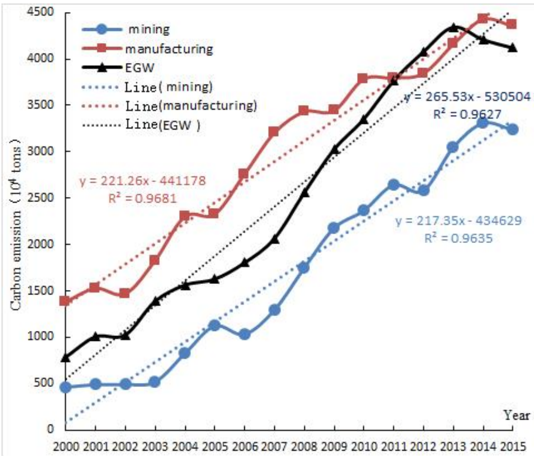

***Figure 3.** Change of carbon emissions of Anhui’s three industrial sectors (2000-2015)*

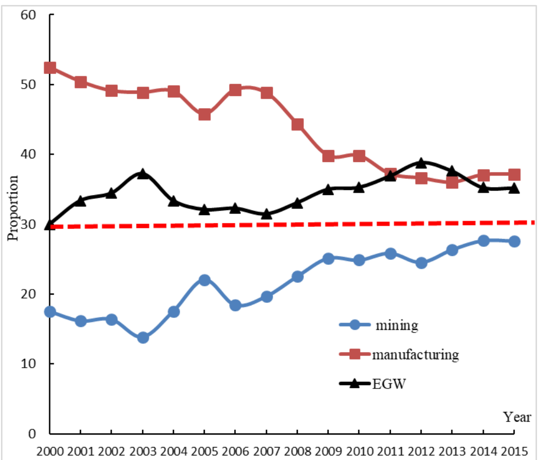

***Figure 4.** Change of carbon emission share of Anhui's three industrial sectors (2000-2015)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42054227

Calculation results with STIRPAT model

7 factors, namely the proportion of the added value of industries above a designated scale in total industrial output value (X_1), total external fund used (X_2), the proportion of secondary industry in GDP (X_3), per capita income (X_4), energy consumption structure (proportion of coal consumption in total energy consumption) (X_5), the proportion of total import-export volume in total industrial output value (X_6) and total external investment (X_7), are selected for regression analysis with SPSS (a statistical analysis software), to reveal their marginal contribution to carbon emission.

In the first place, least square regression model is used in SPSS for pre-evaluation (*Table 2*). The least square regression model has a fitting goodness of fit $R^2 = 0.995$, and an adjusted goodness of fit $AdjR^2 = 0.991$, both of which pass the F test of 0.001 significant level, indicating that the linear model for independent and dependent variables exists and has a high degree of fitting. But only LnX_1 passes the Student's t test (t test) of 0.005 significant level, and other independent variables fail to pass the significance test (Sig). A study of the correlation matrix of the model shows that the independent variables are closely associated with each other. Variance inflation factor (VIF) is currently used for determination of multiple correlation, while the VIF values of 6 factors calculated are all greater than 10, therefore only when the multicollinearity among independent variables are eliminated can robust results be achieved.

Table 2. *Results of the OLS (ordinary least square) regression model*

	Unnormalized coefficient		**Regression coefficient**	**T test**	**Significance**	**Variance inflation factor**
	Regression coefficient	**Standard error**				
Independent variable	-2.455	2.157		-1.138	0.288

LnX_7	-0.016	0.105	-0.026	-0.156	0.88	47.071

Partial least square regression model (PLS) is used to address the practical problems of multiple correlations of variables, small sample volume and low degree of freedom, in an analytical process of:

(1) Standardized processing of variables, to rid of the dimensional effects among variables and make them comparable, and the processed data are expressed as $ZLnX_1$, $ZLnX_2$, $ZLnX_3$, $ZLnX_4$, $ZLnX_5$, $ZLnX_6$, $ZLnX_7$ and ZLn_C.

(2) Principal components are extracted from data processed in procedure (1), refer to *Table 3* for the results.

Table 3 shows that the accumulative contribution of FAC_1, FAC_2 and FAC_3 reaches a high level of 95.602%, so 2 principal components are extracted. *Table 4* indicates the following relations between FAC_1, FAC_2 and original variables:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42054227

$$FAC_1 = -0.142 \times ZLnX_1 + 0.155 \times ZLnX_2 + 0.155 \times ZLnX_3 + 0.157 \times ZLnX_4 + 0.149 \times ZLnX_5 - 0.148 \times ZLnX_6 + 0.145 \times ZLnX_7 \quad \text{(Eq.5)}$$

$$FAC_2 = 1.053 \times ZLnX_1 + 0.052 \times ZLnX_2 + 0.114 \times ZLnX_3 + 0.25 \times ZLnX_4 + 0.529 \times ZLnX_5 + 0.78 \times ZLnX_6 + 0.829 \times ZLnX_7 \quad \text{(Eq.6)}$$

	Unstandardized coefficients		Regression coefficient	T test	Significance
	Regression coefficient	**Standard error**			
Constant	-2.68E^{-15}	0.038		-7.00E^{-14}	1
FAC1_2	0.981	0.04	0.981	24.829	0
FAC2_2	0.128	0.04	0.128	3.239	0.006

The following equation between dependent variable ZLnC and principal components FAC_1 and FAC_2 can be formed when regression coefficient in *Table 6*'s model is adopted, where constant term is deleted for the Sig value of its test = 1, and Sig values of regression coefficient t test for FAC_1 and FAC_2 are less than 0.01, therefore this model has high authenticity.

$$\mathrm{ZLnC} = 0.981\times \mathrm{FAC}_1 + 0.128\times \mathrm{FAC}_2 \qquad \text{(Eq.7)}$$

Based on standardization formula and standardized variables described in *Table 2,* the above formula can be converted into:

$$\begin{aligned} lnC = -0.0045\times LnX_1 + 0.1587 LnX_2 + 0.1666\times LnX_3 + 0.186 \\ \times LnX_4 + 0.2139\times LnX_5 - 0.0453 LnX_6 + 0.2484\times LnX_7 \end{aligned} \qquad \text{(Eq.8)}$$

The final results are as follows:

$$\mathrm{C} = \mathrm{X}_1^{-0.0045}\mathrm{X}_2^{0.1587}\mathrm{X}_3^{0.1666}\mathrm{X}_4^{0.186}\mathrm{X}_5^{0.2139}\mathrm{X}_6^{-0.0453}\mathrm{X}_7^{0.2484} \qquad \text{(Eq.9)}$$

The above formula shows that, among the driving factors that affect Anhui's carbon emission 2000-2015, 5 are positively correlated, but in degree of influence, external investment > energy consumption structure > per capita income > proportion of secondary industry in GDP > total external fund used. Only 2 factors, namely the proportion of total import-export volume in total industrial output value and the proportion of the added value of industries above a designated scale in total industrial output value are negatively associated with the total carbon emission, but far less influential than the other 5 positively correlated factors.

Discussion

Economic development and carbon emissions

According to previous studies (Yang et al., 2018), there are three inverted U-shaped curves (*Fig. 5*) during the evolution of the relationship between economic development and carbon emissions, namely inverted U-shaped curves of carbon emissions, per capita carbon emissions and carbon emission amount. Specifically, during the evolution process, three curves need to cross their peaks respectively, namely the peaks of the inverted U-shaped curves of carbon emission intensity, per capita carbon emissions and carbon emission amount. During the evolution, dominant driving forces of carbon

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42054227

emissions vary from stage to stage. In the period before carbon emission intensity peaks, energy and advance in carbon-intensive technology are the main influencing factors; from the peak of carbon intensity to that of per capita carbon emission amount, economic growth is the main influencing factor; from the peak of per capita carbon emission amount to that of carbon emission amount, advance in carbon emission reduction technology is the main influencing factor but it plays a decisive role after entering the stage in which total carbon emissions decline steadily. As shown in *Figure 6,* Anhui Province's carbon emission intensity reaches its peak in 2005, indicating that energy and carbon-intensive technology advance are the main influencing factors for the growth of carbon emissions before 2005, which is mainly caused by the law of economic development of Anhui Province. Apart from the fact that main economic development remains in the middle stage of accelerated industrialization, Anhui Province (an important area producing coal and iron ore in Central China) has an advanced mining industry in the industrial structure, and most of the industrial types are supported by coal as their main energy and technologies relatively lag behind, so energy and carbon-intensive industries are the important influencing factors for the growth of carbon emissions in this period; from 2005 to 2015, Anhui's carbon intensity continues to decline but per capita carbon emissions keep rising, indicating that economic growth is the leading factor influencing the growth of carbon emissions during the period from 2005 to 2015. This is the golden period for Anhui to take advantage of the industrial transfer, with a large number of foreign capital and traditional industries in the Yangtze River Delta region transferring to Anhui, resulting in rapid industrial growth and further promoting the growth of carbon emissions. It can also be found from the calculation results of STIRPAT model established in this paper that the importance of three coefficients, namely the total amount of out-of-province investment, per capita income and the total amount of actual use of foreign capital, rank the first, third and fifth in positive correlation, which further proves the significance of economic development in carbon emissions. It can be predicted that when the per capita carbon emissions of Anhui Province peak, advance in carbon emission reduction technology will become the main factor influencing the growth of carbon emissions.

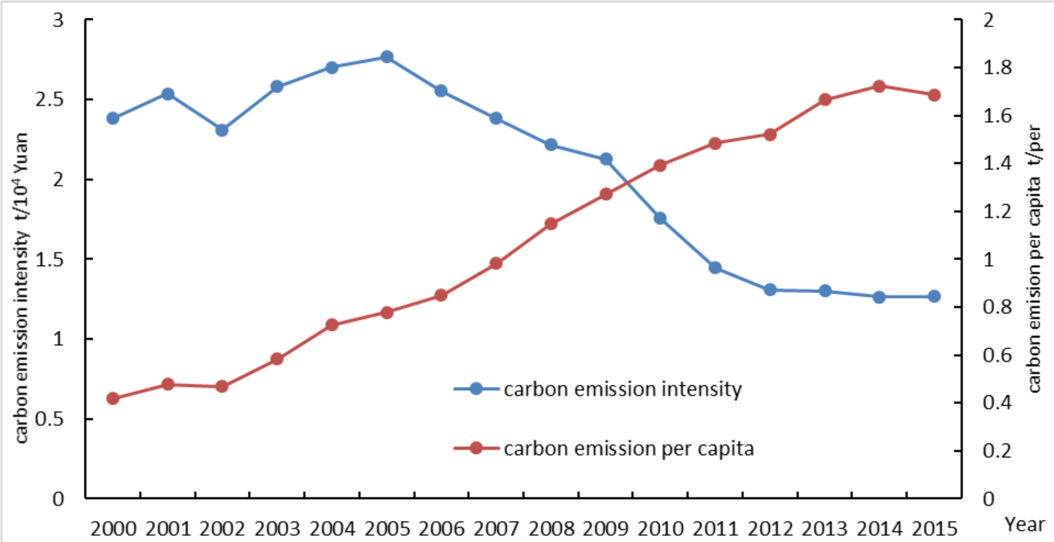

Figure 6. *Change of carbon emission intensity and carbon emission per capita of Anhui province (2000-2015)*

It is worth noting that compared with neighboring developed provinces such as Zhejiang and Jiangsu, Anhui shows an obvious lagged relationship between economic development and carbon emissions. For example, Zhejiang Province has reached the peak of carbon emission intensity as early as 1995 (Yang et al., 2018) and that of Jiangsu has also peaked in 2000 (Zhu et al., 2018). It also reflects that after Zhejiang and Jiangsu implement industrial upgrading and technological transformation, a large number of backward industries move out, thus promoting the reduction in carbon emission intensity. However, as the major industrial undertaking area of the two provinces, Anhui sees an increase in carbon emissions instead, forming a “pollution haven effect”.

Energy structure and carbon emissions

In respect to energy consumption structure, the ratio of coal consumption to total energy promotes the growth of carbon emissions, and the ratio increases by 1% and carbon emission amount will increase by 0.2139%. For a long period of time, fossil energy has been the major resource consumed in Anhui Province, especially coal, which occupies a dominant and gradually consolidated position. The proportion of coal consumption to fossil energy consumption rises from 90.57% in 2000 to 96.08% in 2015 (*Fig. 7*), coal consumption share is 14% higher than the national average and non-fossil energy consumption share is 8.8% lower than the national average. The pressure to reduce the proportion of fossil energy consumption is particularly obvious in the context of China’s increasing emphasis on energy conservation and emission reduction as a way to tackle climate change. There are two main reasons for why coal consumption outshine others: one is the resource endowment of Anhui Province. It has abundant coal resources and is a major coal producer but lacks oil and natural gas, being a typical province with “rich coal but no oil and gas”. In comparison, the coal consumption has taken a dominant position in the province for a long time for its prominent convenience for coal consumption and price advantage; the other is its advanced industrial structure in heavy chemical industries in respect to power, chemical

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42054227

industry and steel for the long-term use of coal, which further deepens its dependence on coal, leading to a large demand for the resource. For example, existing research has shown that in 2011, carbon emissions in Anhui's manufacturing industry mainly comes from ferrous metal smelting and rolling processing industry (37.4%-37.9%), non-metallic mineral products industry (28.9%-29.8%), chemical raw materials and products manufacturing industry (14.3%-14.5%), petroleum processing and coking and nuclear fuel processing industry (9.8%-10.0%). Employees in these four industries account for 18% of the total in industry, the proportion to total industrial added value is not more than 1/4 but carbon emissions are more than 90% (Shen et al., 2018). According to the goals of *the Outline of the 13th Five-Year Plan for National Economic and Social Development of Anhui Province* and *China's 13th Five-Year Plan for Energy Development*, by 2020, provincial demand for primary energy consumption will have been limited to 142 million tons of standard coal, non-fossil energy consumption accounted for 5.5% of total energy consumption and the proportion of coal consumption dropped below 75%. The pressure to cut coal capacity remains heavy, which needs to be brought to the forefront.

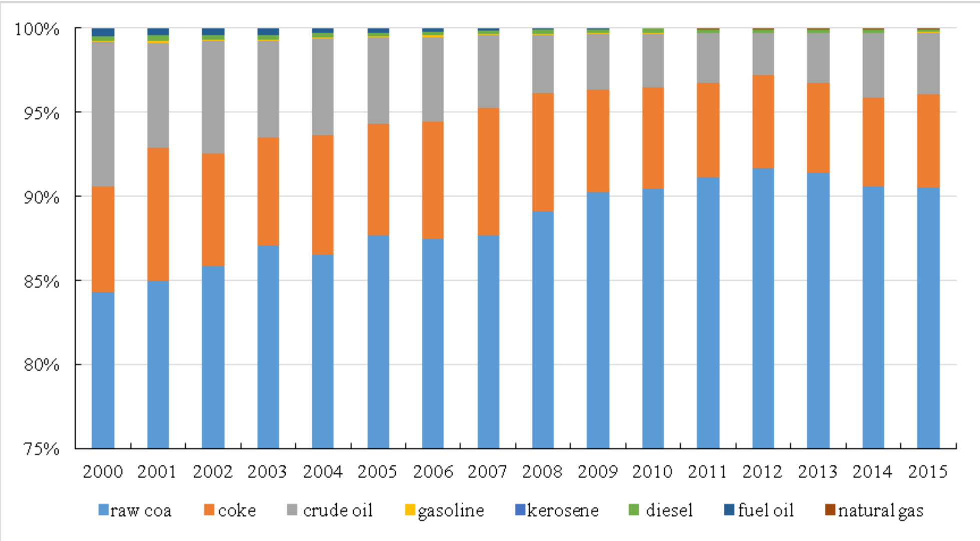

Figure 7. *Change of energy consumption structure changes of Anhui province (2000-2015)*

Industrial agglomeration and carbon emissions

A large number of studies at home and abroad have shown that industrial agglomeration has certain promoting significance for China's carbon emission reduction (Wang et al., 2013). Industrial agglomeration mainly affects carbon emission intensity through scale effect, technology effect and competition effect: firstly, industrial agglomeration can bring scale effect and realize the free flow of production factors within the cluster range so as to improve energy utilization efficiency; secondly, industrial agglomeration can promote the concentration and close connection of industries with upstream and downstream relations in geographical space, so as to save costs such as that of raw materials and transportation, and thus reduce energy consumption intensity; thirdly, agglomeration enables enterprises to communicate more closely with each other, which is conducive to the improvement of technological innovation and competitiveness, and thus promotes the continuous reduction of carbon

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42054227

emission intensity by relying on technological advance in respect to energy conservation and utilization (Moreno et al., 2014). However, for every 1% increase in industrial concentration in Anhui Province, the carbon emission amount decrease by only 0.0045%, which has the least influence among the 7 influencing factors, indicating that the industrial agglomeration in Anhui is not obvious and needed to be further strengthened.

External investment and carbon emissions

In respect to Anhui's utilization of out-of-province investment, the investment promotes the growth of carbon emissions, and every 1% rise in such investment will increase carbon emissions by 0.2484%. In 2004, the country proposed a plan for the rise of Central China, and Anhui Province, which is at the intersection of Central and Eastern China, undertook a large number of industrial transfers from China's eastern coastal provinces. From 2005 to 2015, the annual growth rate of out-of-province investment in projects that were above 100 million yuan increased by an average of 31.52%. In the initial stage, industrial projects were mainly introduced. For example, in 2007, the second industry accounted for 60.2% of the actual funds allocated to projects from outside the province with investment of more than 10 million yuan, and among the second production projects, 75.35 billion yuan was allocated to the manufacturing projects, accounting for 47.3% of the projects with investment of more than 10 million yuan. In the external investment of competitive industries in Anhui Province, the investment of power plant projects, steel product processing projects, coal chemical projects and other projects with high energy consumption accounted for 40% of the total investment. Over time, the investment structure of external capital has been optimized. In 2015, among the projects of over 100 million yuan using eternal capital, the growth rate of investment in the low-energy industries, such as modern service industry projects, electronic information projects, pharmaceutical industry projects and other tertiary industry projects was improved, but the secondary industry still accounted for 60.1% of the total investment, indicating that the transfer of external industries in Anhui Province is still dominated by the second industry, and the increase of carbon emission will continue.

Analysis from the perspective of FDI: FDI promotes the growth of carbon emission. For every 1% increase of FDI, carbon emission will increase by 0.1587%, which is consistent with previous research. For example, Zhang et al. (2018) used data from 1982 to 2016 to conclude that the impact of FDI on China's carbon emissions is positive. Gong et al. (2018), based on STIRPAT model research, concluded that the increase of FDI would promote the growth of carbon emissions in the Yangtze River Delta region. Similarly, foreign investment in Anhui Province is still concentrated in traditional industries. For example, from 2000 to 2015, the manufacturing industry and the hydraulic and electric power industry of Anhui Province absorbed 67.19% of FDI, and the carbon emissions of these two industries accounted for 78.16% of the industrial carbon emissions. FDI is mainly invested in industries with high carbon emissions. While stimulating local economy, it still has a large impact on carbon emissions.

Economic openness and carbon emissions

When many domestic and foreign scholars analyze the relationship between China's import and export trade and carbon emissions, most of them believe that China's

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42054227

foreign trade mode is also dominated by processing industries with high energy consumption and high pollution. Such a trade structure will result in more emissions as the proportion of China's exports increases. That is, the increase in export trade leads to the rise in carbon emissions, while the import trade will reduce carbon emissions. Anhui is a special case. Although its import and export trade is greater than import, its import and export trade is negatively correlated with carbon emissions, that is, for every 1% increase in the proportion of total import and export in total industrial output value, its carbon emission reduces by 0.0453%. The main reason is that Anhui imports a large number of primary products and energy-consuming products, but when exporting, in addition to primary products, it also exports a certain number of high value-added products. On the contrary, in addition to high-tech products, Anhui's imports also include non-metal and chemical materials and other primary products (*Table 7*). However, objectively speaking, the import and export trade is very limited in reducing carbon emissions, reflecting the low level of regional industrial development.

Table 7. *Comparison of some products of import and export trade in Anhui province in 2015 (10^4 $)*

Primary products	Exports	Imports	Exports-imports	Industrial product	Exports	Imports	Exports-imports

Conclusion

Taking Anhui Province as an example, this paper calculates the industrial carbon emissions of Anhui Province by using the terminal energy consumption and social statistics data of different industries in the province from 2000 to 2015. Through the expanded STIRPAT model, it analyzes the influencing factors of Anhui's carbon emissions in the context of industrial transformation. The research results show that:

(1) In respect to total carbon emission, Anhui's carbon emission increased steadily from 2000 to 2015 with an average annual growth rate of 10.50%. In respect to growth rate, the average annual growth of carbon emission decreased to 4.29% from 2010 to 2015, indicating that Anhui's rapid growth momentum of carbon emission was restrained to some extent;

(2) In respect to carbon emissions of sub-sectors, the carbon emissions of mining industry, manufacturing industry and EGW from 2000 to 2015 showed an overall trend of growth. In respect to growth rate, it is shown as: mining industry > EGW > manufacturing industry. The proportion of carbon emission in the manufacturing industry shows a stable downward trend, while the proportion of EGW is relatively stable on the whole, and the proportion of the mining industry has been on the rise, showing a certain convergence on the whole and gradually showing a trend of "each accounting for 1/3 share";

(3) According to the extended STIRPAT model analysis, 5 of the driving factors influencing the carbon emissions of Anhui Province from 2000 to 2015 are positively correlated, which is shown as: external investment > energy consumption structure > per capita income > proportion of the second industrial output in GDP > the amount of the actual use of foreign investment. The two factors, the proportion of total import and export in total industrial output value and the proportion of industrial added value above the scale in total industrial output value, are negatively correlated with total carbon emission, but the influence degree is far less than the other 5 factors;

(4) The relationship between Anhui Province's carbon emissions and economic development also shows an obvious inverted U-shaped curve. The carbon emission intensity of Anhui Province reached its peak in 2005, but per capita carbon emissions still kept increasing, indicating that a large number of foreign investment and traditional industries in the Yangtze River Delta region were transferred to Anhui from 2005 to 2015, leading to rapid industrial growth, and thus promoting the growth of carbon emissions;

(5) The energy consumption structure of Anhui Province has been dominated by coal for a long time, and external investment (including that from foreign countries, Hong Kong, Macao, Taiwan and other provinces) mainly invested in projects with high energy consumption, such as power plant projects, steel products processing projects and coal chemical projects, which are the main reasons for the sustainable growth of Anhui's carbon emissions. Although industrial agglomeration and import and export trade can reduce total carbon emissions, the impact is relatively low. Thus it can be seen that policy makers should pay more attention to the introduction of energy-saving and environmentally friendly enterprises when undertaking industrial transfer in Anhui Province, and actively control the increase of carbon emission by introducing technology and encouraging low-carbon technology.

In order to better reflect the spatial characteristics of industrial carbon emissions in Anhui Province, the next research should focus on the micro-level, pay attention to the changes of total carbon emissions and intensity of enterprises.

Abstract. The study aimed to understand the effects of nitrogen (N) and soil types on maize (*Zea mays* L.). Grain yield (GY) is essential for identifying optimal N fertilizer management practices and agricultural policies. In this study, we report results from an on-farm experiment carried out from 2009 to 2012 with five N levels and three soil types in Northeast China. Results revealed that the GY was affected significantly by soil types, with loam soil having an average GY of 10225 kg ha^{-1}, followed by clay soil (9218 kg ha^{-1}) and sandy soil (6434 kg ha^{-1}). The optimal N rates required to achieve maximum GY were on average 182, 173, and 160 kg ha^{-1}, and the corresponding maximum GYs were 10872, 9999, and 7266 kg ha^{-1} for loam, clay, and sandy soils, respectively. The optimum N treatment (168 kg N ha^{-1}) reduced residual nitrate N content and N losses by 97 and 451 kg N ha^{-1}, respectively, and improved N recovery efficiency (RE_N) by 17%. In conclusion, within-field soil management zones based on soil textural classes could be used to guide soil sampling and establish soil-specific N fertilizer recommendations to achieve high GY with high RE_N in Northeast China.
Keywords: *maize, grain yield, nitrogen recovery efficiency, nitrogen balance, yield stability*

Introduction

The global population is expected to peak at 8.5–10 billion by 2050. Maize (*Zea mays* L.) grain yield (GY) must increase by 101% to feed the livestock industry given the rising meat and poultry consumption, especially in developing countries (Ray et al., 2013). Global maize GY increased slowly and then stagnated for the past 10 years (FAO, 2014), although the GY gap is large, with a 50% GY potential. Grain yield variation among regions, climates, and management practices reduces productivity and contributes to this large GY gap (Liu et al., 2010; Zhang et al., 2013; Tesfaye et al., 2015).

For rain-fed maize production, water is one of the foremost constraints on GY which is dependent on soil water availability at sowing and on rainfall during the cropping season (Calvino et al., 2003; Gang et al., 2019). In a given region with similar climates, soil type often affects the ability to store and use rainfall, which impacts maize GY. Recent research has indicated that GY variability could be as great as 5000-6000 kg ha^{-1}, depending on the soil type and regions in Northeast China (NEC)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42294243

(Lu et al., 2014). However, other research has reported no significant variation in GY between soil types (Tan et al., 2007; Xie et al., 2008).

Nitrogen (N) dynamics and crop responses to N often vary with soil properties, climate, and management (Marjerison et al., 2016; Zhang et al., 2016; Mesbah et al., 2018; Doltra et al., 2019). For example, weather might influence organic N availability, the extent of leaching and denitrification, and crop uptake and residual N at the end of the growing season (Luce et al., 2011; Alotaibi et al., 2018; Bean et al., 2018; Iqbal et al., 2018). Soil texture is another important factor that influences soil productivity and GY by potentially controlling water supply (Cambouris et al., 2006), crop N requirements (Lu et al., 2019), and N mineralization (Luce et al., 2011; Smith, 2018). Variation in the response of maize to N application often leads to poor synchronization between N supply from the soil and fertilizer, and crop requirements resulting in low N-use efficiency (NUE) and low GY (Gao et al., 2012).

NEC is a typical rain-fed maize cultivation region in which the maize planting area was 1121 × 10^4 ha and accounted for 30.4% of the total maize crop in China in 2016 (Chinese Farming Management Department, 2017). Soil conditions, climatic factors, and weather conditions in a given year also influence GY significantly (Benjamin et al., 2003; Yao et al., 2011). A short-term effect could be inconsistent with the results of long-term observations. Agricultural research, as well as other types of research, generally involves short-term studies, but sustainable agriculture requires long-term field and laboratory experiments to understand the complex soil-plant-climate-management interactions (Army, 1991).

In this study, we conducted on-farm experiments with various N levels in three villages in close proximity (< 4 km apart) with the same climatic conditions and differing soil types (loam, clay, and sandy soil) from 2009 to 2012 in Lishu County, Jilin Province. The objectives of this study were: (1) to evaluate GY variation among soil types and years, (2) to evaluate the GY response to N application rate among soil types and years to determine the optimal N rate for different soil types, and (3) to evaluate the soil N balance for different soil types.

Materials and Methods

Study Site

The climate of the study area was warm-temperate, subhumid, and continental monsoon with cold winters and hot summers. Maize was planted at the beginning of May and harvested in early October. The time from maize planting to harvest was 1400–1500 growing degree days (McMaster and Wilhelm, 1997). The annual precipitation was 500–800 mm, with 60–70% of the rainfall occurring during the summer. No irrigation was supplied during the maize growing season. The precipitation and temperature at the experimental site during the maize growing season from 2009 to 2012 are listed in *Figure 1*.

Experimental Design and Management

The experiment was conducted from 2009 to 2012 on three typical soil types (loam, clay, and sandy) in Lishu County, Jilin province. These three soils were located in three nearby villages: Wang-jia-Qiao with loam soil (N43°14’49’’, E124°29’10”), San-Ke-Shu with clay soil (N43°20’17”, E124°00’29”), and Fu-Jia-Jie with sandy soil

DOI: http://dx.doi.org/10.15666/aeer/1702_42294243

(N43°21’48”, E124°05’02”; FAO 2006) (*Figure 2*). The distance between the three sites was < 4 km.The physical and chemical properties of these three soil types are listed in *Table 1*.

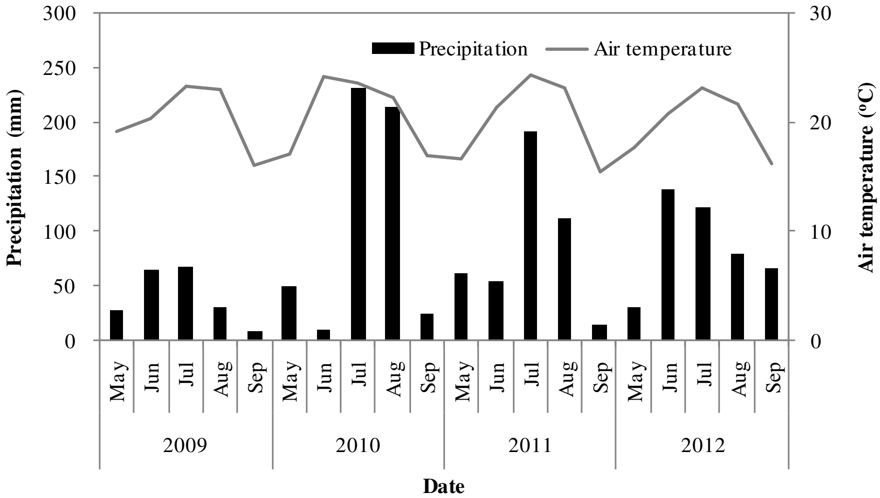

***Figure 1.** Precipitation and temperature at the Li-shu experimental site during the maize growing season from 2009 to 2012*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42294243

For the three soil types, the experiments from 2009 to 2012 were designed as a randomized block with three replicates of five nitrogen (N) treatments were as follows: control (N0), 70% recommendation N rate (N168), recommendation N rate based on local government recommend fertilization (N240), 130% recommendation N rate (N312), and the typical N dose used by farmers (N270). The N application rates were as follows: 0, 168, 240, 270, and 312 kg N ha^{-1} applied as urea. All N fertilizer was granular urea with one-third applied before planting and the remaining two-thirds applied at the V8 stage. All plots received 100 kg P_2O_5 ha^{-1} as calcium superphosphate and 120 kg K_2O ha^{-1} as K_2SO_4 before planting.

The plot size was 60 m^2 (6 × 10 m). Maize was planted continuously from 2009 to 2012. The planting density was 65,000 plants ha^{-1} with a row spacing of 60 cm. Seeds of the XY335 cultivar were hand-sown on May 5, 8, 5, and 4 during 2009, 2010, 2011, and 2012, respectively. The maize was rain-fed and harvested on October 5 during each of the four years. Weeds were controlled by applying atrazine and acetochlor before seedling emergence, and no obvious pest stress was observed during the maize growing season.

Sampling and Laboratory Procedures

At physiological maturity, when more than 50% of the plants showed a visible black layer at the base of the kernel, plants were removed manually from an area of 18 m^2 (six rows, approximately 3.6-m wide × 5-m long) in the middle of each plot to measure GY. Plant samples were taken at harvest. Aboveground biomass was collected by clipping five plants in three rows near the middle of each plot to measure plant dry matter weight and N concentration. Plants were divided into grain and straw. All plant samples were dried at 70°C in a forced-draft oven to constant weight and then weighed. Subsamples were passed through a 1-mm screen in a sample mill and mineralized using H_2SO_4-H_2O_2, after which the N concentration was determined using the Kjeldahl method (Horowitz et al., 1970).

At least five soil samples were taken in every plot to a depth of 100 cm at 20-cm increments before planting and after harvest. Fresh soil samples were sieved, extracted with 0.01 mol L^{-1} $CaCl_2$ solution and NH_4^+-N and NO_3^--N were analyzed by continuous flow analysis (TRAACS2000; Bran + Luebbe, Norderstedt, Germany) in the laboratory. Soil water content was measured by oven drying at 105°C. Soil samples were collected at the 0–20-cm soil layer before planting, air-dried, and sieved through a 0.2-mm mesh to remove undecomposed plant materials. The sieved samples were used to measure organic material (OM), total N, Olsen-P, and NH_4OAc-K.

Data Analysis

After verifying the homogeneity of error variances, all of the data across soil types, N levels, and years were pooled for analysis of variance using the ANOVA procedure of SAS/STAT (SAS Institute, 1993). Differences were compared using the least significant difference test (LSD) at the 0.05 level of probability.

Three response models were evaluated to describe the relationship between N application and GY: quadratic, quadratic with a plateau, and linear with a plateau (Cerrato and Blackmer, 1990). The models were generated using SAS software (SAS Institute, 1993). The calculated optimum N rate for GY was given with a 95% confidence interval.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42294243

The increase in GY with applied N fertilizer (IY_N) was defined as the difference between the maximum GY and the GY of the zero-N (N0) treatment for each experiment. The agronomic N efficiency (AE_N) and N partial factor productivity (PFP_N) were calculated using *equations (1)* and *(2)* below (Ladha et al., 2005). AE_N was the GY increase per unit of N applied, and PFP_N was the most important index for farmers since it integrates the use efficiency of both indigenous and applied N resources.

$$AE_N = (Y_N - Y_0)/N \quad \text{(Eq.1)}$$

$$PFP_N = Y_N/N \quad \text{(Eq.2)}$$

where Y_N and Y_0 are GY values for N application plots and N_0 plots, respectively, and N is supplied by the applied fertilizer.

Results

Grain YieldVariance among Soil Types and Years

Considering all four years and five N treatments, GY was affected significantly by soil type (*Table 2*). The rank order of the GYs for the three soil types was loam > clay > sandy soil with GY values of 10225, 9218, and 6434 kg ha^{-1}, respectively (*Table 2*).

Table 2. *Analysis of variance of maize grain yield, ear number, grain number,and 100 grain weight for various nitrogen treatments in three soil types across 4 years*

Treatments	Yield (kg ha^{-1})	Earnumber (ha^{-1})	Grain number (ear^{-1})	100 Grain weight (g)

Within soil, nitrogen or year, numbers followed by different letters indicate significant differences ($P < 0.05$).
NS: not significant ($P > 0.05$).
*Significant at $P < 0.05$.
**Significant at $P < 0.01$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42294243

Plant density was uniform for all three soil types. The numbers of ears at maturity were significantly different with a rank order of loam > clay > sandy soil (*Table 2*). Similar results were obtained for 100 grain weight among the soils, with a rank order of loam > clay > sandy soil. The grain number was essentially the same for the loam (523 per ear) and clay (526 per ear) soils, which were approximately 31.6% higher than the 399 grains per ear for sandy soil (*Table 2*).

Considering all three soil types and the five N treatments, GY was affected significantly by year (*Table 2*). The highest GYs were observed in 2010 and 2012, which might be explained by greater precipitation during those years (583 and 437 mm for 2010 and 2012, respectively; *Fig. 1*). The lowest GY in 2009 might be explained by rainfall during the maize growth period of only 207 mm and drought during the flowering and early grain filling stages between July and August (*Fig. 1*). Meanwhile, the average GYs in the loam and clay soils were 9574 and 10142 kg ha^{-1}, respectively, which were significantly higher than the GY in sandy soil (981 kg ha^{-1}, *Fig. 3*).

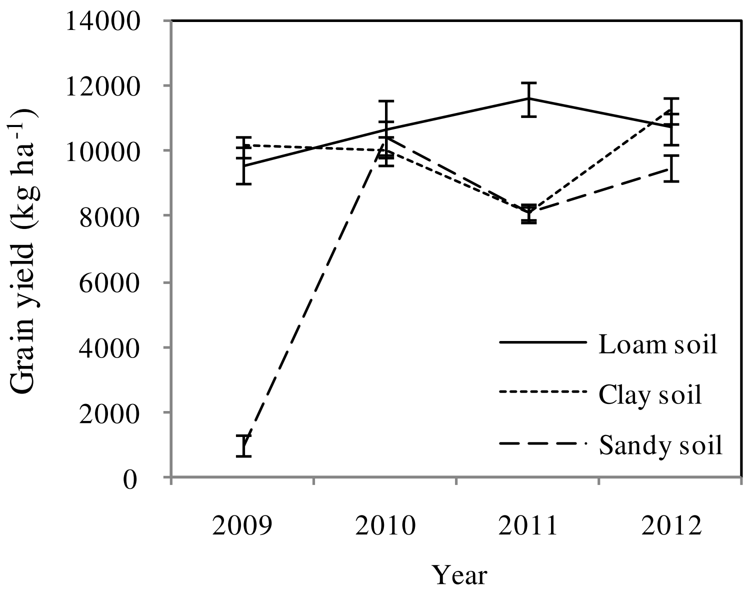

Figure 3. *Yield stability in three soil types with under optimal nitrogen application. Data were pooled across four years (n = 36)*

The low GY in 2011 might have been due to lodging between July 30 and August 1. Due to different lodging rates among the three soil types, with a rank order of clay > loam > sandy soil and values of 29.2, 13.1, and 8.2%, respectively (*Table 3*), the GY for clay and sandy soils averaged 8089 and 8126 kg ha^{-1}, respectively, which was significantly less than the GY in loam soil (11600 kg ha^{-1}; *Fig. 3*).

The effect of year × soil interaction on GY was significant, indicating that the effects of soil on GY differed among years. During the four years (2009–2012), GYs for the N168 treatment in the loam, clay, and sandy soils averaged 10638 kg ha^{-1} with a range of 8960–12021 kg ha^{-1}, 9882 kg ha^{-1} with a range of 7861–11713 kg ha^{-1}, and 7252 kg ha^{-1} with a range of 695–10913 kg ha^{-1}, respectively (*Fig. 3*).

Grain Yield Response to N Application Rate among Soil Types and Years

Grain yield response to increasing N rate differed among the soil types and years as indicated by a significant soil type × year × N interaction effect. A linear-plateau GY response to increasing N rate was the most appropriate model for the three soil types. Across the four years, the optimal N rate required to achieve maximum GY averaged 182, 173, and 160 kg ha^{-1} for loam, clay, and sandy soils, respectively. The corresponding maximum GYs for loam, clay, and sandy soils were 10872, 9999, and 7266 kg ha^{-1}, respectively.

The GY in loam soil increased quadratically with increasing N rate in 2010, while a linear-plateau model was most appropriate for 2009, 2011, and 2012. The minimum N rates needed to achieve maximum GY were 270, 180, 150, and 186 kg ha^{-1} for 2009 (*Fig. 4a*), 2010 (*Fig. 4d*), 2011 (*Fig. 4g*), and 2012 (*Fig. 4j*), respectively. Grain yields for the N0 rate were 8810, 9560, 6538, and 6397 kg ha^{-1} in 2009 (*Fig. 4a*), 2010 (*Fig. 4d*), 2011 (*Fig. 4g*), and 2012 (*Fig. 4j*), respectively.

Similar results were observed for clay soil during the experiment years. The linear-plateau GY responses to N were the most appropriate models for clay soil (*Fig. 4*). Grain yield increased from 9539 kg ha^{-1} for the N0 rate to a maximum GY of 10521 kg ha^{-1} obtained with 320 kg N ha^{-1} in 2009 (*Fig. 4b*). Maximum GYs for 2010 (*Fig. 4e*), 2011 (*Fig. 4h*), and 2012 (*Fig. 4k*) were 10148, 8241, and 11256 kg ha^{-1}, respectively, at minimum N rates of 175, 174, and 155 kg N ha^{-1}, respectively.

A linear-plateau GY response to increasing N rate was the most appropriate model for the sandy soil from 2010 to 2012, while there was no relationship in 2009 (*Fig. 4c*). The minimum N rates needed to achieve maximum GY were 158, 90,and 175 kg ha^{-1} for 2010 (*Fig. 4f*), 2011 (*Fig. 4i*), and 2012 (*Fig. 4l*), respectively. Maximum GYs for 2010, 2011, and 2012 were 9944, 8108, and 9829 kg ha^{-1}, respectively. Grain yields for the N0 rate in 2010 (*Fig. 4f*), 2011 (*Fig. 4i*), and 2012 (*Fig. 4l*) were 4296, 5387, and 1272 kg ha^{-1}, respectively.

Under drought conditions in 2009 (206 mm rainfall during the maize growing season) (*Fig. 1*), a linear-plateau GY response to increasing N rate was the most appropriate model for the loam (*Fig. 4a*) and clay soils (*Fig. 4b*), while there was no relationship in sandy soil (*Fig. 4c*). The total rainfall values during the maize growing seasons in 2010 and 2012 were 583.2 and 437.2 mm, respectively, which were greater than for 2009 (*Fig. 1*). Despite the relatively small GY for the N0 rate in sandy soil, the maximum GY in sandy soil (9944 and 9829 kg ha^{-1} for 2010 and 2012, respectively)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42294243

was similar to the maximum GY observed for loam soil (10428 and 11170 kg ha^{-1} for 2010 and 2012, respectively) and clay soil (10148 and 11256 kg ha^{-1} for 2010 and 2012, respectively).

Across the experiment years, the optimal N rate required to achieve maximum GY was 160–180 kg ha^{-1} for the three soil types. The PFP_N ranged from 57.0 to 69.0 kg kg^{-1} in loam soil and from 48.0 to 67.1 kg kg^{-1} in clay soil. In contrast, the PFP_N ranged from 5.8 to 61.9 kg kg^{-1} in sandy soil, indicating that N efficiencies in loam and clay soils were stable compared with sandy soil, for which the PFP_N of 5.8 kg kg^{-1} was affected by drought in 2009.

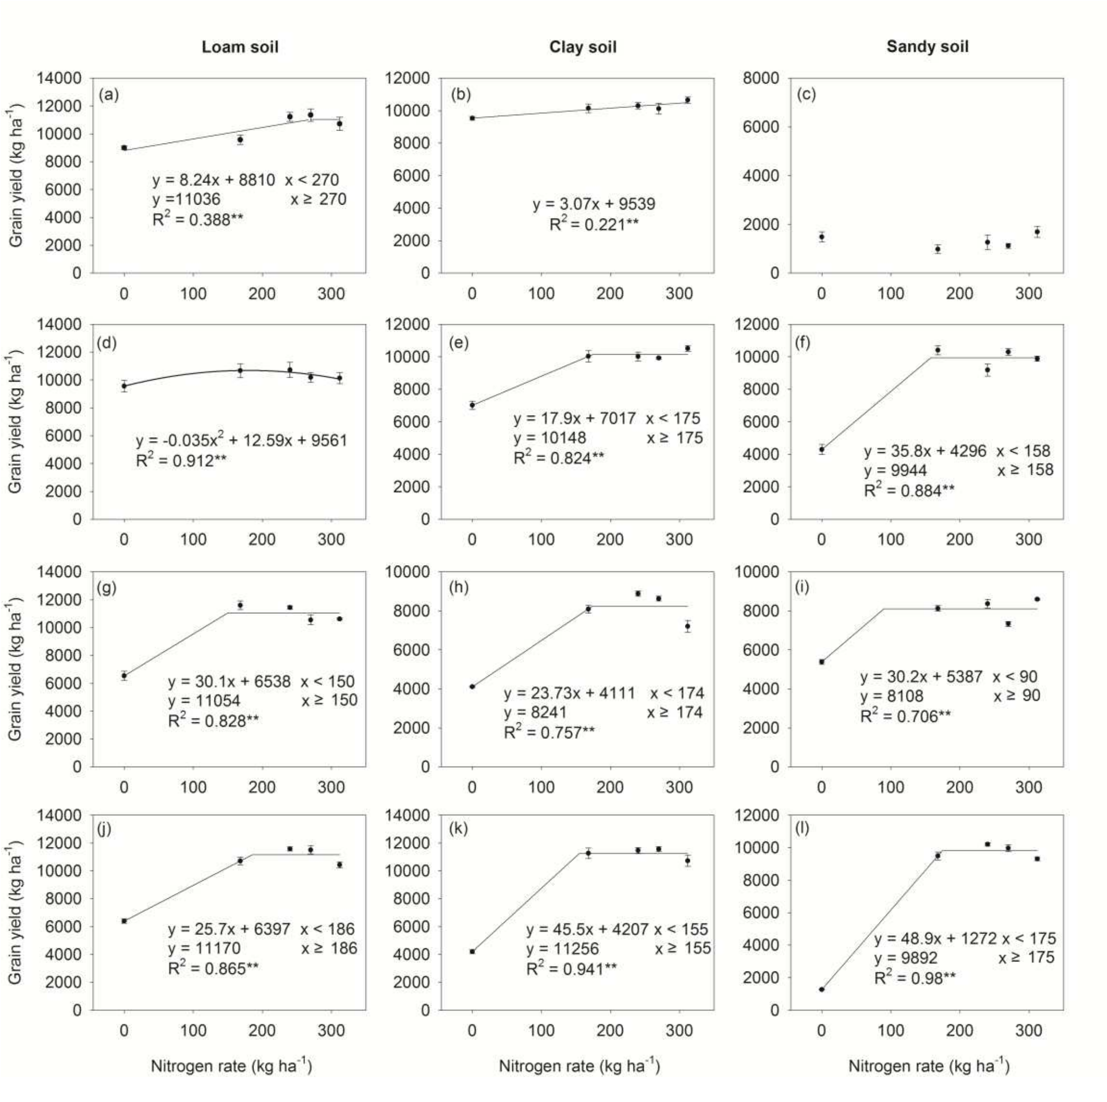

Figure 4. *Effects of nitrogen application on grain yield (at 14% moisture) on loam (left), clay (middle), and sandy soils (right) from 2009 to 2012*

Considering all four years and three soil types, GY was affected significantly by N treatments. Nitrogen fertilizer increased the maize GY significantly, with the GYs of the N168, N240, N270,and N312 treatments increased by 3525 (62%), 3822 (67%), 3647 (64%), and 3475 kg ha^{-1} (61%), respectively, compared with the N0 control ($P < 0.05$, *Table 2*). Compared with the N312 treatment, the N240 treatment increased the maize

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42294243

GY significantly (347 kg ha^{-1}, $P < 0.05$), despite applying an average of 72 kg less N ha^{-1}. The average maize N uptake was affected significantly by the N treatments. The average maize N uptake values for the N240, N270, and N312 treatments were 178, 178, and 176 kg ha^{-1}, respectively, which were significantly higher than for the N0 and N168 treatments (100 and 169 kg ha^{-1}, respectively). The average PFP_N was affected significantly by the N treatments with a rank order of N312 < N270 < N240 < N168 and values of 30, 35, 40, and 55 kg kg^{-1}, respectively (*Table 4*).

Residual Nitrate-N and Soil N Balance

Across the experiment years (2009–2012), residual minimum soil N_{min} data showed an average of 87.2 kg N ha^{-1} with a range of 61.7 to 126.8 kg N ha^{-1} and an average of 183.7 kg N ha^{-1} with a range from 76.5 to 321.3 kg N ha^{-1} in the 0–100-cm soil profile for the N168 and N312 treatments, respectively, after harvest (*Table 5*). Presumably, some of the residual soil N_{min} would be subject to environmental loss, particularly in the period after maize harvest. Soil types affected the residual soil N_{min} significantly, with residual soil N_{min} in the 0–100-cm soil layer of clay soil being significantly higher than that in the loam and sandy soils (*Table 5*). Compared to sandy soil (73.2 and 76.5 kg N ha^{-1} for the N168 and N312 treatments, respectively) and loam soil (61.7 and 153.4 kg N ha^{-1} for the N168 and N312 treatments, respectively), more residual soil nitrate-N was present in clay soil (126.8 and 321.3 kg N ha^{-1} for the N168 and N312 treatments, respectively). Similar results were observed for residual soil NO_3^--N in the 0–100-cm soil layer. The residual soil NO_3^--N in the 0–100-cm soil layer in sandy soil was 26.0 kg ha^{-1} as compared with 74.2 and 57.2 kg ha^{-1} for clay and loam soils, respectively. We attributed these differences to soilfertility and soil texture in addition to high soil silt and clay content (*Table 1*).

The calculated total apparent N losses across the experiment years (2009–2012) ranged from 315 to 481 kg N ha^{-1} with a mean of 372 kg N ha^{-1} and from 678 to 965 kg N ha^{-1} with a mean of 823 kg N ha^{-1} for the N168 and N312 treatments, respectively

DOI: http://dx.doi.org/10.15666/aeer/1702_42294243

(*Table 5*). The calculated total apparent N losses across the experiment years were affected significantly by the soil type. The calculated total apparent N losses in loam and sandy soils increased to 965 and 827 kg N ha^{-1}, respectively, compared with 678 kg N ha^{-1} in clay soil for the N312 treatment.

† Apparent N mineralization was calculated as the difference between the N output (plant N uptake plus residual soil Nmin) and the N input (initial soil Nmin in0–100cm soil layers) in no N treatment (Meisinger, 1984).
‡ Apparent N losses were calculated as the difference between the N input (initial soil Nmin plus apparent N mineralization and N fertilizer) and the N output(plant N uptake plus residual soil Nmin) in N-applied treatments (Zhao et al., 2006).
§ N recovery = (N uptake in N fertilization plot - N uptake in no N fertilization plot)/the amount of N fertilizer ×100.
*Different letters indicate significant difference at $P = 0.05$.

Considering all four years and the three soil types, RE_N was affected significantly by the N treatments compared with the N312 treatment. RE_N for the N168 treatment increased significantly by 17%, from 24 to 41% (*Table 5*). The soil types affected RE_N significantly for loam soil (27.2 and 14.8% for N168 and N312, respectively) and RE_N was higher in clay soil (48 and 28% for N168 and N312, respectively) and sandy soil (48 and 31% for N168 and N312, respectively).

Discussion

Across the experimental years, grain yield was significantly affected by soil types, especially in 2009 and 2011. In 2009, the rainfall during the maize growth period was only 207 mm, and there was a drought in May and early grain filling stage (*Fig. 1*). Drought in seedling stage affected emergence resulted lower seedling emerge rate (Fu et al., 2008), drought stress in flowering and early grain filling stage limited photosynthesis and reduced the flux of assimilates to the developing ears and filling

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42294243

grain (Saini and Westgate, 2000; Beyene et al., 2016; Tao et al., 2016; Kim et al., 2017), and the higher evaporation on sandy soil (Lu et al., 2014), which resulted lower ear number and 100 grain weight, further decreased the GY in sandy soil (*Table 2*). Due to differing degrees of drought vulnerability of the loam, clay, and sandy soils (Egamberdiyeva, 2007), the average GYs in the loam and clay soils were significantly higher than the GY in sandy soil (*Fig. 3*). Root lodging can reduce harvestable yield of many crops including maize (Brune et al., 2018). Root lodging tends to be associated with environmental factors such as heavy rains coinciding with wind (Farkhari et al., 2013), such as in 2011, there was a heavy rain (80.7 mm) with wind in July 30-31. Higher lodging rate in clay soil might be explained by a plow pan which prevent the root grow into deep soil (He, 2006; Qin, 2008).

Grain yield for the zero-N treatment in loam soil, clay soil and sandy soil averaged 7873, 6216 and 3110 kg ha^{-1} respectively, indicated that greater soil N availability supply contributed to greater GY. Additional soil characteristics, especially soil texture (Ziadi et al., 2013), soil water content (Cambouris et al., 2006), and N mineralization (Luce et al., 2011; Smith, 2018), appeared to have contributed to variation in soil N availability, soil productivity and yield potential among in-field location (Tolk et al., 1999).

In general, sandy soil had lower productivity due to lower soil fertility (soil organic matter content), nutrient preserved capability and water retaining capacity, compared with loam and clay soil (Egamberdiyeva, 2007). Such as in 2012, grain yield for the zero-N treatment in sandy soil averaged 1272 kg ha^{-1}, which was significantly lower than that in loam soil (6397 kg ha^{-1}) and clay soil (4206 kg ha^{-1}). The grain yield stability in loam and clay soil soil is significantly higher than that in sandy soil, the coefficients of variation for GY over the four years were 7.8, 13.4, and 59.1% for the loam, clay, and sandy soils, respectively.

In rain-fed maize system, yield response to N fertilizer may various, which has been attributed to differences in soil N supply, N use efficiency, and environments (Meisinger, 1984; Lory and Scharf, 2003). In this study, the GY response to nitrogen was various among the three soil type. The linear-plateau model of GY response to increasing N rate was showed that maximum GY of three soil type followed by loam soil (10872 kg ha^{-1}) > clay soil (9999 kg ha^{-1}) > sandy soil (7266 kg ha^{-1}). However, the IY_N followed by sandy soil (4156 kg ha^{-1}) > clay soil (3783 kg ha^{-1}) > loam soil (2999 kg ha^{-1}). Across the experimental years, the optimal N rate required to achieve the maximum GY maintained 160-180 kg ha^{-1} for the three soil types. Nitrogen partial factor productivity maintained from 57.0 to 69.0 kg kg^{-1} in loam soil, from 48.0 to 67.1 kg kg^{-1} in clay soil. In contrast, the nitrogen partial factor productivityvaried from 5.8 to 61.9 kg kg^{-1} in sandy soil, indicated that nitrogen efficiency in loam soil and clay soil were stable compared with sandy soil, such as nitrogen partial factor productivity just 5.8 kg kg^{-1} affected by drought in 2009.

To achieve satisfactory agronomic performance while minimizing negative environmental impact, N fertilization recommendations must consider the dynamics between N supply from the soil and N demand by the crops (Ayoub et al., 1995; Cassman et al., 2002; Cui et al., 2009). However, in China, pursuing high grain yield has been the top priority in policy and in practice. The typical N rate applied by maize farmers in the Northeast China (NEC) is excess (Chen et al., 2014). As expected, the RE_N in Northeast China maize production systems is low, the potential environmental impact from over fertilization and low N recovery can be substantial. In this study, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42294243

optimum N treatment (N168) reduced residual nitrate N content in the top 100-cm soil layer and N losses by 97 and 451 kg N ha^{-1}, respectively, compared with the excessive N treatment (N312).

In the current corn production system, the big difference in IY_N (increased yield for applied N fertilizer) was attributed to the differences among soil types, suggesting that soil type led to a high degree of field-to-field variability in the yield response to applied N fertilizer. Consequently, the big challenge is how to reduce variation among different soil types and decrease yield gaps.

Conclusions

The challenge of meeting food demand in China during the next 50 years must be met by simultaneously increasing GY and NUE; however, the rain-fed maize GY differed among soil types, indicating a conflict between high GY and improved NUE under current maize production practices. An improved fundamental understanding of GY and NUE in response to management practices and soil types is needed to rectify this situation. Our study demonstrated that higher GY was obtained in loam and clay soils compared to sandy soil, which implies that recommended N fertilizer rates need to be adjusted and take into account soil type. Across the four years, the optimal N rates required to achieve the maximum GY averaged 182, 173, and 160 kg ha^{-1} for loam, clay, and sandy soils, respectively. The corresponding maximumGYs for loam, clay, and sandy soils were 10872, 9999, and 7266 k g ha^{-1}, respectively. The PFP_N averaged 46.0, 42.4, and 30.9 kg kg^{-1} for loam, clay, and sandy soils, respectively. The average RE_N, AE_N, and PFP_N values under the optimum N treatment (N168) were 41%, 21 kg kg^{-1}, and 55 kg kg^{-1}, respectively, which were all significantly higher than for N312 (RE_N, 24%; AE_N, 11 kg kg^{-1}; and PFP_N, 30 kg kg^{-1}). As a result, the optimum N treatment (N168) reduced residual nitrate N content in the top 100-cm soil layer and N losses by 97 and 451 kg N ha^{-1}, respectively, compared withthe excessive N treatment (N312). Such knowledge could be used todevelop robust N management practices to provide effective N management practice recommendations over a wide range of soil-climate combinations.

(Received 20th Dec 2018; accepted 27th Feb 2019)

Abstract. Today, the biggest threats for mammal predators are habitat losses, humans, and other factors. Although brown bears are not under threat in Turkey, there is still risk for fragmented and isolated populations. It is necessary to carry out habitat suitability analysis in order to determine these risks. The study area is the Western Mediterranean Region and the modelling was carried out using Maximum Entropy method with presence data collected from 56 sample areas in Antalya – Akseki. MAXENT method was used since it reveals reliable and valid models in larger areas with little local data. Cross-validation was done separating 90% of data for training and 10% for testing to validate test data in the modelling process. AUC values of the training and test data were found to be 0.956 and 0.909, respectively. The model was also evaluated according to Receiver Operating Characteristic value and Jackknife test. Environmental variables contributing to the model were Ruggedness Index, Elevation, Slope, Normalized Difference Vegetation Index, Solar Illumination Index, and Roughness Index. Habitat suitability map of the brown bear was created following the modelling process and the usability of the model and the map were evaluated for brown bear management plans. To conclude, Brown bear is a significant mammal species the habitat of which must be preserved.
Keywords: *environmental factor, jackknife, MAXENT, maximum entropy, ROC*

Introduction

Populations and habitats of large predators are decreasing at a worrying rate due to anthropogenic effects, habitat fragmentation, and hunting activities. Brown bear, an important large mammal, are at a risk of disappearing as well (Nellemann et al., 2007; Roellig et al., 2014; Støen et al., 2015; Fernández-Gil et al., 2016). Brown bears having few individuals in isolated populations are stated to be under threat for spreading out in large areas, even though their total population is large and their IUCN red list category and criteria is LC (McLellan et al., 2017). Today, the majority of the brown bear population is isolated in mountainous regions under the effect of conservation activities (Swenson et al., 2000; Zedrosser et al., 2001). Although brown bears are stated to live in areas far from human pressure, a large part of the areas occupied by humans provide potentially optimal habitat conditions for the distribution of this species (Roellig et al., 2014). Despite this situation, populations living in the same space or being close to residential areas are under further threat and are more heavily isolated, as interaction among these populations are hindered due to many factors (McLellan et al., 2017). Thus, it is necessary to make conservation plans revealing actual and potential habitats for brown bears and other species.

Distributions, biology, and ecological needs of species should be known for their conservation status and action plans (Pacifici et al., 2015). Modelling and mapping of species habitat within a good planning is of great importance. MAXENT is known to be one of the most appropriate methods in habitat modelling studies of wild animal species. This method works well with presence data and gives correct results with little data. It is also based on modelling of relationships with environmental factors in areas where the species exists (Elith et al., 2006; Hernandez et al., 2006; Phillips et al., 2006).

In Turkey, brown bears live in deciduous forests, conifer forests, and mix forests up to a height of 3500 to 4000 m, and in scrublands, shrubs, valleys being close to seas, alpine valleys, and cliffs (Başkaya et al., 2008; Ambarlı, 2012). Habitat variables of brown bears are height, anthropogenic factors, slope, roughness, roughness index, heat index, solar illumination index, and vegetation index as well as forests, open spaces, closedness, and ecological factors such as roads and climate (Apps et al., 2004; Ambarlı, 2012; Bojarska and Selva, 2012). Habitat type and quality play an important role in brown bear distribution (Can and Togan, 2004) and it is necessary to use environmental factors and to determine their effects on brown bear distribution in studies. Brown bears spread in the Black Sea and East Anatolian regions of Turkey densely (Ambarlı et al., 2016). It is known that the species live in the Mediterranean region and (Turan, 1984) have intact and natural habitats in Antalya district (Can and Togan, 2004). When the distribution map of brown bears prepared in accordance with the IUCN data is examined, it is clearly seen that the species has disappeared in many areas and information regarding with their reproduction in their living areas are insufficient in the Mediterranean region (McLellan et al., 2017). In addition, populations of brown bear are fragmented and isolated in the Western Mediterranean region. This is seen to be a big threat for this species and it is important to determine the factors affecting its distribution and to reveal potential regions to maintain its continuity in the region. In other words, studies involving latest information regarding with the actual distribution and potential appropriate habitats of this species in the region should be done. This study aims to do suitability modelling and mapping to determine the distribution of brown bears in the Western Mediterranean region.

Materials and method

Data collection

West Mediterranean region in the south-west of Turkey was picked as the study area (*Fig. 1*). Inventory study was conducted in Akseki district to represent this region. West Taurus Mountains are surrounded by Bey Mountains, Elmalı Mountains, Katrancık Mountains, and Boncuk Mountains in the west and Akçalı Mountains, Geyik Mountains, Dedegöl Mountains, Kuyucak and Erenler Mountains in the east. There are many karstic shapes in this topography since this area is formed by limestone bedrock (Öztürk et al., 2018). The area is used extensively by locals for transhumance practices (Sarı, 2013). In this study, indirect observation technique was used in the collection of land data. Presence data of indirect inventory was obtained belonging to tracks, feces, and other signs of brown bears in 56 points Akseki district in 2016.

Environmental variables

Slope, Aspect, and Elevation maps of the region were created using Digital Elevation Model (DEM) on ArcMap 10.2 software. Topographic Position Index (TPI) was created using ArcMap 10.2 software with "Topography Tools "extension developed by Jennes (2016). Also, Topographic Convergence Index (TWI), Landform Classification (Jenness), Solar Illumination Index (6 am, 8 am, 10 am, noon, 2 pm, 4 pm, 6 pm, and 8 pm) (Tagil and Jennes, 2008) were created. Terrain Ruggedness Index (Ruggedness)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42454255

was created via Terrain Tools extension (Riley et al., 1999). Roughness Index, (Roughness) and Heat load index (HLI) were created with the help of Geomorphometric and Gradient Metrics Toolbox. Beers Aspect (BA) (*Eq. 1*) (Beers et al., 1966) and topographic radiation index (TRASP) (*Eq. 2*) (Moisen and Frescino, 2002) values were calculated and maps were created using different equations, respectively.

$$BA = \cos(Amax\text{-}A) + 1 \quad \text{(Eq.1)}$$

$$TRASP = [1 - \cos((\pi/180)(\Theta - 30))]/2 \quad \text{(Eq.2)}$$

Normalized Difference Vegetation Index (NDVI) was obtained from MOD13Q1 module, one of the satellite data of MODIS VI, monthly. (Didan et al., 2015). NDVI values range between -2000 (-0, 2) and 10000 (1, 0). Negative values of NDVI show water bodies; values approximate to 0 show bare soil); values 0.1 and lower show barren areas of rock, sand, or snow; values between 0.2 and 0.3 show shrub and grassland, and values between 0.6 and 0.8 show temperate and tropical rainforests (Karaburun, 2010; Xei et al., 2010; Bhandari et al., 2012).

Climate data was downloaded on the following website (http://www.worldclim.org). Nineteen pieces bio-climate data were prepared (Hijmans et al., 2005). This climate data were cut according to the study area size and prepared according to 19 climatic data.

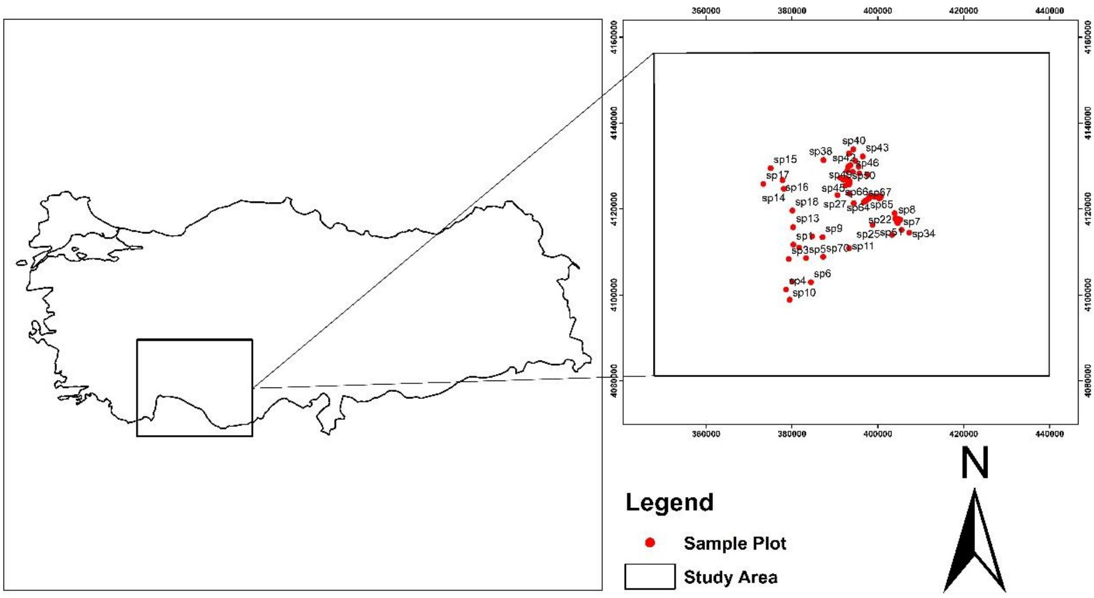

Figure 1. *Study area and map of sample areas*

Modelling and mapping processes

Factor analysis between elevation and nineteen bio-climate variables was applied in the modelling process in order to prevent independent variables from causing any bias. As a result of the analysis, elevation was chosen as representative variable since strong relationship between elevation and nineteen bio-climate variables might cause bias (Mert and Kıraç, 2017; Suel et al., 2018). After this process, potential habitat suitability modelling process was completed using MAXENT method.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42454255

This method creates suitability model evaluating the data collected in the study area where the species exists and areas with similar features together (Baldwin, 2009). When compared to other modelling processes of presence data, MAXENT enables to create more realistic distribution and suitability models with less data (Phillips et al., 2004, 2006; Hernandez et al., 2006; Wisz et al., 2008; Baldwin, 2009; Elith et al., 2010).

3.4. lk version of MAXENT is used for habitat suitability analysis. 90% of the brown bear presence data was allocated as training value and 10% was allocated as test value and modelled with environmental variables. The success of MAXENT model was assessed using ROC (Receiver Operating Characteristic) curves; AUC values of training-test data and their contribution to model levels were assessed with jackknife graphs (Deleo, 1993; Fielding and Bell, 1997; Phillips et al., 2006; Baldwin, 2009; Monterroso et al., 2009). Potential distribution map ranging between 0 and 1 was illustrated in ArcMap 10.2 software (Özkan et al., 2015)

Results

A successful and valid model with the ROC value of 0.956 was obtained in this study (*Fig. 2*). AUC value of the test data is 0.909 whereas AUC value of training data is higher than test data, yet the discrepancy is not high. However, the area under the ROC curve is higher than the area under the random prediction line. These results show that the model can be used as it gives realistic results.

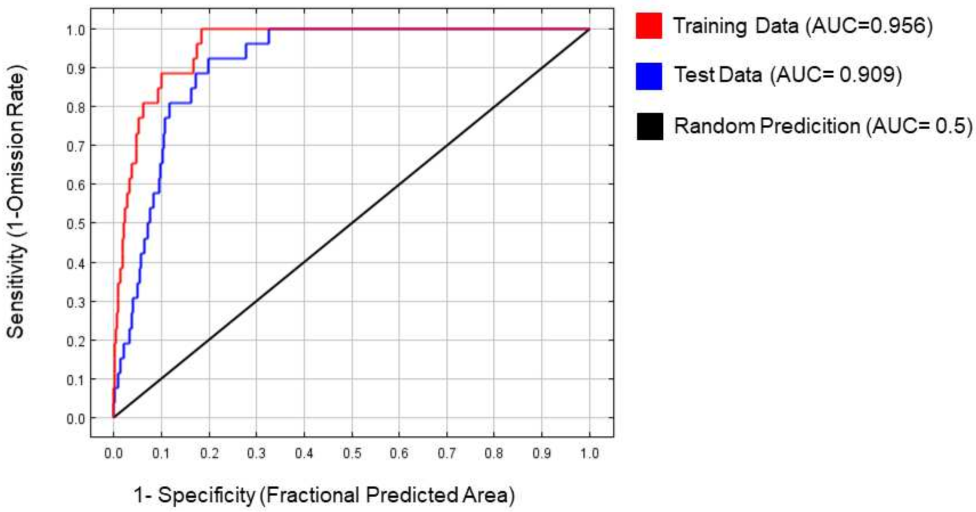

Figure 2. *ROC and AUC MAXENT values of the model*

Environmental variables are 2 pm, 6 am, Elevation, Slope, NDVI (September), Roughness, and Ruggedness (*Table 1*). Variables that contribute most to the model are roughness, elevation, and NDVI (*Table 1*).

When the results of jackknife statistics are examined, it is seen that ruggedness makes the most contribution to the model. Although the contribution level of roughness is high, excluding it would not cause a great loss in the model, in which case it can be said that elevation is more descriptive compared to roughness and thus is the second highest contributor of the model. Another significant variable in terms of model gain is

NDVI. 6 am and slope also play a role in the model's success. 2 pm has the lowest contribution alone and in terms of total model gain (*Fig. 3*).

Table 1. *Variables contributing to the model and their contribution levels*

Environmental variable	Contribution %
Ruggedness	59.9
Elevation	23
NDVI	9.2
6 am	3.1
Slope	2.5
Roughness	1.6
2 pm	0.8

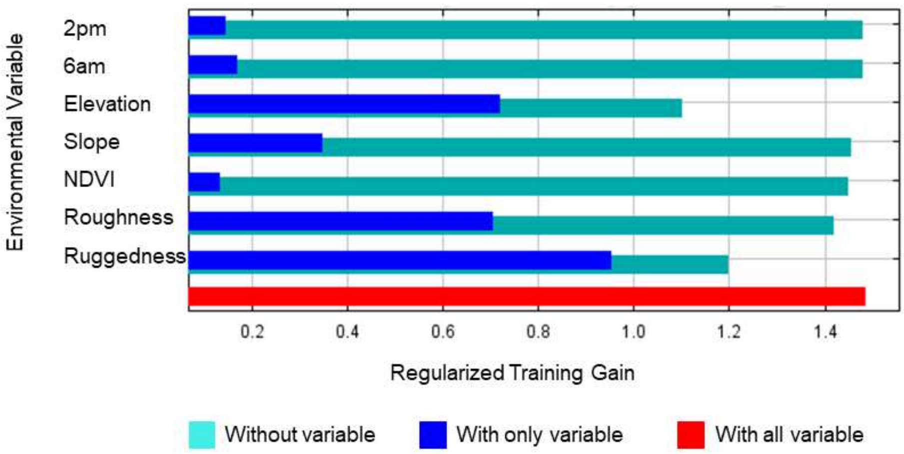

Figure 3. *Jackknife test for evaluating the relative importance of environmental variables*

Three variables making the most contribution to the model in percentages are ruggedness, elevation, and NDVI and when examined together with roughness, the highest contributor according to jackknife results, it is seen that brown bears prefer rugged areas up to a specific point and avoid extremely rugged terrains topographically (*Fig. 4*).

Elevation has a positive effect on the habitat of this specific species up to about 2000 m whereas this effect becomes negative in higher locations. In terms of NDVI results, it is seen that brown bears prefer natural, open areas and forests and avoid dense forests. Finally, these species prefer rough areas up to a point meaning it avoids flat spaces (*Fig. 4*).

The scale regarding with the potential habitat suitability of brown bear on the habitat suitability map ranges between 0 and 0.97. Red areas are the most suitable habitats potentially whereas blue areas show unsuitable terrains for brown bears (*Fig. 5*). Currently, brown bear populations are available in Kuyucak, Civikli, Geyik and Gidengelmez Mountains and their surroundings. Although there is no brown bear population apart from these areas such as Akçal, Cehennem, Aygır, Çamurlu and Gelincik mountains, model results reveal these as potential habitats for brown bears.

Discussion

Modelling studies provide significant guide for potential distribution and habitat suitability maps of animal and plant species. In terms of its topographic structure, forests, and geographical location, West Mediterranean Region deserves its potential to be revealed (Özkan et al., 2015). In this study, habitat suitability modelling and mapping of brown bears were performed. Although the data is relatively little and involves a local area, successful and real results were obtained thanks to the MAXENT method. The model was verified via ROC graph, difference between training (AUC: 0.956) and test values (AUC: 0.909), and jackknife tests (Phillips et al., 2006; Wisz et al., 2008; Baldwin, 2009; Elith et al., 2010; Tekin et al., 2018). Both researchers and executors can use the habitat suitability map.

Variables forming the MAXENT model are Elevation, Slope, Solar Illuminations Index, Ruggedness Index, Roughness Index, and NDVI according to their contribution percentages and the results of jackknife test. These results show that rugged areas play an important role in brown bear distribution and brown bears prefer areas with specific slope degrees. In previous studies, slope is stated to be a significant environmental factor that affects habitat preferences of brown bears (Štofík, and Saniga, 2012). When topographic structure of West Taurus Mountains is considered, it is understood that it is an expected situation for slope to contribute to the model in especially cliffy areas and that brown bears do not prefer excessively sloped areas. Ruggedness is also another important variable in habitats potentially suitable for brown bears and previous studies point out that brown bears prefer rugged terrains for they are not affected by human activities and rich in terms of vegetation (Apps et al., 2004; Nielsen et al., 2004; Nellemann et al., 2007.).

It was observed in field studies that rugged areas with their local vegetation in West Taurus Mountains, which form the topography in the West Mediterranean Region, overlap with areas where there are brown bears. Field studies carried out in Akseki district show that brown bears choose rugged areas with rich vegetation. Moreover, Brown bears use rugged areas where there is Juniperus drupacea for nutrition and use some other rugged fields for shelter. As for roughness index, brown bears are seen to avoid flat and extremely rough surfaces and use rough areas for daily activities. Although there is not clear information about this in the literature, roughness index overlaps and shows similarities with other variables such as ruggedness and slope.

The natural forests in altitudes between 500 and 2000 m in Western Mediterranean have been found to be ideal habitats for brown bears. Can and Togan (2004) stated the terrains with same features are potential habitats for brown bears. In addition, the reason why brown bears prefer altitudes between 800 and 1000 m as habitat is related to vegetation, human impact and land structure (Posillico et al., 2004). The information here overlaps with the interpretations related to ruggedness as mentioned above and the effects of this can be clearly seen in brown bear distribution map.

NDVI was determined as a significant variable that contributes to habitat suitability model of the brown bear- an omnivorous living being and this reveals that brown bears prefer to live in areas where there are dense natural forests in the Western Mediteranean region. This overlaps directly with the living spaces of brown bears where there are coniferous trees or mix forests. The relationship between habitat preferences of brown bears and NDVI was revealed in previous studies, brown bears have been found to prefer green vegetation (Can and Togan, 2004; Bojarska and Selva, 2012).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42454255

This study found out that Solar Illuminations index contributes to the habitat suitability model, though this contribution is small. It is therefore understood that brown bears prefer noon to early morning hours and avoid extensive sunlight. It was pointed out in the literature that brown bears are more active during day in shorter days of the year (Ordiz et al., 2012) and that there are differences in their daily activities by seasons and light period (Ware et al., 2018). Hence, all these results show that brown bears react to sunlight, yet this situation might differ by seasons.

The habitat suitability map shows that our map is consistent with the distribution maps presented in the literature (Ambarlı et al., 2016; McLellan et al., 2017). Besides, the habitat suitability map shows potential areas for brown bears. Suitable areas for brown bears in the Western Mediterranean region were presented on the map.

Conclusion

In conclusion, habitat suitability modelling and mapping study was carried out successfully in the Western Mediterranean region and supported with the literature. The actual state and potential distribution areas of the species under the effect of basic environmental variables that affect habitats of brown bears were revealed. In fact, brown bears are not under the threat of extinction; however, they are large mammals and their populations are divided, they are also in the risky group. This study determined habitat factors of and potential areas for brown bears and this is of great importance for action plans to be prepared. Thus, the findings of this study are expected to provide guidance for action plans to be created for this species.

Abstract. Four-year-old trees grown in open-top chambers (OTCs) were exposed to elevated O_3 (80 nmol/mol, EO) or/and elevated CO_2 (700 μmol/mol, EC) levels. The object is to study the responses of photosynthesis and stomata in leaves of Mongolian oak (Quer*cus mongolica*) to EO and/or EC for two successive growing seasons in an urban area. The experiment was conducted in the arboretum located at the center of Shenyang city. The results show that: (1) EO decreased P_n (Light-saturated net photosynthesis rate), g_s (stomatal conductance) and T_r (transpiration rate). The stomata closure maybe associated with the direct effect of EO on guard cells. The decreases of F_0, F_m and F_v/F_m indicated that EO limits the capability of the plant to use photon energy and thus alters photosynthesis. (2) EC increased P_n and C_i (intercellular CO_2 concentration) of leaves, but decreased g_s and T_r slightly. Stomatal density decreased significantly at the end of the second season. Perhaps, EC was detected by mature leaves in the first season which signaled to the developing leaves in the next season, the stomatal developments of which altered accordingly. (3) Under EC+EO, EC relieved most of the O_3-induced adverse effects to P_n. The decreases of g_s and T_r were mainly caused by EO. There was no significant difference of F_v/F_m detected compared to the control, EC can largely relieve the adverse effects of EO on the PSII reaction center. Changes of stomatal parameters were just like the changes under EC. Perhaps the morphological changes of the stomata were mainly caused by EC.
Keywords: *photosynthetic CO_2 exchange, chlorophyll fluorescence, stomatal density, stomatal area*

Introduction

Since the industrial revolution, accumulating greenhouse gas (O_3 and CO_2) levels have increased over two-fold (Guo et al., 2017). The atmospheric concentrations of CO_2 have increased since 1750. In 2011, the concentration of CO_2 was 391 μmol/mol and exceeded the pre-industrial levels by about 40%. The rise primarily resulted from emissions of fossil fuel burning and secondarily from net land use change (IPCC, 2013). This rise has been accompanied by the increase in troposphere O_3 concentrations, which is not only a significant greenhouse gas but is also recognized as a serious phytotoxic air pollutant that damages plants (Serengil et al., 2011). As concentrations of NOx and VOCs increase through industrialization and vehicle exhausts, the daily surface O_3 levels in industrialized countries have increased remarkably from 10 nmol/mol prior to the industrial revolution to 60 nmol/mol in the current summer seasons, and are predicted to increase by another

http://www.aloki.hu • ISSN 1589 1623 (Print) • ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42574268

20% by 2050 (IPCC, 2007). Ground-level O_3 concentrations have significantly increased over the past decades, especially in northeast Eurasian region (Akimoto et al., 2015; Feng et al., 2015; Verstraeten et al., 2015).

These two co-occurring pollutants are quite interesting as they act in diametrically different directions. Stomatal aperture and density influence the rate of photosynthesis and transpiration of plant directly. Regulation of stomatal development and stomatal conductance is a key factor for plant in its adaptation to the environment changes and plants have evolved sophisticated mechanisms to control stomata density and behavior (Engineer et al., 2014). The stomatal control is achieved by the regulation of stomatal aperture through changes in guard cell turgor, and by alteration of stomatal density through modification of stomatal initiation and leaf expansion during leaf development (Haworth et al., 2013). Research of Frey et al. (1996) showed that stomatal density of birch could be increased under a consistently O_3 exposure. A reduction in stomatal conductance is commonly observed in response to elevated CO_2 (Woodward, 1987). Reported changes in stomatal density with growth at elevated CO_2 include increases, decreases, and no change (Drake and Gonzàlez-Meler, 1997). Those species with little or no control of stomatal aperture were more likely to exhibit a reduction in stomatal density under elevated CO_2 (Haworth et al., 2013). But how can stomatal response to both elevated O_3 and elevated CO_2? The stomatal development and stomatal conductance of leaves would how to be regulated to adapt to the combinational environments? The objective of this study was to measure photosynthetic and stomatal parameters of leaves of *Q. mongolica* (*Quercus mongolica*) trees grown in open-top chambers (OTCs) for two growing seasons to evaluate the photosynthesis and stomata responses of *Q. mongolica* to elevated concentrations of O_3 and/or CO_2. Cities are with concentrated industrial plants and heavy traffic. Trees grown in urban regions are more likely affected by elevated O_3 and CO_2, so the OTCs of this experiment were built in the center of the city to simulate the O_3 and CO_2 effects on leaves of *Q. mongolica*.

Research design and methods

Site and OTCs

The experiment site is located in Shenyang Arboretum of Chinese Academy of Sciences (41°46′ N, 123°26′ E and 41 m above sea level), which is located in the metropolitan area of Shenyang, Liaoning province, China). In this area, average annual precipitation is 755.4 mm and average annual temperature is 7.4 °C. The mean daytime temperature and the mean relative humidity in the OTCs showed no significant differences among treatments (Tmean = 26 °C Hmean = 70%). Ambient rainfall was occasionally supplemented to minimize water stress. The soil in the OTCs was loamy, supplemental fertilizer was provided and weeds were removed regularly. The factorial design of the OTCs has already been reported, they are 4 m in diameter and 3 m in height with a 45° sloping frustum, and distance among them is at least 4 m (He et al., 2006). There are twelve OTCs provided for four treatments, each with 3 replicates (in 3 OTCs randomly). The treatments were (1) control (ambient air, CK), (2) elevated O_3 (80 nmol/mol O_3 + ambient CO_2, EO), (3) elevated CO_2 (ambient O_3 + 700 μmol/mol CO_2, EC), (4) elevated O_3 + elevated CO_2 (80 nmol/mol O_3 + 700 μmol/mol CO_2, EO+EC).

O_3 was produced from bottled pure oxygen with an ozone generator (GP-5J, China) and pure CO_2 was injected into the chambers from cylinders. In order to monitor O_3 and CO_2 concentrations, O_3 transducer (S-900, Aeroqual, New Zealand) and CO_2 infrared

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42574268

transducer (SenseAir, Sweden) were used inside the chambers. Elevated CO_2 was applied for 24 h/day. Elevated O_3 was applied for 9 h/day (08:00-17:00).

Plant material

In April, uniform and healthy *Q. mongolica* trees (four-year-old) from local nursery were randomly planted in the soil of twelve OTCs (three OTCs were used as replicates for each treatment), 20 trees per chamber. These young trees were exposed to CK, EO and/or EC from 18 June to 10 October in the first season, overwintered in the OTCs and then re-exposed from 18 June to 10 October in the second season.

Gas exchange measurements

One leaf per plant and three plants per OTC (three OTC_S per treatment, n = 9) were measured by a portable photosynthesis system (LI-6400, Li-Cor Inc., Lincoln NE, USA) to attain a mean value every 15 days. The same method of gas exchange measurements has been reported (Wang et al., 2009).

Chlorophyll a fluorescence measurements

Chlorophyll a fluorescence was measured once every 15 days at ambient temperature in the OTC's in the second year, using a portable fluorometer (Handy-PEA, Hansatech, England). One leaf per plant and three plants per OTC (three OTC_S per treatment, n = 9). The environmental conditions were similar to gas exchange measurement. The same method of Chlorophyll a fluorescence measurement has been reported (Wang et al., 2009).

Stomatal parameters measurements

Q. mongolica leaves were collected after 0, 60 days (in the first season) and 210 days exposure (in the second season). Three leaf per plant, three plants per OTC and three OTC_S per treatment (n = 27). The top, middle and bottom of leaves were painted with transparent nail polish, and then the films were torn off after it dried. The temporary microscopic slides of dried nail polish were observed and photographed with picture pick-up system of bright-field microscope (Olympus BX-50, 1.3 million pixels), and image processing software (Motic Images Advanced 3.0) was used to measure and calculate the stomatal parameters including stomatal density, stomatal length, stomatal width, stomatal perimeter and stomatal area.

Statistical analysis

ANOVA was carried out using SPSS 13.0 computer package to analyze all sets of data and the means were compared by the Tukey test at 5% probability Levels. Sample variability is given as the standard deviation (S.D.) for presentation.

Results

Effects of elevated O_3 and/or CO_2 on Pn, gs, Ci and Tr of Q. mongolica leaves

EO suppressed P_n of *Q. mongolica* leaves significantly ($p < 0.05$) over two growing seasons compared to the control. The maximum difference (about 72%) was recorded

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42574268

after 45 days exposure in the first season, while EC increased it generally. P_n of leaves exposed to EO+EC was generally significantly higher than that exposed to EO alone, but lower than control except the last measurement (*Fig. 1a* and *b*).

In the first season, there was decrease of C_i detected in the EO environment compared to the control. While in the second season, there was almost no significant difference between EO and control treatments. However, EC and EO+EC treatments increased C_i of leaves compared to the control, and it was higher under EC than EO+EC (*Fig. 1c* and *d*).

EO and EO+EC generally decreased g_s of leaves significantly ($p < 0.05$), compared to the control and EC alone. However, there was no significant difference between EO+EC and EO treatments except after 60 days exposure in the second season. Compared to the control, EC slightly decreased g_s of leaves over the two growing seasons (*Fig. 1e* and *f*).

Similar change was shown between T_r and g_s of *Q. mongolica* leaves (*Fig. 1g* and *h*).

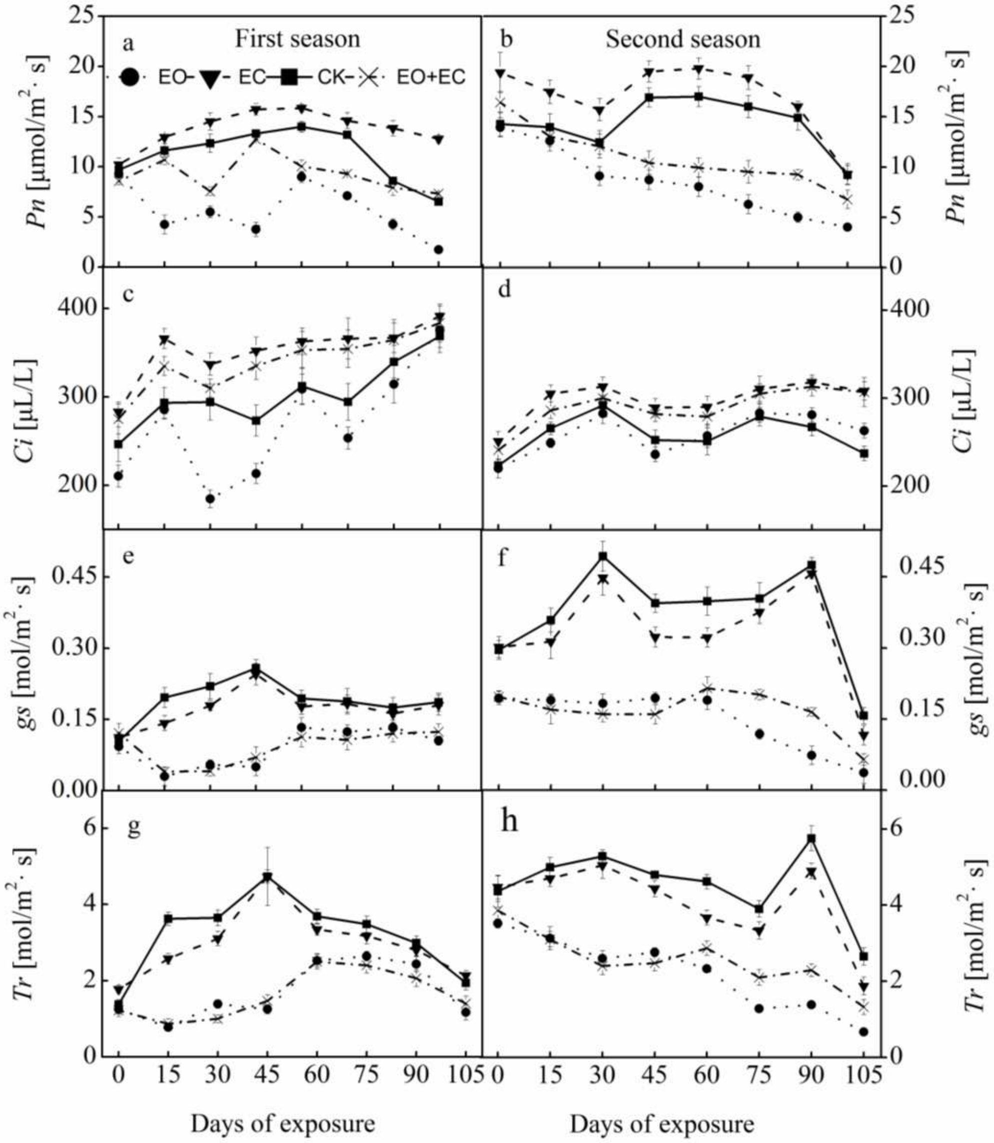

Figure 1. *Effect of elevated CO_2 and/or O_3 on the seasonal changes of P_n, g_s, C_i and T_r of Q. mongolica leaves. Each value represents the mean ± SD*

DOI: http://dx.doi.org/10.15666/aeer/1702_42574268

Effects of elevated O_3 and/or CO_2 on chlorophyll fluorescence parameters of Q. mongolica leaves

EO decreased F_0, F_m and F_v/F_m of *Q. mongolica* leaves after 75 days in the second season compared to the control. The differences were significant in the later dates ($P < 0.05$), but there was no significant differences detected in other treatments (*Fig. 2*).

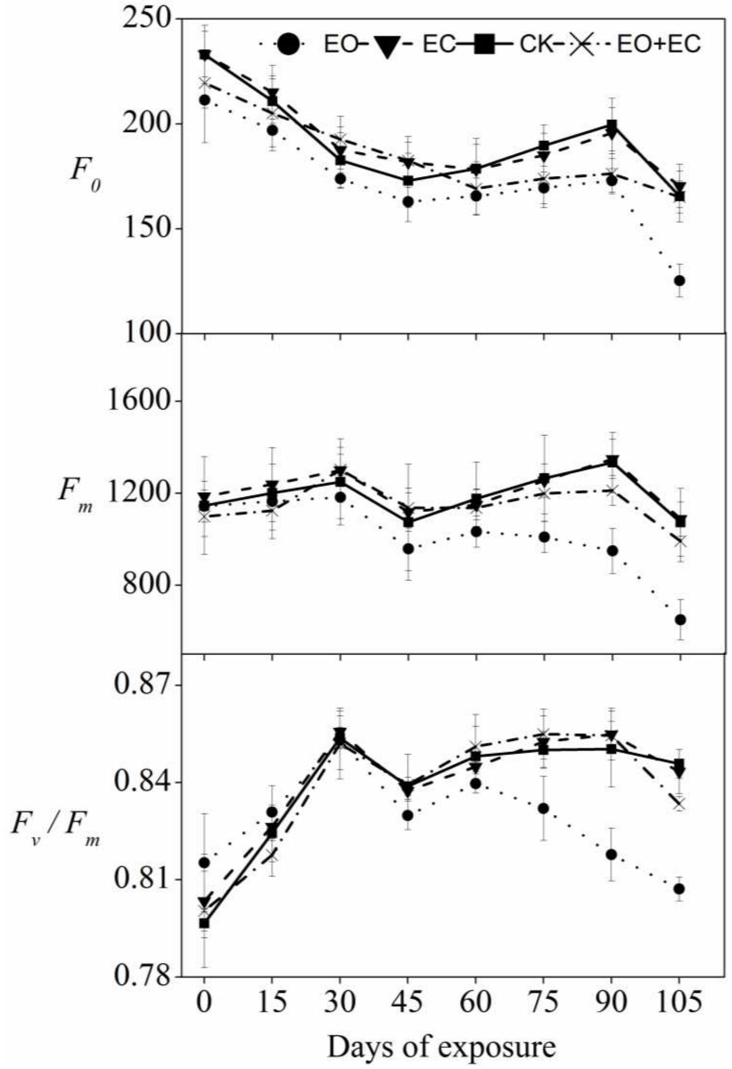

***Figure 2.** Effect of elevated CO_2 and/or O_3 on the seasonal changes of F_0, Fm and Fv/Fm (the maximum quantum yield of PSII photochemistry) of Q. mongolica leaves. Each value represents the mean ± SD*

Effects of elevated O_3 and/or CO_2 on stomatal parameters of Q. mongolica leaves

There was no difference of stomatal density of leaves detected in all the treatments in fist season (0th, 60th day in the first season), but in the end of the second season (210th day), EC and EO+EC significantly decreased it compared to the control ($P < 0.05$). There was only a slight increase of stomatal width of leaves by EC compared to the control on 60th day ($P < 0.05$). There were no significant differences of stomatal length, stomatal perimeter and stomatal area of leaves in the all treatments (*Table 1).*

Each value represents the mean ± SD. (Different letters indicate significant differences between treatments at the same time at $P < 0.05$)

Discussion

Effects of elevated O_3

Many authors have found that photosynthetic processes are very sensitive to high O_3, and a decrease in the rate of light-saturated net photosynthesis as a result of exposure to elevated O_3 has been reported (Farage and Long, 1999). In our experiment, from the apparent decreases in P_n of *Q. mongolica* leaves under EO fumigation appear in early of the growing season, It can be concluded that EO has a severe impact on P_n of *Q. mongolica* leaves and *Q. mongolica* is an O_3-sensitive tree species. Since Bortier et al. (2000) suggested that faster growing species tend to be more sensitive than slower growing species. Also compared with mature trees, young trees are more susceptible to O_3 stress because of their high metabolic activity (Laurence et al., 1994). The sensitivity of *Q. mongolica* to EO in our experiment may be related to their young age. It has been correlated observed that photosynthesis decreased with a reduction in stomatal conductance under O_3 exposure (Mansfeld, 1998). In other cases it was assumed that the decline in photosynthetic rate was the result of the interaction of O_3 with photosynthetically active mesophyll cells (Farage and Long, 1995).

Stomatal conductance plays an important role in the photosynthetic efficiency of O_3 stressed plants by controlling the amount of pollutant entering the plants through the stomata (Matyssek et al., 2004). It is well known that species with high stomatal conductance are more prone to injury because of enhanced pollutant uptake (Matyssek et al., 2004). Our results showed that g_s of *Q. mongolica* leaves were significantly decreased by EO at the beginning of the experiment, while the similar decrease was appeared in T_r of leaves. These results indicate that the partial closure of stomata can be induced by EO to avoid the further ozone uptake. Stomatal limitation is mainly attributed to stomata closure and, subsequently, to the decrement of Ci under normal conditions (Salazar-Parra et al., 2015), however, many authors suggested

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42574268

that stomata closure is not a direct response to O_3 insult, but a reaction to an increased intercellular CO_2 concentration resulted from the inhibition of carbon assimilation (Weber et al., 1993; Heath and Taylor, 1997). In our study, there was nearly no increase in C_i of leaves under EO, compared to the control at 15 days when g_s of leaves had decreased to minimum, so we propose that the stomata closure maybe associated with the direct effect of EO on guard cells of *Q. mongolica* leaves.

In low O_3 environments, photosynthesis and stomatal conductance are typically tightly coupled because the stomatal aperture equivalently controls the exchange of CO_2 and water at the leaf surface (Lombardozzi et al., 2012). However, from our study we can see that the typical coupling of stomatal conductance and photosynthesis does not always hold under EO and the decreases in P_n can be independent (in some extent) of g_s, suggesting that decreases in carboxylation, rather than g_s, are responsible for decreases in P_n.

The reduction in photosynthesis may also occur due to structural damage of thylakoids, which affects the photosynthetic electron transport and is indicated by the reduction in F_v/F_m ratio (Rai and Agrawal, 2012). F_v/F_m ratio is an indicator of the photoinhibition to PS II complexes. Under O_3 exposure, there are reports on wheat and rice showing increase in F_0 and a parallel decrease in F_m, suggesting impairment of PS II activity (Feng et al., 2011; Ishii et al., 2004). In our experiment, in the end of season, under EO exposure (after 75 days), there were decreases of F_0, F_m and F_v/F_m. Decreases of F_0 and F_v/F_m are the characteristics of thermal dissipation which depend on xanthophyll cycle and that dissipation reduces the photon energy to the photochemical reaction center (Xu, 2002). This can be seen as an important protection mechanism to avoid the destruction of PSII reaction centre. The decreases of F_0, F_m and F_v/F_m indicate that O_3 can limit the capability of the plant to use photon energy and thus alter photosynthetic processes. Decrease in the F_v/F_m is generally attributed to damage to the PSII reaction centre, apart from the down-regulation of the capacity of PSII electron transport (Chaumont et al., 1995).

Increased stomatal density seems to be a consistent effect related to ozone exposure and has been reported by Matyssek et al. (1991), but the same result was not found in this study, there were nearly no significant differences of stomatal parameters under EO compared to the control.

Effects of elevated CO_2

Rising CO_2 will impact plants through two processes, reducing g_s and increasing P_n (Ainsworth and Rogers, 2007). It has been reported that elevated CO_2 stimulated light-saturated photosynthesis in C_3 plants (Ainsworth and Rogers, 2007; Lahive et al., 2018; Panigrahi et al., 2016). In our experiment, EC also increased P_n of *Q. mongolica* leaves generally in two growing seasons until in the late of the second season (after 90 days).

Decreases in g_s of some plants induced by high CO_2 have been measured (Gao et al., 2012). However, the CO_2-sensing mechanism in guard cells that is responsible for the short-term sensitivity of g_s to elevated CO_2 is still unknown (Ainsworth and Rogers, 2007). In our experiment, EC decreased g_s slightly. Interestingly, unstressed plants tend to express a rather conservative range of C_i during steady-state photosynthesis, C_i is generally maintained at 0.7 C_a (concentration of ambient CO_2) even when C_a is varied (Drake and Gonzàlez-Meler, 1997). In our experiment, C_i of leaves under EC was generally higher than under ambient CO_2 treatments, that means perhaps change in C_i is closely related to C_a, and it also may be the reason of why g_s was decreased by EC.

DOI: http://dx.doi.org/10.15666/aeer/1702_42574268

Shifts in stomatal function and morphological response to CO_2 are likely to affect transpiration rates under rising atmospheric CO_2. In our study, reduction of stomatal aperture and conductance (g_s) explains the reduction in T_r observed in plants grown in EC.

Stomata display a wide range in short-term behavioral and long-term morphological responses to atmospheric CO_2 concentration (Haworth et al., 2013). In the short term, stomatal aperture generally decreases in response to high CO_2, as described earlier. In the long term, decreases in g_s can be caused by changes in stomatal density, as well as stomatal aperture (Ainsworth and Rogers, 2007), in the other hand, changes in leaf stomatal densities which in turn can control maximum values of stomatal conductance.

Ainsworth and Rogers' study (2007) showed that elevation of CO_2 in FACE experiments reduced stomatal conductance by 22%, yet this reduction was not associated with a similar change in stomatal density. However, some researchers believe that plants adapt to the elevated CO_2 by reducing their stomatal density (that is, the number of stomata per unit of epidermal surface area) (Engineer et al., 2014). One expectation at increased C_a is that fewer stomata are required because the rate of CO_2 diffusion into the leaf will be a decreasing limitation to photosynthesis as C_a rises (Drake and Gonzàlez-Meler, 1997). While in our experiment, there were no difference in stomatal density of mature *Q. mongolica* leaves detected among all treatments on 60th day (in the first season), but at the end of the second season (210th day), a significant decrease in stomatal density in response to EC was shown. Perhaps high CO_2 was detected by mature leaves in the first year and signaled to developing leaves in the next year, whose stomatal developments altered accordingly (Lake et al., 2001). Researchers believed that those species with little or no control of stomatal aperture (termed passive) to C_a were more likely to exhibit a reduction in stomatal density than species with active stomatal control when grown in atmospheres of elevated CO_2 (Haworth et al., 2013), that is perhaps why there was only a slight decrease in g_s of leaves detected in our experiment.

Modification to stomata abundance and size as a stress response is also stated an important pollutant absorption-controlling mechanism, and these parameters mutually affected each other. An inverse relationship between stomatal pore length or size and stomatal density has been observed in the gas exchange responses of plants in response to increased CO_2. However, a similar pattern was not observed in the species analyzed in Haworth's study (2013). While in our study, we can only see a slight increase in stomatal width of leaves in EC on 60th day ($P < 0.05$).

Effects of elevated CO_2 and O_3

It is concluded that season-long exposure to elevated CO_2 had a greater effect on photosynthetic parameters than elevated O_3 (Alison et al., 2001), while this result is opposite to ours. When high O_3 and high CO_2 were given in our experiment, P_n of leaves was still lower than control in the whole growing season except at the end of the season. It is also found that the combination of elevated O_3 and CO_2 can led to a significant decrease in the light-saturated rate of photosynthesis, but compared to elevated O_3 alone, the level of decrease was lower (Kellomäki and Wang, 1997). The study of the combined effects of elevated CO_2 and O_3 on photosynthesis show that elevated CO_2 compensated most of the adverse effects of O_3 (Reid and Fiscus, 1998). In our study, P_n of *Q. mongolica* leaves under EO+EC were nearly all significantly higher than EO in the whole seasons ($p < 0.05$). This suggests that O_3-induced adverse effects

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42574268

to photosynthesis can be ameliorated, at least partly, by high CO_2, but the complete mechanism behind this interaction is, however, still unclear.

There was no significant difference of g_s between the combination and EO treatments except after 60 days in the second season, which was mainly caused by EO but not EC.

It is found there was a significant interaction between elevated CO_2 and increased O_3, elevated $O_3 + CO_2$ led to a 14% decrease in F_v/F_m compared to the control (Kellomäki and Wang, 1997). While in this experiment, there was no significant difference in F_v/F_m detected under the combined treatment, compared to the control. High CO_2 can largely relieve the adverse effects of high O_3 to PSII reaction center.

Changes in stomatal parameters of *Q. mongolica* leaves under EO+EC were just like the changes of them under only EC exposure. Perhaps the effect of stomatal morphology was mainly caused by EC but not EO.

Conclusion

Q. mongolica is an O_3-sensitive tree species and EO had a severe impact on P_n of *Q. mongolica* leaves because of their young age. g_s and T_r of leaves was significantly decreased by EO at the beginning of the experiment, which indicates that the partial closure of stomata can be induced by EO to avoid the further ozone uptake. The stomata closure maybe associated with the direct effect of EO on guard cells. Under EO, there were decreases in F_0, F_m and F_v/F_m at the end of the season (after 75 days). This indicates EO can limit the capability of the plant to use photon energy and thus alter photosynthetic processes; EC generally increased P_n of *Q. mongolica* leaves, but decreased g_s slightly. The decrease of g_s is thought to maintain the ratio of C_i and C_a, and regulate the WUE of trees. A significant decrease in stomatal density in response to EC was shown only at the end of the second season (210th day) but not in the first season. Maybe, EC was detected by mature leaves in the first growing season and signaled to developing leaves in the next growing season, whose stomatal developments altered accordingly; Under EO+EC, P_n of leaves were still lower than that control, but nearly all significantly higher than EO in the whole seasons ($p < 0.05$). This suggests that O_3-induced adverse effects to photosynthesis can be ameliorated, at least partly, by CO_2. The decrease in g_s was mainly caused by EO but not EC. There was no significant difference in F_v/Fm detected under EO+EC, compared to control. EC can largely relieve the adverse effects of EO to PSII reaction center. Changes in stomatal parameters of leaves under EO+EC were just like the changes of them under only EC. Perhaps the effect of stomatal morphology was mainly caused by EC, but not EO.

Abstract. Flooding management is an effective and environmental-friendly way to reduce weed populations in paddy fields. However, flooding would also cause waterlogging in direct seeding rice production. The present study was conducted to explore the effect of different water management methods at the germination stage on rice growth and yield, with six rice varieties as materials. 0, 1, 2, and 3 cm water layer treatments at germination stage were set and named as I0, I1, I2 and I3, respectively. The result showed that I1 and I2 treatments significantly reduced seedling rate and seedling quality compared to I0. The highest yield was recorded during I0, while the yield in the case of I3 treatment was lower than the former but higher than I1 and I2. Similar trends were also recorded in dry matter weight at heading stage and maturity stage.
Keywords: *rice, water condition, seedling rate, seedling quality, yield, dry matter accumulation*

Introduction

Rice (*Oryza sativa* L.), as one of the main stable food crops, feeds more than half of the world's population (Ashraf et al., 2017). Pan et al. (2016) demonstrated that more than 60% of the population live on rice in China while rice makes up 40% of the country's total grain. It is very important to maintain the rice productivity and improved the yield potential of rice in China.

In Chinese history, transplanted rice production system has been the main rice production modern for a very long time (CabangonTuong and Abdullah, 2002). Traditionally, rice seedlings were transplanted in puddling condition. However, with the severe labor scarcity and low efficiency due to laborious nature of work and lower net returns, transplanted rice production system is becoming more and more unsuitable for Chinese agriculture (Tao et al., 2016). Direct-seeded rice, as a substitutive rice growing technique, has the benefit to reduced production costs, labor and extra efforts for nursery raising, seedling uprooting and transplanting (Liu et al., 2015). Pan et al. (2017) indicated that this new rice production system not only favors earlier crop establishments, but also provides an opportunity to make better use of early season rainfall, and finally leading

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer1702_42694279

towards increase the grain yield. Nevertheless, direct-seeded rice production system still has many parts no perfect enough.

Water management is an important part in rice production which could greatly affect rice yield and quality. The study of Kong et al. (2017) revealed that short term water management at filling stage was able to improve antioxidant enzyme activity and alleviate the damage from heat stress to rice. Ren et al. (2017) also demonstrated that feebly arid conditions (water potential of - (15 ± 5) kPa) at booting stage could increase 2-acetyl-1-pyrroline content in fragrant rice grains significantly. Normally, pre-germinated seeds would be hill-seeded in paddy filed in direct-seeded rice production system. The water management during the germination stage would be important for seedling growth and development. The research of Luo et al. (2018) showed that water layer higher than 4.5 cm would significantly inhibit the germination and seedling growth and decreased the antioxidant enzyme activity. However, there was no much report about the water management during the germination stage in direct-seeded rice production.

Therefore, present study was conducted in Experimental Research Farm, College of Agriculture, Yangtze University in order to investigate the effect of different water conditions at germination stage on rice growth and development.

Materials and methods

Seed materials

Seeds from six rice cultivars, *Wandao107*, *Liangyou168*, *Fengliangyouxiang-1*, *Fengliangyou-2*, *Guofeng-1*, *Quanyou801* were used as the experimental materials in this pot experiment. Those rice varieties were all widely grown in Middle China.

Treatment description and growth conditions

Before sowing, the seeds were soaked in water for 24 h, germinated in manual climatic boxes for another 10 h (33 °C), then shade-dried. Then, seeds were direct-seeded into soil containing plastic pots (30 cm in height and 450 cm^2 in surface area) and 50 seeds for each pot in triplicate. The different water managements were applied after the sowing and sustained for 25 days. The water layer treatment description is as below:

I0: Maintenance of 0 cm water layer at soil surface throughout day and night.

I1: Maintenance of 1 cm water layer at soil surface throughout day and night.

I2: Maintenance of 2 cm water layer at soil surface throughout day and night.

I3: Maintenance of 3 cm water layer at soil surface throughout day and night.

15 days after the sowing, the seedling rate was recorded and at 25 days after the sowing, twenty seedlings were collected randomly from each pot for the estimation of dry matter, seedling length, leaf surface area and chlorophyll content. Chlorophyll content was determined by using the SPAD meter ‘SPAD-502’ (Konica Minolta, Japan). Leaf area of all green leaf blades was measured with Li-Cor area meter (Li-Cor Model 3100, Lincoln, NE). Then, ten seedlings were retained for each pot and every pot in the experiment was remained at 3 cm water layer at soil surface until harvest. The experiment soil was sandy loam consisting 23.78 g/kg organic matter, 1.61 g/kg total nitrogen, 78.66 mg/kg available nitrogen, 0.87 g/kg total phosphorus, 21.79 mg/kg available phosphorus, 17.64 mg/kg total potassium, 151.09 mg/kg available potassium and 6.48 soil pH. The environment of climatic box were set as: 33 °C days and 27 °C nights, under 1200X yellow light intensity and 75% humidity.

Estimation of dry matter accumulation transportation

At heading stage and maturity, ten rice plants were collected for the determination of dry matter weight. The leaves, stem-sheaths and grains were separated from the plants and dried under the condition of 80 °C respectively in order to get the estimation of dry matter. Some parameters were calculated as below:

$$\text{Transportation rate in leaf} = \frac{\text{leaf weight at heading stage} - \text{leaf weight at maturity stage}}{\text{leaf weight at heading stage}}$$

$$\text{Transportation rate in stem} - \text{sheath} = \frac{\text{stem} - \text{sheath weight at heading stage} - \text{stem} - \text{sheath weight at maturity stage}}{\text{grain weight at maturity stage}}$$

$$\text{Contribution rate in leaf} = \frac{\text{leaf weight at heading stage} - \text{leaf weight at maturity stage}}{\text{grain weight at heading stage} - \text{grain weight at maturity stage}}$$

$$\text{Contribution rate in stem} - \text{sheath} = \frac{\text{stem} - \text{sheath weight at heading stage} - \text{stem} - \text{sheath weight at maturity stage}}{\text{grain weight at heading stage} - \text{grain weight at maturity stage}}$$

Determination of yield and yield related attributes

At maturity, twenty random rice plants were harvested and threshed manually and sun dried (adjusted to ~14% moisture contents) to get the grain yield per pot and expressed in grams per plant (g $plant^{-1}$). Grains were separated manually from each panicle to count total number of grains and number of filled grains per panicle. To record 1000-grain weight, six random samples from filled grains were counted, weighed and averaged. Panicle number per pot was measured by counting the panicle numbers of each plant in three pots in each treatment and averaged.

Statistical analysis

This study was managed as a randomized complete block design with three replicates (n = 3). Data were analyzed on Statistix 8.1 (Analytical Software, Tallahassee, FL, USA) at the probability level of 5% ($P < 0.05$). Differences among means were separated by using least significant difference (LSD) test.

Results

Seedling rate

As shown in *Table 1*, different water management affected seedling rate of different rice varieties differently. The highest seedling rate was recorded in I3 condition. Compared to other rice varieties, *Wandao107* had the highest seedling rate which was 67.50%. The lowest seedling rate was recorded in I1 treatment while the seedling rate in *Liangyou168* was lower than other rice varieties.

Seedling quality

There were some differences in seedling quality of different varieties under different water managements (*Table 2*). Compared to I0, I1 treatment significantly reduced leaf area and SPAD values while there was no remarkable difference among I0, I2 and I3 in leaf area and SPAD values. The highest plant height and shoot dry weight were both

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer1702_42694279

recorded in I3 and the lowest plant height, root length, shoot dry weight and root dry weight were all recorded in I1.

Dry matter accumulation

As shown in *Table 3*, different water managements at germination stage affected dry matter accumulation differently. At heading stage, the trend of leaf dry weight at heading stage was recorded as I0 > I3 > I2 > I1. Similar conditions were also observed in stem-sheath weight and grain weight. At maturity, the highest dry weight of leaf, stem-sheath and grain were all recorded in I0. There was no significant difference between I2 and I3 in stem-sheath dry weight and total dry weight. Moreover, the lowest dry matter weight was recorded in I1 at both heading stage and maturity.

Matter transportation and contribution during the filling stage

As shown in *Table 4*, different water managements during the germination stage affected the matter transportation during the filling stage differently. The leaf transportation rate in I0 was significantly higher than I2 and I3 which were 0.394, 0.374 and 0.372 while there was no significant difference among I0, I1, I2 and I3 in leaf contrition. The lowest stem-sheath transportation rate was recorded in I1 and there was no significant difference among I0, I2 and I3. Furthermore, the highest photosynthesis contribution rate was recorded in I1 and the lowest was recorded in I0.

Yield and related attributes

Different water management during the germination stage affected rice yield by regulating the yield related attributes (*Table 5*). The highest yield was recorded in I0 treatment as well as panicle number, grain number, seed-setting rate and grain weight.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer1702_42694279

There was no significant difference between I2 and I3 in yield, 1000-grain weight, seed-setting rate and grain number. Furthermore, I1 treatment had the lowest yield due to the lowest panicle number, grain number and 1000-grain weight.

Correlation analysis

As showed in *Table 6*, the rice yield had significant positive correlation with root length, leaf area, SPAD value and root dry weight of seedling. There also exited a significant positive correlation between panicle number and SPAD value of seedling. Furthermore, the dry matter weight of leaf, stem-sheath and grain at both heading stage and maturity had significant positive correlation with seedling quality (height, root length, leaf area, SPAD value, shoot dry weight and root dry weight).

Table 6. *Relationship among seedling quality, yield and dry matter weight*

		Height	Root length	Leaf area	SPAD value	Shoot dry weight	Root dry weight
Panicle number per plant		0.155	0.281*	0.260*	0.371**	0.132	0.220
Grains number per panicle		0.107	0.210	0.205	0.164	0.172	0.218
Seed-setting rate (%)		-0.218	0.110	-0.121	-0.162	-0.118	0.066
1000-grain weight (g)		0.060	0.141	0.077	0.141	0.125	0.153
Yield (g plant^{-1})		0.148	0.453**	0.259*	0.341**	0.152	0.412**
Heading stage	Leaf dry weight	0.616**	0.492**	0.658**	0.307**	0.529**	0.605**
	Stem dry weight	0.485**	0.6320**	0.482**	0.329**	0.440**	0.694**
	Grain dry weight	0.499**	0.592**	0.509**	0.331**	0.459**	0.685**
	Total dry weight	0.569**	0.623**	0.584**	0.347**	0.508**	0.715**
Maturity	Leaf dry weight	0.664**	0.558**	0.688**	0.357**	0.577**	0.659**
	Stem dry weight	0.476**	0.643**	0.462**	0.313**	0.427**	0.669**
	Grain dry weight	0.531**	0.635**	0.557**	0.417**	0.477**	0.663**
	Total dry weight	0.558**	0.658**	0.567**	0.383**	0.498**	0.699**

As shown in *Table 7*, there exited a significant positive correlation between seed-setting rate and stem-sheath dry weight. Both panicle number and yield had significant positive correlation with dry weight of leaf, stem and grain. Moreover, there was a significant positive correlation between grain number and stem-sheath dry weight.

Discussion

It is well known that water condition is one of the most important factors affecting the seed germination. Ismail et al. (2009) demonstrated water layer at 10 cm would greatly inhibit the germination and early seedling growth of rice. The study of Prakash et al. (2016) had evidenced that flooding treatments not only could significantly influenced the survival rate of rice seedling, but also was able to affect all the parameters of seedling quality such as shoot, root and total dry matter production. Present study also showed the similar conditions. Compared to I0, I1 treatment reduced the seedling rate significantly whilst there was no remarkable difference I0 and I3 in seedling rate. The possible reason might be the flooding stress at I3 level could stimulate the mechanisms which were associated with tolerance to flooding for some rice varieties (Zhang et al., 2017). For example, the lowest seedling rates of both *Wandao107* and *Fengliangyouxiang-1* were recorded in I2 while there was no significant difference between I0 and I3. Furthermore, we noticed that there was no much significant difference between I0 and I3 in seedling quality. Some parameters (seedling height and shoot dry weight) in I3 were even higher than I0. It might because the 3 cm water layer conditions would also be suitable for early seedling growth. Similar discovery was reported by Fan et al. (2017) who demonstrated shallow water irrigation during the seedling stage could significant improved seedling quality of fragrant rice.

Seedling quality is one of the factors which could greatly affect the rice yield. Previous study had shown that different seedling age significantly affected yield and economics of hybrid rice by influencing the growth and chlorophyll content (Pramanik and Bera, 2013). The study of Xia et al. (2000) revealed that magnetic treatment was able to up-regulate the rice yield by improving the seedling growth. Normally, it is generally recognized that good quality of rice seedling would be the base for high yield. Our study emphasized this point by showing the significant positive correlation between seedling quality and dry matter accumulation at heading stage and maturity while there exited a significant positive correlation between dry matter production and rice yield. Our founding was also consistent with previous study (Farooq et al., 2006) which stated that seedling establishment is a key part in rice production and good seedling quality could improve the potential of rice yield.

Furthermore, the highest yield was recorded in I0 and the yield in I3 treatment was lower than I0 but higher than I1 and I2. Luo et al. (2018) demonstrated that water layer higher than 3 cm would inhibit germination and growth of weed and volunteer rice. Thus, 3 cm water irrigation might be a management which is able to reduce the weed and volunteer without causing a great yield loss.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer1702_42694279

Conclusion

Compared to I0, I1 and I2 treatments significantly reduced seedling rate, seedling quality and the grain yield. I3 treatment was lower than I0 but higher than I1 and I2. Similar trends were also recorded in dry matter weight at heading stage and maturity stage. Therefore, the 3 cm water irrigation might be considered as a management which is able to reduce the weed and volunteer without causing a great yield loss. More studies should be conducted at the field trials or at molecular level before the real application.

(Received 26th Dec 2018; accepted 25th Feb 2019)

Abstract. Phosphorus (P) fertilizer application and increasing soil total P can cause environmental issues. Therefore, in the present study an experiment was carried out with optimal P-fertilizer recommendation based on the environmental aspects for two years (2015 & 2016). In 2015, 90 soil samples were collected from agricultural lands of Iran and their environmental P index (EPI) was estimated. Also, through maize greenhouse cultivation, the available P critical level was determined. Then, P requirement for 90 fields was assessed based on EPI and soil available P. In 2016, through an onsite field experiment, the effects of P fertilizer levels on yield were estimated. The results revealed that the farmers are permitted to apply P fertilizer only at 8 fields out of 90 according to EPI. While based on the soil available P, 36 farms of 90 need to receive P-fertilizer, and the farmers can apply P fertilizer only at 4 fields out of 36 according to EPI. Considering EPI with no P application farmers faced a 23% yield reduction. If the farmers are not satisfied with this reduction, increasing EPI with P application should reduce soil erosion. Using a 50 kg ha^{-1} P_2O_5 application should reduce soil erosion from 7 to 2 ton ha^{-1}.
Keywords: *maize, P-accumulation, total phosphorus, P index, P-fertilizer*

Introduction

Phosphorous (P), one of the macro elements essential for plant growth. Therefore, P-fertilizer application is crucial to reach the optimum economical yield. For decades, soil testing has been used for proper fertilization recommendation. In this method, the critical level of available P is considered as the criteria of P-fertilization (Malakouti, 2016). However, based on soil testing, P-fertilizer application may lead to P-accumulation, precipitation and increasing total P that may lead to environmental problems. It has been proven that most of the P-fertilizers (~80%) were precipitated in acidic soils (due to fixation by iron and aluminum oxides) and in calcareous soils (due to fixation by calcium carbonate) (Leytem and Mikkelsen, 2005). Recent studies have shown that soil total P is increased by long term P-fertilizer application in many countries (Li et al., 2015; Wei-Xia et al., 2015; Wang et al., 2015; Powers et al., 2016). For instance, Sun et al. (2015) reported that on average about 1.1 mg P-available per kg soil had been added to some Chinese soils annually in the 1997-2002 period. They also showed that the total P increased from 702 to 840 mg kg^{-1} from 1983 to 2002. Xiaoying et al. (2015) showed that changes in soil Olsen-P follow the application of P fertilizer, so that each 100 kg P ha^{-1} surplus increase the Olsen-P by 1~6 mg P kg^{-1}. Their results also indicated that soil organic matter and pH have important effects on the changes in soil Olsen-P by 1 kg ha^{-1} of P balance.

DOI: http://dx.doi.org/10.15666/aeer/1702_42814296

When soils' P increases, soil water erosion and runoff may able to transfer it into the surface water, rivers, lakes, etc. This may lead to bio-environmental issues such as cultural eutrophication (Sharpley et al., 2003; Bolster et al., 2014). Cultural eutrophication is the process that speeds up natural eutrophication because of human activity. Natural eutrophication is when a body of water becomes overly enriched with minerals and nutrients that induce excessive growth of plants and algae (Schindler, 2012). Surveys showed that 54% of lakes in Asia are eutrophic; in Europe, 53%; in North America, 48%; in South America, 41%; and in Africa, 28% (Ansari et al., 2010). On top of that based on scientific reports, in the region with enriched drinking water by P, the health of habitants is in risk e.g. neurological disorders (Yang et al., 2008). Fataei (2010) reported results from a laboratory experiment designed to study pollution condition of the Aras River in Moghan. Agricultural lands around the Aras River in Moghan are intensively farmed, and P pollution to surface waters and Aras River via surface runoff resulting from application of P-fertilization is a major concern. He has reported that the concentration of phosphorus has increased from 0.10 mg L^{-1} at the beginning of the river to 0.44 mg L^{-1} at the end of the river. Stephen et al. (2016) investigate long-term accumulation and transport of anthropogenic phosphorus in three river basins. They presented an analysis of P fluxes in three rivers, including harvested crops, published data on P-fertilizer, sewages and river fluxes. Their analysis show that the magnitude of P accumulation has varied over the past 40-70 years in mixed agricultural–urban landscapes of the Thames Basin, UK, the Yangtze Basin, China, and the rural Maumee Basin, USA. They demonstrated that human-dominated river basins may undergo a prolonged but finite accumulation phase when P inputs exceed agricultural demand.

Heretofore environmental scientists of developed countries have been used and established indexes and tough rules and regulations for environmental protection purposes (Bolster, 2011). Phosphorus sorption index (PSI) (Sims et al., 2000), the simple soil test (STP) (Nelson and Shober, 2012), the degree of Phosphorus saturation (DPS) (Ige et al., 2005) and environmental P index (EPI) (Nelson and Shober, 2012) have been successfully applied for this aim.

Among these indicators, EPI is a more accurate and complete index due to incorporate into a single index, factors related to soil management and to P-transport (Sharpley et al., 2003). The most recent EPI was presented by Bolster et al. (2014) which was categorized in three levels as low (less than 40), moderate (between 40 to 100) and high (more than 100). Based on this index categories, P-fertilizer application is not allowed if the total P equal or higher than 800, 600 and 400 mg kg^{-1}, respectively. In this method, EPI influenced by various parameters such as the amount of P fertilizer, available P, total P, soil erosion and method of P fertilizer application.

In this index risk, the agricultural yield was not considered and the reduction in biomass has not been taken into account. In contrast, the environmental index risk is not considered by the agricultural engineers and their fertilization recommendations are based on crop yield and response to fertilizer. This indicates the existence of the gap between environmental and agricultural scientist's perspectives.

Overall, as mentioned above, traditional P fertilizer application can cause environmental issues in all over of the world and continuing this trend may increase crop yield and production but may destroy and damage the environment. So, it seems necessary to carry out the research to fill the gap between the two mentioned aspects in which the optimum yield with low environmental risk is achieved.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42814296

The main aim of this study, that is conducted the first time till now, is assessing and investigating P fertilizer recommendation based on the combination of agricultural and environmental aspects. Within this research we are trying to answer the following questions “how would be the yield reduction if the farmers consider environmental risk index comparing to considering only soil testing analysis in P-fertilizer application?” and “if the yield reduction is not the favor of farmers and so they tend to apply maximum P fertilizer for maximum economical yield, what should they do to reduce environmental risk index?”

Materials and methods

At the present study, three experiments including determination of EPI, determination of available-P critical level for maize and field experiment were carried out to optimal P-fertilizer recommendation based on the environmental aspects in two years (2015 & 2016).

The Study area description

This experiment was carried out in 90 fields of Moghan Agricultural lands. Moghan is located at latitudes 39^{O}20'N and 47^{O}30'E with 40-50 m above sea level, in the North-West of Iran (*Figure 1*). The climate of this region is considered as semi-arid with average annual precipitation of 271.2 mm. This region with more than 62024 hectares of cultivated land is surrounded by the Aras river. The river has got thousands of branches, so the eroded soils, sediments and runoff from these lands flow into this river. Aras river provides drinking water to tens of cities and villages and irrigation water to thousands of hectares of land (Nasrabadi et al., 2009).

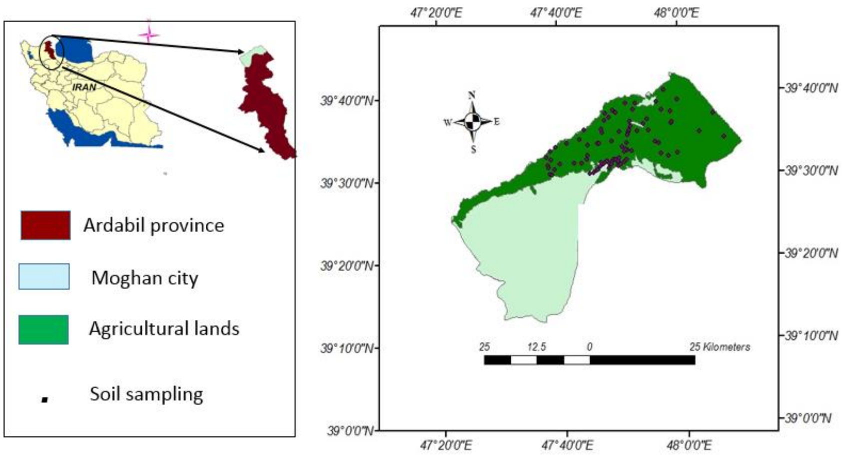

Figure 1. *The location, layout and sampling locations of the study site*

First experiment: determination of EPI for 90 fields and assessment of the P-fertilizer recommendation

In this part of the study, some soil factors such as soil total-P, available-P was obtained from laboratory analysis of soil samples. A number of other factors, including the method and amount of phosphate and organic fertilizers, were asked from farmers, and factors such as soil erosion were estimated from the defined models.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42814296

The EPI, used in this study, was estimated based on the method presented by Bolster et al. (2014). In this section, the generalities are explained briefly. The general formula (*Eq. 1*) for EPI and how to calculate the sub-formulas can be written as:

$$\mathbf{EPI=18\ [(DP_{Soil}+ DP_{Fert}+ DP_{Man})\ BMP_{DP}+ P_{Sed}\ (BMP_{Psed})]} \quad \text{(Eq.1)}$$

DP: Dissolved P; **BMP**: Best management practice; **P_{sed}**: Particulate P loss from erosion; **Fert**: inorganic fertilizers; **Man**: organic fertilizers.

Where all the components are explained in detail as follow:

DP_{Soil} estimation method: DP_{Soil} refers to the part of the dissolved P in runoff released from the soil. The following equation (*Eq. 2*) was used to calculate the DP_{soil}:

$$\mathbf{DP_{Soil}} = 0.1 \times STP \times PX \times RQ \quad \text{(Eq.2)}$$

where STP is the amount of soil P (mg kg^{-1}). **PX** refers to the coefficient of P extraction (µg L^{-1}), obtained from the relation, Y = 1.8X + 78.9, where Y and X are PX (µg L^{-1}) and soil P (mg kg^{-1}), respectively (Vadas et al., 2005; Bolster et al., 2014). RQ is the average annual runoff (cm).

DP_{fert} estimation method: This identifies the role of chemical fertilizers used in runoff dissolved P. The following equation (*Eq. 3*) was used to calculate this factor.

$$\mathbf{DP_{Fert}} = 0.5 \times 0.43 \times P_F \times (RQ \div PT) \times AF_F \quad \text{(Eq.3)}$$

where DF is Amount of fertilizer added (Kg $_{P2O5}$ ha^{-1}). AF_F is related to the time and method of using the fertilizer. It is obtained from the tables provided by Bolster et al. (2014). **PT** refers to the average annual sediment (cm) and is calculated from the following formula (*Eq. 4*).

$$\mathbf{PT} = 38.77\ e^{0.0353\ R} \quad \text{(Eq.4)}$$

in which, R is degree of sedimentation (the total sum of the scores considered in the MPSIAC model), **PT** is annual deposition rate (m^3 km^{-2}) and P_{sed} estimation method: In fact, this factor estimates the particulate P transferred by soil erosion. The following formula (*Eq.5*) was used to calculate it.

$$\mathbf{P_{Sed}} = 10^{-6} \times TP \times SED \times PER \times SDR \quad \text{(Eq.5)}$$

where, **TP** is related to soil total P (mg kg^{-1}) which was obtained in this experiment by alkaline melting method for all the samples. **SED** refers to the annual average soil erosion (kg ha^{-1}), which was estimated by the MPSIC method. **PER** refers to the ratio of soil particle enrichment, which means that fine particles are much richer in P than coarse particles. **SDR** refers to the proportion of sediment delivery and part of the amount of erosion soil that goes to the runoff.

SDR=1 slope length < 3 (m), **SDR** = -0.17* in (slope length) + 0.9 slope length ≥ 3 (m).

In general, in this study, soil erosion estimated by MPSIC method. Modified Pacific Southwest Inter-Agency Committee (MPSIC) uses nine factors including geology, soil, climate (including isotherm and isohyets), runoff, topography (including elevation and land slope), land cover, land use, upland erosion, and channel erosion. The values of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42814296

these factors are ranked based on the corresponding tables. Each of these factors is to be ranked based on a visual appraisal of the watershed. Generally, this model has been widely applied at a watershed scale in arid and semiarid regions of the USA and was assessed for its applicability to Iranian watershed environments (Bagherzadeh and Daneshvar, 2013). In *Figure 2*, a part of the water erosion is observed in the studied area.

Figure 2. *Flooding of river and eroded soils from the studied area*

BMP_{DP} and **BMP_{Psed}**: are based on tables provided by Bolster et al. (2014). In fact, these are related to any land conservation operation that can reduce DP (DP_{Soil}+DP_{Fert}+DP_{Man}) and P_{sed}.

DP_{fert}: Considering that the use of organic fertilizers in this area is negligible, this sector was considered insignificant.

Based on EPI explained above, P-fertilizer recommendation is summarized in *Table 1*.

Table 1. *Recommendation of P-fertilizer based EPI (Bolster et al., 2014)*

Range	Category	Interpretation
0-40	**Low**	If the soil total P is ≥800 (mg kg^{-1}), P- fertilizer should not be used
40-100	**Moderate**	If the soil total P is ≥600 (mg kg^{-1}), P- fertilizer should not be used
>100	**High**	If the soil total P is ≥400 (mg kg^{-1}), P- fertilizer should not be used

In this section of the study, for calculation and better interpenetrating the DOP (Deviation from optimal percentage) equation (*Eq. 6*) (Montanes et al., 1993) can be used as follow:

$$DOP = \left(\frac{Soil\ total\ P}{Maximum\ acceptable\ P} * 100\right) - 100 \quad \text{(Eq.6)}$$

In this equation soil total P and maximum acceptable P were driven based on EPI according to *Table 1*.

DOI: http://dx.doi.org/10.15666/aeer/1702_42814296

Second experiment: determination of available-P critical level for maize and spatial assessment of P-fertilizer requirement

In order to determine a critical level of available-P for maize (SC 704, (MO_{17}×B_{73}), in maturity group of late hybrid with a growth period of 274 days), the greenhouse experiment was carried out. The experimental design was randomized completely plots with two treatments and three replications. Initially, 30 soil samples with significant variation of available and total P were selected and P-fertilizer treatments were applied at two levels of 0 and 100 kg ha^{-1} from super phosphate [$CaH_4(PO_4)_2$ H_2O]. To do so, 180 pots of 10 kg soil were used. The similar amount of other nutritious elements (100 mg kg^{-1} N from urea [$CO(NH_2)_2$] in two times, 50 mg kg^{-1} K of potassium sulfate (K_2SO_4), 20 mg kg^{-1} Mg from magnesium sulfate ($MgSO_4$), 10 mg kg^{-1} Fe from Iron sulfate [$Fe_2(SO_4)_3$], 2 mg kg^{-1} Cu from copper sulfate ($CuSO_4.5H_2O$) and 2 mg kg^{-1} boron from boric acid (H_3BO_3)) were applied to all pots equally.

One day after soil amendment, six corn seedlings (pre-germinated by placing pre-soaked corn seeds on wet paper towels for five days) were transplanted per pot, and then thinned to two after one week. Pots were periodically weighed to maintain soil moisture at 80% field capacity. Corn was harvested after 185 days by cutting above-ground biomass at the soil surface, which was weighed. Then, critical level of available–P was calculated based on Cate and Nelson method (Cate and Nelson, 1971). Finally, the P requirement of 90 fields was compared and assessed with soil available P and measured critical level.

Third experiment: field experiment and yield reduction estimation due to integrating environmental index and fertilizer recommendation

The field experimental design was a randomized complete block design and three replications. Treatments were 0 (the control without P application), 100, 150, 200 and 250 kg ha^{-1} of super phosphate. As mentioned above other nutrients were applied to all plots equally. The size of each plot was 3×4 m in which 300 seeds were planted in each (in 20 cm interval). After harvesting, in addition to measuring P in the plant, the shoot yield of each treatment and environmental index of different treatments were calculated. In *Figure 3*, field experiment of corn cultivation is observed in the studied area.

Figure 3. *Field experiment of corn cultivation*

Soil Samples laboratory analysis

Soil samples were air-dried and sieved through 2 mm sieve. Soil properties were determined according to Page et al. (1982). Particle size analysis was made using the hydrometer method (Gee and Bauder, 1986). The pH of the soil samples was measured in a 1:1 (w/v) soil to water ratio suspension (McLean, 1982). Organic matter was measured using Walky and Black method (Nelson and Sommers, 1982). The available-P and total-P were measured using the Olsen method (Olsen, 1954; Pasricha et al., 2002) and alkaline melting (Jackson, 1958), respectively.

Investigating spatial variation and the mapping of variables

To assess the spatial variability, first, the most important statistical description and distribution indexes were performed for all soil samples. The mean, min, max, variance, mod, skewness and coefficient of variation of available-P, total-P and EPI were calculated. The out of ranged data has been removed and some properties were logarithmically transformed to have a lognormal distribution. After all, the semivariogram was plotted and the correlation coefficient was evaluated. Statistical and geostatistical analysis have been performed using IBM SPSS (version 20) and GS+(version 5). For the statistical analysis, Analysis of variance (ANOVA) was used in combination with Duncan method at 0.05 significant different tests. The distribution maps of soil properties in the study area were mapped using ArcGIS (version 10.4).

Results and discussion

Results of the first experiment

Determination of EPI for 90 fields and assessment of the P-fertilizer recommendation

The EPI status of 90 fields of the study area is presented in *Figure 4*. The minimum and maximum and average values of EPI were 40, 72 and 55, respectively. According to categories and the recommendation of this index (*Table 1*), most of the fields are classified in medium level in view of risk assessment. In the fields with total-P more than 600 mg kg^{-1}, application of P fertilizer is limited (*Table 1*).

Considering *Eq. 6* shows that if DOP is positive it means soil total P was higher than total P of the environmental index and thus P fertilizer cannot be used in that field (and vice versa). Results of this part of study are shown in *Figure 5*. Results showed the farmers are permitted to apply P fertilizer only at 8 fields of 90 fields according to EPI. In other words, in case of plant requirement, P fertilizer application in current condition causes environmental degradation.

It should be noted that EPI has been introduced for decades in which the first one was presented by Lemunyon and Gilbert (1993). Reports and assessments based on EPI were presented by many environmental scientists. Heathwaite and Sharpley (1999) used the soil available P between 75 to 200 mg kg^{-1} as the critical level for environmental protection and P fertilizer application. This critical level was obtained based on significant statistical relation between available and soluble P (r^2= 0.58 – 0.98). Nair et al. (2004) reported the critical environmental index based on P saturation ratio (molar ratio of P to Fe+Al). Based on statistical relation between dissolved P in runoff and soil P saturation ration, they observed if P saturation ratio become more than a value (normally 0.1), the P concentration in runoff increased by applying P fertilizer.

DOI: http://dx.doi.org/10.15666/aeer/1702_42814296

These methods are under critics by agricultural scientists. Because these recommendations are based only on environmental parameters and plant growth is not considered. Therefore, in such cases, a method that considers both the agricultural and environmental aspects is worthwhile (Malakouti, 2016).

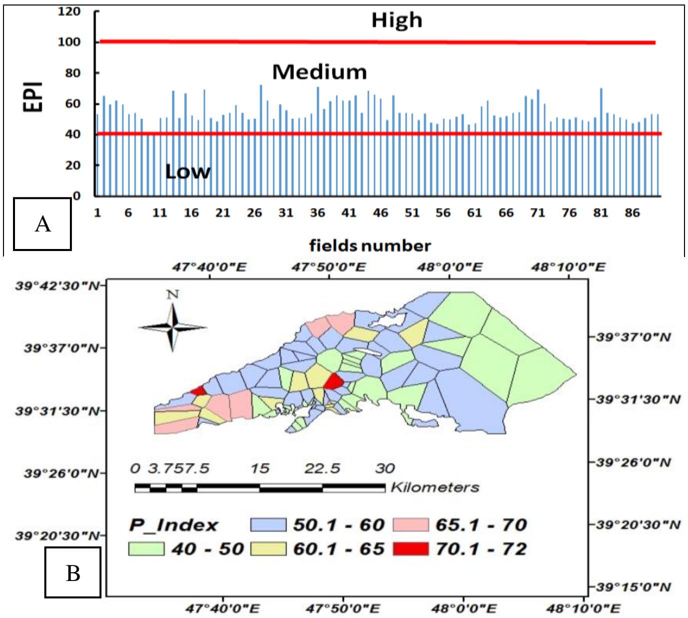

Figure 4. *EPI values in the fields (A) and zoning of agricultural fields based on EPI (B).* ***Low****: 0<EPI<40; If the soil total P is ≥800 (mg kg^{-1}), P-fertilizer should not be used.* ***Medium****: 40<EPI<100; If the soil total P is ≥600 (mg kg^{-1}), P-fertilizer should not be used.* ***High****: 100<EPI; If the soil total P is ≥400 (mg kg^{-1}), P- fertilizer should not be used (Bolster et al. 2014)*

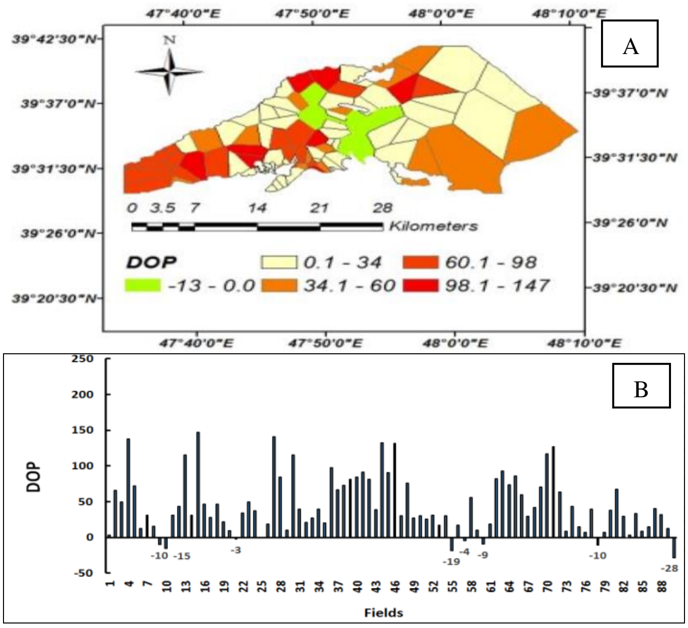

Figure 5. *DOP values in the fields (A) and zoning of agricultural fields based on DOP (B). If* ***DOP*** *<0, farmer can use P-fertilizer; If* ***DOP*** *>0, farmer cannot use P-fertilizer*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42814296

The effects of soil total P and soil water erosion on EPI are indicated in *Figure 6*. According to scientific reports, soil water erosion is very effective in the runoff enrichment potential. So, deflation and some environmental indexes like phosphorus sorption index and degree of phosphorus saturation (because of ignoring the importance of soil erosion) cannot be accurately used to assess the potential of P losses from fields (Sims et al., 2000). Although in the studied area, the annual amount of rainfall is low, but a large part of the annual precipitation occurs in four months when the land is free of vegetation cover. This factor and other factors such as heavy texture, low organic matter, and low permeability caused high soil water erosion. Also, in this area, wind erosion (deflation) is less important because of the low wind speed. In general, the amount of phosphorus in the river is more affected by water erosion. Because, in the water erosion, all the eroded soil and both forms of phosphorus (dissolved and particulate P) enters the river. The significant correlation between EPI and soil total P and soil erosion indicates that EPI is strongly influenced by these parameters. t is obvious that when soil total P is high, more P can be removed from the field with particles of soil. In this regard, scientists have criticized the accuracy of EPI in which soil total P is not involved (Bolstre et al., 2014).

Overall, from this part of the study, fields that EPI does not allow farmers to use P-fertilizers, was identified. It was also found that a farmer can reduce EPI by controlling soil erosion or reducing soil total P. The important thing is that we must combine these finding with agricultural finding, which we have tried to do with the next experiments of this study.

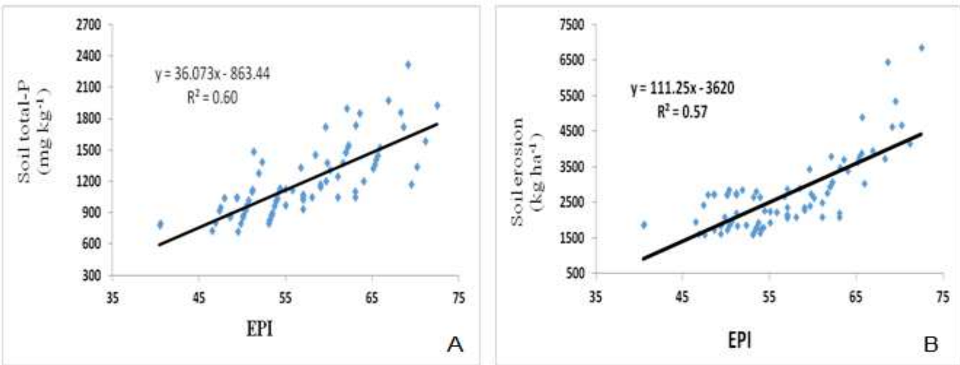

Figure 6. *Relationship between EPI and soil total P (A) and soil erosion (B)*

Investigation of spatial distribution of EPI and total P

Some of the descriptive statistics of data and semivariogram of total P and EPI are shown in *Table 2* and *Figure 7*, respectively. In this kind of experiments, understanding the variation of factors affecting soil total P and EPI are important whether from soil interstice properties (parent material or topography) or management practice (fertilizing) are affecting them. In geostatistics, it can be achieved by calculating spatial dependence of variables. Spatial dependence can be calculated by the effect of the part over the threshold level. If this ration is less than 25, or between 25-75 and higher than 75 so, spatial dependence is considered as high, moderate and week respectively (Chien et al., 1997). In most cases, high spatial dependence is affected by internal processes (parent material, hydrological situation, etc.) and week spatial dependence is affected by

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42814296

management practice and fertigation (Cambardella et al., 1994). According to variograms of variables (*Figure 7*), it can be noticed that both semivariograms of soil total P and EPI have the limits and are moderate spatial dependence. So, they are influenced by interstice soil properties and management practices.

***Table 2.** Descriptive statistics of soil total-P and environmental P index data*

Factors	Minimum	Maximum	Average	Middle	Standard deviation	Variance	Skewness	Kurtosis
Soil total-P (kg ha^{-1})	618	2315	1186	1107	331	1.1	0.36	-0.74
EPI	40	72	55.5	53.4	7.2	51.9	0.30	-0.48

Results of the second experiment

Determination of available-P critical level for maize and assessing P requirement for 90 fields

Figure 8 shows available P critical level of study soils (the data for this figure is provided in the *Appendix*). Critical level indicates field requirement to P-fertilizers but does not show the amount of P to be applied. As it is obvious, the critical level of soil available P was 13 mg kg^{-1} using Olsen method. For maize in various locations, different values were reported (Fernandes et al., 2000; Malakouti, 2016). The reasons for the differences may be climate conditions, soil texture, crop yield potential and etc. Results of assessing P requirement for 90 fields based on soil available P critical level are presented in *Figure 9*. Generally, 36 fields have got available P less than 13 mg kg^{-1}. Many years ago, this method was one of the most principled methods of fertilizer recommendation in agriculture and many countries still use it.

Recently, the use of this method has been challenged due to increasing EPI and soil total-P (Gou et al., 2000; Ma et al., 2009; Malakouti, 2016). This method and phosphorus chemistry in the soil causes its accumulation in the soil. Thus, about 20% of the fertilizer that is consumed is absorbed by the plant and the remaining is deposited in acidic (high Al^{2+} and Fe^{3+}) and calcareous (high Ca^{2+}) soils (Marschner, 2011). Many researchers have reported that the use of P fertilizer based on this fertilization method, causes P accumulation in most regions of the world and in the future will restrict farmers in the use of P-fertilizers (Johnston and Steen, 2000; Li et al., 2015; Keke et al., 2016). In this regard, it has been reported that change in the current fertilizers recommendation is necessary because P accumulation subject (increasing EPI) is in contrast to sustainable agriculture (Malakouti, 2016).

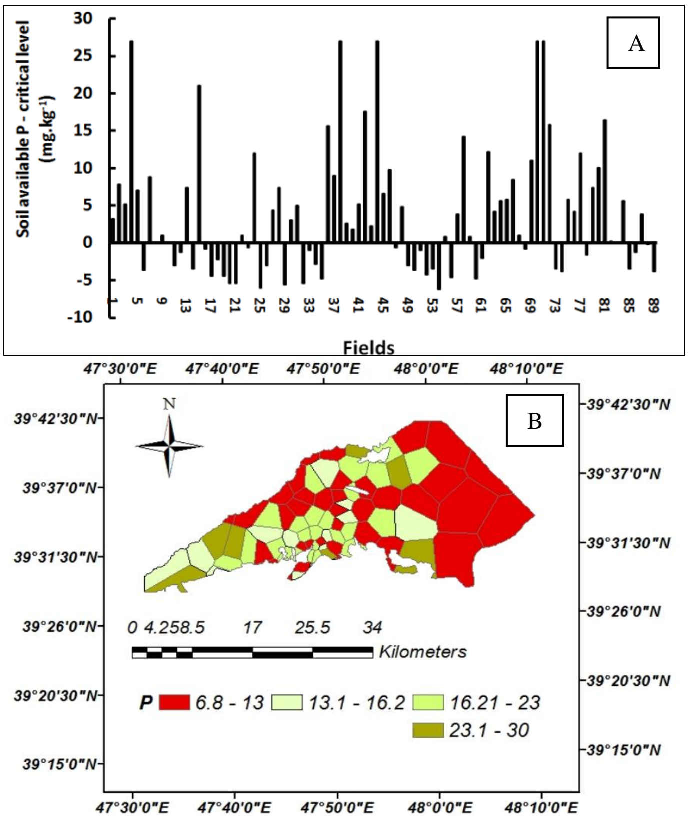

Figure 9. *Available P status of fields as compared to critical level (A) and zoning of agricultural fields based on soil available P (B). If (Soil available P - critical level) <0, P-fertilizer should be used*

Using the results of the first experiment and its match with the results of this part of study can help us.

Considering *Figure 5* in which field were assessed based on EPI, it can be noticed that the farmers can apply P fertilizer only at 4 fields where their DOP are negative. In other fields, P application can causes environmental problems while they need P-fertilizer. Therefore in this case, the fields can be divided into 3 groups. First, the regions where do not need any P fertilizer; second the regions where need P-fertilizer

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42814296

and do not have any limitation for P application; and third the region where need for P-fertilizer but the application of P is limited by EPI. When a farmer cannot use P-fertilizer (based on EPI), he can take one of the following decisions:

- The farmer doesn't apply P-fertilizer and accept yield reduction. In this case, the state or the environmental organization must pay subsidies to farmers. Otherwise, it would be hard to recommend environmental indicators and acceptance of financial compensation for farmers.
- The farmer provides possibility of P-fertilizer by reducing EPI.

This issue can be examined in the next results of the present study.

Third experiment

In the field, experiment, available-P and total P were 8.6 and 1025 mg kg^{-1}, respectively. In this field the EPI is 26, in case of without P application and with erosion rate of 7 ton ha^{-1} y^{-1}. According to EPI (*Table 1*) P fertilizer is limited while based on low available P (<13 mg kg^{-1}) P application is needed.

Effects of P fertilizer level on soil total P

According to *Table 3* and the soil P balance (amount of P extract by crop - applied P by fertilization ignoring runoff), 3.8, .24, 1.26, 2.7 and 6.02 mg P was added to each hectare while using 0, 15, 20, 25 and 35 kg P_2O_5 per hectare respectively during growing season. However, these values are not comparable to soil total P. In other words, in the same condition the differences between total P and these values do not change EPI during a growing season. But for longer period fertilization can significantly effect on total P and EPI.

It should be mentioned that reports related to P application on increasing soil total P are based on long period i.e. 20 years. For instance, Sun et al. (2015) in their geostatistics study, investigated long period (20 years) of P accumulation in Chinese agricultural fields. They reported that P was added from 60 to 159 kg ha^{-1} during 1982 until 2002 and soil total P increased from 0.72 to 0.84 gr kg^{-1} (16.7%). Li et al. (2015) investigated long-term (20 years) P fertilizers application on soil available and total P and of rice. Their results showed P application increased soil total P considerably and changed it from 600 to 719 mg kg^{-1}.

Effects of P- fertilizer on yield, EPI and reduce EPI by controlling erosion

Based on *Table 3*, considering EPI and no P application farmers faced with 23% yield reduction. If the farmers with any reason are not satisfied with this reduction, the minimum things to be done is considering the management practice in which EPI is not increased. In other words, increasing environmental index from P application is reduced by other factors like soil total P and soil erosion.

Based on short-term results there is not any option to reduce total P but based on *Table 4* controlling soil erosion can be one of the immediate and effective solutions in protecting environment for farmers. According to *Table 4*, the farmers can reduce EPI by reducing erosion rate from 7 to 4 ton ha^{-1} y^{-1} so they can apply 25 Kg ha^{-1} P_2O_5 without increasing EPI. In the aim of this protocol, for using 50 kg ha^{-1} P_2O_5 the applicant should reduce soil erosion from 7 to 2 ton ha^{-1} where increasing EPI will not occur.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42814296

Bolster (2014) showed that reducing water erosion by conservation practices can reduce 50% of EPI. In this study, in six fields with excessively high (>2.24×1000 kg ha^{-1}) soil erosion rates, soil erosion was reduced by conservation practices such as buffer/filter strip, sediment basin, and water control structure and effect of soil erosion on environmental P index was investigated.

Table 3. *Effects of P-fertilizer level on yield and bill of P in soil*

Treatment	Added-P to soil	Yield (dry weight)	P concentration in plant	Removed-P by plant	Soil P balance	Reduced yield
	(kg ha^{-1})		%	(kg ha^{-1})		%
T_0	0	7381^1	0.15^1	11.32^1	11.32-	-23
T_1	15	8737^2	$0.16^{1,2}$	14.27^2	0.73	-8.8
T_2	20	9359^3	$0.17^{2,3}$	16.22^3	3.78	-2.3
T_3	25	9564^4	0.18^3	16.90^3	8.1	-1.9
T_4	35	9582^4	0.18^3	16.93^3	18.07	0

In each column, similar numbers indicate that meanings do not differ significantly in the 5% level
Soil P balance= amount of P extract by crop - applied P by fertilization ignoring runoff

Table 4. *Interaction of soil erosion and P-fertilizer on P environmental index*

P-fertilizer (kg P_2O_5 ha^{-1})	Soil erosion (kg ha^{-1})							
	0	1000	2000	3000	4000	5000	6000	7000
0	1	6	10	14	17	20	23	**26**
25	9	15	19	22	**25**	28	31	34
50	17	23	**27**	31	34	37	40	43
75	**26***	32	36	40	43	47	50	53
100	35	41	45	48	51	54	57	60

* Bold numbers are the minimum amount of EPI that farmer should avoid increasing it by appropriate ratio of P-fertilizer and soil erosion

Conclusions

Results of this study showed that minimum, maximum and mean of the EPI are 40, 72 and 55, respectively. According to categories and recommendations of the environmental index used in this study, only 8 fields of 90 fields are allowed to apply P fertilizers.

The soil available P of 36 fields was less than 13 mg kg^{-1} (critical level of available P) and P fertilizer application is crucial. But based on EPI, P fertilizer can be applied only at 4 fields of 36 fields. P application can be depredated environment for other fields.

In the meanwhile, without P application, yield reduction will be about 23%. If the farmers with any reason are not satisfied with this reduction, the minimum things to be done is considering the management practice in which EPI is not increased. In the other words, increasing EPI from P application is reduced by other factors like soil total P and soil erosion.

Results showed controlling soil erosion can be one of the immediate and effective solutions in protecting the environment for farmers.

It should be noted that the cumulative increasing of soil total P cannot be ignored. Because in short-term (one growing season) P application may not increase total P significantly, but in the longer period it can be influenced on to EPI.

DOI: http://dx.doi.org/10.15666/aeer/1702_42814296

Finally, the uncertainty of the results for other region is obvious, but each researcher by applying this methodology can recommend fertilizer application more precisely and multi-purposes considering agro-environmental.

EFFECT OF PARACETAMOL ON ANTIOXIDANT SYSTEM AND OSMOPROTECTANTS OF MUNG BEAN (*VIGNA RADIATA)*

ALMOHISEN, IBRAHEM A. A.

Shaqra University, College of Science and Humanitarian Studies, Qwaieah 11971, Saudi Arabia
(e-mail: ibraheem@su.edu.sa)

(Received 26th Dec 2018; accepted 20th Feb 2019)

Abstract. There is no report on panadol mediated changes in antioxidant system and osmoprotectants of *Vigna radiata* plants. An experiment was carried out to dissect the response of activities of antioxidant enzymes, stress biomarkers and proline accumulation in the presence of panadol in *Vigna radiata* plants. 10 days after germination, a range of panadol concentration (0.0005, 0.01, 0.1 or 1.0 ppm) was administered to the foliage of *Vigna radiata* plants, at the end of germination process (30 days from the beginning of germination) the plants were sampled to evaluate stress biomarkers, leaf water potential, antioxidant enzymes and proline content. The results demonstrate that the highest concentration of panadol was 1.0 ppm that induced oxidative stress that was noticeable via increasing levels of lipid peroxidation, and H_2O_2 accumulation in *Vigna radiata* plants. On the other hand, 0.1 ppm of PD treatment modified the antioxidant system and the range of osmolytes to make the plants tolerate unfavorable conditions and helped to increase gross production through increasing photosynthetic activity.
Keywords: *panadol, proline, mung bean, biomarker, stress physiology*

Introduction

In the recent years, researchers have dissected out the role of pharmaceutical drugs and how they can affect target organs in the human body and how to make the drugs insistent so to maintain their chemical structure long enough to do their remedial work (Heberer, 2002; Kümmerer, 2004). However, the possible physiological and ecological influence of those compounds on non-target species or the environment are neglected (Hilton and Thomas, 2003). Therefore, the release of pharmaceuticals compounds in the environment is going to emerge as a great concern for both the ecosystem and human health (Kümmerer, 2004; Picó et al., 2017). Many prescribed drugs for humans are not completely absorbed by patients' body following intake, and approximately more than fifty percent of these are excreted as human waste to sewage systems in a non-biodegradable form or degraded to only a certain extent (Breton and Boxall, 2003; Hilton and Thomas, 2003).

Panadol (Paracetamol/Acetaminophen; PD) which represents one of the most widespread pharmaceuticals in surface waters and sediments even after wastewater treatment in the world, has negative effects on humans, animals, microbes, and plants (Kümmerer, 2004; An et al., 2009). Kolpin et al. (2002) found that 10 USA streams are contaminated with PD at maximum concentrations up to 10 ppm. In Madinah City-Saudi Arabia alone, tons of PD had been dispensed by public hospitals and medical clinics in the year of 2009 (Shraim et al., 2017). Even though wastewater treatment plant may remove 80% of PD in the water, they are far from the negligible amount (Ternes, 1998, 2000; Heberer, 2002). Increased human population in Saudi Arabia also may increase the consumed and unused PD, which lead to steady continual increase of PD in the wastewater. Continual use of sewage sludge and reclaimed waters in irrigation may lead to increased concentration of Panadol in agricultural lands (Kümmerer, 2004; Alyemeni et al., 2014).

Mung bean, *Vigna radiata*, Fabaceae, *Vigna* genus include about 150 species. One of the most important crop plants among these species is *Vigna radiata* with green seeds. Mung bean contains about 23.9% protein; rich in lysine which is generally low or deficient in cereals. Mature seeds are rich in proteins. The tender pods of mung bean are also consumed as vegetable (Agrawal et al., 2006). Its fast growth and sensitivity to abiotic stress make it suitable as a test subject to understood the phytotoxic effect of PD toward crop plant (Fariduddin et al., 2014).

In our previous study, we have found that varied concentrations of Panadol influences the photosynthetic efficiency of *Vigna radiata* plants in a concentration dependent manner (Al-Muwayhi, 2018; Almohisen, 2018). Therefore, it is essential to dissect out the behavior of antioxidant enzymes and osmoprotectants to unravel the panadol mediated changes in antioxidant systems and osmoprotectants.

Materials and Methods

Growth conditions and analysis of various parameters

Seeds source of *Vigna radiata* was from National Seed Corporation Ltd., New Delhi, India. Healthy seeds were decontaminated with 1% Chlorox (NaOCl) for ten minutes, and then washed twice with distilled water. Panadol was used as the source of Paracetamol. It was acquired from Sigma Aldrich India Ltd. The stock solution of PD (10 ppm) was obtained by dissolving the required amount (0.0000005, 0.00001, 0.0001 and 1 mg) of paracetamol in distilled water in a volumetric flask and the final volume was made up to the required volume. The required concentrations (0.0005, 0.01, 0.1 or 1.0 ppm) of PD were prepared by diluting stock solution and the concentrations of PD was based on the screening of various concentrations (Data unpublished).The seeds were sown in washed sand media, and allowed to germinate in growth chamber. The sand media kept moist using deionized water. When germination completed, the seedlings were irrigated with a solution of nutrients (Hewitt, 1966) every other day during the experimental period. At day 10^{th}, the seedlings sprayed with deionized water (control), and 0.0005, 0.01, 0.1 or 1.0 ppm of PD for 10 days. Each seedling was speckled. The sprayer nozzle was adjusted to push out approximately 1 mL in one spray. Thus, each seedling received 3 mL of deionized water or PD treatement. The plants were grown under controlled conditions that is the average temperature ranged between 28/22°C day/night, maximum 75% relative humidity (RH) at day and minimum RH was 65% at night, and the photoperiod was 14 hour. Irrigation was applied with deionized water and nutrient solution on every other day. Harvesting of plants began at 30 days stage to estimate the chlorophyll content, net photosynthetic rate, maximum quantum yield of PSII and related attributes. The experimental design was completely randomized block design (CRB). Total cups were 25, cup size was 350 mL, each cup contained three plant and replicated five times. The replication of treatment was five times. The leaf water potential (LWP) was measured in the fully expanded leaves of the plant using Psypro Water Potential System (Wescor, Inc. 370 West 1700 South Logan, Utah 84321, USA).

Estimation of Lipid peroxidation rates was performed with the measurement of the malondialdehyde equivalents as described by Hodges et al. (1999). 80% ethanol was used to homogenize 0.5 g of the leaf. Then the homogeneous sample was centrifuged at 3000g for 10 minutes under 4°C temperatures. The pellet was extracted twice with the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42974303

same solvent. 1 mL of supernatant was added to a test tube containing the same volume of a solution of 20% trichloroacetic acid, 0.01% butylated hydroxy toluene and 0.65% thiobarbutyric acid.

Samples were heated for 25 min at 95°C, and then cooled down to 24±1°C. Wavelengths of 440, 532 and 600 nm were used to measure absorbance of the samples. The formula of Hodges et al. (1999) was used to calculate Lipid peroxidation rates equivalent (nano mole malondialdehyde mL^{-1}).

The accumulation of hydrogen peroxide was estimated according to the method explained by Jana and Choudhuri (1982). 500 mg from samples was homogenized in 3.0 mL of phosphate buffer (50 mM and pH 6.8). Then the homogeneous sample was centrifuged for 25 minutes at 6000g.

3.0 mL from the extract was mixed with 0.1% titanium chloride in 20% (v/v) sulphuric acid, the mixture was centrifuged at 6000g for 15 minutes. A spectrophotometer was used for the measurement of color absorbance at 410 nm, and the color absorbance was compared with that of the calibration curve. The standard curve of known concentration of H_2O_2 was used to compute H_2O_2 content on fresh mass basis. 0.5 g from leaf was homogenized in 50 mM phosphate buffer (pH 7.0) containing 1% polyvinylpyrrolidone, for the assessment of antioxidant enzymes. The homogeneous sample was centrifuged for 10 minutes at 27600 g under a temperature of 4°C, the supernatant was used as the source of catalase, peroxidase and superoxide dismutase enzymes. The procedure described by Chance and Maehly (1955) was followed to assay Peroxidase and catalase. Catalase was measured by titrating the reaction mixture consisting of phosphate buffer (pH 6.8), 0.1 M H_2O_2, enzyme extract and 2% H_2SO_4, against solution of 0.1 N potassium permagnate. The reaction mixture for peroxidase consisted of pyragallol, phosphate buffer (pH 6.8), 1% H_2O_2 and enzyme extract. Change in absorbance caused by catalytic conversion of pyragallol to purpurogallin, was noticed at an interval time of 20 second and 2 minutes, at wavelength 420 nm on a spectrophotometer. Control set was prepared by using distilled water as an alternative of enzyme extract. The activity of superoxide dismutase was computed by estimating its capability to inhibit the photochemical reduction of nitroblue tetrazolium by following Beauchamp and Fridovich (1971). The reaction mixture contained 50 mM phosphate buffer (pH 7.8), 13 mM methionine, 75 mM nitroblue tetrazolium, 2 mM riboflavin, 0.1 mM EDTA and 0–50 mL enzyme extract and was situated under 15W fluorescent lamp. The reaction began by switch on the light and run for 10 minutes. The reaction was stopped by switching off the light. 50% inhibition by light was considered as one enzyme unit. The estimation of proline content in fresh leaves samples was carried out according to Bates et al. (1973). Sulphosalicylic acid was used for sample extraction. Equivalent volume of glacial acetic acid and ninhydrin solutions were added to the extracted sample. The mixture was boiled at 100°C after adding 5 mL of toluene. The toluene layer absorption was recorded at 528 nm wavelength on a spectrophotometer.

Statistical analysis

Data were analyzed by using SPSS, 17.0 for Windows (SPSS, Chicago, IL, USA). Analysis of variance (ANOVA) was achieved to examine vitiations between treatments at $P<0.05$, least significant difference (LSD) was used for comparison of the means.

Results

Lipid peroxidation (LPO), H_2O_2 content and leaf water potential

It is evident from *Table 1* that LPO and H_2O_2 accumulation in plant leaves significantly increased with increasing of PD concentration. Plants treated by 1.0 ppm of PD accumulated 27.96 and 24.95% LPO and H_2O_2, respectively, as compared to control plants. However, plants treated by 1.0 ppm of PD accumulated higher content of LPO than H_2O_2. The plants treated by 0.005, 0.01, 0.1 or 1.0 ppm of PD had varied leaf water potential compared with control plants in a concentration dependent manner and maximum increase was noted at 0.1 ppm of PD (*Table 1*) whereas the minimum increase was noted at 1.0 ppm of PD.

Table 1. *Effect of panadol (PD; 0.005, 0.01, 0.1, or 1.0 ppm) induced changes on lipid peroxidation, H_2O_2 content and leaf water potential of Vigna radiata 30 days after sowing*

Proline and sugar content

The leaf proline and sugar content significantly increased with increasing concentrations of PD (0.005, 0.01, 0.1 or 1.0 ppm) but 1.0 ppm showed the highest increase of proline and sugar content by 29.95% and 25.96%, respectively, in comparison to control plant contents. Also catalase activity was increased by 31.87% and 24.49% in plants treated by 0.1 and 1.0 ppm PD, respectively, as compared to control plants (*Table 2*).

Activities of antioxidants enzymes CAT, POX, and SOD

PD significantly affect the antioxidant enzyme activities (catalase/CAT, peroxidase/POX, and super oxide dismutase/SOD) in all plants treated by the PD, and the three enzyme activities increased with the increasing level of PD. The highest enzyme activities were recorded in plants treated by 0.1 ppm PD (*Table 3*). The highest activity rate for CAT, POX, and SOD were recorded at 0.1 ppm of PD in *Vigna radiata* plants demonstrating increases of 24.94%, 21.92%, and 17.51%, respectively, in comparison to the control plants.

Table 3. *Effect of panadol (PD; 0.005, 0.01, 0.1, or 1.0 ppm) induced changes on catalase, peroxidase activity, and superoxide dismutase activity of Vigna radiata 30 days after sowing*

Discussion

Lipid peroxidation and H_2O_2 accumulation are considered biochemical markers for the free radical attributed injury under different environmental cues and external stimuli (Verma and Dubey, 2003). Furthermore, these biochemical processes are commonly defined by increasing formation of reactive oxygen species (ROS) (Foryer and Noctor, 2000; Gill and Tuteja, 2010). The results of this study, confirmed and verified this phenomenon, as our results showed an increasing accumulation level of lipid peroxidation, and H_2O_2 at the highest concentration (1 ppm) of PD (*Table 1*).

Therefore, it could be assumed that higher concentration would be toxic to *Vigna radiata* plants and lead to excess production of reactive oxygen species (ROS). ROS in plant tissues are regulated by plant antioxidant systems or antioxidant enzymes such as Catalase, Peroxidase, and Superoxide dismutase (Schutzendubel, 2002) as well as osmoprotectants i.e. proline (Szabados and Savouré, 2010). The present study revealed that treatment of plants with 0.1 ppm of PD boosted the activity of antioxidant enzymes (CAT, POX and SOD; *Tables 2 and 3*) along with the level of proline accumulation (*Table 2*). In the similar line with An et al. (2009) who found that the activities of peroxidase and superoxide dismutase significantly increased in the wheat plant when exposed to paracetamol in a duration dependent manner. Proline increase plant stress tolerance by maintaining NADPH/$NADP^+$ balance, GSH levels, and during infection, drives the oxidative rupture of the hypersensitive response (Miller et al., 2009; Ben Rejeb et al., 2014). As Szabados and Savouré (2010) confirmed proline as a signaling molecule to modest mitochondrial functions, and it activates specific gene expression that could be

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_42974303

necessary for plant recovery in stress conditions. The findings of this study are in consistence with these previous studies, as this study showed that presence of PD significantly increased the proline accumulation and sugar content (*Table 2*). With cumulative effort of enhanced antioxidant system and proline accumulation under exogenously sourced PD i.e. paracetamol enhanced tolerance capacity of *Vigna radiata* plants to withstand various environment cues and helped in increasing their gross production.

In this study, we determined that the limit of PD in rivers and agricultural irrigation systems should be less than 1 ppm to decrease the negative effect of PD on mung bean plantation. Environmental Protection Agency and Saudi Government may use this limit as one of the allowable pharmaceutical water quality standard for the protection of the plant.

Conclusions

The highest concentration of panadol that induced oxidative stress was 1.0 ppm that was obvious through increased levels of lipid peroxidation, and H_2O_2 accumulation in *Vigna radiata* plants. On the other hand, 0.1 ppm of PD treatment improved the antioxidant system and the level of osmolytes to make the plants tolerate unfavorable conditions and helped in the increase of gross production through increasing the photosynthetic activity.

(Received 23rd Dec 2018; accepted 22nd Feb 2019)

Abstract. In order to estimate the global air pollution of the Moroccan Atlantic coast Safi-Essaouira, we have used a qualitative approach based on the spatial distribution of saxicolous-calcicolous lichens that reflect special ecological and pollution conditions. The measurement of the beta diversity by the calculation of the Jaccard index makes it possible to quantify the similarity between the studied sites and has made it possible to measure the gradient of change of this diversity along an increasing gradient of the pollution supposed high in the industrial zone of the Safi city and decreasing going north or south. The hierarchical clustering has made it possible to partition the seven studied sites into two different classes and differentiate four groups of indicator species of poleotolerance and eutrophication. The identification of 36 species of lichens including indicator species of SO_2 and NOx pollutions, the study of the impact of climate and pollution on the lichens biological spectrum, and the exploitation of the poleotolerance index and eutrophication index were necessary to elucidate the global air quality of the region.
Keywords: *air pollution, beta diversity, poleotolerance index, eutrophication index, biological spectrum*

Introduction

Since the beginning of the industrial era, human activities have been transforming the atmosphere of the globe more and more rapidly. Because of its geographical situation and its socio-economic development, Morocco is among the most vulnerable countries to the disturbances atmospheric. The cost of air degradation and its impacts has been estimated at 370 million USD per year (Worldwide air quality, 2018), which represents about 1.03% of Morocco's GDP in 2014. Ambient air pollution is responsible for nearly three quarters of this cost (Croitoru et al., 2017). In May 2016, World Health Organization in a report on urban air quality around the world, decreed Casablanca as the most polluted city of Morocco with a concentration level of small particles in the air of 61 $\mu g/m^3$ (the maximum annual threshold tolerated by the WHO is 20 $\mu g/m^3$); in the city of Safi, the concentration of small particles in the air is 21 $\mu g/m^3$.

The use of lichens is one of the biological assessment approaches to environmental changes. At the regional scale, the lichens distribution is explained by the sensitivity to pollution (Bobbink et al., 2010; van denBerg et al., 2011), climate variations (Werth et al., 2005; Giordani et al., 2008; Hickling et al., 2006; Gottfried et al., 2012) and the continuity of the habitat (Selva, 1994; Hauck, 2011). Temporal and spatial variation in lichen diversity could be evaluated using beta diversity and similarity. This information could then be used to quantify anthropogenic impacts in a given region (Giordani et al., 2018).

Without root system, protective cuticle or regulating mechanisms of matter flow, nutrients and toxic substances dissolved in the atmosphere can be absorbed over the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43054323

entire surface of the lichen thallus (Tyler, 1989; Bačkor et al., 2009). Since the early works of Nylander (1866), lichens are widely used as bioindicators for assessing air pollution (Garrec et al., 2002). Bioindication is an ecological approach that seeks to evaluate possible air disturbances from the presence/absence of key species in a specific lichenic survey.

The first catalog of Moroccan lichens was published by Werner and Gattefossé (1931) and includes 542 species. An important scientific study of Moroccan lichenic flora was conducted by Werner between 1931 and 1976. Egea (1996) in his catalog of lichens in Morocco reviews the studies of Moroccan lichen flora between 1879 and 1990 and gives a commented list of lichens in our country. In 2013, a synthesis on the lichens of the Rabat herbarium (RAB) was published by Ajaj et al. (2013).

The lichenic bioindication approaches used and still mostly use corticolous lichens. Comparatively, there are no bioindication studies of air quality using saxicolous lichens and especially saxicolous-calcicolous species. The reason we chose the calcicolous lichens is the ecological nature of the biotope of this study area harboring few corticolous and terricolous lichens, but showing a remarkable presence of calcicolous lichens.

The present study aims to study the lichen flora of the Atlantic coastal fringe of the Safi-Essaouira regions over 120 km, to use the beta diversity measure to quantify the similarity between the studied sites, to study the climate impact and air pollutants (SO_2 and NOx) on this diversity and to exploit the poleotolerance index and the eutrophication index to highlight air pollution and map the overall air quality of the region.

Materials and methods

The Moroccan Atlantic coast Safi-Essaouira includes two urbanized areas (the city of Safi and the city of Essaouira) and less urbanized areas. Since the 1960s, it is home to a major industrial phosphate processing plant located in the south of the Safi, and accused of being one of the contributors to the deterioration of the air quality. In the near future, a coal-fired power plant, already installed 12 km south of Safi, will be operational by the end of 2018; it aims to cover 25% of Morocco’s electricity needs. The impacts of its construction and operation are expected to have an impact on the air quality caused by the dust generated during construction and the emissions that will be associated with coal combustion (sulfur, trace metals, radioactive elements, etc.).

The Atlantic coast Safi-Essaouira is characterized by a semi-arid climate with rains fall regularly in autumn and winter. The average annual rainfall is estimated at 350 mm. Temperatures are moderate with an average annual value of 18 °C. In August, the average temperature is M = 25.7 °C; it is the hottest month of the year. The coldest month is January with an average temperature of m = 8.9 °C. The drought period is 7 months, from April to October. The relative humidity of the air is on average between 70 and 80%. The winds are particularly strong in the coastal zone. They are predominantly northwest and are frequent towards the end of the afternoon.

Seven sites were selected assuming an increasing air pollution gradient from non-urban areas to urban areas (*Fig. 1*). Lichen sampling focused on saxicolous species on limestone rock formations with homogeneous lichenic cover exposed to the air while avoiding sheltered rocky surfaces and surfaces directly exposed to the sea. Sometimes the species are taken with their support using a hammer and a chisel.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43054323

The sampling campaigns covered the period from February 2016 to June 2016 and were updated in 2017 and 2018.

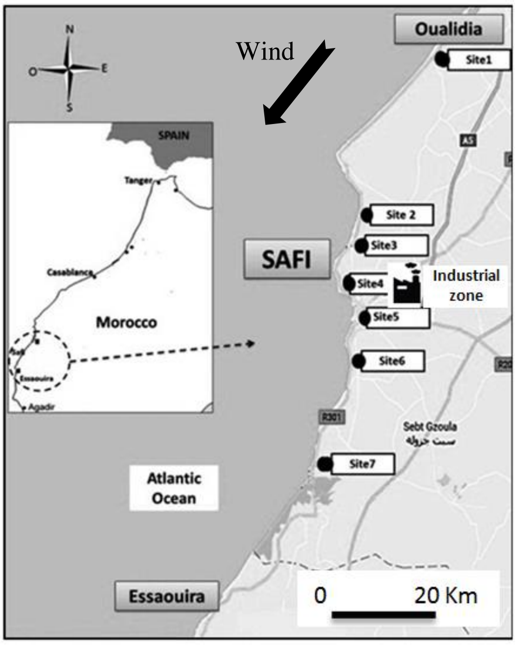

Figure 1. *Location of the Safi-Essaouira coastline and the seven sites. The arrow indicates the general direction of the wind*

Species determination was performed using a binocular loupe and an optical microscope for thallus sections. Different bibliographic sources were used in the determination, especially "Likenoj of Okcidenta Eŭropo" by Clauzade and Roux (1985): "Lichens: Biological study and illustrated flora", by Ozenda and Clauzade (1970) and "Guide of the lichens-350 species of lichens of Europe" (Thievant, 2001).

The following chemicals have been used in the determination of species: saturated potash for reactions on the thallus and medulla; chlorine in the form of sodium hypochlorite solution and paraphenylenediamine in stabilized solution.

Lichen diversity is also used for biomonitoring (Nimis et al., 1990; Loppi et al., 2004; Giordani, 2007; Giordani et al., 2014; Matos et al., 2017). To compare the studies sites in pairs, we considered the β diversity that corresponds to the importance of species replacement along environmental gradients (Whittaker, 1972; Podani et al., 2013). The comparison of the number of taxa that are unique to each site makes it possible to measure the gradient of change of diversity along the increasing gradient of the supposed pollution from the industrial zone and going to the north or the south.

As bioindication approach, the method of the index of atmospheric purity (IAP) has not been used; this method requires the determination of the entire lichenic flora. The method of Hawksworth and Rose, established in the British Isles (1970), is inapplicable in the Mediterranean (Semadi et al., 1995). The method of Van Haluwyn and Lerond (1986), although adaptable to all the study areas, has been validated only for the corticolous species.

To overcome this situation, and considering the available means, we have selected among recent methods the studies of Nimis and Martellos (2017) which attributed to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43054323

different species of lichens a poleotolerance index and an eutrophication index. This work done in Italy has the advantage of being interested in lichens from Mediterranean region whose ecological characteristics are close to those of Morocco, It is also a solution in the absence of cartographic studies of the overall air quality using saxicolous lichens and especially saxicolous-calcicolous and facing the absence of similar works on the Moroccan territory.

To illustrate the arrangement of sites and species of lichens studied in terms of ecological parameters, we have processed the databases using the SPSS statistics 20.0 software and the R software using the FactoMineR and factoextra package that divide datasets, containing n observations, into a set of k groups (ie clusters) in which each cluster is represented by the center or the means of the data points belonging to the cluster (K-means clustering).

Results

Beta diversity and spatial bioindication of air quality

It is evident that the exhaustive study of all lichens in the region cannot be established because of the difficulty of identifying all species in particular crustose saxicolous calcicolous lichens. The number of taxa identified in the study area is 36 saxicolous lichens (*Table A1* in the *Appendix*). As we move further away from the industrial zone (Site 4), the number and diversity of lichens increases.

Morphologically, fruticose forms such as Roccella phycopsis and Ramalina pollinaria disappear 20 km far from the S4 site. The foliose forms penetrate up to around 4 km from the S4 site, only a few crustose forms settle in the S4 site. Of the 36 calcicolous species there is a diversity of 22 different genera. This diversity is between 36 and 3 species per station. There are 30 species of crustose, 4 foliose species and 2 fruticose species.

Among the indices used to measure beta diversity, we used the Jaccard index (1908) to quantify the similarity between the studied sites. The similarity increases with the value of the index which takes the value 0 when two sites have no similarity (no species in common) and 1 when the similarity is maximal (all the species are in common). The equation of this index is (*Eq. 1*):

$$Sj = \frac{c}{a+b+c} \tag{Eq.1}$$

c = number of common species

a = species of the site a

b = species of the site b

Table 1 illustrates the similarity matrix between sites taken two by two: The two most similar sites are S1 and S7 (Sj = 1), the least similar are S4 and S1 (Sj = 0). A hierarchical K-means clustering has allowed partitioning the sites according to their degree of similarity: On the dendrogram (*Fig. 2*), a cutoff passing through the value combination distance 5 individualizes three groups of sites: group 1 “S1, S2, S6 and S7”, group 2 “S3 and S5” and group3 “S4”.

These results reflect the grouping of these sites according to the habitat quality they represent. The study of beta diversity via the similarity index and the hierarchical

DOI: http://dx.doi.org/10.15666/aeer/1702_43054323

ascending classification (*Fig. 2*) show a differentiation of these sites into three groups of lichenic biodiversity.

Use of the poleotolerance index and the eutrophication index

Nimis and Martellos (2017) have attributed to a variety of lichen species an index of poleotolerance: This value points to the tendency of a lichen to occur in areas with different degrees of human disturbance. It is expressed on 4 classes, as follows:
3 = species occurring in heavily disturbed areas, including. large towns.
2 = species occurring in moderately disturbed areas (agricultural areas, small settlements etc.).
1 = species occurring in natural or semi-natural habitats.
0 = species which exclusively occur on old trees in ancient, undisturbed forests. Contrary to the other values, this one has been assigned to epiphytic species only, since it is useful to point out indicators of long ecological continuity of forests.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43054323

The authors also proposed an eutrophication index: this value expresses the degree of nitrogen pollution, including deposition of dust and nitrogen compounds, there are 5 values:
1 = no eutrophication
2 = very weak eutrophication
3 = weak eutrophication
4 = rather high eutrophication
5 = very high eutrophication (*Table A2* in the *Appendix*).

The species with a low eutrophication index are confined in the S1, S2, S6 and S7 sites (*Table A2*): This is the case of Acrocordia conoidea and Parabagliettoa cyanea. Although its poleotolerance index is low to medium (1-2), others species with an eutrophication index of 2-3 like Coscinocladium gaditanum can grow in sites near industrial zone (Sites S3 and S5). Only species with an index of 4-5 such as Caloplaca citrina and Lecania erysibe seem to support the air quality of the S4 site (industrial zone).

Discussion

Due to their close dependence on the atmosphere for their metabolic processes (Rundel, 1988; Nash, 1996), lichens are strongly influenced by environmental variables, which affect their richness and distribution. The species composition and its richness is often used for spatial analysis in ecosystems (Brunialti et al., 2003; Kapusta et al.,2004; Giordani, 2006; Will-Wolf et al., 2006). Numerous studies have shown that different disturbances of the biotope have a limiting effect on lichen communities: SO_2 in the 1970s in Great Britain (Hawksworth and Rose1970), dust (Loppi and De Dominicis, 1996,), fire (Longán et al., 1999) in the Mediterranean regions, and nitrogen compounds in the Netherlands (van Dobben et al., 2001; van Herk, 2002). The differences in species richness between the studied sites (S1 to S7) can be correlated with the action of environmental fluctuations (Seaward1977; Nash, 1996).

Bioindication of climate as a limiting factor

The study of the biological spectrum of calcicolous lichens harvested in unpolluted rural sites (S1 and S7) shows that crustose forms reach a frequency of 80% (*Fig. 3*). This value reflects the bioclimatic nature of the region. According to the climatic data we can calculate the aridity Martonne index (I) (*Eq. 2;* De Martonne, 1923) and the pluviometric Quotient of Emberger (Q) (*Eq. 3;* Emberger, 1955):

$$I = \frac{P}{T + 10} \tag{Eq.2}$$

where I = 12.07.

$$Q = \frac{2000P}{M^2 - m^2} \tag{Eq.3}$$

where Q= 57.57.

http://www.aloki.hu • ISSN 1589 1623 (Print) • ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43054323

To correlate the biological spectrum of lichens with the ecological conditions of the biotope Renaut et al. (1968) reported, in a study conducted in Morocco, that a biological spectrum with 50% crustose forms corresponds to Q = 80, with 70% crustose forms Q is close to 60. Finally with 80% crustose forms Q is less than 60.

In our study Q = 57.57 and the biological spectrum of harvested lichens is dominated by crustose forms (80%) which corresponds to the observations made by Renaut et al. (1968). On the other hand, the regional semi-arid climate (I = 12.07 and Q = 57.57) imposes a steppe-type vegetation which explains a relatively small number of trees that can support corticolous lichens. The dominance of limestone rocks combined with a semi-arid climatic is such that our study biotope is colonized by calcicolous lichens.

Bioindication of the pollution as limiting factors

The closer we get to the industrial zone (site S4), the more the lichenic biological spectrum is dominated by crustose forms (*Fig. 3*). Fruticose lichens are more sensitive to pollution than foliose and crustose forms.

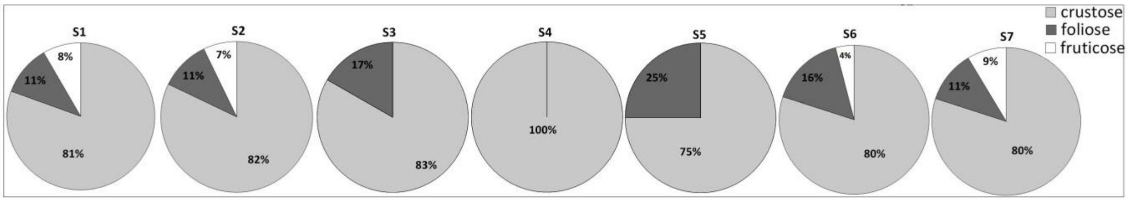

Figure 3. *Spatial variation of the biological spectrum of harvested lichens, according to the distance to Safi industrial zone (site S4)*

Studies have shown a relationship between the lichen growth form and its resistance to pollution. Maizi et al. (2017) reported that the Fruticose lichen Ramalina is more sensitive to metal trace element than the foliose lichen Xanthoria parietina and the absorption capacity of MTE is different depending on the type of thallus (foliose or fruticose).

Gauslaa et al. (2002) reported that in polluted sites, the medullary metabolites in Ramalina have been reduced and lichen is less protected. Weissman et al. (2006) reported that under conditions of low pollution, occur in Ramalina antioxidant activities as protective mechanisms. However, after prolonged exposure, these protective mechanisms are overwhelmed and damage to cellular components begins to accumulate. It follows a decrease in antioxidant activities and degradation of lichen. The disappearance of the fruticose forms from the site S3 and S4 can be related to the death of these lichens as a result of damage to their biological components caused by air pollution.

Bioindication of SO_2 as a limiting factor

To give credibility to the bioindication approaches adopted in this work, the results of a research project on the bioaccumulation of metallic trace elements by lichens (Essilmi et al., 2018) made it possible to quantify and characterize air pollution trends in the seven studied sites. These results and other measurements of air quality, shown in *Table 2*, present exact values of air pollution and its distribution in space, which must be verified and supplemented by lichen bioindication.

The "Office chérifien des phosphates" group (OCP, 2011), owner of the chemical industry "Maroc Phosphore", reported in its 2011 report, the measurements of SO_2 of the air (*Table 2*). In its 4th report of 2014, the Moroccan Ministry of Energy (2014) reported an annual average NO_2 of 53.62 µg/m³, in Safi city, which exceeds the annual norm of 50 µg/m³.

In the absence of studies on the susceptibility of calcicolous lichens to pollution, the cortical form of Xanthoria parietina is an example of nitrophytic lichen (NO2) and sulfur toxitolerant (SO_2) which disappears at a high concentration of SO_2 sulfur dioxide ≥67 µg/m³ (Wetmore, 1983) (*Table 3*). In 1970 Hawksworth and Rose reported that Ramalina pollinaria disappear at 38.78 µg/m³, in 2014 Duman et al., reveal that Ramalina pollinaria is sensitive to pollution stresses as evernia prunastri. The disappearance of Xanthoria parietina and Ramalina Pollinaria from the S4 site confirms the rate of 50 µg/m³ of SO_2 reported by the measurements. On the other hand, the disappearance of Physcia adscendens from S4 may be due to its oligotrophy for NOx.

Table 3. *Examples of SO2 and NOx tolerance threshold in lichens*

	SO_2 tolerance threshold	NOx tolerance threshold
Xanthoria parietina	Absent at 67 µg/m³ (Wetmore, 1983)	Eutroph with a high N requirement, peak detection frequency occurs at 6.1 kg N per ha per year (McCune and Geiser, 2009)
Ramalina pollinaria	Absent at 38.78 µg/m³ (Hawksworth and Rose, 1970)	Oligotroph with a low N requirement, peak detection frequency occurs at 1.1 kg N per ha per year (McCune and Geiser, 2009)
Physcia adscendens	Absent at 87.24 µg/m³ (Wetmore, 1983)	Oligotroph with a low N requirement, peak detection frequency occurs at 1.1 kg N per ha per year (McCune and Geiser, 2009)

The Hawksworth and Rose scale showed absolute SO_2 concentrations as the only factor influencing lichen species rather than the acidity of their support. Several studies have tried to find an explanation of the physiological impact of SO_2 on lichens. The sensitivity of lichens living on acid bark, tested in the laboratory, showed the same physiological symptoms as in the field. However, for species living on alkaline supports

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43054323

the correlation appeared to be negative (Baddeley et al., 1972; Ferry et al.,1979). Most nitrophytic species appear to have low sensitivity to the toxic effects of SO_2; their only requirement is a high pH of the support. Van Herk (2001) reported that an increase in the pH of the substrate appears to be the main cause of the considerable increase in the number of nitrophytic species and the

disappearance of acidophyte species during the 1990s in the Netherlands. Other studies suggest that species tolerant to SO_2 are sensitive to NH_3 and vice versa (Van Dobben, 1999).

It has been found that, with considerable SO_2 pollution in an area, the first loss of the same pH-sensitive lichens occurs on birches and conifers (acid bark and low buffering capacity); the next loss on oaks and sycamore (intermediate acidity and buffering capacity); the last on trees like elm (alkaline bark and high buffering capacity). In general, an alkaline substrate such as basic bark or limestone counteracts the acidity of SO_2 pollution (New York State's Urban Forestry council 2018).

Methods using the diversity of lichen species to estimate SO_2 air pollution should be used with caution. This is the case of calcicolous lichens studied in this work and living on a limestone support whose pH is alkaline. The decrease in lichen species richness in the S3 and S4 sites can be correlated with an increase in the pH of the support; the disappearance of oligotrophic species such as Ramalina pollinaria and Physcia adscendens indicates that the increase in pH is due to an increase in NOx levels in the air, this indication is confirmed by the annual rate of 53.62 $\mu g/m^3$ of NO_2 which exceeds the annual norm of 50 $\mu g/m^3$ (Ministry of Energy (2014). Current evidences suggest that increases in substrate pH due to NH_3 may be a driving force of change of the lichenic communities (Wolseley et al., 2006).

Bioindication of human disturbance and nitrogen pollution

The use of the poléotolérance index and the eutrophication index show that species with a low poleotolerance index (PI = 1) and a low eutrophication index (EI = 1) are absent in the S3 and S4 sites; Species with low poleotolerance index and low eutrophication index are restricted to sites S1, S2, S6 and S7 indicating low levels of anthropogenic disturbance and low eutrophication; this is the case of Acrocordia conoidea and Parabagliettoa cyanea. Only species with high value indices, such as Caloplaca citrina and Lecania erysibe, can withstand high levels of eutrophication and anthropogenic disturbances and are able to settle in site S4 indicating high pollution.

The HCPC statistical analysis (Hierarchical Clustering on Principal Components) (Husson et al., 2010), allows to group lichens according to 4 ecological variables: Poléotolérance index (PI), eutrophication index (EI), the biological spectrum and the specific présence in each site (*Figs. 4*, *5* and *6*).

There are 4 types of species profile indicator of poleotolerance and eutrophication (*Table 4*):

- Species in natural habitats without disturbance and without eutrophication (Cluster 1)
- Species present in moderately disturbed habitats and support low eutrophication (Cluster 2)
- Nitrophytic species present in moderately disturbed areas (Cluster 3)
- Highly nitrophytic species present in heavily disturbed areas (Cluster 4)

DOI: http://dx.doi.org/10.15666/aeer/1702_43054323

Depending on the value of these indices we can classify the sites S1 to S7 into 3 classes (*Table 5*).

***Table 4.** Differentiation of four groups of Poléotolérance and eutrophication species indicator*

Cluster 1	Cluster 2	Cluster 3	Cluster 4
Caloplaca subochracea	Alyxoria subelevata	Aspicilia calcarea	Caloplaca lactea
Alyxoria variiformis	Arthonia calcarea	Caloplaca aurantia	Lecania erysibe
Dirina massiliensis	Buellia dispersa	Caloplaca crenulatella	Caloplaca citrina
Bagliettoa calciseda	Caloplaca chalybaea	Coscinocladium gaditanum	
Myriolecis crenulata	Caloplaca erythrocarpa	Diplotomma alboatrum	
Parabagliettoa cyanea	Diploicia canescens	Lecania spadicea	
Acrocordia conoidea	Diploschistes scruposus	Myriolecis albescens	
	Lecania atrynoide	Myriolecis dispersa	
	Myriolecis bandolensis	Physcia adscendens	
	Opegrapha rupestris	Verrucaria nigrescens	
	Ramalina pollinaria	Verrucaria viridula	
	Rocella phycopsis	Xanthoria calcicola	
	Toninia aromatica	Xanthoria parietina

Table 5. *Classification of sites according to the poleotolerance index and the eutrophication index of harvested lichens*

Classes	Sites	Species indicator	PI	EI	Degrees of disturbance
1	S1 S2 S6 S7	*Acrocordia conoidea* *Dirina massiliensis* *Parabagliettoa cyanea*	1 1 1	1 1-2 1	- Natural or semi-natural habitats - Very low eutrophication
2	S3 S5	*Caloplaca erythrocarpa* *Diplotomma alboatrum* *Lecania spadicea*	1-2 1-2 1-2	2-3 3-4 3-4	- Areas with moderate human disturbance - Low eutrophication
3	S4	*Caloplaca citrina* *Lecania erysibe* *Xanthoria calcicola* *Caloplaca crenulatella*	1-3 1-3 1-2 1-2	4-5 4-5 4-5 4	The disappearance of all the species and the presence of these 2 species indicates that they are zones with strong disturbance of anthropic origin and strong eutrophication

Despite its low poleotolerance index (PI = 1-2), Xanthoria calcicola has been identified at the periphery of the S4 site characterized by a high degree of human disturbance: the explanation can be approached according to the following considerations:

- The effect of pollution on lichen depends on the pH of the substrate. Soils containing calcium and limestone are better able to neutralize sulfuric and nitric acid deposits than siliceous soils. The calcareous substrate moderates the effects of an acid pollution by SO_2 and NOx. The sulfuric acid reacts with the limestone in a neutralization reaction.
  Limestone: $CaCO_3 + H_2SO_4 \dashrightarrow CaSO_4 + H_2CO_3$
  The calcium sulfate is soluble in water and hences the limestone dissolves and crumbles.
  $H_2CO_3 \dashrightarrow CO_2 + H_2O$
  The original acid (hydrogen ions) have been converted to water in these reactions.
- Thanks to a high tolerance to eutrophication, species with low poleotolerance manage to settle in heavily polluted areas; Lachat et al. (2011) report that eutrophication promotes the differential development of some lichen species that resist the effects of pollution. Recently it has been shown that lichen community composition near motorways is shifting towards species associations with more nitrophytic lichens (Madl, 2009). Generally, changes in N-deposition affect the composition of plant diversity and may induce a dominance of nitrophytic species over those species that are more susceptible to nitric-enrichment in nutrient-poor habitats (Frati et al., 2007; Bowman et al., 2006; Riddell et al., 2011). One mechanism leading to this extreme sensitivity of some lichens to excessive supply of nitrogen compounds may be the ability to bind such compounds within cell walls until the concentrations become toxic by causing electrolyte leakage as was shown for *Evernia prunastri* by Munzi et al. (2009a, b).
- In the dried condition the lichens were clearly more resistant. Xerophytic species may appear to be more tolerant to SO_2 pollution only because they are

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1702_43054323

dry for longer periods of time during which they are quite tolerant (Beekley et al., 1981). Under low relative humidity conditions, lichens are more resistant to high SO_2 concentrations.

Sites S1 and S2 are characterized by the development of crustose, foliose and fruticose lichens, the fruticose form is represented by only two species: Ramalina pollinaria and Roccella phycopsis which disappear from sites S3, S4 and S5.

Foliose species such as Xanthoria calcicola and Coscinocladium gaditanum were collected at the S3 and S5 sites but absent at S4. Only crustose forms such as Lecania erysibe and caloplaca citrina persist in S4. Overall, there is a decrease in the abundance and diversity of lichens with urbanization and industrialization.

Three categories of calcicolous lichens can be distinguished:

- Species “resistant” to air pollution, encountered in the S4 site
- Moderately resistant species that disappear from S4
- Poleophobe species whose presence is limited to sites S1 S2, S6, and S7

It can be concluded that there is a pollution gradient whose maximum in the S4 site and which decreases as we moves north or south. The results of the two bioindication approaches “Presence/absence of key species” and the “Use of the poleotolerance index and the eutrophication index” have led to the conclusion that in the industrial zone (site S4) the air quality is disturbed by urbanization and industry, the further we get from the S4 site, the better the air quality, and 20 km from the S4 site we have good air quality. Thanks to these results it is possible to model a global map of air pollution in the study area (*Fig. 7*).

It is clear that in nature lichen responds to a mixture of pollutants that may have synergistic, protective or harmful effects on it. The lichens are different in their sensitivity to pollutants and their response to pollutant mixtures (Hyvärinen et al., 1992; Gilbert, 1986; Farmer et al., 1992).

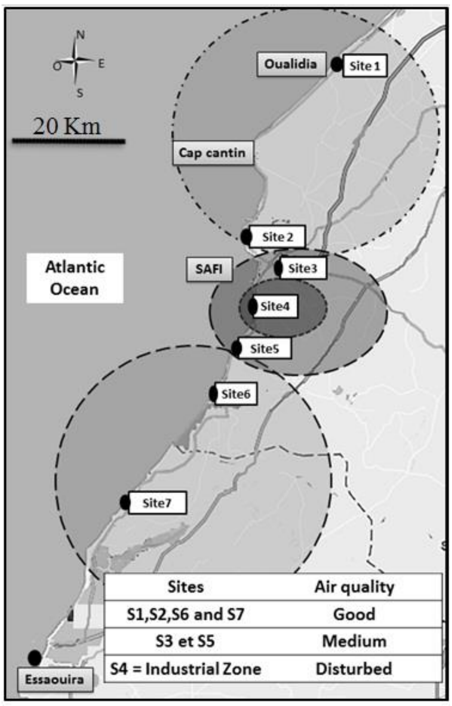

Figure 7. *Delineation of the air quality of the studied sites*

Conclusion

The study of beta diversity via the similarity index revealed a gradual decrease in beta diversity due to an increasing gradient of pollution, while the hierarchical clustering has allowed a partitioning of the sites studied into three groups of lichenic biodiversity. The bioindication study using the calcicolous lichens has allowed to deduce that sites S3, S4 and S5 S5 are in a circle of 20 km diameter whose center is the industrial zone and where air quality is more or less disrupted by urbanization and industry; while sites S1, S2, S6 and S7 are outside this circle indicating good air quality. The further away from the industrial site (S4), the greater the number and diversity of lichens: The fruticose and foliose forms disappear at 20 km and 4 km respectively around site S4. Only a few crustose forms inhabit the S4 site, however the lichenic desert is not observed.

By using the poleotolerance index and the eutrophication index we conclude that the S4 site suffers a strong anthropogenic disturbance and a strong eutrophication: Further we get from this site, more the environment becomes natural and its rate of eutrophication decreases. This approach has shown that medium poleotolerance combined with high eutrophication resistance allows some calcicolous lichen species, such as Xanthoria Calcicola, to withstand areas of high pollution.

The present study confirms that lichens are good indicators of climatic parameters: the abundance of crustose forms and the low presence of fruticose and foliose forms, indicates an arid character of the regional climate.
