Abstract. Vegetation, climate and anthropogenic factors in the country of Togo are thought to mutually correlate, however, the degrees to which they correlate remains unclear. This study examined and analyzed patterns of climate variability and how these patterns have influenced vegetation cover dynamics in Togo. Based on data collected from eight meteorological stations, the global climate monitor and European Space Agency, this study analyzed existing trends and relationships between vegetation cover, climate and Normalized Difference Vegetation Index (NDVI) using Mann Kendall non-parametric test, ANOVA and p-value tests. The results showed that (1) rainfall correlated strongly with NDVI (p-value < 0.00001), (2) evapotranspiration was influenced by annual temperatures in the eight sampled meteorological stations across the country (p-values < 0.0001), (3) evapotranspiration and rainfall were negatively correlated, (4) annual NDVI changes can be used to monitor annual rainfalls, (5) Anthropogenic disturbances, such as deforestation from uncontrolled tree logging, farming and low household income, can be quoted among the limiting factors of vegetation cover.
Keywords: *greenness drivers, remote sensing, NDVI, sustainable forest management, plant seasonality*

Introduction

From 1990 to 2015, the total forest coverage in Togo decreased from 12.59 to 3.46% showing a loss of 9.13% as estimated by the United Nations Food and Agricultural Organization. Studies have shown many significant interchanges occurring between climate, vegetation and human activities, for example, interactions have been found between the soil and atmosphere (Zhang et al., 2011), and vegetation is thought to respond to climate changes through temperature and rainfall variations, and obviously or subtly by seasonal changes (Weiss et al., 2004.; Cui and Shi, 2010.; Meng et al., 2011).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_67616781

Various studies have analyzed vegetation indices to understand the impacts of climate on vegetation cover, showing that rainfall regimes correlate strongly with Normalized Difference Vegetation Index (NDVI) (Martiny et al., 2006; Capodici et al., 2008), green biomass estimation (Rosental et al., 1985; Prince et al., 1991; Julien, 2014) and as vegetation photosynthetic activity indicator (Gausman et al., 1985; Gilabert et al., 1985). Even early satellite data from the 1970's were used to monitor vegetation and climate patterns conditions for management purposes (Rouse et al., 1974). Some research findings showed that an increase of temperature could potentially change the ecosystem composition of the vegetation cover (Serreze et al., 2000). Other studies have shown broad results that NDVI and rainfall correlated effectively (Kendall et al., 1975; Nicholson et al., 1994; Richard et al., 1998; Foody et al., 2003; Ma et al., 2006). For instance, the influence of temperature on NDVI was significant only during the early and the late growing season, while NDVI correlated with rainfall within the growing season (Wang et al., 2012). However, NDVI time series were not strongly correlated with climate variations at global scale, even if rainfall was reported to have the capacity to limit vegetation growth in semi-arid areas (Schultz, 1995; Ichii et al., 2002).

Literature review

Dominated by the Sahel's arid and semi-arid climatic conditions, West Africa reported obvious climatic changes by the early and late drought period (1970 and 1980), shown by decadal increases of the temperature and a decrease of rainfall (Biasutti et al., 2009). These findings have been consistent in Togo, with climate changes being assessed through slight increases of temperature and irregular rainfall regimes (Adjoussi, et al., 2000). Climate change in the area is also projected to continue exacerbating weather and climate conditions the future decades (IPCC, 2013).

Moreover, many other studies addressing climate change showed that in West Africa, and especially in Togo, temperatures have been increasing steadily each year from 0.4 to 1.6 °C, depending on the ecoregions in Togo (Badameli et al., 2015). Estimates of green vegetation dynamics in West Africa, especially in the North mountainous region of Togo, have revealed that since 1987 vegetation has been declining, and socio-economic factors were thought to be the main dynamic factors of this decrease (FAO, 2017). Togo was quoted as having some of the highest deforestation rates in the world, with a deforestation rate of 4.5% from 2002 to 2005 and 5.75% from 2005 to 2010 (FAO, 2006; Biasutti et al., 2009). These deforestation rates are due to supplying firewood as main source of energy for 90% of the household energy needs (Fontodji et al., 2007; Gazull et al., 2009; Koku et al., 2009). Other factors for vegetation degradation include agricultural pressure, animal husbandry and bush fires (Traore et al., 1998)

Within the past decades, most of the studies related to vegetation in Togo were analyzed at the local level for vegetation management strategies or plant species inventory. This is the first study to explore climatic variations and the drivers between climate variations and vegetation at two scales from local to national level. The current study bridge gaps in the research about Togo by putting together climate and vegetation variations using NDVI, temperature, rainfall and potential evapotranspiration (PET) data to clarify the relationship of vegetation and climate changes under a tropical climate conditions.

Materials and methods

Study area

Togo (6°06'N; 11°08'N; 0°09'W and 1°49'W), a West African country, covers a total area of 56,600 km² and is bordered by the Atlantic Ocean, Benin, Ghana, and Burkina-Fasso to the South, East, West and North respectively. With 61% urban population and 229 persons/km² of density, his total population was 7,965,055 persons in 2017 according to the United Nation for Food and Agriculture Organization (FAO). This population has quadrupled from 1960 to 2010, since gaining independence, with 60% under the age of 25 years. Togo's tropical climate is characterised by two main regimes from the south to the north. The Guinean regime comprises two rainy seasons and two dry seasons with an annual rainfall from 1000 to 1600 mm while the Sudanese regime in the North has only one short rainy season and one long dry season with an annual rainfall of 850-1400 mm (Badameli et al., 2015) and an annual average temperature around 27.8 °C. The country has rich vegetation with more than 4000 plant species, mainly from the forest species as discovered recently (Brunei et al., 1984; Akpagana et al., 1994; Kouami et al., 2009). Unfortunately, this rich flora is threatened by anthropogenic activities which depend on forest resources for fire wood energy and charcoal (Folega et al., 2011). The soils of Togo are diverse and include ferralitic soils, vertisols, tropical ferruginous soils, although mainly dominated by poorly developed soils (Folega et al., 2015). The hydrology of Togo comprises three southern rivers including Mono (450 km) the longest, Zio (176 km) Haho (140 km) and lagoons, Togoville, Lomé and Aneho lagoons. In the northern part the Oti basin, there is the only one river watering the vegetations. The climate of Togo is under the influence of two high-pressure air masses, Harmattan and Monsoon, whose encounter produces an Inter-Tropical Front (FIT) that determines the seasons by its fluctuation. In terms of botany, Togo comprises five ecofloristic areas (Ern et al., 1979; Kokou et al., 2009) which combine ecological, floristic and physiognomic patterns, including Sudanese savannas in the northern plains, dry savannahs and forests covering the northern mountains, Guinean woodland savannahs in the central plains, dense semi-deciduous forests in the southern section in the Mont's of Togo, and mosaics (savannahs, forest relics and fallow forests) in the coastal plains of southern Togo. Land use cover is estimated at 67.4% of agricultural land, 45.2% of arable land, 3.8% of permanent crops, 18.4% of permanent pasture and of forest 4.9% others estimates to 27.7% in 2011.

Data collection

Meteorological data and NDVI

Data were downloaded from eight meteorological stations located in various ecofloristic regions of the country (*Fig. 1*). The meteorological stations are found in open air environments free from shade. These meteorological stations include Lomé (6°9'56"N, 1°15'16.24"E), Tabligbo (6°34'59"N, 1°30'00"E), Atakpamé (7°31'37"N, 1°7'36"E), Kouma konda (6°95'N, 0°58'E), Mango (10.37°N/0.47°E,), Sokodé (8.98°N/1.15°E), Kara (9.55°N/1.17°E), Dapaong (10.87°N/0.25°E) from 1984 to 2017. The NDVI annual time series data were available from the European Space agency at the resolution of 500 m completed from the MODIS website for the years 1992 and 1993 at the same resolution. The annual evapotranspiration data were freely available in the global climate monitoring website. The Normalized Difference Vegetation Index

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_67616781

(NDVI) ranged from (-)1 to (+)1. It can be extremely negative for water surfaces, zero for barren areas or rocks, sands or snow and highly positive for healthy vegetation including grassland, shrub land, temperate and tropical rainforest (Tucker et al., 1979; Tarpley et al., 1984; Gausman et al., 1985; Goward et al., 1985; Rosental., 1985; Sellers et al., 1985; Townshend et al., 1985; Bartlett et al., 1988; Wilson et al., 2002).

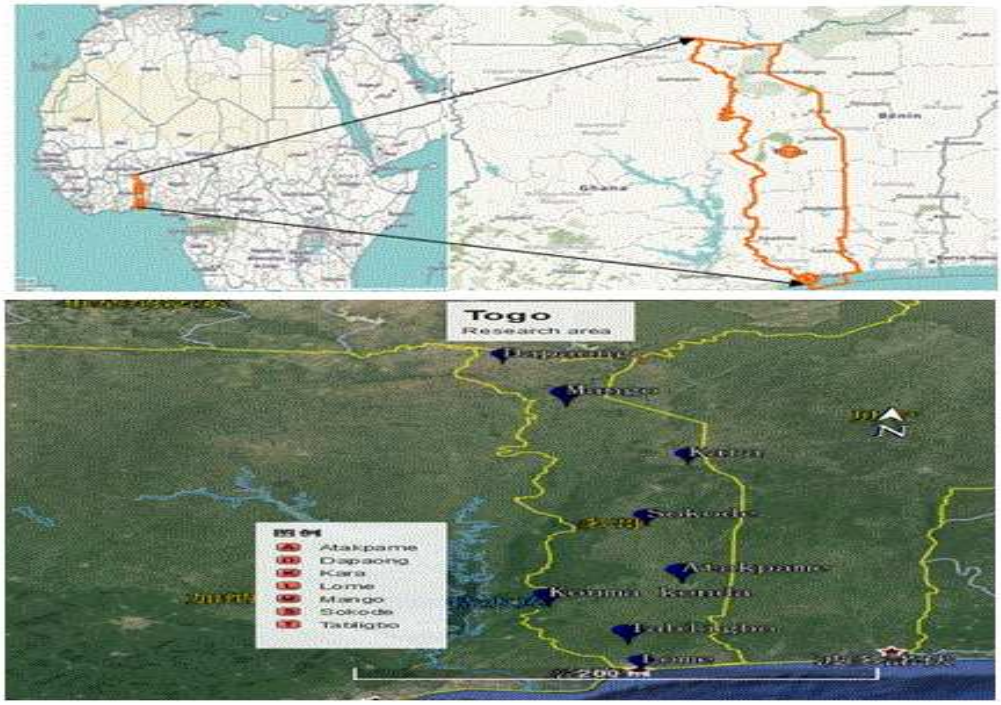

Figure 1. *Location map of the study area*

Statistical analyses

Regression analysis

All collected data were analyzed by regression (*Eq. 1*) method with SPSS software to determine the relationship between dependent and independent variables. Thus, the dependent variables were regressed on the independents in order to determine if their relation was significant and how much the confidence of the dependents explain the independents. The p-value < 0.05 represents statistically a significant relationship to 95% of confidence interval (Kleinbaum et al., 1998; Mbatu et al., 2006; Mukete et al., 2018).

$$y = ax + b \qquad \text{(Eq.1)}$$

where y is the dependent variable and x the independent variable.

Non parametric test of Mann Kendall (MK)

Non-parametric analysis known as Mann Kendall (MK) was performed using the following steps: the observed data in year Y_j and Y_i respectively differ and the sign (Y_j - Y_i) equals to 1, -1 or 0 with j > i. The test statistic, S, was then calculated (*Eq. 2*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_67616781

$$S = \sum_{i=1}^{n-1} \sum_{j=i+1}^{n} Sign(y_j - y_i) \quad \text{(Eq.2)}$$

When S is a larger positive integer, the values measured later tend to be larger than earlier values and an upward trend is indicated. When S is a larger negative number, later values tend to be smaller than earlier values and a downward trend is indicated. When the absolute value of S is small, no trend is indicated. The test static τ was calculated (*Eq. 3*).

$$\tau = \frac{S}{n(n-1)/2} \quad \text{(Eq.3)}$$

τ has a range from -1 to +1 and is analogous to the correlation coefficient in regression analysis. The null hypothesis of no trend is rejected when **S** and τ are significantly different from zero. If a significant trend is found, the rate of change can be calculated using the Sen slope estimator (*Eq. 4*).

$$\beta = median(\frac{y_j - y_i}{x_j - x_i}) \quad \text{(Eq.4)}$$

For all i < j and I = 1, 2,…, n-1 and j = 2,3,…n; in order words, computing the slope for all pairs of data that were used to compute S. The median of those slopes is the Sen slope estimator. For Mann et al. (1945), the S statistic is roughly in the norms if and only if the time interval is greater than eight. When there is no tie between the values of the data, see *Equations 5* and *6*.

$$E(s) = 0 \quad \text{(Eq.5)}$$

$$Var(S) = \frac{n(n-)(2n+5)}{18} = \sigma \quad \text{(Eq.6)}$$

The standard test statistic Z is calculated by the following formula:

$$\begin{aligned} Z &= \frac{S\ -1}{\sqrt{Var(s)}} For S \geq 0 \\ Z &= 0 For S = 0 \\ Z &= \frac{S+1}{\sqrt{Var(s)}} For S \leq 0 \end{aligned} \quad \text{(Eq.7)}$$

When there is no trend or a null hypothesis, Z evolves with mean zero. A positive Z value indicates an upward trend value while a negative value indicates a downward trend. The p-value of a Mann-Kendall S can then be determined using the normal cumulative distribution function (*Eq. 8;* Blain, 2013; Helsel et al., 1992).

$$p = 2\left[1 - \phi(|z)|\right] \quad \text{(Eq.8)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_67616781

where Φ(p) describes the cumulative distribution function of a standard normal variate.

Results

Climate variability and vegetation dynamics

The NDVI analysis showed variations in vegetation cover throughout the country, (*Fig. 2*), and correlation analysis performed also showed climatic factors to correlate with NDVI, (*Figs. 9-10*). Observing the correlation between NDVI and temperature at the national level.

NDVI, temperature, rainfall and evapotranspiration changes at local level

The annual time series of temperature, rainfall, evapotranspiration and NDVI in Togo at national level from 1984 to 2017 (*Fig. 2)*, shows obvious changes in each parameter during these three last decades in Togo. Temperatures is increasing continuously especially from 1990 in the country. The NDVI and mean rainfall are changing in the same way so that an uptrend year of rainfall corresponds to an uptrend year of NDVI. The temperature and the evapotranspiration both changed at certain time period in the opposite directions especially from 1990 till 2017.

From the analysis we can conclude NDVI and rainfall correlate strongly and positively, similarly with mean annual temperature and evapotranspiration, while the annual rainfall and evapotranspiration correlate negatively (*Fig. 3*). It can be seen also that, there is no correlation between mean NDVI and mean annual temperature under the tropical climate condition that prevails in the research area.

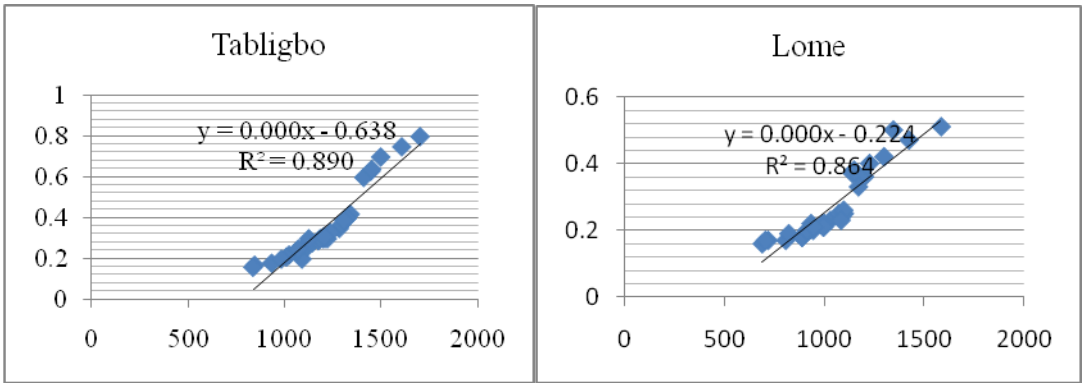

Figure 10. *Annual changes in NDVI, rainfall (mm) for the eight sampled meteorological stations in Togo during 1984-2017*

Through the regressions analysis between temperature and NDVI in one hand and between NDVI and annual rainfall at local scale in the eight sampled meteorological stations areas, several observation can be seen from 1984 to 2017

Under the Guinean subequatorial climate including Lome, Tabligbo, Kouma konda and Atakpame meteorological stations

- At Lome area, the relationship between NDVI and rainfall was significant at $p < 0.05$. The Kendall coefficient between NDVI and rainfall was 0.912 with a Pearson coefficient of 0.92 (*Table 1*; *Figs. 9* and *10*).
- In the Tabligbo area, the correlation between NDVI and rainfall is significant at $p < 0.05$. The Kendall coefficient between NDVI and rainfall is 0.944 and the Pearson coefficient is also 0.94 (*Figs. 9* and *10*).
- For the Kouma konda area, the correlation between NDVI and rainfall is significant at $p < 0.05$. The Kendall coefficient between NDVI and rainfall is 0.92 while the Pearson coefficient is 0.98 (*Fig. 9*).
- For the Atakpame area, NDVI changes according to rainfall more than temperature (*Figs. 9* and *10*). The Kendal's coefficient is -0.104 between temperature and rainfall and 0.625 between NDVI and rainfall and 0.028 between temperature and NDVI.
- In the Sokode area, the relationship between NDVI and rainfall is significant at $p < 0.05$. The Kendall coefficient between NDVI and precipitation is 0.845 while the Pearson coefficient is 0.88 (*Table 1; Figs. 9* and *10*).

Under the Tropical Sudanese climate including Dapaong, Mango, Kara and Sokode meteorological stations

- At Sokode station, NDVI was found to correlate strongly with NDVI with a p-value less than 0.00001 and statistic Z equal to 4.26489. The Pearson coefficient and the Kendall's were 0.85 and 0.88 respectively. But the temperature did not correlate strongly with the NDVI with a p-value less than 0.05. The correlation coefficient for temperature and NDVI were -0.101 for Kendall's and -0.05404108 for Pearson's.

In the Mango region, the only significant relationship also is that between NDVI and rainfall which is significant at $p < 0.05$. The Kendall coefficient between NDVI and rainfall is 0.92 while the Pearson coefficient is 0.98 (*Fig. 9* and *10*).

At Dapaong, the sole statistical relationship was between NDVI and rainfall, and was significant at $p < 0.05$. The Kendall coefficient between NDVI and rainfall is 0.896 while the Pearson coefficient is 0.94 (*Fig. 9* and *10*).

In addition, both at local and national scale the climatic parameters showed obvious changes for annual temperatures and annual rainfalls. At national level, the general trend of temperature is increasing since 1990. Before this upward trend, there has a slight decrease from 1984 to 1990 (*Fig. 2*). This observation is the same at local scale as the entire national trend of temperature (*Fig. 4*).

For the annual rainfall, the general trend at national level showed as constant trend ($y = 0.611x + 176.8$, $R^2 = 0.002$) (*Fig. 2*) with slights changes. It decreases from 1948 to 2000 and increases from 2000 to 2010 before dropping till 2015 and started increasing from 2015 to 2017. The general trend of rainfall is the same at national level for annual mean NDVI while at local level, NDVI showed different trends at each meteorological station areas.

In Dapaong, the general trend of NDVI is increasing (Dapaong annual rainfall = 0.001x - 2.776 $R^2 = 0.024$; *Fig. 4*) with maximum values in 1999 and 2007 and minimums in 1990, 1995 and 2014 mainly.

In the Mango area, NDVI increased from 1984-1990 and then decreased from 1990-2000 and then increased again from 2000-2010 before decreasing from 2010 to 2017 (Mango annual rainfall = 0.001x - 2.456 $R^2 = 0.016$; *Fig. 4*).

In the Kara area, the general trend of ndvi showed an increase (Kara annual ndvi mean = 0.004x - 8.987, $R^2 = 0.098$ (*Fig. 4*). It peaked down in 1990, 2000, 2005 and 2015 mainly with maximums in 1989, 1995, 2003and 2010 mainly.

At Sokode, the NDVI showed a general upward trend during these last three decades from 1984 with a regression equation from *Fig. 4* (Sokode annual NDVI = 0.002x -

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_67616781

4.005, $R^2 = 0.038$). Maximums were observed in the years 1989, 1995, 1997, 2003, 2008 and 2010 mainly.

At Atakpame, the general trend of NDVI is decreasing ($y = -0.0001x + 1.493$, $R^2 = 0.002$). At Kouma Konda, the NDVI trend is increasing slightly (*Fig. 4*) ($y = 0.000x - 1.026$, $R^2 = 0.002$) with maximums in 1985, 1989, 1995, 2002 and 2008 mainly and minimums in 1986, 1990, 1992, 1996, 2000, 2004, 2012 and 2015 mainly.

At Tabligbo it can be seen that the general trend of NDVI is decreasing ($y = -0.002x + 6.120$).

Lome station showed that the uptrend years of the annual temperature were different from that of rainfall and NDVIPlots revealed hanges in average NDVI between the eight sampled meteorological stations and their surroundings for NDVI, temperature and rainfall from 1984 to 2017 in Togo for chlorophyllous vegetation (green plants) (*Figs. 5-7*). There was a remarkable increase in (year) at (area name). All annual uptrend of NDVI can be interpreted us a vegetation growing.

Discussion

NDVI and climatic variability analysis at national level

The inter-annual variation of temperature trend at the national level has been increasing since 1984 in Togo. This increase of temperature has been already found by some previous studies related to climate change (Badameli et al., 2015). At the same time, the general trend of annual evapotranspiration is being increasing, these two factors correlated strongly (*Figs. 9-10*).

In addition, NDVI, which reflects chlorophyll (green plant material), correlated remarkably with rainfall at national level. These two findings showed a couple of factors which correlate one another: (NDVI, rainfall), and (temperature, evapotranspiration) while an increase of annual rainfall decreases the evapotranspiration (*Figs. 2-3*). This last observation can be explained by the decrease of temperature by rainfall which caused the evapotranspiration to decrease.

In other studies, an obvious impact of climatic factors on annual NDVI trends was shown, and differences can exist among the chlorophyll of plant species responding to the climate changes (Gang et al., 2016).

NDVI and climatic variability analysis at local level

All of the eight selected meteorological stations showed that a correlation between rainfall and NDVI was significant (*Figs. 9-10*) with a p-value < 0.00001. The correlation coefficients both of Pearson and Kendall are highly positive and near 1 with a statistic $Z = 4.26489$. Except for KARA area where both the coefficient of Kendall is high and above 0.3 (*Fig. 10*) between NDVI and temperature and above 0.8 between NDVI and rainfall (*Fig. 10*). Between temperature and NDVI, the correlation is not significant (*Fig. 9-10*). These findings implied that NDVI which reflects the vegetation activity becomes rainfall dependent in the research area. This statement confirms the fact that green plants depend on water for their photosynthesis activities as all these findings are consistent with some of the previous studies related to the topic of rainfall and NDVI correlation (Malo et al., 1990). In addition, the NDVI is known not only to correlate well with rainfall, and also can be used as a useful tool to monitor rainfall under different climatic conditions (Di et al., 1994).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_67616781

Other studies found that water availability is a limiting factor of green plant activity especially in carbon sequestration and photosynthesis activities (Gang et al., 2016). It has been found that, evapotranspiration can be used as a tool to measure the chlorophyll of green plants, with the capacity to influence rainfall, for instance, in the research area, the evapotranspiration correlates strongly with temperature (*Fig. 3*). An increase in temperature accelerates the evapotranspiration both by plants (transpiration) and rivers or soil (evaporation) explaining the positive correlation between annual mean temperature and evapotranspiration during these last three decades in Togo. These findings were consistent to the one found previously by (Shouichi et al., 1979) who reported that, between soil and vegetation there is the transfer of energy due to consumption of net radiation by green plants through photosynthesis, which will be used for evapotranspiration. Some other previous findings recognized the relationship between evapotranspiration and temperature due to solar radiation and chlorophyllous plant requirements for their several biosynthesis functions (Chapman et al., 1972; Julian et al., 1973; Wickham et al., 1978). In fact, not only the solar radiation (sunshine) but also temperature and rainfall (water availability) impacts deeply green plants photosynthetic activities under any climatic conditions (Gang et al., 2016).

This study showed that, the general trend of annual temperature is obviously increasing since 1990 in Togo. This upward trend could probably explained by global climate changes in the West Africa and the whole world. Many other studies confirmed this findings (IPCC, 2007) stressing the need to survey the influence of climatic factors especially temperature on vegetation.

Many other studies are of the opinion that the increase of annual temperature influences vegetation growth (Rustad, 2001). This statement is contrary to the observations made during our research in Togo where the upward trend of temperature does not correlate with the vegetation (NDVI) growth. Thus, the climatic factors are not the only factors to influence chlorophyllous plants growth.

Socio-economic drivers of NDVI and climatic inter annual changes

Any changes of NDVI reflects directly the variation of green plant covers, an indicator of chlorophyll or plants activity (photosynthesis and evapotranspiration) (Tucker et al., 1979). Therefore, the decrease of NDVI at national level from 1990 can be due to uncontrolled tree logging during the political events as bad implementation and understanding of democratization which put more pressure on the protected areas especially on forestland. From this year, the half part the Togolese national protected areas has been spoilt away putting the country on the list of highest rate of deforestation countries (Blaser J., 201) with a deforestation rate reported at 4.5% each year in 2000 (*Fig. 4*). Thus, the anthropogenic pressure on vegetation can be also justified by domestic energy needs as the population is increasing sharply, as their household energy use relies mainly on firewood and charcoal, and also for traditional medicinal use (Wala et al., 2005; Folega, 2011). Natural gas energy can be promoted and subsidized by the national leaders and reinforcements can be required in woodland, forest and natural protected areas management for more stringent restrictions for sustainability in nature conservation and green recovery.

In other perspectives, the high dependency of the majority of households on plant resources and farming related activities are also explained by the low income of the population in developing countries and the general conditions of poverty related resource use (Mukete, 2016). Therefore, the unceasing decrease of the forestlands in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_67616781

Togo is due to anthropogenic pressure, especially in rural areas to the detriment of the forest and green vegetation in Togo.

Conclusions

During these last three decades in Togo from 1984 to 2017, the annual temperature, rainfall, evapotranspiration and NVDI obviously changed. A correlation analysis based on the annual time series data of temperature, rainfall, NDVI and evapotranspiration showed that, (1) rainfall correlated strongly with NDVI which reflect the chlorophyllous plants activities both at local and national scale. (2) evapotranspiration was influenced by annual temperatures all over the country in the eight sampled meteorological stations while (3) evapotranspiration and rainfall correlated negatively. (4) annual NDVI changes can be used to monitor annual rainfalls. (5) anthropogenic activities such as deforestation by uncontrolled tree logging, farming and low household income were the main contributing factors in addition to climate change. Among the high deforestation countries in the world, the Togo a national leaders would mitigate this challenge by promoting alternative energy sources to replace firewood for households, especially natural gas and reinforcements to be implemented in the current resources managements plans by participative management for sustainable development in Togo. The national level of climatic variations measurements and their impacts on some main species in the study areas is encouraged in next research projects to clarify the specific influence of climate change on each plant species.

Acknowledgements. This research was funded by the International Science & Technology cooperation Programme of China (2015DFR31130) and the National Natural Science Foundation of China (31670715; 41471029; 41371500). We are also grateful to the Chinese and Togolese Government for the cooperation scholarship and to my Supervisors and to Eve Bohnett for their generous help in the field investigation and English improvement during this research.

Abstract. A field experiments was conducted to investigate the soil application of humic acid and nitrogen levels at Agricultural Research Station, Swabi, Pakistan during 2014. Experimental soil was deficient in organic matter (0.52%) and total nitrogen (0.029%). Effect of humic acid and nitrogen levels on plant height, leaves plant^{-1}, leaf area plant^{-1}, leaf area index, grain yield, total N uptake, net assimilation rate as well as nitrate reductase activity in leaves were determined using maize variety Jalal and Iqbal. Four levels of humic acid (0, 0.6, 1.2 and 1.8 kg ha^{-1}) and two levels of nitrogen (0 and 120 kg ha^{-1}) were applied in soil along with basal fertilization of phosphorus and potassium. Nitrogen concentrations and uptake were determined from the grain and stover. All the applied levels of humic acid significantly enhanced growth and yield attributes of both maize varieties in the presence of nitrogen. However, application of 1.2 and 1.8 kg ha^{-1} were only effective to increase growth and yield attributes in the absence of nitrogen. Soil application of nitrogen significantly increased growth and yield of both maize verities; however, it was significantly lower than all the soil applied HA levels with nitrogen. Maize variety Iqbal showed significantly higher NR activity in leaves, net assimilation rate, grain yield and harvest index than Jalal. Nitrogen concentration and uptake were significantly augmented with increasing level of humic acid in grain and stover. However, maximum total N uptake was recorded with the application of 1.8 kg ha^{-1} HA+N in maize variety Iqbal. Among different applied HA levels, maximum grain yield was obtained from the soil application of 1.8 kg HA ha^{-1} with nitrogen in both varieties. Therefore, 1.8 kg ha^{-1} HA along with 120 kg N ha^{-1} in maize variety Iqbal could be recommended for higher grain yield in calcareous N deficient soil conditions.

Keywords: *grain yield, leaf area index, net assimilation rate, humic acid, nitrogen levels*

Introduction

Maize is considered a major crop in Pakistan, as it occupy third most important position after wheat and rice in terms of area and grain yield (Government of Pakistan, 2016). Maize is cultivated for fodder and grain in various tropical, subtropical and temperate areas of the world; including Pakistan. Due to rapid increase in human population, horizontal increase in maize area is not possible. Therefore, the only way to increase maize productivity lies in increasing yield of existing maize genotypes through various integrated nutrient management practices (Grassini et al., 2011). Pakistani soils are mostly calcareous, alkaline and deficient in organic matter (Azam et al., 2001). Nutrients deficiencies prevail in the soil due to insufficient and poor

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_67836799

nutrient management which adversely affect the yield of crops and fertility of the soil with the course of time (Afzal and Ahmad, 2009). Different management practices are applied to enhance and sustain soil fertility. For example, production of field crops had been successfully improved with the application of farm yard manure, green manure, composting and application of some organic fertilizers. Nitrogen has main role in various physiological, biochemical processes and yield traits of maize (Amanullah, 2016; Maheswari et al., 2017). Nitrogen application improves growth rate of the plants with greater leaf expansion, reduced senescence and higher dry matter accumulation (Rizwan et al., 2003). It performs a crucial role in crop production as it contributes significantly to the yield and yield components of maize crop (Sharifi and Taghizadeh, 2009). However, its scarcity is regarded as one of the major yield retarding factors because it is prone to a number of losses.

Humic acid is an organically charged bio-stimulant (Moghadam et al., 2015) made by the bacterial and chemical processes in the soil. It is an essential part of organic matter that improves physical, biological and chemical properties of the soil, for example water holding capacity, nutrient availability, soil penetrability and soil structure (Nardi et al., 2002; Khan et al., 2013). It increases organic matter, organic carbon and water retention which ultimately augment fertilizer retention in the soil (Dong et al., 2006). It has the potential to enhance various physiological and biochemical process within the plant; for example, chlorophyll, net assimilation rate, carbohydrate, leaf area and roots development (Turkmen et al., 2004; Khan et al., 2013; Traversa et al., 2014). It can diminish nitrogen losses by stimulating soil exchangeable ammonium (NH_4^+) and available nitrate (NO_3^-) which leads towards higher nitrogen retention in the soil and uptake by the plants (Mohd et al., 2009). Therefore, adequate application of humic substances in the soil has capability to increase the availability of macro (N, P, K and Ca) and micro nutrients (Fe, Zn and Mn) as well as their uptake in the plants (Saruhan et al., 2011; Daur and Bakhashwain, 2013; Khan et al., 2013). It is important to identify maize varieties which have the ability to produce higher grain yield under the cropping systems practiced by the small land holder farmers, as very little effort has been made in this regard (Tolessa et al., 2007). Sustainable crop production depends on the continuous renewal of soil fertility through a balance between N demand and supply in cropping systems (Yousaf et al., 2016). There seems to be a synergistic relationship between humic acid and N as it has a crucial role on the fate of organic nitrogen in the soil, N cycling, distribution and its availability to the plants (Dong et al., 2009).

Soil of arid and semi-arid region having low precipitation and high evapotranspiration resulted in lower organic matter, nutrient deficiencies and high pH. The beneficial effect of humic acid and nitrogen in various plant species has been well reported; however, specific effect of different levels of HA with and without nitrogen in maize has yet to be explored. In addition, we will determine the potential of humic acid to trigger net assimilation rate, nitrate reductase activity, total nitrogen uptake and grain yield in two different maize varieties under field conditions.

Materials and methods

Experimental site

The study was conducted at experimental field located at 34° 7' 12 N and 72° 28' 12 E in Agricultural Research Station Swabi, Pakistan. The climate of the experimental site is sub-tropical, semi-arid, hot and continental with 568 mm annual rainfall on average basis. The average temperature of 40°C was recorded in the summer season, while the lower level of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_67836799

temperature was 25°C in the same season. Average maximum temperature during the winter months was 18.4°C while the minimum temperature was 4°C.

Experimental procedure

Before starting the experiment, soil samples were collected from 0-30 cm depth at different locations of the field to determine the physico-chemical properties of soil. Soil was air dried, grinded and passed through 2 mm sieve to remove clods and materials other than soil. Soil characteristics were silt loam textural class with pH 7.8, electrical conductivity 0.20 dS m^{-1}, organic matter 0.52%, total nitrogen 0.029%, available phosphorous 5.72 mg kg^{-1}, potassium 118 mg kg^{-1}, zinc 2.30 mg kg^{-1}, copper 2.70 mg kg^{-1}, iron 2.41 mg kg^{-1} and manganese 97 mg kg^{-1}. Field experiment was conducted during the summer 2014 in a randomized complete block design with split plot arrangement having three replications. Factorial experiment comprised of two maize varieties Jalal and Iqbal in the main plot, while the treatments of humic acids and N levels were allotted to the subplots. The area of each subplot was 4.9 m x 3 m (14.7 m^2). Manual method of sowing was used for planting with plant to plant distance of 20 cm and row to row distance of 70 cm. Detail of treatments is given in *Table 1*. The Humic harvest, USA was purchased from market and used in the research study at 2000 ppm (2 g humic acid $liter^{-1}$) solution from the matured dried stems and empty heads of sunflower after seed removal. Basal fertilizer of P and K was applied at 100 and 60 kg ha^{-1} in the form of single super phosphate and sulphate of potash. Soil was prepared well for sowing of maize varieties with the help of primary and secondary tillage. The required N levels were applied to the subplots of maize varieties in two split applications (17 days-after-sowing (DAS) and 35 DAS. Humic acid was applied to maize varieties 14 DAS in a single application. Weeds were controlled by the application of Primextra 400 mL (Atrazine 223 g/L + Metolachlor 277 g L^{-1}) weedicide before pre-emergence. Five irrigations were applied to the crop at knee stage (grand growth stage), pre-tasseling, silking, dough stage and seed fill stage with the help of canal water. Various cultural practices were done all over the growing period.

Table 1. *Detail of treatments is given below*

Treatments	Detail
T1	Control (without HA and N)
T2	Soil application of 0.6 kg HA + 0 kg N ha^{-1}
T3	Soil application of 1.2 kg HA + 0 kg N ha^{-1}
T4	Soil application of 1.8 kg HA + 0 kg N ha^{-1}
T5	Soil application of 0 kg HA + 120 kg N ha^{-1}
T6	Soil application of 0.6 kg HA + 120 kg N ha^{-1}
T7	Soil application of 1.2 kg HA + 120 kg N ha^{-1}
T8	Soil application of 1.8 kg HA + 120 kg N ha^{-1}

The data on plant height, leaves $plant^{-1}$ at silking, leaf area $plant^{-1}$ at silking, leaf area index (LAI) at silking, nitrate reductase (NR) activity in leaves at 30 DAS, net assimilation rate (NAR) at 30-75 DAS, ears m^{-2}, ears $plant^{-1}$, ear length (cm), thousand grain weight (g), grain yield (kg ha^{-1}), stover yield (kg ha^{-1}), harvest index (%), grain N concentration (%), stover N concentration (%), grain N uptake (kg ha^{-1}), stover N uptake (kg ha^{-1}) and total N uptake (kg ha^{-1}) were determined. For determining plant height, five maize plants were selected randomly at silking from each subplot and the average length was measured from ground level to the top of tassel by using a measuring tape. Likewise,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_67836799

at silking five maize plants were taken at random from each subplot, leaves counted and the average calculated. The leaf area (cm^2) $plant^{-1}$ was measured by multiplying average leaf area with number of leaves $plant^{-1}$ and the LAI was calculated by digital hand held laser leaf area meter (CI-203 Bio- Science, USA). The enzyme nitrate reductase (NR EC 1.7.1.1) activity in leaves was measured from fresh plant tissues of three top leaves at 30 DAS and expressed as unit per mg protein (Lewis et al., 1982). One unit equivalents to the production of 1 µmol of NO_2 per minute at 25°C. Net assimilation rate (30-75 DAS) was determined by dividing the total dry matter of plants by their leaf area duration (Beadle, 1993). It was expressed as g m^{-2} day^{-1}.

The number of ears m^{-2} was calculated by dividing the number of ears by row length (m) x r-r distance x number of rows. The number of ears $plant^{-1}$ was recorded by dividing the numbers of ears by the number of ears in each subplot. For ear length of maize varieties, after harvesting and dehusking, the length of five ears was recorded and averaged. At crop maturity, the two central rows were harvested manually. All the plots of the crop were bundled separately, labeled properly and brought to the threshing room. The 1000-grain weight, stover yield and grain yield were estimated with electrical balance. Likewise, the harvest index (HI) was recorded by dividing the grain yield by biological yield and then multiplying by 100. The grain and stover N concentration (%) was calculated by the Bremner and Mulvaney (1982) method, which is known as Kjeldahl method. The grain and stover N uptake (kg ha^{-1}) were measured by multiplying the grain and stover N concentration (%) with grain and stover yield (kg ha^{-1}) respectively and then dividing by 100. Furthermore, the total N uptake was calculated by adding the grain N uptake and stover N uptake.

Statistical analysis

Data were statistically analyzed using the analysis of variance using the method described by Steel et al. (1997), and means between treatments was compared by least significant difference ($P \leq 0.05$). All the parameters mean values were expressed as mean value with standard error (SE).

Results

Plant height (cm)

Plant height of both maize varieties were significantly increased with the combined effect of all the applied levels of humic acid with N; however, alone application of humic acid was only significant in 1.8 kg ha^{-1} in both varieties. The sole application of N substantially increased plant height of both varieties, however, it was significantly lower than the application of 1.2 and 1.8 kg HA with N (*Table 2*). Plant height increase due to the application of 1.2 and 1.8 kg HA ha^{-1} with N was statistically at par with each other. Maximum plant height was recorded with the application of 1.8 kg HA ha^{-1} with N; while the minimum was achieved with control plants in both maize varieties. Plant height of maize variety Jalal was significantly higher than Iqbal.

Leaves plant^{-1}

The sole application of 1.2 and 1.8 kg HA ha^{-1} significantly enhanced the number of leaves $plant^{-1}$, however, any increase due to individual application of 0.6 Kg HA ha^{-1} was statistically not different as compared to control in both maize varieties (*Table 2*). The alone effect of 1.2

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_67836799

and 1.8 kg HA ha^{-1} was statistically at par with each other in terms of number of leaves $plant^{-1}$. Individual application of N and all the combined applications of HA with N significantly increased number of leaves $plant^{-1}$ in both the maize varieties. The maximum number of leaves $plant^{-1}$ was observed with the combined application of 1.8 kg HA ha^{-1} + N which was at par with 1.2 kg HA ha^{-1} + N. Higher number of leaves $plant^{-1}$ were recorded in maize variety Jalal as compared to Iqbal.

Means	205.2 a	186.0 b	12.25 a	11.33 b

Mean followed by same letters in a column do no differ significantly at $P \leq 0.05$

Leaf area (cm^2) $plant^{-1}$

Leaf area index was significantly improved with all the applied levels of humic acid, except 0.6 Kg HA ha^{-1} in the absence of N in both maize varieties. (*Table 3*). The alone impact of 1.2 and 1.8 kg HA ha^{-1} on leaf area $plant^{-1}$ of both maize varieties were statistically same with each other. However, the effect of alone application of humic acid on leaf area $plant^{-1}$ was lower than sole use of N. The integrated application of all the HA levels with N significantly accelerated the leaf area $plant^{-1}$ in both maize varieties. Maximum leaf area $plant^{-1}$ was recorded with 1.8 Kg ha^{-1} HA+N in maize variety Jalal, while the minimum was recorded with control plants in Iqbal.

Leaf area index (LAI)

All the levels of applied humic acid in the absence and presence of nitrogen and alone application of nitrogen improved leaf area index in both maize varieties (*Table 3*). However, in the absence of nitrogen, 1.8 kg ha^{-1} humic acid significantly enhanced leaf area index in both varieties. The leaf area index increase due to the individual application of HA at 0.6 and 1.2 kg HA ha^{-1} was at par with each other in either maize variety. The combined use of 1.8 kg HA ha^{-1} + N resulted in maximum leaf area index which was at par with 1.2 kg HA ha^{-1} + N in both varieties. Maize variety Jalal exhibited higher leaf area index as compared to Iqbal. Lower leaf area index was recorded in control plots of humic acid and N.

Nitrate reductase activity in leaves (unit mg^{-1} protein)

Nitrate reductase (NR) activity in leaves was significantly accelerated with the increasing level of humic acid in the absence and presence of nitrogen in both maize varieties (*Table 4*). The sole impact of 1.2 and 1.8 kg HA ha^{-1} on NR activity of maize

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_67836799

varieties was statistically at par with each other. Although, the alone application of N significantly increased NR activity; however, the magnitude of increase was higher under the combined use of humic acid and nitrogen. Moreover, highest NR activity was observed at 1.8 kg HA ha^{-1} + N while the lowest was recorded with control plants in both varieties. The impact of 1.8 kg HA ha^{-1} + N on NR activity was at par with 1.2 kg HA ha^{-1} + N in each variety. The average mean of Iqbal superseded the mean of Jalal variety.

Net assimilation rate (g m^{-2} day) (30-75 DAS)

Increasing level of applied humic acid significantly improved net assimilation rate (NAR) respectively in the absence and presence of nitrogen, except individual application of humic acid at 0.6 kg ha^{-1} in both varieties (*Table 4*). Each variety showed similar net assimilation rate due to the individual application of 1.2 and 1.8 kg HA ha^{-1}. The application of 1.8 kg HA ha^{-1} along with N showed highest net assimilation rate in both varieties. Maize variety Iqbal exhibited higher NAR than Jalal. Net assimilation rate increase due to the application of humic acid at 1.2 kg ha^{-1} and 1.8 kg ha^{-1} along with nitrogen was statistically at par with each other in maize variety Jalal. Likewise, net assimilation rate increase due to the alone application of nitrogen and 0.6 kg ha^{-1} HA+N was statistically at par with each other in Jalal.

DOI: http://dx.doi.org/10.15666/aeer/1703_67836799

Ears m^{-2}

Both of the maize varieties showed a significant response for the number of ears m^{-2} against the applied levels of humic acid in the presence and absence of N, except the sole application of humic acid at 0.6 kg ha^{-1}. The alone application of N had a significant impact on the number of ears m^{-2} in both maize varieties (*Table 5*). Individual application of humic acid at 1.2 and 1.8 kg ha^{-1} on ears m^{-2} was statistically at par with each other in both the maize varieties. The highest number of ears m^{-2} was observed at 1.8 kg HA ha^{-1} + N in both varieties. The effect of 1.8 kg HA ha^{-1} + N was statistically at par with 1.2 kg HA ha^{-1} in Jalal regarding the number of ears m^{-2}. The lowest number of ears m^{-2} was recorded in the control plots of Jalal, while the highest was achieved with Iqbal.

Ears plant^{-1}

The application of humic acid in the presence and absence of N, as well as the alone application of N significantly influenced the number of ears plant^{-1} in both the maize varieties of Jalal and Iqbal. However, the alone application of 0.6 kg HA ha^{-1} did not cause any significant increase in the number of ears plant^{-1} (*Table 5*). The sole application of humic acid at1.8 kg HA ha^{-1} produced the highest number of ears palnt^{-1}. Though the sole application of N enhanced the ear bearing capacity of maize varieties, but the maximum number of ears plant^{-1} was recorded with 1.8 kg HA ha^{-1} + N. The minimum number of ears plant^{-1} was observed in the control plots. The higher number of ears plant^{-1} was measured in Iqbal variety of maize as compared with Jalal.

Ear length (cm)

The ear length of both maize varieties exhibited a significant response to the sole application of N as well as all the applied levels of humic acid with and without N, except the alone application of humic acid at 0.6 kg ha^{-1} (*Table 5*). The alone impact of 1.2 and 1.8 kg HA ha^{-1} on ear length of maize variety Jalal was statistically at par with each other. The maximum ear length was recorded with the combined use of 1.8 kg HA ha^{-1} + N, although the sole use of N also had a significant impact on the bulk of increase in each variety. The effect 1.8 HA ha^{-1} + N and 1.2 kg HA ha^{-1} + N on ear length of each variety was statistically at par with each other in both varieties. The minimum ear length was measured in control plots of both varieties. The mean average of ear length of Iqbal was significantly higher than Jalal variety of maize.

Thousand grain weight (g)

The individual application of humic acid and N as well as their integrations had a substantial influence on thousand grain weight of maize variety Jalal and Iqbal (*Table 6*). Under the sole application of humic acid, the plots treated with 1.8 kg HA ha^{-1} produced highest thousand grain weight in both maize varieties. The individual effect of 0.6 and 1.2 kg HA ha^{-1} was statistically at par with each other in both varieties. The highest thousand grain weight was recorded in plots supplied with 1.8 kg HA ha^{-1} + N in Iqbal while the lowest was recorded in control plots of Jalal. Furthermore, the plots treated with sole N and 0.6 kg HA ha^{-1} + N produced the same thousand grain weight in Jalal.

Grain yield (kg ha^{-1})

The grain yield of both varieties was substantially enhanced with the increasing levels of humic acid, nitrogen as well as their combined application (*Table 7*). Under the alone application of humic acid, 1.8 kg HA ha^{-1} resulted in higher grain yield in each variety. The application of humic acid at 1.8 kg ha^{-1} with N, produced the plants with the highest grain yield in both the maize varieties. The impact of 1.8 HA ha^{-1} + N and 1.2 kg HA ha^{-1} + N on grain yield of both varieties was statistically at par with each other. The highest grain yield was achieved in plots of Iqbal treated with 1.8 kg HA ha^{-1} + N while the lowest was recorded in control plots of Jalal.

Stover yield (kg ha^{-1})

Stover yield of both maize varieties were significantly increased with the combined application of humic acid + N as well as under the alone application of humic acid and N (*Table 7*). The alone effect of 0.6 and 1.2 kg HA ha^{-1} on stover yield of both varieties was statistically at par with each other. Though the sole application of N improved stover yield of maize varieties but the maximum response was observed at 1.8 kg HA ha^{-1} + N which was at par with 1.2 kg HA ha^{-1} + N. The Jalal variety of maize exhibited highest stover yield than Iqbal. In Iqbal variety of maize, the individual effect of N was similar with the combined effect of 0.6 kg HA ha^{-1} + N.

Harvest index (%)

The integration of humic acid and nitrogen as well as their alone applications considerably affected the harvest index of both maize varieties. The individual effect of 0.6 and 1.2 kg HA ha^{-1} on harvest index was statistically at par with 1.8 kg HA ha^{-1} in both varieties (*Table 8*). Maximum harvest index was recorded at 1.8 kg HA ha^{-1} + N in each variety of maize. However, the impact of 1.8 kg HA ha^{-1} + N was similar with 1.2 kg HA ha^{-1} + N in both the varieties. Moreover, in Jalal variety of maize the integrated impact of 0.6 kg HA ha^{-1} + N were found to be at par with individual application of N in terms of harvest index. The Iqbal variety of maize exhibited higher harvest index than Jalal.

Grain N concentration (%)

The response of maize varieties Jalal and Iqbal for grain N concentration was found to be significant against all the applied levels of humic acid, nitrogen and their combination. However, the effect of sole application of 1.2 and 1.8 kg HA ha^{-1} on grain N concentration was statistically at par with each other in both the varieties (*Table 8*). Likewise, the impact of alone application of N and 1.8 kg HA ha^{-1} on grain N concentration was statistically not different from each other in either of the maize variety. In both varieties, the combined application of 1.8 kg HA ha^{-1} + N produced the plants with the highest grain N concentration. Furthermore, the grain N concentration of maize variety Iqbal were higher than Jalal. The control plots of maize varieties resulted in lower grain N concentration.

Stover N concentration (%)

The different application levels of humic acid in the absence and presence of nitrogen as well as the sole application of N substantially enhanced the stover N concentration of maize varieties Jalal and Iqbal, except the alone application of humic acid at 0.6 kg ha^{-1} (*Table 9*). Humic acid application at 1.8 kg HA ha^{-1} produced the highest stover N concentration in both varieties which was at par with 1.2 kg HA ha^{-1} and the individual application of N. Although, the alone N accelerated the grain N concentration of both varieties but the maximum N concentration was recorded at 1.8 kg HA ha^{-1} + N which was statistically at par with 1.2 kg HA ha^{-1} + N. The higher stover N concentration was observed in the maize variety Jalal as compared to Iqbal. The plants of control plots were studied to be lower in the stover N concentration in both the maize varieties.

Grain N uptake (kg ha^{-1})

In both the maize varieties the grain N uptake were significantly affected by the alone application of humic acid, nitrogen as well as their integration (*Table 9*). Although the sole use of N fertilizer enhanced the grain N uptake of each variety, but the maximum N uptake was observed at 1.8 kg HA ha^{-1} + N. The minimum grain uptake of maize varieties was observed in the control plots of humic acid and nitrogen. The plants of Iqbal variety showed the highest grain N uptake when they were compared with the maize plants of Jalal variety.

Stover N uptake (kg ha^{-1})

The sole application of N as well as the applied levels of humic acid in combination with N and without N substantially influenced the stover N uptake of both maize varieties, except at 0.6 kg ha^{-1} in Iqbal (*Table 10*). However, under the alone application of humic acid, 1.8 kg HA ha^{-1} resulted in higher stover N uptake which was statistically at par with 1.2 kg HA ha^{-1} in both varieties. The sole use of N significantly increased the stover N uptake in both maize varieties. Moreover, the integrated application of 1.8 kg HA ha^{-1} + N produced the highest stover N uptake in both varieties which was statistically at par with 1.2 kg HA ha^{-1} + N. The higher average mean of stover N uptake was recorded in the maize variety Jalal than Iqbal.

DOI: http://dx.doi.org/10.15666/aeer/1703_67836799

Total N uptake (kg ha^{-1})

The total N uptake of both maize varieties had significant response to the alone application of N as well as applied levels of humic acid in the presence and absence of N (*Table 10*). As far as the sole application of humic acid is concerned, 1.8 kg HA ha^{-1} resulted in maximum uptake of N in both the varieties. Likewise, the alone application of N increased the total N uptake in both maize varieties but the maximum response was observed under the combined application at 1.8 kg HA ha^{-1} + N. The total N uptake was lower in control plots of humic acid and N as compared with other treatments. The Iqbal variety of maize exhibited higher total N uptake than Jalal.

Discussion

The application of humic acid and N caused significant increase in the plant height and leaf growth of both maize varieties. Maximum plant height, leaves plant^{-1}, leaf area plant^{-1} and leaf area index was recorded in the Jalal variety of maize at 1.8 kg HA ha^{-1}. The beneficial effect of humic acid on crop growth, number of leaves plant^{-1}, leaf growth and its expansion in maize and other species has been reported by a number of plant researchers (Atiyeh et al., 2002; Daur and Bakhashwain, 2013). The possible explanation is the higher number of sinks produced, uptake of nutrients, and increased plant biomass due to humic acid application (El-Mekser et al., 2014). Likewise, the experimental plots treated with N fertilizer showed maximum plant height, number of leaves plant^{-1}, leaf area plant^{-1} and leaf area index in maize varieties Jalal and Iqbal. The stimulatory impact of N on plant height and leaf growth has been studied by many researchers (Onasanya et al., 2009; Inamullah et al., 2011; Kolari et al., 2014). The underlying reason is that N is an integral constituent of chlorophyll tissues of plant (Rizwan et al., 2003) which accelerated vegetative growth of the crop (Gokmen et al., 2001), leaf production and its size (Jasemi et al., 2013).

The nitrate reductase (NR) activity of leaves and net assimilation rate of both maize varieties significantly enhanced with the integration of humic acid and N. Higher NR activity of leaves and net assimilation rate was recorded in Iqbal as compared to Jalal variety of maize. The plants supplied with 1.8 kg HA ha^{-1} produced higher nitrate reductase (NR) activity and net assimilation rate. These findings are supported by Vaccaro et al. (2015) and Azeem et al. (2015) who found an acceleration in the NR activity and net assimilation rate of maize when they treated it with 5 mg of humic acid

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_67836799

liter^{-1} of water and 1.5 kg HA ha^{-1}, respectively. The possible explanation is the optimum nutrients availability, H^+-ATPase synthesis (Canellas et al., 2013), and increased root length that in turn made better use of the available nutrients (Motaghi and Nejad, 2014). Similarly, the N nutrient activated the NR activity of leaves and net assimilation rate of both maize varieties against control plots of N. As a result of higher N concentrations in the soil, higher nitrate accumulation occurred within the leaves of maize (Soleymani and Shahrajabian, 2013) with the activation of NR activity in leaves. It is because NR activity seemed to be directly related to nitrate or N availability within the plants (Vincentz et al., 1993; Cazetta et al., 2004). Habib et al. (2016) has also reported an increase in the net assimilation rate of maize due to N application. It is due to the beneficial effect of N on maize as it is a nitro positive crop (Gokmen et al., 2001) and responds well to N application under favourable soil moisture conditions. It is because humic acid has a crucial role in mineral nutrition and moisture retention capacity of the soil (Celik et al., 2011).

The integration of humic acid with N substantially increased the number of ears m^{-2} and ears plant^{-1} in maize varieties Jalal and Iqbal. The higher ear density was measured in Iqbal variety of maize at 1.8 kg HA ha^{-1}. These results are in line with the findings of Iqbal (2014) who reported maximum productive tillers in wheat crop, treated with humic acid as compared to control. It could be due to the rapid penetration of humic acid in the plant cells, direct effect on chlorophyll content, acceleration of respiration, activation of growth enzymes, and indirectly through improved biological, physical and chemical conditions of the soil (Rajpar et al., 2011). The experimental application of N fertilizer increased the number of ears in maize varieties. The increase in number of ears with inorganic N fertilizer has been demonstrated by many researchers in maize crop (Hago and Sawi, 1995; Inamullah et al., 2011). The hidden reason is the provision of N nutrient in proper amount at reproductive growth stage of the crop (Shah et al., 2009) which accelerated the rate of photosynthesis (Kolari et al., 2014) and ear bearing capacity of maize crop (Bashir et al., 2012).

The ear length, thousand grain weight, grain yield, stover yield amd harvest index of both maize varieties significantly increased with the application of humic acid and N. The Iqbal variety of maize produced maximum ear length, thousand grain weight, grain yield and harvest with the application of 1.8 kg HA ha^{-1} while the Jalal showed higher magnitude of stover yield with the same dose of humic acid. Various studies have shown the significant impact of humic acid on yield, yield components, stover yield and harvest index of maize crop (Ghorbani et al., 2010; Mohana et al., 2015). The reason is that humic acid creates an improvement in the physico-chemical properties of soil, and increased biomass production then occurs as a result of acceleration in plant biochemistry, physiology and productivity (Canellas and Olivares, 2014). Furthermore, N application accelerated the yield, yield components, stover yield and harvest index of maize varieties Jalal and Iqbal as compared to control plots of N (Sharifi and Taghizadeh, 2009). It is because N is a major plant nutrient and yield deciding factor for maize crop production (Manzoor et al., 2006) as it forms an integral component of protein and amino acids in the plants (Bakht et al., 2007). It enhanced nutrients uptake, assimilate production (Cirilo et al., 2009) and translocation of photosynthates from source to sink (Jena et al., 2015) which positively contributed to the increase in yield components of maize crop (Kaur et al., 2012).

The grain and stover N concentration of both maize varieties as well as their N uptake (grain N uptake, stover N uptake and total N uptake) considerably improved with the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_67836799

integration of humic acid and nitrogen. The plants of Iqbal variety treated with 1.8 kg HA ha^{-1} showed higher grain and stover N concentration, grain N uptake and total N uptake. A number of plant researchers has described the significant impact of humic acid on enhancing the grain and stover N concentration of maize crop as well as its N uptake (Celik et al., 2010; Anees et al., 2016; Niaz et al., 2016). It is due to the stimulatory effect of humic acid on physical (Varanini et al., 1995), chemical and biological properties of soil (Khattak, 2004), nutrients concentrations, their availability, and transportation to the growing parts of maize plants (Celik et al., 2011). It is highly involved in the hormonal activities and enzymatic reactions within the plants (Nardi et al., 2002) and is responsible for the reduction and assimilation of N nutrient (Vaccaro et al., 2015). It provides particular bioactive molecules to the cell membranes of plants roots for N uptake (Canellas and Olivares, 2014). Likewise, higher N concentration, and N uptake were studied in the grain and stover of maize varieties Jalal and Iqbal with the use of N fertilizer because maize crop is an aggressive utilizer of available plant nutrients (Ayoola and Makinde, 2009). The possible explanation could be the increase in total N of soil, residual N of soil (Yang et al., 2007), mineralization of soil organic N (Li et al., 2003), amino acid formation (Almodares et al., 2009), an acceleration in physiological and bio-chemical processes of the plants (Rawal and Kuligod, 2014) that promoted N concentration and N uptake of maize varieties. These findings are supported by El-Hassan et al. (2014), Biswas and Ma (2014) and Niaz et al. (2016) who reported an increase in the grain and stover N concentration, and total N uptake of maize crop with applications of N fertilizer.

Conclusion

It was concluded that 1.8 kg HA ha^{-1} + 120 kg N ha^{-1} resulted in maximum plant height, leaves $plant^{-1}$, leaf area $plant^{-1}$, leaf area index, NR activity in leaves, net assimilation rate, ears m^{-2}, ears $plant^{-1}$, ear length, thousand grain weight, grain yield, stover yield, harvest index, grain N concentration, stover N concentration, grain N uptake, stover N uptake and total N uptake of maize varieties. However, the maize variety Iqbal out yielded than Jalal under the applied levels of humic acid with nitrogen. Therefore, against the sole use of inorganic N, the local growers should use integration of 1.8 kg HA ha^{-1} + 120 kg N ha^{-1} along with maize variety Iqbal for obtaining higher yield of maize crop under the local environmental conditions. With this combination, it will be possible for local growers to accelerate the growth, physiology and yield of maize varieties with acceleration in the uptake of N nutrient which is often a limiting factor for crop production under the local semi-arid conditions. However, further research is needed to investigate the impact of higher levels of humic acids in integration with N on maize yield under the local agro-ecology.

(Received 11th Feb 2019 ; accepted 8th Apr 2019)

Abstract. The paper investigates the relation between environmental degradation and economic development. The authors focused on the situation specific to the EU-28 Member States for the timeframe 1960-2014. The study used the variables CO_2 emissions, GDP per capita, imports of goods and services, exports of goods and services and energy use. The research has been divided in three distinct stages. The first stage consisted in data collection and management by analysing the existence of the unit root and determining the level at which the data is stationary. The second stage consisted in the testing Granger Causality relations between the variables for 2-5 lags. The third stage consisted in the estimation of a regression equation of the environmental Kuznets curve type. The results demonstrate the applicability of environmental Kuznets curve for the EU-28 Member States. These results can be used for design of industrial policies of these states, considering these states sustainable development goals. The public authorities are aware of the importance of environmental protection and of the correlation between environment and the economy development. The authors consider that the results of this article are an useful instrument to establish the macroeconomic policies while considering the perspective of sustainable development.
Keywords: *environment, economic development, CO_2 emissions, energy, imports, exports*

Introduction

The Kuznets Curve has extended its applicability from the social field to the environmental field. We are witnessing the promotion of new concepts, such as the environmental Kuznets (EKC) curve or the forest transition curve (Kuznets, 1955). Simon Kuznets launched a hypothesis in the 1950s on the existence of a relationship between the level of development of a country and the income of the population. As the level of development of a country increases, in the first stage, there is a deepening of the inequality between the population incomes, as the investment opportunities are capitalized by the persons with important capital, and the migration from the villages to the cities of cheap labor force keeps the salaries at a reduced level. The mechanization of agriculture and industrialization generate international migration and a reduction in the rural population. Increasing the level of development ultimately generates revenue growth, thus recording a negative relationship between income inequality and economic development. For this reason, the Kuznets curve is shaped as a U curve.

In the first stage of industrialization, environmental issues were not a main concern either for authorities or for citizens, as everyone was focused to income (profit-making) and increasing the number of jobs. Also, the small number of strict regulations on environmental protection and, after that, the costs of protective measures, contributed to some secondary concerns and measuring of business development and diversification to environment preservation. The pressure on the environment is very high during

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68016820

industrialization, as industrial production increases are based on excessive consumption of resources and increased pollution (Marcu et al., 2016). As the level of development of a state increases, authorities, citizens and companies become more aware of the impact of their activities on the environment; environmental protection rules and regulations are strictly enforced and adhered to, and investments are made to protect the environment. In addition, factors such as income elasticity to environmental quality and changes in the composition of consumption and production (Selden and Song, 1994; Bo, 2011) have led to a decrease in pollution. Moving to a higher level of industrialization reduces environmental pressure, measured with various instruments such as pollution levels, emissions flows, resource depletion. Therefore, the pressure on the environment grows faster than the incomes in the first stages of development. The pressure will slow down as a country develops (Dinda, 2004).

The specialists concerns about the relationship between the environment and economic growth have been generated by the intensification, in the last decade of environmental degradation, with major economic, social and political implications; this has generated a change in the behaviour of companies and public institutions that have tried to identify solutions to the development of this problem (Al-Mulali et al., 2015b; Popescu et al., 2016; Andrei et al., 2017; Cristea and Dobrota, 2017). Sustainable development and corporate social responsibility are concepts accepted and promoted by authorities, companies, consumers, portfolio investors, universities, financial institutions, etc. (Ciutacu et al., 2005; Zaman, 2005; Vasile and Balan, 2008; Anghelache, 2011; Ene, 2011; Nica, 2015; Andrei et al., 2014; Sima and Georgiana, 2014; Voica et al., 2015; Ene et al., 2017; Popescu et al., 2017).

The Kuznets Curve, which was initially used for demonstrating the relation between the level of development of a country and the income of its population, has had its applicability extended, from the social field to the environmental field; we are witnessing the promotion of new concepts, such as the environmental Kuznets (EKC) curve or the forest transition curve (Kuznets, 1955).

In international scientific literature, the Kuznets curve environmental analysis was conducted, in a first phase, by researchers such as Grossman and Krueger (1991), then the issue entered into the areas of concern of international financial institutions such as the World Bank, which dedicated the 1992 report to the relationship between economic development and the environment. The 1992 report of the World Bank presents the links between the environment and economic development and draws attention to the importance of integrating environmental aspects into public policies promoted by the authorities in view of the negative environmental impacts on the quality of life, productivity and further development of a country (World Bank, 1992). Although it does not use the environmental Kuznets curve term, this report called “Development and the Environment”, considers that “As incomes rise, the demand for improvements in environmental quality will increase, as will the resources available for investment”. The dedication of the EKC term came a few years later, when Panayiotou (1993) named the inverted U-shaped relationship as environmental Kuznets curve (EKC).

We consider that our paper contributes to the debate on environmental degradation by estimating an EKC for the EU member states CO_2 emissions over the period 1960-2014. The major contribution of this paper is the analysis of the relationship between CO_2 emissions and the level of development of the states in the European Union. We consider that CO_2 emissions is a relevant indicator in the research of the EKC as they

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68016820

alone are responsible for almost 60% of all greenhouse gas emissions. As we will present in the literature review section, studies made by other researchers have focused on other groups of countries and do not target the period we are considering. Our analysis was done on two levels. The first step consisted in carrying out a causal analysis of variables using the Granger causality test, and the second level consisted in identifying a regression equation based on the Kuznets theory (1955) applied to the medium-economic relationship. A series of researchers (Panayotou et al., 1999; Cole et al., 1997; Scmalensee et al., 1998) has demonstrated that the theory is valid for greenhouse gas emissions by using "environmental Kuznets curves" (EKC) term.

The novelty of our research lies in the fact that the analysis is done at the level of the 28 countries in the EU and for a period of more than 50 years. Using and interpreting data for the period 1960-2014, allows the authors to capture several stages of development specific to the EU countries, which contributes to a better substantiation of the obtained results.

The objective of this article is to determine the impact of economic development on the environment in the 28 EU countries for the period 1960-2014. This article aims to examine the potential for convergence in the environmental policy field of the 28 EU member states, on the assumption that they represent a specific, easily identifiable model in the environmental field, namely in the field of reducing the environmental impact. Environmental taxation and other (internal) variables imply some specific behavior in the field of environmental economics and political sector, but EU countries form a functional model with specificities that can be translated into the case of other states. In this case, we consider the possibility of substantiating a European environmental and ecological model

Even if the EU member states have gradually joined to this construction over several decades, we believe that we can have an aggregated approach of these states taking in consideration aspects like geographic proximity, the existence of European values that can be traced back to history and the obligation of fulfilling certain criteria for EU membership. Therefore, economic and political convergence is ensured at the moment a state enters the EU, thus ensuring a certain level of economic development, political and ideological harmonization.

The expansion of the EU after the fall of the communist era was a normal phenomenon, despite a period of rupture of the former Central and Eastern European countries by the capitalist system. The accession of the former communist countries was progressively achieved, as they have met the criteria imposed by the European Treaties and have proved consistency with European values by having the status of associated countries in the EU. Even though the current EU member states have had different political regimes in the past, they have undergone an intense economic development and industrialization process with negative impact on the environment. The classification and grouping of states in a model, depending on the previous political situation, influences to a relatively insignificant degree the behaviour in the field of environmental policy. Reducing sectoral environmental disparities across the 28 EU states requires a holistic analysis of these in terms of the specificities of countries where reality variables are insignificant in the model under analysis.

The novelty of our study is to select the sum of countries, i.e. the EU countries, for which there have not been too many studies on this issue, as we will present in the literature review section, but also in the selection of variables for 1990-2014. The accession of the countries to the EU has had an impact not only on the legislative

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68016820

system, but to a large extent to the intra-community trade that have been dynamized, which is why we analyzed the imports and exports as variables. In addition, they contribute to increased production, with direct effects on the environment.

Review of literature

This section is dedicated to the literature review of the main researches regarding the implications of economic development on the environment. The link between the environment and economic development was analyzed a few decades before the EKC concept was crystallized through the famous IPAT equation (I = PAT), which established a relationship between Impact (e.g., pollution, or natural resource use) to Population, Affluence often proxied with per capita income, and Technology (Ehrlich and Holdren, 1971; Commoner, 1972).

The Growth Limit Report, developed by Dennis Meadows of the Massachusetts Institute of Technology for the Club of Rome, is a work that draws attention to the link between economic growth and environmental pollution (Carson, 2010; Bo, 2011). So, the concerns in this area are old, but the first reference work for the EKC is the study by Grossman and Krueger in 1991 that analyzed the environmental impact of North American Free Trade Agreement. Therefore, trade/ development economists have a major influence on promoting the concept of environmental Kuznets curve in the context of an international trade agreement rather than environmental/resource economists in a pollution control context (Carson, 2010). These American economists (Grossman and Krueger, 1991) analyzed the influence of the policy promoting trade and foreign investments on pollution and the rate of depletion of natural resources.

Liberalization of trade and capital flows generates:

- Increased economic activity with direct implications on the pollution (scale effect).
- Increasing the country's specialization in accordance with the comparative advantage, which will contribute to the increase of production in those sectors where the costs of pollution abatement are relatively low, and the resources will be directed to those industries that use them intensively (composition effect).
- Transfer of new technology from foreign investors and more stringent environmental protection standards by public authorities as the level of development of the host country increases (technique effect).

This first study (Grossman and Krueger, 1991) has demonstrated the link in the form of EKC between the income and sulphur dioxide (SO_2), suspended particle matter (SPM) as environmental pollutants. Other studies have also considered other pollutants that reflect air quality such as nitrogen oxide, carbon monoxide or CO_2 (Selden and Song, 1994).

The environmental Kuznets curve has generated numerous debates in the literature, and it has been accepted by most specialists who have tried to measure its parameters and determine the income/inhabitant from which the level of pollution trend changes, as well as the shape of this curve considering various factors of influence. The regressions have indicated different income per capita as the inflection point for Kuznets environmental curves depends on the variables considered (Grossman and Krueger, 1991; Stern et al., 1996; Dasgupta et al., 2002). In addition, a change in the shape of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68016820

Kuznets curve has been observed in the sense that it is flatten downward due to the influence of factors such as economic liberalization, improvement and transparency of information, environmental protection and pollution prevention regulations from developing countries conditions based on the actions taken internationally (Dasgupta et al., 2002). So, the shape of the EKC is influenced by certain factors. In addition to the factors presented above, other researchers insist on specific elements of influence such as Inward elasticity of environmental quality demand, scale, technological and compositional effects, international trade (Dinda, 2004), but also liberalization and financial development, institutional quality (Tamazian and Rao, 2010), political and civil liberties (Shafik and Bandyopadhyay, 1992; Torras and Boyce, 1998).

The impact of economic development on the environment has been analyzed through EKG across different countries or groups of countries, with results underestimating in some cases the EKG hypothesis, as follows:

- Shahbaz et al. (2013) conducted an empirical analysis based on the 1970-2010 annual data for Turkey based on CO_2 emissions and economic growth, taking in consideration the candidate status of this country to theEU. The main conclusion of the article is that an inverted U-shaped relationship is found between economic growth and CO_2 emissions.
- Esteve and Tamarit (2012) confirmed the non-linearity of the link between per capita CO_2 and per capita income for Spain over the period 1857-2007;
- Al-Mulali et al. (2015b) demonstrated, based on data from 1987 to 2011, that the EKC hypothesis does not exist for Vietnam because GDP and pollution have a positive relationship in the short and long run.
- Apergis and Ozturk (2015) test the environmental Kuznets curve (EKC) hypothesis for some Asian countries using data for the period 1990-2011; the main indicators used are CO_2 emissions, GDP per capita, population density, land, industry shares in GDP. The result of this study was the presence of an inverted U-shape association between emissions and income per capita for 14 Asian countries.
- Li et al. (2016) used data for 28 provinces of China from 1996 to 2012 and demonstrated that the Environmental Kuznets Curve (EKC) hypothesis is verified for some of the pollutant emissions (carbon dioxide, waste water and waste solid emissions).
- Al-Mulali, Tang and Ozturk (2015a) made a study and explored the impact of economic growth (GDP), renewable energy (RE) and financial development (FD) on CO_2 emissions (CO_2); the sample was composed by Latin America and Caribbean countries and data were collected for the period 1980-2010. The conclusion was that CO_2 emission, GDP growth, renewable energy consumption and financial development are cointegrated and an inverted U-shaped relationship between GDP growth and CO_2 emission exists.
- Cristea and Dobrota (2017) analyzed the CO_2 emissions, greenhouse gas emissions (GGE), the renewable energy consumption (REC) and the consumption of biofuel (BC) in Romania in relation with the intensity of energy in economy (IEE) and the population number (PN). The authors underlined “the need to adopt Green Energy Economy in Romania, in relation to the economic activity and demographic changes…focusing mainly on energy technologies with low-carbon”.

DOI: http://dx.doi.org/10.15666/aeer/1703_68016820

According to our knowledge, the issue of economic development`s impact on the environment at EU level has not been the subject of many scientific researches published in the mainstream in recent years. In international scientific literature, we have identified several studies published in ISI-indexed journals, the results of which are presented below.

Thus, Wawrzyniak (2018) has tested the environmental Kuznets curve in European Union countries and his econometric study was based on data for EU-28 countries in years 1990-2013. This study focuses on the impact of energy consumption, foreign direct investment, trade openness and GDP on CO_2 emissions in EU states. The conclusion was that for these countries an inverted U-shaped relationship between CO_2 emissions per capita and GDP per capita is observed.

Kasperowicz (2015) was interested in the study of the relationship between economic growth and CO_2 emissions for 18 EU Member States from 1995 to 2012. The analysis was based on the ECM estimation, the panel cointegration test and EGLS estimator for some European countries (including some former communist countries) and demonstrated that the long-term relationship between GDP and CO_2 emissions is negative.

Armeanu et al. (2018) have explored the link between environmental pollution and economic growth in EU-28 countries; the results of the analysis confirm the EKC hypothesis in the case of emissions of sulphur oxides and emissions of nonmethane volatile organic compounds

Sterpu et al. (2018) analyzes the relationship of economic growth and energy consumption on greenhouse gas emissions for a panel of 28 countries of the European Union in the period 1990-2016. They used four macroeconomic indicators: Gross Domestic Product (GDP), Gross Inland Energy Consumption (GIC), Renewable Energy Consumption (REC), and Greenhouse Gas Emissions (GHG), in order to statistically test the EKC hypothesis. The results of the study demonstrate a non-conclusive evidence for the EKC hypothesis.

Lapinskienė et al. (2017) conducted a scientific research based on the expanded EKC model to estimate the relationship between GHG and GDP and additional factors such as energy consumption, energy taxes and R & D. The panel used is formed by twenty EU countries, including three Baltic States, and the data are for the period 1995-2014. The main conclusion of the article is the presence of the inverse U-shaped relationship for these EU countries.

Materials and methods

In order to evaluate the relationship between CO_2 emissions and the economic development, we have analyzed the following variables: CO_2 emissions (metric tons per capita), GDP per capita (constant 2010 US$), imports of goods and services (constant 2010 US$), exports of goods and services (constant 2010 US$) and energy use (kg of oil equivalent per capita). The research was applied for the European Union - 28 Member States. The database used for collecting the data was the World Bank, for the 1960-2014 period. For the analysis, we have opted for the World Bank database to avoid the lack of data for certain countries and the inconsistency of the data series.

First, we will make a short presentation of the average evolution for the independent variables at the EU level. We must acknowledge that different countries joined the EU at different times and so many factors influenced each country's independent variables.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68016820

We will start by analyzing the evolution of CO_2 per capita emissions. World Bank uses this definition: carbon dioxide emissions are those stemming from the burning of fossil fuels and the manufacture of cement. They include carbon dioxide produced during consumption of solid, liquid, and gas fuels and gas flaring. The source of the data is Carbon Dioxide Information Analysis Center, Environmental Sciences Division, Oak Ridge National Laboratory, Tennessee, United States.

As we can see in *Figure 1,* the CO_2 emissions per capita started to decrease after reaching the peak of 10 metric tons per capita in 1979. Since that moment, the trend was downward. By following that trend, we can pinpoint major events in the evolution of the European countries, like 1989-1990 fall of the communism in the Eastern European member states, 1997 signing of Kyoto protocol, 2008 triggering of international financial crisis. All these events had a favourable impact on the evolution of CO_2 emissions. Another important aspect is that the EU member states are reducing their CO_2 per capita emissions, closing on the 1960 level.

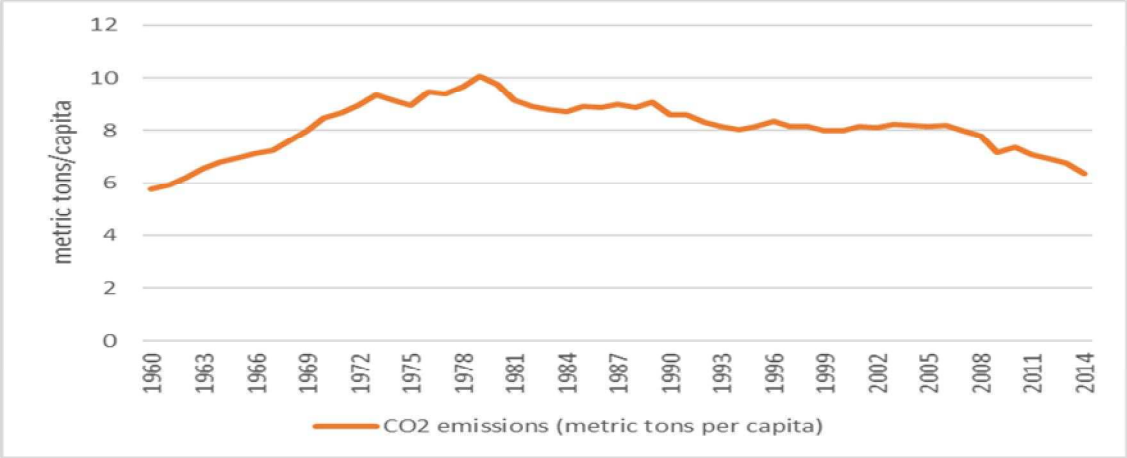

Figure 1. *EU-28 average CO_2 emissions (metric tons per capita) for the period 1960-2014. (Source: World Bank)*

The second variable is GDP per capita. GDP per capita is gross domestic product divided by midyear population. According to World Bank, GDP is the sum of gross value added by all resident producers in the economy plus any product taxes and minus any subsidies not included in the value of the products. It is calculated without making deductions for depreciation of fabricated assets or for depletion and degradation of natural resources. Data is in constant 2010 U.S. dollars.

The third variable is represented by exports. According to the World Bank, exports of goods and services represent the value of all goods and other market services provided to the rest of the world. They include the value of merchandise, freight, insurance, transport, travel, royalties, license fees, and other services, such as communication, construction, financial, information, business, personal, and government services. They exclude compensation of employees and investment income (formerly called factor services) and transfer payments. Data is in constant 2010 U.S. dollars.

The fourth variable is represented by imports. According to the World Bank, imports of goods and services represent the value of all goods and other market services

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68016820

received from the rest of the world. They include the value of merchandise, freight, insurance, transport, travel, royalties, license fees, and other services, such as communication, construction, financial, information, business, personal, and government services. They exclude compensation of employees and investment income (formerly called factor services) and transfer payments. Data are in constant 2010 U.S. dollars.

The data for these three variables is obtained from World Bank national accounts data, and OECD National Accounts data files.

In *Figure 2* we can observe the evolution of the three variables. The most relevant observation is that the imports have a higher increase than the exports. This trend became more obvious after the 1990. This can be explained by the fact that the former communist countries started their transition to the open market. The GDP/capita had a steady trend in the analyzed period and, only after the financial crisis of 2008, the ascending trend of GDP/capita slowed down. Like in the case of GDP/capita, imports and exports also have been influenced by the financial crisis.

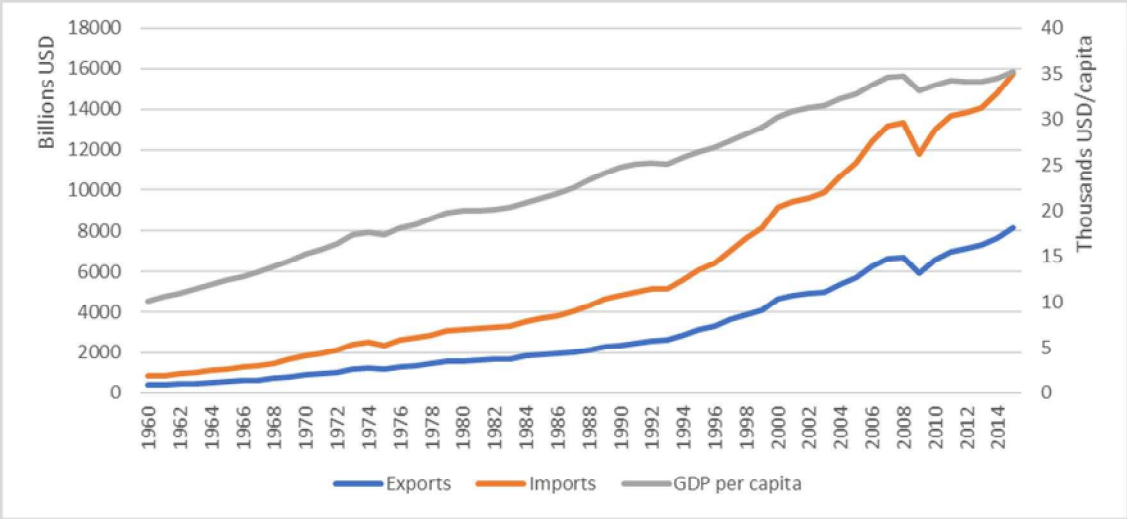

Figure 2. *EU-28 average GDP/capita, exports and imports for the period 1960-2014 (constant US $ 2010). (Source: World Bank)*

The fifth variable presented in *Figure 3* is energy use. According to the World Bank, energy use refers to use of primary energy before transformation to other end-use fuels, which is equal to indigenous production plus imports and stock changes, minus exports and fuels supplied to ships and aircraft engaged in international transport. The source of the data is IEA Statistics © OECD/IEA 2014.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68016820

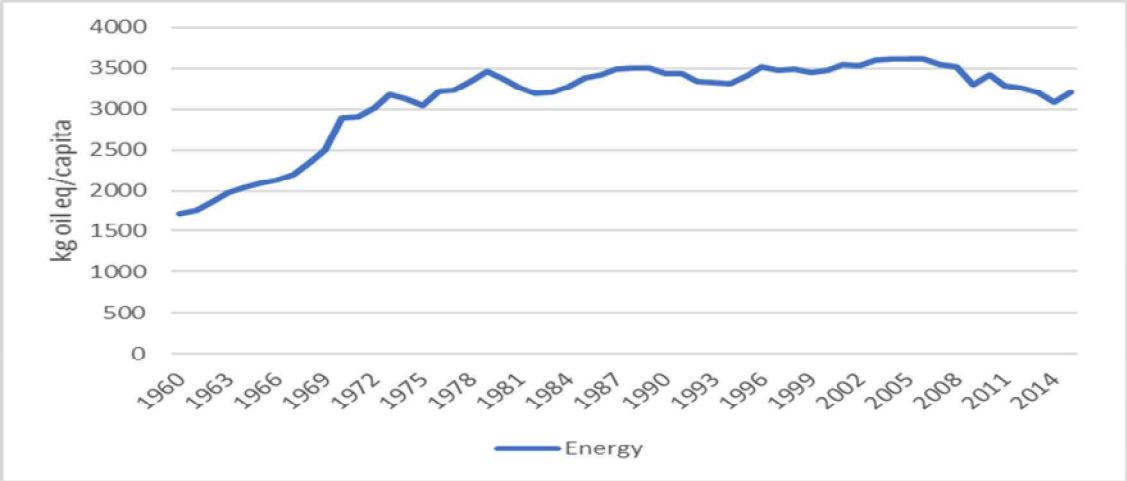

Figure 3. *EU-28 average energy use (kg of oil equivalent per capita) for the period 1960-2014. (Source: World Bank)*

The energy use in the analyzed period shoved an ascending trend until 1979, and after that the evolution was constant until 2008, when the trend changed direction.

The research has been divided in three distinct stages. The first stage consisted in data collection and treatment by analyzing the existence of the unit root and determining the level at which the data is stationary. The second stage consisted in the testing of Granger Causality relations between the variables for 2-5 lags. The third stage consisted in the estimation of a regression equation of the environmental Kuznets curve type.

Unit root was tested using Levin et al. (2002) (LLC) test, ADF Fisher-type test, Im, Pesaran and Shin (2003) W-stat and PP Fisher-type test (Choi, 2001; Maddala, 1999). For a better understanding of these tests forward we provide a review of them (Kuzume, 2005).

Levin et al. (2002) tested the null hypothesis $H_0: \delta = 0$ compared with the alternative hypothesis $H_0: \delta < 0$, using:

$$\Delta q_{i,t} = \alpha_{mi} d_{mt} + \delta q_{i,t-1} + \sum_{k=1}^{p} \gamma_k \Delta q_{i,t-k} + \epsilon_{i,t}, \quad \text{(Eq.1)}$$

where d_{mt} denotes the determinant parts and $\epsilon_{i,t}$ is considered to be independent distributed among I and t, with i = 1,…, N and t = 1,…, T. Immediately after the normalized interference and the correspondent of the pseudo ratio t of cumulated OLS estimations of δ in *Equation 1* are properly normalized, the convergence at a standard limit of normal distribution is achieved as $N \to \infty$, $T \to \infty$ so that $\sqrt{N}/T \to 0$.

Im et al. (2003) test is built on the estimation (*Eq. 1*) but changing δ with δ_i. The null hypothesis is $H_0: \delta = 0 \forall_i$, while the alternative hypothesis is $H_1: \delta < 0$ i = 1…N_1; δ_i =0, i=N_1 + 1, …, N. So, the null hypothesis is rejected if the is a subset (N_1) of stationary data. First test is the standardized group-mean Lagrange Multiplier (LM) bar test statistic

$$\psi_{\overline{LM}} = \frac{\sqrt{N}\left[\overline{LM} - N^{-1}\sum_{i=1}^{N} E(LM_i)\right]}{\sqrt{N^{-1}\sum_{i=1}^{N} Var(LM_i)}} \quad \text{(Eq.2)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68016820

with $\overline{LM} = N^{-1}\sum_{i=1}^{N} LM_i$, where LM_i denotes the individual LM tests for testing $\delta_i = 0$ in *Equation 1,* and $E(LM_i)$ and $Var(LM_i)$ are achieved through Monte Carlo simulation.

The next test is the standardized group mean *t* bar test statistic $\psi_{\bar{t}}$, with a similar expression like *Equation 2,* replacing $\overline{LM}$ and LM_i with $\bar{t}$ and t_i.

We defined $\bar{t} = N^{-1}\sum_{i=1}^{N} t_i$, where t_i denotes the individual pseudo *t* ratio for testing $\delta_i = 0$ in *Equation* 2, and $E(t_i)$ and $Var(t_i)$ are computed using the Monte Carlo simulation. In Im et al. (2003), because $N \to \infty$, $T \to \infty$ and $N/T \to k$, both statistic tests for distribution limitation are standard normal.

Fisher-ADF and Fisher-PP test are an alternative approach to test for unit root in panel data that uses the results of Fisher (1932) in testing for combined *p* values of the individual test of unit root, as they were propose by Maddala and Wu (1999) and Choi (2001).

If π_i is the *p* value of any individual unit root test for transversal section *i*, then, under the nullity of unit root for every transversal section *N*, we have the asymptotic result:

$$-2\sum_{i=1}^{N} \log(\pi_i) \to \chi^2_{2N} \qquad \text{(Eq.3)}$$

Choi (2001) proves that:

$$Z = \frac{1}{\sqrt{N}}\sum_{i=1}^{N} \Phi^{-1}(\pi_i) \to N(0,1) \qquad \text{(Eq.4)}$$

where $\Phi^{-1}$is the inverse of the standard normal distributed cumulative function.

For the unit root tests, we used Schwarz info criterion, Newey-Vest automatic band width selection and Bartlett kernel.

In order to test the causality relation between the variables, we start from the Granger (1969) Hypothesis that asked how much of the variable y may be deduced from the past values of y and then asked if by adding the past values of x he can obtain a better approximation of y. A variable y is Granger caused by x when x improves the predictive capacity of y, or when the past coefficients of variable x are statistically significant. We must acknowledge that a two-way causality is a frequent case when x Granger causes y and y Granger causes x.

In order to apply a Granger causality, test we must specify the lag length l. Usually it is better to use more lags in order to get the relevant information form the past. In our study we tested the Granger causality relation between the variables for 2, 3, 4, and 5.

After establishing the lag length, we will estimate a bivariate regression of the form:

$$y_t = \alpha_0 + \alpha_1 y_{t+1} + \cdots + \alpha_l y_{t-l} + \beta_1 x_{t+1} + \cdots + \beta_l x_{t-l} + \varepsilon_t \qquad \text{(Eq.5)}$$

$$x_t = \alpha_0 + \alpha_1 x_{t+1} + \cdots + \alpha_l x_{t-l} + \beta_1 y_{t+1} + \cdots + \beta_l y_{t-l} + \mu_t \qquad \text{(Eq.6)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68016820

for each possible pair of (x,y) series of the group. F-statistic reported values are the Wald statistics for the consolidated hypotheses:

$$\beta_1 = \beta_2 = \cdots = \beta_l = 0 \quad \text{(Eq.7)}$$

for each equation, the null hypothesis is that *x* does not Granger cause *y* in the first regression and *y* does not Granger cause *x* in the second regression.

In order to estimate the regression equation, we started from the linear regression using the OLS method with panel data of the form:

$$Y_{it} = f(X_{it}, \beta) + \delta_i + \gamma_t + \epsilon_{it} \quad \text{(Eq.8)}$$

This specific case implies a conditional mean linear specification so that we achieve:

$$Y_{it} = \alpha + X'_{it}\beta + \delta_i + \gamma_t + \epsilon_{it} \quad \text{(Eq.9)}$$

where Y_{it} is the dependent variable, X_{it} is a regressor vector *k* and ϵ_{it} error terms for $i = 1, 2, \ldots, M$ transversal units, observed for the dated periods $t = 1, 2, \ldots, T$. α is the general constant of the model while δ_i and γ_t represents the effects specific to transversal section or time period.

By introducing the variables specific to our study and of EKC conditions in *Equation 9* we achieve a regression of the form:

$$\ln CO2 = \beta_0 + \beta_1 \ln GDP + \beta_2 \ln GDP^2 + \beta_3 \ln ENERGY + \beta_4 \ln EXP + \beta_5 \ln IMP + \epsilon \quad \text{(Eq.10)}$$

where: CO_2 – CO_2 emissions (metric tons per capita), GDP – GDP per capita (constant 2010 US$), ENERGY – Energy use (kg of oil equivalent per capita), IMP – Imports of goods and services (constant 2010 US$), EXP – Exports of goods and services (constant 2010 US$), $\beta_0, \beta_1, \beta_2, \beta_3, \beta_4, \beta_5$ – regression coefficients, ϵ – estimation error.

Results and discussions

Unit root tests

In this part, we present the summary statistics for each variable in *Table 1* and we have tested the variables for unit root in order to find the correct level at which the data has achieved stationarity. Because we are working with monetary units, first, we will apply logarithms to the variables and after will proceed with the unit root tests. For unit root testing we use Augmented Dickey–Fuller Fisher Chi-square test, Phillips–Perron Fischer Chi-square test, Im, Pesaran and Shin W-stat test and Levin, Lin & Chu t* test. Probabilities for Fisher tests are computed using an asymptotic Chi-square distribution. All other tests assume asymptotic normality. The results of the unit root test are presented in *Table2*.

As we can see in *Table 2,* the CO_2 emissions (CO2) are not stationary at level so we proceed to 1st difference in order to achieve a stationary series. In the case of GDP per capita (GDP), energy use (ENERGY), imports of goods and services (IMP) and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68016820

exports of goods and services (EXP) they are stationary at level so there is no need for the first difference in their case. After the unit root testing we can proceed to the next steps of pair wise Granger causality tests and estimating the regression equation.

Granger causality test

As we already explained, the pair wise Granger causality test consists in determining if avariable y is Granger-caused by x when x improves the prediction of y, or when the coefficients of the lagged x are statistically significant. We must acknowledge that a two-way causation is a frequent case in which x Granger causes y and y Granger

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68016820

causes x. In *Table 3* we have the results of the pair wise Granger causality tests for our variables for a lag range from 2 to 5.

By analyzing the data from *Table 3* we observe that between the pairs of variables there are two-way Granger causality of a high level of statistical significance at a level of 1%. Another interesting thing observed is that the significance tends to be lower only for a smaller number of lags and as we past lag three all pairs have a two-way Granger causality significance lower than 1%, which is a logic evolution as time must pass before the evolution from one variable fully affect the evolution of the other variables.

Table 3. *Pair wise Granger causality tests*

Pair	Lags	2	3	4	5

*significance at 10%; **significance at 5%; ***significance at 1%

As we can observe from the data presented in *Table 3,* the CO_2 has two-way relations with the independent variables from the study. These relations have been explained in previous studies (Pirlogea and Cicea, 2012; Allen, 2012; Su and Ang, 2016; López, et al., 2013) and our results provide similar conclusions. The CO_2 emissions have always been linked to the level of development, quantified by the GDP per capita. As a country reaches a higher level of development, its technological endowment changes from high pollution generating machinery, to environmentally friendly ones. This happens through the change of policy towards CO_2 emissions. The increase of GDP is linked with intensified activity on the international market quantified in our study by the imports and exports. Our results support this link, as the growth of CO_2 emissions is generated by the industrial production and other sectors growth. This growth generates, on one hand, a need for raw materials and intermediate goods, which takes the form of imports, and, on the other hand, the need to sell the produced goods to new markets which takes the form of exports. Another problem that must be acknowledged in respect to the international trade is the shift of CO_2 emissions from one country to another through imports and exports. As a country reaches a higher level of development and the pressure regarding the CO_2 emissions from policymakers, NGOs or other forms increases, there is the possibility to import the goods whose production generates high levels of CO_2 emissions. In this case, we have only a false reduction of CO_2 emissions, as the quantity of CO_2 emissions is shifted from the importing country to the exporting one, usually a developing country where there is a lower pressure regarding the CO_2 emissions and a higher demand for development. The link between CO_2 and energy consumption is one of the easiest to explain as the production of energy generates the largest amount of CO_2 apart from the energy produced from renewable sources, but even here the topic is under debate.

Environmental Kuznets curves for EU

We chose the EU for our study because the EU took a lot of steps toward reducing the CO_2 emissions and it has a proactive approach on the climate change issue that troubles the world leaders' minds. In this stage, we are going use the EKC model to estimate an equation with the CO_2 emissions as the dependent variable, and GDP/capita, energy consumption, imports and exports, as the independent variables. Previous studies (Apergis and Ozturk, 2015; Li et al., 2016; Al-Mulali et al., 2015a) added different variables to the model in order to better estimate the evolution of the dependent variable. For our estimation, we used the panel least squares method with a sample of 53 periods, between 1961 and 2013 and 28 cross-sections for each of the Member States, resulting a number 1484 observations.

In *Table 4* we have presented the results for the regression coefficients and forward the regression equation will be of the form:

$$\ln CO2 = 35.89 - 7.42 \ln GDP + 0.36 \ln GDP^2 + 0.27 \ln ENERGY - 0.17 \ln EXP + 0.18 \ln IMP \quad \text{(Eq.11)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68016820

Our regression equation has an R-square value of 0.30 which means the model can explain only a part of the evolution of the CO_2, and a value of 1.94 for the Durbin-Watson test. The values of the coefficients provide us important information regarding the influence of each independent variable on the CO_2 evolution.

Table 4. *EKC regression coefficients*

Variable	Coefficient	Std. error	t-statistic	Prob.
C	35.88499	3.068164	11.69592	0.0000
GDP	-7.420802	0.635589	-11.67548	0.0000
GDP^2	0.360973	0.031047	11.62684	0.0000
ENERGY	0.266519	0.022969	11.60349	0.0000
EXP	-0.174257	0.026417	-6.596447	0.0000
IMP	0.176767	0.028129	6.284131	0.0000

According to EKC, the coefficient of GDP should be positive, while the coefficient of GDP^2 should be negative. In our results, we observe that the coefficients do not have the same signs as the EKC and the sign of GDP is negative while the sign of GDP^2 is positive.

The plus sign of the per capita energy consumption coefficient confirms that as the energy consumption increases, the CO_2 emission will follow a similar trend, fact discovered in previous studies (Du et al., 2012; Shahbaz et al., 2012; Jalil and Mahmud, 2009; Saboori and Sulaiman, 2013; Andrei et al., 2017). The CO_2 emissions have always been in relation with the energy consumption as its production generates a high percentage of the total amount of greenhouse gas emissions. The only way to reduce the emissions generated from energy production is the technological conversion to renewable sources and the general adoption of clean technologies. The main problem of renewable energy is that they also have an impact on the environment as the materials and the production process of the renewable sources power plants generates greenhouse gases. Also, they impact the environment by affecting the landscape and in some cases negatively impacting the food production by converting the land used for food production to land used for energy plants in the case of biomass, biogas and biodiesel.

The exports have a negative impact on CO_2 emissions. There can be many explanations about this relation and this depends on the level of development of each country, the structure of the industrial endowment. As an example, we can say that the exports may have a negative impact on CO_2 emissions in the case of a country which exports raw materials or low fabrication ones. Also, a country could execute only some operations of the supply chain with a low level of emissions, and then export them to continue production in countries with a less strict regulation on environment.

In the case of imports, the same examples are available but from the opposed side as importing raw materials and executing the high CO_2 emitting activities from the production chain of goods.

We must acknowledge that the model has its limitations and even Kuznets had his caveats regarding the original model mainly regarding the fragility of the data and even if the data turned out to be valid, it pertained to an extremely limited period and to exceptional historical experiences (Fogel, 1987).

DOI: http://dx.doi.org/10.15666/aeer/1703_68016820

Starting from this statement, we further stress that there were gaps in the availability of data, especially in the case of former communist countries. Also, there is a development gap between the older members of the EU and the newcomers which generated real convergence problem acknowledge by the EU and which was discussed on many occasions. Although the problem is well known, little has been done to reduce the gap and many times we found ourselves talking about a two speed European Union or a center-periphery relation between groups of member states.

Conclusions

The sample of countries chosen for this analysis was based on several considerations. The EU countries are characterized by high growth rates, and commercial and financial liberalization has a bivalent impact on the environment. On the one hand, the accession of Central and Eastern European countries can lead to a significant increase in the production of domestic companies and the attraction of important foreign capital flows, which can have a negative impact on the environment. On the other hand, environmental protection is a constant preoccupation of the European authorities, and the accession to the EU supposes the transposition of the European directives in the national legislation (Marcu et al., 2015). The liberalization of trade flows between Member States is an important factor of economic development (fact emphasized in the very first article dedicated to the EKC), which has a strong impact on the environment.

More and more specialists have drawn attention to the modification of the EKC in terms of its flattening, given that the environmental protection regulations adopted in the developed countries have been rapidly copied by the authorities in the developing countries. In addition, international efforts by institutions such as the United Nations or the OECD have had their effects, and their concerns about environmental protection, sustainable development and corporate social responsibility have been promoted both in developed countries and in developing countries. The levers by which the negative impact of economic activity on the environment can be limited have also multiplied. For example, the Kyoto Protocol of the United Nations Framework Convention on Climate Change was signed in 1997 (and entered into force in February 2005) and the parties committed to reducing greenhouse gas (GHG) emissions in line with specific targets. It is the first step towards a truly global emission reduction regime. In addition, the principles of sustainable development or social responsibility are followed by companies, financial institutions and portfolio investors.

The free movement of capital in the EU has generated robust financial flows in new member countries from both EU-developed companies and companies from other host countries that wanted to have fast access to the entire European market. Transferred technology has not always been last generation and environment friendly, which is why the impact of foreign direct investment on the environment in the host country, in some cases, may be negative.

The presence of large European financial groups in the new member states also determines the development of local financial markets, as well as the promotion of sustainable financing techniques for local companies. More and more banks are concerned not only with the economic impact of the investment projects they finance, but also with the environmental impact, which is why the financing of green investments is a reality in these countries as well.

The results of the study show us that the EU countries followed the Kuznets environmental curve; however, the multitude of levels of development may interfere with the end conclusion. The EU has its core problems regarding the real convergence of the new member states, fact highlighted by the latest talks about a two-speed union.

The data used for the study has some gaps in the case of the former communist countries data from before 1990, when these countries started the transition towards democracy. Also, in some of these countries, the reduction of CO_2 emissions was the result of industrial activity reduction generated by the restructuring or closing of entire facilities.

Based on these limitations of the study, we further intend to expand the research and try a deeper analysis of the EU member states by using a grouping analysis to observe the evolution of variables for countries in different stages of development.

Abstract. This paper analysed chlorophyll degradation in spinach leaves from plants affected by cadmium and tetracycline soil contamination, stored for 32 weeks at t= -18 °C. The first-order reaction kinetics were determined for chlorophyll degradation. In plants growing on soil containing tetracycline and cadmium, two ranges of chlorophyll degradation occur: 1 – a slow degradation, during storage for up to 20 weeks, occurring at constant degradation rate, $k = 0.00594 \pm 0.00029$ week^{-1} for tetracycline and $k = 0.00761 \pm 0.00026$ week^{-1} for cadmium, and 2 – a fast degradation, occurring later, with constant $k = 0.04484 \pm 0.00137$ week^{-1} and $k = 0.06777 \pm 0.00171$ week^{-1} for tetracycline and cadmium, respectively. Those two ranges were not observed for spinach growing without contamination ($k = 0.00679 \pm 0.00027$ week^{-1}). Chlorophyll degradation occurred eight times faster for tetracycline and ten times faster for cadmium. After 32 weeks of storage 19.4% and 13.6% of chlorophyll were left in small leaves affected by tetracycline and cadmium, respectively. In spinach leaves of harvesting maturity (50-days-old, large leaves), lower values of rate constants were found for range 2, amounting for dose (90 mg/kg soil) to $k = 0.02945 \pm 0.00151$ week^{-1} (for tetracycline) and $k = 0.03511 \pm 0.00124$ week^{-1} (for cadmium) and 50% chlorophyll was left after 32 weeks. Chlorophyll degradation degree depends on soil contamination, leaf size and time of exposure to contaminants.
Keywords: *chlorophyll content, chlorophyll degradation, absorption and fluorescence spectra, degradation rate, storage of spinach*

Introduction

The spinach is a popular vegetable due to its taste and sensory values. Spinach leaf chemical composition is also significant, including the high level of vitamin (C, E), folic acid, polyphenols, β-carotene, mineral component and dietary fibre, as well as strong antioxidant properties related to the high chlorophyll content (Jaworska, 2005; Lisiewska et al., 2009; Xie et al., 2013). A drawback of spinach is its short shelf life in a chilled state. After being subject to minimum processing, spinach packed in perforated bags remains fit for consumption for eight days when stored in the refrigerator at 8 °C (Kou et al., 2014). For this reason, spinach leaves are very often purchased by consumers in a frozen form (Jaworska and Kmiecik, 2000). Freezing is one of the most

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68216835

frequently applied food storage methods. Despite undeniable usefulness of spinach storage at freezing temperatures, such treatments also have negative effects on food quality. Freezing involves physical changes, such as re-crystallization of ice and moisture migration, resulting in a decrease in weight and nutrient content, as well as changes in the product texture (Van Buggenhout et al., 2006; Pukszta and Palich, 2007). In the freezing process, chemical changes also take place, which can result in a change in taste or colour (Lisiewska et al., 2009). The colour is of great importance, since it is one of main factors considered by consumers purchasing fruit and vegetables. Orange and yellow colour of vegetables is, to a significant extent, caused by carotenoids, while green is related to the presence of chlorophyll (Sánchez et al., 2014). The change of the green colour in frozen products is related to degradation of chlorophyll content in plants (Koca et al., 2007). Chlorophyll degradation occurs not only when leaves are being frozen, but also in plants growing in a contaminated environment (Bartha et al., 2010; Kong et al., 2007). The main environmental contaminants include heavy metals and antibiotics, which have also been emphasized recently as cropland contaminating factors (Zhang et al., 2016). Progressive contamination results in increasing the content of antibiotics and heavy metals in soils and surface water (Azeez et al., 2009; Kim and Carlson, 2007; Nicholson et al., 2003). Contamination of arable soils in Poland with cadmium exceeded 90.87 mg/kg in 2000 (IUNG, 2017). Both heavy metals and antibiotics are taken up by plants from soil (Pan and Chu, 2017). After taking up, they are transported to the above-ground parts, including leaves, where they disturb the process of photosynthesis. The plant's response to environmental contamination caused by heavy metals has been quite well explored. It is known that heavy metals replace a magnesium atom in chlorophyll, creating chlorophyll-metal bonds (Küpper et al., 2000, 2001). Chlorophyll and metal complexes, even if they occur in low amounts in relation to pure chlorophyll, can entirely inhibit the process of photosynthesis (Küpper et al., 1996). Metals with high toxicity towards plants include cadmium (Smeets et al., 2005; Mishra et al., 2006), this toxicity mainly results from changes occurring in the process of photosynthesis and changes in the structure and the content of photosynthetic dyes (Kummerova et al., 2006; López-Millán et al., 2009). Just like heavy metals, antibiotics also reduce the chlorophyll content in plants, thus reducing the process of photosynthesis (D'Abrosca et al., 2008; Li et al., 2011; Liu et al., 2013).

The effect of plant contamination with heavy metals or antibiotics on chlorophyll concentration in leaves intended for freezing has not yet been examined. The aim of this study was to determine changes in chlorophyll concentration during the storage of spinach containing cadmium and tetracycline. Additionally, the contents of tetracycline and cadmium, as soil pollutants, were analysed for any effect on the quality of frozen raw material.

Material and methods

Materials

The research material consisted of spinach (*Spinacia oleracea* L.) plants, Matador cultivar. The seeds were sown to the soil in 300 ml pots. After 20 or 40 days of plant growth, aqueous solutions of cadmium sulphate (Cd) and tetracycline (TC) at concentrations of 3, 45 and 90 mg/kg soil were added to the pots. Due to the fact that soil pollution in Poland exceeds 90 mg/kg of cadmium, the same concentrations for cadmium and tetracycline were used for comparison. Additionally, we applied to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68216835

smaller doses for large leaves – 3 and 45 mg/kg. After ten days as of adding metal and antibiotics to the soil, the leaves were cut, washed with water and prepared for freezing.

The spinach was frozen in two variants:

1. Small leaves (SL) – with a surface area of 10 ± 0.5 cm^2, growing for 30 days, of which 10 days on the soil containing TC and Cd in the dose of 90 mg/kg soil.
2. Large leaves (BL) – with a surface area of 55 ± 2 cm^2, growing for 50 days (harvesting maturity of leaves) of which 10 days on the soil containing with TC and Cd in the dose of 3, 45 and 90 mg kg soil.

BL and SL leaves were homogenized and stored in the freezer at -18 °C for 32 weeks. The temperature was additionally monitored with a thermometer located in the freezer. Samples from the freezer were collected at one week intervals. Analyses were performed in five replications. Leaves from plants growing on soil not contaminated with cadmium or tetracycline were used as control. The leaves were stored in parallel with the plant material from contaminated soil.

Chlorophyll extraction

Chlorophyll was extracted from spinach leaves (300 mg) with 5 ml of methanol (Rydzyński et al., 2017). The obtained homogenate was centrifuged at room temperature at 4,000 RPM. The extract was then 5-fold diluted and used for spectrophotometric and fluorometric analyses. All extraction procedures were conducted in cold temperatures and dim light.

Absorption and fluorescence spectra

The absorption and fluorescence spectra of solutions were measured using, respectively, the Carry 5000 UV-Visible Spectrophotometer (Varian, Inc) and a Cary Eclipse Fluorescence Spectrophotometer (Varian, Inc) with right-angle geometry. The fluorescence spectra were measured at excitation wavelength $\lambda_{exc} = 650$ nm. Chlorophyll concentrations were calculated, based on Lambert-Beer law, on the basis of the known molar extinction coefficient of chlorophyll in methanol, which is $\varepsilon = 66600\ M^{-1}\ cm^{-1}$ in the first chlorophyll absorption band maximum (Seely and Jensen, 1965).

Results and discussion

Chlorophyll is not only an indispensable plant dye, but has also been proven to be an important compound for the human body, with favourable antihyperglycemic and antihyperlipidemic properties (Patar et al., 2016). Chlorophyll also demonstrates antioxidant effects, eliminates free radicals and shows a positive effect in cancer treatment (Gore et al., 2017). Therefore, reduction of the chlorophyll content in the human diet is highly undesirable.

It was proven (Rydzyński et al., 2017) that plants growing on soils contaminated with antibiotics feature a high decrease in chlorophyll. Therefore, the consumption quality of plants growing on such soils is impaired. The present study examined the process of chlorophyll degradation in plants growing on soil contaminated with antibiotics and heavy metal (cadmium), during the storage of such leaves at t = -18 °C for 32 weeks.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68216835

Figure 1A and *A'* present changes in the absorption and fluorescence spectra of chlorophyll extracted from spinach grown on soil without (control) the content of tetracycline or cadmium and stored at t = -18°C for 32 weeks. During the storage, absorption decreased from $A_1 = 1.122$ to $A_{32} = 0.874$. Chlorophyll concentration was reduced from the value of $C_0 = 8.42 \times 10^{-5}$ M to $C_{32} = 6.56 \times 10^{-5}$ M. Chlorophyll concentration decreased by 22%, which is in agreement with the results obtained by Dermesonluoglu et al. (2015) in the storage of frozen spinach at -18 °C.

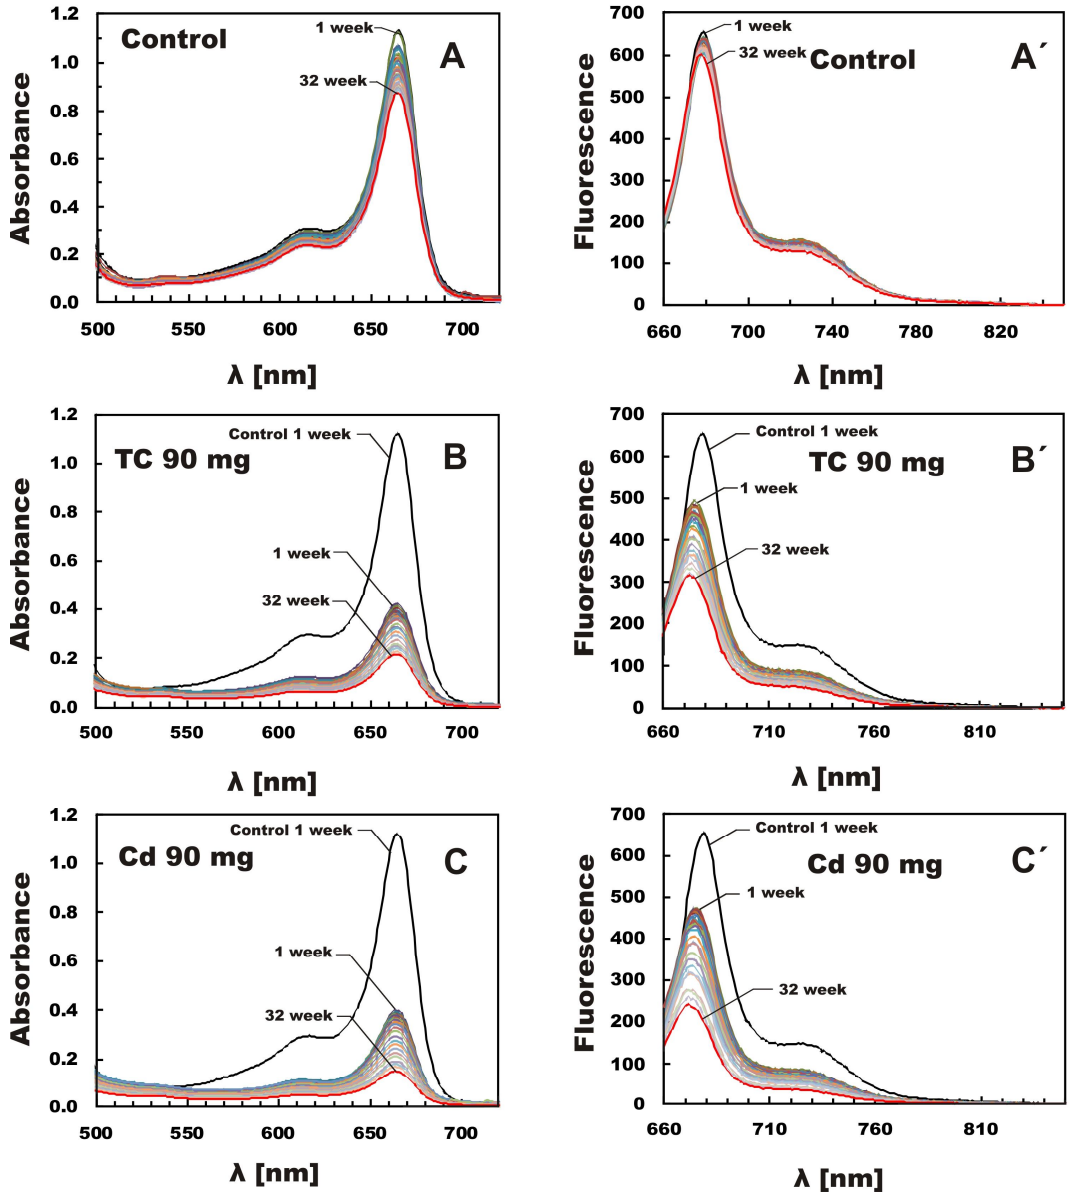

Figure 1. *Absorption (A, B, C) and fluorescence (A', B', C') spectra for chlorophyll extracted from stored (small) spinach leaves growing on soil: A, A' - without contamination (contol); B, B' - containing 90 mg tetracycline (TC); C, C' - containing 90 mg cadmium (Cd) per kg soil*

Figure 1B, B', C and *C'* present, respectively, the absorption and fluorescence spectra of chlorophyll obtained from spinach plants growing on soil containing TC and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68216835

Cd, and stored at t = -18°C for 32 weeks. In these figures, the chlorophyll absorption and fluorescence spectrum for spinach without TC and Cd treatment (control) was added.

As *Figure 1B* shows, the absorption of chlorophyll extracted from plant leaves growing for 10 days in soil containing TC (90 mg/kg) decreased by 64% in relation to the control sample (from the value of A = 1.12 to A = 0.407) and *Figure 1C* demonstrates that for cadmium treatment (90 mg/kg), a decrease of 65% was observed (to the value of A = 0.394). The decrease observed occurred in leaves growing on contaminated soil, even before spinach leaves underwent the freezing process. The leaves growing on soil contaminated with TC and Cd, containing less chlorophyll, were then subject to the freezing process, as a result of which, as can be seen in *Figure 1B* and *C*, a further decrease in chlorophyll took place: absorption was reduced from $A_1 = 0.407$ to $A_{32} = 0.217$ (a further decrease in chlorophyll concentration to the value of $C_{32} = 1.63 \times 10^{-5}$M) for TC, and to the value of $A_{32} = 0.152$ (a decrease in concentration to the value of $C_{32} = 1.14 \times 10^{-5}$ M) for Cd. After 32 weeks of storage, 19.4% chlorophyll content remained in TC contaminated leaves and 13.6% in Cd contaminated leaves.

It can be clearly seen that during the low temperature storage of spinach leaves grown on soil contaminated with TC and Cd, a further process of chlorophyll degradation took place. In the fluorescence spectra (*Fig. 1B'* and *C'*) major changes are observed – a large decrease in fluorescence concentration, particularly for samples containing cadmium. The fluorescence spectrum clearly shifted towards shorter wavelengths by 6 nm at TC contamination, and by 8 nm at Cd contamination, which clearly proves the formation of chlorophyll degradation products. A high decrease in absorbance between the control sample and the first week of freezing for spinach containing TC or Cd results from chlorophyll degradation in the plant under the effect of tetracycline and cadmium, while a further decrease in chlorophyll content was caused by the storage process.

Figure 2 presents the relation between chlorophyll concentration in spinach leaves (SL) and the time of storage at t = -18 °C. These figures present the values of chlorophyll concentration for five independent samples of spinach leaves in the function of storage time. Statistical data of these changes is shown in *Table A1* in the *Appendix*. For spinach grown on soil contaminated with antibiotic and metal, two ranges of chlorophyll degradation can be distinguished: the first range of slow degradation up to week 20, and the second range, of the so-called faster degradation. King et al. (2001) also observed a two-range course of chlorophyll degradation rate, but during dehydration by freeze-drying at -5 °C, -20 °C, -30 °C and 45 °C. At the beginning, for 6 days of the process, they observed fast Chl degradation, followed by slow degradation. Those two ranges were recorded for blanched spinach, particularly at -5 °C and -30 °C. In the current study, two ranges of chlorophyll degradation were not observed for spinach growing on uncontaminated soil (control).

On the basis of concentrations obtained, the kinetics of chlorophyll degradation during spinach storage time was examined. As provided in the literature (Koca et al., 2007; Dermesonluoglu et al., 2015; Steet and Tong, 1996) in the examined cases, total chlorophyll loss in vegetables during various technological processes was described by 1st order reaction kinetics.

The concentration of chlorophyll as a function of time at a constant temperature for a first-order degradation kinetics model is:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68216835

$$C = C_0 e^{-kt} \quad \text{(Eq.1)}$$

where C is the chlorophyll concentration at any time t, C_o is the initial concentration, and *k* is the first-order constant estimated by slope of the linearized plot of lnC vs *t*.

Chlorophyll degradation reactions during spinach storage for 32 weeks at low temperature t = -18 °C were described by 1st order kinetics (*Fig. 3*). The lnC function linearly described the dependence of chlorophyll concentration decrease in the time of leaf storage at t = -18 °C in both ranges for contaminated spinach, and in one range for uncontaminated spinach.

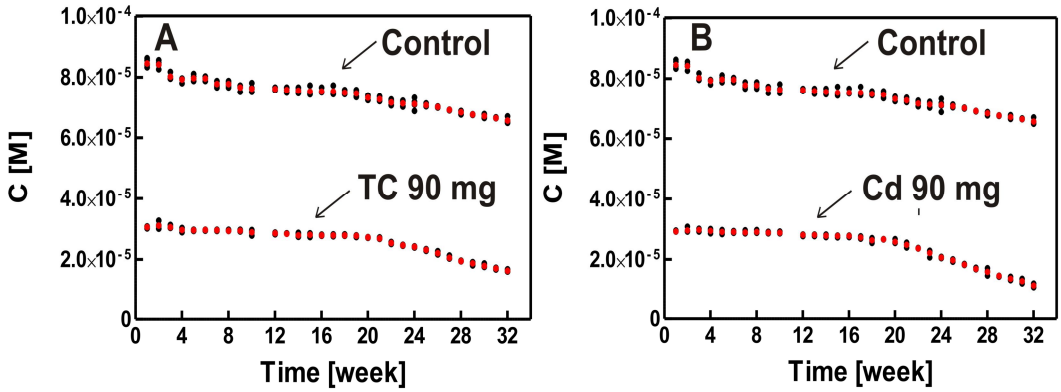

Figure 2. *Relation between chlorophyll concentration (C[M]) in small spinach leaves and storage time. A – plants growing with TC (90 mg/kg soil), B - with Cd (90 mg/kg soil). The results were given for 5 independent measurements, the average value is shown in red. Data provided for 5 samples (●a, ●b, ●c, ●d, ●e, ●av – average for five samples) during 32 weeks of storage at t = -18 °C. The time dependence of chlorophyll concentration on leaf storage time has also been drawn for control (without contamination).*

Figure 3 presents the linear adjustment of lnC relation to spinach storage time. In frozen spinach, grown on uncontaminated soil, the chlorophyll degradation reaction occurred at a rate constant of $k = 0.00679 \pm 0.00027$ week^{-1} ($R^2 = 0.958$). On the other hand, in spinach with TC, $k = 0.00594 \pm 0.00029$ week^{-1} ($R^2 = 0.966$) in the slow degradation range, the process occurred faster in the second range, with constant $k = 0.04484 \pm 0.00137$ week^{-1}($R^2 = 0.989$). For cadmium, *k* constants were higher and amounted to $k = 0.00761 \pm 0.00026$ week^{-1} ($R^2 = 0.982$) in the first range, and in the second – $k = 0.06777 \pm 0.00171$ week^{-1} ($R^2 = 0.993$). The value of the constant describing chlorophyll degradation rate in leaves growing without contamination (antibiotics and Cd) in this study corresponds to the values obtained by other authors. Dermesonluoglu et al. (2015) observed a 25% decrease in chlorophyll content after 36 weeks of storage at -18 °C. The value of the first-order chlorophyll degradation constant they obtained, converted into the same units, is equal, within the margin of error, to the rate constant *k* obtained for uncontaminated spinach in the current study.

Some authors suggest that during spinach storage, chlorophyll is decomposed to pheophytin. After three weeks of spinach storage at 8 °C, pheophytin becomes the main chlorophyll degradation product (López-Ayerra et al., 1998). Moharram and Rofael (1993) and Symons (1994) suggest that during storage at low temperatures, chlorophyll is also degraded to pheophytin. Kidmose et al. (2002) indicate that during freezing,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68216835

storage and thermal treatment, chlorophyll is converted or degraded to pheophytin, pheophorbide, pyropheophytin and pyropheophorbide. Niedzielski and Mokrosinska (1990) indicate that before low temperature storage of leaves, their blanching is recommended, as this process causes denaturation of the protein complex, which reduces chlorophyll content loss.

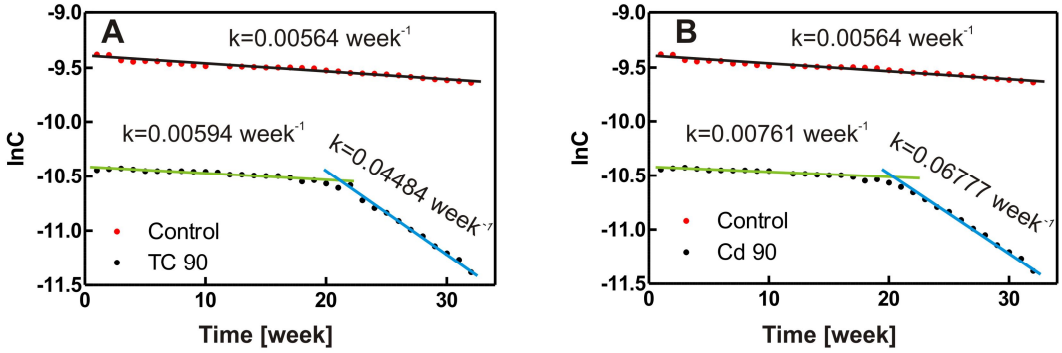

Figure 3. *Relation between concentration of chlorophyll extracted from plants growing with antibiotics (A) or cadmium (B) (90 mg/kg soil) and leaf storage time at t = -18 °C. Doted points – experimental data, line – obtained from the linear regression based on the experimental data. The following equation was applied:* $C = C_o e^{-kt}$

In our paper we postulated that the two-range chlorophyll degradation observed in the current study results from the fact that chlorophyll subject to the freezing process is quite quickly degraded in plants growing for 10 days on TC and Cd contaminated soil and, afterwards, during the storage of such spinach, degradation occurred slower in the first period, with further strong chlorophyll degradation taking place only after 20 weeks of freezing, as a result of which after 32 weeks, only 19.4% and 13.6% chlorophyll was remain in plants contaminated with TC and Cd, respectively. However, for freezing leaves growing without antibiotics or Cd, it was observed that after 32 weeks (in control spinach), 78% chlorophyll was left. Therefore, 22% chlorophyll degradation occurred (*Fig. 2*).

When freezing spinach leaves at t = -18 °C, Dermesonluoglu et al. (2015) observed a similar course of degradation as we observed for uncontaminated spinach. On the other hand, King et al. (2001) observed freeze-drying of dehydrated spinach at various temperatures (from -5 °C to -45 °C) and found very fast chlorophyll degradation at the beginning, within six weeks, followed by slow degradation. After twelve weeks, chlorophyll degradation reached 45% at t = -20 °C. Even faster chlorophyll degradation in comparison to spinach occurs in turnip greens (*Brasica rapa* var. *rapa* L.). During 28-day storage at -30 °C, chlorophyll a is 40% degraded and chlorophyll b is 44% degraded (Martínez et al., 2013). An interesting result of chlorophyll degradation was obtained by Grzeszczuk et al. (2007) for New Zealand spinach stored at t = -25 °C. Changes in chlorophyll content during storage are completely different. Grzeszczuk et al. (2007) observed an initial growth in chlorophyll content in New Zealand spinach in the first three months of storage, and only between month 3 and 6 of storage at about -26 °C, a decrease in chlorophyll content takes place. On the other hand, in dill frozen at -20 °C, Lisiewska et al. (2004) observed a slow decrease in chlorophyll content up to about week 24, after which chlorophyll degradation was accelerated, similar to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68216835

contaminated spinach leaves examined in the our current research. As it can be concluded from the data quoted above, depending on the plants, chlorophyll degradation during storage at low temperature can have various courses.

Our study also examined the process of chlorophyll degradation in harvest-ready, large, developed spinach leaves. Such spinach (growing for 50 days, of which 10 days with 3, 45 and 90 mg TC and Cd per kg soil) was subject to the freezing process and stored at t = -18 °C for 32 days. The absorption spectra of chlorophyll extracted every week from those leaves are presented in *Figure 4*. As shown in *Figure 4*, the decrease in chlorophyll absorption during the storage of harvest-mature leaves contaminated with TC was slower in the first weeks. For three doses of TC and Cd, for 3, 45, 90 mg/kg soil, absorbance decreased after 32 weeks to the following values: $A_3 = 0.724$, $A_{45} = 0.637$, $A_{90} = 0.500$ for TC, and for Cd treatment: $A_3 = 0.714$, $A_{45} = 0.583$, $A_{90} = 0.498$ It can be noted that chlorophyll degradation was only slightly lower after Cd application.

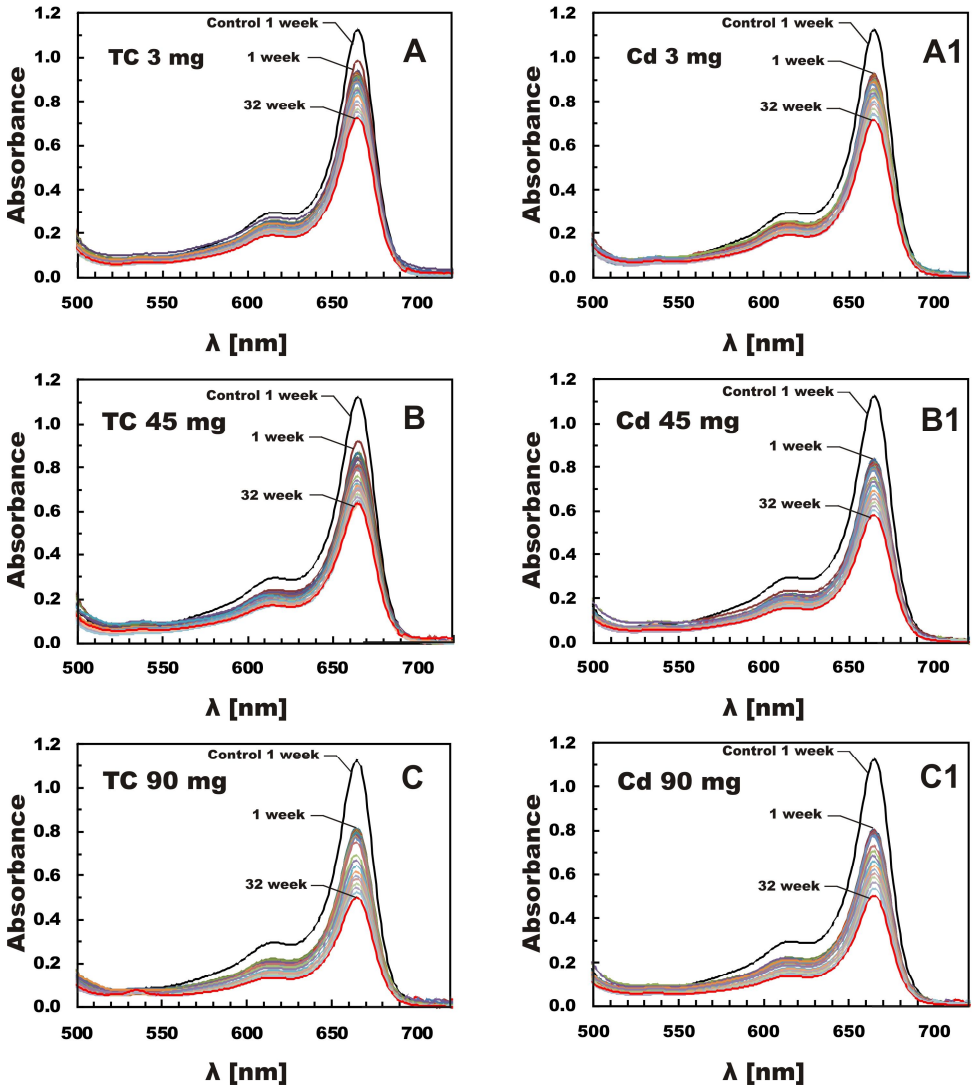

Figure 4. *Absorption spectra for chlorophyll extracted from fully developed spinach leaves growing on soil contaminated with tetracycline and cadmium at the dose of: 3 mg/kg soil (A - tetracycline, A1 - cadmium), 45 mg/kg soil (B - tetracycline, B1 - cadmium) and 90 mg/kg soil (C - tetracycline, C1 - cadmium)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68216835

Figure 5 presents storage time dependence of chlorophyll concentration in subsequent weeks of its storage at t = -18 °C for developed spinach leaves. Statistical data of these changes is shown in *Table A2*. The percentage content of chlorophyll remaining in spinach after 32 weeks of freezing in relation to the control sample, in which chlorophyll concentration was $C_o = 8.42 \times 10^{-5}$ M (chlorophyll concentration in leaves uncontaminated with TC and Cd), depending on the dose and was amounted for TC: 64.49% (3 mg) and 56.65% (45 mg), 44.42% (90 mg) and for Cd: 63.68% (3 mg), 51.90% (45 mg) and 44.54% (90 mg). The results show that chlorophyll degradation is lower in large, developed leaves, which were subject to the antibiotic and metal treatment only after their development. Undoubtedly, degradation would have taken a completely different course if the plants had grown on the contaminated soil for 50 days. The results clearly indicate that in developed spinach leaves, degradation is also a two-stage process.

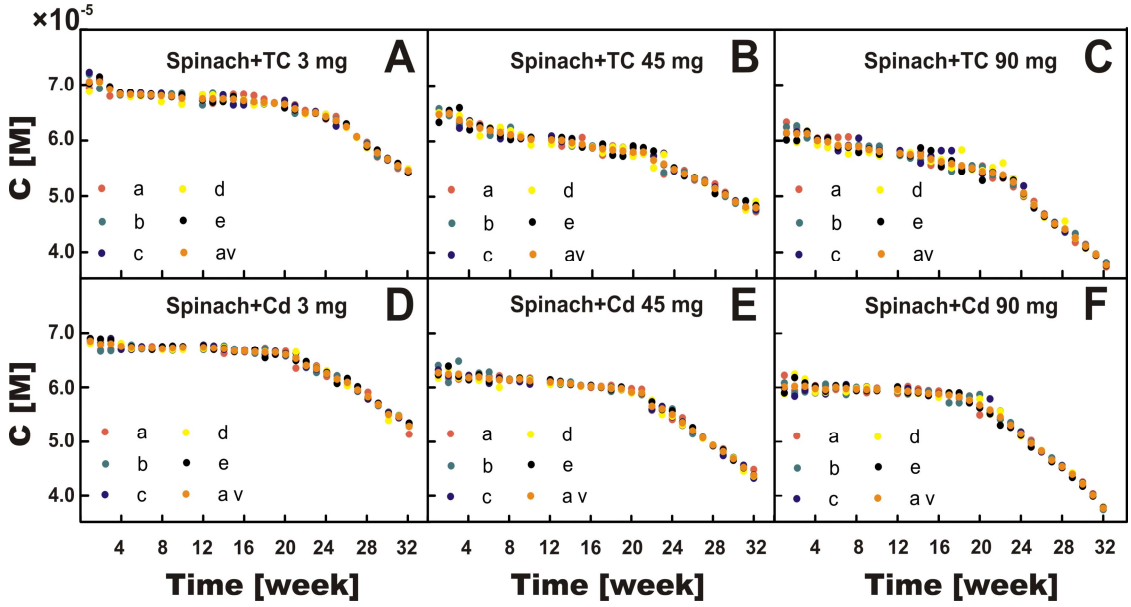

Figure 5. *Relation between chlorophyll concentration (C[M]) in large spinach leaves and storage time. Panel A, B, C – plants growing with tetracycline (3, 45 and 90 mg/kg soil), Panel D, E, F - with cadmium (3, 45 and 90 mg/kg soil). The results were given for 5 independent measurements, the average value is shown in red. Data provided for 5 samples (●a, ●b, ●c, ●d, ●e, ●av – average for five samples) during 32 weeks of storage at t = -18 °C*

Table 1 shows degradation rate constants for 50-day spinach contaminated with TC and Cd. As shown in the table, chlorophyll degradation rate constants depend on the TC and Cd dose, which indicates that Cd is more toxic in the second range, while degradation occurs faster in plants growing on soil contaminated with Cd. In the first range, degradation rate constants did not differ much, and varied from $k = 0.00168 \pm 0.00006$ week^{-1} to $k = 0.00550 \pm 0.00019$ week^{-1} for TC, and from $k = 0.00134 \pm 0.00014$ week^{-1} to $k = 0.002217 \pm 0.00017$ week^{-1} for Cd. In the second range, the values of k were 10 times higher (Tab.1) and took significantly higher values for Cd. It is also worth emphasizing that degradation rate constants k for Cd in the first range are lower than for TC. This probably results from the fact that plants have an efficient cadmium resistance mechanism. Metal transporters can play a significant role in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68216835

controlling plant tolerance to Cd (Rui et al., 2018). It was also demonstrated that plants more readily take up tetracycline from soil than cadmium (Rydzyński et al., 2018).

Conclusion

The research demonstrated that the degree of chlorophyll degradation depends on the soil contamination degree, the leaf size and the time for which the plant grew on contaminated soil. At the same time, cadmium toxicity is higher despite the plants taking it up in smaller amounts, since chlorophyll degradation is higher in the presence of Cd than TC. To preserve the highest consumption quality of spinach leaves (high chlorophyll content), the leaves intended for freezing should be large and should grow on soil free of any contamination. We recommend storing spinach leaves at -18 °C for not longer than 20 weeks. In addition to the analysis of chlorophyll quality, the studies of stored leaves from spinach grown on contaminated soils will be carried out in the immediate future to consider biologically active substances such as vitamins, carotenes, xanthophylls that have a significant impact on the biological value of the vegetable raw material.

(Received 12th Feb 2019; accepted 10th Apr 2019)

Abstract. The response and force effect of rigid body swing (RBS) on transverse flow direction is not negligible. Based on slender beam model, wave action (WA), RBS model and in-line movement of suspension point (TSM) are simulated. And structural response effect of RBS is simulated and estimated. The simulation and evaluation display that in terms of overall motion pattern, response in xy plane develops gradually from a narrow swing in x direction to a narrow swing in y direction. It is important to consider a particular location conservation of energy in three directions with water depth. As water depth increases, displacement and main frequency decrease. The decrease amplitude is strongest or most severe in top suspension region. For the spectrum analysis, the response main frequency and wave frequency are very close, and the motion is a forced motion. As water depth increases, the main frequency first increases then decreases. The trend is similarly to corresponding response change and contrary to energy or amplitude of xy plane change. As the energy decreases and then increases in xy plane, the z direction increase of RBS presents the opposite change in three directions. The effect of RBS on structural response can reach 20% after simulation. The effect of RBS is different from that of WA and TSM, which decreases with depth increase. And RBS is positively correlated to vector diameter S. It is expected that analysis and study may provide some advice for simulation of SCR and its RBS.
Keywords: *SCR, rigid body swing, wave action, platform motion, spectrum analysis*

Introduction

Steel catenary riser (SCR) is one of important facility for oil exploitation. It has recently been researched extensively and in-depth on the dynamic and vibration characteristics. And in particular the phenomenon of RBS is important and affected in the deep-sea environment. It is due to the waves, currents and other large range of loads, and it has attracted the attention.

The phenomenon of RBS is a large range and whole rotation from moving suspension point in top region to touch down point (TDP) in the seabed region. This paper focuses on the influence that WA and TSM are in the same in-line (x) direction. And RBS is in cross flow (z) direction. These motions are mutually perpendicular in the plane. A simulation was realized on the basis of Cable3D (Bai, 2009; Chen, 2002). Liu (2013), Liu and Huang (2014a, 2014b, 2013) proposed and simulated the phenomenon of RBS. And the simulation was on the basis of vibration theory of large-deflection beam and RBS model. Liu and Huang (2014c) compare analysis of coupling between RBS and bending vibration to that without RBS. They concluded that RBS has a relatively great impact on transverse flow direction response. Yao et al. (2018) did the model analysis of RBS and then carried out the spectral analysis. And he believed

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68376852

experiment could prove the existence of RBS and give the frequency formula. Yao et al. (2017) simulated RBS phenomenon coupling the vortex-induced vibration model. And he proposed a RBS model considering vortex-induced vibration. Lin and Wang (2019) adopted DVM code in 2 dimensions for riser VIV analysis. Kim and O'Reilly (2019) provided a research on the dynamic, stability and vibration of riser with Kirchhoff's theory. Lotsberg (2019) did an overview of fatigue design standards. Wu et al. (2019) provided a relatively reliable combined IL and CF load model. Yamamoto and Morooka (2019) carried out simulation for riser and platform with nonlinear models. Guan et al. (2019) obtained understanding of the mechanics of scour such as steel catenary riser without currents and waves. He et al. (2019) adopted beam bending model of large deformation characteristics and estimated the critical factors for flexible riser. Numkam et al. (2019) researched the drilling muds which display liquid and solid flow characteristics. Zhao and Van der Heijden (2019) solved the wave equation that governs the prebulking torision dynamics and boundary conditions. Wang and Pei (2019) applied a structural strain model to determine elastic characteristic of pipe core and pseudo parameters of stress.

RBS is a kind of rotation, which has rotation axis, angular velocity, angular acceleration, etc. It is different from the physical quantities such as vibration velocity and mode of bending vibration. And RBS is a rotation movement normal to bending vibration plane of riser. In the article, the effect of RBS on riser response is simulated and analyzed. And the effect of in-line (x) direction TSM and WA are studied.

The purpose of the study is in order to better discuss the RBS effect on cross flow displacement. Discussion includes the following viewpoints.

1. The RBS's effect on cross flow response cannot be ignored. And it is indispensable to pay more attention to long-term load terms and need more efforts for simulation and check.
2. Structural RBS is an inherent phenomenon of structures. And the calculation program explains RBS more from influence of WA and suspension movements.
3. The analysis of three-dimensional motion and energy conservation is very important for RBS analysis.
4. In particular, it is essential to understand characteristics of RBS when external energy of system decreases, vibration intensity of structure increases. Especially for wave reduction in this paper, RBS response increases.
5. When wave and natural vibration are in the same direction, the response is similar to that of shallow water. From top to bottom, the dominant influence of natural vibration on the structure is constantly enhanced.
6. The contribution of different loads to structural response can be calculated from frequency amplitude.

Study methods

SCR beam model considering large deformation

Basic equations

Vibration control equation (Liu, 2013) of steel catenary riser is *Equation 1:*

$$M\ddot{r} + Br^{(4)} - (\lambda r')' = q \quad \text{(Eq.1)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68376852

M – mass matrix, q – load matrix and λ – Lagrange operator.

SCR RBS model

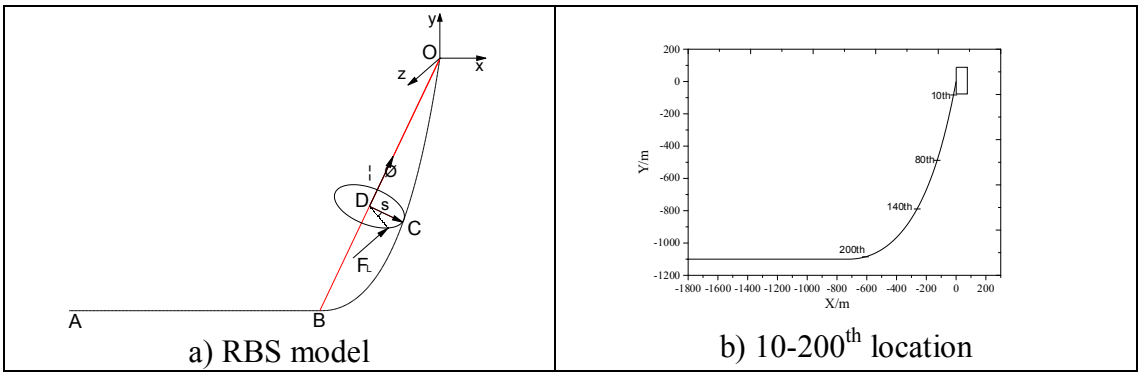
Figure 1 shows RBS model. Point A is the connection location of wellhead. Point B is TDP. Top suspension point (TSP) is Point O. ω is rotation axis vector of ODB. S is vector from rotation axis to point C (Liu and Huang, 2013; Liang et al., 2016; Du, 2016 ; Yao et al., 2018).

According to kinetic moment theorem, the equation is:

$$(m+m_a)s^2\ddot{a}_r + c_a s^2 \dot{a}_r + mgc_1 s a_r = q_z\sqrt{s_1^2+s_2^2} + q_x c_2 s_3 \quad \text{(Eq.2)}$$

m, m_a – mass and additional mass, c_a – coefficient for additional damping. q_x, q_z – distribution load of environment, $\ddot{a}_r$, $\dot{a}_r$, a_r – angular acceleration, velocity and displacement.

Node location:
Node 10th, x=-15.8273 m, y=-54.1376 m.
Node 80th, x=-163.2674 m, y=-467.0530 m.
Node140th, x=-343.3629 m, y=-796.3470 m.
Node200th, x=-616.8364 m, y=-1049.0293 m.



a) RBS model b) 10-200th location

Figure 1. *SCR RBS system*

Wave force simulation model

Morison formula for wave force is *Equation 3:*

$$f_H = \frac{1}{2}C_D\rho A(u_x-\dot{x})|u_x-\dot{x}| + C_M\rho\frac{\pi D^2}{4}\frac{\partial u_X}{\partial t} - C_m\rho\frac{\pi D^2}{4}\ddot{x} \quad \text{(Eq.3)}$$

In the formula, A – projected area, ρ – density of seawater, C_m – coefficient of additional mass, C_M – coefficient of mass, C_D – coefficient of drag force, u_x – water horizontal velocity, $\dot{x}$ – cylinder horizontal velocity.

Adding *Equations 2* and *3* to *Equation 1,* we can get:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68376852

$$M\ddot{r} + Br^{(4)} - (\lambda r')' = q + mg - (m + m_a)\ddot{r}_r - c_a\dot{r}_r + f_H + Q_x \quad \text{(Eq.4)}$$

SCR movement boundary conditions

Fixed constraints are adopted for wellhead and TSP of SCR. And TSM affects riser's whole movement. During simulation and analysis, the motion in the in-line (x) direction is added into a calculation input file. And the effect of RBS is superimposed through a load term. Then variation characteristics of the structural amplitude and frequency are studied under WA, RBS. and TSM.

SCR seabed boundary conditions

In addition to both ends fixed constraints of SCR, there are also constraints during streamline and seabed coupling interaction. It includes normal elastic and plastic support, seabed suction, tangential friction and resistance of grooves (Liu, 2013; Liu and Huang, 2014a; Yang, 2014; Zhou et al., 2017). Seabed normal constraints are simulated by spring and spring-damping system during the static and dynamic analysis. Since this part is not the focus of paper, it is not expanded in detail.

Results and discussion

Response numerical simulation of RBS under linear TSM and WA

RBS (Liu and Huang, 2014a) is an important part of SCR response study. Simulation superimposed x direction WA and TSM (Du, 2016) is rarely recorded in domestic and foreign literature. This section expects to analyze and summarize simulation characteristics under action of RBS, WA and TSM. It is expected to obtain some new understandings of RBS under influence of complex motion.

In this part, Cable3D and Cable3D_Vswing newly developed program (Yao et al., 2018) are adopted during numerical simulation respectively. The program of Cable3D_Vswing has a promotion of original program through Qforce subroutine. It couples and improves vortex-induced vibration, RBS and load model. It also considers the fact that wave and structure move relative to each other.

Cable3D calculates the structure's response of x direction WA and TSM without taking into account the action of water flow and its fluid-solid coupling. Cable3D _Vswing is adopted to simulate response under effect of WA, TSM and RBS. The difference is whether RBS is taken into account during simulation.

In this paper, SCR works at a depth of 1100 m and is subjected to a pretension of 2100 KN. Other specific SCR parameters are shown in *Table 1*. The parameters of linear wave height is 3.5 m, and cycle is 8.60 s. WA Frequency is 0.11622 Hz and it is relative to x axis for 6.67°.

Table 1. *SCR key parameters. (Yao et al., 2018)*

Parameters	Values	Parameters	Values
Fluid density in the riser (kg.m^{-3})	865	Elasticity Modulus (Gpa)	207
SCR material density (kg.m^{-3})	7850	Coefficient of Lift force	0.7
Seawater density (kg.m^{-3})	1025	Coefficient of drag force	1.2
Outer diameter (m)	0.355	Quality factor	1.0
Inner diameter (m)	0.305	Hydrodynamic parameter (m)	0.355

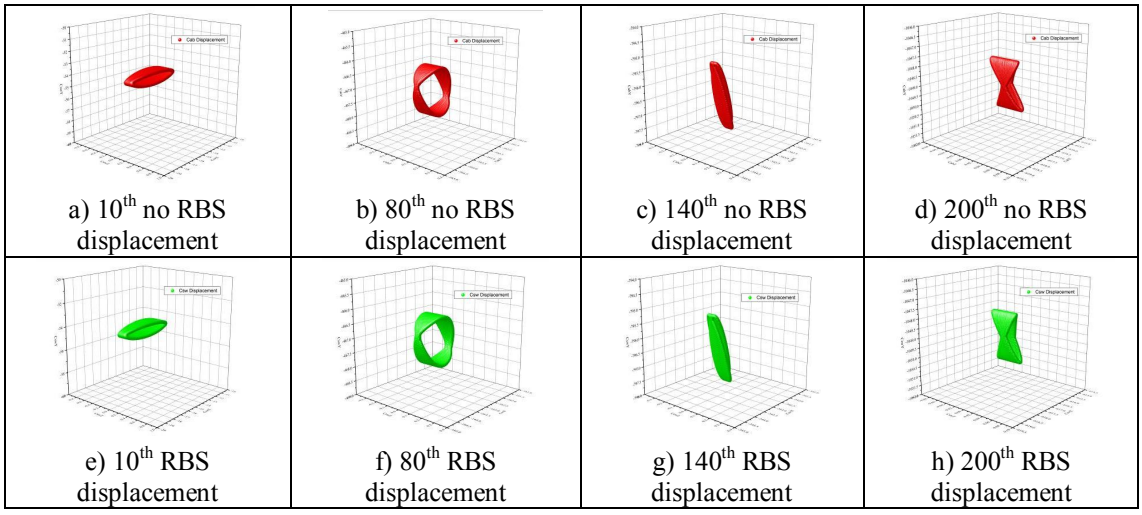
Coordinate system: X (in-line flow), Y (heave or vertical) and Z (cross flow). This paper applies TSM of the SCR to simulate floating platform response. *Table 2* shows TSM parameters under different conditions.

Table 2. *Motion parameters of different conditions. (Yao et al., 2018)*

Conditions	Direction	Amplitude /m	Period /s	Frequency /Hz	*Cab*	*Csw*
1	*x*	3.00	10.8	0.093	√	√
2	*x*	2.00	9.90	0.101	√	√
3	*x*	1.00	9.00	0.111	√	√

Three-dimensional response diagram of particle displacement of the structure

The structure is subjected to WA, TSM and RBS. The node 10th-200th displacement of riser could be got through simulation. 10th-200th node displacements have been plotted for three-dimensional view with no RBS and with RBS in *Figure 2*. And an xy plan with RBS and no RBS is in *Figure 3*.



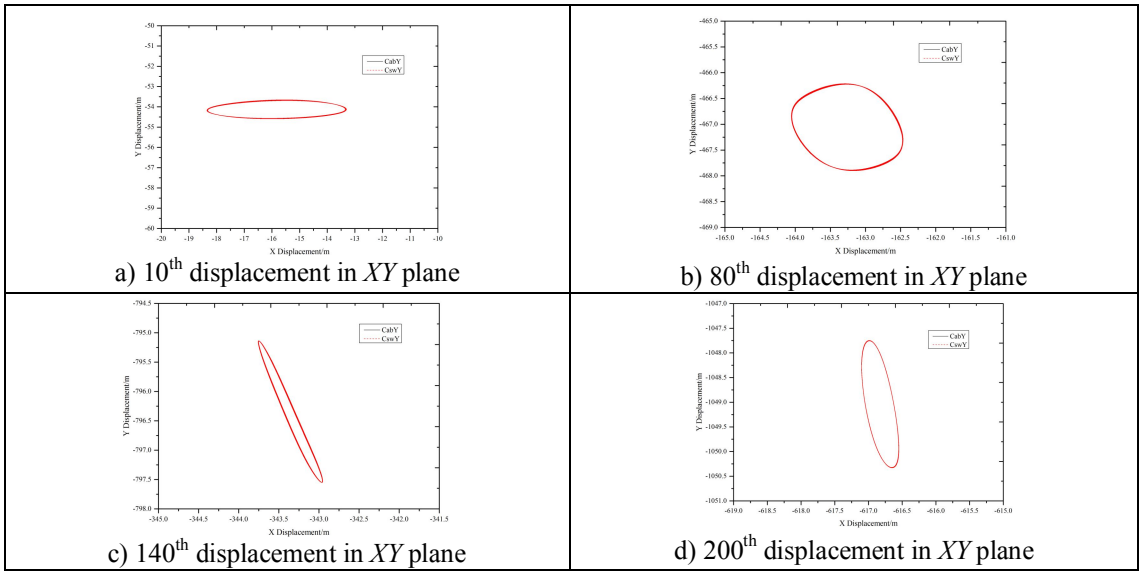
a) 10th no RBS displacement | b) 80th no RBS displacement | c) 140th no RBS displacement | d) 200th no RBS displacement

e) 10th RBS displacement | f) 80th RBS displacement | g) 140th RBS displacement | h) 200th RBS displacement

Figure 2. *10-200th displacement response of RBS and no RBS*

In terms of transverse comparison, *Figure 2* is a three-dimensional graph of response with or without RBS under TSM and WA. There is no obvious difference between two groups of graphs in morphology or overall graph. It indicates that effect of RBS is weak, which can be proved by graph with or no RBS in xy plane in *Figure 3*. The xy plane is the projection of structural response on the plane with x-direction (in-line) and y-direction (vertical) axis. There is no important difference between two graphs in plane with in-line direction and heave direction axis. It means that there is no significant difference in the response of the bending plane of the SCR. And the effect of RBS on this plane is feeble. It can be acknowledged from a perspective of orthogonality of RBS and bending vibration. And RBS is planar motions perpendicular to bending vibrations. There is no obvious difference in the xy plane. However, the difference in z direction is the difference of the amplitude and curve form of the structural response. And graph and text are described in detail in the following chapters and are not expanded here.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68376852



a) 10th displacement in *XY* plane

b) 80th displacement in *XY* plane

c) 140th displacement in *XY* plane

d) 200th displacement in *XY* plane

Figure 3. *10-200th displacement of RBS and no RBS in XY plane*

For a longitudinal comparison, *Figure 2* corresponds to node 10th-200th displacement responses, respectively. It is more appropriate to understand *Figure 2* from the two-dimensional plane in *Figure 3*. With the increase of water depth, response on xy plane changed from a narrower swing in x direction to a narrower oscillation in y direction. The specific forms of swing are: the oscillation of 10th is a narrow range of swing in x direction. The oscillation of 80th is a wide range of oscillation about 40° deflection x direction. The oscillation of 140th is a narrow range of oscillation around 70° deflection x direction. The oscillation of 200th is a narrow range of oscillation around 80° deflection x direction.

For vibration amplitude, vibration gradually reduces. The maximum displacement of 10th, 80th, 140th and 200th are 2.523235 m, 0.911102346 m, 1.270945958 m and 1.315001323 m. It means that structural response or the energy of the xy plane goes down and then goes up. After RBS is superimposed, structural response and motion in xy plane increases slightly. *Table 3* shows the detailed parameters.

Table 3. *Amplitude and Angle of XY plane oscillation for condition 1*

Node	***AmpCab* (m)**	***AmpCsw* (m)**	***Amp* difference rate**	***AngCab* (°)**	***AngCsw* (°)**	***Ang* difference rate**
10	2.52323500	2.52324300	0.000%	0.91561700	0.9127021	-0.318%
80	0.911102346	0.911394511	0.032%	-40.149901	-41.391644	3.093%
140	1.270945958	1.270957523	0.001%	-72.166466	-72.166832	0.001%
200	1.315001323	1.315305591	0.023%	-81.537765	-81.537482	0.000%

With depth increase, movement of structure in xy plane vibrates from the narrow amplitude oscillation in x direction gradually to the narrow amplitude oscillation in y direction. The amplitude oscillation of upper node decreases to a maximum near top suspension region 10th-80th. As water depth increases, amplitude of y-direction swing

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68376852

gradually increases, and the structural response or energy of xy plane decreases first and then rises.

The study above helps understand response of SCR structural particles at different positions from a space angle.

Analysis of transverse direction of SCR response under linear TSM, RBS and WA.

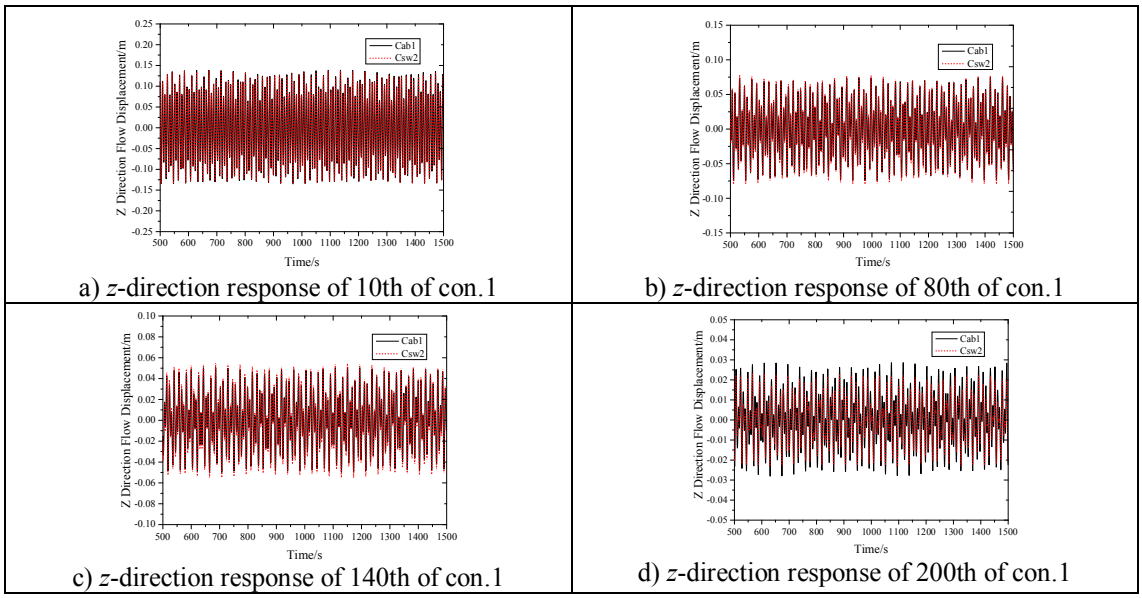
For riser, the above displacement research in xy plane is response in the SCR pipe body plane. This chapter mainly focuses on the response of z direction (transverse flow).

The displacement and its frequency in transverse direction is simulated from perspective normal to xy plane, which is non-negligible part of three-dimensional analysis. It is an important problem for structural vibration system study.

Cross flow response of structure including response caused by vortex-induced vibration (VIV), transverse direction action, RBS and so on is worth studying.

Compared with structural response caused by bending vibration and vortex-induced vibration, the response study of RBS in transverse direction is relatively few. This chapter focuses on the response characteristics in the transverse direction under linear WA, linear TSM and RBS.

Figure 4 shows the displacement of node 10-200th in condition 1.



a) *z*-direction response of 10th of con.1

b) *z*-direction response of 80th of con.1

c) *z*-direction response of 140th of con.1

d) *z*-direction response of 200th of con.1

Figure 4. *The transverse-direction response of 10th-200th of riser of con.1*

Figure 4 shows simulation results of con.1, respectively, and results of node 10th-200th are random sequences. The maximum of response are 0.13922 m, 0.07491 m, 0.0509 m and 0.0286 m, and minimum of response are -0.13483 m, -0.07496 m, -0.05014 m and -0.02802 m. Standard deviation of fluctuation are 0.07544, 0.03754, 0.02523 and 0.01304. It shows that with node number increase, that is, the region away from top suspension point or water depth increase, cross flow response of riser is weakened. And *Figure 6* shows it is under the action of WA and TSM. Not considering

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68376852

action of current, the WA on the structure and TSM both weaken with the depth increase, and then response weakens.

Under WA and TSM coupling RBS model, results of node 10th-200th are still random sequences. The maximum of the response are 0.1383 m, 0.0782 m, 0.0550 m, and 0.0237 m. And minimum of response are -0.1350 m, -0.08003 m, -0.0551 m and -0.0237 m. The standard deviation of fluctuation are 0.07534, 0.03959, 0.02733.0.01143. It can be seen that as distance of region away from the top suspension point increases, transverse flow response of structure is weakened. *Figure 6* shows the response under WA, TSM and RBS. It is noteworthy that when RBS is superimposed, response trend is equivalent to that only under WA and TSM. And effect of RBS on the riser does not exceed that of WA and TSM.

RBS influence with WA and TSM is briefly regarded as a linear overlay or superposition. Node 10-200th have a maximum increase of -0.69%, 4.35%, 8.02% and -17.48%. The minimum increases by 0.14%, 6.76%, 9.79% and -15.45%. With increase of water depth, RBS effect first augments and then reduces. That is, the trend is positively related to S which is RBS vector diameter, as shown in *Figure 1*. And this change is related to response of xy plane or the trend that energy decreasing and then increasing. It can be explained in terms of the total energy conservation of the structure. Other conditions have similar trends, as shown in *Figures 5-6* and *Tables 4-6*.

With the increase of nodes, the attenuation of maximum for node 10th, 80th, 140th and 200th are 46.19%, 17.25%, 15.97% and 20.59%. The attenuation of minimum are 44.40%, 18.41%, 16.41% and 20.78%. And the attenuation of standard deviation are 50.24%, 16.32%, 16.16% and 17.29%. With water depth increase, maximum, minimum and standard deviation of structure attenuate the most in top suspension point region, followed by touch down point region. The structural response decays to zero gradually, and attenuation amplitude in the intermediate region of riser is small. It is related to decrease of WA and TSM on the structure, with increase of depth. SCR is gradually close to the seabed, and finally presents as the submarine streamline section. The structure is subject to the reaction force of seabed support, which is more obvious in the bottom contact area. In middle region, TSM is related to the attenuation of WA and increasing of RBS, and the reduction shows a small attenuation.

With the increase of conditions, the attenuation of node 10th maximum are 46.19%, 41.87%, and 34.70%. The attenuation of minimum are 44.40%, 38.27% and 30.67%. The attenuation of standard deviation are 50.24%, 46.38% and 38.05%. As the condition increases, the attenuation of maximum, minimum and standard deviation gradually decreases. And the structural attenuation is more affected by the amplitude of condition of TSM as shown in *Table 2*, showing a positive correlation.

The rest of the nodes are shown in *Tables 5-6*. It is noteworthy that after RBS superimposed, the attenuation tendency of response is equivalent to that only under WA and TSM. And the effect of RBS on riser does not exceed that of WA and TSM.

Node response of 10-200th are compared in *Figures 5-6*. With motion amplitude decrease, each node response decreases or increases in different location. On the whole, the hanging point 10th have a more obvious decrease with conditions, and the response have an increase near the touch down point. The maximum influence coefficient of structure is about 20%, as shown in *Figure 6* and *Table 4*.

Spectrum analysis

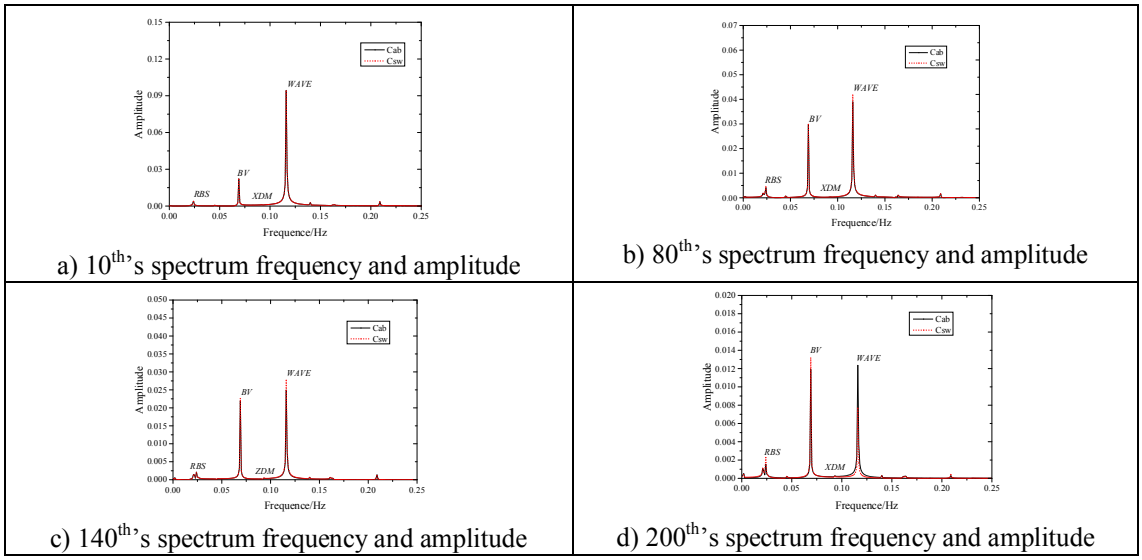
For z-response, spectrum analysis can transform the random signal in time domain into the signal in the frequency domain. Spectrum analysis can obtain main frequency

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68376852

of structure. It shows that there is a large value at a certain frequency point, and there is a maximum at one or more frequencies. By extracting maximum, this chapter mainly analyzes it:

1. Relative attenuation with the increase of water depth;
2. Increase or decrease of frequency caused by RBS;
3. The variation characteristics of structural displacement response frequency with the TSM frequency.

Through spectrum analysis, displacement spectrum responses of 10th, 80th, 140th and 200th are obtained, as shown in *Figure 7*.



a) 10th's spectrum frequency and amplitude

b) 80th's spectrum frequency and amplitude

c) 140th's spectrum frequency and amplitude

d) 200th's spectrum frequency and amplitude

Figure 7. *10-200th's spectrum amplitude of con.1*

Figure 7 shows displacement spectrum response of condition 1's node 10-200th. The x value is 0.115988 Hz, which is very close to WA frequency 0.11622 Hz. It could be considered that the structure's frequency is the same as that of the applied external load, and it is a forced motion.

For y value (spectral amplitude), as the node increases, amplitude values of each node are shown in *Table 7*. Spectrum response of 10th, 80th, 140th and 200th are 0.094425, 0.039063, 0.025002 and 0.012396. The amplitude of node is decreasing, indicating that maximum energy point of structure is decreasing, as shown in *Table 7*. This point can be proved from response of z-direction displacement of the structure, as shown in *Table 4*. For *Table 7*, it is similar to the corresponding change of displacement in terms of main frequency first increasing and then decreasing with increase of node. In contrast to change of energy or amplitude in xy plane, main frequency and displacement in z direction can be explained from energy conservation in three directions. With the decrease in the xy plane before the increase, the z direction displacement due to RBS in the 3d direction presents an opposite change, as shown in *Table 4*.

From the calculation of the same node in different conditions, the values of node 10th in condition 1-3 without RBS are 0.094425 m, 0.086288 m and 0.077539 m. And considering the RBS, the values are 0.094317 m, 0.086327 m and 0.078034 m. Relatively speaking, the difference between the RBS and non-RBS are -0.11%, 0.05%

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68376852

and 0.64%. It indicates that main frequency of the structure increases or decreases after the RBS is applied. The maximum influence for 10th is 0.64%. At nodes 80th, 140th and 200th, the main frequency of the structure increases by 8.17%, 11.27% and -37.71%. It indicates that when RBS applied, main frequency of riser changes. It increases above 140th or in non-touch down area, and decreases in touch down area, as shown in *Tables 7-8*.

2	200th	0.115988	0.016743	0.011225	-32.96%	2	140th	1.12	1.08
3	10th	0.115988	0.077539	0.078034	0.64%	3	140th	1.20	1.17
3	80th	0.115988	0.047149	0.050597	7.31%	1	200th	1.00	1.00
3	140th	0.115988	0.030059	0.032412	7.83%	2	200th	1.35	1.45
3	200th	0.115988	0.019296	0.013983	-27.53%	3	200th	1.56	1.81

At the same time, with the increase of conditions, the main frequency of 10th decreases. The other nodes show an increase of main frequency, with an increase of 80% in the bottom touch down area. The energy goes down at 10th, and the amplitude goes down, while it goes up in other areas, with amplitude shown in *Table 8*. After the normalized operation, coefficient in touch down point without RBS are 1.00, 1.35 and 1.56. And the coefficient superposed RBS are 1.00, 1.45 and 1.81. The coefficients of the two groups differ greatly, and the differences in other conditions are not significant.

DOI: http://dx.doi.org/10.15666/aeer/1703_68376852

In addition, it indicates that Z direction response of each position or node is proportional to the frequency of load applied. There is a certain resonance between loads and the response increases.

It is worth that *Table 9* gives some data of wave main frequency influence. *Figure 8* shows the effect of RBS on spectrum amplitude of different loads of the structure. These data can make some judgments about the effects of different loads. From 10th to 200th, the wave main frequency has an influence of 77.62%, 53.31%, 50.32%, and 47.35%. With the increase of water depth, the influence gradually decreases. RBS increases the spectral analysis amplitude of structural RBS, bending vibration, TSM and WA. The RBS increases response of riser to different degrees. It is worth noting that the bottom contact point is 200th. And RBS reduces both WA response and TSM response, as shown in *Figure 8*. To some extent, WA and TSM reduce oscillation of RBS at bottom TDP. It is similar to decrease of riser displacement in *Table 4*. In a word, spectrum analysis is of great significance for structural response interpretation.

Conclusion

It is a relatively important problem to simulate the transverse response of riser under RBS. The swing is around the rotating axis with TSP and TDP under WA. In this paper, without considering current, the relatively complicated response of riser coupled RBS is studied. And response is influenced by linear WA and TSM on the structure.

From a perspective of the overall motion pattern, response on the xy plane has developed from a narrow range swing in x direction to a narrow range oscillation in y direction. Under the WA, response of riser reduces gradually with depth. When coupling x direction TSM, phenomenon that response decreases when water depth increases still persists. In terms of variation in the depth direction of the structure, with increase of water depth, displacement decreases. And attenuation range is more intense in the top suspension region, while attenuation is weak in bottom region.

From the frequency of structure, it can be considered that the response of structure is the same as that of external load, and the response is forced motion. In terms of the conditions, as the node increases or the water depth increases, the main frequency first increases and then decreases, which is similar to the change of the structural response. In contrast to the change of energy or amplitude of response in the xy plane, it can be explained from the energy conservation of the structure in three directions of the node. As the response in the xy plane decreases first and then increases, the z direction response of RBS presents an opposite change.

After RBS is applied to structure, the main frequency increases above 140th or in the non-touch down area, and decreases in the touch down area. And the z-direction response of structure is inversely proportional to frequency increase of load applied and proportional to amplitude reduction.

Recommendations for future studies include the following points:

1) For the load term of the structural vibration equation, it is also necessary to consider the internal flow, isolated wave, etc. And multiple coupling calculation is needed to expand the program development and response calculation range.

2) To be specific, in this paper, linear wave is adopted, and more random wave check is required. Fluid-solid coupling phenomenon also needs to be taken into consideration. And it is suggested to adopt wake oscillator programming for the further calculation.

3) It is necessary to study response from a three-dimensional perspective, and spatial response characteristics cannot be easily ignored.

4) This paper considers contribution of load to response from the perspective of frequency amplitude. And it needs more detailed and accurate calculation from the contribution of load response.

5) In this paper, the number of conditions is few and it is suggested to search for more conditions to evaluate the effect of RBS by a safety ratio.

6) In this paper, there is also a deficiency in analytical calculation of structural vibration. It is suggested to increase the analytical solution of RBS, such as multi-load vibration matrix for verification, which may further increase the solution speed.

For analysis in Cable3D, the prospects are slightly better. It is expected that work of this paper could give some simulation advice for RBS research.

Abstract. African indigenous vegetables (AIVs) play a very significant role in food security of poor households. However, some AIVs are still underutilised in many African countries. The aim of this study was to analyse the effect of farm support program on market participation and profitability of AIV production in South Africa. Data were collected from 86 AIV farmers from South Africa. Probit regression and Stochastic Frontier efficiency analyses were employed for data analyses. The results revealed that infrastructure support assisted farmers to improve participation in markets. In addition, engagement in growing spinach and amaranth vegetables, farm income, gender, cooperative membership and access to EDSP significantly increased the probability of participating in informal markets ($p<0.05$). Also, the determinants of indigenous vegetable farmers' profit were seed input, land area cultivated, interactions of fertilizer with fertilizer, seed with seed and fertiliser with seed. Profit efficiency was significantly influenced by farm distance, road conditions and access to EDSP. It was concluded that EDSP enhanced farmers' access to informal markets and profit efficiency.

Introduction

African indigenous vegetables (AIVs) play a very significant role in promoting food security for under-privileged households in many African countries (Weinberger and Msuya, 2004). Their importance is underscored as prime facilitators of food security and sources of essential nutrients (Muhanji et al., 2011). Food and Agriculture Organisation (FAO) (2010) noted that as primary sources of food for many people, AIVs are not only associated with provision of vital energy and micronutrients in the diets of isolated communities (Grivetti and Ogle, 2000), but also constitute part of the conglomeration of African indigenous or traditional medicinal plants (Spring, 2015). Some investment opportunities for promoting availability of AIVs have been embarked upon by some African farmers given the growing knowledge of their nutritive values.

However, in sub-Saharan Africa, the potential benefits of AIVs have been overlooked over time due to negligence by consumers (FAO, 2005; Yang and Kedin, 2009). In some developing countries, including South Africa, AIVs hold excellent potentials to improve nutrition and increase households' dietary diversity (Lotter et al., 2014). A study by the World Bank (2010) found that despite the nutritional significance of vegetables, malnutrition remains a problem with stunting greatly affecting children and pregnant women (Fanzo et al., 2013). Inadequate consumption of vegetables is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68536864

resulting in Vitamin A deficiency in about 43.6% of children and 46% of pregnant women (Shisana et al., 2014).

In South Africa, there has been a shift towards non-indigenous food by the majority of the population. This has been driven by urbanization and wrong perception of nutritional worth of indigenous food and vegetables (Taleni and Goduka, 2013). Therefore, the government of South Africa has taken some policy measures for promoting production, consumption and marketing of AIVs. The Farmers' Support Program (FSP) was introduced in the mid-1980s and financed by the Development Bank of Southern Africa (DBSA) with the aim of supporting all sub-sectors of agronomy and horticulture agricultural systems. The aim of FSP was to promote structural changes to ensure agricultural commercialisation through the provision of comprehensive agricultural support services and incentives to existing farmers (PSPPD, 2010). In order to support government's efforts, some non-parastatal organisations such as the Agricultural Research Council (ARC) embarked on agricultural programs that are aimed at promoting vegetable production and marketing. ARC's programs are aimed at smallholding crop production, agro-processing, food technology and agricultural commercialisation, among others.

There is dearth of studies on the marketing and significance of AIVs in South Africa. Chetty (2013) conducted a study on the dietary analysis of South African indigenous vegetables and traditional food. The findings did not account for the marketing aspect of vegetable production. Mavengahama et al. (2013) analysed the contributions of indigenous vegetables to food security and nutrition across selected communities in South Africa. They pointed out the significance of indigenous vegetables on households' nutritional status given its high composition of micronutrients.

Many smallholder farmers can benefit from agricultural markets. Markelova et al. (2009) conducted a study on the challenges and constraints faced by smallholder farmers in market participation. The study did not cover the issue of farm profits obtained from participating in agricultural markets. It only focused on identifying barriers and innovations to alleviating constraints and challenges. Another study conducted by Maponya et al. *(*2015) examined the determinants of participation in agricultural markets in the Eastern Cape province of South Africa. Despite the numerous policies and studies regarding vegetables and their significance to human life, the study of vegetable marketing and profitability in South Africa has not been properly researched. It is, therefore, imperative to examine the effect of enterprise development support program on market participation and profitability of indigenous vegetable farmers in South Africa.

Different studies have identified the factors that limit farmers' production and marketing of vegetables. Okoruwa et al. (2009) identified farm size, access to credit facilities, transportation costs and contact with extension agents as the factors that affect market participation. Randela et al. (2008) reported that age, literacy level, ability to speak English, ownership of transport, access to market information, distance to market, dependency ratio and land size have significant influence on market participation. These constraints constitute the greatest barrier to smallholding agriculture, in terms of having access to high value markets (Vink and Kirsten, 2000). The aim of this study is therefore to analyse how enterprise development support affects marketing and profitability of indigenous vegetable production in South Africa.

Materials and Methods

Sampling methods

The study was conducted in Limpopo, Mpumalanga, Eastern Cape and KwaZulu-Natal provinces of South Africa. These provinces are involved in agricultural projects that support the promotion and cultivation of AIVs on commercial basis. The respondents were therefore drawn from those farmers that are growing AIVs namely Amaranth, Spinach and Mustard.

Data were collected with structured questionnaire largely comprising of close-ended questions. Eighty six (86) of AIV farmers were interviewed comprising 41 ARC beneficiaries and 45 non-ARC beneficiaries. The survey was conducted with the assitance of agricultural extension officers from the Department of Agriculture. The questionnaire requested information on demographic and household characteristics of respondents such as age, gender, education and marital status, farm specific characteristics, remittances, form of assistance as well as other major challenges to AIV marketing.

Market Participation Modelling

Probit model was used to model determinants of market participation. This is a type of regression where the dependent variable can only take two values (Yes coded as 1 and No coded as 0). The model estimates the probability that an observation with certain characteristics will fall into a specific category. The model can be specified as follows:

$$P_i^* = \beta X_i + \mu_i \quad \text{(Eq.1)}$$

which determines the value of participation by

$$P_i = \begin{cases} 1 \; if P_i^* > 0 \\ 0 \; if P_i^* \leq 0 \end{cases} \quad \text{(Eq.2)}$$

where P_i^*= latent continuous index measuring market participation for the ith farmer. β is a vector of estimated parameters. X_i is a vector of factors which affect participation which are planted mustard (yes =1, 0 otherwise), planted spinach (yes =1, 0 otherwise), planted amaranth (yes =1, 0 otherwise), market price per kg (Rand), farm revenue (Rand), distance to markets (km), condition of roads (bad road =1, 0 otherwise), land area used (hectares), gender (female = 1, 0 otherwise), age of farmers (years), marital status of farmers (married = 1, 0 otherwise), formal education (yes =1, 0 otherwise), household size, member of cooperative (yes =1, 0 otherwise), farming experience (years), extension support (yes =1, 0 otherwise), market linkage (yes =1, 0 otherwise) EDSP farmers (yes =1, 0 otherwise). μ_i is the random error term.

Profitability of AIVs modelling

The profit function was specified as:

$$\pi(x) = R(x) - C(x) = 0 \quad \text{(Eq.3)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68536864

where:
$\pi(x)$ = profit from AIV production
$R(x)$ = total revenue for sale of AIV
$C(x)$ = Cost of associated vegetable farming.

The profit function was estimated with Trans log profit function model as:

$$\ln \pi' = \alpha_o + \alpha_1 \ln f_i + \alpha_2 \ln lb_i + \alpha_3 \ln S_i + \alpha_4 \ln t_i + \alpha_5 \ln ld_i + \alpha_6 \ln lb_i^2 + \alpha_7 \ln ld_i^2 + \alpha_8 \ln f_i^2 + \alpha_9 \ln s_i^2 + \alpha_{10} f_i * S_i + \alpha_{10} lb_{i_i} * f_i + z_i + k_i \quad \text{(Eq.4)}$$

where: In = natural log
π' = normalised profit
α_o= constant parameter
fi = fertiliser, lbi = labour, Si = seed, ti = transport, $\ln lb_i^2$ = labour*labour, $\ln ld_i^2$ = land*land, $\ln f_i^2$ = fertiliser*fertiliser, $\ln S_i^2$ = Seed*seed, $f_i * S_i$ = fertiliser*seed, $lb_i * f_i$ = labour*fertiliser and z_i = random error term and k_i is the inefficiency error term.

The profit inefficiency model is specified as:

$$k_i = \delta + \sum_{k=1}^{14} G_{ik} + m_i \quad \text{(Eq.5)}$$

where planted spinach (yes =1, 0 otherwise), planted amaranth (yes =1, 0 otherwise), market price per kg (Rand), distance to markets (km), condition of roads (bad road =1, 0 otherwise), gender (female = 1, 0 otherwise), age of farmers (years), marital status of farmers (married = 1, 0 otherwise), formal education (yes =1, 0 otherwise), household size, non-farm income (Rand), member of cooperative (yes =1, 0 otherwise), farming experience (years), extension support (yes =1, 0 otherwise), market linkage (yes =1, 0 otherwise) EDSP farmers (yes =1, 0 otherwise). μ_i is the random error term.

Results and Discussions

Socio-economic and demographic characteristics of vegetable farmers

The results in *Table 1* show the socioeconomic characteristics of AIV farmers who were being categorized into EDSP benficiaries and non EDSP beneficiaries. The results show that 51% of the farmers that were supported by EDSP were female, while most of the non-EDSP farmers were male. Similar results had been reported by Ozkan et al. (2000) who found that production of vegetables was associated with female. On the contrary, Mumbi et al. (2006) found that male farmers were taking the lead in the production and marketing of vegetables.

The results in *Table 1* further revealed that 59% of the farmers that were supported by EDSP were more than 40 years old. Some farmers are involved in AIV production as a livelihood strategy for promoting households' nutrition and incomes. The age of AIV farmers as well as their years of farming experience are essential in agricultural market participation (Ramoroka, 2012). In both categories of farmers, those who were married formed a larger proportion than those who were not married. The results are in agreement with those reported by Baba et al. (2010) who found that married farmers participated more in vegetable farming in order to support their families.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68536864

Household size could play an important role in farming as it can be an important source of family labour. About 41% of the respondents who received support from the Agricultural Research Council (EDSP) had a family size of 4-6 members; an indication that family labour was still a common practice among farmers in order to reduce the cost of hiring labour.Non-EDSP farmers had household sizes of 1-3 members. In South Africa, the average household size is 3.4 members (Stats SA, 2010).

More than half of EDSP farmers (54%) had secondary education. Masuku and Xaba (2013) highlighted the importance of education in farming and maintained that it enables farmers to adopt change and innovation faster than the uneducated. An average of 62% of the farmers from EDSP and non-EDSP had farm size of three hectares, while 25% had ten hectares and more. Land plays an important role in the production of vegetables because it grants farmers an opportunity to expand their farming enterprises. According to Mumbi et al. (2006), the bigger the size of the farm, the higher the yield and the better the chances of the farmer participating in the markets. The average number of years of farming experience was 8 years. Over 30% of EDSP farmers had substantial farming experience, while non-EDSP farmers had 15 years or more. Farmers with adequate experience are reported by Osmani and Hossain (2015) to participate in the markets better than those who do not have any farming experience.

Determinants of Market Participation

The results in *Table 2* are for econometric modeling of determinants of AIV farmers' particpation in informal markets. The results show that revenue, condition of roads, gender and market linkage had negative relationship with market participation, while growing of Spinach, growing of Amaranths, membership of cooperative and being EDSP farmers showed positive statistically significant relationship ($p<0.05$). Growing of Amaranth was statistically significant at 5% level, while growing of Spinach was statistically significant at 1% level. Thus, involvement of farmers in growing Spinach or Amaranths increased the probability of participating in informal markets ($p<0.05$). However, the results of the marginal effect show that the three indigenous vegetables (mustard, spinach and amaranth) produced by farmers were statistically significant and had a positive relation to informal participation in markets. The results imply that growing of each of these vegetables increased the probability of farmers' participation in informal markets.

Increase in farm revenue will decrease the probability of participating in informal markets as farmers will produce more and target formal markets to sell their farm

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68536864

produce. This is in agreement with results reported by Moyo (2010), Montshwe et al. (2005) and Magingxa et al. (2005) that an increase in revenue increases participation in formal markets. Similarly, the parameter of condition of roads showed statistical significance with negative sign. According to Hlomendlini (2015), condition of roads influences participation in informal markets negatively. However, as the condition of the roads improves, participation will improve. The negative relationship implies that the probability of participating in informal market decreased by -0.781 when the condition of the road networds is bad. The same results were reported by Ramoroka (2012) who pointed out that the condition of roads is one of the fundamental factors that enables farmers to deliver their produce to the markets.

The age of farmers showed a negative relationship with participation in markets but was statistically significant at 5% level. This implies that as a farmer grows older, the probability of participating in informal markets also decreases. Arega and Manyong (2007) argued that participation in both formal and informal markets decreases with age because older people consider farming as a way of life rather than business. They are also reluctant to adopt new technologies in farming due to production uncertainties. In this study, a positive and statistically significant relationship between membership of cooperative and market participation was found at 5% level of significance. Similarly, being an EDSP farmer showed a positive relationship with participation in markets. This is in agreement with results obtained by Sikwela and Mushunye (2013) who found that farmers who received supports performed better in the agricultural food chains. The results of market linkage showed a statistical significance to participation in informal markets ($p<0.01$). As reported by Rios et al. (2009), farmers who are linked to the market participate better and tend to stay longer for better profits.

AIVs Profitability Analysis

Increasing profitability is the major production goal of farmers. Various factors affect the level of profit and hence determine the growth potential of farm business. This section provides the results of some of the factors that influence profitability of vegetable farmers. Variables that are assumed to have an impact are then interacted to determine which combinations best influence profitability of farmers positively.

The results in *Table 3* show that the coefficient of seed is with negative sign and is statistically significant at 10%. This implies that a 1% increase in seed will result in a decrease in AIVs profit by 0.2985%. Rachmina et al. (2014) maintained that an increase in seed seldom results in an increase in yields. On the contrary, transportation cost has positive and significant impact on profit with a parameter of 0.2772 ($p<0.01$). Therefore, increase in trnasportation cost by 1% increases profits from AIV cultivation by 0.2772%. According to Mérel et al. (2006), high cost of transportation affects profitability of farm business. The results further showed that the parameter of land is statistically significant ($p<0.01$). This parameter indicates that a 1% increase in land areas cultivated would decrease profit from AIV cultivation by 0.007%.

Some of the variables were further interacted in order to determine their interactive impacts on AIV profitability. Interaction of labour with itself shows a negative relationship to AIV profit level but statistically significant ($p<0.01$). This implies that multiplication of currently engaged labour in AIV production will reduce profit. This may occur through increase in labour cost and reduction in the level of output due to excessive intensification. Feroz et al. (2009) found that labour plays an important role in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68536864

farm profitability. According to Sikwela and Mushunye (2013), most of the sampled farmers made use of their household members as labour in order to increase profit.

Multiplication of the quantity of fertiliser shows a statistically significant ($p<0.01$) negative relationship with profit relaized from AIV production. The results imply that if the amount of fertiliser used in AIV production increases, outputs and profit will decrease. On the contrary, other researchers such as Pender and Gebremedhin (2008), Murthy et al. (2009), and Tilman et al. (2002) found that an increase in fertiliser resulted in increase in profitability. However, multiplication of quality of seeds shows a positive relationship that is statistically significant with profit ($p<0.01$). This result is in accordance with that of Abu and Asember (2011). The parameter of interacting fertiliser with seed shows negative relationship with profit. This implies that interaction of these inputs will decrease profit. However, a positive and statistically significant parameter was estimated with interaction of labour and fertiliser ($p<0.01$). This result implies that an increase in both labour and fertiliser will increase profit.

Table 3. *Translog profit function modelling of AIV Production*

Determinants of AIV Profit Inefficiency

From the results that are presented in *Table 4*, distance to the market shows a negative effect on profit inefficiency with a coefficient of -0.988 ($p<0.05$). This result implies that as market distance increases, profit inefficiency decreases. Renkow et al. (2004) had reported similar results. The objective of the condition of roads is to maintain and increase frequency to markets which is important in profit making. It is the major means of transporting agricultural produce from the farms to the markets. In this study, it is revealed that the condition of roads has a positive and significant effect on inefficiency of profit. Thus, inefficiency increased among farmers that had access to bad roads. Ogunniyi (2011) also reported that profit efficiency was affected by the condition roads. This result is also supported by research conducted by Rachmina et al. (2014). With the rapid transformation of marketing systems, traditional marketing channels are being replaced by coordinated links between farmers, processors and retailers. The results of this study show that support on market linkage has a positive and statistically

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68536864

significant effect on profit inefficiency. This result is a pointer to inadequate access that AIV farmers are having to formal markets. Presently, majority of them only sold at some informally organized markets. However, Morgan et al. (2009) found that market linkage improves the efficiency of farm profit.

Table 4. *Analysis of profit inefficiency of profitability of indigenous vegetable farmers*

Conclusion

The aim of this study was to examine the effects of enterprise development support program on market participation and profit efficiency of AIV farmers. The results have indicated that the support program enhanced access to informal markets by AIV farmers. This suggests that the program had been able to facilitate marketing of AIV although such linkages are yet to explore some more lucrative formal markets. It was also found that the condition of road influenced access to market and profit inefficiency. These results are reemphasizing the importance of adequate maintenance of feeder roads to the villages on market participation and production efficiency. There should be adequate efforts from government to properly link farmers in some interior villages to urban markets through adequate maintenance and construction of more roads.

Abstract. Topography determines the nature of hydrodynamic processes and its changes potentially affect the water quantity and quality. This study assessed the spatiotemporal impacts of topography changes on hydrological and hydrodynamic characteristics of China's largest freshwater lake, Poyang Lake. Results from simulation of different channel erosion intensities indicated that topography changes induced hydrological and hydrodynamic variations with spatiotemporal heterogeneity. Water levels in the lake decreased and the effect was enhanced with stronger erosion intensities. The decrease in water level was significant during the dry period, but negligible during the wet period. Water levels decreased by an average of 0.90-1.1 m in the northern channel during the dry period, and 0.27 m and 0.20 m in the central and eastern lakes during the rising and recession periods. The changing water level further affected the distribution of water with the effect of gathering water to the channel from nearby areas. Moreover, channel erosion altered the lake-river interactions. During the dry period, outflow discharges increased as the channel conveyance capacity increased by 25-136%. In contrast, during the wet period, outflow discharges decreased as the inflow regulation volume increased by 3.8-8.2 × 10^8 m^3. Particularly, backflow frequency and volume increased during the flooding period of the Yangtze River. In addition, the dry period in Poyang Lake was extended, and the frequency of low-water events increased significantly. This study demonstrated the spatiotemporal impacts of topographical changes on hydrodynamic processes in Poyang Lake, therefore providing a better understanding of variations in water regimes and lake-river interactions.

Keywords: *topography changes, hydrological and hydrodynamic impacts, numeric model, eco-hydrology, Poyang Lake*

Introduction

Topography has a fundamental control on the flow of water in gravity-driven shallow waters. It has a strong influence on the hydrological and hydrodynamic characteristics of water systems, and is closely related to water quantity and quality (Oliveira et al., 2006; Rinaldi et al., 2008; Malhadas et al., 2009; Mosley, 2015). Changes in topography affect flow patterns and material transportation, and these variations, in turn, alter the topographic evolution. Erosion and sedimentation processes occur frequently through interaction between water and suspended matters (Yang et al., 2007). As water usually contains suspended matters, such as mud, sand, salt, and floating algae, suspended particles contained in the flow can be deposited and attach to the surface of the bed or the bank of the watercourse. Thus depositional processes may increase the bottom surface and make the cross section of the waterway narrower. Conversely, the erosion process entrains particles from the bottom surface into the water and scours the bed and

DOI: http://dx.doi.org/10.15666/aeer/1703_68656886

sidewalls, making the watercourse deeper and wider. Under the combined effects of deposition and erosion, underwater topography usually changes slowly. Therefore, topography is regarded to be stable over short timescales and deformation is often neglected in studies of hydrological and hydrodynamic processes. However, disasters such as landslides, earthquakes, and debris flows, as well as human activities, such as dredging, lake infilling, and dam construction, can change topography in a short amount of time. The bottom may be raised or lowered, or the watercourse may be broken up, blocked, or diverted. Thus the spatial characteristics may change significantly. As an influential factor to hydrodynamic processes, topography changes have a substantial impact on water flow, water distribution, and material transportation, affecting the availability of water consumption for living organisms, agriculture and industry, as well as for ecological processes.

Poyang Lake, the largest freshwater lake in China, is one of the few existing lakes connected to the Yangtze River. The lake has a complex underwater topography (Feng et al., 2011) influenced by erosion and deposition processes. Moreover, human activities in Poyang Lake, including lake reclamation, reservoir construction and sand mining, induced significant changes (Min, 2000; Lai et al., 2014). Studies have indicated that active sand dredging in Poyang Lake after the enactment of a sand mining ban in Yangtze River in 2001 have altered the lake to an erosional system (Lai et al., 2014; Li et al., 2014). Monitoring the sand-dredging activities in Poyang Lake through remote sensing imagery was used to estimate the location and extent of decrease in elevation (Leeuw et al., 2010; Li et al., 2014). Further comparison of DEMs extracted from remote sensing images and in situ bathymetry measurements showed that the outflow channel was deeper and wider than before (Cui et al., 2009; Feng et al.,. 2011; Lai et al., 2014; Qi et al., 2014; Wu et al., 2015; Yao et al., 2018). Using the bathymetry data acquired in 1998 and 2010, Wu et al. (2015) found that the bottom elevation decreased 3.7 m on average in the outflow channel of the lake and 2 m on average in the inflow channel of the western branch of Ganjiang from 1998 to 2010, respectively. These studies traced topography changes using multiple methods, and provided the foundation for further studies on the impact of topography changes on hydrodynamic processes in the lake.

In recent years, serious problems, such as severe drought, the earlier arrival of the dry period, and wetland recession, have attracted wide attentions. Topographical changes across Poyang Lake are considered a critical element impacting the hydrology and hydrodynamic characteristics of the lake. Empirical analysis based on observations were used to show the correlation between channel deformation and hydrological and hydrodynamic fluctuations. Gao et al. (2014) analyzed and examined water discharges and sediment load data of Poyang Lake. The study deduced that a deepened channel increased the outflow and sediment flowing from the lake. Moreover, the river-lake interaction was potentially altered by channel morphological changes. Lai et al. (2014) estimated the lake conveyance capacity using outflow discharge and water level observations and deduced that the discharge ability of the lake increased during the dry period. The study demonstrated that the decreasing channel elevation influenced the abnormal low water levels during the winter dry season. These studies, based on observations and empirical analysis, suggested a link between channel erosion and hydrological and hydrodynamic changes in Poyang Lake. However, the impact of channel erosion cannot be fully explained by physical processes. Yao et al. (2018) quantified the impact of bathymetric changes on the lake's water level using a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68656886

hydrodynamic model. The influence on hydrological and hydrodynamic characteristics, such as water distribution and lake-river interaction, were not considered. It is necessary to assess the spatiotemporal influence of channel erosion through a physically based hydrodynamic model to better understand the hydrological, hydrodynamic, and ecological changes in the lake.

In this study, we aim to assess the spatiotemporal hydrological and hydrodynamic responses to channel erosion in Poyang Lake using a numeric method. A hydrodynamic model is constructed to reveal the flow characteristics. The established model is used for simulating the streamflow processes with different channel erosion intensities. The spatiotemporal impacts of topography changes on hydrological and hydrodynamic characteristics, including the lake water level, water distribution, lake-river interaction, and the wet-dry characteristics, are assessed. This study shows the spatiotemporal impact of topography change on water regime fluctuations and water quality changes in a shallow water system. The simulation supports analysis of spatiotemporal variations of hydrological and hydrodynamic characteristics, which will assist analysis of the driving forces related to water shortage problems, as well as terrestrial and aquatic environment dynamics. Therefore, more effective measures can be taken to solve problems in water supply shortages and water pollution.

Materials and methods

Study area and dataset

Poyang Lake is located in the middle section of the Yangtze River. The lake has a complex topography with shallow floodplain areas separated and alternating with deeper channels. The elevation of the lake bottom decreases markedly from south to north. The local annual precipitation around Poyang Lake fluctuates by approximately 1620 mm, and it changes dramatically affected by the subtropical humid monsoon climate. Water regimes and hydrodynamic characteristics of Poyang Lake show spatiotemporal heterogeneity. In the wet season period, usually from April to September, water level at Duchang (the representative gauge in Poyang Lake) rises to more than 12.8 m (Min and Zhan, 2012) and the inundation area expands to more than 3000 km² (Feng et al., 2012a), covering most of the lake extent. In the dry period, usually from October to March, the inundation area can shrink to less than 1000 km², and the lake assumes a river-like shape. The difference in water surface elevation from south to north can be more than 5 m in the dry period, whereas there is little difference during the wet period. Consequently, the flow velocity in the dry period is much faster than in the wet period. As a throughput type lake, Poyang Lake usually regulates water from five main rivers in the catchment, including the Xiushui, Ganjiang, Fuhe, Xinjiang, and Raohe (*Fig. 1*), and drains into the Yangtze River through the Hukou outlet. During flooding periods however, high water level in the Yangtze River, usually from July to September, may lead to backflow into the lake as well. The lake-river interactions exert a profound impact on the hydrological and hydrodynamic characteristics of Poyang Lake.

Three types of data were used in this study, including in situ measurements and products of the bottom elevation, daily water level and discharge data from the gauge stations, and satellite remote sensing images. Underwater terrain data was acquired in 1998 by the Changjiang Water Resources Commission of China. Changes in channel elevation between 1998 and 2010 were provided by the Jiangxi Administration of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68656886

Surveying, Mapping and Geoinformation (http://www.jxcehui.gov.cn). The bottom elevation data was processed to generate bathymetry for our numeric model. Time series of daily station discharge and water level data over the study period (January 1, 2001 to December 31, 2002) were collected from the Jiangxi Bureau Hydrology Department (http://www.jxsw.cn/). Upstream discharge data were collected from seven gauging stations (Qiujin, Wanjiabu, Waizhou, Lijiadu, Meigang, Hushan, and Dufengkeng) on the five main rivers in the catchment. Among them, Qiujin and Wanjiabu measure discharge from the Xiushui, Waizhou for Ganjiang, Lijiadu for Fuhe, Meigang for Xinjiang, and Hushan and Dufengkeng for Raohe (*Fig. 1*). Downstream discharge data at Hukou, which monitors the lake-river interaction, was collected. Water level data from six hydrological stations (Hukou, Xingzi, Duchang, Tangyin, Longkou, Kangshan) across Poyang Lake were collected to document the water regime of the lake. Besides, the 40-year (from 1970 to 2009) time series daily water level data at Duchang and Hukou were collected to analyze the water regime changes. A Landsat ETM+ image acquired on August 12, 2010 when a large flood occurred in Poyang Lake, was obtained from the USGS (https://glovis.usgs.gov/) to extract the extent of the water boundary.

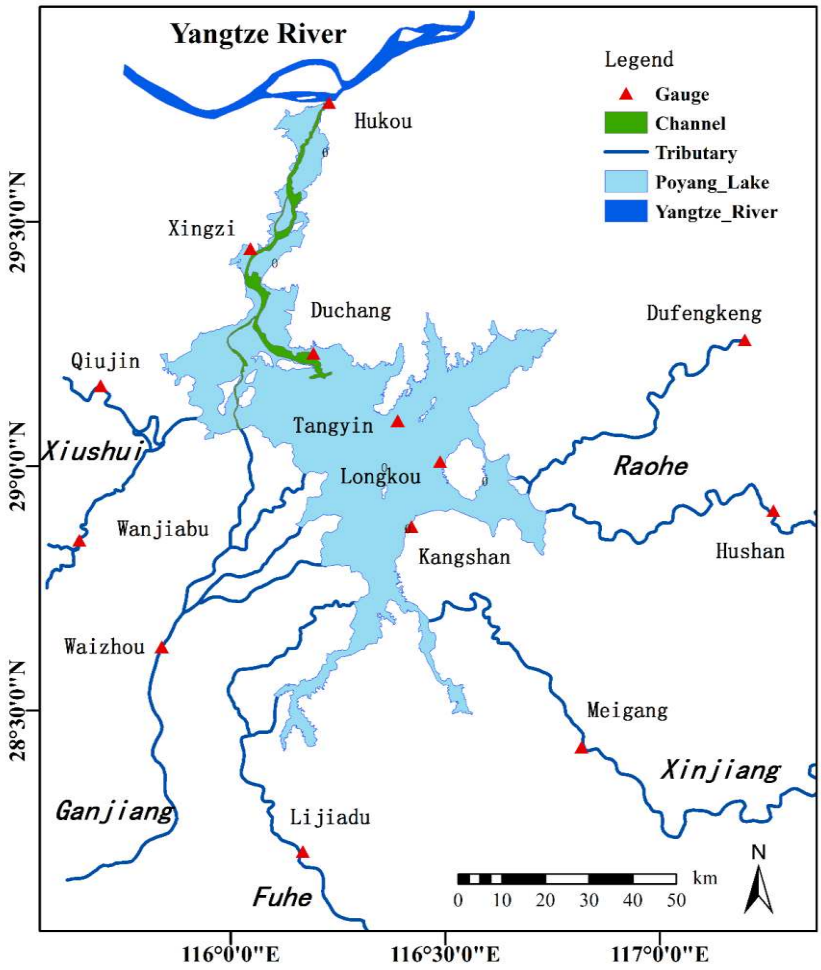

Figure 1. *Location of Poyang Lake and gauging stations. The lake inflow sources consist of five main tributaries: Xiushui, Ganjiang, Fuhe, Xinjiang, and Raohe. Water flow into the lake and run south-to-north through the channel into the Yangtze River at Hukou. Gauging stations on the tributaries and hydrological stations in the lake are marked as red triangles*

Methodology

Hydrodynamic model of Poyang Lake

In this study, a hydrodynamic model of Poyang Lake was established based on Delft3D-Flow, which is a module of the open source software Deltares (Delft Hydraulics, 2014). The software was developed to investigate hydrodynamics, sediment transport and water quality for fluvial, estuarine and coastal environments. As vertical currents could be neglected in Poyang Lake (Li et al., 2014; Zhang et al., 2015), a 2D free-surface model was constructed. The numerical program has been widely used to reveal hydrodynamic processes and transport phenomena in shallow waters.

Delft-Flow calculates multidimensional hydrodynamics based on the Navier Stokes equations, which consist of the continuity equation and the momentum equations. In an orthogonal coordinate system, the depth-averaged continuity and momentum equations are described as follows (*Eqs. 1-3*):

Continuity equation:

$$\frac{\partial \varsigma}{\partial t}+\frac{1}{\sqrt{G_{\xi\xi}G_{\eta\eta}}}\frac{\partial[(d+\varsigma)U\sqrt{G_{\eta\eta}}]}{\partial \xi}+\frac{1}{\sqrt{G_{\xi\xi}G_{\eta\eta}}}\frac{\partial[(d+\varsigma)V\sqrt{G_{\eta\eta}}]}{\partial \eta}=(d+\varsigma)q \quad \text{(Eq.1)}$$

Momentum equations:

$$\frac{\partial u}{\partial t}+\frac{u}{\sqrt{G_{\xi\xi}}}\frac{\partial u}{\partial \xi}+\frac{v}{\sqrt{G_{\eta\eta}}}\frac{\partial u}{\partial \eta}+\frac{\omega}{d+\varsigma}\frac{\partial u}{\partial \sigma}-\frac{v^2}{\sqrt{G_{\xi\xi}G_{\eta\eta}}}\frac{\partial\sqrt{G_{\eta\eta}}}{\partial \xi}+\frac{uv}{\sqrt{G_{\xi\xi}G_{\eta\eta}}}\frac{\partial\sqrt{G_{\xi\xi}}}{\partial \eta}-fv$$
$$=-\frac{1}{\rho\sqrt{G_{\xi\xi}}}P_{\xi}+F_{\xi}+\frac{1}{(d+\varsigma)^2}\frac{\partial}{\partial \sigma}(\nu_{v}\frac{\partial u}{\partial \sigma}) \quad \text{(Eq.2)}$$

$$\frac{\partial v}{\partial t}+\frac{u}{\sqrt{G_{\xi\xi}}}\frac{\partial v}{\partial \xi}+\frac{v}{\sqrt{G_{\eta\eta}}}\frac{\partial v}{\partial \eta}+\frac{\omega}{d+\varsigma}\frac{\partial v}{\partial \sigma}-\frac{u^2}{\sqrt{G_{\xi\xi}G_{\eta\eta}}}\frac{\partial\sqrt{G_{\xi\xi}}}{\partial \eta}+\frac{uv}{\sqrt{G_{\xi\xi}G_{\eta\eta}}}\frac{\partial\sqrt{G_{\eta\eta}}}{\partial \xi}+fu$$
$$=-\frac{1}{\rho\sqrt{G_{\eta\eta}}}P_{\eta}+F_{\eta}+\frac{1}{(d+\varsigma)^2}\frac{\partial}{\partial \sigma}(\nu_{v}\frac{\partial v}{\partial \sigma}) \quad \text{(Eq.3)}$$

where ξ, η are the horizontal curvilinear coordinates and σ is the scaled vertical coordinate; $G_{\xi\xi}$ and $G_{\eta\eta}$ are the coefficients to transform curvilinear to rectangular coordinates; ζ represents water level above the reference plane, and d represents water depth below the reference plane; (u, v) represent the flow velocity and (U, V) represent the depth-averaged flow velocity of the ξ- and η-direction, respectively; q represents the contributions of source and sink terms per unit area; ω represents the vertical velocity in the adapting σ-coordinate; ν_v represent the vertical eddy viscosity coefficient; f represents the Coriolis coefficient; P_ξ and P_η represent the pressure gradients; F_ξ and F_η represent the unbalance of horizontal Reynold's stresses; ρ represents the density of water.

The set of partial differential equations were solved by an implicit finite difference method on a staggered grid. To get a good solution from the hydrodynamic model, we should specified a set of model inputs, which can be divided into four data groups

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68656886

including model domain and time parameters, boundary conditions, initial conditions, and physical parameters. Model domain is usually defined by the computational grid and bathymetry. The time parameters contain the simulation runtime and computation steps. In the numeric model, the inflow and outflow boundary conditions are often used to restrict the computation, and the initial hydrodynamic state of the computation domain are used to launch the model. Physical parameters contain physical constants, such as water density, and calibration factors, such as bottom roughness.

To obtain the maximum water boundary for model calculation, a Landsat image acquired on August 12, 2010 was employed when a large flood occurred and the entire lake was covered by water (Zhang et al., 2015). Disconnected segments separated by islands and artificial structures were removed. Rectangle model grids were generated based on the maximum water boundary with a resolution of 300 m. The bottom topography data was processed to fit the coordinate system in Delft3D and interpolated into the model grid points. The run time of the simulation extended from January 1, 2001 to December 31, 2002, covering both complete wet and dry periods. The computation time step was set as 1 minute to meet the Courant-Friedrichs-Lewy (CFL) condition, which is related to model stability and accuracy (Delft Hydraulics, 2014). To simulate the dramatically and rapidly changing inundation extent in Poyang Lake, a drying and flooding algorithm was used in our study. Grids were removed from the computation domain when grids became dry as the water fell. Conversely, grids were added to the computation domain when grids became wet as the water rose.

Boundary conditions at the inflow and outflow were specified to restrict the computation. The upper open boundary was prescribed as the daily inflow discharges of Poyang Lake. As there is an ungauged area of 19,867 km^2 between the gauging stations of the five main inflow rivers and Poyang Lake (Zhang et al., 2014; Li et al., 2014; Zhang et al., 2017), daily total inflow discharges were calculated from the gauged discharges by using a simple water balance model put forward by Zhang et al. (2014). The lower open boundary of the model was prescribed as the daily water level at Hukou. Initial conditions were obtained by interpolating the measured water levels from the gauge stations in Poyang Lake.

After establishing the hydrodynamic model, the calibration and validation process were performed to make the model suitable for use. In this study, initial parameter values of the constructed hydrodynamic model were defined based on literature values (Zhang et al., 2015; Li et al., 2016; Qi et al., 2016) and recommended values in the Delft3D user manual (Delft Hydraulics, 2014). A trial-and-error method was used to adjust the critical parameters (Zhang et al., 2015), including bottom roughness, eddy viscosity, and threshold depth for drying and flooding, to optimal values by comparing simulated results with station observations. Daily water levels at the five hydrological stations in the lake (Xingzi, Duchang, Tangyin, Longkou, and Kangshan) and discharge data at Hukou station in 2001 was employed for model calibration and data in 2002 was used for model validation. Statistical indices, including the coefficient of determination (R^2), the Nash-Sutcliffe Efficiency coefficient (NSE), and percent bias (PBIAS), were calculated for evaluating the performance of the model (Moriasi et al., 2007).

Channel erosion simulation

To evaluate the impact of bottom deformation on hydrodynamic characteristics of rivers and lakes, the deformation area and intensity should be estimated firstly. *Figure 2a* shows the bottom elevation of Poyang Lake in 1998 and *Figure 2b* shows the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68656886

elevation change from 1998 to 2010. The remarkable decrease in channel elevation was the main feature of topographical changes in Poyang Lake during this period. The bottom elevation in the main channel and the inflow channel of the western branch of Ganjiang (as shown in *Fig. 1*) decreased by an average of 4.0 m and 2.1 m, respectively. In our experiment, channel erosion in these areas was considered. Four scenarios, including slight, moderate, serious and severe intensity, were set to simulate different intensities of channel erosion in the lake. The severe channel erosion was set as the loss in channel bottom elevation from 1998 to 2010 by average of 4.0 m. The bottom elevation after slight, moderate and serious intensity of channel were obtained by interpolation, with an average of 1.0 m, 2.0 m, and 3.0 m decrease in the main channel. Bottom topography was processed and re-interpolated to hydrodynamic model grid points. In order to distinguish the impact of channel erosion on the hydrological and hydrodynamic characteristics in Poyang Lake, the same model configurations, except for bathymetry data, were used for simulations in all four scenarios.

Results

Observed changes of water regime

Figure 3 shows the variations of the averages of daily water levels from 2000 to 2009 at Duchang and Hukou, compared to the 40-year (from 1970 to 2009) average conditions. Water levels in Poyang Lake were generally lower during the 2000s. Compared to the 40-year average, mean water level during the 2000s decreased approximately 0.68 m and 0.55 m at Duchang and Hukou, respectively. And the dry

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68656886

period in the lake during the 2000s became approximately 40-day longer. The results indicated that Poyang Lake experienced a more severe dry condition in the 2000s.

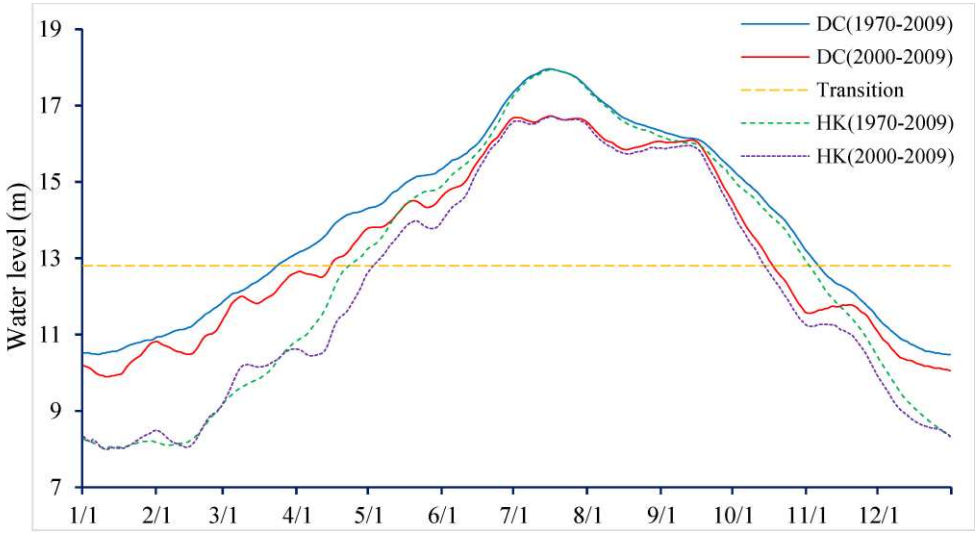

Figure 3. *Daily mean water level variations of the 2000s compared to the averages from 1970 to 2009 at Duchang (DC) and Hukou (HK). The "Transition" water level represents the transition water level of the wet and dry periods at Duchang in Poyang Lake*

Hydrodynamic model evaluation

Parameters of the hydrodynamic model were calibrated by comparing the simulated water levels and discharges to the measurements in 2001. After many tests by repeatedly refining the critical parameters, the Manning roughness was set to be 0.020 $s/m^{1/3}$ for the channel and 0.030 $s/m^{1/3}$ for floodplain area according to the terrain features. Eddy viscosity was set to 1 m^2/s and the threshold depth for drying and flooding was set to 0.10 m. The calibrated model was validated based on a comparison between simulation results and observations in 2002. Statistic indices were calculated to evaluate model performance (*Table 1*). Simulated water levels and outflow discharges were compared to station observations over the calibration and validation period, as shown in *Figure 4*. Results show that the hydrodynamic model is capable of capturing the dynamic changes of Poyang Lake. Simulated water levels are consistent with observations from the five hydrological stations (Xingzi, Duchang, Tangyin, Longkou and Kangshan) from north to south of the lake in both the calibration and validation periods. The R^2 and NSE of Xingzi, Duchang, Tangyin, Longkou and Kangshan gauging stations are all higher than 0.95 and 0.93, respectively, which indicate that most of the variance in the measured data could be explained by the model and the simulated results fit the observations well. The PBIAS values vary from -0.72% to 0.76%, which suggests no significant overestimation or underestimation in the model. In particular, the significant overestimation of water levels during the dry period caused by bathymetry errors (Lai et al., 2011) was eliminated. The results indicate that the hydrodynamic model is able to reproduce the rapid water level changes over wet and dry periods, as well as the remarkable spatial variation. The associated R^2 and NSE of simulated discharge at Hukou station are all larger than 0.9 and the PBIAS during calibration and validation are 5.78% and 1.18% respectively, which suggests an

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68656886

acceptable level of accuracy for the discharge simulation. Generally, the calibrated and validated hydrodynamic model employed in this study has the capability to simulate the hydrological and hydrodynamic characteristics of Poyang Lake. Thus, it provides the possibility of reproducing and predicting of hydrodynamics of the lake.

Water levels influenced by channel erosion

The simulated daily water levels under different channel erosion intensities at the five stations were compared to the conditions before channel erosion. *Figure 5* indicates that water levels in Poyang Lake became lower after channel erosion. An increased reduction in water levels occurred at the five stations as the channel became deeper. However, the impact of channel erosion on water levels is spatially and temporally heterogeneous. The extent of water level decline varies over time and space.

Table 2 shows the changes of mean water level at the five gauging stations under different channel erosion intensities. Mean water level reductions during the simulation period all increased with downcutting depth, nonlinearly. Water levels at Duchang station decreased the most after channel erosion, followed by Xingzi, Tangyin, Longkou, and Kangshan. Under severe channel erosion conditions, mean water levels at Duchang and Xingzi decreased by 0.551 m and 0.422 m, respectively. Meanwhile, mean water level decreased by approximately 0.1 m at Tangyin and less than 0.1 m at Longkou and Kangshan.

Table 2. *Changes of mean water level (unit: m) under different channel erosion intensities (slight, moderate, serious, severe intensity) compared to the original scenario at five hydrological stations in Poyang Lake during the simulation period*

	Xingzi	Duchang	Tangyin	Longkou	Kangshan
Slight	-0.183	-0.229	-0.049	-0.025	-0.021
Moderate	-0.301	-0.401	-0.075	-0.040	-0.025
Serious	-0.378	-0.501	-0.091	-0.050	-0.034
Severe	-0.422	-0.551	-0.101	-0.057	-0.041

Moreover, spatial differences in channel erosion impact on water level leads to changes in water surface slope. Generally, the water surface elevation decreases from south to north in Poyang Lake and the water head from Kangshang to Hukou can be more than 7 m during the dry period. Water level declines caused by channel erosion increased gradually from Kangshan, through Longkou to Tangyin, and reached a maximum at Duchang (*Table 2*). Therefore, the water surface slope increased significantly from Kangshan to Duchang. Under severe channel erosion conditions, the mean water head between Kangshan and Duchang increases by approximately 0.5 m

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68656886

and the maximum increase reaches approximately 1.4 m. However, due to the blocking effect of the Yangtze River, the impact of channel erosion on water levels decreased from Duchang to the north end of the lake. In particular, water level at Hukou are thought to be determined by the Yangtze River (Cai et al., 2015), thus the impact of channel erosion can be neglected. The water surface gradient from Duchang to Hukou declined after channel erosion. The water head decreased by an average of 0.6 m under severe channel erosion condition.

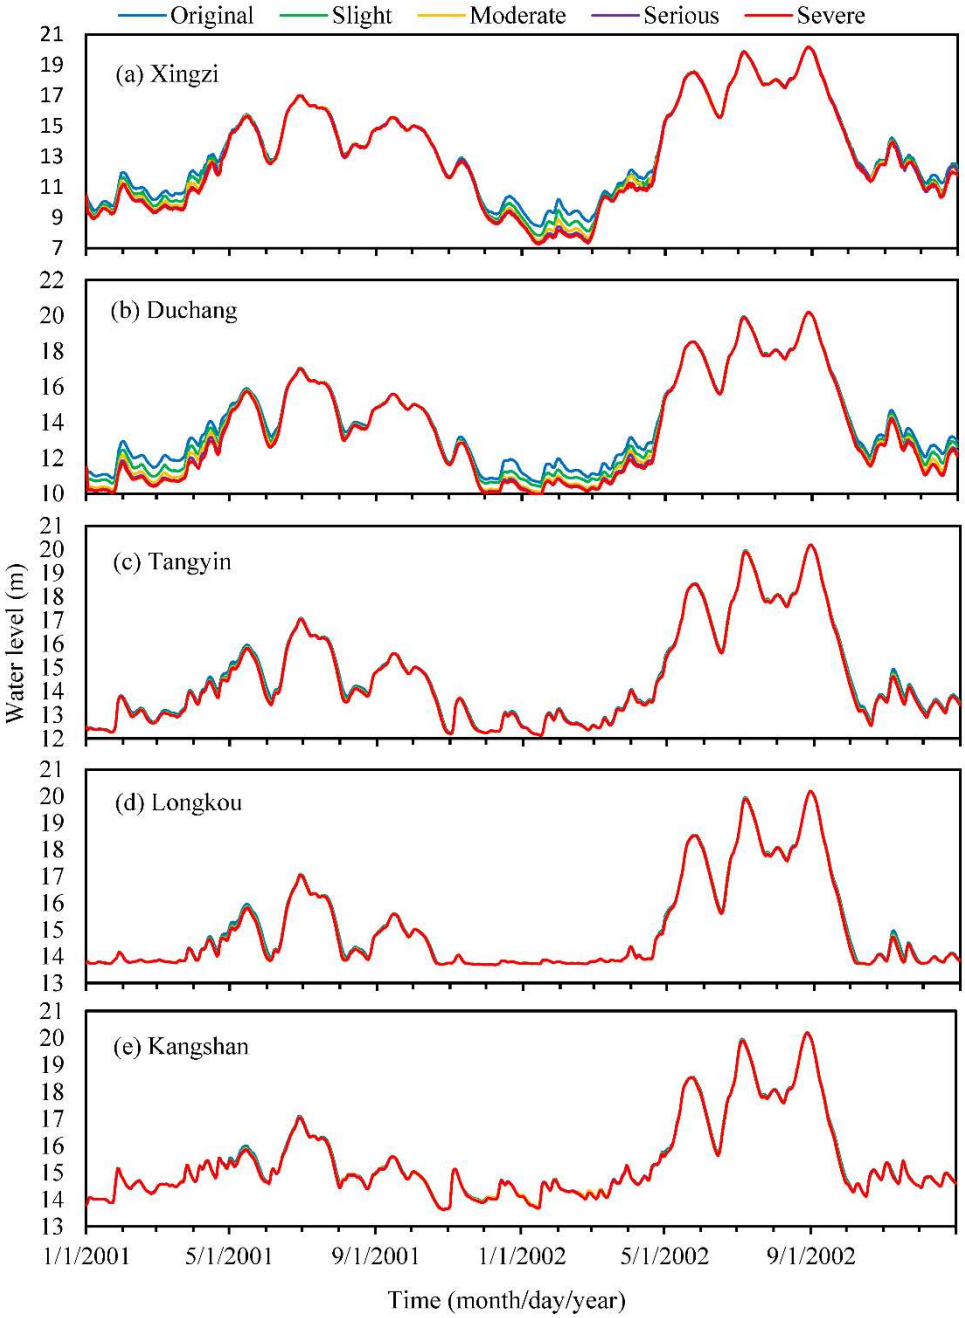

Figure 5. *Comparison of the simulated water levels under different channel erosion intensities (slight, moderate, serious, severe intensity) with the water levels before channel erosion (original) at* ***a*** *Xingzi,* ***b*** *Duchang,* ***c*** *Tangyin,* ***d*** *Longkou,* ***e*** *Kangshan. Water levels at the five gauging stations all decreased after channel erosion*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68656886

Furthermore, the decrease in water level at the five stations influenced by channel erosion were not temporally identical. *Figure 6* shows the amplitude of decrease in monthly average water levels under severe channel erosion conditions. In general, water levels in the dry period were more sensitive to channel erosion than in the wet period. During the dry period, the water level in the northern channel was most affected. The water levels at Xingzi and Duchang decreased significantly, by an average of 0.90 m and 1.1 m. Monthly average water levels at Xingzi and Duchang all reduced more than 0.52 m and 0.70 m, respectively. The maximum daily water level reduction in Xingzi and Duchang station occurred on January 31, 2002, and March 30, 2001, reaching 2.05 m and 1.37 m, respectively. During the rising and receding water periods, water levels at Xingzi and Duchang decreased an average of 0.40 m and 0.61 m. Water levels in the central and eastern part of the lake decreased by an average of 0.27 m and 0.20 m at Tangyin and Longkou, respectively. The maximum water level reductions at Tangyin and Longkou all occurred in May 2001, reaching 0.46 m, and 0.37 m, respectively. During the wet period, water level changes were all less than 0.1 m.

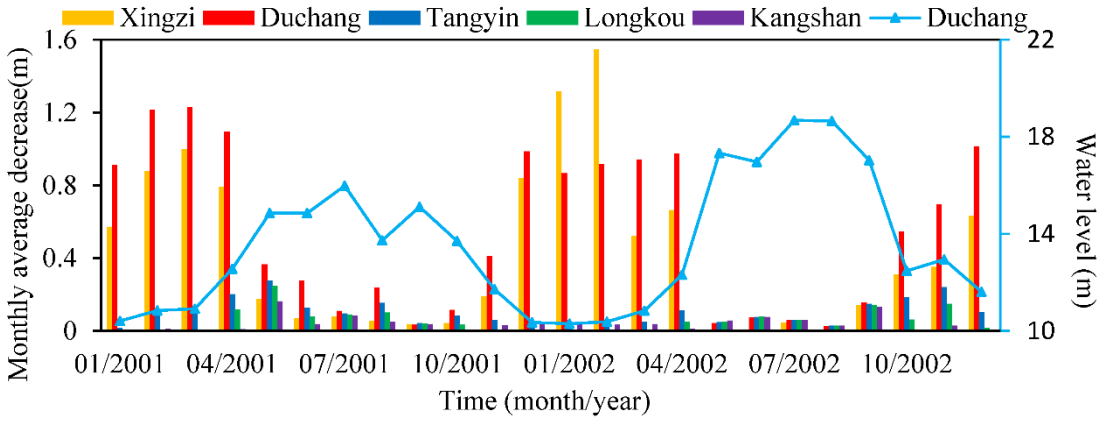

Figure 6. *Decrease in monthly average water level (marked as bars) at Xingzi, Duchang, Tangyin, Longkou and Kangshan under severe channel erosion conditions. Decrease of water level caused by channel erosion was more significant in the dry period when water level in the lake (marked as dots with solid line, Duchang) is low*

Channel erosion impact on water distribution in the lake

An additional study was performed on the effect of water distribution in Poyang Lake, which was represented by water depth changes after channel erosion. *Figure 7* shows the water depth changes after a severe intensity of erosion during a low water period, rising water period, high water period, and receding water period in 2001. Although water levels in the channel from Duchang to Hukou decreased, the water depth in the channel increased by 2.0 m to 4.0 m over the whole year. Similarly, the water depth in the northern branch inflow channel of Ganjiang increased by 0.5 m to 1.0 m. However, the influence of water depth on the floodplain areas changed in the different periods. During the low water period, the water depth in the floodplain between Xingzi and Duchang decreased by 1.0 to 2.0 m. In addition, the water depth in the middle of the lake decreased by 0.1 to 0.5 m. During the rising water period, the water depth decreased by 0.5 to 1.0 m in the central lake area, and 0.1 to 0.5 m in the eastern floodplain. During the high water period, the impact of water depth on the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68656886

floodplain area was negligible. During the receding water period, the water depth decreased by 0.1 to 0.5 m in the central and eastern part of the lake. Changing water depths in Poyang Lake indicated that channel erosion redistributed water in the lake, namely, water in the middle and eastern floodplain and areas nearby the channel drained to the outflow channel.

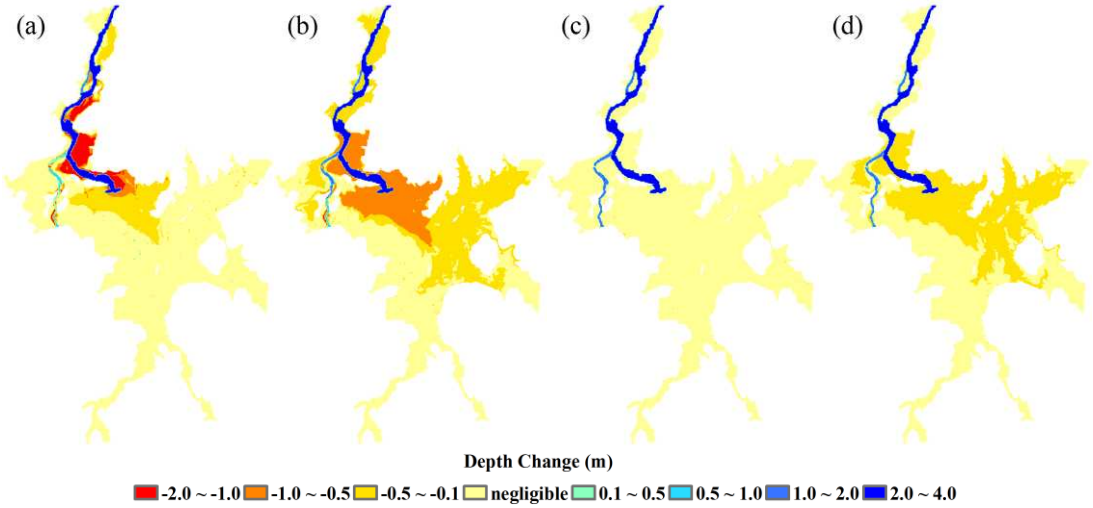

Figure 7. *Water depth changes under sever channel erosion conditions on* ***a*** *March 30, 2001, during low water period,* ***b*** *May 30, 2001, during rising water period,* ***c*** *June 29, 2001, during high water period, and* ***d*** *October 17, 2001, during the receding water period*

Impact of channel erosion on lake-river interactions

Simulated daily discharge at Hukou under different channel erosion intensities were compared with the outflow before channel erosion. The results in *Table 3* show that channel erosion increased the total outflow discharge to the Yangtze River from the Poyang Lake slightly during the simulation period. Although the channel's morphological changes influence on the outflow discharge was not as great as the inflow volumes and the outlet water level variations, the temporally heterogeneous influence changed lake-river interactions. The results indicate that outflow discharges increased in the dry period, but tended to decrease in the wet period. The impact on outflow discharge enhanced due to stronger channel erosion intensities. Topographical changes altered the lake volume and hydraulic condition of the lake, thereby changing the lake's discharge ability and regulation capacity. As erosion decreased the bottom elevation, the lake volume in the four scenarios with different intensities of channel erosion increased by 1.3×10^8 m³, 2.6×10^8 m³, 3.9×10^8 m³, and 5.2×10^8 m³, respectively. The increasing storage capacity of the lake might decrease the outflow discharge since the lake was able to hold more water. However, variations in the channel bottom topography elevation increased the wetted cross-sectional area and the hydraulic gradient. These two different processes induced a considerable variation in lake-river interaction.

During the dry period, the lake outflow into the Yangtze River increased with channel downcutting depth. During this period, inflow water flow ran through the channel in the lake and drained into the Yangtze River due to the large difference in water level between the southern and the northern part of the lake (an average of 4.5 m

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68656886

from Kangshan to Hukou) and the weak blocking effect of the Yangtze River. Channel erosion increased the wetted cross-sectional area and the hydraulic radius of the lake outflow channel, thus increasing the lake conveyance capacity, which represents the essential discharge ability of an open lake outflow channel (Lai et al., 2014). The results in *Figure 8* show that Poyang Lake's outflow channel conveyance capacity increased with different intensities of channel erosion. The average lake conveyance capacity before channel erosion was approximately 2290 $m^{2.5}/s$, and for the four channel erosion scenarios in this study it increased by 25.0%, 58.7%, 99.4%, and 135.8%, respectively. The increasing conveyance capacity implies that water flows more easily from the channel into the Yangtze River. A larger increase in the outflow channel conveyance capacity occurred during the low water period of Hukou. For example it increased by 260% at a level of 7.2 m, which has the potential to intensify the drought during this period. Moreover, significant decrease in water levels in the northern watercourse caused by channel erosion increased the water surface slope during the dry period, accelerating the water flow into the channel, and increasing the total outflow discharge.

Table 3. *Relative change rate of outflow discharge at Hukou station compared to that before channel erosion after slight, moderate, serious, severe intensity of channel erosion*

	Dry period	Wet period	All
Slight	0.38%	-0.01%	0.05%
Moderate	0.76%	-0.06%	0.08%
Serious	1.02%	-0.09%	0.10%
Severe	1.20%	-0.11%	0.11%

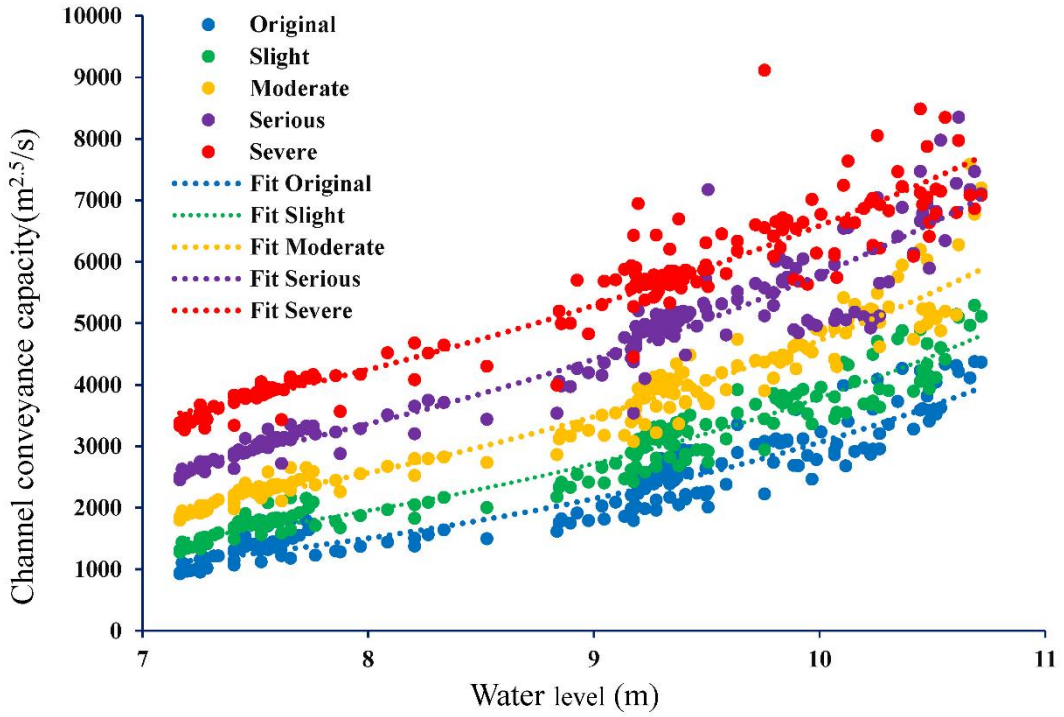

Figure 8. *The impact of channel erosion on the relationship between the lake conveyance capacity and Hukou water level during the low water period*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68656886

During the wet period, outflow discharge tended to decrease. During this period, the water head between the southern upstream and the northern downstream in Poyang Lake decreased dramatically (an average of 1.0 m from Kangshan to Hukou). Simultaneously, higher water levels in the Yangtze River significantly enhanced the blocking effect to Poyang Lake outflow. The changing hydraulic conditions and lake volume caused by channel morphological variations altered the regulation process, thereby affecting the river-lake interaction and outflow discharge. A quantitative analysis of the lake's water balance can be expressed as *Equation 4:*

$$\Delta V = I - Q \tag{Eq.4}$$

where Q is the outflow at Hukou, I is the inflow of Poyang Lake, and ΔV is the change in lake water storage (positive for volume increase). *Figure 9a* shows a good-fit linear relationship between the lake volume (V) and water level (Z) during high water period. Therefore, the change in lake water storage can be represented as a curve differential coefficient (*Eq. 5*).

$$\Delta V = \Delta f(Z) / \Delta Z \tag{Eq.5}$$

The relationship between lake water storage and water levels before channel erosion and after severe channel erosion is shown in *Figure 9b,* which indicates that channel erosion altered the lake volume change rate. In the four channel erosion scenarios, the change in lake volume caused by per meter variation in water level at Hukou increased 1.7×10^7 m³, 2.8×10^7 m³, 3.6×10^7 m³, and 4.1×10^7 m³, respectively. During the high water period, the lake pondage of inflows (Huang, 2011) increased by 3.8×10^8 m³, 5.8×10^8 m³, 7.3×10^8 m³, and 8.2×10^8 m³, respectively. Thereby, outflow discharge to the Yangtze River decreased.

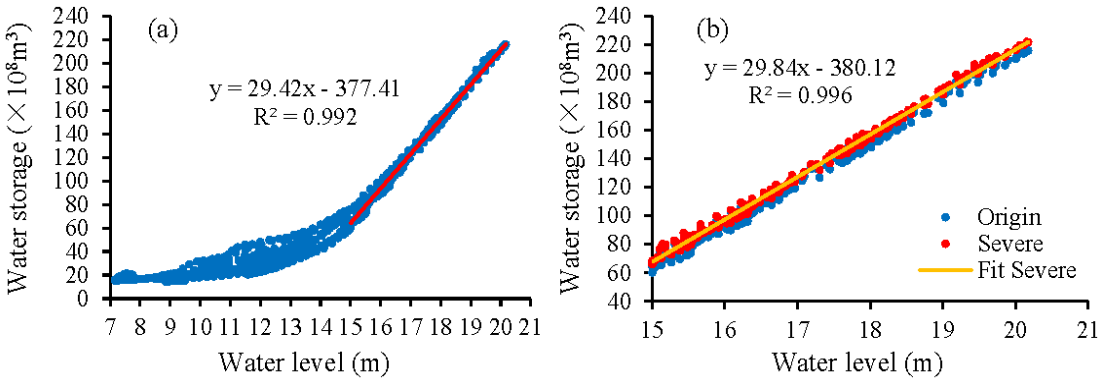

Figure 9. a *Relationship between water storage in Poyang Lake and water level at Hukou, and there is a good-fit linear relationship during high water period.* ***b*** *The changing relationship between the lake water storage and Hukou water level under severe channel erosion condition during high water period*

Furthermore, a larger storage capacity and lower water levels in the lake theoretically increased the backflow frequency and volume from the Yangtze River towards Poyang Lake (Gao et al., 2014). During the simulation period, backflow occurred from August

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68656886

23 to August 26, 2002, and the volume of backflow was approximately 3.2×10^8 m³. In our four different intensities of channel erosion scenarios, the backflow volume increased to 3.3×10^8 m³, 4.5×10^8 m³, 4.6×10^8 m³, and 5.1×10^8 m³, respectively. The backflow occurred 3 days in advance under severe channel erosion conditions. Therefore, channel erosion has a significant influence on the water exchange between the Yangtze River and Poyang Lake.

Changes of wet-dry characteristics

Poyang Lake shows significant seasonal variations, alternating between wet and dry periods. Using six decades (1952-2011) of observed water level data from Duchang station, the representative hydrological station of Poyang Lake, Min and Zhan (2012) divided the dry period into five low-water level statuses, including a general low-water level (11.8 m < H ≤ 12.8 m), a moderate low-water level (10.8 m<H ≤ 11.8 m), a serious low-water level (9.8 m < H ≤ 10.8 m), a severe low-water level (8.8 m < H ≤ 9.8 m) and an extreme low-water level (H ≤ 8.8 m). The wet-dry characteristics are closely associated with water supply, irrigation and shipping. During the simulation period, water level at Duchang station varied from 9.90 m to 20.12 m, encompassing the low-water level status except for severe and extreme low-water level.

Figure 10 shows the alteration of wet and dry periods in Poyang Lake during 2001 and 2002. The results imply that channel downcutting made the dry period start earlier and end later, resulting in a longer dry period and an emergence of lower water levels. As bottom erosion increased the outflow channel conveyance capacity and the hydraulic slope from the channel to the floodplain area, the transitional process from dry to wet slowed down. The date the dry period ended in 2001 and 2002 was delayed 6 to 27 days under different channel erosion intensities. Generally, the time delay increased with the channel erosion depth. The effect in drier years was more significant as less water supply was available to supplement the water loss in the lake. Moreover, the results indicate an earlier arrival of the dry period due to larger bottom slope that accelerated water drainage to the channel. The date the dry period started in 2001 and 2002 advanced 1 to 5 days. The two effects of channel erosion on wet-dry characteristics extended the dry period time in Poyang Lake.

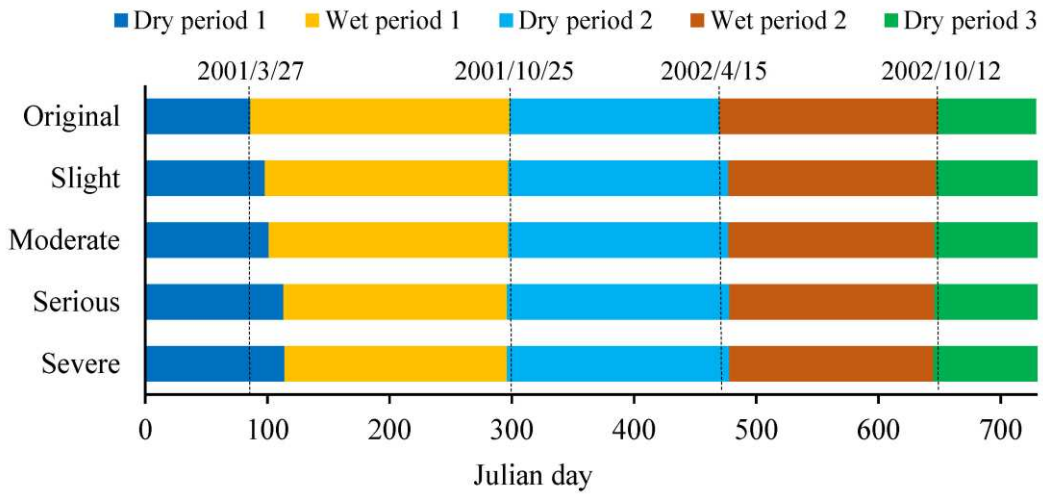

Figure 10. *Comparison of the distribution of wet and dry periods in 2001 and 2002 without or under different channel erosion intensities*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68656886

Furthermore, days of general low-water level (T1 in *Fig. 11*), moderate low-water level (T2 in *Fig. 11*) and serious low-water level (T3 in *Fig. 11*) displayed on an upward trend with an increase in the channel erosion intensity. Cumulative days of general low-water level increased 15%, 22%, 28%, and 32%, respectively under slight, moderate, serious, and severe channel erosion conditions. In addition, moderate low-water level days increased 47%, 63%, 81% and 92%, respectively. In particular, days of serious low-water level were 5.2 to 14.6 times that before channel downcutting. The results under severe channel erosion show that the frequency of serious low-water level increased dramatically from 1.5 to 23.6%. Additionally, the lowest water levels over the runtime decreased 0.23 m, 0.54 m, 0.68 m, and 0.73 m. Extreme low water level may occur as the bottom elevation of the channel decreases.

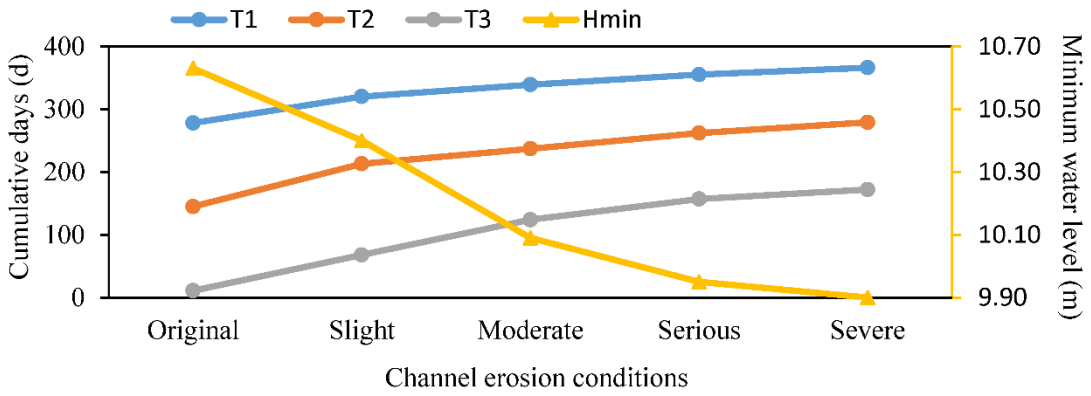

Figure 11. *Cumulative days of low-water level and lowest water level under different channel erosion conditions. T1, T2, and T3 represent cumulative days of general low water level, moderate low water level, and serious low water level during the simulation period.* H_{min} *is the minimum water level occurred at Duchang station*

Discussion

A long-term examination of lake water levels conducted by Min and Zhan (2012) and trend testing of lake water levels conducted by Zhang et al. (2014) showed that water levels of Poyang Lake were significantly lower during the 2000s. In addition to the influence of variations in Yangtze River water regime, local catchment precipitation, lake inflow runoff (Hu et al., 2007; Zhang et al., 2012; Feng et al., 2012b; Liu et al., 2013), the changes in bottom topography were identified as one of the influential factors (Lai et al., 2014; Yao et al., 2018). Our study further investigated the spatiotemporal impact of channel erosion on the hydrological and hydrodynamic characteristics. The results of this work agreed with the previous studies, which suggested that decreases in channel elevation lead to lower water levels in the lake during the dry period. An assessment of the lake water level variations indicated significant spatiotemporal heterogeneity in channel erosion impact. Water surface elevation during the dry period near the channel decreased most and water levels in the middle of the lake near Duchang and the floodplain area in the eastern and southern part of the lake were evidently affected. In contrast, water levels during the wet period were almost unaffected. Thus the influences of topography changes on specific low-water regimes in the lake needs further evaluation combined with the spatiotemporal characteristics of the events. The results from the simulation of different channel erosion intensities

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68656886

showed that the reduction of water levels increased with the downcutting depth of the watercourse. Lower water levels, especially during the dry period, potentially caused great water intake difficulties for industry, agriculture and living organisms. With the influence of both climate changes and human activities, dramatic changes in water regime and hydro-environment have occurred in many shallow waters (Ma et al., 2010; Feng et al., 2012; Gosling et al., 2016; Lu et al., 2019; Zhou et al., 2019). Topography changes were often ignored in water balance analysis, as much effort was expended on the changes of inflow volume and outflow boundary conditions. However, topography changes can also induced significant variations in hydrological and hydrodynamic processes. Thus consideration of topography changes and their impacts promote understanding of the water regime fluctuation and assist management of water resources.

Erosion in the outflow channel influenced water exchanges between the Yangtze River and Poyang Lake. The results in this study suggest that outflow discharge during the dry period was larger after channel erosion, which agreed with the analysis of Lai et al. (2014). The increase in outflow discharge from Poyang Lake enhanced the emptying effects (Zhang et al., 2012), which may lead to a drier lake environment. Moreover, larger outflow discharge increased the sediment load from the lake, which in turn decreased the bottom of the lake basin. Gao (2014) investigated the sand budget between Poyang Lake and Yangtze River and stressed that sediment load from the lake over the low-water period increased by 10.08 Mt during the 2003-2010 owing the outflow discharge increase. Our study further analyzed the impact of channel erosion on lake-river interactions during the high water period, which was not considered in previous studies. The results indicated that channel erosion increased the regulation capacity of Poyang Lake during the wet period, therefore increasing the pondage volume of inflows. The increase in regulation capacity of Poyang Lake reduced outflow discharges into the Yangtze River during the flooding period and it reduced the flood pressure of downstream. In addition, channel erosion facilitated backflow from the Yangtze River to Poyang Lake. The increase of backflow frequency and volume altered the exchange of suspended sediments and nutrients between Poyang Lake and the Yangtze River, which further affected ecological processes. Cui (2009) estimated the spatiotemporal effects of backflow on the water clarity in Poyang Lake by satellite images. As the river water contains a higher concentration of sediment, the increase of backflow would result in decline of water clarity in the northern and central lake. The changing lake-river interaction has a vitally important influence on water regimes in Poyang Lake, as well as the hydro-environment.

Further studies on changes of the wet-dry characteristics indicated that channel erosion may have a substantial influence on vegetation and ecosystems. An extension of the dry period would affect vegetation growth since water is a critical factor for vegetation growth. Moreover, as the water demand for growth varies for different vegetation, changes in the growth environment may also alter the competitive advantage of different species, causing related ecological and environmental problems. Wu (2017) found that the early arrival of dry period caused the expanding of Phalaris to mudflat zone in Poyang Lake after 2000. Longer duration and lower water levels of the dry period resulted in sharp decrease of lake grass land and increase of woodland and reed (Yang et al., 2016). Additionally, long dry periods are not beneficial to water self-purification, and increases the risk of water pollution. Ni (2015) examined the effects of hydrological conditions on organic phosphorus and found that the prolonged dry period

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68656886

caused a longer exposed time of sediments and resulted in a higher concentration of organic phosphorus. Therefore, variations in hydrological and hydrodynamic processes induced by topography changes deserve attention for maintaining reasonable conditions for the hydro-environment.

Conclusions

This study assessed the spatiotemporal impacts induced by topography changes, specifically channel erosion, on hydrological and hydrodynamic characteristics in China's largest freshwater lake, Poyang Lake. A hydrodynamic model was used to simulate hydrodynamic processes under different erosion intensities. The spatiotemporal impacts of channel erosion on water levels, water distribution, lake-river interactions, and wet-dry characteristics were assessed. The results show that channel erosion induced variations in hydrological and hydrodynamic characteristics in Poyang Lake with spatiotemporal heterogeneity. The channel erosion caused lower water levels in the lake, and the reduction in water level was enhanced due to stronger erosion intensity. The decrease in water level was significant during the dry period, whereas it was negligible during the wet period. The topographical changes affected water levels the most in the northern channel with an average water level decrease of 0.9-1.1 m during the dry period. Water levels in the central and eastern part of the lake decreased by an average of 0.27 m and 0.20 m, respectively, during the rising water and receding water period. In contrast, the water level decreased an average of $\leq$ 0.1 m in the southern lake. Moreover, the water surface slope changed and further influenced the distribution of water by gathering water to the channel from nearby floodplain areas. Furthermore, the topographic changes affected the exchange of water between Poyang Lake and the Yangtze River, as well as interactions between Poyang Lake and inflow tributaries. During the dry period, the channel conveyance capacity increased by 25-136%, resulting in a larger outflow discharge into the Yangtze River. In contrast, during the wet period, the regulation capacity increased the pondage volume of inflows by 3.8-8.2 $\times$ 10^8 m^3, decreasing outflow discharges. In particular, the backflow frequency and volume from the Yangtze River to Poyang Lake increased after channel erosion during the flooding period of the Yangtze River. Additionally, the hydrological and hydrodynamic changes increased the duration of the dry period of Poyang Lake and significantly increased the frequency of the low water regime events. The decreased minimum water level in the lake indicated that Poyang Lake faced more serious drought conditions after channel erosion.

Results in this study indicate that topographic changes have substantial impacts on flow patterns and material transportation in shallow waters such as Poyang Lake. Hydrological and hydrodynamic changes, resulting in water shortage and ecological problems in shallow water, are not only associated with inflow water regime and outflow conditions, but also significantly influenced by topographic changes. Bathymetry monitoring would provide fundamental data for assessment of topographic variations caused by natural factors and human activities, which supports further studies on the hydrological and environmental impacts induced by topography changes. Extensive sand mining is a critical cause of channel erosion in Poyang Lake. The lower water level and extended dry period, in turn, aggravates scour of the channel bottom. Thus, supervision of human activities such as sand dredging in the lake is necessary. The numerical simulation method provided in this study to analyze hydrological and

DOI: http://dx.doi.org/10.15666/aeer/1703_68656886

hydrodynamic changes can be extended to other rivers or lake basins, where significant topographic changes such as erosion and deposition occur. Further study should investigate the impacts of topography changes on water quality and eco-hydrological environment, coupling the water quality models and ecological models. Reproduction and prediction with numeric models can inform quantitative assessment of the impacts of topography deformation, supporting analysis of water resource and management decisions of the watershed.

(Received 15th Feb 2019; accepted 8th Apr 2019)

Abstract. This report describes the 233 pesticide residue in cucumber and grapefruit sold in Turkey. In total, 680 fruit and vegetable samples were analyzed by liquid chromatography connected to tandem mass spectrometry (LC-MS / MS) with the device in which gas chromatography to mass spectrometry (GC-MS) units work together. In cucember, limit of detection (LOD) varied from 0.17 μg kg^{-1} to 11.8 μg kg^{-1} and the limit of quantifications (LOQ) varied from 0.42 μg kg^{-1} to 39.35 μg kg^{-1}; whereas for grapefruit, LOD, and LOQ values varied from 0.13 μg kg^{-1} to 11.80 μg kg^{-1}, 0.42 μg kg^{-1}, and 39.35 μg kg^{-1}, respectively. Recoveries obtained for each pesticide in both matrices ranged between 77.87% and 104.15%. Relative standard deviation (RSD) values calculated were > 20% (24.32%) for clofentazine in cucember at 20.0 mg kg^{-1} and (21.36%) for propyzamide, (29.11%) for fludioxonil grapefruit at 100 μg kg^{-1}. For the other compounds, at both concentration levels evaluated in cucumber and grapefruit, the RSD values were < 20%. The extended measurement uncertainty for individual pesticides ranged from 0.208 to 0.434. In general, 11.6% of cucumbers and 13.8% of grapefruits contained at least one detectable residue, but levels were below the EU legal limits.
Keywords: *QuEChERS, GS-MS, LC-MS / MS, pesticide, grapefruit, cucumber*

Introduction

Pesticide is used in all kinds of chemical substances and preparations used in agricultural researches and applications. The pesticide may be a chemical agent, a biological agent such as a virus or a bacterium, an antimicrobial, a disinfectant or any other vehicle. Although the use of pesticides may have some benefits, it can cause problems for humans and other living things due to their potential toxicity. Such as pesticides, some of which include biopreparations, insect and plant growth regulators, pheromones (hormone-bearing) and other attractants, feed-blockers, repellents (insect repellents), traps, plant activators, preparations used in the treatment of physiological diseases (Epstein and Zhang, 2014).

Turkey is the 4th largest fresh fruit and vegetable producers in the world. As of 2015, about 37% of the total production of the citrus group consisting of lemon, orange, mandarin and grapefruit (3.7 million tons) and cucumber (100 thousand tons) accounted for approximately 2.8% of exports. Almost all of the total value of exported fresh fruits and vegetables has entered the EU, Russian Federation, Ukraine and Iraqi markets (TUIK, 2015; FAO, 2015).

In food, the permissible residual limit values are as low as in parts per million (ppm) and in parts per billion (ppb). Therefore, it is accepted that the most effective approach in pesticide residue analysis is multiresidue analyzes. In recent years, many different methods have been successfully used in the detection of pesticide residues in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68876916

foods, especially fruits and vegetables. In order to use these methods gas chromatography (GC), liquid chromatography (LC), coupled to mass selective detectors (MS), many new sample preparation techniques and extraction methods have been developed. Many sample preparation techniques for the detection of many pesticides used in vegetables and fruits, including solid-phase extraction (SPE) (Campone et al., 2018; Chan et al., 2018), solid-phase microextraction (SPME) (Li et al., 2019; Dong et al., 2019), accelerated solvent extraction (ASE) (Su et al., 2018; Stachniuk, 2018), supercritical fluid extraction (SFE) (Alvarez et al., 2019; Khan et al., 2018), matrix solid-phase dispersion (MSPD) (Liu et al., 2018; Jiang et al., 2018), microwave-assisted extraction (MAE) (Du et al., 2018; Wang et al., 2018), membrane extraction (Salemi et al., 2019), gel permeation chromatography (GPC) (Zhu et al., 2019), and QuEChERS (quick, easy, cheap, effective, rugged and safe) method (Tankiewicz, 2019), have been used. Within these techniques, QuEChERS has become more preferred in recent years, because it reduces the use of solvents in accordance with the 'green chemistry' principles, and provides a simple, inexpensive, fast and reliable result.

In this study, 205 pesticides of different classes, which are suitable for LC-MS/MS analysis, and 28 pesticides for GC-MS analysis, were discussed. In our country, pesticide use is still indispensable within the framework of integrated pest management principles. Selected pesticides, widely used in the production stages of fruits and vegetables in Turkey. Some of the selected pesticides may cause acute and chronic diseases due to their toxicity (Kumar et al., 2018).

In Turkey, along with concepts such as food security, have been a lot of studies in a very food production due to the increased use of pesticides. For example, tomatoes (Cengiz et al., 2018), baby foods (Kilic et al., 2018), oranges (Golge and Kabak, 2015), fish products (Polat et al., 2018), apricots (Ersoy et al., 2018), olive oil (Razzaghi et al., 2018) and milk (Yıldırım et al., 2018). However, there are very little data about the presence and levels of pesticide residues in cucumber and grapefruit consumed in Turkey.

This report aims to determine multi-residue pesticides in cucumber and grapefruits consumed in Turkey, monitor the compliance of the fruit and vegetables with the legal limits for target pesticide residues. In this context, the validated analytical method based on gas chromatography to mass spectrometry (GS-MS) and liquid hromatography coupled with tandem mass spectrometry (LC-MS/MS) was applied to 680 samples for a total of 233 pesticides for the periods 2015–2017.

Material and Metod

Sample collection

A total of 680 fruit and vegetable samples, including 330 cucumber and grapefruits 350 samples, were obtained from three provinces of Turkey, namely Hatay, İskenderun, Adana, Mersin and Antalya. Approximately 2 kg of cucumber and grapefruit samples were suplied from bazaar, supermarkets (2015–2017). The vegetables were transported quickly to the laboratory, chopped and homogenised with a home food processor (Robot Coupe model R10, Turkey). The chopped samples were then stored at −18°C until sample preparation step.

DOI: http://dx.doi.org/10.15666/aeer/1703_68876916

Reagents and chemicals

Standards of pesticides detected in GC-MS were supplied from ChemService (West Chester, PA, USA) and Standards of pesticides detected in LC-MS/MS from Sigma – Aldrich (St. Louis, MO, USA). All standards were of ≥98% purity. Stock solution of multistandard mixture at a concentration of 10 mg L^{-1} for each substance was dissolved in acetonitrile and kept at −18°C in the dark. This solution was used for preparation of matrix-matched calibration standards at concentrations varying from 0.1 to 100 μg kg^{-1} and for spiking the QuEChERS extracts in validation study.

Acetone, acetonitrile and methanol (GS-MS and LC-MS/MS grade), Isooctane, cyclohexane, ethyl acetate, magnesium sulphate, sodium acetat, glacial acetic acid, formic acid and ammonium formate (purity ≥99.9%) were supplied from Sigma – Aldrich (Stenheim, Germany). Helium (purity ≥99.9%) was supplied by Praxair (Colima, Mexico). Ultrapure water of 18.2 MΩ was purchased using a Milli Q water purification system (Milford, MA, USA). The primary-secondary amine (PSA) was supplied from Supelco (Darmstadt, Germany).

Sample preparation

Pesticide residues were extracted from cucumber and grapefruit samples using QuEChERS protocol according to AOAC official method (AOAC, 2007) with some changes. Cucumber representing high water content product groups, grapefruit with high acid and high water content groups were selected as samples for this study. These vegetable and fruit were selected because of their economic importance in export. Fifteen grams of homogenised sample was placed in to a 50 mL polypropylene tube, then 15 mL methanol-acetic acid (99:1, v/v), 6 g $MgSO_4$ and 1.5 g sodium acetate were added. The mixture was shaken vigorously by vortex mixer (Vortex Jr. Mixer from American Scientific Products, catalog no. S82251-1) for 1 min and centrifuged (Eppendorf 022628225 5804R Centrifuge with A-2-DWP-Plate, Germany) for 2 min at 2000 rpm. Later, 8 mL of the upper methanol phase was added in a 15 mL polypropylene tube containing 900 mg of MgSO4 and 150 mg of PSA. The mixture was vortexed for 1 min, followed by centrifugation for 2 min at 2000 rpm. For each sample, 200 μL was injected into GS-MS and LC-MS / MS.

For GC-MS, 0.010, 0.025, 0.05, 0.1, 0.2, 0.5 and 1 ppm prepared standards were given to the device and the corresponding area and retention time were determined. Calibration curve is obtained by plotting the area graph against concentration. For LC-MS/MS, 0.005, 0.010, 0.020, 0.040, 0.080 and 0.160 ppm prepared standards were delivered to the device and the area corresponding to these concentrations and retention time were determined. The fortificated samples were released to equilibrate for 80 minutes before treatment. Blank samples were also prepared according this procedure.

GC-MS conditions

Analyses were carried out with a Agilent GC-MS, 5975C inert MSD Series gas chromatograph equipped with an MS detector. The system was equipped with capillary column (Rtx-440 GC). Oven start temperature was set at 110ºC, increased to 250ºC at a rate of 35ºC/min, increased again at a rate of 40ºC/min to 280ºC, this temperature was kept for 3 minutes. The total run time was 5.5 minutes. One mL of sample was injected in split mode (2:1). The injector temperature was set at 250ºC.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68876916

The helium carrier gas flow was 1.1 mL/min. The mass spectrometer was operated in electron impact ionization mode at 70 eV of collision energy with 2 minute solvent delay to prevent damage to the filament of the ion source. The temperature of the ion source, manifold, and transfer line was set at 250˚C, 40˚C, and 280˚C, respectively. For qualitative analysis a full scan from 75 mass/charge (m/z) to 280 mass/charge (m/z) was applied. For quantitative pesticide analysis preferred ion monitoring (SIM) mode was used.

LC-MSMS conditions

Analyses were carried out with a ThermoQuest Surveyor MS Pump and autosampler. Chromatographic separation was carried out on a Waters C18 analytical column Phenomenex LUNA 5 µm C18 150 x 2 mm from Phenomenex (Torrance, CA, USA). The system was controlled by Xcalibur Home Page, Version 1.2 software. The column temperature was set at 40°C. The solvent systems used were (A) 0.1% acetic acid and 10 mM ammonium acetate in waterand (B) 0.1% acetic acid and 10 mM ammonium acetate in 95:5 CH3CN:Water. A flow rate of 200 uL min^{-1} and an injection volume of 10 µL were applied.

The MS was operated using a Negative Ion Electrospray – with metal needle option. The metal needle was connected with a zero dead volume union to the fused silica capillary delivering the mobile phase to the ESI source. Device parameters optimized for MS are as follows. Precursor ion (m/z): 321, product ions (m/z): 257, 194, 176, 152, spray voltage: 1.5 kV, collision voltage: 26 V, source offset voltage: 5 V, electron multiplier voltage: 1.27 kV, capillary temperature: 350 C, N_2 sheath gas: 80 arbitrary units, N2 auxiliary gas: 35 psi, collision gas: Ar.

Method validation

The proposed method was validated following the European SANTE/11945/2015 Guideline (European Commission, 2015). The established GC-MS and LCMS-MS method were validated in terms of its linearity, limit of detection (LOD), limit of quantification (LOQ), selectivity and recovery. Linearity was evaluated by constructing calibration curves with standard solutions.

Limit of detection (LOD), limit of quantification (LOQ)

For detection limit of detection (LOD) and limit of quantification (LOQ) operation; In GC-MS, 20µg kg^{-1} kg and LC-MS/MS 10 µg kg^{-1} recovery was performed. 205 pesticides were injected 10 times with the LC-MS/MS device and 28 pesticide GC-MS devices. The LOD values and LOQ values were calculated according to the following formula: LOD = 3s, LOQ = 10s, s: Standard deviation.

Linear measurement range

In order to determine the linear measurement range; Standards for 10 different concentrations (5, 10, 20, 40, 80,160 µg kg^{-1}) for LC-MS / MS, 7 different concentrations for GC-MS (10, 25, 50, 100, 200, 500, 1000 µg kg^{-1}) prepared, injected into devices and calibration graphs are drawn.

DOI: http://dx.doi.org/10.15666/aeer/1703_68876916

Precision

Repeatability

For repeatability study; A total of 40 recovery studies were performed by 4 analysts for GC-MS at a concentration of 20 µg kg^{-1} and 100 µg kg^{-1}, for LC-MS/MS at concentrations of 10 µg kg^{-1} and 100 µg kg^{-1}, each with 5 replicates.

For repeatability control, RSD% values were calculated for each person and for each concentration separately. For each individual and for each concentration, the RSD values were calculated from the mean ($\bar{x}$) and standard deviation (s) of the measured concentrations, separately. Then the RSD_{pool} values were calculated and the repeatability control was performed: RSD= $\frac{s}{\bar{x}}$.

Reproducibility

Intra-laboratory reproducibility study; 20 µg kg^{-1} and 100 µg kg^{-1} for GC-MS, LC-MS/ MS at concentrations of 10 µg kg^{-1} and 100 µg kg^{-1}, by 4 analysts for each at five different times, recovery work, was carried out. For each concentration, RSD_{WR} values were calculated and reproducibility checked.

Accuracy

Reality study for accuracy was done with recovery. For the reality parameter; A total of 40 recovery studies were carried out by 4 analysts at concentrations of 20 µg kg^{-1} and 100 µg kg^{-1} for GC-MS 10 µg kg^{-1} and 100 µg kg^{-1} for LC-MS/MS each. For reality control, all recovery values must be in the range of 70-120%.

Percentage recovery (%R) values were calculated for each individual, each concentration and each repetition. %R = $\frac{(C2-C1)}{C3}.100$, C1: Measured sample concentration (blank), C2: Measured, spike made sample concentration (blank+spike), C3: Spike made concentration.

Uncertainty assessment

The standard uncertainty (ux) from reality is equal to the standard deviation ($S_{\bar{x}}$) of the mean, if the unit average recovery value ($\bar{R}$) is not significantly different from 1. t test değer was applied to determine if the unit mean recovery value was significantly different from 1.

- If $t < t_{table}$, then the reality standard uncertainty (ux) is equal to the, mean deviation ($S_{\bar{x}}$) of the mean.
- If $t \geq t_{table}$, the elevated standard uncertainty (ui) value should be calculated.

$$ui = \sqrt{([|1 - \bar{R}|/k])^2 + (u_x)^2} \quad \text{(Eq.1)}$$

where
k: Scope factor (k = 2, for 95% confidence interval)
$\bar{R}$: Unit average recovery value.

$$\bar{R} = \frac{\%\ \bar{R}}{100} \quad \text{(Eq.2)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68876916

$$S_{\bar{x}} = \frac{s}{\sqrt{n}} \quad \text{(Eq.3)}$$

$$t = \frac{|1 - \bar{R}|}{S_{\bar{x}}} \quad \text{(Eq.4)}$$

where
$S_{\bar{x}}$: Standard deviation of mean
s: Standard deviation
n: Total concentrations and total number of repetitions for all contacts.

In cucumber and grapefruit, the standard uncertainty from reality and the relative standard uncertainty were calculated using the *Equations 1, 2, 3 and 4*.

$$RSD_{pool} = \sqrt{\frac{(n_1-1)xRSD_1^2 + (n_2-1)xRSD_2^2 + \cdots + (n_n-1)xRSD_n^2}{(n_1-1)+(n_2-1)+\cdots+(n_n-1)}} \quad \text{(Eq.5)}$$

In cucumber and grapefruit, relative standard uncertainty from repeatability was calculated using *Equation 5*.

$$RSD_{WR(pool)} = \sqrt{\frac{(n_1-1)xRSD_{WR1}^2 + (n_2-1)xRSD_{WR2}^2}{(n_1-1)+(n_2-1)}} \quad \text{(Eq.6)}$$

In cucumber and grapefruit, standard uncertainty from reproducibility was calculated using *Equation 6*. Relative standard uncertainty values are used in the total combined uncertainty calculation; however, since the relative standard deviation values are already used in the reproducibility calculations as in the reproducibility uncertainty calculations, the calculated standard uncertainty value is also equal to the relative standard uncertainty value.

Results and discussion

Method validation and application

Selectivity was evaluated by checking the presence of coextracted interferences in the chromatograms from blank samples. Hence, chromatograms of blank and fortificated (100 µg/kg) samples of cucumber and grapefruit were compared (*Figure 1*). The presence of matrix interferences were interpreted by monitoring the SIM chromatograms for each pesticide at the retention time window expected for each compound. It can be observed that there are no extracted matrix interferences for the determination of the pesticides studied in both fruits; therefore this method can be considered as selective.

The matrix compatible standard calibration curves showed smooth linearity over a concentration range of 20- 100 µg kg^{-1}. As shown in *Figure 2*, correlation coefficients were > 0.98. The values of Limits of detection (LOD) ranged from 0.17 to 11.8 µg kg^{-1} and Limits of quantification (LOQ) ranged from 0.42 to 39.35 µg kg^{-1} in cucumber, whereas for grapefruit, LOD, and LOQ values varied from 0.13 µg kg^{-1} to 11.80 µg kg^{-1}, 0.42 µg kg^{-1}, and 39.47 µg kg^{-1}, respectively.

The baseline (basal signal) in blank samples at the time window in which each pesticide is expected is different due to the quantification being made using different

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68876916

ions. Therefore, the LOD and LOQ calculation are different for each compound. With these results it can be concluded that the method has good sensibility for cucumber and grapefruit fruits because LOD and LOQ values of all pesticides are <0.50 mg / kg. The LOQ were well below the maximum residue levels (MRL) established by European Union for regulated pesticide residues both in cucumber and grapefruit, except for methylparathion, malathion and diazinon.

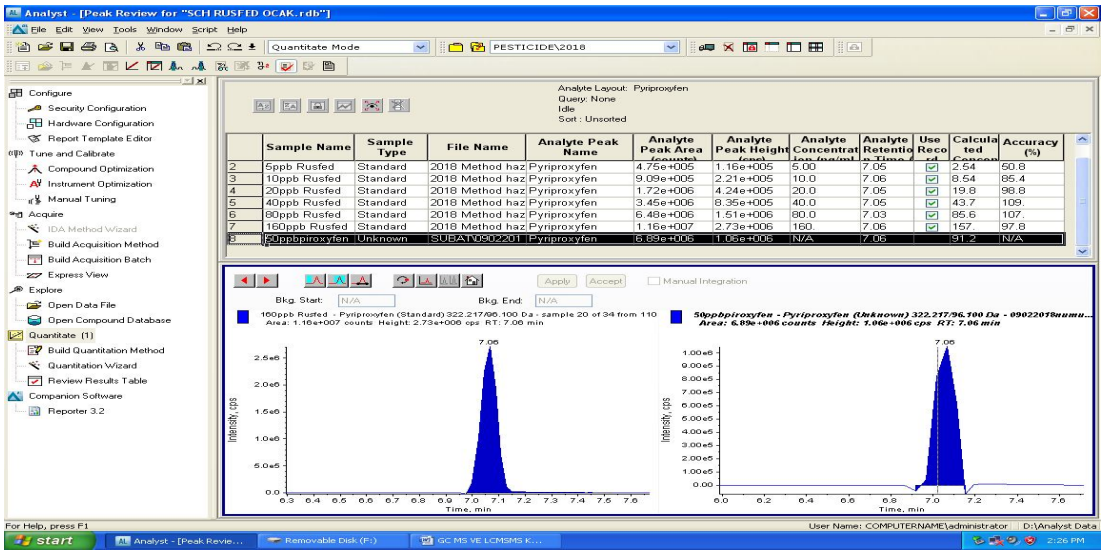

Figure 1. *Chromatograms (SIM mode) obtained for pyrproxyfen injection of blank and fortified samples of cucumber and grapefruit for checking matrix interferences. Pesticide concentration was 100µg/L*

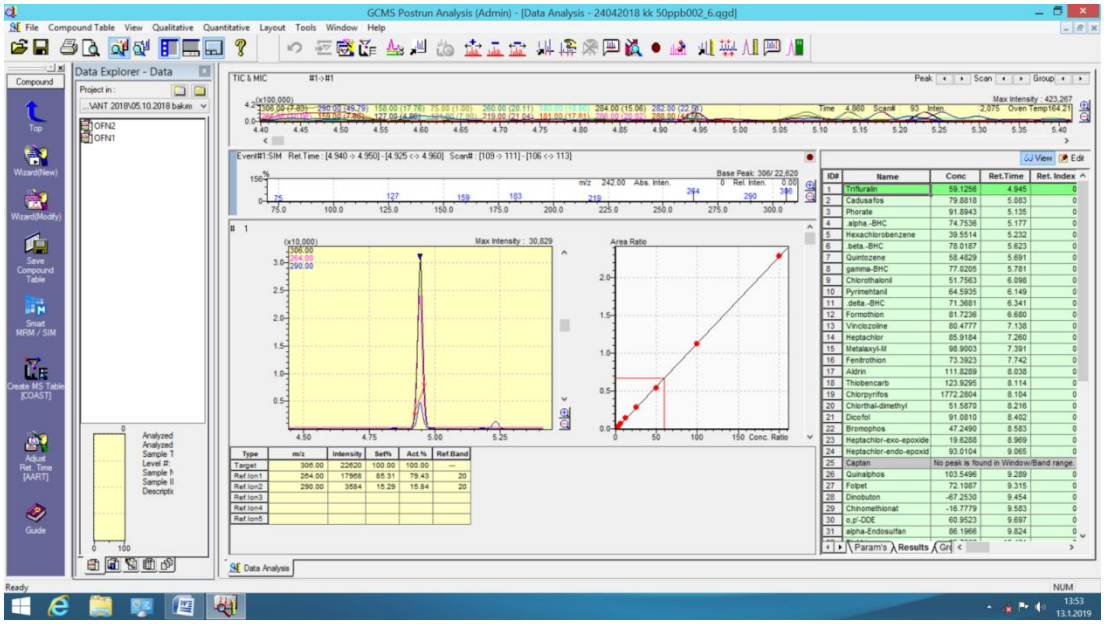

Figure 2. *Chromatograms (SIM mode) obtained for trifluralin injection of blank and fortified samples of cucumber and grapefruit for checking matrix interferences. Pesticide concentration was 100µg/L*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68876916

The recovery values correspond to the lowest and highest concentration of the linear range. The recovery results are as shown in *Table 1*. Recoveries obtained for each pesticide in both matrices ranged between 77.87% and 104.15%. Thus, the recovery data is in the range of values required by the SANTE Guidelines, which recommends a recovery rate of 70-120% (European Commission, 2015).

Precision was expressed as relative standard deviation (RSD) and evaluated in different days (see *Table 1*). For this purpose, 20 μg kg^{-1} and 100 μg kg^{-1} for GC-MS, LC-MS / MS at concentrations of 10 μg kg^{-1} and 100 μg kg^{-1}, by four analysts for each at five different times, recovery work, was carried out. Relative standard deviation (RSD) values calculated were > 20% (24.32%) for clofentazine in cucumber at 20.0 mg kg^{-1} and (21.36%) for propyzamide, (29.11%) for fludioxonil grapefruit at 100 μg kg^{-1}. For the other compounds, at both concentration levels evaluated in cucumber and grapefruit, the RSD values were < 20%. The RSD values obtained are considered satisfactory according to the European SANTE Guideline (European Commission, 2015).

Pesticide analysis in commercial fruit and vegetable samples

The validated analytical method was used to analyse 233 pesticide residues in cucumber and grapefruit samples collected from bazaar, supermarkets in four provinces of Turkey. In our monitoring program, a total of 680 vegetable samples, including 75 cucumbers and 110 grapefruits in 2015, 90 cucumbers and 120 grapefruits in 2016, and 165 cucumbers and 120 grapefruits in 2017, were analysed. Of the 680 fruit and vegetable samples, 11.6% (35 samples) of cucumbers and 13.8% (39 samples) of grapefruits contained at least one detectable residue, but levels were below the EU MRL. There were 1 acaricide, 3 insecticides and 5 fungicides in cucumbers, while 4 insecticides and 4 fungicides were detected in grapefruit samples.

While 27 cucumber samples gave positive results, multiple pesticide residues were found in 8 samples, corresponding to 2.4% of the total samples. Clofentezine was the most frequently detected pesticide measured in cucember with a percentage occurrence value of 4.4%, and in concentrations ranging from 0.021 to 0.042 mg kg^{-1}. This insecticide is an acaricide used in various products (fruit crops, leafy vegetables, some fruiting vegetables, citrus fruits, pome fruits, grapes, cotton etc.) against red spider species. Acaricides in this group are contact effective. They also have a gastric venom effect (European Commission, 2008; Van Leeuwen et al., 2010).

The fungicide propyzamide was the second most abundant pesticide (199 out of 330 samples) in cucumbers, with levels ranging from 0.002 to 0.009 mg kg^{-1}. Propyzamide, effectively controls a wide range of herbicides in several agricultural crops, including hard-shelled fruits, in grape fruits, and tree nuts. It has a chronic toxic effect (European Commission, 2008; Tian et al., 2018).

The fungicide propamocarb was the third most abundant pesticide (230 out of 330 samples) in cucumbers, with levels ranging from 0.022 to 0.032 mg kg^{-1}. Propamocarb, which belongs to the class of carbamate, is used in cucumber against mildew. Does not have toxic effects (FAO, 2012; Bhat et al., 2018).

Azinphosethyl was detected individually in 6 cucumber samples (1.8%) in concentrations between 0.013 and 0.016 mg kg^{-1}. It has a protective and therapeutic properties. Alternaria, Botrytis, Pythium, Rhizoctonia, Venturia and many other diseases are widely used as a fungicide. It has no acute and chronic effects (Polyiem et al., 2018).

LOD: limit of detection (µg/kg); LOQ: limit of quantification (µg/kg)
Calculated at 20 µg/kg and 100 µg/kg in fortificated cucumber matrix
Calculated at 10 µg/kg and 100 µg/kg in fortificated grapefruit matrix

The fungicides metalxyl and procymidone were found in 4 cucumber samples at levels varying from 0.011 to 0.039 mg kg^{-1} and from 0.014 to 0.033 mg kg^{-1}, respectively. The insecticide chlorpyrifos was detectable only in 1 cucumber samples, with a mean concentration of 0.037 mg kg^{-1}. Similarly, two cucumber samples were found to contain iprodione, Carbendazim, which is an authorised neonicotinoid insecticide. The concentrations of iprodione, carbendazim in positive samples were from 0.022 to 0.029 mg kg^{-1} and from 0.014 to 0.032 mg kg^{-1}, respectively.

The results show that grapefruits had slightly higher frequencies (13.8%) of pesticide residues than cucumber samples (11.6%), but the number of residues was less. Of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_68876916

233 target analytes monitored, only 9 pesticide residues were found in grapefruits at concentrations varying from 0.002 to 0.042 mg kg^{-1}; none above the MRL. Multiple residues in grapefruits were found in 3.5% of the samples. While 15 grapefruit samples contained two residues of pesticides, only 2 samples were contaminated with three pesticide residues.

The fungicide fludioxonil was the most prominent pesticide found in grapefruit samples, with a frequency of 9.1%, and with levels ranging from 0.019 to 0.041 mg kg^{-1}. Fludioxonil, which belongs to the class of phenylpyrrole, is used to control a broad spectrum of plant diseases in various vegetables. The acute toxicity of fludioxnil is low. Fludioxonil did not have carcinogenic potential (FAO, 2012).

Imazalil was the second most commonly found pesticide in grapefruits with 4.7% of the samples. The results obtained from the second and third year showed that 7 samples contained imazalil at levels varying from 0.017 to 0.102 mg kg^{-1}, and from 0.021 to 0.109 mg kg^{-1}, respectively. In the first year, 4 samples had this residue at concentrations ranging from 0.016 to 0.032 mg kg^{-1}.

Thiabendazol was detected in 7 samples at levels ranging from 0.014 to 0.081 mg kg^{-1}, of which 5 samples contained simultaneously the fungicide quinophos. Thiabendazol, belongs to the class of benzimidazole. It is a systemic fungicide used in citrus fruits such as orange, lemon and grapefruit against Penicillium digitatum.

The insecticide carbaryl was present in 4 grapefruit samples, with a mean concentration of 0.028 mg kg^{-1}. Carbaryl belongs to the class of carbamate. It is a pesticide and plant growth regulator used in citrus fruits such as orange, lemon, grapefruit.

Uncertainty assessment

The results of method uncertainty assessment considering six sources are presented in *Table 2*. For cucumber samples the overall contributions to U_c of the method of the uncertainties associated with U_1 (standard solution preparation), U_2 (calibration curve preparation), U_3 (sample preparation treatment), U_4 (precision), and U_5 (accuracy/bias) ranged from 5.3% to 10.6% and U_6 (linear least square fitting) ranged from 85.6% to 93.1%. In the same way, for grapefruit, the overall contributions of the uncertainties associated with U_1, U_2, U_3, U_4, and U_5 varied from 5.1% to 11.8% and U_6 ranged from 87.8% to 95.1%. In the light of these results, the uncertainty associated with u6 presents the highest contribution for all the pesticides under study in cucember and grapefruit.

As can be seen in *Table 2*, U_e values at 95% confidence level for cucember ranged from 12.3% to 18.7% and for grapefruit from 15.6% to 23.6%. U_e values of all pesticides detected in cucumber samples generally offer lower values than grapefruit. For all target analytes, the U_e was within the criteria specified in the SANTE Guideline (less than 50%). These results are similar to those reported for methods using GC-MS, LCMS-MS and the QuEChERS procedure. For example, Walorczyk (2014) reported U_e values ranging from 7.0% to 53.0% for samples of black currant, where the majority of pesticides had a uncertainty of <30.0%. In addition, da Silva Sousa et al. (2018) reported U_e values from 7.9% to 36.1% for melon samples. At first glance, the results of this method are high, but the uncertainty acceptance criteria according to the European SANTE / 11945/2015 guideline European Commission (2015) is the time when the value is 50.0%. Although it is recommended to use the internal standard to minimize uncertainties, the proposed method indicated that expanded uncertainties are not necessary.

Conclusions

In this paper, an analytical method for the separation of 233 pesticide in cucumber and grapefruits using QuEChERS method and GC-MS, LC-MS/MS is presented. The validation data showed satisfactory performance of analytical method, in terms of specificity, sensitivity, linearity, recovery, precision and U_e according to the European SANTE/11945/2015 Guideline. One or multiple pesticide residues were detected in 11.6% of cucumber and 13.8% of grapefruit samples, but the levels were below the EU MRLs. The residues found in cucumbers and grapefruits were belonging to the group of fungicides, insecticides, herbicide, acaricide and plant growth regulator. The most frequently detected residues in cucumber samples were Clofentezine (4.4%), propyzamide (3.96), propamocarb (3.03), Azinphosethyl (1.8) ,metalxyl, procymidone, chlorpyrifos and Carbendazim. However, the fungicide propamocarb (8.8%) was the most common residue in cucumbers, followed by propyzamide (6.3%) and Clofentezine (2%). The fungicide fludioxonil was the most prominent pesticide found in grapefruit samples, with a frequency of 9.1%. Imazalil was the second most commonly found pesticide in grapefruits with 4.7% of the samples, followed by Thiabendazol, quinophos and carbaryl. The proposed method was also found to be suitable for different kinds of fruits.

Abstract. The data of annual peak flows in river system is not straight forward but rather complex function of hydrology and geography of the area. In such composite situations, models based on soft computing approaches such Artificial Neural Network (ANN) may increase understanding of the hidden hydrological processes. The primary objective of this study is to determine the best approach among Traditional Artificial Neural Network (T-ANN) and Wavelet Artificial Neural Network (W-ANN) using Annual Peak flows data of Mangla site on River Jhelum, Pakistan. The results reveal the better performance of W-ANN approach under db2 scheme. Further, to justify the authenticity of W-ANN we compared it with the frequency analysis by fitting best probability distribution and non-parametric kernel density estimation (KDE) using Gaussian kernel approach for the same data. Results reveal that probability distribution modeling approach by fitting the Generalized Logistic (GLO) distribution being the most suitable model provides comparable results with W-ANN-db2 approach but outperforms than non-parametric KDE. Overall, the performance of W-ANN-db2 is better in the present study. The findings of the study are useful for better policy implications in water resources management.
Keywords: *flood frequency analysis, water resources management, probability models, kernel density estimation, non-parametric*

Introduction

We are living in the age where we have more awareness than ever about the environmental events around us, including the brittleness of ecosystems, the incompatible needs of human culture, and the complications of geologic records. Scientists are looking for, to create, upgrade, and revise the theories and mathematical models of the Earth's dynamics at an unprecedented rate. Rather than traditional modeling techniques, the Artificial Neural Network (ANN) methodology has the prospective aspects to see the problems in a simpler and more modular form. For sustainable development of the societies it is an urgent need to make predictions with more accuracy of different environmental events including floods, earthquakes, droughts, air pollution, wind gusts and others. Since last few years ANN are widely applied in different fields such as Image Processing, Signal Processing, power systems, medical studies, pattern recognition and hydrology among others (for example, see Rabuñal, 2005; Aziz et al., 2016; Jimeno-Sáez et al., 2017; Kumar et al., 2015; Rahman et al., 2018; Requena et al., 2018 among others). ANN modeling has the capability of learning from the data. They can be proved as time saving for development of the models and especially useful for nonlinear and complicated processes which cannot be modeled through traditional methods. Streamflow forecasting is a challenging task for

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69176935

water resources engineers and managers. Reliable forecasts of streamflows make an efficient operation of water resources systems within legal, political, technical and economical priorities. A forecasting system that considers all important spatial and temporal variation of the whole streamflow regime, delivers a good basis for appropriate control and management of the water resources system.

The principle parameters for flood forecasts are scale and frequency of events. Since the annual peak flows can be used to give flood forecasts. Statistical studies in view of probabilistic methods can be embraced to tell about the probability and frequency of peak flows that cause flooding. The principal parameters for flood forecasts in probabilistic approach are frequency and magnitude of events (for example see Ahmad et al., 2015; Rahman et al., 2013; Drissia et al., 2019; Cassalho et al., 2019; Mostofi et al., 2019). Mostly, the Hydrologic time series are autocorrelated. However annual precipitation and peak flows are generally uncorrelated (Salas et al., 1993). Rarely, substantial autocorrelation might be the result of trends as well as movements in the time series (Salas et al., 1988). There is lot of current literature which discusses about aspects related to flood occasions (Agarwal et al. 2005; Rahimi and Abbaspour, 2011; Guresen et al., 2011.) Peak flows in the stream or waterway is a composite capacity of hydrology of the area and land designs in a given stream basin or waterway being considered as are hard to evaluate precisely. Generally the models which use streamflow data along with many other hydrologic and climatic factors for example precipitation, temperature, and snow water in a completely statistical or stochastic manners are black-box type models (see for example Hipel and MeLeod, 1994).

In the current study, we have applied ANN and W-ANN models to only one variable that is peak flows of Mangla site and compared the results of W-ANN (being the better one) with probability distribution modeling approach and Non-Parametric KDE approach. ANN moeling for peak flows has been performed in some studies (see for example Harinarayan et al., 2015).

Materials and methods

Study area and data collection

The annual peak flows data of Mangla site situated at River Jhelam, Pakistan is being retrieved from Water and Power Development Authority (WAPDA) and Federal Flood Commission of Pakistan. The data used in this study (annual peak flows) have been recorded during monsoon season in Pakistan (from July to September). Monsoon is the peak season of rainfalls and peak flows in Pakistan. The river system of Pakistan begins from the snow-covered Himalayan and the Karakoram series. There are mainly five rivers mostly located in the province of Punjab. These rivers are Sutlej, Ravi, Jhelum, Indus and Chenab. River Jhelum originates from south eastern part of Kashmir and its width is approximately 774 km and it meets with Chenab River at Trimmu. Jhelum also passes through Srinagar before entering Pakistan. Number of barrages and dams have been constructed on River Jhelum. One of them is Mangla dam constructed in 1967. It has a stowage dimensions of approximately 5.9 million acre-feet.

Artificial neural network (ANN)

ANN approach is based on function of the human brain and nervous system. ANNs trace the associations between two types of factors, i.e. inputs and outputs of a task by

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69176935

interlinks of nodes that activate and operate through connecting weights using different functions called "training samples", and in the result we can determine the procedures and relationship between the inputs and outputs. The processing of every neuron is performed in dual steps, in first step, the weighted summation of the inputs is brought and in second they are trailed by the importance of activation function (Bishop, 1995).

Artificial Neural Network are commonly applied by using electrical mechanisms or by imitation on a computer system. They are categorized by the designs of networks amongst the nodes (named as architecture), the procedures of defining weights on the networks (called their learning procedure), the activation function, and the number of layers (single layer, bilayer, and multilayer). When overall signals of a network move in only one direction, the ANN is known as Feed-Forward Network (FFN), otherwise they are known as Recurrent Networks. Generally, the artificial neural networks used in hydrological models are Feed-Forward Multilayer Perceptron's (FFMLPs), which include three layers, and employ monotonic activation functions in all layers. Their weights are generally found by organized training using back-propagation process. The performance and learning capability of artificial neural network depend upon the fitness of its architecture which is needed to be pre-specified more precisely, the number and configuration of its hidden nodes see for example (Hertz, 2018; Denis, 2009).

Composite non-linear problems such as time series data prediction can be solved through ANN being non-linear mathematical model. Multilayer Perceptron (MLP) is the type of Artificial Neural Network which is used to adjust the connection weights. MLP comprises three layers: input layer; hidden layer; and output layer. MLP has only one input and output layer but more than one hidden layer. Each of these layers comprises nodes. These nodes are associated to each other. Input layer can contain that number of nodes while output layer, must have only one node to get output. It is up to user selection how to use hidden layer. There must be an additional dummy neuron as bias node in input layer. Bias node acts as one of the players in the network. The activation function is used to calculate the arriving value and gives the value in output layer for the actual computational process occurrence. Input layer applies linear transfer function. However, a sigmoid function is normally used in hidden and output layer. Following the activation function, we can determine the connection weight by data training. The procedure for the adjustment of weight begins in the output layer and carries backward to the input layer. Until the performance of target is obtained the process of feed-forward and back propagation algorithm continues. The weights of the values are determined when the data training process is completed. Following this, a single feed forward computation is employed. Results are then assessed by conducting performance measures between actual and predicted values (for detail see for example Bishop, 1995; Singh et al., 2004).

This study used Levenberg Marquardt (LM) procedure to streamline the biases and weights in the system. LM procedure is more effective and quicker than the traditional gradient descent procedure (Huang et al., 2015; Kisi and Shiri, 2011). *Figure 1* shows the Multilayer Perceptron with three layers as stated before.

The *Figure 1* shows a three-layer feed forward ANN. The first layer, called the input layer, comprises I nodes and connected with the input variables. This layer performs no computation but is used to distribute I inputs into the network. The last layer is connected to the output variables, and called the output layer. This layer consists of K output nodes. One or more layers of processing units that have no direct relation to the outside variable and are located between the input and output layers are called hidden

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69176935

layers. An MLP may have many hidden layers. However, only one hidden layer is considered in *Figure 1*. This layer consists of J hidden nodes. In each layer, the processing elements are called nodes or neurons. Each of these neurons connected to all the neurons of adjoining layers. The parameters linked with these connections are known as weights. Information used by the network to solve a problem is represented by weights. Generally, all connections are 'feed forward' that allow information to transfer from an earlier layer to the next consecutive layer. The neurons in a layer are not interconnected, and neurons in non-adjoining layers are also not connected, however, for recurrent neural networks this is not the case (Zurada, 1992).

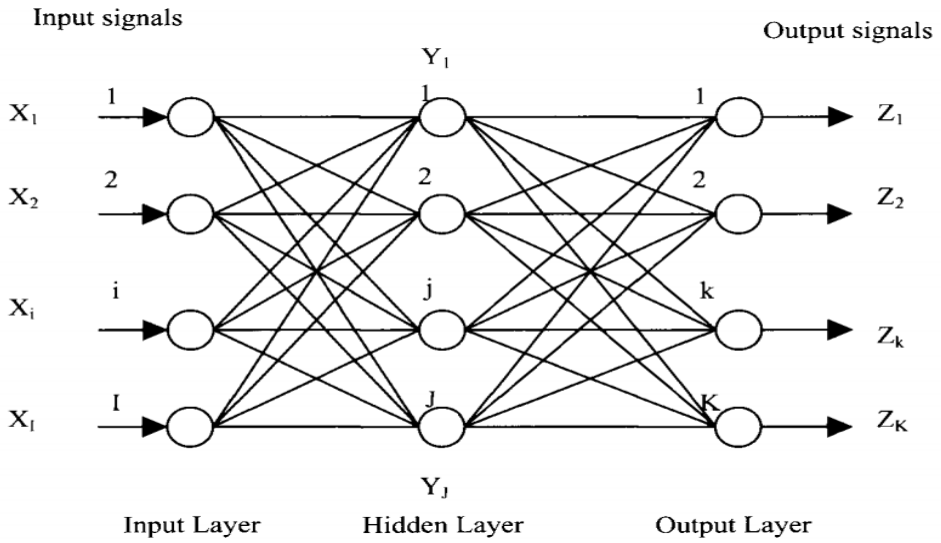

Figure 1. *Multilayer perceptron with three layers artificial neural network model*

The architecture of a typical neuron is shown in the *Figure 2*. Every hidden neuron *j* gets total I arriving signals (X_I, i.e. $X_1, X_2, \ldots X_i \ldots X_I$) from any neuron *i* in the preceding layer (for instance, from Input layer to hidden layer). Connected with every arriving signal (X_i), a weight (W_{ij}) is connected between layer i and j. The effective arriving signal (net_j) to neuron j is the sum of weights of all the arriving signals as follows in *Equation 1*:

$$net_j = \sum_{i=1}^{I} W_{ij} X_i \qquad \text{(Eq.1)}$$

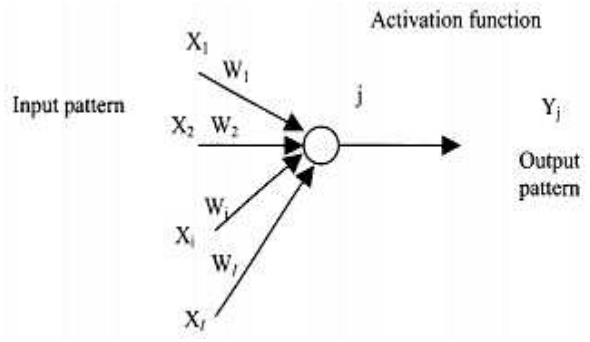

Figure 2. *The architecture of a typical neuron*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69176935

This effective arriving signal (net_j) passes over a non-linear activation function (also called a transfer function or threshold function) that produces the outgoing signal which is called activation or activity level (Y_j) of the neuron. Usually, a neuron sends its activation as a signal to several other neurons. It is pertinent to note that at one time only one signal can be sent by a neuron, though that signal is programmed to numerous other neurons simultaneously.

Delta learning rule for feed-forward multilayer perceptron

The delta learning rule is also called the LMS (Least Mean Square) error back propagation training algorithm. In the feed forward propagation training Input patterns are entered sequentially. If a pattern is entered and its classification or association comes out to be inaccurate, the value of LMS error is minimized through the adjustment of the synaptic weights as well as the thresholds. Therefore, the purpose of this algorithm is to adjust the synaptic weights w_{ij} (i = 1,… I) and w_{jk} {j = 1…. J), which connect input to hidden layer, and then hidden to output layer respectively. In the result, it will assure the minimization of the error function {E_k) given in *Equation 2*. The instantaneous estimate of the mean-square error calculated at the output layer is defined as follows (Derks, 1995; Mukerji, 2009):

$$E_k = \frac{1}{2}(z_k - t_k)^2 \quad \text{(Eq.2)}$$

where z_k the output from output layer and t_k is the target value. The outgoing signal (z_k) is a function of the activation as follows (*Eq. 3*):

$$z_k = (f(net_k) \quad \text{(Eq.3)}$$

The effective incoming signal net_k, comprising weighted sum signals from the hidden layer (y_j) and calculated as follows (*Eq. 4*):

$$net_k = \sum_{j=1}^{J} w_{jk} y_j \quad \text{(Eq.4)}$$

The outgoing signal (y_j) is the result of the incoming signal net_j, being passed through the activation function, which is not necessarily the same as that for z_k, is given as follows (*Eq. 5*):

$$y_j = f(net_j) \quad \text{(Eq.5)}$$

Again, the effective incoming signal net_j, comprising weighted sum signals from input layer (x_i) is calculated as *Equation 6:*

$$net_j = \sum_{i=1}^{I} w_{ij} x_i \quad \text{(Eq.6)}$$

The derivative of the error functions with respect to w_{jk}, can be expressed after applying the chain rule, as follows in *Equation 7:*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69176935

$$\frac{\partial E_k}{\partial w_{jk}} = \frac{\partial E_k}{\partial Z_k}\frac{\partial Z_k}{\partial net_k}\frac{\partial net_k}{\partial w_{jk}} \quad \text{(Eq.7)}$$

Finally, the updated weights are given in *Equation 8:*

$$w_{ij} = w_{ij} + \Delta w_{ij} \quad \text{(Eq.8)}$$

Activation function

Artificial neural network is a procedure to sum the product of the connected weights, the input signals, and produce an output or activation transfer function. The activation function is the specific function for the input units. The nodes of a specific layer get the equivalent type of activation function. Generally, in every case a non-linear activation transfer function is used. There are several activation transfer functions employed in ANNs, but in this study we will focus on unipolar binary function or sigmoid function (S).

The unipolar binary function or sigmoid function (S)

The sigmoid function, as implemented by Hall and Minns (1996) and Dawson and Wilby (2001) is defined as in *Equation 9:*

$$S(\text{net}_j) = \frac{1}{1 + \exp(-\lambda \text{net}_j)} \quad \text{(Eq.9)}$$

where $\lambda > 0$ in above sigmoid function. λ is in proportion to the nodes defining the steepness of the function, which in general is set equal to one. The term λnet_j, will lies between ($-\infty$ and $+\infty$), whereas S (net_j) will lies between (0 and 1).

Wavelet analysis

Two primary types of wavelet transforms are commonly used i.e. continuous wavelet transform (CWT) and Discrete Wavelet Transform (DWT). The CWT works with functions defined over the whole real axis while the DWT deals with functions defined over a range of integers. Wavelets are mathematical processes which represent a time-scale of the time series and their relationships to analyze time series when the data is non-stationary. Wavelet analysis is helpful in the long-time intervals where the frequency information's are low and also in the short time intervals where the frequency information is high.

Wavelet is a small wave function denoted by the notation $\psi(\cdot)$. The range of a wavelet mother function ($\psi(\cdot)$) lies between $-\infty$ and ∞, and it must fulfill the following given properties:

The value of the integral of $\psi(\cdot)$ is always equal to zero as shown in *Equation 10:*

$$\int_{-\infty}^{+\infty} \Psi(u)\,du = 0 \quad \text{(Eq.10)}$$

The integral of the square of $\psi(\cdot)$ is unity as in *Equation 11:*

$$\int_{-\infty}^{+\infty} \Psi^2(u)\,du = 1 \quad \text{(Eq.11)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69176935

Admissibility Condition of Ψ(f) is given in *Equation 12:*

$$C_\Psi(t) = \int_0^\infty \Psi^* \frac{[\Psi(f)]^2}{f} \, df \quad \text{satifies} \quad 0 < C_\Psi < \infty \tag{Eq.12}$$

Haar created a wavelet function in 1910 (*Fig. 3*), named Haar wavelet function (Ogden, 2012) and considered one of the oldest wavelet functions, given in *Equation 13:*

$$\Psi^{(H)}(u) = \begin{cases} +1 & \text{if} \quad 0 \le u < \frac{1}{2} \\ -1 & if \ \frac{1}{2} \le u < 1 \\ 0 & else \end{cases} \tag{Eq.13}$$

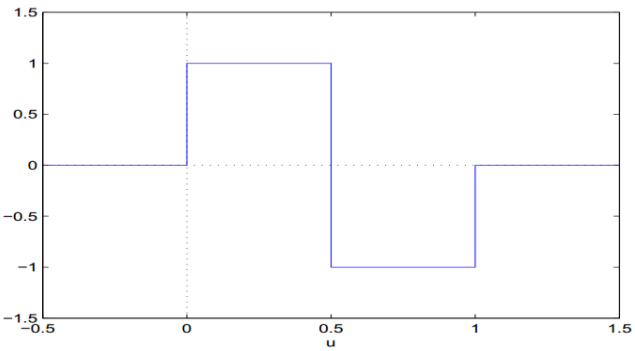

Figure 3. *The Haar wavelet function*

It is a discrete wavelet and looks like a step function. Harr wavelet and Daubechies (db) are the same. Daubechies family wavelets are written as dbN, where N stands for the order of Daubechies family. There is more flexibility in wavelet analysis due to which we can choose a specific Wavelet for matching the type of function under analysis.

The function ψ (·) is the mother wavelet and a double wavelet index family can be constructed by *Equation 14:*

$$\psi_{\lambda,t}(u) = \frac{1}{\sqrt{\lambda}} \psi \left(\frac{u-t}{\lambda} \right) \tag{Eq.14}$$

where λ > 0 and t is finite.

The standardization on the right-hand side of *Equation 14* is:

$$\| \psi_{\lambda,t} \| = \|\psi\| \text{ for all } \lambda, t.$$

Functions are considered linear combination where the information is secure and make no losses to those functions which are in discrete form or as an integral in the continuous form of the selected wavelet family.

Wavelet-ANN conjunction model for flood events prediction

The wavelet analysis is connected to the Artificial Neural Network approach for annual peak flows prediction in this research, also depicted in *Figure 4*. First of all, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69176935

observe annual peak flows time series, Q were decayed into several multi-frequencies time series including details (high frequency, low scale), such as, Q_{D1}(t); Q_{D2}(t); ……Q_{Di}(t), and approximate (high scale, low frequency) such as, Q_{Da}(t) by DWT. The symbol D_i shows the Wavelet-ANN Model for Flood prediction, level *i* decayed details time series and *a* denote approximation time series.

However, the decayed Q(t) time series were used as inputs to ANN model. The original data of time series in the next step, Q(t + 1) is output of the Wavelet-ANN conjunctional model. The graphical representation of above methodology is shown in *Figure 4.*

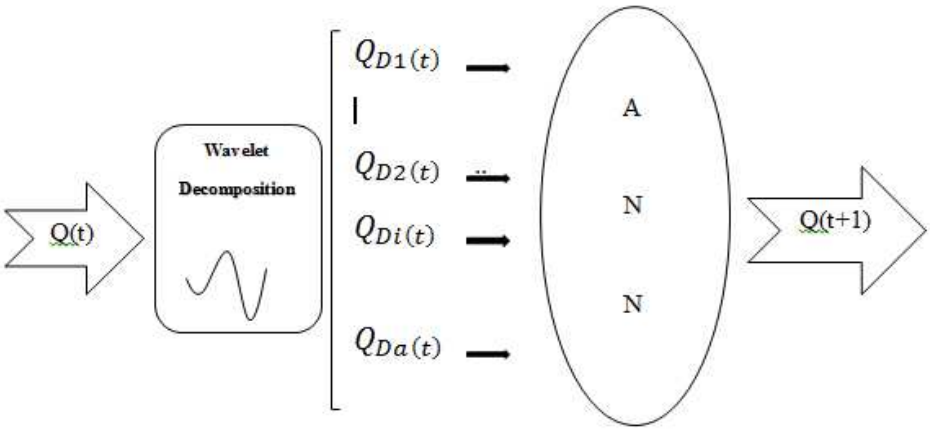

Figure 4. *Schematic diagram of wavelet-ANN conjunction model*

Criteria for the evaluation of a model

To evaluate the consistency of the models, it is compulsory to check the capabilities of ANN in both training and testing period (see for example Beven, 2011). Several statistical techniques are generally used for this purpose. Some of the evaluations measures are given below, which will be used in this study.

Pearson correlation coefficient (R)

Correlation coefficient (R) designates the direction of the linear association among two variables (i.e., model input and output values). The R coefficient is achieved by dividing the co-variance of the two random variables by the multiplication of their standard deviations. The R is given by the formula given in *Equation 15:*

$$R = \frac{\sum_{i=1}^{n}(Y_{mi}-\hat{Y}_{mi})(Y_{ci}-\hat{Y}_{ci})}{\sqrt{\sum_{i=1}^{n}(Y_{mi}-\hat{Y}_{mi})^2 \sum_{i=1}^{n}(Y_{ci}-\hat{Y}_{ci})^2}} \quad \text{(Eq.15)}$$

where Y_{mi} indicate the observed values and Y_{ci} indicate the model or predicted values of annual peak flows at particular site at time$i$., $\hat{Y}_{mi}$ and $\hat{Y}_{ci}$ are the average values of Y_{mi} and Y_{ci} respectively.

If the association is +1 then there is a perfect positive linear relationship between actual and estimated values while a value of -1 refers to perfect negative linear relationship between them. If R comes with 0 value, then it indicates no linear relationship between them.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69176935

Root mean square error (RMSE)

The positive square root of the mean/average of the square of all the errors. RMSE measures the spread/ variation of these residuals. RMSE is a commonly used measure to see the variances between the predicted values and estimated values with a range from 0 to ∞. When $Y_{mi} = Y_{ci}$, then RMSE = 0, which implies that the model is perfectly fitted. The smaller RMSE shows that the model is best fitted. The formula of RMSE is given by *Equation 16:*

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}\left(Y_{mi\_}Y_{ci}\right)^2} \quad \text{(Eq.16)}$$

Mean absolute error (MAE)

MAE calculates the average size of the errors, without caring about the direction of the error. It is average of absolute differences between predicted and estimated values. The minimum value of MAE indicates that the model is best fitted. The formula of MAE is shown as given in *Equation 17:*

$$MAE = \frac{1}{n}\sum_{j=1}^{n}|Y_{mi} - Y_{ci}| \quad \text{(Eq.17)}$$

Nash-Sutcliffe coefficient

To evaluate the prediction of a hydrological model this co-efficient is frequently used. It is proposed by Nash-Sutcliffe coefficient in 1970. The Nash-Sutcliffe coefficient E is defined by *Equation 18:*

$$E = 1 - \frac{\sum_{i=1}^{n}(Y_{mi} - Y_{ci})^2}{\sum_{i=1}^{n}(Y_{mi} - \bar{Y}_{mi})^2} \quad \text{(Eq.18)}$$

The range of E lies between -∞ and 1. A value of E = 1 indicates the perfect match among observed and predicted values while a value of 0 implies that the predictions of model are as correct as the average of the actual data. However the value of $-\infty < E < 0$ arises in case of week prediction. For more details see Grossmann (2010).

Index of agreement (IOA)

The term Index of Agreement established by Willmott (2012) as a standard quantity to evaluate the prediction error of a model and it lies between 0 and 1. The value of $IOA = 1$ shows an accurate prediction while of 0 shows no agreement at all. It is defined as in *Equation 19:*

$$IOA = 1 - \frac{\sum_{i=1}^{n}(Y_{mi} - Y_{ci})^2}{\sum_{i=1}^{n}\left[|Y_{mi} - \bar{Y}_{mi}| + |Y_{ci} - \bar{Y}_{ci}|\right]^2} \quad \text{(Eq.19)}$$

Non-parametric kernel density estimation

We also consider non-parametric kernel density estimation (KDE) approach for comparison with ANN approach. In Statistics, KDE is a well-known nonparametric method, which is used to estimate the probability density estimation (PDF) of a random variable. KDE is a principal data smoothing issue where decisions about the population are made, on the basis of finite data sample. Cross validation (CV) smoothing technique

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69176935

being more efficient is used in this study to estimate the smoothing parameter of the nonparametric KDE for annual peak stream flows of Mangla site. By using the estimates of smoothing parameters we estimate the nonparametric kernel density using Gaussian kernel (for details see Shabri, 2002; Lall, 1995; Silverman, 2018; Gramacki, 2018). Let Y be a random variable with PDF. The PDF *f* provides the actual behavior of the distribution of Y. The probability density function for a certain range is as follows in *Equation 20:*

$$\int_a^b f(y)dy \qquad \forall\, a < b \tag{Eq.20}$$

For parametric approach, it is always necessary to check the all fundamental assumptions but in non-parametric KDE, we move towards the assumption free estimation methodology.

Let K denotes the kernel function which holds the following condition given in *Equation 21:*

$$\int_{-\infty}^{+\infty} K(y) = 1 \tag{Eq.21}$$

The kernel estimator can be defined as in *Equation 22:*

$$\hat{f}(y) = \frac{1}{nh}\sum_{i=1}^{n} K\left(\frac{(y - Y_i)}{h}\right) \tag{Eq.22}$$

where *h* denotes the smoothing parameter or bandwidth or window width. The kernel estimator is the sum of bumps placed at the sample values. Further, kernel function *K* and bandwidth *h* determine the shape of the bumps and width for the kernel estimator, respectively. In NP kernel density estimation, calculation of smoothing parameter h is crucial. If the value of h is too small then used kernel estimator leads to larger variance and smaller bias. The value of smoothing parameter or bandwidth h has to be selected optimally. We have opted Cross Validation (CV) method in this study.

At site flood frequency analysis by fitting appropriate probability model

For fitting probability model to peak flows (*at-site flood frequency analysis*), we considered method of L-moments for estimation of parameters of different probability models and also for different goodness of fit tests. Method of L-moments is considered as more robust in the presence of extreme observations. After fulfilment of the basic assumptions of randomness, stationarity, independence and homogeneity through different statistical tests, the next step is to choose the best fit probability distribution among the most commonly used probability models in hydrology such as generalized Logistic (GLO), Generalized Extreme Value (GEV), Generalized Pareto (GPA), Pearson Type 3 (PE3), an Generalize Normal (GNO) (for example see Ahmad et al., 2015; Rahman et al., 2013; Drissia, 2019; Cassalho et al., 2019; Mostofi, et al., 2019). The best model is selected on the basis of different goodness of fit tests such as Anderson Darling (AD) test, Kolmogrove-Smirknove (KS) and L-moments ratio

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69176935

diagram (LMRD). After finding the best models, the next step is to find the results in the form of Pearson correlation coefficient, Root Mean Square Error (RMSE), Mean Absolute Error (MAE), Nash-Sutcliffe coefficient and Index of Agreement (IOA) for observed and predicted values and then compare these results with other techniques.

Results and discussions

Data exploration

The annual peak flows data of Mangla site located at River Jhelum, Pakistan was retrieved from WAPDA and federal flood commission of Pakistan. The peak flows normally occur in monsoon season of Pakistan i.e. from July to September. The basic statistics of the data used in this research is given in *Table 1*.

Table 1. *Basic information about all of the sites used in the study*

Number of observations	Mean (Cusecs)	Standard deviation (Cusecs)	Coefficient of skewness	Coefficient of variation	Latitude	Longitude	Elevation
$n = 54$	132480	136390	4.2402	1.0295	33.15	73.65	14902.7

Table 1 shows that there are total 54 values of peak flows for Mangla site. Each value represents the maximum value in the whole year. The data of peak flows at Mangla site is positively skewed with the coefficient of skewness as 4.2402. The mean of time series is 132480 cusecs. First estimate of first L-moment is equal to mean of the data. The standard deviation of the data is little bit higher than its mean i.e. 136390 cusecs. The coefficient of variation for this time series is 1.0295.

ANN and W-ANN modeling

Annual peak flows for 54 years (1960-2013) of Mangla site on River Jhelum in Pakistan are used for the performance evaluation of Artificial Neural Network (ANN) and Wavelet-ANN Conjunctional model (W-ANN). Eighty percent annual peak flows (1960-2002) are used for training ANN and Wavelet-ANN conjunctional model. The remaining twenty percent data (2003-2013) are used for testing the trained model,

By using the Discreet Wavelet-transform (DWT-Haar wavelet level 1), the approximation and details sub-signals are obtained from the temporal characteristics of of annual peak observed annual peak flows, which are considered as the inputs for W-ANN model. The output for W-ANN model is the original peak flows in the present time step (*Fig. 5*). In the previous step, original values flows are input and in the present time step the values of annual peak flows are used as output to the T-ANN model. In this way, for both models the output is same.

The approximation and detail sub-signals of the annual peak flows series by using DWT db1 (Haar wavelet level 1) are shown in *Figure 6a* and *b*. The approximation and detail sub-signals for DWT db2 (Haar wavelet level 2) are shown in *Figure 7a* and *b.* In this study, two W-ANN models are introduced for comparing purpose such as db1 and db2 respectively. Utilizing db1 transform as inputs for the first W-ANN model and db2 transform as inputs for the second W-ANN model.

By using the methodology shown in *Figure 4*, the (W-ANN) conjunctional model is used here. Back propagation neural network training algorithm is executed on MATLAB platform. Internal parameters used are, momentum coefficient = 0.5 and number of iterations = 1000 to obtain the ideal architecture. Furthermore, ideal combinations of activation functions in both hidden and output layers are obtained with sigmoid function. In this study we consider two input, two hidden, and one output node (2-2-1) for W-ANN conjunctional model and one input, two hidden, and one output nodes (1-2-1) for T-ANN model. The performance of both models W-ANN-db1 (2-2-1) and T-ANN model (1-2-1) for one step ahead forecasting is compared in *Table 2*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69176935

Table 2. *Training and testing errors for T-ANN and W-ANN-db1*

Models	Evaluation Measures					
	Training/testing	**R**	**RMSE (Cusecs)**	**E**	**IOA**	**MAE (Cusecs)**
W-ANN (2-2-1)	Training	0.6394	1.63E+04	0.4914	0.8965	1.83E+04
	Testing	0.5631	3.85E+04	0.3085	0.7382	2.96E+04
T-ANN (1-2-1)	Training	0.4963	2.13E+04	0.2168	0.7317	1.96E+04
	Testing	0.4891	4.26E+04	0.0938	0.5861	3.05E+04

Table 2 shows the performance of W-ANN and T-ANN model in both phases training and testing by using various statistical evaluations measures. W-ANN-db1 (2-2-1) and T-ANN (1-2-1) are chosen as best models among class of other W-ANN and T-ANN models. From *Table 2*, it is observed that prediction for testing data is not good as compared to the training data using evaluation measures for W-ANN-db1 and T-ANN. From *Table 2*, the R (0.6394 and 0.5631) for training and testing data of W-ANN-db1 model is greater than the R (0.4963 and 0.4891) for training and testing data respectively of T-ANN model. The RMSE of W-ANN-db1 model for training and testing are (1.63E+04 and 3.85E+04) which is less than the RMSE (2.13E+04 and 4.26E+04) of T-ANN model for training and testing data respectively. Nash-Sutcliffe coefficient E (0.4914 and 0.3085) and Index of Agreement IOA (0.8965 and 0.7382) of W-ANN-db1 model for both training and testing data are also greater than the corresponding E (0.2168 and 0.0938) and IOA (0.7317 and 0.5861) of T-ANN model for training and testing data respectively. The MAE (1.83E+04 and 2.96E+04) for training and testing data of W-ANN-db1 model are less than the MAE (1.96E+04 and 3.05E+04) for training and testing data of T-ANN model respectively. Therefore, due to goodness of fit tests (R, RMSE, E, IOA, & MAE) W-ANN conjunctional model (db1) with two input, two hidden, and one output nodes i.e. W-ANN-db1 (2-2-1) is selected as best performing model as compare T-ANN i.e. T-ANN (1-2-1).

Also, *Figure 8*, given below compares the actual and predicted peak flows in result of T-ANN (1-2-1) model. Peak flows in the start were accurately forecasted while at the end these flows were not showing harmony with each other. *Figure 9* compares the actual flows and predicted peak flows in the result of W-ANN-db1 (2-2-1) model. Peak flows were forecated in a better way at different parts as compared to previous T-ANN model.

Results are further improved when approximation and detail sub-signal of the annual peak flows are obtained using DWT at db2 (Haar wavelet level 2) as presented in *Table 3*. Results are improved with W-ANN-db2 (2-2-1) model as compared to W-ANN-db1 (2-2-1). *Table 3,* shows the results of R, RMSE, E, IOA and MAE for T-ANN (1-2-1) and W-ANN-db2 (2-2-1) model for Mangla site.

Table 3 shows the results of W-ANN-db2 model for Mangla site which clearly shows that the R is improved from 0.6394 to 0.7984 for training data and from 0.4963 to 0.6108 for testing data. The value RMSE are reduced from 1.63E+04 to 1.21E+04 for training and from 3.85E+04 to 2.99E+04 for testing data. The statistical measure Nash-Sutcliffe coefficient E is also improved from 0.4914 to 0.6362 and from 0.3085 to 0.4158 for training and testing data respectively. Similarly, the term Index of Agreement (IOA) is improved from 0.8965 to 0.9135 and from 0.7382 to 0.7916 for

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69176935

training and testing data respectively. MAE are reduced from 1.83E+04 to 1.04E+04 and from 2.96E+04 to 2.11E+04 for training and testing data respectively. It could be observed from *Table 3* that the performance of W-ANN-db2 model is better than the W-ANN-db1 model for Mangla station.

Table 3. *Training and testing errors for T-ANN and W-ANN-db2*

Models	Evaluation measures					
	Training/ Testing	R	RMSE (Cusecs)	E	IOA	MAE (Cusecs)
W-ANN (2-2-1)	Training	0.7984	1.21E+04	0.6362	0.9135	1.04E+04
	Testing	0.6108	2.99E+04	0.4158	0.7916	2.11E+04
T-ANN (1-2-1)	Training	0.4963	2.13E+04	0.2168	0.7317	1.96E+0R
	Testing	0.4891	4.26E+04	0.0938	0.5861	3.05E+04

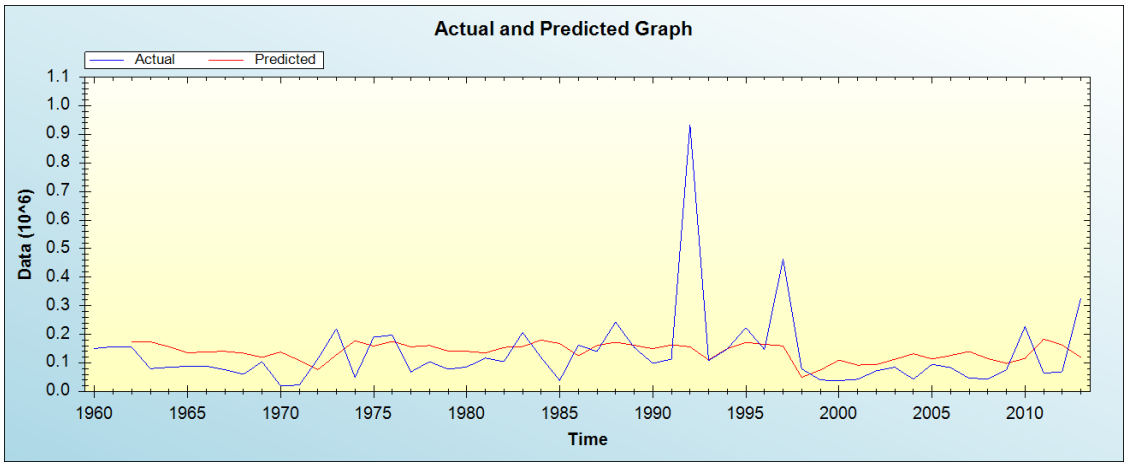

Figure 8. *Graph of observed and predicted flows (cusecs) using T-ANN-db1(1-2-1) for Mangla site*

Figure 10 compares the actual and predicted peak flows from W-ANN-db2 model. Peak flows at different stages were accurately forecasted. It can be seen that the W-ANN-db1 model was not suitable model for forecasting purpose in the present study. On the other side, W-ANN-db2 model provides closer estimates of predicted values to the corresponding observed peak flows for a lead-time of 1 year.

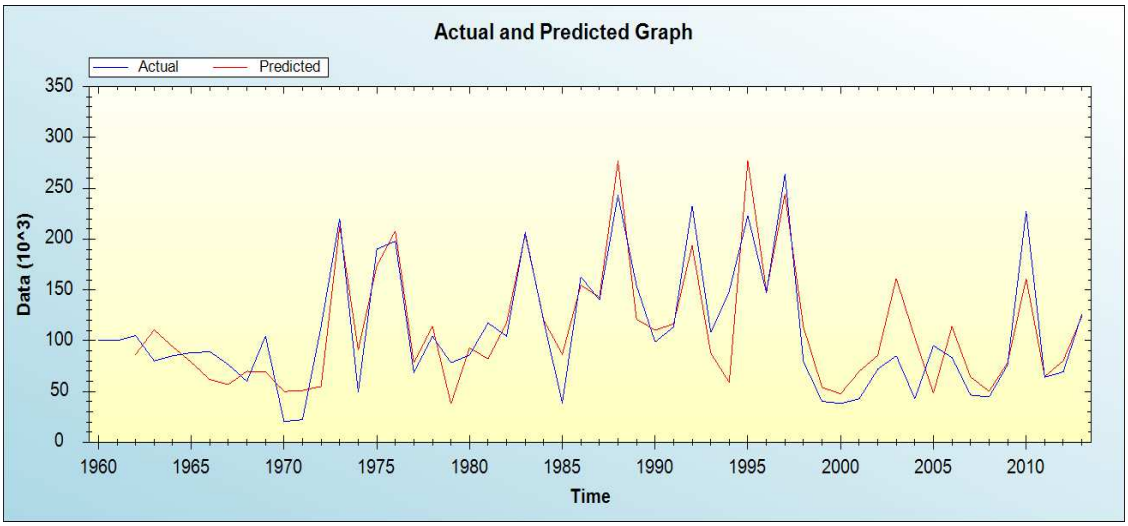

Figure 10. *Graph of observed and predicted flows (cusecs) using W-ANN-db2(2-2-1) for Mangla site*

Probability distribution modeling and kernel density estimation of annual peak flows

There are four basic assumptions of a time series which must be checked before any further probability distribution modeling in statistical hydrology. These assumptions are randomness, stationarity, independence, and homogeneity. These assumptions are of great importance, without them the results are not accurate and may affect the policy implications. We tested these assumptions with the help of different tests such as Mann Kendall's test for trend detection and Mann-Whitney test for homogeneity with respect to location parameters, and for independence we applied the Lag1 correlation test. One sample runs test is also applied for detection of randomness in the present study.

Table 4 shows that all of the fundamental assumptions are fulfilled and we can say that the time series of peak flows is suitable for further analysis. In the next step, we will find best suitable model among GLO, GPA, GEV, GNO and PE3. We used different goodness of fit tests such as Anderson – Darling (AD), Kolmogrove-Smirknove (KS) test and L-moments ratio diagram (LMRD). For estimation of parameters of these distributions we used method of linear moments (L-moments) because of its outperformance in the presence of extreme observations. From KS and AD test, GLO got first rank and declared as the most suitable probability model for peak flows of Mangla site. The same data has also been used in Ahmad et al. (2015). LMRD is a visual inspection for selecting the most appropriate probability model among class of different probability models. It is a graph of theoretical L-moments ratio of skewness and kurtosis of different probability models. This ratio is represented by a curve in the case of three parameters distribution. The sample ratio of these L-moments ratios using the data of Mangla site is shown with "+" sign. The closeness of this "+" to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69176935

any distribution's curve will identify the suitability of that probability model for a particular data. This LMRD, in the present case, also suggest that GLO distribution is the most suitable model for Peak flows of Mangla site see *Figure 10*. The result of LMRD and other goodness fit tests show the same result. After selection of the most suitable model, the next step is find different evaluation measures such as R, RMSE, IOA, MAE for comparison purposes with other approaches. The results are given in *Table 5*.

Kernel density estimation	0.7415	3.8E+04	0.5035	0.5940	5.01E+04

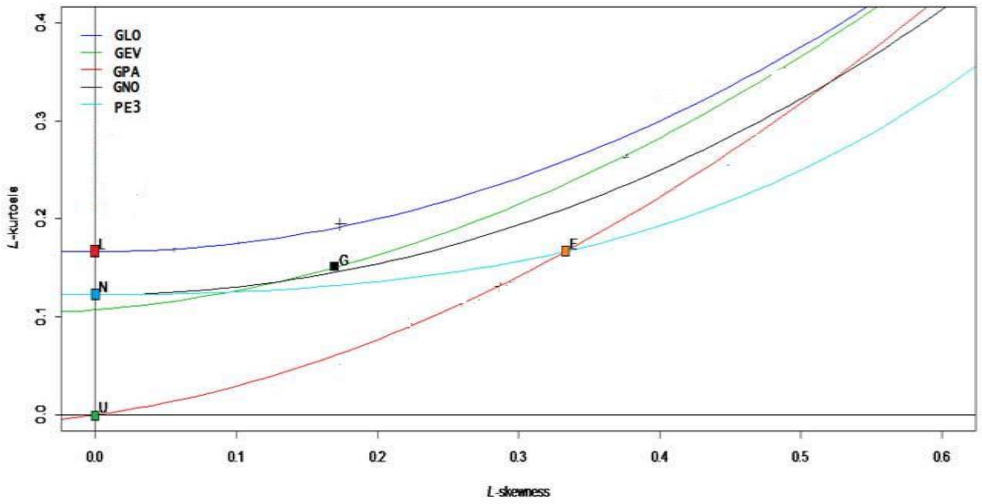

Figure 10. *L-moments ratio diagram for Mangla site*

For KDE, we use Gaussian kernel and cross validation technique for estimation of smoothing parameter. The choice of kernel is not important as compared to choice of smoothing parameter. In KDE, there is no need to check the assumptions of data like probability distribution modeling. The results of KDE are also presented in *Table 5*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69176935

Results show that probability distribution modeling approach is providing comparable results with W-ANN-db2 model, but outperforms than KDE. Overall the performance of W-ANN-db2 model is better than all other approaches discussed in this study for peak flows of Mangla site.

The results of non-parametric KDE are also presented in the *Table* 5, which are not so promising as W-ANN-db2 and Probability distribution modeling approach. Over all, the W-ANN-db2 approach outperforms than T-ANN, probability modeling and KDE.

Conclusion

In this study the annual peal flows series measured in cusecs at Mangla site situated on the river Jhelum, Pakistan with length of 54 years has been considered for identification of the most suitable modeling approach among T-ANN, W-ANN, Probability distribution modeling and non-parametric KDE. In the light of statistical evaluation criteria, it can be seen that W-ANN model under db1 gave more accurate forecasting results than the T-ANN model. The results further are improved by fitting the W-ANN conjunctional models under db2 scheme. Further to check the authenticity of W-ANN-db2 model, we compared it with probability distribution modeling approach by fitting GLO probability model being the most suitable model and KDE approach using Gaussian kernel approach. The comparison reveals that, probability distribution modeling approach gives us comparable results as of W-ANN-db2 model. The results of KDE are not as promising as of W-ANN and probability distribution modeling approach. Overall, comparison among four approaches, we notice that W-ANN-db2 model outperformed in this study. These results are useful in water resources management such as construction of different hydrological structures.

Abstract. The study illustrates application of Regional Flood Frequency Analysis (RFFA) using Annual Maximum Peak Flows (AMPF) of eleven gauging sites of various streams of Khyber-Pakhtunkhwa, Pakistan. Assumptions associated to recorded data at various sites have been validated through various statistical tests. The discordancy measure indicates that there is no discordant site in the cluster of eleven sites. Heterogeneity measure based on l-moments confirms that the group of eleven sites is definitely homogeneous. Criterion of $|Z - Dist|$ statistic and L-moment ratio diagram show that Generalized Pareto (GPA) distribution is the best fitted regional distribution of the study region. Regional flood quantiles for various return periods have been estimated using the quantile function of GPA distribution. Artificial Neural Networks (ANN) and Quadratic Regression (QR) model with robust estimation method have been used for the estimation of quantiles at ungauged sites. Model evaluation criteria's (error comparison of predicted values) suggested that estimated quantiles through ANN are accurate relative to quadratic regression. Historical comparison shows that the quantiles estimated through index flood method and ANN are closely related to the highest recorded values of AMPF at each corresponding site for shorter as well as longer return periods.

Introduction

Reliable estimation of extreme hydrological events is needed for designing and building of hydrological structures on stream channels. These structures are important to provide protection against floods and to regulate the supply of available water. Various approaches including at-site and regional are in practice for flood frequency analysis in different parts of the world. However, regional approach has advantageous results relative to at-site analysis. For instance, the estimated flood quantiles can be

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69376959

interpolated and/or extrapolated to obtain estimates for the poorly gauged or ungauged sites of the study area. The most commonly used techniques for the estimation of quantiles at ungauged sites include the regression techniques, rational method, ANN, etc. The current study has adopted RFFA using index flood method based on L-moments coupled with QR with robust estimation method and ANN, to estimate flood quantiles at gauged and ungauged or poorly gauged sites, emphasizing the complete justifications related to the regression modeling and comparison with the historical record to investigate the practical validity of the resultant estimates.

Pakistan, with integrated river basins, has a long history of floods since 1947 (from the year of its independence). Twenty-four major floods have occurred in the country from 1947 to 2016, resultantly, the country has suffered direct economic loss of about 38.171 million USD (Government of Pakistan, 2016). Secondly, Pakistan, being a developing country with agriculture sector as a major contributor to its gross domestic product (GDP) requires effective planning and management, based on reliable estimates, for optimum utilization of the available water resources. Agriculture sector contributes about 24 percent in the GDP of Pakistan (Pakistan Bureau of Statistics, 2018). Thirdly, Pakistan's major rivers originate in India and Jammu & Kashmir (a disputed territory between India and Pakistan), and flows from north to south in the country. Due to the Indus Waters Treaty signed in 1960 between India and Pakistan for the division of major rivers of Indus river basins, and the lack of planning and development of the hydrological structures (dams and barrages) on the major rivers (Jhelum, Chenab and Indus), Pakistan is facing problems of shortage of water every year. This crisis will become even worst in future (Development Advocate Pakistan, 2017), as officials are forecasting swear crises of usable water by the year 2025. Therefore, planning, management and efficient utilization of available water resources, especially small rivers and stream flows of north-western areas of Pakistan, which originates in Pakistan, using standard methods of analysis is a primary need of time. The current study has focused, for the first time (to the best of author's knowledge), on various sites of the area of Khyber Pakhtunkhwa (KPK) (an important province in the north-west region of the country) to perform RFFA.

RFFA basically involves two principle steps, (1) identification of regions having similar site characteristics and (2) development of forecast equations for the estimation of flood quantiles at gauged and ungauged sites. RFFA has widely been used all over the world (including the neighboring countries of Pakistan) for the estimation of extreme events. For example; in Canada, (Glaves and Waylen, 1997; Pokhrel, 2002; Requena et al., 2017); in India, (Kumar et al., 2003a,b; Kumar and Chatterjee, 2006; Alam et al., 2016); in China, (Jingyi and Hall, 2004; Yang et al., 2010); in Iran, (Modarres, 2008; Malekinezhad and Zare-Garizi, 2014); in Turkey, (Saf, 2009; Aydoğan et al., 2016); in Italy, (Noto and La Loggia, 2009) and many more. In RFFA, several methods are in practice including regression techniques, rational methods, ANNs, etc. for the development of forecast equations to estimate flood quantiles at ungauged sites. Few details of the adopted methods in published studies are illustrated in the following sections.

Regression techniques have been used by various published studies for the estimation of quantiles at ungauged sites (Griffis and Stedinger, 2007; Hailegeorgis and Alfredsen, 2017), but very few of them have illustrated the complete theoretical and statistical justifications of the developed models. Moreover, scarce literature is available analyzing the nonlinear relationships of the site characteristics with observed AMPF of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69376959

gauged sites. Importantly, the relationship between hydrological and physio-meteorological variables is usually categorized as strongly nonlinear (Sivakumar and Singh, 2012). Nonlinear relationships may provide more accurate estimates of flood quantiles at ungauged sites as compared to linear relationships (Ouali et al., 2017). Secondly, due to the existence of outliers in the observed AMPF and availability of fewer values for analysis, the Ordinary Least Squares (OLS) estimation method may no longer be feasible. This problem requires robust methods for the estimation. In the current study, a quadratic term of the most influential site characteristic as independent variable has been introduced in the model along with a robust method for the estimation of the proposed model.

ANN is a nonparametric calculating and modeling approach stimulated by the biological operative of the human brain (Rumelhart et al., 1985). This method has significant advantages over other estimation techniques including regression analyses (Liu et al., 2009; Landi et al., 2010). One major advantage of ANN is their capacity to identify the complex nonlinear relationships and there is no need to express such relationship in mathematical form as the data itself recognizes the model form through use of artificial intelligence (Hjelmfelt and Wang, 1996). ANN approach coupled with RFFA can provide more accurate estimates of flood quantiles for ungauged sites relative to regression models (Dawson et al., 2006; Shu and Ouarda, 2007; Aziz et al., 2014; Anilan et al., 2016). Therefore, adopting recent trends in statistical hydrology, ANN has been used, for the first time in Pakistan, for the estimation of flood quantiles at ungauged sites.

Since, one of the emphases of this study is the identification of optimum method coupled with RFFA to obtain quantiles for ungauged sites. Therefore, the estimates through QR and ANN have been compared using Root Mean Square Error (RMSE), Mean Absolute Percentage Error (MAPE) and Mean Absolute Error (MAE) of predicted values from both the methods of estimation. Moreover, a comparison with the historical flood information has been done to investigate the practical validity of the provided estimates through different methods.

Keeping in view the aforementioned details, major objectives of the study are:

- Estimation of flood quantiles using RFFA based on L-moments for the gauged sites of important streams of KPK with complete justifications of the adopted procedure through various statistical tests.
- Estimating quadratic regression model with robust method of estimation for the estimation of quantiles at ungauged sites.
- Introduction of ANN for the estimation of quantiles for ungagued sites of the study area.
- Comparison of the esitmates obtained through various procedures of estimation for ungauged sites using statistical measures along with histrorical information to identify the optimum method to be used in RFFA for the estimation of quantiles at ungauged sites.

Study area and data utilized

The KPK region, having various small rivers and stream flows, is the second source of river water in Pakistan. KPK has 101,741 km² area with steep geography and a population of about 35.53 million (as per population censes of 2017 by the Government of Pakistan). The terrain of KPK consists of mountainous in the north, sub mountainous and lands surrounded by hills to the south. Due to steep geography and mountain land

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69376959

of KPK the heavy rainfall usually turns into flash flooding affecting the whole of KPK (Pakistan Meteorological Department, 2012). Southern KPK is the most populated area of the province, and due to its downstream location, it has been affected badly due to heavy floods in 1992 and 2010 (Hashmi et al., 2012). Therefore, preventive measures against these natural disasters are a popular demand of the people of KPK which requires quantification of the frequency associated to these floods. Moreover, KPK has an identified potential of hydro-electricity of about 18698 Mega Watt, as reported in a study on Hydel Potential in Pakistan by National Electric Power Regulatory Authority (NEPRA), Pakistan (NEPRA, 2018). None of the published studies so far has used L-moment based RFFA for flood quantiles estimation at various sites of KPK. Few published studies in Pakistan related to statistical hydrology include (Muhammad and Afreen, 2007; Hussain and Pasha, 2009; Hussain, 2011; Ahmad et al., 2015; Ahmad et al., 2016; Batool, 2017; Hussain, 2017; Hussain et al., 2017 etc.). These studies have focused on the areas of Punjab and Sindh only (the two provinces of Pakistan). Other studies including (Shahzadi et al., 2013; Khan et al., 2017) performed rainfall frequency analysis considering few areas of KPK and Sindh.

The current study has performed RFFA using AMPF in cusecs of eleven gauging sites situated in the southern KPK. The data has been provided by the Provincial Irrigation Department of KPK. *Fig. 1* illustrates the geographical information of the sites used for the analyses. The details of these sites and their respective site characteristics, such as, Latitude (lat), Longitude (long), Elevation (ele), Average Annual Rainfall (AARF) and Average Rainfall in Monsoon (ARMS) are given in *Table 1*. Few missing observations have been found in the observed data series of the sites, Wazir Ghari, Chinkar, Bara Tarnab, Khuderzai, Jundi Utmanzai, Lund Khwar East, Jundi Tangi, and Swat Ningolai. The percentage of these missing observations is available in *Table 1*. These missing observations have been replaced by the average value of observed AMPF of the corresponding site.

Table 1. *Site characteristics of eleven sites of Khyber-Pakhtunkhwa, Pakistan*

Methodology

Index Flood Method

This study has adopted L-moments based RFFA, described in details in (Hosking and Wallis, 1997). RFFA is based on certain assumptions related to the observed data series, for instance, the data series is random, stationary and identically distributed etc. These assumptions have been validated using various statistical tests. The first step afterwards is to check whether there exists a discordant site, using D*i* measure, in a group of available sites. The formula of D_i is:

$$D_i = \frac{1}{3} N(u_i - \bar{u})^T S^{-1}(u_i - \bar{u}), i = 1,2,3 \ldots N \quad \text{(Eq.1)}$$

$$S = \sum_{i=1}^{N} (u_i - \bar{u})\,(u_i - \bar{u})^T$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69376959

where u_i is the vector of sample L-moments ratios of site i, $\bar{u}$ is its mean and N is the total number of sites. A site is discordant if its D_i value is greater than the critical value. These critical values are provided in (Hosking and Wallis, 1997).

Next important step in RFFA is the identification of homogeneous region. Homogeneity of the identified region can be checked using regional heterogeneity measure H, for which the formula is:

$$H = \frac{V-\mu_v}{\sigma_v} \quad \text{(Eq.2)}$$

where $V = \left[\frac{\sum_{i=1}^{N} n_i\left(\tau^i-\tau^R\right)^2}{\sum_{i=1}^{N} n_i}\right]^{\frac{1}{2}}$ and μ_v is mean and σ_v is standard deviation of computed inter-site variation figured through simulations using Kappa distribution.

For a region to be declared as statistically homogeneous, the calculated value of H should be less than one. After the identification of homogeneous region, the next obvious step is to check the goodness of fit of the candidate distribution(s) using L-moment ration diagram (a graph of sample L-skewness Vs sample L-kurtosis of the sites) and $Z - Dist$ statistic. The formula for $Z - Dist$ statistic is:

$$Z - Dist = \frac{\tau_4^{Dist}-\tau_4^R+\beta_4}{\sigma_4} \quad \text{(Eq.3)}$$

where $\tau_4^{Dist}$is the L-kurtosis of fitted candidate regional distribution, τ_4^R is the regional L-kurtosis, σ_4 is standard deviation and β_4 is the bias of τ_4^R obtained through simulations. A distribution having minimum $|Z - Dist|$ value can be considered as the best fitted regional probability distribution.

Parameters of best fitted regional distribution can be estimated through method of L-moments and regional quantiles for various return periods can be estimated using the quantile function of the fitted regional distribution. Using the estimated regional quantiles, at-site quantiles can be estimated using:

$$\hat{Q}_i(F) = l_1^{(i)}\hat{q}(F) \quad \text{(Eq.4)}$$

where $\hat{Q}_i(F)$ is the estimated quantile of site i, $l_1^{(i)}$ is the first sample L-moment of site i and $\hat{q}(F)$ is the estimated regional quantile for any return period.

Operational configuration of ANN

For ungauges quantiles estimation QR and ANN have been used. ANN consist of input layer, hidden layers, neurons in each layer, activation function and output layer. Among the various methods of ANN, multilayer feed forward network has been selected for the current study. Back propagation method has been used for the training of ANN which may also be referred as Back Propagation Neural Networks (BPNN). BPNN is a popular tool and dominates for predictions of river flow at different points and well suited to various types of hydrological modelling especially for non-linear regression operations (Maier and Dandy, 2000; Abrahart et al., 2004). Structure of threelayer feed forward network has been dispalyed in *Fig. 2*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69376959

In *Fig. 2* circles represents neurons in the layers of ANN structure and arrow lines for connections between neurons in each layer. Weight function has been used as connection parameter and every input of neurons is multiplied by a weight and then the values are pooled to produce one output value. This value is usually produced with certain bias and then operated by activation function. Therefore, output of each neuron stated as below:

$$Z_j = f(X\ (T_i - b_j)) \quad \text{(Eq.5)}$$

where X is the input vector in the first layer and T_i is the weight vector. Its order of weights leading to the neurons given as:

$$T_{mj} = (t_{1j} \ldots . t_{ij} \ldots . t_{nj})$$

where $j = 1, 2, \ldots n$ and m = number of neurons, t_{ij}= joining weight from the i neuron in the earlier layer to the current neuron.

The output of neuron j is Z_j and obtained by the inner product of the function defined in *Equation 5* where b_j represent the value of bias associated with neuron j.

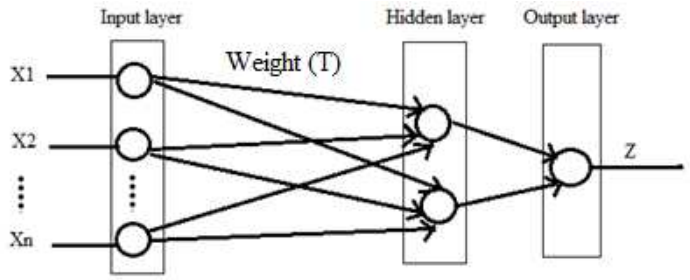

Figure 2. *The Configuration of Artificial Neural Networks*

The main purpose of training ANN with a data set (input and output) is to adjust the weights to minimize the errors between ANN outputs and the desired outputs. Before training of any neural network, data is scaled using z-normalization, minimum-maximum scale, etc. For the present study minimum-maximum scale has been used to scale the data into the interval [0, 1], and randomly splitting the data into training and testing set. Most commonly known activation functions for neural networks are logistic function, hyperbolic tangent function, bipolar function, scaled arctan function, and arctan function. Shamseldin et al. (2002) states that logistic function performs well relative to other activation function for river flow forecasting. Therefore, logistic function has been used as activation function for hidden and output layers. Number of hidden layers and neurons in each layer has been selected by using trial and error method.

Results and discussion

RFFA is based on few critical assumptions related to the observed data series at each site. For instance, the recorded data at different sites is random, independent and identically distributed as well as free of the step changes and trend. There are various methods available in the literature for the validation of these assumptions. For the current

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69376959

study, Run test for randomness (Bradley, 1968), Wald-Wolfowitz test for independence and stationary (Wald and Wolfowitz, 1943), Rank-sum test for homogeneity (Hirsch et al., 1992), have been used and the results are given in *Table 2*. All these tests have been performed using 5% level of significance. The results of *Table 2* show that the recorded data of eleven gauging sites fulfill all the critical assumptions related to RFFA, therefore, can be used for further analysis.

		P-value	0.2416	0.5878	0.9339

Discordancy measure

The calculated values of D_i using *Equation1* for eleven sites along with corresponding descriptive statistics in terms of L-moments have been illustrated in *Table 3*. The results show that the values of D_i for each site are less than the critical value i.e. 2.64 (as proposed by Hosking and Wallis (1997) for eleven sites). Therefore, there is no discordant site in the set of eleven gauging sites.

Descriptive statistics given in *Table 3* show that Wazir Ghari, Chinkar and Lund Khwar East have smaller magnitude of AMPF while Bara Tarnab, Kalpani Saidabad and Swat Ningolai have relatively larger magnitude of AMPF in the region. Sample L-moments ratios L-CV ($\boldsymbol{t}$), L-skewness ($\boldsymbol{t_3}$) and L-kurtosis ($\boldsymbol{t_4}$) for the sites Jundi Utmanzai and Jundi Tangi are very high. This shows that there exists high variations in the observed data series at these sites. Moreover, the shape of the distribution associated

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69376959

to AMPF at these sites is positively skewed with high kurtosis. The sample L-moments ratios for all the sites, in general, show that the observed data series have high variations, positive skewness and hight kurtosis. Moreover, the values of L-skewness are smaller than L-CV while values of L-kurtosis are relatively less than L-skewness for almost all the sites. The site Bara Tarnab have the value of L-skewness greater than L-CV. This high variation within the AMPF may be due to the uncontrolled/natural flow of the stream associated to this site and mountainous and steep geography of the region. An important point is that the flow of the streams in the study region heavily depends on rainfall and the pattern of rainfall in the basin area is irregular. The reason of this high variation within the AMPF has been observed due the presence of outliers, may be due to storm rainfalls in the basin area, especially during monsoon season (from June and August).

Table 3. *L-moments based descriptive statistics and values of discordancy measures*

Note: "n_i" is the number of observations at each site, "l_1" is the first sample l-moment, "t" is the sample L-CV, "t_3" is the sample L-skewness, "t_4" is the sample L-kurtosis and "D_i" is the discordancy measure

Regional heterogeneity measure

Initially, the group of eleven sites has been considered as a single region for the analysis. The reason being these sites are geographically contiguous; therefore, their climate conditions, and topography (the variables affecting the flow behavior of the sites under study) may be similar to each other. For the calculations of *H*, the simulations have been performed using four parameters Kappa distribution. Large number of simulations, i.e. 1000, have been performed to calculate the values of μ_v and σ_v. The calculated value of *H* by using *Equation 2* is 0.09; therefore, the region consisting of eleven sites is homogeneous and suitable for further analysis.

Fitting of regional probability distribution

After the formation of homogeneous region, the next important step is to identify the best fitted regional probability distribution that accurately defines the observed AMPF within the homogeneous region. Graphical/informal method (L-moment ratio diagram) and formal method ($|Z - Dist|$ statistic) have been used for the selection of best fitted regional distribution for the recorded data series. L-moment ratio diagram is presented in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69376959

Fig. 3, in which sample L-skewness has been plotted against the values of sample L-kurtosis. From *Fig. 3*, it has been observed that the regional average value of sample L-skewness and L-kurtosis lies closer to the theoretical curves of Generalized Normal (GNO) and GPA distributions suggesting their appropriateness as regional distribution. Moreover, the tendency of sample L-skewness and L-kurtosis of all the sites is closer to the theoretical curve of GPA distribution.

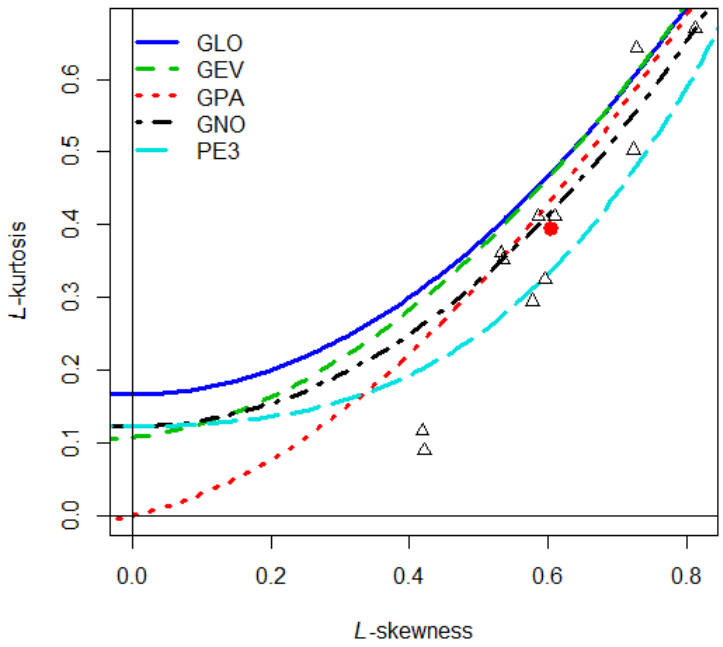

Figure 3. *L-moment ratio diagram. Note: (●) represents the average value of L-skewness & L-kurtosis of the region,* (Δ) *denotes the values of sample L-skewness & L-kurtosis of each site in the region*

Calculated values of $|Z - Dist|$ statistic, using *Equation 3*, for each candidate distributions i.e. Generalized Extreme Value (GEV), Generalized Logistic (GLO), Pearson type-3 (PE3), GNO and GPA have been given in *Table 4*. Four distributions; GNO, GPA, GEV, and GLO fulfill the criteria for best fitted regional distributions, that is, having value of $|Z - Dist| \leq 1.64$. Among these distributions, GPA distribution has minimum value of $|Z - Dist|$ statistic. Therefore, based on the results of L-moment ratio diagram and $|Z - Dist|$ statistic, GPA distribution has been selected as the best fitted distribution for the region under study.

Table 4. *Values of* $|Z - Dist|$ *statistic for each candidate regional distribution*

GLO	GEV	GNO	PE3	GPA
0.46	0.39	0.70	2.45	0.34

Note: Genralized Pareto (GPA), Genralized Logistic (GLO), Genralized Normal (GNO), Genralized Exterem Value (GEV), Pearson type-3 (PE3)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69376959

Estimation of regional probability distribution and quantiles

The parameters of GPA distribution have been estimated using method of L-moments. Dimensionless regional quantiles have been estimated using the quantile function of GPA distribution. The estimated parameters and quantiles for different return periods of GPA distribution are given in *Table 5*. The estimated regional quantiles show increasing trend, as usual, for shorter as well as longer return periods.

Table 5. *Estimated parameters of Generalized Pareto (GPA) distribution and regional quantiles for various return periods*

Distribution	Estimated Parameters			Regional quantiles for various return periods in years				
	ε	α	k	10	20	100	500	1000
GPA	-0.0282	0.5064	-0.5075	2.184	3.538	9.303	22.351	32.207

In RFFA, for a homogeneous region, the selected regional distribution is considered as parent distribution for various sites of the region. The estimated at-site quantiles using *Equation 4* for various return periods are given in *Table 6*. The results show that the estimated quantiles at site Wazir Ghari for 100 years return period is 3967 cusecs which is the lowest as compared to other sites in the region. The highest of the estimated quantile for 100 years return period is at site Bara Tarnab as 110560 cusecs. The estimated quantiles at various sites for smaller to larger return periods, i.e. 10, 20, 100, 500 and 1000 years are greater than the average AMPF of their corresponding sites.

Table 6. *Estimated quantiles for each site obtained using index flood method, i.e. Eq. 4, for various return periods*

Quantiles for ungauged sites

For the current study, quadratic regression and ANN have been used to develop a functional relationship between l_1 (mean of observed AMPF at given sites) and their corresponding available site characteristics within the homogeneous region. This functional relationship will provide the estimates of at-site mean (for ungauged sites) within the homogeneous region for the estimation of T-years flood quantiles.

DOI: http://dx.doi.org/10.15666/aeer/1703_69376959

Quadratic regression analysis

This section describes the development of QR model using the most suitable site characteristic as an explanatory variable (to predict $l_1^{(i)}$, for site i). The details are: *Table 7* provides the correlation matrix, between l_1 and the available site characteristics along with corresponding p-values to check the significance of the respective correlation coefficients.

Table 7. *Values of the correlation coefficients between site characteristics along with their corresponding p-values for testing the significance of correlation coefficients*

Variables		l_1	Latitude	Longitude	Elevation	AARF	ARMS

	P-value	(0.4299)	(0.7829)	(0.7881)	(0.9569)	(0.0587)	(0)

Note: " r " is the correlation coefficient

The results show that the correlations between l_1 and the available site characteristics are statistically insignificant at 5% level of significance; hence there does not exist significant linear relationship between l_1 and the available site characteristics. Therefore, simple/multiple linear regression model (using linear form of available site characteristic(s)) would not be appropriate to predict the values of l_1. The next obvious choice is the use of quadratic forms of the pertinent site characteristic(s) among available to predict the average value of $l_1$for ungauged sites. To select the best independent variable for inclusion in the regression model with linear and quadratic form, following details have been considered. Results of *Table 7* show that the correlation between l_1 and longitude is the highest relative to all other sites characteristics but the problem is that longitude and latitude are imaginary lines on earth glob to identify the geographical location of any site. These site characteristics may be negligible if additional site characteristics are available (Hussain, 2017). The next obvious choice of variable having highest correlation with l_1 as compared to other available site characteristics is ARMS. Therefore, it has been considered as an explanatory variable in the model. Moreover, *Table 8* provides the percentage of occurrence of observed AMPF at different sites during various seasons of a year which shows that a large percentage of values of AMPF have been observed in the monsoon season (from June to August). Therefore, ARMS can be considered as the most influential variable having relatively direct and strong relationship with the observed AMPF in the study region. Based on the aforementioned details, it is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69376959

appropriate to use quadratic form of ARMS as explanatory variable in the regression model. Scatter plot of l_1 and ARMS is illustrated in *Fig. 4* in which a nonlinear relationship between the variables is obvious.

DOI: http://dx.doi.org/10.15666/aeer/1703_69376959

(outliers) create problems of estimation and in such a situation it is very difficult to fulfill the critical assumptions of classical linear regression (normality and constant variance of the error term).

Therefore, robust estimation methods are obvious choice. For the current study, due to the existence of high scatter in the observed data series and the dependent variable is the mean of extreme values, M-estimation method (Huber, 1973) with covariance type Huber type-III as weight function has been used to estimate the developed regression model. M-estimation technique does not rely on the normality assumption of error term and is more resistant to outliers (Stuart, 2011). M-estimates are consistent, asymptotically unbiased and normally distributed (Chen and Wu, 1989; Hengjian, 1997; Ivanov and Orlovs, 2008; Ruckstuhl, 2014). Thus the fitted regression model based on the aforementioned details is.

$$\widehat{l_1} = 9220.21 - 104.20\, ARMS + 0.3107\, (ARMS)^2 \qquad \text{(Eq.6)}$$

Values of the coefficients, standard errors of estimates, t-calculated (to validate the statistical significance of the provided coefficients) and their corresponding p-values are given in *Table 9*.

Table 9. *Estimated values of the fitted regression model, coefficients and their corresponding standard errors (S.E.), t-values and P-values*

S. No.	Independent variables	Coefficients	S.E.	t-value	P-value
1	ARMS	−104.20	32.01	-3.2554	0.001
2	$(\text{ARMS})^2$	0.3107	0.0719	4.3186	0.000

Note: ARMS (Average rainfall in monsoon)

The results show that the coefficients of the fitted regression model in *Equation 6* are highly significant at 5% level of significance. Quadratic term of the model have positive impact on flood flows when rainfall during monsoon season is increased from its average value. Value of the adjusted R_w^2 is 0.89 for the fitted model. Diagnostics plots of fitted vs residuals and residual vs leverage are given in *Fig. 5* and *Fig. 6*, respectively.

These plots show that high residuals are observed for the 4th site (Bara Tarnab) and 8th site (Kalpani Saidabad) observations. These high residuals lies on the cook's distance limit. Diagnostics plots also show that the 10th observation (the site Swat Ningolai) has deviated largely from other plotted points, as its predicted value is very large and much closer to its observed average AMPF. Therefore, these observations don't have any undue influence on the estimated values. These details reveal that the developed regression model is statistically sound; however, another desirable is the practical validity of the model, which has been provided in second last section.

Artificial neural networks

Five input and one output variables have been used for the prediction of the dependent variable (average value of the observed AMPF at various sites (l_1)). Site characteristics, such as, "lat", "long", "ele", "AARF" and "ARMS" have been used as input variables of ANN model. The variable l_1 has been used as the dependent variable of the model. Functional relationship of the dependent and independent variables is given as

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69376959

$$f(l_1) = g(lat, long, ele, AARF, ARMS) \quad \text{(Eq.7)}$$

Two hidden layers, with four neurons in first layer and two in second layer, have been used to perform the algorithm. The graphical representation of the fitted model using the realtionship of *Equation 7* with the weights on each connection and bias has been illustrated in *Fig. 7*.

Predicted values of the dependent variable (l_1 of gauged site) have been provided in *Table 10*. *Table 10* also includes the estimated values of l_1 using QR analysis. The results show that ANN algorithm closely estimates l_1 for the gauged sites (Kalpani Deheri, Bara Tarnab, Khuderzai, Kalpani Saidabad, Jundi Tangi, Swat Ningolai and Bara Kohat Road) using available site characteristics as independent variables. ANN and QR model over estimate the values of l_1 for the sites (Wazir Ghari, Chinkar and Lund Khwar East) having smaller magnitude of AMPF. QR model under estimates l_1 for the sites (Jundi Utmanzai, Kalpani Saidabad and Jundi Tangi) having largre value of L-CV. The site Bara Tarnab have the larger magnitude of AMPF and its l-skewness is greater than L-CV QR model also under estimates its value. QR model provide reliable estimate of the values of l_1 for the sites (Kalpani Deheri, Khuderzai, Swat Ningolai and Bara Kohat Road). Similar results have been reported by (Dawson et al., 2006) showing the under and over estimation of floods at few gauged and ungauged sites for 10, 20 and 30 years return periods through multiple linear regression analysis and ANN. They proposed that this problem may be related to the accuracy and availability of the relevant site characteristics.

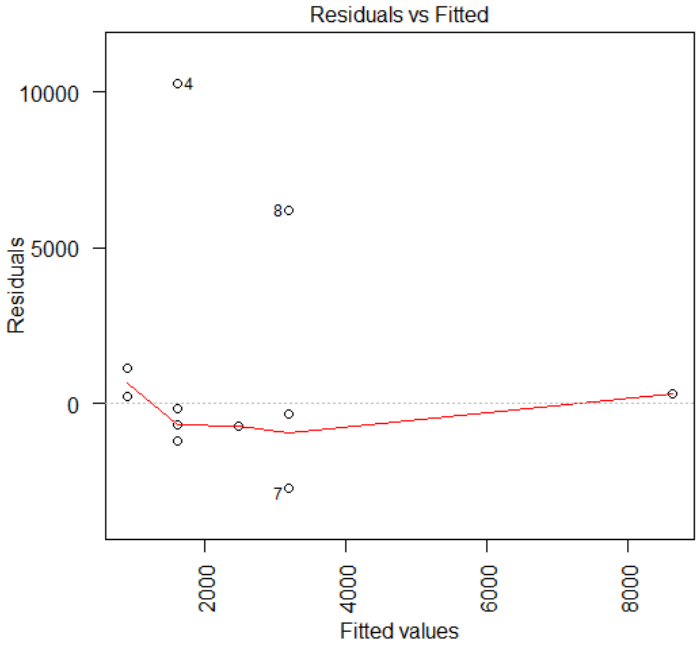

Figure 5. *Plot of fitted values of dependent variable, (first sample l-moment of annual maximum peak flows (l_1)) and residuals of the fitted regression model in Equation 6*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69376959

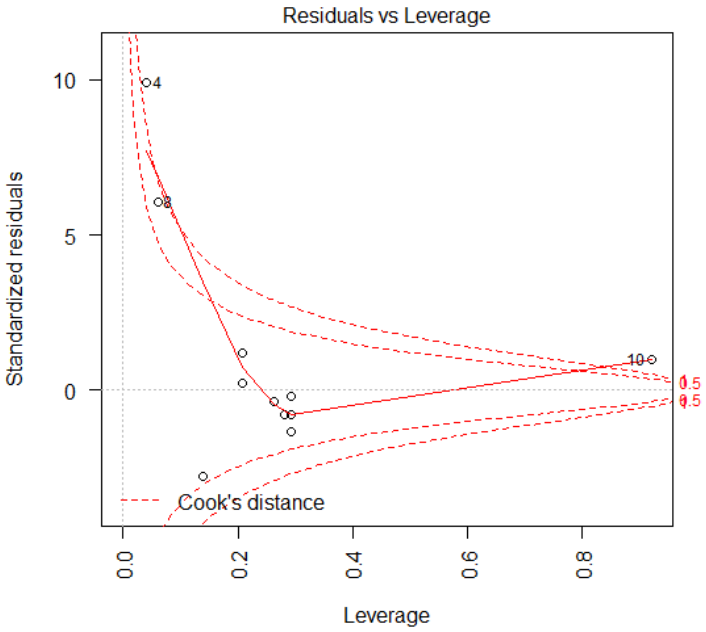

Figure 6. *Diagnostic plot of fitted regression model (Equation 6)*

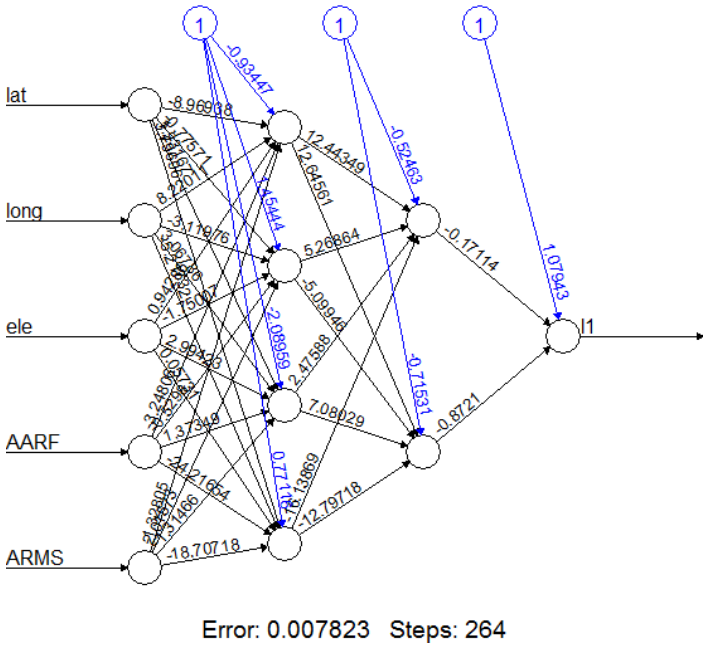

Figure 7. *Graphical representation of artificial neural networks (ANN) procedure adopted for the area under study to show the convergence of the model*

The performance of the QR model is not affective for the gauge site having smaller and larger magnitude of AMPF and for those sites also that show very high variation in the data set. As compared to QR model ANN estimates are more reliable and accurate accept the sites have smaller magnitude of AMPF. In *Fig. 8*, fitted values of dependent variable have been plotted against the observed values of the dependent variable. All the values predicted through ANN lie on the straight line relative to the predicted values

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69376959

through QR. Therefore, the observed and the predicted values of the dependent variable through ANN are quite close to each other, especially, for the sites having larger magnitude of AMPF.

Table 10. *Estimated values of l_1 of gauged sites through artificial neural networks (ANN) and quadratic regression (QR)*

S.No.	Site name	l_1 (observed)	l_1 (fitted) using QR	l_1 (fitted) using ANN
1	Kalpani Deheri	2856.61	2854.886	2697.19
2	Wazir Ghari	426.47	1220.572	845.78
3	Chinkar	922.27	1220.572	1306.46
4	Bara Tarnab	11884.18	1220.572	11651.88
5	Khuderzai	1758.37	2110.622	1880.46
6	Jundi Utmanzai	2052.57	486.3447	842.53

Assessment analysis

The two estimation methods (ANN and QR) have been used for T-year flood quantiles estimation at ungauged sites within the homogeneous region. The development of these two methods is theoretically justified in the study, still an assessment analysis is requisite to check the relative accuracy of estimates of the T-year flood quantiles for gauged, poorly

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69376959

gauged and ungauged sites. To do so, RMSE, MAPE and MAE have been calculated using the information of *Table 10* (observed and fitted values of each site of the homogeneous region) and the results are given in *Table 11*. Their corresponding formulas are:

$$RMSE = \sqrt{\frac{\sum_{i=1}^{n}(\hat{l}_i - l_i)^2}{n}} \quad \text{(Eq.8)}$$

$$MAPE = \left(\frac{1}{n}\sum_{i=1}^{n}\frac{|l_i - \hat{l}_i|}{|l_i|}\right) \times 100 \quad \text{(Eq.9)}$$

$$MAE = \frac{\sum_{i=1}^{n}|l_i - \hat{l}_i|}{n} \quad \text{(Eq.10)}$$

The results of *Table 11* show that the estimates through ANN are more accurate than QR as values of RMSE, MAPE and MAE calculated by using *Equation 8*, *Equation 9* and *Equation 10* respectively are relatively low. Therefore ANN can be preferred over QR to predict the flood quantiles for ungauged and poorly gauged sites of the study region.

Table 11. *Assessment measures for validation of the estimates through Artificial Neural Networks (ANN) and Quadratic Regression (QR)*

	RMSE	**MAPE**	**MAE**
ANN	432.12	27.17%	293.25
QR	3887.42	94.65%	2173.83

Note: Root Mean Square Error (RMSE), Mean Absolute Percentage Error (MAPE), Mean Absolute Error (MAE)

Cross validation of estimated quantiles

The estimates of quantiles for various return periods through RFFA for gauged and ungauged sites are statistically sound but their practical validation is still requisite. A comparison of quantiles estimates obtained using index flood method, QR model and ANN for 10, 20 and 100 year return periods with highest values of observed/historic AMPF (first, second and third as per their order of magnitude along with their year of occurrence) at various sites, has been illustrated in *Table 12*. Due to high variation in the observed AMPF of each site three highest values are selected for the historic comparison of predicted quantiles.

A flood of 2010 has been considered as one of the worst in Pakistan's history (Government of Pakistan, 2016). The current study region is one of the affected areas of this heavy flood. There are four sites Chinkar, Jundi Utmanzai, Kalpani Saidabad and Bara Kohat Road where the highest values of the series of AMPF has been observed in 2010 (as shown in *Table 12*). For these sites, the predicted quantiles for 100 year return period using index flood mehtod for gauged sites and through ANN for ungauged sites are quite close to the highest obserseved AMPF for 2010. At site Jundi Tangi, second highest value of AMPF has been observed in 2010 and similar magnitude of flood has been predicted for 100 year return period through index flood and ANN. For the site Lund Khwar East, third highest value of AMPF has been observed in 2010 and same magnitude

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69376959

of flood has been predicated for 20 year return period through index flood and 10 year return period for ANN. Similar trends of the observed and predicted values are obvious from the results of *Table 12*. This shows the accuracy and reliability in the predictive ability of the adopted procedure.

Table 12. *Cross validation of the estimated flood quantiles through index flood method, Quadratic Regression (QR) model and Artificial Neural Networks (ANN)*

S.No	Site name	Highest values of observed AMPF (year)			Estimated quantiles through index flood			Estimated quantiles through QR			Estimated quantiles through ANN		
		1st Highest	2nd Highest	3rd Highest	10	20	100	10	20	100	10	20	100
1	Kalpani Deheri	10845 (1995)	9380 (1997)	7915(1988)	6239	10106	26575	6236	10100	26559	5891	9542	25092
2	Wazir Ghari	3080 (1998)	2784 (1982)	849 (1994)	931	1508	3967	2666	4318	11355	1847	2992	7868

5	Khuderzai	13952 (1984)	9000 (1997)	5000 (1985)	3840	6220	16358	4610	7467	19635	4107	6653	17494
6	Jundi Utmanzai	19433 (2010)	11360(2008)	6465 (2011)	4483	7261	19095	1062	1720	4524	1840	2981	7838
7	Lund Khwar East	1891 (1997)	1735 (2006)	1546 (2010)	1057	1712	4503	6235	10100	26559	1838	2977	7828
8	Kalpani Saidabad	52912 (2010)	44321(2013)	39259(2015)	20551	33286	87531	6235	10100	26559	20941	33917	89190
9	Jundi Tangi	18679 (2008)	8382 (2010)	5837 (2007)	2412	3908	10276	1062	1720	4524	2621	4244	11161
10	Swat Ningolai	52098 (2016)	44870(2013)	28403(2014)	19513	31605	83110	18508	29976	78827	19384	31395	82557
11	Bara Kohat Road	11698 (2010)	5688 (1991)	5120 (1997)	3173	5140	13517	2666	4318	11355	3192	5170	13594

The results of *Table 12* show that the estimates, obtained using index flood method, are quite close to the historical values of AMPF at all most all of the sites. The results, obtained using QR model (for ungauged sites), have also been compared with the highest observed values of gauged sites. The comparison reveals that the estimates are comparable for the sites Kalpani Deheri, Wazir Ghari, Chinkar, Khuderzai, Swat Ningolai and Bara Kohat Road for smaller return periods with in the span of data. Significant deviations in the estimates have been observed for the sites Bara Tarnab, Jundi Utmanzai, Lund Khwar East, Kalpani Saidabad and Jundi Tangi for the smaller and longer return periods. The performance of QR estimates for the sites having large magnitude of observed AMPF has been observed as less efficient (sites Bara Tarnab and Kalpani Saidabad).

Estimates obtained through ANN are closed to the highest values of observed/historic AMPF of each site. Moreover, for the sites having large magnitude of observed AMPF, the results of ANN have been observed very close to the highest historical values of AMPF for smaller as well as longer return periods. Based on the historical comparison, ANN can be considered as more reliable relative to QR method to estimate quantiles for ungauged sites for smaller as well as larger return periods.

Summary, findings and conclusions

For a developing state with agro centered economy and facing problems of water shortage along with high variations in the stream flows, the importance of precise flood estimates becomes vast, especially for the small streams and rivers which originates with in the country. Some of the conclusions and key findings of the study are given below:

i. Few critical assumptions associated to the observed data series at various sites for RFFA has been tested and validated through various statistical tests. The results have revealed that the observed data at each site is random, independent, homogeneous and free of regular trends. Moreover, the results of the discordancy measure have shown that none of the site is discordant in the set of eleven gauging sites.

ii. Descriptive statistics have shown that there exist high variations, skewness and kurtosis in the observed AMPF of eleven gauging sites. However, the values of L-kurtosis are relatively smaller than the L-skewness. One possible reason of these variations is the irregular patterns of the monsoon rainfall, as flood flows in Pakistan depend mostly on the heavy monsoon rainfall. Similar findings have been reported by (Hussain, 2017) for the sites of major rivers of Punjab, Pakistan.

iii. The geographical locations of eleven sites reveal that the sites are geographically contiguous; therefore, it may be possible that they belong to the similar cluster with respect to their site characteristics. Formal heterogeneity measure, based on 1000 simulations assuming four parameters kappa distribution as regional probability distribution, confirms that the cluster of eleven sites is definitely homogeneous. GPA distribution has been identified as suitable regional distribution for the region under study. Regional quantiles have been estimated using quantile function of the GPA distribution. Estimated flood quantiles for 10 years return period or more at all sites are greater than the average value of observed AMPF of the respective sites.

iv. For flood quantiles estimation at ungauged sites, QR with robust estimation method and ANN have been used to develop a functional relationship between l_1 (mean of observed AMPF) of each site and their respective available site characteristics. The results show that the estimates using ANN are accurate and reliable as compared to QR analysis especially for longer return periods.

v. To assess the practical validity of the provided estimates, for various return periods, through L-moments based RFFA using index flood method, ANN and QR, a comparison has been illustrated using first, second and third highest values of the recorded AMPF at eleven gauging sites. The estimates of RFFA are closer to the recorded highest values of AMPF at all sites for different return periods. Moreover, the estimates obtained through ANN (though comparison has been provided for gauged sites only) are also very close to the highest historic values of AMPF of each corresponding site for different return periods. Therefore, ANN would be a preferred approach as compared to QR for flood quantiles estimation at ungauged sites (especially for longer return periods) within the homogeneous region.

The study contributes in terms of promoting non-linear relationship of the most influential site characteristic with the observed AMPF with robust estimation method emphasizing the complete justifications related to the estimation procedure of the regression modeling. Moreover, the introduction of ANN to obtain flood quantiles for

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69376959

ungauged sites in Pakistan and comparison with the historical record to investigate the practical validity of the resultant estimates. The results of this study not only provide assistance to the officials dealing with flood risks management but will also be useful for management of agriculture water and design capacity of existing and proposed hydrologic structures in the study region. For instance, a proposed project of the provincial government of KPK is the site Bara Dam (an ungauged site of the study area).

Acknowledgements. Authors are very grateful to the Higher Education Commission, Pakistan for financial support under the project number: 5790/Federal/NRPU/R&D/HEC/2016. We are very grateful to the editor of the journal and anonymous reviewers for their constructive comments to improve the quality of the paper. We are also thankful to the Irrigation Department of Khyber Pakhtunkhwa for providing flood data for the study.

Abstract. *Citrullus colocynthis* L. and *Cannabis sativa* L. are well known herbs for their curative value and farming applications. Thus, extraction was performed to examine yield, total phenolic, flavonoids content and antioxidant activities for farming exertions. Qualitative analyses were conducted to scrutinize alkaloids, glycosides, terpenoids, flavonoids, flavones, steroids, tannins, phenols, saponins and quantitative analysis for total phenolic and flavonoids content was assessed by Folin-Ciocalteu and aluminium chloride colourimetric method respectively, while antioxidant activities was assessed by using 1, 1-Diphenyl-1-picrylhydrazyl. Results showed that distilled water afforded the maximum extract yield followed by methanol and ethanol thus, coefficient of determination (R^2) of extract yield present a positive correlation compared to root mean square error (RMSE). Phytoconstituents except terpenoids from *C. sativa* and *C. colocynthis* leaves were reported while, in contrast, steroids, tannins and phenols were absent in *C. colocynthis* roots. The methanol derived maximum phenolic contents from *C. sativa* and *C. colocynthis* leaves were 36.42 and 37.69 mg gallic acid equivalent GAE/g respectively. However, total flavonoids registered from *C. sativa* leaves and *C. colocynthis* leaves and roots were 59.03, 50.58 and 43.32 mg quercetin equivalent QE/g respectively. Interestingly, *C. colocynthis* leaves produced the highest flavonoids 119.63 mg QE/g using ethyl acetate extract. DPPH inhibition (%) was high in acetone 55.57, hexane 45.98 and distilled water 35.5% from *C. sativa*, *C. colocynthis* leaves and roots respectively. Our findings suggest that studied plants contain phytochemicals, reasonable quantity of phenol and flavonoids content confer to the potential antioxidant activity responsible for insecticidal properties as safer alternatives of synthetic pesticides.
Keywords: *solvent extraction, biochemical analysis, DPPH inhibition %, insecticidal agents*

Introduction

Plants are a God-given treasure to human beings; they produce a variety of secondary metabolites, i.e., alkaloids, flavonoids, steroids, glycosides, terpenoids, tannins, saponins, quinine and phenols (Jung et al., 2009) and have the best curative potential of pharmaceutical medicines, biocides and biopesticides (Edeoga et al., 2005; Wells et al., 2009). Plant-produced phytochemicals perform distinctive functions in agriculture, veterinary, and pharmaceutical industries (Vasu et al., 2009).

Several plants are used as herbal medicines and in agriculture farming, including *Citrullus colocynthis* and *Cannabis sativa*. *C. colocynthis*, locally known as Tumba, is viny herbaceous plant that grows in desert or sandy soils, inhabitant to North Africa and is scattered in northern Africa, eastward Sahara, Morocco, Egypt, Sudan, Iran, Afghanistan, Pakistan, India and other tropical areas (Dane et al., 2007; Pravin et al., 2013). It belongs to the family Cucurbitaceae has, gained attention as a natural botanical

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69616979

insecticide; its insecticidal activity has been evaluated against several insect pests' species (Soam et al., 2013). Moreover, extract obtained by dichloromethane from *C. Colocynthis* showed 98.4% mortality against *Culex quinquefasciatus* at 100 ppm concentration and LC_{50} and LC_{90} value were 19.26 ppm and 84.84 ppm respectively after 24 h of exposure period (Arivoli et al., 2015). Dimetry et al., (2007) documented that *C. colocynthis* formulations are effective biopesticides against stored grain pest like adults of *Callosobruchus maculatus.* Similarly, aqueous extract from various parts of this plant extensively reduced the population of *Rhopalosiphum padi* (Asiry, 2015). The ethanolic extract from *C. colocynthis* exhibited the insecticidal effect against *Aphis craccivora* and this insecticidal potential is due to the presence of alkaloids, glycosides and saponins (Torkey et al., 2009). It has antifeedants, deterrent, growth-regulating and infertility properties against insects (Seenivasan et al., 2004) and familiar in the traditional medicine and used as purgative, anti-inflammatory, cathartic and pain relieving properties (Mehrzadi et al., 2016; Memon et al., 2003; Shi et al., 2014)

Cannabis is another paramount annual weedy and dioceous plant belongs to family Cannabaceae. Historically, it appears to have been cultivated in Northern China since 4000 BC (Mabberley, 2008). *Cannabis* is used as a pest repellent and has been grown as a companion crop to kill several insects, fungi, weeds and nematodes. Its extracts have the ability to repel or kill insects, mites, and microorganisms and can be used as allelochemicals. *Cannabis* leaves have great potential against pests (McPartland, 1997) and these insecticidal properties of plants can be found in their secondary metabolites. For example, crude extract from *Chenopodium ficifolium* and *Jatropha curcas* exhibits aphicidal activity, and alkaloids from *Corydalis turtschaninovii* tubers and *Macleaya cordata* seeds harbour insecticidal potential (Abdoul Habou et al., 2011; Le Dang et al., 2010; Park et al., 2011; Rashid et al., 2013). The essential oil of *Cannabis* has demonstrated antimicrobial activity (Nissen et al., 2010; Novak et al., 2001) while, essential oil from Nepalese origin of *C. sativa* was evaluated for cytotoxic, larvicidal and insecticidal activity, and was found as relatively non-toxic (Satyal and Setzer, 2014).

The main bioactive components i.e. flavonoids, alkaloids, terpenoids and phenols from plant origin show strong insecticidal activity. Benelli et al. (2018) reported that essential oil obtained from fresh inflorescence of *C. sativa* dominated by monoterpenes and sesquiterpenes showed strong toxic effects against *M. domestica* at the rate of 43.3 μg/adult and *M. persicae* with LC_{50} of 3.5 ml/l, moderately toxic against *S. littoralis* larvae at the rate of 152.3 μg/larva while least toxic against *C. quinquefasciatus* larvae with LC_{50} of 252.5 ml/l. It contains pesticidal properties however, tetrahydrocannabinol (THC) is the prime constituent and sixty six other cannabinoids are reported including cannabidiol (CBD) and cannabinol (CBN) showing different effects (Fusar-Poli et al., 2009). Moreover, Pellati et al. (2018) analyzed the bioactive components from inflorescences of *C. sativa* (hemp) by means of innovative HPLC and GC methods coupled with GC-MS and GC-FID. Analysis showed the abundance of cannabidiol (CBD) and Cannabidiolic acid (CBDA) while, β-caryophyllene and β-myrcene were the major terpenes.

Plants are also a source of cheap antioxidant substitutes; they have the ability to scavenge free radicals, avoid the reaction transmission and hence prevent humans from their damage (Moure et al., 2001). Phenolic compounds, flavonoids and terpenes collected from natural plant resources have potential free radical scavenger activity (Mathew and Abraham, 2006) and are omnipresent groups of plant secondary metabolites (Singh et al., 2007).

DOI: http://dx.doi.org/10.15666/aeer/1703_69616979

The phytochemical extraction mechanism is important for obtaining better extract yield both qualitatively and quantitatively and scientists have studied the importance of *C. colocynthis* and *C. sativa* as a medicinal, insecticidal and antibacterial agent, but existing knowledge and research presented by different authors is limited to use of few solvents for extraction, extract properties as well as qualitative, quantitative analysis and antioxidants properties are not properly investigated in such a comprehensive way. Although, selected plants belong to different families and also harvested from different locations but it is worth noted that selected plants are potential source of phytochemicals and antioxidants responsible for insecticidal activities. Thus, at present extensive studies have been conducted on qualitative and quantitative extract estimations to identify different phytochemicals responsible for insecticidal potential and to determine the best extraction solvent with maximum phenolic and flavonoid contents and antioxidant activities using seven different solvents from *C. sativa* (leaves) and *C. colocynthis* (leaves and roots) collected from China and Pakistan respectively over the years 2017-2018.

Materials and methods

Plant material collection

Citrullus colocynthis (Colocynth), locally known as Tumba, and *Cannabis indica* formerly called as *Cannabis sativa* sub-species *indica* (Hemp) were the study plants. Young leaves and roots of Colocynthis were collected from (Bahawalnagar) a desert area of Punjab Province, Pakistan from March-April 2018 (*Fig. 1a* and *1b*), while hemp leaves were collected from different locations of Shenyang, Liaoning Province, China from August-September 2017 (*Fig. 1c*). In total ten samples of each plant were collected belongs to same area and same species. Collected samples of colocynthis and hemp were then mixed together separately to obtain bulk volume of each plant. Botanical identification of colocynthis as *C. colocynthis* was performed at Department of Botany Pir Mehar Ali Shah Arid Agriculture University Rawalpindi (PMAS, AAUR) Pakistan, while hemp was identified as *C. sativa* by Professor Ji Mingshan, Department of Pesticides Science, College of Plant Protection, Shenyang Agriculture University, Shenyang Liaoning China.

Sample preparation

Leaves and roots were washed, dried under shade at room temperature, crushed into a fine powder by using an electric blender, sieved through 100 µm mesh and finally 1 kg of each plant sample was obtained and stored in airtight glass jars at 4°C.

Solvent extraction

Different solvents were selected with varying polarity level to extract crude material by cold extraction method which was simple, easy and safe for elution of bioactive compounds along with pigments (Handa et al., 2008). For each solvent extraction of each bulk plant material, 100 g of powdered sample was taken in a 1000 ml conical flask separately and extracted with 400 ml of respective solvent (Mondal, 2015). Extraction was performed at room temperature for 72 h (Mojab et al., 2010; Senguttuvan et al., 2014). The extraction process was repeated thrice to ensure that all polar and non-polar materials were eluted completely (Waiganjo et al., 2013). Filtered the contents, and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69616979

concentrated to reduce the volume on a rotary evaporator (Buchi Switzerland R-210). The concentrated filtrate was dried in a fume cupboard at 25°C. Solvent-free extract was placed in a stoppered glass bottle and stored at 4°C for further use. The physical properties of each extract (colour, stickiness and appearance) were recorded visually.

Figure 1. a *C. colocynthis plant.* ***b*** *C. colocynthis (roots).* ***c*** *C. sativa plant*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69616979

Aqueous extraction

A total of 100 g powdered plant samples was extracted at room temperature with 400 ml of distilled water for 72 h. The rest of the procedure was same as for solvent extraction.

Calculation of extract yield (g)

The extract yield was calculated for each solvent from the respective plant material and stored at 4°C for further studies.

Model validations

The relationship was used to develop the model for yield and for the comparison of coefficient of determination (R^2) values with root mean square error (RMSE). The coefficient of determination R^2 and RMSE represent the standard deviation of the residuals (prediction errors). Residuals are the measures that how the values are far from the regression lines where the data points were. This measure also told us how condensed the data were around the line of best fitness and model validity (Hossain et al., 2017). Performance of the model in the crude extract yield was evaluated by using RMSE. In the experiment with observations 'n', RMSE was calculated by identity *Equation 1* (Debaeke et al., 1997).

$$\mathbf{RMSE} = \sqrt{1/n \times \sum_{j=1}^{n} ((Yield_{mes} - Yield_{sim})^2} \quad \text{(Eq.1)}$$

Qualitative phytochemical analysis

Phytochemical screening tests were performed to evaluate the presence or absence of phytoconstituents in *C. colocynthis* and *C. sativa* extracts using standard methods.

Test for alkaloids

For the estimation of alkaloids, 0.5 ml of each solvent extract was allowed to dry and 2 ml of 2% hydrochloric acid (HCl) was added to the residue in the test tube for 15 min in a water bath at 100°C. After cooling, the mixture was filtered and divided into two equal portions. A few drops of Mayer's reagent were added to one portion, while a few drops of Dragendoff's reagent were added to the other portion. Turbidity or the presence of a yellow precipitate confirm the presence of alkaloids (Siddiqui and Ali, 1997).

Test for glycosides

The presence of glycosides was evaluated by adding 2 ml distilled water and 2 ml 5% ferric chloride ($FeCl_3$) into 2 ml extract. The mixture was heated for 15 min in a water bath and then allowed to cool. Next, 1 ml benzene was added to the mixture and subjected to settle for 1 min after shaking. Next, 4 to 5 drops of concentrated ammonia (NH_3) was added. A pink or red colour indicates the presence of glycosides (Siddiqui and Ali, 1997; Siddiqui et al., 2009; Sofowora, 1993).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69616979

Test for terpenoids and steroids

The presence of terpenoids and steroids was determined by a previously described method (Kantamreddi and Lakshmi; Siddiqui and Ali, 1997) with slight modifications. Briefly, 0.5 g of solvent-free extract was added in 2 ml chloroform and then filtered. The filtrate was placed on ice; addition of 2 ml of acetic acid and then a few drops of concentrated sulfuric acid (H_2SO_4) was carefully applied to the inner sides of the test tubes. The emergence of a pink or pinkish brown colour/ring indicates the terpenoids existence, while a blue or bluish green colour for steroids presence and the combination of pink and blue/bluish green colours confirmed the presence of both terpenoids and steroids.

Test for flavonoids and flavones

Two millilitres of diluted sodium hydroxide (NaOH) was added to the 3 ml extract solution, which turned the solution into a yellow colour. The solution was treated with 1 ml 5N hydrochloric acid (HCl), which turned the solution colourless, indicate flavonoids, and an orange colour indicate flavones (Siddiqui and Ali, 1997; Siddiqui et al., 2009; Sofowora, 1993).

Test for tannins

For the estimation of tannins, 1 ml distilled water and ferric chloride ($FeCl_3$) 1-2 drops were added to 0.5 ml plant extract. The appearance of a blue and green/black colour indicates gallic and catecholic tannin, respectively (Iyengar, 1995).

Test for phenols

To detect phenols, 1 ml of extract solution was added to 2 ml distilled water and a few drops of 10% ferric chloride ($FeCl_3$). The appearance of a green or blue colour is the indication of phenols presence. Next, 0.50 g of plant extract was added and allowed to dissolve in distilled water and then 3 ml of 10% lead acetate was added. The presence of phenolic compounds was confirmed by the appearance of white precipitation (Trease et al., 2003).

Test for saponins

One gram of solvent-free extract was diluted with 20 ml of distilled water and shacked vigorously. The formation of a foam layer (1 cm) indicates the presence of saponins (Siddiqui and Ali, 1997).

Quantitative phytochemical analysis

Determination of total phenolic content (TPC)

The total phenols present in the crude extract of *C. colocynthis* and *C. sativa* was calculated by the Folin-Ciocalteu reagent method, with slight modifications. Briefly, 1 ml plant extract (1 $mgml^{-1}$ of solvent) was added to 2.5 ml of 10% Folin-Ciocalteu reagent (1:1) and 2 ml of 2% sodium carbonate (Na_2CO_3). The consequential mixture was allowed to stand for incubation for 15 min at room temperature in the dark. The solution was then transferred to a 96-well ELISA plate to measure the absorbance at 765 nm using an absorbance microplate reader (SpectraMax 190, manufactured in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69616979

China; designed in USA). All test calculations were carried out in triplicate. A standard calibration curve was constructed using gallic acid (1 $mgml^{-1}$). The results were calculated from the standard curve obtained by using different concentrations of gallic acid (1, 0.50, 0.25, 0.10, 0.05, 0.02, 0.01 and 0 $mgml^{-1}$) and are expressed as gallic acid equivalent (GAE) mgg^{-1} of extracted compounds (Aiyegoro and Okoh, 2010).

Determination of total flavonoid content (TFC)

The amount of total flavonoids in the crude extract of *C. colocynthis* and *C. sativa* was estimated by a colourimetric method using aluminium trichloride ($AlCl_3$) and sodium hydroxide (NaOH). Briefly, 1 ml of extract (1 $mgml^{-1}$ of solvent) was added to 3 ml methanol, 0.2 ml 10% aluminium chloride, 0.2 ml 1M potassium acetate (CH_3COOK) and 5.6 ml distilled water. The resulting mixture was incubated at room temperature in the dark for 30 min. The assay was performed at 420 nm in a 96-well ELISA plate. Quercetin was used as the standard (1 $mgml^{-1}$) and a standard curve was obtained using different concentrations of quercetin (1, 0.50, 0.25, 0.10, 0.05, 0.02, 0.01 and 0 $mgml^{-1}$). Results are expressed as quercetin equivalent (QE) mgg^{-1} of extracted compounds (Aiyegoro and Okoh, 2010). All test determinations were carried out in triplicate.

Determination of DPPH radical scavenging activity

The antioxidant activities of crude extracts of *C. colocynthis* and *C. sativa* were measured on the basis of the scavenging activities of the stable 1,1-diphenyl-1-picrylhydrazyl (DPPH) radical (Yu et al., 2003). Briefly, 0.5 ml of each respective extract was added to a sample cavity containing 3.5 ml of freshly prepared methanol solution of DPPH (0.004 $g100ml^{-1}$). The mixture was subjected to incubation for 30 min at room temperature in the darkness and absorbance was calculated at 517 nm. The percent inhibition of DPPH (I %) was calculated from the decrease of absorbance by *Equation 2*. A lower absorbance value represents higher free radical scavenging activity (Zhao et al., 2008).

$$I\% = \frac{A_{blank} - A_{sample}}{A_{blank}} \times 100 \quad \text{(Eq.2)}$$

Whereas A_{blank} = absorbance of control; A_{sample} = absorbance of samples.

Statistical analysis

Data were analysed statistically by one-way analysis of variance (ANOVA) in Duncan's multiple range test (DMRT) and values are represented as the mean±standard deviation, with P = 0.05 indicating a significant difference. Analyses were conducted by using SPSS 13.0 (Inc.) software while graph was constructed by sigma Plot software.

Results

Potential solvent for extraction

Extraction was performed on *C. colocynthis* leaves and roots and on *C. sativa* leaves using different solvents and distilled water. Extract yields (g) was calculated and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69616979

presented in *Figure 2* while extract properties were described in *Table 1*. *Figure 2* and *Table 1* showed that using distilled water, *C. sativa* leaves produced a significant yield (11.688 g), with the physical properties of dark brown colour, non sticky and dry solid, followed by methanol (9.412 g), black shiny, more sticky, and ethanol (6.296 g), blackish and shiny.

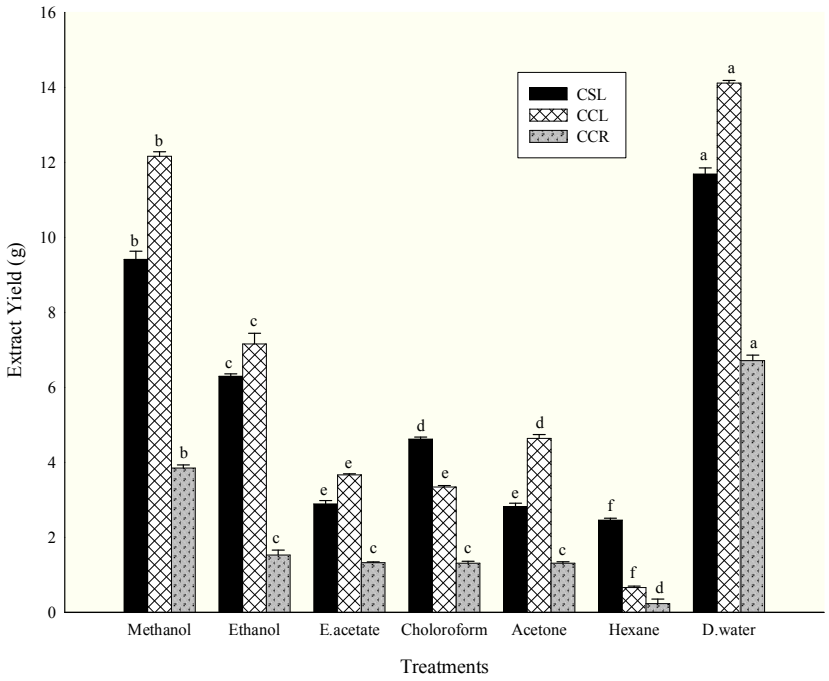

Figure 2. *Extract yield (g) of C. sativa leaves (CSL) and C. colocynthis leaves (CCL) and roots (CCR) by using different solvents. Highest yield produced by D. water and methanol while lower yield produced by hexane from CCL, CSL and CCR respectively. Data corresponding to treatments labelled with different letters are significantly different (Duncan's multiple range test DMRT at P ≤ 0.05); the error bars represent standard of the means*

Table 1. *Properties of CSL, CCL and CCR crude extract*

Solvents extract	CSL			CCL			CCR		
	Colour	Stickiness	Appearance	Colour	Stickiness	Appearance	Colour	Stickiness	Appearance
Methanol	Black, shiny	More sticky	Slowly flowable	Greenish black, shiny	Sticky	Oily, flowable	Brown	Non-sticky	Semi solid, non-oily
Ethanol	Blackish, shiny	More sticky	Slowly flowable	Brownish black, shiny	Sticky	Oily, flowable	Yellowish brown	Non-sticky	Dry, waxy
E. acetate	Blackish	Sticky	Oily, flowable	Blackish	Sticky	Oily	Dark brown	Less sticky	Dry, non-oily
Chloroform	Brownish black	Less sticky	Less oily, non-flowable	Black, Shiny	Less sticky	Less oily, non-flowable	Brown	Less sticky	Semi-solid, non-flowable
Acetone	Brownish black	sticky	Oily, flowable	Greenish black	Sticky	Oily	Yellow	Non-sticky	Dry, Non-flowable
Hexane	Yellowish	Less sticky	Non-oily, non flowable	Yellowish brown	Less sticky	Non-oily, non flowable	Light yellow	Non-sticky	Semi-solid, non-flowable
Distilled water	Dark brown	Non-sticky	Dry solid	Dark brown	Less sticky	Less oily	Brown	Less sticky	Dry, non-flowable

CSL (*C. sativa* leaves), CCL (*C. colocynthis* leaves), CCR (*C. colocynthis* roots)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69616979

C. colocynthis leaves produced significant yield (14.115 g) using distilled water, with the physical properties of dark brown colour, less sticky followed by methanol (12.161 g), greenish shiny black and sticky, and ethanol (7.158 g), brownish black shiny and sticky.

C. colocynthis roots recorded a significantly high yield by distilled water (6.712 g), with the physical properties of dark brown colour and less sticky, followed by methanol (3.848 g), with the physical properties of greenish black, oily and ethanol (1.528 g), yellowish brown and waxy. However, the yields recorded by ethyl acetate (1.324 g), chloroform and acetone (1.312 g) were non significant ($P > 0.05$) to each other but differed significantly compared with all other treatments.

Model validation

The model validation performance for extract yield in response to *C. sativa* leaves and *C. colocynthis* leaves and roots is listed in *Table 2*. The *C. sativa* leaves extract exerted significant ($P < 0.001$) effects on the aqueous extract compared to all other treatments. The extract yield revealed that R^2 values of *C. sativa* using methanol, ethanol, ethyl acetate, chloroform, acetone, hexane and distilled water were 0.99, 0.93, 0.92, 0.87, 0.87, 0.93 and 0.82 respectively showed better performances compared to RMSE. Data on the extract yield for *colocynthis* leaves were statistically analysed and recorded as significant ($P < 0.05$) when obtained by methanol, with R^2 values of 0.99, 0.80, 0.98, 0.99, 0.81, 0.99 and 0.91. These extract yields for *C. colocynthis* roots were highly significant ($P < 0.01$) when obtained by distilled water and methanol compared to all other treatments. However, R^2 values of *C. colocynthis* roots 0.89, 0.84, 0.95, 0.94, 0.99, 0.94 and 0.92 showed the best curvature and best fit to the obtained data.

Table 2. *Regression model for phytochemical screening of cumulative extract yield*

Solvent extract	CSL		CCL		CCR	
	R^2	*RMSE*	R^2	*RMSE*	R^2	*RMSE*

Qualitative phytochemical analysis

Tests for phytochemical screening were conducted to determine the presence of bioactive compounds, namely, alkaloids, glycosides, terpenoids, flavonoids, flavones, steroids, tannins, phenols and saponins from *C. colocynthis* and *C. sativa* (*Tables 3, 4* and *5*). However the confirmation of a bioactive compound was referred as high presence (++) on strong resemblance; moderate presence (+) on medium or weak and (-) with no resemblance, appearance or change of colour of the reactive solution. The detection of alkaloids in the solvent extract was confirmed by turbidity or the emergence of a yellow

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69616979

precipitate. The glycosides presence was confirmed by the appearance of a red or pink colouration in the reaction mixture. Positive results for terpenoids were confirmed by *C. colocynthis* roots, with the appearance of a pink or pinkish brown colour. Flavonoids and flavones were recorded by the transformation of the mixture from yellow to colourless and orange, respectively. The presence of tannins was confirmed by the appearance of a blue colour for gallic tannin and green/black for catecholic tannin. Blue or green colour in the reaction mixture indicated the presence of phenols while, foaming character in extract solution is important for the confirmation of saponins.

Phytochemical analysis indicated a high presence of steroids in chloroform and hexane extracts and a moderate presence in most other solvent extracts from *C. sativa* leaves except for distilled water extract (*Table 3*). Terpenoids were absent in all extracts. Alkaloids were absent in ethyl acetate, chloroform and distilled water extracts, while glycosides were present in all of these extracts except for hexane. Moreover, flavonoids were highly present in methanol and ethanol but moderately present in acetone and hexane. Flavones were present in acetone, as well as hexane and distilled water extracts. Saponins were present in chloroform, hexane and Distilled water extracts. However, gallic tannins were absent in all extracts, while catecholic tannins were absent in acetone, hexane and distilled water extracts. Phytochemical screening showed that phenols were present in methanol, ethyl acetate, ethanol and distilled water extracts.

++high presence, +moderate presence, -absence

C. colocynthis leaves showed a moderate presence of phenols by methanol, ethanol, ethyl acetate, acetone and distilled water but an absence in other extracts. However, a high glycoside presence was recorded by chloroform and hexane, with a moderate presence by ethanol and ethyl acetate (*Table 4*). Alkaloids were absent in all extracts except for methanol. Terpenoids were absent in all extracts. A high presence of flavonoids was recorded in methanol, ethanol and ethyl acetate, while a moderate presence of flavonoids was recorded in chloroform and hexane extracts. Flavones were present in ethyl acetate, chloroform and hexane extracts. Steroids were present in all extracts except for distilled water. Tannins were present in methanol, ethanol, ethyl acetate and acetone extracts, while saponins were present only in distilled water extract.

As shown in (*Table 5*), the phytochemical analysis of *C. colocynthis* roots demonstrated the presence of glycosides and alkaloid in distilled water and acetone extract, respectively. Steroids, tannins and phenols were absent in all extracts. However, terpenoids showed a high presence in ethanol and a moderate presence in ethyl acetate, chloroform and acetone extracts but an absence in methanol and distilled water. Although the presence of flavonoids was recorded in all extracts except for distilled water extract, flavones were recorded by methanol and ethanol only. The presence of saponins was recorded by methanol, ethyl acetate and distilled water extract.

Quantitative analysis

Total phenolic content (TPC)

The total phenolic contents of various extracts from *C. colocynthis* leaves and roots and *C. sativa* leaves varied slightly. The maximum and minimum phenolic contents from *C. sativa* leaves were recorded by methanol and distilled water (36.42±1.905 and 29.98±0.56 mg gallic acid equivalent GAE/g, respectively). However, minimum phenols recorded by ethyl acetate and ethanol were (12.16±0.977 and 2.70±0.109 mg GAE/g) respectively while other solvents recorded negative phenols (*Table 6*). Methanol and distilled water extracts from *C. colocynthis* leaves showed a higher phenolic content of 37.69±0.35 and 37.25±0.83 mg GAE/g, respectively, followed by acetone, ethanol and ethyl acetate (24.08±1.78, 22.82±0.37 and 5.73±0.56 mg GAE/g, respectively). However, *C. colocynthis* roots showed negative results for phenols.

Distilled water	29.98±0.56 [b]	37.25±0.83 [a]	-

Results are presented as the mean values ± standard deviation. Same letters within a column indicate that mean values are not significantly different (P > 0.05) according to Duncan's multiple range test; CSL (*C. sativa* leaves); CCL (*C. colocynthis* leaves); CCR (*C. colocynthis* roots)

Total flavonoid content (TFC)

The total flavonoid content was high in the methanol and ethanol extracts of *C. sativa* leaves (59.03±1.31 and 56.00±1.85 mg quercetin equivalent QE/g, respectively), followed by hexane and acetone (17.35±0.43 and 12.08±0.62 mg QE/g, respectively) (*Table 7*). Thus, ethyl acetate extract from *C. colocynthis* leaves produced the highest flavonoid content (119.63 mg QE/g), followed by ethanol, methanol and hexane (54.84±0.90, 50.58±0.85 and 22.7±1.14 mg QE/g, respectively). However, the lowest flavonoid content was detected by chloroform (1.73±0.09 mg QE/g). The total flavonoid content of *C. colocynthis* roots by methanol and ethanol was the highest (43.32±0.33 and 42.34±0.23 mg QE/g, respectively), followed by ethyl acetate and acetone (28.93 and 8.86 mg QE/g, respectively). Chloroform and hexane extracts showed the lowest flavonoid content (2.23±0.18 and 1.23±0.09 mg QE/g, respectively).

Table 7. *Total flavonoids content (TFC) from CSL, CCL and CCR*

Solvents extract	Total flavonoid contents mg QE/g

DPPH radical scavenging activity

DDPH is a stable and free radical which is easily dissolved in methanol showed characteristics colour absorption at 517 nm using spectrophotometer. Free radicals are scavenged by antioxidant molecules due to donation of hydrogen molecules and the colour of DPPH assay solution changed to light yellow colour causing reduction of absorbance. To determine free radical scavenging activity, the DPPH radicals are widely used. Data on the 1,1-Diphenyl-1-picrylhydrazyl (DPPH) scavenging activity of free radical of *C. sativa* leaves and *C. colocynthis* leaves and roots are presented in (*Table 8*).

Table 8. *DPPH radical scavenging activity from CSL, CCL and CCR*

Solvents extract	DPPH Inhibition (%)		
	CSL	CCL	CCR
Methanol	49.5±0.7 [b]	30.65±1.07 [e]	23.63±0.68 [f]
Ethanol	54.1±0.2 [a]	36.52±0.62 [c]	33.83±0.351 [b]
Ethyl acetate	46±1 [c]	27.66±1.53 [f]	27.65±0.01 [e]
Chloroform	40.6±0.8 [d]	29.64±0.05 [e]	30.69±0.8 [c]
Acetone	55.57±1.2 [a]	33.5±0.51 [d]	30.97±0.98 [c]
Hexane	41.7±0.5 [d]	45.98±0.14 [a]	29.12±0.7 [d]
Distilled water	34.2±1.1 [e]	39.8±0.21 [b]	35.5±0.16 [a]

Results are presented as the mean values ± standard deviation. Same letters within a column indicate that mean values are not significantly different ($P > 0.05$) according to Duncan's multiple range test; CSL (*C. sativa* leaves); CCL (*C. colocynthis* leaves); CCR (*C. colocynthis* roots)

For *C. sativa* leaves, DPPH inhibition (%) by distilled water and acetone ranged from 34.2±1.10 to 55.57±1.20%. For *C. colocynthis* leaves, the DPPH inhibition (%) of chloroform and hexane extract ranged from 29.64±0.05 to 45.98±0.14%. However, the DPPH scavenging activity of *C. colocynthis* roots for methanol and distilled water ranged from 23.63±0.68 to 35.5±0.16%. It was also noted that all extracts of *C. sativa* and *C. colocynthis* showed varying levels of DPPH radical scavenging activity.

Discussion

The comparative extraction of crude extracts from *C. colocynthis* and *C. sativa* demonstrated that using methanol as an extraction solvent resulted in the maximum extract yield followed by ethanol, chloroform, ethyl acetate, acetone and hexane. However, using distilled water instead of organic solvent produced the maximum yield. Our results are consistent with (Awang et al., 2016; Markom et al., 2007; Pin et al. 2009) who reported that the highest extract yield was obtained by using water for extraction from *M. malabathricum* leaves, *Phyllanthus niruri* and *Piper betel*. Among the polarity-based solvents, methanol produced the maximum yield, followed by ethanol. Similar results were demonstrated by (Dhawan and Gupta, 2017; Paulsamy and Jeeshna, 2011) that methanol produced the maximum extract yield from *Datura metel* and *H. radicata* leaves.

The extract yield revealed that R^2 relationship of *C. sativa* ranging from 0.82-0.99 for distilled water and methanol have strong positive correlation compared to RMSE 0.308-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69616979

0.045 which showed better performance of model fitness. The trendline regression R^2 for *C. colocynthis* leaves were 0.99 for methanol, chloroform and hexane showed strong correlation while for *C. colocynthis* roots 0.99 by acetone recorded the best curvature and fitness of the model with recorded data.

The extraction of secondary metabolites highly depends on the extraction technique, solvent used and the chemical properties of the compounds. The analysis of *C. Sativa* leaf extracts showed the presence of alkaloids, glycosides, steroids, flavonoids, flavones, tannins, phenols and saponins and the absence of terpenoids. Relevant results were presented by Audu et al. (2014), who reported the presence of phytochemicals except for saponins and phenols in the leaves and roots of *C. sativa*. Various bioactive compounds such as flavonoids, alkaloids, glycosides, carbohydrates and essential oils have been documented previously from *C. colocynthis* by Wasylikowa and Van der Veen (2004). These isolated compounds like Flavonoids, isovitexin, isosaponarin and isoorientin 3'-*O*-methyl ether are revealed as significant antioxidants (Kumar et al., 2008). The results described by Najafi et al. (2010) on the phytochemical constituents from *C. colocynthis* leaves showed the presence of alkaloids, glycosides, tannins, flavonoids and saponins, consistent with our results. However, the results from our study are strongly correlated with Uma and Sekar (2014), who reported the presence of secondary metabolites in *C. colocynthis* leaves and roots. Singh (2010) reported the presence of bioactive compounds but no saponins or anthraquinones were reported from C. *colocynthis* roots.

C. colocynthis contains mostly flavonoids, while *Ziziphus spina-christi* contains the highest phenolic content (Tawfik et al., 2015). Phenols are biologically active compounds that are potent antioxidants with free radical scavenging behaviour. Haniyeh et al. (2016) reported that phenolic and flavonoid contents from the methanol extract of *C. Colocynthis* leaves were 79.78 and 45.46 μgml^{-1}, respectively. Similar findings were also observed herein, with phenolic and flavonoid contents of 37.69 and 50.58 mgg^{-1}, respectively. However, phenols were absent in all extracts of *C. colocynthis* roots. Moreover, Rizvi et al. (2018) reported the presence of polyphenol content from *C. colocynthis* leaves using different polarity solvent, methanol, ethyl acetate, chloroform, hexane and distilled water 74.34. 55.16, 56.32, 67.61 and 86.6 $mg100g^{-1}$ respectively which is relevant to our findings for phenol content from *C. colocynthis* leaves. Maximum phenol and flavonoids content recorded by methanol from *C. sativa* 36.42 and 59.03 mgg^{-1} are consistent with Abd-Alla and Haggag (2013) who reported total phenol and flavonoid contents of 9.62 mgg^{-1} and 1.9 mgg^{-1}, respectively, with 14.5% antioxidant activity from the leaf extract of *C. sativa*.

The results from different studies have revealed that phenols, flavonoid content and antioxidant properties differ in different parts of *C. colocynthis*. Plants are an active source of valuable chemicals and other bioactive compounds that contain pesticidal activity against numerous insect pests (Koul and Walia, 2009). Salama and Al Rabiah (2015) reported the presence of phenol, flavonoid and antioxidant activities from twenty medicinal plants, with maximum phenol and flavonoid contents of 224.49 mg/100 g and 126.24 $mg100g^{-1}$, respectively, from *C. colocynthis* (seeds). However, the inhibition percent in the ethanol extracts of roots and leaves was 56.8-67.2% and 5.97-6.42 μgml^{-1}, respectively. Among the ethanol extracts, leaves had the highest free radical inhibition activity in *C. colocynthis* (IC_{50} = 2.97, 67.2%) (Hussain et al., 2013). Our findings also demonstrated that inhibition (%) in the ethanolic extract from leaves and roots was 36.52 and 33.83%, respectively. However, there are variations in antioxidants contained

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69616979

by *C. sativa* and *C. colocynthis* among different solvents extract. Additionally, Eddouks et al. (2002) reported that methanolic extract of *C. colocynthis* seed exhibited highest inhibition 79.4 and 72.4% by using 1, 1-diphenyl-2-picrylhydrazyl (DPPH). Rathanavel and Arasu (2014) documented that Colocynth contains several phytoconstituents, such as flavonoids, alkaloids, glycosides, tannins saponins, carbohydrates and essential oils responsible for insecticidal activities.

Results from phytochemical analysis of *C. sativa* and *C. colocynthis* are characterized by the presence of various phytochemicals along with phenols, flavonoids content and antioxidant activity. However, data on previous studies for extraction and comparing the extract yield using different solvent, qualitative and quantitative analysis, antioxidant activity and use of bioactive compounds as alternative of synthetic chemicals from these plants is limited. Also synthetic agents in present era liberate maximum residues in environment and naturally grown population which is burning issue in current agro-ecosystem. So the study was conducted to examine extract yields using seven different solvents by solvent extraction method, to observe physical properties of extract, scrutinize bioactive compounds and to quantify total phenol, flavonoids contents and to asses' antioxidant activities by DPPH radical scavenging from crude extracts of study plants. Also solvents extract from *C. colocynthis* roots, yield calculation and physical properties were studied for the first time in such a comprehensive way.

Conclusion

The results demonstrated that crude extracts obtained by using different solvents from *C. colocynthis* and *C. sativa* possess biological compounds, such as terpenoids, glycosides, alkaloids, flavonoids, flavones, steroids, tannins, phenols and saponins. Owing to extraction, distilled water afforded the maximum yield followed by methanol with high phenol and flavonoid content. Hence, the studied plants are a rich source of phytocompounds, conferring them interesting antioxidant activity and supporting their use as potential insecticidal agents which are safe for environment and biodiversity. However, comprehensive research is needed to identify additional solvents and techniques for the extraction, isolation, purification and identification of active ingredient responsible for insecticidal activities.

Abstract. Remobilization coefficient of 21 winter bread wheat genotypes has been studied under rainfed conditions during two growing seasons with contrasting climate of Mountainous Shirvan district of Azerbaijan Republic. Remobilization coefficient was found to be higher in the year of drought compared to the year with normal precipitation. Remobilization coefficient of short and medium height genotypes was higher than that of tall genotypes, which indicates a negative correlation between plant height and remobilization coefficient. However, this correlation was not observed in the year with severe drought stress.
Keywords: *bread wheat, remobilization coefficient, drought, plant height, grain yield*

Introduction

As all living organisms, plants are also exposed to the effects of adverse environmental factors. Under the influence of these factors, stress or state of the "tension", providing the universal protective reaction during growth, is created. The existence of the "echeloned defense" system provides a necessary tolerance for plant organisms and it is a main condition for the protection of species. Currently, intensive efforts have been made for studying stress mechanisms at molecular-genetic and cellular levels (Mwadzingeni et al., 2016; Gupta et al., 2017). Response of plants to stresses changes depending on plant species and genotype, duration and intensity of water deficiency, plant age and growth phase, plant organ and cell type, and at last cell compartmentalization (Zhu, 2002; Rampino et al., 2006). A high ability of the plant to change its metabolism according to the environment leads to a high reaction norm for this plant, which is a distinctive trait for tolerant plant varieties (Moussa and Abdel-Aziz, 2008).

Various stresses cause a decline in the productivity of agricultural plants. Considering the possibility of future difficulties in the meet of the demand of population in food products, one of the main tasks is developing new productive and tolerant varieties using genotypes tolerant to stress factors-adverse soil and climatic conditions, drought, high temperature, salinity etc. (Aliyev, 2012). Water restriction is main factor that limiting plant growth.

Wheat (*Triticum aestivum* L.) is one of the main crops in human nutrition. Adverse biotic and abiotic stresses negatively affect the productivity of wheat, do not allow the realization of genetic potential (Allahverdiyev et al., 2018). The forming of winter wheat yield depends on the factors affecting plants during a long vegetation period. Annual precipitation and air temperature are very important ecological factors affecting plant productivity. From this point of view developing drought tolerant varieties is of great importance. Therefore, new methods considering physiological properties of plants are to be used along with classical methods.

The process of remobilization has also a great role in the formation of grain yield of wheat plants under drought. Remobilization is a process of the use of compounds, which had been synthesized prior to the reproductive phase and preserved as resources in the stem, at the stages of grain formation and grain filling. Kalayci et al. (1998) argued that remobilization in wheat genotypes is of great importance only when drought is imposed at the grain filling stage. According to Blum and Pnuel (1998) remobilization has no effect on productivity when drought stress is imposed at the tillering stage, plants are not exposed to stress at the grain filling stage and productivity is about 1.78 ton/ha. Yang et al. (2002) reported high variation among genotypes for relative contribution of photosynthesis and stem reserves in wheat grain yield under the heat stress condition. Some genotypes tolerated the heat stress by preserving the stable photosynthesis and some others via the stem reserves. During grain filling, most of assimilates translocated to grains are provided by current photosynthesis in flag, penultimate leaves and spike (Arduini et al., 2006). A substantial part of grain dry matter can originate from remobilization of assimilates accumulated until anthesis and deposited temporarily in different vegetative parts of plants (Dordas, 2012).

Some authors showed that remobilization was more important during ear filling in cases of weakened photosynthesis, when soluble carbohydrates accumulated earlier in stem were transported to grain, because more carbohydrates were accumulated in tall and thick stems (Reynolds et al., 1999).

It was also shown that as leaf yellowing and plant drying processes proceed very fast at high temperatures, because of the short period between the start of yellowing and maturing, less dry matter can be accumulated in grain by remobilization (Zamani et al., 2014). Thus, the study of remobilization is suggested to be very important for developing wheat genotypes with more stable productivity under drought conditions. The presented research is devoted to the study of remobilization in winter wheat under dry rainfed conditions.

Materials and methods

Plant material and growth conditions

The present studies were performed in the field of Gobustan Experimental Station, Research Institute of Crop Husbandry, Azerbaijan. Twelve winter bread wheat varieties and nine stable lines selected for rainfed regions were used in the experiments. The experiments were conducted during the 2012-2013 and 2013-2014 growing seasons under dry rainfed conditions of Mountainous Shirvan district. Each genotype was grown in 1 m^2 areas with three replications according to randomized block design. Sowing was done at an average density 400 seeds × m^{-2}. The cultivated area is at an altitude of 780 m above sea level and it is light chestnut type, medium carbonate soil. According to the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69816987

perennial data, the amount of annual atmospheric precipitation in the region is 350-400 mm. Precipitation occurs mainly during autumn-winter periods.

Treatment

Sprinkling was performed with 4% magnesium chlorate ($Mg(ClO_3)_2$) on 20-25 days after earing in order to dry green parts of the plant. Prior to the sprinkling ear samples were taken. Two days after the sprinkling, plants began to dry. After the complete maturation, samples were taken from unsprinkled area for control and 10 ears were taken from the sprinkled area. The ear samples were kept at 85 °C for 24 h in the dryer, then grains were detached from ears, weighed and the weight of one grain was calculated. Coefficient of remobilization was calculated according to the formula (Kalayci et al., 1998): CR = (WGS - WGB) / (CW - WGB) × 100%, where: CR – coefficient of remobilization, WGS – weight of one grain from the sprinkled area (mg), WGB – weight of one grain before sprinkling (mg), CW – weight of one grain from the control area (mg).

Statistical analyses were performed by SPSS 16 software.

Results and discussion

The monthly rainfall and average temperatures during the wheat vegetation period (September-June) for the two growing seasons and average perennial (1984-2014) shown in *Table 1* were provided by the Gobustan Hydrometeorological Station. As seen in the table amount of the precipitation during the 2012-2013 growing season was 337.7 mm, and during the 2013-2014 growing season it significantly decreased to 222.3 mm. Air temperature also varied during the years of the study. Thus, in 2012-2013 air temperature was in average perennial limits, but in the spring months of the 2013-2104 growing season air temperature was above average perennial values. The mentioned changes in weather conditions affected the remobilization process in winter bread wheat.

The remobilization coefficient of the studied genotypes is presented in *Table 2*. As seen in the table in 2013 the average remobilization coefficient of all studied genotypes was 13.2%. In 2014 this value significantly increased to 21.4%. Low values of the remobilization coefficient in the 2012-2013 and high values in the 2013-2014 growing seasons are attributed to favorable and unfavorable weather conditions of these years, respectively.

Average		**13.2**	**21.4**	**17.3**

In 2013 the remobilization coefficients of the Gyrmyzy gul 1, Murov 2, Vostorg and Aran varieties were found to be higher compared with other studied varieties. This may be due to the late maturation of the varieties, except Murov 2, thus, the ear filling stage of these varieties occurred under high temperature and drought period. There were also reports on late maturing varieties, which remobilization coefficients were higher due to drought and high temperature (Chekich, 2007). Higher remobilization coefficient of Murov 2 compared with other genotypes is probably related to individual biological properties of this genotype. It should be noted that the remobilization coefficients of the Vostorg and Gyrmyzy gul 1 varieties were also higher in 2014. There were reports on the existence of a positive correlation between productivity and remobilization coefficient during drought years (Kalayci et al., 1998; Chekich, 2007). However, we did not observe a significant relation between the remobilization coefficient and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69816987

productivity during favorable 2013 year and unfavorable 2014 drought year. We suggest that remobilization was not very important for the productivity under favorable weather conditions of 2013.

In 2014 remobilization coefficient increased in all genotypes because of severe drought and temperature stress. However, the period between the beginning of leaf yellowing and maturing was very short and other factors appeared to be more important for productivity than remobilization. As a result, in spite of the higher remobilization coefficient during the drought year, there was no correlation between productivity and remobilization coefficient. Moreover, different remobilization coefficients were found for the genotypes during the unfavorable year with higher values for Sonmez, Vostorg, Murov 2, Gyrmyzy gul 1 and 12thIWWYT№17. There was no significant relation between grain yield and water soluble carbohydrate remobilization under heat stress during grain filling (Zamani et al., 2014). Grain yield exhibited a low positive correlation with water soluble carbohydrates at anthesis under water stress (Del Pozo et al., 2016).

In 2012-2013 growing season we detected a negative correlation (*Fig. 1*) between the remobilization coefficient and plant height with $R^2 = 0.38^{**}$ (reliability within 0.01), while there was no correlation between the remobilization coefficient and the length of peduncle. However, in 2014 we observed the absence of the correlation between remobilization coefficient and both mentioned parameters, which could be attributed to severe drought and high temperatures.

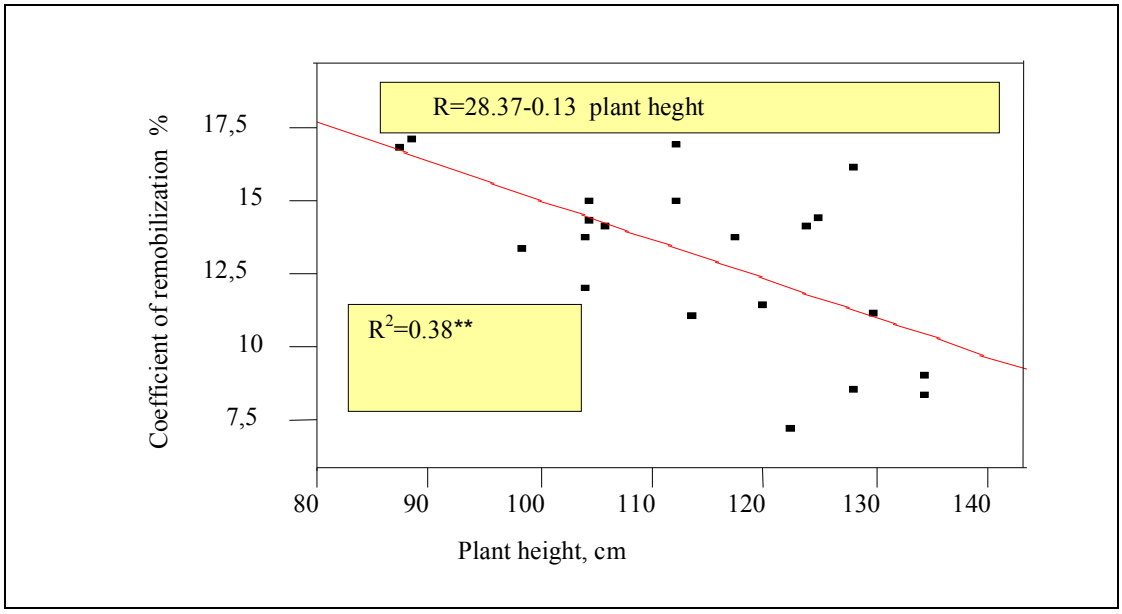

Figure 1. *Interrelation between the plant height and remobilization coefficient in the 2012-2013 growing season*

We suggest that the reason of the low values of remobilization coefficient for the varieties Bezostaya 1, Gyzyl bugda, Shaki 1 and Sonmez is the tallness of these varieties. As assimilates should pass very long distance to be transported to grain.

The high values of the remobilization coefficient in the Gyrmyzy gul 1, Vostorg and other genotypes can be attributed to their late maturation and short stature. Analogical

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69816987

results were obtained in the previous experiments conducted with radioactive C atoms (Jahangirov, 1987).

Conclusion

Thus, the study of remobilization in winter bread wheat genotypes under dry rainfed conditions of Mountainous Shirvan region showed that this parameter was dependent on weather conditions and individual biological properties of the genotypes. Remobilization coefficient was found to be higher during drought years. It was also established that remobilization coefficient was higher in short and medium-height genotypes compared with tall genotypes, which indicate a negative correlation between the remobilization coefficient and plant height.

Acknowledgments. Authors are thankful to Gobustan Hydrometeorological Station for providing information on annual and perennial precipitation and temperature.

(Received 19th Feb 2019; accepted 10th Apr 2019)

Abstract. One of the major problems in many countries is the forest fires. Forest fires are the source of the most of the problems of fire protection organization in every year. Why does Turkey still have too many forest fires? And how do we eliminate forest fires? We are trying to approach this problem under our country conditions, and explain that how we are able to eliminate the forest fires in Izmir Forest Directorate. Forest fires stands out especially in the provinces of forests under the influence of the Mediterranean climate in Turkey. However, the forest directorate that are at risk in terms of both burning areas and fire numbers in these provinces are Mugla, Antalya and Izmir. For this reason, this study was carried out in Izmir Regional Directorate of Forestry between the years 2006-2015, one of the regional directorates that are always at risk.
Keywords: *Izmir, forest fire, forest directorate, burnt area, forest conservation*

Introduction

Forest fires are one of the important factors that jeopardize the continuity of forests in various parts of the world, especially in developed countries. Forest fires do not only damage timber and other forest products, they also harm ecosystem services, such as conserving the top soil etc. They destroy the habitats of forest biota and bring death to all sort of creatures. Even if the burned land is restored and reforested, forest fire change environmental conditions in forest (Mol et al., 1997). According to the recent fire statistics (from 1988 to 2016) in Turkey, the annual average number of forest fire is 2114 and that of burned forested area is 10615 ha (Goltas et al., 2017a).

Today, the importance of forest fires has increased due to global warming. Especially in the European continent, countries in the Mediterranean climate zone with low humidity and high temperature values are under the threat of forest fires with global warming. This situation is a top problem in terms of the sustainability of forests. Because of heat waves and drought, risk of forest fire, fire intensity, number of fire, fire frequency and burning area is expected to increase (Goltas et al., 2017b).

A large proportion of Turkey lies within the Mediterranean climate zone, which is characterized by hot and arid summer seasons, followed by warm and mild winters. Similar to many countries in the Mediterranean basin, Turkey is a country, which is prone to forest fires, which are frequently encountered phenomena due to climatic conditions (Mol and Kucukosmanoglu, 1998). In Turkey, about 35% of total forested areas are sensitive to forest fires at first-degree, 23% at second-degree, and 22% at third-degree (Bilgili and Kucuk, 2001).

Therefore they should be considered as usual events. Unfortunately, forest fires are rarely a result of natural causes such as the lightning. Forest fires are mostly human

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69897001

induced events (Demir et al., 2009). Manager of the fire fighting team should comprehend the behavior of fire and customize a tailor made fire fighting strategy (Ayberk, et al., 2010).

The aim of this study is to make a detailed assessment of forest fires in general Turkey and in particular İzmir benefiting from fire reports, fire statistics, forest inventories and management plans. Results of the study will contribute to fire protection and fire suppression activity in both Turkey and Izmir Forest Directorate.

Materials and methods

The forest fires statistics occurred in Turkey between the years of 2006-2015 were evaluated in various aspects. In this study; Causes of forest fires, distribution in the field (hectare), the numerical distribution to the regional directories and the number of forest fires and total burned area in İzmir Regional Directorate of Forestry has investigated. Among the State forest Enterprises of regional Directorates; Bayındır, Bergama, İzmir, Menderes, Akhisar, Demirci, Gördes and Manisa are particularly considered. The main data of these directorates are sorted by years and calculated one by one in order to create systematic schemes. Moreover to reveal accurate investigation over these numbers, their 10 years total and 10 years average values are conceived and examined. For the investigation of forest fires in 10-year period; forest inventory and forest management plans obtained from İzmir Regional Directorate of Forestry in Izmir region has taken into consideration. In this way, the fire sensitivity of the Izmir Regional Directorate of Forestry has been tried to determine.

Study area

Surrounded by the Mediterranean, the Black Sea, the Sea of Marmara and the Aegean Sea; Turkey has 97% of its land area in Asia and 3% in Europe. It also has 8333 km of coastline and related to its geographical position, properties such as climate, relief and location have caused the formation of different geographical regions within the boundaries of the country (Demir et al., 2009).

Izmir regional directorate of forestry, which includes a large part of the Aegean region, is located within the territorial boundaries of Izmir and Manisa provinces. It is surrounded by Balikesir in the north, Denizli and Kutahya in the east, Mugla Forest Regional Directorates in the south and Aegean Sea in the west. The geographical location of the Izmir Forest Directorate is located between the northern longitude of 39°35’38” – 37°52’30” and eastern latitudes of 26°11’42” – 28°52’28” (*Fig. 1*).

Under the influence of the Mediterranean climate, the plant species determined by this climate are located in İzmir. For many years, a wide variety of plant species have been destroyed due to grazing, breeding, smuggling, fire and insect damages. Especially in these areas where main tree species were damaged, drought resistant forest species were included. Main forest species are *Pinus brutia* and *Pinus nigra* in Izmir. Additionally there are many other tree species like *Pinus pinea*, *Quercus* sp., *Castanea* sp., *Juglans* sp., *Fagus* sp. in Izmir forests. General area of Izmir Forest Directorate is 2,509,336 ha and 39% of this area is forest lands. This value is calculated by creating relevant pie-chart, that presents damaged forests (22%), efficient forests (17%) and non-forest area (61%). 417,910 ha efficient forests, 557,095 ha damaged forest in Izmir Forest Directorate (Uzmez, 2011) (*Fig. 2*).

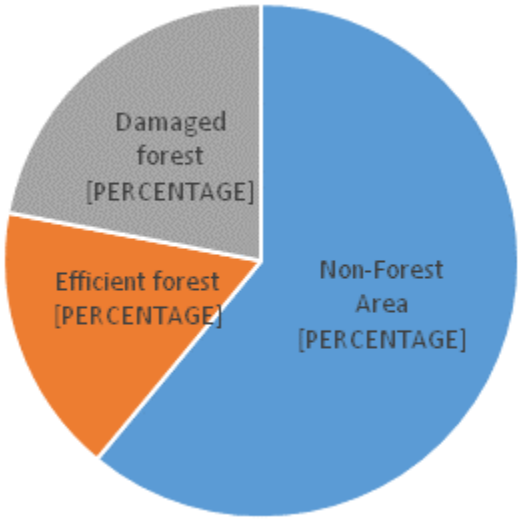

Figure 2. *Forest status in İzmir Forest Directorate*

Results

Different factors influencing forest fire danger

Many factors such as weather conditions, forest vegetation and fire season influence the forest fire danger (Noble et al., 1980). For instance, some weather conditions such as high air temperature, low relative humidity and dry winds reduce the moisture contents of flammable materials. In Mediterranean region the wind of South, South East and South West are oceanic origin, and so they bring more humidity. As a result, the fire danger is less. But the wind of North, North East and North West origin, bring dry air masses, because they are Central Anatolian origin. So, this situation created severe fire seasons (Mol and Kucukosmanoglu, 1998).

Forest vegetation also has a great influence on the damage of the forest fires. Most of the forest fires in Turkey occur in pine forest (49%) At the same time it is difficult to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69897001

prepare a fire season list for different parts of Turkey, because of various climatic conditions and forest fuels. But we frequently notice almost two characteristic types of fire season. Short fire season, this is well illustrated in Black-Sea and Marmara regions. In Black-Sea region July-August, and in Marmara region June-August are the peak points. Long fire season, Mediterranean and Aegean regions are typical examples. It continues about 5-8 months, but some part of these regions has year-long fire season (Demir et al., 2009).

Forest fire statistics in Turkey

The major destructive factor in Turkish forests is forest fires. Large or small, high severity or low severity they have had a profound influences on forests and wildlands. Especially the Mediterranean area has very suitable combustion and spreading factors. Forest fires cause great damage especially in Mediterranean, Aegean and Marmara regions. Forest fires not only cause the destruction of forest resources, but also destroy the balance of the ecological system. The coastal band, which starts from Hatay in particular from the Mediterranean and the Aegean coastal regions to Istanbul, constitutes the most risky area in terms of fires. In this region, the first sensitive area of fire is 7,182,051 ha, the second sensitive area to the fire is 5,091,788 ha. According to this, 12 million ha of the forests corresponding to approximately 60% of our forests are located in areas sensitive to fire (Uzmez, 2011) (*Fig. 3*).

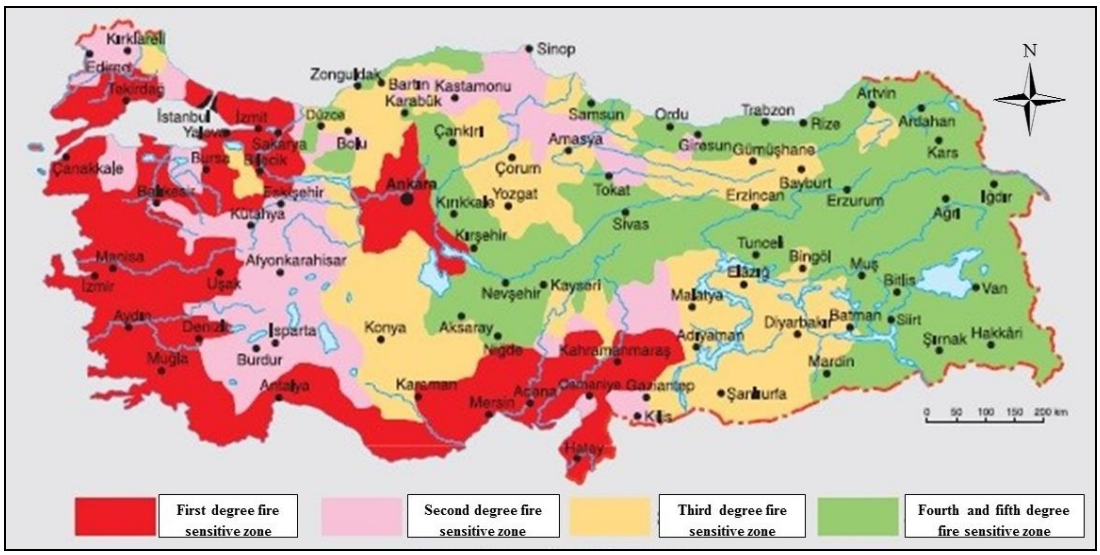

Figure 3. *Sensitive regions of Turkey against to forest fire*

Considering the causes of forest fires, which emerged in Turkey between the years 2006-2015, their numbers and area distributions are shown in *Table 1*. With the examination of *Table 1*, it is possible the state that among the period of 2006-2015; the year 2013 reached the highest level in terms of the number of forest fires (16.1%), yet the year 2008 reached highest value relating to amount of burnt area (33.4%). The reason of why the year 2013 has the highest number of fire, is explained by the social events such as communal violence occurred in Turkey during 2013. It is also emerged that, with respect to amount of burnt area, the year 2008 has the highest value. This situation can be explained with the fact that the temperatures of 2008 were 0.5-2.4 °C

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69897001

higher than the average seasonal normals (1971-2000) as shown in *Figure 4*. This also causes the increase in number and burnt areas by means of forest fire. Moreover, it is obvious that our findings are supported by Kucuk and Saglam (2004).

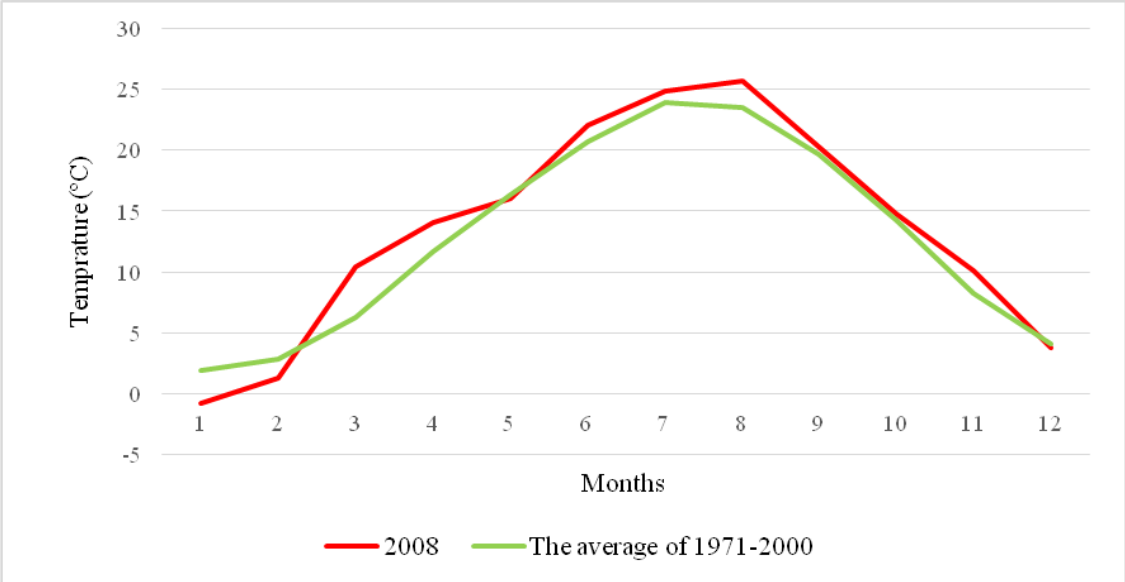

Figure 4. *Average monthly temperatures of 1971-2000 and 2008 (MGM, 2017)*

In Turkey, the main causes of the forest fires are human being (99%) and lightning (1%) (Mol and Kucukosmanoglu, 1998). According to Demir et al. (2009), forest fires have many causes in Turkey, such as; human activities (smoking, negligence, carelessness, accidents, deliberate fire setting etc.), shortage of basic equipment for fire fighting, climate and weather variation (lightning etc.) and unknown reasons.

Among the causes of forest fires, four main subjects; Intentional, Negligence-Accident, Natural (Lightning) and Unknown are particularly chosen and their values by years calculated in detail. In *Table 1*, it is important to point out that during the year 2008; number value of Intentional is 18.1%, field value of Negligence-Accident is 43.7% and field value of Natural (Lightning) is 29.8%. Furthermore, during the year 2013; it is possible to find out that by 24.4% in terms of number value and by 30.7% in terms of field value, Unknown has reached its highest values. During the examination period (2006-2015), within the range of these causes, in respect to number value Intentional and in accordance to its field value, Negligence-Accident comes forward.

For this reason, regarding the protection of forests from fires; more emphasis should be put on to the issues of public awareness and education. These findings and suggestions of ours are also validated by related work of Ryan (2012).

Detailed examination through *Table 2* makes possible to reveal total forest fires within the mentioned years, in terms of number and area. For the year 2008, number value of fires generated from Intentional causes calculated as 1.6% and for the year 2007 field value is found as 1.9%. In addition to this, it is revealed through *Table 2* that in 2013 number value of Negligence-Accident obtained as 6.1% and in 2008 field value as 29.5%. In 2007, number value of Natural (Lightning) is obtained as 1.7% and in 2008 field value as 0.8%. Finally, in 2013 with respect to number value of Unknown as 7.8% and field value as 6.5%; all of these mentioned years have reached their highest rates

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_69897001

within *Table 2*. It seems clear that, likewise in *Table 1*, the year 2008 and the year 2013 comes forward in also *Table 2*. On the other hand, within mentioned decade when the total causes of forest fires are examined; it is seen that the Negligence-Accident has the first place concerning both number value (46.1%) and area value (67.6%). This finding shows that, fires are mostly caused by negligence and accident, rather than natural or unknown ones among the reasons of forest fires. For this reason, in order to protect forests from fire before the fire starts, precautions such as; fire safety roads, firebreaks, transportation roads, silvicultural measures, arrangement of flammable materials etc. are should be given priority and they should be practiced accurately.

In our work, *Tables 3* and *4* show the field distribution of forest fires with respect to regional forest directorates. *Table 3* reveals the field distribution, while *Table 4* shows the numerical distribution.

As it is understood by generating and analyzing *Tables 3* and *4,* related to the regional forest directorates and field distribution of forest fires in terms of number and field (hectare) between the years 2006 and 2015 it is seen that numerical findings of Izmir, Antalya and Mugla reach the highest rates. Therefore it is possible to state that forest fires are mainly concentrated upon these three regions in Turkey. As being sensitive to forest fires; this is one of the reasons why Izmir is selected as our study subject.

It is also seen that our findings regarding to these observations are supported by the research that carried out by Mol and Kucukosmanoglu (1997) and Kucuk and Unal (2011).

Forest fire statistics in İzmir

In Izmir there are many factors that destroy the forests. Among these destruction factors besides grazing, smuggling, insect damages and breeding, fire is the most dangerous one which especially harms plant species. All these mentioned factors are effective in Izmir Regional Directorate of Forestry that located in the west of Turkey as our study area.

Akyuz and Kucukosmanoglu (1997) especially draw attention to the fact that fire is the most important reason leading to destruction of forest resources in Izmir.

Izmir Regional Directorate of Forestry has the total area of 248986 ha. Approximately 968078 ha that constitutes the 39% of this area is covered with forests (GDF, 2016). Bayındır, Bergama, Izmir, Menderes, Akhisar, Demirci, Gördes, and Manisa are the names of the eight enterprises that Izmir Regional Directorate of Forestry contains. Between the years 2006-2015, number distribution of forest fires with respect to these State Forest Enterprises are stated and analyzed in *Table 5*. Within this 10 years period, calculations carried out in *Table 5* expose that total fire number is 2333 and average fire number is 233. Also it is indicated in *Table 6* that amount of burnt area is 7963 ha and the average amount of burnt area is calculated as 796 ha during this 10 years. As can be understood through the detailed investigation of *Tables 5* and *6,* Izmir Forest Enterprise steps forward with highest values in respect to area and number, concerning the forest fires. This situation reveals similar results that forest fires reach the highest values of both number and field value, as we obtained from the examination of Izmir Regional Directorate of Forestry (*Tables 3* and *4*). These relevant findings indicate that Izmir Region has a sensitive status concerning the forest fires. Therefore; during the fire seasons, it is a necessity to take all the required precautions against fires in Izmir.

Turkish Forest Organization and present activities against fires

Ministry of Agriculture and Forestry of Turkey and the Turkish General Directorate of Forestry have the main responsibility over the fire prevention and forest protection. All the organizational framework is set up in accordance with the Turkish Constitution (Dated 07.11.1982, Nr.2709, Section 169) and Turkish Forest Law (Dated 08.09.1956, Nr.6831, Section 68-76) besides relevant rules and regulations. The General Directorate of Forestry contains primary departments of fire control and forest protection.

General Directorate of the Turkish Forestry has three main sections which are: Forest Protection, Control of Forest Pests and Prevention and Control of Forest Fires. Especially, the section of Prevention and Control of Forest Fires is charged to prevent forest fires by means of the Regional forest directorates, forest enterprises and forest rangers. Fire suppression activities are realized by different kind of tools, equipment, man and machine powers and also sometimes by aerial supports which can be summarized as: fire attack crews, fire personnel, fire boss, fire lookouts, power chain saws, bulldozers, tractors, lorries, water trucks, pick-ups, off-road cars, water reservoirs, UHF and FM communication radios, telescopes, different masks, fire resistant clothes, chemical retardants, planes and helicopters. Furthermore; meteorological data is taken from the weather stations. Meantime various firebreaks, fuelbreaks, fire lookout roads and telephone lines are also constructed (Mol and Kucukosmanoglu, 1998).

Discussion and conclusion

Forest fires are one of the major problems in many countries. As we know, in context of location and climate properties; during fire seasons the environmental effects of drought, low rates of relative humidity and wind occur in Mediterranean, Aegean and Marmara Regions of Turkey. Due to these reasons; as being located at Aegean Region, Izmir Regional Directorate of Forestry is also at remarkable risk. However regarding the forest protection and fire prevention, there is no doubt that much development has been achieved in Turkey. Within the results of our study, fires are mostly caused by negligence and accident, rather than natural or unknown ones among the reasons of forest fires. During the examination period (2006-2015), within the range of these causes, in respect to number value Intentional and in accordance to its field value, Negligence-Accident comes forward.

For this reason, regarding the protection of forests from fires; more emphasis should be put on to the issues of public awareness and education. Between the years 2006 and 2015, it is seen that numerical findings of Izmir, Antalya and Muğla reach the highest rates. Therefore it is possible to state that forest fires are mainly concentrated upon these three regions in Turkey. Izmir Forest Enterprise steps forward with highest values in respect to area and number, concerning with forest fires.

There are 603 forest villages in İzmir. It is emphasized that the socio-economic level of the people which are living in or near the forest, is highly below the standard of living. According to statistical data, 343.513 forest villagers live there (GDF, 2016). The average income of forest villagers is $250 per month, mainly from forestry work and farming Forest villagers regularly clear fields from forest land for subsistence farming. So, these villagers would like to use the forest without limitation for their survival. This brought out the forest-human activities relationship. Furthermore, this helps to explain why the three causes of forest fires are negligence, carelessness and accidents, unknown reasons, and deliberate fire setting.

Demir et al. (2019) stated that however, with the fast-growing economy in Turkey, the present situation of forest fire protection is becoming severe. The main causes are that technical forest fire protection work has failed to keep up with social development and that regulation and management systems for forest fire protection are falling behind the present state of social development. Therefore, more effective regulations and rules should be set up soon, and a strategy should be developed in Turkey to carry out timely forest fire research work so as to cope with the new challenges of forest fire hazards in the future.

Boazountas et al. (2005) stated that most of the Mediterranean region suffers from extensive forest fires, and in some cases socioeconomic factors are key determinants in wildfire causality classification. Determinants are those components within the forestry environment that help explain the intensity and spread of wildfires. The module developed here incorporates five factors representing forestry profitability, demographic pressure, social tension, forestry culture, and organizational thinking. These factors are sufficient to explain the increase or decrease of fire risk. These factors can be modelled by considering variables which describe the behaviour of the socioeconomic fire risk (local permanent population, tourists, domestic animals, houses, type and height of vegetation) and constructing transformation functions that will determine the final value of fire risk.

Ayberk et al. (2010) has similar results as our research and stated that fire is a natural element and plays an important role in the natural dynamics of the forest ecosystems. However, fire can be a very destructive force. According to the establishment of new and modern fire prevention and suppression techniques, the number of fires and burning area will be getting decreased. Adverse burning conditions will occur in the future as they have been in the past. The important measures to be taken are firstly to keep away the fire from the forests and secondly to suppress the fire immediately and effectively as it is still at the beginning stage. The sooner a fire is detected and reported, the larger the initial attack force and the quicker it arrives at the fire, the more likely the fire will be contained at a small size. This could be realized by effective protective measures and well-trained fire fighting teams using appropriate high technology and equipment.

Therefore, all relevant findings in our study indicate that Izmir Region has a sensitive status concerning the forest fires. Therefore; during the fire seasons in Izmir, it is a necessity to take all the required measures against fires. Also, fire suppression activities in Izmir should be carried out by different kind of tools, equipment, man and machine powers and aerial supports such as fire attack crews, fire personnel, off-road cars, water reservoirs, UHF and FM communication radios, fire resistant clothes, planes and helicopters, etc. Due to the fact that Izmir Regional Directorate of Forestry where the forest fires are frequently occurred has a long fire season (5-8 months), flammable material reduction and road cleaning works in forests should be performed. Izmir Regional Directorate of Forestry is one of the most dangerous forest region directorate compared to other directorates in terms of both number of fires and burnt area. For this reason, in context of forest fires all essential precautions should be taken and applied carefully.

Abstract. Drought stress affects the normal growth of plant by influencing Physiological, morphological molecular and biochemical traits at cellular level. It is a polygenic trait, controlled by multiple genes, which makes its manipulation difficult by genetic engineering. It seems drought could be major threat in future to high yield of cotton in Pakistan as well around the globe because it is spontaneous and cannot be controlled with manuring and skilled agricultural practices. Gene manipulation could be a solution of this threat by producing transgenic cotton plants. As it is polygenic trait, so, understanding about cellular mechanism of drought tolerance is crucial to impart tolerance by controlling gene expression under stressed conditions. Universal Stress Proteins (USP) genes have already been identified in drought stressed leaves of Gossypium arboreum which make this variety of cotton a rich source of stress tolerance genes. USP genes could be manipulated for drought tolerant transgenic cotton with high yielding as well and it is most important family of proteins in this regard. This family encompasses a conserved group of proteins that has been reported in different organisms which are activating under various abiotic stress conditions. USP is also a regulatory protein; its activity can be increased by manipulating its interactions.
Keywords: *Gossypium arboreum, polygenic traits, drought stress, universal stress proteins, transgenic*

Introduction

Unfavorable environmental conditions usually inhibit the normal plant growth. There are several abiotic factors, which interrupt the bumper growth of crops, among them drought is worth to be mentioned (Farooq et al., 2009). Drought means loss of water either at elevated or normal temperature. It triggers biochemical and physiological modifications at cellular level, among them loss of turgor pressure, changes in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70037025

membrane fluidity, membrane composition, solute concentration, protein-lipid and protein-protein interactions are need to be studied. Plants respond to drought stress at physiological level as well as at molecular level. They activate diverse set of metabolic activities to defend themselves against drought stress and initiate their struggle to be survived at the onset of this extreme unfavorable condition (Fahramand et al., 2014). At genetic level, multiple genes are involved, which are responsible to initiate the defense system of plants. Hence, involvement of multiple genes makes it complex to control the drought resistivity of plants by using genetic engineering. However, different studies like transcriptomics, proteomics and expression of genes have identified the activation and regulation of several stress-related genes at cellular level. It has been observed that expression level of different genes in plants is changed under the spell of drought stress (Ribas et al., 2006).

Plants' responses against stresses are mounted and co-ordinated by two types of signaling pathways namely ABA-independent and ABA-dependent pathways. The products of these genes are classified as regulatory and functional proteins which are responsible to activate stress related pathways (Shinozaki and Yamaguchi-Shinozaki, 2007). Functional and regulatory proteins include enzymes for biosynthesis of osmolyte, water channel proteins, LEA-proteins, chaperones, detoxicating enzymes, proteinases, transcription factors, phospholipases and protein kinases. These functional and regulatory proteins are playing their role to regulate signal transduction mechanism and stress related gene expression (Sivamani et al., 2000). The interaction studies of the genes responsible for plants' biological processes are important to comprehend the mechanism of abiotic stresses in plants. Plants express a multitude of proteins containing USP domains. An analysis of different plant taxa shows that a plant contains an average of 200 different USP domain containing proteins (Maqbool et al., 2009; Isokpehi et al., 2011). Two genes have been identified in cotton which encodes USP proteins named GUSP1 and GUSP2 (Maqbool et al., 2009; Fahramand et al., 2014). These genes are up-regulated during drought stress. Studies conducted on the role of USP in tomato shows that USP activates two gene clusters. One cluster produces LHCB (light harvesting chlorophyll a and b binding proteins) and reduction in aperture of stomata aperture while second cluster produces osmo-protective compounds, i.e. proline. Furthermore, USP is also shown to interact with annexin proteins but the details about how actually the USP performs its functions are still to be elucidated (Loukehaich et al., 2012; Fahramand et al., 2014).

It has been observed that plants respond increasing osmo-protectant production, detoxification of ROS, biosynthesis of chlorophyll, increasing water uptake and stabilizing its proteins (Hayano-Kanashiro et al., 2009), all these processes are triggered by several genes. It is obvious from the previous studies that manipulation of drought responsive genes and maintenance of cellular components has remained as major target of attempts to produce plants having enhanced drought tolerance. Cotton (*Gossypium* spp.), is genetically diverse plant, it has four domesticated species. *G. arboreum* has many remarkable benefits over *G. hirsitum*, it has considerable resistance against biotic and abiotic stresses especially drought stress which makes it priceless gene pool to improve future cotton cultivars (Mehetre et al., 2003; Huang and Liu, 2006; Liu et al., 2006). Several stress proteins and soluble sugars have been reported to act as protectants during cell dehydration in many plants (Kosmas et al., 2006; Padmalatha et al., 2012). The universal stress protein (USP) is one of the most important family of protein for this purpose. USP is a cytoplasmic protein present in bacteria; its expression

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70037025

is enhanced, when cellular viability is challenged by drought spell and other abiotic stresses (Sousa and McKay, 2001; Maqbool et al., 2009; Zahur et al., 2009). The USP super family encompasses a conserved and ancient group of proteins that are present in archaea, bacteria, fungi, plants and flies (Kvint et al., 2003). E. coli contains six USP proteins (USPa, USPb, USPc, USPd, USPe, USPf), which are sub divided into two sub-groups on the basis of their sequence similarity (Gustavsson and Nyström, 2002). It has been reported the presence of USP-genes in different organisms, where they are playing role in response to heat shock, cold shock, DNA management, metabolic control (Persson et al., 2007; Isokpehi et al., 2011; He et al., 2012; Mbah et al., 2013). Furthermore, USP is a regulatory unit protein; its activity can be increased by manipulating its interactions.

This review will cover the role of drought tolerance related gene in plants and their effect on cellular mechanism in response to drought stress (Maqbool et al., 2009; Zahur et al., 2009). A comprehensive screening of Universal Stress Protein gene-2 will enhance our basic knowledge about key metabolic pathways relating to drought and open ways for future engineering of drought stress tolerance. The functional and cellular characterization of USP genes would be investigated to ascertain its potential role in drought stress tolerance mechanism in plants especially in cotton. Understanding the mechanism of interaction of universal stress protein genes and its role in drought tolerance will enable us to breed economically important cotton varieties which are adapted to drought stress. The review will cover the major metabolic pathways in connection with drought tolerance, which will be helpful in providing direction for future metabolic engineering for drought-stress tolerance.

What is abiotic stress?

Negative influence of non living things of environment on living things in an ecosystem is called abiotic stress (Degenkolbe et al., 2009; Ali et al., 2013, 2017). The common stressors are easiest to identify, but some other are less recognizable stress factors which are affecting environment constantly (Kogan et al., 2013). Extreme temperature, drought, salinity, wildfire and sporadic floods are well known abiotic stresses in our ecosystem for plants. Hence, Scarcity of water resources, environmental pollution, salinity, intensified erosional problems are marked in the beginning of 21st century. All these offer abiotic stress to the plant growth, which is the limiting factor in crop yield around the world (Ali et al., 2014, 2016; Wang et al., 2003). Roots are first line of defense against any type of abiotic stress in plants, if soil is healthy, porous, well aerated and contain all essential nutrients then survival rate of plant is automatically increased. Furthermore, abiotic stress not only limits the crop productivity, (Jaleel et al., 2009) but also distribution of plants. Drought stress is major threat among abiotic stresses, which has drastic affects on yield and growth of plants. Drought is a metrological phenomenon which can be defined as a depletion of moisture to the economic injury level, because of prolong period of meager rain fall (Kramer, 1979).

Effects of extreme water deficiency on plant growth

Water deficiency results in loss of turgor pressure and osmotic stress in plants (Mansoor et al., 2003). The osmotic stress results in reduction of plant height, decrease in root length, yellowing of leaves because of reduction in chlorophyll content and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70037025

overall growth rate of plant is reduced. Deficiency in nutrient distribution is another negative effect of drought stress. Reduction in water uptake from the soil to roots also results in slow entry of essential minerals such as nitrate, phosphorus, calcium and potassium into plant and in turn growth rate is ultimately reduced (Zhu et al., 2000). Secondary effect of water deficiency is oxidative stress because of the accumulation of excessive ROS (Reactive Oxygen Species) like hydroxyl radicals, hydrogen peroxide and superoxide anions. Usually ROS are found to be involved in normal metabolic reactions of cells, however, when plants are growing under water deficient environment, the amount of ROS increases to protect the cells from oxidative injuries (Altaf-Khan et al., 2002). The exogenious use of 2,2-diphenyl-1-picrylhydrazyl, 3,3′-diaminobenzidine and methyl viologen in *Arabdopsis thaliana* indicaetd that there was an over accomulation of reactive oxygen species under drought and oxidative stress conditions (Nakabayashi et al., 2014). The dry2/seqe1-5 (*Arabidopsis* drought hypersensitive/squalene epoxidase 1-5) mutant was found to produce antioxidants as far as the RHD2 NADPH oxidase was de-localized under drought stress conditions and caused the formation of reactive oxygen species (Pose et al., 2009). Similarly, water deficiency results in the reduction of root and shoot length and their fresh and dry biomass, therefore roots and shoots may become thinner or thicker (Ashraf and Foolad, 2007). Studies have been revealed that water deficiency is a chief limiting aspect at initial stages of plant growth. Both cell elongation and cell division are severely affected by the drought stress (Bhatt and Rao, 2005; Koroleva et al., 2005; Shao et al., 2008). Various physiological and biochemical processes like ion uptake, respiration, photosynthesis, nutrient metabolism and translocation are severely affected by the reduction in plant growth as a result of drought stress. Similarly studies of Farooq et al. (2009) observed changes in chlorophyll a and b because of drought stress. All cash crops are affected by drought stress among them rice as a submerged crop is more susceptible to the drought stress (Jaleel et al., 2009). Another effect of water deficiency is reduction in the stem length (Specht et al., 2001). Similarly, 25% reduction in plant height was observed in water stresses citrus seedlings (Wu et al., 2008). Significant reduction in the stem length of potato plant was also reported under drought stress (Heuer and Nadler, 1998). The height of other plants like, Petrosolinum crispum (Jaleel et al., 2007), Abelmoschus esculentus (Manivannan et al., 2007), and Vigna unguiculata (Petropoulos et al., 2008) were reported to be decreased. In short, effects of drought stress are characterized by diminished water potential, reduction of total water content, loss of turgor pressure, closing of stomata and reduction of cell division along with cell elongation.

Drought stress and cotton yield

G. arboreum is diploid and possesses several desired characteristics (resistance to diseases and insect pests and tolerance to drought and salinity), while *G. hirsutum* are lacking these characters but it has high crop yield and fiber quality. *G. arboreum* provides space to cultivate it in semiarid and arid regions with minimum farming inputs. Besides this, it is also considered a vital gene pool source because of its distinctive qualities for improvement of other cotton cultivars via genetic engineering. Cost of irrigated cotton production is increasing continuously because of ground water supplies are decreasing in Pakistan; it forces to select drought tolerant cultivars as well as other agricultural commodities. Drought stress at very early stage affected the expansion of leaves in cotton and roots are less sensitive as compared to shoot growth (Malik and Srivastava, 1979; Quisenberry et al., 1985). It was found under drought stress leaf expansion was inhibited which results in decrease in utilization of energy and carbon finally result larger portion of assimilates are translocated to plant roots. Hence, characteristics plant roots can be used as important indicator to drought stress.

The consequence of drought stress on total yield of cotton depends upon severity and timing of drought spell. Krieg 1983) reported that crop yield was decreased under drought stress because of reduction in size and number of leaves and decrease in photosynthetic activity. It has also been observed that initiation of square to first flowering stage is the most susceptible development stage affected by water deficiency. The peak flowering stage was the more susceptible to drought stress which results in heavy losses to crop yield (Golldack et al., 2014). Cotton seeds yield was also decreased because of reduction in total number of bolls per plant under drought stress (Hamada, 2000) and also affected quality of lint in several ways, particularly fiber elongation; maturity and length was reported (Krieg, 1983).

Sensitivity of cotton plant to drought stress

Cotton plant is sensitive to drought stress during boll development and flowering stage (Turner, 1981; Isokpehi et al., 2011). The pollen tube formation in cotton is extremely sensitive to drought stress (Burke et al., 1985; Kawakami et al., 2010). There are several stages of flowering and boll formation in cotton because of perennial growth pattern so, the uncertainty has exists owing to conflicting reports about the sensitive stage of development to water deficiency (Gazanchian et al., 2007). The early flowering period in cotton, according to Umbeck (1987), is sensitive to drought stress while Vereyken et al. (2001) reported that peak flowering stages is more susceptible to drought stress which results in yield reduction of cotton. The production of fructans in phospholipids initiated under drought stress condition of plant cells (Vierling and Kimpel, 1992). Cotton bolls appear to be less sensitive to drought stress than the leaves since they are significantly resistant to water loss and are considered essentially non-transpiring (Quisenberry et al., 1985; Kawakami et al., 2010). A number of researchers however, have reported that limited supply of water during boll development can result in significantly lower yields (Koroleva et al., 2005). In support of these observations, (Quisenberry et al., 1985) it was observed that if drought stress occurs during the first fourteen days after anthesis (on set of flowering), young bolls generally abscise (fall off). Chaves et al., conducted growth chamber experiments where bract and capsule wall water potential of 5-, 20-, and 30-day old bolls was monitored along with leaf water potential under a moderate and a severe drought stress regime. They reported that

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70037025

mild drought stress had no effect on bract and capsule wall water potentials while leaf water potentials were significantly decreased (Chaves et al., 2009).

A similar pattern was observed under severe drought stress conditions with the exception of the dark respiration rates of the capsule wall that were significantly decreased under drought stress conditions. Bayely et al. (1992) reported that the inverted water potential gradient that was observed for the petals was also present in 20-day after anthesis (on set of flowering) bolls. Water and osmotic potential of bracts and subtending to the bolls leaves compared to the bolls. This was attributed to the xylem connections of the fruits being immature and, hence non-functional, until three weeks post anthesis (on set of flowering), and it was concluded that since the water potential gradient is directed from the fruits to the leaves, the main entrance of water in cotton bolls is through the phloem (Vierling and Kimpel, 1992).

Response of plants to drought stress

Morphological and physiological responses of plants

It is reported that drought stress has drastic affects on plant growth while influencing various biochemical, morphological and physiological reactions, like photosynthesis, fluorescence of chlorophyll, stomatal conductance, ion uptake, respiration, translocation, nutrient metabolism, promoters of growth, carbohydrates, proline and malondialdehyde (MDA) contents and cellular integrity, (Jaleel et al., 2008; Shao et al., 2008; Farooq et al., 2009; Filippou et al., 2011). Susceptibility of crops to various environmental stresses frequently changes with growth stages of plant and requirements for best possible and development growth (Specht et al., 2001). In soybean shoot length and dry biomass was decreased under drought stress (Kawakami et al., 2010). Almost 25% decrease in the length of citrus seedlings observed (Wu et al., 2008) under drought stress. In potato, shoot length of plant was considerably affected because of drought stress (Heuer and Nadler, 1998), Vigna unguiculata (Manivannan et al., 2007) and Abelmoschus esculentus (Jaleel et al., 2008). Water uptake is also observed to be reduced under deficiency of which results in the decrease of water contents and elongation of cell is also inhibited because of decrease in turgor pressure.

Leaf water potential

Water potential is a potential energy of water per unit volume relative to pure water. It means to quantify the tendency of water to move from one place to another because of osmosis, gravity and mechanical pressure. Relative water potential is useful to understand the water movement within plants. The measurement of leaf water potential is a reliable indicator of drought stress (Farooq et al., 2009; Fahramand et al., 2014). Morgan (1984) revealed in a study that plants of drought tolerant cotton variety, *G. arboreum* have more number of cells and stomata per unit of leaf relative to the plants of drought intolerant cotton variety, *G. hirsutum*. Ackerson (1981) described while comparing 7 drought resistance and drought prone varieties of cotton that drought resistant varieties have minimum leaf water potential and have ability to maintain turgor at lower relative water potential than that of drought prone cotton plants. Because of turgor maintenance, photosynthesis continues in drought tolerant plants while drought intolerant plants are failed in doing so. Photosynthesis in drought tolerant varieties

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70037025

remain at maximum level because chloroplast of fully turgid leaves contain numerous starch granules and has minimum damage to thylakoid membrane structures. So, Quisenberry and McMicheal (1991) used the leaf turgidity for the selection of drought tolerant cotton plants.

Relative water content (RWC)

Water content and moisture content is quantity of water contained in soil, rocks, ceramics, fruits and in different tissues of the plants. Relative water content is used in wide range of scientific and technical area. Along with other indicators relative water content can also be used for the identification of drought resistant plants. It has been observed that the older leaves of *Gossypium arboreum* have relatively low water potential than that of younger leaves. It was further found that older leaves absorb relatively less water than that of younger one which results in the higher relative water content (Knipling, 1967). Similarly, it has been reported that progressive decline in RWC is because of drought stress in plants especially in *Gossypium hirsutum* (Ferreira et al., 1979). In another experiment Assaad and Signer found a positive relationship between RWC and leaf water content. They also co-relate it with genotype of cotton plants especially desi cotton. However, when the stress is disappeared, RWC progressively recovered within 48 h (Assaad and Signer, 1992).

Cell membrane permeability

Cell membrane is a biological membrane that separates the interior of cell from outside environment. It is a selectively permeable membrane which controls the movement of ions, organic molecules and other important substances (Choffnes et al., 2001). Its basic function is to protect the cell. Various other biochemical reactions are taking place on the interior surface of the cell membrane so, its stability is imperative for all metabolic reactions of the cell. Both biotic and abiotic stresses affect the stability of cell membrane (Kramer, 1979). Cell membrane stability is influenced by age of the plant, growing season, development of stage, degree of hardening, type of tissue culture and plant species. However, it is observed injury to plasma membrane because of drought stress in maize plants is much less severe in developing leaves as compared to mature leaves (Nath et al., 2005). It was also measured an increase in the saturated fatty acid under stress (Singh et al., 2015), which alleviates the melting point of plasma membrane and in turn reduce the stress tolerance in plant. Somerville and Browse, revealed that total lipid content of leaves in the membrane of Arabidopsis plant, growing under high temperature are decreased up to 1/2 and ratio of the unsaturated to saturated fatty acid is also decreased up to 1/3 of the normal temperature. It must be noted, here, that some species cannot co-relate with the degree of lipid saturation (Somerville and Browse, 1991). It was concluded that other factors for membrane stability are also involved along with the fluctuation in temperature. The relationship between the cell membrane stability and crop yield under drought condition may vary from plant to plant (Tanou et al., 2012). For example Showler, described such kind of relationship in few plants especially in sorghum (Showler, 2002). However, before Showler, Martin et al., were failed in defining such kind of relationship in soya bean plants. In short, it can be said that the major cause of yield suppression under drought stress is still obscure and deserve further experimentation (Martin et al., 1993).

Biochemical response of plants under drought stress

Proline content

Proline is an essential amino acid, which is biosynthetically is derived from the glutamate. It is a major osmoregulant in plant tissues under drought conditions. Proline is produced in larger amount as compared to the normal conditions (Alamillo et al., 1995). It is considered as a compatible solute as well as osmo-protectant, which protects the plant tissues by producing stress responsive protein comparative analysis between CIM-496 *G. hirsutum* and FDH-786-*G. arboreum* (Khedr et al., 2003) in plants of *G. arboreum*. Kumar and his coworkers revealed that when water potential becomes the amount of osmolytes which are imperative for osmoregulation, allows additional water from environment. This helps in minimizing the immediate effect of drought stress (Kumar et al., 2003). Similarly, Unyayer and his coworkers, while studying the characteristics of Helianthus annus under drought condition observed a strong correlation between proline content and water deficiency (Ünyayar et al., 2004).

In another experiment the over production of proline in transgenic tobacco was reported, which resulted in increase in biomass of roots (Quisenberry et al., 1985). Similarly, Zhu and his colleagues performed experiment on transgenic rice plants, the conclusion showed that drought stress condition causes the decrease in biomass (Zhu et al., 1998). Other scientists around the world like in sorghum (Yadav et al., 2005), bell pepper (Nath et al., 2005), Gossypium hirsutum (Massacci et al., 2008), wheat (Hamada, 2000) and in Catharanthus roseus (Jaleel et al., 2009) found that amount of proline content increased under drought stress condition.

Chlorophyll content

Chlorophyll is a green pigment present in chloroplast of all green plants and tissues. It is essential for photosynthesis which has ability to absorb light energy and responsible for the carbohydrate metabolism. By measuring the chlorophyll content of a plant tissue, a reliable estimate of photosynthetic rate in green tissues of a plant can be gagged (Ackerson, 1981; Ali et al., 2017; Mahmood et al., 2017). Various studies by different scientists revealed that photosynthetic activity is decreased under drought stress. To prove this notion, Arnon and Whatley, performed experiment on *G. barbadense, G. arboreum, G. herbaceum* and *G. hirsutum*. It was also found that chlorophyll content, soluble sugar content and photosynthetic ratio is higher in G. barbadense, which is followed by *G. arboreum, G. herbaceum* and significantly by *G. hirsutum* (Arnon and Whatley, 1949). Krasichkova and his colleagues observed that rate of photosynthetic activity and chlorophyll content is higher in high yielding cotton varieties (Krasichkova et al., 1989). It is observed that total chlorophyll content in *G. arboreum* is decreased with decreasing the soil water potential (Kvint et al., 2003). Similarly, it was also found that content of the chlorophyll b is higher as compared to the chlorophyll a content in various cotton genotypes in drought condition (Burke et al., 1985). Kar and his colleagues while performing experiment on various lines of *G. hirsutum* plants; they maintained that chlorophyll b has affinity to clear weather condition. They also concluded that moisture deficit condition affects the total chlorophyll as well as proline content in *G. hirsutum* (Kar et al., 2001).

Antioxidant enzymes

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70037025

Antioxidant enzymes in plant tissues, i.e. super oxide dismutase, catalases, glutathione, peroxidase and methadone reductase. An antioxidant is a molecule that inhibits the oxidation of other molecules. Oxidation is a metabolic reaction in which free radicals are produced. In turn these can start chain reactions which can damage or death to the cell. Antioxidant terminates these chain reactions by removing free radicals intermediates and inhibits other oxidation reactions (Wanner and Junttila, 1999). So, antioxidants are reducing agents. Drought stress in addition to dehydration also induces oxidative stress such as generation of active oxygen species (ROS) including super oxide radical (O^{2-}), nasent oxygen (O), hydrogen peroxide (H_2O_2), hydroxyl ion (OH^-). Their production is injurious to the cell (Nepomuceno et al., 1998). Xu and his colleagues revealed that antioxidant species cause the auto-catalytic oxidation of membrane lipids and pigments then leading to the loss of membrane semi permeability and modification in its functions. Among antioxidant species superoxide radical (O^{2-}) is regularly synthesized in a chloroplast and mitochondria (Xu et al., 2006). However, some of its quantity is also produced in micro-bodies. The quenching of super oxide radical by super oxide dismutase (SOD) results in production of hydrogen peroxide (H_2O_2). However, both O^{2-} and H_2O_2 are not toxic to the cell as OH- is injurious to cell, which is formed by the combination of O^{2-} and H_2O_2 in the presence of trace amount of Fe^{2+} and Fe^{3+} (Monk et al., 1989). The O^{2-} can damage chlorophyll, protein, DNA, lipid and other important micro-molecules. Thus affect the plant metabolism and limit the crop yields. Sairam and Tyagi, found that plants have, developed a series of both enzymatic and non-enzymatic detoxification systems to counteract activated oxygen species (AOS), thereby protecting the cells from oxidative damage (Sairam and Tyagi, 2004). Similarly, it was also found by Kosmidou and his colleagues that various physiological and metabolic reactions have been affected by the over expression of super oxide dismutase (SOD) (Voloudakis et al., 2002).

Molecular response of plants to drought stress

The molecular details of a plant's response against stresses are complicated. These involve receptors, transcription factors, genes, noncoding RNAs, ions, and enzymes etc. Despite of the variability the plant response against a stress condition begins with the perception of the signal by specific receptors. Plants perceive dehydration by one of the following two mechanisms (Chaves et al., 2003). Through changes in osmotic potential; the membrane protein AtHK1 (Histidine Kinase 1) senses the change in osmotic potential produced inside the cell, while EcHKT1 works in the similar for sensing changes in extracellular environment. Through changes in membrane texture; the dehydration results in interaction of cationic and anionic amphiphilic substances which changes the membrane texture which is sensed by membranes proteins like OpuA. The above mentioned proteins initiate a series of signaling events. These involve many molecular respondents. Urao and his colleagues identified three phospho-relay intermediates (ATHP1-3) and four response regulators (ATRR1 -4). These molecules are supposed to play role in post perception events; however, their function is not yet clear (Urao et al., 2000). Post perception events are shown to include phosphorylation and dephosphorylation of phosphatases and changes in cytoplasmic Calcium concentration (Luan, 1998). These events then result in activation of various signaling cascades. These relative unclear cascades divide dehydration response in to branching one that involves ABA and the other which works independent of ABA. ABA

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70037025

dependent responses are major cellular responses against stress. Two enzymes of ABA biosynthesis have been shown to respond to the cellular perception of stress namely these enzymes are Zeaxanthin epoxidase (ZEP) and 9-cis-epoxycarotenoid dioxygnase (NCED) (Qin and Zeevaart, 1999; Taylor et al., 2000). Stomata closure, maintenance of root growth and restricted leaf expansion are some of the many consequences of ABA activities in different organs of the plants. ABA mediated signaling cascades that make the mentioned things to happen were reviewed (Bray, 2002). ABA independent pathways are of limited importance for stress response. Mostly these involve genes which have conserved dehydration response element (DRE) in their promoters (Luan, 1998).

Cotton responds to stresses by bringing a large number of changes in its morphology and physiology. Tracking these changes down to molecular level leads to the conclusion that the basic framework of cotton response is similar to other plants but for the large part the specific effectors used by cotton are unique to this plant. ABA mediated responses remain an important part of cotton cells' response to osmotic stress; however, osmotin is shown to be a very important downstream target of ABA in cotton. This protein has binding sites of several TFs in its promoter and has capability to interact with different proteins hence working as a hub in molecular response to osmotic stress (Wilkinson et al., 1995). Trehalose 6 phosphate synthase gene is believed to be important in stress signal transduction suggesting that Trehalose 6 phosphate has a vital role as a secondary messenger in cotton (Kosmas et al., 2006). ABA mediated responses, for the large part, work by the involvement of calcium. In stressed cotton cells calcium based activities are mostly driven by calmodulins. Owing to the importance of calmodulins cotton produce a specific heat shock protein named Heat Shock Protein Camodulin Binding (HSPCB). This protein has the duty to bind with calmodulin and keep it active so that it is able to play its role efficiently (Voloudakis et al., 2002).

Contribution of genetic engineering to drought tolerance

Drought tolerant genes have been identified while investigating the molecular mechanisms of plants response to drought stress. These genes were isolated and characterized by transferring them into drought prone plant species. This approach in some cases has been found successful to increase agronomic performance and crop yield. A good example of this success story is transgenic wheat expressing HVA1 gene from barley, encoding late embryogenesis abundant (LEA) proteins. Results showed that the HVA1 protein confers a significant protection from drought stress (Bahieldin et al., 2015). Aquaporins mediate symplastic water transportation in plants could be a limiting factor for growth under unfavorable environmental conditions. Differential expression of these genes during plant development that encode for aquaporins has been observed to be associated with various physiological processes. Such processes include opening and closing of stomata, cell elongation, cell division and organ movement (Berriman et al., 2009). The SITIP-2 gene coding aquaporin protein was found predominantly effective to improve drought stress tolerance in tomato plants (Hajheidari et al., 2005). Another successful gene is OsNAC10, introduced in rice plants under the control of GOS2 constitutive promoter and RCc3 root-specific promoter (Tang and Page, 2013).

Gene cloning and expression

Gene cloning and expression makes it possible to transfer biological properties from one organism to another. This exciting field of research owes its spectacular development to emergence of tools for DNA manipulation, enhancements and extensions in the existing knowledge, novel ways that investigators are using to apply the available technologies and finally the rapid pace with which research is being carried out in this field. The idea of transferring a gene between organisms was first conceived and materialized in the decade of 1970. Phages have the ability to transfer portions of DNA between bacteria through generalized or specialized transduction mechanisms. It was reported in early 1970s that some linear phage DNAs contain sticky ends on their terminals and that in some abnormal conditions a linear phage DNA may be separated into two or more pieces while retaining the sticky in their original positions. In their first effort to attach two DNA fragments investigators used TdT, an enzyme which adds poly A or poly T tails to 3' blunt ends, and DNA ligase. A small part of bacterial DNA was isolated and it was treated with TdT similarly two fragments of phage DNA were treated with complementary TdT and finally these three fragments were ligated with DNA ligase. This experiment resulted in the creation of a circular phage DNA containing a bacterial DNA fragment in it. The hence produced circular phage DNA was found to be the target of restriction enzyme EcoRI which was observed to cut this circular DNA on one place and make it linear. In final step this EcoRI cut linear phage DNA was ligated with a similarly prepared phage DNA containing antibiotic resistance gene (Berg and Mertz, 2010).

Universal stress protein (USP)

A protein that contains a USP domain (a characteristic USP structure) is be referred to as a universal stress protein (USP). A USP may contain one or more USP domains a fact that allows USPs to perform a board range of functions (Isokpehi et al., 2011). USP gene was first discovered in bacteria via 2D gel electrophoresis and was named as C-13.5 based on its migration during 2D experiment. Later studies recognized these proteins as part of all stress and starvation stimulus known at that time and thus these were renamed as Universal Stress Proteins (Kvint et al., 2003). USP genes are involved in wide range of metabolic activities. These have been described to play role in bacterial virulence, heat shock, cold shock, DNA management and metabolic control (Persson et al., 2007; Loukehaich et al., 2012). In most cases the mechanisms of functions performed by USPs are still undiscovered but for a few functions some information is gathered about the mechanisms. When a plant is subjected to water stress, ABA level is increased which resulted in expression of USP genes. This is consistent with the finding that USPs can bind with transcription factors (Gury et al., 2009). One of the two activated gene clusters produces LHCB (Light Harvesting Chlorophyll a/b Binding) proteins. LHCB keeps the chloroplasts intact and reduces the stomatal aperture to preserve water during water stress. The second gene cluster produces some osmo-protective solutes, e.g. proline which protects the cells from harmful effects of ROSs (Loukehaich et al., 2012). In water stress USP is believed to interact with Annexin protein but the details about how actually the USP performs its functions are still to be elucidated.

E coli responds to salt stress by producing an ion transporter called (KdpFABC) which transports the extra salt ions out of the bacterial cell. The production of this

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70037025

transporter comes after induction of its gene with a complex of KdpD and KdpE. This complex is only formed when KdpE is phosphorylated. In excess ions KdpE phosphorylation is inhibited. Here USP comes to play its part such as USP phosphorylates the KdpE and then hold it with KdpD forming the complex which induces the production of KdpFABC (Heermann et al., 2009). Another similar mechanism is also described in Halomonas elongate. Here the USP instead of inducing the expression of transporter binds itself with the transporter named TeaABC making it active. The study on H. elongate TeaABC and USP interaction stresses on the assertion that ATP binding USP does not play any role in transcription regulation (Huang et al., 2012). Owing to their importance several studies have been conducted to find out the structure of USPs. These investigations reveal that the structure of USP remains similar in different organisms. A USP contains an ATP binding motif at its N-terminal while the C-terminal region takes different forms depending upon the context of the protein. In many proteins the C-terminal region also binds with an ATP molecule making USP capable of binding with two ATPs at a time (Gonzali et al., 2015). The N-terminal ATP binding motif in various USPs have high % of glycine amino acids which allow USP-proteins to attach with ATP molecules (Drumm et al., 2009).

Plant transformation

Conventional breeding methods were slow and laborious; to beat these limitations plant transformation methods were developed for the production of genetically engineered plants. Through transformation gene of interest can be introduced into plants without altering their vital characters. Plant transformation method is the set of events used to introduce a fragment of DNA, having specific trait, into host plant. By utilizing this method plants are engineered to produce new varieties with desirable traits. It can be achieved either by Agrobacterium tumefacien-mediated transformation or by gold particle bombardment. In the first method plant cells are infected with pathogenic *Agrobacterium tumefaciens* bacterium possessing the desired gene. In the later procedure gene gun is used for the gene coded bombardment of particles. Both of these methods are extensively used in research applications (Somerville and Browse, 1991; Tinland, 1996; Tzfira et al., 2004).

Agrobacterium-mediated transformation

Agrobacterium tumefaciens-mediated transformation is leading technology used for production of transgenic plants. The genus *Agrobacterium* has been classified into various species because of its disease symptomology and host range (Otten et al., 1984). *A. tumefacien*, naturally present in soil, it penetrates in plants at wound sites and initiates the formation of tumor, disease commonly known as crown gall (Smith and Townsend, 1907). The crown gall disease has been observed because of the transfer of T-DNA (transfer DNA) from tumor-inducing (Ti) plasmid from A. tumefaciens to plant cells (Zaenen et al., 1974) and integrated into plant genome (Chilton and Que, 2003). Two genetic elements are required for transfer of T DNA to plants. The first element is 25 bp direct repeats defining and flanking region of T-DNA border sequence (Zambryski et al., 1983). The second element virulence genes (vir) encoded by the Ti-Plasmid in a region present outside of the T-DNA region. The vir genes encode a set of proteins responsible for the excision, transfer and integration of the T-DNA into the plant genome. In plant transformation, use of T-DNA process is because of three facts.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70037025

Firstly, the tumor is formed that resulted from integration of T-DNA and its subsequent expression Secondly, the T-DNA genes do not play role during their transfer process, they are only transcribed inside plant cells. Thirdly, any gene of interest placed between T-DNA borders can be transferred to plant cell.

Cellular localization of gene expression

Eukaryotic cell organelles are membrane bounded there for various cellular activities are restricted to specific well defined organelle inside the cell. These cell organelles have been studied via cell fractionation method and by analyzing samples of fixed tissues. Information about localization of sub-cellular protein is first footstep towards understanding its function (Kokkirala et al., 2010) and this process direct the retention and transportation of protein complexes into tissue specific location. It is imperative to understand complex metabolic processes in various plant tissues such as fruits, roots stem and leaves. To study the metabolism in abundant plant tissues is comparatively easy, because the whole tissue can be used as the sample while, less abundant plant tissues are difficult to be used as sample because their basic metabolic reactions are masked by more abundant plant tissues (Carrigan et al., 2011). It is also difficult in case of plants to understand the specific function of single protein due to the presence of multi gene families. So, it is imperative to compare among different patterns of multi gene families at sub-cellular level (Hanson and Köhler, 2001).

The cellular location of different regulatory proteins and enzymes in plant cells during different stages of development, under diverse environmental circumstances is indicated its functional pathway. Mostly, prediction models of bioinformatics are used for location of different proteins. Moreover, localization of several plant proteins has been found at numerous cellular regions (Small et al., 1998). Green fluorescent protein is green light emitting protein, when it is excited with lower wavelength light. Light emitting proteins also know as fluorescent proteins (FPs), they are classified as brand range family of fluorescent proteins and GFP-proteins belong to this family. Now GFPs are being used in various applications of molecular biology (Zhang et al., 2002). Common use of fluorescent protein has one main advantage of its normal light emitting process with involvement of any enzyme or substrate (Ei-Shemy et al., 2009).

Green fluorescent proteins (GFPs)

Green fluorescent protein is a green light emitting protein, when it is excited with lower wavelength light. Now GFPs are being used in various applications of molecular biology (Zhang et al., 2002). Common use of fluorescent protein has one main advantage of its normal light emitting process with involvement of any enzyme or substrate (Ei-Shemy et al., 2009). The 238 amino acids long GFP has a tightly closed structure which is found to be conserved in all different types of FPs characterized so far. Truncation studies show that about 7 amino acids from C- terminal and only the first methionine from N-terminal can be removed without abolishing the GFP function. This signifies that most of the structure of GFP is important for development and maintenance of fluorescence. GFPs (like all FPs) consist of 11 beta sheets, small alpha helices and some irregular peptides. The beta sheets come together and form a rigid structure which is known as “Beta Barrel”. The beta sheets in a barrel are connected with each other through small helices and flexible proline rich peptides. In addition an

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70037025

alpha helix is present in the center of the beta barrel. This helix contains a highly conserved sequence of three amino acids which come together and form the structure which is responsible for the production of fluorescence (Khedr et al., 2003). The structure thus formed is termed as chromophore (sometimes as fluorophore). The location of chromophore in GFP is very important for its function. The beta barrel has polar amino acids branching out towards the chromophore and hold water molecules hence producing an environment for chromophore to exhibit fluorescence. In addition the barrel also protects the chromophore from the outside environment (Zhang et al., 2002; Foolad, 2004). The native GFP which was isolated from Aequorea Victoria is found to be of just a little usage. Research carried out on GFP resulted in modification of native GFP to produce a broad range of derivatives which can be used more readily in the molecular biology applications. These new derivatives of GFP have some properties to make them suitable. The modifications introduced in GFPs along with the resultant properties can be categorized into following categories:

The modification made in the chromophore sequence result in the production of different coloured GFP derivatives. Such changes in the sequence produce different energy states of chromophore as compare to the native, which are capable of emitting light of different wavelengths (producing colours other than green). By using same mechanism, the chromophore modifications can also alter the excitation wavelength of the native GFP hence producing derivatives which absorb different wavelengths while producing same colour (Foolad, 2004). This kind of shift is especially helpful in fine tuning the GFP for the fluorescence detection system present in place. In addition, change in chromophore sequence also is shown to be associated with increased emission of a particular wavelength, i.e. increased luminescence (Berriman et al., 2009).

Site directed mutagenesis

Point mutation or site directed mutagenesis has been used to ascertain the function of unknown gene; this technique causes alteration at specific point in the sequence of a gene. This is also known as oligonucleotide directed mutagenesis. Point mutations can be randomly inserted in the whole sequence of gene at multiple locations or it can be specifically integrated at predetermined location by site directed mutagenesis (Sturm, 2009). It can be carried out both in-vivo and in-vitro. Model organisms are used in case of in-vivo while plasmid constructs are used in case of later. To ascertain the importance of amino acids and their function in protein structure, site directed mutagenesis has been used extensively (Kunkel et al., 1991; Ishii et al., 1998). It can be utilized to study protein function and structural relationship, protein binding sites, active sites present in enzymes, gene characterization and protein-protein interaction.

To alter the sequence of gene of interest, synthetic oligonucleotides are extensively used in research. Numerous protocols have been used and for this purpose while PCR-mediated site directed mutagenesis was found efficient most common method (Saiki et al., 1985). For this purpose two complementary mutagenic primers (40 bp long) with mutated nucleotide in its center are designed by using online software (Zhang et al., 2015). Laible and Boonrod carried out site directed mutagenesis of whole plasmid by using non-PCR thermo cycling reaction. This technique was used to produce mutated enzyme to wipe out its enzymatic activity to utilize as experimental model (Laible and Boonrod, 2009). Dipetarudin protease is potent inhibitor of thrombin it inhibits the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70037025

normal function of trypsin and plasmin (Lopez-Molina et al., 2002). When single amino acid (Arginine-10) was replace by histidine then mutant form, dipetarud in R10H, had lostits activity to inhibit plasmin and trypsin as compared to wild type. In the beginning, artificial oligonucleotides were being used for the rectification of site directed mutagenesis in β-globin gene which causes sickle cell anemia (Saiki et al., 1985). Rectification of sickle cell anemia was a turning point in commercializing this technology (Saiki et al., 1985; Zhang et al., 1995; Beetham et al., 1999; Zhu et al., 2000).

Initially, site directed mutagenesis was used in tobacco and corn, model species. Point mutation in acetohydroxy acid synthase I andIII genes, at specific sites made them resistant agaist herbicide both in corn and tobacco (Zhang et al., 2015). Endo and his colleagues mutated acetolactate Synthase (ALS) gene of rice at specific point by using site directed mutagenesis and developed resistance against bispyribac herbicide. They reported that change in two amino acids separately in two different clones causes tolerance in bispyribac herbicide. These two amino acids are Serine and Tryptophan which replaced with Isoleucine and Leucine respectively (Endo et al., 2007). However, if both amino acids will change at a time then it confers bispyribac herbicide resistance to plant. This technique has broad range of applications because it can create several mutations, insertions and deletions. This can also be used for the characterization of unknown genes responsible for fatal diseases. Now commercial kits are easily available which makes it faster, reliable and efficient (Carrigan et al., 2011). This technique has been utilized for the customization of various crops for introduction of desired traits and for increase per capita yield.

Conclusion

In view of above discussion it can be concluded that drought stress affect morphological, physiological, biochemical and molecular traits of cotton plants which became the major cause of yield reduction. Drought stress is important threat among abiotic stresses, which has drastic affects on normal growth of plants. It is considered as major reason to low productivity of cotton in Pakistan and situation could worse in future because depleting irrigation capacity. Drought stress is natural and spontaneous it cannot be controlled with either synthetic chemicals or skilled agricultural practices. Modern view about control of drought stress is production of transgenic crops having tolerance towards drought stress. Drought tolerance mechanism is controlled by multiple genes, so, manipulation of one or two drought stress related gene could not be much effective. It is need of hour to understand the cellular mechanism of drought tolerance for future engineering of tolerant plants. USP genes have been identified in one variety of cotton which could be manipulated for drought tolerant transgenic cotton plants with high yielding as well. Several soluble sugars and stress proteins have been reported to act as protectant under drought stress and universal stress protein (USP) is the most important family of proteins in this regard. This family encompasses a conserved and ancient group of proteins that are present and has been reported in different organisms including cotton, where they are playing role in response to heat

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70037025

shock, cold shock, DNA management, metabolic control. Furthermore, USP is a regulatory unit protein; its activity can be increased by manipulating its interactions.

Author contribution statement. MNH wrote the initial draft of manuscript. MNH and QA edited the manuscript and made minor corrections. QA made final editing and corrections in manuscript to make it in its final version to be published. All of the authors have proof-read the manuscript before submission. The final approval for publication was given by BR.

Conflict of interests. The authors declared that there is no conflict of interests for the manuscript.

(Received 22nd Feb 2019; accepted 10th Apr 2019)

Abstract. Goat breedings in Turkey is a traditional profession dating back centuries which is carried out in and around forests of rural regions. The purpose of this study was to determine the factors with an impact on sustainable natural resource management based on the opinions of goat breeders and to put forth the contributions that may be provided to establish a sustainable management. The study will contribute to establishing a sustainable goat breeding system in Turkey as well as the management of sustainable forest resources. In this scope, the study was carried out in two different areas in the Mediterranean region of Turkey where goat breeding is widespread. The opinions of goat breeders on demographics, socioeconomic, hair goat breeding and sustainable forest resources management were acquired via survey method and used as the primary data of the study. Descriptive statistics such as frequency, percentage and crosstab values along with Mann-Whitney U Test, Chi-Square Test of Independence and Multivariate Linear Regression Analysis were used as the method. It was determined based on the study results that grazing in forest area is the most important problem for goat breeders and various other problems were also observed related to cooperation with the forest administration. It was observed that goat breeding is carried out via traditional methods by families that are above middle age. The findings indicate that the number of goat breeders decrease as a result of increasing age due to interventions for preventing damages given to trees in the forest by goats during grazing, decrease in the education level and the duration of experience in this profession.
Keywords: *traditional goat breeding, sustainability, goat-grazing damages*

Introduction

People in rural areas have used their natural resources (agricultural areas, forests, pastures, water sources, etc.) by way of implementing the methods they have learned from their ancestors. These methods of production have been criticized and abandoned with the advent of methods aimed at cheaper mass production in agriculture. However, there is increasing concern with regard to the implications of the widely used modern production methods such as environmental pollution and prevention of the sustainability of ecosystems etc. Therefore, traditional land use methods which do not pollute the environment and which prevent loss of soil were re-evaluated and combined under the concept of agroforestry (Gholz, 1986; Ocak et al., 2007; Tolunay et al., 2002).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70277042

There is an increasing interest in sustainable agriculture defined as the preservation and management of the natural resources for meeting the demands of current and future generations at the highest possible level (Schmincke, 1995; Heitschmidt et al., 1987, 1993; Semerci and Çelik, 2016). Sustainable agriculture is a system used for the production of organic substances that does not pollute the agriculture, soil and water resources with pollutants, that minimizes energy consumption while protecting animal species and the environment (Ocak et al., 2010). Because sustainability with regard to the use of natural resources has gained significant importance due to increasing population and energy demand. In this context, goats bred at high elevations have unique skills in using pastures, rangelands and crop residue as well as the side products in the ecosystem and to transform these into food. Thanks to these skills, it is easier to feed the goats that have adapted to high elevation areas. Based on this knowledge, local people living at areas of high elevation have earned their living for centuries by breeding animals by using such traditional methods (Aldezabal and Garin, 2000; Ainalis and Tsiouvaras, 2004; Ainalis et al., 2006; Zarovali et al., 2007).

It is known that traditional land use methods are mostly applied by rural populations in underdeveloped or developing countries. Because majority of these people live far away from modern education opportunities and acquire their knowledge on earning a living and life in general from the information passed down to them by their ancestors. In addition, the importance given to traditional production methods has increased in our day resulting in increased support to such methods. In this scope, traditional goat and hair goat breeding that makes use of mountainous and unfertile rangelands in marginal lands of rural areas are among the activities that stand out (Ocak et al., 2007). Of these, hair goat breeding attracts attention as a form of cultural life in addition to being a unique economical production system (Güney and Darcan, 2005). The relation between socioeconomic, cultural, and recreational needs of the pastoral people and goat breeding is an undeniable reality (Kıvrak, 2014; Bekiroğlu et al., 2016).

The hair goat breeding areas in Europe are located within the borders where certain tree and shrub species considered among Mediterranean scrub vegetation are distributed. It has been determined that Kermes oak (*Qercus coccifera L.*) and Holm oak *(Qercus ilex L.*) species the leaves of which are preferred by hair goats can be found frequently in these areas (Ainalis et al., 2006; Zarovali et al., 2007; Tolunay et al., 2002; Tolunay et al., 2009; Tasligil and Sahin, 2010). Thus, it is accepted that the hair goat population living areas in the Mediterranean region overlap with the areas where these two tree species are naturally distributed. However, grazing bans have been imposed for hair goat owners in state forests where these two tree species are distributed since it is indicated that the goats damage the trees of the forests. Moreover, hair goat breeding villagers have been forced to put an end to their adopted cultural ways of life. Therefore, the hair goat population in the Mediterranean Region has declined drastically (Ince et al., 2009; Ince, 2010; Güney and Darcan, 2005). In addition, the tendency for natural and organic nutrition has increased in recent years resulting in an increased demand in products produced in completely natural environments (Morand-Fehr et al., 2004; Boyazoglu et al., 2005). In line with this tendency, natural products obtained from animals raised at high elevations have started to be preferred more by consumers. Because it has been proven scientifically that the cholesterol and protein values of these animal products (meat, milk, fat, cheese etc.) are superior in comparison with those obtained from other environments of production (Koyuncu and Tuncel, 2010; Laugesen et al., 2003). Indeed, the plant diversity of meadows and rangelands at high elevations is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70277042

higher in comparison with others and the plants that grow on these areas have higher nutritive values. Moreover, industrial activities decrease with increasing elevation resulting in less environmental pollution in such areas. In conclusion, natural environments at high elevation that are not damaged by people have recently started to become centers of attraction as quality grazing areas for animal breeding. As a result, hair goats that have provided natural products such as wool, milk, meat, horn to the breeding local public started to gain importance as a popular economic commodity and the relationship between hair goat-ecosystem has been subject to re-evaluations. Recent scientific studies have shown that hair goats are not actually enemies of the forest as was considered previously but are animals that support the sustainability of the current ecosystem. As a result of this development, countries in the Mediterranean Region are trying to develop traditional goat breeding systems at the distribution areas of especially the Kermes oak (*Qercus coccifera* L.) and Holm oak *(Qercus ilex* L.) species (Aldezabal and Garin, 2000; Ainalis and Tsiouvaras, 2004; Ainalis et al., 2006; Zarovali et al., 2007).

Turkey is one of the countries where the rural population carries out hair goat breeding traditionally and culturally. It is known that hair goat breeding is carried out for thousands of years on a wide geographical area stretching out in south and southeastern Turkey. The hair goat population was decreased in this country by applying the "Hair goat Action Plan" on the basis of the opinion that hair goats are among the animals that harm forests the most thereby resulting in the narrowing down of areas where these animals are bred. However, there is still a certain rural population that insists on sustaining the traditional way of life based on a breeding despite all the imposed sanctions. Isparta is one of the cities where majority of this rural population lives (*Fig. 2*). However, hair goat breeders in the city of Isparta have not yet started to benefit from the positive atmosphere resulting from the increased organic nutrition demand and the global importance given to traditional methods of production. In addition, the breeding of hair goats adopted to these areas dates back centuries in Mediterranean forest ecosystems and is receiving continuously increasing support for the as one of the most successful methods of organic animal breeding (Ince and Karaca, 2009; Ince et al., 2009; Koknaroglu et al., 2007; Basullu and Tolunay, 2010).

The aim of this study was to determine the opinions of breeders at two study areas that have similar demographic, socioeconomic and geographical conditions in the Isparta region on the improvement of sustainable forest resources, rangeland management and the ecosystem conditions in the region. Factors that impact the sustainability of natural resources were determined based on the opinions of goat breeders living on both study areas in the rural region after which the contributions that can be made for a sustainable management were indicated.

Materials and methods

Study area

Merkez and Sutculer districts in the province of Isparta located in the Mediterranean Region of Turkey were selected as the study area (*Fig. 1*). Because, the city of Isparta is one of the most important cities with regard to traditional hair goat breeding.

The study area is a mountainous region with high elevation (the average elevation of Merkez is 1068 m, and the average elevation of Sutculer is 991 m). This is a unique region where air pressure, oxygen amount and climate conditions differ. Therefore, it

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70277042

has an impact on all living population in this region. Hair goat breeding is an important means of living that provides income and food safety for the villagers in this region.

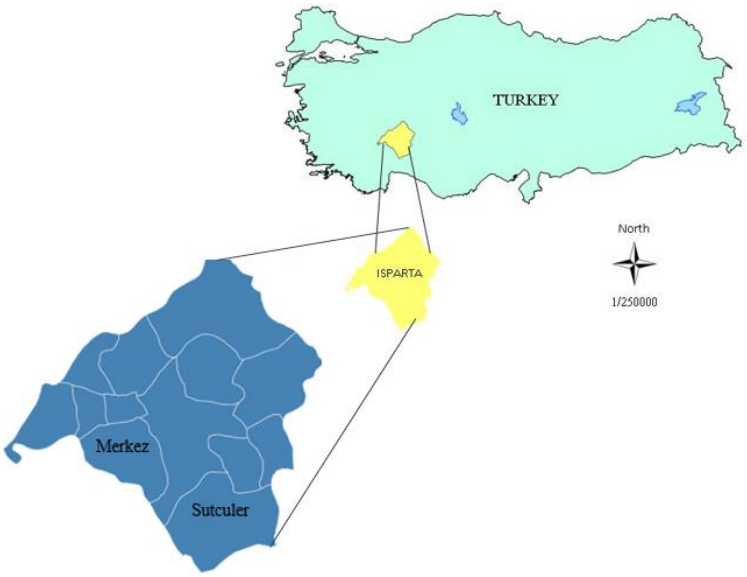

Figure 1. *Map of the study area*

Materials

The survey form prepared for obtaining the opinions of goat breeders on sustainable forest resources management was used for data acquisition. The survey form was comprised of 3 questions on the demographic characteristics of goat breeders, 4 questions on their socioeconomic characteristics, 10 questions on hair goat breeding and 13 questions on sustainable forest resource (forest-rangeland) management. The dependent and independent variables of the study are given in *Table 1*. There were a total of 180 and 144 goat breeders in the first and second study areas respectively and face to face interviews were carried out with 71 (40%) of the breeders in the first study area and 97 (67%) in the second study area. This sample group is considered as sufficient at a confidence interval of 10% (Karaasar, 2012; Sample Size Calculator; 2018). The survey was applied during March–August 2018 on randomly selected hair goat breeders aged above 18. The study variables generated based on the survey questions are given in *Table 1*.

Methods

Descriptive statistics such as frequency, percentage and crosstab values were used as the method of this study along with Mann-Whitney U Test, Chi-Square Test of Independence and Multivariate Linear Regression Analysis. The demographic-socioeconomic characteristics of Sutculer and Isparta districts breeders as well as their characteristics related with hair goat breeding-sustainable forest management were indicated via frequency and percentage values. Crosstab results were calculated for the "Age" and "Marital Status" characteristics as well as the variables of "Grazing penalty from the Forest Administration", "Cooperation with the Forest Administration" and "Quitting the breeding profession".

*Multiple options were marked

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70277042

Mann-Whitney U Test was used for determining whether there are differences in opinion between the breeders of the two selected districts with regard to the study variables (*Table 1*). Chi-Square Test of Independence was used for determining if there is any relationship between the demographic-socioeconomic characteristics and hair goat breeding-sustainable natural resource management characteristics for the two districts. In addition, Multivariate Linear Regression Analysis was applied for predicting the variables of "Cooperation with the forest administration (X18)", "Expelling tree-harming animals from the forest (X20)", "Expelling shoot-harming animals from the forest (X21)", "Desiring the children to be breeders (X27), "quitting the breeding profession (X26)" and "Warning people who can harm the forest (X30)". These analyses were carried out via IBM SPSS 22.0 package software and the reliability level during these statistical tests was accepted as 95%.

Results and discussion

Opinions of goat breeders on demographics, socioeconomics and hair goat breeding and sustainable natural resource management

Figures 2, 3, 4 and *5* provide an overview on the descriptive statistics related with the demographic, socioeconomic and hair goat breeding and sustainable natural resource management characteristics of breeders in Sutculer and Merkez districts.

As can be seen when the demographic characteristics of the Sutculer and Merkez districts breeders are examined that their age interval is 43-55 for 37% of the breeders in Sutculer and 36% in Merkez districts (*Fig. 2*). About 30% of all breeders in both study areas were above the age of 55. It is observed that the desire of the new generation to work as breeders was slightly higher in the Sutculer district (51%) in comparison with Merkez district (*Fig. 2*). Goat breeding is not a preferred profession among the young population in Turkey (Guney and Darcan, 2001). Hence, the concept of "Herd Manager" was tried to be integrated instead of the term "breeder" but to no avail. Recently, goat breeders in Turkey employ breeders from foreign countries such as Afghanistan, Pakistan and Syria (Tolunay et al., 2018).

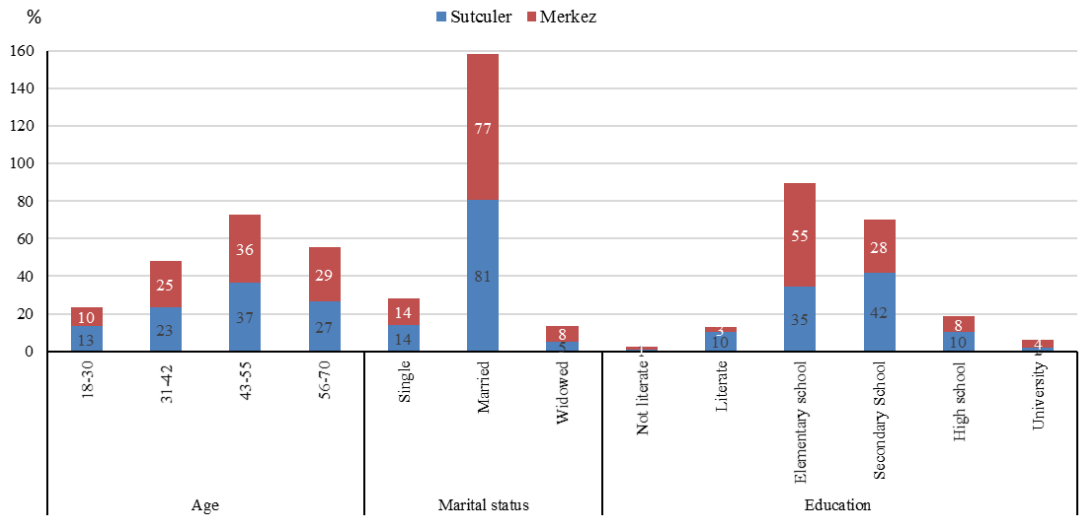

Figure 2. *Demographic characteristics of the samples*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70277042

It was observed that 81% of the goat breeders who participated in the study were married, while this ratio for the Merkez district was 77%. Of the breeders in both study areas, 84-93% continues this profession together with their family members (*Fig. 2*). Goat breeding in Turkey is a family profession (Arac and Daskiran, 2010). If we consider the levels of education, 55% in Merkez district were primary school graduates, whereas 42% in Sutculer district were secondary school graduates. The education level of goat breeders is generally low. The reasons for this can be indicated as nomadic life in rural areas, the distance of rangelands to areas of settlement as well as the fact that breeding is a full time profession (Ince et al., 2009).

Of the breeders, 73% in Sutculer and 59% in Merkez districts have been working in this profession for over 20 years. It was indicated by 96% of the breeders in Sutculer district, and 89% in Merkez district that they are continuing this profession based on traditional methods (*Fig. 3*). Traditional breeding is a unique form of breeding that is mostly based on methods passed down from earlier generations for which a style specific to the related region is adopted with positive impacts on the economy and handcrafts by way of different animal based products. It is of significant importance since these primeval traditions reflect the socio-cultural and economical lives of the local public.

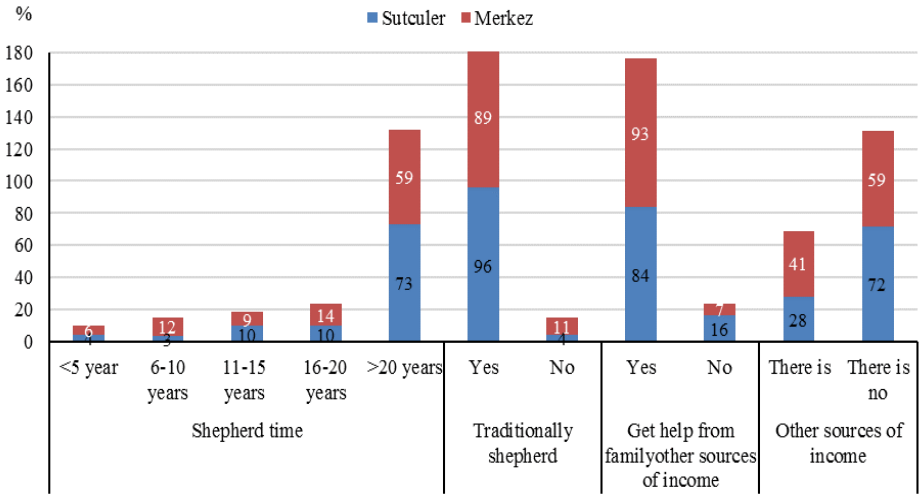

Figure 3. *Socio-economics characteristics of the samples*

When examined with regard to hair goat breeding characteristics, the most important problems that breeders face were grazing in Merkez district (39%) and low income in Sutculer district (55%). Grazing permit to foreign breeders was 83% in Merkez and 63% in Sutculer (*Fig. 4*). Hair goat breeding in Turkey is completely based on Forests and Forest rangelands. Other animal breeding activities either cannot be carried out in these areas due to environmental conditions or they can be carried out at minimum levels. Forests are legally allocated areas for hair goat breeding. However, "Grazing Regulation" has prohibited the grazing of hair goats in forests. The Forest Administration has filed lawsuits against individuals grazing hair goats in state forests based on the provisions of this regulation. Individuals convicted by judicial authorities were subject to fines and prison terms. Rangeland issue is still waiting to be solved as the most important problem of goat breeders (Tolunay et al., 2015).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70277042

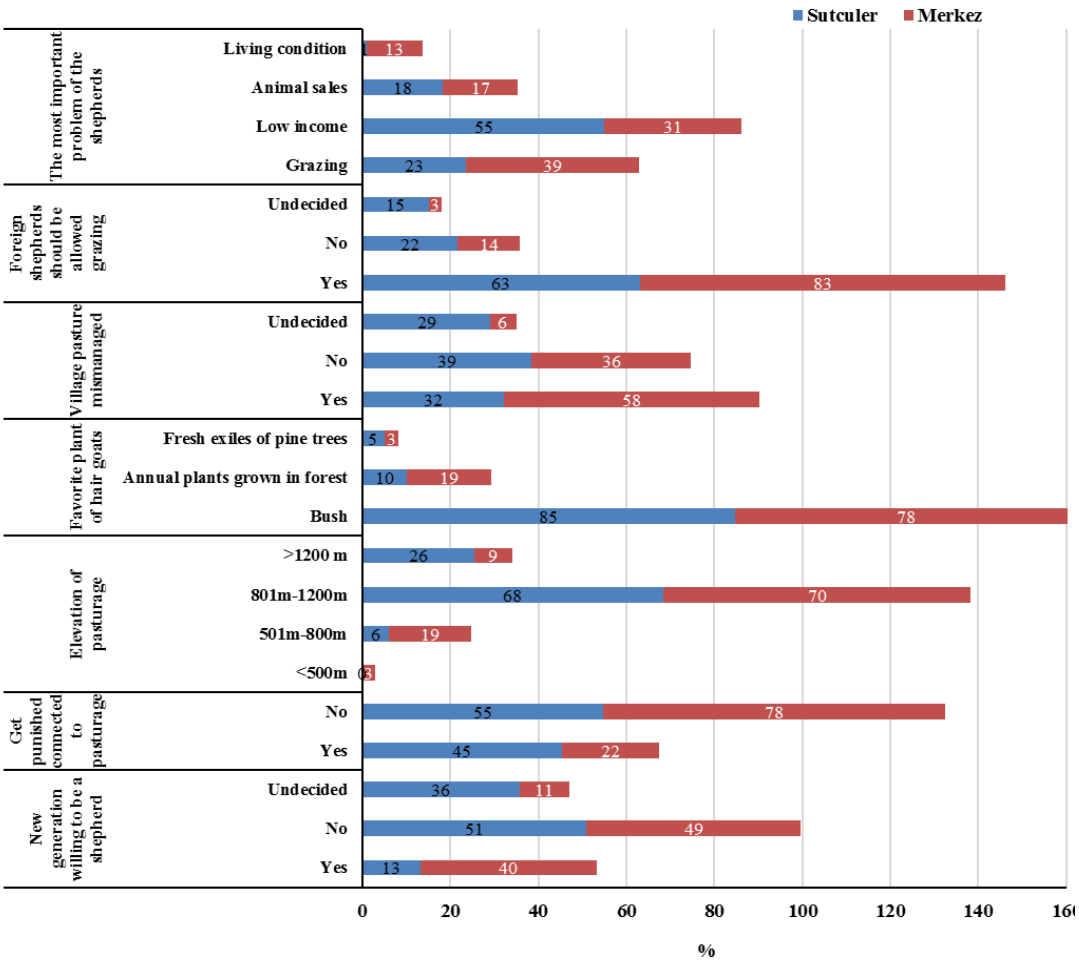

Figure 4. *Characteristics related to hair goat breeding of samples*

The fact that rangelands in Turkey are small and fragmented results in overgrazing pressure. Rangeland and Grazing are still issues waiting to be solved due to reasons such as the lack of planned grazing, excessive damages due to off-season grazing and overgrazing, failure to protect the rangeland borders, infrastructure problems of Rangeland Management Associations, general decisions on Grazing Period (Kaşıkcı et al., 2016).

Of the breeders, 58% are of the opinion that village headmen in Sutculer implement erroneous management with regard to rangelands. This ratio is 32% in Merkez District and is lower. Kermes oak and other shrubbery making up the Mediterranean scrubs were indicated in both groups as food preferred by the goats (85%, 78%). The goats are grazed at elevations ranging between 801-1200 m in both groups. Especially in the Sutculer District, 55% of the breeders were fined by the Forest Administration. Goat breeds of Turkey have been supported by Ministry of Agriculture and Forestry in Turkey. In the study areas, 65% of goat breedings are supported by the state for hair goat breeding, 17% of the others are for Honamli goat, 14% for Kilis goat and 4% of the other breeds. Goats are grazed in 35% mountain areas (around of forest areas), 30% in pastures, 24% in highlands and 11% in other fields.

It attracts attention that there both groups are sensitive with regard to warning those who harm the forests. It is striking that the children of breeders in both groups are

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70277042

conscious with regard to the protection of forests. A very little portion of the breeders want their children to be breeders. Of the breeders, 79% in Sutculer district and 64% in Merkez district indicated the need for new grazing areas. 75% of the breeders stated that there is no pasture in forest areas or around the forest (*Fig. 5*). It is also understood that the breeders are sensitive with regard to the prevention of harming the trees.

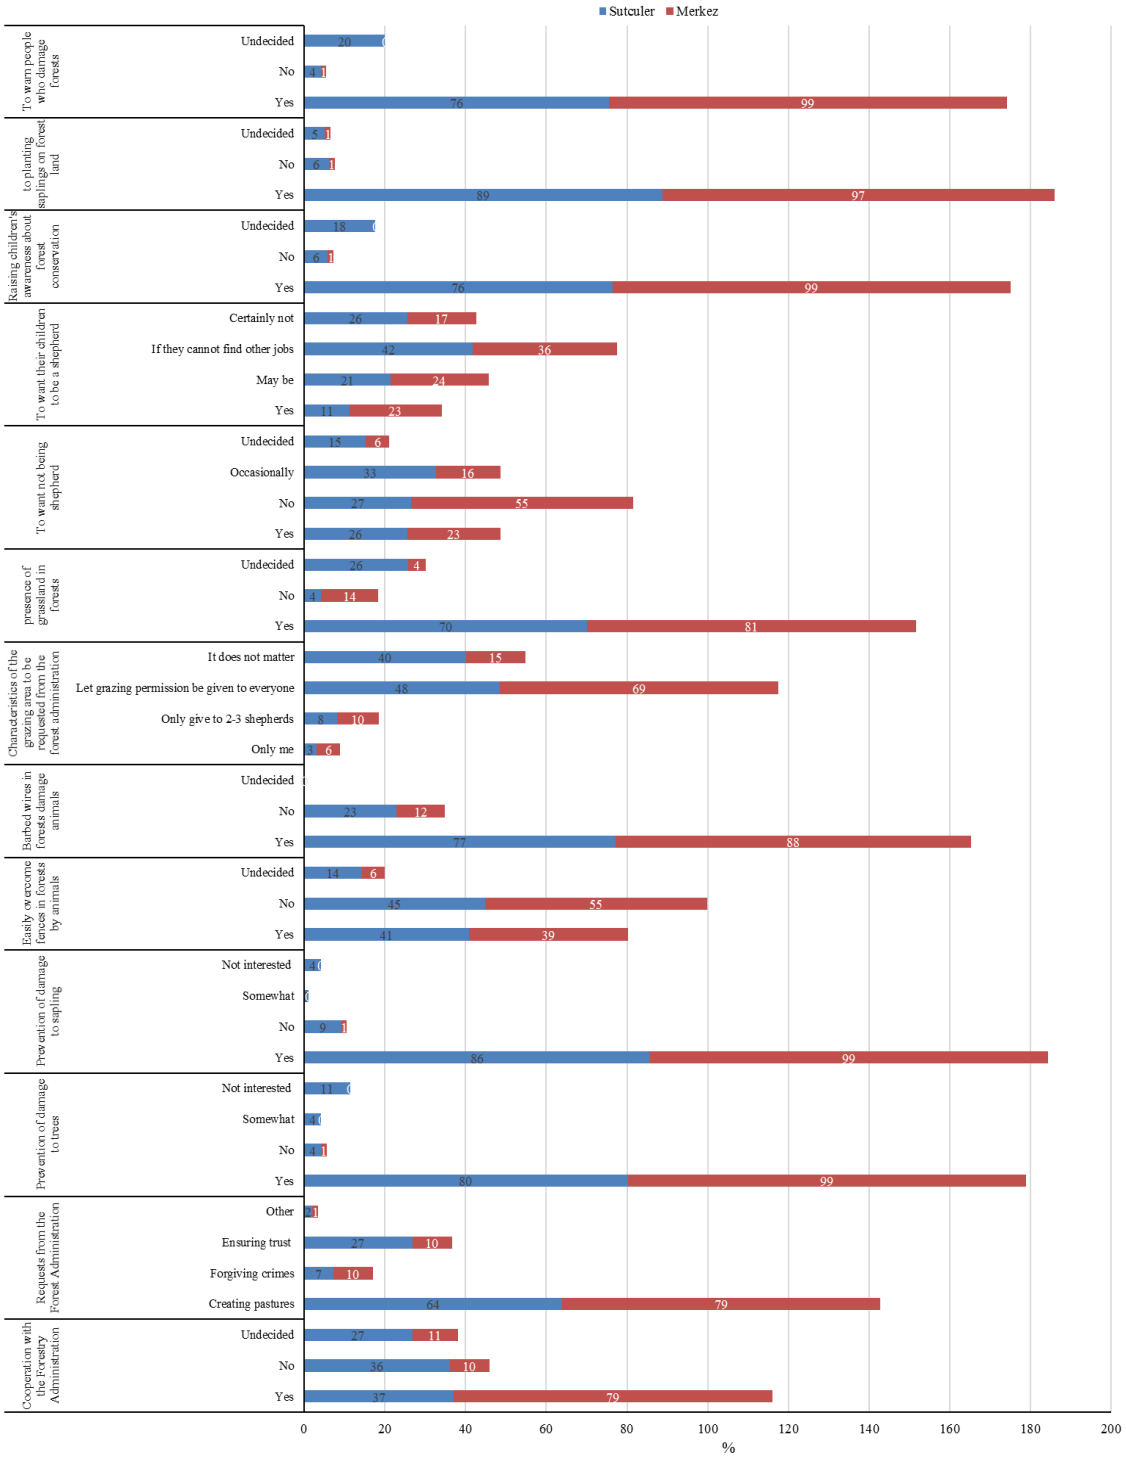

Figure 5. *Characteristics related to sustainable natural resource management of samples*

Examination of the impacts of the age and marital status of goat breeders on the management of sustainable forest resources

Crosstab results were calculated for the relation between the "Age" and "Marital status" characteristics of breeders in Sutculer and Isparta and the variables of "Grazing penalty from the Forest Administration", "Cooperation with the Forest Administration" and "Quitting the breeding profession" (*Tables 2* and *3*).

X_i: having grazing penalty, collaborating with the forest administration, quitting shepherd profession

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70277042

It was observed in the Sutculer district study area that the goat breeders in the age interval of 43-55 received more grazing penalties in comparison with the other age groups, that they are more inclined towards cooperation with the forest administration and that they do not want to quit this profession. It was also determined that the married goat breeders who continue this profession as a family received more grazing penalties in comparison with others but that they are always more inclined towards communication and cooperation with the forest administration. It was found that the individuals in this group do not want to quit the goat breeding profession.

Whereas it was observed in the Merkez district study area that goat breeders in the age interval of 31-42 received more grazing penalties and that they are not inclined towards cooperation with the forest administration. Some of the breeders in this age group stated that they are planning to quit this profession. It was also observed in this study area that the married goat breeders and those who continue this profession with their families were subject to more grazing penalties in comparison with others, that their levels of cooperation with the forest administration were low and that they do not want to quit this profession.

Differences in the opinions of goat breeders in the two study areas

Table 4 presents the Mann Whitney U test results indicating the differences in opinion of the breeders in both districts with regard to the study variables. There are certain differences between the perspectives of Sutculer and Merkez district breeders regarding hair goat breeding and sustainable natural resource management. In other words, the Mann Whitney U Test (*Table 4*) results indicate that 15 out of the 30 opinions obtained from Sutculer and Merkez district breeders differ. Of these, the desire of the new generation to continue the breeding profession for hair goat breeding was higher in the Sutculer district in comparison with the Merkez district. The breeders in Sutculer district suffer more due to grazing penalties. The average grazing elevation for hair goats in Sutculer district was higher in comparison with the Merkez district. It is a common opinion in Sutculer district that the village headmen implement erroneous management applications with regard to the rangelands. While foreign breeders receive more grazing permits in the Merkez district, but this ratio is quite low in Sutculer district. It was observed with regard to the perspective on the management of sustainable natural resources that the capacity to cooperate with the forest administration is quite high in the Merkez district and that the goat breeders are more conscious in the Merkez district in preventing the harms given to trees and young saplings.

Goat breeders in the Merkez district study area request new grazing areas with higher quality from the forest administration. Therefore, it is necessary to provide new grazing areas especially in shrubberies. The goat breeders generally have a tendency to quit the breeding profession, however rural conditions do not present them with job opportunities other than agriculture and ovine breeding. In general, they do not want their children to continue this profession. The breeders in the Merkez district stated that they try to raise the awareness of their children for protecting the forests and nature. They stated that they plant various tree saplings from time to time at certain locations. The goat breeders in the Merkez district indicated that they warn the people harming the forests for a sustainable nature.

According to the Chi-Square Test of Independence, the variables from among the X1, X2; X3, X4, X5, X6 and X7 variables for the breeders in Sutculer and Merkez

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70277042

districts and other study variables for which there are statistically significant relationships are presented in *Tables 5* and *6.*

A statistically significant relationship was determined between the age parameter of the goat breeders in the Merkez district and their children continuing the breeding profession. Elderly breeders indicated that they do not want the new generation to continue this profession. Grazing was determined as a significant problem in this area as well. The environmental awareness of individuals who continue this profession as a tradition increases with increasing levels of education. Those who continue this profession as a family have more requests from the forest administration with regard to the conditions at the grazing areas. Those who have an additional income from professions other than goat breeding want to continue this profession at areas of lower elevation.

Young goat breeders in Sutculer district are of the opinion that the village rangelands are managed erroneously and do not approve of the grazing permits provided for their own regions to breeders from other districts. It was determined that goat breeders with lower education levels are subject to more grazing penalties. Breeders involved in this profession for shorter periods of time are of the opinion that the village rangelands are managed erroneously. It was observed that goat breeders with means of income other than goat breeding graze their goats at lower elevations, follow up state aids and display more sensitive behaviors towards the environment.

The variables with a statistically significant relation between them are indicated in bold in *Tables 5* and *6.*

The results for the Sutculer district Multivariate Linear Regression Analysis carried out via Stepwise method are presented in *Table 7.* However, the R^2 levels were calculated to be very low (below 30%) in the Merkez district Multivariate Linear Regression Analysis carried out via stepwise method and hence the acquired results were not tabulated.

Table 7. *Multivariate regression analysis result of Sutculer district*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70277042

The specificity coefficient (R^2) level in regression models that explain the change in the dependent variables of the Sutculer district in a statistically significant manner was calculated as 44-49% for the X21 dependent variable and as lower than 25% for the other dependent variables. Hence, only the regression equalities for the "Expelling tree-harming animals from the forest" dependent variable can be used for estimation. Therefore, there is a need for other variables to estimate the related dependent variables for the Sutculer and Merkez districts breeders.

Conclusions

It was observed upon evaluating the results related with the general characteristics of goat breeding businesses that the breeders are generally above middle age and that they do not want their children to continue this profession. The education levels of current goat breeders were determined to be quite low. In light of these findings, it can be estimated that traditional goat breeding profession will decrease at a rapid rate in the coming years. The most important problem of goat breeders was determined to be grazing issue and a solution for this problem should be developed in cooperation with the forest administration. Of the goat breeders, 21% in the first study area and 45% in the second study area were subject to fines due to unauthorized grazing in forest resource areas. This is an important finding of the study and it can be stated that goat breeders make certain violations with regard to sustainable forest resources management due to the grazing problem they face. Hence, the cooperation between goat breeders and forest administrators should be increased to provide solutions to this issue.

It was determined that the interventions by goat breeders in the Sutculer district for preventing the goats from harming the trees in the forest during grazing decreased with increasing age, decreasing education level and the duration of experience in this profession (*Table 7*).

According to the study results, the two rural settlement areas are not similar with regard to characteristics related to demographic-socioeconomic and hair goat breeding as well as sustainable management of forests even though they are located in the same geographical region. Therefore, it is not sufficient to only consider geographical area similarity when determining the precautions for preventing breeders from harming the forests or in other words the precautions for enabling them to contribute to the sustainable management of forests. In addition, it was observed that especially age, education level and the duration of experience in breeding are variables that should be taken into consideration with regard to precautions for increasing the participation of breeders in the sustainable management of forest resources.

Acknowledgments. This study was supported by the Turkish Scientific and Technical Research Council of Turkey (TUBITAK) (Project No: 117O549). The authors extend their gratitude to the TUBITAK.

Conflict of interests. The authors declare that there is no conflict of interests regarding the publication of this paper.

Abstract. Dam reservoir capacity estimation is an important issue for operation, design and safety assessments of dam structures. In this study, the reservoir capacity of the Stony Brook dam in the USA was estimated by Generalized Regression Neural Network (GRNN), Support Vector Machines (SVM) and M5 Tree Model (M5T) methods with using 3726 data taken from United States Geological Survey Institute (USGS) for 2012-2015 years. Listed soft computing techniques give opportunities to researchers working on non-linear problems. Based on the non-linear approach, models are generated by using precipitation, flow, temperature hydrological parameters. The models were compared with each other according to the three statistical criteria, namely, mean absolute error (MAE), root mean square error (RMSE), and determination coefficient. As a result of the study, it is seen that Support Vector Machines (SVM) models have better performance in predicting dam reservoir level than the other used soft computing models.
Keywords: *estimation, reservoir management, soft computing techniques, neural network, statistical approach*

Introduction

Control of the water volume in the reservoir is achieved by accumulating and distributing water at the right time. There may be loss of life and property due to non-timely measures and water-related problems such as flood planning and management, design and operation of the hydraulic structures, navigation in the dam reservoirs, water supply for municipalities and industries, irrigation and drainage, flood damage reduction and water quantity modeling in the reservoir. That is why a proper dam reservoir management is a requirement not only in terms of fresh water supply, but also to prevent potential damages. One of the basic requirements for managing the dam reservoir in the most effective way is to determine the reservoir water volume, estimations the elevations and outflows in this volume. There are so many direct or indirect effects on reservoir levels changes. These effects can be listed as influences of atmospheric, natural, social and environmental conditions. Subdivisions of listed effects are seasonal climate changes and global warming, topography of watershed, fresh water demand, water distribution etc. Each of these effects has different impact on reservoir volume fluctuations and it needs to be considered for analyzes.

Artificial Intelligence methods are called black box models and in recent years they are frequently used in hydraulic and water structures planning because of the prediction abilities of these methods on non-linear problems (Demirci and Baltacı, 2013; Demirci et al., 2015a, 2015b, 2019; Kaya et al., 2018; Tasar et al., 2017, 2018). Artificial Neural Networks (ANN) is one of these models. Artificial Neural Networks are able to solve

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70437055

complex problems successfully due to their ability to learn and generalize (Ergezer et al., 2003). The foundations of the first modeling of artificial neural networks were laid in an article by McCulloch and Pitts (1943). They modeled simple artificial nerves on electrical circuits. Nowadays, there are many studies on the application of ANN to various cases frequently experienced in water resources. The ANN approach has been shown to represent the precipitation-flow relationship well (Mason et al., 1996; Minns and Hall, 1996; Fernando and Jayawardena, 1998). Turhan (2012) modeled the precipitation-flow relationship of the Seyhan Basin with the ANN method. Unes (2010a) predicted dam reservoir level by artificial neural network. Unes (2010b) also predicted density flow plunging depth in dam reservoir using artificial neural network. Chitsaz et al. (2016) used different estimation techniques for river flow forecasting and compared the results of generalized regression neural network (GRNN), multi-layer perceptron (MLP), adaptive neuro-fuzzy inference system (ANFIS) with each other. The result illustrated that MLP outperformed ANFIS and GRNN. Demirci et al. (2018) predicted dam reservoir volume using adaptive neuro-fuzzy inference system (ANFIS). Yin et al. (2016) compared abilities of different GRNN models such as rotated general regression neural network (RGRNN), feed-forward error back-propagation (FFBP) for river flow forecasting, models are created for semi arid region in China and results clarify that the combined RGRNN model has better performance on river flow forecasting. Unes et al. (2017) predicted dam reservoir volume using adaptive neuro fuzzy approach (ANFIS).

Support Vector Machines (SVM) are machine learning algorithms developed by Vapnik and other researchers (Vapnik, 1995; Cortes and Vapnik, 1995; Vapnik et al., 1997). This approach was originally developed as a way of interpreting sensor data and includes a two-tier structure. The first layer is a weightless nonlinear nucleus on the support vectors containing the input variable series, and the second is a weighted sum of core outputs. Once support vectors and appropriate core filters have been applied, the performance of SVM can be much better than the one of the other soft computing technique ANN in many cases. Many studies have been done for the learning of possible solving performance of SVM in hydrological problems. Dibike et al. (2001) investigated SVM performance for rainfall-runoff modeling and compared to ANN models. Bray and Han (2004) underlined the difficulty in determining a suitable model structure and related parameters for precipitation modeling. Chen et al. (2010) used SVMs to predict daily rainfall in the Hanjiang basin. The SVM technique has recently been effective in solving forestry problems (Nieto et al., 2012), in determining solar rays (Antonanzas et al., 2015) and predicting daily rainfall-runoff (Hosseini and Mahjouri, 2016). Recently, SVMs have been widely used to predict rainfall-runoff and water reservoirs. (flood and stream flow (Yu et al, 2006), atmospheric temperature (Radhika and Shashi, 2009), lake water levels (Khan and Coulibaly, 2006; Asefa et al., 2005; Khalil et al., 2006). Unes al. (2013) estimated dam reservoir level using artificial neural (ANN) network and support vector machines (SVM). M5T is one of the algorithms of decision trees. Decision trees, classification and regression can be applied to problems, effective, non-parametric, is a method that requires intensive calculation (Rao et al, 2007) The application of decision trees in hydrology is limited; only a part of published articles were used to estimate the dam reservoir capacity. Bhattacharya and Solomatine (2005) and Solomatine and Xue (2004) proved that M5T was very effective technique in the prediction rainfall-runoff. Goyal et al. (2013) applicated ANN, fuzzy logic and decision tree models (M5T) for the development of reservoir operating rules.

DOI: http://dx.doi.org/10.15666/aeer/1703_70437055

Sattari et al. (2013) used M5T for Turkey, Ankara, Sohi River to investigate the potential of daily stream flow. Esmaeilzadeh et al. (2017) studied performance evaluation of ANNs and an M5T model tree in Sattarkhan Reservoir inflow prediction.

Aim of this study is to estimate the reservoir capacity of the Stony Brook dam in Massachusetts, USA. By using temperature, precipitation and flow data, the reservoir capacity was estimated with GRNN, SVM and M5T models and the models were compared with each other.

Materials and methods

Study area

In this study, dam reservoir volume was estimated by using the temperature, precipitation and flow data obtained from the United States Geological Survey (USGS). The Stony Brook dam reservoir in the USA was selected as application area (*Fig. 1*). (USGS station no: 01104480). The Stony Brook dam is located in Middlesex County, Massachusetts with 42° 35' 46.3" (42.5962°) latitude and 71° 26' 18.7" (71.4385°) longitude. Drainage area of dam reservoir is 70.7 km^2. Stony Brook Reservoir reaches a height of 21 m; the deepest point is about 9.15 m, roughly $1.608.10^6$ m^3 of water at full capacity. Stony Brook is relatively small compared to the large basin and is much faster than other dams. Ekstrem air-temperatures were recorded as maximum, 36.5 °C, and minimum, -23.3 °C for all the dam catchment area. Stony Brook dam catchment's climate is classified as warm and temperate. Stony brook catchment has a significant amount of rainfall during the year. The average annual temperature is 11.3 °C in Stony brook. About 1025 mm of precipitation falls annually. 3726 daily data for five years were used between 2012-2017 years.

Daily air average temperature, precipitation, river inflow, lag time reservoir volume are taken as inputs and reservoir volume as output of the models. The temperature, precipitation, flow and past reservoir volume (time, t-1) of the Stony Brook dam were taken as input. 2126 of 3726 data were used for the training; remaining 1600 data were utilized for the test. Probable volumes in the next times are generated by the Generalized Regression Neural Network (GRNN), Support Vector Machines (SVM) and M5 Tree Model (M5T) artificial techniques. Reliability of the model results are examined with error parameters as root mean square error, mean absolute error, and coefficient of determination (R^2) between model volume estimations and observed reservoir volumes.

DOI: http://dx.doi.org/10.15666/aeer/1703_70437055

Methods

In this study 3726 day precipitation, flow and temperature data of the observation station were used in the Stony Brook Reservoir volume prediction. The results of Generalized Neural Network (GRNN), Support Vector Machines (SVM) and M5 Tree Model (M5T) are given as follows. The root mean square error (RMSE), mean absolute error (MAE), and the determination coefficients (R^2) were calculated for each model. The results were also used to compare the performance of the model estimation and observation data. RMSE and MAE are determined as follows in *Equations 1* and *2*, respectively:

$$RMSE = \sqrt{\frac{1}{N}\sum_{i=1}^{N}\left(Y_{i\,observed} - Y_{i\,prediction}\right)^2} \quad \text{(Eq.1)}$$

$$MAE = \frac{1}{N}\sum_{i=1}^{N}\left|Y_{i\,observed} - Y_{i\,prediction}\right| \quad \text{(Eq.2)}$$

where N is the data number and Yi is the reservoir volume data. Determination coefficient (R^2), root mean square error (RMSE) and absolute mean error (MAE) were calculated for the performance evaluation of GRNN, SVM and M5T models.

Support vector machines (SVM)

Support vector (SVM) is machine-learning approach in data-driven research fields which founded by Cortes and Vapnik (1995). SVM is basically used to best distinguish between two data classes. For this purpose decision limits or hyper planes are determined. In a non-linear dataset, SVM cannot draw a linear hyper plane. Therefore, the kernel numbers are used. The Kernel method greatly improves machine learning in nonlinear data. In the kernel method, the SVM estimator (y) process can be expressed as in *Equation 3:*

$$y = (K_{xi} \cdot W_{jk}) + b \quad \text{(Eq.3)}$$

In *Equation 3,* b is the bias term of the SVM network, and W_{jk} is called the weight vector. K_{xi} is a non-linear function that maps input vectors to a high-dimensional property field. The structure of the SVM model with three layers used in this study is given in *Figure 2.* The output value for this example SVM model is equal to the sum of the three products in the inputs and the independent combinations of Lagrange multipliers. Nonlinear nuclear functions used in this study are radial based kernel function and poly kernel functions.

Support vector machines with radial base functions (SVM-RBF)

Lagrange multipliers show the importance of training data sets for output data. The non-linear radial-based kernel function (Hsu et al., 2003) is shown in the *Equation 4:*

$$K_{xi} = e^{-\gamma\|p_i - y_i\|^2} \qquad \gamma > 0 \quad \text{and} \quad i = 1,2,3,\ldots n \quad \text{(Eq.4)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70437055

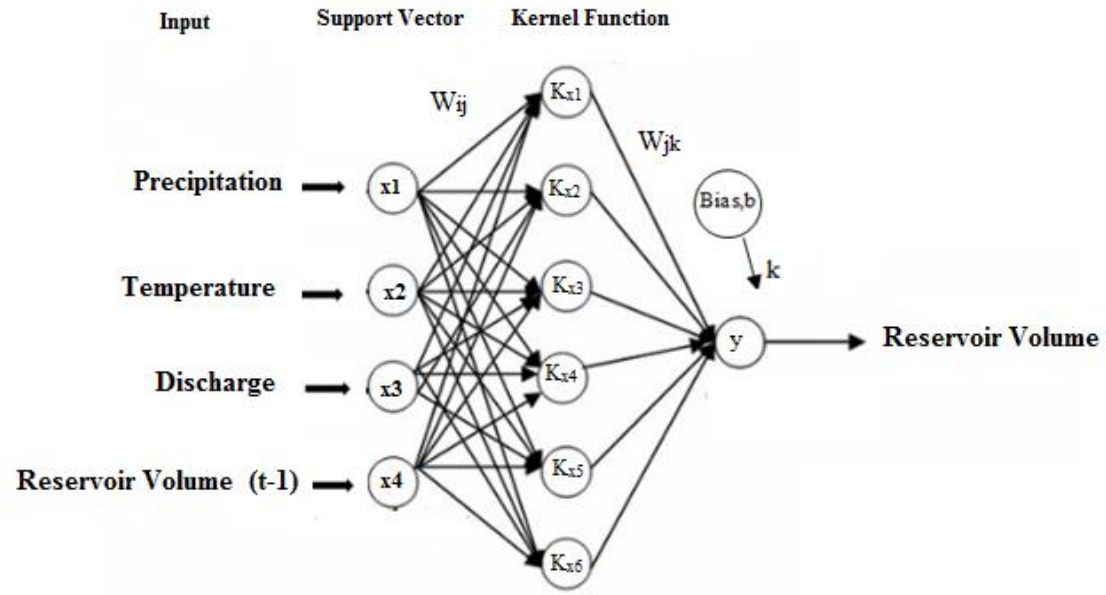

Figure 2. *Structure of SVM-1 model used in this study*

Support vector machines with poly kernel (SVM-PK)

Poly kernel function (Hsu et al, 2003) is shown by the *Equation 5:*

$$K_{xi} = (p.y + c)^d \qquad i = 1,2,3,...n \tag{Eq.5}$$

M5 decision tree method (M5T)

A decision tree is a logical model shown as a binary (two-way split) tree that shows how the value of a dependent variable can be estimated by using the values of the argument set. There are basically two types of decision trees:

(1) Classification trees are the most common and a symbolic class used to estimate the value of a numerical attribute.

(2) Used to predict regression trees (Witten and Frank (2005).

If each leaf in the tree contains a linear regression model used to estimate the target variable in that leaf, then it is called a model tree.

The M5 decision tree algorithm was originally developed by Quinlan (1992). A detailed description of this technique can be found in Witten and Frank (2005). A brief description of this technique is as follows. The M5 algorithm creates a regression sequence by iteratively dividing the sample space using tests on a single attribute that maximizes the variance in the target space. Mathematical formula to calculate standard deviation reduction (SDR) can be written as in *Equation 6:*

$$SDR = sd(T) - \sum I\frac{Ti}{T}I\ sdITiI \tag{Eq.6}$$

where T represents a group of samples reaching the node; Ti represents a subset of samples that are the result of the potential cluster; and sd represents the standard deviation. After the tree is enlarged, a linear multiple regression is created for each

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70437055

internal node using all the attributes associated with that node and the tests in the subtest of that node. Each sub-tree is then taken into account in pruning to overcome the problem of pruning. Pruning occurs when the estimated error for the linear model at the root of a child tree is less than or equal to the expected error for the child tree. Finally, smoothing is used to compensate for sharp discontinuities between adjacent linear models in the leaves of the pruning tree.

Generalized regression neural network (GRNN)

The GRNN architecture (Specht, 1991) includes the radial basic function (RBF) method. Any optional function between input and output vectors is derived directly from training data. GRNN is based on nonlinear regression theory for function estimation. The training set consists of x input values, each of which has a corresponding value of y output. This regression method estimates the y value.

GRNN estimates any function between input and output vectors using the training data. As the training set expands, the prediction error is reduced to zero. GRNN is used for estimation of continuous variables, just like standard regression techniques. *Figure 3* shows the Generalized Regression Neural Network model used in the present study.

Function classification with GRNN is done by using *Equations 7* and *8:*

$$K(x, x_k) = e^{-d_K/2\sigma^2} \quad \text{(Eq.7)}$$

$$d_K = (x - x_k)^T * (x - x_k) \quad \text{(Eq.8)}$$

where d_K is the squared Euclidean distance between the training samples x_k and the input x

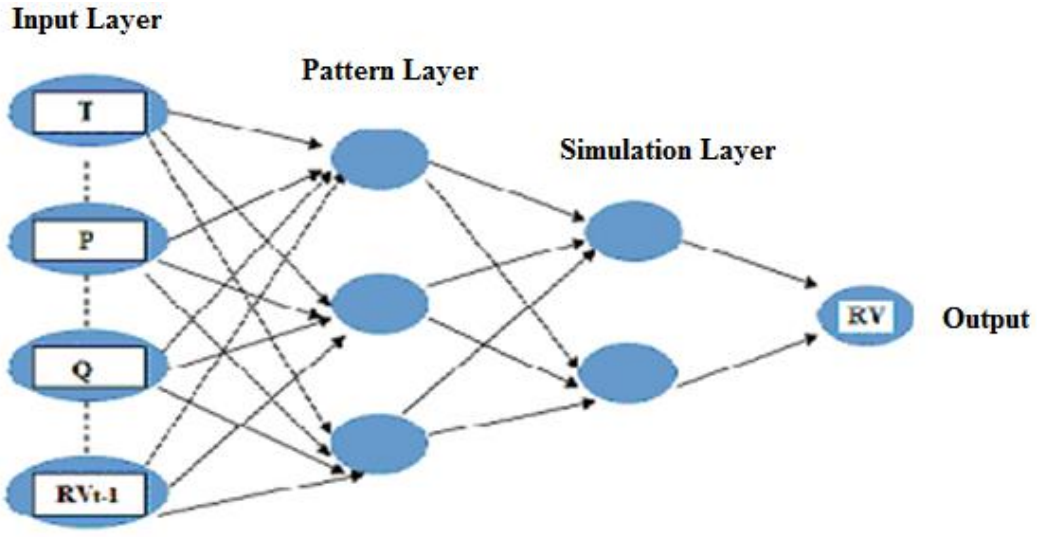

Figure 3. *Structure of GRNN1 model used in this study*

In GRNN1 model, Average temperature (T), Precipitation (P), Flow (Q), 1 lagged day reservoir volume (RVt-1) were taken as input and reservoir volume (RV) was predicted as output.

RMSE: root mean square error, MAE: mean absolute error, R^2: determination coefficient

In this study, Mean Air Temperature (T_t), Flow (Q_t), the lagged time Flow (Q_{t-1}), Mean Precipitation (P_t), the lagged time Precipitation (P_{t-1}) and the lagged time Reservoir Storage (RV_{t-1}) were used to reservoir storage capacity prediction.

The temperature, precipitation, flow and lagged time reservoir volume of the Stony Brook dam were taken as input. 2126 of 3726 data were used for the training; remaining 1600 data were applied for the test. The results obtained by the model were compared with the measured values. Obtained results of these studies are given in *Table 1*.

Predictions were made by using Generalized Neural Network (GRNN), Support Vector Machines with basic radial functions (SVM-RBF), Support Vector Machines with poly kernel (SVM-PK) and Decision Tree Methods (M5T). Three evaluations were made in all three models. Estimation results of the models were compared according to R^2 (Determination Factor), Mean Absolute Error (MAE) and Root Mean Square Error (RMSE) criteria.

In GRNN1, SVM RBF1, SVM PK1 and M5T 1 models, average temperature (T), Precipitation (P), Flow (Q), 1 lagged day reservoir volume (RV_{t-1}) were taken as input, In GRNN2, SVM RBF2, SVM PK2 and M5T 2 models, average temperature (T), Precipitation (P), Flow (Q), 1 lagged day Precipitation (P_{t-1}) and1 lagged day reservoir volume (V_{t-1}) were taken as input In GRNN3, SVM RBF3, SVM PK3 and M5T 3 models, average temperature (T), Precipitation (P), Flow (Q), 1 lagged day Flow (Q_{t-1}), 1 lagged day Precipitation (P_{t-1}) and 1 lagged day reservoir volume (V_{t-1}) were taken as input.

Scatter and distribution graphs showing the relationships of the three models with the real data are shown in *Figure 4* for GRNN, *Figure 5* for M5T, *Figure 6* for SVM PK and *Figure 7* for SVM RBF.

The performance of GRNN model is presented graphically in *Figure 4*. If the distribution and scatter graphs are examined, there is a good relationship between the estimated and observed values. When we looked at the RMSE, MAE and R^2 (21.8718, 14.4796, 0.9605) shown in *Table 1*, compared to other models, GRNN models showed the worst performance.

Data for 3726 days were evaluated for M5T models and the results were defined as follows. The distribution and scatter graphs of the M5T models are shown in *Figure 5*. When the distribution and scatter patterns are examined, the estimated values are close to the actual values. When we look at the benchmark values of RMSE, MAE and R^2 (22.1890, 14.9199, 0.9584) shown in *Table 1*, the M5T 3 model result are better than the other M5T models. Generally M5T model results showed better performance than GRNN models but showed better a little bit worst performance compared with SVM models.

In *Figure 6*, when the SVM RBF models are considered, it is seen that the determination coefficient is high and dam reservoir volume estimations are close to the actual values. The SVM RBF3 model showed low error, high correlation and better performance than other SVM RBF models according to the criteria of RMSE, MAE and R^2 (21.8718, 14.4796, 0.9605) as shown in *Table 1*.

For SVM PK models, the distribution and scatter plots are shown in *Figure 7*. When the scatter graphs were analyzed for the test data, SVM PK model results showed a better performance than SVM RBF models. The SVM PK3 model estimates are close to the actual values. In the SVM PK3 model with the highest coefficient of determination, R^2 = 0.9617. The SVM PK3 model gave best results than the other SVM PK, SVM RBF, GRNN and M5T models according to the criteria of RMSE, MAE and R^2 (21.8393, 14.2555, 0.9617)

Conclusion

In this study, Stony Brook dam reservoir volumes estimated by using Support Vector Machines with Radial Base Functions (SVM-RBF), Support Vector Machines with Poly Kernel (SVM-PK), Generalized Regression Neural Network (GRNN) and M5 Decision Tree (M5T). Precipitation, temperature, discharge parameters were applied as input to the models. The results were compared to the actual results and the relationship between the models was examined. As a result of the study in this paper it is possible to derive the following conclusions.

Different combinations of inputs parameters were used for each model. As it is expected, the model which use the all four suggested parameters as input has better performance than the other combinations in SVM, GRNN and M5T models.

Comparing all models, SVM-PK models have better performance in predicting dam reservoir volume. The SVM PK-3 model provides the best performance according to the low amount of error (RMSE, MAE) ratios and high coefficient of determination (R^2). In all models, GRNN models showed the worst performance in the prediction reservoir dam volume. SVM model performances are preferably better than M5T models. It is possible to state that However, comparisons indicate that Support Vector Machines model solutions can provide a tighter fit to the observed data. It was seen that SVM-PK method had less error than the SVM-RBF method.

The ANN correctly adapts to the changing input conditions, such as irrigation policy changes in this example. This is quite important since similar sudden changes can be

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70437055

observed on the related time series within the reservoir operation management studies. The advantages of applied soft computing techniques in this study over past conventional methods in the prediction of reservoir volume can be explained by saying that soft computing techniques structure includes the non-linear dynamics of the problem in the whole data set.

The monthly reservoir volume estimations obtained results based on this study can be quite informative for the determination of flood planning and management, the hydroelectric energy computations, design and operation of the hydraulic structures, navigation in the dam reservoirs, water supply for municipalities and industries, irrigation and drainage, flood damage reduction and water quantity modeling in the reservoir.

(Received 22nd Feb 2019 ; accepted 8th Apr 2019)

Abstract. The *Chilo infuscatellus* (Pyralidae, Lepidoptera; Snellen) caused significant losses in production and quality of sugarcane in Pakistan. The deficiency of easily discrete morphological and quantitative characters makes it remarkable to identify these characters in pest management. Present study; investigates the impact of morphological and quality traits of pest infestation during different stages of plant growth. Results revealed that varieties US-312, 1491, 718, 133 and CPF-246 performed better in terms of brix, POL, CSS, fiber, recovery, carbohydrates, moisture and fat contents percentage. Correlation values of different varieties in terms of qualitative factors were positive and significant. All plants traits in terms of qualitative factors including plant girth (cm), leaf area (cm), leaf sheath hairiness (cm^2) and leaf thickness (mm) showed positive and had highly significant correlation with pest infestation. The coefficient of determination value $R^2 = 0.821$ was obtained by computing brix, fiber contents, POL and CCS factors mutually from multivariate regression models. It was concluded, that morphological and qualitative plant factors could be helpful for management of sugarcane shoot borer.
Keywords: *Lepidopteran pest, management, plants, shoot borer, sugarcane*

Introduction

Sugarcane (*Saccharum officinarum*) is a perennial, tropical and subtropical crop cultivated in various regions of the world (Kfir et al., 2002). It is grown between tropical and sub-tropical climate (North latitude = 350C and South latitude = 350C) around the world. In Pakistan, sugarcane is a cash as well as industrial crop and grown on an area of 1217 thousand hectares with 73.6 million tons' annual production (Anonymous, 2016-17). The Pakistan sugar industry is second largest industry of the country after textile having GDP of 0.7% (Anonymous, 2016-17). Being a cash crop, it provides a huge quantity of raw material to sugar industry. In Pakistan, the average sugarcane yield is much lower than the other growing countries of the world (Kumarasinghe, 1999). There are many factors which are responsible for low sugarcane yield of sugarcane but most important factors are pests, in which borers are most damaging. Among borers, sugarcane shoot borer (Lepidoptera: Crambidae) is considered as the most damaging and injurious

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70577065

pest of sugarcane that resulted in reduced quality and quantity of cane sugar (Zia et al., 2007; Sabir et al., 2014). The molecular study was described to identify *C. infuscatellus* through PCR by using barcode region CO1sequence between the sugarcane shoot borer and four other species of sugarcane. A 285bp fragment was effectively amplified from all stages of different geographical population (Wang et al., 2017). It has been reported that sugarcane yield had been decreased from 20.78% to 57.9% in most parts of the world including Pakistan (Anwar et al., 2004). The injured plants attacked by this pest produce dead hearts during growing season before till the formation of canes and such plants do not grow further (Shahid et al., 2007). Yield losses could be minimized by planting some resistant varieties i.e. (R570) instead of susceptible i.e. (R579) (Goebel et al., 1999). Knowing the morphological and qualitative plant factors are helpful to examined the relationship between pest infestations (Khaliq et al., 2005). Therefore, objective of the present study was to find out the impact of morphological and quality traits of sugarcane against the pest infestations.

Materials and Methods

The experiment was conducted field area of University of Agriculture, Faisalabad-Pakistan under randomized complete block design (RCBD). The climate is very hot in summer up to 45°C while winter, it is cold up to 22°C. The average rainfall is very low as compared to other areas of Punjab. After the preliminary screening, nine sugarcane varieties including US-676, US-133, US-312, SPF-234, US-1491, US-824, CPF-246, US-718 and CPF-237 were selected.

The plot size was kept 5×10 m^2 and the experiment was repeated thrice. There were five rows in each plot for each variety. Middle three rows were selected for recording the data during preliminary screening. All the recommended agronomic practices (hoeing, earthing up, balance use of fertilizer and irrigations) were applied. The observations were taken at weekly intervals. The number of total internodes and infested internodes were counted separately from each cane and the borer infestation percentage was calculated by the following formula.

$$\text{Borer Infestation (\%)} = \frac{\text{Number of Infested Internodes}}{\text{Number of total Internodes}} x\ 100 \qquad \text{(Eq.1)}$$

Morphological Factors

Leaf thickness

Five plants were selected randomly from each block. The leaves were cut from the upper, middle and lower part of the plant and measured in (mm) to determine the leaf thickness with help of a binocular microscope (Made by Omax).

Leaf Area

Ten plants from each block were selected randomly. Three leaves one from top, middle and bottom portion of the sugarcane was taken and measured in (cm). Leaf area was measured with help of LI-30000, a portable leaf area meter.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70577065

Leaf Sheath Hairiness

Five canes were selected randomly from each block. Each leaf sheath was examined from three different places by a phase contrast stereo microscope (Made by Euromax). The number of hairs was counted in one (cm^2).

Stalk Girth

For stalk girth, 10 cane samples from each block were randomly selected from three different places upper, middle and lower from each the sugarcane sample was selected for stalk girth. The stalk girth was measured with help of ordinary measured (cm) using a measuring tape.

Qualitative Factors

Analysis of Sugar Cane

Analysis of cane includes brix%, POL%, CCS% and fiber% was determined. On the basis of these qualitative factors, the maturity of a cane variety was decided. When a cane variety attains brix (20%), POL (18%) and purity (80%) in any month from October to March, it was considered matured.

Juice Extraction

The representative cane sample consists of 8-10 numbers of canes which were passed through cane crusher to get juice. The extracted juice was collected into a plastic bucket.

Brix (%)

For the brix determination juice 400-500 ml was taken. The Brix was recorded through brix hydrometer (Made by Yuyao Hjiyi Electronics) calibrated at 200°C. When temperature of juice was above 200°C, then a correction factor was added (47) into brix reading, if the temperature was below 20°C, then correction factor was subtracted. Hydrometer was dip to down the movement into cylinder after 25 minutes, after that juice temperature was come at room temperature.

POL (%)

Two hundred ml of extracted juice was placed into a flask and 5g basic lead acetate was added and shaken well. The juice was filtered into a volumetric flask through a filter paper and injected into 200 mm polarimeter tube to record the POL reading. The POL reading was the measurement of the angle of rotation of dextrorotatory substances. Polarity worked on the principle that under certain standard conditions i.e. standard tube length, standard solution concentration and standard room temperature when a polarized light was passed through that sugar solution, then substances present rotate light at a definite angle. The measurement of that angle of rotation was POL reading. Calculations were done by following the formula of Payne (1968).

Commercial Cane Sugarcane (CCS)

The commercial cane sugar percentage (CCS%) was calculated by using following formula (Meade and Chen, 1977).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70577065

$$CCS\ \% = \{Sucrose\ \% - (Brix\ \% - Sucrose\ \%)\ X\ 0.4\}\ X\ 0.74 \quad \text{(Eq.2)}$$

where, 0.4 = multiplication factor, 0.74 = crusher factor.

Fiber Contents

Fiber contents were determined by collecting 12 canes, top internodes of three canes, and middle portion internodes of next three canes while lower internodes of remaining three canes were cut, separated, mixed and fed to the Jaffco cutter grinder (Jeffress Engineering). This instrument was not only cuts and grinds but also minces the internodes. 500 g sample of this grinded bagasse was weighed and pressed less than 2000 pound per square inches on a hydraulic press for two minutes. The fresh fiber cake was then prepared and weighed and dried in oven for 12 hours at 1000ºC. Percentage fiber was calculated using following formula (Payne, 1968).

$$\text{Percent fiber} = \frac{\text{Weight of dried sample}}{\text{Weight of sample (gram)}} x\ 100 \quad \text{(Eq.3)}$$

Sugar Recovery

It was calculated by multiplying CCS with a constant factor 0.94. Actually, to convert brown sugar into white sugar; 6% white sugar was also lost, therefore, a constant factor used. Sugar recovery was calculated with the following formula (Mathur, 1981).

$$Recovery = B.H.E. \times B.H.R. \times POL\%\ juice \times Juice\ extraction\ 0.94 \quad \text{(Eq.4)}$$

where

- B.H .E = Boiling House Efficiency
- B.H.R. = Boiling House Recovery i.e. B.H.R. = S (J-M)

J (S-M), here

- S = Sucrose purity
- J = Juice purity
- M = Molasses purity

Weight of sample + wt. lost during preparation.

Fat Contents

Fat was determined by taking 50 grams of crushed, oven dried sample in thimble plugged with cotton using n-hexane as solvent in a Soxhlet apparatus (Made by Corning Life Sciences) and heating the flask containing solvent. The fat extraction in Soxhlet was done by adjusting 3 drops of n-hexane per second till complete drawing of fat from sample. Then the content of the receiving flask was transferred to a pre weighed Petri dish and dried till to constant weight was obtained. Fat calculated with help of following formula (AOAC, 1996):

$$Fat\ (\%) = \frac{\text{Weight of fat in sample (gram)}}{\text{Weight of sample (gram)}} x\ 100 \quad \text{(Eq.5)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70577065

Moisture Content

For the determination of moisture, 50% sample from each variety was taken in petri dishes dried in hot air oven at 70°C for 24 hours, till constant weight. The moisture contents were calculated by the formula:

$$\text{Moisture}(\%) = \frac{\text{Moisture losses}}{\text{Weight of original sample}} x\ 100 \quad \text{(Eq.6)}$$

Moisture losses = Weight of original sample – Weight of oven dried sample.

Carbohydrates

Carbohydrate contents were determined by following formula:

$$\text{Carbohydrate (\%)} = 100\text{- crude protein + fats\% + crude fiber + ashes} \quad \text{(Eq.7)}$$

Statistical analysis

The data were analysed by analysis of variance (ANOVA) and means were compared by the Tukey's HSD test ($P \leq 0.05$) using software Statistix 8.1.

Results

Role of Physico-Morphic Factors on the Shoot Borer Infestation

The maximum leaf sheath hairiness (102 cm^2) was recorded in CPF-246 and variety SPF-234 showed minimum leaf sheath hairiness (53 cm^2). The maximum leaf thickness (0.660 mm) was found in variety CPF-246 while the variety CPF-237 showed minimum leaf thickness (0.583 mm). The maximum plant girth (5.4 cm^2) in variety US-824 and the variety CPF-246 showed minimum plant girth (4.37 cm^2) (*Table 1*). It is evident from the results (*Table 2*) that plant girth, leaf area, leaf sheath hairiness and leaf thickness showed highly significant correlation with pest infestation with r-value 0.139, 0.181, 0.287 and 0.381, respectively. Plant girth contributes 2% while leaf area contributes 6%. The contribution of leaf sheath hairiness and leaf thickness was 35.6% in fluctuating the pest infestation. The analysis of variance exhibited that all varieties were highly significant in terms of plant girth and leaf area showed significant impact on the pest infestation while leaf sheath hairiness and leaf thickness were important factors which showed maximum per unit change in population fluctuation of the pest. The maximum leaf area 466 cm^2 recorded in variety SPF-234 and the variety US-824 showed minimum leaf area (318 cm^2) (*Table 3*).

Role of Qualitative Factors on the Shoot Borer Infestation

The data regarding qualitative factors were subjected to mean performance, correlation coefficient values and multiple linear regression models to find out the impact of these factors on the infestation. The maximum percentage of brix was recorded in variety US-312 (23.43%) and the variety SPF-234 showed minimum percentage of 18.46%. The POL percentage in US-312 was higher (20.93%) while SPF-234 showed minimum POL percentage (15.27%). The variety US-718 showed maximum (15.84%) of CCS while variety SPF-234 showed minimum percentage of CCS (11.08%). The maximum fiber

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70577065

contents were found in US-676 (13.68%) while US-1491 showed minimum percentage of fiber contents (11.99%). The sugar recovery (11.74% and 11.52%) was maximum in US-312 and US-718, respectively while the variety SPF-234 showed minimum percentage of recovery (8.12%) (*Table 4*).

It is evident from the results (*Table 2*) that Brix and POL percentage showed significant correlation with pest infestation with r-values 0.650 and 0.683, respectively while the fiber and CCS also showed positive and significant correlation with shoot borer infestation with r-values 0.291 and 0.643, respectively. From the results it is concluded that that brix and POL were the important factors which showed significant effect on the infestation. Similarly, fiber contents contributed minimum (8.5%) towards the infestation while the brix contributed 44.6%. The POL contribution was recorded 58.5% when POL was added (*Table 5*). The 100 R^2 value was reached to 61.4% when all the factors computed together. From these results it is concluded that fiber contents showed negligible impact while other qualitative factors showed maximum per unit change in population fluctuation of the pest infestation.

Discussion

The performance of all varieties in terms of morphological plant factors like plant girth, leaf area, leaf sheath hairiness and leaf thickness showed highly significant interaction towards the borer infestation. The present findings are comparable with those of Khliq et al. (2005) who reported that leaf thickness, cane girth and leaf area showed positive and significant correlation with borer infestation. Significant differences were documented among all the trait for recovery. The maximum recovery was exhibited by the trait US-718 whereas the lowest was observed for the trait SPF-234. Similar results were also reported by earlier research of Sarwar et al. (2011). Khan et al. (2004) reported

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70577065

that there was no relation between plant girth and shoot borer infestation. Cornelissen and Fernandes (2001) described that the absorption of sugars in leaves affects the area of leaf damaged by herbivores in Bauhinia brevipes. The accessibility of plants increases with the quantity of reducing sugars, and resistance increases with organic acids according to Comes (1916). The quantity of reducing sugars, affected by insects which increased the vegetable tissues, as a result caused reduction in the organic acids. Correlation among morphological characters may reproduce biological processes that are of considerable evolutionary interest, correlation can be the result of functional, genetic and physiological or developmental characters (Mehmood et al., 2000; Ali et al., 2013, 2014, 2016).

The results are similar in with Baloch et al. (2005) reported that factors like fiber, brix, POL and CCS showed significant variations and reduced the damage. Brix and POL percentage showed significant correlation with pest infestation, while fiber contents and CCS showed significant correlation with infestation. The qualitative parameters after brix% and POL% in (*Table 5*) showed significant differences among the brix% and POL%. The lowest brix% was recorded for SPF-234 whereas highest was displayed by US-312. The maximum POL% was showed by US-312 and US-318 whereas the minimum POL% was showed by US-676. These results are in contrary with the findings of Panhwar et al. (2004). The present results are similar with those of Khan et al. (2004) who reported that there is positive relation between brix and shoot borer infestation. The present findings are partially comparable with those of Gupta and Singh (1997) who reported that brix, POL, fiber contents and CCS are affected by the borer infestation. Chang and Wang (1995) reported that sugar contents, brix and sugar purity are heavily affected by sugarcane borer. The CCS, POL% and brix contents showed significant effect on the borer infestation Khaliq et al. (2005).

Conclusion

It was concluded from present study that varieties US-312, 1491, 718, 133 and CPF-246 could be used to minimize the losses caused by shoot borer pest infestation and all these varieties showed significant qualitative and quantitative interaction towards *Chilo infuscatellus*.

Abstract. A few investigations have been done on characterizing heavy metals at Jazan district, mostly done as analyses of heavy metals associated with water, sediments and shrimps. The current study was carried out mainly to evaluate and characterize heavy metals concentrations in soils of the main Wadi Jazan and its tributaries in order to determine its environmental impacts. The heavy metals were measured by using ICP-MS. Results indicate that soil of Wadi Jazan area has different concentrations of heavy metals; some of them have economic importance such as Au, Ag and U, some other considered useful for the environment (Such as Cu, Se and Zn) and others are harmful for the environment (Such as Cd, Pb, and others). The most extremely soil pollution at Wadi Jazan is by Cd, where all analyzed samples have higher concentration than the maximum permissible concentration by the World Health Organization. Heavy metals concentrations along Wadi Jazan indicate that the most polluted area is located around Abu Arish City. The current investigation conclude that there are a direct effect of the harmful heavy metals on plants, terrestrial animals, fishes and marine organisms and human; due to the ability of these heavy metals to reach and entered the food chain, and hence causes different types of harmful effects and diseases. Present study refers also to the suitability of some recent techniques for soil remediation at Wadi Jazan, such as engineering remediation (Replacement of contaminated soil, soil removal, soil isolation and adsorption) and bioremediation (Phytoremediation).
Keywords: *environment, metals pollution, health risk assessment, sediments, Saudi Arabia*

Introduction

Minerals and rocks are important role in our lives due to their many benefits for humans, especially as they intervene in every industrial, agricultural and economic needs (Mart, 2014). The extent of nations and peoples progress is measured by its ability to find out what their lands contain from metals and rocks of economic value and also minerals and rocks which have a harmful impact on the environment and its components (Uluturhan et al., 2011). Soil pollution by heavy metals is considered one of the hot topics all over the woeld due to its direct and indirect impact on human health. The main objective of the current work is to analyze and characterize heavy metals in soil of Wadi Jazan, in addition the determination of its environmental impacts.

The most harmful minerals to the environment are arsenic, asbestos, cadmium, lead, mercury, manganese, antimony, zinc, barium, beryllium, bismuth, bromine,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70677084

chlorine, thallium and uranium. Recently it is approved that the aluminum is considered as a highly toxic metal (El Tahlawy, 2007). Most of these minerals present in the rocks and nature in very small amounts and for a long time, but as a result of erosion, decomposition and transportation of the exposed rocks by rains, flood, winds and others, as well as the extraction of these metals and their use in the industry led to many environmental and health problems that were not known before (Nadia et al., 2009). Usually these health problems arise due to these heavy metals replace other metals found in the body and perform important role in the organic function. For example, cadmium replaces zinc and lead eliminates calcium anywhere, and when concentrated cadmium or lead in the bone or tissue happens, it becomes difficult to get rid of them and they cannot be able to carry out the operations which were carried out by the original elements. This of course leads to a lot of diseases and health complications (Campbell, 2015).

Human activities at the Red Sea coastal area of Saudi Arabia have been increases during the last three decades causing different types of contaminants including heavy metals (Nadia et al., 2009). A comparative study on the concentrations of heavy metals in sediments and fish at Jazan - Saudi Arabia reported a higher percentage of heavy metals than those at the city of Beech for industrial activities and wastewater. The weathering of rocks and flash floods through valleys carry heavy metals such as Ni and Cr to coastal areas, leading to increase pollution with heavy metals (Alhababy, 2016).

Golam and Fahad (2017) have been studied the concentration of heavy metals at Jazan, Saudi Arabia, Red Sea coast within water, sediments and white shrimp. They indicated that heavy metals concentration is higher in water than those in sediments and white leg shrimp. Al Bratty et al. (2017) in their study of determining trace metals in drinking water sources at Jazan Area, Saudi Arabia, stated that trace and major elements were found to be below the standard guideline values, except for uranium in some tap water samples.

Alzahrani et al. (2018) assessed the heavy metals in grey mangrove (Avicennia marina) and its associated sediments at the Red Sea coast, Saudi Arabia. They stated that mangrove can accumulate heavy metals, notably Cr and Pb. Also sediments within mangrove areas ranged from moderately to heavily contaminate with Cd at Al-Haridhah area, and moderately contaminated with Cd at South Jeddah, Rabigh, Duba, and Jazan waste water treatment station.

Current research identifies types of heavy metals in Wadi Jazan and their concentrations in order to determine their impact on the environment and its natural components. This will cause pollution of not only the Wadi Jazan land, but the tributaries leading from it and the Red Sea coast beyond. The work will also discuss how to avoid the harmful effects of these minerals and rocks on the environment; as well as the economic importance of some analyzed heavy metals.

Materials and methods

The area of study and sampling

The study area was visited several times to conduct field studies, monitor and photograph observations and field relations. Collection and numbering of samples representing the soil and rocks and plotting their places on the topographical map of the study area by using GPS instrument have been done. In each station, a pit of 40 cm

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70677084

depth was made and the sample taken at three levels. Level one at the ground surface while level two at depth of 20 cm and level three at depth of 40 cm. The three parts of the sample were mixed in one sample representing the location of the station (*Fig. 1*).

Figure 1. *Field photographs clarifying sampling pits and GPS usage for determining sample location attitudes*

16 samples were selected for the chemical analysis (Due to the limitation in financial coast which specify for chemical analyses). The chemical analysis carried out for about 25 heavy and rare earths elements which include Li, Be, Al, V, Cr, Mn, Fe, Co, Ni, Cu, Zn, Ga, As, Se, Rb, Sr, Ag, Cd, Sn, Cs, Ba, Au, Tl, Pb and U to identify heavy metals and their concentrations in ppm. The analyzed heavy metals divided into certain groups according to the periodic table of elements. These groups include: Basic metals (Such as Al, Ga, Tl and Pb); transition metals (Such as V, Cr, Mn, Fe, Co, Ni, Cu, Zn, Ag, Cd, and Au); alkali metals (Such as Li, Rb and Cs); alkaline earth metals (Such as Be, Se and Ba); semi-metals as As; basic metal as Sn; nonmetallic as Se; and actinides as U. It is clear that the transition heavy metals represent the main bulk of analyzed metals.

The analyses have been done at King Khalid University, Department of Chemistry-Saudi Arabia by using Inductively Coupled Plasma-Mass Spectrometer (ICP-MS). Argon 99.999% - AH and ICP/ICP-MS standard solution of the 25 analysed elements were used. Microwave Digestion System (Anton Par Multiwave ECO) and (Hydrofluoric, Nitric and Hydrochloric acids and Cyclohexanone ACS reagent 99.0%) were used. Where all vessels have been cleaned with deionized water and 1% HNO_3. 0.2 g has been taken from each sample. The following acids (Reagents) were added to each sample: 1 ml of HF (Conc.), 1.5 ml of HNO_3 (Conc.) and 4.5 ml of HCl (Conc.). Then all samples have been digested using the following conditions: Power (800 W), total time (60 min) and temperature (240 °C). Each sample was repeated 3 times. Blank sample was prepared and spike sample as well. The end result of each metal analysis is considered the mean parameter of the three measured values of the same metal in each sample. Standard Deviation was also measured at every time from the three analysed values of each metal, and then the standard deviation mean was calculated for each metal analysis.

Geographical and geological setting

The studied Wadi Jazan area is located at the south west corner of Saudi Arabia on Red Sea coast. Investigated samples were collected during the field work at academic year 2017/2018, in addition some geological and geomorphological characters of the investigated area have been observed. *Figure 2* shows the satellite image of the investigated area around Wadi Jazan, and the location of the analyzed samples. It is clear from the map that Wadi Jazan up streams came from slightly mountainous areas and the main Wadi Jazan and its delta (downstream) are going towards the Red Sea coast at Jazan City.

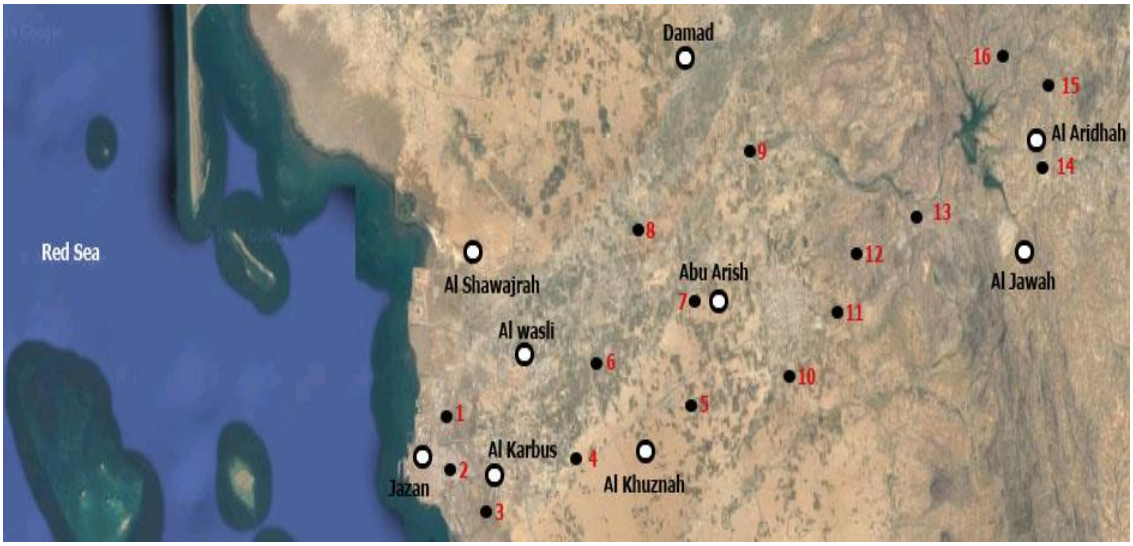

Figure 2. *Satellite image map of Wadi Jazan area, its tributaries, main cities (o) and locations of the analyzed samples (●)*

The investigated area mostly covered by alluvial and compact sediments of recent ages. In some areas near by the Wadi Jazan Dam Lake a volcanic lava flow rocks are present. Upon going further to the east, nearby Al Ardah, mountainous regions are stand up. To the west of Wadi Jazan Dam Lake, alluvial derived sediments are overlying the lava flow rocks. On the ground surface of this area it is observed the presence of rounded pebbles of different composition, shale and andesite flakes and quartz grains. At Wadi Sabiya and its tributaries there are a floodplain sediments of lower relief than its surrounded landscape rocks. These floodplain sediments were covered or capped by a lava flow rocks due to volcanic eruptions (Dabbagh, 1984).

One of the most important field observation at the study area is the presence of wadi floodplain sediments located under the lava flows of volcanic eruption which have been dated locally to 0.8 ± 0.3 mya, K/Ar age dating method (Dabbagh, 1984). There is a possibility to found in Wadi Jazan and its tributaries stratified old relics distributed at different places (Deves et al., 2013). A large numbers of old runes and relics were recovered on the surface of the lava flow on both sides of some tributaries of Wadi Jazan and commonly seen at the base of the quarry sections and represent different historical periods (Inglis, 2014).

Results

Data analysis

Chemical analyses have been done for 16 selected samples from Wadi Jazan area. The selection based on homogenous geographic distribution of samples at Wadi Jazan area and taking in consideration the field observations and surface features examination of mineral grains by using hand lens (10 X magnification). The chemical analyses have been don at King Khalid University, Department of Chemistry-Saudi Arabia by using Inductively Coupled Plasma-Mass Spectrometer (ICP-MS). 25 heavy metals were analyzed in each sample and *Table 1a* shows the chemical analyses of these heavy metals.

In general *Table 1a* delineated that there is richness in the concentration of heavy metals at Wadi Jazan area, in addition to the presence of some concentrations of precious metals such as gold and silver, and the presence of uranium as a radioactive mineral. *Table 1b* provides more comparison between the concentration of analyzed heavy metals in all investigated samples and locations. It shows the average range and the means of analyzed heavy metals concentrations at Wadi Jazan, in addition to the richest areas by heavy metal concentration. For examples: Cadmium (Cd) has an average concentration of 8.98 – 32.97 mg/kg and 20.97 mg/kg as a mean; the richest area is of sample no. 7. Nickel (Ni) ranges from 11.94 to 85.38 mg/kg with average of 48.66 mg/kg, and the richest area is of sample no. 11. Copper (Cu) occurs in-between 12.73 to 132.97 mg/kg and its mean is 72.85 mg/kg; the richest area is of sample No. 15. Lead (Pb) ranges from 6.79 to 32.03 mg/kg with a mean of 19.41 mg/kg; sample no. 7 is considered the richest area. Chromium (Cr) has a range of 23.3 – 131.15 mg/kg and 77.22 mg/kg as a mean; sample no. 16 is the richest area. For uranium (U), the range in-between 0.45 to 23.25 mg/kg and the mean is 11.85 mg/kg while area no. 7 is considered the richest area by uranium. From the data presented in *Table 1b,* it seems that sample no. 7 is the richest sample, of the studied 16 samples, by 9 different heavy metals (Pb, Rb, Sr, As, Se, Tl, Ag, Au and U). This of course will put a great attention on this location at Wadi Jazan (Around Abu Arish City) which will consider as the most polluted area by some harmful heavy metals such as Pb and U. Area of sample no. 11 (also nearby Abu Arish City) is also considered the second polluted locality as it is the richest area by 5 types of heavy metals (Ni, Co, Mn, Be and Ga). One of the most important observation is the more concentrations of heavy metals in areas located mainly nearby the Wadi Jazan upstream (Samples no. 11, 12, 14, 15, and 16), and heavy metal concentrations slightly became lower in areas nearby Wadi Jazan downstream (Samples no 1, 2, 3, 4, 5 and 6). This may explain that the main source of Wadi Jazan heavy metals might be the weathered sedimentary and volcanic rocks that mainly located at Wadi Jazan upstream tributaries. Rains and floods leached these heavy metals and transfer them along through Wadi Jazan to the Red Sea coast. Except the location of samples no 7 and 11 (Around Abu Arish City), which may have additional sources of heavy metals due to human activities in this area (agriculture and industries). *Figure 3* represents histograms for some heavy metals, such as Al, Be, Li and Cr, to show the variation in its concentrations along all analyzed samples.

Comparing current data with world permissible levels, general heavy metals characteristics background and the impact of heavy metal contamination of soils will help to understand the impact of heavy metal contamination of soil at Wadi Jazan.

Figure 3. *Histograms showing the concentrations of some selected heavy metals at different locations of the analyzed samples at the study area: (a) Shows that sample no 5 is the richest in Al, (b) Delineates that sample no. 11 is the richest in Be, (c) Shows that sample no. 14 considered the richest in Li, while (d) Indicate that sample no 16 is the richest in Cr*

Worldwide characteristics of heavy metal contamination of soils

1. Wide distribution: Economy and society development makes heavy metal contamination a serious threat to every country. In the world's top ten environmental events, two events have related to heavy metal contamination (Yang and Sun, 2009).
2. Strong concealment: As a result of colorless and odorless of heavy metal contamination, so it is difficult to be noticed. Nevertheless, when environmental conditions have changed heavy metals in the soil may be activated and cause serious ecological damage. So heavy metal contamination is usually chemical time bombs (Wood, 1974).
3. Difficulty of treatment: Air and water pollution problems can be solved by dilution and self-purification after controlling the sources of pollution. However, it is difficult to apply these techniques to get soils improved. Some soils contaminated by heavy metals could take one or two hundred years to be remediated (Wood, 1974). Therefore, remediation of heavy metal contamination in soils is expensively and the remediation cycle is relatively long.
4. Complex heavy metal contamination: Soil contamination in the past was mainly caused by a single heavy metal. However, in recent years more cases

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70677084

are found to be caused by a variety of heavy metals that led to compose contamination by heavy metal complexes (Zhou, 1995).

Common sources of heavy metals

Heavy metals in soils have different sources which include atmospheric deposition, sewage irrigation, industrial solid waste, mining activities, use of pesticides and fertilizers (Zhang et al., 2011).

1. Atmosphere to soils pathway: Heavy metals in the atmosphere are mainly from gas and dust produced by energy, transport, metallurgy and production of construction materials. The amount of heavy metals which went into the soil through natural deposition and raining sedimentation are related to the level of development of heavy industry, the city's population density, land utilization and traffic level. Soil contamination became to be heavier as closing to the city (Chen, 2002).
2. Sewage to soils pathway: Heavy metals are brought to the soil by irrigative sewage and are fixed in the soil in different ways. It causes heavy metals (Hg, Cd, Pb, Cr, etc.) to continually accumulate in the soil year by year.
3. Solid wastes to soils pathway: Mining and industrial solid waste contamination is the most common. When these wastes are piled or governed, heavy metals move easily due to the facilitation of sunlight, raining and washing leading to spread to the surrounding water and soils (Ding, 2000).
4. Agricultural supplies to soils pathway: Fertilizers, pesticides and mulch are important agricultural inputs for agricultural production (Zhang and Zhang, 2007; Zhang et al., 2011). Heavy metals are the most reported pollutants in fertilizers and the long time using of these products has resulted in the heavy metal contamination of soils (Arao et al., 2010).

Results compared with international permissible contamination

The maximum permissible heavy metal concentration in soil designated by the world health organization (WHO) is tabulated in *Table 2*.

Table 2. *Maximum allowed concentration limits of some toxic metals in soil (mg/kg or ppm). (WHO, 1996)*

Toxic metal	WHO maximum allowed limits (ppm)
Nickel (Ni)	80
Copper (Cu)	30
Cadmium (Cd)	3
Chromium (Cr)	100
Lead (Pb)	100
Zinc (Zn)	300

When comparing analyzed data of heavy metals in Wadi Jazan soils (*Table 1*) with those of WHO (1996) which presented in (*Table 2*) we found that: For Ni, only samples 11 and 16 are highly polluted and toxic by Ni. Samples 4, 7, 11, 12, 14, 15 and 16 at Wadi Jazan are highly polluted by Cu. For Cr only samples 11 and 16 are the most toxic, while for Pb and Zn all analyzed samples at Wadi Jazan are not polluted. The

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70677084

most extremely soil pollution at Wadi Jazan is by Cd, where all analyzed samples have higher concentration than the maximum permissible concentration by WHO. One of the most important observations from this comparison is the high toxicity of samples 11 and 16 by different heavy metals that should be taken in consideration for its environmental impact.

Table 3 presents the results of some trace and heavy metals concentration levels (Range and mean) in soils of Wadi Jazan, compared with international standard permissible levels in mg/kg (Hong, et al., 2014).

Table 3. *Mean concentration of investigated Wadi Jazan heavy metals compared to international standard limits of heavy metals in soil in mg/kg (Hong et al., 2014). EU = European Union Standard, USA = United State of America Standard, UK = United Kingdom standard*

Heavy metal (mg/kg)	Range at Wadi Jazan	Mean at Wadi Jazan	EU standard (mg/kg)	UK standard (mg/kg)	USA standard (mg/kg)
Fe	20.8 - 47601.44	23811.12	-	-	-
Zn	39.26 – 104.34	71.8	300	200	200 - 300
Mn	355.59 – 811.58	583.58	-	-	-
Cu	12.73 – 132.97	72.85	140	63	80 – 200
Cd	8.98 – 32.97	20.97	3	1.4	3
Cr	34.34 – 131.15	82.74	180	6.4	400
Pb	6.79 - 32.03	19.41	300	70	300

The compared results indicate significant variation in heavy metal levels in Wadi Jazan soil with respect to international levels. At all sites higher concentrations of Cd were observed than those compared world permissible Cd concentration. However concentrations of Wadi Jazan Zn, Cu, Cr and Pb heavy metals are lower than the compared international levels.

Heavy metals are specified into three classes of hazard according to (Vodyanitskii, 2016): The first (high-hazard) class includes As, Cd, Hg, Se, Pb, and Zn; the second (medium-hazard) class contains B, Co, Ni, Mo, Cu, Sb, and Cr; and the third (low-hazard) class encompasses Ba, V, W, Mn, and Sr. So it is possible to generalize that the total contamination will apparently be more hazardous in the case when the most toxic elements belonging to the first group are accumulated in soils rather than the low-toxic elements of the third group. Our analyzed data on *Table 1* indicates the presence of the three hazard classes of heavy metals, which led to take the environmental impact of these heavy metals concentration at Wadi Jazan very seriously now.

Discussion

Living organisms require various amounts of heavy metals such as iron, cobalt, copper, manganese, molybdenum, zinc and selenium. Where the consumption of these minerals is necessary and important to activate the metabolism of the body of these organisms. However, the consumption of large amounts (high concentrations) is harmful and even toxic and results in so-called heavy metal poisoning (Bolzan, 2014). Minerals account for 45% of the human body's weight, and most are concentrated in the skeleton. The dangerous of heavy metals comes from their bioaccumulation within the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70677084

human body faster than their degradation through the metabolism or output. The impact of heavy metals is due to the large distribution of biological agents among the various environmental components (water, air, soil) as well as among the components of the food chain. For example, rainwater works to dissolve rocks and raw minerals that are transported to currents and rivers to be distributed among the various environmental components and are bio concentration among organisms and then reach the food chain (Bharti, 2012).

Concentration of heavy metals, whether high or low, depends on several things (Jiwan et al., 2011) including: 1- If these minerals are found in water (Water pollution), their concentration is controlled by temperature, salinity, water waves, density, and the presence of coral reefs. 2- If these minerals are found in the air (Air pollution), they depend on air components in the environment such as carbon dioxide, nitrogen dioxide, temperature, and humidity. 3- If these minerals are present in the soil (Soil pollution), there are several factors that lead to increased concentration (Soil pollution), the presence of binding elements such as zinc to connect cadmium, as well as bacterial and biological groups, and concentration of organic gases such as methane and ethane. 4- If these minerals exist in living organisms (Pollution in living organisms), they are controlled by many factors such as: the movement of enzymes and the type of the organism. Some organisms have found quick absorption of contaminants due to the presence of help factors, and some animals reject heavy elements and contaminants due to the presence of other help factors as well. 5- It has also been scientifically proven that the concentration of minerals in different environments depends on the type of the pollutant and the state of the pollutant (gas, liquid, or solid).

Impact of heavy metal contamination of soils

1. Impact on soil microorganisms and enzymatic activity

Soil pollution can be caused by various pollutants, but heavy metals (Specially Cu, Ni, Cd, Zn, Cr and Pb) considered the main source (Hinojosa et al., 2004). Soil content from organic matter, clay minerals and P^H value have a direct influence on the effects of heavy metals on the soil biochemical characteristics of organisms (Speira et al., 1999). The toxic effect of heavy metals on soil organisms is to disrupt their biological processes, reduce their activity and their numbers. Some heavy metals cause disturbances on the enzyme activities and their chemical effects in the soil by different ways. Cd has more toxic effect to enzymes than Pb due to its higher ability for movements and lower adhesion with soil granules (Karaca et al., 2010). Our investigated samples at Wadi Jazan (*Table 1*) proved the presence of some heavy metals by considerable concentrations that caused soil pollution of Wadi Jazan area. These metals are mostly represented by Cu, Ni, Cd, Zn, Cr and Pb. On the other hand, one of the most important harmful mineral on the soil and all environments is U, which all our analyzed samples indicate its appearance in all over Wadi Jazan soil.

2. Impact on the plants

Plants growth has a physiological relationship with metals content of soil. Some heavy metals as As, Cd, Hg, Pb and Se are not provide any known physiological role in plants, but Co, Cu, Fe, Mn, Mo, Ni and Zn are considered a required metals for normal plants growth and activation of its metabolism processes. When the concentration of these elements increased over the suitable needed amount of plants growth, they

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70677084

become poisoning for plants and its final products (Rascio and Izzo, 2011). According to plant species and its ability for absorbing metals, the accumulation of heavy metals in plants occurs (Khan et al., 2008). In Florida, it was found that if the copper content in soil was more than 50 mg/ kg, it would affect citrus seedlings; if soil copper content reached 200 mg/ kg, wheat would wither (Zhang et al., 1989). This mean that soil of samples 15 (Cu = 132 mg/kg) and 16 (Cu = 73 mg/kg) at wadi Jazan are considered the worst places that have direct poisonous impact on plants. Plants absorption of heavy metals and subsequently its entering to the food chain is consider a harmful effect to animals and human health (Sprynskyy et al., 2007). Heavy metals absorption by plants roots is the main reason of heavy metals entrance to the food chain (Jordao et al., 2006). Presence of high concentrations of some heavy metals in Wadi Jazan area (*Table 1*) such as Cd, Zn, Cr, Mn, Cu, Ni, Pb, U and others may indicate that the growing plants, vegetation and trees at Wadi Jazan could have the chance for pollution by these heavy metals. Further future studies are needed to characterize the effect of high concentrations of some heavy metals in soil of Wadi Jazan area on plants, and to see to what extent these heavy metals were entered to the food chain.

3. Impact on the animals and fish

Terrestrial animals are mostly growing by consumption of water and plants during their daily life. High concentrations of heavy metals at Wadi Jazan soil and ground (*Table 1*) may cause the entrance of these heavy metals to the ground water and plants, hence the transfer to the food chain of animals. Of course these heavy metals cause danger effect on animal health and their growing. Not only this, but also will accumulated in the tissues of these animals and will transfer to human during the food chain.

In aquatic environment heavy metals are toxic even though when they present by small amounts. Heavy metals stand strongly against bacterial alteration and remain always in the marine (Woo et al., 2008). Heavy metals in aquatic environment commonly associated with small particles which precipitated with sediments. Recent surface sediments is considered the main tank of different minerals including heavy ones. Upon accumulation of heavy metals in aquatic microorganisms then fish, the transportation of these heavy metals to higher classes food chain is possible. Humans and other carnivores which represent the food chain top obtained their heavy metals indirectly from marine environments through the food. Fish consider the main factor for transferring heavy metals to higher classes food chain (Ayandiran et al., 2009). Taking into consideration the presence of different types of heavy metals at Wadi Jazan soil and its tributaries (*Table 1*). There is ability of rain water and runoff to transfer these heavy metals to the ground water and the Red Sea aquatic environment.

4. Impact on humans

The transportation of heavy metals from soil to plants, pastoral animals and fish, especially soil of high concentration in heavy metals led to human's health risk. Also taking into consideration the implications of food-chain that contaminated by heavy metals, it is intrinsic to conclude that food-chain considered the main route for humans exposure. Of course when heavy metals are not metabolized by human body they will accumulate in soft tissues causing different diseases. For example, Cd is a toxic heavy metal and has 8.65 specific gravity which is considered greater than water nearly by 8

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70677084

times. The liver, kidneys, lungs, bones and brain are the main target organs for Cd toxicity (Sobha et al., 2007). Cd may damage the metabolism of calcium, which will cause calcium deficiency and result in cartilage disease and bone fractures, etc. Agency for Toxic Substances Management Committee has listed Cd as the sixth most toxic substance that damages human health. Also the toxic clinical characteristics of Zn mainly referred as vomiting, diarrhea, bloody urine, liver and kidney failure and anemia (Duruibe et al., 2007). Despite Cu is considered as an essential element for mammalian nutrition where it is activate electrons movements between enzymes, but when they exposed to high Cu levels a number of harmful health problems could be happened (Stern et al., 2007). Pb affects and damages many of the body organs and systems, such as kidney, liver, reproductive system, nervous system, urinary system, immune system and the basic physiological processes of cells and gene expression. Ni is tumor promoting factor, whose carcinogenesis effect has attracted global concerns. Workers who are in close contact with the nickel powder are more likely to suffer from respiratory cancer, and the content of Ni in the environment is positively correlated with nasopharyngeal carcinoma (Chen, 2011).

According to the previous discussion and explanation about the effect of heavy metals on human, it is possible to reflect to what extent the presence and concentrations of heavy metals (*Table 1*) at Wadi Jazan area have a direct effect on the health of human populations and the environment in general. The source of these heavy metals at Wadi Jazan is most probably the different types of igneous and sedimentary rocks that located at the upper streams of the Wadi. The product of weathering processes of these rocks led to the release of their heavy metals content, and as a result of water runoff along the different wadi tributaries these heavy metals transfer to everywhere at Wadi Jazan and coastal areas. It could be some other additional sources such as industrial activities and the used compost in agriculture activities along the wadi.

From an economic point of view, *Table 1* shows the presence of some economic minerals such as Au, Ag, U, Li and other rare earth elements. In the future the precious metals such as Au and Ag should be evaluated by further studies at Wadi Jazan area, it could be present by economical values. U and Li are very important minerals (strategic minerals) which could be used in different industries. The present study refers preliminary to its presence, of course it need further detailed studies for make full evaluation and prediction of its reserve at Wadi Jazan area. Other occurred rare earth elements participate in different high tech industries and need further investigations as it wasn't the target of this research.

As a result of heavy metals accumulation in food chains and its harmful effect to living organisms a demand was increased around the world to technology of heavy metals separation and purification. Heavy metals can reach to water bodies due to agricultural runoff, industrial activities and applications. There are different technologies that can be used for heavy metals removal from water. These remediation technologies include: Precipitation and coagulation, ion exchange, membrane filtration, bioremediation, heterogeneous photo catalysts and adsorption (Gautam et al., 2015).

Remediation of heavy metal contaminated soils

1. Engineering remediation

Engineering remediation refers to using physical or chemical methods to control heavy metal contamination of soils.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70677084

a) Replacement of contaminated soil, soil removal and soil isolation:

Replacement of contaminated soil means adding large amount of clean soil to cover on the surface of the contaminated soil. Soil removal refers to remove the contaminated soil and renew it with the clean soil. Soil isolation means that to isolate the contaminated soil from the uncontaminated soil, but to completely remedy it still needs other auxiliary engineering measures (Zheng et al., 2002). All of these methods will cost large amount of manpower and material resources, so they can only be applied to small area of soils.

b) Electro kinetic remediation:

Soil electro kinetic remediation is a new economically effective technology. The principle is that the DC-voltage is applied to form the electric field gradient on both sides of the electrolytic tank which contains the contaminated soil. Through the way of electro-migration, electric seepage or electrophoresis, and thus reduce the contamination. The method performs well in the soil with low permeability (Hanson et al., 1992).

c) Soil leaching:

Soil leaching is to wash the heavy metal contaminated soil with specific reagents and thus remove the heavy metal complex and soluble irons adsorbed on the solid phase particles. By using this method, heavy metals are separated from the soil, and heavy metals are then recycled from extracting solution.

d) Adsorption:

Adsorption method is based on the fact that almost all heavy metal ions can be fixed and adsorbed by clay mineral (bentonite, zeolite, etc.), a steel slag, furnace slag, etc. (Wang and Zhou, 2004).

The most suitable techniques for Wadi Jazan are replacement of contaminated soil, soil removal, soil isolation and adsorption because of the small area of soils that have metal toxicity, and also due to the presence of some local resources (Such as used bentonite clay mineral in adsorption technique).

2. Bioremediation

a) Phytoremediation:

Using plants and their coexisting microbial system to remove heavy metals is a new technology. The key of the method is to find the suitable plants with strong ability for heavy metal accumulation and tolerance. Now more than 400 species of such plants have been found in the world, and most of them belong to Cruciferae, including the genus Brassica, Alyssums, and Thlaspi (Xin et al., 2003).

b) Microbial remediation:

Microbial remediation refers to using some microorganisms to perform the absorption, precipitation, oxidation and reduction of heavy metals in the soil. Siegel et al. (1986) found that fungi could secrete amino acids, organic acids and other

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70677084

metabolites to dissolve heavy metals and the mineral containing heavy metals. Fred et al. (2001) reported that the fungi, Gomus intraradices, may improve the tolerance and absorption of sunflower to Cr.

c) Animal remediation:

Some animals living in the soil (maggots, earthworms, etc.) can take heavy metals in the soil. Wang et al. (2007) proved that when the concentration of Cu was low in the soil, the activities and secretion of earthworms could promote the absorption of Cu by ryegrass.

Phytoremediation technique could considered most more effective to use at Wadi Jazan due to the suitability of the environmental conditions at Wadi Jazan for growing some plants which used in removing heavy metals depending on its microbial system (Such as Cruciferae, including the genus Brassica, Alyssums, and Thlaspi).

Conclusion

Sediments of Wadi Jazan area contaminated by different types of heavy metals and by different concentrations. These metals include Li, Be, Al, V, Cr, Mn, Fe, Co, Ni, Cu, Zn, Ga, As, Se, Rb, Sr, Ag, Cd, Sn, Cs, Ba, Au, Tl, Pb and U. Investigated heavy metals has a direct and indirect harmful environmental impact on soil, plants, terrestrial animals, aquatic environment and human health. Comparing analyzed heavy metals with those permissible by WHO indicate that: For Ni, only samples 11 and 16 are highly polluted and toxic by Ni. Samples 4, 7, 11, 12, 14, 15 and 16 at Wadi Jazan are highly polluted by Cu. For Cr only samples 11 and 16 are the most toxic, while for Pb and Zn all analyzed samples at Wadi Jazan are not polluted. The most extremely soil pollution at Wadi Jazan is by Cd, where all analyzed samples have higher concentration than the maximum permissible concentration by WHO. One of the most important observations is the high toxicity of samples 11 and 16 by different heavy metals that should be taken in consideration for its intensive environmental impact.

Heavy metals concentrations along Wadi Jazan indicate that the most polluted area is located around Abu Arish City. The main source of Wadi Jazan heavy metals might be the weathered sedimentary and igneous rocks that located at Wadi Jazan upstream tributaries. Rains and floods leached these heavy metals and transfer them along through Wadi Jazan to the Red Sea coast. Except the location of Abu Arish City which may have additional sources of heavy metals due to human activities in agriculture and industries.

The present study concluded the suitability of some recent techniques for soil remediation at Wadi Jazan, such as engineering remediation (Replacement of contaminated soil, soil removal, soil isolation and adsorption) and bioremediation (Phytoremediation). Selected techniques of engineering remediation are considered the most suitable ones for Wadi Jazan because of the small area of soils that have metal toxicity, and also due to the presence of some local resources (Such as used bentonite mineral in adsorption technique). Phytoremediation technique can also use due to the suitability of the environmental conditions at Wadi Jazan for growing some plants that used in removing heavy metals depending on its microbial system (Such as Cruciferae, including the genus Brassica, Alyssums, and Thlaspi).

Current investigation also clarify that some studied heavy metals have economic importance usage (Such as Au, Ag and U), and need further evaluations in the future.

(Received 23rd Feb 2019; accepted 10th Apr 2019)

Abstract. Nigeria's guinea savanna produces the bulk of the food consumed in the country and climate change is adversely affecting agriculture in the area. Farmers in the area respond differently to climate change based on their perception. Yet, studies that systematically link farmers' perception on climate change to scientific data from meteorological stations are rare in Nigeria's guinea savanna. Much rarer are studies that consider the simultaneity in the adaptation decisions of the farmers. This study therefore aimed at analysing farmers' perception in comparison with meteorological data and the determinants of adaptation efforts of crop farmers in the areas with data from Nasarawa State of Nigeria. To achieve this aim, the study combined time-series data on climatic variables obtained from a weather station and cross-sectional data from 160 smallholder farmers selected from the area. The study applied descriptive statistics, trend analysis, and multivariate probit model in analysing data collected. The study showed reduction in volume of rainfall and significant increase in surface temperature with the farmers having firm perception of these changes. The farmers responded to the changes in temperature and rainfall by choosing adaptation strategies such as use of improved crop varieties, soil and water conservation, tree planting, changing dates of sowing and tillage options, irrigation, diversifying their means of livelihood, and farmland management. Interestingly, these strategies were complementary and farmers' socioeconomic and institutional characteristics significantly determined adaptation in the area. Therefore, considering farmers' socioeconomic characteristics and improving the institutions will help in future and planned adaptation efforts of governments.
Keywords: *crop farmers, climate risk management, determinants, multivariate probit model*

Introduction

Climate change, which can be described at various scales – regional, national, or global – is a non-random change in the average weather conditions of a place overtime (Adejuwon, 2004; BNRCC, 2007; Nigerian Meteorological Agency, 2017). Empirical evidence confirms that the Earth has experienced a significant rise in temperature – between 0.65°C and 1.06°C – over the past 100 years (IPCC, 2013, 2014). The warming is real and significant but has varied across time and space with greenhouse gases, emanating from anthropogenic activities, being the major cause (Crosson, 1997; IPCC, 2014).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70857112

Climate change can retard/impede efforts being made by nations to achieve the sustainable development goals. The region that will suffer most of the impacts of climate change is Africa because it is the most vulnerable among other regions of the world and has the lowest capacity to adapt (Niang et al., 2014). Niang et al. (2014) documented dramatic and widespread evidence of global warming and other climate changes. Some of these impacts include threats to global food supply citing a decrease of up to 2 percent each decade in yields of staple crops like maize, wheat and rice; freshwater and marine species; ecosystem shift and species extinction; negative impact on agriculture; migration and security; heat waves, flood; shortage of water resources; destruction of homes and infrastructure; increased food insecurity; and violent conflict that lead to the destruction of infrastructure, livelihood opportunities and natural resources. Scientific evidence suggests that climate change may decline the output of major staple crops - wheat, maize, and rice (Niang et al., 2014; Olsson et al., 2014; Magrin et al., 2014; Hijioka et al., 2014; IPCC, 2015).

In Africa, the African Union adopted an African Climate Change Strategy in 2011, while, in the West African sub-region, ECOWAS has developed and adopted Climate Change Policy and Strategy Plan (2011). These policy documents provide priority actions in the region, which shape national climate change policies and strategies in member countries. The present research has been informed by the global, regional and national commitments and obligations.

In Nigeria's guinea savanna, the frequency and severity of heat waves, drought and intense rainfall is increasing and this is changing the vulnerability and exposure of economic sectors, livelihoods, people and assets. Agriculture is perhaps the most sensitive of all the sectors as most of the farmers depend on rain-fed agriculture. Reduced growing seasons and higher temperatures will affect agriculture (IPCC, 2007; Babatunde et al., 2011; Federal Ministry of Environment, 2014).

The guinea savanna area of Nigeria is known as the 'food basket' of Nigeria. Therefore, climate change will increase the challenge of food insecurity, compound or worsen the degree of seasonal hunger that pervades in many parts of Nigeria, especially Nasarawa State (Babatunde et al., 2011; DCC, 2013, 2014; Ethan, 2015). Dry-spell occurring any time during the growing season often exposes crops to moisture stress, hence farmers usually face problems of both too much and little moisture (Babatunde et al., 2011; Osabo et al., 2014). These have brought about changes in the way smallholder farmers make decision to adapt to their environment (Ajetomobi et al., 2010).

Lazkano et al. (2016) describe adaptation as any activity that reduces climate change-induced damages. The literature captures well some adaptation practices used by farmers in different parts of Nigeria. These include use of improved crop varieties, conservation practices, planting different crops, farmland management, agroforestry and irrigation (NEST and Woodley, 2011; BNRCC, 2011; Women Farmers Advancement Network, 2014; Onyeneke et al., 2017). Even though there are several studies on crop production and climate change (NEST, 2011; BNRCC, 2011; NEST and Woodley, 2011; Onyeneke et al., 2012; Falaki et al., 2013; Ezeaku et al., 2014; Ibrahim et al., 2014; Women Farmers Advancement Network, 2014; Odiana and Ibrahim, 2015; Tiamiyu et al., 2015; Tsojon, 2017), still little is known regarding the farmers' perceptions and adaptations in smallholder agricultural production systems in Nasarawa State in Nigeria's guinea savanna. In spite of the efforts of researchers in documenting climate risk management measures in agriculture in Nigeria, there is scanty empirical evidence on the determinants of the choice of adaptation strategies

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70857112

used by crop farmers in Nigeria. Furthermore, farmers by nature adopt multiple strategies to manage climate risks and such decisions are made simultaneously. Much rarer are research works accounting for the possibility of simultaneously or sequentially adopting multiple climate change adaptation strategies by farmers in Nigeria in particular and sub-Saharan Africa at large. Previous studies on climate change adaptation of farmers in sub-Saharan Africa mainly treated adaptation strategies singly without considering the joint and simultaneous adaptation decisions of farmers. Our study filled this gap in research by analysing the determinants of sequential adoption of climate risk management of farmers. Understanding farmers' perception, adaptation strategies and the complementarity or substitutability of the chosen strategies and their determinants is important for the determination of the effectiveness of farmers' adaptation efforts. Such knowledge will enhance policies and programmes directed towards enhancing the resilience of the agricultural sector of Nasarawa State and Nigeria. This study therefore aims to assess climate change perception and adaptation practices of farmers in Nasarawa State, Nigeria. In specific terms, the study:

i) described crop farmers' socioeconomic characteristics in Nasarawa State;
ii) compared trend of climatic data from the meteorological station with farmers' perception on the changes observed;
iii) identified and classified farmers' chosen adaptation strategies to deal with climate change; and
iv) analysed the effect of farmers' characteristics on adaptation choices.

Materials and Methods

Study Area

Nasarawa State is located in north-central Nigeria (*Figure 1*). The State lies within the guinea savanna and has a tropical climate. Two major seasons characterise the State – the rainy and dry seasons. The vegetation of Nasarawa is characterised by tall grasses and scattered trees. The population of Nasarawa State is 1,863,275 persons (National Population Commission, 2006). The State has thirteen (13) Local Government Areas namely. The inhabitants of the State depend mainly on agriculture with the production of varieties of cash crops throughout the year.

Sampling Technique

In selecting respondents for this study, the researchers employed purposive and random sampling methods. Firstly, two Local Government Areas (LGAs), Lafia and Toto LGAs, from the thirteen (13) Local Government Areas of Nasarawa State (*Figure 1*), that have high concentration of smallholder farmers and visible impacts of climate change LGAs, were selected. Since Lafia and Toto LGAs have high concentration of smallholder farmers and are affected by climate change, the researchers focused on these LGAs and randomly selected four communities in each of the LGAs. Finally, the researchers selected twenty (20) farmers randomly without replacement in each selected community making the sample size of the study 160 farmers. The sampling frames were provided by the extension agents working in the selected communities. Subjective judgment of ten officials of the Ministries of Agriculture and Environment in the State revealed that about 12 percent of farmers in the LGAs have been adversely affected by climate change hazards. The researchers

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70857112

used this proportion with a z-value of 1.96 for 95% confidence level and 5% error margin to compute the final sample size which gave about 161 farmers. The formula for calculating the final sample size is given in *Equation 1* as:

$$n = p(1 - p)\,(z/E)^2 \qquad \text{(Eq.1)}$$

where:
n = Final sample size;
p = Proportion farmers adversely affected by climate change (12% or 0.12);
z = Z-value at 95% confidence level (1.96);
E = error margin (5% or 0.05).

Types and Sources of Data

The study collected primary and secondary data. Interview schedule developed by the researchers was used to collect primary data from the farmers. The information contained in the interview schedule consisted of household characteristics of the farmers, institutional factors, perception, and adaptation measures. The researchers hired eight enumerators to assist in data collection in the eight communities. That is one enumerator per community. In order to ensure uniform and accurate data collection by all enumerators, one-day training was held for the enumerators. The researchers supervised the data collection as the study progressed. The survey was conducted between January and June 2014. The secondary data collected included climatic data such as annual temperature means, and annual aggregate rainfall. The climatic data were annual time-series data obtained in 2014 from the Nigerian Meteorological Agency for at least a period of thirty years. Due to data availability, the temperature data covered a period of thirty-three years (1981 – 2013) while rainfall covered a period of fifty-three years (1961 – 2013).

Method of Data Analysis

Descriptive statistics, trend analysis and multivariate probit analysis were statistical tools adopted for data analysis. Specific objectives i and iii were achieved with descriptive statistics. To compare farmers' perception on climate change and scientific data from meteorological station, a trend analysis was used to present the change observed in climate variables in the area and then link that to the anecdotal accounts from the farmers to check whether there is convergence or divergence. Many researchers have applied this method to model climate change trend and people's perception (Vedwan and Rhoades, 2001; Maddison, 2006; Gbetibouo, 2009). Multivariate probit regression was used to analyse the determinants of climate change adaptation decisions of farmers.

Multivariate Probit Model (MVP)

Multivariate probit technique was used to determine the interdependency of the adaptation practices and the socioeconomic factors influencing adaptation decisions. Lin et al. (2005) used similar model in their study. The adaptation practices are nominal variables and the researchers constructed a dichotomous dependent variable to capture whether such practice was adopted by a farmer or not. If a farmer used such practice, the researchers coded it as one and coded 0 for farmers who did not use such practice, and this makes the dependent variables binary taking only two values – 0 or 1 – (Gujarati, 1995; Greene, 2003). The study adopted the multivariate probit approach to model the factors influencing adaptation decisions of the farmers. An important advantage of the multivariate probit (MVP) framework is its strength in modeling the simultaneous or sequential decisions farmers make in climate risk management and this informed the choice of the MVP for this study. Farmers usually make complementary or substitutive decisions in choosing climate risk management strategies and the multivariate probit model makes interpretation of such simultaneous adaptation decisions possible and less difficult. The study has a set of eight binary dependent variables representing adaptation choices made by farmers, $Y_1, \ldots, Y_8$ such that:

$$Y_i = 1 \; if \; \beta i X' + \varepsilon i > 0 \qquad \text{(Eq.2)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70857112

and

$$Y_i = 0 \; if \; \beta i X' + \varepsilon i \leq 0, \; i = 1,2, \ldots ,8 \qquad \text{(Eq.3)}$$

where
$i = 1,2, \ldots ,8$ are the chosen climate risk management practices/adaptation options; X represents the vector of the predictors; β_i is the parameter estimates of the predictors; and εi, random error vectors having a zero mean, unitary standard deviation, and an 8×8 correlation matrix. *Equations 2 and 3* represent the multivariate probit framework of this study.

Dependent variables of the MVP

The adaptation strategies identified in this study as dependent variables are planting improved varieties of crops, portfolio diversification, soil and water conservation practices, adjusting the time of planting, changing soil tillage options, tree planting, irrigation, and farmland management. These are defined as follows:

1. Use of improved crop varieties: The adaptation options in this category are use of short gestation crops, use of flood tolerant crop, planting drought-tolerant crops, cultivating disease/pest-resistant crop cultivars, and planting different varieties of crops. These strategies have been documented as climate-resilient practices in the agricultural sector in sub-Saharan Africa (Napier, 1991; Nhemachena and Hassan, 2007; Yegbemey et al., 2014; Wondimagegn and Lemma, 2016; Mulwa et al., 2017). Any farmer who adopted at least fifty percent of the options under this category was considered an adopter of improved crop varieties and was coded 1 while any farmer who adopted less than fifty percent of the options under this category was coded 0.

2. Portfolio diversification: Piya et al. (2012), Gbetibouo (2009) and Deressa et al. (2008) classified portfolio diversification as an important climate risk management measure. The adaptation options in this category include diversifying from agriculture to non-agricultural activities, crop farming to livestock farming and mixed farming. Any farmer who adopted at least fifty percent of the options under this category was considered an adopter of portfolio diversification and was coded 1 while any farmer who adopted less than fifty percent of the options under this category was coded 0.

3. Soil and water conservation practices: These are very important measures in managing climate change because they aid in maintaining soil fertility, increasing yield and improving resilience. The adaptation options here include terracing, mulching, planting of cover crops, crop rotation and water harvesting. Any farmer who adopted at least fifty percent of the options under this category was considered an adopter of soil and water conservation practices and was coded 1 while any farmer who adopted less than fifty percent of the options under this category was coded 0.

4. Adjusting planting dates: This is a straightforward farm-level climate change adaptation strategy in Nigeria. The options here cover adjusting planting dates and shortening the length of growing period. Any farmer who adopted at least fifty percent of the options under this category was considered an adopter of adjusting planting dates and was coded 1 while any farmer who adopted less than fifty percent of the options under this category was coded 0.

5. Changing tillage operations: Changing tillage operations is also very important in climate change adaptation management in Nigeria. This involves planting on mounds and/or ridges. Any farmer who adopted this option/category was considered an adopter

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70857112

of changing tillage operations and was coded 1 while any farmer who adopted less than fifty percent of the options under this category was coded 0.

6. Planting trees: This covers tree planting on the farms for protection against scorching of crops. Any farmer who adopted this option/category was considered an adopter of planting trees on farms and was coded 1 while any farmer who did not adopt it was considered non-adopter and was coded 0.

7. Irrigation: This category includes irrigation and drainage. Any farmer who adopted at least fifty percent of the options under this category was considered an adopter of irrigation and was coded 1 while any farmer who adopted less than fifty percent of the options under this category was coded 0.

8. Farmland management: This involves adjustments in land use and land management. The main option here is changing land area cultivated. Any farmer who adopted this option/category was considered an adopter of farmland management and was coded 1 while any farmer who did not adopt it was considered non-adopter and was coded 0.

Independent variables of the MVP

The independent variables are:
X_1= Education of household head (years spent in school)
X_2= Age of household head (years)
X_3= Household size (number of persons)
X_4= Income (Naira)
X_5= Livestock ownership (number owned)
X_6= Extension contact
X_7= Farming experience (years)
X_8= Availability of credit (Naira)
X_9= Farm size (hectares)
X_{10}= Distance to markets (kilometres)
X_{11}= Distance to water sources (minutes)
X_{12}= Disposed to take crop farming risks (Dummy variable; yes = 1, no = 0)
X_{13}= Membership to farmer groups (Dummy variable; 1=member or 0 =not member)

Results and Discussion

Farmers' Characteristics

Table 1 presents the demographic characteristics of the farmers. Analysing the demographic properties of farmers is very important in understanding the type of farmers studied, which has implications on the adaptive capacity, choice and degree of climate resilient agricultural practices chosen and implemented. *Table 1* showed that the farmers' average age was 45.66 years which is an indication that they are mainly young adults. Younger farmers are more experimental and productive than older farmers and would be more disposed to adopt strategies that build their resilience than their older counterparts. This result is not far from the findings of other researchers in different parts of Nigeria. Onyegbula and Oladeji (2017) noted that the average age of rice farmers in three rice-producing States in Nigeria was 45.3 years while Ifeanyi-Obi et al. (2017) averred that the average age of cocoyam farmers in Southeast Nigeria was 51

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70857112

years. Also, similar findings abound in other parts of Africa. For example, Mulwa et al. (2017), in their study on farmers' response to climate risks in Malawi, found that the average of the farmers was 50 years, Feleke et al. (2016) recorded an average age of 43.4 years among Ethiopian farmers while Nhemachena et al. (2014) found the average age of Southern African farmers to be 47.41 years.

11-15	56	35.00	
Total	**160**	**100.00**	

Majority (98.12%) of the farmers were males. Thus, male-headed households are predominantly involved in agriculture in the area than the female-headed households. This may be connected to ownership of agricultural production resources in the area as men have more access to the resources than females, and hence will adapt more readily to climate change than females. Mulwa et al. (2017), Wondimagegn and Lemma (2016), Asfaw and Admassie (2004), Tenge et al. (2004) documented male dominance in agriculture across sub-Saharan Africa. The majority of the farmers (93.75%) were married with both partners alive which is similar to the percentage (92.00%) recorded by Ifeanyi-Obi et al. (2017) among farmers in Southeast Nigeria. In many rural

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70857112

agricultural communities, husbands, wives and children work in the farm which usually compensates farm labour needs of the household and increases agricultural production.

The level of education of farmers showed that majority of the farmers (85%) received a formal education suggesting that the farmers are literates. Similar level of literacy was recorded by Okpe and Aye (2015) among farmers in Makurdi, Benue State of Nigeria. With this level of education, farmers in the area would be readily disposed to adopting strategies that will help them manage climate change. The result of household size indicates that the farmers have large families with an average of 10 persons per family. The farmers were smallholders because they operated an average farm size of 4.31 ha. This may support or discourage adaptation depending on the farm management options and decisions pursued by the farm household.

Comparison between Farmers' Perception of Climate Change and Meteorological Station's Recorded Data

The study also analysed trend of climate data recorded for a long period. The trends in recorded climate data were then linked to farmers' perception of the changes. Climatic variables (temperature and rainfall) were explained to smallholder farmers using their knowledge of local weather conditions and the researchers sought their perception on changes in the climatic variables for at least for the past twenty years.

Temperature

Perception on changes in temperature is classified into three categories- "decreased", "unchanged" and "increased" (*Table 2*). The result indicates that most farmers (76.25%) perceived that long-term temperature is increasing.

Table 2. *Farmers perception on change in temperature (n = 160)*

Perception	Frequency	Percentage
Decreased	23	14.38
Unchanged	15	9.38
Increased	122	76.25
Total	**160**	**100.0**

Temperature data from the weather station showed an increasing and statistically significant trend and correlation with time (*Figure 2*). Time is therefore, a major determinant of temperature changes observed in Nasarawa State. This confirms that global warming is real and significant in Nasarawa State. Babatunde et al. (2011) and Anuforom (2010) reported significant and steady increase in the temperature of the savanna region of Nigeria where Nasarawa is located. Scientists in different parts of Africa and Asia have documented similar evidence. For example, Fosu-Mensah et al. (2010), Akponikpe et al. (2010), Nwajiuba and Onyeneke (2010), Acquah-de Graft and Onumah (2011), Enete and Onyekuru (2011), Acquah-de Graft (2011), Fosu-Mensah et al. (2012), Falaki et al. (2013), Umeh and Chukwu (2015), Biola et al. (2015), Olujobi (2015), Nkwusi et al. (2015), Ndamani and Watanabe (2016), and Ehiakpor et al. (2016) documented evidence of increasing temperature across different countries in West Africa. Maddison (2006), Kurukulasuriya and Mendelson (2006), Nyanga et al. (2011), Mandleni and Anim (2011), Gandure et al. (2013), Hitayezu et al. (2017) recorded steady increase in surface and atmospheric temperature across Southern Africa while in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70857112

East Africa, Gbegbelegbe et al. (2018), Mkonda and He (2017), Mutunga et al. (2017), Kebede and Gizachew (2017), Mwalusepo et al. (2015) found that most agroecological zones in East Africa are experiencing rising temperature. Shrestha (2014) recorded changing temperature in Nepal.

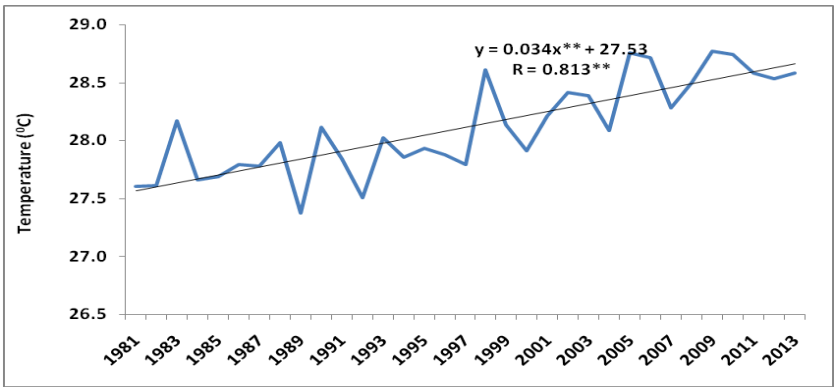

Figure 2. *Trend of average temperature in Nasarawa State from 1981 to 2013. Nb: ** Significant at 1% level of probability*

There is convergence in temperature data from the meteorological station and anecdotal accounts from the local crop farmers. Consequently, farmers' perception of climate change through observation of temperature increase could affect the climate change adaptation decisions they make. This corroborates the findings of Rakgase and Norris (2015), Ugwoke et al. (2012), Onumadu and Okore (2012), Nwosu et al. (2014) in Nigeria; Boansia et al. (2017) in Ghana and Burkina Faso; Ogalleh et al. (2012), Mwalusepo et al. (2015), Mutunga et al. (2017) in Kenya; and Jiri et al. (2015) in Zimbabwe. These scientists showed that farmers perceived increasing temperature in their respective study areas.

Aggregate Rainfall Volume

Most of the farmers (77.50%) averred that rainfall in the area is reducing in aggregate volume (*Table 3*).

Table 3. *Farmers' perception on change in total rainfall volume (n = 160)*

Perception	Frequency	Percentage
Decreased	124	77.50
Unchanged	2	1.25
Increased	34	21.25
Total	**160**	**100.0**

The result of the trend analysis on volume of rainfall in the area shows a high inter-annual variability in volume of rainfall which also resulted in a negative and very low correlation between rainfall volume and time (*Figure 3*). The result implies that aggregate rainfall volume shows a slight but insignificant reduction while surface temperature is getting hotter in Nasarawa State. If this trend continues Nasarawa and the Guinea Savanna may experience increasing challenges of climate change in the nearest future. This may aggravate the risks of floods and droughts as observed by Babatunde et

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70857112

al. (2011) and Anuforom (2010). Farmers' perceptions on aggregate volume of rainfall in other savanna regions across Africa recorded declining aggregate rainfall volume and change in the pattern of rainfall (Maddison, 2006; Nhemachema and Hassan, 2007; Yesuf et al., 2008; Mandleni and Amin, 2011; Sofoluwe et al., 2011; Fosu-Mensah et al., 2012; Tessema et al., 2013; Olujobi, 2015; Mwalusepo et al., 2015; Ehiakpor et al., 2016; Ndamani and Watanabe, 2016; Hitayezu et al., 2017; Mkonda and He, 2017; Mutunga et al., 2017; Kebede and Gizachew, 2017; Boansia et al., 2017; Gbegbelegbe et al., 2018).

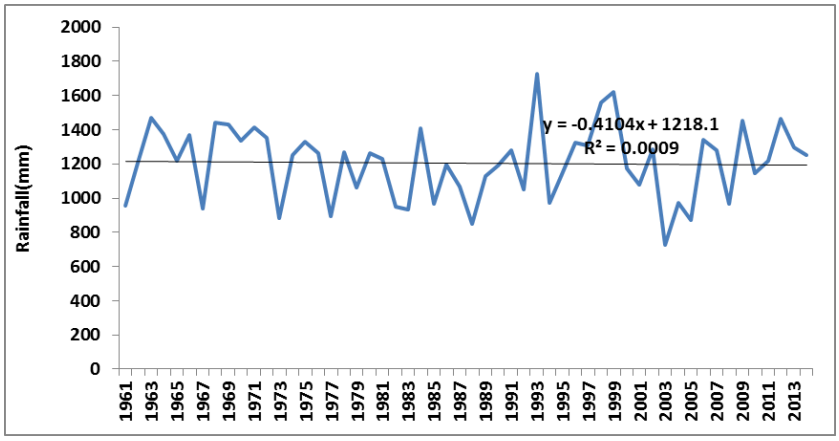

Figure 3. *Trend of total annual rainfall in Nasarawa State from 1961 to 2013*

Adaptation Strategies

The various climate change adaptation measures farmers adopt were classified into eight broad categories as shown in *Table 4* and they include cultivating improved crop varieties, portfolio diversification, practicing soil and water conservation, adjusting time of sowing, changing tillage operations, planting trees, irrigation, and farmland management. These are considered important climate change adaptation strategies in Nigeria (BNRCC, 2011; Okpe and Age, 2015; Onyegbula and Oladeji, 2017; Onyeneke, 2018).

Crop diversification – cultivating different crops – was adopted by majority of the farmers (95.00%). The dominant practice under crop diversification is intercropping of sorghum, maize with sweet potatoes and cowpea or melon (Agboire, 2017). This option is not expensive to practice and farmers have various crops at their disposal to plant. This may be the reason for greater adoption of this option. Furthermore, Bradshaw et al. (2004), Smit and Wandel (2006), Speranza (2006) noted that planting different crop varieties is an important farm-level climate change adaptation strategy. The increasing unpredictable nature of Africa's climate predisposes farmers to risk and shock associated with climate change, hence, makes them to grow different crop varieties. Planting short gestation crop varieties was also commonly practiced by farmers (73.75%) in the area. Farmers living in low rainfall and warm climates switch to short gestation crop varieties in managing climate risks (Wondimagegn and Lemma, 2016).

Mixed farming was the commonly used (68.75%) practice under portfolio diversification by the farmers followed by diversifying from farm to non-farm livelihood activities. Mixed farming is not new to farmers in the area. Farmers who *ab initio* combined livestock production and crop production are gradually intensifying

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70857112

on crop production only because of increasing scarcity of fodder for livestock like cattle, sheep and goat. Farmers in the area whose animals are affected seriously by climate change are resorting to only crop production, especially farmers living in the low-lying plains of the area. This may be connected to the fact that, some farm household members who rear livestock in the area move around in search of pasture, and the rangelands in the State are becoming drier, thereby making fodder unavailable for the farmers and their livestock. Instead of the continuous search of pasture everywhere and the resultant conflicts that follow, the original livestock farmers are now settling near watersheds and low-lying plains where water is almost available all year round, and are cultivating crops and grasses in such areas in order to survive. Another related practice is farmland management which 78.13% of the farmers adopted. This was not far from the adoption level of farmland management reported in the study of Onyeneke et al. (2018).

Table 4. *Distribution of farmers according to climate change adaptation strategies adopted (n = 160)*

Adaptation Strategy	Frequency	Percentage
1.Use of improved varieties		
Use of short gestation crops	118	73.75
Use of flood tolerant crop	93	58.13
Use of drought tolerant crops	91	56.88
Use of disease/pest resistant varieties	94	58.75
Planting different varieties of crops	152	95.00
2. Portfolio diversification		
Diversifying from farm to non-farm activities	109	68.13
Changing from crop farming to livestock farming	106	66.25
Mixed farming	110	68.75
3. Soil and water conservation		
Terracing	77	48.13
Mulching	112	70.00
Planting of cover crops	112	70.00
Crop rotation	113	70.63
Water harvesting	99	61.88
4. Changing planting dates		
Adjusting planting dates	126	78.75
Shortening the length of growing period	122	76.25
5. Changing tillage operations		
Planting on mounds and planting on ridges	126	78.75
6. Planting Trees		
Planting Trees	112	70.00
7. Irrigation and drainage		
Irrigation/watering	70	43.75
Drainage	79	49.38
8. Farmland management		
Changing land area cultivated	125	78.13

The commonly practised conservation strategies were crop rotation, cover cropping and mulching. Mulching was practised due to its benefit in soil moisture conservation and soil fertility management which often increases farmers' yield. These are similar to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70857112

the reasons adduced by Agele et al. (2000) and Onyeneke (2016a) for the high adoption rates of mulching in their research works. The reasons for embarking on cover cropping lies in the fact that cover crops suppress weeds, conserve soil moisture, and add nutrient to the soil. These are in line with the explanations given by Sanginga and Woomer (2009), Olaitan and Omomia (2006) and Egbule et al. (2012). Crop rotation is also a common adaptation strategy by farmers in the area and the probable reason for its adoption by about 70.63% of the farmers is because it enhances production, controls pest and diseases, conserves soil moisture and is less expensive. Sorghum, maize and soybean are very important crops cultivated by many farmers in the State and a very important crop rotation practice in the State observed in the course of data collection of this study was planting of *Striga* suppressive soybean varieties in rotation with sorghum and maize.

Furthermore, about 79.00% of the farming households reported that because of the erratic rainfall pattern in the area, they now change the time of planting to match the current distribution and pattern of rainfall. Also, 76.25% of the farmers reported that the growing periods have been shortened. This is now a common practice that farmers across sub-Saharan Africa use in managing vagaries of rainfall that characterise the region. Tadross and Hewitson (2005) have documented the frequency at which farmers change the time of planting in Zimbabwe.

Changing tillage operations was another common (78.75%) practice because of its characteristic benefit of controlling farm erosion and soil moisture conservation. It can also contribute to soil carbon sequestration (Niggli et al., 2009).

Also, 70.00% of the farmers opted for planting trees on farms to serve as shade and help in protecting crops from scorching and controlling farm erosion. Farmers also opted for this strategy because it contributes to mitigation of carbon and increases their income through sales of the products of the trees planted. This can also be considered as a climate-smart agricultural practice because it brings "triple wins" of increased productivity and adaptation (reducing/eliminating scorching of crops and fertilizes the soil), serving as a sink for carbon dioxide (mitigation of carbon) and increased income and ecosystem resilience (resilience) (Nwajiuba et al., 2015; Fadina and Barjolle, 2018).

Terracing (48.13%) was not common in the area and may be as a result of constraining factors such as high labour requirement, frequent inspection, large expanse of farmland needed, and the huge construction material required (Igbokwe, 1996). Also, irrigation (43.75%) and drainage (49.38%) were not commonly practiced by the farmers, perhaps because these options are capital intensive.

The researchers classified the adaptation options into eight broad categories. For categories having more than one specific adaptation option, the authors summed such adaptation options and divided by the number of specific adaptation practices identified/mentioned under such category as presented in *Table 4*. The quotient was further converted to percentage by multiplying by 100 and any farmer with a percentage score of 50 and above was considered as an adopter of such category while those with a percentage score of less than 50 were considered as non-adopters. These categories were used as the dependent variables in the multivariate probit model of this study reported in *Table 8*.

The result in *Table 5* indicates that the level of adoption of the different categories of climate change adaptation was quite high. Adjusting planting dates and changing tillage operations were the most common in the list of the categories of climate change adaptation while irrigation and drainage was the least common.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70857112

Table 5. *Distribution of farmers according to adaptation categories adopted (n = 160)*

Adaptation Category	Frequency	Percentage
Improved varieties	103	64.40
Portfolio diversification	103	64.40
Soil and water conservation	110	68.80
Changing planting dates	133	83.10
Changing tillage operations	126	78.80
Planting trees on farms	112	70.00
Irrigation and drainage	90	56.30
Farmland management	125	78.10

The number of adaptation categories adopted by the farmers was presented in *Table 6*. It could be deduced from the table that in managing climate risks farmers adopted various adaptation strategies. The average number of strategies adopted by the farmers was approximately 6 reflecting the adoption of multiple strategies by farmers in climate risk management. Therefore, farmers' decision in climate risk management in the Guinea savanna is simultaneous and the choice is not mutually exclusive. Hence, analysis of the determinants of farmers' adaptation decisions should account for the simultaneity in the choice of climate risk management strategies. This informed the choice of the multivariate probit regression which models the sequential decisions farmers make in climate change adaptation.

Table 6. *Distribution of farmers according to number of adaptation categories adopted (n = 160)*

Adaptation Category	Frequency	Percentage
One	23	14.38
Two	3	1.88
Three	4	2.50
Four	17	10.63
Five	17	10.63

Eight	56	35.00
Total	**160**	**100.00**
Average	**5.64**	

Factors determining Choice of Adaptation Category

The multivariate probit model results on the factors determining choices of adaptation options are presented in *Tables 7 and 8*. The model is very fit considering the significance of the likelihood ratio result ($Chi^2 = 202.68$, $p < 0.01$) (*Table 8*). This led to the rejection of the hypothesis of independence of the random errors of the different adaptation models and acceptance of the alternative hypothesis of interdependence of the adaptation practices.

The test of complementarity and/or substitutability of the adaptation measures was done using the pairwise coefficients of the multivariate probit result and is presented in *Table 7*. Two adaptation measures are considered to be complementary when the pairwise coefficient is positive while they are substitutes when the resultant pairwise coefficient has a negative sign. The analysis yielded positive correlations across all the pairs of adaptation categories in this study except between adjusting planting dates and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70857112

changing tillage operations, which yielded a negative but insignificant correlation. This implies that the strategies were mainly interdependent and complementary.

The analysis indicated that there was positive and significant interdependence between household decisions to cultivate improved crop varieties and conserving the soil, cultivating improved crop varieties and portfolio diversification, adjusting planting dates and cultivation of improved crop varieties, planting improved crop varieties and trees on farms, farmland management and cultivating improved crop varieties, planting improved crop varieties and changing tillage operations and irrigation with cultivation of improved crops. The model results also suggested that there was positive and significant interdependence between household decisions to adopt use of irrigation and farmland management, irrigation and soil conservation, use of irrigation and portfolio diversification, adjusting planting dates and portfolio diversification, portfolio diversification and farmland management, portfolio diversification and planting trees on farms, portfolio diversification and changing tillage operations, soil conservation and changing tillage operations, soil conservation and adjusting planting dates, soil conservation and planting trees on farms, and portfolio diversification and soil conservation. It also suggested that there was positive and significant interdependence between household decisions to adopt use of planting trees on farm and adjusting planting date, planting trees on farms and changing tillage operations, and using improved varieties of crops and adjusting planting date.

Table 7. *Correlation coefficients of the adaptation categories (from the MVP) (n=160)*

Adaptation Category	Improved varieties	Portfolio diversification	Soil and water conservation	Changing planting dates	Changing tillage operations	Planting trees	Irrigation and drainage	Farmland management

**$p < 0.01$

The result of the parameter estimates of the multivariate probit model is presented in *Table 8*. Education significantly increased adaptation to climate change through cultivating improved crop varieties, soil conservation, adjusting planting dates, planting of trees, irrigation and farmland management. More educated farmers understand and appreciate the benefits associated with cultivating improved crop varieties, soil conservation, adjusting planting dates, planting of trees, irrigation and farmland management and possess higher managerial ability in farm businesses than the less educated ones. This result is in consonance with the research findings of Onyeneke (2016b) and Nhemachena and Hassan (2007).

Age and adoption of improved crop varieties, portfolio diversification, irrigation and adjusting planting dates yielded significant negative associations while age and soil and water conservation and planting trees yielded positive relationship. The effect of age on soil and water conservation as well as planting trees on farms were surprising in the light of the theory of adoption of technologies. One key reason for this surprising result could be that soil and water conservation practices identified in this study as well as tree planting on farms are relatively old practices in the Guinea savanna and the older farmers are better positioned to adopt such strategies than their younger counterparts because they understand and appreciate the benefits more. The effect of age and climate change adaptation is well captured by research results (Boansi et al., 2017; Gbetibouo, 2009; Deressa et al., 2008).

Farmers' household size significantly increased the likelihood of using soil conservation, changing tillage operations (digging ridges and mounds), planting trees and irrigation. These strategies require additional labour from the farmer, which the household members can provide. Teklewold et al. (2006) also found household size significant in determining the adoption of poultry technologies. However, household size diminished the probability of uptake of adjusting planting dates and farmland management. As the land area cultivated by each farmer reduces, the farm labour needed by such farmers also reduces which in turn frees some members of the family to pursue other income-generating activities (Tizale, 2007).

Income increased the probability of adoption of improved crop varieties, portfolio diversification, changing tillage operations and irrigation. Adaptation to climate change needs financial capital and information and wealthier farmers would adapt more readily than their poorer counterparts (CIMMYT, 1993; Franzel, 1999; Knowler and Bradshaw, 2007; Kassie, 2017).

Livestock ownership significantly increased uptake of all the options. Livestock is an asset to the farmer and could be sold anytime to purchase other farm inputs needed by farmers and could be responsible for the positive and significant impact recorded across all the adaptation options. Moreover, livestock dungs and dropping are used in soil fertility management. Tizale (2007) documented the benefits of livestock in storing wealth and maintaining soil fertility.

Government extension services significantly increased adoption of all the strategies. Most of the practices are an integral part of the packages disseminated to farmers across Nigeria by extension agents. This may be related to the positive and significant impact of extension services on all the climate change adaptation strategies. This confirms the increasing role of extension in climate risk management which supports better and effective agricultural management decisions (Gbetibouo, 2009; Umar et al., 2014; Duniya and Rekwot, 2015). Tripathi and Mishra (2017) and Mulwa et al. (2017) noted that extension services help farmers in adopting climate change management strategies.

Another important determinant of climate change adaptation strategies is experience (Gbetibouo, 2009) and it significantly increased the adoption of improved crop varieties, portfolio diversification, soil and water conservation practices, adjusting planting dates, planting trees, irrigation, and farmland management. Fadina and Barjolle (2018) also found that experience increased uptake of climate change adaptation strategies in Southern Benin.

Credit access enhanced adoption of improved crop varieties, portfolio diversification, irrigation and planting trees. Availability of credit reduces financial challenges of farmers and allows them to buy agrochemicals, seedlings and other inputs. Access to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_70857112

credit enhances the adoption of climate change adaptation strategies (Nhemachena and Hassan, 2007). In rural El Salvador, Saín and Barreto (1996) found access to credit to have positive impact on adoption of soil conservation technology while Hansen et al. (1987) reported same result in the Dominican Republic. In Rondônia area of Brazil in South America, Caviglia-Harris (2002) noted that credit is a significant predictor of adoption of sustainable agricultural practices.

Farm size significantly increased uptake of improved crop varieties, soil conservation practices, adjusting planting dates, and irrigation and farmland management. Most of the climate change adaptation measures are optimally practised in large farms because farmers who have large farm sizes at their disposal and are more likely to adopt soil conservation techniques, irrigation, farmland management for the purpose of increasing soil fertility and efficiency of their farms (Negash, 2013; Erhabor and Ahmadu, 2013; Wondimagegn and Lemma, 2016) and improved crop varieties for incremental yield.

There was a negative and significant relationship between distance to the market and the uptake of improved crop varieties, portfolio diversification, soil conservation practices, changing tillage operations, planting trees, and irrigation. Nearness and availability of input in the market facilitate the adoption and intensive use of adaptation technologies. Also, transportation cost of agricultural inputs increases with market distance which may discourage farmers from purchasing agricultural inputs and selling their outputs too (Ulimwengu et al., 2009; Kiprono and Matsumoto, 2014).

Distance to water source also emerged as a significant predictor climate change adaptation choices of the farmers. This variable was inversely related to the likelihood of adopting improved crop varieties, soil conservation practices, and farmland management. The distance from the water source to the home and farm of the farmer negatively impacts on the quality and volume of water used for farm and domestic consumption.

Risk orientation demonstrated positive and significant association on adoption of all the climate risk management strategies - improved crop varieties, portfolio diversification, soil and water conservation, adjusting planting dates, changing tillage options, planting trees on farms, irrigation, and farmland management. Adaptation to climate change requires adoption of technology which involves risk-taking and farmers who are willing to take the risk of experimenting the technologies will adapt more readily to climate risks. Farmers who are more disposed to risk-taking were significantly more likely to increase the adoption of improved crop varieties, portfolio diversification, soil and water conservation, adjusting planting dates, changing tillage operations, planting trees, irrigation, and farmland management than their counterparts who are less risk-oriented.

Membership of farmer groups positively impacted the adoption of improved crop varieties and irrigation. Farmers get information about innovations from their associations. Membership to such groups increased the uptake of improved crop varieties and irrigation. Targeting farmers who are members of farmer groups will be important in increasing farmers' adaptive capacity. This result is in line with Mulwa et al. (2017) finding in Malawi. They found that membership of farmer groups significantly increased the adoption of disease/pest-tolerant crop varieties in Malawi.

Conclusion

The research matched perception survey with scientific data from meteorological agency. We distinguished scientific data and local peoples' accounts of climate change and matched both datasets to find convergence or divergence and see to what extent perceptions data reflects true empirical reality. Farmers' perception reflects empirical reality and they have adopted some strategies to respond to the observed vagaries in climate.

There is interrelationship in the adaptation strategies employed by the smallholder farmers. Most farming households used improved crop varieties (especially growing different varieties of crops and those with short gestation period), portfolio diversification (especially practicing mixed farming and diversifying to non-farm activities), soil and water conservation (crop rotation, mulching, cover cropping and water harvesting), adjusting planting dates, and changing tillage operations. Demographic and farm characteristics and institutions determined climate change management decisions.

Scientific data and farmers' experience point to changing patterns of temperature and rainfall in the region. Therefore, adaptation measures need to focus more on these climate elements to reduce the impact on farmers by boosting access to the livelihood assets. Support to farmers should strengthen their capacity and ability to cultivate improved crop varieties, adopt portfolio diversification, practice water and soil conservation, and use irrigation. Strengthening public extension services and credit institutions such as microfinance and commercial banks as well as cooperative societies should be the priority of government if climate risk management in agricultural production must be achieved. This will support the achievement of food security and poverty reduction objectives of the Nigerian government. Local responses and the adaptive capacity of the farmers cannot be enough but they are very important in shaping government and development partners' planned adaptation interventions. The adaptation practices identified should be integrated into governments' overall strategies and policies.

Conflict of Interests. The authors declared that they have no conflict of interests.

Abstract. Cadmium (Cd) is highly toxic and causes detrimental effects on plants but the adverse effects of Cd can be alleviated by exogenous applications. Hence, in the current study, the possible alleviative roles of salicylic acid (SA) on accumulation of Cd were investigated in leaves of pistachio species. Mineral accumulation variations in leaves were tested by analysis of variance (ANOVA) followed by multiple comparison test of Duncan using SPSS and chemometric analysis. For the present study, two-year old pistachio species (*Pistacia vera, Pistacia khinjuk, Pistacia terebinthus*) were exposed to the combination Cd (50 and 100 μM) from root and SA (0.5 μM) with foliar applications. Accordingly, both SA treatment and Cd had significant effects on accumulation of minerals but SA acid was found to have a little alleviative effect on accumulation Cd. Of the investigated elements, P (2.151 fold-change; $p<0.001$) and Cu (4.702 fold-change; $p<0.001$) were significant and highly variable over-accumulated elements. According to the principal component analysis (PCA), the multivariate data processing for elements allowing for a large group of diverse data samples was explained in 23.95% and 22.61% as the first and second principal components (PC_1 and PC_2). Two components extracted were describing approximately 46.55% of the common variance.
Keywords: *macro and micro element, cadmium stress, foliar salicylic acid application, environmental health, Pistacia vera, Pistacia khinjuk, Pistacia terebinthus*

Introduction

Expansion of agricultural areas, increment of soil pollutants, chemical fertilizers, uses of wastewater in agriculture and industrialization have led to pollution of agricultural lands. Although heavy metals are not essential elements for plants, they are transported from soil to the plant and subsequently pose a threat to the health of other livings through food chain. Of those heavy metals, Cd as a non-essential element to plants is a highly toxic and persistent environmental poison for plants and animals (di Toppi and Gabbrielli, 1999).

Cd accumulation causes structural, physiological and biochemical changes in plants (Khan et al., 2007; Feng et al., 2010). Disruption of the water balance of the plant by affecting stomatal movements, degradation of carbohydrate and interruption of photosynthesis mechanisms are of the consequences after Cd uptake. Accordingly,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71137133

decrease in yield has been deemed to be associated with Cd accumulation (Mobin et al., 2007; Hossain et al., 2010; Shie et al., 2010). Cd hinders many cellular functions and inhibits essential activities through complex formation with proteins. Albeit those cytoplasmic toxicity mechanisms are similar in all organisms, different plant species and their varieties, populations and genotypes exhibit a wide range of plasticity in response to the Cd accumulation (McGrath et al., 2001). We should note that even sensitive or tolerant species also vary considerably for their responses against Cd.

As a response to unfavorable conditions, signal molecules are synthesized and subsequently activate a range of signal transduction pathways in complex plant system. Furthermore, the plausible protective roles of some signal molecules are known in helping plant to cope with the stress (Ganesan and Thomas, 2001). Calcium, jasmonic, ethylene and ethylene and salicylic acid are of the identified signaling molecules (El Tayeb and Ahmed, 2010). Of the identified molecules, the protective roles of salicylic acid (SA) as a defense signal transducer or messenger under stress conditions has been well-reported (Raskin, 1992; Klessig and Malamy, 1994; Ganesan and Thomas, 2001). SA is a hormone-like and phenolic structured molecule modulating and regulating biochemical, physiological and molecular processes of the plants and then favors plant growth and development. It is worthy to note that SA should not be narrowly discussed as an endogenous molecule but also defined, described and discussed as a potent molecule vital to plant systems once used an exogenous regulator under optimal conditions including optimal concentration, mode of applications, appropriate application time etc. for plants (Kulak, 2018). In many studies with different agricultural crops, the role of exogenous SA application has been well-documented in regulation of physiological processes in plants, such as stomatal closure, ion uptake and transport, membrane permeability, and photosynthesis and growth under stress conditions (Shakirova and Bezrukova, 1997; Mishra and Choudhuri, 1999; Pa´l et al., 2002; Sakhabutdinova et al., 2003; Shakirova et al., 2003; Bhupinder and Usha, 2003). However, there are a few studies on the salicylic acid and cadmium interaction for fruit trees.

For the horticultural plant and crops, rootstocks are of the essential and fundamental issues. In this context, they have been screened and used for propagating temperate fruit trees more than 2000 years due to their influence on scion vigor, cropping, fruit quality, climatic adaptability, and susceptibility to pests and diseases (Webster, 1995; Acar et al., 2017a). In the studies reported by (Acar et al., 2017a, 2017b), the distribution and rootstocks of pistachio have been well-documented, informing that Pistacia genus (Anacardiaceae family) consists of at least eleven species. Of those species, *P. mexicana* and *P. texana* are of USA and Mexico originated. The other species are mainly distributed within the Mediterranean region, Western and Central Asia and the Middle East (Esmail-Pour, 2001). Turkey is of the important pistachio producer and suppliers in the world and possesses many wild species of pistachio nut. Of those species, *P. vera, P. terebinthus, P. khinjuk, P. atlantica, P. mutica, P. palaestina* and *P. lentiscus* exhibit distribution in different regions of Turkey. The main pistachio rootstock used in Turkey is *P. vera*, and followed by *P. khinjuk, P. terebinthus* and *P. atlantica* (Acar et al., 2017b).

Of the environmental factors, heavy metals are well-documented to possess potentially deleterious effects on fruit quality of the plants and subsequently on human health. The response of the grafted plants against stress conditions owing to the nutrient status and the presence of heavy metals in the root environment may differ than that of self-rooted plants and may be dependent on the rootstock genotype (Savvas et al., 2010, 2011). As

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71137133

highlighted by Savvas et al. (2011), appropriate rootstocks selection may be significant step for restriction of heavy metal accumulation in the aerial parts of the plants.

In this context, we monitored the nutritional status of three rootstocks namely, *P. vera, P. terebinthus* and *P. khinjuk* in response to cadmium treatments by addition of foliar salicylic treatments. Along with the study, the results were analyzed using chemometrics and multiple regression analysis in order to discriminate and identify the differences between pistachio rootstocks.

Material and Methods

Plant material, growth conditions, salicylic acid and Cd application

In the study, 2-year old seedlings of *Pistacia vera, Pistacia terebinthus* and *Pistacia khinjuk* pistachio species were used. The experiment was carried out in greenhouses of Kilis 7 Aralık University Agricultural Application and Research Center (Turkey). Experiments were conducted in a greenhouse with a 14 h photoperiod. Mean temperature and relative humidity were 26-30ºC during day and 16-20ºC at night, 60% respectively. The experiments were performed with the replicates including ten pistachio seedlings for each replicate. The physical and chemical properties of experimental soil were as follows: pH (8.15; alkali); water saturation (clay loam); calcium carbonate ($CaCO_3$) content (47.49%; very calcareous); total salt (0.016%; low salt), phosphorus (P_2O_5) (4.12 kg/ha; low); organic matter (2.11%; medium). For the experimental group, pistachio seedlings were regularly root-irrigated with two different concentration of cadmium alone (Cd_1:50 µM; Cd_2:100 µM) for three weeks. Furthermore, the seedlings were foliar sprayed with addition of 0.5 µM salicylic acid once. After 3-week experimental period, leaves of seedlings were harvested and lyophilized for analysis.

Experimental design

The experimental groups with their abbreviations were represented as follows:
T-C: *Pistacia terebinthus* (T)-Control
T+SA: *Pistacia terebinthus* (T)+Salicylic acid (SA)
T+Cd_1: *Pistacia terebinthus* (T)+Cadmium:50 µM (Cd_1)
T+Cd_2: *Pistacia terebinthus* (T)+Cadmium:100 µM (Cd_2)
T+Cd_1+SA: *Pistacia terebinthus* (T)+Cadmium:50 µM (Cd_1) +Salicylic acid (SA)
T+Cd_2+SA: *Pistacia terebinthus* (T)+Cadmium:100 µM (Cd_2) +Salicylic acid (SA)
K+C: *Pistacia khinjuk* (K)-Control
K+SA: *Pistacia khinjuk* (K)+Salicylic acid (SA)
K+Cd_1: *Pistacia khinjuk* (K)+Cadmium:50 µM (Cd_1)
K+Cd_2: *Pistacia khinjuk* (K)+Cadmium:100 µM (Cd_2)
K+Cd_1+SA: *Pistacia khinjuk* (K)+Cadmium:50 µM (Cd_1)+Salicylic acid (SA)
K+Cd_2+SA: *Pistacia khinjuk* (K)+Cadmium:100 µM (Cd_2) +Salicylic acid (SA)
V+C: *Pistacia vera* (V)-Control
V+SA: *Pistacia vera* (V)+Salicylic acid (SA)
V+SA: *Pistacia vera* (V)+Salicylic acid (SA)
V+Cd1: *Pistacia vera* (V)+Cadmium:50 µM (Cd_1)
V+Cd_2: *Pistacia vera* (V)+Cadmium:100 µM (Cd_2)
V+Cd_1+SA: *Pistacia vera* (V)+Cadmium:50 µM (Cd_1) +Salicylic acid (SA)
V+Cd_2+SA: *Pistacia vera* (V)+Cadmium:100 µM (Cd_2) +Salicylic acid (SA)

Preparation of plant samples for mineral content

First of all, the plant samples were cleaned and washed by deionized water, later air dried. Pre-dried samples were de-moisturized at 70°C for 48 h in an oven and ground for chemical analysis. 0.2 g of ground samples was placed into burning cup, 5 ml HNO_3 65% (Merck, Darmstadt, Germany) and 2 ml H_2O_2 30% (Merck, Darmstadt, Germany) were added immediately. After incinerating in a HP-500CEM MARS 5 microwave (crop. Mathews NC, USA) at 200°C, the solution was cooled at room temperature for 45 minutes. The extracts were passed through a filter paper and the filtrates were collected by high-deionized water in a 20 ml of polyethylene bottles and kept at 4°C in laboratory for ICP-AES analysis. Each sample was analyzed in triplicate. Phosphorus (P) and nitrogen (N) content were determined by vanadomolybdate method (Chapman and Pratt, 1961) and modified Kjeldahl method (Kacar and Inal, 2008) while K, Ca, Mg, S, P, Fe, Zn, Mo, Mn and Cu were ascertained by Inductively coupled plasma-optical emission spectrometry (ICP-OES). For all analytical works, distilled-deionized water was used. All the glassware and polyethylene bottles were attentively leached with 2-4% HCl and rinsed through deionized water for three times. Merck standards (R1 and R2 groups) were used as analytical reagent grade chemicals.

Statistical analysis

Three replications were used for each treatment. Data were expressed as mean. The means were compared using the one-way ANOVA followed by Duncan's multiple range tests. The differences between individual means were considered to be significant at $p<0.05$. Moreover, a principal component analysis (PCA) was performed in order to discriminate between pistachio species exposed to the different treatments on the basis of the macro and micro elements identified along with the study. Also, correlation coefficients were calculated on the basis of the elements at different plant species in order to determine whether correlation coefficients among elements are the same or not. All analyses were performed using XLSTAT and SPSS.

Results

To assess the plausible roles of salicylic acid in reducing cadmium toxicity in *P. terebinthus* (T), *P. khinjuk* (K) and *P. vera* (V) plants, the macro and micro elements and protein contents were investigated in pistachio seedlings foliar treated with 0.5 µM SA under 50 (Cd_1) and 100 (Cd_2) µM conditions, respectively.

The results of the study were analyzed using one-way variance analysis (*Tables 1-2*), multiple linear regression analysis (*Tables 3-13*), correlation analysis (*Tables 14-16*) and principal component analysis (*Figs. 1-4*) in order to define, discriminate and clarify the differences between the rootstocks of pistachio.

Nitrogen (N) content

Cadmium (Cd) and salicylic acid separately caused a decrease of N in leaves of *P. terebinthus* but N content increased by the combination of cadmium concentrations with salicylic acid. However, the effects of Cd_2+ and Cd_2+SA were only significant ($p=0.000$ and $p=0.004$, respectively) according to the multiple linear regression analysis. As a result of multiple linear regression analysis, which is thought to have an effect on the accumulation of N, the variables including SA, Cd_1+, Cd_1+SA, Cd_2+ and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71137133

Cd_2+SA exhibited significant effects (R^2=0.897. p<0.005). Moreover, Cd_1+ (p=0.000), Cd_2+ (p=0.000) treatments, SA (p=0.000), Cd_1+SA (p=0.000) and Cd_2+SA (p=0.000) decreased N content in *P. khinjuk*. The significant effects of applications were also exhibited with the regression analysis (R^2=0.955, p<0.005). For *P. vera*, SA alone (p=0.146) and its interaction with Cd_1+ (p=0.006) and Cd_2+ (p=0.315) caused a decline in leaf N content. Regression analysis exhibited non-significant effect of applications together (R^2=0.614, p<0.005) (*Table 3*). Singh and Usha (2003) reported a decline in the nitrogen content in leaves of wheat seedlings treated with salicylic acid.

Phosphorus (P) content

A quantitatively increment in leaf P content of *P. terebinthus* was observed with all treatments. However, the effects of SA (p=0.000) and Cd_2+SA (p=0.001) were deemed as significant according to the multiple linear regression analysis. However, a quantitatively decline in leaf P content of *P. khinjuk* was recorded under SA+ (p=0.146), Cd_1+SA (p=0.006) Cd_2+SA (p=0.315), suggesting the adverse influence of SA on P content for *P. khinjuk*. The similar results regarding P content were observed for *P. vera* in response to treatments (*Table 4*). In the study by Wang et al. (2011), SA alone increased the P concentration whereas Pb decreased the concentration. 50 μM Pb-induced decrease was improved by the addition of 10 μM SA.

Potassium (K) content

Augmented and significant changes were recorded except SA alone treatment, of which effects were not significant (p=0.421) for K content of *P. terebinthus*. For *P. khinjuk*, all treatments adversely affected the K content in leaves. Of the treatments, SA+ (p=0.884) and Cd_1+ (p=0.356) caused decreases in K content for *P. vera* but the changes were not significant. The interaction of SA and Cd_1+ increased the content (p=0.011). Interestingly, whereas Cd_2+ significantly increased the content, Cd_2+ SA interaction did not cause a significant change (p=0.259), proposing the influence of SA on the activities of cadmium treatments (*Table 5*).

The treatments of excessive Mn, salicylic acid and both did not significantly affect K content in leaves (Shi and Zhu, 2008).

Calcium (Ca) content

Attenuated changes were observed with the treatments except SA+, of which effect was not significant (p=0.136). Interaction of Cd_1+SA decreased Ca content (p=0.000) whereas Cd_2+SA caused an increase in Ca content (p=0.011) for *P. terebinthus*. We noted the decreases in Ca content in leaves of *P. khinjuk* under all treatments except Cd_2+SA, which was not significant (p=0.346). The quantitatively attenuated changes were significant for other treatments, whereas SA coupled with Cd_1+ decreased the content; SA suppressed the attenuated change in Ca content by Cd_2+.

The similar responses against treatments were observed by *P. vera*. SA improved quantitatively the adverse effects of Cd_1+ and Cd_2+ treatments (p=0.201 and p=0.570, respectively) (*Table 6*). In the study by Shi and Zhu (2008), salicylic acid increased Ca content and excessive Mn decreased the content but the addition of SA significantly increased Ca concentration under excess Mn condition. Furthermore, Pb treatments and SA alone treatment induced an increase in Ca concentration whereas addition of SA significantly decreased under Pb condition (Wang et al., 2011).

Magnesium (Mg) content

Mg content decreased with Cd_1+ (p=0.101) and Cd_2+ (p=0.101) treatments but the content was quantitatively but not significantly improved with SA+ (p=0.016) alone or interaction with Cd_1+ (p=0.285) and Cd_2+ (p=0.579) in *P. terebinthus*. All treatments

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71137133

except Cd_2+SA (p=0.767) caused significantly decreases in Mg content in *P. khinjuk*. Treatments including SA+ (p=0.029), Cd_1+SA (p=0.762) and Cd_2+SA (p=0.089) improved the Mg content whereas Cd_1+ (p=0.603) and Cd_2+ (p=0.582) decreased the content of Mg in *P. vera* (*Table 7*). For the case in cucumber (Shi and Zhu, 2008), the treatment SA did not significantly influence the Mg concentration but excess Mn significantly decreased the Mg concentration in leaf tissues. After, addition of SA significantly improved the concentration.

Table 7. *Mg contents in leaves of pistachio species under different treatments*

Iron (Fe) content

SA+ alone (p=0.524) and its interaction with Cd_1 (Cd_1+SA; p=0.976) treatments decreased Fe content whereas Cd_1+ (p=0.221) and Cd_2+ (p=0.078) increased the content. The interaction of SA with higher concentration of cadmium (Cd_2+) approximately doubled the content in *P. terebinthus* (p=0.002). Interestingly, *P. khinjuk* exhibited converse responses against treatments in comparison with *P. terebinthus*. Herewith, SA+ (p=0.713) and Cd_1+SA (p=0.040) increased Fe content whereas Cd_1+ and Cd_2+ caused quantitively but non-significant changes (p=0.590 and p=0.818, respectively). On the other hand, treatments including SA+ (p=0.072, Cd_1+ (p=0.015) and Cd_2+ (p=0.042) adversely affected Fe content but the adverse effects of Cd1+ and Cd2+ treatments were quantitively but non-significant improved with SA+ (p=0.085 and p=0.636, respectively) *P. vera*. According to the multiple linear regression analysis, treatments were not significant for *P. khinjuk* and *P. vera* (R^2=0.494, p>0.05; R^2=0.499, p>0.05, respectively) (*Table 8*). Of the heavy metals, excess treatment of Mn and SA diminished Fe concentration in leaves of cucumber. However, addition of SA aggravated the decline in leaves (Shi and Zhu, 2008). Pb alone significantly increased the Fe concentration in comparison with control whereas SA caused a decline in the concentration. With the addition of SA, a statistically significant decrease was observed in the plants grown under Pb (Wang et al., 2011).

Copper (Cu) content

A quantitively but non-significant change was recorded for Cu content under all treatments in *P. terebinthus* (R^2=0.488, p>0.05) but we should note that Cd_1+SA increased the content once compared to SA+ and Cd_1+ whereas Cd_2+SA decreased the content in comparison with SA+ and Cd_2+. Cu contents were positively influenced with the SA+ but Cd_1+ and Cd_2+. However, the adverse effects of Cd_1+ and Cd_2+ were improved with the foliar application of SA+ for *P. khinjuk*.

Interestingly, SA+, Cd_1+ and Cd_2+ increased the content but foliar application of SA to the plants exposed to the Cd_1+ and Cd_2+ diminished the content in *P. vera* (*Table 9*). Shi and Zhu (2008) reported that SA treatment did not significantly change the Cu concentration and excess Mn treatment significantly decreased the concentration. However, addition of SA did not cause any changes in the concentration. The concentration of Cu decreased significantly in leaves of *Vallisneria natans* by SA treatment. Pb treatment did not cause significant changes on the concentration but addition of 100 μM SA significantly decreased the concentration (Wang et al., 2011).

Table 9. *Cu contents in leaves of pistachio species under different treatments*

Cu	*P. terebinthus*			*P. khinjuk*			*P. vera*		
	B	**Mean Dif.**	**Sig.**	**B**	**Mean Dif.**	**Sig.**	**B**	**Mean Dif.**	**Sig.**
(Constant)	.210		.496	1.120		.015	1.470		.000

Cd_2+SA	.140	-.14000	.746	.910	-.91000	.130	-.525	.523333	.040
R^2	.488; p>.05			.332 (p>.05)			.750		

Zinc (Zn) content

Zn content was significantly decreased with all treatments except Cd_2+SA (p=0.147) but the adverse effects of Cd_1+ and Cd_2+ was improved by foliar application of SA (p=0.001 and p=0.147). The most hazardous effects on Zn content was more pronounced under Cd_1+ and Cd_2+ for *P. terebinthus*. The similar responses in accumulation of Zn against treatments were also recorded for *P. khinjuk*. On the other hand, SA+ and Cd_2+ caused increases in Zn and Cd_1+ decreased the content. The contents in plants exposed to Cd_1+ and Cd_2+ were still decreased with foliar application of SA. We should state that the quantitative changes were not significant (R^2=0.381, p>0.05) for *P. vera* (*Table 10*). The Zn concentration leaves was significantly diminished with the excess Mn treatment but the decrease was alleviated by SA addition under excess Mn treatment in cucumber. Furthermore, SA alone treatment itself did not significantly change the Zn concentration (Shi and Zhu, 2008). Pb treatment did not significantly affect the Zn concentration. SA alone induced a decrease in the concentration (Wang et al., 2011).

Manganese (Mn) content

Mn content was adversely affected with foliar application of SA. Cadmium treatments (Cd_1+; p=0.001 and Cd_2+; p=0.000) increased Mn content but the effects of treatments were suppressed with SA (Cd_1+SA; p=0.006 and Cd_2+SA; p=0.230) for

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71137133

P. terebinthus. SA+ and Cd_2 + decreased the content whereas the lower cadmium treatment (Cd_1+) increased the content. However, SA+ treatment caused a decrease in Mn content in plants exposed to Cd_1+ treatment and vice-verse for the plants under Cd_2+ treatment for *P. khinjuk*. All treatments positively influenced Mn content in *P. vera* (*Table 11*). Of the heavy metals, treatments with 50 µM Pb induced significant decrease of Mn and SA alone did not exhibit significant effects on Mn concentration. However, the decrease was alleviated by SA addition in *Vallisneria natans* under Pb treatment (Wang et al., 2011).

Cadmium (Cd) content

Cd content in leaves significantly decreased with SA alone (p=0.001), Cd_1+ (p=0.002) whereas the content was not significantly influenced with Cd_2+ (p=1.000), Cd_1+SA (p=0.072) and Cd_2+SA (p=0.446) for *P. terebinthus*. For *P. khinjuk*, SA+ (p=0.002), Cd_1+ (p=0.141), Cd_2+ (p=0.001) and Cd2+SA (p=0.002) induced an increase in Cd content in leaves. However, Cd1+SA did not significantly affect the content (p=1.000). Interestingly, all treatments quantitatively but non-significantly influenced the Cd content in leaves of *P. vera* (*Table 12*). The root samples of maize (*Zea mays*) treated with SA contained less Cd than in the plants treated with Cd alone. However, the highest Cd content in the leaves was found in SA+Cd plants (Gondor et al., 2016) but SA+Cd_1 or SA+Cd_2 did not exhibit any significant effects regarding Cd content in leaves of three *Pistacia* species herein.

Protein content

Protein content decreased with SA+(p=0.451) Cd_1+ (p=0.140) and Cd_2+ (p=0.000) but the content in plants under Cd_1+ and Cd_2+ treatments coupled with foliar applications of SA increased for *P. terebinthus*. All treatments reduced the protein

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71137133

content in *P. khinjuk*. SA+ increased content when applied with Cd_1+ in comparison to the single treatment of Cd_1+ (Cd_1+SA; p=0.000) but SA+ did not cause quantitatively changes when applied with Cd_2+ in comparison to the single treatment of Cd_2+ (Cd_2+SA; p=0.000) in *P. khinjuk*. On the other hand, all treatments except Cd_2+ decreased the protein content in *P. vera*. SA+ did not cause quantitatively changes when applied with Cd_1+ in comparison to the single treatment of Cd_1+ but brought about significant changes when applied with Cd_2+ in comparison to the single treatment of Cd_2+. Cd_2+ significantly increased the content but the interaction of Cd_2+SA decreased the content (p=0.965) (*Table 13*).

Salarizadeh et al. (2016) reporting that the excessive copper decreased the protein content in the pistachio plant but the adverse effects were improved with the addition of SA. The decrease in protein content has been attributed to the toxic effects of heavy metals and their reaction with the SH-groups which subsequently causes protein denaturation (Fuhrer, 1982). Furthermore, the protein content along with the decline in nitrogen content was observed in leaves of wheat seedlings treated with salicylic acid (Singh and Usha, 2003).

Correlations

Herewith correlation analysis, it was aimed to determine whether the coefficient and directions of correlation vary with the pistachio species or not. Hence, correlation analyses for pistachio species were separately performed. Accordingly, correlation coefficients between elements of pistachio species leaves were given in *Tables 14-16*. According to the correlation matrix of the elements in leaves of *P. terebinthus*, there were negative correlations between N and Mn (r= -0.606), N and Cu (r= -0.489), N and Cd (r= -0.124), P and K (r= -0.345), P and Mn (r= -0.345), P and Fe (r= -0.042), P and Fe (r= -0.042), P and Cd (r= -0.519), K and Ca (r= -0.796), K and Mg (r= -0.517), K

According to the correlation matrix of the elements in leaves of *P. vera*, there were negative correlations between N and P (r= -0.254), N and Ca (r= -0.466), N and Mg (r= -0.611), N and Mn (r= -0.513), N and Fe (r= -0.202), N and Cd (r= -0.068), P and Ca (r= -0.026), P and Cu (r= -0.755), K and Ca (r= -0.193), K and Mg (r= -0.229), K and Mn (r= -0.253), K and Fe (r= -0.076), K and Cd (r= -0.554), Ca and Cd (r= -0.040), Mg and Cu (r= -0.358), Zn and Fe (r= -0.038), Mn and Fe (r= -0.090), Cu and Fe (r=

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71137133

-0.677), Cu and Cd (r= -0.244). The remained correlation coefficients were positive for *P. vera* (*Table 16*).

Considering all correlation coefficients, Cd negatively correlated with N, Ca and protein content in leaves for all three-pistachio species. We should note that those correlations might differ than that of the other tissues of the plants as a consequence of allocation, transport or sequestration of the elements in order to cope with the exogenous treatments.

Principal component analysis (PCA)

The discrimination can be evaluated from the principal component analysis scores plot between pistachio species using identified macro and micro elements as shown in *Figs. 1-4*. This pair of graphs is a biplot, i.e., macro and micro elements were more expressed in pistachio species leaf samples in the same area of the graph. The experimental groups in each group represent a similar response regarding with element contents, discriminating the experimental group behaviors in response to the treatments. Along with the present study, we discriminated the groups using the macro and micro elements measured. We herein performed four principal component analysis to visualize and discriminate each experimental group (PCA-1: *P. terebinthus*; PCA-2: *P. khinjuk*; PCA-3: *P. vera*; PCA-4: *P. terebinthus, P. khinjuk* and *P. vera*). In this context, it was aimed to determine whether the element changes were species or treatment dependent. For *P. terebinthus* (T-C, T+SA, T+Cd_1, T+Cd_2, T+Cd_1+SA, T+Cd_2+SA), the two principal components accounted for 76.66% of total variance, whereas the first axis and second axis explained 49.396% and 26.70% of total variance (*Fig. 1*). Experimental groups were well-defined and discriminated, suggesting that addition of the SA did not affect the element content of *P. terebinthus* against Cd_1 treatment but significant changes were recorded with the addition of SA to *P. terebinthus* the grown under Cd_2 conditions.

For *P. khinjuk (*K-C, K+SA, K+Cd_1, K+Cd_2, K+Cd_1+SA, K+Cd_2+SA), the two principal components accounted for 58.18% of total variance, whereas the first axis and second axis explained 31.98% and 26.19% of total variance (*Fig. 2*). Experimental groups were well-defined and discriminated from control group (K-C), proposing the responsive structure of *P. khinjuk* against any external stimuli. With addition of SA, the adverse effects of Cd_2 were alleviated.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71137133

For *P. vera* (V-C, V+SA, V+Cd_1, V+Cd_2, V+Cd_1+SA, V+Cd_2+SA), the two principal components accounted for 60.91% of total variance, whereas the first axis and second axis explained 40.91% and 20.00% of total variance (*Fig. 3*). Similar responses were recorded in the circumstances of *P. khinjuk* grown under Cd_2 and addition of SA.

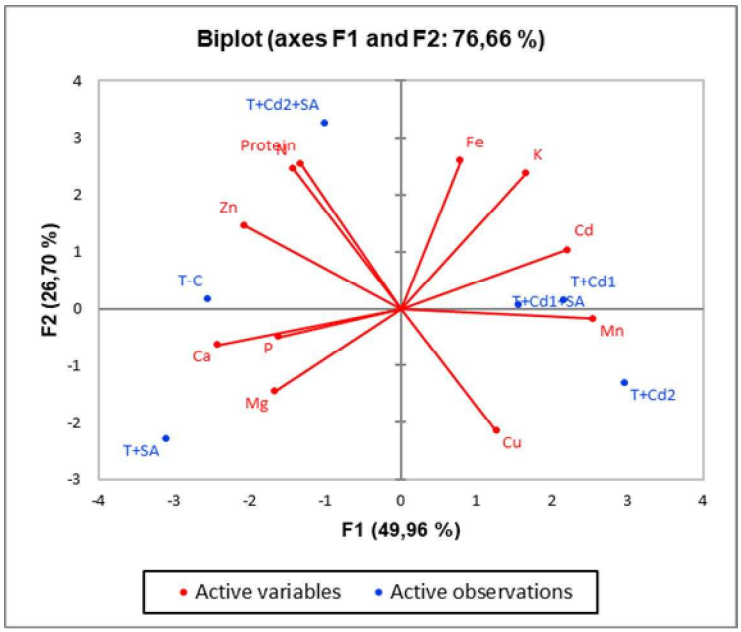

Figure 1. *Principal component analysis for P. terebinthus*

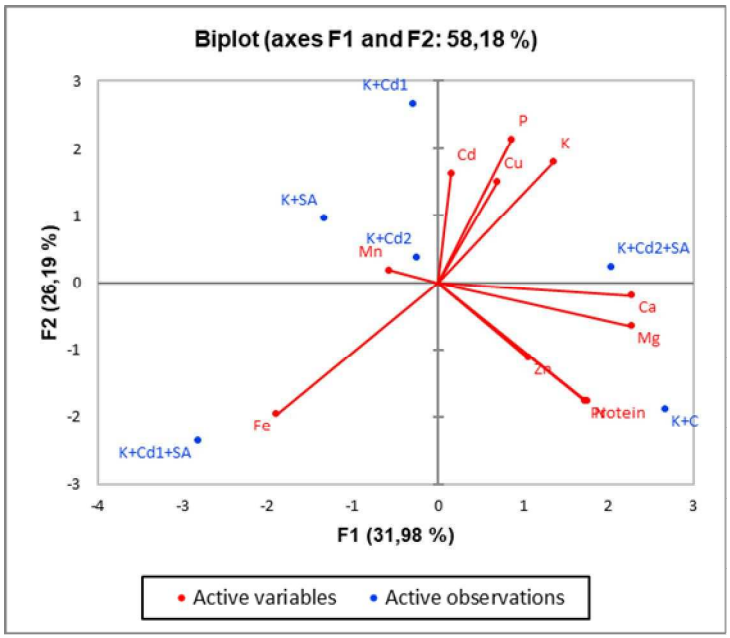

Figure 2. *Principal component analysis for P. khinjuk*

Considered all experimental groups, results obtained from the principal component analysis showed the presence of the well-discriminated and defined groups for pistachio

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71137133

species and exogenous treatments, proposing all species exhibited different mechanisms in accumulation, transport or sequestration of the elements. Along with the visualization provided by principal component analysis, K, Zn and Fe for *P. khinjuk*, Cu, Cd, N, Mn, and Mg for *P. vera*, Mn, Ca and P for *P. terebinthus* were more pronounced (*Fig. 4*).

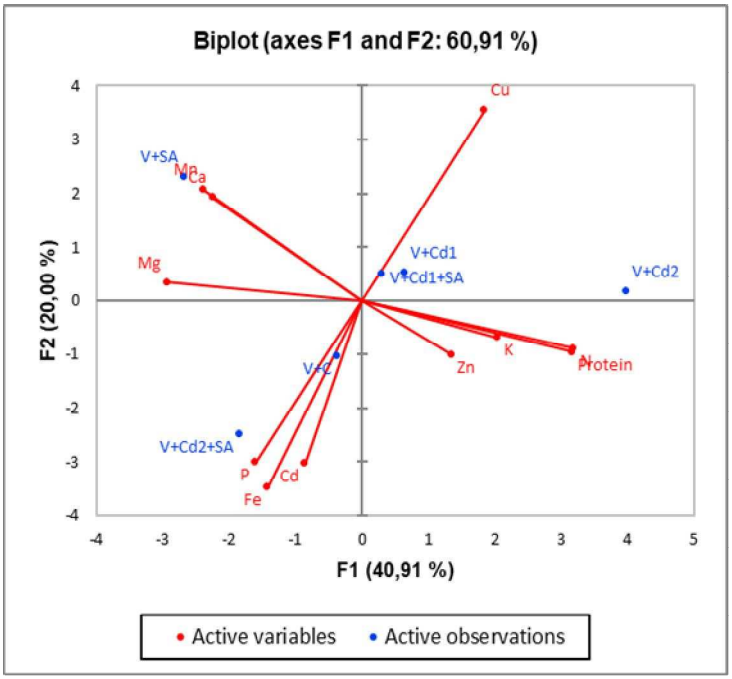

Figure 3. *Principal component analysis for P. vera*

Prominent and over accumulated elements

Of the examined elements, P and Cu concentrations increased 2.151 and 4.702 times by applications of the cadmium and salicylic acid to pistachio species (*Table 17, Figs. 5-6*).

Table 17. *Over-accumulation of P and Cu under various treatments in different pistachio species*

Phosphorus (P), as phosphate (PO_4^{-3}), is a complementary component of important compounds that form plant cells, including sugar-phosphates and phospholipids that form the plant membrane as intermediates in respiration and photosynthesis. Since it is an important part of DNA and RNA molecules, it has been reported that phosphor-specific genes are necessary in the expression mechanism and may be involved in the regulation of enzyme reactions as part of proteins (Dordas, 2009). In addition, phosphorus, as an element of ATP, helps transform energy in many biochemical events (Sieprawska et al., 2014). In the case of arid regions or any disruption in the roots of the plant, the phosphate content decreases in the tissues of the plant. Due to this decrease, the rate of photosynthesis per unit in leaves is also significantly affected. It was reported that the decrease in leaf growth and photosynthetic ratio due to phosphorus may be related to permeability of stomata and ribulose 1,5 biphosphate carboxylase regeneration capacity (Brooks, 1986).

Of the microelements, copper (Cu) plays significant roles in regulation of photosynthesis, respiration, antioxidant activity, cell wall metabolism and hormone perception. Furthermore, Cu is a cofactor of various enzymes such as copper/zinc superoxide dismutase (Cu/ZnSOD), cytochrome-c oxidase (Pilon et al., 2006).

Discussion

Exogenous SA applications have been determined to increase the development and photosynthetic efficiency in plants such as *Oryza sativa* (Chen et al., 2007), *Zea mays* (Krantev et al., 2008), *Phasealus vulgaris* (Zengin, 2014) which have been exposed to various heavy metals. It has also been shown to be effective on antioxidant mechanism by lowering membrane lipid peroxidation (Chen et al., 2007; Zengin, 2014). Moreover, SA application regulates various metabolic processes in plants, encourages the production of osmolyte and secondary metabolites, adjusts the nutrient status and protects the plant under abiotic stress conditions (Khan et al., 2015). SA triggered high production coupled with high concentration of photosynthetic pigments, photosynthetic activities and higher antioxidant enzymes in plants exposed to Cd stress (Zhang et al., 2015). As a regulatory role of SA, Studies have shown that SA applications are an important elicitor that regulates photosynthesis, photosystem II, photosynthetic pigments and enzyme activities in plants under metal stress and controls the formation of H_2O_2 and gives endurance by controlling the formation of H_2O_2 (Al-Whaibi et al., 2012; Noriega et al., 2012; Belkadhi et al., 2014; Zhang et al., 2015).

Furthermore, SA has a role in alleviating heavy metal toxicity (Shi and Zhu, 2008; Zhou et al., 2009; Wang et al., 2013). In addition, it has been determined that SA acts as a regulator in the increase of antioxidant enzymes and in the absorption and distribution of nutrients by reducing the Mn transport from the roots to the shoot (Sheng et al., 2015).

Of the studies carried out on the accumulation of nutrients, the content of elements exhibited different responses. Application of SA in salt stressed plants caused a decrease in K, Ca and P content (El-Tayeb, 2005). However, exogenous SA treatments in wheat caused increases in P, K, Ca and Mg contents (Aldesuquy et al., 2012; Hassanein et al., 2012; Loutfy et al., 2012).

Along with the current study, the effect of salicylic acid treatments on the element content of pistachio species was different. According to the results, SA application increased P, Ca, Mg and Cu content and decreased N content in *Pistacia terebinthus*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71137133

While Fe content increased in *Pistacia khinjuk*, the other elements decreased. In *Pistacia vera*, P, Ca, Mg, Zn, Mn, Cu content increased.

50 μM cadmium (Cd_1) reduced the content of most elements. As a result of Cd_1 treatment, *Pistacia terebinthus* has increased K, Mn, Cu, Fe and Cd uptake while other elements and protein have decreased or remained at the same level. While P, Mn, Cu and Cd accumulation increased, N, Ca, Mg, Zn, Fe and protein decreased in *Pistacia khinjuk*. P, Mn, and Cu content increased while N, K, Ca, Mg and Fe content decreased in *Pistacia vera*.

Three pistachio species exhibited different responses against 100 μM cadmium (Cd_2) treatment. As a result of treatment, K, Mn, Cu, Fe and Cd content increased while N, Ca, Mg, Zn, and protein decreased in *Pistacia terebinthus*. P content exhibited an increase whereas other element and protein content decreased in *Pistacia khinjuk*. In *Pistacia vera*, N, K, Zn, Mn, Cu and protein content increased while Ca, Mg and Fe content decreased.

Pistachio species exhibited different responses concerned with the concentration of element under 50 μM with addition of SA (Cd_1+SA). As a result of the treatment, the concentration of K, Mg, Mn, Cu, protein and Cd increased in *P. terebinthus*. In *P. khinjuk*, Mn and Fe concentration increased whereas other elements concentration and protein content decreased. Furthermore, K, Mg, Mn and protein content increased while N, Ca, Zn, Cu, Fe and Cd concentration decreased in *P. vera*.

Herewith the correlation analysis, pistachio species exhibited different behaviors regarding with correlations for their element contents, which might be deemed as consequences of uptake and accumulation in response to the exogenous treatments.

Conclusion

To sum up, pistachio species exhibited different responses with respect to the content of elements and proteins in their leaf tissues under cadmium and salicylic acid treatments. Also, species responded differently against cadmium concentrations and salicylic acid. Generally, the changes in content of elements were more pronounced by 100 μM Cd treatment. Although the response of the species was different, addition of SA positively affected the element and protein content. While cadmium and salicylic acid affected the content of elements in the leaf, the effect of salicylic acid on cadmium was not significant.

Differences concerned with element content and responses against foliar SA among cultivars were revealed and discriminated via chemometric techniques. Also, possible active roles of P and Cu against Cd and SA applications were also determined for pistachio species. By applications of the cadmium and salicylic acid to pistachio species, leaves' P content 2.151 times and leaves' Cu content 4.702 times were increased, suggesting the forthcoming studies to be concentrated on the exogenous applications of P or Cu in order to improve the responses of pistachio species against Cd stress.

Furthermore, these results might be considered to be significant in terms of the selection and use of rootstocks of pistachio species by considering the different reactions regarding with the element and protein content. Subsequently, the element-mediated or induced growth parameters might also be considered under unfavorable environmental conditions.

*(e-mail: emelunalturhan@*gmail.com*; phone: +90-0-328-888-0090; fax: +90-0-328-0091)*

(Received 24th Feb 2019; accepted 11th Apr 2019)

Abstract. Contamination of cheese by foodborne pathogens may pose a risk for human health. Especially, microbiological quality of cheese sold in local market and produced on a small scale is generally lower than industrial production. The aim of the present research was to investigate the presence of pathogenic bacteria such as coagulase positive staphylococci, *Escherichia coli, Listeria monocytogenes* and *Salmonella* spp. in twenty white cheese samples from local market on a small scale in the province of Hatay, Turkey. In this study, none of cheese samples contained *L. monocytogenes* and *Salmonella* spp. while *E. coli* and coagulase positive staphylococci were detected in cheese samples. The higher prevalence of coagulase positive staphylococci (100%) than *E. coli* (65%) were detected in cheese samples, but contamination levels of *E. coli* (mean 4.05 log cfu/g) were found higher that coagulase positive staphylococci (mean 2.47 log cfu/g) in terms of viable cell counts of pathogenic bacteria in cheese samples. The present results indicated that traditional cheeses manufactured in Hatay province were generally satisfactory microbiological safety according to Turkish Food Safety Criteria. As a result, the presence of pathogenic bacteria in traditional cheese from Hatay region could cause outbreaks affecting public health and reduce positive impression on traditional cheeses which have potential for geographical indication.
Keywords: *small scale food producers, Turkish food codex, microbiological criteria, dairy products, contamination*

Introduction

Cheese is fermented dairy product known as a safe and nutritious food with high protein and dietary calcium contents. Cheese is often consumed due to these beneficial impacts on human health, favorable sensorial and nutritional properties (Mikulec and Jovanovic, 2005; Kurşun et al., 2008; Choi et al., 2016). In Turkey, cheese is produced by both traditional methods (manual handling and unmechanized) and industrial methods (production based on mechanization). The production and consumption of domestic natural or traditional cheese in the world is rising year by year. Traditional cheeses which have distinctive taste and odor are produced on a small scale by using raw milk in mostly east, southeast region of Turkey (Hayaloğlu et al., 2002; Ozer et al., 2004; Jorgensen et al., 2005). East, south east and south of Turkey are famous for quite high summer temperatures, for example Hatay. Hatay is one of the cities where food products are frequently sold in open market places or local market on a small scale due to traditional habits (Cokal et al., 2012).

Turkish traditional white cheese is usually produced under unmechanized or artisanal conditions and is handled at various stages of manufacture. Thus, various types of microorganisms may enter the cheese during manufacture and subsequent handling (Hayaloglu et al., 2002). As a result of climate and improper hygiene conditions, white cheese producer on a small scale of Turkey often encounter with contamination risk of pathogens. In particular traditional cheese sold local market have low hygienic quality

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71357145

(Ozer et al., 2004; Başkaya et al., 2006; Uraz et al., 2008). Four bacterial pathogens including *Listeria monocytogenes, Salmonella* spp., *Staphylococcus aureus* and pathogenic *Escherichia coli* are the predominant microorganisms that caused outbreaks as result of contaminated traditional cheese (Motarjemi et al., 2002; Hudson et al., 2003). *Salmonella* spp. is gram negative gastroenteritis-inducing pathogens and the majority of Salmonella cases are foodborne (Donnelly et al., 2018). The primary source of *Salmonella* spp. is humans and animals as carrier (mostly their feces). Animal products are among the most common foodstuffs of *Salmonella*. The main foods as source of *Salmonella* are meat, milk and eggs and their products and also inadequately heat treated food products (Akkaya and Alişarlı, 2006). In many reports, the outbreaks of *Salmonella* were associated with raw milk cheese (Donnelly, 2018). *Staphylococcus aureus* as coagulase positive staphylococci plays an important role on human health due to the production of thermo-stable enterotoxins that causes foodborne illness. Particularly, in the dairy industry *S. aureus* is mostly pathogen as it can induce foodborne intoxications through dairy products including cheeses (Donnely, 2018). *S. aureus* is usually transmitted to food by personnel (hands, coughing, sneezing, etc.). Milk and milk products are the main foods that cause poisoning from *S. aureus* (Pacheco and Galindo, 2010). *L. monocytogenes* is gram positive facultative anaerobic foodborne pathogen and one of the most dangerous pathogens in food industry. It is usually found in soil, surface waters, sewage, plants, faeces and animal feed. Diseases from *L. monocytogenes* are more rare than others, but their effect is more severe and even fatal (Chavant et al., 2002; Pacheco and Galindo, 2010). Human listeriosis outbreaks are often associated with ready-to-eat food products including cheese. Several outbreaks and sporadic cases of disease associated with the consumption of pasteurized milk, cheeses made from unpasteurized milk, and other dairy products in USA and Europe in the past decade (Esho et al., 2013). *L. monocytogenes* contamination was mostly found in raw milk (Esho et al., 2013). *Escherichia coli* is gram negative, *Enterobacteriaceae* family of *Escherichia* genus dependent, facultative anaerob, mostly moving, non-spore, rod-shaped bacteria. *E. coli* infection may cause foodborne diseases such as diarrhea, hemorrhagic colitis, and hemolytic uremic syndrome. According to epidemiological findings, *E. coli* epidemic is generally seen as a result of cucumber, carrot and lettuce consumption (Almosoud et al., 2015). *E. coli* are known as indicator organisms of fecal contamination during cheese processing (IDF, 2016).

Today, foodborne diseases related to cheese consumption are common problems in many countries. Microbial contamination in traditional cheese as the main potential risk factor is increasingly growing and has detrimental effects on public health (Belli et al., 2013). High pathogen risk in milk and dairy products originates from cow itself, inefficient animal health control, insufficient training of farmers, dairy raw milk used unpasteurized for the production, processing environment and employees about milk hygiene, utensils, post processing, retail process collection, transport and weakness in the cold chain during production processes and storage (Telli et al., 2012; Cokal et al., 2012; Belli et al., 2013). Especially traditional cheeses produced from raw milk (unpasteurized) pose a risk due to its pathogenic contents (Atasoy et al., 2003). Microbial safety of cheese is dependent on good manufacturing practices. Cheese producers have to comply with hygienic practices to ensure safety (Donnelly, 2018). Considering that traditional cheese is mostly made from raw milk, the application of food safety policy are essential in order to avoid microbial spoilage of milk, especially in local small scale dairy processing plants (Belli et al., 2013). The World Health Organization requires that small scale dairy

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71357145

processing plants in the developing countries urgently comply with the Codex Alimentarius principles (WHO, 2007). Hazard Analysis of Critical Control Points (HACCP) and Good Manufacturing Practices (GMP) are also recommended for the small production units (Belli et al., 2013).

There are limited studies based on microbial safety of traditional cheese in the province of Hatay. The present study was aimed to evaluate hygienic quality and safety of traditional cheese from local market on a small scale in Hatay province, Turkey.

Material and Methods

Samples and indicator microorganisms

In this study, totally 20 cheese samples were collected from small scaled local market in Hatay province, Turkey (*Figure 1 and Figure 2*). For all identification tests, pathogenic bacteria including *Escherichia coli* ATCC-35150, *Salmonella* spp., *Listeria monocytogenes* ATCC7644 (Remel-USA) and *Staphylococcus aureus* ATCC-25923 was used as indicator organisms for the aim of positive control. Pathogen bacteria were grown in BHI (Merck, Germany) and stocked at -20°C in BHI supplemented with 20% (v/v) glycerol.

Figure 1. *Traditional cheese collected from local market on a small scale in Hatay province*

Figure 2. *Hatay province of Turkey (Demirkesen, 2012)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71357145

The preparation of samples for microbiological analysis

The homogenates of cheese samples were prepared by aseptically removing 25 g of cheese into sterile filter-stomaching bags (Isolab). A 225 mL of buffered peptone water was also added into the stomaching bags containing the samples and homogeneously mixed in stomacher (Bagmixer-interscience, France) twice for 1 min. The sample homogenates were serially diluted with buffered peptone water.

Isolation and enumeration of microorganisms

The isolation of pathogenic bacteria in cheese samples was performed according to the reference methods of EN/ISO 6888 for coagulase positive staphylococci, EN/ISO 11290-1 for *L. monocytogenes* and EN/ISO 6579 for *Salmonella* spp. and EN/ISO 16649 for *E.coli* (Halkman, 2005; Turkish Food Codex, 2011).

For *E. coli* enumeration, decimal serial dilutions of the homogenate were plated in duplicate on TBX agar (Merck) plates. After incubation of plates at 44ºC for 18-24 hours, the blue green colonies were counted as *E. coli*.

For coagulase positive staphylococci (*S. aureus* and other species) enumeration, decimal serial dilutions of the homogenate were plated in duplicate on Baird parker-RPF agar (Oxoid) plates. After at 37ºC, for 24 hours, typical black and bright colonies were counted as coagulase positive staphylococci.

For the isolation of *Salmonella* spp., homogenate of cheese samples in erlenmeyer flask were incubated at 35-37ºC for 16-20 hours. Then, 10 mL homogenate were added to RVS broth (Oxoid) as selective pre-enrichment medium and incubated at 42-43ºC for 24 hours. Afterthat, inocula from the pre-enrichment medium were streaked in duplicate onto Brilliant Green agar plates (Oxoid). After incubation of plates at 37ºC for 24 hours, typical *Salmonella* colonies reproduced or not on the selective agar plates.

For the isolation of *L. monocytogenes*, 25 g of each sample was taken aseptically and homogenized in 225 mL Fraser broth (Oxoid) using a stochmacher (Bagmixer-interscience, France) for 1 min and incubated at 30ºC for 48 hours. Then, inocula from the enrichment culture were streaked in duplicate onto each of two selective agars, Oxford agar (Oxoid) and PALCAM agar (Oxoid). After incubation of both selective plates at 35-37ºC for 48 h, typical *Listeria* colonies reproduced or not on the selective agar plates.

Results

To asses microbiological safety of traditional cheese in Hatay province, a total of 20 cheese samples were collected from local market on a small scale in Hatay. *Table 1* represented the presence of pathogenic bacteria in traditional cheese samples from local markets on a small scale in Hatay. Additionally, viable cell counts of these pathogens which are present in these cheese were given in *Figure 3*. In this study, while *E. coli* (n=13) and coagulase positive staphyloccoci (n=20) were isolated in cheese samples, *Salmonella* spp. and *L. monocytogenes* were not isolated from any cheese samples. 45% of coagulase postive staphylococci exceeded the acceptable levels in Turkish Food Safety Criteria. However, since the Turkish Food Safety Criteria does not include any limitation on the number of *E. coli* that is allowed to be present in the white cheese, no comment could be made for *E.coli* levels in the present study.

Discussion

Farmhouse or small scale production of traditional cheeses was associated with higher microbiological risk. Food safety was seen as a critical factor in the production of such cheese types. Various small-scale production of raw milk products has performed in the world (Obrien et al., 2009). However, there is some concern that such foods may pose a risk of pathogenic bacterial food poisoning to consumers (Jorgensen et al., 2005). Similarly, in Turkey traditional cheeses were obtained with small scale production and sold in local markets. Traditional handmade cheese in Hatay, mostly reach to local market without retaining ripening duration or without providing cold chain. Thus, these cheeses are susceptible to the development of pathogenic bacteria.

In brief, as known, cheese produced with unpasteurized milk may result in foodborne outbreaks. On this sense, food industry which purposes microbiological safety prefers the use of pasteurized milk for the production of cheese. However, sensorial properties of cheeses from unpasteurized milk and pasteurized milk are different from each other and according to consumer demands both type cheese were also sold on the market. Therefore the achievement of microbiological safety in traditional cheese is essential during processing including manual handling, molding and ripening. Additionally, concentration of brine solution, storage conditions, ingredients, cheese composition and packaging etc. play an important role on microbial charge of cheese. The safety of traditional cheese

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71357145

could particularly ensure with microbial risk assessments based on ripening duration, water activity and storage conditions (Choi et al., 2016).

L. monocytogenes, *S. aureus*, *E. coli* and *Salmonella* spp. are well-recognized foodborne bacterial pathogens. Traditional cheese from raw milk could support the growth of such foodborne pathogens. Therefore, there is concern for microbiological safety of domestically produced traditional cheeses (Esho et al., 2013). If pathogens are present in raw milk, they can be present throughout a cheese. Raw milk or contaminated milk was seen as the source of *L. monocytogenes*, however the primary route of *Listeria* contamination of dairy products results from environmental contamination during processing (Donnelly, 2018). Various reports detected its presence in milk and cheese (Akkaya and Alişarlı, 2006). In addition to this, traditional cheeses are at risk of containing pathogenic bacteria due to post-processing contamination that can occur during manufacture, as well as during ripening and washing, or at retail (Donnelly, 2018). The incidence of high *E. coli* and *S. aureus* count in food is considered as indicator for poor hygienic condition in production process (Obrien et al., 2009; Samouris et al., 2011; Esho et al., 2013).

The result of this study showed that 65% and 100% of cheese samples contains *E. coli* and coagulase positive staphylococci, respectively. The presence of *E. coli* and coagulase positive staphylococci showed that microbiological quality of traditional white cheese samples was generally poor because of inadequate hygienic conditions during production (Hayaloğlu et al., 2002; Ozer et al., 2004; Telli et al., 2012; Belli et al., 2013). In general while the presence of *S. aureus, L. monocytogenes* and *Salmonella* spp. in cheese stemmed from raw milk, the presence of *E. coli* associated with inappropriate or hygienic conditions (Torkar et al., 2006; Obrien et al., 2009; Pacheco and Galindo, 2010; Yücel and Anıl, 2011). According to microbiological criteria linked to food safety policy in Turkey, while the presence of *L. monocytogenes* and *Salmonella* spp. are not allowed in cheese, the presence of coagulase positive staphylococci are limited between 2 and 3 log cfu/g (Turkish Food Codex, 2011). Similarly, microbiological criteria prepared by European commission associated with food safety and hygiene referred the same limits with regard to *L. monocytogenes*, *Salmonella* spp. and coagulase positive staphylococci in cheese. Our results about the presence of *L. monocytogenes* and *Salmonella* spp. in cheese samples comply with microbiological criteria. However, the amount of coagulase positive staphylococci isolated from some cheese samples used in this study has exceed the limit values. As seen in *Figure 3*, higher amounts of coagulase positive staphylococci than microbiological criteria were found as 4.69 and 4.68 log cfu/g in samples 12 and 14. Although microbiological criteria for *L. monocytogenes, Salmonella* spp. and coagulase positive staphylococci in cheese are described by Turkish Food Safety criteria and European Commission microbiological criteria, *E. coli* are not specified. In case of using unpasteurized raw milk, producers must process products under equivalent temperature condition (63^{o}C for 30 min) to eliminate the risk of pathogenic bacteria. Thus, *E. coli* are not expected to exist due to the heating process in the production of traditional cheese. Additionally, postproduction contamination, poor hygienic practices and equipment are the challenging factors in cheese-related foodborne illness (Esho et al., 2013). As shown in *Table 1*, traditional white cheese in Hatay province contained detectable numbers of coagulase positive staphylococci between 1 and 4.69 log cfu/g and *E. coli* between 1.91 and 5.67 log cfu/g. Similar to our results, according to the previous reports based on Turkish traditional white cheese, *E. coli* and *S. aureus* amounts in white cheese were between 0.60-5.15 log cfu/g and 1.30-1.70 log cfu/g, respectively, whereas *Salmonella*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71357145

spp. and *L. monocytogenes* were generally not present from the cheese samples (Hayaloğlu et al., 2002).

The presence of *Staphylococcus aureus*, *Salmonella* spp. and *L. monocytogenes* were mostly found during the cheese making process in small-scale raw milk cheese production. The main reason for such contamination is considered as the use of raw milk (Jorgensen et al., 2005; Kaynar et al., 2005; Jakobsen et al., 2011; Esho et al., 2013; Rola et al., 2016). *E. coli* are one of indicators of fecal contamination during cheese processing. Especially, cheese produced from unpasteurised milk (raw) can contain *E.coli*. Because *E. coli* is seen as a hygiene indicator for raw milk cheese, a manufacturer need to attempt to implement an appropriate HACCP plan. (Samouris et al., 2011; IDF, 2016). *E. coli* and *S. aureus* are the dominant pathogenic microflora in traditional cheese (Ozer et al., 2004). Previous studies were usually referred *E. coli* and *S. aureus* as the main contamination sources of cheeses whereas contamination of cheese by *Salmonella* spp. and *L. monocytogenes* stated as very few or none (Torkar et al., 2006; Obiren et al., 2009; Pacheco and Galindo, 2010). The presence of *L. monocytogenes* and *Salmonella* spp. in traditional cheese samples was highly rare and generally at rate of between 1and 3% or none (Kara, 1999; Kaynar et al., 2005; Torkar at al., 2006; Keskin et al., 2006; Jakobsen et al., 2011; Telli et al., 2012; Esho et al, 2013). The present results confirmed this literature information.

S. aureus is common in milk and milk products and could cause intoxications with its toxins during processing (Ünlütürk, 2003). In international literature information, coagulase positive staphylococci were isolated on farms with small scale production of saw milk cheeses in Poland and their concentrations were ranged from approximately 0.5 to 7.5 log cfu/g (Rola et al., 2016). For example, Jorgensen et al. (2005) detected the presence of *S. aureus* in raw milk cheese with small scale production at levels of 3 log cfu/g. On the other hand, *E. coli* amounts of cheese made with raw milk were ranged from 0.46 to 5.38 log cfu/g (Samouris et al., 2011).

In previous studies based on microbiological quality of white cheese in Turkey, the presence of *S. aureus* and *E. coli* were found about between 40% and 100% and their amounts were varied from 1 and 6 log cfu/g. For instance, Torkar et al. (2006) investigated the occurrence of pathogenic bacteria in cheese produced at small dairy processing plants. Accordingly, all tested samples contained coagulase staphylococci (approximately 4 log cfu/g) and *E. coli* (approximately 6 log cfu/g) whereas *Salmonella* spp. and *L. monocytogenes* were not detected. Ozer et al (2004) reported that at the end of the 90-day storage period (at different brine concentration) in white Urfa cheese samples, *S. aureus* and *E. coli* were respectively found at level of between 3 and 4 log cfu/g and 0 and 3.5 log cfu/g however, *Salmonella* spp. could not detected. As seen, up to 90 days *S. aureus* and *E. coli* protected their viability. Our result also supported the hypothesis that the presence of *E. coli* and coagulase positive staphlococci in traditional cheese produced from raw milk in local market is possible. Additionally, Cokal et al (2012) reported that while contamination levels of *L. monocytogenes*, *E. coli* and *S. aureus* in Turkish traditional cheese samples were found 5%, 43% and 100%, respectively, none of food samples contained *Salmonella* spp. In accordance with this, the highest pathogen contamination arisen from coagulase positive staphylococci and followed *E. coli*. In the present study none of 20 samples had the presence of *L. monocytogenes* and *Salmonella* spp., however it does not mean that *L. monocytogenes* is not present in the whole cheese samples sold in Hatay. If more cheese samples were collected in Hatay, the prediction of pathogen contamination levels could be increased.

Keskin et al. (2006) investigated microbiological quality of the white cheese sold on street markets. The presence of 86% *E. coli* and 66% *S. aureus* were detected and were not present *Salmonella* spp. and *L. monocytogenes*. Başkaya et al. (2006) determined approximately 2 log cfu/g *E. coli* and *S. aureus* in civil cheese (another Turkish traditional cheese). Bilge and Karaboz (2005) detected the presence of *Staphylococcus aureus* (about 2-3 log cfu/) in some white cheese marketed in Izmir. Our results are in accordance with these previous reports.

To improve the food safety in small-scale cheese production, producers should be increasingly aware of the importance of some pre-requisites and process control points. As process control in cheese production, producers could focus on the quality of milk, regular cleaning of equipment and facilities, optimal concentrations of brine and processing factors such as time, pH and temperature. To reveal strengths and weaknesses of small scale cheese production, survey including questions such as personnel, education, dairy premises, utensils, production volume, hygiene barriers, control measures, water supply, pasteurization conditions and procedures for handling starter cultures should be implemented to producers (Rosengren et al., 2012; Damico et al., 2017). For example, by food safety authority of Ireland, a workbook has been produced to assist farmhouse cheesemakers meet their legal obligation to develop and implement a food safety management system based on the principles of HACCP (Hazard Analysis and Critical Control Point), also referred to as HACCP-based procedures. This workbook provides a controlled approach by describing and recording each step during individual operations in cheesemaking, from raw material production/purchasing through to the storage and dispatch of cheese (Food Safety Authority of Ireland, 2019). On this sense, small scale cheese producers need to develop and implement HACCP plan based on their specific productions (Zhao et al., 2003; Hof et al., 2008). HACCP system as one of the most important systems in quality assurance programs is a plant-specific and product-specific quality system. The application of HACCP plan in small-scale cheese plant could ensure the food safety via the identification of microbiological hazards (Nasr et al., 2017).

Conclusion

The present study concluded that the microbiological quality and hygienic status of traditional cheese analyzed in this study were mainly favorable. Most of traditional cheese samples analyzed in this paper complied with the microbiological criteria notifications on food safety by Turkish government. In Turkey, cheese is automatically produced in industrial plants with large food factories or traditionally on a small scale in local markets. Handmade cheeses with raw milk could have deficiencies from utensils, staff and other unstable processing conditions in terms of hygienic quality. In particular, raw milk constitutes the critical control point in the production process of traditional cheeses. Pathogen risk is inevitable in cheeses manufactured from low microbial quality milk. As a matter of fact such contaminated cheese could result in the outbreaks of foodborne pathogens including *L. monocytogenes, Salmonella* spp., *E. coli* and *S. aureus*. Policies on food safety and protection have focused on ensuring food safety in conventional products. On this sense, for the sustainability of traditional cheeses, microbial safety must be ensured with a HACCP or other food safety plan in manufacturing field and producers should focus on the hygienic conditions during milking and cheese processing.

Abstract. Ecosystem services (ES) are essential to human well-being. Assessing dynamics of ES is crucial to shaping the concept of sustainable development and creating public understanding of the status of ES. This study proposes to quantify the change in ES value in response to Land cover/land use (LCLU) changes over the past 33 years in the Rift Valley Lakes Region of Ethiopia. A combined approach of LCLU classification and modified ES value coefficients was employed for quantifying the ES value. Results revealed that approximately USD196.04 $\times 10^6$ (12.4%) of ES value was lost during the study period. Although cropland experienced a dramatic expansion, the total gain in ES value of the cropland was too small to balance out the overall loss. A continuous reduction in values of specific ES functions has also occurred except for food production, biological control, and pollination service function over the last three decades, indicating an apparent deterioration of the fragile Rift Valley ecosystem. Hence, to enhance the continuous supply of ES and economic development, an integrated approach to managing land and water resources is recommended. Moreover, payment for ES is also a potential remedy for ES loss at the regional and local scale.

Keywords: *combined approach, benefit transfer, modified coefficient, East Africa Rift system, average ecosystem service value, loss, water bodies, woodland, cropland*

Introduction

Ecosystem services (ES) are essential to human welfare (Xu and Ding, 2018; Costanza et al., 2014; Braat and de Groot, 2012; MEA, 2005). These include regulating, provisioning, supporting, and cultural services (MEA, 2005; Costanza et al., 1997). The amount and quality of ES depend on the types of ecosystem and their status (Tolessa et al., 2017a; MEA, 2005). Each ecosystem provides distinct services that could not be substituted with another (Gashaw et al., 2018). ES are closely related with land cover/land uses (LCLU), and they alter across time and space (Xu and Ding, 2018; Schirpke et al., 2017; Tolessa et al., 2017a; Costanza et al., 2014). Land cover/land use change (LCLUC) is altering the amount and quality of ES provided by ecosystems. LCLUC is an essential landscape process (Schröter et al., 2005; Daily, 1997) designed by the interaction between the social-economical activities of human beings and the natural environment (Chang et al., 2018).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71477173

Changes in LCLU may lead to differences in the value of ES (Locatelli et al., 2017; Polasky et al., 2011; Hu et al., 2008; Kreuter et al., 2001). It may raise the value of some services while reducing that of others, which affects the capability of the biological system to sustain human needs, indicating ecological deterioration (Polasky et al., 2011), or may cause conversely (Kindu et al., 2016). For example, studies show that the transformation of forest land to cropland increases food production while reduces the regulating services provided by the forest land (Fedele et al., 2018; Rodríguez et al., 2006; Foley et al., 2005). However, a recent land development activity in marginal grassland have effected in the conversion of ES from provisioning to regulating services as a result of natural reforestation processes (Schirpke et al., 2017; Vigl et al., 2016). Thus, the study of ES value changes caused by the change in LCLU has implications (Chen et al., 2015) through creating public awareness of the continuing LCLU dynamics and is vital to indicate the vulnerability of each ES (Cabral et al., 2016).

Monetization of ES has been promoted by numerous as a model strategy to create public alertness, provide evidence for consultations with decision makers, flag up the opportunity costs of rehabilitation and/or restoration, and assist in payments for ES (Alarcon et al., 2016; Baveye et al., 2013; de Groot et al., 2012; Nelson et al., 2009; Costanza et al., 1997). Recognising and quantifying the influence of LCLUCs on global, regional, and local ES is a practical approach to evaluating the costs and benefits to the environment and supporting sustainable land management decisions (Xu and Ding, 2018; Song and Deng, 2017; Liang et al., 2017). It also assists with devising a land use planning framework suitable for sustaining the health and sustainability of land resources (Bartkowski, 2017; Cabral et al., 2016; Jacobs et al., 2016).

The results of many studies that estimated ES value in response to LCLUC were location specific. For example, some studies reveal an overall increase in ES value (Temesgen et al., 2018; Wang et al., 2014; Sawut et al., 2013) while others confirm the opposite, i.e. a decreasing trend (Gashaw et al., 2018; Leh et al., 2013; Tolessa et al., 2017a); whereas, globally, the total net loss due to LCLUC has been estimated at USD 20.2 trillion/ year between 1997 and 2011 (Costanza et al., 2014). However, estimation of ES value change at a regional scale from the global study is challenging; in fact, a regional study of a country often results in a different yield due to various approaches and classifications. Moreover, the prevailing ES valuation in response to LCLUC is not comprehensive across the whole world due to the lack of inclusion of vast ecological regions and services (Tadesse et al., 2014; Satz et al., 2013; de Bello et al., 2010); its applicability to different regions leads to improper valuation of ES (Wang et al., 2015). Even though a number of recent works have quantified and mapped ES (e.g. Leh et al., 2013; Egoh et al., 2009; Nelson et al., 2009), despite some efforts (by Arowolo et al., 2018; Niquisse and Cabral, 2018; Gashaw et al., 2018; Temesgen et al., 2018; Tolessa et al., 2017a; Kindu et al., 2016), such studies are lacking in other regions of Africa (Leh et al., 2013; Seppelt et al., 2011) that serve as a source of the world's biodiversity.

Many regions of Africa are facing rapid and profound transformation economically, socially, and environmentally a transformation that is already endangering the long-standing conservation of its substantial natural heritage and biodiversity (Mwampamba et al., 2016). Hence, the ongoing deterioration of ecosystems occurs in many regions of the continent at the expense of the well-being

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71477173

of the coming generations (Kubiszewski et al., 2017; de Groot et al., 2012); this is particularly true for Ethiopia, which lost approximately 17.7% of its overall terrestrial ES values due to LCLUC (Sutton et al., 2016).

In Ethiopia, LCLUC is a common and ever-present phenomenon because agricultural activities mainly dominate rural landscapes, affecting ES (Tolessa et al., 2017a). Integrating LCLU and an ES value dataset can assist in detecting the areas highly susceptible to change in ES at the landscape scale and provide an avenue for land management opportunities in the future. Moreover, research works carried out on LCLUC in the country mainly focuses on the driving factors and the LCLU dynamics (Meshesha et al., 2012; Tsegaye et al., 2010; Reid et al., 2000). However, the consequence of LCLUC on a wide-range of ES is rarely attempted. Currently, there has been no estimation of the impacts of such changes at a regional scale, just a few efforts made to evaluate ES in response to LCLUC at the local scale (Gashaw et al., 2018; Temesgen et al., 2018; Tolessa et al., 2017a; Kindu et al., 2016).

The study area, the Rift Valley Lakes Region (RVLR) of Ethiopia, is situated in the Eastern part of the African Rift System, and consists of lakes, streams and wetlands with unique hydro-ecological characteristics (Jansen et al., 2007; Hengsdijk and Jansen, 2006), and a wide range of landscapes with high biodiversity. It is the largest freshwater ecosystem in the nation with considerable social, economic and ecological significance. However, the RVLR is one of the most environmentally susceptible areas in Ethiopia. Being a landlocked basin, relatively little intervention in the water and land resources can have substantial consequences for ecosystems goods and services, and weaken the potential sustainable use of the region (Ayenew, 2004; Legesse et al., 2004).

Therefore, recognising the influences of LCLUC on ES value in the study region is vital to increasing public understanding and indicating the proper land use policy direction. Previous studies emphasised potential LCLUC, although the majority were carried-out at a local scale and described the LCLUC qualitatively. The consequences of the existing LCLU and land degradation are huge, including declining crop and livestock production and exacerbated food shortages in the area (Meshesha et al., 2012). Hence, the objective of this study was 1) to characterise changes in LCLU over the last three decades and 2) to quantify and map the ES value alteration in response to LCLUC using a modified ES value coefficient in the RVLR of Ethiopia from 1986 to 2018.

This study estimates changes of ES in response to LCLUC using a conservative ES coefficient modified by (Kindu et al., 2016) using benefit transfer approach. Kindu et al. (2016) developed modified conservative value coefficients through a review of the previous studies, and dataset available from the Economics of Ecosystems and Biodiversity (TEEB) database. This value coefficient is assumed to be suitable for the RVLR of Ethiopia, which is a developing region with a rapidly growing population (Legesse et al., 2004), abundant livestock (Meshesha et al., 2012) and a vulnerable ecosystem, and for other areas with a similar landscape setting.

This paper has five sections: The first section is the introduction of the study. The second section gives a concise description of the study area, introduces methods to assess LCLUC, quantifies ES change in response to LCLUC, and statistical analysis. The third and fourth sections give the results and discussion, respectively, and the fifth section concludes and provides some future recommendations.

Materials and methods

Study area

The RVLR of Ethiopia (38°11' to 39°9' E and 6°55' to 8°29' N) (*Fig. 1*), is located in the Eastern part of the Great African Rift system, with an altitude ranging from 1,384 m at the valley floor to more than 3,040 m asl at the escarpment (*Fig. 1*). The region where the study conducted includes eight administrative districts and two town districts with a total area of about 0.81 million ha (*Table 6*) and a projected population for 2017 of 2.1 million (CSA, 2013). The national GDP per capita was about USD233.82 in 1986 and USD706.76 in 2016 (WorldBank, 2019). The study region is characterised by rift valley lakes, namely Ziway, Langano, Shalla, Abiyata, Hawasa Lakes and Koka. Lake Ziway is one of the centres for agricultural development in the country (Hengsdijk and Jansen, 2006); Lake Abyata and Lake Shalla are important nature reserves, integrating the Abyata-Shala Lakes National Park, primarily established for aquatic bird protection (de Francisco et al., 2008; Hengsdijk and Jansen, 2006), which is currently heavily invaded by human and cattle populations (Scholten, 2007). Lake Hawasa, situated at the high elevation in the central main Ethiopian Rift Valley, is one of the essential bird sanctuaries in the country and is significant source of tourism income (Wondrade et al., 2014; Ayenew and Gebreegziabher, 2006). Lake Koka (artificial) is the second oldest hydro-power dam in the country. It provides multiple services besides hydropower (Gebretsadik, 2016). The study area also covers another sanctuary established for protecting Swayne's hartebeest (*Alcelaphus buselaphus swaynei*) which is called Sinkele sanctuary, located in the southwest of the study area (Nishizaki, 2004). The climate is arid to semi-arid (Scholten, 2007), but varies markedly with altitude (Jansen et al., 2007), with an annual precipitation of about 600 mm. About 70% of the rainfall is received from July to September.

Methods

The methods followed were an analysis of remotely-sensed data to detect LCLUCs and to estimate economic values for ES in response to LCLUC using a modified ES value coefficient.

Data processing and LCLUC detection

The LCLU datasets were derived from multi-spectral Landsat imageries (Landsat-5 Thematic Mapper (TM) 1986, Landsat-7 Enhanced Thematic Mapper Plus (ETM+) 2000, and Landsat-8 Operational Land Imager (OLI) 2018 with 30 m resolution (USGS, 2018). Two Landsat imageries were needed to get complete coverage of the study region. Therefore, a total of six imageries were acquired free of charge from the USGS (United States Geological Survey) Center for Earth Resources Observation and Science (EROS). Detailed characteristics of the remote sensing data (i.e. Landsat imageries) are tabulated in *Table 1*.

Table 1. *Description of remote sensing data used in the study*

Year	Sensors	Path and row	Resolution	Date of acquisition	Source
1986	Landsat-5 Thematic Mapper (TM)	168/054, 168/055	30 m	21 Jan, 1986	USGS, 2018
2000	Landsat-7 Enhanced Thematic Mapper Plus (ETM+)	168/054, 168/055	30 m	29 Feb, 2000	USGS, 2018
2018	Landsat-8 Operational Land Imager (OLI)	168/054, 168/055	30 m	13 Jan, 2018	USGS, 2018

Each of the acquired imageries was clear and nearly free of clouds. Imageries were pre-processed in ERDAS Imagine 2015 software (Hexagon Geospatial, Alabama, USA) for geometric corrections, geo-referencing, mosaicking and sub-setting of the images (Lin et al., 2018; Gashaw et al., 2017; Mosammam et al., 2017; Gebrehiwot et al., 2014; Schulz et al., 2010; Teferi et al., 2010). All of Landsat imageries were geo-rectified to UTM/WGS84, zone 37 N coordinates using 1:250,000 topographic maps and 20 GPS (global positioning system) points gathered during field observation using Garmin eTrex handheld instrument. Each of the pre-processed imageries was classified using a hybrid classification method that integrates both the supervised and unsupervised classification techniques (Gashaw et al., 2017; Gebrehiwot et al., 2014; Teferi et al., 2010). The unsupervised techniques utilizing Iterative Self-Organizing Data Analysis (ISODATA) grouping (Boakye et al., 2008) were employed as a starting point for collecting GPS points as ground truth points. Using signature editors (spectral signatures) of the unsupervised categories, a pixel-based supervised classification technique with the Maximum Likelihood algorithm (MLC) (Gebrehiwot et al., 2014) was conducted using GPS points collected. The GPS points (i.e., 80 from each LCLU class) were gathered for classifying LCLU classes of the year 2018. A brief description of the identified LCLU classes in the RVLR of Ethiopia is given in *Table 2*. Reference data from topographic maps (scale: 1:50,000 and 1:250,000) obtained from the Ethiopia Mapping Agency, Google Earth, raw images, focus group discussions, and researchers' experience of the area were also used for the classification of the 1986 and 2000

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71477173

images. Moreover, geo-linking Google Earth with ERDAS Imagine 2015 software was employed for classification. ERDAS Imagine 2015 software was employed for classification purposes.

Table 2. *A brief description of LCLU classes identified in the RVLR of Ethiopia*

LCLU classes	Brief descriptions
Cropland	Land used for rain-fed and irrigated cropping (small plot to large scale)
Bare land	Non-vegetated areas dominated by rock outcrops, eroded and degraded land
Forest land	Land dominated by plantation and natural forest
Grassland	Grass & herb cover with scattered trees and shrubs
Marsh	Includes: river beds, intermittent ponds and marshy areas with shallow water and permanent reed vegetation
Urban/built-up	Land mainly towns dominated by permanent residential areas of varied patterns and scale occupied by backyards, compounds, individual houses, and industries
Water body	open water, lakes (Abiyata, Shalla, Ziway, Langano, and Koka), ponds, rivers and streams
Woodland	Woody acacia dominated areas, and trees outside forest

Lastly, to confirm the quality and usability of each of the classified imageries, classification accuracy was computed from the error matrix. The error matrix compares the information obtained by sample LCLU sites with that provided by the classified image. It is also used to calculate the user's, producer's and overall accuracies (Congalton, 1991). About 85 random points were generated for each LCLU class using a stratified random sampling approach for better accuracy assessment (Congalton, 1991). The reference sample points for the 1986 and 2000 images were collected from the respective historical Google Earth images (i.e., January 1986 and February 2000). A similar technique was conducted by Gashaw et al. (2017).

Accuracy classification assessments were performed for classified imageries of 1986, 2000 and 2018. Accordingly, the results of imagery classification showed that the overall accuracies were higher than 80%, and the Kappa coefficients were found to be higher than 0.77 (*Table 3*). This clarified that the results of image classification were satisfactory for further analysis.

Table 3. *Accuracy assessment of the1986, 2000, and 2018 classified images*

LCLU class	Classification accuracy					
	1986		2000		2018	
	Producer's	User's	Producer's	User's	Producer's	User's
Cropland	81.48	81.48	81.82	90	77.27	85
Bare Land	84.62	88	85.42	80.39	85.42	80.39
Urban/built-up	87.1	72.97	86.96	80	89.19	89.19
Forest land	76.92	80	73.68	82.35	72.22	81.25
Grassland	67.86	86.36	86.67	96.3	86.36	95
Marsh areas	85.71	73.68	80.43	75.51	80.43	74
Water body	80	96	83.33	89.29	79.31	88.46
Woodland	85.29	85.29	84	95.45	80.77	95.45
Overall accuracy (%)	80.05		81.82		80.37	
Kappa statistics	0.77		0.77		0.74	

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71477173

Finally, the classified images were exported to ArcGIS 10.2 software (Esri, California, USA) for further spatial analysis and ES value spatial distribution mapping. The percentage of dynamics of LCLUC were computed using the following equation:

$$\Delta L = \frac{A_2 - A_1}{A_1} \times 100 \quad \text{(Eq.1)}$$

where ΔL is the LCLUC proportion, and A_2 and A_1 are final and initial area cover of the LCLU classes.

Estimation of ES values

Many scholars have used a range of methods to estimate ES value since 1970 (Zhang et al., 2015). Costanza et al. (1997) categorised the global biosphere into sixteen types of ecosystem and seventeen types of service functions and estimated their ES value. Although Costanza's method is criticised for its uncertainties (Braat and de Groot, 2012; Kreuter et al., 2001), it served as the basis for further progress in the development and use of monetary valuation studies (Braat and de Groot, 2012). Referring to Costanza's parameter, Xie et al. (2003) provided the equivalent weighting factors of ES per hectare of terrestrial ecosystems and used these factors to adjust the value coefficient for the ecosystems of China. Although Xie et al.'s (2003) approach to quantifying ES value is also criticised for its uncertainties, it is still broadly applied for its feasibility, particularly in data-scarce areas (Lin et al., 2018). The ES value coefficient was also modified by Van der Ploeg and De Groot (2010) for 11 biomes based on Costanza et al.'s (1997) estimates, which are very general and could not represent the regional context.

Moreover, an additional estimation of global ecosystems was undertaken by de Groot et al. (2012) and Costanza et al. (2014). Their estimates were also criticised for overemphasising some ES (Tolessa et al., 2017a). Hence, referring to the existing dataset of TEEB, compiled by the international Ecosystem Service Partnership (ESP-www.es-partnership.org), as well as the ES value coefficients of Costanza et al. (1997), and dataset from peer-reviewed included in (de Groot et al., 2012), other related research and expert knowledge of the study landscape conditions, Kindu et al. (2016) has modified the ES value coefficients for nine biomes for the Ethiopian case. A summary of LCLU categories and corresponding ES coefficients is provided in *Table 4*. We associated the eight LCLU classes in the RVLR of Ethiopia (*Table 5*) with the biomes identified by Kindu et al. (2016), and the closest equivalent biome was used as a proxy. Cropland was used as a substitute for cropland, grass/rangelands for grasslands, tropical forest for forest land and woodland, lakes/rivers for a water body and marsh areas, desert for bare land, and urban for urban/built-up.

In this study, we rely upon a more conservative ES coefficient using the benefit transfer approach, which provides a means to estimate values (both the market and the non-market components) of various ES by transferring information of the existing valuation research from a similar location (Costanza et al., 1997; Kubiszewski et al., 2017). It is the approach most often used to estimate the economic value of ES when time, funding, information accessibility or other difficulties prevent the usage of primary studies (Kreuter et al., 2001; Rolfe et al., 2015; Temesgen et al., 2018; Wilson and Hoehn, 2006). This approach has been used in numerous studies for instance, (Costanza et al., 1997; Kramer et al., 1997; Kubiszewski et al., 2013; Liu et al., 2010;

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71477173

Temesgen et al., 2018; Torras, 2000) to quantify the worth of ES. Although, there are some weaknesses to this approach such as the context sensitivity of value estimates the accuracy will noticeably improve as the extent, richness, and detail of the information increases (Troy and Wilson, 2006; Wilson and Hoehn, 2006).

Table 4. *Details of modified annual value coefficient for ESs of individual LCLU classes (Kindu et al., 2016)*

ESs	LCLU classes /biome (USD ha $^{-1}$ yr $^{-1}$)

Table 5. *Summary of LCLU categories and corresponding ES coefficients based on modified estimates (Kindu et al., 2016)*

LCLU Type	Equivalent biome	Modified value coefficient (USD ha $^{-1}$ yr $^{-1}$)
Cropland	Cropland	225.56
Bare land	Desert	0
Forest land	Tropical Forest	986.69
Grassland	Grass/rangelands	293.25
Marsh areas	Lakes/rivers	8103.5
Urban/built-up	Urban	0
Water body	Lakes/rivers	8103.5
Woodland	Tropical Forest	986.69

The ES value of each LCLU category, their corresponding service function and the total ES values for 1986, 2000 and 2018 were calculated using *Equations 2, 4,* and *3,* respectively, as considered by (Temesgen et al., 2018; Hu et al., 2008; Li et al., 2007). The modified annual value coefficients that were used for this study are presented in *Tables 4* and *5*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71477173

$$ES\ Value_K = A_K \times VC_k \quad \text{(Eq.2)}$$

$$ES\ Value = \sum(A_K \times VC_k) \quad \text{(Eq.3)}$$

$$ES\ Value_f = \sum(A_K \times VC_{kf}) \quad \text{(Eq.4)}$$

where ES $value_k$ ES value and ES $value_f$ denotes the ES value of the LCLU category "k", the total ES value, and the value of ES function category "f", respectively. A_k is the area (ha) for LCLU category k; VC_{kf} is the value coefficient (USD ha $^{-1}$ yr $^{-1}$) for LCLU category k; and VC_{kf} is the value coefficient (USD ha $^{-1}$yr $^{-1}$) for LCLU category k with ES function category "f".

Estimation of the average ES values of the study area was undertaken using *Equation 5,* following the method employed in (Gashaw et al., 2018). The average ES value was calculated by dividing the total ES value by the area of the study region:

$$ES\ Value_{av} - \frac{ES\ Value_t}{Area_t} \quad \text{(Eq.5)}$$

where ES $value_{av}$ is the average ES value of the study region (USD ha^{-1} yr^{-1}) during the specific year, ES $value_t$ is the total ES value in that particular year, and Area is the area coverage of the study region.

Statistical analysis

To analyse the relationship between LCLUC, dynamics in ES value, and socioeconomic shift (i.e., GDP, population), one-way analysis of variance (ANOVA) was conducted. Moreover, to quantitatively scrutinise the relationship between LCLUC, and hence provide more information for this work, the analyses were carried out using IBM SPSS Statistics Version 20. By carefully examining whether the detected changes were significant or not, and the interaction effects of the variables, it was decided that nonlinear regression models were suitable and thus were adopted.

Results

Land cover/land use change (1986–2018)

The area coverage of LCLU classes (*Table 6; Fig. 3*) extracted as a result of the classification indicated that grassland, cropland, woodland, water bodies, forest land, bare land, urban/built-up and marsh areas were the dominant LCLU classes in the study period. The dominant LCLU classes that declined progressively over the study period were woodland, water bodies, grassland, forest land, and marsh areas. However, the highest decline was observed for woodland, which declined from 20.96% of the total area in 1986 to 16.75% in 2000 (i.e., declined by 20.09%), and then declined to 11.52% in 2018 (i.e., declined by 31.24%). The overall decrement of woodland was 45.05% between 1986 and 2018. Forest land decreased from 3.65% in 1986 to 2.52% in 2018. Marsh areas also decreased from 2.28% in 1986 to 1.80% in 2018. Grassland decreased from 26.77% in 1986 to 25.46% in 2018. Water bodies decreased from 17.21% in 1986 to 15.72% in 2018. During the last three decades (1986–2018), woodland, water bodies, forest land, marsh areas, and grassland all decreased, while cropland increased

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71477173

continually and remarkably from 25.89% of the total land in 1986 to 37.21% in 2018. The aggregate area of bare land and urban/built-up, which constituted the smallest proportion of the study area (3.25%) in 1986 speed up its expansion to 3.65% in 2000 and further to 5.78% in 2018. On the other hand, a higher percent increment was indicated for urban/built-up by 34.79% from 1986 to 2000 and by 191.68%, from 2000 to 2018. The overall increment for urban/built-up was 293.14%. The higher increment for urban/built-up does not mean a more extensive area covered by urban/built; instead, it refers to the proportional increment observed during the study period. Moreover, cropland and bare land increased by 43.72% and 50.10% from 1986 to 2018, respectively.

Table 6. *LCLU classes with their areas and changes (1986–2018)*

LCLU Classes	LCLU area coverage						LCLUC between periods (ΔL)		
	1986		2000		2018		1986–2000	2000–2018	1986–2018

ES value dynamics (1986–2018)

The value of ES for each LCLU class and the total ES value for 1986, 2000 and 2018 were estimated with the modified ES value coefficients (*Table 5*) and the area covered by each LCLU class in the RVLR of Ethiopia (*Table 6*). The finding indicated that the total ES value of the region was USD 1586.37×10^6 in 1986, USD 1513.3×10^6 in 2000 and USD 1390.32×10^6 in 2018 (*Tables 7* and *8*). The total ES value showed a reduction of about USD 196.04×10^6 from 1986 to 2018 (*Tables 7* and *8; Fig. 2* and *3*), mainly due to the decreased areas of water bodies, woodland, marsh areas, and forest land. Even though the ES value of cropland increased, such increments were so small as to counterbalance the decreases in ES value of water bodies, woodland, marsh areas, and forest land.

Due to the highest value coefficient of water bodies (*Table 4*), they produce the highest ES value compared to the rest of the LCLU categories. Next to water bodies, woodland also produces a high ES value during 1986 because of its large area, which covered 20.96% of the studied region (*Tables 6* and *7*). The value coefficient of the marsh areas was also similar to that of the water body, and it produces the second highest ES value in 2000 and 2018 followed by woodland. The sub-total ES value of water body, woodland and marsh covered more than 89.32% of the total value (*Tables 7* and *8*). Even though the value coefficient of the forest land was similar to that of woodland, because forest land covered a small area in the study region, it contributed to low ES value. The ES value for cropland and grassland is also low owing to the low ES

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71477173

value coefficient (*Table 7*). Thus, the water body, woodland, and marsh LCLU categories were significant contributors to the ES value in the RVLR of Ethiopia in the last three decades (*Fig. 3*).

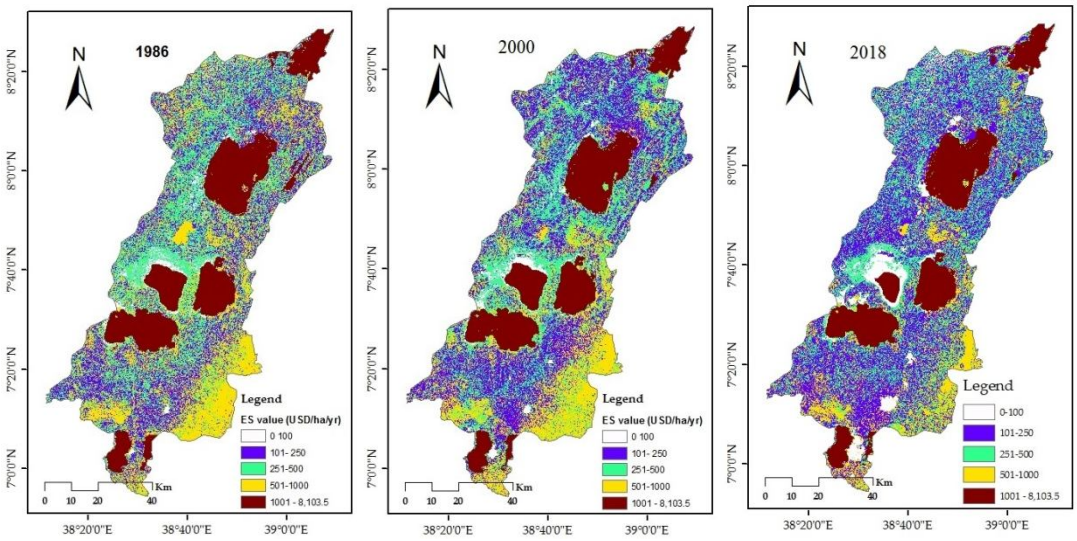

Figure 2. *Spatial distribution of ES value in the RVLR of Ethiopia in 1986, 2000 and 2018 using modified estimates adopted from (Kindu et al., 2016)*

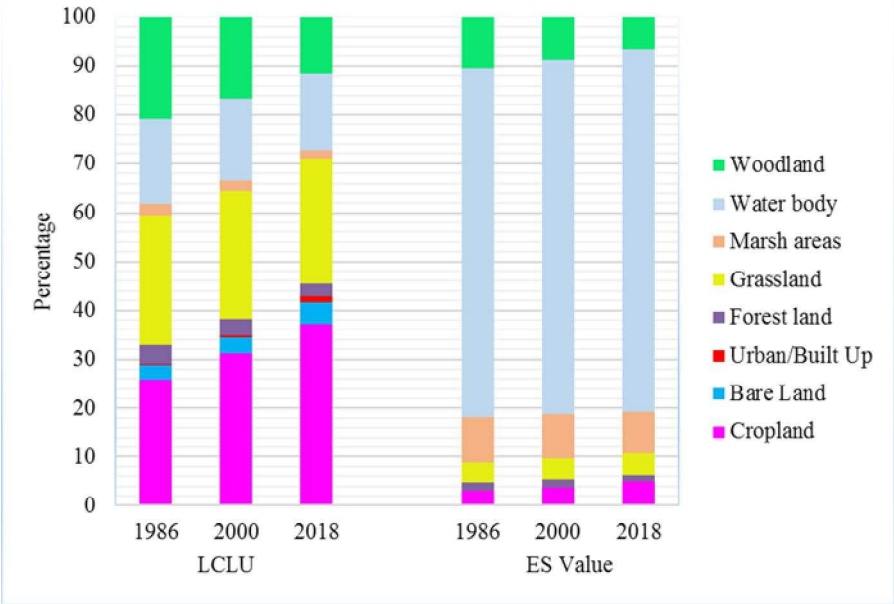

Figure 3. *Proportions of LCLU (%) and ES value (%) for 1986, 2000 and 2018 in the RVLR of Ethiopia*

Table 8 estimates an annual value of 17 ES. Concerning their contribution to the overall ES value, individual ES value functions were ranked from 1 to 17 (*Table* 8). The top six individual ES value functions were predominantly from the ES category of regulating (water regulation, water treatment, erosion control, climate regulation),

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71477173

provisioning (water supply and food production) for the study period (*Table 8*). Their combined contribution represented about USD 1488.11×10^6, 1426.50×10^6, and 1319.12×10^6 in 1986, 2000 and 2018, respectively. The combined contribution of other ES functions of each ES category, i.e. supporting (nutrient cycling, pollination, habitat/refugia and soil formation), regulating (biological control, gas regulation and disturbance regulation), provisioning (genetic resources), and cultural services (recreation and cultural), were about USD98.25×10^6 (6.19%), USD 86.8×10^6 (5.74%), USD 71.21×10^6 (5.12%) in 1986, 2000 and 2018, respectively. This order of contribution by ES categories remained unchanged over the three study periods.

Table 7. *Total ES values estimated for each LCLU categories and changes from 1986 to 2018 in the study area*

LCLU Classes	ES value (USD million)					
	1986	**2000**	**2018**	**1986–2000**	**2000–2018**	**1986–2018**
Cropland	47.29	57.03	67.97	9.74	10.94	20.67
Bare Land	0.00	0.00	0.00	0.00	0.00	0.00
Urban/built-up	0.00	0.00	0.00	0.00	0.00	0.00
Forest land	29.16	26.15	20.10	-3.00	−6.05	−9.06
Grassland	63.56	62.47	60.46	-1.09	−2.01	−3.10
Marsh areas	149.88	138.20	118.13	-11.67	−20.08	−31.75
Water body	1129.04	1095.64	1031.66	-33.40	−63.98	−97.38
Woodland	167.45	133.81	92.02	-33.63	−41.80	−75.43

In general, the total regulatory services contributed to more than two-thirds (about 67%) of ES value, followed by provisioning (approximately 27%), supporting (approximately 2.48%), and cultural services (approximately 0.78%) (*Table 8*). During the period 1986–2000, the ES values of supporting services declined more rapidly than any other ES (−14.62%), followed by cultural (−5.23%) and regulating services (−5.10%).

The contribution of water regulation service to overall ES value was higher than 54% (the highest value), and cultural service was about 0.02% (the lowest value) (*Table 8*). The aggregate contributions of water regulation, water supply, water treatment, and food production, were more than 87% of the total ES value. During those three decades, the contribution of water regulation, water supply, and water treatment decreased, while the contribution of food production increased.

The change rate of each ecosystem functions was computed and the loss in ES value was observed in service functions of water regulation (USD 87.31×10^6), water supply (USD 34.42×10^6), erosion control (USD 21.29×10^6), water treatment (USD 19.44×10^6), climate regulation (USD19.10×10^6), nutrient cycling (USD15.79×10^6), raw materials (USD 4.39×10^6), and genetic resources (USD 3.51×10^6), while the gains observed in ES values were in food production (USD 12.59×10^6), biological control (USD 1.96×10^6) and pollination (USD0.4×10^6). The aggregate contribution of food production, biological control, and pollination was less than 9%. The finding also indicated that dramatic expansion of cropland in the study landscape results in a consistent increment in the food production service function, though the increment was not drastic.

Variations of ES value in response to LCLUC and socioeconomic drivers

Figure 4 indicates a negative non-linear relationship ES value per capita and GDP per capita. Regional GDP per capita in constant year-1986 prices increased by 69.5%, from USD 233.82 in 1986 to USD 767.56 in 2018. At the same time, Regional ES value per capita reduced by 76.97%, from USD 2706.86 in 1986 to USD 623.45 in 2018. Moreover, *Figure 5* indicates a polynomial decline in the ratio of total ES value to total GDP from 1986 to 2018.

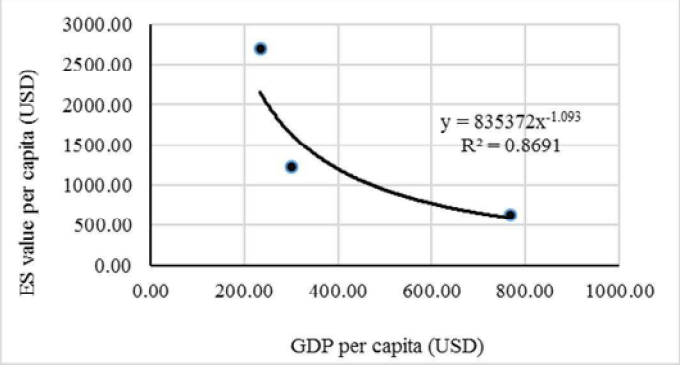

Figure 4. *The relationship between ES value per capita and GDP per capita from 1986 to 2018*

Discussion

Dynamics of LCLU and ES value change

In general, the area coverage of woodland, forest land, grassland, marsh areas, and water bodies consistently declined in varying proportions in the study period. The declines in these LCLU classes were mainly because of the conversion of the areas to cropland. The finding indicated that LCLUC is consistent with the results of previous research conducted in Ethiopia. For instance, the decline in woodland and the increase in cropland were also observed in Ziway-shalla basin (Bekele et al., 2018), Arsi-Negele district (Molla, 2015; Garedew et al., 2009), Munessa–Shashemene landscapes (Kindu et al., 2013), Central Rift Valley (Meshesha et al., 2012) in 1973–2010, 1973–2006, 1973–2006 and 1973–2012, respectively. Moreover, Kindu et al. (2013) and Meshesha et al. (2012) also reported a decrease in water bodies and forest land.

The loss of ES value in the RVLR of Ethiopia is predominantly due to the decreased areas of the water body, woodland, marsh areas, and forest land categories. According to *Table 6* and *Figure 3*, there was a significant rise in the area of cropland over the other LCLU categories from 209,659.05 ha in 1986 to 301,319.55 ha in 2018. Remarkably, this increment exceeds the extent of land that changed from cropland to other LCLU types. The increment in the area of cropland increased the value of ES over the study period, but such increments were so small as to counterbalance the decreases in the total ES value in water bodies, woodland and forest land.

The trend of changes in ES value conforms with other studies in Ethiopia and elsewhere. For instance, in the Munessa–Shashemene landscapes, Kindu et al. (2016) reported a decline in ES value from 1973 to 2013. Gashaw et al. (2018) estimated a massive loss of ES value of about 21.7% from 1986 to 2015 as a result of the altered forest, shrubland and grassland ecosystems in Andessa watershed, Ethiopia. Tolessa et al. (2017a) point out a cumulative decline of ES value of 40.7% from 1973 to 2015 in Chilimo Forest, Ethiopia, which was attributed to a reduction in forest cover. Another study by Tolessa et al. (2017b) also revealed an overall loss of 68% of ES value from 1973 to 2014 in Toke Kutaye district, Ethiopia, was mainly as a result of the loss of forest cover. A study mapping and quantifying ES in West Africa also reported an overall decline in ES value during 2000–2009 (Leh et al., 2013). Similarly, in Pingbian

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71477173

County, China (Li et al., 2007) revealed a 19.4% decline of ES value during 1973–2004. San Antonio, Texas, (Kreuter et al., 2001) also reported a general decline of ES value of about USD 6×10^6 during 1976–1991. All these findings are in line with our finding that the dynamics of LCLU have resulted in a significant decline of ES value. On the other hand, an increase in ES values has been reported by studies in Ethiopia and elsewhere. For example, there were increases in the value of ES in Gedeo-Abay, Ethiopia (Temesgen et al., 2018), Ningxia, China (Wang et al., 2014), and Chengdu, China (Li et al., 2018) of 14.2% during 1986–2015, 22.7% during 2000–2010, and 75.46% during 2000–2015, respectively.

Specifically, the results of the study showed that the predominant types of LCLU by which the ES value in RVLR were water body, marsh areas, and woodland, which contributed over 89% of the total values. For water bodies, the ES value accounted for 74.2% of the total value in 2018, which related to the high ES value coefficient in water bodies. According to Zhou et al. (2017), water bodies and wetlands were significant contributors to ES value, which covers more than 60% of the total, in Denqing, China during 1995–2015. The ES value of water bodies in the study region was high during the study period; however, its ES value was declining due to the degradation of the water environment, especially weak protection and rehabilitation of Feeder rivers, and water conservation in the study region. Bekele et al. (2018) noted the occurrence of severe lake water degradation in the region such as accelerated retreat of Lake Ziway and Lake Abiyata, drying /reduction of Rivers and Stream volumes (e.g., Bulbula River), huge water abstraction for irrigation (Raventós Vilalta, 2010; Legesse and Ayenew, 2006), and water pollution from the chemical intensified farming. The most apparent effect of water abstraction for trona or soda ash production during the last three decades, has been decline in the water level at Lake Abiyata (Legesse and Ayenew, 2006) and reduced about 50% of the area between 1973 and 2006 (Hengsdijk et al., 2009), which could forms as terminal lake of the closed Central Rift valley basin (Getnet et al., 2014).

The projected dynamics by Jansen et al. (2007) and Raventós Vilalta (2010) indicated that Lake Abiyata and Lake Ziway would continue to lose more than 10% of their area coverage until 2034. Studies also projected that Lake Abiyata would dry up within the coming five decades (Seyoum et al., 2015; Temesgen et al., 2013; Jansen et al., 2007). In line with this, unless rehabilitation and restoration actions are taken, the adjacent Lake Ziway also faces a similar fate of drying shortly (Bekele et al., 2018; Jansen et al., 2007) since it is an open lake connected to Lake Abiyata through Bulbula River. The lowering in the discharge of the Feeder River and the declining of the water level of Ziway Lake are owing to the development of recently irrigated land (Scholten, 2007). According to Jansen et al. (2007), Lake Ziway has declined by about 0.5 m since 2002 that is equivalent to a loss of approximately 200×10^6 cubic meters of water. Similarly, Lake Cheleka whose area coverage was 11.3 km^2 in 1973, was gone entirely in the year 2011, changed into swamp and mud flats, while Lake Hawasa showed an increment from 91.9 km^2 in 1973 to 95.2 km^2 in 2011, which is a rise of about 3.3 km^2 between 1973 and 2011 (Wondrade et al., 2014). However, early research works showed a relatively broad area cover estimates inclusive of Lake Cheleka. For example, 150 km^2 (Zanon, 1942 cited in Ayenew and Gebreegziabher, 2006). Moreover, a study by Bewketu (2010) revealed a decline in Lake Langano's water level. This, in turn, constitutes a significant threat to biodiversity loss, especially fish and bird species besides a significant loss to ES value at large.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71477173

Therefore, protecting those LCLU classes that have high ES values is crucial for formulating a sustainable land use/cover policy, since this high ES value will help to maintain a sense of balance between ecosystem health and economic development in the future (Sawut et al., 2013). Similarly, Tianhong et al. (2010) suggested that land use planning should focus on LCLU classes with the highest ES value including water bodies, wetlands, and woodland.

The decline in the average ES value of the study region over the study period is because of the decline in water bodies, woodland, marsh areas and forest land and the expansion of cropland and urban/built-up areas. The calculated average ES value of the RVLR is higher than in other studies such as in Kashgar Region, (Mamat et al., 2018), Andassa watershed (Gashaw et al., 2018), Gedeo–Abaya landscape (Temesgen et al., 2018), Munessa–Shashemene landscape (Kindu et al., 2016), Chillimo Forest (Tolessa et al., 2017a), Toke Kutaye district (Tolessa et al., 2017b), and Menglun (Hu et al., 2008) (*Table 9*). The high average ES value of the RVLR could be attributed to the size of the water body, which cover more than 15% of the study region during the study period and high ES value coefficient for the water body. However, studies such as Wang et al. (2015) conducted in Nenjiang River Basin, Heilongjiang Province, Northeast China have shown higher average ES value as compared with our findings. If our study had employed the coefficient developed by Costanza et al. (1997) for a similar LCLU/biome (i.e. 8498 for water bodies, 2008 for woodland, 14,785 for marsh areas, 244 for grassland, 2008 for forest land and 92 for cropland) the overall ES value of the RVLR would have been USD1929.73 in 1986, USD1801.91 in 2000, and USD1603.59 in 2018. Subsequently, the average ES value of the study region would have slightly increased to USD2383 in 1986, USD2225 in 2000, and USD1980 in 2018. Moreover, considering the coefficients developed by Temesgen et al. (2018) for similar biomes (i.e. 3226.8 for water bodies, 897 for woodland, 2856.1 for marsh areas, 355.5 for grassland, 1093.2 for forest land and 169.2 for cropland) the overall ES value of the RVLR would have been USD 799.46 in 1986, USD754.12 in 2000, and USD682.64 in 2018. Subsequently, the average ES value of the study region would have dropped to USD987.2 in 1986, USD931.2 in 2000, and USD843.0 in 2018.

The reduction of most ES value functions during the study period is highly related to the decline in water bodies, marsh areas, woodland, and grassland. In line with this finding, a decline in the aquatic regions, grassland, and woodland between 2003 and 2013 period in Manas River Basin, China has caused a drop in the value of gas regulation, climate regulation and various types of ES value functions (Wang et al., 2017).

In this research, the consistent increase in food production, biological control, and pollination services over the study period is undoubtedly attributed to the expansion of cropland. The cropland category gained areas, which is negatively affecting the overall ES value for the study region. In the future, cropland area and the associated ES value will likely increase because of the increased need for food production to meet the growing population (WorldBank, 2019). These dynamics hurt the ES offered by other LCLU categories such as water bodies, woodland, marsh areas, grassland, and forest land. For example, the conversion of woodland and forest land to cropland is a negative factor affecting the provision of several ES, such as erosion control, which is a severe problem in the study region. It is evident that LCLU dynamics in Ethiopia has resulted in severe soil erosion and land deterioration, which in turn threaten food security and cause economic and social problems across the country (Zeleke and Hurni, 2001). On

DOI: http://dx.doi.org/10.15666/aeer/1703_71477173

the other hand, loss of vegetation cover and deforestation induce erosion, and the deposition of nutrients and sediment accounts for the eutrophication in Lake Abiyata, which is already killing fish and other aquatic organisms inhabiting (Ayenew, 2007).

Woodland and forest land provide services such as raw materials, food production, gas regulation, water regulation, water treatment, and recreation. However, this study confirmed the massive conversion of these LCLU categories to cropland during the study period. According to Arndt et al. (2011), the most common farming system in Ethiopia is small-scale subsistence rain-fed farming, which accounts for 90% of the country's agricultural output. Farming in the country was characterised with a low level of productivity due to a lack of production technologies, weak extension services, low use of improved seed, and minimal application of pesticides and fertilisers (Deressa, 2007). Consequently, to increase agricultural production, small farms expand their growing area by converting other LCLU categories to cropland. Similar to this finding,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71477173

the increment in the intensity of cultivated land was attributed to the decline in the woodland and forest land categories between 1973 and 2006 in the Central Rift Valley, Ethiopia (Meshesha et al., 2012). A study by Kibret et al. (2016) also revealed that agricultural land is expanding to the maximum suitable size, even to the peripheral land, thus endangering biodiversity. Also, the conversion of marsh areas to cropland is a negative factor regarding the provision of several ES, such as water regulation, water supply, water treatment, and recreation services, which is a prevalent problem in the RVLR. Therefore, changing the widely employed traditional farming system through the improved farming technologies would play an important role in intensifying the productivity of the cropland thereby increasing agricultural production rather than converting other LCLUC classes to cropland.

Limitation of the study

The method of employing LCLUC in estimating ES value for the period 1986–2018 includes various sources of limitation. The primary constraint of this research is related to the accuracy of the LCLU classification. The LCLU classification of 1986, 2000, and 2018 was attained with an overall accuracy of 80.05%, 81.82% and 80.37%, and kappa coefficient of 0.77, 0.76, and 0.74 (*Table 3*), respectively. Although the classification result meets the standard requirement (kappa coefficient higher than 0.70) (Monserud, 1990), there are still some limitations that are associated with the classification. There are also limitations from the adopted benefit transfer approach, such as considering all biomes/LCLU classes as a similar unit and using the same ES value coefficient derived from another site as an average unit value. This approach presumes the sameness of ESs values within the whole biomes/LCLU classes (Arowolo et al., 2018). Although there are drawbacks, this approach is often the only or the best option available for policy analysts and resource managers when time, information accessibility, or other difficulties prevent the usage of primary studies. Furthermore, funding limitations for gathering the primary data in developing countries such as Ethiopia often make benefit transfer is the sole feasible option.

Moreover, numerous studies used the coefficient of sensitivity approach to check the reliability of the ES value estimations, and mostly the value coefficients of ES value were corrected by ±50%, (e.g. Hu et al., 2008; Temesgen et al., 2018; Tolessa et al., 2017a; Yirsaw et al., 2017). Nevertheless, employing this approach to test the reliability of evaluation results is disapproved of since the value of the coefficient of sensitivity is often less than 1 even when the values of the coefficients of sensitivity were corrected by ±25%, which implies incorrectly robust coefficients (Aschonitis et al., 2016). Thus, this study did not conduct a coefficient of sensitivity analysis to check the validity of the estimation with another approach. Hence, another reliable approach that accounts the uncertainty needs to be considered. However, this study will contribute to the development of scientific literature on a similar topic to scrutinise how ES value is altering in response to the existing LCLUC.

Research of this kind is limited in many regions of Africa, which has resulted in a lack of information for decision making procedure about resource conservation and sustainable utilisation. It could also be used in data-short areas of developing regions with a similar landscape. Therefore, the findings of this study will offer regional-scale information to be added to global values for decision-making procedures. Besides the local level estimation, this study also emphasises the importance of regional-level and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71477173

country-level ES value estimation based on expert knowledge of the region for better estimation of the LCLU/biome.

Conclusions

This study provides estimations of the ES value alteration in response to the dynamics of LCLU in the Rift Valley Lakes region of Ethiopia. The dynamics of LCLU over the past 33 years have resulted in a decline in the specific and overall ES value. Our estimation of the ES value alteration in response to LCLUC has indicated an overall reduction of approximately USD 5.77×10^6 per year, or a total loss of about 12.4% over the last 33 years. These changes are mostly associated with the decreased areas of the water body, woodland, marsh areas, forest land, and grassland categories. However, cropland has experienced a dramatic expansion by 43.72% during the study period. The estimation of lost ES value is about 9.5 times larger than the whole value of cropland in the study area. Water bodies, woodland and marsh areas were the three major contributors to the ES value in the RVLR of Ethiopia, contributing more than 89.32% of the overall ES value in 2018, indicating that these LCLU classes play an essential role in the ES of the study area.

LCLUC in the RVLR of Ethiopia affects the supply of ES, including water regulation, water supply, water treatment, and food production, erosion control, climate regulation, nutrient cycling, recreation, raw material, genetic resources, gas regulation, habitat/refugia, soil formation, disturbance regulation, and cultural service function. However, as a result of the dramatic expansion of cropland, the worth of food production, biological control, and pollination service function has invariably increased, though not drastically, over the study period. Except for these three ES functions, all other values have been decreasing continuously over the last three decades, indicating the deterioration of the fragile Rift Valley ecosystem.

In this research, the loss of ES value in RVLR was attributed to the dynamics of LCLU, which can impede the ability of the ecosystem to offer sustainable ES, possibly causing a long-term deterioration of the natural environment quality. In other words, these changes signify severe environmental repercussions for the fragile RVLR ecosystem. To enhance the continuous supply of ES, management should focus on LCLU classes with the highest ES values. Moreover, a nation-wide food security strategy of boosting crop production should work towards sustainable agricultural intensification rather than expanding cropland at the expense of the other LCLU classes. Hence, to improve the continuous supply of ES and economic development, an integrated approach to managing land and water resources needs to be considered. Furthermore, designing and operating a payment scheme for ES at the regional and local is also a potential remedy for ES loss. Moreover, quantitative assessment of ES value at local and regional scales should be considered as a conservation strategy to encourage resource conservation and utilisation.

Abstract. 'Yield maximization' is the last word of modern agriculture for food security of ever-increasing population of the world. Maximizing world's agricultural efficiency depends largely on controlling pests and diseases. Although, demand for insecticides and fungicides by successful breeding for resistant cultivars has reduced, use of herbicides is still increasing globally. Application of heavy doses of herbicides is directly/indirectly causing negative impact on quality of produce, human health and environment. Allelopathic weeds and their allelochemicals have wide application prospects in increasing crop production, plant protection and biological control. This study was aimed at evaluating allelopathic activity of methanol extracts of *Rhazya stricta* (Harmal), *Pinus roxburghii* (Chir-Pine), *Carica papaya* (Papaw) and *Lantana camara* (Wild-sage) against selected weeds viz. *Phalaris minor* (Canary grass), *Avena fatua* (Wild oat), *Chenopodium album* (Goosefoot), *Euphorbia helioscopia* (Sun-spurge) and *Rumex dentatus* (Knotweed) on filter paper, soil and agar at 100%, 75%, 50% and 0% concentration. Germination percentage (%), radicle length (cm) and plumule length (cm) were parameters to assess allelopathic potential. The STATISTIX 9 software was used to analyse data. Based on results, it was concluded that methanolic extract of *R. stricta, P. roxburghii, C. papaya* and *L. camara* possess potential inhibitory effects amongst which *L. camara* showed most prominent inhibitory effects towards selected weeds. The germination and growth inhibition effects were found in order *L. camara*>*P. roxburghii*>*C. papaya*>*R. stricta*. Detailed field study is recommended to establish allelopathic potential of these species to be utilized as phytoherbicide.

Keywords: *third generation herbicides, ecofriendly weed management, bioassay screening, polar phytochemicals, seedling growth inhibition*

Introduction

Agriculture is the backbone of Pakistan's economy. This sector gave 20.9% of the Gross Domestic Product (GDP) for the fiscal year 2014-15. Moreover, agriculture is a source of income for 43.5% of the village population of the country. Food security depends upon a sustainable agricultural production and higher levels of yield. It may also enable the agricultural sector less vulnerable to the threat of climate change (Shah et al., 2016).

Wheat (*Triticum aestivum* L.), is one of the most important cereal crops of the world. Its role is quite important in the provision of human nutrition. It has been shown that wheat farmers are offering very little time and attention to the weed management practices, consequently, 15 to 25% wheat grain losses occur. Weeds are causing annual damage of about 10% in agricultural yields globally (Cavero et al., 2011). In Pakistan, weeds cause 45% loss in wheat production (Anwar et al., 2016).

In Pakistan, however, annual economic loss, due to weeds in agricultural production is estimated around 18.2 billion dollars. Including, 3-6 billion dollars spent on weeds control methods. There are around 30 different weed species generally found in the wheat crop, becoming the sources of losses. As the smaller farmers lack related tact and necessary resources, it becomes quite impossible to remove these weeds from the cultivated field. Weed harms most of the crops and grain. Moreover, it remains as a perennial problem in Pakistan's agriculture sector (Mubarik et al., 2015). Weeds are growing with cultivated crops and compete with crop for light, moisture, other vital elements of nutrition and space. The referred result cause low quality and less production of crops with raised costs of production. According to an estimate, grain produce in Pakistan can be enhanced by up to 41% if weeds are managed properly. The controlling of weeds through traditional methods is time consuming, weather hinged and exhibit more labour cost. While modern weed control techniques have not been up to the mark in solving this problem (Arafat et al., 2015).

Synthetic chemicals are in wider use for controlling weeds. These chemicals may enhance crop production, but concurrently these may have a negative effect on the environment as well as upon human health. In addition to these, the heading up of synthetic herbicides resistant weeds is another major area of concern. Excessive use of herbicides for controlling weeds during the last few years is becoming one of the noteworthy ecological and environmental threats for the world. Herbicide remnants in crops, soil and underground water, which cause an evolution of various resistant weed biotypes and linked health threats, are some of the huge dangers that scientists are facing these days in devising various weed management techniques. Due to the negative effect of using synthetic chemicals, one may highly be in demand the new classes of chemicals, especially, biodegradable products such as those originating from plants, which have the potential of being developed as herbicides (Aryakia et al., 2015). This guides us forward for searching new weed management strategies, which may be cost effective, easy and eco-friendly.

Allelopathy is a natural and eco-friendly technique. This strategy might be one of the very efficient tools for weed management and thereby increasing crop production (Kamran et al., 2017). An Austrian Professor Hans Molisch first used the term allelopathy in 1937. He got it from two Greek roots: allelon (of each other) and pathos (to suffer). It can be translated as the harmful effect of one organism upon any other. In the beginning, allelopathy referred to both killing and favorable interactions between

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71757187

any species. However, lately allelopathy is being used for only harmful plant interactions, rather for the both.

In 1996, the International Allelopathy Society defined allelopathy in the following words "The science that studies any process involving secondary metabolites produced by plants, micro-organisms, viruses, and fungi that influence growth and development of agricultural and biological systems" (Kong et al., 2006). Natural herbicides obtained from allelopathic plants can help in reducing usage of synthetic herbicides for weed control that will cause less pollution as well as alleviate human health concerns. The most commonly available allelochemicals are cinnamic and benzoic acids, alkaloids, flavonoids, phenolics, glucosionates and various terpenes (Khan et al., 2014).

Keeping all this in view, the present study was performed for evaluating *Rhazya stricta* (Harmal), *Lantana camara* (Wild-sage), *Carica papaya* (Papaw) and *Pinus roxburghii* (Chir-Pine), for their allelopathic activity against major weeds viz. *Phalaris minor* (Canary grass), *Avena fatua* (Wild oat), *Chenopodium album* (Goosefoot), *Euphorbia helioscopia* (Sun-spurge) and *Rumex dentatus* (Knotweed) of wheat (*Triticum aestivum*).

Materials and methods

Allelopathic potential of leaves of selected plants viz., *R. stricta, P. roxburgii, C. papaya* and *L. camara* was evaluated. Fresh leaves (~50 g) for each species were collected (73°02' E longitude and 33°36' N latitude) during March-April 2018 (*Fig. 1*). Collected plant material was washed under running tap water and dried at 30 °C in laboratory that was crushed using heavy duty blender to make fine powder (mesh size 2 mm) and preserved in air tight plastic zip lock bags (Ramsumair et al., 2014; Anwar et al., 2016). Seeds of test weeds viz. *Phalaris minor, Avena fatua, Chenopodium album, Euphorbia helioscopia* and *Rumex dentatus* were procured from the Barani Agricultural Research Institute (BARI), Pakistan. Seeds were surface sterilized by 2% solution of Sodium hypochlorite (NaOCl) (Biljana and Kragujevac, 2015).

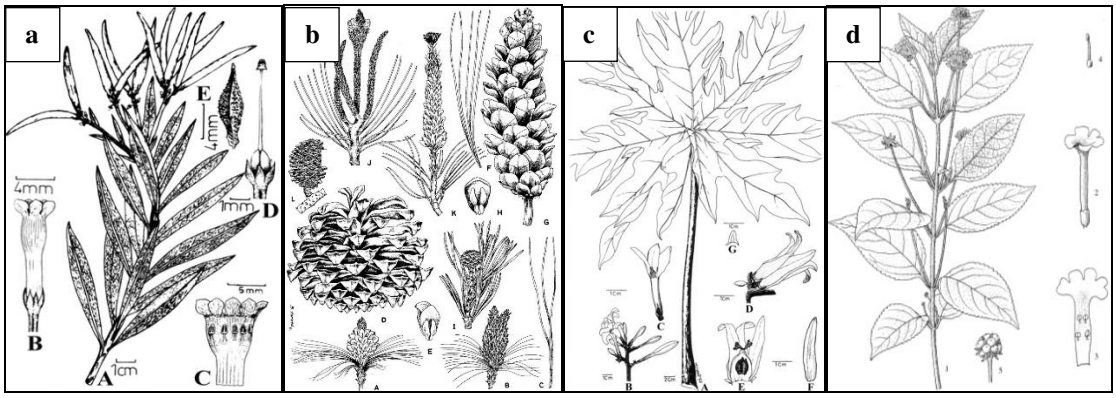

Figure 1. *Illustrations of plants studied for their phytotoxic activity (a) Rhazya stricta, (b) Pinus roxburghii, (c) Carica papaya (d): Lantana camara (Pakistan eflora; http://www.efloras.org/flora)*

Dried leaf powder of each plant species (40 g) was soaked in 400 ml methanol and agitated for 24 h (25 °C) at 160 rpm on orbital shaker. The filtrate was obtained through

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71757187

Whatman filter paper No. 1. The final volume of filtrate was adjusted to 400 ml that gave 10% methanol extract as stock solution. Three concentrations i.e. T1 (100%), T2 (75%), T3 (50%) while T4 (0%) were further prepared.

Bioassays were carried out using soil and filter paper as medium. An aliquot (15 ml) of extract for each of three concentrations was added on 25 g soil per petri dish while 5 ml extract on filter paper per petri dish. Ten seeds of weed test species were used per petri dish. Each treatment was replicated three times. The petri dishes were wrapped with aluminium foil and incubated in growth chamber (NTS Model MI-25S set at 28 °C) for 15 days.

The germination percentage (%), lengths of radicle and plumule (cm) were calculated by comparing with control (Maharjan et al., 2007; Anwar et al., 2017). The statistical analysis was carried out using STATISTIX 9 and means were separated by Fisher‘s protected LSD test (Nekonam et al., 2014).

Results and discussion

Allelopathic potential of R. stricta

The results obtained in indicated that *R. stricta* methanolic extract significantly inhibited germination of *C. album* (42%) followed by *P. minor* (41%) and *R. dentatus* (37%) on filter paper, whereas, no significant effect on germination of *A. fatua* and *E. helioscopia* showing resistance against extract. Similarly, *R. stricta* methanolic extract on soil significantly suppressed seed germination of *C. album* (47%) followed by *P. minor* (43%) and *R. dentatus* (42%). Maximum (95%) germination was observed for *A. fatua* and *E. helioscopia*. It was recognized that minimum germination was noted for *C. album* i.e. 68% and 53% on filter paper and soil, respectively. The results revealed that germination reduction for *C. album, P. minor* and *R. dentatus* was concentration dependent (*Fig. 2a*).

The statistical data revealed that *R. stricta* methanolic extract significantly inhibited radical length of *R. dentatus* (45%) and *A. fatua* (44%) on filter paper, whereas, no significant effect was noted for *P. minor*, *E. helioscopia* and *C. album* showing resistance against extract. Similarly, the applications of extract into soil significantly suppressed radical length of *R. dentatus* (51%) and *A. fatua* (50%) as compared to control. The maximum (96%) radical length was observed for *P. minor, E. helioscopia* and *C. album*. The final data concluded that minimum radical length was noted for *R. dentatus* i.e. 55% and 49% on filter paper and soil, respectively (*Fig. 2b*).

Analysis of the data revealed that *R. stricta* methanolic extract significantly suppressed the plumule length of *A. fatua* (33%) and *R. dentatus* (28%) as compared control on filter paper. Interestingly, there was no significant effect on plumule elongation of *P. minor, E. helioscopia* and *C. album*. Likewise, *R. stricta* methanolic extract significantly inhibited plumule length of *A. fatua* (55%) and *R. dentatus* (34%) in soil. The statistical figures also proposed that maximum plumule length (96%) was noted for *P. minor, E. helioscopia* and *C. album* (*Fig. 2c*).

The plumule, radicle length and germination of cowpea and rice were significantly reduced with increasing concentration of *R. stricta* leaf extract (Jadhar and Gayanar, 1992). Moreover, inhibitory potential of different plants had pointedly checked seedling growth and seed germination of different crops and weed (Lisanework and Michelson, 1993; Khan et al., 2004) and their results exposed that extract of *R. stricta* inhibited plumule length of weed species. Similar results were also explained by Tefera, 2002 and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71757187

Siddiqui et al., 2009. They noticed a suppressive effect on plumule length and seed germination. These findings were in accordance to Kaul and Bansal (2002) who stated that *R. stricta* leaf extract reduced growth of weeds species. Likewise, Maciel et al. (2003) also observed the same findings. The differences in germination response of tested species were expected and agree with those of Patil (1994) who reported variations in germination response of various field crops in the presence of *R. stricta* leaf extract. Some current revisions demonstrate the allelopathic potential of *Parthenium hysterophorus* (Tawaha and Turk, 2003), *Brassica nigra* (Singh et al., 2003) and *Raphanus raphanistrum* (Batish et al., 2002). All these revisions designate the production of allelochemicals during the preparation of extract. Likewise, results had been noted by Norsworthy (2003) while studying the inhibitory potential of different plants. They noticed that the leaf extracts had been more allelopathic in nature. The current results agree with the earlier findings described by Bora et al. (1999) who noticed the suppressive potential of *R. stricta* extract.

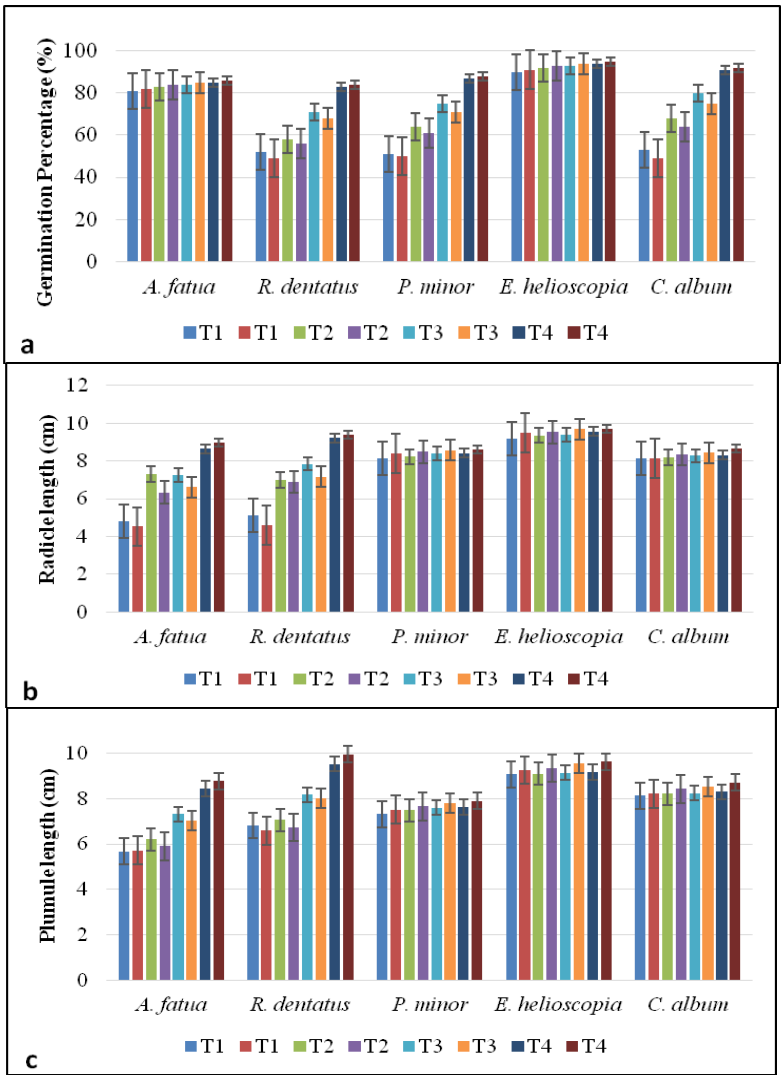

Figure 2. *Allelopathic potential of R. stricta methanol extract on (a) germination (%), (b) radicle length (cm) and (c) plumule length (cm) against weed test species on filter paper (FP) and soil (S) where; T_1 (100%), T_2 (75%), T_3 (50%) and T_4 (control)*

DOI: http://dx.doi.org/10.15666/aeer/1703_71757187

Allelopathic potential of L. camara

The statistical data exposed that *L. camara* methanolic extract significantly inhibited germination of *R. dentatus* (68%), *A. fatua* (66%), *E. helioscopia* (63%) and *P. minor* (62%) on filter paper, whereas, no significant effect on germination of *C. album* showing resistance against extract. Similarly, *L. camara* methanolic extract on soil significantly suppressed seed germination of *A. fatua* (76%), *E. helioscopia* (73%), *R. dentatus* (70%) and *P. minor* (69%). It was noted that maximum (95%) germination was observed for *C. album*. In the present study, it was recognized that minimum germination percentage was noted for *R. dentatus* (32%) followed by *A. fatua* (24%) on filter paper and soil, respectively. The results revealed that germination reduction of the *R. dentatus, A. fatua, E. helioscopia* and *P. minor* were concentration dependent (*Fig. 3a*).

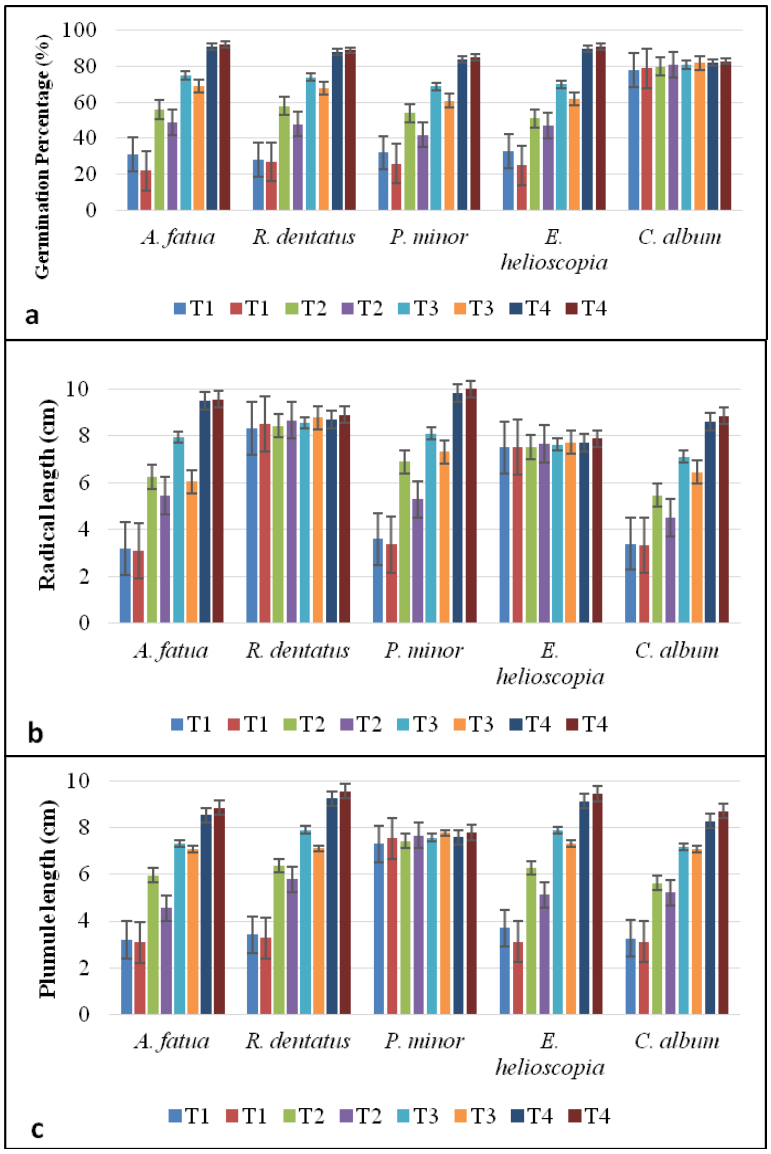

Figure 3. *Allelopathic potential of L. camara methanol extract on (a) germination (%), (b) radicle length (cm) and (c) plumule length (cm) against weed test species on filter paper (FP) and soil (S) where; T_1 (100%), T_2 (75%), T_3 (50%) and T_4 (control)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71757187

The results obtained in the study indicated that *L. camara* methanolic extract significantly inhibited radical length of *C. album* (40%), *P. minor* (37%) and *A. fatua* (34%) on filter paper, whereas, no significant effect was noted for *R. dentatus* and *E. helioscopia* showing resistance against extract. Similarly, the applications of extract into soil significantly suppressed radical length of *A. fatua* (68%), *P. minor* (66%) and *E. helioscopia* (63%) as compared to control. The maximum (96%) radical length was observed for *R. dentatus* and *E. helioscopia*. The final data concluded that minimum radical length was noted for *C. album* (60%) and *A. fatua* (32%) on filter paper and soil, respectively (*Fig. 3b*).

The data obtained exhibited that *L. camara* methanolic extract significantly suppressed the plumule length of *R. dentatus* (63%), *A. fatua* (62%), *C. album* (60%) and *E. helioscopia* (61%) as compared control on filter paper. Interestingly, there was no significant effect on plumule elongation of *P. minor*. Likewise, *L. camara* methanolic extract significantly inhibited plumule length of *E. helioscopia* (67%), *R. dentatus* (66%), *A. fatua* (65%) and *C. album* (64%) in soil. The statistical data concluded that minimum plumule length was noted for *R. dentatus* (37%) and *E. helioscopia* (33%) on filter paper and soil, respectively. The statistical figures also proposed that maximum plumule length (96%) was noted for *P. minor* (*Fig. 3c*).

The results revealed that maximum germination was observed for *C. album*. The results further revealed that minimum germination was noted for *R. dentatus* and *A. fatua* showed being most susceptible to *L. camara* methanolic extract on filter paper and soil respectively. The data suggested that the maximum radical length was observed for *R. dentatus* and *E. helioscopia* showed most tolerance to allelopathic *L. camara* methanolic extract. The results indicated that minimum radical length was noticed for *A. fatua*. The study indicated that maximum plumule length was measured for *P. minor*. However, the lowermost plumule length was noticed for *R. dentatus* and *E. helioscopia* on filter paper and soil respectively. Mishra (2015) stated similar results that growth inhibitory effect of plants was concentration dependent. These results stated that *L. camara* has allelopathic effect on *Lepidium sativum* germination and growth. Ahmed et al. (2007) described the inhibitory potential of *L. camara* in different crops. Mishra (2012) stated that *L. camara* extract checked Parthenium hysterophorus seed germination demonstrating that the presence of inhibitory phytochemicals. Oudhia (2000) noticed germination of *Melilotus alba* was significant inhibited by extract of *L. camara*.

Allelopathic potential of C. papaya

The data illustrated that *C. papaya* methanolic extract significantly inhibited germination of *P. minor* (41%), *E. helioscopia* (37%) and *A. fatua* (36%) on filter paper, whereas, no significant effect on germination of *R. dentatus* and *C. album* showing resistance against extract. Similarly, *C. papaya* methanolic extract on soil significantly suppressed seed germination of *E. helioscopia* (50%), *P. minor* (45%) and *A. fatua* (41%). It was noted that maximum (95%) germination percentage was observed for *R. dentatus* and *C. album*. In the present study, it was recognized that minimum germination was noted for *P. minor* (59%) and *E. helioscopia* (50%) on filter paper and soil, respectively. The results revealed that germination reduction of the *P. minor*, *E. helioscopia* and *A. fatua* were concentration dependent (*Fig. 4a*).

The data revealed that *C. papaya* methanolic extract significantly inhibited radical length of *P. minor* (47%), *R. dentatus* (45%) and *A. fatua* (42%) on filter paper,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71757187

whereas, no significant effect was noted for *C. album* and *E. helioscopia* showing resistance against extract. Similarly, the applications of extract into soil significantly suppressed radical length of *R. dentatus* (50%), *P. minor* (49%) and *A. fatua* (46%) as compared to control. The maximum (96%) radical length was observed for *C. album* and *E. Helioscopia* (*Fig. 4b*).

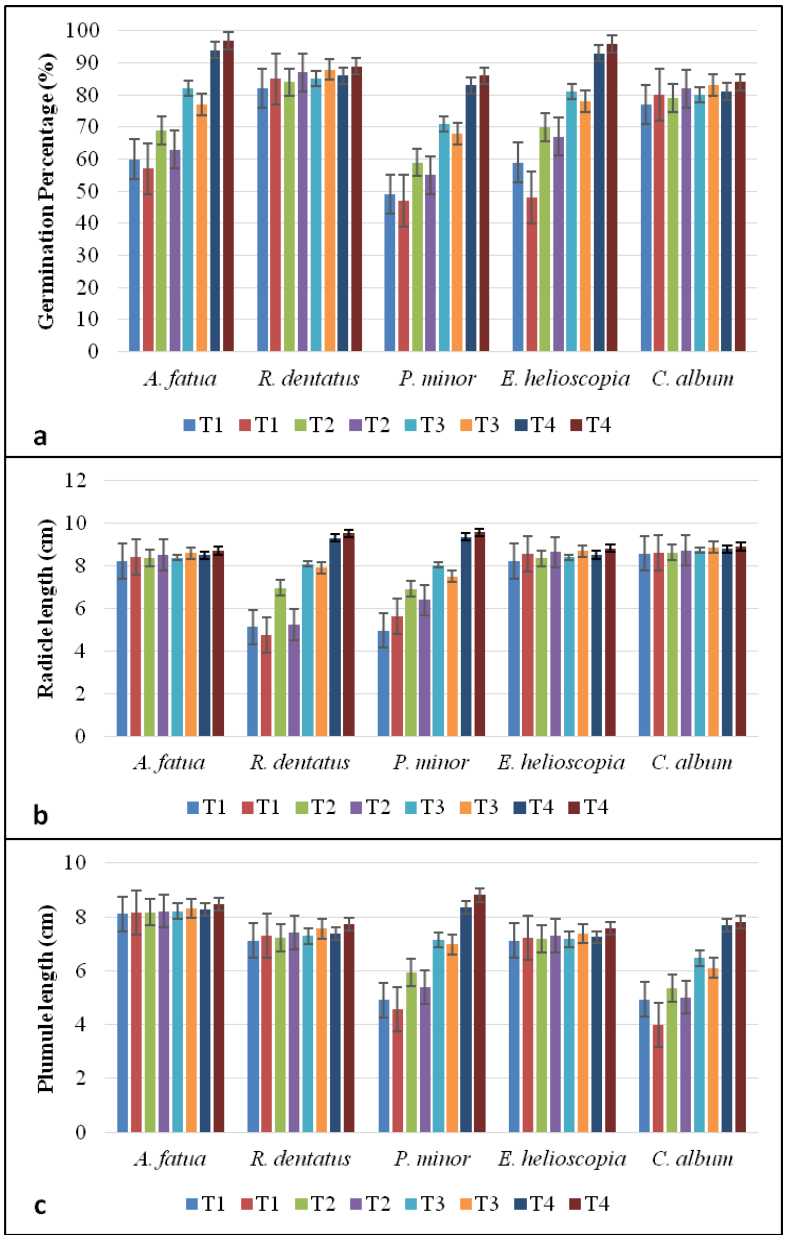

Figure 4. *Allelopathic potential of C. papaya methanol extract on (a) germination (%), (b) radicle length (cm) and (c) plumule length (cm) against weed test species on filter paper (FP) and soil (S) where; T_1 (100%), T_2 (75%), T_3 (50%) and T_4 (control)*

The data obtained exhibited that *C. papaya* methanolic extract significantly suppressed the plumule length of *P. minor* (41%) and *C. album* (36%) as compared control on filter paper. Interestingly, there was no significant effect on plumule elongation of *A. fatua*, *R. dentatus* and *E. helioscopia*. Likewise, *C. papaya* methanolic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71757187

extract significantly inhibited plumule length of *C. album* (49%) and *P. minor* (48%) in soil. The statistical data concluded that minimum plumule length was noted for *P. minor* (59%) and *C. album* (51%) on filter paper and soil, respectively. The statistical figures also proposed that maximum plumule length (96%) was noted for *A. fatua*, *R. dentatus* and *E. helioscopia* (*Fig. 4c*).

The data also suggested that the maximum germination was observed for *R. dentatus* and *C. album*. The statistical results recommended that minimum germination percentage was noted for *P. minor* and *E. helioscopia* on filter paper and soil respectively. The highest radical length inhibition was measured for *C. album* and *E. helioscopia*. The statistical data concluded that maximum plumule length was measured for *A. fatua*, *R. dentatus* and *E. helioscopia*. The statistical results of the data showed that lowermost plumule length was noticed for *C. album* and *P. minor* on soil and filter paper respectively. Likewise, observations were also reported by Turk and Tawaha (2003) showing negative germination effects by *C. papaya* extract of on Avena fatua. According to observations of Bajwa et al. (2013) different types of plant extracts were observed to be completely inhibitory on germination of *A. fatua*. Likewise, finding was also reported by Oudhi (2001) and Maharjan et al. (2007).

Allelopathic potential of P. roxburghii

P. roxburghii methanolic extract on filter paper showed significant inhibitory activity on seed germination of *C. album* (49%) and *A. fatua* (46%), respectively as compared to control. Likewise, P. roxburghii methanolic extract on soil exhibited the highest degree of inhibition germination for *C. album* (52%) and *A. fatua* (49%) respectively as compared to control. The statistical data also suggested that the there was no significant effect on germination percentage of *P. minor*, *R. dentatus* and *E. helioscopia*. The maximum (98%) germination was observed for *P. minor*, *R. dentatus* and *E. helioscopia*. The statistics recommended that allelopathic inhibitory effect was concentration dependent for *C. album* and *A. fatua* (*Fig. 5a*).

The data revealed that the highest radical length inhibition activity exhibited by *R. dentatus* (47%) followed by *C. album* (43%) in P. roxburghii methanolic extract on filter paper. Likewise, methanolic extract on soil caused significant radical length reduction of *R. dentatus* and *C. album* measuring 50% and 48%, respectively as compared to control, while *P. minor*, *E. helioscopia* and *A. fatua* remained unaffected. The maximum radical length was noted for *P. minor*, *E. helioscopia* and *A. fatua* (98%). The results also illustrated that minimum radical length was noted for *R. dentatus* i.e. 53% and 50% on filter paper and soil, respectively. The results revealed that allelopathic inhibitory effect was concentration dependent for *R. dentatus* and *C. album* (*Fig. 5b*).

P. roxburghii methanolic extract on filter paper significantly inhibited plumule length of *R. dentatus* (46%) and *A. fatua* (42%). Likewise, the highest degree of inhibition in plumule length was measured for *R. dentatus* (49%) and *A. fatua* (45%) in methanolic extract applied into soil. The data further suggested that there was no significant effect on germination of *P. minor*, *E. helioscopia* and *C. album*. The statistical results recommended that highest plumule length (98%) was exhibited by *P. minor*, *E. helioscopia* and *C. album*. The results further indicated that minimum plumule length noticed for *R. dentatus* i.e. 54% and 51% on filter paper and soil, respectively. The statistics also recommended that allelopathic inhibitory effect was concentration dependent for *R. dentatus* and *A. fatua* (*Fig. 5c*).

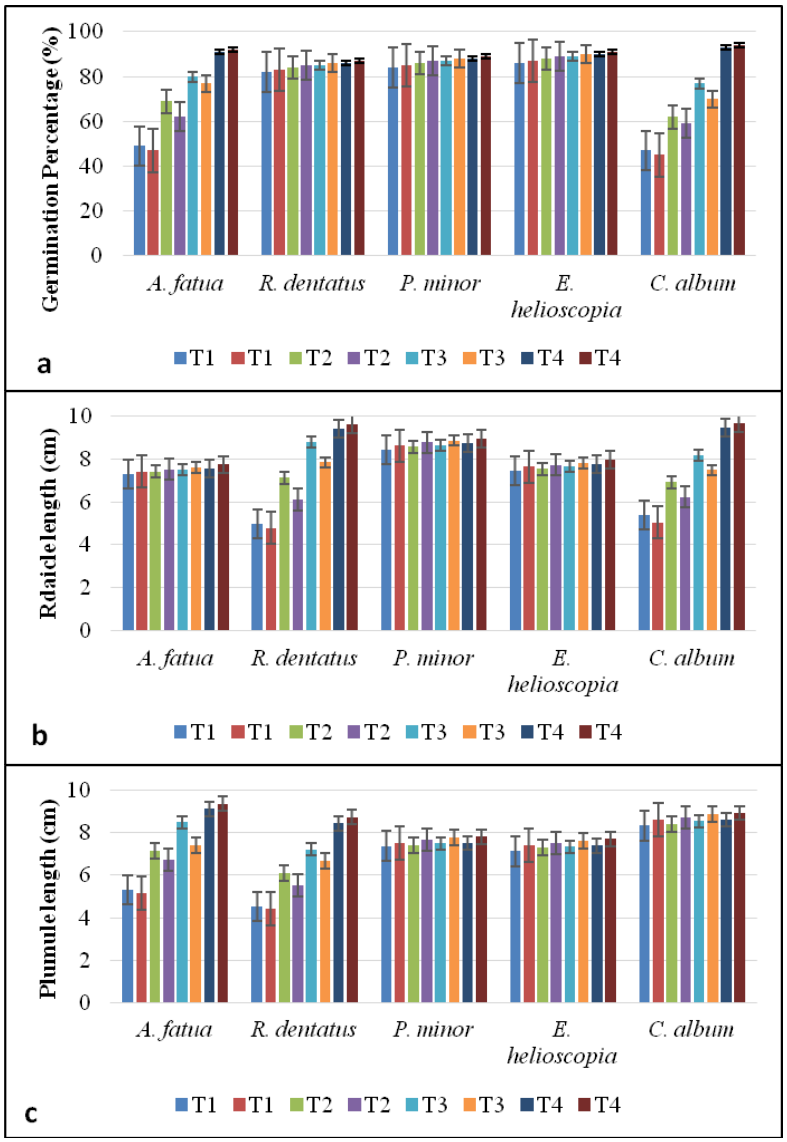

Figure 5. *Allelopathic potential of P. roxburghii methanol extract on (a) germination (%), (b) radicle length (cm) and (c) plumule length (cm) against weed test species on filter paper (FP) and soil (S) where; T_1 (100%), T_2 (75%), T_3 (50%) and T_4 (control)*

It was revealed that maximum germination was observed for *P. minor*, *R. dentatus* and *E. helioscopia*. The results recommended that the maximum radical length was noted for *P. minor*, *E. helioscopia* and *A. fatua*. The results illustrated that minimum radical length was noted for *R. dentatus*. It was observed that *P. minor*, *E. helioscopia* and *C. album* exhibited highest activity for plumule length. The results further indicated that minimum plumule length noticed for *R. dentatus*. The black pine was shown to inhibit the growth of *Phalaris canariensis, Trifolium campestre* and *Sinapis arvensis* seeds (Amri et al., 2013). Different pinene isomers exhibited allelopathic potential against *Zea mays* seed germination (Areco et al., 2014). The leaf methanolic extract from *P. nigra* suppressed the seed germination of perennial ryegrass and tall fescue (Robert, 1986; Terzi et al., 2013). Valera-Burgos et al. (2012) noticed inhibitory

DOI: http://dx.doi.org/10.15666/aeer/1703_71757187

potential of *Pinus pinea* needles extract on seedling growth and seed germination of three Mediterranean shrub species.

Some recent studies indicating the phytotoxic/allelopathic effect of weeds include *Raphanus raphanistrum* (Ali, 2016), *Brassica napus* (Rodriguez et al., 2016), *Ageratum conyzoides* (Kumar et al., 2018) and *Parthenium hysterophorus* (Saranya et al., 2019). All these studies indicate the release of phototoxic chemicals. Based on this, studies were further extended to explore the impact of selected species, as they possessed greater phytotoxicity on the emergence and growth of weed plants in wheat crop.

Conclusions

Experiments showed that methanolic extracts of selected plants at higher concentrations reduce the seed germination, radicle and plumule length of weeds associated with the wheat crop. Results provided evidence about herbicidal potential of tested plant species viz. *L. camara*, *P. roxburghhii, C. Papaya* and *R. stricta* against weeds of wheat crop (*Avena fatua, Phalaris minor, Chenopodium album* and *Rumex dentatus*). Further work is recommended to appraise the potential inhibitory effects of allelochemicals from these plants.

Abstract. In this study, the effects of sirmo *(Allium vineale* L.*)*, mendi *(Chaerophyllum macropodum* Boiss.*)* and siyabo *(Ferula rigidula* DC.) on mineral compositions of herby cheese produced from raw and pasteurized milk in brine and vacuum package during 90 days ripening were determined. Macroelements (Ca, Mg, Na, K) and micro elements (Fe, Zn, Mn) concentration of herby cheese samples were examined by Inductively Coupled Plasma-Optical Emission Spectrometer (ICP-OES). It was determined that the mineral concentration was changed from highest to lowest Na>Ca>K>Mg>Zn>Fe>Mn in the herby cheese. The highest mean concentration of Na was found in Sirmo added cheeses manufactured from raw milk in brine on the second day of ripening and the lowest mean concentration of Mn was found in Sirmo added cheeses produced from pasteurized milk in brine at the end of 90 days. Na, Ca, K, Mg, Zn, Fe and Mn content of cheeses in brine and vacuum package decreased during ripening period.
Keywords: *herbs, mineral content, ripening period, packaging type*

Introduction

Herby cheese is one of the most popular cheeses traditionally produced from raw sheep's milk in the Eastern and South eastern region of Turkey (Tarakci and Temiz, 2009) particularly around Van province. If sheep milk is not available, sheep milk can be mixed with goat and cow milk for cheese production (Tarakci et al., 2004). Herby cheese variety has a salty taste, semi hard texture and is produced in small families (Andic et al., 2010, 2015; Tuncturk et al., 2014) between May and June (Tarakci and Temiz, 2009). It has been traditionally produced more than 200 years in Van and Eastern region of Turkey (Tarakci and Akyuz, 2009). But nowadays the cheeses are also manufactured commercially using pasteurized milk, starter culture in some dairies (in Van or other parts of Turkey). Almost 12 kinds of herbs are used for the production of Herby cheese. However, the most preferred herbs are sirmo *(Allium vineale* L.*)*, mendi *(Chaerophyllum macropodum* Boiss.*)* and siyabo *(Ferula rigidula* DC.) (Kose, 2015). The herbs ensure the cheese its characteristic aroma/flavour and appearance, but also prolong the shelf-life of cheese (Hayaloglu and Fox, 2008).

There are many macro and micro minerals in milk and dairy products. These minerals are very important both in terms of nutritional physiology and physical stability of the cows and the catalytic effects of milk and dairy products (Ocak and Kose, 2015). The mineral content of cheese sample depends on various factors such as feeding, genetic, lactation period, geographical area of milk production, environmental conditions, lack of a standart technique in cheese production and possible contamination from the equipment during the cheese production (Altun and Kose, 2016).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71897201

There are many studies related to mineral content of herby cheese. The concentration of cheese samples were found by Tarakci and Kucukoner (2008) as 313.7, 552.6, 2606, 12.70 mg/100 g for Ca, P, Na, Mg, respectively. Heavy metals (ppm) were determined as 41.79, 33.99, 6.25, 2.05 mg/kg for Fe, Zn, Cu and Mn, respectively. Tarakci et al. (2005) determined the mineral contents of herby cheese samples (mg/100 g) as 289.49, 499.54, 2798.61, 3.20, 31.93, 46.07, 5.95 for Ca, P, Na, Mg, Zn, Fe and Cu, respectively. The same study, Mn, Cr, Co, Cd and Ni concentrations (ppm) were determined as 2.18, 0.23, 0.29, 0.22 and 0.19, respectively. Ocak and Kose (2015) determined Ca, K, Mg, Cu, Mn, Fe and Zn content of 26 Herby cheese samples obtained from retail markets in Van. They determined the concentration ranges in the cheese samples as 268.7-678.7, 84.6-163.2, 26.3-80.8, mg/100 g, 0.38-2.23, 8.13-25.94, 0.29-2.60, 3.14-29.25 mg/kg for Ca, K, Mg, Mn, Zn, Cu and Fe, respectively. Sagun et al. (2005) determined mineral contents of herby cheeses during ripening (90 days). It was determined that Ca, Mg, Fe, Zn, Mn, Ni and Cr contents decreased ($P < 0.05$), the Na content of cheeses increased ($P < 0.05$).

Many studies were performed to determine mineral contents of herby cheese samples but there is no study focusing on the effect of packaging, ripening and different herbs on macro and micro element accumulations in herby cheese. Therefore, the purpose of this investigation was to determine the effect of packaging, ripening and different herbs on the mineral content of herby cheese produced from raw and pasteurized milk during ripening.

Materials and methods

Production of herby cheese

Two different manufacturing methods were applied for production of herby cheese samples.

In the first method, milk and herbs were not pasteurized and the starter culture was not used. The pickled forms of the most preferred three local herbs such as Sirmo *(Allium vineale* L.*)*, Mendi *(Chaerophyllum macropodum* Boiss.*)* and Siyabo *(Ferula rigidula* DC.) were separately and mixed used for cheese production. The raw milk is filtered through a cloth filter and heated to 32 °C and is then coagulated by using commercial rennet (Mayasan company, İstanbul, Turkey) for 1 h. After coagulation, the curd is cut into small cubes. The curd partly drained and divided into 5 groups (A1 control group, A2 sirmo-added groups, A3 mendi-added groups, A4 siyabo-added groups, A5 sirmo, mendi and siyabo mixture added groups). Then the pickled herbs were added at levels of 2 kg to the curd obtained from 100 kg of milk. The mixture of curd and herbs were pressed with a heavy object for 3 h and then cut into blocks (7 × 7 × 2 cm). The cheese blocks were placed in glass jars which are salted with 14% brine and held 12 h. At the end of this time, some of cheeses were continue to ripened in glass jars which were salted with 14% brine concentration, a portion of cheese were vacuum packed in plastic bags and were ripened at 4 °C for 90 days.

In the second method, the raw milk was filtered and pasteurized at 65 °C for 30 min. Then milk was cooled to 32 °C, $CaCl_2$ and starter culture (*Streptococcus thermophilus*, *Lactococcus lactis* subsp. *lactis* and *Lactococcus lactis* subsp. *cremoris*) were added at the ratios of 0.02 and 1.5%, respectively. Then, milk was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71897201

coagulated with rennet enzyme. After coagulation, the curd was cut into small pieces. The curd partly drained and divided into 5 groups as in the first method (B1 control group, B2 sirmo-added groups, B3 mendi-added groups, B4 siyabo-added groups, B5 sirmo, mendi and siyabo mixture added groups). The pasteurized herbs (at 95 °C for 5 min) were added into the curd and mixed well. Then the mixture of curd and herbs were pressed for 3 h to remove the whey sufficiently and the curd was cut into the blocks (7 × 7 × 2 cm). The cheese blocks were placed in glass jars which were salted with 14% brine and held 12 h. At the end of this time, some of cheeses were continue to ripened in glass jars which were salted with 14% brine concentration, a portion of cheeses were vacuum packaged in plastic bags and were ripened at 4 °C for 90 days. Mineral compositions of samples were analyzed 2, 30, 60, 90 days of storage at 4 °C. Each assay was performed in triplicate.

Mineral analysis

The cheese samples were burned by using dry ashing method in a ash furnace at 550 °C for 16 h. Before the samples were put in the ash furnace, they were dried in the oven at 105 °C for 1 h (IDF, 1992). The ash was dissolved with 5 ml nitric acid (1 N HNO_3) on heating plate and were filtered using (Whatman no: 41) filter paper. Then the solution was diluted with 1 N HNO3 and completed in 50 ml with 1 N HNO_3. The concentrations of Ca, Mg, K, Na, Zn, Fe and Mn of the samples were measured by Inductively Coupled Plasma-Optical Emission Spectrometer (ICP-OES) (Thermo Scientific ICAP 6300 DUO, England) at 317.93, 279.55, 766.49, 588.99, 213.86, 259.94, and 257.61 respectively. Also, blank samples were prepared for use in calculations.

Statistical analysis

Concentrations of cheese samples were recorded as means± standard deviation of triplicate measurements. In the analysis of the data, SPSS (V.20) package program was used. A general linear model (GLM) analysis was used to determine the differences between the groups and the Duncan multiple comparison test was used to determine differences among the three groups. Also, for comparison of two independent groups, t test was used.

Results and discussion

The mineral content of herby cheese manufactured from raw and pasteurized milk in vacuum and brine are given *Tables 1-7*.

Calcium

The calcium concentration of vacuum and brine herby cheese samples varied from 2362.47-4820.35 mg/kg. Our results were accordance with findings of Ocak and Kose (2015), Mendil (2006) and higher than the values of determined by Ozlu et al. (2012).

As seen *Table 1,* the calcium content of cheese samples decreased from the 2th until 90 th days. The Ca loss of cheeses in brine were higher than in vacuum packaged, due to salt uptake from brine during the ripening period. Transport of Na^+ and Cl^- ions from brine into the cheese, as a consequence of the osmotic pressure

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71897201

difference between the brine and the moisture of the cheese. Depending on the amount of lactose and minerals in it, moisture of cheese has a certain osmotic pressure. The osmotic pressure of the brine is higher due to the excess of salt. For this reason, the pressure difference between the brine and cheese causes diffusion. When a moulded cheese is placed in brine, diffusions of Na^+ and Cl^- ions from brine into the cheese and diffusions of H_2O, lactose, serum protein, various mineral substances such as Ca, Mg, K, P from cheese into the brine until the osmotic pressure between both phases is equalized. The amount of water lost is about twice the amount of salt obtained. For this reason, the weight of cheese decreases during the storage period (Gider, 2006). As long as the ripening period is long, transport of Na^+ and Cl^- ions from brine into the cheese increases with very rapid salt uptake in the beginning but decreases during the storage periods (Guinee and Fox, 1986). Similarly, in our study the Ca concentrations of the herby cheeses in brine rapidly decreased from the 2nd until the 30th day of storage but the loss of Ca has decreased from the 30th until the 90th days. The reason for this explained by the some researchers as a reduction of NaCl concentration difference between brine and cheese moisture (Guinee and Fox, 1986; Gider, 2006).

Table 1. *The effects of Sirmo, Mendi and Siyabo on Ca concentrations of herby cheese produced from pasteurized and raw milk in brine and vacuum package during ripening*

Magnesium

It was determined that the magnesium content of samples ranged from 114.79-282.30 mg/kg. Therefore, the level of magnesium in the vacuum cheeses were higher than in brine cheeses. These results were agreement with findings obtained by Cetinkaya et al. (2016) as 111.20-214 mg/kg for Camibogazı and Ozlu et al. (2012) as 65.83-210.09 mg/kg for Kasar cheese but higher than the value determined by Kırdar et al. (2013) as 49.62 mg/kg for Akçakatik and Kirdar et al. (2015) as 72.6 to 88.9 for Kargı Tulum cheese.

The magnesium concentration of herby cheese decreased throughout the storage period similar to that Ca content. The possible reason for this situation, 70% of the Mg is in soluble form (Ocak and Kose, 2015) so transport of Mg from cheese into the brine until the osmotic pressure between brine and cheese phase is equalized during the storage period.

At the end of the ripening period, Siyabo added herby cheese (A4 and B4) in vacuum packaged had higher Mg values. This is probably due to the high Mg content of Siyabo in comparison to Sirmo and Mendi and loss of Mg in brine cheeses were higher than vacuum packaged.

Table 2. *The effects of Sirmo, Mendi and Siyabo on Mg concentrations of herby cheese produced from pasteurized and raw milk in brine and vacuum package during ripening*

Sodium

The 2005 Dietary Guidelines for Americans recommends that healthy adults limit consumption of sodium 2300 mg/d (5.84 g of NaCI or about 1 teaspoon of table salt) and hypertensive patients and the older adults should not take more than 1500 mg of sodium per day (Agarwal et al., 2011). The main source of sodium in diet is NaCl, most of salt comes from commercial food in the improved countries. Sodium is important for regulation of blood and osmotic pressure, transport of water into and out of cells and transmission of nerve cell impulses (Cruz et al., 2011). However, excess intake of Na causes high blood pressure and other chronic diseases (Felicio et al., 2013). Another symptom that may be caused by high intake of sodium is the interference in bioavailability of calcium due to the increase in the renal excretion of this mineral. According to predictive equations, it is believed that urinary excretion of calcium will increase by 30-40 mg, for each 2 g of sodium consumed. However, if the intake of sodium is below 2.4 g per day, there will be no negative effect on the bones (Cruz et al., 2011).

The sodium content of cheese samples ranged from 5719.61 to 10063.22 mg/kg. It has been exhibited that the sodium levels suggested for a healthy person can be met by consuming about 250 g of Herby cheese. Sodium in herby cheese is due to milk naturally contain some sodium as well as due to added salt and pickled herbs. Our results were similar with findings obtained by Cetinkaya et al. (2016) as 4852.5-10520 mg/kg for Camiboğazı, by Holland et al. (1995) as 700 mg/100 g for Brie cheese, lower than the value determined by Tarakci and Kucukoner (2008) as 2606 mg/100 g for herby cheese and higher than the value determined by Holland et al. (1995) as 380 mg/100 g for Cottage cheese, by Felicio et al. (2013) as 574.5, 473.4, 588.8 mg/100 g for Mozzarella, Minas and Prato cheeses, respectively.

Potassium

The metabolism of water is affected and myoneural activities are stimulated by Na as well as K, in the human body. According to nutritional recommendations, the sufficient Na and K proportion in diet must be of 0.6 for adults and 0.5 for children (Cruz et al., 2011).

As seen in *Table 4,* the K values of herby cheese samples were significantly decreased during the ripening period. The K values of brine cheeses were determined lower than vacuum packaged cheeses at the end of the storage periods. The possible reason for this situation, the cheese that was ripened in a brine had a higher salt content than the cheese ripened in vacuum packaging. In general, as the salt content increases, the acidity decreases and the pH value increases in the cheese (Kose, 2015; Almenara et al., 2007). The final average values were lower than those described by Ocak and Kose (2015) and similar with findings obtained by Mendil (2006) for herby cheeses and by Murtaza et al. (2014) for cheddar cheese.

Iron

Iron is an essential trace element is incorporated as a catalyst in various metabolic reactions. It is a component of hemoglobin, myoglobin, cytochrome and other proteins and plays an important role in the transport, storage and use of oxygen. Milk and dairy products are insufficient source in terms of Fe for human nutrition (Zamberlin et al., 2012). Its deficiency causes anaemia, decrease in immunity and alteration in mental development (Gaucheron, 2000).

Zinc

Zinc is an essential mineral that is very nutritionally for human and deficiency creates significant implications for human health. The deficiency of Zn results in a wide spectrum. Its clinical effects depending on age, stage of development and deficiencies of related metals (Bakircioglu et al., 2011). The maximum tolerable daily intake of Zn is 60 mg (FAO/WHO, 1999, 1999). In this study, the content of Zn for herby cheeses in brine and vacuum packages were lower than the WHO's values.

Table 6. *The effects of Sirmo, Mendi and Siyabo on Zn concentrations of herby cheese produced from pasteurized and raw milk in brine and vacuum package during ripening*

A1: control cheese manufactured from raw milk, A2: sirmo-added cheese manufactured from raw milk, A3: mendi-added cheese manufactured from raw milk, A4: siyabo-added cheese manufactured from raw milk, A5: sirmo, mendi and siyabo mixture added cheese manufactured from raw milk, B1: control cheese manufactured from pasteurized milk, B2: sirmo-added cheese manufactured from pasteurized milk B3: mendi-added cheese manufactured from pasteurized milk, B4: siyabo-added cheese manufactured from pasteurized milk, B5: sirmo, mendi and siyabo mixture added cheese manufactured from pasteurized milk

The Zn concentration of herby cheeses produced from raw and pasteurized milk changed from 11.28 to 16.67, 12.96 to 16.59 mg/kg, respectively. It has been found that the Zn concentration of cheese produced from both pasteurized and raw milk decreased during the storage period. But, at the end of the storage periods, the Zn content of brine cheeses were found lower than vacuum packaged cheeses. When the findings are compared with the literature, our results were lower than the value determined by Oksuztepe et al. (2013) as 20.50 mg/kg for white cheese, by Isleten et al. (2007) as 2.12-8.19 mg/100 g for Ezine cheese, by Cichoscki et al. (2002) as 29.21-36.60 mg/kg

for Prato cheese, by Altun and Kose (2016) as 22.70 to 65.37 for Kelle cheese, by Bilandzic et al. (2015) as 46 mg/kg for semi hard fat cheese consumed in Croatia.

Manganese

The Institute of Medicine suggests that intake of Mn should not exceed the tolerable daily maximum limit of 11 mg/day (National Research Council, 1989). In this study, Mn concentrations of cheese samples changed from 0.70 to 0.26 mg/kg. The content of Mn for Herby cheese samples in brine and vacuum packages were lower than the National Research Council.

Table 7. *The effects of Sirmo, Mendi and Siyabo on Mn concentrations of herby cheese produced from pasteurized and raw milk in brine and vacuum package during ripening*

Decrease in the Mn concentrations of pasteurized and raw milk herby cheeses were determined during the ripening period. The possible decrease in pH can induce this situation. In general, Mn are linked to the insoluble fraction of casein micelle of milk in a ratio of 95% (Cichoscki et al., 2002). However, as the pH in cheese decreases during ripening, migration of Mn towards the soluble fraction is monitored (Macedo and Malcata, 1997). As a result, the loss of Mn content occurs in brine or vacuum packaged

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_71897201

samples. Our results showed similar behaviour with findings obtained by Cichoscki et al. (2002) as 0.36 to 0.26 mg/kg for Prato cheese, were higher than the value determined by Kirdar et al. (2015) as 0.11 to 0.19 μg/g for Kargi Tulum Cheese and were lower than the value determined by Macedo and Malcata (1997) as 1.17 to 1.40 mg/kg for Serra cheese.

Conclusions

As a result, Na, Ca, K, Mg, Zn, Fe and Mn content of cheese samples were influenced by herbs, packaging, ripening and heat treatment. It was observed that ripening has the most pronounced effect on studied variables. The concentrations of minerals in cheese samples decreased and the changes of ratios of mineral compounds were different during storage period. The vacuum packaged cheeses were found to have a higher mineral content than the cheeses stored in brine at the end of 90 days. Because of the mineral loss of cheeses in brine were higher than in vacuum packaged due to diffusions of mineral substances from cheese into the brine during maturation. This investigation is first study comparing herbs species, packaging type and ripening period on the mineral content of herby cheeses produced from pasteurized and raw milk. Therefore, further investigations are needed to determine the influence of various factors on the mineral compositions of herby cheeses.

(Received 28th Feb 2019; accepted 10th Apr 2019)

Abstract. The field experiment was carried out in 2016-2019 at the Agricultural Experimental Station - Zawady belonging to the University of Natural Sciences and Humanities in Siedlce. The experiment was established in a random split-plot system in three repetitions. The surface of one plot was 21 m^{-2}. The examined factors were I - three varieties of winter rape: Monolit (population variety), PX115 (hybrid variety restored with a semi-dwarf growth type), PT248 (hybrid variety restored with a traditional growth type). II - four types of foliar feeding: 1. control object (without foliar feeding and biostimulator were sprayed with distilled water), 2. biostimulator Aminoplant, 3. Foliar fertilizer Siarkomag + foliar fertilizer Bormax, 4. Foliar fertilizer Siarkomag + foliar fertilizer Bormax + biostimulator Aminoplant. The aim of the study was to determine the effect of foliar feeding on the growth of fresh and dry mass of plants (leaf rosette, root) of three winter rape varieties. On the basis of the conducted research, it was found that autumn foliar feeding of plants significantly increased the fresh and dry weight of the rosette and the root system in comparison to the control variant. The highest growth of plant weight and root system was recorded on object 4, which proves that the biostimulator applied with foliar fertilizers had a positive effect on the uptake and accumulation of micro and macro-elements provided with foliar fertilizers. The Monolit population variety was distinguished by the largest green and dry mass of the rosette and root system. In the growing season 2018-2019 characterized by very hot and dry autumn, the largest fresh and dry mass of plants (rosettes and root system) was found.
Keywords: *morphotype, leaf rosette, root, foliar fertilization, biostimulator, amino acids*

Introduction

Insufficient feeding of plants leads to the disturbances of basic physiological processes, which adversely affects the growth and development of plants, contributing as a consequence to a decrease in yields (Kocot and Grenda, 2004). Sienkiewicz-Cholewa and Kieloch (2015) and Jankowski et al. (2016b) they emphasize that during the growing season some nutrients can be delivered directly on the plant leaves.

Foliar feeding of plants supplying, in addition to the necessary nutrients, biostimulator compounds, is more and more often treated as permanent elements of the proper agrotechnology of many crop plants. According to Harris et al. (2018) the foliar application is the fastest method of providing nutrients for plants.

Szewczuk (2003) and Kocoń (2009) in their research emphasized the beneficial effect of foliar nutrition in winter plants in the period of autumn growing season.

The macro and microelements provided at the time influence the accumulation of sugars in plant cells, which is associated with the hardening of plants and increased

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_72037211

resistance to wintering conditions (Szewczuk and Sugier, 2009). Noreen et al. (2018) and Yakhin et al. (2017) they stated that plants well fed with essential nutrients have greater tolerance to environmental stress.

According to Jankowski et al. (2016a) and White et al. (2015) foliar fertilization is an alternative method of providing macro-elements, it can be used only to reverse the effects of nutritional deficiencies and can serve as the main technique of fertilization only to provide plants with the required micronutrients.

Kocira et al. (2016) and Złotek and Wójcik (2014) biostimulators and agents containing micronutrient additives are safe to use and do not exhibit any destructive effects on the environment.

The study assumes the hypothesis that the use of foliar fertilizers and biostimulators may affect the growth of fresh and dry mass of plants (rosettes, root system). The aim of the research was to determine the effect of foliar nutrition on the growth of fresh and dry mass of the aboveground part of the rosette and fresh and dry mass of the root system of three varieties of winter rape.

Materials and methods

Experimental and agronomic management

The field experiment was carried out in 2016-2019 at the Agricultural Experimental Station Zawady (52°03'N and 22°33'E) belonging to the University of Natural Sciences and Humanities in Siedlce. The experiment was established in a random split-plot system in three repetitions. The surface of one plat was 21 m^{-2}.

The following factors were studied in the experiment:

Factor I - three varieties of rape:

1. Monolit (population variety)
2. PT 248 (hybrid variety restored with a traditional growth type)
3. PX 115 (hybrid variety restored with a semi-dwarf growth type)

Factor II - four types of foliar feeding:

1. Control object - without using foliar feeding and a biostimulator were sprayed with distilled water
2. Biostimulator Aminoplant (N_{total} - 8.5%): I term - in autumn in the 4-6 leaf phase (BBCH 14-16) at a dose of 1.0 $dm^3 \cdot ha^{-1}$
3. Foliar fertilizer Siarkomag (MgO - 5%. SO_{3total} - 85%. $SO_{3soluble}$ in water - 10%) + foliar fertilizer Bormax (B - 11%): I term - in autumn in the 4-6 leaf phase (BBCH 14-16) at a dose of 2.0 $dm^3 \cdot ha^{-1}$ + 0.5 $dm^3 \cdot ha^{-1}$
4. Foliar fertilizer Siarkomag + foliar fertilizer Bormax + biostimulator Aminoplant: I term - in autumn in the 4-6 leaf phase (BBCH 14-16) at a dose of 2.0 $dm^3 \cdot ha^{-1}$ + 0.5 $dm^3 \cdot ha^{-1}$ + 1.0 $dm^3 \cdot ha^{-1}$

The forecrop for winter rape in particular years of the research was spring wheat (1st year of research), winter triticale (2nd year of research), winter triticale (3rd year of research). The experiment was carried out on soil classified in the order of soils with clay translocation, type – Luvisols, subtype - Albic Luvisols (WBR FAO 2014). This soil was classified as IVa bonitation class soil, of very good rye complex for agricultural use. During the years of the experiment, soil pH (in 1n KCl) was slightly acidic, ranging from 5.68 to 5.75. The soil was characterized by a low total content of nitrogen (on

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_72037211

average 0.85 g·kg^{-1}), phosphorus (on average 0.44 g·kg^{-1}), potassium (on average 0.65 g·kg^{-1}) and calcium (on average 0.83 g·kg^{-1}) and the medium content of magnesium (on average 0.42 g·kg^{-1}) and sulphur (on average 0.13 g·kg^{-1}). It demonstrated low content of available phosphorus forms (on average from 75 to 80 mg·kg^{-1}) and medium content of available forms of potassium (on average from 200 to 205 mg·kg^{-1}) and magnesium (on average from 59 to 61 mg·kg^{-1}).

After forecrop harvest, a set of post-harvest procedures was carried out using the ploughing aggregate + open cage roller, and then two weeks after the first procedure, pre-sow ploughing at the depth of 20.0 cm was carried out, using a ring roller at the same time. To prepare the soil for sowing and to mix fertilizers, a complex soil tillage unit was used. Before sowing, phosphorus-potassium fertilization was applied at the dose of 40 kg P·ha^{-1} and 110 kg K·ha^{-1} and the first dose of 40 kg N·ha^{-1}. Fertilization was applied in the form of Lubofos at the dose of 600 kg. Fertilizing doses were supplemented with 55.9 kg·ha^{-1} of ammonium nitrate (19 kg N·ha^{-1}), 29.6 kg·ha^{-1} triple superphosphate (13.6 kg P·ha^{-1}) and 29 kg·ha^{-1} potassium salt (17.9 kg K·ha^{-1}). The second dose of nitrogen in the amount of 100 kg·ha^{-1} was applied in spring, before vegetation started (BBCH 28-30) applying ammonium nitrate at the dose of 255.5 kg·ha^{-1} (86.9 kg N·ha^{-1}) and ammonium sulphate at the dose of 62.5 kg·ha^{-1}. The third dose of ammonium 60 kg·ha^{-1} was applied at the inflorescence emergence (BBCH 50) by applying ammonium nitrate at the dose of 176.5 kg·ha^{-1} (60 kg N·ha^{-1}).

Winter rapeseed sowing was made at spacing between rows of 22.5 cm, assuming the sow of 60 pcs·m^{-2}. Sowing was made at the optimal time recommended for this region (in 2016 - on 12 August, 2017 - on 14 August, and in 2018 - on 13 August).

Chemical protection against weeds, diseases and pests was applied in accordance with the recommendations of good agricultural practice.

Immediately before the inhibition of the autumn vegetation the following biometric characteristics were identified on the randomly selected sample of 20 plants:

- Fresh mass of the aboveground part of 1 rosette (g)
- Dry mass of the aboveground part of 1 rosette (g)
- Fresh mass of the root system of 1 plant (g)
- Dry mass of the root system of 1 plant (g)

In all years of conducting experiments, plant samples were collected in the 16-19 BBCH phase, in the second decade of October.

The method of determining air dry matter in fresh plant material consisted in drying the sample to air-dry state in a natural way, and then at a temperature not exceeding 105 °C for 3 h.

Statistical analysis

The results of the study were statistically analysed with the use of the analysis of variance. The significance of variation sources was tested with the "F" Fischer-Snedecor test and the assessment of significance at the significance level of $p = 0.05$ between compared means with Tukey's range test.

Weather conditions

In autumn, varied weather conditions prevailed in the analysed vegetation seasons (*Table 1*). In the first year of research, autumn was quite dry ($K = 1.30$). The period

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_72037211

from August to October was characterized by a smaller average of 11.3 mm of rainfall compared to the average of that period from 1996-2010, while the average air temperature was similar to the long-term period of 13.3 °C. In the growing season of 2017-2018 based on the calculated Sielianinow coefficient (Skowera, 2014), it was found that autumn was quite wet (K = 1.76). The sum of precipitation from August to October was higher by an average of 61.9 mm compared to the average for many years, and the average air temperature was higher by 0.5 °C. In the last year of research, autumn was very dry (K = 0.68). The sum of precipitation from August to October was lower by 51.2 mm compared to the long-term, and the average air temperature was higher on average by 2.1 °C compared to many years.

*Index value (Skowera, 2014): extremely dry $k \leq 0.4$, very dry $0.4 < k \leq 0.7$, dry $0.7 < k \leq 1.0$, rather dry $1.0 < k \leq 1.3$, optimal $1.3 < k \leq 1.6$, rather humid $1.6 < k \leq 2.0$, humid $2.0 < k \leq 2.5$, very humid $2.5 < k \leq 3.0$, extremely humid $k > 3.0$

Results and discussion

On the basis of the conducted research, it was found that the applied foliar nutrition significantly influenced the increase of fresh and dry mass of the aboveground part of the rosette and root system in comparison to the control variant (*Tables 2, 4, 6* and *7*). This is consistent with the results of Gawrońska et al. (2008) and Sikorska et al. (2017). The authors after using biostimulators Asahi SL, Tytanit and Silvit noted an increase in the value of these features compared to the control object. Albayrak and Camas (2005), Soheir et al. (2012) and Aisha et al. (2014) under the influence of stimulation with humic acids received a greater fresh and dry mass of the aboveground part of the rosette and root system in comparison of the object on which no fertilization was applied. Similarly, Krawczyk and Skoczyński (2008) showed a beneficial effect of the foliar fertilizer Route on the fresh and dry mass of the root system. In own studies, the largest increase in plant mass and root system was noted on object 4, where the foliar fertilizer Siarkomag. Bormax and biostimulator Aminoplant were used. This proves that the applied biostimulator positively influenced the uptake and accumulation of micro and macro-elements provided with foliar fertilizers. In our own research, the genetic factor

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_72037211

significantly affected the fresh and dry mass of aboveground part of the rosette and root system. The highest values of the discussed features were found in the Monolit population variety, while the lowest in the restored hybrid with a semi-dwarf growth type (PX 115) (*Tables 2, 4, 6* and *7*). This is in line with the results of studies by Kotecki et al. (2007) and Sikorska et al. (2017). These authors also recorded the largest fresh and dry mass of the aboveground part of the rosette and root system in the Monolit population variety, while the smallest in the semi-dwarf PR44D06. Similarly, Wielebski and Wójtowicz (2018) showed that the hybrid morphotype with a semi-dwarf growth type PR45D03 was characterized by a smaller fresh mass compared to the varieties with a traditional type of growth: hybrid Poznaniak and population Starter. Jankowski and Budzyński (2007) and Wielebski (2007) came to different conclusions, who showed that hybrid forms produced a rosette with a larger fresh and dry mass of 1 plant and the root system. The largest fresh and dry mass of the above-ground of 1 rosette and the root system was noted in the last year of research, in which autumn was very dry and warm, while the lowest in the fairly humid vegetation season 2017-2018 (*Tables 2, 4, 6* and *7*). In turn, in earlier studies by Sikorska et al. (2017), the highest values of the discussed features were demonstrated in the season characterized by heavy rainfall in August and alternate rainfall in September and higher than the average air temperature in September and October, while the lowest in the season in which strong drought occurred in August and the first two decades of September.

The statistical calculations showed the interaction of years and studied varieties with the fresh and dry matter of the aboveground part of 1 rosette and the root system, which means that varieties reacted to the humidity and thermal conditions differently in the years of research (*Tables 2, 4, 6* and *7*). Based on the conducted studies, the interaction of varieties and types of foliar feeding was found, which means that varieties reacted differently to the types of foliar feeding (*Tables 2* and *4*). The fresh and dry mass of the above ground part of 1 rosette of the Monolit variety after the application of the Aminoplant biostimulator containing amino acids was the same as in the control object. In all studied varieties, the highest increase in fresh and dry matter was recorded as a result of the application of the Aminoplant biostimulator with foliar fertilizers Siarkomag and Bormax. The impact of biostimulators and foliar fertilizers on the fresh and dry mass of the aboveground part of 1 rosette was determined by the climatic

DOI: http://dx.doi.org/10.15666/aeer/1703_72037211

conditions prevailing in the years of research (*Tables 3* and *5*). In autumn in the growing seasons 2017-2018 and 2018-2019, the fresh mass of aboveground part of rosette after the application of the Aminoplant biostimulator was the same as in the control object, while the dry mass of the aboveground part after using the bioregulator with the amino acid was the same as in the control object only in the last growing season.

Conclusions

1. Autumn foliar feeding of plants significantly increased the fresh and dry mass of the rosette and root system in comparison to the control variant. The highest growth of plant weight and root system was noted on object 4. Biostimulator applied with foliar fertilizers had a positive effect on the uptake and accumulation of micro and macro-elements provided with foliar fertilizers.
2. Spraying plants of the Monolit variety only with the Aminoplant amino acid meant that dry and fresh mass of the aboveground part of 1 plant was at a similar level as in the control object.
3. From the compared morphotypes, the Monolit population variety was characterized by the largest green and dry mass of the rosette and root system, whereas the smallest hybrid variety with a semi-dwarf growth-type PX 115.
4. The largest fresh and dry mass of the aboveground part of rosette and root system was obtained in the warmest and driest autumn period.

Abstract. Ongoing climate change has led to more extreme global temperature variations, and coupled with other environmental issues such as soil salinization, these changes pose serious challenges to future farming efforts. As such, it is vitally important both to identify crops able to resist temperature and salt stress and to explore the underlying molecular mechanisms governing such resistance in order to facilitate the selective production of crops with superior resistance traits able to persist in an increasingly harsh global environment. To that end, in this study, PCR was used to isolate the *AnTPS1* gene, which encodes trehalose 6-phosphate synthases (TPS). Real-time PCR was used to detect the expression of the gene in different tissues and under low temperature. We used a bioinformatics approach to assess key characteristics of the *AnTPS1* gene, determining its physicochemical properties, signal peptides, transmembrane structural domains, hydrophilicity, hydrophobicity, secondary structures, modules, and tertiary structures. We isolated an important abiotic stress resistance gene *AnTPS1* in naked oats. Real-time quantitative PCR analysis showed *AnTPS1* to be expressed in different tissues of naked oats, and we found that low temperature stress was sufficient to induce the upregulation of this gene. We determined that the protein encoded by *AnTPS1* gene is a soluble hydrophobic protein composed of 326 amino acids, containing signal peptides and transmembrane structures. The protein does not feature crimp spirals, instead featuring α-helices and irregular crimps are the main secondary structure elements. Together, these results provide an important biochemical foundation for the study of *AnTPS1* as a putative cold-resistance gene in naked oats, and may offer valuable insights necessary for enabling selective production of temperature-resistant crops suitable for growth in previously untenable locations.

Keywords: *naked oats, AnTPS1, gene, bioinformatics, trehalose 6-phosphate synthase (TPS), cold stress*

Introduction

Constant global climate change and rapid population increase pose significant challenges for securing a sufficient global food supply (Tai et al., 2014). There is a vital need to breed key staple crops that are able to resist abiotic stressors such as drought

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_72137227

conditions, extreme cold, and highly saline soil stress (Flowers, 2004; Hu and Xiong, 2014). It is thus critically important that crops with ideal resistance traits be identified, and that the molecular mechanisms governing their resistance behaviors be fully elucidated to allow for the selective production of resistant crops capable of meeting future global food production needs.

Naked oat (*Avena nuda* L.), also known as oil wheat, jade wheat, and bell wheat, is a member of the family of Gramineae, genus Hordeum, of Chinese origin (Zhou et al., 2016). Naked oats are a cold-tolerant crop, withstanding temperatures as low as -2 to -4°C in the seedling and tillering growth stages (Liu et al., 2013). Naked oats are additionally a quick-growing, drought-resistant, and saline-alkali-resistant species. Given these key resistance characteristics, naked oats are well-suited for growth in harsh environments, and are primarily distributed in northern China and in the arid and semi-arid areas of northwest China (Ma et al., 2013). Naked oats are high in nutritional value, being rich in eight necessary amino acids, various trace elements, abundant linoleic acid, dietary fiber, and other important nutritional compounds (Wang et al., 2017). The levels of vitamin E and B in naked oats are similarly high, and the levels of protein and fat in the seeds are higher than in most food crops (Lin et al., 2011). Naked oats are primarily harvested and used for human consumption, medicine, and feeding poultry. The optimal resistance characteristics of this strain to environmental stressors make it ideal in harsh environments. Characterizing the specific molecular mechanisms underlying these resistance traits therefore offers a unique opportunity to facilitate the selective breeding or modification of strains of oats and other crops in order to allow them to better grow in non-permissive environments.

Trehalose is an important sugar molecule that is known to be vital for plant resistance to abiotic stress (Oide and Inui, 2017). Trehalose can prevent the transition of a cellular phospholipid bilayer from a liquid crystal state to the solid state, thus stabilizing proteins and other macromolecules within the bilayer and thereby enhancing the resistance of plant cells to various forms of abiotic stress (van Dijken et al., 2004). The synthesis of trehalose is catalyzed by TPS and trehalose-6-phosphate phosphatase (TPP), with the former being the rate-limiting enzyme for its production (Xu et al., 2017). The introduction of fusion genes for TPS and TPP from *Escherichia coli* and yeast into transgenic tobacco, potato, rice and *Arabidopsis* plants has been found to increase resistance to abiotic stress such as drought tolerance among these transgenic plants (Delorge et al., 2015). These studies thus indicate the TPS gene plays an important role in enhancing plant stress resistance, making it an important target of research aimed at improving the resistance characteristics of crops. This has led to extensive efforts to better understand the role of trehalose in the context of abiotic stress resistance, and as such TPS gene sequences have been isolated and validated from herbaceous plants such as *Arabidopsis thaliana* in recent years (Xu et al., 2017). Whether particular species of plants possess unique TPS genes with potentially advantageous properties remains to be determined, and at present there are no reports on the characteristics of TPS in naked

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_72137227

oats. As such, in the present study we used a bioinformatics approach to assess the properties of the *AnTPS1* gene in naked oats, exploring its physicochemical properties, signal peptides, transmembrane structural domains, hydrophilicity, hydrophobicity, secondary structures, modules, and tertiary structures. Through these efforts, this study aimed to provide a theoretical basis both for improving naked oats yield and quality, and to more broadly produce information that may be of value for the selective production of crops with advantageous abiotic stress resistant traits.

Materials and methods

Materials and cold treatment

Naked oats cultivar Jinyan 17 was used in this study. Seeds were sterilized through incubation for 1 min in 75% ethanol, and thoroughly being washed with sterile water. The seeds were germinated in soil in pots at 20°C under long-day conditions (16 h of cool white fluorescent light, photon flux of 70 umol m^{-2} s^{-1}). 50 Seedlings at the four-leaf stage were subjected to cold stress. 50 Seedlings in the control group were grown at 20°C continuously. To induce cold stress, seedlings were transferred to an artificial climate box at 4°C under the same light and photoperiodic conditions. The leaves were then treated with cold temperature at 4°C for 0 h, 1 h, 3 h, 6 h, 12 h, 24 h (Indeok, 2016). This stressor procedure was conducted in triplicate.

AnTPS1 gene expression analysis

Total RNA was extracted from plants using the RNA Plant Plus Reagent Kit (Tiangen Biochemical Technology Co., Ltd.) and was reverse transcribed into cDNA using the FastQuant RT Kit. The cDNA of *AnTPS1* was amplified by PCR and sequenced. The primer sequences were: AnTPS1-F1 (5'- CATCACGCTG CTCTCTCTAC -3') and AnTPS1-R1 (5'- GAGGTCCGACACTTGCGTT -3'). The relative expression of *AnTPS1* was then detected by real-time fluorescent quantitative PCR (Guo et al., 2015; Reem et al., 2017). The cDNA derived from root, stem, and leaves of plants exposed to temperature stress treatment were used for all qPCR reactions. The primer sequences for *AnTPS1* were: AnTPS1-F2 (5'- TCCTATGCTGTGTCCCAATC -3') and AnTPS1-R2 (5'- CAGACCAGTGAACAATAGGG -3'). *Actin* served as an internal reference gene; the primer sequences for actin were: Actin-F (5' TATTGCTTTCTCCTGCTGTC-3') and Actin-R (5'-CTATGTATCCTGGTATTGCG-3'). The qPCR reaction was conducted under the following conditions: pre-denaturation at 95°C for 3 min; denaturation at 94°C for 30 s, annealing at 60°C for 30 s, extension at 72°C for 30 s, 30 cycles. A melting curve was then constructed via the system default procedure. All samples were run in triplicate.

Biological information analysis of AnTPS1

A comprehensive bioinformatics analysis was conducted using tools including the NCBI, PDB, and ExPASy databases and further online ones (*Table 1*) (Lu et al., 2018), in order to predict and analyze characteristics such as conserved domains, the physicochemical properties of the primary structure, signal peptides, transmembrane structural domains, subcellular localization, hydrophilicity and hydrophobicity, secondary structure, modules, and tertiary structures (Mao et al., 2018). Briefly, bioinformatics tools were used as follows: CD Search was used for conservative domain prediction; the ExPASy Protparam tool was used to predict the physiochemical properties of the encoded protein; the ExPASy Protscale tool was used for hydrophobicity/hydrophilicity predictions; SignalP4.1 Server was used for signal peptide predictions; TMHMM Server v.2.0 was used for predicting transmembrane regions; SOSUI was used to predict protein solubility; SOMPA was used for secondary structure predictions; CILS was used for crimp spiral analyses; SWISS-MODEL was used for tertiary structure modeling.

Results and analysis

Expression analysis of the AnTPS1 gene

The cDNA of *AnTPS1* was amplified by PCR (*Fig. 1*) and then sequenced (*Fig. 2*). To assess the expression and relevance *AnTPS1* to cold stress in naked oats, we used real-time qPCR to assess its expression within various parts of the naked oats plant. Results showed the *AnTPS1* gene to be most abundantly expressed in the leaves of naked oats, with lower levels in stems, and limited expression in roots (*Fig. 3*). Under low temperature cold stress conditions, the expression of *AnTPS1* changed significantly. The gene expression was significantly increased at 3 h and 6 h. After 6 h, the expression level reached its maximum – roughly twice that of the control plants - and then decreased significantly (*Fig. 4*).

Analysis of AnTPS1 primary structure and physicochemical properties

We predicted and analyzed the amino acid composition and physicochemical properties of AnTPS1, which encodes TPS, using the ProtParam tool available from ExPASy. We found *AnTPS1* to encode a 326 amino acid protein enriched in serine and leucine (8.6% each), and with a low glutamine content (1.8%). The protein formula for AnTPS1 was $C_{1694}H_{2592}N_{448}O_{458}S_{28}$, with 5220 total atoms and a relative molecular weight of 37459.62 Da. The total number of negatively charged amino acid residues (Asp and Glu) and positively charged amino acid residues (Arg and Lys) were 32 and 34, respectively. The theoretical isoelectric point (pI) of this protein was 7.99, leaning towards alkalinity. The extinction coefficients at 280 nm for this protein were 68005 $M^{-1} \cdot cm^{-1}$ when assuming all cysteine residues were from cysteine, and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_72137227

67380 $M^{-1} \cdot cm^{-1}$ when assuming none were. Based on an N-terminal methionine, the estimated half-lives of this protein in mammalian reticular cells (*in vitro*), yeast (*in vivo*), and colibacillus (*in vivo*) were 30 hours, more than 20 hours, and more than 10 hours, respectively. The instability coefficient was 82.55, classifying AnTPS1 as an unstable protein. The fat coefficient of AnTPS1 was 51.90. The total average of hydrophilicity of this protein was 0.052, classifying *AnTPS1* as a hydrophobic protein.

AnTPS1 protein signal peptide, transmembrane domain, and hydrophilicity predictions

Through the measurement of protein shearing sites, signal peptide predictions can categorize the functional domains of proteins and determine their likely subcellular localization. An assessment of AnTPS1 using the SignalP4.1Server yielded a cleavage site score (C-score) of 0.168, a synthetic shearing site score (Y-score) of 0.167, and a signal peptide score (S-score) of 0.248 (*Fig. 5*). These results were consistent with AnTPS1 being a secretory protein containing a signal peptide, suggesting that the resultant TPS protein may be involved with transmembrane transport within cells.

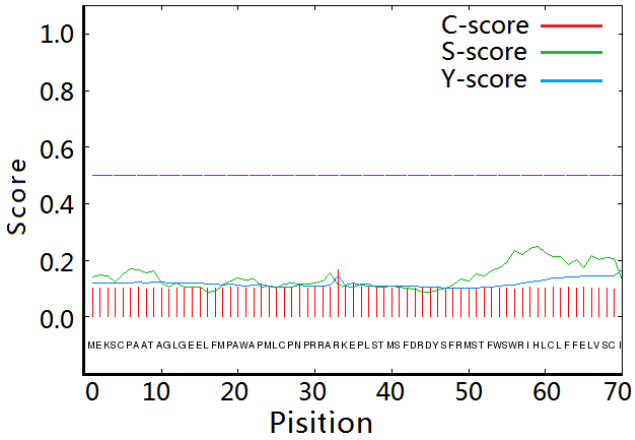

Figure 5. *Signal peptide analysis of the AnTPS1 protein by SignalP 4.1*

Membrane proteins may have extracellular, transmembrane and intracellular domains (Fraihat et al., 2018; Radwan et al., 2018; Saeed et al., 2018; Rajagopalan et al., 2018). Transmembrane regions generally are α-helical structures with hydrophobic amino acids embedded in the cytoplasmic membrane. A transmembrane structure analysis of the *AnTPS1* protein using the TMHMM Server v2.0 revealed that the encoded protein has a transmembrane helix (TMH) with a TMH value of 57.31 (*Fig. 6*). The value of the non-transmembrane helical region (ExpAA) of this protein was 6.41447, consistent with it being transmembrane protein. The probability of the N-terminal domain of the protein locating inside the membrane was 0.2999, and this sequence is typically located outside the membrane, further suggesting that the protein encoded by *AnTPS1* is a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_72137227

transmembrane protein. An analysis of the solubility of the *AnTPS1*-encoded protein via SOSUI revealed that this protein was a membrane protein with two transmembrane helices and a total length of 326 amino acids – slightly longer than the initial prediction. This protein was predicted to be soluble, with an average hydrophobicity of 0.037160.

Amino acid hydrophilicity is the primary force driving protein folding, and it can thus help in the evaluation of secondary structural features such as transmembrane helices and amino acid surface distributions within a given protein (Woldesemayat et al., 2017). The hydrophilicity of the naked oats *AnTPS1* amino acid sequence was predicted using the ExPASY ProtScale tool (*Fig. 7*), revealing the 131st amino acid in the peptide chain to be the most hydrophobic, with a positive score of 3.222; while amino acids 31 and 32 were the most hydrophilic, with a negative score of -2.867. *Figure 4* illustrates that the N-terminal domain of this protein is negative (hydrophilic), while the C-terminal domain is positive (hydrophobic), with fewer hydrophilic amino acids in the overall peptide chain than hydrophobic ones. This suggests *AnTPS1* is a soluble hydrophobic protein.

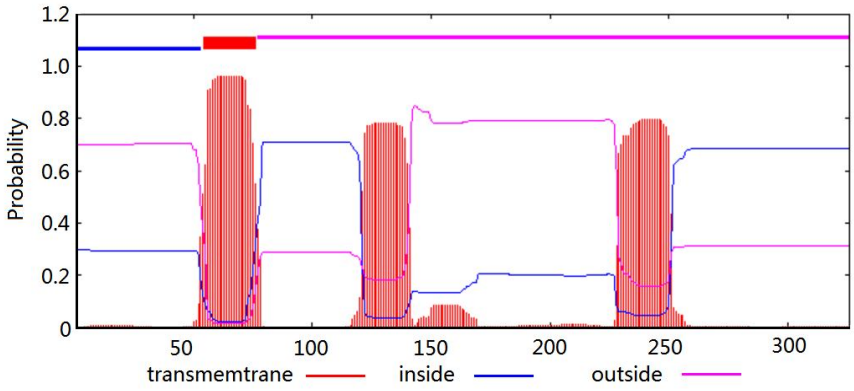

Figure 6. *Transmembrane analysis of the AnTPS1 protein by TMHMM*

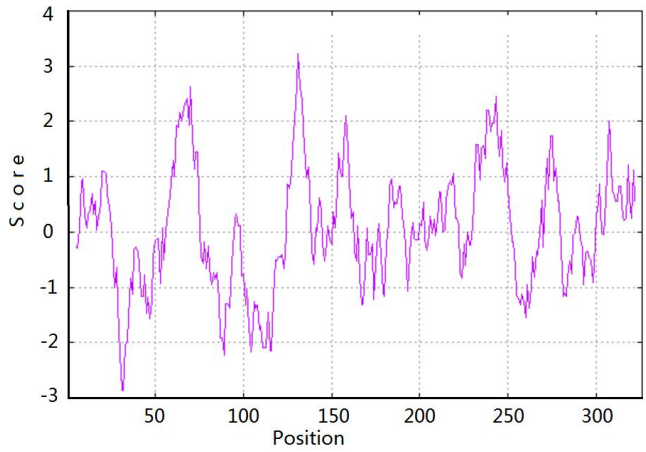

Figure 7. *Prediction of hydrophilicity of the AnTPS1 protein by ProtScale*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

Prediction and analysis of AnTPS1 protein secondary structure and modules

The secondary structure of the AnTPS1 protein was assessed using the SOMPA online prediction program, which predicted 113 amino acid residues in the protein to be, accounting for 34.66% of the overall peptide chain. In total, 63 amino acid residues had an extended chain structure (19.33% of the overall peptide chain), 29 amino acid residues had a β-rotation structure (8.90% of the overall peptide chain), and 121 amino acid residues had an irregular curl structure (37.12% of the overall peptide chain) (*Fig. 8*). The α-helix and irregular crimp were the main structural components of the AnTPS1 protein, contributing to its structural stability (Geourjon and Deléage, 1995). The PredictProtein tool was used to predict the presence of disulfide bonds, none of which were predicted to reside within the resultant protein. Functional sites were analyzed using the PROSITE tool, identifying 11 phosphorylation sites, 2 glycosylation sites, and 5 acylation sites.

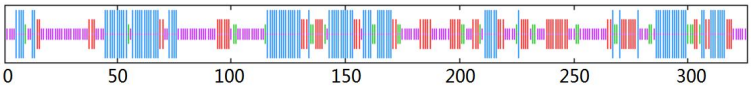

Figure 8. *Analysis of the secondary structure of the AnTPS1 protein by SOMPA. Note: blue represents α-helical, red represents extended strand, green represents β-rotation, purple represents irregular curl*

AnTPS1 protein tertiary structure modeling and binding site prediction

SWISS-MODEL was utilized for homology modeling of this predicted protein (using PyMOL view) (*Fig. 9*), while a Ramachandran evaluation in MolProbity software was employed to evaluate the tertiary structure of the AnTPS1-encoded protein as previously described (Liu et al., 2017). Modeling by the SWISS-MODEL server is based on the A chain of PDB ID 3d79.1, with a sequence consistency value of 20.41%. Ramachandran plot-based evaluation determined that 93.64% (103/126) of amino acid sites are located in the favored region, while 100% (126/126) are located in the permitted region, indicating that the tertiary structure model is accurate and reliable.

Figure 9. *Tertiary structure of the AnTPS1 protein predicted by SWISS-MODEL*

Discussion

Trehalose is a stress metabolite, only accumulating in plants under conditions of stress such as drought, extreme temperatures, and high salinity (Chary et al., 2008). The accumulation of trehalose enhances the protection of proteins, enzymes, and cell membranes, preserving cellular and organismal viability. Trehalose is degraded when the noxious environmental conditions subside (Lunn et al., 2014). The TPS gene is essential for the synthesis of trehalose in plants. Introduction of the exogenous TPS allows for the synthesis of trehalose 6-phosphate (T6P), which is dephosphorylated to form trehalose by a wide range of non-specific phosphatases, making TPS the rate-limiting enzyme for trehalose accumulation (Cai et al., 2009).

TPS is important for glycometabolism, embryonic development, and the response to abiotic stress, making it essential for overall crop development. The TPS gene family has been evaluated structurally, functionally and evolutionarily in rice, Arabidopsis thaliana, poplar, and cotton (Tang et al., 2018). However, similar studies have not been conducted to date in naked oats, despite the notable hardiness of this species and its effective stress resistance, making it an important species in which to study such a key abiotic stress resistance gene. Bioinformatics allow for the detailed prediction and analysis of predicted proteins encoded by particular gene sequences, offering potential insights into the structure and function thereof. Our assessment of the peptide sequence of the AnTPS1-encoded protein revealed the ORF to encode for 326 amino acids without multiple domains. The N-terminal TPS (T6P synthase) domain catalyzes the production of T6P using glucose-6-phosphate and UDP-glucose as substrates, whereas the C-terminal TPP domaindephosphorylates T6P, generating trehalose (Matsuda et al., 2015). The protein formula of AnTPS1 is C1694H2592N448O458S28, with a relative molecular weight of 37459.62 Da and a predicted isoelectric point (pI) of 5.75. The protein is positively charged and leans towards alkalinity. It is a soluble hydrophobic protein containing a signal peptide and transmembrane helix. The α-helix and irregular crimp are the main structural components of the AnTPS1 protein. In a previous study by Tang et al. (2018) in N. lugens, three TPS genes were cloned, and their protein secondary structures contained similar components to those identified in the present study, with α-helices, β-sheets, and random coils. We further verified that the AnTPS1 protein had a signal peptide, consistent with the results of the transmembrane structure analysis. Subcellular localization revealed the AnTPS1 protein to be potentially located in the cytoplasm, which is consistent with a finding by Xu et al. (2017) which revealed that the majority of TPS in Solanum tuberosum may be located in the cytoplasm, with only limited quantities located in the plasma membrane or nucleus. This variation in localization may be dynamic, potentially having a relationship with stress response behavior, although further microscopy-based studies would be needed to verify this hypothesis. The localization of a given protein is closely related to its functional involvement. In assessing the functional domains of the protein encoded by *AnTPS1*, we

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_72137227

identified 11 phosphorylation sites, 2 glycosylation sites and 5 acylation sites without crimp helix domain in the protein. Together, these predictive bioinformatics analyses confirmed that the protein encoded by AnTPS1 is consistent with other published TPS protein sequences and structures, suggesting that such structural homology is likely accompanied by functional homology as well in the context of stress responses.

Analysis of the expression of *AnTPS1* in different tissues of naked oats revealed that this gene is expressed at the highest level in leaves and at the lowest level in roots. This differential expression may be due to differences in developmental differentiation, spatial location, function, metabolic activity, and environmental conditions among these different organs and tissues (Jin et al., 2016). We found that the *AnTPS1* gene was up-regulated by cold temperature stress, indicating it to have an expression pattern consistent with the abiotic stress response to cold and potentially to other factors as well. Thus, *AnTPS1* may play a role in the resistance of naked oats to low temperature stress, as has been found in other studies. Indeed, transgenic plants expressing TPS have increased tolerance to stress (Mu et al., 2016). In Arabidopsis plants, transgenic TPS expression was shown to substantially increase resistance to extreme stress without disrupting normal cellular morphology (Miranda et al., 2007). Despite these promising results, some authors have raised concerns that trehalose expression may be advantageous under stress conditions, but may become deleterious over time, making plants more susceptible to certain plant pathogens and potentially altering growth kinetics (Fernandez et al., 2010). Interestingly, we found that the expression of *AnTPS1* increased substantially under cold stress conditions, before declining at later time points, potentially suggesting that the *AnTPS1* gene from naked oats may be regulated in an optimal fashion that allows it to be acutely expressed as a part of the early stress response, before decreasing expression levels over time to reduce potential adverse outcomes of prolonged expression. Selective expression of comparably regulated proteins in other crops could feasibly offer optimal resistance characteristics without disrupting normal morphology, although more work will be needed to confirm such a hypothesis. In naked oats, the intermediate metabolite T6P catalyzed by the TPS domain may participate in the response to cold stress by acting as signaling molecule, or by catalyzing the production of trehalose which is important for the osmotic regulation of naked oats in response to abiotic stress.

There are limitations to the present study that should be considered. For one, the bioinformatics-based predictive approaches are by their very nature uncertain. While all tools were used as intended, inherent uncertainties in the resultant predicted *AnTPS1* protein structure and localization can result in apparent inconsistencies in its characteristics. Further molecular approaches will be needed to therefore validate its subcellular localization and expression patterns, and to determine whether its localization changes depending on the functional context. In addition, while our *in vivo* assessment of *AnTPS1* expression revealed patterns of expression consistent with a stress response, formal knockout experiments will be needed to fully validate the role of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1703_72137227

this gene in abiotic stress responses in naked oats. Given that naked oats are well-adapted to growth under adverse conditions, and that we observed time-dependent expression of this trehalose-producing gene in response to stress, it is possible that further study of the optimal regulation and expression patterns of this gene will yield further fundamental insights into optimal stress resistance strategies suitable for improving global crop yields.

Conclusion

Ongoing environmental changes and a rapidly increasing global population both necessitate the growth of selectively bred or transgenic crops capable of withstanding serious environmental stress conditions. In this study, we analyzed the expression and bioinformatics analysis of *AnTPS1* gene. *AnTPS1* was upregulated by low temperature. The expression of *AnTPS1* in naked oats represents an important step towards understanding the molecular mechanisms governing the responses of plants to abiotic stressors. While further study will be necessary to validate these results using genetic modifications and molecular imaging approaches, this work represents an important step towards the production of robust and resistant plant species.

Contributions. Wenying Liu and Feng Li conceived and designed the study. Rui Liu, Lizhen Liu, and Yongfang Zhang performed the experiments. Gang Li and Hongxian Tian provided the seeds. Wenying Liu and Jianxia Liu wrote the paper. Runmei Wang, Feng Zhou, and Dongxu Zhang reviewed and edited the manuscript. All authors read and approved the manuscript.
