Abstract. Based on the investigation of the water environment factors and aquatic biodiversity of AiYi River from March to November 2018, 14 indicators were selected from water environment factors and aquatic biodiversity index using principal component analysis to construct the evaluation index system of aquatic ecosystem health of AiYi River. The gray correlative degree method was also used to evaluate the aquatic ecosystem's health condition of AiYi River from March to November 2018. The result showed that the aquatic ecosystem health condition of AiYi River was healthy in March and November, and that was sub-health in May, July, September. The aquatic ecosystem health of AiYi River was in the sub-health state due to the higher content of nitrogen, phosphorus and organic matter.
Keywords: *aquatic ecosystem, principal component analysis, gray correlative degree analysis*

Introduction

Ecosystem health refers to the structural integrity and functional stability of the ecosystem, and the ability of self-maintenance and self-repair. A healthy aquatic ecosystem plays an important role in protecting the water environment and maintaining its normal functions of the water environment. Accurate diagnosis and evaluation of the health status of the aquatic ecosystem has high theoretical and practical significance.

Aquatic ecosystem is a complex large-scale system. It is difficult to diagnose and evaluate the health status of aquatic ecosystem accurately by a single method. At present, the widely used method in the health evaluation of aquatic ecosystem is the index system method (Hossain et al., 2017; Milani et al., 2017; Janssens et al., 2017; Rongrong et al., 2018). A reasonable index system should reflect not only the overall health level of aquatic ecosystems, but also the changing trend of aquatic ecosystem health. The "Clean Water Act" issued by the United States in 1972 holds that maintaining the physical, chemical and biological integrity of the structure and function of river aquatic ecosystems is an important principle for river health assessment (Milani et al., 2017). Obolewski et al. (2019) proposed 16 indicators in 2019, including riparian zone integrity, river bed conditions, fish, aquatic plants, and classified the river health into five grades for evaluation. Some work has been done on the evaluation index system and methods of aquatic ecosystem health in China. Yu et al. (2017) put forward the contents of aquatic ecosystem health evaluation, such as the quality evaluation of biological habitat, hydrological evaluation and the evaluation of biological community. Maloney (2019) put forward the evaluation index system of water quantity, water quality, aquatic organism, physical structure and riparian zone,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1001310025

as well as five evaluation criteria of "very healthy, healthy, sub-healthy, unhealthy and sick". Du et al. (2017) constructed the evaluation index system of aquatic ecosystem health, and used the analytic hierarchy process to evaluate the Luanhe River Basin comprehensively.

Although the index system method can well reflect the health status of aquatic ecosystems well, selecting reasonable indicators to construct the evaluation index system has not yet formed a recognized theoretical system and methods. In this study, the principal component analysis method was used to screen the candidate indicators for the health assessment of the Aquatic Ecosystem of Aiyi River, construct the evaluation index system, determine the weight of the corresponding indicators, and use the grey correlation method to evaluate the health status of the Aquatic Ecosystem of Aiyi River comprehensively, in order to provide some basis for the restoration of the Aquatic Ecosystem of Aiyi River and the comprehensive prevention and control of water pollution.

Materials and methods

Research area

Ningxia is short of water resources, arid and windy, and vegetation is scarce, which determines that its environmental capacity is small, the stability of ecosystem is poor, and the water environment is vulnerable to pollution and destruction. At present, the water environment situation in Ningxia is severe, and the regional water environmental pollution has become one of the biggest environmental problems. Aiyi River is the key project of river-lake system connection in Yinchuan City. It is the key water conservancy project of autonomous region integrating flood control, drainage, ecology and landscape. It is a National Water Conservancy Scenic spot. It has important social significance and far-reaching history for improving flood control and drainage conditions, Regulating Groundwater level, beautifying human settlement environment, upgrading urban grade, realizing human-water harmony and social harmony in Yinchuan City. Significance. The total length of Aiyi River is 158.5 km, the water surface is more than 50,000 mu, and the drainage area is controlled at 1.75 million mu. The main source of water is flood, Gully Water and channel discarded water. The amount of water that can be reused in the upper reaches of Aiyi River reaches 51 million m3 every year, of which farmland drainage accounts for 68.9%, rich in nitrogen and phosphorus nutrients. Agricultural and rural non-point source pollution in irrigation area is becoming the basic restrictive factor of the water quality of Aiyi River, and the backwater pollution in irrigation area with farmland as the core is becoming the main pollution source affecting the water quality of Aiyi River. Due to the large input of exogenous nutrients, the water exchange between rivers and lakes is weak, which makes the water body of Aiyi River tend to eutrophication gradually.

Screening of comprehensive assessment indicators of aquatic ecosystem health in Aiyi River

Composition of candidate index system

According to the results of factor analysis of water environment of Aiyi River, the main factors affecting water environment of Aiyi River are total phosphorus (TP), electrical conductivity (EC), ammonia nitrogen (NH3-N), total nitrogen (TN),

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1001310025

permanganate index (CODMn), five-day biochemical oxygen demand (BOD5), suspended solids (SS), transparency (SD), chlorophyll a (Chl.a), so this paper determines these nine physical and chemical indicators as love. Candidate indicators of comprehensive evaluation index system of aquatic ecosystem health of Yihe River. Biological indicators include phytoplankton biomass, phytoplankton Shannon-Wiener index (H'_a), zooplankton Shannon-Wiener index (H'_b), benthic animal Shannon-Wiener index (H'_c), aquatic plant Shannon-Wiener index (H'_d), and sediment heterotrophic bacteria. At the same time, the comprehensive trophic status index ($TLI_{(\Sigma)}$) which can reflect the eutrophication characteristics of water body is selected. The above indicators together constitute the candidate indicators of the Aiyi River aquatic ecosystem health evaluation index system.

Indicator screening method

Principal component analysis was carried out for each index value of Aiyi River in March, May, July, September and November 2018. The factor load matrix was rotated by maximum variance orthogonal rotation method. The principal component was extracted according to 85% cumulative variance contribution rate. Then, the index with load value greater than 0.6 after rotation was selected as the index for evaluating the health attributes of Aiyi River (Boltovskoy, 2017).

Determination of weight of evaluation index system

The above selected indicators constitute an index system for evaluating the health attributes of Aiyi River, and then the principal component analysis is carried out. The eigenvalues of principal components, the contribution rate of variance and the load value of factor after rotation are obtained. According to the 85% cumulative variance contribution rate, four principal components are extracted. According to the corresponding eigenvalues and contribution rate of variance of the four principal components, the weight of the index can be calculated (David et al., 2017; Łuczyńska et al., 2018). The calculation formula is as follows:

$$W_i = \sum_{j=1}^{k} \left| a_{ij} \right| \bullet E_j \qquad \text{(Eq.1)}$$

In the formula, a_{ij} is the factor score coefficient (eigenvalue) of factor i in the j principal component, that is the contribution of factor i to the j principal component; E_j is the contribution rate of the principal component to the variance; W_i is the weight value of factor i. Then the weights of each evaluation factor can be obtained by normalizing the W_i.

Determination of evaluation standard system

Referring to "Standard for Surface Water Environmental Quality" (GB 3838-2002) (Gdara et al., 2018) and Hyun et al. (2017), Boltovskoy (2017) and Xiao-Yun et al. (2018), the evaluation standard system of Aquatic Ecosystem Health of Aiyi River was established, which was divided into five evaluation levels: very healthy, sub-healthy, unhealthy and morbid (*Table 1*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1001310025

Table 1. *Classification of health assessment standard system*

Grade	Very healthy	Healthy	Sub-healthy	Unhealthy	Morbid
Meaning	The structure and function of aquatic ecosystem are complete and balanced, the flow of substance and energy is smooth, the vitality and resilience are very strong, and the health condition is very good	Aquatic ecosystems maintain a dynamic balance, strong vitality, reasonable structure, coordination, strong resilience and good health	The structure of aquatic ecosystem has changed, its function has declined, its ecological quality has declined, its vitality and resilience are general, and its health status is general	Aquatic ecosystems are deteriorating further, with weak vitality, inconsistent structure, poor resilience and poor health	Aquatic ecosystem deteriorates seriously, its vitality is very weak, its structure is completely unreasonable, its resilience is very poor, and its health is very poor

Health grade assessment of aquatic ecosystem in Aiyi River

The health grade of Aiyi River was evaluated by grey correlation method. Taking health standard grading as comparison series, the measured values of each index are reference series, and the correlation degree between monthly and annual average values and health levels is calculated. The health level of water body in each period is judged by the magnitude of correlation degree (Boltovskoy, 2017; Fleming et al., 2002).

The evaluation steps are as follows (Boltovskoy, 2017; Fleming et al., 2002):

(1) Normalize the evaluation month and the index values of the evaluation criteria;

(2) Calculate the absolute difference between the normalized index value and the corresponding evaluation criteria of five evaluation grades [$\Delta_{ik}(j)$].

(3) Find out the minimum absolute difference [$\Delta\min$] and the maximum absolute difference [$\Delta\max$] between all indexes and five evaluation grades.

(4) The correlation coefficients [$\varepsilon_{ik}(j)$] between the five-month and annual average values of each index and the corresponding evaluation criteria were calculated by taking the resolution coefficient p = 0.5.

$$\varepsilon_{ik}(j) = \frac{\Delta\min + \rho\Delta\max}{\Delta_{ik}(j) + \rho\Delta\max} \quad \text{(Eq.2)}$$

(5) According to the weight value of each index, the grey correlation degree (γ_{ij}) between the monthly and annual average and the five evaluation grades was calculated.

$$\gamma_{ij} = W_i \varepsilon_{ik}(j) \quad \text{(Eq.3)}$$

(6) According to the principle of maximum membership degree, the average health grade of 5 months and the whole year was evaluated.

Results

Selection of health assessment indicators for aquatic ecosystem of Aiyi River

Four principal components were extracted according to 85% cumulative variance contribution rate (*Table 2*). Fifteen factors were selected according to the principle that the factor load value was greater than 0.6. However, the number of heterotrophic bacteria in sediment has not been reported as an indicator of aquatic ecosystem health assessment. The evaluation criteria are uncertain, so 14 factors such as SS, EC, COD_{Mn}, BOD_5, TN, NH_3-N, TP, Chl.a, $TLI_{(\Sigma)}$, phytoplankton biomass (D), phytoplankton H'_a, zooplankton H'_b, benthic animal H'_c, and aquatic plant H'_d, are identified as the indicators for the health evaluation of the Aquatic Ecosystem of Aiyi River (see *Table 3*).

Composition and weight of health evaluation index system for aquatic ecosystem of Aiyi River

Fourteen health assessment factors of Aquatic Ecosystem of Aiyi River, including SS, EC, COD_{Mn}, BOD_5, TN, NH_3-N, TP, Chl.a, $TLI_{(\Sigma)}$, phytoplankton biomass (D), phytoplankton H'_a, zooplankton H'_b, benthic animal H'_c, and aquatic plant H'_d were screened and analyzed by principal component analysis. According to the analysis results (*Table 4*), the weights of each evaluation index were calculated, and the weights of 14 indicators were summed up. The normalized weights of each index can be obtained by dividing the weights of each index by the sum of weights (*Table 5*).

Standard system for health assessment of aquatic ecosystem in Aiyi River

The classification standard of physical and chemical indexes of water body is based on "Surface Water Environmental Quality Standard" (GB 3838-2002). Five grades of very healthy, healthy, sub-healthy, unhealthy and sick correspond to I, II, III, IV and V water standards respectively. The classification standard of suspended solids (SS) and conductivity (EC) is determined by reference (Boltovskoy, 2017).

According to the relevant provisions of the "Evaluation Method of Eutrophication of Lakes (Reservoirs) and Technical Regulations for Classification" (Yang et al., 2019; Ochoa-Rivero et al., 2017; Sorokovikova et al., 2017), the comprehensive nutritional status index N = 50 is medium nutrition, which is regarded as sub-health level, N < 30 is poor nutrition, which is very healthy level, N > 70 is severe eutrophication, which is morbid level, 30-50 is health level, 60-70 is unhealthy level.

The Shannon-Wiener diversity index (H') of phytoplankton, zooplankton, benthic and aquatic plants reflects the diversity of community species. The value of H'(0-1) is eutrophic, 1-3 is mesotrophic and more than 3 is poor nutrition (Kozlov et al., 2017). Accordingly, 2-3 is considered as sub-health grade, 4 is considered as very health grade, H'(1) is considered as morbid grade, 3-4 is health grade, 1-2 is unhealthy grade.

According to the relevant evaluation criteria of lake eutrophication in China (Suzuki et al., 2018), phytoplankton biomass < 3 mg L^{-1} is a poor nutrition type, which is regarded as very healthy and healthy grade. 3-5 mg L^{-1} is a middle nutrition type, which is regarded as sub-health grade, 5-10 mg L^{-1} as eutrophic type, which is unhealthy grade, and > 10 mg L^{-1} as extremely eutrophic type, which is a morbid grade.

Health grade assessment of aquatic ecosystem in Aiyi River

Taking the annual average index of Aiyi River as an example, the correlation degree between each evaluation index and evaluation standard grade was calculated (*Table 7*). The results of the difference calculation are shown in *Table 8*, and the correlation coefficient and correlation degree are shown in *Tables 9* and *10*.

The correlation between each month and the grade of evaluation criteria is calculated in *Table 11*. From *Table 11* we can see that the evaluation results of the Aiyi River in March and November are healthy, the evaluation results in May, July and September are sub-healthy, and the overall evaluation of the health status of the Aiyi River aquatic ecosystem is sub-healthy.

Conclusion

Health evaluation index of aquatic ecosystem in Aiyi River

The evaluation index of Aquatic Ecosystem Health of Aiyi River is mainly composed of four parts: The first part includes the factors of phytoplankton biomass (D), phytoplankton H'_a, zooplankton H'_b, benthic animal H'_c and aquatic plant H'_d which are the comprehensive reflection of the diversity and integrity of aquatic ecosystem structure, and the most important part of the evaluation index of aquatic ecosystem health. The second part includes SS, EC, Chl.a and $TLI_{(\Sigma)}$ which mainly describe the content of suspended solids and dissolved salts in water. The third part includes TN, NH_3-N and TP, which mainly describe the composition and content of nitrogen and phosphorus nutrients in water. The fourth part includes COD_{Mn} and BOD_5 which mainly describe the content of organic matter in water. The above indicators cover the main water quality factors such as suspended matter, dissolved salts, nutrients and organic matter, which can fully reflect the water environment quality of the Aiyi River. Biological indicators include phytoplankton biomass (D), phytoplankton H'_a, zooplankton H'_b, benthic animal H'_c, and aquatic plant H'_d which are comprehensive reflections of the structural diversity of aquatic ecosystems. In the process of research,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1001310025

due to the lack of microbial research results, microbial indicators can not be included in the evaluation index system, and further in-depth and systematic research is needed to further improve the theory and methods of aquatic ecosystem health assessment.

Health status of aquatic ecosystem in Aiyi River

The contents of S S, CODMn, BOD5, NH3-N, TN and TP in Aiyi River in May, July and September were significantly higher than those in March and November, indicating that the contents of nutrients and organic matter in the water body of Aiyi River were higher in May, July and September, and the pollution degree of the water body was higher. The reason was that a large amount of organic matter and nutrients entered the water body due to the large amount of water recharge in the three periods. At the same time, under the high nutrient and high temperature environment, cyanobacteria multiply in large quantities, forming dominant species, inhibiting the growth of other phytoplankton species, decreasing phytoplankton diversity, increasing chlorophyll a content, phytoplankton density and biomass, resulting in serious impacts on the structure of the aquatic ecosystem and functional degradation of the Aiyi River, so the health status in May, July and September is worse than that in March and November. To be poor, in a sub-health state. $TLI_{(\Sigma)}$ indicates the degree of eutrophication of the water body. The $TLI_{(\Sigma)}$ in July and September of the Aiyi River is higher than that in March and November. It also shows that the water body of the Aiyi River has been moderately polluted, in a state of medium eutrophication, and its health has declined. In addition, the community structure of aquatic plants and benthic fauna in Aiyi River is not balanced and the diversity is low. The natural succession rate of aquatic plants and benthic fauna in Aiyi River can not adapt to the pressures of exogenous pollutants, and the inadequate ability to degrade nitrogen, phosphorus nutrients and organic matter is also an important reason for the sub-health of the aquatic ecosystem in Aiyi River.

The water source of Aiyi River is mainly farmland recession with high nutrient and organic matter content, which is the main cause of water pollution of Aiyi River. The aquatic ecosystem is greatly affected by external stress factors, resulting in sub-health of the overall health of the aquatic ecosystem of Aiyi River. The comprehensive evaluation results also reflect the water environment characteristics of the aquatic ecosystem of Aiyi River comprehensively. According to the results of health assessment of aquatic ecosystem, the prevention and control of water pollution in Aiyi River should mainly focus on reducing the content of exogenous nutrients and organic matter, rebuilding and restoring aquatic ecosystem, ensuring its structural integrity and functional stability.

The health status of river aquatic ecosystem varies greatly in different time and space scales. Based on the actual monitoring data in 2018, the health status of Aiyi River aquatic ecosystem is preliminarily evaluated. In the future, the characteristics of aquatic plant community, the characteristics of algae community and its diversity index, biological integrity index and comprehensive quality evaluation index of habitat need to be strengthened. In order to further improve the theory and method of river aquatic ecosystem health assessment, we should strengthen the observation of long time series aquatic ecosystem in different water periods.

Abstract. The marine clastic rock of the Silurian in the Tabei Area is a favorable reservoir. Based on an analysis of geological data such as core, logging, and seismic information, this study investigated the characteristics and differences of the Silurian rocks in the Tabei area main sedimentary system types. Both tidal flat and littoral have been meticulously depicted. In addition, the paleogeographic environment and depositional evolution features of the Silurian rocks in this area have been remodeled. The obtained results show that: (1) according to the difference in sedimentary environment, tidal flat facies have been subdivided into shallow tidal flat and bay tidal flat. (2) During the Early Silurian stage, the center-western region of the study area developed an incised channel with curved characteristics, which was associated with the coastal plain. (3) The whole Silurian deposition was significantly controlled by tectonic movement. Consequently, under the background of Late Caledonian orogeny, the Tabei area was gradually uplifted, and its depocenter constantly migrated southward. This resulted in the vertical transformation of sedimentary types from an incised channel-coastal plain-shallow tidal flat system to a littoral-bay tidal flat system. Moreover, Backshore and supratidal zone were generally denuded due to uplifting at a later stage.
Keywords: *sedimentary facies, marine clastic rock, Kepingtage formation, stratigraphy, coastal plain*

Introduction

The Tabei Area is located in the northern parts of the Tarim Basin and includes the Halahatang Sag, the Akekule Uplift, the Caohu Sag, and the Shaya Uplift. Vertically, Silurian strata are divided into three formations, namely the Kalpintake formation (S_1k), the Tataiertage formation (S_1t), and the Yimugantawu (S_2y) formation from low to upper levels. In particular, the Yimugantawu formation was missing because it was denuded during the early Hercynian movement. Moreover, Kalpintake formation was subdivided into three parts, which are the lower part of the Kalpintake formation (S_1k^1), the middle part (S_1k^2), and the upper part (S_1k^3) (*Fig. 1a, b*).

During the Late Caledonian movement, sedimentary the facies of the Silurian in the Tabei area was controlled by factors such as constant uplifting and multiple cycles of increasing and descending sea level (*Fig. 1c, d*). With constant discoveries of oil and gas reservoirs, marine clastic rocks as favorable reservoirs developed in the Silurian formations, have attracted the attention of experts and scholars.

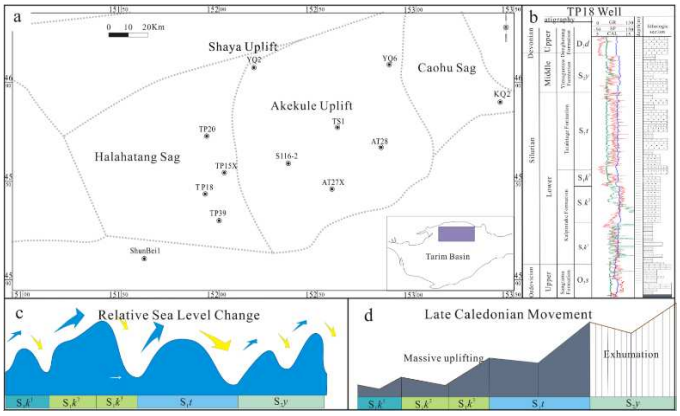

Figure 1. *Tectonic setting and stratigraphic characteristics in the Tabei area*

In recent years, the study of sedimentary facies of marine clastic rocks has achieved significant progress both in China and internationally. For example, Yamashita et al. (2009) analyzed the coefficient of variance (CV) of grain-size distribution and reported the three-dimensional distribution of the tidal flat sand body in the estuary of the Chlamara River. Tillmann and Wunderlich (2014) combined the ground penetrating radar (GPR) with sedimentology and defined different coastal environments of southern Sylt, an island in the North Sea. Zhao et al. (2015) proposed the use of grain-size-sensitive indicators to identify sedimentary facies in a study of modern tidal flat sediments. Gong et al. (2018) studied the relationship between the evolution of tidal channels and the changing sea level. In combination, these studies offer a new way of thinking for the study of marine clastic rocks. Furthermore, many studies have investigated the sedimentary characteristics and the depositional systems of the Silurian in the Tarim Basin. For example, Hu et al. (2007), Jiang et al. (2009), Liu et al. (2016), and Zeng et al. (2018) all suggested that the Tarim Basin developed a barrier-free clastic littoral, offshore shelf, tidal flat, and river delta during the Silurian. Niu et al. (2013) studied the sediment source. Liu et al. (2016) studied the palaeogeomorphology evolution during the Silurian in the Tarim Basin. On the one hand, it is important to clarify sedimentary characteristics, the underlying system, and its evolution, as these still remain poorly understood, which restricts the exploration and research of oil and gas resources resources. On the other hand, previous research typically focused on the description of sedimentary facies and their characteristics (El-Wahed, 2010; Guilbaud et al., 2012; Zhang et al., 2012; Zhang, 2014; Zhang, 2017). However, they ignored the relationship between the transformations of different sedimentary facies and the influence of tectonic movement. At present, the main questions are as follows: (1) What are the differences between the sedimentary characteristics of both shallow tidal flat and bay tidal flat under different depositional environments? (2) What are the sedimentary characteristics and distributions of the coastal plain and its incised channel? (3) How can different facies transform from one form to the other? The results of this study provide answers for these questions which offer a solid geological basis for further oil and gas exploration and their development.

Materials and methods

The utilized geological data contains 137 core sample photos of Silurian rocks, logging data, and seismic profiles, which were provided by the Sinopec Group Northwest Petroleum

Branch. The analysis is based on core observations, identification of sedimentary facies markers, analysis of single well, and interpretation of logging and seismic information. The aim was to define the different types of sedimentary facies and both its subfacies and microfacies. Through seismic profiles information, the sedimentary distribution was determined. Then, the distributions were combined with the tectonic evolution process to identify the depositional filling process and sedimentary systems in each period of the Silurian age.

Results

Sedimentary types and characteristics

In the study area, Silurian formations mainly deposited marine clastic rocks, developed tidal flat facies, littoral facies, coastal plain facies, and neritic shelf facies.

Tidal flat facies

Silurian formations in the Tabei area ware distributed as a clastic tidal flat. During the Early-middle Silurian period, the lower part of the Kalpintage (S_1k^1) extensively developed the shallow water tidal flat facies, while the upper part (S_1k^3) locally deposited the Bay tidal flat facies. Their subfacies are intertidal zone and subtidal zone. Furthermore, its microfacies include mud flat, mixed flat, sand flat, tidal channel, and tidal sand bar.

Shallow tidal flat facies

The shallow tidal flat facies is distributed throughout the lower part of the lower Silurian Kalpintage formation in the Tabei area. During the early Early Silurian period (S_1k^1 sedimentary period), a small-scale uplift of the terrain under the late Caledonian movement resulted in a stable subsidence. It is worth mentioning that the sedimentary environment at that time in the study was a wide epicontinental sea without barrier. The waves were weakened due to the particular environment with shallow water and gentle slope. As a result, the area widely developed shallow tidal flat facies, which directly contacted the neritic shelf, forming a widely distributed shallow sea shelf contact.

The log curve and seismic profile of the AT27X well provides the natural gamma (GR) curve of the shallow tidal flat in the lower part of the formation and shows the median value and the dentate type (*Fig. 2a*). The seismic reflection structure consists of two types: low continuity and middle amplitude as well as high continuity and middle-high amplitude. The shallow tidal flat facies above the Ordovician system shows the retrogradation progress and reflects the rise of the sea level (*Fig. 2b*).

Bay tidal flat

In contrast, bay tidal flat facies is locally distributed in the upper part of the Kalpintage formation (S_1k^3) and the Tataiertage formation (S_1t) of the lower-middle Silurian in the Tabei area. With the sustained enhancement of late Caledonian movement during the Early-Middle Silurian period, except the eastern and western region, the study area was subjected to rapid uplifting and formed a steep slope. At the same time, waves were significantly strengthened. However, the eastern and western

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1002710035

areas featured by no obvious barrier bay, which could have obstructed wave formation and thus boosted tidal shifts. The facies contacted the shelf or upper nearshore.

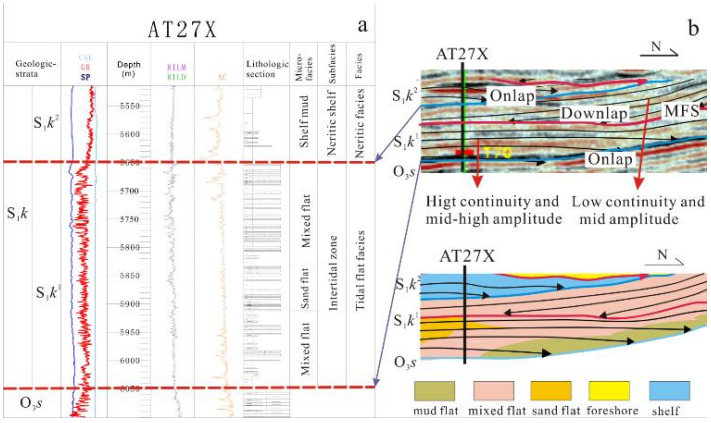

Figure 2. *Geophysical response characteristics of shallow tidal flat in the AT27X well*

Furthermore, the shallow tidal flat has a relatively high shale content. Its mud flat is well developed and other microfacies contain mixed flat, sand flat, and tidal bar. Especially the tidal channel is little developed. The mud flat consists of grey-green grey mudstone and silty mudstone (*Fig. 3a*). The mixed flat has an unequal thickness, is interbeded with fine sandstone and mudstone, and developed both tidal bedding and cross bedding (*Fig. 3b, c, d*). The lithology of the sand flat consist of gray-green gray fine litharenite with separation, cross bedding, and oblique bedding (*Fig. 3e*).

Because the strong uplift led to a rapid decrease of relative sea level, rocks of the bay tidal flat facies contain less muddy sediment but more sandy depositions, which differs from shallow tidal flat. It includes grey-green grey brown sandstone, reflecting the weak reduction/weak oxidation sedimentary environment. Its tidal channels are well developed and other microfacies include mixed flat, sand flat, and tidal sand bar, but no mud flat.

Then, the characteristics of the tidal channel lithology contains comparatively rough granularity with poor separation. Furthermore, the fine-coarse litharenite is visible. Sandy, argillaceous, and lime conglomerate developed at the bottom, with many erosion and truncated surfaces, and the fine gravelly deposit (*Fig. 3f, g, h*).

Littoral facies

Under the background of late Caledonian movement during the Early-Middle Silurian period, the central part of the Tabei area was greatly uplifted and became steep. Consequently, the hydrodynamic wave force was greatly strengthened. As a result, the upper part of the Kalpintage formation (S_1k^3) and the Tataaiertage formation (S_1t) developed littoral deposition.

In general, the facies have three main features in common: (1) as the near source deposits, the have a general composition and structural maturity; (2) the foreshore and nearshore developed, while backshore lacked. According to the lithologic difference of nearshore, the latter can be subdivided into an upper shoreface and a lower shoreface; (3) sand bodies were characteristic by acceleration progradation and reverse cycle due to the rapid descending of the relative sea level.

DOI: http://dx.doi.org/10.15666/aeer/1704_1002710035

The lithology of foreshore contains gray and green-grayish medium-fine grained lithic quartz sandstone, with bidirectional cross bedding, oblique bedding, parallel bedding, and bottom scour upgrowing (*Fig. 3i, j, k*).

Due to the strong hydrodynamic force at the upper shore face, the lithology contains grey-grey green fine sandstone and gritstone. Parallel bedding and plate cross bedding developed (*Fig. 3l, m, n*). However, the lower part shore face, with its lower water hydrodynamic condition, is mainly composed of grey fine sandstone and siltstone with few gray-green gray silt and silty mudstone. The sandstone shows parallel bedding and striped argillaceous (*Fig. 3o, p*).

Coastal plain

The coastal plain and its incised channels formed during the early Early Silurian period (S_1k^1 sedimentary period), and were distributed throughout the Tuopu district, central Tabei. Two main channels developed (*Fig. 4a*) whose lithology consisted of gray black fine grain lithic quartz sandstone and gray black mudstone with part of silty sand and a large number of brachiopoda. It showed characteristics of high value box type, bell type + funnel type, and bell type + box type of the GR curve (*Fig. 4b*). The seismic event of the channel through process of erosion and filling can be distinguished as incised valley and the seismic response is a strong amplitude and a medium continuous reflection *(Fig. 4c*).

Discussion

Depositional filling process

During the early Early Silurian period (S_1k^1 sedimentary period), the sedimentary center was located in the northeast of the study area. The uplift was not obvious, which led to a wide sedimentary range with great thickness. The shallow water tidal flat developed (*Fig. 5a*).

During the period of the middle part (S_1k^2 sedimentary period), the sea level rapidly rose, a large-scale transgression occurred, the sedimentary center moved southward, and the neristic shelf facies (*Fig. 5b*) developed. During the period of the upper part (S_1k^3 sedimentary period), the tidal flat and littoral developed, including sand flat, sandy foreshore, upper of shore, and the lower member (*Fig.5c*). The depositional period of the Tataaiertage formation (S_1t sedimentary period) is mainly dominated by both tidal flat and littoral deposits (*Fig. 5d*).

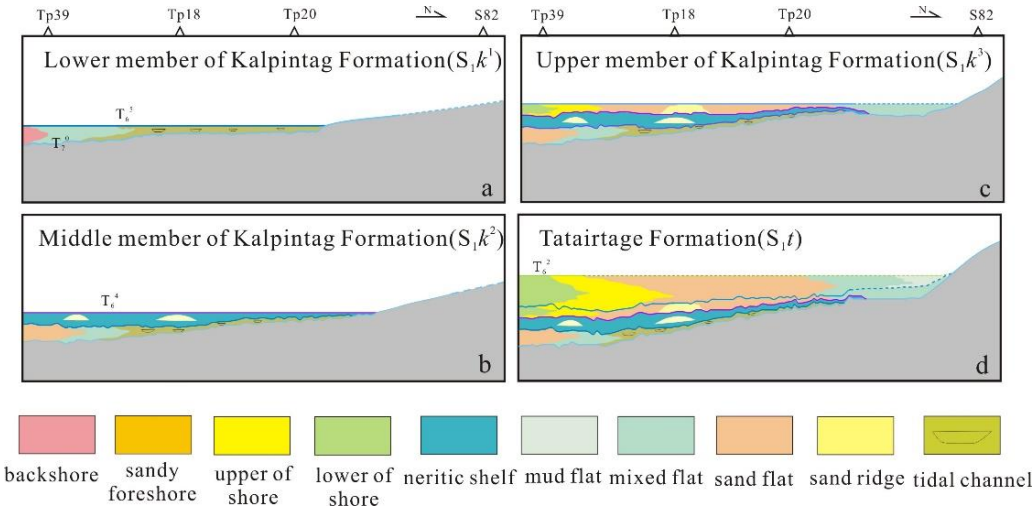

Figure 5. *Filling progress of Silurian sedimentary facies in the Tabei area*

Sedimentary system and depositional evolution

In the lower part of the Kalpintage formation of the Early Silurian age (S_1k^1 period), the uplift is not significant in the study area. This is a broad epicontinental sea sedimentary environment that features shallow water, gentle slopes, and wide intertidal zones, which results in weak wave action and the wide development of the shallow water clastic rock tidal flat. As a result, it is characterized by the shallow water tidal flat-coastal plain-incised channel depositional system. The tidal flat is stably distributed in east-west direction along the coast, developing sedimentary microfacies of mud flat, mixed flat, and sand flat, which reflects the gradual weakening of tidal hydrodynamic forces from sea and coast. In addition, the mud flat is thin due to erosion caused by the later-stage uplifting. The development of coastal plain deposits in the Tuopu area features two main channels and outwards into tidal flat facies (*Fig. 6a*).

During the middle part, the tectonic movement resulted in a slight uplift (S_1k^2 period). At the same time, the sea level rose rapidly, large-scale transgression occurred, and the sediment center migrated southward, which led to the development of the neritic shelf facies in most areas and sand ridges in part of the areas (*Fig. 6b*).

In the upper part (S_1k^3 period), the uplifting and topography variation of the Tabei area is more obvious. The center area is raised and the slope increased, which strengthened the wave action. The near source littoral facies developed. However, the relatively gentle slope and the shading of the bay weakened the action of the waves in the west and east area, which is dominated by bay tidal flat facies. Therefore, the Tabei area developed a bay tidal flat-littoral depositional system *(Fig. 6c*).

During the sedimentary period of the Tataaiertag formation of the Middle Silurian age (S_1t period), the area inherited the geomorphic features of the upper part and the sedimentary center continued to migrate southward. At the same time, the bay tidal flat-littoral depositional system developed (*Fig. 6d*).

Conclusion

(1) The Silurian tidal flat in the study area can be divided into shallow tidal flat and bay tidal flat. The shallow tidal flat is located in the barrier-free and wide epicontinental sea during the stable subsidence period. This is characterized by extensive distribution and high mud content, among which, the mud flat developed very well, but the tidal channel did not develop; distribution in the bay area without obvious barrier during the period of rapidly declining sea level, thus limiting the bay tidal flat. The sand content of rocks is high and the tidal channel developed.

(2) During the Early Silurian period (the S_1k^1 period), the coastal plain and its incised channels in the central-western regions of the study area were characterized by the incised valley shape of the seismic profile, and the high amplitude and medium continuous reflection.

(3) The Silurian deposit is controlled by the late Caledonian movement. The Tabei area continues to rise and the sedimentary center moves southward. The depositional system is transformed from an incised channels-shallow tidal flat system to a littoral-bay tidal flat system. Among these, the backshore and the upper tidal zone are generally denuded by the late uplifting.

This research identified the Silurian strata sedimentary characteristics and how they evolved in the Tarim Basin, which provides a basis for further research. In addition, this paper discussed a previously ignored relationship between transformations of different sedimentary facies and the influence of the orogeny of the Late Caledonian. The next step will be to semi-quantitatively determine the relationship between tectonic movement, the changing sea level, and the depositional filling process to establish a relationship model between the depositional filling process and the changing sea level under this specific tectonic setting.

Abstract. Accurate and rapid assessment of soil salinity is a prerequisite for monitoring and management of soil salinization. Electromagnetic induction technology (EMI) has been broadly applied for scientific research and soil salinity monitoring. In this study, the path analysis method was used to analyze the influence of the soil properties of different soil layers and groundwater (GW) characteristics on apparent electrical conductivity (ECa) values measured at different heights of an EM38. The results showed that for all soil layers, the standard electrical conductivity of a saturated soil extract (ECe) was the most important factor affecting ECa measured at different heights. Both soil moisture content and GW characteristics (GW depth, GW conductivity) had an obvious effect on ECa, whereas the soil clay content had little effect. The reliability of ECe prediction models for different soil layers was improved to various degrees by the addition of soil water content and GW characteristics as auxiliary factors. The ECe prediction model was validated with the coefficient of determination (R^2) between the predicted and measured ECe values of each layer reaching more than 0.70. The ECe prediction model can be used to accurately estimate any unsampled points in a study area.

Introduction

Soil salinization is a global problem, affecting more than 930 million hectares of land, and the extent of the problem continues to increase (Rengasamy, 2006). High evaporation rates in arid and semi-arid areas increase the problem of soil salinization (Butcher et al., 2016; Li et al., 2014). Soil salinization negatively affects soil quality and sustainable agricultural development (Cassel et al., 2015). Land areas that are potentially impacted by soil salinization remain important resources for agricultural development. The key strategy to ensure the development and utilization of such land resources lies in the development of accurate and rapid soil salinity assessment and measurement techniques (Kasim et al., 2018; Abdu et al., 2007; Yao et al., 2010; Singh, 2018). At present, electromagnetic induction (EMI) is the most important and broadly-applied scientific method for measuring and assessing soil salinity. EMI is used to measure soil apparent electrical conductivity (ECa) to predict the salt content of the soil profile (Heil and Schmidhalter, 2017). Based on the existing research results, soil salinity (Dakak et al., 2017; Scudiero et al., 2016; Aboelsoud and Abdel-Rahman, 2017), soil moisture (Hossain et al., 2010; Huang et al., 2018), soil clay content (Doolittle et al., 2002; Triantafilis and Lesch, 2005), cation exchange capacity (Triantafilis and Santos, 2010; Suddth, 2005), organic matter content (Martinez et al., 2016; Bekele et al., 2005), soil temperature (Brevik et al., 2004), soil compaction

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1003710057

(Krajco, 2007) and other major physical and chemical properties of the soil have an impact on its ECa. Therefore, the major factors affecting EMI of areas with different in soil properties differ considerably.

EM38 is a tool for rapid determination of ECa (McNeill, 1980). The assessment of soil salinity using ECa should be calibrated relative to the standard electrical conductivity of a saturated soil extract (ECe). Many scholars have used the EM38 to determine ECa to quantify and monitor soil salinity in arid and semi-arid irrigated agricultural areas (Jadoon et al., 2015; Ding and Yu, 2014; He et al., 2018). In the aforementioned research, almost all other soil physical and chemical properties were considered to be uniform; however, in the actual investigation process, the measurement accuracy of EM38 was often reduced due to uneven irrigation and differences in soil texture. A soil survey by Lesch and Corwin (2003) concluded that minimum water content should be at least 65% of the total capacity whenever possible. However, in arid and semi-arid regions, limited rainfall and irrigation water usually result inlarge differences in soil water (SW) content between plots. Therefore, the establishment of a calibration relationship between ECa and ECe depends on the soil type under specific field conditions and moisture status. In addition, the soil ECa increases with increasing clay content due to the fact that the clay content affects electromagnetic conductivity, whereas on the other hand soil clay content is closely related to cation exchange capacity (CEC) (Triantafilis and Lesch, 2005; Sudduth et al., 2005). In addition, partially exchangeable ions can produce ionic conductance, thus affecting ECa, and studies have shown that the variability of ECa conversion to ECe is greater in coarse-grained soils than in medium or fine-textured soils (McKenzie, 1993).

There have been many studies of the effects of SW content and soil salinity on ECa (Hanson and Kaita, 1997; Bennett et al., 2000; Wittler et al., 2006; Jiang et al., 2017). The results have shown that there is a linear relationship between SW content and ECa (Hanson and Kaita, 1997). ECa readings vary considerably with changes in SW content. Norman (1990) demonstrated that for clay soils, the water content of the soil profile should be greater than 20% to accurately obtain soil salinity values from the observed ECa data. Rahimian and Hasheminejhad (2011) found that the regression equation between ECah (horizontal mode) and ECav (vertical mode) and soil salinity obtained in the field with SW content of 35% was more reliable. Silberstein et al. (2007) found a significant correlation between ECa and groundwater (GW) level and GW conductivity ($R^2 = 0.75$, $P < 0.001$). Mankin and Karthikeyan (2002) conducted research in the central and mid-south regions of Kansas, USA to distinguish between the saline exudation zone and non-exudation zone and assessed the extent of saline exudation by means of ECa measured by EM38.

In summary, although the relationship between soil ECe and ECa is reliable, the factors affecting different regions and different soil layers (e.g., moisture, clay content, GW depth and GW conductivity) differ. To construct an accurate interpretation model of soil profile salt content, the present study aimed to characterize the soil characteristics of the Xinjiang arid area by: (1) analysis of soil properties at different depths and determining the influence of GW characteristics on EM38 readings; (2) determine the dominant factors impacting on ECa determination, and establishing an accurate soil ECe interpretation model; (3) validate the precision and stability of the soil ECe interpretation model.

Materials and methods

Overview of research region

The present study focused on the Karamay agricultural development area located within the lacustrine plain region on the southern side of the Dzungaria Basin in Xinjiang Province (84°50′–85°20′ E and 45°22′–45°40′ N). The region has a desert climate with an annual mean temperature of 8 °C and an annual rainfall of 105.3 mm. The average depth of GW in the area has risen by 6.90 m since 2000 due to improper irrigation methods, which has consequently resulted in soil salinization. To date, more than 66% of the area has been affected by soil salinization (Han et al., 2011).

The field within the Karamay agricultural development area of approximately 68 ha with the shallowest GW was chosen for the present study. Other factors considered were soil texture, salt status, vegetation types and irrigation methods. As shown in *Figure 1*, the GW depth (DGW) and quality were monitored from 11 positions. Sunflowers and matrimony vines planted in the field in 2016 were replaced with cotton in 2017. The crops were irrigated manually during their periods of growth using drip irrigation under mulch. Soil moisture content and GW characteristics were highly variable across the research region since the types of crops differ and the terrain is uneven, as shown in *Table 2*. Soil clay content at a depth of 1 m was spatially homogeneous, with an average value of approximately 56%. On the other hand, serious soil salinization has occurred with a minimum and maximum ECe of 1.69 mS cm^{-1} and 2.90 mS cm^{-1}, respectively. This relatively high salt content has restricted crop growth. *Table 1* lists the monthly mean variations of DGW in the research region from 2013 to 2017, which show that DGW has been significantly influenced by agricultural irrigation before 2016 with an annual mean depth ranging from 0.78 m to 1.12 m, and that DGW increased to a certain extent in 2016 and 2017 with a mean depth of 1.40 m.

Data collection

Electromagnetic interference (EMI) data collection

The EM38 had two receiver coils spaced at 0.5 m and 1 m from the transmitter coil. The transmitter coil was energised with an alternating current, generating a time-varying magnetic field in the earth. This magnetic field resulted in current flow in the soil, resulting in the generation of a secondary magnetic field. The strength of this secondary electromagnetic field was directly proportional to the ECa of the soil.

$$ECa = 4(Hs/Hp)/\omega\mu_0 S^2 \quad \text{(Eq.1)}$$

where ECa is the apparent electrical conductivity, Hs and Hp are the secondary magnetic field and the primary magnetic field, respectively, $\omega = 2\pi f$, where f is the transmission frequency (Hz), S is the distance between the transmitting end and the receiving end (m) and μ_0 is the spatial magnetic field conduction coefficient.

In the present study, the EM38-MK2 instrument (Geonics Limited, On-tario, Canada) with effective investigation depths in the vertical and horizontal modes of 1.5 m and 0.75 m (McNeill, 1980), respectively and transmitting coil and receiving coil separated by 1 m was used to measure EMI data throughout the research region. According to previous studies, ECa is influenced by both soil properties and soil depth, and soil layers at different depths contribute to ECa at different degrees. *Equations 2* and *3,* representing density functions of the contributions of a soil layer at a certain depth to ECa in the vertical and horizontal modes, respectively, show that 20% of ECa in the horizontal mode is contributed by soil layers at depths < 1.2 m and 27% of ECa in the vertical mode is contributed by soil layers at depths < 1.8 m. In the present study, the heights of EM38 during measurement were set at 1.30 m, 1.10 m, 0.90 m, 0.70 m and 0.50 m in sequence, corresponding to effective investigation depths of 0.20 m, 0.40 m, 0.60 m, 0.80 m and 1.00 m, respectively, in the vertical mode.

A total of 100 measurement positions were deployed using the systematic distribution method and the data were collected by EM38 in May, 2017. Before the measurement, EM38 was calibrated at a height of 1.5 m, following which the values of ECa were measured at the heights of 1.30 m, 1.10 m, 0.90 m, 0.70 m and 0.50 m in the horizontal and vertical modes. In addition, the positions of the measurement points were recorded via GPS (Trimble, USA).

$$\varphi^v(Z) = \frac{4Z}{(4Z^2+1)^{3/2}} \quad \text{(Eq.2)}$$

DOI: http://dx.doi.org/10.15666/aeer/1704_1003710057

$$\varphi^h(z) = 2 - \frac{4z}{(4z^2+1)^{1/2}} \quad \text{(Eq.3)}$$

where z denotes the depth of EM38 in the vertical direction.

Collection and treatment of soil samples and GW

To obtain soil property information, manual sampling procedures were implemented at the measurement points. The soil was separated into five layers: 0 m to 0.20 m (L1),0.20 m to 0.40 m (L2), 0.40 m to 0.60 m (L3), 0.60 m to 0.80 m (L4) and 0.80 m to 1.00 m (L5). Effective soil profiles totaling 90 were chosen and 450 soil samples were collected in total. Soil profiles totaling 60 were used to derive the salt content prediction model whereas the remaining 30 were used to validate the model.

The collected soil samples were mixed and then transported to the laboratory for characterization. The soil moisture content per unit mass (θ) was determined using the oven drying method. EC of 5:1 water to soil extract (ECe) was determined using a conductivity meter. Soil clay content (γ) was determined using the hydrometer method.

The characteristic GW data were obtained from the 11 automated monitoring points. The monitored indices included GW depth (DGW), monitored by the DATA-5111 sensor (China), and GW EC (ECGW), monitored by the DATA-5102 water conductivity sensor (China). The sensors were set to collect data once every 2 h.

Data analysis method

Path analysis and its principles

A number of factors need to be considered when deriving an accurate model for interpreting soil salt information based on EMI. At the same time, path analysis is a useful numerical analysis method suitable for determining the effects of multiple factors. Path analysis divides correlation coefficients into those exerting direct and indirect effects, which indicates the relative importance of the factors. Therefore, when studying the linear relationships between multiple correlated variables, path analysis can reveal the direct and indirect contributions of each independent variable to the dependent variable. With that in mind, path analysis was used in the present study to establish the contribution of soil properties and GW characteristics to ECa.

Path coefficient

Path analysis is a statistical multiple linear regression analysis method applied to standardized variables and path coefficients are partial regression coefficients for standardized variables. The path coefficient of an independent variable reflects its relative magnitude and property in relation to the dependent variable.

Assuming the existence of a linear relationship between the dependent variable *y* and the independent variables x_i (i = 1,2,3,..., n), the regression equation can be written as:

$$y = b_0 + b_1x_1 + b_2x_2 + \cdots + b_nx_n \quad \text{(Eq.4)}$$

Then, based on the standardized multiple linear regression equation, the canonical equations can be derived as:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1003710057

$$\begin{cases} P_{yx_1} + r_{x_1x_2}P_{yx_2} + \cdots + r_{x_1x_n}P_{yx_n} = r_{x_1y} \\ r_{x_1x_2}P_{yx_2} + P_{yx_2} + \cdots + r_{x_2x_n}P_{yx_n} = r_{x_2y} \\ \vdots \quad \vdots \quad \vdots \quad \vdots \quad \cdots \quad \vdots \quad \vdots \quad \vdots \\ r_{x_nx_1}P_{yx_1} + r_{x_nx_2}P_{yx_2} + \cdots + P_{yx_n} = r_{x_ny} \end{cases} \quad \text{(Eq.5)}$$

Equation 5 can be transformed into a normal matrix equation as:

$$\begin{bmatrix} 1 & r_{x_1x_2} & \cdots & r_{x_1x_n} \\ r_{x_2x_1} & 1 & \cdots & r_{x_2x_n} \\ \vdots & \vdots & \ddots & \vdots \\ r_{x_nx_1} & r_{x_nx_2} & \cdots & 1 \end{bmatrix} \begin{bmatrix} P_{yx_1} \\ P_{yx_2} \\ \vdots \\ P_{yx_n} \end{bmatrix} = \begin{bmatrix} r_{x_1y} \\ r_{x_2y} \\ \vdots \\ r_{x_ny} \end{bmatrix} \quad \text{(Eq.6)}$$

where $r_{x_ix_j}$ is the simple correlation coefficient of x_i and x_j, and r_{x_iy} is the simple correlation coefficient of x_i and y. The path coefficient P_{yx_i} can be obtained by solving *Equation 5*. $r_{x_ix_j}P_{yx_i}$ represents the indirect path coefficient of *xi* to *y* via x_j.

Contribution rates of variables

The influencing factors can be ordered according to their path coefficients. Furthermore, since the contributions of the variables are calculated from their direct path coefficients, the contribution rates of the influencing factors to ECa can also be calculated:

$$\eta = |a| / \left(|a| + |b| + |c| + |d| + \cdots \right) \quad \text{(Eq.7)}$$

where a, b, c, d… denote the direct path coefficients of the corresponding variables and η denotes the contribution rate of the first variable.

Derivation of the ECe prediction model

Path analysis was used to analyze how soil properties (including θ, γ and ECe) and GW characteristics are related to ECa as measured by EM38 at different heights. The non-salt factors with high contribution rates to ECa were then chosen as independent variables with soil conductivity as the dependent variable. The optimal soil salt interpretation model was then derived using multiple linear regression (MLR). The data analysis and model derivation were conducted using SPSS 20.0 (IBM, USA), and the figures and tables were compiled using Sigmaplot 12.0 (Systat Software, USA).

Model validation

The reserved 30 soil profiles were used to validate the reliability of the ECe prediction model using three indices: mean error (ME), root mean square error (RMSE) and coefficient of determination (R^2).

Among them:

Mean Error (ME):

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1003710057

$$ME = \frac{1}{N}\sum_{i=1}^{N}\left|x_i - y_i\right| \quad \text{(Eq.8)}$$

Root Mean Square Error (RMSE):

$$\mathrm{RMSE} = \sqrt{\frac{1}{\mathrm{N}}\sum_{i=1}^{N}(x_i - y_i)^2} \quad \text{(Eq.9)}$$

where *xi* is the interpreted value, y_i is the observed value and N is the number of data points.

When using the test model, root mean squared error (RMSE) was always used for statistical analysis of conformity between simulated values and measured values. The smaller the RMSE value, the better the consistency and the smaller the deviation between simulated values and measured values, and thus the more accurate and reliable the model.

Results and discussion

Data analysis

Table 2 lists the soil properties and GW characteristics (including ECGW and DGW) of different soil layers and readings of EM38 at different heights. The soil texture in the research region ranged from heavy loam to light clay, and the soil profile clay content was distributed relatively evenly. At L1–L5, γ ranged from 49% to 62%, with the maximum in L3. θ showed a trend of increasing from the top soil layer (8%) to the bottom soil layer (25%) and was not evenly distributed in the soil profiles. According Lesch and Corwin (2003), if θ is far less than field moisture capacity, the spatial variation in θ is likely to become the most important factor contributing to EM data, even if salt content shows significant spatial variation. Norman (1990) found that soil profile θ should be greater than 20% in clay soil to accurately estimate soil salt content according to measured EM data. Given the above information, the θ of the study area in the present study could preclude the development of an effective soil salt prediction model. At the same time, ECe showed a clear variation among different soil layers, with average ECe of each layer ranging from 1.69 mS cm^{-1} to 2.9 mS cm^{-1}. At L1–L4, the coefficient of variation of ECe decreased from 60.69% to 34.66% with increasing soil depth, whereas at L5, the coefficient of variation of ECe increased to 50.69%. This illustrated the complex spatial distribution of ECe. DGW was highly variable across the region with a minimum, maximum and average DGW of 1.12 m, 1.38 m and 1.34 m, respectively, and ECGW ranged from 35.8 mS cm^{-1} to 62.8 mS cm^{-1} with an average of 2.36 mS cm^{-1} due to high GW mineralization and poor water quality. Therefore, the moisture and salt contents of the soil profiles could be influenced by the shallow depths and high salt content of GW, thereby influencing EM38 measurements.

Corwin and Rhoades (1982) derived the EC of the soil profile in the vertical direction based on the linear hypothesis and using the values of ECa measured by EMI at different heights, a method which has been proven to effectively improve the accuracy of predicting soil salt using EM38 (Cook and Walker, 1992). In the present study, the EM38 readings decreased with increasing height. The signals received by

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1003710057

EM38 were generated mainly by the top soil layer and the contribution of the bottom soil layer to the EM38 readings decreased with increasing soil depth (McNeil, 1990). Soil at depths of 0 m–1.50 m accounted for 70% of the readings in the vertical mode, and with increasing EM38 height, the effective investigation depth decreased (Abdu et al., 2007). In addition, the aboveground atmosphere with an ECa of 0 made no contribution to EM38 readings (Misra and Padhi, 2014). The aforementioned facts explain the reason for a noticeable decrease in EM38 readings as height increased. Huang et al. (2015) found that ECa variations decreased significantly as height increased, which is consistent with the results of the present study.

Analysis of factors influencing ECa in different soil layers

Factors influencing ECa as measured by EM38 at a height of 1.30 m (EM1.30)

Path analysis in two modes was used to determine the factors influencing ECa (EMh1.30 and EMv1.30) and their degrees of influence. When conducting path analysisat L1, θ, γ, ECe, ECGW and DGW were regarded as independent variables and EMh1.30 and EMv1.30 were regarded as dependent variables. *Table 3* lists the results

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1003710057

of path analysis used to determine the factors influencing ECa (i.e., EMh1.30 and EMv1.30) measured at a height of 1.30 m. W) except for ECe, indicating that θ had a certain degree of influence on EMv1.30 at L1. ECe showed the best correlation with EMh1.30 and EMv1.30 at L1 measured at a height of 1.30 m, with the correlation being extremely significant at the P = 0.01 level with correlation coefficients of 0.86 and 0.83, respectively. On the other hand, no significant correlations were evident between ECa and θ, γ, ECGW or DGW, among which the correlation between ECa and θ was the lowest (R < 0.10). According to the results, the order of independent variables in regards to their influence on EMv1.30 at L1 was: ECe > θ > γ > ECGW > DGW. The order of independent variables in regards to their influence on EMh1.30 was ECe > DGW > γ > θ > ECGW. Therefore, since ECe had the largest effect on both EMh1.30 and EMv1.30 at L1, it can be concluded that ECe was the most important factor influencing ECa as measured by EM38 at a height of 1.30 m. Thus, ECe can be used to ECa. Among the other influencing factors, the influence of DGW on EMh1.30 was larger than that of θ, γ or ECGW. Generally speaking, with EM38 height set to 1.30 m, the effective investigation depth for EMh1.30 was not sufficiently deep to reach the soil surface. However, an extremely significant linear relationship (P < 0.001) existed between EMh1.30 and EMv1.30, and a significant correlation (R = −0.432, P < 0.01) existed between DGW and ECe at L1. Therefore, it is likely that the influence of DGW on ECe was responsible for the correlation between DGW and EMh1.30. On the other hand, the contribution of θ to EMv1.30 was 10.93%, larger than those of the other influencing factors (γ, ECGW and DG).

Factors influencing EC as measured by EM38 at a height of 1.10 m (EM1.10)

When conducting path analysis at L2, θ, γ, ECe, ECGW and DGW were regarded as independent variables whereas EMh1.10 and EMv1.10 were regarded as dependent

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1003710057

variables. *Table 4* lists the results of path analysis used to determine the factors influencing ECa (i.e., EMh1.10 and EMv1.10) measured at a height of 1.10 m. ECe also had a significant correlation with EMh1.10 and EMv1.10 measured at a height of 1.10 m in the two modes at L2, with correlation coefficients of 0.89 and 0.86 ($P < 0.01$), respectively. At L2, the correlations between θ and EMh1.10 and θ and EMv1.10 were 0.53 ($P < 0.05$) and 0.67 ($P < 0.01$), respectively, indicating that θ had an influence on ECa at L2. On the other hand, no significant correlations were evident between ECa measured at a height of 1.10 m and γ, ECGW or DGW. According to the results, the order of the independent variables according to their influence on EMv1.10 at L2 was: ECe > θ > DGW > ECGW > γ. The order of the independent variables according to their influence on EMh1.10 was: ECe > θ > DGW > ECGW > γ. Therefore, since ECe also had the largest influence on both EMh1.10 and EMv1.10 at L2, it can be concluded that ECe was the most important factor influencing ECa as measured by EM38 at a height of 1.30 m. Among the other factors, the contribution rates of θ to EMh1.10 and EMv1.10 (7.85% and 25.16%, respectively) were larger than those of DGW, γ, or ECGW, indicating that θ had a relatively significant influence on the data measured by EM38 at L2.

According to the density functions of EM38, i.e., *Equations 3* and *4,* at an EM38 height < 1.10 m, EMv1.10 was mainly influenced by soil properties at L1–L2. According to the present results, ECe at L2 had the largest influence on EMv1.10 and EMh1.10, with the second-most important factor being θ with a rate of contribution of 25.16%. Huang et al. (2015) found that at an EM38 height of 1.00 m, ECe showed the best correlations with EMh and EMv in the 0.15 m–0.30 m soil layer ($R = 0.750$ and $R = 0.773$, respectively), which supports the reliability of the results of the present

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1003710057

study. In addition, the correlations of ECe with EMh and EMv at L2 in the present study were even stronger (R = 0.86 and R = 0.89, respectively).

Factors influencing ECa as measured by EM38 at a height of 0.90 m (EM0.90)

When conducting path analysis at L3, θ, γ, ECe, ECGW and DGW were regarded as independent variables, whereas and EMh0.90 and EMv0.90 were regarded as dependent variables. *Table 5* lists the results of path analysis used to determine the factors influencing ECa (i.e., EMh0.90 and EMv0.90) measured at a height of 0.90 m. At L3, ECe showed significant correlations with both EMh0.90 and EMv0.90, with correlation coefficients of 0.86 for both ($P < 0.01$). θ and DGW also showed significant correlations with EM0.90 ($P < 0.05$) at L3, indicating that θ and DGW influenced ECa measured at a height of 0.90 m. According to the results, the rates of contribution of ECe to EMh0.90 and EMv0.90 at L3 were the highest among all the factors at 65.79% and 56.12%, respectively. The rates of contribution of ECGW and DGW to EMv0.90 were 12.75% and 10.64%, respectively, and they also had relatively significant influences on EMh0.90 with rates of contribution of 10.23% and 13.55%, respectively.

Factors influencing ECa as measured by EM38 at a height of 0.70 m (EM0.70)

When conducting path analysis at L4, θ, γ, ECe, ECGW and DGW were regarded as independent variables and EMh0.70 and EMv0.70 were regarded as dependent variables. *Table 6* shows the results of path analysis to determine the factors influencing ECa (i.e., EMh0.70 and EMv0.70) measured at a height of 0.70 m. At L4, ECe showed significant correlations with both EMh0.70 and EMv0.70, with correlation coefficients of 0.81 and 0.80 ($P < 0.01$), respectively. θ and DGW also showed significant correlations with EM0.70 ($P < 0.05$) at L4, indicating that θ and DGW influenced ECa

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1003710057

measured at a height of 0.70 m. According to the results, the rates of contribution of ECe to EMh0.70 and EMv0.70 at L4 were 49.26% and 39.49%, respectively. On the other hand, θ and DGW had relatively significant influences on EMh0.70 and EMv0.70 with rates of contribution of 16.64% and 24.14% and 22.62% and 18.55%, respectively. Therefore, it can be inferred that as the height of EM38 decreased, the rates of contribution of ECe to EMh0.70 and EMv0.70 decreased with increasing soil depth, whereas the contribution rates of the other factors increased.

Factors influencing ECa as measured by EM38 at a height of 0.50 m (EM0.50)

When conducting the path analysis at L5, θ, γ, ECe, ECGW and DGW were regarded as the independent variables and EMh0.50 and EMv0.50 were regarded as dependent variables. *Table 7* lists the results of path analysis conducted to determine the factors influencing ECa (i.e., EMh0.50 and EMv0.50) measured at a height of 0.50 m. At L5, ECe showed significant correlations with both EMh0.50 and EMv0.50 with correlation coefficients of 0.80 and 0.78 ($P < 0.01$), respectively. θ and DGW also showed significant correlations with ECa ($P < 0.05$), possibly because ECa at L5 had shown a significant correlation with DGW (REC-Dgw = 0.34*, $P < 0.05$), which indirectly imposed an influence on EM0.50 through ECe. According to the results, the rates of contribution of ECe to EMh0.50 and EMv0.50 at L5 were 36.98% and 32.58%, respectively. On the other hand, θ had a greater influence on EMh0.50 than ECe, indicating that θ had a large influence at L5. GW characteristics also showed relatively significant influences on EMh0.50 and EMv0.50, with rates of contribution of 21.45% and 17.16%, respectively. DGW and ECGW showed negative correlations with ECa measured at a height of 0.50 m, although the correlation was only significant for DGW ($R = -0.58^{**}, -0.54^{**}$, $P < 0.01$), consistent with the study of Bouksila et al. (2012).

ECa measured by EM38 at a height of 0 m showed the best correlation with ECe at all soil layers (Huang et al., 2015; Yao and Yang, 2010). However, in the present study, the height of EM38 was set at 1.30 m, 1.10 m, 0.90 m, 0.70 m and 0.50 m in sequence, where the corresponding effective investigation depths were 0.20 m, 0.40 m, 0.60 m, 0.80 m and 1.00 m respectively. This approach was taken to more directly analyze influences of soil properties on ECa in the different layers. The results showed that ECe had the greatest influence on EMv regardless of EM38 height, with the influences of θ, DGW and ECGW increasing as EM38 height decreased, whereas the influence of clay content remained negligible. In general, soil ECa has been found to be mainly influenced by the factor showing the most spatial variability across the research region (Doolittle and Brevik, 2014). As a result, since γ showed less spatial variability than that of soil ECe and θ in the vertical direction, the fact that γ had a negligible effect on ECa was expected.

Prediction of ECe in different soil layers

Linear regression has been widely used to study the relationship between ECe and ECa of soil (Triantafilis et al., 2000; Bennett and George, 1995). In the present study, ECe of different soil layers was taken as the dependent variable and EMh and EMv were taken as the independent variables within simple linear regression analysis. ECe of different soil layers was then taken as the dependent variable and both EMh and EMv were taken as independent variables within binary linear regression analysis. Furthermore, the factors with large influences on ECa were gradually introduced as additional independent variables together with ECa to generate an MLR model for different soil layers. For all soil layers, θ, DGW and ECGW were chosen as the additional independent variables and were gradually introduced into the prediction

DOI: http://dx.doi.org/10.15666/aeer/1704_1003710057

model. *Figure 2* shows the change in R^2 with the gradual addition of different variables into the prediction model. The optimal ECe interpretation models for different soil layers are shown in *Table 2*.

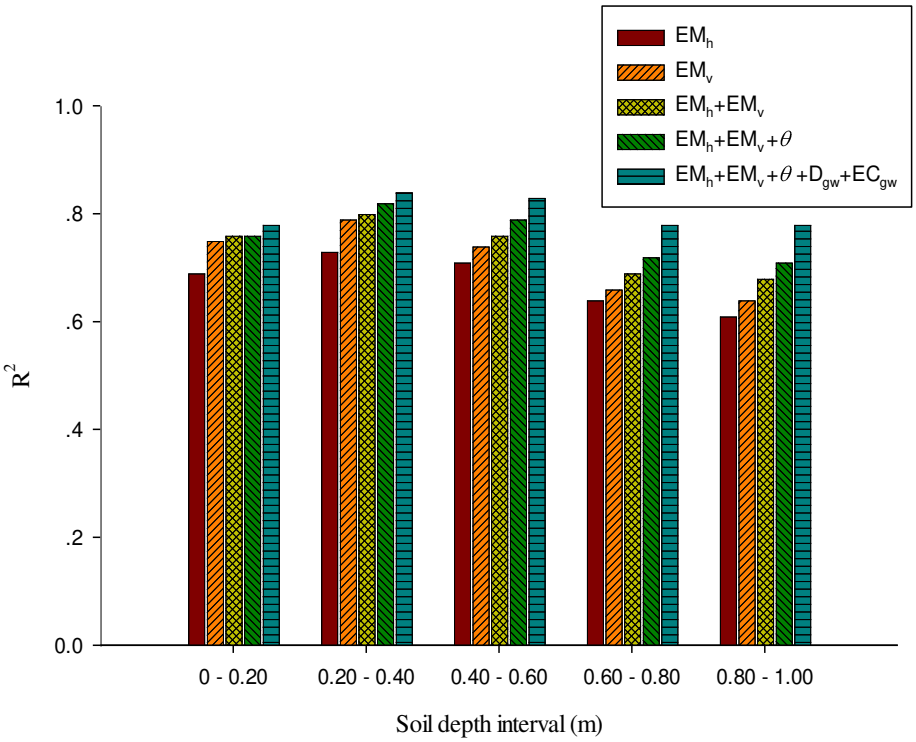

Figure 2. *The change in R^2 with the gradual addition of different variables into the prediction*

In general, at an EM38 height of 0 m and a separation of 1 m between the receiving coil and transmitting coil, the effective investigation depth was 0.75 m in the horizontal mode and 1.5 m in the vertical mode. Therefore, the correlation between ECe at the top soil layer and ECa measured in the horizontal mode was higher than that between ECe at the top soil layer and ECa measured in the vertical mode (Huang et al., 2015; Yao and Yang, 2010), whereas the correlation between ECe at the bottom soil layer and ECa measured in the vertical mode was higher than that between ECe at the bottom soil layer and ECa measured in the horizontal mode. In the present study, ECe values at different soil layers (L1–L5) were interpreted using ECa data measured at the corresponding heights (1.30 m, 1.10 m, 0.90 m, 0.70 m and 0.50 m, respectively). As shown in *Figure 2*, the effectiveness of EMv in providing an interpretation was better than that of EMh for all soil layers because at an EM38 height < 1.5 m, soil information could be effectively investigated in the vertical mode, whereas this was only true for the horizontal mode at EM38 height < 0.75 m. The prediction accuracy of ECe at L1 using EMv1.30 was low. On the other hand, the highest prediction accuracy of ECe using EMv1.10 was at L2. Below L2, the prediction accuracy of ECe decreased with increasing soil depth. A possible explanation is that since θ at L1 is low, some salt at L1 is likely to remain undissolved, thereby providing no contribution to the reading of EM38. In addition, with decreasing EM38 height, the thickness of the soil that can influence ECa increases; thus, the prediction accuracy of ECe using ECa within the deeper soil layer decreases.

Various studies have used EM38 data in both the horizontal and vertical modes to interpret soil salt content, and ECe prediction models have been developed with relatively high accuracies (Liu et al., 2016; Lesch et al., 2000). As shown in *Figure 1*, the accuracy of the model developed in the present study improved with the incorporation of both EMh and EMv. However, with the use of EMh1.30 and EMv1.30 to interpret ECe at L1 and EMh1.10 and EMv1.10 to interpret ECe at L2, the improvement in the accuracy of the interpretation model was not as high as those in the other three cases. This observation can be explained by the fact that the effective investigation depth in the horizontal mode was only 0.75 m. More specifically, at EM38 heights of 1.10 m or 1.30 m, despite EMh showing an extremely significant correlation with ECe, ECe was in fact mainly influenced by EMv because the linear relationship between EMv and EMh could be identified during EM38 calibration. This explains why introducing EMh into the model did not increase the accuracy of the model for predicting salt content at L1 and L2.

Among all the factors that can influence soil ECa in salinized regions, the concentration of soluble salt is the most prominent (Williams et al., 2006). However, due to upward leaching and evaporative processes, GW salt tends to accumulate in the soil (Richardson and Williams, 1994). Liu et al (2010) showed θ and ECGW to be the most important non-salt factors in regions of relatively shallow GW. Therefore, the accuracy of the soil salt prediction model can be improved by introducing θ and ECGW into the model as additional independent variables. Similar conclusions were made in the present study. At L1, DGW and ECGW showed significant correlations with ECe ($P < 0.05$), whereas θ did not. As a result, the introduction of θ into the model did not improve the model's accuracy, whereas the opposite was found with the introduction of GW characteristics (R^2 increased from 0.76 to 0.78). At L2, θ showed a significant correlation with γ and DGW ($P < 0.05$), indicating that θ at L2 is greatly affected by γ and GW characteristics. With an increase in θ, salt dissolved; thus, when θ, ECGW and DGW were introduced into the prediction model, R^2 increased from 0.80 to 0.84. This was also observed at L3–L5, where the ECe prediction accuracies increased to 0.83, 0.78 and 0.78 respectively. Hanson and Kaita (1997) found a positive relationship between θ and the sensitivity of EM38 to variation in soil salt content. Therefore, when using EM38 to measure soil salt content, the influence of θ on ECa should be taken into account (Brevik et al., 2002). In the present study, incorporating θ improved the accuracy of the ECe prediction model except at L1. In addition, incorporating GW characteristics improved the model accuracy for the deeper soil layers to a larger degree than that for the top soil layer, possible due to the relatively shallow DGW in the research region.

Validation of interpretation model for soil salt content

Table 8 shows the models used to predict salt content in the different soil layers. The reserved 30 soil profiles were used as test data to validate the reliability of the models. The independent variables can be used by the prediction models to estimate salt content in the test profiles for different soil layers. By comparing the model predictions of salt content with laboratory measurements, the accuracy and practicability of the interpretation model can be validated.

Figure 3 shows the R^2 values for the salt content predictions versus measurements in the test profiles of each layer. All values of R^2 were greater than 0.70, indicating highly significant correlations between the model predictions and the measurements. This

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1003710057

demonstrated that the model represented major processes affecting salt content in the different layers relatively well. On the other hand, the values of ME between the predictions and the ECe measurements for L1–L5 were 0.63, 0.46, 0.53, 0.25 and 0.24, respectively, whereas the values of RMSE were 0.77, 0.48, 0.21, 0.26 and 0.24, respectively.

80~100	$-1.48 + 0.006 \times EMh0.50 + 0.001 \times EMv0.50 - 4.68 \times \theta + 0.001 \times ECGW + 0.017 \times DGW$	0.78

Conclusions

Path analysis was used in the present study to analyze the influences of soil properties and GW characteristics in different soil layers on ECa as measured by EM38 at different heights. The results showed that ECe was the most important factor influencing ECa measured at different heights. The rates of contribution of ECe to EMv at L1–L5 were 65.78%, 82.21%, 65.79%, 49.26% and 36.98%, respectively. The results showed that the degree of influence of the bottom soil layer to ECa decreased whereas those of other soil properties increased with increasing soil depth. In addition, since θ at L1 was relatively low, the rate of contribution of ECe to ECa at L1 was also relatively small. The influence of θ on ECa was also noticeable, with rates of contribution to ECa at L1–L5 being 10.93%, 7.85%, 9.15%, 16.64% and 34.76%, respectively. The rates of contribution of DGW to ECa measured by EM38 at heights of 1.30 m, 1.10 m, 0.90 m, 0.70 m and 0.50 m were 4.67%, 5.27%, 10.64%, 22.62% and 21.45%, respectively, whereas those of ECGW were 9.27%, 4.47%, 12.75%, 11.07% and 2.22%, respectively. In arid and semi-arid areas, due to upward leaching and evaporative processes, GW salt tends to accumulate in the soil. In such areas, the soil salt content has significant correlations with unsuitable irrigation practices, evapotranspiration of farm land and DGW during crop growth. GW characteristics impose an influence on ECa by influencing ECe in each layer. In the research region, the influence of γ on the ECa was minor.

Linear regression was used to derive optimal ECe prediction models for different soil layers. Taking ECe of different soil layers as the dependent variable and EMh and EMv as the independent variables in sequence, simple linear regression analysis was conducted. Binary linear regression analysis was conducted by taking ECe of different soil layers as the dependent variable and both EMh and EMv as the independent variables. θ, DGW and ECGW were then gradually introduced into the prediction model as additional independent variables. The results showed EMv to provide a better interpretation than EMh in each soil layer. This was because at an EM38 height < 1.5 m, the soil information could be effectively investigated in the vertical mode, whereas this was only true for the horizontal mode at an EM38 height < 0.75 m. The ECe prediction accuracy at L1 using EMv1.30 was low due to low θ. On the other hand, the ECe prediction accuracy at L2 was the highest; however, as the depth of the soil layer increased below L2, the ECe prediction accuracy decreased. When EMh and EMv were both used to derive the interpretation model, the model accuracy improved.

θ and GW characteristics were important factors influencing ECa; therefore, their influences on ECa need to be considered when using EM38 to measure soil salt content. With the introduction of θ and GW characteristics to the prediction model as additional independent variables, the reliability of the ECe prediction model in each soil layer

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1003710057

improved. In addition, the addition of GW characteristics improved the prediction accuracy for the bottom soil layer more than that for the top soil layer.

The accuracies of the ECe prediction models for different soil layers were validated. R^2 values showing the correlations between model ECe predictions and measurements of each layer were > 0.70. ME and RMSE values at L1–L5 were 0.63, 0.46, 0.53, 0.25 and 0.24, respectively, and 0.77, 0.48, 0.21, 0.26 and 0.24, respectively. The results suggested that the models for L3–L5 were more accurate than those for L1–L2.

The EMI approach offers potential for improving the prediction accuracy of soil salinity information by the addition of influence factors into the multiple regression model. In the future research, it is necessary to study the denoising of data to help resolve some of the uncertainty issues associated with this non-contacting technology and further improve the accuracy of the interpretation model.

Abstract. In this study, sediment was sampled from the North River in Changzhou at five different loca-tions at the same time. Microbial DNA was extracted from the obtained samples, and the extracted DNA purity was compared by two different methods. After DNA amplification by 16S rRNA PCR, microspectrophotometry and agarose gel electrophoresis, the modified gradient gel electrophoresis (DGGE) was performed. The DGGE map was analyzed using Quantity one software of bio-rad to study the community diversity. The similarity matrix showed that the samples of different locations and time had high similarity, with the highest similarity reaching 82%. The proportion of similarity over 60% is extremely high, which indicates that the microbial population in North River is abundant, but the microbial community structure changes little in space.
Keywords: *sediment, spatial variation, PCR amplifiction, DGGE, microbial diversity*

Introduction

Urban rivers are part of natural river basins, playing an irreplaceable role in the process of urban ecological construction, namely, they have the functions of material circulation and ecological protection, weakening the urban heat island effect and regulating local climate (Yan and Wang, 1999). Due to the rapid development of human urbanization, the natural ecosystem of urban rivers is overused, damaged and difficult to recover. Resulting in the loss of self-purification capacity and the rapid deterioration of the environment, which seriously affects the urban ecological environment and the health of urban residents (Sun, 2015). With the continuous improvement of living standards, people are constantly strengthening their environmental awareness, and the quality of living environment is also constantly improving, which leads to the prominent problem of urban river pollution, and its governance is of great urgency. At present, physical, chemical and biological methods have been used to restore and manage damaged river ecosystems (Hu et al., 2005). Compared to physical and chemical methods, biological methods do not cause secondary pollution in the treatment, and the cost of investment and maintenance is low (Gu et al., 2013). In addition, the study on the microflora of urban river environments in China has been available in the 1980s. For example, since 1986, Zhao et al. used traditional culture methods to study the correlation between organic matter and water temperature in water and microbial quantity and population distribution (Zhao et al., 1986). Therefore, it is of great significance to study the community structure and functional diversity of microorganisms in known environments. Combined with the existing methods of

DOI: http://dx.doi.org/10.15666/aeer/1704_1005910072

environmental microorganism community analysis, there are traditional culture and separation methods (Amann et al., 1995). Community level physiology fingerprint methods (CLPP) (Victorio et al., 1996; Ibekwe and Kennedy, 1998), biological marker methods (Bai, 1997) and modern molecular biology methods (Torsvik et al., 1990; Hill et al., 2002; Handelsman, 2004; Tunlid, 2007). Since 1985, Pace et al. (1997) used the accounting sequencing method to study microbial evolution, molecular biology technology has been gradually introduced into biodiversity research. In 1993, Muyzer et al. (1993) first introduced the denatured gradient gel electrophoresis DGGE technology into the study of microbial ecology (Zhang et al., 2009; Yu et al., 2010). Since then, DGGE technology has been applied and developed in environmental microorganism research. Therefore, in this study, taking the North River in Changzhou city as an example, the microbial community structure of the urban river is analyzed with the PCR-DGGE (Röttgers, 2007) technology. Through analyzing the target environment of microbial community structure and population diversity, we supplied a reference for optimizing the community structure, regulating functions of community, and discovering new important microbial groups.

Materials and methods

Experimental materials

River sediment

The river bottom sediment samples were collected in the North River, and the locations of the river bottom sediment samples were Jingu Manor, Boai Bridge, Chunting Bridge, Zhiyuan Bridge and Yuanfeng Bridge (as shown in *Fig. 1*). In order to facilitate the experimental record, the samples of the above five locations were recorded as no.1,2,3,4 and 5, respectively. As there are residential communities near the river section, part of the sewage will be directly discharged into the river section. But in recent years, beishi river has improved its water quality by adding aeration devices and installing biological floating islands. The samples of river surface sediment (0~20 cm) were collected from January to December 2017 and all of them were gathered using sterile bags. At 4 °C under the condition of back to the laboratory immediately, save under the condition of -80 °C, and completed within a week of sediment microbial total DNA extraction.

Preparation of buffer solution

(1) 50×TAE preparation: Tris 242 g, Na2EDTA·2H2O 37.2 g, and then 800 ml of deionized water was added, which was fully stirred to dissolve. Add 57.1 ml acetic acid and mix well. Finally, add the deionized water to 1 L for storage at room temperature. (50×TAE is the storage fluid. Dilute 50 times to get 1×TAE solution)

(2) 5×Loading buffer preparation: 10 mM tris-hcl, 5 mM EDTA, pH 7.6, 0.03% bromophenol blue, 0.03% xylene blue, 30% glycerin.

Experimental methods

Determination of physical and chemical properties of North River sediment

Dissolved oxygen and water temperature should be measured at the sampling site, and immediately measured by the Shanghai Jingke jpbj-608 portable dissolved oxygen meter. pH, ammonia nitrogen, total nitrogen, total phosphorus, chemical oxygen demand, nitrate nitrogen and chlorophyll a were measured in the laboratory. The determination of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1005910072

chemical oxygen demand, ammonia nitrogen, total nitrogen and total phosphorus was carried out by the 6b-2000 multi-parameter water quality meter of Jiangsu Shengaohua Environmental Protection Technology Co. LTD. The determination of pH was carried out by using a multiple parameter analyzer. Chlorophyll a was determined by spectrophotometer (Röttgers, 2007). The determination of nitrate nitrogen was performed by UV spectrophotometry (Zhu et al., 2011), that is, the absorption area of nitrate ion at the wavelength of 220 nm was used for quantitative determination of nitrate nitrogen.

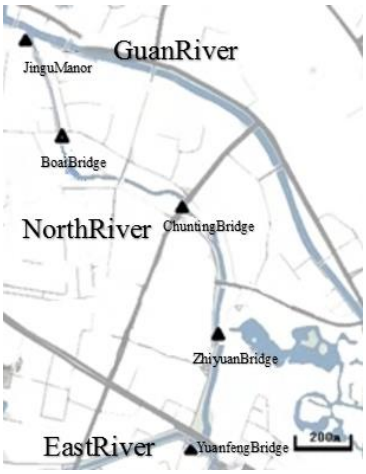

Figure 1. *North River sampling section distribution schematic diagram*

Total DNA extraction of river sediment microorganisms

The 1 g bottom sediment samples were respectively weighed and used in combination with humic acid by bioengineering (Shanghai) company, and 0.2-0.5 g bottom sediment samples were extracted from the bottom sediment samples by using Omega biotek soil DNA small-lift kit. The operation steps were performed according to the instructions, and the extraction effect was compared.

Inspection of DNA concentration and purity

This study used an ultra-micro spectrophotometer to determine the concentration of DNA. 2 μL of DEPC tretd water was taken as a blank sample and 2 μL of the total DNA solution of the sediment sample, and each was dropped in the measurement area of the micro spectrophotometer, and the relevant data was recorded by an analysis software. If the ratio of A260/A280 is around 1.8, it means that higher DNA concentration can be used for subsequent PCR and cloning experiments. If A260/A280 > 2.0, it means that the RNA interference is large and the DNA needs to be re-expressed (Hoefel et al., 2005).

PCR amplification

In the present study, the amplified DNA fragment was subjected to the V3 region of the bacterial 16S rRNA sequence, and the primers were 357f and 518r (Li et al., 2013), and the length was about 194 bp. Further, a "GC" splint having a base number of 40 bp was added to the 5' portion of the primer 357f. which is
"GC" splint: 5′-CGCCCGCCGCGCCCCGCGCCCGGCCCGCCGCCCCCGCCCC -3′

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1005910072

357f: 5′-CCTACGGGAGGCAGCAG-3′
518r: 5′-ATTACCGCGGCTGCTGG-3′

Reaction system: (1) PCR reaction system is 25 μL, the specific reagent amount: 2×Taq Master mix 12.5 μL; upstream primer 2 μL; downstream primer 2 μL; DNA template 1.25 μL; DDH_2O 7.25 μL; (2) PCR reaction system is 50 μL, the specific reagent amount: 2×Taq Master mix 25 μL; upstream primer 1 μL; downstream primer 1 μL. DNA template 2 μL; DDH_2O 21 μL.

Amplification procedure: pre-denaturation at 94 °C for 5 min, then 25 cycles, each cycle includes denaturation at 94 °C for 30 s, annealing at 61-56 °C for 30 s, extension at 72 °C for 1 min, and end of the cycle at 72 °C for a final extension of 7 min. Hold 4 °C.

DNA agarose gel electrophoresis experiment (qualitative analysis)

The extracted total DNA was qualitatively analyzed by agarose gel electrophoresis. 0.25 g of agarose was added to 1×TAE buffer, and a 1% agarose gel was subjected to electrophoresis, and the results were observed after photographing under an ultraviolet lamp.

DNA denaturing gradient gel electrophoresis (DGGE) experiment

Solidifying the gel in 1×TAE buffer, each sample well of a sample of about 15 μL, using horizontal electrophoresis, a gradient of denaturant is allowed to range from 40% to 55%, the voltage75 V, run time 14 h, electrophoresis was carried out at a temperature of 60 °C. After the electrophoresis of the DGGE gel was completed, it was stained with EB (ethidium bromide). After staining, images were taken using a gel imaging system and images were quantified using BIO-RAD's Quantity One software (Li et al., 2013). And by digitally converting DGGE maps, the species diversity was analyzed. In this study, Shannon-Wiener index (*H'*) (Xu et al., 2011), Simpson index (*D*) (Sun and Liu, 2004) and Pielou index (*J*) (Liu et al., 2013) were used to characterize the species diversity of their communities, which calculated as follows:

$$H' = -\sum_{i=1}^{n} p_i \ln p_i \quad \text{(Eq.1)}$$

$$D = \sum_{i=1}^{n} p_i^2 \quad \text{(Eq.2)}$$

$$J = -\sum_{i=1}^{n} (p_i \ln p_i) / \ln S = H' / \ln S \quad \text{(Eq.3)}$$

where *n* indicates the number of bands detected in each sample, and *S* indicates the sum of the different bands detected by DGGE, indicating the gray level of each band in the sample as a percentage of the total gray scale of the sample.

Results and discussion

Analysis of the pollution status of the sediments in The North River

Analysis of pollution status of nitrogen element in sediments of The North River

(1) Ammonia nitrogen

As shown in *Figure 2,* the ammonia nitrogen was varied in the range of 0.2 to 0.7 mg/g, and the average value was 0.45 mg/g. In terms of river flow, the content of ammonia nitrogen in each section is Boai Bridge > Chunting Bridge > Jingu Manor > Yuanfeng Bridge > Zhiyuan Bridge, that is, upstream ammonia nitrogen content > middlestream > inlet > export > downstream; in terms of time, ammonia nitrogen content The monthly value has changed slightly but the change has not changed much. It can be seen that the ammonia nitrogen value of river sediment is not affected by seasonal temperature changes (Qin et al., 2014).

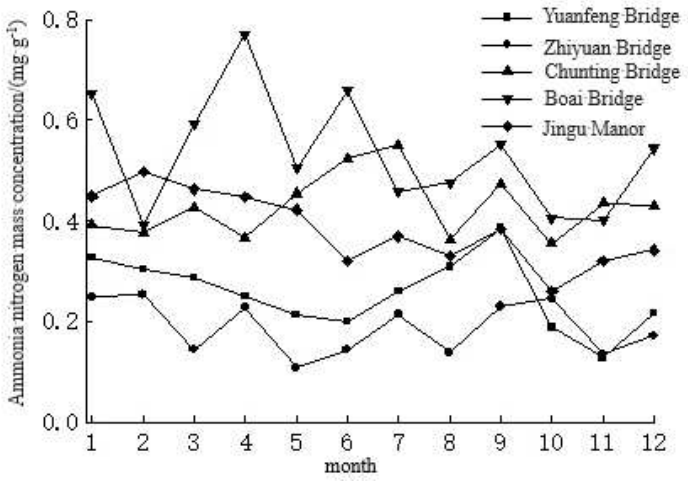

Figure 2. *The change trend of ammonia-nitrogen*

(2) Nitrate nitrogen

As shown in *Figure 3,* the nitrate nitrogen ranged from 0 to 0.06 mg/g with an average of 0.04 mg/g. In terms of river flow, the sediment content of each section is Jinyuan Manor > Boai Bridge > Chunting Bridge > Zheyuan Bridge > Yuanfeng Bridge, which is the inlet nitrate nitrogen content > upstream > middlestream > downstream > export; in terms of time, sediment The content of nitrate nitrogen did not change much, but the Boai Bridge increased slightly in the spring, and the Qiating Bridge increased in summer. The reason for this phenomenon is as follows: (1) The relative error of the measured value is too large due to the low nitrate content of the measured nitrate; (2) The resin adsorption treatment of the sediment sample is not carried out in this experiment, resulting in a high value measured at 220 nm, which causes it to be subjected to Interference with organic matter.

(3) Total nitrogen

As shown in *Figure 4,* the variation range of TN is between 1 and 3.5 mg/g, and the average value is 2.05 mg/g. In terms of river flow, the total nitrogen content of each

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1005910072

section of the sediment is Boai Bridge > Chunting Bridge > Jingu Manor > Yuanfeng Bridge > Zhiyuan Bridge, its variation law is consistent with the change of ammonia nitrogen content in all sections, that is, upstream ammonia nitrogen content > midstream > inlet > export > downstream; in terms of time, the total nitrogen content of sediment has little fluctuation in each month. It can be seen that the total nitrogen content of the sediment is not affected by seasonal temperature changes.

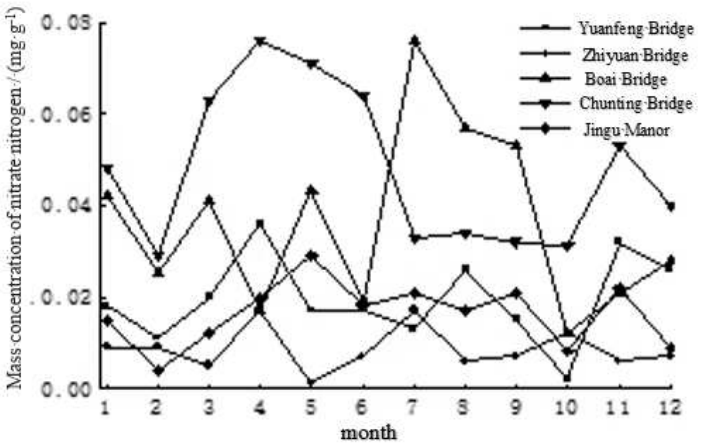

Figure 3. *The change trend of nitrate nitrogen*

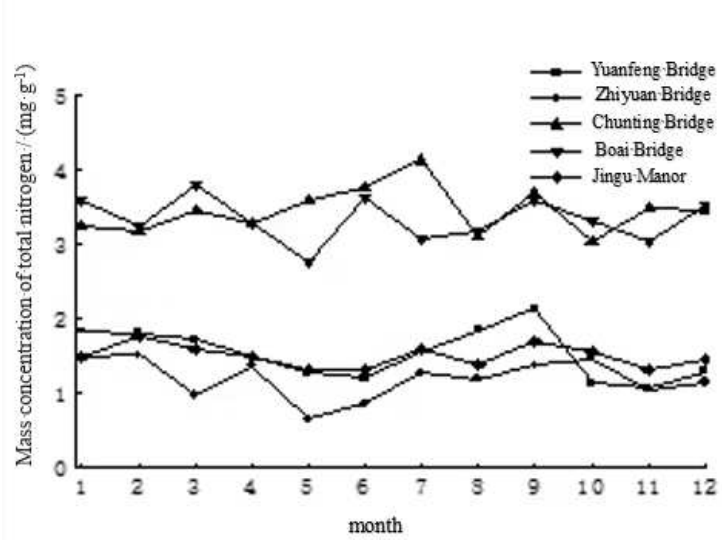

Figure 4. *The change trend of TN*

As Chunting Bridge and Boai Bridge are both in densely populated areas, the river is polluted more seriously, and the nutrient element nitrogen value is higher. In addition, Yuanfeng Bridge and Jinyin Manor are connected to Dongshi River and Guanhe River respectively, so the nutrient nitrogen element the content is affected by Donghe River and Guanhe River; and Zhiyuan Bridge is located in Hongmei Park of Changzhou City. The surrounding trees have a positive impact on the environment, which makes the nitrogen content of nutrient elements low. It can be seen that the nutrient nitrogen

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1005910072

content of the river bottom mud in Beishi is affected by human activities and the surrounding environment.

Analysis of pollution status of phosphorus in the sediment of The North River

As shown in *Figure 5,* the range of TP was 1 to 2 μg/g, and the average value was 1.35 μg/g. In terms of river flow, the content of TP in each section of the sediment is Boai Bridge > Chunting Bridge > Yuanfeng Bridge > Jingu Manor > Zhiyuan Bridge, which is the upstream TP content > middlestream > export > inlet > downstream; in terms of time, TP content in each month There has been a slight change, but the change is not large. It can be seen that the phosphorus content of the nutrient element in the sediment is not affected by seasonal temperature changes (Zeng et al., 2009).

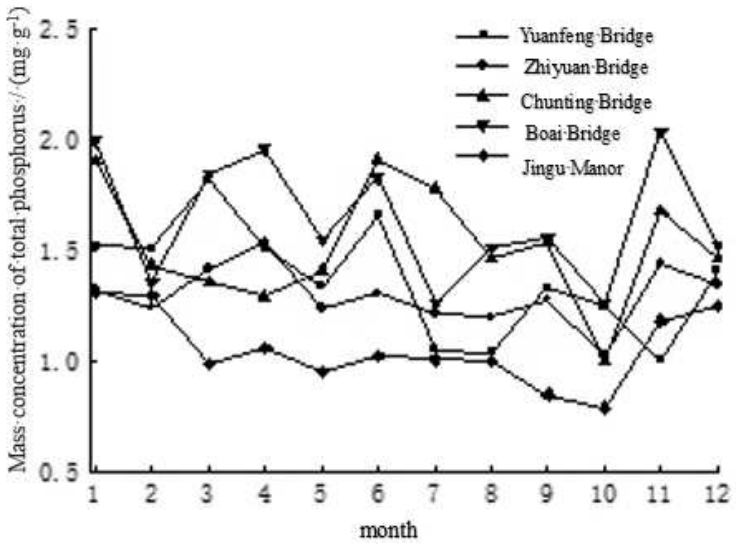

Figure 5. *The change trend of TP*

From the above analysis of pollution conditions, it can be seen that the changes in the contents of N and P in the river bottom mud of Changzhou City are consistent. In terms of time, the content of N and P did not change much in each month, and was basically not affected by seasonal temperature. In terms of river flow, the content of upstream N and P was greater than that of midstream and greater than downstream. The nitrogen and phosphorus in the sediment are mainly derived from the discharge of domestic sewage from nearby residents, landfill leachate, and discharge of restaurant wastewater from nearby restaurants.

The pH value of the sediment varies from 5 to 6.7, which is weakly acidic. The average value of TN is 2.05 mg/g, the average value of TP is 2.05 mg/g, the average value of ammonia nitrogen is 0.45 mg/g, and the average value of nitrate nitrogen is 0.04 mg/g. The river bottom mud has been polluted by N and P, N and P belong to medium pollution level, and the degree of TP pollution is slightly higher than TN. The benthic community has suffered some damage, but it is still within the acceptable range.

The N element in the sediment as a double indicator mainly reflects the pollution degree and nutritional status of the Beishi River, while the P element is one of the important indicators reflecting the pollution degree of the Beihe River. For microbial

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1005910072

community structure analysis, N and P have a certain correlation with microbial community diversity, but the effect of N element on microbial community is not significant, but P element has great influence on microbial community (Peng et al., 2009).

Extraction of microbial total DNA from sediment samples

The total DNA of the extracted sediment sample, if extracted by the soil DNA extraction kit, is invisible after drying, and the solution after dissolution with TE Buffer is light brown; if using the soil total DNA kit and humic acid It can be clearly seen after drying, and the white particles are clearly visible, and the brown matter is formed on the edge, and the solution dissolved by TE Buffer is colorless and transparent, or light brown.

The DNA extracted by the two methods was subjected to agarose gel electrophoresis. The map of the extract of the soil DNA extract kit was shown in *Figure 6*. The extract of the total DNA kit and the humic acid was as shown in *Figure 7*.

By observing the agarose gel electrophoresis patterns of the two methods, the soil extract kit has a small amount of DNA and more impurities. The total DNA kit combined with humic acid extracts more DNA and less impurities. In order to save costs and improve the accuracy of the experiment, only the extract obtained by the combination of the total DNA kit and the humic acid was used as the experimental material in the subsequent experiments.

Test of DNA concentration and purity

It can be seen from *Tables 1* and *2* that the OD260/OD280 values of the DNA extract of the soil extract kit are all greater than 2.0, indicating that the RNA and impurities contained therein are large, which does not meet the requirements of subsequent experiments. The total DNA purity of the sediment samples extracted from the total DNA kit combined with humic acid is higher and the content is higher. The OD260/OD280 values are less than 2.0 and greater than 1.6, which means that the extracted total DNA can be used as Subsequent PCR amplification experiments.

DNA samples 1, 2, 3, 4, and 5 in *Tables 1* and *2* are the DNA extracts of the Beihe River sediment samples from five different locations of Jingu Manor, Boyai Bridge, Qiting Bridge, Zhiyuan Bridge and Yuanfeng Bridge

Agarose gel electrophoresis test of PCR products (qualitative analysis)

After extracting the total DNA of the microbes in the sediment, the agarose gel electrophoresis experiment was carried out, and the DNA content was analyzed qualitatively. Its ultraviolet transmission spectrum is shown in *Figure 8*. This is a PCR amplified DNA agarose gel electrophoresis. Among them, M was the marker (normalruntm100bp-iv DNA Ladder), and 1 to 5 were the electrophoresis bands obtained after the amplification of microbial total DNA at five different sampling points, namely Jingu Manor, Boai Bridge, Chunting Bridge, Zhiyuan Bridge and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1005910072

Yuanfeng Bridge. The figure shows that the amplified target band is bright and clear with good specificity, and the amplified product is about 200bp to 250bp.

Figure 8. *Electrophoresis pattern of PCR products by agarose gel*

Denaturing gradient gel electrophoresis (DGGE) experiment of DNA

The DGGE spectra of the sediment samples from five different sections of The North Riiver (Jingu Manor, Boai Bridge, Chunting Bridge, Zhiyuan Bridge and Yuanfeng Bridge) are shown in *Figure 9*. The DGGE map indicates that the strains in the sediments of The North River have a high degree of richness. In addition, the DGGE band spectrum has some differences in the number and position of the bands and the brightness of the bands, indicating that the microbial community composition of different samples is also different.

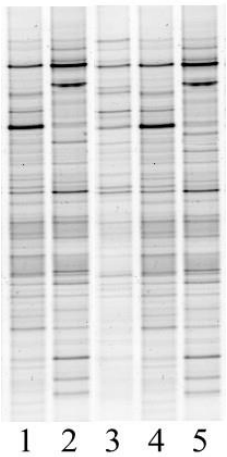

Figure 9. *DGGE map of five samples of North River mud*

BIO-RAD's Quantity One software analyzes DGGE maps, which allow manual and automated quantification of lanes and bands and then output results based on analysis needs. The chart below will be the lane/strip recognition map (*Fig. 10*) and the similarity matrix (*Fig. 11*) analyzed using Quantity One software.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1005910072

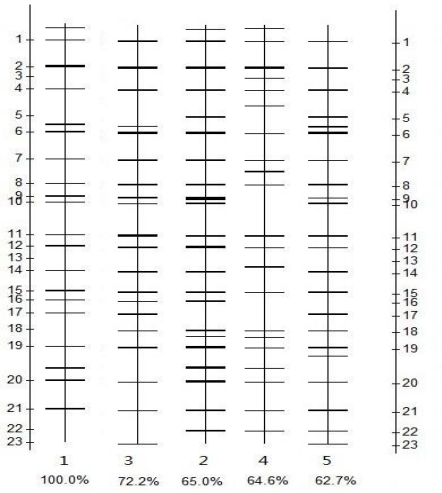

Figure 10. *Lane/strip identification maps of five samples of North River*

The sediment samples of the five different sections of the North River are shown in *Figure 10*. The standard for the lane identification map is C1. Identify the thickness of the lines in the figure, the thick strips indicate that the corresponding density on the DGGE glue is large, and the thin strips indicate that the density is relatively small; in the figure, 23 strips appearing more, 1 and 2 No. 4, No. 6, No. 6, No. 7, No. 8, No. 11, No. 15, No. 15, No. 20 and No. 21 appear in each sample; No. 9, No. 10, No. 14 And the frequency of the band 18 is also very high. The No. 2 strip is thicker in each lane, which means that the microbes represented by this strip are dominant microorganisms in the sediment of the North River.

Using the results of the strip comparison, a matrix of the similarity of each sample can be calculated from the Dyes coefficient Cs, as shown in *Figure 11*: the maximum similarity is 82% (No. 1 and No. 4), and the minimum similarity is 49.6% (4 and 5). By comparing the results of the pairwise comparison, there are 7 groups with similarity exceeding 60%, and the flora structure between them is similar.

Lane	1	2	3	4	5
1	00.0	64.0	66.7	82.0	50.8
2	64.0	100.0	65.0	72.2	64.6
3	66.7	65.0	100.0	65.5	53.2
4	82.0	72.2	65.5	100.0	49.6
5	50.8	64.6	53.2	49.6	100.0

Figure 11. *The similarity matrix of five samples of North River*

The variation of the DGGE band number, the Shannon-Wiener index, the Simpson index and the Pielou index of the five sediment samples of The North River is shown in *Figure 12*. With the increase of DGGE bands, the Shannon-Wiener index and the Pielou index also increased, while the Simpson index decreased accordingly. It can be seen that

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1005910072

with the increase of bacterial species, population diversity and uniformity increase, correspondingly The advantage is reduced. The maximum value of the Shannon-Wiener index appears in the Chunting Bridge in Section 3, and the minimum appears in the Zhiyuan Bridge in Section 4; the maximum value of the Simpson Index appears in the Chunting Bridge in Section 3, and the minimum appears in the Zhiyuan Bridge in Section 4; the Pielou Index The maximum value appears in the Zhiyuan Bridge in Section No.4, and the minimum value appears in the Chunting Bridge in Section No.3.

From the above analysis, the microbial diversity of the different locations of The North River is rich, with up to 23 bands appearing in a single lane. From the similarity matrix, the similarity of samples at different locations and times is high, the highest similarity is 82%, and the similarity is higher than 60%. Therefore, the North River has a rich microbial population, but its microbial community structure does not change much in space.

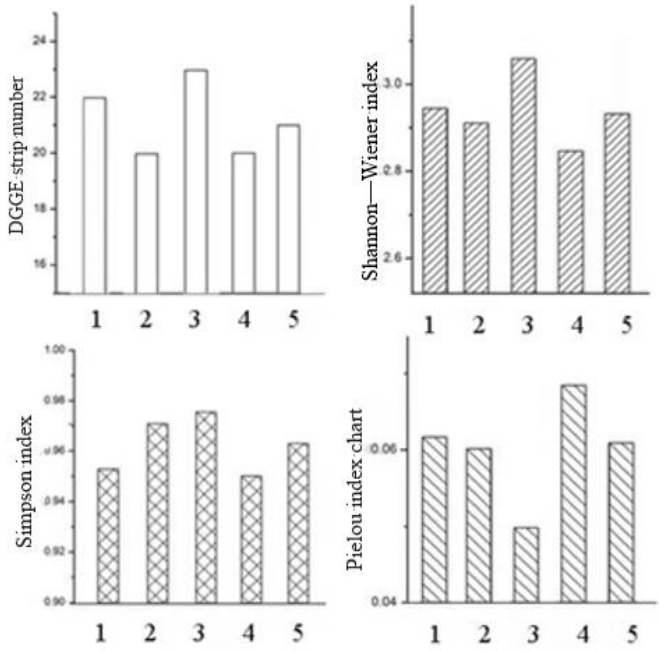

Figure 12. *DGGE number of bands, Shannon-Wiener exponents, Simpson exponents and Pielou exponents*

Conclusion

By comparing two methods of microbial DNA extraction from the sediments of the Beihe River (soil DNA mini-kit method and soil total DNA kit combined with humic acid), the latter can be compared with the former for the sediment samples of the Beihe River. The effect of DNA extraction is good. Although the total DNA purity and content of the sediment sample extracted by the total DNA kit and the humic acid method are high, the purity is still affected by protein, phenol and humus, so it is necessary to extract the total DNA of the environmental sample. Need to pay attention to reduce the pollution of proteins, humus, phenol and other substances.

(2) By analyzing the denaturing gradient gel electrophoresis pattern of the sample DNA, it can be seen that the microbial diversity of different locations in the Beishi River is rich, and at most, 23 bands appear in a single lane. From the similarity matrix,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1005910072

the similarity of samples at different locations and times is high, the highest similarity is 82%, and the similarity is higher than 60%. Therefore, the micro-population of the Beishi River is abundant, but its microbial community structure does not change much in space.

(3) Based on the analysis and research on the microbial community structure diversity of Beizhou River in Changzhou, it will provide corresponding help for optimizing community structure, regulating community function and discovering new important microbial functional groups, and then cultivate specific dominant functional groups. Future studies concerning the treatment of polluted rivers by microorganisms and related research on water body repair in desperately needed.

(Received 10th Apr 2019; accepted 19th Jun 2019)

Abstract. This study was carried out in two growing spring seasons 2017 and 2018 at Kanipanka Agricultural Research Station (Lat. 35°13'12", Long. 45°25'48", 550 MASL) in Shahrazoor valley 35 km east of Sulaimani – Iraqi Kurdistan Region to investigate the effect of two irrigation intervals (5 and 10 days) and thirteen different biotic and abiotic treatments on potatoes yield water use efficiency under the field condition. The results showed that the cumulative depth of irrigation in 2017 and 2018 for 5 and 10 days were 369, 228 and 363, 287 mm, respectively, while for both depth of irrigation and precipitation were 535, 394 and 513,437 mm, respectively. The effect of irrigation intervals on the WUE, IWUE and total yield (tons hectare^{-1}) was significant at 2017 and 2018 season and the average of both seasons, with exception of WUE in the first season. The 5 days irrigation intervals gave the highest values for the second season and the average of both seasons for the character WUE, while 10 days irrigation intervals gave the highest values in both seasons and their average. Regarding the first season and the average of both seasons, the mycorrhizal inoculation treatments gave the highest values of WUE, IWUE and total yield but at the second season, the KCl with *Glycyrrhiza glabra* (6 g L^{-1}) extract treatments gave the highest values for WUE, IWUE and total yield.
Keywords: *Solanum tuberosum, water management, mycorrhizae, KCl application, licorice extract*

Introduction

Potato (*Solanum tuberosum*), which belong Solanaceae family, is the fourth most agronomical important feed crops worldwide after winter wheat, maize, and rice. It is a global crop that is well-adapted wider range of altitude, latitude, and climatic conditions. Potato is a productive and exhaustive crop at the same time, requiring a variety of balanced plant nutrients for growth and development. The total world production of potatoes was 388 million tons in 2017 from this China have 25% of total production around the world with 99 million tons followed by India, Russia, Ukraine, and the United States with 48, 29, 22 and 20 million tons, respectively (FAOSTAT, 2019). Over two-thirds of the global potato production is consumed directly by humans, and the rest is used as animal feeds and starch production (FAOSTAT, 2019). The licorice roots (*Glycyrrhiza glabra*) extracted contain some compounds, which have similar effect to the growth promoters, and also have a wide range of minerals (phosphorus, potassium, zinc, magnesium, iron, calcium), amino acids (alanine, lysine, arginine), vitamins (B_1, B_2, B_6), with carbohydrate and nitrogen. In addition, it also

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1007310090

contains mevalonic acid that can be used in gibberellins synthesis (Sarby *et al.*, 2009). Potassium (K) foliar application is another factor that has been used for improved nutrient management and increasing potato growth and yield (Grewal *et al.*, 1992). Generally, Potassium is one of the vital elements that affect most of the biochemical and physiological processes. The physiological and molecular mechanisms of K function in plant stress resistance are studied by (Wang *et al.*, 2013). These researchers also demonstrated that adequate K nutritional status in the plants living under drought conditions has significant effect on root growth, leaf area, and increased cell membrane stability with total dry mass. In addition, role of potassium may facilitate osmotic adjustment, which is improved uptake of water via roots and minimize water loss during drought periods (regulates transpiratory water), consequently improving the ability of plants to tolerate drought stress (Egilla *et al.*, 2005). Furthermore, it has also a critical role for justifying ROS (reactive oxygen species) damage as induced by drought stress because ROS are significantly accumulated under a biotic stress conditions, which cause oxidative damage and eventually resulting in cell death (Wang *et al.*, 2013).

Microorganisms are vital component of the agricultural system. Arbuscular mycorrhizal (AM) fungi, a global soil microbe, can subordinate with the roots of most terrestrial crop species (Duc, 2017). Several benefits were observed when AM is colonized crops including; increased growth and yield, enhanced plant resistance to environmental adversities, improve plant tolerance to a biotic stress (Birhane *et al.*, 2012) Recently, researcher confirmed that improve stress tolerance of the host plants can be done by several AM-induced mechanisms of host tolerance to a biotic stresses, such as more effective anti-oxidative systems, defense enzymes; modifications in host physiology, e.g. osmotic adjustment, gas exchange, photosynthesis; remarkable alterations of sugars, proline, polyamines, stress phytohormones, expression patterns of stress-responsive genes (Latef and Miransari, 2014). AMF can produce glycoprotein glomalin, which is act similar a glue, binding carbon, nitrogen and other biological components of soil to the mineral components, clay and sand, that has an important role for increased soil organic matter, and consequently collected highly water stability (Duc, 2017). In addition, under drought condition, direct water uptake from soil into the host plant can improved by interlacing external hyphae of mycorrhizae, thus, it is believed that has resistance to drought condition by many mechanisms including; osmotic adjustment and altering display of stomatal conductance (Wu *et al.*, 2006).

Shock *et al.* (1992) studied that potato could be tolerating water deficit before tuber set without reduction in tuber quality under some water stress conditions. Potato may be quite sensitive to drought (Van Loon, 1981) as it needs frequently irrigations for suitable growth and optimum yield (Yuan *et al.*, 2003; Kiziloglu *et al.*, 2006). Hassan *et al.* (2002) found that the Stalinization and Tuberization stages were more sensitive than bulking and tuber enlargement stages. Thornton (2002) and Shock (2004) found that all growing stages of potato, especially tuber formation stage, are very sensitive to water deficit stress.

Irrigation scheduling is a means of supplying water according to crop needs. It is the process of determining when to irrigate and how much water to apply, as for factors which influencing irrigation scheduling which are soil characteristics, climatic factors, crop characters and management factors that are to be supposed in determining irrigation schedules (Reddy, 2007). Beder (2010) proposed that to appropriate irrigation scheduling can, it be conserved and maintained that avoid plant water stress.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1007310090

To achieve this objective specific and fine data of soil, plant and climatic parameters could be gathered and analyzed at specific field conditions. Ati *et al.* (2010) found that the water consumption of potato were 441 mm, 429 mm for the agricultural season 2008 and 2009, respectively. Results showed by Ati and Nafaou (2012) indicated that highest potato production was achieved when the treatment depletion 50% of available water (30.26 ton ha^{-1}) compared to the treatment depletion 75% of available water (25.66 ton ha^{-1}). Ati *et al.* (2013) study the effect of different irrigation treatment (deficit irrigation) and potassium humate fertilizer on yield, the content of nitrogen, potassium, and phosphor in tuber of potato and water use efficiency in the Abu-Ghraib Region, Iraq. Potato was grown under drip irrigation with three treatments: irrigation applied when evaporation 75%, 100% and 125% from pan A, and three potassium humate fertilizers: 0, 1.2 and 2.4 kg ha^{-1} with three times additions. The seasonal potato evapotranspiration ranged from 267 mm to 372 mm. The drip irrigation treatments significantly affected tuber yield of potato and recorded 29.530, 27.630 and 24.880 kg ha^{-1} for 125%, 100% and 75% from pan A evapotranspiration, respectively. Humus fertilizers addition has the lowest value of ETa 309 mm and maximum value of yield 29300 kg ha^{-1}.

Water use efficiency (WUE) defined as the tuber yield obtained per unit of water consumed as ETa or water used in cubic meter by the potato (Doorenbos and Pruitt, 1977). Rashidi and Gholami (2008) illustrated that WUE of potato in Iran ranged from 1.92 to 5.25 kg m^{-3}. They added that few numbers of irrigation could reduce compactness of the soil. Nagaz *et al.* (2007) found that WUE varied around 8-14 kg m^{-3} for planted potato. Wright and Stark (1990) reported that the WUE for maximum yield range from approximately 0.05 to 0.1 kg ha m^{-3}. Kirda (2002) stated that the main objective of deficit irrigation is to increase the WUE of a crop by eliminating irrigation that have little impact on yield. The objective of this study was to determine the effects of irrigation intervals and different treatments biotechnologies on yield of potato (Actrice variety) and water use efficiency in Iraq -Kurdistan region.

Material and Method

This study carried out in two spring growing seasons in 2017 and 2018 at Kanipanka Agricultural Research Station (Lat. 35°13'12", Long. 45°25'48", 550 MASL) in Shahrazoor valley 35 km east of Sulaimani – Iraqi Kurdistan Region. GIS software was used to create the study sites shown in *Fig. 1*. Generally, elevation of this region ranges between 5-2368 m above sea levels. The climate of study area is generally characterised by worm, dry summer and cold winters (Najmaddin *et al.*, 2017).The meteorological data of Kanipanka during both growing seasons is shown in *Table 1* as well as some physical and chemical properties of Kanipanka soil shown in *Table 2*.

Bio Inoculation

The fungal inoculants *Glomus mosseae* was obtained from Al-Zaefaraniya Agricultural Research Station - Ministry of Science and Technology – Baghdad. The inoculants were consisting of mycorrhizal spore with 47 spore g^{-1} dry soil and the residual of the infected roots. Potato tubers were inoculated with the mycorrhizal spores by using 20 g from the mixture of the inoculums and the pet moss inside the pores which specified for inoculation treatment before planting the tubers where the pad method was used to ensure the infection by touching the inoculums during planting.

Preparation of Glycyrriza glabra Extraction

Three and Six gram of *Glycyrriza glabra* roots powder was soaked separately in one litter hot distilled water at 50°C for 24 hours in dark colure bottles with shaking continuously, then the solution filtered through several layers of Tapestry cloth, to obtained two concentrations of the extraction 3 and 6 g L^{-1} and several drop of Twin20 were added as a spread materials to reduce the surface tension. The plants were sprayed two times 45 and 60 days after planting date, after the sun seat in both years 2017 and 2018 (Lazim and Sulaiman, 2012).

Preparation of Potassium Fertilizer (KCl)

Two half five gram of potassium chloride (KCl) was dissolved in one liter hot distilled water at 40°C with shaking the potassium completely dissolved and several drop of Twin20 were added as a spread material to reduce the surface tension. The plants were sprayed at the morning trice 40, 55 and 70 days after planting in both years 2017 and 2018.

Addition of Chemical Fertilizer

Six hundred kilograms per hectare of Di-Ammonium Phosphate (DAP) 18:18:0 fertilizer was added in two times, first during the cultivation of the tubers (spares on the furrows), the second addition was after one month from the first addition as recommended for the chemical fertilizer treatment only, (Esho *et al.*, 2009) while half of the recommended were added for the rest of the treatments.

Field Practices

Each experimental unit (furrow) was 3 m long and 0.8 m apart (2.4 m^2), each furrows consists of 12 plants in one side. Planting dates were 10 March 2017 and 5 March 2018 at the first and the second season respectively, while the harvesting were accomplished after 100 days on 20 June 2017 and 15 June 2018 at the first and the second season respectively. The furrows within the blocks were divided into 4 groups, each group consists of 4 furrows, the last one was one furrow, and each groups were conducted with a 10 cm diameter plastic pipes to feeding them with water from the main stream in order to calculate the timing for watering from the main stream to the furrows. The timing was calculate until the water reached the standardized line in each furrow in order to measure the quantity of water that entered the furrow through the plastic pipes in each irrigation intervals 5 and 10 days. The average volume of water and its operation time was calculated to estimate the discharge of sub main irrigation pipe:

$$Q\ t = A\ d \qquad \text{(Eq.1)}$$

where:

- Q: discharge of sub main (L/sec).
- t: operation time (sec).
- A: area of furrow (2.4 m^2).
- d: depth of irrigation water (mm).

Level furrows were created between rows to ensure uniform water distribution in plots irrigated by furrows. Furrows were closed at the end to prevent runoff and a square meter was used to measure the amounts of applied water. Since the Actual Evapotranspiration (ETa) was calculated using the soil water balance method:

$$ET_a = P + I - D \pm \Delta W \qquad \text{(Eq.2)}$$

where:

- ET_a: actual evapotranspiration (mm).
- P: is the rainfall (mm).
- I: is the irrigation applied to individual plots (mm).
- D: is the deep percolation.
- ΔW: is the change in water storage of the soil profile (mm).

Water use efficiency (WUE) and irrigation water use efficiency (IWUE) were calculated from the following equations (Kirda, 2002) and (Howell *et al.,* 1990):

$$WUE = \frac{Yield\ (kg)}{ETa\ (m^3)} \qquad \text{(Eq.3)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1007310090

$$IWUE = \frac{Yied\ (kg)}{Total\ water\ applied\ (m^3)} \quad \text{(Eq.4)}$$

Statistical Analysis

A factorial experiment was conducted in split-plot design with three replicates; the first factor (Irrigation intervals) were implemented in the main plots and conducted with Randomized Complete Block Design (RCBD), while the second factor (Treatments) were implemented in the sub plots. All possible comparisons among the means were carried out by using Least Significant Difference (L.S.D) test at a significant level of 5% after they show their significance in the general test (Al-Rawi and Khalafallah, 1980).

Results

Water is one of the most essential elements in growing plants, which constitutes more than 80% of the active cells. Thereby, the amount of applied water during crop irrigation, added time, irrigation methods, quality of added water, and prevailing micro-meteorological conditions have found to play limited roles in yield quality and quantity. In Asia, statistics showed that the yields for most crops have increased 100–400% after irrigation. Irrigation allows farmers to use water in the most efficient way and at the crucial times for the crop instead of being subject to the shortage of rainfall. Water becomes scarce, expensive, and necessitates to be utilized in a scientific manner.

In the first season of irrigation intervals 5 and 10 days were applied after 50 days from sowing and were ended at 96 days after sowing, since, the amount of irrigation water for 5 days interval was cover the most of depleted water at this time. The cumulative depth of irrigation for 5 and 10 days from 1 May 2017 to 15 June 2017 were practically measured and formed to be 369 and 228 mm, respectively. Since the numbers of irrigation were 10 and 6 times for 5 and 10 days of irrigation intervals respectively as shown in *Fig. 2*. While the amount of actual evapotranspiration for 2017 and 2018 were 529, 423, 515 and 440 mm, respectively (*Table 4* by applied *Equation 2*), while cumulate depth of irrigation and precipitation were 535 and 394 mm respectively as shown in *Fig. 3.*

Table 4. *Actual evapotranspiration (ETa) for 5 and 10 days in 2017 and 2018*

Component	Season 2017		Season 2018	
	I_5	I_{10}	I_5	I_{10}
Rainfall (P) (mm)	166	166	150	150
Irrigation (I) (mm)	369	228	363	287
Deep percolation (D) (mm)	36	16	34	20
ΔW (mm)	30	45	36	23
Eta (mm)	529	423	515	440

$$\text{Eta } (m^3) \text{ for } (I_5 - 2017) = 1.104 + 0.384 = 1.488\ m^3$$
$$\text{Eta } (m^3) \text{ for } (I_{10} - 2017) = 0.680 + 0.468 = 1.148\ m^3$$
$$\text{Eta } (m^3) \text{ for } (I_5 - 2018) = 1.089 + 0.364 = 1.453\ m^3$$
$$\text{Eta } (m^3) \text{ for } (I_{10} - 2018) = 0.681 + 0.367 = 1.228\ m^3$$

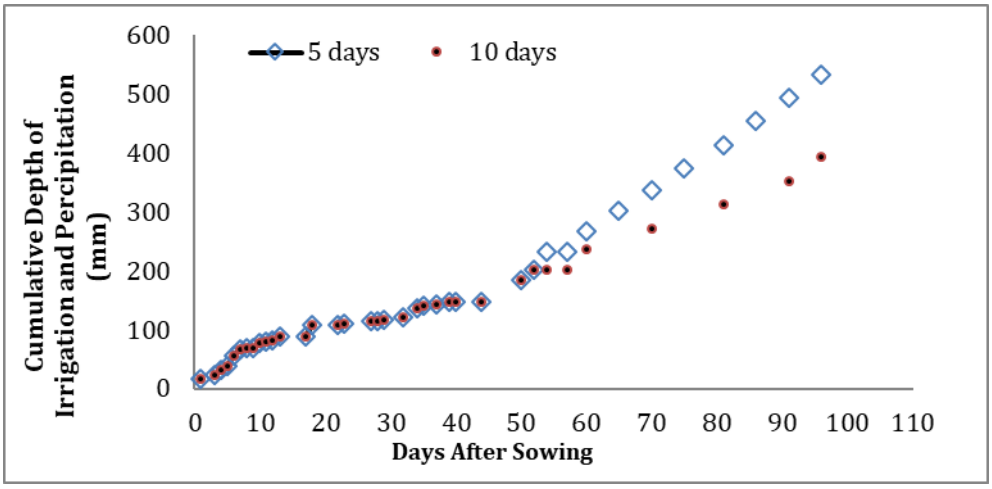

Figure 3. *Cumulative depth of irrigation and precipitation (mm) for 5 and 10 days of irrigation intervals in 2017*

In the season 2018 the irrigation intervals 5 and 10 days was applied from the sowing date and were ended at 95 days after sowing, the amount of irrigation water for 5 days interval which cover the most of depleted from 5 March 2018 to 10 June 2018 were practically measured 363 and 287 mm, respectively. Since the numbers of irrigation were 9 and 5 times for 5 and 10 days of irrigation intervals respectively as shown in *Fig. 4*. While accumulate depth irrigation and precipitation were 513 and 437 mm, respectively as shown in *Fig. 5.* These results are in agreement with the findings of several other researches (Ati *et al.*, 2012; Ati and Nafaou, 2012). Gander and Tanner (1976) showed that mild water stress of -3 to -5 bars greatly reduce leaf expansion in potatoes, and for best tuber yields, a 120-150 day potato crop requires 508-698.5 mm of the water.

The data in *Table 5* and *Appendix 1 and 2* show the effect of the irrigation intervals on the studied characters, significant differences were observed among all of the studied characters at the first, second and average of both seasons with exception of WUE in the first season this may be due to that rain fed in this season distributed throughout the growing season in the way that the deficit does not cause any reduction in the yield. The 5 days irrigation intervals achieved the highest values of WUE and in the second and average of both seasons with 7.085 and 6.802 kg m^{-3}, respectively, while the 10 days irrigation intervals achieved lowest

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1007310090

values with 6.144 and 6.439 kg m^{-3}, respectively. This agrees with the finding of Nagaz *et al.* (2007), which concluded that WUE varied around 8-9, 6-8 and 11-14 kg m^{-3} for autumn and spring planted potato, respectively in Southern Tunisia. Rashidi and Gholami (2008) reported that WUE of potato in Iran ranged from 1.92 to 5.25 kg m^{-3}. Erdem *et al.* (2006) reported that potatoes plant was grown under furrow and drip irrigation methods and three regimens irrigation applied when 30, 50, and 70% of the available water was consumed, water use efficiency values increased from 4.70 to 6.63 kg m^{-3} for furrow-irrigated treatments, and from 5.19 to 9.47 kg m^{-3} for drip-irrigated treatments.

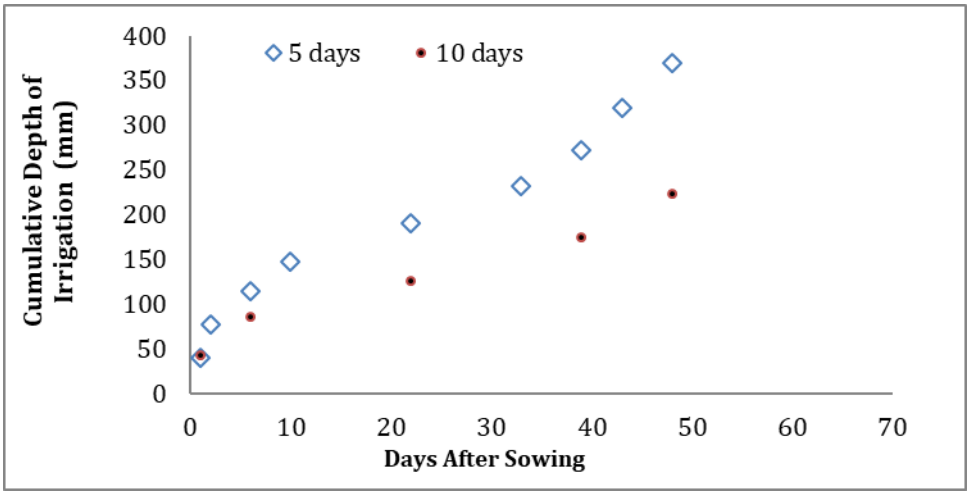

Figure 4. *Cumulative depth of irrigation (mm) for 5 and 10 days irrigation intervals in 2018*

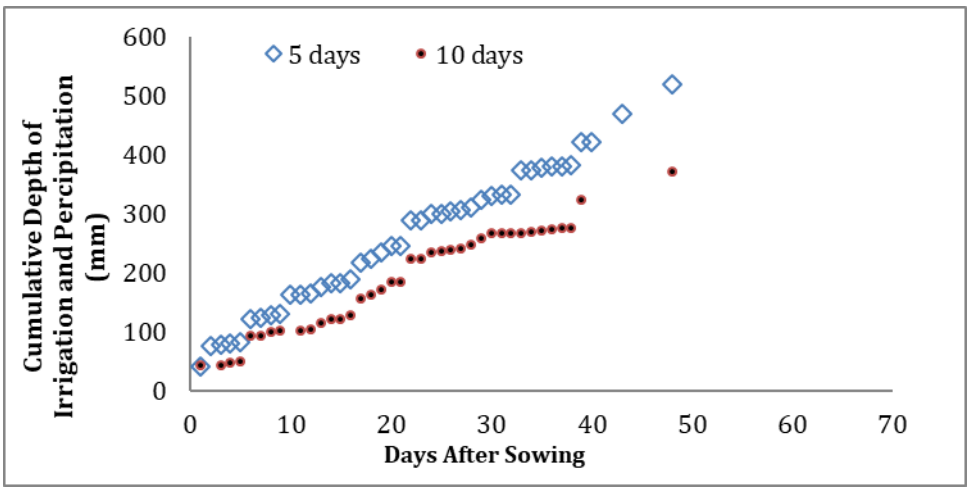

Figure 5. *Cumulative depth of irrigation and precipitation (mm) for 5 and 10 days irrigation intervals in 2018*

Concerning the IWUE in the first, second and average of both seasons the 10 days irrigation intervals gave the maximum values with 11.352, 11.281 and 11.316 kg m^{-3} respectively, while the 5 days irrigation intervals gave the lowest values with 8.788, 9.293 and 9.041kg m^{-3} respectively. Total yield gave the maximum values in the use of the 5 days

irrigation intervals at the first, second and the average of both seasons with 40.418, 42.886, and 41.652 tons hectare^{-1} respectively and overcome the yields of the 10 days intervals which gave 32.205, 31.431, and 31.818 tons hectare^{-1} at the first, second and the average of both seasons, respectively.

This may be due to the use of arbuscular mycorrhizal fungi (AMF) mitigates the effects of this stress in a sustainable way and given the increase in the tolerance to water deficit stress in plants inoculated with these fungi; however, the exact mechanism is unknown because the response depends on the water-deficit stress type and is specific to the AMF and the plant. These mechanisms may include modifications in the content of plant hormones, such as strigolactones, jasmonic acid (JA) and absicic acid (ABA). The JA appears to be involved in the stress signal in mycorrhizal plants through an increase of ABA concentrations and, at the same time, ABA has a regulating effect on strigolactones concentrations. Also, there is improvement of plant water status, stomatal conductance, nutritional status and plant responses to cope with a water deficit, such as osmotic adjustment, and antioxidant activity. These modifications cause an increase in CO_2 assimilation and photoassimilates production, improving plant growth as well as the yield during a drought.

The results in *Table 6B* and *Appendix 1* revealed that the treatments significantly influenced on WUE, IWUE and yield plant^{-1} during the second season 2018. The highest values were obtained by T_{11} with 7.495 kg m^{-3}, 11.655 kg m^{-3} and 42.106 tons hectare^{-1} respectively, while the lowest value was recorded by T_1 with 5.334 kg m^{-3}, 8.456 kg m^{-3}, and 29.678 tons hectare^{-1} for WUE, IWUE and total yield respectively. These results is agree with the study of Ati *et al.* (2013) which they stated that potassium humate had a great impact on tuber of potato and water use efficiency in the Abu-Graib Region, Iraq. In their study potato was grown under drip irrigation with three treatments: irrigation applied when evaporation 75%, 100% and 125% from pan A, and three potassium humate fertilizers: 0, 1.2 and 2.4 kg ha^{-1} with three times additions. The seasonal potato evapotranspiration ranged from 267 mm to 372 mm. The drip irrigation treatments had significant effecting tuber yield of potato recorder 29.530, 27.630 and 24.880 kg ha^{-1} for 125%, 100% and 75% from pan A evapotranspiration, respectively. Humus fertilizers addition has the lowest value of ETa 309 mm and maximum value of yield 29300 kg ha^{-1}.

Table 6C and *Appendix 2* showed the effect of the treatments on WUE, IWUE and total yield. The differences among treatments were significant at the average of both seasons. T_3 gave the maximum values for all of the characters with 7.739 kg m^{-3}, 11.789 kg m^{-3}, and 43.183 tons $hectar^{-1}$ respectively, however the minimum values recorded in T_1 with 5.034 kg m^{-3}, 7.846 kg m^{-3} and 27.831 tons $hectar^{-1}$ respectively. The results agreement with the finding of several other researches. Goussous and Mohammad (2009) reported that Arbuscular Mycorrhizal Fungi (AMF) and plant roots improve water and nutrient uptake such as phosphorus, nitrogen and micronutrients, thus enhance potato plants growth, and yield. AMF can produce glycoprotein glomalin, which is act similar a glue, binding carbon, nitrogen and other biological components of soil to the mineral components, clay and sand, that has an important role for increased soil organic matter, and consequently collected highly water stability (Duc, 2017). In addition, under drought condition, direct water uptake from soil into the host plant can improved by interlacing external hyphae of mycorrhizae, thus, it is believed that has resistance to drought condition by many mechanisms including; osmotic adjustment and altering display of stomatal conductance (Qiang-Sheng *et al.*, 2006).

Discussion

These result accused the role of the interaction of irrigation intervals and different treatments, increased wetted soil volume inside root zone, and this mean increasing in water volume which was stored in root zone. The differences on the total yield can be explained by the influence of the biotic and abiotic application on WUE and IWUE which in return maximize the total yield.

Results of WUE indicated the importance of the treatments to achieve good yield and better utilization of water, which can be attributed to the role of Mycorrhizal inoculation in improving crop resistance to water stress and other stresses. In the first season 2017, no significant difference was observed in term of WUE and this may be due to the distribution and the amount of rainfall in this season was enough to bear plants water requirement in the 10 days irrigation intervals.

Thus, increase of phosphorus uptake by mycorrhizae considering the role of phosphorus in molecular structures such as nucleic acids, stomatal conductance, and photosynthesis increases the tolerance of plants against water stress.

DOI: http://dx.doi.org/10.15666/aeer/1704_1007310090

Biofertilization has emerged in order to minimize environmental impacts and take advantage of the resources available in the field.

Therefore, it can be concluded that the biotic application with good crop management can achieve good productivity and high WUE in Iraqi Kurdistan region conditions.

The treatment of mycorrhizae inoculation for the highest values in WUE and IWUE may be due to its high ability to produce the glomalin compound, which binds the soil minutes to each other and to the aggregation of aggregates, as well as the role played by the mycelium hypha in mass soil actions and increase its stability. Fokom *et al.* (2012) indicates that there are positive correlations of correlations between organic matter and chlorine associated with Glomalin Related Soil Protein (GRSP). Peng *et al.* (2013) noted that the soil fertilized with mycorrhizae increases the stability of its aggregates as a result of the action of the mycorrhizae hypha and the result of its production of glomalin, a watery and insoluble molybdenum protein compound that contributes to the formation and increase stability of the soil complexes where it is released to the and reduce their hydration because it is a glue-absorbing composite. Martin *et al.* (2012) and Wu *et al.* (2013) reported that organic matter also plays an important role in improving the properties of physical, chemical and biological soil. Microorganisms are fertilized with food and increase their activity, which positively affects the increase in the activity of the Mycorrhizae (Ochl *et al.*, 2003). All of these factors improve soil properties and increase their water retention.

The *Glycyrrhiza glabra* extract contains some acids, monosaccharide's, various vitamins (E, C and B), folic acid and various elements such as calcium, iron, silicon, aluminum, magnesium, sulfur, potassium, zinc and phosphorus, which play an important role in growth (Vispute and Khopade, 2011). *Glycyrrhiza glabra* extract also contains mevalonic acid, which enters the synthesis of gibberellins (Moses *et al.*, 2002).

Potassium is also associated with many other important phylogenetic functions, including activation of enzymes, regulation of opening and closing of stents, as well as its important role in the synthesis of ATP, where the electrostatic charge in the ATP production sites is closely related to the K^+ (Prajapati and Modi, 2012) and sugars (Van Brunt and Sultenfnss, 1998), water and nutrient transport (Thomas and Thomas, 2009) and protein synthesis and starch (Patil, 2011).

Conclusion

The irrigation intervals had great influence on WUE and the total yield of potato, the 5 days intervals overcome the 10 days intervals at 2017 and 2018 season's and the average of both seasons with exception of the character WUE of at the first season. Mycorrhizal inoculation maximize the WUE, IWUE and the total yield at the first season 2017 and the average of both seasons, this indicated that the Mycorrhizal inoculation will improve the WUE, IWUE and the total yield depending on the seasonal condition. At the second season the application of (2.5 g L^{-1}) KCl with (6 g L^{-1}) *Glycyrrhiza glabra* extract gave the highest value for the studied characters the rainfall quantity in this season was more in April and May 2018 comparing with the same months in 2017 which leads to increase the role of this combination.

Abstract. Climate extremes are recognized as main drivers of ecosystem functioning in terrestrial biomes. So far impacts and underlying mechanisms of which climate extremes shape ecosystem processes are poorly understood. This gap impedes an understanding of how climatic extremes modulate long-term and large landscape provisions of ecosystem functions. Trait-based studies render a feasible avenue that links climate extremes and ecosystem functioning. Plant functional traits are considered as a sensitive probe in terms of the response to changes in climatic conditions. Approaches that account for effects of climate extremes on plant functional traits may close this gap. We develop a stepwise framework that relates the response of functional traits to climate extremes and resolves relationships between patterns of functional traits and ecosystem functioning by a process-based dynamic vegetation model. We introduce an ongoing case study to demonstrate how this framework permits an accurate evaluation of ecosystem functioning under various scenarios of climate extremes. Our proposed framework may benefit functioning programs by providing key functional traits sensitive to climate extremes or determinants of ecosystem functions. The practice will in turn improve the parameterization and the validation of the vegetation model, especially in regions paucity of field data.
Keywords: *dynamic vegetation model, ecosystem process, patterns of functional traits, precipitation, temperature, alpine ecosystems*

Introduction

The intensity and the frequency of climatic extremes, namely abnormal climate variabilities, significantly shift the functioning of terrestrial ecosystems (Jentsch et al., 2011; Frank et al., 2015). There is an evidence that plant interactions (Filazzola et al., 2018), vegetation net primary productivity (Sun et al., 2016) and the resistant capacity of plant community (Dreesen et al., 2014) seemed to be more vulnerable to climate extremes than to average climatic conditions. Although effects of climate extremes on ecosystem processes and the resulting ecological consequences have been gradually tested (Wilcox et al., 2016), researches of climate extremes in terms of ecosystem functioning are far from perfection. An important reason is a hard quantification of drving impacts of climate extremes on the ecosystem dynamic. Moreover, mechanisms underlying responses of ecosystem processes to climate extremes, e.g. non-linear effects and threshold behaviors (Brotherton and Joyce, 2015), were not fully understood. Thus more concerns should be made on the ecological significance of climate extremes.

Until now, experimenters manipulated the magnitude of climatic factors like treatments of water reduction and open-top chamber warming, and assessed impacts of climate extremes on ecosystem functioning (Walter et al., 2011; Wang et al., 2012; Kreyling et al., 2017). However, they largely neglected potential interactions among climate extremes. Drought might offset effects of warming on aboveground biomass in a short time period. A combination of decreased rainfall and higher temperature was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1009110104

likely to exacerbate deficits in water budgets through an increased evaporation in temperate grasslands (Brotherton and Joyce, 2015). The impact of various climate extremes to ecosystem functions should be disentangled since the complex nature of ecosystem response to climate extremes is non-linear and non-additive.

Understanding ecosystem response to climate extremes can be advanced by incorporating approaches emphasizing the role of plant functional traits. Plant traits are measurable properties of an individual plant such as plant height, leaf area and root depth. The functional characteristics of traits are showed by their depiction on the fitness of plant species (Violle et al., 2007). Distributions of functional traits could indicate selection effects of abnormal climatic variabilities on plant communities. Larger rainfalls together with less rainy days stimulated the growth of deep-rooted plants as individual rainstorm led to a greater infiltration into deeper soil layers (Knapp et al., 2008; Tietjen, 2016). Plants responded to drought stress by structural adjustments such as decreased leaf area and increased root–shoot ratio (Teuling et al., 2006; Greenwood et al., 2017). Drought events were found to enhance the dispersal capacity of plant seeds (Zavalloni et al., 2009). Communities composed of long-lived plants might be resistant to individual extremes but be vulnerable to abrupt changes in climate regimes owing to a low turnover rate (Beier et al., 2012), since long-lived plants were more likely to experience cumulative influences of multiple extremes in the course of their lifespan.

Distributions or compositions of plant functional traits have been broadly found to be related to ecosystem functioning (Orwin et al., 2010; Zirbel et al., 2017). Plant functional traits and their associated trade-offs determined vegetation competitive abilities for light, water resources and nutrients (Kunstler et al., 2016). Trait-based approaches have been proposed incorporating into dynamic vegetation models for predictions of vegetation distribution and ecosystem functions (Webb et al., 2010; Soussana et al., 2012; van Bodegom et al., 2014). Functional trait compositions can advance our understanding of how ecosystem functioning responds to climate change (Helge et al., 2018). Compositional changes in functional traits led to a shift in biomass productions of the grassland community under conditions of increased warming events (White et al., 2000). Biomass productions of the herbaceous community were more determined by reproductive traits than competitive traits under drought stress (Dreesen et al., 2014). However, trait-based studies of climate extremes are constrained by lack of systematically experimental trait data and the highly non-linear plant response to climate extremes. This makes a quantitative assessment of extreme impacts on ecosystem functions virtually difficult. Therefore, the strength and the direction of links between functional trait patterns and ecosystem functions need to be evaluated based on simulating multiple scenarios of climate extremes.

In summary, most studies did not consider the full path from climate extremes via plant functional traits to ecosystem functioning. What extent climate extremes shape variations of plant functional traits or trait combinations is not well understood. Empirical investigations are the fundamental step to deal with the problem. However, owing to their limited complexity of spatio-temporal scales, we might draw an incomplete conclusion of climate extreme effects on patterns of functional traits. To fill out the knowledge gap, a full factorial modelling design, in which properties and interactions of individual climate extremes as well as all combinations of plant functional traits, is simulated to predict long term changes in ecosystem functioning.

In the following, we present a stepwise research framework that includes a simulation of individual climate extremes and their interactions, modelling patterns of plant functional traits and their relationship with ecosystem functioning. Implementing this framework will pave the road towards benefiting practitioners in the aim of predicting ecosystem functioning. The methodology in the framework may play a greater role in regions susceptible to climate change, especially regions short of field data. Although we illustrate the research framework with reference to Qinghai-Tibetan alpine grassland ecosystems, we are confident that the framework is also feasible for studying effects of climate extremes on ecosystem functioning in a global scale.

Construction of the framework

Achieving an accurate prediction of ecosystem functioning toward future climate requires integrative knowledge from properties of climate extremes and trait-based studies as well as process-based dynamic vegetation models. Such approaches, however, have been so far missing. To achieve the above-mentioned goals, we put forward the following research questions to identify which plant functional traits are reliable indices for predictions of ecosystem functioning under conditions of climate extremes:

1) How should we simulate properties of climate extremes in the dynamic vegetation model?

2) What are patterns of functional traits under different scenarios of climate extremes?

3) How do functional trait patterns affect ecosystem functioning?

Here we briefly propose consecutive steps in a framework that describes how climate extremes and plant functional traits can be linked to achieve the ultimate goal. We thereafter elaborate these steps using an ongoing case study to illustrate the potential value of the approach.

How should we do at first: the simulation of individual climate extremes and their interactions

Assessing vegetation responses to precipitation and temperature should consider properties of climate extremes in reality. The consistent findings on precipitation patterns with increased extremity were not well covered by treatments applied in empirical experiments (Dwyer and O'Gorman, 2017). Similarly, current climate generators in ecosystem models did not fully capture abnormal variabilities of precipitation and temperature time-series recorded data (Reichstein et al., 2013). This may lead to an unrealistic simulation of driving effects on the vegetation dynamic. In addition, increased temperature resulting from long-term global warming was experimentally manipulated in short time periods. Rainfall extremes associated with increased temperature might be underestimated in terms of projections of future climate change (Allan and Soden, 2008). This urges us to simulate precipitation and temperature extremes in a more realistical way. It is necessary to at first identify types, the magnitude and the frequency of climate extremes based on studied regions. Designed scenarios of climate extreme should satisfy requirements that applied treatments are indeed ‘abnormal’ beyond current background variabilities of climate conditions over a time period. Otherwise we may run the risk of killing ‘real’ or maintain ‘no-existed’ plant types.

Link climate extremes with functional traits: Developing a process-based dynamic vegetation model

To assess effects of climate extremes on the vegetation dynamic, fundamental ecosystem processes should be included in the model like water cycle, carbon cycle and vegetation demographical processes (Frank et al., 2015). Simulations of ecosystem processes refer to descriptions in the literature and these need to be adjusted and adapted to the studied system. Dynamic vegetation models used plant functional types depicted by suits of functional traits rather than specific species. This allowed for direct assessments of functional traits responding to climate changes (Mouillot et al., 2013). It was necessary to explicitly incorporate representative functional traits that were closely linked to vegetation dynamics under multiple climatic conditions (Fernandez-Going et al., 2012). Sensitivity analysis is an effective way to find out key trait parameters that should be carefully assigned values. If a sensitive parameter is uncertain, this uncertainty should be conducted through model simulations to establish a full range of potential outcomes. Trait parameterization is a crucial step to gain full confidence of vegetation simulations which should be based on empirical data e.g. the corresponding relationship between simulated trait parameters and measured traits in reality.

Patterns of functional traits and their relationship with ecosystem functioning under different scenarios of climate extremes

A knowledge gap that cannot be filled by experimental data is that effects of climate extremes on ecosystem functioning are not additive. Modelling ecosystem behaviors after climate extremes requires in depth understanding of patterns at the level of plant functional traits. Patterns of functional traits may aid us to identify thresholds of community responses to individual climate extremes. In case pulses exerted by climate extremes went beyond thresholds of community resistance or tolerance, they would cause dramatic changes in ecosystem functioning (Diez et al., 2012). Plant communities adapted to dynamic environmental conditions and with a higher diversity of functional traits might have advantages in the recovery from climate extremes (Brotherton and Joyce, 2015). The relationship between patterns of functional traits and ecosystem functioning should be assessed in a full factorial design under multiple scenarios of climate extremes. We should be aware that specific trait combinations determine one function or single functional trait plays different roles for various function indices.

A case study in Qinghai-Tibetan alpine grasslands

We exemplify the framework using an ongoing case study with a focus on Qinghai-Tibetan alpine grasslands. Climate extremes largely drove ecosystem functioning in cold biomes with high altitudes (Marcolla et al., 2011; Wipf et al., 2013). The unique geographical and climatic conditions in Qinghai-Tibetan Plateau determine processes of water and carbon cycle in eastern Asia (Yao et al., 2012). In addition, most regions are characterized by arid or semi-arid biomes. Low temperature and water shortage were both limiting factors for resource acquisition of alpine plants. Demographical rates closely linked with traits of alpine plants (Blonder et al., 2018). Alpine plants were generally long-lived. Vegetation processes might work at a slower rate than warmer areas (Gottfried et al., 2012). Average plant height usually declined with an increased altitude (Butterfield and Suding, 2013). Alpine plants often developed opportunistic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1009110104

traits in response to late snowmelt due to altitudinal constraints (Almeida et al., 2013). Functional trait diversity of alpine plants can regulate the response of vegetation productivity to regional climate change (Wu et al., 2016). Measured data of functional traits in most regions of Qinghai-Tibetan Plateau were much limited, characterized by a short time scale and lack of the comparability among regions. Thus, simulating effects of climate extremes on ecosystem functioning through plant functional traits may permit us to understand the underlying mechanisms of alpine ecosystem dynamic. We should have an awareness that part of areas in Qinghai-Tibetan Plateau already locate under so-called climate extreme conditions (e.g. very low temperature or covered by snow all year around), where plant functional traits are evolutionary outcomes of their environmental conditions. More extremes of climate conditions probably lead to weak or no changes in ecosystem functioning. To achieve the goal of accurately predicting ecosystem functioning, our approach integrates a database of plant functional traits and community properties in the Haibei station (one of typical experimental stations in Qinghai-Tibetan Plateau) with a process-based dynamic vegetation model. In the following we demonstrate the application of every consecutive step, that is, how we perform the framework in Haibei alpine grasslands to address our research questions (*Fig. 1*).

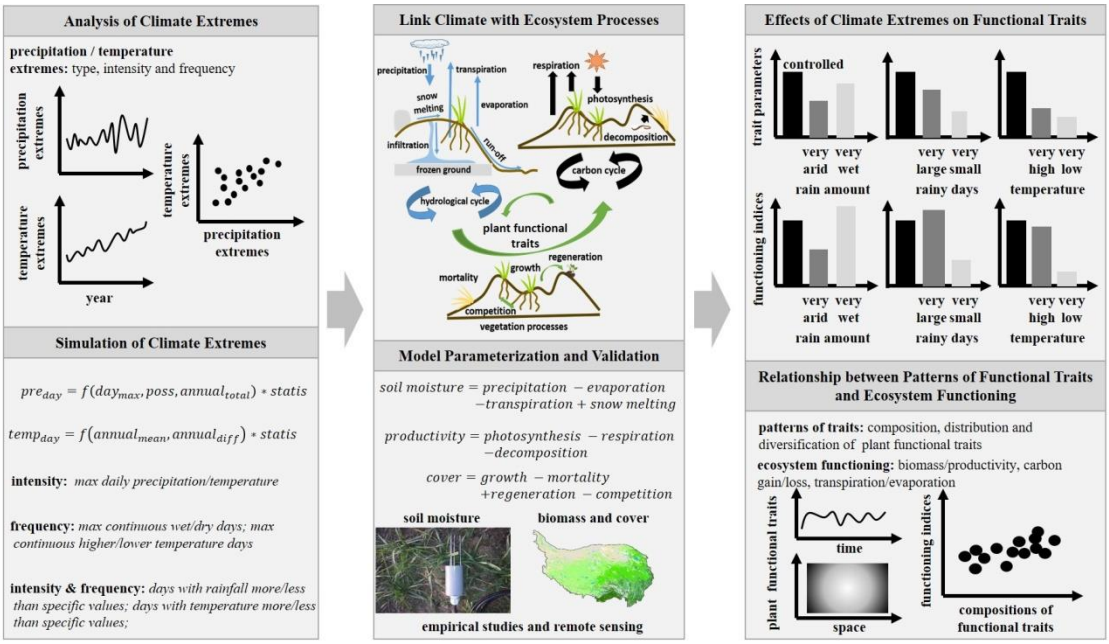

Figure 1. *Every steps performed in our case study for evaluating effects of climate extremes on functional traits patterns and their relationship with ecosystem functioning. The left panel: 1) we analyze temporal variations of precipitation and temperature extremes as well as interactions between individual extreme indices. 2) We incorporate properties of extreme indices into the climate generator to better simulate the vegetation dynamic in the model. The middle panel: 1) We simulate ecosystem processes related to carbon cycle, water cycle and vegetation demography. These processes interconnect and are adjusted by plant functional traits. 2) We calibrate and validate the model based on site-specific measured data at the Haibei station in Qinghai Province. The right panel: 1) We compare patterns of functional traits between the baseline scenario and various climate extreme scenarios; 2) W will evaluate the relationship between patterns of functional traits and ecosystem functioning under respective climatic scenarios*

Simulations of climate extremes

Properties of individual climate extremes should be depicted based on long term climate data. We obtained 56 years (1960 - 2015) climate data from two weather stations nearest to the Haibei station. Thereafter we analyzed the temporal variations of individual climate extreme indices recommended by Expert Team on Climate Change Detection, Monitoring and Indices (Alexander et al., 2006). We selected several representative extreme indices based on ecosystem characteristics of Qinghai-Tibetan Plateau. These extreme properties are incorporated into the climate generator (*Table 1*). To evaluate future threats of respective climate extremes, outcomes of the multiple extreme scenarios are compared with the cumulative outcomes of the single extreme scenario. Based on regional climatic characteristics and the temporal trend of historical data, we conduct an increased extremity for each scenario (a change of 10% and 20%) and covariations of individual climate extremes.

Table 1. *Simulating properties of climate extremes in the dynamic vegetation model*

Climate factors	Types	Dimensions
Precipitation	Max continuous dry/wet days in grow seasons	Frequency
	Increased precipitation intensity	Intensity/Frequency
	Increased inter-annual variability	Intensity/Frequency
	Rainy days larger than specific values in grow seasons	Intensity/Frequency
	Max snowy days and snowfall larger than 2 mm	Intensity/Frequency
Temperature	Increased annual temperature	Intensity
	Max/Min daily temperature deviations	Intensity
	Max continuous higher temperature days in grow seasons	Intensity/Frequency
	Days of temperature higher than specific values in and around grow seasons	Intensity/Frequency

Localizing a dynamic vegetation model in Qinghai-Tibetan alpine grasslands

There were so far few dynamic vegetation models applied in alpine grassland ecosystems. Most models used statistical or remote sensing ways since the parameterization of a dynamic vegetation model is a much difficult task owing to lack of systematically measured soil and plant data. The elements considered in the model include the vegetation dynamic, plant functional traits, soil properties, hydrological and carbon cycling processes. We simulate different scenarios of climate extremes and analyze the influences of extremes on ecosystem elements. In the model, we should be careful of the specificity of alpine ecosystem processes and their potential interactions. The alpine grasslands at high altitudes are characterized by a low temperature over a long time period, especially in winters the evaporation flux is quite low. Low temperature also leads to a slow decomposition rate of organic carbon. Thus the soil stock might be deemed as a carbon sink, which indirectly benefits vegetation growth. In addition, effects of snow cover on the vegetation dynamic were largely ignored in most vegetation models. We localize the dynamic vegetation model adapted to Qinghai-Tibetan alpine grasslands by calculating all relevant ecosystem processes with a reference to a process-based dynamic vegetation model (Tietjen et al., 2009, 2010; Guo et al., 2016, 2018). The model is characterized by explicit ecosystem processes and spatio-temporal scales.

Model overview

We simulate the landscape based on geographical characteristics, e.g. the elevation, the slope and soil conditions, of Haibei station. The simulated landscape is separated into grid cells (each cell: 20 by 20 m^2) and different layers per cell. We assume a homogeneity of soil properties within the size of grid cells. The depth of soil layers is determined by site-specific soil heterogeneity. The simulated soil depth is not more than 1 m as we do not consider the ecosystem dynamic in permafrost layers. Each layer is depicted by a combination of soil parameters (Guo et al., 2018). These parameters are calibrated by measured soil physic-chemical and hydraulic indices. Representative plant functional types (PFTs) are selected based on local dominant and constructive species. Proxies indicating ecosystem functioning include above- and belowground plant biomass, litter and dead biomass, carbon storage in plant and soil, plant transpiration and soil evaporation. In order to track the changes in these functions, water, carbon cycle and vegetation processes are calculated for each grid cell. We briefly describe these interrelated processes as follows.

Vegetation processes and the parameterization of plant functional traits

Vegetation processes capture the entire life cycle and describe demographical characteristics of herbaceous plants distributing over the landscape. Main processes include photosynthetic growth, seed dispersal/establishment, mortality and grazing by livestock. The competition among PFTs is explicitly simulated in terms of water, light and space. Vegetation processes dependent on specific plant functional traits (*Table 2*) are driven by available soil water and soil temperature.

Table 2. *Main vegetation processes and trait parameters in the model*

Vegetation processes	Influencing factors	Measured traits	Trait parameters
Growth	Precipitation Temperature	Biomass calculation in leaf, shoot and root	Growth rate
		Allocation of water in leaf, shoot and root	Water uptake and transmission rate
		Allocation of organic carbon in leaf, shoot and root	Carbon uptake and transmission rate
Mortality	Precipitation Temperature	Biomass reduction in leaf, shoot and root The decreased number of plant species or individuals	Mortality rate
Reproduction	Precipitation Temperature	The number and the size of seeds	Dispersal rate
		The distance between adult and child plants	Range of distance
		The number of child plants	Establishment rate
Competition	Precipitation Temperature	Vegetation cover or leaf area index	Competition for space
		Distribution of leaf and root	Competition for water and carbon

Equations of vegetation processes are mainly constructed through vegetation cover and biomass (Tietjen et al., 2010; Guo et al., 2016). Trait combinations of plant functional types are parameterized by local plant species based on their light and water capture strategy, growth form, leaf size, plant height, rooting depth. The trait parameterization mainly relies on the investigation of dominant and constructive species

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1009110104

in local areas. Moreover functional traits are assigned values partly based on reference data of Qinghai-Tibetan ecosystems (He et al., 2006; Qi et al., 2014; Wang et al., 2014). The sensitivity of trait variations has to be assessed through single trait change or joint trait changes. The simulated plant community is composed of different plant functional types depicted by sound trait combinations including covariations (e.g., growth rate & resistance to grazing; seed size & seed number; leaf area & plant height). There existed diverse trade-offs among traits in Qinghai alpine ecosystems (Du and Qi, 2010). The diversification of plant functional types in the model is constrained by proper values (maximum, minimum and average) of individual functional traits. We assume a completely balanced state of trade-offs within a newly constructed PFT. That is, the number of traits, whose values locate between average and maximum, equals the number of traits with values assigned between minimum and average. To test whether we define the 'right' functional types that match the real plant community, we should repeatedly and randomly conduct various trait combinations of plant functional types in long term simulations. Moreover, the local richness of plant species should be investigated to evaluate the simulated number of PFTs in grid cells.

Hydrological and carbon processes

Hydrological processes revolve round the calculation of soil moisture for different layers across all grid cells. Relevant processes include infiltration, runoff, evaporation and transpiration. These processes depend on site-specific soil texture, topography, weather and community properties. A challenge during this procedure is that water processes act on different temporal and spatial scales. This can be solved using a hierarchical setting, which calculated processes in separated sub-modules running on various spatio-temporal scales (Tietjen et al., 2009). Carbon storage and fluxes are assessed for each grid cell dependent on soil properties, soil moisture, vegetation cover and above- and belowground biomass. Main processes include photosynthesis, respiration, litter decomposition, biomass degradation. The parameterization and equations of water and carbon processes refer to previous empirical or modelling studies (Gu et al., 2008; Tan et al., 2010; Yan et al., 2015). Coupled interactions between water and carbon processes are very crucial for vegetation dynamic and ecosystem functioning. Carbon cycle was verified to be linked with nitrogen cycle in Qinghai-Tibetan Plateau (Lee et al., 2013). However, the model is currently not considering any nutrient cycling processes. To test the suitability of every ecosystem process in the selected areas, the model should be run under the very same climatic conditions. In addition, all indices that are employed to quantify ecosystem functions should be validated. Specifically, simulated soil moisture, community cover and biomass, plant and soil carbon content are compared to measured dynamics of the Haibei station.

Patterns of functional traits and their relationship with ecosystem functioning

In the following, we implement simulation experiments under various scenarios of climate extremes to assess how future climate extremes shape patterns of functional traits and the associated ecosystem functioning in alpine grasslands. Ecosystem functions like biomass, fluxes of resource cycling are evaluated via absolute as well as proxy measurements. We firstly assess the effects of climate extremes on ecosystem functioning with a limited number of plant functional types. To test the separated and interactive effects of individual climate extremes, all other extreme properties are kept

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1009110104

on a constant level. That is, all climate extremes should be run separately and in different combinations in a full factorial design. Then we diversify trait combinations and observe this effect. Combinations of functional traits are detected that are sensitive to specific climate extremes. More importantly we can know which plant functional traits are reliable indicators of ecosystem functions under different scenarios of climate extremes. The relationship between patterns of functional traits and ecosystem functioning should be assessed across all treatments of climate extremes. Our model approach clearly demonstrates site-specific characteristics of the Haibei station such as geographical and community properties. Through the application of a case study like this, we can propose specific plant functional traits or trait combinations that indicate abnormal variabilities in climatic conditions and thus strengthen assessments of ecosystem functioning. In a follow-up analysis, we can advance our knowledge on the Qinghai-Tibetan alpine ecosystems in general. E.g. in case we test whether the framework works in other Qinghai-Tibetan Plateau sites, we could modify soil, weather conditions and vegetation type if necessary while keeping ecosystem processes consistent. Model experiments can be performed for different Qinghai-Tibetan areas after the model has been calibrated and validated for respective sites. This can verify whether functional traits and trait combinations respond to climate extremes as well relate with ecosystem functioning is site specific. Future work could also consider other global change factors (grazing or nitrogen deposition) and trade-offs among ecosystem functions that deserve great attentions for the land restoration.

Conclusion

To our knowledge, there are few mechanistic approaches that can assess long-term vegetation dynamic and ecosystem functioning through patterns of functional traits under impacts of climate extremes. We believe that the proposed framework fill the gaps and therefore closely link abiotic climatic factors with biotic agents like alpine vegetation. We use the response of plant functional traits to climate extremes to predict ecosystem functioning since variations of ecosystem functions are sometimes difficultly captured by changes in climatic conditions. Through this endeavor, the relationship between patterns of functional traits and ecosystem functioning can be better understood under different scenarios of climate extremes. Achieving the goal of a precise prediction of ecosystem functioning under complex climatic conditions needs an integration of different research approaches. Our proposed framework provides a promising scheme for a scientific assessment of ecosystem functioning in Qinghai-Tibetan alpine ecosystems lack of long term measured data.

(Received 11th Apr 2019; accepted 19th Jun 2019)

Abstract. This research was planned to determine the correct sowing times of quinoa (*Chenopodium quinoa* Willd.) varieties under the ecological conditions of Turkey-Mardin. The study was conducted in three different sowing times (15 March, 30 March and 15 April) using 2 quinoa varieties in aqueous conditions in 2017 spring period with three repetitions. At the end of the research; according to the data obtained, the number of plants in the harvest (15.4- 29.2 plants/m^2), plant height (73.9-90.3 cm), the main panicle length (31.1-43.9 cm), the number of panicle branches (23.7-29.7 units plant), thousand weight (3.37-3.46 g), grain yield (125.6-1339 kg ha^{-1}), hectoliter weight (6220-6280 kg ha^{-1}) and crude protein ratio (14.8-15.7%) ranged. The highest grain yield was obtained from the application of Valiente and Titicaca (April 15) with 1345-1333 kg ha^{-1}, respectively. As a result of these properties, it was concluded that the most suitable planting time for quinoa (*Chenopodium quinoa* Willd.) cultivation in Mardin may be the second week of April.
Keywords: *quinoa, Mardin ecology, sowing date, grain yield, agronomy*

Introduction

Parallel to the increasing population of the world in our day, the dependency to the natural resources and consumption has increased. Additionally, the global warming, which has increased in the same period, caused important problems about sufficient and balanced nutrition (Kaya and Karaer, 2017). This case encouraged human beings to find and develop new resources. Particularly the usage of types and varieties of plants, which will increase the yield and quality in animal and plant production and which will be produced under all climates and natural conditions, has been obligatory (Kır, 2016). It is a known fact that grains such as wheat, barley, and rice, which constitute the most basic food source in human nutrition, cause celiac disease (Özkaya, 1999; Battais et al., 2005). Therefore, quinoa (*Chenopodium quinoa* Willd.) can play an important role as an alternative plant, which can be cultivated in a large geography and which has the potential to remove this negativity for the nutrition. To define botanically, quinoa (*Chenopodium quinoa* Willd.) is a dicotyledonous annual plant from the *Chenopodiaceae* family. It has been cultivated in many countries such as Bolivia, Peru, Ecuador, and Chile since the ancient times and its homeland is known to be the South America (Pearsall, 1992). In recent years, the trend in the US and European countries have started to plant quinoa while newly recognized in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1010510117

Turkey. However, consumption in the world and Turkey is increasing rapidly. Quinoa is a region in the And mountain region on the west coast of South America, where its homeland is very cold and has high plateaus. It is mainly grown in Colombia, Argentina, Peru, Bolivia, Chile and Ecuador. According to data, 146.735 tons of yield is obtained from 173.242 hectares in the world (FAO, 2017). In our country there is no official data. The fact that this plant has a rich nutritional value caused a rapid increment in cultivation sites. Known little in our country, this plant attracted intensive attention particularly in America and Europe. In return to this attraction, the year 2013 was declared as the year of quinoa (*Chenopodium quinoa* Willd.) by the United Nations (Miranda et al., 2012).

Particularly today, when more than half of the world population is exposed to poor or irregular nutrition, there is a need for alternative products to solve this problem. Accepted as one of these plants, quinoa is named as "super food", "miracle grain", or "astronaut grain". The main reason to define it in these terms is the existence of protein and amino acid at high levels in the grains. Besides this content, the levels of A, B, C, D, E, and K vitamins are at high levels as well (FAO, 2017).

Quinoa cultivation should be generalized as an alternative product in our country and in regions with grain agriculture. It will make important contributions in adding a significant amount of marginal terrains, mined terrains being in the first place, to the production (Kır and Temel, 2017). For this purpose, successful results were obtained by the contracted farmers in the production of these seeds, which certain firms brought to Mardin province. Thus, an agricultural production with high added value will be introduced to the region. In this purpose, it is necessary to determine the most appropriate sowing time and accurate cultivation methods of the quinoa varieties and to encourage its cultivation.

In this study, it was aimed at determining the yield and yield components of quinoa (*Chenopodium quinoa* Willd.) varieties in different sowing times that are not being widely cultivated in our region but considered to increase in a short period.

Materials and methods

This study was conducted in a single year during the cropping season of the 2017 spring period in the ecological conditions of Mardin-Kızıltepe (37°11'12"N and 40°36'43"E) (*Fig. 1*). In the trial, South American-origin Valiente and Titicaca quinoa (*Chenopodium quinoa* Willd.) varieties were used, which were provided by certain companies.

The climate information concerning the research area is given in the *Table 1* and the properties of the soil are given in *Table 2*. As is seen in *Table 1*, it was observed that the temperature and precipitation were lower while the relative humidity was high during the research in the production season of 2017. According to these results, the distribution and amount of the precipitation over the year caused differences between the yield and yield components based on the cultivation times.

As the conclusion of the analysis of the soil samples taken from the research area, it was observed that there was no problem about the salinity and alkalinity. Moreover, it was determined that the soil samples were mid-calcareous and weak in terms of organic matters. The results concerning the pH, salt, lime, and organic matter analyses of the soil samples are given in *Table 2*.

This study randomized blocks were developed as 3-repeat according to the experimental design. The quinoa varieties (Valiente and Titicaca), which were obtained by a special company and used in the research, were applied to main parcels, and the sowing times (15 March, 30 March, and 15 April) were applied to the sub-parcels (*Figs. 2* and *3*). In the trial, each parcel (6 m-long and 2 m-wide) was sewn at a 1.0-1.5 cm depth as 6 lines. The distances among the lines were 40 cm. The tillage process was elaborately conducted to prevent clods in the soil and for an orderly germination and first emergence. Since the quinoa seeds are not sewn too deep, and in order for the germination and the first emergence not to be interrupted as a conclusion of the shallow sowing and the crusting soil, springer irrigation was applied after each sowing time. In order to guarantee the number of plants in a unit area, the sowings were applied denser, and once the plants reached a height of 10-15 cm, the distances between the plants were kept at 8 cm through thinning. A distance of 2 m was left among the blocks and 0.5 m among the parcels. Before the sowing, 150 kg ha^{-1} DAP (Diammonium Phosphate) was applied as the bottom fertilizer. After the thinning (while the plants were about 10-15 cm) second nitrogenous manure (ammonium sulphate) was implemented with a calculation of 50 kg N ha^{-1}. One month after the sowing, hoeing was applied to clean the weeds. Hand and hoes were used mechanically in weeding. As the foils turned yellow, started to drop and as the flower clusters dried, the plants were harvested.

In each parcel, 10 plants were selected among the ones that became harvestable, and the following measurements were obtained respectively. Leaving the edge effect, the remaining parts of the parcels were sickled and they were blended after several days of drying. After the seeds matured in the plants were neglected as the edge effect of 50 cm from the parcel heads with 1 and 6 rows. The remaining $5 \times 1.2\ m^2 = 6\ m^2$ area was harvested and yield per decare was calculated. The observations in the research were determined as the number of plants in the harvest (plant number m^{-2}), plant height (cm), the main panicle length (cm), the number of panicle branches (plant $number^{-1}$), total yield (kg ha^{-1}), grain yield (kg ha^{-1}), harvest index (%), thousand weight (g), hectoliter weight (kg) and crude protein ratio (%) (Kır and Temel, 2017).

The data obtained from the research were analyzed through variance analysis by means of CoStat (version 6.303) program, and LSD (0.05, 0.01) multiple comparison test was implemented to determine the significance levels of the differences among the implementations.

Results

The mean squares, which were obtained through the variance analysis concerning the mean values of number of plants in the harvest (NPH), plant height (PH), the main panicle length (MPL), the number of panicle branches (NPB), grain yield (GY), thousand weight (TW), hectoliter weight (HW) and crude protein ratio (CPR) that were obtained from trials of 2 quinoa (*Chenopodium quinoa* Willd.) varieties in different times, are given in *Table 3* and the results of the comparisons of the mean values are given in *Table 4*.

Number of plants in the harvest (plants/m^2) and the plant height (cm)

According to the results of the research, the variety and the sowing time (ST) values of the quinoa were determined to be statistically significant (*Table 3*). The number of plants in the harvest was detected higher in the Titicaca (23.5 plants/m^2) variety

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1010510117

compared to the Valiente (20.1 plants/m^2) variety (*Table 4*). Based on the sowing times, it was determined that the highest NPH was 26.9 plants/m^2 during the 3rd sowing time (15 April), while the lowest NPH was 17.1 plants/m^2 in the 1st sowing time (1 March) (*Fig. 4*).

Table 4. *The impact of different sowing times on the number of plants in harvest and plant height of quinoa varieties*

Number of plants in the harvest (plants/m^2)					Plant height (cm)			
Sowing times					Sowing times			
Variety	**1**	**2**	**3**	**Mean**	**1**	**2**	**3**	**Mean**
Valiente	15.4	20.1	24.7	20.1 B	87.5	82.9	90.3	86.4 A

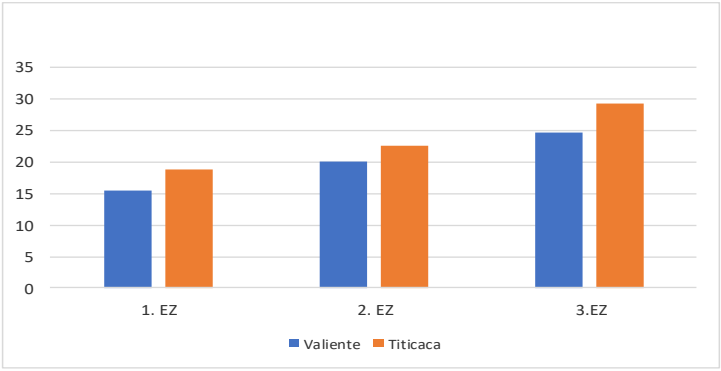

Figure 4. *The impact of sowing times on the number of plants in the harvest in Quinoa. (EZ: sowing time)*

The impact of different sowing times (ST) on the plant height in quinoa varieties was determined to be statistically significant ($p < 0.01$) (*Table 3*). According to the results, the plant height was detected as 86.9 cm in the Valiente variety, while it was 72.9 in Titicaca variety (*Table 4; Fig. 5*).

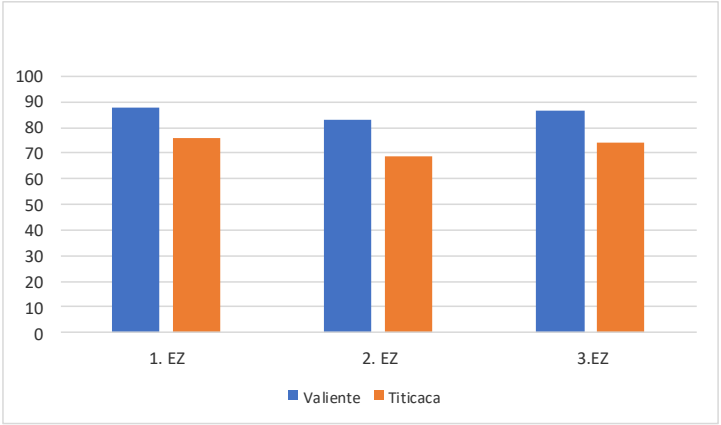

Figure 5. *The impact of sowing times on the plant heights in Quinoa. (EZ: sowing time)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_10105010117

The main panicle length (cm) and the number of panicle branches (panicle branch^{-1})

As is seen in *Table 3*, according to the results, the variety and variety × sowing time (ST) interactions were determined to be statistically significant. According to the obtained results, the main panicle length in the Titicaca variety (38.1 cm) was lower compared to the Valiente variety (42.8 cm) (*Table 5*).

Table 5. *The impact of different sowing times on the main panicle length and number of panicle branches of quinoa varieties*

Number of plants in the harvest (plants/m^2)					Plant height (cm)			
Sowing times					Sowing times			
Variety	**1**	**2**	**3**	**Mean**	**1**	**2**	**3**	**Mean**
Valiente	43.1 e	41.4 e	43.9 cd	42.8 A	23.7	24.0	29.7	26.7
Titicaca	31.1 ef	43.1 cd	41.1 gh	38.4 B	27.7	27.6	24.7	25.7
Mean	37.1	42.2	42.5		25.7 B	25.8 B	27.2 A	

In this research, where the interaction of variety × sowing time was determined to be significant, the highest main panicle length was (42.8 cm) determined in the 3rd sowing time of the Valiente variety, while the lowest main panicle length was (31.1 cm) determined in the 1st sowing time of the Titicaca variety (*Fig. 6*).

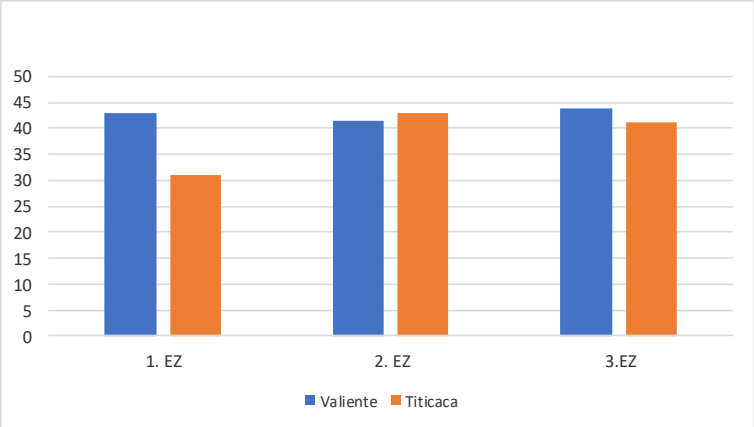

Figure 6. *The impact of sowing times on the main panicle length in Quinoa. (EZ: sowing time)*

In our study, it was determined that the impact of interactions of variety × sowing time (ST) on the number of panicle branches was insignificant, while the impact of the sowing time was determined to be statistically significant (*Table 3*). In this study, the highest number of panicle branches was 27.2 panicle branches^{-1} in the 3rd sowing time, while the lowest was 25.7 panicle branches^{-1} in the 1st sowing time (*Table 5; Fig. 7*).

Thousand weight (g) and grain yield (g)

In this study, the impact of sowing times (ST) on the thousand weight of the quinoa varieties was determined to be statistically insignificant (*Table 3*). According to these results, the thousand weights varied between 3.37-3.46 g (*Table 6; Fig. 8*).

Mean	37.1	42.2			25.7 B	25.8 B	27.2 A	

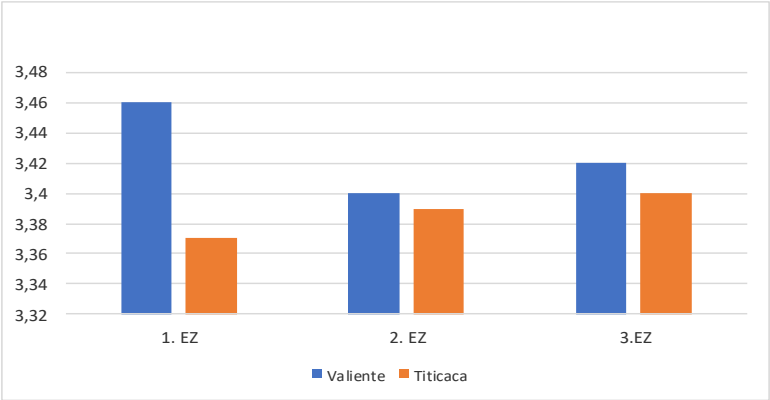

Figure 8. *The impact of sowing times on the thousand weight in Quinoa. (EZ: sowing time)*

As is seen in the *Table 3*, 131.9 g grain yield was obtained from the Valiente variety, which was found to be statistically significant for the variety and variety × sowing time interaction, and 128.7 g grain yield from the Titicaca variety (*Tables 3* and 6). The highest grain yield was 134.5 g in the 3rd sowing time of the Valiente variety, while the lowest grain yield was determined as 125.6 g in the 1st sowing time of the Titicaca variety (*Fig. 9*).

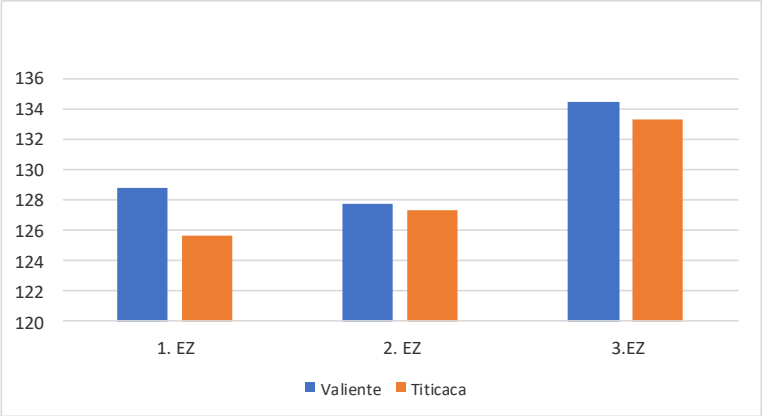

Figure 9. *The impact of sowing times on the grain yield in Quinoa. (EZ: sowing time)*

Hectoliter weight (kg) and crude protein ratio (%)

As is seen in the *Table 3*, while there was statistically no significant impact of the variety and sowing times (ST) on the hectoliter weight, the variety and sowing times interaction was determined to be statistically significant. According to the results of the study, the highest hectoliter weight was 62.8 kg in the 3rd sowing time of the Valiente variety, while the lowest was 62.2 kg in the 1st and 3rd sowing times of the Titicaca variety (*Table 7; Fig. 10*).

Table 7. *The impact of different sowing times on the hectoliter weight and crude protein ratio of quinoa varieties*

Hectoliter weight (kg)					Crude protein (cm)			
Sowing times					Sowing times			
Variety	**1**	**2**	**3**	**Mean**	**1**	**2**	**3**	**Mean**
Valiente	62.4 b	62.2 bc	62.8 a	62.5	15.7	15.2	15.1	15.3
Titicaca	62.2 bc	62.6 ab	62.2 ab	62.3	15.5	14.8	15.0	15.1
Mean	62.3	62.4	62.5		15.6	15.0	15.0	

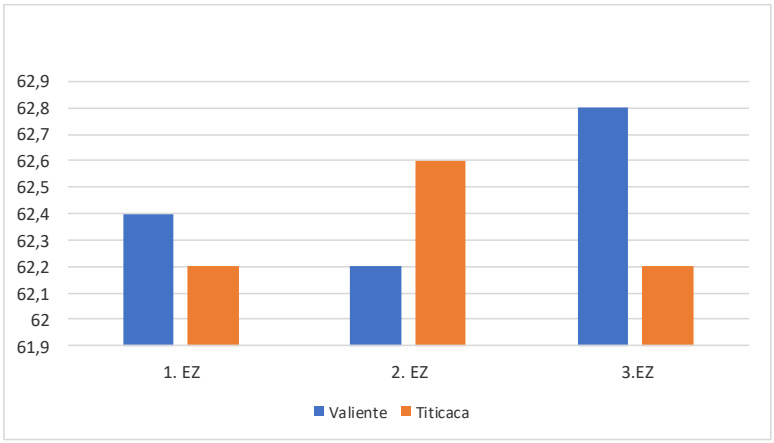

Figure 10. *The impact of sowing times on the hectoliter weight in Quinoa. (EZ: sowing time)*

DOI: http://dx.doi.org/10.15666/aeer/1704_1010510117

It was determined that there was statistically no significant impact of the variety and sowing times (EZ) on the crude protein ratios (*Table 3*). However, the mean crude protein ratios obtained in different sowing times from the Valiente and Titicaca varieties were respectively, 15.3% and 15.1% (*Table 7; Fig. 11*).

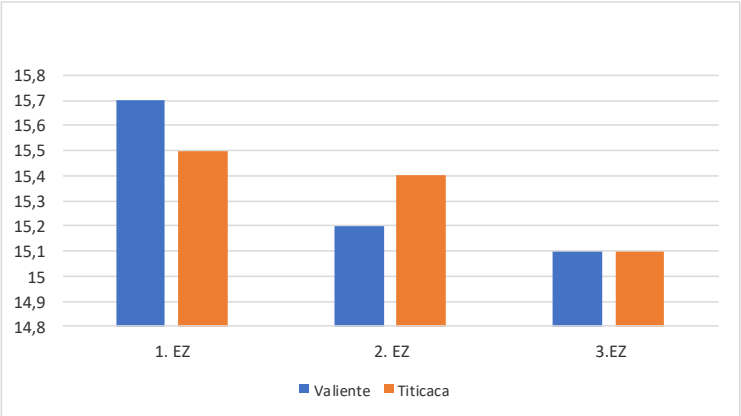

Figure 11. *The impact of sowing times on the crude protein ratios in Quinoa. (EZ: sowing time)*

Discussion

In similar studies, it was reported that the number of plants in the harvest is directly relevant to the grain yield (Bertero et al., 2004). The main reason of the lower NPH figure in the 1st sowing time was estimated to be emerging from that the precipitation and temperature levels of the March were lower compared to those of the April. Lower temperature and precipitation negatively influence the first emergence and development of quinoa, causing a decrease in the number of plants in the harvest (Geren et al., 2014).

In a study conducted by Geren et al. (2014), it was reported that the plant height varied between 63.8 cm and 111.7 cm. According to these results, it is estimated that the plant heights are influenced, to a large extent, from the agricultural implementations applied to the genotypes under different ecological conditions. In a study conducted on different ecology and genotypes, Pulvento et al. (2010) concluded that there were differences in the plant heights of the genotypes. According to the results of the study, the main reason behind the high results of the 3rd sowing time is the increasing temperature and the precipitation in our region. Therefore, we are of the opinion that the first week of the April month might be an appropriate time for a successful quinoa cultivation in our province. In similar studies, it was reported that main panicle length and number of panicle branches had a high and positive impact on the grain yield (Bertero et al., 2004; Bhargava et al., 2007). In a study conducted by Hirich et al. (2014) in the Southern Morocco, different sowing times were implemented ranging between 15 October and 15 March. In that study it was determined that the panicle weight per plant was firstly 24 g, subsequently increasing to 57 g and ultimately decreasing to 15 g.

Besides the fact that thousand weight is a genotypic characteristic, it is known that it is influenced from the environmental conditions. In a study conducted by Koziol (1993), it was reported that the thousand weight varied between 1.9 - 4.3 g based on the variety. In another study conducted by Kaya (2010) under Çukurove conditions, the thousand weight was determined between 2.1 g and 2.6 g (*Fig. 8*). It was considered that the most important motive behind the impact of the sowing times on the grain

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1010510117

yields of the varieties in the quinoa was that impact of changes in the temperature and precipitation on emergence and germination. This impact influences other herbal characteristics, particularly the number of plants in the unit area, and causes fluctuations in the grain yield (Geren et al., 2014). In similar studies, it was reported that not only the sowings in March, but also sowings in May negatively influence the blossoming and pollination, thus decrease the grain yield (Gonzales et al., 2012). Therefore, in order to determine the accurate sowing time, it was determined that over precipitation and humidity had negative impacts on pollen activity in addition to the negative impacts of dry and hot weather (Aguilar and Jacobsen, 2003). Hectoliter weight is an important criterion in particularly milling, and especially in grains. Moreover, it was reported that ecological factors and cultural implementations can significantly influence the storage and putting on market the seeds (Chauhan et al., 1992; Lindeboom, 2005; Peralta et al., 2006).

The protein ratio of the quinoa was reported to be higher compared to other grains, ranging between 8-22% (Jancurova et al., 2009). The growing season length has been affected by accumulated radiation. In addition to abiotic factors (temperature, radiation, rainfall) affecting quinoa growth, biotic factors such as downy mildew and weeds affected the yield (Hirich et al., 2014).

Conclusion

According to the results of this research study, it was considered that the most appropriate sowing time for the quinoa in Mardin province was the second week of April. The best values concerning the most important characters for the cultivation, the grain yield (133.9 g) and thousand weight (3.41 g) were obtained from the April 15 sowing time. In our region, where the first product wheat and second product corn agriculture is densely implemented, an alternative income can be created by cropping system among various products. Quinoa is quite appropriate for the mechanized agriculture, the sowing can be employed by the sowing machine, and the harvest can be conducted through harvester. The plant is resistant to drought, needing 250-380 mm water in the growing period. Particularly in our province, where the irrigation water is insufficient, if there is precipitation after the sowing in the first and second weeks of April, no need arises for irrigation until the mid-June. After this period, it is necessary to employ irrigation. Therefore, considering the high costs of the water obtained from wells based on intense drilling activities, it is necessary to encourage the cultivation of products with high added values and with an economical water use. Further studies can be conducted in this region as well, supporting this product to become widespread. After this study, similar multi-year researches will be conducted on quinoa. Fertilizer, frequency, irrigation time and other quality analyzes are planned for sowing.

(Received 12th Apr 2019; accepted 22nd May 2019)

Abstract. The present study was aimed at examining the combined effect of five species of rhizobial inoculation (Control, *Bradyrhizobium sp.* (Vigna), *Rhizobium leguminosarum bv. viciae*, *Bradyrhizobium* Mungbean, *Mesorhizobium ciceri*, and *Rhizobium leguminosarum bv phaseoli*) at three levels (120, 240, 360 kg.ha^{-1}) of NPK on the physiological characteristics, yield components, and leaf chemical content of two wheat species. The results indicated that all physiological characteristics and all nutrient contents of leaf under study, total dry weight of plant at harvest, spike weight, grain number, grain yield, biological yield, and harvest index increased significantly as a result of the interaction between the chemical fertilizer, the biofertilizer, and the wheat species. It was observed that the combination of rhizobial bacteria and wheat species had a positive effect on the physiological characteristics, leaf nutrient contents, and yield components, but not on spike length, spikelet number, and weight of 1000 grains. Our data suggested that a lower level of NPK fertilizer and rhizobial inoculation should be combined in order to achieve the greatest effect on yield components. Also, different types of rhizobial bacteria should be used as biofertilizer in order to improve wheat production.
Keywords: *physiological characteristics, bacteria, production, leaf, Triticum sp.*

Introduction

As one of the first cultivated plants, wheat is regarded as the most significant cereal because it is a major food supply for human. There are numerous species of wheat. For example, macaroni wheat (*Triticum durum*) is a tetraploid wheat species which are cultivated in order to fulfill the demands of the pasta market, whereas *Triticum aestivum* is a hexaploid species that is widely grown throughout the planet (Abou-Taleb and Gomaa, 2012). This species (i.e. *Triticum aestivum*) is one of the most important crops worldwide (Wang et al., 2018). Given the fact that there has been a huge global demand for food as a result of increased world population over the last few decades, a large number of research studies have been aimed at increasing food production so as to meet humanity needs around the world. These diverse researches have included environmental, physiological, agricultural, and genetic studies which all aimed to increased crops productivity (Elghair, 2012).

In order to increase the yields, there has been an increase in the use of mineral fertilizers which are very costly and cause pollution in many ways. Therefore, researchers have always attempted to control such threats by producing alternative substitutes which are more economical, environmentally friendly, and properly improved. In this regard, use of beneficial microbes or plant growth promoting rhizobacteria has been proposed as the best approach to improve crop yield (Adnan et al., 2014). Another widely utilized method to enhance soil fertility and crop productivity is the use of chemical fertilizers which have a negative effect on the complex system of biogeochemical cycles. One of their negative effects, for example,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1011910138

is environmental degradation due to runoff and leaching of nutrients, particularly P and N (Yildirim et al., 2011). Another method to increase crop productivity is to use biofertilizers which are substances that contains living microorganisms and applied to plant surface, seeds, or soil. Biofertilizers add nutrients by stimulating plant growth through the synthesis of growth promoting substances and through the natural processes of nitrogen fixation, solubilizing phosphorus. By utilizing biofertilizers, it is expected that there will be a remarkable decrease in the use of chemical fertilizer and pesticides. It is stated that natural nutrient cycle of the soil can be restored and the soil organic matter can be built through the microorganisms in biofertilizers (Al-Shamma and Al-Shahwany, 2014). Moreover, soil contains a wide range of microbes that can act in symbiosis or non-symbiosis association with their host plant (Gray and Smith, 2005).

A range of bacterial genera like *Rhizobium*, *Bradyrhizobium, Sinorhizobium, Mesorhizobium, Allorhizobium,* and *Azorhizobium* exist in rhizobia through which a symbiosis can be established with leguminous plants. Special organs that are known as nodules are produced by these genera on the stems and roots of the hosts, leading to a decrease in atmospheric nitrogen that is delivered to the plant (Sessitsch et al., 2002). As plant growth promoting rhizobacteria (PGPR), rhizobia can also be used in non-legumes (Yanni et al., 1997). Moreover, by producing IAA, gibberellins, and cytokinins, it can enhance growth and yield of cereals (Zahir et al., 2010). Moreover, by producing organic acids, it increase the supply of insoluble nutrients such as phosphorus and iron (Fatima et al., 2006), making these nutrients easily available for plant uptake (Biswas et al., 2000). It is widely reported that the growth parameters, yield, components, and chemical constituents in treated plants can be improved through inoculation of such plants with *Azospirillum*, *Azotobacter*, *Rhizobium*, and *Pseudomonas* in dual or different combinations with organic and mineral fertilizers. According to previous experiments, the best results were obtained by mixing the various inoculations and applying on wheat plants, leading to reduced amount of mineral fertilizers (Mitkees et al., 1996).

The present study was carried out in order to assess the effectiveness of rhizobial bacteria in reducing the use of chemical fertilizer and improving wheat production.

Materials and methods

Pot experiment

The experiment was carried out in the Glasshouse of Biology Department, College of Science, University of Salahaddin-Erbil during winter 2016-2017. The experimental plants used in this experiment included wheat (*Triticum aestivum*) cultivar Hawler2 and (*Triticum durum*) cultivar Seminto that were obtained from the Agricultural Research Center in Erbil. The experiments were carried out using plastic pots with a depth of 25 cm and a diameter of 30 cm. Using a 4 mm pore size sieve, the soil was sieved and then sterilized using formalin 40% as described by Elia et al. (1987). Each pot was filled with 8 kg sandy clay loam soil. *Table 1* presents some of the chemical and physical properties of the soil before the treatments. A sufficient number of wheat seeds were separated and disinfected with 95% ethanol for 30 s and then washed with sterilized distilled water at least 8 times (Etesami et al., 2009). In each pot, 5 seeds were sown at a depth of 3-4 cm and later thinned to four plants.

Total phosphorous%		0.144
Total potassium%		0.056
Calcium%		0.253
Iron%		0.078

Isolation of Rhizobial sp

Five strains of rhizobia including *Bradyrhizobium sp*. (Vigna), *Rhizobium leguminosarum* bv. viciae, Bradyrhizobium Mungbean, *Mesorhizobium ciceri* and *Rhizobium leguminosarum* bv. phaseoli were isolated from *Vigna unguiculata*, *Vicia faba, Vigna radiata L., Cicer arietinum L.,* and *Phaseoulus vulgasrous* root nodules, respectively which were growing for 2-3 months under field conditions at a different area of Erbil city. Afterwards, the host plants which had some non-rhizopheric soil on them were uprooted, and they were placed in polythene bags and taken to the laboratory. By shaking the uprooted plants, their non-rhizospheric soil was removed. Moreover, by dipping and shaking them in water, their rhizospheric soil was removed. The nodules were separated from the roots with a sterilized razor blade, and each of them was placed in a separate Petri plates. The surface of the nodules was disinfected by dipping them in ethanol (95%) for 20 s and then in $HgCl_2$ (0.2%) solution for 3 min followed by washing them with sterilized distilled water 6 times. Using a sterilized glass rod, the surface-disinfected nodules of each host were crushed in a sterilized test tube containing sterilized distilled water. The obtained suspension was used to inoculate Petri plates that contained autoclaved and solidified yeast extract mannitol (YEM) media which was then incubated at 28 ± 1 °C for bacterial growth (Mehboob et al., 2011).

Preparation of inoculums

In order to complete the preparation of inoculum, the selected isolates of rhizobia were grown in 250 mL conical flask containing 100 mL YEM broth by incubating at 28 ± 1 °C in an orbital shaking incubator at 100 rpm for 3 days. In order to obtain uniform cell density (i.e. 10^8 to 10^9 CFU mL^{-1}), dilution method was employed in so as to record an optical density of 0.5 at a wavelength of 535 nm (Mehboob et al., 2011). Inoculation of 10 ml (10^8–10^9 $CFU.mL^{-1}$) per seedling was done at the base of the plant ten days after germination.

Experimental design and treatment

The current experiment included 6 treatments of rhizobial inoculums (i.e. Control, *Bradyrhizobium sp.* (Vigna), *Rhizobium leguminosarum bv. viciae*, *Bradyrhizobium*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1011910138

Mungbean, *Mesorhizobium ciceri*, and *Rhizobium leguminosarum bv. phaseoli*) and 3 levels of NPK (20:20:20) fertilizers (120, 240 and 360 kg.ha^{-1}), making a total of 36 treatments per replication. The experiment was carried out using a factorial complete randomized design (Factorial C.R.D.) with 3 replications. The comparisons between means were made using Tukey test at significant level of 5% for field experiment parameters and 1% for laboratory parameters. SPSS version 16 was used for data analysis.

Experimental parameters

Physiological parameters

The spectrophotometric method as described by Lichtenthaler (1987) was employed to measure chlorophyll a, chlorophyll b, and carotenoid based on the flag leaf samples that were collected at flowering stage during the growing period.

$$Chlorophyll\ a = (13.36 \times A664.2) - (5.19 \times A648.6)$$

$$Chlorophyll\ b = (27.43 \times A648.6) - (8.12 \times A664.2)$$

$$Total\ Chlorophyll = Chlorophy\ a + Chlorophy\ b$$

$$Carotenoid = \{(1000 \times A470) - (2.13 \times Ch\ a) - (97.64 \times Ch\ b)\}/209$$

In order to determine the membrane stability index (MSI), the method proposed by Premachandra et al. (1991) was utilized.

$$MSI = [1 - (C1/C2)] \times 100$$

Biochemical contents

Dried leaves at flowering stage were ground by an electrical grinder. Afterwards, 0.3 g of the ground samples was digested by adding 10 ml H_2O_2 and 10 ml concentrated H_2SO_4, and they were heated. After that, Kjeldahl method was employed to determine the total nitrogen, spectrophotometer method was used to estimate the total phosphorus, atomic absorption method was utilized to estimate the total calcium and iron, and flame-photometer method as described by Ryan et al. (2001) was used to determine the total potassium determined. Moreover, by multiplying the value of total nitrogen by 5.75, the total protein was calculated (Dalaly and Al-Hakim, 1987). Also, the Anthron method (Sadasivam, 1996) was utilized to determine the total soluble carbohydrate.

Yield components

At harvest, main spike length (cm), number of grains.plant^{-1}, weight of spikes.plant^{-1}, grain yield (kg.ha^{-1}), biological yield (kg.ha^{-1}), number of spikelets.spike^{-1}, harvest index (%), weight of 1000 grains (g), and increase grain yield (%) were estimated. The following formula proposed by Ye et al. (2005) was employed to determine the increased grain yield.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1011910138

$$Increase\ grain\ yield\% = \big((Grain\ yield\ of\ fertilized\ pot - Grain\ yield\ of\ control)/Grain\ yield\ of\ control\big) \times 100$$

Results

Physiological parameters

According to the data presented in *Table 2,* it was detected that soil application of B3 led to the highest levels of chlorophyll a, chlorophyll b, total chlorophyll, and carotenoid, while the highest value of cell membrane stability was obtained by utilizing B5.

Table 2. *Effects of different species of rhizobial bacteria on some physiological characteristics*

Bacterial species	Chlorophyll a ($mg.g^{-1}$)	Chlorophyll b ($mg.g^{-1}$)	Total chlorophyll ($mg.g^{-1}$)	Carotenoid ($mg.g^{-1}$)	Cell membrane stability %

B1: *Bradyrhizobium sp.* (Vigna), B2: *Rhizobium leguminosarum bv. viciae*, B3: *Bradyrhizobium* Mungbean, B4: *Mesorhizobium ciceri,* B5: *Rhizobium leguminosarum bv phaseoli*

The results also indicated that the highest values of chlorophyll a and cell membrane stability were obtained by adding 360 $kg.ha^{-1}$ of NPK (see *Table 3*). On the other hand, using 240 $kg.ha^{-1}$ of NPK led to obtaining the maximum value of total chlorophyll and carotenoid.

Table 3. *Effects of different levels of chemical fertilizers on some physiological characteristic*

Chemical fertilizer ($kg.ha^{-1}$)	Chlorophyll a $(mg.g)^{-1}$	Chlorophyll b ($mg.g^{-1}$)	Total chlorophyll ($mg.g^{-1}$)	Carotenoid ($mg.g^{-1}$)	Cell membrane stability %

Tukey 0.01	n.s.	n.s.	0.087	n.s.	0.057

As indicated in *Table 5*, Rhizobium inoculation resulted in significant increase in physiological parameters in both wheat species. The highest values of chlorophyll a and carotenoid were respectively 1.501 and 0.750 $mg.g^{-1}$ that were recorded in B2 of *Triticum durum*, while highest value of chlorophyll b was 1.258 $mg.g^{-1}$ and the total chlorophyll was 2.737 $mg.g^{-1}$, which were recorded in B3 of *Triticum durum.* The results presented in *Table 5* also revealed that the highest value of cell membrane stability was 94.417% that was recorded in B1 of *Triticum durum.*

Table 5. *Interaction effects of wheat species and rhizobial bacteria on some physiological characteristics*

B1: *Bradyrhizobium sp.* (Vigna), B2: *Rhizobium leguminosarum bv. viciae*, B3: *Bradyrhizobium* Mungbean, B4: *Mesorhizobium ciceri,* B5: *Rhizobium leguminosarum bv phaseoli*

According to the results presented in *Table 6*, different levels of NPK fertilizer led to significant increase in photosynthetic pigments and cell membrane stability of the two wheat species. The highest value of all photosynthetic pigments was recorded at 240 $kg.ha^{-1}$ of *Triticum durum*, while using 360 $kg.ha^{-1}$ of *Triticum durum* resulted in the highest value of cell membrane stability.

The data presented in *Table 7* show how photosynthetic pigments and cell membrane stability were influenced by different combinations of different levels of NPK fertilizer and different species of rhizobial bacteria. As indicated, using 240 $kg.ha^{-1}$ with B4 led

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1011910138

to highly significant increases in chlorophyll a, total chlorophyll, and carotenoid. However, the highest value of chlorophyll b was obtained as result of using 240 kg.ha^{-1} with B5. Moreover, using 360 kg.ha^{-1} of NPK with B5 led to the highest cell membrane stability.

Leaf photosynthetic pigments and cell membrane stability increased significantly in both wheat species as a result of *Rhizobium* inoculation and chemical fertilizer treatments (see *Table 8*). *Triticum durum* with 240 kg.ha^{-1} of NPK combined with B2 surpassed other interactions and resulted in the highest chlorophyll a and total chlorophyll. Furthermore, *Triticum durum* with 240 kg.ha^{-1} of NPK integrated with B5 and B4 led to the maximum chlorophyll b and carotenoid pigments, respectively, while adding 360 kg.ha^{-1} of NPK with B1 in *Triticum durum* brought about the highest value of cell membrane stability.

Biochemical contents

The results presented in *Table 9* demonstrate that the highest values of nitrogen, iron, and protein were recorded by adding B3. Also, phosphorus and carbohydrate reached their highest values as a result of adding B5. Moreover, the maximum values of potassium and calcium were recorded by adding B1 and B4, respectively.

In was also observed that the highest values of nitrogen, phosphorus, iron, and protein were obtained as a result of using 360 kg.ha^{-1} of NPK (see *Table 10*). Furthermore, adding 120 kg.ha^{-1} of NPK resulted in the greatest potassium content of leaves. Also, 240 kg.ha^{-1} of NPK brought about the highest values of calcium and carbohydrate.

According to the data presented in *Table 11, Triticum durum* surpassed *Triticum aestivum* significantly in all leaf nutrient contents under study except potassium and calcium which were better in *Triticum aestivum* than *Triticum durum*.

Table 9. *Effects of different species of rhizobial bacteria on some nutrient content of leaves*

It was also observed that the nutrient contents of the leaves in both wheat species increased significantly as a result of different species of Rhizobial inoculation compared with the control species (see *Table 12*). The highest values of N (50079.67 $mg.kg^{-1}$), Fe (263.34 $mg.kg^{-1}$), protein (287.96 $mg.g^{-1}$), and carbohydrate (356.79 $mg.g^{-1}$) were observed in B3 of *Triticum durum*, while the highest values of P (4350.08 $mg.kg^{-1}$), K (10555.82 $mg.kg^{-1}$), and Ca (8841.02 $mg.kg^{-1}$) were respectively recorded in B5 of *Triticum durum*, B1 of *Triticum aestivum*, B4 of *Triticum aestivum*.

Table 12. *Interaction effect of wheat species and rhizobial species on some nutrient content of leaves*

B1: *Bradyrhizobium sp.* (Vigna), B2: *Rhizobium leguminosarum bv. viciae*, B3: *Bradyrhizobium* Mungbean, B4: *Mesorhizobium ciceri,* B5: *Rhizobium leguminosarum bv phaseoli*

The results also revealed that NPK fertilizer had a significant effect on all nutrient contents of the leaves in both wheat species (see *Table 13*). In addition, using 360 $kg.ha^{-1}$ of NPK for *Triticum durum* led to the highest values of nitrogen, phosphorus, and protein. Moreover, 120 $kg.ha^{-1}$ NPK of *Triticum aestivum* and 240 $kg.ha^{-1}$ NPK of *Triticum aestivum* led to the maximum values of potassium and calcium, respectively. Furthermore, adding 120 $kg.ha^{-1}$ NPK of *Triticum durum* brought about the highest iron and carbohydrate content of the leaves.

Table 14 presents the data related to the effects of the chemical fertilizer combined with biofertilizer on the nutrient contents of the leaves. As observed, the highest values of nitrogen and protein contents of the leaves were obtained at 360 $kg.ha^{-1}$ of NPK with B3. On the other hand the maximum value of phosphorus contents of the leaves was obtained at 360 $kg.ha^{-1}$ of NPK with B5, while the greatest values of potassium and calcium were obtained in 240 $kg.ha^{-1}$ of NPK with B4. Moreover, adding 120 $kg.ha^{-1}$ with B3 led to the maximum values of iron and carbohydrate.

The interaction effects of different species of rhizobial bacteria and different levels of NPK on the two wheat species are presented in *Table 15*. Adding different types of rhizobial bacteria to the soil at different levels of NPK led to significant increase in Fe, P, N, Ca, K, protein, and the leaves' carbohydrate contents in both wheat species. Application of 360 $kg.ha^{-1}$ of NPK with B3 led to the highest nitrogen and protein

contents of the leaves in *Triticum durum*. The highest values of carbohydrate, phosphorus, and iron were recorded by utilizing 360 kg.ha^{-1} of NPK with B4 of *Triticum durum*, 120 kg.ha^{-1} of NPK with B5 of *Triticum durum*, and (120 kg.ha^{-1} of NPK with B3 of *Triticum durum*, respectively, while the highest values of potassium and calcium were obtained through 240 kg.ha^{-1} of NPK with B4 of *Triticum aestivum*.

components. In addition, using B4 led to the maximum values of total dry weight of 54.31 g.plant^{-1}, spike weight of 8.09 g, grain number of 106.22, and biological yield of 7895.18 kg.ha^{-1}, and utilizing B3 resulted in the highest grain yield of 2823.15 kg.ha^{-1} and harvest index of 38.43%.

Table 16. *Effects of different species of rhizobial bacteria on some yield components*

Bacterial species	Total dry weight g.pot^{-1}	Spike length plant^{-1}	Spike weight. plant^{-1}	Spikelet number plant^{-1}	Grain number plant^{-1}	Grain yield kg.ha^{-1}	Biological yield kg.ha^{-1}	Weight of 1000 grain (g)	Harvest index %

B1: *Bradyrhizobium sp.* (Vigna), B2: *Rhizobium leguminosarum bv. viciae*, B3: *Bradyrhizobium* Mungbean, B4: *Mesorhizobium ciceri,* B5: *Rhizobium leguminosarum bv phaseoli*

According to the results presented in *Table 17,* it can clearly be observed that adding 360 kg.ha^{-1} resulted in the maximum increment of total dry weight, spike weight, grain number, grain yield, and biological yield. Moreover, using 120 kg.ha^{-1} of NPK led to the highest value of harvest index.

According to *Table 18,* some yield components were affected by wheat species, such that *Triticum aestivum* surpassed *Triticum durum* regarding spike length, grain number, and harvest index, while *Triticum durum* surpassed *Triticum aestivum* significantly in terms of total dry weight, spike weight, grain yield, biological yield, and weight of 1000 grains.

The results presented in *Table 19* revealed that different species of rhizobial bacteria had a significant effect on some yield components of both wheat species. Applying B2 with *Triticum durum* resulted in the highest values of grain yield (2941.26 kg.ha^{-1}), total dry weight of plant (63.04 g.plant^{-1}), and biological yield (8922.86 kg.ha^{-1}). Also, B4 with *Triticum durum* led to the highest value of spike weight (9.21 g). Moreover, the highest value of grain number (127.50) was obtained by utilizing B5 with *Triticum aestivum*, and the maximum value of harvest index (45.76%) was obtained as a result of using B3 with *Triticum aestivum*.

Table 19. *Interaction effect of wheat species and rhizobial bacteria on some yield components*

Wheat species	Bacterial species	Total dry weight g.pot^{-1}	Spike length plant^{-1}	Spike weight plant^{-1}	Spikelet number plant^{-1}	Grain number plant^{-1}	Grain yield kg.ha^{-1}	Biological yield kg.ha^{-1}	Weight of 1000 grain (g)	Harvest index %

In addition, the two wheat species were significantly different in terms NPK levels (see *Table 20*). In general, the highest values of most yield components were observed at NPK3 for both species, while the highest values of weight of 1000 grains and harvest index were obtained by adding 240 kg.ha^{-1} of NPK of *Triticum durum* and 120 kg.ha^{-1} of NPK *Triticum aestivum*, respectively.

The results presented in *Table 21* indicate the interaction effects of chemical fertilizer and rhizobial bacteria on some yield components. As observed, the highest values of total dry weight, spike weight, grain number, and biological yield were gained by adding 360 kg.ha^{-1} of NPK with B4, and the highest values of grain yield and harvest index were obtained by adding 240 kg.ha^{-1} of NPK with B4.

B1: *Bradyrhizobium sp.* (Vigna), B2: *Rhizobium leguminosarum bv. viciae*, B3: *Bradyrhizobium* Mungbean, B4: *Mesorhizobium ciceri,* B5: *Rhizobium leguminosarum bv phaseoli.* NPK1 = 120 kg.ha^{-1}, NPK2 = 240 kg.ha^{-1}, NPK3 = 360 kg.ha^{-1}

The results presented in *Table 22* indicate that combining different species of rhizobium with different levels of NPK had significant effects on some yield components including total dry weight of plant, weight of spike, number of grains, grain yield, biological yield, and harvest index in both species. As observed, the highest grain number was obtained in *Triticum aestivum* with 360 kg.ha^{-1} of NPK with B5, while the maximum total dry weight and biological yield were observed in *Triticum durum* with 120 kg.ha^{-1} of NPK with B2. Moreover, the greatest grain yield was achieved in *Triticum aestivum* by adding 120 kg.ha^{-1} of NPK with B3, and the highest value of spike weight was recorded in *Triticum durum* by adding 240 kg.ha^{-1} of NPK with B4. Furthermore, the highest value of harvest index was obtained in *Triticum aestivum* by adding 120 kg.ha^{-1} of NPK with B3. *Figure 1* indicates that soil application of 120 kg.ha^{-1} of NPK with B2 increased the grain yield by 111.19% compared to the control. The results also showed that combining the lower level of NPK fertilizer with rhizobial inoculation had the greatest effect on the yield components.

Discussion

A common anthropogenic alteration to terrestrial systems is application of fertilizers. An increase in nutrient input can have a direct impact on soil microbial diversity or function by altering soil environments, or an indirect effect through plant-microbe feedbacks with potentially important effects on ecologically-important plant-associated mutualists (Simonsen et al., 2015). Chemical fertilizers can be used in order to increase soil nutrients and crop yields (Jia et al., 2018). Nitrogen (N), phosphorus (P), and potassium (K) are the major nutrients required by the crop, and the reproductive capability, growth, and yield of the plant can negatively be affected by inadequate supply of any of these nutrients during crop growth (Okechukwu, 2011). However, excessive use of mineral fertilizers can generate several environmental problems such as potential pollution to soil, water, and air (Stajković-Srbinović et al., 2014). The present study was aimed at minimizing the use of chemical fertilizer and improving wheat production and environmental risks. The results showed that combining chemical fertilizer and biofertilizer can improve wheat growth and development. The positive effects of the biofertilizer on physiological parameters, biochemical contents of leaves, and yield components under study can be attributed to the fact that rhizobial bacteria are involved in the production of phytohormone, leading to changes in root morphology and physiology that resulted in an increase in nutrient and water uptake of the wheat species from the soil (Mia and Shamsuddin, 2010). Adesemoye and Kloepper (2009) pointed out that plant–PGPR interactions can lead to various benefits such as improvement in seed shoot weights, germination rate, yield, chlorophyll content, leaf area, hydraulic activity, and protein content. Given the production of siderophores and nutrient uptake due to better root system, rhizobial bacteria have mostly been used to promote photosynthetic pigments. Research has indicated that bacterial production of siderophores enhances chlorophyll content and growth of plants due to the selective iron uptake from the solutions of trace elements, and production of siderophores inhibits free radical formation, substantiates the oxidative stress, and prevents the uptake of heavy metals (Ullah et al., 2017). Moreover, the role of *Rhizobium sp.* in enhancement of stress tolerance leads to an increase in cell membrane stability (Mia and Shamsuddin, 2010) because cell membranes are one of the first targets of many plant stresses (Bajji et al., 2002). Due to urgent need for increased global wheat production, wheat tolerance to biotic and abiotic stresses should be should be improved more (ElBasyoni et al., 2017). As pointed out by Mehboob et al. (2011), growth and yield of wheat can be promoted by isolates of *Rhizobium spp*. Rhizobium inoculation can lead to yield enhancement in wheat parameters, which can be attributed to the fact that applying biofertilizers have been proved to lead to high quality yield and avoid environmental pollution (Das et al., 2008). The findings of the present study are in agreement with those of the studies carried out by Agamy et al. (2012) and Adnan et al. (2016). It should be noted that plant species and their genotypes are genetically different in terms of their ability to uptake and metabolize elements.

Conclusion

Based on the results of the present study, it was observed that the combination between lower levels of NPK fertilizer and rhizobial inoculation had the greatest effect on yield components; therefore, such combinations are recommended to be utilized. Recently, biofertilizers have become an important means in agriculture because they use

DOI: http://dx.doi.org/10.15666/aeer/1704_1011910138

beneficial rhizobial bacteria to improve wheat production in a more economical and environmentally friendly way. Therefore, we suggested that the influence of combined effect of NPK fertilizer and rhizobial inoculation on growth and yield of wheat in soil needs further investigation to arrive at a conclusion where the effects are synergistic.

Acknowledgements. The authors of the present study would like to thank the staff of the greenhouse for their support and help with this research. Sincere thanks also go to the reviewers and editors for their exceptionally helpful comments on the manuscript.

(Received 16th Oct 2018; accepted 28th Jan 2019)

Abstract. Increasing the crop yield is very important and depends relatively on high plant density. The high grain yield per unit area of cereals is due to the optimum plant density. In this review, recent improvements and future insights to obtain better information for the regulation of nitrogen use efficiency in cereals under high plant density are presented. An updated knowledge of the basic mechanisms controlling plant nitrogen interaction is very important in cereals, to increase nitrogen use efficiency and for decreasing high cost of fertilizers, to obtain high output. In view of this fact, we should emphasize to develop plant morpho-physiological, agronomic and molecular studies which focuses on phenomics, genomics, and metabolite profiling to understand comprehensive knowledge of the different steps of nitrogen uptake, assimilation, and recycling under high plant density in cereals. A very important piece of information is provided on understanding of the physiological assimilation of N under different environmental conditions in cereals under different plant densities that has been improved through the use of different strategies for future research. According to the global economic and environmental constraints for future, agronomic and physiological principles and application which were adapted to less fertilizer inputs are discussed under high plant density.

Introduction

Cereals are sine qua non for current and projected human food security being staple food nearly in every region and country. Across the globe, merely 5% of staple derives from root crops like cassava, yams and potato, while the rest is provided by cereals with a range of health benefits. To ensure and secure food security on sustainable basis, cereals have to produce grains with many-fold larger quantity. Further increase in yield

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1013910153

would largely come from optimal planting density in field (Tokatlidis et al., 2011; Sher et al., 2017, 2018). Increasing the planting density of cereals is an agronomical task/deed/process has evolved over the time and this management practice has changed from the past six decades (Tollenaar, 1992; Sher et al., 2016; Noor, 2017). For example in USA Corn Belt, maize planting density has evolved from 3 plants m^{-2} to 8 plants m^{-2} in 85 years from 1930 to 2015 (Li et al., 2015) which caused many fold increase in average yield.

In the USA hybrids of central Iowa have increased nearly 79 kg ha^{-1} annually (Duvick, 1996). These yield escalations have occurred however mean yield per plant has not been changed significantly, increased by just an average of 0.05 kg $plant^{-1}$ over the past 40 years (USDA, 2010) while average plant population has increased by an average 720 plants ha^{-1} per year over the past 44 years (USDA, 1965-2009). In European countries where climate is heterogeneous than USA row spacing for planting density of maize vary between 70-75 cm to facilitate intensive cultivation (Sharratt and McWilliams, 2005). Developing countries produced lower grains of maize from a unit of land than developed countries though environmental and irrigation are satisfactory for maize production. Therefore the main constrain is low plant density per unit of land than those of developed countries. Mean planting density of 58000 ha^{-1} in developed countries is about two times less intensive than current cultivation stand density in developed countries. Grain yield per unit land area is the product of grain yield $plant^{-1}$ and number of plants per unit area (Hashemi et al., 2005). Maximum yield per unit area may be obtained by growing cereals hybrids that can withstand high plant density, up to 100,000 plants ha^{-1} (Huseyin et al., 2003). Growing hybrid by maintaining high density may causes a radical decline in grain yield as these hybrids can be susceptible to high stand density. In such hybrids, one-eared bearing pattern, recumbent leaf, plant height and large-type plants are the reasons of non-significant tolerance against high plant population (Tang et al., 2018; Hou et al., 2019). On other hand, developed countries grow hybrids that are characterized by high yielding ability per unit land due to prolificacy, early silking and tasseling, short anthesis-silking interval (ASI), more grain filling period, rare barren stalks backed them to adopt high density field environments. Likewise genotypes with erect leaves intercept light more efficiently and are very desirable for increased population densities (Radenovic et al., 2007). Therefore, there is a great genetic difference in grains production by cereals owing to their response to altering planting density (Liu et al., 2004). Main purpose of higher plant densities is to increase grain yield or biomass over per unit of land which make the cropping system more efficient over a piece of land. In absence of environmental stresses, grain production is directly proportional to amount of solar radiation intercepted by plants. Thus, efficient light harvesting is of paramount importance for plants growing in competition in dense stands under natural conditions (Pearcy et al., 2004; Valladares and Niinemets, 2008). The plant density has been evolving for decades, but now more enhancements in density fails to upsurge grains production has been rising steadily. But advancement in hybrids to tolerate high canopy still can attain the goal. Researchers believes that high densities like 90,000 plants ha^{-1} are still below potential maximum yield densities, indicating even higher tolerance to stand density may be possible in advanced hybrids (Widdicombe and Thelen, 2002). Planting density is also critical for the wheat because it directly affects the morphological parameters like number of ears per unit area. Currently, the plant density for the wheat ranges from 250 to 400 viable

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1013910153

seeds. This is based on the hybrid cycle, as well as its dual ability as a forage and grain crop (Comissão et al., 2007).

In the rice production system higher densities are helpful in suppression of weeds (Ahmed et al., 2016). But extra cost on more seeds for high seedling density should be set off with more yield. Sorghum is most favorable for those areas where water availability is limited as it produced grains with less water compared to other cereals. Plant population of sorghum influence both tillering and panicle weight. The greater densities did support fewer tillers per plant. This response is due to the competitiveness of the stand and is normally associated with reduced weight of the inflorescence (Gardner et al., 2010). Yield response of barley also varies with changing planting densities (Soleymani et al., 2011). Therefore, optimal grains production come from optimal planting stand by taking into account the specific set of environmental conditions and available resources including the particular cultivar characteristic which are responsible for tolerance to dense canopy architecture. Several factors, such as hybrid maturity group, water availability, soil fertility and row spacing (Sangoi et al., 2002) are crucial in determining proper plant number per unit area. In this study the response of cereals to plant population and nutrient management are presented and future prospects and insights are discussed.

Importance of nitrogen use efficiency

For food security it is necessary to enhance NUE in cereal crops at low input of fertilizers (White and Brown, 2010). Cereal crops need large amount of nitrogen to produce optimum yield and for which NUE is calculated is below 50% (Wang et al., 2018; Zhu, 2000; Ruan and Johnson, 1999). Irrigation, fertilizer and soil management practices are very important to enhance the crop yield (Ruan and Johnson, 1999).

Nitrogen plays an important role in crop growth and yield (Noor, 2017). Among the major plants nutrient N is taken up by the plants in largest amount. N is an essential component of plant growth (protein, enzymes, DNA, RNA) and photosynthesis i.e. chlorophyll. Symbiosis process in leguminous crops provides more nitrogen to soil which ultimately increased crop yield. Plants use nitrogen in the form of ammonium and nitrate (*Fig. 1*). Excess of nitrogen adversely affect plant growth and environment and surface nitrogen often leads to its contamination, eutrophication which later produces a decline in oxygen content of water. To improve NUE in cereals, some strategies need to apply for example N management, plant breeding and genetics. NUE is economically and also environmentally beneficial to enhance irrigation use efficiency, diminish soil erosion, reduces the pest infestation, to maintain soil texture, increase soil organic matter and humidity, less reliance on agricultural chemicals and improve crop NUE (Noor, 2017; Halvorson et al., 2001; Riedell et al., 2009).

The plant life cycle in response to the nitrogen management is divided into two parts: the vegetative part and the reproductive part. During vegetative growth, smaller roots and leaves respond as sink organs before flowering and then reduced by the nitrate assimilatory pathway (Hirel and Lea, 2001). The amino acids are further used for the synthesis of enzymes and proteins which are involved in growing plant architecture and the different components of the photosynthetic pigments, in C3 species 50% of the total soluble leaf protein can be represent alone by Rubisco (ribulose 1,5- isphosphate carboxylase) (Mae, 1997) and 20% in C4 species.

Before anthesis in wheat, 60–95% N comes from the remobilization of N stored in young roots and shoots (Palta and Fillery, 1995). Post-flowering N uptake and N translocation to the grain is available in a very less quantity. Under N-deficient conditions the size and the N content of the grain significantly decreased (Dupont and Altenbach, 2003). Nitrogen (N) deficiency, is one of the major problem diminishing crop growth (Tanner et al., 1993; Teklu and Hailemariam, 2009). Three split applications at anthesis showed significant result for Higher NHI (Jan et al., 2010). It is not clear that storage protein synthesis and plant N availability or that decreases the determination of grain yield and protein synthesis N applications in wheat are generally calculated by the total N budget method. Until tillering, the soil supplies nitrogen to the plant. Three applications are generally recommended: one at tillering (50–80 kg ha^{-1}), one at the beginning of stem elongation (around 50 kg ha^{-1}), and one at the second node stage (40–50 kg h^{-1}). SPAD meter is a potential instrument used for predicting grain N requirements in cereals (Lopez-Bellido et al., 2004). In rice crop same pattern of N management exists but the plant mostly uses ammonium instead of nitrate. Vegetative organs uses the remobilized N 70–90% of the total panicle N (Mae, 1997; Tabuchi et al., 2005). Crop residues in rice belt farming patterns have small or no short-term benefits on rice yield (Thuy et al., 2008). In the field, at early growth phase and tillering 40 to 110 kg N ha^{-1} used in the form of ammonium or urea. At panicle primordial stage and the late stage of spikelet initiation, additional top-dressing N (15–45 kg ha^{-1}) is applied and is effective for spikelet production. Sink size of rice crop is little effected by N uptake. During the grain-filling stag, in a leaf blades N is accumulated and large part used by the grain and that contributes to grain N protein synthesis (Mae, 1997). Plant density and nitrogen use efficiency of cereals are represented in *Table 1*.

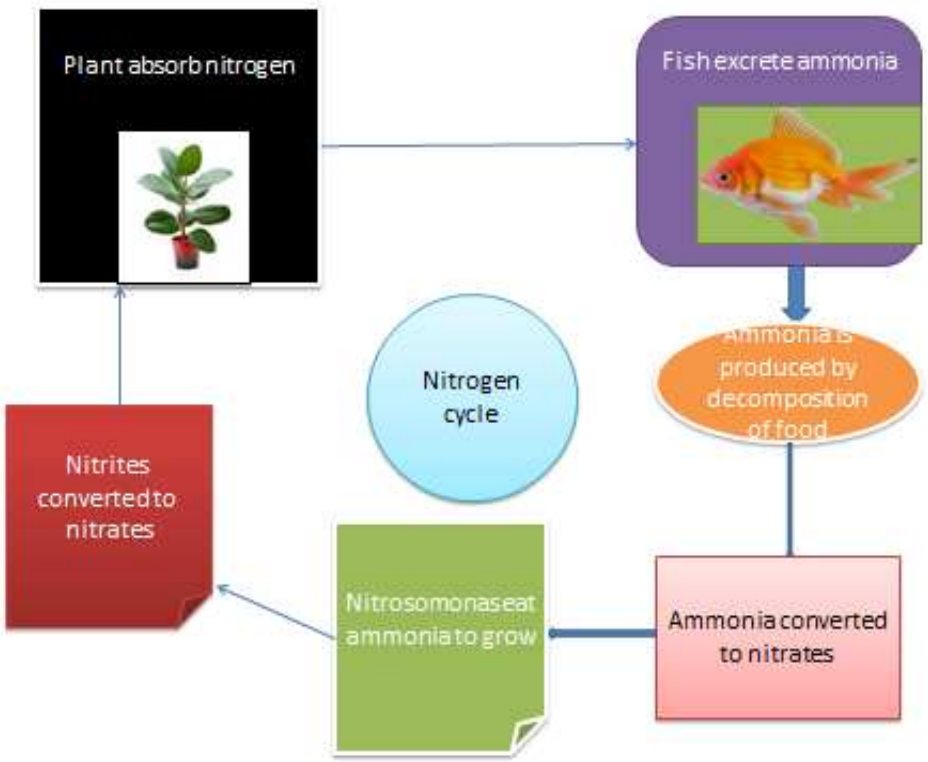

Figure 1. *Nitrogen cycle in agricultural systems.*

Physiological response of cereals to nitrogen use efficiency

Good et al. (2004) and Lea and Azevedo (2006), defined nitrogen use efficiency as nitrogen in grain per total N uptake. NUE is further divided into two parts i.e. uptake and utilization efficiency (Moose and Below, 2009). Winter wheat response to next crop and crop management the effect of next crop on the N uptake of the following crop has long been studied (Anderson, 2008).

Table 1. *Nitrogen use efficiency for different plant density and nitrogen regimes*

Planting density	Crop	Seed rate/PD*	Yield	NUE	Ref	Exp. duration

LD = low density, HD = high density MD = medium density

NHI is defined as the ratio of grain protein content to the nutritional quality (Sinclair, 2004). Jan et al. (2010) reported that the higher NHI in the three split application at anthesis gave significant result. The genomics for grain composition indicates that grain yield and protein concentration in most grain crops has been reduced by an apparent inverse genetic relationship (Simmonds, 1995), including wheat (Canevara et al., 1994), oilseed rape (Brennan et al., 2000; Jackson, 2000) and maize (Feil et al., 1990). A negative regression is used to predict higher grain protein content among wheat line (Oury et al., 2003; Kade et al., 2005).

High yielding and high protein varieties are used to determine negative control present between yield and grain protein content. This is also helpful for understanding the comparison of N uptake and N use for protein deposition under less and high N condition (Uribalarrea et al., 2007). Modern varieties showed greater NUE than older ones (Sylvester-Bradley and Kindred, 2009), but this phenomena has not been identified. Crop management, fertilizer application methods to develop high yielding varieties through breeding are the two ways to enhance NUE for example root system can be modify in up taking the nitrate from the below soil that have negative effects on the uptake efficiency of phosphate, which is present in upper soil.

Impact of nitrogen use efficiency and plant density on photosynthesis

To increase light interception on plants to improve photosynthesis there is a tight relationship among radiation use efficiency (RUE), leaf N distribution, leaf photosynthetic pigments and N supply and plant population (Gastal and Lemaire, 2002) when C3 or C4 crop species are studied. It is very important to study the level of CO_2 saturation of Rubisco. As an example of a tillering Gramineae species, Bos and Vos (2000) analysed for wheat which morphological leaf components were influenced by plant population and which mechanisms were involved. They reported that the most significant effect of higher plant population on leaf area per plant was the absence of later formed tillers. When a species does not form tillers, plant density can only affect the growth of leaves on the main stem. A study into the effects of environmental factors on the morphological development of such a plant type could lead to a better understanding of mechanisms involved in the effects of plant density on leaf-area development. Moreover, at higher plant densities, leaf area per plant is decreased in later phases of growth (Hay and Walker, 1989).

In both Sorghum and maize N uptake capacity depends leaf senescence is the cause of increased photosynthetic activity (Borrel et al., 2001). For improving the characterization of plants that are stay-green, N uptake, N assimilation and N recycling of the fine regulatory mechanisms is very important (Rampino et al, 2006). To know more about the physiological and molecular basis of the stay-green phenotype, further research is needed. To characterize whether such a phenotype are used when N fertilization is decreased and when water resources are decreased in relation to nitrogen availability, root N uptake capacity and architecture (Borrell et al., 2000).

Plant N economy and their species specificities

Nitrogen (N) deficiency is big threat for limiting wheat production and yield (Tanner et al., 1993; Teklu and Hailemariam, 2009). In maize (*Zea mays* L.) before silking about 45–65% of the grain N already exists in stover and the remaining 35–55% of the grain N produces from post-silking N (Ta and Weiland, 1992; Rajcan and Tollenaar, 1999; Gallais and Coque, 2005). To obtain maximum yield, one application of N fertilizer is recommended at sowing, ranging from 100 to 240 kg N ha $^{-1}$. Chlorophyll meter is the best instrument to estimate leaf N in maize crop (Chapman and Baretto, 1997).

Barley (*Hordeum vulgare* L.) is the fourth major crop in cereals. Due to genetic, physiological and agronomic studies it is an established model plant (Raun and Jonhson, 1999). However, N uptake and assimilation through biochemical and molecular mechanisms and recycling is best in this crop. Future improvements require studying N fertilizer levels and timing of application to achieve best grain yield and good quality of protein content. However, symbiotic N crop species contributes half of the amount of N applied in inorganic N fertilizers (Smil, 2006).

Plant development stages related to nutrition and plant density

Cereal yield is linearly correlated to high plant density. Improved morphology was the key for promoting light use efficiency per plant (Yu et al., 1998; Li and Li, 2004) which influenced canopy architecture, light interception and yield (Maddoni et al., 2001; Stewart et al., 2003; Tollenaar et al., 2006; Li and Wang, 2010). Superoptimal

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1013910153

planting densities can affect canopy architecture particularly during the period bracketing silking and can lead to reduce the yield (Tollenar and Wu., 1999; Maddoni et al., 2001; Christopher et al., 2009). Increasing panting density accelerated leaf senescence (Tethio-Kagho and Gardner, 1988), increased the shading of leaves (Hashemi-Dezfouli and Herbert, 1992), and reduced the net assimilation of individual plants. An increase in plant population of 2–13 plants per m^2 reduced net assimilation per plant from 0.85 to 0.11 mg CO_2 m^{-2} s^{-1}, but increased grain yield per area (Dwyer et al., 1991). This enhancement in grain yield can be explained by the increase in LAI and net crop assimilation rate. Corn cultivars having erect leaves are very desirable for increased population densities, which increases light interception (Radenovic et al., 2007).

In plants N availability influences several developmental processes the number i.e. leaves and their rate of appearance (Snyder and Bunce, 1983; Mae, 1997), and the number of tillers (Vos and Biemond, 1992; Trapani and Hall, 1996) are reduced under N-limiting conditions both in spring wheat. The valuable contribution of Arabidopsis research community is to verifying the connection between N, N uptake and root development (Remans et al., 2006); However, recent studies have suggested that an increased acidification capacity of the rhizosphere could be targeted to increase nitrate uptake and improve NUE in addition, the NUE of agricultural system may be improved if plants could maintain internal nutrient concentrations and optimal growth with a lower outside concentration in the soil. Therefore understanding the response mechanisms of NAcE to nutrient deficiencies may improve the ability of crops to tolerate lower nutrient concentrations in the soil and thereby save fertilizer and reduce potential pollution. All abbreviations are added in *Table 2*.

Table 2. *Abbreviations*

LD	Low density
MD	Medium density
HD	High medium density
NUE	Nitrogen Use efficiency
NHI	Nitrogen harvest index
HHV	High heat value
AN	Ammonium nitrate
CN	calcium ammonium nitrate

Manufacturing and cost of production of nitrogenous fertilizers

The products of the fertilizer industry are unique and different, every product needs different production processes. Fertilizer industries use many input as raw materials for example (energy, electricity natural gas, and other hydrocarbons), mineral phosphate, potassium salts, sulphur ammonia and acids (phosphoric, sulphuric, nitric), blending mixtures. There are different small companies' uses basic fertilizer materials to process, blends and mix compounds, which may or may not be further processed into mixtures, blends or compound to make fertilizers. Due to this complex process, basic fertilizer material such as phosphate, potassium salts, sulphur and ammonia should be used to the soil directly, according to this scenario, one company raw material may be another company product.

DOI: http://dx.doi.org/10.15666/aeer/1704_1013910153

Cost of production for nitric acid, ammonium nitrate (AN) and calcium ammonium (CN) nitrate production

Basic inputs per ton of AN in modern plants include 0.21 t NH3, 0.78 t 100% HNO_3 and 25-40 kWh of electricity. Steam and turbine power are according to the nitric acid concentration. Thus, the net steam requirement may vary from zero to 50 kg/t, and it depends if final product is only AN solution, steam may be exported (UNEP et al., 1998). Anhydrous ammonia production is represented in *Figure 2.*

The complete N budget is calculated as a function of N mineralization and the soil nitrate levels are used at the beginning of the season. Nitrogen mineralization are calculated as a function of soil texture and organic matter content. Most agricultural soils contain less naturally occurring plant available nitrogen to meet the needs of a crop throughout the growing season. Supplementary nitrogen applications are normally made each year to meet crop demand.

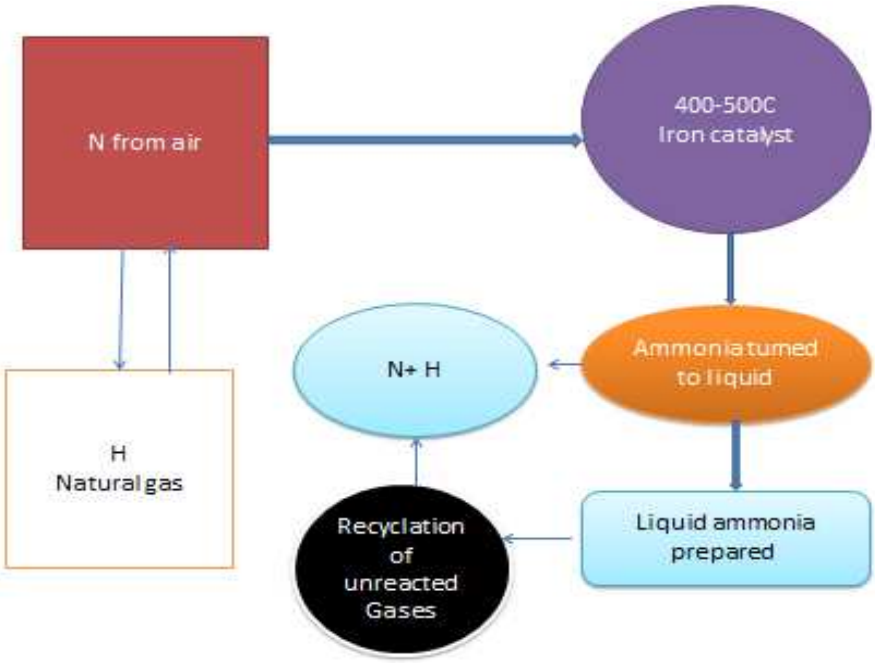

Figure 2. *Anhydrous ammonia production*

Strategies and practices to improve nitrogen use efficiency

Soil physical properties are very important to improve nitrogen use efficiency for example, soil texture, soil structure, organic matter.

Soil texture: Top soil texture is very important to determine lime requirement.

Soil structure: To obtain optimum economic yields, crops need sufficient nutrients and water from the soil through roots. To maintain good soil structure root growth is very important soil parameter, such as compaction.

Soil organic matter: Soil organic matter is a vital source of N used by crops. Organic matter consists of stable material called humus that has cumulated over a period of time.

There are different ways and procedure which are used to lower the price of fertilizers at farm-gate and to reduce the farmers' perception of the risk in the use of fertilizers by: (i) Hashemi-Dezfouli and Herbert (1992) sting in distribution

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1013910153

infrastructure; (ii) Researching innovative ideas to avoid losses and to provide finance; (iii) Encouraging sub regional measurement for country-level fertilizer manufacturing companies, facilities and/or procurement; and (iv) Encouraging dialogue between different agencies to arrive at a common approach to increase nitrogen use efficiency. Nitrogen management for intensification of cereals is widely researched topic across the globe.

Soil quality and NUE: Cycling of nutrients depends on the quality of agricultural soils, either directly through their capacity to receive nutrients and to convert them into or keep them in forms that are available to crops, or indirectly by governing the productivity and harvestability of crops and thereby the effective capture of nutrients from soils (Giller et al., 1997; Harris et al., 2011; Keesstra et al., 2016). Generally to improve nitrogen use efficiency following points should be considered (1) fertilizer use timing (2) Risk of N loss; (3) Placing N close to the period of maximum crop growth; (4) Even application of fertilizer and Fertilizer application rate; (5) Nitrogen fertilizer sources; (6) Application methods (7) Additives to reduce losses; (8) Managing nitrogen from manure; (9) Promoting efficient uptake and special consideration. Agronomic factors affecting plant population are (i) cultivar, (ii) length of the growing season, (iii) time of planting, (iv) water availability, (v) row spacing. Management and sources of nitrogen fertilizers are represented in *Figure 3.*

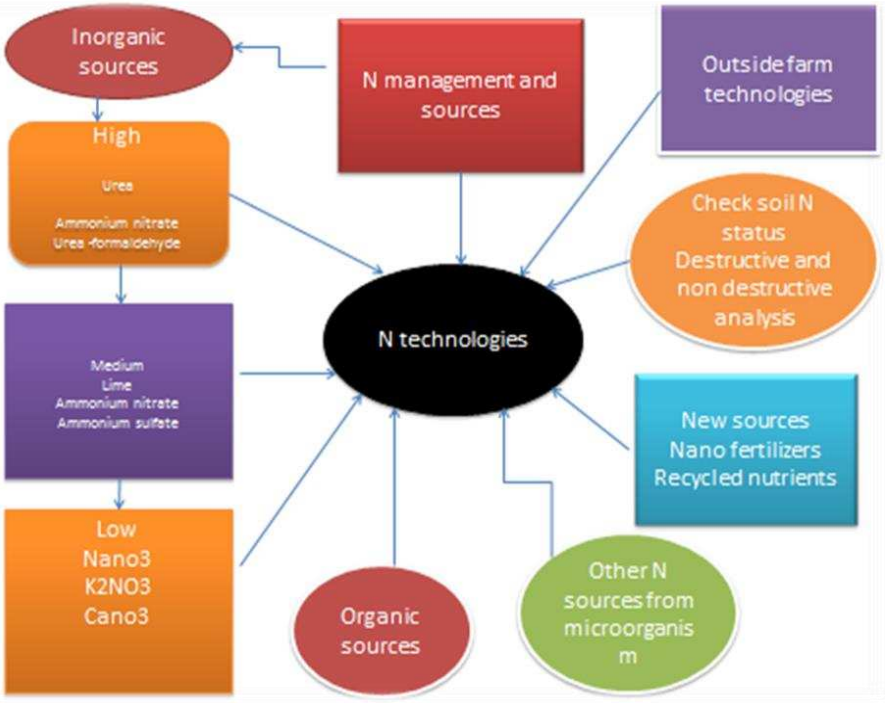

Figure 3. *Nitrogen production sources and management*

Concluding remarks

A genetic, physiological, and agronomic approach to N response and plant density will be useful for the use of NUE and is necessary to get key selection criteria for researchers and is important tool for farmers for fertilization protocol. This review will enhance the understanding to develop an integrated research work for discovering genes

by means of a complete phenotypic, agronomical, physiological, and biochemical under different plant population densities. High population density, important for high yields, causes greater competition for resources and morphological changes in the plant and may lead kernel abortion and lodging. Under different plant populations, due to leaching of NO_3-N and contamination of water the sufficient amount of N is not available to plant thus the NUE reduced. The future prospect is that how genetic, physiological, and agronomic approaches to high plant density and nitrogen to improve yield and quality of cereals. The breeders and agronomists should focus molecular and genetic aspects of cereals and should breed cultivars which are resistant to lodging and other problems under different plant densities.

(Received 13th Apr 2019; accepted 1st Jul 2019)

Abstract. In this study, it was aimed to use diatoms as representatives of phytobenthos for estimating the ecological status in Upper Sakarya Basin. Samples were taken seasonally from ten stations from April 2015 to December 2015. Stations 1, 2, 3, 4, 5, 6 and 7 were selected from rivers, stations 8 and 9 were selected from ponds which form Sakarya Springs. Station 10 was located at the outlet of Cifteler Aquaculture and Research Station. Diatoms were identified, counted and 19 diatom indices were calculated. Moreover, water temperature, dissolved oxygen, pH, electrical conductivity were measured *in situ*, and total nitrogen, orthophosphate and alkalinity were analysed. Finally, ecological status was estimated by evaluating biological, chemical and hydromorphological status according to Water Framework Directive. In total, 96 diatom species were identified from samples and *Achnanthidium minutissimum*, *Cymbella excisa*, *Craticula subminuscula* and *Fragilaria brevistriata* were the dominant species. Among diatom indices, IDP index which shows a high correlation with total nitrogen was used for the evaluation of the biological status. As a result, ecological status of the station 2 was estimated as high (class I), the status of stations 1, 4, 7, 8, 9 and 10 was estimated as good (class II), and the status of stations 3, 5, 6 was estimated as moderate (class III).
Keywords: *diatom, index, biological monitoring, reference site, water quality*

Introduction

Biological, chemical and hydromorphological monitoring has been carried out in Turkey since 2011 within the scope of alignment of Water Framework Directive (WFD). Rivers, lakes, coastal and transitional waters were monitored in 25 river basins. Water bodies were delineated, typology system was established, and sensitive areas were determined for that purpose. Preparation of river basin management plans and identification of reference sites are still ongoing.

The WFD requires to assess the status of rivers and lakes by using numerous parameters, one of which is phytobenthos. “Macrophytes and phytobenthos” are treated as two separate biological quality elements, and diatoms are frequently considered as representatives of phytobenthos (Kelly, 2013). Ecological status assessment is based on the status of biological, hydromorphological and physicochemical quality elements, by comparing data with the reference conditions (Muxika et al., 2007).

Phytobenthos is composed of many groups of living organisms such as macroalgae. However, reliable methods are developed mostly for diatoms. Some countries such as Czech Republic, Austria, Germany and Spain developed assessment methods for non-diatom communities. For instance, the activities regarding the identification of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1015510172

macroalgae and development of indices are still ongoing. However, mostly diatoms are used for ecological status classification within the scope of the WFD.

Several studies were conducted on diatom indices for water quality assessment (Cemagref, 1982; Kelly and Whitton, 1995; Lenoir and Coste, 1996; Rott et al., 1999; Gomez and Licursi, 2001). Some studies were carried out in order to classify the water quality by using diatom indices in Turkey (Kalyoncu et al., 2009; Kıvrak et al., 2012; Morkoyunlu Yüce and Gönülol, 2016; Atıcı et al., 2018). In addition, other studies are also available which evaluate the phytobenthos for each river basin (Demir et al., 2017; Toudjani et al., 2017).

In diatom studies carried out in the Sakarya Basin, 117 epilithic diatoms were identified as a result of sampling from June 2006 to February 2007 from five stations in Felent Creek. Water quality was then assessed according to the Watanabe index (Watanabe et al., 1990) and the Sladecek index (Sladecek, 1986). In the light of results, organic pollution was recorded in summer, and species richness was higher mostly in winter than in summer (Solak et al., 2012). In total, 45 epipelic diatoms were identified in spring 2010 in Gürleyik stream, and the water quality was determined according to the Trophic Diatom Index (TDI) (Kelly and Whitton, 1995) and Biological Diatom Index (IBD) (Coste et al., 2009) as mesotrophic (Tokatlı, 2012).

The Upper Sakarya Basin which is covered by one of the largest river basins in Turkey (Sakarya Basin) was selected in this study. The aim of the study is to investigate the seasonal variation of diatom composition, and to estimate the ecological status with hydromorphological and physicochemical quality elements in the Upper Sakarya Basin.

Materials and methods

The Upper Sakarya Basin is located between 38°45'-39°45' latitudes and 30°15'-31°50' longitudes in the southeast of Eskişehir province in Turkey (DSİ, 1978). The most important stream in the basin is the Sakarya River which covers 5.816.000 ha, with 6.4×10^9 m^3 annual water potential and 824 km of length. In addition, Sakarbasi ponds consisting of East Pond (2.1 m^3 s^{-1}) and West Pond (0.41 m^3 s^{-1}) are among the most important sources of the river. The West Pond is the main water source of Cifteler Aquaculture and Research Station (CARS) which has a trout production capacity of 60 tons yr^{-1}. 10 stations were sampled (7 rivers, 2 ponds and the outlet of CARS) in April, July, September and December 2015 (*Fig. 1*). The coordinates of the sampling stations are given in *Table 1*.

Water temperature (°C), dissolved oxygen (DO), pH and electrical conductivity (EC) were measured *in situ* using WTW Multi 3430 Set G. Sampling bottles were submerged towards the main flow of the river in the homogeneous zone to collect a sample below the surface film. Water samples were taken below the surface (50 cm depth) from the ponds. At least 2 L of water was taken for each station per sampling season. They were then stored in iceboxes with ice packs and transferred immediately to the laboratory for later analyses. Total nitrogen (TN), orthophosphate (PO_4-P) and alkalinity were measured according to APHA (2012). The results of parameters were checked against the Surface Water Quality By-Law (YSKY, 2016).

Approximately 10 m river stretch or pond shore was selected for diatom sampling. In rivers, riffles were selected to better indicate the variety of natural hard surfaces. Single substrate was chosen for comparability of the samples. At least five cobbles were used for sampling. However, if cobbles were not present, five small boulders were sampled

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1015510172

instead. Epilithic diatoms were brushed from submerged substrates from removable cobbles and boulders approximately 10 cm^2. One epilithic diatom sample was taken for one station per sampling season. The samples were fixed with ethanol solution immediately after collection (European Committee for Standardization, 2014a). Hot hydrogen peroxide method was used to clean diatom frustules in the laboratory, and slides were prepared with Naphrax (European Committee for Standardization, 2014b). Diatoms were identified with a trinocular Leica microscope and a camera using the relevant taxonomic literature (Krammer and Lange-Bertalot, 1985, 1986, 1988, 1991a, b; Hofmann et al., 2013). At least three slides per sample and 400 specimen in each slide were counted. Diatom indices were calculated with OMNIDIA 6.0.2 (Lecointe et al., 1993) and brief information was given for diatom indices in *Table 2*.

Detrended Correspondence Analysis (DCA) was performed to determine whether the ordination model was linear or unimodal before proceeding with the Canonical Correspondence Analysis (Leps and Smilauer, 2003). In order to link diatom species with water quality parameters, CCA was made with CANOCO 4.5 (ter Braak and Smilauer, 2002) and XLSTAT because the longest gradient length is above 4.0. Diatom species which were over 1% of general composition were taken into consideration. Physicochemical parameters were transformed $\ln(x + 1)$ except for pH in order to decrease skewness. CCA analysis was tested with 499 unrestricted permutations according to Monte Carlo simulation to clarify the significance of environmental variables on diatom species data. Significant variables ($P < 0.01$) were included in CCA analysis. The Pearson correlation between diatom indices and water quality parameters was calculated with XLSTAT software. In order to normalize the data, all index results were transformed to the scale 0-20 by the OMNIDIA 6.0.2. Since orthophosphate results were lower than the detection limits (< 0.01 mg L^{-1}) in some stations, they were excluded from CCA analysis. It was performed for 39 variables (22 diatom species and 6 physicochemical parameters) in 10 stations for 4 sampling periods due to the fact that station 2 was dry in September. The seasonal variations in physicochemical parameters and community structure were analysed by using one-way variance analysis (ANOVA). Diversity and evenness of diatoms calculated for community structure.

IHF index (Fluvial Habitat Index) (Pardo et al., 2002) and MPCA Stream Habitat Assessment (MSHA) (MPCA, 2014) were used in rivers, and the ECELS index (Boix et al., 2010) was used in ponds to estimate the hydromorphological status.

Ecological status was determined according to one-out-all-out principle in the WFD (Directive, 2000). According to this principle, the lowest score of all assessment results determined the overall ecological quality class in this study.

Results

Physical and chemical water quality parameters

In the research period, the lowest mean temperature (8.53 °C), alkalinity (11.55 mg L^{-1}), electrical conductivity (68.73 µS cm^{-1}), total nitrogen (0.50 mg L^{-1}) and the highest mean dissolved oxygen (9.99 mg L^{-1}) were measured in station 2 (*Table 3*). pH ranged between 7.05 and 8.0. The highest temperature (21.50 °C) and total nitrogen (4.06 mg L^{-1}) were found in station 6.

Diatom composition

In total, 96 diatom species which belong to 43 genera were identified from the sampling stations of the Upper Sakarya Basin (*Table 4*). The dominant species were *Achnanthidium minutissimum, Cymbella excisa, Craticula subminuscula, Fragilaria brevistriata, Amphora pediculus, Diatoma moniliformis, Ulnaria ulna* and *Denticula kuetzingii*. On the other hand, *Cymatopleura elliptica, Caloneis bacillum, Nitzschia vitrea, Cocconeis disculus, Cymbella compacta, Cymbella parva, Gomphonema truncatum, Navicula oblonga* and *Pinnularia viridiformis* were found rarely.

Diatom indices

The seasonal average scores of diatom indices in the sampling stations were given in *Table 5*. Different diatom indices revealed different water quality classes in the stations.

Statistical analyses

The seasonal variations in physicochemical parameters were found to be significant ($P < 0.05$). The unimodal ordination model was found between physicochemical parameters and diatom taxa since the longest gradient length was above 4.0. CCA analysis was performed to explain the link between physicochemical parameters and diatom taxa. The eigenvalues of the first two CCA axes were 0.792 and 0.515. 18.8% of the cumulative variance (axis 1: 11.4%, axis 2: 7.4) in the diatom species was explained by the first two CCA axes with 92% of the diatom species-environment correlation (*Fig. 2*). The amount of species-environment variance explained was 63.4% (*Table 6*). The Monte Carlo test confirmed that temperature, dissolved oxygen, total nitrogen, alkalinity ($P = 0.002$) and pH ($P = 0.004$) were statistically significant ($P < 0.01$).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1015510172

temperature and dissolved oxygen whereas a positive relation was found between alkalinity and conductivity. *Gomphonema micropus* and *Meridion circulare* were found to be in a separate quadrat from the other species and physicochemical parameters. Conductivity, alkalinity, total nitrogen and temperature were the parameters playing an important role in the distribution of species. When the clusters of species were examined, a large percentage of the species were clustered around temperature. In terms of nutrients, total nitrogen showed a close relation with temperature in the distribution of species. Pearson correlations between physicochemical parameters and diatom indices were shown in *Table 7*.

Table 7. *Pearson correlations between physicochemical parameters and diatom indices (n = 39) (see abbreviations in Table 2)*

*$P < 0.05$, **$P < 0.01$

The IDP index which has the highest correlation with temperature and which plays an essential role in the distribution of species, was used to evaluate the diatom results. IPS, DI-CH and EPI-D indices were also correlated with temperature respectively after IDP index. The IDP index results regressed against total nitrogen which also affected the distribution of diatom species (*Fig. 2*). Station 2 is excluded from the regression since the species were found to be in completely different quadrats.

Hydromorphological results

The hydromorphological quality in the sampling stations varied between high and moderate (*Table 8*). Station 2 is in high hydromorphological status, whereas stations 5, 6 and 10 are in moderate hydromorphological status.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1015510172

Table 8. *Hydromorphological status in sampling stations*

Stations	MSHA Score	IHF Score	ECELS Score	Status
1	62	65	-	Good
2	82	82	-	High
3	71	68	-	Good
4	61	66	-	Good
5	54	58	-	Moderate
6	49	56	-	Moderate
7	61	67	-	Good
8	-	-	71	Good
9	-	-	70	Good
10	45	52	-	Moderate

Ecological status

Ecological status was classified based on physicochemical parameters, biological results obtained by IDP index and hydromorphological findings (*Table 9*).

Table 9. *Ecological status in sampling stations*

Stations	Physicochemical status	Biological index results	Biological status	Hydromorphological status	Ecological status
1	I	1.80	II	II	II
2	I	1.13	I	I	I
3	II	2.20	III	II	III
4	II	1.49	I	II	II
5	III	1.29*	I*	III	III
6	III	1.21*	I*	III	III
7	II	1.98	II	II	II
8	II	1.73	II	II	II
9	II	1.95	II	II	II
10	II	1.86	II	III	II

*Given that *Achnanthidium minutissimum* which is found in stations 5 and 6 dominantly is excluded from the assessment, station 5 is found to be in class II (1.79) and station 6 is found to be in class III (2.04) according to IDP results

Discussion

Distribution of diatom species

In this study, *Achnanthidium minutissimum*, *Cymbella excisa*, *Craticula subminuscula* and *Fragilaria brevistriata* were determined as dominant species. The most dominant species, *Achnanthidium minutissimum*, is reported as a problematic both from taxonomic and ecological perspectives (Potapova, 2007). Kelly and Whitton (1995) stated that this species is dominant in high-altitude regions and in oligo-mesotrophic rivers. According to Steinberg and Schiefele (1988), it is a species that avoids conditions worse than β-mesosaprobic. In addition, according to Cox (1996), it is described as a species which commonly occurs in waters with a wide range of quality,

DOI: http://dx.doi.org/10.15666/aeer/1704_1015510172

but which is sensitive to waste water and β-α-mesosaprobic conditions. In the present study, *Achnanthidium minutissimum* was found to be a dominant species in some stations with diverse water quality. This might result from the fact that this species occurs in wide quality range from clean to polluted waters.

Statistical analyses and diatom index

In this study, most of the species clustered around the temperature. Toman et al. (2014) reported that temperature is listed among critical parameters for diatom composition which covers *Achnanthidium minutissimum* as a dominant species. Similarly, Izagirre and Elosegi (2005) determined that temperature was a parameter which affected diatom composition.

CCA showed that station 2 revealed the greatest differences compared to the other stations. Station 2 could only be sampled three times since it was dry in September, and it was observed that the results of these three sampling campaigns were concentrated in a different quadrat from other stations. Türkmen Mountain, with an altitude of 1829 m, is the highest mountain in Eskişehir province (ÇSB, 2014). Solak ve Wojtal (2012) identified 304 species in a study conducted on that mountain, and described 59 species out of 304 as the most common ones for Turkey, on the other side which can occur in completely different water bodies. According to Levkov et al. (2013), new species such as *Luticola kemalii*, *Luticola angusta* and *Luticola rotunda* were identified in samples taken from Türkmen Mountain. The number of species in station 2 was found higher than the other stations.

When examining the correlations between the indices and temperature which affects the distribution of the large percentage of species, it was found out that the highest correlation is obtained with IDP ($r = -0.4264$, $P < 0.01$) index. The IDP index has also a correlation in the distribution of species with alkalinity which varies significantly ($r = -0.3224$, $P < 0.05$). A significant correlation was found between the index results of IDP, which is an eutrophication index, and log total nitrogen ($R^2 = 0.7091$). As a result, IDP index was used in the evaluation of diatoms in the Upper Sakarya Basin.

The IDP index was developed for rivers located in the Pampean Plain of Argentina. Sensitivity values of 210 diatom species against organic richness and eutrophication were determined taking into account BOD_5, $NH4^+$ and $PO4^{-3}$ (Gomez and Licursi, 2001). The IDP index was first used in Turkey by Kalyoncu et al. (2009) to determine the water quality of the Aksu River. In that study, the IDP index and $NH4^+$ ($r = 0.854$, $P < 0.01$) provided the highest correlation between diatom indices and physicochemical parameters.

Ecological status

Concerning chemical, biological and hydromorphological water quality, station 2 was estimated to be in class I according to Surface Water Quality By-law, IDP index and hydromorphological assessment respectively. According to one-out-all-out principle of WFD, the ecological status of station 2 is estimated as class I. Since the station 2 is located far away from pressures and species diversity of this station is different from the other stations, monitoring effort should be sustained in here. It is the only station in this study with a high hydromorphological status, which might be a reference site.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1015510172

Stations 5 and 6 were estimated to be in class III chemical water quality according to the Surface Water Quality By-law, class I biological water quality according to the IDP index and class III according to hydromorphological assessments. This two-class difference between chemical and biological classification was only observed in these stations. According to one-out-all-out principle, the ecological status of both stations was estimated as class III. Both stations are fed by groundwater and there are agricultural areas in the vicinity. In addition, *Achnanthidium minutissimum* was the dominant species in each station. When these findings were tried to be confirmed by different indices, it was found out that stations 5 and 6 are categorized in class I water quality according to the IBD index but class V water quality according to the LOBO index. For this reason, station 5 is categorized in class II water quality (1.79) and station 6 is categorized in class III water quality (2.04) according to IDP index when *Achnanthidium minutissimum* is excluded from the assessment.

Station 10 is categorized in class II chemical and biological water quality according to the Surface Water Quality By-law and IDP index respectively, and in class III water quality according to hydromorphological assessment. According to one-out-all-out principle, the ecological status of station 10 was estimated as class II. Station 10 is located on a small creek where the effluents of CARS -which is fed by waters coming from station 9- confluence with the Sakarya River. However, chemical and biological classification results do not differ too much between stations 9 and 10. Only the diatom composition differs between the stations but this difference did not have any implications in the index results. Kırkağaç et al. (2009) stated that the invertebrate abundance in the inlet water was lower than the outlet water of CARS. However, the composition did not differ and only the Gastropoda species which are tolerant to pollution were found in the inlet and outlet water. As a result of this study, diatoms are concluded as important biological indicators for the monitoring the effluents of fish farms.

Generally, the results of chemical and biological assessment were similar for all stations. The results of five stations (2, 7, 8, 9, 10) were observed in the same quality class and there was one class difference among three stations (1, 3, 4). Two-class quality difference was only observed in stations 5 and 6, and the dominant species in those stations is *Achnanthidium minutissimum*, which is problematic in terms of taxonomy and ecology. According to the results of IDP index, which is calculated leaving aside this species, there is only one-class quality difference between chemical and biological status in station 5, while the same results were obtained in station 6.

According to a study conducted by Kalyoncu et al. (2004) in Ağlasun Stream, two different water quality classes were identified in terms of physicochemical parameters and epilithic algae. Water quality was then classified based on epilithic algae, which positively deviated half water quality class. In another study, Kalyoncu (2006) reported that water quality assessment was made according to epilithic diatoms, which positively deviated half water quality class from the assessment based on the results of physicochemical parameters. The differences between physicochemical and biological quality assessment observed in this study conducted in the Upper Sakarya Basin reveal similarities with the studies mentioned above.

Conclusions

As a summary, it is essential to develop biological indices for ecological status classification for water resources. Turkey is a very rich country in terms of biological diversity because of its geographical position. This diversity varies from region to region, and it affects the application of biological indices. For this reason, it might be recommended that eco-regions should be determined for monitoring of aquatic organisms, and the class boundaries of biological indices should be developed for these eco-regions.

Biological monitoring is carried out in river basins throughout Turkey. In this study, ecological status was estimated based on diatoms which are used as biological quality elements in rivers and ponds. The findings of this study may serve as an example both for water quality monitoring and management in Turkey. Sakarbasi Springs, which are the source of the Sakarya River, are used for several purposes, such as agriculture, recreation and aquaculture. It is therefore important to monitor these water bodies for controlling the pollution of the river.

In conclusion, it is necessary to take action for water bodies which are in moderate ecological status according to this study, and water bodies in good ecological status should be maintained. The Upper Sakarya Basin was monitored within the scope of the reference monitoring network since it forms the headwaters of the Sakarya Basin and has a high water potential. Station 2, Akin River which is in high ecological status might be proposed as a reference site for mountainous rivers with low alkalinity.

Acknowledgements. This study is a part of doctoral thesis "The Use of Phytobenthos for the Ecological Status Assessment in Upper Sakarya Basin" which was prepared in Turkey.

(Received 15th Apr 2019; accepted 13th Jun 2019)

Abstract. In this study, it was aimed to determine the epiphytic and non-epiphytic lichen diversity variations in Mediterranean maquis and arborescent matorral habitats. One of Turkey's national parks, Altınbeşik Cave National Park in Antalya, Turkey, was chosen as the research area as this habitat type is very common in the park. In this research, lichen diversity was calculated according to the data of species richness and species frequency. For identify possible variations of the lichen species composition in this habitat type, this research was planned on three major hills in the park. In addition, localities were selected from four different slope directions and tops of the hills. Statistical tests were used to analyze whether there was a difference or similarity on data. Moreover, the statistical relationships between the data of grouped localities with the data of diversity calculation classes were investigated. As a result of this study; lichen diversity of Mediterranean maquis and arborescent matorral habitats was put forth. Secondly, species richness and frequency of northern localities of Mediterranean maquis and arborescent matorral habitats were found to be significantly higher and community composition of northern localities was found to be much different than other localities.
Keywords: *Altınbeşik Cave National Park, biodiversity, community composition, Eastern Mediterranean, four cardinal directions, Turkey*

Introduction

Lichens are sensitive to even weak changes in their environments (Rose and Hawksworth, 1981; Ellis et al., 2007; Johansson, 2008; Nascimbene et al., 2012). Their sensitivity to environmental changes has been subject to numerous investigations (Gombert et al., 2004; Svoboda et al., 2010; De Guevara et al., 2014; Branquinho et al., 2015). When a change occurs in the environment of lichens, species richness and community composition changes to ones that are suitable for new conditions and replace previous lichen (Gadsdon et al., 2010; Johansson et al., 2012; Lang et al., 2012). This characteristic of the lichens is the reason why they are indicators of different ecosystem and habitat diversity (McCune, 2000; Rogers and Ryel, 2008; Nascimbene et al., 2012). In addition, by monitoring changes in lichen diversity, forest health can be determined (McCune, 2000; Thormann, 2006; Fenn et al., 1998; Geiser and Neitlich, 2007; McMurray et al., 2015). In order to determine the ecological condition of the areas according to the lichen diversity, it should be known which lichen composition is seen in which habitat.

Many researches have been done on lichen diversity variations of forests until now (Rogers and Ryel, 2008; McMullin et al., 2010; Koch et al., 2013; Bartels and Chen., 2015). There is also a large number of studies on the determination of the lichen richness in Mediterranean habitats (John, 1996; Litterski, 1997; Nimis and John, 1998;

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1017310193

Christensen and Svane, 2007; Ravera et al., 2011; Sipman and Raus, 2015). However, there are very few studies including variations of lichen diversity in the habitat composition of Mediterranean maquis and arborescent matorral (Aragón et al., 2006).

Mediterranean maquis and arborescent matorral habitat type is found across the entire Mediterranean biogeographical zone (Portugal, Spain, France, Italy, Sardinia, Sicily, Malta, Croatia, Macedonia, Montenegro, Serbia, Bulgaria, Greece, Crete, Aegean Islands, Cyprus, Turkey and Northern Africa) (EEA, 2016). According to the habitat types of EUNIS, this habitat has evergreen sclerophilous or lauriphyllous shrub vegetation which forms a dense enclosed canopy with or without emergent trees (EEA, 2017). In this habitat type there are matorrals that are covered top to bottom with leaves that hides the stem and some of these are arborescent that are sociologically isolated, with non-competitive root system (Tomaselli, 1977). *Quercus coccifera* L., *Pistacia palaestina* (Boiss) Engl., *Olea europaea* L. var. *sylvestris* (Mill.) Brot., *Phillyrea latifolia* L., *Juniperus excelsa* M. Bieb., *Pinus brutia* Ten are examples of Mediterranean arborescent matorrals. Although *J. excelsa* and *P. brutia* are originally forest trees but they are also found as arborescent matorrals within maquis in Mediterranean biogeography. This interesting habitat composition may suggest that its lichen diversity is unusual.

In this study, it was aimed to determine the epiphytic and non-epiphytic lichen diversity in Mediterranean maquis and arborescent matorral habitats. Therefore, one of Turkey's national parks, Altınbeşik Cave National Park, was chosen to determine lichen diversity of Mediterranean maquis and arborescent matorral habitats of park. Besides, there is a study showing that the vegetation type of park is suitable for this research (Çinbilgel and Gökçeoğlu, 2010a). Lichen diversity in this study was calculated according to the data of species richness and species frequency. The obtained data was used not only to examine the lichen diversity in Mediterranean maquis and arborescent matorral habitats but also to examine the existing differences or similarities of lichen diversity at different directions, altitudes, and substrates (epiphytic and non-epiphytic) in this habitat type. For identify possible variations of the lichen species composition, localities were selected on three major hills (Altınbeşik Hill, İnönü Hill, Kale Hill) and from four different slope directions, tops of the hills. Moreover, the statistical relationships between the data of grouped localities (according to directions, tops and hills) with the data of diversity classes (total richness, total frequency, epiphytic and non-epiphytic richness, epiphytic and non-epiphytic frequency) were investigated.

Materials and methods

Study area

Altınbeşik Cave and surrounding area were declared as national park in 1994; located between 37°01.19' to 37°04.37' N, and 31°35.49' to 31°38.52' E (*Fig. 1*). The park covers 1156 ha area, where the lowest altitude is 380 m, and the highest is 1165 m. The study was conducted on three major hills (Altınbeşik, İnönü and Kale) in the national park. The park is located in the rainy Mediterranean bioclimate zone according to the Emberger quotient (Çinbilgel and Gökçeoğlu, 2010b). The park generally covers with maqius and arborescent matorral habitats due to Mediterranean climate and karstic geomorphological structure of the area. *Quercus coccifera* L., *Pistacia palaestina* (Boiss) Engl., *Olea europea* L. var. *sylvestris* (Mill.) Brot., *Phillyrea latifolia* L., *Juniperus excelsa* M. Bieb., *Pinus brutia* Ten. are the most common members of the

DOI: http://dx.doi.org/10.15666/aeer/1704_1017310193

park vegetation. In addition, although the surface geology of Altınbeşik Cave National Park is generally calcareous, there are also siliceous rocks on the area.

Sampling and data collection techniques

The lichen samples have been collected in April 2017, January 2019 and deposited in O. Tufan-Çetin's private fungarium in Akdeniz University. Field studies were carried out in 15 localities (sampling area approximately 1.5 ha) (*Table 1; Fig. 1*). The localities were selected from four different directions and tops of the 3 hills (Altınbeşik, İnönü and Kale; *Fig. 1*) and contain same habitat patterns (maquis and arborescent matorral habitat) and same superficial geological structure. The hills represent three different altitude groups: Altınbeşik (500-700 m), Kale (700-900 m), İnönü (900-1100 m). Detail information and the abbreviated names of all localities were listed in *Table 1*. Sampling for richness and frequency data of lichens were recorded in 5 × 25 cm quadrats with five units (5 × 5 cm) for both epiphytic and non-epiphytic lichens. Frequency data was determined that based on the ratio of occurrence of the species in quadrats (Asta et al., 2002a, b). Epiphytic lichens were obtained from the trunks or stems of *J. excelsa*, *P. latifolia, P. palaestina* and *Q. coccifera* that found on all localities. Six individuals of each four plant species were selected and quadrats were placed 1 m above the ground and on four sides of the trees in each locality (Asta et al., 2002a). Also; non-epiphytic lichens from ground and rocks (calcareous and siliceous) were sampled 96 times.

Identification of samples

Dried samples were examined by using a light microscope for microscopic characters; and a stereoscopic zoom microscope for macroscopic characters. For identification of the species, the following literature has been used: Moberg (1977), Goward et al. (1994), Fryday and Coppins (1997), Tucker and Thiers (1998), Giralt (2001), Wasser and Nevo (2005), Wetmore (2005), Smith et al. (2009), Wirth et al. (2013) and McCune (2016). When required spot tests, ultra violet light (UV) tests and thin layer chromatography (TLC) have also been carried out.

Data analysis

The relations in recorded richness and frequency data from Altınbeşik Cave National Park were analyzed by correlation tests. First, the normality of the data was examined by the Shapiro-Wilk test. Pearson correlation test was used for normal distribution data set where Spearman's rho was used in other cases. The significance of all rankings was calculated by linear regression analysis. As of species richness and frequency data were not normally distributed, the Kruskal Wallis test (Kruskal and Wallis, 1952) was used to determine whether there is a difference within the data obtained from the localities. Since the variances were found unequal, Tamhane's T2 post-hoc test was applied to determine which localities differ from the others. All these analyses were performed by SPSS 23.0.

In terms of the lichen richness data, similarity of localities was calculated by Sørensen (Bray-Curtis) similarity index with group average algorithm (UPGMA). On the other hand, differences of community composition on maquis and arborescent matorral habitats were analyzed with non-metric multidimensional scaling (NMS) (McCune et al., 2002) using "medium" autopilot mode with the Sørensen (Bray-Curtis) distance measurement. The relationship of diversity calculation classes (joint plots) with the community composition was also investigated. Joint plots (total richness, total frequency, epiphytic and non-epiphytic richness, epiphytic and non-epiphytic frequency) were included in NMS analysis. By multi-response permutation procedure (MRPP) analysis (McCune et al., 2002), community composition of four slope directions and tops of hills, also separately three hills were compared on PC-ORD 6.08.

Results

Total 123 lichen taxa were identified from 15 selected Mediterranean maquis and arborescent matorral habitat localities in Altınbeşik Cave National Park. They are listed in *Table 2* in alphabetic order. New lichen taxa for Antalya Province of Turkey are highlighted by an asterisk (*) in this list. Also, the list includes average frequencies of epiphytic and non-epiphytic taxa and their total average frequencies (total frequency) and total richness data. Total frequency and total richness data for each locality were examined and were not found normally distributed. Therefore, Spearman's rho test was used to determine whether there is any relationship between total frequency and total richness data. As a result; a strong linear relationship was found between total frequency and total richness of each localities in the positive direction ($p = 0.000$, $r = 0.991$).

Based on the data of total frequency and total richness of each locality, the graph in *Figure 2* was formed (The altitude of the localities are also shown in the graph). As shown in the graph, each localities were sorted from high to low total richness as follows N-A > N-K > S-A > T-A > T-K > N-I > E-I > W-K > S-I > S-K > T-I > W-A > E-A > W-I > E-K ($r = 0.868$) and according to total frequency; from high to low: N-A > N-K > W-K > S-A > T-K > S-I > T-I > T-A > S-K > N-I > E-A > W-I > E-I > W-A > E-K ($r = 0.852$). In terms of total richness and frequency, the highest results were obtained from northern slopes of Altınbeşik Hill (N-A), whereas lowest results were from eastern slopes of Kale Hill (E-K). In addition, while data of N-A constitutes 16.11% of the total frequency and 21.14 of the total richness, data of E-K constitutes 2.60% of the total frequency and 10.57% of the total richness. It can be seen from the *Figure 2* while the northern slopes show the highest variation in lichen diversity in maquis and arborescent matorral habitats, the eastern slopes show least. On the other hand, in terms of data of species richness and species frequency, at least one locality was found significantly different than the other localities,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1017310193

statistically (Kruskal Wallis, p = 0.000). Since all variances are not homogeneous, non-parametric Tamhane's T2 post-hoc test was preferred to understand which localities are different. According to richness and frequency data, especially two north localities N-A and secondly N-K are different than other 13 localities. The post-hoc test results of both localities are given at *Table 3*. While the similarity of localities was examined, a Sørensen dendogram based on species richness was obtained (*Fig. 3*). According to dendrogram, lichen richness of same slope directions is similar and also tops localities show similarity. The northern localities are in a separate similarity group the rest being in another similarity group; top localities and western localities are also in separate similarity groups.

After Kruskal Wallis analyses were used, at least one locality was found significantly different than the other localities. Since all variances are not homogeneous, non-parametric Tamhane's T2 post-hoc test was preferred

-A: Altınbeşik Hill, -I: İnönü Hill, -K: Kale Hill, E: East slopes, N: North slope, S: South slopes, W: West slopes, T: Tops

After these results were determined, total frequency and total richness data were grouped based on localities at different slope directions and tops of the hills (*Fig. 4*). Also; localities from three hills grouped separately and plotted accordingly (*Fig. 5*). As two comparison data showed normal distribution, Pearson test was used for correlation analysis of these. While there was a very strong linear relation in data of four slope directions and data of tops ($p = 0.008$, $r = 0.963$), no relation was found within the data of the three hills (and the three altitude groups). As seen from the graphs, the total

DOI: http://dx.doi.org/10.15666/aeer/1704_1017310193

Also; total frequency data results obtained from the three hills are as follows from high to low (These hills also represent different altitude groups): Altınbeşik (500-700 m) > Kale (700-900 m) > İnönü (900-1100 m) (r = 0.917); total richness data as: İnönü (900-1100 m) > Altınbeşik (500-700 m) > Kale (700-900 m) (r = 0.952) (*Fig. 5*). When Kruskal Wallis test was applied for data of species richness and species frequency of different slope directions and tops, at least one data group statistically differentiates from others (p = 0.000). In addition, according to Tamhane's T2 post-hoc test results; northern slopes data significantly differ from the data of other directions and tops (*Table 4*). When species richness and frequency data of the three hills were analyzed; difference is available for the frequency data (Kruskal Wallis, p = 0.033) and richness data (Kruskal Wallis, p = 0.011) of the three hill. Tamhane's T2 post-hoc test result showed; Inönü Hill (900-1100 m) is different from Altınbeşik Hill (500-700 m) based on species richness data and it is different from Altınbeşik and Kale (700-900 m) Hills based on frequency data (*Table 5*).

*The mean difference is significant at the 0.05 level
After Kruskal Wallis analysis were used. At least one hill data was found significantly different than the other localities. Since all variances are not homogeneous. non-parametric Tamhane's T2 post-hoc test was preferred
A: Altınbeşik Hill, I: İnönü Hill, K: Kale Hill

When species community composition was summarized according to frequency data by non-metric multidimensional scaling (NMS), it was seen that 3 axes explained total variation with 82.89% (axis 1 48.20%; axis 2 21.81%; axes 3 12.88%). For 3-dimensional solution, the final stress rate was 12.41% and instability was 0.00000. At *Figure 6*, an ordination graph was given based on these NMS results with joint plot vectors (total richness, total frequency, epiphytic and non-epiphytic richness, epiphytic and non-epiphytic frequency). Examining Pearson correlation of axes and vectors; it was found that total richness (r = 0.624), epiphytic richness (r = 0.610), non-epiphytic richness (r = 0.470), epiphytic frequency (r = 0.552), non-epiphytic frequency (r = 0.462) and total frequency (r = 0.556) showed high positive correlations with axis 1. At axis 2; whereas all diversity vectors had descending relation, epiphytic richness (r = 0.708) and epiphytic frequency (r = 0.715) were associated with ascending gradient. It can be understood from the results and graph; the epiphytic richness and frequency are more related to the data from southern slopes than data from the top and other slopes. Furthermore, while all other vector parameters were associated with the northern slopes, *Figure 6* shows non-epiphytic richness and frequency are also associated with the data of tops of hills.

Lichen community composition of tops and four slope directions of hills were compared as small-scale with MRPP. The results were presented in *Table 6.* In a MRPP analysis, in case chance-corrected within-group agreement (*A*) value is higher than 0.3, this *A* value is enough to say the compositions are different (McCune et al., 2002). When the results of analysis were evaluated according to this information, species composition of northern slopes versus southern, eastern, western slopes and tops were found distinctly different as well as western slopes versus tops (*Table 6*). On NMS graph, also MRPP results are reflected (*Fig. 6*). Also it was experimented comparison of lichen community composition as large-scale with the data of three hills. In *Table 6*, MRPP comparison of lichen community composition of three hills is given separately. According to this table, no significant difference is observed in any pairwise comparison.

Discussion

The study was carried out to determine the compositional diversity of lichen species in selected Mediterranean maquis and arborescent matorral habitats in Altınbeşik Cave National Park. Nascimbene et al. (2013) listed 35 articles examining lichen richness, diversity and composition of different habitats in different European countries. These articles were based on epiphytic lichens that live on forest trees. This study differentiates from those articles by examining epiphytic and non-epiphytic lichens on maquis and arborescent matorral habitats in the Mediterranean region. Therefore; it is the first research about lichen community composition subject on maquis habitats in Eastern Mediterranean Region.

Among the frequency and richness data of selected Mediterranean maquis and arborescent matorral habitats from tops and four slope directions of three hills in the northern data were found significantly higher and differ than others. According to results from Sorensen Similarity Index: slopes at same directions are similar, also top localities shows similarity within themselves. Among them northern localities shows the highest similarity. According to MRPP results; species composition of northern slopes is statistically different than southern, eastern, western slopes and top localities. In addition, it was found; all lichen diversity calculation classes (total richness, total frequency, epiphytic and non-epiphytic richness, epiphytic and non-epiphytic frequency) are related with the northern slopes according to NMS ordination test. Hence, it was concluded that all lichen diversity calculation classes are high in the northern localities. North slopes of hills are typically cool, shady and have high atmospheric humidity (Moser et al., 1979). As lichens are poikilohydric organisms, their water content changes according to the surrounding environmental conditions (Nash, 2008). After recurring hydration – drying cycles, they become metabolically active in humid air (Bidussi et al., 2013). In Mediterranean Region when temperature is sufficient for metabolic activity of lichens, humidity becomes more critical than light in terms of vitality (Aragón et al., 2010). Furthermore, dew is a very important water supply for lichens. Dew at Northern slopes has higher frequency and longer duration than the ones at the other directions (Kidron et al., 2002). All this information may be used to explain the reason for the higher similarities and diversities of the northern slopes in Mediterranean maquis and arborescent matorral habitats compared to the other localities observed in this study.

In a previous study, the response of lichen richness and abundance were examined according to land use intensity. According to this study; epilithic lichen diversity increases along the gradient of increase intensity of land use from forested to non-forested areas (Giordani et al., 2010). Similarly, according to NMS ordination test of current study; richness of non-epiphytic lichens, which lives on rocks and ground, was found to associate with the data of the tops of the hills which are the most non-vegetation areas of the Mediterranean maquis and arborescent matorral habitats. Besides, the epiphytic richness was determined to be more related to the southern slopes than other slopes. The most important environmental factor for epiphytic lichens is diffuse but fairly bright light (Rose, 1992; Renhorn et al., 1997; Sillett et al., 2000). This kind of light is mostly on the southern slopes. This may be one of the reasons to explain the relationship between southern slopes and epiphytic lichens in Mediterranean maquis and arborescent matorral habitats.

According to the results obtained from three hills in the Altınbeşik Cave National Park, least amount of lichen species richness but most frequency data were determined

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1017310193

from İnönü Hill. While species frequency of this hill was found statistically different than other hills, species richness is different than only Altınbeşik Hill. As İnönü hill represents altitudes of 900-1100 m, this finding suggests; it is possible to find interesting lichen composition in Mediterranean maquis and arborescent matorral habitats at these altitudes in comparison to other altitudes.

Also lichen community composition of 3 hills was found similar according to NMS results. In a similar research on macro lichen diversity; the species richness and species abundance of areas were compared (Wiersma and McMullin, 2018). According to this study, it is reported that there is no difference in species richness or abundance in large-scale areas. This case suggests that similarity and difference measurements of lichen community compositions may be misleading on large-scale research areas. Similarly in this study, it was found that the composition of lichen in Mediterranean maquis and arborescent matorral habitats can show great variation in small-scale areas.

Conclusion

Mediterranean maquis and arborescent matorral habitat type is found across the entire Mediterranean biogeographical zone. In this study, it was aimed to determine the epiphytic and non-epiphytic lichen diversity in Mediterranean maquis and arborescent matorral habitats. Lichen diversity in this study was calculated according to the data of species richness and species frequency. In addition, it was examined the existing differences or similarities of lichen diversity at different directions, altitudes, and substrates (epiphytic and non-epiphytic) in this habitat type. Among the frequency and richness data of selected Mediterranean maquis and arborescent matorral habitats from tops and four slope directions of three hills, the northern data were found significantly higher and differ than others. According to results from Sorensen Similarity Index: slopes at same directions are similar, also top localities shows similarity within themselves. Among them northern localities shows the highest similarity. According to MRPP results; species composition of northern slopes is statistically different than southern, eastern, western slopes and top localities. In addition, it was found; all lichen diversity calculation classes (total richness, total frequency, epiphytic and non-epiphytic richness, epiphytic and non-epiphytic frequency) are related with the northern slopes according to NMS ordination test. In addition, richness of non-epiphytic lichens, which lives on rocks and ground, was found to associate with the data of the tops of the hills which are the most non-vegetation areas of the Mediterranean maquis and arborescent matorral habitats. Besides, the epiphytic richness was determined to be more related to the southern slopes than other slopes. Though it was found that lichen community composition shows great variation in Mediterranean maquis and arborescent matorral habitat, community composition of 3 hills was found similar according to NMS results. This result suggests that choosing large-scale areas for determining differences on lichen communities may have misleading results.

(Received 16th Apr 2019; accepted 13th Jun 2019)

Abstract. It is only possible by way of highly efficient system performance to provide uniform water distribution and sufficient soil moisture at the plant root zone in drip irrigation systems. Factors related with hydraulic and the emitter performance change should be known well for determining irrigation uniformity. In the study, 4 different emitter laterals were tested under 4 different pressure loads (5-10-15 and 20 m). The accordance of flow characteristics for the laterals, manufacturing variety coefficient (CV), emitter uniformity (EU) and irrigation water uniform distribution coefficient or Cristiansen Uniformity Coefficient (CU) and Statistical Uniformity (Us) values were evaluated in with regard to the American Society of Agricultural Engineers standards. It was determined based on the acquired results that there is an increase in the flow rates of emitters corresponding to the increasing pressure values and it was also determined that there were differences ranging between 0.75% to 25.5% with the flow values provided by manufacturing companies under 1 atm pressure. While the manufacturing variety coefficient class values were "weak", "moderate" and "good" for the A emitter, class values of "good" and "very good" were determined for irrigation uniformity (CU) and emitter uniformity (EU).
Keywords: *operating pressure, uniformity, drip irrigation, flow-rate, test-table*

Introduction

Recently, irrigation is also considered as, "maintaining the usable water at a suitable level at the root zone in addition to providing the water required for plant production". Irrigation applications are carried out using different methods due to changes in the topographic structure of the land, soil and plant type as well as changes in farmer preferences and cost factors. Among these methods, drip irrigation is preferred due to its superiorities over other methods with regard to yield, efficiency, irrigation water savings when compared with other irrigation methods, it is indicated that drip irrigation provides 44% water savings on apple trees in comparison with other surface irrigation methods (Mohammed, 2018), whereas drip irrigation consumes 60% less water in grapevine irrigation compared with furrow irrigation and 56% less water compared with micro sprink irrigation (Baştuğ et al., 1998). In general, about 30-60% water saving is possible with drip irrigation method in comparison to sprinkling and flood irrigation in agricultural irrigation (Anonymous, 2004). Drip irrigation is defined as, "slowly delivering filtered water to the plant roots in small amounts and at high intervals". Deep percolation, surface flow and evaporation losses can be minimized with this method (Wu et al., 1979; Korukçu, 1980; cited from Altın, 2009). Uniform distribution of water is a desired characteristic in drip irrigation. Failure of the system to distribute the water uniformly results in excessive or deficit irrigation of the plant roots. Both cases will inevitably yield to the emergence of conditions that are not suited for plant growth. Excessive irrigation leads to insufficient aeration of the roots due to bad drainage, washing of nutrients at the root and thereby reduced effectiveness of the fertilizer, while deficit irrigation results in higher energy consumption and low irrigation efficiency

(Çiçek, 2015). Hence, hydraulic change and emitter performance change should be taken into consideration as two important parameters causing changes in emitter flow rates when determining irrigation uniformity which is an important element when evaluating the drip irrigation system performances. Hydraulic change develops due to the pressure change resulting from the incline of side pipes and laterals on the land as well as pipe diameter and lateral length. Whereas emitter performance change can be considered as changes in emitters due to factors such as manufacturing varieties of emitters, level of clogging due to irrigation water, changes in irrigation water temperature and wear in emitters over time (Çamoğlu and Yavuz, 2004). Similarly, many factors such as operating pressure, water chemical and temperature, construction changes, effecting the uniformity of water distrubition. Therefore, the lack of such mentioned factors that caused to poor desing will bring changing in discharge and the distribution uniformity and low irrigation efficiency. The uniformity parameters are the main and basic criteria for designing an efficient of drip irrigation system (Elamin et al., 2017). Ideally, all emitters in a drip irrigation system should have equal flow rates (Özekici and Bozkurt, 1996). However, this is not possible in practice. Accurate emitter manufacturing is the main criteria and necessary in order to ensure a high effective system uniformity. Also the emission uniformity is essential to determining the total dept of water applied (Yeeshu et al., 2014). Manufacturing varieties that have a significant impact on system performance also cause variations in emitter flow rates. Emitters may differ with regard to characteristics such as volume, weight, surface shape and length due to factors such as raw materials used in manufacturing, manufacturing temperature, mold properties, manufacturing pressure and rate, cooling time etc. (Demir and Yürdem, 2000). There may be flow regime differences even in two emitters manufactured with the same technology using the same machine and the same manufacturing conditions (Solomon, 1979; Özekici and Sneed, 1995). Uniform distribution of irrigation water is one of the primary criteria taking into consideration when evaluating irrigation systems. However, irrigation systems differ with regard to uniform distribution due to many different reasons. Factors such as the uniform distribution of water at the application area, friction losses at the side pipe and laterals of the system, pressure changes due to the elevation differences between system elements, how well the system is maintained, level of clogs in the emitter due to contamination of irrigation water and the number of emitters per plant affect the uniform distribution of water (Ünal, 2011). It is also inevitable that there will be differences between local and foreign emitter laterals due to factors such as manufacturing conditions, raw material and manufacturing temperature even if they have been manufactured using similar technologies.

The purpose of this study was to put forth the impacts of manufacturing differences among emitters on their irrigation performances and to provide information to users on the different types of emitters in the market by carrying out analyses on their operating performances under different operating pressures as well as various hydraulic performance parameters. In the literature review, resently, there is no study in the GAP region which is compatible with the subject of this study or to determine the dripper hydraulic performances. There are large agricultural areas where pressurized irrigation systems are used in the region. Considering the excess amount of dripper lateral to be used in these areas, the use of drippers with good hydraulic performance is very important in terms of protection of water resources and providing the expected benefit from irrigation.

Materials and Methods

Test setup preparation

The present study was carried out at Siirt University which is located in the Southest Anatolia Region of Turkey Faculty of Agriculture Department of Biosystem Engineering irrigation laboratory. The test table in the laboratory (*Fig. 1*) was arranged such that the specially manufactured 4 lateral lines with an elevation of 1.2 m from ground level, lenght of 6 m and width of 1.8 m can be tested simultaneously.

Figure 1. *A view of test table used in this study*

The test setup was comprised of a main pipe, mounting system and lateral pipe lines. A 32 mm PPRC (Polypropylene Random Copolymer) pipe integrated to the municipal water outlet at the laboratory which is controlled by a ball valve was used as the main pipeline. The mounting system was affixed from its starting and ending points using a steel wire to make the incline at the laterals zero and the test laterals were fixed on these steel wires via clips. The test table for steel wires and laterals was mounted on a moving table at an elevation of 40 cm and a setup with 4 rows was prepared with lateral gaps of 35 cm. Plastic ball valves and manometers were used as return valve on the end of the main pipeline for pressure control at the lateral inlets and for ensuring lateral safety under high pressure conditions. The municipal water used in the test setup was directly connected since there was no contamination that may cause clogging. An additional electrical pump was not used in the system since the municipal operating pressure may reach up to 6 bars, however a 2 kW electrical pump was integrated to the system as a precaution against pressure drops. The municipal pressure was applied on the laterals after being reduced to the desired test pressure via ball valves. Temperature changes in the municipal water were monitored during the test at varying intervals using a portable thermometer and a difference of $\pm 0.5^{o}C$ was not included in the calculations since it is not effective on flow rate changes. Transparent plastic cups of 1.2 liters were used for collecting the water from the emitters.

Execution of the tests

Lateral flow rate tests were carried out at 4 different pressure intervals (5-10-15 and 20 m) on emitters the characteristics of which are given in *Table 1*.

A total of 28 emitters were selected on each lateral for determining the relationship between emitter pressure – flow rate and measurements were carried out with 3 repetitions. Water was given to the system which was subject to 10 minutes of natural dripping prior to starting the measurements and it was waited until the lateral input pressures became constant. Measurements were started and stopped simultaneously for all laterals. The emitter flow rates were determined in accordance with the volume

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1019510205

principle using the amount of water accumulated in drip pans placed under the laterals by way of 10 ml graded 1000 ml glass beakers (Tekin et al., 2016). The flow rate values determined for each emitter were evaluated in Excel software after which the flow regime, flow index subject to flow regime (x), flow coefficient (k), correlation coefficient (r), emitter uniformity (EU), Cristiansen Uniformity coefficient (CU), statistical uniformity coefficient (Us), manufacturing variety coefficient (CV) values were determined and the changes in these values subject to pressure were evaluated.

Table 1. *Characteristics of the emitters used in the test*

Emitter name	Flow rate(l h^{-1})	Emitter distance (m)	Type of lateral	Emitter Type
A (local)	4	0.33	Round	in-line-no diaphragm
B (local)	4	0.33	Round	in-line-no diaphragm
C (foreign)	4	0.33	Round	in-line-no diaphragm
D (foreign)	4	0.33	Round	in-line-no diaphragm

Determination of emitter flow characteristics

Emitter flow rate is a function of the pressure that characterizes flow. Hence, certain emitter characteristics such as manufacturing variety, emitter parameters can be easily determined via experimental studies (Karaca, 2008). The relationship between emitter inlet pressure and emitter flow rate is defined as a flow characteristic and is indicated with the $Q=kh^x$ equality given in *Table 2* and calculated using *Eq.1*. Here; Q: emitter flow rate, (l/h); k: coefficient expressing emitter dimensions, h: emitter inlet pressure (m) and x: emitter flow regime coefficient. The values of k and x indicate emitter characteristics and are two important parameters with an impact on uniform water distribution in drip irrigation as coefficients indicating emitter flow regime (Demir and Yürdem, 2000).

Table 2. *Hydraulic parameters and equations used in calculation*

Hydrolic parameters	Equations	
Flow Equation (Korukçu, 1980; Bralts, 1986)	$Q = kh^x$	(Eq.1)
Manufacturing Variety Coefficient (CV) (ASAE, 2002)	$Cv = \frac{S}{X_{ort}}$	(Eq.2)
Emitter uniformity (EU) (Keller and Karmeli, 1974)	$EU = 100 * \frac{q_x}{q_a}$	(Eq.3)
Irrigation water distrubition uniformity (CU) (Cristiansen, 1942)	$CU = 100(1 - \frac{\Delta q_o}{q_a})$	(Eq.4)
Statistical Uniformity (Us) (Bralts and Kesner, 1983)	$Us = 100(1 - \frac{S_q}{q_{ort}})$	(Eq.5)

In the above equations; q: emitter flowrate (l h^{-1}); k: flow coefficient; h: operating pressure, m; x: flow index subject to flow regime; q_x: average of ¼ of the emitters with the lowest flow rate (l h^{-1}); q_a: average of all emitter flow rates, (l h^{-1}); Δq_o: average of the absolute deviations from the average for each emitter or lateral flow rate, q_o: emitter or lateral input flow rate average, (l h^{-1}); S_q: standard deviation of emitter flow rates; q_{ort}: average emitter flow rate (l h^{-1}); X_{ort}: average emitter flow rate; (l h^{-1}); S: standard deviation of emitter flow rates

Flow index values suggested by different researchers that define emitter flow rate characteristics are given in *Table 3*. Results for the flow regime obtained in the study were evaluated according to *Table 3* and the flow regimes of the laterals used were determined.

Table 3. *Emitter flow regime coefficient values (Demir and Yürdem, 2000; Karaca, 2008)*

Flow Regime	**x value** (Bralts et al., 1987)
In pressure regülatör emitters	0-0.5
Partially turbulent flow and unstabil flow conditions	0.5-1.0
Full turbulance	0.5
Laminar flow	0.5-1.0
Partially regulated pressure	0-0.5
Regulated pressure fully	0

The evaluation principles provided in *Table 4* were used when determining emitter hydraulic parameters and the numerical values acquired as a result of the calculations were classified according to the provided criteria.

Table 4. *Recommended limits of coefficients (Tüzel, 1993; ASAE, 1994, 2002)*

Classification	**CV (%)**	**Us (%)**	**EU (%)**	**CU (%)**
Very good	<5	100-95	≥94	>90
Good	5-7	90-85	81-77	80-90
Moderate	7-11	80-75	68-75	70-80
Weak	11-15	70-65	56-62	60-70
Unacceptable	>15	<60	≤50	<60

Results and Discussion

Emitter flow characteristics

Table 5 summarizes the results related with flow characteristics for the emitters used in the study. Flow index values were determined between 0-0.5 for the B, C and D emitters used in the study and display a partially turbulent flow characteristic without pressure regulator. The flow index (x) value determined via graphic method for the emitter of A company was 0.5035 and it was evaluated to have a full turbulent flow regime.

Table 5. *Flow properties of emitters*

	Flow properties of emitters

Pressure-Flow Rate relationship

The emitters used in the study were tested under 4 different operating pressures and the acquired results have been summarized in *Table 6* and *Figure 2*. It can be observed upon examining the pressure-flow rate change of emitters that different values have been obtained at different operating pressures. Whereas the lowest average flow rate value was 2.79 l h^{-1} for the B emitter at the lowest operating pressure (5 m), the highest

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1019510205

average flow rate value was obtained as 7.73 l h^{-1} for the A emitter at an operating pressure of 20 m.

As can be seen in *Table 6*, the flow rate values determined during the study carried out for determining the flow characteristics of the emitters displayed a tendency to increase with increasing operating pressure. Parallel to the developments in irrigation technologies, studies have been carried out by many researchers for determining the variation in emitter pipes as well as the flow characteristics of these emitters (Özekici and Sneed, 1995; Demir and Yürdem, 2000; Kırnak et al., 2004; Üğlü and Tanrıverdi, 2013; Tekin et al., 2016). It was put forth in studies carried out by researchers that flow rate changes especially in systems using emitters without pressure regulator tended to increase with increasing operating pressure. Results acquired in this study regarding the pressure-flow rate changes were in accordance with the findings of other researchers and an increase was observed in emitter flow rates corresponding to an increase in operating pressure.

Table 6. *Emitters' pressure-flow relationship*

Pressure (m)	Flow (l h^{-1})			
	A (local)	B (local)	C (foreign)	D (foreign)
5	3.89	2.79	2.87	3.02
10	5.02	3.75	3.86	4.03
15	6.70	4.36	4.57	4.65
20	7.73	5.35	5.61	6.02

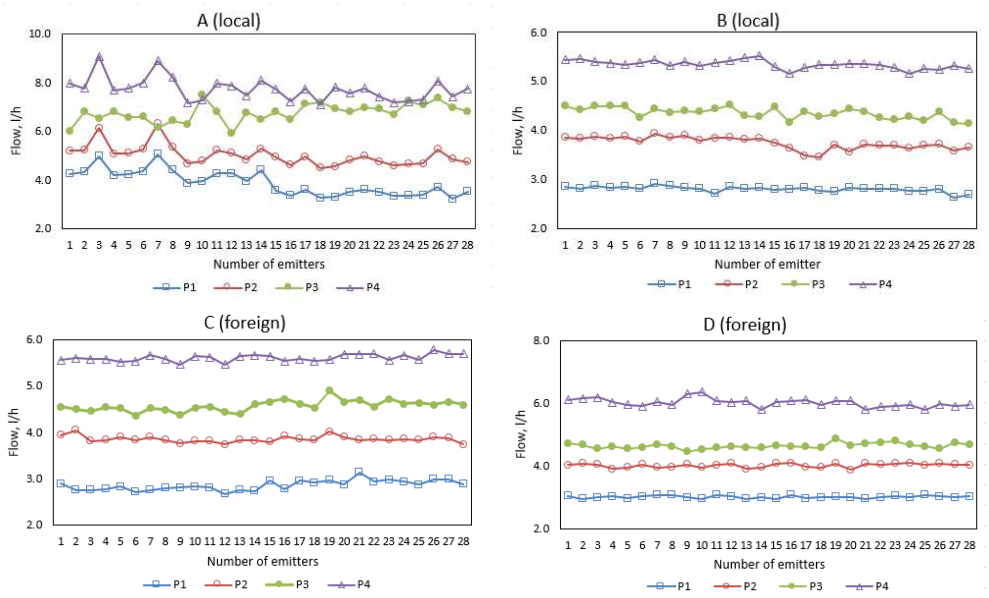

Figure 2. *Pressure-flow change in foreign dripper pipes*

Even though the flow rate for 1 atm pressure suggested by manufacturers of the emitters used in the study was 4 l h^{-1}, deviations from this value were observed. While the highest % change from the suggested flow rate was observed for the A emitter with 25.5%, the lowest change % was observed for the D emitter with 0.75%. The aforementioned values are similar with the findings of Tekin et al. (2016). Researchers

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1019510205

determined this change to vary between 1-15.5% subject to the companies of emitters used. The sudden decrease and increase in emitter B shown in *Figure 2* is thought to be due to the instantaneous pressure change in the emitter. The preference of emitters by system users with less flow rate change and which are classified as either "good" or "very good" should be taken into consideration with regard to both system performance and first facility cost.

Manufacturing variety coefficient

The manufacturing variety coefficients of the emitters used in the study were calculated using *Eq.2* and evaluated according to Wu and Gittling (1974) and ASAE (1994) and the manufacturing variety coefficients (CV) acquired along with classification have been given in *Table 7.* As can be seen when the table is examined that the CV coefficients have been subject to an evaluation based on different classification groups and received group values ranging between "very good" and "unacceptable". The emitters were classified into 4 groups as a result of this evaluation.

Table 7. *Manufacturing variety coefficient values*

Pressure (m)	CV_{cal} and Classification values							
	A (local)		B (local)		C (foreign)		D (foreign)	
5	13.27	*W*	5.68	G	3.74	VG	1.39	VG
10	8.46	*M*	3.33	VG	1.80	VG	1.57	VG
15	5.60	*G*	2.64	VG	2.50	VG	1.89	VG
20	6.16	*G*	1.62	VG	1.34	VG	2.25	VG

While the A emitter with an operating pressure of 5 m yielded a high (13.27) CV value, it was classified as "weak". Similarly, while the same emitter took on the value of "moderate with a load of 8.46 at a pressure load of 10 m, it was classified as "good" at pressure loads of 15 m and 20 m. The classification change interval ranged between "good" and "very good" for the B emitter as well even though the changes were not as dramatic as those of the emitter A. The change interval for the manufacturing variety coefficients under different pressure loads for exported emitters C and D was not very high with the lowest value of 1.34, highest value of 3.74 and a classification of "very good". Demir and Yürdem (2000) carried out a study in which a total of 32 emitters (22 without pressure regulator, 6 with pressure regulator and 4 with on-line emitters) were subject to tests under 5 different operating pressures and controlled laboratory conditions. It was observed as a result of the evaluation based on manufacturing variety coefficients that the emitters without pressure regulator were classified as "unacceptable" and "moderately perfect". The changes in CV values subject to pressure in the present study were in accordance with the findings of other researchers in literature. Even though the manufacturing variety coefficients of emitters vary between 2-15%, it is possible to obtain higher values (Çiçek, 2015). The CV values acquired in this study remained in the limits indicated by the researchers.

Emitter uniformity (EU)

The emitter uniformity coefficients for the emitters subject to the tests in the study were calculated using *Eq.3* and evaluated in accordance with ASAE (1994) and the acquired results together with the classification results are given in *Table 8*. As can be

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1019510205

seen upon examining the table that the emitter uniformity coefficients displayed increasing or decreasing changes. Whereas an increase was observed in emitters A, B and C subject to an increase in pressure, the converse was true for the emitter D. Tekin et al. (2016) carried out a study in which the emitter uniformity coefficient decreased at all pressures applied, only the results for emitter D were in accordance while the contrary was observed for all other emitters and the acquired results were not in accordance with the findings of other researchers. This is due to the fact that different brand laterals and emitters have been used.

Table 8. *Emitter Uniformity, EU*

Pressure (m)	EU_{cal} and classification values							
	A (local)		B (local)		C (foreign)		D (foreign)	
5	85.49	*G*	94.53	*VG*	95.64	*VG*	98.27	*VG*
10	91.86	*G*	95.46	*VG*	98.11	*VG*	97.82	*VG*
15	92.69	*G*	96.50	*VG*	96.93	*VG*	97.87	*VG*
20	93.23	*G*	97.93	*VG*	98.39	*VG*	97.37	*VG*

While emitter A was below the value of 94% for all applied pressures and took on the classification of "good", the other emitters were classified as "very good". The lowest emitter uniformity coefficient was determined as 85.49 for emitter A under a pressure load of 5 m, while the highest value was determined as 98.39 for emitter C under a pressure load of 20 m. Emitter uniformity coefficients were classified as "good" and "very good" for emitter A as was the case according to the findings of Özekici and Bozkurt (1996), the other emitters remained above 94% and were classified as "very good" in accordance with the results of studies by Çamoğlu and Yavuz (2004), Tekin et al. (2016). Uygan and Çetin (2015) carried out a study in which the emitter uniformity coefficient varied between 80-99% in plants using the emitter system in the Eskişehir-Sakarya region.

Irrigation water uniform distribution coefficient (CU)

The compliance of the irrigation water uniform distribution coefficients of emitters were calculated using *Eq.4* and evaluated according to ASAE (1994) and given in *Table 9.* While all coefficients obtained in the study were classified as "very good", only emitter A took on the "good" classification under a pressure load of 5 m. In general, Cu values increased with increasing pressure for emitters A, B and C, while all values were similar for emitter D under all pressure values. Çamoğlu and Yavuz (2004) determined the average CU value as 97.41, while Tekin et al. (2016) determined the average CU value as 97.20% and classified it as "very good". Based on these results, they concluded that the operating pressure value has an impact on the uniformity coefficient.

Statistical uniformity (Us)

The compliance of statistical uniformity coefficient values for the emitters was calculated using *Eq.5* and evaluated subject to ASAE (1994) and the acquired Us coefficients are given in *Table 10.* As can be seen when the table is examined that the lowest statistical uniformity coefficient was obtained as 5 m for emitter A under a pressure load of as 86.73, while the highest value was obtained as 98.66 for emitter C

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1019510205

under a pressure load of 20 m. In this case, the statistical uniformity classification values varied between "good" and "very good". In general, the Us values were determined to be under 94% only for emitter A under pressure loads of 5-10 and 20 m, while the average Us value was determined as above 94% and was classified as "very good". Çamoğlu and Yavuz (2004) carried out a study in which this value was determined as 97.11%, while Tekin et al. (2016) determined it as 96.49.

Selvaperumal et al. (2019) conducted a study in India on drip irrigation system in order to determine manufacturing variety coefficient (CV), uniformity coefficient (UC) and statistical uniformity (US) with the soil moisture distribution. Researchers declared that the coefficient of variation (CV) was obtained 0.0207 percent at a constant pressure of 50.66 kPa, statistical uniformity (US) as 97 percent and coefficient of uniformity (CU) as 0.9518. While US and CU values were consistent with our findings, CV values were found to be very low.

Conclusion

The fact that this study is conducted for the first time in the region is important in terms of guiding the future studies on this subject. The fact that this study is conducted for the first time in the region is important in terms of guiding the future studies on this subject. Beneficiaries who will benefit from the study outputs will be able to make more conscious choice in system planning, installation and dripper selection and thus contribute to the protection of water resources. It is expected from the drip irrigation system to provide the required performance, to be operated profitably and to provide the sufficient amount of water to the plant under optimum conditions with the best system hydraulic and flow parameters. Lowest values of the manufacturing variety coefficients which are among the most important factors that make up the system parameters lead to low flow rate variations between emitters and the ability to provide sufficient water to the plant root region. High values of Emitter Uniformity (EU), Cristiansen Uniformity Coefficient (CU) and statistical uniformity coefficients (Us) for all emitters increases the success of irrigation while also resulting in a uniform plant development and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1019510205

optimum increase in yield. Due to the aforementioned reasons, all factors with adverse impacts on hydraulic performance should be eliminated when setting up the drip irrigation system and the system should be operated efficiently based on the principle of efficacy.

Acknowledgements. This study was carried out at the Siirt University, Biosystems Engineering Department Irrigation Laboratory in Siirt/TURKEY, using a test table manufactured under the scope of the 2017-SIUZIR-53 Research Project supported by Siirt University Scientific Research Project Office.

(Received 17th Apr 2019; accepted 13th Jun 2019)

Abstract. This two-year study was aimed at determining the efficacy of different sampling methods in pest monitoring of direct seeded rice in southeastern Anatolia, Turkey. Four direct seeded rice fields were selected in Sanliurfa and Diyarbakir provinces and insect species were monitored at four different BBCH rice growth stages (i.e., 21-39, 41-49, 51-69 and 71-89) with two different sampling methods (D-Vac and sweep net). The highest density of insects belonging to Tipulidae family was observed at Biologische Bundesanstalt, Bundessortenamt and Chemical industry (BBCH) 21-39 growth stage the both years of the study. Similarly, the highest density of Phloeothripidae species was noted during BBCH 71-89 growth stage during 1st year and BBCH 21-39 growth stage during 2nd year of the study. Likewise, the highest density for Tettigonidae insects was recorded at BBCH 51-69 growth stage during both years. The greatest density of Acrididae family was recorded at BBCH 41-649 growth stage during both years of study. Overall, D-Vac sampling method trapped higher number of insects belonging to Tipulidae and Acrididae families, whereas sweep net method trapped higher number of insects belonging to Tettigonidae and Phloeothripidae families. It is concluded that D-Vac sampling method can be used for sampling Tipulidae and Acrididae insect species infesting rice in the future studies.

Introduction

Rice provides dietary and caloric supplies for half of the population of the world (Muthayya et al., 2014). Globally rice is cultivated on 167 million hectares of land with an annual production of 769 million tons and an average yield of 4601 kg ha^{-1}. In Turkey, rice is grown on 109 thousand hectares with an annual production of 900 thousand tones with an average yield of 8218 kg ha^{-1} (FAOSTAT, 2019). In the Southeastern Anatolia Region of Turkey, rice occupies 1965 hectares, producing 9 thousand tones with an average yield of 4580 kg ha^{-1} (TURKSTAT, 2016). Turkey is among the top five countries in terms of average rice yield (FAOSTAT, 2019), yet there exists a yield gap compared to developed countries of the world, i.e., Australia and the United States. Rice cultivation faces various limitations ranging from climate, soil type and fertility, water supply, irrigation, pest and disease problems in Turkey.

Rice farming is gaining popularity among Turkish farmers due to higher demands and government support policies to increase production for gaining self-sufficiency in rice production (Duman and Mutlu, 2011; Duman et al., 2013, 2014; Mutlu et al., 2016). The increasing rice cultivation has given rise to several problems such as insect, disease and weed' infestation, which hamper the quantity and quality of rice. Several studies have determined the beneficial and harmful insect fauna in rice cultivation areas of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1020710220

Aegean, Black Sea and Marmara regions in Turkey (Uzunali, 1976; Teoman and Kavut, 1979; Yürüten et al., 1982).

Transplanted rice fields are considered as the most diverse agricultural systems on the planet (Horgan, 2017). The rice productivity depends upon the flood cycles in transplanted rice where periodic shifts are recorded from flooded to dry period during the crop cycle. These changes in flood cycles promote a rich diversity of flora and fauna in transplanted rice (Catling, 1992; Way and Heong, 1994; Settle et al., 1996; Horgan et al., 2017). Over 800 insects have been recorded to feed on rice; however, ~20 of these species are considered as damaging pests of rice crop (Castro, 1970; Pathak and Dyck, 1973; Kiritani, 1979; Pathak and Khan, 1994). The most damaging pest species of rice include stem borers, gall midge, defoliators and vectors such as leaf and plant hoppers that cause direct damages and transmit various diseases. These pest species incur heavy losses to rice crop and various management strategies are opted or devised to keep their level below economic threshold. China, the largest rice producer has developed enough genomic strategies, which keep the harmful pests below their threshold level, whereas rice producers in the rest of the rice producing countries are still dependent on conventional pest management strategies.

Turkey is among the countries where farmers are still dependent on conventional pest management strategies for rice crop. The pest management studies in rice are mostly concentrated on the identification of beneficial and harmful pest species. Most of these studies have been conducted in transplanted rice, whereas direct seeded rice has been less studied (Duman and Mutlu, 2011; Duman et al., 2013, 2014; Mutlu et al., 2016). Rice is sown through direct seeding method in southeastern Anatolia region and scanty information is available on the pests of direct seeded rice crop in the region. Moreover, no information is available regarding the pest species' infestation at different growth stages of direct seeded rice in southeastern Anatolia region. Various studies in transplanted rice crop has revealed that relatively small number of arthropod herbivores damage rice plants; however, most arthropods species are beneficial. Herbivores invade the rice fields as crop grows and a small number of these can become pests if not effectively regulated. The pest attack at early crop growth stage relatively less damaging and negligible yield losses happen (Rubia et al., 1996; Horgan et al., 2016) or in some cases early stage pest attack results in more yield compared to pest attack-free crop (Nik Mohammad Noor et al., 1995; Islam and Karim, 1997). However, the pest attack at later growth stages can be more damaging and could result in heavy economic losses (Horgan, 2017). Therefore, monitoring pest density at different growth stages is necessary for effective pest management in rice crop (Reissig et al., 1986).

Different sampling methods are used to monitor pest densities in different crops. The sweep net and D-Vac sampling methods are most frequently used for pest monitoring (Turnipseed, 1974; Reissig et al., 1986; Schotzko and O'Keeffe, 1989; Buffington and Redak, 1998). These sampling methods have differential efficacy for trapping different insect species. The selection of accurate sampling method could help in effective monitoring of insect species (Schotzko and O'Keeffe, 1989; Binns and Nyrop, 1992; Buffington and Redak, 1998) However, limited information is available on the efficacy of insect monitoring in rice crop at different growth stages.

Therefore, the current study was designed with three major objectives, i.e., i) identify the harmful pest species infesting direct seeded rice crop in different districts of southeastern Anatolia region, ii) infer the density of different harmful pest species at different growth stages of rice and iii) determine the efficacy of different sampling

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1020710220

methods in monitoring insect species at different growth stages of rice crop. It was hypothesized that sampling districts and growth stages will significantly differ for the density of harmful pest species. It was further hypothesized that different sampling methods will differ in their efficacy for monitoring/trapping different insect species. To test these hypotheses, survey studies were conducted during two consecutive years in four districts of southeastern Anatolia region, Turkey. The results of the study will help to devise effective management strategies for the harmful pest species in direct seeded rice and help to improve sampling methods for pest monitoring of rice crop.

Material and Methods

Study area

This survey study was conducted in three districts of Diyarbakir province (Ergani, Cinar and Hazro) and one district of Sanliurfa (Siverek) province during rice growing seasons of 2010 and 2011. One rice field was selected from each district and surveys were accomplished in these selected fields during both years of the study. The geographic location of each surveyed field and prevailing long-term climatic conditions are provided in *Table 1*. Rice is cultivated by direct seeding method in the region. The farmers use different herbicide to manage weed infestation. Penoxulam, Bispyribac-Sodium and Bentazone+MCPA herbicides are used at the initial stage of rice crop for weed management. Insecticides are generally not used to control insect pests of rice crop in southeastern Anatolia region of Turkey.

Table 1. *Geographic location and long-term average (1979-2013) weather attributes of surveyed fields in southeastern Anatolia region, Turkey*

Surveyed Field	Latitude °N	Longitude °E	Area (ha)	Altitude	Rainfall (mm)	Max T °C	Min T °C	Avg T °C	Sunshine Hours	Aridity Index
Siverek	37.710583	39.246194	10.5	630	490.43	27.66	9.55	21.07	6.32	0.39

Max = Maximum, Min = Minimum, Avg = Average, Aridity index is opted from Çetin et al. (2007)

Survey timing and methods

Rice is typically cultivated during the month of May in southeastern Anatolia region of Turkey. The exploratory surveys to collect the insect species infesting rice crop were conducted at four different growth stages of rice. The growth stages according to BBCH scale were; 21-39 (tillering and stem elongation), 41-49 (booting), 51-69 (inflorescence emergence and anthesis) and 71-89 (fruit development and ripening) (Lancashire et al., 1991; Meier, 1997). The surveys were started from mid-June and continued until maturity with a fortnight interval. Two different sampling methods were used to test their efficacy in collecting the insect species. For sweep net method, insects were collected by sweeping the standard sweep net (Yiğit et al., 2003) at four different locations of each field. Twenty-five nets were swept at each location within a field making 100 sweeps per field. Similarly, in the D-Vac method (Mutlu et al., 2008; Yılmaz and Karsavuran, 2009), insects were sucked from four different locations within

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1020710220

each sampled field. The insects were sucked for one minute with vacuum sucking. For the sake of uniformity, twenty-five suctions were made at each location within each field. The collected insect species from both sampling methods were put in transparent polyethylene bags, labeled and brought to the laboratory. The collected species were identified according to the earlier specimens in the region, whereas the unidentified specimens were sent to taxonomists for accurate identification. The grasshopper specimens were identified by Prof. Dr. Ali SATAR (Faculty of Science and Literature, Dicle University, Diyarbakir, Turkey). Similarly, thrips specimens were identified by Prof. Dr. İrfan TUNÇ (Department of Plant Protection, Faculty of Agriculture, Akdeniz University, Antalya, Turkey). Crane fly (*Tipula orientalis*) was identified by Prof. Dr. Hasan KOÇ (Department of Biology, Faculty of Sciences, Muğla Sıtkı Koçman University, Muğla, Turkey).

The polyethene bags were kept in deep freezer to kill the insect species collected during the survey. The insect species were then placed over white papers and carefully counted. The counted species were separated into two groups (i.e., beneficial and harmful insects), and data relating to harmful insect species were used in this manuscript. The identified harmful insect species were then grouped into different families. The density of the insect species was then counted at family level and used for the interpretation of the results. A total 13 harmful insect species belonging to 4 families, i.e., Tipulidae (1 species), Acrididae (8 species), Tettigonidae (2 species) and Phloeothripidae (2 species) were identified during the survey.

Statistical analyses

The collected data regarding the density of insect species in different families were tested for normality, which indicated a normal distribution. Therefore, the statistical analyses were performed on non-transformed, original data. A paired t test was used to infer the differences among years, which indicated significant differences. Therefore, the data of both study years were analyzed and interpreted separately. Three-way Analysis of variance (ANOVA) technique was used to infer the effect of different growth stages, sampling methods and surveyed fields on the density of insect species belonging to different families (Steel et al., 1997). Least significant difference test at 99% probability level was used as post-hoc test to separate the means where ANOVA indicated significance. ANOVA indicated that all individual and interactive effects of growth stage, sampling method and surveyed field were significant for all insect families. Therefore, three-way interactions, i.e., growth stage × sampling method × surveyed fields were used for the interpretation of the results. All statistical analyses were performed using SPSS Version 20.0 (IBM, 2012).

Results

A total of 2472 insects belonging to 4 families were collected during 2010, whereas 3104 insects belonging to the same families were collected during 2011. The highest percentage (45.28%) of the insects belonged to Tettigonidae family, whereas the lowest percentage (8.09%) of the collected insect species belonged to Acrididae family (*Figure 1*).

The identified insect species with their corresponding families are summarized in *Table 2*. Some of the identified insect species are shown in *Figure 2*.

The individual and interactive effects of growth stage, sampling methods and surveyed fields significantly influenced the density of Tipulidae insect species during both years of the study, with an exception of non-significant effect of sampling methods × surveyed fields during 2011 (*Table 3*).

Thysanoptera	Phloeothripidae	*Haplothrips reuteri* (Karny)

Figure 2. *Different hamrful insect species, (a) Conocephalus fuscus Fabricius (Tettigoniidae), (b) Thisoicetrinus pterostichus F.W. (Catantopidae) and (c) Tipula orientalis Lackschewitz identified from rice fields in southeastern Anatolia region, Turkey during 2010 and 2011*

The highest density of Tipulidae insect species during 2010 was recorded at BBCH 21-39 growth stage in Siverek field with D-Vac sampling method, whereas the lowest density was noted at BBCH 51-69 and BBCH 71-89 growth stages in Hazro and Cinar fields with D-Vac sampling method (*Table 4*). Similarly, D-Vac sampling method

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1020710220

collected the highest number of Tipulidae insect species at BBCH 21-39 growth stage from Cinar field during 2011, while the lowest number of insects were trapped by sweep net sampling method from Cinar field at BBCH 41-49 growth stage of rice (*Table 4*). Overall, D-Vac sampling method trapped higher number of Tipulidae insect species compared with sweep net sampling method during both years of the study. Siverek field had the higher density of Tipulidae insect species during both years of the study compared to the rest of the sampling fields (*Table 4*).

The density of insect species belonging to Phloeothripidae family was significantly altered by the individual and interactive effects of growth stage, sampling methods and surveyed fields, with only a non-significant effect of sampling methods 2011 (*Table 3*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1020710220

The highest and the lowest number of Phloeothripidae insect species were trapped by sweep net sampling method at BBCH 71-89 growth stage from Cinar and Siverek fields, respectively during 2010 (*Table 5*). However, the highest number of insect species belonging to Phloeothripidae family were trapped by D-Vac sampling method at BBCH 21-39 growth stage from Ergani field and by sweep net sampling method at BBCH 51-69 growth stage from Siverek field during 2011. The lowest number of Phloeothripidae insect species during 2011 were collected by sweep net sampling method at BBCH 71-89 growth stage from all the sampling fields included in the study (*Table 5*). The sweep net sampling method exhibited higher efficacy in trapping Phloeothripidae insect species during the first year, while both sampling method indicated similar performance during the second year of the study (*Table 5*).

All individual and interactive effects growth stage, sampling methods and surveyed fields significantly affected the density of insect species belonging to Tettigonidae family during both years of study (*Table 3*). The highest density of insect species belonging to Tettigonidae family was observed at BBCH 51-69 growth stage from Siverek field during both years of the study (*Table 6*). The sweep net sampling method collected the highest number of Tettigonidae insect species from Siverek field at BBCH 51-69 growth stage during both survey years. Similarly, the lowest number of insect species belonging to Tettigonidae family were trapped from Ergani field by both sampling methods at BBCH 71-89 growth stage during 2010. However, the lowest number of Tettigonidae insect species were trapped by D-Vac sampling method from Siverek field at BBCH 71-89 growth stage during 2011 (*Table 6*).

The density of Acrididae insect species belonging to family was significantly altered by all individual and interactive effects of growth stage, sampling methods and surveyed fields during both study years except non-significant effects of sampling methods during 2010 and surveyed fields during 2011 (*Table 3*). The highest number of Acrididae insect species were recorded at BBCH 41-49 growth stage of rice during both years of the study (*Table 7*). The D-Vac sampling method from Siverek field and sweep net sampling method from Cinar field collected the highest number of insects belonging to Acrididae family at BBCH 41-49 growth stage during first year of the study

Discussion

The current study identified harmful insect species infesting direct seeded rice crop at different growth stages, which will provide valuable insights for the management of these species. A total of 13 species belonging to 4 families were identified, which are regarded as pests of different cultivated crops in earlier studies conducted by different researchers in Turkey. *Thisoicetrinus pteroschus* (Fischer de Waldheim) has been reported to cause significant damage to vegetables, tobacco and paddy fields in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1020710220

Diyarbakir and its vicinity between 1960 and 1961 (Balamir, 1962). Similarly, *Euprepocnemis plorans* (Charpentier) is the most dangerous pest species of maize and cereals (Şimsek, 1988). *Platycleis escalerai* Bolívar, *Calliptamus barbarus* Fisher-Waldheim and *Aiolopus strepens* (Latr.) have been reported as harmful pests in numerous crops (Karabağ et al., 1971; Karabağ, 1975; Çıplak et al., 1991, 1996). Different studies have reported that different orthopteran species, i.e, *Gryllo gryllotalpa* (L.), *T. pterostichus*, *Locusta migratoria migratorioides* (R. & F.) and *Conocephalus discolor* (Thunberg) are noxious pests of rice crop (Alkan, 1948; Balamir, 1962; Uzunali, 1976; Serel, 1978). The identified insect species in the current study infest rice crop at different growth stages. Therefore, management strategies/efforts should be opted according to the infestation time of harmful insect species.

Different growth stages of rice crop, sampling methods and surveyed rice fields significantly differed for insect infestation. It is known that the life cycle of many insect pest species is closely linked with the development of the rice plant (Reissig et al., 1986) and the differences in the insect density at different growth stages of rice crop are owed to the feeding preference, life form and damaging habit of the insect species (Reissig et al., 1986; Pathak and Khan, 1994). Similarly, the differences among different surveyed fields are thought to be the result of micro environmental conditions (*Table 1*), weed infestation and site-specific management practices opted by the farmers (Reissig et al., 1986; Pathak and Khan, 1994). Likewise, the differences in the efficacy of different sampling methods for trapping insect species can be explained with the size, weight and life stage of the insect species (Reissig et al., 1986). The D-Vac sampling method usually sucks the insect which are smaller sized, lighter in weight and at the most mobile stage, whereas the sweep net method traps heavier insects, relatively less mobile and bigger in size (Turnipseed, 1974; Kogan and Herzog, 2012). Therefore, the selection of sampling methods should be based on the target insect species and growth stage of the crop.

Crane fly (Tipulidae) species infested the rice crop during early growth season, i.e., BBCH 21-39 growth stage during both years of the study. The highest density of crane fly species at early growth stage is directly linked to their damage caused to the rice crop. The larvae of crane fly species feed on pastures and spring cereals, roots and young seedlings of rice crop (Rao et al., 2006; Duman et al., 2014). The larval movement below soil uproots the emerging rice seedling leading to plant mortality (Duman et al., 2014). Therefore, the highest density of crane fly species at initial growth stage can be linked with the damaging habit, life cycle and growth stage of the species. The identified crane fly species (*Tipula orientalis*) is a widespread cosmopolitan species frequently found near streams and in cultivated wheat and rice fields (Duman et al., 2014). Rice is cultivated through direct seeding method in southeastern Anatolia region, and the irrigation applied to direct-seeded rice creates favorable environment for the development of *T. orientalis* larvae. Thus, sowing method of rice in the region is another reason of higher density of crane fly. The lowest density of crane fly species at later growth stages of rice crop can be explained with the life cycle of the pest. The pest completes its life cycle and switches to diapause at later growth stages of rice due to which the lowest number of insects were trapped at BBCH 71-89 growth stage of rice crop. Xingquan et al. (1993) stated that cold swamps and meadows are the primary habitats of *Tipula* sp and the larva of the species cause highest damage at the end of

DOI: http://dx.doi.org/10.15666/aeer/1704_1020710220

May. The current results of the highest density of Tipulidae species at initial growth stage of rice crop are like the findings of Qian (1982) and Xingquan et al. (1993).

Thrips species had the highest infestation at different growth stages of rice crop in 1st and 2nd year of the study. The highest density was recorded at maturity (BBCH 71-89) during 1st year of the study, whereas the highest density was noted at BBCH 21-39 during 2nd year. The reasons for the differences in the density of thrips species at different growth stages in different years can be explained by the prevailing climatic conditions and weeds' infestation at different growth stages of rice crop. The farmers of southeastern Anatolia region stop irrigation at BBCH 71-89 growth stage of rice whereas temperature is high compared to the rest of the growth stages. The increased temperature coupled with no irrigation decreases relative humidity, thus, creating favorable conditions for the population development of thrips species. Thrips outbreaks are frequently reported during dry periods in rice crop (Hsu et al., 1978; Pathak and Khan, 1994). It is well known that thrips species mostly live in flowers, but many species complete their life cycle on leaves (Ananthakrishnan, 1993; Trdan et al. 2005; Van Haperen et al., 2019). A few of thrips species are predatory and probably about half of thrips species feed on fungi (Palmer et al., 1989). The damage caused to plants by thrips through feeding or egg laying is often ascribed to other pest species. Two thrips species were detected in the current study and discoloration on the leaves was noted during seedling stage. Besides feeding damage was also recorded during heading stage of rice (Hsu et al., 1978). *Stenchaetothrips biformis* (Bagnall) and *Haplothrips aculeatus* (Fabricius) have been recorded throughout rice growth season; however, these species are more abundant during the seedling and flowering stages of rice in some Asia countries (Madhusudhan and Gopalan, 1989; Pathak and Khan, 1994). The population declines in early September and disappears by mid-September (Pathak and Khan, 1994). Like the results of the first year of the current study, thrips infestation is generally recorded during the first week of August, with peak infestation during the second and third weeks in India. Hsu et al. (1978) reported that *Baliothrips biformis* (Bagn.) infests rice crop at 3-4-leaf seedling and tillering stages, whereas *Frankliniella tenuicornis* (Uzel) and *Haplothrips aculeatus* (F.) at late head-bearing and heading stages. These findings support the observation of current study.

Grasshopper species (Tettigonidae and Acrididae) had the highest density at BBCH 41-49 and BBCH 51-69 growth stages of rice crop. These findings are line with the results of Serel (1978) reported that grasshoppers appear in rice crop during first week of July. These results indicated that grasshopper species infest rice crop during mid to late growth season. Due to this reason, rice farmers use insecticides to control grasshopper species during July. However, the farmers in southeastern Anatolia region do not use any control measures against grasshoppers in rice crop. The insecticides are occasionally used to control grasshoppers in the region once the densities of grasshopper species are high. The higher density of grasshopper species observed in the current study is because the selected rice fields were closer to overwintering/migration areas of grasshoppers. The results obtained in the current study are similar to the results of several earlier studies reporting the identified insect species as harmful pests of rice crop (Balamir, 1962; Karabağ et al., 1971; Karabağ, 1975; Serel, 1978; Memişoğlu et al., 1986; Şimşek, 1988; Çıplak and Demirsoy, 1991; Çıplak et al., 1996; Satar and Özbay, 2003).

Conclusion

The current study concludes that different insect species infest direct seeded rice crop at different growth stages in southeastern Anatolia region of Turkey; however, actual losses caused by these species are still unknown. The studies relating to the losses caused by the identified insect species in the region are needed. It is also concluded that the differences in density of the insect species at different growth stages and in different fields necessitate site-specific and growth stage-specific management practices for the identified insect species in the region. Moreover, different sampling methods can be used for trapping harmful insect species (based on their size, weight and growth stage etc.) at different growth stages of rice.

Acknowledgements. The authors express their sincere gratitude to Commission of General Directorate of Agricultural Researches and Policies (TAGEM) for funding this study under project number TAGEM-B10/07-04(01-02)-08. We would like to thank several rice farmers who allowed the authors to conduct this research in their cultivated fields. Authors also express sincere thanks to Mahsum DEMİR and Deniz ÇAPLIK for their assistance in field selection and technical support.

(Received 23rd Apr 2019; accepted 4th Jul 2019)

Abstract. Accumulation levels of heavy metals in the feathers of birds reflect the abundance of these pollutants in the medium and birds can be useful indicators of this kind of pollution. The aim of the present study was to detected levels of some heavy metals of juvenile and adult Armenian Gull (*Larus armenicus*) and in the surface water of Hazar Lake, Turkey. The feather samples from different parts of the bodies of dead adult and juvenile Armenian Gulls were collected. Water samples were taken from different sampling stations distributed across the lake. Heavy metal concentrations were measured using a Thermo Scientific ICAP 600 Spectrometer. There was no significant statistical difference for bioaccumulation of heavy metals and trace elemets in adult and juvenile gull feathers ($p>0.05$). However, the highest metal concentrations were measured in juveniles. The highest average residue amounts in juvenile cover feathers were 0.02 mg/kg Cd, 0.46 mg/kg Pb, 0.72 mg/kg Cu, 58,31 mg/kg Fe, 0.04 mg/kg Ni, 8.38 mg/kg Zn, 0.07 mg/kg Se, 1.3 mg/kg Mn, 0.005 mg/kg Cr and 0. 01 mg/kg As. Mean values of all metals were within the acceptable limits of normal values for waterbirds, except Pb and Mn. When we evaluated the findings heavy metal concentration of the water were detected decrease in sequence of; Fe>As>Zn>Ni>Cd>Cu>Cr>Pb>Mn>Se. Compared with WHO (World Health Organization) and TSE-266 (Turkish Standarts Institution) standards; Cd, Cu, Zn and Cr concentrations in water were higher than the permissible levels for drinking water. It seems Armenian Gull feathers are useful monitoring tool for assessing heavy metal contamination.
Keywords: *bioindicator, biomonitoring, birds, toxic effect, wetland*

Introduction

Environmental degradation of wetland ecosystems by metals is a worldwide problem because of their toxic effects and long persistence (Mansouri et al., 2012; Klaassen, 2013; Zhang et al., 2018). As the trophic level rises in a food chain, the amount of toxic pollutant build up increases and therefore they involve great threat for all species and ecosystems (Ullah et al., 2014).

Indicator species are used to biomonitor environmental changes and to assess effects of pollution. Birds have been recognized as the useful bioindicators of environmental health (Erwin and Custer, 2000). They can be exposed to heavy metals through intake of food, drinking contaminated water and by physical contact (Becker, 2003; Burger and Gochfeld, 2004; Bostan et al., 2007).

One of the suitable methods of assessing level of the metal pollution in natural habitats is to determine the amount of it in bird feathers. Especially birds of prey species occupying higher trophic levels deemed indicative for bioaccumulation in the whole food chain (Boncompagni et al., 2003; Barbieri et al., 2010). Gulls are top predator species of their food web and they can give information about a large area around sampling site.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1022110227

The Armenian Gull (*L. armenicus*) breeds in eastern Turkey, Armenia, southern Georgia and northwestern Iran. It is known that breeding population of species in Turkey has declined rapidly in recent years (Adızel et al., 2010; Nergiz and Durmuş, 2017; Durmuş et al., 2018). There is one known crowded native resident population of Armenian Gull in Hazar Lake in East Anatolia. But studies about Hazar Lake population of the species are scanty.

In this study, we measured levels of Cd, Pb, Cu, Fe, Ni, Zn, Se, Mn, Cr and As in feathers of *L. armenicus* and water samples of its foraging areas at Hazar Lake. The objectives of this study were was to assess relationships between the metal levels in the feather of adult and juvenile Armenian Gulls and to compare the concentration of these metals in feathers of the species and their habitat at Hazar Lake, Turkey. We hope that this study will be a useful reference for the determination of regional contamination and realization of a protection plan for this bioindicator species.

Materials and methods

Feather samples of Armenian Gull were collected during 2015-2016 breeding season from the dead individuals in Hazar Lake. Water samples (n=48) were taken once a month at sampling station distributed across the lake. The details of each sampling station are given in *Figure 1*. Collected specimens were labeled and transported to the laboratory under appropriate conditions.

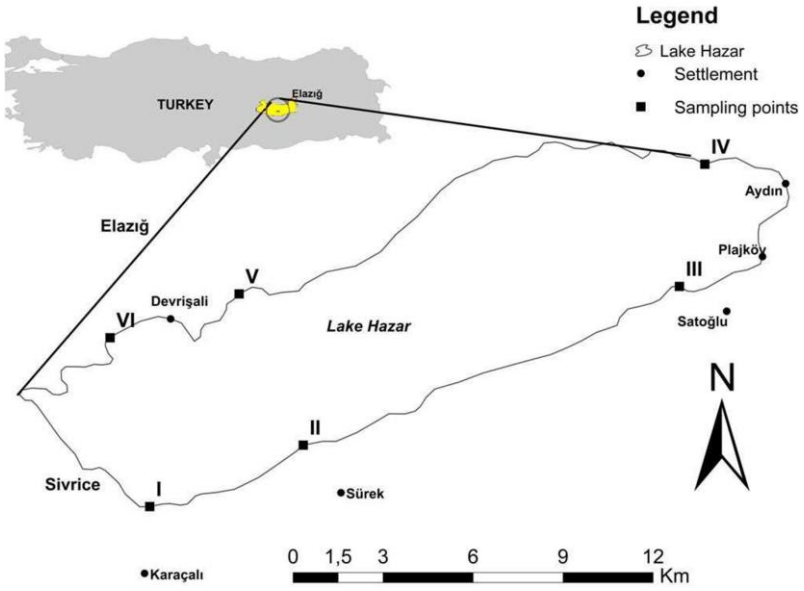

Figure 1. *Location of sampling stations in Lake Hazar*

Surface water samples were taken from 50 cm below the water surface using 100 ml sterile bottles, filtered and acidified with 1 ml of concentrated HNO_3 and then kept in a freezer at 4ºC until measured. Total 40 feather samples from different parts of the bodies of adult and juvenile Armenian Gulls were collected (APF: Adult Primary Wing Feather; ASF: Adult Secondary Wing Feather; ACF: Adult Cover Feather; JCF: Juvenile Cover Feather). Samples of feather transferred to the laboratory were washed with deionized water and rinsed with acetone to wash away the organic materials which

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1022110227

the water cannot dissolve. All samples were dried at 60ºC for 24 h to remove moisture. The dried feather samples were cut into small pieces with a steel scissors. 0.2 g (dry weight) from each sample were put into glass dissolution vessels and 5 ml HNO_3 (65%) added to each, and stored at room temperature for 24 h. The samples were heated to boiling on a hot plate until the color vapors of the samples vanished slowly and they were completely mineralized. After this, all samples were diluted to 10 ml with deionized water. Each sample was analysed at least three times for Cd, Pb, Cu, Fe, Ni, Zn, Se, Mn, Cr and As using ICP-AAS (Thermo Scientific ICAP 600 series).

Statistical analysis

All metal concentrations were detected as milligrams per liter for water samples and on a dry weight basis as milligrams per gram for feather samples. For this reason, average heavy metal levels were calculated as milligrams per kilogram. Statistical analysis was conducted in order to assess and compare the average values of metals in *L. armenicus*. Data were analyzed with SPSS software (Version 23). The average distribution of metals in *L. armenicus* (adults and juveniles) and water samples were assessed with independent t-test.

Results and discussion

The distribution of heavy metal and trace elements in feathers of *L. armenicus* for adults and juveniles respectively are given in *Table 1*. Results of our work confirm the findings by Burger (1993), Boncompagni et al. (2003) and Malik and Zeb (2009) that heavy metals pile up at different concentrations in feathers of adult and juvenile birds.

Table 1. *Concentrations of heavy metals and trace elements in feathers (mg/kg dry weight) of L. armenicus and in water samples of Hazar Lake (mg/l)*

Metal	Adults Mean ± SD	Juveniles Mean ± SD	Water samples Mean ± SD	p

*BDL: Below Detection Limit, statistically significance was accepted at $p<0.05$

Some studies have been conducted on heavy metals levels in feather of birds. Barbieri et al. (2010) showed that the levels of Cd, Co, Cr, Mn, Ni, Zn, and Pb increased with age. Furthermore, Burger (1996) indicated that the ratio of cadmium and lead in feathers of Franklin's gulls were lower in juveniles. Mansouri et al. (2012) pointed out that metal levels were always higher in adults, because of the age-related bioaccumulation. In the contrast, several studies have reported that there are significant differences in metal contamination in feathers with age related in which chicks had

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1022110227

significantly higher concentration of metal than adults (Stewart et al., 1997; Dauwe et al., 2000; Burger and Gochfeld, 2009; García-Tarrasón et al., 2013).

Present study provides additional supports for the suggestions by Burger et al. (2008) and Movalli (2000), that there was no significant statistical difference between feather samples taken from adults and juveniles for bioaccumulation of heavy metal and trace elements ($p>0.05$). The average levels of heavy metals detected in juvenile feathers in the present study were as; Cd 0.02 mg/kg, Pb 0.46 mg/kg, Cu 0.72 mg/kg, Fe 58.316 mg/kg, Ni 0.04 mg/kg, Zn 8.38 mg/kg, Se 0.07 mg/kg, Mn 1.3 mg/kg, Cr 0.005 mg/kg and As 0. 01 mg/kg. The chemical profiles of juveniles were as follows: Fe>Zn>Mn>Cu>Pb>Se>Cd>As>Ni>Cr. The highest trace metal concentrations were measured in juveniles. But the differences were smaller (*Figure 2*). This age related differences may be due to diet differences. Juveniles may have foraged in different habitats and fed more often than adults would have higher levels of metals in their feathers. The high levels of heavy metal accumulation in juveniles can be correlated with the egg and their food, which is derived locally.

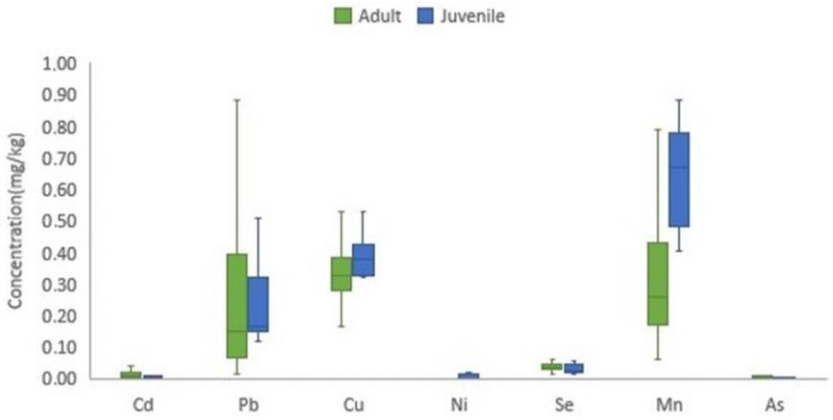

Figure 2. *Comparison of heavy metals in the feather samples taken from adult and juvenile Armenian Gulls*

Pb and Mn levels measured in present study were higher than those reported in previous researches. In the literature, an average of 0.51 ppm Mn and 0.19 ppm Cd was detected for marine birds (Burger, 2002). These values are much lower than that measured in our study. Greater than 2 mg/kg (dw) Cd, 4 mg/kg (dw) Pb, 1200 mg/kg (dw) Zn, 2.8 mg/kg (dw) Cr, 26 mg/kg (dw) Se, 0.96 mg/kg (dw) As concentrations in feathers were considered as abnormal poisoning and indicates increased environmental pollution (Burger, 1993; Heinz, 1996; Burger and Gochfeld, 2000; Taggart et al., 2006; Nighat, 2013). In the present study, mean heavy metal and trace element levels during 2015/2016 were in order of magnitude below known toxic effect levels.

Durmuş et al. (2018) studied metal deposition (Mg, Zn, Cu, Mn, Li, Sn, Co and Se) in feathers of the Armenian Gull from various regions of Van Lake Basin in Turkey. We found the mean concentration of Cr to be lower than their results but Zn, Mn and Se concentrations were slightly higher in our study which might be due to different nutrient density.

The heavy metal levels in water are given in *Table 1*. The mean values revealed that accumulation levels of heavy metals and trace elements in water varied from each other depending on the different sampling site. Pb, Fe, Zn and As were noted in all seasons.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1022110227

Among the analyzed metals Fe was the highest and Se was the lowest metal which was below detection limit in all seasons while Cd and Cr were recorded only in autumn and winter, Mn in winter, Cu and Ni in summer, autumn and winter. There were no statistically significant differences in the concentration of metal among seasons ($p>0.05$). The highest levels of Cu, Cr, Fe, Mn, Ni, and Zn were noted during spring, Cd and Pb in summer and autumn (*Table 2*).

The heavy metal and trace elements accumulation in water decreased in the following order; Fe>As>Zn>Ni>Cd >Cu>Cr> Pb>Mn>Se. The highest Fe (1.29 mg/l), As (0.03 mg/l), Zn (0.28 mg/l), Ni (0.18 mg/l) levels were in sites 4 and 5. The highest heavy metal concentrations in the two sampling sites were associated with natural sources and human related activities.

Table 2. *The concentrations (mg/l) of some heavy metals in Hazar Lake*

*BDL: Below Detection Limit

We compared the results of heavy metals in water of Hazar Lake with WHO and TSE-266 standards. According to these standards, Cu, Zn and Cr were higher than the permissible levels for drinking water in spring while Cd was in spring and summer.

Özmen et al. (2014) researched level of bioaccumulation of heavy metal and trace elements in water of Hazar Lake and recorded following highest concentrations (in mg/l) 0.43±0.11 Fe, 0.071±0.018 Zn, 0.012±0.002 Ni, 0.025–0.22 Cu. Their results indicated that a general absence of serious pollution caused by heavy metals such as Cd, Pb and As in the lake. Alp et al. (2011) reported that Cr, Pb and Cd levels were below detection limit in all seasons. According to our results the heavy metal concentrations of Hazar Lake' water increased which is presumed to be because of increased anthropological pressures.

Conclusions

Present study, we assessed the concentration of heavy metal and trace elements in feathers of Armenian gull, resident in the eastern Anatolia region of Turkey and breeding on Hazar Lake, for which scarce information existed. The results provide evidence that feathers are efficient metarial to understand heavy metals pollution levels and bioaccumulation along the wetland food chain with higher concentrations found in bird feathers than water. Metal concentrations detected during the study were within the acceptable range of normal concentrations for waterbirds except for Pb and Mn. Furthermore, the heavy metals (Cd, Cu, Zn, Cr) concentrations in water did exceeded WHO and TSE-266 guidelines in spring and summer. Although levels of heavy metals were not high, our results revealed that precautions need to be taken in order to prevent future heavy metal pollution in the lake basin. Consequently, we confirmed that feathers of Armenian Gull can reveal local contamination around the foraging and breeding sites and can be a very useful monitoring instrument for assessing heavy metal contamination.

Abstract. Wheat gluten proteins are extremely important proteins in terms of quality. Glutenin from the sub-units of gluten, because of the multi-polymer structure is effective in the rheological properties of the dough. In the study, samples taken from the endosperm section of local bread wheat (*Triticum aestivum* L.) genotypes; The *HMW-GS* band patterns in the *1A, 1B, 1D* genomes were determined, and the band patterns of the glutenin were determined using the vertical electrophoresis apparatus by *SDS-PAGE*. During the determination of *HMW-GSs*; *Cheyenne, Gabo, Chinese Spring, Janz, Insignia* genotypes were used as markers. According to the data obtained, some bread wheat genotypes carry high-quality glutenin bands found in the markers used in the study. As a result, in accordance with the data obtained from the study, the use of some bread wheat genotypes with high-quality scores in production will contribute to the development of high-quality products. However, a high-quality score with the improvement of genotypes used as parental lines, yield, and quality of high-new bread wheat cultivars will be developed.
Keywords: *band, genotype, HMW-GS, local bread wheat, mobility, molecular weight, quality, score*

Introduction

Wheat is a very important food material in terms of being the raw material of various nutrients. In order to meet the needs of the world population, the quality of flour should be increased due to wheat quality in order to meet the increasing demands along with the efficiency of the unit area. The quality of wheat produced in Turkey some years due to inadequate quality flour in some areas to meet the consumer demand is made by blending high-quality wheat. In addition, considering the self-sufficiency and the export of approximately 3.32 million tons of flour annually, it is essential to increase the flour quality of the bread wheat varieties (Anonymous, 2018). The most important parameter that determines the flour quality characteristics obtained from wheat is gluten proteins (Tatham and Shewry, 2000; Özberk, 2018). Gluten proteins are examined in two parts, gliadins and glutenins, and glutenin polymers form a multi-polymer structure by cross-linking of *HMW-GS* and *LMW-GSs* (Wrigley, 1996; D'Ovidio and Masci, 2004; Appelbee, 2006). Although *HMW-GSs* have a determinative role in dough basic properties, *LMW-GSs* also play an important factor (Cornish et al., 2001; D'Ovidio and Masci, 2004). Researchers also indicate that gluten proteins are highly effective in environmental factors as well as genetic factors (Payne et al., 1981; Troccoli et al., 2000). The use of sulfur fertilizers during wheat cultivation, in particular, increases the quality of gluten and thus increases the technological properties of flour (Zhao et al., 1999). *HMW-GS* is the bands that vary between *1-5* in bread and durum wheat (Waines and Payne,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1022910238

1987), that number between *1-3* due to the absence in the durum wheat genome *1D*, the glutenin banding varies from *3-5* and in bread wheat. In the studies carried out by the researchers, the sulfur-deficient *omega-gliadin* and *HMW-GS* proteins increased in the wheat grown in the areas where sulfur deficiency was observed, on the other hand, they reported that sulfur-rich proteins such as *gamma* and *LMW-GS* were reduced (Wieser et al., 2004). *HMW-GS* in the long arms of *1A, 1B, 1D* genomes in bread wheat (*Triticum aestivum* L.) and gliadins found in short arms of *6A, 6B, 6D* genomes are extremely important for the quality of the flour (Garg et al., 2006). In particular, *HMW-GSs* are effective on the baking quality of the products obtained from bread wheat (Shewry et al., 1995). In terms of gluten quality, in the grain filling process, the *1D* genome *HMW-GSs* are more susceptible to the formation of poor gluten content with the high temperature occurring in the bread wheat (Deng et al., 2008) and this indicates the importance of environmental factors (Raza, et al., 2019). In this study, it was aimed to determine and score the *HMW-GS* protein bands in the *1A, 1B, 1D* genomes of local bread wheat genotypes which have a significant effect on the quality and to determine the bread wheat genotypes with superior quality bands.

Review of literature

HMW-GSs are important parameters to determine gluten quality characteristics. Numerous studies have been conducted to determine the formation and functional relationships of gluten in many researchers and research groups (Payne et al., 1987; Lawrence et al., 1988; Popineau et al., 1994; Gupta et al., 1995; Yu et al., 2019). However, the effect of the *Glu-1* locus allelic variations on dough formation and development was not fully characterized (Li et al., 2016a). Some researchers stated that hydrogen and disulfide bonds are important factors for gluten rheology during dough formation and development (Wang et al., 2013; Li et al., 2016b). According to Wang et al. (2003), the glutenin macropolymer structure and *HMW-GS* formations determine the rheological properties of dough and glutenin macropolymer structure with have found a close correlation between the end-use quality. Shewry and Halford (2003) stated that although *HMW-GSs* constitute approximately 20% of all glutenin proteins, they have a major effect on the viscoelastic properties of the dough. The number and distribution of cysteine residues in the *1A, 1B, 1D* genomes found in *HMW-GSs* is important for the formation of proteins due to the di-sulfide bonds they contain. These structures are important factors related to the technological properties of the dough. *HMW-GS* cysteine residues are important in determining the elastic and polymeric structure of the dough (Tatham et al., 1985; Buonocore et al., 1998; Wang et al., 2016). Payne (1987) and Roy et al. (2018) *Glu-1* locus allelic varieties have a significant effect on bread quality characteristics, especially in the end-use quality development has stated that a very high potential has been obtained. Zhang et al. (2018) *HMW-GSs* have been highly effective on dough elasticity and baking quality. *Glu-B1* and *Glu-D1* genomes were found in the study of different bread wheat genotypes, respectively; *17 + 18* and *5 + 10* bands have a high effect on the amount and quality of gluten (Gupta et al., 1994). The technological quality development of flour can be achieved by increasing the number of active *HMW-GS* in genomes or by regulation of allelic formation (Lafiandra et al., 1998).

Materials and methods

The research was conducted in Tokat Gaziosmanpaşa University Faculty of Agriculture, Grain Laboratory (*Fig. 1*). Gluten quality of bread wheat genotypes with *HMW-GS* bands (Gianibelli et al., 2002; Singh et al. 1991) were determined by using vertical electrophoresis device with a modified method of *Sodium Dodecyl Sulfate Polyacrylamide Gel Electrophoresis* (*SDS-PAGE*) (Koyuncu's, 2009) (*Fig. 2*). The used of 21 bread wheat genotypes in the study was obtained from Turkey Seed Gene Bank. Six bread wheat varieties used in the study were obtained from the International Maize and Wheat Improvement Center and used as a marker (*Table 1*). The scoring of the bands in *1A, 1B, 1D* genomes was determined by the method of scoring (*Figs. 3* and *4*) defined by Lasztity (2002), Lasztity and Abonyi (2009) and Payne (1987).

Results and discussion

Wheat breeders aim to ensure high gluten growth in genotypes where quality comes to the forefront with their yield characteristics (He et al., 2001). Studies conducted by researchers at *Glu-1* locus *1A, 1B, 1D* in wheat *HMW-GS* genome bands were detected in the relationship to between wheat quality (Payne et al., 1987; Vapa et al., 1996). Approximately 13-14%, 55-58% and 28-30% of *HMW-GSs* respectively; They were found in the *1A, 1B, 1D* genomes (Li et al., 2016a). Larroque et al. (2004) stated that in terms of the functional properties of bands contained *1A, 1B, 1D* genomes were found to be highly effective. In different studies examining the functional properties of *HMW-GSs*, they reported that it affects approximately 70% of the quality of bread, although it accounts for approximately 11% of the total protein content (Yu et al., 2019). In the study in which quality scoring was performed according to the protein bands found in the *HMW-GS; 1A, 1B, 1D* genomes, the genotypes examined were found to have *8, 7, 6, 5* (*Table 2*). *TR63581, TGB000534* genotypes *2** in the *1A* genome, *TGB000526* genotypes in the *1*, *1A* genome in the other genotypes have a null band (*Figs. 5* and *6*). The *1A* genome affects about 15% of the wheat quality changes according to the *1B* and *1D* genomes (Yu et al., 2019). One of the important quality parameters in terms of Farinograph values *1* and *2** bands in the genome *1A* has a higher value than the genotypes contain null bands (Bagulho et al., 2004), especially the *2** band has been determined to have a high *Farinograph-PSI* value. The *2** band carrying TR63581, *TGB000534* genotypes were determined to have a higher *Farinograph-PSI (Table 2). 1B* genome of *12* genotypes *7 + 8*, *7* genotypes *7 + 9*, *1* genotype *7*, *1* genotype determined to carry the *20* bands (*Fig. 3*), *7 + 8* band of the other band (*7 + 9, 7, 20*) having a higher quality score (*Fig. 4*). In the studies performed, the researchers found that *1A* genome *1, 2*, 1B* genome *14 + 15, 13 + 16, 7 + 8* and *7 + 9* bands were positive for the quality of gluten and thus the quality of the products (Kaan et al., 1995). Other researchers reported that *20* and *6 + 8* bands have negative effects (Oak et al., 2004; Naghavi et al., 2009). According to the obtained results, it was determined that the examined genotype of *TR44433* carrying *20* bands in the *1B* genome was determined that could show negative quality characteristics *(Table 2).* The *1B* genome of the *TGB000534* genotype only carries bands with high scores in the *1A* and *1D* genomes, despite the presence of only *7* bands *(Fig. 6).* Examined other genotypes had *7 + 8* or *7 + 9* bands that had positive gluten quality in *1B* genomes *(Table 2).* Branlard and Dardevet (1985) in the study; The dough elasticity of *17 + 18, 7 + 8* bands determined a positive effect on elasticity, Li et al. (2016b) reported that *17 + 18 > 14 + 15 > 7 + 8 > 7 + 9* sorting was performed between the bands in the 1B genome. In the *1D* genome, *8* genotypes with a high *HMW-GS* band score (*Fig. 4*) carry *5 + 10, 13* genotypes *2 + 12* bands (*Table 2*). The bands found in the genome *1D* affect the quality rather than the amount of protein. The *1A* genome was found to be more effective on the dough strength and gluten quality compared with the *1D* genome (Zhang et al., 2018). According to *1* and null bands, *2** in genome *1A* and, particularly, *5 + 10* bands in the *1D* genome had extra-strong flour and baking characteristics compared to the *2 + 12* band (Payne et al., 1981; Payne and Lawrence, 1983; Kolster et al., 1991; Lukow, 1991; Maruyama-Funatsuki et al., 2004). Altpeter et al. (1996) and Barro et al. (1997) examined the bands found in the *1D* genome and stated that the *10* band has an important relationship with the dough strength and bread-making quality (Wang et al., 2016).

Conclusion

HMW-GS is an important parameter in terms of quality in wheat. *TGB003247, TR63581, TGB000543, TGB000534, DİMENİT, TR63497* local bread wheat genotypes have high *HMW-GS* scores according to bands found in *1A, 1B, 1D* genomes. *TR63581, TGB000534, TGB000526* genotypes have come to the fore in some quality parameters with the bands they have in the genome *1A*. In this research, the *Glu-band* pattern of *1A, 1B, 1D* genomes of local bread wheat genotypes were determined and the effects of *HMW-GS* were explained in detail. Local bread wheat genotypes with high scores in terms of the parameters examined can be used as parental lines in breeding studies.

COMPARISON OF DIFFERENT DETERMINING METHODS OF REFERENCE ET_O BASED ON LIMITED WEATHER CONDITIONS IN GAP REGION

AYDIN, Y.

Department of Biosystem Engineering, Faculty of Agriculture, Siirt University, Siirt, Turkey
(e-mail: yusufaydin@siirt.edu.tr; phone: +90-484-212-1111; fax: +90-484-223-1998)

(Received 30th Apr 2019; accepted 13th Jun 2019)

Abstract. Reference crop evapotranspiration (ET_o) is among the most important components of the hydrologic cycle. Standard FAO-Penman-Monteith method is the most frequently used equation to estimate of ET_o. However, the usability of this method is limited due to its complexity Hargreaveas-Samani (HS) and Turc methods that can be operated with limited data such as temperature and solar radiation are used as an alternative to the standard method. In the present study, the reference ET_o values estimated with FAO-PM as the standard method, Hargreaveas-Samani and Turc methods were compared at semi-arid climate conditions. Based on the acquired results; highest R^2 value at the GAP region with semi-arid climate conditions was determined as 0.9872 from the monthly averages of $ET_{o\text{-}PM}$ and $ET_{o\text{-}HS}$ comparison, whereas the lowest RMSE value was also obtained from the same monthly comparison (0.08). $ET_{o\text{-}Turc}$ method yielded a monthly average comparison of 0.981 for the R^2 values comparison. While $ET_{o\text{-}CAP}$ put forth the lowest values for all three intervals. It is suggested that HS method can be used instead of Standart Penman-Monteith method (FAO-PM) under GAP region semi arid climate conditions for reference ET_o estimation if Penman-Monteith can not be calculated. The Turc method is also can be a good alternative to estimate potential evapotranspiration that can be measured by Class A pan. And that ET_o estimation should be made by determining the K_p value in case CAP based ET_o estimation is carried out.
Keywords: *reference ET_o, FAO-PM equation, Hargreaves-Samani equation, Turc equation, pistachio*

Introduction

Evapotranspiration is the most important component of the hydrologic cycle and occurs with the mutual impact of evaporation and transpiration from the soil and the leaf. In this regard, it is the most important parameter for water source planning, water budget methods and irrigation software used in crop water consumption calculations. Continuity and high yield in agricultural production is possible only by the accurate and timely completion of losses due to evaporation and transpiration. For this purpose, ET_o should be estimated accurately since it plays a critical role in the accurate estimation of water losses from the soil and the leaf, carrying out the plans accordingly as well as the planning of irrigation systems (Trajkovic, 2008; Çobaner et al., 2016). Evapotranspiration is generally estimated in two stages. It can be determined by estimating the evaporation gap of the air around the plant subject to certain climate parameters as well as by calculating the water consumption of the grass covering the soil surface completely which is used in estimating plant water consumption (ET_c) and multiplying it by a certain coefficient specific to the crop. It is known that there are over 50 methods or models for the estimation of potential evapotranspiration subject to the data sets used (temperature, radiation, Class A Pan, mass transfer etc.), ecological conditions (arid or humid) and assumptions (Lu et al., 2005). Many researchers have tested the compliance of these methods under certain ecological conditions while also carrying out studies for putting forth the performances of difference methods under different climate conditions (Castaneda and Rao, 2005; Tabari et al., 2013).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1023910251

Empirical equations based on energy and mass transfer in compliance with different climate and environmental conditions have been developed for estimating ET_o. For this purpose, Allen et al. (1998) developed the FAO-56 Penman-Monteith method (PMF-56) which is the standard method that is widely used all over the world under different climate and agricultural conditions for ensuring that ET_o estimation is more understandable as well as for ensuring that the information provided is used commonly and frequently (Fisher and Pringle, 2013). This method is widely used for determining reference ET_o (Çobaner et al., 2016). However, there are difficulties related with the use of this model for estimating ETo due to its complexity. Daily data for many meteorological parameters such as temperature, relative humidity, solar radiation, evaporation, wind speed are required for using this model. It is not always possible to obtain this data set in full due to both technological and human based reasons and due to the fact that it is partially costly. On the other hand, calculation of water consumption on has become difficult in Turkey with a surface area of 783.562 km^2 since there are 275 meteorological stations with one station per each 275 km^2 (Çobaner et al., 2016). Therefore, researchers have developed easy to use reference ET_o methods which can be an alternative method for regions where it is not possible to provide the data set in full. Reference ET_o should be calculated using methods that require less climate data in cases when sufficient climate data are not available. For this purpose, Todoroviç et al. (2013) suggests the use of the best known Hargreveas-Samani equation and the "Penman Monteith Temperature Method" (PMT) in which the data required for calculation is calculated from the already existing climate data. Hargreavas and Samani (1985) developed an equation that can calculate the reference evapotranspiration value making use of only temperature and radiation data. Similarly, the Turc formula (1961) that uses only radiation, temperature and relative humidity values for determining reference ET_o was first developed for the regions of Southern France and Northern Africa (Diouf et al., 2016). The fact that the data used can be acquired easily is evaluated as the superiority of this formula for cases when the parameters required by other methods cannot be obtained. In addition, new methods developed which require a smaller data set have been used by many different researchers under different climate conditions for determining their performances in humid (Lu et al., 2005; Fisher and Pringle, 2013; Tabari et al., 2013) and arid regions (Todorovic et al., 2013) and for making a comparison with the FAO-56 PM method (Trajkovic, 2008; Gavilan et al., 2006; Castaneda and Rao, 2005; Shahidian et al., 2012). Since the Turc method is an empirical equation developed for estimating reference ET_o in humid regions, it uses only temperature and solar radiation as the data set. The radiation term used in this method is solved by the method provided in the Hargreaves-Samani equation. In addition to these methods, methods based on Class A Pan evaporation method as an alternative for many regions in the world where meteorological data cannot be obtained in full are used widely due to their ease of use, low cost and ease of application in irrigation software (Tabari et al., 2013). Different researchers (Kanber et al., 1992; Bilgel et al., 1999; Aydın, 2004) have carried out a limited number of studies on the determination of crop water consumption (ET_c) for pistachio. In these studies, ET_o-PM method has been used as the standard method for determining reference ET_o. The Food and Agriculture Organization (FAO) declared in 1990 together with the International Irrigation and Drainage Commission and World Meteorological Organization (WMO) that the FAO-PM (Allen et al., 1998) method can be taken as a reference since it yields more consistent and reliable results in comparison with other methods (Castaneda and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1023910251

Rao, 2005; Çobaner et al., 2016). Hence, FAO-56-PM method was taken as the standard in this study with which the other methods were compared. Hargreaveas-Samani and Turc equations can be used frequently for crop water consumption calculations since they are easy to use, require less data and can be used only with temperature data. Therefore, some empirical methods used for determining reference crop water consumption and CAP evaporation method were evaluated comparatively in this study. The climate data used for this purpose in the study were acquired from the Provincial directorate of meteorology in Siirt. In this study, climate data and FAO-56 Penman Monteith values which are used as reference method were taken from the study carried out in Gaziantep in order to determine crop water consumption (ET_c) in pistachio by Aydın (2004). Gaziantep, one of the most important provinces for pistachio production was selected as the study area. Pistachio is produced in 56 provinces in Turkey (Anonymous, 2001) with the highest amount of production in Gaziantep and Şanlıurfa. Gaziantep is ranked first in Turkey with regard to its pistachio production area and product amount (Aslan, 2017) which is an important economical input for the economy of the province. In the aforementioned study, reference (ET_o) were determined according to FAO-56 Penman Monteith method and ET_c was calculated according to water budget technique. From this point of view, crop coefficients (K_c) were determined for the phenological stages of pistachio. The maximum and minimum values of K_c for the suggested treatment in July and November were calculated as 1.51 and 0.39, respectively. These values range from 0.49 to 1.1 for the Southeast 1st Region (Gaziantep, Şanlıurfa and Diyarbakır) (Anonymous, 2017). However, since it is not always possible to determine the ET_o by the Penman-Monteith method, it is possible to eliminate this deficiency with the Hargreaves-Samani model and to estimate ET_c using the determined K_c coefficients. On the other hand, no studies were conducted to determine pan coefficient (K_p) for Gaziantep and Southeastern Anatolia region. Similarly, Since a new issue in Southeastern Anatolia Region, there is no study about determination of K_p in pistachio. On the other hand, the K_p coefficients, which changed periodically for Pistachio in California conditions, were proposed as 0.96 in June and August (Anonymous, 2019). Therefore, K_p coefficient was accepted as 1 in this study.

The purpose of the present study was to carry out reference ET_o estimation in pistachio production regions, carry out reference ET_o estimations via FAO-PM, Hargreaves-Samani and Turc equations in addition to Class A Pan (CAP) method, evaluate the usability of these methods for alternative reference crop water consumption (ET_o) estimation in the GAP region and the put forth the relations between these methods. In addition, this study aims to contribute to the studies on determination of crop coefficient (K_c), evaporation pan coefficient (K_p) or crop-pan coefficient ($K_{cp\text{-}dual}$) in Southeast Anatolia region where pistachio is grown widely.

Materials and methods

Description of study area and weather data

The city of Gaziantep is located in the Southeast Anatolia Region (*Fig. 1*) between 36° 28’ and 38° 0’ eastern longitudes and 36° 38’ and 37° 32’ northern latitudes in WGS84 system and according to ED-50, 3° Central Meridian (CM): 36 coordinate system was shown in *Table 1*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1023910251

Figure1. *Locational view of the study area*

Table 1. *The place of Gaziantep in ED-50, 3° CM: 36 coordinate system*

Points	X	Y

4	541765.9807594	4056095.7171703

Gaziantep has a climate structure with transition characteristics between the Mediterranean and the continental climate. Summers are quite hot and arid, while winters are cold and rainy. Mean annual temperature is + 14.9 °C, with the highest temperature of + 44 °C and lowest temperature of -17.5 °C. The hottest month is July with 27.7, while the coldest month is January with 3.4 and the annual rainfall for the province is 544.3 mm. Rains generally occur during the winter period with less rain during the summer months when evapotranspiration is high and the crops need plenty of water (Aydın, 2004). Thus, irrigation operation and management stands out for pistachio production.

ET_o estimation methods

FAO-56 PM method was used in this study for comparing the reference ET_o estimations obtained via Hargreaveas-Samani and Turc equations. For this purpose, the daily $ET_{o\text{-}PM}$ values were used which have been calculated in the study on pistachio by Aydın (2004) and Ünlü (2005). The climate data of Gaziantep, located in Southeastern Anatolia Region which is known as the most important pistachio producing region of Turkey were used in the aforementioned study. Climate data for the same province were used in Hargreaveas-Samani and Turc equations used for estimating reference ET_o.

FAO-56 Penman Monteith method

The FAO-56 Penman Monteith method used for determining reference crop water consumption requires only daily meteorological data. This equation can be written as indicated below (Allen et al., 1998).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1023910251

$$ET_o = \frac{0.408*(R_n-G)+\gamma\frac{900}{T+273}\,u_2(e_s-e_a)}{\Delta+\gamma\ 1+0.34u_2} \quad \text{(Eq.1)}$$

where ET_o: reference evapotranspiration (mm day^{-1}); R_n: net radiation (MJ m^{-2}), G: soil heat flux ($MJ.m^{-2}$); T_{mean}: average air temperature (°C); U_2: wind speed at 2 m height ($m.sn^{-1}$), e_s: saturation vapor pressure (kPa), Δ: slope of vapor pressure curve ($kPa.°C^{-1}$), γ: psycrometric constant ($kPa.°C^{-1}$)

The ET_o software developed by FAO-56 was used for determining reference ET_o. All parameters used in this software are data measured daily and acquired from the meteorological station.

Hargreaves-Samani method

The Hargreaves-Samani equation used for determining reference crop water consumption which requires only the maximum and minimum (T_{max}-T_{min}) temperature values and extraterrestrial radiation (global radiation) (R_a) can be indicated as below (Hargreaves and Samani, 1985).

$$ET_{O-HS} = 0.0023\frac{R_a}{\lambda}\sqrt{(T_{max}-T_{min})}(T+17.8) \quad \text{(Eq.2)}$$

ET_o: Reference evapotranspiration (mm day^{-1}), 0.0023: an empirical coefficient, R_a: extraterrestrial radiation (mm day^{-1}), λ: the latent heat of vaporization (MJ kg^{-1}) for the mean air temperature (T_{mean} in °C) given as:

$$\lambda = 2.501 - 0.002361 * T_{mean} \quad \text{(Eq.3)}$$

λ is generally assumed 2.45 $MJ.kg^{-1}$

Since the temperature, humidity and radiation values used in the equation can be accessed easily, it has been used by many researchers for determining the reference crop water consumption (Todorovic et al., 2013; Fisher and Pringle., 2013; Djaman et al., 2015; Çobaner et al., 2016; Diouf et al., 2016; Yamaç, 2018). The R_a value used for calculating $ET_{o\text{-}HS}$ was calculated using the following equation suggested by Fisher and Pringle (2013) for the Turc method which is solved subject to temperature and by making use of the solar radiation data obtained from the meteorology.

$$R_s = 0.16(T_{max}-T_{min})^{0.5}\,R_a \quad \text{(Eq.4)}$$

R_s is the solar radiation (MJ m^{-2} day^{-1}).

Turc method

The Turc formula derived by Turc (1961) which is used for calculating the daily potential evapotranspiration can be written as below:

$$ET_{o-Turc} = a * C * (R_G + b)\frac{T}{r+15} \quad \text{(Eq.5)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1023910251

where ET_o: reference evapotranspiration (mm day^{-1}), T: mean daily temperature (°C), R_G: Global radiation (MJ m^{-2} day^{-1}), a and b: empirical constants and a = 0.31 (m^2 MJ^{-1} mm^{-1}) and b = 2.094 (MJ m^{-2} day^{-1}), C: defined by the relative humidity RH, (%) as:

$$C = 1 + \frac{50 - RH}{70} \quad if\ RH < 50\% \qquad \text{(Eq.6)}$$

$$C = 1 \quad if\ RH \geq 50\% \qquad \text{(Eq.7)}$$

Similarly, relative humidity and temperature values were obtained from meteorological records of Provincial Directorate of Meteorology in Siirt. The C value in the $ET_{o\text{-}Turc}$ equation used for calculating daily potential evapotranspiration was calculated using the aforementioned equations based on the average relative humidity ratio.

Pan evaporation method ($ET_{o\text{-}CAP}$)

The following equation suggested by Allen et al. (1998) was used for calculating reference crop water consumption (ET_o) according to the Class A Pan evaporation method.

$$ET_o = K_p * E_{pan} \qquad \text{(Eq.8)}$$

where ET_o: Reference evapotranspiration, mm day^{-1}; K_p: pan coefficient (assumed 1 as average value in this study). E_{pan}: pan evaporation, mm day^{-1}. However, the K_p value was not calculated separately in this comparison and was assumed theoretically as 1 and therefore the measured E_{pan} value was assumed to be equivalent to ET_o.

Statistical analysis

The ET_o values calculated daily according to the FAO-PM method were compared statistically with the daily ET_o values. Paired comparisons were made for determining the value of R^2 which were then subject to linear regression analysis and the R^2 equation was determined for the obtained curve. The equalities suggested by Djaman (2015) which are provided in *Table 2* were used for a more advanced evaluation of the compared equations.

Results and discussion

The climate data for 1999-2002 obtained from the meteorological records were used in the study. For this purpose, the maximum and minimum temperatures used in the Hargreaveas-Samani and Turc equations along with the relative humidity and radiation values used in the Turc equation were evaluated separately for each year and than converted to monthly average (*Fig. 2a*).

The solar radiation values measured in cal cm^{-2} day^{-1} at the meteorology stations were converted into the unit of MJ m^{-2} day^{-1} after which they were used for solving the equation. The radiation values for the study years are provided in *Figure 2b* as monthly average annually. As can be seen when the figures are examined, while solar radiation values were low in the beginning of the year (January-February) and in the last two months (November-December) of the year, the number of sunny days and sunshine

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1023910251

duration along with the amount of reflected radiation increased parallel to the increase in seasonal temperatures. Cloudy weather that sometimes occurred during measurement days appears as sudden decreases in radiation.

Table 2. *Statistical analysis equations*

Source	Equation	
Root mean squared error (RMSE	$RMSE = \sqrt{\sum_{k=0}^{n} \frac{(P_i - O_i)^2}{n}}$	(Eq.9)
Mean absolute error (MAE)	MAE = n-1$\sum_{1}^{n}(P_i - O_i)$	(Eq.10)
Percentage error (PE)	PE = $\left\lvert \frac{P_{ave} - O_{ave}}{O_{ave}} \right\rvert 100\%$	(Eq.11)
Mean ratio (MR)	MR = n-1$\sum_{1}^{n} \frac{P_i}{O_i}$	(Eq.12)
Determination coefficient (R2) (Todorovic et al., 2013)	$R^2 = \left\{ \frac{\sum_{i=1}^{n}(O_i - \bar{O}).(P_i - \bar{P})}{\sqrt{\sum_{i=1}^{n}(O_i - \bar{O})^2}.\sqrt{\sum_{i=1}^{n}(P_i - \bar{P})^2}} \right\}^2$	(Eq.13)

RMSE: root mean squared error; MAE: mean absolute error; MR: mean ratio; PE: percentage error of estimate; n: number of observations, P_i: estimated ET_o by other equations, O_i: PM-estimated ET_o (actual), P_{ave}: mean of the estimated ET_o, O_{ave}: mean of the O_i. In order to determine R^2, the pair wise comparisons were made by using linear regression

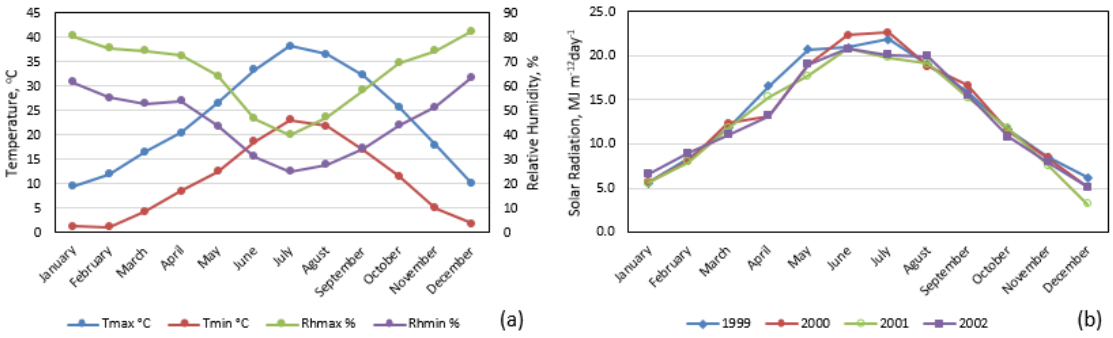

Figure 2. *Variation of long-term monthly average temperature and relative humidity (a) and solar radiation during study years (b)*

The 4 year mean values were calculated for the reference crop water consumption (ET_o) daily values obtained via the Hargreaveas-Samani ($ET_{o\text{-}HS}$), Turc ($ET_{o\text{-}TURC}$) and Pan evaporation methods ($ET_{o\text{-}CAP}$) compared in the study thereby obtaining long term average and annually total ET_o values which are presented in *Figure 3a* and *b*. As shown in *Figure 3a,* in the months which Class A Pan evaporation values measured were taken into consideration to compare the predicted plant water consumption values estimated by the models with the measured values. The period mentioned is the period in which pistachio is phenologically active and in this term, full bloom period is completed and begins the leafout period. The comparison of estimated and measured evaporation values was made until the end of October, which is the post-harvest period.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1023910251

Likewise, as shown in *Figure 3b,* the monthly totals of the estimated and measured ET_o values were calculated for the mentioned period.

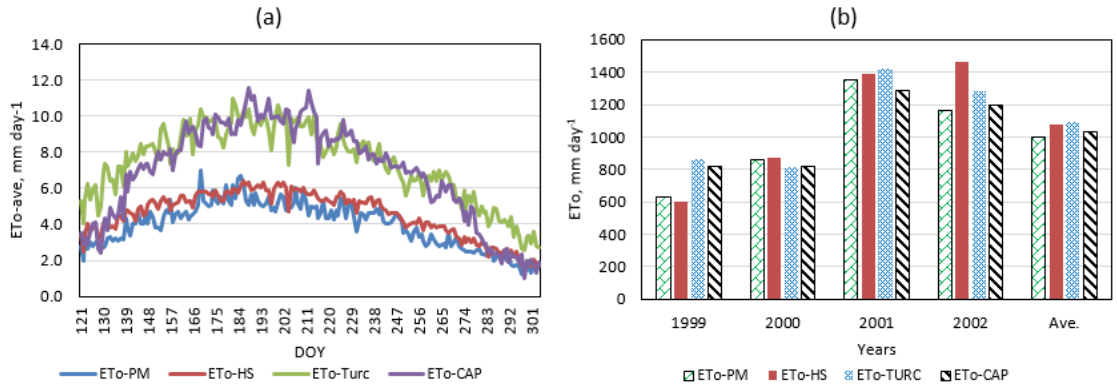

Figure 3. *Comparison of 4-year mean daily and total seasonally ET_o calculated from 4 methods during study years for evaporation season*

Average daily ET_o changing during study years. Similarly, The long term monthly mean values were calculated by taking the monthly mean ET_o values for the same years which are given in *Figure 4*. As can be seen in *Figure 4*, $ET_{o\text{-}PM}$ and $ET_{o\text{-}HS}$ values were determined to be close to each other, however the $ET_{o\text{-}Turc}$ and $ET_{o\text{-}Pan}$ values were observed to be greater than the $ET_{o\text{-}PM}$ and $ET_{o\text{-}HS}$ they were compared with. Long term mean monthly mean comparisons have yielded similar results as can be seen in *Figure 4.* Evaporation measurements are not carried out during the winter months (from November till April) in the study region, however other climate parameters are measured daily. Hence, it is not possible to calculate the $ET_{o\text{-}CAP}$ values for the aforementioned months. Çobaner et al. (2016) carried out a study for determining the best Hargreavas-Samani equation for the Mediterranean region as a result of which they put forth that the Hargreavas-Samani equation calibrated according to the temperature and humidity values put forth similar results with those calculated via Penman-Monteith. These findings of the researchers are in accordance with the results of the present study. Small differences in our results are due to the fact that the HS equation has not been calibrated for the GAP region and that it is used directly. Similarly, Trajkovic (2005) states that the Hargreaveas-Samani equation predicts ET_o higher than the actual value. The average values calculated via $ET_{o\text{-}CAP}$ and $ET_{o\text{-}Turc}$ methods showed a parallel change, similar to the change of radiation by temperature, as shown in *Figure 3a.* The $ET_{o\text{-}CAP}$ values increased rapidly during summer months when evaporation is measured.

Diouf et al. (2016) carried out a study for determining reference ET_o via Turc equation due to limited climate data under Senegal conditions as a result of which it was reported that the annual ET_o values were higher for the humid seasons according to the FAO-PM method. The researchers indicated that ET_o is mostly due to radiation and temperature under conditions of high humidity and that humidity does not have any impact on ET_o under any circumstance.

Fisher and Pringle (2013) carried out a study under humid regional conditions for comparing the Hargreavas–Samani and Turc methods with the FAO-56 model operated with reduced data as a result of which it was indicated that the FAO-56 reduced dataset

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1023910251

model yielded better results in comparison with the other two methods. The Turc equation developed for using the measured temperature and radiation value was tested with the equation using estimated radiation values and it was put forth that FAO-56 provides better estimations in comparison with the other methods.

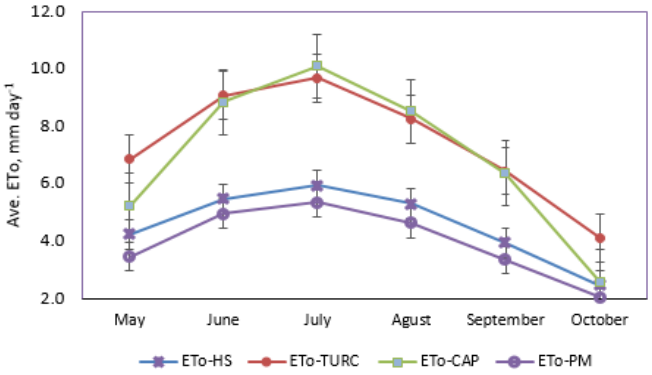

Figure. 4. *Comparison of 4-year mean monthly ET_o calculated from 4 methods during study years.*

Paired comparisons at the daily, 10 days and monthly average value levels were carried out for the reference crop water consumption values calculated in accordance with the methods used and the acquired results are presented graphically in *Figures 5–7*. As can be seen from *Figure 5,* the onset of the curve is at low levels during the first months when evaporation measured is not made in winter months while comparing $ET_{o\text{-}PM}$ and $ET_{o\text{-}CAP}$ values.

The methods used for reference ET_o were compared statistically and the acquired results have been summarized in *Table 3*.

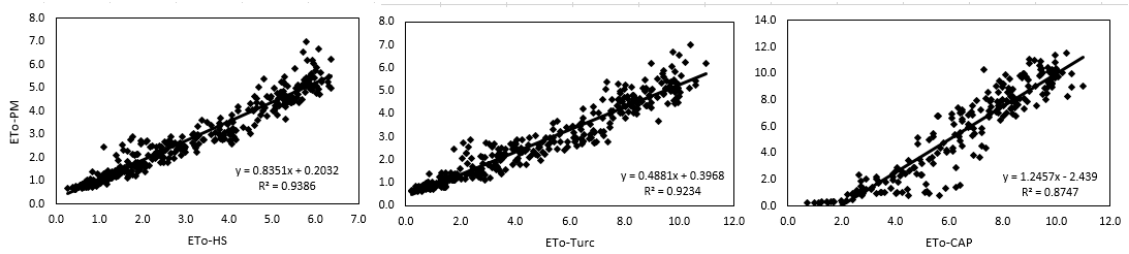

Figure 5. *Comparison of daily average ET_o for (1999-2002)*

DOI: http://dx.doi.org/10.15666/aeer/1704_1023910251

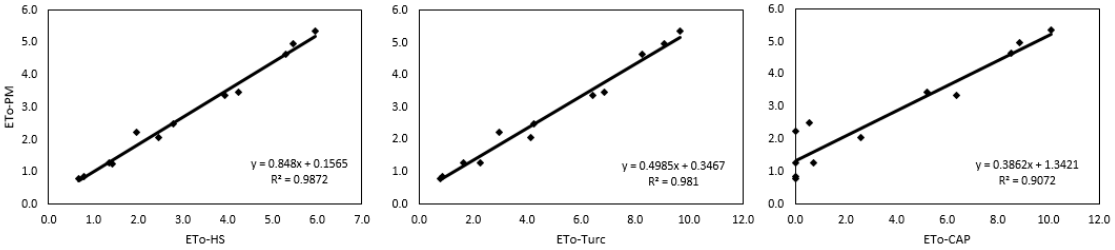

Figure 7. *Comparison of monthly average ET_o for (1999-2002)*

Table 3. *Error values of average daily ET_o estimates on daily basis as compared to FAO-PM method*

	Daily			10 days interval			Monthly		
	HS-PM	**Turc-PM**	**CAP-PM**	**HS-PM**	**Turc-PM**	**CAP-PM**	**HS-PM**	**Turc-PM**	**CAP-PM**
RMSE (mm/day)	0.58	2.65	2.62	0.15	0.82	0.81	0.08	0.47	0.46
MAE (mm)	0.45	2.11	2.14	0.04	0.21	0.21	0.01	0.07	0.07
MR	1.08	1.63	0.92	0.11	0.16	0.09	0.04	0.05	0.03
PE (%)	10.84	75.09	31.96	10.73	74.80	31.51	11.15	75.07	31.39
R^2	0.9386	0.9234	0.8747	0.9784	0.9686	0.947	0.9872	0.981	0.9072

Quantitative methods were applied for carrying out a statistical evaluation of the equations used in ET_o estimation. It is considered that the R^2 value approaching 1 and RMSE, MAE, MR and PE values approaching zero (0) from among the parameters given in *Table 3* which are used as criteria for comparing the methods indicate good performance and a high level of accordance between the compared values (Fisher and Pringle, 2013; Kaya et al., 2016).

The R^2 values of the studied methods were determined to be close but different in daily, weekly and monthly performance comparisons. It was determined as a result of the comparison made between reference crop water consumption methods for each of the three period intervals that the highest R^2 value was obtained as 0.9872 for $ET_{o\text{-}HS}$ and $ET_{o\text{-}PM}$ at the monthly level, while the lowest R^2 value was determined as 0.9386 for the comparison made at the daily level. The lowest R^2 value was also obtained as 0.8747 for the $ET_{o\text{-}PM}$-$ET_{o\text{-}CAP}$ method as a result of the comparison made for all three periods. Castaneda and Rao, (2005) compared Thornthwaite, Blaney Criddle, Turc and Makkink methods. It was indicated that the Turc method had the best performance among the compared methods since the values obtained were closest to the estimated values of the $ET_{o\text{-}PM}$ method prior to recalibration. They also put forth that other ET_o estimation methods also yield results within acceptable limits close to FAO-PM values in case regional parameters are used and the parameters are calibrated for the region. It will not be misleading to use the HS and Turc methods used in this study for making ET_o estimations in the region. When the compared methods are evaluated according to the RMSE values, lowest RMSE value should be obtained as is the case for other error parameters. As can be seen from the table, while the $ET_{o\text{-}HS}$-$ET_{o\text{-}PM}$ pair had the lowest RMSE value for monthly averages with 0.08, highest RMSE value was obtained as 2.65 from the $ET_{o\text{-}Turc}$ and $ET_{o\text{-}PM}$ paired comparison. Todorovic et al. (2013) carried out a comparison between HS and PMT models for reference ET_o estimation in the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_1023910251

Mediterranean climate region with limited data as a result of which similar HS and PMT values were obtained for the excessively arid and arid regions with those of MSE. While PMT yielded a lower RMSE value in semi-arid and humid regions as a result of which it was indicated to have a better performance in comparison with HS. It was observed as a result of the percentage error (PE) evaluations that the lowest percentage error was obtained as 10.73 for the 10 day interval comparison, while the highest percentage error was obtained as 75.09 for the $ET_{o\text{-}Turc}$ and $ET_{o\text{-}PM}$ comparison. Djaman et al. (2015) states that calibrated models display a better performance at cold and hot humid regions thereby leading to monthly values at an acceptable level, while the same performance has not been obtained for the semi-arid and tropical humid regions. Since the models are developed for use in the regional climate conditions for which they have been developed, they yield acceptable results only in similar climate conditions.

It was observed as a result of the statistical comparison between the studied methods that the highest R^2 value and the lowest percentage error value were obtained for the $ET_{o\text{-}HS}$-$ET_{o\text{-}PM}$ paired comparison in monthly average ET_o calculation. The results are observed to be in accordance with those of Çobaner et al. (2016) and Todorovic et al. (2013).

Conclusion

It was determined as a result of the study that the Hargreaveas-Samani model can be used for reference crop water consumption estimation in regions for Penman-Monteith model which full climate data cannot be obtained due to various reasons since these methods can be operated only with limited climate data and maximum temperature, minimum temperature, mean relative humidity and solar radiation inputs. Likewise the Turc model can also be a good alternative to estimate potential evapotranspiration which can be measured by Class A Pan. Moreover, the Penman-Monteith Temperature based (PMT) method used for ET_o estimation only with temperature data can also be used as an alternative for semi-arid climate conditions such as the GAP region.

(Received 8th Dec 2018; accepted 10th Apr 2019)

Abstract. The aim of this study is to compare environmental management of waste between consumers of the former Yugoslavian republics. The starting points are H1: there are differences in environmental management of waste between consumers from the former Yugoslavian republics and H2: there are demographic differences in consumers' environmental management of waste between consumers from the former Yugoslavian republics. The survey was conducted on a sample of 1550 respondents from all the former Yugoslavian republics. The obtained results show that there are differences between consumers from Macedonia and all other former Yugoslavian republics as well as between Montenegro and Serbia, Croatia and Slovenia. Also, differences were noticed between consumers' environmental management of various types of waste. At the same time, results indicate that there are no differences in gender but differences in age, degree of education and monthly income by households exist related to environmental management of waste between consumers from former Yugoslavian republics. Through adequate implementation of obtained results, consumers' environmental management of waste may become a powerful tool of environmental protection, because it would contribute to the increase of environmentally responsible behavior of consumers in the region of former Yugoslavian republics as well as on a global basis.
Keywords: *consumers, waste disposal, ecological, former Yugoslavian republics, cross-cultural*

Introduction

Present level of consumer waste management is worrying level. This is indicated, among others, by facts related to plastic and electronic waste:

- 90% of waste floating in the oceans is plastic waste (http1://www.theworldcounts.com/stories/Plastic-Waste-Facts=).
- In the North Pacific Ocean there is 6 times more plastic waste than plankton, causing the death of the living world in the ocean (http1://www.theworldcounts.com/stories/Plastic-Waste-Facts=).
- Plastics are made from toxic materials such as benzene and vinyl hydrochloride, and these chemicals are known to cause cancer (http1://www.theworldcounts.com/stories/Plastic-Waste-Facts=).
- We generate about 40 million tons of electronic waste worldwide every year (http1://www.theworldcounts.com/stories/Plastic-Waste-Facts=).
- E-waste contains hundreds of substances, many of which are toxic. This includes mercury, lead, arsenic, cadmium, selenium, and chromium (http2://www.theworldcounts.com/stories/Electronic-Waste-Facts).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72297248

- 70% of total toxic waste is e-waste (http2://www.theworldcounts.com/stories/Electronic-Waste-Facts).

This suggests that the adequate waste management by consumers, in a way that would not degrade the environment, is a necessity and a global problem today.

Disposal of waste in an ecological way implies the disposal of products that have expired or are defective and the disposal of product packaging after consuming the products at designated locations, in adequate containers and warehouses, and in an adequate manner.

Since consumers' environmental management of waste is a global problem, cross-cultural studies of consumers' habits regarding management of waste are excellent tools to provide information on the consumers' environmental management of waste and the way in which it may be improved at the regional level.

However, there are not enough cross-cultural studies on the topic of consumers' environmental management of waste, but only those comparing consumers from two countries: French – USA (United States of America) (Arbuthnot and Lingg, 1975), Belgium – Poland (Roozen and Pelsmacker, 2000), Switzerland – India (Sinha-Khetriwala et al., 2005), Norway – USA (Kipperberg, 2007) and USA – China (Xu et al., 2014).

Therefore the authors have concluded that there is no relevant cross-cultural research paper which analyses consumers' environmental management of waste between consumers from former Yugoslavian republics: the Republic of Serbia (Serbia), the Republic of Croatia (Croatia), the Republic of Slovenia (Slovenia), the Former Yugoslav Republic of Macedonia (FYR Macedonia), the Federation of Bosnia and Herzegovina (Bosnia and Herzegovina) and Republic of Montenegro (Montenegro).

There are two cross-cultural studies conducted on a sample of all six of the former Yugoslavian republics regarding environmentally responsible purchasing (Raletić Jotanović et al., 2016) and environmentally responsible consumption (Raletić Jotanović et al., 2017).

The aim of this study is to compare environmental management of waste between consumers from former Yugoslavian republics. The former Yugoslavian republics are selected for comparison because: a) they had 73 years of shared history which certainly influenced similarities in consumer behavior, and b) today all the former Yugoslavian republics are independent countries with different macro, structural, demographic, socio-economic, and other characteristics (State Statistical Office of Macedonia, 2018; Institute for Statistics of Serbia, 2018; Statistical Office of the Slovenia, 2018; Statistical Office of the Montenegro, 2018; Croatian Bureau of Statistics, 2018; Federal Office of Statistics of Bosnia and Herzegovina, 2018). According to the authors' knowledge this will be the first cross-cultural study of the former Yugoslavian republics regarding consumers' environmental management of waste.

Environmental management of waste between consumers from different countries

Consumers' environmental management of waste is different in different countries, according to the results of previous empirical comparative cross-cultural researches: (Arbuthnot and Lingg, 1975; Roozen and Pelsmacker, 2000; Sinha-Khetriwala et al., 2005; Kipperberg, 2007; Xu et al., 2014). Minimal differences were observed in consumers' environmental management of waste between in France and USA (Arbuthnot and Lingg, 1975). Belgian consumers manage their waste more environmentally than Polish ones (Roozen and Pelsmacker, 2000). The consumers from

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72297248

the Switzerland manage their e-waste (computers, television sets, microwave ovens, etc.) more environmentally than consumers from India (Sinha-Khetriwala et al., 2005). Environmental management of waste sometimes is better with consumers from Norway and sometimes with consumers from the USA, depending on the type of waste (Kipperberg, 2007). The consumers from the USA are more prone to dispose clothing and footwear at environmental way (using and buying second-hand clothing and footwear) than consumers from China (Xu et al., 2014). All these differences may be explained by differences in level of consciousness, knowledge and attitude towards environment in consumers from different countries (Arbuthnot and Lingg, 1975; Roozen and Pelsmacker, 2000; Sinha-Khetriwala et al., 2005; Kipperberg, 2007; Xu et al., 2014)

According to the results of previous studies, numerous macro factors have affected environmentally responsible consumer choice which also includes consumers' environmental management of waste (Dolan, 2002; Schaefer and Crane, 2005; Thøgersen, 2005; Assadourian, 2010; Marx et al., 2010). In other words, macro factors may be the basis for differences in environmental management of waste between consumers from various countries. Factors that could affect these differences between the former Yugoslavian countries are shown in *Table 1*.

Table 1. *Macro factors of former Yugoslavian countries. (Sources: WEF, 2018 pp. 499, 519, 363, 109, 403, 179; WEF, 2016 pp. 122, 156, 244, 266, 314, 322; WEF, 2014 p. 68)*

Factors \ Country	Serbia	Slovenia	Macedonia	Bosnia and Herzegovina	Montenegro	Croatia
GDP per capita (US$)	5,899.0[1]	20,732.5[2]	5,474.4[3]	5,149.0[4]	7,647.0[5]	13,138.3[6]
Environmental footprint	2.9[1]	4.7[2]	3.1[3]	3.3[4]	3.4[5]	3.6[6]
Quality of education	3.55[7]	4.6[8]	3.85[9]	3.15[10]	3.92[11]	3.7[12]
Sophistication of business	3.00[7]	4.03[8]	3.6[9]	3.23[10]	3.46[11]	3.53[12]
Environmental sustainability[13]	3.86 →	4.78 ↗	3.66 ↘		4.38 →	4.21 →

The World Economic Forum does not publish each year all the parameters for ranking countries listed *Table 1*, so, for example, environmental sustainability as a factor was last measured and published in the Global Competitive Report for 2014-2015.

Table 1 is obviously missing values for environmental sustainability for Bosnia and Herzegovina. Also, data in *Table 1* show that Slovenia had the highest values for all factors. Serbia had the lowest values for environmental footprint and sophisticated business, Bosnia and Herzegovina had the lowest values of GDP (gross domestic product) per capita and quality of education, while Macedonia had the lowest value of environmental sustainability.

Considering the results of earlier cross-cultural researches (Arbuthnot and Lingg, 1975; Roozen and Pelsmacker, 2000; Sinha-Khetriwala etal., 2005; Kipperberg, 2007;

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72297248

Xu et al., 2014) and macro and structural factors of former Yugoslavian republics shown in the *Table 1*, it can be assumed that:

H1: There are differences in consumers' environmental management of waste for different former Yugoslavian republics.

Relationships between consumers' environmental management of waste and demographic characteristics of consumers: gender, age, professional qualifications and monthly income by household, were analyzed in numerous studies conducted in different countries (Samdahland Robertson, 1989; Granzin and Olsen, 1991; Shamdasaniet al., 1993; Chan, 2001; Gilg et al., 2005; Jain and Kaur, 2006; Tilikidou and Delistavrou, 2008; Abeliotis et al., 2010; De Paço and Raposo, 2010; Pedrini and Ferri, 2014; Pinto et al., 2014; Pagiaslis and Krontalis, 2014; Aschemann-Witzel et al., 2017; Paço andLavrador, 2017; Pérez-Belis et al., 2017; Zhanget al., 2018; Scherer et al., 2018; Savchenkoet al., 2019; Talia et al., 2019). These relationships are shown in the *Table 2a-d*.

Germany	Pagiaslis and Krontalis, 2014; Pinto et al., 2014		Scherer et al., 2018
Denmark	Aschemann-Witzel et al., 2017		

Given the results of previously conducted research from *Table 2*, the basic assumption is that:

H2: There are differences in demographic characteristics of consumers related to consumers' environmental management of waste from different former Yugoslavian republics.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72297248

Materials and methods

Sample

The study included 1,550 respondents from six former Yugoslavian republics: 17.81% (276) participants from Serbia, 16.13% (250) participants from Croatia, 17.10% (265) participants from Bosnia and Herzegovina, 16.13% (250) participants from Montenegro, 16.32% (253) participants from Macedonia and 16.51% (256) participants from Slovenia (*Table 3*).

Table 3. *Sample composition. (Source: authors' data)*

Demographic characteristics in %		Serbia	Slovenia	Macedonia	Bosnia and Herzegovina	Montenegro	Croatia	Total %
Gender	Male	41.30	27.34	36.76	41.89	43.6	31.2	**37.01**

	MSc/PhD	18.12	21.88	27.67	18.11	15.20	12.8	**19.61**
Monthly income by household	Below average	25.36	19.53	11.07	7.92	22.8	16.8	**33.68**
	Average	40.22	47.27	57.70	72.83	47.00	69.6	**48.90**
	Above average	34.06	32.81	31.23	19.25	30.2	13.6	**17.30**
Total		**276**	**256**	**253**	**265**	**250**	**250**	
%		**17.81**	**16.51**	**16.32**	**17.10**	**16.13**	**16.13**	**100**

When analyzing sample structure regarding the gender, that there is twice as much women than men (62.90% and 37.01%, respectively) (*Table 3*).

When considering the age structure of the sample, respondents between 18 and years of age make up the majority of the sample, i.e., 50.76% of the sample, while respondents between 71 and 80 are the least represented in the sample with <1% (*Table 3*). The second biggest category in the sample, according to age, is composed of respondents aged 31 to 40 with 25.23% of the sample, followed by respondents aged 41 to 50 years with 12.52% of the sample, then respondents between the age of 51 and 60 which make up 7.68% of the sample, while subjects between 61 and 70 years make up 2.65% of the sample. Seven of the respondents did not answer the question about their age (*Table 3*).

When considering the structure of the sample according to the professional qualification, the same number of respondents (39.81%) has graduated from a university and has completed high school. These categories make up the majority of respondents

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72297248

in the sample. Respondents with completed master studies, magisterium or doctorate make 19.16% of the sample. Less than 1% of the sample has completed elementary school only. Four respondents did not provide information on the qualifications (*Table 3*).

Finally, through the analysis of *Table 3*, it can be noted that most of the sample consists of respondents who live in the household with average monthly income, 48.90% of them. Respondents living in households below average monthly income make up 33.68% of the sample (*Table 3*). The lowest percentage of respondents, 17.30%, lives in households with monthly income above the average (*Table 3*). Two respondents did not answer the question about the monthly income of their households (*Table 3*).

The sampling method was the stratified sample. The total population from the territory of the former Yugoslavian republics is divided into strata, which are now independent countries: Serbia, Croatia, Bosnia and Herzegovina, Montenegro, Macedonia, and Slovenia. After that, simple random sample method was used for each stratum.

The total population from the territory of the former Yugoslavian republics is about 20 million people while the size of the sample analyzed is 1,550 respondents. The sample size is small but acceptable, having in mind that this sample mostly reflects demographic structure of the analyzed population (in all ex-Yugoslavian republics women are more numerous than men, most of population has graduated from a high school and then those with an university degree are following, most people live in household with average monthly income) (State Statistical Office of Macedonia, 2018; Institute for Statistics of Serbia, 2018; Statistical Office of the Slovenia, 2018; Statistical Office of the Montenegro, 2018; Croatian Bureau of Statistics, 2018; Federal Office of Statistics of Bosnia and Herzegovina, 2018). The sample size is small but acceptable regarding the nature of investigation, changes of population characteristics, changes of investigation object.

Instrument

For the purposes of this study, and following the example of previously conducted research (Roozen and Pelsmacker, 2000; Gilg et al., 2005; Sinha-Khetriwala etal., 2005; Kipperberg, 2007; Xu et al., 2014) an instrument – the questionnaire – was composed to test the difference between consumers' environmental management of waste in different former Yugoslavian republics. The items in the questionnaire were adapted to the national and the international environment of the countries in which the research was conducted.

The questionnaire is composed of three parts (see *Appendix*). The first part of the questionnaire is the respondents' consent for filling the questionnaire. Completing the questionnaire was anonymous. The second part of the questionnaire is based on the demographic characteristics of the respondents: state, gender, age, education and monthly household income. State, gender, education and household monthly income inquiries are of a closed type, while the question of the age of the respondents is of open type. In order to maximally adjust the questionnaire to cross-cultural research, it was necessary to standardize the data relating to monthly household income, given the fact that this data is differently shown in Statistical Yearbooks for the year 2018 of analyzed countries. Data on household income is reduced to a monthly level per household, because such type of data was found in most of the Statistical Yearbooks analyzed from former Yugoslavian republics. Questions related to monthly household income were set

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72297248

in the currency of the country in which the questionnaire was distributed, for easier understanding and answering questions. The third part of the questionnaire refers to consumers' environmental management of waste (*Table 4*). It has 7 items and every item connected to different group of waste (products): 1) food, 2) chemicals and pharmacy products, 3) clothing and footwear, 4) furniture, 5) electrical appliances, 6) means of transport, and 7) products of paper and cardboard (*Table 5*). Answers to the questionnaire were measured by Likert scale: 1-strongly disagree, 2-mostly disagree, 3-undefined, 4-mostly agree, and 5- completely agree.

Table 4. *Descriptive statistics of items in the total sample. (Source: authors' data)*

	Items	**M**	**SD**
Consumers' environmental management of waste	When possible, I put my leftover food in compost	3.23	1.39
	I do not throw expired medication in waste	3.04	1.50
	I do not throw away old clothes but rather donate it	4.42	.91
	I would leave an old sofa by the garbage container	3.01	1.60
	I put old electric appliances in the garbage container	2.33	1.41
	Parts of unusable bicycle, car and/or engine I would place next to the garbage container	2.59	1.50
	I put old paper into a paper container	3.64	1.45

The questionnaires were translated into Slovenian, Macedonian, Croatian, and Serbian. Respondents from Serbia, Bosnia and Herzegovina, and Montenegro filled in questionnaires in Serbian considering that they can be classified in the same language area.

The questionnaire was distributed personally "paper and pencil" (PAPI – Paper and pencil interviewing) (Lavrakas, 2008) and through various Internet platforms (Google Drive, Facebook, email, etc.). It was given to the respondents by researchers, who had asked their colleagues, friends and family to fill the questionnaire and to send other

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72297248

copies to their friends and colleagues. Also, it was sent by the Internet to the e-mail addresses of various entities: private individuals, non-governmental organizations, higher education institutions, businesses, statistical bureaus of the countries, etc.

Variables

Independent variables in this study are: country, gender, age, professional qualification and monthly income by household, while the dependent variable is consumers' environmental management of waste.

Data analysis

For data processing, authors used the software package SPSS:16 (Norusis, 2008).

Preparing the data for the main analysis included the replacement of missing values by EM method and the treatment of extreme values that resulted in not showing even one outlier.

After preparing the data, exploratory factor analysis (EFA) was conducted. The results of EFA suggested that there is a relative satisfactory factor structure of the questionnaire. EFA was conducted for each country separately. Next, the obtained factor structure was confirmed by confirmatory factor analysis (CFA) in statistical packages "lavaan" and "semTools", written for the R environment.

One-way ANOVA with country as a factor (6 levels) and Tukey's HSD post hoc test were used as the methods for determining the differences in consumers' environmental management of waste between the former Yugoslavian republics. Also, two-way ANOVA and Tukey's HSD post hoc test were used to test the differences in demographic characteristics of respondents related to consumers' environmental management of waste between former Yugoslavian republics, with the following factors: country (6 levels) and gender (2 levels), country (6 levels) and age of respondents (6 levels), country (6 levels) and degree of education (4 levels), and country (6 levels) and monthly income by household (3 levels).

Results

Descriptive statistics

Descriptive statistics by arithmetic mean (M) and standard deviation (SD) of the questionnaire items regarding the consumers' environmental management of waste is shown in *Table 4*.

Table 5 shows descriptive statistics by arithmetic mean (M) and standard deviation (SD) of items regarding different groups of waste by products relative to former Yugoslavian republics.

Table 6 shows descriptive statistics for reliability of questionnaires by arithmetic mean (M) and standard deviation (SD). Results do not deviate significantly from the norm (the values of the skewness and kurtosis are within the allowed limits), despite the significant values of the K-S statistics (Kolmogorov-Smirnov test). Subscales reliability coefficients (α) for most of the individual countries are not proven to be quite adequate, since their values are lower than .70 (*Table 6*). The overall reliability coefficient for the sample is not entirely satisfactory since it is lower than the prescribed one. The reliability coefficient values could be explained by a small number of items for each subscale. The authors decided on a small number of items due to the nature of this cross-cultural study.

*p < .01

Differences in waste disposal among consumers from former Yugoslavian republics

The results of the one-factor variance analysis with country as an independent variable (6 levels) and the dependent variable of consumers' environmental management of waste show that there is a statistically significant difference between the respondents from different countries in terms of consumers' environmental management of waste, $F(5, 1544) = 14.91$, $p < .01$, $\eta^2_p = .05$. Post hoc tests (Tukey's HSD) showed that respondents from Macedonia (M = 20.22, SD = 5.42), dispose their waste in ecological way in the lowest degree in comparison to respondents from all other countries in the sample ($p < .01$). Also, it has been shown that respondents from Montenegro (M = 21.74, SD = 5.1) disposed less of the waste in an ecological manner compared to respondents from Serbia (M = 23.21, SD = 4.89, $p < .01$), Croatia (M = 23, SD = 5.27, $p < .01$), and Slovenia (M = 23.22, SD = 3.28, $p < .01$).

The results of the one-factor analysis of the variance with the country as a factor (6 levels) and the consumers' environmental management of food waste as a dependent variable indicate that there are significant differences between respondents from different countries, $F(5, 1544) = 48.02$, $p < .01$, $\eta^2_p = .14$. Post hoc tests show that respondents from Slovenia show a significantly higher level of ecological disposal of food waste, compared to respondents from all other countries ($p < .01$). Respondents from Macedonia are less prone to dispose of food waste in ecological manner in comparison to respondents from Bosnia and Herzegovina and Croatia ($p < .01$).

The results of the one-factor analysis of variance with the country as a factor (6 levels) and the consumers'' environmental management of medicament waste as a dependent variable indicate the existence of significant differences between respondents from different countries, $F (5, 1544) = 38.98$, $p < .01$, $\eta^2_p = .11$. Post hoc tests ($p < .01$ - .05) suggest that respondents from Slovenia apply more ecological disposal of medicament waste in comparison to respondents from all other countries, and that respondents from Macedonia and Montenegro are less prone to ecological disposal of medication waste in comparison to respondents from Serbia and Croatia ($p < .01$ - .05).

The results of the one-factor variance analysis with the country as a factor (6 levels) and the consumers' environmental disposal of clothing and footwear waste as a dependent variable show that there are significant differences between the respondents, $F (5, 1544) = 3.47$, $p < .01$, $\eta^2_p = .01$. Post hoc tests further show that respondents from Slovenia are ecologically disposing their clothing and footwear waste in a slightly higher degree, compared to respondents from Croatia and Montenegro ($p < .01$ - .05)

The results of the one-factor analysis of variance with the country as a factor (6 levels) and the consumers' environmental disposal of furniture waste as a dependent

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72297248

variable show significant differences between respondents, $F(5, 1544) = 29.47$, $p < .01$, $\eta^2_p = .09$. Post hoc tests ($p < .01$ - $.05$) further demonstrated that respondents from Slovenia and Macedonia dispose of waste from furniture in an environmentally friendly manner to the lowest degree when compared to respondents from all other countries. Also, it has been shown that respondents from Serbia are using this behavior to a greater extent in comparison to respondents from Croatia and Bosnia and Herzegovina.

The results of the one-factor analysis of variance with the country as a factor (6 levels) and the consumers' environmental management of electronic waste as a dependent variable show that there are significant differences between the respondents, $F (5, 1544) = 23.94$, $p < .01$, $\eta^2_p = .07$. Post hoc tests have shown ($p < .01$ - $.05$) that respondents from Slovenia are more prone to ecological disposing of electrical waste compared to respondents from all other countries.

The results of the one-factor analysis of variance with the country as a factor (6 levels) and the consumers' environmental management of waste from means of transport as a dependent variable indicate that there are significant differences between the respondents, $F (5, 1544) = 28.78$, $p < .01$, $\eta^2_p = .09$. Post hoc tests ($p < .01$ - $.05$) indicate that respondents from Slovenia, again, are most prone to ecologically dispose their means of transport waste, compared to respondents from all other countries. On the other hand, respondents from Serbia are more environmentally irresponsible when it comes to the disposal of waste from means of transport, in comparison to respondents from Croatia and Macedonia.

The results of the one-factor analysis of variance with the country as a factor (6 levels) and the consumers' environmental management of paper waste as a dependent variable indicate that there are statistically significant differences between respondents from different countries, $F (5, 1544) = 77.01$, $p < .01$, $\eta^2_p = .20$. Post hoc tests ($p < .01$) further demonstrated that respondents from Slovenia and Croatia to the greatest extent ecologically dispose their paper waste in comparison to respondents from all other countries. Also, it has been shown that the respondents from Montenegro are least prone to ecologically manage their paper waste in comparison to respondents from other countries ($p < .01$).

Differences in demographic characteristics in relation to waste disposal in an environmentally friendly manner

Gender – Disposal of waste in an environmentally friendly way: The results of a two-factor variance analysis with factors country (6 levels) and gender (2 levels) point to a statistically significant main effect of the sex, $F (1, 1537) = 5.44$, $p < .05$, $= .02$ $\eta p2 = .01$, and a statistically significant main effect of the country, $F (5, 1537) = 13.18$, $p < .01$, $\eta p2 = .04$. *Gender-to-country interaction is not statistically significant*, $F (5, 1537) = 1.97$, ns. The results of post hoc tests (Tukey's HSD) indicate that female respondents ($M = 22.53$, $SD = 4.85$) more dispose the waste in a way that does not degrade the environment, compared to male respondents ($M = 21.79$, $SD = 5.00$) in all countries.

Age – Disposal of waste in an environmentally friendly way: The results of a two-factor analysis of variance with factor country (6 levels) and age (5 levels) point to a statistically significant main effect of age, $F (2, 1537) = 19.27$, $p < . 01$, $.02 = \eta p2 = .02$, statistically significant main effect of the country, $F (4, 1510) = 11.84$, $p < .01$ $\eta p2 = .02$, and *statistically significant interaction between country and age*, $F (22, 1510) = 1.77$, $p < .05$, $\eta p2 = .02$. Post hock test (Tukey's HSD) indicates that the youngest respondents from Macedonia, aged 18-30 years ($M = 19.14$, $SD = 4.65$; $p < .01$), are less prone to disposing the waste in an ecological manner polluting the waste in an

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72297248

environmentally-friendly manner than respondents from Croatia, aged 31-40 (M = 25.22, SD = 4.86; p < .01).

Education – Disposal of waste in an environmentally friendly way: The results of a two-factor analysis of variance with factors country (6 levels) and education level (4 levels) point to the statistically significant main effect of the country, F (13, 1524) = 10.92, p < .01, ηp2 = .02, that the main effect of the education level is not statistically significant, F (2, 1524) = <1, ns, and that *the interaction between the country and the education level* is statistically significant, F (13, 1524) = 3.37, p < .01, ηp2 = .02. Post hoc test (Tukey's HSD) indicates that respondents from Macedonia with university degree (M = 19.43, SD = 5.26) are less involved in the disposal of waste in such a way as not to degrade the environment than respondents from: a) Serbia with completed high school (M = 23.37, SD = 4.99, p < .01), b) Croatia with university education (M = 23.61, SD = 5.01, p < .01), and c) Slovenia with a completed university education (M = 23.22, SD = 3.01; p < .01).

Monthly household income – Disposal of waste in an environmentally friendly way: The results of a two-factor variance analysis with factors country (6 levels) and monthly household income (3 levels) point to the statistically significant main effect of the country, F (5, 1530) = 8.99, p < .01, ηp2 = .02, that the main effect of monthly household income is not statistically significant, F (2, 1530) = 1.63, ns., and that the *interaction between the state and monthly household income*, F (10, 1530) = 2.02, p < .01, ηp2 = .01., is statistically significant. Post hoc test (Tukey's HSD) indicates that respondents from Macedonia with above-average household income (M = 19.53, SD = 5.49) are less involved in waste disposal in a way that does not degrade the environment than respondents from: a) Serbia with above-average monthly household income (M = 22.71, SD = 5.08, p < .01), with average monthly household income (M = 24, SD), and with below-average monthly household income (AS = 23.19, SD = 4.92, p < = 4.51, p < .01); b) Croatia with above-average monthly household income (AS = 24.92, SD = 5.04, p < .01) and average monthly household income (AS = 22.63, SD = 5.37, p < .01), c) Slovenia with above-average monthly household income (AS = 23.40, SD = 3.52, p < .01).

Discussion

The results show that there are differences in waste management in an environmentally friendly manner among consumers from different former Yugoslavian republics. The results obtained confirm the hypothesis H0 - there are differences in environmental management of waste between consumers from former Yugoslavian republics.

The results obtained confirm the differences between consumers' environmental management of waste in different countries, found in previously conducted cross-cultural studies (Arbuthnot and Lingg, 1975; Roozen and Pelsmacker, 2000; Sinha-Khetriwala et al., 2005; Kipperberg, 2007; Xu et al., 2014). The obtained results can be explained by the various macroeconomic factors mentioned in *Table 1*. Earlier studies confirm that different macroeconomic factors affect the diversity in the environmentally responsible behavior of consumers, which is the elimination of waste in an environmentally friendly manner (Dolan, 2002; Schaefer and Crane, 2005; Thøgersen, 2005; Assadourian, 2010; Marx et al., 2010). The results point that:

- Regarding the overall waste management in an environmentally friendly way (regardless of the type of waste), it can be concluded that the consumers from

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72297248

Macedonia have a lowest level of waste management in an environmentally friendly manner in comparison to all other countries in the sample. The above can be explained by the fact that Macedonia has the lowest value of the macroeconomic factor "Environmental sustainability" in comparison to all other former Yugoslavian republics (*Table 1*). Also, the "Environmental sustainability" factor has the decrease tendency for Macedonia only. Environmental sustainability is a factor that directly indicates the country's readiness to protect its environment, while managing waste in an ecologically friendly manner is the type of environmentally responsible consumer behavior that significantly depends on the government activity and the functionality of the waste management system at the state level.

- When consumers from Slovenia were analyzed, it was concluded that they are more ready than consumers from all other countries in the sample to environmentally manage different types of waste: food, medicaments, electrical appliances, means of transport and paper. This can be explained by the fact that Slovenia has the highest values for all of the macro factors analyzed in *Table 1*: GDP per capita, quality of education, sophisticated business and environmental sustainability, and each in its own way positively affects the environmental management of waste.
- Regarding the differences in the disposal of food waste in an environmentally friendly manner, the difference between the respondents from Macedonia and the respondents from Montenegro is evident, which can be explained by the fact that Montenegro has higher values for most of the factors analyzed in *Table 1*: GDP per capita, quality of education, and environmental sustainability.
- Respondents from Macedonia and Montenegro are less disposing of medical and chemical waste in an environmentally-friendly manner than respondents from Croatia, which can be explained by the fact that Macedonia and Montenegro in relation to Croatia have lower values for all mentioned macroeconomic factors from *Table 1*: GDP per capita, quality of education, sophisticated business and environmental sustainability.
- Respondents from Slovenia are more prone to disposing of clothing and footwear in an environmentally-friendly way than respondents from Croatia and Montenegro, which can also be explained by the fact that Slovenia in comparison to Croatia and Montenegro has higher values for all macroeconomic factors from *Table 1*: GDP per capita, quality of education, sophisticated business and environmental sustainability)
- If the disposal of furniture in an ecologically friendly way is analyzed, there are differences observed between Serbia on one side and Croatia and Bosnia and Herzegovina on the other side, where respondents from Serbia are more environmentally responsible when disposing of furniture waste than respondents from Croatia and Bosnia and Herzegovina, which can be explained by the fact that Serbia has the lowest value of the factor "Environmental footprint" (*Table 1*), which implies that Serbia is less prone to waste and degradation its natural resources for the better quality of life in relation to Croatia and Bosnia and Herzegovina. In other words, respondents from Serbia pollute less and less degrade the environment, among other things, with furniture waste.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72297248

- Also, the observed differences in the disposal of furniture waste in an environmentally friendly manner are present between Slovenia and all other countries of the sample, in the sense that respondents from Slovenia are less likely to dispose of furniture waste in an environmentally friendly way than respondents from all other countries of the sample, which is explained by the fact that Slovenia has the highest value of the "Environmental footprint" factor (*Table 1*) than all other analyzed countries, which means that Slovenia mostly consumes and degrades its natural resources for a better standard of living, which includes furniture and waste disposal from it.
- Further, the observed differences between the disposal of waste in an environmentally friendly manner are such that respondents from Macedonia are less prone to dispose their furniture waste in an environmentally-friendly way than those from all other sample countries, which is explained by the lowest value of the macroeconomic factor "Environmental sustainability" in comparison with all other former Yugoslavian republics and the fact that this factor only in Macedonia has a decrease tendency in Macedonia only (*Table 1*).
- Respondents from Serbia are less able to dispose their transport vehicles and parts of transport vehicles in an environmentally-friendly manner than respondents from Croatia and Macedonia, which can be explained by the fact that Serbia has the lowest degree of macroeconomic factor "Sophistication of business", which also includes educational promotional campaigns on the importance of ecological manner of disposal of transportation means and their parts.

The obtained differences between countries that can not be explained by variations in macroeconomic factors (*Table 1*) can be explained by differences in the awareness, knowledge and attitude towards the environment in consumers from different analyzed countries (Arbuthnot and Lingg, 1975; Roozen and Pelsmacker, 2000; Sinha-Khetriwala et al., 2005; Kipperberg, 2007; Xu et al., 2014).

The obtained results indicate that there are no gender differences, while there are differences in age, education and monthly household income in relation to the disposal of waste in an environmentally friendly manner among consumers from the territory of the former Yugoslavia. The obtained results partially confirm the H2 hypothesis - there are demographic differences in the disposal of waste in a way that does not degrade the environment among consumers from the territory of the former Yugoslavia.

In all former Yugoslavian republics women environmentally dispose of waste more than men, which is also confirmed by previous research results conducted in: Singapore (Shamdasani et al., 1993), United Kingdom (Gilg et al., 2005), Greece (Tilikidou and Delistavrou, 2008; Abeliotis et al., 2010), Portugal (De Paço and Raposo, 2010; Paçoand Lavrador, 2017), Italy (Pedrini and Ferri, 2014; Talia et al., 2019), Germany (Scherer et al., 2018). Studies conducted in: United States of America (Granzin and Olsen, 1991; Savchenko et al., 2019), United Kingdom (Samdahl and Robertson, 1989; Gilg et al., 2005), China (Chan, 2001), Portugal (De Paço and Raposo, 2010), Italy (Talia et al., 2019), Germany (Pagiaslis and Krontalis, 2014), Spain (Pérez-Belis et al., 2017) and Denmark (Aschemann-Witzel et al., 2017) confirm that there are differences in consumers age related to their ecologically responsible waste disposal. Studies conducted in: United States of America (Arbuthnotand Lingg, 1975; Granzin and Olsen, 1991), United Kingdom (Samdahl and Robertson, 1989), China (Chan, 2001), India (Jain andKaur, 2006), Greece (Tilikidou and Delistavrou, 2008; Abeliotis et al., 2010), Portugal (De Paço and Raposo, 2010), Italy (Pedriniand Feri, 2014; Talia et al., 2019),

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72297248

Denmark (Aschemann-Witzel et al., 2017) and Germany (Pinto et al., 2014; Pagiaslis and Krontalis, 2014) confirm that there are differences in consumers' education level in comparison to environmentally responsible disposal of waste of consumers. That there are differences in certain countries regarding monthly household income in comparison to consumers' ecological waste disposal is confirmed by studies conducted in: United States of America (Granzin and Olsen, 1991), United Kingdom (Samdahl and Robertson, 1989), China (Chan, 2001; Zhang et al., 2018), India (Jain and Kaur, 2006), Greece (Tilikidou and Delistavrou, 2008; Abeliotis et al., 2010), Portugal (De Paço and Raposo, 2010), Italy (Pedrini and Feri, 2014; Talia et al., 2019) and Germany (Pinto et al., 2014; Pagiaslis and Krontalis, 2014) and Denmark (Aschemann-Witzel et al., 2017).

Limitations of research

Although this cross-cultural research was done with caution, it has certain limitations. The firstcan be that the questionnaire was designed for research purposes and it was not used elsewhere, and cannot be characterized as being of multiple uses. The second limitation can be the number of items in the questionnaire – seven. That is a small number of items, which is why maybe the structure of the questionnaire is not ideal. Consumers' environmental management of waste is a socially desirable behavior and it is assumed that respondents were subjective and that they were giving socially desirable answers, which is also considered a limitation of the study.

Conclusion

This is the first cross-cultural research of differences in environmental management of waste by consumers from the former Yugoslavian republics, and as such it provides valuable information.

The results indicate that there are differences in environmental management of waste between consumers from: Macedonia and all other former Yugoslavian republics, and from Montenegro in comparison to Serbia, Croatia and Slovenia. There are differences in consumers' environmental management of different types of waste: regarding food waste – between Slovenia and all other former Yugoslavian republics and Macedonia in comparison to Bosnia and Herzegovina and Croatia; regarding medicament waste – between Slovenia and all other former Yugoslavian republics and between Macedonia and Montenegro in comparison to Croatia and Serbia; regarding clothing and footwear waste – between Slovenia on one hand and Croatia and Montenegro on the other hand; regarding furniture waste –between Slovenia and Macedonia in comparison to all other former Yugoslavian republics; regarding e-waste – between Slovenia and all other former Yugoslavian republics; regarding waste from means of transport – between Slovenia and all other former Yugoslavian republics and Serbia in comparison to Croatia and Macedonia; regarding paper waste – between Slovenia and Croatia in comparison to all other former Yugoslavian republics and between Montenegro and all other former Yugoslavian republics.

Differences in environmental waste recycling between countries can largely be explained by the macroeconomic factors, while part of the results can be explained by differences in consumer awareness, attitude and knowledge regarding environment.

Results indicate that there are no differences in gender but that there are differences in age, degree of education and monthly income by households related to environmental management of waste between consumers from former Yugoslavian republics. As for the age, differences were noted between the youngest respondents from Macedonia,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72297248

aged 18 to 30, and respondents from Croatia aged from 31 to 40 years, in sense that respondents from Macedonia are less likely to dispose of waste in an ecological way than respondents from Croatia. Regarding the level of education, respondents from Macedonia with higher education are less involved in the disposal of waste in such a way that the environment is not degraded than the respondents from: a) Serbia with a completed high school, b) Croatia with a university degree, and c) Slovenia with completed university degree. When it comes to monthly household income, the results show that respondents from Macedonia with above-average household income are less involved in waste disposal in a way that does not degrade the environment than respondents from: a) Serbia with above-average monthly household income, with average monthly household income, and below-average monthly income; b) Croatia with above-average monthly household income, and with average monthly household income, c) Slovenia with above-average monthly household income.

The practical application of the results is reflected in the possibility of more efficient management of consumer waste in an environmentally friendly manner on the territory of former Yugoslavian republics and also globally. Therefore, the consumer behavior can become a tool of environmental management and improve the quality of life in the region. The results indicate that in the territory of the former Yugoslavian republics there are different segments of consumers regarding behavioral variable of consumers' ecological waste management. However, it is necessary to adapt consumer waste management strategies in an environmentally friendly way to different segments i. e. countries. The most resources should be invested in order to bring the consumer waste management strategy in an environmentally friendly manner "most intensively" for consumers in Macedonia and the least resources for a consumer waste management strategy in an environmentally friendly way are needed for consumers from Slovenia. Also, the results indicate that there are market segments if we look at consumer management of different types of waste in an environmentally friendly manner, such as food, medicaments, clothing and footwear, furniture, e-waste, means of transport, or paper. For example, when analyzing waste from furniture, consumers from Slovenia only in this type of waste are less environmentally conscious than consumers from other countries in the sample, which indicates that the waste management strategy for ecologically oriented consumers in Slovenia should be created in such a way that it contributes most to the disposal of furniture waste in an environmentally friendly way in comparison to other types of waste. Or, if consumers from Montenegro are observed, it is concluded that of all the countries in the sample they are the least prone to ecological managing of paper waste. It further implies that the environmental management strategy for consumers in Montenegro should be focused on the environmentally friendly disposal of paper waste in comparison to other types of waste. If we look at the results obtained by analyzing the differences in demographic characteristics with respect to the environmentally responsible disposal of waste, it is concluded that in all the countries of the former Yugoslavia, male part of population should be encourage more to disposed of waste in ecological terms, since in all countries it has been observed that women are more represented in this type of behavior. Also, the same segment of results indicates that consumers from Macedonia aged 18-30 years should be encouraged, as well as consumers from Macedonia who have completed university education and those from Macedonia with above-average monthly income, since it was observed that these demographic groups were least involved in the disposal of waste in an environmentally friendly manner. The obtained data can serve as a starting point for entering into horizontal and vertical partnerships between different entities on national and

DOI: http://dx.doi.org/10.15666/aeer/1704_72297248

international levels, with the aim of protecting the environment through increased consumers' environmental management of waste.

From a theoretical perspective, the data obtained is important because it provides an empirical basis for other studies by creating an environmental profile of responsible consumers. Also, the research was conducted with a newly created questionnaire that can be used for other research, and for creating other questionnaires on the same topic.

It is also proposed to carry out research in the territory of former Yugoslavia republics in order to determine the correlation between macroeconomic factors and different types of ecologically responsible behavior of consumers, including disposal of waste in an environmentally friendly way, which would show whether and which - if any - macroeconomic factors influence different ecological responsible consumers' behavior. Finally, the authors suggest that more studies should be carried out on the topic of consumers' environmental management of waste, as this is the only way to analyze the limits and motivators of the environmentally responsible behavior of consumers.

APPENDIX

Questionnaire used in this study

Dear Sir/Madam,

Bearing in mind that this is one of rare cross cultural studies in our region, and that the results will provide valuable information on similarities and differences regarding our behavior as consumers, we kindly ask you to devote 10 minutes of your time, which will be enough to fill out this questionnaire.

This survey is entirely ANONYMOUS, which means that nobody will be able to associate you with your answers. Survey data will be processed in groups and will be used for scientific research purpose only.

We kindly ask you to answer ALL of the questions and check carefully whether you have completed the ENTIRE questionnaire.

You are free to send all of your questions and doubts relative to this research via e-mail: rsasaca@hotmail.com.

Filling out the questionnaire is voluntary and requires your consent. If you agree to participate in this survey, circle YES.

I AGREE TO PARTICIPATE IN THIS SURVEY:

YES NO

THANK YOU IN ADVANCE FOR YOUR COOPERATION!

Circle the number in front of the statement that applies to you.

Country:
1. Serbia 2. Croatia 3. Bosnia and Herzegovina 4. Slovenia 5. Macedonia 6. Monetenegro

Abstract. In this paper, novel fluorescent carbon quantum dots (CQDs) were successfully prepared from pig liver by a simple one-step hydrothermal method. The prepared CQDs were characterized using TEM, XRD, XPS, FT-IR, UV-Vis, and fluorescence spectroscopy. It was found that the CQDs were uniformly distributed in size and exhibited good excitation dependence and excellent photostability. Fluorescent probe was used for detection of permanganate. This paper also studied the fluorescent staining performance of pig liver-based CQDs on four live/dead bacteria to evaluate the low toxicity and application prospects of the CQDs. Under the optimum experimental conditions, the probe showed a good linear range (R^2 = 0.9967) and a low detection limit (0.06 μM) in the concentration range of 0.1-50 μM. The pig liver based-CQDs were proved to be a low toxicity fluorescent dye. These attractive properties indicated that the new CQDs could adapt to various complex pH environments, and thus had extensive prospect and promising application for detection of permanganate in complex environmental samples.
Keywords: *carbon quantum dots, pig liver, bacterial staining, in vivo bio-imaging, MnO_4^-*

Introduction

Manganese is an essential trace element of human body. Too much or too little manganese in the body can cause adverse consequences (Teo and Chen, 2001). Manganese deficiency affects the body's reproductive function, lipid metabolism (da Silva et al., 2006), glucose metabolism (Doroschuk et al., 2004) and immune function (Rask et al., 2015), thus causing mental retardation, dysmotility and balance disorders (Gunter et al., 2010), and skeletal dysfunction (Liang et al., 2006). It can also deform the next generation. The excessive amount of manganese in the body can lead to mental symptoms (Zeng et al., 2017). Therefore, the analysis of manganese in food and environment samples is of important practical significance, and it is highly necessary to monitor the level of manganese in body fluids or environmental samples.

Permanganate is usually oxidable, hazardous explosion chemicals, precursor chemicals, and easy to decompose by heating because they all have the same anions-permanganate ions. Permanganate ion has strong oxidation in acidic solution (acidic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72497263

$KMnO_4$ (potassium permanganate)). It also has certain oxidation in alkaline solution, which is purple red in solution. The oxidation of potassium permanganate can be found in both acidity and alkalinity, but it is more obvious in acidity. In recent years, many methods of manganese detection have been developed, including catalytic kinetic spectrophotometric for the determination of trace manganese, but there are few methods for the determination of permanganate ions. A new fluorescence method for the determination of trace manganese was established (Xu et al., 2004), where the concentration range of MnO_4^- is 1.0~2.4 mg/L, the maximum excitation wavelength is 278 nm, the maximum emission wavelength is 616 nm, and the fluorescence intensity and concentration show a good linear relationship by transforming the manganese into MnO_4^-. The results obtained in this method were satisfactory.

Carbon quantum dots (CQDs) are one of the most popular carbon nanomaterials after fullerene, carbon nanotubes and graphene. They were first discovered in 2004 (Wang and Hu, 2014) when electrophoresis was used to purify single-walled carbon nanotubes. They have attracted great attention due to their excellent optical properties, such as water solubility, chemical inertia, low toxicity, easy functionalization (Li et al., 2012) and high fluorescence intensity, photobleaching resistance and adjustable luminescence color. They have been widely used in detection of metal ions (Lu et al., 2012), anions (Zhao et al., 2011), small organic molecules (Li et al., 2013) and biological molecules (Deng et al., 2014). The method of detecting metal ions or other environmental pollutants using CQDs as a fluorescent probe has received extensive attention due to its excellent sensitivity and selectivity (Clarkson and Magos, 2006). Zhang and Chen (2014) used folic acid as carbon source and nitrogen source to trace mercury ions by nitrogen-doped carbon dots, and the detection limit was 0.23 mol/L.

In this study, fluorescent carbon quantum dots (CQDs) were successfully prepared by simple one-step hydrothermal method using pig liver as a carbon source. Since pig liver is a complex that contains a number of organics and biomolecules including fat, proteins, vitamin B, vitamin C, vitamin E, carbohydrates, cholesterol and minerals, it can be useful for doping of multiple hetero atoms in the CQDs without addition of any additives. In the experiment, we found that MnO_4^- could quench the fluorescence of CQDs, and the quenching degree was related to the concentration of MnO_4^-. To our knowledge, there is no report used CQDs fluorescent probe from pig liver for detection of MnO_4^- yet, which provides a new method for sensitive detection of MnO_4^-. In addition, this method has been successfully applied to detecting MnO_4^- in environmental water and soil samples.

Experiment

Instruments and reagents

Pig liver was purchased from a local supermarket in Kunming (Yunnan, China); all analytical reagents, including potassium permanganate ($KMnO_4$), citric acid, disodium hydrogen phosphate (Na_2HPO_4), $FeCl_3 \cdot 6H_2O$ and $FeCl_2 \cdot 4H_2O$, sodium nitrite, sodium nitrate, KI, NaCl, NaF, copper sulfate, aluminum sulfate, calcium chloride, $MnSO_4$, $BaCl_2$, $MgCl_2$ and sodium sulfide (NaS) were purchased from Shanghai Aladdin Biochemical Technology Co., Ltd. (Shanghai, China); and all solutions were prepared from Milli-Q system ultrapure water (18.2 MΩ.cm, 25 °C).

G9800A fluorospectrophotometer (Agilent Technologies, USA) was used to determine the fluorescence spectrum and its intensity; UV-2600 spectrophotometer

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72497263

(Shimadzu, Japan) was used to determine UV spectra; Tecnai G2 F30S-Twin high resolution field emission transmission electron microscope (FEI, Netherlands) was used to detect the particle size and morphology of fluorescent quantum dots; TENSOR 27 Fourier transform infrared spectrometer (Bruker, Germany) was used to determine the infrared spectrum and the structure of the material; D8-advance X-ray powder diffractometer (Bruker, Germany) was used to determine the crystal structure morphology; Thermo Scientific K-Alpha X-ray photoelectron spectrometer (Thermo Fisher Scientific Inc. U.S.A.) was used to analyze the elemental composition ratio and chemical oxidation state; XH-B vortex instrument (Shanghai Hanuo Instrument Co., Ltd., China) was used for vortex mixing; and 80-2 high speed centrifuge (Shanghai Surgical Instrument Factory, China) was used for centrifugal filtration.

Preparation of pig liver-based CQDs

The pig liver was dried naturally at room temperature and grinded into powders in a mortar. The CQDs of pig liver were prepared by simple hydrothermal method using pig liver powder as carbon source. Five grams of pig liver powder was dispersed in 150 mL deionized water. Then, the mixture was transferred into a high-pressure autoclave (200 mL) lined with polytetrafluoroethylene (PTFE), heated at 180 °C for 10 h, cooled naturally to room temperature, and centrifuged at 13,000 rpm for 20 min to obtain bright yellow solution, and filtered to remove insoluble substances. In order to obtain pure pig liver-based CQDs, the solution was filtered by 0.22 μm membrane. Finally, the obtained pig liver CQDs were stored at 4 °C for further use. Compared with other synthetic methods, the hydrothermal synthesis of pig liver CQDs is simpler and more feasible. In addition, pig liver as raw material for synthesis is cheap and easily available, and this method is greener and more environmentally friendly.

Fluorescence quenching test for permanganate

Typically, 50 μL of prepared pig liver-based CQDs solution and 1 mL of pH 7.0 citric acid-disodium hydrogen phosphate buffer solution mixed and diluted to 3.0 mL with deionized water were placed in a 10 mL glass centrifuge tube. Then, 2mL permanganate solution or sample with a different concentration was added to the centrifuge tube and the vortex was mixed with 30 s. After 3 min, the fluorescence intensity was measured at excitation wavelength 278 nm and emission wavelength 616 nm on the fluorescence spectrophotometer, and the fluorescence intensity was recorded. The slit width of excitation and emission was 5 nm. In order to evaluate the effect of coexisting interfering substances on the fluorescence intensity of pig liver-based CQDs and the selectivity of permanganate and other substances or ions (including $FeCl_3 \cdot 6H_2O$ and $FeCl_2 \cdot 4H_2O$, sodium nitrite, sodium nitrate, KI, NaCl, NaF, copper sulfate, aluminum sulfate, calcium chloride, $MnSO_4$, $BaCl_2$, $MgCl_2$ and sodium sulfide), the fluorescence quenching test was carried out under the same experimental conditions. The schematic diagram of detection of MnO_4^- with pig liver-based CQDs was shown in *Figure 1*.

DOI: http://dx.doi.org/10.15666/aeer/1704_72497263

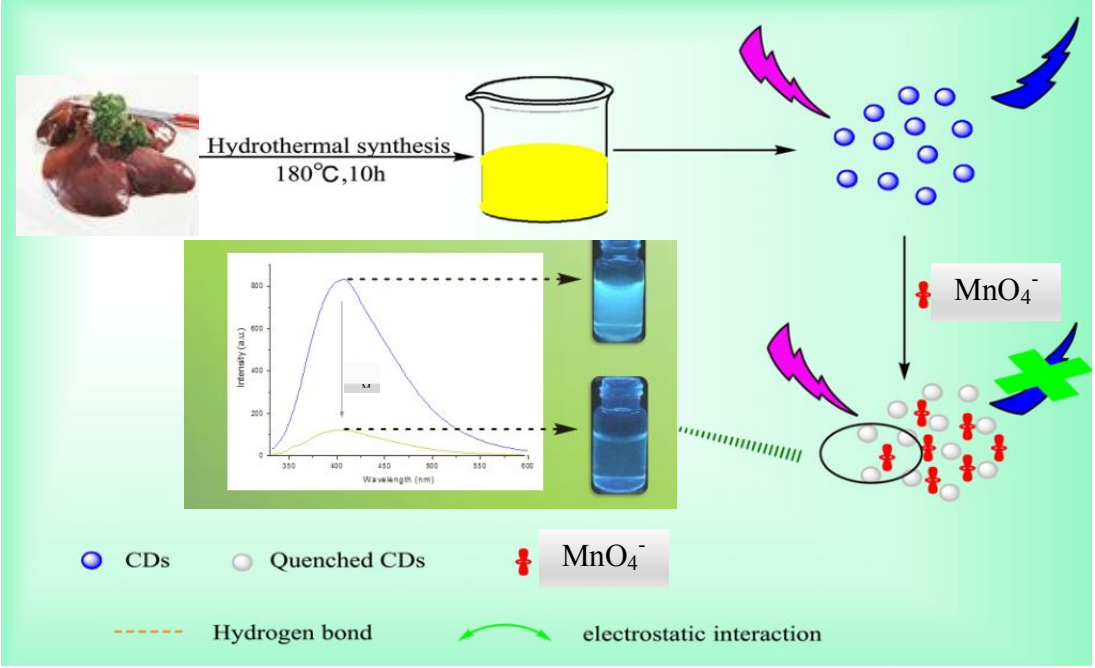

Figure 1. *Processing diagram for the synthesis and application of CQDs*

Collection and pretreatment of environmental samples

In this study, water samples were collected directly from our laboratory, Laoyuhe Lake and the domestic wastewater of the community next to a school. All water samples were filtered by simple centrifugal filtration to remove solid particles and suspended solids and then by 0.22 μm microporous membrane, and stored at 4 °C. The permanganate ion was added to the samples at a concentration of 0.01 mg/mL for spiked fluorescence analysis.

Soil samples were collected from the road outside the school after rain and dried under suitable environmental conditions (final moisture content 0.32%). One milliliter of methanol solution containing different concentrations of permanganate ions was added to 200 mg soil, mixed for 1 h on a 50 rpm shaker, and then allowed to stand overnight at room temperature (RT). On the second morning, the mixture was again vortexed and centrifuged for 2 min at 5,000 rpm and the supernatant was used for fluorescence detection.

Results and discussion

Characterization of the CQDs

The transmission electron microscopy (TEM) technique was used to explore the morphology and particle size distributions of CQDs. As shown in *Figure 2,* the CQDs present high dispersity, uniform spherical shapes, and a size distribution within the range of 3–10 nm and an average diameter of about 5.0 nm. The surface chemistry of CQDs was studied using Fourier transform infrared (FT-IR) spectroscopy. As shown in *Figure 3,* the strong absorption peak at 1469 cm^{-1} reveals the existence of -COOH stretching vibrations; the peak at 1652 cm^{-1} reveals the existence of O = C-NH stretching vibrations; and the absorption peak at 3190 cm^{-1} displays O-H stretching vibrations. As shown in *Figure 4,* the full scan XPS spectra present distinct peaks at

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72497263

287.3 and 532.7 eV, which are attributed to C1s and O1s, respectively. The result of XPS diagram was consistent with that of FT-IR analysis. Therefore, there should be hydrophilic groups on the surface of pig liver-based CQDs, such as -COOH, -OH, etc., which have good water solubility and broad application prospects.

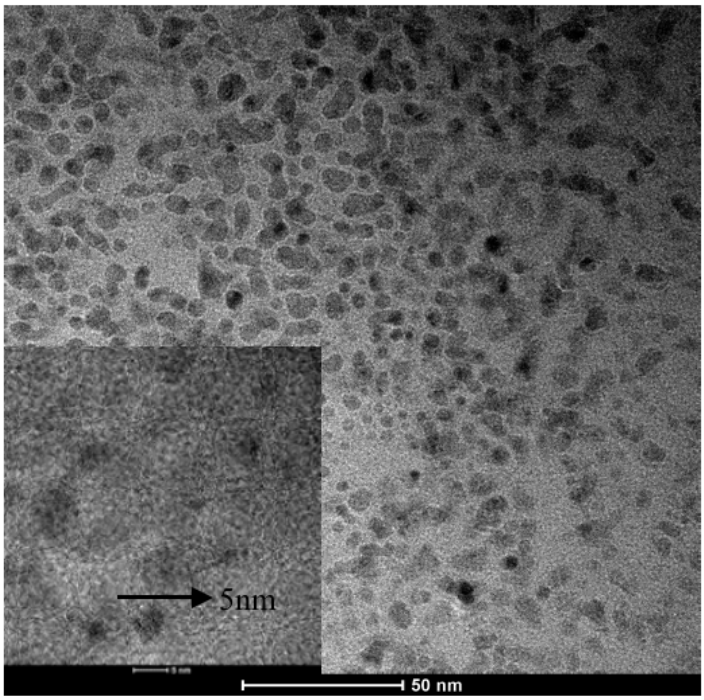

Figure 2. *TEM image (inset: HR-TEM image) of the synthesized CQDs*

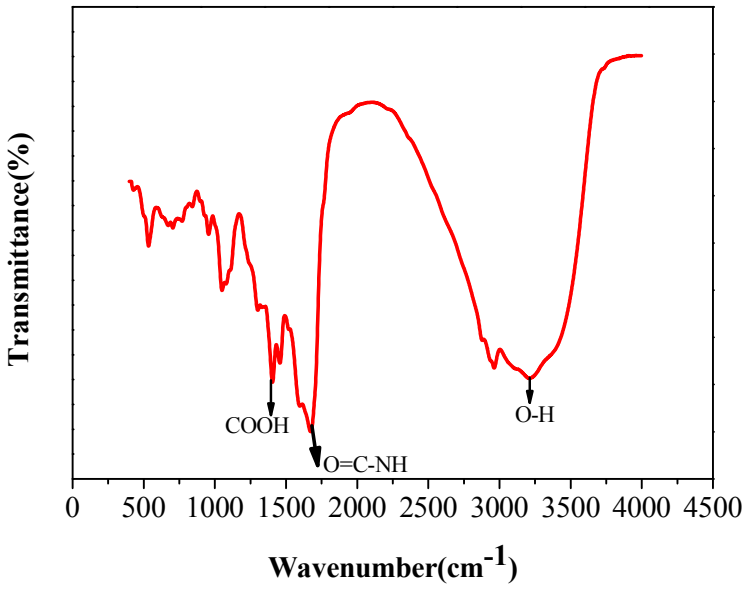

Figure 3. *FT-IR spectrum of pig liver-based CQDs*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72497263

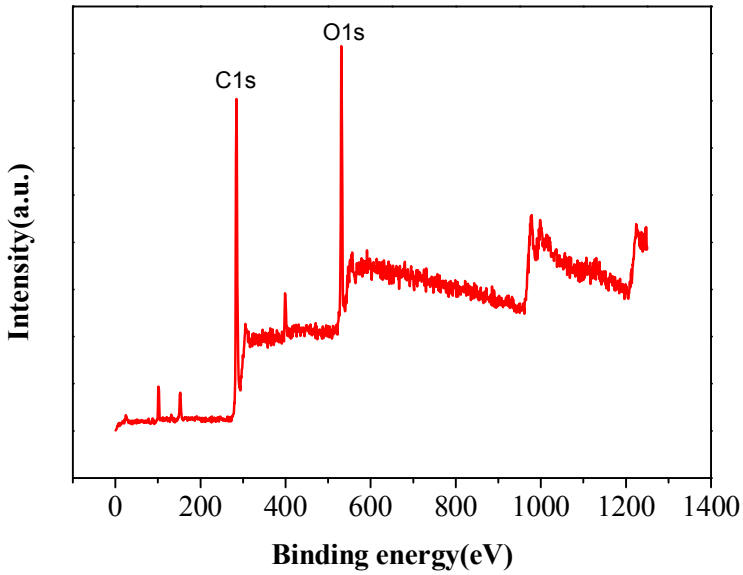

Figure 4. *XPS spectra of pig liver-based CQDs*

In order to study the optical properties of pig liver-based CQDS, the pig liver-based CQDs were characterized by UV-vis absorption spectrum and fluorescence emission spectrum. The UV-vis absorption spectrum (UV-vis) of pig liver-based CQDs is shown in *Figure 5*. The prepared pig liver-based CQDs had a weak absorption peak around 258 nm and an excitation wavelength of 278 nm at the maximum emission wavelength of 616 nm, as shown in *Figure 6,* a fluorescence spectrum (FS) and an excitation-dependent emission spectrum of pig liver-based CQDs. The results showed that when the excitation wavelength was changed from 300 to 360 nm in increments of 10 nm, the emission peak shifted toward the long wavelength direction.

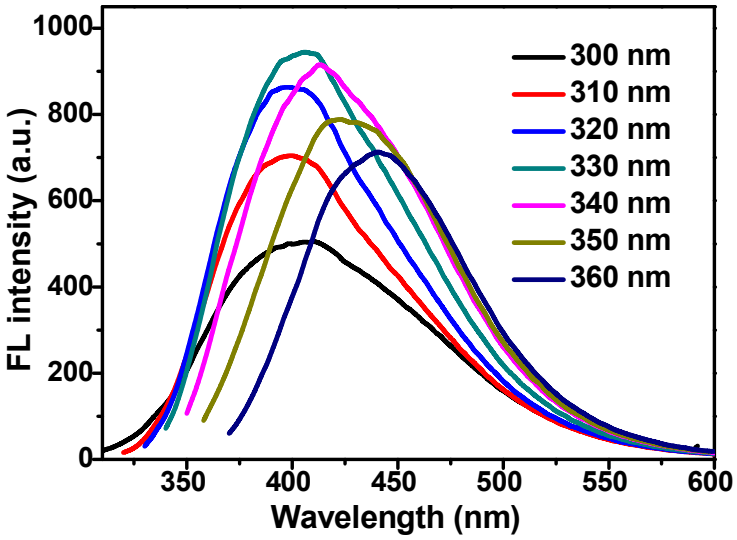

Figure 6. *Fluorescence emission spectra of pig liver-based CQDs at different excitation wavelengths*

Light stability test of pig liver-based CQDs

In order to study the stability of pig liver-based CQDs in detecting permanganate, the fluorescence intensity of pig liver-based CQDs at different storage time was studied. As shown in *Figure 7A,* the fluorescence intensity of the pig liver based-CQDs is substantially constant. In addition, the reaction time increased while the fluorescence intensity of the experimental system remained constant, indicating that the storage time had no effect on the fluorescence intensity of pig liver-based CQDs. The effects of ionic strength and pH on the fluorescence intensity of pig liver-based CQDs were also studied, as shown in *Figure 7B* and *C*. It is observed from the figures that with the gradual increase of the concentration of NaCl solution, the fluorescence intensity only slightly fluctuated without significant change; the pH of the citric acid-dibasic sodium phosphate buffer changed from 2.0 to 8.0; and the fluorescence intensity of pig liver-based CQDs remain unchanged, this demonstrates that pig liver-based CQDs can be used as fluorescent nanoprobe in any environmental conditions.

Selectivity

The selectivity of pig liver based-CQDs was investigated by monitoring the fluorescence intensity of different possible interfering substances such as MnO_4^-, Fe^{3+}, Fe^{2+}, NO_2, NO_3, I^-, Cl^-, F^-, Na^+, K^+, Cu^{2+}, Al^{3+}, Ca^{2+}, Mn^{2+}, Ba^{2+}, Mg^{2+} and S^{2-} in the presence of different concentrations or ions. As shown in *Figure 8,* only permanganate ion can effectively quench the fluorescence intensity of CQDs in pig liver, while the quenching effect of other possible interfering substances is negligible. The results show that there may be some quenching relationship between pig liver-based CQDs and permanganate ions, which is worthy of further study. Therefore, there is a high selectivity between permanganate ions and pig liver-based CQDs. This demonstrates that pig liver-based CQDs can be used to detect permanganate ions.

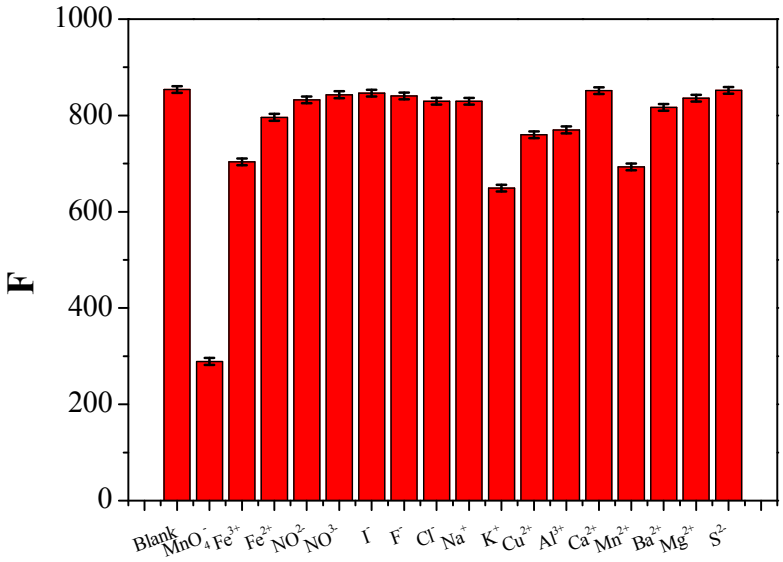

Figure 8. *Evaluation of method selectivity against possible interferents*

Optimization of experimental conditions

PH affects not only the fluorescence intensity of pig liver-based CQDs, but also the fluorescence quenching effect of permanganate ions on pig liver-based CQDs. Therefore, the effect of pH from 2.2 to 8.0 on the experimental system was investigated. As shown in *Figure 9A,* the fluorescence intensity of pig liver-based CQDs is related to pH. In the range of pH2.0-7.0, the fluorescence intensity increased gradually and the fluorescence quenching efficiency reached its maximum, but after pH 7.0, the fluorescence intensity decreased gradually. The results show that the fluorescence quenching response of the system is the largest at pH 7.0, according to which pH 70 is the optimum pH value of citric acid-disodium hydrogen phosphate buffer.

In order to study the stability of pig liver-based CQDs in detecting permanganate ions, the fluorescence intensity of pig liver-based CQDs in the presence of permanganate ions at the same concentration under different reaction time was studied. As shown in *Figure 9B,* the fluorescence intensity of pig liver based-CQDs decreased sharply within 0-1 min and gradually within 1-10 min, then tended to be stable, and reached the lowest fluorescence intensity in 2 min. Therefore, the reaction time of 2 min was chosen as the optimal fluorescence quenching response time.

Method performance study

Under the optimal experimental conditions, the relationship between the fluorescence quenching intensity of pig liver-based CQDs and the concentration of MnO_4^- was studied, and the quantitative analysis method for fluorescence quenching of MnO_4^- was established. As shown in *Figure 10,* the fluorescence intensity of pig liver-based CQDs decreases gradually with the addition of MnO_4^- of different concentrations, and shows regular changes. As shown in *Figure 11,* the ratio of fluorescence intensity of the system was linear with the concentration of MnO_4^- in the range of 0-50 μM both before and after addition of pig liver-based CQDs. The regression equation is F/F0 = 0.0151C – 0.0112 (R^2 = 0.9967), where F and F0 are the fluorescence intensity of pig liver-based CQDs in the presence or absence of MnO_4^- respectively and C is the concentration of MnO_4^-. The detection limit of MnO_4^- was 0.06 μM and the signal-noise ratio was 3(S/N).

Possible fluorescence quenching mechanism

In recent years, many sensors have been established based on the fluorescence variation of carbon quantum dots. These sensors were primarily analytes that quenched or increased the fluorescence of the carbon dots (Mariappan et al., 2017). Theoretically, this fluorescence phenomenon is related to different mechanisms. For fluorescence

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72497263

quenching, the mechanism is usually divided into dynamic quenching and static quenching, caused by the collision between fluorescent materials and quencher and the formation of ground state complexes respectively (Kaviyarasu et al., 2017). In case of dynamic quenching, the Stern-Volmer equation can be used for analysis (Guo et al., 2015) with the following formula:

$$F0/F = 1 + K_{q\tau 0}[Q] = 1 + K_{SV}[Q]$$

where: F0 and F indicate the fluorescence intensity before and after the addition of MnO_4^- respectively, K_q is the bimolecular quenching constant, τ0 is the average lifetime of CQDs, generally 10^{-8} s, KSV is the Stern-Walmer quenching constant, and [Q] was the concentration of MnO_4^-. Therefore, the fluorescence quenching process may be caused by static quenching, i.e. the formation of ground state complexes in the reaction system (Lakowicz, 2006; Sun et al., 2015; Formica et al., 2012). The absorption strength of CQDs increased and the peak shifted to blue after addition of MnO_4^-, indicating that the interaction between MnO_4^- and CQDs produced the ground state complex. According to almost constant fluorescence lifetime, the fluorescence quenching caused by MnO_4^- may be static quenching due to the formation of stable non-fluorescent complexes (Zuo et al., 2016; Sun and Lei, 2017; Wu et al., 2011; Liu et al., 2017, 2014). FT-IR and XPS confirmed the presence of -COOH, -OH, etc. on the surface of CQDs, indicating good water solubility and good application prospect of the synthesized CQDs.

Analysis of MnO_4^- in real samples

The above mentioned environmental water and soil samples were pretreated, and then MnO_4^- in environmental water and soil samples was detected by prepared pig liver-based CQDs. The environmental water samples and soil samples were spiked and recovered using different concentrations of MnO_4^- and pretreated according to the same procedure. As shown in *Table 1,* the recovery of MnO_4^- in water samples is 94.2~102.5% and the relative standard deviations (RSD) of all samples are less than 5.8%. As shown in *Table 2,* the recovery of MnO_4^- in soil samples is 90.5 to 99.5% and the relative standard deviations (RSD) of all samples are below 4.7%. Therefore, this method has the potential for detecting MnO_4^- in environmental water samples and soil samples.

Conclusion

In summary, novel fluorescent CQDs were prepared from pig liver by hydrothermal synthesis method and the fluorescence intensity of CQDs could be quenched by MnO_4^-, so the CQDs were used as nanosensors for the sensitive and selective detection of MnO_4^- in environmental samples. For instance, morphology, particle size, crystal form, chemical element composition and optical properties of the prepared pig liver-based CQDs were characterized by TEM, FT-IR, XPS, UV-Vis and FS. The results showed that it had good stability and fluorescence characteristics. In addition, a good linear relationship was achieved between the fluorescence response of CQDs and the concentration of MnO_4^- in the range from 0.1 to 50 μM. The detection limit was 0.06 μM under optimized conditions. The developed method has been successfully applied to the determination of MnO_4^- in water samples and soils of environmental samples. This method is green, environmental friendly, simple and easy to operate, and shows great potential for application.

Abstract. The aim of this study was to determine the impacts of anthropogenic disturbances on compositions of prokaryote communites (CPCs) in Chaohu Lake and its three urban tributaries, in China. Prokaryotic diversity in Chaohu Lake and its tributaries was high, and prokaryotic communities showed lower richness in Nanfei River than in Zhegao River and Hangbu River, with waterbody nutrient levels negatively corresponding to prokaryotic diversity. Except for a few rare prokaryotes, or where classification was unclear, the prokaryotes were distributed into 13 phyla and 924 genera. The dominant prokaryotic phyla were Proteobacteria (31.51%), Bacteroidetes (26.50%), Cyanobacteria (19.05%), and Actinobacteria (10.71%). Redundancy analysis (RDA) results showed CPCs, as well as abundances of Proteobacteria, Actinobacteria, and Firmicutes to be primarily affected by the concentration of total phosphorus (TP). Furthermore, Cyanobacteria showed a significant correlation with the concentrations of total nitrogen (TN), nitrate (NO_3) and ammonia nitrogen (NH_4). pH was correlated with Planctomycetes, while Thermotogae was generally associated with water temperature (WT). These results suggest that trophic status could play an important role in shaping CPCs in both freshwater lakes and rivers. Ultimately, urbanization was found to cause the deterioration of water quality within Chaohu Lake and its tributaries.

Keywords: *prokaryotic community structure, diversity, high-throughput sequencing, redundancy analysis, freshwater*

Introduction

With continued worldwide urban expansion and rapid economic and industrial development, discharge from anthropogenic activities (municipal, industrial, and agricultural) continues to expose freshwater systems to large quantities of anthropogenic pollutants. This pollution has resulted in a notable deterioration of freshwater quality (Martinuzzi et al., 2014; Jordaan and Bezuidenhout, 2016). In aquatic ecosystems, prokaryotes drive the transformation and cycling of most biologically active elements, so they play a critical role in the regeneration and mobilization of nutrients in freshwater food webs (Newton et al., 2011; Ren et al., 2013). Short generation times, high diversity, and quick reaction to (and recovery from) environmental change make prokaryotes ideal indicators of stress in freshwater systems. Anthropogenic disturbances on freshwater systems have major repercussion on the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72657281

overall prokaryotic structure and function of these habitats (Jordaan and Bezuidenhout, 2016). To better manage and maintain the ecological environments of freshwater systems, we need to more fully understand how prokaryotic community diversity and distribution characteristics function in these environments. In recent years, culture-independent methods were used to characterize prokaryotic diversity. This approach avoids the cultivation bias and yields detailed insight into the prokaryotic diversity of diverse ecosystems (Ni et al., 2017; Wu et al., 2017; Xiang et al., 2018). The use of high-throughput sequencing has become an increasingly popular technique for the analysis of prokaryotic communities in a variety of freshwater ecosystems, and has led to the increased detection of rare prokaryotic species (Lin et al., 2012; Bashenkhaeva et al., 2015; Dai et al., 2016; Wu et al., 2017).

Chaohu Lake, one of the five largest freshwater lakes in China, is a shallow and subtropical freshwater system. Chaohu Lake has three urban-river tributaries–Nanfei, Zhegao, and Hangbu Rivers–which drain into the lake (Wang et al., 2011; *Fig. 1*). Chaohu Lake plays an important role in commercial fishing, water supply, irrigation, navigation, tourism, and recreational activity throughout the region. However, in recently years, due to the increase in anthropogenic activity within the lake's watershed, Chaohu Lake has suffered from severe pollution and eutrophication (Zan et al., 2011). This has resulted in large blooms of blue-green algae during the summer months, which have caused the production of highly toxic microcystins, and the subsequent fouling (and temporary interruption) of the local drinking water supply. The water quality of Chaohu Lake's three tributaries has also been adversely affected by human activity–including agricultural runoff, urban development, and the construction of informal settlements. The establishment of water management strategies requires previous knowledge of the ecological dynamics of target communities in the water body. To date, however, only two studies (Bao et al., 2008; Wei et al., 2008) have analyzed the phylogenetic composition of bacterioplankton communities in Chaohu Lake. This was accomplished by partially sequencing cloned 16S rRNA genes and PCR-DGGE (denaturing gradient gel electrophoresis) analysis. No further research has attempted to characterize the compositions of prokaryote communites (CPCs) in Chaohu Lake by way of high-throughput sequencing, and the information on the CPCs of the lake's three tributaries is virtually nonexistent. Ultimately, this has restricted the creation of an effective water management plan. Thus, it is important to collect data and conduct research on prokaryotic diversity within Chaohu Lake and its surrounding watershed. Moreover, much of our current understanding of local CPCs is primarily based on inter-lake or inter-river investigations, with less attention being given to the areas where rivers drain into the lake.

The objectives of this project were as follows: 1) characterize the CPCs in Chaohu Lake and its tributaries using high-throughput sequencing; 2) compare the CPCs among Chaohu Lake and its tributaries, and evaluate the importance of physicochemical parameters in the structuring of CPCs; 3) provide basic information for the restoration of Chaohu Lake and its tributaries.

Materials and methods

Study area

Chaohu Lake (E117°35'52.2", N31°40'26.5") has a surface area of 770 km^2, and is situated on the floodplain between the Yangtze River and the Huaihe River in the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72657281

central Anhui Province of eastern China (Wang and Dou, 1998). The Nanfei River, Zhegao River, and Hangbu River, three tributaries of Chaohu Lake, flow through Hefei City, Zhegao Town, and Sanhe Town, respectively (*Fig. 1*). Farmland primarily surrounds the upper reaches of the three rivers, whereas cities and towns envelop the middle and lower reaches. Thus the middle and lower stretches are stressed from multiple anthropogenic sources, including untreated domestic and industrial wastewater discharge.

Sampling sites and sample collection

Samples were collected on 22 December 2017. We studied the Nanfei, Zhegao, and Hangbu Rivers, and established three sites along the upper reaches (U), middle reaches (M), and lower reaches (L) of all three rivers. Additionally, based on the shape and size of Chaohu Lake, three sites (I, II, III) were selected (*Fig. 1*). All stations were sampled within a 24-h period. The samples of three rivers were collected from the center of rivers. 500-ml water samples were collected at each sampling site for microbial DNA extraction. At each sampling site, 500-ml water samples were collected from surface waters (the top 50 cm) and filtered through 0.2-μm-pore-size Isopore filters (Millipore, Billerica, MA, USA). All samples were collected only once. DNA extraction was carried out within 24 h from the time of sample collection. Simultaneously, 1 L water samples were collected at each sampling site for physicochemical characterization (Huang, 2000).

Measurement of physical and chemical indices

Water temperature was measured using a multi-parameter water quality monitoring sonde (YSI 6600, USA). One liter of water was collected to measure pH, total phosphorus (TP), total nitrogen (TN), nitrate (NO_3) and ammonia nitrogen (NH_4). All of these physiochemical factors were measured according to standard methods (Huang, 2000).

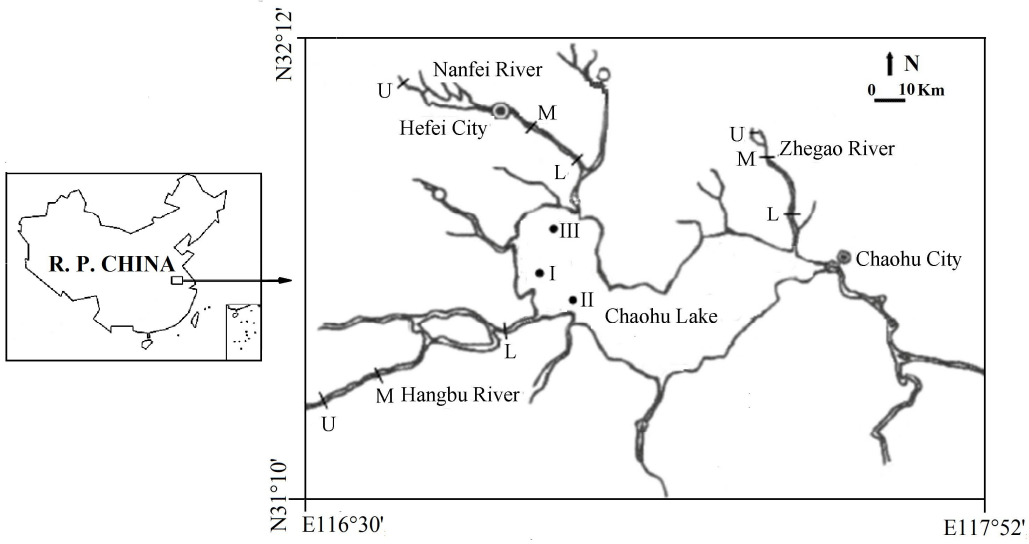

Figure 1. *Sampling sites of Chaohu Lake and three rivers. U, upper reaches; M, middle reaches; and L, lower reaches; I, site I of Chaohu Lake; II, site II of Chaohu Lake; III, site III of Chaohu Lake*

DNA extraction and high-throughput sequencing of prokaryotic 16S rRNA gene

Genomic DNA of the water microbiota was extracted using the standard phenol-chloroform method (Wu et al., 2017). The extracted DNA was diluted to 10 ng/μL and stored at −40 °C for downstream use.

A prokaryotic universal primers 515F and 909R with a 12 nt unique barcode was used to amplify the V4-V5 hypervariable region of 16S rRNA gene for high-throughput sequencing according to a previous report (Ni et al., 2017). The PCR mixture (25 μl) contained 1× PCR buffer, 1.5 mM MgCl2, deoxynucleoside triphosphate at 0.4 μM, primer at 1.0 μM and 0.5 U of Ex Taq (TaKaRa, China), and 10 ng genomic DNA. The PCR amplification program included initial denaturation at 94 °C for 10 min, followed by 30 cycles of 94 °C for 40 s, 56 °C for 60 s, and 72 °C for 60 s, and a final extension at 72 °C for 10 min. Two PCR reactions were conducted for each sample and combined together after PCR amplification. PCR products were subjected to electrophoresis using 1% agarose gel. Each band showing the target size was excised and purified using a SanPrep DNA Gel Extraction Kit (Sangon Biotech, China) and quantified with Nanodrop. All samples were pooled together with equal molar amounts from each sample. The sequence samples were prepared using TruSeq DNA kit according to the manufacturer's instructions. The purified library was diluted, denatured, re-diluted, and mixed with PhiX (equal to 30% of the final DNA amount–as described in the Illumina library preparation protocols), and applied to an Illumina Miseq benchtop sequencer (Illumina, USA) at Guangdong Meilikang Bio-Science Ltd., China with the Reagent Kit (v2) 2 × 250 bp according to the manufacture manual.

Data analysis

The raw sequence data were merged using FLASH–1.2.8 software (Magoc and Salzberg, 2011). The merged sequences were trimmed and assigned to each sample based on their respective barcode sequences using QIIME Pipeline Version 1.7.0 (Caporaso et al., 2010). The sequences that are more than 300 bp of length, without ambiguous base 'N', and more than 30 of the average base quality score were used for downstream analysis (Xiang et al., 2018). Sequences were clustered into operational taxonomic units (OTUs) at a 97% identity threshold. The aligned gene sequences were used for chimera check using the Uchime algorithm (Edgar et al., 2011). Taxonomy was assigned using the Ribosomal Database Project classifier (Wang et al., 2007). Shannon index was calculated using QIIME 1.7.0 based on the composition of OTUs. Principal coordinate analysis (PCoA) based on a weighted UniFrac distance matrix was conducted using QIIME 1.7.0. Redundancy analysis (RDA) with a Monte Carlo permutation test was carried out using the 'vegan' package in R (Oksanen et al., 2015). P-values < 0.05 were considered statistically significant. We performed one-way analysis of variance (ANOVA) to test for significant differences in physicochemical characteristics. All statistical analyses were performed using SPSS 13.0.

Results

Physicochemical analysis

Concentrations of TP and NH_4 exhibited maxima in the Nanfei River, while concentrations of TN and NO_3 were greater in Chaohu Lake than in the three rivers (*Table 1*). According to the standard established by the Organisation for Economic and

Co-operation and Development (OECD) (1982)–which is based on the concentration of total phosphorus (TP)–Chaohu Lake and its three associated rivers are eutrophic or hypereutrophic. The degree of eutrophication was as follows: Nanfei River > Chaohu Lake > Zhegao River > Hangbu River.

Table 1. *Physicochemical characteristics of Chaohu Lake and three rivers*

Prokaryote community composition

In total, 296,004 effective sequences and 39,350 OTUs (not include the averages number of OTUs in Chaohu Lake and three rivers) were obtained from these samples (*Table 2*). Chaohu Lake had the highest number of OTUs (3,289) (*Table 2*). Additionally, prokaryote communities in Chaohu Lake showed higher richness than in the three rivers. The average Shannon diversity index for prokaryote communities in Chaohu Lake was 6.81. Among the three rivers, the highest observed prokaryotic diversity was in Zhegao River (7.60), followed by Hangbu River (6.99), and Nanfei River (6.21; *Table 2*). Thus, Chaohu Lake and its tributaries exhibited high prokaryotic diversity as well as an inverse relationship between water body trophic level and prokaryotic diversity.

Except for a small number of unclassified (0.03%) and rare (2.98%) prokaryotes, a total of 13 prokaryotic phyla were identified from Chaohu Lake and its tributaries. There were 13 dominant prokaryotic phyla, including Proteobacteria (31.51%), Bacteroidetes (26.50%), Cyanobacteria (19.05%), Actinobacteria (10.71%),

DOI: http://dx.doi.org/10.15666/aeer/1704_72657281

Verrucomicrobia (2.73%), Firmicutes (2.29%), Planctomycetes (1.02%), Chloroflexi (0.82%), Acidobacteria (0.62%), Chlorobi (0.51%), Thermotogae (0.50%), Crenarchaeota (0.38%), and Euryarchaeota (0.35%; *Fig. 2A* and *Table 3*). The Proteobacteria were distributed (in descending order) as Betaproteobacteria (19.88%), Alphaproteobacteria (6.41%), Gammaproteobacteria (4.47%) and Deltaproteobacteria (0.57%). Within the Bacteroidetes phylum, Flavobacteriia (17.75%), Sphingobacteriia (7.11%) and Bacteroidia (1.16%) were the most frequently detected. Nostocophycideae (8.70%), Synechococcophycideae (1.55%), and Oscillatoriophycideae (1.24%) were the dominant classes of Cyanobacteria phylum; Actinobacteria (9.73%) and Verrucomicrobiae (1.57%) were the main classes of the Actinobacteria and Verrucomicrobia phyla; the Firmicutes phylum predominantly consisted of the Clostridia (1.20%) and Bacilli classes (1.00%; *Table 3*).

Table 2. *The richness and diversity of the prokaryotic community in Chaohu Lake and its tributaries*

	Site	Number of sequences	No. of OTU (97% identity)	Shannon index

	Average	25291	3289	6.81
Total		296004	39350	

Abbreviations are the same as those in *Table 1*

There was a distinct difference in the distribution of the dominant prokaryotic phyla in Chaohu Lake and its tributaries. For example, Proteobacteria exhibited the highest abundance in all of the collection stations–especially in Nanfei River–while Bacteroidetes abundance was highest in Hangbu River. Furthermore, Chaohu Lake and Zhegao River had high abundances of Cyanobacteria, Nanfei River had a high abundance of Firmicutes, and the middle reaches of Zhegao River (ZGM) had a high abundance of Verrucomicrobia. The upper reaches of Hangbu River (HBU) and upper reaches of Nanfei River (NFU) exhibited lower nutrient levels than the other stations, and also had the lowest abundance of Acidobacteria (*Fig. 2A* and *Table 3*).

Abbreviations are the same as those in *Table 1*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72657281

We identified 924 genera in 12 samples, with 12 dominant genera including *Flavobacterium* (16.60%), *Dolichospermum* (8.62%), *Limnohabitans* (5.57%), *Hydrogenophaga* (4.47%), *Prochlorococcus* (1.49%), *Pseudomonas* (1.04%), and 6 unidentified genera. These 6 identified genera included 3 dominant genera of Proteobacteria, 2 dominant genera of Cyanobacteria, 1 dominant genus of Bacteroidetes (*Table 3*). The changes in CPCs were mainly concentrated in Proteobacteria, Bacteroidetes, and Cyanobacteria.

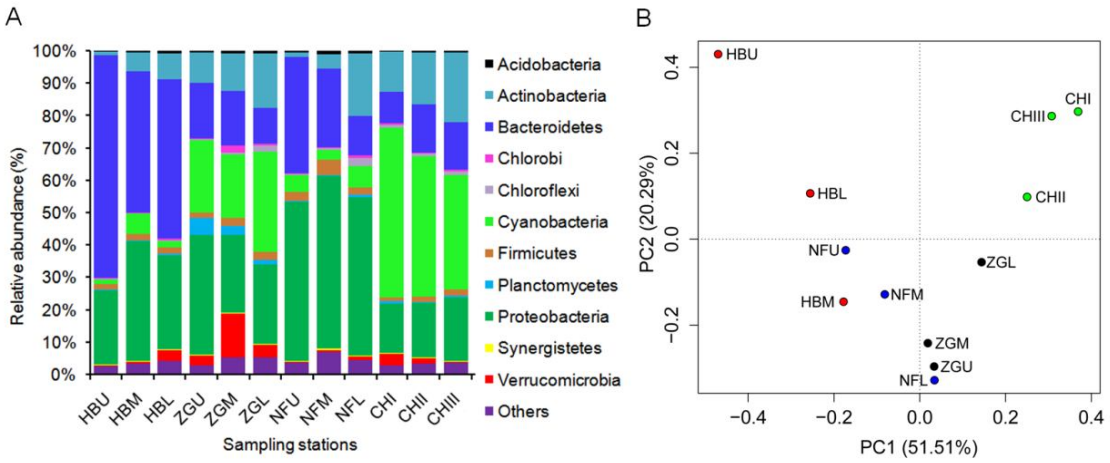

Figure 2. *Relative abundances of dominant phyla (A) and principal coordinate analysis (PCoA) profile (B) of samples. The PCoA profile was drawn based on a weighted UniFrac distance matrix. Abbreviations are the same as those in Table 1*

The results of PCoA showed a strong clustering of samples from Chaohu Lake, and a dispersed distribution among the rivers samples. This likely indicates a higher susceptibility among prokaryotic communities in Chaohu Lake than in the three rivers (*Fig. 2B*). Furthermore, the CPCs in Chaohu Lake were different from those in the three rivers and the spatial change patterns for prokaryotic communities were lake-specific and river-specific. This could imply that CPCs exhibit a high degree of spatial heterogeneity between the lake and the rivers.

Relationship between prokaryotic communities and environmental factors

According to the RDA analyses, 66% of the cumulative variance in the species-environment relationship was explained by the first two RDA axes. Furthermore, following forward selection and the Monte Carlo test, the prokaryotic community showed a significant correlation with the concentration of TP ($p < 0.01$; *Fig. 3* and *Table 4*). For example, among the 13 phyla, Proteobacteria, Actinobacteria, and Firmicutes were primarily affected by the concentration of total phosphorus (TP; $p < 0.05$, $p < 0.05$, $p < 0.05$, respectively). In contrast, Cyanobacteria showed a significant correlation with TN ($p < 0.01$), NH_4 ($p < 0.01$), and NO_3 ($p < 0.05$). Planctomycete showed a correlation with pH ($p < 0.05$), and Thermotogae was generally associated to WT ($p < 0.05$; *Fig. 3* and *Table 4*). Bacteroidetes, Acidobacteria, Chlorobi, Verrucomicrobia, Euryarchaeota, Chloroflexi, and Crenarchaeota exhibited no correlation with the examined physicochemical factors.

Discussion

Prokaryotic community structure characteristics

High-throughput sequencing has been widely used to study differences in prokaryotic communities (Dai et al., 2016; Jordaan and Bezuidenhout, 2016; Liu et al., 2015; Yang et al., 2016). Bao (2008) analyzed the CCBs of Chaohu Lake, using a combination of PCR amplification of 16S rRNA genes and DGGE, and reported that Chaohu Lake had 4 dominant phyla. In the present study, Chaohu Lake prokaryotes were distributed among 13 dominant phyla. Compared with the PCR-DGGE approach, high-throughput sequencing could identify more prokaryotic species, and is thus more suitable for describing prokaryotic community diversity in aquatic systems.

Proteobacteria, Cyanobacteria, Bacteroidetes, Actinobacteria, and Verrucomicrobia are the main prokaryotic phyla in freshwater ecosystems (Ren, 2013). Similarly, our results found Proteobacteria, Cyanobacteria, Bacteroidetes, and Actinobacteria to be the most common prokaryotic phyla of Chaohu Lake and its tributaries–results that are in agreement with those from previous studies (Wu et al., 2007; Dai et al., 2016; Jordaan and Bezuidenhout, 2016). Proteobacteria was the largest prokaryotic phylum of Chaohu Lake and its adjoining rivers, and exhibited high abundances in all samples, especially in Nanfei River, which showed the highest nutrient concentration. Proteobacteria abundance is known to be higher when environmental conditions are poor (Sun et al., 2016) and hence the present study suggests that the water quality of Chaohu Lake and its three tributaries is deteriorating.

Among the Proteoprokaryotic communities, Alphaproteobacteria, Betaproteobacteria, and Gammaproteobacteria dominated–with Betaproteobacteria exhibiting the highest abundance of the three. Betaproteobacteria represent one of the key components of freshwater bacterioplankton and play an important role in freshwater ecosystems (Crump and Hobbie, 2005; Newton et al., 2006; Salcher et al., 2013). *Limnohabitans* and *Hydrogenophaga* were the dominant genera of Betaproteobacteria. *Limnohabitans* belongs to BetI lineage of Betaproteobacteria, is the most abundant type of prokaryotes, and is widely distributed throughout of the world (Ren, 2013). Furthermore, *Limnohabitans* plays an important role in phosphorus cycling in eutrophic water and wastewater, and its distribution includes urban rivers (Jordaan and Bezuidenhout, 2016). The PhoD gene of the genus *Limnohabitans* codes the APase, which promotes the process of eutrophication by increasing the bioavailability of phosphorus (Zhao et al., 2015). Gammaproteobacteria and Alphaproteobacteria, the second and third classes of Proteobacteria, respectively, are found in a variety of aquatic habitats (Crump and Hobbie, 2005; Newton et al., 2011; Liu et al., 2012), but are generally more dominant in marine prokaryotic communities (Biers et al., 2009).

Hangbu River exhibited the highest abundance of Bacteroidetes, the second most abundant phylum. Within the Bacteroidetes, *Flavobacterium* was the most frequently detected genus–results that are consistent with bacterioplankton communities of Taihu Lake (Wu et al., 2007). Due to its algicidal activity and antagonism toward other bacteria, *Flavobacterium* has been associated with harmful algal blooms (Roth et al., 2008). Furthermore, it is often found in high abundance in eutrophic and hypertrophic urban rivers–usually correlating with high nutrient levels (Drury et al., 2013; Jordaan and Bezuidenhout, 2016).

Chaohu Lake and Zhegao River showed the highest abundances of Cyanobacteria, the third most dominant phylum. Cyanobacteria are the oldest known oxygen-producing

DOI: http://dx.doi.org/10.15666/aeer/1704_72657281

organisms on Earth, and are widely distributed in freshwater ecosystems. Furthermore, these organisms are capable of adapting to environmental stresses, such as elevated nutrients (Paerl, 2008) and high temperatures (Briand et al., 2004). In shallow, non-stratified, lakes it has been suggested that the potential for cyanobacteria to dominate is greatest when the water temperature is high and the nutrient load is elevated (Elliot et al., 2006). In the present study, Cyanobacteria comprised four dominant genera: *Dolichospermum*, *Prochlorococcus*, and two unclassified genera. It should be noted that *Dolichospermum* is the most common genus in Cyanobacterial blooms (Liu et al., 2015).

Actinobacteria, the fourth dominant phylum in our study, are globally distributed and are often the most abundant phylum in a variety of freshwater ecosystems (Crump and Hobbie, 2005; Wilhelm et al., 2014). In Lake Taihu, a shallow hypertrophic freshwater lake in China, Actinobacteria are considered to be the most significant lineage (Wu et al., 2007).

Less abundant phylotypes were grouped with the Firmicutes, Verrucomicrobia, Chloroflexi, Planctomycetes, Acidobacteria, Chlorobi, Thermotogae, Crenarchaeota, Euryarchaeota, and unaffiliated. Firmicutes make up a small fraction of the prokaryotic community in some freshwater systems (Eiler and Bertilsson, 2004; Lymperopoulou et al., 2012), and predominantly consist of Gram-positive, rod-shaped, bacteria in the class Bacilli. Most of the species in this class exhibit strong environmental adaptability and can form stress resistant spores. Thus Bacilli play an important biological role in a variety of ecological systems, such as the treatment of industrial wastewater (Song et al., 2015). In this study, the highest abundance of Bacilli was found in the Nanfei River, in which the highest nutrient concentration was recorded. Verrucomicrobia exhibited a low abundance (1–4%) in all of our sample collections. This phylum is widely distributed in rivers and lakes, and its low abundance may be associated with surplus nutrients (Haukka et al., 2006).

There are contradictory reports of Bacteroidetes abundance in the literature. For example, Bacteroidetes have been detected in high frequencies in lakes associated with Cyanobacterial blooms (Eiler and Bertilsson, 2004; Newton et al., 2011). However, this phylum has characteristically been found in association with clear water or mesotrophic lakes (Van der Gucht et al., 2005; McLaughlin et al., 2015). We found that Bacteroidetes were more abundant at sample stations exhibiting relatively low nutrient concentrations. In contrast, Actinobacteria and Cyanobacteria were primarily distributed among stations with high nutrient levels.

The recorded dominance of phylotypes belonging to Bacteroidetes, Betaproteobacteria, Alphaproteobacteria, Cyanobacteria, and Actinobacteria may be the result of the strong eutrophication of Chaohu Lake and its three tributaries. For example, similar results have been recorded for other eutrophic water bodies, and this may indicate a decline in water quality in the near future (Eiler and Bertilsson, 2004; Van Der Gucht et al., 2005; de Figueiredo et al., 2007; Wiedner et al., 2007; Wu et al., 2007). Furthermore, the CPCs is altered with the production of some groups such as Cyanobacteria and Actinobacteria, whose abundances may threaten water quality (Van Der Gucht et al., 2005; de Figueiredo et al., 2007; Wiedner et al., 2007). In the present study, Actinobacteria, Bacteroidetes, Alphaproteobacteria, Cyanobacteria, and Betaproteobacteria were co-dominant in Chaohu Lake and its three tributaries–environments that were characterized as eutrophic or hypereutrophic.

Environmental effects on prokaryotic community

The nutrient content of waterbodies has a significant impact on the diversity of prokaryotes (Lindström, 2000; Yan et al., 2017). Our RDA analysis showed that the prokaryotic communities and 3 prokaryotic phyla–including Proteobacteria, Actinobacteria, and Firmicutes–were significantly associated with TP. Furthermore, Cyanobacteria showed a significant correlation with TN, NH_4, and NO_3. These findings are consistent with those of previous studies (Liu et al., 2011; Zhang et al., 2012; Niu et al., 2015; Wang et al., 2015). Of the measured explanatory variables, phosphorus and nitrogen were shown to have the greatest effect on CPCs, and this result may hold the greatest significance for the management of nature reserves. Specifically, understanding how phosphorus and nitrogen affect CPCs could aid in the search for new strategies to combat the degradation of freshwater ecosystems due to anthropogenic pollution.

Previous research has shown prokaryotic diversity to increase with elevated nutrient levels (Feng et al., 2007; Pang et al., 2014). However, other studies have found prokaryotic community diversity to significant decrease with the increase of freshwater nutrients (Van der Gucht et al., 2005; McLaughlin et al., 2015). Compared with the Zhegao and Hangbu Rivers, Nanfei River and Chaohu Lake had higher nutrient levels, and lower prokaryotic diversity. Our results have shown a link between higher waterbody nutrients and lower prokaryotic diversity. Microorganisms that can use and/or survive in the presence of pollutants often dominate contaminated ecosystems. As the result, the diversity of microbial communities is less than that of non-contaminated systems (McLaughlin et al., 2015). Van der Gucht et al. (2005) indicated that, as a result of the disappearance of submerged macrophyte stands, this transition is associated with a loss of structural diversity and, consequently, a decrease in biodiversity at higher trophic levels.

Our RDA results indicate that pH is correlated with Planctomycetes, this result is consistent with those of Ren et al. (2015), who observed that pH was the strongest determinant of both overall bacterioplankton community composition and the composition of abundant bacterioplankton groups. Previous literature has shown that water temperature can affect freshwater bacterioplankton communities (Adams et al., 2010; de Figueiredo et al., 2010; Zhang et al., 2012; Jordaan and Bezuidenhout, 2016). We observed that water temperature (WT) is generally associated with Thermotogae. Hence, this study suggests that pH and water temperature may play crucial roles in shaping bacterioplankton community structure in freshwater lakes and rivers.

Conclusions

In this study, CPCs were characterized using high-throughput sequencing and the relationship between CPCs and environment factors was explored in Chaohu Lake and its three urban tributaries. Our results indicated that elevated nutrients, pH, and water temperature may be the primary environmental controllers of the variation in CPCs in Chaohu Lake and its three tributaries. Furthermore, we found that the variation of CPCs was influenced by anthropogenic perturbations–eutrophication processes that are continuing to increase within the Chaohu Lake watershed. Ultimately, these results add to our growing understanding of the ecology of CPCs in Chaohu Lake and its tributaries, and may offer crucial ecological background data for the development of management plans for this important urban freshwater system.

Abstract. The paper comprehensively considers the interaction and balance between urban construction and protection of water ecology, breaks through the original concept of water protection, and formulates the planning concept of "balanced construction". In terms of planning strategy, a diversified strategy integrating empirical sampling, software simulation and an evaluation system is applied to realize the dynamic monitoring of urban construction and protection of water ecology. Firstly, the basis of water environment analysis is laid by collecting and analyzing current water samples. Secondly, the water quality and flow field are simulated and analyzed by DHI Mike 21 simulation software, which provides a basis for the planning of the surrounding water system. Thirdly, based on the calculation of water pollution capacity and future planning pollution load, the key factors affecting water quality are identified, and the urban land use planning model based on the concept of "balanced construction" is completed. Finally, the comprehensive evaluation index system of ecological water health is established to realize the objective evaluation of the balance between protection of water ecology and urban construction.
Keywords: *quantitative analysis of water, dynamic equilibrium, software simulation, indicator evaluation system, protection of water ecology, rapid urban development, DHI Mike 21*

Introduction

As a prerequisite to the development of civilization and the basis of human existence, water is of great importance to urban construction and development. There are numerous recordings of famous cities belonging to early human civilizations being built near water sources. Overall, the world is still in the process of rapid urbanization, especially in most developing countries. According to the forecast of the United Nations, by 2050, 6.7 billion people will live in cities, accounting for 68% of the total population, which is an increase of about 13% over the current proportion (United Nations, 2018). Significant changes have taken place during urbanization, including the fact that impervious materials such as asphalt and concrete have replaced soil; buildings have replaced forests; rainwater pipelines have replaced natural runoff. Urbanization has dramatically changed the original natural hydrological environment (Jacobson, 2011). While changing rainwater runoff, water pollution caused by urban development has become an important issue that cannot be ignored, especially in highly sensitive areas of water ecology.

In recent years, many cities have suffered from waterlogging disasters. Apart from the bad weather caused by climate and environmental changes, the built environment of the city itself is also one of the essential reasons. It is estimated that about 85% of precipitations becomes the runoff of completely hardened roads or roofs in urban areas,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72837299

and another 15% is intercepted by streets, buildings, roofs or walls and other paved or gentle slope surfaces (Lull and Sopper, 1969; Hough, 2004). This not only leads to floods and erosion, but also reduces water quality. Meanwhile, rainwater resources are not effectively utilized, which is also one of the reasons of water shortage in some cities. Moreover, the impact of urbanization on water quality is shocking. The lack of supervision on pollutant discharge, the failure of discharge standards, the inadequate control of urban non-point source pollution, and the mixing of rainwater and sewage have caused severe pollution of urban surface water resources, including lakes and rivers. Facing such urban water environment problems, various countries have put forward diversified strategies, mainly including Low Impact Development (LID) in America (Pyke et al., 2011), Water Sensitive Urban Design (WSUD) in Australia (Morison and Brown, 2011), Sponge City in China (Chan et al., 2018), Sustainable Urban Drainage System (SuDs) (Griffiths, 2017; Mitchell, 2005) and Blue-Green Cities (BGCs) (Thorne et al., 2015) in England, Low Impact Urban Design and Development (LIDUD) in New Zealand (Voyde et al., 2010). The purpose of these strategies is to enhance the city's ability to deal with water environmental problems and enhance the overall utilization efficiency of water resources through planning strategies and engineering measures. According to the current similar development concepts, resilient cities (RC) mainly focus on the coping strategies and flexibility of cities when facing uncertainties, especially climate change (Meerow et al., 2016). In terms of overall development strategy, the International Symposium on Ecological Wisdom of Urban Sustainable Development held in Chongqing, China, in October 2014, focused on the ecological wisdom presented in urban development and construction (Xiang, 2014; Wang and Xiang, 2016), which provided a strategic reference for exploring the direction of urban construction in water-ecologically sensitive areas.

As an essential ecological and habitat bearing space of cities, highly sensitive areas of water ecology are also facing the intrusion of urban construction under the background of rapid urbanization. The solution to deal with the relationship between urban construction and ecological protection; positive measures to reduce the damage and interference of the urbanization process on the natural environment and a balance between urban construction and protection of water ecology are all important issues that cannot be avoided in the development of cities in highly sensitive areas of water ecology. Based on the summary of the current development model of water ecology in highly sensitive areas, it is found that there are two different tendencies in the current planning strategy. One is to emphasize the importance of water ecology protection while ignoring the actual needs of urban development. The other is to overemphasize the economic benefits of urban development while ignoring the protection of water ecology, thus causing severe damage to the natural ecological environment. Therefore, the two tendencies both have some defects in the actual development of cities. Therefore, it can be concluded that the current model is more from a single perspective to examine the future development scenarios of highly sensitive areas of water ecology, but lacks comprehensive, holistic, top-down planning and thinking.

On this basis, the authors put forward the idea of “balanced construction” in highly sensitive areas of water ecology, which takes into account the two-way value of environmental protection and urban development, to seek the balance between urban construction and ecological protection. Specifically, it can be divided into the following aspects:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72837299

(1) The balance between dynamic development and static protection

The development of a city is a dynamic process, on which different times background, development direction and decision-making ideas will have a significant impact, while ecological protection is a relatively stable state. The balance between dynamic development and static protection through corresponding planning measures is the development basis of "balanced construction" in highly sensitive areas of water ecology.

(2) The balance between ecological benefit and economic benefit

The development of a city is a process of maximizing the comprehensive benefits of economy, society, culture and ecology. Ecological benefits are the basis and starting point of urban construction in highly sensitive areas of water ecology, but comprehensive benefits are the ultimate goal of urban construction. In urban construction, we should abandon the original idea of mechanical protection and pursue the maximization of comprehensive benefits. Urban construction and ecological protection are not entirely opposed to each other. By taking appropriate planning measures, urban construction can effectively promote ecological protection and achieve the balance between ecological benefits and economic benefits.

(3) The balance between natural environment and urban landscape

Urbanization has resulted in the fragmentation of natural ecological environment and landscape. As a heterogeneous factor, the method that helps urban landscape be more actively integrated into the natural environment is worth exploring. The continuity of natural ecological environment can be ensured by setting ecological patches, corridors and springboards. At the same time, the overall style, height and volume of the urban construction area are controlled and guided to maximize the balance between the natural environment and the urban landscape.

(4) The balance between ecological conservation and land use function

Based on ecology, a barrier has been established for urban construction. Negative list and other planning measures can be utilized to support urban development and construction in highly sensitive areas of water ecology. On the premise of ecological conservation, the central planning principles of urban industry selection, land use function layout and spatial structure form are defined to achieve the balance between ecological conservation and urban land use function.

(5) The balance between environmental capacity and the quantity of development and construction

The capacity of the natural environment is limited, and the restriction of environmental capacity is more stringent in highly sensitive areas of water ecology. Sustainable development cities are built on the basis of holding the restriction of limited capacity and seeking reasonable and moderate development and construction, and it needs rational planning for urban development mode and the total amount of development and construction, so as to achieve the balance between environmental capacity and development and construction quantity.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72837299

While defining the planning concept, we should use corresponding planning strategies to achieve rational planning objectives. In order to realize the dynamic monitoring of urban construction and protection of water ecology, a diversified strategy of integrating empirical sampling, software simulation and evaluation system was constructed. On the basis of breaking through the original framework of mechanical protection of water ecological environment, this paper puts forward the planning concept of "balanced construction" between urban construction and water ecological health, which provides a new way of thinking for the development and construction of highly sensitive areas of water ecology. Therefore, this investigation aims to find out a method to monitor the dynamic mechanism of urban construction and water protection by utilizing the quantitative analysis of water ecology in the context of rapid urbanization. Moreover, based on this method, this investigation can achieve the dynamic balance between protection of water ecology and rapid urban development. It can also provide a reference for urbanization of water sensitive areas in other fast-growing regions of the world.

Materials and methods

Research framework

Under the guidance of the planning concept of "balanced construction", by taking the measures of mountain and water resources protection, water body ecological control, natural ecological environment conservation, ecological purification measures, ecological corridor control, urban construction guidance, urban landscape shaping, and evaluation index system construction, it is critical to adhere to the principle of protection of water ecology and build the ecological background of regional development. At the same time, it is necessary to actively guide urban development and construction, attach importance to and meet the actual needs of urban development on the basis of ecological protection, seek a sufficient balance between urban construction and protection of water ecology, and obtain the comprehensive optimal solution of economic, social, cultural and ecological benefits (Kiss and Kiss, 2018; Ahern, 2011).

In terms of research process, firstly, through collecting and analyzing the current water samples, the foundation of water environment analysis is laid, and the main focus of water ecological control is clarified. Secondly, DHI Mike 21 simulation software is used to simulate the water quality and flow field, which provides a basis for the planning of surrounding water system and guidance for the spatial layout of green and blue infrastructure. Thirdly, based on the calculation of water pollution capacity and future planning pollution load, the key factors affecting water quality are clarified, the urban land use planning model based on the concept of "balanced construction" is constructed, and the requirements of urban construction scale, spatial layout structure and urban dominant function are put forward. Finally, the comprehensive evaluation index system of water ecological health is established to realize the objective and dynamic evaluation of the balance between protection of water ecology and urban construction.

Step 1: Water environment and ecological investigation

The highly sensitive areas of water ecology have the superior ecological background and abundant habitat communities, and in the tide of urbanization, both water

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72837299

environment and natural ecology will be challenged severely. Seeking the path of balanced development of urban construction and protection of water ecology must be based on a thorough grasp of the current situation, including water environment, ecological resources, ecological community, water flow direction, water depth, control objectives and so on. Through collecting and analyzing the current water environment and ecological situation, the database of follow-up research and analysis is laid, and the criteria and key points of future water ecological control are defined in combination with the goal orientation, which provides the basis and support for the later urban spatial layout and the location of ecological facilities.

The investigation methods are mainly on-site survey and water sampling analysis, supplemented by literature review. Firstly, according to the judgment of the water shape and the relationship between the water body and the surrounding water body, the spot water quality sampling points are determined, and the water samples will be uniformly collected on the spot in good weather. The main purpose of field sampling is to acquire the current characteristics of a diversified water environment, to grasp the water environment and ecological situation in an all-around way. Therefore, the principle of sampling point setting is to select the heterogeneous water environment samples as many as possible and emphasize the uniqueness and representativeness of samples to ensure the comprehensiveness and integrity of water environment and ecological survey. The concentration of pollutants such as COD, TN, NH_3-N, TP and dissolved oxygen (DO) in water samples are measured. DO is measured on the spot by portable dissolved oxygen meter on the day of sampling, so as to grasp the pollutants in different locations and development environments of the current water body, and help to apply targeted planning strategies.

Step 2: Simulation analysis of water flow distribution and quality via MIKE 21 software

Based on the collection and analysis of water samples in the present, pollutant sources and types that need emphatically solving are determined during the city construction period and the computer simulation analysis of water flow distribution and quality is finished via DHI MIKE 21 software. The analysis and simulation not only help to confirm the potential blind spots and stagnant zones during the water circulation and water flow under the overall conditions such as the specific form of water and coastline layout, but also provide research support for the future urban space planning, coastline optimizing and water ecological facilities distributing.

The simulated results have important reference to water circulation optimization, water form, coastline setting and others since DHI Mike 21, the two-dimensional mathematical model developed by Denmark Hydra Institution, has been widely applied in water simulation and it has strong functions on the simulation of two-dimensional fluid data with a free-surface (Xu et al., 2012; Thompson et al., 2004; Devi et al., 2015).

Model equations of water flow distribution

The control equation of DHI MIKE 21 simulation software is the Navier-Stokes equation that is incompressible in three dimensions, enjoys uniformly distributed Reynolds values and complies with the Boussinesq assumption and hydrostatic pressure (Danish Hydraulic Institute (DHI), 2012). In the numerical calculation aspect, Finite Volume Method, which divides continuum into non-superposed units (the units uses the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72837299

triangle mesh) is utilized to solve the spatial dispersion and model resolution of the computational area. In addition, the two-dimensional shallow water equation set can be expressed as follows (*Eqs. 1-3*):

$$\frac{\partial h}{\partial t}+\frac{\partial h\bar{u}}{\partial x}+\frac{\partial h\bar{v}}{\partial y}=hS \quad \text{(Eq.1)}$$

$$\frac{\partial h\bar{u}}{\partial t}+\frac{\partial h\bar{u}^2}{\partial x}+\frac{\partial h\bar{u}\bar{v}}{\partial y}=f\bar{v}h-gh\frac{\partial \eta}{\partial x}-\frac{h}{\rho_0}\frac{\partial p_a}{\partial x}-\frac{gh^2}{2\rho_0}\frac{\partial \rho}{\partial x}+\frac{\tau_{sx}}{\rho_0}-\frac{\tau_{bx}}{\rho_0}-\frac{1}{\rho_0}\left(\frac{\partial s_{xx}}{\partial x}+\frac{\partial s_{xy}}{\partial y}\right)+\frac{\partial}{\partial x}(hT_{xx})+\frac{\partial}{\partial y}(hT_{xy})+hu_sS \quad \text{(Eq.2)}$$

$$\frac{\partial h\bar{v}}{\partial t}+\frac{\partial h\bar{u}\bar{v}}{\partial x}+\frac{\partial h\bar{v}^2}{\partial y}=-f\bar{u}h-gh\frac{\partial \eta}{\partial y}-\frac{h}{\rho_0}\frac{\partial p_a}{\partial y}-\frac{gh^2}{2\rho_0}\frac{\partial \rho}{\partial y}+\frac{\tau_{sy}}{\rho_0}-\frac{\tau_{by}}{\rho_0}-\frac{1}{\rho_0}\left(\frac{\partial s_{yx}}{\partial x}+\frac{\partial s_{yy}}{\partial y}\right)+\frac{\partial}{\partial x}(hT_{xy})+\frac{\partial}{\partial y}(hT_{yy})+hv_sS \quad \text{(Eq.3)}$$

where t is the time. x,y is the coordinates of Cartesian coordinate system. η is the water level. d is the still depth of water. $h=\eta+d$ represents the total depth of water. u and v are the velocity components in x and y direction respectively. f is the coefficient of Coriolis force. In the $f=2\omega\sin\varphi$, ω represents rotational angular velocity of the earth and φ represents local latitude. g is the gravity acceleration. ρ is the density of water. s_{xx}, s_{xy} and s_{yy} are radiation stresses component. S is the source item. (u_s,v_s) represents water velocity of source item.

The letter with a line above represents average value. For instance, $\bar{u}$ and $\bar{v}$ is average water velocity along the water depth, which is defined as follows (*Eq. 4*):

$$h\bar{u}=\int_{-d}^{\eta}udz,\quad h\bar{v}=\int_{-d}^{\eta}vdz \quad \text{(Eq.4)}$$

T_{ij} is horizontal vibration stress term, including viscous force, turbulent stress and advection, and the calculation can be expressed as (*Eq. 5*):

$$T_{xx}=2A\frac{\partial\bar{u}}{\partial x},\quad T_{xy}=A(\frac{\partial\bar{u}}{\partial y}+\frac{\partial\bar{v}}{\partial x}),\quad T_{yy}=2A\frac{\partial\bar{v}}{\partial y} \quad \text{(Eq.5)}$$

Model equations of water quality

Based on the existing results, basic parameters of water quality collected from water simulation and surrounding out and in river are acquired by combining flow-field simulation and collected data of water samples as well as referring to recent water monitoring data. The simulation and analysis on the content of each pollutant that the future water could bear and special distribution of pollution are finished and the relative solutions are proposed based on the results.

2-d water quality simulation mainly uses ECO Lab software and HD Integrated Computing of MIKE 21. DO, which has significantly affected the water quality, TN, TP and other pollutants, should be focused continuously. Eutrophication Module (EU) mainly describes water oxygen dissolved state and nutrient recycling (*Eq. 6*).

$$\frac{\partial C}{\partial t}+u\frac{\partial C}{\partial x}+v\frac{\partial C}{\partial y}+w\frac{\partial C}{\partial z}=D_x\frac{\partial^2 C}{\partial x^2}+D_y\frac{\partial^2 C}{\partial y^2}+D_z\frac{\partial^2 C}{\partial z^2}+S_c+P_c \quad \text{(Eq.6)}$$

where C is the concentration of water quality index; u, v, w are the water velocity components in x, y and z direction respectively; S_c is the source sink term; P_c is the ecological process.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72837299

Step 3: Calculation and analysis of assimilative capacity and pollution load

The hydrological conditions in the natural areas are changed due to the progress of urbanization and new pollutants are generated due to city development and construction as well as human activities. Overall, the polluted sources are the city-polluted water (point source pollution) that directly discharged to surrounding waters and the non-point source pollution brought by surrounding water in the city. However, with the improving facilities of city and upgrading planning and monitoring level, the negative influence of point source pollution has been controlled effectively. The non-point source has more noticeable effect on the local water environment, which continuously becomes the focus of water pollutant control in water sensitive area.

Calculation of assimilative capacity

Usually, lake and reservoir are regarded as completely homogeneous mixing water quality model to estimate the long-term dynamic change of water quality. When being steady, the environmental capacity model could be calculated via a water balance equation as shown in *Equation 7*.

$$V(t)\frac{dc}{dt} = Q_{in}(t) \times C_{in}(t) - Q_{out}(t) \times C_{out}(t) + S_c + kV(t)C \quad \text{(Eq.7)}$$

where V(t) is the water yield of time t (m^3). dc/dt is the change rate of the parameters such as COD and ammonia. Qin (t) is the input water yield (m^3/a) at time t. Qout (t) is the output water yield (m^3/a) at time t. Cin (t) is the input concentration (mg/L) at time t. Cout (t) is the output concentration (mg/L) at time t. C(t) is the lake concentration (mg/L) at time t. Sc is the external polluted content. k is the comprehensive degradation coefficient of COD and ammonia.

Without considering the mixing area, when the demand mass concentration is Cs in the water functional zone of lake and reservoir, the equation of their environmental capacity can be expressed as follows (*Eq. 8*):

$$W_{capacity} = 31.54 \times (QC_s + KC_sV \div 86400) \quad \text{(Eq.8)}$$

where $W_{capacity}$ is the environmental capacity (t/a); Cs is the target value of water quality (mg/L); Q is the input and output water yield at steady state; k is the comprehensive degradation coefficient of COD and ammonia; V is the water volume in lake and reservoir (m^3).

Step 3: Calculation and analysis of assimilative capacity and pollution load

The hydrological conditions in the natural areas are changed due to the progress of urbanization and new pollutants are generated due to city development and construction as well as human activities. Overall, the polluted sources are the city-polluted water (point source pollution) that directly discharged to surrounding waters and the non-point source pollution brought by surrounding water in the city. However, with the improving facilities of city and upgrading planning and monitoring level, the negative influence of point source pollution has been controlled effectively. The non-point source has more noticeable effect on the local water environment, which continuously becomes the focus of water pollutant control in water sensitive area.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72837299

Calculation of assimilative capacity

Usually, lake and reservoir are regarded as completely homogeneous mixing water quality model to estimate the long-term dynamic change of water quality. When being steady, the environmental capacity model could be calculated via a water balance equation as shown in *Equation 7*.

$$V(t)\frac{dc}{dt} = Q_{in}(t) \times C_{in}(t) - Q_{out}(t) \times C_{out}(t) + S_c + kV(t)C \quad \text{(Eq.7)}$$

where V(t) is the water yield of time t (m^3). dc/dt is the change rate of the parameters such as COD and ammonia. Qin (t) is the input water yield (m^3/a) at time t. Qout (t) is the output water yield (m^3/a) at time t. Cin (t) is the input concentration (mg/L) at time t. Cout (t) is the output concentration (mg/L) at time t. C(t) is the lake concentration (mg/L) at time t. Sc is the external polluted content. k is the comprehensive degradation coefficient of COD and ammonia.

Without considering the mixing area, when the demand mass concentration is Cs in the water functional zone of lake and reservoir, the equation of their environmental capacity can be expressed as follows (*Eq. 8*):

$$W_{capacity} = 31.54 \times (QC_s + KC_sV \div 86400) \quad \text{(Eq.8)}$$

where $W_{capacity}$ is the environmental capacity (t/a); Cs is the target value of water quality (mg/L); Q is the input and output water yield at steady state; k is the comprehensive degradation coefficient of COD and ammonia; V is the water volume in lake and reservoir (m^3).

Calculation of pollution load

The water pollutant mainly comes from point source pollution and non-point source pollution. When calculating pollution load, one premise needs to be confirmed, that is, pollution load should focus more on the effect of non-point source pollution when the point source pollution of city is controlled effectively. The capacity of non-point source pollution in different land use is different. The dynamic relationship between pollution load produced in city construction and pollutant carrying capacity of water is explicated in different developing states and situations via analyzing and calculating the current and future urban land, thus adjusting, analyzing and checking the direction of city construction as well as constructing the foundation of balanced construction theory.

Firstly, the terrain features and the situation of city construction in water sensitive area are concluded. After confirming the water catchment regionalization via GIS and other analyzing tools, it is known that the regionalization includes direct water catchment area (overland runoff directly flows into main water body, getting through overland flow, concentration of channel flow and others) and indirect water catchment. Then, the construction situations of water catchment regionalization are classified by mathematical statistics method, thus calculating non-point source pollution load caused by different land types.

The land types for non-point source pollution load calculating in water catchment regionalization mainly includes residential, commercial, cultural, educational, industrial, scientific, road and entertainment, etc. The composite output coefficient of COD, TN and TP are 320 kg/(ha.a), 40 kg/(ha.a) and 7.0 kg/(ha.a) via weighted

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72837299

calculation after confirming the non-point source pollution load through relative experience numbers (Qi, 2005; Li, 2000).

In the water highly sensitive area, with the target of collecting and solving point source pollution, planning drainage pipe network of polluted water and constructing sewage treatment infrastructure could guarantee the effective solution of polluted water. At the same time, protective greenbelt, sponge facilities, constructed wetlands and others could assist intercepting and purifying non-point source pollutant generated by runoff water, thus making sure that the pollution load of the non-point source is smaller than the assimilative capacity of the main water body.

Step 4: Construction of a diagnostic indicator system for water ecosystem health

Diagnostic sand table for water ecosystem health

Based on "balanced construction" logos, the diagnostic indicator system for water ecosystem health is constructed, whose aim is to construct the evaluating trend and ideal sand table for water ecosystem. By dynamic monitor and adjustment based on water ecosystem and city construction, the objective evaluation concerning water ecosystem protection and balanced city construction is realized. This evaluating system is divided into rule hierarchy including water quality characteristic, hydrological characteristics, physical shape structure, ecosystem indicators, lake landscape, and marker bed which fractionalizes and dismantles the rule hierarchy, finally forming evaluating indicator system including two tiers, five types and seventeen subclasses (*Table 1*).

Table 1. *Diagnostic indicator system for water ecosystem health*

Rule hierarchy	Marker bed	Quantitative criteria
Water quality characteristic B1	Nemerow multi-factor index method (C11)	COD, NH_3-N, TN, TP
	Nutritional index (C12)	TLI
	Dissolve oxygen (C13)	DO
Hydrological characteristics B2	The lowest ecological water level satisfied state (C21)	The lowest ecological water level satisfied rate
	Water exchanging cycle period (C22)	Water exchanging cycle period
Physical shape structure B3	Lake basin stability (C31)	Stable degree of lake basin
	Lakeshore stability (C32)	Stable degree of lakeshore
	Vegetation integrity (C33)	Vegetation coverage
	Form of coastline and revetment (C34)	Hardening rate of slope
Ecosystem indicators B4	Green belt vegetation coverage (C41)	Coverage of shore side buffer, barrier and island
	Diversity of phytoplankton (C42)	Diversity of plankton
	Conservation rate of indigenous plant (C43)	Proportion of indigenous plant
	Proportion of natural surface (C44)	Proportion of natural surface
	Quality index of habitat (C45)	Diversity index of water habitats
Lake landscape B5	Aesthetic measure (C51)	Aesthetic measure
	Accessibility of landscape (C52)	Accessible degree of landscape
	Width of green belt in lakeside (C53)	Lake greening rate

The city construction in water highly sensitive should obey balance construction planning theory, seeking the balance between city construction and ecological protection. Moreover, the control of the ecological quality of water body has become

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72837299

the ecological basis of city development, especially the development of water sensitive area. By diversified city construction management and purification treatment measures, the focus of water ecosystem control is put into water quality conservation. It guarantees the quality of water body and fully plays the role of the water body, thus producing comprehensive profits in ecology, landscape, society, economy. Therefore, when constructing evaluating indicator system which synthetically and roundly reflects multiple values of water ecosystem sensitive area, it is necessary to fully consider the influence of city construction, ecology conservation, function constitute and other factors, take ecological protection as background and regards city construction as extension.

Weight of evaluation indicator for water ecological health

For water quality characteristic, hydrological characteristics, physical shape, biological state and landscape aesthetics, judgment matrix as shown in *Table 2* is established based on a 1-9 scale norm.

Table 2. *Judgment matrix of marker bed*

	Water quality characteristic	**Hydrological characteristics**	**Physical shape structure**	**Biological state**	**Landscape aesthetics**
Water quality characteristic	1	3	5	2	5
Hydrological characteristics	0.33	1	3	0.5	2
Physical shape structure	0.2	0.33	1	0.33	1
Biological state	0.5	2	3	1	4
Landscape aesthetics	0.2	0.5	1	0.25	1

By calculating and judging the max eigenvalue and relevant feature vector of the matrix, the obtained weight of rule hierarchy relative to the overall goal $w = [0.43\ 0.16\ 0.07\ 0.26\ 0.08]$, CI = 0.013, RI = 1.12, CR = 0.0117 < 0.1 obtains consistency checks. For rule hierarchy of water quality characteristic, the judgment matrix is established as shown in *Table 3*.

Table 3. *Judgment matrix of water quality indicator*

Indicator	**Nemerow multi-factor index**	**Trophic status index**	**Dissolve oxygen**
Nemerow multi-factor index	1	3	5
Trophic status index	0.33	1	3
Dissolve oxygen	0.2	0.33	1

Compared with the rule hierarchy of water quality characteristic, the weights of Nemerow multi-factor index, trophic status index, and dissolved oxygen are $w_1 = [0.64\ 0.26\ 0.1]$, respectively. Similarly, the weights of the rest marker beds are $w_2 = [0.75\ 0.25]$, $w_3 = [0.25\ 0.25\ 0.25\ 0.25]$, $w_4 = [0.09\ 0.06\ 0.07\ 0.39\ 0.39]$, $w_5 = [0.33\ 0.33\ 0.33]$. According to the index system of Lake Ecosystem health risk

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72837299

assessment integrated from top to bottom and combined with the weight of each index, the comprehensive index of Lake Ecosystem health risk assessment is as follows (*Eq. 9*):

$$EHRI = \sum_{i=1}^{n} w_i I_i \quad \text{(Eq.9)}$$

In the equation, EHRI is the comprehensive index of lake healthy risk assessment. w_i is the weight of the evaluation index and I_i is the result of the evaluation index. Referring to the relevant standards of lake health research at home and abroad, we can divide the lake healthy risk assessment level into five levels: excellent, good, medium, poor and very poor, as shown in *Table 4*.

Table 4. *Level division of lake ecological health risk evaluation*

Level	*EHRI*	Health risk status
I	4	Excellent
II	3	Good
III	2	Medium
IV	1	Poor

Results: case study of Xianghu Lake

We applied this method to the actual urban planning practice to test the operability of the method. We apply it in the urban planning of the Xianghu area in Hangzhou. The site of planning practice is located on the eastern coast of China, Hangzhou, Zhejiang Province. The geographical coordinates of Hangzhou are 118°21′-120°30′ east longitude and 29°11′-30°33′ north latitude. It is one of the critical central cities in the Yangtze River Delta region of eastern China. In 2018, the urban population was about 9.8 million. The rapid development of the urban economy and the concentration of the urban population have also caused a dramatic expansion of urban space.

The Xianghu area is located in the northeast of Hangzhou, which is adjacent to the Qiantang River (*Fig. 1*). As a backup water source for urban development, its water body has higher ecological sensitivity and protection requirements. In addition, the landscape resources in the area are one of the critical parts of the urban habitat core. In recent years, with the rapid development of urbanization taking tourism industry as an engine, Xianghu region is gradually being incorporated into a series of built-up areas. Therefore, Xianghu Lake is facing tremendous pressure of urban development and construction. How to protect the natural ecological background and landscape characteristics of Xianghu Lake under the premise of ensuring the city's rapid development and its gradually improving function? How to seek the balance between urban development and ecological environment protection? How to place the fast-growing city in the superior natural ecological environment? These problems deserve our attention.

(1) Results of current water quality sampling analysis

At present, the catchment area of Xianghu Lake is about 10.6 km^2, the water area is 3.2 km^2, and the total water storage capacity is 13.5 million m^3. With the expansion of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72837299

the lake in the future, the water of Qiantang River will be introduced into the lake. The total water area of Xianghu Lake can exceed 6 km^2. The water storage capacity can reach 23 million cubic meters. According to the relationship between the shape of Xianghu Lake and the surrounding water bodies, a total of 16 water sampling points were set up for sampling and analysis, including 12 points in the water of Xianghu Lake (*Fig. 2*), 3 points in surrounding rivers, and one sampling point in Qiantang River. On December 16, 2017, the water samples were collected on site and brought back to the Southeast University Environmental Laboratory for testing and analysis. The DO was tested by a portable dissolved oxygen meter. The temperature on the day of sampling was 4~15 °C, and the weather was fine.

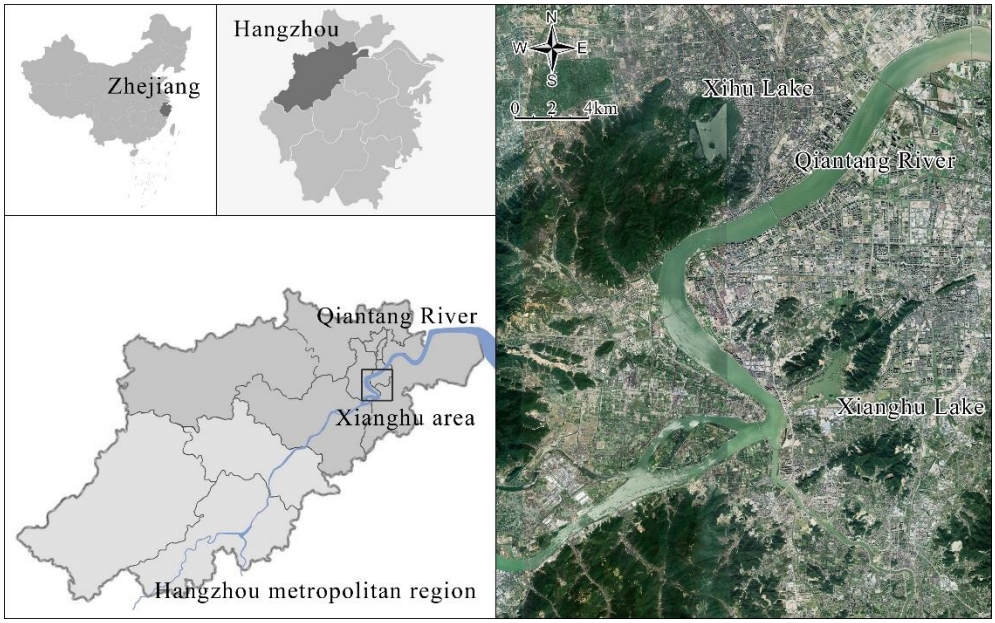

Figure 1. *Location of Xianghu Lake*

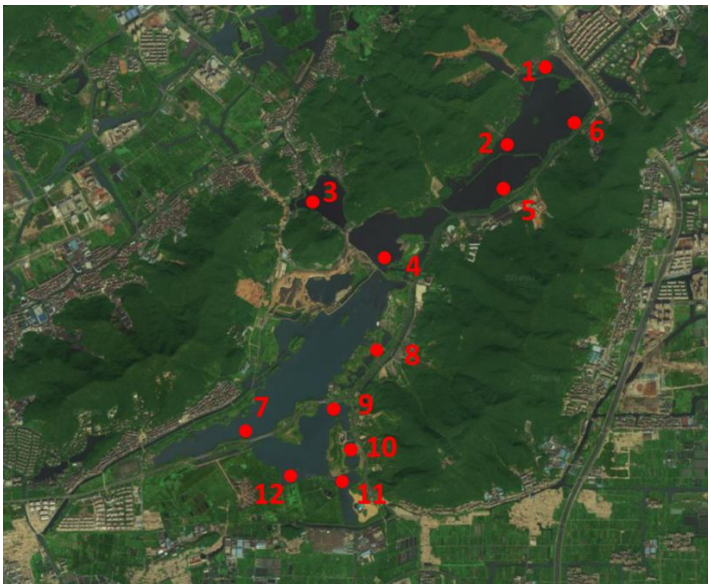

Figure 2. *Water quality sampling point of Xianghu Lake*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72837299

Through experimental analysis of sample water collected on field, the water quality of Xianghu Lake is IV or V (GB3838-2002) according to the single factor evaluation method. Compared with the set water quality target of Class III, the main factor that exceeds the standard is TN. Therefore, controlling TN concentration is the primary way to improve the water quality of Xianghu Lake. The water quality of nearby rivers is IV or V. The main pollutant factors are COD_{Mn} and ammonia nitrogen. The water quality of rural rivers is better than that of urban rivers, and urban built-up areas have a significant impact on the water quality of rivers. Ensuring sufficient width of ecological corridor is also one of the measures to reduce the impact of water quality.

(2) Results of Mike 21 flow field and water quality simulation

The water flow field plays an active role in improving water purification capacity and environmental capacity. Through the simulation with DHI Mike 21, the critical areas of Xianghu Lake featured with slow flow, vulnerable to pollution and eutrophication are identified. The external running water from the Qiantang River is introduced to enhance the water cycle of Xianghu Lake (*Fig. 3*). Measures are taken including setting up ecological wetlands, increasing the width of ecological corridors, planting purified aquatic plants, and controlling the inflow of pollution sources to enhance the self-purification capacity of the water body in the region, which can greatly meet the needs of urbanization development and construction, enhance nearby construction capacity and raise the threshold of "balanced construction" under the premise of ensuring ecological priority.

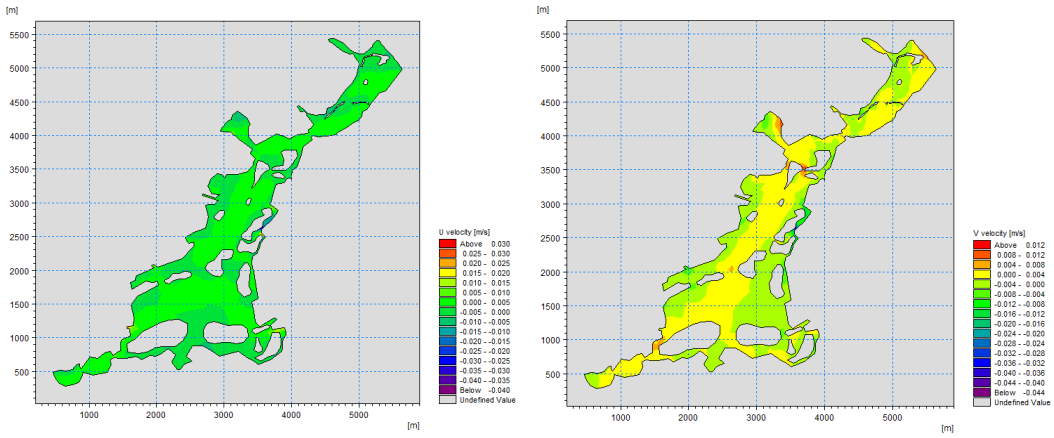

Figure 3. *Simulated distribution of X (left) and Y (right) directional velocity of Xianghu Lake with introduce of running water of Qiangtang River*

(3) Comparisons between pollution capacity and pollution load

The capacity of Xianghu water body to absorb pollutants directly affects the scale of urban development and construction. After clarifying the significant influence of non-point source pollution on the water quality conservation of Xianghu Lake, the authors optimized the proportion of land use and the division of spatial groups in the planning scheme by calculating the non-point source pollution load od the planning land use scheme and comparing with the capacity of Xianghu water body to absorb pollutants

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72837299

horizontally. Through many times of adjustments, analyses and checks, the interaction and balance between the layout of planned land and water ecology have been achieved.

(4) Calculation of ecological health evaluation index of Xianghu Lake

Through calculation of current ecological health evaluation index of Xianghu Lake, the health status of it can be reflected as feedback to urban development and construction in order to seek a dynamic balance between protection and construction. The weight of the health evaluation index reflects the importance of each index in the health system of Xianghu Lake. The weight of water quality index and ecosystem index is larger, 0.43 and 0.26, respectively, followed by hydrological characteristics, which is consistent with the status of Xianghu Lake as an important backup water source and habitat core of the city. The specific calculation process is shown in *Table 5*. The final calculation result is 2.95, indicating the current health evaluation level of Xianghu Lake is good.

Table 5. *The weight and assignment of health evaluation index of Xianghu Lake in 2018*

Rule hierarchy	Weight	Marker bed	Weight	Assignment
Water quality characteristic B1	0.43	Nemerow multi-factor index (C11)	0.64	3
		Nutrition index (C12)	0.26	2
		Dissolved oxygen (C13)	0.10	1.55
Hydrologcial characteristics B2	0.16	The lowest ecological water level satisfied state (C21)	0.75	4
		Water exchanging cycle period (C22)	0.25	3
Physical shape B3	0.07	Lake basin stability (C31)	0.25	3
		Lakeshore stability (C32)	0.25	3
		Vegetation integrity (C33)	0.25	3
		Form of coastline and revetment (C34)	0.25	4
Ecosystem indicators B4	0.26	Green belt vegetation coverage (C41)	0.09	4
		Diversity of phytoplankton (C42)	0.06	3
		Conservation rate of indigenous plant (C43)	0.07	4
		Proportion of natural surface (C44)	0.39	2
		Quality index of habitat (C45)	0.39	3
Lakeside landscape B5	0.08	Aesthetic measure (C51)	0.33	4
		Accessibility of landscape (C52)	0.33	3
		Green belt vegetation coverage (C53)	0.34	4

According to the orientation of the ecological function of Xianghu Lake, the health evaluation factors constructed include 17 evaluation indexes, such as hydrology and water resources, water system structure, ecological function, ecosystem health, and tourism landscape value. The calculation results can show the health status of Xianghu Lake with the level from good to excellent. Based on guaranteeing excellent ecological background, the healthy evaluation index system provides not only a dynamic grasp for monitoring the water ecological quality of Xianghu Lake, but also regular feedback for urban construction. The urban development and construction is a dynamic and long-term process. The results of water health assessment of Xianghu Lake can provide a basis of optimization for the development and construction of Xianghu Lake region, to achieve the dynamic balance between protection of water ecology and urban

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72837299

construction. Moreover, the results of health assessment can reflect the direction of improving the water health of Xianghu Lake in the future. For Xianghu Lake, if the water quality pollution index, natural water area and habitat index can be taken up to one higher level respectively, the health index of Xianghu Lake can reach 3.53, namely, the excellent level of health.

Discussion and conclusion

In the process of "balanced construction" in highly sensitive areas of water ecology, we utilized calculation of water ecology and software simulation to lay the ecological foundation of subsequent urban planning and design and seek for interaction between water ecology and subsequent urban planning and design. According to the results of simulation analysis, measures to help seek urban design strategies are included as follows:

(1) Flow field simulation of water body. We collect and investigate the current water body. Then, we simulate and analyze the water body by using Mike simulation software. In this way, we find out the current problems and areas with poor fluidity (water quality is vulnerable to deterioration) so that we can take appropriate measures to deal with in the planning process.

(2) Water purification methods. After clarifying the types of main pollution sources in the future development process, we should strictly control the point source pollution and minimize its adverse impact on the environment. Besides, we should pay full attention to the calculation and treatment of non-point source pollution. We can take diversified ecological purification measures such as eco-embankment, constructed wetlands, aquatic animal and plant communities to improve the capacity of water to absorb and treat pollutants. At the same time, through the ecological treatment of peripheral rivers and construction of sponge facilities, the water quality of the catchment can be purified to ensure the water quality health and finally achieve the stated planning goals of water ecological conservation.

(3) Dynamic balanced monitoring methods. Supported by the established water healthy evaluation index system, periodic and dynamic inspection of water health status is carried out to reflect the impacts of urban construction on highly sensitive areas of water ecology. Based on the evaluation results, feedback and guidance are provided for urban development and construction in terms of construction and development capacity, spatial distribution, selection of leading functions, blue-green infrastructure construction and urban landscape construction, to achieve the dynamic balance between protection of water ecology and urban construction.

In this paper, there are also several aspects that need to be discussed:

(1) In this paper, the evaluation of water quality and related application standards are all based on the national standards of China. If the methods are applied in other areas, the corresponding standards need to be re-checked to meet the actual local requirements.

(2) In this paper, the research object is the lake. If the lake is transformed into other kinds of water form, the corresponding Mike 21 simulation analysis equation may need to be adjusted accordingly.

(3) The paper focuses on the current development of Chinese cities, especially the big cities. The control standard of point source pollution in cities is relatively higher, which can achieve municipal collection and treatment. Therefore, the impact of point

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_72837299

source pollution on water quality has not been fully considered in the calculation of pollution load. If point source pollution cannot be effectively controlled, the development of water ecologically sensitive area could be catastrophic. Under such prerequisite, it is necessary to take a relatively conservative attitude towards urban construction in water ecologically sensitive areas. When the cities fail to deal with the discharge of point source pollutants, urban development and construction in highly sensitive areas of water ecology need to be controlled.

Overall, the urbanization process of the world is still in a stage of rapid development. In the process of rapid urbanization, urban and natural, construction and protection are two factors that cannot be avoided. Based on the experience in China's urbanization practice, the paper summarizes the planning evaluation methods that seek the dynamic equilibrium of construction and protection. It can also provide a reference for subsequent research. Ecological protection is the foundation of urban development. The development should be high quality and sustainable, which is under the premise of protection. It is recommended that in the future research and practice process, the importance of ecological protection should be fully emphasized. By the application of scientific quantitative research methods, we can seek the maximum comprehensive benefits of urban development on the basis of meeting ecological capacity.

(Received 5th Feb 2019; accepted 8th Apr 2019)

Abstract. Microplastics and heavy metals represent two pollutant classes which have adverse impacts on aquatic ecosystems. This study has investigated the adsorption of two heavy metals [Lead (Pb)II and Aluminum (Al)III] on three different types of microplastics [polyethylene terephthalate (PET), polyamide (PA), ethylene vinyl acetate (EVA)]. The Scanning Electron Microscope (SEM) analysis has shown that microplastics have different surface characteristics. The effects of parameters such as the pH of solution, duration of contact, initial concentration and temperature on adsorption capacity have been examined. Experimental results have been applied to the adsorption isotherm models of Langmuir and Freundlich and it has been seen that the Freundlich model has been seen as more suitable than the Langmuir model. Moreover, the pseudo-second kinetic has been found to be more appropriate than the pseudo-first kinetic model. Adsorption percentages have changed according to the type of microplastic and working conditions. Finally, the study has investigated the potential of microplastics to act as an instrument of transport for heavy metals to the food chain and for their bioaccumulation.
Keywords: *polyethylene terephthalate, polyamide, ethylene vinyl acetate, bioaccumulation*

Introduction

The term microplastic was first used in 2004 to define microscopic plastic particles with a diameter of approximately 20 microns (Thompson et al., 2004). In time, this definition widened to include plastic parts with diameters smaller than 5 mm (Arthur et al., 2008). Today, it is estimated that there are at least 5.25 trillion microplastics in the seas with a weight of 268,940 tons. Microplastics are generally transported to the seas and oceans by river flows (Okubo et al., 2018). It is thought that 10% of plastics in the oceans stem from ships and fishing activities. Furthermore, detergents, cleaning agents and cosmetic products contain microplastics as well (Aytan et al., 2016).

It is known that plastic parts in the seas and freshwater ecosystems are divided into tiny particles by small sea creatures. Microplastics can spread widely in water environment through currents and hydrodynamic processes due to their persistent characteristics (Ng and Obbard, 2006). Particles with a high density deposit and accumulate, while low-density particles float on water (Cauwenberghe and Janssen, 2014). Moreover, it is more likely for buoyant particles into be swallowed and transferred to the food chain (Boerger et al., 2010). Micrometer-sized plastic particles are swallowed by sea creatures like fish, worms, sea birds, crustaceans and clams (Hu et al., 2017). This type of feeding might obstruct the gastrointestinal tract, leading to limited nutrition. These particles might even be transferred into the circulation system through intestinal wall. Swallowing microplastics may cause serious harm to vital functions of living creatures (Cauwenberghe and Janssen, 2014).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73017310

Microplastics are potential carriers that can adsorb heavy metals in aquatic environments due to their specific surface areas. It is even possible for heavy metals adsorbed onto microplastics to be transferred to a great variety of aquatic organisms in both seas and freshwaters (Digka et al., 2018). Thus, microplastics have bioaccumulation potential throughout the food chain (Galloway, 2015).

Metal pollution is rather high in seas and freshwaters due to industrial wastes, paints containing metals and fuel combustion (Fu and Wang, 2011; Brennecke et al., 2016; Yousefzadeh et al., 2018). In the same manner, microplastics are known to abound in seas and freshwaters because of human activities (Brennecke et al., 2016). Until recently, interactions between plastics and metals have not been considered important. It is probably thought that polymers are ineffective against metals. However, microplastics are an important intermediary for the transportation of metals in aquatic environments and they display a higher inclination for adsorption of heavy metals in freshwaters (Holmes et al., 2012).

The adsorption of heavy metals by microplastics may differ according to the physical properties of microplastics, the size of pores, surface area and the type of microplastics. Therefore, the type of microplastics is influential on adsorption efficiency. Three different types of microplastics were used in this experimental study, which are polyethylene terephthalate (PET), polyamide (PA) and ethylene vinyl acetate (EVA) found in the sea ecosystem. The aim of this study is to investigate the adsorption of heavy metals onto microplastics.

Material and Methods

Stock Solutions of Lead and Aluminum Ions

As the lead stock solution, 1000 mg/L of $Pb(NO_3)_2$ (Merck) was used and as the aluminum stock solution, 1000 mg/L of $Al(NO_3)_3$ (Merck) was used. Solutions with varying concentrations were prepared with these stock solutions and 1 gr of microplastics was added.

Microplastic Pellets

PET, PA and EVA were purchased as granules. These granules had sizes of 0.5-1 mm. The morphological features of plastics were examined in the Scanning Electron Microscope (SEM). *Figure 1* displays the SEM micrographs of PET, PA and EVA, respectively. As can be seen in *Figure 1*, the surfaces of microplastics vary according to their type.

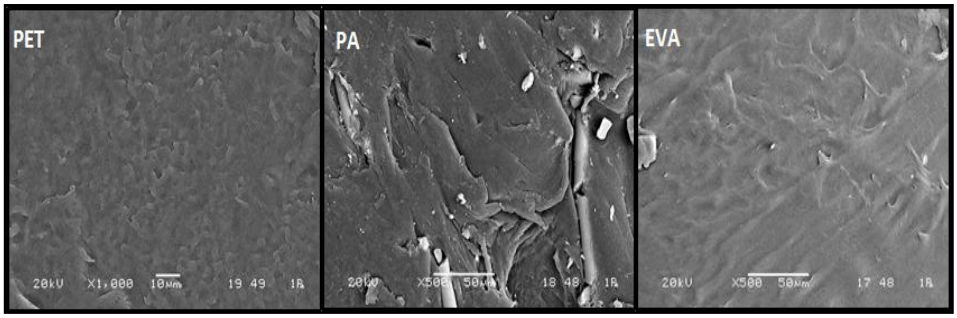

Figure 1. *SEM images of PET, PA, and EVA raw pellets*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73017310

Experimental Study Methods

This study investigated how the adsorption capacity is affected by pH (2, 3, 4, 5, 6, 7, 8, 9, 10) duration of contact (5, 15, 30, 60, 90 min), initial concentration (0.5, 1, 2, 3, 4, 5, 6, 7 ppm) and temperature (25, 35, 45, 55°C), which are significant parameters in adsorption processes and which affect the solution, and the features of the adsorbent and it was tried to find optimum conditions. A solution volume of 1000 mL was used in all the adsorption experiments. The pH adjustment was carried out with 0.1 M HCl or NaOH solutions. Solutions with different concentrations were prepared by diluting the standard stock solution of Pb or A1. The solutions were added with 1 gr of PET, PA and EVA, respectively, and stirred on a magnetic stirrer with a fixed stirring speed of 180 rpm. The filtrate water was put into falcon tubes of 50 mL. Three replicates were carried out for each experiment. The concentration of metal in the filtrate was examined with ICP-OES and adsorption removal efficiencies were determined based on the results. The adsorption percentage was calculated based on the *Equation 1*.

$$\%Ads = 100 - \frac{[A]_t}{[A]_0} \times 100 \quad \text{(Eq.1)}$$

where, %ads is the adsorption percentage; $[A]_t$ is the concentration of heavy metal remaining in the solution after time t; and $[A]_0$ is the concentration of heavy metal at time 0.

Adsorption models

The adsorption isotherm models of Langmuir and Freundlich were used in this study. Linear forms of the Langmuir isotherm are shown in *Equations 2, 3 and 4*:

$$q_e = \frac{Q_{max}\, a_L\, C_e}{1 + a_L\, C_e} \quad \text{(Eq.2)}$$

$$q_e = \frac{K_L\, C_e}{1 + a_L\, C_e} \quad \text{(Eq.3)}$$

To show this in a linear way;

$$\frac{1}{q_e} = \left(\frac{1}{K_L}\right).\frac{1}{C_e} + \frac{a_L}{K_L} \quad \text{(Eq.4)}$$

where, q_{max} is the single layer capacity of heavy metal (mg/g); C_e is the concentration of heavy metal molecules remaining in solution at equilibrium (mg/L); K is the Langmuir constant related to the adsorption balance and energy (L/mg); a_L is the constant based on adsorption energy (L/mg); and q_e is the amount of material adsorbed on unit adsorbent (mg/g).

When the graph of C_e/q_e was drawn against C_e, the curve of the linear graph gives a_L/K_L and the point where it cuts the y-axis gives $1/K_L$. The R^2 constant was calculated to find the suitability of adsorption and this constant requires the suitability condition to have values between 0 and 1 (Hamdaoui and Naffrechoux, 2007).

The linear forms of the Freundlich isotherm are shown in the *Equations 5 and 6*.

$$qe = K_f\, Ce^{1/n} \quad \text{(Eq.5)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73017310

where; C_e is the concentration of the material remaining after adsorption (mg/L); q_e is the amount of adsorbed material on unit adsorbent (mg/g); K_f is calculated experimentally. Adsorption capacity (L/g); n is the heterogeneity factor (without unit).

In the Freundlich isotherm, the logarithm of both sides of the *Equation 5* is taken and linearized.

$$q_e = \log K_f + \frac{1}{n} \log C_e \quad \text{(Eq.6)}$$

The K_f and n constants are determined by drawing the change of log q_e according to log C_e. The cut off point of the y-axis of the line obtained from the graph gives log K_f and its curve 1/n (Aksu and Yener, 2001).

Adsorption Kinetics

In order to explain the adsorption of heavy metals on any adsorbent, usually the pseudo-first order and pseudo-second order models are used. In the pseudo-first order model of Lagergren, it is seen that a proportional change occurs in time when solid surface is saturated in different concentrations.

The pseudo-first order equation is given with (*Eq. 7*);

$$\ln(qe - qt) = \ln qe - k1t \quad \text{(Eq.7)}$$

where; q_t is the amount of adsorbate on adsorbent at any time (mg/g); k_1 is the first order kinetic rate constant (min^{-1}).

If a graph is drawn between ln(q_e-q_t) and t, a straight line is obtained. The curve of this line gives the k_1 constant and the point where it cuts the y-axis gives the lnqe value (Lagergren, 1898).

The pseudo-second order equation is given with (*Eq. 8*);

$$\frac{t}{q_t} = \left[\frac{1}{k_2 . q_e 2}\right] + \frac{1}{q_e} . t \quad \text{(Eq.8)}$$

where; k_2 is the second order kinetic rate constant is (gr/mg.min).

When a graph is drawn between t/q_t and t, a straight line is obtained. The curve of this line gives the 1/q_e value and the point where it cuts the y-axis gives the 1/k_2.qe_2 value (Ho and Mckay, 1999).

Results and Discussion

Adsorption Experiments

The most significant factor in heavy metal adsorption is pH. During the experiments, initially concentration, the duration of contact and temperature were kept constant and pH values ranging between 2–10 were used. When heavy metals had a tendency to precipitate at pH 6 or higher, the pH was determined to be 5.5.

The optimum pH was set as 5.5 against the precipitation tendency of heavy metals (Li et al., 2008). Pb(II) or Al(III) solutions were studied for 5–90 min in pH 5.5 with a concentration of 1 ppm and it was established that the optimum duration of contact was 60 min. Furthermore, solutions were prepared with a pH value of 5.5 between the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73017310

ranges of 0.5–7 ppm and stirred at 25°C for 60 min in order to examine the concentration changes of Pb(II) and Al(III) ions. At the end of the experiment, it was seen that the optimum concentration was 4 ppm for Pb(II) and 3 ppm for Al(III).

The experiment results in *Figure 2* and *Figure 3* were obtained by working at optimum pH, contact time and initial concentration to investigate the temperature effect of Pb (II) and Al (III) ions on adsorption. The highest adsorption capacities were obtained in experiments conducted in optimum conditions with a pH value of 5.5, an initial concentration of 4 ppm, a temperature of 55°C and with a 60-min stirring time.

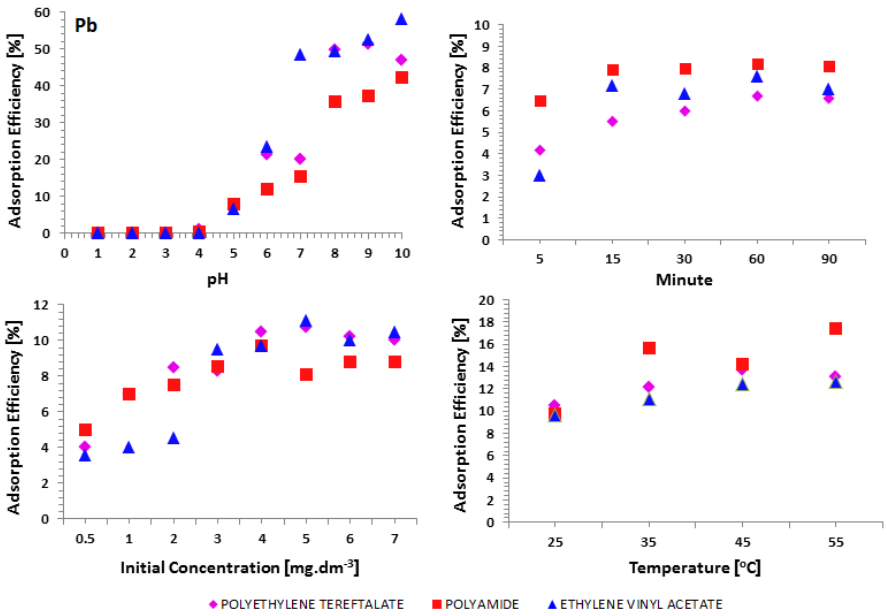

Figure 2. *Pb(II) adsorption temperature (pH: 5.5, time: 60 min, initial concentration: 4 ppm)*

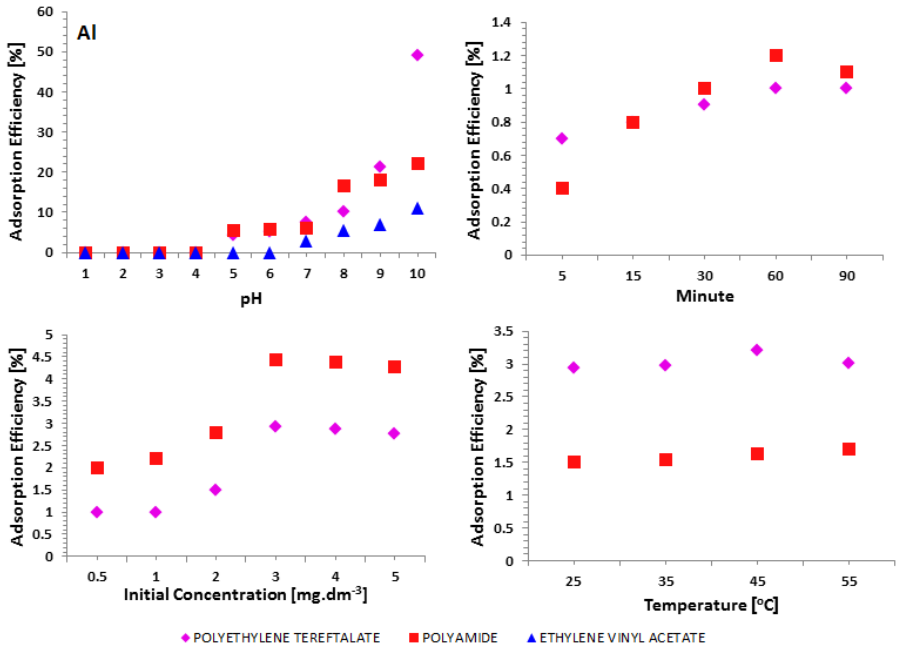

Figure 3. *Al (III) adsorption temperature (pH: 5.5, time: 60 min, initial concentration: 3 ppm)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73017310

It is seen in the graph given in *Figure 2* that the adsorption capacity increased for PET, PA and EVA with increasing temperatures but it was not affected much. The adsorption capacity also changed based on the type of microplastic. The adsorption capacities were detected as PA, PET, and EVA in the descending order. The high adsorption capacity of PA supports the results of other studies in literature (Wang et al., 2015; Li et al., 2018).

Experiments were repeated for the adsorption of PET, PA and EVA on Al(III) and the adsorption of EVA on Al(III) did not occur in any circumstances. It is seen in the graph given in *Figure 3* that the adsorption capacity of PET and PA increased with increasing temperatures but it was not affected much. The adsorption capacity also changed based on the type of microplastic. The adsorption capacity of PET was higher than that of PA in adsorption experiments carried out under the same conditions. The studies suggest that the polarity of MPs can affect the adsorption levels of polar chemicals. Physicochemical properties of MPs may affect the adsorption capacity (Teuten et al., 2009; Wang et al., 2015; Li et al., 2018).

Adsorption isotherm of heavy metals in microplastics

Experiments for adsorption isotherms were carried out in concentrations of 0.5-1-2-3-4-5-6-7 mg/L. When the R^2 values of the Langmuir and Freundlich isotherms were studied in experimental results obtained in adsorption equilibrium state for all three microplastics, it was determined that the regression coefficients of the Freundlich isotherm were higher than the Langmuir isotherm and they were more suitable for the Freundlich isotherm (*Figure 4*). Several studies have reported that the sorption of pollutants on microplastics fit well with Freundlich model (Razanajatovo et al., 2018; Zhang et al., 2018; Llorca et al., 2018; Wu et al., 2019). This indicates that the relationship between microplastics and heavy metals is multi-layer adsorption on heterogeneous surfaces (Andersson et al., 2011).

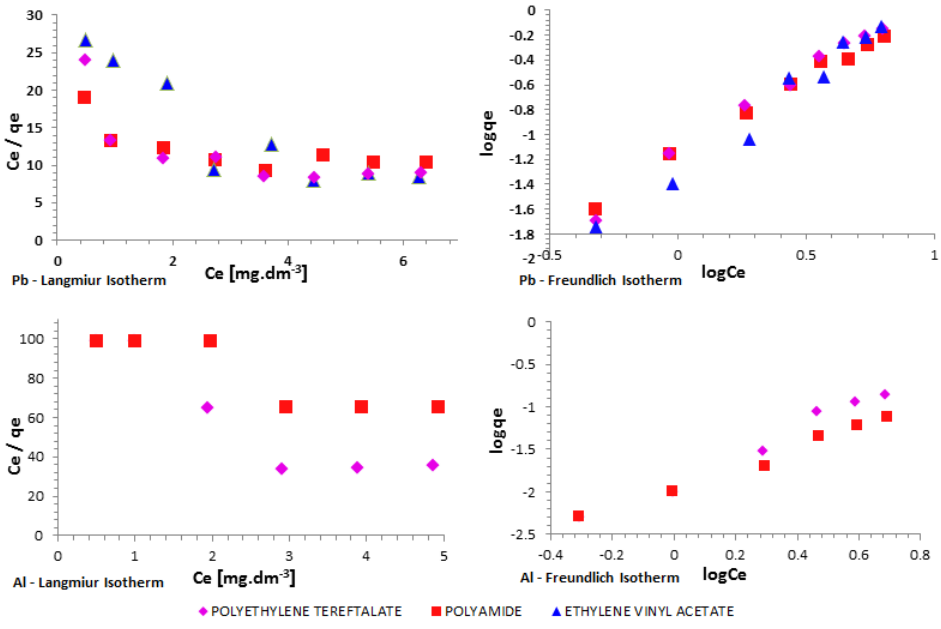

Figure 4. *Adsorption isotherms of Pb(II) and Al(III) onto PET, PA, EVA*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73017310

The balance data obtained were applied to the Freundlich and Langmuir models, which are widely used to explain the adsorption process, and the constants of both isotherms were calculated. The predicted Langmuir and Freundlich constants are summarized in *Table 1* and *Table 2*.

Table 1. *Parameters of Langmuir and Freundlich isotherms for Pb(II) adsorption*

Pb	Langmuir Isotherm Constants			Freundlich Isotherm Constants		
	q_{max} (mg / gr)	K_L (L / mg)	R^2	K_f (mg / gr)	n	R^2
PET	-0.551	-0.103	0.526	0.065	0.733	0.988
PA	-0.978	-0.065	0.513	0.069	0.822	0.991
EVA	-0.303	-0.128	0.791	0.047	0.661	0.978

Table 2. *Parameters of Langmuir and Freundlich isotherms for Al(III) adsorption*

Al	Langmuir Isotherm Constants			Freundlich Isotherm Constants		
	q_{max} (mg / gr)	K_L (L / mg)	R^2	K_f (mg / gr)	n	R^2
PET	-0.058	-0.165	0.831	0.012	0.64	0.98
PA	-0.105	-0.089	0.79	0.01	0.821	0.987

Adsorption Kinetic of Microplastics and Heavy Metals

Adsorption kinetics is important when assessing adsorption efficiency. The kinetic study was conducted in order to understand the time-dependent behavior of heavy metal adsorption on microplastics. Adsorption capacities (q_e) and adsorption rate constants (k_1 and k_2) were calculated using the curve values of the lines in the graphs which were drawn by calculating the values corresponding to different adsorption durations (t) and given in *Figure 5*. For Pb(II) and Al(III), the adsorption efficiency in the first 60 min after adsorption experiments began and later it reached adsorption equilibrium and slowed down. Based on these results, a contact duration of 60 min was selected.

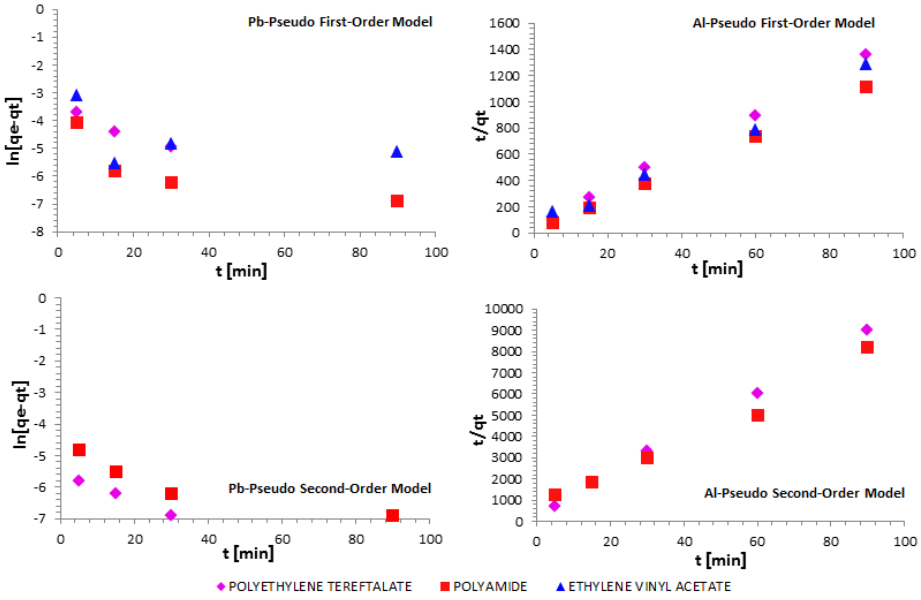

Figure 5. *Pseudo-first order and pseudo-second order kinetic models for Pb(II) and Al(III)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73017310

The pseudo-first and pseudo-second order models determine the adsorption rate. While the adsorption rate is a physical process for the pseudo-first order model, it is a chemical process for the pseudo-second order model involving the adsorbent force (Mohan et al., 2006). Therefore, the data in the kinetic study in *Figure 5* were applied to the pseudo-first and pseudo-second order models to investigate rate limiting mechanisms. The results of the pseudo-first and pseudo-second order models are summarized in *Table 3* and *Table 4* including parameters like k_1 and k_2 and experimental ($q_{e,exp}$). For both metals ($q_{e,cal}$), the values of the balance adsorption amount and the correlation coefficient (R^2) are suitable with the pseudo-second order model, which is higher than the pseudo-first order model.

Table 3. *Parameters of pseudo-first order and pseudo-second order kinetic models for Pb(II)*

Pb			**pseudo first-order (PFO)**			**pseudo second-order (PSO)**		
	Co (mg/L)	$q_{e,exp}$ (mg/gr)	k_1 (1/min)	$q_{e,cal}$ (mg/gr)	R^2	k_2 (gr/mg.min)	$q_{e,cal}$ (mg/gr)	R^2
PET	1	0.067	0.035	0.023	0.982	4.03	0.069	0.999
PA	1	0.082	0.0254	0.007	0.642	14.49	0.082	0.999

Conclusion

Microplastics and heavy metals are sources of pollution in sea and freshwater ecosystems. The interaction between these two pollutants may create a serious problem to aquatic ecosystems. This study investigated the role of PA, PET and EVA in the transport of the heavy metals of Pb and Al to the food chain and in their bioaccumulation.

The adsorption behaviors of 2 heavy metals on 3 types of microplastic pellets were carefully evaluated. Our results showed that adsorption capacities varied among heavy metals, plastic types, and environmental conditions (e.g., pH). Overall, the adsorption percentage in the study was low. In addition, literature studies, laboratory tests and environmental monitoring using plastic pellets have shown that plastics can accumulate metals (Wang et al., 2017). Heavy metals and persistent organic pollutants enter into the food chain and bioaccumulation may occur in living things that swallow these microplastics (Wang et al., 2016). Because of the abundance of plastics in aquatic ecosystem their role in respect of bioaccumulation of a broader range of contaminants merits further study.

Abstract. *Petunia hybrida* is considered as an important and beautiful ornamental flowering plant, grown throughout the world for its beauty and attractiveness. Various petunia hybrids have been produced by different countries. The present study was carried out to investigate the higher seed yield petunia line developed through selfing to produce F_1 hybrids during the experimental seasons of the 2011-2014 period. The lines IAGS-P8, IAGS-P9 and IAGS-P11 performed well, both in the cluster analysis and minimum spanning tree, the inbred lines IAGS-P8 and IAGS-P9 showed to a higher similarity percentage. From statistical and regression analysis showed that stomata conductance, chlorophyll 'a' contents, chlorophyll 'b' contents, flowers per plant, flower fresh weight, seed area, seed weight and abscisic acid contributed higher to seed yield per plant in petunia. The higher abscisic acid concentration suggested that the petunia genotypes may be used to develop better seed yields and higher number of flowers per plant in petunia under environmental stress. This method proved to be more efficient as it reduced the cost, time and efficacy for better selection in petunia improvement program. Still, further studies are required which should cover different years and locations.
Keywords: *Petunia hybrida, abscisic acid, multivariate analysis, heritability, genetic advance*

Introduction

Petunia hybrida is an important and the mostly used ornamental plant throughout the world from several years as commercially grown ornamental plant. *Petunia hybrida* is an important and mostly used genera to develop *Petunia* new varieties and hybrids. Griesbach (2007) has reported that *Petunia* has an old history in sense of development as an ornamental plant as compared with new emerging ornamental crops plant species. Ganga et al. (2011) suggested that the production of hybrid seed has been adapted by various ornamental crop plants breeding program to develop new colour and varieties of ornamental plants. It has been found that there are 20 South American origin species of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73117332

Petunia (Selaru, 2008), 14 herbaceous species (Toma, 2009). Selaru (2008) reported that the specie *Petunia hybrida* Hort. (*P. axillaris Lam.* × *P. violacea* Lindl.) has been presented with higher decorative value. It has been confirmed from findings of various researchers that the 14 familiar species are consisted of genus *Petunia* (Stehmann et al., 2009). The *Petunia hybrida* Hort. as an ornamental plant species, used as ornamental plant in loans, fields and gardens for its abundant flowering ability (Toma et al., 2011). Dole and Wilkins (1999) reported that most of the *Petunia* species have been developed in Brazil, Uruguay or Argentina. In modern era a large number of cultivars have been developed in the form of varieties, hybrids and cultivars with variety of colors and patterns. Depending on flower size, color and habit, four groups of *Petunias* have been defined as, multiflora, milliflora, grandiflora, ground cover or spreading. Even every year new varieties of *Petunia* have been developed by ornamental breeders (Toma, 2009).

Bender (2006) found that the new and modern species of petunias are hybrids in nature like garden petunia (*Petunia axillaris*) or ambrosial white and violet *petunia* (*P. integrifolia*, and *P. violacea*). The old or wild type *petunia* species, varieties or hybrids use has been less down now a day. *Petunia* is grown throughout the world for its beauty, higher growth rate, different color ranges and continued flowering up to about 6 months of plant life cycle. It blossoms most abundantly under hot summers conditions (Bala, 2012; Selaru, 2008). Erwin (2006) found that the higher blooming ability, *petunia* is even grown in baskets, landscaping by the forms, in alloyed trays on roads and even in room open spaces (Erwin, 2006). The present study was conducted to develop inbred lines of petunia through selfing at growing seasons. The data of various morphological, physiological and seed yield traits was recorded to access the performance of inbred lines under development. The identification of promising inbred lines was also done.

Material and methods

The prescribed study was carried out in the research area of Institute of Agricultural Sciences, University of the Punjab Lahore, Pakistan located at 31.4779° N, 74.2623° E with average higher temperature of about 37 °C with highest up to 45 °C during summer season, 11 °C with lowest 3 °C during winter season. Twelve petunia lines, IAGS-P1, IAGS-P2, IAGS-P3, IAGS-P4, IAGS-P5, IAGS-P6, IAGS-P7, IAGS-P8, IAGS-P9, IAGS-P10, IAGS-P11 and IAGS-P12 were selected and grown in the field during 2014, selfing of all the lines was carried out for three successive growing seasons (2011-13) to develop inbred lines, the selfed seed were collected to develop next generation (*Figs. 1* and *2*). The selfed seed was grown in three replication under completely randomized block design during growing season of 2014, and data for various traits of 10 selected plants from each of three replications was recorded during all three growing seasons and average of data was used for results and interpretation, the traits were included photosynthetic rate (A), leaf temperature (LT), transpiration rate (E), stomata conductance (gs) and Sub-stomata CO_2 Concentration (Ci) through the use of IRGA (Infrared Gas Analyzer, Model: LI-6400XT), chlorophyll 'a' content (Chl. a), chlorophyll 'b' content (Chl. b) in fresh matter was measured using the dimethyl sulfoxide extraction method (Hiscox and Israelstam, 1978), leaves per plant (LPP), plant height (PH), stem diameter (SD), flowers per plant (FPP), leaf length (LL), leaf width (LW), leaf area (LA), fresh leaf weight (FLW), fresh stem weight (FSW), flower

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73117332

weight (FW), seeds per fruit (SPF), 100-seed weight (HSW), seed area (SA), capsule weight (CW), abscisic acid (ABA) by using HPLC method (Seo and Koshiba, 2002), and seed yield per plant (SYP) were collected. Water use efficiency (WUE) was recorded through using given formula:

$$\text{Water use efficiency } (\%) = \frac{\text{Transpiration rate}}{\text{Photosynthetic rate}} \times 100$$

The collected data was statistically analyzed by using analysis of variance technique, principal component analysis, correlation analysis, regression analysis, factor analysis, spinning tree and cluster analysis (Steel et al., 1997) through using GenStat 18 (SP1) version.

Figure 1. *Twelve lines petunia hybrida grown in filed*

Heritability estimate

Broad sense heritability was calculated by using genotypic, phenotypic and environmental variances according to Burton (1951):

$$\text{Broad sense heritability} = \frac{\left(\partial^2_g + \partial^2_e\right) - \partial^2_e}{\partial^2_g + \partial^2_e} \times 100$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73117332

∂^2_g = genotypic variance, ∂^2_e = environmental variance, $\partial^2_g + \partial^2_e$ = phenotypic variance, $(\partial^2_g + \partial^2_e) - \partial^2_e$ = genotypic variance.

Genetic advance (GA) was calculated by the following formula (Falconer, 1989):

$$GA = \sigma_p x\, h^2 x\, i$$

where: σ_p = the phenotypic standard deviation; h^2 = estimate of broad sense heritability; i = constant value (1.755) that reflects selection intensity (10%).

Figure 2. *Close view of different petunia hybrid in field and pot (for transplanting in field)*

Results and discussions

It was persuaded from the results (*Table 1*) that significant differences were found for all studied traits. Broad sense heritability was found higher for photosynthetic rate (90.825%), stomata conductance (80.268%), sub-stomata CO_2 concentration (96.035%), water use efficiency (89.847%), leaves per plant (98.750%), plant height (92.613%), leaf length (83.584%), flowers per plant (92.911%), leaf area (84.460%), fresh stem weight (85.266%), seeds per fruit (96.379%) and abscisic acid (85.205%) while lower for chlorophyll b (23.527%), leaf width (37.084%), fresh leaf weight (24.074%), flower weight (26.145%), seed area (26.781%) and seed yield per plant (4.359%). Genetic advance was found higher for all of the studied traits seeds per fruit. Higher heritability suggested that the selection of petunia lines on the basis of these traits for the development of hybrids may be fruitful. Various researchers while working on different crop plants have described about higher heritability for these traits as reported in our study (Ali et al., 2013, 2014; Fawad et al., 2017). Higher genetic advance suggested that the selection of lines may also be helpful to develop synthetic varieties. The similar findings for different crops have been reported by various researchers (Ali et al., 2013, 2016). It was found from results (see *Appendix*) that the line IAGS-P8, IAGS-P9 and IAGS-P11 performed better than all other lines. Correlation analysis provides an opportunity to the research to select genotypes of crop plant to improve crop plant growth and production. In our study, significant correlation (*Table 2*) was found for

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73117332

photosynthetic rate with chlorophyll 'a' contents, sub-stomata CO_2 concentration, water use efficiency, plant height, flowers per plant, leaf width and abscisic acid. Abscisic acid was found to be significantly correlated with most of the studied traits including seed yield per plant. Stomata conductance showed also significant correlation with transpiration rate, water use efficiency, flowers per plant, leaf area, fresh shoot weight, seeds per fruit, abscisic acid and leaf width. Seed yield per plant was significantly correlated with photosynthetic rate, leaf temperature, leaves per plant, stem diameter, seed weight and abscisic acid. The positive and significant correlation suggested that the selection of lines to develop hybrids and synthetic varieties may be helpful to improve the growth and development of petunia, the significant correlation of abscisic acid with morphological, seed yield and physiological traits indicated that the selection of petunia lines on the basis of good abscisic acid production may be fruitful to improve drought tolerance in petunia (Mahmood et al., 2017; Sah et al., 2016; Skubacz et al., 2016; Zao et al., 2016; Saradadevi et al., 2017). Kaczperski et al. (1991) estimated growth of the petunia and development in combined effects of light and temperatures. The adverse effect of an optimum temperature environment for minimum time to *petunia hybrida* was begin to be 25 °C, and a minimum circadian light intensity for adequate growth was begin to be 13 $molm^{-2}$ d^{-1}. The adeptness for petunia to growth and development with increase in light and temperature has afresh been appeared, so there is befalling to optimize development, crop plant growth, crop scheduling and higher with ecology changes in light and increase in temperature. However, the accessible delay of growth and development with top abundance and the access of CO_2 in an optimized environment showed not extensively have adverse effects (Ahmad and Tahir, 2017; Blanchard and Runkle, 2009; Mustafa et al., 2017).

The stepwise regression (*Table 3*) was performed to find out the traits that were highly contributing to the seed yield per plant of petunia, from results it was predicted that stomata conductance (120.311), chlorophyll 'a' contents (2.775), chlorophyll 'b' contents (2.1040, flowers per plant (2.484), flower fresh weight (11.364), seed area (7.062), seed weight (31.497) and abscisic acid (15.356) contributed higher to seed yield per plant in petunia but it could be biased as previous literature also reported the error effect of stepwise regression (El-Badaway and Mehasen, 2011; Ahmad et al.; 2012, 2016) while handling a large number of independent variables. The Intercept = 128.387, $R^2 = 0.832$, Adjust $R^2 = 0.276$ and Standard Error = 0.728 was found with expected regression equation as follows:

$$\begin{aligned} Y = {} & 128.387 + (0.224X_1) + (-0.235\,X_2) + (2.775\,X_3) + (2.2.104X_4) + (120.311X_5) \\ & + (-4.418X_6) + (-0.007X_7) + (-0.070X_8) + (-0.252X_9) + (0.116X_{10}) + (0.004X_{11}) \\ & + (2.484X_{12}) + (-0.115X_{13}) + (-17.234X_{14}) + (-80.073X_{15}) + (11.364X_{16}) + (-10.121X_{17}) \\ & + (0.068X_{18}) + (-12.101X_{19}) + (-0.033X_{20}) + (7.062X_{21}) + (31.497X_{22}) + (15.356X_{23}) \end{aligned}$$

Various researchers have used PCA (Principal Component Analysis) to evaluate the effects of independent traits (*Table 4*) in large number for selecting the fruitful variability percentage from a large population (Fawad et al., 2017; Ali et al., 2014). It has been reported from study conducted by Greenacre (2010) that the eigenvalues (used in PCA) shows the primary importance of numerical diagnostics for assessing the variation which a number of large traits/variables contributed for the dependent structure also to display the data matrix in a graphical form.

We performed principle component analysis to investigate the traits contributing higher towards seed yield per plant in petunia, four PCA (*Table 4*) were estimated which diverse variation among the studied traits. The PC1, PC2, PC3 and PC4 contributed variations of 29.60%, 16.60%, 13.90% and 10.5% while their cumulative proportion was 29.6%, 46.20%, 60.10% and 70.60% respectively. PC1 and PC2 contributed higher variation for respective studied traits (*Fig. 3a*) the eigenvalues of PCs was higher than 1 (*Fig. 3b*). Through the use of principle component analysis, principle factor analysis was performed to check the traits that were directly and highly associated with the seed yield per plant in petunia. The highly contributing factor traits from factor 1 which contributes 36.20% in total variation were chlorophyll a, chlorophyll b, stomata conductance, transpiration rate, water use efficiency, leaves per plant, stem diameter, leaf length, leaf area, seed yield per plant and abscisic acid (*Table 5*). Fawad et al. (2017) and Ali et al. (2014) suggested that the selection of genotypes on the basis of factor analysis (traits from factor 1) may be helpful to develop higher yield synthetic varieties and hybrids. The traits in factor 2 (from factor loading *Table 5*) showed that the selection on the basis of these traits will not be useful as segregation takes place in the next generation. The higher performance of petunia genotypes for chlorophyll a, chlorophyll b, stomata conductance, transpiration rate, water use efficiency, leaves per plant, stem diameter, leaf length, leaf area, seed yield per plant and abscisic acid indicated that the accumulation of organic compounds will be higher in the plant body. The accumulation of biomass in plant body is essential for

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73117332

the proper and enhanced growth and development of petunia (Huang, 2007; Huang and Yeh, 2009; Ali et al., 2011; Munir et al., 2016), the accumulation is generally in the leaf, stem and flowering parts of the plant body. Our findings are well supported by Filipovic et al. (2014) who demonstrated the role of factor analysis for effective selection criteria in maize breeding program. For understanding of the association among the petunia lines, we performed cluster analysis (Mahmood et al., 2016; Khorasani et al., 2011; Mostafavi et al., 2011; Ali et al. 2015, 2016). The results from clustering showed that the petunia lines IAGS-P8 and IAGS-P9 were highly associated with each other as compared with all other petunia lines (*Fig. 4a*) the association was verified through the development of minimum spanning tree (*Fig. 4b*) that showed very less distance between petunia lines IAGS-P8 and IAGS-P9 through the use of eigen values. The results showed that the petunia lines IAGS-P8 and IAGS-P9 may be used as two separate male or female lines to develop petunia hybrids. The petunia line IAGS-P11 performed better for almost all studied traits, it may be used as male to develop good quality petunia hybrids. It also indicated that in future breeding program of IAGS-P8, IAGS-P9 and IAGS-P11, these traits are important for primary selection to increase seed yield per plant of petunia under various environmental regimes. Moreover, this method proved to be more efficient as it reduced the cost, money, time and efficacy for better selection in petunia improvement program because the hybridization procedure of petunia is very difficult. When researcher take important traits like seed yield and flower size in account then there may be a chance to improve yield and quality of petunia. However, further studies are required which should cover different years and locations.

Conclusion

The present study was carried out to investigate the higher seed yield petunia line during the experimental seasons of 2011-2014. The data for various morphological, physiological and seed yield traits were recorded, analyzed and interpreted for final inferences. It was found that the lines IAGS-P8, IAGS-P9 and IAGS-P11 performed well. From correlation analysis, heritability, genetic advance, principle component analysis, factor analysis and regression analysis that stomata conductance, chlorophyll 'a' contents, chlorophyll 'b' contents, flowers per plant, flower fresh weight, seed area, seed weight and abscisic acid contributed higher to seed yield per plant in petunia. The higher abscisic acid contribution suggested that the petunia genotypes may be used to develop good seed yield per plant and large number of flowers per plant in petunia. The more research and experimentation should be carried out to improve yield and quality of petunia flower.

Conflict of interests. The authors declare the absence of potential conflict of interests.

(Received 12th Feb 2019; accepted 8th Apr 2019)

Abstract. Potato is the most important indispensable part of human food. Cold induced sweetening is a phenomenon in which reducing sugars react with free available amino acid and give brown to black color when fried at high temperature which is not acceptable at end consumers. Moreover, acrylamide a potent carcinogenic is also produced during this process. So many wild and cultivated species have been utilized for screening the best potato germplasm against many potato diseases and quality but only a small sample of the available biodiversity has been exploited. An effort was made in this study to sort out the best potato germplasm from five different wild families on the basis of fine Molecular screening at different research station against cold induced sweetening. Crosses were made between potato families and then stored at 4 °C. Total RNA was isolated for Quantification of mRNA. Protein was isolated and invertase activity was measured through Plate reader at 5.9 λ. Sucrose and reducing sugars were measured through High Performance Liquid Chromatography. After 4 months of 4 °C storage incubation families were screened on the basis of chips color, invertase enzyme activity, Sucrose, reducing sugars contents and mRNA expression level. Resistance against cold induced sweetening was genotype and trial dependent especially for chip color. Invertase activity was corresponding with genotypes and trails. Locations with good chip color were having low invertase action and reducing sugars along with low mRNA expression of invertase enzyme while at other locations vice versa. Same genotype showed variable resistance at different trial satiations and conclusively invertase activity was genotypes and trials dependent. Significant trial effects were detected; all subsequent analyses were carried by trial.
Keywords: *fine screening, mRNA, invertase, germplasm, cold induced sweetening*

Introduction

In most potato producing regions worldwide, the crop is typically harvested during a narrow window of time, but it is consumed throughout the year. Consequently, most of the potato crop is stored before it is shipped to packing facilities and processing plants. Metabolic stability of potato tubers during this storage period is one of the prime trait targets for breeding programs worldwide (Bradshaw and Ramsay, 2005; Dale and Bradshaw, 2003; Hirsch et al., 2013). Potatoes need to be cool-stored throughout the year to maintain a continuous supply to the industry, and storage at low temperature (<8 °C) is beneficial because it reduces bacterial soft rots, decreases water and dry matter loss, and prevents sprouting without the need to add sprout inhibitors (Sowokinos, 2001a). However, storage at low temperature leads to an accumulation of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73337344

the reducing sugars glucose and fructose, in a process known as cold-induced sweetening (CIS) (Herrman et al., 1996). Sugars that accumulate in non-photosynthetic tissues are recruited from the starch degradation pathway (Malone et al., 2006; Sowokinos et al., 2004). Tuber sugar content is affected by amount and activity of carbohydrate metabolizing enzymes in source (leaf) and sink (tuber) tissues and by the flux of sucrose from source (Menéndez et al., 2002). When potatoes that have undergone CIS are processed into crisps or chips, high fry temperature causes reducing sugars to react with free amino acids via the Millard reaction, resulting in an unacceptable blackening of the product (Benzing-Purdie et al., 1985). The Millard reaction also leads to the formation of the probable carcinogen acrylamide (Mottram et al., 2002).

Studies on carbohydrate metabolism in potato have shown that several enzymes contribute to low temperature sweetening. During low temperature storage, starch breakdown into sucrose is usually driven by UDP-glucose pyrophosphorylase and sucrose-6-phosphate synthase (Sowokinos, 2001b; McKenzie et al., 2005). Acid invertase converts sucrose into the reducing sugars glucose and fructose. A relationship between light chip color and low levels UDP-glucose pyrophosphorylase activity has been demonstrated (Menéndez et al., 2002; Sowokinos, 2001a). Similarly, low acid invertase activity is associated with light chip color (Bhaskar et al., 2010; Li et al., 2005; Liu et al., 2011; Wu et al., 2011). However, QTL studies have found associations between a number of additional carbohydrate metabolism genes and cold-induced sweetening (Draffehn et al., 2010). More recently, association genetics demonstrated that DNA polymorphisms in genes encoding invertase and starch phosphorylases were associated with potato chip color; starch content and starch yield. Association analysis found that SNP2746 in the StLapN gene was strongly associated with chip quality (Urbany et al., 2011). These genetic studies support the working model that natural variation in tuber starch and sugar content is controlled by allelic variants of enzymes that function in starch and sugar metabolism (Fischer et al., 2013; Theocharis et al., 2012).

Microarray hybridization experiments using a tomato gene chip hybridized with potato mRNA allowed the identification of known and novel genes that were differentially expressed during tuber cold storage in a potato clone. Transcript levels of known candidate genes, such as invertase, were correlated with sugar accumulation (Bagnaresi et al., 2008). Comparative proteome analysis has previously proven successful in identifying new candidate genes controlling tuber quality traits (Yang et al., 2011; Hoehenwarter et al., 2008). One approach to breeding for resistance to CIS is to reduce acid invertase activity. Silencing of the acid invertase gene has effectively reduced CIS, resulting in acceptable fry products (Bhaskar et al., 2010). Alternatively, resistance to CIS is found in wild relatives of potato. The wild diploid species *Solanum raphanifolium* is sexually compatible with diploid forms of cultivated potato. Its hybrid offspring have been shown to exhibit resistance to CIS (Hamernik et al., 2009). In fact, acid invertase activity in germplasm carrying CIS resistance genes from *S. raphanifolium* is as low as that in clones in which the gene has been silenced (Bhaskar et al., 2010). Wild potato species are useful sources of genes for potato improvement (Bradshaw and Ramsay, 2005; Herrman et al., 1996; Jansky et al., 2009; Bethke and Jansky, 2008). However, most wild germplasm is self-incompatible and maintained by intercrossing within populations. Consequently, genetic variation within and among accessions is common (Jansky et al., 2009; Cai et al., 2011; Chung et al., 2011; Jansky,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73337344

2000; Jansky et al., 2006). It is important, therefore, to identify individuals within a population carrying genes of interest. We followed for two purposes in the present study: First, we were interested in fine screening a population of *S. raphanifolium* for resistance to CIS at different stations within country. Second, we determined the relationship between chip color and potential sources of chip color variation. Since we know that low levels of acid invertase are associated with resistance to CIS in this germplasm, we focused on expression of the acid invertase gene, acid invertase enzyme activity, and levels of the sugars sucrose, glucose, and fructose.

Materials and methods

Potato plant crosses

Crosses were made between clone hap-chc as a female and five plants of *S. raphanifolium* PI 310998 as a male. Hap-chc is a hybrid between a *S. tuberosum* dihaploid (US-W730) and *S. chacoense* PI 310998 from Horticulture Lab, University of Wisconsin Madison USA. In previous work, this cross has produced clones with moderate resistance to cold-induced sweetening (Bhaskar et al., 2010; Hamernik et al., 2009). Seeds were sown on August 14, 2009, transplanted to 48-well flats three weeks later (*Fig. 1a*) and then 16-21 plants per family were transplanted into 10 cm square pots on October 5 (*Fig. 1b*). They were grown in a greenhouse at Muree, Pakistan, until maturity. Plants were harvested on January 27-29, 2010 and placed in 4 °C storage on February 2. Two tubers of each plant in each family were chipped during the first week of June and two were retained for clonal maintenance. This trial is designated M1. Thirty-five clones produced at least eight tubers each, so four tubers were planted in the field at Sahiwal, Pakistan, on May 6, 2010. Two replications of two plants each were included in a randomized complete block design. On September 10, each plant was harvested by hand and tubers were collected. The tubers were stored at 4.4 °C until the first week of June, 2011, when two tubers per plot were chipped and were named trial S1. On September 30, 2010, one tuber per clone from the M1 trial was planted again at Sahiwal, Pakistan. Tubers were harvested from mature plants on January 28, 2011. They were stored at 4 °C until June 6, when they were chipped. This was trial S2. Tubers from the S2 trial were planted on September 15, 2011 at a greenhouse in CEMB, Pakistan. Mature plants were harvested on March 8, 2012 and stored at 6 °C. On April 9, samples were collected for sugar, RNA, and invertase assays as described below. In addition, two tubers per clone were chipped. This was trial L1. Each clone was again planted in the Multan greenhouse on April 16, harvested on July 27, and tubers were stored at 6 °C for one month. Two tubers per clone were then chipped. This was trial M2.

Chipping analysis

Chip color was evaluated by taking a 1-2 mm slice from the center of a transverse tuber cut, rinsing it in tap water and frying it in 190 °C corn oil until bubbling ceased. Each chip was visually scored for color using a scale of 1 (light) to 10 (dark), at 0.5 intervals, based on the International Chip Color Institute (Cleveland, OH) color chart). In the M1 trial, each of two tubers per clone was cut into half longitudinally and one half was again cut in half longitudinally. After cutting, the samples were immediately frozen in liquid nitrogen and stored at -70 °C for gene expression analysis. The tuber

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73337344

halves were used for sugar analyses. One of the quarter tuber pieces was used for the invertase enzyme activity assay and the other quarter was used for mRNA isolation. Tuber samples were passed through a Wiley freeze mill with a 40 mesh screen and stored in a -80 °C freezer.

a b

Invertase assay

For the invertase enzyme assay, 100 g protein was extracted by using PD Midi Trap G25 column. The extraction buffer consisted of 0.50 mM HEPES-KOH pH 7.5, 5 mM $MgCl_2.6H_20$, 1 mM EDTA, 1 mM EGTA, 0.1% w/v Triton X-100, and 10% w/v glycerol. Phenyl methyl sulfonyl fluoride (PMSF) was added to extraction buffer to a final concentration of 5 mM immediately before use. Before using the Midi Trap column, the cap was removed and the storage solution was poured off. The bottom cap was also removed and the column was put into 50 ml Falcon tube on ice. Then, 5 ml extraction buffer was put into column to wash it; this step was repeated thrice to a total volume ~15 ml extraction buffer and flow through was discarded. Then, 1 g tuber sample was put into a 15 ml tube along with 2 ml extraction buffer and 2-3 small glass beads. After incubating on ice for 10 min, samples were spun in a micro centrifuge for 10 min at 4 °C at maximum speed to pellet debris, and 1 ml supernatant was added to the equilibrated Midi Trap column and allowed to pack the bed completely. Flow through was discarded and the column was placed into a new Falcon tube. Then, 1.5 ml extraction buffer, along with dichlorodiphenyltrichloroethane DDT and PMSF, was added and this time the flow through was collected as it contained the protein sample. A 450 µl sample of protein was collected, frozen in liquid nitrogen, and stored at 0 °C.

Protein concentration measurements

Protein concentration was measured using the Bio-Rad assay. 10 µl sample of Bovine Serum Albumin (BSA) were used as standard. 2 ul of extracted protein along with dye was loaded into a 96 well plate. After incubating for 30 min at room temperature, absorbance at 595 nm was taken using a plate reader. Vacuolar Acid Invertase activity was measured before and after destroying invertase inhibitor proteins. The crude extract of potato tubers contains proteins which may inhibit soluble invertase activity (Pressey, 1971; Ewing and McAdoo, 1971; Barichello et al., 1990; Steel and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73337344

Whitehead, 1994). However, Ross and Davis have pointed out that technique to destroy inhibitors, such as rapid vortexing of the extract, may result in a loss of invertase (Ross and Davies, 1992). So, the protein aliquot was divided in half and one half was vortexed at low speed for 30 min in cold room (10 °C) while the remaining half was also put in cold room for 30 min, but was not vortexed. The reaction buffer was prepared for measuring enzyme activity by using 133 mM sucrose, 26.7 mM sodium acetate (NaOAc) pH 4.7, 0.1 M sodium phosphate (Napi) pH 7.4 and 50 mM NaPi pH 7.4 were prepared separately, 100 U/ml glucose oxidase (GO), 100 U/ml Horseradish Peroxide (HRP), 10 mM Amplex red (AR) and dimethyl Sulfoxide (DMSO) for preparing Amplex red was also used. 10 mM NaOAc pH 5 was also used for making up volume. For each sample two tubes of 0.2 ml were used. Each containing 20 µg total protein and 10 mM sodium acetate pH 5 was used to bring volume upto 20 µl. One set of tube was put on ice to serve as zero min control, while in other 60 µl reaction buffer was used and incubated at 30 °C for 60 min. After incubating at 30 °C the reaction buffer was added to zero min control, and 8 µl 1 M NaPi pH 7.4 to each of the zero and 60-min tubes to stop the reaction. After mixing well, the reaction was incubated at 97 °C for 3 min to deactivate the enzyme.72 µl 50 mM NaPi was added and centrifuged to pellet the precipitated protein. Then, the enzyme assay mix was prepared using 5.3 ml 50 mM NaPi pH 7.4, 100 µl GO, 100 µl HRP and 100 µl AR. 50 µl enzyme assay mix was added into 96 well plates along with 50 µl reaction mixture. 200 µM glucose was used as standard. After incubating the plates for 30 min in dark reading of absorbance were taken at 560 nm. Activity of VInv was calculated as nmol glucose formed per minute per mg of protein.

Reducing sugars analysis

For sugar analyses (Spiro, 1966), freeze dried 5 mg samples were put into 1.5 ml tubes along with 4-5 beads and shaken in pulverize shaker for ~1 min to pulverize the sample. Samples were suspended in 4 ml 80% ethanol and then vortexes and placed in a 60 °C shaking water bath overnight. The next day, tubes were spin for 10 min at 20 °C at 4000 rpm and the supernatant was transferred into new tubes. The pellets were re-suspended in 4 ml 80% ethanol and placed in a 60 °C shaking water bath set overnight. The next day, samples were spin for 10 min at 20 °C at 4000 rpm and the supernatant was transferred added to the tubes from the first extraction. At this point, the supernatant was nearly 8 ml and the volume was brought to 10 ml with 80% ethanol. The sample was mixed by inversion and a 1.5 ml sample was pipetted into a 2 ml tube. The tube was placed in a vacuumfuge overnight to dry it without heat. For HPLC, 1 ml of distilled water was added to the dried sample and incubated at room temperature for 30 min and vortexes at high speed for 10 min to dissolve the pellet completely. Then samples were placed in centrifuge at 13,000 rpm for 10 min. The supernatant was filtered using a tuberculin syringe, carrying 0.2 um regenerated cellulose filter with care. Then HPLC was done, glucose, fructose, and sucrose were calculated in mg/ml.

mRNA extraction and analysis

RNA was extracted using Agilent Plant RNA isolation Mini Kit (catalog no. 5155-2780). DNA was degraded using with Ambion DNase treatment Kit (Catalogue no. AM1906). Single-stranded cDNA was synthesized using the Invitrogen Super-Script III kit (Catalogue no.18080-051). Then, this cDNA was used as a template for quantitative

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73337344

PCR using a Bio Rad PCR system. The PCR reaction mix consisted of 2 µl of cDNA (200 ng), short length primers 10 pico mole (Forward-AAACGGGTTGGACACATCAT, Reverse -AACCCAATTCCACAATCCAA) for Vacuolar Acid Invertase gene and Fermentas Maxima SYBP Green /fluorescein qPCR Master mix (catalog no. K0241). Actin was used as the control (forward primer 5'ATGTTCCCGGGTATTGCTGACAGA-3'; reverse 5'-CTGCCTTTGCAATCCACATCTGCT-3'). Reaction containing primers of actin and invertase samples were run in on 96-well plates, PCR cycles were run at 95 °C for 10 min, 95 °C for 15 s, 55 °C for 30 s,72 °C for 30 s at melt curve 55- 95 °C. One sample each positive control (genomic DNA) of actin and invertase was also run on each plate. Fluorescence data during the extension phase and melt curve temperatures were recorded. Real time PCR Data were analyzed using the general linear model in SAS. Means comparison was carried out using a least significant difference test at $p = 0.05$. Pearson correlation coefficients were used to evaluate relationships among chips scores and biochemical parameters. The data on all studied traits was recorded from all of the performed experiments, the average data from all experiments was calculated for statistical analysis by using analysis of variance technique and significance of mean differences (Steel et al., 1997) through using SPSS 23 version.

Results

The significant differences were found among all of the families under study as shown by *Table 1*. Family 15 consistently produced light chips, while Family 14 produced darker chips (*Table 2*). All five families were generated by crossing the same female clone (HC) to plants from one wild species accession. The *S. raphanifolium* clone that was crossed to hap-chc to produce Family 15 is more desirable than the others tested in PI 310998. The lightest chips were produced from Murree (M1) greenhouse tubers stored for 4 months at 4 °C, followed by Sahiwal-1 greenhouse tubers stored for 1 month at 6 °C (*Table 2*). The darkest chips were produced from tubers grown at Sahiwal-2 and stored for 9 months at 4 °C. Significant differences ($P = 0.05$) were detected among families in this trial for PCR cycle time, enzyme activity, sucrose, glucose, and fructose. There was a significant effect of clone on PCR cycle time ($P = 0.0009$), enzyme activity ($P < 0.0001$), sucrose ($P < 0.0001$), glucose ($P < 0.0001$), and fructose ($P < 0.0001$) (*Table 3*). However, there was a significant correlation between sucrose and glucose ($P = 0.0002$), sucrose and fructose ($P = 0.0213$) and glucose and fructose ($P < 0.0001$). There was no correlation between clone chip score in the M1 trial and any of the biochemical traits. Based on clone means, correlations between pairs of biochemical traits were calculated (*Table 4*). There was found a significant but negative correlation between enzymes with Multan location, sucrose with mRNA expression. Positive and significant correlation of mRNA expression with glucose and fructose was recorded.

Table 1a. *ANOVA for chip color and biochemical traits*

Traits/locations	CEMB (L1)	Sahiwal (S1)	Multan (M2)	Murree (M1)

Discussion

HC is a heterozygous interspecific hybrid, so it may segregate for CIS alleles. However, the set of alleles it contributes to offspring is expected to be the same among the five families. Consequently, differences among families are likely due mainly to differences genetic variability among male parents from the same *S. raphanifolium* accession within each trial. All five families were generated by crossing the same female clone (HC) to plants from one wild species accession. ANOVA revealed a significant effect of family ($P < 0.05$), but not replication, on chip score at all locations except S2 (*Table 1*). Family 15 consistently produced light chips, while Family 14 produced darker chips (*Table 2*). Individuals from a population of an outcrossing species are likely to be heterozygous and heterogeneous. While PI 310998 is a good source of CIS resistance genes, fine screening of the population for individuals that produce a high proportion of resistant offspring is likely to be productive. Fine screening of accessions for individuals carrying traits of interest has been reported in potato (Bamberg et al., 1996; Bamberg et al., 1998; Douches et al., 2001). The *S. raphanifolium* clone that was crossed to hap-chc to produce Family 15 is more desirable than the others tested in PI 310998.

The lightest chips were produced from Murree (M1) greenhouse tubers stored for 4 months at 4 °C, followed by Sahiwal-1 greenhouse tubers stored for 1 month at 6 °C (*Table 2*). The darkest chips were produced from tubers grown at Sahiwal-2 and stored for 9 months at 4 °C. We did not expect lighter chip color from tubers stored at 6 °C than at 4 °C. However, the combined effect of environmental and cultural practices can affect tuber quality, which we visualized in the finished processed products. Suboptimal environments result in an increase in internal tuber disorders (Zhou et al., 1994). Long-term storage of potato tubers (six month or more) has significant, variety-dependent effects on sugar and amino acid concentrations (Muttucumaru et al., 2014). Consequently, darker chip color in the long storage trials (M2 and L1) was expected. Tubers from trial Murree were chosen for analyses of acid invertase RNA levels (as measured by the number of PCR cycles to reach the threshold), acid invertase activity, and levels of the sugars sucrose, glucose, and fructose. Significant differences ($P = 0.05$) were detected among families in this trial for PCR cycle time, enzyme activity, sucrose, glucose, and fructose. However, since there was no difference in chip color among families in trial Murree, additional analyses were based on clones without regard to family. There was a significant effect of clone on PCR cycle time ($P = 0.0009$), enzyme activity ($P < 0.0001$), sucrose ($P < 0.0001$), glucose ($P < 0.0001$), and fructose ($P < 0.0001$) (*Table 3*).

Based on clone means, correlations between pairs of biochemical traits were calculated. There was no significant correlation between acid invertase RNA or activity and any of the three sugars. However, there was a significant correlation between sucrose and glucose ($P = 0.0002$), sucrose and fructose ($P = 0.0213$) and glucose and fructose ($P < 0.0001$). There was no correlation between clone chip score in the M1 trial and any of the biochemical traits. Based on clone means, correlations between pairs of biochemical traits were calculated (*Table 4*). There was found a significant but negative correlation between enzymes with Multan location, sucrose with mRNA expression. Positive and significant correlation of mRNA expression with glucose and fructose was recorded. It was suggested from positive correlation may be used to improve in the quality traits while improving the related traits and improvement may be fixed in next generations. The negative correlations suggested that the decrease in the trait may be

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73337344

fixed in next generations. For the improvement of qualitative and quantitative traits positive correlations are used for selection (Ali and Jansky, 2015; Ali et al., 2014, 2016, 2013). The ratio of sucrose to glucose is a reflection of acid invertase enzyme activity. Again however, there was no significant difference in the sucrose: glucose ratio between the clones with high enzyme activity and those with low activity. It is interesting that acid invertase enzyme activity and mRNA production is negatively correlated with chip color in this study. In a previous study using the same accession of *S. raphanifolium*, silencing the potato vacuolar acid invertase gene resulted in light colored chips (Bhaskar et al., 2010). In that study, relatively high levels of invertase transcript were detected in hap-chc, but transcript levels were low in some hap-chc x *S. raphanifolium* 310998 hybrids. Several studies have demonstrated high sequence variability and genotype specific variants among potato protease inhibitors. These inhibitors significantly affect the Vacuolar Acid invertase activity (Bauw et al., 2006; Jørgensen et al., 2005). Effects of patatins and phospholipas in altering membrane lipid composition could explain differences between genotypes with strong (CIS-s) and weak (CIS-t) cold acclimation responses (Theocharis et al., 2012). More recently, association genetics demonstrated that DNA polymorphisms in genes encoding invertases and starch phosphorylases were associated with potato chip color, starch content and starch yield (Fischer et al., 2013).

Conclusions

Same genotype can show variable resistance in different trial satiations and in conclusive invertase activity is genotypes and trials dependent. Significant trial effects can be detected; if all subsequent analyses are carried by trial. Invertase enzyme is responsible for cold induced sweetening but not exclusively. Its activity is trail, genotype and environmental conditions dependent. Along with fine screening it is the need of time to sort out best potato germplasm based on the action of other genes involved in glycolysis pathway.

PERCEPTIONS OF SMALL-SCALE MAIZE FARMERS ON CLIMATE CHANGE IMPACTS IN HHOHHO, MANZINI AND SHISELWENI REGIONS OF THE KINGDOM OF ESWATINI

(Received 15th Feb 2019; accepted 10th Apr 2019)

Abstract. The study examined the perceptions of small-scale maize farmers in the Kingdom of eSwatini regarding the impacts of climate change. These perceptions were assessed by means of a five-point Likert scale; 59% of the respondents strongly agreed and 41% agreed that climate change has a significant influence on maize production and low yield. Multi-stage sampling involving purposive and random sampling was used in the study. The study was based on data from 188 small-scale maize farmers supplying the National Maize Corporation (NMC) depots in eSwatini. Principal component analysis (PCA) was used to analyse the data, and four factors that farmers perceived as influencing climate change were identified. The conclusion reached was that any adaptation strategies developed by smallholder maize farmers to combat climate change were largely influenced by the farmers' perceptions of climate change.
Keywords: *principal component analysis, maize, National Maize Corporation, climate change, eSwatini*

Introduction

Maize is a staple food in the Kingdom of eSwatini, and most small-scale farmers cultivate this crop, which is their most important source of income. Maize is highly susceptible to climate change (Sutcliffe et al., 2016); the small-scale farmers who participated in the study mentioned heat waves, drought, floods, water scarcity and plant diseases as the main factors affecting their maize production and associated these phenomena with climate change. The perceptions of small-scale maize farmers with regard to external influences are an important element determining their decisions and course of action. However, limited research has been conducted into the perceptions of maize farmers in the Kingdom of eSwatini relating to climate change. According to Debela et al. (2015), many of the studies on perceptions regarding climate change are aimed at better understanding the extent of farmers' perceptions but fail to identify the factors that influence the level at which small-scale farmers perceive climate change and its impact. Small-scale farmers and the general population find it necessary to make decisions every day concerning how to cope with and adapt to the impacts of climate change in both agricultural production and their daily lives. In eSwatini, smallholder maize farmers are already experiencing the unfavourable effects of climate change, and the impact of this phenomenon is already being felt across the socio-economic and agricultural sectors. The degree of vulnerability of communities to the effects of climate change has increased sharply, and this has negatively affected various sectors of the economy such as agriculture, water, energy, health and forestry. Establishing the perceptions of small-scale maize farmers is necessary for informed policy decisions and mitigation strategies among farmers, hence the study objective of investigating the

DOI: http://dx.doi.org/10.15666/aeer/1704_73457356

perceptions of small-scale maize farmers in the Hhohho, Manzini and Shiselweni regions of eSwatini as these related to the impact of climate change.

Literature review

Sub-Saharan Africa is expected to have rainfall above the global average, yet rainfall is declining. There is growing evidence that extreme events, such as drought and floods, have been common occurrences, and these affect small-scale farmers in developing countries, who depend heavily on rainfed agriculture for their livelihoods (Belay et al., 2017). As stated above, smallholder farmers and the general population find it necessary to make decisions every day concerning how to cope with and adapt to the impacts of climate change both in agricultural production and in their daily lives. A study by Jacobi et al. (2015) indicated that small-scale farmers are affected by the negative impacts of global climate change and that livelihood based on small-scale agriculture tends to be highly vulnerable to climate change, since these farmers have limited coping options. A better understanding of farmers' concerns and the way they perceive climate change is crucial and will assist in equipping farmers to take the correct adaptive measures (Abid et al., 2017; Ayanlade et al., 2016). Perception significantly affects the way in which farmers deal with climate-induced risks and opportunities (Debela et al., 2015).

The rapid pace of climate change has been seen to have marked effects on food availability in Swaziland, as it affects crop production (Mamba et al., 2015). Adebayo et al. (2012) have reported that smallholder maize farmers with poor resources demonstrate low levels of awareness concerning climate change, and that this in turn affects their food production. Therefore, the need to identify farmers' perceptions regarding climate change is a vital step in dealing with the impacts of this phenomenon (Abid et al., 2015).

Materials and methods

Sampling and data collection

The study reported on in this article was carried out in the Kingdom of eSwatini, previously known as the Kingdom of Swaziland. The Kingdom of eSwatini (*Fig. 1*) is a small, landlocked, mountainous country in southern Africa, covering an area of 17 364 km^2 (Mamba et al., 2015). The sample frame error was controlled by obtaining a list of the 539 maize farmers who supplied maize to National Maize Corporation (NMC) depots from 2010 to 2014. This list was obtained from the NMC in 2017, and data was collected during the period 2017 to 2018. The multi-stage sampling technique was used in the study; to involve maize farmers who produced for both consumption and for sale, purposive selection criteria were used. These criteria were very useful for identifying those farmers who supplied maize to NMC depots during the period 2012 to 2014; random sampling was then used to give each small-scale farmer a chance to be selected for questionnaire administration. According to Krejcie and Morgan, as discussed by Rahi (2017), the sample size for a population of 539 should be 217; in this study, 219 questionnaires were administered to small-scale maize farmers in the three maize-producing regions of eSwatini, namely, Hhohho, Manzini and Shiselweni. During data capture and analysis, 31 questionnaires were found to be incomplete and invalid, and the sample size was therefore reduced to 188 respondents.

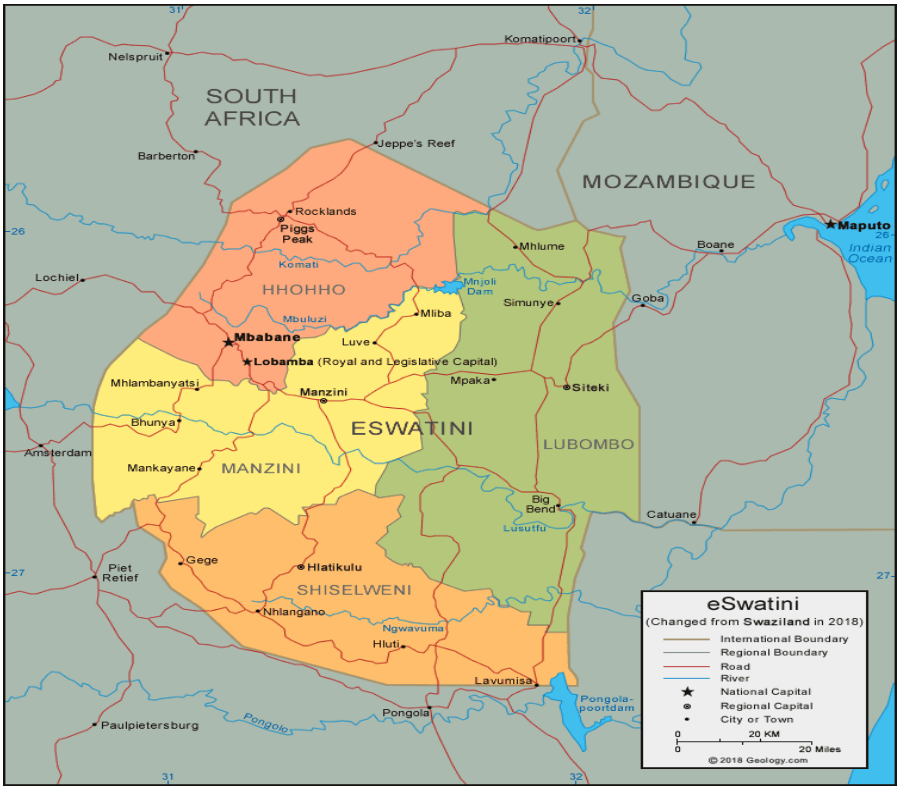

Figure 1. *Map of eSwatini. (Source: https://geology.com/world/swaziland-satellite-image.shtml – accessed: 10 March 2019)*

Analysis of variance results

The Kaiser-Meyer-Olkin (KMO) measure of sampling adequacy and Bartlett's test of sphericity were used to assess the appropriateness of the data for factor analysis. The Chi-square was 480.330 with 36 degrees of freedom, which was significant at ($p < 0.05$), as shown in *Table 1*. At 0.471, the KMO measure of sampling adequacy was less than 0.50, and so factor analysis was considered an appropriate technique for further analysis of the data.

Table 1. *Analysis of variance results and KMO Bartlett's test of sphericity. (Source: own calculations based on the survey (2017–2018); Kaiser-Meyer-Olkin measure of sampling adequacy = 0.471)*

Chi-square	df	Significance
480.330	36	0.000

Data analysis

In terms of gender distribution, 47.9% of the respondents were male and 52.1% female. The respondents' perceptions were measured using a five-point Likert scale, which was applied to rank responses according to how respondents perceived climate change impact in the three maize producing regions; responses ranged as follows: 1. Strongly agree, 2. Agree, 3. Don't know 4. Disagree, and 5. Strongly disagree. A mean

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73457356

score for each variable was calculated based on questions measuring perceptions. Questions relating to how the small-scale maize farmers perceived climate change covered the following domains: incidences of floods, shifts in rainfall seasonality, persistent droughts, increasing food crop costs, destruction of buildings, infrastructure and soil erosion. A "strongly agree" score on the scale indicated a positive perception of climate change and a "strongly disagree" indicated a negative perception of climate change.

Principal component analysis (PCA) was used to rank a small number of variables that could account for the variability found in a relatively large number of variables, not including all the original variables in the analysis. This method allowed the researcher to find new variables representing the underlying or latent variables of the dataset of the statement, considered to be the factors that best described the ideas that conveyed farmers' perceptions of the impacts of climate change. Criteria such as eigenvalues greater than one and cumulative variance were explained by increasing the number of factors that were included in the factor model, and the interpretability of extracted factors was used to guide the choice of the appropriate number of factors to be included in the model of choice, or best fit model.

Results and discussion

Demographic of respondents

According to Debela et al. (2015), perceptions regarding climate change among small-scale farmers and rural communities is driven by multiple forces, such as household demographics and farm factors. The demographics of the respondents are presented in *Table 2*.

Table 2. *Summary of demographics. (Source: own calculations based on the survey (2017–2018), N = 188)*

Variables	Percentages
Age of the respondents	
Below the age of 25 years	7.5%
25–30 years old	3.9%
31–40 years old	30.3%
41–50 years old	25%
Over the age of 51 years	
Educational level	33.3%
No formal education	15.4%
Primary education	39.9%
Secondary education	27.1%
Tertiary education	17.6%
Household size	
Fewer than 2 members	11.7%
3–6 members	40.4%
7–10 members	36.2%
More than 10 members	11.7 %

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73457356

Age of the respondents

Table 2 presents the age distribution of respondents. The age of the respondents was analysed as a reflection of their agricultural production experience. Debela et al. (2015) identified a close relationship between the age of a farmer and farming experience and his or her accumulated knowledge of the environment, including changes in climate conditions. 33.3% of the respondents were over the age of 50, 30.3% of the respondents were between the ages of 31 and 40, and 25% of the respondents were between the ages of 41 and 50. The remaining 3.9% of the respondents were between the ages of 25 and 30. This suggests that maize farming in the Kingdom is dominated by older smallholder farmers. The results also revealed that 30.3% of the heads of households were in the productive age group of 31 to 40 and more than 51 and would therefore be in a position to take action with regard to climate change.

Education level

The distribution of respondents by education level is shown in *Table 2*. The highest number of respondents (39.9%) had higher primary education, followed by secondary education (27.1%), tertiary education (17.6%) and non-formal education (15.4%). Farmers with a higher level of education had slightly more knowledge and information about good agricultural principles, and those with university education were able to analyse and interpret information much better than farmers with no formal education. The results also showed that farmers with education and agricultural skills made a significant contribution in the context of maize production activities. The level of formal education attained by farmers influences their ability to perceive climate change and its impact (Debela et al., 2015).

Household size

In the maize production areas in the three regions, 11.7% of households consisted of fewer than 2 members, and a further 11.7% of households consisted of more than 10 members. 40.4% of households consisted of 3 to 6 members, and 36.2% of households comprised 7 to 10 members (*Table 2*). The fact that there were so many large households would be expected to have a positive impact on maize production when all household members were fully engaged in agricultural activities. The results also showed that as the number of household members increased, so did the chances that the household was engaged in agricultural production, since it would be possible to take advantage of a readily available labour force, and the chances of adapting to climate change impact would therefore be high. According to Debela et al. (2015), households consisting of many members are more likely to engage in non-farm income generating activities, because non-farm income buffers financial losses from farming; in consequence, householders are less likely to perceive climate change.

Percentage ratings of the perceptions regarding climate change impact

Table 3 presents the descriptive statistics of the variables that indicated perceptions of climate change. About 59% of the respondents perceived climate change to have a very significant influence on maize production, while 44.7% of the farmers strongly agreed that shifts in rainfall patterns have caused crop failures and low yield.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73457356

Table 3. *Percentage ratings of respondents' perceptions regarding climate change impact. (Source: own calculations based on the survey (2017–2018), N = 188)*

Perceptions regarding climate change impact	Strongly agree	Agree	I do not know	Disagree	Strongly disagree
Climate change has a very big impact on maize production	59%	41%	00%	00%	00%
Variations in climate have caused an increase in incidences of floods	7.4%	12.2%	29.3%	16.5%	34.6%
Shifts in rainfall seasonality have caused crop failures and low yield	44.7%	34.0%	12.2%	4.8%	4.3%
Crop varieties have no longer been productive due to persistent droughts	25.5%	20.7%	29.3%	14.9%	9.6%
Climate change has led to crop infestation and diseases due to droughts	7.4%	31.9%	37.8%	22.9%	00%
Climate change has led to rural–urban migration	00%	15.4%	46.3%	24.5%	13.8%
Excessive rainfall contributes to destruction of buildings and infrastructure	67.0%	17.6%	11.7%	3.7%	00%
Flood does not contribute to soil erosion	20.2%	5.9%	28.7%	24.5%	20.7%
Water becomes scarce due to droughts and low rainfall	72.3%	20.2%	00%	3.2%	4.3%
Dry spell of crops is the result of drought	30.9%	45.7%	12.2%	3.7%	7.4%
Climate variability has an impact on rain-fed production	42.0%	10.1%	31.9%	7.4%	8.5%
Decrease in rainfall reduces water stored in bands	27.7%	27.7%	3.1.9%	4.3%	8.5%
Climate change has led to deforestation	20.7%	31.4%	42.0%	3.7%	2.1%
The cost of food crops is increasing because of climate change	24.5%	36.2%	25.0%	4.3%	10.1%

67% of the small-scale maize farmers strongly agreed that excessive rainfall contributes to destruction of buildings and infrastructure, 72.3% strongly agreed that water becomes scarce due to droughts and low rainfall. The results further reveal that 42% of smallholder maize farmers perceived climate variability to have a significant impact on rainfed maize production. Mamba et al. (2015) reported different perceptions of climate change among farmers, further showing that these farmers tended to overestimate the negative impact of climate change, and that this misperception affected crop production.

Scree plot

In the scree plot in *Figure 2,* eigenvalues were plotted against principal component (PC) numbers. The PC numbers were plotted on the X-axis, while the eigenvalues were plotted on the Y-axis. The PCs that were kept were those on the slope of the graph before the decrease in eigenvalues levels off to the right of the plot. Using this criterion,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73457356

4 PCs, namely: impact on maize production, climate change, flood incidences, shifts in rainfall and droughts were retained in the analysis of this study.

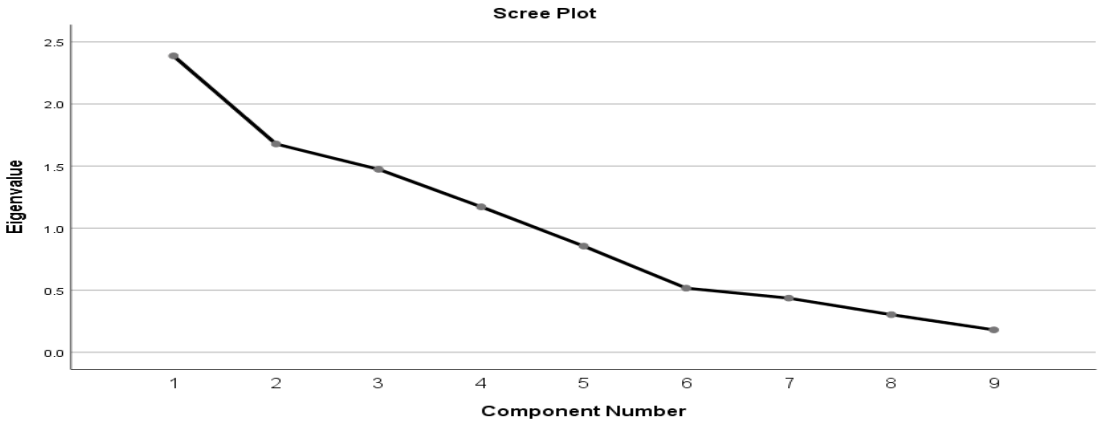

Figure 2. *Scree plot*

In *Figure 2,* the different variables represented different patterns of perceptions of small-scale maize farmers regarding climate change. The grouping of the original variables was done by observing the magnitude of the factor loadings. Each PC was considered a weighted linear combination of the variables and was written with the heavy loadings and given the most descriptive name.

Cumulative column

The eigenvalue table was divided into three sub-sections, namely Initial eigenvalues, Extracted sums of squared loadings and Rotation of sums of squared loadings. For analysis and interpretation purposes we were concerned only with the extracted sums of squared loadings. Note that the first factor accounts for 26.525% of the variance, the second 18.640%, the third 16.373% and the fourth 13.017%. All the remaining factors were not significant. *Table 4* presents the number of principals, from which 4 were selected. The cumulative column indicates that extracting the 4 factors made it possible to explain roughly 75% of the variation in the data.

Principal component factor analysis (Rotated factor pattern)

Principal component 1 (PC1) contributed 26.525% of the variations, with an eigenvalue of 29.419, and represented small-scale farmers who were aware of the impact of climate change, such as floods, soil erosion and water scarcity between 2010 and 2014 (see the Component 1 column in *Table 5*). Of the four coefficients, three were positive, indicating a positive correlation among the significant variables, for instance, an increase in flood incidences will result in an increase in soil erosion; on the other hand, an increase in flood incidences decreases water scarcity. The PC1 equation is presented below:

$$PC1 = 0.465X_1 + 0.754X_2 + 0.400X_8 - 0.907X_9 \quad \text{(Eq.1)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73457356

Table 4. *Cumulative percentages of variance. (Source: own calculations based on the survey (2017–2018), N = 188)*

	Initial eigenvalues			Extraction sums of squared loading			Rotation sums of squared loadings		
Variables	**Total**	**% of variance**	**Cumulative %**	**Total**	**% of variance**	**Cumulative %**	**Total**	**% of variance**	**Cumulative %**
Impact on maize production	2.39	26.53	29.419	2.39	26.53	26.53	1.86	20.66	20.66
Flood incidences	1.678	18.640	45.165	1.678	18.640	45.165	1.762	19.577	40.240
Shifts in rainfall	1.474	16.373	61.537	1.47	16.373	61.537	1.671	18.562	58.802

Water scarcity	0.180	2.004	100.000						

Table 5. *Rotated factor pattern. (Source: own calculations based on the survey (2017–2018))*

Variables	Component 1	Component 2	Component 3	Component 4
Impact on maize production (X_1)	**0.465**	**-0.349**	0.429	**0.477**
Flood incidences (X_2)	**0.754**	-0.051	0.184	-0.097
Shifts in rainfall (X_3)	-0.057	**0.298**	**- 0.646**	**0.404**
Droughts (X_4)	0.006	0.080	**0.860**	0.191
Crop disease (X_5)	0.159	**0.897**	0.016	-0.070
Rural–urban migration (X_6)	0.082	0.082	**0.519**	-0.366
Structural destruction (X_7)	-0.238	0.069	-0.029	**0.859**
Soil erosion (X_8)	**0.400**	**-0.729**	0.072	-0.286
Water scarcity (X_9)	**-0.907**	-0.076	0.143	0.146

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73457356

Principal component 2 (PC2) contributed 18.640% of the variations, with an eigenvalue of 45.165. The variables included small-scale maize farmers who were aware of the impacts of climate change on maize production, and experienced shifts in rainfall, crop diseases and soil erosion between 2010 and 2014. The results in the Component 2 column in *Table 5* imply that shifts in rainfall to higher levels decreases the impact on maize production. However, an increase in shifts in rainfall increases crop diseases. The PC2 equation is presented below:

$$PC2 = -0.349X_1 + 0.298X_3 + 0.897X_5 - 0.729X_8 \quad \text{(Eq.2)}$$

Principal component 3 (PC3) contributed 16.373% of the variations, with an eigenvalue of 61.537. The variables included small-scale maize farmers who held perceptions on climate change and who had experienced a significant shift in rainfall, droughts patterns and rural–urban migration. The results in the Component 3 column in *Table 5* indicate that a decrease in rainfall increases drought patterns and rural urban migration. The PC equation between 2010 and 2014 is presented below:

$$PC3 = -0.646X_3 + 0.860X_4 + 0.519X_6 \quad \text{(Eq.3)}$$

Principal component 4 (PC4) contributed to 13.017% of the variations, with an eigenvalue of 70.506. The variables included small-scale maize farmers who held perceptions on climate change and who had experienced impact on maize production, shifts in rainfall and structural destruction between 2010 and 2014. The results in the Component 4 column in *Table 5* show a positive correlation among the variables. The PC equation between 2010 and 2014 is presented below:

$$PC4 = 0.477X_1 + 0.404X_3 + 0.859X_7 \quad \text{(Eq.4)}$$

Correlation between the explanatory variables in the analysis of variance

To determine the degree and nature of the relationship and the direction of association among the independent and dependent variables, a correlation analysis was worked out and presented in the form of a correlation matrix. *Table 6* shows a correlation or relationship between the perceptions of small-scale maize farmers regarding impacts of climate change and the independent variables: the impact on maize production, floods, shifts in rainfall, droughts, crop diseases, rural–urban migration, structural destruction, soil erosion and water scarcity. A positive relationship between perception and the independent variables was established. Of the nine independent variables, five, namely crop diseases, rural–urban migration, structural destruction, soil erosion and water scarcity, were positively and significantly correlated ($p < 0.05$) with the perceptions of farmers regarding climate change.

Table 6 shows that crop diseases were positively and significantly correlated ($p < 0.373$) with floods and droughts (0.375). This meant that farmers who perceived that crop diseases were associated with climate change had high perceptions of floods and droughts as the effects of climate change. A study conducted in Swaziland by Mamba et al. (2015) showed that the majority of farmers (88.1%) indicated that they had noted changes in the frequency, intensity and duration of drought over the preceding years.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73457356

Table 6. *Correlation between the explanatory variable in the analysis of variance. (Source: own calculations based on the survey (2017–2018))*

Variables	1	2	3	4	5	6	7	8	9
1. Impact on maize production	1.000								
2. Flood incidences	0.002	1.000							
3. Shifts in rainfall	0.016	0.000	1.000						
4. Droughts	0.000	0.003	0.000	1.000					
5. Crop disease	0.008	**0.373**	0.033	**0.375**	1.000				
6. Rural–urban migration	**0.305**	**0.307**	0.005	0.000	0.000	1.000			
7. Structural destruction	0.010	0.000	0.000	**0.250**	**0.274**	0.001	1.000		
8. Soil erosion	0.000	0.002	0.000	0.129	0.000	0.001	0.000	1.000	
9. Water scarcity	0.001	0.000	**0.255**	0.069	0.003	0.118	0.000	0.000	1.000

$P < 0.05$, $P < 0.01$, $N = 188$

Rural–urban migration was positively correlated (sig. 0.305) with impact on maize production and floods (0.307), and it affected the perceptions of farmers regarding climate change. The more aware the farmers were of rural–urban migration, the more they perceived maize production and floods to be effects of climate change.

The results in *Table 6* showed that structural destruction was positively associated with drought at (sig. 0.250) and crop diseases at (sig. 0.274). From the results, it could be inferred that farmers who perceived structural destruction to be caused by climate change also perceived that droughts and crop diseases were caused by climate change. Water scarcity was also positively correlated with shifts in rainfall. The likelihood of water scarcity as a result of shifts in rainfall was statistically significant (sig. 0.255).

Interpretation of the independent variables

The results of descriptive statistics for all the variables under investigation is presented in *Table 7*. The means and the standard deviation of respondents are given. The means showed rural–urban migration, floods, soil erosion, crop diseases and droughts to be the most important variables influencing small-scale maize farmers' perceptions of climate change. These variables had the highest means, namely 3.4734, 3.4043. 3.2340, 2.9894 and 2.6755, respectively.

Table 7. *Descriptive statistics of the variables. (Source: own calculations based on the survey (2017–2018), N = 188)*

Variables	Mean	Std. deviation
Impact on maize production	1.4096	0.49307
Flood incidences	3.4043	1.12644
Shifts in rainfall	1.9043	1.08040
Droughts	2.6755	1.35079
Crop disease	2.9894	1.24096
Rural–urban migration	3.4734	1.02604
Structural destruction	1.5585	0.96560
Soil erosion	3.2340	1.41743
Water scarcity	1.41743	0.94405

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73457356

Box plots

Box plots were used to show patterns of responses for each group, as shown in *Figure 3.* They provided a useful way of visualising the range and other characteristics of responses for large groups. As an indicator of centrality, the box plot was of a sample of 5 points from a population centred on 3. As an indicator of symmetry, the box plot was a sample of 5 points from a symmetrical population.

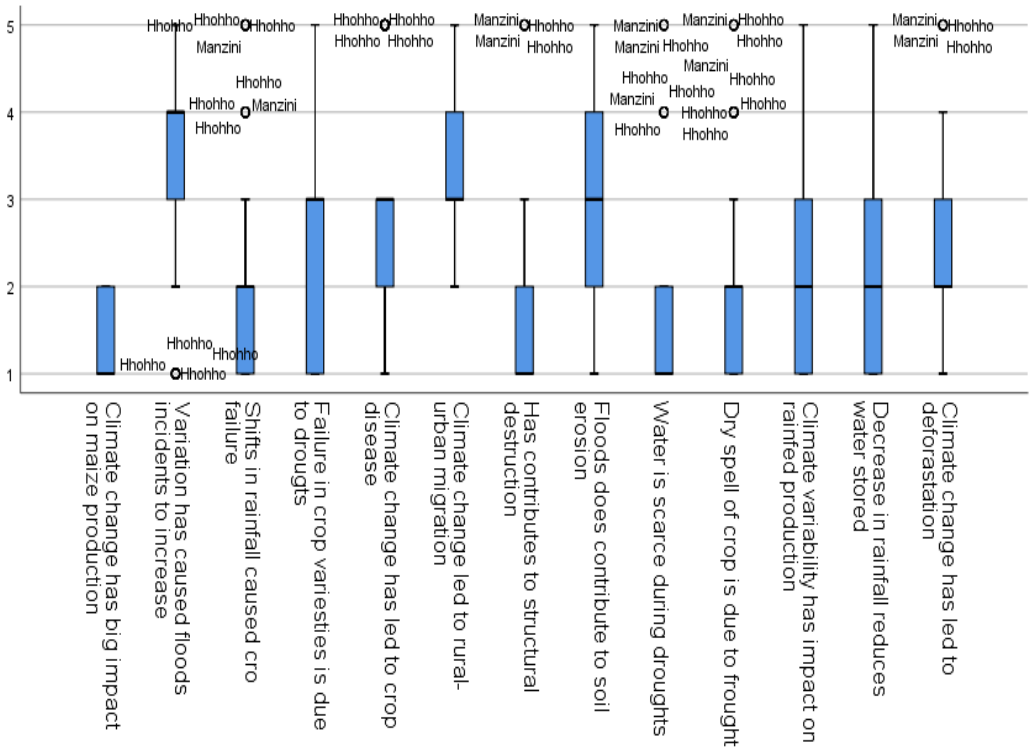

Figure 3. *Box plots showing overall patterns of response for groups*

The data sets for variables 1 and 9, namely impacts on maize production and water scarcity during drought, were skewed to the left with a median of 1. Variables 2 and 6, namely caused floods to increase and rural–urban migration, were skewed to the right and to the left, respectively. The data sets for variables 3 and 10, shift in rainfall caused crop failure and dry spells of crops due to drought, were skewed to the right. According to Debela et al. (2015), farmers perceived the onset of rainfall to be much later over the past ten years than 20 years ago, and they also perceived rainfall to cease halfway through the growing season. Variable 8, floods which contributed to soil erosion, was symmetrical. This showed that small-scale maize farmers perceived soil erosion to be a significant result of climate change.

The line for 1 variable (Floods contributes to soil erosion) is in the centre of the box, and the whisker lengths are the same. In the case of 6 variables (shift in rainfall, structural destruction, dry spells, climate variability and reduced rainfall), the top whisker is much longer than the bottom whisker, and the line gravitates towards the bottom of the box. In the case of 1 variable (climate change has led to crop failure), the bottom whisker is much longer than the top whisker, and the line rises to the top of the box.

DOI: http://dx.doi.org/10.15666/aeer/1704_73457356

Conclusion

The perceptions of small-scale maize farmers regarding climate change was analysed using information from maize farmers relating to the farming seasons during the period 2010 to 2014. Results showed that farmers had different levels of perception regarding climate change. They also showed that maize production declined in the 2012 to 2014 cropping seasons. Principal component analysis revealed that it was possible to place different perception factors affecting climate change in different groups. In conclusion, smallholder maize farmers in the three regions held a range of perceptions regarding climate change. The results indicated that any adaptation strategies developed by smallholder maize farmers to combat climate change were largely influenced by their perceptions regarding climate changes. Farmers' perceptions, if well articulated, have a significant influence on how the government responds or intervenes in such situations.

Abstract. Heat negatively affects wheat production in the world. At present, heat tolerance remains one least understood field in wheat genetics and breeding, because there are not enough effective methods for identification of heat stress and tolerance. This study used sixteen cultivars of winter wheat to evaluate a new method with stress intensity (δ) and heat tolerance index (HTI), and assess the susceptibility index of canopy temperature (SCT) and leaf chlorophyll content (SLCC) at different days after the anthesis to identify heat tolerance. The result showed HTI had significant positive correlations with yield under heat stress, and significant negative correlations with yield reduction rate, indicating that HTI is a good indicator of both yield potential and stability under heat stress which can be used to identify heat tolerance in later generations. SCT at 28 DAA had significant positive correlation with yield and significant negative correlation with yield reduction rate under heat stress. SLCC at 29 DAA had positive correlation with yield and significant negative correlation with yield reduction rate, and especially kernel weight reduction under heat stress. The two indicators may be used to screen for heat tolerant germplasm in early generations, or to identify a large number of wheat cultivars concurrently.
Keywords: *wheat, heat stress, stress intensity, yield, yield reduction*

Introduction

Wheat (*Triticum aestivum* L.) is one of the most important foods in the world, and it has become a basic food staple in Asia, Europe, and North Africa. Therefore, global wheat yield needs to be increased to meet the rising demand for this grain, and high grain value must be maintained under climate change to ensure ongoing human nutrition, end-use functional properties, as well as commodity value (Nuttall et al., 2017). As climates warm, heat stress during the post-anthesis period (terminal heat) negatively affects wheat production. This increased temperature not only hastens the phenological stages of wheat development but also reduces the duration of the grain filling stages, thereby lowering grain yield and quality (Faroop et al., 2011; Figueiredo et al., 2015; Gooding et al., 2003; Hoffmann et al., 2006). Increases in mean daily air temperatures of 1 °C during wheat development are projected to shorten the grain filling period by 3.1 d and decrease the weight per grain by as much as 2.8 mg (Wiegand and Cuellar, 1981). These wheat yield losses severely threaten global food security.

Most heat stress studies were aimed at predicting and maximizing yield (Amani et al., 1996; Blum et al., 2001; Rane and Nagarajan, 2004; Reynolds et al., 1998; Tewolde

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73577369

et al., 2006; Xu et al., 2000). Some other studies focused on stability under heat stress. For example, some wheat genotypes were demonstrated to be tolerant to the effects of heat stress on grain quality at 29 days after anthesis (days after anthesis, DAA) (Blumenthal et al., 1995). In a recent paper, 54 genotypes were classified in two overall groups: stable and unstable, based on their rank shifts in different environments (Hernández-Espinosa et al., 2018). However, these numerical values cannot completely reflect the heat resistance of different wheat cultivars. The ultimate indicator of cultivar-specific heat resistance is manifested in the absolute and relative yield, that is, both yield potential and stability. Ideal heat resistance would be displayed as a durable, consistent yield with minimal yield reduction under heat stress conditions.

Some characteristics like leaf chlorophyll content and canopy temperature depression may be correlated with field performance, especially under heat stress (Jin et al., 2012; Wu et al., 2015). Ayeneh et al. (2002) compared the leaf, spike, peduncle, and canopy temperature depression in wheat under heat stress. Bahar et al. (2008) studied the effect of canopy temperature depression on grain yield and yield components in bread and durum wheat. Webber et al. (2015) used a multi-model approach including canopy temperature to simulate heat stress in irrigated wheat in a semi-arid environment. Gautam et al. (2015) found canopy temperature may be used as a selection parameter for grain yield and its components in Durum Wheat under terminal heat stress in late sown conditions. The term of susceptibility index ($1\text{-}Y/Y_p$) was used to reflect response of plant yield to heat stress, where Y is yield under stress, Yp is yield without stress, which was commonly used for estimating stress resistance (Li et al., 2018; Mason et al., 2010).

The purpose of this study was to evaluate a new method for identifying the heat tolerance of wheat cultivars based on yield and yield reduction under heat stress, and the related physiological indicators of canopy temperature and leaf chlorophyll content at different times after heat stress treatment. We designed a movable greenhouse for temperature control and created a heat tolerance index (heat tolerance index, HTI) for testing different wheat cultivars. This identifying method combining yield potential and stability could be a useful selection method for characterizing cultivar performance under heat stress. The susceptibility index of canopy temperature (susceptibility index of canopy temperature, S_{CT}) and leaf chlorophyll content (susceptibility index of leaf chlorophyll content, S_{LCC}) at different days after the anthesis have potential application for breeding in indirect selection to identify physiologically superior genotypes under heat stressed environment.

Materials and methods

Cultivars

The 16 winter wheat (*Triticum aestivum* L.) cultivars most commonly grown in the North China Plain (*Table 1*) were evaluated for heat tolerance. Cultivars were mechanically sown by Wintersteiger plotseed TC at the research station in Hebei Hengshui (37°44′N, 115°42′E; elev. 20 m). Meteorological data for this area is shown in *Figure 1*.

The experiment was conducted on sandy loam soil in field conditions. A split block design with 3 × 2 treatments and three replicates was employed during the 2016-2017 and 2017-2018 crop seasons. Each cultivar was grown in an 11.16-m^2 plot (nine rows of 8 m length with 15.5 cm space between rows). After adjusting for seed size, the seed

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73577369

density was maintained at a uniform population of 300 plants per m^2 (3 million plants per hectare), according to the 1000 grain weight and germination percentage. Standard agronomic practices recommended for normal fertility (340 kg/ha N: 172.5 kg/ha P_2O_5: 40 kg/ha K_2O) were followed. All K_2O and P_2O_5 were applied at the time of sowing. Nitrogen was supplied in split applications: 170 kg/ha N at sowing and 170 kg/ha N at the first irrigation. Care was taken to avoid moisture and biotic stress by ensuring timely irrigation and pesticide control. Cultivars were harvested by Wintersteiger and weighted by electronic scale.

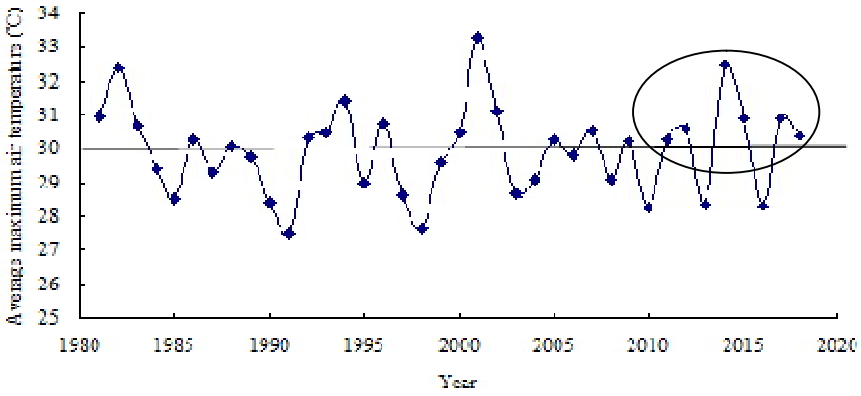

Figure 1. *Average daily maximum air temperature (14 May - 14 June) per year from 1981 to 2018 in the wheat growing region from this study. Temperature varied from 27.5 °C in 1991 to 33.3 °C in 2001. The increased frequency with higher daily maximum temperature than average value in a 10-year cycle indicates an increased risk in environmental heat pressure during the wheat grain filling stage in this region*

Heat treatments

On 14 May 2016, the mobile temperature-controlled greenhouse was used to cover the 16 cultivars at 14 DAA (for 80% of individuals). Heat treatments continued for 32 d, increasing the daily maximum temperature from 28.1 °C to 48.0 °C during 2016-2017 and from 22.3 °C to 48.6 °C during 2017-2018 (*Fig. 2*). Temperature was maintained 5 °C (± 1 °C) higher than ambient conditions.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73577369

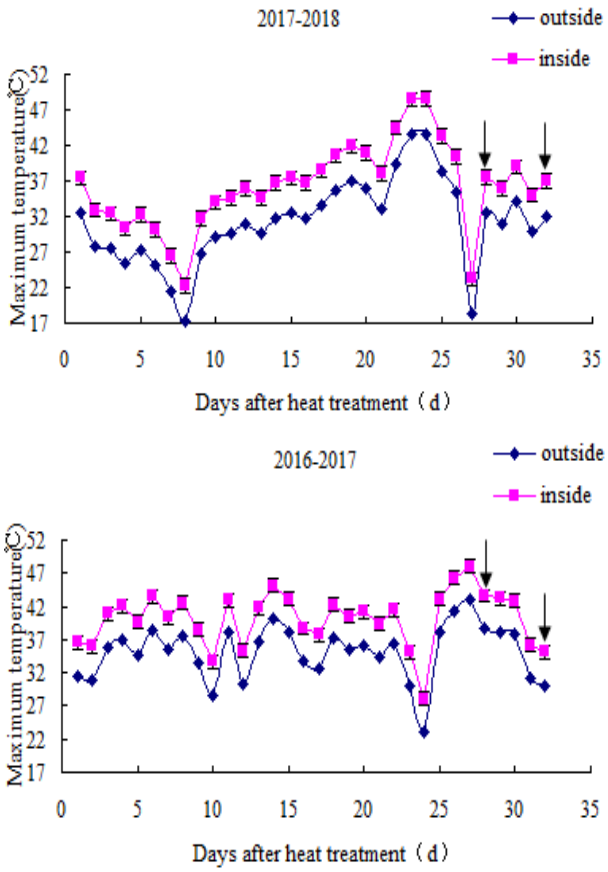

Figure 2. *Daily maximum temperature inside and outside of the greenhouse in the 2016-2017 and 2017-2018 seasons. An approximate 5 °C difference between the inside and outside temperatures was maintained for 32 d. Bars mean SE. Arrows indicate the time of canopy temperature measurements. The air temperature had been measured parallel with the canopy temperature*

X and Xp indicate yield averaged over all cultivars under stress and control treatments, respectively. 1-X/Xp represents 'stress intensity' (δ). These criteria can be used to estimate resistance to stress (Li et al., 2018; Mason et al., 2010).

The heat tolerance index (HTI) includes both yield potential and stability after heat stress. To include the value of yield potential after heat stress, we substituted absolute yield under heat stress (yield, Y) into the formula, resulting in:

$$HTI = \frac{Y_S^{\,2}}{Y_{S.P}} \times \frac{Y_{CK.P}}{Y_{CK}^{\,2}} \qquad \text{(Eq.1)}$$

where Y_S: yield of identified cultivars under heat stress; $Y_{S.P}$: yield of identified cultivars under normal treatment; $Y_{CK.P}$: yield of CK cultivar under normal treatment; Y_{CK}: yield of CK cultivar under heat stress. We calculated relative yield (Y/Y_P) to account for variation in yield under the control conditions. Relative yield is commonly used in studies of stress resistance (Blum, 1973; Fischer and Maurer, 1978). We also included control data to account for variability in other environmental factors.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73577369

HTI was used to classify each cultivar (*Table 2*) as tolerant (≥ 1.20), moderately tolerant (1.00 to ≤ 1.19), moderately susceptible (0.80 to ≤ 0.99), or susceptible (≤ 0.79).

Table 2. *HTI scale for tolerance of or susceptibility to heat stress for different wheat cultivars*

Scale	HRI	Opinion
1	≥ 1.20	Tolerant
2	1.00-1.19	Moderately tolerant
3	0.80-0.99	Moderately susceptible
4	≤ 0.79	Susceptible

Canopy temperature measurements

Canopy temperature was measured using a hand-held infrared thermometer (IRT) (Model AG-42, Telatemp Crop, Fullerton, CA) at 15 and 20 d after heat treatment (28 May and 2 June). Three measurements were taken per plot with the instrument held at an angle of 30° to the horizontal plane, 1 m away from the edge of the plot and approximately 50 cm above the plants, giving a canopy view of 10 cm × 25 cm. Measurements were taken 0.5 h before and 2 h after solar noon, in full sunshine, 3 or 4 d after irrigation had been applied, as recommended by Amani et al. (1996). The equation of S_{CT} is as follows:

$$S_{CT} = \frac{CT}{CT_P} - 1 \qquad \text{(Eq.2)}$$

where CT (canopy temperature, CT) is canopy temperature under stress, CT_p is canopy temperature without stress.

Leaf chlorophyll content measurements

Chlorophyll content was measured in 10 randomly selected flag leaves in each plot by using a portable chlorophyll content meter (CCM-200, Opti-Sciences Inc., NH, USA). Ten measurements were taken for each plot. The measurements were taken at 29DAA and 33DAA. The equation of S_{LCC} is as follows:

$$SLCC = 1 - \frac{LCC}{LCC_P} \qquad \text{(Eq.3)}$$

where LCC (leaf chlorophyll content, LCC) is leaf chlorophyll content under stress, LCCp is leaf chlorophyll content without stress.

Statistical analysis

Statistical analysis was done using SAS software (SAS Institute 2003). Statistical analysis using HTI values, SCT, SLCC, yield and yield reduction were performed for sixteen genotypes. The linear correlation coefficient was calculated to determine the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73577369

association among of HTI values, SCT and SLCC with yield and yield reduction under heat stress. Differences were considered significant at the $P < 0.01$ level.

Results

Meteorological data

The average maximum temperature (14^{th} May - 14^{th} June) in Hengshui from 1981 to 2018 was 30 °C. The highest average temperature recorded was 27.5 °C in 1991, and the highest temperature during the grain filling stage was 33.3 °C in 2001. These maximum temperatures have a difference of 5.8 °C. We used this temperature difference in the controlled greenhouse experiments by exposing the treatment plants to a heat stress treatment 5 °C higher than the control treatment. In the first decade (1981-1990), the average maximum temperature was 30 °C, and five of these years were greater than the average value; in the second decade (1991-2000), the average maximum temperature was 29.6 °C, and five years were greater than the average value; in the third decade (2001-2010), the average maximum temperature was 30 °C, with another five years greater than the average value; in 2011-2018, the average maximum temperature was 30.3 °C, which has been higher than the long-term average during six years. The increased frequency with higher daily maximum temperature than average value in a 10-year cycle indicates an increased risk in environmental heat pressure during the wheat grain filling stage in this region.

We obtained the values for 'stress intensity' of $\delta_{2017} = 0.33$ and $\delta_{2018} = 0.11$ in 2016-2017 and 2017-2018 respectively, in accordance with the trend of average maximum air temperature change from 2017 to 2018.

The maximum daily temperature inside and outside of the greenhouse during the 2016-2017 and 2017-2018 crop growing seasons are presented in *Figure 2*. The ranges of the daily maximum temperature inside the greenhouse were from 28.1 °C to 48.0 °C and from 22.3 °C to 48.6 °C during 2016-2017 and 2017-2018, respectively.

Evaluation and application of heat tolerance index (HTI)

Heat stress affected values for mean yield, which dropped from 8864.9 to 5978 kg/ha in 2017 and from 7425.8 to 6588.3 kg/ha in 2018, when comparing the control to the heat stress treatments (*Table 3*). Stress intensity (δ) was 0.33 in 2017 and 0.11 in 2018 (*Fig. 3*). Average yield of the 16 wheat cultivars decreased by 18 kg/ha (2017) and 5.2 kg/ha (2018) under heat stress during the grain filling stages.

HTI calculated by *Equation 1* with maximum value in cultivars exhibited lower YR and higher yield under heat stress. HTI reached a maximum of 1.42 for the HengH15-4489 cultivar in 2017 and of 1.16 for the Heng14-K2-3 cultivar in 2018. HTI attained a minimum of 0.74 for the Heng9966 cultivar in 2017 and 0.84 for the HengH14-5051 cultivar in 2018. There was no detectable difference in HTI between the two experimental years. Cultivars, yield, reduction under heat stress, and HTI showed significant correlations (*Table 4*). Positive correlations ($R = 0.9775$ and $R = 0.9415$ in 2017 and 2018, respectively) were found between HTI and mean yield under heat stress (*Fig. 3*). Significant negative correlations ($R = -0.9419$ and $R = -0.7458$ in 2017 and 2018, respectively) existed between HTI and YR rate (*Fig. 3*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73577369

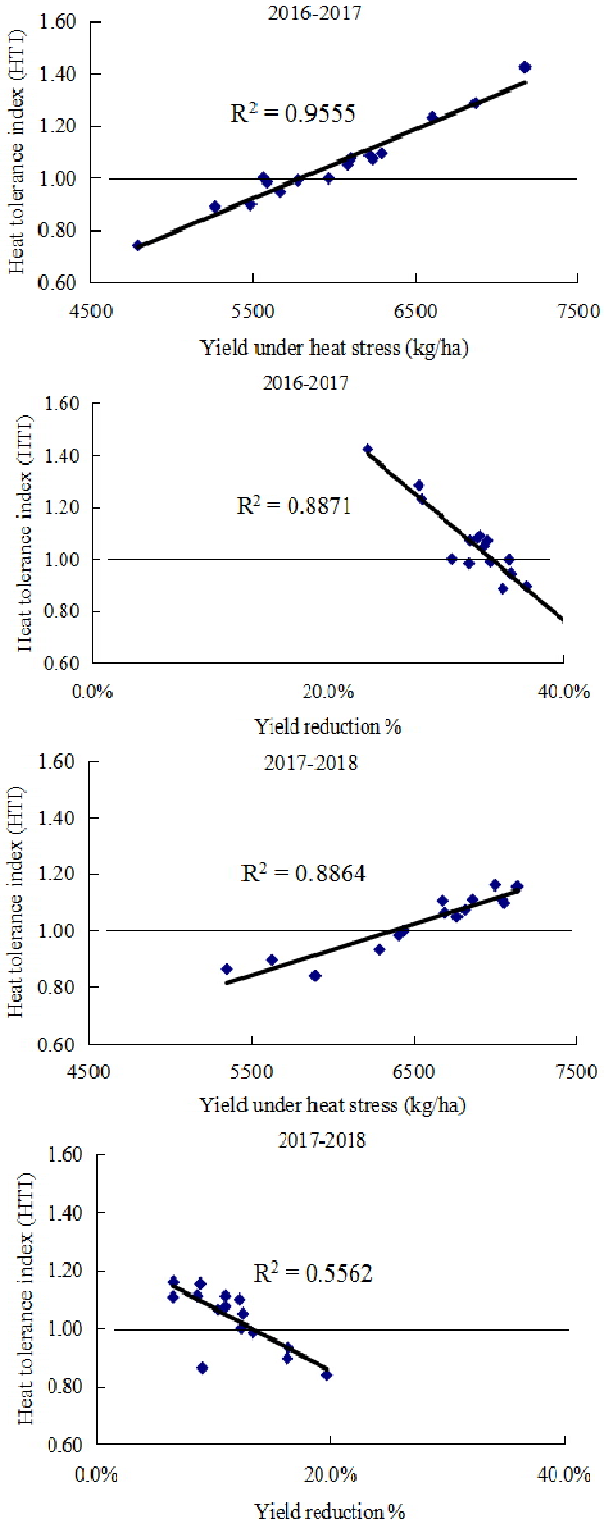

Figure 3. *Correlations based on averaged values for the 16 wheat studied cultivars for yield under heat stress (kg/ha) and yield reduction (YR) with heat tolerance index (HTI) in the 2016-2017 and 2017-2018 growth seasons. Positive correlations (R = 0.9775 in 2016-2017; R = 0.9415 in 2017-2018, P < 0.001) existed between HTI and yield under heat stress. Negative correlations (R = -0.9419 in 2016-2017; R = -0.7458 in 2017-2018, P < 0.001) were observed between HTI and YR. The line at 1 on the y-axis indicates standard heat tolerance. Dots indicate average values for each cultivar*

DOI: http://dx.doi.org/10.15666/aeer/1704_73577369

Across the two years, 5 cultivars consistently showed HTI < 1 (Heng9966, Heng12-6098, Hengs13-5022, Heng5835, and Hengh14-5051) with low yield and high yield reduction under heat stress (*Table 3*). There were 8 cultivars, HTI > 1 (Heng5109, Jimai22, Heng11-6021, Heng14-K2-3, HengH15-4585, HengH13Guan26, HengH14-4019, and HengH15-4489), indicating high yield and low yield reduction under heat stress.

Evaluation of susceptibility index of canopy temperature (S_{CT}) and leaf chlorophyll content (S_{LCC})

In order to evaluate the susceptibility index related physiological indicators, we detected canopy temperature and chlorophyll content. S_{CT} and S_{LCC} were calculated by *Equations 2* and *3* respectively. S_{CT} reached a maximum of average value 0.36 for the HengH15-4489 in 2017 and 2018. Meanwhile S_{CT} attained a minimum of average value 0.07 for the HengS13-5022 in 2017 and 2018. S_{LCC} reached a maximum of average value 0.46 for the HengH15-4489 in 2017 and 2018. Meanwhile S_{LCC} attained a minimum of average value 0.05 for the HengH14Guan14 in 2017 and 2018. The result (*Table 4*) showed that there were significant positive correlations (R = 0.7356 and R = 0.6579 in 2017 and 2018, respectively; $P < 0.01$) between S_{CT} at 28DAA and yield under heat stress, and significant negative correlations (R = -0.7645 and R = -0.8164 in 2017 and 2018, respectively; $P < 0.001$) between S_{CT} and yield reduction under heat treatment. Meanwhile there were significant negative correlations (R = -0.6762 and R = -0.5548 in 2017 and 2018, $P < 0.01$ and $P < 0.05$, respectively) between S_{LCC} at 29 DAA and yield reduction under heat stress, and significant negative correlations (R = -

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73577369

0.7497 and R = -0.8556 in 2017 and 2018, respectively; $P < 0.001$) between S_{LCC} and kernel weight reduction under heat treatment.

Discussion

Meteorological change

According to the meteorological data in 38 years, the frequency of the average maximum temperatures appeared in the winter wheat grain filling stage (14 May-14 June) in Hengshui are increasing, which is similar with findings of the Intergovernmental Panel on Climatic Change (IPCC, 2013). Heat tolerance identification and breeding should be preferred to be researched, even with extremely high temperature.

Evaluation and application of heat tolerance index (HTI)

HTI showed significant correlations with yield and yield reduction under heat stress in 2 crop seasons, which supports the conclusion that HTI can be used to identify heat tolerance by indicating the yield potential and yield stability of wheat cultivars under heat stress.

HTI has several advantages over other methods for identifying heat tolerance. It is easier to quantify using the 'stress intensity' (δ) and HTI. Correlations between HTI, yield, and yield reduction were significant across the two experimental years, indicating reliability across variable growth conditions. HTI can also measure heat tolerance by incorporating both the values of yield stability and potential, linking yield reduction under heat stress to maximum possible yield.

There were 8 wheat cultivars whose HTI reached or exceeded level 2 ('moderately tolerant') across both years indicating adequate heat tolerance. These cultivars should be considered for wheat breeding with high heat tolerance. There were 5 wheat cultivars that reached level 3-4, indicating adequate heat susceptibility, and may be used for genetic analysis. In further study, we can use HengH15-4489 with the highest HTI and Heng9966 with the lowest HTI according to the two-year average, as parents to construct genetic population to analysis heat tolerant mechanism, heat tolerant genes mapping and tagging.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73577369

HTI can give a fuller picture of heat tolerance than yield reduction alone. In one cultivar, Heng5835, HTI in 2017-2018 was low as 0.86, but the yield reduction reached only 9.1%. This may be due to its early and low yield in the control treatment. Therefore, the use of only yield reduction may give incorrect information about heat tolerance.

HTI may be more able to identify heat tolerance when stress intensity is higher. In 2017-2018, stress intensity reached $\delta_{2018} = 0.11$ due to the severe heat waves that occurred in late stage of filling, and the yield under the control treatment reduced. Results would otherwise be clustered due to this strong effect, but HTI was reliable.

Evaluation of susceptibility index of canopy temperature (S_{CT}) and leaf chlorophyll content (S_{LCC})

Measuring Canopy temperature and leaf chlorophyll content was inexpensive, fast, easy, and suitable for breeding applications (Brennan et al., 2007; Reynolds et al., 2007). In this study we used susceptibility index of canopy temperature (S_{CT}) and leaf chlorophyll content (S_{LCC}) at different days after the anthesis to identify heat tolerance. The wheat cultivar with the highest S_{CT} and S_{LCC} during 2017-2018 was HengH15-4489, which was in agreement with the result of HTI. This cultivar performed heat tolerance well during 2017-2018. In further research, we can study on heat tolerant mechanism by using this cultivar.

The result showed that S_{CT} at 28 DAA had significant positive correlation with yield and significant negative correlation with yield reduction rate under heat stress, indicating that the wheat lines with higher S_{CT} may have high yield potential and yield stability in early generation under heat stress. It was reported that the canopy temperature and transpiration rate had a very significant negative correlation (Wall et al., 2006). Here, the canopy temperature of the cultivars with good heat tolerance increases greatly. It may be related to the regulation of reducing the transpiration rate with water loss getting slower and plant function keeping longer. The result need to be further verified.

S_{LCC} at 29 DAA had positive correlation with yield and significant negative correlation with yield reduction rate, and especially kernel weight reduction under heat stress, indicating that wheat lines with higher S_{LCC} may have lower yield and kernel weight reduction for stability under heat stress**.** The results agree with previous studies, showing that plant adapt to stress environment by reducing chlorophyll content in plant leaves to alleviate photo-inhibition and improve photosynthesis (Melis, 2009; Ort et al., 2011, 2015; Polle et al., 2003).

The result also indirectly proved the mechanism of heat tolerance: under heat stress, stomatal closure reduces transpiration, and then canopy temperature rise; meanwhile chlorophyll content in plant leaves reduce to alleviate photo-inhibition then improve photosynthesis, and to reduce light absorption then reduce canopy temperature.

The new methodology better estimated heat tolerance compared to other methods for four reasons. First, the heat treatment was easier to quantify because of using ‘stress intensity’ (δi). Second, HTI, SCT and SLCC had greater repeatability over different years and different stress intensities. Third, the correlations among HTI, SCT, SLCC, yield and yield reduction under heat stress was always significant in different years. Finally, HTI, SCT and SLCC linked the yield under heat stress to the yield reduction and reflected a heat tolerance with yield potential and stability in heat stress of different wheat cultivars simultaneously.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73577369

The different cultivar responses to heat stress indicated that the heat resistance ability of wheat cultivars varied. HTI and SCT was able to represent these varied responses and significantly correlate with the yield and yield reduction of wheat under heat stress. Accordingly, this new methodology can be used to reflect the yield potential and the stability to heat stress of different wheat varieties simultaneously. Cultivars with a high HTI (> 1) or higher SCT can be considered to be heat tolerance, as they exhibited higher yield and smaller yield reductions under heat stress compared with the other cultivars. The new methodology was a reliable evaluation for heat-tolerance of wheat cultivars. HTI is a good indicator of both yield potential and stability under heat stress which can be used to identify heat tolerance in advanced generations. The other two indicators SCT and SLCC may be used to screen for heat tolerance germplasm in early generations, or to identify a large number of wheat cultivars concurrently. HTI combined with SCT and SLCC maybe a good breeding strategy for heat tolerance improving.

Conclusions

In this study of heat tolerance across 16 wheat cultivars, HTI, S_{CT} and S_{LCC} showed significant correlations with yield and yield reduction under heat stress, and may be efficient indicators reflecting heat tolerance, including both yield potential and stability simultaneously. HTI can be used to identify heat tolerance of wheat cultivars in advanced generations, and S_{CT} at 28 DAA and S_{LCC} at 29 DAA may be used to screen for heat tolerant germplasm in early generations, or to identify a large number of wheat cultivars concurrently.

(Received 22nd Feb 2019; accepted 3rd May 2019)

Abstract. This study was carried out to find the energy equivalents of inputs and outputs in tomato cultivation in the Mediterranean region of Mersin province. For this aim, the energy balance between values of the input and output energies per unit field for tomato cultivation in open-field and greenhouses was investigated. Energy efficiency, energy density, energy efficiency were compared in terms of cost-benefit ratio. Data were collected and analyzed in open-field (112) and in greenhouses (14) from producers of tomato cultivation. The results showed that the total energy requirement in open fields and greenhouses was 56127.77 and 245246.78 MJ ha^{-1}, respectively. Energy use efficiency in the open-fields and in greenhouses was realized as 1.12 and 0.75 respectively. The cost-benefit-ratios were 2.32 in open-fields and 3.06 in greenhouses. According to the current results, the open-fields tomato production system has a higher energy efficiency than the greenhouse tomato production system, while the greenhouse system has a higher economic benefit.
Keywords: *tomato production, greenhouse, energy, energy consumption, cost benefit ratio*

Introduction

Tomato (*Lycopersicon esculentum* Mill.) is a perennial plant in tropical regions which is Solanales of the family of Solanaceae Lycopersicon family, depending on the single-year in temperate climates (Kinet and Peet, 1997). In total vegetable production, which is 1.1 billion tons in the world, tomatoes have 15% ratio with 162 million tons. In Turkey, the share of total vegetable production with production reaching 12.6 million tons exceeded 40%. In the current figures of tomato production; Turkey ranks 4th in the world (FAO, 2013). High adaptability, open the predisposition to greenhouse cultivation next to agriculture, as well as one of the various forms of reasons such as the availability of the processing industry, where most heavily cultivated and most widely consumed and the Mediterranean Basin which Turkey involved in. The amount of tomato consumption per capita in Turkey is 115 kg/year around (Yanmaz et al., 2015). Regional distribution in the largest ratio, is Mediterranean region with the 31% of the total (Abak, 2018). Mersin province is one of Turkey's largest tomato growing fields (ha) (Anonymous, 2017). From 2000 to 2015; Turkey's greenhouse fields increased with the ratio of 58.41%, from 47355.5 ha to 75015.5 (Turemiş, 2015). Today agricultural production is dependent on the consumption of fossil fuels (Taskın and Vardar, 2016). The use of energy in agriculture has increased due to the increasing human population, the limited supply of arable land and the will to improve the standard of living (Banaeian et al., 2010). Agriculture is an energy user and energy supplier (Alam et al., 2005). From the sowing-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73717379

planting processes to the harvest-blending operations, direct energy is needed (Singh, 2007). Indirect energy is needed in the process from sowing to harvesting and transportation of products (Ozkan et al., 2004a). Yield, annual production, energy consumption, investments and costs are very high in greenhouses (Heidari and Omid, 2011). Inputs such as electricity, machinery, seeds, chemical fertilizers constitute a significant part of the inputs in the tomato production system (Hatirli et al., 2006). On the other hand, efficient use of energy contributes to increased production, profitability and competitiveness (Singh et al., 2002). Thus, sustainability in agriculture can be achieved in rural life (Park and Seaton, 1996). By using energy efficient in agriculture and by saving fossil fuels, air pollution can be reduced (Pervanchon et al., 2002). More efficient use of energy can be achieved so that the same level of development can be achieved with less energy use and less emissions (Ozturk et al., 2018). Using energy efficiently is very important for the terms of sustainability and the reduction of emissions of greenhouse gases (Alluvione et al., 2011). Energy used in agriculture is 17% of the world's energy (Mohammadi and Omid, 2010). The financial and technical analysis of the tomato production system is called the energy budget (Canakci and Akıncı, 2006). In terms of energy input-output relations, seed bed preparation, fertilizer quantity, soil cultivation processes and productivity etc. subjects are looked at (Mandal et al., 2002). In terms of production efficiency, input-output energy analysis is used (Alluvione et al., 2011). Production efficiency can be increased by reducing energy inputs. In the energy consumption in agriculture, mechanization is important (Ozkan et al., 2004b). The efficient use of energy provides sustainability (Dalgaard et al., 2001). In the world; there are important researches had done about field crops, fruits and the use of energy for vegetables. Energy inputs and outputs of apricot cultivation were examined (Gezer et al., 2003). Many researchers; soybean, corn and wheat in Italy (Sartori et al., 2005), tomatoes and tomato paste in Turkey (Esengün et al., 2007), lettuce in Colombia, radishes and spinach (Bojaca and Schrevens, 2010), rice in Malaysia (Bockari et al., 2005), kiwi in Iran production (Mohammadi et al., 2010), apple (Rafiee et al., 2010), onion and coriander Pennsylvania in the USA (Moore, 2010), the productivity of crops such as sugar cane production in Morocco (Mrini et al., 2001) has made energy issues and economic analysis. Work efficiency and alternative energy consumption in tomato production were analyzed (Onal and Tozan, 1986). Detailed energy usability surveys were conducted (Yılmaz et al., 2005). Greenhouse energy and cost analysis were carried out in the Serik district of Antalya for the production of grapes in open-field and greenhouses (Ozkan et al., 2007). Some studies have been carried out on the use of energy in peach production in Tokat province (Goktolga et al., 2006). Economic analysis of the input energy requirements and costs are made in tomato production in Turkey (Cetin and Vardar, 2008).

The objectives of this study are; determine the effectiveness of tomato production systems, energy utilization rates, energy output-input ratio, cost/benefit ratio, energy inputs optimization of energy use efficiency and to determine the economic analysis. Thus in Mersin, greenhouse tomatoes and open-field tomato production systems will be compared.

Materials and methods

In this study, data were collected from 126 producers in open-fields and greenhouses in Mersin. In the Mediterranean city of Mersin, located south of Turkey. 36° 48' north

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73717379

latitude and 34° 38' east longitude. The average annual temperature is approximately 19.2 °C and the total annual rainfall is 592.1 mm. Approximately 94% rainfall falls from October to May (TSMS, 2017). The total number of registered farmers in Mersin, in 2016 is 35039 (MAF, 2016). Data on the production of tomatoes collected by face-to-face survey from growers are belong to 2016 production period. in the province of Mersin, 941.232 tons of tomatoes were obtained from 91.211 decares of field. Sample farms were randomly selected from the study area by using a random sampling technique. However, it should be taken into account the factor in which variability can be observed in basic datasets. The sample size was calculated using the Neyman method (*Eq. 1*) (Yamane, 1967).

$$n = \frac{N \times S^2}{(N-1)S^2_x + S^2} \quad \text{(Eq.1)}$$

For this equation; n is the required sample size, N population volume, S standard deviation, Sx standard deviation of the sample average (Sx = d/z), z reliability coefficient, d is based on the allowable error equation of the sample size. For open-field and greenhouse tomato cultivation, the number of samples examined was 112 and 14 (126) respectively. The permissible error (d) was defined as 5%, and for the 95% reliability (z), 126 sampling sizes were calculated. Firstly, the most common production systems for each product were identified, and then all inputs and outputs from the systems were identified and digitized, and then converted to energy units. By adding partial energies to total energies (ha) per production unit; energy inputs include human labor, diesel fuel, machinery, farm manure, irrigation, nitrogenous, phosphorus and potassium chemical fertilizers. In order to estimate the energy in MJ/ha and to find the amount of inputs in terms of efficiency values by the energy analysis of the tomato, the equivalents in *Table 1* are used.

Table 1. *Energy equivalents for different inputs and outputs in agricultural production*

Particulars	Unit	Energy equivalent (MJ unit^{-1})	Reference
A. Inputs			
1. Human labor	h	1.96	Mohammadi et al., 2008
2. Machinery	h	64.80	Singh et al., 2002

(c) Pesticides		101.20	Esengun et al., 2007
(d) Fungicides		216.00	Esengun et al., 2007
6. Cattle manure	kg	0.30	Mohammadi et al., 2008
7. Electricity	kWh	11.93	Mani et al., 2007
8. Water for irrigation	m3	1.02	Rafiee et al., 2010
9. Seeds	kg	1.00	Esengun et al., 2007
B. Outputs			
1. Fruit yield	kg	0.80	Taki et al., 2012

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73717379

Energy use efficiency (*Eq. 2*), energy productivity (*Eq. 3*), specific energy (*Eq. 4*), energy intensiveness (*Eq. 5*) and net energy (*Eq. 6*) were calculated (Banaeian et al., 2010; Ghorbani et al., 2011).

$$\text{Energy use efficiency} = \frac{\text{Energy output}(MJha^{-1})}{\text{Energy input}(MJha^{-1})} \quad \text{(Eq.2)}$$

$$\text{Energy produvtivity} = \frac{\text{Crops output}(Kgha^{-1})}{\text{Energy input}(MJha^{-1})} \quad \text{(Eq.3)}$$

$$\text{Specific energy} = \frac{\text{Energy inpute}(MJha^{-1})}{\text{Crops output}(t.ha^{-1})} \quad \text{(Eq.4)}$$

$$\text{Energy intensiveness} = \frac{\text{Energy inpute}(MJha^{-1})}{\text{Cost of cultivation}(\$\,ha^{-1})} \quad \text{(Eq.5)}$$

$$\text{Net energy} = \left[\text{Energy output}(MJha^{-1}) - \text{Energy input}(MJha^{-1})\right] \quad \text{(Eq.6)}$$

The energy equivalents of the inputs are mega joule (MJ) per unit. In particularly this calculated ratio was used to express energy deficiency with input fossil fuel energy and output food ratio. The increase in the rate of crop production indicates improvement. It is possible to determine the energy efficiency trends of agricultural production by evaluating energy efficiency rates. Total value of production (*Eq. 7*), Gross return (*Eq. 8*), Net return (*Eq. 9*), Total cost of production (*Eq. 10*), Benefit to cost ratio (*Eq. 11*) and Productivity (*Eq. 12*) (Economic analysis of tomato cultivation) were investigated (Zangeneh et al., 2010):

$$\text{Total value of production} = \text{tomato yield (kg ha}^{-1}) \times \text{tomato price (\$ kg}^{-1}) \quad \text{(Eq.7)}$$

$$\text{Gross return} = \text{total value of production (\$ ha}^{-1}) - \text{variable cost of production (\$ ha}^{-1}) \quad \text{(Eq.8)}$$

$$\text{Net return} = \text{total value of production (\$ ha}^{-1}) - \text{total cost of production (\$ ha}^{-1}) \quad \text{(Eq.9)}$$

$$\text{Total cost of production} = \text{variable cost of production (\$ ha}^{-1}) + \text{fixed cost of production (\$ ha}^{-1}) \quad \text{(Eq.10)}$$

$$\text{Benefit to cost ratio} = \text{total value of production (\$ ha}^{-1}) / \text{total cost of production (\$ ha}^{-1}) \quad \text{(Eq.11)}$$

$$\text{Productivity} = \text{tomato yield (kg ha}^{-1}) / \text{total cost of production (\$ ha}^{-1}) \quad \text{(Eq.12)}$$

Results

Energy input-output relationship in open-field and greenhouse tomato production system

In tomato production systems, per hectare in open-fields and greenhouses, 1088.25 and 2347.82 h of human labor respectively and showed that 32.44 and 98.65 h machine power

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73717379

is required. The total energy used in production in open fields and green houses is 62862.93 and 183866.38 MJ ha^{-1} (*Table 2*). It is the electricity sector which has the highest energy consumption in tomato production system in open-fields (32.89%), followed by nitrogen (22.08%), irrigation (13.55%) and diesel fuel (12.66%) (*Table 2*) If the highest energy consumption in the tomato production system in greenhouses is diesel fuel (60.90% of total energy input), followed by electricity (14.68%) and micro nutrients (fertilizer, 11.34%) (*Table 2*). For tomato production systems, the average fruit yield in open fields and greenhouses were 147854 kg ha^{-1} with 52429.8 respectively, while the straw yield were 2789.21 and 8744.37 kg ha^{-1}. While total energy output per hectare was 62862.93 MJ in open fields and 183866.38 MJ in greenhouses. The input-output energy ratio in open fields and greenhouse systems is 1.12 and 0.75, respectively. The energy use efficiency in the open-field was nearly 1.49 times more than the greenhouse system due to the use of more input energy than the greenhouse system.

Table 2. *Energy input-output relationship in openfield and greenhouse tomato production system*

Energy inputs	Quantity per unit area (ha)		Energy equivalent (MJ $unit^{-1}$)		Total energy equivalent (MJ)		Percentage of total energy input (%)

Efficiency and specific energy in open-field and greenhouse systems

Energy use efficiency is 1.12 in open-field and 0.75 in greenhouse tomato production systems. The energy intensiveness was calculated as 14.61 in open-field and 3.79 MJ$\$^{-1}$ in greenhouse systems. The average energy productivity of the open-field and greenhouse is 0.93 and 0.60 kg MJ^{-1}, respectively. Specific energy is 1.07 and 1.66 MJ

Net energy	MJ ha^{-1}	6735.16	-61380.40

Relationship between economic indices and analysis in tomato production system in open-field and greenhouse

The production cost of our two works and our gross product can be seen at *Table 4*. In open-field and greenhouse tomato production systems, the gross production value is 14680.35 and 93148.34 \$ ha^{-1}. The tomato production and stability in the open-field was 3925.23 and 2390.94 \$ ha^{-1}, greenhouse facilities 15977.42 and 14486.52 \$ ha^{-1}. The production amount per hectare (6316.16 \$ ha^{-1}) in the open-field is lower than the greenhouse system (30463.94 \$ ha^{-1}). Total production amount in the greenhouse system is 79.27% higher than the open-field system. The gross return and net return (10755.12 and 8364.19 \$ ha^{-1}) available in open-field production is very low from the greenhouse production system (77170.92 and 62684.40 \$ ha^{-1}). The gross and net return in the open field system is 7.2 and 7.5 times lower. In greenhouses (3.06), the benefit cost ratio is higher than the open-field system (2.32). Productivity is expressed in 1 US\$, this means how much product we can produce with 1 US dollar. This study efficiency is 8.30 and 4.85 kg^{-1} for open-field and greenhouse systems.

Table 4. *Economic indices of tomato production in open space and greenhouse systems and relationship between analysis*

Cost and return components	Open field (value)	Greenhouse (value)
Fruit yield (kg ha^{-1})	52429.82	147854.51
Sale price (\$ kg^{-1})	0.28	0.63
Gross value of production (\$ ha^{-1})	14680.35	93148.34
Variable cost of production (\$ ha^{-1})	3925.23	15977.42
Fixed cost of production (\$ ha^{-1})	2390.94	14486.52
Total cost of production (\$ ha^{-1})	6316.16	30463.94
Total cost of production (\$ kg^{-1})	0.12	0.21
Total cost production (\$ MJ^{-1})	0.06	0.09
Gross return (\$ ha^{-1})	10755.12	77170.92
Gross return (\$ kg^{-1})	0.21	0.52

Discussion

In tomato production systems, the total energy input (56127.77 MJ ha^{-1}) used in the open-field has shown that it is approximately 4.37 times lower than the greenhouse production system (245246.78 MJ ha^{-1}). Diesel fuel consumption in the production of tomatoes in greenhouses is very high. In addition, energy consumption in greenhouse production systems is higher than the open-field production system. But, the energy use rate is lower (Cetin and Vardar, 2008). In addition, tomato yield in the open field (52429.82 kg ha^{-1}) is 2.82 times lower than the greenhouse system (147854.51 kg ha^{-1}) (Özkan et al., 2004b). Energy output-input ratio is higher in open-field (1.12) than in greenhouse systems (0.75).

Conclusions

Reducing the share of fertilizers and diesel fuel may increase energy efficiency. Net energy is -61380.40 and 6735.16 MJ ha^{-1} in greenhouse systems and outdoor field. A negative value of the energy gain in the greenhouse is due to the heating technology used for heating diesel engines at high temperatures, such as low heating technology (Banaeian et al., 2010). In the open field, respectively, 10755.12 $, 8364.19 $ and 2.32; The gross, net return and benefit cost ratio is lower than the greenhouse tomato production system. Total production cost of greenhouse is higher than open-field due to heavy fuel usage. The high price of greenhouse tomatoes is owing to the lack of tomatoes in autumn and winter. Effective use of inputs contributes to economic profitability and competitiveness, while increasing productivity (Singh et al., 2002). The results show that water for diesel fuel, irrigation, fertilization, machinery and electrical energies is the major part of the energy inputs used in tomato production systems. In terms of energy efficiency, the tomato production system in the open-field is 1.49 times higher than the greenhouse system. This leads to an increase towards higher sustainability. In addition, the most effective factors affecting the efficiency of energy use in greenhouse and open-field systems are diesel fuel and nitrogen fertilizer inputs. Therefore, reducing the consumption of these inputs may increase the efficiency of energy use in tomato production systems in Mersin province.

ASSESSMENT AND MONITORING OF REHABILITATION STUDIES ON COAL MINE DUMP SITE WITH UAV'S

KUN, M.

Department of Mining Engineering, Faculty of Engineering, Dokuz Eylul University
Izmir, Turkey
(e-mail: mete.kun@deu.edu.tr; phone: +90-232-301-7540; fax: +90-232-453-0868)

(Received 25th Feb 2019; accepted 1st May 2019)

Abstract. Today, the rapidly increasing environmental awareness and the need for available space posed environmentally sensitive change of mining activities and created the target of producing alternative economic values in the fields it is used. For this reason, especially for the last two decades, in the context of the rehabilitation and reactivation in the nature of open-cast mines whose production is either finisher or ongoing, nature restoration work after mining activities have gained momentum. In terms of country and regional planning studies, in the mining activities especially carried out in large areas, the rehabilitation of the sites in terms of the preservation and sustainability of the natural balance within the area is of great importance. With advanced technological equipment, remote sensing systems, unmanned aerial vehicles and increasing data processing techniques, it is possible to follow up the mining initiatives and rehabilitation works carried out especially in large areas. In this way, transaction tracking and success percentages of transactions can be revealed. In the study prepared for this purpose, a sample coal operation was taken into consideration and the rehabilitation works carried out especially at the dump sites were examined. As a result of the study, the adaptation of the species planted to the nature and the survival percent obtained were revealed. In addition to this, the rehabilitation processes on the dump sites were monitored with the help of plant index maps obtained by using unmanned aerial vehicle (UAV) and photogrammetric software and the success of applied methods was evaluated.
Keywords: *mining, reclamation, plant index map, UAV, TGI, VARI*

Introduction

Mines and mining are of great importance in continuation of today's modern lifestyle and achieving the goals set. Today, as in the past, mining is one of the largest industries. Some adverse effects on the environment are inevitable according to the methods followed during the running of a mine. When compared to underground mining, open pit mining has a more negative effect on the natural environment and the negative visual impact it creates is known to be greater than the underground mining.

The negative impacts of mining activities on the environment can be local and regional, as well as globally. These effects may vary slightly depending on the characteristics of the natural environment, the structure of the mine, the mining technique applied and the nature of the enterprise. Additionally, the realization, estimation, prevention or reduction of these environmental impacts caused by mining activities in real terms is possible with the measures to be taken during the planning of the activity.

Since mining is an activity that changes terrain surfaces, active mining activities in a given time period significantly change the landscape and tend to destroy all traces of land use in the past. The negative effects such as degradation of the visual environment, damage to the landscape, damage to agricultural and forest areas, erosion, land subsidence, etc. are focused on (Sengupta, 1993). However, the dump sites, which are formed in the immediate vicinity of the mine areas, are often larger than the active mining sites. The rehabilitation of these dump sites is a necessary and compulsory

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73817393

action (Mallı. et al., 2018). For this reason, field rehabilitation practices were included in the operation procedure and costs, before starting the production, taking into account in the feasibility stages of their enterprises. Thus, when the mining works in the sites are completed, a large part of the sites become rehabilitated (*Fig. 1*).

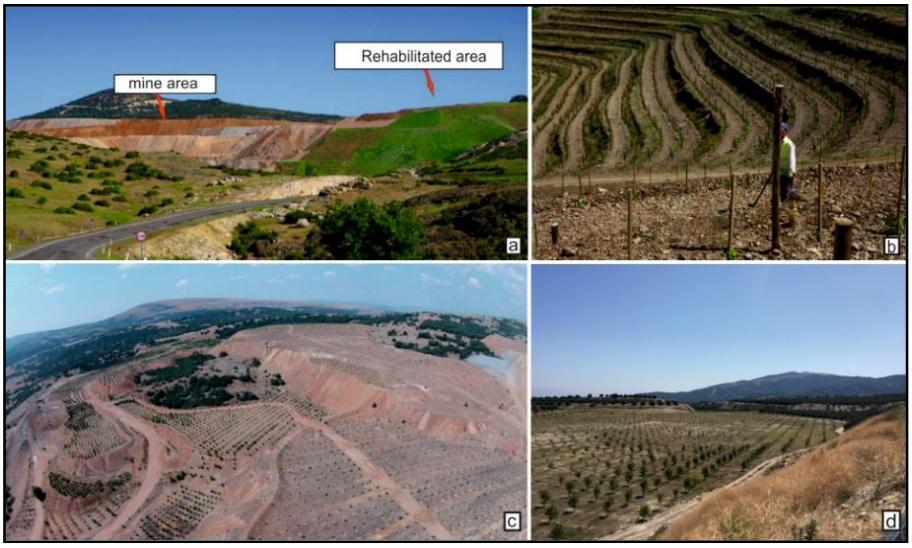

Figure 1. *Rehabilitated mining sites [(a),(b) – Kısladag gold mine in Uşak /Turkey; (c)- Tutluca magnesite quary in Eskisehir/Turkey; (d)-coal mine rehabilitated area in Aydın/Turkey)]*

Rehabilitation studies are generally divided into four stages by different researchers. These stages are classified as the site usage plan, reorganizing, improvement, monitoring and maintenance works (Topay and Kaya, 2007; Düzgün, 2009; Mallı et al., 2018). All of these steps were completed in the prepared study and especially as a result of the completed studies, the use of UAVs in the monitoring and research of tree planting sections were put forward.

Firstly planted areas were followed in five to seven year period and the results of planting studies in different fields were evaluated for this purpose. Secondly, the fields were visualized with UAV progress and the results were evaluated by using TGI and VARI values. As a result of the study, especially the planting of large areas, using UAVs and related visual processing software, according to the indexes given above as a result of the evaluation of plant life and long-term follow-up of the results obtained by classical means overlapped. This situation shows that the results of UAVs, 3D mining software, TGI and VARI values together can be performed accurately, reliably and fast, especially in the pursuit of the rehabilitation of large mining sites.

Review of Literature

Claim is the preparation of the mining operation area for post-mining use, and also the consolidation of the post-operational land by adapting to the environment (Ramani, 1990). In other words, it is defined as returning the area to its natural state or to a more suitable use, as bringing out the efficient, useful, clean and aesthetically beautiful appearance of the destroyed area (Michaud, 1981). The re-efficiency of a destroyed area and regaining its ecological, economic and aesthetic values is possible by the nature repair works.

Site usage plan is defined as the formation of the conditions for the land and the determination of ecological targets for re-planting before mining. Reorganizing involves activities such as excavation, soil laying, planting, drainage works etc. The improvement phase is the studies of recovery of biological efficiency in the destroyed area and evaluation and improvement of the soil and the re-planting. The monitoring phase, which is the last stage, can be defined as the phase during which plant development is monitored and evaluated in line with the determined targets after the stages of organizing and improvement. In the study, these processes were done both by classical means and with the help of UAVs and the results were compared.

There are many studies that show the use of UAVs and their successful use in the fields of mining and the environmental relation. For example, Ozcan and Sari (2019) and Gül (2019), in their studies on the environmental effects and monitoring of quarries, respectively, have demonstrated the success of UAVs in open mines planning. Again, Lee and Choi (2016) focused on the safe use of UAVs for different purposes (planning and monitoring) in mining operations in a study called reviews of unmanned aerial vehicle (drone) technology trends and its applications in the mining industry. Shahbazi et al. (2014) the management, monitoring and management of natural resources unmanned aerial imagery has clearly demonstrated the latest developments and achievements. Özcan (2017) and Öztürk et al. (2017), the effects of the images taken with different elevation and camera angles, respectively, were investigated and the differences between the steep and sloping image acquisition from mining sites were determined.

There can be found several other examples in the literature that have assessed suitability of mined lands for post-mining land-uses, and mentioned the effective criteria in the evaluations. For expample, Maiti and Ghose (2005); Tafi (2006) and Carrick and Kruger (2007) have evaluated the factors limiting plant growth on mined soils and mentioned the most serious soil limitations. Some other researchers e.g. Gizikoff (2004) and Zavadskas and Antucheviciene (2006) have investigated on so many other factors such as topography, climate, environment, society, economy, etc. which arise in land-use evaluations of mined or other disturbed lands. Paschke et al. (2003); Meech et al. (2006); Li (2006) and Cao (2007) have focused on special post-mining land-uses thatwere exercised in some mine sites.

Moreover, extensive studies are carried out in different parts of the world. For example, the value of claim costs in the US West Kentucky basin was estimated to be around 8% of the total operating cost. In another study, it was determined that the cover/coal ratio was 8:1 and for each 100 tons production, 0.2 hectares of land was damaged; the cost of claim in an open pit mine was determined to be $ 0.32 / ton or 7.6% of the total cost. In the literature, this value varies between $ 1000 and $ 20000 per hectare. In addition, with the project of East Germany rehabilitation of lignite mines, more than 100 thousand hectares of land became usable and was regained to the environment by spending 7.5 billion euros (Kuyumcu, 2005).

As seen in the above-mentioned similar studies, the necessity of rehabilitation of the sites as well as the need to regain economic values from the mining areas, encourages enterprises in this direction. Therefore, in the following parts of the study, the rehabilitation studies carried out in the new and old dump sites of the coal mine discussed and follow-up and monitoring of these studies with today's technologies were mentioned.

Materials and Methods

Description of the study area

Lignite production site discussed in the study is located in western Turkey, on the Aegean Coast, in the province of Aydin. Until the year 1984 the production was only underground and since 84 to the present day it has functioned as both underground and open-pit production. Until today, about 7 million tons of coal were produced from underground mine and 10 million tons of coal were produced from the open pit mine. In the production process, approximately 160 million m^3 of excavation was carried out on the open pit mine. *Fig. 2* shows the site location map, the study area and the rehabilitation areas belonging to the lignite pit.

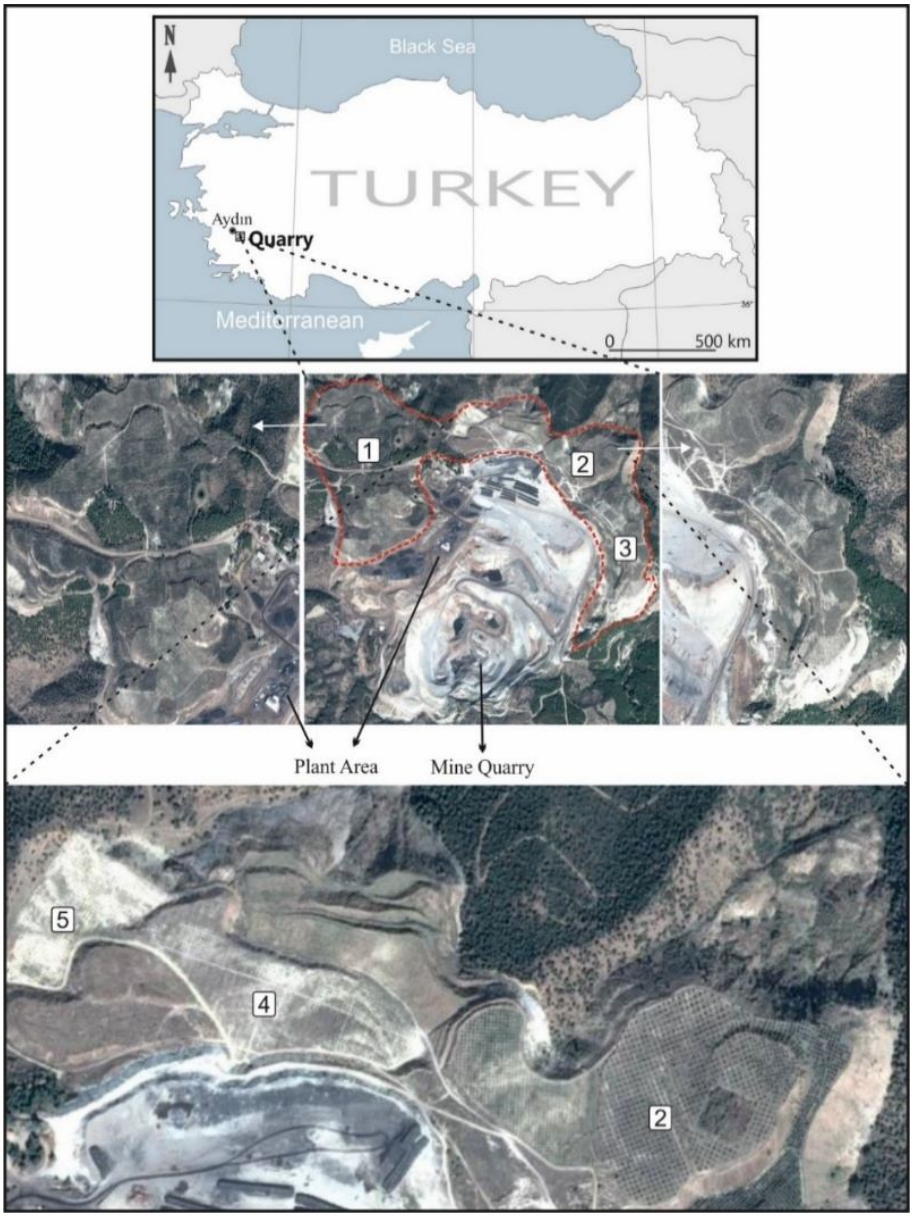

Figure 2. *Open pit mine quaryy and dump sites (number 1-5 and area coordinates: between longitudes 27° 56' 12.80" E to 27° 55' 44.25" E and latitudes 37° 46' 47.86" N to 37° 46' 32.87" N).*

Data collection

Planting studies and applications in the field

Field studies are listed as the determination of the species that are available before the mining operation, establishment of research zones on the damaged areas and the casting areas, conducting the soil analysis of the areas, sapling planting in the areas formed and maintenance and monitoring of the planted areas.

According to this, the active species in the vicinity of the mine and in the region were determined. Most active tree species in the region are; *Pinus Brutia Ten*, *Rolium Olivaru*m, *Robinia Pseudoacacia* and *Amygdolus Communi*s. These identified species were planted in the experimental areas determined on the casting areas whose analysis are given in *Table 1*. Soil analyzes in the determined planting areas were made every 6 months starting 1 year before planting, and every 50 x 100 meters. The average values of these soil analyzes in *Table 1* are given. In addition, the planting process has been completed with a 5 x 5 meter square and a 20-25 square meter seedling has been completed.

Table 1. *The characteristics of soil used in plantation*

Parameters	Unit	
Sand	%	54.5 ± 2.5
Dust	%	38.56 ± 2.11
Clay	%	6.88 ± 1.2
$CaCO_3$	%	9.98 ± 2
pH	-	6.92 ± 1.2
Organic Subs.	%	2.55 ± 0.7
N	%	0.008 ± 0.001
P	mg kg^{-1}	3.0 ± 0.5
K	mg kg^{-1}	156 ± 12
Ca	mg kg^{-1}	2700 ± 22
Na	mg kg^{-1}	75 ± 8
B	mg kg^{-1}	3.22 ± 1.03

*The samples were taken from 30/50 centimeter depth

The evaluation of the seven years data for *Rolium Olivaru*m and also two years data for *Amygdolus Communi*s obtained from this phase were made by evaluating min 1000 saplings and the data were interpreted statistically. As a result of the evaluations, there were differences in terms of survival percent among the species mentioned above. According to this; about 99% of *Rolium Olivarum*, about 94% of *Robinia Pseudoacacia*, 82% of *Amygdolus Communi*s and about % 77 of *Pinus Brutia Ten* survived in the dump sites (*Table 2*). These values were obtained for *Rolium Olivarum* eight years later and for *Amygdalus Communis* two years after planting.

Table 2. *Survival statistics of several tree species on dump sites (%)*

Tree Specie	Chance of Survival (%)
Rolium Olivarum	99
Robinia Pseudoacacia	94
Amygdolus Communis	80
Pinus Brutia Ten	77

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73817393

Considering the high survival percent of *Rolium Olivarum*; both because it would increase the success in the rehabilitation process and in order to commercially evaluate the crop obtained from *Rolium Olivarum* planting, areas numbered 1,2,3 in the casting areas shown in *Fig. 2* were totally planted Olivarum trees. The casting sites where *Rolium Olivarum* are planted in a geometry of 5 m x 5 m and crop today (20 kg oil/tree) are given in *Fig. 3*.

Figure 3. *Planting dump sites (Rolium Olivarum)*

Because of the factors such as the spreading of open pit casting sites to a very large area, the presence of *Amygdolus Communis* with *Rolium Olivarum* among the primary tree species in the region, ensuring diversity in the areas to be planted, and economic yield obtained from the crop of *Amygdolus Communis* trees, areas numbered 4 and 5 shown in *Fig. 2* were planned to plant *Amygdolus Communis*. For this reason, samples were taken from 30/50 cm from the casting sites corresponding to the regions numbered 4 and 5 in the site and the soil properties given in *Table 3* were obtained. Soil samples were taken for each 50 x 100 meter square area. The planting of 1750 *Amygdolus Communis* trees in the area of approximately 70 hectares numbered 5 and 6 in *Fig. 2* and their current situation are shown in *Fig. 4*. About 2 years old trees were planted in 5 x 5 geometry. Watering the trees is done by drip irrigation as in olive.

In addition to this, the fertilization process done when necessary (rarely applied) also yielded positive results. As a result of research, the main element of the success in the afforestation was determined as the suitability of the characteristics of the soil (casting material) to be planted to the rapid root development. The plants tested in the field can be evaluated in the selection of species in the afforestation of different fields unless there is another restriction giving positive results in the expected direction. However, when afforestation is done with mixed tree species, planting in groups should be preferred by taking different biology of species into consideration (fast growing tree species are light trees). It is also advised to fertilize with organic fertilizers where possible and to irrigate especially in the first two years. Due to the facts that it has the highest survival percent in the area of re-cultivation and will provide economic contribution in terms of mine's economy in the future, approximately 50,000 olive saplings were planted. As a result of the investigations carried out in this area, it was determined that about 20 kg of crop per tree is obtained from these saplings and approximately 1000 tons of olives are produced annually.

UAV data's and technical parameters

UAV used in the acquisition of images has 1 inch 20 MP CMOS sensor and 35 mm focal length, with a single piece lens also the device can take 5472 × 3648 pixel resolution in JPG and RAW format image. In addition, it has GLONASS and GPS satellite support positioning module, 10 m / s wind resistance, 7 km horizontal, 500 m vertical control control distance, 0 - 40°C temperature range, between 2.4 and 5.8 Ghz frequency channels in case of need can make the transition.

In addition to the UAV used in the study, the Ashtech Promark 800 GNSS device was used as the positioning system. Real time positioning most accurate tolerance are 10 mm ± 1.0 ppm in horizontally and 20 mm ± 1.0 ppm in vertically. The system is able to deliver real-time raw data and location output up to 20 Hz. Also, unmanned aerial system flight parameters are clearly shown in *Table 4*.

Average ground sampling distance	2.84 centimeters

Research methodology

Unmanned aerial vehicles and photogrammetric software, which are used in many different branches of industry, are used effectively in mining industry especially in planning and rehabilitation studies. The facts that the rehabilitation areas are quite large and difficult to access from time to time, and that the measurements and determinations are made in a short time and they are repeatable allowed the UAVs to be included in these areas. With the UAV, "plant index maps" of the fields can be obtained and the health status of the areas that are brought back to the nature can be determined and controlled.

In the field of especially newly planted *Amygdolus Communis (Fig. 2*, field numbered 4) and olive fields in close vicinity (*Fig. 2*, field numbered 2) shown in *Fig. 4*, flights were made on the dump sites to reveal the rehabilitation model of the site. The flight plans for the flights are given in *Fig. 5a*. In total 313 visual reception fields, four aboveground control points were used for the purpose of controlling the system. In the study which especially focused on the new planting areas where *Amygdolus Communis* trees are located and the vicinity, an area of approximately five hectares was investigated in the first place. The position of the UAV on the site numbered 4 (*Amygdolus Communis* tree planting area) is shown in *Fig. 5b* as an example.

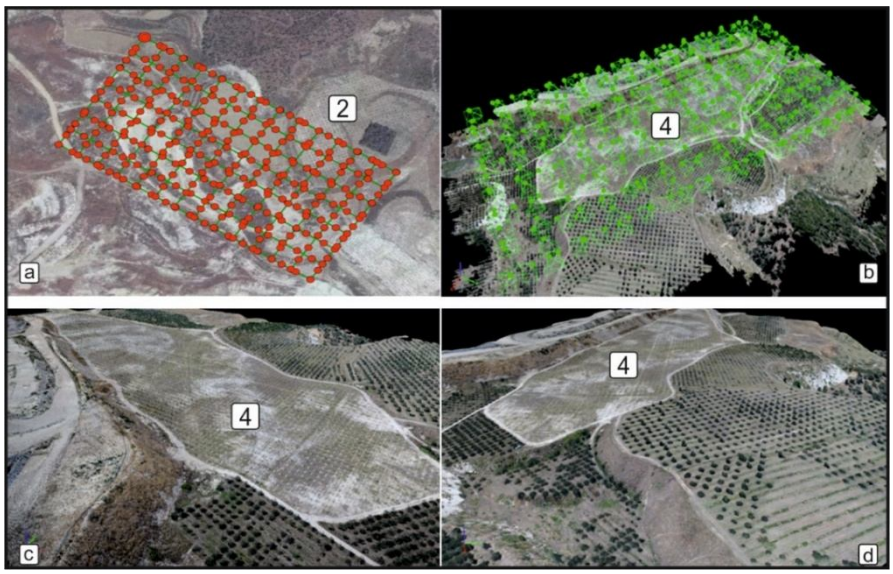

Figure 5. *UAV datas on dump sites [(a) UAV fligth plan; (b) UAV position on Amygdolus Communis plant area; (c) and (d) solid models]*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73817393

High-resolution images of the planted area were processed using pix4D software, and a cloud of approximately 10 million 735 thousand points was obtained from the entire area with a mean error margin of less than 4 cm in the measurement. *Fig. 5d* shows the solid model of the sites produced from the point cloud.

"Vegetation index maps" were obtained by processing of received images. The purpose here is to determine the health status of the plants in the field studied and to follow the development process. Since the study was done with a UAV with integrated RGB camera, TGI (Triangular Greenness Index) and VARI (Visible Atmospheric Resistant Index) indices were used together as vegetation index. The TGI and VARI indices were preferred because of the facts that they stand out among other visual indexes and especially that the VARI index can be used in all stages of plant life (Hunt et al., 2011).

TGI index, the reflected spectrum value from the plant; is the junction area of the triangle that ground on blue (480 nm), green (550 nm) and red (670 nm) spectral values as the corner point (*Fig. 6*). The TGI index value (green reflection value) is has a positive value if it is above the line combining 480nm and 670 nm values; and if not it has a negative value. While the positive value (green color) indicates healthy vegetation, the negative value (red color) indicates soil cover (Hunt et al., 2011).

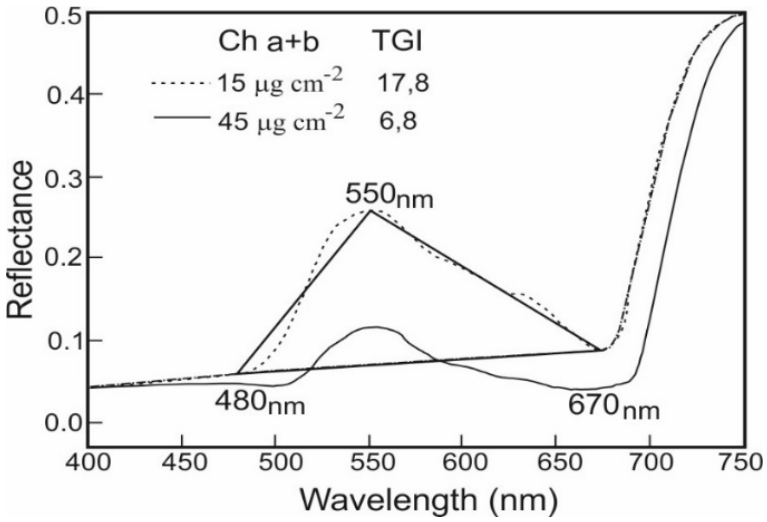

Figure 6. *TGI indeks (Reflected spectrum value from the plant)*

Red, green and blue colors contain information throughout the growing season. The VARI index is determined by the transitions of the green's reflection value with the red edges. VARI is designed to provide an atmospheric correction and is a good and valid index to predict the vegetation fraction from the visible range of the spectrum. This index can be used to analyze plants in all growth stages (Gitelson et al., 2002).

The VARI and TGI index maps and index value distributions divided into four parts of the rehabilitation area studied are visualized as histograms in *Fig. 7* and *Fig. 8*.

Because newly planted almond seedlings are considered first, TGI index was used as subsidiary index by basing on the VARI index applicable to all stages of plant life. The range of values for the VARI index: Value ranges changing between "-1"and "1" that are frequently used in field work are used. In *Table 5*, VARI index values and their meanings are given.

DOI: http://dx.doi.org/10.15666/aeer/1704_73817393

Results

Within the scope of the study, the close geography of the site was examined and the experimental plantings for olive and almond trees, which were determined as a priority, were observed and examined between two and seven years. When the experimental plantings in the casting areas yielded positive results by 99% in *Rolium Olivaru*m and by 80-82% in *Amygdolus Communis*, the sites were mainly afforested with these two species. 50.000 olive saplings were planted in a large part of the dump sites, which has the highest percentage of survival, and which will provide economic contribution in terms of business economy. Today, an average of 20 kg crop per tree is obtained from these planted sites and approximately 1000 tons of olives are produced annually. In other dump sites, to increase plant diversity and produce economic return, *Amygdolus Communis* were planted in almost 70 hectares and they were monitored.

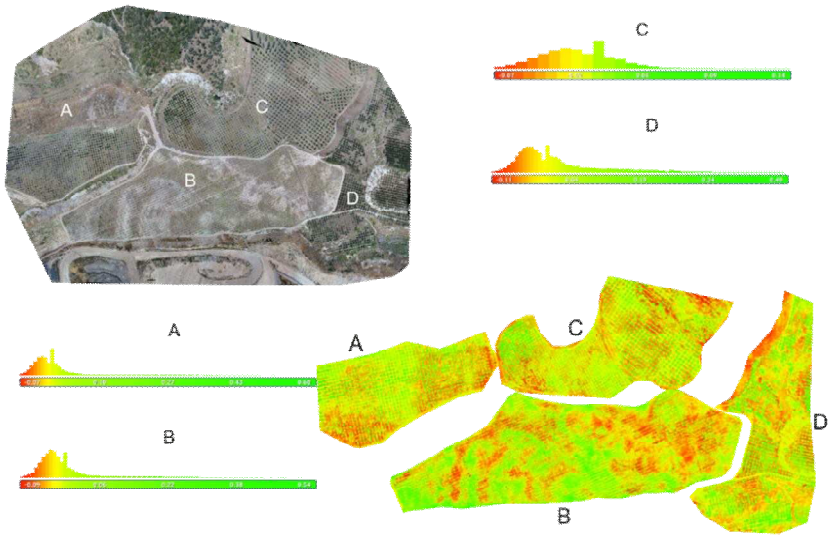

Figure 7. *Visible atmospherically resistant indeks (VARI) of planting dump sites*

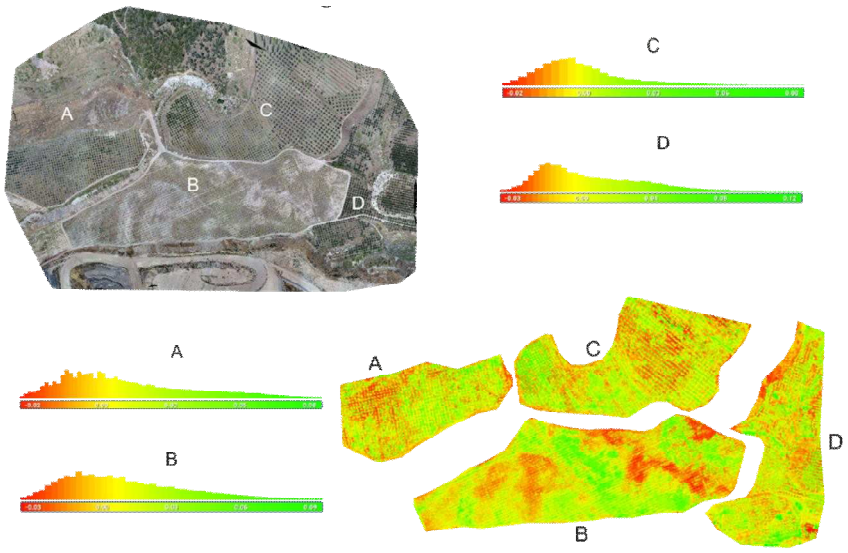

Figure 8. *Triangular greenness indeks (TGI) of dump sites planting dump sites*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73817393

Table 5. *VARI Index value range and meanings*

VARI index value	Meanings
< 0	Lifeless or dead plant
0 – 0.33	Immature plant
0.33 – 0.66	Healty plant
> 0.66	Very healthy plant

"Plant index maps" were prepared in the site in order to follow and evaluate the plantation and afforestation processes, which is another stage of the study, with UAVs (*Fig. 7* and *Fig. 8*). According to the obtained plant index maps, when the VARI index values are examined in parallel with the high survival percent of *Rolium Olivarum* both in the experimental areas and in the site, it was determined that it the ones in the range of 0.33 and 0.66 are in the class of "Healthy Plant". This value indicates the class of "immature plant". Additionally, with the UAVs, the visualization of the sites and the processing of the obtained point clouds and the success of the planting process in the site were followed by color scales. Similarly, the intense green color (90-92%) observed in the olive tree region demonstrates the success of the application and monitoring technique. This ratio was obtained between 75-80% in *Amygdolus Communis* planting area.

Discussions

In the present study, a sample study was conducted in order to rehabilitate the heaps of dump sites formed by pickling materials in open coal pits and to monitor the rehabilitated sites. The purpose of the rehabilitation site while mining activities continue was determined as to ensure nature restoration after mining activities by re-creating natural vegetation of the site before mining activities and to generate economic income by planting in these fields.

In this context, the field studies conducted with the help of long-term field studies and the UAVs can be used actively in monitoring the plants and determining the faces of life. Furthermore, with the help of the UAVs, the removal of plant index maps in the course of the restoration of large mining sites has been shown to be a fast, reliable and modern method to control the success of the rehabilitation processes at the sites.

(Received 28th Feb 2019; accepted 3rd May 2019)

Abstract. Herein, 15 fungi species belonging to different genera of Pezizales were studied morphologically and molecularly. During the morphological analyses performed by means of Primer 7 software, 28 characters were used, mainly including the stalk, cap, asci, and spores, to assess the taxonomical relationships of the fungi species. The data matrix and nMDS plot approaches based on the morphological data were highly functional in the determination of the taxonomical relationship of very closely related fungi taxa, particularly at the genus level. Moreover, the data from the ISSR locus analyses significantly supported the current morphological relationships on a wide scale. Contrary to the morphological data expressing taxonomical relationships related to morels or early morels, a minor exceptional condition was determined inferring to the relatively higher genetic similarity among Verpa and Gyromitra in the dendrogram connected with the ISSR analyses.
Keywords: *fungi, DNA, genetic relationships, ISSR, numerical analyses*

Introduction

Helvella L. is a widespread and interesting genus of large apothecial ascomycet (Pezizomycete: *Pezizales* J. Schröt.) that are found in terrestrial biomes of the Northern and Southern Hemispheres. The genus contains many of the larger and charismatic species of the order *Pezizales* and comprises a range of elaborate apothecia, from cupulate to saddle-shaped, and convex to campanulate, including species with folded and lobed caps seated on a simple, ribbed, or furrowed stipe (Skrede et al., 2017). Compared to other close relatives, *Helvella* is a relatively more crowded group in terms of the number of taxa and it is represented by 21 species in Turkey (Sesli and Denchev, 2014).

Morchella Dill. ex Pers. taxa are known as Morels, which occur in different types of forests with different mycelial dynamics, alternating between saprotrophic and symbiotic behaviors (Stefani et al., 2010). The changes in the developmental process may induce a high degree of variability in the ascocarps (Yoon et al., 1990).

Verpa Sw. is a genus of ascomycete fungi related to the morels, resembling the latter genus; hence, they are called false or early morels. There are 5 species in the widespread genus (Kirk et al., 2008). *Verpa* comes from the Latin for erection or little rod. Thus, the 3 genera are now included in the family *Morchellaceae* Rchb. (O'Donnell et al., 1997).

Gyromitra esculenta (Pers.) Fr. is a beautiful spring time mushroom that is often encountered by morel hunters in northern and montane areas of the continent. It can be distinguished from other species of *Gyromitra* Fr. by its convoluted and brain-like, reddish-brown cap, and by the fact that its stem is not massive in proportion to its cap

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73957405

(Kuo, 2014). Additionally, the species display high similarity with morel taxa in terms of their ascocarp features.

Sarcoscypha coccinea (Jacq.) Sacc., commonly known as the scarlet elf cup, or the scarlet cup, is a species of fungus in the family *Sarcoscyphaceae* Le Gal ex Eckblad of the order Pezizales. The fungus, widely distributed in the Northern Hemisphere, has been found in Africa, Asia, Europe, North and South America, and Australia. The type species of the genus *Sarcoscypha* Roum., *S. coccinea*, has been known by many names since its first appearance in the scientific literature in 1772. The species was originally named *Helvella coccinea* by the Italian naturalist Giovanni Antonio Scopoli in 1772 (Scopoli, 1772). Other early names include *Peziza coccinea* (Jacquin, 1774) and *Peziza dichroa* (Holmskjold, 1799). Although some authors in older literature have applied the generic name *Plectania* to the taxon, following Fuckel's 1870 name change (e.g., Seaver, 1928; Kanouse, 1948; Nannfeldt, 1949; Le Gal, 1953), that name is now used for a fungus with brownish-black fruit bodies (Korf and Harrington, 1990). *S. coccinea* was given its current name by Lambotte in 1889.

In recent years, developments in molecular biology and genetic have made inevitable the emergence of new techniques in the systematic field, and these developments have also been effective in fungal systematics. Previous classifications of the fungi could be checked via molecular studies to determine whether it is natural or not. The marker system, called inter-simple sequence repeats (ISSRs), is also a polymerase chain reaction (PCR)-based technique (Wolfe, 1998) that has been successfully applied for the genetic analyses of plants (Fang et al., 1997; Prevost et al., 1999; Song et al., 2006; Uysal et al., 2012 a, b; Bozkurt et al., 2013) and fungal classification (Tang et al., 2005). In particular, ISSR markers can be highly variable within a species and have an advantage over others in utilizing longer primers that allow more stringent annealing temperatures (Camacho and Liston., 2001; Tsumura et al., 1996; Nazrul and Bian, 2010). Recently, the development of molecular systematics, thanks to ISSR and similar molecular markers, has made it possible to identify specimens of closely related species and, to some extent, it has been applied to taxonomic studies of *Helvella* (Landvik et al., 1999; Nguyen et al., 2013; Landeros et al., 2015; Ariyawansa et al., 2015; Zhao et al., 2017). In previous studies were also reported that some cryptic fungi species would be recognized by means of applying molecular markers (Nguyen et al., 2013; Balasundaram et al., 2015). Hence, ISSR has been chosen for the taxonomical characterization of some *Helvella* taxa from Turkey herein. Our aim was to first reveal the natural taxonomical positions of some *Helvella* species with their taxonomical characters and then solve the natural relationships between *Helvella* and its relatives.

Materials and methods

In this study, 15 *Ascomycota* taxa were collected from different localities in Turkey (*Table 1* and *Fig. 1)*.

Morphology

The morphological analyses of the studied fungi taxa were conducted on 15 samples from each taxa in the field from 2011–2016. A total of 28 qualitative (15) and quantitative (13) morphological characters were used (*Table 2*). The diagnostic traits at the species or genera level were measured, including the stalk, ascocarp, cap, spores, and asci. The qualitative and quantitative characters determined were measured and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73957405

scored over the samples and finally turned into a data matrix. Morphometric data (*Table 2*) were analyzed using multivariate techniques with the PRIMER7 software package (Plymouth Marine Laboratory, Plymouth, UK; Clarke and Warwick, 1994). The Bray-Curtis similarity matrix was used to generate a 2-dimensional ordination plot applying non-metric multidimensional scaling in the PRIMER7 software (nMDS; Clarke, 1993).

Table 2. *Characters used in numerical analysis*

Diagnostic characters of the Ascomycota species		
Stalk	Absent (0), present (1)	HS1
Stalk	Whitish (0), yellowish (1), brownish (2), blackish (3), absent (4)	HS2
Stalk	Smooth (0), ribbed or veined (1), absent (2)	HS3
Stalk	Narrowed at the base (0), enlarged at the base (1), same anywhere (2), absent (3)	HS4
Stalk	Up to 20 mm (0), between 21–50 mm (1), 51–80 mm (2), more than 81 mm (3)	HS5
Stalk	Up to 15 mm (0), between 16–30 mm (1), more than 31 mm (2)	HS6
Rate of stalk length/diameter	Unit	HS7
The type of ascocarp	Apothecium (0), other (1)	HS8
Ascocarp	Saddle-shaped (0), cup-shaped (1), Globose (2), conical (3)	HS9
Ascocarp	Smooth (0), lobed (1), curved-brain (2), alveolate (3)	HS10
Ascocarp (outer surface)	Cream (0), reddish-brown (1), yellowish (2), greyish (3)	HS11
Ascocarp (inner surface; Hymenium)	Greyish brown (0) brownish-black (1) yellowish (2), reddish-brown (3), red (4), light brown (5)	HS12
Ascocarp (inner surface; Hymenium)	Glabrous (0), hairy (1)	HS13
Cap	Up to 25 mm (0), 26–60 mm (1), more than 61 mm (2)	HS14
Cap	Up to 25 mm (0), 26–60 mm (1), more than 61 mm (2)	HS15
Rate of cap length/diameter	Unit	HS16
Cap	Convex (0), concave (1), semi-convex (2)	HS17
Spores	Ellipsoidal (0), elliptic (1), weakly-elliptic (2)	HS18
Spores (oil drop number)	Only one (0), two (1), more (2)	HS19
Spores (oil drop position)	Inside of spores (0), outside of spores (1)	HS20
Spores	Between 16 and 21 µm (0), 22–27 µm (1), more than 27 µm (2)	HS21
Spores	Between 8 and 10 µm (0), 11–13 µm (1), 14-16 µm (2)	HS22
Rate of spore length/diameter	Unit	HS23
Spores (surfacial)	Smooth (0), verrucose (1)	HS24
Asci	Between 225 and 300 µm (0), 301–375 µm (1), more than 376 µm (2)	HS25
Asci	Between 14 and 18 µm (0), more than 18 µm (1)	HS26
Rate of asci length/width	Unit	HS27
Asci (number of spores)	Number	HS28

DNA extraction

Total genomic DNA was extracted following the 2xCTAB method of Doyle and Doyle (1987) as was modified by Soltis et al. (1991) and Cullings (1992) from silica gel-dried leaves collected in the field.

ISSR-PCR

Our modified ISSR-PCR analyses were basically performed according to the method of Zietkiewicz et al. (1994). During the PCR-optimization reactions, some modifications were quantitatively carried out, particularly for the Mg and primer amounts, as well as the Tm selection. The designed ISSR primers by British Colombia University were chosen for the PCR-amplifications. Amplification products were separated by electrophoresis in 1.2% agarose gel run in a TAE buffer at 100 V. The fragment size was estimated using a 20,000–75 bp molecular size DNA ladder (Thermoscientific, SM1331).

Data analysis

The ISSR profiles were scored as present (1) or absent (0). Only reproducible bands were scored as monomorphic or polymorphic. The dendrogram was created using NTSYS-pc version 2.1 (Rohlf, 1998).

Results

Molecular results

A total of 15 taxa were tested with 20 ISSR primers and only 10 of them provided reproducible and analyzable amplification products for all taxa and a total of 477 bands ranging from 80–2500 bp were obtained to put the relativeness of the fungi species (*Fig. 2*). All of the ISSR primers showed 100% polymorphism for Ascomycota taxa (*Table 3*).

Table 3. *Number and percentage of polymorphic ISSR markers*

Primers	Primer sequences (5'-3')	Fragment size (bp)	Total number of bands	Total number of polymorphic bands
UBC827	ACA CAC ACA CAC ACA CG	1500-100	47	47
UBC812	GAG AGA GAG AGA GAG AA	1400-80	47	47

UBC856	ACA CAC ACA CAC ACA CYA	1250-80	36	36

When we look at the dendrogram that was created using the locus analysis based on the ISSR primers, all of the *Helvella* taxa were positioned together as only one group (*Fig. 3*). However, the relationships and positions of the *Helvella* species among

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_73957405

themselves did not fit exactly with the performed previously classification on a morphology basis. In the dendrogram, the *Helvella* species displayed very close genetic relationships with at least 80% similarity and they were placed in the core of dendrogram. As the furthest taxa, *Morchella esculenta* was placed in the outermost area with 75% similarity to others. Compared to the first taxa, *Sarcoscypha coccinea* showed a closer similarity with the remaining taxa and its genetic relationship was more than 76%. Another relatively smaller group (subclade B) consisted of 3 taxa representing 3 different genera and they showed at least 81% genetic similarity. Even if classified morphologically in different families, *Gyromitra esculenta* is genetically closer to *Verpa conica* when compared to *Peziza* and others analyzed herein. Naturally, *Peziza michelii* and *P. varia* are very similar genetically and the distance between them is less than 15%.

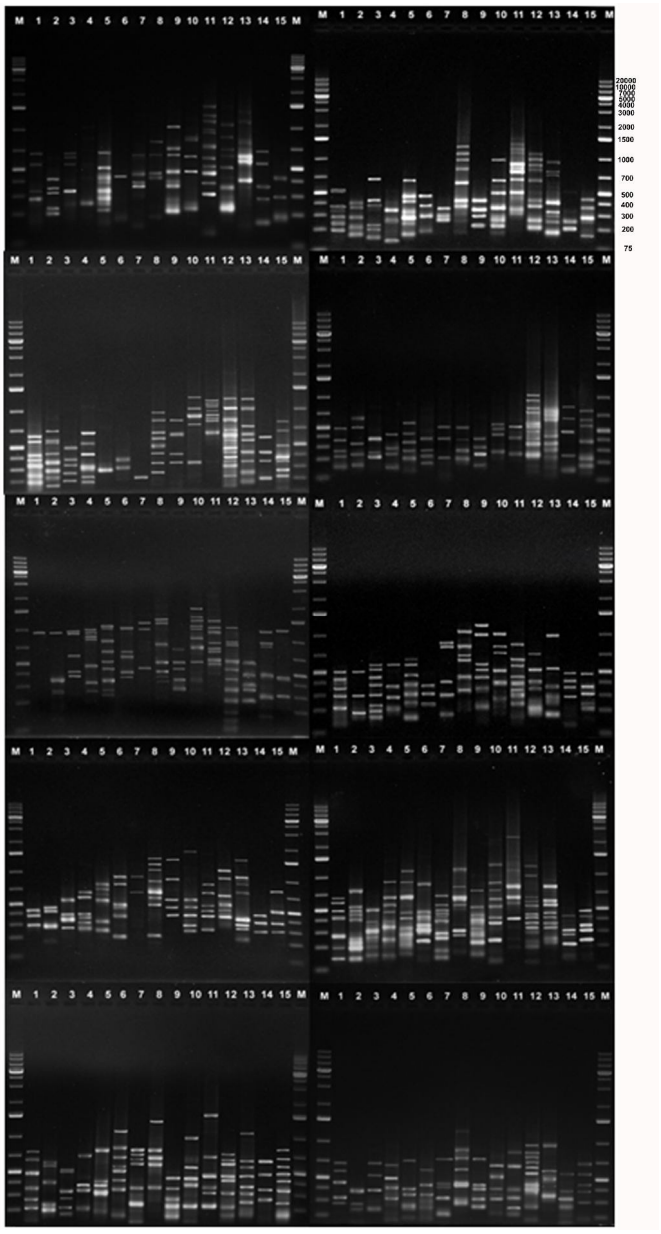

Figure 2. *Electrophoresis Patterns of ISSR products amplified with primers UBC827, 812, 810, 847, 857, 808, 855, 834, 840 and 856 for Ascomycota taxa*

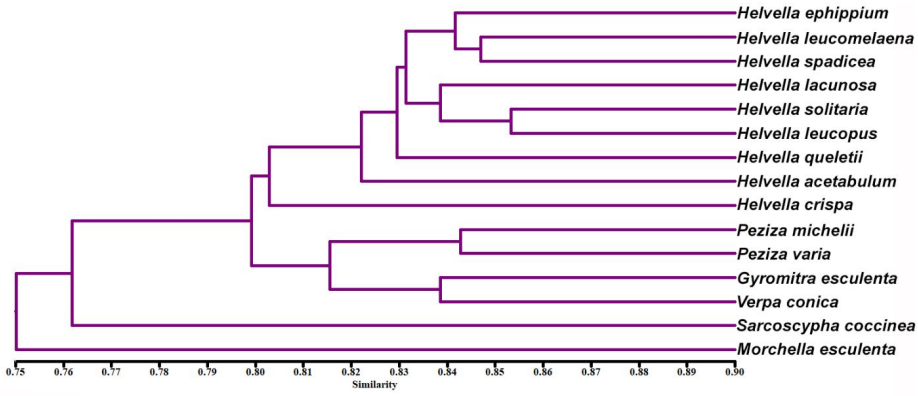

Figure 3. *The dendrogram showing the genetic relationships among Ascomycota taxa based on ISSR data*

Morphological results

The nMDS plots revealed the morphological differences among the studied taxa and helped to make prominent separations among them (*Fig. 4*). The phenogram pointed out very important characters which were very functional in classifying the fungi at different taxonomical levels (for instance, levels of species, genera, or higher). According to the phenogram (*Fig. 5*), it could be said that the characters belonging to the cap and the stalk are important at the primary level; hence, the taxa were divided in the main 2 groups according to these characters. Second, it was seen that the fungal species were divided into 2 subgroups according to whether the cap surface was smooth or not, and that this separation was largely compatible with previous classifications based on morphology. Finally, it was determined that the structural ornamentations made by the cap inside or outside were important in the classification of the fungi, especially to determine the 2 different groups of taxa located in the *Helvella* genus as saddle or cup (*Fig. 5*).

Discussion and conclusion

True morels (*Morchella* spp.) are highly popular for their edibility and appearance, and they have been examined in many broad-scale studies at different times (Kirk et al., 2011); however, other relatives have not be researched as deeply until now. We can emphasize clearly from our results that ISSR markers and morphometric analyses are very effective tools to assess close relative fungi, particularly at the genera level.

Traditionally, *Verpa* and *Gyromitra* were found to be very close to the genus *Morchella* and so, they were named false morels (Kirk et al., 2008). Our examinations indicated that these taxonomical groups are very close in terms of genetic and morphological features, and clear differences can be displayed among them. According to our findings, *Morchella esculenta* is the farthest taxa genetically and the alveolate ascocarp was not seen in any other relatives. From these, we can say that the alveolate cap is an important character for true morels to separate it from its close relative genera. Analysis of the ribosomal DNA of many of the *Pezizales* showed the genus *Verpa* to be closely related to the genus *Morchella* (Bunyard et al., 1995; O'Donnell et al., 1997). The results from the ISSR analyses did not exactly reflect this information, such that *S. coccinea* was positioned exceptionally among them.

The morphological data has been found largely correlated with the genetic information based on the ISSR locus analyses in except of a limited homoplasy and pseudocriptic variation. It is an interesting finding that species such as *H. lacunosa* and *H. crispa*, which are very close taxa morphologically within the genus *Helvella*, constituted the main body of this study, and are taken place genetically relatively remote (*Fig. 3*). This observed homoplasic similarity on their morphologies might be sourced from similar environmental conditions and habitats rather than genealogy. As together with this, Skrede et al. (2017) reported a pseudocryptic variation, in which 2 taxa could be recognized morphologically, only after molecular systematic data unveiled their existence. The authors suggested that the morphologically similar species pairs of *H. corium/H. macrosperma, H. lactea/H. pallescens,* and *H. elastica/H. panormitana*, which were initially indiscernible due to the lack of discriminating morphological characters, could be resolved as genealogically exclusive using the sequence data. This was true with our 4 fungi, such as with *H. lacunosa* and *H. crispa* or *H. spadicea* and *H. leucopus*. The results indicated that these species pairs are genetically divergent and located in relatively distant related *Helvella* lineages according to the ISSR data. The use of molecular characters is important in cases whether the morphological characters of the taxa are identical to each other or not, or may have been reduced or absent from the taxa (Blackwell et al., 2007). The genus *Helvella*, which constitutes the main body of this work, is relatively taxonomically problematic and shows a series of relationships with the other genera mentioned in this paper. Although easily separated from other macrofungi by conspicuous polymorphic apothecia, it is surprisingly difficult to distinguish between *Helvella* species. Historically, the shape, color, and outer surface characters have been emphasized in species discrimination, while the microanatomy of the sterile and fertile structures added few characters of value in species recognition. In a previous study performed on *Helvella* (Weber, 1972), it was concluded that most morphological and anatomical characters exhibited a nearly continuous variation in the genus as a whole. Unlike the expressed critics, we think that the trustable and functional characters could be revealed for the genus *Helvella* in light of the molecular or morphological data, as illustrated via the nMDS plot of Primer7, and they could be used to explain taxonomical relationships. In conclusion, it was decided that both the stalk and cap features were quite efficient when the characters were handled comprehensively.

(Received 28th Feb 2019; accepted 3rd May 2019)

Abstract. *Sideritis* L. species that we based on in this study are annual or perennial flowering plants which are widely used as herbal medicine, and also called mountain tea or shepherd's tea. They are common in the Mediterranean Region, the Balkans, Iberian Peninsula, Greece, Central Asia and Anatolia. They are xerophytic shrub or herbs between 8 and 90 cm. They usually grow on arid cliffs, calcareous slopes, high-altitude mountainous regions (650-1400 m). Full bloom usually occurs in July. It is commonly used in Albania, Greece, Kosova, Bulgaria, Macedonia, Asia, Central Europe and Anatolia as herbal tea and for therapeutic purposes. It is usually used to aid digestion, strengthen the immune system, suppress common cold, allergy, sinusitis and influenza and as therapeutic for pain and mild anxiety. The methanol extracts obtained from the flower and leaf parts of the species *Sideritis ozturkii* Aytaç & Aksoy, which is endemic in Turkey, were applied at different concentrations and for different times on DLD-1 human colorectal cancer cells cultured in RPMI-1640 medium. The cytotoxicity measurements were made through the use of MTT and the cytotoxicity indices were calculated using an Elisa Reader. As a result of the study, it was determined that the flower and leaf extracts obtained from the species *Sideritis ozturkii* exhibit cytotoxic activity on DLD-1 cells in a dose- and time-dependent manner. It is believed that the extracts obtained from the species *Sideritis ozturkii* could be beneficial as a natural anti-proliferative agent.
Keywords: *Sideritis, cytotoxicity, cancer, phenolic, DLD-1, MTT*

Introduction

Cancer is characterized by abnormal growth of cells that have the potential to spread to other parts of the body, and the body's normal control mechanism is a disease that develops when it stops working and causes death. Today more than 100 types of cancer affect people. Cancer is a global health problem; it is known that 9% of deaths in developed countries and 21% of deaths in developing countries are caused by cancer. The World Health Organization estimates that in the year 2050, about 27 million new cases of cancer will occur annually and 17.5 million people will die from these cases (Hussain et al., 2016).

The word cancer means the growth of malignant tumors resulting from the irregular division and proliferation of the cells in an organ or tissue. In the general sense, the cancer refers to a group of more than 100 diseases caused by the uncontrolled proliferation of the cells in various regions of our body. Although there are a great variety of cancer types, all begin with an uncontrolled proliferation of the abnormal cells. These may cause serious disorders, even death, in case left untreated (Horner et al., 2009).

Colon cancer is the third most common type of cancer in the world, and colorectal cancer is the second most common cause of death. Although colon cancer is a disease that can be seen at any age, its incidence is generally higher in people aged 40 years and older. Among all cancers, the incidence is in the third place in females and the second in males (Giardiello, 2014). According to the Ministry of Health data, it is among the five most

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74077419

common types of cancer in Turkey. Globally, more than a million people per year are caught in colorectal cancer. In 1990, 490,000 people per year of death of the colon cancer, which led to the death of 715,000 people annually was announced to cause death. Colorectal cancer is the second largest cause of male and female deaths in the United States. In 2011, there were 141,210 cases per year in the United States and 41,000 cases in the United Kingdom. Environmental factors are the major factors in the incidence of colon cancer in the community. Especially in developed countries, unhealthy eating habits of people with unbalanced life and high fat increase the incidence of colon cancer. In addition, the genetic predispositions and characteristics of people as well as environmental factors increase the incidence of colon cancer.

Increase in the incidence of cancer cases, chemotherapy and radiotherapy used in the treatment of many cancer patients to damage the normal cells and reducing the percentage of success of these treatments in targeted cancer cells has encouraged scientists to develop new anticancer drugs from plants (Shah et al., 2013).

It is seen that in many archaeological findings, people have been using plants for treatment and nutrition purposes for thousands of years (Koçyiğit, 2005). The belief in the power of plants to treat diseases is almost as old as the history of humanity. Throughout the history of humanity, plants with many different forms have been used in the treatment of diseases. There is much historical evidence that plants are used for treatment in all continents of the world. The first written information about the ethnobotanical field, which refers to the use of plants for medical purposes, dates back to 3000 BC, namely the periods of Egypt, Hittite, Greek and Roman periods (Dağcı et al., 2002).

At the end of the 5th century BC, the book de De Mataria Medica rod by Diockrodidas in the 1st century AD is shown as the basis of modern pharmacology. Plants still present in these works and new species of these plants continue to be used in traditional treatment (Cowan, 1999).

In recent years, especially after the 1980s, the chemical industry began to take the place of herbal medicines as a result of the rapid progress of the synthetic (chemical) drugs. However, because of the occurrence of many side effects of these synthetic drugs and the high prices of many of them, people have turned to prefer treatment with herbal remedies (Yücel, 2010).

As in all countries of the world, plants are seen important from a medical point of centuries people in Turkey, tea, ointments, spices and so on. used in the treatment of diseases in the shapes. Nowadays, interest in natural herbal medicines has increased again because microorganisms have more resistance to synthetic drugs (Nakipoğlu and Otan, 1992).

The genus *Sideritis* L. constituting the basis for our present study are the annual or perennial flowering plants, which are also called the mountain tea or the shepherd's tea and are commonly used as herbal medicine (Barber et al., 2015). They are abundant in Mediterranean region, the Balkans, the Iberian Peninsula, Greece, Central Asia and Anatolia. These are xerophilous shrubs or herbs with a height in the range of 8-90 cm. They usually grow on the arid rocks, on calcareous slopes and in mountainous regions with high altitude (650-1400 m). The inflorescence is generally verticillate. The blooming is usually observed in July (Aytaç and Aksoy, 2000). It is commonly used as herbal tea for therapeutic purposes in Albania, Greece, Kosovo, Bulgaria, Macedonia, Asia, Central Europe and Anatolia. It is generally used to aid digestion, strengthen the immune system, suppress common cold, allergies, sinusitis and flu and treat pain and mild anxiety (Todorova and Trendafilova, 2014).

DOI: http://dx.doi.org/10.15666/aeer/1704_74077419

Studies have been made regarding the plant's antimicrobial, antibacterial, anti-inflammatory, antioxidant and cytotoxic effects on the diseases. Diterpenes and flavonoids were identified as the predominant active ingredients as the result of the extraction process (Petreska et al., 2011).

The cytotoxicity is the quality of being toxic to cells (Tokur and Aksoy, 2017). Cytotoxicity determines the effect of the active ingredients, particularly flavonoids, glucosides, alkaloids, terpenoids, which are obtained as a result of the extraction of the medicinal plants, on the cancer cells (Kuntz et al., 1999). The most important stage in the research related to the anticancer drugs is the determination of the in-vitro cytotoxicity B. The cultures of the human or animal cancer cells are performed in-vitro in the culture plates where the reproducing cells are grown. Then, the effective dose is determined as a result of a study that is based on the steps of collecting the plants, subjecting the same to mechanical fractionation followed by extraction, introducing to the cancer cells the active ingredients resulting from the extraction and identifying the dose of these active ingredients that kills 50 percent of the cancer cells (Riss et al., 2014).

In the light of this information, this study is to determine the cytotoxic effect of the extracts obtained from the leaves and flower parts of the Sideritis ozturkii species (*Fig. 1*) which are endemic to the province of Konya endemic to the province of Konya on the DLD-1 cell line and to have fewer side effects in the treatment of the cancer of our time. In order to support the production of an economical drug, which is more effective, it has been researched. The cytotoxic effects of *Sideritis* species on the cancer cells began in 1981 and have continued until the present (Jeremic et al., 2013). The literature research on the *Sideritis* species reveals that the studies are generally focused on the species *Sideritis scardia* Griseb. In the present study, the cytotoxic effects of the species *Sideritis ozturkii* of the plant *Sideritis*, an endemic species of Konya Province that has not yet been studied, were investigated on the cancer cells (particularly on the colon cancer cells).

Sideritis ozturkii is an endemic plant in the province of Konya and this is the first study on colon cancer cell line with *Sideritis ozturkii*. Therefore, we believe that this study will contribute to the literature. With the present study, it was aimed to provide support for the manufacture of an economical drug with fewer side effects and with the possibility of being more effective in treating the cancer, the disease of our age. The distribution map of the species *Sideritis ozturkii* is given in *Figure 2*.

Materials and methods

Collection material

Sideritis ozturkii type used in this study is located 3 km north of Konya Derebucak district Çamlık village; Kızıldağ's 1450-1700 m high mountainous area collected approximately 1 kg in flowering period in July 2016.

Drying of the plant

The plant was allowed to dry in a room away from the direct sunlight. When the plant was completely dried after two months, the flower and leaf parts were separated. Next, the leaf and flower parts were separately triturated with a plant grinder, subjected to sieving and then moved on to the extraction process. The reason for collecting the plant during flowering period. The extract of the flower part was also intended to be obtained.

Extraction

Of the triturated plants, first a quantity of 15 g was weighed from the leaf part by means of precision scales, placed into the soxhlet apparatus and subjected to the extraction process with 200 mL of methanol for 6-8 h. We have used methanol in our study because methanol is often preferred in studies with *Sideritis*. The extracts recovered from the extraction process were kept overnight in a refrigerator at + 4 °C. On the following day, the extracts were evaporated in a rotary evaporator at 40 °C in order to remove the solvents thereof. The recovered raw extracts were kept at -20 °C until their use in order to prevent any loss of activity. The extraction process with the Soxhlet device is shown in *Figure 3*.

Preparation of cell culture

In order to ensure that DLD-1 cells proliferate in vitro such as in vivo, the appropriate medium was prepared. For this purpose; 10% fetal bovine serum (FBS) and 1% penicillin-streptomycin RPMI-1640 (Sigma) cell medium were used. A few minutes were kept at 37 °C for fast dissolution of DLD-1 cells from the liquid nitrogen tank. The dissolved cells were added to a falcon tube and FBS was added to remove DMSO and pipetted several times. It was then centrifuged for 5 min. After centrifugation, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74077419

supernatant was discarded and the remaining cell pellet was plated on the prepared medium and sown to 25 cm² flask. Cells were cultured in 25 cm² flasks with 95% humidity and 5% CO2 gas and 37 °C CO2 incubator. The density of DLD-1 cells in the flask maintained in the CO 2 incubator was increased over time by invert microscopy, and the cells from the flask were observed to be propagated by passaging.

Figure 3. *Soxhlet device extraction process*

Determination of cytotoxic effect

The cytotoxic effect of the obtained extracts was tested on the DLD-1 cell line comprising the colorectal cancer cells where in said cell line was cultured in RPMI-1640 medium. The obtained extract was subjected to characterization via HPLC in order to reveal the phenolic substance composition. The extract was first dissolved in a solvent, was then passed through the respective chromatography column under high pressure and the phenolic substance content was checked.

High performance liquid chromatography (HPLC)

HPLC is the most widely used device for the purpose of analytical separation techniques. The reasons for widespread use are that it is easily adaptable to quantitative determinations, suitable for the separation of compounds that are not volatile or easily decomposed by temperature. Most importantly, it is the wide applicability of many disciplines of science to the subjects of primary interest of the society. Examples of such compounds include amino acids, proteins, nucleic acids, carbohydrates, drugs and pesticides. HPLC unit: Degasser, pump, autosampler, column and detector consist of four parts. The Degasser; It provides removal of dissolved gases present in mobile phases.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74077419

HPLC (High Performance Liquid Chromatography) High Performance Liquid Chromatography is briefly referred to as HPLC.

High performance; expresses high resolution. It is also called High-pressure Liquid Chromatography since the mobile phase is progressed with high pressure (Lindsay, 1987).

Calculation of cytotoxicity indexes

The prepared extract was dissolved using DMSO at a nontoxic level and it was used on the cell line at different concentrations and for different time intervals. After different concentrations of the extract were added on the cell line, the measurement of cytotoxicity was performed through the use of MTT. Four hours after the addition of MTT on the cells, DMSO or isopropanol was added and the cells were incubated for four hours in an ambience not exposed to light. After the exposure of the cells to the extract for 24 and 48 h, the cytotoxicity indices based on absorbance were calculated by using an Elisa Reader. The cells allowed to proliferate under appropriate conditions were removed from the flask base by treatment with trypsin-EDTA when they covered 70% of the flask surface. The cells stained with Trypan blue dye were counted 3 times with the help of thoma slide and suspended in the number of cells required for MTT testing. 100 µl of cell suspension was then transferred to a 96-well cell culture plate. 24 h incubation at 37 °C was achieved to allow the cells to adhere and adapt to the new environment. After 24 h, fresh media containing (100 µg/ml, 250 µg/ml, 500 µg/ml, 750 µg/ml and 1000 µg/ml) the desired final concentrations of extracts were added to the cells to determine the cytotoxic effects of the extracts and incubated for 24 and 48 h at 37 °C in a CO2 incubator.

Results

The % viability graphs obtained in line with the MTT test data, which were measured at time points of 24 and 48 h after the application, on DLD-1 cell line, of the methanolic extracts obtained from the leaf and flower parts of the plant *Sideritis ozturkii* and of the extract obtained by way of brewing from the leaf thereof are in *Figures 4, 5* and *6*.

When the mitochondrial activity after 24 h of application was evaluated as the % viability in the plates that were started with equal numbers of cells, the extract obtained from the leaf led to the cell death rates of 1% at the dose of 100 µg/mL, 26% at the dose of 250 µg/mL, 54% at the dose of 500 µg/mL, 67% at the dose of 750 µg/mL and 74% at the dose of 1000 µg/mL, while the extract obtained from the flower part, though causing an increase in the number of cells at the dose of 100 µg/mL, resulted in the death of the cells at increasing doses; namely the cell death rates of 12% at the dose of 250 µg/mL, 32% at the dose of 500 µg/mL, 45% at the dose of 750 µg/mL and 80% at the dose of 1000 µg/mL. On the other hand, the extract obtained by the brewing method from the leaf resulted in cell death rates of 57% at the dilution of 1/10, 70% at the dilution of 1/5 and 79% at the dilution of 1/2. Taking the % viability values into consideration, it was observed that the extracts obtained from the leaf were more effective in causing the death of the DLD-1 cells as compared to the extract obtained from the flower. The extracts obtained from the flower were also effective in providing the cell death, but they exhibited lower effect than the leaf extracts.

DOI: http://dx.doi.org/10.15666/aeer/1704_74077419

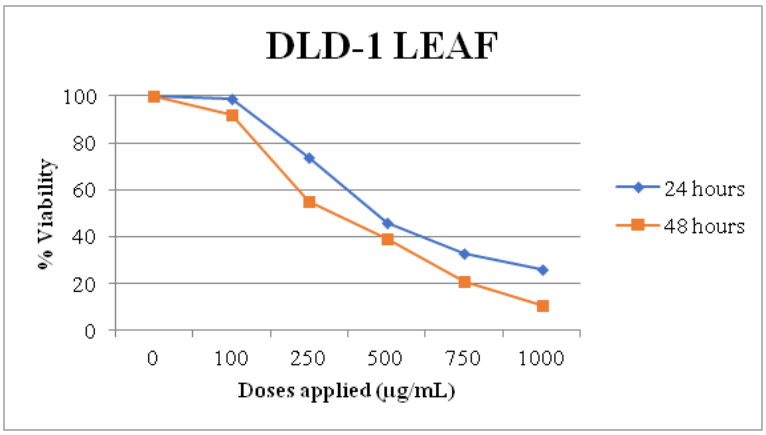

Figure 4. *24- and 48-h effects of the extract obtained from the leaf on DLD-1 cell line*

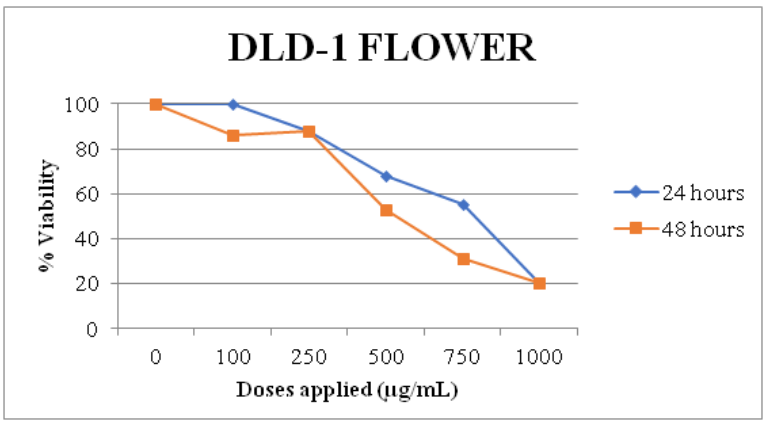

Figure 5. *24- and 48-h effects of the extract obtained from the flower on DLD-1 cell line*

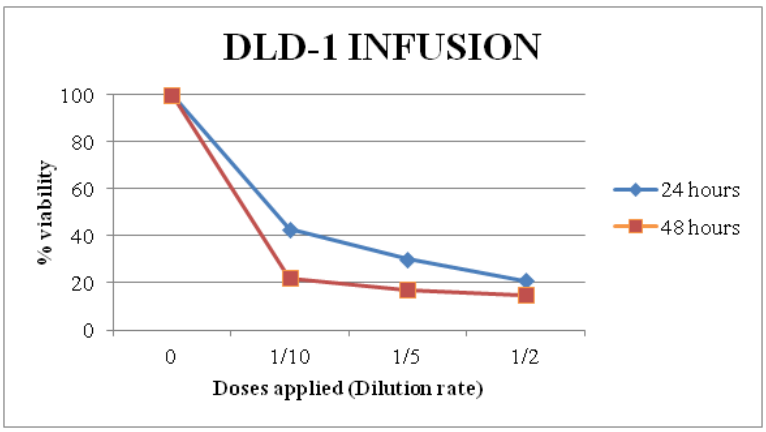

Figure 6. *24- and 48-h effects of the extract obtained by way of brewing from the leaf on DLD-1 cell line*

When the results for 48 h of extract application were compared to those for the 24-h application, some increase was observed in the cell death in a time-dependent manner. The extract obtained from the leaf led to the cell death rates of8% at the dose of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74077419

100 µg/mL, 45% at the dose of 250 µg/mL, 61% at the dose of 500 µg/mL, 79% at the dose of 750 µg/mL and 89% at the dose of 1000 µg/mL; the extract obtained from the flower part led to the cell death rates of 24% at the dose of 100 µg/mL, 22% at the dose of 250 µg/mL, 47% at the dose of 500 µg/mL, 69% at the dose of 750 µg/mL and 80% at the dose of 1000 µg/mL; and the extract obtained by the brewing method from the leaf led to the cell death rates of 78% at the dilution of 1/10, 83% at the dilution of 1/5 and 85% at the dilution of 1/2.

The IC_{50} dose for the extract obtained from the leaf was calculated as 0.46 mg/mL for 24 h and 0.33 mg/mL for 48 h. On the other hand, a higher IC_{50} dose was found for the extract obtained from the flower, as compared to the extract obtained from the leaf. For the extract obtained from the flower, the values of 0.7 mg/mL and 0.53 mg/mL were calculated for 24 h and 48 h, respectively (*Fig. 7*).

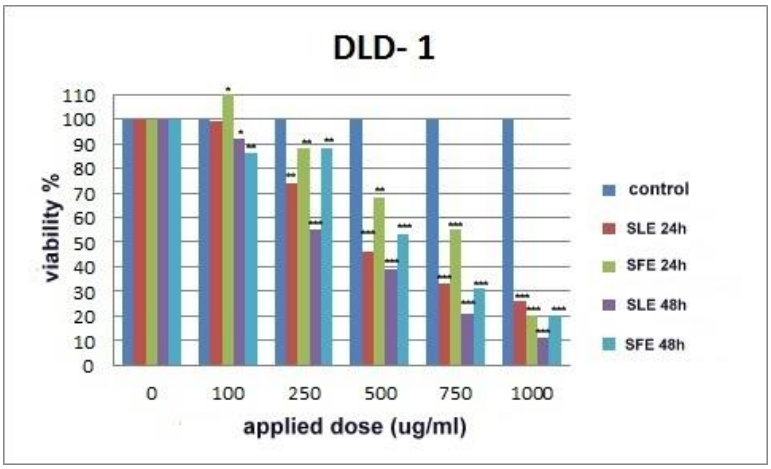

Figure 7. *24- and 48-h effects of the obtained extracts on DLD-1 cell line*

The graphs for the results of HPLC (high pressure liquid chromatography) we performed on two methanolic extracts obtained from the plant *Sideritis ozturkii* are in *Figures 8* and *9*.

DOI: http://dx.doi.org/10.15666/aeer/1704_74077419

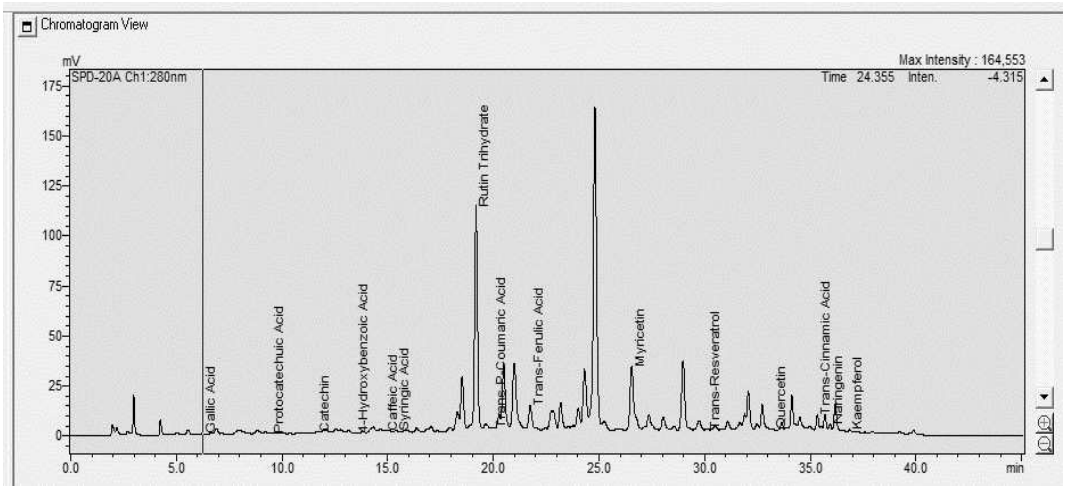

Figure 9. *View of the HPLC chromatogram for the methanolic extract obtained from the flower of Sideritis ozturkii*

The screening was performed on both extracts for 15 phenolic substances. The phenolic substances used as the standard were as follows: Gallic Acid, Protocatechuic Acid, Catechin, 4-Hydroxybenzoic Acid, Caffeic Acid, Syringic Acid, Rutin Trihydrate, Trans-P-Coumaric Acid, Trans-Ferulic Acid, Myricetin, Trans-Resveratrol, Quercetin, Trans-Cinnamic Acid, Naringenin and Kaempferol. The standards were prepared by way of dissolving the same in methanol. The phenolic substances found in each extract and their respective quantities are given in (*Table 1*).

When the extracts were compared in terms of the phenolic substance content, the extract obtained from the leaf was found to contain the highest quantities of rutin trihydrate and Trans-P-Coumaric Acid.

Table 1. *Phenolic substances present in the extracts obtained from Sideritis ozturkii and their respective quantities*

Phenolic substance	***Sideritis ozturkii* leaf (mg/100 g)**	***Sideritis ozturkii* flower (mg/100 g)**
Gallic Acid	7.278	11.067
Protocatechuic Acid	10.244	4.972
Catechin	70.056	64.100
4-Hydroxybenzoic Acid	11.178	15.922
Caffeic Acid	8.844	8.467
Syringic Acid	12.722	13.472
Rutin Trihydrate	1805.756	823.367
Trans-P-Coumaric Acid	49.811	9.556
Trans-Ferulic Acid	24.289	98.372
Myricetin	37.811	424.517
Trans-Resveratrol	6.089	29.856
Quercetin	19.811	22.433
Trans-Cinnamic Acid	4.900	4.506
Naringenin	14.367	12.328
Kaempferol	7.900	72.367

Discussion

Cancer is one of the most important reasons of disease-caused deaths in the world. World Health Organization reports that approximately 84 million people lost their lives due to cancer between 2005 and 2012 (Behzad et al., 2014). Despite the frequent use of chemotherapy in the treatment of cancer, the toxic effects that occur over time limit the use of these drugs. Both the high mortality rate of cancer cases and the emergence of serious side effects of chemotherapy and radiotherapy lead cancer patients to alternative and/or complementary therapies (Shah et al., 2013). At this point, natural products are viewed as potential raw materials for new drug discoveries, and phenolic compounds found in natural products come to the forefront with their structures and activities. For this reason, the search for the anticancer effects of natural products, either as whole extracts or compounds isolated from them, has become one of the most popular study areas. In preliminary studies to determine the availability of natural products for humans, the use of in vitro methods is recommended. Clinical trials are recommended only if positive results are obtained from in vitro and in vivo studies (Demir et al., 2016, 2017). Some criteria have been established to demonstrate if a natural compound is effective and acceptable in terms of chemopreventive or chemotherapeutic efficacy. The most important of these criteria is that the natural product (that is cytotoxic to cancerous cells) used should not exhibit the cytotoxic effect in normal cells, and should be effective against multiple cancer cell lines (Demir et al., 2017).

In line with this information, in order to support the production of a herbal preparation that has less side effects in treating cancer -the disease of the century- or at least has the potential to reduce the side effects of chemotherapy; *Sideritis ozturkii* (which is endemic to Konya province and has not been studied before) extracts of leaf and flower parts (extracted with methanol) were isolated and their cytotoxic effects on colon cancer were examined through MTT method.

Tadić et al. (2012) evaluated the cytotoxic effects of plant extracts in PBMC, B16 and HL-60 cells. Cytotoxic effects were analyzed by dual staining of apoptosis cell death and neurotic cell death with annexin V and PI-coupled fluorescein isothiocyanate (FITC). All plant extracts were also analyzed phytochemically. Analysis by HPLC revealed that ferulic acid was the predominant active ingredient of the phenolic compounds. It has been determined that this phenolic compound has a higher cytotoxic effect in PBMC, B16 and HL-60 cells than that of the other active substances. In this study, the cytotoxic effects of the extracts of the flower and leaves of the *Sideritis ozturkii* plant on the DLD-1 cell line were investigated. Cytotoxicity was analyzed by MTT test. All phytochemical analysis of the plant was carried out by HPLC method. As a result of this analysis, it was determined that the dominant active substances of the plant were routine trihydrate, myricetin and catechin. It has been found that routine trihydrate, the predominant active ingredient in the leaf, has a higher cytotoxic effect on colon cancer cells than other active agents.

Jeremic et al. (2015) have examined the mechanisms of cytotoxic action of flavonoids (from the active ingredients of *Sideritis scardia* L. extracts) on rat C6 glioma cells. As a result of their study, flavonoids (detected as the predominant active ingredient in *Sideritis scardia* L. extracts) were found to have elevated rates of apoptosis, necrosis and autophagic cancer cell death in C6 glioma cells, and thus have a high cytotoxic effect. In this study, cytotoxic effects of *Sideritis ozturkii* extracts on colon cancer cells were investigated. In the results, it was found that mathanol extracts had a significant cytotoxic effect on the detected tumor line. As a result of the HPLC

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74077419

analysis, it is thought that *Sideritis ozturkii* has an anti-tumor characteristic due to its rich flavonoid content and therefore it can be proposed as an anti-tumor agent with cancer prevention and an alternative cancer prevention food.

Radovaroic (2015) in this study, chemical components of plants with cytotoxic activity and plant extracts selected for producing chemotherapeutic drugs were evaluated. Various plant extracts (*Sideritis scardia* L. *S. linearifolia*) were studied and polyphenolic, diterpenoids, flavanoids, betulinic acid, triterpenoids, anthraquinone and berberine were determined as predominant active agents and their effect rates on cytotoxicity were compared. These active ingredients were measured on the effects of apoptosis to stop the cycle of cancer cells on viability. As a result of these studies, it has been determined that plant extracts have potential cytotoxic effects on cancer cells and especially flavonoids are effective anti-chemotherapeutic agents.

Zegerac (2015) investigated the cytotoxic, antioxidant and antimicrobial effects of the active substances in extracts extracted from *Sideritis lamiaceae* in in vitro studies on cancer cells in mice. However, *Sideritis lamiaceae* L. extracts were not as effective as *Sideritis scardia* L. in cancer cells. However, flavonoids, the dominant active ingredient in antioxidant properties, were found to be positive according to ORAC 5.0 assay. The in-vitro studies of the active ingredients in extracts from the leaves and flower parts of the endemic Sideritis ozturkii investigated the cytotoxic effects on the DLD-1 cell line (colon cancer cells). Sideritis ozturkii extracts have been found to have a higher cytotoxic effect than Sideritis congesta species in which Zegerac works in cancer cells. This has also shown us that Sideritis ozturkii's cancer prevention may also be an alternative anti-cancer agent.

To our knowledge, no cytotoxic effect studies on *Sideritis ozturkii* have been reported so far. However, studies on similar species of *Sideritis* have shown cytotoxic effects on cancer cells.

In this study, cytotoxic effects of methanol extracts, obtained from endemic *Sideritis ozturkii* leaves and flowers, on DLD-1 cell line were investigated by MTT method and Elisa reading. As a result of this study, leaf and flower extracts obtained from *Sideritis ozturkii* displayed cytotoxic effects on DLD-1 cells, depending on the dose and time. The extracts obtained from the leaves were found to be more effective than the ones obtained from the flowers. The IC_{50} doses for leaves and flowers were estimated to be approximately 0.3 μg/ml and 0.5 μg/ml, respectively. When extracts were compared to phenolic substance content, it was found that the extract obtained from leaf yielded the highest amount of routine trihydrate and Trans-P-Coumaric Acid. We think that this phenolic substance content of the leaves causes these results.

Conclusions

According to the results obtained from the MTT test, the extracts obtained from the leaf and flower parts of the species *Sideritis ozturkii* showed cytotoxic effects on DLD-1 cells in a dose- and time-dependent manner. The leaf extract was determined to be more effective than the flower extract. The IC_{50} dose was calculated to be approximately 0.3 μg/mL for the leaf extract and 0.5 μg/mL for the flower extract. The data suggest that the extracts obtained from the species *Sideritis ozturkii* could be beneficial as a natural anti-proliferative agent.

(Received 1st Mar 2019; accepted 3rd May 2019)

Abstract. The purpose of this research has been to identify the fungi communities abundance and structure of different fertilization management and their relationship with soil environment with 32-year fertilization experiment which included no fertilization (CK), phosphorus plus potassium fertilization (PK) and nitrogen, phosphorus and potassium fertilization (NPK) on Mollisol in Northeast China by pyrosequencing analysis. It was found that mineral fertilizer application caused shifts in the structure of fungi communities. Soil physical and chemical properties and fungi diversity and abundance were significantly affected by long-term mineral fertilization, especially in fungi diversity reduction and soil acidification.
Keywords: *long-term experiment, diversity, enzyme activity, phylogenetic analysis, CCA analysis*

Introduction

Fertilization has been widely used as a common agricultural practice to maintain soil fertility and increase crop production (Robertson and Vitousek, 2009; Shen et al., 2010). Microbial community composition is sensitive to nitrogen (N), phosphorus (P), and potassium (K) fertilization (Allison and Martiny, 2008), especially in the long-term fertilizer experiments (Shen et al., 2010). N fertilizer is the limiting nutrient for primary production in many countries. N input to unmanaged agricultural ecosystem often resulted in microorganism composition and diversity change, which finally impacted microbial and fungi communities (Cleland and Harpole, 2010; Clark et al., 2007). Many researches found that inorganic fertilizer applications change the soil physical and chemical characteristics, such as pH (Tripathi et al., 2012), electrolytic conductivity (EC) (Rezapouret al., 2013) and organic materials concentration (Chávez-Romero et al., 2016; Sul et al., 2013). Furthermore, previous studies have shown that the application of N fertilizer suppressed microbial activity in soil (Lu et al., 2011; Liu and Greaver, 2010). China began to large-scale application of mineral fertilizer since 1980s, to better understand how Phosphorus plus Potassium (PK) and nitrogen addition (NPK) impact the soil environment in black soil, we have set up a series of long-term fertilizer experiments in order to explore the effect of mineral fertilizer on soil environment and soil quality since 1984.

Previous studies were mainly focused on the impact of long-term fertilization on crop production and microbial communities. However, little information is obtainable about

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74217429

the fungi construction and the relationship between fungi community and soil environment under long-term fertilization. In this study, we collected soil samples of three kinds of fertilization management from a 32-year fertilization experiment which included no fertilization (CK), phosphorus and potassium fertilization (PK) and nitrogen, phosphorus and potassium fertilization (NPK) to investigate the effect of different fertilization management on soil fungi communities. The objective of this study was therefore to know the fungi communities abundance and structure of different fertilization management and their relationship with soil environment by pyrosequencing analysis.

Materials and methods

Sampling site

Soil samples were collected from long-term fertilizer experiment station in Jilin Agricultural University, Changchun city, Jilin Province, Northeast China (43°26'N, 125°45'E). The station was established in 1984 with continuous maize cropping system in a Mollisol. The region was characterized by a temperate continental monsoon climate, with an average annual precipitation of 570 mm and an average temperature of 4.8 °C. Three fertilization treatments with three replicates for each treatment were selected for the present study, i.e., CK (no fertilizer), PK (phosphorus and potassium fertilization at a rate of 75 kg P/ha and 75 kg K/ha), and NPK (nitrogen, phosphorus and potassium fertilization at a rate of 150 kg N/ha, 75 kg P/ha and 75 kg K/ha). In September 2015, four soil cores from each plot were collected from the top 30 cm soil layer with auger (10 cm diameter) and then mixed into a composite sample. The soil samples were sieved through a 2 mm sieve, and preserved at -80 °C for DNA extraction.

Soil characteristics

pH was determined using a glass combination electrode with soil: water of 1:1. Soil organic matter and total N were determined by the ultraviolet spectrophotometric method, the total phosphorus (TP) were determined using the acidic molybdate-ascorbic acid spectrophotometric method. The initial physical and chemical characteristics of soil in 1983 were shown in *Table 1*. Catalase and sucrase activity was determined according to Claiborne (1985) and Tabatabai (1977). Phosphatases were analyzed by soil zymography according to Spohn et al. (2013).

Table 1. *The basic physical and chemical characteristics of background soil which was tested in 1983 (Lu et al., 2006)*

pH	OM (g/kg)	T N (g/kg)	T P (g/kg)	Available N (mg/kg)	Available P (mg/kg)	Available K (mg/kg)	Organic C (g/kg)
7.4	22.8	1.39	0.53	125.0	13.6	218	17.90

OM: organic matter; TN: total nitrogen; TP: total phosphorus. Available N: available nitrogen; Available P: available phosphorus; Available K: available potassium; Organic C: organic carbon

Soil DNA extraction

The DNA was extracted from 0.25 g soil using the Power soil DNA Isolation Kit (MOBIO Laboratories Inc., Carlsbad, CA, USA) according to the manufacturer's instructions. The DNA samples were purified with Axyprep^{TM} DNA Gel Extraction Kit.

DOI: http://dx.doi.org/10.15666/aeer/1704_74217429

ITS gene amplification and sequencing

To amplify the fungal specific fragments for Miseq, primers ITS1F (5'-CTTGGTCATTTAGAGGAAGTAA-3') and ITS2R (5'-TCCTCCGCTTATTGATATGC-3') which target for fungal ITS genes were selected. Both forward and reverse primers were tagged with adapter, pad and linker sequences. Each barcode sequence (12 mer) was added to the reverse primer for pooling multiple samples in one run of Miseq sequencing. The PCR conditions were 94 °C for 2 min, 32 cycles of 94 °C for 1 min, 59 °C for 45 s and 72 °C for 1 min of extension, followed by 72 °C for 7 min. PCR products were purified and combined in equimolar rations with the quantitative DNA binding method in order to create a DNA pool that was further used for sequencing from the adaptor. The ITS genes were sequenced using the Illumina Miseq platform. The resultant high-quality sequences were then clustered into operational taxonomic units (OTUs) at 97% similarity using UPARSE (Edgar, 2013). The RDP fungal ITS database was used as a reference for classification.

Phylogenetic analysis

After sequencing, the raw fastq files were demultiplexed and quality-filtered using QIIME (version 1.17). As the number of spurious phylotypes increases with sequencing effort, equal number of sequence reads should be used to compare microbial community among samples to minimize the sequencing artifact (Schloss et al., 2011). In this work, about 74503 reads from every sample were randomly picked and grouped into operational units (OTUs) with 97% similarity cutoff using UPARSE (version 7.1 http://drive5.com/uparse/). Chimeric sequences were identified and removed using UCHIME. Community diversity index (Chao, Simpson, Coverage, Shannon diversity index) and rarefaction curves were generated using the MOTHUR program. The taxonomic assignment of OTUs was performed by RDP Classifier (http://rdp.cme.msu.edu/) against the Warcup fungal ITS database.

Statistical analysis

Canonical correspondence analyses (CCA) were carried out by Canoco 4.5 to compare the effects of soil characteristics on fungi community structure. Statistical significant analyses were performed by SPSS ($p < 0.05$).

Results and discussion

Soil characteristics

After 32 years with different fertilizer application, the physical and chemical properties of soil significantly changed (*Table 2*). Comparing with the initial soil, the pH value in the CK treatment only slightly decreased, which was probably attributed to the continuous crop system with no nutrient input. Among the three fertilizer treatments, the pH value in the NPK treatment was the lowest, indicating that soil acidification occurred. N additions have resulted in a significant decrease in soil pH (Guo et al., 2010; Zhou et al., 2016). Stamatiadis (1999) reported that an intensive soil nitrification process resulted in soil acidification which is the main predictor of bacterial diversity in soils (Zhalnina et al., 2015), when amounts of ammonium fertilizer input, especially as N fertilizer was applied. The content of soil organic matter decreased

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74217429

significantly from 22.8 g kg^{-1} to lowest 17.4 g kg^{-1}, which resulted from long-term chemical fertilization or no nutrient management without organic materials input. Soil organic carbon also exhibited the same trend. Achiba et al. (2010) showed that manure application could increase soil organic carbon content. Tian (2015) reported the crop straw residue could improve microbial population and increased soil organic carbon content. Comparing with the initial soil, the contents of available N and K reduced slightly, while the content of available P increased remarkably. This indicated that the application of nitrogen and potassium fertilizer was little deficiency and the application of phosphorus fertilizer was in excessive.

Table 2. *The physical and chemical characteristics of soil samples in 2015*

Treatment	pH	OM (g/kg)	Available N (mg/kg)	Available P (mg/kg)	Available K (mg/kg)	Organic C (g/kg)

S_0NPK	7.10 c	20.13 a	115.67 a	41.43 b	185.13 a	11.68 a

Microbial community diversity

Illumina Miseq sequencing analysis was performed to investigate the microbial community structure in the three fertilizer treatments. There were 98793, 74503 and 120939 effective sequence tags were observed in the CK, PK and NPK treatment, respectively, with an average red length of 320 bp. A total of 74503 reads from each sample were picked randomly for further analysis. The OTUs, richness, diversity, and rerefaction curves of microbial communities were shown in *Table 1*. A total of 670, 618 and 664 OTUs were obtained in CK, PK and NPK treatments, respectively, with clustering at a 97% similarity level. There are significant differences in the OTUs and Shannon index for different fertilization. PK treatment has less OTUs than the other treatments. The higher the Shannon index, the more the microbial community diversity. Among the three treatments, the Shannon index in the NPK treatment was lower than that in the CK and PK treatments, suggesting that N addition has significant effect on fungus diversity. Geisseler (2014) reported that increasing N inputs could suppress soil microbial activity according to the meta-analysis of predominantly unmanaged ecosystems (Paungfoo-Lonhienne et al., 2015; Lu et al., 2011; Liu and Greaver, 2010; Theseder, 2008). As one of the most important microbial parameters in soils (Zhang and Cai, 2007; Tian et al., 2015), microbial diversity was affected remarkably by fertilization (Zhang et al., 2012; Esperschuetz et al., 2007).

ITS pyrosequencing method can reveal the differences of soil fungi communities under long-term fertilization. The mean effective reads obtained from the CK, PK and NPK treatments were 98 793, 74 503 and 120 939, respectively. The coverage showed that the three fertilization samples were greater than 0.99, indicating that the sequencing capability was large enough to capture the complete diversity of each sample. Three fertilization treatments had no significant effect on fungi richness, however, balanced fertilization management (NPK) treatment had significantly influenced on fungi diversity according to Shannon indices; and PK treatment remarkably reduced the OTUs number. Fungi diversity is one of the most important fungi parameters in soil (Zhong and Cai, 2007).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74217429

Changes of microbial composition at different levels

The classifiable sequences in the CK treatment were affiliated with 5 phyla, 19 classes and 125 genera; the classifiable sequence in the PK treatment were affiliated with 6 phyla, 19 classes and 118 genera; and the classifiable sequences in the NPK treatment were affiliated with 5 phyla, 19 classes and 123 genera. The phylogenetic classification of sequences at phylum, class and genus levels from the three treatments was summarized in *Figure 1*. Ascomycota was the first dominant phyla in all the three treatments, representing 89.13%, 86.72% and 87.70%, respectively. And other main dominant phyla included Basidiomycota, Chytridiomycota, Glomeromycota, and Zygomycota. The rate of Basidiomycota Phylum in the PK and NPK treatments was higher compared with that in the CK treatment, which was favorable to the cultivation of crops and afforestation. Furthermore, the rate of Zygomycota and Chytridiomycota Phylum in the NPK treatment increased two times and five times than that in the others fertilizer treatments.

At class level by the phylogenetic classification, *Dothideomycetes* and *Sordariomycetes* are the main compositions in the three fertilizer treatments, followed by *Eurotiomycetes*, *Leotiomycetes* and *Agaricomycetes*. Thus, the long-term application of mineral fertilizers has no significant impacts on fungi community composition, which was consistent with findings from previous studies (Esperschuetz et al., 2007; Ogilvie et al., 2008; Boerjesson et al., 2012). Dothideomycetes Class as the second most abundant Class is very important for ecosystem environment and global carbon cycle by speeding up cell wall decay (Freedman et al., 2015), the results in our research showed that long-term only P plus K addition would reduce the composition rate in soil. The application of NPK fertilizer significantly increased *Alternaria* and *Pseudogymnoascus* at genus level, compared with the CK and PK treatments. Many pesudogymnoascus species are cellulolytic, function as saprothrophs and are either psychrophilic or psychrotolerant. *Alternaria* is a genus of *ascomycete* fungi. *Alternaria* species are known as major plant pathogens. They are also common allergens in humans, growing indoors and causing hay fever or hypersensitivity reactions that sometimes lead to asthma. At least 20% of agricultural spoilage is caused by Alternaria species; most severe losses may reach up to 80% of yield (Nowicki, et al., 2012). The above results indicated that N fertilizer application could improve the resistance, but also bring about the risk of plant diseases. However, the rate of *Fusarium* at genus level in the NPK treatment reduced less 70% than that of the others treatments. Some species in *Fusarium* genus produce mycotoxins in cereal crops that can affect human and animal health if they enter the food chain. The rate of genus of Penicillium in Eurotiomycetes Class in the NPK treatment obviously increased; on the contrary, the rate of genus of and Ceratobasidium in Agaricomycetes class decreased significantly, comparing with the CK and PK treatments. *Penicillium* bacteria can decompose many agricultural products, and Gratobasidium cornigerum (Bourd.) Rogers in Ceratobasidium could result in crop banded sclerotial blight. Therefore, suitable N addition could improve soil ability of degraded cellulose, as well as reduce the chance of plant banded sclerotial blight.

Relationships between fungi community and environmental variables

According to CCA analysis, catalase had large variance inflation factor (VIF), which implied that its variables are redundant with other variables in the environmental factors

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74217429

(*Fig. 2*). All the environmental variables together explained 99.3% of the variation in fungi communities among fertilizer treatments. A total of 32.2% of the total variance were explained by the first two constrained axes of CCA analysis, in which the first axis explaining 23.0% and second explaining 8.9% of the total variance. The CCA clearly demonstrates that *Pseudogymnoascus*, *Alternaria*, *Penicillium* and *Chaetomium* are sensitive to N fertilizer application.

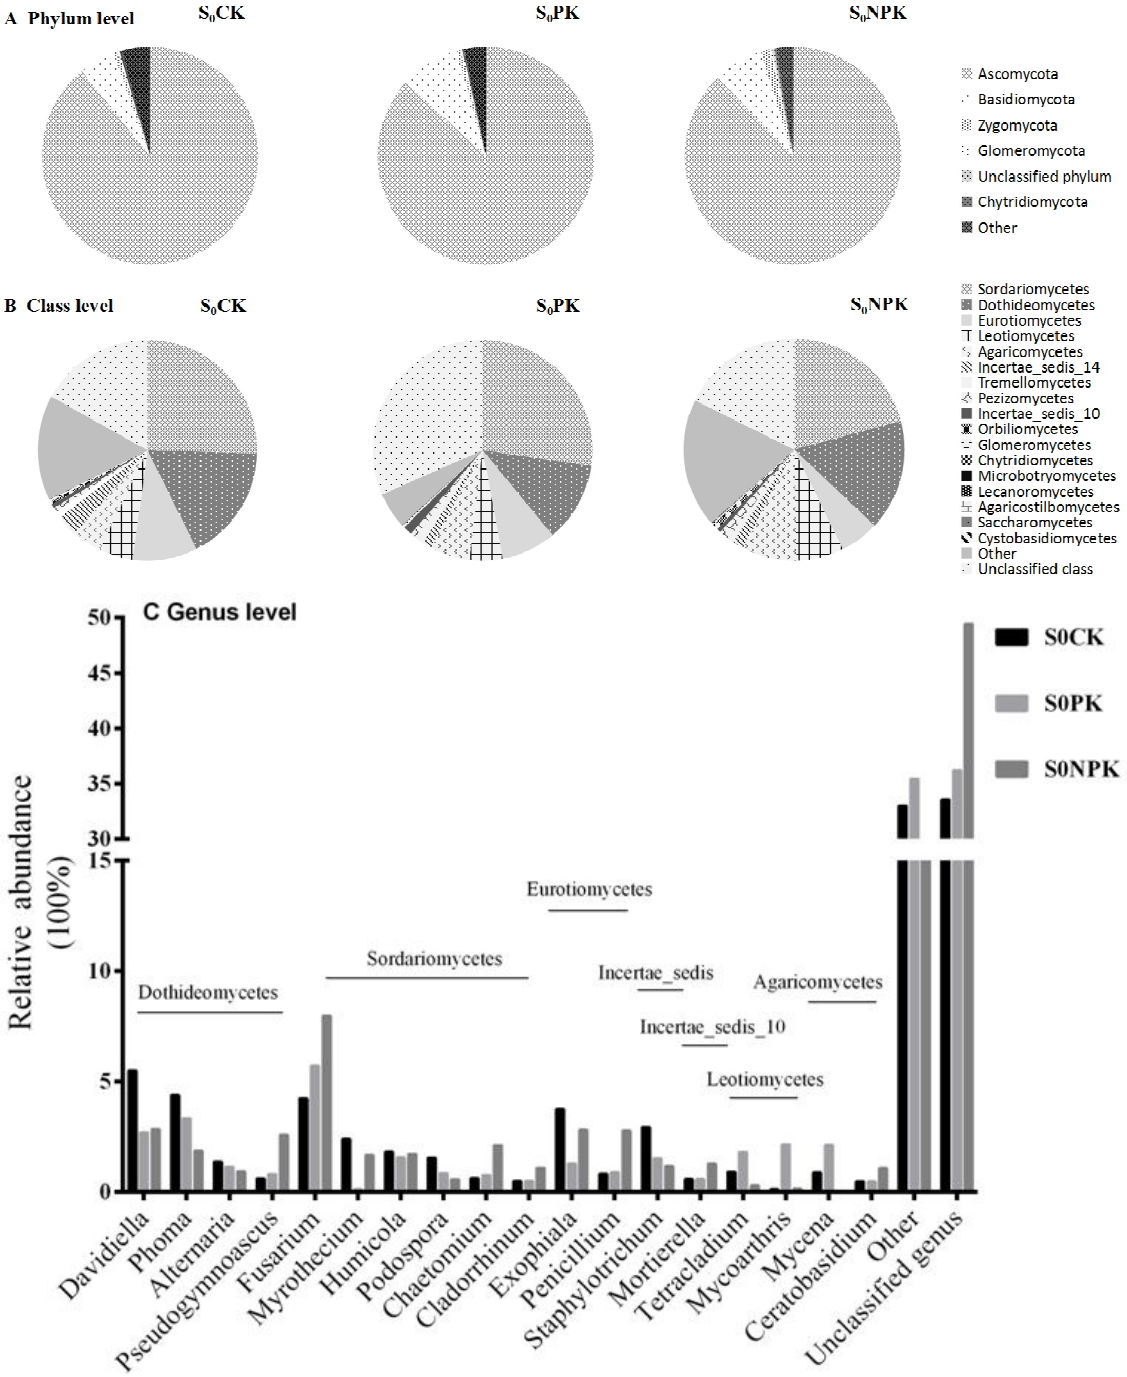

Figure 1. *Fungal community structures at (A) Phylum level, (B) Class and (C) genus level of the SoCK, SoPK and SoNPK. The relative abundance was defined as the percentage of the in total effective fungal sequences in sample. Genera making up less than 1% of total composition was classified as 'other'*

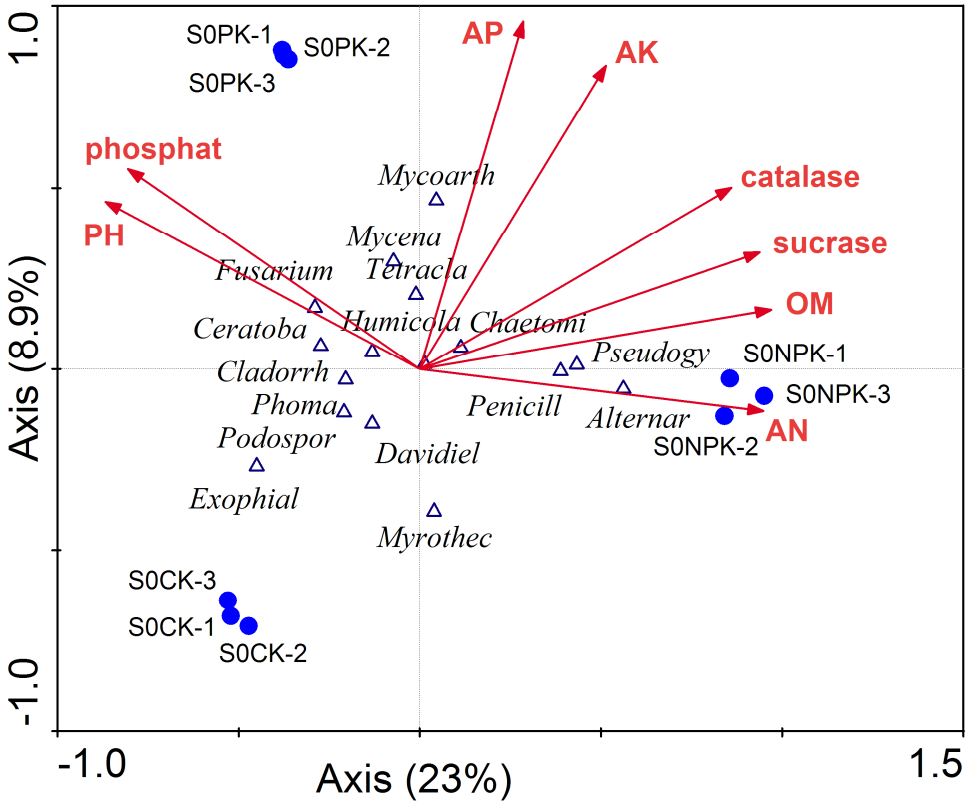

Figure 2. *CCA analysis of different fertilization treatments with soil environmental characteristics as arrows. Triangle symbols represent different genus fungal community structures. OM: organic matter; AN: available nitrogen; AP: available phosphorus; AK: available potassium*

Conclusion

The results presented in this paper unequivocally demonstrate that mineral fertilizer application caused shifts in the structure of fungi communities in Mollisol soil. Soil physical and chemical properties and fungi diversity and abundance were significantly affected by long-term mineral fertilization, especially in fungi diversity reduction and soil acidification.

Abstract. Extremophilic bacteria surviving in extreme environmental conditions possess the special abilities to adapt adverse environment. There are very high salinization and alkalinization contents in Panjin Red Beach's soil. A productive alkline protease strain HHT597 was isolated from the soil samples and identified as *Bacillus altitudinis* based on the 16s rDNA sequence. The HHT597 strain was characterized as a gram positive, rod-shaped bacterial strain with flagellum. The optimum temperature for protease activity by the strain HHT597 was 60°C. There was a broad pH active range of protease from 7.0–11.0 with having optima pH 9.0. The media containing 2.0% glucose and 1% yeast extract as carbon and nitrogen sources could improve protease activity. The strain HHT597 could degrade casein, hemoglobin (HGB) and albumin (ALB) protein. The results indicated that the strain HHT597 might be potential for biotechnological applications.
Keywords: *extreme environment, isolation, 16S rRNA gene, identification, Bacillus*

Introduction

Proteases, which catalyze proteolysis by performing cleavage of peptide bonds, are widely used industrial enzymes, accounting for more than 65% of the total worldwide sale of the enzymes (Rao et al., 1998; Shankar et al., 2011; Annamalai et al., 2014). Proteases include alkaline, acid, thiol and metallo proteases. Among these categories of proteases, alkaline proteases are a class of extracellular enzyme that performs proteolysis and have wide applications as industrial catalysts in various of industries and research laboratories, which could be used in enzymatic peptide synthesis, biotransformation reactions, detergent, surfactants, food processing, diagnostic reagents, preparation of organic fertilizers, silver recovery from used X-ray film and wastes treatment (Kalisz, 1988; Anwar and Saleemuddin, 1998; Shah et al., 2010; Rathod and Pathak, 2016; Hakim et al., 2018). A wide range of sources was found to produce alkaline protease such as bacteria, molds, yeasts, certain insects or mammalian tissues (Mabrouk et al., 1999; Kumar et al., 2014). Bacteria producing

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74317438

alkaline protease are the most important approach relative to plants, animal, and fungus because of their extracellular nature, high yield of production, limited space, convenient cultivation and feasibility to genetic manipulation (Breithaupt, 2001; Selvamohan and Sherin, 2010).

With previous studies gaining a better understanding of the physical, chemical and biological properties of alkaline proteases, researchers nowadays focus more on searching for alkaline proteases with specificities such as high temperature and pH tolerance. Active ranges of temperatures of alkaline (serine) proteases were 35°C–80°C and pH was 7–12 (Rao et al., 1998). Morozkina et al. (2010) reported that the extremophiles could produce extremozymes. Through the long term of natural selection, extremophilic bacteria possess the special abilities associated tightly with their structures, physiological mechanisms, genetic characteristics and biochemical pathways. For example, they can produce extracellular proteases. At high pH and temperatures, there were remarkable activity and stability in alkaline protease produced by marine bacteria (Arastoo and Zahra, 2013). Therefore, extreme environments, in particular, marine environments are a valuable approach for bacteria producing microbial enzymes (Mirete et al., 2016).

Panjin Red Beach which locates in Liaoning, China, is a famous wetland landscape covering an area of 133.33 km^2 on a flat and broad terrain (Wang et al., 2011). Years of marine corrosion leads to the soil a sandy, humid and heavy texture with a high level of salinization and alkalinization. The inartificial edatope creates a unique ecosystem that provides native habitats for variety of halophilic and basophilic microorganisms. Therefore, it is likely to find functional strains that are adaptation to saline-alkali environment. Our research focused on isolating and identification bacteria producing alkaline protease with protease activity in the natural saline-alkaline soil of the Red Beach.

Materials and Methods

Isolation of Bacterial Strain Producing Alkaline Protease

Five representative plots were selected during September 2017 in Panjin Red Beach. Soil samples, five soil cores (5 cm diameter) were collected in triplicate from the topsoil (0-15 cm) in each sampling site and mixed evenly, then placed in aseptic polyvinyl chloride soil bag.

Soil samples (10 g) collected were suspended in 90 mL of sterile distilled water. After a serial dilution (10^{-3} to 10^{-5}) of the soil suspension with sterile distilled water, 0.1 mL soil suspension was spread on selective agar plates and incubated at 37℃ for 2 d. The selective agent in the agar plates contained beef extract 0.3% (w/v), casein 1% (w/v), NaCl 1.5% (w/v), agar 2% (w/v). Ten plates were screened in soil samples and about 150 plates altogether were screened. The strain having the largest clear zone was selected by secondary screening for this study.

DOI: http://dx.doi.org/10.15666/aeer/1704_74317438

Identification of Bacteria Strain

Bacteria strain was performed by Gram staining and biochemical tests such as methyl red test, V-P test, carbohydrate fermentation test and hydrogen sulfide production test following commonly used microbial identification manuals like Bergey's manual (Holt, 1994). Each treatment was conducted with three replicates.

The total genomic DNA of the bacteria strain was extracted and purified using Bacterial DNA Isolation Kit (Sangon Biotech Co., Ltd, China) according to maufacturer's instructions. The 16S rDNA of the isolate was amplified through PCR reaction using the universal primers 27f (5'-AGAGTTTGATCATCCTGGCTCAG-3') and 1492r (5'-TACGGTTACCTTGTTACGACTT-3') synthesized by Sangon Biotech Co., Ltd (Shanghai, China). The PCR reaction process was as follows: 95°C for 5 min, 35 cycles of 95°C for 1 min, 55°C for 1 min, 72°C for 2 min, and a final extension at 72°C for 10 min. PCR product was sent to Sangon BiotechCo., Ltd (Shanghai, China) for sequencing. The similarities of the sequence were identified using online EzBioCloud database (https://www.ezbiocloud.net/). Construction of phylogenetic tree was carried out using MEGA 7 (Kumar et al., 2016).

Enzyme Assay Estimation

Alkaline protease activity was determined by using casein as a substrate by method of Yang and Wang (1999). One unit of protease activity was defined as the amount of the enzyme that produces 1μg/mL/min of tyrosine equivalent under the assay conditions.

Optimum Conditions for Protease Activity

Optimum Temperature and pH: Preheat 2.0% casein solution for 5 min by water bath at temperature ranging from 10°C to 80°C. Mix 1 mL of each casein solution with 1mL preheated crude protease solution and water bath at 40℃ for 10 min, then end the reaction with 5 mL TCA solution. The basal media was adjusted to seven different pH ranging 6.0-12.0. The seed culture (1.0% V/V) was inoculated to each 150 mL liquid medium and was carried out at 37°C, 160 rpm for 2 d. Enzyme assay determination was as stated above.

Carbon and Nitrogen Sources: 2.0% each of glucose, maltose, sucrose and lactose was added in the basal media to investigate the effects of different carbon sources. To observe the effects of various nitrogen sources on protease activity, 1.0% each of beef extract, peptone, yeast extract, sodium nitrate, ammonium nitrate and ammonium chloride was added to the basal media. Fermentation was carried out under optimum temperature and pH at 130 rpm for optimum period. Enzyme assay determination was as stated according to the method described above.

Substrate Specificity Assay: Prepare 2% (w/v) of each casein, gelatin, hemoglobin (HGB), albumin (ALB) solution as substrate. Mix 1 mL substrate solution with 1 mL preheated the crude protease solution and water bath at 40°C for 10 min, then end the reaction with 5 mL TCA solution. Enzyme assay determination was as already mentioned.

Statistical analysis

All data were analyzed according to Duncan's multiple range tests using the SPSS 11.0 software package.

Results and Discussion

Isolation, Screening and Identification of Strain HHT597

Eight isolates from soil samples showed clear zone around bacterial colonies on the selective medium, indicating that these strains can produce extracellular alkaline protease. These eight strains were named for from HHT591 to 598. Finally, bacterium strain HHT597 was chosen for further study based on the intensity of clear zone.

The strain HHT597 was characterized as a gram positive, rod-shaped bacterial strain with flagellum (*Figure 1A*). Colony morphology was faint yellow, round, marginal tidy, dry surface (*Figure 1B, C*).

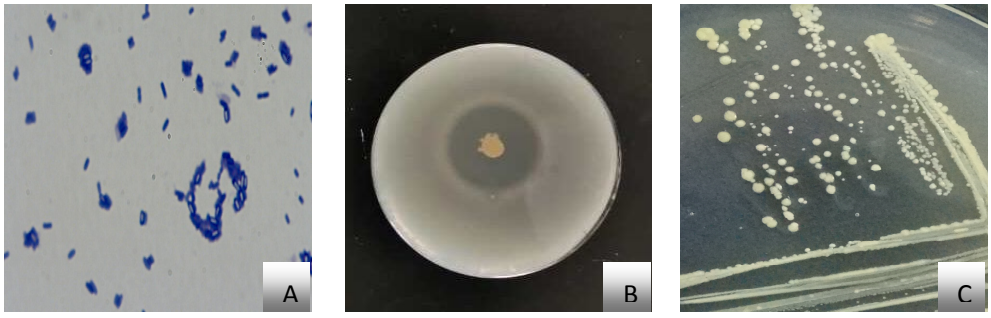

Figure 1. *The colony morphology (A, B) and Gram stain (C) of bacteria strain HHT597*

Biochemical characteristics were listed in *Table 1*. Based on the morphological and biochemical characteristics, isolate HHT597 was identified as *Bacillus* sp. Among all the alkaolphilic microorganisms, *Bacillus* spp. is the most predominant and a prolific source of alkaline proteases (Kumar and Takagi, 1999).

Table 1. *Biochemical characteristics of strain HHT597*

Glucose	Lactose	Acid production	Gas production	Voges Proskauer	Methyl red	H_2S production
+	-	-	+	+	+	+

To carry out the 16S rDNA gene sequencing analysis, the genome of strain HHT597 was used for PCR amplification of 16S rDNA. The molecular weight of PCR product of strain HHT597 was corresponding to 1500 bp of the DNA marker and the amplification was successful. The DNA sequence of 1456 bp product was uploaded to EzBioCloud database for phylogenetic identification and comparison. Phylogenetic tree was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74317438

constructed based on neighbour-joining statistical algorithms. According to phylogenetic tree (*Figure 2*), the strain HHT597 were clustered with *Bacillus* altitudinis strain G65 with high (99%) 16S rDNA sequence similarity. The strain HHT597 was affiliated to the genus *Bacillus*.

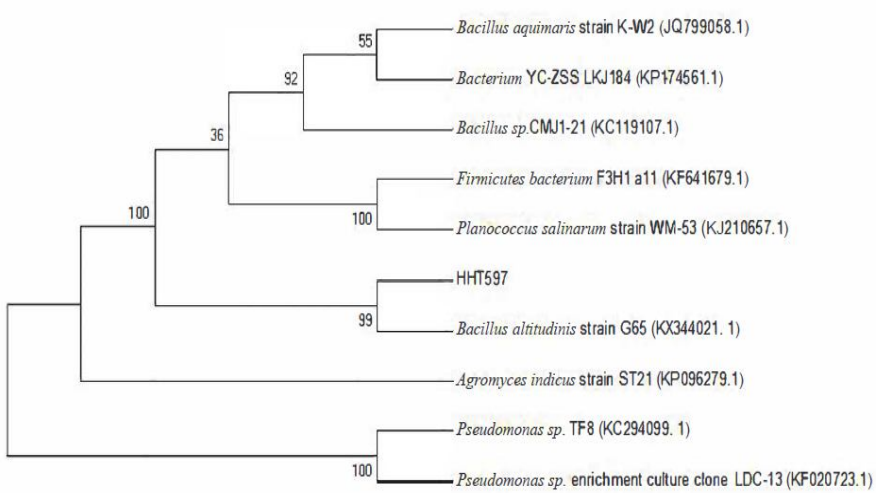

Figure 2. *Phylogenetic tree of HHT597 and B. altitudinis strain G65 with other B. species*

Effects of Temperature and pH on Protease Activity

Generally, the protease activity is easily decreased by high temperature. The temperature optima of protease depended on the bacterial species (Iqbal et al., 2018). In the present study, the alkaline protease activity first gradually increased then gradually decreased with increasing temperature (*Figure 3a*).

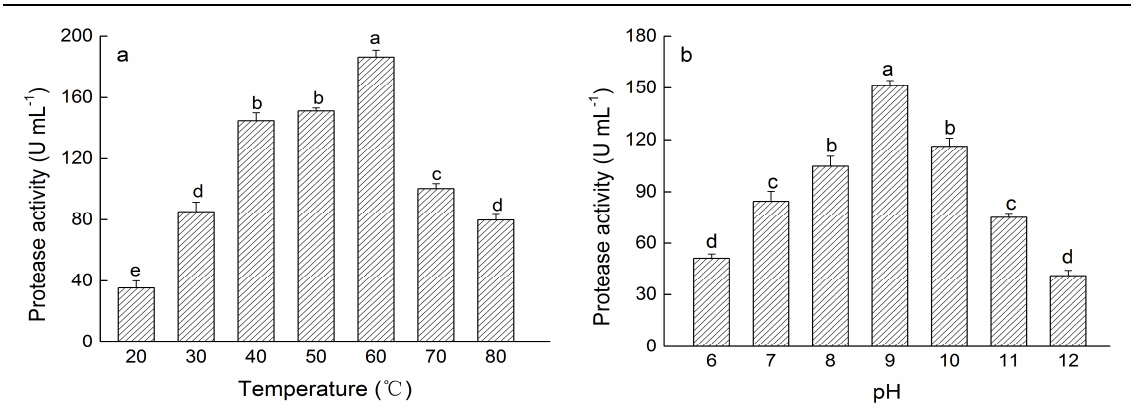

Figure 3. *Effects of temperature (a) and pH (b) sources on alkaline protease activity*

The optimum temperature of protease activity produced by strain HHT597 was 60°C and protease activity reached 186.35 U/mL. When temperature was up to 70°C, the protease activity began gradually to decrease. The results indicated that the protease

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74317438

produced by the strain HHT597 could work at high temperatures. Nevertheless, almost similar protease activity was found at 40–50°C (Hakim et al., 2018).

Many enzymatic processes are strongly influenced by the pH (Ellaiah et al., 2002; Hakim et al., 2018). In the present study, the pH active range of protease was from 7.0 to 11.0. The optimum pH for alkline protease activity was 9.0, and the protease activity was 151.21 U/mL (*Figure 3b*). Rao et al (1998) reported that pH optima of alkaline protease in commerce were from 8.0 to 12.0.

Effects of Carbon and Nitrogen Sources on Protease Activity

The carbon and nitrogen sources used in the media highly influenced production of alkaline protease (Hakim et al., 2018). The media containing glucose at 2% was the most favorable source supported the highest alkaline protease production compared to other carbon sources (*Table 2*). The results were similar with other reports (Ellaiah et al., 2002; Hakim et al., 2018). Among the different nitrogen sources studies, 1% yeast extract was the most benefit for alkaline protease production (*Table 2*), which is consistent with previous results of *B*. subtilis AKAL7 (Hakim et al., 2018) and *B*. sp MA6 (Azad and Hoq, 2000). However, the strain HHT597 could not use inorganic nitrogen compounds as nitrogen sources.

Table 2. *Effects of carbon source, nitrogen source and substrate on alkaline protease activity*

Treatment		Protease activity（U/mL）
Carbon source	Glucose	89.26±1.73a
	Maltose	79.37±2.38b
	Sucrose	35.43±1.2c
	Lactose	78.34±1.34b
Nitrogen source	Beef extract	117.26±4.16b
	Yeast extract	186.24±8.56a
	Peptone	109.32±6.52b
	Ammonium nitrate	—
	Sodium nitrate	—
	Ammonium chloride	—
Substrate	Casein	136.63±7.65a
	Gelatin	—
	Hemoglobin	112.06±4.31b
	Albumin	108.63±2.62b

The different letters indicate significant differences at $P < 0.05$

Optimum Substrate on Protease Activity

Casein, HGB, AHL and gelatin was used as substrate to detect the protease degradation ability, respectively. Among four substrates, casein was the most appropriate substrate and the maximum protease activity was 136.63 U/mL (*Table 2*). HGB and AHL could also be the substrate of alkline protease extracted from HHT597. However, gelatin was not used as the protease substrate.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74317438

Conclusion

A productive alkline protease, gram positive bacterial strain of the genus *Bacillus* was isolated from the soil samples of Panjin Red in China and identified as *B. altitudinis* strain HHT597. The optimum temperature for maximum protease activity produced by the strain HHT597 was 60°C. There was a broad pH active range of protease from 7.0-11.0. The optimum carbon and nitrogen sources for protease activity produced by the strain HHT597 was 2% glucose and 1% yeast extract, respectively. The strain HHT597 could degrade casein, HGB and AHL protein. The research results showed that the strain HHT597 might be potential for industrial applications.

Abstract. The morphological similarities of species of *Capoeta* and *Planiliza* genera make the identification difficult in some cases. Thus, this classification should be confirmed by molecular examination. In this study, 150 specimens of *Capoeta trutta* (Cyprinidae) were collected from Dukan Lake and 120 specimens of *Planiliza abu* (Mugilidae) from Sirwan River in northwestern and southeastern Sulaimani Governorate, respectively. The two fish species recorded were native species. The DNA sequences of both species of fish (*C. trutta* and *P. abu*) were mitochondrial DNA cytochrome c oxidase subunit I (mtDNA COI) locus 617 bp with 61 cytochrome b (cytb) gene, partial cds; mitochondrial, 446 bp respectively. Following analysis the sequences were compared with sequences of other genera and fish species stored in GenBank. DNA sequencing results showed that studied species belong to *Capoeta trutta* and *Planiliza abu*. We conclude, in the view of the results of the present study, that DNA sequence analysis revealed and confirmed the validity of these two species.
Keywords: *fishes, morphometric measure and meristic, molecular examination, DNA sequencing, Iraq*

Introduction

Among the several families of freshwater fishes in the world the most diverse one is Cyprinidae having 220 genera including 2420 species, which belong to Cypriniformes order (Nelson, 2006). Most of Iraqi fish belong to Cyprinidae family, which involving 16 genera with 32 cyprinid species (Coad, 1998; Coad and Hussein, 2007). The distribution area of cyprinid genus *Capoeta* includes Western to Central Asia, such as Armenia, Azerbaijan, Afghanistan, Israel, Anatolia, Iraq, Uzbekistan, Georgia, and Iran (Banarescu, 1991). Genus *Capoeta* includes almost 10 species, 4 out of these occur in Iraq (Coad, 2010). The species commonly appear in streams and lakes, thus in both fast and slow flowing waters (Geldiay and Balik, 1996). *Capoeta trutta* (Heckel, 1843) is a fish species having economic importance with wide distribution in Turkey, Iran, Iraq and Syria (Gunduz et al., 2014), which is dominantly thriving in both the Euphrates and Tigris river systems (Geldiay and Balik, 2007).

The grey mullets or mullets were discovered world-wide in temperate to tropical coastal waters directly entering in estuaries and they are also resident in freshwaters. There are around 75 species and 20 genera in world (Nelson et al., 2016). In Iraq only four species are exist (Coad, 2010). *Planiliza abu* is a mugilid species discovered in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74397451

channels, drains, lakes, reservoirs ponds, canals, rivers, and streams on fish farms with entering estuaries. Ozdilek (2003) and Kuru (1979) state that in Syria, Iraq, Pakistan, Turkey and Iran, mullet often occurs in inhabited places or schools. *Liza abu*, mugilid fish (Heckel, 1843), locally known as khisni, is distributed in all part of mid and south inland waters of Iraq (Al-Daham, 1984).

Fishes in the genera *Chelon*, *Ellochelon* and *Planiliza* were previously in the genus *Liza* (Jordan and Swain, 1884). Molecular data has caused a re-assessment that can be found in the literature (Durand et al., 2012*;* Nematzadeh et al., 2013; Xia et al., 2016). Various authors have or have not accepted, these generic replacements but the review of these opinions is beyond the scope of this paper. Most of the literature cited below refers to the species discussed under the genus *Liza* (except for *Mugil cephalus*) but the genus name has been changed in this text for consistency.

Nowadays via using characteristics other than morphological traits mullet species phylogenic relationships were determined based on molecular genetics and advanced techniques have been developed for studying DNAs in diverse populations and also for identifying fish species via using nuclear (nDNA) and mitochondrial (mtDNA) genomes (Semina et al., 2007; Avis, 1991; Papasotiropoulos et al., 2007). For the study of phylogenetic relationships and molecular systematic in population genetics the mtDNA is an efficient genetic marker due to maternal inheritance, and lesser mean rate of recombination, of replacement and exchange in mtDNA nucleotides than those in nDNA (Ghorashi et al., 2008; Asensio, 2007).

The morphological similarities of species of *Capoeta* and *Planiliza* genera make the identification difficult in some cases. Thus, the aim of this study is to confirm this classification by molecular examination.

Materials and methods

Description of study area

Dukan Lake is situated in north western Sulaimani City, Kurdistan Region, in the north of Iraq. It is approximately 76 km far from the city center (Shaban, 1980). According to Toma (2000) the lake has unregulated spillway at 515 m above sea level and full-pool operating altitude of 511 m, its boundaries extend between 34°17'N – 36°33'N latitude with 43°17'E – 46°24'E longitude (*Fig. 1*).

Sirwan River is situated in south eastern Sulaimani City. It is called Diyala in Arabic and Sirwan in Kurdish. It flows in western Iran from its headwaters in Zagros Mountains to south of Baghdad to its ultimate confluence with the Tigris River. The latitude of Sirwan River is 33° 13' 14.88" N and its longitude is 44° 30' 23.04" E (*Fig. 1*).

Sample collection

A total of 150 *Capoeta trutta* specimens have been collected from Dukan Lake in north western Sulaimani governorate and 120 individual of *Planiliza abu* were collected from Sirwan River in the Sulaimani governorate by fishermen using gill nets, during the period from November, 2017 until May 2018. Fish were transported with local river water in a cool box to laboratory.

DOI: http://dx.doi.org/10.15666/aeer/1704_74397451

Figure 1. *Map of Iraq showing Dukan Lake and Sirwan River*

Morphometric measure and meristic study

The specimens were brought out of the cool box and the body length was measured using a one-meter measuring board graduated in millimetres (mm). The morphometric parameters were measured from left side of each specimen. According to Beckman (1962) and Coad (2010, 2017), morphometric characters and meristic were studied as shown in *Table 1*.

Extraction of DNA

Samples were taken from the liver of two fish species their identification by morphological characters only. Samples (20 mg) collected from the liver tissue samples were digested and homogenized, and stored in liquid nitrogen. According the protocol of AccuPrep® Genomic DNA extraction Kit (Bioneer Corporation Cat. No.: K-3032 Korea), genomic DNA was extracted.

Agarose gel (1%) electrophoresis used to assess and identify the quality of the extracted DNA.

PCR amplification

In *Capoeta trutta* to amplify mtDNA COI locus by Darabi (2014) viz., the following primer was used COI-625F: 5'-TCAACCAACCACAAAGACATTGGCAC-3' and COI-625 R: 5'-GACTTCTGGGTGGCCAAA-GAATCA-3' have been used in this study. Amplifications of DNA were performed using a thermal cycler (MultiGene OptiMax Thermal Cycler TC9610 /TC9610-230, Applied Bio systems, USA) with the

DOI: http://dx.doi.org/10.15666/aeer/1704_74397451

final reaction volume of 25 µl. Each reaction contained prime *taq* premix (2X) Genet Bio PCR master mix (*Taq* DNA Polymerase 1 unit/10 µl, 20 mM Tris-HCl, 80 mM KCl, 4 mM MgCl2, enzyme stabilizer, sediment, loading dye, pH 9.0, 0.5 mM of each dATP, dCTP, dGTP, dTTP), primers (10 pmoles/µl), DNA template (40 ng) and water free DNase. Initial denaturation was carried out for 3 min at 95 °C, followed by 35 cycles of denaturation at 95 °C for 30 s; annealing at 62 °C for 30 s and extension at 72 °C for 45 s followed by a final extension at 72 °C for 10 min (Parmaksiz and Eksi, 2017).

Table 1. *Morphological characters and meristic abbreviations and description*

Abbreviations	Description
TL	Total length
SL	Standard length
HL	Head length
BD	Body depth
ED	Eye diameter
SnL	Snout length
Pre-O	Pre orbital distance
PrD	Pre dorsal fin distance
LD	Length of the dorsal-fin ray
Pre-Pectoral	Pre pectoral fin distance
Pre-Pelv	Pre pelvic fin distance
Pre-ans	Pre – anal distance
LA	Length of the anal-fin ray
ALL	Above lateral line scales
BLL	Below lateral line scales
PrD1	First pre dorsal fin distance
PrD2	Second pre dorsal fin distance

Primers have been used to amplify 61 cytochrome b (cytb) gene, partial cds; mitochondrial, primers designed from cytochrome b (cytb) gene GenBank: (JQ060190.1), F: CTGCATTCGTAGGCTATGTC and R: GTGCTAGAACCCCTCCTAGC for *Planiliza abu* fish. PCR was performed with a profile of initial denaturation at 95 °C for 5 min, followed by 40 cycles of denaturation at 95 °C for 30 s, annealing at 61 °C for 30 s, extension at 72 °C for 30 s and final extension at 72 °C for10 min.

Agarose gel electrophoresis separation

A volume of 10 µl PCR product on 2% agarose gel was electrophoresed. Ethidium bromide was used to stain bands, which were visualized on a gel documentation (ENDURO™ GDS Touch Gel Documentation System) by using 100 bp DNA ladder (gene direx). The ladder was supplied in a ready for using format having fluorescent tracking dyes and DNA stain. The expected size of the PCR amplicon was 625 bp for *Capoeta trutta* and 521 bp for *Planiliza abu*.

DOI: http://dx.doi.org/10.15666/aeer/1704_74397451

DNA sequencing

A mitochondrial DNA cytochrome c oxidase subunit I (mtDNA *COI*) locus and cytochrome b (cytb) gene were amplified by PCR. In the present study, Genetic analyzer 3500, Applied Bio systems (USA) was used to find the nucleotides order of mtDNA *COI* and cytb for *C. trutta* and *P. abu* fish samples, respectively. The PCR product of the fish samples were used for sequence specific PCR amplification and sent to the Macrogen Company in South Korea for nucleotide sequence analyses.

Results

A total of 150 *Capoeta trutta* specimens were collected from Dukan Lake in north western Sulaimani governorate and 120 specimens of the *Planiliza abu* were collected from Sirwan River in south eastern Sulaimani governorate.

Morphology

The morphological characters and meristic of *Capoeta trutta* and *Planiliza abu* are indicated in *Table 2*. *Figures 2* and *3* show the general morphology of *Capoeta trutta* and *Planiliza abu*, respectively.

Discussion

Traditionally, in the freshwaters of Iraq, four species (*Capoeta aculeata*, *Capoeta barroisi*, *Capoeta damascina* and *Capoeta trutta*) represent the genus *Capoeta* and four species (*Liza abu*, *Liza klunzingeri*, *Liza oligolepis* and *Liza subviridis*) represent the genus *Liza* (Coad, 2010).

The presences of two species of fish in this study are showed belonging to the family of Cyprinidae and Mugilidae. The description and measurement of present samples of two fish species in this study are similar to those received from Beckman (1962) and Coad (2010).

As a comparison between some characteristics of *Capoeta trutta* in this study such as standard length, total length, body depth, head length, eye diameter, length of the dorsal-fin ray, snout length, length of the anal-fin ray, above lateral line scales and below lateral line scales are 25, 21.25, 4.5, 5.75, 1, 1.2, 4.35, 4, (14-17) and (11-14), respectively are in agreement with the results of Agha (2017), which are 28.18, 23.74, 4.86, 5.7, 0.76, 1.5, 4.98, 3.6, (15-16) and (10-11).

Standard length, total length, body depth, head length, eye diameter, length of the dorsal-fin ray, snout length, length of the anal-fin ray, above lateral line scales and below lateral line scales of *Planiliza abu* in this study are 17.5, 15, 3.25, 4.75, 0.85, 1, 7 and 6, respectively are in agreement with the results of Agha (2017), which are 18.38, 16, 3.53, 4.45, 0.75, 1, 7, 6.

The morphological results of *Planiliza abu* in this study are similar to the results of Khayyami et al. (2014) on morphological variability of *Liza abu* and Mohamed et al. (2016) on comparative taxonomical for (*Planiliza subviridis*, *P. klunzingeri*, *P. carinata* and *Osteomugil speigleri*). Standard length of *Planiliza abu* in this study is in agreement with the results of Mohamed et al. (2018)**.**

In Iraq, there has not been any molecular research on *Capoeta trutta* and *Planiliza abu*, but Cyprinidae and Mugilidae families have been examined. The results of *Capoeta trutta* in family Cyprinidae in this study are in agreement with the results of Faddagh et al. (2012a) who identified eight cyprinid fish species, and discovered high similarity between *Barbus* species, from 84.4% between *B. Kersin* and *B. xanthopterus* to 52% between *B. sharpeyi* and *B. barbulus* to 86.9% between *A. vorax* and *B. grypus.* Faddagh et al. (2012b) also used the mitochondrial 16S rRNA gene fragment as a molecular marker to study taxonomical status of seven cyprinin fish species in Iraqi inland waters: *Barbus kersin*, *B. xanthopterus*, *B. barbulus*, *B. sharpeyi*, *B. grypus*, *Cyprinus carpio* and *C. luteus,* the results assured that the six *Barbus* species genetically belong to sub-family Cyprininae which belong to family Cyprinidae. Aziz (2015) examined nine species of Cyprinidae family, the result of DNA sequencing showed that all species belong to family Cyprinidae the phylogenetic relationship degree with this family for *C. luteus* was a BP of 87%, for *C. regium*, *C. carpio* and *C. Carassius* was a BP of 75%, for *C. macrostomum*, *L. esocinus*, *C. trutta* and *L. xanthopterus*a was a BP of 90% and for *Barbus grypus* was a BP of 76%.

In this study the results are in agreement with Parmaksiz and Eksi (2017) who used mtDNA *COI* 625 locus to study the genetic diversity of populations from 47 samples of *Capoeta trutta.* The result of sequence analysis showed six polymorphic sites and seven haplotypes on that locus, which is also in agreement with Turan (2008) determination of subspecies of *Capoeta* corresponding to taxonomic entities and defined species using traditional gene sequencing of mitochondrial 16S rDNA. The database included 124 variable sites, parsimony informative was 103 sites. The results in this study are similar

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74397451

to the results of Zareian et al. (2016) who used mitochondrial cytochrome *b* gene sequences for phylogenetic relationship of *Capoeta* species, and it was found that three major groups were detected: Clade I: *Capoeta trutta* group which is the Mesopotamian *Capoeta* group having very close related taxa (*barroisi*, *trutta and turani)*. Clade II: *Capoeta damascina* complex group (*capoeta* group small scale) including the Anatolian-Iranian groups such us (*buhsei*, *saadii*, *banarescui* and *damascina*) and widespread highly diversified groups. Clade III comprises closely related taxa; *Capoeta capoeta* complex group (the Aralo-Caspian group, large scale *capoeta* group).

The results in this study are in agreement with Nematzadeh et al. (2013) using PCR-sequencing method to establish phylogenetic relationships among six mugilidae species (*M. capito*, *Valamugil buchanani*, *Mugil cephalus*, *Liza subviridis*, *L. saliens* and *L. aurata)* and genetic differences were determined. The results demonstrate that in the mitochondrial 16s rRNA genome number of bases was approximated 600 base pairs. Also (Lai et al., 2011) (80) random primers for random amplified polymorphic DNA (RAPD) were used for the examination of 15 fish families. Results clarify that in the Mugilidae family a novel specific PCR product was found, OPAV04 primer was employed also in the *Liza* genus, by using OPAV10 primer other novel specific PCR product was found.

The results of the present study are not in agreement with Faddagh et al. (2012b the *Liza abu* and *Liza klunzingeri* did not respond to the modified primer in mitochondrial 16S rRNA gene but in this study *Planiliza abu* responded to the cytochrome b (cytb) gene, partial cds; mitochondrial.

This taxonomic position has changed and most researchers in the field now agree that DNA coding is a useful tool in the process of identifying and indexing species. There are still researchers who doubt that one can distinguish the gene of all species and refers to the fact that taxonomists who evaluate their findings on morphological basis have a range of many different characters, not one, to help them identify, for this the present study used a molecular tool for identification. Molecular techniques such as PCR and DNA sequencing were proven to be very specific and highly sensitive to detect species of fish. However, using them in diagnostic laboratories are very rare.. Moreover, DNA amplification is not cheap and it is tedious, also samples can face cross contamination which is dangerous, fortunately nowadays by developed methods these issues are decreased (Agha, 2017).

In the present study, 617 and 446 bp were aligned for *Capoeta trutta* and *Planiliza abu* respectively; the two specimens were morphologically identified by using Coad keys. The sequences compared with sequences of other genera and fish species stored in Gen Bank. The results showed that the morphometric data and molecular methods were successful in identifying of *C. trutta* and *P. abu*.

Samples of *Capoeta trutta* and *Planiliza abu* have been morphologically identified. DNA sequencing results showed that the studied two fish species belong to *Capoeta trutta* and *Planiliza abu.* Gen Bank analysis indicated that the two sequenced species were correctly identified.

Conclusions

In the view of the results of the present study, *Capoeta trutta* and *Planiliza abu* were morphologically identified. The results of DNA sequencing revealed and confirmed the

DOI: http://dx.doi.org/10.15666/aeer/1704_74397451

validity of the two fish species and indicated that the two sequenced species were correctly identified by using *COI* and cytochrom b gene.

(Received 4th Mar 2019; accepted 1st May 2019)

Abstract. This study was carried out to determine the most appropriate trap design for monitoring *Tropinota hirta* (Poda, 1761) (Coleoptera: Cetoniidae) among the commonly used traps in the world during the 2018. For this purpose, cherry gardens with three different loc. Atabey district, İslamköy and Pembeli villages of Isparta province were selected and the adult catch rates of the known binary attractant mixture (cinnamyl alcohol (3-phenyl-2-propen-1-ol) and transanethole [(1-methoxy-4-(1-propenyl) benzene)]) and white, light and dark blue color traps were compared with each other during the blooming period. As a result of the present study, the amount of adult catch of light blue color traps in the cherry blooming period was found to be significantly higher than the attractant and dark blue color traps which are regularly used in the world hence the use of this mentioned trap was found as the most effective biotechnical method for the controlling of *T. hirta* among the frequently used traps.
Keywords: *apple blossom beetle, attractant traps, cherry, color traps, Isparta*

Introduction

Apple blossom beetle has been expressed in the INPN which is the reference information system for data related to Nature (INPN) (https://inpn.mnhn.fr/accueil/a-propos-inpn) as *Tropinota hirta* (Poda, 1761) (Coleoptera: Cetoniidae) however the species every so often expressed as *Epicometris (Tropinota) hirta* (Poda, 1761) (57 scientific articles), *Tropinota* (*Epicometris*) *hirta* (33 scientific articles), *E. hirta* (11) and or *T. hirta* (12) and sometimes even expressed as under the family of Scarabaeidae instead of Cetoniidae.

Adults of *T. hirta* is polifagous and causing serious damage through feeding on pistils and stamens of the flowers of numerous plants such as apple, barley, blackberry, blackcurrant, broomrape, canola, cherry, lupine, narcissus, pear quince, plum, raspberry, rye, tulip, wheat, and other plants of agricultural importance even ornamental plants (Milenkovic and Stanisavljevic, 2003; Çetin et al., 2006; Ertop and Özpınar, 2011; Perez and Traveset, 2011). *T. hirta* may damage 70% of the blossoms on some plants of agricultural importance (Kutinkova and Andreev, 2004; Ražov et al., 2009). Control of *T. hirta* is difficult since most of the pesticide cannot applied during blooming period without affecting beneficial organisms that provide pollination, specially honey bees (Vuts et al., 2011a, b). Besides, long-acting pesticides also have an adverse effect on exports. Therefore, the application of biotechnical methods to control of the mentioned

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74537462

pest will be extremely beneficial both in terms of environment and human-animal health. Recent studies show that the most recommended biotechnical methods are color traps and color with attractant against *T. hirta* which is widespread in parts of Eurasia, from the Mediterranean to the Middle East and Central Asia. Baits have been used as biotechnical method to control and monitoring of *T. hirta* and it has been mostly prepared with *cinnamyl alcohol* (3-*phenyl*-2-*propen*-1-*ol*) and *transanethole* [(1-*methoxy*-4-(1-*propenyl*) *benzene*)] which compounds are common flower scent constituents by a 1:1 mixture (Knudsen et al., 1993).

Lot of valuable research have been conducted on controlling of *T. hirta* however it has been found that the results of scientific studies on the best biotechnical methods to be used for *T. hirta* have not corresponded with each other. Therefore the present study was conducted in order to find out the most suitable biotechnical methods for *T. hirta*.

Materials and methods

The study was carried out in cherry blooming period between April 30 and May 14 to compare efficiency of attractant (cinnamyl alcohol and transanethole) and color traps (dark blue, light blue and white) for sampling adults of apple blossom beetle adults during 2018.

Localities

Three different locations; (Atabey district (a: loc.1), (37°56'48.58"N/30°39'5.16"E) Pembeli (p: loc.2) (37°56'20.07"N/30°41'12.60"E) and İslamköy (i: loc.3) (37°54'51.77"N/30°39'14.76"E) villages in Isparta province, Turkey) were selected for the study. While color traps were placed in each locations with 10 pieces (3 colors × 10 pieces × 4 locations = 120 units), attractant traps were set up in Atabey district with 10 pieces.

Traps

Ten attractive traps (A) were placed on the cherry branches which are approximately 2 m high from the ground for the purpose of sampling of the adults of *T. hirta* in the cherry orchard in Atabey district, Isparta province, Turkey. Three different colors (hex code are inside brackets), light blue (LB) (#87CEFA), dark blue (DB) (#1E90FF), and white (W) (#FFFAF0), and 10 pieces for each one, were set up for three cherry orchards in Atabey, Pembeli and İslamköy (Isparta province). The ratios of *T. hirta* adults sampled from attractants and color traps were compared during the blooming period.

Baits were prepared with *cinnamyl alcohol* (3-*phenyl*-2-*propen*-1-*ol*) and *transanethole* [(1-*methoxy*-4-(1-*propenyl*) *benzene*)] by a 1:1 mixture according to the suggestions of Tóth et al. (2004) and Schmera et al. (2004) suggestions to catch *T. hirta*. A total of 10 units of cottons prepared in equal length were impregnated with attractive (1:1 mixture-20 µl) and placed inside the perforated (20 pieces with a diameter of 0.3 mm) falcon tubes (50 ml). Falcon tubes (3 × 13 cm length) with lures fixed with upside part of the light blue funnels (22 cm diameters and 25 cm length). Five liters (approx. 1.32 gallon) of plastic water containers which placed at the bottom of the funnels were used as traps to collect adults of apple blossom beetles. Totally 10 attractant traps prepared as mentioned above were hung tree branches nearly 2 meters

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74537462

above from the ground where the traps were a location representing the cherry garden. These attractive traps were placed only in Atabey district.

Color traps were designed as 25 cm in diameter and 10 cm in depth plastic basins. The order of colored traps were changed incidentally and set up 10 pieces for each locations. The distance between color traps were about one meter within a block and each block were set up 50 m distant from the next. 1/3 water was filled into the color traps to prevent adult of *T. hirta* from escaping. Blocks containing 3 traps with the above colors, were replicated 10 times, in the cherry orchard at each of the 3 locations. Each block the colors were distributed randomly hence the total number of traps was 90. Traps were set up on the soil surface in sunny places within the cherry orchards.

Both attractant and color traps were checked daily and the captured adults were counted and recorded.

Data analysis

All data from both adult numbers for each traps and groups of traps were analysed using ANOVA (one-way analysis of variance) and separated by Tukey's HSD (honestly significant difference) test at $P < 0.05$ to examine the differences between capture capability of attractant and color traps in SPSS.

Cluster analysis was performed using percent similarity and dendrogram based on the data was constructed with the help of MVSP software using the unweighted pair group method of arithmetic mean (UPGMA).

Results

It was found out that the number of individuals caught with color traps was found higher than individuals caught with attractant traps and differences was found out statistically significant. It was also compared the effects of the color traps with each other during the sampling adults of *T. hirta*. Light blue color traps were sampled more adults than the dark blue color traps.

Totally 776 individuals of *T. hirta* adults were sampled by attractant and color traps during the present study. The most of the proportion of *T. hirta* adults were caught by LB traps at Atabey, Pembeli, and Islamköy with 152, 136, and 126 individuals respectively. This means; nearly half of the specimens were sampled with LB traps at three loc. (Average: 138; individuals; proportion: 43.58%). The lowest of individuals were sampled by W traps at loc.1, loc.2, and loc.3 8, 12, and 11 respectively (Average: 10.33 individuals; proportion: 3.26%). Average of sampled adults of *T. hirta* were found similar with attractant and DB traps, with 87.0 and 81.3, respectively (Proportion: 27.47% and 25.68% respectively).

Capture rates of *T. hirta* adults with W set up at loc.1; loc.2, and loc.3 were found statistically different from the captures of other traps (*Table 1*).

It was determined that the least attractive trap for the adults of apple blossom beetle was W while the most attractive one was LB. Although no statistical differences were found between LBi with A, the adult capture averages of LBa and LBp were found statistically different from all other traps (*Table 1*). A was found not statistically significant with all DB traps at loc.1, loc.2, and loc.3 (*Table 1*).

Traps with the same color were grouped in terms of ease of understanding capture rates differences between color and attractant traps. Result of the capture means of all traps were given in *Table 2*.

Table 1. *Comparison of capture rates of T. hirta adults sampled by attractant and color traps at loc.1., loc. 2, and loc. 3 in Isparta province*

Traps*	N	Mean ± Std. error	Std. deviation
Aa	10	8.7 ± 0.84 bc**	2.6687
LBa	10	15.2 ± 1.85 d	5.8652
DBa	10	8.6 ± 0.65 bc	2.0656
Wa	10	0.8 ± 0.25 a	0.7888
LBp	10	13.6 ± 1.34 d	4.2216
DBp	10	8.8 ± 0.74 bc	2.3476
Wp	10	1.2 ± 0.42 a	1.3166
LBi	10	12.6 ± 0.73 cd	2.3190
DBi	10	7.0 ± 0.67 b	2.1082
Wi	10	1.1 ± 0.31 a	0.9944

*A: Attractant; LB: Light Blue; DB: Dark Blue; W: White; a: loc. 1 (Atabey); p: loc. 2 (Pembeli); i: loc. 3 (Islamköy)
**According to a Tukey HSD test; means with the same letter in their superscript are not significantly different ($P < 0.05$)

Table 2. *Comparison of capture rates of T. hirta adults sampled by attractant and grouped color traps (values obtained from the same color were combined)*

Traps*	N	Mean ± Std. error	Std. deviation
Aa	10	8.7 ± 0.84 b	2.669
LB	30	13.8 ± 0.80 c	4.366
DB	30	8.13 ± 0.41 b	2.255
W	30	1.03 ± 0.19 a	1.033

*A: Attractant; LB: Light Blue; DB: Dark Blue; W: White; a: loc. 1 (Atabey); p: loc. 2 (Pembeli); i: loc. 3 (İslamköy)
**According to a Tukey HSD test; means with the same letter in their superscript are not significantly different ($P < 0.05$)

ANOVA test of data showed that no difference was found between the capture rates of A and DB traps ($P = 0.949$) however capture rates differences between them and the other traps (DB and W) were considered statistically significant (*Table 2*). The differences of catch proportions between DB-W and DB-LB traps were also found statistically significant ($P \leq 0.000$) (*Table 2*).

The dendrogram composed from the insect numbers sampled in all the set traps distinctly showed that all the same colors come together as a group while attractant trap was included with the DB color group (*Fig. 1*). Besides similarity values of A and DBa was found 90.17% as the most similar traps. It was seen that three main groups, W, LB, and DB with A were formed on the dendrogram. The similarity values of Wa and Wi traps captured by the least number of adults were seen as 63.15% (*Fig. 1*). Similarity values of Wp and the group formed by Wa and Wi was found 36.74% as the most dissimilar. The group formed by W traps at three localities showed 13.7% similarity with the group designed by all other traps, LB, DB, and A.

The following dendrogram is better at explaining dissimilarities and also shows statistically significant grades between groups. It was seen that A and DB traps were

DOI: http://dx.doi.org/10.15666/aeer/1704_74537462

similar to each other by 84% while LB trap was found similar with this mentioned group by 74.9% (*Fig. 2*). W was equivalent to only with 19.2% of all other groups.

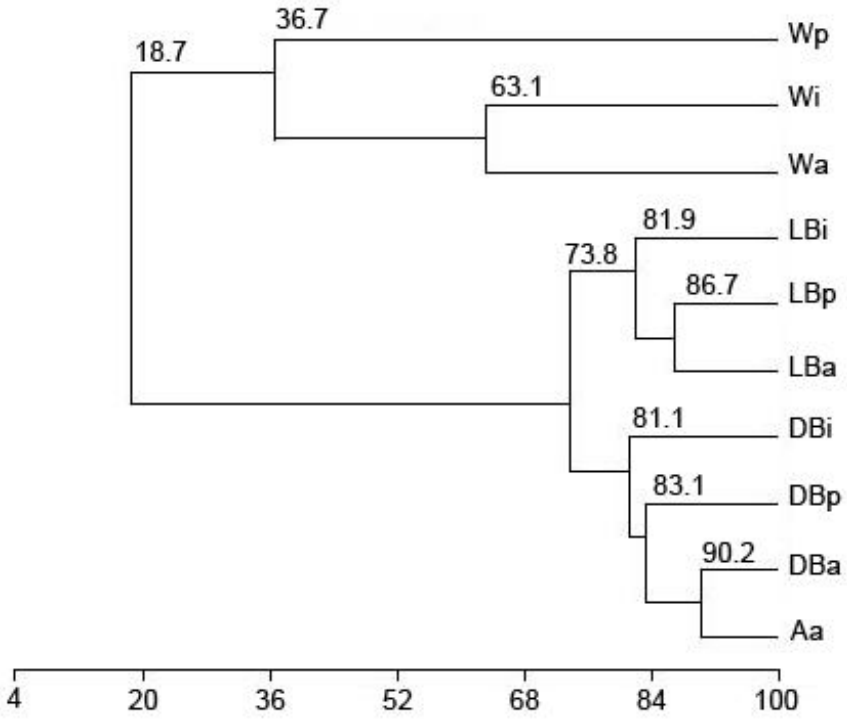

Figure 1. *Dendrogram of sampled T. hirta adults from the 9 colors and one attractant traps (A: Attractant; LB: Light Blue; DB: Dark Blue; W: White) in study locations (a: Atabey (loc. 1); p: Pembeli (loc. 2); i: İslamköy (loc. 3)). The cluster analysis was performed using Percent similarity*

Discussion

Many colors, yellow, fluorescent yellow, white, brown, transparent, chartreuse, coral, dodger blue, golden rod, hot pink, light sea green, light sky blue, medium orchid, etc have been evaluated to find out the most attractant colors for *T. hirta* in numerous scientific studies (Schmera et al., 2004; Kozár, 1972; Tóth et al., 2005, 2009; Aydın, 2011; Subchev et al., 2011; Vuts et al., 2012; Trotus et al., 2015). Some researchers declared that adults of *T. hirta* were strongly attracted to objects of light blue color (Kozár, 1972; Aydın, 2011) while some of them affirmed that the blue color has been the most attractive color for *T. hirta* (Tóth et al., 2005). Likewise some of the scientific study results showed that *T. hirta* had been attracted to yellow, light blue or white color in a field test, but they found no significant differences between colors (Schmera et al., 2004). On the contrary of the mentioned results, Aydin (2011) declared that the susceptibility of *T. hirta* to white and light blue colors was found statistically significant. We have tried three different colors of traps; white, light blue and dark blue during the blooming period of cherry orchard. Result of our study has showed that light blue color trap is the best attractant compared the other used traps for adults of apple blossom beetle and can be used for controlling of *T. hirta*

For the last decades researchers have tried different colors with different lures (Tóth et al., 2004, 2009, 1998, 2003; Schmera et al., 2004; Vuts et al., 2012; Trotus et al., 2015; Subchev et al., 2012) experiments were also carried out in different places at the same time (Vuts et al., 2010a). Cinnamyl alcohol, transanethol and cinnamyl acetate were found as compounds attracting *T. hirta* by Tóth et al. (2003). Thereupon Schmera et al. (2004) declared that combination of light blue color and a bait of 1:1 mixture of *cinnamyl alcohol* and *transanethol* used in dry funnel traps were very effective tool for catching of *T. hirta.* As for chemical attractive stimuli for *T. hirta*, a binary floral attractant consisting of (E)-cinnamyl alcohol and (E)-anethol has been optimised (Tóth et al., 2004, 2009, 1998, 2003). Finally a new coattractant, 4-methoxyphenethyl alcohol, developed for increasing the attractiveness of known binary attractant mixture, cinnamyl alcohol/trans-anethol (Vuts et al., 2010b). Vuts et al. (2010b) found that traps baited with the mixtures of known binary attractant with 4-methoxyphenethyl in 1:1:1 or 1:1:0.3 ratios sampled significantly more *T. hirta* than known binary attractant alone. However, Güvenç and Yaşar (2014) declared that there were no statistical differences between known binary attractant mixtures and known binary attractant with 4-methoxyphenethyl for catching of *T. hirta.* We have tried known binary attractant in our study. When we compare the effective of colors with mentioned attractant, almost similar number of individuals of *T. hirta* were caught with both attractant and dark blue color (87 individuals with attractant; 86, 88, and 70 with dark blue color in loc.1, loc.2, and loc.3, respectively) while the light blue color has been found the most effective tool for catching of adults of *T. hirta* (152, 136 and 126 individuals in loc.1, loc.2, and loc.3, respectively).

Some of the traps were used in the study of Yasar and Sagdas (2014) at apple orchards. Authors declared that the highest number of adults were obtained through the blue funnel trap in loc.1 however the most of the adults were caught by blue funnel + attractant traps when they compare with all four locations of the study. The results of our study coincide with study of Yasar and Sagdas (2014) however light blue traps were not include the mentioned previous study to compare efficiency of traps. Attractant and dark blue traps have been used detection and monitoring of apple

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74537462

blossom beetle on the other hand using light blue trap is highly recommended to control of *T. hirta* in cherry orchards according to our study results.

The study of Yasar and Uysal (2013) was conducted to evaluate the most effective traps for capturing *T. hirta* on plum and pear orchards. The most of the adults were sampled by blue funnel plus water traps with attractant (containing cinnamyl alcohol, trans-anethol, dipropylene glycol and 2 - propanol, 1, 1 - oxybis). They declared that use of an attractant with a blue funnel trap is an effective biotechnical method for controlling *T. hirta* when insecticides cannot be applied during the blooming period. Our study results showed that the attractant and dark blue color have not been found statistically different for catching adults of *T. hirta*. However the light blue traps caught the most individuals while the white color caught the least individuals when they compare to each other.

Gezer and Ozpinar (2015) were tested the different traps to determine the adult density of apple blossom beetle, in different orchards; peach, cherry, apricot and apple in Canakkale. They declared that the highest number of adults had been captured by the blue bowl plus water traps with attractant in all orchards. However there were no statistical differences between blue color bowl traps and blue color bowl traps with attractant containing trans-anethole + cinamyl alcohol, (1:1). It is an interesting result of the mentioned study that just blue bowl plus water trap was found the most effective than the all other traps with attractant. The authors explained this situation as the wind effect (Gezer and Ozpinar, 2015). Although we have got similar result with the mentioned study showed that blue color trap was the most effective traps, we believe that color is very effective tool for adult of *T. hirta* instead of wind condition instead of attractant.

The several scientific studies have been carried out on the subject and mentioned attractant mixtures have been used for controlling and/or seasonal monitoring of T. *hirta* in most of Central and Eastern Europe (Bulgaria, Hungary, Croatia and Italy) (Vuts et al., 2010a; Tóth et al., 2005, 2009; Subchev et al., 2011; Mircheva et al., 2004; Sivcev et al., 2006). We agree with these results that blue funnel with attractant trap can be suggested as an effective biotechnical method for controlling *T. hirta* however we believe that it is possible to control *T. hirta* without applying insecticide and population density of the mentioned species can be kept below the "economic damage threshold" by using the correct traps at the right time.

Some studies show that white color is the most attractive trap in terms of individual catching of *T. hirta* adults compared with light and dark blue color traps (Aydın, 2011). But some authors do not agree with this result and they declared that light or dark blue color has been found more attractive for the species than white color trap. On the other hand, the results of the studies carried out under different geographical conditions that do not coincide with each other as in the case of the study carried out in Central and Eastern Europe. The result of the study has been showed that CA-baited trap caught the most individual in Bulgaria, Hungary, and Croatia however scientists could not found the same result in Italy.

In fact, many studies have shown that the apple blossom beetle responds to different colors at different times. Scarcely, no studies reveal this result openly or expressed. It can be revealed that the color sensitivity of the beetle is in fact related to the plant phenology when all the results of the works are taken together instead of evaluating all the works separately.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74537462

Result of our study showed that there is no statistically significant difference between the attractant and dark blue color whereas highest number of individuals caught with light blue color trap has been found statistically significant compared the other used traps. However, we are not sure that the same result can be obtained in studies to be done pre and post bloom period because we think that the color preference of the *T. hirta* changed depending on blooming periods. If behaviour pattern of apple blossom beetle is linked to plant phenology the color of traps should be changed considering the bloom period. Aydin (2011) has found same result with our study during blooming period of cherry however he has suggested using white color traps instead of traps with dark and light blue colors to catch more individuals of adult of *T. hirta* during pre and post blooming periods.

Results of many scientific studies and present study results showed that known binary attractant or known binary attractant with 4-methoxyphenethyl used with the light blue or dark blue colors cannot catch the similar number of individuals as the light blue traps which are set up at the ground surface. We think that the traps placed in the ground level can be more easily and earlier recognized than attractants hanged on branches of trees by *T. hirta*. Moreover it should be investigated that the rate of pest's flower damage on branches with an attractant hanging might be higher than the branches with not attractant hanging (Aydin and Yaşar, 2019). If pest is attracted to the trees with attractants damage rate can be increased. It may be more appropriate to set up the traps at a distance from the trees where adults of *T. hirta* can recognize easily rather than hang the traps on the branches.

Conclusion

There have been many scientific studies to understand which color or the attractant or even color and attractant use in conjunction is the best attraction method for sampling of *T. hirta*. When the studies conducted so far have been evaluated, we see that different sampling tools are suggested. Despite these confusing conclusions we wonder whether or not it is possible that the *T. hirta* color sensitivity changes at different times.

The second contradiction is that the necessity of using the attractors with color has not been explained in scientific studies. If the species is attracted to known binary attractant mixtures (or even known binary attractant with 4-methoxyphenethyl) why is the attractant has been recommended usage with color? It is understood from the related studies that only attractors do not affect the adults of apple blossom beetle. If the attractant used alone does not affect the insect and it is necessary to use it with color, so it can be said that the color is important. Some studies have emphasized that the use of color with known binary attractant and the use of only color (shades of blue) have not been found that has a statistically significant difference between their roles in attracting the insect. Our study results show that there is no difference between the number of individuals caught with the attractant and dark blue color trap. However, it is revealed that the number of individuals caught with light blue color is considerably higher than the others while the number of individuals caught with white color is very low. Both results have been found statistically significant.

The results of our study and the other related studies so far have been examined can be summarized as follows:

1. Plant phenology related shifts in color preferences of *T. hirta* adults.

1.1. Light blue color traps can be used during blooming periods of cherry orchards

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74537462

1.2. White color traps can be used during the pre and post blooming periods. The white color traps set up during pre-bloom can reduce the damage of *T. hirta* adults at present season while white color traps set up during post-bloom can reduce the population of the next year. Thus application order of this methods can be suggested both "as an effective biotechnical method for controlling *T. hirta*" and "population density of the pest can be kept below the "economic damage threshold".

1.3. Pesticide application against mentioned pest may not be needed with choosing right traps on time for monitoring of *T. hirta.* Thus non-target organisms such as honey bees, predator ladybirds, etc would not be negatively affected by applying insecticides.

2. Traps even including attractants should be installed in a visible place where the pest can easily recognize instead of hanging them on tree branches. Thus the rate of flower damage caused by the pest can be decreased and more numbers of adults can be caught

(Received 6th Mar 2019; accepted 3rd May 2019)

Abstract. Low-temperature thermo-alkaline pretreatment with alkyl polyglucosides (APGs) was employed for improving the utilization of low-organic-content sludge in anaerobic digestion (AD). An orthogonal experiment (L_9 (3^4)) was designed to estimate the influence of four factors on pretreatment, and the order determined by significance level was: pH > temperature > APG dosage > time. Under the conditions of pH 11, 60 °C, and 60 min, the content of organic matter dissolved from sludge increased as the APG dosage increased to 18 g/L. When fermenting at a dosage above its critical micelle concentration (CMC), however, APG inhibited aerogenesis due to the adverse impact on methanogen activity. Thus, the optimal APG dosage was fixed at 3.0 g/L. After 35 days of mesophilic AD, the biogas volume, the methane volume fraction, and the organics utilization rate reached their respective peaks. The methane volume fraction (45.8%) was lower than normal biogas (at least 53%), so further evaluation is needed.
Keywords: *surfactant, CMC, mesophilic, methanogenesis, orthogonal experiment*

Introduction

The large amount of sludge generated by wastewater treatment plants (WWTPs) has been a great challenge and has raised significant concerns in China (Yang et al., 2015). Disposal methods, including sanitary landfill, land application, and incineration, are the main final destinations of sludge after treatment (Murakami et al., 2009; Song and Lee, 2010; Hale et al., 2012). Processes such as thickening, conditioning, dewatering, stabilization, and drying are commonly employed as sludge treatment methods (Yang et al., 2015). Stabilization, a well-developed approach, is an important way to reduce the environmental risks of sewage sludge. In particular, anaerobic and aerobic digestion are the most common stabilization methods, and they are usually applied in cases of small WWTPs, although the majority of produced sludge is treated anaerobically (Kelessidis and Stasinakis, 2012).

Anaerobic digestion (AD) is a complex process which is generally considered to have a rate limited by the hydrolysis of sludge (Appels et al., 2008). Therefore, pretreatments facilitating sludge hydrolysis enhance the efficiency of AD. Generally speaking, pretreatment methods include biological, thermal, mechanical (ultrasonic treatment, lysis-centrifugation, liquid shear, and grinding), and chemical (oxidation and alkalization) (Carrere et al., 2010) treatments, among which thermal treatment has been paid much attention. Thermal pretreatment can be mainly classified into two categories

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74637476

based on the temperature applied, i.e., pretreatment higher than 100 °C (need a high-pressure installation) (Bougrier et al., 2008; Ennouri et al., 2016; Jae et al., 2018) and pretreatment lower than 100 °C (under atmospheric pressure) (Appels et al., 2010; Fernández-Marchante, 2018). However, treatment in a mild temperature is often combined with a chemical method (Mendez et al., 2013), most commonly with an alkali. Some researchers (Kim et al., 2015; Zhang et al., 2015; Li et al., 2016; Du et al., 2019) have concluded that a low-temperature thermo-alkali pretreatment significantly enhances the efficiency of AD.

From studies on sludge dewatering, it was found that surfactants were highly effective in releasing extracellular polymeric substances (EPSs) from sludge (Wang et al., 2014; Liu et al., 2019). EPSs consist of high-molecular-weight secretions from microorganisms, and products of cellular lysis and macromolecule hydrolysis. A higher EPS content in sludge results in greater sludge stability (Sheng et al., 2010), so the release of EPSs from cells can facilitate the dissolution of organics, thus making a positive contribution to the hydrolysis of sludge. In short, surfactants can be chosen for sludge pretreatment (Guan et al., 2017), but their environmental friendliness must be taken into consideration.

Alkyl polyglucoside (APG) is a nonionic surfactant synthesized from renewable raw materials, and it has excellent ecotoxicological profiles, so it is readily biodegradable (Geetha and Tyagi, 2012). Luo et al. (2015) reported that adding APG to an anaerobic treatment system of waste activated sludge (WAS) improved the production of short-chain fatty acids remarkably. However, so far, no one has tried to pretreat sludge with APG before AD.

WAS with comparatively low organic content has not been qualified for AD. This study, therefore, explored the effect of low-temperature thermo-alkaline pretreatment, optimized by APG dosing of low-organic-content sludge, on AD. An orthogonal experiment was firstly designed to estimate the effects of pH, temperature, APG dosage, and time on the pretreatment, and single factor experiments were also conducted to meet the shortcomings of the orthogonal experiment. More importantly, the role of APG dosage in AD was investigated by a series of fermentation experiments.

Materials and methods

Test materials

Waste activated sludge

The sludge used in this study was collected from Kaifu Wastewater Treatment Plant (Changsha, China) through a Modified Sequencing Batch Reactor (MSBR). It was dewatered by belt filter press in the plant, and it was then stored in a plastic hermetic bag at 4 °C in the laboratory. The moisture content of the sludge was 81.3 ± 0.05%.

Before each experiment, the dewatered sludge was diluted with deionized water into approximate 15 g/L (total solids), and the ratio of volatile solids (VS) to total solids (TS) was 51.32 ± 0.10%, which is comparatively low (VS/TS of WAS for AD in the literature was generally above 70%). The main characteristics of the sludge solution were total chemical oxygen demand (TCOD) = 6976.8 ± 77.5 mg/L, soluble chemical oxygen demand (SCOD) = 85.3 ± 7.7 mg/L, soluble total organic carbon (STOC) = 60.45 ± 5.38 mg/L, soluble total phosphorus (soluble TP) = 10.18 ± 0.20 mg/L, pH = 6.96 ± 0.01.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74637476

Inocula

For the anaerobic digestion tests, the sludge solution was anaerobically cultivated at 37 °C for 3 days in a constant-temperature incubator in order to activate the anaerobe, and to prepare for the inocula (it is feasible to use raw WAS as inocula, as shown in the literature; Nguyen et al., 2014). Its main characteristics were TCOD = 6821.8 ± 155.0 mg/L, SCOD = 100.8 ± 23.3 mg/L, STOC = 66.45 ± 3.62 mg/L, soluble TP = 14.30 ± 0.11 mg/L, pH = 6.91 ± 0.01.

Alkyl polyglucoside

The surfactant alkyl polyglucoside (APG0810), which was a faint yellow thick fluid (solid content≥50%), was purchased from Shanghai Fine Chemical CO., LTD and was used with no further purification. Thus, APG concentration in this paper refers to the concentration of the fluid. Its carbon content was 34.9 ± 0.3%.

Critical micelle concentration (CMC) is an important characteristic of a surfactant, and it is defined as the concentration of surfactants above which micelles form, and all additional surfactants added to the system form micelles (IUPAC, 1997). Before reaching the CMC, the surface tension changes strongly with the concentration of the surfactant. After reaching the CMC, the surface tension remains relatively constant, or it changes at a slower rate.

The surface tensions of the surfactant aqueous solution and sludge solution were measured and are shown in *Figure 1*. The CMC of the APG aqueous solution was about 1.5 g/L, which corresponds with the data provided by the manufacturer, while the CMC of the APG sludge solution was approximately 3.0 g/L. *Figure 1* also indicates that NaOH treatment nearly had no effect on the surface tension of the sludge solution.

Methods

Low-temperature thermo-alkaline pretreatment with APG

The pretreatment tests were conducted in 150 mL conical flasks with covers (to avoid water loss by evaporation) fed with 100 mL of sludge solution. Different volumes of 1 mol/L NaOH and 100 g/L APG solution were added to adjust the pH and APG concentration, respectively. The volume of NaOH added for reaching a set pH was determined by a preliminary experiment, whose results are shown in *Table 1*.

Table 1. *The relationship between pH and volumes of NaOH*

Volume of NaOH (mL/100 mL)	0.0	0.6	1.4	2.0
pH	7	10	11	12

All flasks were maintained in a digital thermostat water bath oscillator, and the solution temperatures were detected by a thermometer. The timer was started as soon as the temperature reached the desired value. Each test was repeated twice.

After completion, samples were centrifuged at 8000 rpm (3785×*g*) for 15 min, the supernatant was filtered by a 0.45 μm microporous membrane, and the soluble total organic carbon and soluble total phosphorus were analyzed. In the present study, mixed-STOC = the data from the experimental analysis which included organic carbon both from sludge and APG, and STOC = mixed-STOC –APG × 349 (1 g APG = 349 mg TOC, which can be deduced from section 2.1.3), which included the TOC dissolved just from sludge.

DOI: http://dx.doi.org/10.15666/aeer/1704_74637476

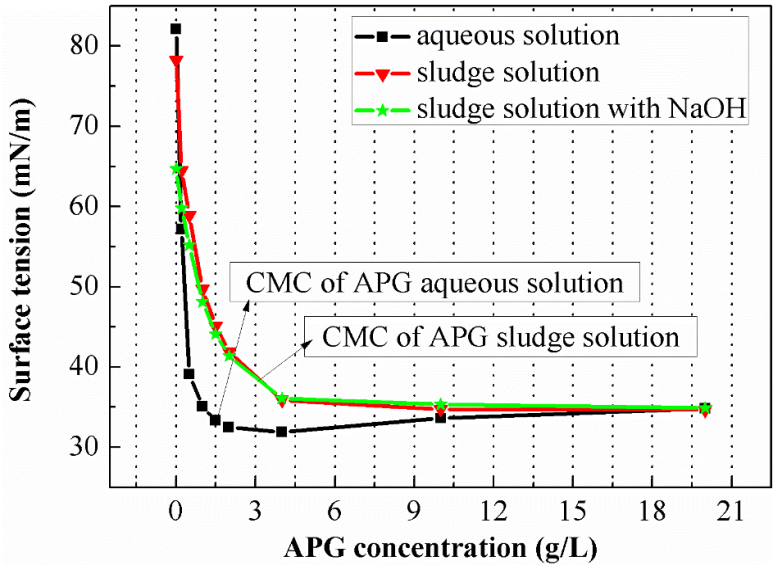

Figure 1. *Surface tension of different APG concentrations*

STOC represents the effect of the pretreatment. Soluble TP indicates the disintegration of the microbial cells due to those in the WWTPs, polyphosphate accumulation organisms (PAOs) are able to store phosphate as intracellular polyphosphate, leading to P removal via PAO cells in WAS (Oehmen et al., 2007). As a result, soluble TP comes almost entirely from the cellular interior, having dissolved when cells were destroyed.

Orthogonal experiment design

For the pretreatment tests, sludge was mainly affected by temperature, time, pH, and APG concentration. It was assumed that the four factors had significant influences on pretreatment. The results described herein are from an orthogonal experiment, which was designed for evaluating such experimental factors. Each factor includes three levels, as follows. Temperature: 40, 60, and 80 °C; time: 30, 60, and 90 min; pH: 7, 10, and 12 (neutral, alkaline, and strongly alkaline); and APG: 1.5, 3, and 4.5 g/L (below CMC, CMC, and above CMC). Since there were four experimental factors and three levels for each factor, the orthogonal matrix denoted as $L_9(3^4)$ was chosen as the experimental scheme to arrange the tests. Each test was repeated two times, and SPSS software was used for the experiment design and statistical analysis.

Anaerobic digestion tests

The experiments were conducted using conical flasks in duplicate with a working volume of 500 mL. The bottles contained a magnet rotor (for stirring automatically once a day) and were filled with 200 mL inocula and 300 mL pretreated sludge. All pretreatments were under the conditions of pH = 11, temperature = 60 °C, time = 60 min, APG = 0, 1.5, 3.0, and 5.0 g/L (preliminary experiments had proved that when pretreating at APG > 5 g/L, there is no gas produced in the AD system). The bottles of APG were named T0, T1.5, T3.0, and T5.0, respectively. For comparison, a blank test was run in a flask filled with 200 mL inocula and 300 mL raw sludge solution.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74637476

All flasks were incubated at 35 °C in an electrically heated thermostatic water bath for 35 days until gas was no longer produced. The gas was collected by aluminum foil gas-collecting bags, and gas volume was measured using a syringe. Moreover, the biogas composition was analyzed using gas chromatography (GC). Each test was repeated twice.

Analysis methods

The analyses of sludge moisture content, TS, VS, COD, TP, and pH were conducted according to standard methods (APHA, 2005). The surface tension was determined by pulling escape using a JZ-200A automatic interface tensiometer. By using a Shimadzu TOC-Vcph/cpn instrument, TOC was detected by catalytic oxidation nondispersive infrared analysis. The methane was analyzed by a gas chromatograph (Agilent, 6890N) equipped with a flame ionization detector (FID) and a 30 m × 0.32 mm capillary column (HP-5). The temperature of the injector, detector, and column were kept at 100 °C, 180 °C, and 80 °C, respectively. Helium was used as the carrier gas at a flow rate of 30 mL/min. Three parallel samples were used for each analysis.

Data calculation formula

The energy efficiency from the single factor experiments was calculated as in *Equation 1*.

$$\text{energy efficiency} = \frac{c \times v}{m \times (T - 20) \times C} \quad \text{(Eq.1)}$$

where c is the average concentration value when time ≥ 30 min, v is the volume, m is the mass, T is the desired temperature, 20 is the room temperature, and C is the specific heat capacity of water (4.2 kJ/°C·kg). The unit for energy efficiency is mg/kJ, which refers to the dissolved quantity of sludge per kJ energy consumed. The heat loss that occurs during the constant temperature process was ignored because of its small value and the difficulties in its calculation.

Results and discussion

Orthogonal experiment

The results of the orthogonal experiment for estimating the effects of temperature, time, pH, and APG concentration on the pretreatment of sludge are summarized in *Table 2*. The F-value shown in *Table 2* indicates that the order of the effects of factors on STOC is pH > temperature > APG concentration > time. For soluble TP, the order of pH and temperature was the same, but the order of the other two factors (APG concentration and time) was opposite. This distinction indicates that the dissolution of organics was not caused solely by cell disintegration, but was also related to the dissolution of EPSs.

However, dissolution of EPSs contributes to the destruction of cells, and, as a result, the effects of the factors on STOC and soluble TP have a lot in common. As shown in *Figure 2,* pH (the most important factor) and temperature (the second most important factor) have similar effects, agreeing with the previous literature (Kim et al., 2015) that an increase of pH and temperature both enhance the dissolution of organics and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74637476

phosphorus from sludge. Taking into consideration the effects of pH and temperature on anaerobic digestion (Zhao et al., 2015a) and the energy consumption of the pretreatment, the final pH of the pretreatment was adjusted to 11 for both pretreatment efficiency and the reducing effect of alkalinity on AD, but the temperature needed some additional experiments.

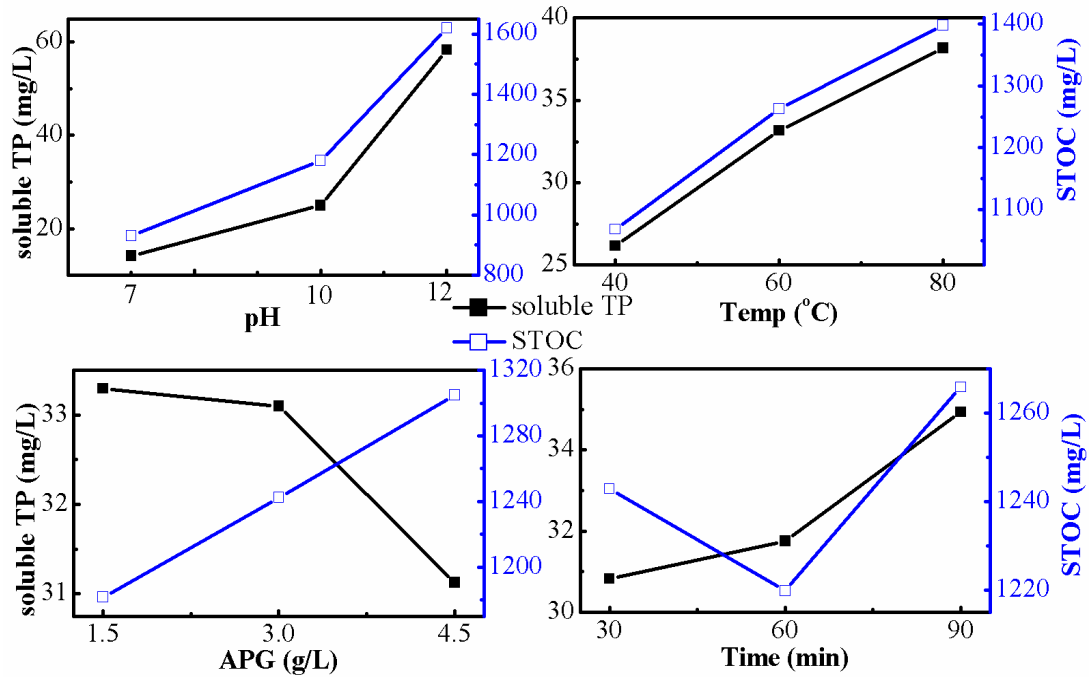

Figure 2. *Level effects of each factor on STOC and soluble TP*

Figure 2 also shows that for STOC and soluble TP, the least significant factors (time of STOC, APG concentration of soluble TP) have abnormal data, which could be explained by that time and APG concentration were easily affected by the other factors. The orthogonal design has two fundamental limitations: one is that it considers only first-order effects, and the other is that it does not account for the interaction among factors (Zeng et al., 2004). As a result, single factor experiments were required for demonstrating the effects of those two factors.

Single factor experiments

Effect of time and determination of appropriate temperature

The effect of time at various temperatures is shown in *Figure 3a* for the conditions: pH = 11; APG = 5 g/L; and temperature = 40 °C, 60 °C, and 80 °C. Once alkali and APG were added to the sludge solution, organic matter and phosphorus dissolved in the water rapidly until 30 min had elapsed, then the dissolving speed slowed down considerably. Referring to the literature (Kim et al., 2013; Ruffino et al., 2016), 60 min was chosen as a pretreatment time to ensure that the pretreatment was comparatively complete.

It is shown in *Figure 3a* that temperature enhanced the dissolution of organics and phosphorus in the sludge, which is consistent with the result of the orthogonal experiment. However, in *Figure 3b,* the energy efficiency decreased as the temperature increased, which negates the notion that the hotter the better. Although the dissolved quantity of sludge at 80 °C was higher than that at 60 °C, the amount of energy consumed at 80 °C was higher, or the energy efficiency was lower at 80 °C. Besides, it shows that the energy efficiency at 40 °C was the highest, but the dissolved quantity was compromised (the lowest). Thus, to obtain both the optimal dissolved quantity and energy efficiency, 60 °C was selected as the optimal temperature.

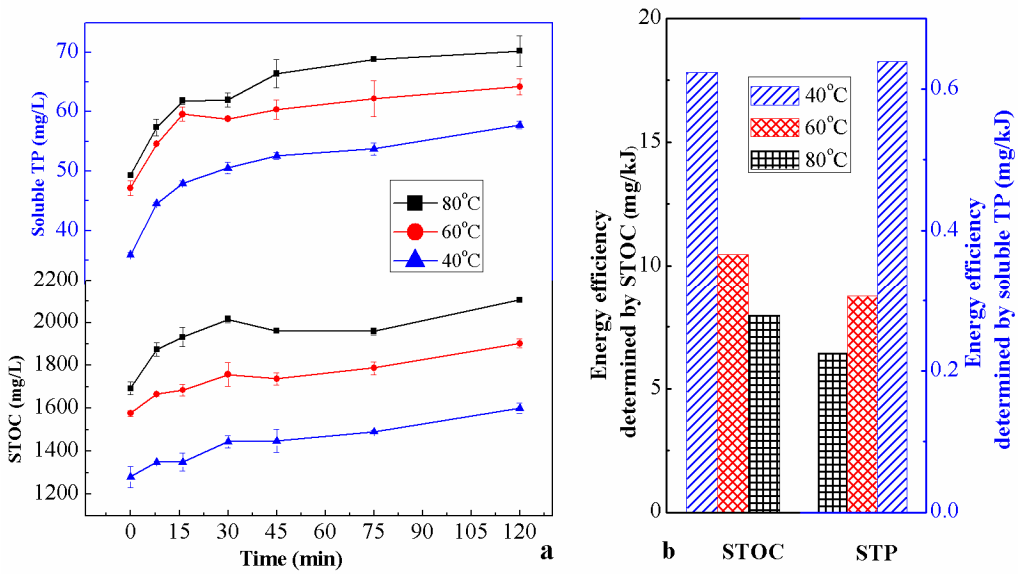

Figure 3. *Effects of time on pretreatment*

Effect of APG concentration

The effect of APG is shown in *Figure 4* for the conditions of pH = 11, temperature = 60 °C, and time = 60 min. The mixed-TOC (TOC from both sludge and APG) had a good linear relationship with APG (*Table 3*), but there is a discontinuity when APG = 18 g/L (*Fig. 4a*). The trend of STOC is from rising to declining, which could be explained as follows: Setting APG as x and mixed-STOC as y, then $y = k x + b$, and setting STOC as y', then $y' = (k - 349) x + b$. It is easy to conclude from the equation that the slope coefficient of y' (k – 349) changed due to the change of the coefficient of y (k, from 446.1 to 275.4) at the point where APG = 18 g/L. Also, it is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74637476

clear from the figure that at the point where APG = 18 g/L, the efficiency of APG decreased slowly and then rapidly.

Table 3. *Linear fitting equation of APG (x) and mixed-STOC (y)*

APG concentration (mg/L)	Linear equation	R^2
[0,18]	y = 446.1x + 970.7	0.999
[18,30]	y = 275.4x + 4017	0.998

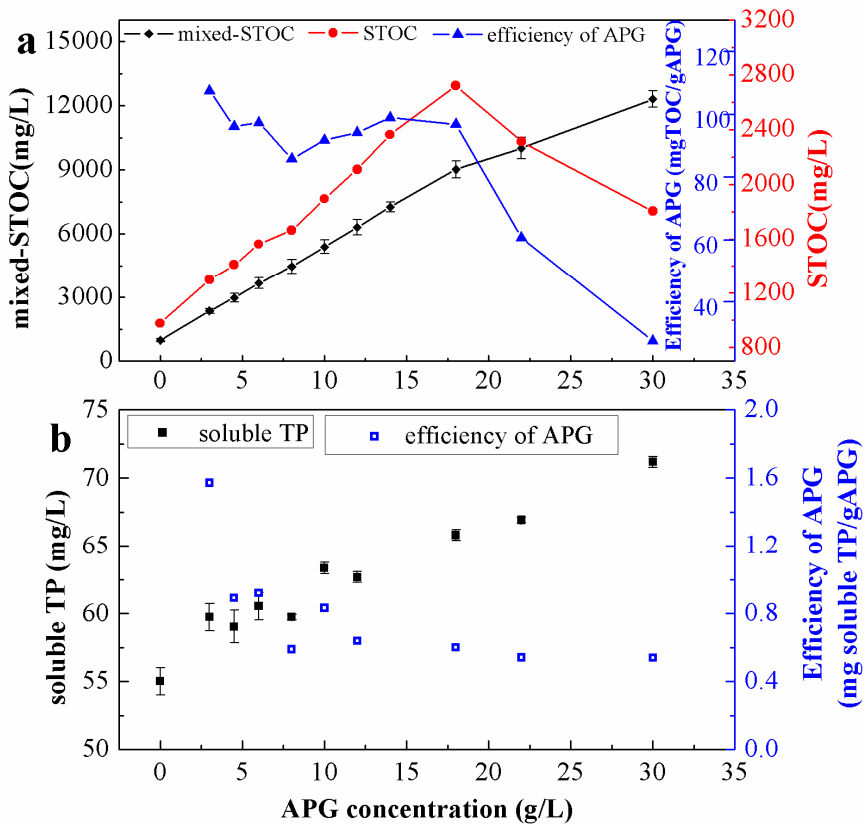

Figure 4. *Effects of APG concentration on STOC (a) and soluble TP (b). In (a), the efficiency of APG = (STOC – $STOC_0$)/APG, where the $STOC_0$ is STOC with APG = 0 mg/L. In (b), the efficiency of APG = (soluble TP – soluble TP_0)/APG, where the soluble TP_0 is soluble TP with APG = 0 g/L*

In *Figure 4a,* when APG < 18 g/L, the higher the APG concentration, the more organics dissolved from the sludge. However, when APG concentration is over 18 g/L, STOC inversely decreases as APG increases. This could be explained as follows: When the concentration of a surfactant is above its CMC, micelles transform from spherical to rod-like. The rod-like micelles would even become associated if continuously adding the surfactant (Rakshit, 2008). In other words, a concentration above the CMC induces the formation of bigger micelles. When the micelles are large enough to be blocked by a microporous membrane, the organics in these micelles may not appear in the dissolved form. In this solution system, 18 g/L was the critical concentration, at which there were micelles blocked by a 0.45 μm microporous membrane.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74637476

In *Figure 4b,* soluble TP increases with increasing APG dosage, which indicates that more APG led to more cell disintegration. Phosphorus was not contained in micelles, so big micelles blocked by the microporous membrane did not affect it; therefore, there was no discontinuity insoluble TP.

Similar to other surfactants, some APG molecules formed micelles when the concentration was above its CMC. Thus, the quantity of effective APG molecules did not have a linear increase with its concentration, resulting in the decreasing efficiency of APG in both *Figure 4a* and *b*.

Anaerobic digestion

Gas production

The biogas production from AD is shown in *Figure 5* as a function of fermentation time (on the x-axis) and cumulative gas volume (on they-axis). Comparing the blank with T0 shows that after the low-temperature thermo-alkaline pretreatment without APG, there was higher biogas production efficiency of T0, which is consistent with the literature (Li et al., 2016). However, pretreatment with different dosages of APG had a significant effect on the gas production.

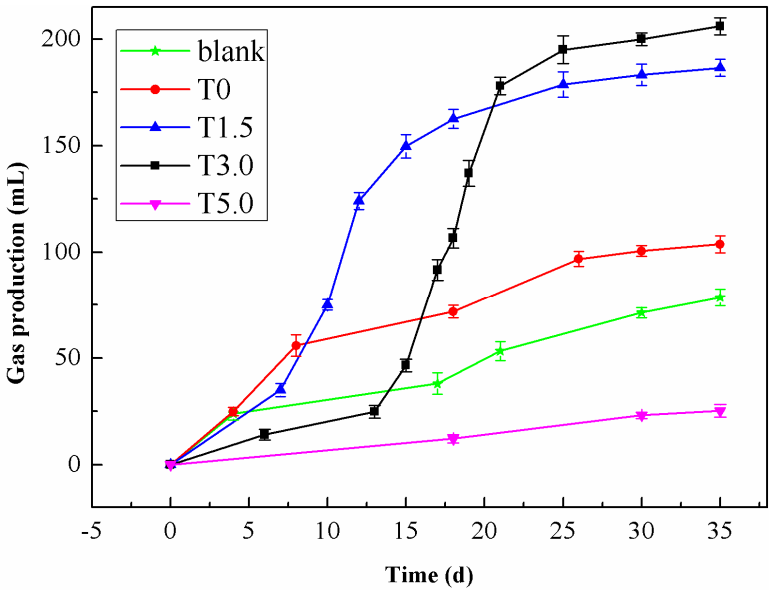

Figure 5. *Total volume of biogas in AD*

Comparing T0 with T1.5, it was found that adding APG to the pretreatment had a greater impact on AD than adding solely alkali. Moreover, the gas production of T1.5 increased rapidly about 7 days later, which means that the microorganisms in T1.5 had an adaptive phase of 7 days.

In comparison with T1.5, it was observed that the gas production rate of T3.0 started rising rapidly on the 13th day. The longer adaptive phase defines the inhibiting effect of APG on the microorganisms in the anaerobic system. When the APG concentration is less than the CMC, the adaptive phase increases with increasing APG dosage.

Assuming that there was no wastage of APG during the process of pretreatment, APG concentration in the fermentation broth was 0.9 g/L for T1.5, 1.8 g/L for T3.0, and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74637476

3.0 g/L for T5.0 (APG was diluted 5/3 times by inocula). It is shown in *Figure 5* that T5.0 produced a small amount of biogas, which suggests that the aerogen can hardly adapt to the APG concentration at CMC (the CMC of the APG sludge solution was approximately 3.0 g/L, section 2.1.3). Considering the result of preliminary experiments indicating that there were no bubbles in the fermentation liquor when pretreating at APG > 5.0 g/L, it is the APG micelles that have a negative impact of activity on the aerogen. However, in the study by Xia and Onyukse (2000), they found that it was the surfactant monomer, not the micelle, that went through the cell membrane to damage the cell. Therefore, as they stated, "micelles may act as a depot to continuously replace aqueous surfactant monomers taken up by the membrane."

Property analysis of fermentation liquor and biogas

The compositions of the liquor and biogas during fermentation are shown in *Figure 6*. The sludge solutions of T0, T1.5, T3.0, and T5.0 pretreated by the low-temperature thermo-alkaline method (initial pH = 11) were mixed with inocula. All pH was between 8.8 and 8.9, as shown in *Figure 6a,* and all pH values were significantly reduced after 35 days. The AD of the organic material basically follows hydrolysis, acidogenesis, acetogenesis, and methanogenesis (Appels et al., 2008). It could be deduced that the main cause of the pH reduction was acidogenesis and acetogenesis.

It is known that methanogens are extremely sensitive to pH, with an optimum between 6.5 and 7.2 (Appels et al., 2008), and the optimal pH of hydrolysis and acidogenesis is between 5.5 and 6.5 (Ward et al., 2008). As shown in *Figure 6a,* the pH values of the blank, T0, T1.5, and T3.0 after AD were between 6.5 and 7.2, which may indicate that the maximal activity strain in the fermentation reactor was a methanogen. However, *Figure 6b* also shows that it is only in T1.5 and T3.0 that there was a relatively large CH_4 volume fraction. Only 1.66 vol% methane in the blank was produced, which is because the poor efficiency of hydrolysis made acidogenesis difficult (the pH changed just from 6.97 to 6.80), so of course acetogenesis and methanogenesis were limited. In T0, the pretreatment facilitated hydrolysis, so acidogenesis and acetogenesis made the pH drop sharply from 8.80 to 7.13. The low methane yield may be caused by the limitation of low organic substrate concentration, since the ratio of VS to TS of sludge used in this study was just 51.32 ± 0.10% (shown in section2.1.1). Adding APG to the pretreatments more effectively promoted the dissolution of organics in the sludge, and APG could even act as an organic substrate, thus leading to the relatively large amount of CH_4 in T1.5 and T3.0, compared to that in T0.

Meanwhile, the pH of T5.0 was at the optimum for hydrolysis and acidogenesis (5.5–6.5, *Fig. 6a*), and there was no methane detected (*Fig. 6b*), both of which suggest that the activity of the methanogens in the T5.0 anaerobic system was extremely low. This conclusion could be also deduced by its STOC reduction rate (*Fig. 6c*).

The STOC reduction rate is unequal to the carbon utilization rate of methanogens, because hydrolysis, acidogenesis, acetogenesis, and methanogenesis simultaneously occur in a mixed anaerobic system. That is to say, when soluble carbon was being converted into CH_4, and CO_2 volatilizing from the liquor, the carbon in the suspended solids was being dissolved into the water by hydrolysis and acidogenesis. However, it is only soluble carbon that methanogens can utilize, so the STOC reduction rate is, to some extent, equal to the activity of methanogens. *Figure 6c* shows that T5.0 had a STOC reduction rate far below that of the other tests, showing its low methanogen

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74637476

activity. Taking the conclusion of section 3.3.1 into consideration, APGs have more of a negative impact of activity on methanogens than on other strains in the AD system. The literature (Luo et al., 2015) reports that there was far more Firmicutes in WAS anaerobic reactors with APG than without APG (42.6% vs. 9.8%), from which it could be deduced that a firm cell wall can help to protect the bacteria from the toxic effect of APG. Methanogens belong to Archaea, whose cell wall is comparatively weak, so APG monomers easily go through cell membranes and cause them damage.

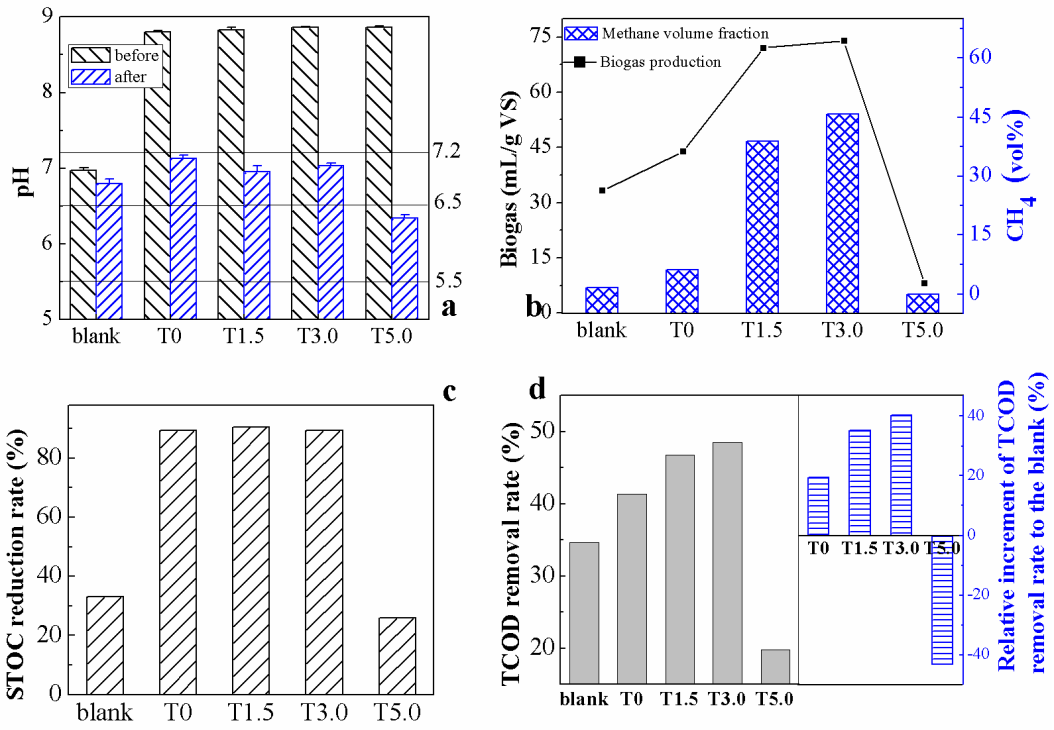

Figure 6. *Property analysis of fermentation liquor and biogas. (a) The change of pH before and after AD. (b) Biogas yield and volume fraction of CH_4. In (c), STOC reduction rate = ($STOC_b$– $STOC_a$)/$STOC_b$, where $STOC_b$ is soluble total organic carbon in the fermentation broth before fermenting, and $STOC_a$ is after fermenting. In (d), TCOD removal rate = ($TCOD_b$ – $TCOD_a$)/$TCOD_b$, where $TCOD_b$ is total chemical oxygen demand in the fermentation broth before fermenting, and $TCOD_a$ is after fermenting. The relative increase of the TCOD removal rate, compared to the blank = TCOD removal rate of (Tα– blank)/blank × 100%, which quantifies the comparison between TCOD removed by AD with pretreatment (T0, T1.5, T3.0, T5.0) and without pretreatment (blank)*

The rate of TCOD removal can be considered to represent the organics utilization rate in the AD system. It is observed from *Figure 6d* that the APG dosage increased the organics utilization rate when the APG concentration was under the CMC. However, when the APG was plentiful enough to generate abundant micelles (APG concentration ≥ CMC), the micelles sharply lowered the activity of the methanogens to inhibit methanogenesis, so the organics utilization rate of T5.0 decreased obviously. This is why Zhao et al. (2015b) and Luo et al. (2015) added APG to anaerobic fermentation systems to inhibit methanogenesis in order to accumulate short-chain fatty acids (SCFAs).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74637476

The relative increase of the TCOD removal rate compared to the blank (*Fig. 6d*) suggests that pretreatment does improve the efficiency of AD. The relative increase of T0 was 19.37%, and that of T3.0 was 40.30%. It was easy to calculate that 40.30 is108.07% greater than 19.37, significantly demonstrating that 3.0 g/L is a reasonable selection for the optimal APG dosage. This is due to the fact that, during pretreatment, APG at the CMC promotes dissolution of EPSs, which accelerates hydrolysis. Further, when fermenting, APG is diluted to below CMC, so its toxicity to methanogens is reduced.

In addition, the methane volume fraction of T3.0 was 45.84% (*Fig. 6b*), which is lower than normal biogas (CH_4 volume fraction of digestion biogas was 53–70%; Appels et al., 2008). In comparison with the blank (1.66%) and T0 (6.17%), T3.0 nearly realized sludge recycling.

Although there was an adaption phase in the AD system because of APG, this disadvantage could be overcome by additional high-efficiency gas production studies in a continuous fermentation system (not in a sequencing batch reactor, as in the present experiment). Further, although the methane content was low because of the lack of organic substrate, other degradable organic waste, such as food waste, could be used to increase the organic substrate concentration. However, these suppositions need to be confirmed by more experiments.

Conclusion

A low-temperature thermo-alkaline pretreatment with APG for WAS with low organic content could greatly improve the sludge utilization in AD systems. More APG led to more dissolution of organic matter during the pretreatment, but in fermentation, APG above the CMC severely inhibited methanogenesis. As a result, 3.0 g/L was chosen as the optimal APG dosage. Under optimum conditions, pretreated sludge was fermented anaerobically at mesophilic temperatures to obtain the best biogas production, CH_4 volume fraction, and organics utilization rate. Although there was an adaptive phase of 13 days and the methane content was low, additional experiments could be conducted to find solutions that overcome these disadvantages.

(Received 27th Feb 2019; accepted 3rd May 2019)

Abstract. As a nature reserve with extremely vulnerable ecological system, Jiuzhai Valley must strike a balance between climate change, tourism growth and environmental protection in the future development. Carbon footprint is a key tool to measure the environmental impact of human activities. The key factors of carbon emission reduction in Jiuzhai Valley Nature Reserve can be found through carbon footprint evaluation and targeted carbon emission reduction measures can be put forward. In this paper, the carbon emission inventory based on mixed life cycle is introduced to calculate the carbon emissions within the boundary of Jiuzhai Valley Nature Reserve, evaluate its carbon footprint and find out its spatial distribution pattern in order to find out the key factors and links in the improvement of the low-carbon management in Jiuzhai Valley. The study found that the commercial activities of operating companies providing services to tourists (such as transportation and catering) are a major part of carbon emissions, followed by tourist tours and the management and maintenance activities of the Authority, the residential carbon emissions which come from the village daily life and private car driving. The low carbon emission reduction in Jiuzhai Valley should focus on the optimization of land use, the control of the number of residents and tourists, and the sharing of responsibility for emission reduction.
Keywords: *carbon emission, carbon footprint, spatial distribution, human activities, Jiuzhai Valley scenic area*

Introduction

Jiuzhai Valley Nature Reserve was established in 1978, and was approved to establish national scenic area in 1984. In 1992, UNESCO designated Jiuzhai Valley as "World Natural Heritage", and then Jiuzhai Valley joined the World Network of Man and Biosphere Reserves. Jiuzhai Valley Nature Reserve is located on the eastern edge of the Qinghai-Tibet Plateau. In general, it belongs to the alpine and gorge region landform。 The unique geological, geomorphological and natural geography conditions have created the alpine karst landscape and lake canyon scenery with large scale and unique shape. The ecological environment of Jiuzhai Valley is very fragile and sensitive, belonging to the "environmentally and cultural vulnerable areas" (Zhang and Zhu, 2007). In theory, Jiuzhai Valley should rely on ecotourism to protect the World Natural Heritage through

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74777493

small scale tourism that strictly limits the number of tourists according to the environmental capacity. However, this concept is challenged by mass tourism, aboriginal people getting rich from poverty and local economic growth in practice. Therefore, Jiuzhai Valley's scenic area management needs to consider a variety of demands to promote operational strategies.

This paper selects Jiuzhai Valley to carry out carbon footprint research based on the following considerations: first of all, tourism has become the economic artery of Jiuzhai Valley, and Jiuzhai Valley scenic area has become the local pillar industry and economic artery. Since its development in 1980, Jiuzhai Valley has experienced an average annual increase of 27%. In 2012, the number of tourists has reached 3,638,618, and tourism income has accounted for more than 90% of the local economic income. Tourism has effectively promoted local economic development and the employment of residents out of poverty. Secondly, tourism growth poses a severe challenge to the ecological carrying capacity of scenic spot, which are often overloaded. According to Zhang Xiaoping, former director general of Jiuzhai Valley Administration, and related scholars, the daily tourist psychological capacity of Jiuzhai Valley scenic area is 12000 people (with different values in different seasons), the best (most appropriate) daily capacity is 18000 people, and the comprehensive environmental capacity is 22000 people, the maximum daily capacity can reach 28000 people, and the annual capacity is 2.6 million to 4.38 million people (Zhang and Zhu, 2007). According to the tourism scale of Jiuzhai Valley in 2016, the number of tourists was already at the carrying capacity boundary and breaking the limiting value. Thirdly, Jiuzhai Valley Administration ecological protection work has been carried out in an orderly manner and the data has been sorted out and improved. The Academic Research Office and Protection Department of Jiuzhai Valley Administration has carried out a general survey and quantitative statistics on the species of animals and plants inside the reserve area, and has more detailed records and observation data on the land use change of Jiuzhai Valley. The Protection Department is responsible for the disposal of waste and feces and sewage in the scenic area of Jiuzhai Valley, which can obtain basic information through interviews. The Jiuzhai Valley Administration has a Resident Management Office, which is responsible for the management of residents in the scenic area, has relatively complete information on residents' living conditions, income changes, vehicle ownership situation and so on.

This paper applies the theory of carbon footprint to Jiuzhai Valley Nature Reserve and discusses how to reduce carbon footprint and implement carbon management to balance ecological vulnerability protection and tourism economic growth. This paper combines the international common carbon footprint inventory to construct the evaluation model of tourism carbon footprint suitable for minority areas, and verifies it through the field interview data of Jiuzhai Valley, introduces stakeholders to distinguish the responsibilities of Jiuzhai Valley tourism industry in reducing emissions according to the results of carbon footprint evaluation, and provides theoretical and empirical support for putting forward and perfecting low-carbon construction and sustainable development of Jiuzhai Valley tourism industry.

Research object and scheme design

The basic situation of Jiuzhai Valley scenic area

Tourism activities are mainly carried out in the experimental area of Jiuzhai Valley scenic area, accounting for 8.53% of the total area of nature reserve. The changes in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74777493

population and land use in Jiuzhai Valley are closely related to its history of development. *Figure 1* shows the changes of tourists and population in Jiuzhai Valley from 1978 to 2012. The number of tourists fluctuated greatly during that period. The two biggest fluctuations occurred in the early stages of tourism development in Jiuzhai Valley in 1980 with a sharp increase of tourists and the rapid development of tourism after 1989, followed by three small fluctuations, which are respectively after the 1997 financial crisis, after SARS in 2003 and after Sichuan earthquake in 2008. In contrast, the number of residents has maintained a steady and slow growth, its population growth rate showed a downward trend.

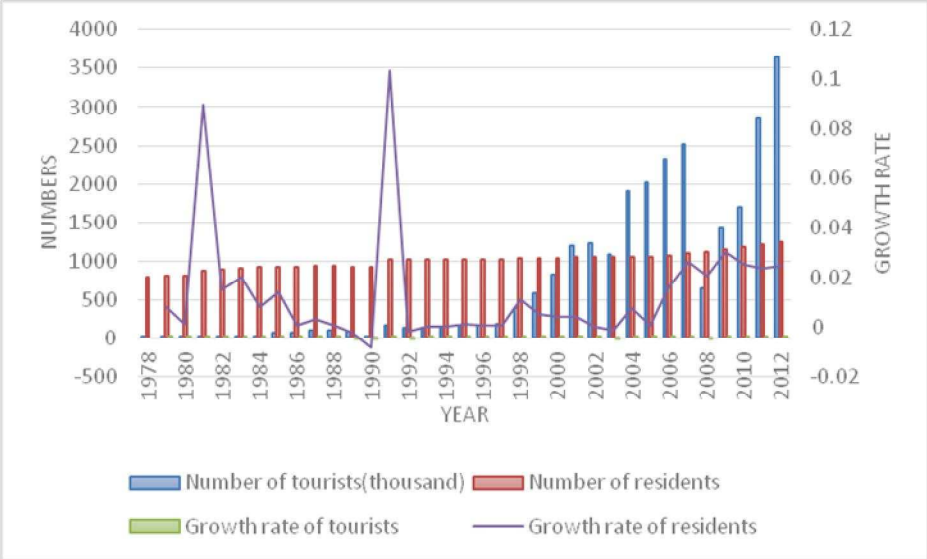

Figure 1. *Changes in the number of tourists and residents in Jiuzhai Valley*

Human activities in different periods have a great influence on the landscape pattern and land use of Jiuzhai Valley Nature Reserve. *Figure 2* reflects the land use changes in Jiuzhai Valley Nature Reserve in four periods from 1975 to 2012. The reasons of the land use change of each period can be found in the development decision and course of the specific period at that time.

Before 1978, Jiuzhai Valley production method and life style were mainly agricultural grazing and forestry felling. The local people made a living by logging, farming, grazing, hunting and digging medicine and lived a life of half farming and half grazing. In 1966, the original Bailong River Forestry Bureau began opening work circle to felling timber in Jiuzhai Valley. Jiuzhai Valley Nature Reserve was established in 1978, but forest logging was not completely banned because of sectoral economic interest until 1992 when it was listed as the World Natural Heritage. In 1984, the national scenic spot was established, and Jiuzhai Valley officially opened to the outside world. Tourism started and the construction of tourist facilities was started. Since 1987, especially in 1990, Jiuzhai Valley tourism has entered a period of rapid growth-the number of tourists had increased exponentially and the tourism economy had grown rapidly. However, due to extensive management, the phenomenon of urbanization and over-commercialization gradually appeared in the reserve, which caused certain damage to the ecological environment (Zhou, 1998). Since 1999, Jiuzhai Valley has taken strict and scientific measures to protect the environment. On the one hand, the traditional

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74777493

living habits of residents have been changed, and natural gas cooking has been realized. In 2000, the hotels in the reserve was dismantled comprehensively, and implement the policy of returning the grain plots to forestry. From 2008 till now, Jiuzhai Valley has been hit hard by the earthquake and the tourists have plummeted, and the water area and mountain body within the territory have been significantly destroyed by earthquake and debris flow. Post-disaster reconstruction of the scenic area and tourism industry recovery has become the main theme. From the perspective of land use changes in Jiuzhai Valley, such events as stopping forest harvesting, developing tourism, returning the grain plots to forestry, demolishing hotels and other operational sites in scenic spots, and rebuilding after the earthquake have played a very important role in restoring and increasing the forest land of Jiuzhai Valley, changing the way of residents life by returning grain plots to forestry to engage in tourism, reducing a large amount of constructive land and standardizing the land management of Jiuzhai Valley.

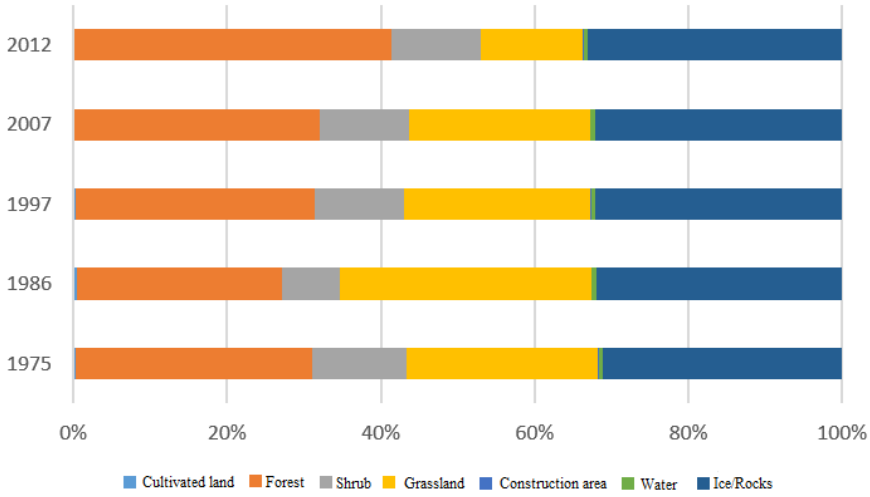

Figure 2. *Percentage change of different land use types in Jiuzhai Valley*

Review of carbon footprint research

From the perspective of source and nature, carbon footprint is a spatial concept, which is measured in the unit of area. Kitzes and other scholars (Kitzes et al., 2009, 2007) regard carbon footprint as part of the ecological footprint, known as the "fossil energy footprint" or "carbon dioxide land", which is measured in gha (gha, the abbreviation of global hectare, one unit global hectare refers to a productivity space of 1 ha with an average global yield, the unit is hm^2). There are also many scholars who tend to express carbon footprint in terms of carbon dioxide emissions or carbon dioxide equivalents, typical of which is that Wiedmann and Minx (2007) and Hertwich and Peters (2009) define carbon footprint as the total amount of carbon dioxide and other greenhouse gases emitted by a product's supply chain or life-cycle. Although the carbon footprint originated from the ecological footprint, it has formed its unique meaning on the basis of its "ecological footprint of carbon emissions" in practice, which becomes a token of greenhouse gas emissions taking into account global warming potential (GWP). Whether the area or the quality of measurement units are inadequate. Converting greenhouse gas emissions into land area requires a series of assumptions that increase the error and uncertainty of carbon footprint accounting (Lenzen, 2006).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74777493

On the other hand, it is not accurate to express the carbon footprint by the quality of greenhouse gas, because carbon footprint is a spatial concept, and it is easy to lead misunderstanding if taking mass as the unit (Hertwich and Peters, 2009).

In order to distinguish the concept of carbon footprint and carbon emission, this paper adopts the definition of "productive land area needed to absorb carbon dioxide emissions from human activities". Carbon emissions are defined as "the direct or indirect carbon dioxide emissions in the entire life cycle or within a certain geographical range of an activity, a product (or service)".

Carbon footprint inventory of carbon emission sources is the first step in carbon footprint evaluation. Although greenhouse gas accounting standard is commonly used in footprint calculations, there is no mandatory carbon footprint verification (Pandey et al., 2011). The domestic and international studies on carbon emissions in specific regions based on greenhouse gas emission inventories mainly focus on the research of regional carbon emissions on the large and mesoscale scale, with the largest number of studies on the assessment of carbon footprint between countries and continents on a large scale. In view of the pressure of greenhouse gas emission reduction on countries brought by global climate change, different scholars put forward some practical amendments to the IPCC and other emission inventories and carry out the design and statistics of carbon emission inventory according to the characteristics of their respective countries and regions characteristics. Some scholars also put forward their views on the design and method of greenhouse gas emission inventory (Ravindranath and Ostwald, 2008). Ramaswami et al. (2008) developed a demand-oriented hybrid life-cycle approach that focuses on demand-oriented mixed greenhouse gas inventory method including urban direct greenhouse gas emissions related to final energy use, and indirect greenhouse gas emissions related to the main substances supporting the city. After that, some scholars have improved and applied the city inventory method based on the mixed life cycle inventory method (Kennedy et al., 2010, 2011).

Evaluation and design of carbon footprint in Jiuzhai Valley

Tourism is the only economic industry in Jiuzhai Valley. The type of economic activity in Jiuzhai Valley is tourism industry. All the main bodies in Jiuzhai Valley can be divided into tourists and organizations and individuals who provide services for tourists. Tourist activities in the scenic area impact on the environment is waste and sewage, feces. Organizations and individuals providing services to tourists include: residents, the commercial sector of the scenic area and the administration in Jiuzhai Valley. Jiuzhai Valley residents basically turn to tourism employment, their working carbon emissions can basically be included in the tourism industry carbon emissions, so the resident carbon emissions in Jiuzhai Valley come from the daily life and transportation of residents. The scenic area commerce provides the service of catering, shopping, transportation and sightseeing for tourists. Its environmental impact includes: fuel and electricity consumption, waste gas and waste water produced by business activities and so on. Administration carbon emissions are reflected in the daily office energy use, construction waste and vehicle use for construction and maintenance of scenic area, and the use of working vehicles for safety management and protection in scenic area.

According to the types of human activities in Jiuzhai Valley scenic area, there are mainly four kinds of activities: the first is the daily life of the residents in the reserve and the activities of participating in tourism management. The second is the tourism

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74777493

activities of tourists. The third is the commercial operation activities in the scenic area, involving the business activities of the three companies under the jurisdiction of the Jiuzhai Valley Administration, such as the joint venture company (operating the Nourilang Center), the tourist products company (operating the Shopping Center, VIP building and Heye Guesthouse), and sightseeing company (operating tourist vehicles). The fourth kind is the management and maintenance activities of the scenic area, including the construction and repair of the scenic area, the daily office work of the Administration Bureau, the safety protection and management of the scenic spot of the Administration, etc. *Figure 3* lists the various departments involved in the statistics of the carbon emission inventory, among which, the Administration Bureau belongs to scenic area management department, the tourism company, the product company, and the jointly venture company are the scenic area commercial operation company.

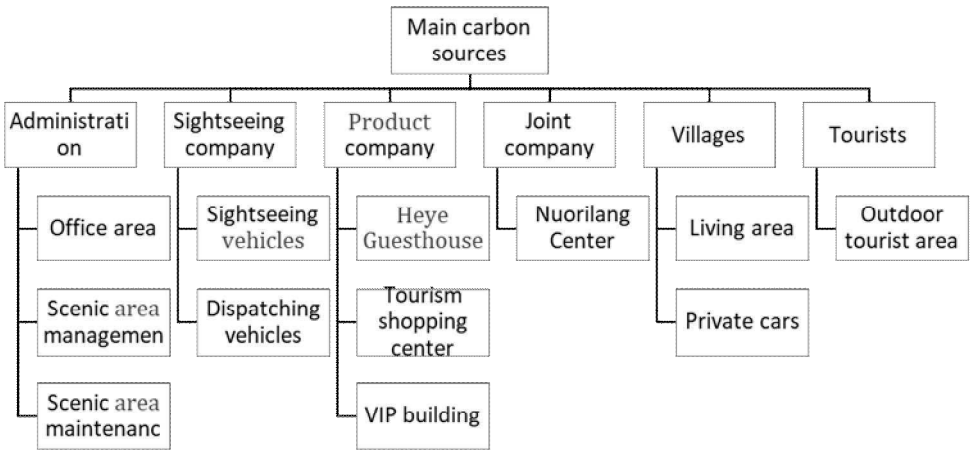

Figure 3. *The main bodies involved in the Jiuzhai Valley carbon inventory*

The inventory of carbon emissions based on mixed life cycle includes not only direct carbon emissions from energy activities but also indirect carbon emissions from power consumption and indirect carbon emissions from waste disposal. Direct carbon emissions of Jiuzhai Valley mainly come from energy activities, such as fuel consumption of traffic vehicles, use of natural gas, energy consumption of Nourilang diesel stove and charcoal heating in winter of residents in the scenic area. Electricity belongs to indirect carbon emissions. The feces, garbage, sewage are also considered as indirect carbon emission because all of them are transported out of Jiuzhai Valley for treatment and its carbon emissions occur outside the scenic area. The projects in Jiuzhai Valley that can be included in carbon inventory statistics are as follows, as shown in *Figure 4*.

Greenhouse gas emissions need to focus not only on direct emissions inside the nature reserve, but also on indirect emissions from energy consumption and waste disposal. Compared with the IPCC inventory classification statistics, Jiuzhai Valley's greenhouse gas accounting is clear and simple, because Jiuzhai Valley's economic activity type is only tourism industry. All the main bodies in Jiuzhai Valley can be divided into tourists and organizations and individuals that provide services for tourists. Tourist activities in the scenic area impact on the environment is waste and sewage, feces. Organizations and individuals providing services to tourists include: residents, the commercial sector of the scenic area and the administration in Jiuzhai Valley. Jiuzhai

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74777493

Valley residents basically turn to tourism employment, their working carbon emissions can basically be included in the tourism industry carbon emissions, so the resident carbon emissions in Jiuzhai Valley come from the daily life and transportation of residents. The scenic area commerce provides the service of catering, shopping, transportation and sightseeing for tourists. Its environmental impact includes: fuel and electricity consumption, waste gas and waste water produced by business activities and so on. Administration carbon emissions are reflected in the daily office energy use, construction waste and vehicle use for construction and maintenance of scenic area, and the use of working vehicles for safety management and protection in scenic area.

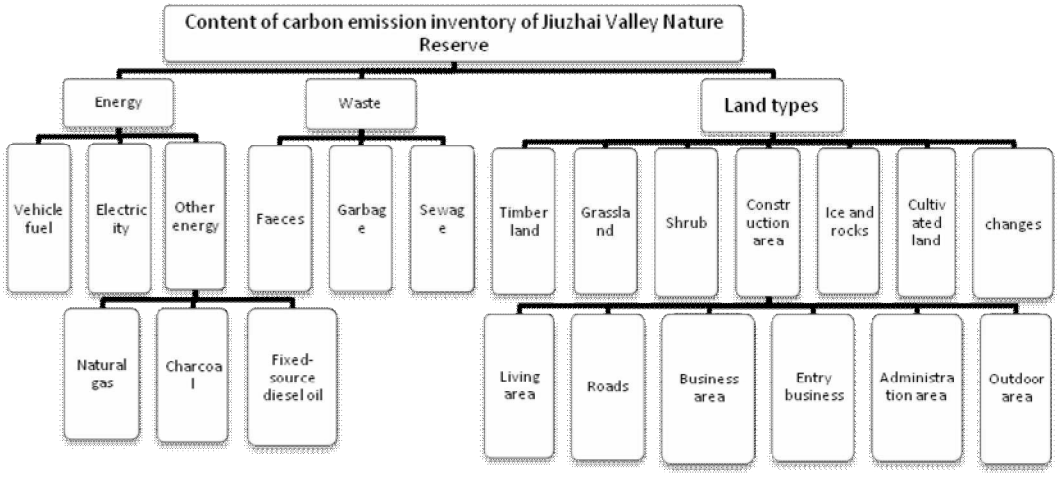

Figure 4. *Statistics on carbon emission inventory in Jiuzhai Valley*

There are three sources of carbon emissions in Jiuzhai Valley: energy, waste, and land use. Among them, construction land and cultivated land in land use are sources of carbon emissions. But since 2003-2004, the cultivated land in Jiuzhai Valley has been converted into forestry, and the carbon source of cultivated land has not existed. Carbon emissions from construction land are energy consumption and waste emissions from that region, so there is no need for double counting. The other land types of Jiuzhai Valley play a role of carbon sink and have the function of carbon storage and carbon absorption except for construction land. According to the carbon emission inventory, the activities data level of the carbon source in Jiuzhai Valley is counted, and the emission coefficient method is used to calculate the carbon emissions of each carbon source in Jiuzhai Valley. NPP carbon sink method can be adopted in the evaluation of carbon footprint and carbon balance. *Figure 5* shows the process of carbon footprint evaluation in Jiuzhai Valley Nature Reserve.

Evaluation methods and data acquisition

Evaluation methods

The evaluation of carbon emission and the selection of emission coefficient

The calculation of carbon emissions from energy and waste refers to the calculation method recommended by *IPCC2006 Greenhouse Gas Emission Inventory Guidelines*, which is also adopted and used for reference by international general inventory

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74777493

guidelines such as PAS2050, ISO14064. Energy carbon emission calculation is relatively simple, the key of which is to determine the corresponding energy carbon emission coefficient. As for the units of measurement, carbon emissions, carbon storage, and carbon absorption all use kilograms or tons (kg or t), the unit of land area and carbon footprint is hectares (hm^2), and the units of other indexes in this paper all refer to the national standard *GB 3101-1993 General Principles of Quantities, Units and Symbols*.

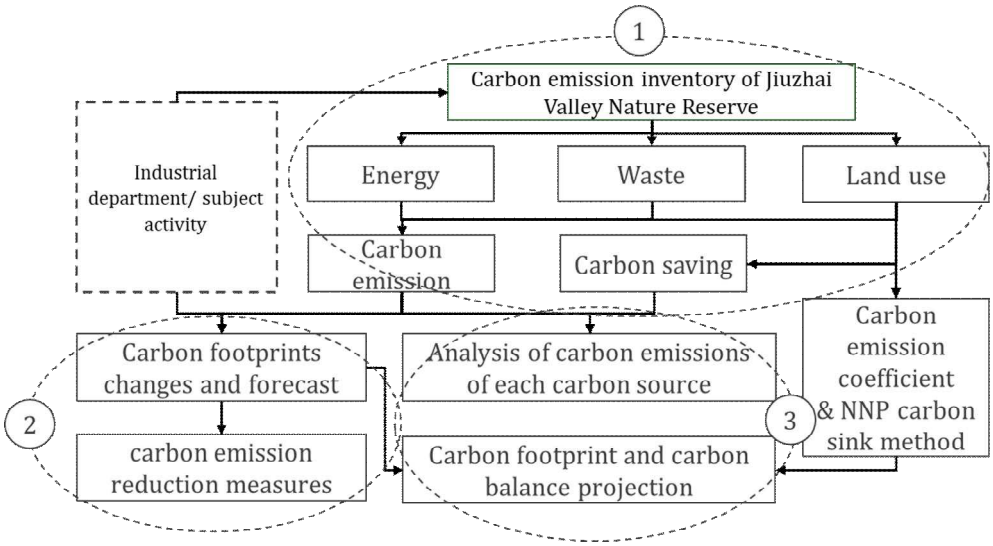

Figure 5. *Evaluation design of carbon footprint in Jiuzhai Valley*

Carbon footprint calculation

This paper adopts the net primary productivity (NPP) index to reflect the carbon absorption of different vegetation, and calculate the area of productive land needed to absorb carbon emissions, that is, carbon footprint. The NPP of forests, grasslands, thinly forested shrubs and water bodies refer to the studies of different domestic scholars (Du et al., 2010; Gu et al., 2007; Liu et al., 2010), while the NPP of bare rock refers to Lu et al. (2005) study on Sichuan in the western region, which makes a detailed analysis of the calculation in the paper.

Calculation of carbon balance in Jiuzhai Valley

This paper analyzes the carbon balance of Jiuzhai Valley reserve ecosystem from two aspects. One is the comparison between carbon emission from human activities and carbon storage and carbon absorption in Jiuzhai Valley. The other is the comparison between the human activities carbon footprint and Jiuzhai Valley productive land area. The former analysis is based on the carbon emission inventory. According to the national carbon emission inventory, the types and quantities of carbon emission sources and absorption sinks in Jiuzhai Valley Nature Reserve are listed in the form of incoming and outgoings, which is convenient to observe the situation of carbon balance. The latter one refers to the analysis based on ecological carbon balance index. If the ecological carbon balance index is greater than 1, it means that there is ecological deficit. If the ecological carbon balance index is equal to 1, it shows that ecology is in the critical

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74777493

state of carbon balance. If the ecological carbon balance index is less than 1, it indicates that there is ecological surplus. The smaller the ecological carbon balance index, the more intact the ecosystem is and is less disturbed by human activities.

Data acquisition

The interview with various department in Jiuzhai Valley

In December 2012, the author conducted a half-month departmental interview in Jiuzhai Valley Nature Reserve, covering 16 departments, the departments and interview content are as shown in *Table 1*.

Table 1. *Interview department and content of Jiuzhai Valley administration*

Interview department	Interview content
HR Office	For the division and arrangement of responsibilities of the Jiuzhai Valley Administration, final report of the Administration over the years
Marketing Department	Get the number of tourists, the origin and composition of tourists, the consumption of tourists and sample survey conditions
Information Center	For its management of tourist ticketing and the tracing of tourists
Office of Academic Research	Protection of vegetation, types and changes of land use, boundary of reserve
Resident Management Office	The number of residents, the number of households in village, the building area of village, the conversion of farmland to forests, etc.
Security Department	Reserve waste disposal, fecal disposal, sewage treatment, resident charcoal procurement
Legal Department	Number and type of private cars owned by the residents
Supervision Department	Monitoring the energy consumption of each department
Construction Department	Construction of scenic area, construction waste and use of vehicles
Administration Office and Drivers Office	Number of vehicles, types of vehicles, usage condition in the Valley, mileage and fuel consumption owned by the Administration
Sightseeing Company	Vehicle types and quantity changes, fuel consumption and usage, vehicle scheduling management
Product Company	Energy consumption of the commerce in the Valley such as catering, accommodation, shopping, number of visitors and consumption
Joint Venture Company	Telephone interviews to learn about vehicles, energy use
Tourist Center	Jiuzhai Valley scientific research achievements presentation, tourist survey
Finance Department	Involving confidential not being interviewed
Stockaded Village	Go to the village committee and residents' home of Heye Village, Zharu Village, and Shuzheng Village to interview and observe
Postdoctoral Research Station	Understanding the construction of low carbon scenic area

Public data acquisition

Statistical yearbook

Remote sensing images from the Chinese resource satellite remote sensing processor.

Research results and analysis

According to the carbon emission sources of Jiuzhai Valley scenic area, the carbon emissions from energy, waste and different land use are calculated respectively. The results show that the total carbon emissions of human activities in Jiuzhai Valley in 2012 was 21118.41 tons. From the emission source of the carbon footprint of human activities, the carbon footprint generated by energy consumption accounted for 81.86% of the total carbon footprint, while the carbon footprint of waste accounted for 18.14%. In the energy carbon footprint, the carbon footprint of traffic vehicles using moving source fuel accounted for 54.84%, in which, the size of the carbon footprint was followed by tourists sightseeing transportation, private cars of residents and working vehicles. The carbon footprint of electric power accounted for 35.62%, the other energy consumption produces the smallest carbon footprint, and the size of carbon footprint of which was followed by gas, charcoal and fixed-source diesel.

According to the conversion formula of carbon emission and ecological footprint, the carbon footprint of human activities in Jiuzhai Valley can be calculated to be 3872.9 hm^2 in 2012, accounting for 5.94% of the biological productivity area (excluding construction land) in Jiuzhai Valley Nature Reserve. In terms of ecological footprint, carbon emissions from human activities in Jiuzhai Valley have very little impact on the environment of the reserve, far from reaching the upper limit of ecological carrying capacity in Jiuzhai Valley Nature Reserve. Jiuzhai Valley Nature Reserve still has 94.06% of the land to provide China with carbon sinks while supporting the development of tourism and the life of the residents at the same time.

Carbon footprint analysis of different subjects

From the subjects of human activity carbon footprint, the operating company that provides tourists with transportation, catering, accommodation (guesthouse), shopping company has the largest carbon footprint, accounting for 56.78% of the total. Tourists' carbon footprint due to toilet use, water use, abandonment of waste and other behavior

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74777493

in the process of sightseeing ranks second, accounting for 22.38% of the total. The carbon footprint of the residents in the reserve caused by family life, the family car, the family commerce and so on ranks the third, accounting for 11.12% of the total. The carbon footprint of Administration caused by the daily work, the construction and maintenance of protected area facilities and the management of protected areas accounts for 9.72% of the total.

From the point of view of the final allocation of carbon footprint, the management and maintenance of reserve by commerce and Administration are all carried out to meet the material and spiritual needs of the tourist during their tourism process, and their carbon footprint will eventually be transferred to the tourists. From this point of view, tourists eventually bear 88.88% of the carbon footprint and the rest are born by the residents. In 2012, the total number of tourists in Jiuzhai Valley was 3,638,618, and the total number of residents in Jiuzhai Valley was 1,241. The average carbon footprint per tourist was 0.00095 hm^2, while the carbon footprint per inhabitant was 0.347 hm^2.

Per capita carbon footprint of tourists and residents

As *Table 2* shows, the carbon footprint per resident is 366.81 times the carbon footprint per tourist. In other words, the carbon footprint of 367 tourists is the same as that of one resident. Or one tourists come to Jiuzhai Valley Reserve 367 times can produce a carbon footprint equal to the carbon footprint of one resident. It is true that residents live in the Valley 365 days a year, and each tourist stays for only one day. However, if you compare the carbon footprint of 0.000951 per person per day to that of a tourist, the carbon footprint of the resident is still greater. It shows that the impact of individual resident on the ecological environment of Jiuzhai Valley is greater than that of individual tourist.

Table 2. *Carbon footprint of tourists versus residents in 2012*

Carbon footprint allocation objects	Carbon emissions t	Carbon footprint hm^2	Percentage	Number of people in 2012	Per capita carbon emissions t	Per capita carbon footprint hm^2
Reserve residents	2348.26	430.65	11.78%	1241	1.89	0.35
Tourists	18770.15	3442.26	88.22%	3638618	0.01	0.00095
Total	21118.41	3872.90	100.00%	3639859		

The carbon footprint of one resident is the same as that of 367 tourists in the Reserve. In 2012, for example, 1241 residents in the Reserve produced the same carbon footprint as 455212 tourists. If the number of tourists is less than 455212, the activity of residents is the main cause of the negative impact of human activities on the environment of the Reserve, and tourist activity is the secondary motivation. This also explains why we have observed that residents have much greater impact on the environmental problems of many tourist destinations than tourists. Especially for the tourist destination which is in the early stage of tourism development or has few tourists due to the lack of fame, the carbon footprint of resident activities is the largest among all human activities. The reasons are as follows: firstly, it is due to the lack of effective management of resident activities. Secondly, the tourist facilities and services are not perfect, so that the tourist stay time and consumption are less. Thirdly, the management and operation of tourist

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74777493

destination is not mature, which makes the Reserve lack of attraction and appeal, and lack of lasting competitiveness. As a result, the number of tourists is small, the number of returned customers is also small, and the public praise is not high.

Spatial distribution of carbon footprint in Jiuzhai Valley in 2012

Analysis of carbon footprint distribution and carbon emission sources

In view of that there is NPP coefficient transformation relationship between carbon footprint and carbon emissions, and the carbon footprint can also be explained from the perspective of carbon emissions, this part uses Jiuzhai Valley carbon emissions to analyze.

The location of the carbon footprint is shown in *Figure 6*. The highway in the Reserve is the largest carbon footprint producing area, accounting for 44.89% of the total carbon footprint, which is mainly caused by the traffic carbon emissions of sightseeing vehicles, working vehicles and private cars. Jiuzhai Valley outdoor tourism area (excluding highway) is the second largest area of carbon footprint, accounting for 22.43% of all carbon footprint, which is mainly caused by waste and power consumption in the Reserve. The carbon footprint in the entrance of Jiuzhai Valley accounted for 20.62%, which mainly comes from the work of the commerce and Administration in the entrance of Jiuzhai Valley. Village carbon footprint should not be ignored, accounting for 10.40%, mainly from the lives of residents and a small number of family business activities. The carbon footprint of Nuorilang is the smallest, mainly because there are only 10% tourists eating here, and the office and shopping space is small, so the carbon emission is low, which is 1.67%. If the entrance of Jiuzhai Valley Nature Reserve is taken as the boundary, the carbon footprint inside the gate of Jiuzhai Valley Nature Reserve is only 3073.924 hm^2, accounting for 79.38% of the total carbon footprint and 4.71% of the biological productivity area of Jiuzhai Valley Nature Reserve.

Combined with the area of the site generating carbon footprint, it can be found that there are differences in carbon emission intensity of different plots in Jiuzhai Valley construction land. The road is the highest, which is followed by the village, the entrance of the Valley, Nuorilang, and the tourist area.

Analysis of carbon emission intensity in different regions

From the analysis of *Figure 7*, Jiuzhai Valley entrance Administration office has the highest carbon emission intensity, followed by the business in the entrance, the scenic tourist areas, scenic roads, Shuzheng Village, Zharu Village, Heye Village and so on. The reason for the high carbon emissions in the office building in the entrance lies in the fact that the office building has concentrated most of the staff of the Jiuzhai Valley Administration, and as a scenic spot, the staff are all on duty without holidays in the peak season. The calculation of carbon intensity adopts the land area rather than building area, so the carbon emission intensity is high, but the total amount is not big. The commerce in the entrance is the second largest area of carbon emission intensity, because the tourist's limited tourist demand in Jiuzhai Valley is released outside the Valley, and the commercial location in the entrance is good so that the consumption of dining, shopping and accommodation is increasing, so the intensity of carbon emission is relatively high. Scenic tourist area is the third largest area of carbon emission, because the tourist solid waste, feces, sewage produced the most in this area. Scenic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74777493

road carbon intensity is also large, mainly because the total amount of vehicle carbon emissions is large. In summary, it can be seen that the office of the Administration should design corresponding energy saving and emission reduction daily norms, promote the staff to participate in the construction of low-carbon scenic area. The green consumption standards can be implemented for the commerce in the entrance, and carbon reduction targets should be put forward to commercial organizations. For waste management, it should focus on the management of tourists' abandonment of garbage and the cultivation of water-saving awareness. The management of road carbon emissions can be achieved by improving vehicle emission standards and operational efficiency.

Environmental externality analysis of carbon footprint

From the regional transfer of final carbon emissions, 47.3% of the carbon emissions generated by human activities in Jiuzhai Valley Nature Reserve are transferred outside the Reserve, while 52.7% of which are still in the Reserve. The total carbon footprint generated by 52.7% carbon emissions is 2041.05 hm^2, which accounts for only 3.13% of the biological productivity areas in Jiuzhai Valley, as shown in *Table 3*.

Table 3. *Environmental externalities analysis of carbon footprint in Jiuzhai Valley*

Externality	Carbon emission t	NPP/hm^2a	Carbon footprint (hm^2)	Percentage
Carbon emissions still in the reserve	11129.56	5.45	2041.05	52.70%
Carbon emissions moved out of reserve	9988.85	5.45	1831.85	47.30%

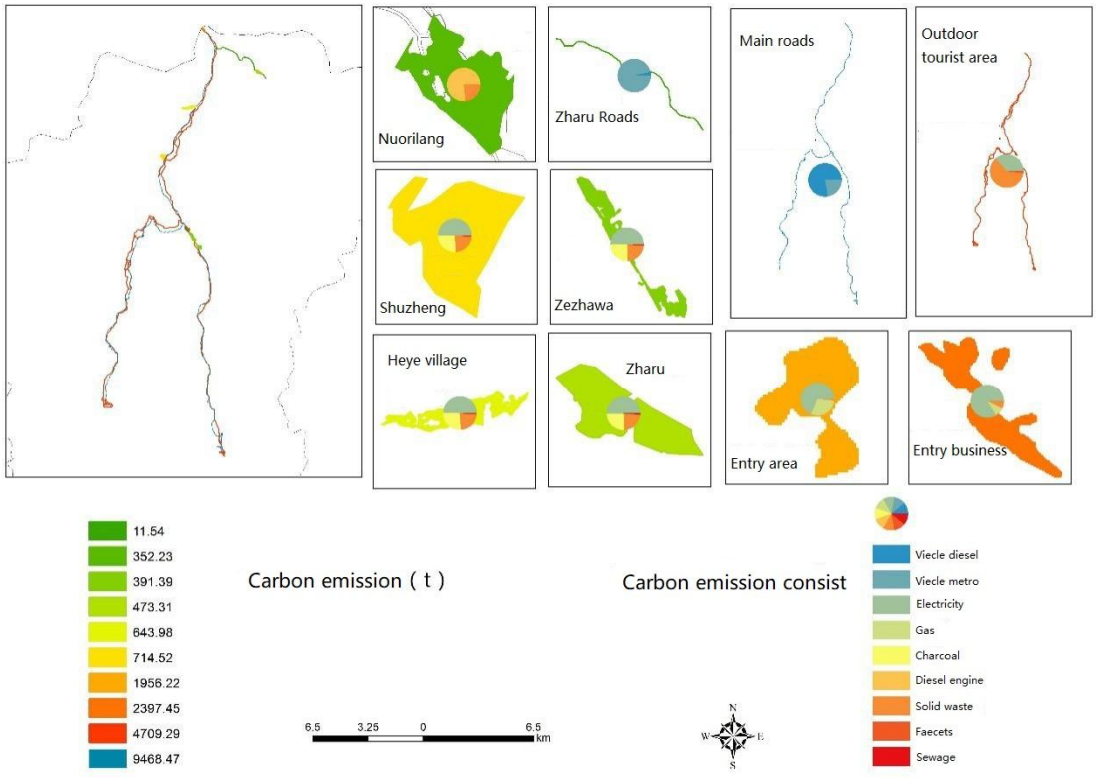

Figure 6. *Regional analysis of carbon emissions in Jiuzhai Valley*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74777493

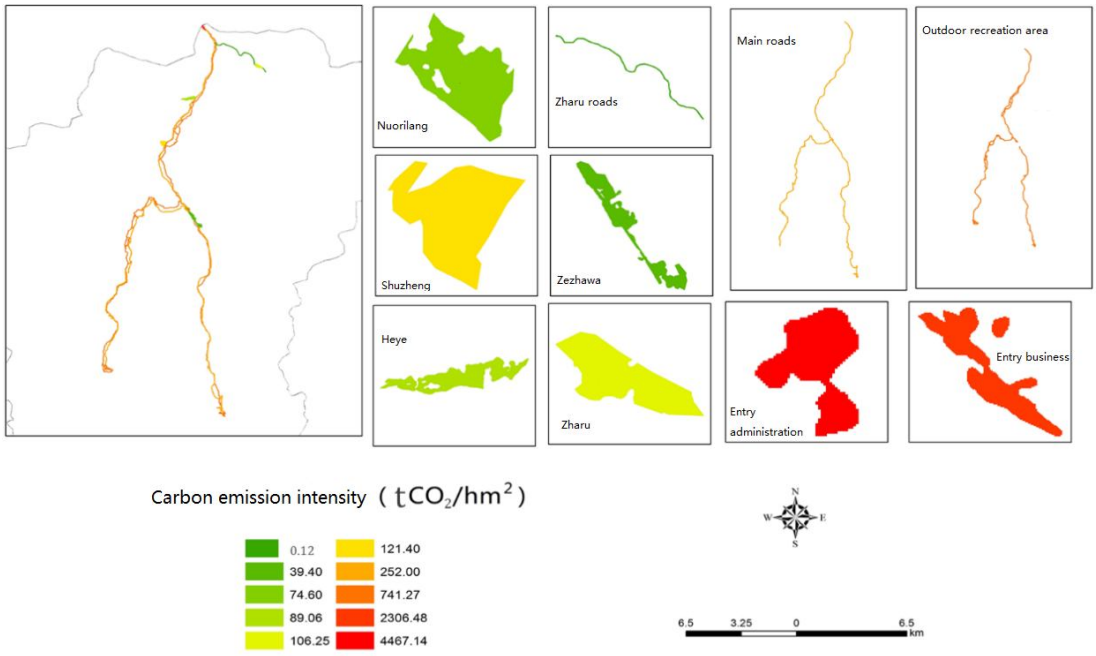

Figure 7. *Carbon intensity analysis of different regions of Jiuzhai Valley construction land*

The main reasons are as follows. First of all, the electric energy that used a lot in Jiuzhai Valley is the indirect carbon emission in the Reserve, and its actual carbon emissions occur in power plants and power stations. The carbon footprint generated by electricity use accounts for 29.16% of the total carbon footprint. Secondly, Jiuzhai Valley transfers all the waste treatment to the treatment plant outside the Valley. For example, the excrement is sent to Jiuzhai Valley fecal plant for decomposition, and sewage and refuse are transported to sewage treatment plant and refuse treatment plant, thus avoiding environmental pollution in the Reserve. The waste carbon footprint accounts for 18.14% of the total carbon footprint of Jiuzhai Valley.

The external transfer of carbon footprint in Jiuzhai Valley Nature Reserve reflects the transfer or shift of environmental costs, or environmental externalities, or the Not In My Back Yard (NIMBY) of the nature reserves. The fact that Jiuzhai Valley Nature Reserve transfers its carbon emissions to the external environment can contribute to the protection of its fragile ecosystem and diverse biological environment and to the increase of carbon storage and carbon absorption capacity of the vegetation in the protected areas, and the prevention of the conversion of soil to carbon emission. It is also beneficial to realize scale effect, save energy cost and improve energy utilization efficiency by unified treatment of waste outside the Valley.

Conclusion and discussion

In 2012, the carbon footprint of human activities in Jiuzhai Valley was 3872.9 hm^2, accounting for only 5.94% of the biological productivity area in Jiuzhai Valley Nature Reserve, and the average carbon emission per capita in Jiuzhai Valley was much lower than that in China and the world. This indicates that there is a huge ecological surplus

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74777493

between the total supply of productive land provided by the ecosystem of Jiuzhai Valley Nature Reserve and the carbon footprint generated by absorbing human activities, which can not only support the sustainable development of tourism in Jiuzhai Valley in the future, but also make a great contribution to our ecological environment, providing a large number of carbon sinks.

From the perspective of the main body of the carbon footprint, the final carbon footprint that tourists need to bear is 88.88% of the total carbon footprint, in which the direct carbon footprint generated by tourists' own activities accounts for only a third of the total carbon footprint, while the other two thirds of the total carbon footprint are transferred by the commerce and Reserve management. The operating company that provide tourists with transportation, catering, accommodation (guesthouse in the entrance), the shopping companies causes the largest carbon footprint, accounting for 44.78% of the total carbon footprint in Jiuzhai Valley.

Comparing the carbon footprint of tourists with that of residents, the carbon footprint produced by one resident in the Reserve is equivalent to that of 367 tourists. In 2012, for example, 1241 residents in the Reserve produced the same carbon footprint as 455212 tourists. If the number of tourists is less than 455212, the activity of residents is the main cause of the negative impact of human activities on the environment of the Reserve, and tourist activity is the secondary motivation.

From the perspective of the location of the carbon footprint, the Reserve road is the largest carbon footprint producing area, accounting for 44.89% of the total carbon footprint, which is caused by the traffic carbon emissions from tourist vehicles, working vehicles and private cars. Jiuzhai Valley outdoor tourism area (excluding highway) is the second largest area of carbon footprint, accounting for 22.43% of all carbon footprint, which is mainly caused by waste and power consumption in the Reserve. The carbon footprint in the entrance of Jiuzhai Valley accounted for 20.62%, which mainly comes from the work of the commerce and Administration in the entrance of Jiuzhai Valley. Village carbon footprint should not be ignored, accounting for 10.40%, mainly from the lives of residents and a small number of family business activities. The carbon footprint of Nuorilang is the smallest, accounting for 1.67%.

From the regional transfer of final carbon emissions, 47.3% of the carbon emissions generated by human activities in Jiuzhai Valley Nature Reserve are transferred outside the Reserve, while 52.7% of which are still in the Reserve. The total carbon footprint generated by 52.7% carbon emissions is 2041.05 hm^2, which accounts for only 3.13% of the biological productivity areas in Jiuzhai Valley. The external transfer of carbon footprint in Jiuzhai Valley Nature Reserve reflects the transfer or shift of environmental costs, or environmental externalities, or the Not In My Back Yard (NIMBY) of the nature reserves.

From the perspective of the role of tourism development in carbon reduction, tourism development cannot reduce the carbon footprint of human activities in tourist areas, and tourism development is only conducive to the industrial transformation of tourist destinations, which may helps to avoid extensive industrial development producing a larger carbon footprint. Tourism development limits the unlimited growth of residents' carbon footprint, but increases the carbon footprint generated by tourists' tourism activities. Tourism activities become the main driving factor of the carbon footprint of nature reserves. If the environmental impact of nature reserve residents is greater than that of tourists, the reason is that the tourist destination is still in its early stage of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74777493

development, or the tourism industry is not attractive enough to allow residents to move to tourism employment, and of course, the lack of supervision should be also to blame.

Acknowledgements. We are very grateful to Shangguan Xiaoyan in Jiuzhai Valley Administration Bureau, for helping data collection, thereby making our investigation proceeding smoothly; to Ye Bin for his unpublished energy consumption data; to director Deng Guiping for help at diverse aspects; to Zhan Qilin for technical help at various phases of the project. Abstract. Preharvest sprouting in wheat (*Triticum aestivum L.*) is the germination of grains in the ears when long range rainfall or damp conditions prior to harvest occur. E3 ubiquitination (type RING-H2) RING finger protein plays a key role in dealing with abiotic stresses in plants, which could be used to improve the PHS resistance of wheat. The full-length cDNA of a wheat RING finger gene named *TaRHA2b* was firstly cloned from wheat. Bioinformatic analysis and expression profile analysis of the *TaRHA2b* gene were carried out. The results indicated that the full-length cDNA of *TaRHA2b* was 845bp containing 465bp open reading frame which encoded 154 amino acid residues. The genomic *TaRHA2b* gene had no introns. The protein encoded by *TaRHA2b* gene was consisted of Zinc finger RING-type profile. Blast and phylogenetic analysis showed that the protein encoded by *TaRHA2b* shared the identity with *RHA2b* from the *Arabidopsis*. The result of semi RT-PCR showed that expression of *TaRHA2b* gene was significantly tissue-specific. The result of qRT-PCR showed that the expression of *TaRHA2b* in the seeds was significantly higher than the expression of gene expression after soaking germination. The sensitivity of this gene to abscisic acid was significantly increased. *TaRHA2b* gene may play an important role in seed dormancy during germination, which could be used to improve the PHS resistance of wheat.
Keywords: *wheat, bioinformatics analysis, expression profile, seed dormancy, preharvest sprouting*

Abbreviations: ABA, abscisic acid; PHS, preharvest sprouting; RING, Really Interesting New Gene; E1, ubiquitin-activating enzymes; E2, ubiquitin-conjugating enzymes; E3, ubiquitin protein ligase; ORF, open reading frame; Rel.Exp, relative expression of gene

Introduction

Pre-harvest sprouting (PHS) is one of the major adverse effects of high yield and stable yield of wheat (Xiao et al., 2002a; Li et al., 2004). In China, the phenomenon of wheat spike germination is particularly serious. Spike germination occurred frequently and seriously in the world's major wheat producers, including Canada, the United States, Britain, Australia, Brazil, Germany, Sweden and so on. Direct annual losses caused by PHS approach $1 billion dollars worldwide (Liu et al., 2013). The yield reduction caused by the problem of wheat spike germination accounts for nearly 83% of the total wheat planting area. Seed viability and hydrolysis of starch and protein in the endosperm are always reduced after PHS (Xiao et al., 2002b). At present, most of the wheat varieties used in the production have certain ear sprouting characteristics. The way to solve the PHS was as follows: firstly, the application of chemical control technology; secondly, breeding varieties with resistance to PHS. Breeding resistant cultivars is the best way to solve the problem of sprouting, but the selection and application was restricted by limited resistance source. It is very important to excavate

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74957510

good genes of PHS resistance, which is an ideal way to solve the PHS problem. In order to make full use of the RING finger gene to improve the resistance to PHS in wheat, a RING finger transcription factor gene *TaRHA2b* was cloned from wheat by RT-PCR and RACE amplification. Bioinformatic analysis and expression profile analysis of the *TaRHA2b* gene with the treatment of different abscisic acid (ABA) concentration were carried out. The research could provide some reference for studying the mechanism of *TaRHA2b* gene in wheat dormancy, which may be used as an excellent gene resource to improve PHS resistance.

Review of literature

The ubiquitination process is accomplished by the continuous action of ubiquitin-activating enzymes (E1), ubiquitin-conjugating enzymes (E2) and ubiquitin protein ligases (E3), and the specificity of the ubiquitin-conjugating enzyme E3 binding substrate to a great extent (Smalle and Vierstra, 2004). In the *Arabidopsis* genome, more than 1300 genes are predicted to encode different types of E3 ligases, which means that ubiquitination is involved in a wide range of cellular metabolic processes and fine adjustment of life activities (Li et al., 2017). It was found that ubiquitination linked many components of plant biology through molecular genetic analysis, including cell cycle, embryonic development, light morphogenesis, regulation of day and night patterns, hormone signaling, homologous transformation, resistance to disease and aging (Liu et al., 2017).

Ubiquitin E3 ligases are mainly classified into three groups: RING (Really Interesting New Gene) finger protein family, HECT protein family and U-box family. At present, Ring finger protein family was found to be the largest among them. There were 469, 488, 399, 725, 330 and 688 possible RING finger E3 ligase family members in *Arabidopsis thaliana*, rice, poplar, soybean, grape and apple, respectively (Kraft et al., 2005; Du et al., 2009; Lim et al., 2010; Li et al., 2011).

RING finger protein consists of a large family of proteins, which is ubiquitous in eukaryotic organisms. The RING finger domain is a typical structural feature, and it has been shown that RING finger domain plays an important role in abiotic stress of plants (Zeba et al., 2009). The RING finger domain contains a conserved amino acid sequence: Cys-X2-Cys-Xn (9-39)-Cys-X (1-3) -His-X (2-3) –Cys/His-X2-Cys-X (4-48) -Cys-X2-Cys (Cys is a cysteine residue, His is a histidine residue, X is an arbitrary amino acid residue) (Kraft et al., 2005). According to the number and location of Zn^{2+} binding residues Cys and His, the RING finger family can be divided into nine subgroups: RING-HC, RING-H2, RING-v, RING-C2, RING-D, RING-S/T, RING-G, RING-mH2 and RING-mHC (Li et al., 2011). At present, many RING finger proteins have been isolated from many plants.

In the previous study, RHA2b played an important positive role in ABA-mediated seed maturity and early germination in *Arabidopsis* (Li et al., 2011). In order to solve the problem of wheat PHS, scholars at home and abroad have conducted a series of studies on the mechanism of wheat ear germination and made many remarkable achievements. The apparent physical and physiological characteristics of wheat seeds, including ear morphology (Zanetti et al., 2000), the color of the seed coat (Torada and Amano, 2002; Bassoi and Flintham, 2005), seed structure and water absorption (King and von Wettstein-Knowles, 2000), seed dormancy (Andreoli et al., 2006; Hughes et al., 2010), ABA content (Gerjets et al., 2010) and α-amylase activity (Major et al., 2001), was studied. The characteristics of genes related to PHS or seed dormancy and the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74957510

positional cloning of QTLs (Zanetti et al., 2000; Major et al., 2001; Bassoi and Flintham, 2005; Somers et al., 2007; Chen et al., 2008) was studied. PHS resistance in wheat is a quantitative trait, and relevant quantitative trait locuses linked to PHS have been reported on almost all chromosomes (Ogbonnaya et al., 2008; Munkvold et al., 2009). From the existing research results, most researchers agree that the germination of wheat spike is the result of the interaction between genotype and environment. The dormancy characteristics of plants are closely related to their spike germination characteristics. PHS-resistant wheat germplasm resources are scarce. The *VP1* and *Trx* genes have been used to increase the PHS resistance of wheat (Li et al., 2009; Huang et al., 2012). Although these attempts have yielded some progress in controlling seed dormancy and PHS, more work is required.

Materials and methods

The wheat variety "Zhengmai 9023" was tested. Zheng mai 9023 is an excellent wheat variety, but it is prone to sprouting. Further research will be carried out based on the transgenic operation of this variety to improve the resistance of PHS. Plant expression vector PGM-T, Escherichia coli DH5a and Taq DNA polymerase were purchased from Tiangen (Tiangen Biotech (Beijing) Co., Ltd., Beijing, China). MiniBEST Plant Genomic DNA Extraction Kit, Plant total RNA extraction reagent Trizol, PrimeScript^{TM} RT reagent Kit (Perfect Real Time) kit, T4 DNA ligase, TranZol^{TM} Plant kit and SYBR Premix Ex Taq^{TM} II (Tli RNaseH plus) were purchased from TaKaRa (TaKaRa Biotechnology (Dalian) Co., Ltd., Dalian, Japan).

Extraction of total DNA and RNA and synthesis of cDNA first strand

DNA was extracted from wheat germ with MiniBEST Plant Genomic DNA Extraction Kit. Trizol reagent was used to extract the total RNA from wheat germ. The extracted RNA was tested for quality and purity and then stored in a refrigerator at -80°C for reserve. PrimeScript^{TM} RT reagent Kit (Perfect Real Time) was used to synthesize cDNA from total RNA. All operations are performed according to the instructions of the kits. The cDNA was stored at -80°C for later use.

Cloning of TaRHA2b gene

According to the amino acid sequence of RING finger gene *AtRHA2b* of *Arabidopsis thaliana*, GenBank EST data was searched and many expression sequences of its highly homologous origin were obtained. By software splicing, analysis and in vitro splicing, a complete cDNA sequence with RING finger structure domain was obtained from wheat database (National Center for Biotechnology information). According to splicing products, specific Primer5.0 software was used to design the primers for the experiment (*Table 1*), and target gene prediction and in vitro splicing were conducted.

The wheat cDNA was used as template for PCR amplification. PCR reaction system 20 μL: 10x PCR Buffer 2.0 μL, 2.5 mM dNTPs 1.6 μL, 10 mM upstream and downstream primers each 0.8 μL, Taq enzyme 0.3 μL, cDNA template 1.0 μL, ddH_2O complement 20 μL. Response procedures: 94°C pre degeneration 3 min; 94°C modified 30 s, 50°C annealing 40 s, 72°C for 1 min, 30 cycle; 72°C extension time for 10 min.

The primer pairs P1-F and P1-R were designed according to the sequence. By using bioinformatics mosaic and RACE amplification, the unknown segment of the gene was

DOI: http://dx.doi.org/10.15666/aeer/1704_74957510

cloned. The full-length cDNA sequence of wheat *TaRHA2b* gene was obtained by RT-PCR amplification with specific primers P2-F and P2-R designed according to the above product sequences. The PCR products were recovered and connected with the pGEMT vector, and the recombinant plasmid transformed into E. coli DH5α competent cells, and the positive clones were screened and sent to BGI (HuaDa Biotechnology co., ltd., China) for sequencing.

Bioinformatics analysis of TaRHA2b gene

Based on cDNA sequence, using NCBI site ORF Finder (https://www.ncbi.nlm.nih.gov/orffinder/) speculation TaRHA2b open reading frame, SingaIP TaRHA2b protein 4.1 (http://www.cbs.dtu.dk/services/SignalP/) analysis of signal peptide, TMHMM Server2.0 (http://www.cbs.dtu.dk/services/TMHMM/) to predict transmembrane regions (Krogh et al., 2001). Using SMART online server (http://smart.embl-heidelberg.de/) domain analysis of protein structure. The consistency of *TaRHA2b* homologous genes with other species was analyzed using DNAMAN, and the evolution tree was constructed with the software MEGA 7.0. The RHA2b interacting proteins network can be predicted by string software.

Tissue specific expression analysis of TaRHA2b gene

The Root, stem, leaf, cob, lemma and endosperm from 25d flowering wheat plants were taken. RNA was extracted, and reverse transcription was conducted to synthesize the first strand of cDNA.

And PCR amplification was conducted with the first strand of cDNA as template. The reaction system was the same as above. Reaction conditions: 94°C for 3 min, 94°C for 30 s, 54°C for 30 s, 72°C for 40 s, a total of 28 cycle, 72°C extension time for 10 min, electrophoresis detection of PCR products.

The *Actin* gene products amplified by wheat *Actin* gene specific primers were taken as internal reference. The primers of *Actin* gene used in PCR reaction were P3-F and P3-R (*Table 1*). And the primers of *TaRHA2b* gene were P4-F and P4-R (*Table 1*). According to the PCR reaction mixture system, PCR amplification conditions as follows: 94°C 3 min, 94°C for 30 s, 54°C for 30 s, 72°C for 35 s, a total of 28 cycle. 72°C

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74957510

for 10 min, RT-PCR product after 1.0% agarose electrophoresis detecting camera, preservation. The experiment was repeated for three times.

Analysis of TaRHA2b gene expression under ABA treatment

To further study the ABA response of *TaRHA2b* gene during seed germination, qRT-PCR was used to analyze the expression of *TaRHA2b* gene by ABA treatment at different concentrations and at different times at the same concentration. ABA solutions of different concentrations (*Table 2*) were used to treat wheat seeds with full and equal grain size three days after germination after disinfection. RNA was extracted with TranZol^{TM} Plant kit after 12 hours of sampling. PrimeScript^{TM} RT reagent Kit (Perfect Real Time) was used to synthesize cDNA from total RNA. All operations are performed according to the instructions of the kits. The cDNA was stored at -80°C for later use.

Table 2. *Different content of the ABA in the present study*

Group number	ABA content (μM)
1	0
2	0.25
3	0.5
4	1.0
5	2.0
6	3.0
7	4.0
8	5.0

Wheat seeds with full and equal size after disinfection were soaked with ABA solution of 0.5 μM, treatment without ABA was set for control, and samples were taken at different time (*Table 3*). RNA of dry seeds without soaking was extracted at the same time. PrimeScript^{TM} RT reagent Kit (Perfect Real Time) was used to synthesize cDNA from total RNA. The cDNA was numbered and stored at -80°C for later use.

Table 3. *Sampling time of the experiments with the treatment of 0.5 μM ABA*

Group number	Sampling time (h)
1	0
2	12
3	24
4	36
5	48

Fluorescence quantitative PCR was used to analyze the *TaRHA2b* gene expression under ABA treatment with the primers P4-F and P4-R and internal reference *Actin* gene primers P3-F and P3-R (*Table 1*). According to the relative quantitative method to calculate: The relative expression of gene (Rel.Exp) = $2^{-\Delta\Delta Ct}$, among them $-\Delta\Delta Ct$ = Calibrator ΔCt - ΔCt (the unknown sample), ΔCt (unknown sample) = (Ct) internal gene - (Ct) target gene, Calibrator ΔCt = (Ct) reference sample internal gene - (Ct) reference sample target gene. The reaction system of fluorescence quantitative PCR was 20 μL: SYBR Premix Ex Taq^{TM} II, 10 μL, PCR Forward Premer (10 μM) 0.8 μL, PCR Reverse Premer (10 μM) 0.8 μL, ROX Reference Dye II (50x), cDNA template 2 μL, ddH_2O up to 20 μL.

Statistical analysis

The software package SPSS 13.0 was used for statistical analysis. For comparing results of different treatments, the Tukey ANOVA test was performed. Differences were considered significant for $P<0.05$.

Results

Analysis of TaRHA2b gene sequence and its coding protein structure

cDNA cloning of wheat *TaRHA2b* gene was synthesized using bioinformatics splicing combined with RACE amplification. First, the amino acid sequence of RING finger gene *AtRHA2b* was used to search for GenBank EST data, and the wheat EST (CA741783) with high homology was obtained (*Fig. 1A*). Secondly, specific primers P2-1-F and P2-1-R, P2-2-F and P2-2-R were designed according to the wheat EST sequence, and 5 'RACE (*Fig. 1B*) and 3' RACE (*Fig. 1C*) were respectively used to clone the unknown regions of the TaRHA2b gene. Finally, according to the above product sequence design, the specific primers P2-F and P2-R were used to amplify the full-length *TaRHA2b* fragment by RT-PCR (*Fig. 1D*), and the target sequence was obtained. The sequencing results confirmed that the length of *TaRHA2b* gene was 845 bp, including the 5 '-end non-coding sequence of 79 bp, the 3' -end non-coding sequence of 301 bp and the open reading frame (ORF) of 465 bp, encoding 155 amino acids (*Fig. 2*), the molecular weight was about 16.94 kD, and the isoelectric point was 7.77, belonging to weakly alkaline protein. This gene was named *TaRHA2b*. The GenBank accession number of the *TaRHA2b* gene is JN661690.1.

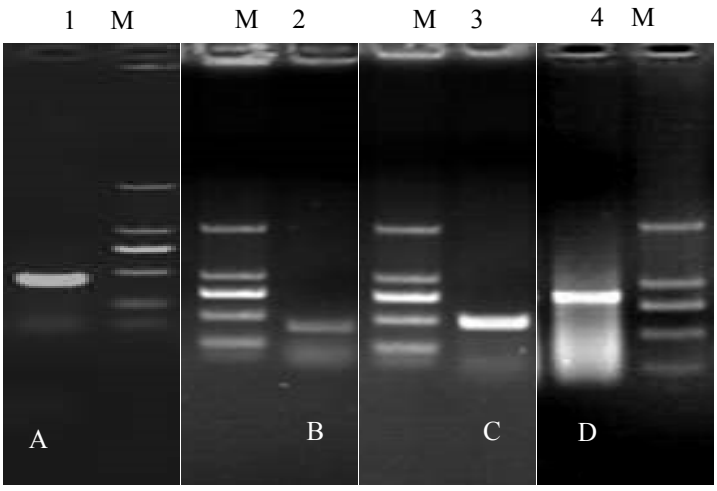

Figure 1. *Amplification of cDNA fragments of TaRHA2b gene in wheat immature endosperm. A, EST of TaRHA2b fragment; B, 3' RACE of TaRHA2b fragment; C, 5' RACE of TaRHA2b fragment; D, full-length TaRHA2b fragment; M, marker*

To further obtain the detailed information of the *TaRHA2b* gene, PCR amplification was performed using primers P2-3-F and P2-3-R (*Table 1*) with wheat genomic DNA as the template. The amplification products were sequenced. The analysis of sequencing showed that *TaRHA2b* gene had no introns.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74957510

The results of SingaIP 4.1 analysis of the signal peptide software showed that TaRHA2b contains a signal peptide sequence with a length of 32 (S^1-F^{32}) and 39 (M^1-M^{40}) amino acid residues, indicating that this kind of protein needs transmembrane transfer (localization) during the synthesis process, and then the signal peptide can be removed under the specific protease to form the mature protein sequence. Further structural analysis revealed that all RHA transcription factors, including TaRHA2b, contained motif with a length of 49 amino acid residues (RING-H2 motif), $CX_2CX_{14-15}CXHX_2HX_2CX_3WX_{6-8}CPXC$.

The sequence combination and similarity analysis of RING-H2 motif with 4 types of RING finger proteins (BOXSHADE 1.80) were performed (*Fig. 4*). The results showed that the amino acid sequence from wheat was similar with RHA2a and RHA2b from the *Arabidopsis*, indicating that this RING finger transcription factor and AtRHA2b belonged to the same family.

Figure 4. *Comparison of the RING finger motif sequences of four type RHA proteins. DOI: http://dx.doi.org/10.15666/aeer/1704_74957510

By applying MAGE software, the protein sequence of RING finger transcription factor was compared multiple times to map the phylogenetic tree (*Fig. 5*). The results showed that *TaRHA2b* gene was very similar to *AtRHA2b* gene.

The interacting protein network of RHA2b includes KIN1(AT5G15960.1), ATDI8(AT5G66400.1), AT5G12110(AT5G12110.1), KUOX1(AT5G07480.1), KUF1(AT1G31350.1), AIRP1(AT4G23450.2), SDIR1(AT3G55530.1), KEG(AT5G13530.1), AT5G58410(AT5G58410.1) and NAC019(AT1G52890.1) (*Fig. 6*). RHA2b is involved in the ubiquitination of proteins, cell protein metabolism, and response to acidic compounds. The function of proteins interacting with RHA2b is listed in *Table 4*. The results showed that *RHA2b* gene is essential for plant growth and development and stress response.

Tissue specific expression analysis of TaRHA2b gene

The root, stem, leaf, cob, lemma and endosperm of wheat were used to detect expression arrays of *TaRHA2b* gene (*Fig. 7*). There was strong expression of *TaRHA2b* gene in the cob, lemma and endosperm tissue, while weak expression of *TaRHA2b* gene in root, stem and leaf tissue. The result showed that the expression of *TaRHA2b* gene in wheat is tissue-specific.

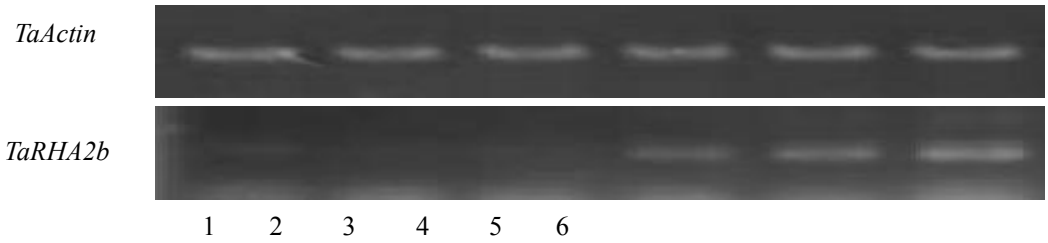

Figure 7. *Expression analysis of TaRHA2b gene in different organs of wheat. Expression was analyzed by semi-quantitative RT-PCR.1, roots; 2, stems; 3, leaves; 4, cob; 5, lemma; 6, endosperm*

Expression profile of TaRHA2b gene under ABA treatment

The results of tissue specific expression analysis of *TaRHA2b* gene showed that *TaRHA2b* gene was highly expressed in endosperm, and it can be inferred that *TaRHA2b* gene may be involved in seed germination. ABA is an important plant hormone that regulates seed maturation, development and germination. Therefore, in order to study whether *TaRHA2b* gene is involved in ABA signaling pathway, we analyzed the response of *TaRHA2b* gene to exogenous ABA during wheat seed germination.

The results showed that the transcription expression of *TaRHA2b* gene was induced by ABA (*Fig. 8*). The different ABA concentration (0 μM, 0.25 μM, 0.5 μM, 1.0 μM, 2.0 μM, 3.0 μM, 4 μM and 5 μM) was used to explore whether the *TaRHA2b* gene was sensitive to ABA or not. With the increase of ABA concentration, the gene expression level gradually increased. The gene expression level was at the expression peak at 0.5 μM, which was extremely significant compared with the control ($p < 0.01$). After that, the *TaRHA2b* gene expression level gradually decreased. And The expression level of the *TaRHA2b* gene was similar between the experimental group and the control group. So the 0.5 μM ABA concentration was used for follow-up research.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74957510

ABA response analysis of TaRHA2b gene in early stage after germination

It showed that *TaRHA2b* gene expression is highest in dry seeds (*Fig. 9*). During seed germination, *TaRHA2b* gene expression decreased as a whole compared with dry seeds. It decreased most significantly at the stage of 12 h with 0.5 μM ABA treatment and increased at the stage of 24 h with 0.5 μM ABA treatment. The expression of *TaRHA2b* gene in the samples with the treatment of 0.5 μM ABA was higher than the samples without the treatment of ABA, and the second half of the S curve of *TaRHA2b* gene expression in the treatment group showed a tendency to be straightened.

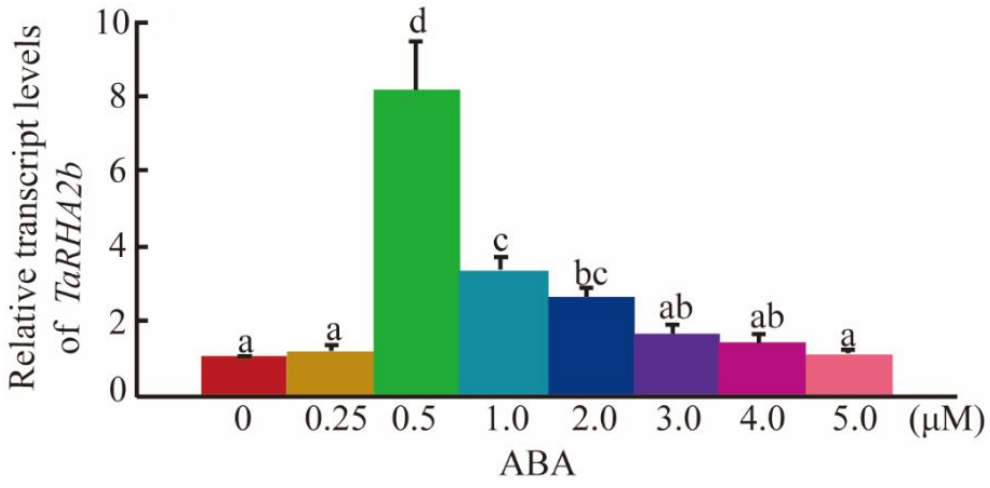

Figure 8. *TaRHA2b expression in 3-d-old seedlings with the treatment of different ABA content for 12h. The letters 'a' to 'd' indicate statistically significant differences by Turkey's least significantly difference test ($p<0.05$)*

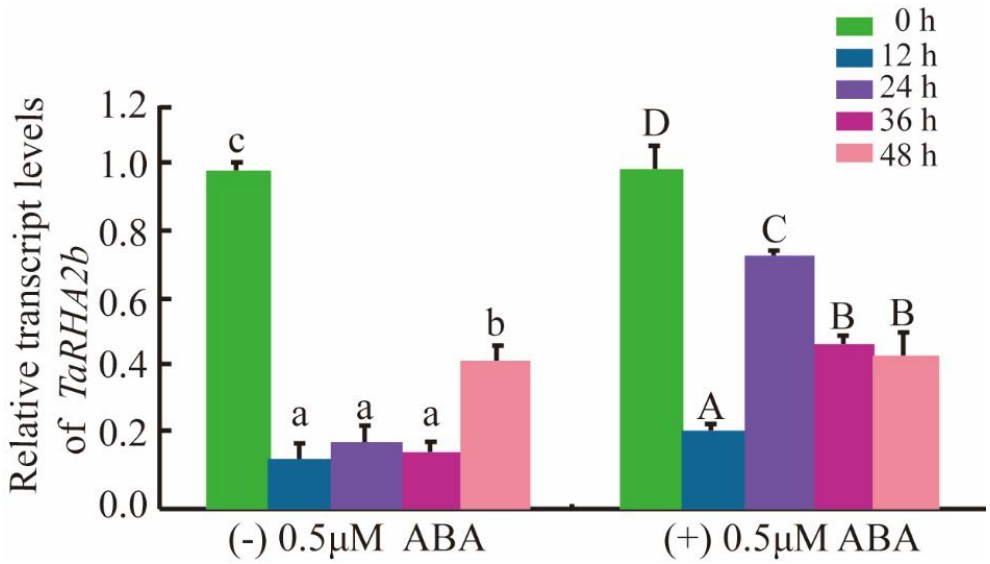

Figure 9. *TaRHA2b expression in seeds during germination with the treatment of 0.5μM ABA. (-) 0.5μM ABA, the letters 'a' to 'd' indicate statistically significant differences by Turkey's least significantly difference test ($p<0.05$); (+) 0.5μM ABA, the letters 'A' to 'D' indicate statistically significant differences by Turkey's least significantly difference test ($p<0.05$)*

Discussion

Many studies have shown that over-expression of RING-H2 protein in model plant can affect abiotic stress (Lyzenga and Stone, 2012; Stone, 2014). Some RING finger type E3 ubiquitin ligase is involved in some specific plant signaling pathways, mainly ABA signaling pathways (Devoto and Turner, 2003; Moon et al., 2004; Schwechheimer and Schwager, 2004; Hoecker, 2005; Dreher and Callis, 2007). Several RING finger genes have been reported. AIP2 and KEG, two proteins with RING finger structure in ABA signaling pathway, are two important positive regulators of ABI3 and ABI5, respectively, which are negative regulators of ABA signaling pathway (Stone et al., 2006). It was found that CIPK26 interacted with KEG through yeast two-hybridization, and proved that CIPK26 participated in ABI5-mediated and KEG-mediated ABA stress response (Lyzenga et al., 2013).Whether there is an interaction among the three protein (CIPK26, ABI5 and KEG) is unclear. SDIRIP1, the substrate of SDIR1, was degraded by ubiquitin-proteasome pathway. SDIR1 controlled ABA related germination and stress response. SDIRIP1 participates in ABA and salt stress pathways by negatively regulating ABI5 expression (Zhang et al., 2015). Overexpression of *AtXerico* in *Arabidopsis thaliana* and rice significantly increased plant sensitivity to ABA and salt, and significantly increased plant drought resistance (Ko et al., 2006; Zeng et al., 2015). Overexpression of *AtXerico* homologous gene *OsRHP1* in rice showed increased drought and salt tolerance, ABA content, and the expression of ABA biosynthetic genes and related genes (Zeng et al., 2014). The overexpression of *ZmXerico* in maize can improve drought resistance and ABA content. It is also proved that *ZmXerico1* plays a role in ABA dynamic equilibrium by regulating the stability of ABA 8 '-hydroxylase protein and is a new control point in the ABA regulation pathway (Brugiere et al., 2017).

A RING finger transcription factor gene *TaRHA2b* was cloned by RT-PCR and RACE in this study. It was found that the gene belonged to the typical RING-H2 finger family. The bioinformatics analysis results showed that *TaRHA2b* gene was very similar to *AtRHA2b*. Therefore, it is speculated that *TaRHA2b* is similar in function to *AtRHA2b*.

It can be seen that spike germination caused certain physiological damage to wheat (*Fig. 10*). The dormancy and germination of seeds are regulated by hormones and metabolic pathways inside the seeds. PHS resistance is closely related to seed dormancy. Varieties with strong dormancy have strong PHS resistance, while those with weak dormancy are easy to germinate. The external environment can influence the PHS resistance of wheat to some extent, but the most critical determinant is seed dormancy, especially the endogenous ABA content and the sensitivity of seeds to ABA. Genetic studies of several species have also confirmed that ABA can effectively induce seed dormancy.

Overexpression of *RHA2a* in transgenic *Arabidopsis* increased the sensitivity to ABA, increased seed dormancy and decreased seed germination rate (Bu et al., 2009). The *rha2b-1* mutant with high homology between AtRHA2b and AtRHA2a also showed ABA insensitive phenotype and drought sensitivity (Li et al., 2011). The interaction between ATAF2 and RHA2a in yeast were found. RHA2a could negatively regulate Flg22-induced root growth inhibition and seedling growth inhibition in *Arabidopsis thaliana* and promote the growth of Pst DC3000. RHA2a can activate positive regulators by mono-ubiquitinating and stabilizing certain key regulators of the ABA signaling pathway. ANAC019 and ANAC055, two closely related NAC family proteins, were identified as RHA2a-interacting proteins (Bu et al., 2008; Jiang et al.,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74957510

2009). RHA2b targets MYB30 degradation to regulate ABA signal transduction (Zheng et al., 2018).

The analysis of the expression of wheat *TaRHA2b* gene showed its tissue specificity. There was higher expression of *TaRHA2b* gene in the cob, lemma and endosperm tissues than other tissues. It showed that *TaRHA2b* gene was involved in the regulation of seed formation and dormancy.

The germination rate of *Arabidopsis thaliana* seeds over-expression *AtRHA2a* and *AtRHA2b* significantly decreased and the sensitivity to exogenous ABA of them were enhanced. It suggested that *TaRHA2b* may play an equally important role in the dormancy-germination process and could be used as an excellent genetic resource to improve the germination characteristics of spike.

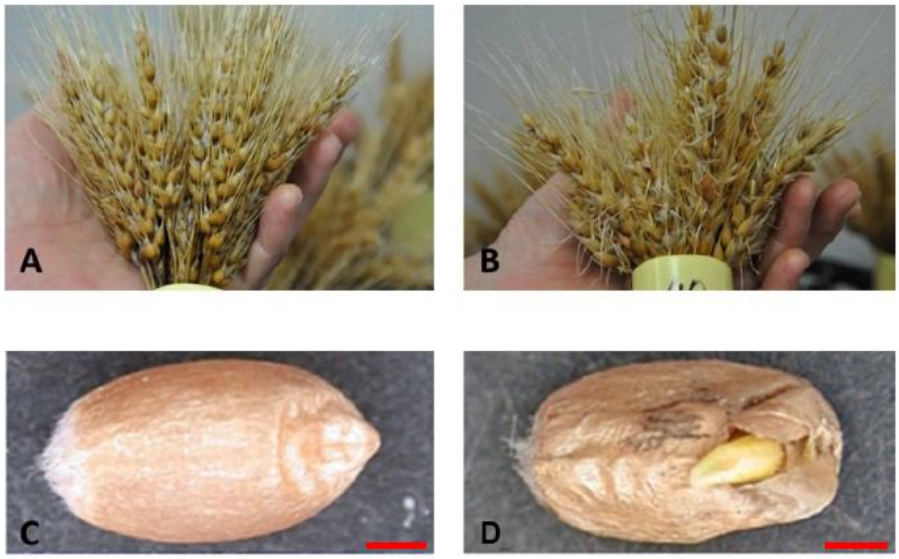

Figure 10. *Physical damage of wheat caused by PHS. A: Spike of PHS-resistant germplasm; B: Spike of PHS-susceptible germplasm; C: Grain of PHS-resistant germplasm; D: Grain of PHS-susceptible germplasm. The bar value is 1 mm*

The expression profile of *TaRHA2b* gene with the treatment of different ABA concentration showed that *TaRHA2b* gene was highly expressed in dry seeds. And its expression decreased rapidly after soaking germination, which was similar to the expression pattern of similar *AtRHA2b* gene in *Arabidopsis thaliana*. The results indicated that the function of *RHA2b* gene in plants is relatively similar, especially in ABA signal transduction pathway. The results showed that *TaRHA2b* gene may be an excellent genetic resource to improve PHS resistance. More work is needed for using *TaRHA2b* gene to improve dormancy and PHS tolerance in wheat.

Conclusion

The full-length cDNA of the RING finger gene *TaRHA2b* was cloned from wheat. The full-length cDNA of *TaRHA2b* encoded 154 amino acid residues, which was consisted of Zinc finger RING-type profile. The genomic *TaRHA2b* gene had no introns. TaRHA2b shared the identity with RHA2b from the *Arabidopsis*. The main result are as

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_74957510

follows: (1) the expression of *TaRHA2b* gene was significantly tissue-specific; (1) the expression of *TaRHA2b* in the seeds was significantly higher than the expression of gene expression after soaking germination; (3) the sensitivity of the *TaRHA2b* gene to ABA was significantly increased. Some questions are as follows: (1) the distribution of *TaRHA2b* gene coding region in donor ancestors and different varieties could be studied to explore the mechanism mediated with *TaRHA2b* gene in PHS resistance;(2) the proteins interacted with TaRHA2b could be screened by yeast two hybrid system, which may be the new genes of PHS resistance genes; (3) how does the *TaRHA2b* gene regulate in ABA signal transduction. Further researches on the mechanism of wheat mediated with *TaRHA2b* gene in PHS resistance should be futher expanded in the future.

Abstract. Improper conversion of grassland utilization patterns leads to soil quality degradation and increased soil erosion. Analysis of the differences and sensitivities of soil physical, chemical and biological quality indicators under different agricultural management practices, research with the development of Xinjiang YiLi Nalati representing the natural grassland grazing grassland, conventional farming and organic farming fields as the research object. The results showed that the degeneration of soil chemical mass will be much more to see for grazing mode. The most sensitive chemical quality index is soil total nitrogen and organic carbon, especially 0.25-2 mm and 2-8 mm soil organic carbon content. The farmland cultivation mode stimulates the soil microorganism's ability of absorbing carbon and nitrogen, which goes against the soil carbon and nitrogen's conservation especially for a long-term fertilizer application in the regular farming mode.
Keywords: *conventional farming, organic farming, land use, lawn, soil quality*

Introduction

Many ecological processes by nature and humans such as vegetation succession, the changes of land use pattern, have influences on the changes of the soil quality. The most profound and directive factors are utilization pattern of soil and the level of management. On the one hand, these factors can lead to soil degradation, soil erosion. On the other hand, they can improve the soil quality and ecological environment. Nowadays, the main reason of the soil degradation is that unreasonable way of land utilization used by humans. There is not a single or multiple index could reflect the combined action between the soil organisms, physics and chemistry. So, there is not established a uniform soil measurement. After many small watershed are developed, the land utilization begins to be diversity. The changes of the soil environment lead to that the function and structure of the ecosystem begin to change. The situation of the soil quality not only reflect the influences of the soil utilization on the soil physics, chemistry and soil quality, but also clear and definite the influences that decision of the soil utilization has on the nutrient cycling, leaching, soil structure, carbon accumulation and other related process.

The change of land to make it arable, which makes the soil organic matter lower. The transformation of arable land from woodland or grassland makes the soil property depredated (Meriles et al., 2008; Chen et al., 2008). For the ecologically fragile area, the soil parent material (parent material), altitude (altitude) and the use of a greater impact on soil properties, which affect the most is how to use the land (Fermont et al., 2008). In recent years, because of the overdevelopment of some where's water and land resource in Ili Valley, the valley terrace pastures which mainly used for animal husbandry degenerate

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75117522

seriously and is becoming the soil and water loss of the basin becoming more and more serious. Yang and Zhang (Yang and Zhang, 2009) analysis the use of change in cross-strait land of the Ili Valley, compared with the year of 1985, the arable land increases of 4.99×10^4 hm^2 entirely. Grassland is the only type of land which is reducing, whose reduced area contains 7.02×10^4 hm^2. The conversion from grassland to cropland accounted for 90.4%. Because of the land development utilization improperly, the net increase of the useless land is 1.07×10^4 hm^2, the net increase of the saline land is 13.04×10^4 hm^2, which all of them cause a series of environmental problems of soil erosion and desertification and salinization. As is regarded to be the research object from the soil in Ili Nalati prairie and developed different kinds of land utilization on soil, the research on grassland development made it a theory evidence to Grazed Grassland, conventional field and organic field on the impact on soil quality and the rational exploitation of regional grassland resources definitely. The research also helps growers make the appropriate land management measures to adjust with.

Materials and methods

Basic situation of region

The study area located at long-term observation sites of grassland management central station of Yili State (North latitude 43°18′-43°22′, East longitude 84°05′-84°09′). The grassland was located in Piedmont plains of altitude 1480 m, perennial resistance to low temperature and drought resistance of Gramineae and soil type was mainly meadow chernozem. The Kunes River was a temperate continental climate type, which belongs to the seasonal snow melt water and rainwater recharge rivers, intra annual variation of small diameter. the length of 258 km, the catchment area of 3532 km^2, The annual average temperature of 8 degrees, the annual rainfall of about 800 mm, The high temperature period is 7-8 months, and the precipitation concentration in 4-6 months, in May the most.

Test design and sample collection

The test set Native Grassland (NG), Grazed Grassland (GG), Six years conventional field (6-yr CF), More than twenty years conventional field (20-yr CF), Six years organic field (6-yr OF) and Thirteen years organic field (13-yr OF) Six treatments. Artificial disturbance of natural grassland is very small, most of the natural grassland has been cultivated for grazing grassland or over 20 years, Grazing period was mainly from September to June. The application of chemical fertilizer (pure nitrogen amount of about 170 kg/hm^2) in Conventional tillage models and The application of organic fertilizer (pure nitrogen amount of about 170 kg/hm^2) in organic cultivation. Soil samples in late September 2010 before the winter collection. Frist dig a pit (30 cm wide and 45 cm deep), and then in the 0-20 cm soil layer collection size consistent with the undisturbed soil sample (length * width * high = 20 cm * 10 cm * 10 cm) and the sampling point as close as possible in the whole soil and bulk density of the samples nearby, to as much as possible to reduce the spatial variability of soil samples, In order to obtain the aggregate distribution of undisturbed soil sample determination. Each treatment takes three undisturbed soil samples, into the square plastic box and carefully transported to the laboratory. Then immediately soil samples screened out by 8 mm soil sieve and the large clods gently crushing along natural fractures, finally analysis of soil aggregates and stability in dried soil samples within the laboratory.

DOI: http://dx.doi.org/10.15666/aeer/1704_75117522

Research methods and measurement items

The study accessed to the soil quality index dividing into soil physical, chemical and biological quality indexes of three types. The first was principal component analysis (PCA), and then was correlation analysis and t-test, which orders to determine the significant factors affecting soil quality changes. Soil aggregate separations use the wet sieving method. According to the above 8 particle size mm soil sieve samples were divided into the following categories: large aggregates (2-8 mm), smaller aggregates (0.250-2 mm), micro-aggregate (0.053-0.25 mm) and silt plus clay group (< 0.053 mm). The soil samples were separated and arranged to determine the particle composition, soil organic carbon, total nitrogen and so on. The soil aggregate : 0.053 mm, 0.053-0.25 mm, 0.250-2 mm < 2-8 mm in turn representing as SAP1, SAP2, SAP3 and SAP4, and the particle size of the soil organic carbon content are expressed as SOC1, SOC2, SOC3 and SOC4, the content of soil organic carbon of 0-20 cm representing SOCT. The main indexes measuring methods are shown in *Table 1*. The AWCD and diversity index calculation methods are as follows:

(1) The average absorbance of AWCD can be used to estimate the total capacity of microbial community in the use of carbon sources. (Ai is the relative absorbance of i, and A A1 is the relative absorbance of A1.)

$$AWCD = \sum(Ai - AA1) / 31 \quad \text{(Eq.1)}$$

(2) Shannon-Wiener richness index H was used to evaluate the species richness.

$$H = -\sum Pi \bullet \ln(Pi) \quad \text{(Eq.2)}$$

(3) Shannon-Wiener richness index E was used to evaluate the species richness. (S is the number of the carbon source.)

$$E = H / \ln S \quad \text{(Eq.3)}$$

(4) Shannon-Wiener advantage of D number is used to evaluate some of the most common species of a moderate.

$$D = 1 - \sum(Pi)^2 \quad \text{(Eq.4)}$$

Statistical analysis

Through the SPSS Base Ver17.0 statistical software (SPSS, Chicago, IL, USA) analysis correlation of the data. The multivariate methods such as principal component analysis (PCA) was employed to determine how the samples were different as a whole.

Results and analyses

The influence of grassland development to soil physical quality index

On soil physical quality index for PCA analysis (*Fig. 1*). The projection information indicates that the land use patterns are divided into three categories. The first category is organic farming for 6 years and 13 years. The second category is conventional farming for 6 years and 20 years. Others are processed as the third category. Using correlation analysis,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75117522

of which the results reached a very significant level, for further description of influencing factors of the soil physical quality indicators are shown in *Table 2*. Soil physical indicator of 0.053-0.25 mm aggregates percentage and first principal component PC1 (principal component 1) is a significant positive correlation, 2-8 mm aggregates percentage and first principal component PC1 is a significant negative correlation. That means the positive direction of PC1 and PC2 spindle are organic farming mode. 0.25-2 mm aggregates percentage and second principal component PC2 is a significant positive correlation. That means the negative direction of PC2 spindle and the positive direction of PC1 spindle are conventional farming mode. The negative direction of PC1 and PC2 spindle are the third type of grass mode. Aggregates of particles percentage change indicate the effect of management measures under different land use patterns on soil aggregate. The positive direction of the first principal component is the percentage increase of 0.053-0.25 mm aggregates. The negative direction of it is the percentage increase of 2-8 mm aggregates. All this shows that the farmland management (organic and conventional) mode causes the macro-aggregates crushing and 0.053-0.25 mm micro-aggregates increasing and the grassland management mode is conducive to maintaining 2-8 mm macro-aggregates. The positive direction of the second principal component is the percentage increase of 0.25-2 mm aggregates. This shows that the organic management mode is conducive to the formation of 0.25-2 mm aggregates, but the effect of its formation rate is less than the breakage rate of 0.053-0.25 mm aggregates. This indicates that after the grassland convert to cropland; farmland mode makes soil crush from macro-aggregates into 0.053-0.25 mm micro-aggregates and the overall degradation of soil physical quality. But organic farming management mode can alleviate soil particles' broken, which can make 0.25-2 mm macro-aggregates increase.

Table 1. *Main index measuring method*

Item	Measuring method
Soil bulk (SB)	Cutting-ring method
Soil pH value (pH)	2.5:1 water-soil ratio electrode
Soil organic carbon (SOC) and total nitrogen (TN)	Analysis of carbon and nitrogen analyzer
Soil available phosphorus (AP) and total phosphorus (TP)	MO Ti Sc colorimetry
Soil available potassium (AK) and total potassium (TK)	Flame photometric determination
Soil alkaline hydrolysis nitrogen (AN)	Alkali solution diffusion method
Soil ammonium nitrogen (NH_4^+-N) and nitrate nitrogen (NO_3^--N)	Flow analyzer determination
Soil microbial carbon (SMC) and soil microbial nitrogen (SMN)	Chloroform fumigation extraction method
Oxidized organic carbon (OOC)	Potassium permanganate oxidation colorimetry
Hot water soluble organic carbon (HWSOC)	Distilled water extraction and Potassium dichromate titration
Acid hydrolysis carbon (AOC)	6 M concentrated hydrochloric acid extraction, Potassium dichromate titration
Average color change rate of soil (AWCD)	Biolog analyzer determination
Soil fungi (SFUNG), Bacteria (SBACT) and Actinomycetes Strain (SACTI)	Plate counting method

The influence of grassland development to soil chemical mass index

The PCA analysis (*Fig. 2*) on soil chemical mass, the projection information indicates that the land use patterns are divided into four categories, the first category includes six years of organic farming, 13 years of organic farming and six years of conventional farming, the second category is grazing meadow, the third category is natural grassland, and the fourth category is 20-year conventional tillage. Use correlation analysis can further indicates that soil chemical quality indicators

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75117522

influencing factors shown in *Table 3,* the correlation analysis results reach a significant level. First principal component PC1 and soil total nitrogen content of the soil chemistry indicators, 0.25-2 mm soil organic carbon content, 2-8 mm soil organic carbon content and soil organic carbon content are a significant positive correlation with soil potassium content, soil phosphorus content, < 0.053 mm soil organic of carbon content, 0.053-0.25 mm soil organic carbon content, namely that the positive direction of PC1 spindle are natural grass, 13 years of organic farming, 6 years of organic farming and 6 years of conventional farming; the second principal component PC2 and available potassium content was extremely significant with positive correlation with ammonium nitrogen content, and an acid solution of carbon content was significantly significant negative correlation, i.e. PC2 spindle positive direction represents natural grassland, 6 years of grazing grassland and six years of conventional tillage, the negative direction means 6 years of organic farming, 13 years of conventional tillage or 20 years beyond. The third principal component the PC3, active carbon dioxide content and hot water-soluble carbon content was significantly positively related. The positive direction of the PC3 spindle represents 6 years of conventional tillage, 6 years of grazing grassland and organic farming; therefore, the land use pattern can be divided into four main categories. Soil organic carbon and its components play an important role in many of the features in the soil, as it is considered to be an important indicator of soil quality. The positive direction of the first principal component represents the increase of soil total nitrogen content of the soil chemistry indicators, 0.25-2 mm soil organic carbon content, 2-8 mm soil organic carbon content, soil organic carbon content of soil potassium content, soil total phosphorus, < 0.053 mm soil increased organic carbon content, 0.053-0.25 mm soil organic carbon content. And it shows that soil organic carbon and soil total nutrient have the essential influence on soil chemical quality, especially soil organic carbon and total nitrogen reached a significant positive correlation, which decides the reaction of soil chemical quality to management measures in the land-use mode. The second principal component in the positive direction for the content of soil soluble potassium and ammonium nitrogen increases, the negative direction for the content of acid solution of carbon increases. It shows that the condition that at a certain level of total nutrient, soil available potassium, ammonium nitrogen and hydrolysable carbon content is most sensitive in the secondary impact factor. The field husbandry (organic and conventional) management model destroys soil aggregates, which made the physical protection of the nutrients reduced. Farmland management model led a significant reduction to the soil available potassium and ammonium nitrogen contents, but the content of acid hydrolysis organic carbon increased significantly. The third main component of the positive direction is the content of active carbon dioxide and hot-water-soluble carbon increases, indicating that under the six years of grazing and short-term farming mode (conventional farming and organic farming) the activity of carbon dioxide and hot water soluble carbon can get easily use. With the growth of the cultivation age, organic carbon which is easy to use gradually reduced. This indicates that after the grassland conversed to cropland, the total nutrient in the soil, organic carbon, active carbon dioxide and hot water-soluble carbon first increased under the short-term tillage. With the growth of cultivation age, the content of soil available potassium and ammonium nitrogen decrease significantly at first, and finally the quality of soil chemistry in the farmland all get decreased gradually. Because grazing pattern does not use any exogenous substances, the degradation of soil chemical quality is the most obvious.

The influence of grassland development to soil bio-quality index

On soil biological quality index for PCA analysis (*Fig. 3*), the projection information indicates that the mode of land use is mainly divided into two categories, the first category for tillage (organic and conventional) mode, second kinds of grass mode, using correlation analysis further illustrate the soil biological quality index impact factors in *Table 4,* the results of correlation analysis at significant level. The first principal component PC1 and soil biological indicators of AWCD, microbial nitrogen content was significant positive correlation, namely PC1 spindle orientation for tillage (organic and conventional) mode, the negative direction for second kinds of grassland pattern; as a result of the second main components of PC2 and biological indicators of the quality of impact factors are not significant correlation exists, so on the mode of land utilization soil biological quality impact is very small. The first principal component is the direction for tillage (organic and conventional) model, AWCD and microbial nitrogen content increased, description of farming (organic and conventional) mode of microbial communities using carbon and microbial nitrogen capability is strong, namely farmland management pattern is enhanced by microorganisms on soil carbon and nitrogen utilization ability, relatively speaking, grassland management model for carbon and nitrogen resources conservation. Suggesting that the conversion of grassland to farmland, farmland tillage mode to promote soil microorganisms on carbon and nitrogen resource utilization ability, is not conducive to the soil carbon and nitrogen retention.

Discussion

Soil physical quality index

The analysis and ordination diagram of the principal component of the soil physical quality indicators can reflect the reaction of the soil physical quality due to the change of the land management practices. As the lawn developed to different form with different pattern of land usage, the 0.053-0.25 mm, 0.25-2 mm, 2-8 mm soil aggregates experience significant influence. With the pattern of grassland turns to be conventional or organic farmland, 2-8 mm soil macro aggregate has broken into the smaller micro aggregate, which is consistent with the former research that the water stable aggregate in natural grassland, forest land and grazing grassland are much higher than the farmlands' (Kremer and Kussman, 2011; Kremer and Li, 2003; Guo et al., 2010).

The increase of 0.25-2 mm soil aggregate is the important reflecting for a stability tend of the basic substance in soil and its function unit (Jastrow, 1996; Puget et al., 2000; Six and Elliott, 1998). The results show that the 0.25-2 mm soil aggregate increases gradually in organic farming at the year of 6 and 13, and the 0.25-2 mm soil aggregate decreases gradually in conventional tillage beyond the year of 6 and 20, it may be directly related to the fresh organic material who return back to the soil (Chen et al., 2016; Cole et al., 1993). This shows that organic farming mode is favorable to optimize the soil aggregate's structure. Therefore, land use patterns are determined to be the major factor of soil physical quality under the premise of same climate, same terrain and same soil property. Soil management behavior can future reflects the good or bad of soil physical property.

Soil chemical quality index

Land use and management measures changed the natural grassland soil chemical characteristics, organic farming mode soil chemistry quality is best, conventional tillage 20 years of soil chemistry quality relative worst, the most sensitive chemical quality index is soil total nitrogen and organic carbon ($P < 0.01$), especially 0.25-2 mm and 2-8 mm soil organic carbon content ($P < 0.01$). Conventional farming mode weakened the soil structure, and lead to soil organic carbon and total nitrogen significantly reduced

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75117522

(Jacobs et al., 2009; Koch and Stockfisch, 2006), this may be as cultivation increased soil organic matter mineralization rate relevant (Blair et al., 2006), but organic farming mode organic material not only directly for aggregate function to provide cementing material, compensation soil mineralization, carbon and nitrogen loss, and for soil biological activity provide energy, promoting the soil large aggregate and micro aggregate composition and the stability of the organic matter (Alagoz and Yilmaz, 2009).

At the same time, land use and management measures first cause, total content of soil nutrients and soil organic carbon content changes ($P < 0.01$), the second is ammonium nitrogen ($P < 0.05$) and phosphorus and potassium content ($P < 0.01$), and the last is easy oxidation of organic carbon and thermal hydrolysis organic carbon content ($P < 0.05$). There have been many literature compared the land use and management measures on soil chemical quality index influence, considered that soil organic carbon, total nitrogen, available phosphorus, pH and vulnerable to agronomic measures influence (Voundi and Tonye, 2003; Nosrati et al., 2011), but not for land use and management measures to the chemical quality index of influence sorting, this may and soil chemical properties vulnerable to soil environmental change and crop management measures about influence (Paudel et al., 2012).

Soil bio-quality index

The principal component analysis and correlation analysis interpret the influence of land use and regulative measure to soil bio-quality index, which changes the value of soil microorganism's ability of utilization from carbon source AWCD ($p < 0.01$) and the content of nitrogen in microbial biomass ($p < 0.01$), and both the influence from the two numerical value of tillage pattern (organic and conventional) are larger than the figure from grass pattern. Via an analysis of utilization ability on soil microbial biomass carbon source by Juliet (Juliet et al., 2002) and Cooksona (Cooksona et al., 2008), they also told planting pattern has a big effect on soil microorganism. Applying organic materials can stimulate microbial activity (Tian et al., 2016), applying chemical fertilizer has a little effect on soil microbial activity and microbial biomass (Lovella et al., 1995); however, the long-term applying chemical fertilizer may decrease soil microbial activity (Li et al., 2017). Thus, soil microbial activity can be enhanced when the grassland exploited to the farmland. But the soil microbial activity whose usage is beyond 20 years by conventional tillage decrease, the farmland need fertilization reasonable in order to optimize the environment of soil microorganism and maintain soil microbial activity.

Conclusion

The effect of land use patterns on soil physical quality is more influential than the land management measures, the farmland cultivation mode break the soil macroaggregate to 0.053-0.25 mm smaller microaggregate, but the organic farming management mode can alleviate soil particle crushing and increase the number of 0.25-2 mm macroaggregate.

After the grassland being conversed to the farmland, total soil nutrient, organic carbon, activated carbon oxide and hot water soluble carbon will get much increase in a short-term cultivation mode. But the content of soil available potassium and ammonium nitrogen will get reduced significantly along with the increasing cultivation time, and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75117522

finally the soil chemistry quality index of farmland are all decreasing generally. For grazing mode, as it does not use any foreign matter, the degeneration of soil chemical mass will be much more to see.

After the grassland being conversed to the farmland, the farmland cultivation mode stimulate the soil microorganism's ability of absorbing carbon and nitrogen, which goes against the soil carbon and nitrogen's conservation especially for a long-term fertilizer application in the regular farming mode.

(Received 27th Feb 2019; accepted 3rd May 2019)

Abstract. The paper calculates carbon emissions, and analyses relationship among economic growth, industrial structure, energy structure and carbon emissions using environmental quality equation based on the terminal energy consumption data in 1990-2017 based on Shanxi province in China. The results show that economic development is the main positive driving factor of carbon emissions, industrial structure has an inverted u-shaped curve related with the carbon emissions and there is not a high linear correlation between energy structure and carbon emissions. Finally, some suggestions are proposed to reduce carbon emissions. The energy-intensive provinces should adjust industrial structure and pay more attention to the improvement of technologies, at the same time, should keep the population rate not increasing rapidly and energy structure not degenerating.
Keywords: *carbon emissions; economic growth; industrial structure; energy structure; diversity factors; environmental quality equation*

Introduction

As the biggest carbon emission increment country in the world, China is facing more and more international pressure on carbon emission reduction. As a responsible big country, the Chinese government, in accordance with China's national conditions, stage of development, sustainable development strategy and international responsibilities, has set the goal of self-action to reach the peak of carbon emissions by 2030 and reach the peak as soon as possible. In China, the implementation of energy-saving target responsibility system and the provincial-level decomposition of energy-saving targets require provinces to find out the evolution law of carbon emissions in accordance with their own natural and geographical conditions, resource endowment constraints, economic development models and economic development stages, based on which, to formulate reasonable emission reduction policies, and to achieve the decomposition goals. Rational emission reduction policies promote the smooth completion of the overall emission reduction targets. On the one hand, Energy-intensive provinces need to provide energy for China's development. On the other hand, they have great pressure on

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75237534

emissions, which has become a bottleneck for China to achieve the overall emission reduction goals. Therefore, it is of great practical significance to study the evolution of carbon emissions in energy-intensive provinces, find out the inherent mechanism of carbon emissions growth, and formulate reasonable emission reduction paths for specific provinces, so as to achieve the overall emission reduction goals in China.

Review of literature

In recent years, the growth of carbon emissions has been a hot topic both at home and abroad, and has made great progress. The existing research is mainly as follows, one aspect is the relationship between carbon emissions and the level of economic development and energy consumption. For example, Qi et al. (2015) selected six provinces in central China as the research object and used a variety of econometric analysis methods to study the relationship between economic growth and carbon emissions. Gao et al. (2017) discussed the possibility of the existence of environmental Kuznets curve and the existence of inflection point between carbon emission and economic growth in urban agricultural sector. Gao (2017) empirically analyzed the relationship between the relationship between energy consumption, carbon emissions and economic growth in Beijing Tianjin and Hebei region. Another aspect is to explore the driving forces of carbon emissions, and analyze the influencing factors of carbon emissions. Such as Chen et al. (2012), he analyzed the driving forces of carbon emissions from the theoretical and empirical level. Zhao and Yang (2012) used the factor analyzing method to study the driving force of China's carbon emissions. Xu et al. (2013) explored the driving force of carbon emissions in resource-based provinces combining with the PATH-STIRPA model. Song and Xu (2011), Wu et al. (2014), Li et al. (2015), Wang and Xie (2015), Ma et al. (2017), Zhou and Mao (2017), Yuan et al. (2017) analyzed the influencing factors of carbon emissions in China's cities and towns, China's provinces, China's power sector, China's industrial sector, China's export implied carbon emissions, China's provincial transport sector and China's provincial agricultural sector. Another aspect is the analysis of carbon emission forecasts. Such as Chi (2007), Huang et al. (2010), Liu (2011), Mirzaei and Bekri (2017), Wang et al. (2017) they used linear regression methods, ARIMA models, Logistic curves, and system dynamics methods to investigate and study issues related to predict carbon emissions in different regions combined with regression analysis methods.

At present, there are not many researches on the evolution of carbon emissions in China. Liu et al. (2013) used the dynamic distribution analysis method (MEDD) to empirically analyze the dynamic distribution and evolution of China's carbon emission intensity. Hu et al. (2016) selected panel data from 30 provinces and municipalities in China from 1997 to 2012 to analyze the evolution trend of carbon emission intensity in China and the regional differences. Tian et al. (2014) and Gao et al. (2017) analyzed the evolution trend of carbon emissions in China's agricultural sector and regional agricultural sector respectively. Sun et al. (2011) and Liang and Li (2014) explored the evolution characteristics of carbon emissions in the Bohai rim and Shandong province. Most of the existing research only selecting a certain industry in China as a whole sample, there are less research on the evolution of carbon emissions. Therefore, the author chose energy-intensive provinces as the research object, constructed the coefficient of diversification of industrial structure, the coefficient of diversification of energy consumption results, studied the evolution law of carbon emissions with the aid of environmental-quality equation and environmental Kuznets curve, and put forward

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75237534

practical policy suggestions for carbon emission reduction to provides policy reference and decision-making basis for the realization of carbon emission reduction goal in energy-intensive provinces.

Estimation of total carbon emission

Calculation method of carbon emission

According to the fourth assessment from IPCC (Intergovernmental Panel on Climate Change) (Lin and Liu, 2010; Lin and Huang, 2011; China National Development and Reform Commission, 2012), the carbon emissions calculated in this section are mainly carbon emissions caused by fossil energy consumption. Shanxi Province in China, a large coal resource province, is chosen as the representative of energy intensive provinces. Carbon emissions are estimated by the method from Lin and Liu (2010).

$$C = \sum_i C_i = \sum_i E_i \times \alpha_i \times f_i \quad \text{(Eq.1)}$$

Among the *equation (1)*, C is total carbon emission, C_i is carbon emissions from category i energy, E_i is the category i energy consumption, α_i is the conversion coefficient of standard coal of the category i energy consumption, f_i is the carbon emission coefficient of the category i energy.

Data sources

The study period was selected from 1990 to 2017, and all the energy data came from the Shanxi statistical yearbook (1991-2018). The final energy consumption is calculated based on the total conversion of physical consumption. In this paper, all the value calculation, was calculated setting 1952 as a benchmark year for the reduction, because the year of 1952 was setting as a base period which value was 100 in the statistical yearbook. In addition, this author estimated the end of fossil energy consumption according to the standard amount of carbon emissions, not calculating the carbon emissions from the energy losses generated during the process of conversion, transportation and distribution. The energy conversion coefficient was calculated by Appendix 4 of China Energy Statistics Yearbook (2018). The emission coefficients of coal, coke and natural gas was calculated by the carbon emission inventory published by IPCC. The numbers are 0.7559, 0.8550, 0.4483 in turn. The oil carbon emission coefficient (Song, 2012) comes from the data published by the Energy Research Institute of the National Development and Reform Commission, the number is 0.5825.

Characteristics of carbon emissions

According to Eq.1, the carbon emission of Shanxi province is shown in *Figure 1*. As can be seen from *Figure 1*, Shanxi's carbon emissions in 1990 were 26.57 million tons, increasing to 73.27 million tons in 2017, an increase of almost two times. The carbon emissions are in the trend of increasing year by year. The growth rate of carbon emissions in the study cycle can be divided into three stages: from 1991 to 1996, the overall carbon emissions in Shanxi Province showed an upward trend, but the growth was slow; from 1997 to 2005, there was a short-term fluctuation in carbon emissions,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75237534

but the overall trend was upward; after 2005, the total carbon emissions entered a linear upward state, in the following year, carbon emissions entered a fluctuation period again.

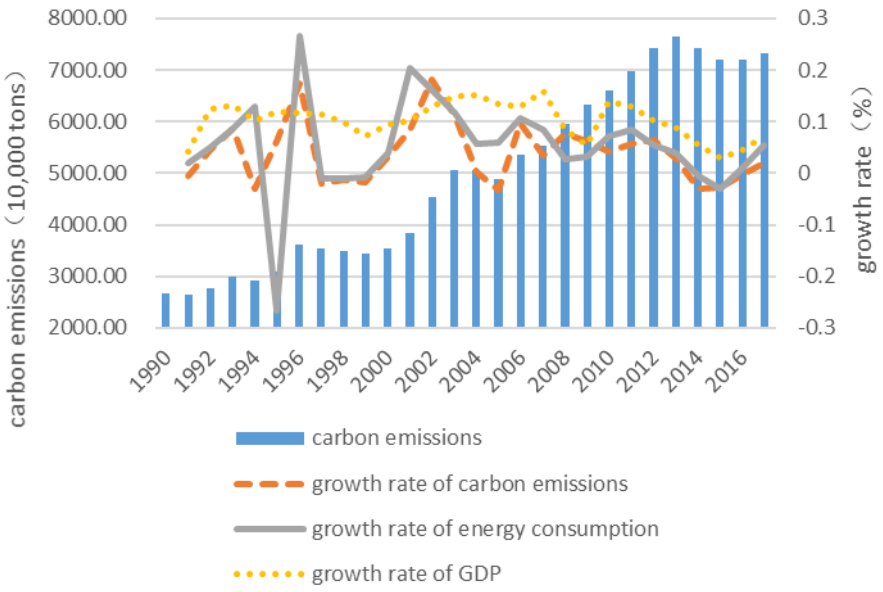

Figure 1. *The carbon emission, energy consumption and GDP output in Shanxi province in 1990-2017*

From 1990 to 2017, the carbon emissions of Shanxi Province basically kept pace with the growth of energy consumption. There was a sudden change in energy consumption in 1995 because an adjustment was made in statistical caliber in this year. From 2000 to 2003, the growth rate of carbon emissions was slightly faster than the growth rate of gross domestic product. After that, with the evolution of energy consumption structure and industrial structure in Shanxi province, the total carbon emissions are increasing, but the growth rate is slowing down. The growth rate of GDP has begun to be slightly faster than the growth rate of carbon emissions (as in *Fig 1*).

Analysis of evolution characteristics of carbon emissions

Existing research on the growth factors of carbon emissions mainly focuses on population, economic growth, industrial structure, energy structure. In this paper, the author does not focus on the analysis of factors affecting the growth of carbon emissions, so she quoted the existing research conclusions (He, 2012; Tong et al., 2015; Ren, 2015; Chen et al., 2016). The academic community has reached a consensus on the role of population in promoting carbon emissions, so the author will not repeat it.

Analysis on the relationship between economic growth and carbon emissions evolution

In order to investigate the quantitative relationship between economic growth and carbon emissions, we use the commonly used environmental Kuznets curve to analyze.

$$c = \beta_0 + \beta_1 y + \beta_2 y^2 + \beta_3 y^3 + u_i \quad \text{(Eq.2)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75237534

In the *equation (2)*, c is the carbon emissions over years, y is GDP per capita over years (The data are derived from the statistical yearbook of Shanxi province. The year 1952 is used as the benchmark year to calculate the reduction). Regression results are obtained by using Eviews8, as shown in *Table 1*.

Table 1. *The regression results of carbon emissions and economic growth in Shanxi province*

Parameters	**Model 1** $c = \beta_0 + \beta_1 y + \mu$	**Model 2** $c = \beta_0 + \beta_1 y + \beta_2 y^2 + \mu$	**Model 3** $c = \beta_0 + \beta_1 y + \beta_2 y^2 + \beta_3 y^3 + u_i$
β_0	2276.179 (22.98478)	1847.739 (-12.46559)	1534.06 (-5.535005)
β_1	0.902713 (-28.01651)	1.297577 (-11.05064)	1.738635 (-4.952082)
β_2		-6.14E-05 (-3.450783)	-0.000217 (-1.835032)
β_3			1.53E-08 (-1.330053)
adjusted R^2	0.971497	0.980945	0.981618
F-statistics	784.9247	593.0045	410.4036

Note: The test value of t statistics for each parameter are in brackets

Regression results show that the three models can effectively fit the relationship between carbon emissions and economic growth, but the parameters are significantly different. The fitting effect of model three is the best, below 5% level. The constant term and the linear term of per capita GDP are checked by significance test and it shows that between 1990 and 2013, there is a monotonic trend between carbon emissions and economic growth in Shanxi Province, the corresponding increase of carbon emissions is 1.74% for every 1% economic growth.

Analysis on the relationship between industrial structure evolution and carbon emissions

Method of calculating the diversity coefficient of industrial structure

The evolution of carbon emissions is not only related to economic growth, but also to industrial structure. In the existing studies, most of the measurement of the impact of industrial structure on carbon emissions is based on the industrial structure diversification coefficient proposed by Zhang et al. (2010) and Huang (2014). This coefficient is representative and reasonable to a certain extent, and can effectively show the proportion of the secondary and tertiary industries in the economic structure, but also has certain limitations. Because this coefficient is based on the primary industry as a benchmark, if the proportion of the primary industry in the economic structure is reduced, the coefficient will increase with the proportion of the primary industry decreasing, while the adjustment coefficient between the secondary industry and the tertiary industry can not be reflected. Therefore, the author used industrial structure correction coefficient from Huang (2014) to analyze the relationship between industrial structure and carbon emissions.

In order to quantitatively measure the impact of industrial structure on the evolution of carbon emissions, the author constructed an environmental-quality regression equation between carbon emissions and industrial structure diversification coefficient by using the industrial structure diversification coefficient.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75237534

The construction method of industrial structure coefficient is to use A (agriculture), I (industry), S (service) to represent the output value of the first, second and third industry respectively, and D to represent the diversification coefficient of industrial structure. Then:

$$ISF = \sum \left(\frac{A}{A}, \frac{I}{A}, \frac{S}{A}\right) \quad \text{(Eq.3)}$$

According to the relevant data of Shanxi Statistical Yearbook, the industrial structure diversification coefficient of Shanxi Province from 1990 to 2017 was calculated by *equation (3)*. The output value is calculated on the basis of the year of 1952 as the following *Figure 2*.

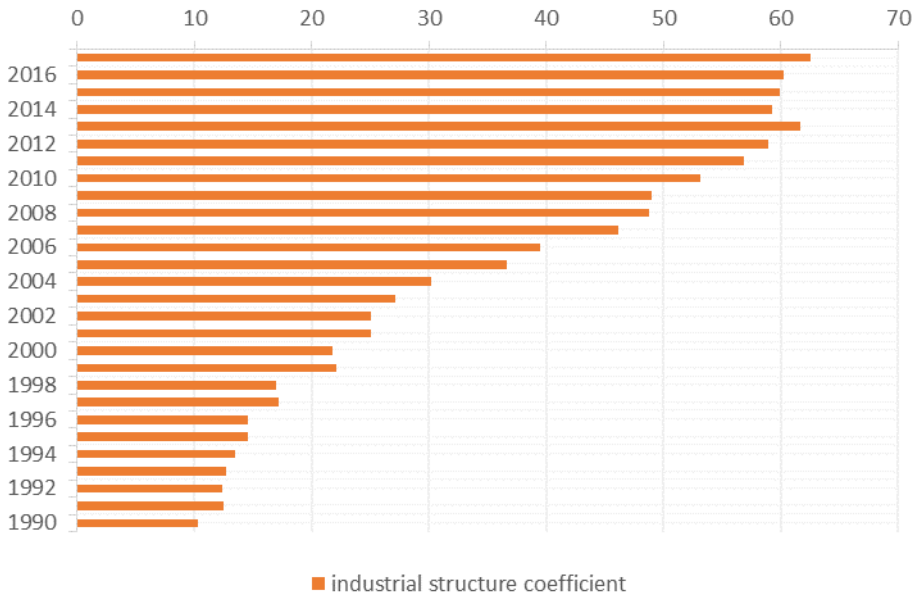

Figure 2. *Industrial structure diversification coefficient of Shanxi province 1990-2017*

From *Figure 2* we can find that, the diversification coefficient of Shanxi province industrial structure basically showed a linear upward trend in the research stage.

Regression result of industrial structure diversification coefficient and carbon emissions

In order to investigate the role of industrial structure change in the evolution process of carbon emissions in Shanxi Province, the regression equation of industrial structure evolution coefficient and carbon emissions was established by using the Environment-Quality equation:

$$c = \beta_0 + \beta_1 y + \beta_2 y^2 + \beta_3 y^3 + u_i \quad \text{(Eq.4)}$$

The parameters were estimated by stepwise changing the curve form by Eq. 4, and the regression results are shown in *Table 2*.

From the regression results of *Table 2*, we can see that the fitting result of Model 3 is the best, which reflects the characteristics between the evolution of industrial structure

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75237534

and carbon emissions. From 1990 to 2017, there is an inverted U-shaped curve between carbon emissions and the coefficient of industrial structure diversification in Shanxi Province. When the coefficient of industrial structure diversification is 25.08, the turning point of the curve corresponding to the time axis between 2002 and 2003 appears. That is, when the diversity coefficient of industrial structure is less than 25.8, the evolution of industrial structure brings about an increase in carbon emissions.

Table 2. *The regression results of carbon emissions and industrial structure diversity coefficient in Shanxi province*

Parameters	**Model 1** $c = \beta_0 + \beta_1 y + \mu$	**Model 2** $c = \beta_0 + \beta_1 y + \beta_2 y^2 + \mu$	**Model 3** $c = \beta_0 + \beta_1 y + \beta_2 y^2 + \beta_3 y^3 + u_i$
β_0	1819.606 (13.6308)	1807.974 (5.638141)	554.082 (0.823589)
β_1	91.27689 (23.67227)	92.17266 (4.062833)	238.2008 (3.247835)
β_2		-0.012914 (-0.040096)	-4.749545 (-2.066715)
β_3			0.044947 (2.078798)
adjusted R^2	0.960507	0.958629	0.964279
F-statistics	560.3766	267.4737	207.9591

Note: The test value of t statistics for each parameter are in brackets

When the coefficient of industrial structure diversification is greater than 25.8, the evolution of industrial structure can promote the reduction of carbon emissions. This coincides with the results of carbon emission growth rate and industrial output value growth rate in *Figure 2*, indicating that the industrial restructuring policy of Shanxi Province has achieved initial effect.

Analysis of the relationship between energy consumption structure and carbon emissions evolution

The energy structure of a country or region will change with the development of economy, from unification to diversification. In order to measure this change, this author constructed a pluralistic model of energy structure. F (first) denotes the dominant energy consumption in the economic development of a country or region, S (second), T (third) … denotes the subsequent energy consumption, and ESF denotes the coefficient of energy structure diversification in Eq. 5.

$$ESF = \sum \left(\frac{F}{F}, \frac{S}{F}, \frac{T}{F} \right) \quad \text{(Eq.5)}$$

From 1990 to 2017, coal has been the dominant energy consumption type in Shanxi Province. Therefore, coal was selected as unitary element in the evolution of energy structure, and other energy types as pluralistic elements of energy consumption structure. So the diversification coefficient of consumption structure in Shanxi province is as follow:

$$ESF = \sum \left(\frac{c}{c}, \frac{o}{c}, \frac{e}{c}, \frac{g}{c} \right) \quad \text{(Eq.6)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75237534

In the *equation (6) c,o,e,g* represents energy consumption of coal, oil, electricity, natural gas and other gases, respectively.

According to *equation (6)* and the data of Shanxi Statistical Yearbook, we calculated the coefficient of energy structure diversification, such as *Table 3*.

Table 3. *The consumption structure diversification coefficient of Shanxi province in 1990-2017*

Year	Coefficient	Year	Coefficient
1990	1.632569	2004	1.727133
1991	1.69738	2005	2.059616
1992	1.709464	2006	2.105542
1993	1.732847	2007	2.204329
1994	1.280864	2008	2.122848
1995	1.287026	2009	2.08718
1996	1.596045	2010	2.143757
1997	1.63661	2011	2.194854
1998	1.642659	2012	2.149954
1999	1.67804	2013	2.181708
2000	1.688116	2014	2.469229
2001	1.604971	2015	2.498509
2002	1.567656	2016	2.506846
2003	1.569563	2017	2.664153

From *Table 3*, we can see that Shanxi Province's energy consumption structure diversification coefficient rose slowly, from 1990 to 2017, it increased by about 1.0, the entire evolution process shows certain phased features. (1) The rising stage from 1990 to 1995. At this stage, the structure of energy consumption is basically on the rise stage, and in very few years, the energy structure has regressed. It shows that the energy consumption structure in this stage has been improved to a certain extent, and the energy structure adjustment policies in Shanxi Province have achieved certain results. The proportion of electricity in the structure of energy consumption is gradually increasing. (2) From 1996 to 2004, the stage of rebound decline. Affected by the Asian financial crisis, in order to stimulate economic development, some of the small coal kilns shut down have been rekindled, and some of the high energy consumption projects have been restarted, resulting in a re-increase in coal consumption, a decline in energy structure coefficient, and a return to the development model relying on coal consumption. (3) The slow recovery stage from 2005 to 2017. At this stage, Shanxi's industrialization was developing rapidly, urbanization was steadily advancing, and energy consumption had undergone some new changes. At the same time, the government of Shanxi Province decided to change the economic structure of "the coal dominant" and put forward the "coal-based, multi-development" strategy. The consumption of electricity and natural gas increased steadily, and the diversification coefficient of energy structure increased steadily (Xu, 2014).

In order to investigate the role of energy structure change in the evolution process of carbon emissions in Shanxi Province, this section still adopts the regression analysis of environmental quality curve. The regression equation is the same as *equation 4*, but the Y in the equation is expressed as the coefficient of energy structure diversification in this section. Model regression estimates are shown in *Table 4*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75237534

Table 4. *the regression results of carbon emissions and energy structure diversity coefficient in Shanxi province*

Parameters	Model 1 $c = \beta_0 + \beta_1 y + \mu$	Model 2 $c = \beta_0 + \beta_1 y + \beta_2 y^2 + \mu$	Model 3 $c = \beta_0 + \beta_1 y + \beta_2 y^2 + \beta_3 y^3 + u_i$
β_0	-3639.798 (-2.952779)	14304.97 (0.0677)	-63060.86 (-1.00861)
β_1	4557.069 (6.7509)	-15796.35 (0.0724)	125231.2 (1.10351)
β_2		5630.887 (2.444072)	-78363.93 (-1.16181)
β_3			16342.16 (1.2460)
adjusted R^2	0.659636	0.722393	0.72951
F-statistics	45.57465	30.92554	21.67697

Note: The test value of t statistics for each parameter are in brackets

The regression results showed that the adjusted R^2 of the third model is the maximum among the three models. However, at the 5% significance level, the parameters of the model are not significant, only the parameters of model 1 are significant at the 5% level and its adjusted number is only 0.66, indicating that between 1990 and 2017, there was no simple linear relationship between the diversity coefficient of energy consumption structure and carbon emissions in Shanxi Province. There was a more complex relationship between energy consumption structure evolution and carbon emissions growth, which needs further discussion. This is similar to the result of the relationship between the diversification coefficient of China's energy consumption structure and carbon emissions calculated by Zhang (2003) and Li and Cui (2011).

Conclusion

Based on the time series data from 1990 to 2017, the author selected Shanxi Province as the representative of energy-intensive provinces, empirically analyzed the changing characteristics of carbon emissions and carbon emissions intensity in energy-intensive provinces. Using environmental Kuznets curve, environmental-quality equation, and with the help of the constructed industrial structure diversification coefficient, energy structure diversification coefficient, the author examined the role of economic growth, industrial restructuring, energy consumption structure changes in the evolution of carbon emissions. The conclusions are as follows:

1) From 1990 to 2017, the carbon emissions of Shanxi Province in general were in the state of growth, but the increase rate was different.
2) Economic growth has a direct pull on the growth of carbon emissions, and every 1% increase in economic growth, carbon emissions will increase accordingly.
3) Industrial evolution is a bi-directional pulling factor of carbon emissions growth: When the industrial structure transits from the primary industry to the secondary industry, the industrial structure evolution has a pulling effect on carbon emissions growth. When the industrial structure transits from the secondary industry to the tertiary industry, the industrial structure reduces the growth of carbon emissions, showing the characteristics of inverted U-shaped curve. Before

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75237534

2003, there was an inflection point between the relationship of industrial structure diversification coefficient and carbon emissions.

4) The linear relationship between the evolution of energy structure and carbon emissions is not obvious. There is no inverted U-shaped curve between energy consumption and carbon emissions in Shanxi Province. This shows that the rebound effect of energy consumption may occur in the evolution process of energy structure in Shanxi Province, which needs further discussion.

At present, most studies believe that to control the growth of carbon emissions is to control the population, adjust the industrial structure, adjust the energy structure, and increase the proportion of non-mineral resource in energy consumption. Among the measures, which measures are more effective for carbon emission reduction in energy intensive provinces? The liberalization of the single second child policy in 2013 did not cause a small peak in fertility, and the implementation of the national family planning policy over the past few decades has changed people's conception of fertility. This shows that the policy effect of controlling population growth to reduce carbon emissions will not be significant for some time to come. From the perspective of energy consumption structure, Shanxi Province is a big province of coal production and consumption, although the energy structure reform has been carried out, but the coal-based energy consumption structure cannot be rapidly changed in a short time. At the same time, with the industrialization and urbanization process of Shanxi Province, the demand for primary energy will increase. The regression results also show that the linear relationship between the evolution of energy consumption structure and carbon emissions is not very obvious, and the potential to reduce carbon emissions through the evolution of energy structure is very small. The most effective policy to reduce carbon emissions in Shanxi is industrial restructuring. In the future, we need to continue to promote industrial restructuring, from the secondary industry to the tertiary industry. At the same time, in order to promote the transformation of high energy-consuming sectors in the secondary industry to low energy-consuming sectors, the support of technological progress is also needed in the process of transformation. To sum up, the main potential of carbon emission reduction in energy-intensive provinces lies in the rational evolution of industrial structure and technological progress, at the same time, ensuring that the population does not soar, the energy structure retrogression or reasonable evolution.

Abstract. In the traditional ecosystem service evaluation, non-material services such as culture and recreation services are difficult to accurately quantify due to the lack of a powerful evaluation model. Compared with ecosystem services, landscape services emphasize all the tangible and intangible services that landscape ecosystems provide to humans in the spatial pattern. Social media photos can be used for perceived services demand evaluation on the landscape scale. The study of spatial relationship between recreation service demand (RSD) and urbanization complements the integrity of the landscape service supply and demand relationship framework. Firstly, this paper analyzes the spatial autocorrelation and seasonal differences of landscape recreation service demand through Global Moran's I. The analysis shows that there is a highly significant spatial agglomeration and certain seasonal differences in landscape recreation service demand. Secondly, the bivariate Global Moran's I is used to analyze spatial correlation between landscape recreation service demand and urbanization, The result shows that there is a positive spatial correlation between urbanization indicators and landscape recreation service demand in different seasons. Thirdly, the bivariate LISA method is used to show the spatial agglomeration relationship between landscape recreation service demand and urbanization indicators in different seasons. Finally, it is verified that the spatial lag model and the spatial error model are more suitable for measuring the dependence than the linear regression least squares (OLS). At the same time, population density (PD) has a positive impact on landscape recreation service demand in different seasons, while landscape recreation service demand in autumn is also positively affected by non-urbanization factors and negative impact of GDP, which also proves space spillover effect between landscape recreation service demand and urbanization. The above conclusions can be used as important information for urban landscape planning and decision-making.

Keywords: *recreation services demand, landscape services, spatial dependence, spatial correlation, Moran's I, urbanization*

Introduction

Today, human beings are considered an indispensable part of the landscape. At the same time, human beings also benefit from the functions provided by the landscape and the natural environment. Therefore, the research on ecosystem service demand is gradually starting (Burkhard et al., 2014; Schroter et al., 2015; Villamagna et al., 2013), the difficulty of data collection and the measurement limitations of time scales have relatively limited the progress of demand research. At the same time, the spatial alienation of ecosystem service demand, supply and consumption have limited the study of ecosystem service supply and demand trade-offs and spatial heterogeneity (Syrbe and Walz, 2012).

DOI: http://dx.doi.org/10.15666/aeer/1704_75357548

The International Classification of Ecosystem Services (Hainesyoung et al., 2009; Hainesyoung and Potschin, 2013) identifies Cultural Ecosystem Services (CES) as a very important component. In recent years, cultural service value assessment research has developed rapidly (Bieling et al., 2014; Hermes et al., 2018; Van Berkel and Verburg, 2014). Recreational services are defined as the "recreational pleasure people derive from natural or cultivated ecosystems" (MEA, 2005; TEEB, 2010), which have a positive impact on social well-being (Hermes et al., 2018). However, non-material services such as cultural services and recreation are difficult to accurately quantify due to the lack of a powerful model for evaluation (Shaw et al., 2016; Tenerelli et al., 2016), the spatial and temporal ectopicity of service supply and demand is more pronounced (Milcu et al., 2013).

The basic spatial unit of the ecosystem service flow includes the supply unit, the connection unit and the use unit. The recreation service can be used by the beneficiary without passing through the carrier, the first assessment perspective should come from the beneficiary itself (Lie et al., 2017). Ecosystem services perceived by consumers and generating benefits can constitute effective demand (Yan et al., 2017), people's aesthetic preferences can be used as a means of recreational services demand assessment (Peña et al., 2015). The social media photos provide an opportunity to "excavate the perception, cognition or activity of many people" and reflect the relationship between landscape attributes and landscape preferences (Tieskens et al., 2018), which can be used for perceived recreation service demand evaluation on a landscape scale (Michael et al., 2018), is becoming an increasingly attractive source of cultural service assessment (Oteros-Rozas et al., 2017). The data and content analysis reflects recreation services supply on the landscape scale, while demonstrating the effective demand of people, and promotes the improvement of existing assessment methods on time scales and spatial scales (Michael et al., 2018).

Population and economic factors often affect ecosystem service demand, while land cover and land use are directly related to ecosystem service supply capacity (Oteros-Rozas et al., 2017). Among them, there is a certain spatial correlation between the supply of ecosystem services and landscape features and urbanization (Oteros-Rozas et al., 2017; Syrbe et al., 2012; Zhang et al., 2018). In recent years, ecosystem services research has emphasized the relationship between ecosystems and human social systems at the landscape scale (Wu et al., 2013), focusing on ecosystem service needs assessments. At present, the spatial correlation between recreational service demand and landscape features has also been verified (Oteros-Rozas et al., 2017). So, is there a spatial correlation between recreational service demand and urbanization? This answer will complement the integrity of the LRS supply-demand relationship study at the landscape scale (*Fig. 1*).

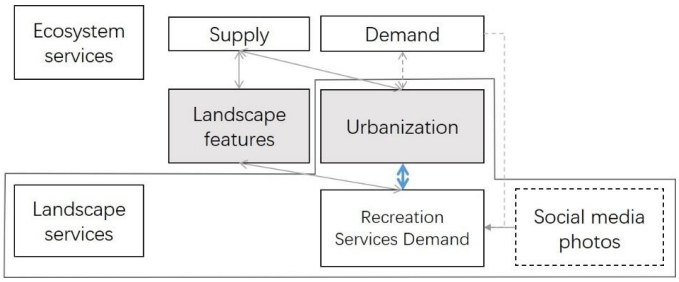

Figure 1. *Conceptual framework linking ecosystem services supply and demand. The contents of block diagram are the research topics of this paper*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75357548

Is there a spatial autocorrelation of landscape recreation service demand in cities with developed tourism (Goal 1)? Is there any seasonal difference in this spatial autocorrelation (Goal 2)? Is there a spatial correlation between landscape recreation service demand and urbanization (Goal 3)? Does the demand for landscape recreation services have a spatial dependence on the level of urbanization (Goal 4)? The above questions are the research objectives of this paper. This paper aims to discuss the spatial distribution of landscape recreation service demand from the perspective of people's needs. This method can explain whether landscape recreation service supply and demand are affected by landscape features and urbanization at the same time, provide important information for landscape planning and decision making (Maes et al., 2012; Syrbe and Walz, 2012).

Methodology

Study area

The city is a region where human society and ecosystems interact closely. Landscape recreation services are an important contribution of landscape to human well-being. As a famous international tourist city, Shanghai's tourism demand has certain seasonal differences, and the off-season and peak seasons are more obvious (*Table 1*).

Table 1. *The number and ratio tourist receptions and social media photos in different seasons*

	Spring	Summer	Autumn	Winter	Whole year
Inbound tourists (thousand)	2273.5	2011.75	2266.5	1745	8297.75
Ratio (%)	27.40%	24.25%	27.32%	21.03%	100%
Social media photos	855	741	838	522	2956
Ratio (%)	28.92%	25.07%	28.35%	17.66%	100%

The number of inbound tourists is calculated by the average of the data from 2014 to 2017. The data comes from the website of the Shanghai Municipal Culture and Tourism Bureau (http://lyw.sh.gov.cn/)

Therefore, this paper selects Shanghai urban area as the research scope. Shanghai's urban ecosystem is highly complex, human activities are intensive, and tourism is developed. It can be used as a typical area for studying landscape recreation service demand (*Fig. 2*).

Data

Social media photos

The data of social media photos used in this study belongs the Yahoo Lab Research Project (Thomee et al., 2015), which includes 100 million global photo information published on the Flickr platform from 2004 to 2014, in addition to photo elements. It includes 23 types of information such as photo number, shooting time, title, description, deep learning label, latitude and longitude. In this database, all photos of Shanghai geographic coordinates are extracted, and several types of information indicators such as photo number, shooting time, deep learning label, and latitude and longitude are selected for this study.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75357548

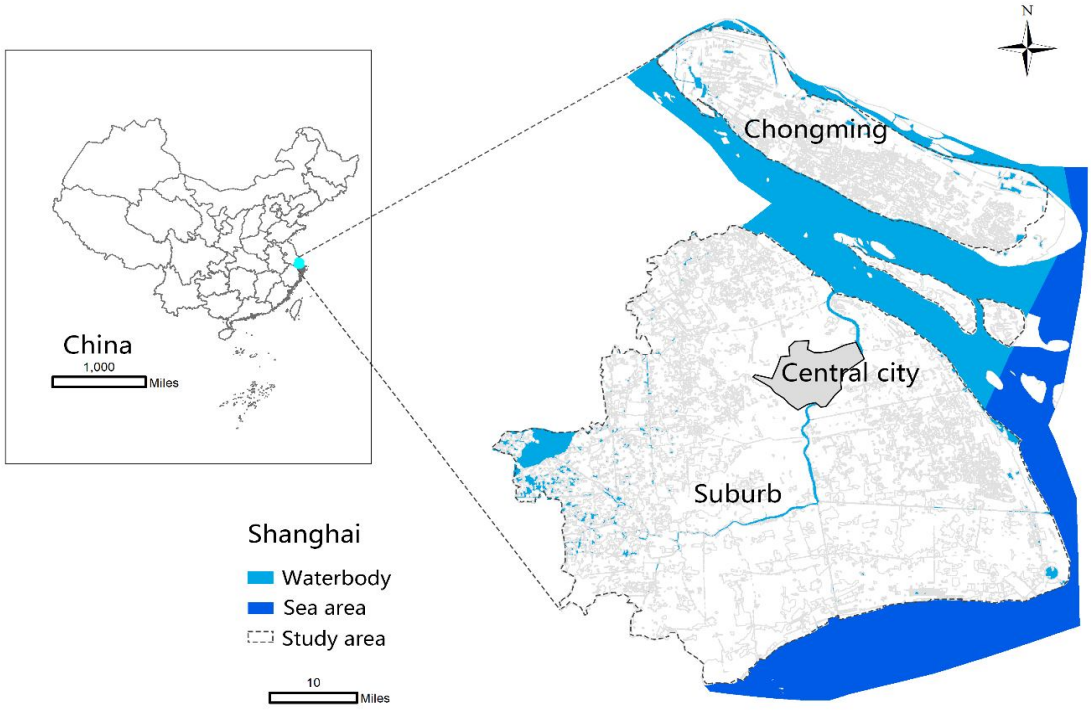

Figure 2. *The dotted line in the figure is the study area*

There are a total of 125,327 photos in Shanghai. First, in order not to repeatedly calculate the same tourist's perception of the same landscape, the duplicate data released at the same time is excluded. Secondly, in order to analyze the tourist's perception of the natural landscape, we remove the deep learning label as "empty". "Indoor", "outdoor", "People", "architecture", etc., which do not reflect the relationship between human activities and natural landscapes; finally, a total of 2,956 data records (*Table 1*) that meet the criteria are selected, according to spring (March to May), summer (June to August), autumn (September to November), winter (December to February), and the whole year. The proportion of photo data in different quarters is similar to that of inbound tourism. The proportion in spring is the highest, which is 11.26% higher than that in winter. It can be seen that the social meida photos data can be used to analyze the seasonal differences in landscape recreation demand. In this paper, the filtered data table is imported into Arcgis10.1 software and converted into projection data. The projection uses the WGS_1984_UTM_Zone_51N coordinate system.

Urbanization

Spatial distribution data of population density and GDP density in 1 × 1 km resolution raster, obtained from the Resource and Environment Data Cloud Platform (http://www.data.ac.cn). The two datasets were spatialized by Interpolating statistical data to spatial grids with consideration of local land use, the nighttime light index, and other remote sensing information. The data format is gird. The author imported the data into ArcGIS10.1 software, intercepted the data according to the boundary of the study

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75357548

area, converted it into vector data, and adjusted the projected coordinate system to be consistent with the photo data.

Spatial correlation analysis

Spatial autocorrelation of landscape recreation services demand

Spatial autocorrelation is an important indicator to test whether the attribute value of an element is significantly associated with the attribute value of its adjacent space point. Global Moran's I is used to assess whether landscape recreation service demand belong to cluster distribution, discrete distribution or random distribution, p value indicates the probability of occurrence of this trend, and z score is a multiple of standard deviation. Moran's $I > 0$ represents spatial positive correlation, the larger the value, the more obvious the spatial correlation; Moran's $I < 0$ represents the spatial negative correlation, the smaller the value, the larger the spatial difference; Moran's $I = 0$, indicating a random distribution.

At the same time, Anselin Local Moran's I is used to identify spatial clusters with high or low value elements, ie, statistically significant hotspots, cold spots, and spatial outliers. This tool can effectively obtain hotspots and cold spots for landscape recreation service demand (Figueroa-Alfaro and Tang, 2016).

In this paper, Arcgis10.1 software is used for data processing to generate a square grid map of 1 km × 1 km in Shanghai urban area. The square grid is superimposed with geotag photo data for spatial feature analysis of landscape recreation services demand. The Spatial Autocorrelation (Global Moran's I) tool and the clustering and outlier analysis (Anselin Local Moran's I) tool were analyzed using GeoDa1.10 software. The spatial clustering analysis in the paper defines the spatial weight based on the polygon Queen contiguity, and uses the average of all adjacent positions to evaluate the degree of correlation between the X variable value of a position and the value of the Y variable.

Spatial correlation between landscape recreation service demand and urbanization

The Bivariate Moran's I tool is used to explore the spatial clustering (positive spatial correlation) and spatial discrete (negative spatial correlation) relationships between landscape recreation service demand and urbanization. The global bivariate Moran's I is used for spatial correlation analysis between landscape recreation service demand and urbanization, and the local bivariate Moran's I can be used for visual spatial correlation analysis (Anselin and Rey, 2014). For the pseudo value obtained, the spatial correlation between RSD and urbanization is set to b0.01. Four types of local spatial autocorrelation are generated by bivariate LISA: quadrant I (HH) represents a high RED value surrounded by high urbanization values; quadrant II (HL) represents a high RSD value surrounded by low urbanization values; quadrant III (LH) represents a low RSD value surrounded by a high urbanization value and a quadrant IV (LL) representing a low RSD value surrounded by a low urbanization value.

Spatial regression analysis

In spatial cluster analysis, if there is no spatial autocorrelation in the variable, the OLS regression model can be used for analysis. If the observed value of the variable has spatial autocorrelation, it means that the residual value is not random. This situation needs to use spatial regression analysis. However, the spatial lag model and the spatial

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75357548

error model are more suitable for regression analysis (Wang, 2009). Therefore, based on the spatial autocorrelation analysis, this paper compares the significance of OLS, SLM and SEM regression analysis results and selects the best analytical model.

Results

Spatial autocorrelation of landscape recreation service demand

The results of Global Moran's I analysis show that (*Table 2*), the annual RSD spatial pattern shows a highly significant spatial agglomeration, with Moran's I index of 0.5094 and Z score of 80.3762, which can reject null hypothesis and random distribution. Compared with different seasons, RSD has the highest concentration in spring, Moran's I index is 0.5256, Z score is 84.0242; LRS demand is the lowest in autumn, Moran's I index is 0.412, Z score is 55.2689. In general, the spatial agglomeration patterns of RSD in different seasons have certain differences, but the differences are not significant.

Table 2. *Spatial autocorrelation analysis of RSD in spring, summer, autumn, winter, and whole year. Statistically significant at 1% level*

RSD	Moran's I index	Expected index	Variance	Z score
Whole year	0.5094	-0.0002	0.0063	80.3762
Winter	0.4748	-0.0002	0.0055	86.5094
Autumn	0.412	-0.0002	0.0074	55.2689
Summer	0.4397	-0.0002	0.0059	74.7128
Spring	0.5256	-0.0002	0.0063	84.0242

The results of Local Moran's I show different types of RSD spatial aggregating patterns. It can be seen from the annual RSD spatial agglomeration feature that the HH area is mainly concentrated in the central area of Shanghai, and this feature has similar performance in different seasons. The HL area distribution is relatively discrete. The LH area is distributed in the southwest and south of the study area, and the spatial aggregation of RSD is most similar in autumn and whole year. The LL area is mainly distributed in Chongming Island and suburban areas in the north; the number of RSD cold spots in spring and summer is large, distributed in the marginal areas of Chongming Island and suburban areas, while the number of cold spots in autumn and winter is small. It can be seen that the regional spatial agglomeration of high RSD is strong, and the seasonal difference is relatively low; the area of low RSD has spatial agglomeration and seasonal differences (*Fig. 3*).

Correlation analysis between landscape recreation service demand and urbanization

This paper uses Bivariate Moran's I to test the spatial correlation between RSD and urbanization. The level of urbanization is represented by two indicators: population density (PD) and GDP. *Figure 4* shows a significant positive correlation between RSD and PD. There is also a positive correlation between RSD and GDP, but the correlation is weak, and the correlation is between 0.084 and 0.118. It can be seen that the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75357548

correlation between urbanization and RSD is relatively stable, and the seasonal difference is not large (*Fig. 4*).

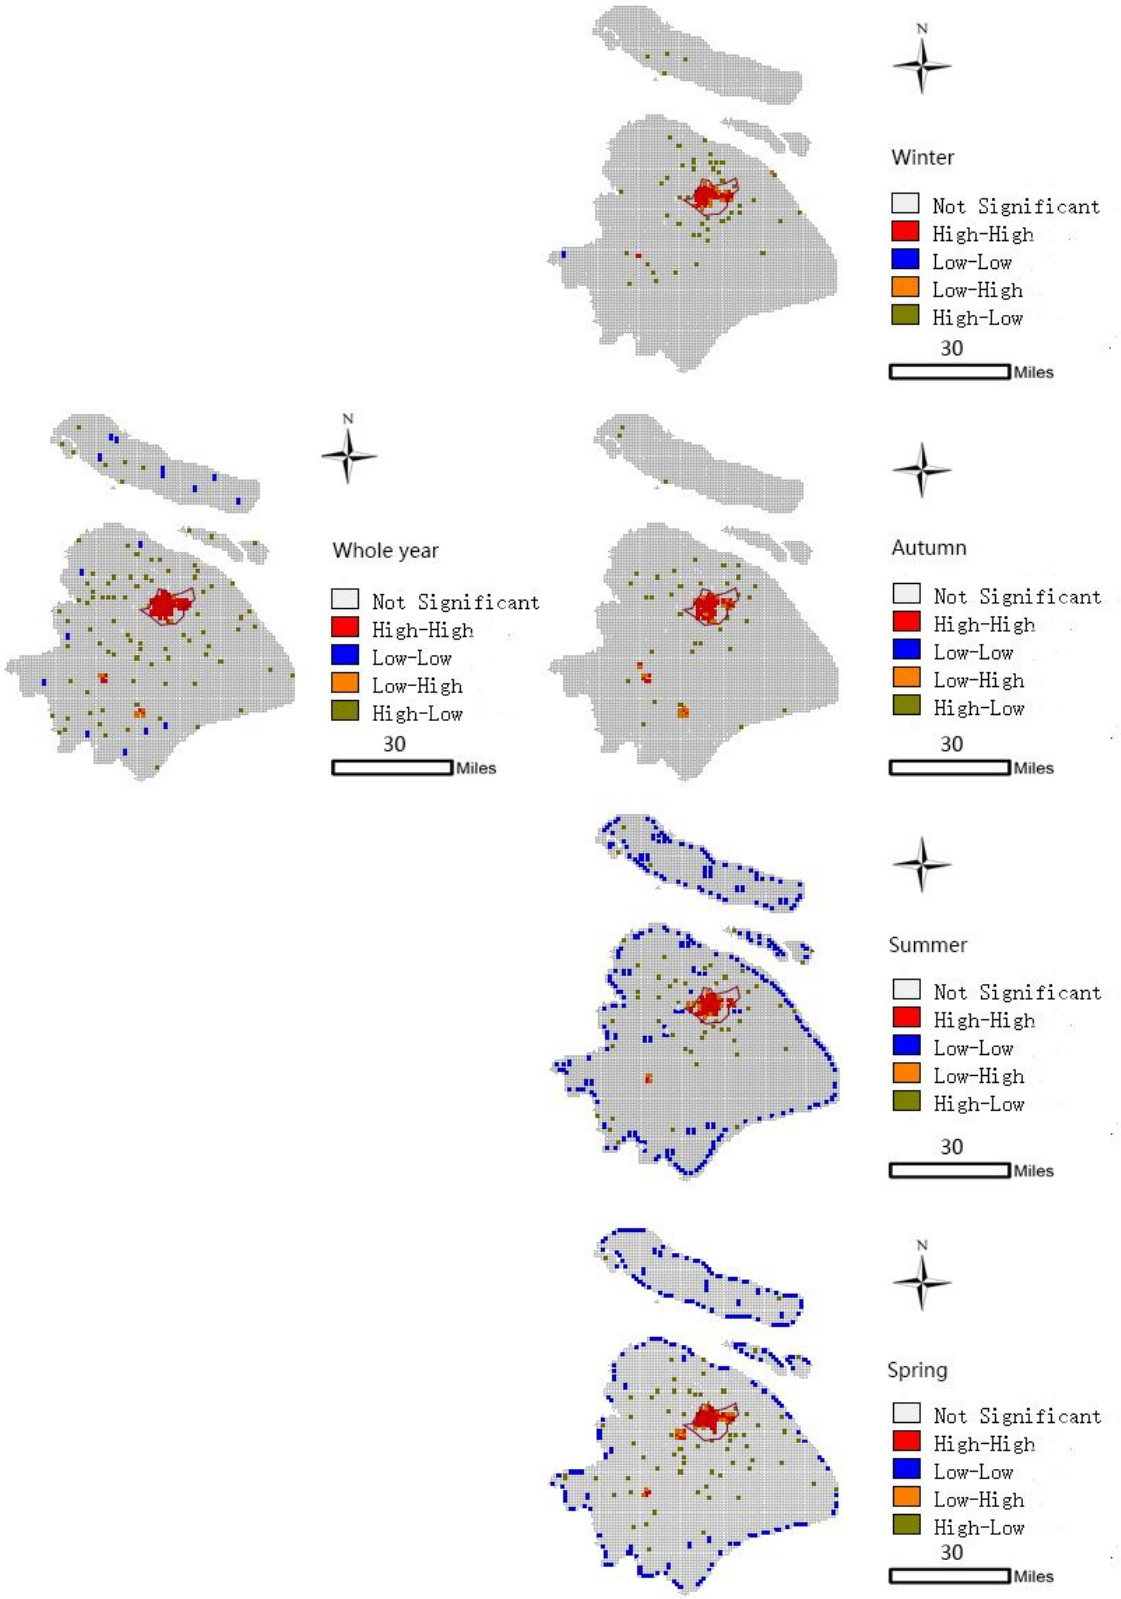

Figure 3. *LISA cluster map of local Moran's I. Statistically significant at 1% level*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75357548

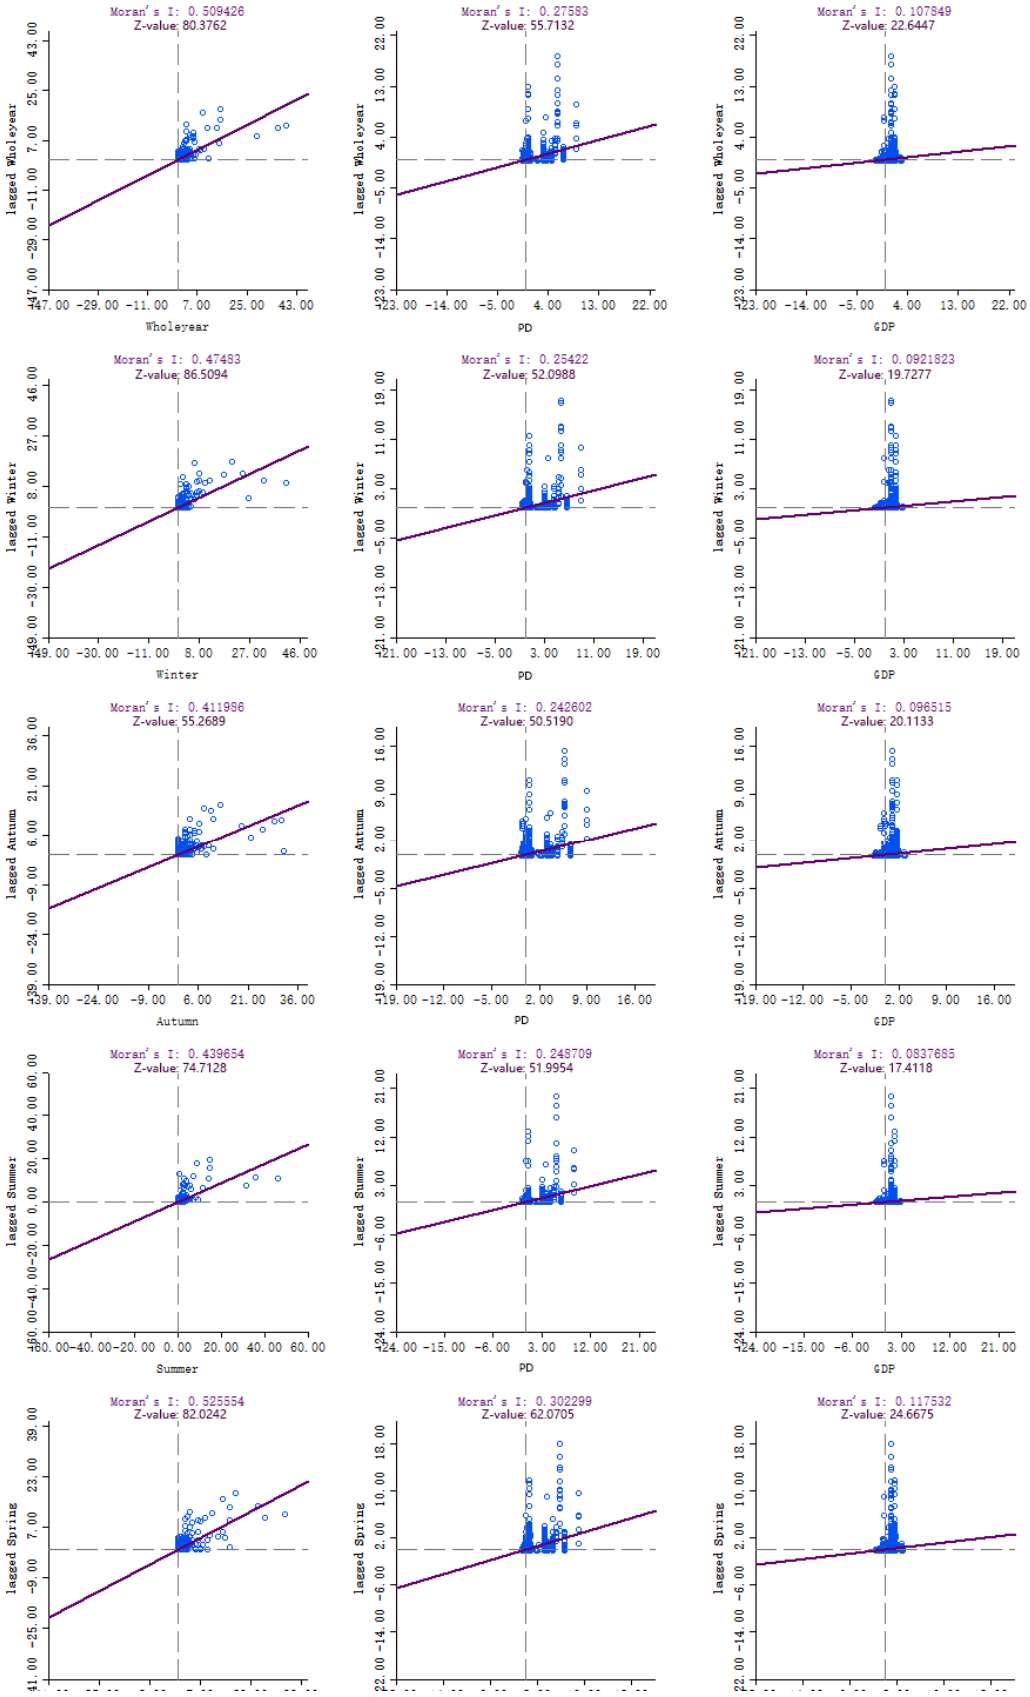

Figure 4. *Bivariate Moran's I between RSD and urbanization (PD & GDP). Statistically significant at 1% level*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75357548

The BiLISA Cluster map (*Fig. 5*) shows the spatial agglomeration of RSD and urbanization in different seasons. The HH area of urbanization and RSD is still mainly concentrated in the central city, with a high degree of concentration. The seasonal distribution of GDP and RSD is not much different; the high values of PD and RSD are the largest in spring. HL has the widest distribution range, PD has a high value distribution in the middle and northeast of the study area, and RSD has a low value distribution, GDP has a high value distribution in the middle and northwest of the study area, while RSD has a low value distribution. The LH region is dispersedly distributed in the southwestern part of the study area. The spatial agglomeration of urbanization and RSD is more obvious in autumn and the whole year. The LL value distribution area presents a certain space and seasonal agglomeration, mainly concentrated in the urban fringe area of spring and summer and the edge area of Chongming Island. We can get several conclusions: First, compared with the spatial distribution of urbanization, the RSD high-value space is more concentrated, mainly concentrated in the central city; second, in the low-value area of urbanization indicators, RSD appears a large range of high values in autumn. At the same time, in the low-value areas of urbanization, the low RSD is mainly in the urban fringe of spring and summer.

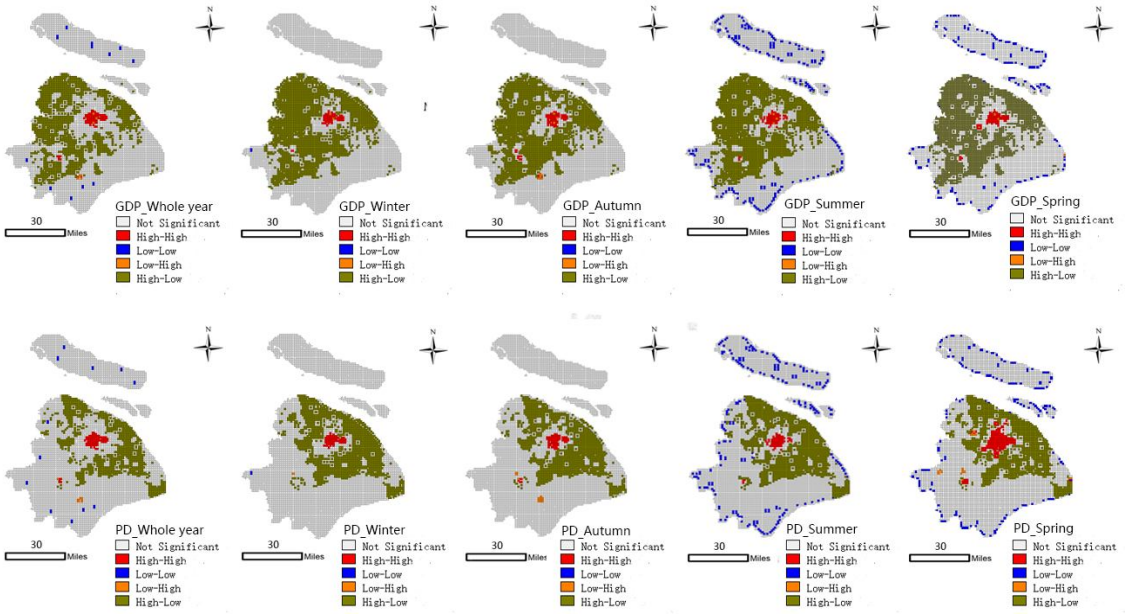

Figure 5. *BiLISA Cluster map between RSD and urbanization (PD & GDP). Statistically significant at 1% level*

Spatial dependence analysis of landscape recreation service demand on urbanization

The previous analysis has obtained that the observation value of RSD is related to the geographical location, then the residuals are no longer independent of each other, and there is a certain spatial positive correlation between RSD and urbanization. Therefore, when further analyzing the causal relationship between urbanization indicators and RSD, the OLS model is no longer applicable. In this paper, the urbanized PD and GDP indicators are used as independent variables, and the RSD of different seasons is used as the dependent variable. The maximum likelihood estimation method (SLM & SEM) is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75357548

used for spatial regression analysis, and the OLS model results are used for comparison test (*Table 3*).

The OLS results show that the simulation fit is not ideal and the adjusted R^2 value is relatively low. Among them, the regression fit of PD with RSD in different seasons is highly significant, while the GDP index only fits significantly with the regression of RSD in autumn and whole year. At the same time, LM tests show that LM (Lag) and LM (Error) are significant for regression analysis of RSD in different seasons, and this indicates that SLM and SEM are more suitable than OLS.

Spatial regression analysis shows that SRM is superior to OLS because Log Likelihood values increase and AIC and SC values decrease (*Tables 3* and *4*). SLM has the best results in RSD regression analysis in spring, summer, winter and whole year. The lag coefficient (W_LRS) in SLM is positive under pb0.001 significant condition, indicating that the RSD of four time dimensions is adjacent. The SEM has the best positive results in autumn, and the error coefficient (LAMBDA) is also positive under the pb 0.001 significance condition in the SEM, indicating that the RSD is also positively affected by non-urbanization factors in autumn.

Table 3. *The results of OLS model between RSD and urbanization*

*Statistically significant at 5% level. **Statistically significant at 1% level. ***Statistically significant at 0.1% level

All PD coefficients are significant positive values, indicating that PD growth drives RSD growth. In the order of decreasing absolute values of PD coefficients, as the PD increases, the RSD in spring increases the most, while the demand for RSD in winter increases the least.

GDP coefficients are only significant negative values in the autumn, indicating that the RSD in the autumn has a degrading effect with the increase of GDP. At the same time, compared with the OLS model analysis, the absolute value of GDP coefficients in the SEM regression analysis of RSD in autumn is higher, indicating that the effect of spatial autocorrelation is that the negative impact of GDP increase on RSD in autumn is reduced.

Discussion

Spatial autocorrelation and seasonal differences in landscape recreation service demand

There are certain seasonal differences in the number of tourists in the city, and this conclusion has been verified in related research on tourism activities. This paper explores the RSD spatial agglomeration model and seasonal differences through Global Moran's I and local Moran's I. The results show that the RSD in different seasons shows a highly significant spatial autocorrelation. Among them, the HH region is concentrated in the central city, and the seasonal difference is low; the LH region shows a certain concentration outside the central city, and the RSD in autumn is the most concentrated obviously. As an international tourist city, the hotspots of RSD in Shanghai are concentrated and stable, and are almost unaffected by the seasons. In September, "Shanghai Tourism Festival" and other events have an impact on RSD and form some new hotspots in the spatial distribution. Although it has not formed a role in other seasons, it has a significant impact on the spatial distribution of RSD throughout the year.

Study on the relationship between supply and demand of recreation services

As mentioned above, the alienation of the demand, supply and consumption of ecosystem services has limited research on supply and demand. This problem is more prominent in non-material services such as recreational services.

On the basis of the verification of the spatial supply of ecosystem services and the spatial characteristics of landscape and urbanization, the spatial correlation between RSD and landscape features is also explained by relevant research results from the perspective of consumer demand. In this paper, there is a significant positive correlation

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75357548

between RSD and urbanization, and it is not affected by seasonal differences, indicating that the spatial relationship is relatively stable. This stable spatial correlation conclusion will complement the research framework for the relationship between supply and demand of recreational services (*Fig. 1*). We can understand that the supply and demand capacity of recreation services is spatially related to landscape characteristics and urbanization, and can be used for supply and demand relationship models. At the same time, photo data based on geographic coordinates provides a data source for the research of recreational service demand in landscape scale and time dimension (Michael et al., 2018). The deep learning of photo content can help to analyze the specific demand of people and promote spatial heterogeneity research.

Enlightenment of spatial dependence analysis on urban landscape planning

The SLM model performed optimally in RSD regression analysis in spring, summer, winter, and year-round, and was positively affected by adjacent values (*Table 4*), indicating that RSD was affected by both PD and adjacent values. Therefore, it is necessary to pay attention to the protection and planning of natural landscapes in densely populated areas. Natural landscape is an important part of maintaining the sustainable development of urban ecosystems. It not only protects the natural landscape of RSD hotspots, but also drives demand growth around hotspots.

As the tourist season in Shanghai in the autumn, the distribution of high-value points of RSD also shows a certain concentration. At the same time, the SEM model is optimal for RSD regression analysis in autumn. The RSD in autumn is affected by the positive influence of PD and the negative impact of GDP, and the RSD in autumn is also positively affected by non-urbanization factors (*Table 4*). The research and management of RSD supply and demand in autumn needs to be comprehensively considered and evaluated, and as far as possible to plan the development of areas with high population density, while avoiding the economic business center area. It is particularly important to note that the RSD cold spots area (urban fringe area and Chongming Island fringe area) in spring and summer can be the focus of landscape planning to promote the balanced development of supply and demand.

Conclusion

This paper improves the supply and demand research framework of landscape recreation services through the study of spatial relationship between RSD and urbanization.

The spatial autocorrelation of RSD is the first research goal of this paper. Global Moran's I analysis shows that RSD has a highly spatial agglomeration. The hotspots are highly concentrated in the central area of the city, and the cold spots are relatively discrete. There are some differences in the RSD spatial agglomeration patterns in different seasons, and the distribution of cold spots in spring and summer is discrete.

The spatial correlation between RSD and urbanization is the second research goal. Bivariate Global Moran's I verifies that there is a positive spatial correlation between urbanization and RSD in different seasons.

The spatial dependence of RSD on urbanization is also a research goal. In order to avoid the influence of spatial autocorrelation, this paper uses the maximum likelihood estimation method (SLM & SEM) for spatial regression analysis, and compares the OLS model results. The LM test showed that LM (Lag) and LM (Error) were significant

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75357548

for RSD regression analysis in different seasons, and this indicates that SLM and SEM are more suitable than OLS. The results show that the regression fit of PD with RSD in different seasons is highly significant, while GDP only fits significantly to the regression between RSD in autumn. SLM has the best results in RSD regression analysis in spring, summer, winter and whole year, indicating that RSD is positively affected by PD and adjacent values; SEM is optimal in RSD regression analysis in autumn, and RSD in autumn is positively affected by PD and non-urbanization factors, while being negatively affected by GDP, also proves the spatial spillover effect between RSD and urbanization.

Abstract. This study aimed to evaluate the effect of control systems, including an intelligent control system (ICS) and a conventional timer control system (TCS), on bacteria community structure. Clone library methods for 16S rDNA were used in sequencing batch biofilm reactors (SBBRs) to treat wastewater. A total of 108 clones were randomly selected and individually sequenced from 16S rDNA libraries. Results indicated that the community structure was different in each SBBR under different controlled systems. The dominant bacterial communities and their contents showed significant differences. The dominant bacterial community Bacteroidetes has a proportion of 45%, whereas β-proteobacteria has 37%. The significant difference in the performance of nitrogen and phosphorus removal in ICS from TCS was the dominant bacterial community.
Keywords: *intelligent control system (ICS), sequencing batch biofilm reactor (SBBR), 16S rDNA library, bacterial community, denitrification*

Introduction

The most fundamental method for controlling water eutrophication and preventing water pollution is to treat pollution sources and control pollutant emissions. This approach will enable the nitrogen and phosphorus obtained from the wastewater treatment plants to meet emission standards (Zou et al., 2006). The wastewater discharge standard at present is increasingly becoming strict in all countries around the world. Many new and original wastewater treatment plants are facing the pressure of standard nitrogen and phosphorus emissions (Mielcarek et al., 2015; Ge, 2010; Wen et al., 2015).

Sequencing batch biofilm reactor (SBBR) is novel of composite biofilm reactor and a new technology for nitrogen and phosphorus removal that is being studied by scholars at home and abroad. SBBR utilizes time sequence. Construction cost is low because biological reaction proceeds in a single tank without physical partition (Yang et al., 2014). Given a large amount of biomass, the reactor can resist shock load (Goh et al., 2009; Fu et al., 2018). Sludge bulking is not a problem because of low sludge

Production (Amulya et al., 2015; Zhao et al., 2017) SBBR has been used in the research of nitrogen and phosphorus removal from urban wastewater (Choi et al., 2008; Zhang et al., 2009; Fu et al., 2010; Hosseini et al., 2012). Microorganisms in SBBR are attached to the carrier to form a biofilm with long sludge age and food chain. The

DOI: http://dx.doi.org/10.15666/aeer/1704_75497559

biofilm has certain thickness. Under aerobic conditions, the biofilm creates a hypoxic microenvironment where nitrification and denitrification can occur simultaneously; this condition leads to high nitrogen removal efficiency (Isanta et al., 2015). Changing the operating conditions of the reactor will change the environment where microorganisms depend on for survival, as well as the bacterial community structure of microorganisms, thus leading to the change of nitrogen and phosphorus removal efficiency (Aydin et al., 2015). Therefore, the present study on the effect of control systems on the bacterial community structure in SBBR system is important to optimize the bacterial community structure and improve the efficiency of nitrogen and phosphorus removal.

The 16S rDNA clone library method is used to amplify and analyze the full-length sequence of 16S rDNA to analyze the bacterial community structure in the environmental samples (Cantafio et al., 1996; Sanapareddy et al., 2009; Yu et al., 2010). Given its high speed, accuracy, good repeatability, and abundant information, this method has become the main approach used in the research of bacterial community structure and diversity in wastewater treatment systems. In the present paper, two SBBRs under different control systems were adopted to treat urban wastewater. SBBR under an intelligent control system (ICS) controls the process of wastewater treatment based on DO and temperature. By contrast, SBBR under a timer control system (TCS) changes the operation conditions based on time setting. The 16S rDNA clone library method was adopted to study the similarities and differences of the bacterial community structures of these two reaction systems and to determine the dominant bacterial communities. This approach identifies the effect of control systems on the bacterial community structure of the system.

Materials and methods

SBBRs configurations and operational conditions

Experiments were conducted in two SBBRs controlled by an ICS and a TCS. *Figure 1* shows that the acrylic reactors were composed of polymethyl methacryate with a capacity of 30 L and a working volume of 20 L. Two SBBRs and operations conditions were described in an earlier publication (Jin et al., 2012).

Synthetic wastewater

Synthetic wastewater was used as feed to evaluate SBBR performance. Wastewater was prepared based on the characteristics of Chinese municipal wastewater with the following composition (concentrations in mg/L): glucose ($C_6H_{12}O_6$) (332); NH_4Cl (213 at C/N ratio of around 5.0) l; KH_2PO_4 (21.95); $ZnCl_2$ (50), $MgSO_4$ (50); and a 1 ml trace element mixture consisting of $CaCl_2$, $CuCl_2$, $NiCl_2$, $FeSO_4$ and H_3BO_3. $NaHCO_3$ measuring 100 mg/L was used to maintain the pH of the wastewater at 6.8 to 7.2. Synthetic wastewater is characterized in *Table 1*. All chemicals and reagents were of analytical grade.

Table 1. *Characteristics of synthetic wastewater during stable operation*

Parameter	COD (mg/L)	NH_4^+-N (mg/L)	TN (mg/L)	TP (mg/L)	pH
Values	326 ± 30	61 ± 10	65 + 10	5 ± 1	7 ± 0.2

Experimental methods

Sample collection and DNA extraction

After about five weeks of domestication, the biofilm was successfully cultured in two reactors before being entered into the operating period. Through 30 days of sample analysis, the results showed that the reaction period was 6 h for ICS and 9 h for TCS. The operation results of a cycle were extracted as the example. The concentrations of COD, TN, NH_4^+-N, and TP in inflow water were 309.5, 63.61, 60.28, and 5.16 mg/L, respectively. The removal rates of COD, TN, NH_4^+-N, and TP were 93.4%, 85.6%, 100%, and 100% in ICS and 91.1%, 70.9%, 100%, and 100% in TCS, respectively. Thus, TN removal rate in ICS was 14.7% higher than that in TCS.

Bacteria Sampling of the two reactors obtained according to the method of Hao et al. (2009). During the stable operation of two SBBRs, the biofilm samples were taken with sterile scissors and sterile brush from the fillers at different vertical depths and horizontal positions in the SBBRs under ICS and TCS. The samples were dissolved in 500 mL distilled water and fully shaken. The supernatants were removed after precipitation for 30 min. Then, 40 mL of the solutions was taken from the precipitation layers and placed in 50 mL centrifuge tubes. After 3 min of centrifugal separation (5147R centrifuge, Germany, Eppdorf) at the rate of 1000 r/min, 30 mL of sterile TE buffers (10 mmol/L, Tris-HCl, 1 mmol EDTA, adjusted to pH = 8, 121 °C and sterilized for 20 min) was added in the solutions. The supernatants were removed after re-centrifugation. Then, 15 mL of distilled water was added and fully shaken. Afterward, 5 mL of solution was taken for DNA extraction in the biofilms. The pretreated water samples were filtered (0.22 μm bacterial filter film). The filter films were soaked in 10 mL of sterilized saline water after filtration and then placed in an ultrasonic cleaning instrument (KH2200DB, Kunshan Hechuang in China) and shaken for 10 min. The solutions were then repeatedly beaten by the liquid drawing gun to enable the cells on the membrane to enter completely into the solutions. The solutions were placed in centrifuge tubes (1.5 mL) and underwent centrifugation for 3 min at the rate of 10000 r/min to facilitate bacteria collection. The metagenomics DNA extraction kits produced by Shanghai Sangon were adopted to extract ICS samples and TCS samples.

16S rDNA gene full-length amplification and carrier connection transformation

Bacteria 16S rDNA universal primer 27F (5'-AGAGTTTGATCCTGGCTCAG-3', M = CorA) and 1492R (5'-CTACGGCTACCTTGTTACGA-3', T = 3', Y = CorT) were adopted to amplify the target genes of two groups of samples (Masoud et al., 2011). The PCR reaction procedure (Hao et al., 2009) was predegenerated at 95 °C for 5 min, degenerated at 94 °C for 30 s; annealed at 52 °C for 30 s, and extended to 72 °C for 2 min for a total of 35 circulations. The procedure also involved extension at 72 °C for 10 min before preservation at 4 °C. PCR amplification products were detected by 1.2% agarose gel electrophoresis. The products were connected to PGEM-T clone by PGEM-T cloning (Promage Company) kits and heat-shock transformed into escherichia coli DH5α competent cells. The products were then coated with Amp/IPTG-Gal that contains LB culture mediums. After 16 h of culture at 37 °C, the samples were subjected to 4 °C color development process for 1 h. White-blue plaque selection and white plaque validation were conducted. The positive clones in each sample were randomly selected for sequencing by Shanghai Sangon Co., Ltd.

System development analysis

Chimera detection was conducted on the sequences using a Chimera detection program on the Ribosomal database project (RDP) website. The obtained sequences were then classified by Dutor software, and similar sequences were excluded. The remaining sequences were entered into the BLAST facility of the National Center for Biotechnology Information (http://www.ncbi.nlm.nih.gov). Comparative analysis was conducted on the remaining sequences and those existing in GenBank + EMBL + DDBJ + PDB. Sequences with the highest similarity and those with species that have high similarity were downloaded as reference. All sequences were compared by ClustalW program in BioEdit. The system development tree diagram was generated using MEGA 4.0.

Results and discussion

Bacterial diversity analysis of samples in ICS and TCS

The sequences were analyzed with Dutor software. After eliminating similar sequences, ICS obtained 30 genotypes and 32 for TCS. The sequence of each genotype in ICS and TCS was entered into the RDP website. The sample system group was determined by a classifier program. After analysis, 16S rDNA sequences of 108 positive clones of bacteria were identified in the ICS sample library, which belonged to 7 bacterial communities (as shown in *Figs. 2* and *3*). These sequences are *Bacteroidetes* (45%), *β-proteobacteria* (27%), *γ-proteobacteria* (16%), *α-proteobacteria* (3%), *Verrucomicrobia (*3%), *Chloroflexi* (3%), and unclassified_Proteobacteria (3%). The dominant bacterial communities were *Bacteroidetes* (45%), *β-proteobacteria (*27%), and *γ-proteobacteria* (16%). The 16S rDNA sequences of 108 positive clones of bacteria in TCS sample library belonged to 9 bacterial communities (as shown in *Figs. 4* and *5*), namely, *β-proteobacteria* (37%), *γ-proteobacteria* (25%), *Bacteroidetes* (24%), *δ-proteobacteria* (3%), *Firmicutes* (3%), *Nitrospira* (3%), *Actinobacteria (*3%), *Acidobacteria (*3%), and unclassified_Proteobacteria (5%). The dominant bacterial communities in ICS were *Bacteroidetes*, *β-proteobacteria*, *andγ-proteobacteria*, which account for 45%, 27%, and 16%, respectively. The dominant bacterial communities in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75497559

TCS were*β-proteobacteria*, *γ-proteobacteria*, and *Bacteroidetes*, accounting 37%, 25%, and 24%, respectively. Different operation modes and different growth environments for microorganism between ICS and TCS led to different dominant bacterial communities and different community structures. In ICS, the growth environment for biofilm microorganisms was (aerobic/hypoxic)^n. *Bacteroidetes* was the dominant bacterial community, which has a proportion of 45%. In TCS, the growth environment for biofilm microorganisms was anaerobic/aerobic, in which *β-proteobacteria* was the dominant bacterial community with a proportion of 37%. The community structure of ICS was more stable than that of TCS, and the communities in ICS were less than those in TCS.

System development analysis of bacteria in samples in ICS and TCS

To further understand the system development of bacteria in biofilm samples in ICS and TCS, the genotypes that represent different sequences were ordered in accordance with the principle of maximum homology. This approach was adopted to construct the system development tree diagrams of Proteobacteria and other communities in ICS and TCS gene libraries, as shown in *Figures 4, 5, 6,* and *7*. *Figures 4* and *5* show the system development trees of Proteobacteria and other communities based on 16S rDNA sequence in ICS system. *Figures 6* and *7* show the system development trees of Proteobacteria and other communities based on 16S rDNA sequence in ICS system.

System development analysis of bacterial in ICS

In ICS, *Bacteroidetes* was the dominant community with a proportion of 45%. This finding means that nearly half of bacteria in the biofilm samples in ICS were *Bacteroidetes*. The most similar structure of this sequence is from eutrophic lakes (Cantafio et al., 1996), which include 12 genotypes of uncultured bacteria. The bacteria in *Bacteroidetes* community were bacillus of different sizes. These bacteria were reported only in the phosphorus removal system, but were barely investigated in the activated sludge and nitrogen removal system (Amann et al., 1995). ICS did not adopt anaerobic phosphorus release, but it showed significant phosphorus removal effect. Moreover, the performance of ICS in TN removal was obviously better than that of TCS. Thus, we can conclude the presence of microorganisms with functions of anoxic phosphorus uptake and denitrifying phosphorus removal, which exist in the form of polyphosphate under the aerobic condition in *Bacteroidetes* (Liu et al., 1996). Therefore, new bacteria exist that are related to nitrogen and phosphorus removal in *Bacteroidetes*. These bacteria accounted for 27% of bacteria in the library, including 9 genotypes. The homology between Z-28 and *Thauera sp.* (CP001281) was as high as 99%. *Thauera sp.* was the denitrification bacterium that could remove NO_3^--N and PO_4^{3-}-P from wastewater through denitrification (Manz et al., 1994; Amann et al., 1995). This bacterium played a very important role in denitrification and in the degradation process of organic matters (Ayara et al., 2011). In the anoxic or aerobic period, the exterior of the biofilm was the aerobic layer and the interior was the special structure for the anaerobic/anoxic layer. This structure provided favorable conditions for the existence of denitrifying bacteria and benefited nitrogen removal or denitrifying phosphorus removal in ICS. The other clones were uncultured bacteria. The *γ-proteobacteria* was the third largest bacterial community with the proportion of 16% in the library. This bacterium included three genotypes, among which the homology

DOI: http://dx.doi.org/10.15666/aeer/1704_75497559

between Z-15 and *Xanthomonas sp.* (AJ786786) was 98%. *Xanthomonas sp.* had strong degradation ability for organic carbon. Thus, it was beneficial for COD removal.

System development analysis of bacterial in TCS

In TCS, *β-proteobacteria* was the dominant bacterial community with proportion of 37%. However, it was the second largest bacterium in ICS with proportion of 27%. This bacterium included 12 genotypes, in which the homology between F-2 and *Bacterium AEOC009* (AB208727) was 99% and that between F-42 and *Arabidopsis lyrata* was 99%. Other clones were uncultured bacteria. According to Amann et al.'s study of the bacterial community structure in the biological reactor, *β-proteobacteria* and *Bacteroidetes* were the most dominant communities in the wastewater treatment system. The former played an important role in organic matter degradation, nitrogen and phosphorus removal, and flocculation structure formation (Burrell et al., 1999). Second, *γ-proteobacteria, δ-proteobacteria, and* unclassified *Proteobacteria* accounted for 25%, 3%, and 5.5% of bacteria in the library, respectively. They were all *Proteobacteri*a, which could efficiently remove organic matters, nitrogen, and phosphorus. *Bacteroidetes* was the third largest community in the library with proportion of 24%, but it was the dominant community in ICS. The bacteria in this community were related to nitrogen and phosphorus removal. Thus, ICS had better performance than TCS in nitrogen and phosphorus removal. *Nitrospira* (nitrification spirillum) accounted for 3% of bacteria in the library. The homology among F-3 and other two unnamed *Nitrospira* (EU55916 and DQ059545) was 99%. *Nitrospira* was an important NO_2^--N oxidation bacterium. The research of Burrell et al. (1999), Lee et al. (2002) and Benítez-Páez et al. (2016) showed that the bacteria in *Nitrospira* species could have played the role of NO_2^--N oxidation during nitrification rather than *nitrobacter*.

Conclusions

(1) The concentrations of COD, TN, NH4 + -N, and TP in inflow water were 309.5, 63.61, 60.28, and 5.16 mg/L, respectively. The removal rates of COD, TN, NH4 + -N, and TP were 93.4%, 85.6%, 100%, and 100% in ICS and 91.1%, 70.9%, 100%, and 100% in TCS, respectively. Thus, TN removal rate in ICS was 14.7% higher than that in TCS.

(2) Different control systems of SBBR will cause differences in bacterial community structures and their relative proportions. In the ICS sample library, 16S rDNA sequences by bacterial clones belonged to 7 bacterial communities, namely, *Bacteroidetes*, *β-proteobacteria*, *γ-proteobacteria*, *α-proteobacteria, Verrucomicrobia*, *Chloroflexi,* and unclassified_Proteobacteria. In the TCS sample library, 16S rDNA sequences by bacterial clones belonged to 9 bacterial communities, namely, *β-proteobacteria*, *γ-proteobacteria, Bacteroidetes*, *δ-proteobacteria*, *Firmicutes*, *Nitrospira, Actinobacteria, Acidobacteria,* and unclassified_Proteobacteria.

(3) The growth environment of the biofilm microorganisms in ICS was aerobic/hypoxic, in which *Bacteroidetes* was the dominant community with the proportion of 45%. The growth environment of the biofilm microorganisms in TCS was anaerobic/aerobic, in which *Betaproteobacteria* was the dominant community with the proportion of 37%.

(Received 27th Feb 2019; accepted 3rd May 2019)

Abstract. To understand changes of soil properties in different years of cultivation abandonment in the midstream and downstream of Shiyang River area, soil physicochemical characteristics, microbial population, soil microbial biomass, relationships between them and comprehensive evaluation of soil fertility quality were analyzed. The results showed that soil pH increased slightly, soil water content, sand content, the number of bacteria ,the number of actinomycetes and SMBN (soil microbial biomass nitrogen) decreased then increased, soil organic carbon, total potassium, Quick-available K, Quick-available P, SMBC (soil microbial biomass carbon), SMBP (soil microbial biomass phosphorus) and SMBC/SMBN increased then decreased, total nitrogen increased then decreased and tended to be stable, total phosphorus and the number of fungi decreased then increased and decreased finally, and different abandoned years had different significant difference. From the correlation analysis and principal component analysis (PCA), there were close correlations among the soil physical characteristics, soil chemical characteristics and the number of soil microbes, soil microbial biomass. The key factors determining the soil quality were the soil pH, sand content, soil water content, soil water content, total nitrogen, Quick-available K, the number of fungi, SMBC and SMBN. The results that the effects of 4a on the soil during restoration were better for soil improvement than the other abandoned years, making the abandoned years of 4a more critical for use in the ecological restoration and control of the midstream and downstream of Shiyang River area.
Keywords: *soil microbial characteristics, soil physicochemical characteristics, soil fertility, midstream and downstream of Shiyang river, years of abandoned cultivated lands*

Introduction

Shiyang River is a typical inland river in the arid regions of northwestern China. Its downstream Minqin area was once a natural oasis with plenty water and rush grass (Feng, 1963). However, in recent decades, with the continuous expansion of the population and economic scale of midstream area of Shiyang River, especially the expansion of artificial oases, the downstream surface water resources are decreasing day by day, the groundwater is seriously over-exploited, the degree of mineralization is rising, natural vegetation is subject to serious disturbance and damage, a series of ecological problems such as desertification and salinization have been intensified (Zhang et al., 2016; Chang et al., 2016), causing large-scale land to be abandoned and uncultivated which deteriorates into secondary grassland. If these secondary grasslands

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75617572

are not properly protected, degradation will speed up, wind erosion and desertification will occur with emergence of new source of sand and dust, forming a vicious circle and seriously damaging soil ecosystem of the secondary grassland in the middle and lower reaches of Shiyang River (Chai et al., 2015). Therefore, how to properly protect and restore secondary grassland in abandoned oasis area in the middle and lower reaches of Shiyang River is an ecological problem that needs to be settled urgently.

Soil serves as the carrier of many ecological processes in ecosystems and the substrate for plant growth (Hu and Guo, 2012). Its physicochemical properties and biological properties are key indicators reflecting restoration degree of soil ecosystems (Yuan et al., 2012). Studies have shown that soil microbes in soil ecosystems mainly participate in material circulation and energy flow by decomposing animal and plant residues, which serve as supply source and reservoir pool of soil nutrients, affecting vegetation succession and soil quality (Kardol et al., 2007). The amount of soil microbes is used to study and evaluate soil microbial regulation functions, which can reflect the effects of various soil factors on soil microbes and its effects on plant growth and soil fertility, and exert certain regulation on the whole ecosystem (Harris, 2003). Soil microbial biomass constitutes living soil organic matter, which is a sign of soil activity and one of the early warning indicators of soil ecosystem changes (Singh et al., 2014). At present, research on the evolution of soil properties mainly focuses on physicochemical properties of soil (Zhao et al., 2012), while there are few reports on the evolution of soil properties in the Shiyang River Basin. In view of this, this paper studies change characteristics of physical properties, chemical properties and microbial properties of secondary grassland with different abandoned years in different middle and lower reaches of Shiyang River, discusses the relationship between them and makes comprehensive evaluation of soil quality in this area, with a view to making in-depth exploration into evolution process of soil properties in Shiyang River Basin, and providing a theoretical basis for ecological restoration and management in the area.

Materials and methods

Overview of the study area

The test site was selected in Huanghui Village and Ziyun Village, Xiqu Town, north of Minqin County, Gansu Province. The geographical coordinates are located at east longitude 103°07′50″~103°37′56″ and north latitude 39°01′30″-39°03′28″. The altitude is 1297~1306 m, the annual average temperature is 7.4°C, the average annual precipitation is 110 mm which is mainly concentrated in July~ September, the annual average evaporation is 2644 mm, the annual sunshine hours are 2832.1 h, and the annual average wind speed is 2.3 m/s. The soil type is gray brown desert soil. The main shrub plants in the plot include Nitraria schoberi, Kalidium foliatum, Lycium chinense, Nitraria sibirica, Reaumuria songarica, etc. The herbaceous plants include Convolvulus arvensis, Chenopodium album, Halogeton arachnoideus, Suaeda glauca, Peganum harmala, Salsola ikonnikovii, etc. (Chai et al., 2015).

Sample site setting and soil sample collection

In September 2012, interview and investigation was conducted in the forestry department and local residents of Minqin County to accurately grasp abandoned time in the middle and lower reaches of Shiyang River. By using method of space replacement

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75617572

time, sections with uniform plant growth, small changes in microtopography, and without topography change owing to natural factors or soil material redistribution caused by human factors were selected as test area. While ensuring that soil parent materials of the sample site was consistent, 9 wastelands where crops have been planted 1, 2, 3, 4, 5, 8, and 15. 24 and 31a with an area of 1 hm2 was selected as sample site (see *Table 1*).

Five soil sample collection points were selected in each site using “S” method, and each collection point was repeated three times. 0～10 cm soil samples were taken with soil drill (soil drills type: SoilMoisture0200.0206L06.0215F1L05). After the same soil samples were uniformly mixed, the soil samples were separated into two parts by quartering and enclosed to be brought back to the laboratory. One part is used for the determination of soil physicochemical properties, and the other part is used for the determination of soil biological properties (at 4°C for less than 24 h).

Determination method

Determination of soil physicochemical properties

Soil pH was determined by pH instrument (PHS-3S), soil moisture content was measured by oven drying method in incubator (Shanghai yiheng DHG-9030A electric thermostat), and the sand content (the sum of coarse sand and fine sand) was measured by Malvern Mastersizer 2000. The organic carbon was determined by potassium dichromate-sulfuric acid external heating method, total nitrogen was determined by Kjeldahl distillation method, total phosphorus, available phosphorus were determined by NaHCO3 extraction- Mo-Sb-Vc colorimetric method, total potassium, available

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75617572

potassium were determined by atomic absorption spectrophotometry. Refer to "Soil Agricultural Chemistry Analysis" for the specific methods (Bao, 2005).

Determination of soil microbial properties

(1) The amount of soil bacteria, fungi and actinomycetes was determined by flat surface smearing (Xu and Zheng, 1986), in which beef extract peptone medium was used for bacteria, Martin-Bengal red medium was used for fungus, and modified Gaoshi No.1 medium was used for actinomycete.

(2) Determination of soil microbial biomass

Soil microbial biomass was determined by chloroform fumigation incubation method (Sparling et al., 1997; Yao and Huang, 2006).

1) Soil microbial biomass carbon (SMBC): was determined by K2Cr2O7-H2SO4 external heating method. The calculation formula is:

$$SMBC\ (mg/kg) = (Ec- Ec0) / kEc \quad (Eq.1)$$

2) Soil microbial biomass nitrogen (SMBN): was determined by Kjeldahl determination method. The calculation formula is:

$$SMBN\ (mg/kg) = (En- En0) / kEn \quad (Eq.2)$$

3) Soil microbial biomass phosphorus (SMBP): was determined by molybdenum blue colorimetric method. The calculation formula is:

$$SMBP\ (mg/kg) = (Ep- Ep0) / kEp \quad (Eq.3)$$

In the formula: Ec, En and Ep are the contents of organic carbon, total nitrogen and phosphorus in the fumigated soil extract, Ec0, En0 and Ep0 are the contents of organic carbon, total nitrogen and phosphorus in the unfumigation soil extract, and kEc, kEn and kEp are correction coefficients which are 0.38, 0.54 and 0.40, respectively.

Data Analysis and Processing

The test data was the average of 3 replications, and analysis of variance, correlation analysis, and principal components analysis (PCA) were performed using SPSS 19.0 software and tabulated with Excel 2010.

Results and analysis

Characteristics of physic-chemical properties of soil

The soil physicochemical properties of secondary grassland with different abandoned years are shown in *Table 2*. With the extension of abandoned years, soil pH generally shows an upward trend with a range of 8.0-8.5; the soil water content decreases first in 1-4a, 8- 24a and then increases in 4-8a, 24-31a, with significant difference between different years ($P<0.05$), of which the maximum is reached at 8a (7.26%); the sand content in the soil decreases first in 1-4a, 5- 8a, 15-24a and then increases in 4-5a, 8-15a, 24-31a, with significant difference between different years ($P<0.05$).

With the extension of abandoned years, soil organic carbon increases first in 1-2a, 3-4a, 5-15a, 24-31a and then decreases in 2-3a, 4-5a, 15-24a, with maximum of 1.76%

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75617572

achieved at 4a; the total nitrogen increases first in 1-2a and 3-4a, then decreases (2-3a) and finally stabilizes (4-31a), with the maximum of 0.07 achieved at 1a, 4a; the total phosphorus decreases first in 1-3a, 4-5a, 8-15a, 24-31a and then increases in 3-4a, 5-8a, 15-24a, with significant difference between different abandoned years($P<0.05$), and the maximum of 0.66 g/kg is achieved at 1a, followed by 4a (0.58 g/kg); the total potassium increases first in 1-2a, 4-5a, 15-24a and then decreases in 2-4a, 5-15a, 24-31a, with the maximum of 38.17g/kg achieved at 5a. The available potassium increases first in 1-3a, 4a-15a, 24-31a and then decreases in 3-4a, 15-24a, with the maximum of 636.09 mg/kg achieved at 15a, showing significant difference between different years ($P<0.05$); the available phosphorus decreases first in 1-2a, 3-5a, 15-24a and then increases in 2- 3a, 5-15a, 24-31a, with the maximum of 0.178 mg/kg achieved at 3a, showing no significant difference between different abandoned years ($P>0.05$).

Soil microbial properties

As can be seen from *Table 3*, the number of soil bacteria decreases sharply (1-2a) with the extension of abandoned years, increasing first after 2a (2-4a, 8-24a) and then decreasing (4-8a, 24- 31a); the number of fungi decreases first (1-2a, 4-5a, 8-31a) and then increases (2-4a, 5-8a); the number of actinomycetes decreases first (1-3a, 4-5a, 8-15a, 24-31a) and then increases (3-4a, 5-8a, 15-24a), reaching the maximum of 8.37×105cfu/g at 8a and showing significant difference between different abandoned years ($P <0.05$); soil microbes have different compositions, and with the extension of abandoned years, the proportion of bacteria, fungi and actinomycetes decreases to a different extent, of which bacteria accounts for the largest proportion, with the maximum of 95.65% achieved at 1a, while the proportion of fungi is less than 1%.

With the extension of abandoned years, SMBC fluctuates, increasing first (1-2a, 3-8a, 15-24a) and then decreasing (2-3a, 8-15a, 24-31a), showing significant difference between different abandoned years ($P< 0.05$), with the maximum of 979.13 mg/kg achieved at 8a; SMBN decreases first (1-2a, 4-8a, 15-24a) and then increases (2-4a, 8-15a, 24-31a); SMBP increases first (1-2a, 3-4a) and then decreases (2-3a, 4-31a), reaching the maximum of 168.35 mg/kg at 4a; SMBC/SMBN increases first (1-2a, 3-8a, 15-24a) and then decreases (2-3a, 8-15a, 24-31a), reaching the maximum of 9.2 at 8a.

Correlation between soil microbial properties and soil physic-chemical properties

From *Table 4*, it can be known that the number of soil bacteria is significantly positively correlated with total phosphorus ($P<0.01$), and significantly negatively correlated with pH, total potassium and available potassium ($P<0.01$). The number of fungi is significantly positively correlated with organic carbon and total nitrogen ($P<0.01$), significantly negatively correlated with available potassium ($P<0.01$), and negatively correlated with water content ($P<0.05$). The number of actinomycetes is significantly negatively correlated with sand ($P<0.01$), and positively correlated with organic carbon ($P<0.05$); SMBC is significantly positively correlated with pH ($P<0.01$), positively correlated with available potassium ($P<0.05$), and negatively correlated with sand and available phosphorus ($P<0.05$). SMBN is significantly positively correlated with organic carbon ($P<0.01$), significantly negatively correlated with water content and available potassium ($P<0.01$), and positively correlated with total nitrogen ($P<0.05$). SMBP is significantly positively correlated with organic carbon ($P<0.01$), and positively correlated with total nitrogen ($P<0.05$). The correlation between the remaining is not obvious.

Comprehensive evaluation of soil fertility quality

Soil quality assessment can provide a theoretical basis for the restoration and management of degraded land (Kirkegaard et al., 2000). In this study, principal component analysis was used to comprehensively evaluate soil quality (*Table 5*). The cumulative contribution rate of the first 5 principal components is 87.61%, which is in line with the requirements of principal component analysis. Therefore, the 5 principal component analysis can represent the variation information of soil quality of secondary lands with different abandoned years in the lower reaches of Shiyang River.

Table 5. *The loading factor, eigenvalue and contribution ratio of 5 PCAs*

Index	The first principal component	The second principal component	The third principal component	The forth principal component	The fifth principal component
pH	-0.634	0.614	0.179	0.184	-0.270
Water content	-0.100	-0.630	0.329	0.168	0.621
Sand content	-0.199	-0.117	-0.770	0.011	0.150
Organic carbon	0.812	0.291	0.098	0.340	0.152
Total nitrogen	0.824	-0.079	0.171	-0.138	0.224
Total phosphorus	0.558	-0.458	0.586	-0.293	-0.171
Total potassium	-0.381	0.293	-0.139	-0.757	0.241
Quick-available K	-0.810	0.252	0.052	0.469	-0.014
Available P	0.164	-0.692	-0.166	0.375	0.091
Bacteria	0.480	-0.596	0.091	-0.031	-0.473
Fungi	0.802	0.530	-0.005	0.155	-0.076
Actinomycetes	0.332	0.506	0.682	0.147	0.147
Soil microbial C	-0.537	0.145	0.785	-0.139	-0.022
Soil microbial N	0.783	0.325	-0.330	-0.055	-0.340
Soil microbial P	0.582	0.574	-0.212	-0.041	0.458
Eigenvalue	5.154	3.065	2.408	1.287	1.227
Rate of variance %	34.361	20.433	16.051	8.578	8.179
Cumulative rate %	34.361	54.794	70.845	79.423	87.603

The first principal component mainly reflects pH, organic matter, total nitrogen, available potassium, fungi and soil microbial biomass nitrogen index (absolute value of load value > 0.6), indicating that it is the most important impact factor in soil quality assessment. The second principal component mainly reflects pH, water content and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75617572

bacteria. The third principal component mainly reflects sand content, actinomycetes and soil microbial biomass carbon. The fourth principal component mainly reflects total potassium, and the fifth principal component mainly reflects water content.

From weighting of the eigenvectors and the normalized data, the scores of the 5 common factors in different abandoned years are obtained, and then comprehensive scores of soil fertility quality under different abandoned years are obtained by weighting of scores of the factors and the variance contribution rate (soil quality comprehensive evaluation index). See *Table 6* for the result, which is sorted as abandoned year 4a (1.087) > abandoned year 8a (0.333) > abandoned year 2a (0.007) > abandoned year 3a (-0.087) > abandoned year 15a (-0.157) > abandoned year 1a (-0.183) > abandoned year 24a (- 0.253) > abandoned year 31a(-0.363) > abandoned year 5a(-0.383), indicating that abandoned year 4a is a key period of restoration. After abandoned year 5a, soil quality decreased to varying degrees. It can be seen that the sorting results of soil quality comprehensive evaluation index are consistent with the previous demonstration results, so the results of principal component analysis can better reflect the actual conditions of the soil.

Discussion

The experimental study found that with the extension of abandoned years, soil pH of the secondary grassland with different abandoned years in the lower reaches of Shiyang River gradually increased but did not show significant difference, which was generally alkaline. Soil available potassium content increased in fluctuations, which may be because soil leaching effect increased the available potassium content in the soil surface (Wang, 2016); the soil water content was generally "V"-shaped, and the maximum value appeared at abandoned year 8a, which may be due to the decline of vegetation coverage and surface exposure with the return of farmland to forest (Wang, 2016). In addition, because of the combined effect of precipitation and natural sedimentation, the soil structure is continuously restored, and the soil capillary water is effectively stored (Wang, 2016). Moreover, as abandoned year 8a vegetation is mainly perennial shrubs, such plants can obtain water in deeper soil layers, while surface soil water content contributes little to it (Walter, 1979); soil sand content decreased gradually during abandoned years 1-4a, fluctuated after 5a, and gradually increased after abandoned year 24a. Soil organic carbon, total nitrogen, total phosphorus, total potassium and available phosphorus decreased with the extension of abandoned years. The reason for this change may be that the vegetation richness index and diversity index decreased in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75617572

varying degrees with the extension of abandoned years, and then the bare soil area increased gradually. In addition, the lower reaches of Shiyang River has strong wind (Chang et al., 2007), desertification and wind erosion of the sample site thus deteriorate, while soil sand is not easily eroded by wind, causing a large loss of nutrients. Due to the limitation of water and heat, the slow decomposition rate of organic matter reduces the ability of nutrient return (Liu et al., 2016). At the same time, with the extension of abandoned years, vegetation coverage and biomass decrease, which reduces the supplement of soil nutrients by plant residue (Li et al., 2010).

Bacteria in the soil constitute the main microbial group, its maximum number is up to 23.06×105 cfu/g, accounting for 95.65% followed by actinomycetes and fungi was the least. This may be because the soil in this study area is slightly alkaline, which is beneficial to the growth of bacteria and actinomycetes, while fungus grows poorly in a slightly alkaline environment. This is consistent with the results of Tan Qiujin (Tan et al., 2014). The number of soil bacteria, fungi and actinomycetes in different abandoned years reaches the highest at abandoned year 1a, abandoned year 4a and abandoned year 8a. During abandoned years 1-8a, field husbandry, fertilization and other agricultural management measures just stopped or stopped for a short time, so the good soil moisture conditions and ventilation, coupled with higher soil nutrient content enabled strong microbial activity. In addition, an increase in the number of soil microbes leads to a corresponding increase in the proportion. With the extension of abandoned years, the trend of soil microbial biomass changed slightly. SMBC content was the highest at abandoned year 8a, SMBN and SMBP contents were the highest at abandoned year 4a, which was significantly higher than that at other abandoned years ($P<0.05$).This may be because vegetation grew fast at abandoned years 4a and 8a, root biomass and root exudates then increased, so that soil nutrients accumulated continuously. It was also related to the fact that the collected sample was surface soil (0~10 cm). The surface layer accumulated a large number of plant residues which enriched soil organic matter, and also the layer had good hydrothermal and ventilation condition (Wen et al., 2010), providing a suitable environment for microbial growth and reproduction, and promoting biological activity of microbes. The soil microbial biomass carbon and nitrogen ratio are important indicators to characterize whether soil microbial growth is restricted by carbon or nitrogen, which affect the community structure of soil microbes (Yang et al., 2014). Soil SMBC/SMBN≥30 and SMBC/SMBN≤20 indicate that soil microbial growth is respectively limited by nitrogen source and carbon source. When SMBC/SMBN=25, it is most beneficial to soil microbial growth, which is conducive to the normal function of soil microbes in ecosystem (Zhang et al., 2012). SMBC/SMBN ranged from 1.5~9.2 in the secondary grassland with different abandoned years in the lower reaches of Shiyang River, indicating that supply quantity of carbon source is the main limiting factor for soil microbial growth. The correlation results also show that soil microbial biomass is related to soil nutrients in different degrees (Niu et al., 2011), which is significantly correlated with soil organic matter, so this conclusion is further confirmed. However, soil represents a relatively complex ecosystem, and soil microbial biomass is also affected by factors such as temperature, air temperature, soil bulk density, etc. which demands comprehensive considerations.

Soil microbes are reservoirs of soil nutrients and play an important role in soil organic matter and nutrient conversion and cycling (Singh et al., 2014). Wang et al. (2010) and Yang et al. (2014) have found that there is a certain correlation between soil microbes and soil physicochemical properties. This study also shows that soil microbial

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75617572

quantity, soil microbial biomass under different abandoned years are closely related to soil physicochemical properties, good physical environment (moisture, pH and gas permeability) will promote the growth of soil bacteria, fungi and actinomycetes, thereby increasing the number of microbes, and the change in soil microbial quantity will accelerate the soil nutrient cycle, leading to an increase in soil nutrients (Taylor et al., 2002). The principal component analysis showed that indicators such as soil pH, sand, water content, organic matter, total nitrogen, available potassium, fungi, soil microbial biomass carbon, soil microbial biomass nitrogen have a large contribution rate in each principal component, which can be used to evaluate important factors in soil fertility quality of the area. The results of comprehensive evaluation of soil fertility indicated that abandoned year 4a> abandoned year 8a> abandoned year 2a> abandoned year 3a> abandoned year 15a> abandoned year 1a> abandoned year 24a> abandoned year 31a> abandoned year 5a, of which abandoned year 4a is a key period of recovery. This conclusion is consistent with the conclusions obtained from single factor analysis to a certain extent and the two are mutually confirmed.

Conclusion

With the extension of abandoned years, soil pH gradually increased, soil water content, sand content, bacteria number, actinomycetes number, SMBN decreased first and then increased; soil organic carbon, total potassium, available potassium, available phosphorus, SMBC, SMBP, The SMBC/SMBN increased first and then decreased; the total nitrogen first increased, then decreased, then increased and finally stabilized; the total phosphorus and fungi decreased first, then increased and finally decreased. There is a close correlation between soil physicochemical properties and soil microbial quantity and soil microbial biomass. Indicators such as soil pH, sand, water content, organic matter, total nitrogen, available potassium, fungi, soil microbial biomass carbon and soil microbial biomass nitrogen are important factors for evaluating soil fertility quality in this area. It can be inferred from the comprehensive evaluation of soil fertility quality that the abandoned year 4a is the key stage of restoration and control process in Shiyang River Basin management.

Abstract. Particle size distribution of the gravelly soil in debris flow source area has a great impact on the formation mechanism of debris-flow. In order to explore the relationship between particle composition and debris flow initiation, we collected 182 soil samples from debris flow source areas. Sieving tests have been conducted in the laboratory to acquire the fundamental particle size distribution data. Subsequently, the fractal theory was employed to compute the fractal dimension of each soil sample, analyzing the results of calculation we found that the gravelly soil in debris flow source area is mainly concentrated in one fractal dimension, the value of which ranges from about 2.250 to 2.798. Comparing the results of calculation and sieving experimentation, the underlying relationship between particle composition and fractal dimension can be revealed: the particle compositions of the gravelly soil tend to remain uniform as the fractal dimension increases. On the basis of the calculation results, the in-situ artificial rainfall experiments can be designed and performed. Analyzing the phenomenon during the processes of the experiments, the initiation mechanism with different fractal dimensions can be preliminarily identified: The gravelly soil which can mobilise into debris flows exhibits significant criticality feature, and the gravelly soil with fractal dimension ranges from 2.4 to 2.6 are more susceptible to mobilise into debris flow, and the scale of the debris flow is relatively larger. For slopes with fractal dimension < 2.4, the possibility of mobilisation into debris flow is extremely low. When fractal dimension ranges from about 2.6 to 2.7, the density of the formed debris flow is relatively lower, under which the formation of debris flows exhibits significant intermittent characteristics.

Introduction

Debris flows form a class of slope failures (Varnes, 1978) encompassing a wide range of characteristics and varying widely in magnitude (Jakob, 2005), composition (Coussot and Meunier, 1996), and mechanism of initiation (Coe et al., 2008a). Debris flows are recognized as a significant hazard in mountainous areas, and have been shown to be an important process controlling the transport of sediment and woody debris from hill slopes to channels in mountainous areas, with implications for channel form and riparian habitat (Brayshaw, 2009; Hogan and Schwab, 1991; Smadja, 1992). Because of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75737589

their high mobility, velocity and density, debris flows can be very destructive and damaging when they encounter infrastructure such as buildings, roads, bridges, pipelines and hydropower facilities, and may lead to loss of human life (Park et al., 2016; Chen and Lee, 2000; Gregoretti et al., 2016; Wang et al., 2017).

To mitigate and prevent hazards induced by debris flows and related risks, one must understand the formation of these in order to make reliable forecasts (Yu et al., 2014). Many factors are related to the occurrence of debris flows such as the basin gradient, the percentage of basin area with slopes greater than or equal to 30%, basin ruggedness, slope aspect, rainfall intensity, and soil properties, including the clay percentage, the percentage of organic matter, the soil composition, and the soil liquid limit (Cannon et al., 2010; Liu et al., 2009). Many researchers have focused on the prediction of their occurrence (Bathurst et al., 1997; Giannecchini et al., 2007; Ho et al., 2000) and estimation of their magnitude and runout distance (Hungr et al., 2008; Johnson et al., 2000; Miller and Burnett, 2008) in order to reduce associated risk. In addition, established prediction models include the Water-Soil coupling forecast model, the I-D (rainfall intensity-duration) prediction model and other statistical prediction models (Yang et al., 2016, 2002; Saito et al., 2010; Zhang et al., 2014a, b). Moreover, other parameter combination modes for defining a threshold for debris flow activity in terms of mean intensity, duration and mean annual precipitation were also presented for the debris flow prediction of dolomites in northeastern Italy (Bacchini and Zannoni, 2003; Giannecchini et al., 2016; Maggioni et al., 2016; Papa et al., 2013). Some researchers carried out experiments on slope stability considering mechanical property variations of the soil mass and established the model of debris flow initiation (Berti and Simoni, 2005; Iverson and LaHusen, 1989; Iverson et al., 1997). Other scientists used different approaches and discussed the relationship between particle composition and properties of debris flows (Li et al., 2007; Yong et al., 2013, 2005), and some models have been established (He et al., 2014; Ningsheng et al., 2004; Zhou et al., 2012), which greatly facilitate debris flows prediction and mitigation. However, due to the complexity of debris flow formation and subsequent dynamic process, the accuracy of the prediction often cannot meet adequately the requirements of disaster mitigation (Turkington et al., 2016). Prediction models based on the formation mechanism of debris flows promises an effective way to ameliorate the impact of such disasters.

Basically, three necessary conditions are required to fulfill debris flow initiation: energy conditions (slope gradient), meteorological conditions (rainfall condition) and material condition (particle size distribution and density). In the short term, the energy conditions can be taken as a constant, and the precipitation can be measured at nearby meteorological stations. The mechanical property of the loose solid material plays an extremely important role in debris flow initiation. From soil mechanics we know that the soil mechanical property with the major influence on debris flow initiation is soil composition. Therefore, identifying the particle size distribution of the loose solid material is the precondition for an accurate analysis of debris flow initiation. But the particle size distribution of the gravelly soil in the debris-flow source area is so wide that the critical particle grading features are not yet well understood. The composition and gradation of the particles in debris flow source areas have significant influence on debris flow formation, subsequent movement and resulting dynamic forces (Chen et al., 2010; He et al., 2016). Previous studies explored the characteristics of the gravelly soil (Li et al., 2007; MacDonald et al., 2012), and some models were established to reveal the relationship between mechanical properties of the gravelly soil and its particle size

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75737589

distribution (Chen, 2004; Hwang and Powers, 2003; Shimizu et al., 2011; Wang and Sassa, 2003; Zhou et al., 2012), but the influential of particle composition on debris flow initiation is still unclear. In addition, the complexity of the particle size distribution results in a non-deterministic and anisotropic gravelly soil structure, which poses great difficulties when attempting to use traditional methods based on linear analysis to quantitatively describe it (https://www.benthamopen.com/contents/pdf/TOCIEJ/TOCIEJ-10-877.pdf).

Based on the aforementioned discussion, to better understand the characteristics of the gravelly soil and reveal the relationship between mechanical properties and debris flow initiation, the main objective of this paper is to explore the characteristics of particle size distribution taken from areas prone to debris flows, and using fractal theory to calculate the fractal dimension of each sample. After the particle size distribution is established, the fractal dimension can be calculated, and the fractal characteristics can be fully understood. Taking into account of this data, the in-situ artificial rainfall experiments can then be conducted. By analyzing rainfall data, water content, and pore water pressure, the initiation mechanism of debris flow can be revealed, and the influence of particle composition on debris flow initiation can be identified, which in turn can greatly facilitate future debris flow prediction and mitigation.

Methodology

In this research, 182 soil samples were taken from 116 gullies before September 2013 that were identified highly prone to debris flows (all of the gullies are situated on Longmenshan fault zone; *Fig. 1*). The soil samples were sorted and dried in the laboratory to facilitate the sieve tests. Using sieve tests, the particle size distribution curves were established, and plotted in both plane-coordinate and double logarithmic coordinates.

Fractal theory

The gravelly soil in the debris-flow source areas shares some characteristics with the fragmented rocks. Therefore, the particle fractal dimension can be calculated using a rock-crushing model, which is derived from fractal theory (Carpinteri et al., 2004; Chen Yong, 1998). It is presumed that the diameter of a gravelly soil particle is R, while $N(R)$ denotes the number of particles whose diameter is larger than R, and these two parameters satisfy the general fractal equation:

$$N(R) = R^{-D} \quad \text{(Eq.1)}$$

where D is the fractal dimension. After differentiating we obtain *Equation 2:*

$$dN(R) \sim R^{-D-1} dR \quad \text{(Eq.2)}$$

The particle size distribution and frequency of gravelly soil fits the Weibull distribution well:

$$\frac{M(<R)}{M_0} = 1 - \exp[-(\frac{R}{R_0})^k] \quad \text{(Eq.3)}$$

where $M(<R)$ denotes the total mass of the particles whose diameter is smaller than R, M_0 is the total mass of the gravelly soil, R_0 is the average diameter of the gravelly soil, and k is a constant. For $R << R_0$, *Equation 3* was further manipulated, ignoring the quadratic term, and the following equation is obtained:

$$\frac{M(<R)}{M_0} = (\frac{R}{R_0})^k \quad \text{(Eq.4)}$$

From which we obtain *Equation 5:*

$$dM(<R) \sim \mathrm{R}^{\mathrm{k-1}} dR \quad \text{(Eq.5)}$$

The particle number of the gravelly soil and the mass of the gravelly soil satisfies the following equation:

$$dM(<R) \sim \mathrm{R}^3 dN(R) \quad \text{(Eq.6)}$$

Combining *Equations 2, 5* and *6,* the following equation can be derived:

$$\mathrm{D} = 3 - \mathrm{k} \quad \text{(Eq.7)}$$

Equation 7 is the function employed in this paper to calculate the fractal dimension, where D is the fractal dimension, while k is the slope of the line we are fitting in the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75737589

double logarithmic coordinates, where the X-axis is $\lg R$ and the Y-axis is $\lg[M(<R)/M_0]$.

A fractal phenomenon approximates self-similarity or statistical self-similarity. This similarity exists only within a certain range of scales. Therefore the similarity will not exist outside certain ranges. Outside of these ranges the objects do not possess fractal feature, which indicates the fractal scale-free interval is limited. On the basis of the complexity and particular nature of the gravelly soil, this paper chooses the coefficient of determination (R^2) of the fitted line as the index to determine if the soil samples possesses fractal features or not. If the coefficient of determination (R^2) of the fitted line is greater than 0.9, it means that the soil samples present good similarity and the fractal dimension can be calculated through $D = 3 - k$. On the other hand, if the coefficient of determination (R^2) of the fitted line is less than 0.9, the soil samples do not have fractal features, and *Equation 7* cannot be employed to calculate the fractal dimension.

Fractal features of the gravelly soil in debris flow source area

In total, 182 samples were sorted and prepared first (*Fig. 2*). Using sieve tests, the particle size distribution data were acquired and the particle size distribution curves were plotted using plane-coordinates and a double logarithmic scale (*Figs. 3* and *4*). By means of linear fitting we obtained the slope of the straight line, and then *Equation 7* was employed to calculate the fractal dimensions of all 182 soil samples. On analyzing the results, we found that the soil samples were mainly concentrated in one fractal dimension. About 161 soil samples satisfied the requirements of fractal theory well, and one fractal dimension accounted for 88.46% of the total samples. Therefore, we concluded that the gravelly soil is mainly concentrated in one fractal dimension. The dimension value ranges from about 2.25 to 2.98. The sample with the largest dimension was taken from Jiangjia gully, while the smallest was taken from Ganxi gully, and their double logarithm curves are depicted in *Figure 4a* and *b,* respectively. The distribution interval of one fractal dimension is illustrated in *Figure 5*. Through *Figure 5,* we found that the fractal dimensions of the 130 soil samples are within the range of 2.4–2.7, with one fractal dimension accounting for 80.75% of the total samples. This raises an obvious question: is it the case that gravelly soil with fractal dimension ranging from 2.4 to 2.7 is more susceptible to debris flow? This question merits further study in the future.

By comparing *Figures 3* and *4,* we found that the particle size distribution tends to remain uniform as the fractal dimension increases. In addition, as the coarse particle content increases, the fractal dimension decreases. The particle composition determines the kind of skeleton or mechanical properties of the gravelly soil, which in turn determines the strength and hydraulic conductivity.

Figures 3 and *4* illustrate that the fractal dimension varied with the particle size distribution. The more uniform the particle size distribution, the larger the fractal dimension becomes. The larger particles formed the skeleton of the gravelly soil, while the relatively smaller particles filled the pores. For soil samples with larger fractal dimension, the pores formed by larger particles are well filled with small particles. Under such circumstances, the hydraulic conductivity can be greatly reduced. Moreover, the strength of a gravelly soil with a larger fractal dimension is mainly provided by cohesion and sliding friction between particles. As the fractal dimension decreases, the porosity formed by larger particles could not be fully filled by the smaller particles. Therefore, the hydraulic conductivity becomes larger. For soil samples with a smaller fractal dimension, the strength of the soil is mainly determined by cohesion and occlusal friction.

In addition, soil strength plays a crucial role in slope stability analysis. Debris-flow initiation can generally be subdivided into two mechanisms: 1) failure of shallow landslides, which transform into debris flows, and 2) concentrated run-off (flash flood) erosion in channels filled with sediments, which may be augmented by landslides from the slope. To better understand the debris-flow initiation mechanism, the relationship between fractal dimension of gravelly soil and debris-flow initiation was investigated by conducting in situ artificial rainfall experiments in areas prone to debris flow.

In-situ debris flow initiation experiment

Based on the aforementioned dataset, a debris flow initiation experiment can be designed and conducted. A schematic diagram of the experiment is shown in *Figure 6*. The artificial rainfall experiment involved mainly the following equipments: an artificial rainfall system (water pump, water tank, bracket and spay nozzle), rainfall gauge, pore-water pressure sensors, water content sensors, video camera, and data collection system. As noted in section 2.2 we found that the soil fractal dimension ranges from about 2.25 to 2.98. Therefore we selected 2.3, 2.35, 2.4, 2.45, 2.5, 2.55, 2.6 and 2.7 as the experimental fractal dimension value to back-calculate the corresponding particle compositions. Through field investigation the dry density of the gravelly soil can be determined. The dry density ranges from 1.55 to 2.2 g/cm^3. In this research the dry density of the soil sample was assumed as 1.7, 1.8 and 1.9 g/cm^3, respectively. Previous research revealed that slope angle ranging from 25 to 45° gives favourable conditions for debris flow initiation. Due to the complexity and difficulties in the process of performing in-situ experiments, the slope angle is assumed as 35°. The slope size is 1.5 m × 2.3 m, the position and depth of the sensors are shown in *Figure 6*. A total of 12 sensors were used in the experiment. The sensors are buried in six locations, 0.7 and 0.17 m in depth, and 0.7 and 1.5 m away from the upper edge of the experimental slope. Rainfall intensity is 75.2 mm/h during the experiments, and the duration time are mainly dependent on the initiation of debris flows, after debris flow initiated, the rainfall processes will last 30-40 minutes in order to identify the scale of the debris flows.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75737589

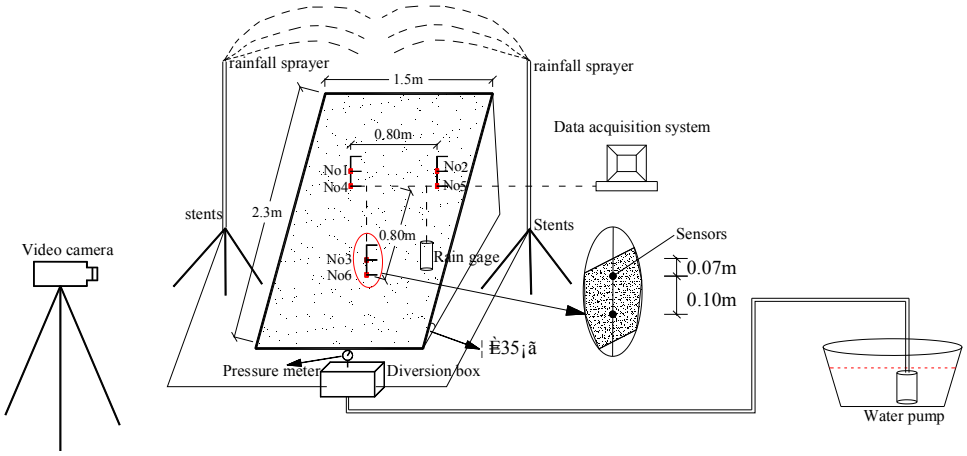

Figure 6. *Experimental scheme figure*

Test preparations

Based on the selected fractal dimension value, the particle size distribution for different particle diameters and different dry densities can be back-calculated, and the soil sample can be prepared. Subsequently the prepared soil can be placed on the slope at the chosen slope angle and the sensors positioned as shown in *Figure 7*. Based on the typical debris flow records in the past, most rainfall intensities that induced debris flows are over 30 mm/h, and in some areas they can exceed 100 mm/h. In this study, the rainfall intensities are controlled by a water pump. The sprinkler nozzle is 11 mm in diameter, and the rainfall intensity is set at 75 mm/h. The actual rainfall intensity of the experiment is found to be 75.2 mm/h during calibration. Then the rainfall gauge, pore water sensors and water content sensors are connected to the data collection system. The video camera, water pump and data collection system are turned on simultaneously to start the experiment (*Fig. 8*).

Experiment procedure

The particle composition under different fractal dimension and dry density can be back-calculated. According to the required slope angle (35°) and the slope size (1.5 m × 2.3 m), the slope can be modified. To facilitate and ensure the homogeneity of the samples, the initial water content is set as 10%, and the required water can be added and mixed uniformly with the gravelly soil. The soil can then be placed step by step on the modified slope. The thickness of the gravely soil is 35 cm, and the soil samples were placed in three layers, with the thickness of the upper, middle and lower layer of 10, 10 and 15 cm, respectively. After the lower layer is fully placed on the slope, the surface is scratched to avoid sliding slip plane between the lower and the mid-layer. Then the pore-water pressure sensors and water content sensors are placed in the correct locations. The sampling process is then repeated until the slope meets the requirements of the experiment. The rainfall gauge was placed on the edge of slope (as shown in *Figs. 6* and *8a*) with the aim of collecting real time precipitation data during the experiment. In order to analyze the formation mechanism, and to better illustrate the underlying reasons for each phenomenon in the experimental process, the video camera was placed in front of the slope. When the experiment was started, the artificial rainfall system, data collection system and video camera were turned on simultaneously.

Results

Following careful analysis of the results of the in-situ artificial rainfall experiments, we found that for gravelly soil, certain conditions are critical for debris flow initiation, and the gravelly soil that mobilized into debris flows manifests obvious criticality: The results indicate that while the fractal dimension of the slope is less than 2.4, regardless of the density or cumulative rainfall amount, no debris flows occurred during the whole

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75737589

rainfall process. Moreover, as the fractal dimension of the soil increased, the probability of debris flow initiating on the slope becomes higher, the unit weight of the formed debris flow becomes larger, varying from dilute debris flow (unit weight less than 1.8 g/cm^3) to viscous debris flow (unit weight greater than 1.8 g/cm^3).

By comparing the data from all the experiments the following results can be established: under identical dry density, slope angle and rainfall condition, the gravelly soil with lower fractal dimension (less than 2.4) experienced short term creep deformation during the rainfall process, which thereafter tends to stabilize, and the slope maintains its stability during the subsequent rainfall process. Under such circumstances, no overland runoff was witnessed on the slope and the infiltrated water flowed out at the base of the slope mainly through internal flow. In addition, the internal flow entrained the vast majority of the fine particles. Therefore the soil structure can be changed dramatically, and obvious sinking can be witnessed on the slope (*Fig. 9*). Due to the washing away of fine particles, the pore water sensors and water content sensors were finally exposed (*Fig. 9d*). But no debris flow was witnessed from beginning to the end of the experiments.

c. During the process of the experiment

d. At the end of the experiment (the sensors were exposed due to the continuous rainfall)

Figure 9. *Phenomenon of the experiment (here the fractal dimension of the soil sample is 2.35)*

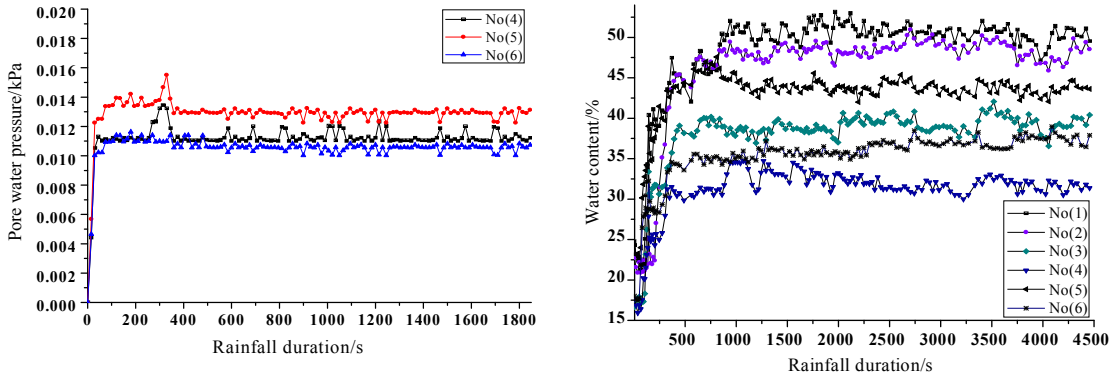
After the fractal dimension exceeds 2.4, the creep deformation lasted longer and the distance of the creep deformation is larger during the rainfall process. By analyzing the recorded videos, two types of runoff were identified: internal runoff and overland

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75737589

runoff. Comparing the internal runoff we found that for larger fractal dimension (larger than 2.4) very little of the fine particle fraction were washed out by the internal runoff. As the rainfall process continued, many erosion gullies were induced by overland flow, which subsequently caused an accumulation of material collapsed from banks. This subsequently failed as shallow slides when saturated, transforming the process into debris in a second stage. After this initial phase, the debris flow volume increased rapidly by a chain of subsequent cascading processes starting with collapses of the sidewalls, damming and breaching, leading to a rapid widening of the erosion channel. In terms of erosion amount, the subsequent mechanisms were much more important than the initial one. The damming and breaching were found to be the main reasons for the huge magnitude of the debris flows, and this agrees well with previous research (Hu et al., 2016).

The samples from the formed debris flows were collected and analyzed. Comparing them, we found that the unit weight of the debris flow increases as the fractal dimension increase. For slopes with fractal dimension 2.4, the unit weight of the formed debris flow is around 1.63 g/cm^3, but the unit weight of samples taken from slope with fractal dimension 2.7 is more than 1.82 g/cm^3. These results indicate that as the fractal dimension of the soil increases, the formed debris flow is likely to change from dilute to viscous debris flow. These results demonstrate that the unit weight of the formed debris flow is closely linked to particle size distribution. This can provide useful information for future debris flow prevention. For slope with identical fractal dimension, as the dry density increases, debris flow initiation process takes a longer time, but for slopes with fractal dimension smaller than 2.4, no debris flows were witnessed.

Analyzing the pore-water pressure and water content pressure we found that regardless of whether a debris flow was formed or not, the pore water pressure and water content curves exhibit similar characteristics. At the beginning of the rainfall process, the pore water pressure gradually increased to its peak value and then decreased to a given value, as shown in *Figure 10*. But the water content first increased and then maintains a peak value for the duration of the rainfall. For soil with different fractal dimension and dry density, the peak value and fixed value may show some variations, but the trends are identical. Here we take the pore water pressure and water content from the slope with fractal dimension 2.35 as an example to illustrate this phenomenon (*Fig. 10*).



a. pore-water pressure curves **b. water content curves**

Figure 10. *Pore-water pressure curves and water content curves of gravelly soil with fractal dimension 2.3*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75737589

Analyzing the pore water pressure curves and debris flow initiation process, it was also found that debris flow initiation always happens before the occurrence of peak pore water pressure. For slopes with different fractal dimensions, the time from initiation to the peak value of pore water pressure varied greatly.

Discussion

Based on the analysis in section 2.2, we concluded that the fine particle portion increases with the increasing of fractal dimension. Previous research (He et al., 2014) revealed that permeability coefficient and fractal dimension displays an exponential relationship, and the function is presented in *Equation 8,* where k denotes coefficient of permeability, D is fractal dimension of the gravelly soil, and ρ_d is dry density. Through *Equation 8* we found that for a given dry density, the permeability coefficient decreased dramatically as fractal dimension increased. The in-situ artificial rainfall experiment agrees well with previous research: for slope with lower fractal dimension (less than 2.4), no overland flow was identified during the entire experiment, and no obvious peak pore-water pressure was witnessed, and the fluctuation of the pore water pressure is relatively small, as shown in *Figure 11*. This is mainly due to the high permeability, so water can freely infiltrate and flow out of the slope in a short time without causing a sharp increase in pore water pressure. Surface sinking of the slope was induced mainly due to the losses of fine particles and structural reorganization. Moreover, the strength of the slope decreased slightly due to a small pore-water pressure increase. Therefore, the strength is sufficient to resist the sliding forces, and the slope can maintain its stability.

$$k = f(\rho_d, D) = 6.051 \times 10^4 \times \rho_d^{-7.297} \times D^{-9.196} \quad \text{(Eq.8)}$$

As the fractal dimension increases, the fine particle fraction increases gradually, and the permeability of the soil decreases rapidly. During the rainfall process, the infiltrated water cannot release timely. This will cause a sharp increase in pore water pressure. Effective stress and pore water pressure is negatively correlated, a sharp increase in pore water pressure directly causing a dramatic decrease in effective stress. Under the combined effect of pore-water pressure increasing, along with an increased entrained and scour capacity of the overland flow, the large-scale debris flow was finally formed. For slopes with fractal dimension more than 2.4, during the rainfall process debris flow was identified. But comparing the videos and pore water pressure curves, we found that even though all such slopes formed debris flows, the mechanism of debris flow formation were radically different.

For slopes with fractal dimension ranging from 2.4 to 2.6, the formation mechanism can be understood using Soil Mechanics: the coefficient of permeability of the slope is larger than slopes with fractal dimension more than 2.6 (He et al., 2014). Therefore, under same rainfall conditions, more water infiltrated into the slope, which resulted in a raised pore-water pressure. Due to the continuous rainfall, the pore-water pressure increased a lot, and finally reached its peak value. The soil strength decreased to its minimal value, and the debris flow formed thereby. Theoretically, debris flow should be formed simultaneously with pore-water pressure reaching its peak value. Owing to the sensitivity of the sensors, it takes a period of time for the sensors to record the data, so

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75737589

the collected data lags behind the real situation. This is the reason why initiation of debris flow appeared to be ahead of the occurrence of peak pore water pressure. For slopes with fractal dimension more than 2.6, the infiltration capacity is relatively lower, little rainfall can infiltrate into the slope. Debris flow formed under such condition can be shown to be due to a run-off generated mechanism (Hu et al., 2016, 2014; Kean et al., 2013b; Yu et al., 2014). Superficial run-off erosion first generated a small erosion gully in the upper part of the slope and the eroded material was deposited in the lower part. The debris flow process initiated through saturation and breaching of this deposited material, which blocked the run-off water. Bed erosion and lateral erosion then continued to enlarge the erosion gully providing future material to the debris flow at lower concentrations. The subsequent erosion peaks with high debris-flow solid concentrations, were related to the cyclic damming by side-wall failures and dam breaching which enlarged the erosion gully, the size and the unit weight of the debris flow (Coe et al., 2008b; Kean et al., 2013a).

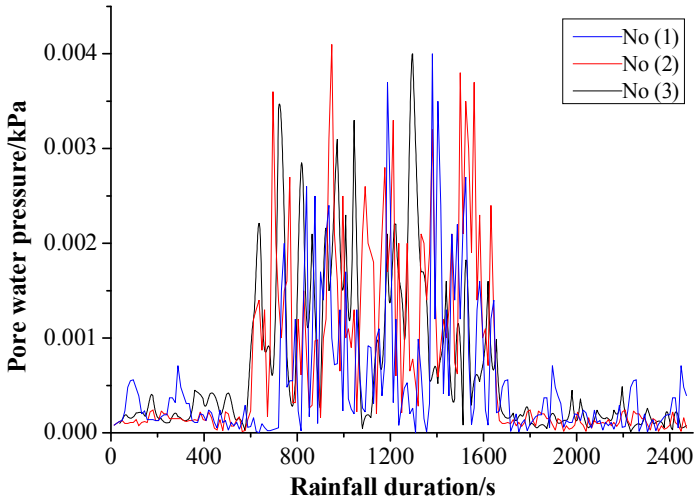


Figure 11. *Pore water pressure curves (slope with fractal dimension 2.35)*

The criticality is mainly due to the internal structure of the gravelly soil, which significantly influenced its coefficient of permeability and strength. When the fractal dimension is less than 2.4, the soil is constituted of coarse particles, and the strength is mainly determined by occlusal forces. Therefore, the permeability is larger and the strength is relatively higher, so the infiltrated water can be released freely without causing a pore-water pressure increase, and the slope can maintain its stability very well under continuous rainfall conditions. When the fractal dimension ranges from 2.4 to 2.6, cohesion forces and the internal friction angle both determined the soil strength, and the permeability coefficient allows water infiltrate into the slope and causes a pore-water pressure increase. The permeability coefficient is smaller than the rainfall intensity, so the rainfall will generate two types of water flow: internal flow and overland flow. The internal flow results in decreasing of soil strength, and the overland flow provides impact force to trigger debris flow. That is why slopes with fractal dimension ranges from 2.4 to 2.6 are more susceptible to debris flow. As the fractal dimension increases to more than 2.6, the soil structure properties are mainly governed by the fine particles. The soil strength is determined by the internal friction angle. Previous research found

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75737589

that water content has a slight influence on internal friction angle. Hence, soil strength decreased slightly during the whole rainfall duration. For soils with fractal dimension larger than 2.6, the coefficient of permeability is extremely small, and the precipitation mainly resulted in overland water flow. Under these circumstances, debris flow initiation is triggered by overland flow, and the mechanism can be understood using hydraulic theory.

Conclusions

From sampling and sieve testing the particle size distributions of the gravelly soil in debris flow source area can be established. With the aid of fractal theory, the fractal dimension of the samples can be computed and the fractal characteristics can be determined. Using the fractal characteristics of the gravelly soil, an in-situ artificial rainfall experiments were conducted, and some important findings were made. Following an analysis of the aforementioned experimental results, the following conclusions can be drawn:

(a) Gravelly soil in debris flow source area is mainly concentrated in one fractal dimension. The dimension value ranges from about 2.25 to 2.98. A close link between fractal dimension and particle size distribution was revealed: as fractal dimension increased, the particle composition tends to be more evenly.

(b) Our previous research established that the strength and permeability coefficient of gravelly soil is governed by fractal dimension (particle size composition or distribution). As fractal dimension increased, the permeability coefficient decreased (He et al., 2014).

(c) Gravelly soil manifests criticality, which means that slopes with fractal dimension less than 2.4 cannot (or can only with extremely low probability) mobilise into debris flow, regardless of rainfall intensity, duration or cumulative rainfall. Moreover, as the fractal dimension of the soil increases, the probability of the slope mobilising into debris flow becomes higher, and the unit weight of the formed debris flow becomes larger, ranging from dilute debris flow (unit weight less than 1.8 g/cm^3) to viscous debris flow (unit weight greater than 1.8 g/cm^3).

(d) As the fractal dimension falls into different intervals, the appropriate debris flow formation or initiation mechanism can be understood using different theories: For slopes with fractal dimension ranges from 2.4 to 2.6 and more than 2.6, the formation mechanism can be understood using soil mechanics and hydraulics theories, respectively.

(e) Debris flow initiation and peak pore-water pressure did not occur simultaneously. The initiation time always happened before the occurrence of peak pore-water pressure.

The results presents in this article provide a useful tool for debris flow forecast and prevention in the future. With the aim of improving the accuracy of debris flow prediction, the soil composition characteristics can be analyzed, and the fractal dimension of the soils can be computed. Comparing the fractal dimension with the results in this paper, a preliminary evaluation of the probability of debris flow initiation can be made. Furthermore, a comprehensive analysis of the slope angles, meteorological conditions and watershed features in the study area should be completed, then the scale, property and probable dynamic processes and dynamic characteristics of the potential debris flow can then be assessed. This can greatly

improve the accuracy of prediction, and provide important information for disaster mitigation.

(Received 6th Mar 2019; accepted 3rd May 2019)

Abstract. This study was conducted in order to determine the effect of Nitrogen (N) and Zinc (Zn) on the yield, yield components and oil ratio of safflower under semi-arid conditions in 2011-2012 and 2012-2013 growing seasons. Field trials was established in the randomized complete blocks design split plots with three replications in the experimental area Department of Field Crops of Agricultural Faculty, Harran University in Turkey. In the study, N applications (N_0 = no fertilization, N_5 = 50 kg ha^{-1}, N_{10} = 100 kg ha^{-1} and N_{15} = 150 kg ha^{-1}) were placed in the main plots, Zn applications (Zn_0 = no fertilization, Zn_1 = 10 kg ha^{-1}, Zn_2 = 20 kg ha^{-1} and Zn_3 = 30 kg ha^{-1}) were in the sub-plots. Seed yield (kg ha^{-1}), seed yield per plant (g plant^{-1}), plant height (cm), number of heads per plant (pieces plant^{-1}), number of seeds per head (pieces head^{-1}), 1000 seeds weight (g), dry petal yield (g plant^{-1}), oil ratio (%) and biomass yield (kg ha^{-1}) were examined in the study. The results indicated that; the highest seed yields were obtained from the N_{15} (1171 and 1651 kg ha^{-1}) and Zn_3 (1233 and 1675 kg ha^{-1}) applications in both years. N applications comparing control plots affected the yield per plant, plant height, number of heads per plant, number of seeds per head, 1000 seed weight and biomass yield, had negative effect on the dry petal yield and oil ratio. Zn applications according to control plots whereas had positive effects on the seed yield per plant and number of heads per plant but had no significant effect on the dry petal yield and oil ratio. NxZn interactions affected the seed yield, number of heads per plant, number of seeds per head and biomass yield. 150 kg N ha^{-1} and 30 kg Zn ha^{-1} should be given to safflower under semi-arid conditions.

Keywords: *Carthamus, nutrients, dry petal, oil ratio, interaction*

Introduction and literature review

Sanliurfa is the hottest province of Southeastern Anatolia Region in Turkey. Harran Plain is located in the Sanliurfa city where continental climate, summers are very hot and dry and the winter are relatively temperate (Kose et al., 2018). Average annual rainfall is around 350-400 mm. Most of the rainfall falls in the winter season. Therefore, it is great important to cultivate drought-resistant plants in areas where irrigation is not possible. Safflower plant can be grown in this region under drought.

Safflower plant (*Carthamus tinctorius* L.) has quite various usage by stem, leaves, seeds and flowers. It is a very important industrial plant neglected and could not reach the place deserved. It is an historical species and it was cultivated in the Middle East 3000 years ago (Knowles, 1982). All parts of the plant are used in the treatment of various illnesses in India and Pakistan (Nimbkar, 2002). The flowers are used in the food, cosmetic, dye and pharmaceutical industries (Dajue and Mundel, 1996; Abd El-Mohsen and Mahmoud, 2013). Safflower was reported to be one of the alternative

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75917604

plants that can be considered in irrigated areas with its tolerance to salinity and weeds, and especially due to its high tolerance to cold and heat climatic conditions in arid regions (Emongor et al., 2015).

Safflower (*Carthamus tinctorius* L.) is one of the most important annual oil plants to be grown in winter season (Eslam, 2010; Gursoy et al., 2018). It is more resistant to drought and lower temperatures than other non-selective oil crops in terms of growth requirements safflower can also be grown in fallow areas especially in arid regions (Johnson et al., 1993). Due to these properties, safflower can be an alternative crop in crop rotation vs. wheat, barley, lentil and tobacco. It can help to alleviate the shortage of vegetable oil demand of Turkey (Eryigit et al., 2015; Kose, 2017). Safflower has yellow, red, orange and cream-colored flowers with thorny and thorn less forms, and it has been used for he production of edible oil and biofuels having 30-45% fat on average in its seeds (Demir and Kara, 2018).

Safflower seeds contain 13-46% oil, about 90% of this oil consisted of unsaturated fatty acids (oleic and linoleic acid) (Johnson et al., 1993; Belgin et al., 2007). Safflower oil containing an average of 75% linoleic acid (Weiss, 2000), and there are also its antioxidant effects and tocopherols with high vitamin E values. Therefore, safflower oil is used in diets applied by cardiovascular patients and has a great importance because of its anti-cholesterol effects (Pongracz et al., 1995).

Safflower petals are very important as a source of medicinal preparations, natural food colour and dyes for colouring fabrics. In addition to the colouring properties, safflower petals are used for curing several chronic diseases such as hypertension, coronary heart ailments, rheumatism and male and female fertility problems (Rajvanshi, 2005).

Since the safflower oil is suitable for biodiesel production, intensive researches on biodiesel production from safflower oil are carried out (Ogut and Oguz, 2006; Nosheen et al., 2011). The cartharmia substance obtained from the safflower is great important as a natural dye raw material (Nagaraj et al., 2001; Emongor, 2010). Especially the petals are used as food dyes and spices have potential to increase income from the unit area in the arid regions (Esendal, 2001).

In addition, some plant nutrients were found to be effective together with irrigation in direct to yield and yield components. Two of these important nutrients are nitrogen and zinc.

Nitrogen fertilizers are one of the important inputs in dry rainfed agricultural systems. In order to obtain optimum yield and quality product in these regions, sufficient amount of nitrogen in suitable time and form should be given to the plant. Excessive or insufficient N fertilizer applications result in some economic losses, excessive nitrogen application causes environmental problems over time (Grant, 2006). It was reported by many researches that the nitrogen fertilizer affected on the safflower growth, yield and quality properties significantly (Ahmed et al., 1985; El-Nakhlawy, 1991; Ibrahim, 1994). N fertilization increased seed yield (Strasil and Vorlicek, 2002); 300, 600 and 900 kg ha^{-1} N applications according to the control plots increased the biomass of safflower by 13.4%, 15.3% and 22.9% respectively (Haghighati, 2010). Nitrogen was effective on the vegetative and reproductive stages of safflower (Bitarafan et al., 2011); nitrogen applications increased seed yield 44.6-60.5% on average compared to the control plots (Singh and Singh, 2013); seed yield, 1000 seed weight, number of heads per plant and plant height were affected positively (Eryigit et al., 2015), and plant height and seed yield were increased (Revant Nathan et al., 2018) by

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75917604

the nitrogen fertilization. The effect of nitrogen may vary according to the amount, time and form of the application.

Zinc applications exhibited positive effect on the oil yield and seed quality, and besides, do the plant more resistant to drought conditions were reported by many researchers (Mengel, 2001; Khoshgoftarmanesh, 2010; Taha et al., 2013). Zinc has an important effect on the oil yield and quality, seed yield and biomass production (Lewis and McFarlane, 1986); Zinc sulphate application under water stress conditions increased seed yield, biomass and biological yield than control plots (Lakzayi, 2015); zinc application comparing central increased seed yield and number of heads per plant (Gulmezoglu and Aytac, 2016).

In this study, it is important to determine the effect of N and Zinc separately and in combination on the safflower crop under semi-arid climate conditions in the Harran Plain conditions. There have not been done such a study before under Harran plain conditions, because of that this study is important. As it is known, the genotypic structure of each plant is affected more or less from the environmental factors. The dose of the plant nutrient that is applied in a region has a good result, may not work well under any other environmental conditions. Therefore, it is great important to conduct these studies and determine the most appropriate doses in every ecological condition.

This study was carried out to asses the appropriate doses of the nitrogen and zinc on to seed yield and seed quality as well as disseminate the cultivation of safflower under semi-arid climatic conditions.

Materials and methods

Remzibey-05 safflower cultivar with yellow flowers, spiny leaves and head was used as plant material. The experimental area has a flat topography. It is well-drained deep, stone-free, with high clay content (54-56%). Soil pH is between 7.3-7.2, the salt content is 0.088-0.092%, and low in organic material 1.25-1.19%. In addition, the amount of pure N 25-19 kg ha^{-1}, P_2O_5 amount of pure 27-30 kg ha^{-1} and K_2O 1086-1129 kg ha^{-1} was determined (*Table 1*).

Table 1. *Some soil properties of experimental area (Anonymous, 2012)*

Years	Total Salt (%)	Lime (%)	Sand (%)	Clay (%)	Silt (%)	Organic Matter (%)	pH	N (kg ha^{-1})	P_2O_5 (kg ha^{-1})	K_2O (kg ha^{-1})
2011	0.088	5.1	25.12	54	20.20	1.25	7.3	25	27	1086
2012	0.092	5.4	26.03	56	20.32	1.19	7.2	19	30	1129

Field trials were setup employing according to the randomized complete block design split plots with three replications in the experimental area Department of Field Crops of Agricultural Faculty, Harran University Eyyubiye Campus (37°06'59.1" N 38°49'15.8" E) (altitude = 510 m from sea level) (*Fig. 1*).

Each plot consisted of 5 m long with 5 rows. Inter-row and intra-row spaces were 35 and 15 cm respectively (*Fig. 2*). After experimental area had been ploughed, herbicide (*Trifluarin* active ingredient) was applied by a sprayer before planting. Then, Disk-harrowing was practiced for trial seedbed preparation tillage.

The sowing was practiced on 5th November, 2011 and 3th November, 2012 by the experimental drill. 2 m alley was left between each plot. After the emergence, thinning

DOI: http://dx.doi.org/10.15666/aeer/1704_75917604

was practised in the stages of 3 or 4 leaves. The cultural practices (hoeing, weeding and pest management) were performed when needed in accordance with the conventional methods.

Figure 1. *The map of the experimental area*

Figure 2. *Experimental area*

In both growing seasons, total precipitation occurred close to each other. The average temperature (13.76 °C) for the 2011-2012 growing season was very close to the average for long years (13.68 °C), but the average temperature for the 2012-2013 growing period (15.31 °C) was higher than the average of the first year and long years of the experiment (*Table 2*). The higher average temperature in the second year of the

In the study, N applications (N_0 = no fertilization, N_5 = 50 kg ha^{-1}, N_{10} = 100 kg ha^{-1} and N_{15} = 150 kg ha^{-1}) were placed in the main plots, Zn applications were assigned in the sub-plots (Zn_0 = no fertilization, Zn_1 = 10 kg ha^{-1}, Zn_2 = 20 kg ha^{-1} and Zn_3 = 30 kg ha^{-1}). Half of the nitrogen was applied in the form of Ammonium Sulphate (21%) with the sowing, the remaining half in the form of ammonium nitrate (33%) at the branching stage. All the zinc in the form of ZnSO4 7H_2O (23%) was applied with the sowing in 5-6 cm next to the plant rows and 5-6 cm deep by hand. Superphosphate (pure phosphorus 80 kg ha^{-1}) was applied as basal fertilizer at sowing.

Harvest was performed by hand for the seed and biomass yield from the remaining area (4 m × 1.05 m = 4.2 m^2) by thrown away the side effects of 0.5 m at the beginning and end of 3 rows in the middle of each plots on 5th June, 2013 and 6th June, 2013. Seed yield per plant (g plant^{-1}), plant height (cm), number of heads per plant (pieces plant^{-1}), number of seeds per head (pieces head^{-1}), 1000 seed weight (g) and dry petal yield (g plant^{-1}) were determined on randomly selected 10 plants (Esendal et al., 1992). A sufficient amount of seed (10 g) was grinded for each application and dried in the oven at 70 °C for 72 hours. 5 g of each sample boiled for 6 hours by using hexane in soxhlet extraction device and so on oil ratios (%) were scored.

The data was subjected to analysis of variance utilizing the JMP 11 (SAS Institute 2013, USA) statistical program in the randomized complete blocks design split plots and averages were grouped by the Tukey HSD test ($p \leq 0.05$).

Results and discussion

In the analysis of variance (ANOVA) according to the combined years of the properties examined in the trial, statistical differences were found between years. Due to that the results of each year were analyzed separately.

Seed yield (kg ha^{-1})

N_{15} application gave the highest seed yield (1171 and 1651 kg ha^{-1}) in both years of the experiment. Strasil and Vorlicek (2002), Singh and Singh (2013), Eryigit et al. (2015) and Revant Nathan et al. (2018) reported that the nitrogen fertilization increased yield is consistent with the research results. The highest seed yield in Zn application was obtained from the Zn_3 application (1233 and 1675 kg ha^{-1}) in both years. Taha et al. (2013), Lakzayi (2015) and Gulmezoglu and Aytac (2016) observed that the zinc applications increased seed yield comparing to the control. In the first year of the experiment N_{15} x Zn_3 interaction (1463 kg ha^{-1}), in the second year N_0 x Zn_3 (1887 kg ha^{-1}), N_{10} x Zn_2 (1865 kg ha^{-1}) and N_{15} x Zn_3 (1900 kg ha^{-1}) interactions gave the highest seed yield (*Table 3*). N_{15} x Zn_3 interaction gave the highest seed yield (1463 and 1900 kg ha^{-1}) in both years shows that the application in these doses increase the seed yield. High yield in second year comparing that of first year can be attributed to fluctuating climate and environmental factors.

Seed yield per plant (g plant^{-1})

Statistically significant differences were found between N and Zn applications in both years. N_{15} (8.44 and 11.98 g) and Zn_3 (8.68 and 11.25 g) applications gave the highest seed yield per plant in both years. In general, obtained the better yields in the second year than the first year can be attributed to environmental and climatic conditions. N_{15} x Zn_3 interaction gave the highest seed yield (10.83 and 13.57 g) in both years indicates that the application at these doses increases seed yield per plant (*Table 3*).

Seed yield per plant is a factor that directly affects seed yield per hectare. As a matter of fact, the highest values obtained from the N_{15} and Zn_3 applications for seed yield per hectare confirmed the research results. Eryigit et al. (2015) and Revant Nathan et al. (2018) reported that the nitrogen fertilization increased seed yield per plant, and Taha et al. (2013); Gulmezoglu and Aytac (2016) zinc fertilization as well.

Plant height (cm)

N_5 application (142.0 cm) in the first year, N_{15} application (141.6 cm) in the second year gave the highest plant height values (*Table 1*). Khalil et al. (2013) and Eryigit et al. (2015) report that the nitrogen fertilization increases plant height which was consistent with the research results. Similar results were also reported by Katar et al. (2012) and Bitarafan et al. (2011).

As the zinc applications had not any effects on the plant height in the first year, Zn_2 application gave the highest plant height (140.3 cm) in the second year. N_5 x Zn_2 interaction (144.8 cm) in the first year, N_0 x Zn_3 (143.3 cm) and N_5 x Zn_2 (143.0 cm) interactions in the second year gave the highest plant height scores (*Table 3*).

Plant height is significantly affected by environmental factors. The highest plant height scores from the different applications in both years can be due to the fact that the plants grow in all kinds of natural areas that are open to various impacts and they are very much under different environmental conditions during the growth and development periods (Arslan and Bayraktar, 2015). However, the highest plant height from the N_5 x Zn_2 (144.8 and 143.0 cm) interaction in both years showed that the application at these doses increases the plant height.

The most important selection criteria for seed yield was the number of heads per plant. The number of heads is a property that is affected by the plant genetic structure, sowing density, fertilization and other environmental factors. Implemented that the difference between the results and applications of other researchers in terms of number of heads per plant could be caused by the variations in climate and soil structure of the location where the research was carried out and cultivar, and the differences between different cultural techniques, sowing and harvest dates.

Number of seeds per head (pieces head^{-1})

N_{10} and N_{15} applications gave the highest number of seeds per head in both years. The highest number of seeds per head by the nitrogen fertilization increased seed yield per plant, and therefore contributed positively to the seed yield per hectare in the trial. Strasil and Vorlicek (2002); Singh and Singh (2013) and Eryigit et al. (2015) reported that the nitrogen fertilization increased yield was consistent with our research results. As the Zn_3 application gave the highest number of seeds per head (15.6 pcs head^{-1}) in the first year, there were no statistically significant differences between the applications in the second year. N_{15}xZn_3 interaction gave the highest number of seeds per head (19.0 and 14.7 pcs head^{-1}) in two years (*Table 4*).

When examined the interactions, N_{15} x Zn_3 interactions was promising. Bitarafan et al. (2011) indicated that nitrogen was effective in vegetative and reproductive development; Soleymani and Shahrajabian (2011), nitrogen increased the number of seeds per head, and Lewis and McFarlane (1986), Zn had an important role on the oil yield and quality, seed yield and biomass production are compatible with the research results. The number of seeds per head as well as the number of heads per plant were the important criterion for yield. The number of seeds per head was directly related to the head size and that can be affected fairly by genetic and environmental factors. Although an average of 100 flowers were formed in each safflower head, 20% of these flowers formed seed (Baydar, 2000).

1000 seed weight (g)

N_{15} application (30.01 g) in the first year of the experiment, N_{10} and N_{15} applications (29.85 and 29.88 g) in the second year gave the highest 1000 seed weight. Nitrogen fertilization gave the more 1000 seed weight values than control plots in both years. Bitarafan et al. (2011); Khalil et al. (2013) and Eryigit et al. (2015) reported that nitrogen doses increased 1000 seed weight comparing the control. Although Zn applications were insignificant in the first year, Zn_0 and Zn_3 applications (29.94 and 30.15 g) gave the maximum 1000 seed weight values in the second year. At the same time, N x Zn interactions were in non-significant in the first year, N_5 x Zn_3 interaction gave the highest 1000 seed weight (31.72 g) in the second year (*Table 4*). These differences between years might be due to different soil and climate factors.

Dry petal yield (g plant^{-1})

The highest petal yields (1.12 and 1.19 g) were obtained from control N_0 subject according to the N application, from the Zn_0 (1.17 and 1.27 g) subject according to the Zn application in both years. N_0 x Zn_1 and N_{10} x Zn_0 interactions gave the highest petal yield in the first (1.47 and 1.45 g) and second year (1.70 and 1.65 g) (*Table 5*). Control

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75917604

plots created more petal yields. This indicated that N and Zn applications had negative effects on the petal yields.

Oil ratio (%)

N_0 (30.0%), N_5 (30.1%) and N_{15} (30.1%) subjects gave the highest oil ratio in the first year, N_0 and N_5 (31.3 and 31.4%) treatments in the second year and these formed in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_75917604

the same group. The formation of similar groups in two years reveals that the application of N did not have a positive effect on oil ratios. Kolsarici et al. (2005) and Elfadl et al. (2009) reported the similar results in their studies. Zn applications had not statistically significant in both years. Although N x Zn interaction was insignificant in the first year, N_0 x Zn_2 interaction gave the highest oil ratio (33.1%) in the second year (*Table 5*). These differences between the experimental years might be due to the various effects of environmental factors.

Biomass yield (tons ha^{-1})

N_5 application gave the highest biomass yield (6.617 tons ha^{-1}) in the first year, N_{10} and N_{15} applications (9.467 and 9.648 tons ha^{-1}) in the second year. When scores of characteristics for two years were evaluated, N applications generated the more biomass yield than the control plots. Several researchers reported that N applications increased biomass yield comparing to the control (Haghighati, 2010; Singh and Singh, 2013 and Revant Nathan et al., 2018). The highest biomass yield (6.571 tons ha^{-1}) in Zn applications was obtained from the Zn_0 application in the first year, from the Zn_1 application (9.600 tons ha^{-1}) in the second year. N_0 x Zn_2 (6.933 tons ha^{-1}) and N_{15} x Zn_3 (6.900 tons ha^{-1}) interactions in the first year, N_{10} x Zn_2 (10.900 tons ha^{-1}) interaction in the second year gave the highest biomass values (*Table 5*).

Biomass yields are affected by environmental factors. Especially, N applications with high precipitation enhance the vegetative development of the plant. Nitrogen with water, is the most vital nutrient. Therefore, it appears to be a nutrient that controls plant growth (Fageria, 2009). Zinc affects the nitrogen metabolism, starch formation and seed maturation in plants. Zinc a plant nutrient element necessary for the production of growth hormones (auxin hormone), and especially for the prolongation of the internode (Gardiner and Miller, 2008; McCauley et al., 2009). For these reasons, N and Zn applications are important in safflower production. The differences between N x Zn interactions in the research may have been caused by the diversities of climate and soil factors.

Conclusions

It was concluded that; the highest seed yield and seed yield per plant were obtained from the both N_{15} x Zn_3 interaction and N_{15} and Zn_3 applications. Although N applications had the positive effects comparing to the control plots on the seed yield per plant, plant height, number of heads per plant, number of seeds per head, 1000 seed weight and biomass yield and had no any positive effects on the dry petal yield and oil ratio. Zn applications had showed positive effects comparing to the control plots on the seed yield per plant and number of heads per plant and had negative effects on the oil ratio and dry petal yield. As a result of the research; the highest seed yield and seed yield per plant from the N_{15} and Zn_3 applications were lower than those of the N_{15} x Zn_3 interaction, and the doses of 150 kg N ha^{-1} and 30 kg Zn ha^{-1} should be given together in N and Zn applications under semi-arid conditions. However, as each region has its own climate and soil conditions, it is useful to perform these studies where safflower cultivation is done.

(Received 8th Mar 2019; accepted 3rd May 2019)

Abstract. Sunflower-like all other plants have several growth stages such as vegetative, flowering, and achene formation. Water stress mainly results in a reduction in seed yield during the flowering more than the achene formation stage. A randomized complete block design was applied with irrigation as main plots (skipping irrigation at stages of vegetation, flowering, achene formation, and full irrigation), and sunflower genotypes (Barolo RO, Velko, and Local) as sub-plots. Each treatment replicated three times. This study was conducted at two different locations (Kanipanka and Qlyasan) under the semiarid region of Sulaimani province, Iraq. Velko genotype had the highest seed yield of 4,993.705, and 6,247.265 kg ha^{-1} respectively at both locations, under full irrigation. Under skipping irrigation, at both stages of flowering and achene formation, irrigation water use efficiency value was lower than the value of water use efficiency. Crop response factor was less than one for all genotypes. At the flowering stage and under skipping irrigation, the crop response factor was higher at both locations. The result of this study concluded that Barolo RO genotype has the highest performance under deficit irrigation. Also, under skipped irrigation, the flowering stage was more effective in seed yield increase than stages of vegetation and achene formation in sunflower. The objective of this study was to determine the sensitivity of sunflower growth stages under deficit irrigation.
Keywords: *irrigation requirement, saving water, seed yield, water use efficiency, yield response factor*

Introduction

Sunflower (*Helianthus annuus* L.) is considered one of the top four edible vegetable oils in the world. Globally, it is counted for about 12% of the edible vegetable oil production following palm, soybean, and canola oil (Demir et al., 2006; Rauf et al., 2017). It is the most effective unconventional oilseed crops in the world due to its high oil quality, and it is advantages in crop rotation systems, such as high adoption capability, suitability to mechanization and low labor needs (Reddy et al., 2003; Kazemeini et al., 2009).

Agriculture uses the highest amount of freshwater which accounts for 70%, that driven from rivers, lakes, and aquifers up to more than 90% in some developing countries (WWP, 2017). The IPCC AR5 (2013) stressed low confidence in a global-scale observed trend in drought, owing to lack of direct observations, dependencies of inferred trends on the index choice, as well as difficulties in distinguishing long-term climate change from decadal-scale drought variability.

Ghani et al. (2000) found that irrigation is a substantial factor which directly influences the yield of sunflower. Wise application in time for irrigation in critical

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76057623

stages of growth from increased sunflower seeds produces dramatically. Sunflower plants can achieve maximum water productivity under water deficit environment (Ali, 2009). Indeed, flowering and seed filling stages have been reported as the most critical for water stress in sunflower (Iqbal et al., 2005). Shafi et al. (2013) indicated that water stress during the flowering stage causes a considerable reduction in seed yield of sunflower.

The identification of the relationship between water use efficiency and seed yield under deficit irrigation has been a high concern for agricultural research in semi-arid areas (Fan et al., 2005; Sun et al., 2006; Sinaki et al., 2007; Faraji et al., 2009). However, one of the biggest challenges facing agriculture is the development of technological options or to improve the efficiency of agricultural water use (Turner, 2004).

Drought is one of the tops stress abiotic factor which causes low yield especially in arid and semi-arid regions of the world (Tian et al., 2016; Viscardi et al., 2016). Martinek (2008) stated that drought tolerance differs strongly between the growth stages of many crops. Deficit irrigation is known as the application of water at levels below full crop water requirements, and it is one of the new strategies designed to improve water savings in agriculture (Bashir and Mohamed, 2014). The purpose of deficit irrigation is to raise the water use efficiency (WUE) and to obtain the highest yield per unit water (Kirda et al., 2006), further De Pascale et al. (2011) describe the ration of crop yield per unit as water use efficiency in agriculture.

By knowing the value of crop response factor, farmers can get optimum yield without withdrawing irrigation water at that stage if water scarcity persists. Doorenbos and Kassam (1979) found the crop response factor (*ky*) for some crops. Crop response factor values of more than one indicate more stress, and from this value, the critical stage can be obtained. As reported by Ali (2009), the response factor various by locations, which influence by soil types, weather conditions, seasons and varieties. Therefore, a location-specific response factor should be considered for the efficient management of water. Here sunflower crop was used to estimate crop response factor as it can tolerate low to medium water and salinity stress (Tolga and Lokman, 2003).

The genotype differences may be due to the differences in genetic structure between the sunflower genotype, to the differences in growth characters and the differences in photosynthetic partitioning (Ahmed and Hassanein, 2000; Abou El-Seoud and Wafaa, 2010). Hybrid seed yield is a condition by its capacity to use the environmental variables efficiently in different phenophases (Gonzáles et al., 2013). Thus, the genetic potential of the hybrid sunflower is reduced by the action of the growth factors, either environmental or technological. In addition to high yield sunflower varieties, agronomic practices are essential for maximum seed yield (Beg et al., 2007). Ibrahim (2012) reported that the plant population and varieties could determine seed yield per unit area.

The objective of this study was to highlight the sensitivity of different growth stages of three genotypes of sunflower to different irrigation levels.

Materials and methods

Study area

This study was carryout during the summer of 2016 at two locations: first the Agricultural Research Station at Kanipanka, Sulaimani with (Longitude of 045° 43’ 22” E, altitude of 548 masL, and latitude of 35° 22’ 22” N). The second location was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76057623

Qlyasan, the experimental station of the College of Agricultural Sciences, the University of Sulaimani, (latitude: 35° 34' 17" N, Longitude: 045° 22' 00" E, altitude: 757 masL) "Garmin, GPSmap60 Cx" (*Fig. 1*).

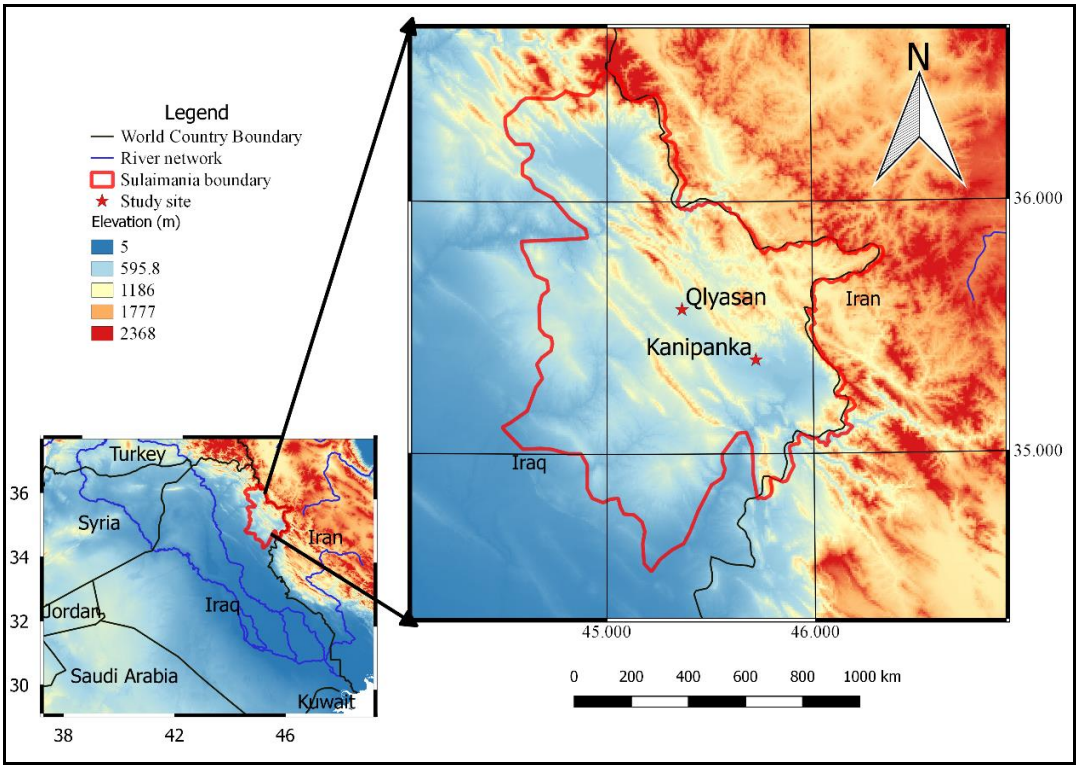

Figure 1. *Map of the study site in Sulaimani-Kurdistan region, Iraq*

At each location, a composite soil sample of about 5 kg was obtained by mixing subsamples from 6 sites using a shovel. Each soil sample was freed from plant roots and other debris. All samples were dried at room temperature for seven days. Each sample was cleaned using 2 mm stainless-steel sieve.

A split-plot factorial with full and deficit irrigation as the main plot was replicated three times, a in randomized complete block design. The water deficit of various degrees was imposed at different growth stages with the irrigation treatments. There were three sunflower growth stages which are vegetative (S_1), flowering (S_2), and achene formation (S_3) stages. The four levels of irrigation treatments were: skipping irrigation at vegetative stage (I_1), skipping irrigation at flowering stage (I_2), skipping irrigation at the achene formation stage (I_3), and full irrigation (I_4). *Table 1* exhibits the details of the irrigation treatments. *Table 2* shows the sum of water applied at different treatments for both locations.

Table 1. *Details of the irrigation treatments*

Irrigation treatments symbol	Description
I_1	Skipping irrigation at vegetative stage
I_2	Skipping irrigation at flowering stage
I_3	Skipping irrigation at the achene formation stage

I_4	18	4073	754.26	7542.59	4902.685

The sub-plot factors encompassed of the genotypes which were a single cross hybrid Barolo RO, single cross hybrid Velko and Local variety.

The size of each sub-plots was 3 m by 1.8 m, and consisted of three rows, with 0.60 m apart. The spaces between plants were 0.30 m. The least significant difference at confidence levels of 0.05 and 0.01 were used for treatments comparison.

Cultural practices

Before planting and delineating the plots, an area with a gentle slope was selected an irrigated. The field was then plowed with moldboard plow at the optimum water content for tillage. At both locations, three sunflower seeds at a depth of 2-4 cm were placed in each hole on July 11 and 15, 2016. After two weeks, the seedling was thine out to one per hole. The nitrogen fertilizer in the form of Urea applied one before the second irrigation and the other before flowering at a rate of 43 kg ha^{-1} as recommended. Hand weeding practiced as needed. There was not treated with any pesticide. At the flowering stage, plants were protected from bird attack by installing a screen over the heads.

Sulaimani governorate climate

The climate of Sulaimani governorate is considered as a semi-arid environment: cold and wet in winter, hot and dry in summer. The average temperature from July to August is between 39-43 °C and often reaching nearly 50 °C. October means high temperatures are 24-29 °C and slightly cooling down in November. The rainfall is limited to winter and spring months Kurdistan Regional Government, 2018; see *Table 3*).

Watering schedules

As recommended by Allen et al. (1988), irrigation scheduling was based on an allowable root zone water depletion of 45% (p = 0.45) during the whole growing cycle. SOTERA digital meter was used to measure the water flow (*Fig. 2*).

Figure 2. *SOTERA digital display meter*

A small auger 5 cm in diameter (Lorenz and Maynard, 1980) was used to observe soil water content. The average water requirement (consumptive crop use) was calculated from soil moisture. The soil moisture was brought to field capacity when the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76057623

available soil moisture was depleted by 45%. The net depth of applied water was calculated from (Michael, 1978):

$$d_n = \frac{(\omega_{FC} - \omega_{WP})}{100} \frac{\rho_b}{\rho_w} P\ D \quad \text{(Eq.1)}$$

where:
d_n = net depth of applied water (mm)
ω_{FC} = Soil water retention at -33 kPa
ω_{PW} = Soil water retention at -1500 kPa
ρ_b = Average soil bulk density of the root zone (gcm^{-3})
ρ_w = Water density (gcm^{-3})
P = Depletion fraction = 0.45
D = Root zone depth (mm)

The gross depth of applied water (dg) was obtained from the following relationship:

$$dg = \frac{d_n}{Ea} \quad \text{(Eq.2)}$$

where Ea = Irrigation application efficiency.
The values of this parameters were 0.70 and 0.65 for Kanipanka and Qlyasan locations, respectively (*Table 4*).

Table 4. *Irrigation application efficiencies for the locations under study based on average land slope and basic infiltration rate*

Locations	Average land slope (%)	Basic infiltration rate, ib (mm hr^{-1})	Irrigation application efficiency, e_a
Kanipanka	Nearly level	44	0.70
Qlyasan	1.16	80	0.65

The consumptive crop use mean during the growing season was comparable with that computed by the Penman-Monteith equation. In each plot, middle row plants were harvested at maturity for seed yield determination at 10% seed moisture content. On October 19 and 24, 2016 mature plants were harvested from a deficit and full irrigation plots, respectively, at Kanipanka location, while the harvesting dates at Qlyasan location, was on October 25 for all the irrigation treatments.

The following equation was used to estimate water use efficiency (WUE), and irrigation water use efficiency (IWUE), as the ratio of crop yield per unit of water applied (Kang et al., 2000):

$$WUE = \frac{Y}{ET_c} \quad \text{(Eq.3)}$$

$$IWUE = \frac{Y}{I} \quad \text{(Eq.4)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76057623

where:
Y = The total sunflower seed yield (kg ha^{-1})
ET_c = The seasonal evapotranspiration (m^3 ha^{-1})
I = The total volume of applied irrigation water (m^3 ha^{-1})

While the irrigation application efficiencies for the locations under study based on average land slop and basic infiltration rate was calculated according to Karim and Karim (2001), and the results are revealed in *Table 4*.

The crop response factor *ky* was based on the formula recommended by (Doorenbos and Kassam, 1979).

$$\left(1 - \frac{Y_a}{Y_m}\right) = ky\left(1 - \frac{ET_a}{ET_{max}}\right) \quad \text{(Eq.5)}$$

where:
Y_a = Actual crop yield (kg ha^{-1})
Y_m = Maximum crop yield (kg ha^{-1})
ET_a = Actual evapotranspiration (mm)
ET_{max} = Maximum evapotranspiration (mm)
ky = Yield response factor (dimensionless)

The crop response factor for different stages of growth can be described by:

$$\frac{Y}{Y_m} = \Pi^n{}_{i=1}\left[1 - K_{yi}\left(1 - \frac{ET}{ET_m}\right)_i\right] \quad \text{(Eq.6)}$$

By expanding *Equation 4,* we find:

$$\frac{Y}{Y_m} = \left[1 - k_{y1}\left(1 - \frac{ET_a}{ET_m}\right)_1\right]\left[1 - k_{y2}\left(1 - \frac{ET_a}{ET_m}\right)_2\right]\left[1 - k_{y3}\left(1 - \frac{ET_a}{ET_m}\right)_3\right] \quad \text{(Eq.7)}$$

where the subscripts 1, 2, and 3 represent the first, second and third stages of growth and the other symbols retain the same meanings.

By putting $\frac{ET_a}{ET_{max}} = 1.0$ for the stages under full irrigation, and replacing $\frac{ET_a}{ET_{max}}$ by stress coefficient (ky) for the stage at which deficit irrigation was applied, we obtain:

$$k_{yi} = \left(1 - \frac{Y_{ai}}{Y_{max}}\right)(1 - k_{si}) \quad \text{(Eq.8)}$$

where the subscript i denotes the stage at which deficit irrigation was implemented.

Table 5 shows the calculation of k_s for different growth stages of sunflower at both locations. The obtained values of k_s from *Table 3* were used for calculating k_y for different growth stages of sunflower genotypes. The study was focused on the stages of sunflower irrespective of genotype due to the soil moisture status under different genotypes.

The uniformity coefficient (UC) for some selected parameters was determined according to (Devitt et al., 1992):

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76057623

$$UC = 1 - (\text{Standard deviation/mean}) \quad \text{(Eq.9)}$$

Laboratory analysis

Table 6 shows the results of the investigated soil parameters. Particle size distribution for textural class assessing was carried out by international pipette method as described by Black et al. (1965). Hydrogen ion concentration (pH) and electrical conductivity (EC) in a suspension ratio of 1:10, soil to H_2O were determined by Thomas (1996), using pH model of WTW 330i, whereas for EC the model WTW 330i EC-meter was used. Organic carbon percentage (O.M%) in soil were determined by wet oxidation method according to the Walkley-Black method (Black et al.,1965). Then after the percent of organic matter was calculated through % Organic matter = % Organic carbon × 1.724 (factor). Calcium carbonate CaCO3% (g kg^{-1}) was determined according to a 23c method of U.S. Salinity Laboratory Staff, 1954 as mentioned in (Black et al., 1965).

Statistical analysis

All collected data were statistically analyzed using XLSTAT (2017). A direct comparison of treatments, the least significant difference test (LSD) at levels of 0.05 and 0.01 levels was used. The analysis of variance (ANOVA) was used for testing the main effects of deficit irrigation on sunflower genotypes.

Results

Table 7 shows that the response of the parameters, seed yield, irrigation water use efficiency, and water use efficiency was highly significant to the effect of skipping irrigation treatments (*Appendix*). As seen in this table the most sensitive stage of irrigation skipping at flowering stage (I_2) at both Kanipanka and Qlyasan locations in which produced the lowest value of these parameters which were 3258.652 kg ha^{-1}, 5.012, and 7.160 kg ha^{-1} mm^{-1} respectively at Kanipanka location, while it reached 3853.858 kg ha^{-1}, 5.714, and 8.791 kg ha^{-1} mm^{-1} respectively at the Qlyasan location. Based on the average values of seed yields at both locations, during skipping irrigation the results showed that the $I_4 > I_1 > I_3 > I_2$. The result indicates that the lowest value for irrigation water use efficiency and water use efficiency were obtained at the flowering stage (I_2) at both locations. The order of different growth stages of irrigation skipping for IWUE, and WUE was as follows: achene formation stage > vegetative stage > flowering stage. The results confirm that the I_2 and I_3 offered the lowest and the highest effect in these two parameters respectively.

Table 7. *Effect of skipping irrigation treatments on seed yield, irrigation water use efficiency, and water use efficiency at Kanipanka and Qlyasan locations*

As shown in *Table 8,* a highly significant difference among the sunflower genotypes for seed yield, as related to IWUE, and WUE at both locations (*Appendix*). In relation to irrigation water use efficiency and water use efficiency, Velko genotype seed yields were higher values at Kanipanka location were 4405.035 kg ha^{-1}, 6.911, and 9.873 kg

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76057623

ha^{-1} mm^{-1} respectively than at the Qlyasan location 5356.999 kg ha^{-1}, 8.47, and 13.03 kg ha^{-1} mm^{-1} respectively. Based on the average values of these parameters for both locations, regarding the genotype performance; the order of performance; Velko > Barolo RO > Local. The results indicated that the Velko and Local genotypes had the highest and lowest performance respectively.

Table 8. *Averages of seed yield, irrigation water use efficiency, and water use efficiency of sunflower genotypes at Kanipanka and Qlyasan locations*

Sunflower genotypes	**Seed yield (kg ha^{-1})**	**Irrigation water use efficiency IWUE (kg ha^{-1} mm^{-1})**	**Water use efficiency WUE (kg ha^{-1} mm^{-1})**
Kanipanka Location

LSD 0.05	250.958 **	0.385 **	0.592 **

There were statistically significant differences in seed yield among the sunflower genotypes under different irrigation treatments (*Table 9* and *Appendix*). The flowering and achene formation stage respectively were the most sensitive stage to water deficit, which had a considerable yield decreases at both locations. It is evident from this table that at Kanipanka location Barolo RO genotype had the lowest yield of 2952.785 kg ha^{-1} under I_2 treatment, while at the Qlyasan location the local genotype showed the lowest seed yield of 3117.805 kg ha^{-1} under I_3 treatment. Seed yield increased with increasing amount of applied irrigation water quantities, for instance, Velko genotype gave the highest seed yield under full irrigation treatment (I_4) at both locations 4993.705 and 6247.265 kg ha^{-1} respectively.

As seen in this table the irrigation water use efficiency and water use efficiency restricted from as low as 4.541 and 6.488 kg ha^{-1} mm^{-1} respectively at first location for the Barolo RO genotype under I_2 treatment, while as high as 10.347 and 15.918 kg ha^{-1} mm^{-1} respectively for the Velko genotype under I_3 irrigation treatment at the second location. The results above stated that both IWUE and WUE values decreased with increasing irrigation water quantities except full irrigation (I_4).

Table 10 represents a yield response (*ky*) factor for three individual sunflower growth stages. The crop response factor value varies depending on season, location and intensity of water deficit. Among three sunflower genotypes and water deficit at different growth stages at both study locations, the highest crop response factor (*ky*) value was found at flowering stage (S_2), followed by achene formation (S_3) and vegetative (S_1) stages at Kanipanka and Qlyasan locations respectively.

The yield response factor *ky* of 0.366, 0.350, and 0.253 was found at S_2 for Velko, Barolo RO, and Local genotypes respectively at Kanipanka location. The water stress at

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76057623

S_1 and S_3 exerted (56.83 and 53.28%; 73.43 and 50.86%; and 44.66 and 18.18%) respectively, less stress than most stressed treatment S_2.

At Qlyasan location, the yield response factor *ky* of 0.426, 0.338 and 0.144 was found at S_2 for Velko, Local, and Barolo RO genotype. The water stress at S_1 and S_3 exerted (43.19 and 41.55%; 39.35 and 6.51%; and 93.75 and 89.58%) respectively, less than the most stressed treatment S_2.

Therefore, the order of sensitive stages to water deficit arrangement for individual growth stages can be written at both locations as follows: $S_2 > S_3 > S_1$ for all of the genotypes.

Table 9. *Seed yield, irrigation water use efficiency, and water use efficiency of three sunflower genotypes as influenced by different irrigation treatments at both locations*

Sunflower genotypes and irrigation treatments		Total applied water (mm)	Total applied water (m^3 ha^{-1})	ET_a (m^3 ha^{-1})	Seed yield (kg ha^{-1})	Irrigation water use efficiency (IWUE) (kg ha^{-1} mm^{-1})	Water use efficiency (WUE) (kg ha^{-1} mm^{-1})

									SE = 0.047

The highest value of *ky* were 0.366, 0.350 and 0.253 at the first location, while it was 0.426, 0.144 and 0.338 at the second locations, for Velko, Barolo RO and Local genotype by imposing water deficit at critical growth stages (flowering stage).

Data represented in *Table 11* illustrate the crop yield response factor (*ky*) for sunflower genotypes at both locations, which estimated according to Doorenbos and Kassam (1979), the results were tabulated in this table. The crop response factor values ranged from the minimum of 0.089 for the Barolo RO genotype at the Qlyasan location to a maximum of 0.781 for the Local genotype at the same location. Also, among the genotypes, Barolo RO exhibited the least value of (*ky*) at both locations. All genotypes yield response factor were of less than 1.0.

Table 11. *Crop response factor for different sunflower genotypes to limited irrigation at both locations*

Table 12 illustrate the yield reduction and water saving for sunflower genotypes under different irrigation treatments. It was shown that the percent yield reduction decreased with an increase in the amount of applied water at various growth stages. The maximum percentage of yield reduction was 24.17 and 24.52% for Velko genotype under skipping irrigation at flowering stage (I_2) at both locations, respectively. Deficit irrigations applied in vegetative stages have fewer effects on seed yield losses, while the effects were higher at flowering and achene formation stages. Also, seed yields were affected by water stress at later growth stages, which could result in about 40% water saving as compared with full irrigation.

Discussion

The lowest and highest seed yields under irrigation water use efficiency (IWUE) and water use efficiency (WUE) at both I_2 and I_3 stages were due to a deficit in irrigation. This may be due the effect of deficit irrigation. Therefore, such effect could be less significant if water stress were applied to the crop during specific growth stages that were less sensitive to moisture deficiency. Kazemeini et al. (2009) also reached the same conclusions. Also, Iqbal et al. (2005) reported that flowering and seed filling stages had been the most critical for water stress in sunflower. Therefore, Anastasi et al. (2010) signified that sunflower provides the highest seed yield under full irrigation.

Genotypes and irrigation stages were the main factors in higher seed yields of Velko genotype. Our results collaborate (Mahender et al., 2000; Kakar and Soomro, 2001) results in which genotypes and irrigation intervals are two main factors in seed yield increases in oilseed sunflower. Various genotypes of sunflower have different responses to water stress. Our results were similar to (Angadi and Entz, 2002; Bakht et al., 2010) who observed the genotypic differences in sunflower for drought tolerance.

Velko genotype produced the highest seed yields under full irrigation (I_4), and drought stress statically decreased seed yield compared to no-stress. This indicates that skipping of irrigation at these stages can minimize seed yield to a great extent. Irrigation skipping at the achene formation stage (I_3) should be preferred due to higher IWUE and WUE if water resources are limited. Our finding collaborates (Cicek et al., 2015; Baba et al., 2016). The results stated that there is a steady decrease in both irrigation water use efficiency and water use efficiency with an increase in the amount of water quantities with the exception of control treatment (I_4). Our study showed that IWUE and WUE values were higher than those in literature in the neighboring countries under limited irrigation. Kassab et al. (2012) found that the WUE under drought condition higher than it is under plain irrigation. Regarding the genotypes, the second and third stage, i.e., skipped irrigation at flowering and achene formation stages are the critical stages for deficit irrigation. Therefore, skipping of irrigation at these stages can minimize crop yield to a great extent. Irrigation skipping at the achene formation stage should be preferred due to higher IWUE and WUE when water resources are limited, and the cost of irrigation water is high.

The crop response (*ky*) factor value for individual growth stages varies depending on season, location and intensity of water deficit. Among three sunflower genotypes and water deficit at different growth stages, the highest crop response factor value was found at flowering (S_2), followed by achene formation (S_3) and vegetative (S_1) stages. This may explain that the flowering stage is critical in sunflower seed production.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76057623

Therefore, the water deficit at flowering stage must be avoided if possible. Martyniak (2008) stated that drought tolerance differs strongly among the growth stages of many crops. Thus, water stress at flowering stage (S_2) will not be allowed because of yield reduction was found higher than other stages (*Table 12*). The flowering stage was the most critical stage to deficit irrigation for sunflower cultivation. The flowering stage is the most sensitive to water deficits which cause considerable seed yield decreases since fewer flower come to full development (Beyazgul et al., 2000; Ali and Shui, 2009). Water deficit at the flowering stage should be avoided. It is clear that the value of response factor varies from location to location (depending on weather and soil), variety to variety, crop to crop, season to season and also for individual growth stages to entire growing season what Ali (2009) discussed in determining response factor of winter wheat in Bangladesh.

The crop response factor (*ky*) value for the entire cropping season was determined by Doorenbos and Kassam (1979). Several research reports exist on yield response of sunflower to water, while other reported that the (*ky*) values were between 0.80 – 0.95 for sunflower (Demir et al., 2006; Moutonnet, 2002). But, Mila and Ali (2016) found that the (*ky*) values were in the range of 0.25 to 0.64 for the whole growing season of sunflower. Similarly, (Sullu and Dagdelen, 2015) reported that the crop response factor as 0.74 for the entire growth season. However, our *ky* values for all genotypes were between 0.09 – 0.78. This confirmed that the genotypes under our study are more tolerant to water deficit, and partly recovering from stress, exhibiting less than relative reductions in yield with reduced water use. Regarding the previous studies, there are agreements ($ky < 1$) (Silva et al., 2014; Steduto et al., 2012) and divergences ($ky > 1$) (Sezen et al., 2011), with respect to tolerance sunflower. However, slight differences in yield response factors were mainly because of differences in climate parameters, plant water consumptions, cultivars, soil conditions, irrigation programs and other cultural practices (Çiçek et al., 2015).

The maximum percentage of seed yield reduction was recorded by Velko genotype under skipping irrigation at flowering stage (I_2) treatment at both locations. This confirmed that the most sensitive stage to water deficit is a flowering stage, which similar to the result reported by Shafi et al. (2013) who indicated a considerable reduction in seed yield of sunflower due to water stress at the flowering stage. Therefore, plant growth stages should be taken into consideration, and irrigation scheduling should accordingly be created to have optimum water use efficiency in semi-arid climates.

It was noticed that the highest uniformity coefficient value recorded by Velko genotype, compared to the values of Barolo RO and Local genotypes, could be due to various factors such as growing season, region and intensity of water deficit (Mila and Ali, 2016).

The study showed that the most active growth stage of irrigation was skipping irrigation at flowering stage, compared with other stages; therefore irrigation during this period would ensure the least yield reduction of sunflower. This implies that irrigation treatment at the middle stage was more efficient to increase the seed yield of sunflower genotypes rather than the early and last irrigation. The tolerance of the full-grown plant to drought may be due to sufficient root penetration without water deficit in the early stages of growth. Also, the increase in the production of antioxidant enzymes when plants are subjected to stress may also provide plant resistance to drought (Langeroodi et al., 2014).

Conclusion

The results indicated that skipping irrigation at the flowering stage was more effective to decrease the seed yield of sunflower genotypes than the achene formation and vegetative stages; it is the most sensitive stage to water deficit which causes considerable yield reduction. It was observed that the water deficit should be avoided at the flowering stage. Thus, water must be ensured at this stage to prevent severe yield loss. Greater water stress may be contributed to higher crop response factor, which indicated that sufficient water supply during flowering and achene formation stage is important. The results showed that water deficit at the flowering stage should be eliminated. However, this will change with location, the intensity of water deficit, and stages of growth. Water stress can influence seed yield in sunflower during the stages of flowering and seed formation due to its effect on reproductive organs and the increase in the number of empty seeds; this may be due to abortion of ovaries, embryo, and sterility of pollen grains.

In view of the existing values of water efficiency, it is recommended to give high priority to Velko genotype coupled with none skipping irrigation at the flowering stage.

(Received ; accepted)

Abstract. Red pine (*Pinus brutia* Ten.) is one of the most common and most processed softwood species in the forest products sector in Turkey. It is essential to learn as much information as possible about potential employee health problems that may occur during processing of this wood. For this reason, sawmill workers that produce lumber from the red pine species were investigated in terms of employee health problems. A face-to-face survey method of employees was used to conduct this study. The questionnaire contained three sub-sections: demographic, physical, and environmental and ergonomic factors that affect employee health. The collected data were statistically evaluated and compared with findings from the literature. Certain important findings are presented as crosstabs and graphs for comparison. Based on the study results, employee complaints about the red pine sawing process during working hours are as follows: allergic reactions due to wood dust: 23.2%; burning eyes and redness: 27.4%; dyspnea: 30.5%; prolonged standing and discomfort: 64.9%; noise-induced hearing loss: 38.5%. It is also realized, however, that occupational diseases such as vascular disorders depend not only on the working environment and conditions but also on the age of employees.
Keywords: *work healthy, woodwork, work-related symptoms, Pinus brutia, occupational hazards*

Introduction

According to a recent press release from the International Council of Forest and Paper Associations (ICFPA), 90% of wood and paper production comes from 43 countries and the forest products industry has a volume of more than $470 billion with more than 14-million people employed worldwide. Approximately 300,000 people provide employment opportunities in Turkey's wood and forestry products industry, with an annual worth of $19-billion (OAIB, 2017).

However, timber manufacturing in Turkey is a sub-sector of the overall manufacturing sector and consists mainly of private sector enterprises of which the majority are small enterprises that grow slowly. Although there is a total of 10.000 sawmills (small or medium to large) with an annual timber capacity of 10 million m^3, at present the current production capacity is reported to be approximately 6-million $m^3$of sawn timber (Sakarya and Canlı, 2011; Görgün and Unsal, 2015).

However, it has been reported that most wood processing plants are exposed to gas, steam, and wood dust that is harmful to workers, but occupational health has not been given enough importance in these enterprises (Barlı, 1996). In recent years, increased sensitivity to occupational health and diseases has led to a comprehensive review of the lumber and forest products sectors. As a result, international authorities have established some legal arrangements with certain risk groups.

One of the first studies on the subject of health problems in the wood-working industry was conducted in England in 1965. This study established that a critical

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76257639

number of workers exposed to furniture and wood dust developed sino-nasal adenocarcinoma. Since then, many scientific studies of employees working in various wood-related industries have been conducted that reported that these types of workers are at risk. It has been reported that beech and oak species are two of the most common species that cause workers to develop some type of disorder, although many other species cause health problems in workers (Demers et al., 1997). It was also reported that quercetin and Δ3-carene isolated from wood is mutagenic (Jensen et al., 2001).

It was reported that wood dust generated different types of processing could cause work-related respiratory and skin problems or disorders, such as eczema, shortness of breath, nasal cancer, headache, and cramps (Bozkurt and Bozkurt, 1979). It was also reported that workers exposed to high levels of hardwood or softwood dust after smoking and consuming alcohol are at risk for laryngeal cancer (Ramroth et al., 2008). In another study conducted on pine wood sawmills, asthma and cough symptoms were observed for employees that were associated with increased levels of eye and nose irritation resulting from dust exposure (Douwers et al., 2001). It was also proposed that cutting of green wood releases essential oils and monoterpenes into the environment along with wood dust that could cause eye irritation, mucous membrane defects, and skin irritation (Rosenberg et al., 2002). It is clear that dust exposure may result in declining lung function, bronchial hyper-responsiveness, and various other problems such as allergic alveolitis, toxic dust syndrome, chronic bronchitis, rhinitis, mucous irritation, and asthma.

The International Agency for Research on Cancer (IARC) has already classified wood dust as a Group 1 agent that is carcinogenic to humans, based on evidence of the effects of exposure to hardwood dust on the nasal cavities and paranasal sinuses of exposed woodworkers (IARC, 1995). In 2009, the IARC concluded that wood dust should be avoided by workers and could cause cancer of the nasal cavities, paranasal sinuses, and nasopharynx (Siew et al., 2012).

In view of the physical and psychological effects of working conditions in the workplace, it was suggested that musculoskeletal injuries of the upper limbs were the most common type of injury in the timber industry (Jones and Kumar, 2004). Similarly, it was found that the highest rate of injury was associated with the transport of logs to timber processing sites (Bello ve Mijinyawa, 2010). Work-related symptoms in sawmill workers typically are chest tightness, cough, dyspnoea, hoarseness, headache, weakness, sweating, eye and body itching, and skin rash (Dutkiewitcz, 2001).

Based on the results of this comprehensive literature survey, a detailed study focused on the occupational health problems of employees working in red pine processing sawmills was not found. However, the red pine species is spread widely throughout not only Turkey but also throughout the forests of Mediterranean countries. The aim of this research was to evaluate the working conditions of red pine processing sawmills in order to identify general health problems for employees and to develop solutions to problems that may arise in terms of occupational health in depends on the perception of employees. Results of this study will provide simple but high-impact information concerning the quality of life of employees.

Materials and methods

In this study, health problems that may occur in employees were directly evaluated with a standard questionnaire that was distributed to employees. This survey was given

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76257639

to 413 employees across 17 enterprises in Turkey. The study was conducted among sawmill workers processing red pine wood in west mediterrian region between July 2013 and February 2014. The open-ended questions included in the questionnaire form were distributed to employees about 10-15 min. Participants were asked to respond and their opinions about the general problems and their solutions were recorded.

According to a forest activity report from the Union of Chambers and Commodity Exchanges of Turkey (TOBB), 13285 people are employed in the sawmill and parquet sector and 67.3% of them are workers (8945) (TOBB, 2012). No official information was available that reported the species of wood processed by the sawmills. However, a previous study conducted on the Isparta region found that 90% of the primary forest production enterprises used red pine (Sütçü et al., 2008).

In order to determine the minimum sample size to be surveyed and to provide statistical reliability, the number of samples needed for a 95% confidence level was determined to be a minimum of 368 people according to the following equation (*Eq. 1*) (Krejcie and Morgan, 1970).

$$s = \frac{X^2 NP(1-P)}{d^2(N-1)+X^2P(1-P)} \quad \text{(Eq.1)}$$

where; s: *required sample size*; χ^2: *the table value of chi-square for one degree of freedom at the desired confidence level (1.96^2)*; N: *the population size (8945)*; P: *the population proportion (assumed to be 0.5 since this would provide the maximum sample size)*; d: *the degree of accuracy expressed as a proportion (0.05), s=368*.

In this study, a total of 413 randomly selected people were given the questionnaire in order to produce more accurate results. The study's data information and survey specifications are shown in *Table 1*.

Table 1. *The survey and questionnaire specifications*

Country	Population*		Samples			
	Number of work places (Nw)	Number of employees (Ne)	Number of work places (nw)	Number of employees (ne)	Workplace rate (nw/Nw)	Employees rate (ne/Ne)
Isparta	402	1.070	12	315	2.99%	29.44%
Burdur	235	780	1	15	0.43%	1.92%
Antalya	1.027	2.496	1	40	0.10%	1.60%
Adana	755	1.699	3	43	0.40%	2.53%
Total	2419	6045	17	413	0.7%	6.83%

* According to TUIK (2007)

The questionnaire forms, which were prepared with the literature reports, contained 23 topics under three headings (demographic, current, physical and environmental factors).

For statistical evaluation of survey data, the necessary analyses were conducted using statistical software SPSS 13.0 and the results of these analyses were interpreted by graphs and tables. Due to the discontinuous data of the study, the results were graded with 0-1 variables that are expressed as discrete variables (yes-no, good-bad, existent-non-existent). Therefore, it was decided to simultaneously use Chi-square for trend test and Student's t-test, assuming $p < 0.05$ as the significance level. However, a Chi-square for trend test was performed whether there was a linear trend for an outcome to increase

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76257639

or decrease over the range of an ordered categorical exposure variable (Peat et al., 2009).

Results and discussion

Evaluation of demographic factors for sawmill employees processing red pine

Demographic data of the employees in the pine wood processing sawmills are presented in *Table 2*. According to the survey results, the majority of the employees in the sector are predominately male with an age distribution greater than middle-age. However, according to the Turkish 2002 general manufacturing industry workplace report, the rate of women working in the sub-sector of sawnwood and cork production (excluding furniture) is 6.84% (TUIK, 2007). In this study, the rate of female employees was found to be only 3.6%. Moreover, more than half of the employees in this sector are in the age group of 30 to 40 years of age. This clearly shows that young people (18-30 years) are not interested in the sawmill industry. It is also important to note that approximately 70% of employees have primary education while the undergraduate level is not even 1%. Similar results were found in Turkish studies of the sawmill sector (Osman and Pala, 2009).

Table 2. *Demographic characteristics of participants*

Gender	**Female**			**Male**	
	%3,6			%96,4	
Age (Year)	**<20**	**20-30**	**31-40**	**41-50**	**50<**
	%1	%19	%50	%23	%7
Education level	**Primary Education**	**High School**	**Vocational High School**		**Higher Education**
	66.8%	14.5%	17.9%		0.7%
Length of employment (in industry)	**<1**	**2-5 year**	**6-10 year**	**10<**	
	%13	%27	%23	%37	

It was also found that approximately 40% of the workers have worked in the same sawmill for 10 years or longer. The work time of employees in the forest products industry also supports the results of our current work (Osman and Pala, 2009). Of the employees in this sector, 45% had previously worked with furniture or as carpenters and 3% worked in other manufacturing sectors such as marble-mining, which is different from woodworking sector.

Working units in sawmills are broadly divided into two parts: the sawmill workshop-manufacturing area and sawmill yards. Sawmill workshops refer to the units where activities such as processing, sawing, planning, and sanding are performed and 67% of employees working in Sawmill workshops. In sawmill yards, activities such as stacking logs, and drying the sawn timber in the open air are performed and 33% of the employees work in sawmill yards.

Evaluation of physical working comfort for red pine sawmill employees

Physical working comfort is dependent on the physical working circumstances and the ergonomic characteristics of the manufacturing environment. Conditions such as a poor working environment, noise, inadequate lighting, ventilation, excessive and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76257639

prolonged work hours, absolute temperature and failure to comply with ergonomic standards adversely affects the productivity of employees. However, the most important work environment factors that affect occupational health in the woodworking industry are noise and wood dust (Barlı, 1996). In this study, noise was found to be the most important factor (*Figure 1*). The main sources of noise in sawmills are band saws, planers, gang saw, and compressors, and the noise level usually exceeds 85 dB (Reinhold et al., 2006; Gomez et al., 2010). Although this situation may cause temporary deafness and hearing loss, it is reported that this noise is effective even on retention of coronary heart failure and this risk continues even after retirement (Virkkunen et al., 2005). De Souza et al. (2015) claims that noise exposure is independently associated to hypertension. In our study, we considered only for auditory effects. As a result 62% of the employees stated that they had experienced hearing loss as a result of excessive noise.

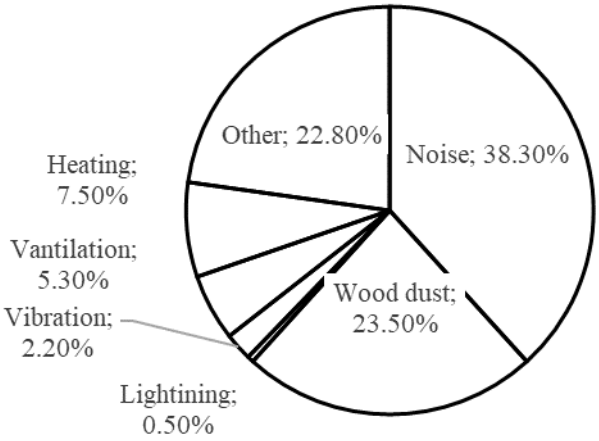

Figure 1. *Response of sawmill workers about working conditions*

It was reported that the woodwork industry usually utilizes low technology and the average age of many machine-plants is over ten years (Sütçü et.al., 2008; Sakarya and Canlı, 2011). The use of old machinery and facilities deprives the sector of new technologies that have taken the necessary measures in terms of the health and safety of employees. As a result of the observations made within the scope of the evaluated enterprises, significant differences in noise and vibration between the use of old and new technology, especially with compressor, multi-slitting, and profile machines, were observed. Ülker (2018) reported that, in furniture manufacturing, most of the machines exceed the threshold of 85 dB, even when operating in the idle position. Vibration, as a noise factor, causes pain in various limbs (e.g., wrist, arm, elbow, leg) of the workers. Pain was reported in the body as a result of exposure to vibration in 60.3 percent of employees.

Another important factor is 'wood dust' (with a rate of about 24%), as shown in *Figure 1*. Wood dust is known to cause respiratory symptoms related to asthma, dermatitis, eye irritation, and upper respiratory tract. However, wood dust is also classified as a human carcinogen by IARC (IARC, 1995). And it has only been conclusively linked to sinonasal cancers, despite individual studies suggesting an association with a range of respiratory tract cancers. Hancock et al. (2014) has

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76257639

demonstrated significant associations between lung cancer and wood dust exposure or employment in wood dust-related occupations. Moreover, respiratory protective equipment and local exhaust ventilation reduce the risk of occupational sinonasal cancer (Emanuelli et al., 2016).

Lighting and ventilation are important working condition factors. Adequate levels of lighting reduces the risk of accidents that may occur when using machinery and equipment. According to this study, the lighting situation is considered to be sufficient by a high percentage of employees (91.5%). However, ventilation conditions were not quite as high by those employees who considered the lighting conditions to be adequate (84.3%).

Temperature and humidity conditions are other important factors that affect the subjective feeling of human comfort. Too low or too high ambient temperature and high humidity negatively affect the productivity of employees. Based on the results of our study, although the majority of the employees thought that thermal comfort was adequate in the winter and summer months, approximately 40% of them reported that they felt very hot or very cold in terms of thermal comfort. This indicates that enterprises do not take adequate measures for heating in cold areas and cooling in hot areas. In regions with cold winter conditions, such as Isparta, experienced warming problems due to the lack of adequate heating systems in the facility; warm regions, such as Adana, due to the heat and humidity in summer conditions, climatic disturbance is felt. Despite this, the ratio of those who feel that thermal comfort is sufficient (62%) should not be underestimated.

Evaluation of general health problems in sawmill activities

In the forest product industry, it is inevitable for employees to avoid joint disturbances as a result of long-term outpatient work, loading and unloading of loggers, transporting large and heavy materials between machines, and loading the machine. But this factor can cause work related musculoskeletal syndrome disorders (MSD's) or different kinds of problems in organisms (Gedik and Akyüz, 2004). However, it was proposed that low back pain, tendonitis, and tenosynovitis are the most common MSD's that accounted for 25% of occupational injuries in the United States in 1997 (Wu et al., 2009). Bello and Mijinyawa (2010) reported that 57.81% of those working in the sawmill industry in Nigeria had pain in the back and in the lower back. According to our findings as summarized in *Table 3*, the number and incidence of joint pain (back, waist, foot) caused by prolonged standing during work has been quite high (64.9%). Also, the situation of vascular diseases that has emerged as an occupational discomfort due to prolonged standing during work conducted by sawmill workers.

Table 3. *Symptoms to body area for sawmill tasks*

Symptoms (n=413)	**Frequency**	**Percentage (%)**
Work Related Musculoskeletal Syndrome Disorders (MSD's)	268	64.9
Joint pain due to vibratory	164	39.7
Hearing Impairment	159	38.5
Respiratory dysfunction (dyspnea)	126	30.5
Eye irritation due to wood dust	113	27.4
Varicose veins	106	25.7
Work related allergic reactions	96	23.2

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76257639

The distribution of vascular disease in the participants according to demographic characteristics is shown in *Table 4*. The incidence of vascular disease was not significantly different according to gender and work unit ($p > 0.005$). Although there was a decrease in the trend of educational status (26.8%; 23.9%; 0.0%), the incidence of vascular disease was not significantly different based on the education level of the employees (χ^2 for trend = 0.820, $p = 0.365$, *Table 4*). According to the data evaluated and the statements of the employees participating in the survey, a significant difference was found between vocational education and vascular disease (χ^2 for trend=24.294, p=0.0001). Although the frequency of vascular disturbance based on length of employment showed a significant difference, the results of the analysis (χ^2 for trend=10.304, p=0.005) show that, when the direction of the trend is taken into consideration and employees with 6-10 years of experience are excluded from the evaluation, the significant difference in the analysis is lost (χ^2 for trend= 4.42, p=0.110). This situation applies to employees who work in the red pine processing sawmills and shows that the length of employment has no effect on the risk of vascular disease.

Based on the t-test, the relative age of patients that developed vascular disease was older than no patients, but the difference was not significant (37.3, SD:7.58; 36.6, SD:4.7; $p = 0.428$).

The incidence of MSD's was not significantly different based on gender, educational status, and occupational education ($p > 0.05$, *Table 4*). However, the relationship of MSD's with the working area showed a significant difference ($\chi^2 = 3.426$, $p < 0.05$). This indicates that workers (71.1%) in the yards face more risk of joint pain than those working in the workshop (61.9%).

According to the length of employment, the incidence of MSD's showed a significant difference (χ^2 for trend = 11.374, $p< 0.05$, *Table 4*). However, when employees with a work duration less than one year were excluded from the evaluation, the significant difference in the analysis was lost (χ^2 for trend = 4.66, $p = 0.097$). According to the results of the analysis, workers with a work duration of less than one year had many complaints about MSD's (80.8%). Although there is a gradual increase in length of employment of more than one year, no significant difference was observed based on the results of the analysis, but this situation can be explained by the "training and practice" effect (Yıldırım, 1989).

Workers in woodwork industries are exposed to hand–arm vibrations, awkward posture, repetitive tasks, and high grip force. Also, vibration has been reported to introduce fatigue in muscles, further augmenting postural stress (Bhardwaj and Khan, 2018). In this study, the change in the occurrence of MSD's (especially joint pain) caused by demographic-based vibration exposure is shown in *Table 4*.

Joint pain caused by vibration and its correlation to gender, working unit, and work time does not show a significant difference. However, there is a significant difference based on the education level of the employees (χ^2 for trend = 5.683, $p < 0.05$, *Table 4*). Based on the occupational education of employees, the presence of joint pain caused by exposure to vibration showed a significant difference ($\chi^2 = 8.077$, $p < 0.05$). However, the mean age (35.7; SD:8.0) of participants with complaints about joint pain resulting from exposure to vibration was lower than the mean age of those without joint pain (37.5; SD:7.6, $p < 0.05$). As a result of these observations made in sawmills, the employment of highly qualified personnel with a higher education level in more qualified jobs, low level of education, new entry into the business and unqualified personnel can be related to the work in units of older model machines, which work more noisily and vibrate.

Wood dust is one of the most important health risks in forest product workplaces, as described in the literature. Required limit values have been established by international organizations (Siew et al., 2012; IARC, 2012). However, the mechanism of pathogenesis involving the lungs in woodworkers could be due to exposure to airborne dust of different particle sizes, concentrations and compositions.

Moreover, these structural components are also responsible for most toxic, irritant, and sensitizing effects which become a cause of impairment and worsening of lung function. In addition, it is well known that wood contains many microorganisms (including fungi) and toxins, agents such as; terpenes, abietic acid, and plicatic acid in different types are, potentially, implicated in the occurrence of asthma by inducing increased bronchial responsiveness or by damaging the bronchial epithelial cells (Kherde et al., 2017). According to the results of the survey, 30% of the workers experienced dyspnea that was caused by exposure to wood dust. *Table 4* illustrates the change in dyspnea frequency caused by participants' exposure to wood dust based on demographic characteristics. The frequency of dyspnea was not significantly different according to gender, occupational education, work unit, and work time. But it was significantly different based on education level of employees (χ^2 for trend=1.679, p=0.0001). This situation can be explained by qualified personnel that graduated from high school working in more qualified work units (technical units-departments which are less exposed to wood dust). When the ratio of university graduates contrasts with the above explanation, only three university graduates participated in the survey, which makes it difficult to propose a valid interpretation.

There was no statistically significant difference ($p > 0,05$) in the mean age between employees who have shortness of breath (37.1; SD:7.3) and those that do not (36.6; SD:8.0).

The frequency of allergic reactions did not show a significant difference based on gender, education, occupational education status, and working area (*Table 4*). The frequency of allergic reactions based on length of employment showed a significant difference (χ^2 for trend = 10.649, $p < 0,05$). This difference is due to the frequency of high allergic reactions in less than one year (40.4%). When employees less than one year are excluded from the evaluation, the significant difference is lost (χ^2 for trend = 0.92, $p> 0,05$).

The mean age (35.4, SD:7.5) of participants having allergic reactions was lower than the mean age of participants without allergic reactions (37.2, SD:7.8; p= 0.051). As a result of exposure to dust in the workplace, 27.4% of the workers had itching, redness, and burning in the eyes caused by wood dust but 72.6% of the participants did not have such complaints (*Table 4*). In the literature, allergic reactions to sawdust from softwood are more common among sawmill workers than allergic reactions to sawdust from hardwood (Dutkiewicz, 2001). Rosenberg et al. (2002) reported for pine processing industries the focused on monoterpene exposure which causes work-related subjective symptoms.

There was no significant difference in the occurrence of redness and burning in the eyes based on gender, the level of vocational education, and the work area (*Table 4*). A significant difference was observed based the education level of the employees (χ^2 for trend = 5.490, $p<0.05$). Similarly, a significant difference was observed based on length of employment (χ^2 for trend = 9.295, $p < 0.05$). This difference was due to redness and burning complaints ranging from 6 to 10 years (34%). When these employees are excluded from the evaluation, the significant difference is lost (χ^2 for trend = 0.59,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76257639

p> 0.05). The mean age (35.3, SD:6.4) of the participants that have redness and burning in the eyes was lower than the mean age of the participants without these complaints (37.3, SD:8.8; p = 0.051).

The percentage of participants who stated that they experienced hearing loss as a result of exposure to noise in the red pine processing sawmill was high (38.5%, *Table 3*). The frequency of hearing loss based on gender showed a significant difference ($\chi 2$=4.163, p=0.033). Male employees (39.4%) expressed that they experienced hearing loss due to more noise so than women. Male employees are exposed to greater levels of noise depend on working in noise-intensive environments and may experience more health problems related to hearing loss. Female are generally employed in classification-standardization and packaging units. In addition, no significant difference was found in terms of hearing loss status based on education level, vocational education, working area, and length of employment. Similarly, there was no significant difference in the 95% confidence level between the average age of the participants with hearing loss and the mean age of those who did not experience hearing loss (p = 0.167). According to *Table 4*, the rate of hearing loss was found to be as high as 50% in employees with less than one year of work experience. However, it is known that at least two years of working in a noisy environment are required for the formation of hearing loss as a result of continuous noise exposure. According to these data, it is estimated that the employees experience temporary hearing loss.

General complaints about ergonomic conditions in red pine processing sawmills

Figure 2 shows a summary for the question of 'What do you think is the most important factor that negatively affects the health of employees in the environment where you work?' The most important complaints expressed by workers were "ignore use of personal protective equipment (PPE)" and "overtime work".

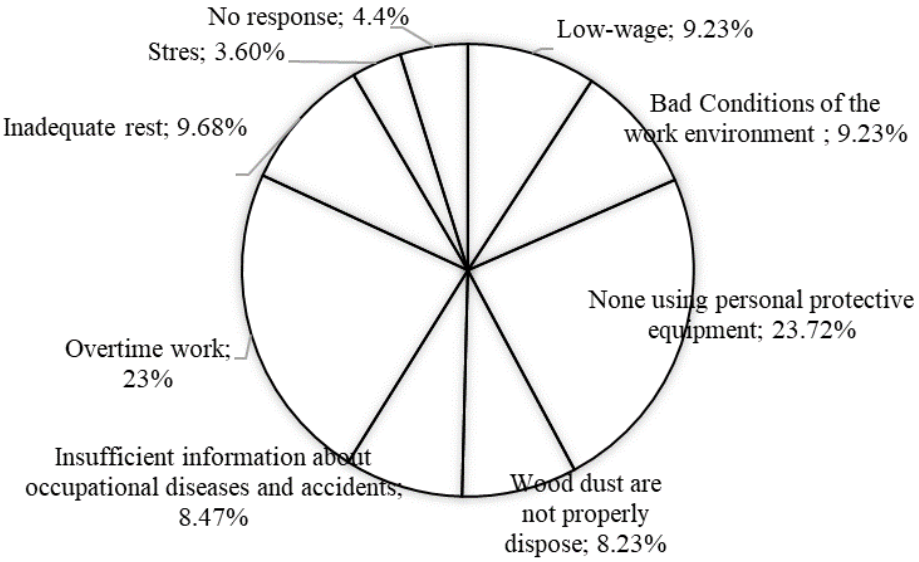

Figure 2. *Complaints in red pine processing sawmills expressed by workers*

It is understood that the use of PPE, such as earmuffs or plugs, hand gloves, or masks, has been poor and inappropriate in the wood processing industries and they are

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76257639

often considered to be irrelevant and disturbing. According to the results of the survey; approximately 25% of employees complain of non-use of PPE in the work environment. One of the most common reason for not using it, was mentioned that PPE causes discomfort while working (Top et al., 2016). Effendi and Pratama (2017) found a significant relationship between knowledge with the use of personal protective equipment. Similar findings were made by other groups (Bello and Mijinyawa, 2010; Jerie, 2012). These groups also reported that some workers (23%) complained about overtime. However, the majority of these employees are ungrudging in to work under the overtime work to meet their economic requirements due to their unqualified employee status and minimum wage. In Turkey, according to the Regulation on Working Hours of Labor Law, uninterrupted work time cannot exceed 11 hours per day (RG, 25425). Overtime work causes problems such as fatigue, weariness, and carelessness in employees and also decreases job dissatisfaction and work performance. This is why the risk of accidents can be reduced while increasing employee motivation and work efficiency with organizational configuration measures such as more efficient organization of break times, job expansion, and job enrichment. In addition, 9% of employees reported that they do not have any information or knowledge about occupational health and safety. This shows that the risks to employees in the work environment, the hazards that may arise from these risks, and the rights of employees against these risks are not known. In this scenario, employers have a significant role. Employers should organize information seminars for their employees through their occupational health and safety experts. The studies done by various authors have also recommended implementation of an occupational health service and development of a means for collective and individual prevention to reduce the risk maximally. It has already proposed that the health risk should be minimized by the mutual collaboration between health officials, woodworkers and their management (Kherde et al., 2016).

Conclusions

The employees studied in this work are exposed to wood dust generated during the processing of red pine wood, to chemicals formed by the extracts and essential oils in the wood, and to hazardous preservatives that are used to prevent biological and physical degradation of these raw materials. In addition, it is inevitable that occupational health problems will be experienced by the employees due to the fact that working conditions are not sufficiently ergonomic, heavy material is manipulated manually, and physical factors such as overtime work.

However, inevitable muscular and skeletal syndrome disorders develop as a result of prolonged standing during work, loading and unloading of loggers, transportation of large and heavy planks between the machines. However, workers in the yards encounter more risk of joint pain than those working in the workshop. In addition, use of PPE, improvements to the working environment, and organization of information seminars about occupational health and safety have been suggested by workers.

The length of the work day causes problems such as fatigue, weariness, absence, turnover, carelessness, poor performance, and decreased job satisfaction. For these reasons, the risk of accidents can be reduced while implementing work structuring principles such as more effective organization of break times, job enrichment, job enlargement, and job rotation to increase motivation and work efficiency.

Abstract. Plough tillage had existed in Chinese agricultural history for a very long time. However, more and more farmers prefer to use the rotary machine to do the land preparation due to its ability to provide better soil fragmentation in recent years. The present study was conducted in order to study the effect of plough tillage on grain yield, quality and soil organic matter in ratooning rice systems, in Hunan Province, China, using a rice cultivar, *Huanghuazhan* as material and two tillage treatments were applied in present study. Conventional rotary tillage was named as CK and plough tillage was named as PT. The result showed that compared to CK, PT treatment not only could improve the grain yield of both main-crop rice and ratooning rice, but also increased the grinding quality and nutrition quality of grains in main-crop rice. Furthermore, higher soil organic matter was recorded under PT.
Keywords: *ratooning rice, grain quality, yield, paddy soil, land preparation methods*

Introduction

Ratooning rice is a special cultivation method in rice production. It has a long history in China which can be traced back to 1700 years ago (Min et al., 2017). It is characterized by cutting only about two-thirds of the upper part of the rice plant, collecting rice panicles, leaving behind one-third of the plant and root system, fertilization and cultivation, so that it can grow another season of rice. Normally, there will be some axillary buds when rice matures in the first season and after harvesting in the first season, they will be retained. On the basis of the original root system, these axillary buds will grow and heading again. After about 2 months, they will mature again and can be harvested (Rogé et al., 2016). Generally, the grain size of rice in the second season is smaller than that in the first season, but the number of panicles in the second season is higher than that in the first season (where the original panicle is cut, more than two panicles will grow), so the yield is not small.

The areas suitable for planting ratooning rice are mainly those where sunshine and heat are not enough to grow two-crop rice, but there are many areas where one-crop rice is planted. Because it grows again on the original roots, it saves the period from the first crop to the middle of the second crop (so it is called Ratooning rice, not Two-crop rice) in the second crop rice growing area. In this way, ratooning rice can be planted in areas with more than one

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76417647

season, thus increasing yield (Kupkanchanakul et al., 1990). At present, many areas in China, such as Sichuan and Fujian provinces, are experimenting to popularize this cultivation (Luzhou and Hz, 2000). Thus, developing ratooning rice is an important task to ensure China's future food security.

As an important part in rice production, tillage is required to reduce the loss of water and fertilizers through excessive percolation and it also could decrease weeds and enhance nutrient availability (Alam et al., 2018). In Chinese agricultural history, there were two tillage methods including plough tillage and rotary tillage. Recently, because of the better soil fragmentation, most of framers are likely to use rotary machine to do the land preparation. However, excessive soil fragmentation under rotary tillage could induce the reduction in soil's ability to regulate water, air and heat (Abu-Hamdeh, 2000). The study of SUN (2017) revealed that compared to rotary tillage, plough tillage not only could improve the soil environment, but also could promote the root activity and the production of tobacco leaf.

In order to study the effect of plough tillage on ratooning rice system productivity and soil organic matter, present study was conducted in Hunan Province (major rice producing province in Central China) with the hypothesis that plough tillage could improve rice yield and grain quality in ratooning rice system.

Materials and methods

Plant material and growing conditions

A rice cultivar, *Huanghuazhan*, which having a growth period of 129-131 days and widely grown in Central China, was used in present experiment and planted at Hongshuo Farm, Datong Lake District, Yiyang, Hunan Province (29 08' N, 112 26' E) in 2017. Before sowing, the seeds were soaked in water for 24 h, germinated in manual climatic boxes for another 12 h and shade-dried. Then, the germinated seeds were sown in polyvinyl chloride trays for nursery raising. The experimental site enjoyed a subtropical monsoon climate and the air temperature during the experiment was shown in *Figure 1*. The soil type of paddy field is fluvo-aquic soil and mechanical composition is as follows: sand (0.05~2 mm) accounts for 34%, silt (0.002~0.05 mm) for 56.7%, clay (0~0.002) for 9.3%. It contained organic matter 29.30 g kg^{-1}, total N 1.94 g kg^{-1}, total P 1.31 g kg^{-1}, and total K 26.70 g kg^{-1}.

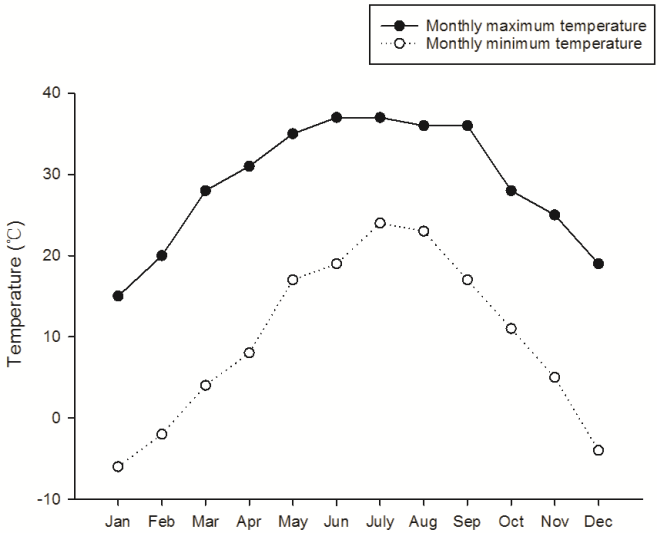

Figure 1. *The temperature during the field experiment*

Treatment description and sampling

Two land preparations, plough tillage and rotary tillage were adopted in present study. We set rotary tillage as control (CK) and name plough tillage as PT.

CK: Before transplanting, the paddy field was puddle twice with rotary cultivator.

PT: Before transplanting, the paddy field was puddle twice with plough cultivator.

The treatments were arranged in randomized complete block design (RCBD) in triplicate with net plot size of 665 m^2. After the harvest of main-crop rice and ratooning rice, five soil cores (0–20 cm depth, 2 cm in diameter) were collected in each plot for the determination of soil organic matter.

Estimation of soil organic matter

The light fraction (LF) and heavy fraction (HF) of soil organic matter were separated using the method described by Camberdella and Elliott (1993). Briefly, 10 g of air-dried soil was homogenized with 30 ml NaI solution (gravity 1.8 g cm^{-3}) in a 100 ml centrifuge tube by shaking on a reciprocating shaker for 60 min at 200 rpm, after which it was centrifuged at 1000 × g for 15 min. The LF, all floating material after centrifugation, was poured into a vacuum filter unit with a 0.45-μm nylon film, and the material retained by the film was washed with 0.01 M CaCl2 and distilled water. This process was repeated three times. The HF remaining in the centrifuge tube was washed three times with ethanol to remove excess NaI, after which it was washed twice with distilled water. Next, the LF and HF were dried at 60 °C for 48 h, and then weighed and ground to pass through a 0.15-mm sieve for organic determinations. The organic matter in LF and HF were determined by the wet oxidation method with K2Cr2O7 at 170–180 °C (Zhao et al., 2016).

Yield and yield related traits

At maturity stage, the rice grains were harvested from ten-unit sampling area (1 m^2) in each plot and then threshed by machine. The harvested grains were sun-dried and weighted in order to determinate the grain yield. Twenty hills of rice from different locations in each plot were sampled for estimate the average effective panicles number per hill. Then, eight hills representative plants were taken for estimation of the yield related traits.

Grain quality

After sun drying, grains were stored at room temperature for at least a month to determine grain quality components. About 1.0 kg rice grains from each treatment was taken from storage and brown rice rate was estimated using a rice huller (Jiangsu, China) while milled rice and head rice recovery rates were calculated by using a Jingmi testing rice grader (Zhejiang, China). Grains with chalkiness and chalkiness degree were estimated by using an SDE-A light box (Guangzhou, China) while an Infratec-1241 grain analyzer (FOSS-TECATOR) was used to determine the grain amylose and protein contents.

Statistical analysis

Data were analyzed on Statistix 8.1 (Analytical Software, Tallahassee, FL, USA) while differences among means were separated by using least significant difference

(LSD) test at 5% probability level. Graphical representation was conducted via Sigma Plot 14.0 (Systat Software Inc., California, USA).

Results

Soil organic matter

As shown in *Figure 2,* plough tillage significantly influenced the soil organic matter compared to CK. After the harvest of main-crop rice, 28.11% higher soil organic matter was recorded in PT than CK. After the harvest of ratooning rice, compared to CK, PT treatment increased soil organic matter by 19.56%.

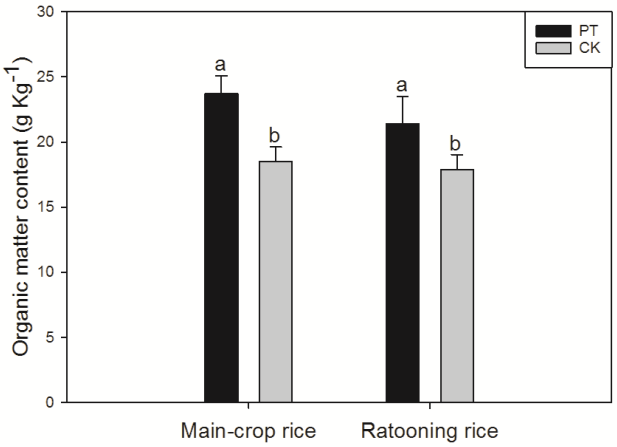

Figure 2. *The effect of plough tillage on soil organic matter in ratooning rice system (Means sharing a common letter do not differ significantly at (P ≤ 0.05) according to least significant difference (LSD) test)*

Yield and yield related trails

As shown in *Table 1*, plough tillage affected rice yield and related trails in ratooning rice system significantly. For main-crop rice, PT treatment increased panicle number, grains number and yield by 12.03, 7.02 and 10.99%, respectively whilst there was no significant difference between PT and CK in both seed-setting rate and 1000-grain weight. For ratooning rice, compared to CK, 4.51, 7.47, 4.42 and 4.72% higher panicle number, grains number, 1000-grain weight and yield were recorded in PT.

Table 1. *The effect of plough tillage on rice yield and related trails in ratooning rice system*

	Treatment	Panicle number per hill	Grains number per panicle	Seed-setting rate (%)	1000-grain weight (g)	Yield (t ha^{-2})
Main-crop rice	PT	326.97±16.78a	128.56±3.76a	86.60±3.71a	22.82±0.65a	7.50±0.39a
	CK	291.87±15.99b	120.12±2.64b	85.61±2.29a	22.42±1.03a	6.76±0.41b
Ratooning rice	PT	355.94±8.65a	56.36±1.48a	78.51±1.90a	22.69±0.43a	3.46±0.06a
	CK	340.70b±6.40b	52.44±0.71b	77.64±2.00a	21.73±0.55b	3.30±0.07b

Values sharing a common letter within a column do not differ significantly at (P ≤ 0.05) according to least significant difference (LSD) test for both the years. The same as below

DOI: http://dx.doi.org/10.15666/aeer/1704_76417647

Grain quality

As shown in *Table 2*, plough tillage affected grain quality in ratooning rice system significantly. For main-crop rice, compared to CK, PT treatment significantly increased brown rice rate, milled rice rate, head rice rate, crude protein content, amylose content and Akali value by 6.27, 1.51, 10.76, 1.40, 8.82 and 2.92%, respectively. Moreover, 25.64% lower chalky rice rate was recorded in PT treatment than CK. For ratooning rice, PT treatment increased both brown rice rate and Akali values significantly compared to CK. However, there was remarkable difference between CK and PT in milled rice rate, head rice rate, crude protein content, amylose content, chalky rice rate and chalkiness.

Table 2. *The effect of plough tillage on grain quality in ratooning rice system*

	Treatment	Brown rice rate (%)	Milled rice rate (%)	Head rice rate (%)	Crude protein content (%)	Amylose content (%)	Akali	Chalky rice rate (%)	Chalkiness (%)
Main-crop rice	PT	73.13±0.34a	64.60±0.33a	42.52±0.05a	7.26±0.03a	18.50±0.04a	5.86±0.07a	19.33±0.88b	14.96±0.90a
	CK	68.82±0.30b	63.64±0.16b	38.39±0.05b	7.16±0.03b	17.00±0.40b	5.70±0.05b	26.00±0.78a	14.10±2.84a
Ratooning rice	PT	73.13±0.32a	65.26±0.94a	46.73±1.97a	10.76±0.09a	17.90±0.10a	7.03±0.07a	5.06±0.58a	14.83±1.36a
	CK	71.10±0.31b	65.78±0.89a	47.99±1.63a	11.00±0.05a	17.77±0.07a	6.90±0.03b	4.33±0.67a	13.16±1.98a

Correlation analysis

As shown in *Figure 3,* there exited a significant positive correlation between rice yield and grain number. However, panicle number, seed-setting rate and grain weight all did not have significant correlation with the grain yield. Furthermore, there also existed a significant positive correlation between yield and soil organic matter (*Fig. 4*).

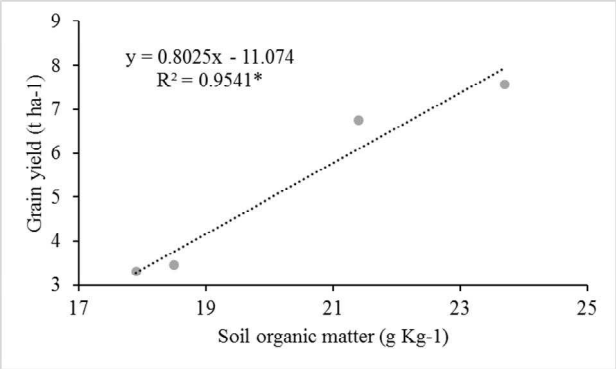

Figure 4. *The correlation between yield and soil organic matter*

Discussion

The development of ratooning rice is a vital way to achieve a full utilization of the solar-thermal resources in autumn and promote the profit of rice field. Previous study (Fu-Xian et al., 2015) already showed some key regulation technologies in ratooning rice cultivation such as varieties selection and fertilizer application. Present study revealed the effect of different tillage on yield, grain quality and soil organic matter in ratooning rice. Compared with conventional rotary tillage, plough tillage significantly increased the yields of both main-crop rice and ratooning rice. The increment in main crop rice yield could be explained by the improvement in panicle number and grain number. The increment in ratooning rice yield not only because of the enhancement of panicle number and grain number, but also due to the higher grain weight under plough tillage. Furthermore, we also observed a significant positive correlation between yield and soil organic matter which indicated that the improvement in soil organic matter due to plough tillage might be the direct reason of the yield increment. This result agreed with the study of Wei et al. (2016) who demonstrated that soil organic matter was an important factor which affected rice productivity significantly. Normally, the degree of soil fragmentation under rotary tillage is higher than plough tillage. But it also means the rotary tillage had rotary tillage destroys the soil more severely and excessive soil fragmentation can induce the decrement of biodiversity in farmland soil (Biswas et al., 2017). Our study showed that plough tillage was more suitable for ratooning rice cultivation because it not only improved the rice yield, but also had less soil fragmentation and improved the soil organic matter.

Moreover, in our study, we observed that plough tillage improved some grain quality attributes. Normally, rice price in market mostly depend on grain quality (Luo et al., 2018). For main-crop rice, plough tillage not only improved rice grinding quality such as brown rice rate, milled rice and head rice rate, but also increased the grain nutrition quality such as protein and amylose content. The increments in grain quality might because the plough tillage improved rice growth and development.

Conclusion

In ratooning rice system, compared to rotary tillage, plough tillage not only could improve the grain yield of both main-crop rice and ratooning rice, but also increased the grinding quality and nutrition quality of grains in main-crop rice. Moreover, higher soil

DOI: http://dx.doi.org/10.15666/aeer/1704_76417647

organic matter was recorded in plough tillage than rotary tillage. In order to explore the mechanism of how tillage affects ratooning rice performance, further investigation should be at the field trials.

(Received 11th Mar 2019; accepted 1st May 2019)

Abstract. The paper deals with the dynamics of changes in livestock production in Slovakia in the period between 2004 and 2017 from the viewpoint of productive and non-productive factors with a special focus on environmental factors in the breeding of four groups of farm animals. The development was evaluated on the basis of the indicator of stock intensity. The data was analysed at the levels of NUTS 3 (regions) and LAU 1 (districts) for Slovakia. The study showed that the changes in the agricultural sector after the year 2004 due to Slovakia´s entering the European Union have manifested themselves in an overall decrease of livestock production as well as in further aggravation of regional disparities. The aforementioned changes not only pose a direct risk to the agrarian sector but they also affect the environment in a broader context. The positive ecological impacts associated with the attenuation of primary livestock production spotted at first glance can negatively affect the environment, biological diversity and quality of life. The current status quo requires a consequent application of the principles of organic farming and its support in form of government subsidies and legislation.
Keywords: *animal production intensity, ecological agriculture, regional disparities, environmental impact, Slovakia*

Introduction

Before the transformation process in the agrarian sector livestock production in Slovakia was to one of those fields, which had been financed by state subsidies. After the transition to the new model of economic relations the government incentives were minimized and abolished respectively. This resulted in a significant decrease of livestock population, particularly in the traditional (majority) groups such as beef cattle and pigs. It became problematic to cover the costs of breeding and producing livestock. The reduction in the number of the individual types of livestock had already started in the 1990´s and it has been continuing ever since. In this period not only the regional disparities in primary livestock production in Slovakia became apparent (Némethová et al., 2017b) but the development insinuated that the stability of the agricultural commodity markets was at stake. This developement persists and livestock production in Slovakia has been on the decline for a long time (Chrastinová et al., 2014). This fact is also connected with the economic conditions such as higher costs of breeding farm animals (Buday et al., 2012). The decline in livestock production is related to the decrease in the numbers of the individual types of farm animals but also to the import of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76497666

finished products of animal origin to the Slovak market. The structural changes in Slovak agriculture after Slovakia´s accession to the European Union (EU) in the year 2004 and the Common Agricultural Policy (CAP) aggravated the regional disparities in livestock production (Némethová et al., 2004). As a result in Slovakia not only livestock population drastically dropped but in some regions the breeding was completely abandoned. The positive aspect in the process is the growing efficiency of farm animals, which is however conditioned by other than economic factors. The EU´s Common Agricultural Policy motivated the farmers with its instruments to reduce livestock production and to favour vegetable production focussing on large-scale crop production and primarily crops in the area of renewable energy sources, which ultimately brought about other specific implications and consequences.

The changes in Slovak agriculture associated with the consequences of a state´s entering the European Union and adopting the EU´s CAP are theoretically reflected in the works of experts from various aspects (Spišiak et al., 2005; Falťanová, 2008; Spišiak and Némethová, 2008; Buday et al., 2012; Némethová and Civáň, 2017; Némethová et al., 2014, 2017a). The problems do not concern only Slovakia. After the dissolution of Czechoslovakia Czech farmers also had to come to terms with the new situation. The impact of the CAP on agriculture and rural areas in the Czech Republic and the issue of regional disparities have been analysed by several authors (Kabrda and Jančák, 2006; Svobodová and Věžník, 2011; Věžník and Konečný, 2011; Král et al., 2012; Doucha et al., 2012 and others). Over the past 30 years the Czech Republic has seen a rapid decline in some types of farm animals as well as a change in their internal structure and method of breeding (Věžník et al., 2013, 2017). The impacts of the EU´s CAP on the development of agriculture, the analyses and evaluation of the impacts are written down in the works of many foreign experts (Kulikowski, 2005; Kołodziejczak, 2006; Buchenrieder and Möllers, 2009; Kołodziejczak and Kossowski, 2011). The approach of the individual farmers in Portugal as far as the impact of the EU´s CAP is concerned is presented by Dos Santos et al. (2010). Rudnicki (2013) assessed the situation in Poland from the viewpoint of a recipient of European subsidies. The approach and opinions of selected farmers in the new EU member states regarding the changes in the CAP after the year 2003 were dealt with by Gorton et al. (2008). Ilbery and Maye (2005) analysed selected changes in the trend of cattle breeding and its importance for the food market in Great Britain.

Ecologization of agriculture and protection of the environment are important on a global scale. The European Union supports this aera of agro-environmental production. Apart from producing healthy food organic farming strives to eliminate damaging and devastating of the environment by preventive measures and special farming and breeding practices (Petrovič et al., 2017). Unlike convenational agriculture it prefers the quality of production, versatile production and a varied cropping pattern. It excludes chemistry and machinery from its production. The system of organic farming is the research topic of several experts in Slovakia, e.g. Schlosserová and Juršík (2009), Némethová and Mesárošová (2013), Kozáková et al. (2015), Némethová et al. (2017b) in the Czech Republic, e.g. Hrabalová and Zander (2006), Brožová (2011), Doležalová et al. (2014). The analysis of the transition from the conventional farming system to organic farming is dealt with by e.g. Lockie and Halpin (2005), Stolze and Lampkin (2009), Moschitz and Stolze (2009), Mzoughi (2011). The measures applied by the government and the market economy aim at supporting organic farming and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76497666

consumption of organic products (Milestad and Darnhofer, 2003; Häring et al., 2004; Nieberg and Kuhnert, 2007).

The aim of the paper was to analyse the developmental trends and the level of animal production in Slovakia in the period 2004 to 2017 and to point out regional disparities – at the level of regions and districts of Slovakia – in the context of environmental effects. Main attention was focused on the dynamics of livestock production developement and potential impact of the changes on the agricultural sector and landscape.

Material and methods

Dataset characteristics

The main statistical set comprised the official data of the Statistical office of the Slovak Republic referring to the basic indicators of livestock production in the period between 2004 and 2017 (MS Excel). The data was analysed at the level of NUTS 3 (regions) and LAU 1 (districts) of Slovakia.

The principal livestock production indicator used in this study was the stock density on the declared area: heads on 100 hectares of agricultural area (cattle and sheep) or arable land (pigs and poultry) and its alternation during the reference period. The impact of the changes in primary livestock production on the subsequent production on the market is illustrated by the data regarding sales from livestock farming during the evalutation period from 2004 to 2017.

Dataset processing

In order to statistically process and cartographically visualize stock density in the initial situation in the year 2004 and the situation in the year 2017 as well as sales development we applied descriptive statitics and the ArcView programme for visualizing spatial information. For the needs of illustrating the modelling of potential development of stock density in the coming period (identification of expected trends) we applied a procedure based on the evaluation of the dynamics of timelines aided by the ARIMA model in the R software.

Results and discussion

Dataset general characteristics

For the needs of the study the basic statistical set was analysed at the level of the regional statististical territorial units NUTS 3 (regions) and LAU 1 (districts). Slovakia is administratively divided into eight self-governing regions: the Bratislava Region, the Trnava Region, the Trenčín Region, the Nitra Region, the Žilina Region, the Bánska Bystrica Region, the Prešov Region and the Košice Region. The regions are further subdivided into 79 districts.

Stock density of selected livestock groups

The dynamics of the changes in livestock farming between the years 2004 and 2017 is processed in form of analyses; the cartographic visualization consists of maps documenting the initial state (the year 2004) and the state in the year 2017.

DOI: http://dx.doi.org/10.15666/aeer/1704_76497666

Stock density of cattle – Situation in the year 2004 and 2017

In the year 1993 more than 900 000 heads of cattle were bred in Slovakia, in the year 2004 it was only 540 146 heads and at present in the year 2017 the figure amounts to 439 826 heads (when comparing the years 2004 and 2017 the decrease equals to 100 320 heads), which is a decline of 18.6%. A decline over 30% was seen in the Nitra and Trnava Regions. All the regions reported a reduction in livestock population except for the Prešov Region, which recorded a moderate increase of 3.5%. The milk producers keep on producing milk with a loss. The level of the purchase prices of milk does not cover the production costs, which are high. For instance in the year 2000 in Slovakia 246 000 milking cows were bred and in the year 2017 it was roughly only 125 000. The drop in the numbers of cattle is also shown in stock density on the declared area, i.e. heads on 100 hectares of agricultural area. This indicator in the year 2004 amounted to 28 heads of cattle per 100 hectares of agricultural area and in the year 2017 it was only 23, which results in a decrease of 17.7%. The decrease of beef cattle numbers expressed by stock density was seen in all Slovak regions except for the Prešov Region (*Fig. 1* and *Fig. 2*).

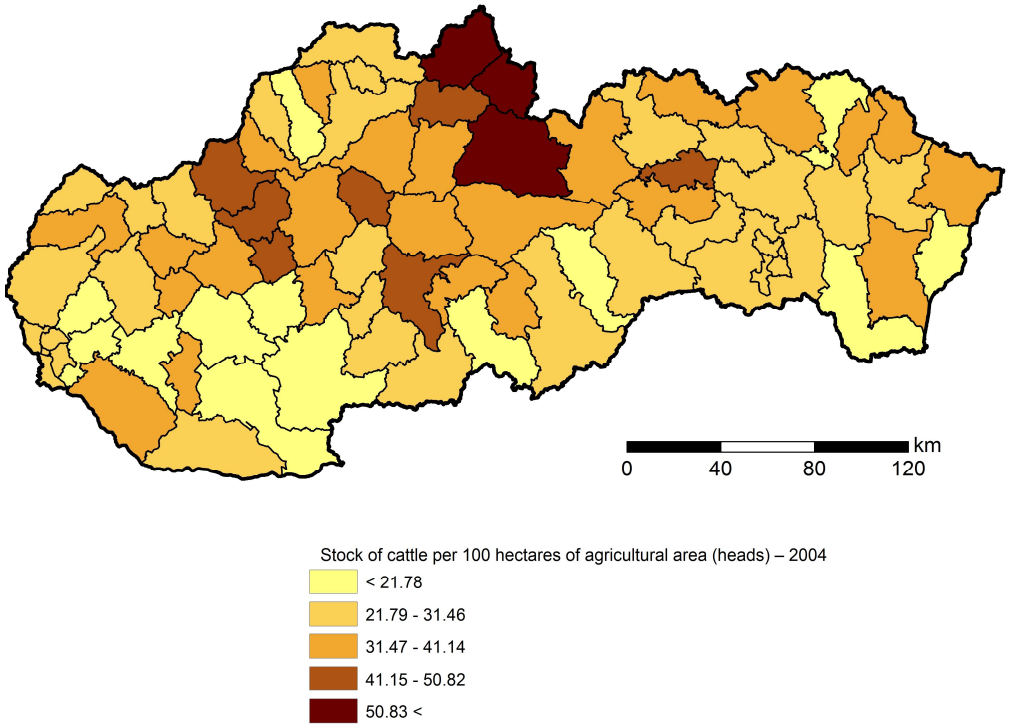

Figure 1. *Stock of cattle per 100 hectares of agricultural area (heads) – 2004*

The falling numbers of cattle influenced the structure of vegetable production particularly the production volume of grain feed and bulk feed. After the entry of Slovakia into the EU the subsidy policy had a positive impact on the breeding of suckler cows. This type of breeding is of relevance especially for landscape maintenance in the agriculturally disadvantaged regions. In the long run an increase of cattle numbers would bring positive results such as for instance the increase of the production of stable manure, which is increasingly lacking on Slovak soils.

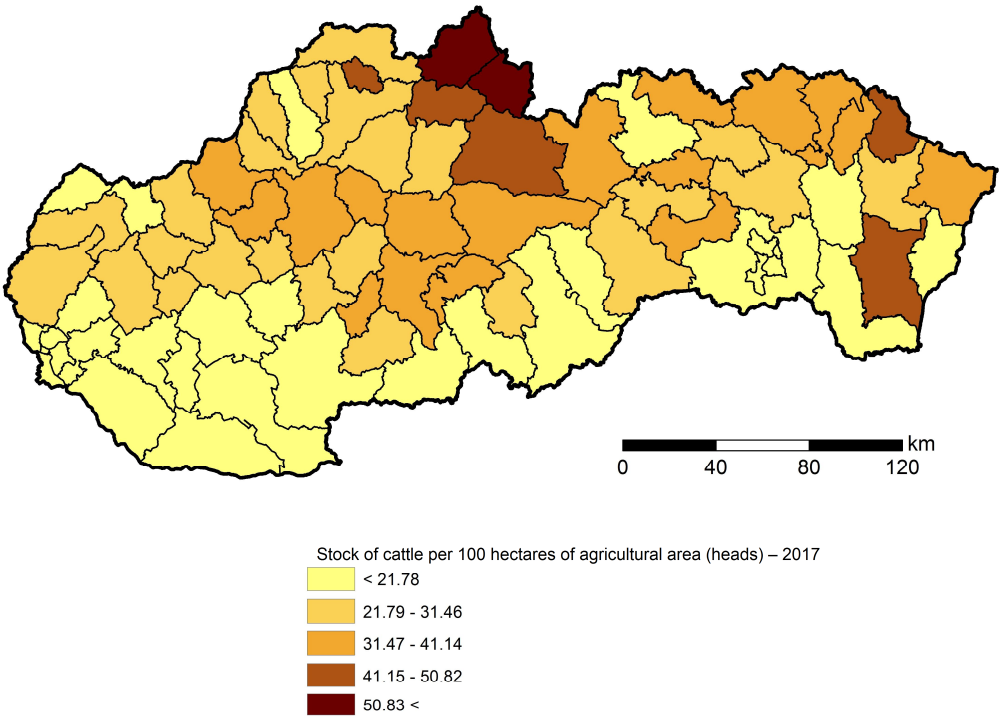

Figure 2. *Stock of cattle per 100 hectares of agricultural area (heads) – 2017*

Stock density of pigs – Situation in the year 2004 and 2017

In the year 1993 in Slovakia 1.8 million heads of pigs were bred. At the time when Slovakia was entering the EU it was 1,1 million heads and in the year 2017 it was only 614 384 heads (a decrease of 534 898 heads). This was the biggest decrease reported among all farm animals (-46.5%). The numbers of pigs fell primarily due to the impossibility to receive subsidies in the field of pig farming as a consequence of the overall surplus production of pigs in the EU states. The next factor influencing the falling numbers of pigs was the increase of the prices of feed, lower purchase prices of pork and cheaper import of meat from abroad. The decrease of the numbers of pigs was seen in all the Slovak regions. In the Košice and Žilina Regions the decline exceeded 70%. A decrease over 50% was reported in the Banská Bystrica, Nitra and Trenčín Regions. Pork is being imported to Slovakia from almost all of Europe, however in particular from the neighbouring countries such as Poland, the Czech Republic and Hungary. More than 50% of the slaughter pigs are being exported due to the closing of a number of important slaugher houses. At the present day in Slovakia there are only smaller slaughter houses in operation such as for example in Myjava, Tešedíkov and Komárno. Most Slovakian slaughter houses process meat from foreign production, which is cheaper and thus more profitable. Slovakia attempts to revitalize the sector of pig farming, which was permanently ignored, with the help of subsidies coming either from the EU or the state itsself. Nowadays Slovakia is beginning to put more emphasis on the freshness and quality of meat, which cannot be guaranteed to the consumer in case of imported meat but only with meat produced by Slovak farmers. From the point of view of future development the growth potential in the area of pig breeding in Slovakia is obvious and it can be expected that the country will become fully

DOI: http://dx.doi.org/10.15666/aeer/1704_76497666

sustainable in pork production. Also the stock density of pigs expressed in the numbers of pigs per 100 hectares of arable land points to a decrease of pig population during the reference period from 2004 to 2017. In Slovakia the stock of pigs in 2004 totalled to 84.5 heads, which in 2017 fell to 45.8 heads, which presents a decrese of 45.9%. A significant decline of more than 70% was reported in the Košice and Žilina Regions (*Fig. 3* and *Fig. 4*). The decrease in the numbers of pigs expressed by stock density of pigs was seen in all the regions of Slovakia.

Stock density of poultry – Situation in the year 2004 and 2017

In case of poultry Slovakia did not record such a significant decline as with pigs and beef cattle. In the year 2004 in Slovakia 13.7 million heads of poultry were bred, before the year 2017 the numbers fell to 13.4 million heads (-2.6%, a decrease of 359 402 heads). A bigger decline was seen in the Trnava Region (-32.2%) and Prešov Region (-53.9%). This decline can be attributed to the common European market connected with the import of cheaper poultry meat from abrod especially from Poland and Hungary. In consequence of the pressure by the supermarket chains regarding the reduction of poultry meat purchase prices, the price fell over several years and does not longer cover the production costs of the breeders. Prior to the year 2000 Slovakia was self-sustainable in the production of poultry meat. As of today the production of poultry meat covers approximately 50% of the consumption of the Slovak population. An increase of the numbers of poultry in the reference period from 2004 to 2017 was seen only in the Bratislava Region and Košice Region. In all the other Slovak regions we state a moderate decline. The decline in poultry numbers can be illustrated with a next indicator, stock density expressed by the number of heads per 100 hectares of arable land. In the year 2004 in Slovakia this value amounted to 1009.8 heads of poultry per 100 hectares of arable land, by 2017 the value went down to 994.4 heads, which presents a 1.5% decrease. The increase in poultry population in the Bratislava and Košice Regions is also reflected in the stock density of poultry (*Fig. 5* and *Fig. 6*). According to this indicator the remaining regions report a decline.

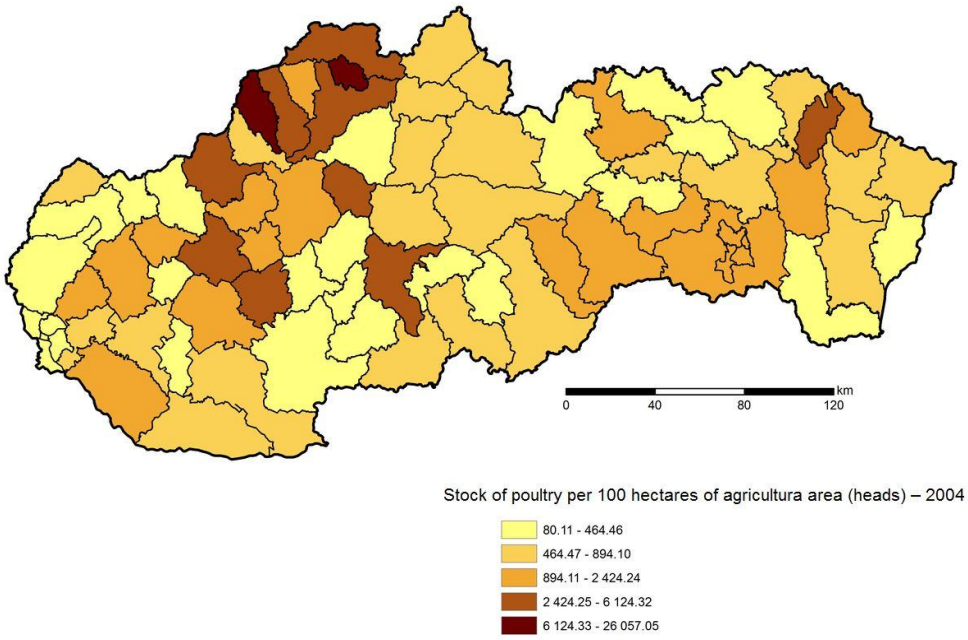

Figure 5. *Stock of poultry per 100 hectares of agricultura area (heads) – 2004*

Stock density of sheep – Situation in the year 2004 and 2017

In case of sheep Slovakia has seen a moderate increase of 13.7%. In the year 2004 the numbers of sheep amounted to 321 227 heads and in the year 2017 it was 365 344 (an increase by 44 117 heads). In all the regions of Slovakia the numbers of sheep

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76497666

increased in the reference period from 2004 to 2017. There was a decrease only in the Nitra Region (-15.1%). The biggest increase was seen in the Bratislava Region (93.3%) and the Trenčín Region (51.6%). In the year 2004 there were 16.6 sheep on 100 hectares of agricultural area and by 2017 the value of the indicator went up to 19.1 heads (an increase by 15%) (*Fig. 7* and *Fig. 8*).

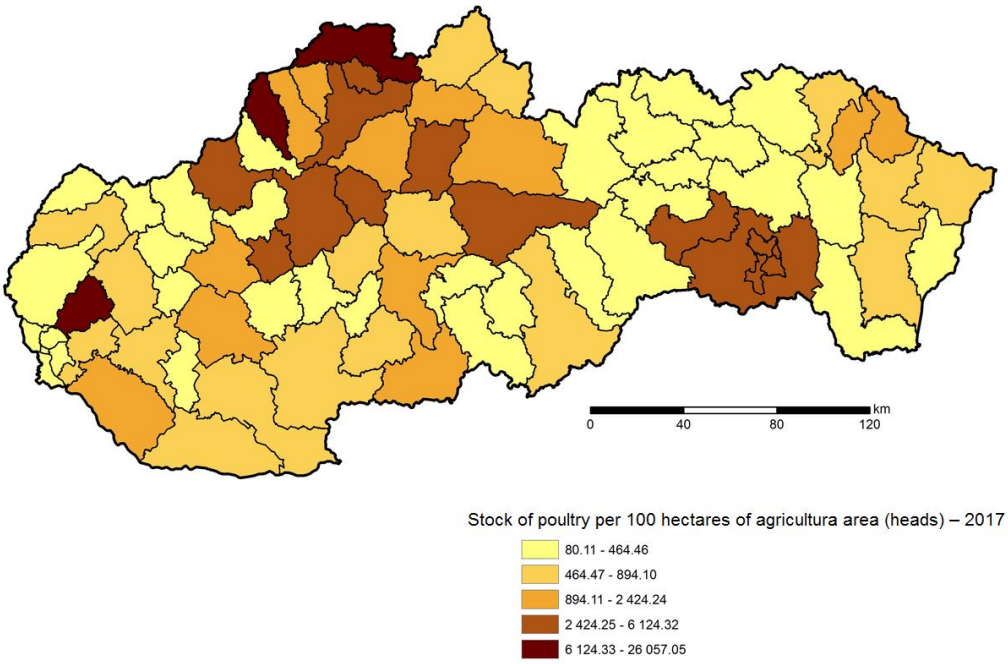

Figure 6. *Stock of poultry per 100 hectares of agicultura area (heads) – 2017*

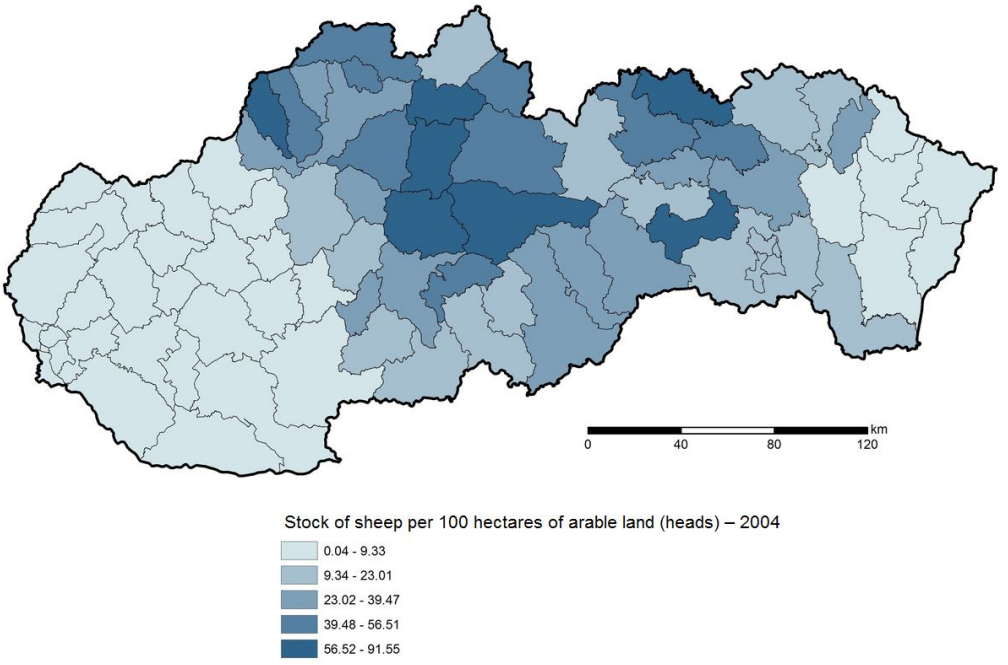

Figure 7. *Stock of sheep per 100 hectares of arable land (heads) – 2004*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76497666

This was primarily due to the EU´s supporting the breeding of farm animals on permanent grassland. The increase in numbers was seen in all the regions of Slovakia except the Nitra Region, in which the stock density of sheep fell by 16%. The domestic consumer market is little interested in sheep meat and thus most of the production is being exported to the markets of developed EU countries. The subsidies and payments in relation to the area of permanent grassland in Slovakia will contribute to further expanding the sector of sheep breeding. Potential development model of stock density in the coming period (identification of expected trends) is presented bellow (*Fig. 9*).

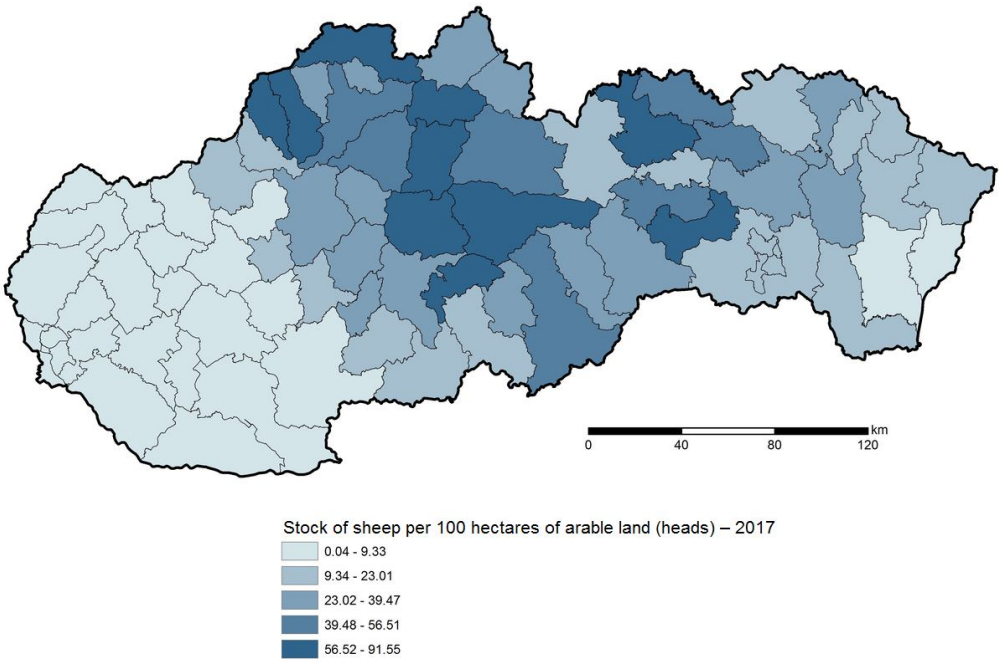

Figure 8. *Stock of sheep per 100 hectares of arable land (heads) – 2017*

Dynamics of sales from livestock production over the period from 2004 to 2017 – share of livestock production sales in total sales from agriculture

Over the past 30 years the breeding of farm animals in Slovakia has significantly decreased especially the breeding of pigs (by more than 66%) and breeding of beef cattle (by more than 50%). This negative phenomenon has translated into the falling employment rates in agriculture. After the accession to the EU Slovak agriculture has not sufficiently used its potential arising from the implementation of the CAP, the common European market and the two rural development programmes. The sector has been financially undernourished for a long period. Unequal conditions among EU countries have contributed to a further decrease of the numbers of farm animals, which led to Slovakia´s not longer being self-sustainable in the field of meat production and meat processing. Also the fact can be seen as negative that the export of living farm animals abroad has increased due to the fact that Slovakia lacks meat-processing enterprises. A next reason is the lower redemption price of meat as compared with abroad. Slovakia is able to cover domestic meat consumption, however over the past years the import of farm animals and mainly the import of meat from abroad have been on the increase. The incorrectly set system of subsidies for livestock production as well

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76497666

as the milk crisis in 2015 made the population of farm animals gradually drop. The unequal level of support among the individual EU member states weakens the competitiveness of Slovak agriculture. A lower level of support on the part of the state does not create favourable conditions for running a farm business either. Slovak agriculture must have adequate conditions for enterprenial activities as it is the case with the other EU states. Livestock production in Slovakia has been on the decline and vegetable production is starting to gain the upperhand. In the year 2004 the share of livestock production sales in the total sales amounted to 58% and in the year 2017 it only made for 44%. The lower share of livestock production in the total sales has been seen since the year 2009, when the livestock production sales amounted to 47.03% and the sales from vegetable production to 52.97%. The share of livestock production sales in the total sales generated in the Slovak Republic reveals a decline in livestock production, as demonstrated of maps from the years 2004 and 2017 (*Fig. 10* and *Fig. 11*). When comparing the years 2004 and 2017 the sales from livestock production in Slovakia fell by 7.6%. The biggiest decrease was seen in the Trenčín Region (-20.7%), the Banská Bystrica Region (-20.2%) and the Nitra Region (-14.7%).

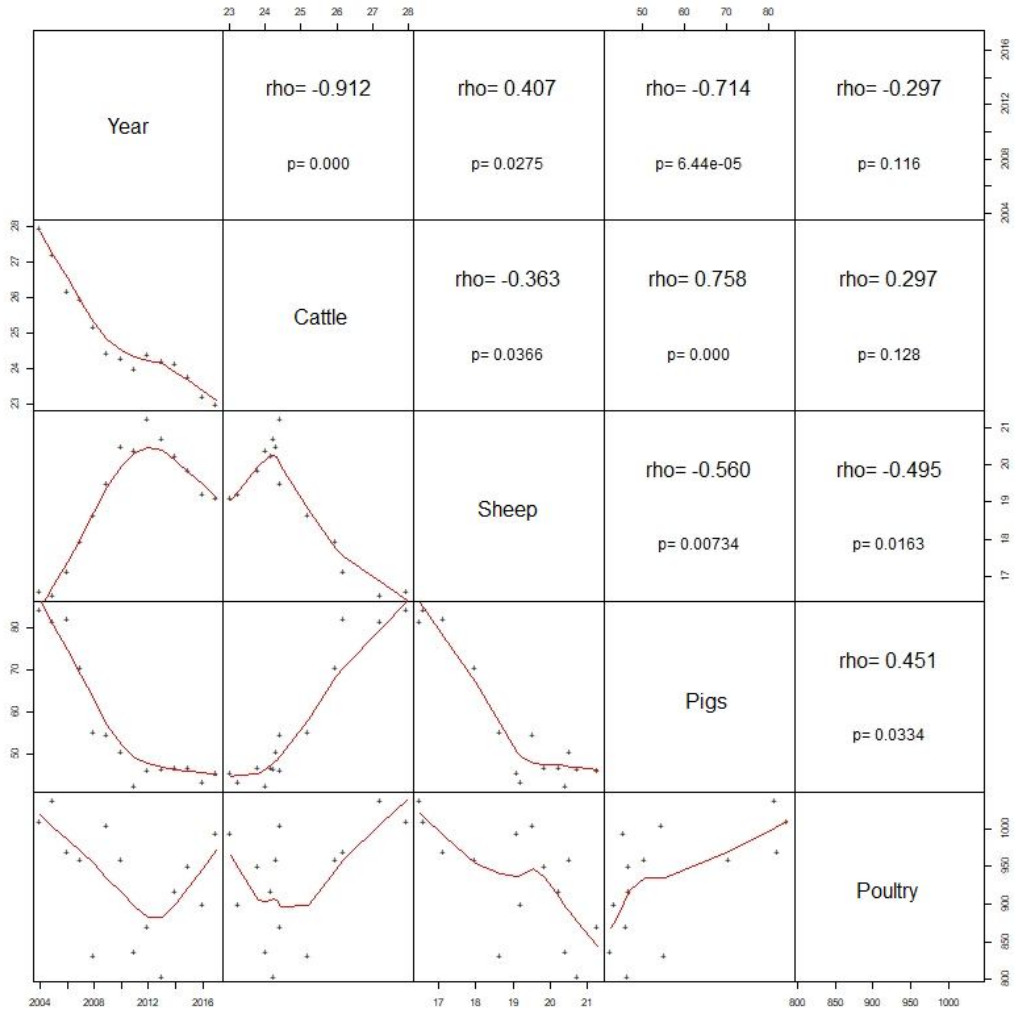

Figure 9. *Animal production trends model in the Slovak Republic (model based on time series analysis)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76497666

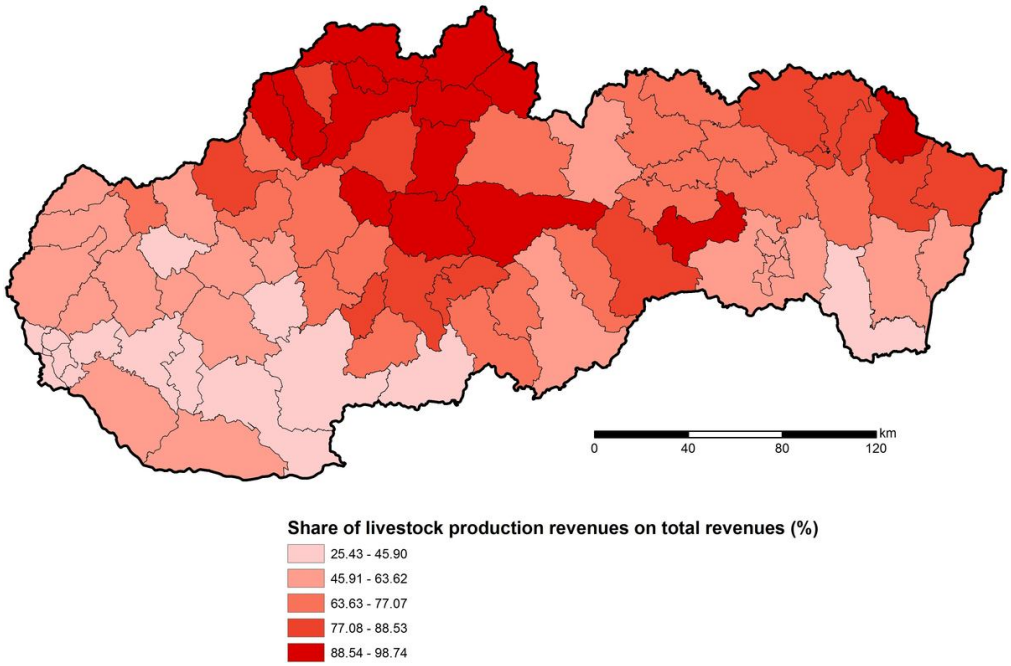

Figure 10. *Share of livestock production revenues on total revenues (%) – 2004*

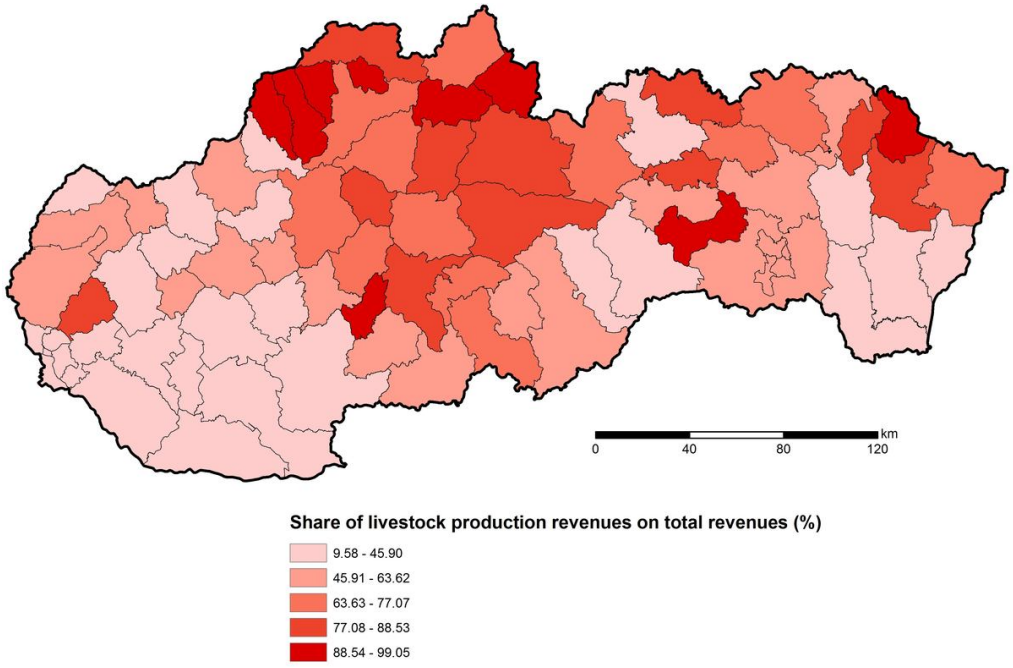

Figure 11. *Share of livestock production revenues on total revenues (%) – 2017*

Vegetable production compared to livestock production is being more supported in Slovakia. According to the Ministry of Agriculture and Rural Development of the Slovak Republic, 2006 the direct payments into agriculture in Slovakia in the year 2005 amounted to 203 MioEUR, while less than 8 MioEUR went to livestock production. It is regarded as positive that the direct payments were gradually increasing and in the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76497666

year 2016 they totalled to 408 MioEUR, from which the breeders of farm animals only received 54 MioEUR (Ministry of Agriculture and Rural Development of the Slovak Republic, 2017). The above-mentioned disproportion in funding the livestock production sector in form of a lower number of types of direct support from the EU could be alleviated by funding from the state budget; however this support can not be compared with the level of funding provided in the remaining EU states.

Changes in livestock production and their potential impact on quality of environment

The changes in livestock production in Slovakia between the years 2004 and 2017 may at first sight suggest a favourable development in reducing damage connected with the direct impact of the agrarian sector on the environment. In case of farm animal breeding it is the potential impact on air quality as well as the quality of soil and water sources. In this respect environmental pollution was particulary seen in relation to large-capacity agricultural farmyards but also with other activities carried out outside the premises of agricultural businesses. The decline in the population of farm animals might in this context appear as a naturally positive factor. However, in a broader context it is necessary to point out the importance of non-productive factors related to a targeted breeding of farm animals. These non-productive factors have a wider impact on the whole society but there is also their biological impact including the preservation of the cultural character of landscape and protection of the environment.

- Reduction of the population of farm animals decreased the production of biomass as renewable energy source and this not only in the form of excrements but also in form of reducing areas under crops for selected commodities, which belonged to the fodder base of livestock production as well as selected types of fermented feed (e.g. silage).
- Reduction of the population of farm animals made natural fertilizers such as the production of stable manure less accessible.
- Livestock production and farm animal breeding generate a quantity of greenhouse gases emissions such as carbon dioxide CO_2 and nitrogen oxide. Most greenhouse gases are released into the air from stable manure. The decrease of the population of farm animals has a positive impact on the reduction of emissions responsible for the greenhouse effect.
- The falling population of farm animals reduces the levels of methane, which has a harmful impact on the climate.
- The drop in the population of farm animals also leads to lowering the level of ammonia (NH_3) emissions. Ammonia contributes to the creation of acid rains.
- Livestock production also causes damage and pollutes soil by excessive overgrazing of pastures by the farm animals and can thus provoke erosive soils. The reduction of the population of livestock therefore has a positive impact on soil.
- Livestock production further contributes to polluting waters. Ground water is mainly polluted by animal droppings, chemicals, synthetic fertilizers, pesticides, hormones and antibiotics that are being served to the animals with fodder. In this respect the decline in the population of farm animals has a positive impact on the environment.
- As it is stated in many documents of the European Union selected groups of farm animals (particularly sheep and beef cattle) play an irreplaceable role in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76497666

form of ecological benefits because they help preserve biodiversity and landscape in areas that are naturally disadvantaged or less fertile. The preserveration of biodiversity affects both the flora and fauna and the whole ecosystems respectively. In many countries, Slovakia included, we find national as well as local breeds, which presents a unique gene pool from the point of view of reproduction and sustainability of the gene pool and animal genetic sources, which foregrounds also the impact on the protection and preservation of agrobiodiversity.

- Farm animals play an equally important role in fighting such phenomena as soil erosion particularly as a result of deforestation but also the changing structure of vegetation, avalanches, fires, inundations and torrential rainfalls.
- The grazing of natural pastures often prevents progradation of various air-raid/ invasive types of plantes (either herbs or woody plants), maintaining i.a. healthy vegetation from the point of view of assimilation of nutrients. Bad accessibility is also a relevant factor.

Possibilities for development of organic farming with focus on livestock production

A sustainable agroecosystem prioritizes organic farming practices, functions and objectives in farming on soil and breeding of animal farms. In comparison with the conventional methods of farming organic farming has more positive effects on the protection of natural elements and landscape. An indispensable factor is the biodiversity of the flora and fauna in areas with arable land, permanent grassland and in the surrounding biotopes as well as the preservation and protection of agrobiodiversity. Since Slovakia entered the EU organic farming has been booming as never before. The positive trend of the development of organic farming in Slovakia has been reflected in an increased number of producers of bioproducts, the area of organic soil has risen and the number of enterprises processing bioproducts has seen a moderate increase too. In the year 2017 there are more than 400 farms operating in the field of organic farming registered in Slovakia. The share in organically farmed land has increased up to 9%. Also the demand of the consumers for organic products significantly contributes to the development of organic farming. In spite of the fact that the prices of organic products are not exactly low the present-day consumers are committed to eating healthy food and protecting their environment at the same time. An essential advantage of organic products is the fact that their production does not pollute the environment. On organic farms, where permanent grassland prevails, the breeding of beef cattle, sheep and goats is strongly represented. As to the orientation of livestock production in the regions of Slovakia it is particularly cattle breeding in combination with other types of farm animals such as sheep, goats and horses. When it comes to cattle breeding two central Slovakian regions stand out: the Žilina and Banská Bystrica Regions and also the Prešov and Košice Regions in eastern Slovakia. The breeding of sheep in combination with other farm animals is less represented (goats, horses and pigs). The farmers deal the least with the breeding of pigs and poultry. It is in this very type of breeding that Slovakia can develop a lot in future. In the Western Slovak Regions and in the Danubian Lowland organic breeding of farm animals is almost not being carried out. In Western Slovakia it is vegetable production of the conventional type but also alternative vegetable production that is more developed. As negative the fact can be regarded that there is an absence of the processors of organic products, their quantity is still not sufficient though the number is rising. As of 2017 Slovakia reports more than 80

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76497666

processors in the field of organic farming, while a majoritiy of the enterprises processing the products of organic farming are located in the regions of Western Slovakia, Eastern Slovakia and in the northern part of the country. These entities mainly concentrate on processing and producing dairy products (17 processors).

In the programming period from 2014 to 2020 the territory of Slovakia falls under the Rural Development Programme 2014 – 2020, which supports organic farming within Priority 4 "Restoring, preserving and enhancing ecosystems related to agriculture and forestry", measures 11 "Organic farming, sub-measures Payments for conversion to organic farming practices and methods" and "Payments for the preservation of organic farming practices and methods". In Slovakia organic farming can become an important element not only when it comes to increasing employment in rural areas, development of agrotourism and production of traditional organic food but in landscape maintenance in particular.

Conclusions

The entry of Slovakia into the European Union introduced new possibilities of receiving subsidies and non-refundable financial resources, which nonetheless did not slow down the falling trend in the population of farm animals particulary of cattle and pigs. Slovak agriculture would not only be helped by a higher level of support from the state budget but also if the direct EU funding were aligned, which would contribute to increasing the employment rates in rural areas and put an end to Slovakia´s lagging behind the other EU countries. Slovakia´s competitiveness on the common European market would increase, while the importation of food from abroad would decrease. The CAP for the period 2014 – 2020 meant a revaluation of direct payments to farmers and of the rural development policy, a greener more ecologically oriented policy of the state, support of smaller farms and small farmers, the support of suckler cows breeding and last but not least the abolishing of the system of milk quotas, which is however related to an overproduction of milk and milk products on the European market. The new reform should enable gradual improvement of efficiency in agriculture and at the same time decrease the share of agrarian policy in the total EU budget (Common Agricultural Policy Reform 2014 – 2020, 2015).

In the new programming period 2014 – 2020 the Ministry of Agriculture of the Slovak Republic has decided to increase the financial support for the breeding of certain farm animals, e.g. milk cows, brood sows, pigs for fattening, broiler chicken and sheep. The amount of the subsidy is derived from the number of the specific animals and the costs necessary for their life (Rural Development Programme of the Slovak Republic 2014 – 2020, 2015). The main objective of this kind of support is to increase the numbers of farm animals in the individual types of breeding.

The funding from the European Union in the new programming period 2014 – 2020 mainly targets revitalization of the dropping livestock production. Although at present Slovakia is not self-sustainable in the production of any kind of meat the country is capable of changing this situation. As far as the breeding of beef cattle is concerned the population of suckle cows is expected to grow. These changes are supported by the transfer of a part of arable land into permanent grassland. Slovakia has a considerable growth potential in the pig farming and there is the assumption to attain full self-sustainability in the production of pork and even to export it. The presently increasing interest of the consumers for poultry meat will contribute to increasing the domestic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76497666

production of slaughtered poultry. Slovak consumers are minimally interested in purchasing sheep meat and most of the production is being exported to developed EU countries. It can be presumed that the breeding of sheep in Slovakia will increase due to support and payments according to the area of permanent grassland. Along with cattle farming sheep breeding is of considerable importance for a sustainable development of rural landscape in mountain and submontane regions. The Slovak consumer is increasingly more interested in not only the quality but also the origin of meat. The freshness of meat is a sign of quality and this cannot be guaranteed by any kind of imported meat. This is the reason why Slovakia endeavours to support young beginning farmers. Young farmers are expected to particularly develop the sensible sectors such as livestock production but also truck farming and fruit growing. It is these very products that are absent on the regional markets (Common Agricultural Policy Partnership between Europe and farmers, 2012). Hole et al. (2004) assess the impact of organic farming on landscape biodiversity compared to conventional farming. Intensification and expansion of modern agriculture rank among the biggest current threats to global biodiversity. Organic farming is a potential solution for increasing biodiversity. This system focusses on food production while minimally damaging the ecosystems. Slovakia meets the preconditions for further development of organic farming.

The dynamics of animal production from 2004 to 2017 in Slovakia, changes of its intensity and structure reflect wider changes in the context of the accession to the European Union and the application of common rules in the form of the CAP. As our study has shown, these changes has been significantly negative impact. The results, among other, are a livestock stocks decrease, a change in the share of livestock production revenues on total revenues, and a deepening of regional disparities. A systematic monitoring of the further development of livestock numbers/stocks (decline, stabilization, increase) and structure of animals / herds appears to be of importance. Furthermore, it will be important to monitor the impact of animal production development on total agricultural production and the agro-food complex, on the agricultural landscape, effect on the environment quality in the context of organic land management and sustainable land development.

Acknowledgements. (Received 11th Mar 2019; accepted 3rd May 2019)

Abstract. This paper assesses of climatic water balance (CWB) in the 2000-2018 vegetation seasons and the rainfall requirements of selected crops. Extreme values and the range of variation for that time period are given emphasis to, paired with statistical significance of the slope of linear trends. The study found that the biggest difference in climatic water balance between 2018 and the 2000-2017 period was recorded in June (29 mm). Water shortages for cereals occurred in all months of the growing seasons both form 2000 to 2017 and in 2018, but in May 2018 water deficit was much larger than in the multiannual period. In the case of maize the last months of the 2018 growing season exhibited high deficiency of rainfall. For early potato varieties water shortages were not higher in 2018 than the average of the multiannual period. However, significant rainfall shortages for sugar beet were recorded in May and August 2018. In the 2000-2017 period the highest average monthly rainfall deficiencies for meadows and pastures were in July. In the same month there was also a statistically significant increase in the CWB value, on average, by about 6.4 mm per 10 years.
Keywords: *precipitation, air temperature, drought, crops, Poland*

Introduction

The ongoing climate change has a direct impact on agriculture. With the change of weather conditions, some factors determining plant yields such as requirements for agro technical practices and for fertilizer also change, together with incidence and severity of diseases and pests. The decisive factor shaping production systems in agriculture in the next few years, alongside climate change, may be the rising demand for food and competition for water. Climate change significantly increases the threat of drought (Sulewski and Czekaj, 2015), but for agriculture global warming may be sometimes beneficial as it opens the possibility of growing new varieties, not used earlier in some parts of the world (Gendron St-Marseille et al., 2019). Scientists predict that the trend in drought incidence in southern Europe and the North-Eastern part of South America will last up to 2050 (Ruane et al., 2018). The increasing frequency of droughts observed in recent years is a result of rising air temperature, lower than average rainfall, or even a complete lack of precipitation for a longer time (Górski, 2006; Kundzewicz et al., 2006; Łabędzki, 2006; Kozyra et al., 2009). Droughts cause significant yield losses (Łabędzki, 2006; Doroszewski et al., 2008). In the drought monitoring system (SMSR) in Poland, weather conditions causing water shortages in agriculture are measured by using climatic water balance (CWB) (Rojek, 1987; Kołodziej et al., 2003; Legates and Mccabe, 2005; Łabędzki, 2006; Kanecka-Geszke and Smarzyńska, 2007; Doroszewski et al., 2008). This period is referred to as agricultural drought (Niedźwiedź, 2003). The agricultural drought monitoring system has been developed on the basis of agro-meteorological studies

DOI: http://dx.doi.org/10.15666/aeer/1704_76677678

(Doroszewski and Górski, 1995; Demidowicz et al., 1996, 1997; Doroszewski et al., 1997).

The aim of the research was to characterise climatic water balance and rainfall deficiency for selected crops in eastern Poland in 2018 compared to the 2000-2017 period. Attention was drawn to extreme values and variation range in that time series. Additionally, statistical significance of linear trend slopes was determined.

Material and methods

The analysis is based on the data recorded between 2000 and 2018 which was provided by the meteorological station in Siedlce (φ°=52°10′03″N ; λ°=22°17′24″E; 150 m above sea level).

The following meteorological elements were analysed:

- daily mean air temperature.
- daily total precipitation.
- daily mean relative humidity.

The basic characteristics of the distribution of the tested parameters were determined: their arithmetic means, and minimum, and maximum values. To present the dynamics of monthly arithmetic means the coefficient of variation was calculated (*Eq.1*).

$$V = \frac{S}{X} * 100\% \quad \text{(Eq.1)}$$

where:

CV – coefficient of variation,

SD – standard deviation,

X – arithmetic mean.

Then evaporation was calculated using Ivanov's equation (Przedpełska, 1971) (*Eq.2*).

$$E = 0.0018(25 + t)^2(100 - f) \quad \text{(Eq.2)}$$

where:

t – mean monthly air temperature, °C,

f – mean monthly relative humidity,%.

Monthly values of climatic water balance were designated using the following formula (*Eq.3*):

$$CWB = P - E \quad \text{(Eq.3)}$$

where:

P – monthly sum of precipitation (mm),

E – monthly evaporation (mm).

Water needs of selected crops were estimated based on optimal precipitation according to the method specified by Klatt (after Nyc, 2006) (*Eq.4*).

$$Popt = Pk + 5 * tk \quad \text{(Eq.4)}$$

where:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76677678

Popt – optimal precipitation (mm),

Pk – optimal monthly precipitation according to the Klatt table (mm),

tk – mean monthly air temperature (°C) for which Klatt determined the optimal precipitation (Pk),

Shortages of rainfall were calculated according to the formula (*Eq.5*):

$$N = Prz - Popt \quad \text{(Eq.5)}$$

where:

N – precipitation deficit (mm),

Prz – recorded precipitation (mm),

Popt – optimal precipitation according to Klatt (mm).

Water shortages were calculated for the following crops: spring wheat, oats, corn, early potato, sugar beet, meadows and pastures.

The values of the analyzed meteorological parameters, climatic water balance, and precipitation deficit in 2018 were compared to the values for the 2000-2017 period. The direction and significance of the trend of climatic water balance changes were established on the basis of the linear trend equation. The significance of the slope of the trend was assessed with Student's t-test with a significance level of $\alpha = 0.05$.

Result analysis and discussion

The greatest average monthly precipitation during the 2000-20017 period was in July (72 mm), and the smallest in October and April with 37 mm and 38 mm, respectively (*Table 1*). The minimum value of this parameter was noted in October (only 2 mm), and the maximum in August (257 mm). Precipitation in October had the largest variation with the CV of 93%. The first half of the growing season (April, May, June and July) exhibited around a 50% monthly variability of rainfall.

The warmest month in the 2000-2017 period was August with the average air temperature of 18,5°C, while October with 8.2°C was the coldest. In the same month the minimum value of this parameter was recorded (5.1°C), while the largest (21.8°C) was in July. The largest variation of the monthly average temperature was in October (CV = 21.1%) and the lowest in August (CV=5,4%).

The observed trend of rising temperature and changing evaporation conditions increased the area of the moderately dry region in Poland from 13% in the 1931-1960 period to 20% in the 1971-2000 period, and the area of land with high soil moisture decreased from 32% to 10% (Ziernicka-Wojtaszek, 2009).

Average relative air humidity in the growing season varied from 69.5% in April to 83.5% in October. The maximum value for this parameter was noted in October (93.8%), and the minimum in July (57.6%). The variability of humidity ranged from 5.5% in October to 8.2% in July. The average monthly values of the climatic water balance in the 2000-2017 growing seasons were negative. The maximum value of this parameter was noted in October (-9 mm) and minimum in July (-168 mm), while CWB variation remained at around 27%.

Multiannual average rainfall (2000-2017) in the growing season was 390 mm, and in 2018 it was 347 mm, which was only about 43 mm less (*Fig. 1*). However, monthly sums of precipitation were slightly larger than the multiannual average only in April, June, and July 2018 (*Fig. 1*). Compared to the average in May 2018 rainfall was lower by 34 mm, in August by about 37 mm, in September by 11 mm, and in October by 3 mm.

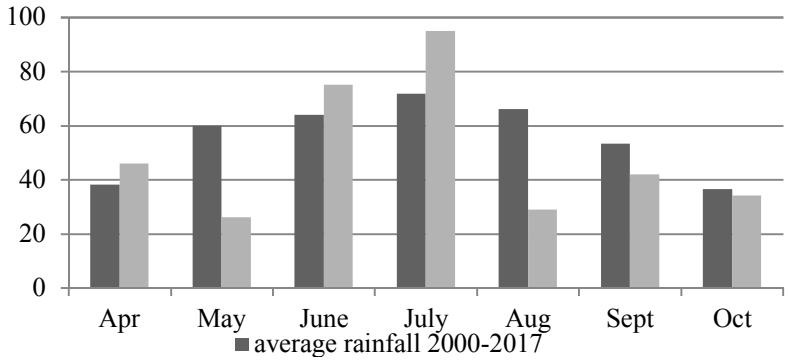

Figure 1. *Average monthly rainfall (mm) of the 2000-2017 period and in 2018 in Siedlce*

It was found that in all months of the 2018 growing season the average monthly air temperature was higher than the average multiannual (*Fig. 2*). In April 2018 it was higher than the average multinational by 4ºC. The smallest difference in thermal conditions between 2018 and the multiannual period was in July, with the temperature in 2018 higher by only 0.3°C.

Changes in relative air humidity in 2018 were inverse to changes in air temperature (*Fig. 3*). In all the months of the 2018 growing season, with the exception of July, the value of this parameter was a few percent less than the multiannual average.

Similarly, the values of climatic water balance in July 2018 were 7 mm higher than the multiannual average (*Figs. 4 and 5*). In the remaining months of the 2018 growing season precipitation shortage was bigger than the perennial values, and the biggest difference was recorded in June (29 mm).

Using the Penman-Monteith equation Łabędzki et al. (2012) found that the average evapotranspiration in Poznań, Olsztyn, and Cracow ranged from 50-60 mm in April and September to 100-120 mm in the remaining months of the growing season. The largest value of evapotranspiration in those areas was in July.

Projected climate change (Watson et al., 1997; Stuczyński et al., 2000) justifies the need for the current monitoring of the incidence and extent of drought. A prolonged lack of precipitation and resulting evapotranspiration processes reduce agricultural productivity. Agricultural drought seriously reduces plant growth, which leads to a significant drop in crop yields. A longer period of reduced precipitation leads to soil drought (Łabędzki, 2007; Vicente-Serrano et al., 2010). Changes in both precipitation and air temperature affect climatic water balance. In 2018 agricultural drought occurred in Poland for all monitored plants in all provinces with 1923 communes affected, which constituted 49% of agricultural land. Analysis of the linear trend of climate change impact on water balance showed that slope values were positive only in May, June, and July (*Table 2*). Furthermore, it was found that in July there was a statistically significant increase in the CBW value, on average, by about 6.4 mm in 10 years. However, in the rest of the growing season there was a declining tendency, but it was not statistically significant. Changes in the structure of water balance led to water deficit which significantly affected the level of plant production and changes in the structure of crop production.

Table 2. *Linear regression of climatic water balance changes in 2000-2018 in Siedlce*

Month	Linear regression
April	y= - 0.136x + 210.95
May	y= 1.214x - 2518.42
June	y= 0.202x - 491.27
July	y= 0.637*x - 1370.89
August	y= - 0.372x + 658.52
September	y= - 0.005x - 43.32
October	y= - 0.005x - 43.32

By analyzing the 1970-2010 period Łabędzki et al. (2012) found that in Poland there had been a significant statistically significant increase of total evapotranspiration in the growing seasons (April-September). There was a change in the temporal distribution of rainfall, with an increase in the amount of precipitation during the winter and early spring, and a decrease in spring and summer. This reduced climatic water balance, with an increase in rainfall shortage in relation to potential evaporation. Especially in recent years, spring and early summer climatic water balance values have been getting smaller, which means that periods of drought are becoming more and more severe. This coincides with the period of greatest water requirements of crops, especially of cereals. The manifestation of water scarcity trends was the extreme drought of 2018, resulting in the average yield of certain crops decreasing by up to 30% in Poland.

In all months of the 2018 growing season there were water shortages for the analyzed cereals (*Fig. 5*). When compared to the average multinational values it was found that they were the biggest in May. For wheat and oats the shortage of rainfall in the same month was 55 mm, and it was larger than the multiannual value by 28 mm. For maize it was 40 mm and surpassed the perennial average by 17 mm.

Demand for water is related to the species and its stage of growth and development. It increases as the weight of the fresh matter and transpiration increase. The greatest demand for water is usually during the critical period in plant development. This corresponds to the end of vegetative development and the beginning of the formation of generative organs. The critical period for cereals is during the following stages: stem formation,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76677678

heading, and grain development and filling (Chmura et al., 2009). Spring wheat reacts to shortage and excess of water particularly adversely during tillering and stem formation. Rain excess causes extension of the growing season, delays maturity, increases the incidence of disease, and it can cause sprouting during the harvest. Dmowski et al. (2008) found that sufficient rainfall in April and May is conducive to germination and tillering, and in June to the formation of the main shoot, side shoots, and grain development. Moderate rainfall in July is conducive to further grain filling and grain maturing on the main and side shoots. Research of Zagdańska and Wiśniewski (2001) has shown that the ability of spring wheat to increase its resilience (acclimatization) under the influence of the previously occurring drought is a varietal characteristic. Among cereals, oat is distinguished by its low resistance to drought due to a high transpiration rate and lower water use efficiency (Anderson and Mc Lean, 1989; Wojcieska, 1993). Considering the frequent occurrence of the shortage of rainfall in the most recent period in Poland, it can be assumed that drought negatively affects not only the yield of oats but also grain quality.

In the case of maize the last months of the 2018 growing season (August and September) also exhibited high water deficiency. In August that year the shortage was 58 mm, and in September it reached as much as 73 mm. Deficiencies in these months exceeded multiannual values by 22 mm and 48 mm. A lack of water during the growing season for maize causes uneven growth and development of plants, and withering in extreme cases (Dudek et al., 2009). According to Stuczyński et al. (2000) despite the prevailing water scarcity the importance of maize in Poland will increase, and it will become the primary spring cereal.

In the case of early potato varieties water shortages in 2018 were not higher than the average multiannual. The critical period of potato plants is during the following stages: flower bud formation, flowering, tuber formation, and leaf yellowing. In the period from planting to shoot formation, the potato plant uses water supplies stored in the parent tuber. During the time from shooting to flower bud formation water needs are also small. From flower bud formation onwards water needs regularly increase (Chmura et al., 2009). Varieties of early potatoes respond to water shortages especially negatively (Rykaczewska, 2007) because of an intense increase in the mass of above-ground parts and fast growth of tubers (Wheeler et al., 2003; Smith, 2006).

For sugar beet significant rainfall shortages were in May and August 2018, with 40 mm in the former and 73 mm in the latter. In the remaining months of the growing season that year they were not higher than average values for the 2000-2017 period. Sugar beet has the greatest sensitivity to a lack of soil moisture in the initial period, and later, especially after the end of August, dry and warm weather is more favourable, increasing its quality (Svachula and Pulkrabek, 2000). The critical stage of sugar beet lasts about 60 days when the leaf canopy covers the ground and during the intense thickening of the root (Chmura et al., 2009).

For meadows and pastures the highest average monthly rainfall deficiency with -43 mm and -53 mm, respectively, occurred in July of the 2000-2017 period (*Fig. 6*). On the other hand, in July 2018 shortages were the smallest (-5 mm for meadows and -15 mm for pastures). It was found that the greatest shortage of rainfall in 2018 was in May (-55 mm for meadows, and -60 mm for pasture) and in August (-68 mm for meadows and pastures). In the remaining months of the 2018 growing season water deficit was smaller than the average multiannual. Meadow water needs are different for each of the growth cycles.

DOI: http://dx.doi.org/10.15666/aeer/1704_76677678

The greatest demand for water is during the second one, i.e. in June and July. Grabarczyk (1989) found that, depending on the region, water needs in the first growth cycle are 125-158 mm, 186-240 mm in the second, and 160-190 mm in the third. On pastures when vegetation becomes yellowish and there is no biomass increase, grazing should stop until grass regenerates after rainfall. Such regeneration should last at least 3 weeks. Kasperska-Wołowicz (2007) points out that the most common instances of insufficient moisture in meadows and pastures can be expected in August. Leśny and Juszczak (2005) report that both in dry and wet growing seasons in grassland areas most winter precipitation surplus evaporates in May. Insufficient rainfall and increasing grassland dryness often lead to very large and adverse changes in both soil and plants. Stuczyński et al. (2000) argue that the period of animals grazing will significantly increase, although in summer it can be inefficient due to periodic droughts.

Conclusions

Values of climatic water balance in July 2018 were 7 mm higher than the multiannual average. In the remaining months of the 2018 growing season precipitation shortage was bigger than the average values of the 2000-2017 period. The biggest difference in climatic water balance between 2018 and the multinational was recorded in June (29 mm). It was found that in July there was a statistically significant increase in the value of CWB, on average, of about 6.4 mm per 10 years. For analysed cereals water shortages occurred in all months of the growing season both in 2000-2017 and in 2018. In May 2018 deficits were much larger than the average perennial value. In the case of maize the last months of the 2018 growing season (August and September) also exhibited high deficiency of rainfall. An important solution will be suitable agricultural practices that can mitigate the effects of drought. Earlier varieties of plants with the period of greatest demand for water before strong droughts will be introduced. For early potato varieties water shortages in 2018 were not higher than the average multinational. However, significant rainfall shortages for sugar beet were in May and August 2018. Those deficiencies were well above the critical values and could have resulted in a decline in the level of crop yield and deterioration of the quality of raw material. For meadows and pastures the highest average monthly rainfall deficiencies in the 2000-2017 period occurred in July (-43 mm for meadows and -53 pastures). In 2018 the greatest shortage of rainfall was recorded in May (-55 mm for the meadows and -60 mm for pastures) and in August (-68 mm both for meadows and pastures).

Drought causes withering and significant loss of some fodder species; forage on meadows should be harvested earlier because in drought conditions its quality worsens every day. Changes of water balance basic components occurring in temperate latitudes are a result of an increase in air temperature and evaporation. An increase in the air temperature with unchanging annual total precipitation can cause water shortages lowering crop yields, especially on sandy soils with poor retention. It can be inferred from the present analysis that the composition of crop species should be adapted to changing climatic conditions. The studies indicate that a drought should be monitored to assess its impact on crops. Persistent unfavourable weather conditions lasting for a longer time may determine the choice of plant species to be grown in the region. Additionally, by designating areas that are particularly vulnerable to the effects of droughts it is possible to carry out a more complete assessment of the impact of climate change on agriculture in Europe.

(Received 11th Mar 2019; accepted 1st May 2019)

Abstract. Artichoke (*Cynara scolymus*), is one of the most important agricultural products of North Cyprus (NC) due to its importance in export. During field surveys in artichokes production fields between 2013 and 2016, little and indistinguishable leaves, light shaded regions taking after mosaic with yellowish wilting of the leaves and little head development plants were gathered and broken down by DAS-ELISA for the examination of infections (most of them mentioned by Gallitelli et al. (2004)) which could be harmful to artichokes (belonging to groups of *Nepovirus*, *Cheravirus*, *Fabavirus, Ilarvirus*, *Cucumovirus*, *Tombusvirus, Tobamovirus, Tobravirus, Potyvirus*, *Carlavirus*, *Potexvirus*, *Crinivirus, Tospovirus*, *Anulavirus*, in the families of *Rhabdoviridae and Bromoviridae* respectively*)*. Thirty-three samples were detected positive for mix infection of *Artichoke Latent Potyvirus* (ArLV) and *Tomato spotted wilt virus* (TSWV) in Laboratory assays (ELISA and RT-PCR). The results were also confirmed by RT-PCR using total RNA which was extracted from the leaves. RT-PCR assay was conducted by newly designed Sense and antisense primer pairs specific to ArLV; L1TSWVR and L2TSWVF primer pairs specific to TSWV. As results of RT-PCR, the region of 485 bp special to coat protein of ArLV and 276 bp of TSWV were obtained in 2% agarose gel. While occurrence of remaining viruses was not detected in the tested samples, it was observed that disease incidence increased due to non-sterile equipment and devices during the harvest. Additionally, infected product materials, transmission with aphid and thrips vectors also increased disease incidence. In NC, the occurrence of ArLV was assigned as a new virus disease in Artichoke and also mixed infection with TSWV.
Keywords: *Northern Cyprus, artichoke, RT-PCR, DAS-ELISA, ArLV, TSWV*

Introduction

Artichoke (*Cynara scolymus Linneus*, 1753) is a financially essential vegetable. It is developed for its huge meaty juvenile inflorescences (capitula) that are broadly expended in both new and saved frame. Production is not confined to the Mediterranean region, yet additional export is needed in the Central East, North Africa, South America United States, and China (FAO, 2015). There are numerous components diminishing the amount and nature of artichoke production in different harvests. Plant viral diseases are amongst the most critical prohibitive components incorporating plant malady and irritations. Among the critical agronomic qualities, as a few maladies caused by infections have significant reproducing targets and have extraordinary monetary effect on artichoke generation around the world. *Cucumber mosaic virus*, *Artichoke mottled crinkle virus*, *Tomato black ring virus*, *Artichoke Italian latent virus*, *Artichoke Aegean ringspot virus*, *Artichoke vein banding virus*, *Broad bean wilt virus, Tobacco streak virus*, *Artichoke yellow ringspot virus*, *Tobacco mosaic virus, Pelargonium zonate spot virus*; *Tobacco rattle virus*; *Artichoke latent virus, Bean yellow mosaic virus*, Artichoke

DOI: http://dx.doi.org/10.15666/aeer/1704_76797691

latent virus S, *Turnip mosaic virus*, Artichoke latent virus M, an anonymous infection remotely related serologically to *Poplar mosaic virus*, Artichoke curly dwarf virus, Artichoke degeneration virus, *Potato virus X*, *Tomato infectious chlorosis virus*, *Tomato spotted wilt virus* have caused infections. Morphology, scientific categorization, symptomatology, cytopathology, the study of disease transmission, determination and sanitation of these Cynara tainting species (since 1950s) have been investigated by Gallitelli et al. (2004). Furthermore, Arabis Mosaic Virus, Alfalfa Mosaic Virus, Tomato Bushy Stunt Virus, Potygroup specific antisera and *Potato Virus Y* were also reviewed in Gallitelli et al. (2004).

Another Artichoke disease caused by Artichoke Yellow Ringspot Virus was first reported in Globe Artichoke in Turkey by Paylan et al. (2013). Same researchers also reported CMV in globe artichoke.

The ArLV is a potyvirus, which is able to transmit experimentally in non-persistent manner to artichoke seedlings by afid species (*Aphis fabae, Myzus persicae and Brachycaudus cardui* by Rana et al., 1982). Its first detection from symptomless globe artichoke plants was found in Tunisia by Marrou and Mehani (1964). Transmission efficiency was higher by the quick re-infection rate (over 75% in two years) registered in a field trial in Sardinia, Italy (Foddai et al., 1985). The *C.* syriaca and C. *cardunculus* species are not resistant to ArLV (Manzanares et al. (1995). The ArLV is responsible for reductions in plant thrive and blossom what is more, instigates misfortunes in the number and the heaviness of gathered plates running from 3 to 47% (Pecaut et al., 1983; Foddai and Man-as, 1984; Migliori et al., 1987). Moreover, ArLV infection causes subjective and quantitative changes in 'Brindisino' artichoke, for example, leaf and bracts staining, opening of head peak, postponement of first reap, shortening of head stalk, decrease of head distance across and diminishing of yield (Rana et al., 1992).

This paper aims to decide the possibility and predictability of regular artichoke infections, incorporating ArLV in North Cyprus (NC) where presence of artichoke infections has not been investigated yet.

Materials and methods

The exploration was led in NC in 2013-2016 (*Fig. 1*). An aggregate of 97 tests were gathered from suspected plants in artichoke fields at various areas in the Island. Amid the overviews, little and indistinguishable leaves, light shaded zones looking like mosaic with yellowish shrinking of the leaves and little head development were seen on artichoke plants. Studies were directed amid the developing season and just symptomatic examples were gathered haphazardly all through the zone in the district.

Serological tests

The samples, were named and put in isolated plastic packs, conveyed to the Virology Lab by putting in ice pail and kept at 4 °C. All examples were handled inside 24 h.

Double antibody sandwich enzyme linked immunosorbent assay (DAS-ELISA)

For distinguishing proof infections contaminating artichoke, leaf tests were tried by DAS-ELISA utilizing polyclonal antiserum explicit to infections which has a place with gatherings of *Nepovirus*, *Cheravirus*, *Fabavirus, Ilarvirus*, *Cucumovirus*, *Tombusvirus, Tobamovirus, Tobravirus, Potyvirus*, *Carlavirus*, *Potexvirus*, *Crinivirus, Tospovirus*, in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76797691

the families of *Rhabdoviridae and Bromoviridae,* which are given in *Table 1,* Each explicit antisera separately obtained from Agdia USA, Bioreba AG, Switzerland and Loewe® Biochemica GmbH, Germany.

Figure 1. *The map of Cyprus Island with positive locations (http://www.cyprus-properties.comcyprusgeography.htm; http://www.emapsworld.comcyprus-location-map.html, in small)*

Tests included location of infections in tainted fresh leaves and conveyed by Clark and Adams (1977). Polystyrene microtiter plates were covered with 1:200 weakening of gamma globulin. The leaves of contaminated fresh explants were grounded in the extraction cradle (phosphate cushioned saline, PBS, pH 7.0). Plant tests were connected at a weakening of l/5 (Wff) in PBS (pH7.0), containing 0.05 volumes Tween-20, 0.2% polyvinyl pyrolidone (PVP-40) and 2% bovine serum albumin (BSA). IgG-conjugate was applied at the concentration of 1 ul/200 ul (Agdia and Loewe) and 1 ul/1000 ul (Bioreba). Alkaline phosphatase conjugate was utilized at a 1/1000 dilution.

Results were obtained spectrophotometrically at 405 nm wave length at Medispec ESR 200 ELISA microplate peruser. Additionally, negative controls (healthy samples), double the mean estimation of healthy sample were considered as positive. Positive controls of all infections were provided in lyophilized frame with the units and were resuspended in the examined support as prescribed by the manufacturer (Agdia, Inc.).

Molecular analysis (phylogeny, total RNA isolation and reverse-transcription polymerase chain reaction (RT-PCR)

Add up to RNA separates (Dellaporta et al., 1983) of ArLV and TSWV contaminated artichoke plants were utilized in a Reverse-Transcription Polymerase Chain Response (RT-PCR) with new sense (Forward primer) 5'-ATCTCGTGACGAAGCAACAA-3' and antisense (Reverse primer) 5'-CGAGACCATCGTGAATCTCC-5' primers, designed based on nucleotide sequences alignment of CP genes of diverse isolates Artichoke latent virus isolates, complete genome GenBank: KF155694.1 7163..7642 /product="CP protein"485 bp from NCBI via Primer-BLAST program and L1TSWVR

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76797691

and L2TSWVF specific to TSWV (Adkins et al., 2005). First and second strand cDNAs were blended from ArLV and TSWV RNAs utilizing Thermo Scientific Verso 1-Step RT-PCR Hot-Start Kit pack according to producer's convention. Enhancement for ArLV continued through a cycle of denaturation at 95 ^{0}C (45 s), toughening at 55 °C (45 s.) and expansion at 72 °C (45 s) for a sum of 35 cycles in Techne Genius thermal cycler. Steps mentioned above were utilized for TSWV likewise.

Analysis of RT-PCR products

Ten microliters of the PCR reaction blend was joined with gel loading buffer and dissected on a 2% agarose gel containing 0.5 mg/ml of ethidium bromide and shot (Sambrook et al., 1989). 100 bp DNA stepping ladder (thermo) or Bio Marker TM Low (Bio Ventures, Inc.) were utilized on each gel to decide the length of the amplified item.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76797691

Phylogenetic analysis

The RT PCR products were sequenced and dnasp5 program conducted for haplodisation analysis. Phylogeny performed by MEGA 7 software program and neighbor joining process, according to convention analysis.

Mechanical inoculation

Inoculation were processed when the first real leaves of seedlings appeared and approximately 15 cm in length. 1 g inoculum (Positive Samples via DAS-ELISA&RT-PCR) was added into 2 ml 0.01% M phosphate buffer solution with carborandum and silicon oxide. The mixture was prepared for mechanical inoculation, and was applied on the first real leaves of plants by hand etching. The temperature was kept at 22-24 °C and proportional humidity at 60-70% in test greenhouses (Garland et al., 2005).

Results

Detection and occurrence of viruses by serology (ELISA)

Positive results were obtained from Tospovirus groups, TSWV and Potyvirus. *Tomato spotted wilt tospovirus (TSWV)* is one of the unique member of *Tospovirus. Orthotospoviruses* or *Tospoviruses* are genera of negative RNA virus found within the *Tospoviridae* family of the *Bunyavirales* order (Lima et al. (2017)).

Assay results were given as positive reactions from samples against both TSWV and Tospovirus group specific antiserum.

Serological analyses were repeated at least two times to approve, 27 out of 33 positive samples also produced positive reaction with the potyvirus group specific antiserum. Samples of artichoke, were 33 positive, collected from six provinces, *6/Girne (Krynea), 8/Güzelyurt (Omorpho), 4/Lefke, 2/ Iskele (Trikomo), 4/Lefkoşa (Nicosea) and 9/ Gazimağusa (Famagusta)* (*Fig. 1*). However, none of the PVY, BCMV, LMV, LYSV, OYDV, PepMoV, TEV, TuMV, WMV, ZYMV viruses has had positive reaction. ArLV member of the Potyvirus genus in the Potyviridae family have been previously reported in Artichoke worldwide (Gallitelli et al., 2004; Martelli and Gallitelli, 2008; Pasquini and Barba, 2003; Erkan et al., 2014; Fidan et al., 2015; Rana et al., 1982). Due to having positive result to Potyvirus group and non-absence of ArLV commercial antiserum, the test by RT-PCR is performed on the artichoke plants.

Type of symptoms

Virus tainted leaves with yellowish wilting in the fields have diminished in size and weight (*Figs. 2* and *3*). There is likewise, leaf twisting or distortion (*Fig. 4*), little head development and general staining were seen on the artichoke plants (*Fig. 5*). Amid head reaping, the plant heads were sliced from start of line to end of line. Rural workers have not changed or surface cleaned all types of cutting gear. Consequently, all collected artichokes have indicated extreme maladies (*Fig. 3*). This unmistakably shows that mechanical reaping will spread the infections. The symptoms from collected samples were similar with Spanò et al. (2018).

Figure 5. *Small-head formation and general discoloration on artichoke plants*

Mechanical inoculation studies

About 20 days after the date of mechanical inoculation, observations and investigations about the symptoms of diseases in tomato, pepper, tobacco and *Chenopodium spp.* plants have been conducted. At the end of the test, characteristic dark brown lesion, yellow concentric ring and necrotic spot, systemic mosaic and Necrotic local lesion symptoms via TSWV and ArLV were recorded between the leaf veins of sensitive plants (*Figs. 6* and *7*). Symptoms on assayed indicators were tested to confirm the infections in these plants by serologic and molecular based diagnosis.

Figure 7. *Severe systemic mosaics on Nicotiana clevelandii (B1). Necrotic local lesions on Chenopodium amaranticolor (B2). (Mechanically inoculated by ArLV Artichoke Cyprus isolate)*

The RT-PCR

With the end goal to confirm the disease, RT-PCR examinations have intensified ArLV RNA, yielding an expected result of 485 bp (*Fig. 8*) on agarose gel (2%) in all samples of artichoke. Subsequently, RT-PCR results affirmed that the diseases of ArLV in DAS-ELISA were positive for the plants. Furthermore, 276 bp cDNA bands of TSWV were observed correspondingly (*Fig. 9*) in all examples. During the test, healthy plant material was used as negative control in order to eliminate plant misleading factors.

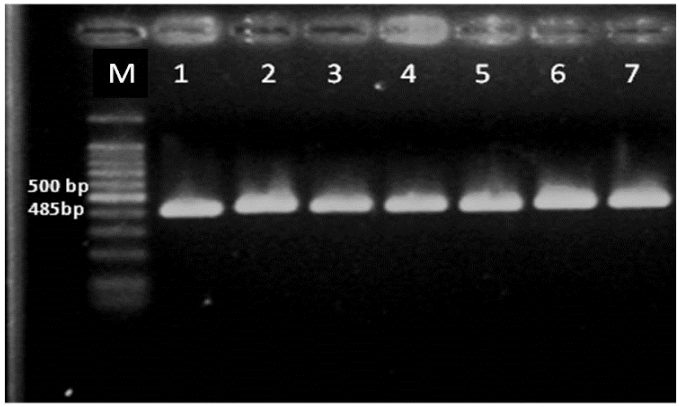

Figure 8. *RT-PCR product of 485 bp of ArLV CP on agarose gel (2%); DNA ladder (first lane M), Lane 1-3 samples positive of Artichoke in NC; Lane 4 positive control; Lane 5-7 samples positive of Artichoke in NC*

Phylogenetic analysis

Phylogeny performed by MEGA 7 software program and neighbor joining process, according to conventional analysis for all ArLV isolates (*Fig. 8*). Two different haplotypes were determined from 7 isolates by RT-PCR and sequences. These two distinctive isolates were compared with each other and other known world's isolates.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76797691

Their outcomes were submitted to NCBI framework as new records. The outcomes were cleared up that these two isolates have comparative homology with KF 155694.1 (99%-Italy) and KP405233.1 (96%-France) separately (*Fig. 10*).

Discussion

This investigation uncovered the characteristic conveyance and event of artichoke infections in territories situated in NC. Our outcomes called attention to the clean conditions for basic plant infections in growing fields in NC. ArLV and TSWV have the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76797691

most across the board infections contaminating artichoke edits in NC. Genera Potyvirus and Tospovirus are transmitted by aphids and thrips separately. The board of these vectors are troublesome. The indications on gathered plants have seriously appointed to ArLV and TSWV by mixed contamination. These outcomes were fitted Testa et al. (2008) results where their Sardinian examples demonstrated a serious mosaic for the most part, and had ArLV mixed infection with Tomato spotted wilt virus (TSWV). The study was focused on ArLV due to first occurrence on artichoke. Although ArLV has a less host range than TSWV, the ArLV may survive in different weed species that are not having a place with the Asteraceae family filling in as a supply. These outcomes permit ArLV to be spread all the more continuously and to happen with high frequency, after essential contamination by infected seedling or inoculums sources. These results have confirmed Costa et al. (1959) results where it was reported that ArLV had isolated from symptomless artichoke plants in California. Severe systemic mosaics on *Nicotiana clevelandii,* necrotic local lesions on *Chenopodium amaranticolor* mechanically inoculated by ArLV Artichoke isolates gave identical symptoms which were confirmed by RT-PCR, previously recorded by Ciffou et al. (2011).

Previous studies have revealed artichoke latent virus found in Northern Cyprus and the Aegean region in Turkey (Fidan et al, 2015; Erkan et al., 2014). The current results have verified the previous results that artichoke plants infection with ArLV is limiting artichoke production in the Mediterranean basin as reported by other articles as well (Rana and Russo, 1980; Ortega et al., 2000). Also Minutillo et al. (2015) impressed that Ranunculus latent virus should be demonstrated as unique strain of ArLV. They also underlined that it is not a distinct species.

This is the first report of TSWV and ArLV + TSWV mix infection for artichoke in NC. This paper also indicates that uncontrolled distribution of infected artichoke plants in countries will create the viral problems. Molecular analyses have distinguished that there are two different ArLV haplotypes present in NC according to their sequence alignments in NCBI system. Although the Mediterranean Sea as a limiting factor separate the island from the mainland the same viral diseases occur on both places. In any case, sequence grouping arrangements have demonstrated NC's ArLV haplotypes are like Italian (KF155694.1 99)% and French (KP405233.1 98%) haplotypes showing all fare and import plant material can be disseminated without any quarantine direction. The NC is an important harbour in the Mediterranean Sea and all sort of business ships have been visiting for exchange (Lumia et al., 2003; Saitou and Nei, 1987; Tamura et al., 2007).

Conclusion

Further investigations ought to be gotten ready for recognizing individual vectors and obscure epidemiological highlights and qualities of the infections for instance potyviruses like ArLV which transmitted by aphids (Adams et al. , 2012). There are new virus infections sustaining in weeds and neighboring yield species in the Island. ArLV is the most severe of the 25 viruses recorded in *Cynara scolymus* L. and *Cynara cardunculus* L. from Europe and the Mediterranean. These viruses were having decreasing effectivity for the aspect of the productivity and the quality artichoke crop head (Gallitelli et al., 2012). The ArLV + TSWV mix infection in artichoke have synergistic effectivity and severity (Acquadro et al., 2010). Elbeaino et al. (2017) reported some artichoke viruses specially Artichoke Italian latent virus via Next

Generation Sequencing technique and molecular analysis, focused on RNA1 and RNA2 sequences. Novel administration techniques for ailments will be formulated upon these examinations to ensure sanitized plants. Accordingly, the disease pathway and transmissibility of major infections could be counteracted.

Salleh et al. (2017) commented that Artichoke viruses could infect broad range of crop species and weeds as reservoir plants due to having potential for spreading by vectors. Also they mentioned the same viral factors could play important role in the ecology and viral epidemiology. Additionally, all verification, the use of inappropriate cuttings practices by farmers have critical point in same objections.

A certification programme for artichoke has become necessary. It is also indispensable for the globe artichoke biodiversity conservation. And breeding of virus free genetic resources is essential (Spanò et al., 2018). In order to block invasion of critical viruses which are potentially destructive for artichoke quarantine applications should be effectively applied in the island.

Abstract. Climate change and variability have been one of the challenges to socioeconomic and environmental sustainability in the twenty-first century. Meteorological analyses of historical drought occurrences are common in East Africa, but studies devoted to its effect on land use change are yet limited. This paper aimed to assess the long-term rainfall and temperature variability and its effects on farmers' land use change in the Central Rift Valley of Ethiopia over the past 30-36 years using a combination of meteorological and socioeconomic data. Results show that the overall coefficient of variation for rainfall was more than 35% for rainy seasons. Out of the 36 years, total rainfall of the rainy season showed negative anomalies for about half of these years. Summer season rainfall started after the average time of onset for about 42% of the database years, and it ceased ahead of the average time of the stop for about 56% of these years. As a result of such rainfall shortage and variability, about 82% of the drought-vulnerable farmers had already changed their land use from pastoralist/agropastoralist to mixed farming while 10% have a wish to shift to other land use options in the future. Hence, future policies need to consider strategies that strengthen the adaptation capacity of farmers to climate change in East Africa.

Introduction

Climate change and variability have been one of the challenges to socioeconomic and environmental sustainability in the twenty-first century (UNFCCC, 2018). The change in climate is accelerating faster than the global effort to address it. Studies show that the atmospheric concentration of greenhouse gases (GHG) has increased more in recent decades than at any time in the past of human history (IPCC, 2007, 2014). This increase in GHGs, in turn, lead to global warming with its related catastrophes to life on Earth like extreme storms, droughts, fires, floods, ice melting, and rising in sea levels (IPCC, 2007, 2014; Eckstein et al., 2017). According to Maharjan and Joshi (2013), global average surface temperature and atmospheric concentration of CO_2 have been rising at an increasing rate, especially since the 1900s. With current mitigation efforts, future projections also indicate a continual increase for GHGs and temperature trends (Ravindranath and Sathaye, 2002; IPCC, 2014). Such threats, in general, made the

DOI: http://dx.doi.org/10.15666/aeer/1704_76937713

climate change issue, one of the top agendas of discussion among the global research community and political leaders in recent decades.

Climate change could affect the ecosystem and human well-being in several ways. For instance, climate change could affect regional agricultural production yield, food price and food security (Sivakumar, 1992; Ravindranath and Sathaye, 2002; Barron et al., 2003), and it could affect human, plant, and animal health through its direct and indirect impact on physiology (Maharjan and Joshi, 2013; Pedrono et al., 2016). Climate change also affects ecosystem services and functioning by deteriorating biological, hydrological and atmospheric systems (Ravindranath and Sathaye, 2002; Pedrono et al., 2016). Additionally, climate change can force vulnerable communities to wholly or partially change their land use systems and livelihoods (Biazin and Sterk, 2013), and hence affect household income and social security. Furthermore, climate change can increase the costs incurred by mitigation and adaptation to overcome its impacts (Maharjan and Joshi, 2013).

The impact of climate change is more severe in developing nations where the income of the majority of the population directly depends on climate-sensitive economic sectors (e.g., agriculture) (UNFCCC, 2007; Torquebiau et al., 2016), as agriculture is not only contributing to climate change through GHG emissions, but is also most affected by it. According to Ravindranath and Sathaye (2002) and UNFCCC (2007), the region of Sub-Saharan Africa, south and east Asia, and the tropics of Latin America are particularly vulnerable to climate change. Studies show that the Sahel region in West Africa is well known for its severe environmental problems of drought and desertification over a long period of its history (Sivakumar, 1992; Agnew and Chappell, 1999). Similarly, the East African region is known for its recurrent severe drought in the last several decades (Barron et al., 2003). Beside such a high degree of vulnerability in developing countries, the adaptive capacity to overcome climate change impact is low due to financial, institutional, technological, and political constraints. For instance, Collier et al. (2008) and Gemeda and Sima (2015), pointed out that the impact of climate change on Africa is probably severe because of high agricultural dependency and limited capacity to adapt.

Besides primary socioeconomic drivers, climate change vulnerability is another crucial factor affecting agricultural land use (Dale, 1997; Reid et al., 2000; Biazin and Sterk, 2013; Ahmed et al., 2016). For example, Ahmed et al. (2016), found that the expansion in agricultural land use was mainly due to climate change in West Africa. These authors pointed out that unless agriculture is intensified, the climate-induced decline in crop yield coupled with a future increase in food demand will continue to increase agricultural area at the expense of forest and grassland loss in West Africa. The other study elsewhere showed that in addition to climatological deviations, drought vulnerability is also affected by the type of land use and social traditions of life. For instance, according to Biazin and Sterk (2013), the pastoral way of life was found to be more vulnerable to severe drought than mixed farming land use system. Similarly, a rain-fed cultivation is likely to be more susceptible to climate change than irrigated cropping, and a mono-cropping system is expected to be more vulnerable than a mixed cropping system, for example, agroforestry. Hence, according to Dale (1997) as a means of adaptation to climate change, vulnerable farmers usually try to modify/shift from a land use system that is more vulnerable to a land use system that is less vulnerable.

Climate change and variability can be evaluated using different climatic indices and datasets. Studies show that temperature and precipitation are the two most frequently used climatic variables for evaluating climate variability and its impacts (Maharjan and Joshi, 2013). This is because there is an advantage of data availability in using, for example, rainfall, to investigate drought occurrence instead of using other variables, for example, river flow, which is increasingly managed by human action (Agnew and Chappell, 1999). Mean, median, a coefficient of variation, standard deviation, and the probability of dry spells are commonly used statistical parameters to describe both rainfall and temperature variability (Stern et al., 2006). In addition, the Standardized Precipitation Index is usually employed to evaluate long-term rainfall deviation from the usual norm (Agnew and Chappell, 1999; Agnew, 2000; Bewket and Conway, 2007; WMO, 2012; Viste et al., 2013). Irrespective of the type of indices used for climate change analysis, most climatologists advise using precipitation and temperature data of the long-term period and data from the wider gaging stations for better accuracy of results (Ali and Lebel, 2009).

Ethiopia is one of the countries in the Horn of East Africa hit by frequent drought over the last century. This was confirmed by various local and national level studies conducted in the country (Bewket and Conway, 2007; Cheung et al., 2008; Viste et al., 2013). For instance, Seleshi and Zanke (2004) found a significant decline in the annual and summer season total rainfalls since 1982 for the eastern, southern, and southwestern parts of the country. Cheung et al. (2008) in their long-term (1960-2002) rainfall data series analysis, found a significant decline in summer rainfall in southwestern and central parts of Ethiopia and pointed rainfall trends as one of the most important factors determining different socioeconomic constraints such as food insecurity in the country. The study by Rosell (2011) for three decades (1987-2007), indicated a decline in rainfall and an increase in temperature for the spring season in the central highlands of Ethiopia. Besides, Viste et al. (2013) found that the years 1972-1975, 1980-1982, 1984, 1987, 1990-1992, 1999-2000, 2002-2003, and 2008-2011 were the periods of severe drought episodes in Ethiopia. Furthermore, the recent 3-5 decades temperature and rainfall data analysis by Fazzini et al. (2015) reported a markedly increasing and decreasing trend for minimum temperature and annual spring season rainfall respectively in the country. However, there are studies reported the absence of significant variation, particularly in terms of total annual rainfall, as opposed to the farmers' usual perception of total rainfall shortage in most parts of Ethiopia (Conway, 2000; Conway et al., 2004; Seleshi and Zanke, 2004; Kassie et al., 2013; Adimassu et al., 2014). The main reason for these divergent results in the trend analysis of the annual rainfall of the country is the difference in base periods used for analysis (Agnew and Chappell, 1999; Bewket and Conway, 2007). In general, Ethiopia as a country whose economy is mainly dependent on rain-fed agriculture, the trend of seasonal rainfall is an important factor determining the socioeconomic functioning, particularly food production potential of the country (Bewket and Conway, 2007; Mideksa, 2010; Fazzini et al., 2015; Fekadu, 2015).

The Central Rift Valley (CRV) of Ethiopia is a semi-arid region known for its persisted shortage of agricultural rainfall in the country. Previous studies indicated the presence of drought vulnerability due to seasonal rainfall variability in the area (Biazin and Sterk, 2013; Kassie et al., 2013; Gizachew and Shimelis, 2014; Getachew and Tesfaye, 2015). However, works of literature devoted to climate variability and its impacts on farmers' land use change are currently limited in Ethiopia. Additionally, in a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76937713

diversified agroclimatic condition, like in Ethiopia, a local level analysis is quite important as meteorological results usually vary for regional, local and even individual gaging stations. Furthermore, for climate change-prone and rain-fed dependent agricultural area, like in CRV, up-to-date climatic trend information is quite crucial to practice climate-responsive agriculture and to minimize climate-related production risks. Hence, this study is intended to 1) assess long-term rainfall and temperature change and variability over the last 30-36 years and 2) assess the possible effects of this climatic variability on land use/livelihood change by vulnerable farmers. It is believed that the output of such analysis partly helps the stakeholders to have an informed decision for future policy direction and better management strategies.

Materials and Methods

The study area

The CRV is located about 160 km south of the capital city Addis Ababa, Ethiopia. Geographically, the study site is situated within 7º10'- 8º30' north latitude and 38º15'-39º25' east longitude (*Figure*). It is part of the Main Ethiopian Rift system which is characterized by an area of depression zone with steep marginal faults along its eastern and western edges. It is found within the current administrative boundary of Oromia and Southern Nations, Nationalities and Peoples (SNNP) Regional States.

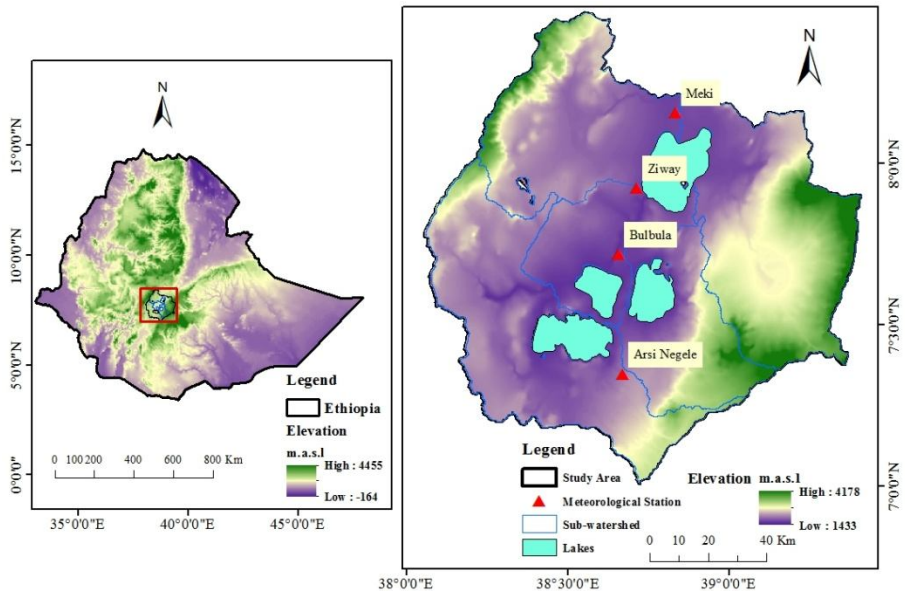

Figure 1. *The study site location map with agroclimatic zones*

Due to the unique topographical and geological feature of the region, the climate of CRV is known to vary markedly with altitude and season (Jansen et al., 2007). It is semi-arid in the areas along rift floor, and humid to sub-humid in the highland zone. As shown in *Figure*, the study area receives a bimodal annual rainfall distribution pattern in which the small light rain occurs during *Belg* (spring) season (February to May), and this is followed by the main rain that occurs during *Kirmet* (summer) season (June to September). The peak rainy months are July and August. The dry season (*Bega*)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_76937713

(winter), on the other hand, extends from October to January. According to data from the National Meteorological Agency (NMA), the mean annual rainfall is about 740 mm, and the mean minimum and maximum annual temperatures are 13ºC and 27ºC, respectively. In general, studies show that rain-fed agriculture in CRV is constrained by the highly erratic nature of rainfall in the region in recent decades (Jansen et al., 2007).

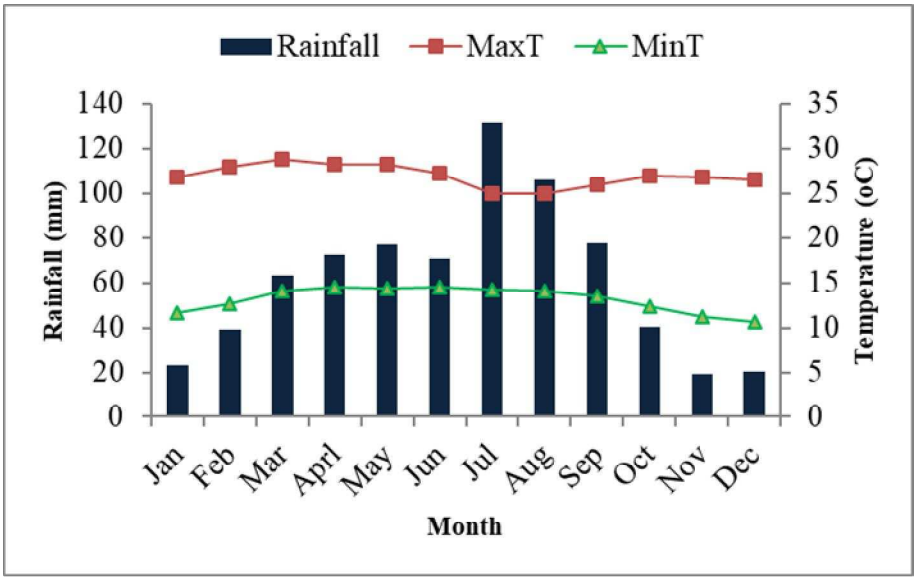

Figure 2. *Average monthly rainfall and temperature at CRV: MaxT = maximum temperature, MinT = minimum temperature: Data from NMA*

The common land use/cover types of the study area include agricultural land, scattered acacia woodland, water body, shrub/bushland, grass/grazing land, marshy/swampy land, and bare land as described in Bekele et al. (2018a). The dominant and peculiar vegetation type in the region is acacia woodland. As a result of continual deforestation for agricultural land expansion, charcoal making, and fuelwood extraction, the acacia woodland of the region has been highly decreased from time to time over the last half century (Garedew et al., 2009; Biazin and Sterk, 2013; Temesgen et al., 2013; Ariti et al., 2015). Four of the principal Ethiopian lakes namely: Abijata, Shalla, Ziway, and Langano are found within the catchment of CRV basin. The first two lakes are known for their soda ash (salt) content and home for a variety of migratory bird species while the latter two are intensively used for a fishery, irrigation, and domestic water consumption currently (Hengsdijk and Jansen, 2006). As a result of such high anthropogenic-induced pressures on land resources and poor management, the study area is presently highly threatened by extensive land degradation, lake water retreat and pollution, and drought and food insecurity (Meshesha et al., 2012; Bekele et al., 2018b).
