correctly understand the suitability of regional topographic conditions and the characteristics of soil types, the rational layout of land use in the region can be explored, the land use structure can be optimized, and optimal allocation and intensive use of low hilly soil resources can be provided. In the next stage of low hilly-red soil management development it is suggested to focus on strengthening the development of economic crops and economic forest fruit, improve agricultural output, build local brand agriculture, and improve the comparative benefits of low hilly red soil governance development.

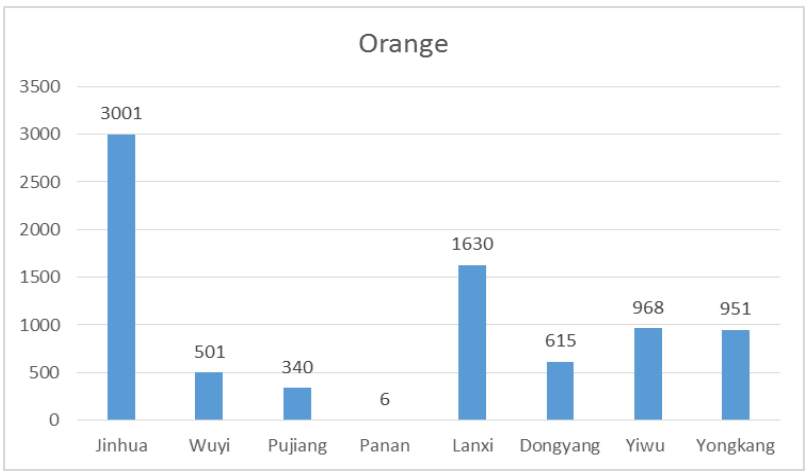

Figure 3. *Orange planting area of each county in Jinhua city (unit: hectare)*

(3) The development of Jinhua characteristic agriculture in the low hilly red soil region

The unique natural conditions such as topography, land and water have created a distinctive geographical environment, forming a regional brand of agricultural products such as Jinhua bergamot and Chun'an Chinese herbal medicine. The tea planting area in Wuyi County, Chun'an County and Dongyang City ranks in the top three in the city (*Figs. 4* and *5*). Most of Jinhua City's medicinal materials are planted in Chun'an

DOI: http://dx.doi.org/10.15666/aeer/1704_83958415

County and Dongyang City, and there are Chinese herbal medicines in Chun'an. In the trading market, the Dapanshan National Chinese Herbal Medicine Nature Reserve has promoted the cultivation of medicinal materials in the adjacent Dongyang City. Jinhua City should focus on supporting the development of characteristic agriculture. Under certain technical, economic and ecological environment conditions, the existing red soil resources that can be exploited and utilized can be rationally developed, and the characteristic agricultural industries should be upgraded through technical measures such as agriculture, water conservancy and biology. The completion of the characteristic agricultural product industry has expanded the production scale, optimized the variety structure, improved the product grade, increased the added value of agricultural products, and fully exerted the social benefits of the project (Yu and Wu, 2018).

Conclusion

This study is based on overall planning, keeping the social economic and ecological benefits unified, adapting to local conditions, maintaining the characteristics of land and agricultural utilization, safe production, efficiency, optimizing resources, comprehensive

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_83958415

development and other principles, and it involves the main distribution area of low-hill red soil in Zhejiang Province. The planting structure was analyzed and it was considered that the rational layout of different landform units was strengthened and the potential of land resources was fully explored. It is necessary to actively develop precision agriculture in the plain area and reduce the occupation of construction land on low hilly red soil. Low-mountain hilly areas should vigorously develop a complex ecosystem of forest and fruit combination, so that grain should be grainy, forest should be forested, fruit should be fruitful, and rational layout should be achieved to achieve the best ecological, economic and environmental effects.

In the next stage of the development of low-hill red soil governance, Jinhua City was regarded as a model project of low hilly red soil agriculture, which involves the followings: (1) Expanding the scale of land management for farmers. Fully understand the importance and urgency of large-scale operation of low hilly red soil land, changing the concept of land use (Le et al., 2017), transforming the economic development mode, and adjust and optimize the economic structure. Strengthening planning guidance, tapping the potential of stocks of low hilly red soil, and increasing the scale of land use. Speeding up the transformation of land to large-scale utilization and improving the land use efficiency of low hilly red soil. (2) Improving the construction of farmland water conservancy infrastructure. In the development of characteristic agriculture in the low hilly red soil region, it is necessary to promote the construction and management of farmland water conservancy projects in the low hilly red soil region, and to increase the end-canal system reform in large and medium-sized irrigation districts, and accelerate the construction of small-scale drainage facilities. It is appropriate to take the form of incentives and subsidies to fully mobilize the enthusiasm of farmers to build farmland water conservancy projects.

(3) Promoting the development of agricultural land consolidation projects. Through the method of finishing low hilly red soil area, the low hilly red soil resources are levelled and the water conservancy facilities, field protection forests, and field roads in the development area are constructed. Reaching Tian Chengfang, the canal is connected, the road is connected, the forest is net, and the irrigation is carried out. The requirements of the row have led to a significant improvement in farmland production conditions. Continuously increasing the effective arable land area and improving the comprehensive agricultural production conditions are also suggested.

(4) Implementing agro-ecological protection projects in low hilly red soil areas, improving the management methods for various types of funds for ecological compensation, incorporating ecological protection indicators for low hilly red soil into comprehensive evaluation system for economic and social development and establishing a comprehensive evaluation system for leading cadres, inspiring internal motivation of the cadres and the masses at all levels to protect the ecological environment. Finally, we will improve the comprehensive agricultural production conditions, change the agricultural planting structure, and achieve the goal of improving agricultural output value and improving agricultural production performance.

In the future the planting structure will be analyzed further and more effective agricultural development planning will be proposed, which will not be limited in low hilly red soil region, but other regions will also be involved to provide reference for further studies.

(Received 8th Mar 2019; accepted 21st May 2019)

Abstract. Previous researches tended to ignore the influence of environmental regulation on technical efficiency, and in this sense, the total factor productivity is easy to be overestimated. This paper establishes the translog stochastic frontier production function model, includes environmental regulation into technical inefficiency equation, calculates the total factor productivity and its composition in China (including eastern, central and western regions) from 1995 to 2015, and also makes an analytical comparison with the value not considering environmental regulation. The results show that: (1) the investment on industrial pollution control and SO_2 emission intensity will significantly promote technology inefficiency, thus exerting a negative impact on economic growth; (2) environmental regulation slows down the growth rate of total factor productivity in China and all of its regions; (3) Considering the environmental regulation, technical efficiency is improved significantly and becomes the major drive behind the grow of total factor productivity, while technological progress, scale efficiency and the allocation efficiency show setback; (4) In terms of different regions, the growth rate of total factor productivity is the fastest in the east of China, and the slowest in the central region. Drives behind the growth of total factor productivity in each region are distinct.
Keywords: *technical efficiency; economic growth; driving force; environmental factor; computing method*

Introduction

The report of the 19th National Congress pointed out that "China's economy has been transitioning from a phase of rapid growth to a stage of high-quality development," so the country should shift from the extensive growth, which focuses on speed and scale, to intensive growth, which emphasizes efficiency. In the new stage, economic growth should not be judged merely by speed, and the quality should be regarded as the key. Over the past 30 years, due to the limitation of productivity, China's economic growth has been based on "high investment, high consumption and high emissions", which although promoted a high speed of economic development, has brought serious environmental pollution at the same time. Global Environmental Performance Index (EPI) ranked China the 109th in 180 participating countries and regions in 2016, which reflects that China's environmental situation is apparently not optimistic. Because of this, the century government has attached great importance to energy conservation and pollution emission, pointing out in "The Thirteenth Five-Year Plan" the target of "greatly improving the efficiency of exploiting energy resources, effectively controlling energy consumption, the total amount of carbon emissions, and greatly reducing major pollution emissions". The realization of this goal cannot be separated from enacting and implementing environmental regulation, the constant

DOI: http://dx.doi.org/10.15666/aeer/1704_84178434

strengthening of which constitutes an inevitable trend of China's economic and social development (Barla and Perelman, 2005; Thanh and Do, 2018).

Total factor productivity, as a critical basis for measuring the quality of economic growth, has attracted wide attention from scholars. Finding a way to improve the contribution of the total factor productivity to economic growth has become a top priority for China's high-quality growth (Cai and Zhou, 2017; Sufiyan et al., 2018). Is it possible to achieve a win-win situation between environmental pollution control and economic growth? Chen (2017) and Abija and Nwankwoala (2018) found that the current establishment and enforcement of environmental regulation in China had a certain inhibitory effect on economic growth for it continuously expands the social welfare cost. It has become an urgent and significant problem in China to formulate a rational environmental regulation to promote total factor productivity. Based on this, this paper discusses the influence of environmental regulation of the growth of total factor productivity through a theoretical perspective.

Literature review

In terms of the influence of environmental regulation on total factor productivity, there are three representative views abroad: first, environmental regulation will have a negative impact on total factor productivity. Granderson and Prior (2013) and Anan (2019) analyzed and tested the influence of environmental regulation on the efficiency of the fossil fuel generation industry in the United States and its total factor productivity, and they pointed out that the increased regulatory intensity of sulfur dioxide emissions resulted in a significant growth in the costs of generating electricity, thus limiting the increase of total factor productivity in the power sector. Research conducted by Aklin (2016) demonstrated that environmental regulation would push production costs of enterprises upward, and that relatively intensified environmental regulation might lead to wrong strategic development decisions for enterprises and deviation from their original development track. This would inhibit technological progress and promotion of productivity. The empirical test results of Zárate-Marco and Vallés-Giménez also proved the above ideas, which they referred to as "following the costs theory" Second (Zárate-Marco and Vallés-Giménez, 2015), environmental regulation will promote the improvement of total factor productivity. Scholars including Klemetsen et al. (2016; Xu, 2018) and Cherkashin et al. (2015) stated that the total factor productivity under the influence of environmental regulation was higher than traditional total factor productivity, and they explained this conclusion by the Potter Hypothesis, arguing that the purpose of moderate environmental regulation was to reduce the negative impact of the environment, which could stimulate the "innovation compensation" effect, promote technological innovation, and make up costs generated by or even beyond the environmental regulation, Guo et al. (2015) conducted sample studies in refineries of Los Angeles from 1990 to 2009, finding that despite the high costs of environmental regulation in the region, the total factor productivity witnessed significant improvement. Brolund and Lundmark (2017) and Gautam et al. (2019), with the aim of exploring whether environmental laws and regulations affected the productivity and technological changes of European paper industry, conducted empirical studies by taking the total factor productivities of the paper industry in eight European countries from 1993 to 2009 as dependent variables, and the intensity of environmental regulation of various pollutants as independent variables. Results showed

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84178434

that the management of nitrogen oxides was related with the improvement of total factor productivity in the following period. Third, the influence of environmental regulation on total factor productivity is uncertain. This view holder believed that various factors such as production scale, industrial characteristics, environmental regulation policy and tools selection made the direction and degree of the influence uncertain (Naso et al., 2017; Zulkapli et al., 2018). Qu (2015) employed the data of Quebec manufacturing sector from 1996 to 2008, and they found that the environmental regulation was negatively related to total factor productivity in the same period, but when the model took lagged variables into consideration, the Potter Hypothesis took effect and they became positively related. Ravetti et al. (2016) believed that no evidence showed that environmental regulation policy had an obvious and continuous effect on innovation, and they found through further empirical tests that environmental regulation had little effect on green technology innovation of enterprises.

Domestic researches on the relationship between environmental regulation and total factor productivity started relatively late, and focused mainly on the influence of environmental regulation on technological progress and technical efficiency. Wang and Sheng (2015), starting from the internal relationship between environmental pollution and China's industrial growth, constructed the total factor productivity limited by environmental regulation, and decomposed it into technological progress and technical efficiency by Malmquist-Luenberger (ML) index method. They found that there was a positive relationship between environmental regulation and technological progress. Liu et al. (2016) and Baharuddin and Samsudin (2018) employed the slack based measure (SBM) directional distance function and the ML index to investigate factors affecting Global Trade Finance Program (GTFP) in China's 29 provinces (cities), and results displayed that appropriate market environment regulations could improve productivity via stimulating technological innovation. Li et al. (2017), with the panel data of China's 30 provinces (cities) from 2005 to 2014, conducted empirical tests on the effect of environmental tax on enterprises' technological progress. Tests results showed that the influence of environmental tax intensity on technological progress was notably positive. Lv et al. (2017) calculated the green total factor productivity of 28 sub-sectors of China's manufacturing industry using data envelopment analysis (DEA)-Malmquist index method, which further verified the relationship between environmental regulation and the green total factor productivity of manufacturing industry. They found that technological progress constituted the core drive for the improvement of the manufacturing industry, and that environmental technology efficiency was generally lower.

The above literature demonstrates that scholars have made fruitful achievements in the study of the relationship between environmental regulation and total factor productivity, but there still exist several problems: first, despite the fact that the DEA method has been used to incorporate environmental factors into the productivity analysis framework to calculate the total factor productivity, potential effects caused by random error are not considered. Second, the study of environmental regulation and total factor productivity is mainly limited to the relationship between environmental regulation and technological progress or technical efficiency. The relationship between environmental regulation and specific components of all factor productivity is not included. Third, the majority of the previous researches start from the micro and macro perspective of environmental regulation and total factor productivity, with little focus on regional studies. In view of the above situation, this paper under the random frontier

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84178434

framework intends to incorporate environmental regulation into technical inefficiency, constructs the economic growth accounting equation with the total amount of energy consumption, capital and labor force as production factors, and calculates the value of total factor productivity and its decomposition part, the result of which will be contrasted with the one made without considering environmental regulation. This way, the internal structure and the drive behind the influence of environmental regulation on total factor productivity growth will be explored. In addition, given that the significant difference of resource distribution, industrial structure and development stage in distinct regions of China, which makes it different the influence of environmental regulation on total factor productivity, this paper divides China into eastern, central and western regions[1] so as to measure the difference of the total factor productivities growth between diverse regions, thus providing theoretical basis for the coordinated growth of total factor productivity in various regions.

Materials and methods

Stochastic frontier model

Existed literatures adopted two methods to build the production frontier, that is, the non-parametric Data Envelopment Analysis (DEA) and the parameter stochastic frontier analysis (SFA). This paper intends to use SFA to calculate the total factor productivity, which has the following advantages over DEA: first, the error structure of SFA constitutes a composite form, which takes into consideration the influence of both technical inefficiency and random factors on efficiency, while the production frontier constructed by DEA is non-random, which attributes all deviations to technical inefficiency, and this may not coincide with the reality; second, SFA can measure efficiency and analyze the factors that affect it at the same time, while DEA must adopt the two steps; third, SFA, with statistical properties, is capable of conducting statistical tests of parameters and models, which DEA fails to achieve; Four, the SFA measures the absolute efficiency, which is convenient for comparison and analysis of different units. In contrast, DEA calculates relative efficiency, which is 1 for all units, making it difficult to compare and analyze these effective units. Therefore, this paper adopts the stochastic frontier model, and the basic form of the empirical model is as follows (*Eq. 1*):

$$Y_{it} = f[x_{it}, \ \beta]\exp(v_{it} - u_{it}) \quad \text{(Eq.1)}$$

In the above formula, i represents the province, t indicates time, Y means output, $f(x_{it},\beta)$ indicates production frontier, x represents input factor, and β is the parameter to be estimated. $(v_{it} - u_{it})$ is a composite error structure, in which v_{it} represents random disturbance variable, u_{it} indicates the technical inefficiency of production and they are independent of each other.

[1]The eastern, central and western regions in China in this paper are divided as follows: the eastern region includes Beijing, Tianjin, Hebei, Liaoning, Shanghai, Jiangsu, Zhejiang, Fujian, Shandong, Guangdong, Hainan and Guangxi. The central region includes Shanxi, Inner Mongolia, Jilin, Heilongjiang, Anhui, Jiangxi, Henan, Hubei and Hunan. The western region includes Chongqing, Sichuan, Guizhou, Yunnan, Shaanxi, Gansu, Qinghai, Ningxia and Xinjiang.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84178434

In actual production activities, although the related factors of environmental regulation cannot be directly included in the production equation, it may exert influence on the total factor productivity by affecting the technical inefficiency. Neglecting these factors will result in the inaccuracy of estimated results. In this sense, the following technical inefficiency regression equation is established as follows (*Eq. 2*):

$$u_{it} = \delta_0 + \delta_i Z_{it} \tag{Eq.2}$$

δ_0 is a constant term, Z_{it} indicates the factor affecting technical inefficiency, δ_i represents estimated coefficient of the factor, which, when positive, indicates that the factor restrain the promotion of technical efficiency, and vice versa.

Selection of production function and decomposition of total factor productivity

Early classical economists regard labor and capital as the main factors affecting economic output, and natural resources are often considered to be able to replace each other or be substituted by other productive factors. This is not consistent with the actual situation in which a large number of non-renewable resources are required in the process of production. In 2016, China surpassed the United States in the consumption of renewable energy, ranking the first in the world, and the total energy consumption in China accounted for 23% that of the world. Massive energy consumption has brought serious environmental pollution and climate change (Xiao et al., 2017; Kumar and Kumar, 2018). Therefore, research regarding economic growth in China cannot overlook the input of energy elements in the production process. This paper intends to employ capital (K), labor force (L) and energy (E) to jointly construct the production function Y = f (K, L, E).

Compared with the Cobb Douglas production function (C-D), the translog production function is inclusive and easier to estimate, which can better avoid the deviation caused by misspecification of production functions (Wang and Qi, 2017; Onwuka et al., 2019). In addition, considering the substitution effect between input factors, whether the technological progress is neutral or the technological progress should all be reflected in the model, this paper selects the time-varying model of translog production function.

$$\begin{aligned}
&\ln y_{it} = \ln f[x_{it}(t), t] + (v_{it} - u_{it}) \\
&= \beta_0 + \beta_l \ln L_{it} + \beta_k \ln K_{it} + \beta_e \ln E_{it} + \beta_t t + \beta_{kl} \ln K_{it} \ln L_{it} + \beta_{ke} \ln K_{it} \ln E_{it} + \beta_{le} \ln L_{it} \ln E_{it} \\
&+ \beta_{kle} \ln K_{it} \ln L_{it} \ln E_{it} + \beta_{kt} t \ln K_{it} + \beta_{lt} t \ln L_{it} + \beta_{et} t \ln E_{it} + \beta_{t^2} t^2 + \beta_{l^2} \ln^2 L_{it} + \beta_{k^2} \ln^2 K_{it} \\
&+ \beta_{e^2} \ln^2 E_{it} + v_{it} - u_{it}
\end{aligned} \tag{Eq.3}$$

According to Solow (1957), the growth of total factor productivity was output growth deduct input growth. He believed that technological progress was the same factor as total factor productivity, and did no segmentation research on total factor productivity. Kumbhakar and Lovell (2000) further decomposed the growth of total factor productivity into four factors: technological progress (△TP), technological efficiency change (△TE), scale efficiency change (△SE) and allocation efficiency change (△AE), which provided a new way for the in-depth study of economic growth pattern. Based on this, this paper decomposes total factor productivity into the following four parts.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84178434

(1) The rate of technological progress. It reflects the technological progress of production frontiers, representing the output with the change of time under the condition of constant input elements. Taking log of formula (*Eq. 3*) and taking derivatives of t can generate the following formula (*Eq. 4*):

$$\Delta TP = \frac{\partial f}{\partial t} = \beta_t + \beta_{lt} \ln L_{it} + \beta_{kt} \ln K_{it} + \beta_{et} \ln E_{it} + 2\beta_{t^2} t \quad \text{(Eq.4)}$$

(2) The rate of technical efficiency change. The index refers to, under the same factor input and technology level, the ratio of actual output and frontier output (maximum output) with the changes of time (*Eq. 5*).

$$\Delta TE = -\frac{du_{it}}{dt} = \frac{TE_{it}}{TE_{it-1}} - 1 \quad \text{(Eq.5)}$$

(3) The rate of scale efficiency change. Scale efficiency refers to the changes of output according to the increase of factor input with the enlargement of production scale. There are three kinds of situations, that is, the increase, decrease and unchanged scale efficiency. The formula for the rate of scale efficiency change (*Eq. 6*) is shown below:

$$\begin{aligned} \Delta SE &= (E-1)\sum_j \frac{E_j}{E}\dot{x}_j = (f_l + f_k + f_e - 1) \\ &\times \left(\frac{f_l}{f_l+f_k+f_e} \times \dot{L} + \frac{f_k}{f_l+f_k+f_e} \times \dot{K} + \frac{f_e}{f_l+f_k+f_e} \times \dot{E}\right) \end{aligned} \quad \text{(Eq.6)}$$

According to the *Equation 3:*

$$f_l = \frac{\partial f}{\partial l} = \beta_l + \beta_{el} \ln E_{it} + \beta_{lk} \ln K_{it} + \beta_{elk} \ln E_{it} \ln K_{it} + \beta_{lt} t + 2\beta_{l^2} \ln L_{it}$$

$$f_k = \frac{\partial f}{\partial k} = \beta_k + \beta_{ek} \ln E_{it} + \beta_{lk} \ln L_{it} + \beta_{elk} \ln E_{it} \ln L_{it} + \beta_{kt} t + 2\beta_{k^2} \ln K_{it}$$

$$f_e = \frac{\partial f}{\partial e} = \beta_e + \beta_{el} \ln L_{it} + \beta_{ek} \ln K_{it} + \beta_{elk} \ln L_{it} \ln K_{it} + \beta_{el} t + 2\beta_{e^2} \ln E_{it}$$

(4) The rate of allocation efficiency change. This mainly examines the contribution of factor structure changes to total factor productivity in the production process under given frontier technological level. The equation is as follows (*Eq. 7*):

$$\begin{aligned} \Delta AE &= \sum_j [(\frac{E_j}{E} - s_j) \times \dot{x}_j] = (\frac{f_l}{f_l + f_k + f_e} - \frac{L}{L+K+E}) \times \dot{L} \\ &+ (\frac{f_k}{f_l + f_k + f_e} - \frac{K}{L+K+E}) \times \dot{K} + (\frac{f_e}{f_l + f_k + f_e} - \frac{E}{L+K+E}) \times \dot{E} \end{aligned} \quad \text{(Eq.7)}$$

The empirical study of the early stochastic frontier model is carried out in two steps. First, the maximum likelihood estimation is made to the frontier production function to obtain the coefficients of the explanatory variables. Then the regression equation is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84178434

reconstructed by separating out the technical inefficiencies and other exogenous explanatory variables of non-factor inputs. However, there still exist the following problems: first, it is necessary to assume that there is no correlation between the exogenous factors and the input factors, the omission of these variables will result in deviation of the technical efficiency in the first step estimation. If the first step is biased, the estimation of coefficient of the technical efficiency equation in the second step will also witness deviation. Second, the stochastic frontier model often assumes that the distribution of the invalid term is the same, but in the second step technical efficiency regression equation, the technical efficiency term is changed with the different external variables, which forms a contradiction (Chen and Zhang, 2016). In contrast, one-step method can avoid these problems. Wang and Schmidt (2002) verified that one step method was superior to the two-steps method by Monte Carlo simulation. In this sense, this paper, for the purpose of attaining more accurate conclusions, employs the maximum likelihood method and one-step regression estimation method. In addition, this paper first assumes that the distribution of the technical invalid term is a truncated normal distribution, because compared with the exponential distribution and the half-normal distribution, it is more flexible. and this hypothesis will be tested later.

Variables selection and data description

According to the constructed stochastic frontier model, this paper adopts K, L and E as input variables and gross domestic product (GDP) as output variables. As for K, the capital stock, according to the estimation results of Shan (2008), through the perpetual inventory method, the data is expanded to 2015 under the assumption of 10.96% capital depreciation rate. The price level is converted to that of the year 1995 according to the corresponding Price Indices of Investment in Fixed Assets. The calculation method of the labor force (L) is the number of the employees at the end of the year in each province multiplied by the average wage of employees, which are handled according to the consumer price index in 1995 as the base period. GDP is based on the retail price index in 1995.

Variables representing environmental regulation are numerous, and in order to comprehensively investigate the impact of different types of environmental regulation on total factor productivity, this paper chooses to measure environmental regulations by environmental pollution control investment (invadd), the number of environmental regulations (fg) and the emission intensity of industrial SO_2 (strs). As the most basic embodiment of the government's environmental regulation, the investment in environmental pollution control is calculated as follows: (the actual pollution control input of the year / total industrial output value) × 1000. As for the variable of environmental regulations number, referring to Cole et al. (2008), the intensity of environmental regulation could be examined by the number of environmental regulations and administrative penalties related to environmental protection. The emission of industrial SO_2 can reflect the enterprise's efforts to improve the environment under the government's environmental regulations (Barla and Perelman, 2005). In addition, taking into consideration other factors that may affect the total factor productivity, this paper selects the economic development level (ag) and the urbanization rate (urban) as control variables, in which the former is measured by the per capita GDP, to be specific, by GDP deflator with the year 1995 as the base period, while the latter variable is evaluated by the ratio of the urban population to the total population in each province at the end of the year (Yuan et al., 2017).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84178434

In this paper, 30 provinces (cities) and autonomous regions (excluding Tibet) in China are used as samples, and the interval is from 1995 to 2015. The data is collected from China Statistical Yearbook, China Energy Statistical Yearbook and China Environment Yearbook (1996-2017).

Discussion

This paper employs the stata14.0 software calculate the stochastic frontier regression of the translog production function. In model 2, results were estimated by introducing environmental regulation into the technical inefficiency equation and performing a one-step regression with the production efficiency equation. Considering that the focus of this paper is to study the influence of environmental regulation on the total factor productivity, modules in the technical invalid equation without factors related to environmental regulation are also estimated (model 1), which makes it possible to further explore the difference of the total factor productivity with and without considering the environmental regulation (Xiong et al., 2017).

The estimation results (*Table 1*) show that the two models have achieved sound regression results, indicating that the stochastic frontier set in this paper is reasonable. In model 1 and model 2, the coefficients of capital, labor and energy factors are positive and constitute at least 10% of the significant level, which means the influence of these three factors on economic growth is positive, but the contribution of capital and labor factors is greater than that of energy factors. Compared with model 1, the regression coefficient of model 2 is more significant. In addition, the value of γ in the two models is close to 1, which indicates that the phenomenon of production inefficiency exists generally in all provinces in China, and that the method of analyzing the trans-logarithm stochastic frontier of technical invalid term to study the dynamic state of total factor productivity with environmental regulation is necessary and reliable.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84178434

The regression coefficient of related indicators of environmental regulation is estimated by the technical inefficiency, which is the result of the industrial pollution control investment and industrial SO_2 emission intensity, as an explanatory variable. From the regression results, the industrial pollution control investment is more significant in the form of technical invalidity as the 1% increase in the proportion of the investment to the industrial added-value would lead to 2.08% growth in the technical invalidity, which is not conducive to economic growth (Mut, 2018). This coincides with the "following the costs theory" of environmental regulation. The coefficient of industrial SO_2 emission intensity is positive, which can be understood as the emission of pollutants in the production process out of enterprises' own interests. This indicates that in the future actions of saving energy and reducing emission, enterprises' emission of SO_2 should be controlled more strictly. The coefficient of the number of environmental legislation published by local governments is 0.0097, but the statistical test value is not significant. Moreover, the coefficients of per capita GDP and urbanization rate are notably negative, indicating that the level of regional economic development and urbanization are favorable for the improvement of technical efficiency (Hajikhani, 2017).

The conclusion of stochastic frontier analysis tends to rely on the function form of the model, and in order to ensure that the model is correct, this paper carries out a likelihood ratio test, in the broad sense, for the translog form of the production function, and the existence of technical inefficiency and technological progress, the statistic is $\lambda = -2\ln[L(H_0)/L(H_1)]$, with $L(H_0)$, $L(H_1)$ as the likelihood function value of the original hypothesis and the alternative hypothesis respectively. If the null hypothesis is established, the test statistic λ obeys the Mixed Chi-square Distribution, and the degree of freedom is the number of the constrained variables. Test results are shown in *Table 2*.

Table 2. *Test results of hypothetical model*

Original hypothesis	$L(H_0)$	λ	Critical value	Test results
$H_0: \beta_{k^2} = \beta_{l^2} = \beta_{e^2} = \beta_{t^2} = \beta_{kl} = \beta_{ke} = \beta_{el} = \beta_{kle} = \beta_{kt} = \beta_{lt} = \beta_{et}$	312.22	360.82	24.72	Refusal
$H_0: \beta_t = \beta_{t^2} = \beta_{kt} = \beta_{lt} = \beta_{et} = 0$	246.21	492.84	15.09	Refusal
$H_0: \gamma = \mu = \eta = 0$	429.98	126.30	15.09	Refusal
$H_0: \beta_{kt} = \beta_{lt} = \beta_{et} = 0$	396.78	191.70	11.34	Refusal

The unlimited log likelihood is $L(H_1) = 492.63$, and the significance level of critical value is 1%

The first original hypothesis indicates that all the interaction items and square term coefficients in the production function are zero, which means that employing the C-D production function is enough, and that no translog form is needed *(Table 2)*; the second original hypothesis assumes that all the time dependent variables in the model are zero, that is, there exists no frontier technological progress; the third original hypothesis is designed to test the existence of the technical inefficiency. When γ is zero, it shows that the proportion of the variance of the technical inefficiency to the variance of stochastic error term is zero, and it is completely not necessary to consider this term. If μ is zero, the technical inefficiency obeys a half-normal distribution rather than a truncated normal distribution. When η is zero, there is no need considering the time-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84178434

varying effect of the technical inefficiency. The last original hypothesis indicates that if the interaction coefficients of time and the three factors are all zero, the technological progress is not Hicks-neutral (Pascual-Córdova, 2018). From the test results, all the zero hypotheses are rejected, which proves that it is reasonable to use the translog form of production function, with the technical inefficiency objectively existing.

Results

According to the regression results of the stochastic frontier model (*Table 3*), the growth rate of total factor productivity can be estimated. At the same time, in order to understand the influence of the environmental regulation, when added the technical inefficiency, on the total factor productivity more clearly, this paper will combine the two situations of considering and not considering the environmental regulation and give an analysis of the two cases according to the regions divided above (eastern, central and western regions of China) to explore the differences between the regional total factor productivity growth (Huang et al., 2017).

When not considering the environmental regulation, although the starting points of economic development is distinct, the total factor productivity (TFP) of the eastern, central and western regions have achieved rapid growth, with the average growth rate of 5.15%, 3.99% and 4.19%, respectively. TFP growth is the fastest in the eastern region, and the slowest in the central region. The total factor productivity of all regions decline significantly in 2006, which is related to the deterioration of the macroeconomic situation in China, such as the stock market turbulence in China, the rising price of crude oil and the hit of domestic export enterprises. In the following years, the gap of TFP growth rate in the three major regions has been gradually narrowed, and the central and western regions had a tendency to catch up with the eastern region. After the inclusion of environmental regulation factors in the technical inefficiency, the growth rate of TFP in the three regions slow down, with the average growth rate of 3.68%, 2.52% and 2.76% respectively, and the central and western regions even take on a negative growth. In the majority of years, the growth rate of TFP is still the highest in the eastern region, and the central region, as the lowest in terms of the average growth rate of TFP, the largest decline also appears after the inclusion of environmental regulation (Perozo, 2016). Since China's reform and opening up, the economic development in the central region is ordinary, and its second and third industries starts late. With the promotion of "the rise of central China strategy", some manufacturing industries and heavy chemical industries of high energy consumption and pollution have achieved development first. However, due to the restrictions of capital and technology as well as relatively relaxed environmental policies, the environmental regulation was "selectively ignored", which, while promoting the economic development in the region, aggravated the problem of environmental pollution (Qu and Xi, 2012). The western region is vast and rich in resources. With the implementation of the strategy of "developing the west", its late-mover advantages gradually become noticeable, forming the trend of catching up with the developed areas. Even in the times of the macroeconomic situation deterioration in China, it still maintained the rising momentum. However, the rapid growth of the area is mainly dependent on its rich resources, and pollutant emission increased rapidly in the development process, leading to the poor TFP growth rate when considering environmental regulation.

In order to explore the influence of environmental regulation on the decompositions of total factor productivity and regional differences after including environmental regulation in technical inefficiency, this paper further analyzes the TFP growth rate by decomposing it into four parts: technological progress (△TP), technical efficiency change (△TE), scale efficiency change (△SE) and allocation efficiency change (△AE). This is much closer to the essence of the growth of total factor productivity. It can be seen from *Table 4* that when not considering the environmental regulation, the technological progress of the three regions shows a positive growth trend, and it has become the major source of the total factor productivity growth (*Table 4*), while the contribution of the technical efficiency change is very small or even negative, which is similar to the conclusions of produced by Wang et al. (2006), Tian et al. (2011). After considering the environmental regulation, the technical efficiency change in the three regions has been obviously improved, with the average value of the eastern region rising from -0.02% to 1.61%, and the central and western regions increasing to 2.14% and 2.08% respectively, which constitutes the main driving force of the TFP growth. In contrast, the technological progress in all regions slows down, in which technological progress growth rate in the eastern region becomes slower although it is still growing. The technological retreat in the central and western regions is more obvious, with the western region most severely affected. The average value of the technological progress

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84178434

in the western region falls from 1.5% to -0.79%, and this index shows negative growth every year from 1995 to 2008. It is not difficult to find that the eastern coastal areas is often close to the production frontier or directly on the frontiers, so a large part of the increase in productivity demonstrates the forward movement of the frontiers, that is, technological progress (Perozo, 2016). However, in the underdeveloped areas like the central and western regions, due to the lack of inner drive of technological progress, production relies on technology introduction and simple imitation, and the increase in productivity takes more of the form of the improvement in technical efficiency.

The research result also shows that the growth rate of scale efficiency demonstrates a declining trend in the western, central and eastern regions regardless of the influence of environmental regulation. However, after taking into consideration the environmental regulation, the growth rate of scale efficiency in the three regions all shows a decrease, with the average growth rate in the eastern region falling most dramatically from 1.1% to 0.45%, during which period there even exist diseconomies of scale. This is related to the overdependence on the increase of production factor input in the process of economic development, which leads to the decrease of the marginal output of the production factors and the loss of the scale efficiency. The change of the scale efficiency of the central and western regions reflects a relatively strong positive effect, indicating that the two regions are in the stage of scale economy (Jamali, 2016). The growth rate of the scale efficiency in the west region is generally higher than that in the central region, indicating that western region has an obvious advantage in terms of scale efficiency, which is a main factor that makes up for the difference of growth of total factor productivity against other regions. In addition, the allocation efficiency of production factors was ignored in the documents in the past, but this paper finds out that the efficiency allocation is an objective existence after calculation, and there is a continuous and obvious fluctuation of the allocation efficiency in different regions over the past 20 years (Yu, 2019). Without taking environmental regulation into consideration, the average growth rates of allocation efficiency in eastern, central and western regions are -0.40%, -0.44% and 0.77%. The allocation efficiency of the three regions declines if taking environmental regulation into account, and the average growth rate of western region, which is the most affected region, declines from 0.77% to -0.17%. This indicates that environmental regulation cannot optimize the allocation of resources.

In general, if taking the technical inefficiency resulted by environmental regulation into consideration, the growth of total factor productivity will slow down in most years, and the growth rate will decrease progressively in eastern, western and central regions, and the sources of the growth of total factor productivity will be different. Eastern region has more obvious advantage of technical progress, and the change rate of scale efficiency is the main reason that stops the growth of total factor productivity in this region. The total factor productivity declines in western region mainly because the range of technical efficiency improved is smaller than the falling range of technical progress and allocation efficiency. The total factor productivity in central region is the lowest, the technical efficiency was improved in the period of analysis, but the returns to scale, allocation efficiency and technical progress all declined to some extent, all these factors resulted in the decrease of the growth of TFP. Therefore, when calculating the total factor productivity, if the impact that environmental regulation exerts on productivity (technical efficiency) is ignored, the total factor productivity of our country is likely to be overestimated, and the related policy suggestions will be misleading to some extent.

Figure 1 compares the two change curves of the total factor productivity in China between 1995 and 2015 (with and without considering environmental regulation), the growth rate of total factor productivity declines in most years if taking environmental regulation into consideration. The total factor productivity that takes environmental regulation into consideration can reflect the performance of green economy growth and indicates that environmental regulation results in technical inefficiency during the development of China's economy, and therefore deters the growth rate of total factor productivity. This goes against the 'the theory of Innovation Compensation" proposed by many scholars in recent years and conforms to the "the theory of Compliance Cost" proposed by scholars at early phase. It indicates that environmental regulation forces enterprises to occupy productive investment, and enterprises will suffer private cost increase to meet environmental requirements and will reduce the production efficiency. This will exert negative effects on China's economic development and deter the growth of total factor productivity in the long run (Alkin, 2016).

Figure 2 makes decomposition of the sources of growth of total factor productivity with environmental regulation considered. It can be figured out that technical efficiency contributes the most. The growth rate of cutting-edge technique progress is negative before 2004, but turns positive gradually after 2004. The change of scale efficiency exerts positive influence on the growth rate of total factor productivity, but the influence is not obvious. It is worth noting that the growth rate of allocation efficiency is negative in most times, and it is an important factor that restricts the growth of total factor productivity.

Conclusion

In this paper, the authors constructs the translog stochastic frontier production function model, brings the index of correlation of environmental regulation into the equation of technical inefficiency to make maximum likelihood estimation, worked out the growth rate and compositions of total factor productivity in China as a whole and Eastern, Central and Western regions from 1995 to 2015, and makes a comparison analysis of the total factor productivity without considering the environmental regulation. The main conclusions are as follows:

(1) Total factor productivity slows down when taking environmental regulation into technical inefficiency. The investment of industrial pollution control and emission intensity of industrial SO_2 all result in technical inefficiency, and are harmful to the improvement of total factor productivity. The influence of the number of environmental legislation published by local governments is not obvious. This indicates that there are still numerous things to be done to achieve China's win-win situation between environment and economy. Governments should carry out functional environmental regulations and manage the implementation of these regulations properly based on local resources and pollution status of local environment during the process of economic development. For enterprises that discharge pollutants out of their own benefits, government should fully arouse enterprises' enthusiasm and initiative of energy conservation and emission reduction to form an incentive and restraint mechanism of energy conservation and emission reduction.

(2) After taking environmental regulation into consideration, technical efficiency change becomes the main source of the growth of total factor productivity, technological progress slows down and the decline of growth of total factor productivity is closely related to the negative growth of allocation efficiency. The majority part of the eastern regions have been in the diseconomy of scale, so for these provinces, it is more important to improve the efficiency of resource utilization and the introduction and application of advanced technology to drive the progress of frontier technology rather than to expand the input and scale.

(3) The difference of total factor productivity growth rate in various regions of China has gradually narrowed in recent years, with the central and western regions even surpassing the eastern region, but it still shows obvious regional characteristics. After considering the environmental regulation, there exist differences in the reasons for the decrease of total factor productivity in various regions. Therefore, when formulating the environmental regulation, practical and feasible measures should be adopted through taking into account the differences in resources endowment, industrial structure and development stages of various regions.

Therefore, in the future, we should properly improve our environmental regulation system and adopt flexible forms of environmental regulation to ensure the positive impact of TFP on the environment.

(Received 8th Mar 2019; accepted 21st May 2019)

Abstract. Thermal power industry is a key area of China's energy conservation and emission reduction. Using the national recommendation method, we calculated the carbon emissions data of Shaanxi's thermal power in the 1995-2015 period, and analyzed the response to environmental management policies. The policy response selects energy industry development and environmental governance as the endogenous variables, and uses the methods of co-integration and error correction model to analyze the long-term ensuring future equilibrium and short-term impact mechanism for the three. Based on variance decomposition, this paper refines the contribution of dynamic energy industry development and environmental governance to thermal power carbon emissions. The research shows that the carbon emission of thermal power in Shaanxi province rose from 1891.63×10^4 t in 1995 to the peak of 11086.14×10^4 t in 2010, and then the improvement of energy efficiency has brought a downward trend of carbon emissions. Energy industry development and environmental governance can negatively effect carbon emissions from thermal power plants. In the long run, carbon emissions from thermal power plants can be gradually reduced. The contribution of the two variables is about 5% and 6% respectively, which has great room for improvement.
Keywords: *energy industry development, environmental governance, call mechanism, efficiency improvement, pollution reduction*

Introduction

Using the heat generated from coal and other combustion-based methods to produce electricity, thermal power generation is the main source of power in China and one of the main CO2 emission sources. At present, the thermal power industry has become a key area of national energy conservation and emission reduction. China's thermal power enterprises are mainly concentrated in Jiangsu, Shandong, Shaanxi and several other, and Shaanxi in 2010 became the first batch of the country's low carbon experimental development province, therefore, the measurement of thermal power carbon emission in Shaanxi province can provide effective data basis for the management of regional energy saving and emission reduction (Nas and Talebian-Kiakalaieh, 2017; Majumder et al., 2019).

In the current research, the calculation of carbon emission of thermal power is mainly expressed as "energy consumption method", that is to sum up energy consumption, and calculate carbon emission volume in combination with various energy carbon emission factors (Licht et al., 2018; Pazand and Hezarkhani, 2018). "Energy consumption law" can be used to estimate the carbon emissions of the industry better, but this method is limited to static research, neglects the carbon emission in the process of power transmission from the thermal power industry and the process of desulfurization, which eventually leads to the leakage calculation of carbon emissions

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84358448

(Bergthorson, 2018; Joseph et al., 2019). Therefore, it is necessary to improve the carbon emission research systematically and dynamically.

In 2013, the State Development and Reform Commission of China issued the Guidelines for the Accounting Methods and Reporting of Greenhouse Gas Emissions by China's Power Generation Enterprises (Trial Implementation) to determine the emission standards of air pollutants in thermal power plants. Based on the national development and Reform Commission's guidance method, this paper calculates the thermal power carbon emission data in Shaanxi province in 1995-2015, probes the response relationship of relevant policies to thermal power carbon emissions, and analyzes its long-term equilibrium and short-term impact mechanism to provide reference for future environmental management policy formulation (Ma et al., 2017; Sufiyan et al., 2018).

Shaanxi, also known as Qin, is located between the eastern longitude 105°29'–111°15' and northern latitude 31°42'–30°35'. It has jurisdiction over 10 prefecture-level cities, such as Xi'an, Xianyang, Yan'an and Hanzhong, and is an important hub connecting eastern, central, northwestern and southwestern China. The topography of Shaanxi includes mountains, highlands, plains and basins (*Fig. 1*). The total area is 205 thousand and 800 km^2. The forest coverage rate was 43.06%. The Yellow River basin covers an area of 133 thousand and 300 km^2, and the Yangtze River Basin has an area of 72 thousand and 300 km^2 (Velea et al., 2009; Rajput et al., 2019). The annual average temperature of the province is 13.6 centigrade; the annual precipitation is 598.1 mm.

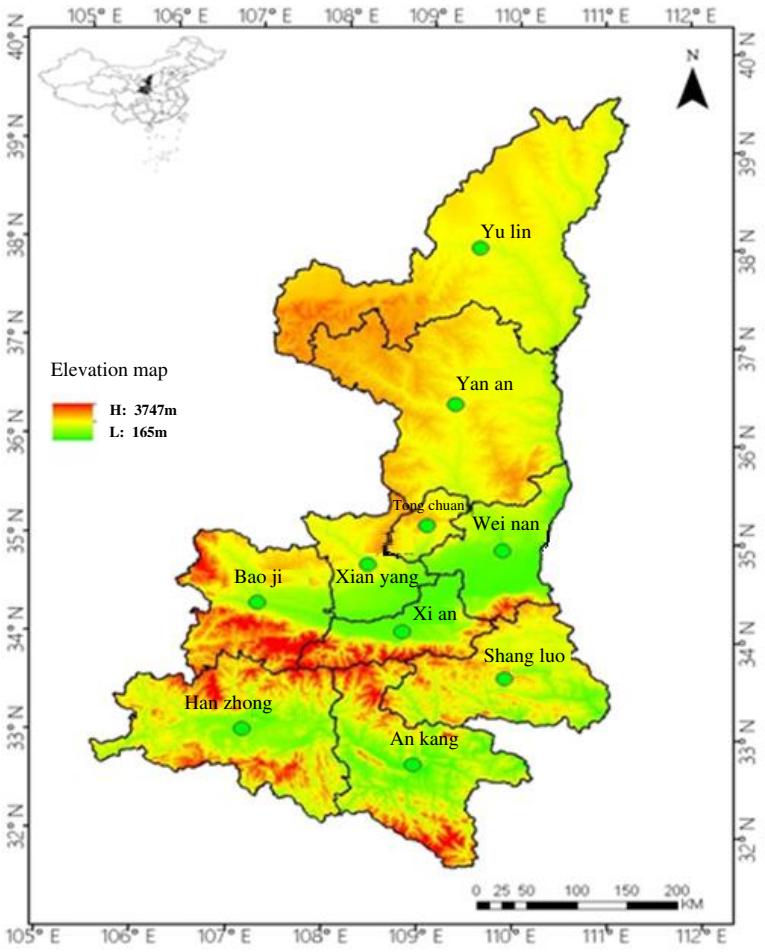

Figure 1. *Elevation map of the Shaanxi Province*

DOI: http://dx.doi.org/10.15666/aeer/1704_84358448

Methodology

Calculation of carbon emission in thermal power

The Accounting Methods and Reporting Guidelines for Greenhouse Gas Emissions from China's power generation enterprises (Trial Implementation) regulates that the total amount of greenhouse gas emissions from power generation enterprises is equal to the emission of fossil fuel combustion in the boundary of the enterprise, the discharge of the desulfurization process and the emissions generated by the net purchase and use of electricity. Among them,

$$E_{energy\ consumption} = \sum AD_i \times EF_i \quad \text{(Eq.1)}$$

$$E_{desulfurization\ process} = \sum CAL \times EF \quad \text{(Eq.2)}$$

$$E_{electricity\ purchase} = \sum AD \times EF \quad \text{(Eq.3)}$$

In *Equations 1, 2* and *3,* AD_i is the level of i energy activity, which is expressed in the calorific value (Atimtay, 2003; Kumar et al., 2017; Kumar, 2018), EF_i is the i emission factor; CAL is the consumption of carbonate in the process of desulfurization; EF is the emission factor of carbonate in the desulfurizer. Based on the real situation of thermal power generation in China, the desulfurizer is limestone, its carbonate content is 90% by default, and the carbon emission factor is 0.44. 2 thousand and 700 tons of limestone is consumed at 100 million kW h of power generation. AD is the purchase of electricity, and error factor (EF) is the emission factor.

Vector autoregression and vector error correction model construction

(1) Vector autoregressive model and error correction model

Vector autoregressive models are often used to predict interconnected time series systems and to analyze the dynamic effects of random disturbances on variable systems. The expression is:

$$Y_t = A_1 Y_{t-1} + A_2 Y_{t-2} + \cdots A_p Y_{t-p} + BX_t + \varepsilon_t, \quad t = 1,2,\cdots T \quad \text{(Eq.4)}$$

Among them, Y_t is a vector of k endogenous variable; X_t is a d dimension exogenous variable vector; p is a lag order; T is a sample number; ε_t is a k dimension error vector, A_1, A_2 A_p, B is an estimated coefficient matrix.

However, the defect of vector autoregressive model is that it cannot describe the relationship between synchronous variables, and the error correction model can deal with this problem better.

$$\Delta Y_t = \alpha ECM_{t-1} + \sum_{i=1}^{p-1} \Gamma_i \Delta Y_{t-i} + \varepsilon_t \quad \text{(Eq.5)}$$

Among them, ECM_{t-1} is the error correction term, α is the adjustment coefficient, and the influence coefficient of Γ_i is ΔY_{t-i}'s short term fluctuation on ΔY_t.

DOI: http://dx.doi.org/10.15666/aeer/1704_84358448

(2) Selection and treatment of index

In the field of environmental governance, energy industry technology upgrading and industrial pollution control are the main strategies for energy conservation and emission reduction (Valiani et al., 2016; Jamil et al., 2018). As the electricity belongs to the energy industry, in order to better reflect the corresponding management, the energy industry investment (EIS) and the industrial pollution control investment (IPS) are selected to represent the status quo of the development of energy industry and the status of environmental governance respectively, and the endogenous variables of the thermal power carbon emission (CES) model are constructed (Reddy and Momoh, 2016; Ali et al., 2018).

According to the selection index, *Equation 4*: $Y = \begin{bmatrix} CES \\ EIS \\ IPS \end{bmatrix}$, $X = 0$. In order to reduce the large fluctuation of data, the natural logarithms of CES, EIS and IPS sequences are taken respectively. The *X, Y, t* value substitution (*Eq. 4*) can be obtained:

$$\begin{bmatrix} LCES \\ LEIS \\ LIPS \end{bmatrix}_t = \begin{bmatrix} a_0 \\ a_1 \\ a_3 \end{bmatrix} + \begin{bmatrix} b_{11} & b_{12} & b_{13} \\ b_{21} & b_{22} & b_{23} \\ b_{31} & b_{32} & b_{33} \end{bmatrix} \begin{bmatrix} LCES \\ LEIS \\ LIPS \end{bmatrix}_{t-1} + \begin{bmatrix} c_{11} & c_{12} & c_{13} \\ c_{21} & c_{22} & c_{23} \\ c_{31} & c_{32} & c_{33} \end{bmatrix} \begin{bmatrix} LCES \\ LEIS \\ LIPS \end{bmatrix}_{t-2} + \begin{bmatrix} \hat{\varepsilon}_0 \\ \hat{\varepsilon}_1 \\ \hat{\varepsilon}_2 \end{bmatrix}_t \quad \text{(Eq.6)}$$

Results, analysis and discussion

The data of thermal power consumption, the average low calorific value of energy and electricity purchased are derived from the《Shaanxi statistical yearbook》. The unit calorific value carbon content data comes from the provincial carbon emission accounting guide and Intergovernmental Panel on Climate Change (IPCC) standard. Some energy data and the average emission factor of regional power grid are derived from "The guide to China's carbon emissions accounting". Among them, the average emission factor of the northwest regional power grid is 0.977 kg/KW h, Over the years, the investment in Shaanxi's energy industry and investment in industrial pollution control came from the National Bureau of statistics of China (Salem, 2018; Hossain et al., 2019).

Empirical results and analysis

(1) Carbon emission of thermal power in Shaanxi

The results of thermal power carbon emission calculation in Shaanxi Province from 1995 to 2015 are in *Table 1*. The carbon emission of thermal power in Shaanxi Province has been increasing since 1995 until the turning point of 2010. The emission reached its peak of 11086.14×10^4 t in 2010, which is due to the 190.52×10^8 KW h increase of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84358448

the thermal power generation in 2010 compared with the previous year. The amount of raw coal used for thermal power generation increased from3949.22 × 10^4 t in 2009 to 4850 × 10^4 t, and then dropped to4107.56 × 10^4 t in 2011 (Boutabba and Lardic, 2016; Shrestha and Baral, 2018).

Table 1. *The carbon emission of thermal power generation in Shaanxi Province (unit: 10^4 t)*

Time	Emission value	Time	Emission value	Time	Emission value
1995	1891.63	2002	3312.53	2009	8177.14
1996	2177.56	2003	4350.98	2010	11086.14
1997	2471.41	2004	5148.33	2011	9206.80
1998	2589.26	2005	5014.09	2012	9428.29
1999	2701.68	2006	5805.92	2013	9445.80
2000	2737.83	2007	6296.26	2014	9502.33
2001	2902.70	2008	7134.40	2015	9533.27

At the same time, according to the composition of Shaanxi's thermal power carbon emissions (*Fig. 2*), we can also see in the purchase of electric power plate, Shaanxi's purchase of electricity carbon emissions also reached a maximum of 1608.92 × 10^4 t in 2010 (Moon and Seo, 2016). Since 2011, the purchase of electricity has been blank, which has led to the historical peak of Shaanxi's thermal power carbon emissions in 2010.

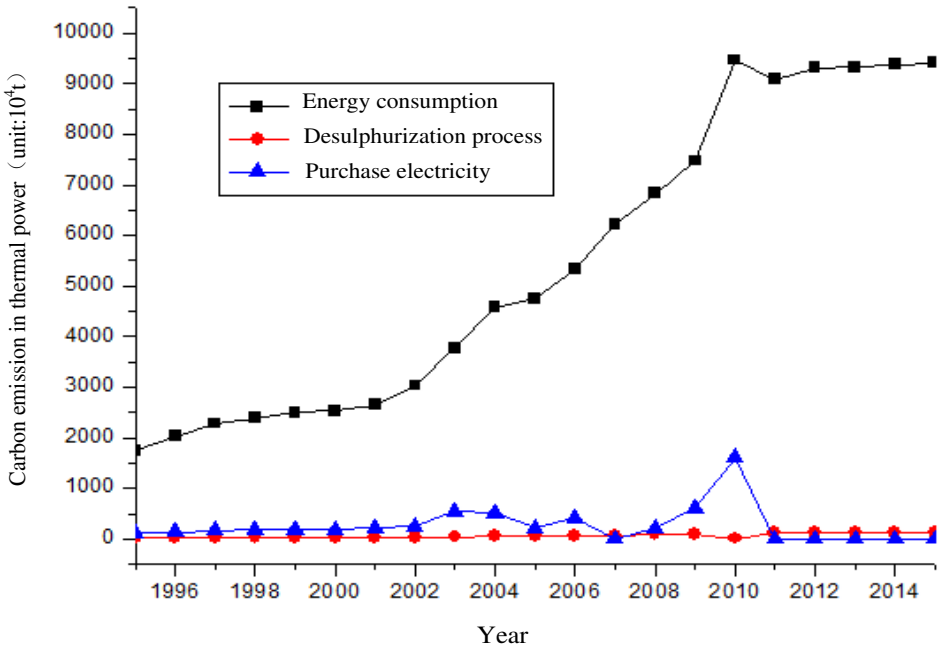

Figure 2. *Carbon emission from Shaanxi Province*

In the comparison of three components of thermal power carbon emissions, energy consumption becomes the key source of carbon emissions again (Moon and Shin, 2017). The total amount of carbon emissions in the desulfurization process is the lowest,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84358448

and the purchase of electricity has been kept low before 2009. In 2010, the purchase of electricity in Shaanxi province increased sharply, followed by a state of "0" in the following years.

For the fluctuation of carbon emission in Shaanxi thermal power industry, the reason is the policy changes (Deleidi, 2017). In the plan of "11th Five-Year" from 2005 to 2010, carbon emission reduction in Shaanxi province is to by the means of "optimize the development of thermal power enterprises", the main measures are to actively improve the power generation technology and to the reduce the coal consumption during the process of power generation. During that period, thermal power generation or province is the main form of power generation (Kalshian, 2016). In the period of "12th Five-Year", the plan clearly proposes to vigorously develop hydropower, wind power and solar power, and carries out the project of "gasification Shaanxi" in an all-round way. So the standard coal consumption per unit energy consumption and thermal power supply were reduced by 16% and 13% on the basis of 2010. In 2011-2015, thermal power generation continued to increase, but carbon emission is under control, indicating that thermal power energy efficiency has been improved. At the same time, the improvement of clean energy production capacity, such as hydropower, has also contributed to the efficiency of carbon emission reduction.

Taking hydroelectric power as an example, the generation of hydropower in Shaanxi Province increased five times from 25.43×10^8 KW˙h in 1995 to112.98×10^8 KW˙h in 2014. The generation of wind power in 2015 was 28×10^8 KW˙h. Average utilization hours of power generation in 2015 were 281 h less than the previous year, 499 h for hydropower, 210 h for wind power and 354 h less for thermal power (Bloom et al., 2016). Therefore, the improvement of energy efficiency and the rapid construction of clean energy such as water conservancy and wind power have promoted the low-carbon development of Shaanxi electric power industry.

In a comprehensive view, although the power generation capacity of hydropower and wind power is increasing annually, the proportion of the total amount of electricity generated by these powers is very small compared with the amount of thermal power generated. The thermal power occupies 90% of the power generation, so currently the thermal power is main the power production in Shaanxi. In 2015, the total installed capacity of China's power generation was149000×10^4 KW, and the total installed capacity of thermal power was 101150×10^4 KW. It is predicted that the total installed capacity of thermal power generation in China will increase to 200000×10^4 KW and 380000×10^4 KW by 2020 and 2050, among which thermal power is also predicted to reach 124650×10^4 KW and 154700×10^4 KW in each year. The increase of the capacity cannot be separated from the capital investment of the country, so in the environment management, the investment in the energy industry and the treatment of industrial pollution will play key roles in the carbon emissions in the related industries (Taylor, 2009).

Model verification and analysis

(1) Model parameter estimation

The stability of time series data is the precondition to ensure the validity of the model. Automatic Direction Finder (ADF) method is used to test the stability of data by unit root (*Table 2*). In the selection of lag order, the optimal lag period is determined to be 2 order based on Chichi information criterion (AIC) and Schwartz criterion (SC).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84358448

Table 2. *ADF stability test*

Variable	ADF statistics	1% critical value	5% critical value	10% critical value	P value	Conclusion
LCE	-0.636	-2.700	-1.961	-1.607	0.2361	Unstable
ΔLCE	-2.910	-2.700	-1.961	-1.607	0.0097	Stable
LEI	-1.602	-2.700	-1.961	-1.607	0.1088	Unstable
ΔLEI	-3.692	-2.700	-1.961	-1.607	0.0018	Stable
LIP	-0.9613	-2.700	-1.961	-1.607	0.2236	Unstable
ΔLIP	-4.299	-2.700	-1.961	-1.607	0.0005	Stable

From *Table 2* we can see that *LCES*, *LEIS* and *LIPS* of the ADF statistics are greater than 10%, which contain unit roots and non-stationary sequences. But the test values of the first difference are less than 1% of the critical value, the difference sequence does not contain the unit root, so the difference sequence is stable, and the data series conforms to the requirement of the construction model. The statistical software EViews7.2 is used to build the model. The result of operation data is substituted (*Eq. 6*), and the vector auto regression model is:

$$\begin{bmatrix} LCES \\ LEIS \\ LIPS \end{bmatrix}_t = \begin{bmatrix} 3.047 \\ -4.290 \\ 0.990 \end{bmatrix} + \begin{bmatrix} 0.596 & 0.319 & 0.109 \\ 0.946 & 0.819 & -0.152 \\ 0.813 & 0244 & 0.167 \end{bmatrix} \begin{bmatrix} LCES \\ LEIS \\ LIPS \end{bmatrix}_{t-1}$$

$$+ \begin{bmatrix} -0.216 & -0.200 & 0.033 \\ -0.117 & -0.163 & 0.095 \\ -0.410 & 0.059 & 0.301 \end{bmatrix} \begin{bmatrix} LCES \\ LEIS \\ LIPS \end{bmatrix}_{t-2} + \begin{bmatrix} \hat{\varepsilon}_0 \\ \hat{\varepsilon}_1 \\ \hat{\varepsilon}_2 \end{bmatrix}_t \quad \text{(Eq.7)}$$

The model (*Eq. 7*) is a variable system of carbon emissions, energy industry development and environmental governance of thermal power plants in Shaanxi. The AR root test of the model is based on the principle that the reciprocal of the model with all the characteristic roots of the model is less than 1. From *Figure 3* we can find that the model has 6 characteristic roots, and the reciprocal of all the eigenvalues of the model is in the unit circle, so the model is stable.

Meanwhile, according to the residual synchronization correlation matrix between variables, we can test the variables have mutual influence, and the correlation coefficients of *LCES* and *LEIS*, *LIPS* are 0.6071 and 0.4259 respectively (Bloch et al., 2012; Rojamary and Uma, 2017). Therefore, in order to explore the response mechanism between the energy industry development, environmental governance and thermal power carbon emission, we need to further cointegration test of the residual sequence of model (*Eq. 7*), in order to understand whether there is a long-term equilibrium relationship between the three variables. The real economic data are often caused by the "unbalanced process", the long-term equilibrium relationship can not reflect the short-term change. So we need to build vector error correction model to analyze what kind of short-term effects the variables will have if they deviate from equilibrium relations.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84358448

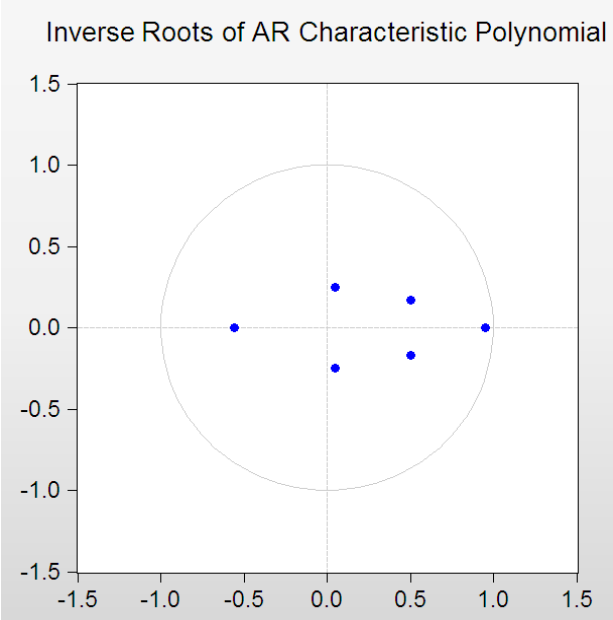

Figure 3. *Unit circle and characteristic root*

(2) Response mechanism of thermal power carbon emissions

Pseudo regression is likely to occur in nonstationary sequences. Johansen cointegration test is used to verify multiple variables, and whether there is a stable relationship between variables (*Table 3*).

Table 3. *Johansen co-integration test*

Number of equations	Characteristic value	Trace statistics	5% critical value	P value	Conclusion
0	0.8225	35.9189	29.7971	0.0087	Refuse
Up to 1	0.3044	6.53111	15.4847	0.6327	Accept
Up to 2	0.0211	0.36107	3.84147	0.5479	Accept

Table 3 shows a co-integration relationship at the 5% level, indicating a long-term equilibrium between energy industry development and environmental governance, and thermal carbon emissions. The cointegration equation is as follows:

$$LCES = 0.3470LEIS - 0.1225LIPS \quad \text{(Eq.8)}$$
$$\text{Standard deviation} = (0.0249) \qquad (0.0252)$$

According to cointegration equation, the elastic coefficient of energy industry development to thermal power carbon emission is 0.3470, that is, the investment of energy industry increases by 1%, the carbon emission of thermal power increases by about 0.35%, and the treatment of environmental pollution is negative (Oluleye et al., 2018 ; Li et al., 2013). It shows that the investment of industrial pollution control can effectively reduce the carbon emissions of thermal power enterprises. At the same time, the error correction term can be constructed based on the cointegration equation (*Eq. 8*) and the error correction model is established (*Table 4*).

DOI: http://dx.doi.org/10.15666/aeer/1704_84358448

Table 4. *Error correction model coefficient vector statistics*

Error correction	D(LCES)	D(LEIS)	D(IPS)
CointEq1	-0.4445	2.0404	-0.0995
D((LCES)-1)	0.3750	-0.7096	1.6479
D((LCES)-2)	0.1972	-0.8650	0.4596
D((LEIS) -1)	0.0163	0.3469	-0.0187
D((LEIS) -2)	-0.1912	0.0351	0.4608
D((IPS) -1)	-0.0544	-0.0020	-0.8466
D((IPS) -2)	-0.1293	-0.0729	-0.5882
C	2.9200	0.6578	39.0031

A vector error correction model (*Eq. 9*) is established from *Table 4:*

$$\begin{bmatrix} D(LCES) \\ D(LEIS) \\ D(LIPS) \end{bmatrix} = \begin{bmatrix} 2.920 \\ 0.658 \\ 39.003 \end{bmatrix} + \begin{bmatrix} 0.375 & 0.016 & -0.054 \\ -0.710 & 0.347 & -0.002 \\ 1.648 & -0.019 & -0.847 \end{bmatrix} \begin{bmatrix} D(LCES) \\ D(LEIS) \\ D(LIPS) \end{bmatrix}_{t-1} + \begin{bmatrix} 0.197 & -0.191 & 0.129 \\ -0.865 & 0.035 & -0.073 \\ 0.460 & 0.461 & -0.588 \end{bmatrix} \begin{bmatrix} D(LCES) \\ D(LEIS) \\ D(LIPS) \end{bmatrix}_{t-2} + \begin{bmatrix} -0.445 \\ 2.040 \\ -0.100 \end{bmatrix} (LCES_t - 0.347LEIS + 0.123LIPS) + \hat{\varepsilon}_t \quad \text{(Eq.9)}$$

Equation 9 the error correction model consists of two parts: one is the short-term effect of itself and other variables, and the other is the effect of deviating from the long-term equilibrium relationship. Among them, -0.445, 2.040 and -0.100 respectively indicate that the carbon emission of thermal power, the development of energy industry and the environmental governance will deviate in the speed and direction from the long-term cointegration. Judging from the absolute value, the development of the energy industry has the fastest speed (Kang et al., 2018; Jiang et al., 2018; Raja, 2017). From the view of direction, the investment of thermal power carbon emissions and the environmental governance have a negative adjustment effect on the cointegration relationship.

Based on the research object of this paper, the error correction model of thermal power carbon emission is emphatically analyzed. Its determinant is:

$$\begin{aligned} D(LCES) = & -0.4445*(LCES(-1) - 0.3470*LEIS(-1) + 0.1225*LIPS(-1) - 5.1705) \\ & + 0.3750*D(LCES(-1)) + 0.1972*D(LCES(-2)) + 0.01630*D(LEIS(-1)) \\ & - 0.1912*D(LEIS(-2)) - 0.0544*D(LIPS(-1)) - 0.1294*D(LIPS(-2)) + 2.9200 \end{aligned} \quad \text{(Eq.10)}$$

From *Equation 10,* we can judge energy industry development and environmental governance can negatively adjust carbon emissions from thermal power plants. Investment in energy industry construction can improve the level of technological

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84358448

productivity, and industrial pollution investment directly promotes the control of various pollution sources. *IPS* lag difference coefficient is - 0.0544 and - 0.1294 respectively, indicating that short-term fluctuations in environmental management can reduce the amount of carbon emissions from thermal power plants. The impact of *EIS* on carbon emissions of thermal power is not stable, but from the view of impact coefficient, it can inhibit carbon emissions.

(3) Analysis of contribution

Co-integration analysis and error correction model estimate the long term equilibrium and short-term impact mechanism between the development of energy industry and environmental governance and the carbon emissions in thermal power plants from a static point of view. The impulse response function can help us understand the dynamic characteristics of the development of the energy industry, environmental governance and the response of thermal power to carbon emissions better.

Figure 4 shows the results of impulse response of carbon emission from thermal power to the energy industry development and environmental governance respectively. The horizontal axis represents the lag period of impact, the vertical axis represents the amount of carbon emissions, the solid line represents the impulse response function, and the dotted line represents the deviation band of positive and negative double standard deviation. According to *Figure 4,* the response of thermal power carbon emissions to energy industry development and environmental governance are similar, reaching the highest value in the second phase. Energy industry investment keeps declining from the third phase until the sixth phase to reach the stability, showing the trend of convergence. Environmental governance has a response fluctuation in the third and fourth periods, and tends to be stable and convergent after the fifth phase. It shows that the development of energy industry and environmental control in Shaanxi Province are effective in the long run, and the carbon emission of thermal power can be slowed down step by step. Variance decomposition is used to analyze the contribution of each structural shock to the change of thermal power carbon emissions (*Table 5*), so as to evaluate the contribution of different variables.

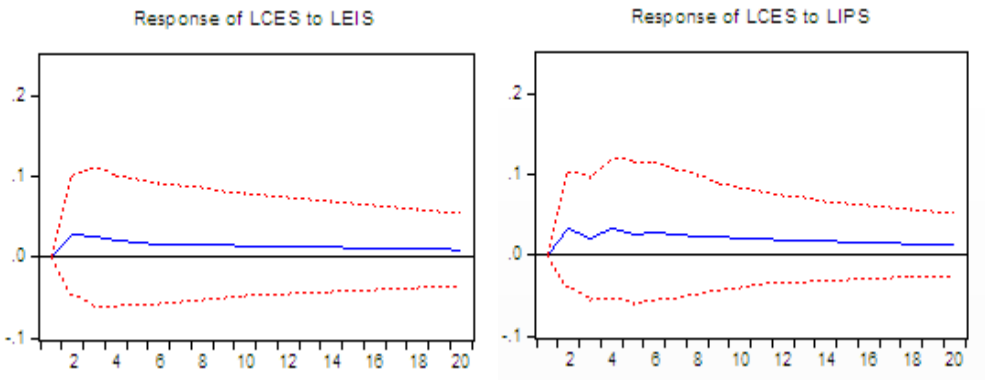

Figure 4. *Impulse response of thermal power carbon emissions to energy industry development and environmental governance*

As can be seen from *Table 5,* the interference response of thermal power carbon emission itself shows the trend of decreasing, and the contribution degree of energy

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84358448

industry development and environmental governance is increasing gradually in the ninth phase. From the second to the fourth, the contribution of the energy industry is higher than the environmental governance, and the improving of energy efficiency can reduce the carbon emissions rapidly. However, due to the phase nature of the technology renewal, the contribution of the energy industry is slowed down from the fifth stage; the contribution of the two is 5% and 6% respectively in the 20 phase. It shows that the development of energy industry and the intensity of environmental pollution control have certain explanatory to the fluctuation of carbon emissions from thermal power plants, which have a greater room for improvement.

Table 5. *Variance decomposition*

Phases	Variance contribution		
	LCES	*LEIS*	*LIPS*
1	100.0000	0.0000	0.0000

20	88.9946	5.1045	5.9009

Conclusions

Economic development depends on the drive of power and energy. Based on the estimated carbon emission values of thermal power in Shaanxi province in 1995-2015, combined with the investment of energy industry and environment governance, the VCE model is constructed to explore the long-term equilibrium and short-term fluctuation response mechanism between the three variables. The following conclusions are drawn:

(1) Shaanxi thermal power carbon emission keeps rising from 1995 until 2010. Because of the drastically increase of the amount of raw coal used in thermal power in 2010, thermal power carbon emissions reaches the peak in the recent 20 years. The development of hydropower, wind power, solar power generation and the reduction of standard coal consumption have promoted the low carbon industry in Shaanxi province.

(2) There is a long-term co-integration relationship between energy industry development, environmental governance and thermal power carbon emissions. Energy industry development and environmental governance can negatively adjust thermal power carbon emissions.

(3) In terms of contribution rate, the contribution rate of energy industry development and environmental governance has gradually increased. The contribution rate of industrial pollution control investment is slightly higher than that of energy industry investment. Therefore, in the future development of Shaanxi thermal power

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84358448

industry, we should adjust the energy structure, make full use of non-fossil energy, and actively optimize and upgrade of industrial structure.

(4) Increase investment in wind power and hydropower to reduce environmental pollution caused by thermal power generation.

Generally speaking, most scholars use the energy consumption method to calculate the carbon emission of thermal power, that is, the energy consumption of thermal power is multiplied by the energy carbon emission factor. On the basis of "energy consumption", this paper takes the desulfurization process and the carbon emission of power transmission into consideration. So it is relatively comprehensive. Industrial pollutants include waste water, waste gas, solid waste, noise and so on, due to the lack of part of the waste gas treatment data, this paper uses the total investment of industrial pollution control to construct the error correction model. Since the average proportion of investment in waste gas control in 2004-2015 was 49.72%, in 2013 and 2014 the annual waste gas investment accounted for 77%, the total investment in environment governance can represent the objective impact of waste gas treatment. Meanwhile, the electricity consumption of specific industries is an important basis for carbon emission reduction of thermal power plants. Based on the analysis of industrial macro data, this paper will further explore the main emission reduction paths of thermal power carbon emissions.

(Received 8th Mar 2019; accepted 21st May 2019)

Abstract. With the development of the Internet, the development of the Internet of Things (IoT) has also been promoted. The IoT is a network of "objects and objects connected." The IoT is based on cloud computing platforms and wireless networks. It acquires data based on sensor groups and conducts decision analysis to change the behavior control and feedback of objects, such as the greenhouse monitoring system studied in this paper. The IoT has subverted the traditional agricultural production model, from the agricultural farming model to the "smart agriculture" production-operation-sales model, which provides a direction for the sustainable development of agriculture in China at this stage. Based on the IoT and Zig Bee wireless sensor network technology, this paper designs a general scheme of an intelligent greenhouse control system based on IoT technology. The greenhouse control strategy was studied using IoT technology and fuzzy adaptive PID control algorithm. The experimental simulation was carried out with MATLAB software. The simulation results show that the optimal control of greenhouse temperature is achieved. The temperature in the greenhouse is always maintained at 16.5 °C -23.0 °C, and the humidity value is always maintained at 68.2% RH-89.3% RH. The test verified that the paper can achieve the expected effect for the greenhouse.
Keywords: *cloud computing platforms, smart agriculture, fuzzy adaptive PID, Zig Bee, MATLAB software*

Introduction

The Internet of Things (IoT) is a new technology that connects every object in a system to make it a whole. Integrating IoT technology into greenhouse control systems can make greenhouse monitoring systems more intelligent and coordinated. The main components of the IoT have the following parts. (1) Storage analysis (Buscheck et al., 2012; Zakeri and Syri, 2015; Dickinson et al., 2017; Patle et al., 2019), the server can receive and display the collected data in real time, and give corresponding processing analysis according to different application environments to achieve effective decision-making. (2) Network transmission (Wertheim et al., 2014; Hale et al., 2016; Choudhari et al., 2018), in order to achieve remote operation of the IoT, the collected information must pass through the sensor gateway and then transmitted to the remote server. (3) Information collection (Timonen et al., 2014; Joseph et al., 2019), in the monitoring area, we should deploy a variety of sensors to collect different data information in the environment, and send data through the transmitting device to form a wireless network. (4) Intelligent control (Kazmierkowski, 2014; Yoh-Han et al., 2016; Li et al., 2017; Jurkowski et al., 2015) combines its module with other controllers to achieve system control. After receiving the sent control command, different submodules will cooperate with each other. (5) Environment (Yahya et al., 2018), the collection and transmission of information is usually done through the environment, first of all, to perceive the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84498464

surrounding environment, and then adjust the information through the corresponding control equipment. IoT technology is the product of the development of new generation information technology, and has been highly valued and widely used in wireless communication applications.

The IoT is generally combined with Zig Bee wireless sensor network technology (Espinosafaller, 2012), which is a short-range, low-rate wireless communication technology. The name of Zig Bee comes from the body language of the bees. When the bees find pollen, they will dance in a zig-zag motion. Through this splay, the message of the pollen's position and distance will be transmitted to the companion. It was formerly known as "Home RF Lite" or "Fire Fly" communication technology for wireless communication at close range (Yusof et al., 2015; Hithnawi et al., 2016; Tianlei, 2019). Zig Bee has the characteristics of small size, low energy consumption, short delay, large network capacity and strong stability. It can be easily integrated into various devices and is suitable for various intelligent control areas (Zheng et al., 2018). Zig Bee's network/security layer is responsible for providing LG WPAN with Zig Bee wireless network formation, network protection and information management services, and defines some common application function interfaces, defining appropriate service interfaces for the application layer to ensure stable operation of the MAC layer (Messo et al., 2013; Jang et al., 2015; Kasim et al., 2019). The application framework layer mainly contains application support layers, Zig Bee device objects, objects provided by the manufacturer, and is used to provide some common application framework models for Zig Bee applications (Fan et al., 2011; Nkwuda et al., 2019). Based on the IoT architecture, Zig Bee wireless sensor network technology has been applied to the greenhouse.

The greenhouse is also called glasshouse. Its main function is to plant crops and to maintain the function of heat preservation and light transmission. In the spring and winter seasons, there are some crops that are not suitable for growing. The greenhouse can artificially provide a growing environment for crops, which in turn increases crop yields. The variety of greenhouses can be divided into many different types depending on the roofing materials, lighting supplies, appearance and heating conditions. From the structure of the greenhouse, it should be a confined space and able to maintain temperature, while also having the function of facilitating ventilation and reducing temperature. Today's modern greenhouses use the computer control system to achieve intelligent control of environmental factors in the greenhouse, which improves the growth environment for crop growth. The greenhouse mainly uses sunshade materials to build some or all of the outer shells, and can build corresponding greenhouses for their crops in cold seasons or in climates where crop growth is not suitable (Messelink, 2014; Snipen, 2015; Azeem et al., 2018).

The main factors affecting the growth and development of crops are: temperature, moisture, light, air, biological factors, etc. (Vakilian and Massah, 2017). These factors do not exist alone, but have a close relationship with each other. The growth of crops is often affected by environmental integration. Crop growth is often affected by complex environments. Among them, factors such as temperature and humidity are the most important, and the stability of the greenhouse ecological environment is maintained by controlling them to maintain the environment in which crops are suitable for growth.

Based on the IoT architecture and Zig Bee wireless sensor network technology (Zhang et al., 2018a; Okpoli, 2019), this paper designs a general scheme of intelligent greenhouse control system based on IoT technology. The application of IoT technology

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84498464

and fuzzy adaptive PID control algorithm combined with greenhouses to analyze the characteristics of greenhouse environmental factors. Just as the above mentioned temperature, moisture, illumination, etc. were verified, the main control parameters in the greenhouse environment were determined. According to the control characteristics of the main factors, the control schemes of various environmental factors in the greenhouse were designed, and the corresponding mathematical models were established. The greenhouse temperature control strategy was studied (Zhang et al., 2018b; Sunny et al., 2018). The experimental test verified that the system design can achieve the expected effect of the greenhouse. Then, based on the characteristics of non-linearity and large hysteresis of greenhouse temperature, a fuzzy adaptive PID controller is designed. According to the actual requirements of greenhouse temperature, the PID parameters are adjusted online to achieve optimal control of greenhouse temperature (Zou, 2018). The simulation results show that the algorithm has good effectiveness in the temperature control process.

Proposed method

Fuzzy PID control algorithm

The greenhouse monitoring system is a group of 15 greenhouses and a complex monitoring system for monitoring the environment. In terms of monitoring, there are mainly indoor temperature, humidity and light. It is also necessary to monitor the multi-parameter complex data such as moisture, pH and even air content in the soil, temperature and humidity of plant foliage. In the control, there are many devices such as fans, heating pipes, sunshades and humidifiers, which need to participate in the environmental change process of the greenhouse.

The fuzzy PID control algorithm can adjust the scale factor, integral factor and differential factor of the conventional PID control in real time according to the pre-designed fuzzy rules to adjust the environmental parameters of the greenhouse. The main core is the PID control method, and the fuzzy control is the method of continuously adjusting the PID parameters.

In practical engineering applications, the most commonly used controller design is the PID controller. It is mainly composed of the proportional coefficient k_p, the integral coefficient k_i and the differential coefficient k_d. The structure of the fuzzy PID controller is shown in *Figure 1*.

Among them, $r(t)$ is the set value of the system, $y(t)$ is the actual measured value of the system, $e(t)$ is the difference between the system set value and the measured value of the system, that is, the deviation, which is generally used as the input of the PID controller, and its calculation formula (*Eq. 1*) is:

$$e(t) = r(t) - y(t) \tag{Eq.1}$$

The output expression of the PID controller (*Eq. 2*) is:

$$u(t) = K_p e(t) + K_I \int_0^t e(\tau) dx + K_D \frac{de(t)}{dt} \tag{Eq.2}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84498464

In the above formula, K_P represents the proportional gain, K_I represents the integral gain, and K_D represents the differential gain. The PID controller adjusts the size of these three parameters to meet the requirements of the control system. According to the fuzzy control process, the precise quantity is transformed into the membership function of the fuzzy set by means of quantization and fuzzification. Fuzzification, by definition, converts the input space of the input domain observation into a mapping in the fuzzy set, essentially finding the fuzzy set membership function of the numerical domain corresponding to the concept.

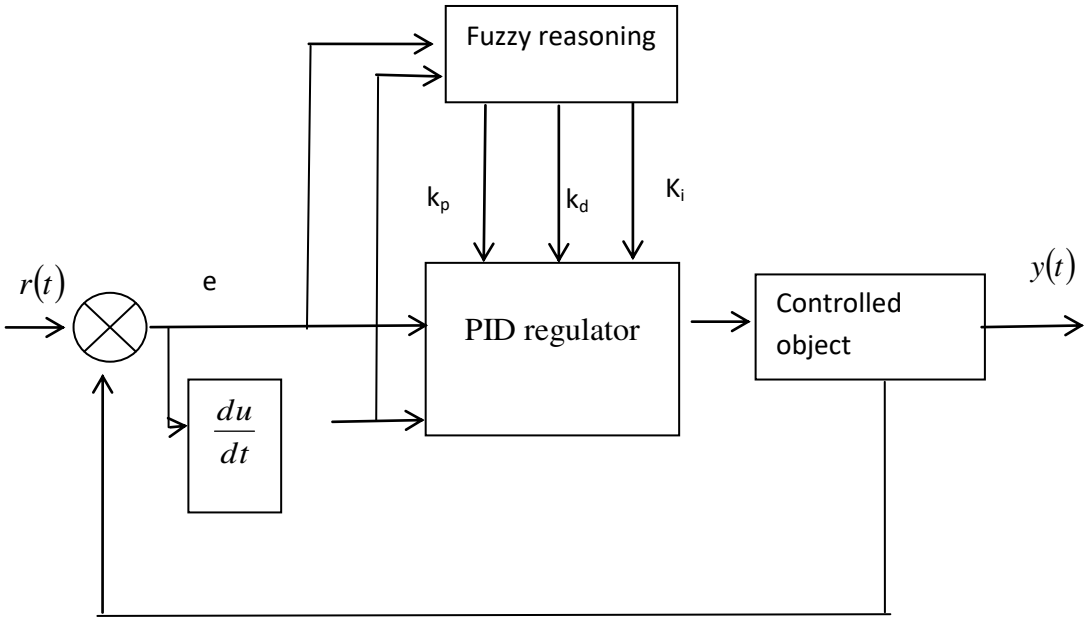

Figure 1. *Fuzzy PID structure diagram*

The tuning of PID parameters must consider the role and mutual influence of proportional integral differential coefficients in different corresponding stages. The traditional PID parameter adjustment experience shows that:

(1) When the deviation is large, a larger proportional coefficient should be taken to ensure the acceleration response speed of the system; in order to avoid the differential saturation caused by excessive deviation change, the control effect is out of range, and the differential coefficient change should be made smaller; The system response is over-adjusted, resulting in integral saturation, and the integral action should be removed;

(2) When the deviation and deviation change rate are medium, take a small proportional coefficient to prevent overshoot, and the integral differential coefficient should take the median value;

(3) When the deviation is small, a smaller proportional coefficient should be taken to ensure that no overshoot is generated, and a larger integral coefficient is taken to improve the dynamic characteristics of the system. The differential coefficient becomes smaller when the rate of change of the deviation is large, and becomes larger when the rate of change of the deviation is small.

(4) When the rate of change of the deviation is large, the smaller the proportional coefficient, the slower the response speed, and the greater the integral strain.

Radial basis function (RBF) neural network data fusion

RBF network belongs to a multilayer forward network. When the BP network is used for function approximation, the weight is adjusted by the negative gradient descent method. This method of adjusting the weight has the disadvantages of slow convergence and local minimum. Since the BP neural network corrects the weight by the gradient descent method in the process of function approximation, this correction method has a slow convergence speed and easily converges to the local minimum point, which has certain limitations. RBF neural networks are superior to BP neural networks in terms of approximation ability, classification ability and learning speed.

The most commonly used RBF is a Gaussian function with two adjustable parameters, the center position and the variance b (the width parameter of the function). When using such a function, there are three sets of tunable parameters (parameters to be trained) of the entire network, that is, the center position, variance, and weight of the output unit of each basis function. Usually, the number of nodes in the hidden layer is selected as the number of training samples, and each node has a center vector of a RBF, which is the input vector of the training sample. Its network structure is shown in *Figure 2.*

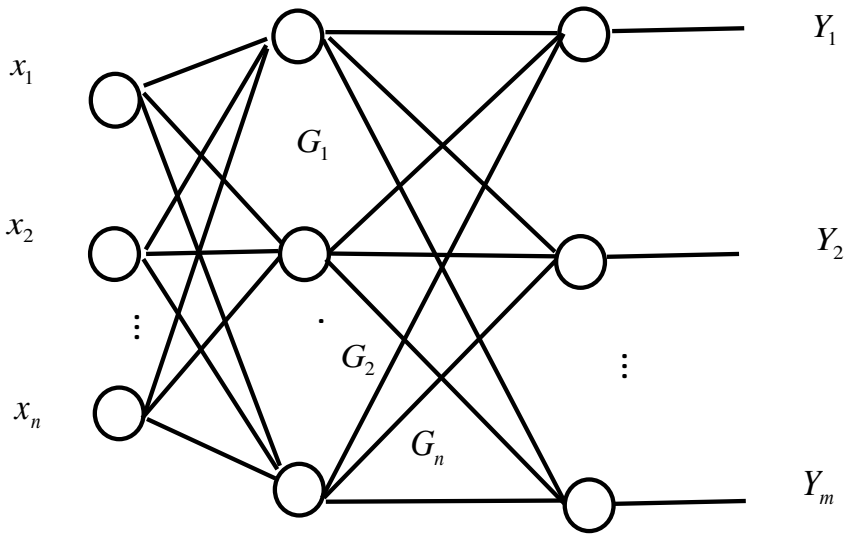

Figure 2. *RBF neural network structure*

The transfer function of the hidden layer node is Gauss function: $f(x) = \exp(-x^2/b) = \exp(-\delta^2 K/b)$, where the parameter *b* controls the effect of the width of the bell-shaped Gaussian curve.

The center value of the Gaussian function of each hidden layer node is $C_K = |C_{K1}, C_{K2}, ..., C_{Kn}|$, $K = 1,2,...N$, and the net input of the hidden node is defined as the Euclidean distance between the input $\boldsymbol{X}$ and the RBF center vector of the hidden node (*Eq. 3*), namely:

$$\delta_K = \|X - C_K\|^2 = \sum_{i=1}^{n} (x_i - C_{Ki})^2 \quad K = 1,2,...N \qquad \text{(Eq.3)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84498464

The output $y_K = f(\delta_K)$ of the hidden layer node represents the extent to which the input mode leaves the center of the RBF represented by the implicit node. The final output layer of the network is a linear combination of the output of the hidden layer node. The output of the node j is: $Y_j = \sum_{K=1}^{N} w_{Kj} \cdot Z_K - \theta = W_j \cdot Z$, where $W_j = [w_{1j}, w_{2j}, \ldots, w_{Nj}]$ is the weight of the output layer and $Z = [z_1, z_2, ..., z_N]$ is the hidden layer output.

The learning process of the RBF network is divided into two phases. In the first stage, the center value C_k and the normalization constant of the Gaussian kernel function of each node of the hidden layer are determined according to all the input samples; in the second stage, the weight of the output layer is obtained by the least square method according to the sample.

In this paper, the RBF neural network model with soil temperature, humidity and soil moisture change per unit time as inputs can effectively predict soil moisture trends and deep soil water content.

Mathematical model of the controlled object

The greenhouse monitoring system is a complex system that comprehensively monitors environmental factor changes and enables the actuator to automatically adjust in real time to the required control algorithms.

In the environmental data monitored by greenhouses, the environmental factors required to monitor crops are multifaceted. The greenhouse group used in this paper consists of 20 large greenhouses. When the actuators act, the environmental parameters change slowly. The greenhouse monitoring system is a multi-parameter, time-varying, nonlinear and hysteresis system. When the system is large, it is inevitable that the external interference factors will increase. The influence of interference factors should be considered, and the parameters such as temperature and humidity, illumination and carbon dioxide that are easy to monitor are directly controlled. The parameters of the equipment that affect each parameter are changed in real time to achieve real-time balance, so that the internal environmental parameters of the greenhouse can promote the growth of plants. This project is a greenhouse group mainly planting peach trees. The growth of peach trees is mainly affected by temperature. Therefore, this chapter takes temperature as an example to illustrate, and other factors are referenced. According to the actual experience of the subject, taking temperature as an example, in the greenhouse temperature, the opening degree of the heating pipe plays the most important role in the temperature inside the greenhouse. At the same time, the plastic film in the greenhouse has the function of heat preservation and heat insulation, and the greenhouse will exhibit convective heat transfer characteristics when the heat changes, and when the temperature changes in a greenhouse, the plastic film has a function of heat storage. When the set temperature value becomes lower and the valve opening degree of the heating pipe is decreased, the hysteresis of slow heat dissipation is exhibited. Because of the large area of the greenhouse, it shows a certain inertia, so it includes the inertia lagging link. Therefore, the transfer function G(s) of the controlled object of the temperature control system of the greenhouse is defined (*Eq. 4*) as the following form:

$$G_{(S)} = \frac{Ke^{-\tau s}}{Ts + 1} \quad \text{(Eq.4)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84498464

The characteristics of the controlled object can be described by three parameters: K (static gain), τ (lag time), and T (time constant).

The static gain K refers to the ratio of the system output to the system input when the system reaches a steady state. It does not change due to other changes. It is only related to the controlled object and is a sign indicating the stability of the controlled object. The larger the K, the worse the stability, and the smaller the K, the stronger the stability.

The lag time τ represents a dynamic parameter describing the hysteresis, and it takes a long time for the controlled quantity to change as the input variable changes.

The time constant T reflects the degree of change of the output variable from the initial state to the steady state after the input signal is applied, reflecting the fast and slow characteristics of the dynamic process of the controlled object (Lu et al., 2019).

Discretization algorithm

The idea of discretization algorithm is to discretize continuous attributes into classification attributes, which provides an important way for the conversion between different types of data. In practical applications, the data set to be clustered contains both continuous attribute data and classification attribute data. But unfortunately, most of the existing algorithms can only process the data of the classification attribute, or the data of the classification attribute is more suitable than the data of the continuous attribute. In order to adapt to this situation, it is required to discretize the data of continuous attributes.

There are many advantages to the discretization of continuous attributes: discretization results reduce the need for storage space in subsequent processing algorithms; discretized data is the specification and simplification of the original data, easier to understand and use; continuous attribute discretization method can be effective to improve the accuracy of data analysis, thus enhancing the robustness to data noise.

Discretization of continuous attributes is a process of transforming quantitative data into qualitative data (Deng, 2019). Firstly, several segmentation points are set in the range of the continuous attribute, then the range of the continuous attribute is divided into discrete intervals, each sub-interval corresponds to a discrete value, and finally the original data is updated to a discrete value. The discretization problem is described as follows:

A decision table is a knowledge expression system consisting of a quad $S=(U,A,V,f)$, where $U=\{x_1,x_2,...,x_n\}$ is the domain and $A=C\bigcup\{d\}$ is the property set. $C=\{a_1,a_2,...,a_m\}$ and $\{d\}$ are the condition attribute set and the decision attribute set respectively, and $C\bigcap\{d\}=\Phi$, V is a set of attribute value ranges, and f is a map of $U\times A\to V$, which represents the value of each object in U on each attribute.

Suppose that for a conditional attribute $a\in C$ and a value field of $V_a=[l_a,r_a]$, where there is a set of points $l_a=c_0^a<c_1^a<c_2^a<...c_{ka}^a<c_{ka+1}^a=r_a$, then this set of points divides the conditional attribute range into: $V_a=[c_0^a,c_1^a)\bigcup[c_1^a,c_2^a)\bigcup....\bigcup[c_{ka}^a,c_{ka+1}^a)$. Here each $[c_i^a,c_{i+1}^a)$ is called an interval, each c_{ka}^a is called a breakpoint, and the set of all breakpoints on the attribute ***a*** constitutes a breakpoint set $Q^a=\{c_{ka}^a\}(I\le k\le m)$ of the attribute a. The ultimate goal of discretization is to find a suitable set Q of breakpoints

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84498464

for all continuous properties. Therefore, $Q = \bigcup Q^a \left(a \in C\right)$ defines a new decision table $S^p = \left(U, A, V^p, f^p\right)$, and for $\vee x \in U$, $i \in \{0,...k_a\}, f^p\left(x,a\right) = i \leftrightarrow f\left(x,a\right) \in \left[c_i^a, c_{i+1}^a\right]$.

The process of discretization of continuous attributes is the process of dividing the range of continuous attributes by using the selected breakpoints. Suppose that an attribute has r attribute values, and then there are $r-1$ breakpoints on this attribute. As the number of attribute values increases, the number of breakable points will increase with the value of the attribute. The process of selecting breakpoints is the process of merging attribute values. The discretization process of continuous attributes can reduce information redundancy and reduce the size of data, thus reducing the requirement for storage space. The discretization of the data can also reduce the complexity of subsequent processing data.

Evaluating the success of a discretization algorithm can be considered from the following three aspects: (1) The completeness of discretization. A successful discretization algorithm needs to be able to discretize multiple continuous attributes because the data set may contain more than one continuous attribute, so the discretization algorithm must be able to handle all of the continuous attributes in the data set rather than selectively processing some of the continuous attributes. (2) The degree of simplicity of discretization results. The number of discretized intervals should be as small as possible. If the number of breakpoints is too large, the recurrence of the data processed by the subsequent algorithm will be increased. (3) The degree of consistency of the data. Discretized results should maintain the original data as much as possible, minimizing the rate of information loss.

Experiments

After completing the software design of the greenhouse remote intelligent control system, the corresponding system debugging is carried out. The successful PC software interface is connected with the corresponding hardware device to test each control function module in the greenhouse to verify the feasibility of the overall system design. This article uses a PC with Windows 10 operating system as the host, and the target is the Tiny6410 development board. Firstly, you need to install the VMware10.0 virtual machine on your PC and then install your own Linux system in the virtual machine. Network training and simulation were carried out using the MATLAB software in the computer to control the temperature, moisture, the concentration of CO_2 and illumination intensity in the greenhouse environment. Compare the data collected by the smart system sensor with the data measured by the humidity meter (Yi, 2018).

Discussion

This paper gives an overall framework considering the limitations of current equipment, the structure of the greenhouse site, and the needs of reality. The greenhouse site is mainly composed of data collection and video surveillance; the server is composed of a data server, a video server and a server, and the three can be on the same server; the client actually refers to the customer and the agricultural monitoring service network that is open to the public (Zeng, 2018). The greenhouse site is connected to the server through a mobile network, and the client and server interact through the Internet, as shown in *Figure 3*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84498464

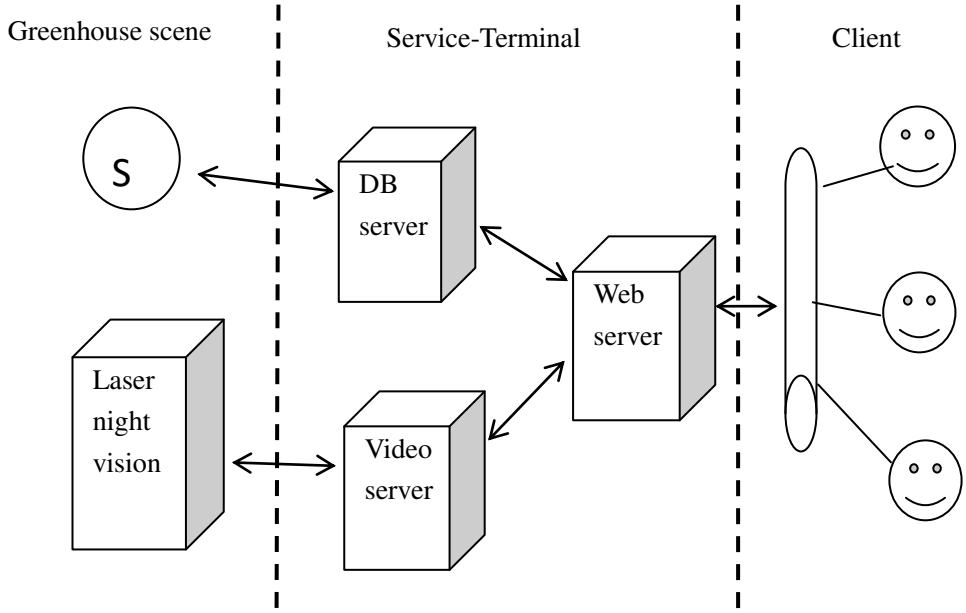

Figure 3. *Overall system framework*

The main environmental factors affecting crop growth in the microclimate environment of greenhouses are temperature, humidity, solar radiation, and carbon dioxide concentration (Shan, 2018). This test mainly collected detailed test parameter values for meteorological conditions such as temperature, humidity, CO_2 concentration and illumination intensity in the greenhouse. Among them, a routing node is set up between each module, which can be regarded as a "data transmission transfer station". When the distance between the module and the coordinator is far, this may result in no way to transmit data. At this time, the routing node plays a role of relaying, providing convenient data transmission channels through the node to ensure the integrity of system data transmission. Therefore, the setting of the node not only ensures the stability of the system control process, but also increases the transmission distance of the data (Zhang et al., 2017).

In order to verify the feasibility of the system, when collecting data on the greenhouse environmental factors, before the experiment, taking into account the accuracy of the reference values, it is necessary to accurately test each sensor module. Various types of sensors are installed in different corners of the laboratory to ensure the integrity of data collection anywhere in the laboratory. When detecting the received data, in order to more intuitively observe the trend of the data, one of the sensors collects the data interface, and the detected value obtained by the interface is compared with the data collected by the actual engineering instrument, thereby verify the validity of the data collection (Lu, 2018). During the interval of every half hour, data of 6 groups of different time periods are collected, and the collected data is detected, and the average value of the data is compared with the actual collected data. The data comparison results are shown in *Tables 1* and *2*.

According to the experimental data comparison analysis table, it can be seen that the temperature sensor used in the laboratory has a temperature error range of ± 0.3 °C compared with the industrial meter, and the humidity sensor used in the laboratory has a humidity error range of -0.6–1.1% RH compared to the industrial instrument. Through

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84498464

the comparison of experimental data, the temperature and humidity sensor measurement error is within a reasonable range, and the data collected by the sensor can be verified to have reliability characteristics.

Table 1. *Comparison of light intensity data*

Serial number	Temperature collected by the sensor °C	Temperature measured by the temperature meter °C	Temperature error value °C
1	17.6	17.7	-0.1
2	19.2	19.1	0.1
3	20.4	20.6	-0.2
4	21.7	21.5	0.2
5	21.7	21.9	-0.2
6	23.2	22.9	0.3

Table 2. *Comparison of humidity data*

Serial number	Humidity collected by the sensor %RH	Humidity measured by humidity meter %RH	Humidity error value %RH
1	41.1	40.4	0.7
2	49.1	48.6	0.5
3	56.8	55.7	1.1
4	68.4	67.8	0.6
5	70.3	71.1	-0.8
6	76.5	77.2	-0.7

For the design of the illumination sensor, an LED light device is used to measure the light intensity in the laboratory. Six sets of data were taken for analysis. The average of the six sets of data was compared with the data collected by the light intensity measuring instrument in the actual project. The results of the comparative analysis of the light intensity data are shown in *Table 3*.

Table 3. *Comparison of light intensity data*

Serial number	Light intensity collected by the sensor Lx	Data measured by the illuminometer Lx	Error Lx	Relative error %
1	1103	1099	4	0.36
2	1356	1321	35	2.58
3	2689	2660	29	1.72
4	4780	4705	75	1.57
5	6643	6556	87	1.31
6	12453	12343	110	0.88

From the comparison of the above experimental data, it can be seen that the light intensity data collected by the sensors in the laboratory is between 0.36 and 2.58% than the light intensity of the actual engineering light intensity equipment. Therefore, the effectiveness of the data collected by this sensor is indicated.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84498464

Similarly, the CO_2 data will also be valid, so the data acquisition is available, and then the experimental results of the fuzzy adaptive PID controller are tested experimentally, and the pre-designed control system is applied to the greenhouse for experiments. In the aspect of temperature and humidity control, the fuzzy adaptive PID control method is introduced. Since the humidity and temperature control design are similar, the temperature is taken as an example for detailed design, and the illumination is controlled by the upper and lower limit values.

For the regulation of temperature and humidity in the greenhouse, a half-year follow-up test was conducted, and the test time was 08:30-15:00 every day. Through the parameter setting module in the system, the crop is set to a temperature range of 19 to 23 °C and a humidity range of 60–90% RH. According to its variation in the growth cycle, the ideal temperature setting is 20 °C, and the ideal humidity setting is 80% RH. In the parameter setting module, the value of the greenhouse degree is determined, and the value is input into the system, and after the corresponding saving process is performed, the intelligent control module is operated. In the one-week tracking test, the data collection interval is 30 min. The data collected on any day is selected for experimental analysis. The changes in greenhouse environmental factor parameter values are shown in *Table 4*.

Table 4. *Indoor environmental parameter values*

Serial number	Time	Temperature value °C	Humidity value %RH	Sunlight illumination lx	CO_2 concentration ppm
1	8:30	19.0	82.3	4312	1312
2	9:00	19.5	82.1	4641	1411
3	9:30	20.1	79.8	5123	1091
4	10:00	20.4	77.2	6001	901
5	10:30	20.7	78.8	9137	721
6	11:00	20.8	76.9	10011	901
7	11:30	21.2	77.8	12404	1047
8	12:00	21.5	80.9	13115	1109
9	12:30	22.1	82.6	10132	1216
10	13:00	23.0	79.3	11478	1110
11	13:30	22.4	77.8	10014	1921
12	14:00	21.1	76.9	9311	1104
13	14:30	20.1	80.2	8121	1114
14	15:00	19.5	83.1	7123	1220

It can be seen from *Table 4* that the temperature value in the greenhouse is always within the range of 16.5-23.0 °C in different time periods, and the humidity value is always kept within the range of 68.2–89.3% RH. According to the data collected from the outdoor, the indoor and outdoor temperature and humidity are compared, and the indoor and outdoor temperature comparison results are shown in *Figure 4*.

The dotted line represents the outdoor temperature change, the solid line represents the indoor temperature, and the blue line represents the temperature set value of 20 °C. It can be seen from the analysis in *Figure 4* that the error range between the indoor temperature change trend and the set value can be kept within ± 4 °C, while the indoor

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84498464

temperature is affected by the outdoor temperature. The increase of the outdoor temperature causes the indoor temperature to increase. A sudden drop in the outdoor temperature causes a decrease in the indoor temperature.

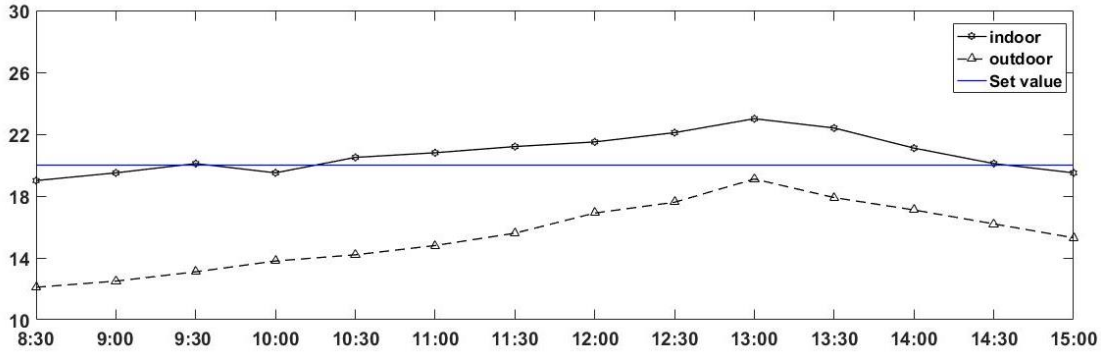

Figure 4. *Comparison of indoor and outdoor temperature*

The indoor humidity comparison results are shown in *Figure 5.*

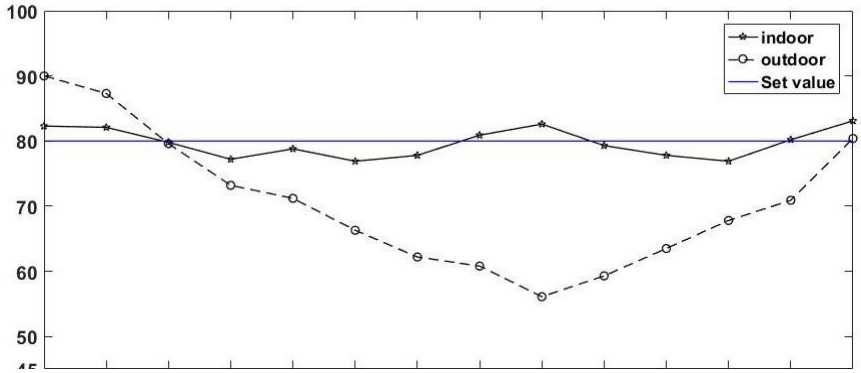

Figure 5. *Comparison of indoor and outdoor humidity*

The blue straight line is set to 80% R, the dotted line is the outdoor humidity, and the solid line is the indoor humidity. It can be seen from the analysis in *Figure 5* that the error range between the change of indoor humidity and the set value is kept at ± 10% RH, the error of humidity can be kept within the set ideal error range. The indoor temperature is increasing when the outdoor humidity is lowered.

Through the comparative analysis of the experimental data, the fuzzy adaptive PID control algorithm can respond to the environmental changes in the system in time, so that the environmental factor control process can have good performance indicators and meet the good control effect.

Conclusions

Greenhouse cultivation in agriculture has brought convenience to improve people's living standards, and has been rapidly promoted and applied. Environmental factors such as temperature, humidity, light intensity, and CO_2 concentration in the greenhouse

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84498464

planting environment have a great impact on crop production. Timely and effective monitoring of these environmental factors will greatly promote production. At the earliest, only the manual monitoring and control methods can be used for greenhouse environmental management. With the development of automation technology and computer technology, monitoring technology has gradually developed and is now applied to the IoT. In this regard, in the framework of the IoT, the Zig Bee node with sensors is placed in the greenhouse to collect data, and the required environmental data is collected in real time. The Zig Bee node self-organizes to form a wireless sensor network, which is passed through the Zig Bee node. Control information is passed to the controller of the actuator to control changes in environmental variables. It mainly monitors environmental parameters such as temperature, humidity, CO_2 concentration and light intensity in greenhouses, as well as remote control of water pump, exhaust, lighting and other equipment in the greenhouse. Finally, based on the characteristics of the greenhouse environment, the mathematical model of the greenhouse was established and the final model optimization was carried out. The mathematical model was established in MATLAB, and the performance of the designed controller was verified by simulation. The simulation experiments show that the fuzzy adaptive PID control algorithm is superior to the conventional PID control algorithm and pure fuzzy control algorithm in the dynamic performance index of system control, and is controlled by the following greenhouse cultivation.

Temperature and humidity control strategy

For example, in the low temperature environment in winter, the principle of controlling the temperature and then controlling the humidity should be followed. After the indoor temperature has reached a certain level, then the humidity is adjusted to meet the set requirements. If the humidity is high and the temperature is low, heating and heat preservation are the main factors. The dehumidification operation can only be achieved when the temperature rises to a specific value. In the summer when the temperature is high, the principle of controlling the humidity and then controlling the temperature should be followed. When the humidity is too low, you should turn on the humidifying device. When the temperature is too high, you need to measure the relative humidity in the room when you need to start the cooling device. The cooling device can only be started when the humidity value is less than a certain setting range.

Light intensity control strategy

The ideal value of the light intensity in the greenhouse is 20,000 to 70,000 lx. The specific implementation scheme is: (1) When the light intensity is greater than 70000 lx, open the outer shade net and close the inner shade net; (2) When the light intensity is between 20000 and 70,000 lx, if the external shading is turned off, the inner shading remains unchanged; if the external shading is turned on, the inner shading is turned off. (3) When the light intensity is less than 20000 lx, the inner and outer shade nets are closed; (4) When the light intensity is below 5000 lx and the time is between 8am and 17pm, turn on the fill light.

It can be seen that the Internet of Things will become a new “smart agriculture” production-operation-sales model, which is subversive to the traditional agricultural tillage. It is conducive to the sustainable development of agriculture in China at the present stage.

(Received 8th Mar 2019; accepted 21st May 2019)

Abstract. Lingdingyang (LDY) is an important navigation waterway for the Pearl River delta (PRD), and an important passage for fresh water and sediments entering the sea. The data and hydrological information, including SSC, current, water level, and bed sediment was collected on July 6-7, 2005 to analyze its characteristics, and sediment transport. The data was entered into a hydrodynamic simulation model used to characterize the processes of sedimentation and morphological evolution of the Pearl River estuary (PRE). LDY was divided into three sub-areas dominated by (1) west shoal area, (2) jet flow area, and (3) saline water area. Navigation engineering and other human activities result in an increase of deposition rate. These characteristics can be greatly accelerated by human activities. Field data and model results indicate that the front system, composed of the shear front and tide incursion front, has an important impact on sedimentation.
Keywords: *fresh water, a hydrodynamic simulation model, navigation engineering, deposition rate, silting characteristics*

Introduction

The Pearl River delta in southern China is one of the most complex deltas in world. It is a typical river network delta including three converging rivers and eight outlets emptying to the sea (Allen et al., 1980; Daniel et al., 2018). The three rivers are the West River (WR), North River (NR) and East River (ER). The eight outlets are the Humen (HM), Jiaomen (JM), Hongqimen (HQM), Hengmen (HM), Modaomen (MDM), Jitimen (JTM), Hutiaomen (HTM), and Aimen (AM). Humen and Aimen are tidal-dominated estuaries. The other six are fluvial-dominated mouths. Humen, Jiaomen, Hongqimen and Henmen, also called the eastern four mouths, empty into the tidal-dominated estuary of Lingdingyang (LDY) bay. LDY is characterized by three shoals and two channels, which refer to the West, Central, and East shoals, and the East, and West channels (Ren et al., 2001; Nwankwoala, 2019). The west shoal is an important buffer between Lingdingyang bay and the eastern three river mouths (JM HQM and HM). It is also a water passage carrying sediment from the three river mouths and a protecting barrier for the Lingding navigation channel.

Tides of LDY belongs to irregular semidiurnal mixing tides, low tides and high tides occurring two times a day, with a tidal coefficient of 0.94 ~ 1.77. The LDY tidal range is less than 2 m, and due to the influence of the trumpet shaped topography, increasing tidal range from outer bay to head. Because of runoff, the tidal range descends from HUM to HM. Outer sea area, greatly affected by tide, ebb duration is approximately equal to flood duration. River outlet, affected by runoff, ebb duration is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84658484

longer than that of the flood. The flood and ebb duration ratio, is 0.93 ~ 1.26 in dry season, 1.05 ~ 1.55 in wet season.

An estuary is a semi-enclosed coastal body of water, which is connected to the open sea, extending to a river to the limit of tidal influence, and within which sea water is diluted with fresh water derived from land drainage (Cameron et al., 1963 ; Van Maren et al., 2016; Dalrymple et al., 1992; Dai et al., 2013, 2012; 2011a; Rahim et al., 2018). The estuary acts as a filter between the land and the ocean (Dai et al., 2011b), and sediment traps, retaining a proportion of their river and marine borne sediment load in the intertidal zone (Dellwig et al., 2000; Sharjeel et al., 2019).

Dynamics of estuarine suspended sediments are very complex and strongly variable over time scales ranging from seconds to years (Dyer et al., 1988). In tidal estuaries, fine sediment dynamics is often related to the Mechanism of turbidity maximum zone (Fettweis et al., 2012; Ferriera et al., 1997; Grabemann et al., 1997; Hume and Herdendorf, 1988; Omini and Akpang, 2018). Subsequently, many literatures studied mainly TMZ and its response to estuarine forces (Jalón-Rojas et al., 2017, 2015; Jia et al., 2013; Chen et al., 1999; Largier, 1992; Shi, 2010). Another important process is estuarine front system, which has been given more attentions to since 1990's (Williams et al., 2015; Li, 2004; Qiao, 2018). Fronts may exert control on the surface and water column sediment and pollutant partitioning and also on the distribution and persistence of bed load transport pathways (Li et al., 2003). Both estuarine circulation and tidal asymmetry are of great importance to the fine sediment processes (Lick et al., 1994), and the two processes are very obvious in front system.

Previous research on sediments of LDY has involved the development of a mathematical tidal model (Lick et al., 1995), physical model (Lu et al., 2005), ground sampling surveys and theoretical analysis (Le Hir et al., 2001; Pinckney and Dustan, 1990; Pritchard, 1967). Estuarine front is an important dynamical process, which exerts an influence on sedimentation (Reeves and Duce, 2001; Sarwar et al., 2019). According to dynamics, there are four types fronts in LDY, tidal intrusion front, head land front, oblique plume front, and shoal front (Ren et al., 2010).

As there are enough gradients of density and velocity in waters, the fronts would be formed. Shelf saline water intruding there that make the difference of sediment dynamic process and sediment grain distribution in spatial, i.e. coarse, fine, and fairly coarse from upper to lower regions (Ren et al., 2006; Sarker et al., 2019).

According to geomorphology, LDY can be divided into three geo-systems, tide inlet of HM (Northwest LDY), fluvial dominated area (West LDY), shelf saline water area (south LDY) (Duck and Wewetzer, 2001). The boundary of these power structures is the interface between two kinds of fronts, namely the continental shelf front and shear front.

This paper focuses on the characteristics and sedimentation, as well as impacts of recent silting. Our goal was to understand the processes associated with front system and human activity leading to sedimentation during the wet season (Jiang et al., 2018). The LDY is dominated by runoff and most sediment comes from eastern outlets of PRD during the wet season. The system of shoals and channels plays an important role in sediment transportation and front systems also result from the geography of the system (Savenije, 2006). Human activity has an enormous impact on sedimentation and this is reflected in system evolution.

Materials and methods

Morphology

LDY is a funnel-shaped estuary located on the east side of the PRD (*Fig. 1*). The width of bay head is 4 km, width of bay mouth is 65 km, longitudinal length is 60 km, and total area 2100 km^2.

The West shoal is located in the west side of the Lingding navigation channel. It receives water and sediments from Hengmen, Hongqimen, Jiaomen, and its area is 185 km^2. In the 1940's, floods scoured out the underwater levee, which gradually eroded then become the North branch. The North branch plays an important role in sediment transportation between the South branch and the Lingding channel (*Fig. 2*). The North branch acts as a flood diversion channel during the flood season, accelerates the flood discharge, and reduces flood pressure on Hongqimen and Henmen. The depths of North branch, South branch, and Lingding channel are 3-5 m, 7-8 m and 15 m respectively. Using the method of dynamic geomorphology, the channel system of the shoal can be divided into flood-dominated channels (flood channel) and ebb-dominated channels (ebb channel) in part B of *Figure 1*. During the dry season, tidal dynamics dominates the shoal, and the net transportation of sediments differs in the two channel types. In the wet season, the entire shoal is dominated by river dynamics and the net transportation of sediments seaward is consistent among the channels. Because the main river bifurcates easterly, the river dynamics weaken. The middle and lower segments evolve from an ebb channel to a flood channel in part B of *Figure 1*.

Hydrology and sediment

The Pearl River has a mild subtropical monsoon climate with relatively abundant precipitation. Mean annual rainfall is 1526 mm and this is concentrated in 9 months which, together, account for 80% of the annual rainfall. SSC of the Pearl River is the lowest of the seven major China rivers. However, sediment transport capacity from runoff is large. Average sediment transport capacity is 85.7 million tons, which is the third largest amount for China rivers. The average SSC of Gaoyao station of West River is 0.320 kg/m^3.

PRE has an irregular semidiurnal tide, and the tidal range is small. The mean tidal range is 1.60 m and the maximum tidal range is 3.36 m. The PRE is a typical weak tidal estuary. Flood tide (current that moves toward shore) duration lasts 7 h and 20 min and mean ebb duration lasts 5 h and 30 min. The flood tide duration during the wet season is shorter than that in the dry season.

LDY is a micro-tidal estuary. With a funnel-shaped topography, the tidal energy converges and tidal range increases from mouth to head. Average ranges of Chiwan, Sanbanzhou, and Dahu stations were 1.36 m, 1.59 m, and 1.69 m respectively. Tides are irregular semidiurnal mixed with ebbing and flooding twice a day. SSC during the wet season is larger than that of dry season, and SSC varies with ebb and flood (*Table 1*). In the wet season, fine sand is the major component of bed sediment at Hongqimen and Jiaomen. Particle size at these two outlets ranges between 0.1 mm and 0.5 mm, which occupies 90% of the total. The bed sediment of Humen is composed of medium coarse sand with a median particle diameter of 0.244 mm.

Data

We used the data of the second phase project of Zhongshan port. Synchronous hydrology sediment testing was completed by the hydrology and Water Resources Survey Bureau of the Yangtze River Water Conservancy Committee.

The survey period included tidal cycles from July 6 to July 7 in 2005. Fourteen boats are used for fixed-point measures, and measured items included velocity, SSC, and salinity. Three water level stations were established. The scale of the topographic survey was 1:5000. *Figure 2* shows the sites of the measuring stations and bed sediment sample points.

Hydrological testing at fixed stations was done by using a conventional current meter that was fixed to a boat. SSC samples were obtained by using the 2000 CC horizontal type sampler once per hour. If the depth was greater than 5 m, we used the six point method (surface, 0.2 h, 0.4 h, 0.6 h, 0.8 h, bottom), or the three point method (0.2 h, 0.6 h, 0.8 h).

Suspended particles were analyzed using a centrifugal sedimentation particle size distribution instrument. We sampled bed sediments for particle size analysis using a cone type sampler, ensuring that the dry weight exceeded 50 g. The distance between two samples sites is less than 3 km. Analysis of bed sediment was done with a sonic vibration automatic sieving particle size analyzer and wide particle size analyzer. Salinity was determined using an electrode salinometer.

Mathematical model

The paper used Delft3D to model current, salinity, sediments. Delft Hydraulics has developed a unique, fully integrated computer software suite for a multi-disciplinary approach and 3D computations for coastal, river and estuarine areas.

It can carry out simulations of flows, sediment transports, waves, water quality, morphological developments and ecology. It has been designed for experts and non-experts alike. The Delft3D suite is composed of several modules, grouped around a mutual interface, while being capable to interact with one another. Delft3D-FLOW, which this manual is about, is one of these modules. Delft3D-FLOW is a multi-dimensional (2D or 3D) hydrodynamic (and transport) simulation program which calculates non-steady flow and transport phenomena that result from tidal and meteorological forcing on a rectilinear or a curvilinear, boundary fitted grid.

In order to model the hydrodynamics and cohesive sediments, a model covering the eight outlets and outer sea was established. The computed area was divided into 2050000 cells. The smallest side length in these cells was 10 m, and the largest was 1000 m. It is depth chart of LDY (*Fig. 3*). The model setup is shown in the following figure (*Fig. 4*), Model correction in the following figure (*Fig. 5*). It is the main modelling parameters for cohesive sediments (*Table 2*).

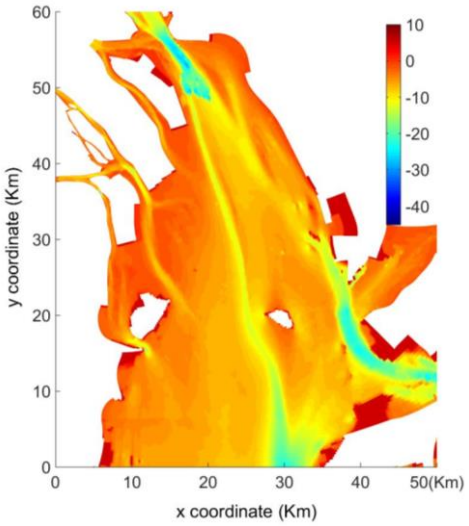

Figure 3. *Depth chart of LDY*

Table 2. *Model parameters for cohesive sediments*

Parameter	Number	Units
Setting velocity	0.06-0.20	mm/s
Bed shear stress of sedimentation	0.30-.0.50	N/m^2
Bed shear stress of erosion	0.55-0.80	N/m^2
Erosion parameter	1.2e-4--1.8e-4	$kg/m^2/s$
Initial layer thickness	0.1	m

Results

Hydrodynamic characters

In wet season, LDY is dominated by discharge from runoff, and Salinity of LYD except a small south fraction is zero. The chart of modeling current field of model is shown in *Figure 6*. In flood tide duration, the velocity is very small in LDY, even no flood tide current in outlets. But, the ebb tide flow is very large, reaching above 1.0 m s^{-1} (*Fig. 6*).

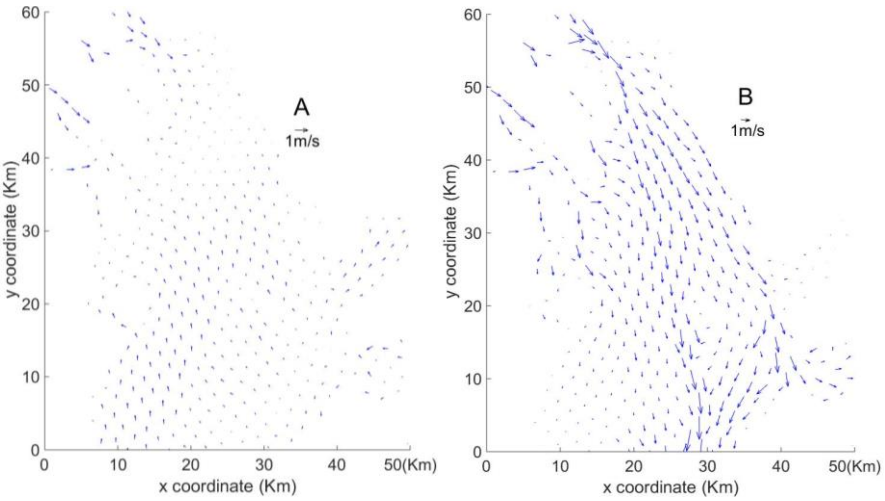

Figure 6. *Current field of model (A: flood tide, B: ebb tide)*

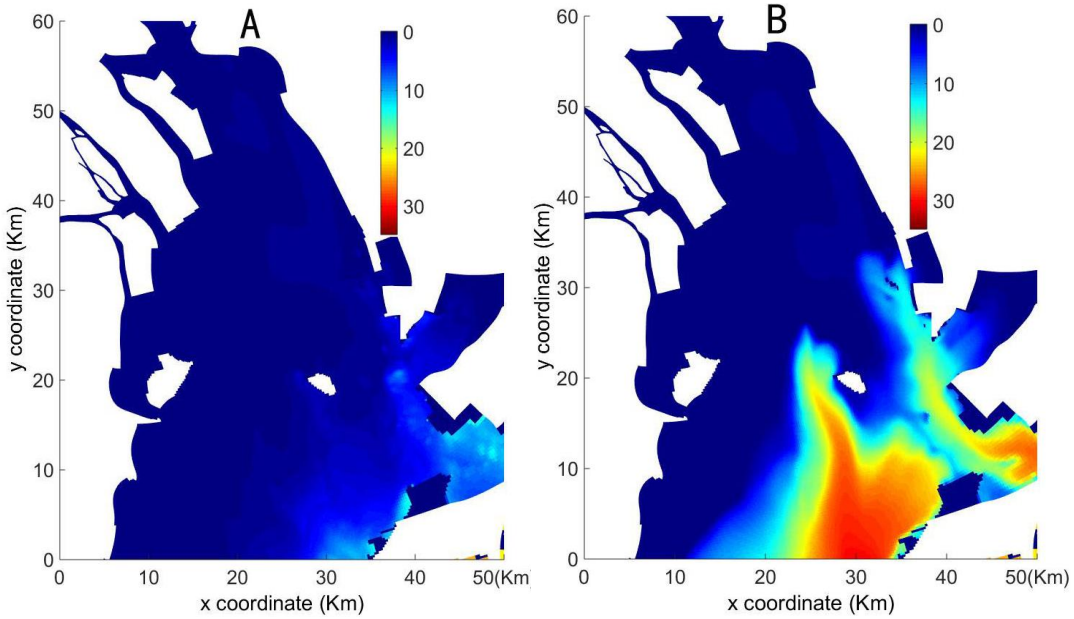
High saline water from continental shelf intruders along both sides of Hong Kong Island to LDY, and salinity of lower layer accounts for over 30‰ (*Fig. 7*). The tide intrusion front (also tide intrusion front) comes into being due to the large gradient of salinity and density. However, because of the difference of velocity and landforms due to shoal and trough in west shoal border zone of LDY, another front is generated.



http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84658484

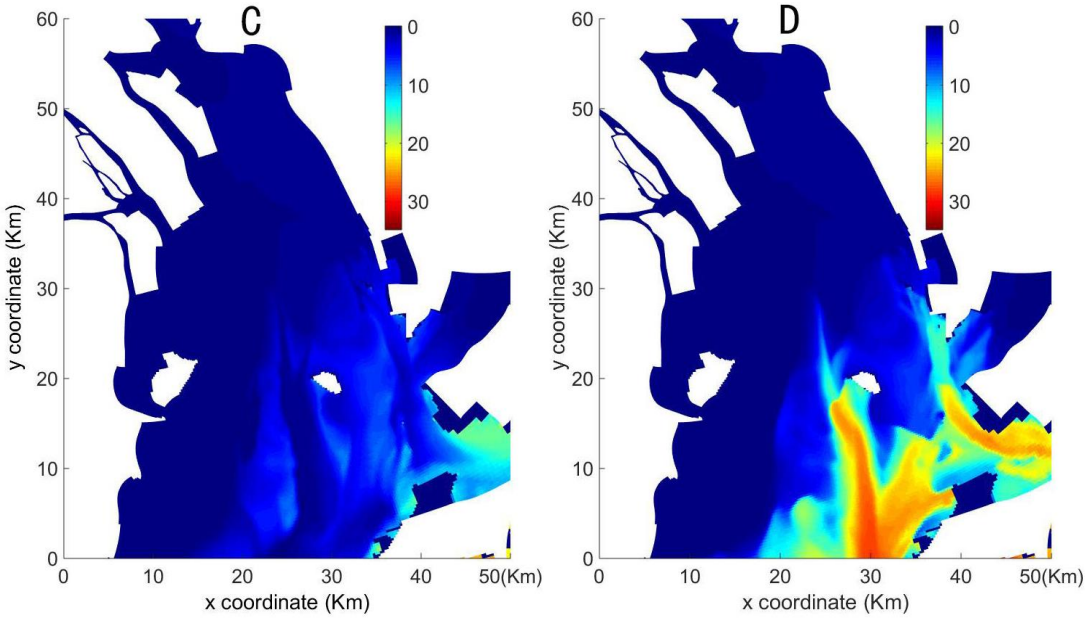


Figure 7. *Salinity charts (‰; A: surface, flood, B: bottom, flood, C: surface, ebb, D: bottom, ebb)*

Based on the analysis above, the LDY can be divided into three type sub-areas of dynamic sedimentation, west area, jet-flow area, salt water area (*Fig. 8*). The west area is dominated by discharge from JM, HQM, HM, and flow seaward along West shoal into outer sea. Salt water area refers to the southeast of LDY, and the main characteristic is high salinity and density, resulting in three dimensionality of flow. Large part area of LDY is affected by jet-flow (Shilun, 1994) due to ebb current from HUM. The jet-flow structure is complicated, and evolves into plume flow in the end of jet-flow, which is suffered from salt water from middle and lower layer due to continental shelf water intrusion. So, fresh water from HUM flow seaward through upper layer.

Three dynamical structures interact through front (*Figs. 9* and *10*), resulting in control of water and sediment movement, also control the stability of main channel and sedimentation balance. According to the salinity, these dynamical structures correspond to three water mass, the fresh water, diluted water and sea water. The core part of the estuary is controlled by diluted water.

The diluted water mass is under the action of runoff discharge, and develops seaward in flood season. During the dry season, it recedes deeper into the land. In the dry season, the length of diluted water can reach 83 km, while the flood season is below 40 km. In above section of stagnation point, the kinetic is barotropic, and the net material is to transport seaward. In lower section of stagnation point, the pressure is baroclinic, and net material transport landward.

According to the surveying data, LDY is dominated by seaward flow. The velocity is faster and the duration is longer during the ebb period than in flood tide. The velocity of the middle and lower layers is greater than the surface downstream from the West shoal during the flooding period. During ebb, the surface velocity is the greatest. During both flood and ebb, the surface velocity upstream is greatest in surface, middle and bottom layers. Because flows from Lingding channel, North branch, and South branch of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84658484

Jiaomen converge in the West shoal, surface velocity increases seaward during ebb. The majority of LDY was dominated by freshwater. Their middle and bottom layers were dominated by highly saline water from the shelf in the summer, especially during the flood period. The bottom maximum salinities of stations 4, 10 and 9 were, respectively, 22‰, 17.1‰, and 7.8‰ during the flood period, and the salinity of the rest stations was zero. *Figure 7B* and *D,* illustrates the lower layer salinity of the lower section of the LDY. During the flood period, a salt wedge intrudes landward, and the salinity structure is highly stratified. This is referred to as the "tide inrush front" (Simpson and Turrell, 1986; Oyedotun, 2019).

Front system and suspended sediment transportation

Sediments, moving from river to sea, must pass through three hydrodynamic sections. The three sections are the river, near mouth, and estuary. The downstream limit of the river section is the tidal limit (Sanshanjiao), the near mouth section is the area between the tide limit and the tidal current limit (near the 21st Stream). The estuary section is the area between the tidal current limit and the front of the shelf water (near Hong Kong). These three sections play important roles in sediment transportation and deposition. When flow enters the tidal limit, the flow will be surfing from the reaction force of the tide and the longitudinal gradient of surface level will flatten out and flow velocity will decrease (Nouaim et al., 2019). As a result, the relative coarse silt group of suspended sediments will settle on the bed and because the transportation force has decreased, the coarse sand and gravel will be deposited. Field data regarding the first settlement ratio is not available but in the Yangtse River estuary, 10-15% of suspended sediment will be deposited on the bed (Simpson and Nunes, 1981). Sediment that enters the estuary section suffers from bidirectional flow during flood and ebb periods. Sediment that is temporarily deposited on the bed during floods erodes due to ebb currents. Flow, which enters the West shoal, diffuses on the shoal surface, velocity declines and sediments deposit on the bed. The two flows from the West shoal and west channel converge at the edge of the West shoal and form a shear front (*Figs. 11* and *12*). Because of significant salt water invasion into the LDY from the middle and bottom layers, tide invasion fronts become important in the southeast area of LDY. Sediments in the front will settle again. According to the July 2005 data, about 3% of the total suspended sediment deposits, and the majority of the bed load is trapped. The ancient riverbed sand can be transported to the estuary from human agitation resulting from sand mining. SSC chart is shown in *Figure 11,* which show clearly transportation trend of suspended sediments in three water mass.

The silting content is high, and Mean percent content of stations 1, 5, 6, 7, 8 is respectively 73.8%, 70%, 68.2%, 66.9% and 66.5%, indicating that the percentage of silt decreases seaward (*Table 3*). Average silt percentage of stations 9 and 10 was 65.5% and 66.1%, respectively, which is less than that of the West shoal. Silt content of suspended matter decreases seaward indicating that coarse sediments settle gradually

during the transportation process, and suspended sediment becomes bed load. Surface velocity at ebb of stations 5, 6, and 4 increased longitudinally and the mean silt content decreased. Median diameter of bed sediment decreases seaward. Median particle diameters at stations 6, 7, 8 and 4 were 0.071 mm, 0.068 mm, 0.026 mm, and 0.026 mm, respectively. The latitudinal change rule of median diameter and percentage of sand in bed sediment is related to the longitudinal variation. Median diameter and percentage of sand decreased from the West shoal to the west channel. *Figure 12* is the SSC section of west channel, which illustrate that suspended sediments is transported through the upper layer of salt water area. Front systems and sediments transportation are shown in *Figures 13* and *14*.

Action of front systems on sedimentation

Estuaries are located in the transition zone between rivers and the sea, and have zones or fronts which have significant impacts on sedimentation and pollutants. There are at least three types of fronts in LDY: tidal intrusion, headland, and shoal fronts (Talke et al., 2009). Based on charts of currents, landforms, and measured data, we propose the use of shear front instead of shoal front. The physical significance of a shear front is clearer than that of a shoal front. *Figure 7* shows that there is salt wedge southeast of the LDY, which varies with ebb and flood (Yang, 2018). In fact, this is the tide intrusion front. Therefore, the tide intrusion front and the shear front become the main front system of the LDY. Fronts are formed by several mechanisms, including tidal intrusion, axial convergence, advective flow, and flow separation. Fronts act as temporary barriers, inhibit exchange of water masses, and entrap free particulate materials. We suggest that, in terms of suspended sediment transport through and within estuaries that are characterized by fronts, such features should be considered as "sieves" in the estuarine sediment transfer system (Townend, 2005). The "sieve" or trapping function for sediment is achieved by front systems of the estuary. Sediment transport characteristics of shear fronts include: (1) in a northerly direction, the surface water and sediments move downward, while in deeper water the sediments move upward; and (2)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84658484

in a westerly direction, the surface water and sediments move into the channels, while in deeper water the sediments move into the shoals (Townend, et al., 2000). Therefore, the shear fronts between the shoals and the channel act as a barrier affecting the sediment deposition into the deep channel from the shoals (Uncles and Stephens, 1993). Fronts play an important role as barriers, traps, and filters for sediments. Sediments from the North branch will be trapped in an area near the shear front. The sedimentation rate of the region with 3-6 m depth is greater than in the region with depths > 6 m. But, the shear front of the West shoal also has an erosion effect. During ebb periods, double-spiral circulation forms on both sides of the shear front, and, driven by longitudinal current, flows seaward with velocity greater than 1.0 m/s. The spiral flow will effectively scour the bed near the Lingding navigation channel. The secondary spiral flow associated with the front had the greatest influence on the lateral distribution of finer grains and the least influence on the lateral distribution of coarser grains (Uncles et al., 2006). So, the sedimentation rate of areas with 6-8 m depths is less than that of areas where the depth < 6 m (*Fig. 15*).

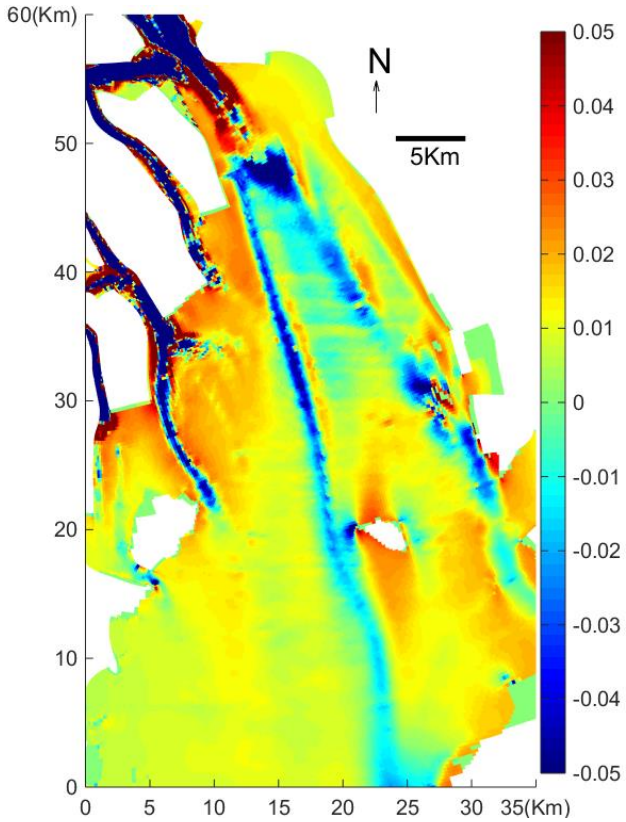

Figure 15. *Depositional thickness of suspended sediment (m, half a year, from model result)*

The tide intrusion front is located southeast of the LDY and varies with ebb and flood. The front penetrates landward under the water during flood, and the salinity structure is highly stratified. In addition, the front retreats seaward during ebb period. The formation and development of the tide intrusion front is opposite to that of the shear front. The functions of the tide intrusion front are similar to that of the shear front, which provides a barrier, filters, and traps material. However, the transportation function of this front is easy to underestimate. The West shoal is an important passage

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84658484

for fresh water, sediments, and pollutants. Materials from land are transported to sea along the front. The tide intrusion front also possesses the function of transportation, not by transport landward under water, but also transport seaward by the fresh water of the middle and top layers (Yang, 2018).

Discussion

Natural sediment sinks have been removed in many estuaries and tidal basins, and the resulting loss in accommodation space likely led to an increase in the suspended sediment concentration (Winterwerp et al., 2013). However, channel deepening also leads to higher SSC levels (Kang et al., 2018; Wu et al., 2003). Larger engineers such as reclamation, port construction, result in a reduction of the tidal prism, leading to smaller tidal flow velocities in the tidal channels, thereby promoting sediment deposition (Zhifu, 1995). Human activities have got attentions in Pearl River estuary (Zhifu, 1994) and Yangtze River estuary.

Economic development and human activity have had a large impact on the LDY estuary. The main human activities of LDY include reclamation, port construction, mining of bed sand, and channel dredging. The reclamation area includes 204 km^2, which is 17% of the total area. Bed sand harvesting is up to 200 million m^3, which is equivalent to 8% of the capacity of LDY.

Human removal of bed sediment for building construction has deepened the riverbed. After 2000, large-scale projects such as construction of the Lingding navigation channel and construction of the Nansha port near the West shoal will increase SSC. Because the front system of the West shoal can trap river-borne and sea-borne sediment, the sedimentation rate has increased after 2000 (*Table 4*). Although there were no human construction projects on the West shoal, the indirect impact of upstream and downstream projects on sedimentation has been significant.

Table 4. *Sedimentation rate of west shoal*

Year	Depth	Area (km^2/a)	Volume (Ten th. m^3/a)	Sed. rate (cm/a)

Conclusion

The LDY is a complex tidal bay, which has two main front systems, tide intrusion front and shear front. These two front systems divided the LDY into three dynamics area, west shoal area, jet-flow area, salinity water area. Sediment transport and deposition processes of the three areas differ (Dager, 2017). Silting characteristics include shoal silting and channel deepening. Sediment transportation and sedimentation are subject to front systems, which sedimentary facies is corresponding to. Human activities such as river estuary regulation and channel dredging increase SSC, which leads to promote sediment deposition. The amount of sediment deposition has greatly increased since 2000.

It can be seen that human activities such as estuary regulation and river dredging are important factors for increasing sediment deposition, and the increasing sediment deposition will make the imbalance of sediment transport more prominent. In order to improve navigation conditions and reduce siltation under sluice gates, measures such as drainage, mechanical dragging and tidal scouring can be taken.

(Received 8th Mar 2019; accepted 21st May 2019)

Abstract. *Decapterus maruadsi* is a small pelagic fish and is of great significance to the ecosystems in the northern South China Sea. We collected and analyzed the data recorded by the fishing vessels in the western Guangdong waters in winter and summer and remote sensing data including sea surface temperature (SST), chlorophyll a concentration (Chl a) and sea level anomalies (SLA) from 2011 to 2015, using generalized additive model (GAM). Results showed that the catch per unit effort (CPUE) of *D. maruadsi* in the western Guangdong waters had a significant positive linear correlation with longitude, and the *D. maruadsi* populations were concentrated in the east of the study area. The total explanation of *D. maruadsi* CPUE in GAMs was 47.40%, among which, the factors year, month, lunar phase, latitude, Chl a, SLA and water depth explained 9.30%, 13.50%, 6.50%, 1.90%, 1.70%, 4.60%, and 9.90%, respectively. The *D. maruadsi* populations in the study were concentrated in the area of latitude 21°N, Chl a 0.1- 0.5 $mg \cdot m^{-3}$, SLA -0.05 m and water depth 80 m. Results of this work will help in understanding the environmental factors affecting *D. maruadsi* distribution in the western Guangdong waters.

Keywords: *generalized additive model, environmental factors, habitat suitability index (HSI), fisheries, main spawning habitats*

Introduction

Decapterus maruadsi, a pelagic fish in the family Carangidae (Perciformes), lives in warm waters, and is widely distributed along the coasts of Southeast China (Deng et al., 1991). It is one of the major species captured by pelagic trawls and light luring seine fishing vessels (Zheng et al., 2014; Thanh and Do, 2018). *D. maruadsi* has a short lifespan and fast growth and reproduction rate, and as an R-selected species, it is susceptible to fishing intensity and marine environment (Chen et al., 2003; Dai, 2017; Austin et al., 2018). The populations of *D. maruadsi* in the northern South China Sea shifted towards younger age and smaller size due to overfishing since the 1990s (Lu, 2000; Chen and Qiu, 2009). But the *D. maruadsi* resource is beginning to recover due to summer fishing moratorium and other fishery industry restructuring policies in recent years (Chen et al., 2010; Geng et al., 2018; Abija and Nwankwoala, 2018). As a small

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84858499

pelagic fish, *D. maruadsi* has an important impact on the ecosystem output of the northern South China Sea (Chen and Qi, 2009). The sea area off western Guangdong is one of the main spawning habitats for *D. maruadsi* in the northern South China Sea (Chen et al., 2003), so it is of great significance to investigate the temporal and spatial distribution of this species in this area. At present, the existing studies on *D. maruadsi* are mostly focused on its biology (Jiang, 2012; Huang, 1995; Da, 2017), resource assessment (Chen and Qiu, 2003; Jamil et al., 2018), etc. Acoustic assessments indicate that carangid fish such as *D. maruadsi* along the east coast of Peninsular Malaysia are concentrated at 40-60 m below the ocean surface (Hashim, 2017; Tao, 2018). The studies that assessed the relationship between *D. maruadsi* fisheries and environmental factors in the northern South China Sea in different seasons based on the habitat suitability index (HSI) model indicated that chlorophyll a (Chl a) concentration is the determinant of the distribution of *D. maruadsi* fisheries in spring. In recent years, due to the increase in offshore fishing intensity, changes in ecological environment and climate, the resource stock and spatial distribution of many marine species have changed, which has a profound impact on fish habitats and ecosystems. Therefore, evaluating the correlation between *D. maruadsi* distribution and marine environmental factors in western Guangdong is important for the sustainable development of fisheries.

The relationship between fishery resources and marine environment is very complicated, as it is non-linear and non-additive (Stenseth et al., 2002, 2004; Dingstor et al., 2007; Tianlei, 2019), and the use of different observational scales can cause large differences in results (Fauchald et al., 2000). Therefore, it is crucial to choose a suitable method for quantitative analysis of the relationship between fishery resources and the marine environment. As the nonparametric extensions of generalized linear models (GLMs), generalized additive models (GAMs) provide flexible method for uncovering the nonlinear relationship between response and predictor variables (Hastie and Tibshirani, 1990; Jegatheesan and Zakaria, 2018), and thus are suitable for exploring the nonlinear relationship between fishery resources and marine environment (Stoner, 2001; Agenbag, 2003). GAMs not only can be used for different species or different seas, but also can be combined with a variety of environmental factors to better reveal the relationship between environmental factors and the variation, spatial distribution, temporal distribution of fishery resources (Venables et al., 2004; La et al., 2016; Bacha et al., 2017). The studies based on GAMs have shown that zooplankton biomass and the location of oceanic fronts have an impact on the distribution of *Clupea harengus* in the vicinity of the Shetland Islands (Maravelias et al., 1997). The spatial distribution of *Loligo spp.* and *Tachysurus* in the Arabian Sea was well predicted based on the data of sea surface temperature (SST), chlorophyll a (Chl a) concentration, photosynthetically active radiation (PRA) and sea level anomalies (SLA) in the study of Solanki (2017). The interaction between upwelling index, year and latitude had a great influence on the spatial distribution of sardines in Mauritanian waters (Bacha et al., 2017; Abdullah and Rahim, 2018). Wang et al. (2018) reported that prey density, water depth, bottom water temperature and distance to shore had a great influence on the distribution of Chinese white dolphin in western Pearl River Estuary.

In this study, generalized additive models (GAMs) were used to quantitatively analyze the main environmental factors affecting the spatiotemporal distribution of *D. maruadsi*, and to explore the formation mechanism of *D. maruadsi* fishery in the western Guangdong waters, and to provide a theoretical basis for fishery management and marine protected area planning under climate changes.

Materials and methods

Data collection

Fishery data

The data of *D. maruadsi* resource were from the observational records of large-scale light-luring seine fishing vessels in western Guangdong waters (19.75° to 21.75°N, 111.25°E to 113.75°E) in January, February, August and September from 2011 to 2015. The data (including working time, voyage, longitude, latitude and fish catch) were generated at a spatial resolution of 0.5° × 0.5° in latitude and longitude (one fishing area), and summarized by day (*Fig. 1*).

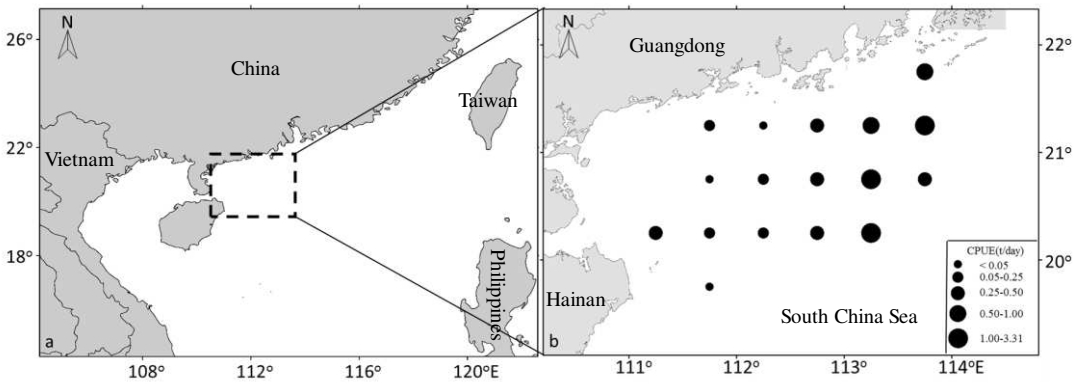

Figure1. *Distribution of D. maruadsi CPUE in western Guangdong waters*

Environmental data

The remote sensing data including chlorophyll a concentration (Chl a), sea surface temperature (SST) and sea level anomalies (SLA) were used in this study. Among them, Chl a and SST were from MODIS Aqua Level 3 data products (https://oceancolor.gsfc.nasa.gov), with a temporal resolution of one day and a spatial resolution of 4 km. SLA data were from CTOH/LEGOS website (https://www.aviso.altimetry.fr/en/home.html) with a temporal resolution of one day and a spatial resolution of 0.25°. Water depth data were acquired from Google Earth, with a spatial resolution of 70 m (Jaimes, 2017).

Data processing

CPUE (catch per unit effort) calculation (Campbel, 2004)

$$CPUE = \frac{c}{f} \quad \text{(Eq.1)}$$

where, CPUE is the average daily *D. maruadsi* catch by a vessel (unit: tons per day), c is daily *D. maruadsi* catch in a 0.5° × 0.5° fishing grid (unit: tons), *f* is the number of operations in a 0.5° × 0.5° fishing grid (days).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84858499

Remote sensing data fusion (Fu et al., 2009)

The remote sensing data (Chl, SST and SLA) of the study area were extracted and merged using the formula as follows:

$$Average_j = \frac{\sum_{i=1}^{m} value(i)_j}{m} \quad \text{(Eq.2)}$$

where, $Average_j$ is the mean value of fused environmental data (Chl, SST and SLA) in fishing grid j, j is a 0.5°×0.5° fishing grid, m is the number of pixels of environmental data (Chl, SST, SLA) in fishing grid j, $Value(_i)$ is the value of a single pixel in fishing area j.

GAM analysis

Generalized additive models (GAM) focus on exploring data nonparametrically, compared to generalized linear models (Feng, 2007; Sudhakaran et al., 2018). In order to avoid excessive computation and over-fitting, the linear correlation between *D. maruadsi* CPUE and each predictor variable was measured according to Pearson correlation coefficient R before GAM was constructed (Li, 2007; Le, 2017). When $R > 0.5$, the predictor variable has a linear relationship with *D. maruadsi* CPUE, and should be removed from the model. The R mgcv package was used to fit the GAM (Wood, 2004, 2011). The general form of the model can be written as:

$$g(\mu) = \beta + f_1(x_1) + \cdots + f_i(x_i) + \varepsilon \quad \text{(Eq.3)}$$

where $g(\mu)$ is the link function, which is the logarithm of CPUE + 1; β is the intercept term; f is a smooth function, i is the number of predictor variables, ε is the error term. The GAM procedure uses smoothing splines s( ).

Diagnosis of GAM

The predictor variables influencing *D. maruadsi* CPUE that should be incorporated into the model were identified applying a stepwise GAM and according to Akaike Information Criterion (AIC) (Shih, 2014; Franco et al., 2018). Models were built by adding in new terms and seeing how much they improved the fit, and by dropping terms that did not degrade the fit significantly. The influence of the predictors was assessed via F-test and chi-square test (Quinn and Deriso, 1999). AIC was calculated as follows (Venables, 2004):

$$AIC = \theta + 2df\delta$$

where θ is the deviance, df is the effective degree of freedom, and δ is the variance.

Violin plot

A violin plot, similar to a box plot with a rotated kernel density plot on each side, simultaneously reflects the statistical features (maximum, minimum, median, and upper and lower quartiles) and distribution of a set of data (Hintze, 1998). The violin plot was made using the ggplot2 package in R software from *D. maruadsi* CPUE in winters

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84858499

(January and February) and summers (August and September). Since the average CPUE differed greatly, the ordinate was scaled logarithmically. Then the violin plot was used to analyze the difference in *D. maruadsi* CPUE between winters and summers in western Guangdong waters (Cortez, 2016).

Results

Linear correlation analysis between D. maruadsi CPUE and the influencing factors

Pearson correlation analysis on *D. maruadsi* CPUE and the factors influencing it including year, month, lunar phase, longitude (Lon), latitude (Lat), SST, Chl a, SLA and water depth (*Table 1*) showed that seven of the factors (month, lunar phase, longitude, latitude, SST, Chl a, SLA and depth) were significantly correlated with *D. maruadsi* CPUE ($P < 0.05$), and the correlation coefficient between longitude and CPUE was greater than 0.5 ($R > 0.5$), indicating that longitude had a strong positive linear correlation with *D. maruadsi* CPUE. Therefore, longitude was removed from the GAM.

Table 1. *Pearson correlation coefficient of Decapterus maruadsi CPUE and Impact factors*

Factors	Cor	P-value
Year	-0.067	0.345
Month	0.292	$2.514*10^{-5}$
Lunar phase	-0.146	0.038
Lon	0.535	$2.678*10^{-16}$
Lat	0.205	0.003
SST	0.261	$1.830*10^{-4}$
Chl a	-0.167	0.018
SLA	-0.178	0.012
Depth	-0.163	0.021

Analysis of longitudinal distribution of *D. maruadsi* CPUE (*Fig. 2*) revealed that the maximum values of *D. maruadsi* CPUE within longitude 115.25°E - 113.75°E were 0.56 t/d, 1.00 t/d, 1.00 t/d, 3.00 t/d, 30.20 t/d and 18.00 t/d, respectively. The upper quartile of *D. maruadsi* CPUE increased with longitude increasing from 112.25°E to 113.75°E. The median value and lower quartile of *D. maruadsi* CPUE also increased with longitude increasing from 111.75°E to 113.75°E. There were fewest data at 111.25°E and most data113.25 °E. To sum up, *D. maruadsi* CPUE value showed a general decreasing trend from east to west in the study area, and the high CPUE values were concentrated within 113.25°E-113.75°E.

Environmental effects on D. maruadsi CPUE based on GAM analysis

The GAM was built by adding in the temporal, spatial and environmental factors stepwise and seeing how much they improved the fit. The temporal, spatial and environmental variables included in the model were year, month, lunar phase, latitude, Chl a, SLA and depth (*Table 2*). The GAM could explain 47.40% of the variability in *D. maruadsi* CPUE in total, and the residual degrees of freedom was 185.23.

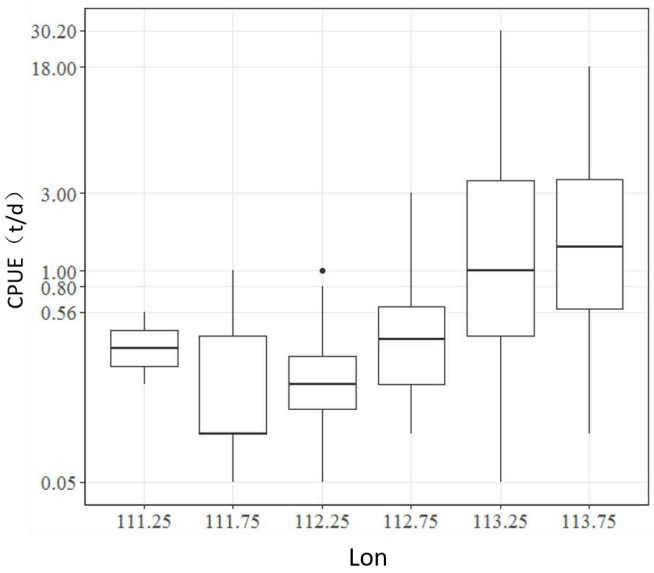

Figure 2. *Box plot of longitudinal distribution of D. maruadsi CPUE*

Table 2. *Generalized additive models (GAMs) fitted to D. maruadsi CPUE and analysis of deviance*

Factors	Residual degree of freedom	AIC value	Cumulative of deviance explained
Log(CPUE + 1) = NULL	200.00	16.34	0.00
Log(CPUE + 1) = s(Year)	196.28	4.16	9.30%
Log(CPUE + 1) = s(Year) + s(Month)	193.73	-23.09	22.80%
Log(CPUE + 1) = s(Year) + s(Month) + s(Lunar phase)	191.87	-37.14	29.30%
Log(CPUE + 1) = s(Year) + s(Month) + s(Lunar phase) + s(Lat)	191.08	-40.88	31.20%
Log(CPUE + 1) = s(Year) + s(Month) + s(Lunar phase) + s(Lat) + s(Chl a)	190.24	-44.22	32.90%
Log(CPUE + 1) = s(Year) + s(Month) + s(Lunar phase) + s(Lat) + s(Chl a) + s(SLA)	190.24	-54.73	37.50%
Log(CPUE + 1) = s(Year) + s(Month) + s(Lunar phase) + s(Lat) + s(Chl a) + s(SLA) + s(Depth)	185.23	-83.23	47.40%
Log(CPUE + 1) = s(Year) + s(Month) + s(Lunar phase) + s(Lat) + s(Chl a) + s(SLA) + s(Depth) + s(SST)	184.21	-82.33	47.70%

The contribution of each factor included in GAMs to *D. maruadsi* CPUE indicated their influence on *D. maruadsi* CPUE (*Table 3*). Among them, the most influential factor was month, which explained 13.50% of the variability in *D. maruadsi* CPUE, followed by depth, year, lunar phase, SLA, latitude, Chl a, which explained 9.9%, 9.30%, 6.50%, 4.60%, 1.90%, and 1.70% of the variability in *D. maruadsi* CPUE respectively. The *F* test and Chi-squared test showed that after SST was added into the model, it did not degrade the fit significantly ($P > 0.05$), while *AIC* value increased, suggesting that SST had no significant effect on *D. maruadsi* CPUE, so it was removed from the model.

Depth	2.71	$7.32*10^{-7}$	1.61 6	$4.31*10^{-7}$	9.90%
SST	1.00	0.317	0.32	0.32	0.30%

Relationship between *D. maruadsi* CPUE and the influencing factors (*Fig. 3*). Among all temporal factors, the year factor showed a positive effect in 2011-2013 and 2014-2015 (*Fig. 3a*) and a negative effect in 2013-2014, with no significant change in the confidence interval (*Fig. 3b*). From January to February, and from August to September, *D. maruadsi* CPUE increased monotonously over time; the width of the confidence interval decreased between different seasons (from February to August), and increased within the same seasons (January to February, August to September). *D. maruadsi* CPUE monotonously decreased with lunar phase changing from 1 to 15, and monotonously increased with lunar phase changing from 15 to 30 (*Fig. 3c*), with no significant change in the confidence interval.

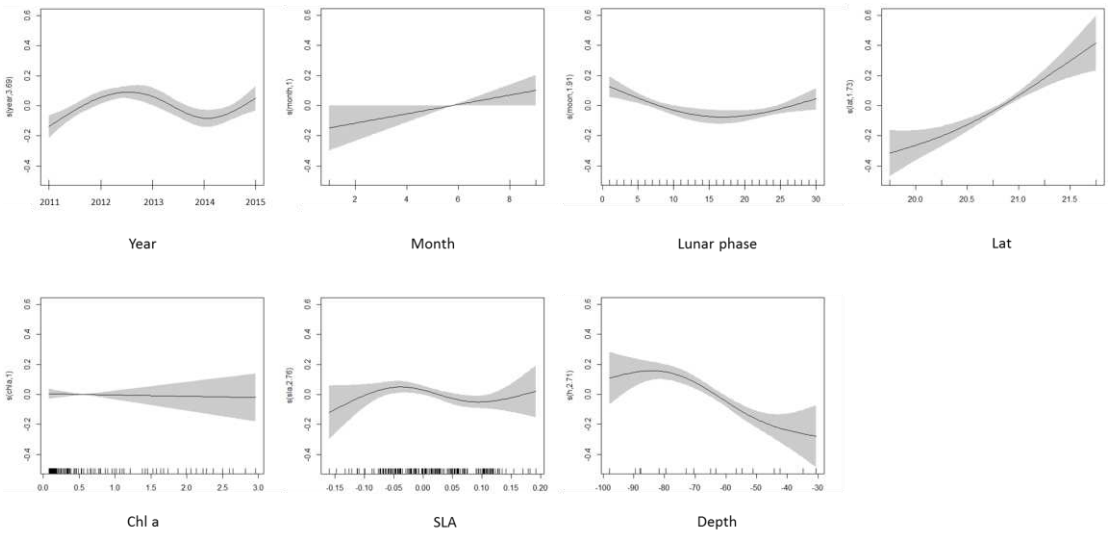

Figure 3. *Effects of different factors on D. CPUE from GAM analysis. The shadow area indicates the 95% confidence intervals. Rug plots on the x-axis indicate data density*

D. maruadsi CPUE increased monotonically with latitude increasing from 20°N to 21.5°N (*Fig. 3d*). The width of the confidence interval decreased within 20.5°N - 21.0°N, suggesting increased reliability of the estimation. The width of the confidence interval increased within 20.0°N -20.5°N and 21.0°N -21.5°N suggesting decreased reliability of the estimation.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84858499

D. maruadsi CPUE changed little with Chl a increasing (*Fig. 3e*). The data were concentrated within Chl a range of 0.1-0.5 $mg \cdot m^{-3}$, and the narrow confidence interval indicated high reliability of the estimation. With Chl a increasing in the range of 0.5-3.0 $mg \cdot m^{-3}$, the amount of data decreased, the width of confidence interval increased, indicating the reliability of the estimation decreased. It showed the effect of SLA on *D. maruadsi* CPUE (*Fig. 3f*). With SLA increasing from -0.15 to -0.05 m, *D. maruadsi* CPUE increased, and the width of confidence interval decreased. As SLA increased from -0.05 to 0.10 m, *D. maruadsi* CPUE decreased, the confidence interval became narrower, indicating the reliability of the estimation increased. As SLA increased from 0.10 to 0.20 m, *D. maruadsi* CPUE increased again, while the confidence interval became broader, and the reliability of the estimation decreased. The data were concentrated within SLA range of -0.8 to 0.13 m. It showed the effect of water depth on *D. maruadsi* CPUE (*Fig. 3g*). In detail, *D. maruadsi* CPUE increased with depth increasing from 30 to 80 m, while the width of confidence interval increased, indicating that the reliability of the estimation increased. With water depth increasing from 80 to 100 m, *D. maruadsi* CPUE declined, while the width of confidence interval increased, indicating that the reliability of the estimation reduced.

Seasonal variation in D. maruadsi CPUE

According to GAM analysis, the effect of the month factor which was most influential to *D. maruadsi* CPUE was further analyzed. The fishing vessels were operated in the sea area within 19.75°-21.75°N and 111.25°-113.75°E in January, February, August and September every year. Our data revealed that *D. maruadsi* CPUE was high in summer, with a maximum value of 18.00. t/d, a median value of 1.28 t/d, a minimum value of 0.00 t/d, and the abnormally high value in summer was 30.20 t/d. *D. maruadsi* CPUE was low in winter, with a maximum value of 1.25 t/d, a median of 0.20 t/d, and a minimum value of 0.00 t/d. Comparing the kernel density distribution plots of *D. maruadsi* CPUE between summer and winter, we found that the distribution of *D. maruadsi* CPUE in summer was discrete, with a peak value around 0.60, and that in winter was concentrated, with a peak value around 0.20. All the maximum value, upper quartile, median, and lower quartile of *D. maruadsi* CPUE in summer were higher than in winter (*Fig. 4*).

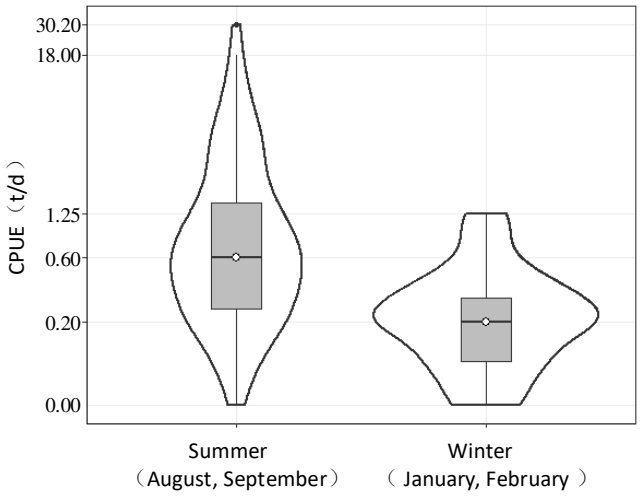

Figure 4. *Violin plot of CPUE distribution of Decapterus maruadsi in summer and winter*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84858499

Discussion

Relationship between D. maruadsi CPUE and temporal/spatial factors

GAMs analyze the relationship between response and predictor variables based on data model. They possess obvious advantages in analyzing the highly nonlinear and non-monotonic relationship between response and predictor variables, and can be used to reveal the unknown ecological relationships in fishery (Hastie et al., 1999; La et al., 2016; Bacha et al., 2017). Among all the factors included in GAM, the month factor made the greatest contribution to the GAM, up to13.50% (*Table 3*). There was an obvious seasonal variation in *D. maruadsi* resources in western Guangdong waters, and its CPUE was higher in summer (August and September) than in winter (January and February) (*Fig. 3b*). Studies have shown that the spawning period of *D. maruadsi* begins at the end of winter and ends in summer (Chen et al., 2003; Wu, 2000). Previous studies on *D. maruadsi* in the Beibu Gulf and the Taiwan Strait indicates that summer is an important season for *D. maruadsi* to fatten up (Huang, 1995; Yang, 2016). *D. maruadsi* populations are able to increase during summer fishing moratorium (SFM) in June and July, and then gradually decrease from August to November due to the continuous high-intensity fishing in this period, resulting in significant difference in *D. maruadsi* CPUE between winter and summer.

The year factor explained 9.30% of the variability in *D. maruadsi* CPUE (*Table 3*). *D. maruadsi* CPUE fluctuated during 2011-2015 (*Fig. 3a*), and the decrease in 2014 was probably due to the unusually late summer monsoon season in the South China Sea in this year (Yuan, 2014). As an R-selected species, it is susceptible to environmental influence (Chen et al., 2003; Yan et al., 1987). The reduced fishing intensity during summer moratorium from June to July (Zhu, 2009; Qu, 2018), and the increased primary productivity caused by the upwelling in western Guangdong waters (Song, 2012) provide favorable conditions for the replenishment of *D. maruadsi* resources. It is widely accepted that summer winds may be the reason for the strong upwellings in the study area from June to July (Xie, 2016). The summer monsoon in the South China Sea in 2014 started unusually late, which might delay the occurrence of upwelling in this area, as a result, the *D. maruadsi* resources were not sufficiently replenished. In 2015, the summer monsoon in South China Sea occurred at the usual time (Si et al., 2016), and thus the *D. maruadsi* resources were able to recover during moratorium, so its CPUE in 2015 was higher than in 2014.

Lunar phase explained 6.50% of the deviance of the model (*Table 3*). The relationship between *D. maruadsi* CPUE and lunar phase was represented by an inverted U-shaped curve, with the minimum CPUE value at lunar phase 15 (*Fig. 3c*), which might be caused by the light luring seine used by the vessels. The moon is at its brightest when full in a month, and the moonlight lowers the attractiveness of light luring seines to cephalopods (Chen et al., 2006; Yan, 2015). As the major catch of light luring seine fishing in western Guangdong waters (Yang et al., 2009), similar results were obtained in *D. maruadsi* in our study. In addition to the influence of moonlight intensity, whether the changes in the marine environment caused by lunar phase have an impact on *D. maruadsi* CPUE needs to be further studied.

Correlation analysis indicated that there was a positive linear correlation between longitude and *D. maruadsi* CPUE in western Guangdong waters (*Table 1*). The violin plot (*Fig. 2*) showed that the maximum value, median value, and the amount of data of *D. maruadsi* CPUE were all higher at longitude 113.25°E-113.75°E. GAM analysis

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84858499

showed that latitude and *D. maruadsi* CPUE had a high positive correlation near longitude 21°N (*Fig. 3d*). *D. maruadsi* tends to spawn in the areas where seawater is diluted by fresh water, and the spawning season lasts for a long period until the end of summer (Chen et al., 2003; Zhu, 1984). Therefore, *D. maruadsi* population tends to concentrate in the Pearl River estuary in winter and summer. The decreased water depth along coasts may be the factor restricting the positive effect of latitude, increasing the width of confidence interval north of 21°N, and reducing the reliability of the estimation.

Relationship between D. maruadsi CPUE and environmental factors

Among the environmental factors, water depth was the most influential to GAM, and it explained 9.90% of the deviance (*Table 3*). In detail, *D. maruadsi* CPUE increased monotonously with depth increasing from 30 to 80 m, and the reliability of the estimation was higher at depth 50-80 m. With further increase in water depth, *D. maruadsi* CPUE declined monotonously (*Fig. 3g*). *D. maruadsi* is a pelagic fish (Deng, 1991). Acoustic assessments indicate that three carangid species including *D. maruadsi* along the east coast of Peninsular Malaysia are concentrated at depth of 40-60 m, and their density is 0 when water depth exceeds 80 m. The depth of study area is about 0-200 m. While some researchers believe that *D. maruadsi* in this sea area lives at or near the bottom of the sea (Fan, 2018). The GAMs showed that in western Guangdong waters, the high CPUE values of *D. maruadsi* appeared at about 80 m, which might have been affected by light luring seines.

SLA explained 4.6% of the total deviance (*Table 3*). The positive effect of SLA on *D. maruadsi* CPUE peaked at SLA around -0.05 m (*Fig. 3f*), which may be related to oceanic currents (such as eddies, upwelling) in this area. Remote sensing data about sea surface height such as SLA and sea surface height anomaly (SSHA) are the indicators of oceanic currents and density stratification of seawater (Thomas, 2012), and are widely used for eddy identification (Wang, 2015; Yi, 2014; Zhan, 2014). Eddies regulates SST, SSS, and Chl a by a complicated mechanism (Chelton, 2011; Schütte, 2016; He, 2016). The center of anticyclonic eddies in the northeastern Atlantic is characterized by a negative SLA value and a reduced SST and SSS (Schütte, 2016). Along the coasts of the southwest Indian Ocean, the cold eddies have a negative SSHA value at their center, and stir up nutrients from the bottom, resulting in an elevation in Chl a. In the northern South China Sea, the positive effect of eddies on Chl a is stronger than the negative effect of anticyclonic eddies. And the eddies in the northern South China Sea increased seawater Chl a and promoted the transport of Chl a along longitude. In addition, SLA in upwelling region also exhibits a certain pattern. In West Africa, the upwelling center has a negative SLA, decreased SST and elevated Chl a (Nieto, 2017). The eastern Hainan-western Guangdong upwelling in the study area increased the Chl a and primary productivity in the area in summer (Song, 2012; He, 2016). Therefore, it is speculated that the oceanic currents (eddies, upwelling, etc.) at SLA -0.05 m provide favorable conditions for *D. maruadsi,* so that the positive effect of SLA on *D. maruadsi* CPUE reaches the maximum level within this SLA range.

No significant correlation between *D. maruadsi* CPUE and Chl a was observed in this study (*Fig. 3e*), but the data density plot indicated that *D. maruadsi* CPUE was concentrated at Chl a ranging from 0.1 to 0.5 $mg \cdot m^{-3}$, suggesting that *D. maruadsi* tends to live in waters with this range of Chl a. As an indicator of marine phytoplankton, Chl a has an important impact on fishery distribution. The study on the Pacific saury

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_84858499

(*Cololabis saira*) distribution in the northwestern Pacific Ocean based on empirical cumulative distribution function (ECDF) showed that high CPUE occurred when Chl a ranged from 0.4 to 0.6 mg·m^{-3} (Tseng, 2013). The study on yellowfin tuna (*Thunnus albacares*) in the western and central Pacific showed that the tuna tends to live in the waters with Chl a of 0.1-0.6 mg·m^{-3} (Wang, 2016; Kang, 2018). It has been reported that *D. maruadsi* in southern Taiwan Strait prefer to live in the waters with Chl a ranging from 0.2 to 1.0 mg·m^{-3} (Li, 2006). The data density distribution based on GAM analysis in this study revealed a Chl a range suitable for *D. maruadsi* in the western Guangdong waters.

Conclusions

To examine the relative influence of environmental factors on the distribution of *D. maruadsi*, data recorded by the fishing vessels and remote sensing including SST, Chl a and SLA in the western Guangdong waters, were analyzed using GAMs combined with correlation analysis in this study. Results showed that *D. maruadsi* CPUE in western Guangdong waters had a significant positive linear correlation with longitude, showing a general trend of decreasing from east to west. The final model explained 47.40% of the variability in *D. maruadsi* CPUE in total. Among all the factors included in the model, month was most influential to the distribution of *D. maruadsi*, followed by depth, year, lunar phase, SLA and latitude, Chl a and SST. The *D. maruadsi* resources were concentrated in the areas where the latitude was 21°N, Chl a ranged from 0.1 to 0.5 mg·m^{-3}, SLA was -0.05 m and water depth was 80 m. The fishing method (light luring seines) used in this study might affect the conclusions about the effects of lunar phase and water depth on *D. maruadsi* CPUE. Therefore, different fishing methods will be used verify the effects of the two factors in the future work.

Abstract. This paper aimed to investigate the effects of elevated [CO_2], [O_3] or [$CO_2 + O_3$] on soil physicochemical properties, microbial biomass and soil enzyme activities in phenanthrene-added and -unadded soils. The results showed that elevated [CO_2] increased the dissolved organic carbon (DOC), total phosphorus (TP), available phosphorus (AP), total potassium (TK), total carbon (TC), and nitric nitrogen (NN) contents to some extent in phenanthrene-untreated soils, which contrary to the elevated [O_3], and thus differentially promoted the contents of microbial biomass carbon (MBC), microbial biomass nitrogen (MBN) as well as activities of soil protease (PRA), sucrase (SA), acid phosphatase (APA) and neutral phosphatase (NPA) in the soils. The elevated [O_3] increased ratios of MBC/MBN, and led to the decrease of the activities of PRA, APA and NPA to some extent. However, to some extent, [$CO_2 + O_3$] alleviated the inhibition of the soil microbial biomass and soil enzyme activities by [O_3] elevation and basically did not change the tendency of the soil physicochemical properties, microbial biomass and enzyme activities, but their contents in phenanthrene-added soils compared with the phenanthrene-untreated soils. Therefore, the alteration of soil microbial biomass and soil enzyme activities can be used for assessment of the effects of elevated atmospheric CO_2, O_3 or phenanthrene-polluted soil on the soil microbial systems.

Keywords: *open top chamber (OTC), phenanthrene-added soils, elevated [CO_2], elevated [O_3], soil physicochemical properties*

Introduction

For the past few years, the continuous increase of CO_2 and O_3 concentration in the atmosphere and global climate change have attracted wide attention of the whole society (Wang et al., 2014). The research results show that elevated atmospheric CO_2 concentration significantly affects the land ecological system through improving the plant photosynthesis changes of plant root secretion and soil microbial community composition and the quantity, flow and distribution of carbon and nitrogen in soil, and the size of soluble carbohydrate pool indirectly changes the physical and chemical properties of soil, so as to affect the alteration of soil microbial ecosystem (Xu et al., 2013; Sulman et al., 2014; Manna et al., 2012).

O_3 is a naturally occurring photochemical oxidant in the troposphere of the Earth, and a major component of greenhouse gases and photochemical smog. Higher O_3 levels can have negative effects on plants. O_3 enters plant tissue thorough stomata, and can reduce stomatal conductance, and then inhibits photosynthesis and nutrient absorption, and finally reduces plant biomass and crop yield (Díaz-de-Quijano et al., 2012; Zhang et al., 2011). Under the stress of O_3, changes in plant root secretions might also change the physical and chemical properties of soil, and reduce soil microbial biomass carbon and nitrogen, and potentially change the rhizosphere microbial community, nutritional status

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85018512

and soil enzyme activity (Wu et al., 2012; Haesler et al., 2014; Cheng et al., 2014; Veeraragavan et al., 2018).

Soil enzymes are involved in the material circulation, energy flow and degradation of organic pollutants in soil, and changes in their activity can reflect the strength and direction of various biochemical processes in soil. The microbial biomass is very sensitive to environmental factors, and is always applied to monitor the scale and activity of soil microbial community (Lou et al., 2011). Therefore, soil microbial biomass and soil enzyme activity have been developed into ecological indicators for evaluating soil environmental quality (Han et al., 2016; Tripathi et al., 2007; Kumar and Jaafar, 2018), and have been applied to evaluate the alteration of soil microecological environment under atmospheric CO_2 and O_3 pollution conditions (Li et al., 2010; Rozuki et al., 2018).

People usually adopt free-air CO_2 enrichment (FACE) or Open top chamber (OTC) system to investigate the elevated atmospheric CO_2 and O_3 concentration influence on plant and soil microbial system (Wu et al., 2012; Formánek et al., 2014). The study found that elevated atmospheric CO_2 and O_3 concentration can change the plant population composition, and then affect plant chemistry (Booker et al., 2005; Johnson and Pregitzer, 2007), and increases the content of phenolic substances (Li et al., 2008; Sen et al., 2018), and finally indirectly change soil chemical characteristics and induce changes in soil microbial functional diversity, biomass and enzyme activity (Xu et al., 2013; Huang et al., 2013; Wu et al., 2015). As a representative of polycyclic aromatic hydrocarbons pollutants, the phenanthrene (PHE) is gradually accumulated in the soil with a low-dose superposition. Its potential ecological risk of soil pollution has been widely concerned (Zhang et al., 2018).

At present, most researches about the change of soil–plant system under elevated CO_2 and O_3 conditions, are to simulate impact and evaluation of a single elevated CO_2 and O_3 on ecosystem safety, while there are few researches on the combined conditions of the two (Tian et al., 2011; Ren et al., 2014), especially on the effect of soil phenanthrene on soil enzyme activity under the condition of atmospheric CO_2 and O_3 rising. Based on OTC platform, under the condition of CO_2, O_3, $CO_2 + O_3$ increase, the research build micro universe soil - green vegetable potted simulation system to discuss the change of soil protease, polyphenol oxidase, phosphatase, urease and invertase as well as the change of soil microbial biomass with or without adding phenanthrene (López-Hernández, 2018), which was aimed to obtain the future elevated atmospheric CO_2 and/or O_3 micro ecological impact on the soil.

Materials and methods

Test platform and processing mode

The test platform is located in Xianlin Campus of Nanjing University (118°57′36.15″E, 31°7′23.99″N). The platform includes 4 air chambers. One is connected to the normal atmosphere. One has 200 ppm more CO_2 concentration than normal atmosphere. One has 50 ppb O_3 concentration than normal atmosphere. One control the compound increase of CO_2 and O_3 concentration. The air chamber is octagon with 2 m of diameter and 2.8 m of height. CO_2 was provided by Du Wa Guan (Q/JB-THB002, Beijing Tianhai Industry Co., Ltd). CO_2 was purchased by Nanjing Tianze Gas Co., Ltd with 99.9% of purity. O_3 is produced by O_3 generator (NPF 10/W, Shandong Tianze). CO_2 and O_3 (gas was controlled by valves and flow meter) mixed

DOI: http://dx.doi.org/10.15666/aeer/1704_85018512

with normal atmosphere by axial flow fan (SFG-2, Shanghai Jia Bao) into the bottom of the chamber. And then the gas entered the chamber through holes (0.5 cm of diameter) on the bottom of the chamber and the stainless steel plate in the middle of the chamber. The gas then entered that outer atmosphere through the opening at the top of the gas chamber. The gas replacement frequency should ensure than the gas will be replaced 3~4 times per minute in the chamber. CO_2 concentration was monitored by CO_2 detector (Li-7000, Li-Cor, USA), and O_3 concentration was monitored by O_3 detector (Model 205, 2B Co., USA). CO_2 was injected into the gas chamber all the times, and the injection time of O_3 was from 9 am to 5 pm (except rainy days).

In July 2014, the soil with 100 ppm of exo-phenanthrene and the soil without adding phenanthrene were prepared. In June 2017, the concentration of phenanthrene in the contaminated soil was measured at about 30 ppm. Meanwhile, these aged soils were divided into flowerpots (10 kg/pot). Fertilizer (2 g/pot, N:P:K = 1:1:1) was added, and then turned over, and mixed well. Then 10 green vegetable seeds were planted. Finally the flowerpots without adding phenanthrene were transferred to 4 chambers in OTC which were ambient[Amb], [CO_2], [O_3] and [$CO_2 + O_3$] representing the normal atmosphere, high CO_2, high O_3 and mixed increase of CO_2 and O_2.

At the same time, the soil polluted by phenanthrene was also transferred to the 4 air chambers represented by [Amb] + [PHE], [CO_2] + [PHE], [O_3] + [PHE] and [$CO_2 + O_3$] + [PHE]. 3 pots were prepared for each treatment. After germination, the seeding began to grow for another week. Each flowerpot kept 3 seedlings with same size. They were replenished regularly with the same amount of deionized water. Soil samples were collected after 30 days for the detection and analysis of the following indicators.

Determination of physical and chemical properties of soil

The method of Shi Cuie and teammates (Shi et al., 2015) was referenced to determine the physical and chemical properties.

Determination of soil microbial biomass carbon (MBC) and microbial biomass nitrogen (MBN)

Soil MBC and MBN were measured by chloroform fumigation - K2SO4 extraction (Shi et al., 2015). The content of organic carbon and total N in the extraction solution (Multi C/N 3100, Jena) were determined by TOC analyzer. The calculation methods of MBC and MBN are as follows. MBC = EC/0.45, MBN = EN/0.45, EC, EN were the differences of organic carbon or total nitrogen between the fumigated and non-fumigated soil leaching solution (Liu et al., 2014), and 0.45 is the proportion coefficient of the extracted biomass after chloroform fumigation (Iqbal et al., 2010). The carbon nitrogen ratio of microorganisms was expressed as MBC/MBN.

Determination of soil enzyme activity

Soil enzyme activity was determined by indanone colorimetry in accordance with the method of Guan (1986). 1 mg NH_2-N produced by 1 g soil after 24 h was defined as 1 mg NH_2-N$\cdot g^{-1}\cdot 24\ h^{-1}$ for soil protease (PRA) activity. Sucrose enzyme (SA) was determined by 3,5-dinitrosalicylic acid colorimetry. 1 g glucose produced by 1 g soil after 24 h was defined as 1 mg glucose$\cdot g^{-1}\cdot 24\ h^{-1}$. Urease activity (UA) was determined by sodium phenol - sodium hypochlorite colorimetric method. 1 μg NH_3-N produced by 1 g soil after

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85018512

24 h under 37 °C was defined as 1 μg NH_3-N·g^{-1}·24 h^{-1}. The activity of polyphenol oxidase (POA) was determined by using purple gallic acid colorimetry. 1 g purple gallic acid colorimetry produced by 1 g soil after 2 h was defined as 1 mg PG·g^{-1}·2 h^{-1}. The activity of soil acid phosphatase (APA) and neutral phosphatase (NPA) were determined by disodium phenyl phosphate. 1 mg P_2O_5 produced by 100 g soil after 2 h under 37 °C was defined as 1 mg P_2O_5·100 g^{-1}·2 h^{-1}.

Data processing

Raw data were sorted out by Excel 2003. SPSS 20.0 was applied for statistical analysis. Variance analysis was used to test the differences between the factors, and SNK method was used for multiple comparisons between the two factors.

Results and analysis

Effects of the rising of CO_2 and O_3 in atmosphere and phenanthrene in soil on physical and chemical properties of soil

With the increase of CO_2 or/and O_3 in OTC, the content alteration of NN, TP, TK and TC in the soil without adding phenanthrene soil presents a trend of [CO_2] > [Amb] > [CO_2 + O_3] > [O_3]. The trend of content alteration of AN, DON, TN and DOC was [CO_2] > [CO_2 + O_3] > [Amb] > [O_3]. The trend of content alteration SWC and AP was [CO_2] > [CO_2 + O_3] > [O_3] > [Amb], while the decline of pH value was as the trend of [O_3] > [CO_2 + O_3] > [Amb] > [CO_2] (*Table 1*).

SWC: Soil water content; TP: Total phosphorus; TC: Total carbon; TN: Total nitrogen; TK: Total K; AN: NH_4^+-N: NN: NO_3—N; AP: Available P; DOC: Dissolved organic carbon; DON: Dissolved organic nitrogen. Values represent mean ± SD, n = 3. Different small letters in the same column represent significant differences at 0.05 level. The same as follows

The increase of CO_2 or/and O_3 also induced the change of physical and chemical properties of the soil with adding phenanthrene. In the soil with adding phenanthrene,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85018512

the content trend of NN, TP, TK, TC, AN and DON was [CO_2] + [PHE] > [Amb] + [PHE] > [CO_2 + O_3] + [PHE] > [O_3] + [PHE]. The content alteration of TN, SWC and DOC was [CO_2] + [PHE] >[CO_2 + O_3] + [PHE] > [Amb] + [PHE] > [O_3] + [PHE], while the soil pH alteration was [O_3] + [PHE] > [CO_2 + O_3] + [PHE] > [Amb] + [PHE] > [CO_2] + [PHE].

The results also indicated that the contents of NN, TP, AN, DON, TK, TC and TN in the soil with adding phenanthrene were slightly higher than that of the soil without adding phenanthrene (*Table 1*). Therefore, the increase of atmospheric CO_2 or/and O_3, as well as the pollution of phenanthrene in soil, induced the change of physical and chemical properties of the experimental soil to some extent.

Effects of rising of CO_2, O_3 in atmosphere and phenanthrene in soil on soil microbial biomass

The change of soil microbial biomass carbon (MBC) and nitrogen (MBN) in the soil without adding phenanthrene was [CO_2] > [CO_2 + O_3] > [Amb] > [O_3]. Multiple comparison results showed that compared with [Amp], CO_2 injection induced a significant increase in MBC and MBN content ($P < 0.05$), while only O_3 injection induced a significant decrease in MBN content ($P < 0.05$). The carbon nitrogen ratio (MBC/MBN) of microbial biomass showed a trend of [O_3] > [CO_2 + O_3]> [CO_2] > [Amb]. Multiple comparison results showed that only [O_3] induced significant increase in MBC/MBN compared with [Amb] ($P < 0.05$).

In the soil with adding phenanthrene, the content change of MBC and MBN was [CO_2] + [PHE] > [Amb] + [PHE] > [CO_2 + O_3] + [PHE] > [O_3] + [PHE]. Multiple comparison results suggested that compared with [Amb] + [PHE], [O_3] + [PHE] induced a significant decrease in MBC and MBN ($P < 0.05$), while no significant change was observed in other treatment groups. Under normal atmospheric conditions, MBC and MBN in soil with adding phenanthrene increased by 47% and 45% ($P < 0.05$) respectively compared with that of the soil without adding phenanthrene (*Table 2*). MBC/MBN presented an alteration trend of [O_3] + [PHE] > [CO_2] + [PHE] > [Amb] + [PHE] > [CO_2 + O_3] + [PHE], while the changes within the treatment groups was not significant ($P > 0.05$).

MBC: Microbial biomass carbon; MBN: Microbial biomass nitrogen; MBC/MBN: ratio of microbial biomass carbon/nitrogen

The results of multivariate analysis of variance showed suggested that the effects of different treatment groups [CO_2], [CO_2 + O_3], [Amb] and [O_3], (Pascual-Córdova, 2018)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85018512

as well as the soil treatment model with adding phenanthrene and the model without adding phenanthrene on soil microbial biomass carbon and nitrogen were extremely significant ($P < 0.05$). At the same time, the interaction between different treatment groups and two soil treatment models had no significant influence on soil microbial biomass carbon and nitrogen.

Effects of rising of CO_2, O_3 in atmosphere and phenanthrene on soil enzyme activity

The alteration trends in the activity of soil protease (PRA), invertase (SA), urease (UA), (Espinoza, 2017) polyphenol oxidase (POA) and acidic phosphatase (APA) under the condition of increase of atmospheric CO_2 or and O_3 without adding phenanthrene was like $[CO_2] > [CO_2 + O_3] > [Amb] > [O_3]$ that was consistent with the alteration trends of MBC and MBN in soil. Multiple comparison results showed that, compared with [Amb], only the injection of O_3 induced significant decrease of APA ($P < 0.05$), and only the injection of CO_2 induced significant increase of SA ($P < 0.05$). However, there was no significant difference between UA or POA in each treatment group ($P > 0.05$). Meanwhile, NPA showed a trend of $[CO_2] > [Amb] > [CO_2 + O_3] > [O_3]$, and CO_2 injection induced significant increase of NPA ($P < 0.05$) (*Fig. 1*).

In the soil with adding phenanthrene, with the increase of CO_2 or/and O_3, the alteration trend of PRA, SA, UA, POA, APA and NPA was all $[CO_2]$ + [phenanthrene] > [Amb] + [PHE] > $[CO_2 + O_3]$ + [PHE] > $[O_3]$ + [PHE] which was same as the trend of MBC and MBN. Multiple comparison results showed that, compared with [Amb] + [PHE], $[O_3]$ + [PHE] induced significant decline of PRA ($P < 0.05$), and significant increase of NPA ($P < 0.05$), while the $[O_3]$ + [PHE] and $[CO_2 + O_3]$ + [PHE] induced significant decrease of SA ($P < 0.05$). In addition, under normal atmospheric conditions, the PRA, SA and APA activity in soil with adding phenanthrene increased by 53%, 37% and 30% respectively compared with that in soil without adding phenanthrene. The activity of UA and POA increased in soil with adding phenanthrene, but the trend was not significant ($P > 0.05$).

The results of multifactorial variance analysis showed that the effects of $[CO_2]$, $[CO_2 + O_3]$, [Amb] and $[O_3]$ had significant influence on PRA, SA, UA, APA, NPA ($P < 0.05$), while had few influences on POA ($P > 0.05$) (Jaimes, 2017). The two soil groups with and without adding phenanthrene had significant influences on PRA, APA and NPA ($P < 0.05$), while had few influences on SA, UA and POA ($P > 0.05$). Meanwhile, interaction within different treatment groups and two soil treatment models had bare influence on PRA, SA, UA, POA, APA and NPA.

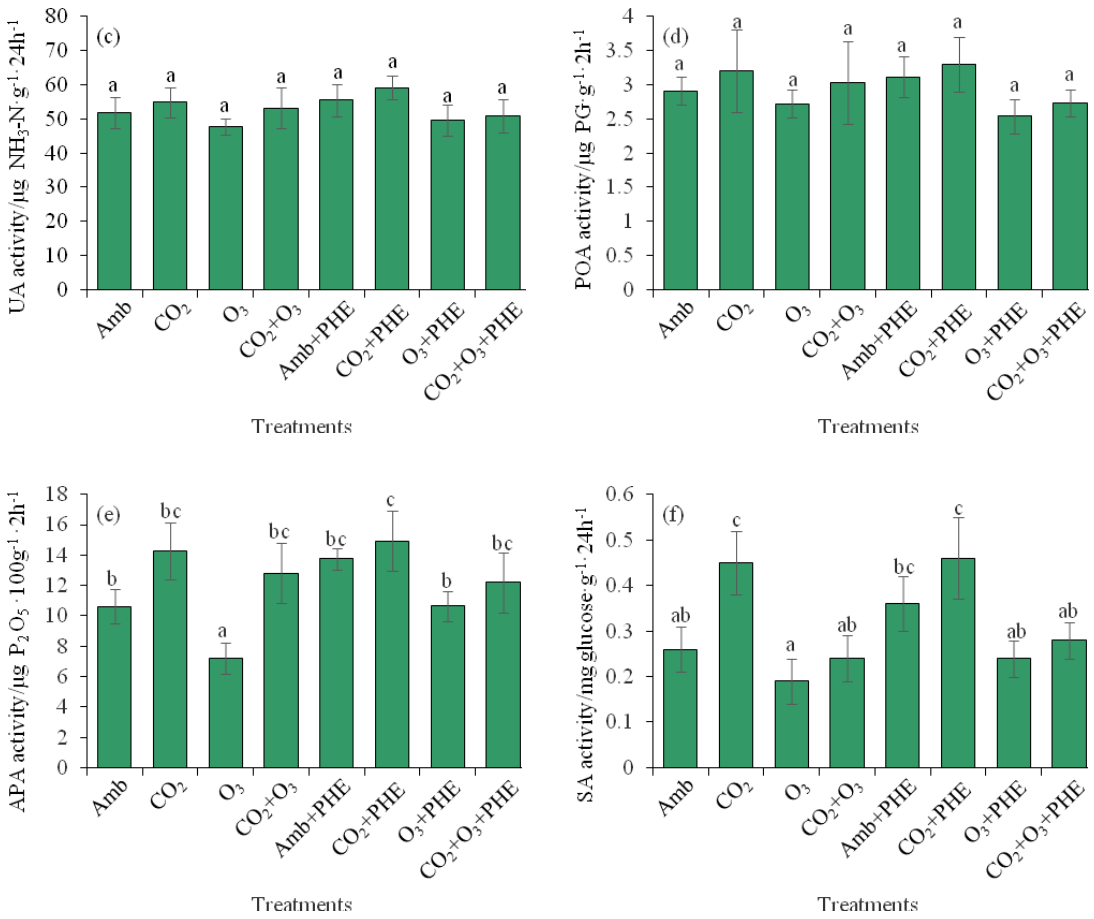

Figure 1. *Effect of elevated atmospheric CO_2 and/or O_3 on soil enzymatic activities in phenanthrene-added and -unadded soils. (PRA: Protease; SA: Sucrase; UA: Urease; POA: Phenol oxidase; APA: Acid phosphatase; NPA: neutral phosphatase)*

Discussion

Elevated atmospheric CO_2 or/and O_3 induce changes in the physical and chemical properties and enzyme activity of soil without adding phenanthrene

In this experiment, and OTC platform was used to build a soil-vegetable pot simulation system, and the changes of soil physical and chemical properties and soil enzyme activities under the elevated environment of CO_2 or/and O_3 were studied (Dager, 2017). The results showed that the increase of [CO_2] induced the increase of physical and chemical indicators such as NN, TP, TK, TC, DOC, AP, and MBC and MBN in the soil without adding phenanthrene, and the alteration trend was [CO_2] > [Amb]. Meanwhile, it was also found that soil enzyme activities such as NPA, PRA, SA and APA showed similar alteration trend. It was speculated that the increase of [CO_2] promoted the above soil physical and chemical indicators and soil enzyme activity. Studies have reported that the increase of atmospheric CO_2 concentration can promote the photosynthesis of plants, and improve the biomass and secretion of roots, and change the material composition of roots into soil (Xu et al., 2013; Sulman et al., 2014; Sunny et al., 2018). The increase of atmospheric CO_2 can also improve total organic carbon content and rhizospheric carbon availability through the metabolism of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85018512

plants, which lead to the increase of the soil microbial biomass C, N and microbial activity (Tian et al., 2011; Ren et al., 2014; Shrestha and Baral, 2018). Changes in soil microorganism amount induced changes in soil enzyme activities such as PRA, SA, UA, POA, APA and NPA (Ren et al., 2014; Larson et al., 2002; Mahmood et al., 2018). Therefore, in this experiment, the increase of [CO_2] improved soil NN, TP, TK, TC, DOC, AP and other physical and chemical indicators, and MBC and MBN probably through promoting photosynthesis of vegetables and the synthesis and output of root secretions, and then induced the increase the soil enzyme activity of NPA, PRA, SA and APA (*Tables 1* and *2*).

It was also found that the increase of [O_3] decreased the physical and chemical indicators and enzyme activity of the above soil, and they showed a decline trend of [O_3] < [Amb]. Meanwhile, the increase of [O_3] also led to the increase of MBC/MBN ratio of microorganisms (*Table 2*). Studies have reported that the increase of atmospheric O_3 concentration can close the stomata of leaves and restrict the entering of CO_2 into the leaf tissue, thus reducing the photosynthetic rate and the carbohydrate content in plants (Chen et al., 2012; Anan, 2019). Increased O_3 concentration can reduce root secretions and change the types of secretions (Díaz-de-Quijano et al., 2012; Hu et al., 2011). It can also reduce the metabolism of soil microorganism C and the content of N, and increase the ratio of MBC/MBN (Li et al., 2014), which indirectly interferes with soil nutrients, rhizosphere microecological environment and soil enzyme activity (Johnson and Pregitzer, 2007; Huang et al., 2013; Cheng et al., 2011; Xu et al., 2013; Qiao, 2018). It was speculated that the rise of [O_3] reduces and changes the vegetables root secretion through inhibiting photosynthesis of green vegetables, and changed the soil C and N metabolism to some extent, and leads to abnormal changes in physical and chemical indicators such as NN, AN, TP, AP, TK, DOC, DON and MBC, MBN, which indirectly inhibits the activity of soil enzymes such as NPA, PRA, APA and NPA (*Tables 1* and *2*).

The results also showed that the soil enzyme activity of NN, AN, TN, AP, TP, TK, TC, DOC, DON and MBC, MBN, and NPA, PRA, SA, UA, POA, APA showed a trend of [CO_2 + O_3] > [O_3] (*Tables 1* and *2*). [CO_2] might reduce the damage of [O_3] to the leaf tissue of vegetables and the interference of physiological and biochemical process such as photosynthesis on the leaf tissue of vegetables, thus indirectly inducing the increase of soil physical and chemical indicators such as TP, TK, AN, AP, DOC, DON, and MBC, MBN, as well as enzyme activities such as APA, NPA and PRA. The correlation mechanism remains to be further discussed.

Elevated atmospheric CO_2 or/and O_3 induce changes in the physical and chemical properties and enzyme activities of the soil with adding phenanthrene

Phenanthrene is one of the typical polycyclic aromatic hydrocarbon pollutants in soil. Studies on the effects of atmospheric CO_2 or/and O_3 increase on the microecological environment of the phenanthrene polluted soil have not been reported (Olivares et al., 2017). The results of this study showed that [CO_2] increased the physical and chemical indicators (NN, AN, TP, AP, TC, DOC, DON, etc.), and MBC, MBN, and the soil enzyme activities of NPA, PRA, SA and APA. The alteration trend of above indicators was [CO_2] + [PHE] > [Amb] + [phenanthrene]. It was also found that the increase of [O_3] decreased the above soil physical and chemical indicators and enzyme activity, and showed the trend of [O3] + [PHE] < [Amb] + [PHE]. Therefore, the alteration trend of [CO_2] + [PHE] > [Amb] + [PHE] > [O_3] + [PHE] showed by the above indicators was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85018512

consistent with the soil with adding phenanthrene. The direct effects of CO_2 and O_3 on the leaf tissue of vegetables might promote or interfere with the secretion of root substances through affecting the photosynthesis of leaves, thus causing the change of coil microecological environment (Wang et al., 2014; Cheng et al., 2011; Gautam et al., 2019). Soil phenanthrene affect directly on the root system of vegetables, and its target organs are different from CO_2 and O_3. Therefore, in the same CO_2 and O_3 exposure environment, the addition of phenanthrene to soil only changed the size of physical and chemical indicators but did not change its alteration trend (*Table 1*).

It was also found that [CO_2 + O_3] could alleviate the inhibition of [O_3] on the physical and chemical indicators and enzyme activity of the above mentioned soil, and its alteration trend of [CO_2 + O_3] + [PHE] > [O_3] + [PHE] was consistent with the that in soil without adding phenanthrene. The potential mechanism might be related to the alleviation of CO_2 on damage of O_3 to vegetables or the reduction of inhibition effect of O_3 on photosynthesis of vegetables. The interaction between soil pollution and atmospheric CO_2 or/and O_3 increase is a complex process, and its microscopic mechanism remains to be further studied.

Conclusion

(1) In the soil without adding phenanthrene, the increase of [CO_2] induced the increase of physical and chemical indicators, NN, TP, TK, TC, DOC and AP, and MBC, MBN, as well as soil enzyme activities of NPA, PRA, SA, APA with a trend of [CO_2] > [Amb]. The increase of [O_3] decreased the above soil physical and chemical indicators and enzyme activity ([Amb] > [O_3]), while increased the ratio of soil microorganism MBC/MBN. [CO_2 + O_3], to some extent, decreased the inhibition effect of [O_3] on soil microbial biomass and enzyme activity, and also released the stimulating effect of [CO2] increase on soil microbial biomass and enzyme activity.

(2) In the soil with adding phenanthrene, [CO_2] increased physical and chemical indicators, NN, AN, TP, AP, TC, DOC, DON and the ratio MBC/MBN with a rising trend of [CO_2] + [PHE] > [Amb] + [PHE]. [O_3] exposure decreased the above indicators and enzyme activities ([Amb] + [PHE] > [O_3] + [PHE]). [CO_2 + O_3] + [PHE] could alleviate the inhibition effect of [O_3] + [PHE] on those indicators and enzyme activities. These trends were basically consistent with the alteration trend in soil without adding phenanthrene. Moreover, the interaction within [CO_2], [CO_2 + O_3], [Amb], [O_3] and the two soil treatment models groups had no significant impact on MBC, MBN, PRA, SA, UA, POA, APA, NPA, the reason of which might be that CO_2 and O_3 directly affect of leaf tissue of cabbage, while the soil phenanthrene directly affect the root system of cabbage. The increase of CO2 or/and O2 might play an indirect role with soil phenanthrene through affecting photosynthesis of leaves and secretion of root system of cabbage, and only changed the value of physical and medical while did not change its trend. Its microscopic mechanism remains to be further studied.

(Received 8th Mar 2019; accepted 21st May 2019)

Abstract. As a major sport event attracting global attention, the Olympic Games reflect the overall national strength, and highlight the international influence and competitiveness of the host country. As the competitive events have a requirement for the environment of the host country, which is a good opportunity to improve the ecological civilization of the host country. Beijing 2008 Olympic Games has played an important role in improving the ecological environment of Beijing. With the approaching of the Winter Olympics in 2022, we have ushered in new opportunities to promote the construction of Beijing's ecological civilization. Taking Beijing's ecological civilization as the research subject, we construct the evaluation index system of the index of ecological civilization, and use the coefficient of variation method to determine the weight of the index. It evaluates Beijing's ecological civilization from five aspects: growth quality, environmental protection, environmental quality, resource utilization and environmental governance. It is concluded that the index of Beijing's ecological civilization is on the rise as a whole. It has a significant impact on the construction of ecological civilization, and the measures taken by the government are ready for the successful hosting of the 2022 Winter Olympic Games.
Keywords: *ecological environment, host country, Beijing, evaluation index system, comprehensive national strength*

Introduction

The Olympic Games held every four years are the most influential international event in the world; it is of great consequences and will bring far-reaching significance for any hosting country. The 2008 Beijing Olympic Games not only promoted the economic development of various industries (Kang et al., 2017; Ogunyele et al., 2018), but also improved the urban ecological environment. On the occasion of the Olympics Games, Beijing municipal government carried out environmental protection activities such as increasing green areas, reducing emissions and pollution to further promote ecological development (Geisendorf and Klippert, 2017; Khanchoul et al., 2018). A report delivered at the 19th National Congress stated that we must realize that lucid waters and lush mountains are invaluable assets and we should have a strong commitment to socialist ecological civilization and work to develop a new model of modernization with humans developing in harmony with nature. The concept of ecological civilization has continuously penetrated into all aspects of China's social and economic development. To be better prepared for the 2022 Winter Olympics, we should not only maintain steady economic growth, but also

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85138525

maintain a good environmental quality (Zhou et al., 2018; Nawaz et al., 2018). As the capital of China, Beijing must play a leading role in the construction of an ecological civilization.

The term building an ecological civilization is proposed concerning China's construction, while foreign research mainly focuses on environmental aspects of resource utilization, environment and sustainable development. International organizations, foreign governments and scholars at home and abroad have constructed a number of sustainable development evaluation index systems from different perspectives. So far, there are four versions namely EPI2008, EPI2010, EPI2012 and EPI2014. Foreign researches on the ecological environment have been relatively complete, providing a good foundation for us. Eco-civilization is a concept with Chinese characteristics, which is of great significance to the sustainable development of China. Since the successful completion of the 2008 Beijing Olympic Games, more attention has been paid to the ecological environment (Shen, 2018). Chinese scholars have provided new strategies for environmental improvement (Fernando, 2016; Arslan et al., 2018) from the perspective of behavioral science. From the perspective of green ecological planning and economy, they have found that new urban planning can promote the construction of resource-based cities (Guan, 2016). Eighteen evaluation indicators were selected from water carrying capacity, land carrying capacity, atmospheric environmental carrying capacity, energy carrying capacity and environmental carrying capacity. An index system of carrying capacity of urban resources and environmentally friendly living in ecological civilization (Zhang et al., 2017; Kumar, 2018) was established. The model method of ecological benefit and trade-off in circular economy practice was also provided, as well as the development of regional ecological industry (Sun et al., 2017). For China's rapid urbanization, Guiyang and Port, as typical eco-civilized cities, provide an ideal laboratory to develop a hybrid model of carbon emissions and energy consumption (Fang et al., 2017; Liang and Wenshun, 2019), and provide policy guidance for the port to promote the construction of ecological civilization from the perspective of PECC (Li, et al., 2018). Not only should we pay attention to the education of ecological civilization, but also to the regional ecological innovation in China (Yu et al., 2016). Scholars have established a comprehensive evaluation model of ecological civilization education in Colleges and universities (Ping et al., 2018; Suhaili and Samsudin, 2018), and selected 30 provinces. The level of regional ecological innovation was evaluated, and the factors influencing regional ecological innovation in China (Chen et al., 2017; Rajendran and Mohsin, 2018) were obtained.

To sum up, scholars at home and abroad have inherited rich experience and achieved fruitful research results. Because of different research directions, there is no uniform standard for evaluation index. Most of the studies at home and abroad focus on the macro level of environment and city, without considering the impact of major historical events on ecological civilization. Based on this, this paper takes Beijing as the research object, evaluates the development of ecological civilization after the Olympic Games, and predicts the ecological civilization of the Olympic Games in 2022, which is also the starting point and innovation of this paper.

Materials and methods

Evaluation of research thought of ecological civilization

Ecological civilization is the inevitable requirement for the harmonious coexistence of man and nature. It is a synthesis of eco-politics, eco-economy, eco-environment, eco-culture

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85138525

and eco-system. On the basis of previous studies, this paper draws lessons from the existing index system, relevant policies and the actual situation of Beijing, constructs the evaluation index system of ecological civilization, which can better measure the ecological civilization index of Beijing (Serpe, 2018; Madhav et al., 2018). In order to establish a harmonious development between human and nature, there are five secondary indicators, namely, growth quality, environmental protection, environmental quality, resource utilization and environmental governance. Each secondary indicator has corresponding three-level indicators, totaling 27 three-level indicators. The ecological civilization index is calculated more scientifically from five different aspects. Based on scientific principles and from the practical point of view of the construction of ecological civilization, this paper takes Beijing and 16 regions as the research objects, adopts the time series data of Beijing from 2009 to 2016 and the panel data of air quality of each region, carries out the comprehensive evaluation of ecological civilization, and predicts the ecological civilization index of the 2022 Winter Olympic Games. By comparing the air quality of different regions (Lee, 2016), the regional disparities and shortcomings in the process of ecological civilization construction in Beijing and other regions are analyzed, the main influencing factors of ecological civilization in Beijing are revealed, and the direction of efforts is determined (Lee et al., 2016; Raj and Prabhakaran, 2018), so as to provide a better living environment for the hosting of the Winter Olympic Games.

Construct an evaluation index system and weight determination

The scientific indicator system is crucial for the objective evaluation of ecological civilization. The quality of indicators directly affects the scientific nature and accuracy of results of ecological civilization evaluation. Based on the scientific nature of indicators (Marinelli, 2018), the availability of data, the comparability of regional data, the measurability of results, and the principles of predictability, an ecological civilization indicator system is constructed. It is necessary to consider the new elements arising from the 2008 Olympic Games. In the light of the resource-constrained objectives set out in the 12th Five-Year Plan Outline for National Economic and Social Development and the 13th Five-Year Plan Outline for National Economic and Social Development (Oglu Nasirov, 2018), the 19th National Congress put forward the socialist ecological concept. The General Office of the State Council issued the Evaluation and Evaluation System for the Objectives of Ecological Civilization Construction and Green Hair. On the basis of the exhibition index system and the "Three-year Action Plan for Winning the Blue Sky and Defending the War" issued by the State Council, as well as the existing research results on ecological civilization at home and abroad, the index system of ecological civilization in Beijing is constructed.

According to the connotation of ecological civilization and the design principle of the index system, the three-level index system is constructed, and the comprehensive evaluation index system is progressive step by step (Sun et al., 2016). The whole index system is divided into three levels, the first level is the target level and the general goal; the second level is the factor level, which is the factor influencing the overall goal. The ecological civilization index of the target level is divided into five elements, namely, growth quality, ecological protection, air quality, resource utilization and environmental governance; the third level is the index level, which is composed of 27 indicators. In the total index system, there are 11 absolute indexes and 16 relative indexes. Among them, there are 20 positive indicators and 5 negative indicators. This paper takes Beijing as the research object., the evaluation data comes from Beijing Statistical Yearbook 2009-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85138525

2016, Statistical Yearbook 2009-2016 of Beijing Municipal Environmental Protection Bureau, Statistical Yearbook 2009-2016 of Beijing Water Affairs Bureau, Annual Report on Ecological Civilization of Beijing Environmental Protection Bureau in 2009-2016, Statistical Yearbook of Beijing Municipal Bureau of Landscape Architecture 2009-2016 and other relevant statistical yearbooks (Song et al., 2016). Because some data are not available, the method of interpolation is used to calculate the missing data.

The determination of index weight is a key factor in the evaluation of ecological civilization index (*Table 1*). The weight of the index affects the scientific nature of the evaluation results. According to the nature of the evaluation indicators (Zhang et al., 2016), the evaluation indicators are divided into two categories: positive indicators and negative indicators. The positive indicator is the indicator that the bigger the value, the better, and the negative index is just the opposite. Considering the characteristics of ecological civilization, research needs and actual situation, this paper will use the variable coefficient in the objective weighting method to determine the weight of each index. The weights of each indicator are calculated as shown in *Table 1*.

Table 1. *Weight of each indicator in the indicator system*

Grade 1 indicator	Grade 2 indicators	Weight	Grade 3 indicators	Nature	Weight
ECI	Growth quality	0.220892487	GDP per capita (yuan/person)	Positive	0.031709382
			Urban per capita disposable income (yuan)	Positive	0.038115002
			Rural per capita disposable income (yuan)	Positive	0.032653215
			Contribution of tertiary industry to regional GDP growth (%)	Positive	0.039223131
			R&D fund investment (%)	Positive	0.019192412
			Urbanization rate (%)	Positive	0.019983622
	Ecological protection	0.131205615	Forest coverage rate (%)	Positive	0.03765499
			Living wood growing stock (10,000 m^3)	Positive	0.035318786
			Proportion of nature reserve in urban area (%)	Positive	0.043285846
			Urban green coverage ratio (%)	Positive	0.032408979
			Forest coverage rate (%)	Positive	0.035415529
			Per capita park green space (m^2/person)	Positive	0.025207522
	Environment quality	0.212767028	Chemical oxygen demand (10,000 tons)	Negative	0.044148014
			Ammonia nitrogen emissions (10,000 tons)	Negative	0.058856794
			Sulfur dioxide emissions (10,000 tons)	Negative	0.039333396
			Soot emissions (10,000 tons)	Negative	0.037713962
			Mean noise of regional environment (%)	Negative	0.035089344
			Mean noise of trunk roads (%)	Negative	0.02527412
	Resource utilization	0.22308159	Comprehensive utilization rate of general industrial solid wastes (%)	Positive	0.03247559
			Comprehensive utilization rate of hazardous waste (%)	Positive	0.033620128
			Per capita water resources (100 million m^3/person)	Positive	0.036348532
			Per capita water consumption (10,000 m^3/person)	Positive	0.058662852
	Environmental governance	0.21205328	Sewage treatment rate (%)	Positive	0.038919427
			Harmless treatment rate of domestic garbage	Positive	0.023913285
			Proportion of environmental pollution prevention investment in GDP (%)	Positive	0.054794877
			Proportion of pollution reduction investment in GDP (%)	Positive	0.041328738
			Proportion of natural ecological protection investment in GDP (%)	Positive	0.049352524

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85138525

As can be seen from *Table 1,* Beijing's ecological civilization is evaluated from these five aspects (Glenys, 2017). Among grade 2 indicators, growth quality, environmental quality and resource utilization account have a large weight ratio, which is due to reasonable and effective policies implemented by government. The weight of ecological protection is relatively small. It is because the areas of Beijing, nature reserves and forests will not have major changes in years to come, and the amount of change is too small to adjust (Sun, 2018). The Grade 3 indicators of chemical oxygen demand, ammonia nitrogen emissions, sulfur dioxide emissions, the proportion of nature reserves in urban areas, urban green coverage, and proportion of natural ecological protection investment in GDP have a large weight. In the construction of ecological civilization, we should pay attention to the indicators with greater weight and make an improvement from these aspects.

Determination of ECI

ECI of Beijing and the secondary indicators are calculated by multiplying weight of each indicator by the standardized value. Obviously, the greater the value of the ecological civilization index, the higher the level of ecological civilization, and vice versa. The overall ecological civilization index of Beijing is obtained, which is shown (*Table 2*).

Table 2. *Beijing's ecological civilization index*

Year	Growth quality	Ecological protection	Environmental quality	Resource utilization	Environmental governance	ECI
2009	0.03922313	0.02045288	0.08077432	0.00000000	0.09824335	0.23869369

Results

(1) The ECI shows a trend of decreasing first and then rising (*Fig. 1*).

The ecological index from 2009 to 2011 has slightly decreased. The main reason is that the implementation measures lag behind; as hosting the Olympic Games require financial expenditures in all aspects, many factories were put into production after the Olympic Games to increase positive growth in a timely manner, which emitted a large amount of pollutants, resulting in a decline in the ecological index (Zhang, 2017).

The ECI continued to grow from 2012 to 2016. The main reason is that 2012 is the most crucial year for the implementation of the 12th Five-Year Plan for the prevention and control of dangerous pollutants and solid pollutants. Beijing has fully implemented the environmental management system for solid wastes, actively explored the management model of hazardous wastes from social sources, and fully safeguarded the environmental safety of the capital. Secondly, the number of nature reserves has

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85138525

increased, resource utilization has become more rationalized, and the government has invested a large amount of money to manage the environment.

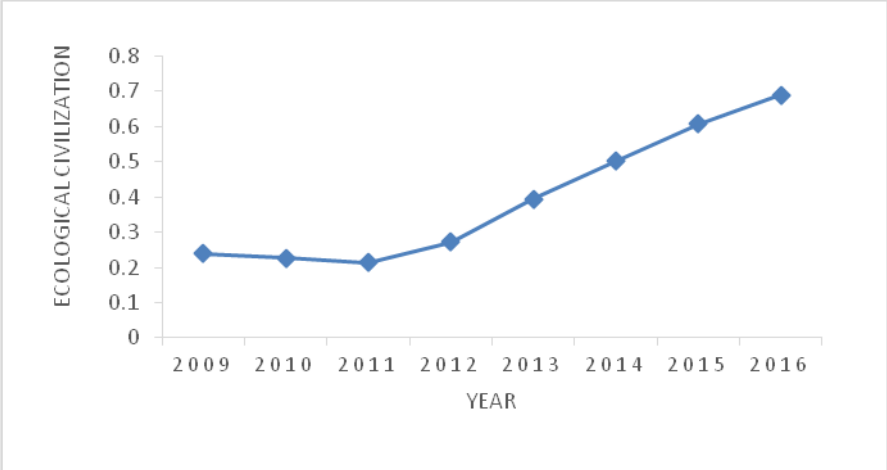

Figure 1. *ECI of Beijing after 2008 Olympic Games*

(2) The growth quality index first grew at a faster rate, then increased slowly, and finally tended to be stable (*Fig. 2*).

Beijing's growth quality index is growing steadily. The main reason is that Beijing has actively expanded domestic demand and deepened supply-side structural reforms for the past eight years. The overall economy is stable and positive. Secondly, as a capital city, Beijing is a place that many people yearn for, and a large number of people swarmed into Beijing. In order to solve the employment problem, Beijing government has continued to promote the adjustment of industrial structure, accelerated the construction of science and technology innovation centers, and increased the disposable income of residents. Science and technology innovation has become a new engine of economic growth, and Beijing's investment in testing and research and development has been increasing. As a result, the Beijing's quality growth index is growing steadily (Zhang, 2018).

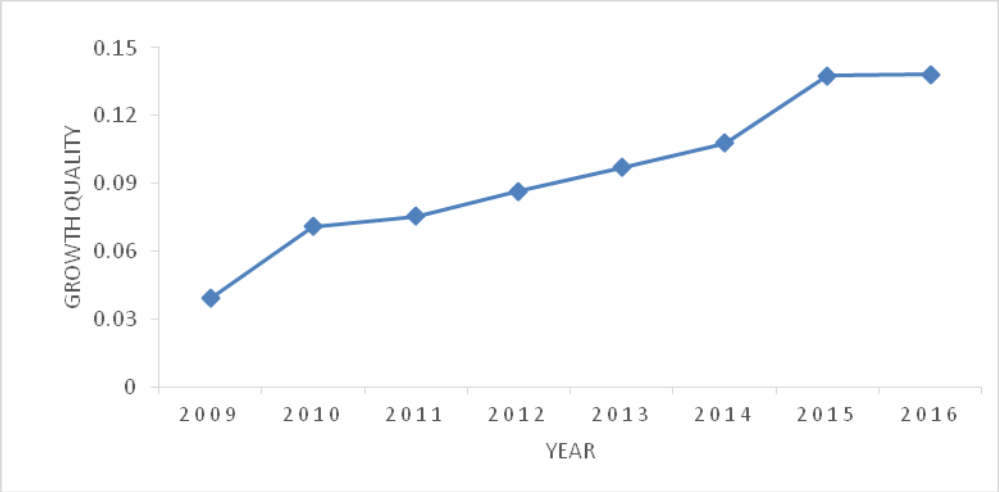

Figure 2. *Growth quality index of Beijing after 2008 Olympic Games*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85138525

(3) The ecological protection index is growing steadily (*Fig. 3*).

In 2009-2015, the ecological protection index grew steadily, and it did not change too much in 2016. It was mainly because that the stationarity of Beijing area, forest coverage rate and the proportion of nature reserves in urban areas increased. Furthermore, Beijing government implemented construction projects of nature reserves protection, developed biodiversity protection action plans; and finally, urban greening coverage has been increasing thanks to the construction of national environmental protection model urban areas, ecological zones, and ecological civilization pilot areas.

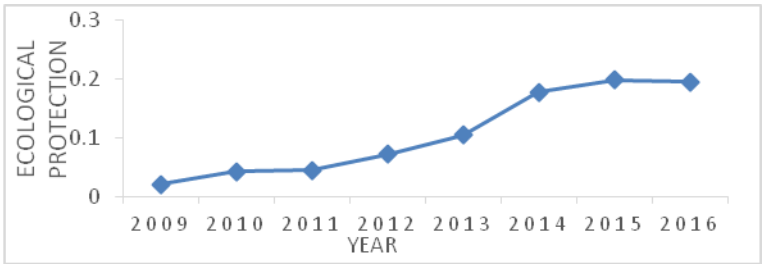

Figure 3. *Ecological protection index of Beijing after 2008 Olympic Games*

(4) The environmental quality index declined firstly and then rose (*Fig. 4*).

The environmental quality of Beijing continued to decline during 2009-2011, which was mainly due to construction of a large amount of infrastructure and the investment of a large amount of funds. Besides, the shutdown of a few heavy industries led to a decline in the economic level. In the post-Olympic period, in order to make the economy grow as before, the manufacturing industry resumed production and emitted a large amount of pollutants.

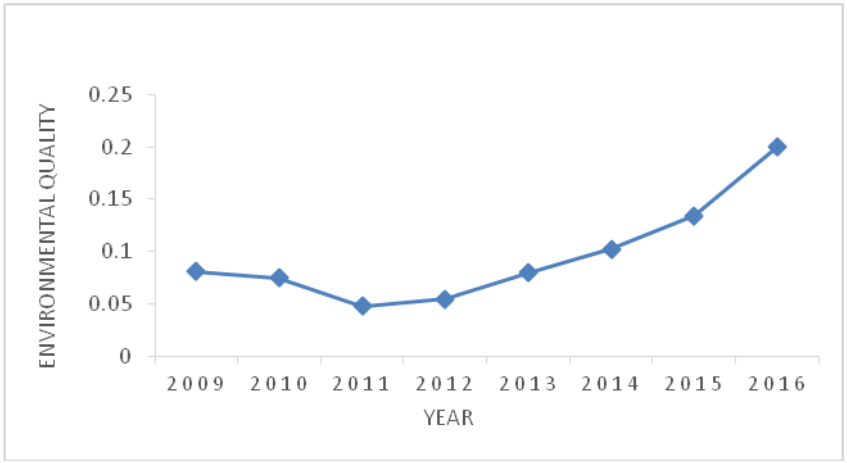

Figure 4. *Environmental quality index of Beijing after 2008 Olympic Games*

The environmental quality began to increase year by year during 2012-2016. The main reason is that the Environmental Protection Agency has significantly enhanced the prevention and control of atmospheric pollution, pollution reduction and air pollution prevention and control (Feng et al., 2018); secondly, pollution reduction efforts

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85138525

continued to be maintained, and air cleaning activities were carried out; finally, unified management was implemented on heavy air pollution (Hao et al., 2019).

(5) Resource utilization index continued to increase (*Fig. 5*).

The resource utilization index has increased year by year during 2009-2016. Firstly, it was because the solid waste environmental management system was fully implemented and industrial pollution prevention strategies and means were optimized from multiple angles. Secondly, solid waste supervision was strengthened to promote industrial pollution reduction, and the utilization rate of industrial solid waste has increased. Finally, the process will be improved if the pollutants were substandard, so the sewage treatment rate continued to increase.

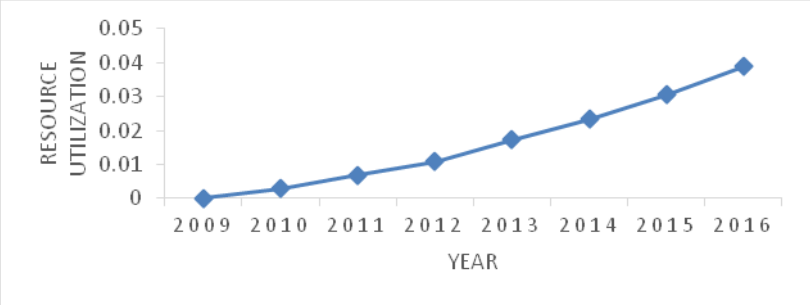

Figure 5. *Resource utilization index of Beijing after 2008 Olympic Games*

(6) The environmental governance index dropped sharply first, then increased year by year, and finally stabilized (*Fig. 6*).

The environmental management in 2009-2010 dropped drastically. It was mainly due to project expenditure in terms of pollution prevention in 2009 and less investment in similar projects in 2010. Besides, major pollutant emission reduction projects were invested in 2009, and the budget for similar projects in 2010 decreased (Pu, 2019)

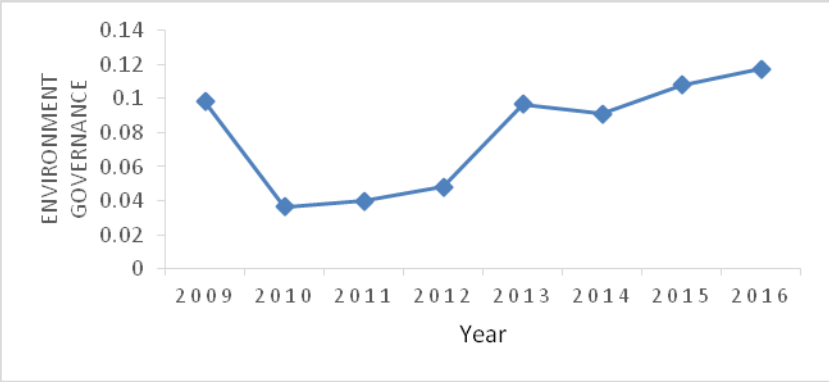

Figure 6. *Environmental governance index of Beijing after 2008 Olympic Games*

It remained on a slow-growth path in the 2010-2012 and 2013-2016 periods, but achieved rapid growth from 2012 to 2013, which was mainly due to the implementation of the 2013-2016 Clean Air Action Plan. Besides, the unliquidated funds that in the previous year were paid (Wang et al., 2019).

Discussion

In this paper, we use the quadratic fit to predict and present a relatively smooth curve. If a fitting is used, a regression straight line will be made, which makes a large error for the result. At this time, a quadratic fitting is required to obtain a quadratic regression equation, making the prediction result more accurate and reliable. The 2009-2016 data will be used to predict the growth quality, ecological protection, environmental quality, resource utilization, environmental quality and ecological civilization index of the 2022 Winter Olympics. The forecast trend is shown (*Fig. 7*).

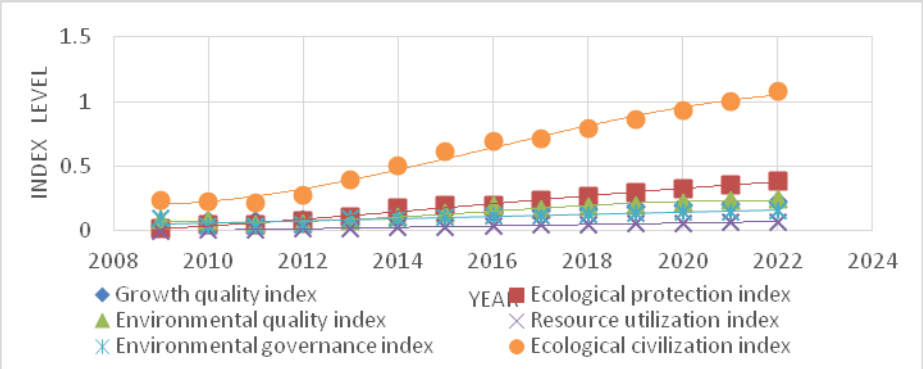

Figure 7. *Prediction map of various indicators in Beijing*

It can be seen from *Figure 7* that the growth quality, ecological protection, environmental quality, resource utilization, and environmental quality index increase in the 2022 Winter Olympics. Therefore, Beijing's ECI has also been increasing year by year. Compared with the ECI of 1.077 in 2020 and 0.717 in 2017, the ECI in the 2022 Winter Olympics increase significantly. Therefore, we believe that the predicted ECI can be achieved if we implement protection policies and improve public awareness of environmental protection.

Conclusions and suggestions

Conclusions

(1) Major events such as the Olympic Games have a major impact on the construction of ecological civilization

There are obvious differences in the index of ecological civilization before and after the Olympic Games. The index of ecological civilization has increased significantly after the Olympic Games, which shows that the Olympic Games have a significant impact on the construction of ecological civilization (Chang, 2018).

In order to successfully hold the Olympic Games, the government has adopted effective policies and the index of ecological civilization has increased, which shows that the policy has a great impact on the development of ecological civilization. The economic and ecological development of each region cannot be separated from the regional characteristics and policy impact of each region, which makes the ecological index and air quality index of Beijing and each region improved.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85138525

The Olympic Games is an undertaking that our country has spent a lot of money to accomplish. It is not only to enhance our international status and influence, but also to promote the rapid development of all aspects of our country. The Olympic Games have received the attention of the media from all walks of life, forcing us to issue relevant policy documents, to pay attention to the construction of ecological civilization, and to take the Olympic Games as an important opportunity to promote the coordinated development of ecology and economy.

(2) Get prepared for the 2022 Winter Olympics

According to the prediction of air quality in Beijing and various regions, the 2022 Winter Olympics will be held in Yanqing District, Beijing, which has laid a good foundation for ecological construction. The ECI and air quality index will reach the ecological environment indicators required for hosting the Olympic Games.

Therefore, before the coming of the Winter Olympic Games in 2022, we must take measures to protect the environment, improve the quality of the environment, and pay attention to the construction of ecological civilization, so as to leave a good impression on the people of the world.

Suggestions

With the end of the 2008 Summer Olympics, Beijing's ecological civilization has shown a trend of continuous growing of ecological civilization index and the air quality index so far, but there are also some shortcomings. This paper makes the following suggestions for reference.

(1) Enhance protection and improve the effectiveness of environmental policy implementation

It can be seen from the chart of ECI that the ecological civilization index has dropped significantly after the 2008 Olympic Games. Therefore, in preparing for the 2022 Winter Olympics, we must avoid the occurrence of similar problems, and adopt a long-term mechanism to build an ecological civilization. We cannot rely on temporary management and control, otherwise, it will happen again. Firstly, we should develop effective and targeted measures at regular intervals: environmental pollution control actions; secondly, we will promote the application of new clean energy, prevent and control from the source to reduce tail gas pollution; and finally, develop coordinated development strategy between humans and nature to achieve green development (Hu, 2018).

We should carry out the development strategy of ecological civilization from the following four aspects: in the aspect of eco-economy, vigorously develop tourism and rationally develop local natural resources; in the aspect of ecological environment, we should attach great importance to forestry construction and constantly strengthen the project of benefiting people and increasing green; in the aspect of ecological life, we should save water, reduce waste discharge and improve the rate of waste water treatment; and in the aspect of ecological system. To implement the Party's guidelines and establish a sound ecological environment supervision system. In order to achieve the win-win situation of economic and social development and ecological environment protection, a compound ecological and social system with virtuous circle of economy, society and nature is established.

DOI: http://dx.doi.org/10.15666/aeer/1704_85138525

(2) Enhance public awareness of ecological protection and enhance environmental responsibility

We are about to usher in the 2022 Winter Olympics, combined with the socialist ecological concept put forward by the 19th National Congress of CPC, it is a good opportunity for us to strengthen the education of environmental awareness, to put forward the idea of ecological protection, and to achieve it through practice. A series of specific measures can be taken (Chen et al., 2018). For example, the government can conduct environmental education first, so that citizens can establish environmental awareness, form the concept of common development between man and nature in the mind, and secondly, vigorously promote environmental protection knowledge through the influence of the news media. Everyone protects the environment, increases participation in environmental protection issues, and promotes ecological development. Finally, lectures or seminars to protect the environment can be held to raise the awareness of citizen protection. This will enhance the sense of responsibility for environmental protection in the whole society and make the ecological civilization construction of the 2022 Winter Olympics better.

(Received 8th Mar 2019; accepted 21st May 2019)

Abstract. General Secretary Xi Jinping clearly pointed out in the report of the Nineteenth Party Congress that speeding up the reform of ecological civilization system and building ecological civilization are the millennium plan for the sustainable development of the Chinese nation. The ecological problems of mega-cities are related to the sustainable development of economy and society. Because the radiation area of mega-cities is relatively wide, the geographical environment of various city regions is different, and so is the functional orientation, the selection of evaluation criteria and evaluation indicators is particularly important in the evaluation process. Based on the perspective of mega-city functional areas and combining it with the urban development planning of Beijing, this paper discusses the evaluation of ecological civilization in mega-cities, constructs the evaluation index system of ecological civilization index, and uses the coefficient of variation method of objective empowerment method to determine the index weight, and evaluates the ecological civilization of each functional area in Beijing from three aspects: growth quality, ecological protection and air quality. It can be concluded that the index of ecological civilization in Beijing shows an upward trend as a whole, each functional area presents different characteristics, and the implementation of policies has a significant impact on the construction and development of ecological civilization.

Keywords: *urban development, functional areas, judgement standard, coefficient variation, sustainable development*

Introduction

At present, China's rapid development is facing the ecological dilemma brought about by economic development and social transformation. In the Amendment to the Constitution of the People's Republic of China adopted in 2018, ecological civilization was written into the Constitution, which had a higher legal status and had stronger legal effects (Lai, 2013; Nwankwo and Nwankwoala, 2018). It was written into the Party Constitution and Constitution, which made the idea of ecological civilization a vivid manifestation of the will of the state. With the improvement of urbanization level, people pay more and more attention to ecological problems (Yan, 2017; Yang et al., 2018b, c; Sufiyan et al., 2018). The number of megacities is rising, and the proportion of GDP and total population is expanding. Therefore, the evaluation of ecological civilization in megacities is particularly important. As a typical megacity, Beijing's ecological civilization building is related to the image of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85278540

the country and the capital, and it relates to the quality of the city and the welfare of the people.

As the center of human activities and social civilization, the city has further reduced the living standards of human beings and hindered the sustainable development of urban ecosystems at the expense of severe environmental degradation and enormous ecological environmental pressures (Liu et al., 2014; Yilmaz, 2018; Azeem et al., 2018). Chinese government promotes ecological civilization in the "13th five year plan" (2016-2020) period. As a result, ecological impacts become highlighted in the national circular economy practices (Sun et al., 2016; Nkwuda et al., 2019). According to official statistics, 70% of China's population will live in cities in 2030, and China's urbanization will have a great development. The report points out that China's urbanization draws on the theory of ecological modernization and uses "sustainability" and "governance" and "ecological civilization". It is very meaningful to see that the rise in the research on ecological civilization can be attributed to this decision (Muldavin, 2015; Xu, 2018).

The national strategy of building an ecological civilization is not simply to focus on environmental issues, but to create a new "five-pronged" civilization based on a new historical orientation. Turning to ecological civilization, realizing national strategy, and benefiting and leading the world with China's program of ecological civilization, education is not only an important starting point, but the only way. The research and construction of the education evaluation index system of China's efficient ecological civilization will provide a new method (Ping, 2018; Kasim et al., 2019). Low-carbon m & a is a new mode of merger and acquisition under the ecological civilization education (Tian, 2017; Dali and Kamarudin, 2018). The historical assessment and future prediction of ecological security (Yang et al., 2018a) and the study on the establishment of safety factor system model for the construction of water ecological civilization (Zhang, 2017; Baharuddin and Samsudin, 2018) are also very important. Regional landscape-ecological studies have acquired a special topicality as they assure efficient environmental conservation and sustainable use of natural resources. A landscape-ecological analysis was performed based on four basic integral indices: (1) ecological potential, (2) ecological stability, (3) ecological load and (4) ecological tension (Muradyan and Asmaryan, 2015; Emeh and Igwe, 2018). Urban ecological vulnerability is measured on the basis of ecological sensitivity and resilience based on the concept analysis of vulnerability. GIS-based multicriteria decision analysis (GIS-MCDA) methods are used, supported by the spatial analysis tools of GIS, to define different levels of vulnerability for areas of the urban ecology. These areas are further classified into different types of regulatory zones. In this way, five types of vulnerability areas have been classified as follows: very low vulnerability, low vulnerability, medium vulnerability, high vulnerability and very high vulnerability (Zhang et al., 2015; Karaoui et al., 2018).

The establishment of ecological civilization evaluation index plays a decisive role in evaluating the level of ecological civilization in a region. Different scholars, according to different practical significance to put forward the index system of different, consider URECC evaluation index system (Zhang et al., 2018) and the index system of people-oriented EC (Zhang et al., 2016), which are for the overall, different areas have different characteristics, establish a comprehensive index of regional ecological civilization in China, the regional ecological civilization construction is particularly important to carry on the scientific and objective evaluation (Liu et al.,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85278540

2016). Understanding the link between ecological civilization and performance assessment will help to better monitor the level of ecological civilization (Tan et al., 2014).

In summary, scholars have inherited rich experience and have rich research results, covering a wide range of areas, and the evaluation indicators vary widely. For megacities, they should pay attention to regional differences, different functional areas, existing natural resources, economic conditions, etc. Different, then the role played is different. The division of functional areas has given us a new perspective on the study of Beijing's ecological civilization. On this basis, we can conduct ecological civilization evaluation from the perspective of functional areas and explore the ecological civilization of Beijing's functional areas.

According to the ecological civilization evaluation of the functional areas, we can see that the division of the functional areas of Beijing has, to a certain extent, rationalized the management system of the functional areas and the administrative area. Each function area has its own characteristics, is of great significance in resource integration, urban space expansion and urban efficiency. This is the key point for the future development of Beijing's ecology, and it is also the research entry point and academic innovation of this paper.

Methodology

Construction of Beijing's ecological civilization evaluation system

Overall evaluation ideas

Beijing Regional Statistical Yearbook officially divided functional areas from 2011. Based on this, from the perspective of the practice of ecological civilization construction, the four functional areas of Beijing are taken as the basic unit, the panel data of various functional areas in Beijing from 2011 to 2016 (12th Five-Year Plan and 18th National Congress periods) are selected to carry out comprehensive evaluation of the level of ecological civilization, compare and analyze the pattern characteristics and existing deficiencies of various functional areas in Beijing during the process of ecological civilization construction, and reveal the main influencing factors of ecological civilization in various functional areas of Beijing to determine what we should work on in the future.

Building an indicator system

Based on the 13th Five-Year Plan for Economic and Social Development, the Assessment System for Ecological Civilization Construction and the Green Development Indicator System, and the existing research results at home and abroad, the index system of ecological civilization index the various functional areas in Beijing will be built.

According to the connotation of ecological civilization and the design principle of index system, a set of three-level superposition and layered recursive comprehensive evaluation index system is constructed. However, due to the lack of indicators in each district and the data released by the National Bureau of Statistics, the indicators were adjusted. The target ecological civilization index (ECI) is divided into three elements, namely, growth quality, ecological protection, and air quality (*Table 1*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85278540

Table 1. *ECI System of functional areas in Beijing*

Grade 1 indicator	Grade 2 indicators	Grade 3 indicators	Unit	Nature
Ecological civilization	Growth quality	GDP per capita	10,000 yuan/person	Positive
		Urban per capita disposable income	Yuan	Positive
		R&D	10,000 yuan	Positive
		Urbanization rate	%	Positive
	Ecological protection	Woody plant cover rate	%	Positive
		Proportion of wetland area in urban area	%	Positive
		Forest stock	10,000 m^3	Positive
		Forest coverage rate	%	Positive
		Harmless disposal rate of household garbage	%	Positive
	Air quality	Annual average concentration of SO2	mcg/m3	Negative
		Annual average concentration of NO2	mcg/m3	Negative
		Annual average concentration of inhalable particulate matter	mcg/m3	Negative
		Average annual concentration of fine particles (PM2.5)	mcg/m3	Negative

Data source and evaluation method

The evaluation data of the ECI in Beijing and various districts come from Beijing Statistical Yearbook, Statistical Yearbook of Beijing Municipal Environmental Protection Bureau, Statistical Yearbook of Beijing Water Affairs Bureau, Statistical Yearbook of Beijing Municipal Bureau of Landscape Architecture and related statistical yearbooks. This paper uses the ecological civilization index to evaluate the ecological civilization. The specific process of the ecological civilization index evaluation is as follows.

(1) Build an original indicator data matrix

Suppose there are m evaluation indicators, n years, forming the original indicator data matrix:

$$Xij = (Xij)m \times n(0 \leq i \leq m; 0 \leq j \leq n) \quad \text{(Eq.1)}$$

In *Equation 1,* Xij refers to the i-th indicator, and the index value of the j-th year.

(2) Data standardization processing method

Since the attributes of the ecological civilization evaluation index are inconsistent with the measurement unit, in order to make calculation by a unified method, the data needs to be dimensionlessly standardized. According to the nature of the evaluation indicators, the evaluation indicators are divided into two categories: positive indicators and negative indicators (Rojamary and Uma, 2017). The standardization method is:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85278540

Positive indicator:

$$Z = \frac{Yij - y\min j}{Yj\max - yj\min} \quad (i = 1,2,\ldots,n;j = 1,2,\ldots,n) \qquad \text{(Eq.2)}$$

Negative indicator:

$$Z = \frac{Ymaxj - yij}{Yj\max - yj\min} \quad (i = 1,2,\ldots,n;j = 1,2,\ldots,n) \qquad \text{(Eq.3)}$$

wherein: *Yj*max and *Ymin*j the maximum and minimum of X_{ij} indicator, the decision matric is Zij after standardized processing, this allows the data of the decision matrix to be processed.

(3) Determination of the weight of evaluation indicators

Considering the characteristics of ecological civilization and the needs and practice of the research, this paper will use the coefficient of variation method in the objective weighting method to determine the weight of each indicator. The method is:

$$Wi = \frac{Vi}{\sum_{i=I}^{m} Vi}, \quad Vi = \frac{\sigma i}{Zi} \qquad \text{(Eq.4)}$$

wherein: σ is the standard deviation of the i-th indicator, Z is the average of the i-th indicator, and V is the coefficient of variation of the i-th indicator. W refers to the weight of the i-th indicator (*Table 2*). In the process of calculating the weights, Beijing is given a weight as a whole, and the weights of each indicator are calculated.

Table 2. *Weights of indicators in the indicator system*

Grade 1 indicator	Grade 2 indicators	Weight	Grade 3 indicators	Weight
Ecological civilization	Growth quality	0.326289465	GDP per capita (10,000 yuan/person)	0.104145517
			Urban per capita disposable income (Yuan)	0.074994926
			R&D (10,000 yuan)	0.17295373
			Urbanization rate	0.02682463
	Ecological protection	0.539946483	Woody plant cover rate %	0.060229909
			Proportion of wetland area in urban area	0.262925633
			Forest stock	0.060981161
			Forest coverage rate	0.059912983
			Harmless disposal rate of household garbage (calculated by amount of garbage clean-up %)	0.021883686
	Air quality	0.139531838	Annual average concentration of SO2 (mcg/m3)	0.028731574
			Annual average concentration of NO2 (mcg/m3)	0.048975187
			Annual average concentration of inhalable particulate matter (mcg/m3)	0.047048155
			Fine particles (PM2.5) annual average concentration (mcg/m3)	0.030392911

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85278540

(4) Determination of ECI

$$Rij = \sum_{i=1}^{m} Zij * Wi \quad \text{(Eq.5)}$$

In the *Equation 5,* R represents the ecological civilization index. Based on this formula, the ecological civilization index Rij and Grade 2 indicators of various regions in Beijing can be calculated (*Table 3*). The data of each functional area is an average of the indexes of the districts and counties belonging to each functional area, so that it is convenient to compare the differences between the functional areas of Beijing.

Table 3. *Beijing ecological civilization index*

Functional areas	Year	Growth quality	Ecological protection	Air quality	Ecological civilization index

Result analysis and discussion

Dongcheng and Xicheng districts in Beijing have been identified as "the core functional area of the capital"; the four districts of Chaoyang, Haidian, Fengtai and Shijingshan are the "urban functional expansion areas" in Beijing; the "New Urban Development Area" include Fangshan, Tongzhou, Daxing, Shunyi and Changping districts; Mentougou, Pinggu, Huairou, Miyun and Yanqing are Ecological Conservation Development Area.

Index changes

Core functional area of the capital

Growth quality has the greatest influence on the ecological civilization index. It is related to the characteristics of the core functional area of the capital (*Fig. 1*). The core functional area of the capital are the highest level of urbanization of Beijing, gather most of the city-level and some important district-level commercial centers, and economic level is higher than other regions; the ecological protection index is the lowest and tends to be stable, mainly because its plant cover rate and forest coverage are not high; the effect of air quality on ecological civilization is on the rise. Based on this, the regional positioning of the core functional area of the capital is highlighted to promote financial service industry and a national business district, and to strengthen efforts for air quality control, in doing so, it is more conducive to promoting the ecological civilization level of the core functional area.

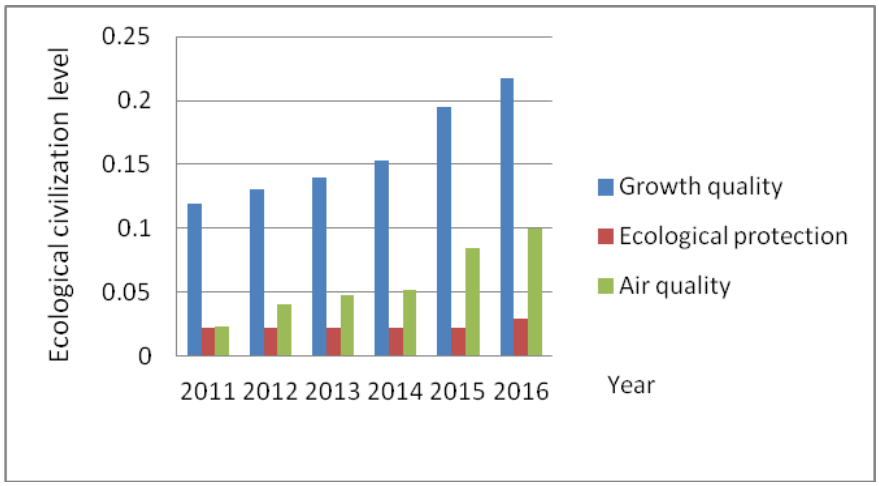

Figure 1. *Comparison of ECI in capital core functional areas*

Urban functional expansion area

The quality growth index of the urban functional expansion area continues to rise, and the quality growth index is the main influencing factor affecting the urban functional expansion area. Overall, the ecological protection index tends to be stable, the air quality index rises, and the urban function expansion area covers the Zhongguancun Science and Technology Park, and the important functional areas such as Beijing Central Business District (*Fig. 2*). It is a main area for the development of commercial and high-end industries in the metropolitan area with high level of economy

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85278540

and large population, and an important area that reflects Beijing's modern economy and the function of international exchanges.

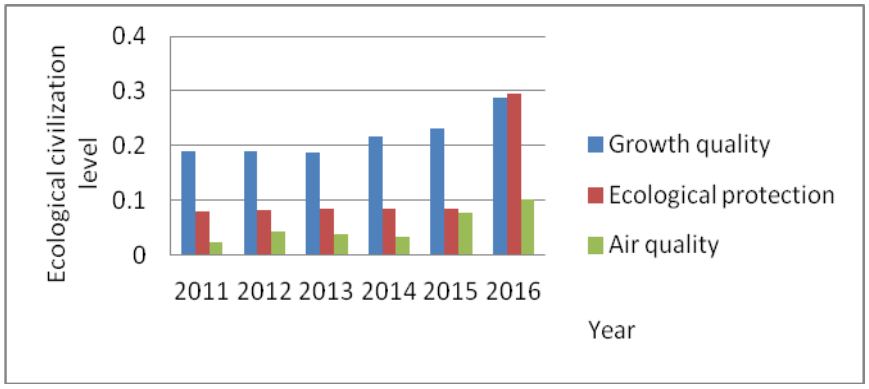

Figure 2. *Comparison of ECI in urban functional expansion areas*

New urban development area

It can be seen from *Figure 3* that the ecological protection index is the main influencing factor of the ecological civilization of the new urban development area, because the urban development new area is the main carrier of Beijing's high-tech industries, modern manufacturing and modern agriculture, and is the future development of Beijing's economic center and future cities (*Fig. 3*). Although the growth quality and the air quality index are inferior to the ecological protection index, the index has shown an upward trend over time (Olivares, 2017). We should introduce talents while maintaining the ecological environment, create a good business environment, and continuously improve the air quality.

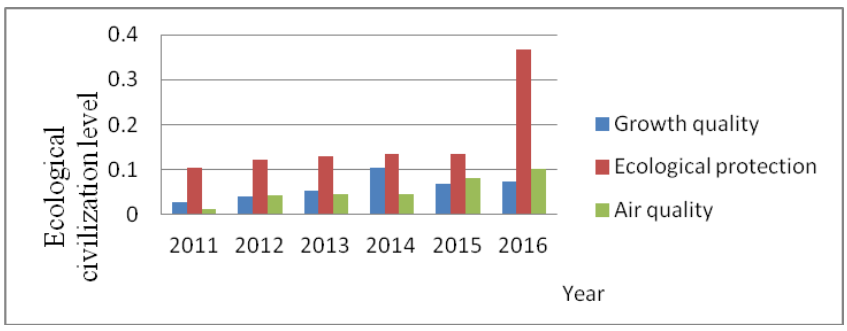

Figure 3. *Comparison of ECI in new urban development area*

Ecological conservation development area

The ecological protection and air quality index in the ecological conservation development area ranked first. It can be seen that ecological protection has always been a major factor affecting the ecological conservation development area, mainly because the ecological conservation development area is Beijing's ecological barrier and water source protection site, the environmentally friendly industrial base, and also an ideal space for Beijing citizens to take a leisurely life (Jaimes, 2017; Higuchi, 2017) (*Fig. 4*). We must strengthen the construction of ecological protection.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85278540

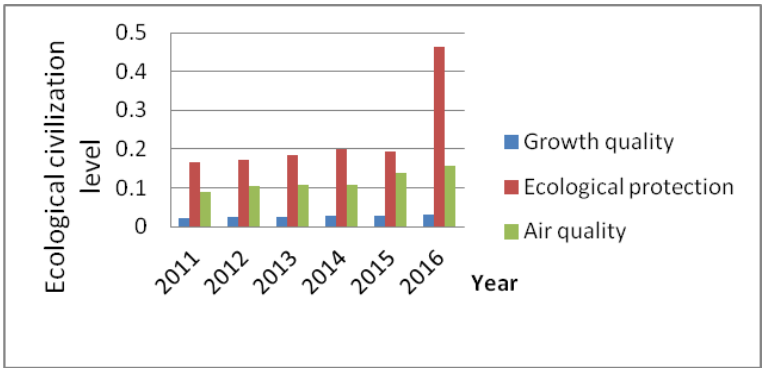

Figure 4. *Comparison of ECI in ecological conservation development area*

Change in growth rate

Comparison of functional areas under the same indicator

From 2011 to 2016, the air quality index had the highest growth rate in core functional area of the capital, urban function development area, and urban development new area, indicating that during the "Twelfth Five-Year Plan" and the implementation of the spirit of the 18th National Congress, air pollution control has made significant achievements (*Fig. 5*). The ecological protection index had the highest growth rate in the ecological conservation development area, indicating that the ecological conservation zone adapts to local conditions and develops its own advantages (Guevara-Hernández, 2018).

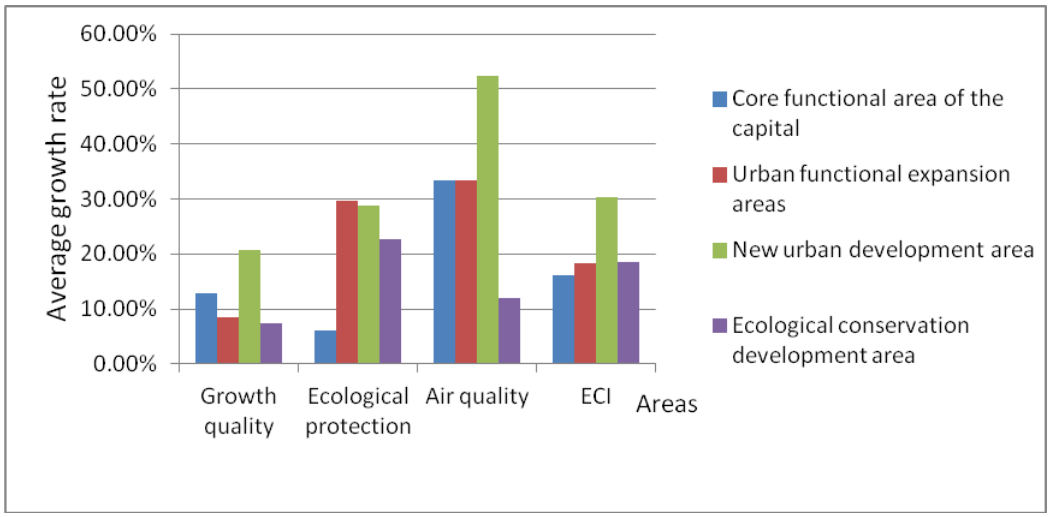

Figure 5. *Growth rate of various indicators in functional areas in 2011-2016*

Comparison of growth rate indicators for the same functional areas

From 2011 to 2016, the air quality index, ecological civilization index and growth quality index of the new urban development area have the highest growth rate (*Fig. 6*). The Outline of the Plan for Coordinated Development for the Beijing-Tianjin-Hebei Region released in 2015 pointed out that the core of promoting the coordinated development of Beijing-Tianjin-Hebei is to orderly relocate all non-essential functions

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85278540

from Beijing. Fangshan District is located in the southwest of the Beijing-Tianjin-Hebei region, shouldering the responsibility of "connection between inside and outside" (Naustdalslid, 2014). The economic and ecological development of Fangshan District has driven the development of new urban development area. Due to the promotion of policy or development needs, the development of new urban development area from 2011 to 2016 was extremely fast.

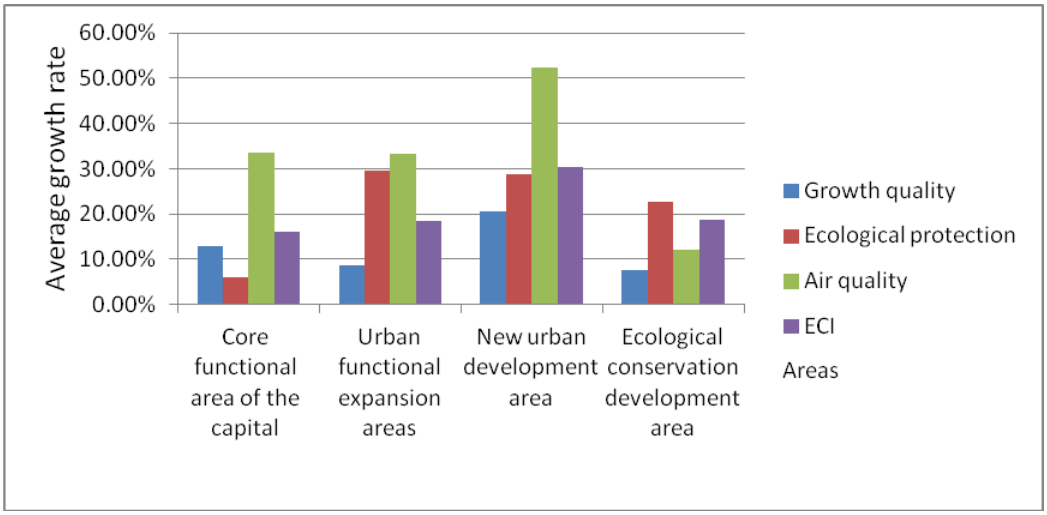

Figure 6. *Growth rate of various indicators in functional areas in 2011-2016*

Analysis of the factors affecting the development of ecological civilization in various functional areas

It can be seen from *Figures 1–4* that in 2016, apart from the core functional area of the capital, the ecological protection index of the other three areas increased rapidly, even surpassing the main influencing factors affecting these areas (Pechurkin and Somova, 2014; Olivares, 2017). This is mainly because 2016 is a crucial year for all kinds of people-benefit projects and green projects for Beijing, and Beijing has achieved fruitful results in ecological protection in 2016. At the same time, it can be seen that the ecological protection in the core functional area of the capital is currently in a state of saturation, and it is not suitable for large-scale tree planting (Mendoza, 2018; Jaimes, 2017).

Conclusions and suggestions

Conclusions

(1) The development of ecological civilization presents different characteristics in different functional areas

From the main influencing factors of various functional areas, quality growth is the main factor in the capital functional core area and urban functional expansion area, which is mainly related to the characteristics of these two areas, namely, high economic level and dense population (Higuchi, 2017); Ecological protection is the main influencing factor of urban development new area and ecological conservation area. The ecological environment and air quality of these two areas are excellent, with abundant

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85278540

forest resources and sparse population. Different functional areas present different characteristics, so we need to manage functional areas according to local conditions.

(2) The implementation of policies significantly affects the construction and development of ecological civilization

The impact of policies on the development of ecological civilization is enormous. With the conclusion of Beijing's people-benefit projects in 2016, except the core functional area of the capital in 2016, the ecological protection index of the other three areas has made a great leap forward. The development of various functional areas is inseparable from the development of other functional areas. The introduction of the Outline of the Plan for Coordinated Development for the Beijing-Tianjin-Hebei Region has driven economic development of new urban development area and brought changes to air quality. The implementation of policies will be more targeted and effective in improving the problems in the ecological civilization.

(3) Functional areas not optimally positioned

From the perspective of vertical time evolution, the level of ecological civilization in the four functional areas of Beijing is constantly improving. However, from the analysis of the horizontal dimension, urban functional expansion areas and ecological conservation development area have the highest level of ecological civilization, followed by new urban development area and core functional area of the capital. The core functional area of the capital is the most important carrier of the capital's function and "four services". However, the air quality index of the core functional area of the capital is not high, which will affect the impression of the capital and the people's healthier and more comfortable life.

Suggestions

(1) Develop regional ecological civilization according to local conditions

According to the development goals of Beijing's functional areas, we will vigorously implement the regional coordinated development strategy and give full play to the advantages and potentials of each region (Guevara-Hernández, 2018). There is no one-size-fits-all approach to technology and model, specific conditions require concrete analysis, and we should develop regional ecological civilization in accordance with local conditions. The capital functional core area and the urban function development area have developed rapidly. We should focus on quality growth, while the urban development new area and the ecological conservation development area are characterized by geographical marginality and abundant natural resources, and they have great advantages and potential in air quality and ecological protection. We will always adhere to the principle of developing regional ecological civilization according to local conditions to improve the level of ecological civilization.

(2) Ecological civilization driven by policies

Since the 18th National Congress of the Communist Party of China, the CPC Central Committee with Comrade Xi Jinping as the core has attached great importance to the construction of ecological civilization and environmental protection, and emphasized that promoting a green development mode and lifestyle is an inevitable requirement for

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85278540

implementing the new development concept. It is necessary to put ecological civilization construction in a prominent position of the whole work. Relevant national laws and regulations such as the Opinions on Accelerating the Construction of Ecological Civilization and other laws have been successively released. We cannot be a giant of ideas and a dwarf in action. We must implement the policy, strengthen the intensity of supervision, and constantly improve the level of ecological civilization in China.

(3) Build an ecological civilization evaluation system for megacities based on the main functional areas

This paper provides an ecological civilization evaluation from the perspective of functional areas, and provides a new idea for the construction of the evaluation system based on the main functional areas theory. The main functional area theory has gradually become the main basis for the development of ecological civilization throughout the country. The reason is that the evaluation of the functional areas is in line with the national macro requirements, and closely follows the footsteps of economic and social construction. It has both practical significance and referential significance.

(4) Promote mutual development

The shortcomings of ecological conservation development area are mainly focused on quality growth. Governments at all levels should have a series of special policy support for the ecological conservation development area. These policies are essential for the development of these regions. Since the ecological conservation development area is Beijing's ecological barrier and water conservation site, it should be compensated as much as possible in the form of policies, for example, funding for the construction of tourist attractions, the giving living subsidies to people who live in the area.

STUDY ON HYDROGEN PRODUCTION OYF BIO-OIL CATALYTIC REFORMING BY CHARCOAL CATALYST

ZHANG, Y.

College of Chemical Engineering, Guangdong University of Petrochemical Technology, Maoming 525000, China
(e-mail: 280512356@qq.com; fax: +86-066-8298-1080)

(Received 8th Mar 2019; accepted 21st May 2019)

Abstract. In this study Charcoal was used as a primary bio-oil steam reforming catalyst. The performance of the catalyst was investigated. The dynamic parameters of the first order dynamic equation were calculated. The stability of charcoal was also examined. The results indicated that first, when reforming temperatures were lower than 700 °C, the bio-oil contents in the outlet dry gas were very high. This indicated unsuitability for further catalytic reforming over a metal catalyst. Second, the catalytic activity of charcoal became very significant under high temperature conditions (≥ 800 °C); thus, the apparent activation energy of the first order kinetic rate constant is 56.98 kJ/mol, and the pre-exponential factor is $1.58 \times 10^4 s^{-1}$. Third, the bio-oil contents in the outlet dry gas varied from a decrease to a slight increase in the first 2 h under a catalytic reforming temperature of 900 °C, a WHSV (weight hourly space velocity) of 2.6 h^{-1}, a bio-oil feeding rate of 47.02 g/h, and a S/B (mass steam-to-bio-oil) ratio of 2. Overall, the charcoal exhibited an excellent bio-oil removal rate (conversion > 99.6%) and the bio-oil contents in the outlet dry gas were lower than 1.89 g/Nm^3, hence signifying suitability for further reforming over metal catalysts.
Keywords: *catalyzer, stability, char, gas cleaning, steam reforming process*

Introduction

Interest in the hydrogen economy is increasing due to its potential applications in hydrogen fuel cell vehicles and fuel cell power generation (Li et al., 2018). Currently, the main hydrogen production processes are catalytic reforming of naphtha, light hydrocarbons and methane (Zhou et al., 2017a), while coal gasification is also widely used (Zhang, 2018; Daniel et al., 2018). However, the sustainable energy development can be realized only by using renewable energy as raw material to produce hydrogen (Bizkarra et al., 2018; Hossain et al., 2019). In this regard, steam reforming of bio-oil has been reported in many journals (Beatriz et al., 2018; Asghar et al., 2018). Bio-oil is produced by rapid pyrolysis of biomass. And its main components include alcohol, furan, acid, sugar, phenol, ketone and aldehyde (Arandia et al., 2018; Ilyas et al., 2018). The catalytic reforming of bio-oil mainly depends on the catalytic capacity of the catalyst for steam reforming reaction ($C_nH_mO_k + (n - k)\ H_2O = (n + m/2 - k)\ H_2 + nCO$) and water gas shift reaction ($CO + H_2O = H_2 + CO_2$). When bio-oil is reformed at high temperature, the Boudoard reaction ($2CO = C + CO_2$) and partial thermal decomposition of bio-oil may occur simultaneously (Zhou et al., 2017b).

Preliminary economic analysis shows that bio-oil steam reforming for hydrogen production is profitable in the current market (Czernik and French, 2014; Omini and Akpang, 2018). However, bio-oil catalytic reforming for hydrogen production is still facing many technical difficulties in order to become a commercially mature technology. Zeng et al. (2015) and Rajput et al. (2019) reported that carbon deposition on catalyst supports leads to low purity hydrogen in gas products. Li et al. (2017) proposed that a significant challenge in bio-oil hydrodeoxygenation was the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85418553

deactivation of coke deposits on zeolite catalysts. Wu et al. (2008) proposed dolomite catalyst with low cost to be chosen as the first-order catalyst for tar steam reforming, and then methane and tar are further reformed on nickel metal catalyst (Zhang et al., 2017). This technological process can protect the metal catalyst from quick deactivation and the economic loss could be reduced efficiently (Li et al., 2008). This technological process can effectively prevent the rapid deactivation of nickel metal catalysts and reduce economic losses (Cho et al., 2014; Yahya et al., 2018). However, since the calcined dolomite is easy to break up under the impact of air flow, powder dolomite may cause the resistance of the catalyst bed to rise sharply (Thakkar et al., 2016).

The research on catalytic reforming of tar over charcoal during biomass gasification can be used as a reference for steam reforming of bio-oil (El-Rub et al., 2008; Masri and Samsudin, 2018). Char itself has some activity for biomass tar conversion (Nestler et al., 2016), and its conversion activity is affected by surface area (Mun et al., 2010), pore size and ash composition (Zanzi et al., 1996). The coke deposited on the charcoal will block the pore and reduce the surface area, thus reducing the activity of the charcoal. However (Morishita et al., 2002), coke can also be consumed by gaseous products such as steam and carbon dioxide, and its deactivation can be suppressed by generating new pores (Hosokai et al., 2005; Sharma and Yadav, 2018). Furthermore, char catalysts would have low costs and be simply burned/gasified to recover the energy of the char without the need of often expensive regeneration after deactivation (Li, 2007). Hence, choosing a char catalyst as the primary steam reforming catalyst is more promising (Kai et al., 2018). It is important to study the catalytic activity and stability of the char catalysts for bio-oil conversion.

In this study, char is used as a primary steam reforming catalyst (Min et al., 2011; Naidu et al., 2018). The catalytic performance of the catalyst for bio-oil catalytic steam reforming under different operating conditions was studied. The stability of the charcoal catalyst was also investigated. The kinetic parameters were calculated by using the first-order kinetic equation (Qian and Kumar, 2015).

Materials and Methods

Test material

Bio-oil was produced by rapid pyrolysis of sawdust with fluidizer N_2 in the temperature range of 450 to 500 °C. The reactor used was a fluidized bed designed by East China University of Technology (Shanghai, China). Bio-oil components were determined by a gas chromatography-mass spectrometry. The results are shown in *Table 1*.

Properties of char

The commercial charcoal was supplied by Shanghai Canature Environmental Products Co., Ltd. (Shanghai, China). Elemental analysis of dried samples showed that it contained C 74.09%, O 17.51%, H 4.80%, S 0.018% and N 0.1%. Industrial analysis showed that ash content was 3.48%.

Before the catalytic test, the commercial biomass charcoal was heated to 900 °C at a heating rate of 27 K/min under the condition of air isolation, and the temperature was maintained for 30 min. *Table 2* shows the elemental analysis and ash content of the treated charcoal samples. Elemental C, N, and H analyses were performed using an

DOI: http://dx.doi.org/10.15666/aeer/1704_85418553

elemental analyzer, Elementar Vario EL III (Langenselbold, Germany). A sulfur analysis was accomplished on a Coulomb sulfur analyzer, CLS-2 (Jiangsu Jiangfen Electric Instrument Co. Ltd., Jiangyan, China). The composition of ash was determined *via* Sequential X-ray fluorescence spectrometry, (XRF-1800, Thermofisher, Beijing, China). The char samples were screened to the particle sizes of 1 mm to 2 mm.

Installation and procedure for experiment

As shown (*Fig. 1*), the catalytic reforming was performed in a fixed-bed reactor made of stainless steel. The height and diameter of the reactor are 800 mm and 20 mm respectively. The reaction pressure is atmospheric. The char catalysts were placed in the middle of the fixed-bed tube and the fixed bed was heated by an electric heating furnace equipped with a temperature control device. The nitrogen purged the system prior to the reactor heating. Bio-oil and water were fed into the reactor at a constant rate by two separate metering pumps. The reaction products were first condensed by tap water, then by ice-water mixtures, and the condensate was collected in liquid containers. The non-condensed components of the product gases were determined using an online gas analyzer (Gasboard-3100, Cubic Optoelectronics Co., Ltd., Wuhan, China) and the gas flow rate was measured using a soap membrane flow-meter (Agilent technologies Co., Ltd., Santa Clara, USA). When the feed is finished, the reactor is cooled to room temperature by nitrogen flow with a flow rate of 0.6 L/min, then the char catalysts are collected and weighed.

Analysis of bio-oil in liquid condensate

TOC (Total Organic Carbon) method was used to analyze liquid products. Liquid products can be divided into water-soluble and non-water-soluble substances, namely light hydrocarbons and heavy hydrocarbons, and oxygenates. Both fractions were called 'tars.' Although the water-soluble tar was a complex mixture of organic compounds, phenol represented the "average" tar compound. The tar yield determination was made in the same manner as previously indicated by Corella et al. (1991).

Experimental data evaluation

The conversion of bio-oil was calculated from their mass inlet and outlet as shown in *Equation 1:*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85418553

$$X = \frac{F_{in} - F_{out}}{F_{in}} \times 100 \quad \text{(Eq.1)}$$

where X (%) is the bio-oil conversion, F_{in} (g) is the total mass of the inlet bio-oil, and F_{out} (g) is the total mass of the outlet bio-oil.

The main property selected for determining the suitability of further catalytic steam reforming over a metal catalyst was the bio-oil contents in the outlet dry gas (Y). It was defined as the ratio of the mass flow rate of bio-oil (g/min) over the flow rate of dry gas (Nm^3/min) in an outlet as shown in *Equation 2:*

$$Y = F_{out} / \text{(Total vol. of non-condensed gaseous products except for } Nm^3) \quad \text{(Eq.2)}$$

The residence time (s) in the catalyst bed were defined as *Equation 3:*

$$t = \frac{\varepsilon \times V_{char}}{Q_{in,T}} \quad \text{(Eq.3)}$$

where ε (dimensionless) was the bed porosity of the catalyst (with a value of 0.38 in), V_{char} was the volume (L) of char in the bed, and $Q_{in,\,T}$ was the total inlet flow rate (L/s) of N_2, bio-oil, and water vapor under reactor temperature. The $Q_{in,\,T}$ was calculated by the equation for the state of ideal gas, as shown in *Equation 4:*

$$Q_{in,T} = \frac{1000 \times F_{inlet,n} \times R \times T}{P} \quad \text{(Eq.4)}$$

where $F_{\text{inlet,n}}$ (mol/s) was the total inlet molar flow rate of N_2, bio-oil, and water vapor, R = 8.314 (J/mol/K), T (K) is the reactor temperature, and P = 101325 (Pa).

Results and discussion

Effect of catalytic reforming temperature

The effects of catalytic reforming temperatures in the range from 600 to 900 °C on the dry gas composition, bio-oil conversion, and bio-oil contents in the outlet dry gas were investigated while the N_2 flow rate, WHSV (Weight hourly space velocity), feeding rate of bio-oil, and S/B (mass steam-to-bio-oil ratio) were fixed at 30 mL/min, 5.2 h^{-1}, 47.02 g/h, and 2, respectively. As can be seen from *Table 3,* as expected, the concentration of hydrogen in the gaseous product and the bio-oil conversion increased with the catalytic reforming temperature, while the concentration of carbon dioxide in the gaseous product and the bio-oil content in the outlet dry gas decreased. Comparing the results with that of Wang et al. (2007), it can be seen that the catalytic activity of the char catalyst is higher than the C12A7-O^-/18% Mg catalyst at 600 to 700 °C. This indicated that the char catalyst had good catalytic performance for the bio-oil conversion. However, comparison with the results of Wang et al. (Wang et al., 1998) found that the total concentration of H_2 and CO was about 80% over the commercial catalysts of the UCI G-90C and ICI 46-series. Nevertheless, the total composition of H_2 and CO was lower than 64% over the char catalyst at 800 to 900 °C. A reason for this was because the concentration of CH_4 in the gaseous product was high. This indicated

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85418553

that the char catalyst had limited effects on the CH_4 transformation (Yang et al., 2019). When the temperature was lower than 700 °C, the bio-oil contents in the outlet dry gas was very high, and therefore is not suitable for further catalytic steam reforming over the metal catalyst. The catalytic activity of char became very prominent at high temperatures (≥ 800 °C). The bio-oil conversion was higher than 80% and the bio-oil contents in the outlet dry gas became much lower, though the technological parameters should be further optimized to reduce the bio-oil contents in outlet dry gas.

Table 3. *Effects of catalytic reforming temperatures on dry gas composition and bio-oil conversion as well as bio-oil contents in outlet dry gas*

Temperature (°C)	Dry gas composition (vol.%)				Bio-oil	
	H_2	CO	CH_4	CO_2	Conversion (wt.%)	In outlet dry gas (g/Nm^3)
600	0.33	6.14	17.45	76.09	49.00	2664.44
700	12.24	10.84	21.79	55.13	62.65	1105.79
800	18.62	19.50	27.93	33.95	82.22	237.50
900	45.85	18.36	11.34	24.45	93.87	53.25

Kinetic aspects of catalytic reforming

From the previous sections it was found that the catalytic activity of char became very significant at high temperatures above 800 °C. The temperature and char dosage effects on the bio-oil conversion were studied in the temperature range of 800 to 900 °C and the char dosage range of 9 to 18 g.

A first order kinetic equation is used to calculate the kinetic parameters (*Eq. 5*), for the overall bio-oil catalytic reforming reactions:

$$\frac{dF}{dt} = -kF \qquad \text{(Eq.5)}$$

where F (mol/s) is the molar flow rate of bio-oil at the reactor inlet and k is the apparent kinetic constant.

To verify plug flow conditions in the fixed bed, the longitudinal or axial dispersion coefficient (D), which characterizes the degree of back mixing during the flow, needed to be calculated. This coefficient is used in the dimensionless Peclet number (Pe) to determine the type of flow, according to *Equation 6:*

$$Pe = \frac{v \times L}{D} \qquad \text{(Eq.6)}$$

$Pe \rightarrow 0$ large dispersion, hence the use of a mixed flow; $Pe \rightarrow \infty$ negligible dispersion, hence the use of a plug flow, where L is the length of the bed (units) and m and v are the average actual fluid velocity (m/s).

The Peclet number was very high (approximately 1.81×10^4), hence the plug flow conditions can be assumed. Under the plug flow conditions, the first-order kinetic equation can be integrated according to *Equation 7*:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85418553

$$\ln(\frac{F_{in}}{F_{out}}) = kt \quad \text{(Eq.7)}$$

The slopes of those lines were calculated by a linear regression to give the apparent kinetic constant, *k*, under the catalytic gasification temperature of 800 °C, 850 °C, and 900 °C as shown in *Figure 2*.

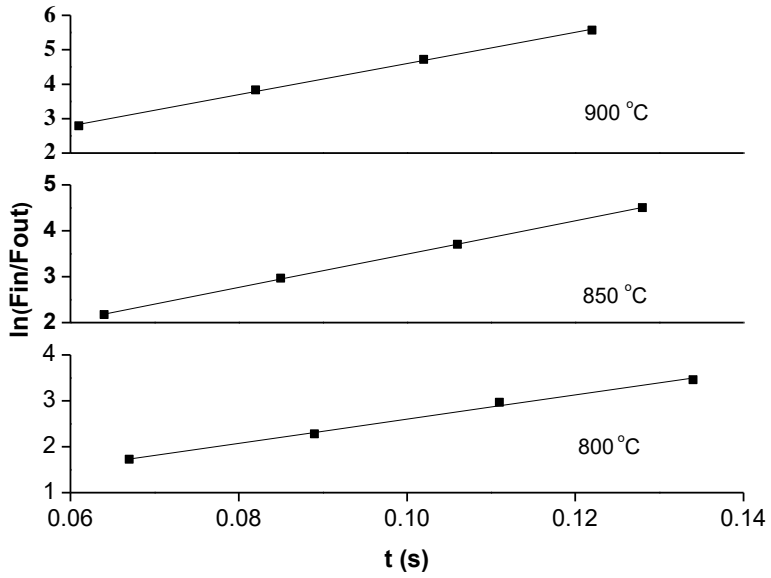

Figure 2. *Effects of the residence time in the catalyst bed on ln(Fin/Fout) under catalytic gasification temperature of 800 °C, 850 °C, and 900 °C. (Dosage of char rose from 9 to 18 g at a rate of 3 g, feeding rate of bio-oil was 47.02 g/h and S/B was 2)*

The apparent rate constant of the bio-oil conversion over char was estimated according to the Arrhenius' law, seen in *Equation 8*. The estimated apparent activation energy of char was assumed to be constant in the studied temperature range (800 to 900 °C).

$$k = k_0 e^{(-E_a/RT)} \quad \text{(Eq.8)}$$

where k_0 is the apparent frequency factor, s^{-1} and E_a are the apparent activation energy (J/mol).

The Arrhenius plots and Cremer-Constable diagram of the catalytic gasification (800 to 900 °C) are shown in *Figure 3*. The slopes and intercepts of the line were calculated by a linear regression to give the apparent activation energies (E_a) of 56.98 KJ/mol and the pre-exponential factors (k_0) of 1.58×10^4 s^{-1} for a catalytic reforming with the char catalyst. It would be interesting to compare the results with the results of other researchers. However, research on the bio-oil conversion kinetic parameters for the biomass char could not be found. Only a comparison with tar reduction was made (Shan et al., 2018). The Charcoal in this work gave lower apparent activation energies (E_a) values in comparison to several different chars (85.8 KJ/mol for sorbent-free coal char (Shamsi et al., 1996), 61 KJ/mol (El-Rub et al., 2008), 81.2 KJ/mol for foster wheeler

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85418553

char (Shamsi et al., 1996), BASF (58 KJ/mol) (Aznar, 1998), and G1-25 S (58 KJ/mol) (Aznar, 1998). And it gives pre-exponential factors (k_0) higher than the commercial biomass char (1.0×10^4 s^{-1}) (El-Rub et al., 2008), and foster wheeler char (1.30×10^4 s^{-1}) (Shamsi et al., 1996). Therefore, bio-oil can be considered an easier removal than tar either from biomass gasification or coal gasification.

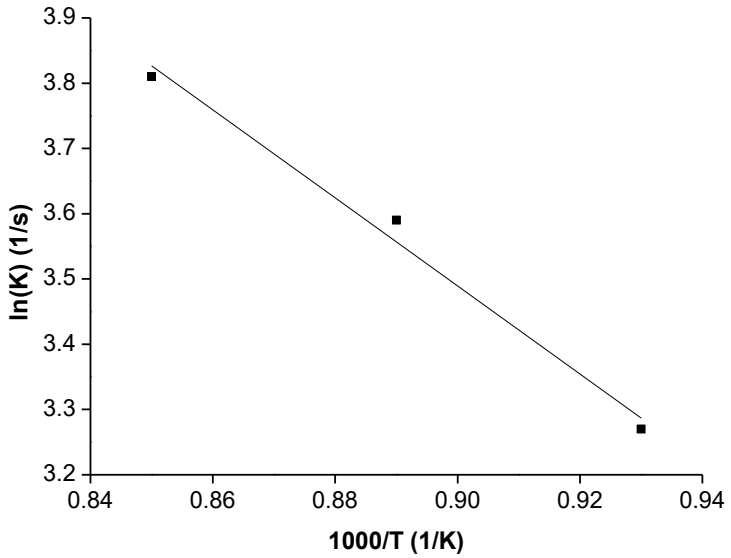

Figure 3. *The relationship between apparent reaction rate constant and temperature according to Arrhenius' law*

Stability of the char catalyst on bio-oil catalytic reforming

From the previous sections it was found that the bio-oil contents in the outlet dry gas was low under the catalytic reforming conditions, with a catalytic temperature of 900 °C, N_2 flow rate, 30 mL/min, WHSV, 2.6 h^{-1}, a feeding rate of bio-oil, 47.02 g/h and S/B of 2. It was suitable for further catalytic steam reforming over the metal catalyst (Mengping et al., 2018). However, the stability of the char catalyst should be well understood (Chang et al., 2018). Thus, dry gas composition, bio-oil conversion, bio-oil contents in outlet dry gas, char waste, and the weight percentage of char consumed were studied as a function of time (Li et al., 2019). The experimental results (*Table 4*) show that the increase in time resulted in the bio-oil contents of outlet dry gas to vary from decreasing to a slight increase, whereas the bio-oil conversion varied from increasing to a slight reduction (Zhang et al., 2018). These phenomena indicated that as time increased from 0.5 h to 1 h, the char catalyst was consumed by steam and CO_2, which produced new pores. In contrast, more alkali metals, such as CaO and K_2O (*Table 2*), which have a better catalytic performance on the bio-oil gasification (Wang et al., 2018), were exposed on the char surface so that the catalytic performance of char increased. However, as the reaction time increased, more char catalysts are deactivation for sticking together. When the reaction time increased from 0.5 to 1 h, the weight percentage of char catalyst consumption increased from 9.51 to 12.22%, which confirmed that the char catalyst was consumed by steam and CO_2 (Kang et al., 2017). As the reaction time increased from 1 h to 2 h, the weight percentage of char consumed decreased to 4.02%, which indicated that the coke deposition increased. All in all, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85418553

char catalyst exhibited an excellent bio-oil removal rate (bio-oil conversion > 99.6%) in the first 2 h. Aznar (1999) has confirmed in his work that in order to avoid deactivation of the catalyst by coke, the tar content in the gas product must be less than 2 g/Nm^3. In this work, the bio-oil contents of the outlet dry gas were lower than 1.89 g/Nm^3 in the first 2 h, thus it is suitable for further catalytic steam reforming over a metal catalyst. The CO_2 and H_2 concentrations showed similar trends of a small increase, whereas both the CO and CH_4 concentrations decreased as the reaction time rose. From the dry gas composition point of view, it is suitable for hydrogen production.

When the experiment was performed in nearly 3 h, the water-metering pump could not feed water into the reactor because of the high pressure in the reactor. This was caused by char catalysts sticking together. A further study should include understanding on the reason for char sticking together and how to reduce such.

Table 4. *Stability of char catalyst*

Time (h)	Dry gas composition (vol.%)				Bio-oil		Char waste	
	H_2	CO	CH_4	CO_2	Conversion (wt.%)	In the outlet dry gas (g/Nm^3)	g	wt.%
0.5	51.69	15.88	8.90	23.53	99.62	1.89	1.69	9.51
1	52.74	14.25	8.80	24.20	99.91	0.38	2.31	12.22
2	54.35	13.12	7.64	24.89	99.89	0.47	0.74	4.02

Reason for char sticking together and methods to overcome it

There are three possible reasons for char sticking together, (1) the char catalysts tended to slag because of high alkali content and lower fusion temperatures, (2) as the char catalyst was consumed by steam and CO_2, the framework of char collapsed, and (3) carbon deposition between the char catalysts. If char stickiness was mainly caused by slagging, the char catalyst would have a slower sticking rate under lower catalytic temperatures. To verify whether char sticking together was caused by slagging, a test was performed under the catalytic reforming conditions with a catalytic temperature of 800 °C, N_2 flow rate, 30 mL/min, WHSV, 1.9 h^{-1}, feeding rate of bio-oil, 35 g/h and a S/B of 2. The experimental results indicated that water also could not be fed into the reactor through the water-metering pump after 118 min. Lower reaction temperatures caused char to stick faster, which indicated that slagging could not be the main factor causing the char to stick together. It is known that char catalysts always stick at the top of the char bed, which is near to the inlet of the reactor, and only a very small part of char stick together. Therefore, it is believed that the temperature at the top of the char bed is much lower than 900 °C for the continuously feeding thus carbon was formed. In other words, bio-oil and water need to be preheated. Prior to being fed into the catalytic reforming reactor, bio-oil, water, and N_2 were preheated at 800 °C. The catalytic reforming test was performed under conditions that were identical to the previous sections. The result shows that char sticking together and char collapsing were not found. This confirmed that char sticking together was caused only by carbon deposition between the char catalysts and preheating the bio-oil. It also confirmed that water was an effective method to overcome the char from sticking together.

Conclusions

(1) When catalytic gasification temperatures were lower than 700 °C, the bio-oil contents in the outlet dry gas were very high. Reforming product was not suitable for further catalytic steam reforming over a metal catalyst. The catalytic activity of char catalysts became very prominent at high temperatures (≥ 800 °C).

(2) The first order kinetic rate constant of char for bio-oil conversion, in the temperature range of 800 to 900 °C, was found to have an apparent activation energy (E_a) of 56.98 KJ/mol and a pre-exponential factor (k_0) of 1.58×10^4 s^{-1}.

(3) Bio-oil contents in the outlet dry gas varied from decreasing to a slight increase in the first 2 h under the catalytic gasification conditions with a catalytic temperature of 900 °C, WHSV, 2.6 h^{-1}, feeding rate of bio-oil of 47.02 g/h and S/B of 2. In comparison, bio-oil conversions vary from increasing to a slight reduction. All in all, the char catalyst exhibited an excellent bio-oil removal rate (bio-oil conversion > 99.6%) and the bio-oil contents in the outlet dry gas were lower than 1.89 g/Nm^3, thus it was suitable for further catalytic steam reforming over a metal catalyst.

(4) The feeding materials temperature should be allowed to achieve the designed reaction temperature before reaching the char catalysts, to block the char catalysts from sticking together.

In the study of catalytic reforming of biomass pyrolysis oil for hydrogen production, only a small number of catalysts have been studied. It is necessary to study in depth the catalysts suitable for the reforming of biomass pyrolysis oil for hydrogen production with good selectivity, high activity and long life. In this way, the research on hydrogen production from Bio-oil reforming catalyzed by activated carbon will make progress in the future.

Abstract. In the trial stage of Xiluodu-Zhexi ± 800 kV HVDC project, grounding current trough DC electrode incurred severe DC bias in substation transformers near the Jinsi electrode, indicating further research on the factors influencing such DC bias problem and since vertical and lateral change of soli resistivity could be one of the main factors, their mechanisms should be studied. Besides a normal layered earth resistivity model, a complex model was established to simulate forms of lateral resistivity changes according to measured soil resistivity data at the site of Jinsi electrode. Then ESP was calculated with finite element method and the effect of lateral change on ESP and its characteristics was analyzed. Later, an assumed case example demonstrated the error of DC bias estimation caused by such ESP distortion. The results suggest the distance from DC electrode to the lateral change interface influences ESP distortion the most, and a high resistivity region in shallow layers at 5 km from DC electrode could incur a relative error of 25.9% in DC bias estimation. The grounding location and impact assessment has indicated that the measurement range of the earth resistivity should be investigated.

Introduction

In the trial stage of XiluoduWestern Zhejiang ± 800 kV High Voltage Direct Current (HVDC) project, grounding current trough Direct Current (DC) electrode incurred severe DC bias in substation transformers near Jinsi electrode (Yang et al., 2018). During the trial stage of March 28, 2014, the measured DC bias current of some transformer neutral point is more than 10 A while the grounding current of the grounding electrode is only 500 A (Kazerooni et al., 2016a; Wali et al., 2018). According to the rated transmission power XiluoduWestern Zhejiang ± 800 kV HVDC project, the grounding current of the grounding electrode can reach 5000 A during full load operation with single pole. Due to the transformer DC bias current is linear with the ground current, the 5000 A ground current will produce 100200 A DC bias current in the substation transformer near the grounding electrode, which may threat the safety of the power system and transformer (Kang et al., 2018). Although a large number of DC transmission projects have been successfully constructed and put into operation, the problem of DC bias in XiluoduWestern Zhejiang Ultra High Voltage Direct Current

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85558568

(UHVDC) Project shows that the influence factors and mechanism of DC bias have not been fully understood in the study of grounding electrode effect.

The influence assessment of grounding electrode on DC bias of transformer is based on the establishment of power grid model, Earth resistivity model, and the network topology. The accuracy of the former depends on power grid parameters. The latter depends on the mastery of the stratified data of the earth's resistivity and the differential data of the transverse and longitudinal directions. The problem belongs to the geodetic and geodetic problems in the field of Geophysics (Mousavi and Bonmann, 2017; Kazerooni et al., 2016b; Austin et al., 2018). In the grounding location selection and its impact assessment of HVDC and UHVDC, selection and design of grounding electrode are only based on the comprehensive calculation of the earth resistivity from several dozens of measuring points near the electrode. The ground potential is calculated by horizontal homogeneous layered earth resistivity model with the measured data of ground resistivity. The influence of grounding electrode current on the dc bias of transformer is evaluated. The influence of the lateral variation factors of the earth resistivity is not considered. Compared with uniform distribution of the earth resistivity, the research result of geomagnetic storm induced electric field shows that within 1000 km around the earth resistivity lateral variation interface, the surface potential always changes. When the change frequency of geomagnetic storm surface current is 0.03 Hz, the electric field increases at 70% near the low conduction proximity interface (Hussein and Ali, 2017; Arslan et al., 2018). Compared with the influence of geomagnetic storms, geomagnetic storms have greater impact scale and mainly consider the distribution of geoelectric field along the transmission line. Although the effect of DC grounding electrode current is relatively small, usually in the range of 100 km, it is necessary to consider the potential distribution of the circular area with the earth electrode as the center. In theory, the grounding electrode current penetrates the earth deeper, and the lithosphere structure of China is the most complicated in the world (Choi et al., 2018; Moon et al., 2017; Liu and Liu, 2017; Wang et al., 2015; Okpoli and Ehinmitan, 2019). Therefore, in the site selection and impact assessment of ground electrode, it is very complicated to clarify the influencing factors and mechanism of the electrode site resistivity.

Whether the serious DC bias problem in Xiluodu-western Zhejiang UHVDC Project is influenced by the earth structure around the Jinsi electrode, or the resistivity of the deep earth, due to the lack of detailed magnetotelluric data of the earth, there is no inference at present. However, the test report on soil resistivity of Jinsi electrode in Xiluodu-western Zhejiang UHVDC Project shows that, the soil structure of electrode surrounding and the horizontal uniformity of shallow soil has a great influence on the surface potential distribution. The related papers are also discussed (Wei-Li and Liu, 2013). In this paper, according to the test data of soil resistivity in the site selection and design of Jinsi grounding electrode, and the types of lateral variation of soil resistivity reported in the test report, the earth resistivity model and surface potential algorithm considering lateral variation of earth resistivity are established (Zhou et al., 2016; Kasim et al., 2019). The influence of the width, depth, resistivity, distance from interface to ground electrode on the surface potential distribution around the electrode site and its characteristics are studied. According to the influence characteristics, the mechanism of serious DC bias caused by Jinsi grounding electrode is revealed, which provides basis for site selection of UHVDC grounding electrode and resistivity test scheme.

DOI: http://dx.doi.org/10.15666/aeer/1704_85558568

According to the earth resistivity data near the Jinsi grounding electrode of Xiluodu-Western Zhejiang UHVDC project, based on the lateral variation of the resistivity between the faults in the soil structure and the shallow-layer resistance, a model of the earth resistivity considering lateral variation is proposed. The surface potential distribution near grounding electrode is calculated by finite element method. The influence of lateral variation on surface potential distribution and its characteristics are compared and analyzed with different soil parameters. The error of the DC bias current caused by the change of the uneven potential distribution of the earth's transverse resistivity distribution is analyzed with an example. The conclusions provide a theoretical reference for accurate estimation of DC bias level and site selection of grounding electrode in practical engineering.

Materials and methods

Horizontal homogeneous layered earth resistivity model

Earth resistivity of Jinsi grounding electrode is obtained by 87 measuring points near the electrode with conventional symmetrical quadrupole method, 4 measuring lines of Controlled Source Audiofrequency Magnetotelluric (CSAMT) and 3 measuring points of Magnetic Tube (MT). Based on the 6 layer earth resistivity model, a horizontal homogeneous layered earth resistivity model is proposed and shown in *Figure 1,* and the parameters of each layer are shown in *Table 1*.

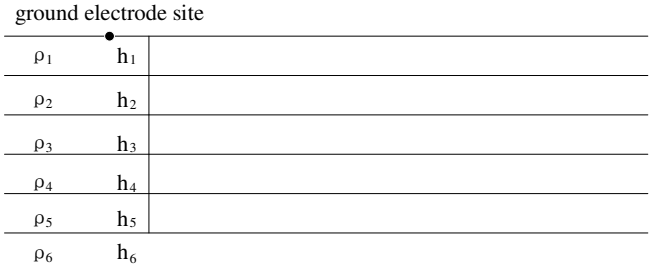

Figure 1. *Layered earth resistivity model*

Table 1. *Parameters of layered earth resistivity around electrode*

Layer	Depth（m）	Resistivity（Ω·m）
1	0 - 45	50
2	45 - 155	250
3	155 - 300	2500
4	300 - 600	400
5	600 - 2000	1500
6	> 2000	4000

A composite model considering the lateral variation of earth resistivity

The above horizontal homogeneous earth resistivity model is a common model for the calculation of surface potential at present. The earth resistivity test of Jinsi electrode

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85558568

covers only 1 km^2 range, and the results of some measurement points reflect the earth fracture and high and low resistance mixed in this area. To study the influence of the lateral variation of the earth resistivity on the surface potential of ground electrode (Liu et al., 2018; Rajput et al., 2019), a composite geodetic resistivity model considering lateral variation based on the type of horizontal change reflected by the resistivity test has been proposed and shown in *Figure 2*.

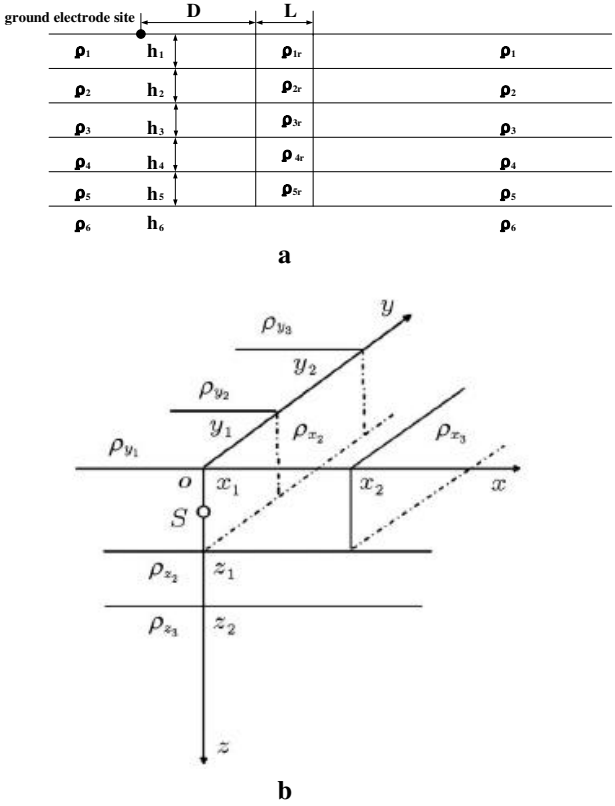

Figure 2. *Complex earth resistivity model concerning resistivity lateral change*

Ground surface potential model DC around ground electrode

Grounding current from electrode formed a constant DC current field. The differential equations of the current field can be represented as follows (*Eqs. 1* and *2*):

$$\nabla \times \vec{E} = 0 \tag{Eq.1}$$

$$\nabla \cdot \vec{J} = -\frac{\partial \rho}{\partial t} \tag{Eq.2}$$

Auxiliary equation is (*Eqs. 3* and *4*):

$$\vec{J} = \sigma \vec{E} \tag{Eq.3}$$

$$\vec{E} = -\nabla V \tag{Eq.4}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

where, E is electric field intensity (V/m), J is current density (A/m2), ρ is charge density (C/m3), σ is conductivity (S/m), and V is electric potential (V).

In the field except the current source, the equation (*Eq. 5*) of the current field can be expressed as:

$$\nabla^2 \cdot V = 0 \quad \text{(Eq.5)}$$

In this paper, the finite element software Ansys is proposed to calculate the surface potential distribution of Jinsi grounding electrode. Based on the three-dimensional composite Earth resistivity model established above, the lateral variation of Earth resistivity should be considered when analyzing the influence mechanism of earth resistivity lateral change on ground surface potential. Three-dimensional problem is transferred into two-dimensional finite element problem. Based on the measured resistivity lateral difference type, to solve the surface potential by axisymmetric analysis with 2D Quad 230 unit, decouple network, input load data and boundary condition (Birchfield et al., 2016; Zulkapli et al., 2018).

External boundary condition (*Eq. 6*) is:

$$V = 0 \quad \text{(Eq.6)}$$

At the air interface (*Eq. 7*):

$$\frac{dV}{dn} = 0 \quad \text{(Eq.7)}$$

where n is exterior normal direction (*Eqs. 8* and *9*), and resistivity adjacent soil interface can be obtained:

$$V_i = V_j \quad \text{(Eq.8)}$$

$$\frac{1}{\rho_i}\frac{dV_i}{dn} = \frac{1}{\rho_j}\frac{dV_j}{dn} \quad \text{(Eq.9)}$$

The earth surface potential affects up to dozens of km or greater (Harrison and Anderson, 2016; Barsainya and Rawat, 2017; Rezaei-Zare et al., 2016; Boteler and Bradley, 2016; Pan et al., 2016; Boteler and Pirjola, 1998; Viljanen et al., 2004; Baharuddin and Samsudin, 2018). Since the rated earth current is 5000 A, this paper selected 150 km as the distance between grounding electrode and 0 potential boundary. Moreover, the Jinsi grounding electrode is double-ring body structure. The polar ring is 1140 m in the east-west direction, 480 m in the north and south, 3.5 m in depth and 0.326 Ω in the grounding resistance. Because the size of the grounding electrode is far less than the influence range of its surface potential, treat the grounding electrode to a point power supply (Zhu and Overbye, 2015; Prabhakaran and Raj, 2018).

Select the rectangular coordinate system, x refers to the north, y refers to the East, z is vertical to ground. The model is shown in *Figure 3*. In *Figure 3,* six boundary interfaces for the rectangular structure of the earth model are shown. The arrow reflects a possible flow of the grounding current at the inner and side boundary of the earth conductor. The lateral difference of resistivity may exist inside the conductor, thus

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85558568

changing the flow direction of the grounding current to the earth (Zhang et al., 2018). The truncated boundary is selected far away from the zone of resistivity sudden change. It is considered that there is no lateral difference, and the grounding current flow into and out of the model horizontally (Lewicki, 2007; Bernabeu, 2015; Barakat et al., 2018).

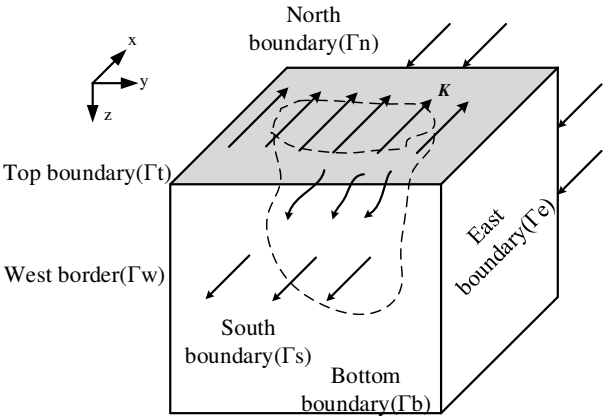

Figure 3. *Sketch of earth conductivity model*

In this paper, the type of earth resistivity lateral difference should be considered, when analyzing the mechanism of the influence of lateral variation of earth resistivity on ground electrode. According to the resistivity lateral difference type from the experiment, parameters as shown in *Table 2*. In *Table 2,* the scheme 1~4 simulate 4 kinds of fracture situations, because the earth resistivity is generally less than 200 Ω•m in the fracture area, the value here is 150 Ω•m (Guo et al., 2017). The scheme 5~8 simulate the high and low resistance of surface layer, and the values of shallow-layer high resistance is 1000 Ω•m and 5000 Ω•m.

Table 2. *Parameter scenarios to simulate different soil resistivity lateral changes*

Scheme	1	2	3	4	5	6	7	8

Results and discussion

Analysis of the influence of the lateral variation of earth resistivity on the surface potential

In this paper, two kinds of Earth resistivity models are proposed, and by using Ansys, the distribution of surface potential of the Jinsi grounding electrode is calculated, based on the 8 scenarios of earth resistivity lateral variation. The results are shown in *Figures 4* and *5*. In *Figures 4* and *5,* (a) is the potential distribution within 50 km. In

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85558568

order to observe the difference of local potential distribution and its influence, (b) is the enlarged display of the surface potential distribution change near the place where the earth resistivity lateral change happens, and (b) is corresponded to the calculated result in (a). In the figure, the curve "0" corresponds to the surface potential distribution in the horizontal homogeneous layered earth resistivity model, and the other curves correspond to the resistivity lateral change plans (*Table 2*). In the scheme 1~4, the surface potential distribution near the Jinsi ground electrode are shown in *Figure 4*.

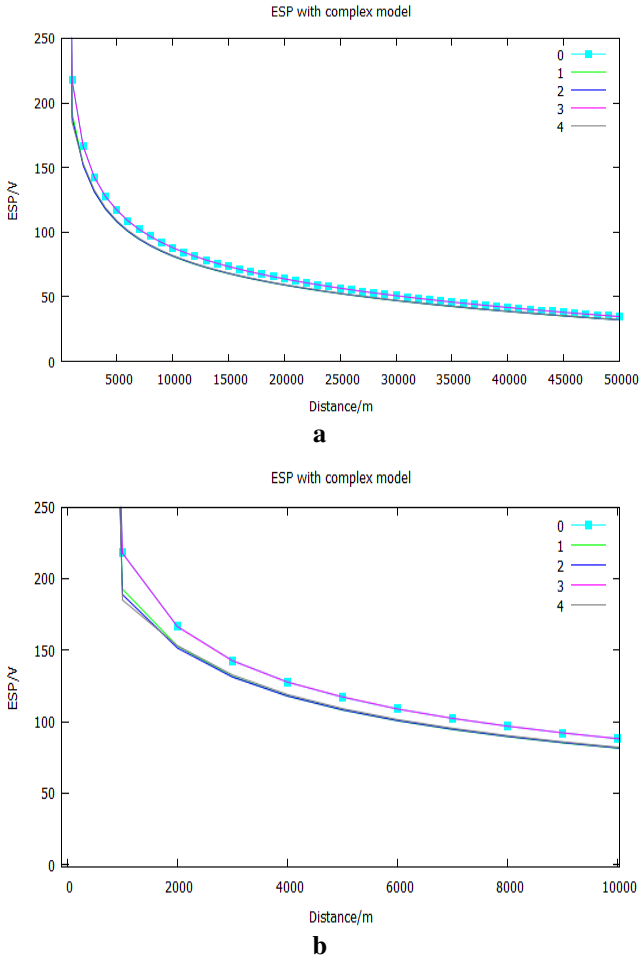

Figure 4. *Earth conductivity model ESP around Jinsi electrode under resistivity lateral change scenarios 1-4*

As *Figure 4a* shows the surface potential from the grounding electrode to the fracture interface is overall reduction. Compared with the curve 0, the surface potential of the curve 1 is obviously reduced, and the curve 3 is almost coincided with the curve 0. Because the curve 1 is fractured at 800 m, the curve 3 is fractured at 5000 m. The rest of the parameters are the same. This indicates that the closer the fracture interface to the ground electrode, the more significant lateral resistivity change effects on the surface potential. And the fracture in a far position has little effect on the earth surface potential. Moreover, the depth or width parameters among the 3 types of breakages shown in the curves 1, 2, and 4 are different. But the location of the fracture is 800 m, and the surface

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85558568

potential of the 3 types are similar. This shows that the distance between the fracture interface and the ground electrode has a greater influence on the surface potential distribution than the depth and width.

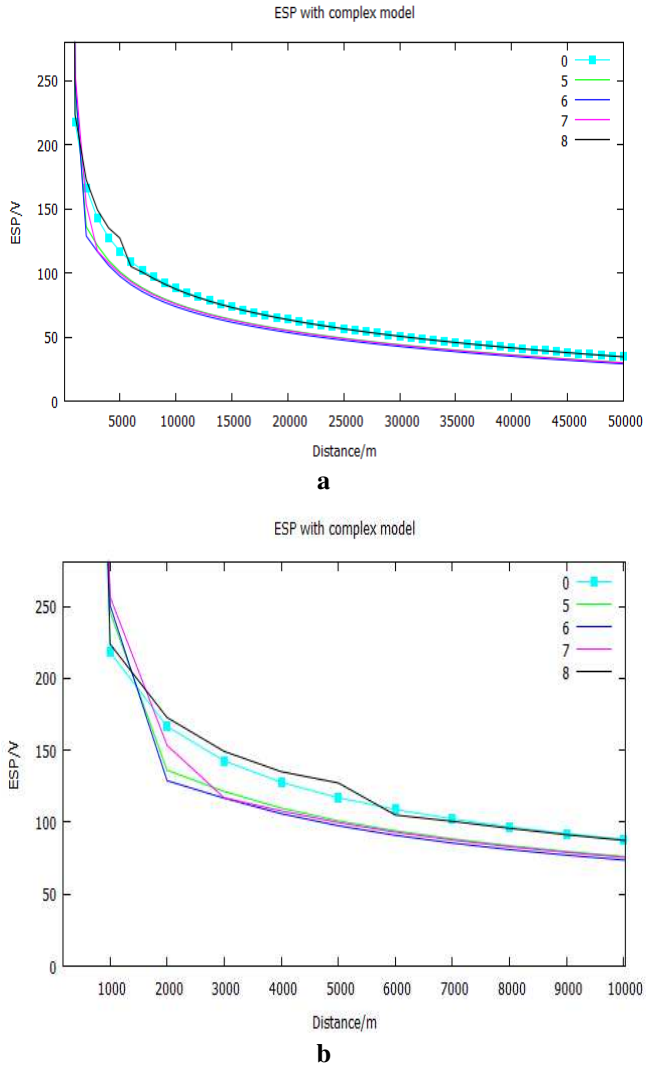

Figure 5. *ESP around Jinsi electrode under resistivity lateral change scenarios 5-8 (b)*

Near the fracture position, the surface potential dropping of the curves 1, 2, and 4 are different (*Fig. 4b*). The curve 4 is lower than the curve 1. This indicates that the greater the width of the fracture, the greater the decrease of the surface potential caused by the influence. The curve 2 is lower than the curve 1. This indicates that the deeper the depth of the fracture is, the greater the decrease of the surface potential caused by its influence.

In the earth resistivity lateral variation case 5-8, the surface potential distribution around the Jinsi grounding electrode is shown in *Figure 5*.

Comparing with the horizontal homogeneous layered situations, when considering the resistivity lateral variation caused by the high and low resistance mixture in the surface layer, in front of the high resistance area, the surface potential rises (*Fig. 5a*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85558568

And behind the high resistance area, the surface potential drops, and the surface potential drops significantly in the area with high resistance. Comparing with the width and resistivity of the high resistance area, the distance between the interface and the grounding electrode has a greater influence on the surface potential.

In curves 5, 6 and 7, surface potential from the front section of the curve near the high resistance region are different. The surface potential uplift of the front section of the curve 6 is slightly higher than that of the curve 5 (*Fig. 5b*). The surface potential behind the high resistance region is slightly lower than that of the curve 5. The higher resistance in high resistance area, the greater the surface potential drops, and the greater the influence on the overall surface potential distribution. Comparing the curves 5 and 7, it can be seen that the greater the width of the high resistance region is, the greater the surface potential drops in the region, and the greater the effect on the overall surface potential. It is noteworthy that the contrast curves 8 and 0 can be seen, when the surface layer high resistance area is far from the grounding electrode, although the surface potential distribution of the high resistance area will not be significantly affected, there will still be obvious surface potential rise in front of the interface, and intensify the surface potential drop in the surface layer high resistance area. Compared with the curve 0, the surface potential drop between 5 and 6 km in the curve 8 is 14 V.

The effect of Lateral change of earth resistivity on the intensification of magnetic bias current

The results of the above calculation and analysis show that, the lateral change of the earth resistivity will cause a significant change in the surface potential around the grounding electrode. Considering the influence of the grounding current, the DC bias current of the nearby power grid is directly affected by the surface potential distribution (Liu et al., 2016). Therefore, it is necessary to investigate the influence of the potential distribution change on the magnetic current of the nearby power grid. Taking case 8 in *Table 2* as an example, and the analysis shows that comparing with the earth resistivity homogeneous stratified model, the intensification of lateral resistivity variation on the bias current of the power grid.

Power grid model and parameters

Since there is no accurate earth resistivity data of the Jinsi grounding electrode at present, it is assumed that there is a power grid containing four 500 kV substations, and the substations distribute along the grounding electrode, numbered respectively with A, B, C and D. The distances of each transformer to the ground electrode are 5 km, 10 km, 15 km and 20 km. Two sets of single-phase autotransformer are used in each substations. The high voltage and middle voltage windings of the transformer are 0.238 Ω and 0.097 Ω. The grounding resistance of the substation is 0.2 Ω. The transmission lines between the substations are four split conductors. The single phase DC resistance of the wire is 0.0187 Ω/km. Its equivalent DC circuit is shown in *Figure 6*. DC is the neutral grounding equivalent DC potential of the surrounding AC substations under the influence of DC grounding current from grounding electrode (Babazadeh et al., 2017; Shetye and Overbye, 2015; Rezaei-Zare, 2015; Kovan and De Leon, 2016).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85558568

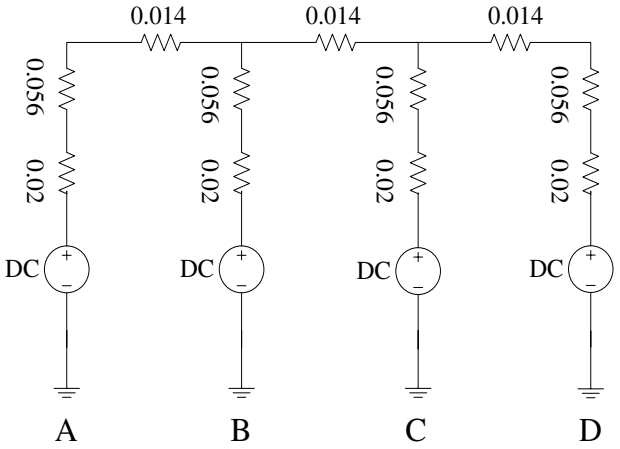

Figure 6. *DC bias circuit of the AC network*

Calculation results and analysis

According to the comparative analysis above, the surface potential distribution is calculated by selecting the earth resistivity parameters from scheme 01 and 8 in *Table 2*. The surface potential calculation results of each substation are shown in *Table 3* (Aboura and Touhami, 2017; Marti and Yin, 2015).

Table 3. *ESP distributions under two scenarios (V)*

Distance	5 km	10 km	15 km	20 km
Scheme1	117.01	88.039	73.465	63.840
Scheme8	127.22	87.387	73.086	63.554

By using the node voltage method, the DC bias current of the transformer in the AC network from *Figure 6* is calculated according to the earth surface potential corresponding to the two cases in *Table 3*. The result of the calculation is shown in *Table 4*. The positive value indicates the current flows from the earth to the neutral point (Girgis and Vedante, 2015; Rezaei-Zare, 2015).

Table 4. *DC bias currents in substations (A)*

Transformer substation	A	B	C	D
Scheme1	113.74	6.80	-43.54	-76.93
Scheme8	143.17	-4.60	-52.89	-85.45

The results of the calculation in *Table 4* show that, comparing with the horizontal homogeneous layered earth resistivity model, the change of surface potential distribution caused by the high resistance of surface layer between 5 and 6 km from the grounding electrode. It leads to the bias current increase of some substations in the power grid. Influenced by it, the bias current of substation A, C and D are obviously increased, and the growth rates are 25.9%, 21.5% and 11.1%.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85558568

It can be seen that the change of surface potential distribution caused by lateral variation of earth resistivity will significantly affect the DC bias current level across the grid. However, the surface layer high resistance area is located between substation A and B, it is the horizontal changing area, the potential difference between the two sides of the substation is increased. And the bias current will flow across the entire power gird, this surface potential distribution change will cause the bias current increase of distant substation C and D (Wu et al., 2014; Gilbert, 2015; Boteler, 2015; Kwon et al., 2017; Zhou et al., 2016).

Conclusions

In this paper, a composite model of earth resistivity considering lateral variation is established. The influence mechanism of the earth resistivity lateral variation on the surface potential is analyzed. It is revealed that the earth resistivity measurement is not elaborate and the data are inaccurate during the site selection and impact assessment of the grounding electrode at present. The conclusions are as follows:

(1) When calculating surface potential caused by grounding current of earth electrode, comparing with calculation results from the horizontal homogeneous layered earth resistivity model, the resistivity lateral change caused by the earth fracture and high and low resistance mixture of surface conducting layer, will significantly affect the scale and distribution of surface potential. The scale of its influence is most affected by the distance between the lateral variation interface to the grounding electrode, The influence of distant fracture can be neglected, but far from the shallow high resistance region will have a greater potential drop in the region, the front curve of ground electric potential rise significantly, and it can not be neglected in the surface potential distribution calculation.

(2) In the calculation of DC bias, the accurate calculation of ESP is the key, and the calculation shows that the variation of ground potential caused by lateral variation of earth resistivity will increase the bias current of the entire power grid when the nearby power grid goes through the lateral resistivity variation area. And because the bias current will circulate in the grid, the change of ground potential in local area will cause the increase of the bias current in a larger region, and if the comprehensive value horizontal homogeneous layered earth resistivity model is adopted, the large error will appear, and the surface layer high resistance at 5 km in the example will cause the substation bias estimated value to be 25.9% lower.

(3) Because of the lateral variation of the resistivity at a distance can also cause a significant change in the surface potential distribution, which affects the magnetic current level of the surrounding grid, considering that the distance between the boundary surface and the grounding electrode is the primary influencing factor, and the lateral variation of the 5 km outside the electrode site can still make a large error in the estimation of the bias current. So at present, the resistivity measurement in the range of the grounding electrode location can not satisfy the requirement of the bias current estimation, and the range of the resistivity measurement should be considered in the siting stage of the grounding pole. The lateral variation of earth resistivity has a great effect on the surface potential distribution, and its scale is related to the range of fracture width, depth, lateral variation, distance to grounding electrode and the level of resistivity change.

DOI: http://dx.doi.org/10.15666/aeer/1704_85558568

In addition, due to the analysis of the influence mechanism of earth resistivity lateral variation on surface potential, only considering the two-dimensional resistivity model of the Earth, the three-dimensional problem is converted into two-dimensional finite element analysis, and the actual earth resistivity is changed in the three-dimensional land space, which may have a greater effect on the distribution of ground potential. This impact needs to be further studied.

(Received 8th Mar 2019; accepted 21st May 2019)

Abstract. Based on the SPOT-5 images in 2004 and 2010 and SPOT-6 images in 2016 on the northern region of Hexi new town of Nanjing, the urban green space pattern of 2022 was predicted using the CA-Markov model. On this basis, four landscape indexes were used to analyze the evolution of green landscape pattern in the study area from 2004 to 2022. The results showed that the spatial accuracy of urban green space simulated by CA-Markov model was as high as 87.23%, and the Kappa index was 0.8533, which means high reliability. It is predicted that the scale of urban green space in the northern region of Hexi new town will continue to increase in 2016-2022, accounting for 17.28%, and the patch area of the dominant green space will keep increasing. The number of green patches NP and complexity LSI show a downward trend, the green landscape begins to become orderly, the fragmentation is lessening, the green space network system is gradually formed, and the spatial layout of urban green space tends to be reasonable. The simulation results can provide decision-making basis for the dynamic control of urban green space of Hexi new town of Nanjing.
Keywords: *the spatial accuracy of urban, Kappa index, the number of green patches, landscape index, the remote sensing image data*

Introduction

Since the beginning of the 21st century, with the advancement of global urbanization, China has been in the stage of urban space expansion driven by rapid urbanization. However, with the extensive and inefficient urbanization of land, the urban natural ecosystem is degrading, which further restricts the sustainable development of cites (Weber and Puissant, 2003; Daniel et al., 2018). Therefore, the land use and land cover change research has become a frontier and hot topic of global change research (Mooney et al., 2013; Ismail et al., 2019), and its importance is increasingly prominent in the study of global environmental change and sustainable development (Blumstein and Thompson, 2015; Mahmood et al., 2018). In urban planning, strengthening the control of green space layout can optimize the living environment and reduce the impact of urban development on the natural ecosystem. With the continuous development of the construction of the green space system, the intervention of its layout is a dynamic approach process, so the dynamic simulation method can effectively guide the planning of urban green space layout.

In recent years, the cellular automata model (CA) and the Markov model (Markov) are important predictive models in the field of land use dynamic simulation. The cellular automata, as a discrete grid dynamics model, has strong spatial computing ability and spatiotemporal coupling characteristics, which can effectively simulate complex spatiotemporal change processes (White and Engelen, 1993; Al-shalabi et al., 2013; Anan,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85698581

2019). The Markov model was a prediction method created by A. Markov in 1940s, and it is also called Markov chain. The Markov chain is an analytical tool that can predict the future trends of variables (Paul et al., 2016). The Markov model was used by Hulst to solve the problem of vegetation ecological prediction (Hulst, 1979), and was also used by Balzter and Pastor to analyze vegetation changes (Balzter, 2000; Pastor et al., 2005; Xu, 2018).

At present, cellular automata model and Markov model have been widely used in land use change prediction. Markov model has great advantages in studying time evolution, but it is weak in spatial computing ability, while CA model has strong spatial computing ability (Liu and Chen, 2002). Therefore, the CA-Markov model, which combines the two methods, can simulate the land use change from both quantitative and spatial aspects (Halmy et al., 2015). It is more and more widely used (Weng, 2002; Ye, 2007), and has achieved better prediction results (Guan et al., 2011; Moghadam and Helbich, 2013; Anputhes et al., 2016). In addition, the CA-Markov model is mainly used to study large-scale land use change, and there are a few dynamic simulation studies on open space or green infrastructure in foreign countries (Mitsova et al., 2016; Joseph et al., 2019). However, there are few dynamic simulation studies on urban green space expansion.

Compared with the simulation of dynamic change of construction land, the simulation of dynamic change of green space has two characteristics: (1) The green space has its own spreading process, because with the green plant growth, it will increase the vegetation coverage. (2) Another characteristic of green space expansion is that it is obviously influenced by human activities, for example, both sides of the new road and the waterfront space are highly adaptable to the green space layout. In this paper, CA-Markov model is applied to green space simulation, because the model can simulate the suitable green space spread phenomenon, this is an attempt and breakthrough for the study of green space (Lin, 2018a; Sarker et al., 2019). Using this method to study the law of spatial expansion of green space in the process of urbanization is not only helpful to forecast the law of green space development, but also to provide targeted optimization measures for urban green space layout. However, this study is particularly important for the control and optimization of green space layout in China's rapidly urbanized areas (Pascual-Córdova, 2018).

This paper takes the northern region of Hexi of Nanjing as the research area, takes the SPOT images of 2004, 2010 and 2016 as the land use information source, using CA-Markov model to construct the conversion rules of urban green space micro-land cells in the cellular automaton model and then use logistic regression model to construct a comprehensive evaluation model of urban green space expansion (Asgari, 2018). In this way, the spatial change of urban green space in the study area in 2022 is predicted and the landscape indexes is used to analyze the evolution characteristics of the overall green space landscape pattern in the study area from 2004 to 2022. The results can provide reference for the dynamic regulation of green space expansion in fast urbanized areas (Liu, 2018; Bind et al., 2018). At the same time, it also explores the scientific way of urban green space planning and construction, and explores new methods for the layout of urban green space.

Research data and methods

Overview of the study area

Nanjing Hexi new town is located in the southwest of Nanjing main city zone. According to the temporal evaluation, it is divided into three regions: the north, the middle

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85698581

and the south. The study area is the northern region of Hexi new town of Nanjing (*Fig. 1*), which is located on the west side of Nanjing main city zone, with Yangtze River in the west, external Qinhuai River in the east, Sancha River in the north, and Yingtian Avenue in the south, with a total area of 27.74 km^2. The study area and its surrounding areas have rich natural and cultural landscapes such as Qingliang Mountain park, Stone park, Mochou lake park, Gulin park and Peach garden scenic belt and so on.

In recent years, Hexi new town of Nanjing has successfully hosted a series of major international and domestic events, such as the 10th National Games of China, China EU summit, Asian Youth Games, the Summer Youth Olympic Games, Nanjing International Marathon and World Speed Roller Skating Championships. At present, Hexi new town has become a city center with great potential for development, beautiful living environment and first-class functional quality in Nanjing.

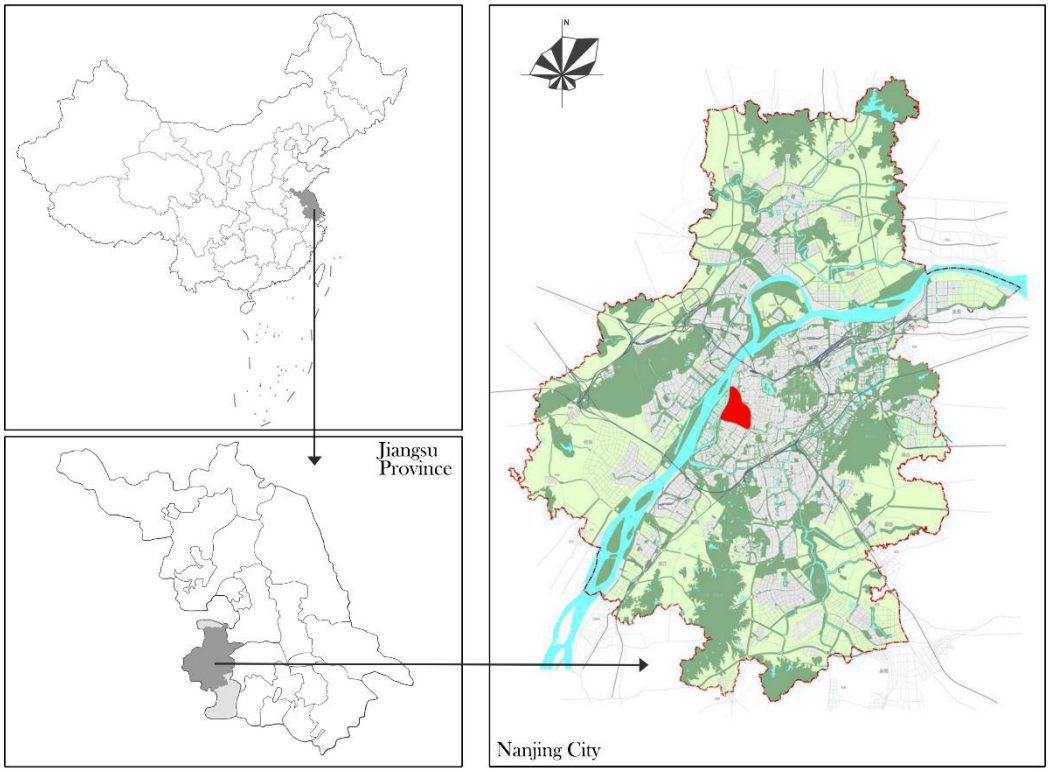

Figure 1. *Study area*

Research data and preprocessing

The remote sensing data used was three SPOT images covering the study area, including two SPOT-5 images (the acquisition time is June 2004 and June 2010, and spatial resolution is 2 m), and one SPOT-6 image (the acquisition time is July 2016, and spatial resolution is 2 m). Based on 1:25,000 topographic map, Gaussian Kriging projection (Xi'an 80 coordinate system, and central meridian 120°E) was selected, and geometric accurate correction was carried out for SPOT images by two polynomial correction methods (the root mean square error is within 0.5 pixels). According to the first class classification standard in "LUCC (Land-Use and Land-Cover Change) Classification System" of the Chinese Academy of Sciences and "Technical

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85698581

Regulations for Land Use Investigation" in China, combined with the characteristics of the study area, the land use types of the study area were divided into five categories: water area, urban green space, urban road land, urban construction land, and open land (unused land). Based on the field survey data and the existing sample database, the remote sensing interpretation marks in the study area were established (Lin, 2018b; Naidu et al., 2018). The three images were supervised and classified by Maximum Likelihood (ML) in Easy Feature software and ARCGIS software, and the classification results were manually revised. Using field survey data, Google Earth image and Ovi interactive map, 100 points were randomly selected to evaluate the classification map. The overall accuracy of the image classification maps in 2004, 2010 and 2016 was 95%, 96% and 97% respectively, which met the requirements of remote sensing interpretation accuracy. In ARCgis, the spatial distribution map of land use in the study area in 2004, 2010 and 2016 was formed.

CA-Markov prediction model construction

The CA-Markov model has both the predictive ability of Markov model and the advantage of cellular automata model in simulating the spatial changes of complex systems (Kamusoko et al., 2009). With the support of IDRISI software, the data probability transformation matrix in the study area is added to the cellular automata model. In the model, the transfer area and probability of each land use type were generated by Markov chain, and the image set of land use transfer suitability was created by logistic regression model. Finally, the future land use situation was simulated by CA cellular automata combined with transfer probability and transfer suitability atlas (Hu et al., 2013) (*Fig. 2*).

It should be pointed out that according to the principle of urban planning, the water and construction land cannot be converted between each other in study area. In addition, the time interval between remote sensing images is equal to 6 years, so each period of the change is iterated the same 6 times.

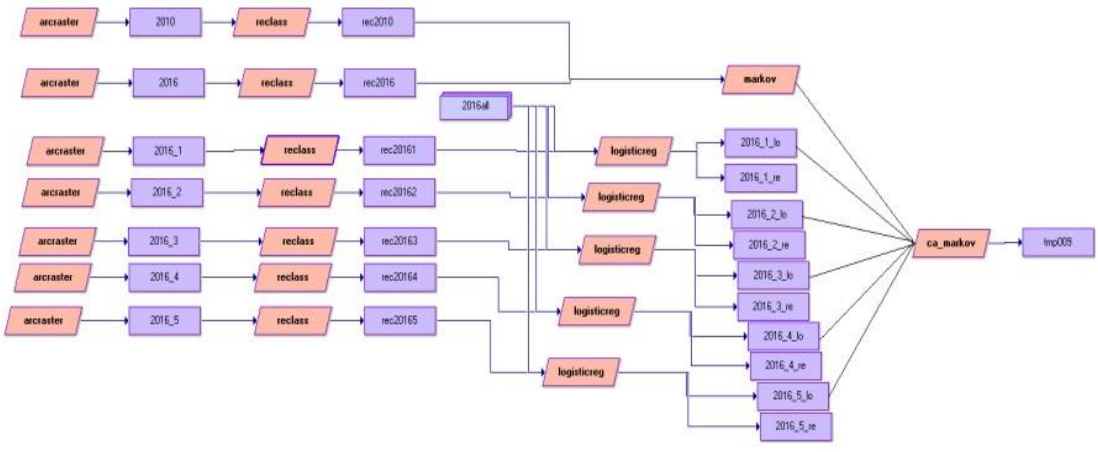

Figure 2. *The flow chart of urban green space simulated dynamically by CA-Markov model*

In this study, the dynamic simulation prediction of urban green space was realized based on the CA-Markov model. It should be carried out on the premise of ensuring the accuracy of the model, and the experimental periods were 2004, 2010 and 2016, with a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85698581

time interval of 6 years. The prediction process was achieved through 2 steps. The first was the data accuracy test (Zuo et al., 2014) and spatial data test (Han et al., 2016). That was to say, the green space data and distribution in 2016 were predicted by the images from 2004 to 2010, and compared with the measured green space data in 2016, so as to test the feasibility and accuracy of this method. If the accuracy met the requirements, the second part was studied, that was the data and distribution of green space in 2022 were predicted through the 2010-2016 image data (Jiménez et al., 2016).

The specific steps were as follows: (1) According to the land use classification results of remote sensing images in the study area in 2004 and 2010, the transfer area matrix and transfer probability matrix of land use in 2004-2010 were obtained by Markov model. (2) The land change suitability image in 2004-2010 was made by using Logistic regression model. (3) Using CA-Markov model, the land use distribution map of 2010 was superimposed on the road network of 2016. On this basis, the land use transfer probability matrix and transfer suitability image set from 2004 to 2010 were used to predict the green land data and its distribution in 2016 (Huang, 2019). The proximity filter was set to 5 × 5. (4) In order to test the reliability of simulation results, the accuracy of the CA-Markov model should be verified. The land use classification map in 2010 was used as the initial image to predict the distribution of urban green space in 2016, and the predicted value in 2016 was compared with the actual value. In this paper, area accuracy (*Eq. 1*) and spatial accuracy (*Eq. 2*) are used to compare their consistency. In *Equation 1,* m_{iy} and m_{ix} are respectively the simulated area and the actual area of the i land, the higher of the E1 numerical value, the better the consistency between the simulated area and the actual area. In *Equation 2,* c_{iy} is the grid number of i land in the land use simulation map, and c_{ix} is the grid number of I class land in the land use actual map at the same location as c_{iy}. The same meaning, the higher of the E2 numerical value, the higher the spatial precision. In this study, it was feasible that *E2* was set to 85%. (5) According to the above (1)-(4) steps, the land use distribution map of 2016 was taken as the initial image, and the land use classification results of 2010 and 2016 remote sensing images in the study area were used to generate transfer probability matrix and land change suitability image set to predict the spatial distribution of green space in the study area in 2022.

$$E1 = \left\{1 - \frac{\left|m_{iy} - m_{iy}\right|}{m_{ix}}\right\} \times 100\% \quad \text{(Eq.1)}$$

$$E2 = \frac{c_{iy}}{c_{ix}} \times 100\% \quad \text{(Eq.2)}$$

Urban green space landscape index acquisition

Landscape index is used to quantitatively analyze the characteristics of landscape pattern (Riitters et al., 1995). In the landscape index analysis, four indexes of number of patches (NP), landscape shape index (LSI), the proportion of the largest patch to the landscape area (LPI) and Shannon diversity index (SHDI) were selected as the characteristic indexes reflecting landscape pattern (Zhang et al., 2014; Wu et al., 2016) (*Table 1*). The vector land use map was transformed into raster map by ArcGIS, and the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85698581

vector diagram was transformed into Arc Grid format data with a size of 10 m ×10 m, and the above landscape indexes were calculated by Fragstats 4.2 software.

Table 1. *Main landscape index and its ecological significance*

Index type	Index name	English abbreviation	Application scale	Ecological significance
Density and diversity index	Number of plaques	NP	Type/landscape	It reflects the total number of patches reflecting the patch type in the landscape, which is positively correlated with the degree of fragmentation of the landscape. Generally, the larger the NP, the higher the degree of fragmentation, the smaller the NP, and the lower the broken degree
Shape index	Landscape shape index	LSI	Type/landscape	It reflects the shape complexity of the overall landscape. The closer the LSI to 1, the simpler the overall landscape. The larger the LSI is, the more complex it is
Area index	The proportion of the largest patch to the landscape area	LPI	Type/landscape	It reflects the degree of plaque concentration and the dominant type of landscape
Diversity standard	Shannon diversity index	SHDI	Landscape	It reflects the change of the quantity and proportion of landscape components. In the landscape composed of multiple components, when the proportion of each component is equal, the diversity index is the highest

Results and analysis

Change of land use structure in the study region in 2004-2016

Based on the classification results of ARCGIS, all kinds of land use scale is shown in *Table 2*, and the mutual transformation of each land use type is complicated (*Fig. 3*). It can be seen that in 2004-2016: (1) The scale of construction land has been decreasing. This is mainly because in the process of urban construction, road and green space have been increasing, reducing the projection area of construction land. (2) The scale of roads increases first and then decreases because a large number of new roads have been added between 2004 and 2010, but the road green space has not been improved during this period. Between 2010 and 2016, the road green space has been gradually improved. With the increase of road green coverage, the roads are covered with greenery. (3) The scale of urban green space has increased rapidly. From 2004 to 2016, the scale of green space has been expanding and a green network system along the river and road has been formed. (4) During this period, the scale of open land (unused land) declined, mainly because a lot of wasteland was changed to construction land. (5) The size of water area changes little, indicating that the water system is well preserved.

CA-Markov model constructed for prediction test

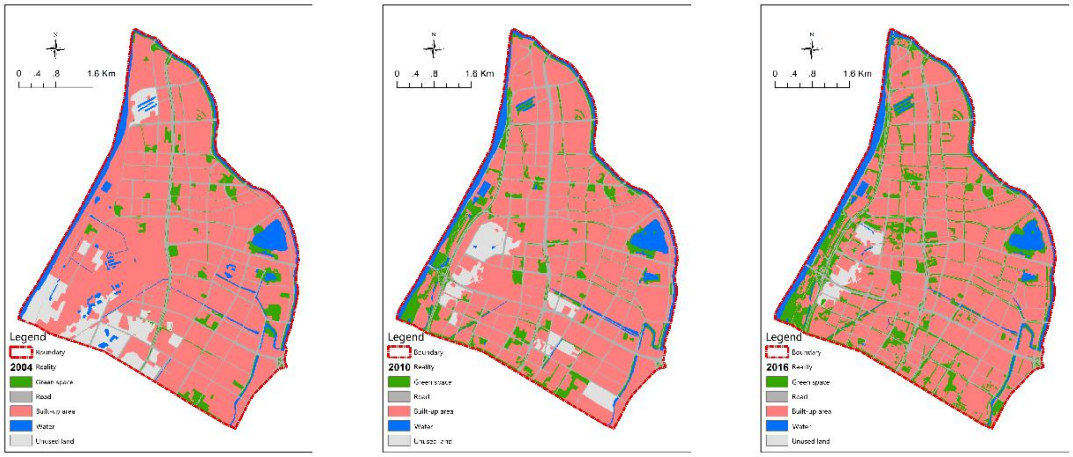
Based on the CA-Markov urban green space prediction model constructed in *Figure 2,* the distribution and scale of green space and all kinds of land in 2016 were

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85698581

predicted by using data from 2004 to 2010 (Wang, 2019). The results are shown in *Figure 4* and *Table 2*. The predicted results were only 5% less than the measured data in 2016, the data precision E of simulated green space was 87.23%, and the spatial precision kappa coefficient was 0.8533, indicating that it was feasible to use CA-Markov model to predict the dynamic change of green space (*Fig. 4*). Therefore, it was reliable to use this method to predict the size and layout of urban green space in 2022 by using the actual measurement of urban green space in 2010 and 2016.

Table 2. *Statistics of all kinds of land use scale (unit: km^2)*

	Land used for building	Road	Green space	River system	Open space	Total
2004 actual measurement	19.32	2.81	1.52	1.79	2.31	27.74
2010 actual measurement	18.09	3.81	2.65	1.72	1.48	27.74
2016 actual measurement	17.73	3.55	4.20	1.73	0.54	27.74
2016 premeasurement	17.66	3.91	3.97	1.70	0.50	27.74
2022 premeasurement	17.28	3.48	4.79	1.73	0.46	27.74



(a) 2004 **(b) 2010** **(c) 2016**

Figure 3. *Results of remote sensing image classification in the study area*

Prediction of urban green space change trend in 2022

According to the land use change prediction of CA-Markov model (*Table 2* and *Fig. 5*), in 2010-2016, on the whole, the change range of all kinds of land was smaller than the previous 12 years from 2004 to 2016. The urban green space will continue to improve in 2016-2022, and the scale will continue to increase. According to the forecast, the greening level of the riverside park of the Yangtze River and key roads will be higher than 2016, the width of green bandwidth will be further improved, the overall scale will be increased from 4.20 km^2 in 2016 to 4.79 km^2, but the improvement of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85698581

green space network will make the construction land and road (projected area) scale of the study area continue to decline, and the overall scale of both will be reduced by about 0.59 km^2 (Yanyan et al., 2019).

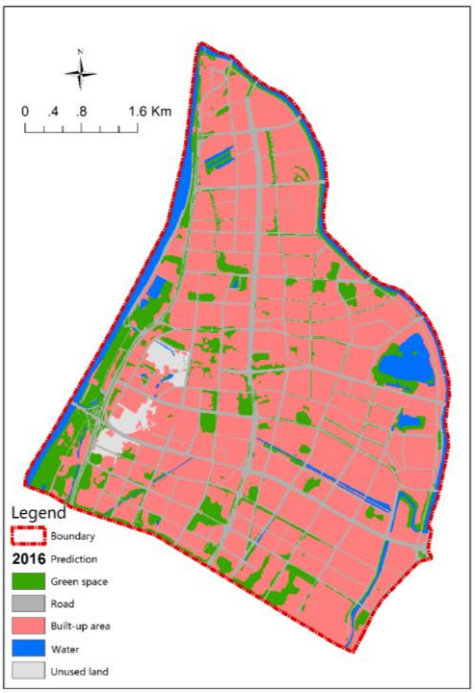


Figure 4. *Prediction of green space distribution in 2016 based on remote sensing image data in 2004 and 2010*

Figure 5. *Prediction of green space distribution in 2022 based on remote sensing image data in 2004 and 2010*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85698581

Green space landscape pattern analysis in 2004-2022

Based on the measured land use distribution maps of 2004, 2010 and 2016 and the predicted land use distribution maps of 2022, 16 landscape indexes of four periods were calculated (*Table 3*). From *Table 3* it can be seen that the number of patches of green space NP and the complexity LSI are on the rise, which indicates that the fragmentation and disorder degree of green space landscape in the study area became more and more serious between 2004 and 2016, and the mutual relationship between green space and all kinds of land became complex, and the degree of mosaic increased (Yu, 2019). From 2016 to 2022, the number of patches NP and complexity LSI of green space show a downward trend, the landscape of green space starts to become orderly, the fragmentation is reduced, and the green space network system is gradually formed. The landscape shape index (LPI) shows an increasing trend, indicating that the patch area of green space with dominant effect increases all the time (Perdomo-Valentín, 2016). Shannon diversity index (SHDI) increases slightly, indicating that the heterogeneity of urban green space decreases and presents a trend of balanced distribution, and the spatial layout of urban green space tends to be reasonable (Ebrahimian, 2017).

Table 3. *Landscape pattern analysis in 2004-2022*

Year	Green Space NP	Green space LSI	Green space LPI	Total SHDI
2004 actual measurement	598	23.3065	0.1347	1.03
2010 actual measurement	674	34.1506	0.3674	1.10
2016 actual measurement	802	46.9604	0.4323	1.08
2022 premeasurement	715	44.152	0.4648	1.11

Conclusions and discussion

Based on the remote sensing image data of 2004 and 2010, the spatial distribution of urban green space in the northern area of Hexi new town of Nanjing in 2016 and 2022 was simulated and predicted by using CA-Markov model. The evolution of green space landscape pattern in the study area was analyzed by using four landscape indices. The following conclusions can be drawn:

(1) In this study, based on CA-Markov model and GIS and RS technologies, taking the spatial transformation of construction land, road, green space, water system and open land (unused land) as the research objects, the CA-Markov model was used to predict the scale and distribution of urban green space in northern region of Hexi new town of Nanjing in 2022. The predicted results in 2016 obtained by the experiment show that the simulation accuracy is up to 87.23% and the Kappa index is 0.8533, indicating that the proposed conversion rules are feasible and the predicted model has high reliability. It also shows that the CA-Markov model can not only predict urban land use change, but also predict the future development of urban green space. The results can provide decision support for the dynamic regulation of urban green space.

(2) From 2004 to 2016, the area of green space in the study area has increased year by year. There are two main reasons for this result: first, due to the impact of urban

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85698581

planning and construction, green space was mainly transformed from the unused land of the study area, the unused land was reduced from 2.31 km^2 in 2004 to 0.50 km^2 in 2016; another reason is that along with the roadside trees grow up, the coverage area of road greening is also gradually increased. Therefore, the scale of green space in the study area increased from 1.52 km^2 in 2004 to 3.97 km^2 in 2016, and the scale of green space will continue to increase gradually in the future.

(3) According to the change of the landscape index from 2004 to 2016, the green space in the study area has undergone a process from disorderly development to orderly development, and the layout of green space has also changed from plaque fragmentation to system network. Therefore, the spatial layout of urban green space system will become more and more reasonable.

(4) This study is an attempt to introduce CA-Markov model into the dynamic simulation of urban green space, hoping to provide a method for dynamic regulation of urban green space. However, this study is only based on the size and distribution of urban green space in 2004, 2010 and 2016 to dynamically simulate the changes of urban green space in the future. The impact of the adjustment of urban planning, the occurrence of major events and other policy changes on the construction of green space has not been considered, which may lead to greater errors in the prediction of urban green space. Therefore, in the further study, different scenarios can be set to formulate constraints, so as to make the simulation results more reasonable.

(Received 8th Mar 2019; accepted 21st May 2019)

Abstract. *Atriplex canescens* is a C_4 fodder shrub that is excellent for phytore-mediation in saline-alkali environments. However, little is known about the response of this shrub species to salt and alkaline stress and its underlying physiological adaptive mechanisms. In this study, we treated 8-week-old *A. canescens* seedlings in the lab with neutral salt (NS) (1:1 molar ratio of NaCl to Na_2SO_4, pH 6.65-6.95) and alkali salt (AS) (1:1 molar ratio of $NaHCO_3$ to Na_2CO_3, pH 9.75-10.12) at five concentrations (0-400 mM). Our results showed that individual *A. canescens* seedlings could maintain growth under certain ranges of both NS stress and AS stress. These findings suggest that AS can more strongly inhibit *A. canescens* seedlings than can NS. This result was attributed to a decrease in photosynthetic ability and damage to Na^+/K^+ homeostasis under alkali salinity. Differences were evident in the NS and AS treatments for almost all of the considered parameters.
Keywords: *adaptive mechanism, concentration, chlorophyll, photosynthesis, environmental science*

Introduction

Primary and secondary soil salinization and alkalization are well-known constraints against the sustainable development of agriculture and land conservation, as they are critical environmental factors that can inhibit plant productivity (Flowers, 2004; Kalaji et al., 2016; Ogunyele et al., 2018). Natural salt-alkalinized soils are driven by various cations, such as Na^+, K^+, Ca^{2+} and Mg^{2+}, and various anions, such as Cl^-, SO_4^{2-}, HCO_3^- and CO_3^{2-} (Läuchli and Lüttge, 2002; Nwankwo and Nwankwoala, 2018). Based on salt characteristics, two types of stresses can be incurred from salt-alkalinized soils. Neutral salt (NS) stress, which is induced by a high amount of NS such as NaCl and Na_2SO_4. And alkali salt (AS) stress, which is caused by $NaHCO_3$ and Na_2CO_3 (Shi and Yin, 1993; Jamil et al., 2018). AS stress can impact plants more severely than deleted NS stress (Shi and Yin, 1993; Gong et al., 2014; Nkwuda et al., 2019). Furthermore, plants growing in salt-alkalinized soils are affected by both NS and AS.

Salinity can exert osmotic and toxic effects on plants, consequently damaging the photosynthetic process and impeding plant growth (Benzart Maali et al., 2012; Kumar, 2018). High-salt environments can disrupt ionic homeostasis in plant tissues. The re-establishment of both ionic balance and osmotic adjustment is a key functional mechanism for plant survival under NS stress (Li et al., 2003; Tianlei, 2019). Compared to that of NS stress, the higher pH value of AS stress can impose greater effects on plants, probably because the alkalinity of saline soils can severely disrupt both ionic and pH homeostases in plant tissues (Yang et al., 2008; Rajendran and Mohsin, 2018).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85838598

Therefore, plants under AS stress may suffer not only from ion toxicity and physiological drought but also from alkaline stress in high-pH environments. To resist AS stress, plants must allocate higher amounts of energy to regulate the pH in their roots to maintain intracellular ionic balance (Yang et al., 2007; Sufiyan et al., 2018).

Due to the high adaptability of halophytes to saline and alkaline environments, many studies have examined the physiological responses of these types of plants to salt stress (Maali Benzart et al., 2014). Many studies have found that moderate salt solutions can stimulate net photosynthetic rates (Pns) (i.e., the highest rates of net photosynthesis ar found in plants under moderate salt concentrations). For example, the growth rate of the C_3 perennial halophyte shrub *Atriplex portulacoides* peaked at 200 mM NaCl concentrations (Redondo-Gómez et al., 2007; Madhav et al., 2018). Halophytes can survive in saline environments by employing the following mechanisms: enhancing photosynthetic ability, reducing Na^+ concentrations in the cytosol and using Na^+ as an osmoregulator to maintain cellular ion homeostasis, as well as improving water status via osmotic adjustment by producing compatible solutes (Shabala et al., 2014; Flowers et al., 2015). For instance, *Puccinellia tenuiflora* can limit Na^+ influx to maintain a high K^+/Na^+ ratio in the shoots (Niu et al., 2016; Raj and Prabhakaran, 2018). However, studies on the effects of salt stress on plants have mainly focused on NS environments dominated by NaCl. Few studies have investigated the impact of alkaline stress on halophytes and their underlying mechanisms, which may have implications for better utilization and restoration of salt-alkalinized soil.

Furthermore, recent studies have typically used herbs and crops, including *Chloris virgate*, *P. tenuiflora*, *Kochia sieversiana*, wheat, oats and tomato, to investigate the effects of salt and alkaline stress on plants (Yang et al., 2008). However, how halophytes are affected by salt and alkaline stress and the way they physiologically respond in saline and alkaline environments are not well understood. The saline-alkali region in Northwest China also experiences long periods of drought, gale-force winds and dust. Therefore, shrubs have great implications in land restoration and local economies, as shrubs cannot be replaced by herbs and crops due to the lack of ecological functions, such as disrupting wind and preventing erosion, of those two plant types. The C_4 perennial evergreen shrub *Atriplex canescens*, which belongs to the Chenopodiaceae family, is native to xeric and saline deserts in North America. Due to its strong resistance to drought (annual rainfall of 90-350 mm), salinity（soil salinity of 0.5-1.5%, and cold (elevation of 500-3500 m) (Glenn and Brown, 1999; Kong, 2013), this species is well naturalized and adapted to a wide range of environments. It is widely used as fodder and screens and for preventing soil erosion and soil recovery (Peterson et al., 1987; Benzarti et al., 2013). This shrub species was introduced to China in 1990 and has shown the ability to maintain high levels of photosynthesis and growth rates throughout a wide range of NaCl concentrations (Pan et al., 2016). Therefore, *A. canescens* represents an excellent phytoremediation plant in saline-alkali environments (Benzarti et al., 2013). However, it is not clear whether the photosynthesis and growth of *A. canescens* differ between AS and NS environments. In this study, we conducted a controlled experiment by simulating neutral and alkali soil salt conditions along a concentration gradient from 0 to 400 mM in order to compare the different effects of NS and AS on the growth and physiological response of *A. canescens*. To understand the different impact of salt and alkaline stress on their plants and their physiological response traits, we tested the following three hypotheses:

1. AS more strongly inhibits plant growth than does NS.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85838598

2. AS more strongly inhibits plant photosynthetic ability than does NS.
3. The Na^+ and K^+ contents in *A. canescens* seedlings are more strongly influenced by AS than by NS.

Materials and methods

Experimental treatments

Plant materials

We collected seeds of *A. canescens* from the Academy of Agriculture and Forestry Sciences, Qinghai University, China. The seeds were treated with H_2SO_4 and distilled water and then were germinated in washed sand under dark conditions for 8 days in a greenhouse. A total of 100 plastic pots were used to house the germinated *A. canescens* seeds; the size of each pot was 10 cm × 10 cm × 10 cm. Each pot was filled with 1 kg of washed soil (1.36 g/cm^3 of soil bulk density) and contained 2 seedlings. The seedlings were watered with 1/2-strength Hoagland nutrient solution at 2-day intervals until a suitable soil moisture content (19.96 ± 1.32%, 79.64% percentage of field capacity) was reached. We examined the relationship between the diurnal variation in soil water and seedling growth and defined the suitable soil moisture content as that at which the highest plant growth rates occurred. The climatic conditions of the greenhouse included a temperature of 27.5 ± 1.5 °C/19.0 ± 1.5 °C (day/night) and a photoperiod of 16 h/8 h (light/dark). We controlled the photosynthetically active radiation (PAR) to be 800 μmol m^{-2} s^{-1} and the relative humidity to be 60 ± 2.5%.

Design of simulated salt and alkali conditions

The northwestern inland saline-alkali area in China is characterized by a low annual precipitation (43.5 mm) and a very high intensity of solar radiation (2940 KJ cm^{-2}). The soil salts are mainly composed of NaCl, Na_2SO_4, $NaHCO_3$ and Na_2CO_3. Accordingly, we simulated the NS conditions by mixing NaCl and Na_2SO_4 at a molar ratio of 1:1. To simulate the AS conditions, we mixed $NaHCO_3$ and Na_2CO_3 at a molar ratio of 1:1. Under each salt condition, five levels of soil solution salt concentrations were applied: 80, 160, 240, 320, and 400 mmol L^{-1} (mM).

Stress treatment

A total of 72 uniform 8-week-old seedlings (36 pots) were selected and randomly divided into 12 sets. Each set consisted of 3 pots, and each pot contained two plants. One set was used to measure the initial size of the seedlings at the beginning of the treatment, and one set was used as a control group during the whole treatment. Five sets were used for AS stress treatments, while the other five sets were used for NS stress treatments.

By using the soil solution's salt concentrations, soil bulk density and soil moisture content data, we calculated the quantity of the four different salts added to each treatment. One fifth of the salt quantity were added to the plants along with 200 mL 1/2-strength Hoagland nutrient solution between 17:30 and 18:30 every day for five days until the salt quantity reached the desired level. After the desired salt concentrations in the soil were met, the treatments continued for 20 days in the greenhouse. And the soil

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85838598

moisture contents in all pots were kept constant at 19.96 ± 1.32% throughout the whole experiment.

Measurement of parameters

Growth

Shoot and root relative growth rates (RGRs) were measured. After the experiment, we harvested the whole plants, separated the shoots from the roots and then dried the tissue at 80 °C for 48 h. We calculated the RGR of both the shoots and roots in accordance with the methods of Kingsbury et al. (1984) as follows: RGR = (ln DM_1-ln DM_0)/D, where DM_1 denotes the dry mass at the end of the stress treatment, DM_0 refers to the initial dry mass at the beginning of the stress treatment, and DM is the total treatment duration in days.

Photosynthesis

To measure the photosynthetic ability of the plants, the Pn, stomatal conductance (Gs), transpiration rate (Tr) and chlorophyll (chl) content were measured. Before harvesting the plants, we selected a total of three fully expanded leaves on the upper, middle and lower parts of the seedlings for measuring their Pn, Gs and Tr under a light intensity of 1000 μmol m^{-2} s^{-1} by using an Li-6400 portable photosynthesis system (LiCor, Lincoln, NE, USA) between 10:00 and 11:00. For each leaf, three replicate measurements were performed for each parameter. The same leaves used for measuring Pn were used for measuring leaf area and chl content. We used a photo scanner (CS4200F; Canon, Inc., Tokyo, Japan) to estimate the leaf area. The water use efficiency (WUE) was calculated as the Pn/Tr ratio. The chl a (Chla), chl b (Chlb) and carotenoids (Car) were extracted by using acetone, and their contents were determined with a spectrophotometer (UV-6100PCS; Mapada Instruments, Co., Ltd., Shanghai, China) at 440-, 654-, and 663-nm wavelengths, respectively. Their concentrations were calculated in accordance with the equations (Lichtenthaler, 1987).

Na^+, K^+ concentrations

The roots, stems and leaves were carefully separated and rinsed with deionized water, after which they were dried in an oven at 80 °C for 72 h. The Na^+ and K^+ ions were extracted from the dried tissues by using 100 mM acetic acid at 90 °C for at least 2 h. The extractions were then transferred to a water bath, cooled and filtered, after which the cation accumulation was determined by using a flame spectrophotometer (Model 410 Flame; Sherwood Scientific, Ltd., Cambridge, UK) (Bao et al., 2016). Three replicates were used per measurement.

Statistical analysis

One-way analysis of variance (ANOVA) was performed for each measurement by using SPSS statistical software (Ver. 19.0, SPSS, Inc., Chicago, IL, USA). Duncan's multiple range test (DMRT) was used to identify significant differences among the means at a significance level of $P < 0.05$. All the acquired data were presented as the average values and their standard errors (SEs).

DOI: http://dx.doi.org/10.15666/aeer/1704_85838598

Results

In total, 66 seedlings (1 set of control treatment, 5 sets of NS treatment and 5 sets of AS treatment) were analysed. The mean height of the *A. canescens* seedlings was 12.26 ± 1.90 cm and 10.43 ± 1.21 cm under NS and AS conditions (0-400 mM), respectively, after 20 days.

Effects of NS and AS on the growth of A. canescens seedlings

The growth of *A. canescens* seedlings under the AS treatment differed from that under the NS treatment at the same level of salinity (*Fig. 1*). A moderate NS concentration (i.e., 160 mM) caused a growth peak for both the shoots and roots. When the NS concentration reached 240 mM or greater (< 400 mM), the shoot growth rates did not significantly differ from those under the non-saline conditions. Under AS conditions, the peak growth of the both the shoots and roots occurred at the lowest AS concentration (80 mM). Further increases in the AS concentrations considerably reduced the growth rates, especially for the root RGR above the AS concentration of 240 mM, which had already significantly inhibited root growth.

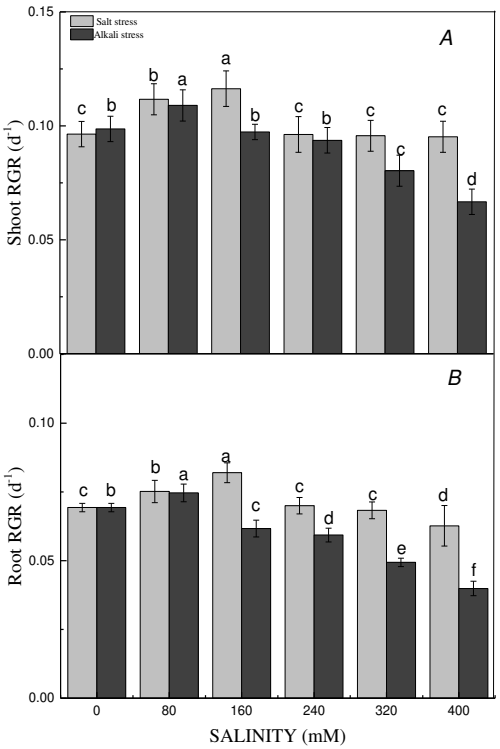

Figure 1. *The mean relative growth rates (RGRs) of the shoots (A) and roots (B) of A. canescens seedlings under different neutral salt (NS) and alkali salt (AS) concentrations (0-400 mM) after 20 days. The error bars indicate the 95% confidence intervals of the means. Different letters in the same panel indicate significant differences at $P < 0.05$ according to the Duncan test*

Effects of NS and AS on photosynthetic ability of A. canescens seedlings

The variation in leaf Pn as salinity increased under AS conditions differed from that under NS conditions (*Fig. 2*). The Pn significantly and continuously increased as

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85838598

salinity increased under NS conditions. Moderate AS concentrations increased the Pn; however, compared with that of the control, the Pn decreased dramatically when the AS concentration reached 320 mM or above. NS concentrations of 160 mM and AS concentrations of 80 mM resulted in highest leaf Gs values. The leaf Gs gradually decreased as salinity further increased. However, *A. canescens* seedlings subjected to NS and AS conditions presented different leaf Ci contents. When exposed to NS, the Ci continuously decreased as the salt concentration increased in NS treatment, and similar trend was observed under AS conditions. Furthermore, under AS conditions, after reaching the lowest content at 240 mM, the Ci sharply increased at 320 mM. Correspondingly, leaf WUE was significantly reduced at 160 mM but gradually increased as the salinity concentration increased. At salinity concentrations of 320 mM, the leaf WUE was higher under NS conditions than under AS conditions.

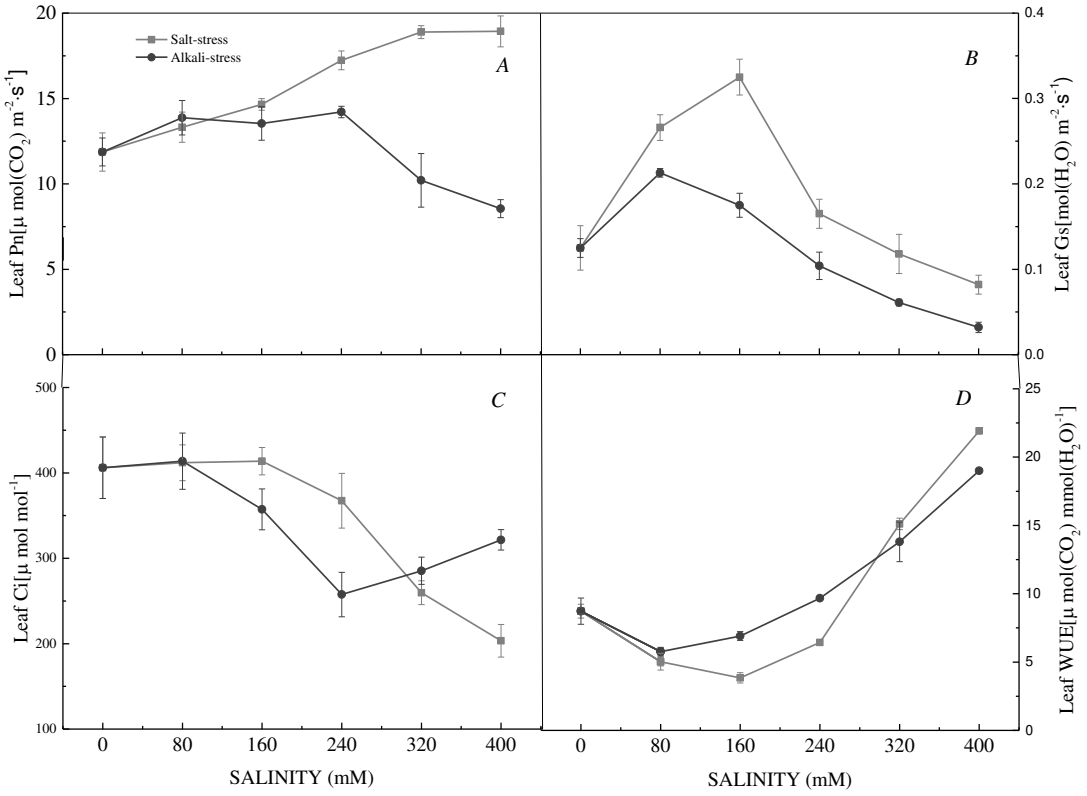

Figure 2. *Mean leaf net photosynthetic rate (Pn) (A), leaf stomatal conductance (Gs) (B), leaf intercellular CO_2 concentration (Ci) (C), and leaf water use efficiency (WUE) (D) of A. canescens seedlings under different NS and AS concentrations (0-400 mM) after 20 days. The error bars indicate the 95% confidence intervals of the means*

The leaf chl contents of the *A. canescens* seedlings under AS conditions were lower than those under NS conditions ($P < 0.05$) (*Table 1*). Leaves produced more Chla, Chlb and Car as the NS concentration increased (*Table 1*). At 400 mM NS, the leaf Chla and Chlb contents were 52% and 44% higher than those under non-saline soil conditions, respectively. However, the Chla, Chlb and Car of leaves responded differently to AS stress than to NS stress. The leaf chl content slightly increased as the AS concentration increased but significantly decreased at the AS concentration of 320 mM. Leaf Car were

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85838598

not affected by AS concentrations less than 320 mM; however, the Car increased at AS concentrations of 400 mM. The ratio of leaf Chla and Chlb increased as NS concentrations increased but decreased as AS concentrations increased.

Table 1. *The mean contents of photosynthetic pigments (Chl – chlorophyll, Car – carotenoids) [g kg^{-1} of fresh matter (FM)] in A. canescens seedlings under different NS and AS concentrations (0-400 mM) after 20 days*

In each column, different letters indicate significant differences at $P < 0.05$ according to the Duncan test

Effects of NS and AS on the Na^+/K^+ of A. canescens seedlings

The Na^+ and K^+ contents in *A. canescens* seedlings were differently influenced by AS than by NS. The Na^+ content in the leaves, stems and roots under AS conditions was higher than that under NS conditions, with the exception of the roots in which the AS concentrations of 320 and 400 mM significantly inhibited root Na^+ absorption. At 400 mM NS, the leaf, stem, and root Na^+ contents were approximately 17.25-, 14.89- and 3.86-fold higher than those of the control plants, respectively. Compared with NS stress, AS stress had a more profound effect on reducing the K^+ content in all plant organs.

Under NS conditions, the K^+ content in shoot tissue remained relatively constant as salinity increased, whereas the root K^+ content decreased as salinity increased. Similarly, the K^+ content significantly decreased in the leaves and the roots as the AS concentration increased (*Fig. 3D-F*). The Na^+/K^+ ratios in the leaves and stems significantly increased as salinity increased, and a larger magnitude of increase occurred under NS conditions than under AS conditions. However, in the roots, the Na^+/K^+ ratio peaked at 240 mM under both NS and AS conditions, but the ratio decreased thereafter as the NS concentration increased (*Fig. 3G-I*).

Discussion

The RGR reflects the life-sustaining activities of plants and how they respond to stress (Wang et al., 2015). Our results showed that *A. canescens* can adjust to NS stress and AS stress. However, higher AS stress more strongly inhibits plant growth, which confirms our first hypothesis. We found that the growth rates peaked at moderate NS concentrations (160 mM), and growth was maintained in non-saline environments at NS

DOI: http://dx.doi.org/10.15666/aeer/1704_85838598

concentrations up to 400 mM. Similarly, Pan et al. (Pan et al., 2016) reported that *A. canescens* grew better under 100 mM NaCl conditions than under non-saline conditions; however, the salinity level at which the peak growth occurred was lower than the level we recorded in our experiments (100 mM vs. 160 mM). This finding might be attributed to the salt mixtures (i.e., NaCl and Na_2SO_4) that we used (Qiu et al., 2003). In contrast, growth was inhibited by external AS treatment (> 320 mM). Previous reports have also shown greater deleterious effects from alkaline stress than salt stress on other plant species, such as *Aneurolepidium chinense*, *Chloris virgate*, *Suaeda corniculata*, (Shi and Wang, 2005; Yang et al., 2007, 2008). The different influence of both kinds of stress on plant growth might be due to the different underlying mechanisms. Plant survival in AS soil relies not only on the ability to address ion toxicity and low water potential but also on the ability to tolerate high pH (Shi and Wang, 2005; Yang et al., 2007, 2008). Adjustments of the pH outside the roots may represent another key physiological mechanism of alkalinity resistance. Under high AS conditions, a high pH around the roots could disrupt the governing ion balance and nutrient supplies; this disruption could lead to the inhibition of transmembrane electrochemical potential gradients in the root cells, which would negatively impact photosynthetic parameters and growth. Moreover, our results also demonstrated that the different responses of the photosynthetic ability (Shabala et al., 2014), ion homeostasis and osmotic adjustment capacity of the *A. canescens* seedlings represented the mechanisms that drove the stronger growth inhibition under AS conditions than under NS conditions (*Fig. 1*).

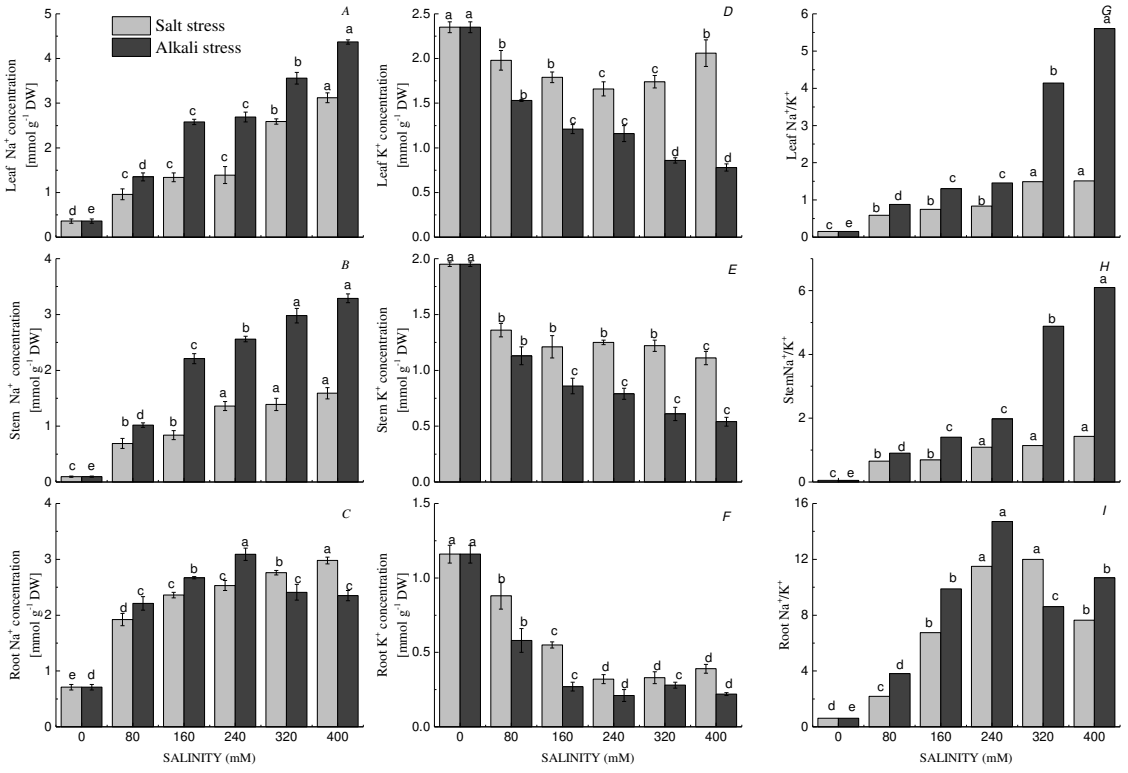

Figure 3. *The mean Na^+ and K^+ contents and Na^+/K^+ ratios in the leaves (A, D, G), stems (B, E, H) and roots (C, F, I) of A. canescens seedlings under different NS and AS concentrations (0-400 mM) after 20 days. The error bars indicate 95% confidence intervals of the means. Different letters in the same panel indicate significant differences at $P < 0.05$ according to the Duncan test*

Plants must spend energy to adapt and exhibit resistance to stressful environments. The amount of energy spent directly depends on the photosynthetic ability (Wellburn and Lichtenthaler, 1984). The different growth rates of the *A. canescens* seedlings under the different treatments were basically the result of the Pn (Wang et al., 2004). In the present study, the Pn of the *A. canescens* seedlings significantly increased as both NS and AS concentrations increased, with the exception of that at 320 and 400 mM AS (Tsutsumi et al., 2015). This finding indicated that the *A. canescens* seedlings strongly tolerated more than just salt and alkaline stress (Shi and Wang, 2015). However, the AS more strongly inhibited the Pn of the plants than did the NS, which is in line with our second hypothesis.

The responses of the Pn might be mediated by the photochemical process, resistance to gas exchange and the assimilatory system. Under moderate stress, *A. canescens* seedlings can increase cyclical electron transport (Bukhov and Carpentier, 2004) and photorespiration (Parida and Das, 2005) as mechanisms for protection against salinity. Furthermore, *A. canescens* seedlings can cope with excessive salt by decreasing their stomatal aperture to increase leaf WUE and carboxylation (Guy et al., 1980; Megdiche et al., 2008). Our results showed that the Gs first increased but then decreased as salinity increased. In contrast (Ma et al., 2012) reported that the Pn and Gs of *Zygophyllum xanthoxylum* were positively correlated. This correlation might be due to the different properties of C_3 and C_4 plants (Yang et al., 2017). Moderate Na^+ concentrations may promote the C_4 photosynthesis of *A. canescens* by facilitating the activity of photosystem II (PSII), converting pyruvate to phosphoenolpyruvate, as well as other biochemical processes in the photosynthetic pathway (Chaves et al., 2011; Kronzucker et al., 2013). In this study, we also found that the contents of Chla, Chlb and Car increased as the NS concentration increased. Under moderate stress, the *A. canescens* seedlings might accumulate photosynthetic pigments and metabolically regulate chl to adapt to NS or AS conditions. In addition, Car are not only photosynthetic pigments but also endogenous antioxidants. Apart from the photosynthetic function of Car, they can also prevent membrane lipid peroxidation (Yang et al., 2008). In contrast to the stimulating effects of the high levels of neutral salinity on the Pn, high concentrations of AS significantly reduced the Pn. This result might be due to the dual effects of stimulation and inhibition caused by the AS (Zhao et al., 2013). At AS concentrations of 320 mM, the inhibitory effects gradually strengthened as salinity increased and exceeded the stimulatory effects. High pH values may injure the photosynthetic system, possibly inhibiting the transmembrane electrochemical potential of PSII. The sudden increase in Ci also indicated a damaged photosynthetic system when the AS concentrations reached 320 mM or greater (Yang et al., 2012). This Ci enhancement at AS concentrations of 320 mM was probably caused by non-stomatal limitations in accordance with the Farquhar gas exchange model. For example, limiting Rubisco carboxylase activity and destroying chloroplast structure could explain the reductions in the Pn, causing Ci to increase (Bethke and Drew, 1992; James et al., 2006). Salinity induces a wide range of perturbations in terms of chl concentration and chloroplast structure (Abdelkader et al., 2007). In our study, the reduced chl content after an initial increase as the AS concentration increased might also indicate a stronger inhibitory impact of AS compared with NS on chl synthesis, and Mg^{2+} precipitation (Shi and Zhao, 1997). Furthermore, Chlb is an important component of the light-harvesting complex. The decrease in Chlb in our results might also impair the light-harvesting complex structure and function, consequently weakening the light

DOI: http://dx.doi.org/10.15666/aeer/1704_85838598

absorption ability of the chloroplasts. To summarize the above results, the inhibition of *A. canescens* seedling growth under AS conditions might result from a decrease in the Pn, which might be due to non-stomatal limitations and lower chl concentrations caused by a high pH (Zhao et al., 2014).

In saline soil, Na^+ is considered a major toxic ion. Low Na^+ and high K^+ contents in plant cells are preconditions to the maintenance of enzymatic processes (Munns and Tester, 2008). Thus, maintaining a relatively constant intracellular Na^+/K^+ homeostasis is crucial for plants to acclimate to salinity stress conditions (Zhu, 2003; Tang et al., 2014). In the present study, the Na^+ content was higher and the K^+ content was lower under AS conditions than under NS conditions (Volkov, 2015). The Na^+/K^+ ratios increased along the salinity gradient. However, compared with the AS treatment, the NS treatment resulted in Na^+/K^+ ratios that remained relatively constant as salinity increased. This finding confirmed our third hypothesis that AS more strongly influenced the Na^+ and K^+ contents in *A. canescens* seedlings than did NS (Zhang, 2013). The increased accumulation of Na^+ and decreased accumulation of K^+ represent mechanisms for adapting to salinity in *Atriplex* (Bajji et al., 1998; Bose et al., 2015; Ma et al., 2016). In the present study, the growth of *A. canescens* seedlings was positively affected by NS despite the increased Na^+ content, which might be attributed to two physiological processes. First, ion compartmentation enables plants to sequester a large quantity of excess Na^+ into epidermal bladder cells to avoid ion toxicity in organelles (Flowers and Colmer, 2008; Ding et al., 2010; Shabala, 2011, 2014). Second, *A. canescens* is capable of transporting K^+ instead of Na^+ from the roots to the stem or from the stem to the leaves to maintain a relatively constant cytosolic Na^+/K^+ ratio in the shoots (Flowers and Colmer, 2008; Pan et al., 2016). In contrast, under AS conditions, the over-accumulation of Na^+ had adverse impact on the *A. canescens* seedlings. This finding might be related to reduced Na^+ sequestration within vacuoles and weakened control over Na^+ transport within plant tissues driven by high pH values (Chen et al., 2009). These phenomena can thus lead to a significant increase in Na^+ concentration and can disrupt ionic balance in tissues. Furthermore, AS can also neutralize the number of protons and weaken the establishment of Na^+/H^+ antiporters in the plasma membrane, leading to the failure of Na^+ compartmentation (Munns and Tester, 2008; Pan et al., 2016). Our results further showed that the AS environment more strongly impeded the ability of plants to maintain K^+ uptake than did the NS environment. Similarly, excess Na^+ competes with K^+ uptake in many species. This phenomenon can inhibit K^+-dependent metabolic process, such as the induction of the photosynthetic ATPase enzyme, and can inhibit the participation of K^+ during carbohydrate biosynthesis, consequently resulting in oxidative stress (Munns and Tester, 2008; Flowers et al., 2015; Volkov, 2015). We demonstrated that the disrupted K^+ and Na^+ homeostasis due to the high pH value is probably responsible for the inhibited growth and reduced Pn of *A. canescens* seedlings in AS environments.

Conclusion

Our results indicated that *A. canescens* seedlings can adapt to NS stress and AS stress though strengthening the photosynthetic ability and maintaining ionic homeostasis capacity. However, at higher concentrations (> 240 mM), alkali salinity more strongly inhibited plant performance than did neutral salinity, and the change was associated with a decrease in photosynthetic ability and damage to Na^+/K^+ homeostasis under

alkali salinity. *A. canescens* as an exotic tree species can used to achieve the ecological recovery and city afforestation for moderate salinization areas of northwest China. In this study, we compared the growth responses of *Atriplex canescens* to salt and alkaline stress under an optimal soil water condition. In the future, experiments may be conducted under different soil water conditions.

(Received 8th Mar 2019; accepted 21st May 2019)

Abstract. Study of soil water repellency (SWR) has been very systematized in Europe and America but underdeveloped in Asia. This study aims to comprehensively and systematically analyze SWR in China and Israel, and to contribute to the knowledge on SWR in the world. We collected all documents about SWR that were published in China. Research sites were all over the China and typical areas of Israel. 4647 datasets were obtained from these documents. We have done a rounded analysis based on the influencing factors like soil type, soil depth, land type, interference type. Through the data collection and analysis, we found most of the soil in China and Israel is water-repellent, and almost all of the soil types are water-repellent. However, most of the soil types only have low water repellency. The level of soil water repellency of different soil types is different. The soil in forest ecosystem generally has a higher water repellency than that in the non-forest ecosystem. SWR will increase after the interference of water or fire, and the effect of water is more significant. The results provide theoretical basis for soil improvement and vegetation restoration in China and Israel even the World.
Keywords: *water repellency, fire disturbance, soil type, forest ecosystem, external disturbance*

Introduction

Soil water repellency has perplexed people for almost one century. Soil water repellency is mainly caused by organic hydrophobic matter which originated from plants, external disturbance, and microbial activities, resulting soil hard to be wetted or wet soil difficult to be wetted again after drying. It is pervasive and prevalent to evaluate SWR by Bisdom classification (1993) (Bisdom et al., 1993; Sunny et al., 2018), using water drop penetration time (WDPT): wettable soil (<5 s), good for wettability; slightly water repellent (5-60 s), decreasing water holding capacity (Doerr et al., 2000; Hossain et al., 2019); strongly water repellent (60-600 s), resulting uneven water infiltration and potential risk to groundwater polluted (Bogner et al., 2008; Ali et al., 2018); severely water repellent (600-3600 s), and extremely water repellent (>3600 s), causing severe soil erosion, environmental damage, and economic loss (Craswell and Lefroy, 2001; Sharjeel et al., 2019).

The climate of China and Israel are different, there is no Mediterranean climate in China. China and Israel are completely different in rainfall characteristics but both of their water resources are uneven distribution. SWR is an important index in soil health evaluation system. The water conservation capacity of soil is weak because of the SWR; this lead to the water cannot be conservation well by soil. China and Israel are facing available water crisis. There have no researches evaluated the soil quality of China and Israel according to the SWR. Our research filled the gap and supplied data of SWR of China and Israel for world SWR database. And our research can also provide reference to soil quality evaluate in other areas.

China, as a principle Asian country, the SWR researches began in the 1990s (Ebelhar et al., 2008; Tao, 2018). The scientists paid little attention on the correlative studies which started late and lacked of deep research. Only a few simple introductions that lacked of standard, unified and comprehensive analysis could be found in the existing documents discussing about SWR determination methods (Crockford et al., 1991; Liang and Wenshun, 2019), the influential factors of desert SWR (Dahlgren et al., 2008) and the influences of fire disturbance on forest SWR (Chesworth et al., 2008) etc. All terrains types and agrotypes could be discovered in China where had a large range of altitude (-154-8844.43 m), a high precipitation disparity of different regions (5.9-1600 mm), different climate and a big regional heterogeneity. Israel has typical Mediterranean climate and the research of SWR in desert soil in Israel is developed. The comprehensive and objective research on Chinese and Israel SWR hasn't been reported.

By collecting the existing research data, for the first time, the Chinese and Israel's SWR records were combined and analyzed, and unified the calibration of the data unit and classification by utilizing various international standards. Research 1) the overall distribution characteristics of Chinese and Israel's SWR; and 2) the integrated characteristics of Chinese and Israel's SWR.

Materials and Methods

The database

This study had collected and sorted out all published SWR documents in China. The data screening work had complied with the following requirements: (1) The experiment design had no obvious flaws. This study did not probe into the uncertainty of different measurement, only took WDPT as a measurement and quantitative index of SWR. (2) Include WDPT measurement data. (3) The properties of the variables in the experiment were related to the temporal or spatial distribution patterns, the control experiment variables like the contact angle between soil and water were excluded. We extracted original information such as geographic information (longitude, latitude, altitude and so on), time (experimental time), land use (vegetation cover type, vegetation type, vegetation composition etc.), soil information (soil type, soil depth etc.), and interference (interference types) from each document. Moreover, some literature data were published in the form of pictures. According to the ordinary way, we intercepted these pictures and employed image analysis software (DigitizeIt, version 1.5.8 http://www.digitizeit.de/) to digitize the data and recover it to the raw data. Great efforts were devoted to data standardized after extraction: (1) WDPT data was unified in second. (2) As for the researches did not mention the specific experiment time, we could reasonably calculate the experiment time according to the data published time. (3) The classification of the land use and ecological regions were based on Hou Hsioh-yu's classification of natural ecological regions in China in 1988. (4) The identification and classification of soil types referred to the soil classification system of the Food and Agriculture Organization of the United Nations (FAO). Compared the soil samples with the data in Chinese Soil Database and the World Soil Database on the basis of the soil background and soil name of those sampling sites to identify the standard names, then contrasted with FAO 85 and FAO 90 to screen and determine the accurate classification of the sample soil by the FAO standard.

In this study, we arranged 4647 data regarding with all SWR data in China and Israel. At first, We mapped and visualized the spatial and temporal distribution of WDPT data there (*Fig. 1, Fig. S1*). The research sites were across Chinese provinces in the western, northern, central, southern area and Israel and the research time were span from the earliest WDPT reports in 2009 to 2016.

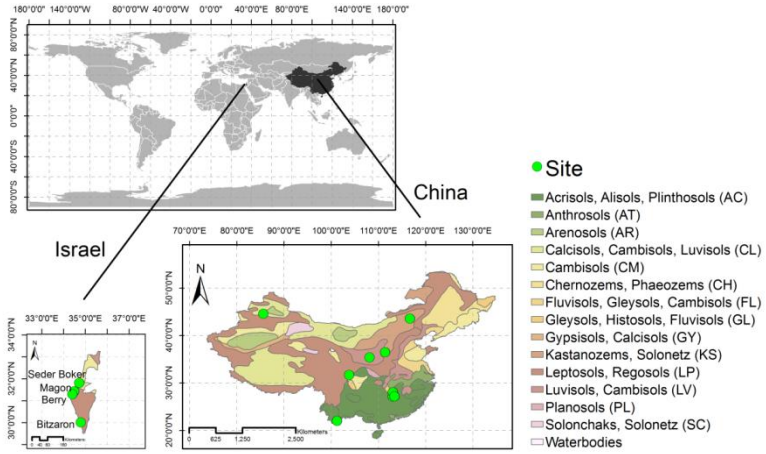

Figure 1. *Geographic distributions and sites of data collected. The map on the top is the location of sampling countries in the world. Two maps below are location and Soil backgrounds of sampling sites in China and Israel. Green points represent the location of the sampling sites of data. The background of the soil type distributions were obtainable from the FAO web page (http://www.fao.org/AG/agL/agll/wrb/soilres.stm), to process soil map backgrounds using ArcGIS9.3 at a scale of 1:25 000 000(WRB2003). The soil classification follows world reference base for soil resources (FAO 1990)*

4 different environment gradients were set: (1) Land use, including forest (n=970) and non - forest (grassland and farmland, n=3673), had 8 different natural ecological periods and more than 20 forest types such as Cunninghamia lanceolata plantation, Pinus massoniana plantation and Schima superba mixed forest (*Table 1*). (2) Soil type, contained 8 soil types, that were Aeolian soils (n=288), Calcisols (n=72), Red earth (n=62), Red-yellow earth (n=260), Gray-brown desert soil (n=100), Yellow-brown earth (n=3529), Castano-cinnamon soil (n=44), Regosols (n=288) (*Table 2*). (3) Soil depth, can be reduced to 2 levels, topsoil (0-5cm, n=4439) and subsoil (depth> 5cm, n=204). (4) Processing gradients, no processing (n=3807), sewage irrigation (n=528), fire disturbance (n=308).

Statistical analysis

In this study, WDPT data were logarithmically (Log10WDPT) normalized. We divided the data into five grades according to the SWR grading standards: wettable (<5 s), slightly water repellent (5-60 s), strongly water repellent (60-600 s), severely water repellent (600-3600 s), extremely water repellent (>3600 s). The data were differentiated by different environmental factors (such as land use, soil type, soil depth and interference type) and the impacts of different environmental factors on SWR were analyzed. We sorted the data with Microsoft Excel 2010 at first, and did the further description and analysis job with IBM SPSS Statistics21.0, finally drew the charts with Origin8.0.

Results

SWR

China and Israel soil WDPT was (median) 7 s, from 0.503-4990.84 s (*Fig. 2, Table S1*). Most soils had water repellency (75.96%) in which slightly water-repellent soil predominated (58.22%), followed by no water-repellent soil (close to 24.04% of the total), strong water repellency and severe water repellency soil added up to 17.49%, and few extremely water-repellent soil (0.26%) (*Fig. 3, Table S2*).

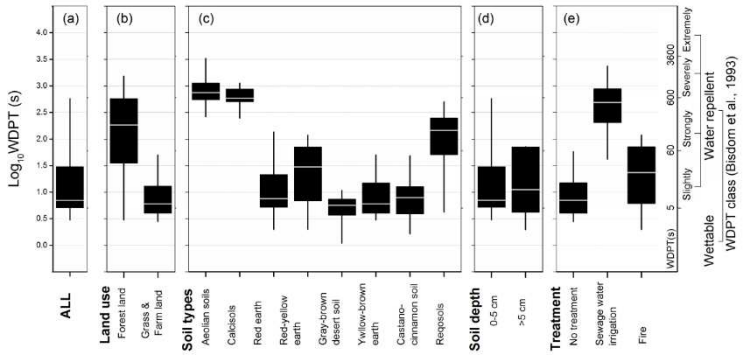

Figure 2. *Distribution of soil water repellency characteristics in China and Israel. WDPT data were standardized into Log_{10}, SWR was divided into five levels according to WDPT (Bisdom et al., 1993): wettable soil(WDPT<5 s), slightly water repellent(WDPT range 5−60 s), strongly water repellent (WDPT range 60−600 s), severely water repellent (WDPT range 600−3600 s), extremely water repellent (WDPT>3600s). (a)Summary distribution characteristics of SWR; (b)−(e)SWR distribution along different environmental gradients: (b)land use, (c)soil type, (d)soil depth, (e)treatment. In the boxplot, the line within the box represents the median, the lower boundary of each box means the first quartile (25^{th} percentile), while the upper boundary is the third quartile (75^{th} percentile) of the distribution. The lower the upper error bars are the 1^{st} and 99^{th} percentile value in the distribution, respectively*

SWR distribution

Most Chinese soils were slightly water-repellent, but they showed different SWR differentiation characteristics under different gradients of land use, soil type, soil depth and disturbance type (*Fig. 2, Fig. 3*).

In different land uses, the forest ecosystem SWR was stronger than grassland and farmland ecosystem SWR. The forest ecosystem soil WDPT ranged from 0.9 s to 4988.8 s with nearly half of the soils showed strong water repellency (WDPT median value was 183.831 s and the strong water repellent soil accounted for 45.77%). The non-forest soil WDPT was in the range of 0.5 s to 350 s with most soils showed a slight water repellency (WDPT median value was 6 s and the slightly water-repellent soil accounted for 67.76%) (*Table S1, Table S2*).

The SWR differentiation characteristics of different soil types was significant, especially the Aeolian soils, Calcisols and Regosols (The WDPT median values were 740.876 s, 580.694 s and 144.273 s, respectively). Most Aeolian soils showed severely water repellency (61.11%), Calcisols mainly showed strong soil water repellent and severely soil water repellent (55.56% and 44.44%), and the Regosols mainly were strong water repellent (69.44%).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85998614

The rest soils (Gray-brown desert soil, Yellow-brown earth, Red earth, Castano-cinnamon soil, Red-yellow earth) were slightly water-repellent (The WDPT median values were 5.649, 6, 7.534, 7.877, 29.825 s), occupied 58%, 68.09%, 66.13%, 63.64%, and 42.69%. The cumulative percentage of the slight water repellency were 100%, 95.66%, 88.71%, 97.73%, and 62.69%. As for the SWR of different soil depth, the overall topsoil (0-5 cm)WDPT was less than subsoil (> 5 cm) (The WDPT median values were 7 s and 11.077 s), but the topsoil SWR showed a greater variation than subsoil. The subsoil SWR was obviously the strong water repellency, the topsoil sometimes was severely water repellency or even extremely water repellency. The topsoil WDPT ranged from 0.503 s to 4990.84 s, covering wettable, slightly water repellent, strongly water repellency, severely water repellency and even extremely water repellency (occupied 23.81%, 58.98%, 12.12%, 4.82%, and 0.27%, respectively), mainly showed the slight water repellency (the cumulative percentage was 82.79%). The subsoil WDPT ranged from 0.902 s to 95.266 s with the wettable and slightly water repellency accounted for 28.92% and 41.67%, respectively, but the characteristics of severe water repellency were more obvious than the topsoil (29.41%, the cumulative percentage was 100%).

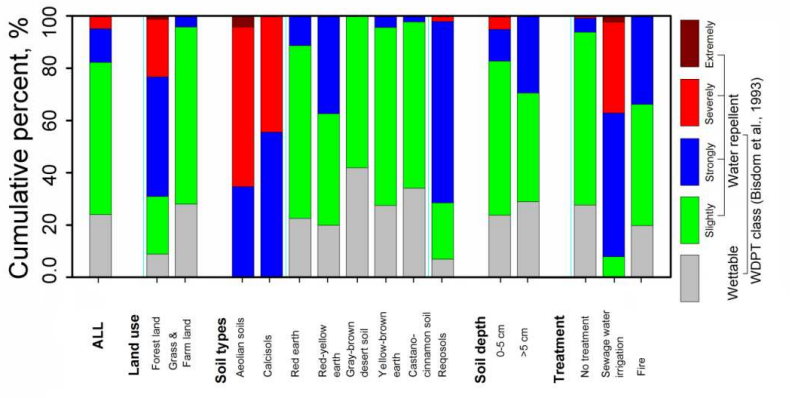

Figure 3. *Cumulative percentage distribution of five levels of SWR along different gradients. Gray bars mean wettable soil; green bars represent slight water repellency; blue bars mean strong water repellency; red bars are severe water repellency; while brown bars stand for extreme water repellency*

Under different process gradients (no processing, sewage irrigation and fire), no processing soil showed slight soil water repellent (the WDPT median value was 7 s, ranged from 0.503 s to 1225.211 s, slightly soil water repellent occupied 66.14%, the cumulative percentage was 93.85%). Sewage irrigation had the greatest impact on SWR and definitely will cause SWR (wettable soil account for 0%). The soil under sewage irrigation (The WDPT median value was 485.584 s, ranged from 6.315 s to 4990.84 s) showed strongly soil water repellency (54.92%, cumulative percentage of 62.88%) and severely soil water repellency (34.85%, cumulative percentage of 97.73%) and a few extremely soil water repellency (2.27%).

The soil after fire disturbance (the WDPT median value is 23.183 s, ranged from 0.902 s to 369.766 s) might not cause SWR (wettable soil accounted for 19.81%), most were slightly water repellent (46.43%), and partially strongly water repellency (33.77%), without severely water repellency and extremely water repellent soil (0%).

Discussions

Synthesis

Existing researches tended to measure SWR at specific sites through a single experiment or long-term monitoring. The choice of sites most depended on the research contents, for example, some researches specifically concentrated in the regions where the distribution of SWR were common and the climate was arid and semi-arid Mediterranean climate areas (e.g. Germany, Spain and California). Some researches chose the humid forest of Central Europe (Buczko et al., 2002; Hubbert and Oriol, 2005; Khanchoul and Boubehziz, 2019). The researches that study the SWR in large scale area were few. China has a vast territory; some regions are humid (South Central) and some are arid and semi-arid regions (West and North). China and Israel faced frequent droughts and the crisis of reclaimed water and available water in recent years (Medina, 2010; Joseph et al., 2019). Most soils in China and Israel showed SWR, mainly were slightly water repellent and contained different degrees (the range of WDPT were 0.503 s-4990.84 s). For example, it could be seen from the SWR reports about the Mediterranean climate region (semi-arid zone) that some researchers suggested that the soils were slightly water-repellent with the WDPT ranged from 10 s to 30 s (Mataix-Solera et al., 2007), and some other researchers found that the forest soil in the Mediterranean climate region was strong water repellency and even extremely water repellency (Crockford et al., 1991; Wahl, 2008; Oyedotun, 2018). In this study, we sampled all SWR researches which could represent the SWR in China.

Characterization

Soil as a giant container and complicate system, it currently focuses on the causes of SWR (such as fire or hydrophobic organic matter) (Jiménez-Pinilla et al., 2016; Siteur et al., 2016), predicts and simulates the emergence of SWR through some leading factors, such as land type, litter type, soil properties, operation mode, microbe activity, seasonal variation, etc. (Buczko et al., 2007; Schmitt et al., 2010; Jordán et al., 2013; Cesarano et al., 2016), and compares and improves the research methods (Doerr, 1998; Wahl, 2008; Sharma and Yadav, 2018). But the previous researches were always just a single experiment report, no one described SWR integratedly and from different gradients. In this study, the SWR distribution situation and distribution pattern were described from four perspectives: land use, soil type, soil depth and interference type.

There were more comparative studies about the impact of land use on SWR than others. Previous studies suggested that the bare land or wilderness would show extreme water repellency, while the soils under vegetation showed less significant, SWR could be limited by vegetation cover type and availability of litter (Arcenegui et al., 2007; Zavala et al., 2009). The influence of different vegetation cover types on SWR had great different, this result was same as our research. It universally accepted that grass and farmland which were generally wettable soil and slightly water-repellent soil showed less severity water repellency than forest that usually showed strong water repellency as well as severe water repellency and even some serious water repellency (Mataix-Solera et al., 2007; Buczko et al., 2007; Verheijen and Cammeraat, 2007; Kořenková et al., 2015; Walden et al., 2015). Human disturbance, such as different farming methods did not seem to be the cause of these differences (Malvar et al., 2016), different soil organic contents (SOC) of different land types might be the reason. There was a significant positive correlation between SOC and SWR (r2=0•74, p=0•01), and the soil with SOC

DOI: http://dx.doi.org/10.15666/aeer/1704_85998614

content higher than 8.06% might have SWR. There were different views in some researches. By comparing three different land uses (eucalyptus, grassland and shrub) in Australia, it was found that the diversity of SWR was independent of soil properties such as SOC content and composition, that might be caused by inducing a small amount of hydrophobic compounds from the trees. However, eucalyptus seemed to be a significant tree species in terms of SWR. Compared with other species, the eucalyptus SWR had a greater variation range and a more complex dynamic change process (Rodríguez-Alleres and Benito, 2011; Santos et al., 2013). And SWR might vary according to different forest types, for example, pure forest exhibited relatively low SWR when compared with mixed forest (Buczko et al., 2002, 2005). Deciduous broad-leaved forest showed a higher SWR when compared to coniferous forest (Gimbel et al., 2016). Some studies assumed that SWR might be irrelevant to forest types (Wahl, 2008). However, they suggested that the diversity in humus brought about different levels of SWR. For example, the humus species of mixed and deciduous broad-leaved forests were more complex and the surface soil humus was thicker than pure forest and coniferous forest (Buczko et al., 2002, 2005; Wahl et al., 2005). On the other hand, the higher SWR may be accompanied by the humus form of "ecologically less favorable" (e.g. moder and mor-like forms) (Sevink et al., 1989; Scott and Wyk, 1990; Crockford et al., 1991; Imeson et al., 1992).

Different soil types played an important role in SWR diversity, and the SWR might be the loopholes in soil system operation. Therefore, it was overgeneralization to study and explain the causes of SWR and predict the variation trend only from the individual soil properties. This study described the SWR distribution patterns of 8 different soil types (Aeolian soils, Calcisols, Regosols, Red earth, Red-yellow earth, Yellow-brown earth, Gray-brown desert soil, Castano-cinnamon soil) that were common in China and Israel. Aeolian soils and Calcisols, the two most serious water-repellent soil types were typical sandy soils with poor water holding capacity and widely distributed in arid and semi-arid areas (Zhenghu et al., 2007; Chesworth et al., 2008). Regosols which considered to be "taxonomic rest group" exhibited serious SWR, its particle size was between sand and clay (Meek et al., 2008). Other soil types were slightly water repellent and some strongly water repellent. Among them, Red earth (Alisols), Red-yellow earth (Acrisols), Yellow-brown earth (luvisols) belonged to mafic soils, the difference between them were the different properties and the development of the parent rock and the initial rock (Lal and Stewart, 2011), higher clay content, stronger acidity and the water holding capacity, limited agricultural use. They were usually forested areas and some low intensity pasture (Yu, 1997; Ebelhar et al., 2008; Dahlgren et al., 2008). Gray-brown desert soil was a typical Fluvisols that was adaptable for xerophytes. It usually possessed the features of sedimentary soils in lakes and seas that might exhibit low pH, high aluminum and salt content (Paz et al., 2008). Castano-cinnamon soil with relatively high humus content was a typical grassland soil (Spaargaren, 2008). The study on integrated report of different soil types had been done little so far, and the existing studies usually was a small sample (dozens of samples), small scale (covers few soil types), focusing on the nature of soil as well as trying to explain and forecast the SWR from a single perspective, and so on. The few existing studies made a comparison among several particular soil types, such as Regosol in the semi-arid regions of the Mediterranean was more prone to SWR than Luvisol (Arcenegui et al., 2007). Cambisols and Podsols in broad-leaved and coniferous forests in northern Europe (Jutland and Denmark) were strong water-repellent soil (Wahl, 2008). Most Cambreeol

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85998614

and Leptosol in the European mountains were slightly water-repellent soils and little parts were strongly water-repellent soil, Luvisol and Regosols were slightly water-repellent and strongly water-repellent soil, Fluvisols were slightly water-repellent soil (Kořenková et al., 2015). Most of the studies focused on the influence of different soil properties on SWR, and tried to explain the differences of SWR in different soil types (Mirbabaei et al., 2013). The focused soil properties were concentrated on the soil texture, SOC, pH, moisture content, the role of clay particle, soil elements content, etc., but there were different opinions about the dominant factor. In this study, Aeolian soils, Calcisols and Regosols from arid and semi-arid areas had a higher sediment concentration, the clay content was lower and water repellent was most significant comparing with the remaining five soils. It had been widely believed that soils from forest or farmland systems which were rich in sediment concentration were more likely to exhibit SWR. SWR might be positively correlated with sediment concentration, and there was a negative correlation with clay content, but the magnitude of correlation was still controversial (Mirbabaei et al., 2013; Kořenková et al., 2015). However, there were reports that SWR (South Africa) negatively correlated with sediment concentration (Scott, 2000), and different amounts of sediment in the same soil type were not significantly associated with SWR (Dekker and Ritsema, 1994; Wahl, 2008) and so on. Similar to the reports of different land uses, SOC was also considered to be the cause of SWR differences in different soil uses. Mafic soils which widely distributed in the south-central part of China had a large amount of cosmid content, low SOC and pH content and showed slightly water repellent. The previous studies concluded that SOC content positively correlated with SWR (Buczko et al., 2002; Mirbabaei et al., 2013; Kořenková et al., 2015), however, it also been suggested that SOC was not the main cause of SWR (Wahl, 2008; Vogelmann et al., 2010), pH which negatively correlated with SWR was the dominant property of SWR differences, and we could alleviate SWR by increasing the soil pH (Ritsema et al., 1998; Hurraß and Schaumann, 2006; Mataix-Solera et al., 2007; Mirbabaei et al., 2013; Kořenková et al., 2015).

Most of the SWR research would first assume that the soil humus had a huge impact and effect, their research often focused on topsoil (0-5 cm) (Santos et al., 2013; Bachmann et al., 2016; Robichaud et al., 2016). However, most of these studies drew conclusions from a single experiment, it often could not verify all SWR changes in topsoil and subsoil (>5 cm) by this single experiment. SWR occurred mainly in topsoil which was more prone to produce strong or stronger water repellency than subsoil according to previous studies (Reeder and Jurgensen, 1979; Wahl, 2008; Robichaud et al., 2016). By analyzing the SWR distribution pattern along different depths in different areas, vegetation cover types and soil types, it had been found that topsoil had a great SWR variation, covering strongly water repellency, severely water repellency and extremely water repellency (17.21%), but the median value of WDPT was less than subsoil, and although subsoil didn't show severely water repellency and extremely water repellency, the probability of SWR was greater than topsoil (29.4%). Therefore, it might be incomplete that most studies had found SWR might decrease with increasing soil depth (Barrett and Slaymaker, 1989; Doerr et al., 2000; Walden et al., 2015; Malvar et al., 2016), the gradient variation and trend of SWR along different soil layer depth might be more complicated than the existing researches.

Many studies suggested that fire interference was the main reason of SWR and would exacerbate SWR (Reeder and Jurgensen, 1979; DeBano, 2000; Doerr et al., 2000; Jordán et al., 2013; Jiménez-Pinilla et al., 2016). More than 40% of SWR was due to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_85998614

fire disturbance (Reeder and Jurgensen, 1979), hence a large number of experiments designed with different fire intensities to measure the forest soil SWR, investigate the response of forest types, structures, soil infiltration capacity and runoff rate after fire disturbance (Robichaud et al., 2016), so as to guide forest management, forest soil protection and restoration, forest reconstruction after fire, etc. However, it had found that the fire did not always lead to SWR by integrating the fire interference experiments data, appropriate small fire might not affect SWR (wettable soil 27.71%), the maximum WDPT caused by fire even less than the WDPT of no interference soil (369.766 and 1225.211 s). In contrast to fire, sewage irrigation might be a more serious problem for SWR, especially in China and Israel where droughts, reclaimed water and available water crises occurred frequently (Medina, 2010). Irrigation with sewage would be common in the future, especially in arid and semi-arid areas where available water was short. Unlike fire interference, sewage irrigation would certainly cause SWR (wettable soil 0%), and far more serious. This might be related to the ingredients of sewage. It had been found that diluted soapy water could accelerate the wetting rate of the water repellent soil at the beginning, but when the moisture was slowly lost, the soil that added the surfactant showed even more severe water repellency than before (Jamison, 1943). Various cationic, anionic, non-ionic substances could humidify soil faster (Cisar et al., 2000), but the surface-active substances would increase soil hydrophobicity after being wet (Adhikari and Chakrabarti, 1976). In addition, sewage irrigation also increased the biological activity and abundance of soil organisms (Barkle et al., 2000), which might also be responsible for increasing SWR (Bond and Harris, 1964).

Summary and Conclusions

Through full sampling analysis of SWR in China and Israel, it had found that SWR were widespread in China, but most were only slightly water-repellent. Only a small part of the soil had strong water repellency or stronger water repellency. The main factors affecting SWR were soil type, soil depth, land use, type of disturbance, etc. There was a significant difference in SWR between different soil types, due to different soil properties. The order of SWR is Aeolian soils > Calcisols > Regosols > Red-yellow earth > Red earth > Yellow-brown earth > Castano-cinnamon soil > Gray-brown desert soil. SWR tended to decrease with the increase of soil depth, and the external disturbance had a great influence on the water repellency of topsoil, and had little effect on subsoil. There was a significant difference in SWR between different land use, and there was a significant SWR in forest ecosystems compared with grassland and farmland. A certain intensity of fire interference and sewage irrigation would exacerbate the water repellent in the soil, in which the impact of sewage irrigation on SWR was more significant, the SWR would increase with the increase of fire intensity. The reasons for different SWR will be worth studying in the future. The results of this study filled the gaps in the evaluation of the overall water repellency of soils in China and Israel, and summarized the factors affecting SWR, which would provide the basis for soil improvement and ecological restoration in China and even the world.

No. 1575 Wan Hangdu Road, 200042 Shanghai, China

(Received 8th Mar 2019; accepted 21st May 2019)

Abstract. This study aims to discuss the dilemmas and solutions for the issues of high seas marine protected areas during the BBNJ negotiation. It expounds the dilemmas of BBNJ negotiations on the issue of MPAs (such as there is no single universally agreed definition of MPAs, the selection criteria for MPAs are still not clear and no clear consensus on the designation process of MPAs), analyzes the reasons for dilemmas of MPAs in the process of BBNJ negotiations and proposes the solutions of main issues in the process of BBNJ negotiations. The result of this research is that MPAs, as a breakthrough to the traditional marine management tools, are becoming an important means for the international community to protect marine biodiversity. Finally, it concluded that after dealing with dilemmas of lack of definition, unclear selection criteria and disputes over the governance model, the negotiation of the issue of MPAs in ABNJ will inevitably reach a reasonable institutional framework, and further promote marine biodiversity protection.
Keywords: *marine biological diversity, global governance model, international instrument, marine resources, alternative management approach*

Introduction

Since the end of 20th century, MPAs, as alternative management approach of marine resources, have been proposed to remedy the defect of traditional marine management methods and to be established in large numbers. Among them, those established on the high seas or other areas beyond national jurisdiction are collectively referred to as marine protected areas beyond national jurisdiction (hereinafter referred to as "ABNJ marine protected areas"). While emphasizing the protection of the marine environment, ABNJ marine protected areas usually restrict the rights of countries to exploit and utilize marine resources to a certain extent. During the four Pre-committee meetings and the first BBNJ Intergovernmental Conference in 2018, as an important part of the ILBI, the issue of ABNJ marine protected areas has induced an intense debate between countries or groups of countries concerned. The purpose of this research is to discuss the dilemmas and solutions during the BBNJ negotiation for the issue of High Seas Marine Protected Areas.

Methods

Dilemmas of BBNJ negotiations on the issue of MPAs

At its 47th meeting, the Preparatory committee adopted the recommendations, which clearly stated that the text of ILBI would set out objectives of area-based management tools, including marine protected areas, relationship to measures under relevant instruments, frameworks and bodies, process, implementation, monitoring, and review (Afonso et al., 2018; Sufiyan et al., 2018). Most countries expressed their positions and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86158629

suggestions regarding the definitions of MPAs, objectives and principles, criteria, governance, and institutional mechanisms. By sorting out the positions of all sides, we can conclude that the current BBNJ negotiations are mainly facing the following dilemmas:

There is a dispute on the definitions for MPAs

Given that the definition of MPAs is the logical starting point for other issues related, it should be clear in the negotiations. Whether the ILBI defines the MPAs in ABNJ or not and its general definition leads to contention among parties.

With regard to this issue, some states supported that the ILBI should be based on existing concepts, such as the definition of the CBD Technical Expert Group on Marine and Coastal Protected Areas or the IUCN's definition of MPAs. Others suggested that the MPA definition should be sufficiently broad to encompass specific types of conservation and impact restrictions, for example, High Seas Alliance favored adapting CBD and IUCN definitions, also including cultural values. However, the North-East Atlantic Fisheries Commission (NEAFC) underscored that ABMTs by RFMOs are functioning well and that the ILBI should enhance harmony between tools of different sectoral bodies, rather than define ABMTs (Alger and Dauvergne, 2017; Khanchoul et al., 2018). It is noteworthy that Costa Rica suggested a working concept of MPAs as "a clearly defined geographic space recognized, dedicated and managed through legal and other effective means to achieve the conservation of biodiversity, ecosystem services, and other cultural values."

The selection criteria for MPAs are still not clear

The so-called selection criteria for designing marine protected areas mainly refer to which scientific standard should be introduced to estimate the level of biodiversity, in order to further evaluate whether an area needs to protect and what the extent of protection should be deleted. The selection criteria for MPAs are vital to determine the location and geographic scope of MPAs, constituting a basis for the establishment of ABNJ marine protected areas.

Many countries proposed to draw lessons from the EBSA (ecologically or biologically significant marine areas) criteria, and CBD guidelines on MPA networks (Ayer et al., 2018; Ilyas et al., 2018). Others noted that criteria would vary depending on the regional circumstances and should include, inter alia, biological productivity and/or diversity (Ban et al., 2017; Rahim et al., 2018). In addition, countries called for establishing MPAs in vulnerable areas and important areas for certain species (Cabral et al., 2017; Abdullah and Rahim, 2018). The positions of countries on this issue were dispersed, and the main dispute lies in which scientific criteria should be introduced into the ILBI.

However, the preparatory committee just listed the criteria which belong to existing criteria that countries proposed during the discussion. Thus, there were still a lack of unified selection criteria for MPAs finally and the issue of selection criteria would be further discussed at the intergovernmental conferences.

No clear consensus on the designation process of MPAs

In the substantive recommendations, the preparatory committee summarized the proposal, consultation on and assessment of the proposal, decision-making as the issue of the designation process.

In terms of the proposal, the dispute on the issue is whether the international organizations can be authorized to submit a proposal for the establishment of MPAs, but the preparatory committee did not explain it in the recommendations. Some countries supported that state parties, other organizations, even a scientific and technical body can propose to establish MPA (Carr et al., 2017; Sarwar at al., 2018). Other countries consider that the proposal of MPAs should be put forward by state parties individually or jointly, but they did not mention whether international organizations can enjoy the right to submit proposals. For example, the EU highlighted that proposals to designate or recognize MPAs should come from state parties, individually or as a group. Though Japan, Argentina and Sweden had the generally same position as the EU, they emphasized on adequate communication with stakeholders prior to the proposal (Dias et al., 2017; Majumder et al., 2019). The US also underscored lack of clarity regarding who can submit proposals (Duarte et al., 2017).

With respect to consultation on and assessment of the proposal, a major point of dispute is whether ILBI needs to establish an independent global body to decide on proposed MPAs. For this issue, the US, supported by Canada and Australia, favored referring to a "scientific process," rather than a "scientific committee," providing input to "policy making," instead of a policy-making "body" (Feng et al., 2017). By contrast, most of the countries called for creating a scientific subsidiary body to technically assess proposals (Ferrari et al., 2018). Hence, no consensus has been reached on the establishment of a new scientific body at the global level.

In respect of decision-making, divisions mainly lie in whether establish a decision-making body or entitle existing regional institution to decide on MPAs proposals. The African Group, supported by the EU, called for global-level, consensus-based decision-making on ABMTs (Area-Based Management Tools) or MPAs (Gonson et al., 2017; Nouaim et al., 2019). However, Australia preferred a regional action-oriented process, including regional decision-making and Norway, supported RFMOs and the ISA designating and implementing MPAs (Havermans et al., 2018). Moreover, the Russian Federation opposed the creation of a new global mechanism for creating ABMTs and Norway noted lack of consensus on creating a new organization for establishing ABMTs during the fourth session of the preparatory committee (Hughes and Grant, 2017). To sum up, there are many countries opposed the global mechanism for MPAs.

Discussion

Analysis of the reasons for dilemmas of MPAs in the process of BBNJ negotiations

There is no single universally agreed definition of MPAs

As an instrument for marine biodiversity conservation and sustainable use, MPAs have been receiving increasing attention from policymakers. A reasonable concept of marine protected areas should include at least three elements: clear objectives, scope, and management measures. But there is a lack of a definition accepted by most countries in the international community.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86158629

At the level of the global treatise, no conventions clearly defined the concept of MPAs in their text, but there are several related concepts similar to MPAs. For example, according to the Convention on Biological Diversity (CBD), "protected areas" means a geographically defined area which is designated or regulated and managed to achieve specific conservation objectives (Jabou and Smith, 2018). But the concept of "protected areas" is different from the concept of "marine protected areas", especially the concept of "marine protected areas beyond national jurisdiction". In 2004, the CBD conference of the parties adopted the Decision VII/5, defined "marine and coastal protected areas" as "an area within or adjacent to the marine environment, together with its overlying waters and associated flora, fauna, and historical and cultural features, which has been reserved by legislation or other effective means, including custom, with the effect that its marine and/or coastal biodiversity enjoys a higher level of protection than its surroundings". However, the definition of "marine and coastal protected areas" is still a broad concept that includes "historical and cultural features", which remains further discussion for applying to ILBI. The Convention Concerning the Protection of the World Cultural and Natural Heritage which has been ratified by 193 states parties, defined the "natural heritage" as "natural features consisting of physical and biological formations or groups of such formations, which are of outstanding universal value from the aesthetic or scientific point of view; geological and physiographical formations and precisely delineated areas which constitute the habitat of threatened species of animals and plants of outstanding universal value from the point of view of science or conservation; natural sites or precisely delineated natural areas of outstanding universal value from the point of view of science, conservation or natural beauty." It can be seen that the concept of "natural heritage" not only emphasizes the protection of the habitat of threatened species but also the value of aesthetic. Hence, a definition of MPAs is absent at the level of global treatise.

At the level of regional frameworks or bodies, The International Convention for the Prevention of Pollution from Ships, 1978 (MARPOL 78) that was developed by the International Maritime Organization (IMO), defining the "Special Areas" as "a sea area where for recognized technical reasons in relation to its oceanographical and ecological condition and to the particular character of its traffic the adoption of special mandatory methods for the prevention of sea pollution by oil is required" (Kay and Butenschön, 2018). In 1991, IMO introduced a new concept called "Particular Sensitive Sea Area (PSSA)" to protect the marine environment and ecosystem (Laffoley and Freestone, 2017). Moreover, in 2011, the Council of the international seabed authority proposed an environmental management plan in the area of the Clarion-Clipperton Zone to protect the biodiversity and ecosystem structure. In this plan, the international seabed authority adopted the term of "Area of Particular Environmental Interest (APEI)", which refers to "protect biodiversity and ecosystem structure and function by a system of representative seafloor areas closed to mining activities." As the report of Secretary-General pointed, a number of expressions are used to refer to the various area-based management tools presently in use, include: "special areas"; "specially protected areas"; "marine protected areas"; "spatial and temporal closures" in the fisheries context; "particularly sensitive sea areas" in the shipping context; "sanctuaries"; and "reserves" (Lambert et al., 2017). Thus, there is no single universally agreed definition of MPAs and the above definitions or concepts similar to "marine protected areas" at the global or regional level cannot be viewed as the concept of MPAs essentially, but they may only offer references for the ILBI.

DOI: http://dx.doi.org/10.15666/aeer/1704_86158629

The reasons for lacking a universally accepted definition for MPAs, in my opinion, mainly are as follows:

First, the history of MPAs is relatively short, which leads to the understanding of countries to MPA is still in its infancy. The global extent of MPAs only really began to increase significantly from the late 1970s, notably with the declaration of the Great Barrier Reef Marine Park in Australia (Lathrop et al., 2017). Furthermore, the proportion of marine protected areas to the total ocean area increased from only 0 to 3% between 1960 and 2013, compared with less than 1% in 1990 (Madrigal et al., 2017). While MPAs in ABNJ emerged later and the first Pelagos Sanctuary, which is designated in 1999 and is not absolutely located in the high seas. It can be seen that the management tool of MPAs not only has a relatively short history, but the process of development is slow, which leads to the lack of a more unified understanding of MPA among countries. For instance, even though the US with the world's largest exclusive economic zone and has established over 1700 MPAs, its definition of MPAs is different from the definition used by the World Conservation Union (IUCN) (Mazaris, 2017).

Second, MPAs can be classified into different types according to their purpose, which may easily cause some misalignment of understanding in different countries. In fact, MPAs can be further divided into 5 different types, each of them is: (1) MPAs for purpose of fishery management and resources conservation; (2) the marine development zone for purpose of ecosystem or habitat conservation; (3) MPAs for purpose of marine biodiversity conservation; (4) MPAs for purpose of rare or endangered species preservation; (5) MPAs for tourism, entertainment, education and scientific research. Moreover, the International Union for Conservation of Nature (IUCN) divided MPA into six types, depending on their objectives: (1) Strict Nature Reserve/Wilderness Area; (2) National Park; (3) Natural Monument; (4) Habitat/Species Management Area; (5) Protected Landscape/Seascape; (6) Managed Resource Protected Area (Mcneill et al., 2018). Consequently, some countries may have only established the single type of MPAs mentioned above, while others may have established several different types of MPAs at the same time, resulting in an inconsistent understanding of MPAs among countries.

Finally, there are still a few countries in the world have the capacity to establish and manage MPAs effectively. Most countries are too inexperienced to establish MPAs, especially the large-scale MPAs. According to statistics, there are more than 70 countries in the world including China, Indian and Canada, whose area of MPAs is less than 1% of their exclusive economic zones, while just only 14 countries' MPAs account for more than 10% of their exclusive economic zones. In addition, according to statistics, it can also be concluded that countries with the capacity and experience in establishing very large MPAs are just limited to several countries, such as Australia, Russia, the US, New Zealand, the United Kingdom and France (Mrema, 2017). Judging from the current practice, the four "high seas MPAs" are only a short period of 5 to 15 years, which is slightly short-lived and the actual effect is not obvious. However, MPAs established by the ILBI are precisely those large-scale pelagic marine protected areas, so most countries are in fact lack of experience in setting up such MPAs and not to reach an agreement on the definition of MPAs.

A variety of selection criteria have made ILBI difficult to choose and coordinate

On the premise of defining MPAs, it's necessary to further define the selection criteria for MPAs. At present, the existing selection criteria for MPAs mainly include

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86158629

scientific criteria for identifying ecologically or biologically significant marine areas (EBSA), guidelines on designating a "particularly sensitive sea area" (PSSA), vulnerable marine ecosystems (VME) criteria, the general design guidelines for area of particular environmental interest (APEI), key biodiversity areas (KBA) adopted by IUCN and etc. The ILBI would eventually choose a set of selection criteria, but now there are at least 7 set of selection criteria with different elements that make the ILBI difficult to choose and coordinate.

From the regional organizations or bodies of these selection criteria, different types of selection criteria are proposed and implemented by different international organizations that they have seldom interaction with each other. From the emphasis of these selection criteria, different priorities lead to the different selection criteria. For instance, the criteria of VME pays the more attention to the ecological damages caused by deep-sea fisheries. Thus, the FAO proposed a distinct standard from the EBSA, named “Functional significance of the habitat” which is to protect habitats that are necessary for the survival, function, spawning/reproduction or recovery of fish stocks. In addition, the application scope and the amounts of the region selected by these criteria are also different. The VME has been adopted by some regional fishery management organizations, such as NEAFC, CCAMLR, NAFO GFCM, SEAFO and SPRFMO. Currently, IMO has also designated 17 particularly sensitive sea areas around the world, most of which are located within national jurisdiction. The EBSA description work is also constantly updated and deepened, 71 out of 279 ecologically or biologically significant areas (EBSAs) are located in ABNJ, covering 21% of total surface area of ABNJ (Nikitine et al., 2018). It can be seen that the inconsistencies and even coincidences in the scope of different selection criteria have made it difficult for ILBI to determine the selection criteria.

Given that the ILBI should coordinate the relationship of different selection criteria for MPAs or other area-based management tools and prevent duplication, the negotiations of the ILBI are actually facing the dual difficulty in choosing and coordinating the selection criteria. In fact, the relationship between choosing and coordinating is like the two sides of the coin. It is manifested that when making the final decision on the issue of selection criteria, it is necessary to make trade-offs between existing criteria and avoid conflicts with existing criteria. Therefore, the situation of dual difficulty faced in determining the selection criteria is an important reason for the delay in reaching a consensus on this issue during the BBNJ negotiations.

MPAs in ABNJ will impose a significant impact on some states’ fishery interests

The designation process is directly related to the management model of MPAs. In the third session of the preparatory committee, Chair Duarte proposed focusing on three options: a global model, a hybrid model and a regional and sectoral model (Pereira et al., 2018). Specifically, the states with skeptical and negative views on the global model are Australia, New Zealand, Norway, Iceland, Russia, Canada and the Pacific small island developing States (PSIDS). These states undoubtedly all advocated the leading role of regional organizations in the establishment of ABNJ marine protected areas and considered that excessive intervention from the global level should be reduced or avoided. The regional and sectoral model means to essentially authorize the regional fisheries management organizations (RFMO) the decision-making powers for initiating and managing a high seas MPA. However, whether the regional fisheries management organizations or bodies actually establish an ABNJ marine protected area in accordance

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86158629

with the ILBI depends on the will of the all contracting parties of the organizations and their internal decision-making rules.

At present, there are many regional fisheries management organizations, including the Commission for the Conservation of Antarctic Marine Living Resources (CCAMLR), Northwest Atlantic Fisheries Organization (NAFO), the North East Atlantic Fisheries Commission (NEAFC), the South East Atlantic Fisheries Organization (SEAFO), The South Pacific Regional Fisheries Management Organization (SPRFMO), the North Pacific Fisheries Commission (NPFC), the Western and Central Pacific Fisheries Commission (WCPFC), the Southern Indian Ocean Fisheries Agreement (SIOFA), the General Fisheries Commission for the Mediterranean (GFCM) and etc.

The current governance model of high seas fisheries is mainly relied on regional fisheries management organizations and there are 20 regional fishery management organizations with mandate, covering the main fishing areas of the global ocean. In respect to the number of the contracting parties, members of the CCAMLR currently include 24 States and the European Union, NAFO has 12 Contracting Parties, the NEAFC has 5 contracting parties and 5 non- cooperating contracting parties, the SEAFO has 7 contracting parties, the SPRFMO has currently 15 Members, the NPFC has 8 contracting parties, the WCPFC has 26 contracting parties, the SIOFA has 9 contracting parties and the GFCM has 24 contracting parties. To sum up, despite the WCPFC has the largest number of the contracting parties among the regional fisheries management organizations mentioned above, but it only has the 26 contracting parties. Among the countries that do not approve of the global model, Norway, Iceland, Russia and Canada are all members of NAFO, while Norway, Iceland and Russia are also parties to NEAFC (Wu, 2018). Therefore, the leadership of establishing the high seas MPAs is easily controlled by the RFMO that is represented by a few states.

From the states with skeptical and negative attitude to the global model, their capture production of fisheries usually depends heavily on the single region under the management of the RFMO. For example, Norway, Iceland, Russia and Canada are all the contracting parties of the NAFO, while Norway, Iceland and Russia are also the members of the NEAFC at the same time. Australia and New Zealand are both contracting parties of the WCPFC and the SPRFMO. According to the statistics of FAO in 2016, total capture production of Norway is 203,8810 tons in the area of Northeast Atlantic, accounting for 92% of its annual total capture production; It is worth noting that the geographic scope of FAO fishing area 27 is the same to the areas of the NEAFC Convention. Furthermore, all the capture production of Iceland in 2016 come from the area of Northeast Atlantic; The capture production of Canada in the Northwest Atlantic is 663,680 tons, accounting for 78% of its annual total capture production; In addition, the capture production of New Zealand in the Northwest Pacific is 421,646 tons, accounting for 99% of its annual total capture production (Plassjohnson et al., 2017). However, as the country with the highest capture production of fisheries in the world, China’s marine fisheries production in 2016 was 15,331,960 tons, but the 97% of the total annual production came from the Northwest Pacific. According to the "13th Five-Year Plan" issued by the Ministry of Agriculture in 2017, by the end of 2016, the total production of China's far-off ocean fisheries was 1.99 million tons, including 1.32 million tons of high seas fisheries. Hence, China’s fishery production on the high seas only accounts for 8% of its annual marine capture production and the fishing area

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86158629

of China in Northwest Pacific is not entirely within the scope of regional fisheries management organizations.

From the decision-making mechanism of the relevant regional fisheries organizations, the NEAFC and the SPRFMO, which are composed mainly of states with negative attitude to the global model as mentioned above, provided for their respective decision-making mechanisms. According to the NEAFC Convention, decisions of the Commission shall be taken by a simple majority or by a two-thirds majority (Postaire et al., 2017). The SPRFMO Convention provided that decisions by the Commission shall be taken by consensus (Schulze et al., 2017). It can be concluded that the decision-making mechanism of regional fisheries management organizations has an obvious dependence on the will of the members. When the contracting parties hold different or opposing positions on the proposals, the regional fisheries management organizations will not effectively make a decision and implement it. Furthermore, the Objection Procedure is also prevalent in regional fisheries organizations, as long as members formally raise objections during the decision-making process of regional fisheries management organizations. This procedure has led regional fisheries organizations to reach the consensus of all members so as to a better compliance. Therefore, if the ILBI authorizes the RFMO the autonomy to establish MPAs, it is the same as granting the minority contracting parties of these RFMO the right to establish MPAs.

The establishment of the high seas MPAs will inevitably impose restrictions on the fishing activities, for example, the conservation measures of the Ross Sea established in 2016 provided for "fishing activities are prohibited within the MPA" (Soares and Lucas, 2018). Thus, the states whose fishery productions highly depend on the single region under the management of the RFMO do not hope it adopts the decision to establish MPA. To this end, from external relations, these fishing nations of the RFMO will emphasize the role of RFMO in the BBNJ negotiations and tend to retain their respective autonomies in establishing the ABNJ marine protected areas. From the internal relations of the RFMO, these states will also make full use of the decision-making mechanism in order to minimize the impact of MPAs on their fishing interests.

Results

The solutions of main issues in the process of BBNJ negotiations

The ILBI should clarify the definition of MPAs on the basis of existing definitions

The definition of MPAs not only should be clarified in the process of BBNJ negotiations but also defined in the ILBI. As an important newly emerging marine management measure, the concept of MPAs is not clearly defined in the existing international conventions, including the UNCLOS and there is no universally accepted concept of MPAs in the international community. When the UNCLOS was enacted between 1973 and 1982, marine biodiversity beyond national jurisdiction did not attract the attention of all countries, leaving many gaps in the Convention. Thus, the legal and institutional frameworks that govern marine biodiversity in areas beyond national jurisdiction (ABNJ) are widely perceived as inadequate for ensuring the long-term health and equitable use of the living resources of this vast area and the ILBI should fill the gaps of UNCLOS (Solovyev et al., 2017). Therefore, before creating an MPA system in the ILBI, country participants must agree on what they understand by this term.

DOI: http://dx.doi.org/10.15666/aeer/1704_86158629

According to the definition of IUCN, it comprises both legal approaches and other approaches; it can be applied in three-dimensional scope of protection, including not only the intertidal zone or the sub-tidal zone of the ocean, but also the seabed environment within this scope; the protection objectives are also broad, including historical and cultural features (Urra et al., 2018). Strictly speaking, the historical and cultural features of the IUCN's definition are not consistent with the objective of protecting marine biodiversity. The definition of protected areas in CBD is an ambiguous definition that does not specify the objectives and management methods of MPAs, and whether the nature of the management methods adopted is a "no-take" MPAs. The OSPAR Commission established by the Convention for the Protection of the Marine Environment of the North-East Atlantic (OSPAR Convention) defined the "marine protected areas" as "an area within the maritime area for which protective, conservation, restorative or precautionary measures, consistent with international law have been instituted for the purpose of protecting and conserving species, habitats, ecosystems or ecological processes of the marine environment." Despite the definition of the OSPAR Commission has the elements of objectives, geographic scope and management measures, but it is not clear whether this definition includes MPAs established in the seabed area. However, the MPA networks of the North-East Atlantic are so far consisted by 7 high seas MPAs and 5 of them are located in the seamount or mid-ocean ridge areas (Young and Friedman, 2018). Hence, the ILBI should determine whether the geographic scope of MPAs' definition includes the seabed areas.

In conclusion, the definitions of MPAs mentioned above are more or less unreasonable when applied to the ILBI, so it is difficult to directly copy the existing definitions of MPAs to the ILBI. The intergovernmental conference on an ILBI under the UNCLOS on the conservation and sustainable use of the marine biological diversity of areas beyond national jurisdiction needs to specify the definition of MPA. First, the ILBI should make clear the geographic scope of MPAs' definition, especially whether the scope should include the international seabed areas. Second, the ILBI should set up specific objectives and take proper account of whether the objectives should comprise the characteristic and historical features. Third, it needs to be further clarified whether the management measures in the ILBI should be defined in a general or enumerated way (Tagle, 2018).

The selection criteria for MPAs in the ILBI should draw lessons from the existing criteria

The possible ways to cope with the dual difficulty that ILBI faced in determining the selection criteria is to draw lessons from the existing criteria and provide for the inclusive criteria for the ILBI. Thus, its necessary to make a comparative analysis of the existing selection criteria.

According to the statistics of the *Table 1*, despite different organizations have their selection criteria, but the most of the selection criteria are similar and the nine selection criteria mentioned in have almost covered the existing selection criteria for MPAs in the international community. First, most of the definitions of 9 selection criteria in the were clearly defined in Resolution A.982(24) adopted by the 24th Assembly of the IMO, while the remaining selection criteria are defined in decision IX/20 adopted by the conference of the parties to the convention on biological diversity at its 9th meeting. Second, only the operational guidelines for the Implementation of the World Heritage Convention includes the criteria of "historical geomorphological importance". However,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86158629

the so-called "historical geomorphological importance" refers to "the property represents major stages of earth's history, including the record of life, significant on-going geological processes in the development of landforms, or significant geomorphic or physiographic features" (Bokuniewicz and Jang, 2018). Hence, the criteria of the historical geomorphological importance, in fact, should be excluded when the ILBI set out the selection criteria for MPAs.

Table 1. *Correspondence between the CBD EBSA criteria and other international criteria used by IGOs and NGOs (i.e. Birdlife and IUCN) mentioned in this manuscript. Correspondence is indicated by either a check where it exists, an X where it doesn't, or a? where there is uncertainty or the criteria suite is under review (Tommasi et al., 2017)*

Third, the criteria of "Uniqueness or rarity", "Special importance for life history stages of species" and "Importance to threatened or endangered species" are all stipulated in the existing selection criteria lists and the criteria of "Biodiversity" and "Naturalness" are also adopted by four selection criteria. Hence, these criteria have been accepted by the international community. Fourth, 15 specific selection criteria were listed in the recommendations of the preparatory committee, of which five are beyond the scope of the existing criteria, namely "Representativeness", "Dependency", "Connectivity", "Ecological processes" as well as "Economic and social factors." These five selection criteria need to be further discussed during the intergovernmental conferences. Finally, no matter what selection criteria are adopted by the ILBI, the activities of identifying MPAs are in fact the scientific exercise, which should not be regarded as bringing about any potential management measures and any obligations to establish MPAs. Therefore, the issue of selection criteria for MPAs under the ILBI should be strictly distinguished from the establishment, management, review of MPAs, so that it can continue to be the scientific exercise and provide references for the establishment of MPAs.

To sum up, under the premise of the scientific activities, the ILBI should coordinate the different existing criteria and draw lessons from the regional practice, providing for a set of comprehensive and unified selection criteria for the high seas MPAs.

The ILBI should adopt the global model for the high seas MPAs

The adoption of the General Assembly resolution evinces a growing recognition within the international community that the regime governing the marine biodiversity in ABNJ is no longer fit for purpose, and that further action to develop a legal and institutional framework is necessary (Wang et al., 2018). The global model has obvious advantages compared with the hybrid model or regional and sectoral model.

First, a treaty shall not create either obligations or rights for a third State without its consent in pursuant to Article 34 of Vienna Convention on the Law of Treaties and this provision is also considered to be a customary international law rule. Therefore, the management measures of MPAs adopted by regional organizations or institutions cannot generally create obligations for third states without its consent. The number of Parties in each regional organization or institution under the regional model is far less than those of a universally representative global convention. Hence, the MPAs in ABNJ under the regional model will not be able to directly restrict non-Parties, which will result in the management measures of MPAs cannot be universally observed and regional model have deficiencies in the general principles of international law.

Second, a regional and sectoral model is unable to take unified actions at the global level and are likely to further deepen the fragmentation of marine biodiversity protection beyond national jurisdictions, thus making cooperation and coordination between different regions or sectors more difficult. On the one hand, the ILBI is facing the status quo of "divided governance" between the water column and the international seabed areas, which further leads to possibly apply different governance rules to living resources and mineral resources beyond national jurisdiction. But in the world of the deep sea, minerals and organisms are usually inseparable, that is, they are two aspects of one thing and should be managed as a whole (Tapia et al., 2018). Consequently, the application of different rules is inconsistent with the laws of nature, artificially increasing the difficulties of coordination and may to a certain extent reduce the effectiveness of marine biodiversity protection. On the other hand, if the ILBI were to adopt a regional model and authorize the regional bodies to establish, manage and review the high seas MPAs, the laws of nature that ocean creatures and their communities are moving all the time is also ignored. Thus, the approaches by dividing the marine ecosystem into different areas are no help to protect the marine biological diversity and further deepens the degree of fragmentation of existing international frameworks.

Third, apart from deepening fragmentation of international frameworks, a regional and sectoral model cannot provide the basis of international law for the establishment of MPAs in areas beyond national jurisdiction. In addition, a regional and sectoral model easily leads to a crisis of trust. For example, in the process of establishing the Ross Sea protected areas, Russia, Ukraine, China and other states raised doubts about the legal capacity of CCAMLR in establishing MPAs and lacking a definition of MPA at the annual CCAMLR conference. In 2012 and 2013, Russia even pointed that it would refuse further negotiations if the two issues were not resolved (Shoda et al., 2017). Moreover, in 2014, Russia submitted a working paper "Marine Protected Areas in the Antarctic Treaty System" to the Antarctic Treaty Consultative Meeting (ATCM) and stated that "Taking into account that seven countries of those which have signed the Antarctic Treaty and the CCAMLR Convention have earlier declared territorial claims to Antarctica, Russia is obliged to consider the potential possibility that an MPA may be used as an instrument to establish geopolitical control over southern polar regions over

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86158629

which territorial claims were made earlier" (Botte, 2017). It can be seen that the legitimacy of the high seas MPAs is vulnerable to be challenged when the regional model is not authorized at the global level. The non-contracting parties of the RFMO may concern about their freedoms on the high seas which will be imposed further restrictions by the RFMO.

Final, the main purpose of a hybrid model is to provide guidance and legal basis for regional bodies or the RFMO through the ILBI, which cannot avoid the defects of the regional model mentioned above. Moreover, as a compromise, the effectiveness of a hybrid model is difficult to guarantee and the relationship between a global framework and regional organizations is not easy to put in order. If we can solve this problem, hybrid model may be a good choice.

To sum up, the advantages of the global model are obvious, and it is foreseeable that ILBI should finally establish a global governance model for MPAs.

Conclusion

As a breakthrough to the traditional marine management tools, MPAs are becoming an important means for the international community to protect marine biodiversity. The negotiation of the issue of MPAs in ABNJ will, after dealing with dilemmas of lack of definition, unclear selection criteria, and disputes over the governance model, inevitably reach a reasonable institutional framework, and further promote marine biodiversity protection. The above is only a preliminary discussion on this issue. In the future, specific planning and implementation measures are needed to make this problem better solved.

(Received 8th Mar 2019; accepted 21st May 2019)

Abstract. In order to better understand the specific effect of process parameters on porous titanium micro-arc oxidation coating. In this paper, TiO_2 membrane layer was prepared on porous titanium matrix with 67 % porosity by microarc oxidation method (MAO), which use a phosphoric acid solution as electrolyte. The samples were characterized using XRD and SEM. The results showed that the samples prepared under the experimental parameters of 350 V and 30 min had a good surface morphology and could provide a higher specific surface area. After soaking in SBF for 7 days, the formation of hydroxyapatite (HA) can be induced, indicating that porous titanium after micro-arc oxidation modification has good biological activity.
Keywords: *phosphoric acid, hydroxyapatite, carbon dioxide film, process parameters, biological activity*

Introduction

Titanium (Ti) and its alloys are widely used as hard tissue repair materials in clinics owing to their high biocompatibility (Choi and Kim, 2016; Nune et al., 2016; Thanh and Do, 2018). However, their far larger elastic moduli and the mismatched mechanical properties compared to human bones would lead to post-implant stress shield and finally to the loosening and failure of implants (Nomura et al., 2005; Shrestha and Baral, 2018). Nevertheless, the emerging porous structures can efficiently improve the mechanical properties of Ti to the levels of human bone tissues. Moreover, porous Ti has high biocompatibility, and (Hao, 2018) its unique structures are favorable for the body fluid transmission and tissue regeneration / reconstruction and accelerate the healing process. (Zhang et al., 2017). Generally, a higher porosity offers a larger space for tissue growth, which is favorable for the inward growth of peripheral cells and the growth of new bones and strengthens the bio-fixation with bone tissues (Wen et al., 2001; Ali et al., 2018).

However, Ti is a biologically inert material that can hardly bind with bone tissues to form bone bonding (Wang et al., 2014; Rahim et al., 2018), which limits its further application in the medical field (Das et al., 2016; Qiao, 2018). Thus, surface modification is required to improve the biological performances of porous Ti. The emerging microarc oxidation surface modification in recent years can be used to prepare porous ceramic coating layers on surfaces of Ti and thereby to largely improve its properties (Chien et al., 2017; Gautam et al., 2019). The phases and morphology largely affect the bioactivity of porous ceramic films (Zhao et al., 2014), but there is rare research on microarc oxidation coating of porous Ti. Thus, the microarc oxidation technology was used to prepare porous coatings on the porous Ti matrix. The effects of anode voltage and oxidation time on the surface morphology and phases of the coatings were systematically studied (Chen et al., 2017; Dali and Kamarudin, 2018). The findings offer some reference for subsequent research.

Materials and Method

Preparation of porous Ti

The 300-mesh commercial pure Ti powder and NH_4HCO_3 (granularity=100-300 μm) as the pore-forming agent were mixed at the mass fraction ratio of 1:1, uniformly stirred, and placed (Zhang et al., 2018; Masri and Samsudin, 2018) into a mold, which was pressed by a miniature hydraulic press at the pressure of 80 MPa. The molded specimens were preserved in an ordinary muffle furnace at 100ºC for 5 h in order to completely remove the pore-forming agent, then heated to 1300ºC in a vacuum sintering furnace (< 10^{-3} MPa), heat-preserved for 2 h and naturally cooled, forming the porous Ti substrate.

Preparation of surface TiO_2 films on porous Ti via microarc oxidation

The sintered porous Ti was cut into sheets (Φ10 mm × H2 mm), which were ultrasonically washed with ethanol and deionized water and then dried. (Zhang et al., 2018). The porous Ti sheets were used as the anode, graphite sheets as the cathode, and a 0.5 mol/L H_3PO_4 solution as the electrolytic solution in the microarc oxidation experiments at the time of 5 - 30 min and voltage of 250-450 V. When the electrolytic solution was controlled below 30ºC, porous Ti MAO films were formed and the oxidized specimens were washed in distilled water and dried.

Characterization of TiO_2 films

Morphology was observed under a Quanta200 scanning electron microscope (SEM) and phases were analyzed under an X'Pert Pro MPD X-ray diffractometer (XRD).

Bioactivity experiments

A simulated body fluid (SBF) was made according to the composition by Tadashi Kokubo. The specimens after the above microarc oxidation were soaked in the SBF at 37ºC. The SBF was changed once every day. After 7 days, the specimens were taken out, rinsed with deionized water and air-dried.

Results and discussion

Effects of electrode voltage

Effects on the surface morphology of microarc oxidized film layers

The figure below (*Fig. 1*) shows the surface morphology of the oxidized films prepared after 30 min of oxidation at different electrode voltages. Clearly, (Kang et al., 2017) numerous fine micropores (1-2 μm) were formed on surfaces at the constant voltage of 250 V (*Fig. 1a*). At the voltage of 300 V, however, the specimen surfaces were uneven, with irregularly-shaped heaves in some places and irregular porous surfaces in other places, and the micropores were minor, unevenly-sized and nonuniformly distributed *(Fig. 1b*). At the voltage of 350 V, the surface oxidation films were rough, and the number of micropores significantly increased, but the sizes and distributions were uniform, and the pore sizes were enlarged to 4 - 6 μm (*Fig. 1c*). At the voltage of 450 V, the micropores on their surface oxidation films were significantly enlarged, but the numbers considerably decreased, and a part of the micropores fused

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86318641

and the walls were broken *(Fig. 1d*). The above results suggest that the pores in the surface films are gradually enlarged and the numbers decline along with the increase of electrode voltage.

This was because due to the overly low voltage, the resulting oxidation films were very thin and weak and could be easily punctured, (Kai et al., 2018; Babaranti et al., 2019) and together with the low discharge quantity, the resulting micropores were large in number and small in size. At high voltage, the enlarged discharge channels due to intense discharge led to the enlarged pores. Thus, when constant-voltage 250 V was applied, the low voltage, small discharge and gentle surface reactions made it easier to puncture the surface thin films, and consequently, a large number of small-sized micropores were formed. At voltage 300 V (Yang et al., 2019), the relatively low voltage and small discharge decelerated the metal surface oxidation, and thus decreased the numbers of micropores on the oxidation films. The slow oxidation led to less heat release and nonuniform oxidation, and irregular convexes and irregular micropores were formed on the oxidation film layers. As the electrode voltage rose to 350 V, the voltage and discharge increased and the metal surface oxidation was quickened, (Zeng et al., 2018) which led to the increased amount of uniformly-distributed micropores on the oxidation films. At the voltage of 450 V, the excessive voltage led to intense discharge, while the released high-energy caused micropore melting and enlarged the discharge channels and micropores.

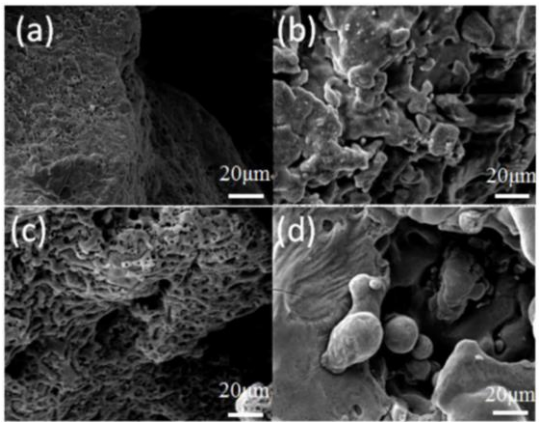

Figure 1. *Surface morphology of specimen under different voltage treatment (a) 250V; (b) 300V; (c) 350V; (d) 450V*

Moreover, (Sheng et al., 2018) the film thickening or densening reduced the conductivity, thereby decelerated the metal surface oxidation and decreased the amount of micropores on the oxidation film layers (Zhu et al., 2008; Pazand and Hezarkhani, 2018). At the electrode voltage of 450 V, evident cracks appeared at the oxidation film surfaces and between pores (*Fig. 1d*). The possible reason was that at higher voltage, the discharge quantity increased and the melting led to the formation of more oxides, (Tang et al., 2019) but during the sudden cooling under the action of external electrolytic solutions, the melts gradually clustered together rather than slowly dispersing or solidifying, leading to the formation of internal stress inside the structures. As the microarc oxidation proceeded, (Xiao, 2019) the inner stress was gradually intensified and finally was macroscopically embodied as local forced cracking on the oxidation films, which explained the formation of microcracks.

DOI: http://dx.doi.org/10.15666/aeer/1704_86318641

According to the basic principles of microarc oxidation, as the microarc oxidation reaction proceeds, the electrode voltage, after exceeding the critical level, will puncture the relatively weak parts on the surfaces of the anode specimens. At the early stage of microarc oxidation, the newly- formed oxide layer is very weak and is likely to be first penetrated, and the short-term overly high temperature subjects the locally-discharged anode to splashed melting, forming current channels for discharge, and after a certain period of external cooling, the penetrated oxidation film layer and the current channels are all reserved. At the same place of puncturing, the new matrix is oxidized into a new oxidation film layer, and the weak parts are punctured again. Thereby, this procedure circulates and consequently the oxidation film layer accumulates and thickens, forming a porous film structure on specimen surfaces in which large pores cover small pores (*Fig. 1c*). In this structure, the film layers and the matrix are mutually inlayed and bond more firmly, which also enlarge the specific surface areas. After 30 min of oxidation, when the constant voltage is 350 V, porous microarc oxidation films with rough surfaces and more micropores are formed on specimen surfaces, and the large pores in the micropores cover the small pores. Under this condition, the specific surface areas are the largest, and the oxidation film layers bond firmly with the matrix. It is deduced that microarc oxidation for surface processing of porous Ti would form the most ideal microarc oxidation films under this condition.

Effects of electrode voltage on the phases of the microarc oxidation films

The following figure shows the XRD images of the surface oxidation films formed from microarc oxidation at different electrode voltages. Clearly, the diffraction peaks of Anatase TiO_2 are very obvious (*Fig. 2*), suggesting the surface oxidation films formed from microarc oxidation under different conditions are all rich in Anatase TiO_2, (Selvaraj, 2017) which is the major component of the oxidation film layers.

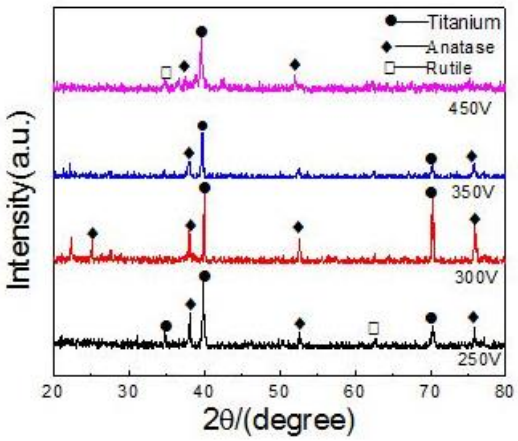

Figure 2. *X-ray diffraction (XRD) patterns of microarc oxide film with different electrode voltage*

Moreover, the diffraction peaks of the base material -- pure Ti are also very strong, but the peaks of Rutile TiO_2 are very weak and only appear at a part of the electrode voltages. These XRD results imply the major phase of the oxidation films formed under different oxidation conditions is anatase TiO_2, and Rutile TiO_2 did appear under certain

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86318641

conditions, but no rules concerning its concentration were found. This is because rutile TiO_2 has higher activation energy than anatase TiO_2, and the conversion from anatase TiO_2 to rutile TiO_2 relies on very high temperature. Thus, the reason why the rutile TiO_2 concentration did not increase with the rising electrode voltage was deduced. Specifically, the temperature during the microarc oxidation was controlled by the cooling in an ice-water mixture, which was hard to reach the high-temperature needed for the formation of rutile TiO_2. As a result, in the surface oxidation film layers after the microarc oxidation under different conditions, the rutile TiO_2 concentration did not change regularly and was very low.

Effects of time

Effects of time on surface morphology of microarc oxidized films

The figure below shows the surface morphology (×500) of the oxidation films prepared under electrode voltage of 350 V and different time durations (*Fig. 3*). Compared with the blank group (*Fig. 3a*), when the microarc oxidation proceeded under the constant voltage of 350 V, surface porous film layers were formed and the surface roughness was significantly intensified with the reaction time prolonged from 5 to 30 min. At this magnification factor, the specimen surfaces after 5 min of oxidation became rough and contained numerous fine micropores (*Fig. 3*). The surface roughness decreased after 15 to 30 min of oxidation. After 30 min of oxidation, porous film layers containing numerous evenly-distributed and large-sized pores were evidently formed (*Fig. 3d*). Clearly, the numbers and sizes of micropores in the film layers both changed at the same electrode voltage and after different durations of oxidation.

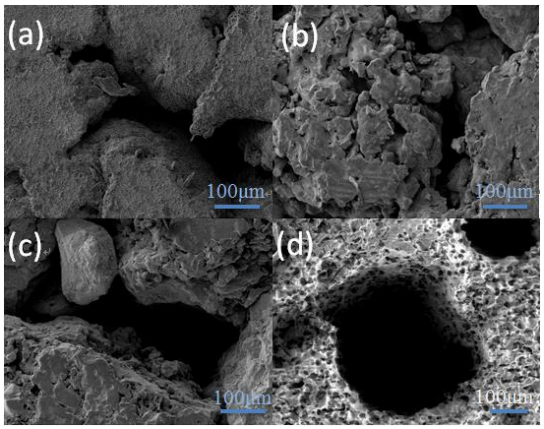

Figure 3. *Low ploid morphology (500 ×) of microarc oxide film surface at different oxidation times*
(a) 5 min; (b) 15min; (c) 25 min; (d) 30 min

The figure below shows the surface morphology (×3000) of the oxidation films prepared under the same electrode voltage of 350 V and different time durations (*Fig. 4*). During the microarc oxidation at the constant voltage of 350 V, very rough porous oxidation film layers were formed after 5 min of oxidation, which contained numerous micropores below 5 μm and were obviously melted (*Fig. 4a*). After 15 min of oxidation, the surface roughness decreased significantly and the numbers of micropores decreased, and the porous film layers contained size-varying and unevenly-distributed

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86318641

micropores, and the pore sizes decreased, the small pores were in size of ~ 500 nm and the large pores were about 3 μm (*Fig. 4b*). After 25 min of oxidation, the surface oxidation film layers were relatively even, and the sizes (1-2 μm) and distribution of micropores were relatively uniform (*Fig. 4c*). After 30 min, the surface oxidation films were very regular and formed a complete porous structure of small pores in large pores, but the micropores significantly decreased in number and considerably enlarged to about 6 μm (*Fig. 4d*). Clearly, with the prolonging of time before 25 min, the surface roughness gradually decreased, and the micropore distribution in the oxidation film layers became uniform, but the pore sizes decreased slowly. At about 30 min, the micropores were significantly enlarged in size and obviously decreased in numbers, and the porous layer structure of small pores in large pores was the most regular. Thus, at a constant voltage of 350 V was applied, the porous oxidation film layers formed from the micro-arc oxidation were optimized when the oxidation time was 30 min.

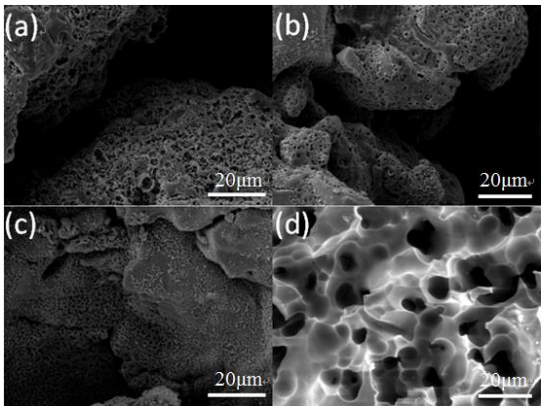

Figure 4. *The surface of the micro-arc oxide film has a high multiple morphology(3000 ×) (a) 5 min at different oxidation times; (b) 15min; (c) 25 min; (d) 30 min*

According to the fundamental principles of oxidation, at the early stage of reaction after 5 min of oxidation, a weak oxidation film layer that could be easily punctured was first formed on the surfaces of the base material. At the voltage of 350 V, the discharge and energy were very large, but the corresponding discharge channels were very small, and numerous fine-sized micropores were formed. However, the instant high-energy release would melt the walls of a part of the surface fine micropores, locally forming large-sized micropores (*Fig. 4a*). With the oxidation time prolonged from 15 to 25 min, the oxidation film layers thickened, reducing conductivity and making the films unpuncturable, but the residual discharge channels were gradually narrowed. The micropores formed at this moment decreased in size, while the residual energy accumulated inside the porous layer structures and would not easily released, leading to the gradual decrease of surface roughness (*Fig. 4b,c*). After 30 min of oxidation, due to the small discharge channels and the gradual energy accumulation, the relatively high energy caused the ablation of film layers and the consequent local melting of micropore walls, forming a smaller amount of larger-sized micropores. At this moment, the oxidation, dissolution and solidification speeds were relatively balanced and thus, regular porous layer surfaces with large pores containing small pores were formed (*Fig. 4a*). It was deduced that as the oxidation time was prolonged, surface ablation would be intensified and thereby more micropores were melted, and consequently, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86318641

oxidation film layers might be punctured and locally shed (Yan et al., 2010). Thus, the time of microarc oxidation should be controlled within a reasonable range.

Effects of time on the phases of the microarc oxidation film layers

The figure below (*Fig. 5*) shows the XRD images of the surface oxidation films formed from different time durations of microarc oxidation. Clearly, the diffraction peaks of Anatase TiO2 are very obvious (*Fig. 5*), suggesting the surface oxidation films formed from different time durations of microarc oxidation are all rich in anatase TiO_2, which is the major phase of the oxidation film layers.

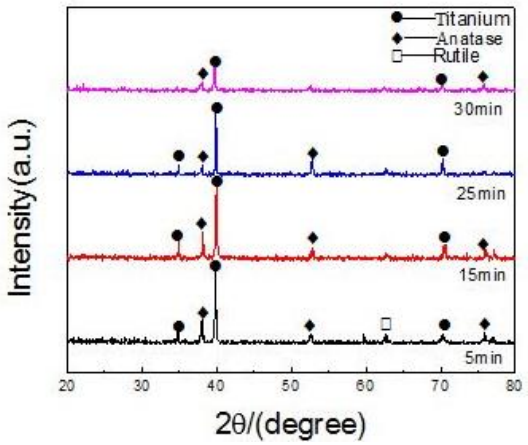

Figure 5. *XRD patterns of microarc oxide films at different oxidation times*

Effects of modification on bioactivity

The figure below (*Fig. 6*) shows the morphology of porous Ti (30 min of oxidation at 350 V, or without oxidation) after soaking in SBF for 7 days. After the non-oxidized porous Ti was soaked in the SBF, new substances were formed (*Fig. 6a*), but in the oxidized porous Ti, the surfaces were fully covered by a sediment after 7 days of mineralization (*Fig. 6b*). XRD patterns confirm this sediment is apatite (*Fig. 7*).

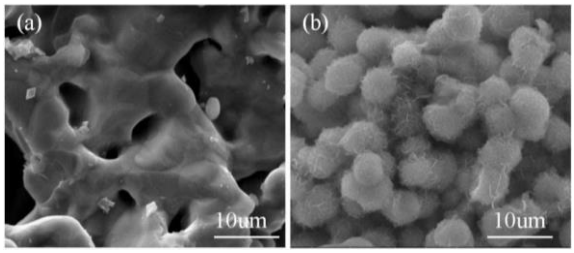

Figure 6. *Morphology of biomimetic mineralization of SEM(a) and(b) before and after microarc oxidation after 7 days of soaking in SBF with porous titanium oxidized by 350V voltage, respectively*

Microarc oxidation, also called plasma electrolysis oxidation or anode sparkle oxidation, is a relatively convenient technique to prepare oxide layers on metal surfaces. Compared with common anode oxidation, its major difference is the higher oxidation

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86318641

voltage. After microarc oxidation, surface coatings can form on porous metals or irregularly-shaped metals that have complex geometric morphology. The principle of this method in activating Ti and its alloys is attributed to the effect of microstructures on biological reactions. Chen et al. (2010) created different crystal forms of TiO_2 coatings atop β Ti alloys by regulating the microarc oxidation voltage and investigated the effects of crystal forms on osteoblast growth.

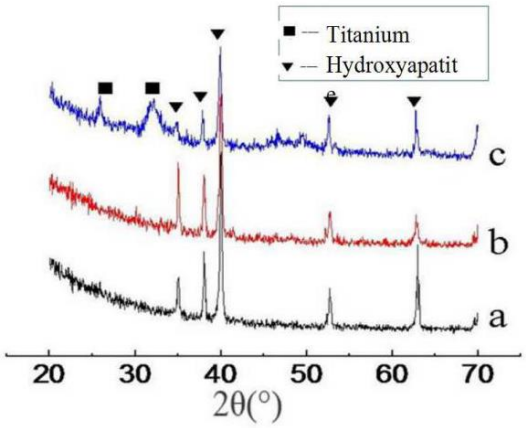

Figure 7. *XRD map of different samples*
a) Porous titanium prepared by vacuum sintering; b) is a sample of porous titanium that has not been treated with microarc oxidation after being soaked in SBF for 7 days; c) is a porous titanium after microarc oxidation (voltage 350V, oxidation time 30 min) and then soaked in SBF for 7 days

They found the TiO_2 after microarc oxidation possessed the bioactivity and Ca deposition ability like cells. Bayati et al. (2010) found with the increasing oxidation voltage, the surface pore sizes and roughness both significantly increased, but the number of pores first rose and then declined, while the contact angle first decreased and then enlarged. Furthermore, the variation of hydrophilicity was caused by mainly two factors, including the existence of surface oxidation films and the variation of specific surface (Yang et al., 2019). Since we conducted microarc oxidation on surfaces of porous Ti, the oxidation parameters were different from those of dense Ti. Firstly, the films formed under our experimental conditions were all porous and were TiO_2 films, and these film microstructures were favorable for the formation of the precipitate HA. Secondly, the hierarchical microstructures formed from porous Ti oxidation increased the specific surface areas and hydrophilicity. The enlarged specific surface areas enhanced the specific surface energy and surface activity of porous Ti, which created more sites for apatite nucleation. The more hydrophilic surfaces were more likely to contact and bind with polar ions in SBF, which accelerated the apatite nucleation and crystallization. The different mineralization results in our study can be explained from two reasons. The first reason is the change of surface morphology, since the increase in pore number and specific surface area offer more sites for the nucleation of precipitates. The second reason might be related to the phases of post-oxidation surface film layers. The above analysis suggests the surface activity can be enhanced by surface-modifying the porous Ti through microarc oxidation. Thus, microarc oxidation may be used to modify the surface activation of porous Ti.

Conclusions

(1) When the time of oxidation was constant, the pores in the surface oxidation film layers gradually increased in size and decreased in number with the increment of electrode voltage. The oxidized film layers contained both rutile TiO_2 and anatase TiO_2.

(2) When the voltage was constant, with the prolonging of oxidation time within 5 and 25 min, the surface roughness gradually decreased, the micropores on the oxidation film layers became uniformly-distributed and decreased slowly in size. At about 30 min, the micropores were significantly enlarged in size and obviously decreased in number, and the porous layer structure of small pores in large pores was the most regular. The oxidation film layers were mainly composed of anatase TiO_2.

(3) After 30 min of oxidation at voltage 350 V, the oxidized film layers on pore walls of porous Ti became uniform micropore structures in pore size of ~ 6 μm, and these structures had large specific surface areas, which were the optimal experimental parameters under the tested conditions.

(4) The porous Ti modified by microarc oxidation induced apatite generation and was more bioactive compared with the porous Ti surface without microarc oxidation.

In the future, when the porous Ti micro-arc oxidation film is applied in specific fields, all the parameters in this paper can provide beneficial value.

Abstract. Among most existing residential areas, the planning designs mainly focus on the function rationality and environment beautification, but neglect the effects of residential layout on micro-climate environment. This work simulated the wind environment with different residential planning schemes using computational fluid. Then, the results of different monsoon environments were analyzed. Taking the planning scheme in Kazi Wanzhen, Urumqi as a case study, the overall rate of calm wind was higher than 50% with the calm wind in winter up to 92%. It shows that the environmental effect of winter monsoon was the worst. Therefore, the original layout was optimized based on the current development strength by simulating the wind environment in this work. After optimization, the rate of calm wind in all four seasons decreased by more than 10%. This result shows that the wind environment can be improved by dislocated and disclosed layout with an opening at windward side and leeward side. Therefore, the deterioration of wind environment can be relieved to improve the living environment and the overall micro-climate.

Keywords: *micro-climate, computational fluid dynamics, winter monsoon, wind speed velocity, the rate of calm wind*

Introduction

In recent years, people have found it important to lead the natural wind surrounding the urban area to the city when solving air pollution. The wind can be led by optimizing urban layout and constructing a natural ventilation corridor. In fact, wind field plays an important role in spreading and diluting pollutants in the air. In terms of residential areas, using wind environment is technically feasible to improve the air quality by optimizing residential planning with natural ventilation.

For a long time, residential planning has emphasized living comfort, convenience, security, beauty, energy preservation, environment protection, etc. People have not paid enough attention to the micro-climate environment up until now. The most newly-built residential areas have rational functions and complete environmental landscape and facilities with convenience. However, the irrational layouts of these areas have caused poor ventilation with air pollutants. Especially in the megacities with severe air pollution, such a problem can be more obvious. Therefore, the residential planning in urban area should focus on the effects of building layout on micro-climate environment. At present, it has become a grand new task and challenge to feasibly improve the living quality by maximizing the improvement of residential ventilation through building layout.

Materials and Methods

Research status

There have been some research achievements about evaluating the atmospheric thermal environment with CFD at home and abroad. The studies by Oke (1973) and Summers (1965) show that the strength and location of a heat island have a certain relation with wind speed. Natural ventilation can relieve urban heat island effect and decrease air pollution (Summers, 1965; Oke, 1973; Junior et al., 2019). Dabberdt and Hoydysh (1991) made thumbnail models of street canyons in different scales for wind tunnel experiment. This study compares the distribution of wind speed field in different wind directions (Dabberdt and Hoydysh, 1991; Choudhari et al., 2018). Stathopoulos and Baskaran (1996) stimulated a wind field of a single high-level building and that of a block, respectively, for wind tunnel experiments. These studies test the simulation results (Stathopoulos and Baskaran, 1996; Rozuki et al., 2018). Yang and Li (2011) established two simple models of Hong Kong with relatively complex landforms in a small scale. The effects of thermal stratification on the thermal conditions and ventilation were studied according to thermal buoyancy and wind speed (Yang and Li, 2011; Kumar and Jaafar, 2018). Hang et al. (2012) stimulated the pollutant distribution of 9- or 18-row high-level building array in a small scale. This study showed the effects of the height diversity on the pollutant diffusion in the air and the ventilation at pedestrian height in an ideal urban area with high-level buildings. Ouyang and Jiang (2003) found the rules of wind environment and pollutant diffusion in urban areas by data measurement (Ouyang and Jiang, 2003; Tianlei, 2019). Pontiggia et al. (2010) simulated the diffusion of hazardous gas in the city with CFD (Pontiggia et al., 2010; Omini and Akpang, 2018). In 2011, Lin and Liu studied the natural ventilation indoors and in the courtyard of traditional Yi Nationality's settlements in Yunnan by CFD simulation. It analyzes the relationship between various influence factors and the natural ventilation inside and outside of the building (Lin and Liu, 2011; Nkwuda et al., 2019). Wang (2012) studied the diffusion of air pollutant around high-level residential buildings in natural ventilation through wind tunnel test (Wang, 2012; Abija and Nwankwoala, 2018). Yuan et al. (2014) studied the diffusion of hazardous gas in the city with CFD model. In 2014, Huang studied the relationship between village form and rural settlement type in Boyang Lake Bioeconomic Zone and the natural ventilation by CFD simulation. This study further proposed the strategies about natural ventilation in the planning and design of new rural area (Huang, 2014; Sufiyan et al., 2018). With CFD, Peng (2015) stimulated and analyzed the natural ventilation effects inside of two different planes in plate-type and tower-type residential forms, which are common in Jinan. In 2016, Zhang and Jin studied the relationship between village forms and wind monsoon of the typical village clusters in the severe cold Northeast China. Strategies of optimizing the wind environment in these villages are proposed in terms of village form (Zhang and Jin, 2016).

The research status at home and abroad shows that studies on the wind environment in a region start earlier in foreign countries than in China. Such studies were mainly taken by wind tunnel experiment. With the improvement of computer hardware and simulation software, these studies are gradually taken by value simulation with wind tunnel experiment for verification. As the wind fields in different suburbs are interconnected, the overall wind field in a city should be simulated to get the correct wind fields in different suburbs. All of these studies set a foundation to this work.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86438654

However, the existing studies with CFD simulation pay little attention to a complete residential area, especially in Western China, which becomes the subject root. Aiming at simulating the wind environment in the residential planning, this work explored the optimal mode of wind environment in a residential area for the layout optimization of residential buildings and the overall improvement of atmospheric environment.

Research methods

With the development of computer technology, digital simulations by computer can provide numerical solution to nonlinear partial differential equations. In other words, various data can be obtained by computational fluid dynamics (CFD) to save substantial experimental cost. As CFD is developing, the simulation of flow fields by computer can replace aerodynamics experiment. In the planning, it is safer and more reasonable to use aerodynamics when urban micro-climate is simulated.

CFD is realized as follows:

(1) Establishment of mathematic model (*Eq.1*, *Eq.2*). It means assigning a flow control equation, selecting a value discretization scheme, setting boundary conditions, etc. This process can be completed with commercial CFD software (i.e., ANSYS FLUENT) (Yuan et al., 2014; Wali et al., 2018). The equation (*Eq.1*) is the most common control equation, Navier-Stokes equation in CFD:

$$\frac{\partial \boldsymbol{Q}}{\partial t}+\frac{\partial \boldsymbol{F}_i}{\partial \boldsymbol{x}_i}-\frac{\partial \boldsymbol{F}_i^{\mathrm{v}}}{\partial \boldsymbol{x}_i}=0 \tag{Eq.1}$$

$$\boldsymbol{Q}=\begin{bmatrix}\rho\\ \rho \boldsymbol{u}_i\\ \rho E\end{bmatrix},\ \boldsymbol{F}_i=\begin{bmatrix}\rho \boldsymbol{u}_i\\ \rho \boldsymbol{u}_i \boldsymbol{u}_j+p\delta_{ij}\\ \rho \boldsymbol{u}_i H\end{bmatrix},\ \boldsymbol{F}_i^{\mathrm{v}}=\begin{bmatrix}0\\ \tau_{ij}\\ \boldsymbol{u}_k \tau_{ki}-\boldsymbol{q}_i\end{bmatrix} \tag{Eq.2}$$

(2) Establishment of geometric model. It means drawing corresponding geometric forms in the computer according to the actual size of buildings, landforms, etc. The geometric model is simplified because the actual geographic shapes are complicated.

(3) Generation of computational grid. It means dispersing the actually continuous flow space into intermittent grid units for discrete solutions to CFD.

(4) Numerical solution to CFD. It is realized by setting the assigned turbulence model, iterative steps, residual criterion for convergence, etc. of the commercial software (Hang et al., 2012).

(5) Analysis of numerical results. After solving CFD, the results are analyzed to ensure the rationality of numerical values. Then, the actual issues are analyzed with rational numerical results to draw the wind field around buildings for modifying the irrational layout of buildings.

Results and Discussion

Analysis on regional situation in the case

Kaziwan Community in the north of Urumqi is taken as the research object due to following three reasons:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86438654

(1) Urumqi faces a severe problem of atmospheric environment. Located in the interior of Eurasia far away from the ocean, Urumqi has temperate continental climate with dry air. According to 2015 City Rank of Haze Severity of China, Urumqi ranks at No. 76. The weather statistics show that the annual pm2.5 concentration of Urumqi is 72 μg/m^3 which is much higher than 35 μg/m^3 regulated in Ambient Air Quality Standards released by Ministry of Environmental Protection (Ge et al., 2016).

(2) With a long winter in Urumqi, the environmental problem caused by heating supply is obvious. According to Code for Thermal Design of Civil Building (GB50176), Urumqi is in a severe cold area. The period with monthly lowest temperature ≤-10ºC or daily lowest temperature ≤5ºC is longer than 145 days. Due to the cold weather, the heating supply period is from October to April the next year in Urumqi. The heating period here is longer than other areas, while the fire coal for heating may cause atmospheric pollution and jeopardize the public health.

(3) Enterprises with heavy pollution are concentrated in Kaziwan. There are two cement plants (Xingong Cement Plant and Qingsong Cement Plant) within 1 mile from Kaziwan Community. A large amount of dust, sulfur dioxide, nitric oxide and other pollutants may be generated when producing cement to cause severe environmental pollution and harm the health of residents nearby. Although the government has shut down the enterprises causing heavy pollution, the environment pollution in big cities are still unsolved. The current status of pollution is especially severe in winter due to the fire coal for heating. Reducing pollution sources is an important measure, but self-attenuation of air pollutants is more positive by maximizing the ventilation.

Case overview

Located in Midong District in northeast of the city center of Urumqi, Kaziwan Community covers 55,000 m^2 of land use with a volume fraction index of 3.2 and architectural density of 30.14%. The overall floorage is 190,000 m^2 (including the above ground floor area of 176,000 m^2 and underground floor area of 14,000 m^2).

The overall residential buildings are high level with enclosed building layout. Roads are laid surrounding the community, where pedestrian are separated from traffic. In the southwestern corner, two dotted apartments are built. Greening is concentrated in the center of community, while the greenery landscape distributes in trapezoid. Leisure footpath, hard pavage, featured landscape, green trees, etc. are composed of a rich and lifeful common activity area which provides a pleasant outdoor shared area to residents. The planning scheme creates a modern residential area with healthy biology, beautiful environment and reasonable function layout by integrating the site culture and natural conditions.

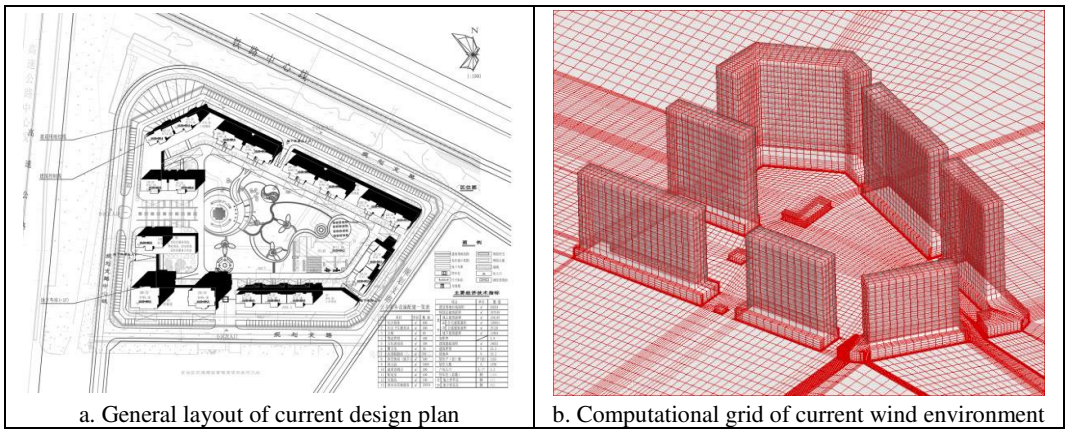
Model construction and parameter analysis

Kaziwan Community uses the traditional model of residential layout in northern China which is a typical enclosed layout. This model is a spatial layout with strong closure made of surrounding roads (*Fig. 1a*). For the convenience of model construction, effects of plants were neglected in this work by simplifying the whole community as a solid model composed of buildings. With this model, relatively correct simulation results can be obtained by appropriate parameter adjustment. Moreover, this model has advantages of convenient construction, rapid calculation and good convergence.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86438654

A computational grid of Kaziwan Community (*Fig. 1b*) is established with ICEM software with about 1.2 million grids. This calculated quantity can ensure accuracy and realize the optimal calculation process (Nikolopoulou and Lykoudis, 2006).

In this case, the incoming flow direction of wind speed is the speed income when the boundary conditions are set within the computational scope. Based on the meteorological data of Urumqi in recent 50 years, the annual average wind speed in Urumqi is 2.47 ms^{-1} from 1961 to 2003. The wind speed in summer is the fastest, followed by that in spring, autumn and winter in order. The average wind speeds are 3.08 ms^{-1}, 2.94 ms^{-1}, 2.31 ms^{-1} and 1.52 ms^{-1}, respectively, in four seasons. The wind in spring is southeaster and summer and that in autumn and winter is northwester (Le et al., 2017; Fu et al., 2018). The export downstream is the pressure export and the boundary condition on ground is the wall space. The boundary conditions in other parts are symmetrically set. To avoid the result error, the parameters should be further rectified (Jing, 2018).



a. General layout of current design plan | b. Computational grid of current wind environment

Figure 1. *Overall appraisal for the current plan of Kaziwan Community and computational grid of wind environment*

Analysis and optimization of research results in the empirical case

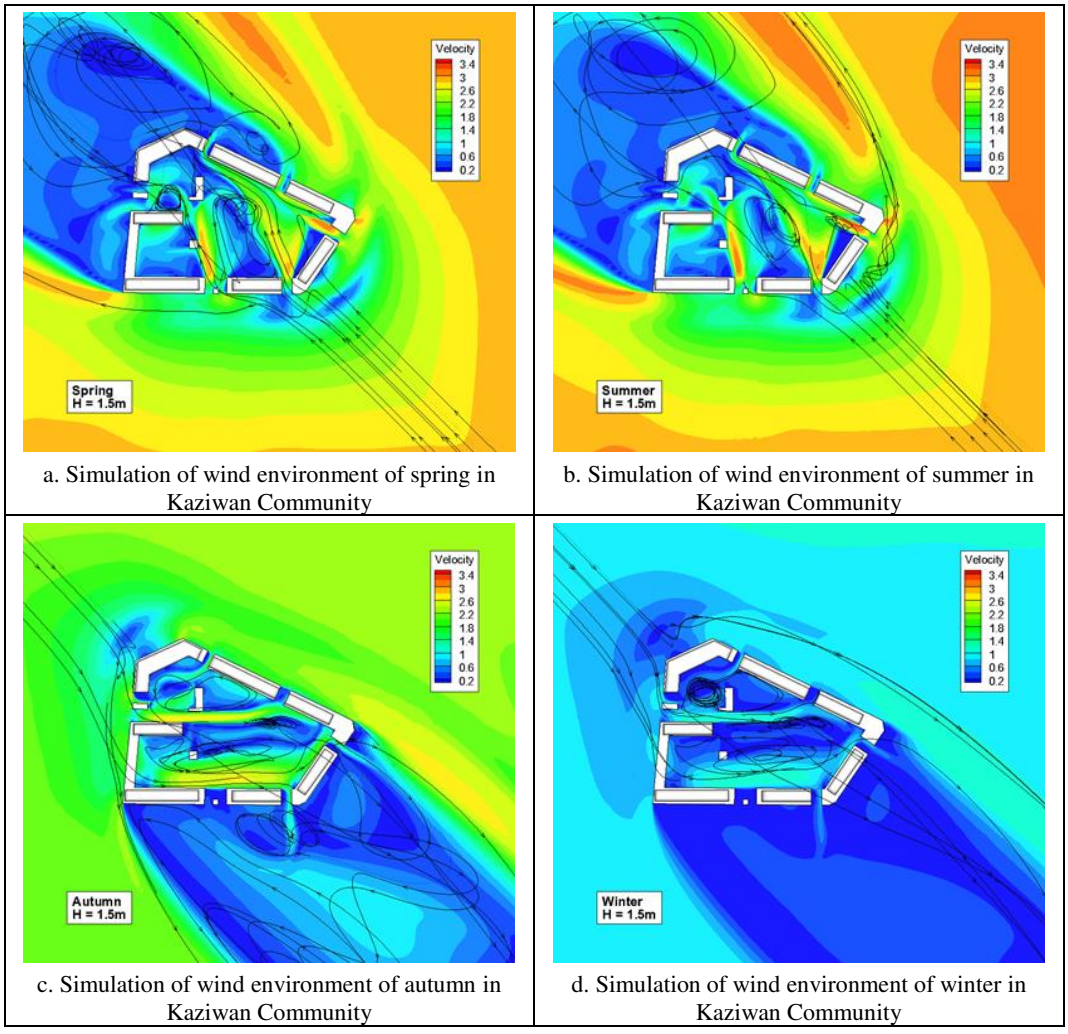
The theoretical research shows that the height of 1.5 m is the most obvious thermal inductance for human. The wind speed simulated for this height can intuitively display the comfort and safety in such an environment. Therefore, the wind speed field in the height of pedestrians is simulated by computational fluid mechanics in four seasons. The figures show the simulation results (*Fig. 2 a-d*). Meanwhile, the air pollutant cannot disperse to form a calm zone when the calm rate is lower than 1.04 m/s under 1.5 m as the evaluation criterion. The calm rate is the ratio between this area and the total site area. The higher calm rate means the worse effect of wind environment.

Result analysis of wind speed field in the current plan

The computational results of different monsoon fields in this plan (*Table 1*) show that the calm rates in four seasons are 56.25, 55.32, 55.96 and 91.82%, respectively. The higher the calm rate is, the worse the wind environment will be. Therefore, the monsoon environment in winter is the worst in this case, while that in other three seasons is average. However, the calm rate in all the seasons has been over 50%. Thus, it is urgent to improve the ventilation effect, especially in winter.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86438654

According to the distribution of wind speed shown (*Table 1*), the maximum wind speed in winter is 1.17 m/s, 3.17 m/s in spring, 3.27 m/s in summer and 2.71 m/s in autumn. The area with quick wind speed in spring and summer is in three openings in the south and southeast of the area. Moreover, there are also two obvious air channels in the community in autumn. Only in winter, there is no obvious air channel due to the weak wind environment. This is because there is an opening among the buildings towards the wind direction with the maximum wind speed of 3.27 m/s which is lower than the safety threshold of 5 m/s. It is believed that the wind environment formed in this plan is much lower than the standard of windburn. Therefore, this plan with small effects on outdoor activities can satisfy various activities at this site in terms of security (Sheng et al., 2018). Massive annex buildings cause the closure of community environment to the great extent; however, these buildings form a local calm area that is disadvantageous to pollutant dispersion.



a. Simulation of wind environment of spring in Kaziwan Community

b. Simulation of wind environment of summer in Kaziwan Community

c. Simulation of wind environment of autumn in Kaziwan Community

d. Simulation of wind environment of winter in Kaziwan Community

Figure 2. *Simulation of current plan of four monsoons in Kaziwan Community*

The areas with fast wind speed in winter are in the western entrance and the scenery greenbelt in the south. The maximum wind speed is 1.17 m/s, lower than the speed threshold of 5 m/s. Therefore, this plan with small effects on outdoor activities can

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86438654

satisfy various activities at this site. It is because the building layout at the northeast corner is vertical to the leading wind direction in winter. The enclosed layout in the north can shield the leading wind in winter. However, such a shield forms a large area of calm wind among the massive enclosed buildings in the north, making pollution more severe (Shan and Lai, 2018).

Table 1. *Simulation results of wind environment in Kaziwan Community*

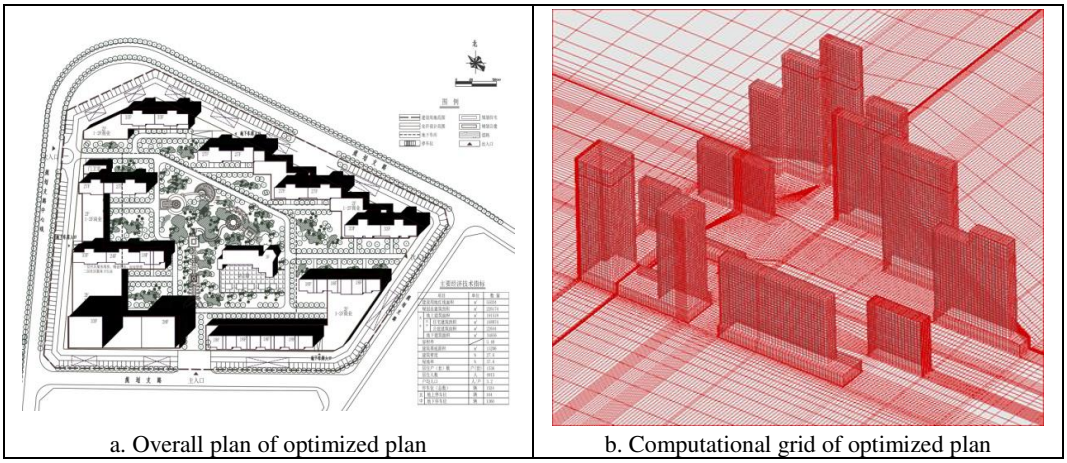
Current plan	Spring	Summer	Autumn	Winter
Calm rate	56.25%	55.32%	55.96%	91.82%
Maximum wind speed	3.17	3.27	2.71	1.17
Minimum wind speed	0	0.01	0.00	0.00
Building density	0.143	30.14	30.14	30.14

Results analysis on the wind speed fields of four seasons in the optimized plan

The current plan does not cause the windburn but forms an area with severe calm wind, especially in winter. Therefore, adjustment is necessary for this layout to improve the calm wind area in the community during winter to the greatest extent. In this way, the pollutant gathering in the air during winter can be effectively released.

Now, the original plan is optimized with the volume rate and building height constant. The layout is optimized from the traditional enclosure to the dislocated enclosure. In other words, the overall building layout is still enclosed, while the partial layout will be adjusted to plate-type dislocated layout (*Fig. 3a*) to leave a corridor for ventilation for the improvement of wind environment.

With the computational grid established with ICEM (*Fig. 3b*), the computational quantity, 100 W, is the same as the previous plan. The same parameters are set for calculation and simulation.



a. Overall plan of optimized plan

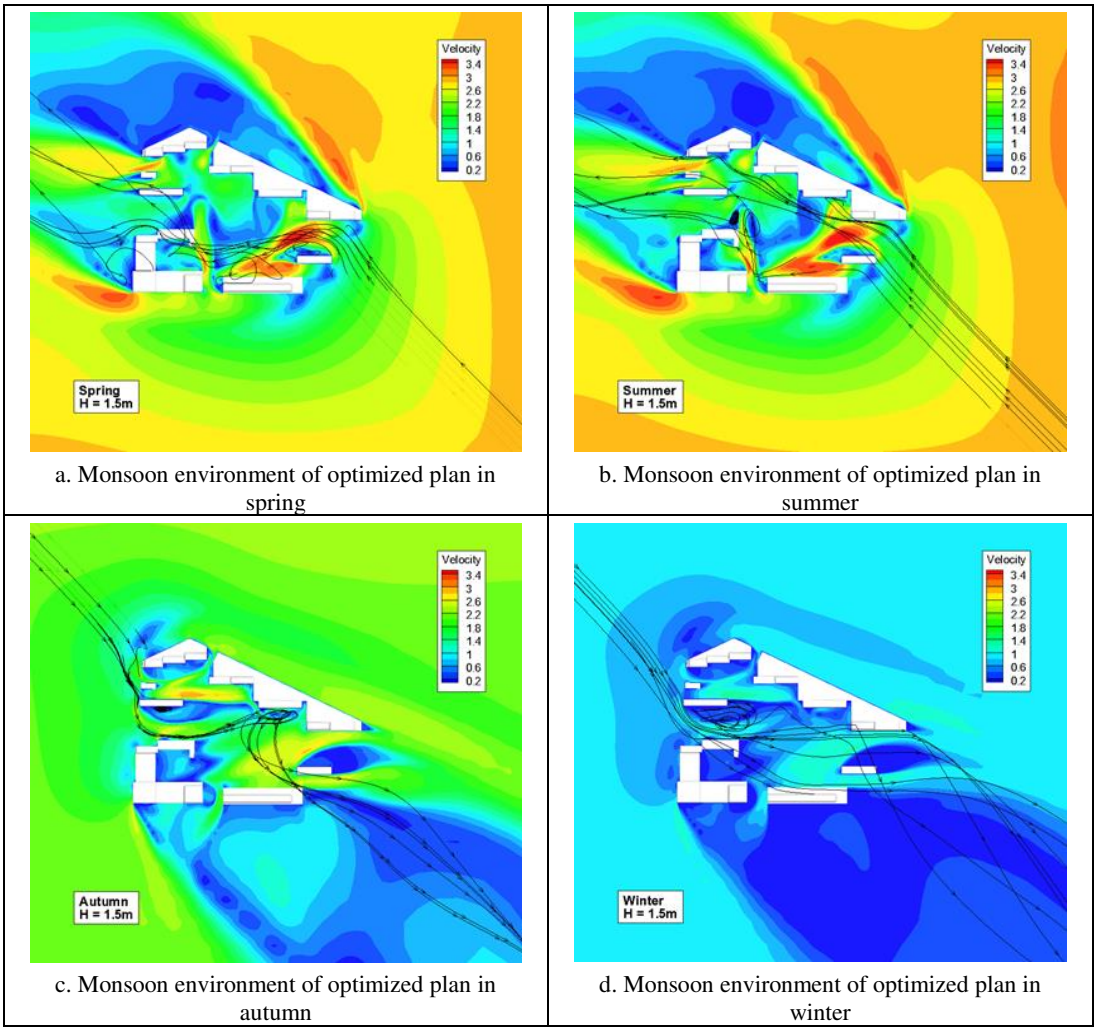
b. Computational grid of optimized plan

Figure 3. *Overall evaluation of the optimized plan and the computational grid of wind environment in Kaziwan Community*

For different monsoon speed fields, the optimized plan is simulated in the height of pedestrians in four seasons by computational fluid dynamics. The simulation results are as follows (*Fig. 4a-d and Table 2*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86438654

The figure and the table show that the calm rate in the optimized plan is 40.05, 33.02, 36.35 and 87.27% in spring, summer, autumn and winter, respectively (*Fig. 5, Table 2*). In terms of the environmental effect, the calm rate in winter is still the highest, while that in other three seasons shows small difference. Compared with the current plan, the optimized plan solves the problem of high calm rate. In the optimized plan, the calm rate in every season decreases by about 10%. It shows that the adjustment of building layout will change the wind environment inside of a community to decrease calm rate and improve air quality.



a. Monsoon environment of optimized plan in spring

b. Monsoon environment of optimized plan in summer

c. Monsoon environment of optimized plan in autumn

d. Monsoon environment of optimized plan in winter

Comparative analysis on the building layout improvement

This work studied the comfort and safety of pedestrians. As the current plan and the optimized plan in this work are the most typical layouts in community design, this research is more persuasive for the future simulation of computational micro-environment with the universal CFD. By comparing the calculation of these two plans, following characteristics can be obtained:

(1) Layout difference between plans

Above computational results show that the changes to current layout significantly decrease the calm rate. It means that the layout has significant effect on wind environment. There are following similarities and differences between the optimized plan and current plan. First, the development strength is almost the same with the volume rate and building height constant. Second, the layout is different. In the optimized plan, the layout changes from the traditional enclosure to dislocated enclosure. In other words, the overall layout is still enclosed with the adjustment of plate-type dislocated layout in partial. This optimized layout leaves a corridor for ventilation for the improvement of wind environment.

(2) Comparative analysis on results

Simulation results show that the wind speed is fast in spring and summer when southeaster prevails. In terms of overall environmental effect, this plan has a large effect on the wind speed field of the whole environment due to the closure. In this plan, a series of calm areas form surrounding high-level buildings, which is disadvantageous to the overall ventilation in the environment. By optimizing this plan, an open corridor forms, making the overall effect of wind environment in the community constant with the external environment. This is advantageous to the ventilation in the community. In terms of internal micro-environment of the community, the wind speed is low in the current plan with only three tiny air flues in incoherency. It is difficult to fluid air exchange with the outside world. After optimization, the overall wind speed in the internal environment is slightly higher with a complete ventilated corridor.

The wind speed in autumn and winter is low when northwester prevails. The difference between internal and external wind speed is significant in the current plan, while the difference is small in the optimized plan. However, the small pattern of internal wind speed field shows that two air flues with high wind speed form near the residential area in the current plan. These flues will make pedestrians uncomfortable in autumn and winter. The optimized plan forms an open air flue in the middle but effectively resist the cold wind due to some random shelter and small enclosure near buildings. Therefore, the optimized plan makes pedestrians more comfortable.

Relation of the internal ventilation with the community and development strength is not strong, while that with the layout pattern is obvious. Dislocated enclosure can more effectively enhance the ventilation effect in the community to improve the overall air quality than surrounding enclosure (Zhang et al., 2018).

Conclusions

By simulating the wind environment in Kaziwan Community of Urumqi and its optimization analysis, following advises are obtained for the reference of creating a comfortable residential environment. First, the problem of severe wind environment due to development strength can be solved by proper layout optimization. Second, the dislocated enclosure can ensure a certain enclosure for heating and leave a ventilation

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86438654

corridor for the improvement of wind environment (David, 2017). Third, a certain ventilation opening can be left in the building layout at windward side, making the wind enter the community. This opening can optimize the wind environment in the residential area to some extent. Forth, a ventilation opening can be added in partial building layout at leeside to reduce the building separation in the direction of air flue. Therefore, the air flue is continuous in the community for a good circulating wind environment (Lu et al., 2019).

In this work, the wind environment was analyzed with the optimization strategies discussed. The results showed that the planning design of residential area should consider various aspects. Except for the urban esthetics, economic benefits, sunshine spacing and other factors, the wind environment should be optimized to improve the living environment. After optimizing wind environment, the pollutant concentration decreases, and the haze pollution is relieved by accelerating air circulation. Moreover, the green energy preservation can be realized to make a positive effect on human health to some extent (Qi, 2018).

Urban planning is a discipline crossing several disciplines. The impact factors of wind environment cannot be neglected, but more factors should be considered in the actual design. Therefore, the design should be optimized by the analysis technology of wind environment in the basic design principle (Li, 2018). However, as a specific case is taken as background, the conclusion about the layout mode based on the analysis on wind environment effect is only suitable for the case. The university requires further rectification by experiment for different regions.

(Received 8th Mar 2019; accepted 21st May 2019)

Abstract. The interactions between electromagnetic field and the biological system can lead to the change of biological morphology, structure, function and other aspects at the different levels of biological targets. The domestic sewage is secondarily disinfected using continuous electromagnetic waves, the microscopic molecules have a certain dipole-moment and the biological molecular aggregates with dielectric properties of the cell may generate dielectric loss under the effect of the applied electromagnetic field. The thermal effect will be produced by putting the microwave energy into the heat of irregular movement which increases biological system's temperature. Under the influence of an applied electromagnetic field, the membrane potentially undergoes conformational changes that would affect K^+ ion, Na^+ ion channels open and make the voltage-dependant Ca^{2+} ion open, the high concentration of Ca^{2+} ion of the membrane into the cell along the potential gradient, which leads to cell death, resulting in the biological non-thermal effects, the greater the changes of cellular transmembrane voltage, the higher the rate of cell death. The experiment results show that the microwave secondary sterilization has a good sterilizing effect, the method has the advantages of high efficiency, low cost, simple operation, easy automation, without adding any substance and does not produce any secondary pollution, etc.
Keywords: *electromagnetic field, biology system, biological morphology, microscopic molecular, high efficiency*

Introduction

Water is an indispensable natural resource in human production and life, and also an important factor in promoting social development and promoting the progress of civilization. The reform and opening up has made China's economic achievements a great achievement. The people's living standards are getting higher and higher, the urban population is also increasing, the demand for water resources is increasing, and the same domestic sewage discharge is also increasing. China is actually a relatively scarce water resource with low per capita possession, which is a country with severe water shortage.

The application of domestic sewage treatment and reuse technology has historical significance for solving water shortage and environmental pollution. On the one hand, domestic sewage treatment reduces domestic sewage discharge, which is very beneficial to avoid water eutrophication and water pollution caused by water pollution, and greatly reduces the cost of water pollution control. On the other hand, the treatment and reuse of sewage will help people solve the problem of water shortage, and reuse the reused water for urban greening, landscape hydration and road sprinkling, flushing and car washing, industrial, building fire protection and many other aspects. It has had a tremendous impact on agriculture, industry and people's lives, and promoted the sustainable development of society. However, in the past 100 years, urban domestic sewage treatment technology has been in a state of slow progress, lacking technological innovation and innovation (Zhao, 2016; Patle et al., 2019).

Current status of urban domestic sewage

Urban domestic sewage characteristics

Urban domestic sewage contains high levels of suspended solids, such as food residues, grease and other types of domestic waste, which cause the color of the sewage to be heavy. In addition, because there are many organic residues such as food residues contained in urban domestic sewage, when the organic matter rots, it will produce extremely heavy odor and cause the most direct pollution to the environment. In addition, laundry wastewater, because of detergent, generally contains phosphorus and nitrogen. It is easy to cause eutrophication of water bodies. Hospital wastewater may carry a large number of pathogenic microorganisms.

Urban domestic sewage source

Urban domestic sewage mainly comes from wastewater generated by urban residents in daily life. It includes various sewer waste water, washing wastewater, toilet wastewater, hospital sewage, rainwater, etc., which are discharged from living quarters, schools, hospitals, shopping malls, hotels, etc. (Mcleod and Liboff, 1986; Sen et al., 2018). The source is extensive, and the source domestic sewage discharge management is not standardized. The amount produced is large, unstable, and has obvious seasonality.

Urban domestic sewage impact

In general, the hazards of urban domestic sewage at this stage are mainly reflected in the following aspects:

1) The eutrophication of water bodies, with the discharge of domestic sewage, a large amount of organic substances, chemical substances, metal substances, etc., and the increase of chemical substances such as nitrogen and phosphorus substances will pollute the water bodies, resulting in eutrophication of water bodies (Huang, 2000; Yahya et al., 2018). There may even be red tides and the like;
2) Polluted urban environment, some domestic sewage has odor. If it is not treated in time, it will be stinking, directly polluting the urban environment, causing troubles for people's daily life and work. In addition, odor Diffuse can endanger the health of the human body and affect the development of green cities;
3) Affecting groundwater sources. At this stage, due to the complexity of the composition of urban domestic sewage, various chemical substances may be mixed together to produce some chemical reactions, which may cause some toxic substances, if not treated in time (Durney et al., 1988; Suhaili and Samsudin, 2018). It will cause toxic substances to enter the groundwater and urban residents' water, causing residents to poison, directly threatening the life and health and personal safety of urban residents. There are also a large number of pathogenic microorganisms in urban domestic sewage. It poses a great threat to people's health and so on.

Domestic sewage sterilization is an important process to ensure the health and safety of domestic sewage (Lednev, 1991; Kasim et al., 2019). Generally the sterilization methods to water are chlorine, chlorine dioxide, ozone, etc, in which the chlorine is a common method which has the characteristic of low cost, simple process and easy to operate, but the chlorine has powerful oxidation and easy to acting with organic matter

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86558666

in water to produce halogenated hydrocarbons, chloroform and PCBs that is harmful to people and animals (Zhang, 2002; Tao, 2018). The effect of chlorine dioxide sterilization is better than chlorine and will not easy produce organochloride, but chlorine dioxide is unstable and sensitive to temperature, pressure and light. It is easy to explosive when it meets fire or organics. So it only be produced and used on the spot (Chen and Wang, 2001; Jamil et al., 2018). Ozone has strong oxidation ability, fast, good sterilization effect and not produces odor smell, but the Ozone treatment requires high technique, complicated equipment and high energy (Jin, 1999; Nawaz et al., 2018).

Microwave treatment has unique advantages. The material is heated by way of molecule polarization or ion- conduction effect through microwave. The heated polar molecule or ions rapid motion and orientation in the electromagnetic field which leads to heat by the tearing and mutual friction (Li and Niu, 1990; Austin et al., 2018). Microwave can kill various microorganisms. The thermal effect and mechanism of microwave have been a fact which is widely accepted by people, but there still exists the big dispute to the mechanism of non–thermal effects of electromagnetic (Liboff and Mcleod, 1988; Ismail et al., 2019). The work describes the sterilization effect of microwave to domestic sewage and analyze the phenomena and mechanism of microwave sterilization from the experimental and theoretical (Yang, 2018).

Experiment apparatus and method

It shows the related experimental equipment 1 (*Fig. 1*) and the related experimental equipment 2 (*Fig. 2*).

Figure 1. *The related experimental equipment 1*

The domestic sewage is taken from the domestic sewage well of xianyang normal University living quarters and the water pH's value is 7.3~7.8, the domestic sewage has been treated by bio-oxidation, then be disinfected by microwave, the total amount of bacteria and fecal coliform was decreases with the suspended solids significantly reduce in domestic sewage (Zhou and Zhang, 2000). However, the concentration of the two kinds of germs was still so high that it must be disinfected before discharge. The

DOI: http://dx.doi.org/10.15666/aeer/1704_86558666

continuous microwave is used to disinfect to domestic sewage which has been treated by bio-oxidation in the experiment (Niu et al., 2002). It shows the principle chart of electromagnetic radiation (*Fig. 3*). The microwave frequency is better to be higher (Zhang, 1998), taking into account the depth of penetration and other reasons, the microwave frequency is 2450 MHz and the average power density is 520 MW/cm2 was adopted in this experiment.

Figure 2. *The related experimental equipment 2*

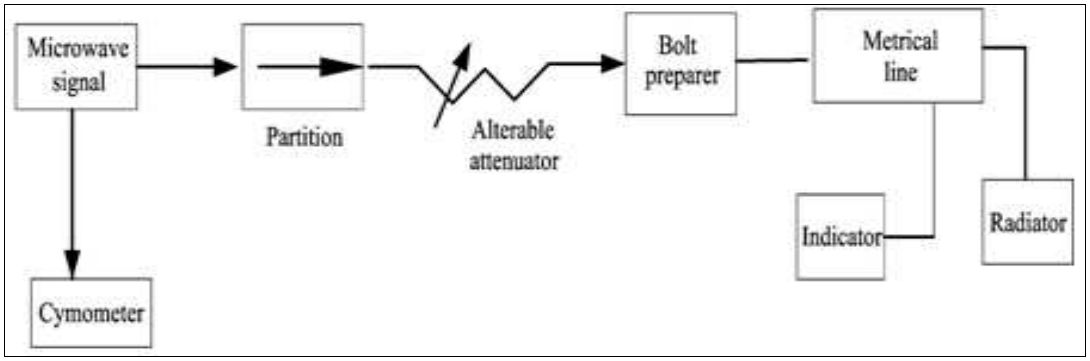

Figure 3. *The principle chart of electromagnetic radiation*

It shows the schematic diagram of domestic sewage sterilization (*Fig. 4*). The diameter of waterpipe is 15 mm; length of 2 m insulated wire wound on a 20 cm long pipeline. The water samples which have different domestic sewage quality were processed by microwave under the identical condition then placed it into incubator about 24 h~48 h (Lu et al., 1996). The plate culture method using detects the number of germs. Three groups constitute a parallel sample contain and each group has three subsets sample. The same water quality domestic sewage as comparison sample, which isn't treatment by microwave. An 828 type pH's apparatuses measure the pH value before and after the sample treated by microwave. It lists the total germs and the corresponding sterilization rate at 40 mins (*Table. 1*). It lists the sterilization rate at

Sample number	The sum of bacteria in original sample (Entries/mL)	The sum of bacteria in worked sample (Entries/mL)	The efficiency of kill bacteria / %
1	3.5×10^6	3.5×10^4	99.0
2	4.9×10^6	3.0×10^4	99.3
3	5.3×10^6	3.2×10^4	99.4
4	1.5×10^7	5.1×10^4	99.7

Table 2. *Sterilization effect under different times*

Sample	*t* /min				
	0	10	20	30	40
1	3.2×10^6	1.92×10^6	8×10^5	3.2×10^4	2.56×10^4
2	3.7×10^6	2.294×10^6	8.88×10^5	2.96×10^4	2.59×10^4
3	5.0×10^6	2.85×10^6	1.25×10^6	5×10^4	3×10^4
4	1.9×10^7	1.045×10^7	4.37×10^6	7.6×10^4	4.75×10^4

The result and discussion

The total amount of germs and the sterilization rate of four kinds of water samples disinfected by microwave at 40 mins are listed in *Table 1*. It can be seen from *Table 1* that the sterilization rate of samples 1 to 4 over reaches 99%, but the electromagnetic sterilization effect of sample 4 is better than sample 1. The data in *Table 2* are obtained for samples irradiated by microwave at different time and the trend of the data is the same, that is, with increasing of irradiation time, the higher sterilization rate (Yanyan et al., 2019). However, different samples have different sterilization rate at the same time. For example, it can be seen from sample 1 and sample 2, the efficiency of sterilization rate of sample 1 is about 57% at 20 mins, while the sample 2 is 76% at the same time. The different sterilization rate between samples may be due to, first, different water

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86558666

samples contained different amounts of bacteria before sterilization. Second, different water samples contained different kinds of bacteria, and thus the electric parameters (permittivity ε, conductivity σ) are different. So microwave energy absorbed is different. In generally, the stronger the microwave energy absorption of bacteria, the better the sterilization rate. If the sample has more fungi, shapeless spores and thermophilric bacteria, then it needs more time to reach the same sterilization effect (Kang, 2018). Therefore, under the same condition, the fewer the sample contained the fungus talked above, the better sterilization effect. The fittest pH value to most bacteria is 7.3~7.8. The pH value of the sample before and after sterilization had been test with 828 type pH's tester. The pH value before sterilization is about 7.4, while after sterilization it is about 7.5. Thus it can be seen that the pH value of sample has slightly changes before and after sterilization, but still between 7.3~7.8. Therefore, the influence brought by the pH value slightly change can be neglected (Li et al., 2019).

Analysis of the mechanism

The mechanism of heating effect

A material may be having many dielectric mechanism or polarization influence. In fact, material loss can be expressed as dielectric loss and conduction loss caused by the electrical conductivity (σ), namely:

$$\varepsilon_{\mathrm{r}}^{''}(\omega) = \varepsilon_{\mathrm{r}}^{''} + \frac{\sigma}{\omega\varepsilon_{\mathrm{O}}} \quad \text{(Eq.1)}$$

Under the action of the electromagnetic wave, the electromagnetic energy is absorbed by material

$$P = \frac{1}{2}\omega\varepsilon_{\mathrm{rd}}^{''}\int_{\mathrm{v}}|E|^2 \mathrm{d}v \quad \text{(Eq.2)}$$

where $\varepsilon_{rd}^{''}$ is dielectric loss of the material, ω is the frequency of electromagnetic wave, and E is the electric field strength.

There exists mass water inside every life body, which distributed in all parts of the living body such as cell membrane, cytoplasm, cell nucleus, cells, tissues, blood and lymph liquid water molecules is polar molecule which has the bigger dipole moment (Cheng and Lin, 1981). At the subcellular level, the orderly biomolecule gathered body also showed significant dielectric properties, such as cell membrane which is bilayer structure dielectric material composed of the lipid molecule. All membrane dipole moments can be fully polarized under the transmembrane resting potential difference and maintain a certain conformation. The force to maintain the conformation of macromolecules primarily is the static electricity of intermolecular and intramolecular (including interaction between dipole and dipole) and other interaction force (for example: van der Waals force). Under the effect of microwave, the negative charges of molecule are distributed again that leads to the change itself of dipole moment and polarization state, which may induce the change of molecule construction. The displace-polarization time of general material establishes needs about 10-16--10-12 s, which can be neglected in microwave scope (microwave priod is 10-9--10-12 s). However, the dipole needs long time which over 10-10 s. For example, water molecules have a strong

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86558666

intrinsic dipole moment and its relaxation time is 0.25×10-10 s which justly in the scope of microwave, therefore the attenuation effect of water to microwave is bigger than the general material (Zhai et al., 1998), The polarization would appear hysteresis phenomenon which produce the dielectric loss. With the dielectric method of time domain reflection, it has been found that there has significant dielectric loss in the vicinity of 10 MHz when natural DNA was dissolved degeneration (Richard and Stephen, 1998). It can be seen that the thermal effect is more notable at the condition of a higher frequency and a bigger of from the *Equations 1 and 2* under the affection of microwave. These dipoles constantly change from one equilibrium state to another equilibrium state, a molecule dipole would frequently colliding with surrounding other molecules in this course, thus the microwave energy consumed and converted into heat. When the temperature exceeds the temperature of microbes to survive, it will lead to germ death, which is identical to the mechanism of pasteurization (Li, 2018).

The mechanism of non-heating effect

The microwave non-heating mechanism of the body has related discussion (Liu and Wang, 2003), but there is no unified knowledge and many kinds of hypothesis are put forward. Main hypothesis such as cell membrane perforation effect, Ion cyclotron resonance model, Ion parametric resonance model, State parameter representation, an electromagnetism mechanism model ect. The cell membrane perforation effect argues that the cell membrane is a kind of phospholipid bilayer construction which has certain permeability, a certain degree of toughness and a certain charge is absorbed to the surface. Therefore, there has certain potential difference between the inner and outer surface of membrane. The potential difference will be enlarged when an electric field is applied membrane, at this time the permeability of cell membrane also increases. The permeability of cell membrane would dramatic increase and many holes will appear on the membrane which reduces the toughness of membrane when the electric field strength to the critical value. Since the special structure of the cell membrane, it will produce an adaptive adjustment trying to maintain the original way of life, the membrane can control the outside influences within the capacity of the adaptive and the life living with original method (Li et al., 2019). If the outside influences exceed the body's adaptive capacity, which may produce the variations and lead to new existence method. If outside influences exceeded the limit of adaptation, it will destroy the original structure of membrane and lose their function can't be restored, thus cell death. The experiment proves there has clear rift on the cell after the yeast was killed (Jayaran et al., 1994). Though bacterial cell structure is small but there no essential difference of internal structure between general biological cell and bacterial cell. The main effect of electromagnetic wave on the cell is at the cell membrane. Under the condition of resting, the transmembrane resting potential difference of cell membrane is 60~100 mV, which is mount to 107 V/m strong electric field, therefore all dipole moments of the membrane can be full polarization under the strong electric field action. Therefore, it is not hard to understand the electromagnetic field can play significant effect on the membrane (Shan et al., 2018).

With the spherical cell as the research object, the transmembrane voltage Uion is formed due to ion accumulation and transmembrane transport both side of the membrane under the resting state, the Uion value can be calculated from the Goldman's equation (Plonsey and Barr, 2000).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86558666

$$U_{\text{ion}} = \frac{RT}{F} \ln \frac{P_{\text{K}}\left[K^{+}\right]_0 + P_{\text{N}_\text{a}}\left[N_{\text{a}}{}^{+}\right]_0 + P_{\text{Cl}}\left[Cl^{-}\right]_0}{P_{\text{K}}\left[K^{+}\right]_{\text{i}} + P_{\text{N}_\text{a}}\left[N_{\text{a}}{}^{+}\right]_{\text{i}} + P_{\text{Cl}}\left[Cl^{-}\right]_{\text{i}}} + \Delta U \quad \text{(Eq.3)}$$

In this state, the membrane permeability to K^+ ion is much larger than Ca^{2+} ion and Na^+ ion. At this moment the ion channels are closed to Ca^{2+} ion and Na^+ ion. Under the applied additional alternating electric field E, the interior cytoplasm and the external medium of the cell as good conductor and the cell membrane as a dielectric. The induced transmembrane voltage UE is superimposed on Uion. According to the classical theory of cell membrane induction electromotive force (Tadej and Damijan, 2000), the induction electromotive force UE is generated on both sides in the cell membrane is

$$U_{\text{E}} = \frac{3}{2} E_{\text{e}}(t) R \cos\alpha \frac{1}{1 + j\omega\tau_{\text{m}}} \quad \text{(Eq.4)}$$

where Ee(t) is outer electric field intensity, R is the cell radius, α is the angle of between the external electric field direction and the axial of ion channels, $\omega = 2\pi f$, f is frequency of the applied electric field, and τ_m is the inductive time constant of membrane that can be expressed through first-order system as:

$$\tau_{\text{m}} = \frac{RC_{\text{m}}}{\frac{2\lambda_{\text{i}}\lambda_{\text{e}}}{\lambda_{\text{i}} + 2\lambda_{\text{e}}} + \frac{R}{d}\lambda_{\text{m}}} \quad \text{(Eq.5)}$$

where Cm is the equivalent capacitance of the cell membrane, λ_i, λ_e and λ_m is respectively the conductivity of inside and outside of cell membrane and the cell membrane, *d* is the average thickness of the membrane (Yang, 2018).

From *Equations 4 and 5*, we know that the amount of change of cell transmembrane potential has relation with the electromagnetic wave field strong and power, has relation with the cell type and size, has relation with the intracellular fluid and extracellular fluid dielectric constant and conductivity (Li, 2018). The external electric field causes the membrane voltage change, thereby enabling the ion permeation rate change of the cell membrane. The ion permeation ratio is direct proportional to the change of membrane voltage caused by the external electric field (Zhang et al., 2004). The studies have shown that Ca^{2+} ion channel is a voltage dependent of membrane. Some kinds of channel activity of K^+ ion and Na^+ ion are relation with Ca^{2+} ion. So the influx of Ca^{2+} ion may also cause the channel open of K^+ ion and Na^+ ion. When the influx volume increasing of Ca^{2+} ion. The influx of Na^+ ion is predominated, while the influx of Ca^{2+} ion can open K^+ channel that is relies on Ca^{2+} ion, which make the outflow of K^+ dominant. Under the action of an applied electromagnetic field, the external electric field, the cell transmembrane potential increases, when the membrane voltage is increased to a certain value so that the voltage-dependent Ca^{2+} ion channels open, the larger concentration of Ca^{2+} ion outside the cell membrane into the cell along the potential gradient (Yang et al., 2018). The experiment and theoretical indicate that the greater the change in cell membrane voltage, the higher the rate of cell death. In addition, from the dielectric properties of the cell membrane to see, the role of the applied voltage causes the inside and outside charge density of cell membrane will

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86558666

change. The cell membrane surface charge density and the pressure difference between inside and outside of the cell membrane has the following relationship (Gao et al., 2002)

$$\Delta P_{\mathrm{E}} = \frac{\left(\sigma_{\mathrm{i}}^2 + \sigma_0^2\right)}{2\varepsilon_0} + \frac{\sigma_0 \sigma_{\mathrm{i}} r_{\mathrm{i}}}{\varepsilon_0 r_0} \quad \text{(Eq.6)}$$

where σ_i is the surface charge density of the inner surface of cell membrane, σ_0 is the surface charge density of the outer surface of cell membrane, r_i is the curvature radius of the inner membrane, and r_0 is the curvature radius of the outer membrane (Hai et al., 2017).

From *Equation 6*, we know that the greater the surface charge density, the greater the pressure difference between inside and outside of the cell membrane, and thus an impact on the ion channel Open and close (Amit et al., 2017). When the effect of above combination factors exceeds the limits of adaptive of membrane, the original structure of the membrane was destroyed and could not be restored, the cell death, the purpose of sterilization is achieved. The non-heating effect of electromagnetic biological less significant than the thermal effects of electromagnetic biological, it requires a process of accumulation.

Outlook

With the continuous enrichment of material life, people's demand for domestic water is also increasing. The reserves of water resources on the earth are limited and they are non-renewable natural resources (Yanyan et al., 2019). Urban sewage treatment and reuse can effectively solve the shortage of urban water resources, and at the same time reduce environmental pollution, strengthen water recycling and sewage utilization rate, and achieve sustainable development of urban water resources (Kang et al., 2018). Therefore, in the process of treating urban domestic sewage, it is necessary to adhere to the principle of sustainable development and energy conservation and consumption reduction to ensure that urban domestic sewage treatment technologies and treatment processes can meet these requirements in practical applications (Shan et al., 2019).

The microwave sterilization technology can also serve the domestic sewage treatment well. The pathogens such as worm eggs, enteroviruses and pathogenic bacteria can be killed by using the combined action of the biological heating effect and biological non-heating effect. This method is a physics method, there is no obvious chemical treatment, the composition and structure of water was not change and sterilization fast. Compared with traditional domestic sewage treatment and sterilization technologies such as liquid chlorine, chlorine dioxide and ultraviolet sterilization, microwave sterilization technology not only has high sterilization efficiency, no secondary pollution, broad spectrum of sterilization, no noise, no odor, etc. (Yang et al., 2018). All the advantages of the technology, but also have the advantages of stable control system, long service life, low operating cost, excellent energy saving, safe and reliable, easy maintenance, and the ability to provide residual sterilization (Zhang et al., 2017). In order to better promote the technology, the utilization of microwave energy conversion and the expansion of the application range of microwave technology should be paid attention to by the industry. It should popularize the use of the technology on a

large scale, so that the technology can gradually replace some traditional technology and sterilization technology in the future life more efficient, environmentally friendly and more convenient for human production and life (Zhang, 2017).

(Received 8th Mar 2019; accepted 21st May 2019)

Abstract. The chemical composition of dissolved constituents in aquatic ecosystems is of fundamental importance in regulating chemical and biological dynamics and processes. There are many factors that can determine and affect chemical composition of lakes and rivers. This paper presents fundamental geochemical information for the waters in Qinghai Lake area in China and assesses geochemical patterns, relationships between the elements, and potential mechanisms for these patterns. The concentrations of 30 elements from 16 water samples were measured. The results showed that Ca (8.1-88.9 mg/L), K (5.1-372.7 mg/L), Mg (6.3-1127.0 mg/L), Na (10.0-6459.0 mg/L), and S (4.8-2002.0 mg/L) were the dominant elements in all water samples but exhibited considerable variation among systems. The tributaries had high Ca, relatively low Na+K, and low salinity, indicating rock weathering as the dominant factor determining their geochemistry. The satellite lakes (except the two largest ones) showed low Ca, moderate Na+K and Mg, and low salinity, indicating the combined effects of many factors. Correlation analyses suggested that B, K, Li, Mg, and Na concentrations are determined by evaporation and crystallization and dissolution of sulfate minerals while Al and Fe concentrations are affected mostly by rock weathering.

Introduction

Major and trace elements are natural components in aquatic ecosystems worldwide and play important roles in chemical and biological processes (Gaillardet et al., 2003; Bounouira et al., 2013; Qin et al., 2015; Sunny et al., 2018). Some trace elements are commonly required by biota due to their key role in biosynthetic processes and metabolism as cofactors for enzymes (Havig et al., 2015; Daniel et al., 2018). These elements include aluminum (Al), boron (B), chlorine (Cl), chromium (Cr), cobalt (Co), copper (Cu), fluorine (F), iodine (I), iron (Fe), manganese (Mn), molybdenum (Mo), nickel (Ni), selenium (Se), silicon (Si), tin (Sn), vanadium (V), and zinc (Zn) (Çelik and Oehlenschläger, 2007; Tuzen, 2009; Mahmood et al., 2018). However, due to their toxicity, non-degradability, persistence, and bioaccumulation, trace element pollution of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86678678

the environment has become one of the most serious global issues in recent years (Tam and Wong, 2000; Cui et al., 2011; Hsieh et al., 2013; Li et al., 2015). Indeed, even bioessential elements will yield toxic effects at high concentrations (Goldhaber, 2003; Anan, 2019).

Major and trace elements are added to an aquatic ecosystem through different pathways, including geological erosion, atmospheric deposition, or anthropogenic sources (Vystavna et al., 2012; Al Abdullah et al., 2014; Shakeri et al., 2014; Xu, 2018). Under natural conditions, the chemical composition of aquatic ecosystems is determined by the weathering of terrigenous minerals, evaporation and crystallization, and precipitation (Négrel et al., 1993; Liang and Wenshun, 2019). Elements originated from rock weathering are transported to downstream water bodies through streams and rivers, carrying the characteristic features of their source's lithology. Upon reaching standing water, evaporation and crystallization are important mechanisms that produce Na-rich and highly saline lakes and ponds, due to sodium's high solubility (Gibbs, 1970). In addition, concentrations of various elements in aquatic systems can be strongly altered by anthropogenic activities, including mining, wastewater discharge, atmospheric deposition, and fertilizer runoff (Yang and Rose, 2005; Yu et al., 2014; Hayzoun et al., 2015; Lynam et al., 2015; Otachi et al., 2015; Baharuddin and Samsudin, 2018). Even remote lakes are not exempt from contamination by the long-range transported trace elements (Battarbee et al., 2009; Elser et al., 2009; Kyllonen et al., 2009). Thus, geochemical signatures of rivers and lakes are determined by and in turn provide important information about the geology of the area, types of rock weathering, anthropogenic activities, biological processes, and atmospheric deposition in drainage basins (Foster and Charlesworth, 1996; Xu et al., 2010; Singh et al., 2015; Walther and Nims, 2015; Wang et al., 2018).

Qinghai Lake, located on the northeastern margin of the Qinghai-Tibet Plateau, is an endorheic brackish lake and the largest natural lake in China. It is also a globally important wetland for biological diversity conservation (Ramsar, 2015; Sarker et al., 2019). However, due to global climate change and human activities, the lake level declined by 4.33 m from 1955 to 2005 and grassland degradation in its catchment has expanded to 37% of the whole watershed area in 2010 (Li et al., 2007, 2009; Chen et al., 2011; Luo et al., 2013). Because of its fragility, sensitivity to global climate change and anthropogenic impacts, and its importance in maintaining ecological security of northeast Qinghai-Tibet Plateau, the Qinghai Lake watershed has recently become an intensive place for research (An et al., 2006; Hao, 2008; Barakat et al., 2018). Furthermore, this area has special hydrological and limnological characteristics. Adjacent to the main lake, there are a number of "satellite lakes"; these are separated from the main lake by barrier dunes and do not receive river or stream inflows (except Erhai Lake, which receives stream inflow). In contrast, the main lake has more than 40 tributaries. Reflecting these differences, Qinghai Lake and the satellite lakes are significantly different from each other in biological, chemical, and hydrologic conditions (Liu et al., 2009; Ao et al., 2014; Meng et al., 2014; Rawat and Singh, 2018). Previous studies of Qinghai Lake have focused on the reconstruction of the region's paleoenvironment and paleoclimate, geology, hydrology, ecological management, hydrobiology, fishery resources, climate change, soil, and sediment geochemistry and have especially emphasized the main lake (Shi et al., 2004; Henderson and Holmes, 2009; Cao and An, 2010; Jin et al., 2010; Liu and Lai, 2013). However, integrated and comparative studies on multi-element geochemistry in the main lake, its satellite lakes,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86678678

and tributaries are lacking. Hence, both from a fundamental and an environmental point of view, it is crucial to assess the geochemical signatures of the aquatic ecosystems in Qinghai Lake area. The main objectives of this study were: (1) to document the basic geochemistry of Qinghai Lake, its adjacent lakes, and its inflowing rivers; (2) to identify the geochemical patterns of elements in those systems; (3) to evaluate possible determinant mechanisms causing these differences. The results provide an integrative view of the geochemical characteristics, distribution patterns, and processes of Qinghai Lake area.

Materials and methods

Study area

Qinghai Lake (QL, 36°32′ - 37°15′ N, 99°36′ - 100°47′ E) is a remote endorheic saline lake located at 3194 m above sea level on the Qinghai-Tibet Plateau and lies at a junction of three major climatic systems, the Westerlies, the East Asian, and Indian summer monsoons (An et al., 2012; Chen et al., 2015). It is the largest lake in China with a surface area of 4260 km^2, a catchment area of 29,660 km^2, and an average depth of 21 m. Mean annual precipitation in the basin is 389.1 mm and average annual evaporation is 895.4 mm. Annual mean temperature is -0.3°C with a linear warming rate of 0.28°C /10a. More than 40 rivers and streams flow into Qinghai Lake but most of them are seasonal. There are five main tributaries: the Buha River (BHR), the Shaliu River (SLR), the Haergai River (HER), the Quanji River (QJR), and the Heima River (HMR). Together, these contribute 83% of the total runoff. On the eastern margin of Qinghai Lake there are number of satellite lakes, separated from the main lake by barrier dunes or sand bars (Li et al., 1996). None of the satellite lakes have stream inflows with the exception of Erhai Lake which receives input from the Daotang River (DTR).

Sampling

Field surveys were conducted in late July 2015. A total of 16 water samples was collected, including 10 lake samples and 6 river samples (*Fig. 1*). Of the 10 lake samples, 3 were collected from Qinghai Lake (QL-1, QL-2, and QL-3) and the others were collected from 7 satellite lakes (Moon Lake (ML), Sun Lake (SL), Lanhua Lake (LHL), Ganzihe Lake (GZL), Erhai Lake (EHL), Haiyanwan Lake (HYL), and Gahai Lake (GHL)). Because there was no boat available to reach the center of the lakes, lake water samples were taken from sites about 20-30 m away from the edge of the lakes at depths>50 cm. River water samples were collected in the deepest part of the channel at depths of ~10 cm. All water was filtered through 0.2-μm GF/F filters, stored in 100-ml acid-cleaned polyethylene bottles, fixed with 0.1 ml of concentrated nitric acid, shipped to the laboratory under refrigeration, and frozen until analysis.

Analyses

Element concentrations in the water samples were measured using an Inductively Coupled Plasma Optical Emission Spectrometer (ICP–OES). There were 30 elements measured in total: Ag, Al, As, B, Ba, Be, Bi, Ca, Cd, Co, Cr, Cu, Fe, K, Li, Mg, Mn, Mo, Na, Ni, P, Pb, S, Sb, Se, Si, Sr, Tl, V, and Zn.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86678678

Cluster analysis (CA) and Analysis of Variance (ANOVA) were performed to assess general patterns of element concentrations. A Gibbs plot was used to assess the dominant determining mechanisms. Correlation analyses were conducted to identify between-element associations. All the analyses and graphs were done using SPSS 20.0 and ORIGIN 9.2.

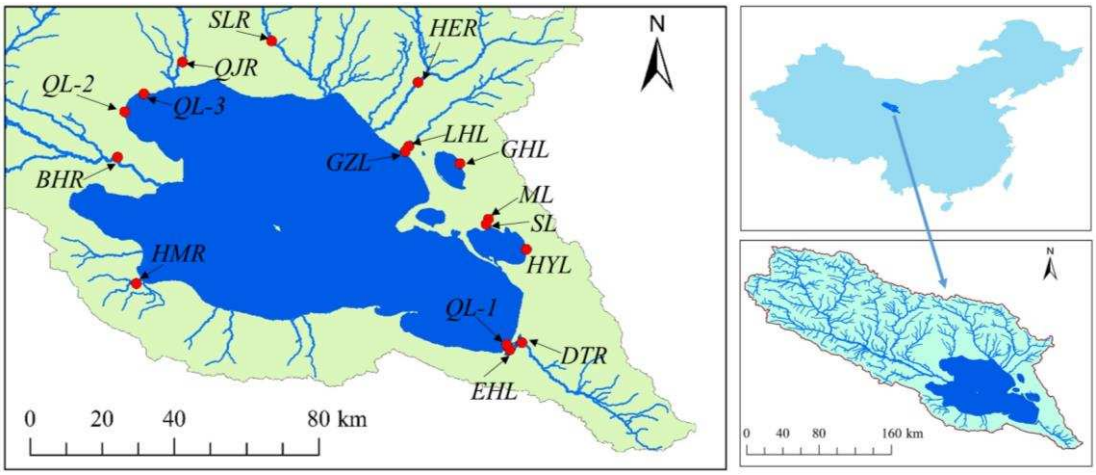

Figure 1. *Study area and sample sites. HMR, DTR, HER, SLR, QJR, and BHR are river sample sites. EHL, HYL, SL, ML, GHL, GZL, LHL, QL-1, QL-2, and QL-3 are lake sample sites*

Results and discussion

Basic geochemical patterns

The concentrations of studied elements in the water samples are shown (*Table 1*). Concentrations of Cr and Sb were below the limits of detection for all sites. Arsenic was detected only in the main lake and the two satellite lakes. P was detected only in five satellite lakes and one tributary (Heima River) with low concentrations (3.8-22.2 μg/L), indicating that the waters in Qinghai Lake area are oligotrophic, especially the main lake. Ca (8.1-88.9 mg/L), K (5.1-372.7 mg/L), Mg (6.3-1127.0 mg/L), Na (10.0-6459.0 mg/L), and S (4.8-2002.0 mg/L) were the dominant elements in all water samples (>1 mg/L, *Table 1*), with a high CV of 88.21%, 209.78%, 132.49%, 158.26%, and 163.37%, respectively. The coefficient of variation (CV) also showed that 22 elements had a CV higher than 50%, which means that most of the element distributions have very high variation.

Cluster Analysis (CA) of the chemical data grouped the samples into four statistically significant clusters: main lake cluster (including HYL and GHL), satellite lake cluster, tributary cluster (excepting DTR), and DTR (*Fig. 2*). DTR was separated from the tributary cluster because of higher concentrations for most elements, which might be caused by intensive anthropogenic activities and low runoff. Based on the ANOVA analysis, the main lake cluster had significantly higher Ag, B, Co, Li, Mg, Na, S, and Ti concentrations ($P<0.05$) than the satellite lake cluster but significantly lower V concentration ($P<0.05$). Compared to the tributary cluster, the main lake cluster had significantly higher concentrations of B, Co, Li, Mg, Na, S, and Ti ($P<0.05$) but significantly lower Al, Ca, Cu, and V concentrations ($P<0.05$). Relative to the tributary cluster, the satellite lake cluster had significantly higher Mg ($P<0.05$) but significantly

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86678678

lower Ag, Al, Ca, and Cu concentrations ($P<0.05$). HYL and GHL are the two largest satellite lakes and are separated from the main lake by sand bars, which likely allowed some degree of hydrological connectivity. Thus, it is not surprising that GHL and HYL were grouped in the main lake cluster. Nevertheless, GHL had higher concentrations of B, K, Li, Mg, Na, and S than HYL and these concentrations in HYL were higher than in the main lake. Other satellite lakes are surrounded by grassland and are considerably smaller. Their chemical composition is likely to be more easily affected by the terrestrial environment as well as precipitation and in-lake biological processes.

The relative amounts of the dominant elements (Na, K, Ca, and Mg) in the water samples can be seen more clearly in the ternary diagram (*Fig. 3*). The main lake cluster is grouped in the high Na+K sector but with low Mg and Ca. In contrast, the satellite lake cluster was grouped in the middle of the diagram with low Ca but relatively high Mg and Na+K. The tributary waters were very different from the lake waters, situated in a sector with high Ca but relatively low Mg and Na+K. Overall, Ca was the most abundant element in tributaries.

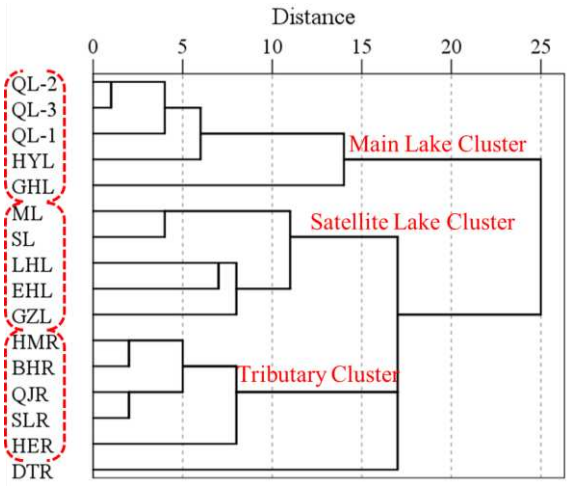

Figure 2. *Cluster dendrogram of the sample sites based on the studied elements*

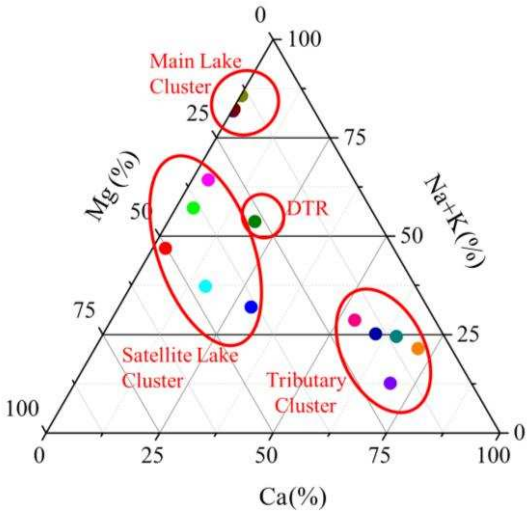

Figure 3. *Ternary diagram of dominant elements in the water samples*

Determinants of water geochemistry

There are three main factors that determine surface water geochemistry: evaporation and crystallization, rock weathering, and precipitation. The relative importance of these factors can assessed via the relationship between total dissolved solids(TDS) and the weight ratio of Na/(Na+Ca). In this model, water with high TDS and high Na (high Na/(Na+Ca)) has chemistry dominated by evaporation and crystallization, while waters

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86678678

with moderate TDS and high Ca (low Na/(Na+Ca)) are dominated by rock weathering and those with low TDS and high Na are dominated by precipitation. The water samples from Qinghai Lake's tributaries are located in the middle part of the plot (*Fig. 4*), indicating that rock weathering is the dominant factor determining their chemical composition (Ca-rich and moderate salinity) of the tributaries.

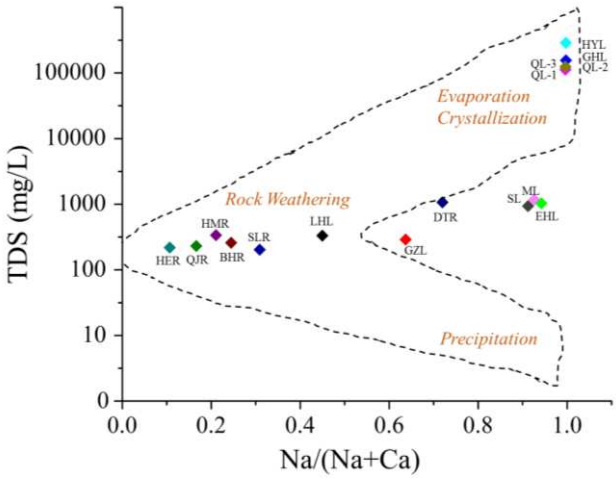

Figure 4. *The relationship between TDS and the weight ratio Na/(Na+Ca) in the water samples (the dash line is cited from Gibbs 1970)*

In contrast, the water samples from the main lake, HYL, and GHL are Na-rich and high in salinity (*Fig. 4*), indicating the evaporation and crystallization are the dominant determining factors for those lakes. Other water samples, which are mostly from the satellite lakes, are located in a zone intermediate between the precipitation end and the evaporation and crystallization end (*Fig. 4*), indicating that combination of factors determines the water geochemistry of the satellite lakes, including evaporation and crystallization, rock weathering, precipitation, hydrology, and biological processes (Shiller, 1997; Zwolsman and Van Eck, 1999).

The relationships between elements

The relationships between elements may provide further insights into their sources or the processes affecting the overall geochemical composition (Mwanamoki et al., 2015). If the elements show high correlation, they likely originated from the same source or are affected by similar mechanisms. *Table 2* shows correlation relationships for the elements that had higher average concentrations (>0.01 mg/L) in the water samples. B, K, Li, Mg, S, and Se all had significantly positive relationships with Na, indicating that they are strongly affected by evaporation and crystallization processes. B, K, Li, Mg, S, and Se also had significantly positive relationships with each other, consistent with joint regulation via interactions with Na solubility during evaporation and crystallization. In contrast, Al and Si had significant relationships with Ca, indicating that they were largely determined by rock weathering. Al and Fe also showed significantly positive relationships with Si, indicating a source associated with silicate weathering. Moreover, there was a significant relationship ($r=0.88$, $P<0.01$) between Ba and Sr. Ba and Sr have

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86678678

similar geochemical behavior, and their concentrations are largely determined by geological composition of the drainage basin and weathering processes (An et al., 2006; Watmough, 2014; Fu et al., 2018). In the water samples, the main lake cluster had very high S concentrations (697.7-2002.0 mg/L), followed by tributaries (6.6-53.2 mg/L) and satellite lakes (4.8-52.4 mg/L). S also had significantly positive relationships with B, K, Li, Mg, and Na, suggesting that sulfate mineral dissolution is another possible source of these elements in Qinghai Lake regional waters.

Conclusion

This paper reports patterns in the aqueous geochemistry in the main lake, satellite lakes, and tributaries in Qinghai Lake area, including basic water geochemistry information. Our analyses provide an integrated and comparative view of the multi-element geochemistry among different waters in this particular area. The element distributions in the waters varied considerably. In general, the main lake had higher concentrations of most elements than the satellite lakes and the tributaries. However, the two largest satellite lakes showed the highest concentrations of B, K, Li, Mg, Na, and S. The satellite lakes seem to have different degrees of communication with the main lake and with external influences. The geochemical differences among the lakes may necessitate different physiological adjustments among aquatic biota in coping with the geochemical environment. Meanwhile, the low P concentrations that we document indicate the aquatic ecosystems in Qinghai Lake are oligotrophic or ultra-oligotrophic and thus likely sensitive to changes in external nutrient loading, such as inputs from non-point (fertilizer runoff) or point (sewage outfalls) sources. Therefore, further studies with more extensive biological and chemical scope and taken from whole watershed are recommended to better understand the lake basin's spatial geochemistry patterns and consequently to assess the effects of geochemical variations on biological and ecological processes in the aquatic ecosystems in Qinghai Lake area.

Abstract. In order to reduce the emission of ecological environment and the pollution of ecological environments and improve the sustainable development of ecological economy, so an improved model of the wavelet (War) based on the improved gravity optimization algorithm (IGSA) is proposed (IGSA-War). The method uses an improved gravitational algorithm to optimize the wavelet, establish an optimization model, and predict the different NOx emissions of coal-fired boilers. Firstly, the grid algorithm is used to initialize the population, and the particle is updated based on the fitness value adaptive decrements inertia weight. Numerical simulation results verify the effectiveness and superiority of the proposed algorithm (López-Hernández, 2018). Then the IGSA is used to optimize the selected hyper-parameters to improve the prediction accuracy and generalization ability of the model; the wavelet model optimizes the noisy emission data to reduce the impact of noise on the system. Finally, taking the discharge of 330 MW coal-fired boiler in a thermal power plant as the research object, the NOx soft measurement model of IGSA-War is established. The simulation results show that the optimization model has high prediction accuracy and generalization ability, and can effectively measure NOx emissions.
Keywords: *nitrogen oxide, gravitational algorithm, wavelet model, IGSA-War, numerical optimization*

Introduction

With the rapid development of chinese economy, ecological deterioration has become an important factor constraining economic development. emissions are in a deteriorating state (Tan and Xia, 2014; Niu et al., 2016; Khanchoul et al., 2018). In order to effectively predict and rationally manage ecological NOx, [something has to be done] thereby reducing NOx emissions and establishing a predictive model of NOx (Lv et al., 2017; Hossain et al., 2019). Artificial intelligence technology is a typical representative of neural network and support vector machine due to its good ability to deal with non-linearity (Li et al., 2003; Zhang et al., 2015; Franco et al., 2018), which can better solve the problem of NOx modeling. In the NOx model prediction process,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86798691

the support vector machine (Rashedi et al., 2009; Niu et al., 2014; Nouaim et al., 2019), has received more and more attention in the modeling of NOx emissions due to the lack of over-fitting and generalization of neural networks. The NOx emission prediction problem has complex non-linearity, mufti-dimensional mufti-mode, and few data samples, and needs to solve the problem of structural risk minimization. How to obtain the optimal super-parameter is the key to the accuracy of NOx emission model (Yazdani et al., 2014; Gouthamkumar et al., 2015; Azeem et al., 2018). In fact, the wavelet analysis hyper-parameter adjustment process is also a parameter optimization process. The combustion optimization based on wavelet and optimization technology is an effective way to reduce NOx emissions of boilers (Liu and Niu, 2015; Sharjeel et al., 2019).

Materials and methods

Basic Principles of GSA Algorithm

In the GSA, the position $\{X_i\}, i=1,2,\cdots,N$ of each particle is a feasible solution to the optimization problem, (Pascual-Córdova, 2018) and N is the size of the population, where the position of the i-th particle is $X_i=(x_i^1,x_i^2,\cdots,x_i^s)$, and s is the dimension of the optimization problem. The GSA is based on the fitness value and uses the *Eq.1* to update the quality of the particle:

$$\begin{cases} m_i(t)=\dfrac{fit_i(t)-worst(t)}{best(t)-worst(t)} \\ M_i(t)=\dfrac{m_i(t)}{\sum_{j=1}^{N} m_j(t)} \end{cases} \quad \text{(Eq.1)}$$

where $fit_i(t)$ is the fitness value of the i-th particle; for minimization: $best(t)=\max\limits_{j\in\{1,\cdots N\}} fit_j(t)$, $worst(t)=\min\limits_{j\in\{1,\cdots N\}} fit_j(t)$.

At a specific time t, the gravitational force acting between particle j and particle i is defined as:

$$F_{ij}^d(t)=G(t)\frac{M_i(t)\times M_j(t)}{R_{ij}(t)+\varepsilon}\left(x_j^d(t)-x_i^d(t)\right) \quad \text{(Eq.2)}$$

where M_i and M_j are the masses of the mass points; ε is a smaller constant; $R_{ij}(t)$ is the distance between the mass points; $G(t)$ is the gravitational constant. Then the resultant force acting on the d-th dimension of the i-th particle is:

$$F_i^d(t)=\sum_{j=1,j\neq i}^{N} rank_j F_{ij}^d(t) \quad \text{(Eq.3)}$$

where $rank_j$ is a random number in [0, 1].

Through the law of motion, (Espinoza, 2017) the acceleration of the mass point i in the d dimension at time t:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86798691

$$a_i^d(t) = \frac{F_i^d(t)}{M_i(t)} \quad \text{(Eq.4)}$$

In the GSA algorithm, the speed and position of the particle are updated as follows:

$$\begin{cases} v_i^k(t+1) = rank_i \times v_i^k(t) + a_i^k(t) \\ x_i^k(t+1) = x_i^k(t) + v_i^k(t+1) \end{cases} \quad \text{(Eq.5)}$$

where $rank_j$ is a random number in [0, 1].

Improved GSA algorithm

Although the GSA algorithm has better optimization performance, when dealing with some complex optimization problems, GSA still has the disadvantages of premature convergence and easy to fall into the local optimal solution. Therefore, its ability to seek still needs further improvement.

Grid-based algorithm for initializing populations

The first step in the GSA algorithm is to initialize the population. (Jaimes, 2017). A good initial population that covers the entire solution space can help improve the speed of evolution and improve the quality of the solution. If the local solution space containing the global optimal solution is not in the initial group space, and the position update algorithm of the particle cannot extend the coverage space to the region where the global optimal solution is located within a finite number of evolution, premature convergence is not possible. Avoid, it can be seen that the distribution of the initial population individuals directly affects the global convergence performance of the algorithm. The initial population of the original GSA algorithm is randomly distributed, and its coverage space has a large uncertainty. In this paper, the grid algorithm is used to initialize the position group of the particle, so that the initial individual is evenly distributed in the sea, and its expression is as a *Eq.6*:

$$x_i^k = \min(k) + \frac{\max(k) - \min(k)}{n-1} * i \quad \text{(Eq.6)}$$

where: x_i^k represents the k-th component of the i-th (i = 1, 2, ..., N) motion mass points; $\max(k)$, $\min(k)$ are the upper and lower bounds of the k-th component.

It is not difficult to find that the population is initialized by gridding, so that the ergodicity of the population can be improved under the premise of ensuring the randomness of the initial variables, so that the algorithm traverses all possible states, (Dager, 2017) which is beneficial to overcome the general random initialization of the population and the optimization algorithm search. Limitations.

Adaptive weight based on fitness value

In order to further improve the optimization performance of the GSA algorithm and avoid the premature phenomenon appearing in the optimization of complex high-dimensional multi-mode functions, (Olivares et al., 2017) the researchers have carried out a lot of research work and proposed a linear decreasing weight strategy. Although it

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86798691

is beneficial to improve the optimization performance to a certain extent, (Li and Zhao, 2017; Kumar, 2018) the algorithm does not take into account the fitness value of the optimization problem, and it may reduce the optimization performance when dealing with some complex nonlinear optimization problems. Therefore, based on the linear decreasing inertia weight, this paper proposes an adaptive decreasing inertia weight position update strategy based on the fitness:

$$\begin{cases} t_i = (t_{start} - t_{end}) \frac{maxier - i}{maxiter} + t_{end} \\ \Phi_{fit} = \frac{2}{1 + e^{-\frac{fit_i}{maxiter}}} \\ w_i = \Phi_{fit} * t_i \end{cases} \quad \text{(Eq.7)}$$

where t_{start} and t_{end} are the initial value and the final value, respectively, and $0<t_{end}<t_{start}<1$, $maxier$ and i are the maximum number of iterations of the GSA and the current algebra, respectively, t_i is the linearly decreasing inertia weight, and Φ_{fit} is the fitness value factor whose value fit changes, w_i is an adapt decreasing inertia weight.

Substituting *Eq.7* into equation *Eq.5* to obtain the position update formula of the particle:

$$x_i^k(t+1) = w_i * x_i^k(t) + v_i^k(t+1) \quad \text{(Eq.8)}$$

w_i determines the domain range generated by x_i^k. This range will decrease correspondingly as the search approaches the optimal solution, which will help the GSA to better use prior knowledge to improve the optimization ability of the algorithm.

IGSA optimization steps

Figure 1 shows a flow chart of the improved IGSA algorithm. The specific steps are as follows:

1) Initialization parameters: maximum number of iterations max=1000, population number N=50;
2) The grid algorithm initializes the population;
3) Calculating the fitness value of the population point;
4) update data $\mathrm{G(t)}, \mathrm{best(t)}, \mathrm{worst(t)}$ and $\mathrm{M}_i, i = 1,2,\ldots,N$;
5) Update the resultant force of the particles in all directions according to *Eq.3*;
6) Calculate the velocity of the particle according to *Eq.5*;
7) Update the position of the mass point according to *Eq.7* and *Eq.8*, t_{start} and t_{end} are set to 1 and 0, respectively;
8) Repeat steps (3)~(7) until the stop condition is met.

IGSA performance verification

Complex function optimization has become a research hotspot in the field of optimization algorithms. This paper selects 13 standard functions to evaluate the optimization performance of IGSA. f1~f7 are single-mode functions with only one extreme point. They are mainly used to investigate the execution ability of the algorithm (Chen et al., 2017) and test the optimization precision of the algorithm; f8~f13 is a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86798691

multi-modal function, which has a large number of local best advantages, and is a well-recognized function that is well-recognized in the optimization field. Most optimization algorithms often seek to optimize them. Will fall into the local best, they are mainly used to test whether the algorithm has the ability to avoid premature and search for the global optimal solution, except for the minimum value of f8 is -418.9829 × n (n is the dimension of the solution), the other 12 functions. The minimum values are all zero. Reference (Liu et al., 2015; Rajput et al., 2019) describes in detail the range of values for the standard function solution, and points out that the original GSA is superior to PSO, RGA and CFO. This paper will conduct a comparative study of IGSA and the original GSA algorithm (Kang et al., 2017, 2018; Zulkapli et al., 2018).

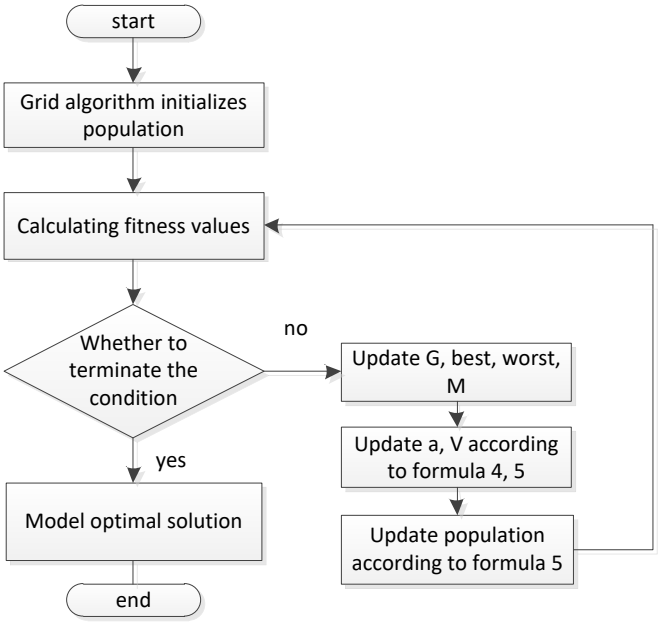

Figure 1. *The program flowchart of IGSA*

In order to effectively reduce the impact of random interference, each runs independently 30 times. *Table 1* gives the statistics data of the average convergence iteration number (CI), average optimal fitness value (Mean) and standard deviation (SD) of the function in 30-dimensional and 50-dimensional cases.

Observe and analyze the optimization results of the 13 standard test functions given in *Table 1*. It is found that for the single-mode function, except for f6, in the three algorithms, (Zhang and Khalique, 2018) whether the function is 30 or 50, the optimization effect of IGSA is the best. And the advantages are obvious; for multi-modal functions, except for f12, the optimization effect of IGSA is the best. Therefore, the superior solution of IGSA has the highest accuracy compared to GSA. At the same time, (Pang et al., 2016) it is found that when n=50, the optimization precision of IGSA is basically close to the accuracy of n=30, which indicates to some extent that the optimization effect of IGSA has not been weakened as the complexity of the problem increases. In comparison, with the increase of the dimension of GSA, most of the optimization effects show a downward trend (*Table 1*).

The standard deviation reflects the robustness of the algorithm, and the average function convergence times C.I. reflects the computational convergence speed of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86798691

algorithm. It can be seen from *Table 1* that ABC and GSA can't always solve the 13 standard functions accurately. It can be clearly observed that the optimization performance of IGSA is more accurate than that of GSA, and the ability to jump out of local extremum is stronger. In terms of optimization speed, the CI index of IGSA is small; from the standard deviation, it can be seen that the GSA is unstable in solving the single-peak and multi-peak continuous functions. Relatively speaking, IGSA is the most stable.

Table 1. *The comparison of performance of 2 algorithms for 13 standard functions with dim=30,50*

Ecological emission prediction models

Wavelet prediction model

Wavelet analysis is based on the Fourier transform. However, the problem is that the transformation discards the time information, and the transformation result cannot accurately analyze the occurrence of traffic and related indicators. (Zhang et al., 2017) The general wavelet transform refers to the inner product of the signal x(t) to be analyzed after the basic wavelet function $\psi(t)$ is translated by m and at different scales n.

$$WT_x(n,m) = \frac{1}{\sqrt{a}} x(t)\psi^*\left(\frac{t-m}{n}\right)dt \quad \text{(Eq.9)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86798691

$$= \int x(t)\,\psi^{*}_{n,m}(t)dt$$

The equivalent time domain expression is:

$$WT_x(n,m) = \frac{1}{\sqrt{a}}\int x(\omega)\,\psi^{*}\left(\frac{\omega-m}{n}\right)e^{j\omega}dt \quad a>0 \qquad \text{(Eq.10)}$$

Prediction model based on IGSA-War combination

For the predicted emissions to meet the predicted effect, the specific test steps are given here:

When t is used, the actual NOx output of the boiler is O, and the actual discharge amount W_t is St. In order to reduce the suddenness of the emissions and improve the prediction accuracy, the delay D_t and the length L_t of the emissions are mainly used here. Analysis, ie S_t=[D_t, L_t]. In order to effectively deal with the possible occurrence of emission congestion, reasonable queue management is implemented by analyzing the current and past time emissions status to obtain the next-time emission status Z_{t+1}. The following combines the emission state prediction algorithm:

Step 1: Initialize the ecological emission model and its related parameters at the starting time t=0;

Step 2: At time t, the actual emission amount W_t at node O is obtained, and its state vector S_t is obtained, and it is judged according to the IGSA model whether the service is distributed therefrom, if the measurement is satisfied, the process jumps to step 3, otherwise, the process proceeds to step 7;

Step 3: solves the delay D'_{t+1} and the length L'_{t+1} of the service flow at time t+1;

$$\begin{cases} D'_{t+1} = 1-(1-\lambda)\sum_{n=0}^{\infty}\Omega_{m+n+1}((n+1)b-t) \\ L'_{t+1} = (1-\lambda)\sum_{n=0}^{\infty}\Omega_{k+n}(n+1)b \end{cases} \qquad \text{(Eq.11)}$$

where □ is the discharge load size, b is the buffer size, and Ω_{k+n} is the distribution function of the actual emissions.

Step 4: For the fractal and burst characteristics of the actual traffic flow, a wavelet transform is introduced to process the traffic flow. According to the wavelet transform shown in *Eq.11*, the state of the service flow Y_t is determined by the Harr wavelet base (time delay D_t and queue length L_t) is decomposed to obtain the wavelet coefficient $d_j(k)$ and the scale factor $a_j(k)$:

$$\begin{cases} \sqrt{2}a_j(k) = a_{j+1}(2k) + a_j(2k+1) \\ \sqrt{2}d_j(k) = d_{j+1}(2k) + d_j(2k+1) \end{cases} \qquad \text{(Eq.12)}$$

where j is the wavelet decomposition level;

Step 5: Predict the wavelet coefficients according to the IGSA model, and use the inverse wavelet transform to synthesize the delay $D''_{t+1}(t+1)$ and the length$L''_{t+1}(t+1)$;

$$\mu_{t+1} = -\sum_{k=1}^{\xi}\tau_k\mu_{t-1} + \sum_{k=0}^{\delta}\rho_k\mu_{t-k} \qquad \text{(Eq.13)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86798691

Step 6: According to step (3) and step (5), the time delay and the captain status information of the actual emissions at time t+1 are performed here. The following fusion operations reduce the prediction error:

$$\begin{cases} D_{t+1} = \phi D'_{t+1} + \varphi D''_{t+1} \\ L_{t+1} = \phi L'_{t+1} + \varphi L''_{t+1} \end{cases} \quad \text{(Eq.14)}$$

wherein, the fusion parameters □ and □ represent the weight distribution of the two prediction results, and can be dynamically adjusted to obtain an optimal result, and 0≤□≤1, 0≤□≤1, □+□=1;

Step 7: Let t=t+1, jump to step (1), and repeatedly calculate the actual emission vector at the next moment until the end;

Step 8: The algorithm ends.

Example simulation and analysis

Data pre-processing evaluation criteria

There is a nonlinear and strong coupling relationship between the main steam flow and its related parameters. Conventional modeling methods are often difficult to accurately establish a mathematical model of the main steam flow of the turbine. When selecting the unit model parameters, based on the magnitude of the correlation between the main steam flow and the thermal parameters, combined with the selected load, the adjusted stage pressure, a section of extraction steam temperature, a section of extraction pressure and high pressure cylinder exhaust pressure Enter the variable and the main steam flow as the output variable. Since the historical training data involves different quantities (power, wind speed and temperature), the data needs to be normalized. The normalization formula is:

$$\hat{x}_i = \frac{x_i - x_{min}}{x_{max} - x_{min}} \quad i = 1,2,\cdots,N \quad \text{(Eq.15)}$$

where $\hat{x}_i$ is the normalized value; $x_{max} = \max(x_i)$; $x_{min} = \max(x_i)$.

For the normalized prediction result y^', the actual prediction value is $y(x) = y'(x_{max} - x_{min}) + x_{min}$.

In order to evaluate the prediction effect of IGSA optimized wavelet model, the normalized MAE, MAPE and RMSE were used to evaluate the model prediction performance. The error formula is

$$\text{MAE} = \frac{1}{N}\sum_{i=1}^{N} |y_i - y_p| \quad \text{(Eq.16)}$$

$$\text{MAPE} = \frac{1}{N}\sum_{i=1}^{N} \frac{|y_i - y_p|}{y_i} * 100\% \quad \text{(Eq.17)}$$

$$\text{RMSE} = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(y_i - y_p)^2} \quad \text{(Eq.18)}$$

where N, y_i ,y_p are the measured, predicted values and the predicted value of the i-th point respectively.

IGSA-War predicts NOx emissions

The IGSA algorithm was used to optimize the parameters of the wavelet model to predict the NOx concentration of a 330 MW pulverized coal drum boiler. The prediction results were compared with the standard GSA, the improved GSA algorithm (IGSA) and the improved GSA and wavelet combination (IGSA-War) optimization method (*Table 2*). In the NOx emission multi-case test, specific data including various operating parameters affecting the combustion characteristics of the boiler, such as power generation load, coal feeder speed, and primary air are shown in *Table 2*.

Table 2. *Part of the original data of boiler operation*

working	load /MW	4 coal feeder speeds /r/m				Secondary wind speed /m/s					Burn out wind opening /%			exhaust temperature /%	Oxygen content /%
		A	B	C	D	AA	AB	BC	CD	DE	OFA up	OFA down	SOFA

19	58.37	3.81	5.1	1.21	6.4	25	20.29	28.3	28.4	28.9	28.7	627.5

The IGSA is used to optimize the penalty coefficient C and the kernel function parameter σ^2 in the wavelet, and the optimized wavelet model is used to predict the NOx emissions. Using IGSA to optimize the wavelet model parameters, set the IGSA population size to 50. In the 19 sets of conditions in *Table 3*, select 3 to 17 sets of data for training optimization modeling, and 1 and 2 groups as prediction data to verify Optimized performance of IGSA.

The value of the optimal model parameters (C, σ^2) obtained by IGSA is (655, 184). This group of parameters is used to predict the regression data of 1 and 2 sets of prediction data and another 17 sets of training data, and simultaneously with the other three methods. The model is compared experimentally, and the prediction error is shown in *Figure 2* below. *Table 3* shows the relative error (RE) of the four prediction methods for predicting NOx emissions.

Table 3. *Precision analysis of forecast results of 4 algorithms for testing set*

working	NOx value	GSA	RE(%)	IGSA	RE(%)	IGSA-War	RE(%)
1	585.9	596.0512	1.7326	581.1867	0.8045	589.0208	0.5326
2	906.15	911.5982	0.6012	901.9478	0.4637	908.0396	0.2085

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86798691

From *Figure 3* and *Table 3*, we can see that the IGSA optimizes the wavelet model parameters, and then the prediction accuracy based on the optimized parameters is higher than that of the GSA, IGSA, and IGSA-War optimization models. That is, IGSA-War can compare with GSA, IGSA, IGSA-War finds better model parameters.

Comparison of models considering the existence of noise

Random noise is added to the ecological emissions in *Figure 1* to test the robustness. The noise emission prediction results and prediction errors of IGSA-War are shown in *Figures 3 and 4*.

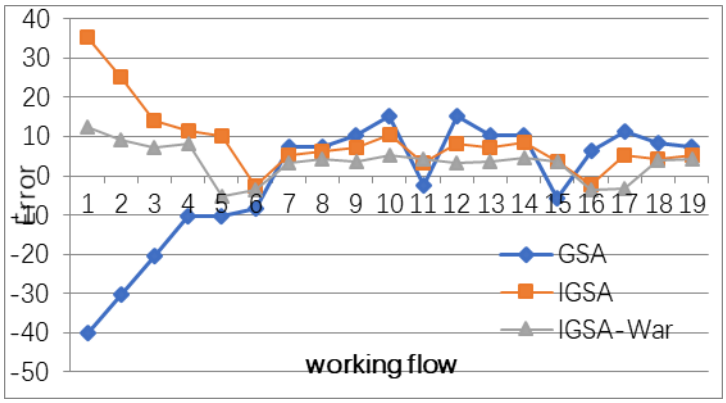

Figure 2. *Error curve between prediction value s and true values of 4 algorithms*

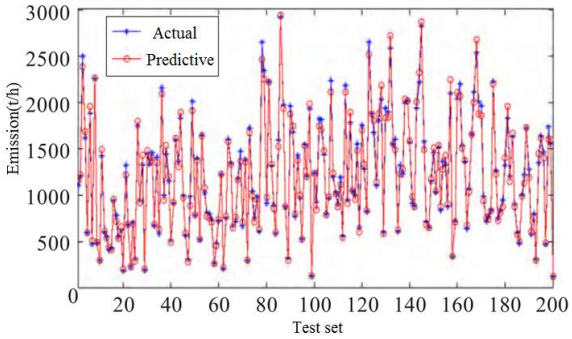

Figure 3. *Prediction in the test data set*

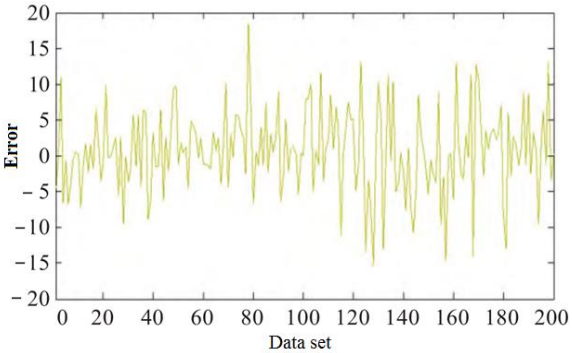

Figure 4. *Error in the test data set*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86798691

For noise emission prediction (*Fig. 3*), IGSA-War also obtains an ideal prediction effect, and the prediction error is controlled within an effective range (Khanchoul and Boubehziz, 2019). This is because IGSA-War comprehensively weighs the principle of structural risk minimization and empirical risk minimization, so that the model has certain Anti-noise ability, can adapt to the characteristics of complex and variable, noisy ecological environment changes. The data set is used as the test set, and the other data is used as the training set. The experimental results once again prove the effectiveness of IGSA-War for ecological emission prediction (*Fig. 4*).

Conclusion

The characteristics of NOx emissions from ecological emissions are affected by many factors, and the impact relationship is complicated. The prediction and control of NOx emissions are difficult. This paper uses IGSA-War to establish a NOx emission prediction model. In order to improve the prediction accuracy and generalization ability of IGSA, an improved gravitational search algorithm is used to optimize the model parameters of wavelet selection. Taking a 330 MW pulverized coal fired boiler as a test object, the IGSA algorithm is used to optimize the super-parameters of the wavelet and establish a prediction model of NOx emissions. By using the relevant data collected by the DCS as training samples and test samples, the model is trained and tested. Experiments show that the IGSA-optimized wavelet NOx emission prediction model has better accuracy and stronger generalization ability.

Abstract. This paper uses potential function to build a coupling model: firstly, it divides forest value into three subsystems including economic value, ecological value, and social value, and set the index according to their characteristics; then it studies empirically the coupling relationship among economic value, ecological value, and social value of forest in China from 2008 to 2016. The results show that from 2008 to 2016, the overall coordination among economic value, ecological value, and social value of forest in China is poor while the overall trend is continuous growing, and ecological value of forest has a higher weight. In the future, China should pay attention to the development, protection and utilization of ecological forest value to achieve their sustainable development.

Keywords: *sustainable development, overall coordination, coupling model, subsystem, environmental science*

Introduction

Forests are the larges ecosystems on land, supporting the humanity's important mission of sustainable development, regulation of ecological balance, and development of low-carbon economy (Li and Zhao, 2017). With the changes in current social environment and natural economic environment, human beings traditional use pattern of forest could no longer meet the needs of modern economic development.

On the one hand, the sustainable growth of the forestry industry economy is inseparable from the demand for forest resources; on the other hand, the deteriorating ecological environment and people's demand for a better society require us to protect the only remaining forest resources. In terms of the products and functions provided by forest, it can not only provide ecological services such as water conservation, carbon fixation and oxygen production, and air purification, etc. but also develop tourism; it is also a major production materials for the manufacturing industry, promoting economic development (Chen et al., 2017). For this reason, ways to develop forest resources and maximize their own value is of particular importance. Should we protect forest ecological environment or develop forestry economic industry? And what is the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86938712

relationship between these two? This issue has become one of the key forest issues for scholars' research. From the perspective of value, Deng et al. (2002) use "shadow engineering" and other methods to study the value of water conservation in the forest ecosystem in the upper reaches of the Yangtze River, Zhang and Khalique (2018) showing that the annual economic value of water conservation in the forest ecosystem is 160.6179 billion yuan (equivalent to a quarter of the GDP in that region in 1999), and the forest ecosystem is so effective for human beings that the country should pay attention to and protect the ecological value of forest. Through the evaluation method combining quality and value, Zhang et al. (2007) and Shrestha and Baral (2018) use shadow engineering approach, market value approach, and production cost, etc. to quantitatively study the service value of forest ecosystem in Gansu Province. The results show that the economic value of water conservation in the forest ecosystem in Gansu is 256 million yuan/a; the economic value of forest-maintained soil is 4.748 billion yuan/a; the value of forest purified water is 248 million yuan/a; the value of CO_2 fixation is 11.532 billion yuan/a; the value of O_2 release is 13.124 billion yuan/a; the value of SO_2 absorption is 388 million yuan/a; the value of dust retention is 15.639 billion yuan/a; and the value of forest ecological service function in Gansu Province is 44.712 billion yuan, accounting for 23.19% of the province's GNP. These help to see visually the important role of the ecological value of forest, requiring formulation of more reasonable operation model to achieve sustainable development of ecological economy. Pang et al. (2016), Cong et al. (2017) and Austin et al. (2018) use distributed measurement to evaluate the service value of forest ecosystem in Helan Mountain National Nature Reserve in Ningxia. The results show that the total value of forest ecological service function in that region in 2015 was 1.68708 billion yuan/a, accounting for 6.68% of the gross output value of agriculture, forestry, animal husbandry, sideline production, and fishery in Ningxia Autonomous Region in 2014; while the total forest area of the nature reserve accounts for 3.03% of the land area of Ningxia Autonomous Region, indicating that forest ecosystem can not only provide forestry by-product value but also has huge ecological value. Wang et al. (2015) take the analysis of increasing demand for tourism in national forest parks as well as the ecological environment and tourist needs of the scenic spot as background, use choice experiment method and conditional Logit model to empirically analyze the main attributes of Shenyang National Forest Park and evaluate its economic value (Zhang et al., 2017). The results show that vegetation coverage, water clarity, garbage quantity, and crowding degree all have significant impact on the recreation effect. The current economic value of the scenic spot is 27.3 yuan per person, however, when vegetation coverage increases by 10% every time, the economic value of the park will increase 30 yuan; when water clarity improves 0.5 m every time, the economic value of the park will increase 24 yuan; when garbage quantity increase 5 pieces every 20 m^2, the economic value of the park will decrease 20 yuan (Olivares et al., 2017). It can be seen that changing the ecological environment plays an important role in improving the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86938712

economic and social benefits of national forest parks. Wang et al. (2015) and Ali et al. (2018) start from the perspective of producers to calculate the recreational value of 39 forest parks in Qinling via marginal opportunity cost method. The results show that the total value of forest recreation is 21.63 billion yuan while the ecological value of forest itself accounts for 74.12%, showing that the ecological function of forest itself can better promote the development of forest tourism. From the perspective of theoretical innovation, Liu and Huang (2007) and Jamil et al. (2018) make theoretical innovation from interest-orientation principle, public product theory, and spillover benefit correction theory to coordinate the relationship between forestry ecological benefits and economic benefits; they also propose to rely on market mechanism to adjust the average level of profit by government imputing certain profit parameters to the market so that both forestry activities with or without lumbering can achieve social average profit. Based on complex system theory, Dong and Zhang (2013) use gray correlation evaluation model, and take the calculation method of slope correlation to build a coupling model of the forestry industry and the forest ecosystem; they also take Yichun Shuangfeng Forestry Bureau as an example (Marina et al., 2013; Gautam et al., 2019), and conduct experimental study to find that the degree of coupling between forestry industry and forest ecosystem in that area is 0.47, thus further draw the conclusion that the relationship between forestry industry development and forest ecosystem in that area is moderate and their relevant impact is general (Liao and Zhang, 2017; Tao, 2018). It can be seen that the researches on forest value by Chinese and foreign experts and scholars stays on the basis of comparison to obtain the ratio of the ecological value of the forest to the total value or the differences between the social value of forest and the income that is already earned, while they do not involve the degree of relationship among the three or the content of coordination relationship. This study conducts an empirical study by building a coupling relationship model of the economic value, ecological value, and social value of forest (Dong et al., 2017), trying to explain the coordination relationship among the three major values of forest and provide a theoretical basis for specifying the future development of forest value.

Materials and Methods

Coupling, in physics, refers to the phenomenon in which two or more systems or two forms of motion connect by impact on each other through various interactions, and such dynamic phenomenon is also called coupling effect. The coordination degree of coupling effect is related to dynamic cycle operation of the whole system; at the same time (Zhang, 2016; Dali and Kamarudin, 2018), it can also reflect the coordination state of the development of things that strong coordination means good development while discordance or conflict means development degeneration or stagnation. Coupling effect has been widely used in many fields including sociology, ecology, and economics, etc. based on its characteristics (Wu et al., 2014; Sarwar et al., 2019). This study applies this

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86938712

concept to analyze the coordination relationship and dynamic development relationship among social value, economic value, and ecological value of forest, providing a theoretical basis for future forest value enhancement and forest sustainable development. The premise of presenting the efficacy of economic value, ecological value, and social value of forest is to build a potential function based on coupling effect. Assume U1 represents the economic value subsystem of forest, U2 represents the ecological value subsystem of forest, U3 represents the social value subsystem of forest (Zhou et al., 2018; Babaranti et al., 2019), and u_{ij} represents the observation value of the jth statistical indicator in subsystem i, then the potential function of subsystem i, subsystem j, and subsystem z is (*Eq.1*):

$$U_i = \sum_{j=1}^{n} \omega_{ij}\mu_{ij}\,, U_j = \sum_{i=1}^{m} \omega_{ij}\mu_{ij}\,, U_z = \sum_{j=1}^{n} \omega_{zj}\mu_{zj} \quad \text{(Eq.1)}$$

where μ_{ij} represents the normalized value of the jth statistical indicator in subsystem i. The normalized processing formulae for this value include positive normalization and negative normalization, respectively (*Eq.2*):

$$\begin{aligned} \mu_1 &= \left[\mu_{ij} - \min \mu_{ij} / \max \mu_{ij} - \min \mu_{ij}\right] \times 0.9 + 0.1 \\ \mu_2 &= \left[\min \mu_{ij} - \mu_{ij} / \max \mu_{ij} - \min \mu_{ij}\right] \times 0.9 + 0.1 \end{aligned} \quad \text{(Eq.2)}$$

ω_{ij} represents the weight of the jth statistical indicator in subsystem i, and meets the following condition (*Eq.3*):

$$\sum_{j=1}^{n} \omega_{ij} = 1, \sum_{i=1}^{m} \omega_{ij} = 1 \quad \text{(Eq.3)}$$

Based on the coupling model built by potential function, the generalized expression of the n-dimensional coupling degree model is (*Eq.4*):

$$H_n = n\left(U_1 U_2 U_3 \cdots U_n / \prod\left(U_i + U_j + U_z\right)\right)^{\frac{1}{n}} \quad \text{(Eq.4)}$$

Since the subsystems involved in this study are economic value, social value, and ecological value of forest, the coupling models of the following three subsystems can be derived (*Eq.5*):

$$H_3 = 3(U_1 U_2 U_3 / \prod(U_1 + U_2 + U_3))^{\frac{1}{3}} \quad \text{(Eq.5)}$$

where H represents the direct coupling degree of each subsystem (Pascual-Córdova, 2018). The value range is [0, 1]. Higher H value means higher coupling degree of each

subsystem, better coordination among systems, and benign and healthy development of the whole system; and lower H value means lower coupling degree of each subsystem, worse coordination among systems, and stagnant or degraded development of the whole system.

In order to further measure the overall coordination degree and efficacy coordination of the system (Yang et al., 2019; Majumder et al., 2019), we also need to formulate a coupling coordination function to measure the coupling degree among economic value, social value, and ecological value of forest in China. The expression formula of D the coupling coordination function is (*Eq.6*):

$$D:\begin{cases} T = (H \times C) \times k \\ C = \alpha U_1 + \beta U_2 + \gamma U_3 \end{cases} \quad \text{(Eq.6)}$$

where T represents the coupling coordination degree among economic value subsystem, social value subsystem, and ecological value subsystem of forest; H represents the degree of coupling among the subsystems; C represents the coordination coefficient among the subsystems; k, α, β, and γ are parameters; k is a constant quantity value of 0.5; α, β, and γ are determined in accordance with the degrees of importance of the economic value, social value, and ecological value of forest in total value of forest. This study first assumes the values of α, β and γ are 0.33 - in equally important position.

In accordance with the coupling relationship among economic value, social value, and ecological value of forest, such coupling relationship can be divided into three categories: sound development, moderate development and slow development; and the coordination degree can be divided into five levels: excellent coordination, good coordination, moderate coordination, weak coordination, and poor coordination. The details are shown in *Table 1*.

Results

Based on the existing research and the principles of scientificity, reliability, systematicness, availability, and measurability, etc., this study selects appropriate measurement index, uses the combination of qualitative and quantitative methods to express the data, and conducts a comparative study of index data to achieve accurate measurement results with more reference valuable. The evaluation system designed in this study includes three subsystems, namely economic value of forest, ecological value of forest and social value of forest. Economic value of forest is mainly reflected in the two aspects including economic benefit and economic structure.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86938712

Economic benefit is objective expression of the total amount of forest economy, mainly in five aspects: (1) total output value of forestry industry, namely the sum of the value created by various production and processing based on forestry industry; (2) contribution rate of forestry industry, namely the ratio of the total output value increase of forestry in national GDP growth; (3) the central government's investment amount in the development of forestry economy, namely state's funds for ecological construction, ecological compensation, and forest disaster management; (4) investment amount of local finance in forestry economic development, namely local governments' construction capital for forestry economic development, and (5) ecological construction and protection funds, namely the central and local governments' total ecological compensation that is absorbed because of the ecological benefits of forestry industry.

Forestry economic structure shows the resource allocation of forestry resource elements in various industries, and the industrial structure of forestry is an important factor to promote the development of forestry economy. This study chooses the structural proportions of various industries in forestry industry to reflect if the forestry industry structure is reasonable. By referring to the evaluation system of forest ecological status in Specifications for Assessment of Forest Ecosystem Services in China and National Level Criteria and Indicators of Sustainable Forest Management in China, this study's selection of forest ecological index mainly reflects the ecological basis, ecological structure, forest health, and ecological protection of forest. Ecological basis of forest mainly focuses on three aspects: (1) forest coverage rate, namely the proportion of forest area on land, the degree of greening of land, and the abundance of ecological resources in China; (2) the amount of forest reserves, namely the total amount of various kinds of forest wood in the forests; and (3) afforestation area, the sum of national afforestation area each year. Ecological structure reflects the accumulation of each forest species. Forest health mainly investigates disaster situation of forests. The indicator system of ecological protection function is established based on the indicator system of ecological service of forest. As there are multiple methods to estimate the value of ecological service of forest, and the measurement of some physical quantities cannot be objective and accurate, this study chooses the construction situation of ecological protection projects of forest to reflect the service function of forest. The first is the natural forest protection project. Natural forest has natural advantages that artificial forest cannot match, including great biodiversity, strong self-recovering ability and adaptability to environment and anti-disaster ability. It can better exert forests' functions of water conservation, climate regulation, and biodiversity increase, therefore the construction area of natural forest protection project can reflect the ecological benefits of forests. The second is the project of returning farmland to forests. This project is one of the important national policies for implementing the western development strategy in China. It can improve soil erosion and desert wasteland; at the same time, number of its acres can also be used as a basis for national subsidy. The third is the sand control project. It can improve wind prevention and sand fixation of forest to further reflect the ecological

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86938712

service value of wind prevention and sand fixation of forest. The fourth is the shelter forest system project. It can resist natural disasters, protect infrastructure and production, improve the environment, maintain ecological peace, and reduce pollution, etc. In accordance with different protection purposes, we can establish various forests with ecological service functions such as water conservation forest, soil and water conservation forest, and landscape shelter forests, etc. Therefore the construction area of shelter forest can be regarded as an important indicator that reflects the ecological protection function. The fifth is the area of nature reserve. This can be taken as an indicator that has impact on the biodiversity of forest. The sixth is the value of forestry ecological service. This is the value of forestry ecological service that has formed industrial activities in the tertiary industry of forestry, e.g. recreation in forest, soil and water conservation, carbon sequestration, and conservation of biodiversity, etc. For social value of forest, as its accounting system is not complete and there are no national accounting indicators, this study integrates the existing literature research and divides the social value of forest in three aspects - value of people's livelihood, value of tourism, and value of culture. Value of people's livelihood uses the number of forestry employees and their average salary to reflect the beneficial contribution of forestry economic development to society. Value of tourism uses the tourism and leisure service value of forestry for reflection. And value of culture reflects the abstract value of forest. Therefore, this study chooses the approximate forest park area and popularity index of forest park to alternatively reflect the cultural value of the forest (Meza, 2018).

Since there is a certain difference in the importance of indicators in different systems, the indicators need to be weighted before coupling analysis. At present, the weighted analysis methods (e.g. expert investigation and analytic hierarchy process) used by most scholars have strong subjectivity; therefore the obtained index weights may have some errors. This study uses objective weighting method and entropy method based on the variation coefficient of objective things to weight each indicator. Specific steps are as follows:

(1) Standardize the index by standardized formula (*Eq.7*):

$$y_i = x_i - \bar{x}/s \tag{Eq.7}$$

where y represents the value after standardization and s is standard deviation with the formula as (*Eq.8*):

$$s = \sqrt{\frac{1}{n-1}\sum_{i=1}^{n}(x_i - \bar{x})^2} \tag{Eq.8}$$

$\bar{x}$ is the average of the variables with the calculation formula as (*Eq.9*):

$$\bar{x} = \frac{1}{n}\sum_{i=1}^{n} x_i \tag{Eq.9}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86938712

After standardization, different data variables have the same variance and mean value, so they can be directly compared.

(2) Calculate the proportion of the standardized values in the subsystem, a_{ij} represents the proportion of indicator j in subsystem i in the standardized subsystem, and u_{ij} represents the standardized value of indicator j in subsystem i, the formula is (*Eq.10*):

$$a_{ij} = u_{ij} / \sum_{i=1}^{n} u_{ij} \quad \text{(Eq.10)}$$

The entropy value p_j of indicator j in subsystem i can be calculated in accordance with the formula (*Eq.11*):

$$p_j = -k \sum_{i=1}^{n} a_{ij} \ln a_{ij}, k = \frac{1}{\ln(n)} > 0 \quad \text{(Eq.11)}$$

where k is coordinating parameter.

(3) Calculate the variation coefficient l of indicator j in subsystem i, the formula is (*Eq.12*):

$$l_j = 1 - p_j/m - g_p, \ (g_p = \sum_{j=1}^{m} p_j) \quad \text{(Eq.12)}$$

(4) The calculation formula for the weight ω_j of indicator j in subsystem i is (*Eq.13*):

$$\omega_j = l_j / \sum_{j=1}^{m} l_j, \ j = 1, 2, 3 \cdots, m \quad \text{(Eq.13)}$$

The weights of the indicators in each system calculated with this method are shown in *Table 2.*

Discussion

As an important resource asset, forest can not only provide timber and other plant assets for the development of national economy and people's life, but also functions as an important environmental asset and the largest environmental carrier on land with a basic status in developing low-carbon economy and ecological civilization; meanwhile, as an important part of terrestrial ecosystem, forest is also the habitat of biodiversity, playing the role of water conservation, soil conservation, wind prevention and sand fixation, and climate regulation and change, etc. while functioning as the important site to absorb carbon dioxide and sulfur dioxide (Hernández, 2019). It undertakes two major missions of optimizing environment and promoting production. General Secretary Xi Jinping also proposes that we need both valuable assets, and more importantly, lucid waters and lush mountains; after all, lucid waters and lush mountains are invaluable assets.

		The area of nature reserve U245	hectare	0.034
		Value of forestry ecological service U246	100 million yuan	0.032
Social valueU3	Value of people's livelihood U31	Employed populationU311	person	0.018
		Average annual salary of in-service employees U312	100 million yuan	0.033
	Tourism value of forest U32	Recreation value of forest U321	100 million yuan	0.041
	Cultural value of forest U33	Area of forest park U331	hectare	0.028
		Popularity index of forest park U332	%	0.016

Therefore, it is an inevitable choice for forestry sustainable development to implement win-win development of forestry with coordination of economic, social and ecological environment, and maximize the economic value, social value and ecological value of forest on the basis of adhering to the virtuous cycle of ecological environment.Under this

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86938712

development trend, this study chooses the original data in China Forestry Statistical Yearbook from 2008 to 2016 for coupling degree analysis, trying to indicate the direction for future sustainable development of forestry in China through the research results in addition to analyzing the relationship among the three major values of forests (Shan and Lai, 2018).

First, the original data is standardized; then the weight of each index system is calculated by "entropy weight method" and the calculation result is brought into the potential function to obtain the values of economic value, ecological value and social value of forest; finally, coupling model and coupling coordination model are used to calculate the final results shown in *Tables 3 and 4*.

Table 3. *2008 to 2016 calculation result of coupling value H*

2008	2009	2010	2011	2012	2013	2014	2015	2016
0.724	0.729	0.877	0.926	0.948	0.781	0.861	0.796	0.841

Table 4. *2008 to 2016 calculation result of coupling coordination value T*

2008	2009	2010	2011	2012	2013	2014	2015	2016
0.048	0.064	0.077	0.084	0.105	0.153	0.155	0.189	0.203

Table 3 is the coupling values of the economic value, ecological value and social value of forest. In accordance with the coupling degree indicator H described above, the value range is 0 to 1, higher value means higher coupling degree, and conversely, lower value means lower coupling degree. It can be seen from the data in *Table 3* that the coupling degree among economic value, ecological value and social value of forest is high with the average value of all values reaching 0.83, proving the great influence among the economic value, ecological value and social value of forest; the coupling degree increased year by year from 2008 to 2012, showing that the country has made basic achievements in forestry construction since the reform and opening up, a series of initiatives such as the construction of six major ecological protection projects, development of forest tourism, rapid development of the forestry tertiary industry, and continuous implementation of national policy to change desertification have made the value of forest more and more prominent, and the values of forest are moving toward healthy and good development trend steadily.

It can be seen from *Table 4* that the coupling coordination value T of the economic value, ecological value and social value of forest in China from 2008 to 2016 also shows an increasing trend year by year; however, if graded by coordination degree, the coordination differences from 2008 to 2015 were basically in the same level while the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86938712

coordination degree in 2016 was weaker with one level up compared with the previous, but the value was not high. The biggest increase was in 2013, this is mainly because since the 18th CPC National Congress, General Secretary Xi Jinping has put forward a series of important speeches on promoting the construction of ecological civilization and made a series of important instructions and profound discussions, while forest, as a main part and important resource of ecosystem on land, is an important ecological guarantee for the survival and development of human beings. Under such background, State Forestry Administration organized experts to prepare Outline of State Forestry Administration's Plan for Promoting Ecological Civilization Construction, which clearly defined the national ecological red line, requiring the forest stock volume of no less than 20 billion cubic meters, so the afforestation area in 2013 increased by 504,270 thousand hectares compared with 2012. However, the growth rate of the ecological value indicators of forest in 2014 decreased compared with that in 2013, resulting in the least increase in the coupling coordination value in 2014. From an overall perspective, the development of the economic value, ecological value and social value of forest in China is transiting from incoordination to coordination. From the perspective of the system's potential function, as shown in the following table (*Table 5*), the ecological value of forest is also significantly higher than the economic value and social value of forest (Wang, 2019).

Table 5. *Potential functions of sub-systems of forest*

Year	**Economic value of forest**	**Ecological value of forest**	**Social value of forest**
2008	0.05890141	0.1270031	0.01534795
2009	0.05427371	0.1832762	0.02660406
2010	0.0795104	0.1457341	0.04059887
2011	0.09396559	0.1296828	0.04896527
2012	0.1177569	0.149074	0.06672682
2013	0.1300533	0.3863547	0.07166745
2014	0.1411518	0.3171471	0.08459407
2015	0.1475089	0.4659078	0.09828729
2016	0.1569462	0.4499682	0.1201707

The following figure shows the variation curves of the potential function of economic value, ecological value and social value subsystems of forest (*Fig. 1*). It can be seen that since 2009, the forestry economic value in China has increased year by year and the social value has also increased, showing that Chinese forestry keeps developing and the social economy is also growing. The reason is that on one hand, the output value of the forestry industry is increasing year by year, and contributions of the secondary industry and tertiary industry are increasing; on the other hand, the level of urbanization is increasing and the per capita income of forestry people rises as well. The curve of ecological value

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86938712

of forest is more fluctuating, showing an inverted U-shape development. The rising of ecological value curve in 2009 indicates increasing carrying capacity of forest environment, and this is inseparable from the afforestation area and forestry ecological construction in that year.

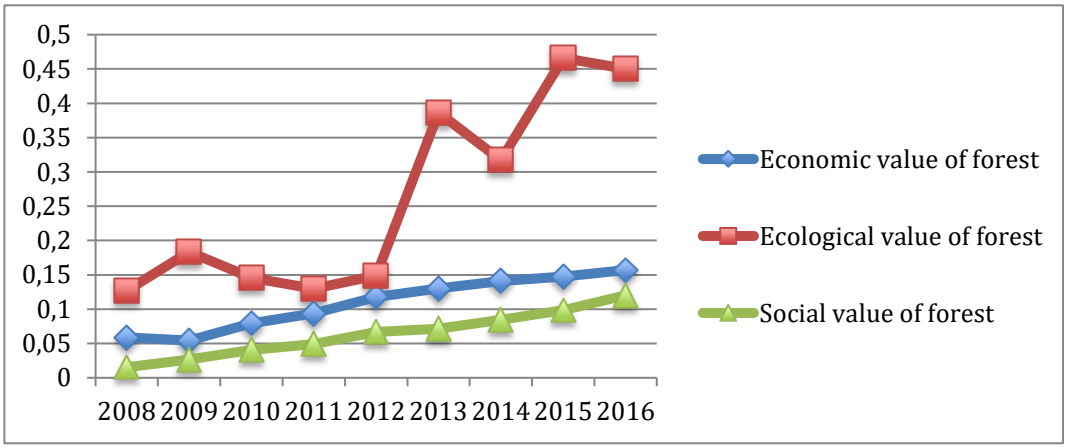

Figure 1. *Variation curves of the potential function of subsystems of forest value*

There was an inflection point in 2011 with the minimum of 0.129. The reason may be related to the forestry development policy in recent years such as the reform of collective forest property right system. In addition, forest is a complex system integrating the primary industry (forest management, etc.), the secondary industry (wood processing, etc.), and tertiary industry (ecological service construction, etc.), increase in the primary industry can promote the development of tertiary industry, and efforts in ecological construction can also increase the output value of the primary industry. For the output value of forestry industry in the past few years, the output value of the second industry was the largest in 2011, while such increase would inevitably lead to excessive exploitation and utilization of forest resources, resulting in imbalanced forest resource structure. This, together with an increase in the damage area of forest and decrease in the construction of ecological protection, will inevitably lead to degradation of forest ecosystem and the lowest ecological value of forest.

In addition, when studying the weight of each subsystem, the author finds that the weight of each indicator in subsystems of forest value is higher than other indicators, and their rankings are higher; therefore, the author adjusts the parameters in the coordination function with the adjusted ratio of $\alpha:\beta:\gamma = 4:21:1$, and takes them into the coupling coordination model to obtain *Table 6*.

It can be seen from the data in *Table 6* that the coupling coordination degree among subsystems of forest value showed a fluctuating rise from 2008 to 2016, and it increased by one level from 2013 with the highest increase. The reason is that in 2011, the State Council held Working Conference on National Natural Forest Resources Protection

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86938712

Project, and State Forestry Administration actively implemented the spirit of the conference and held Work Arrangement Conference on the 2nd Phase of National Natural Forest Resources Protection Project, requiring to further implement the forest management subsidy and related social insurance subsidy policies; meanwhile, State Forestry Administration also issued *Twelfth Five-Year Plan for Forestry Development*, which affirmed the achievements of forestry construction during the Eleventh Five-Year Plan period, pointed out the three major goals of forestry construction (i.e., to build a sound forestry ecosystem, a developed forestry industry system, and a prosperous ecological and cultural system) to achieve scientific development and sustainable development of forestry, took construction of ecological civilization as the primary task of developing forestry, and clearly gave forestry five main functions including ecological function, economic function, social function, carbon sink function and cultural function, and set the main indicators for forestry development during the Twelfth Five-Year Plan period.

Table 6. *2008 to 2016 calculation result of coupling coordination degree T after adjusting coefficient*

2008	2009	2010	2011	2012	2013	2014	2015	2016
0.081	0.114	0.115	0.112	0.133	0.261	0.242	0.321	0.330

Therefore, under such policy, the coupling coordination indicator of forest values rose greatly from 2012 and increase in the ecological value of forest played a crucial role (Zhang et al., 2017). The reason for fall in 2014 was that the afforestation area in 2014 was 550.45 million hectares less than that in 2013, at the same time, the construction area of natural forest protection project and the area of sand control project were also less than in 2013, and slow growth of forest ecological construction caused slow increase in the ecological value of forest and reduced coupling coordination degree among forest values (Martínez, 2019). To sum up, it can be seen from the above that the development of ecological value of forest plays an important role in the development of the entire forestry economy, and insisting on implementation of afforestation, development of six major forestry projects, and development of forest recreation value is an inevitable choice for China to develop forestry economy as well as a necessary condition for sustainable development of forestry (Asgari, 2018).

To reflect the role of the ecological value of forest in the total value of forest more clearly, the coupling coordination degree T' after adjusting coefficients is compared with the coupling coordination degree T before adjustment (*Fig. 2*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86938712

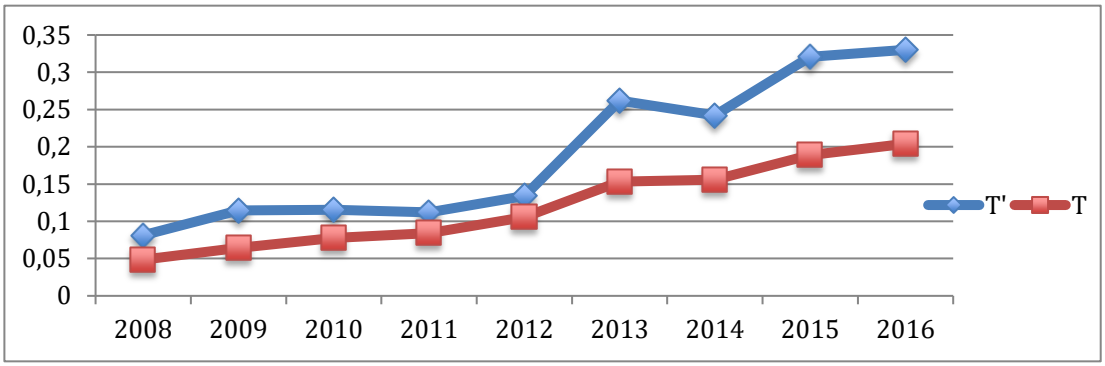

Figure 2. *Comparison analysis of coupling coordination degree after adjusting coefficient*

It can be seen clearly that from 2012, the ecological value of forest greatly increased the coupling coordination degree among the total values of forest, having better function in coordination and development of subsystems.

Conclusion

This study uses potential function and the coupling effect in physics to build a coupling model, conducts research on the economic value, ecological value and social value of forest from the quantitative point of view, and builds indicator systems from nine perspectives respectively including economic benefit, economic structure, ecological basis, ecological structure, forest health condition, ecological protection function, value of people's livelihood, tourism value of forest, and cultural value of forest (Zeng et al., 2018); it also studies the coupling relationship among economic value, ecological value and social value of forest in China from 2008 to 2016 and draws the following conclusions:

(1) The overall coordination degree among economic value, ecological value and social value of forest in China is poor. The coordination degree of all samples was at the level of poor coordination before 2016 and entered into the level of weak coordination after 2016 (Lu et al., 2019). Both levels belong to the state of slow and uncoordinated development, but the ecological value of forest always accounted for a higher proportion than economic value and social value. Therefore, China should continue to adhere to the construction of ecological civilization, improve the ecological environment of forest, and enhance the level of coordination degree of forest values.

(2) From the perspective of national policies, in 2011, State Forestry Administration promulgated the Twelfth Five-Year Plan for forestry and began to implement the 2nd Phase of National Natural Forest Resources Protection Project, having an important impact on the promotion of the ecological value of forest. After 2012, the coordination degree among forest values also improved faster than before and gradually developed to the upper level. This also shows that the promotion of the ecological value of forest can

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_86938712

more effectively promote the economic value and social value of forest so that the relationship among forest values would become more harmonious, and developing the ecological value of forest is an important measure to achieve sustainable development of forest in future.

(3) From the perspective of the index weight of subsystems, what impacts greatly on the weights of index systems is mainly concentrated in the ecological value subsystem of forest with afforestation area accounting for the largest proportion. Therefore, China should adhere to afforestation and restore forest ecological barrier. Secondly, the value of forest tourism has increased year by year with its weight also higher compared with the index in other social value subsystems. This shows that with the development of society, people have better payment ability and increasing recognition that forest tourism can bring more physical and mental pleasure. People's willingness to return to nature and close to nature rises, and the income of national forest tourism also rises continuously. Development of forest tourism can promote the overall increase of the social value and economic value of forest. From the economic structure of forestry industry, with the increasing output value of the tertiary industry of forestry, the potential function value of economic value of forest also increases year by year, showing that the tertiary industry of forest and the economic value of forest are positively related, and active development of the tertiary industry of forest will help improve the economic and ecological value of forest.

(4) By adjusting the parameters of the coupling coordination model, we can clearly see the impact of the ecological value of forest on the overall forest value coordination model. However, increase in only the ecological basis and ecological protection function of forest is not enough to improve the ecological value of forest and exert the ecological benefits of forest, and the country must give certain financial support. Although the country started pilots for ecological benefit subsidy in 2001 and provided certain ecological construction investment every year, ecological subsidy still accounted for a small proportion, not enough to compensate the speed of ecological damage. Therefore, China should promulgate relevant laws and regulations, follow the principle of "whoever benefits shall pay" and "whoever damages shall compensate", and charge certain ecological compensation fee from the direct beneficiaries and direct wrongdoers of forest ecology to increase forest ecological compensation funds, improve social awareness of ecological construction and environmental protection, and promote sustainable development of forests (Zhang et al., 2017).

Forest ecological protection work is a systematic project that needs the participation of the whole people. It needs the strength of the people to complete. Therefore, if we want to achieve the protection of forest ecological resources, we must do a good job in propaganda, enhance the awareness of the importance of forest protection, let them fully realize the importance of forest ecological resources protection, consciously participate in the ranks of forest ecological resources protection.

Abstract. This study was dealt with aiming to examine the most important factors (education and self-development, administrative competence, success mentality, motivation and rewarding) affecting administrative and organizational success in the forest resource management of Turkey. For this purpose, four different questionnaires were applied to the total of 565 interviewees related to the forestry section of the Ministry of Forestry and Water Affairs and four different interest groups (employees, subject experts, related institutions and nongovernmental organizations representatives) in nine geographical regions of Turkey. To gather data about the subject and to reach the results, face to face interviews were conducted with interest groups, a questionnaire was applied. The layered-simple random sampling method was used as a sampling method. All obtained data were used as material. The research data were evaluated with descriptive statistics, it was inspected with the Kruskal-Wallis H-Test whether the thoughts of the interviewees related to the most important factors affecting administrative and organizational success differ according to the regions, and the departments, the position and the experience. The different groups were determined by the Duncan Test. Accordingly, most of the interviewees think that the undergraduate education, prevocational and in-service training are inadequate and that they need the most social and economic comprehensive information in the management of forest resources. Middle and upper level managers have the opportunity to further develop themselves, as the duration of experience increases, the administrative competence about forest resources management increases, but scientific studies and research results related to forestry are mostly not followed. The majority of the interviewees correctly identified administrative and organizational success in forestry, determined the most important factors affecting success as organizational and administrative factors and found that there was little or no relationship between success and reward. To increase the success in the forestry, the employees should participate in decisions and the success should be measured and evaluated objectively and numerically in the form of institutional success. According to the results, some suggestions were put forward for development of forest resources management.

Keywords: *forest resource management, education, administrative competence, success mentality, motivation and rewarding, Turkey*

Introduction

Sustainability and multiple utilization principles in forest resources management form the basis of contemporary forestry approach (Aktan, 2013; Lorincova et al., 2016; Albuquerque da Silva et al., 2016; Sanchez Badini et al., 2018). Many issues such as sustainable forest management, participatory management, conflict management, certification, carbon management and strategic management come to the fore in the field of forestry all over the world (Wibowo and Giessen, 2015; Kim et al., 2016). Human

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87138735

resources is the key factor to fulfill the innovations in those mentioned fields and provide sustainability in forestry and sustainability couldn't be ensured unless sufficient development is achieved in terms of human resources (Pinstrup-Andersen et al., 1998; Szaro et al., 2000). Considering the multifunctional services of forests in the planning and management processes are gradually becoming important in terms of conservation, development and expansion of the forest lands within the context of sustainable management (Baynes et al., 2015; Miteva et al., 2015). Parallel to this approach human resources, particularly the technical staff, has an important role in utilizing forest resources, actualizing new approaches in forestry and achieving the goals of forestry policy (Krott, 2005; Mendes, 2006). In other words, it is impossible to determine and implement effective policies, to solve numerous problems and to achieve sectoral progress without solving the problems of human resources in forestry (Hasanagas, 2014; Wibowo and Giessen, 2015).

Conserving the forest lands and providing the society with forest products sustainably are the duties, which are assigned through the constitution and the legislation, of the forestry organization in Turkey. Fulfillment of this duty as precisely as possible makes it obligatory for the organization to be dispersed and nature compatible (Toksoy et al., 2011). The country-wide problems such as complicated organizational structure, political oppression over the forestry organization and the employees, unequal distribution of human resources to central and provincial units, various unjust appointment and promotion issues are of the main factors that affect human resources (Özdönmez et al., 1998; Gümüş, 2014). Considering the issues listed above for Turkey, it can be clearly observed how essential it is to provide the employees, particularly the technical staff, with job satisfaction. In other words, human resources require to be managed well to ensure sustainable forest resources management. Within this context, it is seen that the concepts such as education, motivation, organizational and administrative success become prominent with regard to sustainable forest resources management (Torres-Rojo et al., 2016; Tumbach et al., 2018).

The characteristics of the forestry practices and the duties of the forestry organization require the staff that is to be employed in the field be specialized in terms of training and education (Kaplan, 1998; Hansman et al., 2016). The organizational structure which is established for the performance of forestry practices also diversifies the training and education of the personnel (Özdönmez et al., 1998). Meanwhile, the absence of a widespread and well-organized education system is a common obstacle against properly benefiting from educated staff for many countries. Although developing countries possess 50% of the whole world's forest lands, they employ only a small proportion of professional foresters and technicians (Schmithüsen, 1983; Elands et al., 2004; MacDicken et al., 2015). On the other hand, when forestry is analyzed in terms of human resources in developed countries, it is seen that training and development of the staff is among the mostly emphasized issues (Imamura, 1982; Hajjar and Oldekop, 2018). Therefore, the importance of well-trained and educated professional human resources for the sake of sustainable forest resources management can be clearly observed.

Monitoring the moral and physical needs of the employees, providing the work environment that meet their goals and expectations, ensuring the consistency among the organizational goals and staff goals in order to enhance motivation and improve labor productivity are considered as basic management processes not only for the motivation of the employees but also for the achievement of organizational goals (Gümüş and Beşir, 2012; Lyons et al., 2016). The most effective motivation tools are determined as

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87138735

satisfying wages, appreciation, job security, promotion and work satisfaction (Wiley, 1997; Burns and Giessen, 2016). In this regard, the motivation of the employees of the organization in parallel with the job satisfaction among them is crucially important when organizational success and the achievement of future goals are considered.

Forestry organization is an economic organization with public responsibilities, goals and duties to achieve (Daşdemir, 1998). Before determining the factors that affect success in this organization, it is necessary to identify what success means for it. In general, success for an organization is a multi-dimensional concept according to contemporary management approach and can be identified as the level of qualitative and quantitative achievement in scheduled activities, duties and goals with the interactive cooperation of all components of the system (Daşdemir, 1996; Akal, 2005). Despite it is possible to measure success in absolute and relative terms; it is possible to mention about different kinds of success such as economic success, technical success, biological and biophysical success, administrative and organizational success etc. Administrative and organizational success mostly related with organizational, environmental and human factors. The administrative dimension of success is a factor of production that actualizes the administration function. The core of this production factor is human, in other words, the administrators. Accordingly, administrators are responsible for the achievement of organizational goals by combining the efforts of the employees with the other resources within a process that consists of activities such as planning, decision making, organizing, leading, coordinating and supervising. Then, the characteristics that administrators should bear, emerge as the factors that form the most crucial dimension of organizational success. These factors affect the administrative success and hence are dependent on the environmental, organizational and administrative ones (Daşdemir, 1998).

Forestry in Turkey is based on public administration and public property. The institutions which are responsible for forest resources management in Turkey are the General Directorate of Forestry (GDF), the General Directorate of Nature Conservation and National Parks (GDNCNP) and the General Directorate of Combating Desertification and Erosion (GDCDE) under the Ministry of Forestry and Water Affairs (MFWA). The forestry organization, which is responsible for sustainable forest resources management, needs not only an ideal organizational structure but also employees with sufficiency and performance in order to achieve organizational goals and success. For this reason, it is important to identify the factors that affect the administrative and organizational success of the employees.

Therefore, this study aims to evaluate sustainable forest resources management efficiency, training, knowledge and supervision levels of the employees that work as administrators and technical staff in the forestry organization in Turkey. The study also aims to evaluate the administrative and organizational success mentality of the staff, their motivation level, motivation-success relation, measures to take in order to improve success and success measuring system. While evaluating the mentioned issues, the study considers the attitudes of four different interest groups which are the employees, experts, related institutions and nongovernmental organizations (NGO) representatives. The study has been conducted throughout the country among 565 participants including administrators and technical staff who work in forestry sector (GDF, GDNCNP and GDCDE) of the Ministry of Forestry and Water Affairs, and experts, related institutions and NGO representatives. The study has been carried out through interviews and questionnaires. The results are thought to contribute to sustainable forest resources

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87138735

management, human resources management, administrative and organizational success of forestry organization.

Material and Method

Material

The study has been carried out among the sample group that consists of the employees working in the forestry sector (GDF, GDNCNP and GDCDE) of the MFWA. The provinces (İstanbul, İzmir, Antalya, Adana, Bolu, Trabzon, Erzurum, Şanlıurfa and Ankara) with intense forestry activities have been included to represent the nine geographical regions of Turkey.

Participants belonging to four different interest groups, which are the employees, experts, related institutions and NGO representatives, from the cities listed above have been interviewed and questionnaires have been applied in order to evaluate the factors that affect administrative and organizational success in Turkish forestry sector. Four different interview and questionnaire forms had been prepared for each interest group. The questions in the forms are generally as follows: (1) The sufficiency of the education and the opportunity of self-development, (2) Administrative competence of the employees, (3) Success mentality and (4) Motivation. Similar and different questions were asked for each interest group in the questionnaire forms. The forms include both open-ended and closed-end questions. All kinds of qualitative and quantitative data obtained from research on four different interest groups and literature review are the main materials of the study.

Data Collection Method

The population of the study consists of the technical staff and administrators working in central and provincial units of forestry organization of the MFWA (N=4704) (MFWA, 2016). The number of employees within the scope of this study was calculated using the following formula (*Eq.1*) related to the sample size in measurable groups (Orhunbilge, 2000; Daşdemir, 2016);

$$n \geq \frac{Z^2 \times N \times p \times q}{N \times D^2 + Z^2 \times p \times q} \qquad \text{(Eq.1)}$$

where n is the size of the sample, Z is reliability coefficient (Z=1.96 for 95 % of confidence level), N is the size of the population (N=4704), p is the existence possibility of the measured feature in the population, q is absence possibility of the measured feature in the population (p=0.5; q=0.5 a) and D is acceptable sampling error (0.05).

According to this, n was calculated as 355 and so the minimum number of the interviewees was determined. The minimum number of the participants to be interviewed for each region was calculated by multiplying the number of the employees in each region with the calculated n/N coefficient which represents that each layer has been sampled in proportion to its percent. On the other hand, the number 355 was exceeded and 463 participants, who are technical staffs and administrators, were interviewed during the study (*Table 1*).

The interviewee and the questionnaire participants were selected randomly in each region. Thus, stratified-simple random sampling method was utilized in the study.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87138735

As well as the staffs in the forestry organization, a survey research was carried out on 32 representatives of related institutions (municipal authorities, forestry faculties, provincial directorate of agriculture etc.), 37 NGO representatives (the Chamber of Forest Engineers, the Foresters' Association of Turkey, the Foundation for the Promotion and Protection of the Environment and Cultural Heritage, forestry cooperatives, Village Headmen Association, Forestry Union etc.) and 33 experts who have scientific studies on forest resources management or who have been working in forestry organization as administrator for many years and have knowledge on administration of forestry organization and restructuring. Since the actual numbers of other interest groups in each region were small, the survey was conducted in full field (on all their numbers) in each region. Therefore, the sample sizes of other interest groups are equal to their actual numbers. Thus, a total of 565 participants from the four different interest groups were interviewed (*Table 1*).

Table 1. *Numbers of the interviewed participants for all interest groups*

Regions	Staffs in Forestry Organization												Institutions	NGO	Experts	General Total
	GDF		GDNCNP		GDCDE		Center of the MFWA		Total Staff	General						
										Sample						
	Staff	Sample	Staff	Sample	Staff	Sample	Staff	Sample		Technical staffs	Adminis-trators	Total				
Marmara (İstanbul)	721	62	73	9					794	57	14	71	7	10	10	98

Southeastern Anatolia (Şanlıurfa)	89	18	38	7					127	13	12	25	2			27
TOTAL	4220	398	382	56	48	5	54	4	4704	273	190	463	32	37	33	565

The interviews were conducted in 2016. A pretesting was applied for the questionnaire. In the pretesting process, the attitudes of the participants about the questionnaire, the convenience of the questionnaire forms, the clarity of the questions and missing parts were determined, questionnaire form was rearranged. Then the participants were informed about the importance of the subject and the questionnaires were conducted through face to face meetings.

Data Evaluation Method

The data which are mostly qualitative and obtained from four different interest groups' questionnaire survey have been identified and digitized as variables in *Table 2*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87138735

The data was evaluated through descriptive statistics, the Kruskal–Wallis (K-W) H Test and the Duncan's Test and the results were shown in tables. The software Excel-2010 and SPSS (22.0 version) were utilized to evaluate the data.

Results

General Results on Participants and Evaluations

A total of 565 people from four interest groups located in 9 geographical regions in Turkey were interviewed and questionnaires were conducted during this study. 463 of them work as manager and technical staff in the forestry organization. 59% of the participants of the questionnaire are engineers, 11% are forest chiefs, 2% are deputy director of forest enterprises, 2% are managers of forest enterprises, and 24% are branch managers, deputy director or directors of regional directorates of forestry. Also, 52% of the *experts*, number of which is 33, work under the MFWA, 42% are academicians from faculties of forestry and 6% are retired forest engineers. 28% of the 32 participants from *related organization representatives* are the employees of municipalities or various ministries, 53% are of forestry faculties, 19% are of other institutions related to forestry such as General Directorate of State Hydraulic Works (DSI) and General Directorate of Highways (TCK) etc. 34% of these mentioned participants are technical staff, 13% are administrators and 53% are academicians. On the other hand, 51% of the 37 participants, who are *NGO representatives*, are either the members of the Chamber of Forest Engineers or the Foresters' Association, 8% are the members of unions and 41% are the members of foundations etc. related to forestry. 68% of them are members, 32% are either managers or deputy managers.

The educational status, the administrative task duration and experience for the 463 participants who work as administrators and technical staff in the forestry sector across Turkey are indicated in *Table 3*.

Considering the *Table 3*, it can be understood that most of the questionnaire participants (65%) have been working in their current administrative positions between 0-5 years. The rate of those who have been working in the same administrative position more than 11 years is 13%. In other words, 87% of the staff working as administrators have worked in their position maximum for 10 years. Whereas 51% of the survey participants have a 20-year job experience, 49% of the participants have an experience of 21 years or more. 73% of the participants have a bachelor's degree in forest engineering. Only 24% of them have either master or Ph.D. degree while 3% are graduates of some other faculties. This is an important progress in training qualified administrators and technical staff. Approximately 70% of the participants who were consulted as experts are either graduates of two different faculties or have graduate degree (master or Ph.D.).

Sufficiency of Education and Opportunity of Self-Improvement

In this part of the study, the employees in the forestry sector and the experts on organizational structure and administration were asked their attitudes about the sufficiency of the education received in forestry faculties on forest resources management, the sufficiency of the prevocational training, in-service training and human resources development activities provided by the forestry organization.

Education	Undergraduate		339	73
	Graduate		111	24
	Get degree from two Undergraduate Programs		13	3
	Total		463	100

Besides, those working as administrators (on planning, organization, operation, and supervision) and technical staff were also asked what kind of knowledge background they require mostly and their attitudes on the opportunity of self-improvement. The attitudes of the participants were evaluated and the results were indicated in *Table 4*. The question, whether the attitudes of the employees differ depending on the regions, departments, position and job experience or not was tested through statistical analyses as well (*Table 5*).

Sixty-four percent of the participants who work for forestry organization and 73% of the experts define *the sufficiency of the education received in forestry faculties on forest resources management* as "moderately sufficient" (*Table 4*). As it is indicated in *Table 5*, the region, department and position have no significant effect on their attitude. However, as for job experience, 95% of reliability level makes a significant difference. It has been observed that less experienced employees (0-10 years of experience) generally define the sufficiency of the education received in forestry faculties on forest resources management as "slightly sufficient" and "moderately sufficient" whereas those with medium, high and quite high experience (≥11 years) mostly define as "reasonably sufficient".

Forty-six percent of the employees find *the prevocational training provided by the organization* "moderately sufficient" (*Table 4*). At this point, the attitudes of the employees differ depending on the region with a reliability level of 99% whereas their attitudes have differences in terms of the position, department and experience with a reliability level of 95%. While those who work in İstanbul, Şanlıurfa, Adana, Antalya and İzmir generally find prevocational training "slightly sufficient", the staff work in Ankara, Bolu, Trabzon and Erzurum mostly find "moderately sufficient". When the departments are considered, those working at the General Directorate of Forestry (GDF) and the General Directorate of Nature Conservation and National Parks (GDNCNP) define training as "slightly sufficient" and "moderately sufficient". On the other hand, the employees working at the General Directorate of Combating Desertification and Erosion (GDCDE) find the mentioned training "moderately sufficient" and "very sufficient". Engineers also find the prevocational training provided by the organization "slightly sufficient" and "moderately sufficient" whereas operation chiefs, assistant

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87138735

operation managers, operation managers, branch managers, district managers and their assistants mostly find it "moderately sufficient". When job experience is considered, less experienced staff and those with medium experience (0-20 years) define their attitude as "hardly sufficient" and "moderately sufficient" whereas those with high and quite high experience (≥21 years) generally define it as "moderately sufficient" (*Table 5*).

Table 4. *Participants' attitudes on sufficiency of the education and opportunity of self-improvement*

Attitudes	Scale	Percentages of attitudes (%)	
		Staff	Experts
1. Sufficiency of undergraduate education on forest resources management	a) Not all	6	0
	b) Slightly	20	9
	c) Moderately	64	73
	d) Very	8	15
	e) Extremely	2	3
2. Sufficiency of prevocational training	a) Not all	8	-
	b) Slightly	38	-
	c) Moderately	46	-
	d) Very	7	-
	e) Extremely	1	-
3. Sufficiency of in-service training	a) Not all	4	-
	b) Slightly	22	-
	c) Moderately	60	-
	d) Very	13	-
	e) Extremely	1	-
4. Knowledge requirement in the management of forestry activities	a) Basic knowledge (biology, physics, chemistry, mathematics, statistics etc.)	2	0
	b) Technical knowledge (construction, transportation, cadastre, watershed management etc.)	18	0
	c) Biological and ecological knowledge (ecology, entomology, silviculture, afforestation etc.)	30	18
	d) Social and economic knowledge (economy, business administration, production-marketing, finance, planning, law, public relations etc.)	50	82
5. Opportunity for self-improvement in administrative and technical issues	a) Not all	3	0
	b) Slightly	19	9
	c) Moderately	57	70
	d) Very	19	18
	e) Extremely	2	3

On the other hand, when *the sufficiency of the in-service training* is considered, 92% of the employees (60+22+4) find it "moderately sufficient", "slightly sufficient" and "not sufficient" (*Table 4*). The attitudes of the employees regarding this matter differ depending on the position with a reliability level of 99% and on the region, department and experience with a reliability level of 95%. Those working in İstanbul, Adana, Antalya, İzmir, Ankara, Bolu, Trabzon and Erzurum define the sufficiency of the in-service training and human resources development activities as "moderately sufficient" whereas those who work in Şanlıurfa mostly define it as "slightly sufficient". When the department is considered, employees at the GDF state "slightly sufficient" and "moderately sufficient" while the employees at the GDNCNP and the GDCDE generally state "moderately sufficient" and "very sufficient". Those working as engineers, forest chiefs and managers of forest enterprises generally state their attitudes

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87138735

as "slightly sufficient" and "moderately sufficient". However, deputy managers of forest enterprises, branch managers, directors and deputy directors of regional forest directorates define their attitude as "moderately sufficient" and "very sufficient". Similarly, employees with less, medium and high experience (0 -30 years) find related activities of the organization "slightly sufficient" and "moderately sufficient". Those with quite high experience (≥31 years), on the other hand, generally find the activities "moderately sufficient" and "very sufficient" (*Table 5*).

* is significant at 0.05 confidence level; ** is significant at 0.01 confidence level

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87138735

The complexity of tasks and responsibilities of national forestry organization and the overload job definition of forest engineers who work as land managers makes the importance of the education and training critical for Turkish forestry. The findings showed that both the undergraduate education and vocational education should be developed especially in the context of social and economic aspect. Also the training program's sufficiency is considered lower by GDF's staff than the others. The main reason of this result depends on the diversity of work, work load, task and responsibilities and also the size of organizational structure of GDF. Thus the priority should be given to this institute. This could affect both the personal and organizational performance.

Fifty percent of the employees working in forestry sector and 82% of the experts state that they mostly require social and economic (economics, management, production-marketing, accounting, planning, law and public relations etc.) knowledge background when they are asked *"What kind of knowledge background do you require mostly with your position in the management of forestry activities (planning, organization, operation, and supervision)?"* (*Table 4*). The difference of region, department, position and experience do not significantly affect the employees' attitude related to that aspect (*Table 5*).

Fifty-seven percent of the employees and 70% of the experts answer the question *"Do you find the opportunity for self-improvement in your profession and technical issues?"* as "moderately sufficient" (*Table 4*). The difference in department and experience do not significantly affect the employees' attitude related to the subject. However, it has been observed that the attitude of the employees differ depending on the region and position with a reliability level of 99%. According to the scores of Duncan's test which was applied in order to find the difference among the groups, it has been found out that employees in İstanbul, Ankara, Şanlıurfa, Adana and İzmir generally state that self-development opportunity is "slightly" and "moderately sufficient". However, those working in Bolu, Trabzon, Erzurum and Antalya answer the same question as "moderately sufficient" and "very sufficient". On the other hand, engineers, forest chiefs and branch managers state this aspect as "moderately sufficient" whereas managers and deputy managers of forest enterprises and regional forest directorates state it as "moderately sufficient" (*Table 5*).

Self-improvement is also another important factor that affects the organizational success. It was found out that the self-improvement opportunities were commented in different levels by the regions. Especially the participants of the regions with higher development level such as Istanbul and Ankara expressed that they have lower level of related opportunities. The evaluation of this result in human resources management policies could support the regional level activities. The other interesting finding showed that the level of considering the sufficiency of self-improvement opportunities increase by the position. The reason of this result could be the differences between the duty places and conditions of the staff at different organizational levels. In this context, the staff with lower position level should be supported as a general policy.

Results Related to Administrative Competence

In this part of the study, the employees that work as administrator and technical in the forestry organization were asked to consider the sufficiency of themselves, their subordinates, superiors and technical staff about forest resources management, legislative knowledge and also their attitudes about following the research and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87138735

development activities and outputs. Related results were indicated in *Table 6*. The question whether the attitudes of the employees relating the issue differ depending on the regions, departments, position and experience were tested through statistical analyses as well and the results were indicated in *Table 7*.

Table 6. *Employees' attitudes on their administrative competence*

Attitudes	Scale	Percentages of attitudes (%) Staff
1. Sufficiency of personal knowledge in administrative and technical issues	a) Not all	1
	b) Slightly	8
	c) Moderately	60
	d) Very	28

	b) No	26
	c) Moderately	62
7. Reason of not following research and development activities sufficiently	a) I don't care	1
	b) I care, however I don't have enough time	42
	c) I'm not of interest	8
	d) The research results aren't applied	23
	e) I don't believe in researches and find them insufficient	8
	f) Other	18

As it can be concluded from *Table 6*, 60% of the employees working in forestry organization find themselves "moderately sufficient" in forest resources management. The difference of department has no significant effect on the employees' attitudes related to the subject. However, when region and experience are considered, significant effect on the attitude can be seen with a reliability level of 99% and this rate is 95% when position is considered. Those who work in İstanbul, Ankara, Erzurum and Şanlıurfa find themselves "moderately sufficient" in forest resources management, whereas those working in Bolu, Trabzon, Adana, Antalya and İzmir state their competence as "very sufficient" (*Table 7*). As for their position, engineers, forest chiefs

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87138735

and managers of forest enterprises define themselves as "moderately sufficient" while deputy manager of forest enterprises, branch managers, managers and deputy managers of regional directorate mostly find themselves "very sufficient". Besides, less experienced employees and those with medium experience (0-20 years) evaluate themselves to be "moderately sufficient" and those with high and quite high experience (≥21 years) find themselves "very sufficient" (*Table 7*).

Table 7. *Differences of participants' attitudes on administrative competence depending on region, department, position and experience*

Attitudes	Kruskal-Wallis H-Test Results			Identify differences by Duncan Test (Groups and in-group components are ranked as to their significance level)			
	Criteria	Khi-square value	SD	Groups with significant differences

5. Sufficiency on legislative knowledge	There is no significant difference with respect to region and department					--	--
	Position	24.56**	5	1	Engineer, forest chief, manager of forest enterprise	3.28	332
				2	Deputy manager of forest enterprise, branch manager, manager and deputy manager of regional directorate	3.59	131
	Experience	33.68**	3	1	Staff with low, medium and high experience (0-30 years)	3.27	423
				2	Staff with very high level experience (≥31 years)	3.68	40
6. Following research and development activities	There is no significant difference with respect to region, department, position and experience					--	--

Sixty percent of the participant employees working in the forestry organization think that their superiors are "moderately sufficient" in forest resources management (*Table 6*). The attitudes of the participants do not indicate a significant difference depending on region and department with a reliability level of 95%. However, when position and experience are considered a significant difference is observed in terms of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87138735

reliability levels of 95% and 99% respectively. Engineers, managers and deputy managers of forest enterprises, and branch managers generally define their superiors "slightly sufficient" or "moderately sufficient". Forest chiefs, managers and deputy managers of regional forest directorates on the other hand, generally find their superiors "moderately sufficient" or "very sufficient". On the other hand, less experienced employees (0-10 years) in forest resources management generally find their superiors "moderately sufficient" or "very sufficient". Employees with medium, high and quite high experience (≥11 years) think that their superiors are "moderately sufficient" or "slightly sufficient" (*Table 7*). It can be understood that the higher job experience levels that the employees have mean the less competence attitude on their superiors.

Sixty percent of the participants define their subordinates as "moderately sufficient" when their attitude is asked about forest resources management (*Table 6*). Region, department, position and experience difference do not have a significant effect on the attitudes of participants (*Table 7*).

When they are asked about the technical staff, 68% of the participants working in the forestry sector think that they are "moderately sufficient" in forest resources management (*Table 6*). Region, department, position and experience difference do not have a significant effect on the attitudes of participants (*Table 7*). Most of the participants find not only themselves but also their superiors - subordinates and technical staff "moderately sufficient" in forest resources management related issues.

The results showed that the staff defines themselves, their superiors and subornitaes and also the technical staff moderately sufficient in terms of aspects regarding forest resources management. This could be a prominent issue in terms of success of the organization. Determination of the related insufficiencies and their reason could have priority for the forestry sector in Turkey. Thus the key solutions could be designed for improving sustainability of forest resources. Also it was found out that the focus group should be engineers and forest chiefs who are at the lowest position and have much more task and workload. Besides both the managers, land managers and technical staff should be supported about their managerial ability related forest resources.

When the participants are asked as *"How sufficient is your knowledge about the law, regulations and instructions etc. related to your position-department?"* 52% of them define themselves as "moderately sufficient" on legislative knowledge. 34% state that they are "very sufficient" (*Table 6*). Region and department difference do not have a significant effect on the attitudes of participants. However, when their position and experience are considered, a significant difference can be observed with a reliability score of 99%. While engineers, forest chiefs and managers of forest enterprises find themselves "moderately sufficient" and "very sufficient" on legislative, deputy managers of forest enterprises, branch managers, managers and deputy managers of regional forest directorates mostly state that they are "very sufficient" (*Table 7*). Particularly mid-level and senior managers such as branch manager, managers and deputy managers of regional forest directorates define themselves as more sufficient on legislative knowledge when compared with the rest of the employees is both ordinary and necessary. Employees with less, medium and high job experience (0-30 years) find themselves "moderately sufficient" and "very sufficient". Those with a quite high job experience (≥31 years) define themselves as "very sufficient" on legislative knowledge (*Table 7*). It can be stated that the more experienced the employees become, the more sufficient they find themselves on legislative knowledge, which is a realistic situation.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87138735

When they are asked as *"Are you able to follow scientific studies and researches related to forestry?"* 12% of the participants answer "Yes"; 26% "No" and 62% "Partially" (*Table 6*). It is observed that the participants (42%) whose answer is "No" or "Partially", give the answer *"I care about them but I am too busy"* as an excuse for not being able to follow research and development activities and their outputs. The second most commonly (23%) given excuse is *"I don't follow because I don't find them applicable"*. As it can be concluded here, 65% (42+23) of the employee state that they are not able to follow research and development activities and their outputs because they do not have enough time or they do not follow them because of not believing the activities to be applicable. No significant difference depending on region, department, position and experience can be found related to the subject (*Table 7*).

It was found out that the staff evaluated their legal knowledge sufficiency at a high level. This is a favorable situation in terms of Turkish Forestry because there are lots of problems derived from application of legislations and the sufficiency of the technical staff about legislative issues makes the forestry organization stronger. However, the level of following research and development activities is low. The interaction between research and decision making and also implementation processes of forestry play critical role on organizational success. This potential should be developed by effective mechanisms to strengthen the managerial process of Turkish forestry.

Results Related to Success Mentality

The attitude of the managers, technical staff and the experts about administrative success, most important factors affecting success and success measurement systems were questioned at this part. Related institution representatives and the representatives from NGOs were also asked about their thoughts on administrative success in forestry. The results were given in the *Table 8*. Besides, the question, whether participants' thoughts differ depending on region, department, position and experience was statistically analyzed and results were given in *Table 9*.

Seventy-for percent of the employees working in forestry sector, 76% of the experts, 63% of related institution representatives and 81% of NGO representatives replied the question *"How do you identify administrative and organizational success in forestry?"* as *"achieving the goals through efficient use of resources"*. The answer by NGO representatives with the highest rate and accuracy indicates how conscious they are about the issue (*Table 8*). Region, department and position difference has no significant effect on the participants' thoughts. However, experience has an effect with a 99% reliability score. According to the Duncan's test score which was performed to find out which group is different, it is understood that the answer *"achieving the goals through efficient use of resources"* is more common among those with medium job experience (11-20 years) when compared with the answers of those with less, high and quite high job experience (0-10 years and ≥21 years) (*Table 9*).

Fifty-six percent of the employees and 73% of the experts identify "organizational and administrative factors such as organizational structure, administrative competence, number of the staff and their level of education as *"the most important factors affecting success"* (*Table 8*). No significant difference depending on region, position and experience can be found related to the subject (*Table 9*) but, a significant difference is found depending on departments with a reliability score of 95%. According to Duncan's test results, employees working at the GDF and the GDCDE are more likely to identify

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87138735

"organizational and administrative factors" as "the most important factors affecting success" when compared with those working at the GDNCNP (*Table 9*).

The understanding of success of technical staff is toward achieving the goals through efficient use of resources. The common understanding about organizational success could contribute to coordination and cooperation in the forestry organization. Besides the participants evaluated organizational and administrative factors as the most important factor that affects the organizational success. The forest organization's structure is very complex and had changed many times in the historical period. This situation is seen as the source of many forestry-related problems. Also it is seen that it has effect on organizational success. Thus forming an effective organizational structure and administrative system seem to be a prominent aspect in terms of increasing the success of the organization.

Table 8. *Attitudes of participants about administrative success in forestry*

Attitudes	Scale	Percentages of attitudes (%)			
		Staff	Experts	Representatives of Related Institutions	Representatives of NGOs
1. Mentality of administrative and organizational success	a) Maximization of profit	1	0	3	0
	b) Maximization of goods and services production	2	3	3	3
	c) Producing highest output from the least input	6	0	6	5
	d) Achieving the goals through efficient use of resources	74	76	63	81
	e) Producing the highest amount of goods and services through the market demand	3	3	10	0
	f) Fulfilling the need of society regarding forest resources	7	12	6	0
	g) Other	7	6	9	11
2. Most important factors affecting success	a) Physical factors (forest area, forest stock, forest productivity, road density etc.)	4	3	-	-
	b) Economic and financial factors	4	0	-	-
	c) Socio-economic factors	18	15	-	-
	d) Technical factors (technical knowledge, number of machines etc.)	7	0	-	-
	e) Organizational and administrative factors (organizational structure, efficiency of managers, number and training of staff etc.)	56	73	-	-
	f) Ecological and geographical factors (location, climate, soil etc.)	5	9	-	-
	g) Other	6	0	-	-
2. Attitudes on success measurement of forestry organization	a) Assessment and Evaluation Unit that will be established under Ministry or General Directorate should measure the organizational success by using some objective criteria and depending on the records of the organizations.	49	67	-	54
	b) Register managers should measure the success by scoring the staff utilizing criteria of standard forms.	10	3	-	6
	c) The success of the staff should be measured by examination and supervision system that will be managed by an expert commission	27	24	-	24
	d) Other	14	6	-	16

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87138735

Forty-nine percent of the employees, 67% of the experts and 54% of the NGO representatives stated that organizational success should be considered when they were asked about *"success measurement system for organizational structure success (performance)"* (*Table 8*). No significant difference depending on region, department, position and experience can be found relating to this issue *(Table 9*).

Table 9. *Difference of participants' attitudes on administrative success mentality depending on region, department, position and experience*

Attitudes	Kruskal-Wallis H-Test Results			Identify differences by Duncan Test (Groups and in-group components are ranked as to their significance level)			
	Criteria	Khi-square value	SD	Groups with significant differences			
				No	Component of the groups	$\overline{X}$	N
1. Mentality of administrative success in forestry	There is no significant difference with respect to region, department and position.					--	--
	Experience	13.78**	3	1	Staff with low, high and very high experience (0 -10 years and ≥21 years)	51.36	346
				2	Staff with medium experience (11-20 years)	64.04	117
2. Most important factors affecting success	There is no significant difference with respect to region, position and experience.					--	--
	Department	6.54*	2	1	GDNCNP	29.34	53
				2	GDF, GDCDE	42.11	410
3. Attitudes on success measurement system	There is no significant difference with respect to region, department, position and experience.					--	--

Success measurement system is an important lack which has direct relations with the performance of staff and whole organization. While improving the system as the participants emphasized objectivity should be the essential principle. In other case the staff would develop a negative attitude towards the organizational justice.

Results Related to Motivation and Reward

Motivation has a great role on employees' willingness of fulfilling their tasks (Newman, 1972). Therefore, to increase the motivation of the employees shall increase the success. In this part of the study, the participants were asked their attitudes about the relationship between the success at work and designation, promotion and reward, what should be done to raise the motivation of the employees and accordingly to increase the success and how the performance measuring system should be within the structure of the organization. The answers by the participants were indicated in *Table 10* and the question whether participants' thoughts differ depending on region, department, position and experience was statistically analyzed (*Table 11*).

Fifty-three percent of the employees answered "there is no relationship", 25% answered "there is a slight positive relationship" and 14% answered "there is an inverse relationship" the question "*Is there a relationship between your success at work and designation, promotion, appreciation, premium and being rewarded?"* The rate of those who find "very close relationship" is just 8%. The answers of the experts for the same question are as follows: 49% "there is a slight positive relationship", 27% "there is no relationship" and 3% "there is an inverse relationship" (*Table 10*). The difference of region and position has no significant effect on the participants' attitudes. However, it has been concluded that different departments (95% reliability) and different job experiences (99% reliability) have a significant effect on the issue. Employees working

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87138735

at the GDF generally think that there is no relationship between success and promotion or being rewarded whereas, the GDNCNP and the GDCDE employees generally think that there is a slight positive relationship. On the other hand, employees with high and quite high job experience (≥21 years) find no relationship while less and medium-experienced ones (0-20 years) generally think that there is a slight positive relationship (*Table 11*).

Table 10. *Participants' attitudes about motivation and reward*

Attitudes	Scale	Percentages of attitudes (%)			
		Staff	Experts	Representatives of Related Institutions	Representatives of NGOs
1. Relationship between the success and designation, promotion, premium, being appreciated and being rewarded	a) There is a negative relation	14	3		
	b) There is not any relation.	53	27		
	c) There is a low-level positive relation	25	49		
	d) There is a high-level positive relation	8	21		
2. Opportunities of raising the motivation / success of staff	a) Premium should be paid	15	18	13	5
	b) Staff should be promoted	5	3	0	0
	c) Designation should be made in accordance with the preference of the staff	7	0	3	0
	d) Staff should be appreciated	14	18	3	8
	e) The attitudes of the staff should be considered and they should participate in decision-making processes	42	55	72	65
	f) Staff should be joined to national and international vocational trips	4	0	3	0
	g) Other	13	6	6	22

Forty-two percent of the employees, 55% of the experts, 72% of the relevant institution representatives and 65% of the NGO representatives answered the question *"What should be done in order to raise the motivation/increase the success of the employees in forestry sector?"* as "their attitudes should be considered and they should participate in decision-making processes" (*Table 10*). This approach was found to be dominant in all interest groups. No significant difference depending on region, department, position and experience can be found relating to this issue (*Table 11*).

This is one of the very critical results of the study. As the staff mentioned without contacting the success with designation, promotion, premium, being appreciated and being rewarded then the system could be evaluated as unjust by the staff. Also it's understood that the staff evaluated participation in decision making process and consideration of their attitudes as the main factor in rising the motivation and success. It should be considered in the context of national level policies on both decision making process and human resources management. Providing active participation of the staff would also support the participatory management mechanism which is also a lack for Turkish forestry. This result could also be a starting point of the new researches regarding administration and organizational behavior related studies for the country and the similar countries.

				2	Staff with high and very high experience (≥21 years)	0.11	225
2. Opportunities of raising the motivation / success of staff	There is no significant difference with respect to region, department, position and experience.					--	--

Discussion

The results of the study are important in terms of contribution of related national policy making process. Also the results contribute to analyze regional differences and gives opportunity to focus on local level decisions. Both the national and regional level findings can guide to the countries where the forests are publicly managed. Also the results represent the problems and trends of the forestry organizations that have complex organizational structure and managed centrally. Thus the study contributes to international literature and expresses decision makers in national and regional level managers of forestry organizations which have public institution characteristics.

In the study, the most important factors (education and self-development, administrative competence, success mentality, motivation and rewarding) affecting administrative and organizational success in the forest resource management of Turkey were analyzed and evaluated from the perspectives of staff, experts, representatives of related institutions and NGOs. According to the results, a great majority of the participants' think the undergraduate education is insufficient. However, it is seen that as the task duration increases the belief on the education provided by the faculties be sufficient increases as well. It is known that the rate of courses with socioeconomic content, accordingly socioeconomic aspect, is more important in forestry education and training in countries where modern forestry understanding is dominant (Geray, 1991, 1993; Lorincová et al., 2016). In some of the researches conducted in the country (İnal, 1968; Kalıpsız et al., 1969; Pamay et al., 1973; Çepel, 1984; Daşdemir, 1998), it has been determined that forest engineers mostly need courses with socioeconomic content whereas courses related to management and organization, public relations, decision-making methods and scientific research methods dominate provided education. The rate of the courses with socioeconomic content in the curriculum of forestry education in some of the universities in the USA, Australia and Sweden, differs from 23% to 36% while this rate is only 14 %-17% in Turkey (Elands et al., 2004). Therefore, the education system given in the forest faculties should be rearranged as compatible with contemporary forestry approach by considering the attitudes of all partners on the issue, particularly applied training and courses with socioeconomic content should be focused on.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87138735

A large part of the participants' state prevocational and in-service training activities to be insufficient which suggests that prevocational and in-service training activities related to the profession should focus on self-improvement of administrators and technical staff besides being solution-oriented. It is observed that former studies had come a similar conclusion (Yurdakul, 2005; Şenyaz, 2008; Şafak, 2008).

Turkey forestry organization has encountered structural changes for several times due to political decisions that are not based on scientific foundations and that lack of participation principle and consequently the problems with administration, organization, planning, supervision etc. has increased and it has encountered problems in achieving organizational goals. Whereas it is necessary to increase the number of those who actually run the business within this context, it is seen that the number of senior managers had raised and the majority of the staff had gathered at the central organization.

Most of the employees, experts, relevant institution representatives and NGO representatives state that "the employees' attitudes should be considered and they should participate in decision-making processes" when the issue *"What should be done in order to raise the motivation/increase the success of the employees in forestry sector?"* is asked. No significant difference depending on region, department, position and experience can be found related this issue. In a study carried out among the technical staff employed at the İstanbul Regional Directorate of Forestry (Yurdakul Erol, 2017; Yurdakul Erol and Köse, 2017); the most satisfying factor is stated to be "the characteristic of the job to enable someone to do something for others". The second most satisfying component about the occupation is stated to be that "the job gives a chance to be a respectable person in the society". "To be able to find the opportunity to guide people" and "employment security" are also found to be other satisfying points of the occupation. As it can be understood from these results, regarding the employees' attitudes, participation in decision-making processes, the idea of being socially beneficial and the desire to be respected in the society should be used as means of motivation in forestry organization.

Organizational success (performance) is a multi-dimensional concept that indicates the level of achievement to organization goals according to contemporary management approach. Performance measurement systems that are not well designed prevent the organization from successfully adapting to the competitive environment. Because, performance measurement with incorrect methods leads to a reduction in the accuracy of the data that will support the application. In this context, it has been concluded that Measurement and Evaluation Center for Success to be established under Ministry or General Directorate should measure the organizational success by using some objective criteria and depending on the records of the organizations. This shows that the presence of a system based on entirely objective criteria without discrimination (attitudes, beliefs, race etc.) is preferred by the employees. Consequently, success measurement system which will be applied in this manner should form the basis for the institutional structure of forestry organization in Turkey and for promoting organizational success.

Conclusion

To achieve organizational success, determination of related problems by considering both internal and external stakeholders is an essential aspect for Turkish forestry. Also

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87138735

focusing on differences between the stakeholders and regions supports development of specific and solution-oriented decisions and implementations.

Especially education and training is one of the important factors that affect the organizational success as an instrument. Insufficiency about knowledge on socio-economic issues was found out and then the observed prominent problems were parallel to this content. Besides, the interaction between scientific researches and forestry organization is the other key factor what could have direct affect on improvement of forestry organizations' success. The Turkish forestry experience also showed that the foremost factor that affects organizational success is related with organizational and administrative issues. The role of participatory management and objective performance measurement system was considered as the main components of success in Turkish forestry organization. These issues should be considered in forestry-related national level policy and strategy making processes immediately. Further, focusing on region and local level properties could increase the success of implementations of these policies and strategies.

Acknowledgements. This study was produced in the context of the research project entitled "Development of Alternative Organizational Models for Turkish Forestry" and numbered 10.5301/2014-2017 which was supported by the General Directorate of Forestry and directed by the Marmara Forestry Research Institute.

Abstract. The improper disposal of household waste is a major reason for the deterioration of rural ecological environment in developing countries. As the main producer of rural household waste, farmers' behavior is very important to solve the problem. Based on the data of 671 surveys in Jiangsu, China, the influencing factors of farmers' household waste disposal behavior and their hierarchical relationships were determined by Logit-ISM model. The study finds that there are 7 factors that significantly affect household waste disposal behavior of farmers, among which Major domestic fuel, Clearance of centralized waste dump site and Neighbor's way of disposing household waste are the surface factors; Identifying capacity for pollutants, Major economic source and Availability of centralized waste disposal facility are the intermediate factors; Fixed-point waste disposal policy and its implementation effect is the deep- rooted factor.
Keywords: *farmer household behavior, Lewin's behavior model, Logit model, ISM method, sorted reachability matrix, interpretative structure model*

Introduction

The construction of ecological civilization has increasingly become a hot topic of common concern to mankind. All countries in the world are committed to exploring the road of harmonious coexistence between human and nature. Due to the dominant position of developed countries, relevant organizations and associations mainly focused on the prevention and control of industrial pollution and urban pollution (Petraru and Gavrilescu, 2010; Gong et al., 2019), and less on rural environmental issues. However, for the vast majority of developing countries, rural areas are the largest hinterland of biological resources, carrying the majority of the country's population. Construction of rural ecological civilization occupies a more fundamental position. In the past, kitchen residues were the main part of rural household waste, which was recycled reasonably, resulting in little pollution to the surrounding environment. In recent years, with the rise of the economy in developing countries, the consumption structure of rural residents has changed greatly. As a result, the composition of rural household waste becomes more complex. Plastic products, electronic waste and other non-decomposable items are becoming more common (Hakami and Seif, 2015; Du et al., 2018). The original self-purification ability of rural areas can hardly play an effective role. The impact of household waste on rural ecological environment is becoming increasingly serious.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87378748

This phenomenon is particularly prominent in China. Due to the long-standing views of farmers, it is quite common for waste to be dumped at will, resulting in serious soil pollution (Zeng et al., 2018), water pollution (Zhang et al., 2013) and air pollution (Jin et al., 2006). Ultimately, the health of villagers has been damaged. It can be seen that the control of household waste discharge arbitrarily is a very important task. However, the current rural household waste management method is a government-dominant model, which marginalizes farmers and makes them spectators, passives and even adversaries. It needs to be deeply realized that farmers are not only the producers of household waste, but also the direct victims of the pollution. Farmer should be the core subject of the governance of rural environmental problems. However, previous studies mainly focused on the productive environmental behavior of farmers, and paid less attention to the impact of farmers' daily life behavior on the environment.

This paper analyses the impact of farmers' daily life behavior on the environment from their perspective, which is not only related to the quality of life of 900 million rural populations in China, but also directly affects the sustainable development of China's economy. Meanwhile, as a representative of developing countries, China's rural household waste disposal problem is a microcosm of the same problem in developing countries. This study can provide new ways for other developing countries to promote rural ecological environment construction.

Theoretical basis and variable selection

Theoretical basis

Since the 1960s, the process of industrialization and urbanization has been accelerating. Environmental protection has gradually become a consensus of mankind. Sociological circles have begun to pay close attention to this problem. In 1978, American sociologists Catton and Dunlap published their paper *Environmental Sociology: A New Paradigm*, which clearly pointed out that Environmental Sociology should focus on the interaction between environment and human society. Subsequently, the famous Japanese sociologist Torigoe Hiroyuki emphasized that the subject of environmental pollution is human itself. Meanwhile, Kurt Lewin pointed out that individual behavior is the product of the interaction between individual and environment. He put forward the famous Lewin behavior model, namely $B = F(P, E)$, in which B is human behavior; P is the internal condition and characteristics of an individual, E refers to the external environment. Lewin's behavior model provides a solid theoretical basis for people to explore human behavior including environmental behavior.

Variable selection

With the comprehensive study of scholars, based on Lewin behavior model, this paper analyses the influencing factors of farmers' household waste disposal behavior from the perspectives of personal and environment. Personal factors can be divided into physiological characteristics and psychological characteristics. Physiological characteristics are age, gender and cadre status; psychological characteristics include recognition of fixed-point waste disposal, perception of the surrounding environment, and knowledge of environmental protection. Environmental factors can be divided into family environment, social environment and natural environment. Family environment

DOI: http://dx.doi.org/10.15666/aeer/1704_87378748

includes education environment and business environment; social environment includes propaganda and education, incentive and punishment, policy system, organizational setting, infrastructure and social culture; natural environment in this paper mainly refers to geographical location. Variable selection and measurement are shown in *Table 1*.

Sample characteristics and research method

Sample characteristics

The data used in this study are from the field survey of 128 administrative villages in 13 cities of Jiangsu. 800 questionnaires were sent out and 726 were recovered. After eliminating the invalid information questionnaire, 671 valid questionnaires remained, with an effective rate of 83.9%. According to the basic characteristics of the sample, 453 were women, accounting for 68%; population under 35 years old accounted for 72%; family members with the highest degree of university or above accounted for 35%; nearly half of the annual family income is 50,000-100,000 CNY. The household waste disposal behavior of sample farmers is shown in *Fig. 1*. Generally speaking, majority of rural households can properly dispose of household waste.

Research method

Logit model

There are two ways for household garbage disposal: random and proper, which belong to the typical binary variables. Therefore, Logit Model should be adopted. The derivation of the model is as follows. The actual reaction variable is y_k, with a value of 0 and 1. Explanatory variables are represented by x_k, and error is represented by ε_k. Assuming that there is a linear relationship between y_k^* and x_k, namely (*Eq. 1*)

$$y_k^* = \alpha + \beta x_k + \varepsilon_k \quad \text{(Eq.1)}$$

There is a critical point c, when $y_k^* > c$, then $y_k=1$, when $y_k^* \leq c$, then $y_k=0$. Assuming that the critical point $c = 0$, the error term ε_k obeys Logistic distribution and its cumulative distribution function is $F(.)$, and p_k is the probability of occurrence of case k, there is (*Eq. 2*):

$$\begin{aligned} p_k = P(y_k = 1 | x_k) &= P[(\alpha + \beta x_k + \varepsilon_k) \rangle 0] \\ &= P(\varepsilon_k \langle \alpha + \beta x_k) \\ &= F(\alpha + \beta x_k) \\ &= \frac{exp(\alpha + \beta x_k)}{1 + exp(\alpha + \beta x_k)} \end{aligned} \quad \text{(Eq.2)}$$

After logarithmic transformation, the above formula can be transformed into *Eq. 3*:

$$ln\left(\frac{p_k}{1 - p_k}\right) = \alpha + \beta x_k \quad \text{(Eq.3)}$$

Among them, p_k is the probability of occurrence of case k. It is a non-linear function consisting of the explanatory variable x_k. When there are N independent variables, the binary regression model and its logarithmic transformation are shown in *Eq. 4* and *Eq. 5*, respectively.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87378748

$$p_k = P\left(y_k = 1 \middle| x_{1k}, x_{2k}, ..., x_{nk}\right) = \frac{exp\left(\alpha + \sum_{n=1}^{N} \beta_n x_{nk}\right)}{1 + exp\left(\alpha + \sum_{n=1}^{N} \beta_n x_{nk}\right)} \quad \text{(Eq.4)}$$

$$\ln\left(\frac{p_k}{1 - p_k}\right) = \alpha + \sum_{n=1}^{N} \beta_n x_{nk} \ (k=1, 2... K, n=1, 2... N) \quad \text{(Eq.5)}$$

For this study, p is the probability of household waste disposal properly, 1-p is the probability of household waste disposal randomly; α is the constant of regression equation of various factors; β_i is the coefficient of regression equation of various factors; x_i is a variety of influencing factors; n is the number of influencing factors. Maximum likelihood (ML) is generally used to estimate the parameters. For case i, there is a distribution function (*Eq. 6*):

$$p\left(Y_i\right) = p_i^{Y_i}\left(1 - p_i\right)^{1-Y_i} \quad \text{(Eq.6)}$$

Then the logarithmic likelihood function is (*Eq. 7*):

$$\begin{aligned} l(\beta) &= \sum_{i=1}^{n}\left(Y_i \ln p_i + (1 - Y_i)\ln(1 - p_i)\right) \\ &= \sum_{i-1}^{n}\left(Y_i \ln \frac{p_i}{1 - p_i} + \ln(1 - p_i)\right) \\ &= \sum_{i=1}^{n}\left(Y_i(X_i\beta) - \ln(1 + exp(X_i\beta))\right) \end{aligned} \quad \text{(Eq.7)}$$

In order to estimate the value of β, we can derive the partial derivative of $l(\beta)$ over β and make it equal to 0 (*Eq. 8*):

$$\begin{aligned} \frac{\partial l(\beta)}{\partial \beta_1} &= \sum_{i=1}^{n}\left(Y_i - \frac{X_i\beta}{1 + exp(X_i\beta)}\right) = 0 \\ \frac{\partial l(\beta)}{\partial \beta_j} &= \sum_{i=1}^{n}\left(Y_i - \frac{X_i\beta}{1 + exp(X_i\beta)}\right) X_{ji} = 0, \ j = 2, ..., k \end{aligned} \quad \text{(Eq.8)}$$

ISM method

ISM method can transform vague ideas into well-structured models by using people's knowledge as well as the help of computer (Warfield, 1974). The main steps of ISM method are as follows. Step 1: Drawing the corresponding digraph according to Boolean operation. Then, constructing adjacent matrix A. Where a satisfies *Eq. 9*. Step 2: Establishing the reachable matrix M. Operations are defined as *Eq. 10*. Step 3: Obtaining reduced matrix of reachable matrix. Step 4: The reduced matrix is processed hierarchically, and the interpretative structure model is obtained.

$$a_{ij} = \begin{cases} 1, S_i RS_j, R\ says\ S_i\ has\ a\ relationship\ with\ S_j \\ 0, S_i \overline{RS}_j, \overline{R}\ says\ S_i\ has\ no\ relationship\ with\ S_j \end{cases} \quad \text{(Eq.9)}$$

$$if\ (A+I)^r = (A+I)^{r+1} \neq (A+I)^{r-1}, M = (A+I)^r \quad \text{(Eq.10)}$$

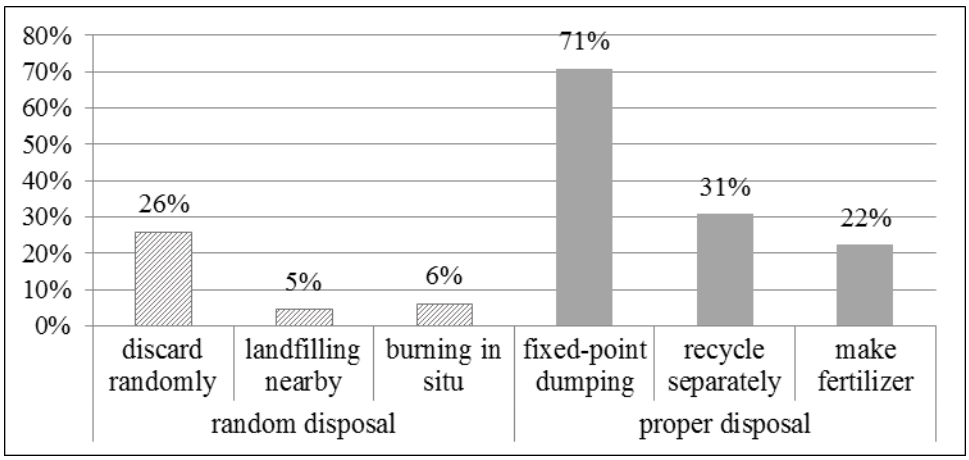

Figure 1. *Household waste disposal behavior of sample farmers*

Results and discussions

Logit model regression results

Firstly, we consider the relationship between all independent variables and dependent variables separately, screen out some variables that may not be meaningful, and then conduct multivariate analysis. Results shown in Model 1 in *Table 2* indicate that variables that may have statistical significance include: X1, X4, X6, X7, X8, X12, X13, X14, X15, X16, X17, X18, X19, X20, X21, X22, X23, and X24. Secondly, after eliminating the insignificant variables, the variables other than X21 and X22 are put into the Logit model according to Forward: LR rules. As shown in Model 2 in *Table 2*, six variables have passed the significance test (*Eq. 11*).

$$y = \ln\left(\frac{p}{1-p}\right) = 0.602 - 0.368 \times X8 + 0.462 \times X12 + 0.623 \times X13 - 0.311 \times X17 - 0.735 \times X20 + 1.516 \times X23 \quad \text{(Eq.11)}$$

The regression results show that: The stronger the identifying capacity for pollutants, the better the household waste can be properly disposed of. Farmers who choose traditional fuels are more likely to dispose waste randomly. Farmers with wages as the main source of livelihood are more inclined to properly dispose of household waste. The village has a fixed-point waste disposal policy and the implementation effect is good, farmers are more likely to show standard waste disposal behavior, and vice versa. Whether there is a centralized waste disposal facility is closely related to the farmers' household waste disposal behavior. If neighbors can take appropriate disposal ways, farmers themselves tend to adopt the similar ways.

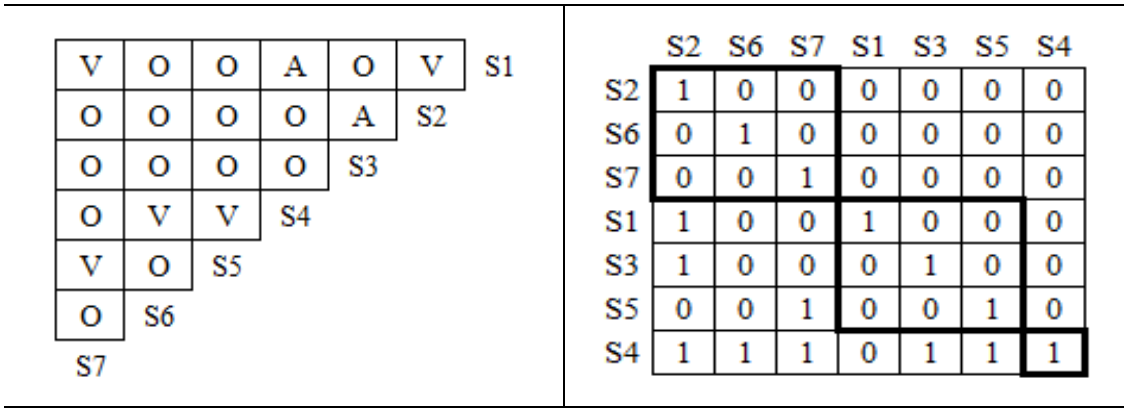
X24	-0.573***	0.000		0.085		

In the above analysis, X20 has passed the significant test, so it is necessary to further test the significance of Distance to centralized waste disposal facilities (X21) and Clearance of centralized waste dump site (X22). Firstly, 546 data are obtained by eliminating the NONE data selected under the variable X20. Then the other five variables selected by multivariate Logit analysis are used as control variables, and X21 and X22 are used as independent variables. As shown in Model 3 in Table 2, X22 passed the significant test. The more timely the disposal of waste centralized dump site is, the more appropriate waste disposal behavior can be promoted. X21 had no significant impact on Y. In conclusion, seven variables, X8, X12, X13, X17, X20, X22 and X23, have significant effects on household waste disposal behavior of farmers.

ISM model analysis results

In order to further determine the logical relationship and hierarchical structure among the seven factors identified above, this paper uses S1, S2, S3, S4, S5, S6 and S7 to represent those seven significant factors, namely Identifying capacity for pollutants (S1), Major domestic fuel (S2), Major economic source (S3), Fixed-point waste disposal policy and its implementation effect (S4), Availability of centralized waste disposal facility (S5), Clearance of centralized waste dump site (S6) and Neighbor's way of disposing household waste (S7). Combining the experience knowledge of experts, the logical relationship among the factors is determined (*Fig. 2a*). V denotes that row elements influence column elements; A indicates that column elements affect row elements; O indicates that there is no relationship between rows and columns. Then, the reachable matrix is obtained (*Fig. 2b*). Seven factors can be divided into three layers.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87378748



a. b.

Figure 2. *Logical relationship among the factors and sorted reachability matrix*

As can be seen from *Fig. 3*, variables at different levels have different effects on Y. Specifically: At the bottom is S4, which runs through almost all the important parts of the model and becomes the deep-seated root cause of affecting household waste disposal behavior of farmers. S1, S3 and S5 are located in the middle layer, which are important factors affecting Y. Moreover, the influence mode of S3 has certain independence. At the first level are S2, S6, and S7, which have direct impact on farmers' household waste disposal behavior. Meanwhile, S2 is affected by both S1 and S3 from the middle layer, and S7 is affected by S5.

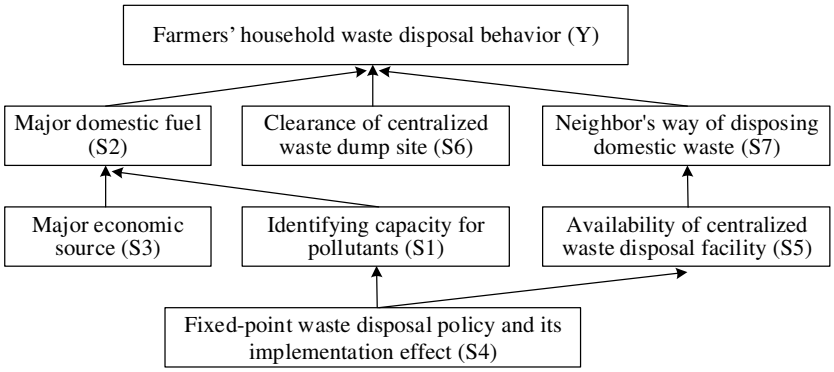


Figure 3. *Interpretative structure model of influencing factors*

Result discussion

As far as the physiological characteristics of farmers are concerned, Age (X2) and Cadre status (X3) have not passed the significant test, which is inconsistent with the research results of Yang et al. (2017). The reason may be that the development of the Internet has reduced the space-time distance, enabling everyone to receive information conveniently and timely, thus reducing the influence of individual differences. In univariate analysis, although Gender (X1) has a certain impact on the dependent variable, the impact of gender is weaker than other factors.

From the regression results of the psychological characteristics of farmers, only Identifying capacity for pollutants (X8) passed the significance test. On the one hand,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87378748

Jiangsu paid more attention to the problem of rural household waste disposal. It began to publicize the consequences of waste discarding at will earlier, giving farmers a certain understanding of fixed-point waste disposal. Therefore, the samples have a small difference in the recognition of the relevant factors. On the other hand, the impact of other variables representing farmers' psychological characteristics on Y may have been included in the impact caused by X8, so they failed to pass the significance test. In addition, farmers may have certain psychological pressure when filling in the questionnaires face-to-face. They fail to give an objective assessment of the environment, resulting in the insignificant of X6.

For the family environment, Family educational level (X9) failed to pass the significant test. The reason may be the education situation of rural students in China. In China, schools above junior high school are generally distributed in cities and towns with more developed economy. Rural students need to leave home for a long time, causing them to lack enough opportunities to influence others. Because of the petty farmer idea has not been completely eliminated in China, the improvement of economic conditions will not significantly promote farmers to adopt appropriate waste disposal behavior, resulting in the insignificant of X10. The reason why Number of migrant workers (X11) is not significant is that most families have less migrant workers, and the level of work is not very high.

In terms of social environment, the reason why X19, X14 and X15 are not significant is also because of Jiangsu has attached great importance to rural waste management, narrowing the gap between villages in terms of these factors. Meanwhile, propaganda, education and behavioral management measures can be regarded as part of the policy system. The impact of X14, X15 and X16 on dependent variable may have been included in the impact caused by Fixed-point waste disposal policy and its implementation effect (X17), so these variables have not passed the significance test, which is another possible reason why X19 is not significant.

The reason why Distance to the city center (X24) has not passed the significance test lies in Jiangsu's dense population. On the whole, the geographical space separation between rural and urban areas is not very large, thus the results of questionnaire show little difference in this factor, affecting the result of the significance test.

The intrinsic reasons for the influence of Major domestic fuel (X12) on Y are Major economic source (X13) and Identifying capacity for pollutants (X8). Families whose economic sources are mainly wages are relatively affected by the living habits of urban residents, and more likely to use modern living fuels. Moreover, farmers with wages as their main source of economy are more able to afford modern energy. Besides, the more familiar farmers are with environmental protection knowledge, the more willing they are to adopt pro-environmental behavior (Estrada et al., 2017), and more willing to use less polluted domestic fuels.

The impact of Fixed-point waste disposal policy and its implementation effect (X17) runs through the whole process. If the relevant policies can be promulgated and implemented, it can directly increase investment in waste centralized treatment facilities, increase the frequency of waste pool cleaning, and then promote farmers to adopt appropriate ways of household waste treatment. Meanwhile, X17 can promote the popularization of environmental protection knowledge in a wider range, so that more farmers are aware of the hazards of random disposal of household waste, and have the ability to identify pollutants. Therefore, they are more willing to make environmentally friendly behavior, such as using clean fuels.

Conclusions

Based on Lewin's behavior model and the data of 671 households in Jiangsu, this paper used Logit-ISM model to analyze farmers' household waste disposal behavior and its influencing factors. The results show that seven factors have significant effects on household waste disposal behavior, namely Identifying capacity for pollutants (X8), Major domestic fuel (X12), Major economic source (X13), Fixed-point waste disposal policy and its implementation effect (X17), Availability of centralized waste disposal facility (X20), Clearance of centralized waste dump site (X22) and Neighbour's way of disposing household waste (X23).

The stronger the ability of farmers to discriminate pollutants, the more willing they are to dispose of waste properly. Compared with the areas without fixed-point disposal policy of household waste, those have ones tend to show standardized disposal behaviour of household waste. In areas where centralized waste disposal facilities are available and can be cleaned in time, farmers tend to dispose of household waste properly. Using coal, wood and other traditional energy as main fuel and taking farming as the main source of livelihood have a certain negative impact on farmers' proper waste disposal behavior. Neighbors' disposal of household waste will have a strong assimilation effect on individual's behavior of household waste disposal.

At the same time, there are mutual influences among these seven significant factors. X17 is a deep-seated influencing factor, which has a root effect on farmers' household waste disposal behavior. X8, X13 and X20 are the middle factors. X13 has certain independent impact. X8 and X20 are the nodes that connect the deep factors with surface factors, and play a key intermediary role. X12, X22 and X23 have direct impact, belonging to surface factors.

Based on above conclusions, we put forward the following suggestions: First, establish a long-term mechanism of fixed-point treatment of rural household waste, strengthen the effect of policy implementation. Second, strengthen the propaganda of environmental protection knowledge, especially focusing on the popularization among farmers, and encourage them to replace traditional fuels with clean energy. Third, add waste collection and treatment facilities such as garbage cans, garbage tanks and garbage collection trucks, and clean up these facilities in time. Fourth, set up models, commend and reward villages achieving remarkable results in the treatment of household waste, giving full play to the exemplary driving effect.

Although this paper explored the influencing factors of farmers' household waste disposal behavior in Jiangsu Province and put forward the corresponding countermeasure proposals through qualitative and empirical research, due to time constraints and data acquisition constraints, the research still need to be further investigated. On the one hand, through the case study of typical villages, the impact degree of each influencing factor can be refined with the help of structural equation model, so as to further improve the effectiveness of the policy. On the other hand, future research can be done based on the theory of planned behavior (TPB) in social psychology, or from the perspective of A-B-C theory.

Abstract. In order to explore the impact of the government' regulatory strategy on the informal recycling channel of electric vehicle batteries, this paper compares and analyzes the evolutionary strategy of the government and the informal recycling channel of electric vehicle batteries group under fixed and dynamic punishment model. The results show that: (1) the dynamic system of replication under the fixed punishment model consists of four saddle points and one central point. The evolution process of the strategy is repetitive and periodic, and cannot reach equilibrium. (2) The dynamic system of replication under the dynamic punishment model consists of four saddle points and one focal point, and the stable Nash equilibrium can be achieved. That is to say, the optimized scenario is valid. (3) In order to improve the probability of the informal recycling channel of electric vehicle batteries choosing the transformation upgrading strategy, improving the legal environmental incomes after the transformation upgrading of the informal recycling channel of electric vehicle batteries group, and reducing the recycling cost of the available components extracted from the waste electric vehicle batteries through formal channels are effective approaches.
Keywords: *dynamic punishment, evolutionary strategy, fixed punishment, recycling channel decision*

Introduction

In recent years, environmental pollution, climate change and energy shortages have caused widespread concern in the world. One of the key factors in aggravating these problems is the transportation industry, which consumes a lot of energy and generates a lot of greenhouse gases (Gong et al., 2019). In order to protect national energy security, alleviate fuel supply conflicts, reduce exhaust emissions, and improve the atmospheric environment, China has proposed a national strategy to vigorously develop new energy vehicles (Zhao et al., 2016). In 2016, China's new energy vehicle sales reached 777,000 units, with a total promotion of more than 1.7 million units, accounting for more than 50% of the global new energy vehicle market. The rapid development of new energy vehicles has also brought about some new problems. It is predicted that the number of power battery scraps will exceed 500,000 tons by 2020, about 20 times the amount recorded in 2016. The contradiction between the development of pure electric vehicle industry and the resource environment is becoming more and more prominent (Li et al., 2014). If the waste power battery is not properly disposed, the potential harmful substances contained in it will cause environmental pollution (Ordoñez et al., 2016). On the other hand, lithium, cobalt, copper and aluminum in the scrapped power battery are recyclable materials, which have extremely high recovery value (Xu et al., 2008; Tan et al., 2015). In fact, China's power battery recycling rate is low. In 2016, China's waste power battery recycling amount was less than 10,000 tons, and the recovery rate was less than 20%. If the power battery recovery rate is still at the current low level, there

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87498762

will be a large number of used power batteries flowing into private small workshops or abandoned, posing great threat to the ecological environment.

At present, research on used power batteries focuses on the status of recycling, recycling models and the impact of government environmental regulations on recycling strategies. China's recycling process for power batteries is still in the exploratory stage, and recycling technology aiming at recycling manufacturing has not been carried out (Yu et al., 2014). There are no specific measures and equipment guarantees for the production safety and environmental issues involved in the recycling of lithium-ion batteries (Gu et al., 2017). Scholars have done a lot of research on the recycling mode of closed-loop supply chain, for example, Savaskan et al.(2004) considered a decentralized model and a centralized model of a monopolist manufacturer and a retailer, compared and analyzed three modes of manufacturer recycling, retailer recycling and third-party recycling. They found that retailer recycling was the most efficient way. Savaskan et al. (2006) studied the recycling problem from the perspective of the manufacturer's benefit and found that in the homogeneous market, if the competition between retailers is fierce, the manufacturer will adopt the direct recycling model; otherwise, the retailer recycling model will be adopted. De Giovanni et al. (2014) established a two-cycle closed-loop supply chain game model of a monopolist manufacturer and a retailer, and analyzed the corporate, environmental and social benefits of the three modes of manufacturer recycling, retailer recycling and third-party recycling through numerical examples. It was pointed out that only in a small scope, manufacturers outsourcing their recycling business can contribute to corporate, environmental and social benefits. The research on the decision-making problem of power battery recovery mode is still in the initial stage. Liu and Gong (2014) studied the matching behavior of vehicles and batteries in the retailer recycling mode, and analyzed the influencing factors of recycling and the influence degree of various factors. Turner et al. (2016) analyzed and compared of EPR (Extended Producer Responsibility) and EOL (End of life) on recovery rate, recovery efficiency, management cost, etc., and concluded that the effective implementation of EPR is more conducive to the recycling of power batteries. Hong and Yeh (2012) comparative analyzed of retailer recycling and third-party recycling models revealed that retailer recycling models were more effective when third parties are non-profit organizations. Ma et al. (2016) studied on WEEE closed-loop supply chain decision-making problem of mixed channel sales/recycling under government regulation. As China's power battery recycling system is still not perfect, environmental pollution and resource waste in the recycling process are very serious, which will adversely affect the development of the industry (Han et al., 2016). China has no specific legislation on the recycling of new energy vehicle power batteries, and the healthy and sustainable development of the scrapped power battery recycling industry has been restricted (Han et al., 2017). Therefore, the recycling industry is still in the early stages of development, and government intervention is required at this time (Capon et al., 2015). Zhang et al. (2016) pointed out that incentives such as recycling regulatory policies and subsidies are not perfect, resulting in many enterprises power battery recycling interest is very low. Wang and Wu (2017) pointed out that the non-mandatory policy has caused battery manufacturers and OEMs not to plan battery recycling. Wang et al. (2014) studied the effects of four subsidy policy schemes, including direct subsidies, recycling subsidies, research and development subsidies and product subsidies on the recycling of auto parts (Wang et al., 2014; Du et al., 2018). Li

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87498762

and Mu (2018) analyzed the impact of subsidized 4S stores, OEMs and battery manufacturers on recycling efficiency.

Through the above literature, it is found that there are few studies on the relevant regulatory policies for power battery recycling and the recycling targets are mainly based on formal recycling group. In fact, more than 80% of used power batteries in China have flowed into the informal recycling group. Such groups are spontaneously driven by economic interests, and formal recycling companies lack competitiveness in terms of cost and price. In addition, it is impossible for the government and the informal recycling group to have sufficient information. The two sides cannot be completely rational, and the decisions made can only be completed under bounded rational conditions. Moreover, the government's regulation of recycling vendors is also in its infancy. How the government's incentives for formal and informal recyclers evolved and how the informal recycling community should decide is worth studying.

How to effectively supervise the power recycling industry has become an urgent problem to be solved in the development of circular economy. At present, this issue has not attracted enough attention. The research on reverse recycling of power battery also pays little attention to the informal recycling group. Based on the bounded rationality hypothesis and using the relevant theory of evolutionary game, this paper studies the dynamic game relationship between the informal recycling channel of electric vehicle batteries and the government, and analyzes the stability of different strategies and proposes corresponding management enlightenment.

Evolutionary game model

Model assumptions and description

(1) It is assumed that the participants in the game include the government and the informal recycling channel of electric vehicle batteries, and the two sides of the game are bounded rational.

(2) The informal recycling channel of electric vehicle batteries group consists of n informal recyclers, assuming that n informal recyclers are independent of each other.

(3) There are only two strategies for the government and the informal recycling channel of electric vehicle batteries to participate in the game. The strategies available to the government are {positive regulation, negative regulation}. Positive regulation means the government's punishment measures or subsidy policies for different recycling behaviors of informal recycling channel. Negative regulation means that the government regulatory departments do not supervise and regulate the informal recycling channel groups of electric vehicle batteries. The informal recycling channel groups of electric vehicle batteries have two recycling strategies, the strategies are {transformation upgrading, non-transformation upgrading}. Transformation upgrading strategy means that the informal recycling group of electric vehicle batteries is upgraded into a legal and regular recycling group through technology upgrade, and the non-transformation upgrading strategy means that the informal recycling group of power battery continues to be lucky to recycle through informal recycling channels.

(4) Suppose that the probability of the government choosing the positive regulation strategy is x and the probability of the negative regulation is $1 - x$, meanwhile, the probability of the informal recycling channel of electric vehicle batteries choosing the transformation upgrading strategy is y, and the probability of the non-transformation upgrading strategy is $1 - y$.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87498762

(5) The cost and benefit parameters are assumed and explained as follows: C is the recycling cost of the power waste battery that can be utilized without disassembly; C_1 and C_2 are the recycling cost of the available components extracted from the waste electric vehicle batteries through formal channels and informal channels; C_3 is the governance cost that the government needs to pay due to environmental pollution when the informal recyclers choose non-transformation upgrading strategies; α is the proportion of the part of the electric vehicle batteries that does not need to be dismantled; R_1 and R_2 are illegal and legal environmental incomes before and after the transformation upgrading of the informal recycling channel of electric vehicle batteries group; R_3 is the social benefit that the government receives when the informal recycling channel of electric vehicle batteries group choose the transformation upgrading strategy and the government choose the positive regulation strategy; the informal recycling channel of electric vehicle batteries group will receive subsidies from the government when choosing the transformation upgrading strategy, and the subsidy is G; if the informal recycling channel of electric vehicle batteries group chooses the non-transformation upgrading, the probability of being discovered by the government is ε, and the punishment of p is obtained.

According to the above model description and assumptions, the payoff matrix of the government and the informal recycling channel of electric vehicle batteries group evolution game is shown in *Table 1*.

Table 1. *Payoff matrix between the government and the informal recycling channel of electric vehicle batteries group*

The game		**The informal recycling channel of electric vehicle batteries group**	
		Transformation upgrading (y)	**Non-transformation upgrading (1-y)**
The government	Positive regulation (x)	$R_3 - G$ $nR_1 - n\alpha C - n(1-\alpha)C_1 + G$	$R_3 - C_3 + \varepsilon np$ $nR_2 - n\alpha C - n(1-\alpha)C_2 - \varepsilon np$
	Negative regulation (1-x)	0 $nR_1 - n\alpha C - n(1-\alpha)C_1$	$-C_3$ $nR_2 - n\alpha C - n(1-\alpha)C_2$

The model

According to the payoff matrix of the government and the informal recycling channel of electric vehicle batteries group evolution game in *Table 1*, we assume that the expected return of the government's positive regulation strategy is E_{11}, the expected return of negative regulation strategy is E_{12}, and the average expected return of the group is E_1, then we can obtain *Equations 1-3*.

$$E_{11} = x(R_3 - G) + (1-x)(R_3 - C_3 + \varepsilon np) \quad \text{(Eq.1)}$$

$$E_{12} = x \times 0 + (1-x) \times -C_3 \quad \text{(Eq.2)}$$

$$E_1 = yE_{11} + (1-y)E_{12} \quad \text{(Eq.3)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87498762

Meanwhile, we assume that the expected return of informal recycling channel of electric vehicle batteries group's transformation upgrading strategy is E_{21}, the expected return of non-transformation upgrading strategy is E_{22}, and the average expected return of the group is E_2, then we can obtain *Equations 4-6*.

$$E_{21} = y(nR_1 - n\alpha C - n(1-\alpha)C_1 + G) + (1-y)(nR_1 - n\alpha C - n(1-\alpha)C_1) \quad \text{(Eq.4)}$$

$$E_{22} = y(nR_2 - n\alpha C - n(1-\alpha)C_2 - \varepsilon np) + (1-y)(nR_2 - n\alpha C - n(1-\alpha)C_{21}) \quad \text{(Eq.5)}$$

$$E_2 = xE_{21} + (1-x)E_{22} \quad \text{(Eq.6)}$$

The complex dynamic equation is actually a dynamic differential equation that describes the frequency or frequency of a particular strategy being used in a population (Friedman, 1991, 1998). So the replication dynamic equation of the government and the informal recycling channel of electric vehicle batteries group evolution game is in the form of *Equation 7*.

$$\begin{cases} \dfrac{dx}{dt} = x(1-x)[nR_1 - nR_2 - n(1-\alpha)(C_1 - C_2) + y(G + \varepsilon np)] \\ \dfrac{dy}{dt} = y(1-y)[R_3 + \varepsilon np - x(G + \varepsilon np)] \end{cases} \quad \text{(Eq.7)}$$

The Jacobian matrix of the evolutionary system of the government and the informal recycling channel of electric vehicle batteries group is in the form of *Equation 8*.

$$J = \begin{vmatrix} (1-2x)[nR_1 - nR_2 - n(1-\alpha)(C_1 - C_2) + y(G + \varepsilon np)] & x(1-x)(G + \varepsilon np) \\ y(1-y)[-x(G + \varepsilon np)] & (1-2y)[R + \varepsilon np - x(G + \varepsilon np)] \end{vmatrix} \quad \text{(Eq.8)}$$

Analysis of equilibrium point of evolutionary game

In order to make the revenue of the government and the informal recycling channel of electric vehicle batteries group more consistent with the reality, this paper considers the following situation: when the government chooses a positive regulation strategy, due to the existence of subsidies and penalties, the benefits of the transformation upgrading of power battery recycling enterprises will be greater than the benefits of non-transformation upgrading; similarly, when the informal recycling channel of electric vehicle batteries group chooses a non-transformation upgrading strategy, the benefits of the positive regulation of the government will be greater than the benefits of the negative regulation. Therefore the following inequalities can be obtained (see *Eq. 9*).

$$\begin{cases} 0 < nR_2 - nR_1 - C_3 + n(C_2 - C_1) < (G + \varepsilon np) \\ 0 < R_3 + \varepsilon np < G + \varepsilon np \end{cases} \quad \text{(Eq.9)}$$

Therefore, the five Nash equilibrium points of the dynamic evolution of the government and the informal recycling channel of electric vehicle batteries group

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87498762

systems are $(0,0)$, $(1,0)$, $(1,1)$, $(0,1)$ and (x^*, y^*), where $x^* = [nR_2 - nR_1 - n(1-\alpha)(C_2 - C_1)] / (G + \varepsilon np)$, $y^* = (R_3 + \varepsilon np) / (G + \varepsilon np)$. The stability of the five equilibrium points is analyzed by D. Friedman's method for determining the equilibrium point. The analysis results of the five equilibrium points are shown in *Table 2*.

Table 2. *Stability of the dynamic evolution of the government and the informal recycling channel of electric vehicle batteries group evolution*

Equilibrium point	Det(J)	Tr(J)	stability
(0,0)	-	Uncertain	Saddle point
(1,0)	-	Uncertain	Saddle point
(1,1)	-	Uncertain	Saddle point
(0,1)	-	Uncertain	Saddle point
(x^*, y^*)	-	0	Center point

According to the above analysis, the stability of the stability point of the evolutionary game model between the government and the informal recycling channel of electric vehicle batteries group are: the evolutionary state of points $(0,0)$, $(1,0)$, $(1,1)$ and $(0,1)$ are saddle point, and the evolutionary state of point (x^*, y^*) is center point. Since the value of the real part of the feature root corresponding to the center point is zero, we know that (x^*, y^*) is the equilibrium point, but it is not the stable point of evolution. The evolutionary trajectory of the government and the informal recycling channel of electric vehicle batteries group is a closed loop curve without (x^*, y^*). Due to the choice of the initial strategy of both parties and the disturbance in the evolution process, the development of the system will have a certain randomness, which will have a greater impact on environmental protection and social harmony, and also make the management of the government very difficult. The system does not have an evolutionary stability strategy, which may be one of the important reasons why the informal recycling channel of electric vehicle batteries group chooses not to upgrade and lead to environmental pollution.

Optimization model of the evolutionary game

The optimization model

Based on the content of the previous section, we know that the evolutionary behavior of the government and the informal recycling channel of electric vehicle batteries group games under fixed punishment. In fact, in the process of evolutionary game between the two sides, different punishments should be applied to the specific fraudulent behaviors adopted by the informal recycling channel of electric vehicle batteries group. The punishment measures at this time can be called dynamic punishment mechanisms. It is assumed that the punishment measures adopted by the government are directly proportional to the degree to which the informal recycling channel of electric vehicle batteries group adopts a non-transformation upgrading strategy, that is, the punishment value received by the informal recycling channel of electric vehicle batteries group at

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87498762

this time is changed from p to dynamic $g(y)=(1-y)q$, where q indicates the maximum degree of punishment. After the dynamic punishment measures are taken, the game payoff matrix between the government and the informal recycling channel of electric vehicle batteries group under dynamic punishment mechanism is shown in *Table 3*.

Table 3. *Payoff matrix between the government and the informal recycling channel of electric vehicle batteries group under dynamic punishment mechanism*

The game		The informal recycling channel of electric vehicle batteries group	
		Transformation upgrading (y)	**Non-transformation upgrading (1-y)**
The government	Positive regulation (x)	R_3-G $nR_1-n\alpha C-n(1-\alpha)C_1+G$	$R_3-C_3+\varepsilon ng(y)$ $nR_2-n\alpha C-n(1-\alpha)C_2-\varepsilon ng(y)$
	Negative regulation (1-x)	0 $nR_1-n\alpha C-n(1-\alpha)C_1$	$-C_3$ $nR_2-n\alpha C-n(1-\alpha)C_2$

Based on *Table 3*, we analyze the evolution stability of the government and the informal recycling channel of electric vehicle batteries group under dynamic punishment mechanism. Similar to the fixed punishment mechanism, the dynamic replication equation of the game between the two sides under the dynamic punishment mechanism is in the form of *Equation 10*.

$$\begin{cases} \dfrac{dx}{dt}=x(1-x)[nR_1-nR_2-n(1-\alpha)(C_1-C_2)+y(G+\varepsilon ng(y))] \\ \dfrac{dy}{dt}=y(1-y)[R_3+\varepsilon ng(y)-x(G+\varepsilon ng(y))] \end{cases} \quad \text{(Eq.10)}$$

The equilibrium point after optimization

The Nash equilibrium points of the dynamic evolution of the government and the informal recycling channel of electric vehicle batteries group systems under dynamic punishment mechanism are $(0,0)$, $(1,0)$, $(1,1)$, $(0,1)$ and (x^{**},y^{**}), where $x^{**}=[nR_2-nR_1-n(1-\alpha)(C_2-C_1)]/\ (G+\varepsilon ng(y))$, $y^{**}=(R_3+\varepsilon ng(y))/(G+\varepsilon ng(y))$. The Jacobian matrix of the evolutionary system of the two sides is in the form of *Equation 11*.

$$J_1=\begin{vmatrix} (1-2x)[nR_1-nR_2-n(1-\alpha)(C_1-C_2)+y(G+\varepsilon ng(y))] & x(1-x)(G+\varepsilon ng(y)) \\ y(1-y)[-x(G+\varepsilon ng(y))] & (1-2y)[R+\varepsilon ng(y)-x(G+\varepsilon ng(y))] \end{vmatrix} \quad \text{(Eq.11)}$$

The analysis conditions under the dynamic punishment mechanism are similar to the fixed punishment model, that is, see *Equation 12*.

$$\begin{cases} 0<nR_2-nR_1-n(1-\alpha)(C_2-C_1)<(G+\varepsilon ng(y)) \\ 0<R_3+\varepsilon ng(y)<G+\varepsilon ng(y) \end{cases} \quad \text{(Eq.12)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87498762

According to the calculation, the value of the matrix of the determinant corresponding to points $(0,0)$, $(1,0)$, $(1,1)$ and $(0,1)$ are negative, we know that points $(0,0)$, $(1,0)$, $(1,1)$ and $(0,1)$ are saddle points. Substituting point (x^{**}, y^{**}) into formula (11), we can get that the characteristic root of (x^{**}, y^{**}) is a bunch of characteristic negative roots with negative real parts. Point (x^{**}, y^{**}) is the focus of evolutionary stability, and the state of system evolution has asymptotic stability, see *Table 4*.

Table 4. *Stability of the dynamic evolution of the government and the informal recycling channel of electric vehicle batteries group evolution under dynamic punishment mechanism*

Equilibrium point	Det(J)	Tr(J)	stability
(0,0)	-	Uncertain	Saddle point
(1,0)	-	Uncertain	Saddle point
(1,1)	-	Uncertain	Saddle point
(0,1)	-	Uncertain	Saddle point
(x^{**}, y^{**})	-	0	Stable point

Similar to the analysis of evolutionary stability in fixed punishment model, we know that (x^{**}, y^{**}) is the stable equalization point of the system evolution. We can get x^{**}, y^{**} as *Equation 13*.

$$x^{**} = \frac{nR_2 - nR_1 - n(1-\alpha)(C_2 - C_1)}{G + \varepsilon ng(y^{**})}, \quad y^{**} = \frac{R_3 + \varepsilon ng(y^{**})}{G + \varepsilon ng(y^{**})} \qquad \text{(Eq.13)}$$

According to *Equation 13,* we can get x^{**}, y^{**} as *Equation 14*.

$$x^{**} = \frac{2[nR_2 - nR_1 - n(1-\alpha)(C_2 - C_1)]}{G + \sqrt{G^2 + 4(G - R_3)\varepsilon nq}}, \quad y^{**} = 1 + \frac{G - \sqrt{G^2 + 4(G - R_3)\varepsilon nq}}{2\varepsilon nq} \qquad \text{(Eq.14)}$$

According to *Equation 14,* we analyze the influence of the main parameters on the evolutionary equilibrium under the dynamic punishment model. The results of the analysis are as follows:

(1) According to x^{**}, we can get that: $dx^{**}/dn > 0$, $dx^{**}/dR_2 > 0$, $dx^{**}/dC_2 > 0$, $dx^{**}/dR_1 < 0$, $dx^{**}/dC_1 < 0$, $dx^{**}/d\alpha < 0$, $dx^{**}/dG < 0$, $dx^{**}/dR_3 > 0$, $dx^{**}/dR_3 > 0$, $dx^{**}/dq < 0$, $dx^{**}/d\varepsilon < 0$.

(2) According to y^{**}, we can get that: $dy^{**}/dR_3 > 0$, $dy^{**}/dG < 0$, $dy^{**}/dn > 0$, $dy^{**}/d\varepsilon > 0$, $dy^{**}/dq > 0$.

Based on the above analysis, we can get the following conclusion: (1) Number of the informal recycling channel of electric vehicle batteries, the probability of being discovered by the government when the informal recycling channel of electric vehicle batteries group chooses the non-transformation upgrading, the social benefit that the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87498762

government receives when the informal recycling channel of electric vehicle batteries group choose the transformation upgrading strategy and the government choose the positive regulation strategy, the maximum degree of punishment and the subsidy when the informal recycling channel of electric vehicle batteries group choose the transformation upgrading strategy will affect the size of x^{**} and y^{**}.

(2) When q and ε increase, x^{**} will decrease, and y^{**} will increase, indicating that the probability that the informal recycling channel of electric vehicle batteries choose the strategic probability of transformation upgrading will increase, and the probability that the government choose the strategic probability of positive regulation will decrease. R_3, G and n have the same effect on the changing trend of x^{**} and y^{**}.

(3) For the government, improving the legal environmental incomes after the transformation upgrading of the informal recycling channel of electric vehicle batteries group, and reducing the recycling cost of the available components extracted from the waste electric vehicle batteries through formal channels can reduce the probability of the government taking positive regulation strategy.

Numerical analysis

We first analyze the evolutionary game between the government and the informal recycling channel of electric vehicle batteries group under the fixed punishment model, the results of the analysis are shown as follows:

The results under the fixed punishment model

(1) When $0 < nR_2 - nR_1 - n(1-\alpha)(C_2 - C_1) < (G + \varepsilon ng(y))$ and $0 < R_3 + \varepsilon ng(y) < G + \varepsilon ng(y)$, the initial probability of the government choosing the positive regulation strategy is x = 0.2, and the initial probability of the informal recycling channel of electric vehicle batteries group choosing transformation upgrading strategy is y = 0.6. The evolutionary game process of the mixed strategy under the fixed punishment mechanism can be shown in *Figure 1*.

It can be seen from *Figure 1* that the evolution process between the government and the informal recycling channel of electric vehicle batteries group under the fixed punishment model is a closed-loop curve with a center cycle. At this time, the game process of both parties is periodic behavior, and there is no stable point.

(2) When $0 < nR_2 - nR_1 - n(1-\alpha)(C_2 - C_1) < (G + \varepsilon ng(y))$ and $0 < R_3 + \varepsilon ng(y) < G + \varepsilon ng(y)$, the initial probability of the government choosing the positive regulation strategy is x = 0.2, and the initial probability of the informal recycling channel of electric vehicle batteries group choosing transformation upgrading strategy is y = 0.2 and y = 0.6, respectively. The evolutionary game process of the strategy that the informal recycling channel of electric vehicle batteries group transformation upgrading strategy under different initial probabilities under the fixed punishment model can be shown in *Figure 2*.

It can be seen from *Figure 2* that the informal recycling channel of electric vehicle batteries group transformation upgrading strategy under the fixed punishment model presents a state of fluctuation, and the fluctuation state is related to the initial probability of the government's strategy, and the fluctuation is larger when the initial strategy of the government's positive regulation is low.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87498762

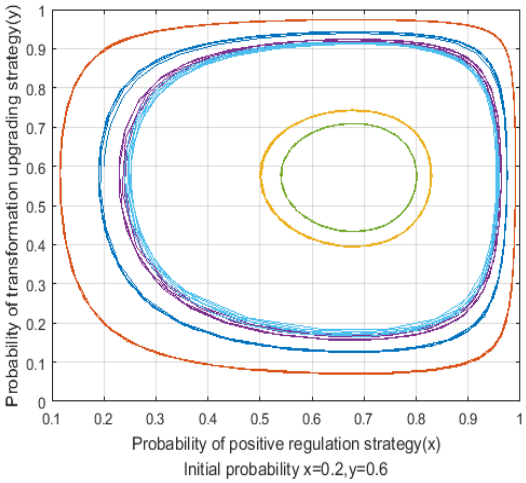

Figure 1. *Hybrid strategy evolution process of the government and the informal recycling channel of electric vehicle batteries group under fixed punishment model*

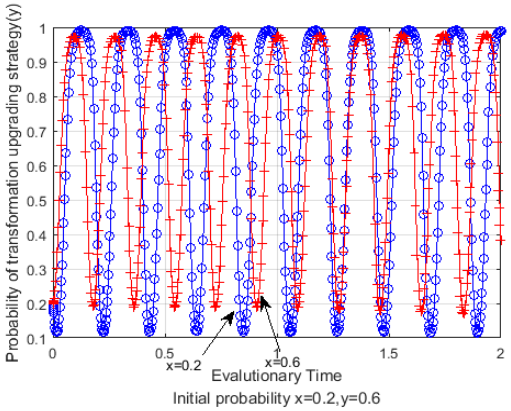

Figure 2. *Evolution process of the informal recycling channel of electric vehicle batteries group's strategy under different initial probabilities under fixed punishment model*

Then we analyze the evolutionary game between the government and the informal recycling channel of electric vehicle batteries group under the dynamic punishment mechanism, the results of the analysis are shown as follows:

The results under the dynamic punishment model

(3) When $0 < nR_2 - nR_1 - n(1-\alpha)(C_2 - C_1) < (G + \varepsilon ng(y))$ and $0 < R_3 + \varepsilon ng(y) < G + \varepsilon ng(y)$, the initial probability of the government choosing the positive regulation strategy is $x = 0.2$, and the initial probability of the informal recycling channel of electric vehicle batteries group choosing transformation upgrading strategy is $y = 0.6$. The evolutionary game process of the mixed strategy under the dynamic punishment model can be shown in *Figure 3*.

It can be seen from *Figure 3* that although the evolution process between the government and the informal recycling channel of electric vehicle batteries group under dynamic penalty model fluctuates, the system will finally converge to the central point,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87498762

indicating that the introduction of dynamic punishment model, can gradually stabilize the evolution of the two sides.

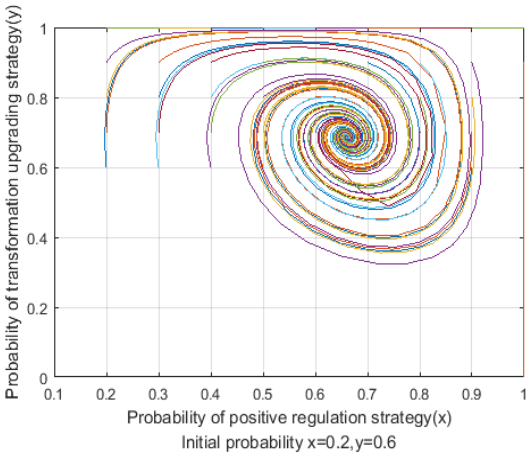

Figure 3. *Hybrid strategy evolution process of the government and the informal recycling channel of electric vehicle batteries group under dynamic punishment model*

(4) When $0 < nR_2 - nR_1 - n(1-\alpha)(C_2 - C_1) < (G + \varepsilon ng(y))$ and $0 < R_3 + \varepsilon ng(y) < G + \varepsilon ng(y)$, the initial probability of the government choosing the positive regulation strategy is $x = 0.2$, and the initial probability of the informal recycling channel of electric vehicle batteries group choosing transformation upgrading strategy is $y = 0.2$ and $y = 0.6$, respectively. The evolutionary game process of the strategy that the informal recycling channel of electric vehicle batteries group transformation upgrading strategy under different initial probabilities under the dynamic punishment model can be shown in *Figure 4*.

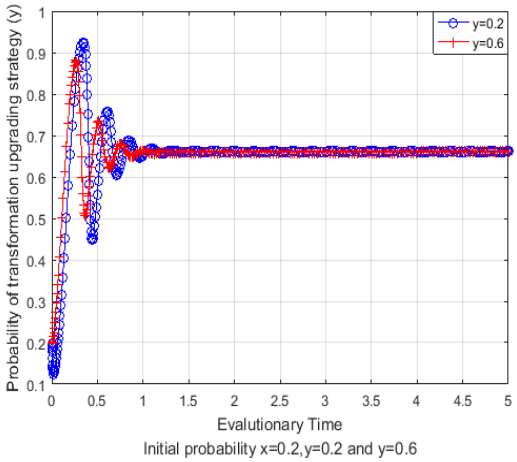

Figure 4. *Hybrid strategy evolution process of the government and the informal recycling channel of electric vehicle batteries group under dynamic punishment model*

It can be seen from *Figure 4* that the strategy of the informal recycling channel of electric vehicle batteries group choose transformation upgrading under the dynamic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87498762

punishment model presents a state of volatility. Although the initial stage shows a fluctuating state, it gradually converges with time and finally converges to the central point.

Conclusions

This paper uses evolutionary game theory to explore the strategic choices of the interaction between the government and the informal recycling channel of electric vehicle batteries group. It is found that the evolutionary game model does not have an evolutionary stability strategy under the fixed punishment strategy. Then, the dynamic punishment optimization model is proposed, so that an evolutionary stability strategy emerges in the optimized system, which effectively suppresses the fluctuations in the evolution. When the initial transformation upgrading strategy of the informal recycling channel of electric vehicle batteries group is different, the performance is converged to different equalization values. Increase the upper limit of punishment, the probability of the informal recycling channel of electric vehicle batteries group choosing the transformation upgrading strategy increases.

Based on the above research conclusions, this paper proposes the following management implications. (1) Formulate policies, improve recycling management measures, and gradually improve the support system for power battery recycling. Increase subsidies for formal recycling channels and severely punish informal recycling channels. (2) Learn from the successful experience of developed countries and introduce third-party inspection agencies to assist in management. (3) Relevant enterprises should fulfill the responsibility of electric vehicle batteries, ensure the effective use of power storage batteries and environmental protection, and form a closed-loop management system. (4) Establish a power battery traceability information system to realize the source of power battery can be checked, the direction can be chased, the node can be controlled, and the responsibility can be investigated.

In the research of dynamic punishment mechanism, this paper does not consider the irrational factors of both sides of the game. The next step is to sort out the irrational factors of the two sides of the game under the dynamic punishment mechanism and analyze the impact of the game, and then propose a governance framework of dynamic punishment mechanism. Meanwhile, the simulation of this paper is carried out under the condition of numerical simulation, and the next step can be analyzed in the empirical direction.

(Received 8th Mar 2019; accepted 1st May 2019)

Abstract. In organizations, green creativity of the employees is an essential part of implementing sustainable development. Our research proposed that workplace status has a significant impact on green creativity. Through an empirical study, we came to the conclusion that an increase in workplace status can lead to green creativity and prosocial motivation mediates the process. Since workplace status promotes the attention for group interests, employees will evaluate their self-worth considering the sustainable development of the environment. Based on the analysis framework of moderated mediation model, this study indicated that organization identification had a positive moderating effect on the relationship between workplace status and green creativity, and it is the boundary condition for workplace status to be effective.
Keywords: *prosocial motivation, organization identification, moderated mediation model, sustainable development, innovation*

Introduction

With the aggravation of environmental problems, researchers in different areas have been studying the issues of global ecosystem protection and sustainable development of the human environment. Responding to environmental challenges, a new manifestation of innovation can bring competitive advantages for organizations (Chen and Chang, 2013). As a result, green creativity has received widespread attention for it enables firms to gain competitive advantages (Gong et al., 2018). The notion of green creativity represents behaviors when companies or individuals propose new ideas for environmental sustainability (Amabile et al., 1996). Among them, natural scientists focus mainly on the technical perspective, which includes how to develop and apply pro-environmental materials and energies (Du et al., 2018; Huppmann et al., 2019), and how to design production models that cause the least harm to the environment (Pombo et al., 2019; Moratis and Melissen, 2019). However, environmental sustainability is ultimately an issue of human behavior, which depends on the complex relationships between individuals, society and natural environment. In other words, it is the interaction of people in the social system with the environment that play a significant role in sustainable development. At the micro level of psychological cognition, green creativity refers to the behavior where individuals generate new ideas to reduce ecological damage, protect natural resources and promote the sustainable development of the economy and the environment (Chen and Chang, 2013). In other words, green creativity reflects the inherent knowledge, beliefs, and value conception systems of an individual or an organization (Song and Yu, 2018; Lichtenfeld et al., 2018). Currently, green creativity has gradually become a research hotspot in social psychology and environmental psychology (Aebischer, 2003; Eisenhandler, 2009; Song and Yu, 2018). Exploring the psychosocial mechanisms of green creativity will not only identify factors

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87638774

that impede positive environmental behavior but also clarify mechanisms that promote positive environmental behavior. In addition, more and more researchers are starting to focus on the social interaction under in an organization context (Song and Yu, 2018).

However, in the perspective of social psychology or environmental psychology, many scholars have discussed the ways of promoting individual green creativity from the aspects of environmental education, suggestion, reinforcement and feedback (Albort-Morant et al., 2016; Zhu et al., 2018; Zhou et al., 2018; Wang et al., 2018). In fact, personality, self-construal, intrinsic motivation and extrinsic motivation will influence social interaction and green creativity (Amabile, 1997; Hennessey and Amabile, 1998; Sawyer, 2017). In recent research, the relationship between organizational situational factors and green creativity are attracting more and more attention, this article will integrate existing research from the perspective of social psychology. Based on the multi-dimensional perspectives such as psychology, society, and culture, will be good for constructing an effective model and institutional design transformation. Therefore, this paper will systematically study the relationship between workplace status and green creativity, with the purpose of providing some reference for future research and policymaking in this field.

In management practice, workplace status as an incentive means widely exists in the design of organizational systems (Djurdjevic et al., 2017). In general, people are eager to gain respect, admiration, and voluntary obedience from other members of the organization (Magee and Galinsky, 2008), and this kind of respect or admiration from others is called workplace status. Status is a concept of sociology, which refers to the universally recognized ranking of individuals in their organization, and the level or grade of a person in an organization. For individuals, workplace status represents the quantity and quality of individuals' valuable resources in the organization (Zinko et al., 2012). Workplace status affects an individual’s resources, development and determines how individuals are restricted in the workplace. As the high value and high demand for workplace status, it is very common for using status as an approach of encouragement. However, how does workplace status affect employee green creativity and the underlying mechanisms are unclear. In terms of influencing factors, little research has paid attention to the internal mediation effect of workplace status on green creativity. Therefore, in this study, we consider how workplace status can contribute to enhancing employees green creativity and explore the boundary conditions for this process.

Research background and hypotheses

Academic research on pro-environmental behavior has a history of nearly 40 years. Green creativity as a representative of pro-environmental behavior is the driving force of sustainable development, therefore every company wants to stimulate the green creativity of its employees more effectively. According to Jia et al. (2018), improving green creativity depends on cooperation between company environmental strategies and corresponding human resource management (HRM) practices. Research on green human resource management mainly focuses on the encouragement of employees to come up with new green ideas and actively participate. The green creativity of employees is of great significance to the sustainable development of enterprises. Therefore, how to effectively stimulate the green creativity of employees in management has received extensive attention.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)

Workplace status and green creativity

Workplace status reflects the respect and admiration in the workplace, and it requires both recognition and good relationships. In order to gain a position in the workplace, a person needs to make great efforts to make their competence recognized. Then, the person must show a friendly attitude to get a warm impression. In general, workplace status represents the social worth of the person and everyone in the organization aim to achieve a high position in the workplace. The social worth will confer the person more useful social resource and access to acquirea positive emotion (Anderson et al., 2015).

Given the complexity of the creative process, social resources and positive emotions may motivate employees to take more participation in green innovation activities. As the high value and high demand for workplace status, it is very common for using status as an approach of encouragement. However, how does workplace status affect employee creativity and the underlying mechanisms are unclear, and little research has paid attention to the internal mediation effect of workplace status on creativity (Song and Yu, 2018). As a result, it is possible to have uncontrollable outcomes in the approach of status encouragement. In other words, the idea is to use status to promote creativity may lead to the opposite result. Based on the interaction theory of creativity, this study explores the mechanism of workplace status on creativity from the perspective of the social interaction generated by green creativity (Wang et al., 2018). In the formation stage of green creativity, the higher workplace status will enhance the interactive relationship in the workplace to activate the internal resources of the organization and promote the transmission of non-redundant information contributing to an internal ecological environment conducive to green innovation (Wrzesniewski et al., 2003). Workplace status is a comprehensive reflection of the ability, prestige, resources, and influence of employees in the workplace. When someone has a high workplace status, it means that he or she will be easier to be recognized and adored. As a result, the person has more probability to believe in his ability and easier to succeed. At the same time, a higher position in the workplace can promote the continuous improvement of green innovative thinking, which is very important to the integration and realization of green ideas. Therefore, this paper assumes that individuals with higher workplace status are more likely to perform green creativity. Based on this, this paper proposed hypothesis 1.

H_1: Workplace status has a positive effect on green creativity.

The mediator role of prosocial motivation

Prosocial motivation refers to encouraging employees to form motivations of benefiting organizations and other members (Grant, 2007), which is a dynamic psychological factor that occurs in social interaction. Since prosocial motivation pays more attention to the interests of others, it shows altruistic behavioral tendencies and cognitive attitudes of respecting others. Workplace status has a significant impact on prosocial motivation for three reasons. First, workplace status reflects the social value of employees in the process of social interaction within the organization and forms an effective social proof in the workplace (Zhu et al., 2018). The prosocial motivation one of the most important internal motivation of individuals meets the value needs of the organization since members of the organization normally have high social expectations for those with high workplace status. Based on the expectation theory, when someone

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87638774

has a higher workplace status, he will have more internal motivation to strive for green innovation.

Second, members with high workplace status have more internal resources and have the obligation to help the organization achieve higher goals. Workplace status is the public's overall evaluation of an individual. In other words, workplace status is a characteristic or trait attributed to a person, which is an intangible capital of the subject (Anderson et al., 2015). Forming prosocial motivation is an effective way for high-level members to achieve organizational goals and this makes workplace status more socially beneficial in the organization.

Third, according to social exchange theory, when employees feel that the organization provides more support, this positive perception will promote green creativity through the mediator role of organizational commitment and job satisfaction. Employees with higher workplace status will pay more attention to the interests of others and have more prosocial behavioral tendencies. In certain circumstances, environmental information in a social situation will trigger people's green creativity intent (Lichtenfeld et al., 2018). Therefore, workplace status will stimulate the prosocial motivation, and then promoting green creativity of the employees. Based on this, we proposed hypothesis 2.

H_2: Prosocial motivation mediates the relationship between workplace status and green creativity.

The moderator role of organization identification

In terms of social perception, recent research indicates the impact of personal beliefs on green creativity. When dealing with environmental issues, people face conflicts between the two goals of achieving enjoyment and following environmental regulations. Therefore, green creativity often means a certain price. Based on the basic premise of cost-benefit, Spanjol et al. (2015) integrated factors such as values, situations, and goals in their theoretical framework. The research for green creativity follows two paths within this framework, one is the external approach, which reduces the cost of pro-environmental decision; the other is the internal approach, which is to strengthen the normative goal and digest the pro-environmental value. Compared with the external approach, the internal approach depends on the corresponding values and the situational factors that can activate such values, so the mechanism of promoting green creativity is very stable (Wang et al., 2018). Within an integrated and diversified framework of green creativity, the role of social perception still exists systematically (Huppmann et al., 2019).

Organization Identification defined as the perception and sense of belonging of individual in an organization has a dramatic impact on employee attitudes, behaviors, and perceptions (Ashforth et al., 2008). According to social identity theory, organizational members have a behavioral tendency to define their social identity according to the social situation they face. Organization identification is a comprehensive reflection of employees' social interaction in the organization and it reflects the cognitive overlap between individual and organization (Farooq et al., 2017). Through this method, an organization's interests can be internalized by employees and organizational success is equivalent to their own success. In other words, organization identification can increase an individual focus on the organization's interests members with a high level oforganization identification may achieve self-positive identity through achieving the organizational goals. This study suggests that organizational

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87638774

identity can enhance the effect of workplace status on green creativity. Therefore, this paper proposes hypothesis 3.

H_3: Organization identification moderates the relationship between workplace status and green creativity.

In summary, in order to further explore the relationship between workplace status and green creativity, this paper establishes a regulated mediation model to reveal the internal mechanism. The model is shown in *Figure 1*.

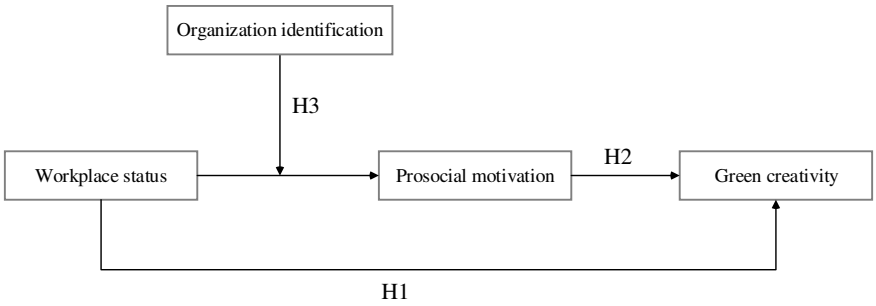

Figure 1. *Theory research model*

Methodology

Data collection

This research mainly aimed at front-line workers in the industry of electricity, telecommunications, and manufacturing. The survey mainly relied on relevant entrusting contact to issue questionnaires and communicated with the responsible persons in detail before the questionnaire. Forty-five companies were selected, and 400 questionnaires were distributed throughout the study. After eliminating invalid questionnaires such as repeated answers and serious missing data, 342 valid questionnaires were obtained (effectiveness 85.4%). Among the employee samples, 54.2% were male; the education level was mainly junior college (66.3%); the age was 26-35 years old (73.7%); the working age was mainly 6 years (36.4%).

The scales used in this study are mature scales widely used in at domestic and abroad areas. Accurate and reliable measurement tools are the basis for exploring green innovative influencing factors and building theoretical models. Recently, researchers havepaid more attention to the scientific and reproducible functionality of behavioral measurement models and have adopted a richer and diverse approach to integrating more effective evaluation structures.

Workplace status is measured based on the 5-question scale developed by Djurdjevic et al. (2017). The paper questionnaire is distributed on-site and the item is like “I enjoy a high status in the workplace”. The prosocial motivation is based on the 4-question scale developed by Grant (2007), measuring items such as “It is important for me to have the opportunity to do my best to help others”. The organization identification is based on the 6-question scale developed by Mael and Ashforth (1992), measuring items such as “The success of the organization is my success”. In addition, we used the model proposed by Chen and Chang (2013) to measure green creativity, and green creativity was measured using the questionnaire in *Table 1*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87638774

All English scales were translated into Chinese using the translation-translation back program to maximize the effective understanding of the scale. The scales are all measured by Likert 7 points, from 1 to 7, respectively, indicating that the degree of conformity to the described situation is low to high.The evaluation methods used in the study are self-subjective evaluations of the employees. Therefore, it is necessary to use a rigorous mathematical analysis method to verify the validity of the data.

Table 1. *Measurement items for green creativity (Chen and Chang, 2013)*

No.	Description
1	The members of the green product development project suggest new ways to achieve environmental goals.
2	The members of the green product development project propose new green ideas to improve environmental performance.
3	The members of the green product development project promote and champion new green ideas to others.
4	The members of the green product development project develop adequate plans for the implementation of new green ideas.
5	The members of the green product development project would rethink new green ideas.
6	The members of the green product development project would find out creative solutions to environmental problems.

The framework of moderated mediation model

Mediation models of psychological processes are widely used in the research of organizational behavior because they can reveal the process and mechanism of the influence between variables that get more in-depth results compared with the regression analysis. Applying these models allow us to develop new ideas in theoretical development and explore the possible points of intervention in practice (Shrout and Niall, 2002). In these models, the putative intermediate variables account for the association between independent variables and outcome variables. When the empirical analysis results support the hypothesis proposed by the model, it will provide invaluable information for subsequent experimental research and theoretical exploration (Bollen and Stine, 1990; Mackinnon et al., 2002).

According to Baron and Kenny (1986), a mediation model can be written as:

$$M = i_M + a_X + e_M \quad \text{(Eq.1)}$$

$$Y = i_Y + c'X + bM + e_Y \quad \text{(Eq.2)}$$

In *Equation 1* and *Equation 2*: *i* represents intercept and e represents error, *M* is the mediator between *X* and *Y*, and the indirect effect of this model can be quantified as the product of coefficients *a* and *b*.

In the research of management, psychology and other disciplines, the relationship between two variables is dependent on a third variable is common in many theories. The variables that affect the strength of the relationship between two variables called moderator variables. In other words, a moderation model occurs when the relationship between *X* and *Y* is affected by a moderator variable *Z*. According to Dawson (2014), a moderation model can be written as *Equation 3*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87638774

$$Y = i_{1Y} + i_{2Y}Z + c_1X + c_2XZ + e_Y \quad \text{(Eq.3)}$$

When a model contains both mediation variables and moderation variables, it is called a moderated mediation model. According to the basic concepts of the model, a moderated mediation effect occurs when the mediation effect changes with the moderating variable, see in *Figure 2*. Based on previous research (Wang and Preacher, 2015), a moderated mediation model can be written as *Equation 4* and *Equation 5*.

$$M = i_{1M} + i_{2M}Z + a_1X + a_2XZ + e_M \quad \text{(Eq.4)}$$

$$Y = i_{1Y} + i_{2Y}Z + c_1'XZ + c_2'XZ + b_1M + b_2MZ + e_Y \quad \text{(Eq.5)}$$

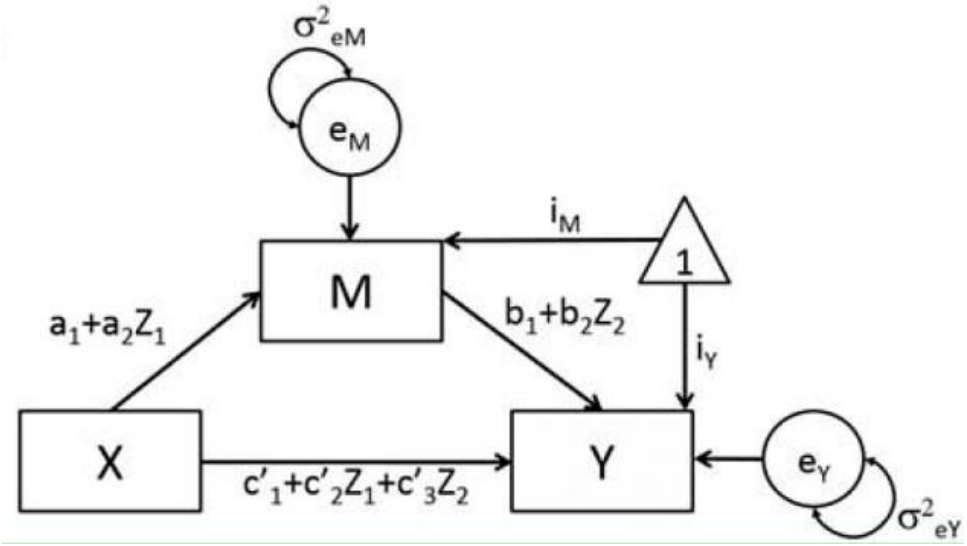

Figure 2. *A moderated mediation model (Wang and Preacher, 2015)*

Results and analysis

Validity and reliability analysis

The exploratory factor analysis and reliability analysis results of the scale are shown in *Table 2* and *Table 3*. From *Table 2*, the interpretable variance of pro-environmentally behaviors is 21.59%, the interpretable variance of organization identification is 19.50%, the interpretable variance of workplace status is 17.06%, and the interpretable variance of prosocial motivation is 14.53%. And greater than 50%. Therefore, this test has good explanatory validity.

It can be seen from *Table 3* that the internal consistency coefficients of all the scales in this study exceeded 0.89, indicating that they all have good measurements.

Descriptive statistics

Table 4 shows the correlation between the various constructs. From the data in the table, the correlation between the variables is good, and the hypothesis is initially supported.

Discriminant validity analysis

In order to test the discriminant validity between the main variables, this paper conducts a confirmatory factor analysis of workplace status, prosocial motivation, green creativity, and organization identification. As shown in *Table 5*, compared with the other four competing models, the four-factor model is optimally fitted, and each parameter can reach the fitting standard *($X^2/df=3.66$, NFI=0.96, IFI=0.97, GFI=0.94, RMSEA=0.068, SRMR=0.054)*, indicating that the four variables in this study have good discriminant validity, see in *Figure 3*.

Hierarchical regression analysis

First, we used a method of hierarchical regression analysis to test the mediating effect (Hayes, 2013). After controlling the four variables including age, working years, educational level and technical grade, workplace status still has a significant effect on green creativity, shown in *Table 6*. And we found prosocial motivation partly mediated the relationship between workplace status and green creativity. The regression

DOI: http://dx.doi.org/10.15666/aeer/1704_87638774

coefficients with organizational identification were significant that confirmed the moderation effect.

Moderated mediation effect test

In addition, we performed a Bootstrap to get the confidence intervals of the moderated mediation model. With the increase of organizational identification, the correlation coefficient between workplace status and green creativity increased gradually, and the 95% confidence interval does not contain zero, see in *Table 7*. This suggests that organizational identification can moderate the indirect effect between workplace status and green creativity, and the hypothesis H_3 is confirmed. Organizational identification is the boundary condition for workplace status to have an effect on green creativity.

Table 7. *Result of the moderated mediation effect*

Organization Identification	***β***	***Boot SE***	Confidence interval	
			Lower 95%CI	**Lower 95%CI**
1-SD	0.135	0.038	0.067	0.216
1	0.148	0.028	0.099	0.207
1+SD	0.160	0.028	0.112	0.222

Conclusion

In this paper, we proposed a moderated mediation model to explore the relationship between workplace status and green creativity. First, we found workplace status has a significant positive effect on green creativity, and this is very important for the management practices. Second, we confirmed the mediation effect of prosocial motivation, which is an effective complement to the theoretical study of green creativity. In the end, we found organization identification can moderate the indirect effect, and this has a pioneering role in the research of workplace status and green creativity.

Abstract. Through model hypothesis and simulation experiment method, this paper demonstrates the behaviour choice of the market maker and emission discharge enterprise after a certain long-term operation with market maker mechanism in the emission trading market under certain pre-defined conditions. Each subject's and overall utility are explored. After analysing the impact of market demand and price difference on market maker trading, the relevant suggestions for introducing the market maker mechanism in the emissions trading market are given.
Keywords: *emission discharge, market maker mechanism, dynamic system, market fluctuations, environment protection*

Introduction

The management of emission rights is an inevitable way to create a harmonious living environment, and it is also a serious issue facing all countries in the world (Du, et al., 2018). International experience shows that emissions trading mechanisms can maximize social benefits while protecting wealth creation, compared to administrative orders and taxation. In a market where market makers participate, the spread (the difference between the asking price and the bid) is not only the price that the market maker provides, which is adjusted according to the change of the market maker's optimal choice (Shen and Starr, 2002), but also a major indicator of the liquidity provided by market makers. It is generally believed that the greater the spread, the greater the risk of holding inventory and thus the lower liquidity (Tarun and Richard, 2001), and vice versa. There are two main theories about the interpretation of the price difference: inventory control theory and reverse selection theory.

The starting point of the inventory control theory is that the market maker must have a certain inventory reserve in order to make the market. Due to the changes in market factors such as interest rates, the market makers will be affected by the uncertainty of the inventory value changes (Gong, et al., 2018). Therefore, the market makers will adjust the ask price and bid price in the quotation to balance inventory risk. The transaction cost problem involved in the spread can be understood by considering the analysis of a neglected problem "foreseeable transaction immediateness" (Demsetz, 1968).

The inverse selection model assumes that there is information asymmetry in the market. There is a market maker and two types of traders in the market: liquid traders and traders with information advantages. Market makers optimize their offers to get the most benefit, that is, by setting a spread to maximize Gains earned by liquidity traders and losses suffered by information advantage traders (Glosten and Milgrom, 1985; Kyle, 1985; Bondarenko, 2001; Calcagno and Lovo, 2006; Zhang and Li, 2011).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87758791

From the monopolistic of market makers and the impact of competition on the market, centralized model research shows that the monopolistic expert system on the New York Stock Exchange enables market makers to enhance social welfare because in the scattered market, it partially internalizes the externalities of the spread (Miao, 2006).

From the transparency aspect of information, researchers examined the price display effect in the market maker market and found that in the opaque market, the open spread is large and trading volume is low due to higher search costs, but higher search costs lead to more aggressive pricing strategies, so price discovery speeds are faster in opaque markets (Flood, et al., 1999; Bloomfield and O'Hara, 2000).

In addition, some studies have investigated the aspects of market stability, market maker financing, and locality of market makers. Financial market models were used to test the stability of market makers to the market (Zhu et al., 2009). They assumed that there are two types of investors in the market: fundamental investors and trend investors, market makers acting as liquidity providers and active investors. The research results show that when market makers actively manage their inventory to maximize profits, they do not stabilize the market; and the behavior of market makers depends on the behavior of speculators (Zhu, et al., 2009). The information advantage of local market makers is a very valuable factor in reducing transaction costs (Kedia and Zhou, 2011).

Overall, the research on the market maker system of emission trading at home and abroad is still very imperfect. The Emission trading market should play an active role in pollution control. The market mechanism needs to be improved. The market makers acting as emission trading intermediaries are one of the important components of micro market structures. To introduce market maker trading in the pilot trading phase of China, the most urgent task is to have a complete set of incentives and constraints for market makers to ensure the effectiveness of market makers' behavior. This is also the shortcoming of the current research.

Methods

Since China's emission trading market has not adopted the market maker trading system, this study uses the simulation experiment method to study the trading efficiency of market makers in the emission trading market. The experimental method is one of the main methods for researchers at home and abroad to study emissions trading. In order to reflect the transaction efficiency of the market maker's quotation, the trading system set up by the research institute contains a market maker and a number of emission discharging enterprises. The transactions of the emission discharging enterprises are carried out by the market makers, and the current emission discharge certificates cannot be stored in the conditions of next stage of transaction. Due to the need of market making, the market maker needs to balance the relationship between the current transaction income and the storage cost. under the established supervision, the emission discharge enterprises trade considering the quote of the market maker and its own emission reduction cost. Based on this, this paper explores the long-term behavioral evolution of each participant, studies the transaction efficiency of market makers' quotations in the emission discharge trading market, and provides theoretical guidance for the application of market maker quotation system in China's emissions trading practice.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87758791

Hypothesis 1: Each trading entity adjusts its decisions based on their respective profit conditions. In the emission trading system, the amount and quotation of the emission right of the market maker is private information and the quotation setting needs the market maker's information collection of each emission enterprise. Due to the incompleteness of the information, the decision of the market maker and the emission enterprise Behaviors are adjusted only based on the information they have. Under the condition of profit maximization, the profit value can be regarded as the most credible indicator, so it is assumed that each transaction entity adjusts the decision according to their respective profit conditions.

Hypothesis 2: The spread of each period is fixed, but the market maker will adjust the ask price and bid for the next period based on the information of this period. The market makers need to make quotations during making the market. If the price difference is too large, it will damage the interests of the traders, and it is not conducive to the liquidity of the market. In order to standardize the market making behavior of market makers, it is in practice to set the price difference magnitude or upper limit. Therefore, this paper sets a fixed spread and assumes that the spread will remain the same in each period, but the market maker will adjust the bid and bid for the next period based on the information in this period. The model parameters are set as follows:

D - the total market demand of the product, assuming a normal distribution;
D_i - the market demand for the products of enterprise i;
AP - the asking price of the market maker;
BP - the bid of the market maker;
N - the number of emission enterprises;
R_i - the product profit obtained by use of each unit of the emission certificate;
L - the total amount of emission permits available for distribution;
L_i - the number of emission control certificates assigned by each company;
C_i - the cost of abatement of enterprise i, assumed to follow a normal distribution;
Q_i - the trading volume of the emission certificate;
Q_{1i} - the amount of sales of emission control certificates;
Q_{2i} - the purchase amount of the pollutant discharge certificate;
P - the probability of effective supervision;
F - cost of violation punishment.

According to the question, the amount of emission certificates traded by the enterprises is given by *Equations 1* and *2*.

$$Q_{1i}(Sell)=\begin{cases}L_i-D_i, L_i\geq D_i, C_i\geq BP\\ L_i, L_i\geq D_i, C_i\leq BP\\ L_i, L_i\leq D_i, C_i\leq BP\\ 0, \text{else}\end{cases} \quad \text{(Eq.1)}$$

$$Q2i(Buy)=\begin{cases}D_i-L_i, L_i<D_i, R_i>AP, C_i>BP, (D_i-L_i)AP\leq F\times p\\ 0, \text{else}\end{cases} \quad \text{(Eq.2)}$$

Enterprise i's profit model is given by *Equation 3*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87758791

$$\pi^{c}(i)=\begin{cases} D_i \times R_i + (L_i - D_i)BP, C_i \geq BP, L_i \geq D_i \\ D_i \times R_i + L_i \times BP, C_i < BP \\ L_i \times R_i, L_i < D_i, R_i < AP \\ D_i \times R_i - (D_i - L_i)AP, L_i < D_i, R_i \geq AP, C_i \geq BP, (D_i - L_i)AP < p \times F \\ L_i \times R_i, L_i < D_i, R_i \geq AP, C_i \geq BP, (D_i - L_i)AP \geq p \times F \end{cases} \quad \text{(Eq.3)}$$

The market maker's profit model is given by *Equation 4*.

$$\pi^{(M)}=\begin{cases} \sum_{i=1}^{N} \mathrm{Q}_{1i}(AP - BP), Q_{1i} < Q_{2i} \\ \sum_{i=1}^{N} \mathrm{Q}_{2i}(AP - BP) - \sum_{i=1}^{N}(Q_{1i} - Q_{2i})BP, Q_{1i} \geq Q_{2i} \end{cases} \quad \text{(Eq.4)}$$

The total system profit is given by *Equation 5*.

$$\pi^{(s)} = \sum_{i=1}^{N} Q2i(Ci - AP) \quad \text{(Eq.5)}$$

Under normal circumstances, the market price changes with the supply of the two enterprises. Since the two emission enterprises is aware that their respective production will affect the market price, that is, the market price of the product, each enterprise will carefully trade the emission permit.

Proposition 1: Under the condition of complete information, the sufficient condition for the emissions trading is that there is a non-empty emission permit price range which makes $\partial\Pi_1/\partial Q > 0$ and $\partial\Pi_2/\partial Q > 0$.

Proof: The price of the emission permit is set as. Because the rational enterprise aims to maximize the profit, considering that permit trading will cause the change buyer's the marginal emission reduction cost and the market price, the trading is not made, unless the buyer and the seller's profit increment is positive.

According to the profit function, the response curve for deriving the maximum benefit of the emission discharge enterprise is given by *Equations 6* and *7*.

$$Q_1 = \frac{a - bQ_2 - MSC_1 - MCA_1}{2b} \quad \text{(Eq.6)}$$

$$Q_2 = \frac{a - bQ_1 - MSC_2 - MCA_2}{2b} \quad \text{(Eq.7)}$$

The total production is given by *Equation 8*.

$$Q = Q_1 + Q_2 = \frac{2a - MSC_1 - MSC_2 - MCA_1 - MCA_2}{3b} \quad \text{(Eq.8)}$$

Cournot-Nash equilibrium production is given by *Equation 9*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87758791

$$Q_1 = Q_2 = \frac{2a - 2MSC_1 - MCA_1 - MCA_2}{6b} \quad \text{(Eq.9)}$$

At this point, the market price of the product is given by *Equation 10*.

$$P = \frac{a + 2MSC_1 + MCA_1 + MCA_2}{3} \quad \text{(Eq.10)}$$

Emission discharge enterprises are producing under balanced production. It is obvious that emission discharge enterprise 1 will obtain higher profits with lower marginal emission reduction costs. Therefore, in terms of balanced production, the enterprise 2's profit before trade is given by *Equation 11*.

$$\Pi_2 = PQ_2 - \int_0^{Q_2} (MSC_2 + MCA_2)dt \quad \text{(Eq.11)}$$

After trading, the profit of emission discharge enterprise 2 is given by *Equation 12*

$$\Pi_2^* = P^* Q_2 - L_1 P_L - \int_0^{Q_2} MSC_2 dt - \int_0^{Q_2^*} MCA_2 dt \quad \text{(Eq.12)}$$

The conditions for the transaction are : $\Pi_2^* - \Pi_2 \geq 0$. Therefore, the conditions for emission discharge enterprise 2 can be given by *Equation 13*.

$$P_L \leq \frac{(\Delta MCA_1 + \Delta MCA_2)Q_2 + 3\int_{Q_2^*}^{Q_2} MCA_2 dt}{3L_1} \quad \text{(Eq.13)}$$

Similarly, the conditions for the buyer-- emission discharge enterprise 1 to make the trade can be given by *Equation 14*.

$$P_L \geq \frac{(\Delta MCA_1 + \Delta MCA_2)Q_1 + 3\int_{Q_1^*}^{Q_1} MCA_1 dt}{3L_1} \quad \text{(Eq.14)}$$

In summary, the effective conditions of the trade should satisfy *Equation 15*.

$$\frac{(\Delta MCA_1 + \Delta MCA_2)Q_1 + 3\int_{Q_1^*}^{Q_1} MCA_1 dt}{3L_1} \leq P_L \leq \frac{(\Delta MCA_1 + \Delta MCA_2)Q_2 + 3\int_{Q_2^*}^{Q_2} MCA_2 dt}{3L_1} \quad \text{(Eq.15)}$$

Because $MCA_1 \leq MCA_2$, there is a non-empty price set P_L, and the trade will only occur when the price of the emission permit is in this range. In particular, when the marginal emission reduction cost of the enterprise remains unchanged in the short term, it satisfies: $MCA_1 \leq P_L \leq MCA_2$.

In the market environment with asymmetric information, due to the uncertainty of production and operation, the lack of understanding of the needs of the trading parties, etc., the emission discharge enterprises often consider the question of when to buy and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87758791

sell, how much to buy and sell, which brings the emissions trading Uncertainty. But at this time, if there is a seller in the market, it can be seen that it provides clear information to the market, because the appearance of selling often means the certainty of the remaining. Conversely, the information conveyed by the buyer is often not clear enough, because the existence of uncertainty tends to increase the demand of the enterprise, resulting in more purchases in the market than real demand. Therefore, the emergence of the seller is a key factor in determining the efficiency of the information asymmetry market.

Proposition 2: Under the asymmetric information environment, the trading volume of emission rights depends on the sales volume of the enterprise.

Proof: It is assumed that under the condition that the price range satisfies the trade occurrence, the probability of the emission discharge enterprise 1 selling the permit is: the probability of not selling is. The smaller the probability value, the stronger the uncertainty of the emission discharge enterprise 1 selling the emission permit. In this regard, the emission discharge enterprise 2 has two strategies: buy, not buy, the strategy matrix is shown in the following *Table 1*.

Table 1. *Strategic matrix of sewage enterprises*

	Sell (p)	**Not sell** ($1-p$)
Buy	$P*Q_1+L_1P_L-\int_0^{Q_1}MSC_1dt$, $P*Q_2-L_1P_L-\int_0^{Q_2}MSC_2dt-\int_0^{Q_2*}MCA_2dt$	$PQ_1-\int_0^{Q_1}MSC_1dt-\int_0^{Q_1*}MSC_1dt$, $PQ_2-\int_0^{Q_2}MSC_2dt-\int_0^{Q_2}MCA_2dt$
Not buy	$PQ_1-\int_0^{Q_1}(MSC_1+MCA_1)dt$, $PQ_2-\int_0^{Q_2}(MSC_2+MCA_2)dt$	$PQ_1-\int_0^{Q_1}MSC_1dt-\int_0^{Q_1*}MSC_1dt$, $PQ_2-\int_0^{Q_2}MSC_2dt-\int_0^{Q_2}MCA_2dt$

Under the two strategies, the expected value functions of the emission discharge enterprises 2 are *Equations 16* and *17*.

$$E(\Pi_{2Buy})=p(P*Q_2-L_1P_L-\int_0^{Q_2}MSC_2dt-\int_0^{Q_2*}MCA_2dt)+(1-p)(PQ_2-\int_0^{Q_2}MSC_2dt-\int_0^{Q_2}MCA_2dt) \quad \text{(Eq.16)}$$

$$E(\Pi_{2Notbuy}=PQ_2-\int_0^{Q_2}(MSC_2+MCA_2)dt \quad \text{(Eq.17)}$$

According to the expected value decision rule, the conditions for the trade should satisfy *Equation 18*.

$$E(\Pi_{2Buy})\geq E(\Pi_{2Notbuy}) \quad \text{(Eq.18)}$$

Inferred that the price generated by the trade is given by *Equation 19*.

$$P_L\leq\frac{(MCA_2*-MCA_2)Q_2+3\int_{Q_2*}^{Q_2}MCA_2dt}{3L_1} \quad \text{(Eq.19)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87758791

This price condition is exactly the same as the previous buying condition, that is, as long as the price is in the tradable range, the emission discharge enterprise 2 will certainly buy the emission permit, because the purchasing strategy is always profitable for the emission discharge enterprise 2. Then the key factor restricting the sale and purchase is the probability of the sales of the emission discharge enterprise 1. The greater the probability that the emission discharge enterprise 1 sells, the easier the trade will be generated, conversely, the less likely the trade is. That is: the amount of sales of emission permit is a key factor in determining the volume of emissions trading.

According to Proposition 1 and Proposition 2, whether a market mechanism is effective depends on whether it can make the price in a tradable range and how to form a seller. Based on this analysis, this study compares and analyzes the difference between the market maker's quotation transaction and the current implementation of the emission trading price and the seller's formation mechanism in China.

Data and simulation analysis

For the sake of clarity, it is assumed that there are two emission discharge enterprises in the same region that use the same technology to produce homogeneous products, which have the same marginal social cost (MSC). In terms of quantity, the marginal social cost is equal to the sum of the marginal cost of the production of the emission discharge enterprise (MC) and the marginal external cost of emission caused by the environment (MEC): $MSC = MC + MEC$. Under the conditions of the scale of production, the proportion of input factors, and the fixed level of technology, for the enterprises, the marginal social cost is tilted upwards, because with the increase in production of emission discharge enterprise, the marginal cost of production rises, and with the amount of emission Increase, the harm to the environment also rises. However, due to the different emission reduction technologies adopted, the marginal emission reduction costs (MCA) of the two enterprises are different, and they are respectively MCA_1 and MCA_2. In the short-term, due to the fixed level of emission reduction, the marginal emission reduction cost of emission reduction enterprises should be tilted downwards, because enterprises need to install specific emission reduction equipment when they reduce emissions. When the emission reduction is small, the unit cost will be higher. When the emission reduction is high, the unit cost is reduced accordingly.

It is assumed that the emission discharge enterprises are producing with the goal of maximizing profits, and the target yields of the two enterprises maximizing profits are respectively, and at the same time, because the products are homogeneous, the emission discharge enterprises have the same product demand curve.

Let product price as $P = a - bQ$, Q is the total production of emission discharge enterprise 1 and 2, that is $Q = Q_1 + Q_2$. Then emission discharge enterprise 1's expected income function is *Equation 20*.

$$Max\Pi_1 = PQ_1 - \int_0^{Q_1} (MSC_1 + MCA_1)dt \quad \text{(Eq.20)}$$

Then emission discharge enterprise 2's expected income function is *Equation 21*.

$$Max\Pi_2 = PQ_2 - \int_0^{Q_2} (MSC_2 + MCA_2)dt \quad \text{(Eq.21)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87758791

According to the above mathematical model hypothesis, after compiling and running the Fables program, a graphical interface as shown in *Figure 1* will be formed. The parameters of the model are displayed in the dialog box on the left side of the interface, which includes the emission reduction costs set in the previous section. For parameter values such as asking price and bid, the interface box on the right side of the graph is the area showing the result after the program runs.

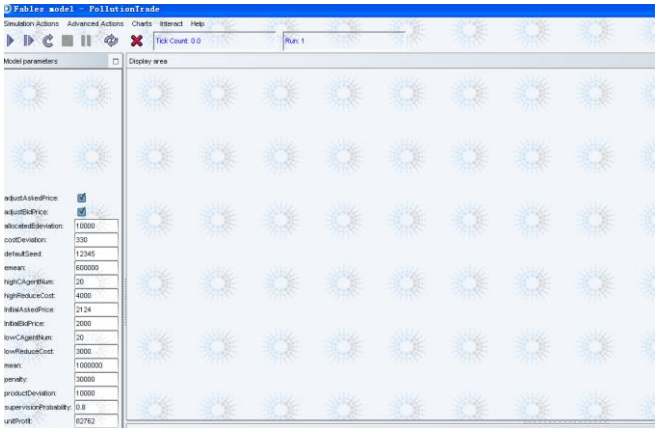

Figure 1. *Running interface of program*

According to the research needs, this study sets four research variables: spread, trading volume, market maker profit, and profit of emission discharge enterprise. The time period is an important factor in the reliability of the reaction simulation results. Therefore, this paper observes the stability of the simulation run for 50 cycles and analyzes the reliability of the indicators. The simulation results are shown in *Figure 2*.

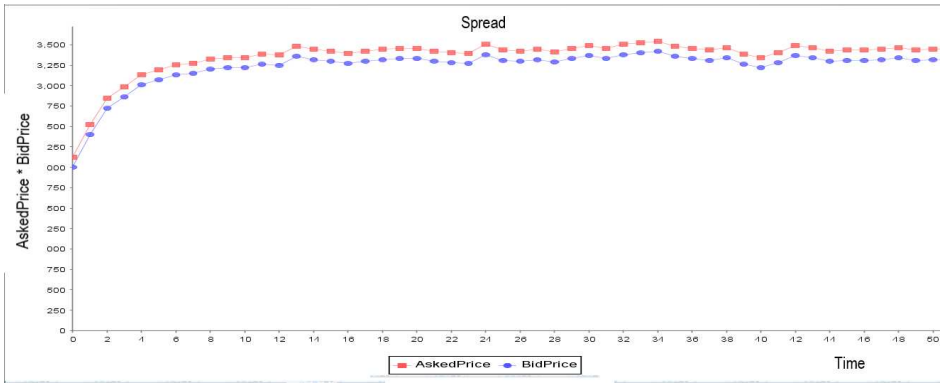

Figure 2. *Simulation diagram of the market maker quotation*

The simulation results of the market maker's quotation in *Figure 2* show that during the 50 cycles of operation, the market maker's quotation and the trend of the price difference are relatively stable, and the volatility of the quotation is small. After about 50 cycles of operation, the quotation increased from the bid of 2,000 yuan/ton and the asking price of 2,124 yuan/ton to the bid of about 3,250 yuan/ton and the asking price of 3,500 yuan/ton, and then stabilized. Through the quote of the market maker, realization of market price discovery mechanism can be enhanced.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87758791

The simulation results of the market trading volume in *Figure 3* show that the average market buying and selling volume fluctuates around 6500 as the axis, and the pattern is in good coincidence. This shows that the buyer and the seller are in the same trend, and the market trade are very active. According to the average purchase and sales volume of 6,500, the total trade volume of each period can reach 260,000 units, calculated according to the total allocation of 600,000. The trade ratio is as high as 43%, which will optimize the rational allocation of emission permits. However, as the average fluctuation of the sales volume is small, the volatility of the purchase volume is relatively large, indicating that the large fluctuations in the purchase volume will increase the uncertainty of the market demand for emission permits. as the market organizer. the market maker has a need to have a certain amount of reserves to deal with market risks.

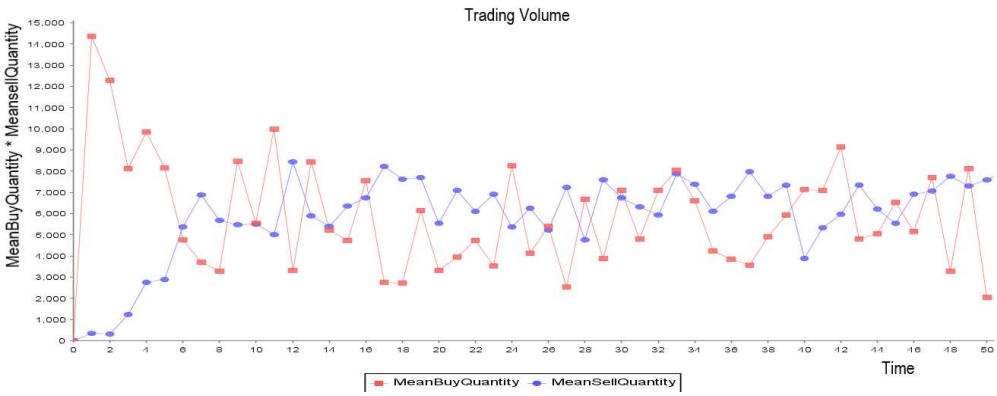

Figure 3. *Simulation diagram of trading volume*

As shown in the simulation results of the market maker's profit in *Figure 4*, in the 50 cycles of operation, the profit of the market maker mainly fluctuates between -5 million and -17.5 million, and the profit fluctuation is large. There are two main reasons for the phenomenon: First, the emission permit is set as not storable, which means that the current permit cannot be used for the next trade. This will bring storage costs and maturity loss risk to the market makers; second, the volume of trading in the company's buying volume fluctuates greatly, which increases the risk of market maker trading.

Figure 4. *Simulation diagram of the market maker profit*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87758791

Although the previous simulation results show that the market maker's profit is negative, *Figure 5* shows that the entire emissions trading system has positive returns, and the return value fluctuates between mainly 1 million and 4 million. This indicates that in the case where storage is not allowed, although the market maker suffers a certain loss, the increase in the profit of the emission discharge enterprises and the saving of the emission reduction cost can make up for this loss. Therefore, a comprehensive analysis of the above simulation results shows that market transactions involving market makers increase market efficiency.

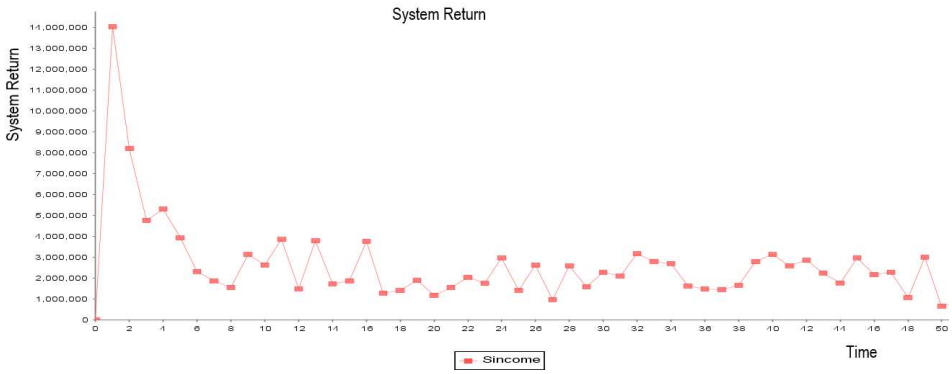

Figure 5. *Simulation diagram of system return*

Results and discussion

In order to understand the performance of the emissions trading market under different market conditions, and to formulate corresponding institutional measures to ensure the operation of the market maker trading market system, this study analyzes the changes in market quotations, system returns and other indicators by changing certain market parameter values and features.

The impact of market demand variance on market maker transactions

When setting the initial value of the simulation, the variance of the market demand variable and the emission right distribution variable is small. This is suitable for the steel industry, which has a small difference between enterprises and a stable market environment. However, in certain industrial environments, or in certain specific environments, market demand changes more severely, and smaller demand variances do not reflect this market change. In addition, in the current allocation of emission rights, the distribution of emission rights often has a higher correlation with the market demand and production volume of the enterprise, and the presence of market power will further aggravate the inequality of the distribution of emission rights.

In order to make the research results more obvious, this study increases the standard deviation of market demand parameters to 10,000, and the standard deviation of emission allocation parameters to 10,000, thus to compare the performance of market makers in different market environments. The simulation results are shown in *Figure 6.*

Figure 6 shows that during the 50 cycles of operation, the volatility of the market maker's quotation increased after the variance increased, although the main quotation range is still concentrated around 3250. The simulation results show that the market

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87758791

maker's quotation level and spread is greatly affected by the balance of market demand and emission permit allocation.

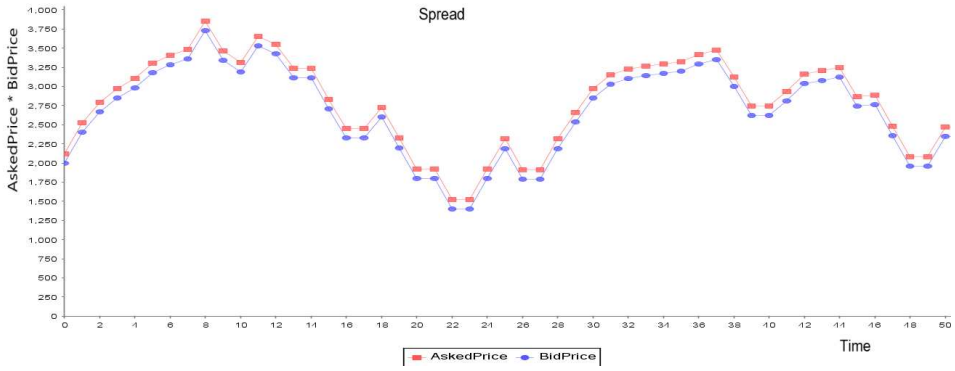

Figure 6. *Simulation diagram of market maker quotation after increasing the variance*

Figure 7 shows that in a drastic market and in the presence of market power, the market's buying and selling volume still have a good coincidence, but the market's trading volume has slightly decreased, and the sales volume is more discrete. The simulation results show that the market trade are in good condition, but the difference between the sales volume and the purchase volume of the market trade becomes larger.

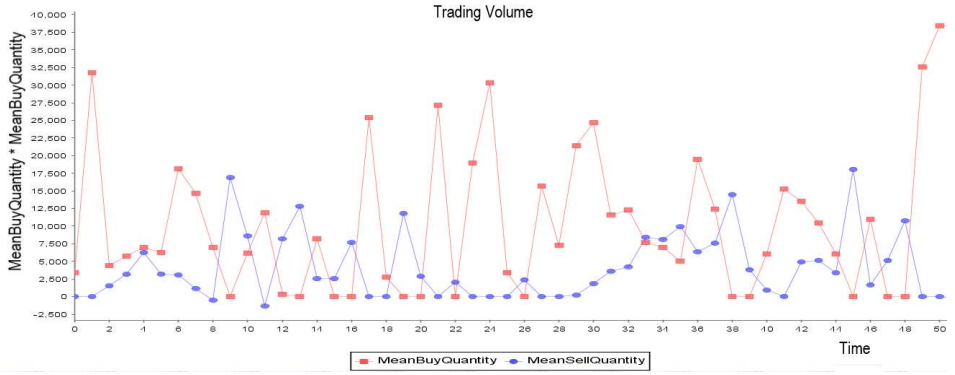

Figure 7. *Simulation diagram of trading volume after increasing the variance*

Figure 8 shows that during the 50 cycles of operation, due to the large fluctuations in the amount of purchases and sales in the market, the profit of market makers also showed strong volatility. But the market makers' profit in some cycles has positive values, which indicates that in the severe market environment, the distribution method of the different emission permits will increase the profit of the market maker.

Figure 9 shows that in the 50 cycles of operation, the system returns are non-negative, and the mean and fluctuation of system benefits are high. The simulation results show that the market demand is uncertain and there is a serious distribution bias. Using market maker transactions can significantly increase the revenue of the entire trading system.

From above simulation analysis it can be seen that under the severe market and the large difference in the market distribution of emission permits, the quotation of market

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87758791

makers is relatively higher, the system transactions will still maintain a high level, and the system returns are higher. Therefore, it is more suitable to use the market maker market transaction in this environment.

Figure 8. *Simulation diagram of market maker profit after increasing the variance*

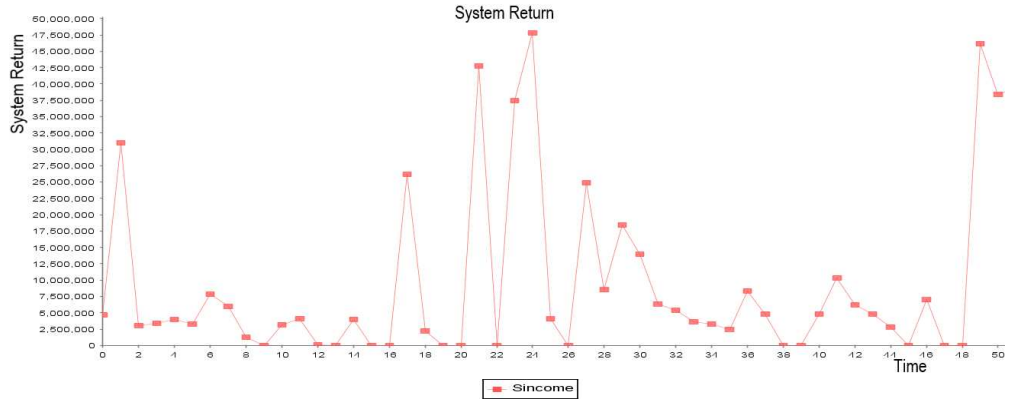

Figure 9. *Simulation diagram of system return profit after increasing the variance*

The effect of spreads on market maker trading

In market maker trading, the price difference is an important factor that restricts the market price and the profit of the market trading entity. In the current financial market, many countries and regions have a clear limit on the price difference of market makers. Therefore, this paper adjusts the spread to compare the impact of the spread on the market for emissions trading.

As shown in *Figures 10* and *11*, the change in the spread during the 50 cycles of operation did not result in large fluctuations in the quoted price of the market maker. However, under the 20% spread, the asking price of the market maker rose to about 3,750, and under the 40% spread, the asking price of the market maker rose to about 4,250. Therefore, the simulation results show that the change in the spread does not change the trend of the quote. However, the change in the price difference will change the absolute value of the market maker's quotation, thus affecting the supply and demand relationship of the market.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87758791

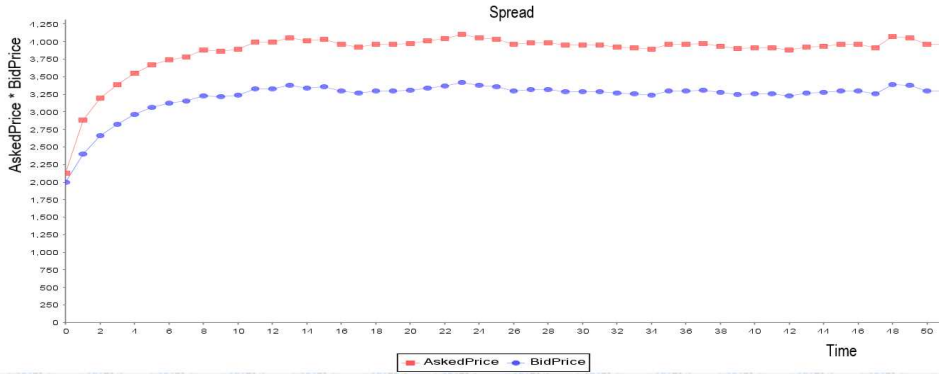

Figure 10. *Simulation diagram of market maker quotation under 20% spread*

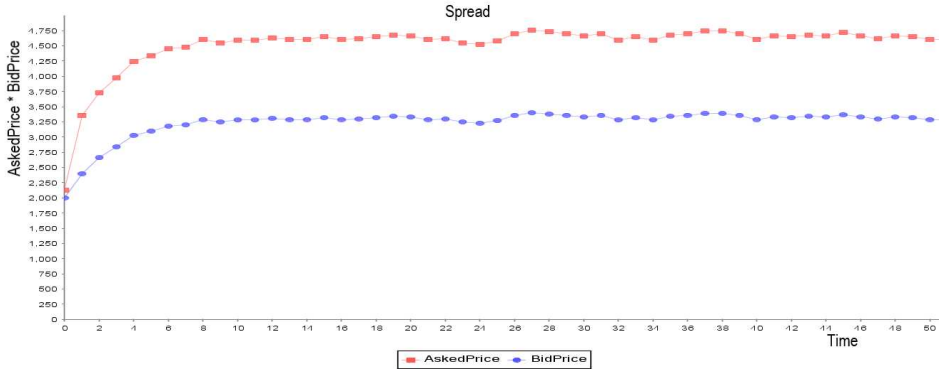

Figure 11. *Simulation diagram of market maker quotation under 40% spread*

As shown in *Figures 12* and *13*, the market's sales volume and purchase volume coincidence are better under different price differences. However, in comparison, under the 40% spread, the market transaction volume is relatively high, indicating that the higher the price difference, the higher the uncertainty of market transactions.

As shown in *Figures 14* and *15*, although the spread of the market maker's offer has increased, the market maker's profit is still negative, and both fluctuate with an axis of -12.5 million. This shows that despite the increase in the spread, the increase in the spread has changed the supply and demand relationship, resulting in fewer purchases. Therefore, the increase in market maker inventory reduces the profit of market makers.

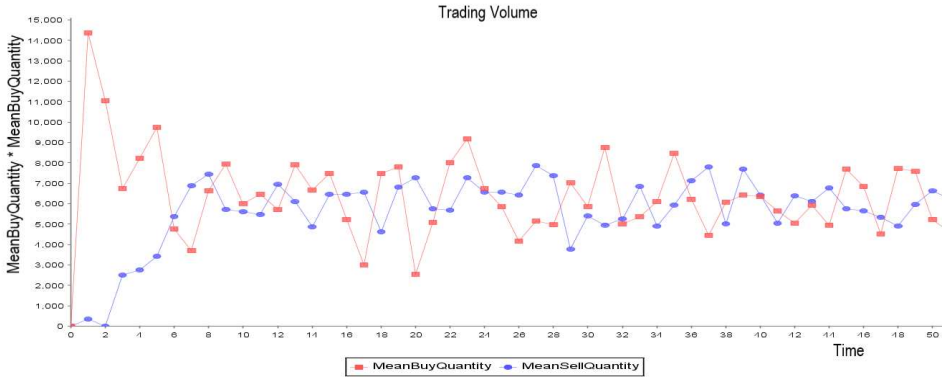

Figure 12. *Simulation diagram of trading volume under 20% spread*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87758791

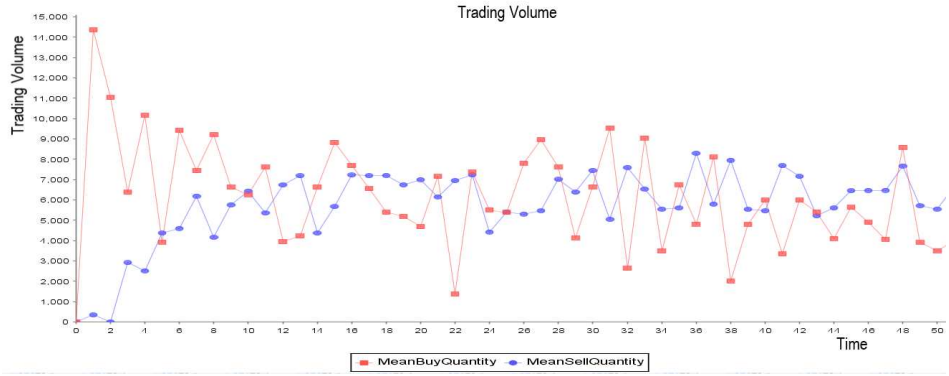

Figure 13. *Simulation diagram of trading volume under 40% spread*

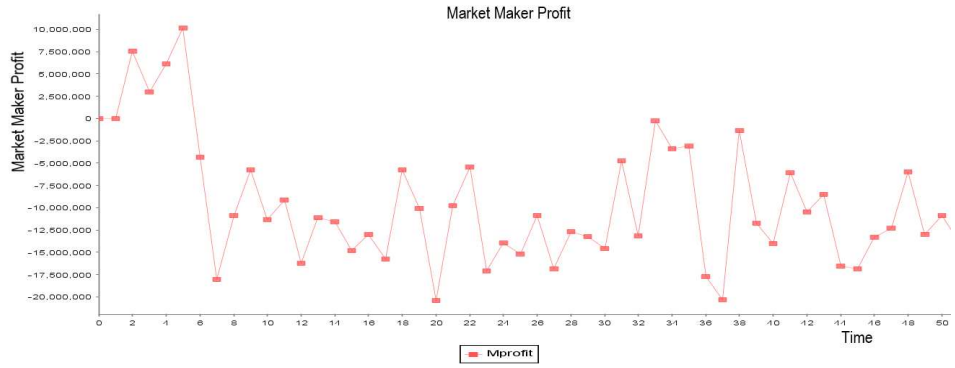

Figure 14. *Simulation diagram of market maker profit under 20% spread*

Figure 15. *Simulation diagram of market maker profit under 40% spread*

As shown in *Figures 16* and *17*, in the 50 operating cycles, the system benefits under the 20% spread have fluctuated near the edge of zero, which has been greatly reduced compared to the previous system benefits. Under the 40% spread, the system returns are all negative, and the average is large, reaching -1 million.

Based on the above analysis, the increase in the spread will reduce the system revenue. Therefore, the market price should be limited in the market maker trading market. According to the analysis of the simulation results, the spread should be controlled within 20%.

Conclusions

In the long run, the emissions trading market is in a dynamic system consisting of market makers, emission discharge enterprises, and government. In this paper, we use the simulation experiment method to simulate the operation mode of the emissions trading complex system, and draw the following main conclusions:

First, market maker trading is applicable to a variety of market environments, and can improve the efficiency of the emissions trading system. The simulation results show that regardless of whether the market yield of the products produced by the enterprise is higher or lower, whether it is fluctuating violently or mildly, whether there is market power in the emission permit market, whether the competition of the emission discharge enterprises is fierce, market maker transactions can make Emissions trading volume at a high level, and system revenue is positive.

Second, even if the market for enterprise products fluctuates drastically and there is a large difference in the initial distribution of warrants, market maker transactions are still suitable. Although the quotes of market makers are higher, the system returns are higher.

Third, the increase in the number of emission discharge enterprises will affect the quotation level of market makers, but will not change the trend of market makers' quotations.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87758791

Fourth, the increase in the spread will reduce the system revenue, and the market price of the market maker should be limited in the emissions trading market. According to the simulation results, the spread should be controlled within 20%.

Fifth, the adverse environment caused by the introduction of new products, the violent market fluctuations, and the rise of raw materials for products does not hinder the smooth conduct of emissions trading. The market makers can lower the quotation to balance supply and demand, so that the system returns are positive.

In future research, the assumptions could be relaxed in the proposed problem settings to observe their effects on the solutions, so that results could serve the needs of the real world. On the other hand, it is necessary to conduct an study of the behavioral rules of all parties involved in, which would provide a better solution for the parties. Finally, to improve the accuracy of the simulation results, some sophisticated methods can be used to set market demand parameters and emission allocation parameters, in which the set of parameters could be needed.

EFFECT OF LOW CARBON ECONOMY ON ENTERPRISE COMPETITIVENESS: A MULTIPLE MEDIATION MODEL

ZHANG, H. W.

School of Economics and Management, Beijing JiaoTong University, Beijing 10044, China
(e-mail: 16241267@bjtu.edu.cn)

(Received 8th Mar 2019; accepted 1st May 2019)

Abstract. The low-carbon economy is an economic model based on low energy consumption, low pollution and low emissions. According to some research, a low-carbon economy model can have a significant impact on a company's competitiveness. However, there are two different types of views on the relationship between environmental regulation and corporate competitiveness. This study uses a method of testing multiple mediations that can explain many complex internal mechanisms in the field of organizational behavior science. The results show that the low carbon economy has a positive effect on technology innovation, and this effect will influence enterprise competitiveness through sustainable development. We also found that the compound multiple mediation model has an advantage in explaining the problems involved with low carbon economy and enterprise competitiveness.
Keywords: *low energy consumption, sustainable development, CO_2 emissions, technology innovation, enterprise strategic*

Introduction

Low-carbon development is a strategic decision that human beings have to face and seek opportunities under the dual pressure of financial crisis and climate and environmental crisis (Louche et al., 2019; Gong, et al., 2018). It will bring about a series of fundamental changes in the whole economy, society and enterprises. It is not an exaggeration to call it a technological revolution or an industrial revolution. The arrival of the low-carbon era will lead to profound changes in the standards of our enterprises, including value standards and evaluation systems (Niamir et al., 2018). Opportunities of emerging industrial revolution brewing under the development mode of low-carbon economy urgently need the strong support of enterprise strategic planning and thus promote the economic development mode from a high carbon economy to low carbon economy (Barron et al., 2018; Du, et al., 2018).

Low-carbon economy refers to an economic development pattern that achieves a win-win situation for economic and social development and ecological environmental protection (Shimada et al., 2007). Under the guidance of the concept of sustainable development, through technical innovation, system innovation, industrial transformation, new energy development and other means to reduce the high carbon energy consumption of coal, oil, greenhouse gas emissions and so on (Hu et al., 2011). With the increase of the global population and the continued economic growth, the environmental problems and consequences caused by the use of fossil energy and other conventional sources have received more and more attention. Environmental hazards such as exhaust gas pollution, photochemical smog, water pollution and acid rain, as well as global climate change caused by the rise of carbon dioxide concentration in the atmosphere, will cause serious consequences (Foxon, 2011). Therefore, a series of new concepts and policies have emerged, such as carbon footprint, low-carbon economy, low-carbon technology, low-carbon development, low-carbon lifestyle, low-carbon society, low-carbon city and a low-carbon world (Nader, 2009; Liu, 2018; Lefevre et al., 2018; Ervine, 2018).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87938803

The arrival of the low-carbon era will lead to profound changes in the standards of our enterprises, including value standards and evaluation systems. Under the guidance of low-carbon economic policies, enterprises must shift from the traditional growth model to directly applying the new century's innovative technology and innovation mechanism and achieving sustainable social development through low-carbon economic model and lifestyle (Tavoni et al., 2012; Li and Sun, 2018; Ropeik, 2017). Opportunities of emerging industrial revolution brewing under the development mode of low-carbon economy urgently need the strong support of enterprise strategic planning and thus promote the economic development mode from a high carbon economy to low carbon economy. From this perspective, the low-carbon economy is both a limitation and an opportunity. Therefore, this study mainly explores the effect of the low-carbon economy on enterprise competitiveness and uses a method of multiple mediation models to reveal the internal mechanism.

Research background and hypotheses

Low carbon economy

The low-carbon economy is an economic model based on low energy consumption, low pollution, and low emissions. The essence of the low-carbon economy is the problem of high energy utilization efficiency and clean energy structure. In the context of global warming, the low-carbon revolution with energy efficiency and low emissions as the core is gradually changing many industrial ecosystems. Therefore, companies must focus on developing low-carbon technologies to seize the opportunities and industry commanding heights.

Tavoni et al. (2012) believe that with the increase in income, the industrial and consumption structures have changed. At the same time, when people began to pay attention to the issue of protecting the environment, the phenomenon of environmental degradation gradually slowed down or even disappeared. Glaser (2003) concluded that CO_2 emissions are in an "N" rather than inverted "U" relationship with economic growth. Smale et al. (2006) believe that in the early stage of industrialization, with the development of the economy and the increase of per capita income, the per capita CO_2 emissions will be at a higher level.

Low-carbon economy and enterprise competitiveness

There are two different types of views on the relationship between environmental regulation and corporate competitiveness. The first perspective is that the implementation of environmental regulations will lead to a decline in the competitiveness of enterprises. The government implements environmental regulations and companies need to add special costs to eliminate pollution and reduce their environmental impact to meet environmental standards. The environmental standards require that the production costs of enterprises will rise sharply, which will directly affect their competitiveness. Healy and Barry (2017) argued that environmental regulation is not only not conducive to technological innovation, but because the entire process of environmental control will cause companies to be forced to transform the original production process, which will have an impact on technological innovation. Garay and Font (2012) pointed out that in order to adapt to environmental regulations, the company's processes are becoming more and more complex, resulting in a large management difficulty, and the management costs

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87938803

are increasing, eventually resulting in a decline in corporate profits and a decline in competitiveness. Ortiz et al. (2009) showed that as environmental governance costs increase, it is increasingly difficult for individual companies to achieve a win-win situation for both environment and competitiveness. The stricter environmental regulations will inevitably worsen the business conditions of enterprises. At the same time, the benefits of adopting new technologies are not enough to boost the profits of enterprises. While environmental protection regulation improves the overall social welfare, it will lead to a decline in industrial production efficiency, and enterprises pay a higher price for it.

However, other scholars believe that companies will actively seek environmental technology innovation and develop environmental products in response to environmental policies, competitors and consumers (Rijsberman, 2017; Ervine, 2018). As a result, the sustainability of the industry will naturally increase, thus causing the competitiveness to transform and transition around the green. From a dynamic perspective, strict environmental standards will encourage companies to accelerate the pace of product innovation, and encourage enterprises to continuously improve the inefficiency in the production process, and reluctantly. The effective use of resources, through continuous technological innovation, brings about a reduction in pollution and an increase in output, resolving the contradiction between the environment and competitiveness, and achieving a win-win situation in which both economic performance and environmental performance are simultaneously changed. At the same time, this technological innovation will also enable companies that comply with environmental standards to gain a "first mover advantage". Managers should take environmental improvement as an opportunity to add economic value and competitive advantage, and should not only be an annoying cost or threat. Based on this, this paper proposes:

H: Low carbon economy influence enterprise competitiveness through a multiple mediation model, see in Figure 1.

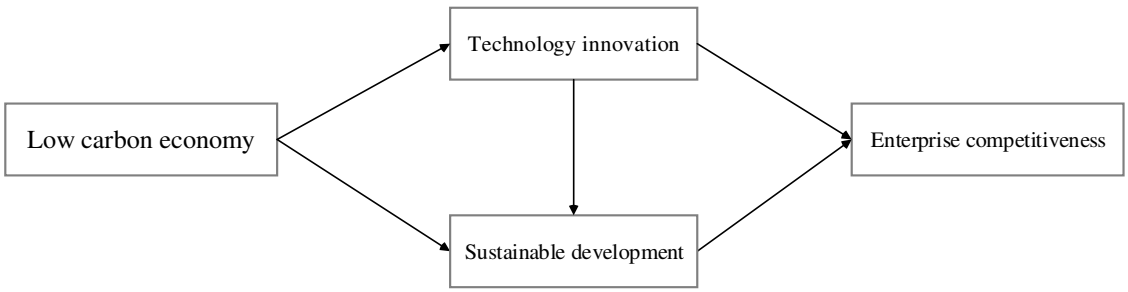

Figure 1. *Theory research model*

Methodology

Sample source

In this paper, we used the multiple mediation models to analyze the relationship between low carbon economy and enterprise competitiveness. First, we selected 42 enterprises in China and got their basic information before the investigation. Then, during the investigation, the managers answered a 20-question questionnaire including all the indicators of this study. The descriptive statistics are in *Table 1*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87938803

Table 1. *Descriptive statistics (n = 42)*

Variable	Low carbon economy	Technology innovation	Sustainable development	Enterprise competitiveness
Low carbon economy	1			
Technology innovation	.639**	1		
Sustainable development	.674**	.751**	1	
Enterprise competitiveness	.641**	.691**	.706**	1

**Correlation is significant at the 0.01 level (double tail)

Multiple mediation model

Ordinary least squares mediation model

The ordinary least squares (OLS) mediation model always present in the form of three regression equations (Preacher and Hayes, 2008):

$$y_i = \beta_{01} + \tau x_i + \varepsilon_{1i} \quad \text{(Eq.1)}$$

$$m_i = \beta_{02} + \alpha x_i + \varepsilon_{2i} \quad \text{(Eq.2)}$$

$$y_i = \beta_{03} + \beta m_i + \tau` x_i + \varepsilon_{3i} \quad \text{(Eq.3)}$$

In these equations (*Eqs. 1–3*), y_i is the dependent variable, m_i is the mediating variable, and x_i is the independent variable. The coefficient between the independent variable and the dependent variable is represented by τ, and $\tau`$ is the coefficient adjusted for the influence of the mediating variable. β_{01}, β_{02}, and β_{03} represent the intercept in the three equations.

To calculate the multiple mediation effects, there are three points to lay the foundation. First, βin the third equation is relating to the dependent variable and the mediating variable. Second, α_i in the second equation is relating to the independent variable and the mediating variable. Third, the product of α and β is the estimator of the indirect effect, and $\tau`$ is the estimator of the direct effect.

The variance of the indirect effect $\sigma^2_{\alpha\beta}$ is based on the variance of α and β, and it is derived using a second-order Taylor series in *Equation 4*:

$$\sigma^2_{\alpha\beta} = \alpha^2\sigma^2_\beta + \beta^2\sigma^2_\alpha + \sigma^2_\alpha\sigma^2_\beta \quad \text{(Eq.4)}$$

If α and β are nonzero values, according to Monte Carlo studies, for a sample size of 100 or more in a simulation model, all three variance estimators appear to have a relative bias of less than 5%. So Confidence limits are constructed in *Equation 5*:

$$\alpha\beta \pm z_{1-\omega/2} \times \sigma_{\alpha\beta} \quad \text{(Eq.5)}$$

where $z_{1-\omega/2}$ is the value on the z-distribution corresponding to the desired Type I error rate, ω.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87938803

As the indirect effect is the product of α and β, and the estimates are normally distributed. The distribution of the product is an index to test the indirect effect. In other words, we can test the indirect effect based on $z_\alpha z_\beta$, where $z_\alpha = \alpha / \sigma_\alpha$ and $z_\beta = \alpha / \sigma_\beta$.

The central moments of the process are as follows (*Eqs. 6–9*).

$$Mean: M_1 = \mu = z_\alpha z_\beta \quad \text{(Eq.6)}$$

$$Variance: M_2 = \sigma^2 = z_\alpha^2 + z_\beta^2 + 1 \quad \text{(Eq.7)}$$

$$Skewness: M_3 = \alpha_3 = \frac{6\left(z_\alpha z_\beta\right)}{\left(z_\alpha^2 + z_\beta^2 + 1\right)^{3/2}} \quad \text{(Eq.8)}$$

$$Kurtosis: M_4 = \alpha_4 = \frac{12\left(z_\alpha^2 + z_\beta^2\right) + 6}{\left(z_\alpha^2 + z_\beta^2 + 1\right)^2} \quad \text{(Eq.9)}$$

To get the analytical solution, a Bessel function with a purely imaginary argument is used in *Equation 10*.

$$f\left(z_\alpha z_\beta\right) = \frac{e^{-\left(z_\alpha^2 + z_\beta^2\right)/2}}{\pi}\left[\sum\nolimits_0 K_0 + \left(z_\alpha^2 + z_\beta^2\right)\frac{z_\alpha z_\beta}{2!}\sum\nolimits_2 K_1 + \left(z_\alpha^4 + z_\beta^4\right)\frac{\left(z_\alpha z_\beta\right)^2}{4!}\sum\nolimits_4 K_2 + \left(z_\alpha^6 + z_\beta^6\right)\frac{\left|z_\alpha z_\beta\right|^3}{6!}\sum\nolimits_6 K_3 + \ldots\right] \quad \text{(Eq.10)}$$

In the equation, K is the Bessel function and Σ is a Laurent series in *Equation 11*.

$$\sum\nolimits_r \left(z_\alpha, z_\beta, z_\alpha z_\beta\right) = 1 + \frac{z_\alpha z_\beta z_\alpha z_\beta}{r+1} + \frac{\left(z_\alpha z_\beta z_\alpha z_\beta\right)^2}{\left(r+1\right)^2 2!} + \frac{\left(z_\alpha z_\beta z_\alpha z_\beta\right)^3}{\left(r+1\right)^3 3!} + \ldots \quad \text{(Eq.11)}$$

In the equation, r is the order of the Laurent series in *Equation 12*.

$$\left(r+k\right)^k = \left(r+k\right)\left(r+k-1\right)\ldots\left(r+1\right) \quad \text{(Eq.12)}$$

To calculate the 95% standard normal confidence limits, it used a Standardized Critical Value (SCV). According to Meeker's suggestion (Meeker et al., 1982), it found the Critical Value (CV) in the table, and then convert to the standardized metric of the regression coefficient (α and β) in *Equation 13*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87938803

$$SCV = \frac{CV - z_\alpha z_\beta}{\sqrt{z_\alpha^2 + z_\beta^2 + 1}} \quad \text{(Eq.13)}$$

Parallel multiple mediation model

Parallel multiple mediation model reflects a situation in which multiple variables simultaneously mediate between the independent and dependent variable, see in *Figure 2.*

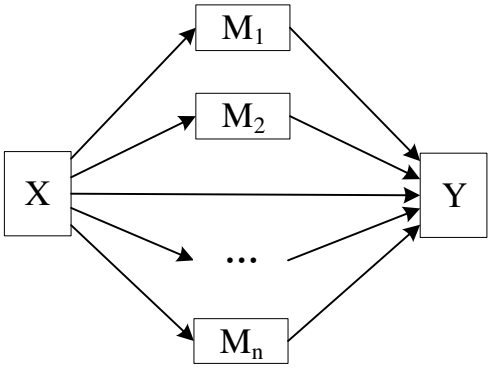

Figure 2. *Parallel multiple mediations model*

The relationship between the dependent variables, independent variables and multiple mediating variables are as follows (*Eqs. 14–16*).

$$Y = \tau X + \varepsilon_X \quad \text{(Eq.14)}$$

$$M_i = \alpha_i X + \varepsilon_i \quad \text{(Eq.15)}$$

$$Y = \sum_{i=1}^{n} \beta_i M_i + \tau` X + \varepsilon \quad \text{(Eq.16)}$$

where i = 1…n, $\tau`$ is the direct effect and τ is the total effect between the dependent variable and independent variable, $\alpha_i \beta_i$ is the indirect effect of each mediation path in *Equation 17*.

$$\tau = \tau` + \sum_{i=1}^{n} \alpha_i \beta_i \quad \text{(Eq.17)}$$

The analysis of parallel multiple mediating effects generally includes three parts: first, the estimation and test of the overall mediating effect; second, the estimation and test of special mediating effects; third, the comparison between the mediating effects.

The total indirect effect is τ - $\tau`$, or $\sum_{i=1}^{n} \alpha_i \beta_i$.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87938803

According to Mackinnon's suggestion (Mackinnon et al., 2007), the McGuigan and Langholtz effect size was to test the significance of the total indirect effect in *Equation 18.*

$$t_{N-2} = \frac{\tau - \tau`}{\sqrt{\sigma_{\tau}^2 + \sigma_{\tau`}^2 - 2\rho_{\tau\tau`}\sigma_{\tau}\sigma_{\tau`}}} \quad \text{(Eq.18)}$$

In the equation, σ_{τ} is the standard error of τ, $\sigma_{\tau`}$ is the standard error of $\tau`$, and $\rho_{\tau\tau`}$ is the regression coefficient between $\tau$ and $\tau`$.

Compound multiple mediation model

The compound multiple mediations model is composed of the both parallel and serial mediating path see in *Figure 3*.

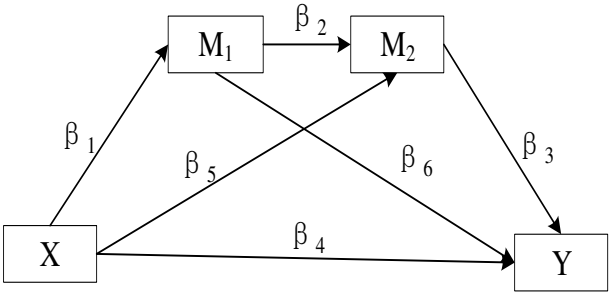

Figure 3 *Compound multiple mediations model*

To test the indirect effect, we need to estimate the following three equations (*Eqs. 19–21*).

$$M_1 = \beta_{01} + \beta_1 + \varepsilon_1 \quad \text{(Eq.19)}$$

$$M_2 = \beta_{02} + \beta_2 M_1 + \beta_5 X + \varepsilon_2 \quad \text{(Eq.20)}$$

$$Y = \beta_{03} + \beta_4 X + \beta_3 M_2 + \beta_6 M_1 + \varepsilon_3 \quad \text{(Eq.21)}$$

Results and analysis

Mediation test

To test the significance of the indirect effect, the multivariate delta method, the unbiased estimate method, and the exact variance estimate method are used. The following is a brief introduction to the principle of these three methods.

Multivariate delta method

As can be seen above, β_1, β_2 and β_3 are the regression coefficients. The product of these three coefficients divides the mediation effect by the estimated standard error. The

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87938803

derivation of the three estimators of the variance of β_1, β_2 and β_3 are as follows in *Equation 22*.

$$\begin{aligned} s^2_{multi} &= \left[\frac{\partial\beta_1\beta_2\beta_3}{\partial\beta_1}, \frac{\partial\beta_1\beta_2\beta_3}{\partial\beta_2}, \frac{\partial\beta_1\beta_2\beta_3}{\partial\beta_3}\right]\begin{bmatrix} s^2_{\beta 1} & s_{\beta 1\beta 2} & s_{\beta 1\beta 3} \\ s_{\beta 2\beta 1} & s^2_{\beta 2} & s_{\beta 2\beta 3} \\ s_{\beta 3\beta 1} & s_{\beta 3\beta 2} & s^2_{\beta 3} \end{bmatrix}\begin{bmatrix} \frac{\partial\beta_1\beta_2\beta_3}{\partial\beta_1} \\ \frac{\partial\beta_1\beta_2\beta_3}{\partial\beta_2} \\ \frac{\partial\beta_1\beta_2\beta_3}{\partial\beta_3} \end{bmatrix} \\ &= \left[\beta_2\beta_3, \beta_1\beta_3, \beta_1\beta_2\right]\begin{bmatrix} s^2_{\beta 1} & s_{\beta 1\beta 2} & s_{\beta 1\beta 3} \\ s_{\beta 2\beta 1} & s^2_{\beta 2} & s_{\beta 2\beta 3} \\ s_{\beta 3\beta 1} & s_{\beta 3\beta 2} & s^2_{\beta 3} \end{bmatrix}\begin{bmatrix} \beta_2\beta_3 \\ \beta_1\beta_3 \\ \beta_1\beta_2 \end{bmatrix} \\ &= \beta_2^2\beta_3^2 s^2_{\beta 1} + \beta_1^2\beta_3^2 s^2_{\beta 2} + \beta_1^2\beta_2^2 s^2_{\beta 3} + 2\beta_1\beta_2\beta_3^2 s_{\beta 1\beta 2} \\ &\quad + 2\beta_1\beta_2^2\beta_3 s_{\beta 1\beta 3} + 2\beta_1^2\beta_2\beta_3 s_{\beta 2\beta 3} \end{aligned} \tag{Eq.22}$$

In the compound multiple mediation model, β_1, β_2 and β_3 are independent, so the last three items are zero, and the variance in the multivariate delta estimate method is in *Equation 23*.

$$s^2_{multi} = \beta_2^2\beta_3^2 s^2_{\beta 1} + \beta_1^2\beta_3^2 s^2_{\beta 2} + \beta_1^2\beta_2^2 s^2_{\beta 3} \tag{Eq.23}$$

Unbiased estimate method

The unbiased estimate method is based on the work of Goodman (1960). His research gives a suggestion for the calculation of unbiased estimate variance of two independent random variables. Extending his research to this case, the equation is in *Equation 24*.

$$\begin{aligned} s^2_{unbiased} &= \left(\beta_1^2 - s^2_{\beta 1}\right)\left(\beta_2^2 - s^2_{\beta 2}\right)s^2_{\beta 3} + \left(\beta_1^2 - s^2_{\beta 1}\right)\left(\beta_3^2 - s^2_{\beta 3}\right)s^2_{\beta 2} \\ &\quad + \left(\beta_2^2 - s^2_{\beta 2}\right)\left(\beta_3^2 - s^2_{\beta 3}\right)s^2_{\beta 1} + \left(\beta_1^2 - s^2_{\beta 1}\right)s^2_{\beta 2}s^2_{\beta 3} \\ &\quad + \left(\beta_2^2 - s^2_{\beta 2}\right)s^2_{\beta 1}s^2_{\beta 3} + \left(\beta_3^2 - s^2_{\beta 3}\right)s^2_{\beta 1}s^2_{\beta 2} + s^2_{\beta 1}s^2_{\beta 2}s^2_{\beta 3} \\ &= \left(\beta_1^2\beta_2^2 s^2_{\beta 1} - \beta_1^2 s^2_{\beta 2}s^2_{\beta 3} + s^2_{\beta 1}s^2_{\beta 2}s^2_{\beta 3} - \beta_2^2 s^2_{\beta 1}s^2_{\beta 3}\right) + \left(\beta_1^2\beta_3^2 s^2_{\beta 2}\right. \\ &\quad \left. - \beta_1^2 s^2_{\beta 3}s^2_{\beta 2} - \beta_3^2 s^2_{\beta 1}s^2_{\beta 2} + s^2_{\beta 1}s^2_{\beta 2}s^2_{\beta 3}\right) + \left(\beta_2^2\beta_3^2 s^2_{\beta 1} - \beta_2^2 s^2_{\beta 3}s^2_{\beta 1}\right. \\ &\quad \left. - \beta_3^2 s^2_{\beta 2}s^2_{\beta 1} + s^2_{\beta 1}s^2_{\beta 2}s^2_{\beta 3}\right) + \left(\beta_1^2 s^2_{\beta 2}s^2_{\beta 3} - s^2_{\beta 1}s^2_{\beta 2}s^2_{\beta 3}\right) + \left(\beta_2^2 s^2_{\beta 1}s^2_{\beta 3}\right. \\ &\quad \left. - s^2_{\beta 2}s^2_{\beta 1}s^2_{\beta 3}\right) + \left(\beta_3^2 s^2_{\beta 1}s^2_{\beta 2} - s^2_{\beta 3}s^2_{\beta 1}s^2_{\beta 2}\right) + s^2_{\beta 1}s^2_{\beta 2}s^2_{\beta 3} \\ &= \beta_1^2 s^2_{\beta 2}s^2_{\beta 3} + \beta_1^2\beta_3^2 s^2_{\beta 2} + \beta_2^2\beta_3^2 s^2_{\beta 1} - \beta_1^2 s^2_{\beta 2}s^2_{\beta 3} - \beta_2^2 s^2_{\beta 3}s^2_{\beta 1} \\ &\quad - \beta_3^2 s^2_{\beta 1}s^2_{\beta 2} + s^2_{\beta 1}s^2_{\beta 2}s^2_{\beta 3} \end{aligned} \tag{Eq.24}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87938803

Exact variance estimate method

The exact variance estimate method is also an extension of Goodman's research. In this method, it draws into the square of the coefficient of variation to accomplish the calculation. For variable β_i, the function is in *Equations 25* and *26*.

$$G(b_i) = s_{\beta i}^2 / \beta_i^2 \tag{Eq.25}$$

$$\begin{aligned} s_{exact}^2 &= (\beta_1\beta_2\beta_3)^2 \left[G(\beta_1) + G(\beta_2) + 2G(\beta_3) + 2G(\beta_1)G(\beta_2)G(\beta_3) \right. \\ &\quad \left. + G(\beta_2)G(\beta_3) \right] \\ &= (\beta_1\beta_2\beta_3)^2 \left[\frac{s_{\beta 1}^2}{\beta_1^2} + \frac{s_{\beta 2}^2}{\beta_2^2} + \frac{2s_{\beta 3}^2}{\beta_3^2} + 2 \times \frac{s_{\beta 1}^2}{\beta_1^2} \times \frac{s_{\beta 2}^2}{\beta_2^2} \times \frac{s_{\beta 3}^2}{\beta_3^2} + \frac{s_{\beta 2}^2}{\beta_2^2} \times \frac{s_{\beta 3}^2}{\beta_3^2} \right] \\ &= \beta_2^2\beta_3^2 s_{\beta 1}^2 + \beta_1^2\beta_3^2 s_{\beta 2}^2 + \beta_1^2\beta_2^2 s_{\beta 3}^2 + \beta_1^2 s_{\beta 2}^2 s_{\beta 3}^2 + \beta_2^2 s_{\beta 3}^2 s_{\beta 1}^2 \\ &\quad + \beta_3^2 s_{\beta 1}^2 s_{\beta 2}^2 + s_{\beta 1}^2 s_{\beta 2}^2 s_{\beta 3}^2 \end{aligned} \tag{Eq.26}$$

According to Sobel's suggestion (Sobel, 1982), we calculate the confidence intervals for each method to test the significance of the model in *Equation 27*.

$$95\%\ confidence\ interval = \beta_1\beta_2\beta_3 \pm z_{.975} \left(s_{type}^2 \right)^{1/2} \tag{Eq.27}$$

In the equation above, $z_{.975} = 1.96$, and type is multivariate delta, unbiased or exact. The hypothesis can be confirmed when the 95% confidence interval does not include zero.

Table 2 shows the results for the methods. As the confidence interval of the model did not include zero, the hypothesis of this study was tested.

Table 2. *Results for each method applied to data*

Method	Estimate	Standard error	Test	Hypothesis test result
Joint significance	β_1=0.862	0.071	T=12.074, P<0.001	
	β_2=0.844	0.055	T=15.428, P<0.001	
	β_3=0.589	0.079	T=7.414, P<0.001	Support hypothesis
Multivariate delta method	$\beta_1\beta_2\beta_3$=0.429	0.08	95%Cl=[0.272,0.586]	Support hypothesis
Unbiased estimate method	$\beta_1\beta_2\beta_3$=0.429	0.079	95%Cl=[0.274,0.584]	Support hypothesis
Exact variance estimate method	$\beta_1\beta_2\beta_3$=0.429	0.084	95%Cl=[0.264,0.594]	Support hypothesis
Percentile bootstrap	$\beta_1\beta_2\beta_3$=0.429	—	95%Cl=[0.266,0.577]	Support hypothesis
Bias-corrected bootstrap	$\beta_1\beta_2\beta_3$=0.429	—	95%Cl=[0.279,0.600]	Support hypothesis

Optimal model selection

By the comparison of the three multiple mediation models (see in *Table 3*), we found that the total indirect effect of the compound multiple mediation model was much better than the series multiple mediations model and parallel multiple mediation model. This

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_87938803

indicates that the compound multiple mediation model was more suitable for the practical problem in this study.

Table 3. *Comparison of three multiple mediation models*

Model	Indirect effect	Standard error	Lower 95%CI	Upper 95%CI
Series multiple mediations model	0.177	0.069	0.067	0.327
Parallel multiple mediation model	0.331	0.082	0.177	0.465
Compound multiple mediation model	0.509	0.057	0.407	0.606

Conclusion

In this paper, we proposed a multiple mediation model to explore the relationship between low carbon economy and enterprise competitiveness. The results show that the low-carbon economy has a positive effect on technology innovation, and this effect will influence enterprise competitiveness through sustainable development. We also found that the compound multiple mediation model has more advantage to explain the problems involved with low carbon economy and enterprise competitiveness. Our finding has made an effective supplement to the study of low carbon economy and enterprise competitiveness theory. Therefore, in the future research on enterprise competitiveness, scholars should pay more attention to technological change and sustainable development to adapt to the low-carbon economy. For example, it is very important to explore how to balance the relationship between technological innovation and sustainable development.

(Received 8th Mar 2019; accepted 1st May 2019)

Abstract. Reducing pollutant emissions of transportation is an important strategy for addressing global climate change, high-speed rail (HSR) transport, an eco-friendly mode, neither emits dust, nor emits too much CO_X and NO_X due to the eclectic traction drive. Instead of focusing on passenger transport as most literatures refer to HSR, this paper addresses the strategy of goods movement, and chooses Beijing-Shanghai (B-S) HSR in China as a case study to explore a new freight transport mode to alleviate the increasingly serious environmental pollution problem. After predicting the intercity parcel demand and distribution based on AR-GM and Gravity model, the paper evaluates the supply capacity between cities based on operating schedule. The result shows Origin-Destination Pairs (ODPs) such as Shanghai-Jinan, Shanghai-Beijing, Beijing-Langfang suit for Mixed-train Mode and others such as Beijing-Tianjin, Shanghai-Suzhou, Shanghai-Xuzhou suit for freight-train mode. It concludes that operating high-speed rail freights on a large-scale is feasible and environmentally friendly due to its advantages of energy saving, land saving, low carbon emission. Since alternatives of modes are determined by the time distances, the scale of cities, flow volumes of intercity parcels, Freight-train mode should be adopted between cities with high economic density and large transportation capacity.
Keywords: *forecast, flow, capacity, mode, high speed rail, intercity transport*

Introduction

The issue of global warming and air pollution caused by greenhouse gas emission has drawn the attention of the international community. Transportation growth has become one of main factors that contributing to the negative environmental impacts (Pejić, 2017; Nanaki et al., 2016; Gong et al., 2019). With the economic development, the proportion of transportation in China's national energy consumption is on the rise, making it the second largest energy-consuming industry with heavy tasks of energy conservation and emission reduction. As regulation becomes more stringent, transport companies are more like to choose an eco-friendly mode to cope with the challenge of an internalization of environmental effects (Ferrón-Vílchez, 2015). Among all of the modes, road transport represents, through its characteristic features – high flexibility and accessibility – the mode of transport largely involved in meeting the needs of mobility, though it is answerable for polluting the environment to a significant degree (Mitran et al., 2012; Limbourg and Jourquin, 2009; Du et al.,2018).

It can be seen from *Table 1* that in comprehensive transportation system, railway has the comparative advantage in energy conservation and environmental protection, and is the only transportation can be widely used in large areas to achieve the green environmental protection of "replace oil with electricity". Many scholars believe that introducing freight transport into passenger rail network is one of the important ways to absorb road traffic (Offer et al., 2010; Van Wee et al., 2012; Van Duin et al., 2013). High speed electric trains involve a fully mature technology that can use power

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88058816

generated by the wind, solar thermal energy and geothermal sources with a carbon footprint of zero. Extensive high-speed rail (HSR) network construction and operation quickly increases the rate of the electrification of the entire railway industry, optimizes the railway energy consumption structure. In fact, HSR not only meets people's growing demand for time-sensitive goods, but also meets the requirements of sustainable development, which shows the strong competitiveness in comparison with other modes of transport.

Table 1. *Comparison of pollutants emission among different transportation mode*

Annual emission (kg/cap)	Rail			Aviation			Truck		
	CO_X	NO_X	SO_X	CO_X	NO_X	SO_X	CO_X	NO_X	SO_X
China	0.031	0.53	4.02	1.76	6.12	9.25	1.81	2.63	4.02
USA	0.17	3.69	11.49	9.62	42.11	26.43	9.9	18.08	11.49
OECD	0.096	1.98	6.45	5.43	22.6	14.86	5.58	9.72	6.47

As shown in *Figure 1,* the mileage of HSR goes up obviously, about 29,000 km in 2018, so does the total income and volume of express industry. In fact, intercity express volume accounts for nearly 70% of the total volume. However, it is difficult to organize and modernize goods transport between large cities (Dablanc, 2007; O'Connor, 2010; Li, et al., 2017; Musolino et al., 2018). Since the two megacities of China, Beijing and Shanghai, connected by HSR in 2011, the transportation and communication between the north and the south of China become more intensive. As economy development depends heavily on transport, investigating the feasibility of coordinating freight and passenger flows using existing and forthcoming rail infrastructure has been a new trend in recent years (Behiri et al., 2018; Talebian and Zou, 2015; Pazour, et al., 2010).

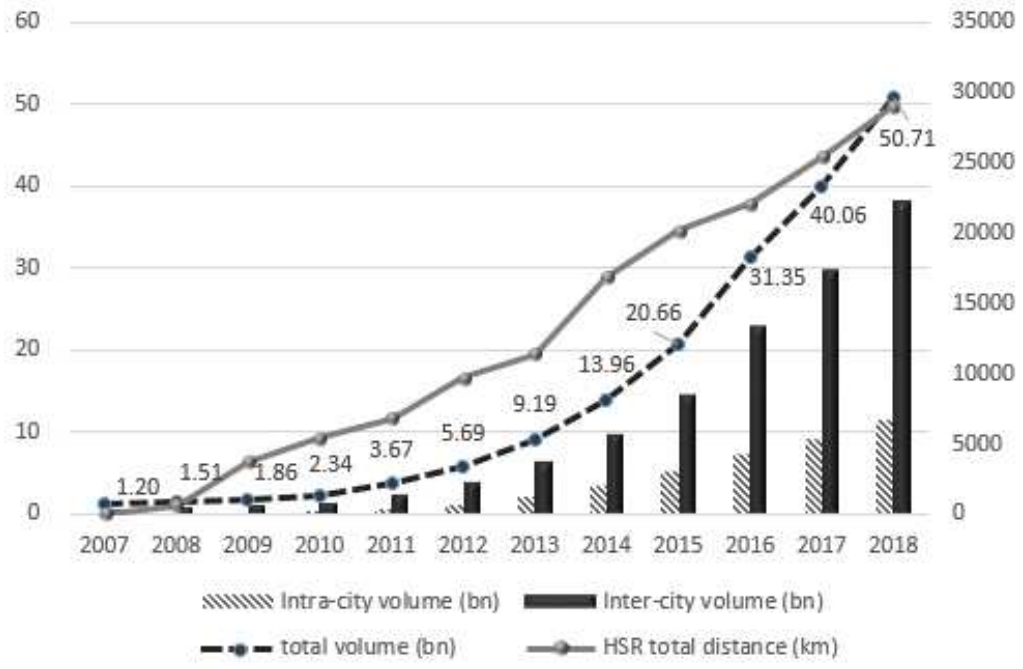

Figure 1. *The development trend of express industry and HSR*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88058816

Currently, there is no unified specific definition about high speed freight transportation (Troche, 2005), this paper supposes the modes can be basically divided into two: Mixed-train Mode, using passenger High Speed Train (HST) for freight transportation, including reserving or adding a couple of carriages; Freight-train Mode, adding exclusive high speed freight train or remoulded existing passenger HSTs for freight transport. Generally, compared with conventional transport modes, the main advantage of HSTs is cheaper than aviation and faster than truck. High speed rail is often touted as a means to reduce congestion of passengers transport instead of freight, but this paper offers a new method to quantitatively analyse the feasibility of such a sustainable freight mode and its positive influence to environment.

In the next section, the paper sets out method and algorithm adopted for forecasting Origin-Destination (OD) parcels demand. Section 3 shows a case study of about future freight distribution and the feasibility of adding HSTs on B-S HSR to transport parcels. Section 4 and 5 respectively presents the results and discussion about the adoption of the two modes. Section 6 ends the paper, setting out the conclusion.

Materials and methods

Forecasting demand based on ARMA model

In order to estimate the feasibility of operating high-speed freight on Beijing-Shanghai (B-S) corridor, freight distribution in future should be considered initially. Urban freight demand forecasting has been a crucial part of analysing the quantity of OD flow matrices (Nuzzolo and Comi, 2014; Börjesson, 2014; Jiang et al., 2014; Garrido, 2000), this paper presents a modelling system that tries to point out the freight relation among cities. Auto-Regression Model has been widely used for forecast analysis of time series (Wang, et al., 2013).

The general form of an ARMA model can be listed in *Equation 1* and transformed into *Equation 2*:

$$x_t = \delta_0 + \delta_1 x_1 + \delta_2 x_2 + \cdots + \delta_p x_{t-p} + \tau_m - \theta_1 \varepsilon_1 - \theta_2 \varepsilon_2 - \cdots - \theta_p \varepsilon_{t-q} \quad \text{(Eq.1)}$$

$$(x_t - \mu) - \delta_1 (x_1 - \mu) - \cdots \delta_p (x_{t-p} - \mu) = \varepsilon_t - \theta_1 \varepsilon_1 - \theta_2 \varepsilon_2 - \cdots - \theta_q \varepsilon_{t-q} \quad \text{(Eq.2)}$$

where $\mu = \frac{\delta_0}{1 - \delta_1 - \cdots - \delta_p}$, usually, μ would be estimated by the sample mean $\bar{x} = \frac{1}{N} \sum_1^N x_t$, and the variance will be shown as *Equation 3* if the series is stationary:

$$Var[\bar{x}] = E[\bar{x} - \mu]^2 = \frac{1}{N^2} E\left[\sum_{s=1}^{N} (X_s - \mu) \cdot \sum_{t=1}^{N} (X_t - \mu) \right] = \frac{1}{N^2} \sum_{s=1}^{N} \sum_{t=1}^{N} c_{t-s} \quad \text{(Eq.3)}$$

Assume k = t-s, then c (k) is an even function leads to *Equation 4:*

$$Var[\bar{x}] = \frac{1}{N^2} \sum_{k=-(N-1)}^{N-1} (N - |k| c_k) = \frac{1}{N} \sum_{k=-(N-1)}^{N-1} (1 - \frac{|k|}{N}) c_k \quad \text{(Eq.4)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88058816

When the N is large enough, from *Equation 4* it may be expressed as *Equation 5:*

$$Var\left[\bar{x}\right] \approx \frac{1}{N}\sum_{k=-\infty}^{+\infty} c(k) = \frac{\gamma(0)}{N}\left[1+2\sum_{k=1}^{+\infty}\rho(k)\right] = O\left(\frac{1}{N}\right) \quad \text{(Eq.5)}$$

If $\bar{x} \in \left[-2\sqrt{Var\left[\bar{x}\right]}, 2\sqrt{Var\left[\bar{x}\right]}\right]$, the stable series can be considered as a series with a zero mean, if not, a new series $\left\{x_t = x_t - \bar{x}, t = 0, \pm 1, \pm 2, \cdots\right\}$ can be generated as a zero mean stationary sequence.

In order to build a suitable ARMA model, we need to observe the character of partial autocorrelation sequence τ_{kk} and autocorrelation sequence σ_k (*Eq. 6*).

$$\hat{\sigma}(k) = \frac{\frac{1}{N}\sum_{i=1}^{N-|k|} X_i X_{i+|k|}}{\frac{1}{N}\sum_{i=1}^{N} X_i^2}, (k = 0, \pm 1, \pm 2, \cdots) \quad \text{(Eq.6)}$$

If $\hat{\sigma}(k) \sim N\left[0, \frac{1}{N}\left(1+2\sum_{l=1}^{q}\hat{\sigma}_l^2\right)\right], (k > q)$, then $P\left[\left|\hat{\sigma}_k\right| \le \frac{2}{\sqrt{N}}\left(1+2\sum_{i=1}^{q}\hat{\sigma}_i^2\right)^{1/2}\right] = 95.5\%$, thus MA (q) should be established if $\left|\hat{\sigma}_{q+i}\right| \le \frac{2}{\sqrt{N}}\left(1+2\sum_{i=1}^{q}\hat{\sigma}_i^2\right)^{1/2}, i = 1, 2, \cdots M-q$. Similarly, AR (p) should be established if $\tau_{kk} \sim N\left[0, \frac{1}{N}\right], (k > p)$ and $\left|\hat{\tau}_{(p+i)(p+i)}\right| \le \frac{2}{\sqrt{N}}, \left(i = 1, 2, \cdots, M-p\right)$.

For ARMA (p, q), estimated residual sequence $\left\{\varepsilon_t\right\}$ can be estimated as *Equation 7*:

$$\tilde{\varepsilon}_t = x_t - \tilde{\delta}_1 x_{t-1} - \tilde{\delta}_2 x_{t-2} - \cdots - \tilde{\delta}_p x_{t-p} + \hat{\theta}_1\tilde{\varepsilon}_{t-1} + \hat{\theta}_2\tilde{\varepsilon}_{t-2} + \cdots + \hat{\theta}_q\tilde{\varepsilon}_{t-q} \quad \text{(Eq.7)}$$

Residual sum of squares is listed as *Equation 8:*

$$Q = \sum_{i=1}^{N}\tilde{\varepsilon}_i^2 \quad \text{(Eq.8)}$$

The variance of a sequence of residuals can be expressed as *Equation 9:*

$$\tilde{\rho}_\varepsilon^2 = \frac{Q}{N_1 - k} \quad \text{(Eq.9)}$$

N_1 is the number of observations actually used in fitting the model, k is the number of parameters that used in building the model. Akaike Information Criterion (AIC) is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88058816

the most popular criterion for identifying the optimal model, which has been used in this paper to find out the suitable model for forecasting the values *Equation 10:*

$$x_m = \delta_0 + \delta_1 T + \delta_2 x_{m-1} + \delta_3 x_{m-2} + \cdots + \delta_p x_{m-p} + \tau_m \quad \text{(Eq.10)}$$

Forecasting demand based on gray model

Liu and Deng (2000) proposed the first-order one-variable gray model (GM (1, 1)) derived from gray system theory, which can be established based on a small amount of incomplete information to describe the fuzzy rule of the development of things in the long term. Since express delivery was only emerging in recent years, which leads to lacking data, the gray model adopted in this paper can help to produce effective results.

We assume the original data sequence is $x^{(0)} = \left(x^{(0)}(1), x^{(0)}(2), \cdots x^{(0)}(n)\right)$, and generate a new sequence: $x^{(1)} = \left(x^{(1)}(1), x^{(1)}(2), \cdots x^{(1)}(n)\right)$, then use accumulated generating operation since $y^{(0)}(m)$ is strictly positive and corresponds to time m. And we can have *Equation 11*:

$$x^{(0)}(m) = x^{(1)}(m) - x^{(1)}(m-1), m = 1, 2, \cdots n-1 \quad \text{(Eq.11)}$$

where $x^{(0)}(1) = x^{(1)}(1)$ $x^{(1)}(m) \in x^{(1)}$. If $n \geq 4$, $x^{(0)}, x^{(1)} \in R^+$, then the GM (1,1) can be expressed by an one-variable, first-order differential equation as *Equation 12:*

$$\frac{dx^{(1)}}{dt} + ax^{(1)} = b \quad \text{(Eq.12)}$$

where a and b are called the development and gray input coefficients respectively. The whitening version of *Equation 5* is shown as $x^{(0)}(m) + az^{(1)}(m) = b$, substitute all values and get *Equation 13*:

$$\begin{aligned} x^{(0)}(2) &= -az^{(1)}(2) + b \\ x^{(0)}(3) &= -az^{(1)}(3) + b \\ x^{(0)}(4) &= -az^{(1)}(4) + b \\ &\cdots \\ x^{(0)}(n) &= -az^{(1)}(n) + b \end{aligned} \quad \text{(Eq.13)}$$

where $z^{(1)}(m)$ is called the background value of $dx^{(1)}/dt$ and is calculated by *Equation 14:*

$$z^{(1)}(m) = \frac{1}{2}\left(x^{(1)}(m) + x^{(1)}(m-1)\right) \quad \text{(Eq.14)}$$

Equation 14 is established based on discrete data and equal spacing in time, by using least-squares method, the coefficients a and b can be obtained as $\begin{bmatrix} a \\ b \end{bmatrix} = \left(B^T B\right)^{-1} B^T x_n$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88058816

where $B=\begin{bmatrix} -z^{(1)}(2) & 1 \\ -z^{(1)}(3) & 1 \\ \vdots & \vdots \\ -z^{(1)}(n) & 1 \end{bmatrix}$ and $x_n=\begin{bmatrix} x^{(0)}(2) \\ x^{(0)}(3) \\ \vdots \\ x^{(0)}(n) \end{bmatrix}$, then the values a and b can be solved, $a=\frac{CD-(n-1)E}{(n-1)F-C^2}$, $b=\frac{DF-CE}{(n-1)F-C^2}$, $C=\sum_{k=2}^{n} z^{(1)}(k)$, $D=\sum_{k=2}^{n} x^{(0)}(k)$, $E=\sum_{k=2}^{n} z^{(1)}(k)x^{(0)}(k)$, $F=\sum_{k=2}^{n} z^{(1)}(k)^2$.

Finally, the predicted equation is expressed as *Equation 15:*

$$\hat{x}^{(0)}(m+1)=(x^{(0)}(1)-\frac{b}{a})(1-e^{a})^{-am} \quad \text{(Eq.15)}$$

Matlab has been widely used to solve the research problems related with gray system theory, in this paper, the class-compare verification and remnant verification are used to validate data, then we deal with data by translating the jumping type sequence into monotonic increasing type sequence, and used Matlab R2018b to complete prediction process.

Forecasting distribution of parcels demand between cities

In fact, Auto-Regression Model has been widely used for forecast analysis of time series, and Gray Model is better at dealing with systems that are characterized with poor information and stable trend data. Jia et al. (2016) find the accuracy degree increases obviously after combining two methods together. Based on the prediction express demand results of GM and AR model, a new combination model can be created as *Equation 16:*

$$X_m=\varepsilon_1(\delta_0+\delta_1 T+\delta_2 x_{m-1}+\delta_3 x_{m-2}+\cdots+\delta_p x_{m-p}+\tau_m)+\varepsilon_2\left(x^{(0)}(1)-\frac{b}{a}\right)(1-e^{a})e^{-am} \quad \text{(Eq.16)}$$

where ε_1 and ε_2 are respectively the weight of demand variable based on the accuracy of forecast value of two methods.

This study assumes intercity parcels of every city are delivered through a nationwide network, and focuses on trunk transport and assumes stations of cities as origin and destination nodes, which leads to the formation of ODPs. By modifying the gravity model, the paper builds *Equation 17* to measure the attraction degree ω_{ij} between city i and city j.

$$\omega_{ij}=\frac{\sqrt{POP_i\times GDP_i\times N_i}\times\sqrt{POP_j\times GDP_j\times N_j}}{S_{ij}^2} \quad \text{(Eq.17)}$$

where S_{ij} indicates the minimum high speed rail distance between city i and city j, i = 1,2,……n, j = 1,2,……n, I ≠ j. POP_i, GDP_i and N_i respectively indicates the population, GDP and the average amount of HSTs stop by the station of city i per day.

DOI: http://dx.doi.org/10.15666/aeer/1704_88058816

A case study

Now the paper tries to estimate the feasibility of operating freight trains on Beijing-Shanghai HSR from supply and demand perspective based on the methods shown above.

Demand: attractive amount of parcels distributed on B-S HSR corridor in future

The data used in this section is based on the intercity volume of main cities along B-S HSR from the official website of the cities' post office from 2010 to 2017. In order to forecast the demand of the main cities on B-S HSR corridor in next seven years, AR-GM model has been adopted by using Eviews 8.0 and Matlab R2018b, the accuracy grade of fitted values are shown in *Table 2*.

Table 2. *The accuracy grade of fitted values of main cities*

	Relative error	Variance ratio	Little probability of error	Development coefficient	Accuracy grade
Beijing	0.00081	0.0059	1	-0.0875	First
Tianjin	0.00072	0.1424	1	-0.0340	First
Jinan	0.00018	0.0776	1	-0.0225	First
Nanjing	0.00054	0.1136	1	-0.0455	First
Shanghai	0.00601	0.0301	1	-0.1391	First

It can be seen from *Table 2* that the model is fitting well, the difference and little probability of error reached the "first class" precision. The absolute values of all the development coefficients are smaller than 0.3, which indicates the model is suitable for mid-long term prediction. Therefore, the intercity volume of each city from 2019 to 2025 is shown as follow (*Table 3*).

Table 3. *The forecast of intercity express volume of main cities (mt)*

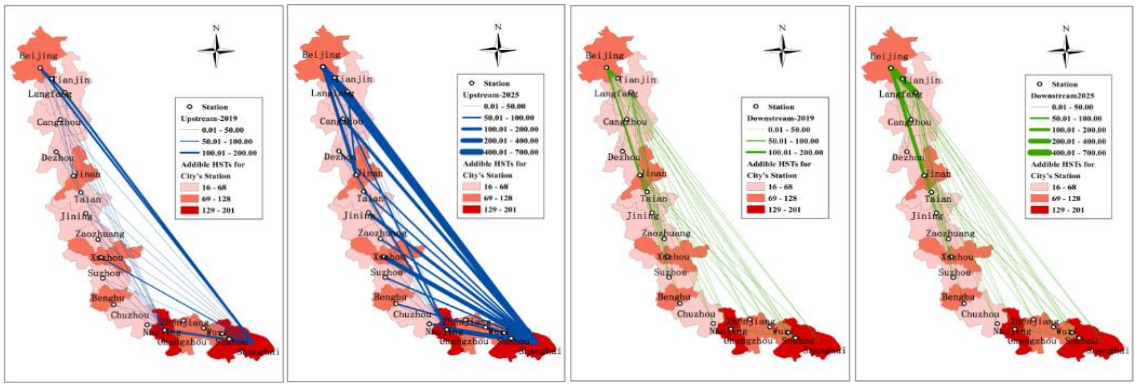
	2019	2020	2021	2022	2023	2024	2025
Beijing	3.35	3.82	4.33	4.89	5.48	6.13	6.83
Tianjin	0.95	1.09	1.24	1.41	1.59	1.80	2.10
Jinan	0.59	0.72	0.82	1.01	1.15	1.43	1.63
Nanjing	1.01	1.13	1.26	1.40	1.54	1.68	1.83
Shanghai	6.17	7.68	9.38	11.62	14.15	17.59	21.48

As shown in *Table 3*, nowadays only the intercity parcels of Beijing and Shanghai are over 1 mt, but most of main cities will transcend the figure soon. Nanjing owns the lowest express volume growth rate with about 10.5% per year on average, and it will be surpassed by Tianjin in 2022 whose volume will reach 1.41 mt. Beijing's is also lower than national average level recently and the rate will keep dropping based on the consistent policy of emphasis on decentralization made by government, but the amount (6.83 mt) in 2025 will be twice bigger than current volume (3.35 mt). Shanghai, the biggest volume owner, also with the highest average growth rate, 23.10%, has shown

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88058816

the potential to triple the amount after seven years and dramatically increase to 21.48 mt.

This paper chooses B-S HSR as a case coz if the most crowded HSR in China has space to operate freight train, other HSRs can operate more. The application of method in section 2 leads to the distribution of Origin-Destination Pairs (ODPs) on B-S HSR corridor. The thickness of lines in *Figure 2* indicates the upstream and downstream of ODPs in 2019 and 2025. The different color depths of cities on map indicates numbers of addible HSTs for cities' station.



2019-upstream 2025-upstream 2019-downstream 2025-downstream

Figure 2. *ODPs distribution of main cities along B-S HSR corridor*

Most of upstream flows are from Shanghai, which has been more obvious over time. The flow volume from Shanghai to other cities in 2025 will be three times as big as the volume in 2019. Among all the flow of ODPs, the volume of Shanghai-Jinan and Shanghai-Beijing are always at top 2, and both of them have been over 200 kt parcels in 2019. Besides, the number of flows over 100 kt has been raised from 6 in 2019 to 12 in 2025. As for downstream flows, most are relative small and varies slightly, but they can still be double in next seven years. Besides, the top 5 pairs are always Beijing-Tianjin, Beijing-Langfang, Beijing-Jinan, Beijing-Cangzhou, Nanjing-Shang. However, only two pairs of which are over 100 kt in 2019, and the third pair cannot break the line until 2025.

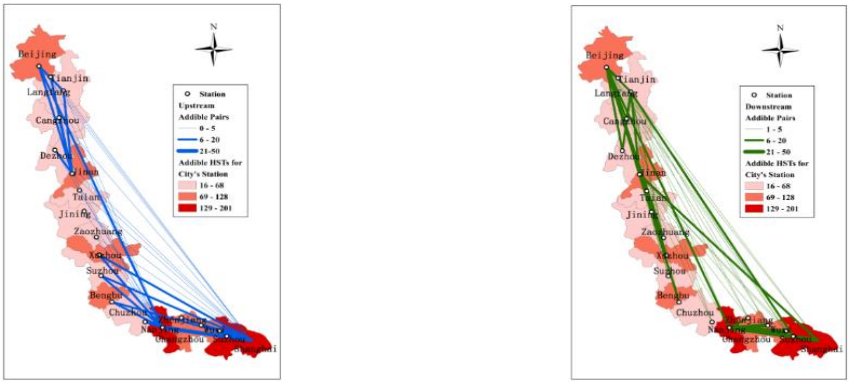
Supply: the addible bullet trains among stations along B-S HSR

This paper believes if China Railway Corportation (CRC) can add more trains to solve the peak congestion, it must own the capacity to add freight trains on workdays if it is necessary. The paper collected the amount of operating trains among 24 stations of B-S HSR from February 9 to March 18 in 2018, which includes the peak time of spring festival and the workdays after. The difference of a high speed station between the peak and workdays indicates that station's capacity of adding freight trains on usual, which has represented by the thickness of line in *Figure 3*.

In general, the densest sheaf of addible trains are among Shanghai city and Jiangsu province. The top of the ODP list is Shanghai-Nanjing, which owns the capacity of adding 50 pairs on usual. And for upstream and downstream addible pairs, there are respectively 13 and 9 ODPs of adding HSTs over 10. Upstream distribution also has similar situation, among all of the cities in northern and southern part, only the ODPs

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88058816

between Beijing and Nanjing are over 5. Thus, it is feasible for CRC to appropriately add various HSTs based on stations' capacity to transit express parcels on usual.



Upstream Downstream

Figure 3. *The supply capacity of high speed stations along B-S HSR corridor*

Results

The optimum alternative of operation mode between cities is determined by demand volume and supply capacity in this paper, we admit that the result will be more convinced if more influential factors are fully considered.

As shown in *Table 4*, those ODPs such as Beijing-Tianjin, Shanghai-Suzhou, Beijing-Jinan, Shanghai-Xuzhou adapt to Freight-train mode because of vast parcels demand and a mass of addible HSTs existing there. Those ODPs like Shanghai-Jinan, Shanghai-Beijing, Beijing-Langfang only have large demand, barely HSTs could be added on usual, so these ODPs suit for adopting Mixed-train mode.

Table 4. *Supply and demand of intercity express volume between cities in 2019*

Origin-destination	Parcels demand (kt)	Addible HSTs	Origin-destination	Parcels demand (kt)	Addible HSTs
Freight train mode			**Mixed-train mode**		
Beijing-Tianjin	320.3	11	Shanghai-Jinan	207.87	1
Tianjin-Beijing	133.55	12	Shanghai-Beijing	196.11	0
Shanghai-Suzhou	127.17	16	Beijing-Langfang	160.22	0
Shanghai-Xuzhou	72.61	8	Shanghai-Tianjin	111.18	0
Shanghai-Wuxi	54.4	7	Shanghai-Nanjing	102.47	1
Beijing-Jinan	54.08	13	Shanghai-Jining	38.08	1
Jinan-Beijing	40.18	14	Nanjing-Jinan	34.31	4
Shanghai-Changzhou	35.79	6	Nanjing-Beijing	32.37	4
Beijing-Cangzhou	30.06	9	Shanghai-Cangzhou	30.91	0
Shanghai-Zhenjiang	26.41	8	Shanghai-Taian	26.41	0

Discussion

The high speed rail freight's emission of dust, NO_X, CO_X, land use and energy consumption are all much lower than truck and air freight, such eco-friendly mode deserves to be applied in a wider scope since environment protection and sustainable development are key issues for the policy-maker (Garau et al., 2011). In fact, Mixed-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88058816

train mode has been widely adopted in China, France, Turkey and many other European countries due to the barely extra cost by loading the parcels on the vacant carriage, but the shortcoming is obvious too, for example, the transport capacity is limited and varies too much because of the frequent fluctuation of passenger flow. Particularly, HSTs in China only stop for about 2 min at most stations, which leaves no time for loading or unloading, therefore, such mode can only operate from the departure station to terminal station. Conversely, Freight-train mode does not have the defect and is able to demonstrate bigger advantage and stronger competitiveness in the areas where own large freight demand (Liang et al., 2016).

Interestingly, the cost of Freight-train mode is hardly accepted by both most enterprises and governments when freight demand is low, but if they do not take this mode, it is hard to get more cargo business from freight market. Faced with the considerable investment required for HSR construction, the determination of policy-maker will play an important role in promoting the process of HSR freight, and clearly, Chinese government has shown more ambition on HSR than other countries', which provides more chances for further research into such eco-friendly transport modes.

Conclusion

This paper improves the accuracy of forecasting by combining ARMA and Gray Model, and discusses the feasibility of operating freight on Beijing-Shanghai HSR corridor and offers the solution with reasons for different Origin Destination pairs. Besides, the flow demand of intercity parcels will keep a growth rate vary from 10% to 23% in the next seven years, and the application of high-speed freight, especially the Freight-train mode, will alleviate the severe air pollution and traffic congestion among those big cities.

However, this paper ignores the possibility of operating freight transport on the checking-train at night since the research is based on the daytime schedule. Moreover, "Door to Door" express freight service cannot be accomplished only by HSR, the multimodal transport needs to be considered in future research. Above all, finding the appropriate routes, identifying the potential hub cities for cargo transfer, optimizing the rail network structure to minimize the transport time are all important ways to improve the efficiency and possibility of operating express freight transport. Apparently, we can not take all of the problems into consideration, but we believe focusing on HSR freight helps people make better use of resources and protect environment well.

(Received 12th Mar 2019; accepted 3rd May 2019)

Abstract. In order to investigate the long-term effects of biochar application on the diversity and community structure of soil fungi, different amount of biochar were applied to the *Machilus pauhoi-Ilex asprella* intercropping system under field conditions. The results showed that biochar significantly increased the pH and the content of organic matter, total nitrogen, total phosphorus, available phosphorus and available potassium in 0-15 cm soils while it had no significant effect on 15-30 cm soil physicochemical properties. The results of species annotation indicated that each biochar treatment increased the relative abundance of *Mortierellomycotina*, *Chytridiomycota*, *Glomeromycota* and *Ascomycota* in 0-15 cm soils. The T2 and T3 treatments increased the abundance of *Ascomycota* in 15-30 cm soils and reduced the abundance of *Basidiomycota*, which were opposite to the results of T1 treatment. At the genus level, in the soil with the depth of 0-15 cm, the application of biochar reduced the relative abundance of *Clitocybula* while significantly increased the relative abundance of *Parascutellinia*, *Glomus*, *Mortierella*, *Funneliformis* and *Plectosphaerella*. In 15-30 cm soils, all biochar treatments increased *Clitocybula* and *Mortierella* relative abundance, but reduced *Glomus* and *Gyroporus* relative abundance. In summary, biochar application has a significant effect on soil physicochemical properties after 3 years of application.
Keywords: *biochar, physicochemical properties, fungal community structure, high-throughput sequencing, RDA analysis*

Introduction

Soil microbes are the basis for material recycling and utilization in ecosystems, and are also a guarantee for ecosystems to maintain stability and normal functioning (Chapin et al., 1997). Soil, as a site for soil microbial activity, has an important impact on microbial composition and activity (Kuramae et al., 2011; Jeanbille et al., 2016). As an important member of soil microbes, fungi play an important role in the decomposition of soil, especially in the degradation of plant residues in the soil (Barbi, et al., 2016). Some soil fungi play a huge role in improving plant stress resistance and maintaining normal plant growth (Mukerji et al., 1996; Filion et al., 1999). Fungi drive the material cycle and energy flow in soil ecosystem. The diversity of soil microbial community structure can reflect the change process of soil environmental quality in advance (Sharma et al., 2010). All soil physical and chemical properties, temperature, moisture, etc., have an effect on soil microbial communities, leading to changes in microbial composition and structure (Alvarado et al., 2010).

Biochar is a stable soil conditioner that biomaterials undergo pyrolysis in a high temperature and oxygen-free environment to form organic carbon-rich (Johannes et al.,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88178834

2015). Biochar porosity and adsorption increase soil nutrients and water content (Schulz et al., 2013), providing a direct habitat for soil microbes (Gul et al., 2015). Biochar plays an important role in regulating soil microbial community structure and diversity due to its special physical and chemical properties (Xu et al., 2016; Kolton et al., 2011). Yao et al. (2017) found that the addition of biochar to black soil significantly increased the relative abundance of Guehomyces and reduced the relative abundance of Fusarium. Zheng et al. (2016) found that biochar significantly increased the relative abundance of Zygomycota and Mortierella fungi in paddy soils, and reduced the relative abundance of Penicillium and Cyphellophora fungi degree. In addition, biochar can affect the colonization of mycorrhizal fungi in crop roots. Matsubara et al. (2002) found that adding coconut shell biochar to soil increased the abundance of asparagus root mycorrhizal fungi. Studies have shown that activated carbon components of biochar can be degraded at the beginning of application, providing a source of carbon for microorganisms and promoting microbial growth (Sagrilo et al., 2015; Smith et al., 2010). Kuzyakov et al. (2009) found that biochar-derived carbon in soil microbes decreased by 42.31% after biochar application for 20 months. Over time, the physical and chemical properties of biochar would change, and its long-term interaction with soil particles would create a new soil-biochar system (Jones et al., 2012). However, the current impact on soil microbes after long-term application of biochar is not clear. Therefore, research on the long-term effects of biochar on soil fungi is of great significance.

In this study, the southern red soil was used as the research object, and the effects of biochar on soil physical and chemical properties and fungal community structure after 3 years of biochar application were measured. The changes of soil physical and chemical properties and soil fungal community succession were analyzed. The study aimed to clarify the effects of biochar on fungal communities and explore the relationships between soil properties and soil fungal communities, hoping to provide a theoretical basis for biochar to improve soil biological characteristics.

Material and method

Experimental material

The soil used in this study was the surface soil (0-20 cm soil layer) in the trees garden of South China Agricultural University in Guangzhou, Guangdong province, and the Guangzhou red soil at lower layer, which were mixed according to the soil thickness of the actual woodland. The basic physical and chemical properties of the soil are shown in *Table 1*.

Biochar was supplied by Shaanxi Yixin Bioenergy Technology Development Co., Ltd., and was milled to pass a 3 mm sieve by thermal cracking of discarded fruit tree trunks and branches in a cracking furnace and oxygen-limited environment (450 °C).

Table 1. *Basic physical and chemical properties of soil*

Soil samples	pH	Organic matter (g/kg)	Total N (g/kg)	Total P (g/kg)	Total K (g/kg)	Available N (mg/kg)	Available P (mg/kg)	Available K (mg/kg)
Woodland surface soil	5.65	15.25	0.305	0.248	2.763	19.32	9.95	36.67
Layer red soils	6.05	3.16	0.203	0.165	1.702	11.59	3.20	20.08

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88178834

The tested plants were 20 cm *Machilus pauhoi* seedlings and 35 cm *Ilex asprella* seedlings, and both plants were selected with good growth and consistency.

Experiment design

This experiment was carried out in outdoor concrete pools in the Resource and Environment College of South China Agricultural University, Guangzhou (N04°09′44.20″, E113°21′57.75″) from 2014 to 2017, with a marine climate of the south subtropical monsoon, a annual average temperature of 21.7 °C and a annual precipitation of 1689.3 mm to 1876.5 mm. The concrete pool has a volume of 1 m × 1 m × 2 m and an area of 2 m^2 (It was about 1 m wide, 2 m long and 1 m deep). There are 12 concrete pools, and each concrete pool serves as a experimental plot. The experiment adopted a randomized block design, and a total of 4 gradients of biochar treatments were set: 0 kg (CK), 1.2 kg (T1), 2.4 kg (T2), 4.8 kg (T3) (the forest charcoal application standard is 12 t/hm^2, which is equivalent to 1.2 kg in this experiment). First, each concrete pool was filled with 80 cm of Guangzhou red soil at the bottom, and then added with the woodland surface soil in the upper part. In 2014, biochar was applied to the surface soil followed by tumbling with tools. Each process was repeated 3 times and all processes were randomly arranged. The soil was pressed to the predetermined height and the conditions of soil were close to that of the actual forest soil. Urea, superphosphate and potassium sulfate was used as N fertilizer, P fertilizer and K fertilizer, respectively, with fertilization ratio at 261:150:181. After conversion according to the number of seedlings, base fertilizer which was composed of 41.76 g urea, 24 g superphosphate and 28.96 g potassium sulphate was added in one concrete pool. Topdressing was carried out with the same fertilizer composition one year later. Each concrete pool was equipped with automatic sprinkler irrigation system. It was irrigated every 3 days at 18:00 in dry season (October-March next year). According to the monthly irrigation allocation, the amount of irrigation was about the average daily rainfall of that monthly rainfall (600 mm). In case of rainy days, the irrigation time was adjusted artificially.

After biochar application, the concrete pools were provided with intercropping system of *Machilus pauhoi* and *Ilex asprella* at a ratio of 9:6. According to the plum planting pattern, the seedlings of *Machilus pauhoi* and *Ilex asprella* were transplanted, as shown in *Figure 1*.

Soil sampling and physical and chemical properties determination

Collection and determination of soil samples: After the seedlings were planted, in March 2017, a 5-point sampling method based on S-shape curve (Smalla et al., 2001) was used to collect soil with the depth of 0-15 cm and 15-30 cm. The five samples from the same depth range were mixed into one. The fresh soil sample was removed from the crop residue and stone by 2 mm sieve, and then divided into two parts. One part was placed in a sterile centrifuge tube and quickly placed in liquid nitrogen for the extraction of soil total DNA and subsequent bioinformatics analysis. The other part was naturally dried in the room and used for the determination of other physical and chemical properties of the soil.

The pH of the soil (water: soil = 2.5:1) was measured with potentiometer. Soil organic matter content was measured by the potassium dichromate volumetric method. Soil total nitrogen mass fraction was determined by Kjeldahl apparatus. Soil total

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88178834

phosphorus, total potassium, available phosphorus, available potassium, and alkaline nitrogen content were determined according to soil agrochemical analysis methods (Bao, 2000).

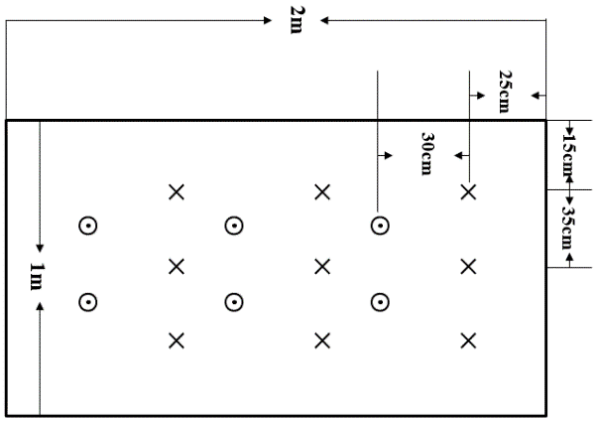

Figure 1. *Experimental planting pattern. (×: Machilus pauhoi; ⊙: Ilex asprella)*

Determination of fungi community structure in the soil

Total DNA extraction and PCR amplification

The total DNA in the soil was extracted using a Power Soil DNA isolation kit (MoBio Laboratories, Inc., Carlsbad, CA, U.S.A.) extraction kit. The integrity and concentration of the extracted DNA were examined using the Qubit 2.0 DNA kit. After passing the assay, the ITS2 region of the total DNA of the fungi was amplified using ITS3 and ITS4 primers (Huang et al., 2006).

Database construction and sequence processing

After purification of the PCR amplification product, all samples were mixed according to the DNA concentration in a ratio of 1:1, and a small fragment library was constructed for Paired-end sequencing using the Illumina (MiSeq PE300) sequencing platform of Guangdong Meige Gene Technology Co., Ltd. According to the similarity threshold of 97%, OTU were divided and clustered with the USEARCH (version 7.1) software for all qualified sequences. The sequence with highest abundance was selected as the representative sequence in each OTU. All representative sequences were species-annotated at the phylum and genus level using the RDP Classifier (classification threshold > 0.8) (Quast et al., 2013).

Data processing and analysis

The Shannon index, Chao1 index and sequencing coverage of samples were calculated using Mothur software (Pitta et al., 2014). Using SPSS software, soil physical and chemical indicators, α diversity of fungi communities and relative abundance of species at different taxonomic levels were analyzed by one-way ANOVA and Multiple comparisons were carried out by Duncan method ($P < 0.05$). The effect of environmental factors on the difference in fungi community structure between samples was analyzed by redundant ordering analysis (RDA). The visualization of RDA is plotted using the "vegan" package of the R software (version 3.3.1).

Results and analysis

Effect of biochar on soil physical and chemical properties

As can be seen from *Table 2*, the application of biochar significantly increased the soil pH in depth of 0-15 cm compared to the control group, while had no significant effect on the pH of soil in 15-30 cm. The contents of soil organic matter and available potassium in the depth of 0-15 cm and 15-30 cm increased with the increase of biochar addition. In general, biochar could significantly increase the content of total nitrogen, total phosphorus and available phosphorus in the soil depth of 0-15 cm, but no significant difference was observed under different biochar additions. In addition, biochar had no significant effect on the content of organic matter, total nitrogen, total phosphorus, total potassium, alkali nitrogen, available phosphorus and available potassium in the soil depth of 15-30 cm. The total nitrogen content of soil as well as total phosphorus, total potassium, alkali nitrogen and available phosphorus in 0-15 cm soil increased first and then decreased with the increase of biochar addition.

Table 2. *Effects of biochar addition on soil physical and chemical properties*

Soil samples	Treatment	pH	Organic matter (g/kg)	Total nitrogen (g/kg)	Total phosphorus (g/kg)	Total potassium (g/kg)	Alkali nitrogen (mg/kg)	Available phosphorus (mg/kg)	Available potassium (mg/kg)
0-15 cm	CK	6.07±0.08a	9.56±2.00a	0.45±0.05a	0.42±0.07a	4.92±1.11a	31.66±5.76a	20.25±7.72a	56.47±11.65a
	T1	6.17±0.01ab	15.9±4.13bc	0.64±0.17b	0.54±0.06b	6.73±1.7ab	43.1±10.24a	28.8±6.53b	80.81±2.67ab

Different letters indicate significant differences ($p < 0.05$) among different treatments.

The OTU of soil samples

A total of 1,193,794 sequences were obtained from 24 soil samples. After optimization, the sequence sequencing amount of each sample was between 40,000 and 55,000. The OTU was clustered at 97% similarity level and the dilution curve of each sample was prepared (*Fig. 2*), and 9,265 OTUs were obtained. The curve gradually becomes flat and the sequencing become saturated, indicating that the library construction was reasonable, and the number of sample sequences was sufficient to reflect the species diversity.

The Venn map can reflect the number of common and unique OTUs between groups or between samples, visually showing the similarity and overlapping between groups or samples. The OTU was analyzed with 97% similarity, and the number of OTUs could also represent the number of strains.

Figure 3 presents the mixed clustering result of the OUT representative sequences of 4 groups of samples in the depth of 0-15 cm and 15-30 cm. It can be seen from *Figure 3* (left) that 744 OTUs can be identified for the soils in the depth of 0-15 cm, of which 440, 448, 545, and 511 OTUs fall in the CK, T1, T2, and T3 communities, respectively. The number of fungi OTUs shared by different treatments was 279. Each treated soil had its unique fungi OTUs, the number of which in CK, T1, T2 and T3 group was 39, 28, 83 and 70, respectively. The number of unique fungi OTUs under T2 and T3

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88178834

treatments was larger than that of the control group, indicating that the application of biochar could lead to the change of fungi specificity in the soil to a certain extent. Although biochar treatment can increase the unique fungi species in the soil, the increased species varies with the application amount of biochar.

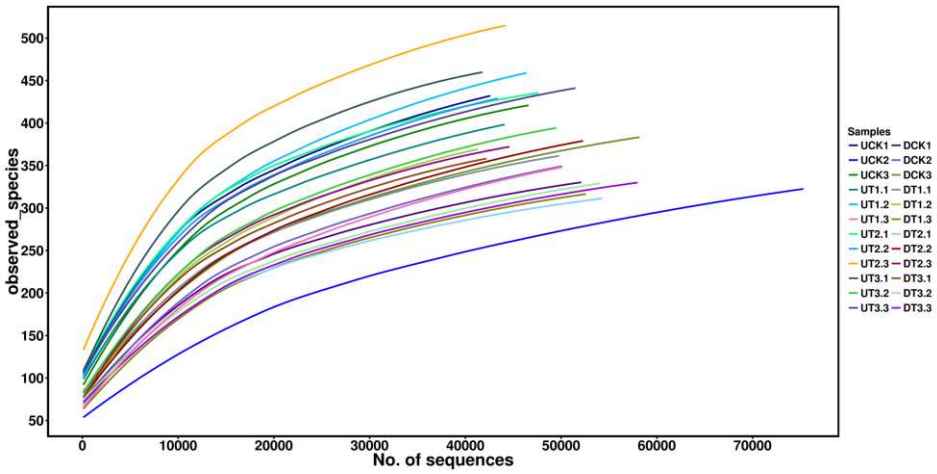

Figure 2. *Rarefaction curve of fungal community in soils. CK, T1, T2 and T3 represent different amounts of biochar, U and D represent soil depths of 0-15 cm and 15-30 cm, respectively*

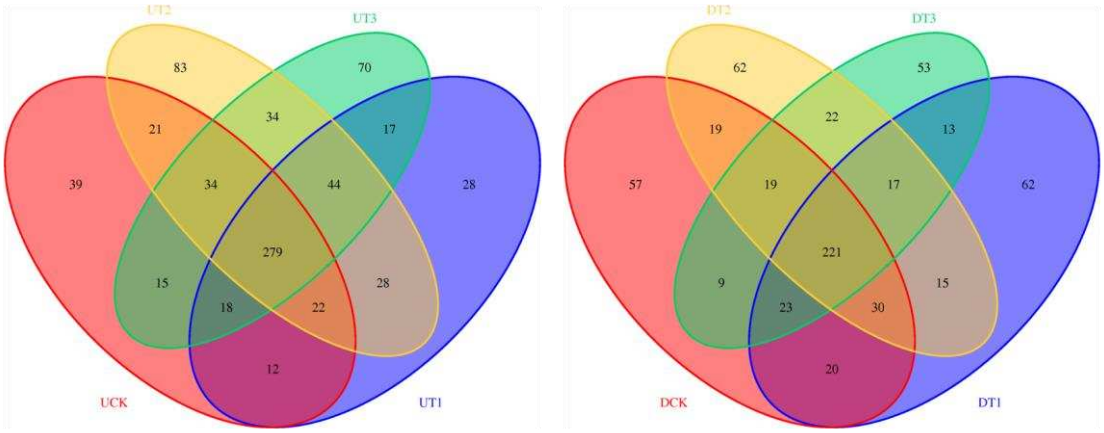

Figure 3. *Venn diagram of fungi in 0-15 cm (left) and 15-30 cm (right) of soil layers with biochar addition*

It can be seen from *Figure 3* (right) that 642 OTUs can be identified in the soils with the depth of 15-30 cm, of which 398, 401, 405, and 377 OTUs fall in the CK, T1, T2, and T3 communities, respectively. The number of fungi OTUs shared by different treatments was 221. Each treated soil had its unique fungi OTUs, the number of which in CK, T1, T2 and T3 group was 57, 62, 62 and 53, respectively. The number of unique fungi OTUs under T1 and T2 treatments was larger than that of the control group, indicating that the application of biochar can lead to the change of fungi specificity in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88178834

the soil with the depth of 15-30 cm to a certain extent as well. Although biochar treatment can increase the unique fungi species in the soil, the increased species varies with the application amount of biochar.

Alpha diversity analysis

The Observed species index and the Chao1 index are used to measure the richness of the community in the sample, i.e., the number of single species (the number of OTUs), without involving the abundance of each species in the community. The larger the value is, the richer the species in the sample. Shannon index, Simpson index and PD whole tree reflect the diversity of the community, which is affected by the species richness and species uniformity in the sample community. The larger the value of Shannon index, PD whole tree and Simpson index indicates the higher diversity of the community in the samples.

It can be seen from *Table 3* that in the 0-15 cm soils, the fungi community richness under biochar treatment is higher than that of the control group, which is consistent with the dilution curve. The sequence of chao1 index and the Observed species (OTUs index) were respectively T2 > T1 > T3 > CK and T2 > T3 > T1 > CK; the chao1 index of 15-30 cm soils under each biochar treatment was slightly lower than that of biochar treatment, but the difference was not significant ($P > 0.05$). The difference in Observed species (OTUs index) was also not significant as well. In general, the difference in the abundance of fungi community in the soil with the depth of 15-30 cm was not significant under different treatment conditions.

For different biochar treatment groups, the order of PD whole tree value and Shannon index of soils with the depth of 0-15 cm were T2 > T3 > T1 > CK. T2 had a higher Simpson index than T3, and both T2 and T3 treatment had a higher Simpson index than T1 and CK. The diversity of soil fungi community under charcoal treatment was higher than that of the control group, and it reaches the peak value under T2 treatment. In the 15-30 cm soils, the PD whole tree value, Shannon index and Simpson index under T1 treatment were slightly higher than those of the control group. Overall, there was no significant difference in fungi community diversity among the 15-30 cm soils.

The fungi dominance index of the 0-15 cm soil after T1 treatment was higher than that of the control group while the index after T2 and T3 treatment were smaller than that of control group. For 15-30 cm soils, the conclusions were just the opposite.

Comparing fungal Alpha diversity index of the 0-15 cm soils with that of 15-30 cm soils, it can be seen that in the 0-15 cm soils, except for the dominance index, other indexes were higher than those of 15-30 cm soils.

Table 3. *Alpha diversity index of soil fungal with biochar application treatment*

Soil fungi community structure under different treatments

Relative abundance of fungal in the soil at phylum level under different treatments

Species annotation results showed that 13 of the fungi were detected in the 24 soil samples, including: *Mortierellomycotina*, *Chytridiomycota*, and *Glomeromycota*. *Ascomycota*, *Basidiomycota* and some fungi classified as undetermined. The sequence of relative abundance from high to low was 50.389% of Ascomycota, which was the dominant species, 32.01% of Basidiomycota, 10.17% of *Glomeromycota*, and 1.69% of *Mortierellomycotina*, and 0.62% of *Chytridiomycota*. Their relative abundances together accounted for more than 90% of the annotated species.

It can be seen from *Figure 4* that biochar has different effects on the abundance of different fungi at phylum level in soils with different depth. In 15-30 cm depth soil layer, *Basidiomycota* had the highest relative abundance, and *Ascomycota* ranked the second place. Biochar could increase the relative abundance of *Mortierellomycotina*, *Chytridiomycota*, *Glomeromycota* and *Ascomycota*, all of which peaked the maximum under T2 treatment. However, this phenomenon was not found in 15-30 cm depth soil. In 15-30 cm depth soil layer, the relative abundance of Ascomycota was the highest, followed by *Basidiomycota*. Compared with CK treatment, the abundance of *Ascomycota* increased while the abundance of the *Basidiomycota* decreased after T2 and T3 treatment, which was the opposite to T1 treatment. The decrease degree of the *Glomeromycota* increased with the amount of biochar application. And there was little difference in relative abundance of the *Chytridiomycota* under different treatment.

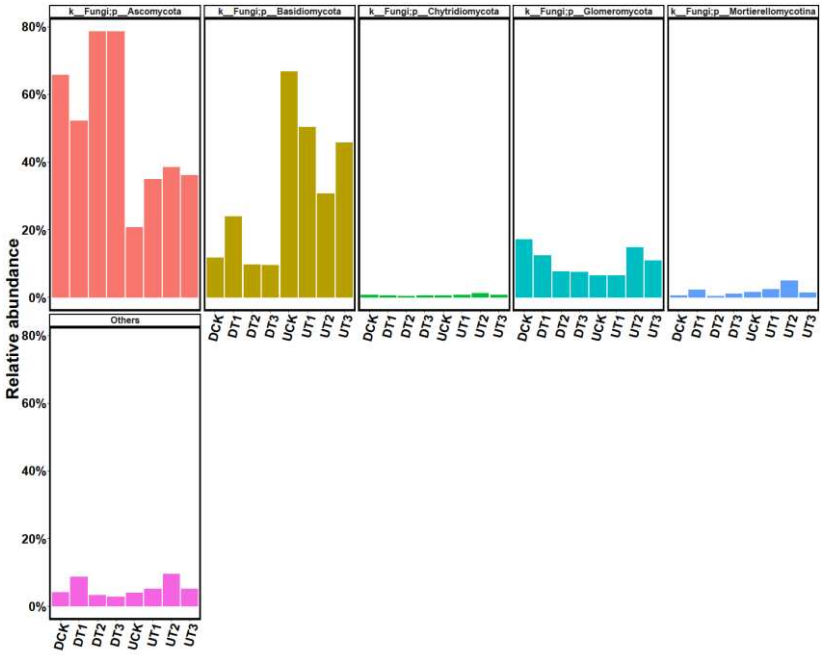

Figure 4. *Relative abundance of fungal communities in soil at phylum level*

Relative abundance of soil fungi at genus level under different treatments

As shown in *Figure 5,* the species annotation results at genus level indicated that the relative abundance of 12 genera was more than 1%. The relative abundance of *Parascutellinia* was the highest, accounting for 42.68% in all the species, followed by

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88178834

clitocybula, accounting for 32.71%. The relative abundance of these two species was significantly higher than that of other species. In 0-15 cm soil, the application of biochar reduced the relative abundance of *Clitocybula*, which was the smallest under T2 treatment. However, biochar application significantly improved the relative abundance of *Parascutellinia*, *Glomus*, *Mortierella*, *Funneliformis*, *Plectosphaerella*. The relative abundance of *Parascutellinia*, *Glomus*, and *Mortierella* under T2 treatment were the highest, while that of Funneliformis and Plectosphaerella increased with the amount of biochar application.

In 15-30 cm soil, the variation of relative abundance of *Parascutellinia* was consistent with that of soil with the depth of 0-15 cm. The relative abundance of *Clitocybula* and *Mortierella* increased significantly under biochar treatment and peaks the maximum value under T1 treatment. The relative abundance of *Phaeococcomyces* and *Plectosphaerella* were the largest under T2 treatment. However, the relative abundance of *Glomus* and *Gyroporus* decreased under biochar treatment. The relative abundance of *Mycotribulus* and *Ostropa* were not significantly changed under different treatments.

For soils in different depth, the abundance of *Parascutellinia*, *Gyroporus*, *Glomus* and *Phaeococcomyces* in the soils with the depth of 15-30 cm were higher than that in the soils with the depth of 15-30 cm. On the contrary, the 0-15 cm soils containd more *Clitocybula*, *Funneliformis*, *Mortierella*, *Mycotribulus*, *Ostropa*, and *Plectosphaerella*.

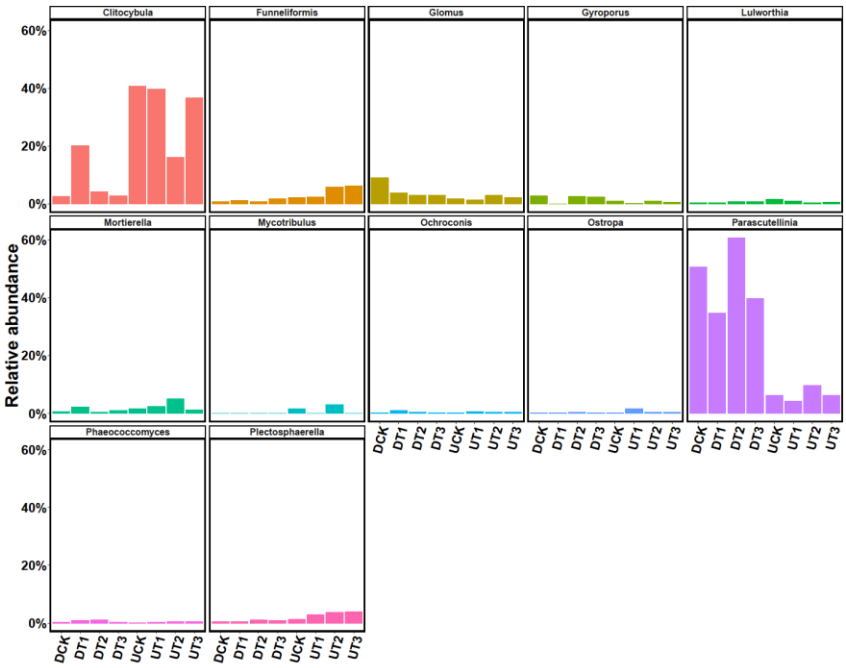

Figure 5. *Relative abundance of fungal communities in soil at genus level*

Cluster analysis on species relative abundance

Cluster analysis on species relative abundance at phylum level

Figure 6 is a species heat map of soil fungi at phylum level. The relative abundances of the species at each level are ranked, and the bacteria in the top 13 are selected (all the species are selected if the number of phylum is less than 13). The heat map is used to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88178834

cluster the abundance similarity between different treatments. The similarity and color gradient are used to reflect the difference and similarity of fungal community composition at each level. The darker the red is, the greater the abundance, while darker the blue is, the lighter the abundance. A color patch represents the abundance of a phylum in a sample. In the figure, the horizontal direction is the sample information, and the vertical direction is the species annotation information. The sample clustering tree lies in the upper part and the species clustering tree lies in the left part of the figure.

As can be seen from *Figure 6,* the species in each sample are: Ascomycota, Basidiomycota, Glomeromycota, Mortierellomycotina, and Chytridiomycota, Zoopagomycotina, Mucoromycotina, Arthropoda, Blastocladiomycota, Kickxellomycotina, Entomophthoromycota, Cryptomycota and Annelida. The similarity between UTI and UCK was the highest, and UCK, UT1, and UT3 were also clustered at the top. These three groups had higher abundances of Basidiomycota and Zoopagomycotina, but were far away from UT2, which indicated that, compared with the control group, the effects of T1 and T3 treatment on the fungi community structure of 0-15 cm soil were not obvious while the effect of T2 treatment on soil fungal community structure was significant. UT2 was clustered as a specific group, and, compared to UCK, the red colors corresponding to Mortierellomycotina, Chytridiomycota, Arthropoda, Cryptomycota, Glomeromycota, Mucoromycotina, and Kickxellomycotina in 0-15 cm depth soils under T2 treatment were much darker than other treated samples. However, the color representing Basidiomycota was shallower, indicating that the abundance of fungi community in 0-15 cm soils under T2 treatment was the highest, and the abundance of the above seven fungi could be significantly increased while the abundance of Basidiomycota was reduced.

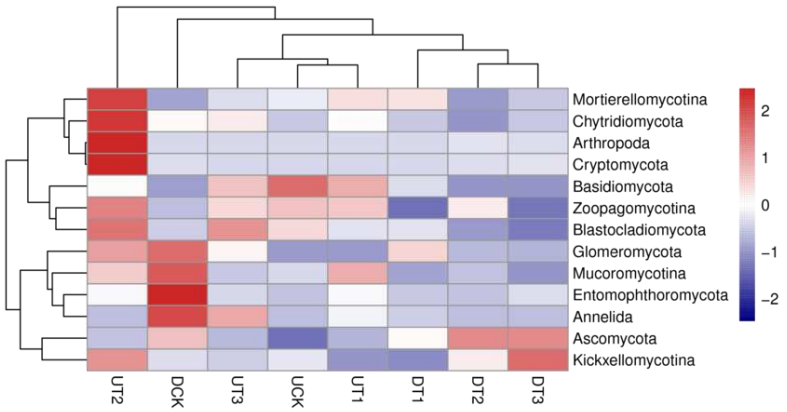

Figure 6. *Thermal map of relative abundance of different fungal phylum in soil. (The sample clustering tree is the clustering tree above and the species clustering tree is the left cluster tree. Similarly hereinafter)*

DT1, DT2 and DT3 are clustered at the top, but they are far away from DCK, indicating that biochar has a great influence on the fungal community structure of 15-30 cm soils. However, different biochar application rates resulted in similar fungi community in 15-30 cm soils. Compared with DCK, the color of *Ascomycota* and *Kickxellomycotina* in the DT2 and DT3 groups were relatively dark while that of *Glomeromycota*, *Mucoromycotina*, *Entomophthoromycota* and *Annelida* was relatively shallow, indicating that the T2 and T3 biochar treatment could increase the abundance

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88178834

of *Ascomycota* and *Kickxellomycotina* while decrease the abundance of *Glomeromycota*, *Mucoromycotina*, *Entomophthoromycota* and *Annelida*.

It can be seen that the effects of different biochar treatments on the abundance of the same species are different. The same biochar treatment had different effects on the abundance of different types of species. Generally, the biochar treatment could increase the abundance of most fungi communities in 0-15 cm soils to some extent. And the effect of T2 treatment effect was the most obvious. Biochar application could reduce the abundance of most fungi communities in the 15-30 cm soils to some extent. In general, the abundance fungi in 0-15 cm soils were higher than that in 15-30 cm soils, which was consistent with the analysis of the relative abundance distribution in the previous section.

Cluster analysis on species relative abundance at genus level

Figure 7 is a species heat map of soil fungi at genus level. The relative abundances of the species at each level are ranked, and the species in the top 30 are selected (all the species are selected if the number of phylum is less than 30).

As can be seen from *Figure 7,* for different treatments, the clustering result at genus level is consistent with that at phylum level. Comparing the aggregation degree of fungi in 0-15 cm soils under different treatments, it could be found that the abundance of *Ostropa*, *Ochroconis*, *Capnobotryella*, *Muyocopron* and *Hydropisphaera* under T1 and T3 treatment were higher than those under CK treatment. The abundance of most fungi in T3 group were significantly higher than those in CK group, and were also higher than those in other groups. Compared to CK treatment, T1, T2 and T3 treatment had seen more abundant *Funneliformis*, *Plectosphaerella*, *Chaetomella*, *Peziza*, and *Hyaloraphidium*. Nevertheless, CK treatment resulted in higher abundance of *Lulworthia* and *Thamnocephalis*.

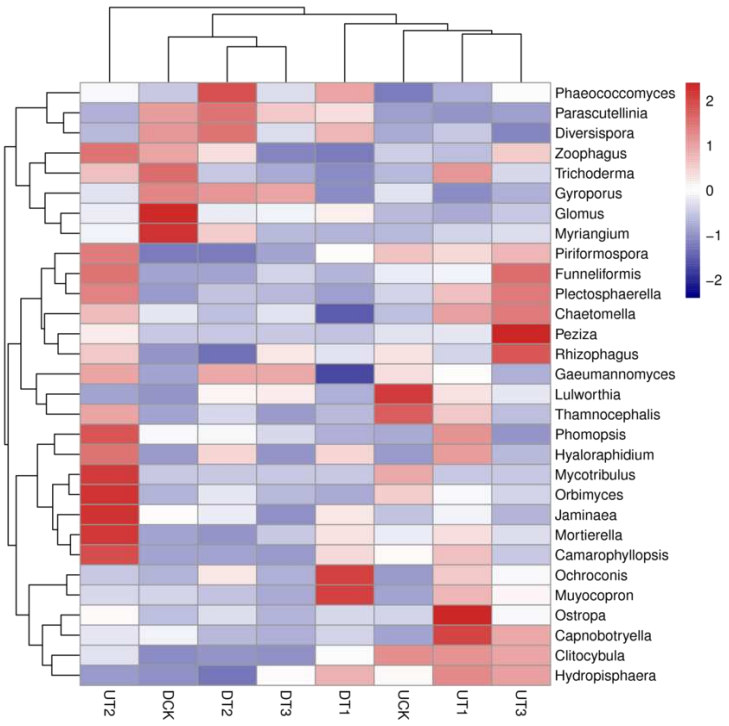

Figure 7. *Thermal map of relative abundance of different fungal genus in soil*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88178834

In 15-30 cm soil layer, the abundance of *Glomus*, *Myriangium*, *Capnobotryella*, *Zoophagus*, and *Trichoderma* were relatively low under the treatment of biochar. However, biochar could increase the abundance of certain fungi species. For example, compared with CK, the abundance of *Mortierella*, *Ochroconis*, *Muyocopron*, *Camarophyllopsis*, *Hyaloraphidium*, and *Jaminaea* were relative high under T1 treatment, which indicated that the application of low-dose biochar to the soil could increase the abundance of some fungi in the 15-30 cm soil layer.

Under the various treatments, there was significant difference in the fungi at genus level in 0-15 cm soil layer. The effect of biochar was prominent. The difference of fungi in 15-30 cm soil layer was relatively small.

Correlation between fungi community structure and soil environmental factors

Figure 8 shows the correlation between fungi at the genus level and soil environmental variables. The first and second axes of the RDA ordering accounted for 53.14% and 19.37% of the fungal genus variables, respectively. 0-15 cm soil and 15-30 cm soil samples were clearly separated in the direction of RDA1 axis. In the 0-15 cm soil samples, DCK and DT3 were separated from DT1 and DT2, indicating there was huge difference between T1 and T2 treatment and CK treatment. In the 15-30 cm soil samples, UCK and UT1 were clearly separated from UT2 and UT3, indicating that T2 and T3 treatments were significantly different from CK. In general, compared with soils with different depths, the points of 15-30 cm soils under different treatments were relatively close and concentrated while the points of 15-30 cm soils were far away from each other and the distribution was relatively scattered, indicating that response of fungi abundance to biochar in 0-15 cm soil was more sensitive.

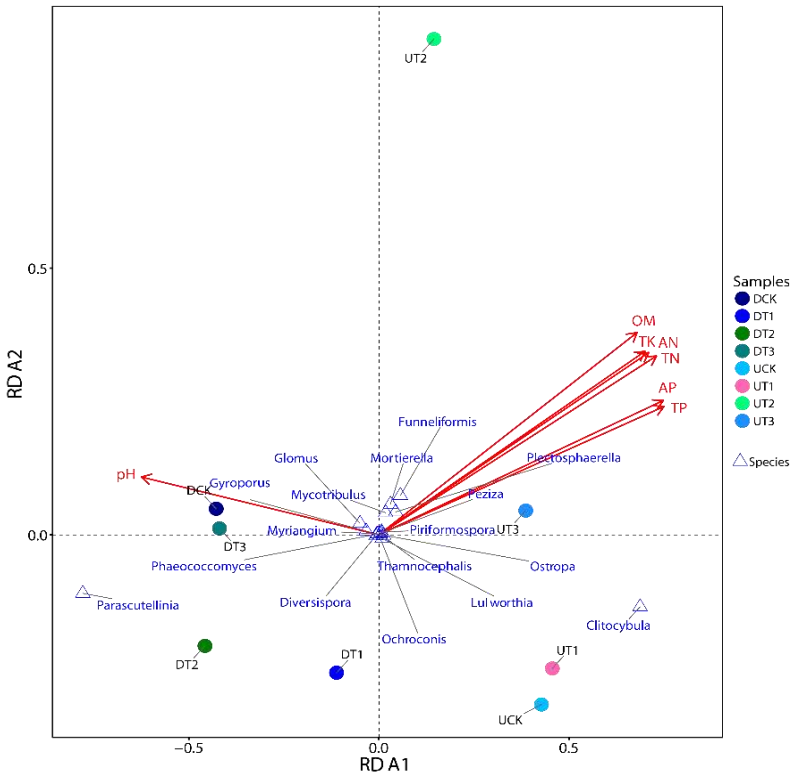

Figure 8. *RDA triplot showing the relationship between the relative abundance of major soil fungal genus in different soil samples and the environmental variables*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88178834

There was a significant positive correlation between the content of organic matter, total nitrogen, total phosphorus, total potassium, alkali nitrogen, available phosphorus and available potassium in the soil, but they were negatively correlated with soil pH. The abundance of *Mortierella*, *Funneliformis*, *Plectosphaerella*, *Peziza*, *Piriformospora*, *Ostropa*, *Lulworthia*, *Clitocybula* and *Thamnocephalis* were positively related to content of organic matter, total nitrogen, total phosphorus, total potassium, alkali nitrogen, available phosphorus, and available potassium, while were negatively correlated with soil pH. Among them, the abundance of *Plectosphaerella* had the largest correlation with the content of total phosphorus and available phosphorus, which corresponded to the farthest point from the origin, indicating that it was the most sensitive to the environment. *Piriformospora* was closest to the origin, indicating that it was the least sensitive to the environment. The abundance of *Glomus*, *Mycotribulus*, *Gyroporus*, *Myriangium*, *Phaeococcomyces*, *Parascutellini* were positively related to soil pH, where the *Gyroporus* was the most relevant and *Parascutellinia* was the most sensitive to the environment.

Discussion

After the biochar was applied, the soil microorganisms were directly or indirectly affected by changing the physical and chemical properties of the soil. Most studies had shown that biochar promotes microbial communities (Kolb et al., 2009; Ameloot et al., 2013). In this study, it was clear that after 3 years of application, the physical and chemical properties of the soil had undergone major changes. Soil pH, the content total nitrogen, total phosphorus and available phosphorus were increased. The abundance and diversity of fungi in the soil changed significantly with the application of different amounts of biochar.

From the number of unique fungi OTU and the relative abundance distribution of fungi communities as shown in the Venn diagram (*Figs. 4* and *5*), the application of biochar had changed the original fungal community structure, inhibited the growth of some original fungi species and increased the population of specific microorganisms that are more adaptable to the environment. Biochar had a void structure and a large specific surface area, as a result, the oxygen content was significantly increased as the application of biochar. The soil fungi had both anaerobic and aerobic groups, and their respective abundance was reduced or increased as the change of soil bulk density. The results of Marluthi et al. (2010) also showed that the application of biochar in soil changed the type of carbon source used by soil microbes. There were also differences in the number of fungi species when different amounts of biochar was applied, but the difference was more prominent in 0-15 cm soils than in 15-30 cm soils. The dilution curve also showed that biochar could increase the amount of soil OTUs, which was more significant in 0-15 cm soils, indicating that the effect of biochar on soil fungal community was mainly concentrated in the directly contacted soil layer (0-15 cm) while the impact on the lower soil layer was relatively slight. This might be related to the porosity and large specific surface area of biochar, which could provide a good attachment site and growth environment for soil fungi to promote the growth and reproduction of fungi and avoid predators as well (Thies et al., 2009).

According to the Alpha diversity analysis, biochar treatment could increase the abundance and diversity of soil fungal communities, which reached the maximum value under T2 treatment. When the biochar application rate was high (T3 treatment), the soil

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88178834

fungal community abundance and diversity did not increase with the increase of the amount of biochar applied. The reason might lie in the fact that the pH of the applewood after carbonization was alkaline, thus adding biochar to the soil would increase the soil pH. It was reported that the higher soil pH could reduce the abundance of soil fungi (Rousk et al., 2010). Biochar with low addition could increase the dominance of fungi in 0-15 cm soil layer, but the effect was not increased as the application rate was increased to T2 and T3. High-volume biochar treatment was not conducive to improving the abundance of soil fungal communities, and the appropriate amount of application was beneficial to the construction of soil micro-ecological environment. Compared with the 15-30 cm soil layer, the fungi abundance and diversity in 15-30 cm soil layer were low, and the difference between the treatments was not obvious. This was also consistent with the OTU quantitative analysis results.

In the soils tested in this experiment, *Mortierellomycotina*, *Chytridiomycota*, *Glomeromycota*, *Ascomycota*, and *Basidiomycota* were dominant species at phylum level. Among them, *Ascomycota* and *Basidiomycota* accounted for more than 80%, which was consistent with previous studies (Roesch et al., 2007). In 0-15 cm soil, the relative abundance of *Mortierellomycotina*, *Chytridiomycota*, *Glomeromycota* and *Ascomycota* under the application of different amounts of biochar were higher than that of control group and were the highest under T2 treatment. Studies have shown that nitrogen application can increase the relative abundance of *Ascomycota* (Paungfoo-Lonhienne et al., 2015), probably because biochar's adsorption to nitrogen fertilizer indirectly increased soil nitrogen content (Clough et al., 2013), thereby increasing the relative abundance of *Ascomycota* in the soil. Different from 0-15 cm soils, the application of biochar could reduce the abundance of certain species, such as *Basidiomycota*, *Glomeromycota*, while increase the abundance of *Ascomycota* in 15-30 cm soils to some extent. This phenomenon was particularly significant under T2 and T3 treatment. It indicated that the dominant fungi in red soil were sensitive to biochar addition. Similarly, at the genus level, biochar also increased the relative abundance of dominant genus such as *Parascutellinia* and *clitocybula*.

Soil chemistry plays an important role in affecting soil microbial community structure (Teague et al., 2011). Previous studies have shown that soil fungi are closely related to many soil physical and chemical properties, such as soil pH (Fierer et al., 2006) and available nitrogen (Frey et al., 2004). Due to the different biological characteristics of the fungi, the soil factors affecting different fungi are also different (Avander et al., 2006). RDA is used to analyze the relationship among environmental factors (pH, soil nutrients), dominant species and different treatments. Due to the composition and structural specificity of biochar, different microbial communities often respond differently to the addition of biochar. In this experiment, the abundance of *Funneliformis*, *Ostropa*, *Piriformospora* and *Plectosphaerella* in soil were positively correlated with the content of organic matter, total nitrogen, total phosphorus, total potassium, alkali nitrogen, and available phosphorus in the soil while were negatively related to soil pH. The abundance of *Glomus*, *Mycotribulus*, and *Gyroporus* were positively correlated with soil pH, where *Gyroporus* had the maximum correlation. In general, neutral and alkaline conditions were considered to be beneficial to bacterial growth but were not conducive to fungi growth (Rousk et al., 2009). Xu et al. (2018) found that soil phosphorus closely affects fungal growth, and insufficient or excessive available phosphorus would inhibit fungi growth and development. In this study, soil total phosphorus and available phosphorus were significantly positively correlated with

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88178834

Plectosphaerella and *Peziza*, while negatively correlated with *Parascutellinia* and *Phaeococcomyces*, which indicated that the fungi was selective for phosphorus levels, providing a valuable insight into the relationship between fungi diversity and phosphate fertilizer, as well as studies on fungal functional genes (such as genes controlling the phosphorus cycle). In addition, in this study, the interpretation rates of the first and second axes for sample changes were mostly lower than 65.0%, indicating that in addition to the soil physical and chemical indicators analyzed in this study, there might be other soil physical and chemical properties that jointly drove the changes in microbial structure.

The promotion of soil microbial abundance by short-term application of biochar is mainly caused by absorption of soluble carbon in biochar through soil microbe activities (Quilliam et al., 2013). However, although this study has not detected the soluble carbon content of biochar after application, many scholars have shown that the soluble carbon will be depleted by soil microbes within one year (Cheng et al., 2008; Kuzyakov et al., 2009; Wang et al., 2016). In addition, in this study, we found that changes in fungi community structure in soils were closely related to the physical and chemical factors including content of organic matter, total nitrogen, total phosphorus, total potassium, alkali nitrogen, available phosphorus, available potassium, and pH. And these factors were also significantly correlated with the amount of biochar (*Table 3*). In summary, the increase in soil abundance and the change in community structure in this study were indirectly driven by changes in soil physical and chemical properties caused by biochar application.

Conclusions

(1) After 3 years of biochar application, soil pH and nutrient content increased to varying degrees. Especially, soil pH, organic matter and available potassium increased proportionally to the biochar addition. Besides, the nutrient content in the upper layer of soil was significantly higher than that of the lower layer, which illustrated that biochar has a significant long-term effect on soil nutrient retention.

(2) Biochar could increase the amount of soil OTU. Different biochar treatments can lead to specific changes of fungi to a certain extent and increased the abundance and diversity of fungi communities, which reached the maximum value under T2 treatment.

(3) Biochar significantly changed (increased or decreased) the relative abundance of some soil fungi, which was reflected at both phylum and genus level.

(4) RDA analysis showed that the addition of biochar could significantly change the physical and chemical properties of soil pH and nutrient content after 3 a. The changes of these environmental factors further affected the soil fungal community structure. And at different depths, different biochar application addition and soil physical and chemical factors affected the abundance of different fungi species.

(Received 12th Mar 2019; accepted 22nd May 2019)

Abstract. Using competitive cultivars can be an important integrated weed management (IWM) tool in sustainable agricultural systems and in cultivation of healthy products. Differential competitive ability of 10 potato cultivars was examined in 2015 and 2016 in the research field of the University of Mohaghegh Ardabili, Ardabil, Iran. Experiment was established using a randomized complete block design with three replications. 10 potato cultivars (Caesar, Kennebec, Banba, Markies, Hermes, Marfona, 397097-14, Difla, Satina, Natascha) were observed that has grown with and without natural weed flora. Potato cultivars differed in ability to reduce weed density and weed biomass. In weed conditions, tuber yield ranged from 19.27 in Hermes to 55.56 t ha^{-1} in Satina. Also yield loss ranged from 0 to 38.93%. Satina cultivar had the highest competitive index (CI) and could reduce the weed dry mass by 2 to 3 times more than Hermes as a poor cultivar. In general, the results of this study declare that Satina cultivar was considered as competitive and recommended more for cultivation in Ardabil region than other cultivars. It is more stable than weed, and could have greatly reduce the density and biomass of weed.
Keywords: *competitive ability, potato, healthy hazards, integrated weed management, sustainable agriculture, weed interference*

Introduction

Besides cereal, potato, *Solanum tuberosum* L., is an important crop in the world. Iran has the 13th place in potato production (FAO Statistic, 2016). Potato is the most important crop in the Ardabil area. Ardabil contains 23000 ha of arable land, of which 18500 ha was used for potato production in Iran in 2017, with an average yield of 23.7 t ha^{-1} (IRANSTAT, 2017), but weeds are the main barrier to potato production. Yield loss in potato due to weed interference has been reported 20-30% in Iran (Khalghani, 2010). Few herbicides and modes of action are usually available for use in potato cultivations, so the risk of developing herbicide-resistant weed populations can increase. On the other hand, weed control is one of the main limitations in sustainable agriculture. Efficient weed management is essential for successful organic crop protection, and finding crop cultivars that confer a high degree of competitive ability against weeds are highly desirable (Mason et al., 2006). Although competitiveness has not traditionally been considered a priority for breeding or farmer cultivar choice the challenge of managing herbicide- resistant weed populations, environmental concerns and the unmet needs of organic producers and smallholder farmers has, however, renewed interest in cultural weed control options, including competitive cultivars (Worthington and Rebery-Horton, 2013; Andrew et al., 2015). Many research in cereals have examined how cultivar selection may be used as a mean of weed control by choosing cultivars that are inherently more competitive with, or more tolerant of, commonly

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88358845

encountered or key weed species (Korres and Froud-Williams, 2002; Worthington and Rebery-Horton, 2013; Lemrele, 2015; Abdollahi and Mohammaddust-Chamanabad, 2017). Some findings presented in complement agronomic and physiological studies of crop- weed interactions in other species such as soybean (Vollman et al., 2010), potato (Nelson and Thoreson, 1981; Love et al., 1995; Khalegi et al., 2007; Colquhoun et al., 2009; Hutchinson et al., 2011; Bashiri-Majd, 2015), tomato (Gonzales-Ponce et al., 1996), canola (Hashem et al., 2010), field pea (Jacob et al., 2016).

There are two aspects of cultivar competitive ability; the ability to compete with weed, is expressed as competitive index (CI) and the ability to tolerate weed interference, is expressed as weed interference tolerance index (WITI). A competitive cultivar (high CI) can maintain high yield in the presence of weeds and can reduce weed biomass or seed production (Tilman, 1987; Goldberg, 1990), while tolerant cultivars only maintain high yield in the presence of weeds. Suppressing weeds is beneficial for weed management in future growing seasons while tolerating weeds is only beneficial in the current growing season. However, the relationship between aspects has not been addressed in potato. According to Cory et al. (2016) it has been reported that pea cultivars that are ranked the highest for AWC were associated with lower weed fecundity, whereas the highest-yielding cultivars generally were those that had the highest CI variation in competitive ability of wheat cultivars (Blackshow, 1994; Lemerle et al., 2001; Mohammaddust-Chamanabad et al., 2014). Abdollahi and Mohammaddust-Chamanabad (2017) also reported positive relationship between the yield of wheat and WITI similarly with CI. Colquhoun (2009) observed that differences in yield among cultivars grown in the presence of weeds suggest differential tolerance of weed competition ability, however, the ability to suppress weeds was similar among cultivars. Khaleghi et al. (2007) reported significant differences among potato cultivars in tolerance of weed presence. According to Bashiri-Majd (2015) late potato cultivars had high competitive ability that produced more yield and reduced weed biomass.

Many long-term studies still conduce on determining cultivars resistance to disease and good combination of traits for logical conditions. While the evaluation of crop cultivars based on competitive ability is necessary. Large genotype by environment interactions may cause difficulties in selecting for competitiveness (Coleman et al., 2001) and selection for competitiveness could be at the expense of other important criteria (Brennan et al., 2001). Nevertheless, within a given climatic zone there appears to be sufficient genetic variation in crop competitive ability (Acciaresi et al., 2001; Coleman et al., 2001) for such selection to be introduced into breeding programs. The over goal of this study was to (1) evaluate the ability potato cultivars to suppress weed density and biomass, (2) rank these cultivars based on competitive ability index, and (3) compare the ability of the same cultivars to maintain tuber yield in the presence of weeds.

Materials and methods

The study was conducted at the Agricultural Research Farm of the University of Mohaghegh Ardabili, Ardabil, Northwestern Iran (longitude 48° 18′ E, latitude 38° 15′ N, 1338 m above sea level) in 2015 and 2016 on loamy clay soil with 1.57% organic matter, and 7.8 pH, EC 1008 μS cm^{-1}. The monthly average air temperatures and total rainfall and long-term averages (1976 to 2014) during the growing season are summarized in *Table 1*. Air temperature and precipitation was different between years compared with the long-term average data. Compared with the long-term averages, air temperatures were

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88358845

lower during both study years. In 2016, rainfall was generally higher during the studied growing season (May to September) compared to the long-term average in 2015, except for lower precipitation in August.

In both years, treatments were arranged in a randomized complete block design, with three replicates. Ten potato cultivars (Caesar, Kennebek, Banba, Markies, Hermes, Marfona, Difla, Satina and one advanced clone, 397007-14) were grown with and without weed interference. The selections were chosen, based on their differing growth attributes (*Table 2*).

Table 1. *Air temperature and rainfall for 2015 and 2016 growing seasons and Long-term averages (1976-2014) at Ardabil, Iran*

Month	Mean Temperature (°C)			Rainfall (mm)		
	Long term	2015	2016	Long term	2015	2016
May	14.8	8	7.5	34.3	35.7	59.6

March	4	0.4	7.5	21.3	24.9	1.2

Plots measured 5 by 4.2 m, including 7 potato rows on 60 cm row spacing. Potato seed pieces were hand-planted with 7.5 plants m^{-2} density on May 1, 2015, and 16 May 2016. After the potato emergence, each plot was divided into two equal parts and in one half all weeds were hand-removed during the growing season as weed free plots. Fertilizer was applied at planting (75, 150, 75 kg ha^{-1} NPK) and at tuber initiation (75 kg N ha^{-1}). Supplemental overhead irrigation was supplied to meet crop water demands. Furrow irrigation during the growing season was carried out at the rate of 6000 m^3 ha^{-1} and 10 days.

Data collection included weed density and biomass at end of the season in the weedy plots and tuber yield in all plots. At the end of the season before tuber harvest, weeds were collected from two 0.5×0.6 m quadrates in each weedy plots. Weeds were counted, dried at 75°C for 48 hours and weighed. Potato tuber yield was quantified at season-end by harvesting the three rows in each plot. The following Equations (*Eqs.1 and 2*) were used for the evaluation of the competitive ability (CI) and tolerance ability (WITI) of potato cultivars (Mohammaddust-Chamanabad, 2011).

$$WITI = \frac{(Yp)(YS)}{(\bar{Y}p)^2} \quad \text{(Eq.1)}$$

where Yp is each cultivar yield from the weed free plot, Ys is each cultivar yield from weedy plot. $\bar{Y}$p mean is the average yield of all potato cultivars from the weed free plot.

$$CI = \left(\frac{Vi}{\bar{V}}\right)/\left(\frac{Di}{\bar{D}}\right) \quad \text{(Eq.2)}$$

where Vi is each cultivar yield from the weedy plot, $\bar{V}$ is the average yield of all potato cultivars from the weedy plot. D_i is weed dry biomass in each potato cultivar and $\bar{D}$ is average weed dry biomass from weedy plots. Relative Yield Loss was calculated as (*Eq.3*):

$$\%Relative\ Yield\ Loss = 100(Yweed\ free - Yweedy)/(\ Yweed\ free) \quad \text{(Eq.3)}$$

Data were subjected to ANOVA, normality was checked using the graphical method in Statistical Package for the Social Sciences (SPSS). Means were separated by Duncan multiple rang test ($P \leq 0.05$). Interaction between treatment and years, as well as between cultivars and weed competition levels were observed for several parameters; therefor, results are presented by year.

Results

Weed density and biomass

The dominant weed species in both years were Turnipweed (*Rapistrum rogosum* L.), Bindweed (*Convolvulus arvensis* L.), common lambsquarters (*Chenopodium album* L.) and red root pigweed (*Amaranthus retroflexus* L.). The cultivars effect was significant for weed density and weed biomass in both years (*Table 3*).

Table 3. *ANOVA for the effect of potato cultivar on weed density and weed biomass*

Source of variation	Mean Square (MS) values			
	2015		2016	
	Weed density		Weed biomass	
Cultivar	94**.3136	4484.41*	11**.154127	**02.10030
Error	867.30	3257.01	23772.97	3657.48
C.V. (%)	43.93	44.71	2.58	30.74

**,* significant at the p≤0.01 and p≤0.05, respectively

Results showed that weed density ranged from 15.6 to 128.9 plant m^{-2} in both years depending on potato cultivar. In both years Satina and Natascha cultivars had the lowest weed density so weed density was lower than 25 plant m^{-2} (*Table 4*). Caesar and Hermes cultivar had the highest weed density. Weed biomass ranged from a minimum of 224.38 for Satina to a maximum of 998.96 for Caesar (*Table 4*). Natascha had consistently a minimum value for weed density in both years. Some cultivars differed substantially in weed biomass among years. For example, Satina, Natascha and Banba had higher ranking in 2015 compared to 2016. Kennebek, Satina, Markies and 397097-14 had higher ranking for weed biomass in 2016 compared to 2015. Results showed that in 2016, all cultivars significantly had less weed biomass. So this may be due to more rainfall in 2016. Regarding the average throughout both year, the highest and the lowest weed biomass was observed in Caesar and Satina cultivars, respectively (*Table 4*).

In each column, means followed by the same letter do not differ significantly according to a Duncan test performed at $p \leq 0.05$

Potato yield and yield loss

The cultivars effect was significant for potato yield in both years, except for yield in weed free plots in 2015 (*Table 5*). In weed free plots, tuber yield ranged from 29.58 t ha^{-1} for Kennebek cultivar to 57.06 t ha^{-1} for Satina cultivar in 2015 compared with 24.44 t ha^{-1} for Difla cultivar to 38.64 t ha^{-1} for Satina cultivar in 2016 (*Table 6*).

Table 5. *ANOVA for the effect of potato cultivar on yield and competition indices*

Source of variation	2015				2016			
	Yield weed free	**Yield weedy**	**CI**	**WITI**	**Yield weed free**	**Yield weedy**	**CI**	**WITI**
Cultivar	325.730^{ns}	459.517**	2.08**	1.01**	65.303*	56.930*	0.56*	0.17^{ns}

C.V. (%)	45.40	87.28	49.77	49.25	57.17	47.18	45.63	38.22

**,* and ns: significant at the $p \leq 0.01$ and $p \leq 0.05$ and non significant, respectively

In weedy plots, tuber yield ranged from 24.33 t ha^{-1} for Hermes cultivar to 55.56 t ha^{-1} for Satina cultivar in 2015 compared with 19.27 t ha^{-1} for Hermes cultivar to 34.53 t ha^{-1} for Satina cultivar in 2016 (*Table 6*). Satina and 397097-14 cultivars had the highest tuber yield in weedy and weed free plots in both years, so their yield loss was down to 9%. In 2015 year, yield loss of Kennebek cultivar was about zero, but it's yield was low too (*Table 6*).

Weed competition indices

The cultivars effect was significant for CI and WITI in both years, except for WITI in 2016 (*Table 5*). Values for CI ranged from 0.31 to 3.15 in 2015 compared with 0.54 to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88358845

1.88 in 2016. Results showed that Satina had the highest CI in both years followed by 397097-14 cultivar, so in both cultivar weed biomass were lower and tuber yield was more than the rest (*Tables 4 ,6 and 7*).

Values for WITI ranged from a minimum of 0.36 for Caesar to a maximum of 2.16 for 397097-14 cultivar in 2015. 397097-14 and Satina had higher ranking in this year (*Table 7*). There were no significant variety for WITI value within cultivars in 2016 (*Table 5*).

In each column, means followed by the same letter do not differ significantly according to a Duncan test performed at $p < 0.05$, $p < 0.01$

To aid in the interpretation of results, potato cultivars were categorized as highly, poorly, and intermediately competitive. Since the lowest weed density, weed biomass, yield loss, and the highest competitive index were recorded in satina in both years (*Tables*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88358845

6 and 7) this may be considered highly competitive. Casear and Hermes had the highest weed characteristics and yield loss and the lowest competitive index in both years (*Tables 4, 6 and 7*) thus these may be considered poorly competitive. The rest were not classed as poorly or highly and were considered intermediately competitive (*Figures 1 and 2*).

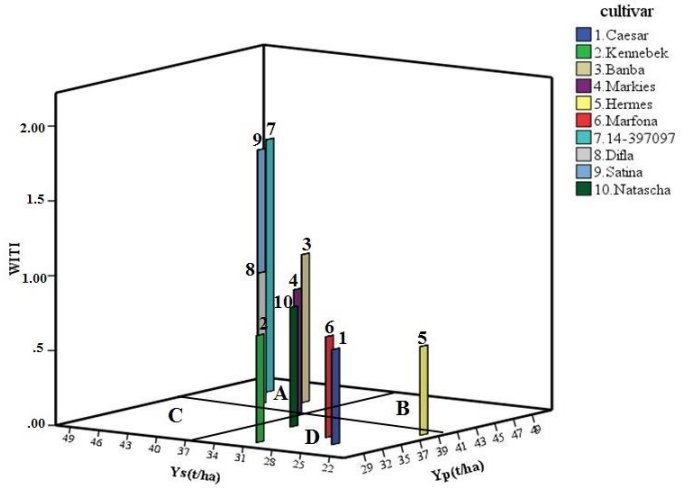

Figure 1. *Three dimensional diagram of WITI index for 10 Potato genotypes based on Potato yield (t ha^{-1}) with weed (Y_s) and without presence of weed (Y_p)*

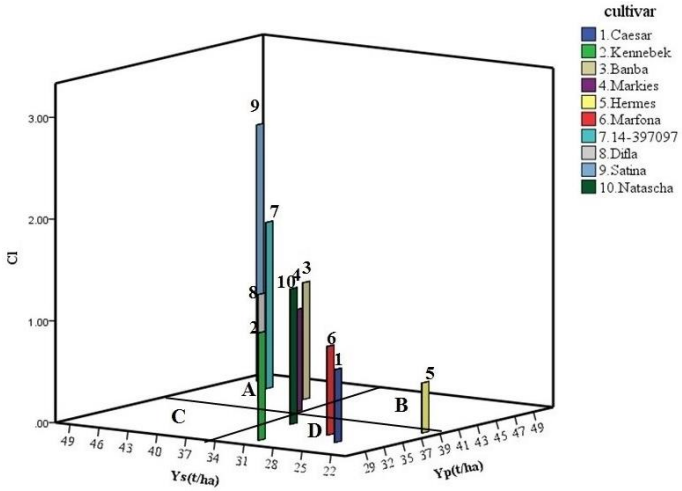

Figure 2. *Three dimensional diagram of CI index for 10 Potato genotypes based on Potato yield (t ha^{-1}) with weed (Y_s) and without presence of weed (Y_p)*

Discussion

Cultivar competitiveness can be expressed as the ability of a cultivar to maintain yield when grown in the presence of weed and can be measured by weed interference tolerance index (WITI) or as one that is able to suppress weed growth, which is measured by competitive index (CI) (Watson et al., 2006). These are important in different production systems. For example, WITI is more suitable for conventional production systems, where

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88358845

herbicides are used. While in organic systems, CI is important to minimize seed return. However, the relationship between these aspects has not been addressed in potato. In this study, the potato cultivars differed significantly in the suppression weed growth. High CI in Satina caused to reduced weed density and weed biomass and allowed minimizing yield loss. This is in agreement with Watson et al. (2006) who reported barley yield loss and reduced weed seed return when high competitiveness barley cultivars were grown. It has been reported that weed biomass differ through potato cultivars (Nelson and Thoreson, 1981; Love et al., 1995; Khalegi et al., 2007; Hutchinson et al., 2011). Although, Conley et al. (2001) and Colquhoun et al. (2009) reported no differences in weed biomass with six potato cultivars.

Our results showed that Satina cultivar had high CI and, while 397097-14 cultivar had high WITI. Jordan (1993) and Lemerle et al. (2001) stated that CI and WITI might not necessarily be present in the same variety. WITI and CI are traits that differ both genetically and agronomically. CI is often associated with traits including vigorous growth, allelopathic potential, large seedling ground cover, height, canopy structure and overall leaf area (Hansen et al., 2008). 397097-14 is a new cultivar and Satina is an old (released 1971) cultivar. Murphy et al. (2008) reported that modern wheat cultivars were competitiveness than older cultivars. In other words, there is no trade-off among yield and competitive ability.

Potato yield and weed biomass for all cultivars was relatively greater in 2015 than in 2016, this difference between years in weed biomass as well as yield could have been caused by a relatively early rainfall in the seasonal growing conditions in 2015 than in 2016. According to various studies, potato responds to improved moisture conditions (Mazurczyk et al., 2009; Rolbiecki et al., 2009; Zaski, 2011; Karanja et al., 2014).

Conclusion

Potato cultivar competitive ability has a substantial range and can be an important IWM tool or it can be used in conjunction with other IWM tools such as yield loss thresholds and reduction of herbicide hazards. Satina and 397097-14 had highly competitive abilities and can be used in sustainable systems.

(Received 13th Mar 2019; accepted 24th May 2019)

Abstract. The main objective of this study was to analyse the shade effect on development, productivity and excellence of grape fruits (*Kishmishi* seedless). To attain this, three sun (AM sun, PM sun, Full sun) treatments was linked with those plants growing in three shade treatments (50% shade, 80% shade and 100% shade). Different physical, chemical, ecological and quality factors were evaluated under six diverse treatments. Results showed that 50% shade plant stimulated differences in physiological attributes such as enhanced photosynthesis and augmented leaf area index (LAI), resultant in improved performance than conceivable in direct sun light. Accordingly, grape plants grown under 50% shade produced greater quantity (number) of fruits for example 10,350 individual fruits/plant and greater fruit weights (49 and 12 g fresh and dry weight/fruit respectively) with better fruits quality, than those grown in direct sun light or in 80% and 100% shade. Moreover, 50% shade plants had greater biochemical (nutritional, minerals and vitamin contents) and physiological attribute improvement i.e. greater fruit weight and fruit length which would benefit grower to uphold great grapes yields in long term. Fruit quality assessment (FQA) was calculated and evaluation classes indicated that the 50% shade plant score highest grade point (5) and stood in very good class, followed by AM and PM sun with grade point 3.0 and categorized in moderate class. Other three treated plants (Full sun, 80 and 100% shade) score 2.0 and 1.0 grade points and classified into poor and very poor classes, respectively.
Keywords: *Kishmishi seedless grapes, environmental variables, nutritional, minerals, vitamins and fruit quality assessment*

Introduction

Plant ability to adapt to varying light can be used to change growing circumstances and has the ability to increase crop incomes of primo cane varieties in semi-arid environmental region. The quantity and concentration of light has an important effect on plant growth and development. The quantity of light absorbed by the leaves superficial area as well as the distribution of light influences crop yield. Alkalai-Tuvia et al. (2014) stated that the light excellence and diverse wave length alters fruit color and maturity of fruits. Shade and sunlight are vital feature for plants growth, expansion and physiological characteristics. Two facts to be deliberate for the influence of light on fruits crop comprised: the capture of existing light on plant and the delivery of light

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88478864

inside plant that outcomes in supreme recital and crops development (Rom, 1991). Ahmed et al. (2016) stated that reducing the absorbance of solar radiation under shade decreases the covering and air temperature as well as transpiration rate in the greenhouse. This therefore decreases the water intake through around 50%, enhances water use efficiency and increases the crop efficiency up to 40%. Approximately consequences of shade on plant growth comprised: plants defence from birds, wind and hail, influence on ecological features (humidity, light and temperature) and augment subtle light that may absorb specific light wavelengths; all of which is subjected to plants growth and development (Stamps, 2009). Alkalai-Tuvia et al. (2014) and Mashabela et al. (2015) reported that the fruit produced in pearl nets shade showed greater fruit weight, pigment contents, ascorbic acid contents and anti-oxidant action. Vendrame et al. (2004) and Jeong et al. (2009) designated that light concentration can affect plants form, flowering, leaf size in both herbaceous and also woody species. Additionally temperature and light can have direct optimistic associations. As light level augmentes beyond of 600 $\mu mol \bullet m^{-2} s^{-1}$ and soil and air temperature exceeded 16 °C and 24 °C, primo canes entered a state of bud dormancy, decreased fruit weight as well as quality (Oliveira et al., 2004). Stamps (1994) documented, that decrease in radioactivity give rise from diverse netting might affect temperature of the environmental air, soil and plant and impact the relative humidity inside shaded structures. This tinted the need for additional investigation to be conducted for the best strength and application of shades to get desired fruit setting and fruits superiority of primo canes. Assumed its complication there are several deliberations that requires to be assessed when determining influences of shade and light on plants growth, development and biological replies. The use of photo selective nets technology is gaining popularity everywhere in the world. This exercise is already general in Europe, particularly in Israel (Fallik et al., 2009; Kong et al., 2013) and other Mediterranean countries (Diaz-Perez, 2014) and in South Africa (Mashabela et al., 2015; Selahle et al., 2015). The usage of shade nets has also become very popular in Serbia due to very high (35–40 °C) temperature in summer season (Ilic et al., 2011, 2015; Milenkovic et al., 2012).

Grapes (*Vitis vinifera* L.) is one of the most cultivated fruit crop not only in the study area but also all-over the world. It have its place in the family Vitaceae and mostly distributed in Asia (app. 40 species), North America (40 species) and Europe (one species) in subtropical, Mediterranean and continental-temperate climatic condition. *V. vinifera* is the only species that attained important commercial attention over time. For agriculturalist's fruits production is a great energy concerning process that offer a wide range of difficulties that could decrease cost-effectiveness and return on investment. Fruits development is a significant feature of cultivation by economic and environmental impacts in the study area (District Mastung, Balochistan, Pakistan). Grapes are usually found growing in full sun. Though, there is no published report about the degree of shade tolerance of these species. Many studies on *Vitis vinifera* L. have been reported on gas exchange (Poni et al., 2014), water-use efficiency (Ghaderi et al., 2011), biochemical changes (Beis and Patakas, 2015), road side dust pollution effect on the growth and total chlorophyll contents in *Vitis vinifera* L. (Leghari et al., 2014), air pollution effect on the leaf morphology of *Vitis vinifera* L. (Leghari and Zaidi, 2013) and biomass distribution (Xiao et al., 2006), in addition to yield and fruit quality (Romero et al., 2015) response to different degrees of drought stress has also been reported. No comprehensive study about the influence of sun and shade on grapes of area has yet been reported. Therefore this investigation aims to calculate in what way

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88478864

diverse ecological controlled conditions of sun and shade treatments might affect plant growth parameters, productivity and quality traits in economically important fruit crop (Grapes) that is frequently cultivated in study area.

Materials and methods

Study area

In order to evaluate the influence of sun and shade on fruit plant i.e. grapes (*V. vinifera)* plants were grown during April 2017-2018 in the open field. The trials started from April 2018 – October 2018 in an experimental plot situated in the village of district Mastung Balochistan, Pakistan. Geologically, study area district Mastung is hilly area comprising of a sequence of parallel mountains range in north and east, with elevation varying from 934 to 3414 m. a.s.l. and located at 29.8° north latitude, 66.85° east longitude. Soil of the area is mostly calcareous and clay loam and are abstemiously deep thereby reflecting it to be appropriate for agriculture. The average maximum, average minimum and overall average temperatures of the area was noted 44.0, 21.5, and 32.2 °C, respectively (*Table 1*). Mastung district is deliberated as one of the original grapes producing areas of the Balochistan province.

Table 1. *Meteorological data of the study area during growing months (April 2018 – October 2018), study year and last 5 year average data*

Variables	Ave. study period	Study year	Last 5 year ave.	LSD (0.05)
Max. Ave. Tem. (°C)	42.71	34.1	33.1	**0.53**
Min. Ave. Tem. (°C)	19.67	8.3	7.2	**0.04**
Overall Ave. Tem. (°C)	30.8	29.0	28.5	**0.23**
Humidity (%)	25.43	30.4	51.5	**0.01**
Rainfall (mm)	6.47	8.12	106.4	**0.02**

Each value is the mean of three replicates. Ave: average, Max: maximum, Min: minimum

Plant material and field plots

The regional well-known and commercially important grape (*V. vinifera*) variety i.e. *Kishmishi* (seedless) were grown in six lights and shades treatments including: full sun; morning full sun (AM sun); afternoon full sun (PM sun); and 50% shade, 80% shade and 100% shade. Each plot was 7.3 x 1.5 m. Boundaries (1.5 m tall) were constructed of chipboard on the east or west side of the AM sun or PM sun plots, respectively. To retain plant in shade as noon loomed, 0.3 m chipboard overhangs were involved upright to the top of the boundary. Shaded cloth canopies were built above plot to give light intensity level of 50% shade, 80% shade or 100% shade. Each canopy was made with dispersal over a row of seven 1.5 m tall and 1.8 m wide arches. Each arch was prepared with drubbing two 0.5 m length of 1.27 cm EMT channel into the ground, sliding a 1.8 m length of 1.9 cm polyvinyl chloride (PVC) pipe over each piece of channel and then linking PVC pipe at the apex with a 90° elbow connector (All the sun and shade tunnels were locally made) as used by Stanton (2010).

Experimental design and analysis

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88478864

The trial was arranged in a split-plot design. Six light and shade treatments were the main plots with grapes plants. Every individual set of 6 sun and shade treatment plots was randomized within one of 16 blocks. There was one replication plant per block. So there was a total of 16 replicates for each genotype treatment level as the method used by Stanton (2010). Plant height at implanting time was 35.8 ± 2.30 cm with no significant variations between ecotypes of either species. The plants were grown following the technique usually implemented by the local producers. All the experimental plots were treated with uniform fertilizer and water. During planting year, a total of 0.5 to 1 ounce of nitrogen (N) fertilizer was applied to each plant, depending on soil fertility. In the second year, plants were fertilized with 1 to 1.5 ounces of N per plant. Transmission of fertilizer was done in a circle about 6 to 18 inches from the trunk. The plants were properly watered to found the soil type and climatic condition and kept the soil sufficiently moist without overwatering and gradually decreased watering in mid to late summer. To control different diseases herbicides (2, 4-D) and fungicides (sulfur) were used and to minimize different pests, traps were applied. Only the plants growing vigorously in April 2018 were used for data collection in each treatment. All measurements were conducted in April 2018 and all values presented are averages of untransformed data.

Environmental variables measurements

Light intensity (lux), air temperature relative humidity (%) and soil temperature at a depth of 10-15 cm were measured by a handheld light meter, thermos-hygrometer and soil thermometer, correspondingly from each treatment. The light sensor was held 1.0 - 1.5 m above soil level in each treatment plot. Interpretations were taken at midday and 3 and 6 h earlier and later midday (*Table 2*).

Table 2. *Averages environmental variables under sun and shaded treatments*

Variables	Treatments						LSD (0.05)
	AM sun	PM sun	Full sun	50% shade	80% shade	100% shade	
Air temperature (°C)	28.0	30.0	31.6	30.4	27.5	25.4	0.14
Soil temperature (°C)	20.1	24.2	25.4	24.0	22.5	22.0	0.04
Relative humidity (RH %)	23.0	23.5	21.0	23.0	25.0	27.0	0.15
Light intensity (lux)	811	1030	1250	842	652	610	14.0

Each value is the mean of three replicates

Plant growth variables measurements

Freshly mature, completely extended leaves (90) were detached from each treatment plants for leaf area parameters measurement and photographed. The Leaf area (LA) was determined by the digital image using Image J 1.38x software and graph paper method at the laboratory of botany department university of Balochistan, Quetta and then average was worked out (Leghari and Zaidi, 2013). Plants Leaves were then dried at 70 °C to get leaf dry weight (DW). Specific leaf area (SLA) was calculated as:

$$SLA = LA/DW \quad \text{(Eq.1)}$$

For relative growth rate (RGR, cm cm^{-1} $month^{-1}$) primary pleiotropic branches were selected, their length was measured at the beginning and at the end of the trial.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88478864

Pigment analysis

Chlorophyll a & b, total chlorophyll, carotenoid, ratio between chl. a & b, and ratio between total chl. and carotenoid were measured from fresh leaf samples. 2 g of fresh leaves from each treatment were ground in acetone (90% v/v), filtered the extract and made up to final volume of 50 mL. Pigment concentrations in mg g^{-1} fresh weight (fw) were calculated [absorbance (A) of extract at 663, 648 and 470 nm) by the methods described by Lichtenthaler (1987).

$$\text{Chlorophyll a} = [(11.75A663 - 2.35A\ 645) \times 50] / 500 \quad \text{(Eq.2)}$$

$$\text{Chlorophyll b} = [(18.61A645 - 3.96\ A663) \times 50] / 500 \quad \text{(Eq.3)}$$

$$\text{Carotenoids} = [1000A470 - (2.27 \times \text{Chl a}) - (8.14 \times \text{Chl b}) / 227 \times 50] / 500 \quad \text{(Eq.4)}$$

$$\text{Total Chlorophyll} = \text{Chl a} + \text{b} \quad \text{(Eq.5)}$$

Measurement of Chl. fluorescence from leaves at different time intervals

All dimensions of Chl. fluorescence were made by a moveable PAM-2000 fluorimeter (Walz, Effeltrich, Germany). Earlier to the each dimension, the sample leaves were dark adapted for 30 min by leaf-chips. Throughout the trials the position and space from the leaf surface to the end of optic-fiber cable were set aside continual. For initial fluorescence (F0) measurement the weak measuring light was turned on and F0 was noted. To get the maximum fluorescence (Fm) the sample leaf was visible to a 0.1 s saturated flash of about 6000 lmol/m^2/s. the ratio of variable to maximum fluorescence (Fv/Fm) was intended automatically rendering to F0 and Fm calculated [Fv/Fm ¼ (Fm) F0)/Fm]. All dimension of Fm were done by the measuring beam set at a frequency of 600 Hz. Leaf chamber poro-meter (LCpro +) was used to determine the transpiration rate (E, mmol m^{-2} s^{-1} of water vapour), stomatal conductance (Gs, mmol m^{-2} s^{-1} of water vapour or CO^2), Photosynthetically Active Radiation (PAR, µmol photons m^{-2} s^{-1}) and leaf temperature (LT, °C). These factors were measured from five complete, new and completely prolonged leaves on third and fourth pairs from top of each treated plant. These leaves were exposed to a period of dark adaptation for 25 min and then visible to a light pulse of high intensity (2000 µmol photons m^{-2} s^{-1}) by means of chlorophyll fluorimeter (OS-30P) to measure chlorophyll fluorescence, representing the electron transport efficiency of photosystem II (PSII). Chlorophyll fluorescence is shown as the Fv/Fm ratio (no dimension) as a degree of relative quantum yield. Moisture contents were determined by Association of Official Analytical Chemists (AOAC, 1995) procedures. It was done by drying 5.0 gm grapes fruits sample from each treatment in vacuum at 70 °C to continuous mass and moistness was intended a gm water g-100 samples. Color difference meter was used to measure the fruit color and the dimensions were done on 10 separate fruits per replicate (Aleid et al., 2014).

Yield variables

Number Cluster arising from the main stem and fruit density per cluster were counted from 5 randomly nominated plants from each treatment at the end of growing season and lastly pooled to become the number of fruits per plant and average was calculated. Fruit length and diameter was intended from 30 randomly chosen fruits of each plant from each

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88478864

treatment. The length of each fruit was noted from base of fruits to the tip and diameter (cm) was measured from the centre of each fruit with the help of Vernier Calliper and the average length and diameter of fruit was computed and represented in centimetre. Average weight of fresh and dry fruits were recorded by using electrical balance. The mean of 30 fruits from each site was worked out and expressed in grams.

Total soluble solids (TSS) measurement

Completely mature grape fruit samples were collected from each treatment. Each fruit sample was cut into small pieces and homogenized in a conventional blender in order to obtain the fruit juice. Then, the fruit juice was filtered by using the whatman filter paper no 4. The filtrate was utilized to measure the total soluble solids (TSS). TSS were determined for each fruit samples in three replications using an Atago DR-A1 digital refractometer (Atago Co., Japan) at 20 °C and shown expressed as %. Moisture and fat free samples were analyzed for their Protein, Dietary fibre (DF) and sugar. The Protein content was determined according to method of AOAC 985.29 (1984) and Sowbhagya et al. (2007). The DF contents were recorded by enzymatic and gravimetric method of the Association of Official Analytical Chemists (AOAC) and (Prosky et al., 1988), by the utilization of TDF-100 kit. Beside the test sample, and blank and reference samples were also analyzed at the same time in triplicate for contrast. Carbohydrates were measured with the difference from the total dietary fiber, lipids, protein and ash contents (Chau and Huang, 2003). Sugars level from soaked grapes fruit were measured by water at 85 °C and it was calculated through 3, 5-dinitrosallicylic acid method as designated by Laurey (1997). Overall sugar (Sucrose, glucose, and fructose) contents were noted by high performance liquid chromatography (HPLC) according to the methods of AOAC (1995). Grapes fruit sample were spiked with several mixtures of average sugars (1-5 ppm) to display recovery and the sugar level was noted from highest area of dimension according to the method of Langemeier and Rogers (1995). Contents of the various fruits analyzed were calculated and expressed on fresh weight basis. Various Minerals (Calcium, Iron, magnesium, manganese, phosphorus, potassium, Zinc and Fe) contents were determined through atomic absorption spectrophotometer and expressed by mg/100 g. Different vitamin (B6, E and K) and Ascorbic acid content of fresh fruit were determined by spectrophotometric methods as the method used by Isam Eldin et al. (2017). Potassium permanganate was used as a chromogenic reagent. The absorbance was measured spectrophotometrically at 530 nm. For acidity measurement the pH of fruit juice was noted with a pH meter (model 725p, Istek Co., Seoul, Korea).

$$\text{Acidity (\%)} = [(\text{ml of 0.1 N NaOH}) \times (\text{N NaOH}) \times 0.067 \text{ (malic acid coefficient)} \times 100] / \text{ml sample} \quad \text{(Eq.6)}$$

Fruit quality assessment (FQA)

Raw quality (shape and make, colour and odour, size of fruit, no of fruit per plant) of different sun and shade treated grapes fruits was valued on a scale starting from 1, the minimum value (indicating small shape and make, brownish color and strong/odd odour) to 5, the maximum value (indicating very good shape and make, bluish color and clean odour). Liquor quality (acidity, taste and flavour) was tested by a panel of six experienced judges and values were given from 1, the minimum value (indicating lacking acidity, thin body and poor taste and flavor) to 6, maximum value (indicating

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88478864

pointed acidity, full taste and very good flavour (unit for both raw and liquor qualities: percentage of score) (Prajapati and Tripathi, 2008; Leghari et al., 2019).

Fruit performance index (FPI) evaluation through fruit quality assessment

For the grapes plant fruit performance index the methods described by Leghari, et al. (2019) and Prajapati and Tripathi (2008) was used. FPI values were calculated by combining the Raw quality fruits and Liquor quality fruits under different sun and shade treatments grapes fruit grown based on character grading (+ or -) fixed to the plant. The principles intended for FPI are specified in *Tables 9* and *10*.

Data analysis

All the collected data was subjected to analysis of variance (ANOVA) using Co-Stat version 6.400 (1998-2008, Co Hort Software). Mean separation was done using the least significant difference test at 0.05 significance level.

Results and discussion

This investigation was not deliberate to measure the hereditary change for light and shade acceptance in the examined species nor it was done to compute the heritability of characters. Nevertheless, the plant species under contrasting natural environments able to change for adaptation to shades and light (Johnson and Cartwright, 2005). In the current investigation there was a fruit crop (grape plant) source-by-treatment dealings and all the results are presented in *Tables 2-10* and *Figs. 1A-F* and *2*.

Meteorological data indicated that the maximum and minimum average temperature in study area during study period and last 5 year average was found 42.71, 34.1 and 33.1 °C and 19.67, 8.3 and 7.2 °C, respectively. Humidity % age was recorded 25.43, 30.4 and 51.5, respectively and Rainfall was found only 6.47 mm and 8.12 mm throughout the study period and study year respectively and last 5year average was 106.4 mm. Significant difference were observed between the periods (study period and study year and last 5 year average) at 0.05 significance level (*Table 1*). Air and soil temperature and light intensity was recorded between 25.4-31.6 and 20.1-25.4 °C, 610-1250 lux, respectively. Maximum air and soil temperature and was found in full sun treatment and minimum in 100% shade and AM sun, respectively. The maximum relative humidity and light intensity was recorded in 100% shade and full sun, while the minimum was found in full sun and 100% shade treatment, respectively. All the investigated variables (air and soil temperature, relative humidity and light intensity) in six different sun and shade treatment were pragmatic significantly different (*Table 2*). Soil temperature shows a very serious role in existence of numerous entities, however in reaction to exchange processes which occur by the soil surface differs. The decrease in soil temperature, noted in 100% shade, was mostly because of the ability of shade soil to steady the native warm air equilibria, the less soil temperature under shade was also noted by Morais et al. (2006). Decreased air temperature noted for grapes plant grown under shade was in agreement with the results reported by Campanha et al. (2005) as they determine that decreased air temperature was mostly due to the reduced straight incidence of solar radiation on coffee canopies. Siebert (2002) also reported that shading decreases soil temperature by decreasing radiant flux reaching the soil and amending the temperature sufficiently at the soil surface thereby shielding the harsh

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88478864

temperature and delivers a microclimate which alleviate harsh effect of high temperature of soil and air and conserves soil surface humidity.

Current study revealed that the average leaf area (ALA), specific leaf area (SLA), leaf area index (LAI), relative growth rate (RGR) and leaf color in different sun and shade treatments (AM sun, PM sun, Full sun, 50%, 80% and 100% shades) were found in ranged between 27.38-34.7 cm^2, 86.2-107 cm^2/g, 2.8-4.2 m^2 m^{-2}, 10.8-16.8 cm cm^{-1} $month^{-1}$ and -9.8 to -5.7, respectively. The maximum ALA, SLA, LAI and RGR was noted in plant grown under 100% shade, while the minimum was in full sun treatment. Least significant difference (LSD) test indicated that all the plant growth variable (ALA, SLA, LAI, RGR and leaf colour) showed significant variation under different sun and shad treatments at 0.05 significant level (*Table 3*). The variation in ALA, SLA, LAI in different sun and shade treatments were also reported by other researchers (Bote and Struik, 2011; Ilić, 2017) they found differences in leaf parameters in different shade nets. Li et al. (2005) reported that the plant having higher SLA showed greater production and have greater possible RGR than those observed by Poorter and Werf (1998). Robakowski et al. (2003) observed that as the light intensity increased the SLA decreased. In our experiment, lesser SLA was observed from grape plants grown under full sun treatment, which is comparable to the results of Bote and Struik (2011). For 100% shaded grape plants, the increased SLA and the formation of a darker green color were mostly accredited to the higher nitrogen contents found in their leaves. It is probable that the larger SLA and the development of dark green leaf color in shade treatment partially contributed for the higher rate of photosynthesis observed in this condition. McNaughton and Jarvis (1983) reported that greater LAI observed for coffee plants growing in shade designated that these plants have greater possibility for CO_2 integration and dry matter manufacture than un-shaded plant.

Table 3. *Plant leaves and growth variables in response to the sun and shade*

Variables	Treatments						LSD (0.05)
	AM sun	PM sun	Full sun	50% shade	80% shade	100% shade	
ALA (cm^2)	30.24	29.8	27.38	30.57	32.42	34.7	0.12
SLA (cm^2/g)	91.31	90.1	86.2	92.2	96.1	107	0.05
LAI (m^2 m^{-2})	3.0	3.3	2.8	3.2	3.9	4.2	0.02
RGR, (cm cm^{-1} $month^{-1}$)	12.4	12.2	10.8	12.7	14.7	16.8	0.05
Leaf color (value on greenness scale)	-6.1	-6.0	-5.7	-7.2	-8.7	-9.8	0.01

Each value is the mean of three replicates. ALA = average leaf area, SLA = specific leaf area, LAI = leaf area index and RGR = relative growth rate

Photosynthetic pigments including Chl a, b, total chl. and carotenoid contents in the plant leaves of different sun and shade treatments (AM sun, PM sun, Full sun, 50%, 80% and 100% shades) were noted and ranged 1.24-2.47, 0.55-0.85, 1.79, 0.42-0.75 mg/g fw, respectively. The maximum chl a, b, total chl and carotenoids were found in plants grown in 100% shade and minimum in full sun. Statistical analysis of variance showed that all the photosynthetic variables were significantly different among treatments (*Table 4*). Generally shaded leaves have greater total chlorophyll (chl. a & b). Similar observation was recorded by Zoran et al. (2017). They found greater total chlorophyll than the leaves from control plants. Shade growing leaves contain highest

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88478864

chlorophyll than the leaves exposed to direct sun. Although shaded leaves were not directly exposed to the sunlight they produced additional chl. to capture diffuse radiation to produce the carbohydrates needed for plant to grow. Alkalai-Tuvia et al. (2014) reported that chl. contents of pepper fruits grown under pearl net was significantly higher than that of fruits grown under the black net.

Table 4. *Photosynthetic pigments (mg/g fw) in grapes leaves in response to sun and shade treatments*

Variables	Treatments						LSD (0.05)
	AM sun	PM sun	Full sun	50% shade	80% shade	100% shade	
Chl a (mg/g fw)	1.89	2.0	1.24	1.56	2.21	2.47	0.08
Chl b (mg/g fw)	0.72	0.7	0.55	0.61	0.75	0.85	0.05
Car (mg/g fw)	0.62	0.6	0.42	0.51	0.71	0.75	0.02
Total Chl (mg/g fw)	2.61	2.7	1.79	2.26	2.96	3.32	0.12

Each value is the mean of three replicates: Chl = Chlorophyll; Car= Carotenoids

No. of clusters/plant, No. of fruits/cluster and No. of fruits/plant, in different sun and shade treatments (AM sun, PM sun, Full sun, 50%, 80% and 100% shades) were found in the ranged; 30-45, 160-230, 4960-10350, respectively. All these parameters were noted maximum in 50% shade which followed by full sun, PM sun, AM sun and minimum was in 100% shade. Variation in average fruit length, fruit diameter and average fresh and dry fruit weight (1.60-1.90 cm, 1.27-1.64 cm, 31.7-49.4 g^{-30} and 7.11-12.69 g^{-30}, respectively) were also noted in different treatments. Statistical analysis indicated that all the investigated Yield parameters were significantly different among treatments at 0.05 significance level (*Table 5*). The variation in fruits production and fruit size in different sun and shade treatments was also observed by Bote and Struik (2011). They found weightier and bigger coffee beans that was chiefly influenced by temperature and ripening period. The grapes plants found in direct sun light were grown in environmental conditions that are more likely to lead to plants stress responses, compared with the environmental conditions under which shaded plants are grown. Muschler (2001) who originate similar results, designated that coffee bean size profoundly and reliably increases with increasing shade levels. Similarly, the shade effect on juice taste was also the result of delayed fruit maturation and ripening. Observation recorded by Ilić (2017) are in agreement to the present results. Number and quality of fruit decreases by increasing shade and light level. In Serbia, bell pepper grown in colored nets with 40% or 50% shade had greater total yield as compared to unshaded plants (Ilic et al., 2011). Santana et al. (2012) observed greater yield and better fruits quality for sweet pepper variety grown in photo-selective (red and blue) shading net houses as compared to those obtain from open field. According to Fallik et al. (2009), the peppers grown in arid region under red and yellow shade-nets (30% relative shading in PAR) had a meaningfully higher yield compared to the black nets of the same shading factors, with no effect on fruit size. Miller et al. (2015) reported that the time of shading obviously exaggerated yield by full shade causing the highest reduction as compared to the partial shade. Vaast et al. (2008) reported that the vegetative development has shown to respond to shade intensity as shown in higher vegetative growth under dense (60%) shade in *Terminalia ivorensis* compared to lighter shade (30 to 40%) in *Eucalyptus deglupta.*

Each value is the mean of three replicates

Data regarding photosynthetic variables (Fluorescence ratio (Fv/Fm), ratio between Chlorophyll a & b, ratio between total Chl. and Carotenoid) in different sun and shade treatments including AM sun, PM sun, Full sun, 50%, 80% and 100% shades were found different, which were in range between; 0.57-0.86, 2.25-2.95, 4.17-4.50, respectively. Stomatal conductance, Transpiration rate, Photosynthetically Active Radiation and Leaf temperature) in different sun and shade treatments including AM sun, PM sun, Full sun, 50%, 80% and 100% shades were found statistically different, which were in range between 60-112 mmol m^{-2} s^{-1}, 910-1220 mmol m^{-2} s^{-1}, 344-2280 µmol photons m^{-2} s^{-1} and 23-30 ºC, respectively. The maximum fluorescence (Fv/Fm) ratio, ratio between Chl. a & b, and ratio between total Chl. and Carotenoid, Stomatal Conductance, Transpiration rate, Photosynthetically Active Radiation and Leaf temperature, was found in 50% shade plant and minimum was recorded under 100% shade (*Fig. 1 A-F*). The higher Fv/Fm ratio noted in 50% shade grape plant exhibited the facts that these plants were less stress by the high level of light intensity than those grown in full sun light. Sethar et al. (2002) supported this view indicating Fv/Fm ratio decreases significantly when plant were exposed to the heat stress. The plants grown in full sun or higher irradiation and 100% shade decreased value of Fv/Fm ratio is an indication of the damage of a proportion of a PSII reaction centres this phenomenon called photo-inhibition. Light energy is essential for photosynthesis which is necessary for the plant life. However the excess light can inhibit photosynthesis and lead to photo-oxidative damage of photosynthetic apparatus, thereby reducing the photosynthetic rate of the plant growing in direct sun light (Li et al., 2010). According to Fahl et al. (1994) and Ramalho et al. (2000), the greater value of Fv/Fm observed in shaded leaves might be connected with higher leaf nitrogen contents. Observations recorded by Wang et al. (2017) are also in the agreement to the present results. They found important effect on Light intensity had significant influence on stomatal conductance, transpiration rate and leaf photosynthetic rate, light compensation point and light saturation point (Bellasio and Griffiths, 2014; Li et al., 2007; Ubierna et al., 2013). Therefore, the study of light stress, especially weak light stress, has important practical significance for the maize production.

Ascorbic acid (vitamin C), total sugar, dietary fibre, protein and carbohydrates contents in the fruits of grape plant grown in different sun and shade treatments (AM sun, PM sun, Full sun, 50%, 80% and 100% shades) were found in ranged between 2.0-2.85 mg/100 ml, 13.30-20.04 g/100 g, 0.8-1.94 g/100 g, 0.61-0.80 g/100 g and 17.72-22.0 g/100 g, respectively. The maximum Ascorbic acid, sugar, Protein and Carbohydrates were noted in 50% shade and minimum in 100% shade, while the dietary fibre was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88478864

highest in 100% shade and minimum was in full sun treatment (*Table 6*). Topuz-Ozdemir (2007) stated that the vitamin C/ Ascorbic acid content in pepper was affected by cultural practices (genotype and agronomic technique) and on the other hand by the abiotic factors (light and temperature) as stated by López-Marín et al. (2011). Vitamin C development in grapes is connected to glucose metabolism and light induction similarly concentrations of both vitamin C and reducing sugars typically increase as the fruit matures. The similar observation was also noted by other researcher (Ilić, 2017). Mashabela et al. (2015) reported that fruits produced in the pearl nets contain more ascorbic acid at harvest and retain more of it after postharvest storage, perhaps through delayed ripening. Moisture contents and total soluble solids in different sun and shade treated plants were found to range between 73.01-83.1% and 36.24-47.69%, respectively (*Fig. 2*). Statistical analysis indicated that all the examined nutritional variables showed significant variation between the 6 sun and shade treatments at 0.05 significance level (*Table 6*). The highest total carbohydrates was also noted by Miller et al. (2015) in partial shaded apple plant with respect to the full sun and complete shade plant. The highest moisture contents was noted in 100% shade fruits and minimum in full sun, while maximum TSS was recorded in 50% shade and minimum was in full sun (*Fig. 2*). The observations recorded by Ilić (2017) are in contradiction to our findings. He found highest level of TSS (8.03%) in pepper fruits grown in open field.

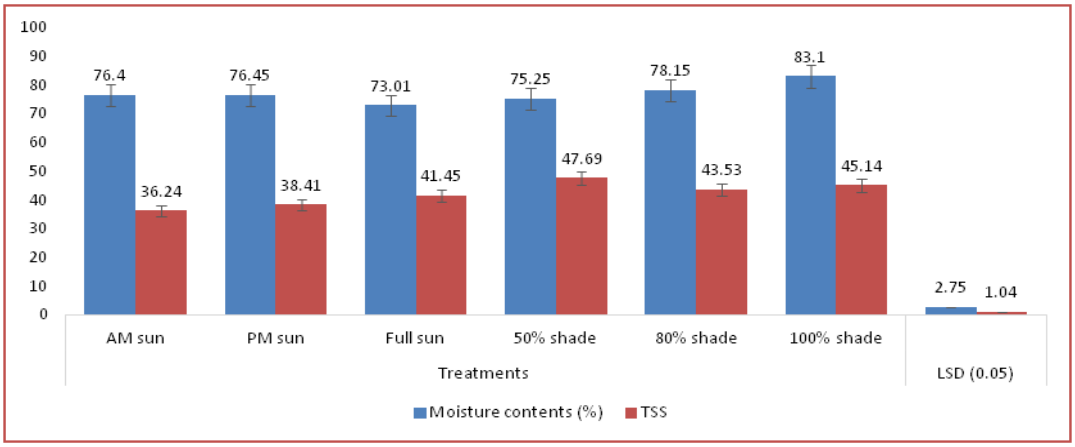

Figure 2. *Moisture contents and TSS (%) in grapes fruits grown in six different sun and shade treatments*

Tables 6. *Variation in nutritional contents in the grape fruits under sun and shade treatments*

Variables	Treatments						LSD (0.05)

Mineral contents (calcium, iron, magnesium, manganese, phosphorous, potassium, sodium, zinc and Fe) in different sun and shade treatments (AM sun, PM sun, Full sun, 50%, 80% and 100% shades) plants were found varied between 5.1-12.8, 0.21-0.41, 6.2-9.4, 0.061-0.095, 14.04-22.2, 171-199, 1.12-2.7, 0.08-0.09 and 0.095-0.65 mg/100 g, respectively. Almost all the investigated mineral contents was found highest in 50% shade treatment and minimum was recorded in 100% shade and Zinc was found almost similar in all the treatments. Statistical analysis indicated that except zinc all the other mineral were found significantly different in sun and shade treatments and on the other hand Zinc was found non-significant between the treatments at 0.05 significance level (*Table 7*). Morais et al. (2006) showed that shading enhances coffee quality, in terms of biochemical composition, including the contents of caffeine, oil and chlorogenic acid. Vitamins including B6, E and K in grapes fruits under the influence of sun and shade treatments (AM sun, PM sun, Full sun, 50%, 80% and 100% shades) were found in the ranged of 0.04-0.183 mg/100 g, 0.42-1.8 mg/100 g and 7.1-17.2 µg/100 g, respectively. Enhanced vitamin concentration was recorded in grapes grown under 50% shade and minimum in the 100% shade fruits. Significant test indicated that all vitamins showed statistically significant variations among the treatments at 0.05 significance level (*Table 8*). Variation in vitamin contents in grapes fruits might be due to environmental factor.

Fruit quality assessment (FQA)

Fruit quality Assessment (FQA) through fruit performance index (FPI) and evaluation classes indicated that the grape plant grown under 50% shade score highest grade point (5) and stand in very good category/class, which followed by AM Sun and PM sun plants with obtaining grade point (3) and fall in moderate categories, while plants of 80 and 100% shade treatment scored lowest grade points (2 and 1) falling in poor and very poor classes, respectively (*Table 9* and *10*). Many other researchers also reported best fruit quality grown under moderate shade as compared to the full sun and completely shaded plants (Stamps, 2009; Ilić et al., 2012, 2015; Morais et al., 2006). Several studies have demonstrated improvement in fruit quality and an increase in commercial fruit production due to the use of colored shading screens (Stamps, 2009; Ilić et al., 2012, 2015). Further, Morais et al. (2006) designated that the quality and size of coffee beans, and the taste of ripened beans were better under shade than in arrangements without shade trees.

Table 9. *Standard of grade point for quality (Prajapati and Tripathi, 2008; Govindaraju et al., 2012; Leghari et al., 2019)*

Valuation classes	Scoring percentage	Grade point
Not recommended	30	0
Very poor	31-40	1
Poor	41-50	2
Moderate	51-60	3
Good	61-70	4
Very good	71-80	5
Excellent	81-90	6
Best	91-100	7

Conclusion

The study concludes that grape plants grown in the 50% shade had higher biochemical and physiological potential as compared to the grape plants grown in direct sun light or under 80 and 100% shade. 50% shade grown grapes plants also produce larger, heavier and healthier fruits with better quality. Growing grapes under 50% shade trees would allow other sources of income such as fruits, fuel wood and timber to be produced, it could be socially more acceptable, economically more viable and environmentally more sustainable. We therefore recommended growing grapes under 50% shade. In addition, 50% shade plants serve as an alternative source of income for grapes producers. Nevertheless, highest yields per hectare can be obtained from grapes plants under 50%shade indicating the need for further research on determining proper plant density and the mechanism involved in all enhanced growth and physiological characteristics. On the basis of above facts and figures we support the recommendations of growing grapes under 50% shade and suggest that the future research should be directed toward deterring the development of fungal diseases and increase of grape yield under shaded conditions.

(Received 15th Mar 2019; accepted 24th May 2019)

Abstract. The aim of this study was to show the relationship between tomato plants grown in soil in different doses of animal manure (AM) and biochar (BC) obtained from hazelnut shell with some soil enzymes, C mineralization, microbial biomass and other soil properties. In this context, 0-5-10-15-20 ton/ha biochar (BC) obtained from hazelnut shell and 5-10-20 ton/ha mature animal manure were applied into the soil. The study repeating 6 times was performed in natural conditions of greenhouse according to the study design of random parcels. Some chemical soil properties (organic material, total N, available P and K) and some soil enzymes of tomato (Lycopersicum esculentum Mill) plant grown in biochar and animal manure applied-soil (dehydrogenase, urease, arylsulfatase and alkaline phosphatase) were identified. Biochar and animal manure applications increased dehydrogenase, urease and arylsulfatase enzyme activities of the soil and it was statistically significant ($p < 0.01$). The activity of alkaline phosphatase enzyme increased but and it was not statistically significant. The biological analyses of the soil showed that the most effective dose varies in each parameter, but it was identified that $BC_5 + AM_5$, $BC_{15} + AM_5$, BC_{20} and AM_{20} doses increased the biological properties. The study showed that biochar and animal manure applications increased the organic material contents of soil and the available macro contents including nitrogen (N), phosphor (P) and potassium (K).
Keywords: *animal manure, nutrition element, biochar, enzyme activity, microbial activity, organic material*

Introduction

The human population increases with a geometric array, and the food demand also rises inevitably at the same speed. The effort to meet the food demand as fast as possible has led to the introduction of a wide range of chemical inputs into the agricultural production processes. Types of chemical manure are a factor accelerating production significantly, however, the destructive aspect for the environment and human health has become a disadvantage in the long term, and the scientists are looking for solutions. Accordingly; organic soil regulators which are compatible with nature, also beneficial for the environment and human health, yielding effective results in agricultural applications in a narrow field, aiming to minimize the use of chemical manure with the same productive capacity for animal and plant production are evaluated. The important preventive measures for food crisis that threatens the future of human life include increasing the amount of organic material in agricultural soils and the use of agricultural methods for the protection, preservation and maintenance of suitable environment for soil organisms. The use of organic manure instead of the chemical manure in organic agriculture helps to increase soil organic materials and microbiological activity. The aim of organic agriculture is to protect the health of the plant, environment, human and animal without causing water, soil and air pollution (Kızılaslan and Olgun, 2012). Besides the natural manuring system, some side products have been tested to improve quality; the most commonly used herbal and woody wastes among these side products are also

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88658876

preferred to be burnt on agricultural soil for reversible soil recovery without environmental pollution. The aim of this application is to provide available plant nutrition elements and to eliminate environmental pollution caused by woody side products of the residues in agricultural soils by pyrolysis method. The new product containing high carbon and mineral material obtained as a result of pyrolysis of organic substances in the oxygen-free environment or gasification by reduced oxygen is called biochar (Lehmann, 2007), and based on its history, it has been used to support organic manures, and to increase productivity in agricultural soils effectively. Pioneering research on the above-mentioned organic soil regulator were performed for seedling cultivation (Retan, 1915) and soil chemistry (Tyron, 1948). Much earlier than the those researches, waste biomass charcoal was used as a manure in an application carried out in China (Liebig, 1878). Biochar-based researches have been remarkably increased in Japan starting from the first quarter of the 80s (Kishimoto and Sugiura, 1980). Despite of all these researches, global interest in biochar was especially rised in the second quarter of the 2000s, but recognized recently in Turkey. When a biochar rich in organic carbon is burnt, an ash consisting of Ca, Mg and inorganic carbonate is obtained. This high-carbon organic regulator is defined as an aromatic material consisting of six chains of carbon atoms connected to each other without oxygen and hydrogen. Carbon atoms connected to each other without oxygen and hydrogen is considered as advantageous due to absence of more atoms in organic material (Roberts et al., 2009). The highest quality criteria for Biochar includes: high cation exchange capacity, adsorption and low portability of components (Glaser et al., 2002; Liang et al., 2006; McClellan et al., 2007; McLaughlin et al., 2009). The research was conducted to evaluate whether the hazelnut shell without commercial value could be used for other purposes except for fuel in the study region (Central and East Black Sea Region). The aim of the research is to show the relationship between tomato plants grown in soil in different doses of animal manure (AG) and biochar (BC) obtained from hazelnut shell with some soil enzymes, C mineralization, microbial biomass and other soil properties.

Material and method

Study area

The experiment was carried out in the high tunnel greenhouse established in Ordu University experiment area. The study area is located in Ordu province, Altınordu district, Eastern Black Sea Region, Turkey in 2016. The province of Ordu is located between the northern latitudes of 4464031-4551905 with eastern longitudes of 304670-420033 (*Fig. 1*).

Figure 1. *Map shows the location of Ordu University experiment area in the Ordu Province, Turkey*

DOI: http://dx.doi.org/10.15666/aeer/1704_88658876

Materials and methods

In the study performed under the conditions of the greenhouse, soil with clayey texture from a depth of 0-30 was used. As an organic material, the hazelnut shell of Ordu has been transformed into biochar. Production temperature for biochar production is 380 °C; the production time is 270 min (*Fig. 2*). The production continued until the end of the gas outlet, including flammable gases from the system. The mature animal manure was obtained from the farmer in Ordu province Mesudiye district. Alsancak tomato seedling was used as a plant material. Before the experiment was established, some basic physical and chemical analyses of the soil sample were performed (*Table 1.*)

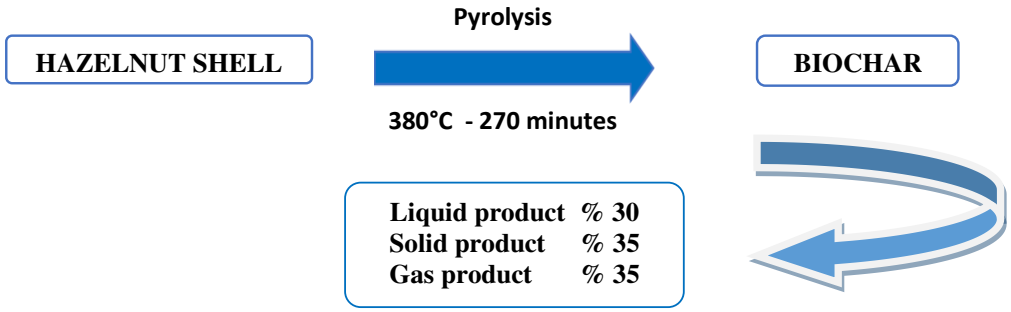

Figure 2. *Biochar pyrolysis process obtained from hazelnut shell (Ronsse et al., 2013)*

Pyrolysis

The process results in the formation of three main products: carbon-rich solid product (biochar), a volatile matter which can further be partially condensed to liquid phase (bio-oil), and the remaining so-called "non-condensable" gases, like CO, CO_2, CH_4, and H_2 (Kambo and Dutta, 2015).

The soil used in the experiment had a clayey structure, having pH value of (6.46) mild acid without saltiness problem. The level of organic material was 1.8%, total N content was 0.045%, P content was 6.7 mg kg^{-1} and K content was 57.1 mg kg^{-1}.

Mature animal manure and biochar, used as organic material, are materials of organic origin, and their properties complement each other. Some chemical and physical properties belonging to the burnt animal manure and biochar used in the experiment is presented in *Table 1*.

Table 1. *Some physical and chemical properties of the soil used in the experiment and biochemical and vermicompost properties*

Material	O.M (%)	C (%)	N (%)	pH	K (mg kg^{-1})	P (mg kg^{-1})	Mg (mg kg^{-1})	Fe (mg kg^{-1})
Soil	1.8	-	0.045	6.46	57.1	6.7	120	8.6
AM		26.4	1.32	7.6	1.24	1.12	-	-
BC		81	1.17	9.24	0.33	-	1690	10.4

Experimental design

In the research, 2 mm grated 2 different organic material (biochar and animal manure) 0-5-10-15-20 ton/ha hazelnut biochar and 5-10-20 ton/ha mature animal

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88658876

manure doses were used proportionately 6 times according to the study design of random parcels in natural conditions of greenhouse (*Table 2*). In addition, % AM and % BC doses were applied to see the effects alone. After the mixtures were prepared and filled separately in the air dry 3 kg soil flowerpots, they were kept for 24 h in order to stabilize the internal dynamics in the medium. At the end of 24 h, Alsancak tomato seedlings, which is used as a plant material, were planted as 1 seedling per flowerpot. During planting, K_2HPO_4 100 ppm K/pot and 125 ppm P/pot and 100 ppm N/pot manures as $Ca(NO_3)_2$ form were applied as a basic manuring. After this process, all flowerpots are irrigated. Irrigation is performed periodically according to weather conditions and soil humidity. Watering was conducted according to plant water demand. The average temperature during the trial is 22.7 °C degrees. At the end of 1 week, regularly inspected and irrigated plants have begun to grown, each seedling was observed until the flowering period. Plants were harvested during flowering period.

Table 2. *Potted trial applications*

Mediums	
C	Control
(BC_5 + AM_5)	10 gr BC – 10 gr AM
(BC_5 + AM_{10})	10 gr BC – 20 gr AM
BC_{10} + AM_5	20 gr BC – 10 gr AM
(BC_{10} + AM_{10})	20 gr BC – 20 gr AM
(BC_{15} + AM_5)	30 gr BC – 10 gr AM
(BC_{15} + AM_{10})	30 gr BC – 20 gr AM
BC_{20}	40 gr BC
AM_{20}	40 gr AM

Soil physicochemical analyses

Soil samples 2 mm grated were waited and prepared for the analyses in +4 °C refrigerator immediately after, and biological analyses were initiated. To identify the properties of sample soil, the texture was examined by hydrometer method as told by Bouyoucos (1962), soil reaction (pH) and saltiness (EC) by U.S. Salinity Laboratory Staff (1954), organic material by Nelson and Sommers (1982), total nitrogen by Bremner (1965), useful phosphor by Olsen et al. (1954), useful potassium by Knudsen et al. (1982) as told by Müftüoğlu et al. (2012).

Soil biological analyses

For the biological analyses of the soil; CO_2 production was identified by the method told by Isermeyer (1952); microbial biomas-C by Anderson and Domsch (1978), dehydrogenase enzyme activity by Thalmann (1968), urease enzyme activity by Kandeler and Gerber (1988), alkalin phosphatase enzyme activity by Tabatabai and Bremner (1969), arylsulfatase enzyme activity by Tabatabai and Bremner (1970) as told by Schinner et al. (1996). For the organic materials in PH and EC 1:3 ratio organic material-pure water mixture in the study (Gabriels and Verdonck, 1992), organic material was burnt at 550 ± 25 °C for 4 h by the method of Kacar (2009); plant nutrition

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88658876

element analyses were performed in organic materials by the methods told by Kacar and Kütük (2010).

Statistical analysis

At the end of the study, the variance analysis of the obtained data was performed using the JMP package program and the important results were evaluated according to the LSD test.

Results and discussion

The effect of organic materials on some enzyme activity of the soils

Different doses of biochar and animal manure applications affected and increased the dehydrogenase enzyme activity in the soils favorably; it was found that application are statistically significant at level 1%, and dehydrogenase enzyme activity values of the soils were between 3.16-40.03 mg TPF/g.k.t. The lowest dehydrogenase activity value was in the control application the highest was in $BC_{10} + AM_5$ application (*Fig. 3a*). This application yielded 12.7 fold increase. When the applications into the soil were evaluated numerically, it was observed that the most effective applications were $BC_{10} + AM_5$, $BC_{10} + AM_{10}$, $BC_{15} + AM_5$ and $BC_{15} + AM_{10}$. Single BC_{20} and AM_{20} applications increased dehydrogenase enzyme activity values less than the application comparing BC and AM. The organic materials added to the application have been used as a source of nutrients and energy by microorganisms living in soil.

Paz-Ferreiro et al. declared that (2012) when biochar in different doses obtained from waste sludge is applied to the soil, it increases the activity by 2.8 times compared to the control, however, Park et al. declared that (2011) biochar obtained from the chicken manure increases the dehydrogenase enzyme activity when applied into the soil in increased doses.

The statistical evaluations showed that the effects of the applications on the urease enzyme activity are significant ($p < 0.01$). Biochar and animal manure applications increased urease enzyme activity in soil (0.28), the highest value was obtained for $BC_5 + AM_5$ and $BC_{15} + AM_5$ applications (0.90) (*Fig. 3b*). $BC_5 + AM_5$ and $BC_{15} + AM_5$ applications into the soil increased urease enzyme activity by 3.2 times compared to the control. Kablan (2005) declared that urea, as a substrate source of microorganisms producing urease enzyme, has increased with organic N forms, which are substrates of N content in different organic wastes. Since biochar has a wide C/N ratio, it is subjected to more fragmentation by microorganisms, resulting in the increase of these enzymes. Nannipieri et al. (1990) showed that the final process of urease, which is the organic phase of organic nitrogen mineralization in soil, is the separation of urea and the responsible enzyme is urease (Kablan, 2005). These enzymes are produced by soil microorganisms in order to break down their nutrient materials, then are kept by colloids such as clay and organic material of the soil, and can sustain their activities without being attached to the microorganism cell that produces these enzymes (Aşkın et al., 2004).

Akça and Namlı declared that (2015) after biochar is applied to the tomato plant, the urease enzyme activity is meaningfully and significantly increased by 5% as compared to the control and chemical manual. It was observed that urease enzyme activity of the soil has a significant relationship with important soil properties such as organic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88658876

material, soil texture, pH cation exchange capacity, and that the organic wastes added to the soil significantly increase urease enzyme activity (Özdemir et al., 2000). The researches declared that when rapid weatherable organic materials are added into the soil, urease activity may be increased by the stimulation of microbial activity. Moreno et al. (1999) declared that when organic materials are added to the soil, the urease activity increases remarkably. On the contrary, Azam and Malik (1985) reported that organic materials did not affect the urease activity. Biochar and animal manure applications increased arylsulfatase enzyme activity in the soil; arylsulfatase enzyme activity values of the soils were 0.07-0.15 µg *P*- N g.k.t^{-1}. The lowest value was at control application, the highest was at $BC_5 + AG_5$ application; this application yielded 2.2 fold increases. Arylsulfatase enzyme has a key role in S cylce in terms of agricultural aspect. It acts as a catalyst for hydrolisation from assimilable organic S to the inorganic S by the plant, and allows the nutrition element required for plant development to be faster and easier in the inorganic form (Kayıkçıoğlu and Okur, 2013). In a study on tomato plant, the biochar obtained from the litter of poultry in different doses has been applied as an application, and enzyme activities were increased significantly with biochar applications (Akça and Namlı, 2015). In the experimental soils, tomato plant increased arylsulfatase enzyme activity as compared to the control (*Fig. 3c*). Because microbial activity increases in the presence of plant roots, increasing arylsulfatase enzyme activity (Kablan, 2005). Sun et al. (2014) reported that the addition of wood-originated biochar into the sandy agricultural soil does not increase the arylsulfatase enzyme activity too much; however, at the end of approximately 50 years, it contributes several enzymes of biological wastes such as arylsulfatase.

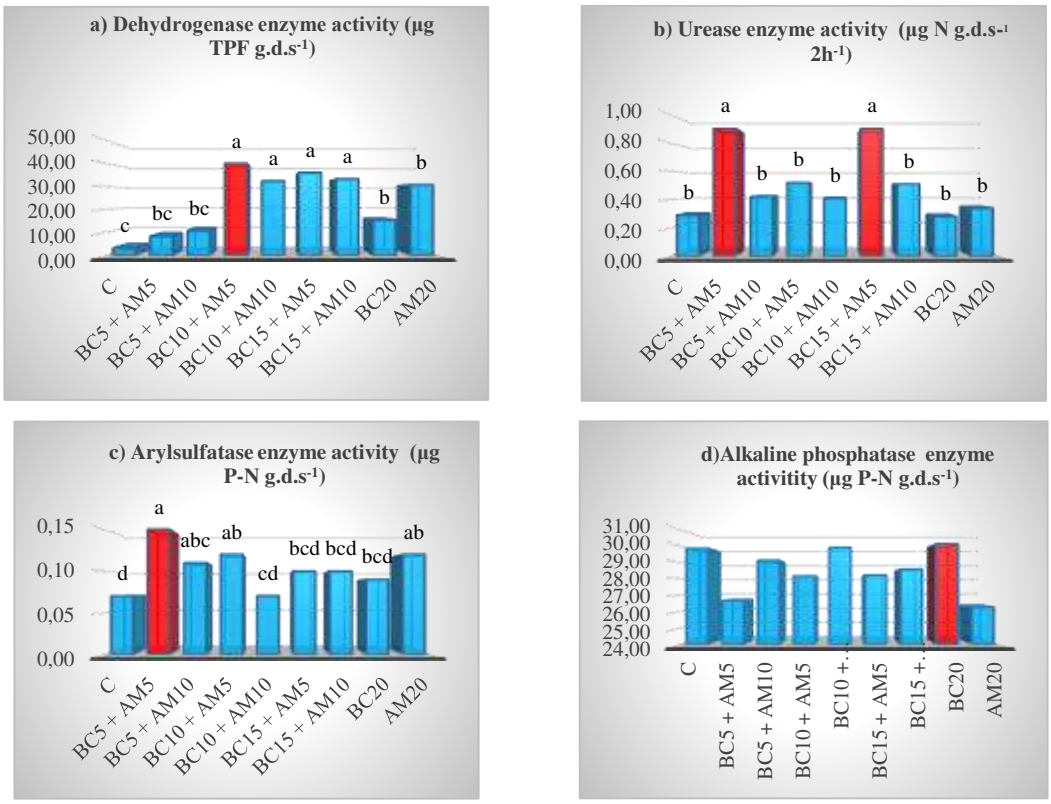

Figure 3. *The effects of biochar and animal manure applied soils on dehydrogenase (a), urease (b), arylsulfatase (c) and alkaline phosphatase (d) enzyme activities (g.d.s : gram dry soil)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88658876

The statistical evaluations showed that the effects of organic wastes on alkaline phosphatase enzyme activity are not significant. However, different doses of biochar and animal manure applications affected the alkaline phosphatase enzyme activity in the soil favorably, and increased numerically; alkaline phosphatase enzyme activity values were between 25.49 and 30.11 (μg *P*- N $g.k.t^{-1}$). The lowest value was at control application, the highest was at BC_{20} application; this application yielded 18% increase (*Fig. 3d*). Phosphor uptake by the plants is performed via the mineralization of the organic phosphor compounds into orthophosphate by phosphatase enzymes. Alkaline phosphotases are secreted only by microorganisms, several bacterial strains produce alkaline phosphotase enzyme (Okur, 1997). It was observed that phosphatase enzyme activity was statistically insignificant, and did not increase in the soils, because if phosphatase is inhibited, PO_4^{-3} synthesis is inhibited and, the formation of orthophosphate acid and alkaline phosphatase enzyme activity of organic phosphor compound is inhibited, meaning that phosphor mineralization is inhibited (Chunderova and Zubets, 1969).

The effect of organic materials on several chemical properties of soils

The effects of biochar and animal manure applications on the organic matter contents of soil are presented in *Table 3*. The statistical evaluations showed that the effects of biochar and animal manure on organic material are significant ($p < 0.05$). The different doses of biochar and animal manure applications increased the organic material content of the soil; the amount of the organic material was increased by 1.80-6.92% (*Table 3*). The lowest value was at control application, the highest was at $BC_{15} + AM_{10}$ application; this application yielded 3.84 fold increase in the organic materials. Mixing of these two materials (organic material and a material with high organic content) in the soil increased the amount of the organic materials in the soil, as expected. Demisie et al. (2014) reported in their study that when the biochar obtained from oak and bamboo is applied into soil, %C value increases between 50 and 286% as compared to the control soil. In agricultural production applications, optimal plant growth in the soil is associated with the physical and chemical indicators of the soil structure.

Analysis of variance for the properties showed that the difference between the mean of at least two groups was statistically significant. The difference between the means shown by the same letter is not significant in its own group.

The most used application to modulate the physical parameters of the soil and maintain its continuity is the addition of organic materials into the soil (Bender et al., 1998). Organic wastes modulate the properties of the soil structure, and provide plant nutrients such as P, K, Ca, Mg, Cu and Zn, especially N. When biochar obtained from poultry is applied to soil of the tomato plant, the value of organic material increases (Akça and Namlı, 2015). Çengel et al. (2009) reported in their study at the organic vineyard region in Manisa that the amount of organic material in the soil with neutral reaction is low; however, additive green manure increase the amount of organic material, and the amount of organic material may yield better results when supported with materials of organic origin. The effects of the application on total N have been found to be significant ($p < 0.01$). Different doses of biochar and animal manure applications increased the % total N amount of the soil; and total N values were between 0.10-0.17% (*Table 3*). The lowest value was at control application, the highest was at $BC_{10} + AM_5$ application; this application yielded 70% increase

DOI: http://dx.doi.org/10.15666/aeer/1704_88658876

Table 3. *The effects of biochar and animal manure applications on the soils organic matter (%), total N, available P and extractable K contents*

Applications	Organic matter (%)	N (%)	P (mg/kg)	K (mg/kg)
Control	1.80 c	0.10 e	2.5d	315 d
$BC_5 + AM_5$	5.10 bc	0.14 bc	3.8 c	408 c
$BC_5 + AM_{10}$	6.07 ab	0.11 de	4.9 bc	373 c
$BC_{10} + AM_5$	6.39 ab	0.17 a	4.3 bc	408. c
$BC_{10} + AM_{10}$	5.72 ab	0.13 cd	4.5 bc	380 c
$BC_{15} + AM_5$	5.30 abc	0.15 ab	6.3 a	554 a
$BC_{15} + AM_{10}$	6.92 a	0.15 abc	4.2 bc	511ab
BC_{20}	6.68 ab	0.16 ab	5.4 ab	477 b
AM_{20}	5.82 ab	0.12 de	4.6 bc	385 c
	LSD ($p < 0.005$) 0.8149	LSD ($p < 0.001$) 0.01028	LSD ($p < 0.001$) 0.65162	LSD ($p < 0.001$) 27.4485

Besides, there has been an effective increase in a short time in test pots with biochar + animal manure. When pine biochar was added into the soil, the useful elements of the material such as N, P, K, Ca, Fe, Mn and Zn increased, biochar plus N application supported plant growth (Sohi et al., 2009; Van Zwieten et al., 2010).

Different doses of biochar and animal manure applications increased the amount of available P in the soil. The available P values are between 2.5-6.3 mg kg in the test soils. The lowest value was at control application, the highest was at $BC_{15} + AM_5$ application (*Table 3*); this application yielded 2,5 fold increase in total N values. This application yielded 1.13 unit increase of the soil pH. According to CFA (California Fertilizer Association, 1995), the highest pH range is 6-7.5 for available phosphor, and the phosphor values in the study were in line with this range. When biochar is applied to soil of the sugar cane, the amount of total phosphor and total dissolved phosphor increase (Alvares-Campos et al., 2018).

Different doses of biochar and animal manure applications increased the amount of available P in the soil; and the values of extractable K in the soil was between 315-554 mg kg^{-1} (*Table 3*). Like 2 other nutrition element contents, the lowest value was at control application, the highest was at $BC_{15} + AM_5$ application; this application yielded 76% increase. The increase of the extractable K value in the soil was thought to be associated with the high extractable K value in the biochar and animal manure. Several researches reported that the amount of extractable K in the soils ranges between 40-150 mg kg^{-1} and no nutrition problem would appear if the extractable K was 150 mg kg^{-1} (Barber, 1985; Namlı et al., 2017).

Conclusion

In general, biochar and manure applications have positive effects on soil biological properties and nutrient content. The statistical evaluation of the enzyme analyses showed that the effects of applications on the enzyme activities of dehydrogenase, urease and arylsulphatase were significant ($p < 0.01$). Dehydrogenase enzyme activity is highest at $BC_{10} + AM_5$ application, urease enzyme activity is highest at $BC_5 + AM_5$ and $BC_{15} + AM_5$ applications, arylsulphatase enzyme activity as well as urease enzyme

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88658876

activity is highest at $BC_5 + AM_5$ application. The statistical evaluation of alkaline phosphatase enzyme activity showed that the effects of the application was found to be insignificant. And it was identified that the highest numeric increase was at BC_{20} application. When the values of organic material in the soils were evaluated, it was identified that biochar and animal manure applications increased the amount of organic material in the soil as compared to control, and the highest values were obtained in the $BC_{15} + AM_{10}$ application. Mixing of these two materials (organic material and a material with high organic content) in the soil increased the amount of the organic materials in the soil, as expected. When the nutrition contents of the soils were evaluated, biochar and animal manure applications increased the values of total N, available P and extractable K; and the most effective doses were $BC_{10} + AM_5$ application for total N, $BC_{15} + AM_5$ application for available P and extractable K. It is thought that biochar has high C content and therefore C/N ratio is not sufficient by itself and C/N ratio is suitable with organic materials such as animal manure. Because these microorganisms living in soil organic materials because they contain plant nutrients like N and P in terms of their chemical stimulates wealth. As a result, the mineralization of the plant nutrients will be increased with the increase of biological activity in the soil. Due to the high content of biochar, the decomposition rate in the soil is low and it has been shown to be effective for a long time.

Abstract. The aim of the study was to analyze grassland areas in relation to the activities and financial support schemes dedicated to the conservation of grassland habitats, with a view to sustainable development of Romania's mountainous area. A multitask analysis was carried out: the geomatic approach of pastoral space and its relations with other environmental components, having "localized" results in space and therefore the possibility of intervention "from the general to the specific". The grasslands cover 22.30% of the Romania's mountainous area, a percentage which gives them a special importance. The large number of identified protected areas (770 entities of different categories) support the idea of the high biodiversity of the mountainous area, implicitly of the grassland habitats. One third of grassland areas (36.65%) are included in one or more environmental protection structures. In addition to biodiversity conservation measures imposed by different protected areas, Romania's mountainous area is fully included in the Agro-Environment and Climate and Ecological Agriculture programs, part of the Common Agricultural Policies, which encourages the pursuit of sustainable agriculture, also the protection of biological resources. This study encouraging and sustaining extensive traditional agricultural practices, determines both the maintenance of biodiversity and the diversity of semi-natural grassland habitats.
Keywords: *analysis, geomatics, pasture, protection, financing, management*

Introduction

The political, social, economic and environmental context of the last century has generated changes and, at the same time, complex and synergistic challenges for the real preservation of nature. For example, changes in livestock and the reorganization of agricultural land have a negative and/or positive impact on natural and semi-natural pastures and on traditional landscapes in agriculture, the relationship being possible on the reverse (Baessler and Klotz, 2006; Garnier et al., 2007; Ceballos et al., 2010; Căluşeru et al., 2015). On the other hand, efficient management of grasslands requires the adoption of strategies according to local conditions in order to respond to the context of reality. In this interaction, managers in protected areas and nature conservation institutions, along with the agricultural sector, have a very important role (Balázsi, 2017). In the territory, the installation of protected areas imposes certain rules

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88778894

and behavior regarding the exploitation of grasslands, which, besides the protection of environmental factors, also aims at preserving biodiversity.

Protected areas, seen as "the key to mitigating climate change, preserving biodiversity, providing ecosystem services and promoting human well-being" (Vega et al., 2017) have seen an upward path in their space-time evolution. Thus, the surface of the globe in the 1990s was "protected" in a proportion of 8.6%, in 2016 this area rising to 14.7% and includes land and estuary ecosystems with the exception of Antarctica (Vega et al., 2017).

The need to set up and extend protected areas is based on a holistic approach, seen at global level and has grown as a result of increased risks generated by climate change (Ruiz-Mallén et al., 2015), concern for the environment (Wandersee et al., 2012), more and more severe deforestation (FAO, 2010) and installation of non-specific or invasive vegetation (Lei et al., 2014), major risks to produce "hydrological" disasters such as floods (Saraswati, 2014) and "unburned" floods, the uncontrolled expansion of urban spaces (McDonald, 2013; López Lambas and Ricci, 2014), in the face of biological formations.

Before 1989, Romania's territory was "protected" by different types of protected areas, at a rate of 4.1% (Iojă et al., 2010). After 2000, interest in protected areas increased significantly; under the pressure of joining the European Union, legislative and normative regulations have been introduced to "extend" the existing protected areas (Geacu et al., 2012). After joining the EU, Romania had to expand its "protected territory" to 17% of the total, making it "joining" the Natura 2000 European Network (Bălteanu et al., 2009).

In 2014, in Romania the protected areas covered 24.84% of the country's territory (protected natural areas, 7% and Natura 2000 sites, 17.84%), being registered: 79 scientific reserves; 13 national parks; 230 monuments of nature; 661 nature reserves, 15 natural parks; 19 Ramsar sites; 3 Biosphere Reserves; 1 World Heritage Site, respectively the Danube Delta (Antonescu et al., 2015).

Declaring a "protected area" has effects on the entire geosystem, depending on its size and profile. There are situations like these (Antonescu et al., 2015): the extension of areas to other areas which do not require protection, initially with other destinations; human settlements located near protected areas are usually underdeveloped and with limited development opportunities, with restricted access to infrastructure, leading to population migration and therefore demographic imbalances.

The management of grasslands from the protected areas is not always economically and socially correlated with the objectives and needs of communities in the deprived areas (Molnár et al., 2016). On the other hand, the "establishment" of the protected areas ensures: preserving biodiversity, attracting european funds and developing projects with multiple benefits, preserving local and regional traditions.

Regarding the use of grasslands in Romania, besides the protective measures imposed by different categories of protected areas, there are several relevant instruments of the Community Agricultural Policy (CAP): direct payments, milk quota, sustainable rural development (Pillar 2 measures) such as investment aid, agri-environmental measures (EMA) and support for mountain areas (Osterburg et al., 2010). Moreover, the CAP has established rules to maintain traditional grassland management through eligibility rules and minimum requirements as a prerequisite for receiving direct payments.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88778894

Exploiting grasslands under the socio-economic and cultural conditions of mountain areas in Romania, has long been and is in most cases in line with the principles and rules imposed by the presence of protected areas or CAP policies, not due to "environmental culture", but relied on the basis of financial and technical underdevelopment. Contrary to intensive farming practices, in the mountain environment, through physic-geographic traces and pastoral culture, some of the principles of sustainable agriculture meet, which place the environment and its resources at the forefront.

Concerns about the sustainability of mountain farming and the conservation of grassland habitats' biodiversity are expressed in numerous researches (Öllerer, 2012; Păcurar et al., 2015; Cojocariu et al., 2018), under various theoretical and applicative aspects, context in which the researches presented in this paper are included.

In this context, ***the aim of the study*** was to analyze grassland areas in relation to the activities and financial support schemes dedicated to the conservation of grassland habitats, with a view to sustainable development of Romania's mountainous area. At the same time, we want to answer a number of questions: *"Where are conservation measures applied? What are the relationships between conservation structures? What are the implications for environmental protection in the organization of the geographical space and especially of the agricultural space".*

With the first stage of the documentation on the theme, we have drawn attention to another topical topic, especially in our country, namely the sustainable agriculture, functionally linked to the action of nature conservation. Under these conditions, we attempted to formulate scientifically reasoned answers also to the questions: *"Under what conditions can sustainable agriculture be practiced on the pastures in the mountainous area of Romania?"* or *"Is there financial support for sustainable agriculture?".*

The ***choice of the study area*** was based on the idea that the mountain area, extended over a third of the entire territory of Romania, represents an area with great biological diversity and the most complex ecosystems, but also a "step-by-step" territory for its inhabitants, from socio-economic point of view, despite the availability of natural resources. Of all the natural resources of the mountain range, grasslands can be regarded as "everyone's reach" with minimal operating costs (compared to forests or arable land) available on large and renewable surfaces under appropriate use conditions. These sometimes contradictory aspects have stimulated us and lead us to the deepening and detailed analysis of the pastoral area of Romania's mountainous area, important both at national and European level.

Being a ***multidisciplinary work***, a multitask analysis was carried out: the geomatic approach of pastoral space and its relations with other environmental components, having "localized" results in space and therefore the possibility of intervention "from the general to the specific"; we also analyzed the conditions under which European programs for nature conservation and changes in agricultural practices can be applied. The study draws attention to the conservation status of biodiversity at present and can be used as a basis or model for other research as well as for the development of future strategies for the mountainous area of Romania and the graphic and non-graphic database can be reused, completed or "rearranged" according to new needs.

Work methodology

Study area

The area analyzed in the present paper is equivalent to the Mountain Area defined in the National Rural Development Program 2014 - 2020 - NRDP 2014 – 2020 (MARD, 2019) as being the sum of the areas of the administrative-territorial units (ATU) located at average altitudes greater than or equal to 600 m and of the units located at an altitude of 400-600 m, but with average values of slopes higher than or equal to 15%. Under these conditions, the study area includes the Carpathian area, but also the adjacent areas, Sub-Carpathians, plateaus and high hills (*Fig. 1*).

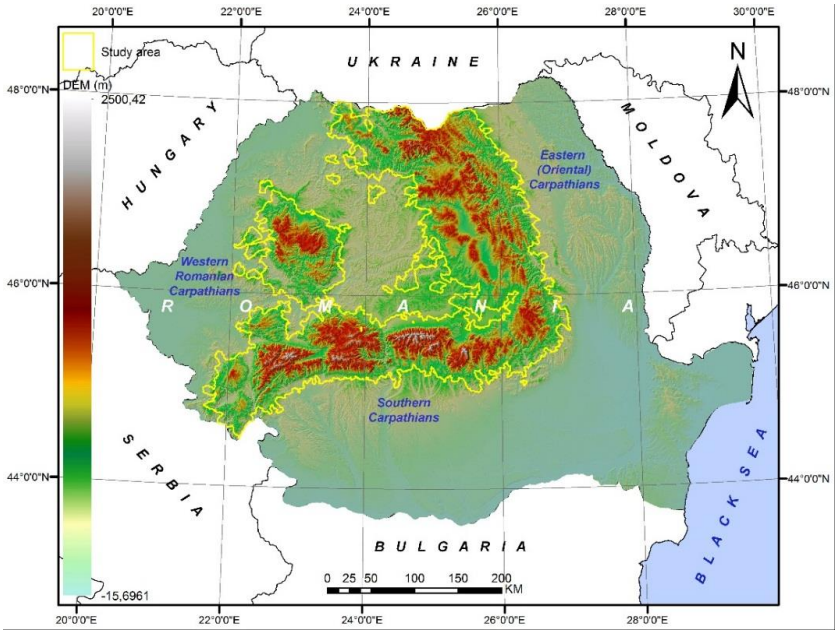

Figure 1. *Location of study area. (processing according to EEA, 2017; MARD, 2019; NACRA, 2019)*

Based on these considerations, the study area with a semi-administrative or semi-physical delimitation comprises 658 ATUs with a total area of 7143943.38 ha (NACRA, 2019), 71439.43 km^2 respectively, being more extensive than the area of the Carpathian Mountains on the territory of Romania, physically and geographically delimited, with the area of 69872 km^2 (Dumitraşcu et al., 2015).

Materials and methods

The four-step systematized research methodology, as well as the materials used in the study, are presented in *Figure 2*. Scientific data and information has been processed and interpreted with the ArcGIS 10.2.1 software, which has also been used to generate cartographic materials.

1. The analysis of grassland surfaces from mountain areas has been based on the Corine Land Cover Database, edition 2012 (EEA, 2012), a program coordinated by the European Environment Agency and part of the Global Monitoring for Environment and Security program, data available on the European Environment Agency website. The database was updated in 2018 by comparison with aerial images (Google Earth

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88778894

platforme, 2018) and data from the National Institute of Statistics of Romania - Land surface by mode of use, by counties and localities (NIS, 2018).

Of the Corine Land Cover Database (EEA, 2012), a total of 26930 entities (all land use categories) were analyzed, and the "grassland" category, interest in this study, with an area of 1593461.64 ha, included: secondary pastures (code 231), with a total of 4474 entities and a total area of 665494.35 ha and natural grassland (code 321), with a total of 2628 entities and a total area of 503622.83 ha. To the two "clear" categories, we may add pastures and hayfields (including wooded pastures), "recovered" from other categories: agricultural land with significant areas occupied with natural vegetation (code 243), agro-forest land (code 244), and bushy vegetation (code 322, 323, 324).

After the identification and framing of each unit, by means of the "joining" procedure (the Merge command), the map of the grassland distribution in the mountain area was obtained in unitary vector format.

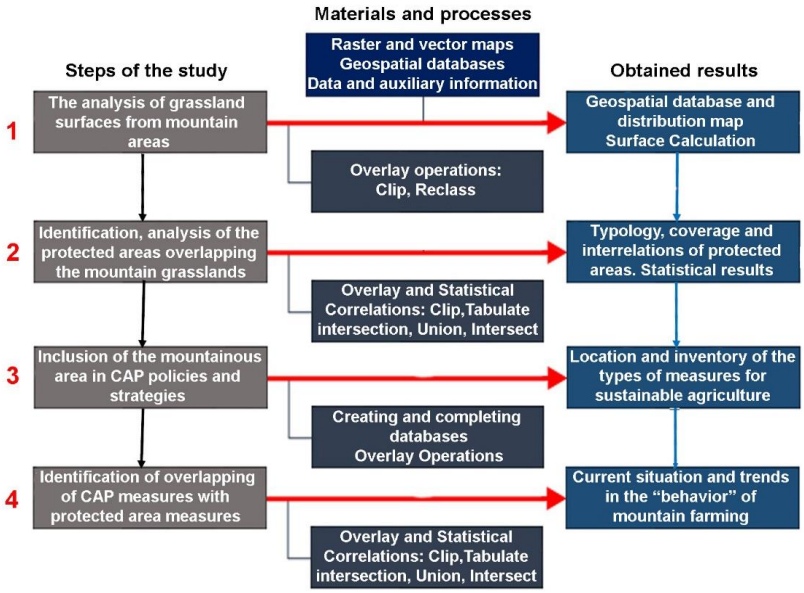

Figure 2. *Methodology of research*

2. The identification and analysis of the protected areas overlapping the grasslands in the mountain area was based on the vector format file with their geometry published on the website of the Ministry of the Environment, in 2017.

In the mountain area, 770 protected areas of different categories were identified, covering a total surface of 4862584.44 ha. Inventory and analysis of protected areas covered all categories of protected sites in the area of interest, both national and international. The "Protected Areas" layer database has been hierarchically structured and categorized.

For each category, we calculated the area and the percentage within the mountain area, and analyzed, as percentage, the situation of the overlapping (*Tabulate Intersection* function), thus calculating the intersection with other areas. Subsequently, the spatial correlation with the grasslands (the *Union* function) was made to determine the "degree and form" of the protection imposed.

3. The inclusion of the mountainous area in CAP policies and strategies was supported by the documentation from NRDP 2014-2020 (MARD, 2019). For each of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88778894

the 658 ATUs, we associated descriptive information (database completion) related to applicable programmes in the case of grasslands (Agro-Medium and Climate and Ecologic Agriculture). After spreading the funding strategies, the overall image and regionalization was outlined.

4. The identification of overlapping areas of CAP measures with protected area specific measures was done through multilayer operations, overlapping and unification of the two databases, resulting in the overall situation of supporting sustainable agriculture.

Working procedures in the GIS (Geografic Information Systems) environment were applied according to technical specifications for ArcGIS 10.2.1 software and ESRI documentation.

Results and discussions

Grassland fund from the mountain region of Romania

The grasslands of Romania's mountainous area, one of the most important natural resources, multifunctional and with deep historical references, are "indispensable" to the inhabitants of these areas, being among the few sources of income and can therefore be treated as "support of subsistence".

The grasslands total 1593461.64 ha, respectively 22.30% of the total area of Romania's mountainous area (defined according to MARD, 2019), which are present in all forms and relief units, ranging from river meadows to high mountain areas (*Fig. 3*).

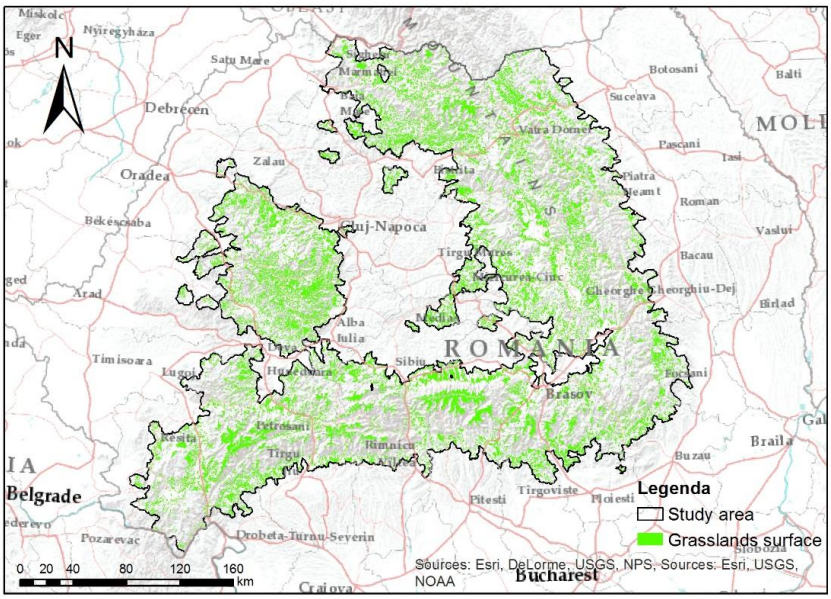

Figure 3. *Distribution of grasslands in the mountainous area of Romania. (processing after EEA, 2012; MARD, 2019)*

Biodiversity conservation structures (Protected areas) in mountain areas, with special reference to the areas used as grasslands

At the level of the mountain area, the protected areas were grouped into 10 categories, presented in *Table 1*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88778894

The statistical data show that Natura 2000 sites have the largest expansion, with 75.62% of the total protected areas, followed by the Protected Areas of National Interest, with a share of 21.45% of the total. Biosphere reserves and Wetlands of international Importance have a reduced share of less than 2% each (*Table 1*).

* data extracted from the geospatial database published on the website of Ministry of the Environment, 2017

National Parks, declared structures to protect nature's wildlife are materialized in 12 entities (*Table 2*) and are the most "restrictive" structures that "dictate" the conservation measures in overlapping areas, irrespective of the presence of other protection entities (Ministry of the Environment, 2000; Stanciu and Florescu, 2009) and were identified on a small area, 4.17% of total.

* data extracted from the geospatial database published on the website of Ministry of the Environment, 2017

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88778894

Mathematically, by summing up the areas of all the protected areas, their total area in the mountain area is 4862584.44 ha (68.05%), but in a more detailed analysis, these entities overlap in many cases on the same territory, which invalidates the information and suggests the *Overlay* approach, in which each layer is analyzed in correlation with the others.

Thus, the statistical calculations show that the total area of the protected areas, the horizontal "footprint" on the surface of the mountain area, irrespective of the number of protected areas overlapped vertically, is 2737574.06 ha, which represents 38.32% of the total area of the area mountain.

The results of the spatial correlation of protected areas – grasslands indicate that 584104.86 ha (36.65%) of the total area of mountain grasslands is under the protection of different categories of sites for biodiversity conservation.

Simple visual analysis of the results indicates the "vertical" upgrading of the protected areas on the grassland units, so complex spatial analysis (*Fig. 4*) and statistical analysis (*Table 3*) were required to determine the type and weight of each entity in the combination of "preservation programmes".

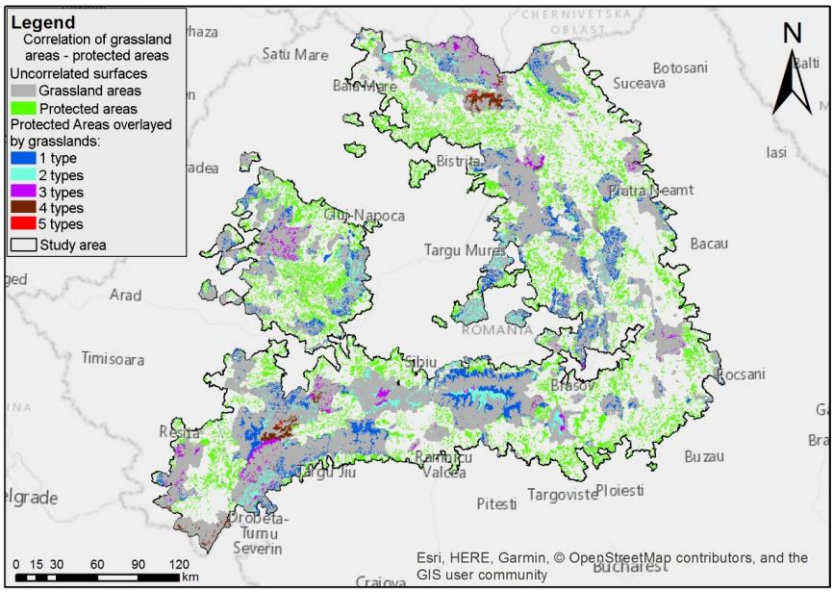

Figure 4. *The correlation of grassland areas with protected areas. (processing after EEA, 2012; Ministry of the Environment, 2017; MARD, 2019)*

From the analysis of the data synthesized in *Figure 4* and *Table 3*, we may remark the following aspects:

- the grasslands are associated only with 27.77% SCIs and SPAs only, 22.96%, these two being the most common in overlapping.
- NP is associated, in most cases, with Natura 2000 sites.
- of the total area of grasslands located in protected areas, there are 15.19% both SCI and SPA areas.
- as share, after SCI and SPA, NP comes into association with other protected areas, in proportions of approx. 5% in each case.
- the grasslands analyzed do not overlap with the category M.N.

Legend: A.P.-Protected area; *Protected area category: A - Natural Reserves from IUCN IV Category (NR), B - Monuments of Nature (MN), C - Special Protection Areas (SPA), D – National Parks (NP), E - Scientific Reserves (SR), F - Wetland of International Importance (RORMS), G - Natural Parks (np), H - Natural Reserves (RONPA), I - Biosphere Reserves (ROMAB), J - Sites of Community Importance (SCI); colored boxes suggest the presence of the protected area; **The figure 0.00 from the column „Affected surface of grasslands" designates surfaces with a percentage of less than 0.001%

The data presented above shows the biological complexity of the Romanian mountainous area, also acknowledged at European level (Mráz and Ronikier, 2016), given by the large number of protected areas (770 entities) and implicitly by the species they protect, irrespective of their location or overlapping.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88778894

Therefore, maintaining biodiversity is done through protection measures imposed by the presence of protected areas, but with the association of other independent or functionally related mechanisms: the continuous use of traditional practices, the fact that a substantial part of the region is represented by high nature value agricultural land (Babai and Molnár, 2014) and CAP measures, which will be described below.

Strategies and measures of the Common Agricultural Policy (CAP) applied in the mountain area

The European Union's rural development policy, introduced as the second pillar of the CAP through the Agenda 2000 reform, is co-financed by the European Agricultural Fund for Rural Development (EAFRD) and regional or national funds and was designed to "stimulate" the development of rural areas, with new economic, social and environmental approaches (European Parliament, 2019).

The rural development policy is implemented on the basis of rural development programs designed by the Member States (or their regions). These multiannual programs implement a personalized strategy that responds simultaneously to the specific needs of Member States (or regions). These programs are based on a combination of measures chosen from a "menu" of European measures detailed in the Rural Development Regulation (Regulation (EU) No 1305/2013) and co-financed by the EAFRD (according to the documentation of the Second pillar of the Common Agricultural Policy: rural development policy).

As the present study focuses on the grasslands in the mountainous area of Romania, only the programs that apply to this segment of agriculture (Regulation (EU) No 1307/2013) will be described in the following.

The preservation of high nature value (HNV) agricultural land is essential in the mountain area, for which the NRDP of Romania has introduced and promoted financial support activities and schemes to farmers in HNV areas through the agri-environment and climate measure. *Figure 5* provides descriptive information on the financing strategies applicable to the land used as grassland and the areas where they are applied.

According to the data from the NRDP 2014 – 2020 (MARD, 2019), on approx. 95% of the mountainous area can be used for agro-environment and climate programs and 5% of the area can also be accessed by programs dedicated to Ecologic Agriculture (*Fig. 5*).

High natural value grasslands (HNVs) are spread throughout the mountain area, with funds being allocated to traditional agricultural practices as a compensatory measure for the natural limitation of land productivity due to the pedo-climatic features of the area or as a result of the operation of agricultural work with manual or animal force.

In the central area of the Eastern Carpathians are located grasslands that support the conservation of bird species (*Crex crex)*, in Suceava County (ATU Solca), grasslands that ensure survival and support the preservation of butterflies (*Maculinea* sp.).

Starting from the idea of preserving biodiversity, supported by numerous european and regional research and structures, we consider high natural value grassland to be of great importance, as rural communities depend on the key components of biodiversity and of ecosystem services that are found in non-domestic habitats (Vîntu et al., 2011).

In the view of the European Environment Agency (EEA, 2002), high natural value lands are those areas of high biological diversity on which extensive agriculture is practiced (Öllerer, 2014), also supported by the Live Viva Grass (2019) portal, according to which, in the category of high value pastures natural areas include those

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88778894

areas where extensive agriculture is practiced, areas with extremely high levels of biodiversity: they support healthy soils and a large number of wild species.

Although between 1947 and 1990 Romania's agriculture was "intensified" under totalitarian policies (Sârbu et al., 2004), large areas of grasslands "survived" these practices, nowadays our country is among the European countries with the highest resources of grasslands rich in "wild" vegetation (Akeroyd and Page, 2011).

Figure 5. *Classification of Romania's mountainous area into the EU's CAP financing programs. (processing after MARD, 2019, list of eligible areas)*

Accessing programs primarily aimed at preserving the biodiversity of habitats and grassland species requires compliance with the requirements for their exploitation in conditions of sustainable "environmentally friendly" agriculture. Considering the fact that a large proportion of the owners and users of grasslands (HNV) in the mountainous area of Romania can receive subsidies through the Agro-Environment and Climate Program (MARD, 2019), these must comply with the conditions imposed by this program on grassland exploitation (*Table 4*).

Among the measures for preserving biodiversity of habitats and species, there is an emphasis on the idea of reducing or eliminating the use of chemical fertilizers. If we analyze the history of Romanian agriculture, chemical fertilization has been for a long

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88778894

time the "immediate" lever for increasing productivity. Starting from this concept, it is understood that reducing chemical fertilization leads to reduced productivity, but scientific research shows that for high natural value meadows the production of biomass is not affected by the depletion of soil in nutrients (Miladkova et al., 2015).

Table 4. *Agro-environmental and climate requirements for grassland exploitation**

Conditions imposed under the subsidized programs	**Agro-environment and climate**			
	High natural value grasslands (HNV)	**Traditional agricultural practices**	**Grasslands that support the conservation of bird species - *Crex crex***	**Grasslands that support the conservation of butterfly species (*Maculinea* sp.)**

Overlay of grassland areas covered by CAP policies with different protected area categories

Of the total surface area of the grasslands in the mountainous area of Romania, 36.65% is covered by different categories of protected areas (*Table 3, Fig. 4*).

The data from the literature show that the Natura 2000 sites as well as the other categories of protected areas in the Carpathians are also found in the HNV regions (Akeroyd and Page, 2011). In order to identify grasslands covered by protected areas but also eligible for different CAP strategies, applied the multilayer analysis (*Fig. 6*).

As a result of the spatial correlations, more than 90% of the grasslands located in protected areas are also classified as high natural value (HNV) land used by traditional practices, and over approx. 8% of the "protected" grasslands meet the optimal conditions for the *Crex crex* species (*Fig. 6*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88778894

Natura 2000 sites, a pan-european network for nature conservation, also include in Romania priority habitats at community level which required their preservation by setting up Special Areas of Conservation (SAC): SPA sites (established by Romanian Government Decision no. 1284/2007) and SCI sites (set up by the Order of the MMDD no. 776/2007, Romanian Government Decision no. 971/2011).

Natura 2000 sites require special management (Cojocariu et al., 2017) but do not prohibit lucrative activities in favor of grassland biodiversity conservation and seek the adoption of sustainable solutions.

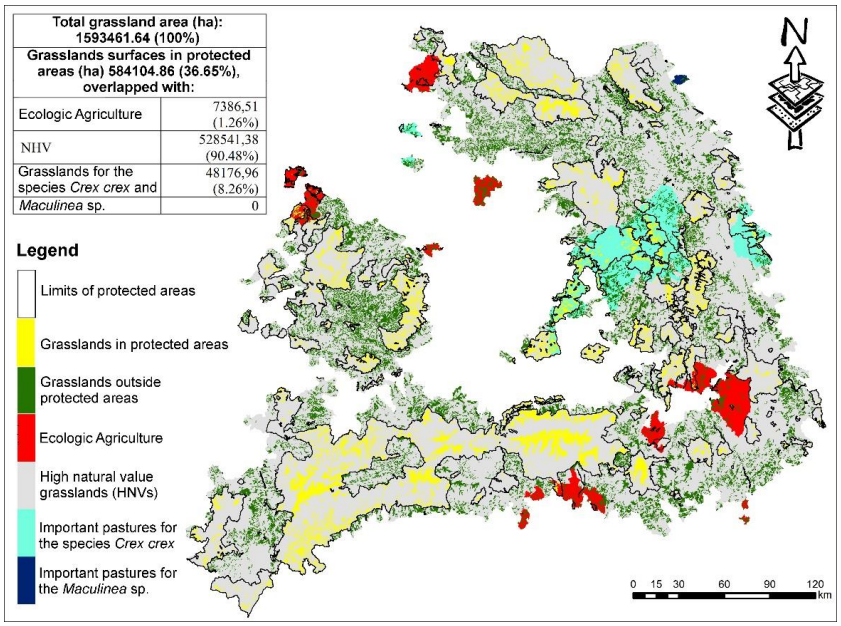

Figure 6. *The correlation of grasslands in protected areas - EU CAP programs. (processing after Ministry of the Environment, 2017; MARD, 2019)*

In order to encourage farmers managing agricultural land within the areas designated as Natura 2000 sites, financial support is expected from Pillar II of the CAP to compensate for the losses suffered.

In addition to the ecoconditionality measures for HNVs summarized in *Table 4*, mountain grassland *users* are also required to comply with a set of minimum conservation measures provided for in the management plan and regulation of the protected area over which they overlap.

Grassland management in protected areas aims to maintain the surface and grassland quality through active management for habitat and species conservation (*Table 5*).

In addition to the general and specific best practice measures for each site, recommended by the management plan, a series of awareness-raising, information and environmental education activities are required in collaboration with local communities and other stakeholders. It is also necessary to inform local communities about the existence and the process of compensation, through EU measures, for the disadvantages suffered by farmers in the mountain area. Therefore, incentives through Agro-Medium, Natura 2000 and conservation projects funded by public funds are very important in preventing mountain abandonment and biodiversity degradation, in the use of ecosystem services and preservation of cultural landscapes (Akeroyd and Page, 2011)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88778894

by rural communities. The presence of several instruments can have synergistic effects (Sutcliffe et al., 2015) on the conservation of semi-natural habitats of mountain grasslands. This beautiful mountainous area of Romania still has many natural values that can be promoted and included in the strategies and programs of local communities' development.

Table 5. *Minimum conservation measures in pastures superposed on protected areas*

General measures	
It is necessary	Compliance with the management plan and area regulation with regard to surface use and pastoral activities.
	Maintaining grassland habitats in good conservation status, through grazing and mowing, respecting animal load and grazing and mowing periods.
	Ensure the conditions necessary to maintain the favorable conservation status of grassland habitats as naturally as possible.
	Ensure the conditions necessary to maintain the favorable conservation status of grassland habitats as naturally as possible.
	Maintaining biodiversity to ensure ecological balance of ecosystems and optimal conditions for protected species.
	Preventing the spread and reducing the spread of invasive species on the territory of the protected area.
	Ensuring the necessary conditions for wild fauna species dependent on grassland habitats.
It is forbidden	Intentional killing or capture of wild birds that make their nest in the shrub / trees in the grasslands.
	Damage, destruction of nests and / or harvesting of eggs from nature.
	Deliberate disturbance of wild birds.
	Damage and/or destruction of breeding or resting places of wild animals.
	Harvesting flowers and fruits, harvesting, cutting, uprooting or deliberately destroying wild plants in their natural habitats.

Conclusions

The grasslands cover 22.30% (1593461.64 ha) of the surface area of Romania's mountainous area, a percentage which gives them a special importance for the mountain population being the natural resource with a multifunctional exploitation potential, realizable according to the conditions of sustainable agriculture, traditional practices.

The large number of identified protected areas (770 entities of different categories) support the idea of the high biodiversity of the mountainous area, implicitly of the grassland habitats.

One third of grassland areas (36.65%) are included in one or more environmental protection structures; which again reveals the complexity of ecosystems: the existence of several protected areas overlapping on the same territory means the presence and protection of distinct habitats.

In addition to biodiversity conservation measures imposed by different protected areas, Romania's mountainous area is fully included in the Agro-Environment and Climate and Ecological Agriculture programs, part of the CAP, which encourages the pursuit of sustainable agriculture, also the protection of biological resources. The grasslands, one of the main economic resources of the mountain range, from the point of view of technological restraints, is suitable for a management or extensive management.

The present study, through scientific arguments, promotes and supports the Common Agricultural Policies, adopted at European level and implicitly in Romania, for a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88778894

particularly important area in ecological, political, economic, geographical terms, both for Romania and at European level.

Encouraging and sustaining extensive traditional agricultural practices determines both the maintenance of biodiversity and the diversity of semi-natural grassland habitats. In addition to the environmental component, the financial support of grassland owners or users (HNV) also includes a socio-economic component. This is to be understood as an opportunity to obtain income from the inhabitants of these areas as a result of the marketing of agri-food products under the name of "mountain product" (Order no. 31/31.01.2018). This capitalization can be done either in a stand-alone activity or in integrated activities such as agro-tourism.

(Received 18th Mar 2019; accepted 17th May 2019)

Abstract. The construction of land use change model is an important means to deeply understand the cause and process of land use change, forecast the future development trend and analyze its environmental influence. In order to reveal the evolution law of the basin Land Use/Cover Change (LUCC) under the changing situation, based on Conversion of Land Use and its Effects at Small Region Extent model (CLUE-S), two scenarios of natural growth and ecological protection are set up with Fuxian Lake located in Yunnan province, China, as the research area to simulate the LUCC of the basin in 2020. The results show that the CLUE-S model has high reliability to simulate the future Land Use/Land Cover (LULC) change in the basin scale and the high simulation accuracy as a whole, and the Kappa coefficient is all above 0.8; under the scenario of natural change, the ecological lands like forest land, cultivated land, grassland and garden land are decreasing, in which the decrease of forest land is the largest, while the non-ecological lands such as construction piling, building area, structure and road is increasing, and the increase of construction piling is the largest. It is bound to pose a serious threat to the ecological security of the basin; under the scenario of ecological protection, the increase of forest land and water area is the largest, while the cultivated land, grassland, construction piling and garden land are greatly reduced. It shows that the quantity of ecological land increases obviously while the quantity of construction land, planting land and other land which play a restriction on ecological environment protection is decreasing, which will be beneficial to the ecological environment protection of the river basin.
Keywords: *Fuxian Lake basin, CLUE-S, LUCC, scenario simulation, high-altitude plateau lake ecosystem, LULC conversion rules*

Introduction

LULC changes can have a direct or indirect impact on a variety of eco-environmental factors, thus affecting regional and global sustainable development. The study of its dynamic changes is an important subject of global and regional environmental change (Li, 1996; Wijesekara et al., 2012). Analyzing the change characteristics of LULC, revealing the evolution of different space-time scales and predicting future changes are helpful to reveal the process and mechanism of regional ecological environment change under the influence of human society, and thus provide decision-making basis for regional ecological protection and sustainable development.

At present, the main models of LULC change and simulation in academic circles include system dynamics model, CLUE-S model, multi-agent model, Markov model,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88958914

CA-markov, FLUS model and so on (Bai, 2000; Duan et al., 2004; Hou et al., 2004; Chu et al., 2005; Liu et al., 2006; Qin et al., 2009; Li et al., 2015; Liu et al., 2017; Hu and Zhang, 2018; Wang et al., 2019). Each model has its own advantages and disadvantages, and the CLUE-S model has obvious advantages in reflecting the gradation, relevance and competitiveness of the LULC change space and is unique in the simulation and optimization of LULC change under policy control (Verburg et al., 2002), thus being widely used in the study of LULC change simulation Cities and urban agglomerations (Peng et al., 2007; Li et al., 2009; Guo et al., 2012; Huang et al., 2012; Liu et al., 2012; Feng et al., 2013; Zhang et al., 2013; Wang et al., 2014; Huang et al., 2015; Jiang et al., 2015; Lu et al., 2015; Xu et al., 2016; Li et al., 2017; Liu et al., 2017; Tian et al., 2019), China's rapid economic growth region (Cai et al., 2004; Tan et al., 2006; Sheng et al., 2008; Lu et al., 2009; Wang et al., 2009; Zhang et al., 2011; Zheng et al., 2014; Han et al., 2015), big city fringe area (Meng et al., 2010), inland arid zone (Zhang et al., 2004; Dai et al., 2013), mountainous area (Peng et al., 2007; Zhu et al., 2010; Gao et al., 2013; Zhao et al., 2014), watershed and lake zone (Bai et al., 2005; Wang et al., 2014; Guo et al., 2016; Li et al., 2016; Sun et al., 2016; Bian et al., 2017; Zhu et al., 2019) village and town (Zhu et al., 2010) and forest park (Li et al., 2016) and so on.

Fuxian Lake is a unique low-latitude and high-altitude plateau lake ecosystem in the world. It is an important international lake to study the mechanism of biodiversity formation. Affected by the East Asian and Southwest monsoon, it is the most sensitive representative lake in response to global change. Favored by experts and scholars at home and abroad, it has become one of the hot spots of the research on international lakes, and it is also one of the plateau lake basin systems with the research value of the most ecological fragile areas in geosciences of China. For this reason, this study takes Fuxian Lake Basin as an example and uses CLUE-S model to carry out LUCC simulation research under different scenarios, so as to reveal the characteristics of land use change with high precision and long time series in plateau lake basin, which has the research value of the most ecological fragile area in the field of geosciences in China. The objective of this study is that the impact and effect of quantification and spatial scales of human decision-making factors on the clue-s model. It is of great significance to study the global change response and biodiversity formation mechanism of the unique low-latitude and high-altitude plateau lake ecosystem in the world. At the same time, it provides guidance for how to effectively implement the land use planning, water source protection, ecological restoration and others of Fuxian Lake basin so as to improve the water environment quality of the river basin.

Materials and Methods

General situation of the study region

Located in the center of the Central Yunnan Basin, Yuxi City, central Yunnan Province, Fuxian Lake is China's largest deep-water freshwater lake, the first large lake in the source of the Pearl River, and is the Nanpanjiang River system. Its geographical location is 24°21′28″- 24°38′00″N and 102°49′12″- 102°57′26″E (*Fig. 1*). As one of the nine plateau lakes in Yunnan Province, Fuxian Lake is the second deep-water lake explored in China and the lake area and water storage amount to the 8th and 3rd in China, respectively (Wang et al., 1998). Because of the particularity of its geographical location and its powerful water supply capacity and recreational value, it is known as

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88958914

the "plateau pearl" in central Yunnan, serving as an important resource guarantee for the sustainable social and economic development in central Yunnan, the strategic water resource for the regional development of the Pan-Pearl River Delta, as well as the important strategic source of drinking water in the Pearl River Basin and Southwest China (Gao et al., 2013). The water quality of Fuxian Lake is Class I, and is one of the best natural lakes in China.

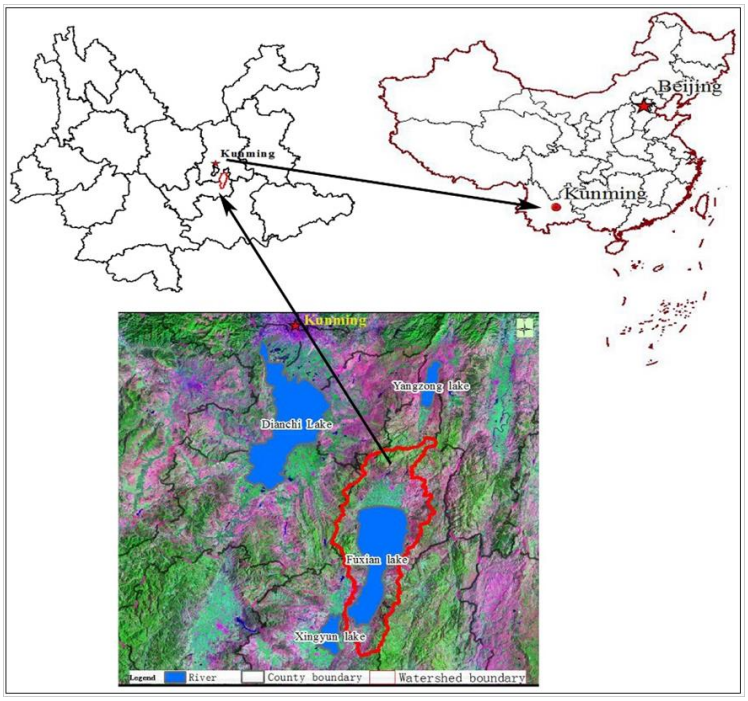

Figure 1. *Location of Fuxian lake watershed*

The vegetation in the basin is mainly secondary vegetation such as grass, shrub and coniferous forest. The population reaches about 160,300, the rural economy mainly comes from crop production, the main food crops include rice, corn, wheat and so on, and economic crops include flue-cured tobacco and rape. The industry is dominated by phosphorus chemical industry, building materials, food processing and aquatic products, of which phosphorus chemical industry is the pillar industry of this area. The land use type of Fuxian Lake Basin has always been dominated by forests and water areas, but with the improvement of the urbanization level of the basin, human activities have increased disturbance on the natural environment, such phenomena as reclamation of lakes, deforestation, over-exploitation of tourism resources, and the rapid increase of functional buildings result in significant change in land coverage types in Fuxian Lake Basin.

Data sources

Because of the obvious seasonal variation of rainfall in Fuxian Lake Basin and the large variation of lake area with season, the remote sensing images of relatively stable lake water level during the dry season from January to March are selected, including 5 phases of high spatial resolution remote sensing image data (*Table 1, Fig. 2*). The reference data are listed in *Table 2*.

Analysis methods

LULC information extraction

The first-class classification system (water area, desert and bare surface, cultivated land, structure, garden land, grassland, forest land, house building, road and construction land) in the general survey contents and indicators of geographical conditions (GDPJ 01-2013) is adopted as a classification system for extracting LULC information of this remote sensing image, and the definition of each type is shown in GDPJ 01-2013. Due to the difference of remote sensing image data sources and time phase, training samples and test samples are collected from the remote sensing images in 2008, 2011, 2014 and 2017, respectively. For each LULC type of images in each phase, 2000 samples are collected, 70% of which are used for training samples and 30% for test samples. The MSORF method (refer to the Reference (Li, 2018) for details) is used to obtain the LULC classification results of the river basin in 2008, 2011, 2014 and 2017. The classification accuracy Kappa is generally 0.8 or more, i.e., 2008 (0.812), 2011 (0.819), 2014 (0.822), and 2017 (0.805). Referring to the current land use map and remote sensing images, the classified data are manually modified to form the final LULC information (*Fig. 3*).

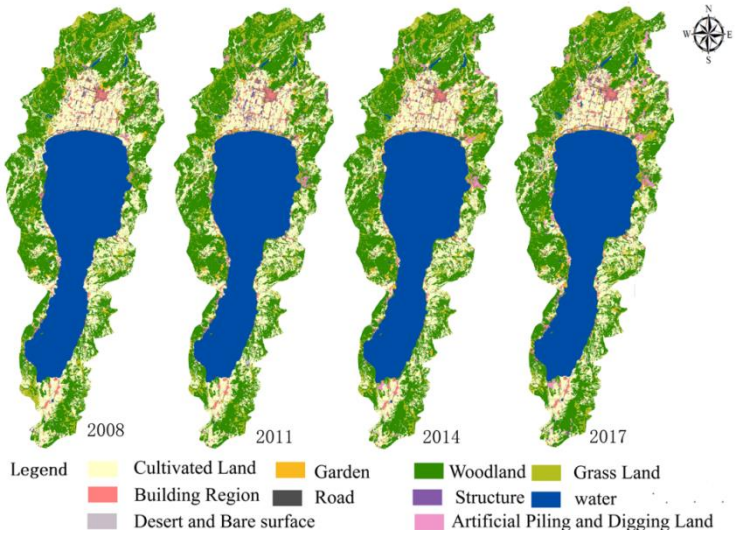

Figure 3. *Classification result of LULC in study area*

In the ArcGIS platform, the LULC classification results were statistically analyzed, and the area change rate of each land type during the study period was obtained to reflect the temporal change characteristics of the LULC (*Table 3*).

Table 3 shows that in 2008-2017, water (W), woodland (WL), cultivated land (CL) and grass land (GL) are the four main types of surface cover. The total area of these four types is 95.00%, 93.89%, 93.43% and 92.50% in 2008, 2011, 2014, 2017, respectively, and Building Region (BR), road (R), garden (G), structure (S), Artificial Piling and Digging Land (APDL), Desert and Bare surface (DB) is 5.00%, 6.11%, 6.57% and 7.50%. The results indicate the area of artificial surface types has increased over years, while that of the natural surface cover types is opposite. The area of artificial excavation land in 2017 is four times of that in 2008. The area of water only decreased 0.03% from 2008 to 2017.

DOI: http://dx.doi.org/10.15666/aeer/1704_88958914

Due to the socio-economic development of the basin and the enhancement of human activities, the LULC type closely related to human economic activities shows a strong growth momentum. Since 2006, due to the implementation of the policy of returning CL to WL and GL, the CL has shown a decreasing trend, and the area of WL has decreased first and then increased. While GL changes little. The main reason is due to natural succession, returning CL to GL, artificial sowing, etc. The area of DB has been changing from increase to decline year by year. The water area remains basically unchanged.

Simulation method of LULC change scenarios in the basin

The CLUE-S model (the conversion of land use and its effects at small regional extent) is the improved CLUE model by Verburg et al. (2002). It is a dynamic and small-scale spatial distribution simulation model of LULC change. Its model framework is composed of spatial allocation model and non-spatial demand module. Non-spatial demand module, based on natural and socio-economic analysis, predicts the annual LULC-type demand area of the study region in the future. However, the spatial allocation model is driven by the LULC demand, based on the rasterized spatial data, and allocate the demand change of the annual LULC type according to the LULC conversion rules and the LULC spatial distribution probability, so as to realize the spatial simulation of LULC change. See the CLUE-S operating manual (Verburg and Overmars, 2009; Verburg et al., 2002) for a detailed description.

Scenario construction of LULC change in the basin

The determination of LULC changing situation is based on the rational thought of "if," and "then". If the set conditions are met, what will happen to the future LULC. Therefore, according to relevant policies and development plans such as the *Regulations on the Protection of Fuxian Lake in Yunnan Province* (implemented on September 29, 2016), and the *Protection and Development Plan for Fuxian Lake Basin* (2016-2020), and the *Overall Land Use Planning of Fuxian Lake Basin*, two scenarios such as "natural change" and "ecological protection" are set to simulate the LULC change of Fuxian Lake Basin in 2020.

The natural change scenario is based on the actual number of LULC changes in the Fuxian Lake Basin from 2008 to 2017, assuming that the LULC changes in the Fuxian

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88958914

Lake Basin are not substantially affected by policy regulation and external policies, and mainly considering the relationship between the natural and socio-economic development indicators and LULC changes, changing with the change rate from 2008 to 2017.

The ecological protection scenario is mainly set according to the contents of the ecological environmental protection planning of the river basin, and the special location and number of ecological lands (water area, forest land, cultivated land and grassland) within the river basin will be adjusted according to the designated and strict requirements of the ecological protection red line. The specific assumption is that the construction land is correspondingly reduced, the water area remains unchanged, the forest land continues to increase, and the forest coverage rate is more than 35% (about 236 square kilometers).

Scenario simulation of LULC changes in the basin based on CLUE-S model

Referring to the CLUE-S model manual and relevant cases and documents, according to the set scenario, the steps of using the CLUE-S model to simulate the LULC change of the basin include the calculation of regression coefficient and land demand, restriction area setting, LULC change driving factor analysis, change matrix setting and other main steps. In order to ensure the reliability and accuracy of the simulation results, the file formed in the above steps must be subject to uniform coordinate and scale, mask, format conversion, etc. before being input into the model, so that the data has a consistent reference system and number of rows and columns, the same coordinate origin and uniform ASCII data format.

(1) Calculation of regression coefficient. The regression parameter file is a file in which the CLUE-S model records the correlation size between each land type and the driving factor calculated by logistic regression analysis. Before calculating the regression coefficient, it is necessary to define the main driving factors of LULC change of the basin. In consideration of the availability and quantification of the data, factors such as the distance from the nearest township center, the distance from the nearest river, the distance from the nearest road, elevation, slope, slope direction, annual average rainfall, annual average temperature, population density, the output value of tertiary industry and soil water content are selected as the driving factors of LULC change of the basin. By means of collinearity analysis, it is found that there is no collinearity among the selected 11 driving factors, and the collinearity coefficient is all less than 0.02, which meets the requirement of model collinearity.

(2) Land use demand in the scenario of basin change. According to the set natural change and ecological protection scenario, combined with the characteristics of CLUE-S model, the demand of LULC type quantity is taken as scenario assumption condition, and input into the model to analyze its influence on the spatial distribution of LULC of the basin. Among them, the cultivated land area, water area and total grain output of the river basin are used as LULC demand files, and the missing year data are supplemented with linear interpolation method. The 2017 simulation of the 2020 demand is based in part on data from previous years using the GM (1,1) model in the DPS. The land use demand for each year are shown in *Table 4*.

In the *Table 4*, Cultivated Land (CL), Woodland (WL), Garden (G), Grass Land (GL), Building Region (BR), Road (R), Structure (S), Artificial Piling and Digging Land (APDL), Water (W), Desert and Bare surface (DB). The bellows is the same.

Total	67532.27									

(3) Restricted area file setting. The spatially restricted area mainly refers to all kinds of planning areas demarcated by government departments, such as land use planning data, ecological environment protection red line and other planning limitation areas of the basin. In the simulation process, the restricted area will not be changed once being set and directly affects the whole simulation process. The restricted area of this study is mainly the basic farmland protection area in the basin, and the red line area of basin ecological protection in the 13th Five-Year Plan (2016-2020) of water environmental protection in Fuxian Lake Basin (*Fig. 4*).

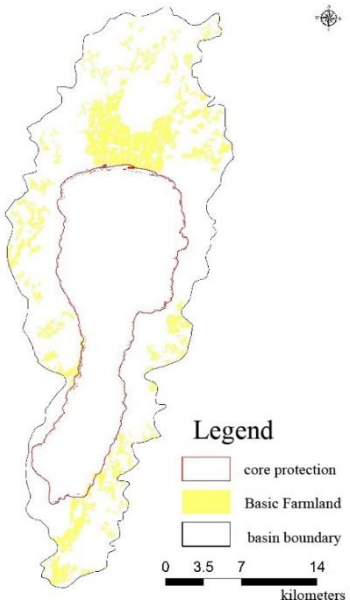

Figure 4. *The restricted spatial area of watershed LULC change simulation under different scenarios*

This file is the restricted area file of the model, but the land use status map is reclassified before the model is input and the value of LULC type must start from 0; the restricted area file is binarized by re-classifying in the same way, that's, water area (0),

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88958914

forest land (1), building area (2), garden land (3), cultivated land (4), grassland (5), road (6), structure (7), desert and bare land (8), and construction land (9). In the CLUE-S model, the LULC active area, i.e., the unrestricted area, the value will be set to be "0", while the value of the restricted area vwill be set to be "-9998".

(4) Map making of LULC change driving factors. Using the annual LULC information classification results, the road and river data are extracted, and the distance map of each pixel from the nearest river, township center and road is calculated using grid space analysis; rainfall, temperature, population density and economic vector map is made through ArcGIS vector space analysis function; elevation, slope and slope direction are derived from DEM; the extraction algorithm of soil water content based on image (wave band) was used to extract soil water content and make soil water content map, as shown in *Fig. 5*.

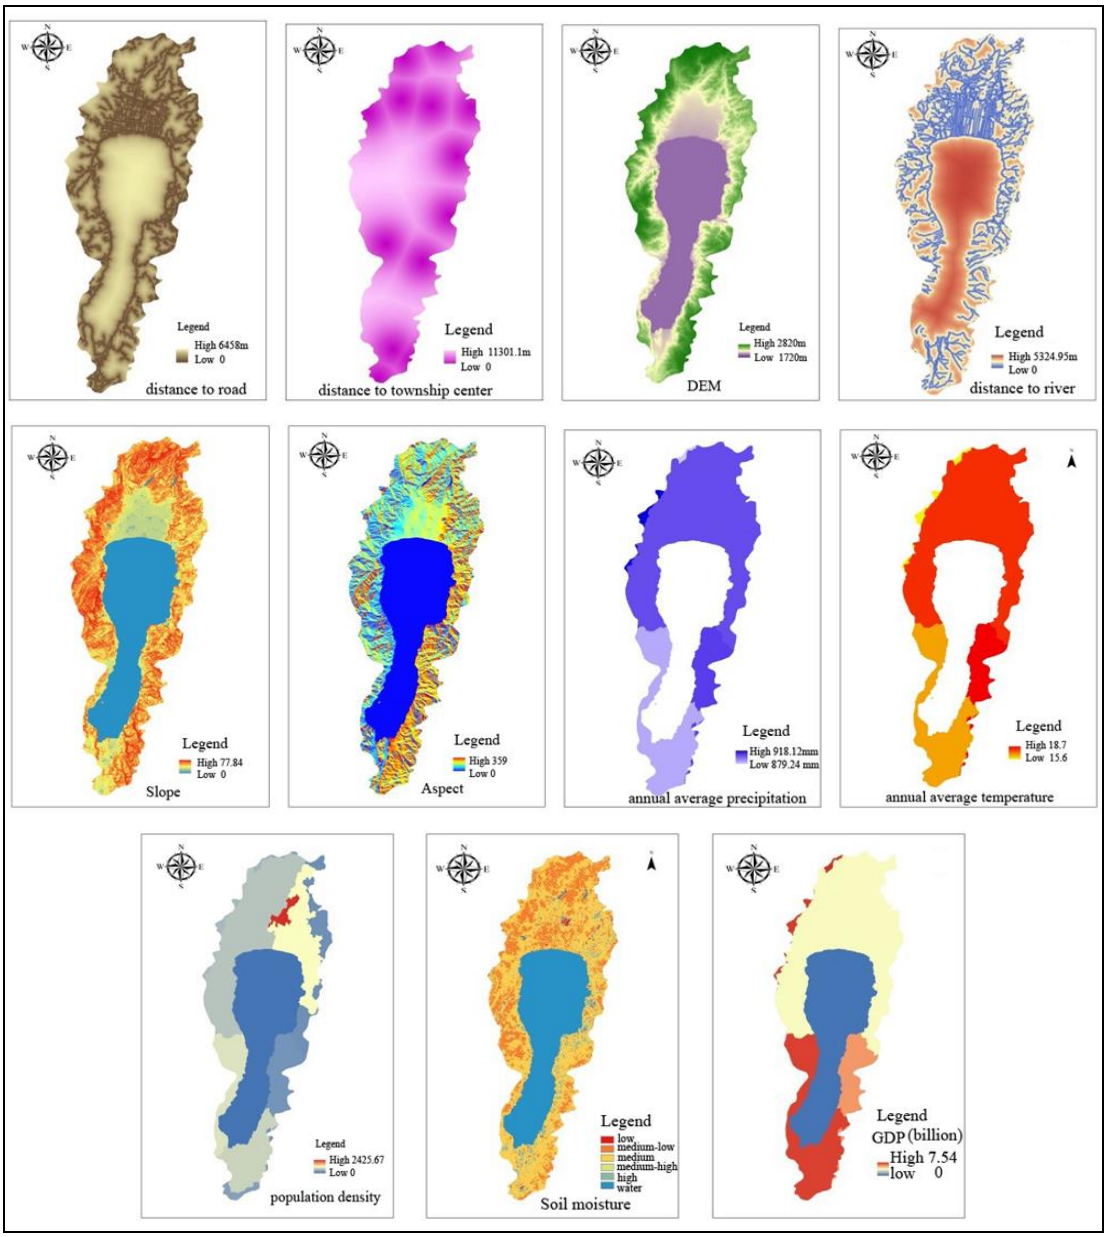

Figure 5. *The driver forces map of land use change*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88958914

(5) LULC change matrix setting. The LULC transfer matrix refers to the possibility matrix of mutual conversion between different LULC types according to the set scenario during the research period. Thus, the conversion matrix is set to 10 * 10, the rows representing the period year LULC type, and the columns representing the target year LULC type. If Class A can be conversed to be Class B, it is 1, otherwise it is 0.

(6) Conversion elasticity settings. Conversion elasticity reflects the difficulty with which each LULC type can be converted to another type. Its value ranges from 0 (easy to convert) to 1 (non-convertible). The closer it is to 1, the more stable it is, and the more difficult it is to be changed. The magnitude of the conversion elasticity is generally expressed by transition probability matrix. Using the LULC classification result of the basin, the LULC transition probability matrix for 2008-2011, 2011-2014 and 2014-2017 can be calculated. The values on the diagonal represent the stability of this LULC type, i.e. the conversion elasticity (*Table 5*).

Table 5. *LULC conversion elasticity in watershed from 2008 to 2017*

LULC type	conversion elasticity			
	2008~2011	2011~2014	2014~2017	average
CL	0.93	0.89	0.92	0.91
G	0.89	0.64	0.90	0.81
WL	0.95	0.95	0.96	0.95
GL	0.80	0.72	0.87	0.80
BR	0.98	0.96	0.98	0.97
R	0.97	0.92	0.97	0.95
S	0.79	0.66	0.52	0.66
APDL	0.78	0.55	0.85	0.73
DB	0.44	0.17	0.58	0.40
W	0.99	0.99	0.99	0.99

Table 5 shows that in 2008-2017, the conversion elasticity of all land types fluctuates less and has a higher conversion elasticity. Among them, the conversion elasticity between desert and bare land is the lowest, which is only 0.4, indicating that it is difficult to convert to other places, while the conversion elasticity of other lands is above 0.7, and the water area is the most stable. Because there is a certain band of the conversion elasticity value of each type in the three periods, and the setting of the stability parameter has a great influence on the simulation result, the average value of the three periods is used as the stability parameter among different LULC types in the study area.

(7) Determination of the simulation scale of LULC change in the river basin. In the CLUE-S model, the iteration of spatial allocation is a process in which the demand of LULC type in the research area interacts with the natural, social and economic factors in the grid element, and has obvious scale effect. Under the influence of the same driving factors, taking 10m, 30m, 60m and 100m as the spatial scales of the experiment, the logistic regression analysis models of various spatial scales of each LULC type are constructed, respectively, and the results are described in terms of Area Under Receiver Operating Characteristic (ROC) Curve (AUC) values (*Fig. 6*); then, the simulation results of each spatial scale are compared with the LULC type result map of the actual year to calculate the Kappa value of the land type. The results show that because there are too many pixels on the 10 m grid scale and the calculation amount is too large, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88958914

results cannot be calculated in the Logistic analysis with errors reported and from the AUC curve, the AUC curves at 30 m scale are above the 60 m and 100 m scale curves as a whole. Moreover, the Kappa value and average value of cultivated land, building area, forest land and garden land reach more than 0.9, which is generally higher than other spatial scales, so 30 m * 30 m is chosen as the optimal spatial scale for this simulation.

	CL	BR	WL	GL	S	W	G	R	AP DL	DB
30m	0,86	0,91	0,91	0,82	0,83	1	0,71	0,73	0,76	0,55
60m	0,78	0,82	0,9	0,81	0,87	1	0,6	0,8	0,73	0,69
100m	0,86	0,57	0,77	0,7	0,75	0,94	0,63	0,63	0,73	0,49

Figure 6. *The AUC change of muti-scale LULC simulation in watershed*

(8) Simulation of LULC change scenarios in the river basin. Determine the analysis grid size of 30 m * 30 m by using the above-set LULC change simulation parameters, and update the population, rainfall amount, temperature, output value and soil water content by using the selected driving factors with the LULC status chart in 2017 as a reference. According to the set scenario and restriction conditions, the LULC change of Fuxian Lake Basin in 2020 is simulated. The results are shown in *Fig. 7*.

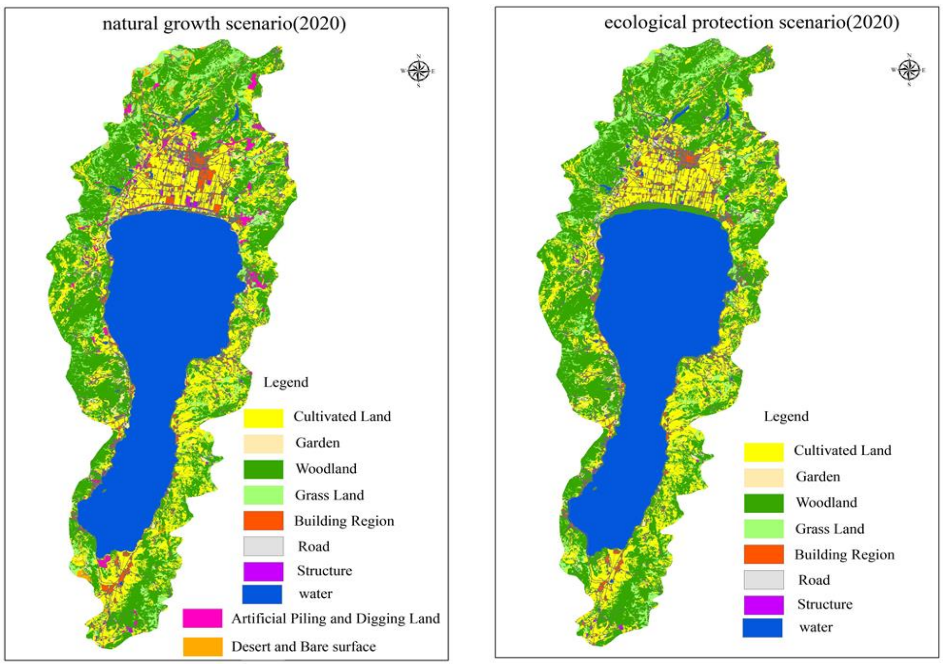

Figure 7. *The results of LULC change simulation under different scenarios in Watershed*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88958914

(9) Verification of simulation accuracy. Based on the LULC results of Fuxian Lake in 2008, 2011 and 2014, the time duration is three years to simulate the LULC changes in 2011, 2014 and 2017 in three times. After the simulation is completed, the result files cov all. * 2011, cov _all. * 2014, and cov all. * 2017 are transformed to form a final simulation result (*Fig. 8*).

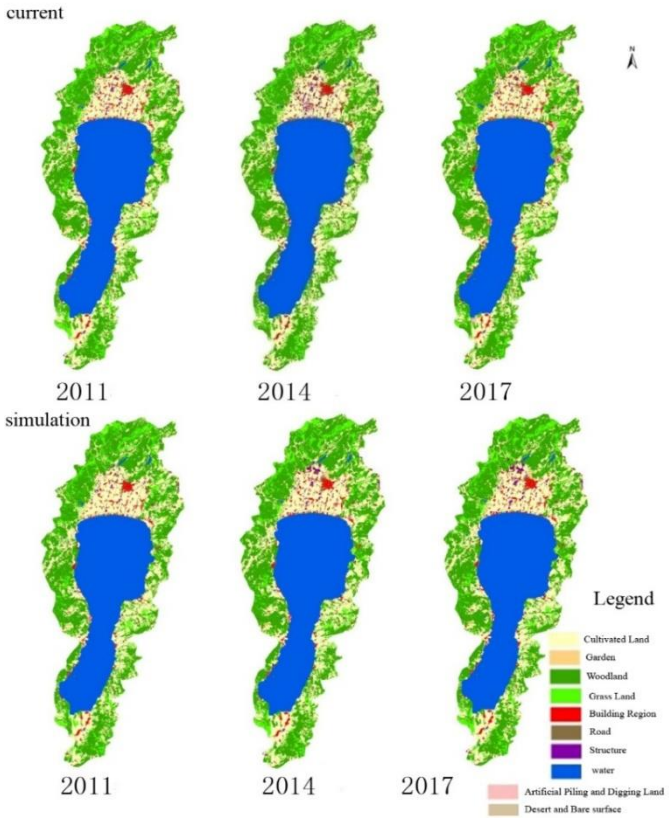

Figure 8. *The Comparison of LULC simulation results with current status map*

It is the most effective method to evaluate the accuracy of the simulation results by comparing the simulation results with the actual LULC graphs in this year (Verberg, 1999). The AUC value and Kappa coefficient of logistic regression analysis are used to verify the accuracy of the simulation results. The simulation results for 2011, 2014, and 2017 are compared with the actual LULC graph for the year to verify the accuracy of the simulation from both spatial and quantitative variations. From the space intersection analysis, the spatial distribution difference of the simulation precision can be obtained, the grid calculation tool is used to subtract the simulation result from the actual result classification graph, and the correct grid number (0-value grid) can be calculated, to obtain Kappa value (*Table 6*).

As can be seen from *Table 6*, the overall simulation accuracy is high, but there is a difference among various land classes. The simulation accuracy of garden land, structure and construction land is relatively low, of which the construction land is the lowest. The Kappa index of the water area and the cultivated land is above 0.9, the water area is above 0.99, which is very high, and the simulation result is almost consistent with the actual result. The results show that the driving factors selected in the study can better explain the spatial change of LULC. Because the garden land, structure,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88958914

construction land, desert and bare land are greatly disturbed by human factors, the simulation effect is not very good.

Table 6. *Accuracy verification of simulation result*

Analysis of Results

The change characteristics of LULC quantity

The simulation results for 2020 under different scenarios are compared with the 2017 LULC type status chart to analyze the quantitative and spatial changes (*Table 7*).

Table 7 shows that under the natural change scenario, the forest land, farmland, grassland and garden land show a decreasing trend, and the forest land decrease is the largest, while the construction land, building area, structure and road show an increasing trend, and the increase of the construction land is the largest.

Table 7. *Simulation results of LULC type change under different scenario*

LULC type	2017	Natural Growth (2020)	Ecological protection(2020)	Natural Growth change (2020)	Ecological protection Change (2020)
CL	13650.52	13460.58	7340.08	-189.94	-6310.44
G	958.98	944.09	462.92	-14.89	-496.06

W	21906.48	21973.66	22089	67.18	182.52

According to the spatial distribution of the change, the cultivated land in the village farmland area decrease obviously, while the impervious surface and other land increase, the forest and grass coverage in the phosphate rock area decreases, and other land increases. However, the impervious surface and other land use in the urban area show an increasing trend, while the cultivated land shows a decreasing trend. The numerical and spatial changes of LULC/coverage changes in the basin in natural situation reflect the comprehensive effects of natural and human factors. Along with the improvement of the urbanization level of the river basin, the construction land of the river basin occupies

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88958914

a large amount of cultivated land, especially the flat area on the north bank (urban area) of Fuxian Lake is the most prominent, which leads to the larger reduction of high-quality cultivated land in the river basin and thus poses a certain threat to the planting level and the safety of grain production in the river basin. At the same time, along with the large increase of other land use in phosphate rock area (desert and bare surface) and impervious surface in urban area promotes surface pollutants to flow into rivers, further aggravating the threat of non-point source pollution to lake-entering rivers, and the forest and grass coverage decreases, which will inevitably pose a serious threat to the ecological security of the river basin.

Under the circumstance of ecological protection, the increase of forest land and water area is the largest, while the cultivated land, grassland, construction land and garden land are greatly reduced. The quantity of ecological land increases obviously, while the quantity of construction land, planting land and other land that restrict the ecological environment protection shows a decreasing trend, which will benefit the ecological environment protection of the river basin. According to the spatial distribution of changes, the other land (desert and bare surface) in the phosphate rock area, the construction land in the urban area, the cultivated land in the village farmland area are greatly reduced, and the forest and grass coverage in the three areas have increased greatly. The result of this change is not only the response of LULC change to the ideal state of the 13th Five-Year Plan on protection the basin, but also the demonstration of the implementation effect of specific policies such as "Four Retreats and Three Returns". This result has greatly increased the forest coverage rate of the basin, and in the core protection area where the pollution source is the most serious, the influence of human activities has been withdrawn, and the ideal state of the natural land types in the core protection area has been realized, forming a natural barrier to the drainage and purification of the lake.

Spatial variation characteristics of LULC

Using the "per category" module of the MCK image comparison tool, the results of scenario simulation are compared with the actual land use in 2014. The results are as shown in the figure. The types of restricted land types such as cultivated land, forestland, garden land, water area, desert and bare land and construction land are mainly analyzed. In the figure, "in one of the maps" indicates the rest of the land types other than this land type, and "in both maps" indicates areas where there is no change in 2014 and 2017, "only in 2014, not in 2017" indicates a reduced area in 2017 relative to 2014, and "only in 2017, not in 2014" refers to the increased area in 2017 relative to 2014.

Fig. 9 shows that from 2008 to 2017, the cultivated land under the natural change scenario was continuously reduced, mainly converted into forest land, garden land and grassland, and a small part was converted into construction land and desert and bare land; but under the ecological protection scenario, the cultivated land also showed the decreasing trend, but the range was smaller than the natural change scenario. The change of the region has been distributed throughout the basin, and for the areas with higher elevation, the part of the cultivated land also has a decreasing trend.

There is a decreasing trend of forest land under natural changes and ecological protection scenarios. It is mainly concentrated in the high altitude area to the north of Fuxian Lake Basin, and the change of forest land within the ecological protection red line is very small.

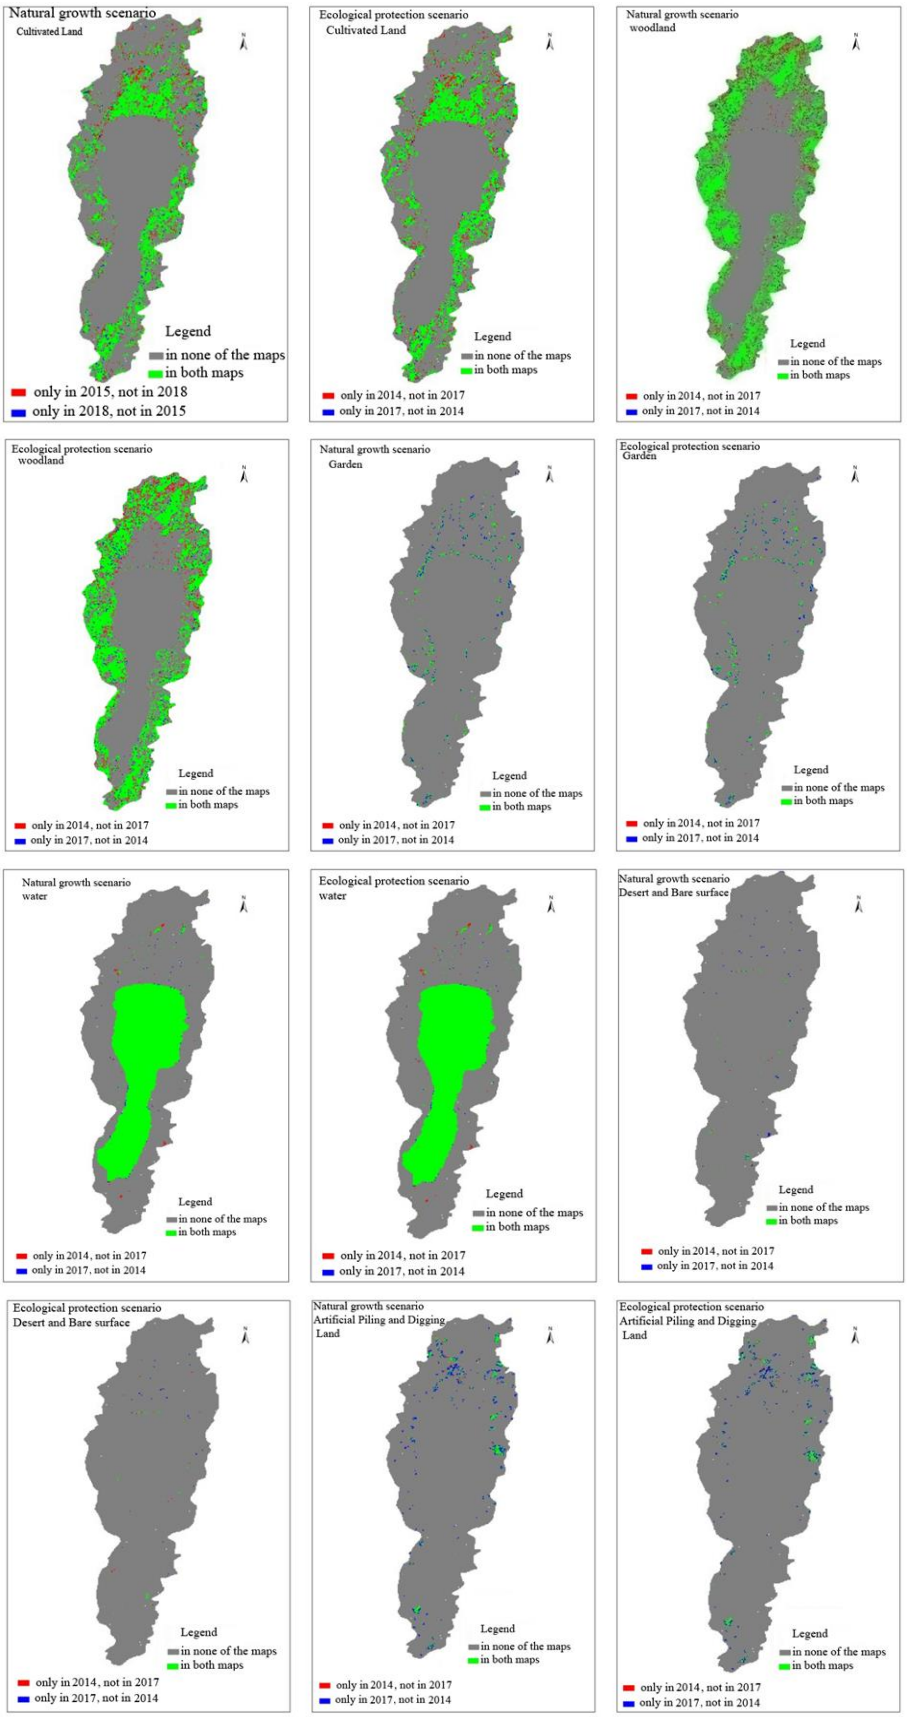

Figure 9. *Spatial distribution of LULC types under different scenarios*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_88958914

Under the natural change and the ecological protection scenarios, the garden land showed an increasing trend. The garden land area of the natural change scenario increased from 993.28 hectares in 2015 to 1,463.94 hectares, while the ecological protection scenario area increased by 48.68%, which is consistent with the requirements of the ecological protection plan. It is mainly distributed in the middle and low elevation area of the river basin, and in the north and west of the river basin, and it is also the most widely distributed and largest area of the garden land in Chengjiang County.

The distribution of increasing and decreasing water area is close to that of natural change and ecological protection scenarios. The reduced area is the north and northwest of Fuxian Lake Basin, and the waters increase along the edge of the Lake. This fully demonstrates the effectiveness of the policy of returning farmland to lakes and forests in Fuxian Lake Basin.

Under the natural change and ecological protection scenarios, the area of desert, bare land and constructed land all showed an increasing trend. Because the total area of desert, bare land and constructed land is relatively small, but it is an important part of the conversion of ground type, with the highest degree of activity. Although the conversion parameters of the land types are limited in scenario simulation, the general direction of change is unchanged. In the stable change trend, its change area mainly distributes in the urban and rural fringe area with frequent human activities.

Conclusions and Discussion

Conclusions

(1) The CLUE-S model has high reliability to simulate the future LULC change in basin scale. The overall simulation accuracy is high, but there are differences in the simulation accuracy of different land types. The simulation accuracy of the garden land, structure, construction land, desert and bare land disturbed by human factors is relatively low, among which the construction land is the lowest. Kappa index of water area and cultivated land are above 0.9 and water area is above 0.99, which indicates that the driving factors selected in the study could better explain the spatial change of LULC.

(2) Under the natural change scenario, the ecological security of the basin will face serious threats. The forest land, farmland, grassland and garden land is reducing and the decrease of garden land is the largest, while the construction land, building area, structure and road is increasing and the increase of the construction land is the largest. According to the spatial distribution of the change, the cultivated land in the village farmland area decreases obviously, while the impervious surface and other land increase, the forest and grass coverage in the phosphate rock area decreases, and other land increases. However, the impervious surface and other land use in the urban area show an increasing trend, while the cultivated land shows a decreasing trend.

(3) The ecological protection scenario will be beneficial to the ecological environment protection of the river basin. The increase of forestland and water area is the largest, while the cultivated land, grassland, construction land and garden land are greatly reduced. It shows that the quantity of ecological land increases obviously, while the quantity of building land, planting land and other land that restrict the ecological environment protection shows a decreasing trend, which will benefit the ecological environment protection of the river basin. According to the spatial distribution of change, the other lands (desert and bare surface) in the phosphate rock area, the

DOI: http://dx.doi.org/10.15666/aeer/1704_88958914

construction land in the urban area and the cultivated land in the village farmland area are greatly reduced, while the forest and grass coverage in the three areas show a significant increase trend.

Discussion

The CLUE-S model is subjective in setting the transition elasticity of land types according to the land use conversion matrix and the land use conversion probability matrix. How to obtain the objective elastic coefficient of land type conversion needs to be further studied. How to couple other models to realize seamless integration of spatial allocation of spatial and non-spatial modules so as to reach the "equilibrium" state of land use change and economic and social development still is not solved. The CLUE-S model needs to be further studied by coupling with other models.

Abstract. To disclose the formation mechanism of flash flood disaster, it is necessary to develop a dynamic critical rainfall model that considers all influencing factors. Targeting the Peihe River watershed in China's Henan Province, this paper designs a runoff convergence calculation plan based on the geomorphological instantaneous unit hydrograph (GIUH), and uses the plan to simulate 8 floods in the target watershed. The simulated results were close to the measured data. Next, the GIUH was adopted to predict the critical rainfalls of 16 floods in the target watershed. The radial basis function neural network (RBFNN) was selected to create a dynamic critical rainfall prediction model, with the preceding rainfall, cumulative rainfall and rainfall intensity as the inputs and the critical rainfall of each event as the output. The model was employed to predict the critical rainfalls of 6 historical floods. The results show that the prewarned critical rainfall reached the pass rates of 100% and 83.3%, respectively, for the 1 h and 3 h periods. Hence, that the GIUH can ensure the calculation accuracy despite the lack of data in regions prone to flash flood; the RBFNN-based dynamic critical rainfall prediction model can effectively improve the accuracy of critical rainfall calculation and the flash flood prewarning.
Keywords: *flash flood disaster, prewarning index, concentration model, disaster prevention object, geomorphological parameters*

Introduction

In recent years, the climate change has induced extreme weather conditions across the world, such as the extreme rainfall events. As a result, the flash flood, a rapid flooding in small hilly regions associated with heavy rainfall, became a frequent global disaster with increasing scope of influence (Gruntfest and Handmer, 1999). With complex influencing factors and severe damages, this disaster is difficult to prevent or mitigate, making it the key to flood prevention and mitigation. The critical rainfall is an important parameter in the prewarning and prevention system of flash flood disasters (Li et al., 2014). A pre-warning should be issued when the rainfall is forecasted to reach the critical level, and a warning should be released once the real-time rainfall reaches the critical value. Therefore, the accuracy of critical rainfall is essential to the reduction of casualties and property losses.

Currently, the critical rainfall is mainly determined by the following methods: flash flood guidance (FFG) (WMO, 1994; Villarini et al., 2010; Carpenter et al., 1999; Diagi, 2018; Norbiato et al., 2008; Georgakakos, 2006; Seo et al., 2013; Vizzari et al., 2018; Clark et al., 2014), single-station or regional critical rainfall method based on the characteristic flood-causing rainfall (Chen and Yuan, 2005; Chen et al., 2014), flood-causing flow inversion based on analytical calculation of runoff generation and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89158930

convergence (RGC) (Mao, 2016; Ma, 2017), dynamic critical rainfall method based on different soil saturations (Liu et al., 2010; Ye et al., 2014) and the dynamic critical rainfall method based on various influencing factors (Guo et al., 2016). Below is a brief introduction to each of these methods.

The FFG method fully considers such three factors as rainfall, antecedent soil moisture and the underlying surface (Ren, 2015). Firstly, a control section is selected at the prewarning location, and the characteristic flow of the section is computed according to the river section data of the watershed. Next, the design rainfall and other parameters are inputted to the model, and the rainfall-caused flood is simulated through RGC calculation. Finally, the critical rainfalls in different periods at the target location are determined, considering the impacts of antecedent soil moisture on flash flood. Based on a physical mechanism, the FFG method provides dynamic information for prewarning, thanks to its consideration of rainfall, the underlying surface as well as the impacts of soil water content. Thus, this method has been trusted and adopted by most countries in Europe, the Americas and Africa (Georgakakos, 2006). However, the FFG requires professional support platforms and high-quality data on rainfall. In practice, it is very difficult to acquire the parameters of hydrological model, or set up a complete historical flash flood database to verify the flash flood warning.

As for the single-station or regional critical rainfall method based on the characteristic flood-causing rainfall, it is necessary to collect the data on multiple flood-causing rainfalls. Without considering antecedent moisture and spatiotemporal rainfall distribution, this method faces a high calculation error in regions with fewer floods.

By the flood-causing flow inversion based on analytical calculation of RGC, the critical rainfalls in different prewarning periods under dry, general and wet conditions are computed based on the flood-causing flow and the RGC model of the watershed. The real-time prewarning is realized through two steps: estimating the soil water content and the corresponding critical rainfall in each prewarning period, and comparing the estimated value with the forecasted value. The estimation is bound to bring a large error, if the rainwater condition in the region is managed by a single department. What is worse, this method, taking account of only a few factors, ignores the effects of spatiotemporal distribution of rainfall and preceding rainfall on the bottom water of the river.

Following the dynamic critical rainfall method based on different soil saturations, the soil saturation and rainfall of the watershed in each prewarning period are illustrated as a scatter plot, and a straight line of critical prewarning rainfall is drawn in the scatter plot, dividing the state space of soil saturation and the maximum rainfall in each period into two parts. In this way, the critical rainfall for flash flood prewarning changes with the soil saturation in the watershed, laying the basis for dynamic prewarning. Compared with the previous methods, this strategy fully considers the dynamic variation in soil saturation in actual floods. Nevertheless, the soil saturation-based prewarning method will produce a constant critical rainfall after the soil is saturated with water, which goes against the actual situation.

In the dynamic critical rainfall method based on various influencing factors, the critical rainfall of each event is computed according to the measured rainfall process and the watershed RGC model, and the critical rainfall of each event is correlated with the rainfall characteristics of each event, forming the dynamic critical rainfall curve. This method improves the accuracy of critical rainfall calculation to some extent, as it fully considers how the critical rainfall is affected by the time variation of rainfall, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89158930

cumulative rainfall, and the antecedent moisture. However, the calculation accuracy needs to be further improved by differentiating the impact degree of various factors on the critical rainfall.

The watershed RGC calculation is fundamental to the computation of the critical rainfall. The calculation of runoff generation, affected by geographic and geomorphic conditions, directly bears on the flooding of the watershed outlet section, which in turn affects the accuracy of critical rainfall and real-time pre-warning. In the existing rainfall calculation methods, the runoff generation is often computed by inference formula method (Liu et al., 2017; Li, 2016) and hydrograph models of multiple units (e.g. empirical unit, instantaneous unit and geomorphological instantaneous unit (Ye et al., 2013; Wang et al., 2018).

Based on five-point generalization, the flood hydrograph obtained by the inference formula method needs manual calibration, as it deviates from the actual situation in the rising and recession phases. Besides, the effects of the underlying surface (e.g. geomorphic conditions) is not taken into account.

The integrated instantaneous unit hydrograph, integrated empirical unit hydrograph, integrated reference formula and geomorphological instantaneous unit hydrograph are all tools to estimate the flood hydrograph in regions lacking the necessary data. Specifically, the integrated unit hydrograph method firstly analyzes the watersheds with measured data in the study area, derives the relationship between the unit hydrograph and the geographic eigenvalues of the watershed, and then deduces the unit hydrograph of the region lacking the necessary data according to the local geographic eigenvalues and the said relationship. Assuming the linearity and time invariance of the set sum, the unit hydrograph is a function of the natural geographic features of the watershed, but cannot be directly adopted for watersheds lacking necessary data.

The geomorphological instantaneous unit hydrograph (GIUH) can acquire the geomorphic features of the watershed in real time, using digital elevation model (DEM), geographic information system (GIS), remote sensing and other means. In addition, these features are digitalized such that the spatiotemporal effects of human activities can be fully considered in hydrological simulation. The overall consideration ensures that the simulated results are close to the actual situation.

In this paper, the geomorphological features of the target watershed are extracted by ArcGIS, and used to establish a runoff generation model based on the geomorphological instantaneous unit hydrograph proposed by Rodriguez-Iturbe and Valdes (R-V GIUH). Then, the established model was adopted to calculate the critical rainfalls of several rainfall events measured in the watershed. Considering such factors as rainfall intensity, cumulative rainfall and antecedent moisture, the author constructed the dynamic critical rainfall model by the radial basis function (RBF), which discloses the dynamic relationship between critical rainfalls of several floods and various influencing factors. The model was trained into the prediction model by the data of several floods, and applied to forecast the dynamic critical rainfall. The research findings shed new light on the calculation of dynamic critical rainfall.

Materials and methods

Watershed overview

Located in the center of Xinxian County, Xinyang Prefecture, Central China's Henan Province, the Peihe River mainly flows through a mountainous region with huge

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89158930

elevation difference and complex geomorphic features. The watershed (*Fig. 1*) is covered by yellow brown soil, paddy soil and moisture soil. The climate is relatively humid, with an annual mean rainfall of 1,335 mm. The low vegetation coverage makes the watershed prone to natural disaster and soil erosion. The weather in the watershed could be vastly different from area to area. Thus, heavy rains are commonplace here, leading to severe flash floods. According to statistics, 12 major flash floods has hit the Peihe River watershed since 1949, causing losses of hundreds of million yuan and affecting tens of thousands of people.

In this research, the villages of Xinxian County are selected from the watershed as the objects of disaster prevention. Many of the widely scattered settlements are highly susceptible to flash floods. The villages along the river cann withstand a 20-year flood at the most. Because of the small watershed and short convergence time, the river water will rise above the banks of the rainfall is too intense, causing damages to the villagers.

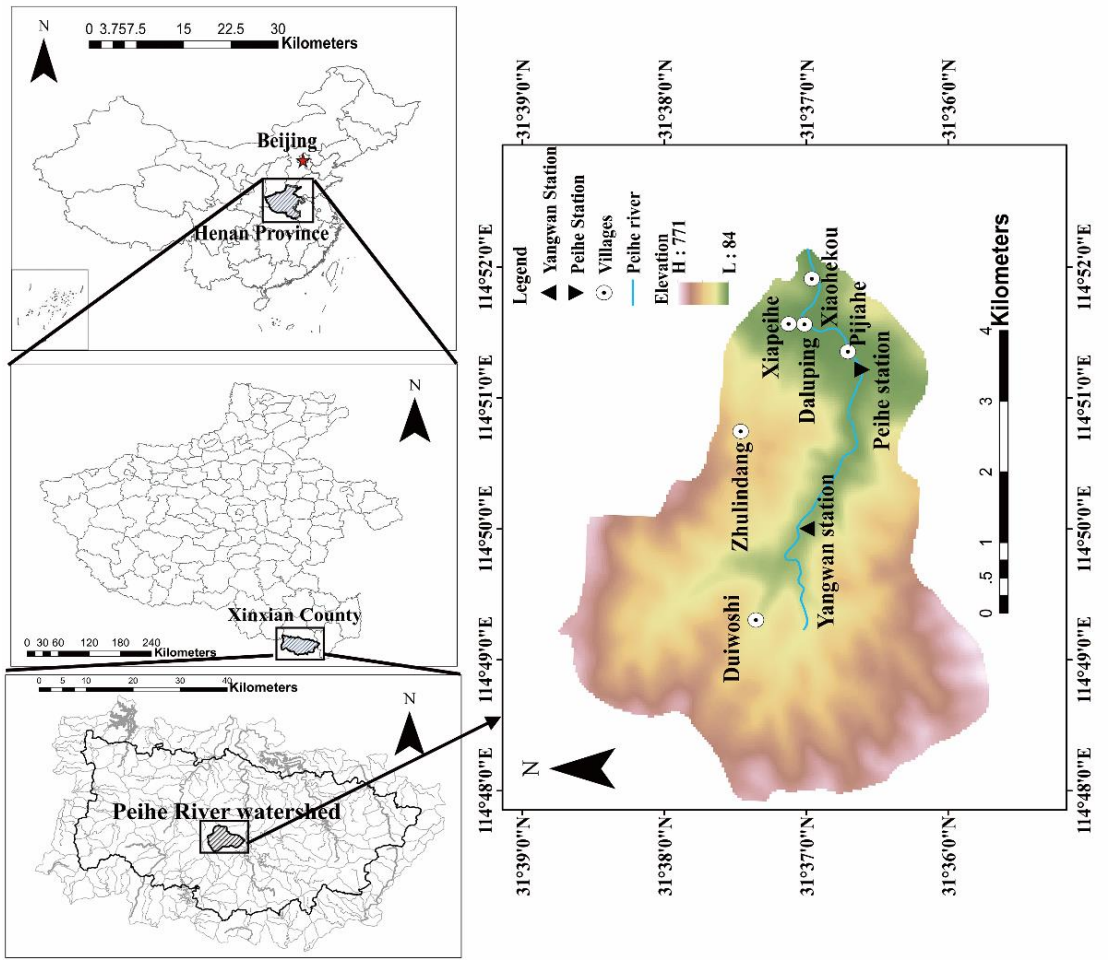

Figure 1. *Overview of the Peihe River watershed*

There is a rainfall station (Yangwan) and a hydrological station (Peihe) in the Peihe River watershed. The two stations observe such items as precipitation, water level and flow rate. The available data cover the heavy rains in flood season over the 32 years between 1982 and 2013. The data period is sufficiently long to have statistical significance, that is, the data can reveal the actual rainfall features in the watershed.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89158930

Most of the natural river sections are either V-shaped or U-shaped, with a total catchment area of about 21 km^2. The prewarning water level of the watershed was determined as 97.3 m according to the measured large section data of the Peihe River watershed provided by Henan Provincial Flood Prevention Drought Relief Headquarters and the *2015 Flash Flood Disaster Analysis and Evaluation Report of Xinxian County, Henan Province*. The flow rate corresponding to the prewarning flow, i.e. the prewarning flow, was determined as 92 m^3/s by looking up the water level-flow rate relationship curve of the watershed, which was obtained based on the perennial measured flow rates and water levels.

Geomorphologic instantaneous unit hydrograph proposed by Rodriguez-Iturbe and Valdes (R-V GIUH)

The runoff convergence model of R-V GIUH theory is established based on geomorphic and hydrodynamic parameters of the watershed. The model can reflect the actual geomorphic features with a few easy-to-obtain parameters. In this paper, the general formula proposed by Wen et al. (1991) is adopted to calculate the R-V GIUH of the watershed (*Eq. 1*):

$$R-VGIUH(t)=-\sum_{j=1}^{\Omega}\left\{\lambda_i\left[\sum_{i=1}^{j}\theta_{i,\Omega}(0)A_{ij}\right]e^{-\lambda_j t}\right\} \quad \text{(Eq.1)}$$

where i and j are the orders of rivers ($i \neq j$); λ_i and λ_j are the mean waiting time of order i and order j rivers, respectively; Ω is the order of the river network; $\theta_{i,\Omega}(0)$ is the initial state probability of a order i river in a order Ω river network, i.e. the size ratio of the watershed of the order i river to the watershed of the entire river network; A_{ij} is the correlation coefficient between the mean waiting time λ_i and the state transition probability P_{ij} (P_{ij} is the ratio of the number of order i rivers flowing into order j rivers to the total number of order i rivers; t is time. All these parameters can be calculated based on the geomorphic and hydrodynamic parameters of the watershed.

Extraction and calculation of geomorphic parameters

The river network of the watershed was extracted from the DEM in the study area using the software Geographic Information System (GIS). Then, the Strahler classification (2015) was performed on the extracted river network, yielding the river section data with watershed orders. On this basis, the geomorphic features of each river section in the watershed were determined, including number, length and catchment area, and the river number ratio R_B, river length ratio R_L and area ratio R_A were respectively calculated as follows by the Horton's law (*Eqs. 2-4*):

$$R_B=\frac{N_{i-1}}{N_i}=C, i=1,2,\cdots,\omega \quad \text{(Eq.2)}$$

$$R_L=\frac{\bar{L}_i}{\bar{L}_{i-1}}=C, i=1,2,\cdots,\omega \quad \text{(Eq.3)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89158930

$$R_A = \frac{\bar{A}_i}{\bar{A}_{i-1}} = C, i = 1, 2, \cdots, \omega \quad \text{(Eq.4)}$$

where N_i and N_{i-1} are the number of order i rivers and that of order i-1 rivers, respectively; $\bar{L}_i$ and $\bar{L}_{i-1}$ are the mean length of order i rivers and that of order i-1 rivers, respectively; $\bar{A}_i$ and $\bar{A}_{i-1}$ are the mean watershed area that contributes to the runoff of order i rivers and that to the runoff of order i-1 rivers, respectively; C is a constant; ω is the highest order of the river system.

Determination and calculation of hydrodynamic parameters

The hydrodynamic parameters of a watershed include the Manning's roughness coefficient n and the mean river width B. The former was obtained by table look-up according to the local conditions. The latter was generalized as an unknown parameter that varies with the net rainfall intensity i_r. The mean waiting time λ_i of rivers on each order was calculated based on the two parameters. The calculation formulas of n, B and λ_i are as follows (*Eqs. 5-7*):

$$v = 0.665\alpha_\Omega^{0.6}(i_r A_\Omega)^{0.4} \quad \text{(Eq.5)}$$

$$\alpha_\Omega = S^{0.5} / (nB^{2/3}) \quad \text{(Eq.6)}$$

$$\lambda_i = v / (\bar{L}_i \cdot R_L^{i-1}) \quad \text{(Eq.7)}$$

where i_r is the net rainfall intensity of each event; v is the flow rate.

Calculation of critical rainfall of each event

The critical rainfall of each event refers to the critical rainfall in the prewarning period of a flood-causing rainfall event. It is the basis for determining the dynamic critical rainfall for the disaster prevention in the target location. In light of the measured rainfall data, the value of this parameter was obtained by the RGC calculation through the following steps.

(1) The rainfall process from the beginning of rainfall to any time T was intercepted from the rainfall data, the RGC process of the watershed was calculated using the rainfall-runoff correlation map and the R-V GIUH, and the flood hydrograph was derived for the rainfall event.

(2) The peak flow Q_{peak} in this rainfall event was obtained based on the flood hydrograph. If the peak flow is greater than the prewarning flow $Q_{prewarning}$, then the flash flood has occurred. In this case, the rainfall process from the beginning of rainfall to any time T was intercepted again, and Step (1) was repeated until the peak flow is smaller than the prewarning flow.

(3) When the peak flow is smaller than the prewarning flow, the rainfall in the T + 1 period was given a value in ascending order, and the flood process induced by the rainfall in this period was derived. If the peak flow is close to the prewarning flow, then the rainfall in the T + 1 period is the critical rainfall of the event after the rainfall event lasts for a period of T.

DOI: http://dx.doi.org/10.15666/aeer/1704_89158930

(4) The critical rainfalls of different events can be determined by the same method.

RBF-based prediction of dynamic critical rainfall

The RBF neural network (RBFNN) is a RBF-based artificial neural network. With a three-layer feedforward structure, the network has a nonlinear mapping from the input layer to the output layer and a linear mapping from the hidden layer to the output layer. The good nonlinearity enables the RBFNN to approximate any nonlinear function, disclose the intractable regularity in the system, and describes the potential relationship between the predictive index and the influencing factors. Known for its good generalization ability, the network has been successfully applied to nonlinear function approximation, time series analysis, data classification, pattern recognition, system modeling and fault diagnosis. Considering the complex nonlinear relationship between critical rainfall and its influencing factors, the RBFNN is a desirable tool to build the dynamic relationship model about the critical rainfall and the influencing factors. This network can be implemented despite the lack of data in regions suffering from flash floods, as it requires only a few training samples and outputs a unique training outcome.

In this paper, antecedent moisture, cumulative rainfall and rainfall intensity are taken as an input, and the critical rainfall of each event was considered as the output to construct a three-layer neural network. Through the training of the learning samples and the checking of the test samples, the dynamic relationships between the critical rainfall and the influencing factors were established, forming the dynamic critical rainfall prediction model (*Fig. 2*). Mathematical theory of RBFNN is detailed in Zeng et al. (2018).

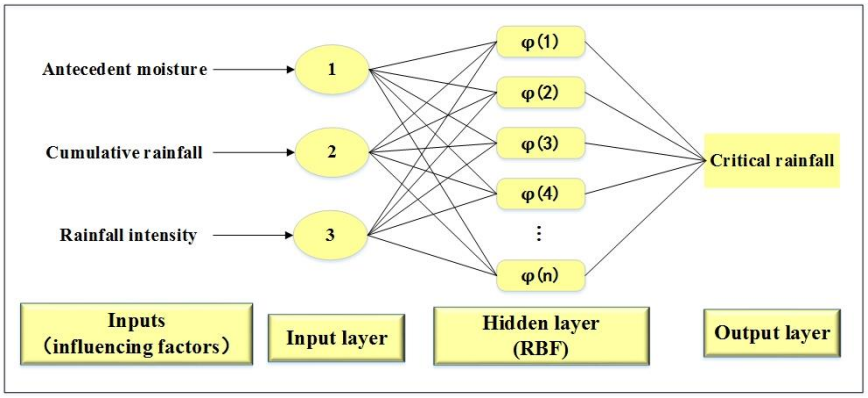

Figure 2. *structure of the dynamic critical rainfall prediction model*

Results

Runoff generation plan

The runoff generation was calculated based on the rainfall-runoff correlation map (*Fig. 3*), which was checked and modified against the 14 typical floods in the Peihe River watershed between 1982 and 2013.

As shown in *Figure 3,* since the 1980s, the actual rainfall-runoff curve in the Peihe River watershed was basically consistent with that in the map, so was the runoff volume. This means the rain and flood data are valid, and the rainfall-runoff correlation map can be adopted for runoff generation calculation.

Runoff convergence plan

Parameter extraction and model construction

The digital elevation data were downloaded from the Geospatial Data Cloud (http://www.gscloud.cn), with a spatial resolution of 30 m. The data about the Peihe River watershed were processed on ArcMap, producing the river network in the watershed. The network was then divided into four orders by the Strahler classification (*Fig. 4*). The number and total length of rivers in each order were counted (*Table 1*). Next, the watershed was split into several sub-watersheds (*Fig. 5*). The area of each sub-watershed was determined, and the relevant geomorphic parameters were computed by *Equations 2-4* (*Table 1*).

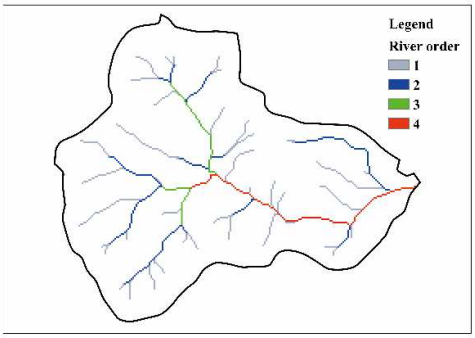

Figure 4. *River network classification*

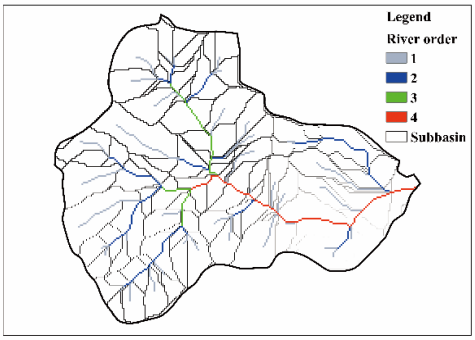

Figure 5. *Vector graph of catchment area*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89158930

Table 1. *Geomorphic parameters of the Peihe River watershed*

River order	River numbers	Total length of the river (km)	Average length of the river (km)	Total area of the catchment (km^2)	Average area of the catchment (km^2)	River number ratio	River length ratio	Area ratio
1	47	20.52	0.43	12.20	0.25	3.63	2.57	2.58
2	12	10.20	0.85	4.14	0.34			
3	3	3.45	1.15	1.85	0.61			
4	1	5.10	5.10	2.86	2.86			

The watershed area was acquired as 21.07 km^2 during the extraction of the river network. The area threshold was 0.1 km^2, and the corresponding stream gradient was 13.51%. The Manning's roughness coefficient was determined as 0.025 m by table lookup. The mean river width B was initially determined as 2 m according to the section data extracted on the GIS. On this basis, the value of B was calibrated through the simulation of 4 measured floods. The data of the 4 floods were fitted to obtain the relationship between B and the net rainfall intensity i_r: $B = 0.326\,ln(i_r) + 1.9312$. With these parameters, the R-V GIUH of each flood was derived by (Eq. 1).

Model verification

To verify the applicability of R-V GIUH in regions lacking hydrological data, the R-V GIUH was created based on the parameters of 8 rainfall events measured by Peihe Hydrological Station from 1982 to 2013, and the resulting unit hydrographs were compared with the measured data. *Figure 6* and *Table 2* show the comparison between the simulated results and the measured results of the 8 floods.

DOI: http://dx.doi.org/10.15666/aeer/1704_89158930

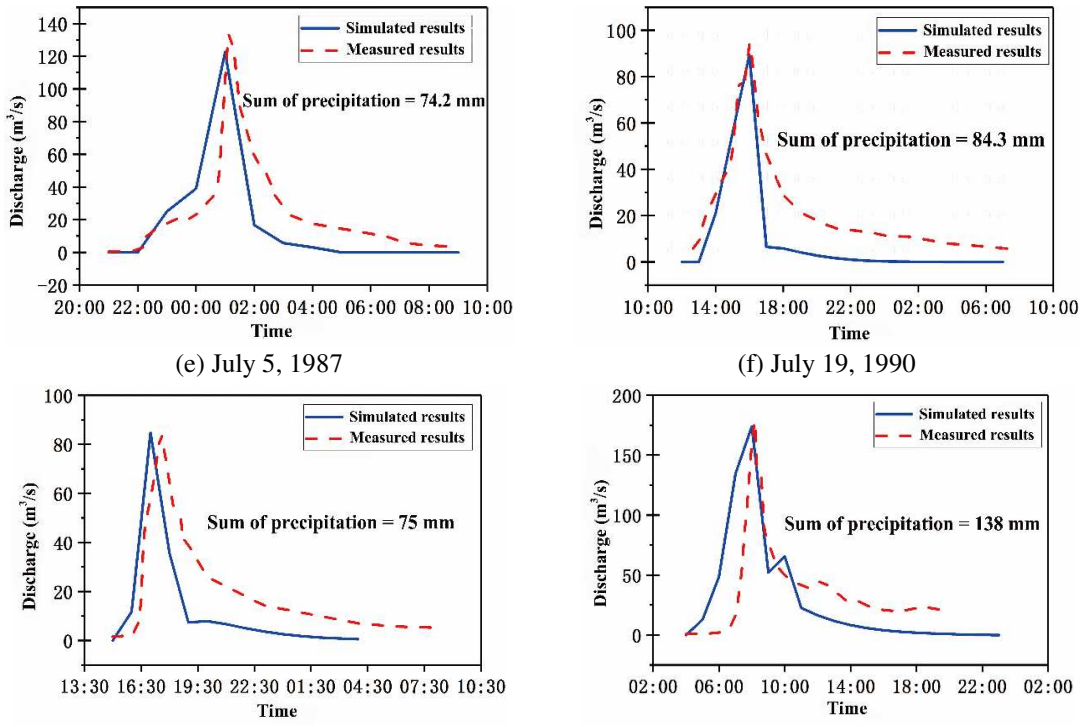

Figure 6. *Comparison between the simulated results and the measured results of the 8 floods*

Table 2. *Comparison between the simulated results and the measured results of the 8 floods*

Flood number	Measured peak/(m^3/s)	Simulated peak/(m^3/s)	Relative error/(m^3/s)	The time error of peak/(min)
July 19, 1982	200	187	-13	18
July 17, 1983	78	75.09	-2.91	40
August 8, 1984	107	98.29	-8.71	25
July 17, 1986	96.6	95.43	-1.17	0
July 5, 1987	133	122.64	-10.36	10
July 19, 1990	94.1	89.6	-4.5	0
July 1, 2007	83.5	84.8	1.3	36
August 16, 2008	178	174.19	-5.81	9

Figure 6 and *Table 2* show that the simulated flood process was basically the same with the measured situation. In the recession phase, the simulated results were slightly faster than the measured results. The minor deviation does not affect the computing accuracy of critical rainfalls, because critical rainfall mainly depends on the peak flow and the situation of the rising phase. Compared with the measured results, the simulated floods rose fast and reached the peak flow early at a low volume. As a result, the simulated critical rainfalls were slightly below the measured values. For safety reasons, the slightly lower critical rainfalls are safer. Overall, the geomorphic-based R-V GIUH model enjoys a high accuracy in runoff generation calculation, and the simulated results are suitable for the simulation of the flood process and the computation of the critical rainfalls.

Analysis of calculated critical rainfall of each event

Two typical prewarning periods, namely 1 h and 3 h, were selected according to the rainstorm features, watershed area and underlying surface of the target region. The critical rainfall of 16 measured floods in the Peihe River between 1982 and 2013 were calculated (*Table 3*). To verify the accuracy of the critical rainfall calculation by R-V GIUH, the critical rainfalls were compared with the actual rainfalls in the prewarning periods to see if flash flood prewarning is necessary, and the prewarning was verified based on whether the actual flow reached the prewarning flow.

Table 3. *Calculated and measured results on critical rainfall of each event*

Prewarning periods	Time	Measured discharge (m^3/s)	Total rainfall of periods (mm)	Critical rainfall (mm)	Prewarned or not	Correct or not

Y: there is prewarning; N: there is no prewarning; √: the prewarning is correct; ×: the prewarning is incorrect

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89158930

Table 3 shows that two prewarning based on the 1 h and 3 h critical rainfalls were incorrect, putting the pass rate at 87.5%. The failed cases were analyzed, revealing that the critical rainfalls deviated slightly from the actual rainfalls. The deviation falls within the error tolerance. Overall, the R-V GIUH outputted accurate critical rainfalls.

Dynamic critical rainfall models and accuracy test

According to the disaster-causing mechanism of flash flood, the occurrence of flash flood in a region not only depends on the preceding rainfall, cumulative rainfall and rainfall intensity, but also on rainfall distribution and the bottom water of the river. The latter two factors are already reflected by the cumulative rainfall and the critical rainfall of each event, respectively. Hence, our dynamic critical rainfall model only considers the preceding rainfall (antecedent moisture), cumulative rainfall (the total rainfall from the start to a moment before the prewarning) and rainfall intensity (the rainfall of a period before the prewarning).

In light of the critical rainfall calculation of the said 16 floods, the preceding rainfall, cumulative rainfall and rainfall intensity were taken as the inputs, and the critical rainfall as the output. The first 12 floods were used as calibration samples and the last 4 as test samples. Then, the prediction model was created in different scales through RBFNN training to predict the dynamic critical rainfall. The simulated results are contrasted with the actual results in *Figure 7*.

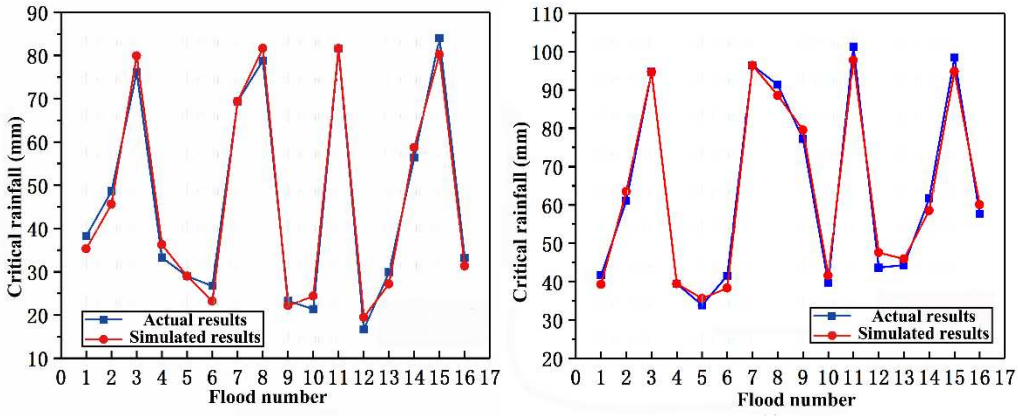

Figure 7. *Simulated results of dynamic critical rainfall prediction*

Figure 7 shows little difference between the simulated and calculated values, indicating that our model is suitable for the prediction of dynamic critical rainfall. To further verify its applicability, the model was adopted to predict the dynamic critical rainfalls of another 6 floods, and the results were also tested by the actual prewarning results (*Table 4*). The flood-causing flow inversion based on analytical calculation of RGC was introduced to determine the static critical rainfalls that only considers the preceding rainfall and to issue prewarning for the 1 h and 3 h periods, aiming to confirm the completeness of our indices and the superiority of our model. The calculated results are listed in *Table 4*.

It can be seen from *Table 4* that all dynamic critical rainfall prewarning for the 1 h period were successful, while five out of the six prewarning for the 3 h period were successful, putting the pass rate at 83.3%. By contrast, the pass rates of static critical

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89158930

rainfall prewarning were 66.6% and 50%, respectively. In fact, the RBF-based dynamic prediction was more accurate than the contrastive calculation method. To sum up, the R-V GIUH-based critical rainfall prewarning is of high accuracy, and the RBFNN-based dynamic prediction model thus established does well in the forecast of the critical rainfall.

Table 4. *Verification of the results predicted by our dynamic critical rainfall model*

Discussion

The critical rainfall is an important tool for the prewarning of flash floods. It is very meaningful to probe into this index. In this paper, the critical rainfall is investigated based on the GIUH and the RBFNN, yielding fruitful results. However, there are some shortcomings with our research. Next, the research findings are compared with the relevant studies in two aspects.

Our research discovers that, while the GIUH-based simulation output close-to-reality flood process, the simulated peak flow appears earlier and smaller than the measured data, causing the underestimation of the critical rainfall. This conclusion agrees well with the research of Tang (2017) and Wang et al. (2018). Meanwhile, the test results in *Table 3* show a good overall accuracy, but the underestimated critical rainfall may lead to wrong prewarning of several floods that do not cause disasters. New solution should be looked for to solve this problem.

Currently, the flash floods can also be simulated by distributed hydrological models, such as the geomorphology-based hydrological model (GBHM) (Liu et al., 2010), the Xin'anjiang (XAJ) model (Ye et al., 2014), the Hydrologic Engineering Center's Hydrological Modeling System (HEC-HMS) model (Liu, 2016; Guan et al., 2017), and the grid XAJ model (Liu et al., 2017). These models can simulate the flood process

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89158930

more realistically and accurately than the GIUH-based model, and can also be adopted to compute the critical rainfall. Nonetheless, most distributed hydrological models have lots of parameters, which need to be determined by a long series of data. In this respect, the GIUH-based method enjoys certain advantages with relatively few and easy-to-obtain parameters. In future research and applications, the flood computing method should be selected according to the local data.

In addition, the prewarning results of rainfall events differed with time scales, as acquired through the calculation of critical rainfall of each event. For example, the 1998070220 rainfall event was prewarned incorrectly on the 1 h scale and correctly on the 3 h scale, while the 1985071310 rainfall event was prewarned incorrectly on the 3 h scale and correctly on the 1 h scale. The results are consistent with the findings of Guo et al. (2016). Analysis shows that the prewarning effect of short, heavy rainfall is negatively correlated with the time scale. In actual application, the critical rainfalls on different time scales should be considered fully in the prewarning process, such as to reduce false warning and increase prewarning accuracy.

Besides flood computation, the dynamic relationship between the critical rainfall and the influencing factors also bears on the prewarning of flash floods. Many scholars (Liu et al., 2010; Ye et al., 2014; Guan et al., 2017; Guo et al., 2016) have explored this relationship via linear regression and correlation analysis. These methods can output accurate dynamic critical rainfall. However, none of them differentiate between influencing factors on their impact over the critical rainfall. In fact, the influencing factors are simply superimposed in the relevant studies. To further improve the computing accuracy of critical rainfall, this paper sets up the dynamic relationships between critical rainfall and multiple influencing factors based on the RBFNN. The model was proved accurate in prewarning through the analysis on its calibration, test and prediction results. However, the RBFNN, as a black box model, cannot clearly quantify the degree of impact of each influencing factor on the critical rainfall. The prediction results only confirm that the critical rainfall is affected in different degrees by various factors, namely, preceding rainfall, rainfall process and the bottom water of the river, and the relationships between critical rainfall and these factors are complex. To enhance the accuracy of flash flood prewarning and rationalize decision-making for disaster prevention and mitigation, it is necessary to further explore how these factors affect the dynamic variation in critical rainfall.

Conclusions

The geomorphic-based R-V GIUH runoff convergence model has a few easy-to-obtain parameters and requires no detailed hydrological or geomorphic data. It is suitable for computing the runoff convergence of flash flood in regions lacking data on the disaster. Besides, the model can output good results on runoff convergence. In particular, the simulated flow and time of flood peaks in the rising phase, which is important to the determination of critical rainfall, are close to the measured results. As a result, the model can predict the critical rainfall very accurately.

The critical rainfall is jointly determined by such factors as preceding rainfall, cumulative rainfall and rainfall intensity. The RBFNN-based dynamic critical rainfall prediction model is a desirable tool to describe the complex relationship between the critical rainfall and its influencing factors, laying a good basis for accurate prewarning.

Abstract. The Fuhe River in Baoding City is one of the rivers entering Baiyangdian Lake, but its pollution is serious, so improving the water quality of the Fuhe River can not be ignored. In this paper, the horizontal subsurface flow constructed wetland was used to purify the water of Fuhe River, and the pollutant removal effect of ceramsite, crushed stone filler, cyperus alternifolius, Reed and yellow iris plants was analyzed. The results showed that the cyperus alternifolius ceramsite constructed wetland has the best removal effect on COD and TP, its average removal rates are 56.18% and 61.97%, respectively, and its average effluent concentrations are 18.64 mg/L and 0.27 mg/L; the reed ceramsite constructed wetland has the best removal effect on NH_4^+-N, with a rate of 64.00%, respectively, and its average effluent concentration is 0.82 mg/L. The results can provide theoretical reference for improving the water quality of Fuhe River.
Keywords: *Baiyangdian, Fuhe River, horizontal subsurface, plant screening, purification effect, substrate*

Introduction

Xiong'an New Area will be built as an ecological city, in which the river is harmonious with the city. Baiyangdian Lake needs a good ecological environment to meet the requirements of Xiong'an New Area (Xia et al., 2017; Li et al., 2013). At present, the flow of water's environment of Baiyangdian Lake is poor, for which the main pollution source is the water from the Fuhe River into the Lake, so it is very important to control the water of Fuhe River. Currently, constructed wetlands are widely applied to the improvement of polluted water due to its high efficiency, ecology and low investment (Machado et al., 2017; Gagnon et al., 2012).

Fillers and plants play an important role in constructed wetland systems. More and more people begin to study the purification effect of different fillers and plants on constructed wetlands (Leto et al., 2013; Xiong et al., 2015). The constructed wetland designed by Tang et al. (2009) uses a combination of crushed stone and shale to study its purification effect on eutrophic water bodies. The horizontal free surface flow integrated constructed wetland (ICW) concept was proposed by Scholz et al. (2007) and combines that goal of purifying farmland water with the goal of incorporating wetland infrastructure into landscape, with good results achieved after commissioning. Ji et al. (2017) studied the filler and its purification mechanism of constructed wetland sewage treatment system. Hao et al. (2017) conducted a study on the purification efficiency of plant water in constructed wetlands.

Under the background of this study, constructed wetland is used to purify the water quality of Fuhe River, study the effect of wetland on the removal of pollutants in the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89318940

river water and the effect of different fillers and plants on the purification effect. In this paper, the polluted river water is taken as the research object, and according to the combination type of different fillers (such as crushed stone and ceramsite) and different plants (cyperus alternifolius, reed and yellow iris), 8 horizontal subsurface constructed wetlands are constructed outdoors to study the purification effect of the river water.

Materials and methods

Raw water quality

The experimental water is taken from the section of Yonghua Bridge, Fuhe River, Baoding City. The water quality of the section for nearly one year is shown in *Table 1*.

Table 1. *Water quality of the section*

pH	DO (mg/L)	Turbidity (NTU)	COD (mg/L)	TP (mg/L)	NH_4^+-N (mg/L)
6-8	0.5-9.0	10-30	30-50	0.6-1.0	1.7-3.0

Construction of experimental device

8 horizontal subsurface flow constructed wetlands are constructed, with the size of the pond as 65 cm × 35 cm × 40 cm and the filling height as 23 cm. They are divided into two group according to the filler, one is ceramsite, other group is crushed stone, the particle diameter of the ceramsite is 10-20 mm, the particle diameter of the crushed stone is 5-10 mm (3 cm), 10-15 mm (10 cm), 15-20 mm (5 cm), and 20-30 mm (5 cm) from the top to the bottom, covering with 5 cm soil on the surface of the filler. According to the principle of strong purifying ability and fast growing to adapt to environment, three kinds of plants are preliminarily selected as wetland plants, such as cyperus alternifolius, reed and yellow iris, with a planting density of 18 plants/square trough. The schematic diagram is shown in *Figure 1*.

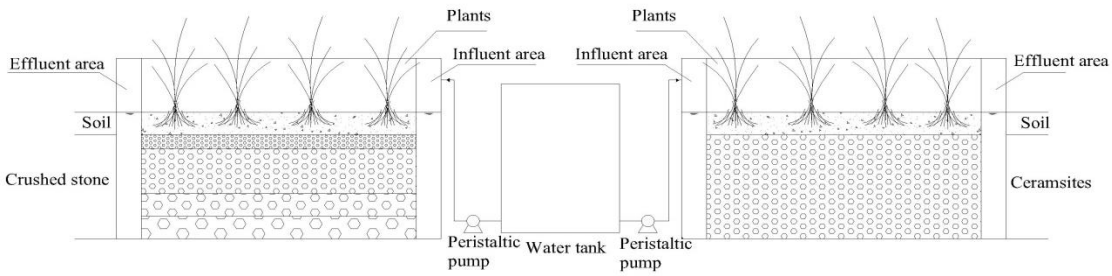

Figure 1. *Schematic diagram of experimental device*

Operation of experimental system

The experimental device adopts continuous water inflow, the hydraulic load is controlled at 0.2-0.4 $m^3/(m^2 \cdot d)$, the hydraulic retention time is 1.5-2.5 d, and the operating water level is located on the soil surface. In order to ensure the stability of water inflow, peristaltic pump is used to quantitatively and constantly supply water to the constructed wetland system. The experimental system lasted 7 months from the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89318940

construction of trial operation to the end of operation, and stably ran 3 months after the plant is mature.

Sample collection and testing

Sample collection includes influent and effluent of each wetland. The sample collection frequency is once every three days, and the detection indicators include temperature (T), dissolved oxygen (DO), pH, turbidity, chemical oxygen demand (COD), total phosphorus (TP), ammonia nitrogen (NH_4^+-N), total nitrogen (TN), nitrite nitrogen (NO_2^--N), and nitrate nitrogen (NO_3^-N). The temperature and dissolved oxygen are measured by a dissolved oxygen meter at the sampling site, and the pH is measured by a PH meter. The determination methods of TN and TP are potassium persulfate oxidation-ultraviolet spectrophotometry and anti-spectrophotometric method of potassium persulfate molybdenum antimony oxidation, respectively. Other indicators are measured in the laboratory by the method of national standard.

Results

Removal effect of COD

Figure 2 is a diagram of removal effect of COD by the horizontal subsurface flow constructed wetland system, in which COD concentration of the influent fluctuates little and COD removal is stable. It can be seen from *Figure 2* that the wetland system with plants is better than the blank wetland system in the removal of COD in the water, and among three plants, cyperus alternifolius has the best removal effect on COD, followed by yellow iris and reed. The average effluent COD concentration of cyperus alternifolius ceramsite-bed wetland is 18.64 mg/L, which reaches Class Ⅲ standard of surface water. The average effluent COD concentration of reed, yellow iris and blank ceramisite-bed wetland is 20.86 mg/L, 21.12 mg/L and 24.98 mg/L, and the average effluent COD concentration of cyperus alternifolius, reed, yellow iris and blank crushed stone-bed wetlands is 21.35 mg/L, 23.39 mg/L, 23.73 mg/L and 27.48 mg/L, all of which reach the class IV standard of surface water.

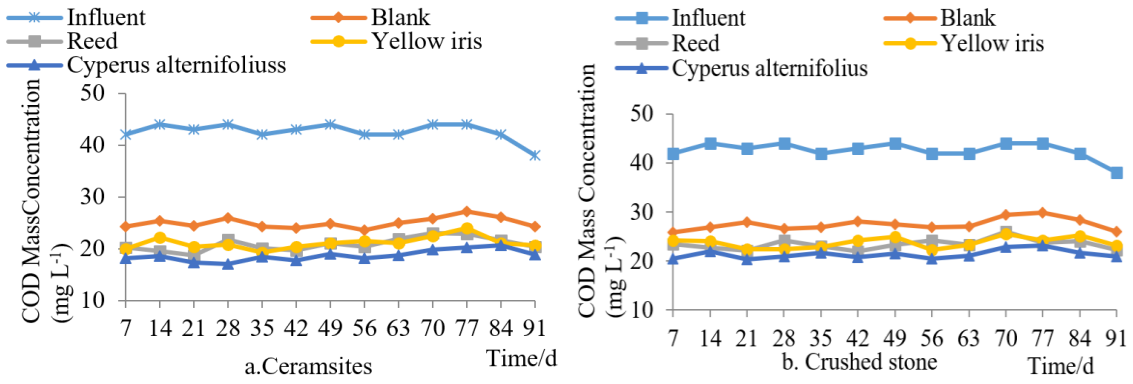

Figure 2. *Removal effect of COD by ceramsite and crushed stone*

In the constructed wetland system, the removal of COD is mainly accomplished by the filtration of substrate and the decomposition of microorganisms. As can be seen from *Figure 2,* compared with the blank wetland group, the removal effect of COD in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89318940

the constructed wetland group with plants differs slightly, for which the filtration of the substrate is the main way to remove COD in the constructed wetland system and the proportion of plant absorption and microbial decomposition is relatively small (Kjellin et al., 2007; Albuquerque et al., 2010). From the above results, it can be seen that compared among the three plants, the removal effect of COD in cyperus alternifolius wetland is better than that of the reed wetland and the yellow iris wetland, for which the root system of cyperus alternifolius is stronger than that of the other two wetland plants, its stem and leaf are lush, and its ability to absorb organic pollutants is stronger.

Figure 3 shows the change trend and removal rate of effluent COD of ceramsite-bed and crushed stone-bed constructed wetland systems. It can be seen from *Figure 3* that when the plants are the same, the removal effect of COD by the ceramsite-bed constructed wetland system is better than that of the crushed stone-bed constructed wetland system, for which the surface areas of ceramsite is greater, and under the same hydraulic load, the contact surface between water and ceramsite is more, which increases the absorption of COD by ceramsite and makes the removal rate of COD in ceramsite-bed higher.

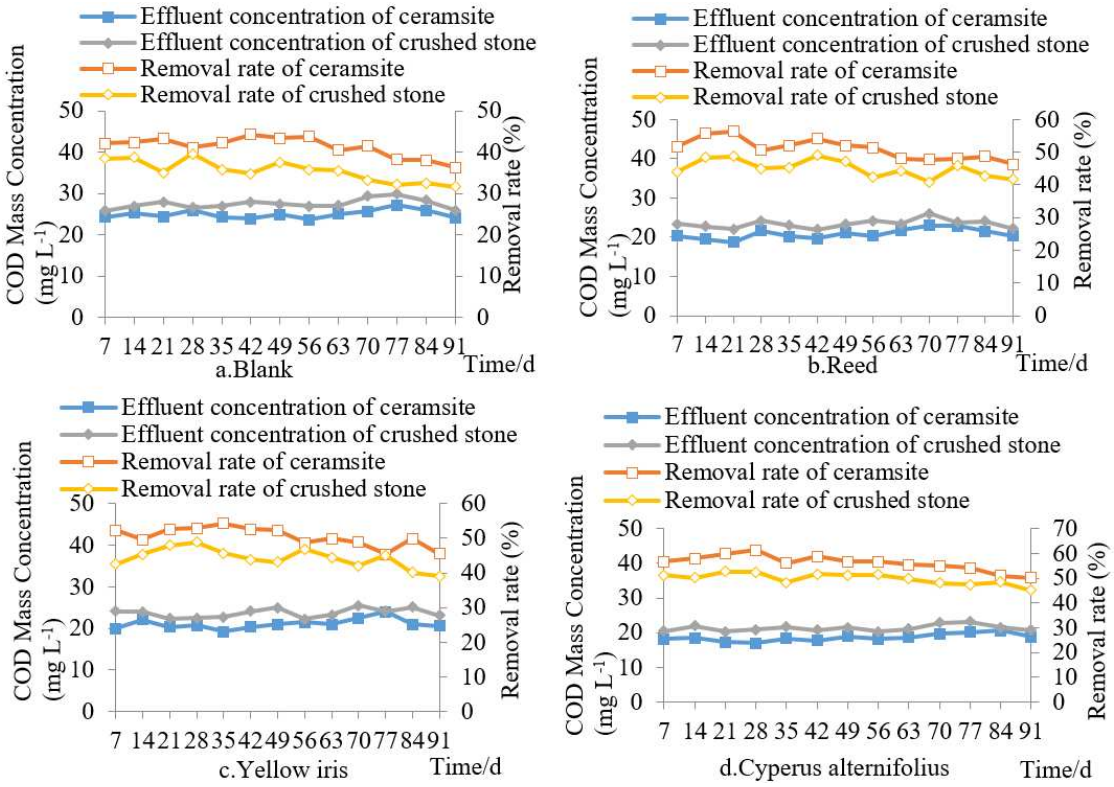

Figure 3. *Comparison of COD removal rate between ceramsite and crushed stone*

It can be seen from *Figure 3* that the removal of COD by the constructed wetland system is relatively uniform and less fluctuating during the operation of the experiment, and the removal rate of the ceramsite-bed wetland and the crushed stone-bed wetland at the later stage of the experiment shows a slow decreasing trend. The reason may be that the plant grows slowly, begins to wither and absorbs less COD, and as the temperature decreases, the activity of microorganisms declines. Meanwhile, with the operation of the experiment, the adsorption of the filler tends to the saturation state, and the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89318940

adsorption capacity decreases, resulting in the slowly decreasing trend in the removal rate of COD in wetland system.

Removal effect of TP

Figure 4 shows the removal effect of TP by the wetland system. It can be seen from the figure that the TP concentration of the influent decreases slowly in the later period of the experimental operation, and the TP concentration of effluent in the wetland with plants is lower than the TP concentration of effluent in the blank wetland. Cyperus alternifolius has the best effect on TP removal. The average TP concentration of effluent in cyperus alternifolius ceramsite-bed wetland and cyperus alternifolius crushed stone-bed wetland is 0.27 mg/L and 0.32 mg/L, respectively. Reed and yellow iris has less effect on TP removal. The average TP concentration of effluent in reed ceramsite-bed wetland, yellow iris ceramsite-bed wetland, reed crushed stone-bed wetland and crushed stone-bed wetland is0.30 mg/L, 0.31 mg/L, 0.35 mg/L and 0.34 mg/L, respectively. The blank wetland system also has a certain removal effect on TP. The average TP concentration of effluent is 0.36 mg/L and 0.40 mg/L in the blank ceramsite wetland and the blank crushed stone wetland, respectively.

The removal of phosphorus in constructed wetlands mainly depends on the interaction of plant absorption, adsorption and filtration of substrate and microbial transformation. As can be seen from *Figure 4,* the difference between wetland with plants and blank wetland in removal of TP in water is slight, for which the content of phosphorus absorbed by plant growth accounts for less proportion to the phosphorus removal, and the adsorption and filtration of substrate, which is combined with its Ca, Al, Fe, and others to form precipitates for removal, which accounts for a large proportion (Kotti et al., 2016).

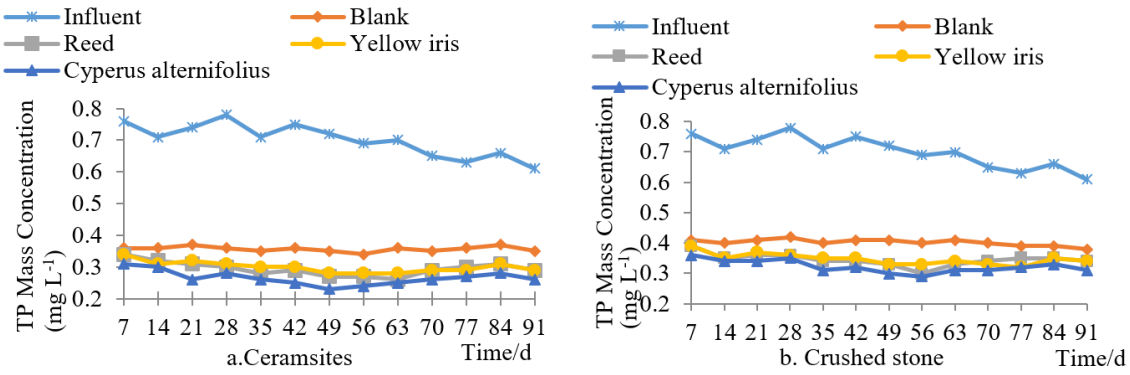

Figure 4. *Removal effect of TP by ceramsite and crushed stone*

Figure 5 shows the change trend and removal rate of effluent TP of ceramsite-bed and crushed stone-bed constructed wetland systems. It can be seen from *Figure 5* that when the plants are the same, the removal effect of TP by the ceramsite-bed constructed wetland system is better than that of the crushed stone-bed constructed wetland system, for which ceramsite is better than crushed stone since its coarse surface is good for the growth of plants and microorganism, and under the same hydraulic load, the contact method between water and ceramsite significantly affects the absorption of TP.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89318940

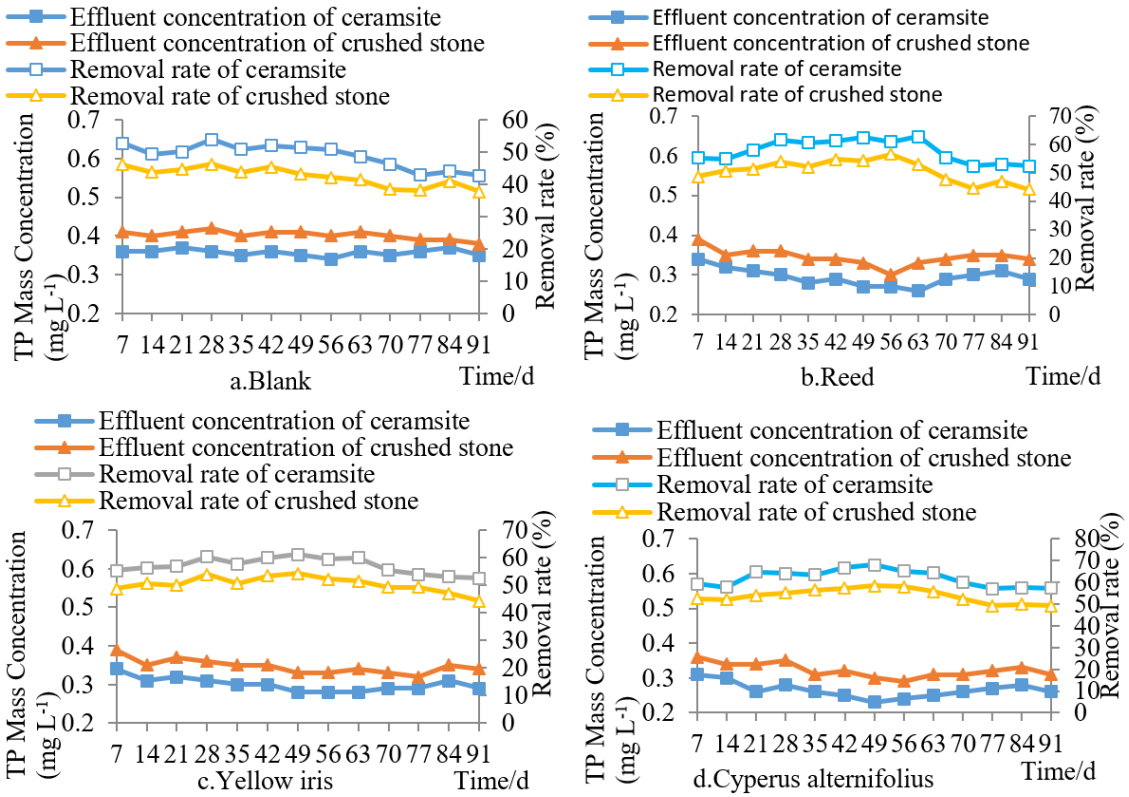

Figure 5. *Comparison of removal rate of TP between ceramsite and crushed stone*

The removal of TP by the constructed wetland system is relatively uniform and less fluctuating during the operation of the experiment, and the removal rate of TP at the later stage of the experiment shows a slow decreasing trend. The reason may be that the plant grows rapidly at the beginning and absorbs more phosphorus, and as the experiments operates, plant grows slowly, begins to wither and absorbs less phosphorus, and even part of the phosphorus in plants is slowly decomposed by microorganisms and released, resulting in the decrease in the removal rate of TP.

Comparing the removal effect of TP between the ceramsite-bed and the crushed stone-bed in *Figure 5,* it is found that the difference between the effluent TP of the ceramsite-bed and the crushed stone-bed with plants is larger than the difference between the blank ceramsite-bed and the blank crushed stone bed. Among them, the difference of the TP concentration of the effluent in the cyperus alternifolius ceramsite-bed wetland and cyperus alternifolius crushed stone-bed wetland is greater than other three experiments, and the reason is that the strong root system of the plants in the wetland system enhances the porosity of the ceramisite, also increases the adsorption of the ceramsite to TP and thus exhibits a strong TP purification capability (Vohla et al., 2011).

Removal effect of NH_4^+-N

As can be seen from *Figure 6,* the NH_4^+-N concentration in the influent gradually increases at the later stage of the experiment. *Figure 6a* shows the removal effect of NH_4^+-N by the constructed wetland system of the ceramsite. As can be seen from the figure, the removal effect of NH_4^+-N by the ceramsite wetland system with plants is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89318940

better than that of the blank group. The reed ceramsite-bed wetland has the best effect on NH_4^+-N removal, the average NH_4^+-N concentration of effluent is 0.82 mg/L, while the removal effect of NH_4^+-N by cyperus alternifolius ceramsite-bed wetland and yellow iris ceramsite-bed wetland is similar. The average NH_4^+-N concentration of effluent is 0.95 mg/L and 0.95 mg/L, respectively, while that of blank group is 1.28 mg/L. *Figure 6b* shows the removal effect of NH_4^+-N by the crushed stone-bed constructed wetland system. It can be seen that the removal effect of NH_4^+-N by the crushed stone-bed constructed wetland system with plants is better than that of the blank group; the reed crushed stone-bed constructed wetland has the best effect on NH_4^+-N removal, and its average NH_4^+-N concentration of effluent is 0.99 mg/L, while the removal effect of NH_4^+-N in cyperus alternifolius crushed stone-bed wetland and yellow iris crushed stone-bed wetland is similar with the average NH_4^+-N concentration of effluent as 1.10 mg/L and 1.11 mg/L respectively, while that of blank group is 1.39 mg/L.

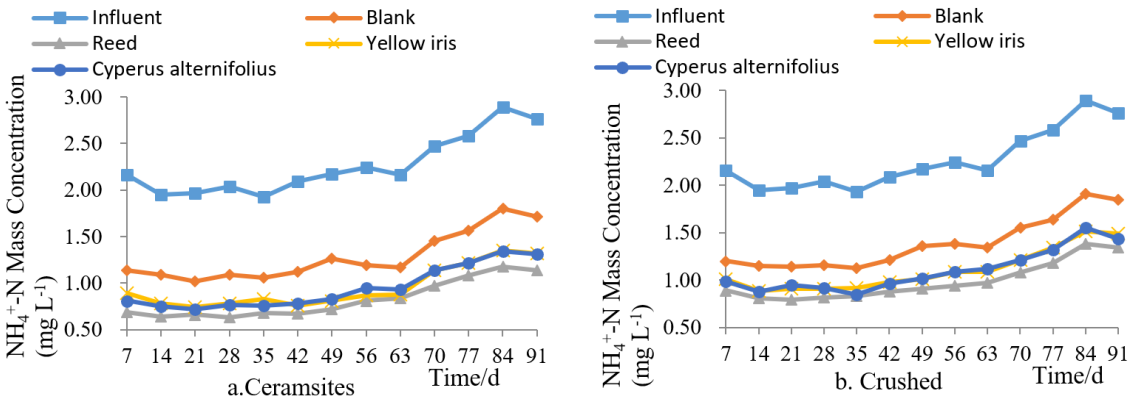

Figure 6. *Removal effect of NH_4^+-N by ceramsite-bed and crushed stone bed*

In the constructed wetland system, the removal of ammonia nitrogen is mainly through the filtration of substrate, the absorption of plants and the nitrification of microorganisms, where nitrification is the main mode, and oxygen supply is a restraint factor affecting nitrification in horizontal subsurface flow constructed wetlands (Vymazal et al., 2007; Saeed et al., 2012). In the experiment, the removal effect of NH_4^+-N by the wetland with plants is much better than that of the blank wetland, and the reason may be that the plants supply most of oxygen for the nitrification reaction through the transportation, release and diffusion of oxygen, strengthening nitrification.

In addition, the root system of the reeds is more developed and its oxygen transport ability is stronger than that of the two plants, so its removal effect of ammonia nitrogen is better.

Figure 7 shows the change trend and removal rate of effluent NH_4^+-N of ceramsite-bed and crushed stone-bed constructed wetland systems. It can be seen from *Figure 7* that the removal of NH_4^+-N by the constructed wetland system is relatively uniform and less fluctuating during the operation of the experiment, and the removal rate at the later stage of the experiment shows a slow decreasing trend. The reason may be that at the later stage the plant grows slowly and has less ability to transport oxygen. At the same time, when the temperature is lower, the activity of nitrifying bacteria and nitrobacteria in the water body will be inhibited to some extent, the nitrification capacity will be

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89318940

reduced, and the removal rate of $NH4^+$-N will be reduced. It is also possible that with the operation of the experiment, the nitrogen-containing organic matter retained by the filler decomposes in the anaerobic environment at the bottom of the wetland bed, resulting in an increase in the $NH4^+$-N content of the effluent water.

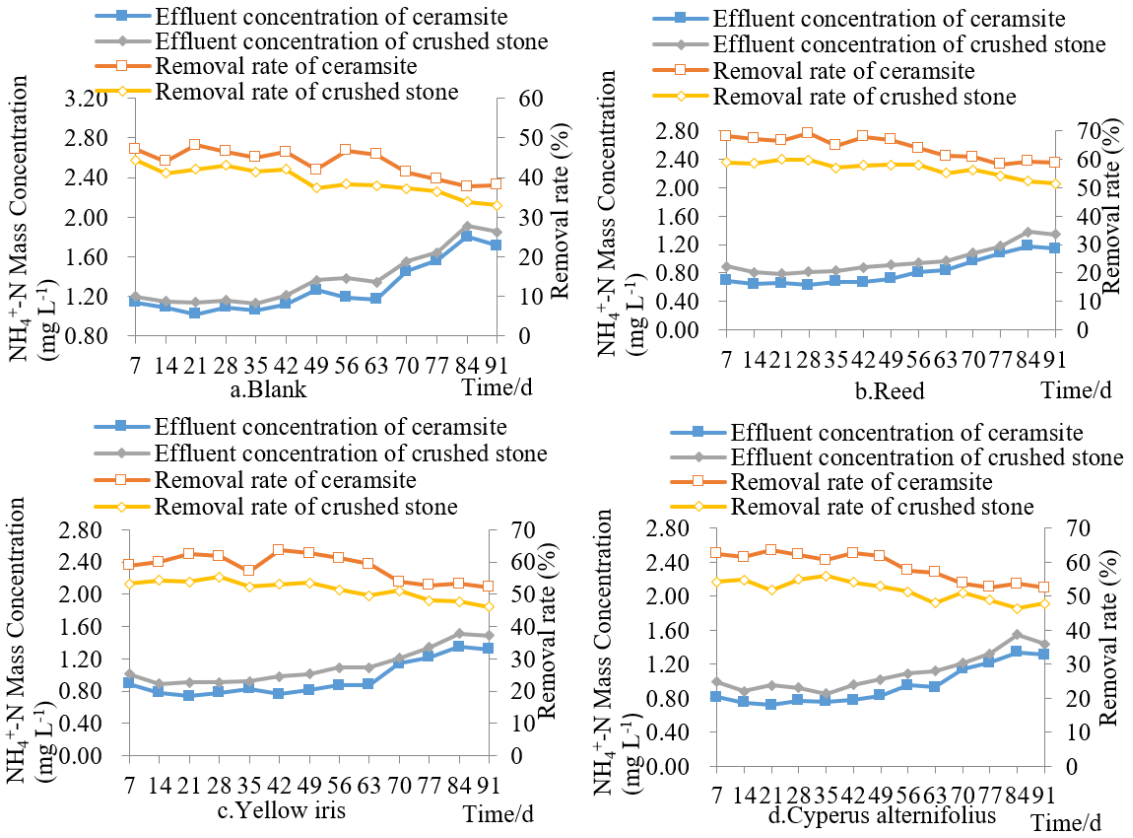

Figure 7. *Comparison of removal rate of NH_4^+-N between ceramsite and crushed stone*

Discussion

From the above experimental results and analysis, it can be seen that the wetland system has good removal effect of pollutants in the water from Fuhe River, and the removal rate tends to decrease slowly in the later stage of the experiment, which has a great effect on the growth cycle of plants. As plants grow rapidly, they will absorb more and more pollutants, which makes the removal rate higher. In the later stage of the experiment, the absorption of pollutants by plants and fillers may reach a saturated state, even release some pollutants, which makes the effluent concentration increase. At end of October, with the decrease in temperature, the life activities of microorganisms are inhibited, the plants begin to wither gradually, with a decrease in the absorption capacity, and the removal rate of pollutants in wetlands gradually decreases.

The removal rate of COD, TP, and NH_4^+-N in ceramsite-bed wetland is higher than that of crushed stone-bed wetland, which is related to the structure of filler. The surface of ceramsite is rough and easy to attach microorganisms, the void ratio is high, and the specific surface area is large, allowing more full contact between the river water and the filler, so its ability of absorbing pollutants is stronger, and the removal rate of pollutants is higher.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89318940

Conclusions

The water quality of Fuhe River is improved by purification through the horizontal subsurface flow constructed wetlands, and the effluent water quality reaches the Class IV standard of surface water. Because of the strong adsorption ability of ceramsite, the wetland system with ceramsite as filler is better than the wetland system with crushed stone to remove the pollutants in the water. Cyperus alternifolius ceramsite-bed constructed wetland system has the best effect on COD and TP removal of Fuhe River, with the average removal rate of COD and TP as 56.18% and 61.97%, respectively, and the average concentration of effluent as 18.64 mg/L and 0.27 mg/L, respectively, reaching Class IV water standard of the Environmental Quality Standard for Surface Water (GB3838-2002); the reed ceramsite-bed constructed wetland system has the best effect on NH_4^+-N removal, with the average removal rate as 64% and the average concentration of effluent as 0.82 mg/L, reaching Class Ⅲ water standard of surface water. Blank ceramsite-bed constructed wetland system and blank crushed stone-bed constructed wetland system have less effect on removal of COD, TP and NH_4^+-N, with the average concentration of effluent as 24.98 mg/L and 27.48 mg/L, 0.36 mg/Land 0.40 mg/L, and 1.28 mg/Land 1.39 mg/L, reaching Class V water standard of surface water. This experiment mainly analyzed the purification effect of wetland system on Fuhe River water in summer and autumn. It can extend the test time in future research and analyze the removal effect of pollutants in water by wetland in different seasons.

Abstract. Considering the transfer of carbon emissions between the countries along the Belt and the Road and the importance of responsibility sharing for carbon emissions to international trade, this paper measures the implicit carbon in the trade between China and other countries along the Belt and the Road by the multi-regional input-output (MRIO) method. The measured results show that the trade between the two sides accounts for 3%~21% of the total carbon emissions in China; China's carbon responsibilities in its trade with the top trade partners along the Belt and the Road differs greatly with responsibility sharing principles; implicit carbon emissions mainly come from industries with relatively high emission intensities; China is advised to adopt the common responsibility mechanism. The research findings shed new light on the estimation of implicit carbon in international trade.
Keywords: *carbon emission, international trade, producer responsibility, consumer responsibility, reduction of carbon emission*

Introduction

Economic development and scientific progress have promoted the international division of labor, affecting the trade circulation of many countries. Typically, commodity production and final consumption occur in different geographic regions. Therefore, a country can reduce domestic production by importing commodities, thereby reducing domestic carbon emissions. This international trade model, while reducing the carbon emissions in consumer countries, causes pollution to rise in producing and exporting countries. The consumer countries should bear the corresponding carbon emission responsibilities. The current responsibility sharing system for carbon emission reduction only highlights the producer responsibility for production-side emissions of each country, that is, a country should be responsible for the greenhouse gases (GHGs) released in the production of commodities for export or domestic consumption. This system fails to consider the responsibility of foreign and domestic consumers for the carbon emissions. Compared with big exporters, large importers need to assume much responsibility for product consumption.

Since joining the World Trade Organization (WTO), China has actively participated in the global division of labor, witnessing a significant growth in the volume of foreign

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89418953

trade.The country has gradually evolved into a major manufacturer in global trade, and won the nickname of the world's factory. From 2001 to 2016, the total import and export volume occupied from 0.51 trillion USD to 3.96 trillion USD (Boamah et al., 2017). The rapid growth in trade is accompanied by the emission of a huge amount of GHG emissions. The 2015 United Nations Climate Change Conference (COP 21) reported that China contributed 20% to the global GHG emissions, most of which originate from the production of export commodities (Cozier, 2016). This means China suffers from the carbon emissions caused by countries importing its commodities, which should be considered in the design of the responsibility sharing system for carbon emission reduction.

In 2013, China, the largest developing country in the world, launched the Belt and Road Initiative, with the aim to deepen the trade exchange with other countries. At present, the trade with the countries along the Belt and the Road occupies an important position in China's international trade. Under the circumstances, it is imperative to China's responsibilities for carbon emission reduction by quantifying the carbon emissions in commodity production and trade and determining the quantity and flow of implicit carbon in trade (Liu et al., 2017; Zhang, 2017; Tu and Ma, 2018).

The implicit carbon in trade is usually estimated by top-down accounting and bottom-up accounting. The former approach is specified in the *IPCC Task Force on National Greenhouse Gas*. This relatively authoritative method requires the classification and decomposition of the carbon emission sources. The latter approach, grounded on enterprise commodities and projects, has certain limitations, as it cannot cover all enterprises or commodities.

The commonly used accounting strategies or carbon emissions can be listed as the emission coefficient method, lifecycle method, and input-output (I-O) method, in light of the research perspective. The emission coefficient method adopts an emission coefficient factor, which is defined as the proportion of air pollutant to all pollutants generated by production activities. For example, Li et al. (2018) employed this method to measure the carbon emissions in the operation phase of a building.

The lifecycle method mainly assess the environmental factors and potential impacts associated with a product or service. Specifically, the related inputs and outputs of a system were recorded, and subjected to correlation analysis. Then, the analysis results are explained through lifecycle assessment, revealing the potential environmental impacts. For instance, Shi (2017) reviewed the development in animal husbandry research fromcarbon emissions to carbon footprint. Bello et al. (2018) calculated the carbon emissions in the lifecycle of buildings, and established a carbon footprint evaluation model for the whole lifecycle of residential buildings. With the aid of lifecycle method, Li (2016) determined the trend and flow of the implicit carbon in China's import and export in the past decade.

The I-O method studies how the commodities of a country affect the environment through international circulation. This strategy can be subdivided into single-regional I-O (SRIO) method, bi-regional I-O (BRIO) method, and multi-regional I-O (MRIO) method. The SRIO treats regions other than the producing country as one entity rather than distinguish between product sources, and assumes that the technology is on the same level at home and abroad. Despite its simplicity, this method cannot measure the consumption of intermediate commodities, or give an accurate depiction of the product flow in global trade. Under the assumption of technical heterogeneity, the BRIO selects different carbon emission factors for different trades. Neither can this method accurately

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89418953

reflect the circulation of intermediate commodities. By contrast, the MRIO fully considers the production and circulation of different industries in different countries, yielding accurate measurement results (Tan et al., 2014). As a result, the MRIO is more widely applied than the other two methods to measure the implicit carbon in international trade.

Diezenbacher et al. (2012) suggested splitting the trade of an enterprise into processing trade and general trade, aiming to prevent the overestimation of implicit carbon in trade by the traditional I-O method (Su and Ang, 2011; Xia et al., 2015). Considering the difference in corporate ownership, Liu et al. (2016) analyzed the implicit carbon of China's trade by extended I-O, and suggested the overlook of corporate heterogeneity will exaggerate the implicit carbon emissions by 20%. Wei and Peng (2017) used the MRIO model to measure the energy sources related to China-US trade between 1995 and 2009, revealing that the exports to the US have become a major emission source to China. Li (2017) estimated the implicit carbon emissions incurred in Chinese and Japanese exports to countries along the Belt and the Road based on the GTAP9 database, discovered the implicit carbon difference in trade between these countries, and attributed the difference to the trade volume, implicit carbon intensity and trade structure of China and Japan. Lan (2015) relied on MRIO to estimate the implicit carbon of China-EU trade, and verified if the bilateral trade causes the flow of EU carbon emissions to China. Sun (2016) measured the implicit carbon in China's export based on the I-O data in 2002, 2005, 2007, 2010 and 2012, concluding that the amount of implicit carbon increased 2.42 times from 471 million tons in 2002 to 1.056 billion tons in 2015. From the angle of intrinsic emissions, Fang and Xu (2013) found that most of the CO_2 generation in China is to satisfy the needs of other countries. Under consumer responsibility, Gao (2016) calculated the implicit carbon of various countries, decomposed the implicit carbon structure, and looked for the causes to difference in carbon emissions through multiple methods. Pan and Wu (2018) measured the implicit carbon of China-Japan trade using the World Input-Output Database (WIOD), pointing out China's deficit of implicit carbon in the trade and the concentration of export implicit carbon in the heavy industry. Yu and Wang (2017) evaluatedthe implicit carbon of trade between China and 36 countries and regions, decomposed the implicit carbon by structural decomposition analysis, and drew the following conclusions: China is faced with a net inflow of implicit carbon and needs to upgrade emission reduction technologies and reduce thecarbon emission intensity.

On the responsibility sharing of carbon emissions, more and more scholars have questioned about the fairness of the current producer responsibility emission reduction model. For instance, Munksgaard (2001) proved that it is difficult for Denmark to achieve its carbon emission reduction target, if the implicit carbon in its export is counted as domestic carbon emissions, as required by the principle of producer responsibility. Using the Trade in Value Added (TiVA) database, Xiao (2016) measured the residual GHG emissions of the producing countries, which arises from the final consumption of commodities in consumer countries, and suggested the consumer countries be the main undertaker of carbon emission responsibilities. Dong et al. (2018) carried out adata envelopment analysis (DEA) on responsibility sharing for implicit carbon in trade among different provinces in China, and divided these provinces into four regions. Comparing producer responsibility and consumer responsibility, Yu and Xu (2017) noted that China will assume fewer responsibilities for emission reduction under consumer responsibility than under producer responsibility. To relieve global

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89418953

environmental pressure, Zhong et al. (2018) came up with an effective strategy for global energy conservation and emission reduction: upgrading production technologies and increasing the proportion of clean energy in total energy consumption. Wang et al. (2017) estimated the carbon emissions of 30 provincial administrative regions in Chinese mainland, discovered obvious net carbon exports from the eastern coast, the southern coast and the Beijing-Tianjin region, and found a clear net carbon transfer from the northwest. Pan et al. (2008) argued that developed countries can manipulate the producer responsibility system and transfer their carbon emissions to developing countries through trade, causing carbon leakage and pushing up global carbon emissions.

Hence, some scholars have proposed to replace the producer responsibility system with consumer responsibility, i.e. including the carbon emissions from the final consumption of self-produced and imported commodities into the total carbon emissions of a country. The consumer responsibility system can mitigate the carbon leakage. However, some problems may occur to the carbon emission efficiency of exporting countries or industries, as the carbon emission responsibility is passed to the final consumers.

In light of the above, this paper selects the major trade partners of China along the Belt and the Road, and employs the MRIO method to calculate the implicit carbon in their trade with China.

Materials and methods

The MRIO model consisting of *n* different countries can be expressed as *Eq.1*:

$$\begin{pmatrix} x_1 \\ x_2 \\ \mathrm{M} \\ x_n \end{pmatrix} = \begin{pmatrix} A_{11} & A_{12} & \mathrm{L} & A_{1n} \\ A_{21} & A_{22} & \mathrm{L} & A_{2n} \\ \mathrm{M} & \mathrm{M} & \mathrm{M} & \mathrm{M} \\ A_{n1} & A_{n2} & \mathrm{L} & A_{nn} \end{pmatrix} \bullet \begin{pmatrix} x_1 \\ x_2 \\ \mathrm{M} \\ x_n \end{pmatrix} + \begin{pmatrix} y_{11} + \sum_{i \neq 1} y_{1i} \\ y_{22} + \sum_{i \neq 2} y_{2i} \\ \mathrm{M} \\ y_{nn} + \sum_{i \neq n} y_{ni} \end{pmatrix} \quad \text{(Eq.1)}$$

where A_{nn} is the direct consumption coefficient of domestic commodities in each country; A_{ij} is the mutual demand between two countries, as reflected by the bilateral trade activities; x_i is the output vector of country i; y_{ii} means country $i$satisfies the domestic demand for commodities; y_{ir} means country i satisfies the demand of country r for commodities, i.e. the final demand. *Eq.1* can be simplified as $X = AX + Y$, and rewritten as $X = (I - A)^{-1}Y$, with X being the world output vector and Y being the final supply vector of each country, including household consumption, government consumption, capital formation and inventory changes.

According to the Kyoto carbon accounting model, the production-side emissions refer to the carbon emissions fromcommodity production in a country, which has nothing to do with the consumption of the commodities. In this case, the total carbon emissions of a country is equivalent to the domestic production emissions. On the contrary, the consumer responsibility system considers both domestic and foreign carbon emissions caused by the final demand as the responsibility of the country. Thus, the consumption-side carbon emissions equalthe domestic emissions plus the foreign emissions.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89418953

Let $F_w = (f_1, f_2 \cdots f_m)$ be the world's emission intensity vector, with f_1~f_m being the carbon emissions from commodity production in different industries of the country, $Y = (y_1, y_2, \cdots, y_i, \cdots, y_n)$ be the final commodities that meet the foreign demand, with y_2, y_i and y_n being the final demand vectors of the country, and $(I - A)^{-1} = L$ be the Leontief I-O matrix. Based on the MIRO model, the production-side carbon emissions of country i can be described as *Eq.2*:

$$E_i^p = f_i x_i = f_i L Y \quad \text{(Eq.2)}$$

where E_i is the total production-side carbon emissions of country i. The production-side carbon emissions can be further split into those meeting domestic demand and those meeting foreign demand, while the commodities that satisfy foreign demand can be subdivided into intermediate commodities and final commodities. Taking China as country i (i=1), the production-side carbon emissions of China can be expressed as *Eq.3*:

$$E_1^p = f_1 x_{11} + f_1 \sum_{i \neq 1} x_{1i} = f_1 x_{11} + f_1 L_{11} \sum_{i \neq 1} \sum_{r \neq 1} A_{1r} x_{ri} + f_1 L_{11} \sum_{i \neq 1} y_{1i} \quad \text{(Eq.3)}$$

where $L_{11} = (I - A_{11})^{-1}$ is the Leontief I-O matrix of China. Similarly, China's consumption-side carbon emissions are generated across the world to satisfy the country's final demand. In this paper, China's consumption-side emissions refer specifically to the country's carbon emissions from the consumption of the final commodities in countries along the Belt and the Road. Hence, the consumption-side emissions of China can be expressed as *Eq.4*:

$$E_1^c = f_i L y_1 \quad \text{(Eq.4)}$$

China's consumption-side emissions can be broken down into domestic emissions and foreign emissions. The former equals the country's production-side emissions that meets domestic demand, while the latter consists of the carbon emissions from foreign countries, which are generated through the intermediate and final commodities imported by China to satisfy its domestic demand. Thus, *Eq.4* can be rewritten as *Eq.5*:

$$E_1^c = f_1 x_{11} + \sum_{i \neq 1} f_i x_{i1} = f_1 x_{11} + \sum_{r \neq 1} f_r L_{rr} (A_{r1} x_{11} + y_{r1}) + \sum_{r \neq 1} \left(f_r L_{rr} \sum_{i \neq 1, i \neq r} A_{ri} x_{i1} \right) \quad \text{(Eq.5)}$$

where $\sum_{r \neq 1} f_r L_{rr} (A_{r1} x_{11} + y_{r1})$ and $\sum_{r \neq 1} \left(f_r L_{rr} \sum_{i \neq 1, i \neq r} A_{ri} x_{i1} \right)$ are the carbon emissions from direct imports and indirect imports, respectively.

There are three responsibility sharing systems for carbon emissions, namely, producer responsibility, consumer responsibility and common responsibility. The producer responsibility means the producer is responsible for the carbon emissions from the commodities produced within its territory, regardless if the commodities are consumed domestically or overseas. Despite its simplicity, this accounting approach neglects the shift of carbon emissions under trade, and hinders the emission reduction in developing countries with high carbon intensity. The consumer responsibility requires the consumer to assume part of the responsibility for carbon emissions. Compared to the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89418953

producer responsibility system, this approach can mitigate carbon leakage, andpromote carbon emissions reduction and economic growth in developing countries like China. The common responsibility means both the producer and consumer should be responsible for carbon emissions. Under this system, a country's responsibilities are the sum of the producer's responsibility and the consumer's responsibility. Inspired by Pan et al. (2008), a country's total carbon emissions can be divided into five parts, as shown in *Eq.6*:

$$E = f_1 x_{11} + f_1 L_{11} \sum_{i\neq 1} \sum_{r\neq 1} A_{1r} x_{ri} + f_1 L_{11} \sum_{i\neq 1} y_{1i} + \sum_{r\neq 1} f_r L_{rr} (A_{r1} x_{11} + y_{r1}) + \sum_{r\neq 1} (f_r L_{rr} \sum_{i\neq 1, i\neq r} A_{ri} x_{i1}) \quad \text{(Eq.6)}$$

Under the common responsibility system, China's responsibilities for carbon emissions can be expressed as *Eq.7*:

$$(1-m)(f_1 L_{11} \sum_{i\neq 1} \sum_{r\neq 1} A_{1r} x_{ri} + f_1 L_{11} \sum_{i\neq 1} y_{1i}) + m\left[\sum_{r\neq 1} f_r L_{rr} (A_{r1} x_{11} + y_{r1}) + \sum_{r\neq 1} (f_r L_{rr} \sum_{i\neq 1, i\neq r} A_{ri} x_{i1})\right] \quad \text{(Eq.7)}$$

where *m* is the sharing factor; the first term in the second pair of brackets is the carbon emissions from intermediate commodities produced to meet domestic demand; the second term of the second pair of brackets is the carbon emissions from commodities produced to meet foreign demand; the part in the pair of square brackets is the carbon emissions from imported commodities that meet the domestic demand. The rest of the responsibilities should be borne by other countries along the Belt and the Road. This paper sets the sharing factor to 60%, such that the most able countries take greater shares and that consumers assume part of the responsibilities.

The research data were extracted from the WIOD database, which includes the I-O data of 40 countries and regions across the world. The data of each country is divided into 56 industries. Here, 36 industries are adopted in the global MRIO table according to the *Industrial Classification for National Economic Activities* (GB/T 4754-2017) (*Table 1*).

The data on the countries appear both in the WIOD database and on the Belt and Road Portal (www.yidaiyilu.gov.cn/) were downloaded, including but not limited to South Korea, India, Indonesia, Russia, Turkey, Czech Republic, Slovakia, Romania, Greece, Slovenia, Estonia, Bulgaria, Lithuania, Latvia, Croatia, Malta and Cyprus. Among them, the top five trade partners of China, namely, South Korea, India, Indonesia, Russia and Turkey, were selected for further analysis. In terms of trade volume, these countries account for 91.98% of China's trade along the Belt and the Road. Thus, it is suitable to compute the production-side and consumption-side implicit carbon with the data of these countries.

Results and Disscussion

By *Equation (3)*, the production-side implicit carbon emissions of China were computed as 5,408.44 million tons, including 5,248.8 Mt to satisfy domestic demand and 159.64 Mt to satisfy the demand of China's top trade partners along the Belt and the Road. The results show that domestic demand is the main driver of China's production-side carbon emissions.

The implicit carbon emissions to satisfy foreign demand can be further divided into those from intermediate export commodities and those from final export commodities. For the top five trade partners of China along the Belt and the Road, the implicit carbon emissions from intermediate export commodities stood at 7.89 Mt for South Korea, 0.023 Mt for India, 0.21 Mt for Indonesia, 0.59 Mt for Russia and 0.21 Mt for Turkey. Hence, South Korea accounts for 90% of the total volume. *Figure 1* shows the industrial classification of China's implicit carbon emissions from intermediate commodities exported to South Korea. Note that the "Sum" means the total implicit carbon emissions from intermediate commodities exported to the five trade partners.

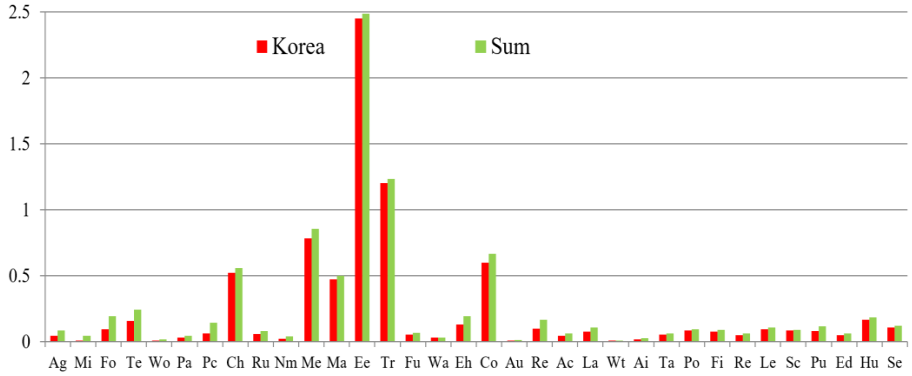

Figure 1. *Industrial classification of China's implicit carbon emissions from intermediate commodities exported to South Korea*

As shown in *Figure 1*, electric equipment production (Ee) generated 2.45 Mt of implicit carbon emissions, about 98% of the total volume of the five trade partners. This industry is clearly the leading contributor to China's implicit carbon emissions from intermediate commodities exported to South Korea, followed by transport equipment production (Tr) (1.20 Mt), metallurgy (Me) (0.79 Mt), construction industry (Co) (0.61 Mt), chemical industry (Ch) (0.52 Mt) and machinery production (Ma) (0.48 Mt).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89418953

Figure 2 shows the industrial classification of China's implicit carbon emissions from intermediate commodities exported to the other four countries (India, Indonesia, Russia and Turkey). For Russia, the top 4 contributors to the said implicit carbon emissions include coke and refined oil production (Pc) (0.06 Mt), retail goods (Re) (0.053 Mt), electricity and heating (Eh) (0.052 Mt) and construction industry (Co) (0.051 Mt). For Turkey, the top contributors include textile industry (Te) (0.071 Mt), food industry (Fo) (0.021 Mt) and construction industry (Co) (0.010 Mt). For India, the top contributors include chemical industry (ch) (0.003 Mt), textile industry (Te) (0.024 Mt), automobile industry (Au) (0.0024 Mt) and metallurgy (Me) (0.0022 Mt). For Indonesia, the top contributors include food industry (Fo) (0.03 Mt), coke and refined oil production (Pc) (0.02 Mt), electric equipment production (Ee) (0.017 Mt) and metallurgy (Me) (0.015 Mt).

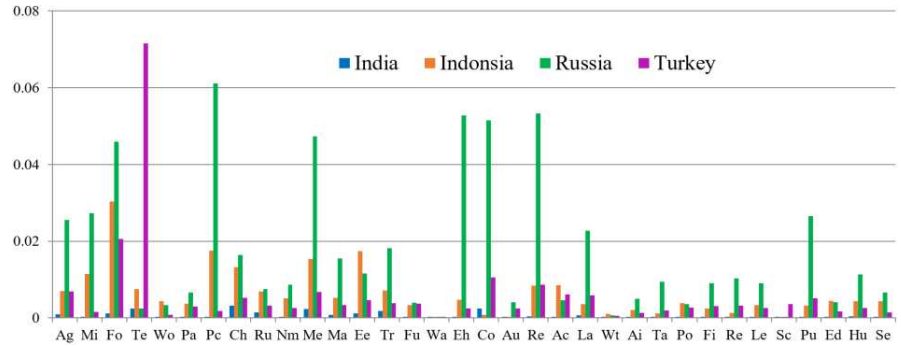

Figure 2. *Industrial classification of China's implicit carbon emissions from intermediate commodities exported to India, Indonesia, Russia and Turkey*

To sum up, the industries that produce high implicit carbon emissions from intermediate export commodities include electric equipment production (Ee), electricity and heating (Eh), metallurgy (Me) and machinery production (Ma), all of which are carbon intensive.

The five trade partners are ranked in descending order as South Korea, India, Indonesia, Russia and Turkey in terms of trade volume with China, and as South Korea, Russia, Indonesia, Turkey and Indiaby carbon emissions. On the implicit carbon emissions from China's intermediate export commodities, Russia comes at the top of the ranking with the volume of 50.98 Mt, followed by South Korea (33.61 Mt), India (27.06 Mt), Indonesia (20.92 Mt) and Turkey (18.15 Mt).

Figure 3 shows the industrial classification of China's implicit carbon emissions from final commodities exported to its top trade partners along the Belt and the Road. It can be seen that 79.95% of the carbon emissions of final exported products come from such industries as electricity and heating (Eh) (70.28 Mt), metallurgy (Me) (14.12 Mt), machinery production (Ma) (15.69 Mt), water transport (Wt) (9.42 Mt) and other transport (Ta) (10.99 Mt).

According to *Equation (5)*, The consumption-side carbon emissions of China, which totals 5,503.89 Mt, are driven by either domestic demand (5,248.8 Mt) and foreign demand (2,282.09 Mt). Thus, most of China's consumption-side carbon emissions (69.70%) originate from domestic demand-driven production. The foreign demand-driven emissions can be further split into those induced by direct import (2,022.28 Mt) and those resulted from indirect trade (259.82 Mt).

As shown in *Figure 4*, electric equipment production (Ee) (303.62 Mt) is the leading contributor to China's consumption-side carbon emissions induced by direct import, followed by metallurgy (Me) (220.61 Mt), construction industry (Co) (219.67 Mt), textile industry (Te) (133.51 Mt), chemical industry (Ch) (143.88 Mt) and food industry (Fo) (110.94 Mt). In total, these six industries take up 55.99% of all direct import-induced carbon emissions.

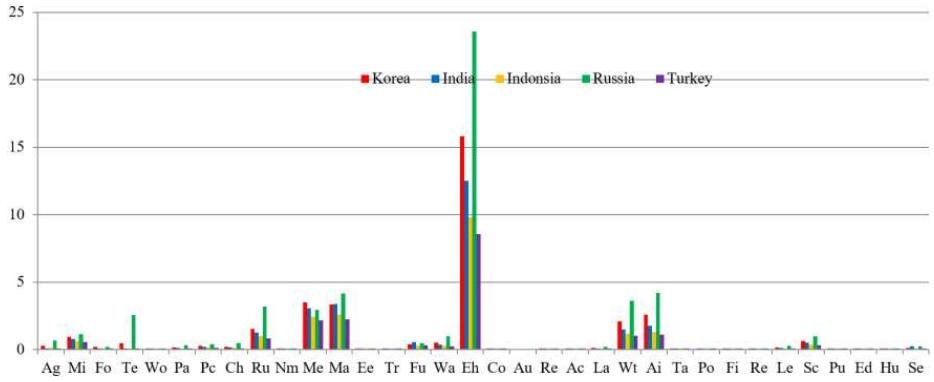

Figure 3. *Industrial classification of China's implicit carbon emissions from final commodities exported to the five trade partners*

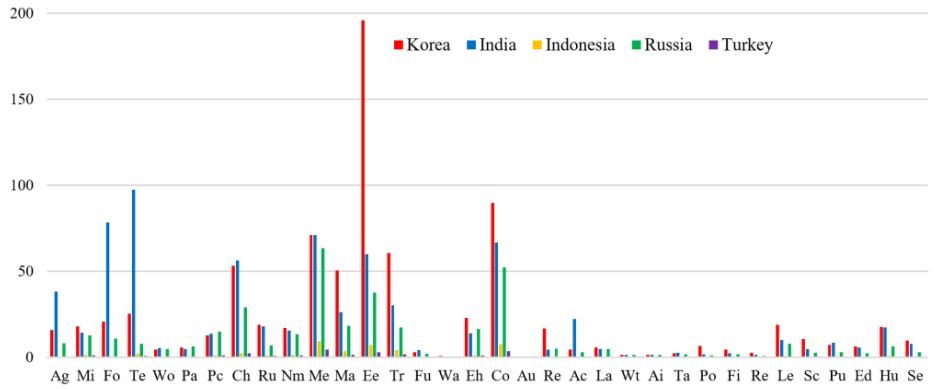

Figure 4. *Industrial classification of China's consumption-side carbon emissions induced by direct import*

The carbon emissions induced by indirect trade refers to those arising from the trade between China and the foreign countries. Coupled with the direct import of intermediate/ final commodities, the indirect trade of commodities determines the final demand of a country in the complex network of global division of labor. For the indirect trade-induced emissions, the leading contributor is electric equipment production (Ee) (52.74 Mt), accounting for 20.30% of the total indirect emissions, followed by metallurgy (Me) (34.34 Mt) (13.22%), coke and refined oil production (Pc) (28.85 Mt) (11.11%), electricity and heating (Eh) (13.47 Mt) (5.52%).

Figure 5 illustrates the calculated responsibilities of China under different sharing principles. As shown in the figure, China needs to assume responsibility for 5,408.44 Mt of carbon emissions in its trade with the countries along the Belt and the Road under the producer responsibility system, 7,503.89 Mt under the consumer

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89418953

responsibility system, and 6,681.91 under the common responsibility system. The responsible amount under the consumer responsibility is 1.39 times that under the producer responsibility, and 1.13 times that under the common responsibility. This is because China imports more commodities from the countries along the Belt and the Road than its export volume to these countries. Comparatively, the common responsibility system is relatively fair, as China needs to assume part of the carbon emissions caused by imported commodities, which is relatively fair.

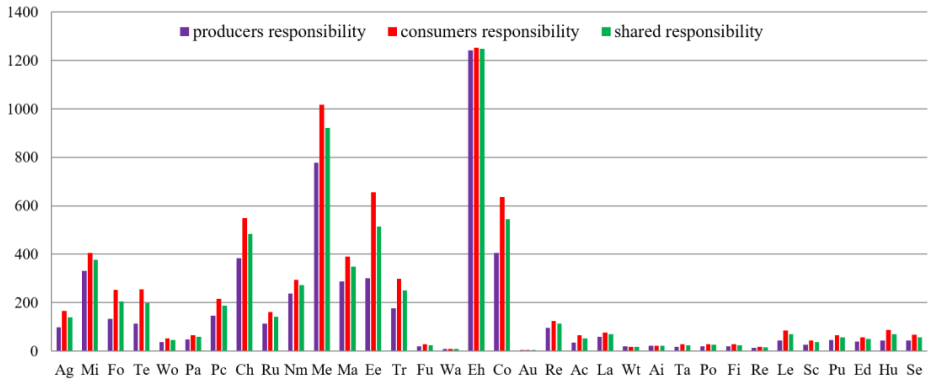

Figure 5. *Responsibility of China under different sharing principles*

The six industries that contribute the most to carbon emissions were selected to analyze their responsibilities under the three sharing principles.

For the leading contributor electricity and heating (Eh), its carbon emission responsibilities will be 1,240.77 Mt, 1,252.49 Mt and 1,247.81 Mt, respectively, under the producer responsibility, consumer responsibility and common responsibility. There is not much difference for this industry under the three sharing principles.

For the second largest emitter metallurgy (Me), its carbon emission responsibilities will be 777.98 Mt, 1,017.96 Mt and 921.97 Mt, respectively, under the producer responsibility, consumer responsibility and common responsibility. The responsible volume under consumer responsibility is 1.31 times that of producer responsibility.

For other large emitters like chemical industry (Ch), electric equipment production (Ee), mining industry (Mi) and machinery production (Ma), the gap between consumer responsibility and producer responsibility in responsible volume is even greater. For these industries, the responsible volume under consumer responsibility is 1.55 times, 2.17 times and 1.22 times that under producer responsibility, respectively.

The huge difference mainly arises from two factors: the industrial difference in carbon emission intensity and the shift in carbon emissions under international trade. For one thing, different industries differ widely in carbon emission intensity. Mining, energy and power industries emit carbon much more intensively than education and scientific research, exerting a high pressure for emission reduction in China. Of course, this also promises a high potential of the country for emission reduction. For another, integration is the main theme of global economic development. This trend brings huge benefits to China's economy. However, it also causes the transfer of carbon emissions, giving the country many unnecessary responsibilities for emission reduction.

Conclusion

As the world's largest carbon emitter, China is facing more and more pressure on coping with global climate change. Based on the WIOD database, this paper measures the trade volume between China and its leading trade partners on the Belt and the Road using the MRIO model, revealing the implicit carbon emissions in the trade, and analyzes China's responsibilities for reducing implicit carbon emissions in trade from different perspectives. The main conclusions of this research are as follows:

(1) China's carbon responsibilities in its trade with the top trade partners differs greatly with responsibility sharing principles. The responsible volume under consumer responsibility is much greater than the traditional producer responsibility system. Thus, China and other developing countries should highlight the fairness of responsibility sharing in international negotiations on climate, trying to develop a carbon accounting mechanism favorable to their own rights and interests.

(2) Implicit carbon emissions mainly come from industries with relatively high emission intensities, such as electricity, energy, mining, and chemical industry. All these industries are featured by high energy-consumption and low efficiency. The coal-based energy structure is the fundamental reason for China's high carbon emissions. In future, efforts should be made to increase energy efficiency, increase the proportion of clean energy in the energy structure, and promote the transition towards a clean and efficient consumption structure.

(3) Comparing the different responsibility sharing principles, China is advised to adopt the common responsibility mechanism, which is relatively fair for regions with a large amount of implicit carbon influx.

The future research will clarify China's carbon responsibilities in international trade, assess its emission reduction potential, and allocate the carbon emission responsibilities.

(Received 18th Mar 2019; accepted 17th May 2019)

Abstract. Despite the importance of landscape resources in ecotourism villages, there is no scientific and complete index system for the evaluation of rural ecotourism landscape. This paper attempts to construct an evaluation index system for the ecotourism villages in the Xi'an section of the northern piedmont of Qinling Mountain. Firstly, the preliminary indices and relevant data were collected through field surveys and expert consultation. Next, the weight of each index was determined using the AHP. The conclusion is that: in the criteria layer, the weights of the elements can be ranked as natural elements (A1) > humanistic material elements (A2) > non-material elements (A3); in the factor layer, the weights of the factors under the natural elements can be ranked as ecological environment (B1) > hydro-geomorphic features (B2) > landscape quality (B3), the factors under the humanistic material elements as settlement landscape (B4) > farmland landscape (B6) > road landscape (B5) > facility construction (B7), and the factors under the non-material elements as folk culture (B8) > community participation (B9). Among the 37 indices, the natural disaster frequency (C3), folk culture diversity (C33) and Preservation of traditional residence (C15) were more important than the remaining 34 indices.
Keywords: *ecotourism villages, rural landscape; landscape resources, landscape character assessment, index system, analytical hierarchy process (AHP)*

Introduction

Ecotourism is an important strategy for Chinese villages, as the country has entered a new phase of high-quality development. The quality and sustainability of ecotourism villages are essential to China's pursuit of ecological civilization and rural development. To achieve sustainable development of ecotourism villages, it is a must to evaluate rural landscape resources in a scientific manner.

Among foreign scholars, Ianas (2013) evaluated the landscape in Almăj rural land system between 1990 and 2010. Hogan et al. (2012) estimated the cumulative ecological effect of local landscape changes in south Florida. Gottero and Cassatella (2017) explained the relationship between rural policymakers, agricultural policies and rural landscape through developing and testing key landscape indices. Steinhardt evaluated and planned small and medium rural landscapes on different levels, and applied the fuzzy evaluation theory into the research (Steinhardt, 1998). Gulinck et al. (2001) carried out rural landscape evaluation with three factors (i.e. completeness, diversity, and visual quality) and six indices (i.e. land use suitability, fragmentation degree, species richness, natural restoration potential, and tourism potential).

About the rural landscape evaluation, the Chinese scholars have mainly tackled three issues: ecological evaluation (Xu, 2007; Meng et al., 2011), aesthetic evaluation (Xie, 2004; Petrova et al., 2015) and the evaluation system. There are two widely accepted rural landscape evaluation systems in China. One of them was a human settlement-oriented one proposed by Liu and Wang (2002). This system consists of such three layers as the goal layer, the criteria layer (5 criteria) and the index layer (21 indices). The five factors are habitability, accessibility, compatibility, sensitivity and beauty. The other evaluation system was designed in light of the features of rural landscapes (Xie et al., 2003). Focusing on the social effect, ecological quality and aesthetic effect of rural landscape, this evaluation system has four layers, including a goal layer, a criteria layer (3 criteria), a factor layer (11 factors) and an index layer (31 indices).

To sum up, the foreign studies on rural landscape evaluation mainly concentrate on the ecological effect and aesthetics of a landscape, while also exploring landscape evaluation systems. The domestic studies have designed comprehensive evaluation indices, yet the evaluation systems are still incomplete due to the lack of weight analysis. Considering the previous studies, this paper attempts to construct an evaluation index system for the ecotourism villages in the Xi'an section of the northern piedmont of the Qinling Mountain (hereinafter referred to as the study area). The remainder of this paper mainly deals with data acquisition, index system construction, index weighting, the possible shortcomings and conclusions.

Materials and methods

Rural ecotourism requires a delicate balance between ecotourism and rural life (Yu, 2015). The ecotourism villages should provide services in line with the functions of rural landscape. These services need to cover natural elements (e.g. topography, hydrological conditions, and animal and plant resources), human elements (e.g. settlement environment, service facilities and farmland landscape), as well as non-material cultural elements (e.g. folk culture). For the sustainable development of rural landscape, the following goals should be fulfilled through rural ecotourism: a memorable travel experience of the original life, customs, humane care and unique agricultural landscape in the villages; the development of the villages and the local economy; full demonstration of the functional, aesthetic and ecological values of rural landscape; the coordination between rural development and eco-environmental protection.

Considering the definition of ecotourism villages and the existing index systems for landscape evaluation, this paper sets up an evaluation index system for ecotourism villages in the study area through qualitative and quantitative methods. A total of 75 indices were obtained for rural landscape elements by the investigation. On this basis, each index was rated by experts, and its weight was determined by the analytic hierarchy process (AHP), using data processing software like the SPSS and Matlab.

Data sources

The author investigated 33 towns across the 6 districts/counties (*Fig. 1*) in the study area. A total of 53 villages were identified as ecotourism villages in this region, according to the definitions and functional classifications on the term by various scholars (Dong, 2013; Wu, 2011). Then, the natural, human, social and ecological resources were sorted out in these villages, revealing that the local landscape of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89558968

ecotourism villages mainly covers the natural element, the humanistic material element and the non-material element (*Fig. 2*). Among them, the natural element contains ecological environment, hydro-geomorphic features and landscape quality; the humanistic material element includes settlement landscape, road landscape, farmland landscape and facility construction; the non-material element encompasses the folk culture and community participation.

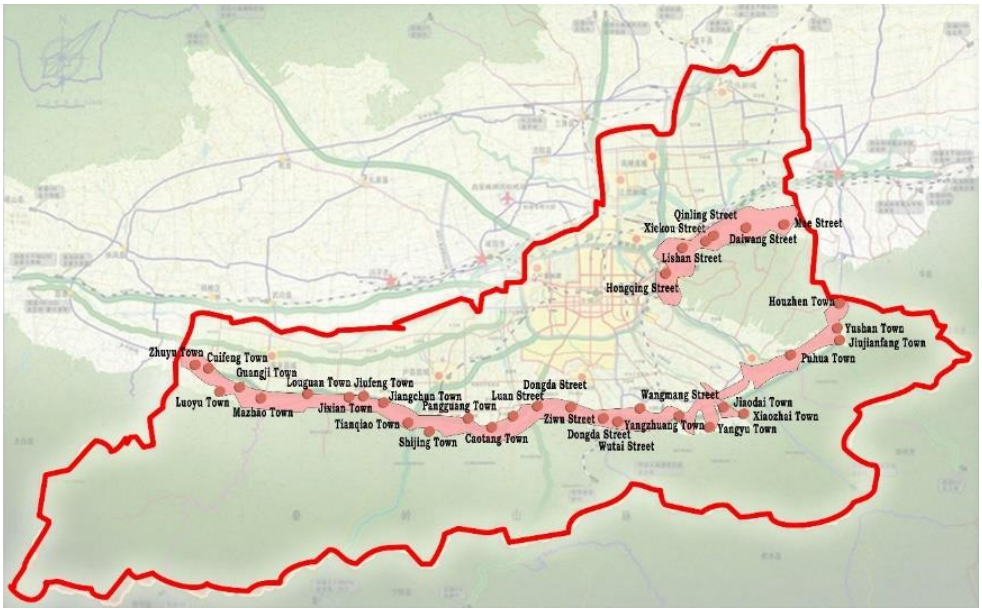

Figure 1. *Towns in the study area*

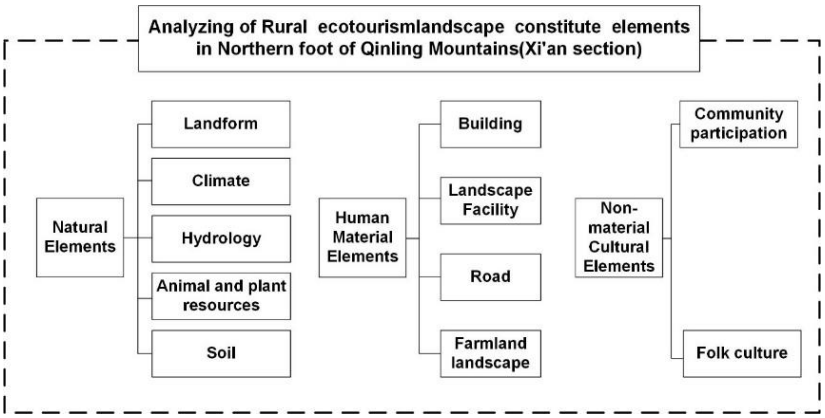

Figure 2. *Elements of rural tourism landscape in the study area*

Structure of the index system

Referring to the relevant studies (Liu and Wang, 2002; Liu and Wu, 2014; Xie et al., 2003), this paper divides the landscape evaluation index system of the ecotourism villages in the study area into four layers according to the landscape features of such villages and the structural features of the research system. From abstract to concrete and from macro to micro, the four layers are respectively the goal layer (G), the criteria layer (C), the factor layer (F) and the index layer (I). As shown in *Figure 3,* the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89558968

proposed index system adopts a 1 + 3 + 9 + N (i.e. 1 goal, 3 criteria, 9 factors and N indices) structure, and evaluates the landscape of ecotourism villages from the perspectives of natural, humanistic material and non-material elements.

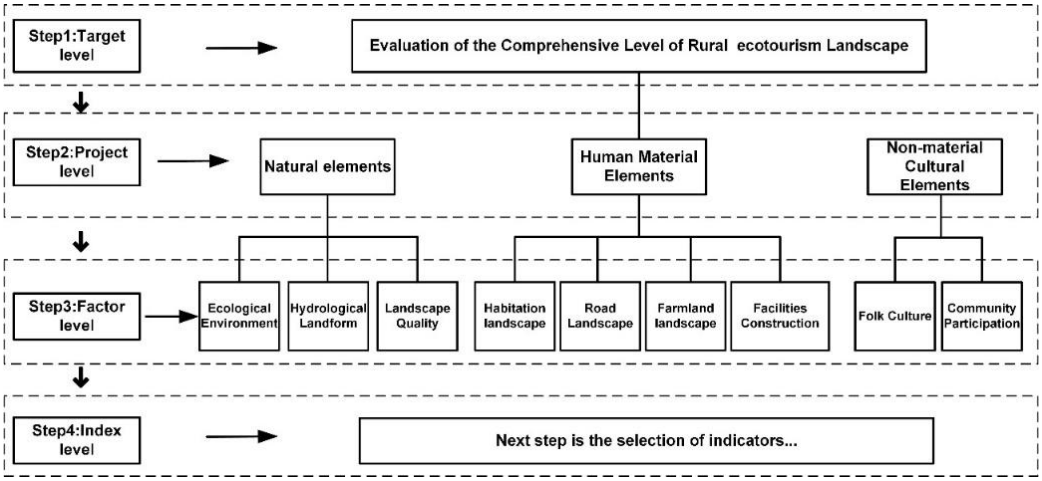

Figure 3. *Structure of landscape evaluation index system of the ecotourism villages*

The first layer is the goal layer (G). This layer specifies the ultimate goal of the index system and reflects the comprehensive level of rural ecotourism landscape in the study area. The second layer is the criteria layer (C). This layer mirrors the status of rural ecotourism landscape in the aspects of natural, humanistic material and non-material elements. The third layer is the factor layer (F). This layer contains 9 factors on the details of the three criteria. The fourth layer is the index layer (I). This layer gives the 37 indices under the 9 factors.

Selection of evaluation indices

The evaluation indices were selected through preliminary selection, screening and correction:

(1) Preliminary selection: A total of 75 indices, more than twice the number of final indices, were selected preliminarily according to the features of rural ecotourism landscape in the study area, the expert opinions and the survey data on local residents. A large number of preliminary indices was designed to ensure the reasonability of the final indices.

(2) Screening: The set of preliminary indices were made into a questionnaire, and rated by experts and scholars in relevant fields. The valid questionnaires were analyzed on the SPSS statistical software. The significance of each index was evaluated by the mean value, and the concentration of expert opinions was determined by the mode percentage and the coefficient of variation. The results are presented in Appendix 2. After two rounds of expert consultation, the 35 indices with a coefficient of variation in [0~0.37] were all retained.

(3) Correction: The index “diversity of riverside greening plants” had large mean value and mode percentage. It was retained after professional discussion. The two indices “perfection of service reception facilities” and “perfection of tourism facilities” were combined into “perfection of tourism service facilities”. Finally, a total of 37 indices were included in the index system (*Table 1*).

Determination of index weights

According to the steps of the AHP, the index weights were determined in a comprehensive manner through questionnaire survey and expert scoring. In total, 13 judgement matrices were set up, 20 questionnaires were sent out, and 10 experts were invited to rate the indices. All returned questionnaires were valid. The elements on each layer were evaluated systematically through pairwise comparison, with respect to their impact on an element above them in the hierarchy. The results of this single hierarchal arrangement include the weights of A relative to P WAi (i = 1, 2, 3), the weights of B relative to A WBi (i = 1, 2, …, 9), the weights of C relative to B WCi (i = 1, 2, …, 37). Finally, the weights of A to P WAi (i = 1, 2, 3) were adopted to check the consistency between the single hierarchal arrangement results on each layer, yielding the final results of index weights.

Evaluation results

Results of single hierarchal arrangement

The single hierarchal arrangement results of the 13 judgement matrices are recorded in *Tables 2–14*.

Discussion

In this research, the indices are selected through field survey and expert consultation, in reference to the previous studies on landscape index system. Besides, the weight of each index was quantified accurately and scientifically using the AHP. Nevertheless, some problems and possible deviations were discovered during the theoretical construction.

First, the AHP is a subjective method that may be biased in the weighting of some qualitative indices.

Second, rural landscape evaluation involves many fields. The selection of indices may not be comprehensive enough due to the limitations of professional knowledge.

Third, the experts involved in this research are all engaged in landscape-related fields; the author did not carry out effective consultations with experts in the fields of ecology, economics, tourism or sociology.

Conclusions

Ecotourism is an important strategy for Chinese villages, as the country has entered a new phase of high-quality development. This paper attempts to design a scientific and effective index system for landscape evaluation of ecotourism villages in the study area. Based on the existing theories on rural landscape evaluation system at home and aboard, the author carried out a field survey and expert consultation to comb the elements of rural ecotourism landscape and determined the weight of each index by the AHP. The following conclusions were drawn from the results and discussion.

This paper sets up a 4-layer index system that evaluates the rural ecotourism landscape from three aspects (i.e. the natural element, the humanistic material element and the non-material element). On this basis, it is necessary to consider the biological impacts of the humanistic material environment, such as the negative effects of settlement landscape, road landscape and facility construction on the biological environment and their indirect impacts on the rational layout of land use in rural planning. Consideration should also be given to the economic impacts of the non-material element, and the effects of landscape index system on agricultural policies and rural housing policies, aiming to create a multi-directional interaction mechanism between ecological, economic, and cultural elements in rural areas.

According to the AHP analysis, in the criteria layer, the weights of the elements can be ranked as natural elements (A1) > humanistic material elements (A2) > non-material elements (A3); in the factor layer, the weights of the factors under the natural elements can be ranked as ecological environment (B1) > hydro-geomorphic features (B2) > landscape quality (B3), the factors under the humanistic material elements as settlement landscape (B4) > farmland landscape (B6) > road landscape (B5) > facility construction (B7), and the factors under the non-material element as folk culture (B8) > community participation (B9). Among the 37 indices, the natural disaster frequency C3, folk culture diversity C33 and Preservation of traditional residence C15 were more important than the rest 34 indices. The natural environment provides the material basis for human survival. There is no time to delay for the protection of the natural environment, facing the severe environmental impacts of human activities. For the study area, the ecotourism villages should rationalize the rural planning, construction and management according to their unique landscape resources and the weights of the proposed indices.

DOI: http://dx.doi.org/10.15666/aeer/1704_89558968

The rural macro-system is involved in the landscape evaluation of ecotourism villages. The future research will improve the rural ecotourism evaluation index system in terms of objective and comprehensive quantification, aiming to provide desirable solutions to rural problems like sustained economic growth, eco-environmental protection and human settlement.

AN EMPIRICAL ANALYSIS ON THE RELATIONSHIP BETWEEN GREEN ECONOMY AND INFLATION IN CHINA

LYU, Y. F.

School of Banking & Finance, University of International Business and Economics
Beijing 100029, China
(e-mail: 283420976@qq.com; phone: +86-178-1209-6625)

(Received 18th Mar 2019; accepted 17th May 2019)

Abstract. Targeting the 21 port provinces of China, this paper constructs a panel vector autoregressive (PVAR) model to explore the dynamic relationship between China's green economy and inflation, and to verify whether China's green economy has a negative effect on inflation. Both the global Malmquist-Luenberger (GML) index and the Malmquist-Luenberger (ML) index, which represent the production efficiency under pollution, were adopted to measure China's green economy. It is assumed that the green economy and inflation interact with each other through the output gap, which is associated with pollution, the side-effect of production. The calculated results were tested by impulse response analysis. The final conclusion goes that China's green economy has a weak but long-lasting negative effect on inflation. In other words, China's green economy can alleviate the inflation. Thus, China should speed up pollution control and green economy development to control inflation.
Keywords: *port provinces, global Malmquist-Luenberger (GML) index, Malmquist-Luenberger (ML) index, monetary policy, panel vector autoregressive (PVAR) model*

Introduction

In recent years, the Chinese economy has entered a "new normal" stage, which is characterized by a balanced and manageable growth. According to the National Bureau of Statistics, China's GDP increased 6.6% to RMB 900.309 billion yuan from 2017 to 2018, about 0.1% higher than expected. The fast growth resulted in a hike in China's consumer price index (CPI), an indicator of inflation rate, posing a huge challenge to further economic development (*Figure 1*).

Recent years have also seen growing awareness of global warming across the world. Both the public and the governments are paying more and more attention to the environmental issues induced by global warming. The World Meteorological Organization (WMO) reported that the global mean temperature from January to October in 2018 was 0.98±0.1℃ higher than that before the industrial revolution, making 2018 the fourth warmest year on record. If El Niño occurs in the near future, 2019 may be even warmer than 2018 (NOAA, 2019).

Against this backdrop, it is imperative to strike a balance between economic growth and pollution control, even though many countries used to prioritize economic gains over the environmental benefits and perceive the two factors as contradictory. In other words, special efforts should be paid to develop a green economy, which generates output while reducing pollution, aiming to curb global warming. The official definition of green economy is "one that results in improved human well-being and social equity, while significantly reducing environmental risks and ecological scarcities (UNEP, 2011).

Considering the above, this paper examines whether the development of China's green economy has relieved inflation. It is assumed that China's green economy can suppress the pollution in production, and thus the inflation rate. This hypothesis was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89698983

tested with the data from the 21 port provinces in China. Meanwhile, a panel vector autoregressive (PVAR) model was employed to study the dynamic relationship between China's green economy and inflation rate.

The port provinces were targeted in this research because they are both transport hubs and industrial centers. In the past three decades, the main coastal economic zones have concentrated 70% of the industries above designated size in China (Chen, 2016). The rapid industrial development, coupled with economic growth, lead to various environmental problems, such as water pollution and land-based wastes (e.g. domestic waste and industrial waste) (Yan et al., 2018). As a result, the port provinces are more polluted than the rest of provinces in the country. Taking SO_2 emissions as an example (*Figure 2*), more SO_2 was emitted in the port provinces than other Chinese provinces in 2016.

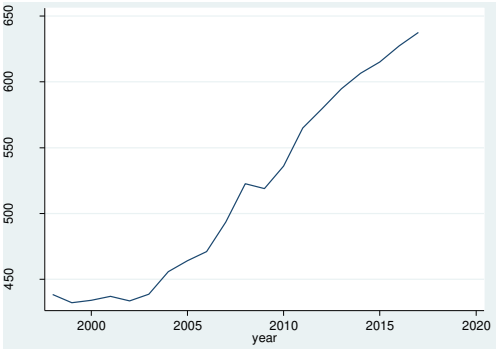

Figure 1. *The variation in China's CPI over time (Data source: The National Bureau of Statistics of China)*

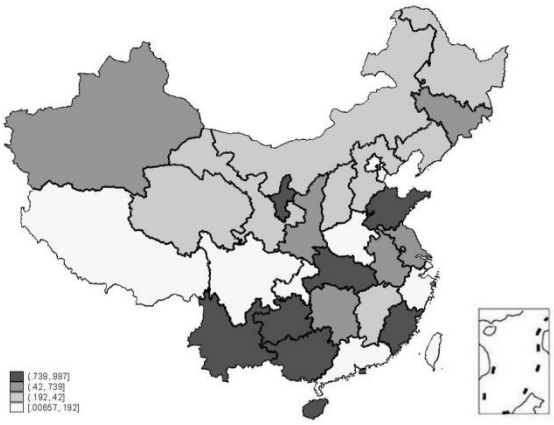

Figure 2. *The distribution of SO2 emissions across China in 2016 (Data source: The National Bureau of Statistics of China)*

Through an impulse response analysis, it is confirmed that the green economy of each port province has a negative effect on inflation. Note that the term "port provinces" refers to provincial administrative regions in Chinese mainland that contains riverside and/or seaside port cities.

The contributions and limitations of this research can be summed up as: (1) The author disclosed the dynamic relationship between China's green economy and the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89698983

macroeconomic variable of inflation; (2) It is verified that the green economy interacts with inflation through the output gap, and that China's green economy has a negative impact on inflation, making it possible to control pollution and inflation at the same time; (3) The conclusions are backed up firmly by the actual data from the 21 port provinces in China, which are more polluted than the other Chinese provinces; (4) Due to the lack of a widely accepted way to measure the size of China's green economy, there might be statistical errors in the calculation of the global Malmquist-Luenberger (GML) index or the Malmquist-Luenberger (ML) index; (5) Some biases may exist in the construction of capital stock and output variables.

The remainder of this paper is organized as follows: Section 2 reviews the previous studies on China's green economy and inflation; Section 3 introduces the main variables and estimation methods in our research; Section 4 empirically analyzes the dynamic relationship between China's green economy and inflation, measures China's green economy with its GML index, and tests the robustness by the ML index; Section 5 wraps up this paper with several conclusions.

Materials and methods

Relationship between inflation and output gap

Much research has been done to disclose the relationship between inflation and output gap. For instance, the Phillips curve (1958) reflects the negative correlation between the inflation rate and the unemployment rate, while the New Keynesian Phillips curve (NKPC) reveals the intrinsic causal link between economic output and inflation (Taylor, 1980; Calvo, 1983).

In addition, Jarociński and Lenza (2018) employed a Bayesian dynamic factor model to estimate the output gap in the Eurozone and illustrated the model's predictive power of inflation. With the aid of discrete and continuous wavelet transforms, Tiwari et al. (2014) explored the relationship between inflation and output gap in France, suggesting that the inflation rate can be predicted by economic output in the short and medium terms. Justiniano et al. (2013) confirmed the significant correlation between output gap and inflation through the analysis of the economic data of the US from 1954 to 2009. Based on the NKPC and hybrid NKPC, Bian and Hu (2016) designed the sticky information Phillips curve (SIPC) and double sticky Phillips curve (DSPC) for China, and proved the significance of output gap coefficients in the models, thus validating the Phillips curve.

Measure of China's green economy

There is not yet a widely accepted way to accurately measure the green economy, despite repeated attempts to do so. This is partially attributable to the significant country differences in the status and policies of green economy. On China's green economy, the existing research methods can be divided into four categories: data envelopment analysis (DEA) (Guo et al., 2017; Bao, 2017; Marino et al., 2017; Wang and Zhao, 2017; Yan, 2017, 2018; Shen et al., 2017; Han et al., 2018; Song, 2018), the stochastic impacts by regression on population, affluence and technology (STIRPAT) (Wang, 2017; He, 2017), the logarithmic mean Divisia index (LMDI) model (Wang and Feng, 2018; Chen, 2018), and the GML/ML index.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89698983

Coupling the DEA and the directional distance function (DDF), the ML index was modified from the Malmquist index (Chung et al., 1997), which is traditionally calculated from the output distance between different technologies. Compared with the Malmquist index, the ML index is still applicable when undesired outputs like CO_2 emissions or pollution are considered. The index was adopted by Li et al. (2018) to measure the carbon productivity of 36 industrial sectors in from 2003 to 2015. However, the ML still has certain shortcomings, such as the inability to solve linear prediction, non-transferability and additivity.

In 2010, the ML index was further improved by Oh into the GML index. Since then, the GML index has been widely adopted to measure economic output. For example, Emrouznejad and Yang (2016) employed the GML index to evaluate China's manufacturing industry between 2004 and 2012, and built a framework to measure the industrial eco-efficiency in terms of CO_2 emissions. Based on the GML index, Lei et al. (2017) constructed a carbon-weighted economic development indicator for 30 Chinese provinces between 1998 and 2014, and evaluated the economic performance of the carbon emissions-aware economy. Ren et al. (2018) relied on the GML index to incorporate undesirable outputs into the measurement of total factor productivity (TFP) for 11 coastal regions of China between 2006 and 2014, and assessed the efficiency of China's marine economy under environmental constraints. With the aid of the GML index, Pan et al. (2018) designed a measure of the green economy of 30 provinces in China between 1999 and 2016, and evaluated the provincial green economic development. In this paper, the GML index proposed by Oh (2010) is taken as a measure of China's green economy.

The effects of China's green economy

Several scholars have studied the drivers and impacts of China's green economy. Among them, Zeng et al. (2017) built a structural vector autoregressive (SVAR) model to analyze the dynamic relationship between carbon subsidy price, stock price and energy price in Beijing between 2014 and 2015. Lin and Zhu (2017) created a PVAR model to investigate the relationship between urbanization, industrial structure, energy density and carbon density in 30 Chinese provinces between 2000 and 2015. Ouyang and Li (2018) probed into the dynamic relationship between energy consumption, M2 money supply, credit, income, and stock price from Q1, 1996 to Q4, 2015. Using the panel data of 30 Chinese provinces between 1998 and 2014, Lei et al. (2017) investigated the dynamic relationship between the industrial structure, energy structure, low carbon index, foreign direct investment (FDI) and trade, using the PVAR model. In fact, the PVAR is the most frequently used model for the dynamic relationship between China's green economy and other variables. Thus, this model was selected for our research.

The price impact of China's green economy has long been a research hotspot. For example, Zeng et al. (2014) found that, while other factors are under control, land pollution induces a net loss of 31% in the value of nearby plots. On the provincial data in 2001~2010, Leng and Du (2016) verified the positive correlation between energy price distortion and haze pollution in China. Zhang (2018) suggested that the pollution control costs of key monitoring enterprises in China has a significant causal effect on the marginal cost and price of multi-product enterprises.

Drawing from the previous research, the author assumed that pollution, as an externality, will affect the production output, and thus the price (Mas-Colell et al., 1995).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89698983

The price change will in turn cause changes in inflation. On the one hand, the mitigation of pollution, a side-effect of production, drags down the output of the whole society and pushes up the marginal production cost, resulting in economic losses (Xi et al., 2013). On the other hand, pollution control also affects the marginal cost of enterprises, e.g. the cost of power generation is influenced by effective energy policies (Zhang et al., 2007; Bianco et al., 2017; Borchiellini et al., 2017; Silvestro et al., 2017; Domenico et al., 2018). In other words, the overall societal cost is subjected to the impacts of externalities. Being a developing country, China tends to suffer greater loss in economic output, which stems from pollution control, than developed countries (Maradan and Anatoli, 2005). Hence, the PVAR model is selected here to study the dynamic relationship between China's green economy and price changes, i.e., inflation.

Methodology of main variables

ML index

The ML index was proposed by Chung et al. (1997) and modified by Oh (2010) to overcome suboptimal properties. In this paper, this index is employed in the robustness test. The ML index of country *i* can be defined by two contemporaneous continuous reference vectors, as in *Equation (1)*:

$$ML^S(x^t, y^t, b^t, x^{t+1}, y^{t+1}, b^{t+1}) = \frac{1+D^s(x^t, y^t, b^t)}{1+D^s(x^{t+1}, y^{t+1}, b^{t+1})} \quad \text{(Eq.1)}$$

where, D^s is the DDF. The DDF can be defined by the synchronous technology set (P^s) in *Equation (2)*:

$$D^s(x, y, b) = \max\{\beta \mid (y+\beta y, b-\beta b\} \in P^S(x)\}, \quad s=t, \quad t+1 \quad \text{(Eq.2)}$$

If the production activity achieves higher output and lower externalities in year *t+1*, then $ML^s > 1$ and production efficiency increases. Otherwise, $ML^s < 1$ and the production efficiency declines. So in *Equation (3)*:

$$ML^t(x^t, y^t, b^t, x^{t+1}, y^{t+1}, b^{t+1}) \neq ML^{t+1}(x^t, y^t, b^t, x^{t+1}, y^{t+1}, b^{t+1}) \quad \text{(Eq.3)}$$

The ML index can also be defined as the geometric mean of two consecutive periods, as in *Equation (4)*:

$$\begin{aligned} ML^{t,t+1}(x^t, y^t, b^t, x^{t+1}, y^{t+1}, b^{t+1}) &= \left[\frac{1+D^t(x^t, y^t, b^t)}{1+D^t(x^{t+1}, y^{t+1}, b^{t+1})} \times \frac{1+D^{t+1}(x^t, y^t, b^t)}{1+D^{t+1}(x^{t+1}, y^{t+1}, b^{t+1})}\right]^{1/2} \\ &= \frac{1+D^t(x^t, y^t, b^t)}{1+D^{t+1}(x^{t+1}, y^{t+1}, b^{t+1})} \times \left[\frac{1+D^{t+1}(x^t, y^t, b^t)}{1+D^t(x^t, y^t, b^t)} \bullet \frac{1+D^{t+1}(x^{t+1}, y^{t+1}, b^{t+1})}{1+D^t(x^{t+1}, y^{t+1}, b^{t+1})}\right]^{1/2} \\ &= \frac{TE^{t+1}}{TE^t} \times \left[TG_t^{t,t+1} \bullet TG_{t+1}^{t,t+1}\right]^{1/2} \\ &= EC^{t,t+1} \times TC^{t,t+1} \end{aligned} \quad \text{(Eq.4)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89698983

where, TE^s is technical efficiency of period s; $TG^{t, t+1}$ is the technical gap between periods t and $t+1$; $EC^{t, t+1}$ is the variation in technical efficiency gap between periods t and $t+1$; $TC^{t,t+1}$ is the variation in technical boundary gap between periods t and $t+1$. Obvious, $EC^{t,t+1}>1$ indicates an increase in technical efficiency, and $EC^{t,t+1} < 1$ indicates the opposite; $TC^{t, t+1}>1$ means the technical boundary increases with the growth in output and the reduction of externalities.

GML index

The GML index can be defined in *Equation (5)*:

$$GML^{t,t+1}(x^t, y^t, b^t, x^{t+1}, y^{t+1}, b^{t+1}) = \frac{1+D^G(x^t, y^t, b^t)}{1+D^G(x^{t+1}, y^{t+1}, b^{t+1})} \quad \text{(Eq.5)}$$

where, D^G is the DDF. The DDF can be defined by the global technology set (P^G) in *Equation (6)*:

$$D^G(x, y, b) = \max\{\beta \,|\, (y+\beta y, b-\beta b\} \in P^G(x)\} \quad \text{(Eq.6)}$$

If production activities achieve higher output and lower externalities, then $GML^{t,t+1} >1$ and productivity increases. Otherwise, $GML^{t, t+1}<1$ and productivity decreases. The GML index can be broken down in *Equation (7)*:

$$\begin{aligned} GML^{t,t+1}(x^t, y^t, b^t, x^{t+1}, y^{t+1}, b^{t+1}) &= \frac{1+D^G(x^t, y^t, b^t)}{1+D^G(x^{t+1}, y^{t+1}, b^{t+1})} \\ &= \frac{1+D^t(x^t, y^t, b^t)}{1+D^{t+1}(x^{t+1}, y^{t+1}, b^{t+1})} \times \left[\frac{(1+D^G(x^t, y^t, b^t))/(1+D^t(x^t, y^t, b^t)}{1+D^G(x^{t+1}, y^{t+1}, b^{t+1})/(1+D^{t+1}(x^{t+1}, y^{t+1}, b^{t+1}))} \right] \\ &= \frac{TE^{t+1}}{TE^t} \times \left[\frac{BPG^{t,t+1}_{t+1}}{BPG^{t,t+1}_{t}} \right] \\ &= EC^{t,t+1} \times BPC^{t,t+1} \end{aligned} \quad \text{(Eq.7)}$$

where, TE^s is technical efficiency of period s; $EC^{t, t+1}$ is the variation in technical efficiency gap between periods t and $t+1$; $BPG^{t,t+1}$ is the optimal practice gap between the synchronous technology boundary and the global technology boundary.

Output gap

The potential output can either be estimated from the time series data of actual output or be determined by the production function. The former approach needs to detrend the data and extrapolate growth rates. However, the estimation is too simple to derive the exact amount of potential output. The latter method mainly considers the factor utilization and the impact of technical progress on output, revealing the supply-side of potential output. The production function method has been adopted by many scholars (Guo and Jia, 2004).

In this paper, the production function method is selected to measure the potential output, such as to determine the output gap of each port province in China. Firstly, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89698983

aggregate production function was estimated based on the data on the actual output, labor and capital stock, laying the basis for acquiring the TFP. The Cobb-Douglas production function is adopted in *Equation (8)*:

$$Y_t = AK_t^{\alpha} L_t^{\beta} \quad \text{(Eq.8)}$$

where, Y_t is the actual output; L_t is the actual labor; K_t *i*s the capital stock; α and β are the output elasticities for capital and labor, respectively. Taking the natural logarithm on both sides of *Equation (8)*, we have *Equation (9)*:

$$\ln Y_t = \ln A + \alpha \ln K_t + \beta \ln L_t \quad \text{(Eq.9)}$$

If the production has constant scale of returns, then $\alpha + \beta = 1$. In this case, a double logarithmic model can be constructed in *Equation (10)*:

$$\ln(Y_t / L_t) = \ln A + \alpha \ln(K_t / L_t) + \gamma_t \quad \text{(Eq.10)}$$

The TFP can be obtained from the residual term of this regression (γ_t). Secondly, the TFP was decomposed by the Hodrick–Prescott (HP) filter, and the potential employment was estimated under the potential output in *Equation (11)*:

$$L_t^{Potential} = L_{St} \times Tr_{p,t} \times (1 - NAWRU_t) \quad \text{(Eq.11)}$$

where, L_{St} is the number of people in the working age; $Tr_{p,t}$ is the trend participation rate; $NAWRU_t$ is the unemployment rate induced by non-wage factors. Thirdly, the potential output was established from the estimated TFP trend, potential employment and potential output. Finally, the output gap was determined as the difference between the estimated output and the potential output.

Research data and calculation results

Research data

The 21 port provinces in China were taken as the research objects. As shown in *Table 1*, some of these provinces have both riverside and seaside port cities, and some have either riverside or seaside port cities.

The annual data of these provinces in 2006~2015 were collected to reduce the regression bias in PVAR model estimation. The annual data were selected for three reasons: the large-scale changes in macroeconomic variables are unlikely to occur within a monthly or quarterly range (Beetsma et al., 2008), the macroeconomic variables may change systematically under the expectation effect, which is more prevalent in shorter time windows, and the annual data do not contain any potential seasonal effect.

Calculation of the GML index

The GML index was computed by the method of Oh (2010) according to the annual data of the 21 provinces in 2006~2015. The following variables were covered in the computing process.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89698983

(i) The desirable output: the annual GDP of the 21 port provinces. This variable was converted into a constant price by the GDP deflator (unit: RMB 100 million yuan). Data source: CEInet Statistics Database.

(ii) The undesirable output: the annual SO_2 emissions (unit: ton) and wastewater discharge (unit: ton). Data source: The National Bureau of Statistics of China.

(iii) The inputs of production technology: the inputs were measured by three indices, namely, capital stock (unit: RMB 100 million yuan), labor force (unit: 10,000 people) and energy consumption (unit: TCE).

The capital stock was calculated by the method of Shan (2008), who computed the capital stock of China and its provinces in 1952~2006 using the perpetual inventory method (PIM). The PIM assumes that the relative efficiency is geometrically decreasing, while the reset rate is constant. Here, the calculation formula of the capital stock can be expressed in *Equation (12)*:

$$K_t = (1-\delta)K_{t-1} + I_t / P_t \quad \text{(Eq.12)}$$

where, K_{t-1} is the capital stock of the year t-1; δ is the economic depreciation rate; I_t is the investment amount in year t; P^t is the investment price index used to convert the investment amount into constant price. Here, the investment amount is measured by the fixed capital formation amount of each province, which comes from the China Economic and Trade Network, while the investment price index of each province was extracted the CEInet Statistics Database. Under the PIM assumption, the economic depreciation rate of the 21 provinces was set to 10.96%.

7	Hainan	Seaside	14	Jiangxi	Riverside	21	Zhejiang	Riverside and seaside

Data source: Chinese Ministry of Transport

In addition, the labor force in each province was obtained by adding up the urban residents employed in the public sector, in the private sector, and self-employed, without considering the employment of rural residents. The employment data before 2008 were drawn from the China Stock Market & Accounting Research (CSMAR) Database, and those after 2008 were extracted from the National Bureau of Statistics of China. The provincial data on annual energy consumption were also downloaded from the CSMAR database.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89698983

Calculation of the output gap

The annual output gap of each port province in 2006~2015 was calculated by the method of Guo and Jia (2004), using the following variables:

(i) The actual output: the annual GDP of each port province.

(ii) The actual labor force: the annual urban labor force of each province.

(iii) The capital stock: this variable was computed the same as in the preceding subsection.

(iv) $L_{St} \cdot Tr_{p,t}$: the number of people in the working age multiplied by the trend value.

(v) $NAWRU_t$: the number of laborers divided by the total number of people involved in social and economic activities. The latter was defined as the sum of the number of laborers and the number of registered unemployed urban residents. The data were collected from the National Bureau of Statistics of China.

(vi) Constant return on scale: The assumption that the scale of return is constant was verified by the Wald test. The original hypothesis H_0 can be expressed as $\alpha + \beta = 1$. The test results are listed in *Table 2* below.

Table 2. *The results of the Wald test*

H_0	x^2 (1)	P>x^2
α+β=1	1.17	0.2803

The results in *Table 2* show that the P-value is greater than 0.05, revealing the validity of the original hypothesis. Thus, the production mode of China's economy was considered as having constant returns to scale between 2006 and 2015.

PVAR model

The PVAR model was established to analyze the relationship between China's green economy and the inflation rate. The variables were treated as endogenous and interdependent. To reflect the real interaction between the variables, the lag term of all variables was included in the model. The basic form of the PVAR model is established as *Equation (13)*:

$$y_{it} = \alpha_0 + \sum_{l}^{L} \alpha_l y_{i,t-l} + I_i + T_t + \mu_{it} \quad \text{(Eq.13)}$$

where, y_{it} is the column vector containing endogenous variables; i is the serial number of port provinces; t is the year; L is the post-order; I_i is the individual effect vector; T_t is the time effect vector; μ_{it} is a random disturbance term (i.e. the white noise).

The individual effect vector does not change with time, and the right side of *Equation (13)* contains the lag term of the dependent variables. Thus, the mean differencing was adopted to prevent the estimation bias from potential endogeneity. More specifically, the forward-mean-differencing method was adopted to remove the fixed effect in the model (Arellano and Bover, 1995). Besides, the generalized method of moments (GMM) was used to obtain a consistent estimator of the coefficient of the explanatory variable, with the lag term of the explanatory variables as the instrumental variables. Furthermore, an impulse response analysis was conducted through Monte-Carlo simulation.

Results

The dynamic relationship between GML index and inflation

Basic regression

Considering the negative correlation between pollution and the GML, it is assumed that the GML has a negative effect on the CPI. The orthogonal impact response function is the disturbance term of the Cholesky decomposition. By exogenous nature, the Cholesky decomposition variables can be ranked as output gap (*outgap*), China's green economy (*GML*) and inflation (*CPI*). The regression model can thus be established as *Equation (14)*:

$$y_{it} = (outgap_{it}, GML_{it}, CPI_{it})^T \quad \text{(Eq.14)}$$

Prior to the regression, the Fisher-Phillips-Perron (PP) test, the Im-Pesaran-Shin (IPS) test and the Levin-Lin-Chu (LLC) test were carried out, proving that the level values of all variables can be directly used for the regression of the PVAR model. The level values of all variables rejected the null hypothesis at a significance level of 1%, that is, the level values of all variables do not possess unit roots, and all sequences are stationary. Moreover, the optimal lag order (2) was determined by the Akaike information criterion (AIC), Bayesian information criterion (BIC) and Hannan & Quinn information criterion (HQIC). The test results are shown in *Table 3* below.

Table 3. *The results on the optimal lag order*

Lag	AIC	BIC	HQIC
1	6.18901	7.04927	6.53857
2	4.62324*	6.16506*	5.23567*
3	4.63834	6.81804	5.46838

Note: ***, ** and * stand for the significance levels of 1%, 5% and 10%, respectively

As such, the PVAR (2) model was selected for our research.

Impulse response analysis

Through Cholesky decomposition, the author analyzed the interaction between China's green economy and inflation, after excluding the effects of other endogenous variables. Since the data run from 2006 to 2015, a total of 10 years, the impact duration was divided into 10 periods. The impulse response function (IRF) graph of the CPI to the GML was obtained through 1,000 random Monte-Carlo simulations.

Robustness test

Basic regression

The same analysis was performed using the ML index, assuming that the ML also has a negative impact on the CPI. The variables were the same as those in the analysis based on the GML. In the ML-based analysis, the PVAR model was still adopted, and the Cholesky decomposition variables were still ranked as the output gap (*outgap*),

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89698983

China's green economy (*ML*) and inflation (*CPI*). Thus, the regression model is parallel to *Equation (13)*.

Prior to the regression, the PP-Fisher test, IPS test and LLC test were conducted as well, and the optimal lag order (3) was determined by the AIC, BIC and HQIC criteria. These results are displayed in *Table 4* below.

Table 4. *The results on the optimal lag order*

Lag	AIC	BIC	HQIC
1	6.00907	6.86933	6.35863
2	9.7832	11.325	10.3956
3	2.53134*	4.71105*	3.36139*

Note: ***, ** and * stand for the significance levels of 1%, 5% and 10%, respectively

As such, the PVAR (3) model was selected for our research.

Impulse response analysis

The IRF graph of the CPI to the ML was obtained through 1,000 random Monte-Carlo simulations.

Discussion

As shown in *Figure 3*, the effect of the GML on the CPI was not observable at the start, decreased in the first period, and slightly increased in the second period. After that, the effect continued to decline until the fourth period, and then tended to be stable through the tenth period. Overall, China's green economy has a weak negative effect on inflation in the long run, which agrees with our hypothesis.

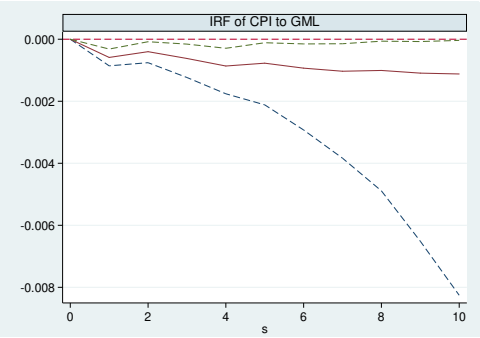

Figure 3. *The IRF graph of the CPI to the GML (Note: The red line is the impulse response curve; the green dotted line stands for the points in the confidence interval of 5%; the blue dotted line stands for the points in the confidence interval of 95%)*

As shown in *Figure 4*, the effect of the ML on the CPI was not observable at the start, decreased in the first period, and slightly increased in the second period. After that, the effect continued to decline until the fourth period, and then tended to be stable through the tenth period. In general, China's green economy has a weak negative effect on inflation in the long run.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89698983

To sum up, China's green economy has a weak but long-lasting negative effect on inflation. In other words, China's green economy can alleviate the inflation.

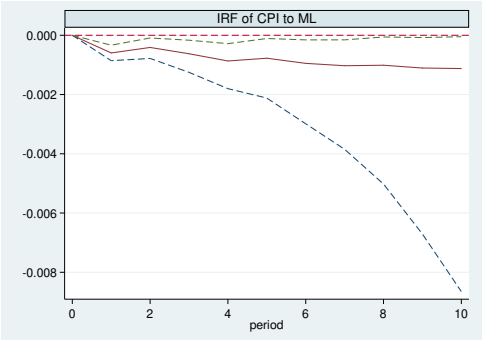

Figure 4. *The IRF graph of the CPI to the ML (Note: The red line is the impulse response curve; the green dotted line stands for the points in the confidence interval of 5%; the blue dotted line stands for the points in the confidence interval of 95%)*

Conclusions

Targeting the most polluted 21 port provinces in China, this paper attempt to disclose the dynamic relationship between China's green economy and inflation, and verify the hypothesis that China's green economy can alleviate the inflation through the output gap. Specifically, a PVAR model was constructed to explore the relationship, and the result was tested by impulse response analysis. It is proved that China's green economy has a causal relationship with inflation, whether it is calculated by the GML or the ML. The final conclusion goes that China's green economy has a weak but long-lasting negative effect on inflation. In other words, China's green economy can alleviate the inflation. Thus, the pollution is positively correlated with inflation.

In light of the findings, China should speed up pollution control and green economy development, such as to complete the 2020 climate targets ahead of schedule and lay the foundation for implementing the 2030 climate targets. Meanwhile, proper monetary policy should be rolled out to enhance the suppression effect of green economy over inflation.

The conclusion about the relationship between the green economy and inflation could indicate that the green economy can be a good signal for monetary policy. So further studies about the analysis of effects of monetary policy signalling within green economy over the clarity of central bank communication could be recommended.

(Received 18th Mar 2019; accepted 17th May 2019)

Abstract. This paper measures the regional environmental efficiency in China by using the super-efficiency slacks-based measure (SBM). It calculates the environmental efficiency in the presence and absence of the environmental pollution variable respectively, and compares the calculation results of the super-efficiency SBM model with the Banker & Charnes & Cooper's (BCC) model, one of the traditional data envelopment analysis (DEA) models. By analyzing the environmental efficiencies in all provinces, it analyzes the slack variables to determine in which direction each region should improve. The results show that the addition of the environmental pollution variable has resulted in significant declines in the efficiencies of provinces with DEA inefficiencies. Among the four regions, the eastern one has the highest environmental efficiency, the western region comes next and the northeastern and central regions are the last ones. There are also some economically developed provinces with low environmental efficiency, and different inefficient provinces need to be improved in different directions.
Keywords: *DEA, regional environmental efficiency, pollution variable, BCC model, slacks-based measure*

Introduction

The continuous environmental deterioration around the world has become a key factor constraining the sustainable development of all countries in the world. Finding a way to prevent further deterioration of the environment has become a significant issue of concern for the global academic community and governments. For China, the increasingly serious environmental problems have also turned into a major issue affecting China's overall economic development and become a "bottleneck" in its sustainable development path. Therefore, studying how to improve environmental efficiency more effectively is of great significance for promoting the scientific frontier development and helping the government achieve energy conservation and emission reduction targets.

Environmental efficiency is a crucial measure of the environmental conditions in a country (or region). There is still no universal agreement on the definition of environmental efficiency, but it is generally divided into two categories. The first defines the ratio of economic aggregate to environmental load as environmental efficiency (Beukes et al., 2010; Halkos and Tzeremes, 2013; Wang et al., 2007; Zhang, 2008). The environmental load refers to the carrying capacity of the external environment when humans are conducting economic activities, e.g. the carrying capacity of energy, land, general resources, water resources and forest resources, etc. The second definition

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89859005

focuses on the perspective of the environmental impact of production activities. In this definition, the environmental efficiency is measured in two ways. First, without considering the efficiency of input, it is measured by the ratio of economic value (GDP) to the impact of environmental pollution, which is the reciprocal of the pollution intensity (Schaltegger and Sturm, 1990; Wang, 2011). The second method considers the efficiencies of both input and output, and it is called comprehensive environmental efficiency or environmental total factor efficiency (Wang et al., 2010; Xu, 2012) or environmental productivity. Obviously, these two definitions of environmental efficiency do not consider the affordability of consumers when pollution is emitted. For example, in densely populated cities, the air pollution emissions impose different environmental impacts than those in the sparsely populated suburbs.

In the measurement of environmental efficiency, Stochastic Frontier Analysis (SFA) (Thijssen, 1999; Tan et al., 2013), Multi-Criteria Decision-Making method (MCDM) (Montanari, 2004), Data Envelopment Analysis (DEA) and other research methods have all been used. Among them, non-parametric methods (such as DEA, etc.) can reduce the subjectivity of the measurement results as there is no need to construct the production function in advance. Therefore, compared with parametric methods (such as SFA), non-parametric methods are more widely used, The DEA method has proven to be a very effective tool to measure the efficiencies and productivities of similar decision-making units (DMUs) and is therefore widely used in industrial, urban, regional, and global productivity and efficiency evaluations. Many scholars have used the DEA model to measure environmental efficiency. Faere et al. (1989) was the first to propose the DEA model for environmental efficiency evaluation. Bevilacqua and Braglia (2002) used the data of seven oil refineries in Italy from 1993 to 1996, selected six indices such as CO, CO_2, SO_2 and petroleum processing output, and evaluated the environmental efficiency using the CCR model. Aldanondo et al. (2014) used the DEA model to quantitatively analyze environmental efficiencies of organic agriculture and traditional agriculture in Spain, and concluded that the organic agriculture is more efficient than the traditional one under the same environmental impact. Many scholars have also used DEA to measure the environmental efficiency in China (Chen, 2008; Reinhard et al., 2000; Tone, 2002). Wang et al. (2009) established a DEA efficiency evaluation model, selected data from 28 provinces in China from 2001 to 2005, and measured environmental efficiency from the perspective of environmental regulation. The results show that areas with better environmental efficiencies account for 10% to 20%. Wu and Ma (2016) used the DEA method to calculate the ecological efficiency of 31 provinces in China from 2009 to 2013, and then used the Tobit model to analyze the factors affecting ecological efficiency. The results show that the per capita GDP and the geographical position of the east have positive impacts on ecological efficiency, while the industrial structure and population density have negative impacts. It can be seen that the DEA method has been widely used to evaluate environmental efficiency. The weight can be determined according to the principle of optimality to calculate the relative efficiency of each DMU, and then the efficiency values and improvement directions of all DMUs can be obtained. However, the radial problem existing in the traditional DEA models affects the accuracy of efficiency evaluation (the technical efficiency of the DMU is 1), and the complete ordering between the evaluated units cannot be addressed. What is more, these models only focus on a single perspective (input or output perspective), which do not fully reflect the actual situation in the excessive investment and production. In order to solve the radial problem in the traditional DEA models, scholars have applied the SBM model,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89859005

the super-efficiency DEA model and a combination of the two to measure the efficiency of various industries. For instance, Yan and Hou (2018) used the super-efficiency SBM model to measure the urban ecological efficiency in China. Zhang and Ma (2018) constructed an efficiency evaluation index system for the urban energy saving and environmental protection industry, based on the principle of the super-efficiency SBM model.

However, most applications of the relevant non-radial model often overlook the environmental efficiency problems that exist in the production process, including environmental pollution.

This paper conducts a comparative study on the measurement of environmental efficiency from the perspective of "environmental impacts of producers' economic activities". It proposes that environmental efficiency is actually the economic efficiency after the environmental factors are taken into account, that is, the economic level achieved at the expense of certain environmental loss. The following innovative research is conducted on this definition: First, this paper uses the entropy weight method to combine undesired outputs (waste gas, wastewater, solid waste) into an indicator to reflect the overall environmental pollution status. Second, this paper fully considers the role of the environmental pollution variable (pollutants) in environmental efficiency, and uses the super-efficiency SBM model to effectively solve the radial problem and the incomplete ordering of units in the traditional model. As a result, the status quo can be more objectively and truly reflected.

The rest of this paper is organized as follows. Section 2 briefly introduces the development of the DEA model, and describes the super-efficiency SBM model used in this paper. Section 3 constructs the input-output index system and comprehensively evaluates environmental pollution indices. Section 4 uses the super-efficiency SBM model to measure the environmental efficiencies of different regions in China, compares them with the measurement results of the BCC model, and analyzes the redundancy rate of input and output. Finally, the conclusions are presented in section 5.

Materials and methods

Data Envelopment Analysis (DEA) is a non-parametric frontier efficiency analysis method. It was proposed by American operation researchers Chames and Copper in 1978. Their first basic model of DEA is the CCR model, established on the relative efficiency evaluation. After the introduction of this model, many different DEA models emerged. Regarding the concept of "return to scale" in economics research, Banker proposed a BCC model based on variable-scale returns by adding constraints. After many years of development, now the DEA model can be divided into two major categories: radial models and non-radial models. CCR and BCC are radial models (i.e., maintaining quantitative output or input so that inputs or outputs are proportionally reduced or increased). This feature of the radial model makes the result very different from the actual situation. Later, some scholars began to study non-radial models and proposed additive DEA and SBM models. In terms of model improvement, many scholars have made a lot of contributions in enriching relevant theories and practices of DEA.

The basic principle of the DEA model is to treat each individual as a single DMU for evaluation. Many DMUs within a system can be regarded as an evaluation group, and then the overall input-output ratio can be measured. The weight of each input or output

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89859005

of a DMU is taken as a variable in the evaluation, so as to determine the efficient production frontier. In the efficiency evaluation, DEA can spontaneously include all data points in the efficiency frontier according to the structural characteristics of the source data, thus saving the prior work like determining the specific function form and improving the process and research efficiency. The relative efficiency (i.e. 1) of all the points on the efficiency frontier represents the highest level, and the relative efficiencies of the remaining points are distributed between 0 and 1. The calculation results can be obtained according to the efficiency frontier ratio, which is obtained from previous calculation.

Model framework

CCR model

The model assumes that there are n DMUs, each of which has m input indices and s output indices, which are similar to the input and output indices in economics. We denote DMU_j as DMU j, x_{ij} as the ith input of DMU j, where $x_{ij} > 0$; y_{rj} as the rth output of DMU j, where $y_{rj} > 0$; v_i as a measure of the ith input, which is also called the weight; u_r as a measure of the rth output, i = 1, 2, 3, …, m; j = 1, 2, 3, …, n; r = 1, 2, 3,…, s. For the sake of convenience, let $X_j = (x_{1j}, x_{2j}, x_{3j}, \ldots x_{mj})$, j = 1, 2, 3, …, n; $Y_j = (y_{1j}, y_{2j}, y_{3j}, \ldots y_{sj})$, j = 1, 2, 3, …, n; $v = (v_1, v_2, \ldots v_m)$; and $u = (u_1, u_2, \ldots u_r)$. Now let us analyze the efficiency evaluation problem of the decision-making unit DMU_j. The fractional model of the CCR model is shown in *Equation 1:*

$$\max \frac{u_r y_0}{v_m x_0} \qquad \text{(Eq.1)}$$
$$s.t. \frac{u_r y_{rj}}{v_m x_{mj}} \le 1, j = 1,2,...n$$
$$u \ge 0, v \ge 0$$

Convert the above fractional model to an equivalent linear model *Equation 2:*

$$\max u_r y_{r0} \qquad \text{(Eq.2)}$$
$$s.t. v_m x_{i0} - u_r x_{r0} \ge 0, j = 1,2,...n$$
$$v_m x_{i0} = 1, v \ge 0, u \ge 0$$

The dual programming expression for the above linear programming is shown in *Equation 3:*

$$\min \theta - \varepsilon \left(\sum_{i=1}^{m} s_i^- + \sum_{r=1}^{s} s_r^+ \right) \qquad \text{(Eq.3)}$$
$$s.t. \sum x_i \lambda_i + s^- \le \theta x_0, i = 1,2,...m$$
$$\sum y_j \lambda_j - s^+ \ge y_0, j = 1,2,...n$$
$$\lambda_j, s^+, s^- \ge 0$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89859005

If the optimal solution to *Equation 3* is (λ^*, θ*, s^+*, s^-*), then the following results can be obtained: 1) If θ* < 1, the obtained DMU is DEA inefficient; 2) If θ* = 1, and s^-* or s^+* is not equal to 0, then the DMU obtained is DEA weakly efficient; 3) If θ* = 1, and, s^-* and s^+* are equal to 0, then the DMU obtained is DEA efficient. The above is based on the DEA model with the same input, and the results will be opposite for the output-oriented DEA, which studies the problem of constant input and maximum output.

The premise for the CCR model is that the return to scale is constant, that is, when a DMU is DEA efficient, it is also efficient in technology and scale. Being efficient in technology means that the production is at its best, and the system can use the existing input to get the best output. Being efficient in scale means that production is in a state of constant scale and efficiency. Under this state, if the input is expanded by N times, the output will also be expanded by N times.

BCC model

The BCC model based on the variable-scale premise is expressed in *Equation 4* (the following BCC model is input-oriented):

$$\max \frac{u_r y_{r0} - u_0}{v_m x_0} \quad \text{(Eq.4)}$$
$$s.t. v_m x_j - u_r y_j + u_0 \geq 0, j = 1,2,...n$$
$$v_m x_0 = 1, v \geq 0, u \geq 0$$

Its dual model expression is *Equation 5:*

$$\min \theta - \varepsilon \left(\sum_{i=1}^{m} s_i^- + \sum_{r=1}^{s} s_r^+\right) \quad \text{(Eq.5)}$$
$$s.t. \sum x_i \lambda_i + s^- \leq \theta x_0, i = 1,2,...m$$
$$\sum y_j \lambda_j - s^+ \geq y_0, j = 1,2,...n$$
$$\sum \lambda_j = 1$$
$$\lambda_j \geq 0, j = 1,2,...n$$

The BCC model is based on the assumption of variable return to scale (VRS), that is, the impact of scale compensation on efficiency is taken into account in the evaluation of DMUs, so this model can be used to obtain the scale benefits of the DMU, helping decision makers adjust their scale and increase their relative efficiency. Based on this, the input-oriented BCC model is selected to calculate the environmental efficiency. Similar to the CCR model, in this model we can also judge whether the DMU is efficient according to the optimal solution of the model and the value of the slack variable. The specific analysis is as follows: If the optimal solution of *Equation 5* is (λ^*, θ*, s^+*, s^-*), then the following results can be obtained: (1) If θ* < *1*, the obtained DMU is DEA inefficient; (2) If θ* = 1, and *s*-* or s^+* is not equal to 0, the DMU

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89859005

obtained is DEA weakly efficient; (3) If $\theta^* = 1$, and, s^{-*} and s^{+*} are equal to 0, then the DMU obtained is DEA efficient.

SBM model

The SBM model (Tone, 2001) solves the efficiency evaluation problem that the units of input or output variables are inconsistent; in other words, this model is units invariant.

$$\min\rho = \frac{1 - \frac{1}{\mathrm{m}}\sum_{i=1}^{m}\frac{s_i^-}{x_{i0}}}{1 + \frac{1}{\mathrm{s}}\sum_{r=1}^{s}\frac{s_r^+}{y_{r0}}} \quad \text{(Eq.6)}$$

$$\text{s.t.}\sum_{j=1}^{n}\lambda_j x_{ij} + s_i^- = x_{i0},, \mathrm{i} = 1,2,...,\mathrm{m}$$

$$\sum_{j=1}^{n}\lambda_j y_{rj} - s_{\mathrm{r}}^+ = y_{r0}, \mathrm{r} = 1,2,...,\mathrm{s}$$

$$\lambda_j, s_i^-, s_r^+ \geq 0, \mathrm{j} = 1,2,...,\mathrm{n}$$

The model in *Equation 6* is a fractional programming, which can be transformed into the following linear programming form:

$$\min\tau = \mathrm{t} - \frac{1}{\mathrm{m}}\sum_{i=1}^{m}\frac{\bar{s}_i^-}{x_{i0}} \quad \text{(Eq.7)}$$

$$\text{s.t.}t + \frac{1}{\mathrm{s}}\sum_{r=1}^{s}\frac{\bar{s}_r^+}{y_{r0}} = 1$$

$$\sum_{j=1}^{n}\bar{\lambda}_j x_{ij} + \bar{s}_i^- = tx_{i0}, \mathrm{i} = 1,2,...,\mathrm{m}$$

$$\sum_{j=1}^{n}\bar{\lambda}_j y_{rj} - \bar{s}_i^+ = ty_{r0}, \mathrm{r} = 1,2,...,\mathrm{s}$$

$$\bar{\lambda}_j, \bar{s}_i^-, \bar{s}_r^+ \geq 0, \mathrm{j} = 1,2,...,\mathrm{n}$$

The optimal solution to linear programming *Equation 7* is τ^*, t^*, $\bar{\lambda}^*\bar{s}^{-*}$, $\bar{s}^{+*}$. The necessary and sufficient condition for the decision-making unit *DMU* to be SBM efficient is: $\tau^* = 1$. The value of the objective function is equal to 1, which means that all slack variables have a value of 0; in other words, there is no excessive input or insufficient output in the evaluated DMU. Similarly, under the assumption of VRS, you only need to add $\sum\lambda_j = 1$ in the constraints of the model.

Super-efficiency DEA model

Andersen and Petersen proposed the super-efficiency DEA model to compare the efficiency values of efficient DMUs. This model makes up for the shortcoming of traditional DEA models that efficient DMUs cannot be compared. The super-efficiency

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89859005

DEA model obtains the DEA efficiency of each DMU by analyzing the data of input and output indices, and points out the reasons why other DMUs are not DEA efficient and also the direction and extent of optimization.

The evaluation diagrams of the traditional DEA model and the super-efficiency DEA model are shown in *Figures 1* and *2*.

Figure 1 is the traditional DEA model, where the DMUs that satisfy the DEA are A, B, C, and D, which constitute the production frontier. Point E is the DEA inefficient DMU. Take the two DMUs B and E for example. The intersection of the connection between the two points and point O and the production frontier are respectively B_1 and E_1. The efficiency value of point B is E_B: $OB_1/OB = 1$, and that of point E is EE: $OE_1/OE < 1$. Similarly, the efficiency values of the three points A, C and D are also 1, and the DMU is DEA efficient here. For DEA inefficient DMUs, the efficiency value is less than 1. *Figure 2* is the super-efficiency DEA model. It is assumed that ACD constitutes the production frontier. At this time, the efficiency value of point B is $EB = OB_1/OB > 1$. Similarly, assuming that ABD constitutes the production frontier, there will also be $EC > 1$. Here comes the problem. As points ABCD are all DEA efficient, they still constitute the production frontier, and the efficiency value of the originally inefficient DMU E is still less than 1.

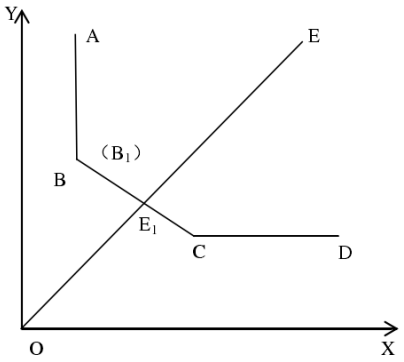

Figure 1. *Traditional DEA model*

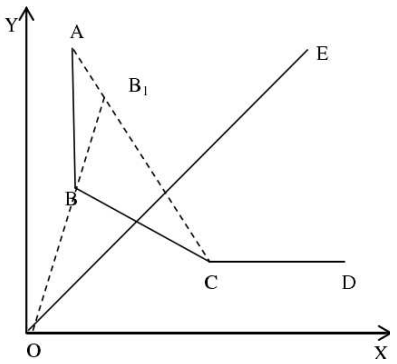

Figure 2. *Super efficiency DEA model*

Super-efficiency SBM model

Considering that a DEA efficient DMU will have an efficiency value of 1 in the SBM model, it is impossible to compare multiple efficient DMUs. This is actually a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89859005

sorting problem. The super-efficiency SBM model makes the measurement results closer to reality. It optimizes the slack variable as the objective function (solving the radial problem of the model) and gives the DMU a more reasonable direction for input and output improvement, and in addition, it can be used for sorting the efficiency values of multiple efficient DMUs. The model combines the super-efficiency DEA model and the SBM model. As the input or output orientation will affect the slack of input or output, here the non-oriented model is selected to ensure the rationality of the calculation results.

Under the condition of variable return to scale, the super-efficiency SBM model is as follows:

$$\rho = \min \frac{\frac{1}{m}\sum_{i=1}^{m} \overline{x_i} / x_{ik}}{\frac{1}{s}\sum_{r=1}^{s} \overline{y_r} / y_{rk}} \quad \text{(Eq.8)}$$

$$\text{s.t.} \sum_{\substack{j=1 \\ j \neq k}}^{n} \lambda_j x_j \leq \overline{x}; \sum_{\substack{j=1 \\ j \neq k}}^{n} \lambda_j y_j \leq \overline{y}$$

$$x_{ik} = \sum_{i=1}^{n} x_{ij}\lambda_j + s_i^-, y_{rk} = \sum_{i=1}^{n} y_{rj}\lambda_j - s_r^+$$

$$\overline{x} \geq x_k, \overline{y} \leq y_k$$

$$\sum_{\substack{j=1 \\ j \neq k}}^{n} \lambda_j = 1, \overline{y} \geq 0, \lambda \geq 0$$

In *Equation 8:* ρ is the efficiency value, ($\overline{x}$, $\overline{y}$) the reference point of the decision variable, s^- the slack variable of the input, s^+ the desired output slack variable, the subscript k of the variable in the model the kth DMU being evaluated, and λ the weight vector. When $\rho < 1$, it indicates that the DMU is inefficient. When $\rho > 1$, the DMU is in an active state.

This paper uses the superior improved DEA model - the super-efficiency SBM model to evaluate the environmental emission efficiencies of different regions in China to solve the radial problem. The super-efficiency SBM model can also sort the efficient DMUs.

Data collection and processing

Data description

Selection of indices: input indices for measuring environmental efficiency include the number of employees at the end of the year, investment in fixed assets, energy consumption and industrial pollution discharge (including wastewater, solid waste and waste gas), etc.; the output index is the total GDP of each province or city. In this paper, three industrial wastes are used as the environmental pollution variable.

This paper selects the data of 30 provinces in China from 2010 to 2015 as samples. Tibet is not included here because its data are unavailable. In addition, the wastewater discharge in 2010 is replaced by industrial wastewater discharge. The original data are extracted from the China Statistical Yearbook, the China Environmental Statistics Yearbook, and the China Energy Statistics Yearbook. The model selected has multiple

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89859005

inputs and multiple outputs, with labour, fixed asset investment and energy consumption as the inputs, three wastes (wastewater, industrial waste gas, industrial solid waste) as the environmental pollution variable, and provincial GDP as the desired output. Specific indices selected are elaborated as follows:

(1) Labour input

Labour is an indispensable input factor in economic activities. In environmental efficiency research, labour input should be considered comprehensively in terms of both quantity and quality. Now in the statistical yearbook, most of the labour input is reflected in the quantity, and the labour flow is frequent, which does not reflect labour efficiency. By referring to the existing literatures, this paper uses the number of employed people at the end of each year as the index of labour input.

(2) Energy input

Energy is an essential factor in production activities. In the related research on environmental efficiency, a large number of researchers have gradually considered energy as an input factor into the index system (Mutani et al., 2018; Vand et al., 2018). The rapid economic growth is inseparable from the massive consumption of energy, but the latter is also accompanied by the generation of a large number of pollutants. Therefore, this paper also incorporates energy consumption as an input index into the model to measure environmental efficiency. Here the specific index is the total energy consumption of each province.

(3) Capital input

In some studies, the capital input variable is the capital stock calculated by the perpetual inventory method. There are methods to determine the base capital stock and depreciation, and different methods will result in different results. Therefore, this paper uses capital investment as the capital input. Fixed assets investment plays a vital role in the system, because it can reflect the country's financial policy support. In order to make the data comparable, the capital input data are all converted according to the fixed assets investment index of each province or city into equivalent data in 2010, with the unit being 100 million RMB.

(4) Pollution discharge

Due to the external effects of production, pollutant discharge is inevitable in production activities. Here, this paper refers to Chen (2009) approach: environmental pollution is taken as an input factor. Considering the incomplete data of pollutants in the yearbooks, and the problem that industrial pollutant discharge occupies a large share, this paper comprehensively evaluates the basic data of "three wastes", and uses an entropy weight method to synthesize a comprehensive environmental pollution index as an input variable in the DEA model reflecting the overall pollution status. This is included in the framework of environmental efficiency measurement.

(5) Desired output

The regional GDP reflects the output of production activities in a region during a certain period. This paper follows the traditional practice and uses the GDP of each province as an important index to reflect output. Taking into account the real output results, the nominal GDP of each province and city will be reduced by 2010 and converted into the real GDP reflecting the actual output of the region. Here the GDP data and indices of each province are from *China Statistical Yearbook* of each year.

The selected input-output indices are explained in *Table 1*.

Table 1. *Selection of input and output indices*

Index	Variable	Variable declaration
Factor input	Labor input	Number of working population at the end of the year in the region
	Capital input	investment in the fixed assets
	Energy consumption	Regional total energy consumption
Pollution emission	Industrial pollutant	Environmental pollution composite index
Expected output	Regional economic output	Regional GDP

Evaluation of the comprehensive environmental pollution index

In order to reflect the pollutant discharges of provinces and municipalities, according to the records of the pollutant indices in the statistical yearbooks and based on the principles of scienticity, rationality and availability, the index system consists of three indices (industrial waste gas emissions, wastewater discharge and industrial solid waste production) to measure the discharge of pollutants nationwide. The environmental pollution index results are a principal part of the environmental efficiency assessment.

First, considering the dimensionality of the three indices, the normalization method is used to normalize the differences between the indices, with the formula expressed as follows *Equation 9:*

$$x'_{ij} = \frac{x_{ij} - \min x_j}{\max x_j - \min x_j} \quad \text{(Eq.9)}$$

where i denotes each province and j denotes a pollutant index.

Second, obtain the information entropy of each index *Equation 10:*

$$e_j = -\ln(n)^{-1} \sum_{i=1}^{n} p_{ij} \ln p_{ij} \quad \text{(Eq.10)}$$

$$p_{ij} = \frac{x'_{ij}}{\sum_{i=1}^{n} x'_{ij}}$$

If $p_{ij} = 0$, then $p_{ij} \ln p_{ij} = 0$.

Third, with the information entropy e_j of each index obtained in step 2, the weight of each index is obtained as follows (*Eq.11*):

$$w_j = \frac{1 - e_j}{k - \sum e_j} \quad \text{(Eq.11)}$$

Fourth, the comprehensive environmental pollution index is *Equation 12:*

$$E = \sum w_j p_{ij} \quad \text{(Eq.12)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89859005

Through the above calculations, the results of the comprehensive environmental pollution indices of provinces and municipalities in China in all years are obtained, as shown in *Table 2*.

Results and discussion

Estimation of environmental efficiency in various provinces and municipalities

Traditional DEA models tend to ignore the undesired output indices such as pollutants, when considering the accuracy of evaluation. This imposes certain constraints on the selection and evaluation of indices in environmental efficiency evaluation. In order to visually reflect the impact of pollutant emission indices on environmental efficiency results, both the traditional BCC model and the super-efficiency SBM model are used here for comparison. The BCC model excludes the environmental pollution index, but other input and output indices remain unchanged. Through calculation, the environmental efficiency values of various provinces and municipalities in China from 2010 to 2015 (the data in Tibet are not available) are obtained, as shown in *Table 3*.

It can be seen from the above table that the environmental efficiency was not balanced in China, and during the investigation period, the extreme difference in environmental efficiency was expanding year by year. The provinces (municipalities) with an efficiency of greater than 1 during the investigation period are Beijing, Tianjin, Qinghai, Shanghai, Guangdong, Hainan and Jiangsu, where the economic environment is relatively stable, and most of which are eastern provinces, with high investments in pollution control; the provinces ranking last in terms of environmental efficiency are Guizhou, Gansu, Shanxi, Yunnan and Xinjiang. This paper analyzes the differences between economic efficiency and environmental efficiency, and the comparison results are shown in the above table. It should be noted that when the relative efficiency evaluation value of the DEA is 1, the DMU is DEA efficient; and when the relative

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89859005

efficiency is less than 1, the DMU is DEA inefficient. Through comparative analysis, the following two conclusions are obtained:

First, the BCC model does not contain any undesired output. Among the evaluation results, 7 DMUs have an economic efficiency of 1, which cannot be further compared, while the super-efficiency SBM model takes the environmental pollution variable into account. It can be seen that there are 7 DMUs that achieve an efficiency value of greater than 1, thus they can be further compared.

Second, after the environmental pollution index is taken into account, except for 6 areas like Hainan, Qinghai, Shanghai and Jiangsu whose environmental efficiencies are all greater than 1, the other 24 DEA inefficient areas see significant declines in the efficiency values: the annual average interval of the BCC model for environmental pollution variable is [0.590, 0.617], and the annual average interval for the super-efficiency SBM model with the environmental pollution variable is [0.440, 0.497]. *Figure 3* compares the calculation results of the two models in 2015. It can be clearly seen that the evaluation efficiencies in the super-efficiency SBM model are all lower than those in the BCC model, except those of the DEA efficient DMUs. If Beijing, Shanghai, Hainan and other provinces in the efficiency frontier are used as benchmarks, there will be a lot to improve in Shanxi, Guizhou and Yunnan with the same input and output. This shows that there are significant gaps in environmental efficiency among provinces, and the lower the efficiency value, the greater the potential for improvement.

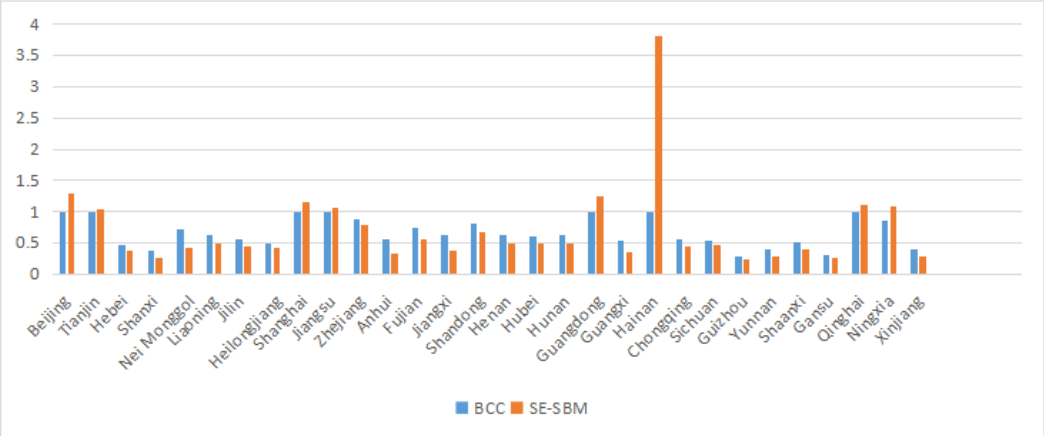

Figure 3. *Overview of environmental efficiency in provinces and municipalities of China in 2015*

To a certain extent, the above results reflect the actual differences in the transformation of the production capacity into environmental efficiency by various provinces and municipalities in China. On the whole, the environmental efficiency performance of the provinces and municipalities in China is generally not good, except for a few regions, which have achieved relatively high environmental efficiencies thanks to the long-term economic accumulation. China has a vast territory, where the regional location and factor endowments vary greatly among provinces and municipalities, so the gaps between environmental efficiency are inevitable and also reasonable. Under the new concept of economic development, it is necessary to improve the regional economy and reduce the damages to the environment. In addition to the above reasons, low-efficiency areas blindly pursue high output without considering the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89859005

environmental tolerance, which also cause environmental inefficiency. Therefore, China still has a long way to go in terms of environmental efficiency improvement.

Considering that there are a few large extremum values in the super-efficiency SBM model, the provinces and municipalities with efficiency values greater than or equal to 1 during the investigation period are excluded, and only the differences in the efficiency of economic output and the efficiency of environmental pollution variable are taken into account. From *Table 4,* it can be seen that the efficiency value in the super-efficiency model sees a significant reduction, indicating that the addition of the environmental pollution index has great negative impact on the efficiency value. Nevertheless, the reduction in efficiency shows a decreasing trend year by year, indicating that the national economic level is improving. At the same time, the environmental quality is also showing a good trend, and the environmental efficiency value considering the environmental pollution variable is getting closer to that without considering the environmental pollution variable. The gaps are being gradually narrowed because during 2011-2015, i.e. the 12th five-year period, China put more emphasis on the ecological civilization construction and developed and implemented strict emission reduction measures and regulations in the production activities under the 12th Five-Year Plan, which greatly improved the awareness of environmental protection in this country.

Differences in efficiency levels among the four regions

Due to geographical reasons, there are large differences in environmental efficiency between regions. According to the regional data from the National Bureau of Statistics, this paper divides the provinces and municipalities in China into four regions, namely the eastern region, including Beijing, Fujian, Guangdong, Hebei, Jiangsu, Shandong, Shanghai, Tianjin, Hainan and Zhejiang; the central region, including Anhui, Henan, Hunan, Jiangxi, Hubei and Shanxi; the western region, including Gansu, Guangxi, Guizhou, Inner Mongolia, Ningxia, Qinghai, Shaanxi, Chongqing, Sichuan, Xinjiang, Tibet and Yunnan; the northeastern region, including Heilongjiang, Jilin, and Liaoning. In this paper, Tibet is not included due to lack of data. The average environmental efficiencies of the four major regions in the major years are compared with the national level, as shown in *Table 5*.

Table 5. *Environmental efficiency mean values of major years in four major regions*

Region \ Year	2010	2011	2012	2013	2014	2015
Eastern	1.0308	1.1906	1.1792	1.075	1.2128	1.2026
Northeastern	0.4745	0.4673	0.4491	0.4589	0.4513	0.4548
Central	0.4407	0.4253	0.4169	0.4136	0.4096	0.4079
Western	0.4997	0.5067	0.4934	0.4895	0.4771	0.485
Nationwide	0.6624	0.7144	0.7023	0.6664	0.7062	0.7058

Table 6 shows that the environmental efficiencies of the above several regions in China are quite different - the efficiency value in the eastern region is [1.03, 1.22], the central region [0.40, 0.45], the western region [0.47, 0.51], the northeast region [0.44, 0.48] and the national level [0.66, 0.72]. Despite a few inefficient provinces, the efficiency value in the eastern region is much higher than those in the other three regions and the national average; on the other hand, the environmental efficiencies of the western region, the northeast region and the central region are all lower than the national average.

Table 6. *Analysis of input and output redundancy of environmental efficiency in provinces and municipalities of China in 2015*

Redundancy analysis of input and output

If the efficiency of a DMU is less than 1, then it is DEA inefficient. The reasons why it is different from the DMUs in the frontier include excessive input, excessive undesired output and insufficient desired output. The super-efficiency SBM model adds slack variables to the objective function to provide information on the input and output redundancy of each DMU, and clearly points out the direction for efficiency improvement. Input redundancy includes fixed asset investment, labour force population, total energy consumption and environmental pollution index. The desired output redundancy is expressed in GDP. Section 3 of this paper uses the super-efficiency SBM model to measure the environmental efficiency values of 30 provinces in China from 2010 to 2015. This section takes the redundancy of input and output of environmental efficiency in various provinces and municipalities in China in 2015 for example.

In *Table 6*, we list the improvement goals for each province (negative data indicate the required reductions). From this table, it can be seen that the provinces and municipalities with lower efficiencies have the problems like excessive investment, insufficient output, unreasonable input of factors, insufficient control of environmental pollution and less-than-desired output. Those with high environmental efficiencies also require efficiency improvement. For example, Jiangsu has met the requirement in terms of economic output, so there is no need for improvement in this area, but compared with Shanghai and Guangdong, it still needs to reduce energy consumption, fixed asset investment and control of environmental pollution (by respectively 1662.856, 18937.337 and 0.085). So with Shanghai and Guangdong as the frontiers, Jiangsu needs to impose reasonable control over the input factors to achieve the optimal level of efficiency.

This paper also conducts more detailed and in-depth analysis of the input and output redundancy of each region. In terms of labour, Tianjin, Shanghai, Jiangsu, Qinghai, and Ningxia need to increase their input, and the remaining provinces and municipalities need to reduce it. Excessive labour input will hinder regional economic growth and also put pressure on the environment. In reality, it is not feasible to reduce the population of labour force, so this requires more rational allocation of labour resources. It is important to improve the quality of the labour force and implement the people-oriented social

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89859005

development concept. In terms of energy consumption, except the four regions - Beijing, Guangdong, Hainan and Qinghai, all provinces and municipalities need reductions. Energy consumption is accompanied by the generation of large amounts of pollutants, so controlling energy consumption is an important way to improve environmental efficiency. As the "fuel" to the social and economic development, energy is essential to the economic growth. Under the current severe energy consumption situation, a lot of effort needs to be made in the energy structure adjustment so as to better control energy consumption and reduce emissions. In terms of fixed assets investment, Qinghai, Hainan, Guangdong and Shanghai need moderate increases, while the other provinces have excessive investment in fixed assets. This shows that the capital investment does not conform to its own actual development in many provinces of China, manifested in unreasonable investment and utilization. Similarly, in terms of the environmental pollution index, most provinces do not have good performances – they all need to reduce the pollution index and control the pollutant emissions. In terms of the desired output, 50% of the provinces do not need to increase GDP, and the total GDP of these regions rank high.

Conclusion

This paper firstly introduces the concept of environmental efficiency, selects the input and output indices of environmental efficiency, and then uses the super-efficiency SBM model considering environmental pollution to measure the environmental efficiency of 30 provinces and municipalities in China from 2010 to 2015.

It can be concluded that the addition of the environmental pollution variable results in significant declines in the efficiencies of DEA inefficient provinces. The overall environmental efficiency in China is low, and the environmental efficiencies of the four regions vary significantly. The areas with high environmental efficiencies fall into two categories: the first are the economically developed provinces in the eastern coastal region, which all have solid economic bases; the second are remote provinces, such as Qinghai and Ningxia in the western region, with small economic aggregate and low environmental pollution. The economic advantage obviously plays a greater role in the evaluation of environmental efficiency, and it is scattered nationwide - Beijing-Tianjin region, Yangtze River Delta region, and Pearl River region, which are consistent with the urban agglomerations in the developed regions of China. The areas with good natural environment and low economic levels represented by Qinghai and Ningxia are examples of high environmental efficiency. These areas focus on the coordinated development of the economic environment. Those that need to improve environmental efficiency include: provinces with regional economic characteristics, such as Fujian and Shandong; and the central and western provinces with obvious industrial characteristics and serious environmental pollution. From the above analysis, it can be seen that the environmental efficiencies of the provinces and municipalities vary greatly, and judging from the data every year, the gaps are gradually increasing.

Through comparative analysis of the four regions, it is found that the environmental efficiency in the eastern region is much higher than those of the other three regions. The overall economic level in the eastern region is high and the pollution control is also better than that in the others. The northeastern and central regions have similarly low environmental efficiencies. Due to the vast territory of the western region, the environmental efficiencies of the provinces there vary greatly, but the overall

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_89859005

environmental efficiency level is better than that in the northeastern and central regions. In terms of environmental efficiency gaps, the difference in the eastern region has been large for many years, those in the northeastern and central regions are maintained at a low level, and that in the western region is increasing year by year, indicating that the gaps are generally expanding in China, which is a bad signal for the coordination between the economy and the environment.

Improper behaviours in production activities should be cut off from the source, rather than be remedied afterwards. The government should play the positive role of economic resources, rationally plan the utilization of investments in environmental protection, and guide enterprises to carry out energy conservation and pollution reduction. Judging from the current situation, the policy environment in China has not yet reached the desired level, and thus it is necessary to build an intellectual property protection system and a fair competition system. At present, the economic development is not balanced among different regions of China. Each region should rationally adjust the proportions of the three major industries in light of its own situation. The central and western regions rely mainly on the secondary industry, which hinders the development of new economic growth points. In order to improve the economic environment and make the regional industries more competitive, enterprises with "high energy consumption and low production" should be restricted and green and low-carbon recycling industries with high added value should be vigorously developed.

In the follow-up study, further exploration and research are needed in the following aspects. (1) The research on the region can further deepen to the prefecture-level city and county level, and expand the research perspective on environmental efficiency measurement. (2) With the continuous improvement of statistical data, the consumer's tolerance for pollution emissions should be included in the research field to further enrich the content of environmental efficiency measurement. (3) This paper considers the macro level more. The follow-up research can analyze the environmental efficiency from a smaller micro level, such as the corporate governance structure and enterprise property rights arrangement.

Abstract. To disclose the exact geochemical features of the hot springs in western Yunnan, China, this paper reviews the geological settings of Changning County, western Yunnan, and analyzes the geochemical features of local hot springs, which are controlled by Kejie Fault and Changning-Menglian (C-M) Structural Belt. On this basis, the author explored the isotopes of H, O, C, recharge source, recharge elevation circulation path and formation age of the geothermal flow, examined the main chemical process in the geothermal flow movement, especially in the mixing process, and determined the geochemical formation model and geological settings of the fault-controlled geothermal field in the research area. The results show that the hot springs are typical fault-controlled geothermal resources; the meteoric water is the main supply source of the hot springs; the hot springs are neither volcanic nor magmatic; despite the slight difference in activities and formation causes, the hot springs in both western and eastern parts of the research area were recharged by paleo-precipitation recharge before Late Pleistocene.
Keywords: *hot springs, isotopes, formation model, geothermal resources, western Yunnan, China*

Introduction

The world boasts huge reserves of geothermal energy, which promises efficient, stable power generation. If properly utilized, geothermal energy could promote energy conservation, reduce carbon emissions and mitigate global warming (Ahmadi et al., 2018; Ba et al., 2018; Mawarni et al., 2018). China is the second largest holder of geothermal reserves, most of which exist in tectonically active belts and large sedimentary basins (Wang et al., 2000; Guo, 2012). In general, there are abundant low-temeprature geothermal resouces in the uplift and subsidence areas of the continental crust, and some high-temperature ones across Yunnan and Tibet in southwestern China (Guo et al., 2013).

In the border areas between Tibet and Yunnan, the heat state of lithosphere has been shaped by the tectonically extrusion of the southeastern edge of Qinghai-Tibet Plateau since the Cenozoic era. The heat flow in this region far exceeds 70 mW/m^2, and peaks at 120.5 mW/m^2 in Tengchong, western Yunan Province, twice the global mean value (61.6 mW/m^2) (Du et al., 2005), revealing the typical geothermal features of a modern tectonically active area. The regional distribution of heat flow, especially that of abnormally high geo-temperature, is highly consistent with the pattern of deep faults.

The deep faults control the regional structure framework, affecting the formation and distribution of secondary structural belts. For example, the fault-controlled geothermal resources in western Yunnan possess the following features: large scale, shallow burial and high temperature (Mongillo, 2010; Ba et al., 2018). These faults also create a good

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90079024

condition for magma intrusion and convection (Edmunds, 2004; Olivier et al., 2011) and a passageway to the heat sources deep in the mantle, providing favorable paths for hot springs (Brown et al., 2003; Lachenbruch et al., 2013; Awaleh et al., 2015). In the said region, there are 139 hot springs with temperatures above 150°C, including 49 (35.3%) in western Yunnan. Many of them correspond with the hydrothermally active spots along the Kejie Fault and its secondary faults.

Over the years, some scholars have explored the distribution features, heat control mechanism and conformation model of Keijie Fault and the nearby Changning-Menglian (C-M) Structural Belt in western Yunnan (Wang et al., 2000; Guo, 2012; Ba et al., 2018). However, none of them has explained the exact geochemical features of the hot springs in this region, not to mention creating a conformation model of the local geothermal field.

To fill in these gaps, this paper reviews the geological settings of Changning County, western Yunnan, analyzes the chemical features of local hot springs, namely, hydro-chemical type, phase equilibrium, water-rock interaction, flow runoff and isotope features, and discusses about the isotopes of H, O, C, recharge source, supply elevation circulation path and formation age of the geothermal flow. In addition, the author examined the main chemical process in the geothermal flow movement, especially in the mixing process, and finally determined the geochemical formation model and geological settings of the fault-controlled geothermal field in the research area.

Materials and methods

Geological background

Located in Changning County, western Yunnan, the research area is high in the north and low in the south, with mountains and river valleys spanning in the north-south direction. In the west of the research area lies a U-shaped basin (elevation: 840~2,525 m) along the Kejie Fault, where the annual mean temperature is 19.5°C and the annual precipitation is 960 mm. In the eastern part, there is the Changning Basin (elevation: 1,562~2,525 m), where the climate is moderate and humid, the annual mean temperature is 14.9°C and the annual precipitation is 1,253.1 mm.

From the perspective of tectonics, the research area belongs to Baoshan Block, a part of the Yunnan-Burma-Thailand-Malaysia microplate, and falls between the C-M Structural Belt and the Yangtze Block (*Figure 1a*). The C-M Structural Belt is formed through the collision between two microcontinents within the remnant Paleo-Tethys Ocean realm. Despite the complex tectonics, the internal structure of the structural belt can be clearly identified (Xu et al., 2016).

Geological settings of Kejie Fault

Kejie Fault is an important fault in western Yunnan, controlling the sedimentation, metamorphism and magmatic activities since the Early Paleozoic era. The control effect is particularly prominent in Late Paleozoic Era. During the Lancang Orogeny, the fault appeared in the junction between Baoshan Block and C-M Structural Belt, and controlled the stratigraphic sedimentation for a longtime before the Permian era.

Kejie Fault consists of a primary fault and two secondary faults. The north-south primary fault spans 1,000 m in 20° east of north from Kejie Town to Kasi Town, and dips steeply towards the east by 60°~90°. The two secondary faults extend from north to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90079024

northwest, and intersect the primary fault at acute angles. Numerous hot springs (S1~S7) are exposed along the two secondary faults (*Figure 1b*).

There is a 200~500 m wide breccia fracture zone within the Kejie Fault, as well as a north-south fold deformation zone in the northwest part. The metamorphic rocks are 90° ∠40° on the eastside, which intersects the fault at an acute angle. The Yanshanian acidic intrusive rocks are also deformed, becoming schistous and partly mylonitic. Many places of the fault are hidden under the Quaternary sediments, forming continuous gullies and beaded Cenozoic sedimentary basins with obvious neo-tectonic features.

Geological settings of C-M Structural Belt

The 10~60 km-wide C-M Structural Belt runs through the research area from the northwest to the south. The belt has been shaped like a narrow wedge in the northwest, adjacent to Xiqianjie Fault and Baoshan- Zhenkang Block in the west, and bordered by Lancangjiang Fault and Yangtze Block in the east. Many hot springs are exposed along the belt in Wenquan Town, southern Changning County.

As a remnant of the C-M ocean basin, the belt mainly consists of Carboniferous metabasites, volcanic rocks, altered diabases and a few low-grade metamorphic siltstones. The rock stratum includes Proterozoic Damenglong Formation, Neoproterozoic Lancang Formation, Devonian Wenquan Formation, Devonian Pingzhang Formation, Devonian- Carboniferous Nanduan Formation and Permian Laba Formation. There are also a few acidic volcanic rocks of Triassic Huaimang Formation, molasses deposit of Triassic Sanchahe Formation, and clastic deposits in continental basins of Pliocene Mangbang Formation.

Sample analysis

A total of 19 geothermal water samples were acquired from the research area, including 4 samples collected by delta δD, 4 by delta $\delta^{18}O$, 4 by $\delta^{3}H$, 2 by $\delta^{14}C$ and 5 by $\delta^{13}C$. All water samples were stored in low-density polyethylene bottles without any special pretreatment. Among them, $\delta^{3}H$, $\delta^{18}O$ and $\delta^{14}C$ samples were measured on a MAT253 isotope ratio mass spectrometer, and $\delta^{13}C$ samples on a stable isotope ratio mass spectrometer (SIRMS), with the aid of acid hydrolysis.

For hydro-chemical analysis of ions, the 50 mL polyethylene sampling bottles were filled up with $\delta^{3}H_{H2O}$ and $\delta^{18}O_{H2O}$ samples, to prevent the formation of bubbles. The cations (Ca^{2+}, Mg^{2+}, Na^{+}, and K^{+}) were analyzed on an AA-100 atomic absorption spectrometer, after super pure HNO_3 (1:1) had been added to the samples until the pH value fell below 2. The HCO_3^- was titrated by an alkalimeter with precision of 0.1 mmol/L, the pH of the water was determined by a WTW Multi3430 multiparameter meter with precision of 0.01. The anions (SO_4^{2-}, Cl^-, and NO_3^-) were measured through high-performance liquid chromatography.

All water samples were analyzed at the Institute of Karst Geology, Chinese Academy of Geological Sciences.

Results

The geothermal resources in the research area mainly exist in the fault zone amidst fold mountains. Most of them are of medium to low temperature. As shown in *Figure 1b*, the research area can be divided into Kejie Town area in the west (the western part) and Wenquan Town area in the east (the eastern part).

Geothermal control area in Kejie Fault

Geochemical features and formation conditions of the hot springs in Kejie Town area

As mentioned in Section 2, the geothermal sources in Kejie Fault are controlled by the primary and secondary faults. At the intersections between the faults, the clastic sediments in the Cenozoic depression provide a good thermal cover for the geothermal reservoirs. Several hot springs are exposed in the western part of the research area. Seven of them were selected for investigation. As shown in *Table 1*, the temperature of every spring is above 40°C (the temperature of the hottest spring: 90°C) and the total flow rate of these springs reaches 11.56 L/s (the flow rate of the fastest flowing spring: 3.42 L/s).

Table 1. *Flow rates and temperatures of the hot springs in the western part*

Area	Tepid hot springs				High temperature hot springs		Medium-high temperature hot springs		Low temperature hot springs	
	Spots	Flow rate (L/s)	High temperature (°C)	Low temperature (°C)	Spots	Flow rate (L/s)	Spots	Flow rate (L/s)	Spots	Flow rate (L/s)

Most of the water samples appear at the bottom of the Piper trilinear diagram of hydro-chemical ions (*Figure 2*). Obviously, the main cations in the water samples are Na^+, Ca^{2+} and K^+, and their contents differ from spring to spring. The water in S5 belongs to the Ca-Na type, with a high content of Ca^{2+}; the water in S3 belongs to the Na-K type, with greater-than-90% contents of Na^+ and K^+; the water in the other springs belongs to the Na-Ca type. The high content of Ca^{2+} in these hot springs can be attributed to the geothermal interaction between water and rock.

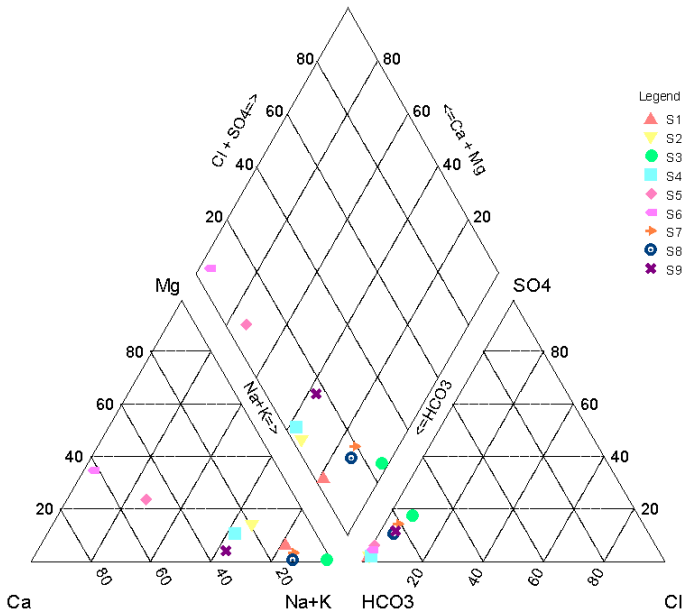

Figure 2. *The Piper trilinear diagram of hydro-chemical ions of the hot springs in the western part*

Since all samples appear at the bottom left of the Piper diagram on anions, HCO_3^- is the dominant anion in all the water samples. In particular, the HCO_3^- contents in S2 and S5 are over 90%, while those of Cl^- and SO_4^{2-} are below 10%. Of course, the springs differ in the exact content of HCO_3^-, due to the varied degrees of carbonate decomposition.

Below is a brief analysis of the ion contents in four of the seven hot springs: S2, S3, S4 and S7.

S2: This group of hot springs is located on the Kejie Fault, with a complete generation-reservoir-cover system. The reservoir stratum is the footwall in the west of the fault, which consists of broken quartz sandstone, siltstone of Xiangyangsi Formation, Lower Devonian Series (D_{1x}), while the cover stratum is the hanging wall of semi-consolidated conglomerate and argillaceous siltstone of Mangbang Formation Pliocene Series (N_2m). As shown in *Table 2*, HCO_3^- (973.75 mg/L) is the dominant anion in S2, accounting for 97.7% of anions in the spring water; other anions like Cl^- and SO_4^{2-} have a very low presence. Na^+ and K^+ are the main cations, taking up 74.84% of all cations in the spring water, while the Ca^{2+} content stands at 17.53%. Meanwhile, the total dissolved solid (TDS) is as high as 938.12 mg/L.

S3: On the north of Ganlahe valley, this group of 10 hot springs belongs to the Yungou Formation, Neoproterozoic Nanhua Series. This formation mainly consists of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90079024

regional low-grade metamorphic rocks like sericite-phyllite. Under the intrusion of Cretaceous biotite adamellite, the rocks have partially evolved into thermal metamorphic hornfels. The formation is well developed, with a secondary joint parallel to the north-northwest fault. The total flow rate of S3 stands at 8.0 L/s (the flow rate of the fastest-flowing spring is 2.5 L/s), and the temperature at the spring mouths reaches 82°C (*Table 2*). The spring water is colorless and transparent, and belongs to the hydro-chemical type of HCO_3-Na+K, owing to the few travertines at the spring mouths.

S4: This group of 18 springs is exposed in the valley and restricted by the northwestern fault, featuring a complete generation-reservoir-cover system. The reservoir stratum is mainly made up of volcanic rocks (dacite liparite) in the Triassic Manghuai Formation, while the cover stratum is semi-consolidated conglomerate and argillaceous siltstone of Pliocene Mangbang Formation (N_2m). The temperature of spring water falls between 42 and 80°C, and that of the hottest spring mouth reaches 90°C (higher than the local boiling point of water (*Table 2*).

S7: The geothermal resource in this group of springs is deep circulating and low in temperature, due to the well-developed, complex fault nearby. The stratum belongs to Yungou Formation, Neoproterozoic Nanhua Series, which encompasses regional low-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90079024

grade metamorphic rocks like sericite-phyllite and mic schist. The spring group is exposed in the east-west secondary fracture, which is perpendicular to the main fault. The flow rate and temperature of S7 are respectively 3.42L/s and 73°C (*Table 2*). The spring water belongs to the hydro-chemical type of HCO_3-Na (*Table 2*), due to the thick travertines around the spring mouths. The TDS is 0.47 g/L, consisting of F, SiO_2, As, Mn, HPO_4, etc. Both H_2S and SiO_2 exist in the spring water, in which the SiO_2 content (124.52 mg/L) far exceeds the standard for mineral water.

According to the hydro-chemical features, the Schoeller plots of the hot springs in the western part were drawn on AquaChem (*Figures 3 and 4*). These plots show that the different ions have similar trend in content in the water samples of different hot springs. This means these springs are recharged by the same reservoir source and formed under the same conditions, forming similar fault-controlled geothermal resources.

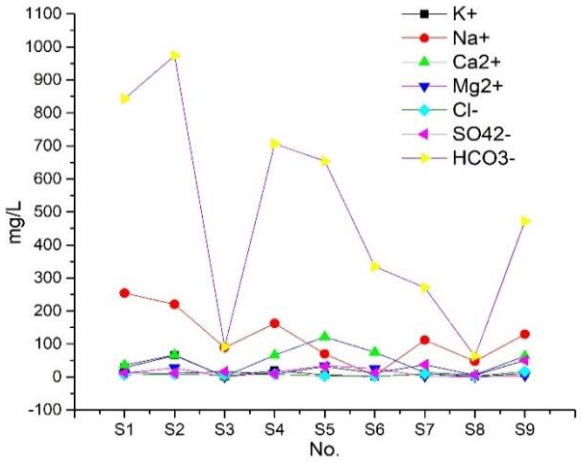

Figure 3. *Main ion contents of the hot springs in the western part*

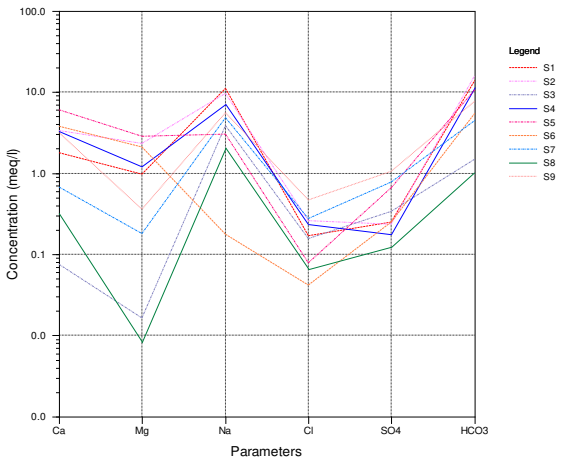

Figure 4. *Schoeller plots of the hot springs in the western part*

In addition, F^- anions were observed in the water of the hot springs in the western part. These anions are produced through the weathering of tourmaline, mica and apatite

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90079024

in geothermal reservoirs. The content of F^- in the spring water has many to do with the groundwater type, lithological features of surrounding rocks, degree of water-rock interaction and environmental temperature. The pH and flow temperature are the leading influencing factors of the content. As shown in *Figure 5*, the F^- content is positively correlated with the temperature of the exposed hot springs.

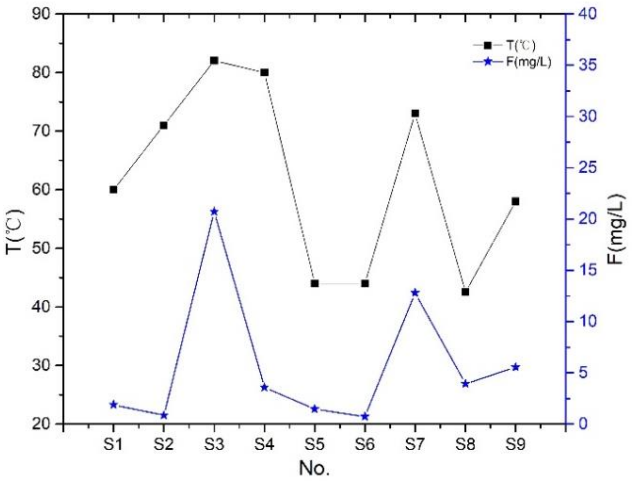

Figure 5. *Relationship between temperature and F− content of the hot springs in the western part*

Potential environmental impacts of the hot springs in the western part

The heavy metal contents of these hot springs were measured. The results show that the spring water enjoys an overall good quality, and can be exploited as geothermal resources. The contents of trace elements in the spring water are listed in *Table 3* below.

Table 3(a). *Trace elements of the hot springs in the western part*

Sample (No.)	Trace elements (mg/L)					
	Zn	Co	Mn	As	Hg	TFe
Kasihe (S1)	<0.002	<0.002	0.056	<0.002	<0.0001	0.014

Ganlanhe (S3)	<0.002	<0.002	0.0022	<0.002	<0.0001	0.015
Jifei (S4)	<0.002	<0.002	0.046	<0.002	<0.0001	0.007
Dadi (S5)	<0.002	<0.002	0.011	0.014	<0.0001	0.110
Suanxi (S6)	<0.002	<0.002	<0.001	<0.002	<0.0001	0.005
Yudili (S7)	<0.002	<0.002	0.049	<0.002	<0.0001	0.016
Xiazhai (S8)	<0.002	<0.002	<0.001	<0.002	<0.0001	0.004
Qingyunge (S9)	<0.002	<0.002	0.026	0.004	<0.0001	0.120

It can be seen that the spring water has high contents of As, Mn, and Hg (2.0~14.0 μg/L, 11.0~82.0 μg/L and 0.1 μg/L, respectively). The As content in S5 (14.00 μg/L) hot springs is much higher than that (2.0~7.0 ug/L) in any other spring. This may be the result of the leaching after water-rock interaction.

Geochemical-chronological features of carbon, hydrogen and oxygen isotopes of the hot springs in the western part

The hot springs S2~S5 and S7 were subjected to isotopic analysis on $\delta D_{(V\text{-}SMOW)}$, $\delta^{18}O_{(V\text{-}SMOW)}$, $^3H_{(TU)}$, dissolved inorganic carbon $\delta^{13}C_{DIC(V\text{-}PDB)}$‰, particulate organic carbon $\delta^{13}C_{POC(V\text{-}PDB)}$‰ and dissolved organic carbon $\delta^{13}C_{DOC(V\text{-}PDB)}$‰. The results in *Tables 4 and 5* show that δD, $\delta^{18}O$ and ^3H fall in the ranges of −79.1~−84.2, −10.66~−11.76 and <2, respectively; the $\delta^{13}C_{DIC}$, $\delta^{13}C_{POC}$ and $\delta^{13}C_{DOC}$ fall in the ranges of −1.37~−4.24, −15.88~−27.08 and −24.62~−31.16, respectively; The $\delta D_{(V\text{-}SMOW)}$, $\delta^{18}O_{(V\text{-}SMOW)}$, $\delta^{13}C_{DIC(V\text{-}PDB)}$‰ and $\delta^{13}C_{POC(V\text{-}PDB)}$‰ average at −81.62, −2.32, −2.04 and −22.84, respectively. In addition, only S2 has a positive value of $\delta^{13}C_{DIC}$, as shown in *Figure 6*.

Table 4. *Isotopic test results on $\delta D_{(V\text{-}SMOW)}$, $\delta^{18}O_{(V\text{-}SMOW)}$ and $^3H_{(TU)}$ of the hot springs in the western part*

Name (No.)	$\delta D_{(V\text{-}SMOW)}$‰	$\delta^{18}O_{(V\text{-}SMOW)}$‰	^3H(TU)
Liangyuan (S2)	−82.1	−11.34	＜2
Ganlanhe (S3)	−82.5	−11.58	＜2
Jifei (S4)	−84.2	−11.26	＜2
Dadi (S5)	−79.1	−10.66	＜2

Table 5. *Isotopic test results on $\delta^{13}C_{DIC(V\text{-}PDB)}$‰, $\delta^{13}C_{POC(V\text{-}PDB)}$‰ and $\delta^{13}C_{DOC(V\text{-}PDB)}$‰ of the hot springs in the western part*

Name (No.)	Sample Type	$\delta^{13}C_{DIC(V\text{-}PDB)}$‰	$\delta^{13}C_{POC(V\text{-}PDB)}$‰	$\delta^{13}C_{DOC(V\text{-}PDB)}$‰
Liangyuan (S2)	water sample	1.37	−27.08	−24.62
Ganlanhe (S3)	water sample	−4.24	−15.88	−31.16
Jifei (S4)	water sample	−1.82	−26.69	-
Dadi (S5)	water sample	−3.45	−25.28	-
Yudili（S7）	water sample	−2.04	−19.27	−29.58

It can also be seen that the pH values of these hot springs range between 6.64 and 8.95 (*Table 3*); the dissolved inorganic carbon exists as HCO_3^-, such that the $\delta^{13}C_{DIC}$ value is basically the same as $\delta^{13}C_{HCO3^-}$.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90079024

Furthermore, the S4 hot spring received ^{14}C isotopic dating (half-life period: 5,730 a), which puts its age at 16,510±1,600a. The result indicates that S4 received paleo-precipitation recharge before Late Pleistocene. The temperature of S4 can reach 90°C, an evidence of good geothermal property and a closed supply condition.

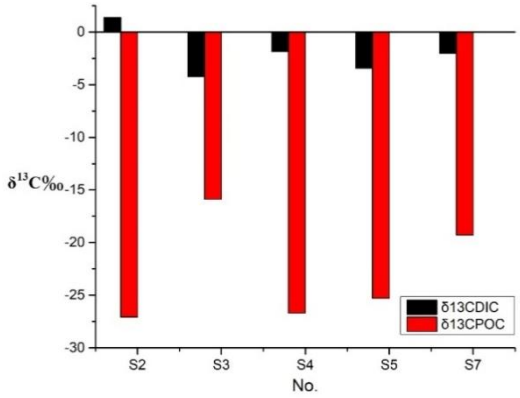

Figure 6. *$\delta^{13}C_{DIC}$ of the hot springs in the western part*

Geothermal control area in C-M Structural Belt

Geochemical features of hot springs in the eastern part

In the eastern part of the research area, the distribution of hot springs is mainly controlled by the C-M structural belt. The typical hot springs in this area are S8~S10. Here, S10 is selected as an example to analyze the geochemical features of hot springs in the eastern part of the research area.

The S10 spring group is exposed on the west side of the valley. The stratum mainly consists of sericite and marble in Pingzhang Formation, Carboniferous system (C_1pz). In terms of nappe structure, the stratum thrusts itself up the intermontane conglomerate and interbedded sandstone and mudstone of Triassic Sanchahe Formation (T_3sc). Thus, the underground geothermal water encounters the T_3sc layer and becomes exposed on the ground (*Figure 7*).

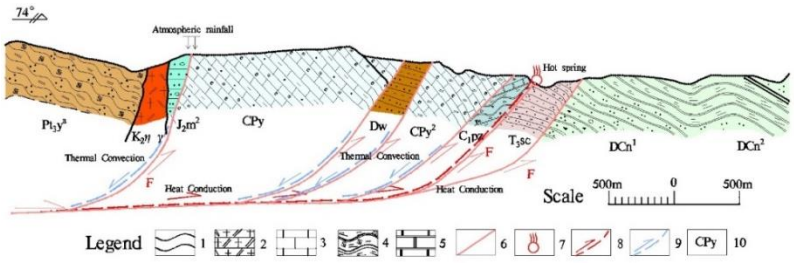

Figure 7. *Hydrothermal circulation of S10*
Note: 1-Schist; 2-Adamellite; 3-Limestone; 4-Slate; 5-Marble; 6-Fault; 7-Hot springs; 8-Geothermal water migration path; 9-Recharge water migration path; 10-Stratigraphic age

For the four-mouth spring group, the total flow rate stands at 11.9 L/s (the flow rate of the fastest flowing mouth is 2.3 L/s), and the temperature falls between 23 and 65°C. With pale yellow sulfur deposits and obvious H_2S gas around some mouths, the spring

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90079024

group belongs to the hydro-chemical type of HCO_3-Na·Ca, the TDS is 0.57 g/L. The contents of F^- and SiO_2 are 5 mg/L and 88.7 mg/L, respectively. In summary, the spring water of S10 fits in with the definition of mineral water.

Geochemical-chronological features of carbon, hydrogen and oxygen isotopes of the hot springs in the eastern part

The hot springs S8~S10 were subjected to isotopic analysis on $\delta D_{(V\text{-}SMOW)}$, $\delta^{18}O_{(V\text{-}SMOW)}$, $^3H_{(TU)}$, $\delta^{13}C_{DIC(V\text{-}PDB)}$‰, $\delta^{13}C_{POC(V\text{-}PDB)}$‰ and $\delta^{13}C_{DOC(V\text{-}PDB)}$‰. The results in *Tables 6 and 7* show that $\delta D_{(V\text{-}SMOW)}$, $\delta^{18}O_{(V\text{-}SMOW)}$ and $^3H_{(TU)}$ fall in the ranges of −78.1~−85.8, −10.76~−11.81 and < 2, respectively. The $\delta^{13}C_{DIC(V\text{-}PDB)}$‰, $\delta^{13}C_{POC(V\text{-}PDB)}$ ‰ and $\delta^{13}C_{DOC(V\text{-}PDB)}$‰ amount to −0.90~−9.26, −23.54 and −25.66~−28.90, respectively. These results are similar with those of the hot springs in the wester part, except for the smaller fraction of biogenic water. This means geothermal water in the eastern part circulates deeper than that in the western part.

Table 6. *Isotopic test results on $\delta D_{(V\text{-}SMOW)}$, $\delta^{18}O_{(V\text{-}SMOW)}$ and $^3H_{(TU)}$ of the hot springs in the eastern part*

Name (No.)	$\delta D_{(V\text{-}SMOW)}$‰	$\delta^{18}O_{(V\text{-}SMOW)}$‰	^3H(TU)

Qingyunge (S9)	−78.1	−10.76	＜2

Table 7. *Isotopic test results on $\delta^{13}C_{DIC(V\text{-}PDB)}$‰, $\delta^{13}C_{POC(V\text{-}PDB)}$‰ and $\delta^{13}C_{DOC(V\text{-}PDB)}$‰ of the hot springs in the eastern part*

Name (No.)	$\delta^{13}C_{DIC(V\text{-}PDB)}$‰	$\delta^{13}C_{POC(V\text{-}PDB)}$‰	$\delta^{13}C_{DOC(V\text{-}PDB)}$‰
Xiazhai (S8)	−9.26	−23.54	−28.90
Qingyunge (S9)	−0.90	-	−25.66

In addition, the hot springs in the eastern part received ^{14}C isotopic dating (half-life period: 5,730 a), which puts their ages at 17,220±550a. The result indicates that the hot springs received paleo-precipitation supply before Late Pleistocene. The geothermal water circulated slowly and formed the springs before S4.

Discussion

Mixing features of hot water and cold water

The geothermal water is inevitably mixed with cold water as it rises to the surface. The fractions of cold water in S3, S4, S7 and S10 were computed, and recorded in *Figure 8*, where the ordinate value of the intersection between curves *X*t and *X*si stands for the theoretical fraction of cold water.

As shown in the figure, the cold-water fractions of S3, S4, S7 and S10 are 66%, 67%, 77% and 70%, respectively. Meanwhile, the temperatures of S3, S4, S7 and S10 are 175°C, 176°C, 250°C and 200°C, respectively. Hence, the cold-water fraction is positively correlated to temperature. Similarly, the cold-water fraction and temperature of S2 were computed as 53% and 130°C, respectively.

Geochemical features of the hot springs

Oxygen isotope shift and water-rock interaction

The supply source of hot springs is generally determined through the comparison of global/local meteoric water line and H-O isotopes in the spring water (White et al., 2005; Dotsika et al., 2006; Han et al., 2015). The elevation effect of H–O isotopes can be used to calculate the recharge elevation of the hot springs, laying the basis for formation modelling of geothermal fields (Kose, 2007; Yamanaka et al., 2010).

Considering the conditions of the research area, δD and $\delta^{18}O$ can be adopted for the computation of the supply elevation. For high-temperature geothermal fields, the recharge sources are usually in remote or mountainous areas. Thus, the δD and $\delta^{18}O$ values of such fields are often lower than those of surface water and shallow groundwater (Zhou et al., 2009; Dotsika et al., 2010; Ba et al., 2018).

In view of the shift in $\delta^{18}O$ value (*Figure 9*) between the spring water and meteoric water line (*Table 1*), the author used *d*-excess = $\delta D - 8\delta^{18}O$ to calculate the exchange degree of $\delta^{18}O$. The *d*-excess of the hot springs in the research area is shown in *Figure 10*, where the line of *d*-excess = 10‰ is the global meteoric water line proposed by Craig in 1961 (Kim et al., 1997; Zuo et al., 2014; Ingvar, 2016). It can be seen that the *d* values of the hot springs mostly fall between the *d* = 0‰ line and the *d* = 10‰ line, and stay close to the latter line as compared to the former line.

The difference between the hot springs in the $\delta^{18}O$ shift can be explained by their difference in vaporization and the mixing features of hot water and cold water.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90079024

The above results show that the $\delta^{18}O$ in the spring water equals that of meteoric water before shifting by 0.5~1.0%. Thus, the hot springs are recharged by meteoric water with $\delta^{18}O$ shifting, and the water-rock interaction conditions of the geothermal reservoir is relative closed. The significant isotope exchange in the hot springs can be attributed to the high temperature of geothermal reservoir and the long circulation distance (Fournier, 1977; Edmunds, 2004; Chandrajith et al., 2013).

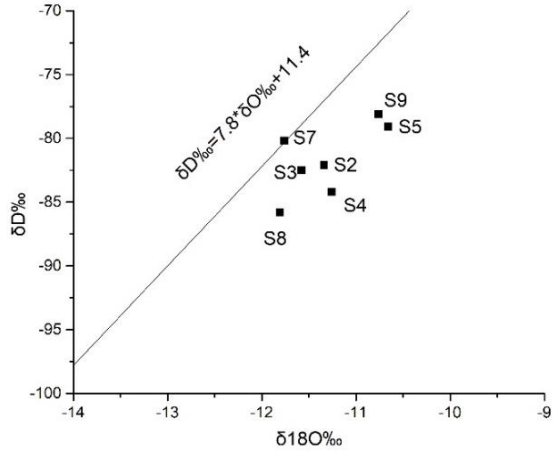

Figure 9. *The δD and $\delta^{18}O$ compositions of the hot springs*

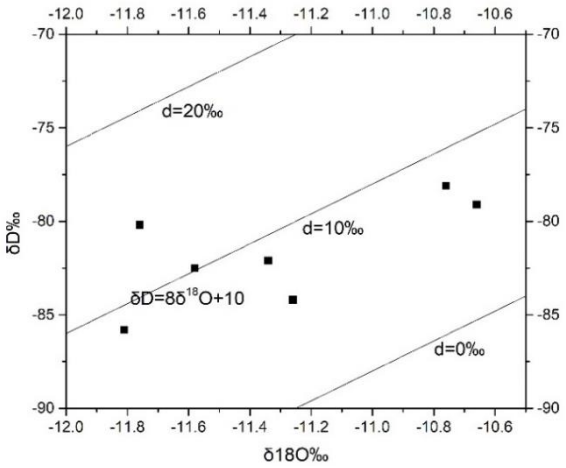

Figure 10. *The δD-$\delta^{18}O$ values of the hot springs*

According to the isotopic analysis, the δD and $\delta^{18}O$ values are close to meteoric water line. This means the hot springs agree with meteoric water in δD and $\delta^{18}O$ features. Besides, the lack of positive shift of $\delta^{18}O$ reflects a relatively low temperature of deep geothermal reservoir. Therefore, the hot springs are neither volcanic nor magmatic (Portugal et al., 2005; Chandrajith et al., 2013).

Considering the elevation effect of δD and $\delta^{18}O$, the groundwater elevation H (i.e. the height above sea level) can be defined as *Eq.1*:

$$H = (\delta_G - \delta_P) / k + h \quad \text{(Eq.1)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90079024

where h is the elevation of sampling point; δ_G is the $\delta^{18}O$ (δD) in the groundwater; δ_P is the $\delta^{18}O$ (δD) in the meteoric water around the sampling point; k is the elevation gradient of $\delta^{18}O$ (or δD) in the meteoric water (‰/100m). Using *Equation (1)*, the H values of hot springs in the research area were computed with K=−2.6‰/100m and δD =−63.5‰ (Xu et al., 2016).

The calculated results in *Table 8* show that the meteoric water is the main recharge source of the hot springs; the recharge elevation lies between 1,549 and 2,403 m (mean value: 1,921 m); the supply elevation is positively correlated with the elevation of the spring mouth; the values of $\delta^{18}O$ and δD are linearly correlated. To sum up, the exposed hot springs are a mixture of low-temperature shallow groundwater and high-temperature deep groundwater. This conclusion echoes with the results of the hydro-chemical analysis.

Table 8. *Elevation features of isotopic recharge area of groundwater in the research area*

Hot Spring No.	δD‰	$\delta^{18}O$‰	Spring Mouth Elevation	H (m)
S2	−82.1	−11.34	943	1658.38

Temperature of geothermal reservoir

The temperature of geothermal reservoir can be measured by "geochemical thermometers", i.e. chemical contents and isotopes like SiO_2, Na-K, Na-K-Ca and $\delta^{18}O$ in sulphate (Zhang et al., 2008; Zhou et al., 2009).

Here, the Na-K-Mg triangular diagram is employed to judge if cationic geochemical thermometers are suitable for the hot springs (Giggenbach, 1988). As shown in *Figure 11*, all the water samples throng the corner of $Mg^{0.5}$, reflecting the high Mg^{2+} content in the samples and its impacts on the calculation of geochemical thermometers. Thus, SiO_2 geochemical thermometers are the best choice to calculate the temperature of our geothermal reservoirs.

In this way, it is learned that the geothermal reservoir temperatures of S2 and S5 are 100.1 and 79.8°C, respectively; the mean annual temperature in the research area is 19.5°C, with a geothermal gradient of 20 m/°C. Setting the annual constant temperature to 30 m, the SiO_2 geochemical thermometer without vapor loss T_1 and the chalcedony geochemical thermometer T_2 can be respectively calculated as *Eq.2* and *Eq.3*:

$$T_1 = 1309 / (5.19 - LgC_{SiO2}) - 273.15 \quad \text{(Eq.2)}$$

$$T_2 = 1032 / (4.69 - LgC_{SiO2}) - 273.15 \quad \text{(Eq.3)}$$

where T is the temperature of geothermal reservoir; C_{SiO2} is the mass concentration of SiO_2 (mg/L). According to the calculated results in *Table 9*, the temperatures of our

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90079024

geothermal reservoirs belong to the interval of 80~146°C, with the mean value of 111.8°C. Thus, there is a great potential for exploitation of geothermal resources in the research area.

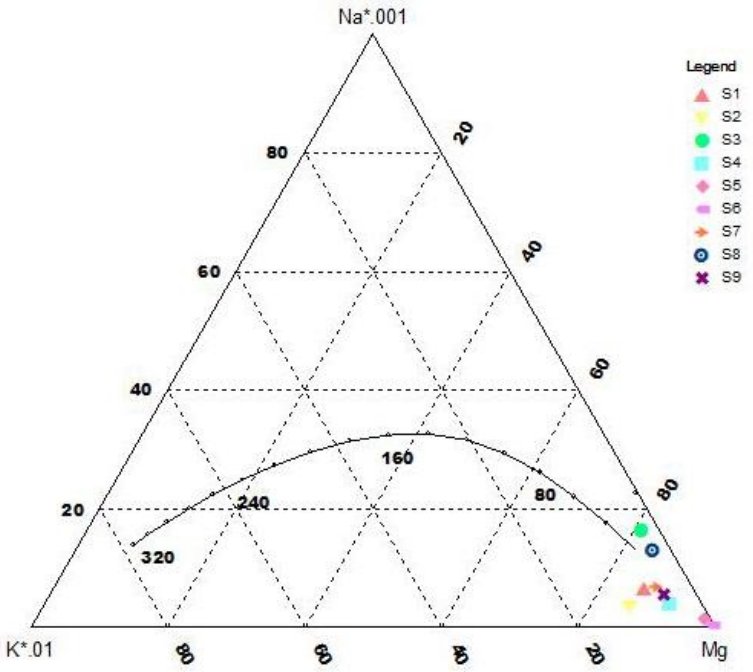

Figure 11. *Na-K-Mg triangular diagram of the hot springs*

Table 9. *Calculation results of geothermal reservoir temperature (°C)*

Sample	SiO_2 (mg/L)	Equation (2)	Equation (3)	Temperature
S2	48.26	100.16	70.11	71.0
S3	73.58	120.74	92.38	82.0
S4	70.37	118.45	89.89	80.0
S5	30.33	79.86	48.53	44.0
S7	117.22	146.26	120.59	73.0

S9	89.97	131.37	104.06	58.0

Conclusions

The geothermal fields in the research area are controlled by the primary and secondary faults. At the intersections between the faults, the clastic sediments in the Cenozoic depression provide a good thermal cover for the geothermal reservoirs. The Kejie Fault controls the sedimentation, metamorphism and magmatic activities since the Early Paleozoic era. The control effect is particularly prominent in Late Paleozoic era. The C-M Structural Belt controls the distribution of geothermal resources in the eastern part of the research area.

The temperature of the hot springs in the research area can reach 90°C. The water of all the hot springs has good quality, belongs to the hydro-chemical type of HCO_3-Na,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90079024

and shares the same recharge source and stable formation conditions. These hot springs provide typical fault-controlled geothermal resources.

The meteoric water is the main supply source of the hot springs; the recharge elevation lies between 1,549 and 2,403 m (mean value: 1,921 m); the recharge elevation is positively correlated with the elevation of the spring mouth; The cold-water fractions in S3, S4, S7 and S1 fall in the range of 66%~77%; the temperatures of our geothermal reservoirs belong to the interval of 80~146°C, with the mean value of 111.8°C, which are controlled by Kejie Fault and C-M Structural Belt.

In the hot springs, the dissolved inorganic carbon exists as HCO_3^-, and the $\delta^{13}C_{DIC}$ value is similar to the value of $\delta^{13}C_{HCO3}$−; the δD and $\delta^{18}O$ features are the same as those of meteoric water; the lack of positive shift of $\delta^{18}O$ reflects a relatively low temperature of deep geothermal reservoir, meaning that the hot springs are neither volcanic nor magmatic; the significant isotope exchange in the hot springs can be attributed to the high temperature of geothermal reservoir and the long circulation distance.

The ^{14}C isotopic dating shows that the hot springs in the eastern part and S4 are respectively aged 17,220±550a and 16,510±1,600a. The C-M Structural Belt has a longer groundwater circulation path than Kejie Fault. Despite the slight difference in activities and formation causes, the hot springs in both western and eastern parts of the research area were recharged by paleo-precipitation recharge before Late Pleistocene.

The geothermal resources have great potential for development in the study area. It is necessary to conduct deep drilling, evaluation and scientific research to identify the potential of resources and provide scientific basis for development and utilization planning.

The potential assessment of geothermal resources in the study area is still in a stable state. It is necessary to strengthen exploration, research and monitoring, accelerate the development and utilization of geothermal energy in deep fault zone, promote the release of energy in fault zone and reduce the risk of earthquake occurrence.

Abstract. In view of the harm caused by sludge in the ecological environment, this paper adopts the solidification treatment technology based on the principle of environmental ecological effect to analyze the heavy metal pollution sources in sludge. With the aid of the solidification technology and considering the physical and chemical blocking effects of heavy metals, it analyzes the effect of the solidification technology in treatment of heavy metals at different ratios. The results show that the smaller the particle size, the better the leaching of heavy metals in the sludge; and that the leaching rate is higher under the acidic condition than under the alkaline one. Through research it is found that the impact of heavy metals in the sludge on the environment is influenced by two factors - the controlled distance and the time, so a model can be constructed to predict the migration parameters of heavy metals in the sludge according to the influencing predictors. Then based on the migration parameters, this paper introduces the inverse problem of pollution source control and the control method to optimize the problem. Through the above discussion, it proposes an environmental-effect-oriented heavy metal pollution control method, that is, optimizing the solidified materials by converting the source control problem to the inverse problem of capacity control. In this way, the concentrations of heavy metals in the sludge after solidification treatment can be effectively controlled to meet the requirements of environmental effects.
Keywords: *heavy metal pollution, ecological effect principle, heavy metal migration parameters, source control method, model prediction*

Introduction

Sludge is an inevitable product of sewage treatment and has a great impact on the environmental and ecological balance (Crivello, 2002; Zhang et al., 2018). The heavy metals, microorganisms and organic impurities attached to the forming process make the sludge treatment extremely complicated. According to statistics (Shukla et al., 2004), the amount of sludge accounts for about 2%-7% of the total treatment volume of sewage, and the annual investment and operating costs of sludge treatment account for 25%-30% and 25-40% of the sewage treatment costs, it takes a large part of the investment, for this reason, many scholars at home and abroad have carried out a lot of research on it, and have proposed the treatment methods and research ideas for the comprehensive utilization of sludge from different degrees. The research of many scholars has carried out meticulous research on it from the perspectives of reduction, stabilization, harmlessness and resource utilization, however, research on the comprehensive impact of heavy metals in sludge on environmental and ecological effects is still rare (Hong et al., 2014; Lee et al., 2014; Maati et al., 2018; Wang et al., 2018). Based on the principle of environmental ecological effects, Alvarez et al. (2002)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90259034

started from an environmental perspective, applied the solidification technology to convert it into a process of non-flowability or solid formation, regardless of whether chemical bonding occurs between the waste and the curing agent, through the separation effect of this technology, they achieved the objective to control the harm of heavy metal to environmental pollution (Olier and Cosgrove, 2004), and improved the quality of the ecological environment.

Solidification technology uses cement to solidify the waste and cement the particles in the waste through the product of the cement hydration reaction (Yan et al., 2011; Zheng and Zhang, 2018). After solidification, the sludge forms denser blocks that have lower water permeability, so that the heavy metals existing in the form of oxides, hydroxides, insoluble salts, etc. in the sludge are continuously extracted and filtered out by adjusting the pH and Eh values of the sludge during the water treatment process. In this way, the harm of sludge is reduced (Nishioka et al., 2000). Based on the above theories, this paper adopts solidification technology to ensure the solidification conditions of heavy metal by changing the chemical and physical conditions of the solidified body, and based on this, it controls the heavy metal pollution control methods by discussing the control mechanism of heavy metals. This paper mainly discusses the control methods of two heavy metal elements Cu and Zn under the ecological effect conditions. The experimental study in this paper can effectively remove heavy metals in sludge and optimize sludge solidification effects and methods.

Materials and methods

During water treatment process, 50%-80% of the heavy metals in the sewage is concentrated in the sludge (Whanger, 2002; Georgieva, 2017). The solidification treatment technology is used to improve the properties of the sludge, making it a useful soil engineering material. The solidification technology mainly treats heavy metals in sludge, reduces the risk of metal leaching and its environmental hazard by reducing the water permeability of solidified sludge (Ying and Fang, 2006). Solidification technology reduces the impact of heavy metals on the environment through physical and chemical effects, the following passages will verify the solidification technology for the treatment of heavy metals in sludge by analyzing the principles and methods based on physical and chemical mechanisms.

Results

Physical blocking effect of solidification methods on heavy metals

This experiment took samples from typical sections from the upstream and midstream reaches of the Tianjin Beitang Sewage River and the Dagu Sewage River. In order to ensure the continuity and representativeness of the samples, the sampling was conducted respectively in the wet season, the normal season, and the dry season; and a total of 36 sets of samples had been taken. Then, the *Soil Physical and Chemical Analysis Method* was adopted to classify and test the collected samples, and the classified samples were subject to solidification process. The solidified sludge is dried and then crushed to different particle sizes, and sieved for classification. Then, X-ray diffraction (Japan Spv019) is used to analyze whether it will cause the destruction of the integrity of the organic matters in the solidified sludge, that is, whether there is a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90259034

possibility of failure using physical method to treat the samples. Experimental method adopts the heavy metal leaching method: cement, sludge and water are arranged in a ratio of 1:2:5 and 2:2:5, respectively. For the heavy metal leaching experiment, at a soil-water ratio of 1:10, the samples with different particle sizes are mixed with the leaching solution, stirred, and shaken at different frequencies, then stand for more than 30 minutes, vacuum filtered, and use spectrophotometer (Beijing Ruili WFX130) to determine the concentration of Cu and Zn. The experimental results and data are shown in *Table 1*.

Table 1. *Relationship between solidified sludge particles and heavy metal leaching*

Particle(mm)	Cu leaching rate(%)		Zn leaching rate(%)

Chemical blocking effect of solidification methods on heavy metals

The previous study shows that, the stabilizing effect of solidified sludge heavy metals is due to the pH of the solidified sludge itself, it produces an incompatible or complexing effect on heavy metals to enhance their stability. The chemical blocking experiment is mainly to clarify the buffering effect of the sludge on the environmental changes after solidification. It changes the influence of its own chemical properties on heavy metal leaching by setting the external acid-base environment. By setting the leaching solution with different PH value and Eh value, the leaching solution of this paper is prepared by using hydrochloric acid and sodium hydroxide solutions, and the designed experiment is carried out according to the experimental ratio method of the physical effect, and the final experimental data is shown in *Table 2* and *Figures 1-2*.

Table 2. *Leaching rate of heavy metals under different pH values*

Through the study of solidification and leaching treatment of heavy metals by physical effects and chemical effects, the experimental results show that different particle sizes have different effects on solidification and leaching of heavy metals. The trend in *Figures 3-4* shows that, the leaching rate of particle size at different pH values first decreases and then increases, with the increase of particle size, the ratio of leached heavy metals shows a decreasing trend. The existing form of heavy metals largely determines the pH value, the trend in *Figures 1-2* shows that the chemical route for solidifying heavy metals is to change the external chemical conditions, and the leaching rate is higher when it is acidic.

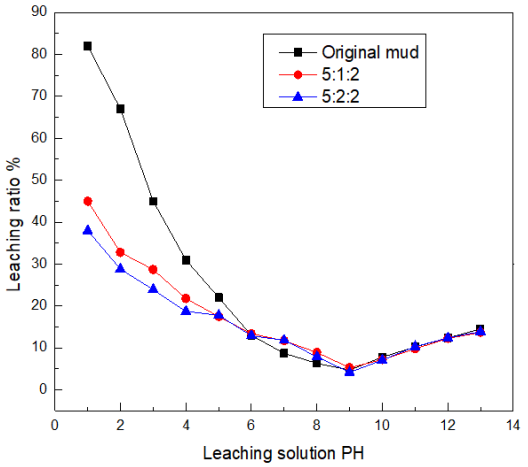

Figure 2. *Leaching rate of Zn under different PH solidified sludge*

Discussion

Prediction of heavy metal pollution in sludge

Assume after solidification, all the indicators of the sludge meet the standards of conventional soils (Xi-Shen et al., 2002), the model diagram of simulating the solidified sludge as the fill soil is as follows:

The mathematical formula of the above physical model is:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90259034

$$Rd\frac{\partial C}{\partial t} = D_L\frac{\partial^2 C}{\partial x^2} + DT\frac{\partial^2 C}{\partial y^2} - Vx\frac{\partial C}{\partial x} - Vy\frac{\partial C}{\partial y} \quad \text{(Eq.1)}$$

where, C is the concentration of the substance, DL and DT are the vertical and horizontal dispersion coefficients, Vx and Vy are the flow rates in the X and Y directions, respectively. Using the above model and numerical method, the conditions of heavy metal sludge at different solidification levels are predicted (Philip et al., 2006), the prediction results are:

$$D_T = a_T\frac{V^2{}_x}{V} + a_L\frac{V^2{}_y}{V} \quad \text{(Eq.2)}$$

$$D_T = a_T\frac{V^2{}_x}{V} + a_L\frac{V^2{}_y}{V} \quad \text{(Eq.3)}$$

Using above theoretical model and numerical method, the diffusion coefficient of the sludge to the environment was calculated by *Eq. (1), Eq. (2) and (3)* respectively measure the pollution degree of different coordinate directions, and predict the heavy metal pollution of solidified sludge of different solidification levels, and the prediction was conducted based on principle of heavy metal migration parameters. This paper took the variation characteristics of Zn as an example to investigate the pollution law of heavy metals to the environment. *Table 3* shows the parameters of the experimental materials.

According to the data in *Tables 3 and 4* and the prediction analysis schemes, it can be known that: (1) The influence of heavy metals in the sludge on environmental pollution gradually increases with time, and the untreated sludge has a much larger groundwater pollution range than the sludge after solidification treatment, and the concentration is higher than the concentration of the sample after solidification; (2) The release rate of heavy metals in the solidified sludge is much smaller than that of untreated sludge, and the released heavy metals will also be diluted by groundwater to reduce the harm to the environment; (3) With the improvement of the solidification level, the pollution of heavy metals to the environment is gradually reduced, and the pollution of heavy metals can be controlled by increasing the solidification level.

Heavy metal migration parameters

Based on the prediction method and control mechanism (Weng et al., 2001; Dragana et al., 2016), the permeability curve of heavy metals in solidified sludge was measured by a flexible permeation meter to obtain the diffusion degree and permeation structure coefficient of two heavy metal elements of Cu and Zn. The test ratios are designed by changing the incorporation amount of cement and sludge, 5 ratios are set to perform the test, respectively are: 5:1:1, 5:1:3, 5:2:2, 5:3:2. According to the prediction results, the heavy metal concentration change values collected in different time periods are classified, and the maximum concentration value is taken as the initial concentration of heavy metals in the solidified sludge, and the calculated actual value of concentration is shown in *Table 5*.

The data in *Table 5* and the trends of *Figures 5-6* show that, the parameter results obtained based on the prediction are close the trend of heavy metals in the solidified sludge of the actual calculation result, so this test method can characterize the demand of the special pollutant parameters.

Table 5. *Concentration of heavy metals in different days under different cement / sludge ratios*

days	Zn migration concentration				Cu migration concentration

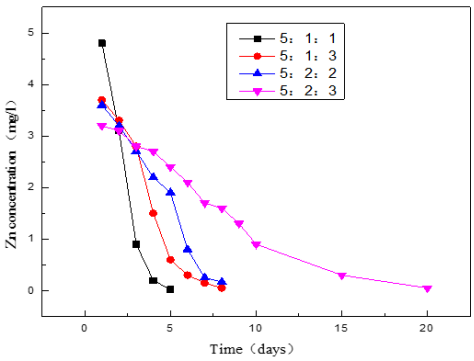

Figure 5. *Concentration migration of heavy metal Zn under different proportions and days*

According to Yao. et al. (2015) and the trend of *Figure 6* we can know that, the pollution intensity of solidified sludge to the environment is mainly determined by the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90259034

migration rate of the metal. The migration rate of the metal is determined by the ratio of cement and sludge, the dispersion degree of the sludge, the retardation coefficient of the metal, and the flow rate, etc. The concentration of heavy metals changes significantly with the migration time. The migration trend of different ratios shows that the concentration migration of heavy metals is most closely related to the number of days in the initial experiment. The migration ability of heavy metals is concentrated in the first 1-2 days. After 5 days, it tends to be balanced or cannot be detected anymore. Different ratios indicate that the migration rate is greater than the diffusion degree. Therefore, when the heavy metal control method is involved, the retardation coefficient of the migration medium should be emphasized.

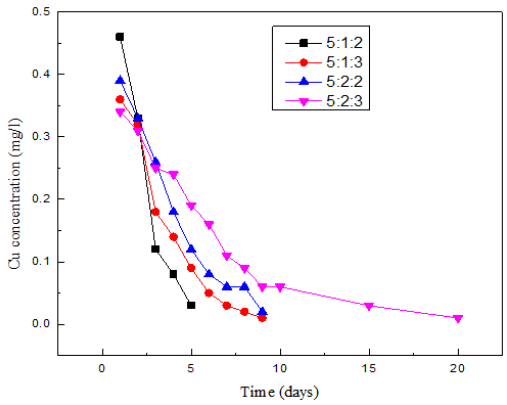

Figure 6. *Concentration migration of heavy metal Zn under different proportions and days*

Heavy metal pollution control method

It can be seen from the discussion that the pollutants contained in the sludge will inevitably enter the surrounding environment by penetrating into groundwater or surface runoff during the formation process, and the heavy metals is a potential danger source to the pollution of groundwater. The existing forms of heavy metals are mostly in a soluble state, and there are many hidden dangers of heavy metal pollution to the environment. According to the principle of environmental ecological effect, the theory of pollution source control reverse problem is used to investigate the concentration of metal in solidified sludge. (Yi et al., 2010) further discussed and optimized the solidified materials, and converted the problem of metal pollution control to the inverse and optimization problem of pollution source control.

To solve the inverse problem of the source item, we must first establish its mathematical model of the reverse source control (Plaia and Bondi, 2006), that is, select a calculation area, and use the solidified sludge as the filling material in the area, establish the model according to the prediction results of section 3.1, try to control the release of heavy metal concentration in the solidified sludge within the environmental tolerance range to meet the environmental capacity requirements.

In order to verify the above model, the solidified sludge sample is subjected to vacuum saturation treatment, and the concentration of heavy metals in the solidified sludge was determined by centrifugal separation method. After solidifying, vacuuming, and twice centrifugal separating, the concentration of heavy metals in pore water is detected, the results of repeated tests are tested for significance using regression

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90259034

equations, and the significant test results are consistent with predicted trends, therefore, the control method discussed above can control the pollution of heavy metals to the environment.

Conclusions

(1) The pollution control problem of heavy metals in solidified sludge can be transformed into source item control inverse problem and solidified material optimization problem. By quantifying the requirements of environmental capacity, we can limit the concentration of heavy metals in the solidified sludge. Through optimizing the solidification conditions and material parameters, we could obtain the pollution control scheme.

(2) Based on the principle of ecological environment effect, the sludge solidification treatment technology can measure the occurrence regularity of heavy metals by physical and chemical environment, and it can improve the leaching rate of heavy metals in the sludge, thereby improving the utilization effect of the sludge after solidification, so that it can meet the requirements of geomaterials.

(3) The control of heavy metal pollution is essentially a problem of source control, through centrifugation, separation and solidification technologies, we can control the pollution of heavy metals to the environment. The research results and methods of this paper can quantitatively reduce metal pollution by solidification technology and separation method.

(Received 18th Mar 2019; accepted 17th May 2019)

Abstract. We used the Slacks-based Model (SBM) to calculate the environmental efficiency value of industrial cluster districts in China based on the panel data of 30 regions from 2007 to 2014, at the same time, in order to make a comparative analysis with the economic efficiency values not considering carbon emissions, the model presented by Banker, Charnes and Cooper (BCC) for estimating technical and scale inefficiencies in data envelopment analysis was used to calculate the environmental efficiency not considering the desirable output of carbon emissions, and we also analyzed the regional differences in China's environmental efficiency. The results showed that the environmental efficiency value of industrial cluster districts in China ranged between 0.83 and 0.94 not considering carbon emission, and it had a certain degree of reduction when considering the effect of undesirable output, maintaining values between 0.74 and 0.84, and which showed that there was much room for improving the environmental condition of the industrial cluster districts in China. Carbon emission had a great impact on the environment of China's industrial cluster, which resulted in a greater degree of efficiency loss. And it showed that the carbon emissions showed a great difference to the sensitivity degree of influence on regional environmental efficiency.
Keywords: *desirable output, undesirable output, carbon emissions, SBM model, economic efficiency*

Introduction

In recent years, several industrial clusters were built in China. Industrial cluster has made great contribution to the development of regional economy as a unique form of industrial organization. However, because of the large-scale converging of industry in the area, it has a greater impact on the regional resources, energy and ecological system, and this way of economic development with high resource consumption and high pollution emissions will directly lead to the high carbon emission. Under the background of low carbon economy and green development, the high carbon emissions seriously restrict the sustainable development of regional ecosystem, so it requires us to carry out theoretical and practical research on the environmental impact owning to the converging of industry. As a comprehensive index to evaluate the development of economy and environment, environmental efficiency is helpful to the decision makers to find out the problems in the process of the development of regional economic, and then put forward the effective measures through assessing the environment efficiency (Cheng et al., 2014). Therefore, it has important practical significance how to promote the low-carbon

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90359049

development of China's industrial cluster districts and improve its environmental efficiency under the background of low-carbon and green development.

In recent years, the domestic and foreign scholars have also made positive progress in the research of environmental efficiency, the research mainly focuses on four aspects: the concept of environmental efficiency, the measuring method of environmental efficiency, the regional difference of environmental benefits, and the influencing factors of environmental benefits. The domestic and foreign scholars have different views on the definition of environmental efficiency. Although there is no uniform definition of environmental efficiency, the formulation also has the difference between environmental efficiency and ecological efficiency, and the definition of the environmental efficiency by WBCSD is widely recognized and accepted. At present, the domestic and foreign scholars mainly use the methods of life cycle method, multi-criteria decision making method, stochastic frontier analysis, distance function method and data envelopment analysis (DEA). For example, Maxime et al. (2006) constructed an evaluation model of environmental efficiency by using the method of JWDEA and the directed distance function. Liu et al. (2011) applied the method of super efficiency DEA to assess the ecological efficiency and the regional ecological efficiency in China. Deng Bo used the model of two stages DEA to make an empirical research on the regional ecological efficiency of China. Wang and Wu (2011) used the data development analysis model to analyze and evaluate the environmental efficiency of China's provinces and cities, and analyzed the influence factors of industrial ecological efficiency by using the Tobit regression model. Wang et al. (2011) built an environmental efficiency measurement model of different process efficiency from the perspective of system integration. About the research of regional differences of environmental benefits, the domestic and foreign scholars have studied the industrial economic development of various districts in China from many aspects and angles. For example, Li (2012) used the SBM model to analyze the environmental efficiency of the Eastern region, central region and Western region in China. Wang et al. (2011) established the energy environment measurement model by using data envelopment analysis and directed distance function and used this model to study the environmental efficiency of China's provinces. Yang and Song (2011) studied the impact of environmental efficiency from three factors of system, regional and economic operating. Qi (2012) used the DEA Max model to study the environmental efficiency of the industry in Guangxi province. The influencing factors of environmental efficiency mainly focused on the international trade and foreign direct investment (FDI) in the early research. However, the speed of economic and social development is so fast that the factors which affect the environmental efficiency are also increasing. Charmondusit and Keartpakpraek evaluated the ecological efficiency from three indicators of material consumption, water use and hazardous waste. Yang et al. (2012) believed that the GDP, FDI, structural factors and the public's environmental awareness have different levels of impact on the environmental efficiency. Tan et al. (2013) used stochastic frontier analysis and beyond logarithmic production function model to assess the environmental efficiency of three provinces in Northeast China from 1991 to 2010. Fu et al. (2013) constructed the evaluation model of coal enterprise ecological efficiency by using the DEA method. Zhang (2013) evaluated and analysed the eco-efficiency based on panel data of Western China's Provinces 2000-2010. Gao (2014) used the Tobit model to analyze the influence factors and the degree of environmental efficiency of Guangdong province and the four major regions from 2000 to 2012. Rong (2015) evaluated the environment of Western in China and analyzed the influence factors of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90359049

environmental efficiency under the carbon emission constraints. Li et al. (2017) analyzed the evolution of environmental regulation strategy among local governments and its impact on regional ecological efficiency in china.

In summary, the researches of environmental efficiency by domestic and foreign scholars have a theoretical summary and exploration of methods, especially the research field of its concept and evaluation, and they offered a certain foundation for our further research. However, from the research point of view, the research on the industrial level and regional level is few, and the research on the regional environmental efficiency of China's industrial cluster is still in a blank stage, at the same time, the research literature about the measurement of environmental efficiency under the constraint of carbon emission is relatively few. From the aspects of the research method, most of the literatures used the data envelopment analysis model, which leads to the distortion of efficiency evaluation. Therefore, we attempted to compensate the lack of the study above, and we used the panel data from 2010 to 2015 and estimated the environmental efficiency under the constraints of carbon emission by using the SBM model to find out the differences of the regional environmental benefits of industrial clusters.

Materials and methods

Research method and establishment of model

It can be seen from the above research, most scholars in previous studies took the environmental pollution as an input or a negative output, and used the DEA model to calculate the efficiency value which including environmental pollution, but it did not take into account the relaxation problem of input-output fully, and it distorted the efficiency of the evaluation object. So Cooper et al. (2007) put forward the SBM model of data envelopment analysis with non radial and non angle (Slacks-based Model), the model considered the slack problem of the input output caused by angle and radial selection as far as possible, it could not only overcome the shortcomings of the traditional model, but also it could effectively deal with the problem of excessive input and output, it reflected the essence of efficiency evaluation more compared with other models. At present, the domestic scholars have already begun to use the SBM model to calculate the environmental benefits in China, for example, Pan and Ying (2013) used the SBM model with non radial, non angle to calculate the agricultural ecological efficiency of China's 30 provinces, and gave the way to improve the efficiency of agricultural ecology. Tian et al. (2014) calculated the China's agricultural environmental efficiency for the 2002-2012 based on the SBM model. Rong (2015) used the SBM model to calculate and analyze the static environmental efficiency of the western region under the constraints of carbon emission in the western region in China from 2000 to 2012. Gao (2014) calculated the economic efficiency values of non-expected output factors without considering the constraints of carbon emission and environmental efficiency values of non-expected output factors with considering the constraints of carbon emission of four major regions in Guangdong province by using the BCC model and SBM-V model. Huang and Shi (2015) built a SBM model including R&D investment and calculated the environmental efficiency and the growth rate of the total factor of environment in China, and the influence factors of total factor productivity of regional environmental factors were analyzed by Tobit model based on the theory of R&D. Guo et al. (2015) used the non expected SBM model system evaluated the total factor energy efficiency of 28 provinces in China, and the spatial convergence of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90359049

provincial total factor energy efficiency was studied by using the spatial econometric model based on the economic geography distance weight. Therefore, the theoretical and empirical researches showed that it was feasible to use the SBM model to evaluate the regional environmental efficiency based on the non-expected output. Based on this, according to the actual situation of industrial cluster district in China, we also use the SBM model with non-expected value to calculate the environmental efficiency of China's industrial clusters region under the constraints of carbon emission.

Due to the SBM model is introduced by the literature above, so we introduce the model of this paper according to the research of Gao (2014) and Rong (2015). The SBM model assumes that there are *n* decision making units, each of which has input (which is expressed by m), expected output (which is expressed by s_1) and non-expected output (which is expressed by s_2), and the three vectors are expressed as $x \in R^m$, $y^g \in R^{s_1}$ and $y^b \in R^{s_2}$, so we can define the following matrix:

$$\begin{aligned} X &= [x_1, x_2, \ldots, x_n] \in R^{m \times n} \\ Y^g &= [y_1^g, y_2^g, \ldots, y_n^g] \in R^{s_1 \times n} \\ Y^b &= [y_1^b, y_2^b, \ldots, y_n^b] \in R^{s_2 \times n} \\ X > 0, Y^g &> 0, Y^b > 0 \end{aligned} \quad \text{(Eq.1)}$$

The production possibility set *p* of constant returns to scale can be defined as follows:

$$P = \left\{(x, y^g, y^b \mid x \geq \lambda X, y^g \leq \lambda Y^g, y^b \geq \lambda Y^b, \lambda \geq 0)\right\},\ \lambda \in R^n \quad \text{(Eq.2)}$$

The above set satisfies the following three assumptions:

(1) Undesirable output of environmental efficiency has the feature of weakly disposal: if $(y, b) \in P(x), 0 \leq \theta \leq 1$, so $(\theta y, \theta b) \in P(x)$ is satisfied, and this condition means that if you want to reduce the desirable output, it is necessary to reduce the desirable output.

(2) Desirable output has the feature of disposing freedom: if $(y, b) \in P(x)$ and $y^* \leq y$, so $(y^*, b) \in P(x)$ is satisfied. This condition means that expected output can be freely controlled, but the desirable output remains the same. In generally, it is not possible for the operational efficiency of the enterprise to achieve a reduction in desirable output without a corresponding reduction in output if sustained input.

(3) Desirable output and undesirable output have zero Union: if $(y, b) \in P(x)$ and b = 0, so y = 0 is satisfied. This condition means that there is undesirable output without the desirable output.

According to the above, the SBM model based on the undesirable output can be expressed as follows:

$$\rho^* = \min \frac{1 - \frac{1}{m}\sum_{i=1}^{m} \frac{s_i^-}{x_{i0}}}{1 + \frac{1}{s_1 + s_2}\left(\sum_{r=1}^{s_1} \frac{s_r^g}{y_{r0}^g} + \sum_{r=1}^{s_2} \frac{s_r^b}{y_{r0}^b}\right)} \quad \text{(Eq.3)}$$

$$s.t.\begin{cases} x_0 = \lambda X + s^- \\ y_0^g = \lambda Y^g - s^g \\ y_0^b = \lambda Y^b + s^b \\ s^- \geq 0, s^g \geq 0, s^b \geq 0, \lambda \geq 0 \end{cases} \quad \text{(Eq.4)}$$

In the above formula, s is the slack variable of input and output, s^- and s^b represent the redundant of the input and the output, s^g expresses the deficiency of expected output, λ is the weight vector. The objective function ρ^* strictly monotone decreasing function of s^- and s^b, and $\rho^* \in (0,1)$. According to the research of Cooper et al. (2007), the loss of environmental efficiency can be decomposed into:

(1) Input redundancy

$$IE_x = \frac{1}{m}\sum_{i=1}^{m}\frac{s_i^-}{x_{i0}} \quad \text{(Eq.5)}$$

It means reduced proportion of input elements.

(2) Desirable output deficiency

$$IE_y = \frac{1}{s_1 + s_2}\sum_{r=1}^{s_1}\frac{s_r^g}{y_{r0}^g} \quad \text{(Eq.6)}$$

It means the expansion ratio of expected output.

(3) Undesirable output redundancy

$$IE_u = \frac{1}{s_1 + s_2}\sum_{r=1}^{s_2}\frac{s_r^b}{y_{r0}^b} \quad \text{(Eq.7)}$$

Selection of the research indexes and data sources

Owning to the environmental efficiency reflects the development of coordination status of resource conservation, environmental protection and regional economic growth. Therefore, we mainly consider the three factors during selecting the rating index of the environmental efficiency. The domestic and foreign scholars have conducted a lot of research about evaluation index of environmental efficiency at the current, based on the existing research on the input indicators and output indicators, and combining with the actual research object, the index selection and calculation methods in this paper are as follows:

(1) Input index

Energy input: It shows that how much energy is used in the process of development in the industrial clusters region. Because the total energy consumption statistics is not appeared yet in all provinces in China over the years, therefore, according to the research result of Guo et al. (2015) as well as the physical consumption of the main energy sources in each province and the conversion coefficient, the calculation method is as follows:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90359049

$$E_{i,t} = \sum_{j=1}^{n} e_{i,t,j} \bullet c_j \quad \text{(Eq.8)}$$

Among them, $E_{i,t}$ represents the total energy consumption of the industrial cluster region i in t year, $e_{i,t,j}$ represents the energy j consumption of the industrial cluster region i in t year, c_j represents the conversion coefficient of energy j.

Capital input: In recent years, a large number of literatures have tried to estimate the stock of capital in China, and the different methods used by different scholars. Some scholars used the method of perpetual inventory, while some scholars used the annual average balance of net fixed assets as capital stock. Here, according to the research result of Rong (2015) and Zhang et al. (2004), we use the method of perpetual inventory to estimate capital stock. The basic formula is as follows:

$$K_t = I_t + (1-\delta)K_{t-1} \quad \text{(Eq.9)}$$

Among them, K_t represents the capital stock at time t, and K_{t-1} represents the capital stock at time $t-1$. I_t represents the amount of investment at time t, δ represents the depreciation rate. We take 2007 year for the initial years of the calculation, and take the total amount of fixed capital formation divided by 10% as the initial capital stock of provinces and municipalities in 2005 year, the formation total of annual fixed capital as the amount of investment, and we calculate the capital stock with of the depreciation rate (which is 9.6%).

Labor factor input: We take the annual average number of employees in the enterprises in the industrial cluster region as the labor input.

Land input: At present, different scholars have different represent ways, some scholars used the built area, some scholars used the area of crop planting and aquaculture, and some scholars used the area of cultivated land and construction land. Here, we use the built area as the evaluation index.

(2) Desirable output

We use the GDP of every industrial clusters region to show the expected output. And the GDP deflator is converted to the constant price GDP in 2007 as the base year.

(3) Undesirable output

In this paper, owning to we study the environmental efficiency under the constraint of carbon emission. Therefore, we choose the index of co_2 emission as the non-expected output. Because the statistics of carbon emissions of monitoring the various provinces and cities in China is not exist, therefore, according to the studies of Rong (2015), and the estimation method of IPCC national greenhouse gas emission inventory guide in the 2006, we take the sum of eight main sources of the product of energy consumption and the respective carbon dioxide emission factors to calculate the co_2 emission. Specific calculation formula is as follows:

$$m_{co_2} = \sum_{i=1}^{8} m_i \times QDW_i \times E_i \quad \text{(Eq.10)}$$

Among them, m_{co_2} represents the emission of co_2 (10000 t), m_i represents the energy consumption by end (10000 t, 100 million m^3), QDW_i represents low calorific value of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90359049

various types of energy (KJ/Kg, KJ/m^3), E_i represents co_2 emission factors of various types of co_2 (Kg/TJ).

(4) Control variables

The regional energy efficiency is not only affected by the factors such as capital, labor and energy inputs, but also is related to the technological progress, regional industrial structure and other variables. According to the research of Guo et al. (2015), we select three control variables in this paper:

Investment of R&D: It is expressed by the value of the ratio of R&D investment to regional GDP in industrial cluster region. It represents the scientific and technological innovation of the regional enterprises and the technical progress of the industry, and the improvement of the production efficiency, and thus improving the overall environmental efficiency of the region.

Industrial structure: It is expressed by the value of the ratio of the second industry in the industrial clusters region to the GDP. Industry is the largest energy consumption in the three major industries, and the efficiency of the industry is relatively low, the greater the proportion may lead to the low efficiency of overall.

System variable: It is expressed by the value of the ratio of fiscal expenditure to GDP in industrial clusters region. The index reflects the government's interference extent to the regional economy, and it affects the regional environmental efficiency to a certain extent.

Data source description

The input-output data are derived from the years of "China Statistical Yearbook", "China Environmental Yearbook", "China Environmental Statistics Yearbook", "Chinese Energy Statistics Yearbook", "China Statistical Yearbook of science and technology", "China land and resources Yearbook", "IPCC national greenhouse gas emission inventory in 2006", and provincial Environmental Statistics Bulletin, and the composition of 2007-2014 in 30 provinces, autonomous regions and municipalities. Taking into account the consistency and availability of data, the panel data set of Tibet and Taiwan, Hongkong, and Macao are not included in the study. In addition, we still divide China into four regions of eastern, central, western and and northeast according to the traditional division method, which includes 11 provinces in the eastern region, 8 provinces in central region and including 11 provinces in western (Except Tibet) when we analyze the environmental efficiency of industrial cluster region.

Results and discussion

Overall environmental efficiency evaluation

We use the SBM model to calculate the value of China's industrial clusters region from 2007 to 2014, and in order to compare the efficiency environment with the situation which does not consider the carbon emissions, we use the BCC model to calculate the efficiency environment which not consider the carbon emissions. We use Matlab7.0 to calculate the economic efficiency and environmental efficiency. The value of environmental efficiency and economic efficiency of China's industrial cluster region from 2007 to 2014 in two cases are shown in *Table 1* and *Figure 1*. As we can see from *Table 1* and *Figure 1,* the environmental efficiency value of industrial cluster districts in China ranged between 0.83 and 0.94 not considering the carbon emissions and other

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90359049

undesirable output if we use the BCC model to evaluate the efficiency of economic growth of industrial cluster districts in China. But the efficiency of China's industrial cluster districts has a certain degree of reduction compared with before when we consider the effect of undesirable output, and the value ranged between 0.74 and 0.84, and they are not up to 1, it shows that there is much room to improve the environmental condition of the industrial cluster districts in China.

Table 1. *The value of environmental efficiency and economic efficiency from 2007 to 2014*

Year	Environmental efficiency value	Year	Economic efficiency value
2007	0.81	2007	0.94
2008	0.79	2008	0.90
2009	0.76	2007	0.86
2010	0.78	2010	0.87
2011	0.80	2011	0.91
2012	0.74	2012	0.83
2013	0.77	2013	0.85
2014	0.84	2014	0.9

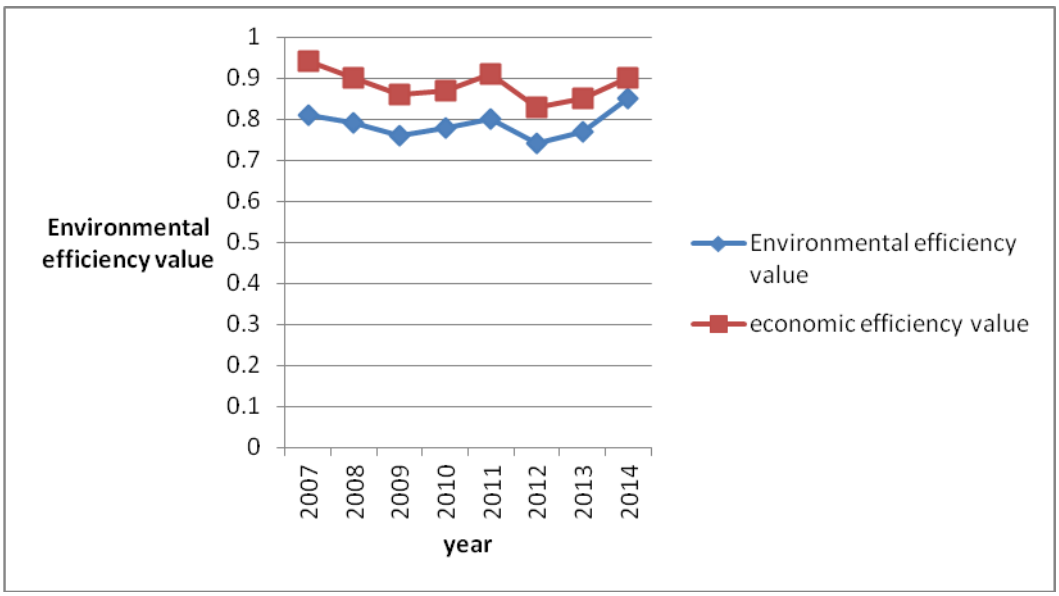

Figure 1. *Environmental efficiency value of carbon emission and not considering carbon emission from 2007 to 2014 years*

The result shows that the carbon emission has a great impact on the environment of China's industrial cluster, and it results in a greater degree of efficiency loss, so the carbon emission has become a problem that cannot be ignored in the environmental governance. It means that the efficiency evaluation is distorted in the case of non-expected output without taking into account the pollution discharge, and it also proves that using the SBM model to evaluate the efficiency of carbon emission is suitable, and this model improves the accuracy and credibility of the environmental efficiency evaluation in the presence. At the same time, from the perspective of the time

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90359049

dimension, the environmental efficiency value of China's industrial cluster region displays the style of "W" under the constraint of carbon emission in the sample range, and the change is relatively large. But they continue to narrow the gap, the main reason is that the government in China implemented the energy-saving emission reduction measures, and put forward the concept of ecological civilization construction, people's awareness of environmental protection had been enhanced.

Analysis on the difference of regional environmental efficiency

According to the general method of regional division, we take the four regions of the Eastern, Central, Western and Northeastern as the research unit in this paper. Also, we use the BCC model to calculate the economic efficiency value for the China's industrial clusters in Eastern region, Central region, Western region and Northeast region from 2007 to 2014 not considering the carbon emissions, and then we use the SBM model to calculate the economic efficiency value for the China's industrial cluster districts in Eastern, Central, Western and Northeast from 2007 to 2014 with considering the carbon emissions, and explore the difference and change features. Owning to the limited space and combine with the characteristics of the stage of China's regional economic development, we only show the results in 2008, 2010, 2012 and 2014 in *Tables 2* and *3*.

(1) Environmental efficiency of various regions of China's industrial cluster not considering carbon emissions. As we can see from *Table 2* and *Figure 2,* the average value of environmental efficiency of the Eastern region, the Central region, the Northeast region and the Western region from 2007 to 2014 is 0.806, 0.686, 0.959 and 0.571 from the perspective of regional, and the result is consistent with the conclusions of the existing literatures, and it means that the eastern region has achieved some results after transforming to the intensive economic growth mode with low consumption, low pollution and high efficiency. At the same time, it reflects a good phenomenon that the environment quality of traditional industry in underdeveloped areas will not be better than the development area, the economy of the eastern region in China is not only better than the central region, the northeast region and the western region, but also the environmental pollution control and to keep less pollution obviously are still better than less developed areas. In addition, the difference of environmental efficiency between the central region and the eastern region decreases with time, and the difference of environmental efficiency among the western region, the northeast region and the central region tends to increase, this result means that the west is in a very unfavorable situation in terms of environmental efficiency. In addition, the annual average value of the environmental efficiency of the eastern region changes relatively stable, while the annual average value of the central region, the northeast region and the western region change greatly from the change trend from 2007 to 2014.

From the level of provincial, the environmental efficiency of the developed areas in the eastern region such as Tianjin, Beijing, Jiangsu, Shanghai, Guangdong, Zhejiang, Shandong has been in the forefront in the above 8 years. The reason is that the modern industrial system which takes the modern service industry as the leading industry in the developed area of eastern region has been built to mature, and the energy consumption continues to decline, and the formulation and implementation of energy-saving emission reduction measures is also ahead of other regions. So it can be seen that changing the mode of economic development and promoting the optimization and upgrading of the industrial structure is very important to improve the efficiency of the regional environment. The lowest efficiency value is Shanxi Province where the coal industry as

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90359049

the core of the in the central region, and because the province ignored the development of technology in the process of industrial, so it results in inefficient use of resources and negative influence on environment efficiency. The environmental efficiency of under-developed areas in the western region such as Ningxia, Qinghai, Guizhou have been in the lag in the above 8 years, and it shows that the economic growth mode of the western region is still mainly extensive, and the economic development is relatively backward.

In summary, the environmental efficiency of China's industrial cluster regional is decreasing from coastal areas to inland and from east to west, and the differences of regional environmental efficiency presents the features of marginalization.

It can be seen from *Figure 3* that the gap of the environmental efficiency value among the four major regions is still large. Compared *Figure 2* with *Figure 3,* we can know that the environmental efficiency value has a certain degree of reduction compared with not considering the carbon emissions. From the perspective of regional, carbon emission has a great impact on the differences degree of regional environmental efficiency. In the consideration of carbon emissions, we found that the environmental efficiency of the eastern region declined, but the change extent is slightly, however, the environmental efficiency value of the central region, the eastern region and the western

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90359049

region decreased significantly, and it also shows that the difference of sensitivity degree of the influence of carbon emissions on the regional environmental efficiency.

(2) The environmental efficiency of various regions of China's industrial clusters with considering the carbon emissions. In the case of considering carbon emissions, the trends of environmental efficiency in the four regions are shown in *Table 3* and in *Figure 3*.

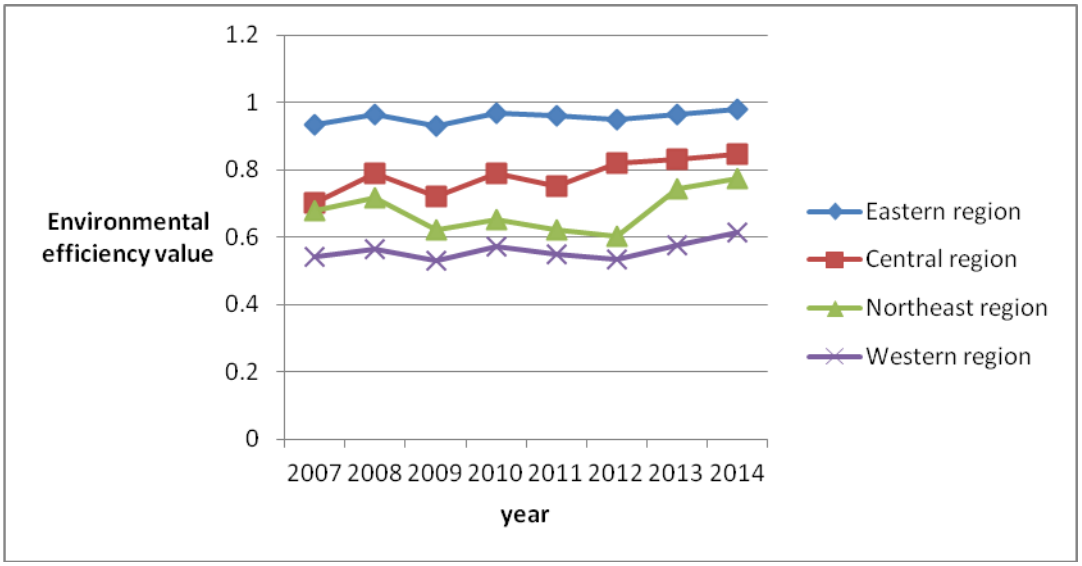

Figure 2. *Change trend of regional environmental efficiency not considering the carbon emissions*

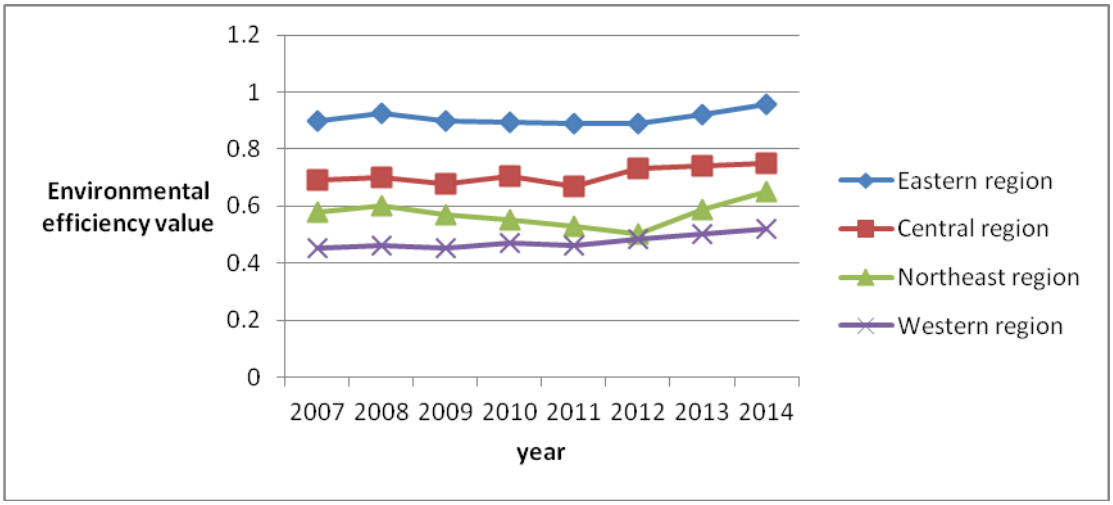

Figure 3. *Change trend of regional environmental efficiency with considering carbon emissions*

Conclusions

According to the above research, we get the main conclusions are as follows:

(1) The environmental efficiency value of industrial clusters region in China ranged between 0.83 and 0.94 without considering the carbon emissions and other undesirable output if we use the BCC model to evaluate the efficiency of economic growth of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90359049

industrial cluster districts in China. But the efficiency of China's industrial clusters region has a certain degree of reduction compared with before when we consider the effect of undesirable output, and the value ranged between 0.74 and 0.84, and they are not up to 1, it shows that there is much room to improve the environmental condition of the industrial cluster districts in China.

(2) The environmental efficiency value of China's industrial cluster region display the style of "W" under the constraint of carbon emission in the sample range, and the change is relatively large. But the gap is becoming narrow continuously, the main reason is that the government in China implemented the energy-saving emission reduction measures, and put forward the concept of ecological civilization construction, people's awareness of environmental protection had been enhanced, but there exits occasional rebound phenomenon.

(3) The carbon emission has a great impact on the environment of China's industrial cluster, and it results in a greater degree of efficiency loss, and it also proves that the SBM model is suitable to evaluate the efficiency of carbon emission, and it improves the accuracy and credibility of the environmental efficiency evaluation.

(4) The results proved that the highest environmental efficiency is the eastern region, the worst environmental efficiency is the western region. In addition, the annual average value of the environmental efficiency of the eastern region changes relatively stable, while the annual average value of the central region, the northeast region and the western region change greatly. That is to say, the environmental efficiency of China's industrial cluster regional is decreasing from coastal areas to inland and from east to west, and the differences of regional environmental efficiency presents of marginalization.

(5) In the case of considering the carbon emissions, the gap among the eastern region, the central region, the northeast region and the western region is still relatively large, and compared with not considering the carbon emissions, the environmental efficiency value has a certain degree of reduction. From the perspective of regional, carbon emission has a great impact on the differences degree of regional environmental efficiency. In the consideration of carbon emissions, we found that the environmental efficiency of the eastern region declined, but the change extent is slightly, however, the environmental efficiency value of the central region, the eastern region and the western region decreased significantly.

Environmental efficiency evaluation is a relatively new issue. However, there are still some problems and shortcomings. Many work needs to be further studied and improved in the future.

(1) We can analyze the mechanism of location selection and product structure on environmental efficiency from the perspective of industry and enterprise.

(2) We can compare China's environmental efficiency with other countries in the world, and find out the gap between China and other countries.

(3) We can evaluate the total factor environmental efficiency under taking into account a variety of pollutants (such as CO_2, SO_2, COD), so we can better find the environment problems.

Abstract. As a global disaster, spontaneous combustion of coal leads to a series of problems, like atmospheric pollution and geological damage, which seriously affects the ecological environment. Therefore, protecting the environment through the prevention of the spontaneous combustion of coal is necessary and worthy of further study. The spontaneous combustion of coal could be characterized by thermogravimetric (TG) characteristics. Thus, the TG test was performed to study the characteristics of non-caking coal during spontaneous combustion. The results show that the combustion process of coal mainly includes loss of water and weight, oxidation, thermal decomposition, combustion and burnout. Both heating rate and oxygen concentration can affect the combustion reaction process of coal. Heating rate is positively correlated with the combustion reaction time, characteristic temperature and oxidation reaction rate of coal. The higher the oxygen concentration, the shorter the combustion reaction time, the lower the characteristic temperature, the higher the oxidation reaction rate. The research results can provide certain theoretical basis for preventing coal spontaneous combustion, and be helpful for the protection of atmospheric environment.
Keywords: *environmental protection, coal fire, disaster prevention, non-caking coal, spontaneous combustion, TG-DSC synchronous analysis*

Introduction

Coal fire disasters spread all over the world. As a global disaster, spontaneous combustion of coal has caused huge environmental pollution and resource loss, seriously threatening the natural environment and safety production of coalmine (Tomescu et al., 2017). As a large coal country, China's coal resources still occupy a major position in the energy industry (Guo et al., 2018; Guo et al., 2019). However, in the process of resource utilization, a series of damages have been caused to the environment, coal fire disasters are often accompanied by secondary disasters, such as induction of gas explosion and dust explosion, and as a result, large amount of poisonous harmful gas and dust is released, causing pollution to atmosphere environment, endangering human health (Toropov et al., 2018; Benmenine and Bentebbiceh, 2018; Habib et al., 2019). Heavy metals produced by combustion will cause pollution to surface water and shallow groundwater, changes water quality and worsens water environment (Wei and Yu, 2017). In addition, coal fire disasters will cause a series of geological effects, leading to changes in geological structure and degradation of surface soil quality (Zeng et al., 2018), and seriously affecting ecological balance.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90519064

By studying the mechanism of spontaneous combustion of coal, a lot of scholars have given a relatively clear explanation of the mechanism of spontaneous combustion of coal (Deng et al., 2016; Wen et al., 2017; Kong et al., 2017; Lu et al., 2018; Wang et al., 2018). Under the condition of high temperature and low oxygen concentration, the coal sample can continue to react and release a lot of heat to maintain the development of the fire area. During the development and evolution of the fire area, the heating rate of coal samples will decrease due to water evaporation and other reasons, but the overall trend is increasing (Jin et al., 2015). Studies have shown that TG and DTG curves of coal combustion reaction under low oxygen concentration are close to the high temperature zone, the ignition temperature is basically unchanged, the burnout temperature increases, and the combustion rate decreases (Wang et al., 2010). Ash, volatiles, moisture and other factors can affect the minimum ignition temperature of coal, and the minimum ignition temperature of coal with different degrees of metamorphism is different (Deng et al., 2014). Yi et al. (2014) compared the combustion characteristics of coal samples under the atmosphere of O_2/N_2 and O_2/CO_2 by using the TG analysis method, and found that the combustion performance of coal samples under the atmosphere of O_2/CO_2 was better. The higher the volatile content of coal, the more obvious the fluctuation of combustion parameters.

Research on the control of coalfire in the coal field and the mine have had a breakthrough, and effectively reduce the environmental pollution caused by spontaneous combustion of coal. However, factors affecting the spontaneous combustion process of coal are very complex, including external factors are and intrinsic factors (Liu et al., 2014). Under the action of different factors, the changing rules of characteristic parameters of the spontaneous combustion of coal appear different. Therefore, there are still many problems to be solved to prevent the spontaneous combustion of coal.

By using TG experiment method, the combustion characteristic of non-caking coal was studied under the conditions of different oxygen concentration and heating rate in this paper, to reveal the influence laws of the above dual factors on spontaneous combustion of coal. This study is helpful to the prevention and control of spontaneous combustion of non-caking coal, and is of great significance to reduce environmental pollution by saving fossil resources.

Materials and Methods

Selection and preparation of samples

In the experiments, the non-caking coal was selected from Shigetai Coal Mine. The central part of raw coal was taken out under the condition of nitrogen protection, and crushed to a particle size of 0.09-0.106 mm. Then, sealed and stored.

Experimental facility and principle

STA 449 F3 synchronous thermal analyser was adopted in the experiment, which mainly consists of sample holder, temperature programmable furnace, water bath and electronic computer.

According to the experimental principle, coal structure and environmental factors can directly impact the combustion process of pulverized coal. The TG-DSC synchronous thermal analysis experiment is to control the temperature and reaction atmosphere

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90519064

conditions by computer; as the temperature in the reaction atmosphere increases according to a certain gradient, the mass change of the pulverized coal can be obtained in real time; as the pulverized coal reaches the set temperature, the relationship between pulverized coal quality and temperature is obtained, i.e., the TG curve. The first-order differentiation of the TG curve can obtain the relationship between the change rate of the pulverized coal mass and the temperature, i.e., the DTG curve.

In the experimental method, the tested coal sample was placed on the top of the sample holder through a ceramic crucible, and directly connected to a precision thermo-balance. The precision thermo-balance can simultaneously measure the mass change of the sample and finally obtain the TG curve. The sample crucible and the reference crucible were placed on the top of the sample holder separately, and the thermocouple wire connected on both sides of the crucible can measure the temperature signals in real time. Then it was converted into the heat signal by temperature signal synchronization to finally obtain the DSC curve.

Experimental conditions

The experiments were conducted in the conductions: the STA 449 F3 synchronous thermal analyser used; the coal sample dosage of 10 mg; the temperature range between 30 -1000°C; the total gas flow rate controlled by software to 100 ml/min; the heating rates of 5, 10, 15°C/min respectively; the pulverized coal in the air atmosphere (21%, 13%, and 5% oxygen concentration).

Results

Thermal weight loss characteristics

TG/DTG curve characteristics

Figures 1-3 show the TG/DTG curves of non-caking coal powder at different oxygen concentrations and heating rates. It can be seen from *Figures 1-3* that the oxidative combustion process of pulverized coal can be divided into five stages, namely, the water and weight loss stage, the weight gain oxidation stage, the thermal decomposition stage, the combustion stage and the burnout stage.

(1) Loss of water and weight stage (30 -180°C)

As the temperature rises, in the initial stage of the pulverized coal, the gas trapped in the non-caking coal clearance is driven to escape from the powder. At the same time, the moisture of the powder also begins to evaporate by heat, which in turn leads to an increase in weight loss. In contrast, with the evolution of the combustion oxidation process of pulverized coal, the coal-oxygen combination gradually begins, making the powder quality increase with the decrease of water loss, and offsetting the initial water loss quality of pulverized coal. As the temperature increases continuously, this offsetting effect works more significantly until the pulverized coal quality reaches a minimum for the first time, indicating that the initial weight loss stage is terminated.

(2) Weight gain oxidation stage (180 -300°C)

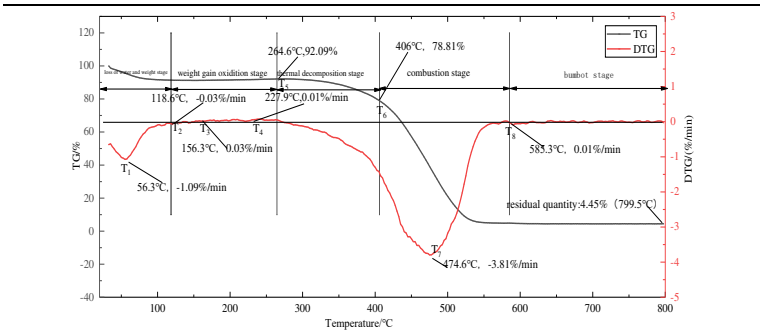
Along with the continuous temperature increase, the active group of the pulverized coal powder released from heat is gradually increased, and then the consumption of oxygen is also increased. Most of the oxygen molecules participate in the coal-oxygen complex reaction (Ma et al., 2014), while those not participating in the oxidation reaction adhere to the surface of the pulverized coal molecules, which restricts the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90519064

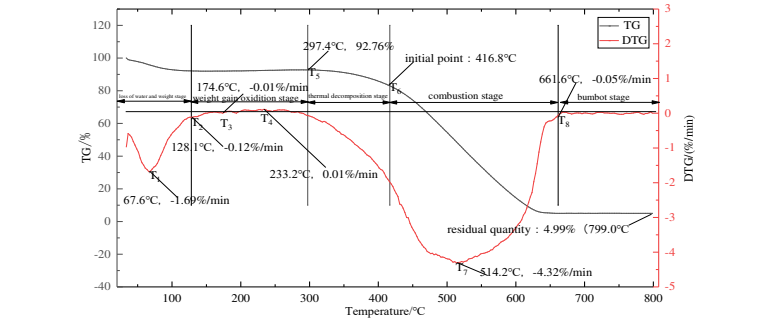
smooth release of the gas in the combustion products, and increasing the quality of the pulverized coal in a short time.

(3) Thermal decomposition stage (300 -410°C)

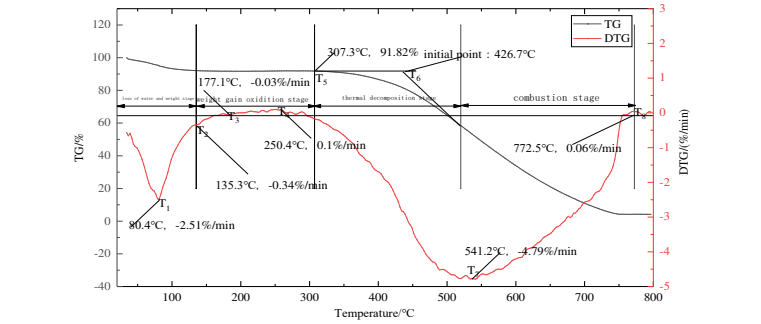
At this stage, the quality of pulverized coal is macroscopically expressed as weight loss again. The reactive functional groups in the pulverized coal molecules are released, in which the aromatic ring nucleus and other groups are largely broken. Then, the active structure that has not participated in the oxidation reaction in the previous stage also begins to bind oxygen molecules to produce CO, CO_2, and H_2O (g) etc. Besides, the pulverized coal itself desorbs due to the temperature increase and produce volatiles, resulting in a more decrease in the quality of the pulverized coal.



(a) At heating rate of 5°C/min



(b) At heating rate of 10°C/min



(c) At heating rate of 15°C/min

Figure 1. *Oxygen concentration of 5%, TG/DTG curve results at different heating rates*

(4) Combustion stage (410 -550°C)

When the temperature reaches the ignition temperature, the pulverized coal begins to react, the powder quality decreases rapidly, and a violent combustion reaction occurs

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90519064

inside the pulverized coal molecules, which release a large amount of heat, and simultaneously generate many gaseous products such as CO, CO_2, and water vapour, etc. until the combustibles of pulverized coal burn completely and the quality no longer changes.

(5) Burnout stage (550 -800°C)

In this stage, the quality of pulverized coal remains basically the same, and the ash content in the pulverized coal directly determines the percentage of the residue remaining after the burnout of pulverized coal.

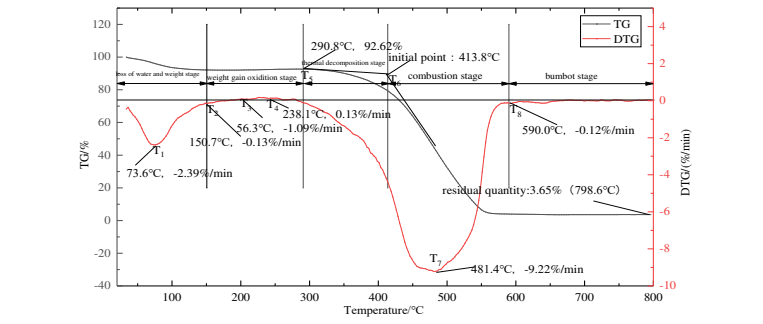
(b) At heating rate of 10°C/min



(c) At heating rate of 15°C/min

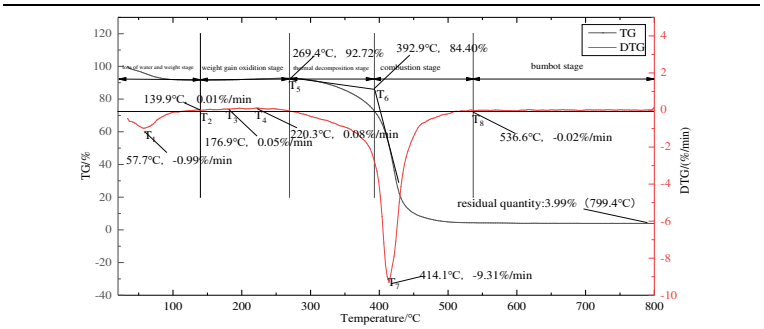
Figure 2. *Oxygen concentration of 13%, TG/DTG curve results at different heating rates*

Characteristic temperature

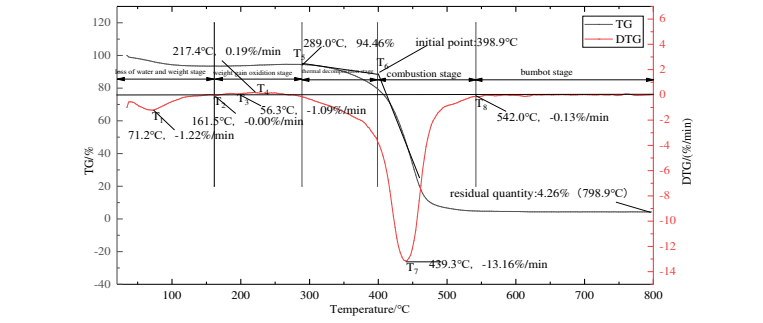
In the oxidative combustion process of coal sample, the characteristic temperature point of coal can be obtained by analysing the experimental TG data (Zhang et al., 2011), which mainly includes the critical temperature (T_1) with the highest weight loss rate during the early-stage water evaporation and index gas escape, the dry cracking

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90519064

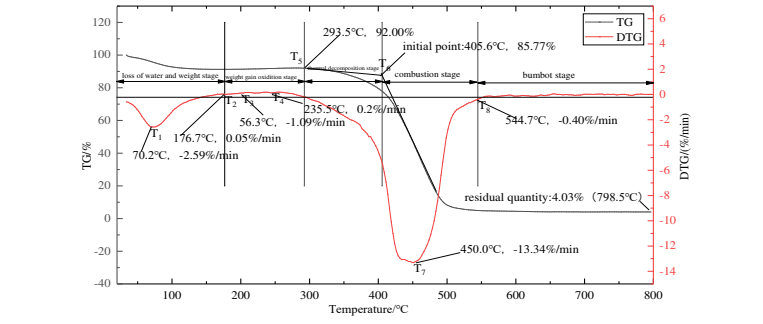
temperature at the lowest weight loss point (T_2), the active temperature of the initial weight gain (T_3), the increasing temperature (T_4), the thermal decomposition temperature (T_5) at the maximum quality of coal sample before combustion, the oxygen absorption weight of the coal sample and the ignition temperature (T_6) at which the reaction consumption reaches equilibrium, the maximum weight loss rate temperature (T_7) corresponding to the maximum trough of the DTG curve, and the burnout temperature (T_8) when the pulverized coal is completely burned and the mass is not changed.



(a) At heating rate of 5°C/min



(b) At heating rate of 10°C/min



(c) At heating rate of 15°C/min

Figure 3. *Oxygen concentration of 21 %, TG/DTG curve results at different heating rates*

Change law of characteristic temperature in combustion process of pulverized coal

The characteristic temperature during the combustion of pulverized coal is shown in *Table 1*. In *Table 1*, the characteristic temperature under different oxygen concentration and different heating rate conditions was compared and analysed. It's found that the characteristic temperature changes significantly from the starting temperature point to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90519064

the ignition temperature range. Therefore, in order to study the combustion process of pulverized coal under the condition of different heating rates and oxygen concentration, the critical temperature T_1, the dry cracking temperature T_2, and the ignition temperature T_6 were selected. *Figure 4* shows the characteristic temperature changes of non-caking coal powder at the same oxygen concentration and different heating rate.

Table 1. *Characteristic temperature table of coal sample*

Oxygen concentration /%	Heating rate/ °C /min	Critical temperature T_1/°C	Dry cracking temperature T_2/℃	Active temperature T_3/°C	Growth temperature T_4/°C	Thermal decomposition temperature T_5/°C	Ignition temperature T_6/°C	Maximum combustion rate temperature T_7/°C	Burnout temperature T_8/°C
5	5	56.3	118.6	156.3	227.9	264.6	410.0	474.5	585.3
5	10	67.6	128.1	174.5	233.2	297.4	416.8	514.2	661.6
5	15	80.4	135.3	177.1	250.4	307.3	426.7	541.1	772.5
13	5	54.0	91.3	111.3	190.8	271.1	403.3	435.7	524.3
13	10	64.6	132.8	180.6	225.9	279.6	409.9	457.2	566.0
13	15	73.6	150.7	201.3	238.1	290.8	413.8	481.4	590.0
21	5	57.7	139.9	176.9	220.3	269.4	392.9	414.1	536.6
21	10	71.2	161.5	188.5	217.4	289.0	398.9	439.3	542.0
21	15	70.2	176.7	198.4	235.5	292.5	405.6	450.0	544.7

Figure 4(a),(b), and (c) depict the changes of characteristic temperature (critical temperature T_1, dry cracking temperature T_2, and ignition temperature T_6) at the oxygen concentration of 5%, 13%, and 21% under different heating rates of the non-caking coal.

For non-caking coal, with the oxygen concentration constant, the overall trend of the characteristic temperature for the coal sample increases with the increase of the heating rate. Taking the oxygen concentration of 5% as an example, for the coal samples at the heating rate of 5°C/min, the critical temperature was 56.3°C, the dry cracking temperature was 118.6°C, and the ignition temperature was 410.0°C; at the heating rate of 10°C/min, the critical temperature was 67.6°C, the cracking temperature was 128.1°C, and the ignition temperature was 416.8°C; at the heating rate of 15°C/min, the critical temperature was increased to 80.4°C, the dry cracking temperature was 135.3°C, and the ignition temperature was 426.7°C.

By comparing *(a), (b), and (c)* in *Figure 4* it can be clearly seen that when the oxygen concentration is constant, the heating rate affects the characteristic temperature during the combustion of the coal sample in different degrees: dry cracking temperature>critical temperature>ignition temperature. The reason may be that the dry cracking temperature is the temperature point at which the weight loss of the coal sample reaches the maximum before combustion; before this temperature point, the coal powder makes the adsorption/desorption and thermal decomposition reaction internally, and these reactions are more affected by the heating rate. Therefore, the heating rate can directly affect the temperature of the cracking temperature. Besides, the heating rate has little effect on the ignition temperature of the coal sample, because a series of reactions by coal ignition shall cause more volatiles and indicator gases from the coal powder., but the heating rate cannot effectively extend the time and progress of these volatiles and gases reacting with oxygen.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90519064

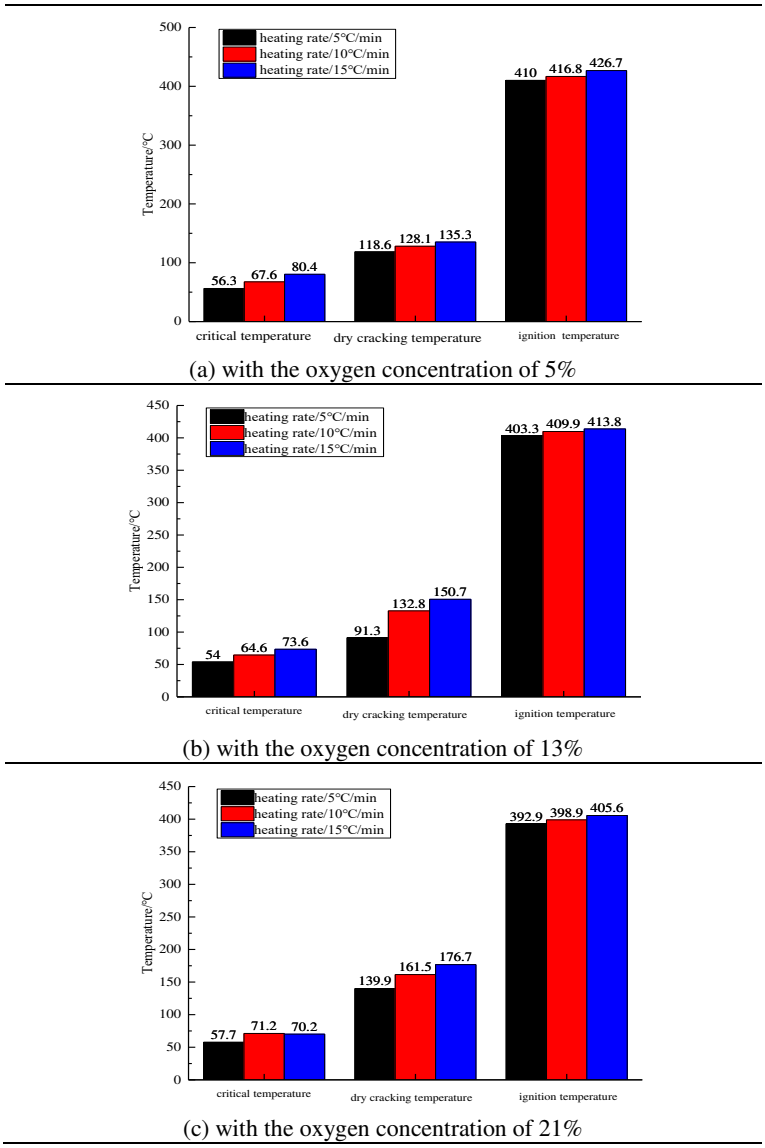


Figure 4. *Characteristic temperature of non-caking coal at the same oxygen concentration and different heating rate*

Figure 5 shows the characteristic temperature changes of non-caking coal powder at the same heating rate and different oxygen concentration. *Figure 5(a),(b), and (c)* show the characteristic temperatures changes of the non-caking coal powder with different oxygen concentrations at the heating rate of 5, 10, and 15°C/min (critical temperature T_1, dry cracking temperature T_2, and ignition point T_6).

Taking the heating rate of 15°C/min as an example, with the oxygen concentration of 5%, the critical temperature of the coal sample was 80.4°C, the dry cracking temperature was 135.3°C, and the ignition temperature was 426.7°C; with the oxygen concentration of 13%, the critical temperature was 73.6°C, the dry cracking temperature was150.7°C, and the ignition temperature was 413.8°C; with the oxygen concentration of 21%, the critical temperature of the coal sample was reduced to 70.2°C, the dry cracking temperature was increased to 176.7°C, and the ignition temperature was lowered to 405.6°C.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90519064

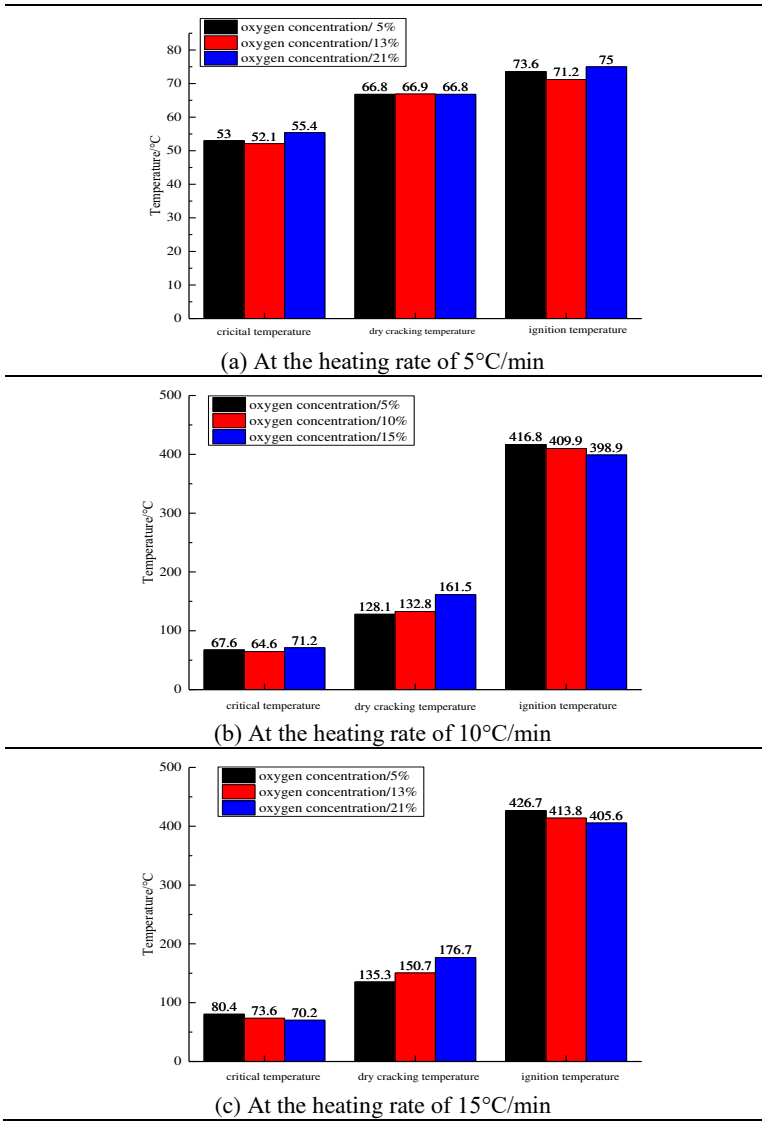

Figure 5. *The characteristic temperature of coal sample in the same heating rate and different oxygen concentration*

By comparing *(a), (b), and (c)* in *Figure 5*, it can be clearly seen that when the heating rate is constant, the oxygen concentration is positively correlated with the dry cracking temperature of the coal sample combustion process, and negatively correlated with the critical temperature and the ignition temperature (Wang et al., 2014). The effect of oxygen concentration on characteristic temperature is: critical temperature<ignition temperature<dry cracking temperature. During the combustion of coal powder before the critical temperature, less of oxygen is required for the counter-reaction is less, so the oxygen concentration has unobvious effects on the change trend of the pulverized coal critical temperature. But the pulverized coal needs to consume a large amount of oxygen for combustion before reaching the ignition temperature, and the oxygen concentration in the environment directly determines the rate of the oxidation reaction, thus, the changes of oxygen concentration have greater effects on the ignition temperature than on heating rate.

Effect of heating rate and oxygen concentration on combustion process of pulverized coal

Effect of heating rate on combustion process of pulverized coal

Under the condition of a certain oxygen concentration, the effect of heating rate on the combustion process of pulverized coal was analysed. Taking the non-caking coal powder under the experimental conditions of 13% oxygen concentration as an example, the TG, DTG and DSC curves at the heating rates of 5, 10, 15°C/min were obtained (*Figure 6*).

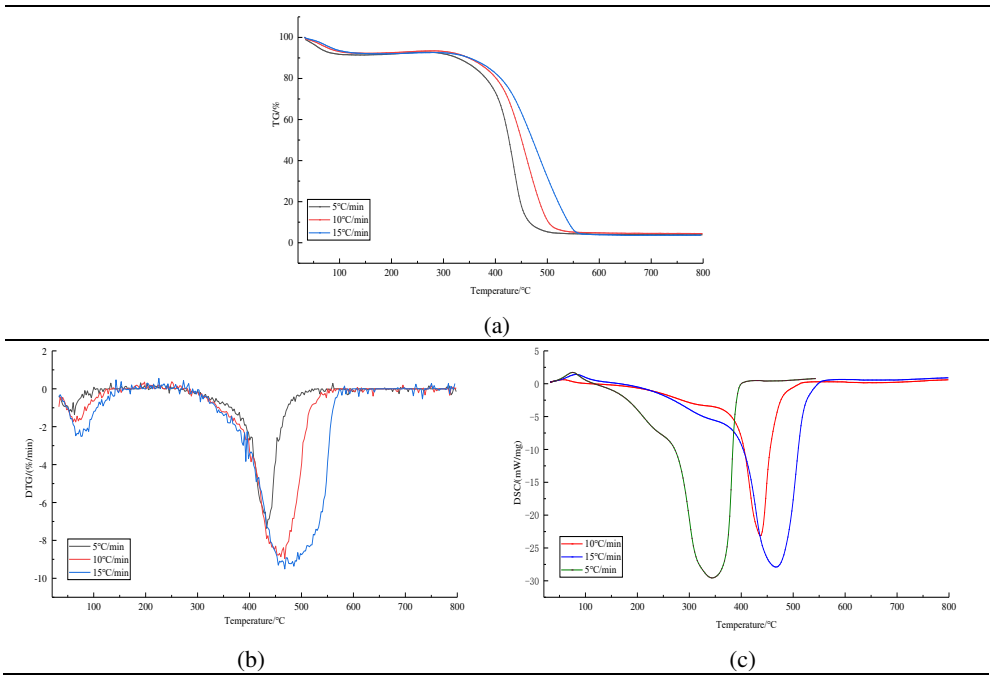

Figure 6. *TG, DTG and DSC curves with oxygen concentration of 13%, heating rate 5, 10 and 15°C/min*

It can be seen from *Figure 6* that under the same oxygen concentration, the heating rate increases continuously, which results in the hysteresis phenomenon of the TG curve. The heating rate can directly determine the temperature of the pulverized coal. However, under the condition of a certain oxygen concentration, the functional groups in the pulverized coal and the structure involved in the pulverized coal combustion reaction cannot all involved in the reaction, and there further occurs the high temperature side shift on the characteristic temperature point of the pulverized coal (Xiao et al., 2007).

It can be seen from the DTG curve that the critical point of the weight loss rate is the ignition point. Before the critical point, the heating rate has little effect on the weight loss rate of coal powder; after the critical point, the effect is more significant. The reason is that the heating rate can prolong or shorten the time of coal and oxygen recombination, and the faster heating rate can cause the non-heterogeneous phase ignition of coal powder, resulting in a longer reaction process. This is expressed as hysteresis in the DTG image.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90519064

The DSC curve shows that the heating rate is positively correlated with the temperature required to reach the maximum exothermic value, which is consistent with the trend of the TG/DTG curve.

Effect of oxygen concentration on combustion process of pulverized coal

Under the condition of constant heating rate, the effect of oxygen concentration on the combustion process of pulverized coal was analysed. Taking the non-caking coal powder under the experimental conditions of heating rate 10°C/min as an example, the TG, DTG and DSC curves with the oxygen concentration of 5, 13, and 21% respectively were obtained (*Figure 7*).

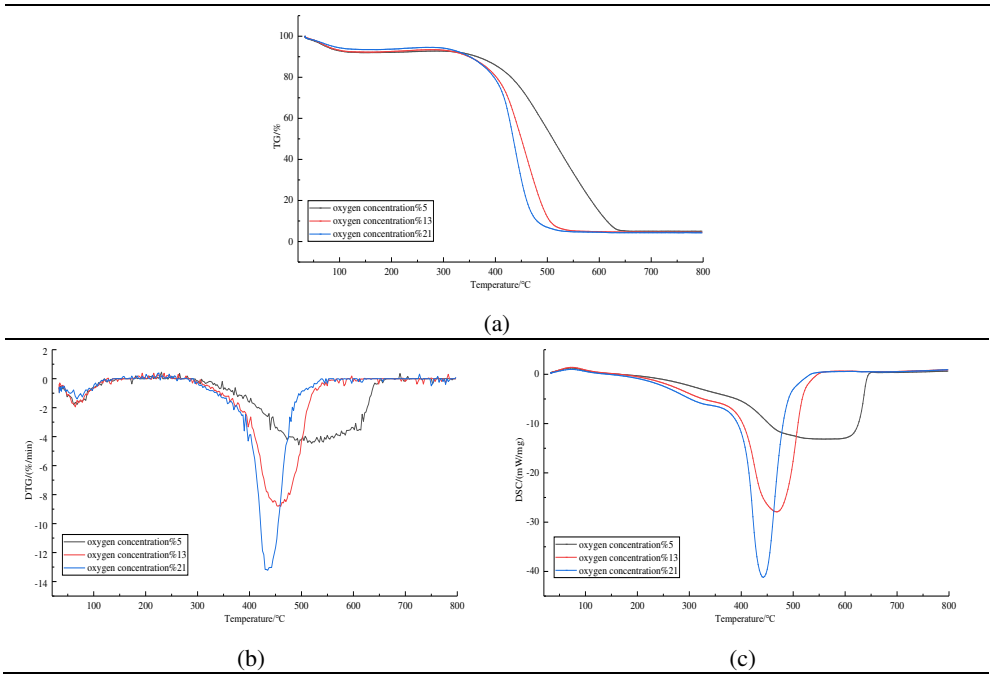

Figure 7. *The results of TG, DTG and DSC curves at the heating rate of 10°C/min, oxygen concentration 5, 13, and 21%*

It can be seen from *Figure 7* that with the heating rate constant, when the oxygen concentration decreases from 21% to 13% and then to 5%, TG, DTG and DSC all show a phenomenon of shifting to high temperature. This is because the oxygen concentration can directly determine the amount of oxygen molecules in the oxidation reaction of coal powder. The greater the oxygen concentration, the more oxygen molecular weight involved in the oxygen reaction of coal powder, which shortens the time required to burn coal samples of the same quality, resulting in a lower reaction temperature.

Discussion

Under the condition of the same oxygen concentration and different heating rate, the characteristic temperature point of non-caking coal samples is shifted to the high temperature point, which is shown as the TG curves will show hysteresis phenomenon with the increase of heating rate. The weight loss rate of coal samples takes the ignition point as the critical point. Before the critical point, the heating rate has little influence on

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90519064

the weight loss rate of coal powder, and after the critical point, the effect is significant. In addition, the heating rate has a promoting effect on the weight loss rate of coal samples, and the maximum exothermic strength increases, which shows the same characteristics as the DSC curves. The higher the heating rate is, the longer the reaction process of the coal sample is, indicating that the higher heating rate leads to the heterogeneous combustion of pulverized coal, which to some extent increases the reaction time.

Under certain heating rate, with the reduction of oxygen concentration of coal sample weight loss rate, the maximum heat strength is reduced, this is due to the decreasing concentration of oxygen in oxidation reaction of oxygen reduction, oxidation of coal sample strength decreased. Moreover, the critical point of coal sample weightlessness with low oxygen concentration move to higher temperature, is largely due to reduced oxygen concentration, lead to slow reaction process.

Heating rate and oxygen concentration will affect the combustion reaction of coal samples. When the oxygen concentration is constant, the key to control the ignition of coal is to reduce the heating rate. Similarly, when the heating rate is constant, the key is to reduce the oxygen concentration for inhibit the development of combustion. Based on the TG experiments with different heating rates and oxygen concentrations, the characteristics of combustion of non-caking coal under two-factor conditions were analysed, so as to control the occurrence of coal combustion, and to reduce the waste of resources and the generation of pollutants.

Conclusions

The combustion process of non-caking coal powder mainly includes the water and weight loss stage of coal, the weight gain oxidation stage, the thermal decomposition stage, the combustion stage and the burnout stage. In the oxidative combustion process of coal samples, the characteristic temperature points of coal samples can be obtained by analysing the TG experimental data, including critical temperature (T_1), dry cracking temperature (T_2), active temperature (T_3), and increasing temperature (T_4), thermal decomposition temperature (T_5), ignition temperature (T_6), DTG maximum weight loss rate temperature (T_7), and burnout temperature (T_8).

The heating rate is positively correlated with the combustion reaction time, characteristic temperature and oxidation reaction rate of pulverized coal. The higher the oxygen concentration, then the shorter the combustion time of the coal sample, the lower its characteristic temperature, and the higher the oxidation reaction rate.

The influence of oxygen concentration on combustion characteristic is more obvious than that of heating rate. Under the condition of high heating rate and oxygen concentration, the maximum exothermic strength of coal sample is the highest, the weight loss is the fastest, and the ignition of the coal is easier.

Due to the diversity of coal types, the TG characteristics of different ranks of coal need to be tested and analysed in future research, so as to reduce resource waste and environmental pollutions, and to prevent spontaneous combustion of coal from damaging ecological environment.

Abstract. In this paper, the numerical simulation method of computational fluid dynamics (CFD) was combined with field experiment to explore the carbon monoxide (CO) diffusion and ventilation in an underground garage. Firstly, a finite-element model was set up for the garage, and used to simulate the CO concentration and air velocity. Then, the simulated results were proved valid against the data of field experiment. After that, a ventilation plan was designed with one fan running for 20 min, three times a day in the rush hours. The simulation results show that this plan could not lower the CO concentration below the required level (30mg/m^3). Thus, the running time of the fan was extended to 30 min per time. It is found that the new ventilation plan could effectively control the CO concentration. Next, the third ventilation plan was developed with two fans running together for 10 min, three times a day in the rush hours, and was proved as valid through simulation. Due to its advantage in power consumption, the third plan was identified as the optimal ventilation plan for the garage. The three-fan or four-fan ventilation plans were not considered because they must be noisier and costlier than the two-fan ventilation plan. Although the structure of underground garages (such as height, area, etc.) is different, most of them are common in high tightness and structural independence. The method mentioned in this study that using the necessary air parameters of measuring points in underground garage to simulate the status of airflow and CO concentration is effective.
Keywords: *underground garage, airflow, pollution diffusion, air quality, numerical simulation*

Introduction

Recent years has seen a growing concern about the air quality in underground garage. In such a highly closed space, it is difficult for the air inside the underground garage to exchange with ground air. The toxic gases emitted by cars in the garage may over-accumulate, such as carbon monoxide (CO), nitrogen oxides (NO_x) and hydrocarbons. Large quantities of harmful gases will reduce the air quality and human body comfort even lead disease or death. And among them, produced CO is more toxic and concentrated than the other harmful gases in process of vehicles cold starting and idle speeding (Chen, 2001). Hence, this paper attempts to control CO concentration by ventilation in order to solve the problem of air quality.

To control CO concentration, the key lies in the relationship between air flow and pollutant distribution, as the air quality in underground garage may vary with the ventilation conditions. So far, this relationship has been mainly explored through field experiment and numerical simulation. The typical field experiments are reviewed as follows.

Xu (2015) investigated the flow field in underground space by tracer gas method, revealing that different ventilation states lead to different distribution of tracer gas. Kierat et

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90659081

al. (2018) applied the same method to assess the exposure of indoor breathing air, and found that the exposure of indoor air pollution is affected by the air flow interaction in the breathing zone. With the aid of federal equivalent method, Zhao et al. (2017) studied the seasonal concentrations of PM 2.5 and other pollutants in underground garage, concluding that natural ventilation alone cannot dilute particles effectively in the residential garage. Targeting a wavy air-water interface, Buckley and Verson (2017) measured the airflow through laser induced fluorescence (LIF) flow visualization and particle image velocimetry (PIV). Zhang et al. (2008) adopted the hydroxybenzene reagent method to capture the concentration of formaldehyde, and discovered that the air quality is severely affected by the emission of materials in the compartments of many compact cars sold in China.

The numerical simulation has been increasingly employed recently, thanks to its low consumption of manpower and materials. The fluid state is usually simulated by the computational fluid dynamics (CFD). For instance, Liu et al. (2019a, 2018, 2016a, b), Yong et al. (2017) studied flow characteristics of gas in a pipe and analyzed the formation mechanism of trailing oil. Kurnia et al. (2014) numerically simulated the methane dispersion in an underground mine. Wang et al. (2016) explored the storage temperature field in a non-ventilated underground granary using the CFD. Choi et al. (2013) relied on the CFD to investigate the hydrogen leakage of cars in underground garage. Papakonstantinou et al. (2003) examined the air quality and CO dispersion of underground garage through the numerical method and experiment. Xue and Ho (2000) set up a model of underground garage and simulated CO diffusion and heat conduction. Wang et al. (2009) simulated the diffusion of dust at underground power house. Widiatmojo et al. (2013) evaluated the gas diffusion of turbulent flow in mine ventilation system by numerical simulation. Hong et al. (2010) studied the influence of branch tunnels on CO diffusion at underground power house. Bai et al. (2016) probed into the flow field of a train running to the rescue station through both experiment and simulation. Wang et al. (2017) simulated and calculated how forced ventilation affects the water spray and dust suppression on the work face of coal mine. Wang and Ren (2013) carried out a CFD analysis on the behavior of dust flow and air flow above an underground bin. Bascompta et al. (2016) and Liu et al. (2019b) tackled the impacts of ventilation layout on the environment using the geographical information system (GIS).

Concerning pollutant distribution and flow field in closed space, the existing studies either resort to CFD simulation or rely on field experiment. There are relatively few studies that combine these two approaches. To make up for this gap, the CFD simulation and field experiment are combined in this paper to discuss the CO concentration at an underground garage. The experimental data help determine parameters of boundary conditions, and verify the availability of the modelling, thus ensuring the simulation accuracy.

Generally, the structure of underground garages is different due to various requirements, however they are common in their special characteristics such as high air tightness and structural independence. Although the results of this real case may not apply to all cases, the proposed method in this paper that combines the CFD and field experiment is proved available. The ventilation analysis of different underground garages only needs to adjust the geometry model and the relevant environmental parameters.

Methodology

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90659081

This paper tackles a real problem in an underground garage within a university of southwestern China's Sichuan Province. The photos and model of the garage are presented in *Figure 1*. The cars in the garage were defined as pollution sources.

As shown in *Figure 1*, the 48 m × 45 m × 3 m (L×W×H) garage has about 200 parking spaces, 3 aisles (b~d) and one secure channel (f). Under pressure difference, a limited amount of fresh air can enter the garage through ventilation shafts (e). The airflow in the garage is driven by the thermal and wind pressures from the natural ventilation system, and the mechanical force of fans.

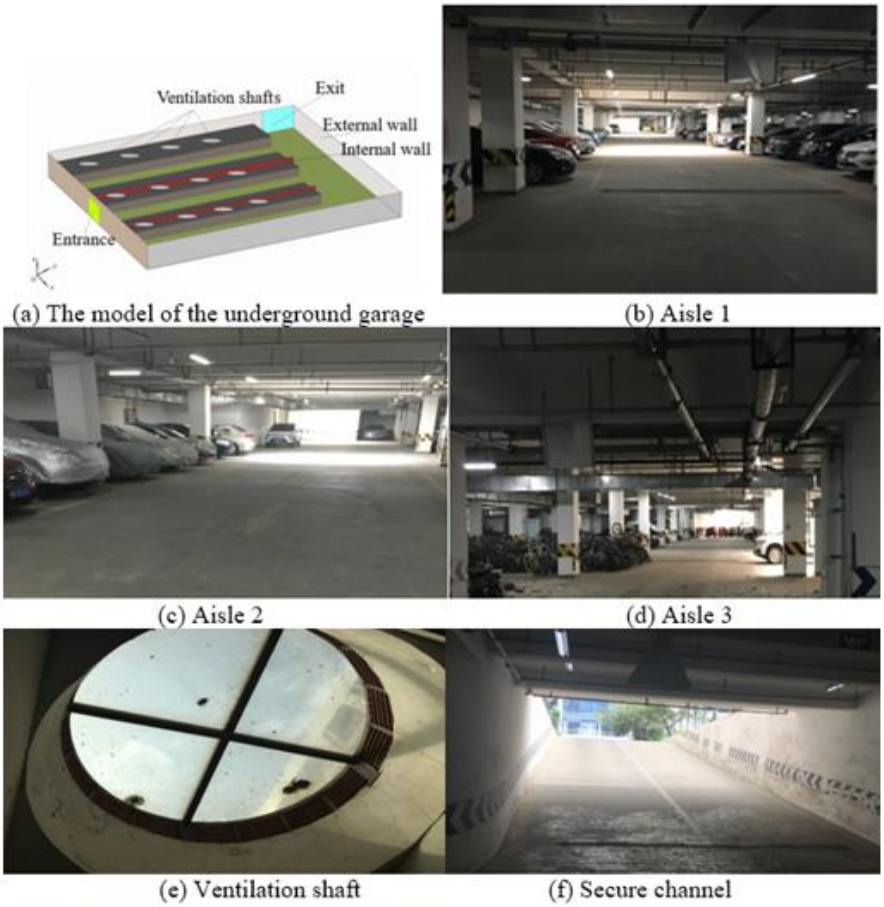

Figure 1. *The model (a) and photos (b~g) of the underground garage*

The measured pressure is positive at each ventilation shaft, and negative at the entrance. This means the fresh air flows into the garage from the entrance and leaves from the shafts. The flowing process is illustrated in *Figure 2*.

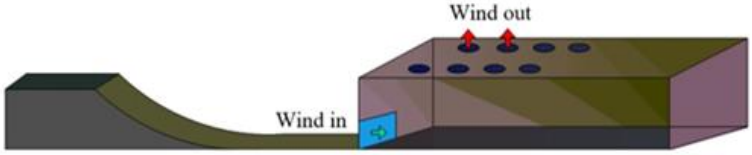

Figure 2. *The flowing process in the underground garage*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90659081

The space of underground garage is divided into three areas by two internal walls with four exhaust fans located in different positions (*Fig. 3*). Each fan runs at 500~750 rpm, propelling 32,000~42,000 m^3 fresh air per hour.

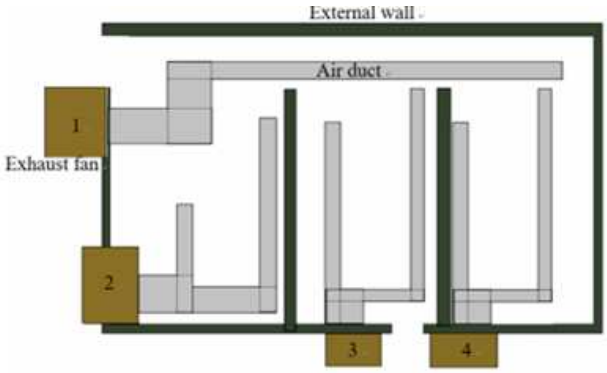

Figure 3. *The layout plan of the underground garage*

In this research, several ventilation conditions were simulated by the CFD, and verified by the experimental data. On this basis, the most cost-effective control plan for CO concentration was selected as the optimal solution.

Field experiment

The underground garage was divided into four areas for measurement, namely, the parking lots (D), secure channel (A), aisles (B), plus the entrance and exit (C) (*Fig. 4*). The CO concentration was measured in rush hours (i.e. 8am, 12pm and 2pm) as well as at 10am and 4pm. The data collected at two hours later were taken as control data.

Figure 4. *The measuring points in the underground garage*

The air velocity and CO concentration were respectively measured by a hot-wire anemometer (error: ± 0.03; range: 0.15~30 m/s) and a Z500XP CO sensor (error: ± 0.05; range: 0~300 ppm) (*Fig. 5*). Before measuring the air velocity, the probe of the hot-wire anemometer should be set perpendicularly to the wind direction. During the measurement, the CO sensor should be turned on and placed at the measuring point for a few minutes.

DOI: http://dx.doi.org/10.15666/aeer/1704_90659081

(a) Hot-wire anemometer (b) CO sensor

Figure 5. *Measuring instruments*

The CO concentration of the aisles must be strictly controlled to protect the health of pedestrians. The three aisles in the underground garage were numbered as aisle 1, aisle 2 and aisle 3. Five measuring points were arranged in the middle of each aisle at an equal interval from the entrance to the exist (*Fig. 6*).

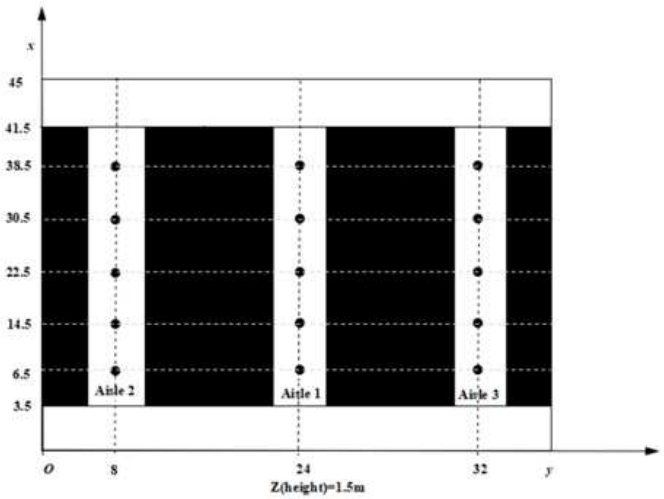

Figure 6. *The aisles and measuring points*

To investigate whether the outside environment will affect the airflow and CO diffusion in the underground garage, air velocity and CO concentration are measured respectively at each measuring point and outdoor for several times in one week. The mean of the five results was taken as the final value, when record the CO concentration, the unit "ppm" was converted into "mg/m^3":

$$\frac{mg}{m^3} = \frac{M}{22.4} \times \text{pp}m \times \frac{273}{273+T} \times \frac{P}{101325} \quad \text{(Eq.1)}$$

where T is the measured temperature; P is the measured pressure (Bar); M is the molecular mass of the measured gas.

The measured data are recorded in *Tables 1* and *2*. The results from *Tables 1* and *2* directly show the CO concentration and air velocity of each measuring point and outdoor. It can be found in *Table 1* that the CO concentration various from 1.8 mg/m^3 to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90659081

2.6 mg/m^3 but the CO concentration of underground garage is much higher. It proofs that CO concentration of underground garage is mainly affected by the parking vehicles, low CO concentration of outdoor cannot greatly affect that of underground garage.

With air velocity ranging from 2.5 to 5.6 m/s, the air flow of each measuring point is stable within 0.5 m/s. This fully demonstrated that the underground garage is a greatly sealed space. Although the environmental factor of outdoor has impact on airflow of underground garage, it affects the entrance and exit which are set as boundary in simulation more. Hence, it is just need change the parameter of boundary condition when simulate the air status of underground garage.

CFD numerical simulation

(1) Governing equations

The governing equations include the conservations of mass and momentum (Dokos, 2017; Su et al., 2019):

Conservation of mass:

$$\frac{\partial P}{\partial \mathrm{t}}+\frac{\partial(\rho \mu_x)}{\partial x}+\frac{\partial(\rho \mu_y)}{\partial y}+\frac{\partial(\rho \mu_z)}{\partial z}=0 \quad \text{(Eq.2)}$$

Conservation of momentum:

$$U_j=\frac{\partial U_i}{x_j}=-\frac{1}{\rho}\frac{\partial \rho}{x_i}+\frac{\partial}{\partial x_i}(vt\frac{\partial U_i}{x_j}-U_iU_j) \quad \text{(Eq.3)}$$

(2) Model selection

There are many CFD models with different functions and applicable scopes.

There are some models can be selected in CFD, the function of each model is different and can be used in various industries. In terms of function, the models were summarized by Varga et al. (2017) standard K-epsilon (k-ε), Re-Normalisation Group (RNG) k-ε, and realizable k-ε. Among them, the standard k-ε model is chosen in our research. The two basic transport equations and the component transport equation of this model can be respectively expressed as:

$$U_j\frac{\partial U_i}{\partial x_j}=\frac{\partial}{\partial x_j}(\frac{vt}{\sigma_k}\frac{\partial k}{\partial x_j})+vt(\frac{\partial U_i}{\partial x_j}+\frac{\partial U_j}{\partial x_i})\frac{\partial U_i}{\partial x_j}-\varepsilon \quad \text{(Eq.4)}$$

$$U_j\frac{\partial \varepsilon}{\partial x_j}=-\frac{\partial}{\partial x_j}(\frac{vt}{\sigma_k}\frac{\partial k}{\partial x_j})+\frac{\varepsilon}{k}\left[C_{\varepsilon 1}vt(\frac{\partial U_i}{\partial x_j}+\frac{\partial U_j}{\partial x_i})\frac{\partial U_i}{\partial x_j}-C_{\varepsilon 2}\varepsilon\right] \quad \text{(Eq.5)}$$

$$\frac{\partial \mu_j}{\partial x_j}=\frac{\partial}{\partial x_j}D\frac{\partial C_i}{\partial x_j}-C_{\varepsilon 2}\varepsilon \quad \text{(Eq.6)}$$

where μ_x, μ_y and μ_z are the velocity component in the x, y and z directions, respectively (m/s); t is the time(s); ρ is the density (kg/m^3); i and j are the serial number of the three directions and the 3D coordinates (i = 1, 2, 3; j = 1, 2, 3); U_j is the mean velocity of the three directions; μ_i and μ_j are the pulsating velocity components of different directions; V_t is turbulence viscosity coefficient; C_i is the per-unit CO concentration; S_i is the pollution source; D is the diffusion coefficient (m/s).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90659081

(3) Computational domain and meshing

Since its birth in 1953, numerical simulation has been steadily improved. In 1973, Bruce and Peaceman simulated the 1D unsteady and radial flow of the gas phase. With the rapid development of computer science, the CFD has proliferated rapidly to various industries. Considering its complex structure, the underground garage was simplified into a collection of regular geometric figures. The parking spaces and internal walls were treated as equal size rectangles, while the ventilation shafts were considered as equal size circles. The entire garage was meshed into 224,094 tetrahedral grids (*Fig. 7*).

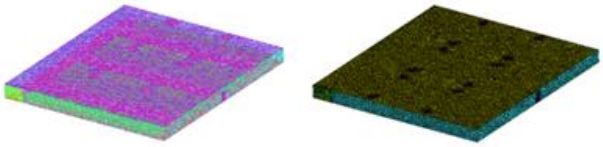

Figure 7. *The grid model of the underground garage*

(4) Boundary conditions and gas components

The entrance, the exit and the ventilation shafts were considered as velocity boundaries. The air velocity measured at such boundaries was 1 m/s in the experiment. The rectangles in the grid model, which represent the parking spaces, are set as pollution sources. The standard wall function was adopted.

The parameter of fluid (i.e. the gas components in underground garage) are necessary, owing to the use of the component transport equation in the simulation. The gas components be added were determined as CO, CO_2, N_2, O_2 and water vapor. The parameter of each gas component was set to be same as the air, except CO and CO_2, which is a source of pollution. The mass diffusivity of CO was obtained from the test: 1.0368 m^2/h.

After defining the boundary conditions, the CO concentration and air velocity were simulated under natural ventilation. Since the breathing height of a person is about 1.5 m, the plane of "axis z = 1.5 m" was selected to output the simulation results.

Results and discussion

Validation and analysis

The simulation results were verified against the data of field experiment, aiming to verify that they are not outliers.

(1) Validation of air velocity

Figure 8 shows the contour of the simulated air velocities and *Figure 9* presents the simulated air velocities of each aisle. Obviously, aisle 1, which is the closest to the entrance, had the fastest air velocity among all aisles. Besides, the air velocity decreased with the growth in the distance to the entrance. In aisles 2 and 3, the air velocities were stabilized between 0 m/s and 0.5 m/s.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90659081

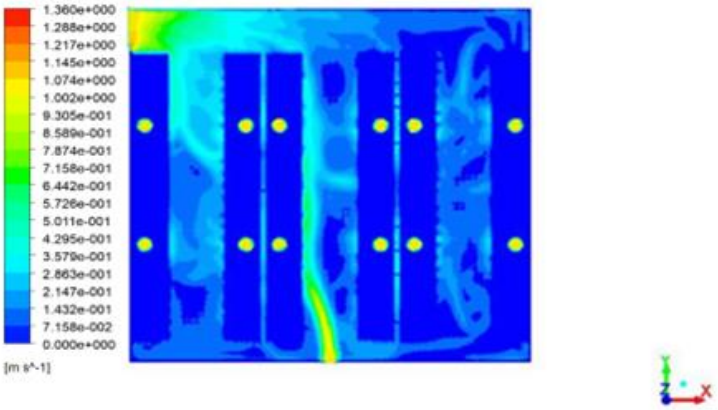

Figure 8. *Contour of air velocity (m/s)*

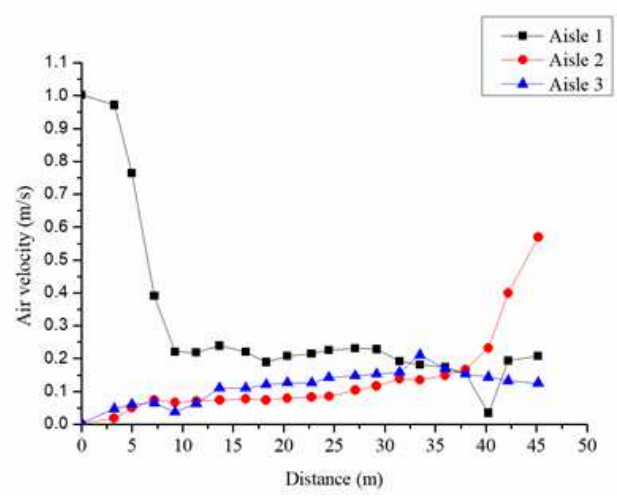

Figure 9. *Simulated air velocity of each aisle (m/s)*

Figure 10 compares the simulated data and experimental data on the air velocity at each measuring point of each aisle. During the experiment, the air velocity of each aisle was measured at 12 points, which were arranged at an equal interval from the entrance to the exit. Distance on the transverse axis of the figures below is the distance between measuring point and wall of where secure channel located. Each experimental value was taken from the mean of five repeated measurements. As shown in *Figure 10*, the simulation error is obviously acceptable.

(2) Validation of CO concentration

The CO concentration of the underground garage was simulated under natural ventilation. The simulated results are shown in *Figures 11* and *12*.

During the field experiment, the CO concentration at each of the five measuring points of each aisle was measured at the five time points of 8 am, 10 am, 12 pm, 2 pm and 4 pm, and compared with the corresponding simulated value. The measured CO concentrations of each area and the rush hour CO concentrations at each measuring point are listed in *Tables 3* and *4*, respectively.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90659081

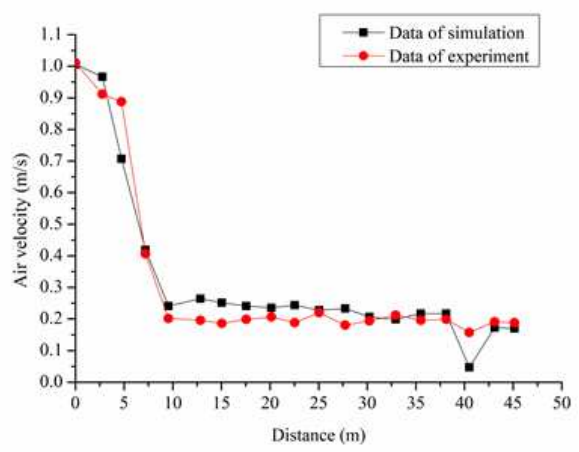

Figure 10. *Simulated air velocities vs. experimental air velocities*

Figure 11. *Contour of simulated CO concentration (mg/m^3)*

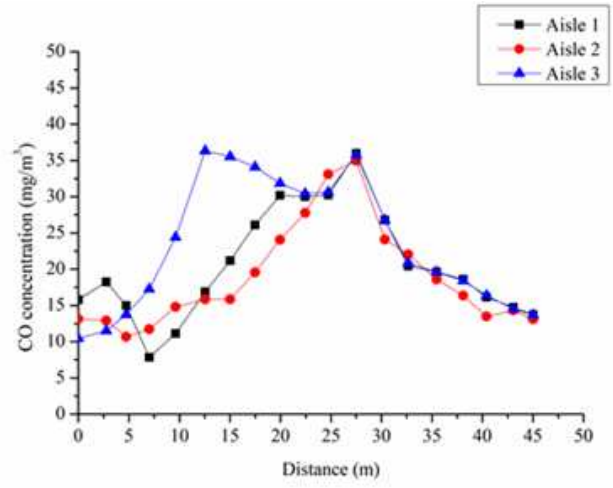

Figure 12. *Simulated CO concentration of each aisle (mg/m^3)*

In rush hour 8 am, 12 am, and 2 pm, the CO concentration in B and D increased obviously, but in A and C, the CO concentration changed slightly. This is because the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90659081

area A and C is close to the outside and is easier to obtain the gas exchange. Area B is the pollution source and the CO concentration in area B that consists of three aisles is major object in the analysis. By comparing the data from *Tables 3* and *4*, it is obtained that in the underground garage, the CO concentration of measuring points will be affected by the inlet and outlet. Hence, the CO is mainly distributed in center underground garage which means the max CO concentration appears in this area.

Table 3. *The CO concentration in different areas (mg/m^3)*

Areas	8am	10am	12pm	2pm	4pm
A	17	15	20	16	21
B	42	32	40	44	31
C	14	13	15	14	12
D	40	32	38	42	33

Table 4. *The rush hour CO concentration at each measuring point (mg/m^3)*

Areas	Point 1	Point 2	Point 3	Point 4	Point 5
Aisle 1	35	33	40	30	25
Aisle 2	13	20	30	25	18
Aisle 3	15	20	30	25	20

As can be seen in *Table 4*, the CO concentration was higher in aisle 1 than in the other two aisles. The CO level in aisle 1 was above the required level of 30 mg/m³, indicating that more fresh air should be introduced to this aisle. The simulated and experimental data of the three aisles are compared in *Figures 13–15*.

The above figures show that the simulated data of each aisle deviated from the experimental data by only 5~20%, far lower than the allowable error (20%) for engineering application. Thus, the simulation results are proved as valid.

Discussion of the ventilation plan

The key to mechanical ventilation lies in the wind volume, which is positively correlated with the running time of the fan. If the fan works continuously for the entire day, the pollutants can absolutely be emptied, leading to a better air quality. However, the prolonged operation of the fan will produce lots of noises and consumes much energy and money. Thus, it is very important to determine the running time of the fan.

The simulated data show that the CO concentration in most areas of the garage was below the required level of 30 mg/m^3, except the central part. Besides, aisle 1 had a higher CO concentration than the other aisles. Therefore, the next step is to simulate the operation of fan 3#, which is responsible for ventilating aisle 1. The running time of the fan was determined by the air volume needed to maintain the air quality in the garage:

$$G = \frac{3600M}{C_2 - C_1} \quad \text{(Eq.7)}$$

where M is the CO volume; C_2 is the maximum CO concentration; C_1 is the minimum CO concentration. M can be calculated as:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90659081

$$M = n \times r \times q \times t \quad \text{(Eq.8)}$$

where n is the number of cars; r is the frequency of cars entering the garage; q is the CO volume released per car; t is the operating time of each car in the garage. The value of M was calculated as 5,304 g and the air volume needed to maintain the air quality in the garage was determined as 53,040 m^3.

The running time was set empirically to 20 min, three times per day in the rush hours, for the following reasons: the CO concentration under natural ventilation is only slightly above the required level; it is unknown how long the fan must run before the CO concentration falls below the required level. Moreover, the outlet of the fan was set as the velocity boundary with the velocity of 6 m/s. Under these conditions, the author performed a simulation on the mechanical ventilation and analyzed whether the CO concentration can meet the required level in rush hours. The simulated CO concentrations are illustrated in *Figures 16* and *17*.

As shown in the figures above, when the fan ran for 20 min, the CO concentration of the whole garage was controlled effectively, except for some points in aisle 1 (> 30 mg/m^3). Thus, the running time of the fan was extended to 30 min each time for another simulation. The simulated CO concentrations are displayed in *Figures 18* and *19*.

The above figures show that, when the fan ran for 30 min, the CO concentration of each aisle was controlled below the required level. The airflow of one fan in operation is different from that of several fans operating together. However, it is unnecessary to turn on all the fans in the garage at the same time, because the CO concentration is only slightly above the required level. Considering that aisle 3 had denser CO than aisle 2, the author continued to simulate the CO concentration in the garages with fan 3# (aisle 1) and fan 4# (aisle 3) running for 10 min, three times a day in the rush hours. The simulated CO concentrations are displayed in *Figures 20* and *21*.

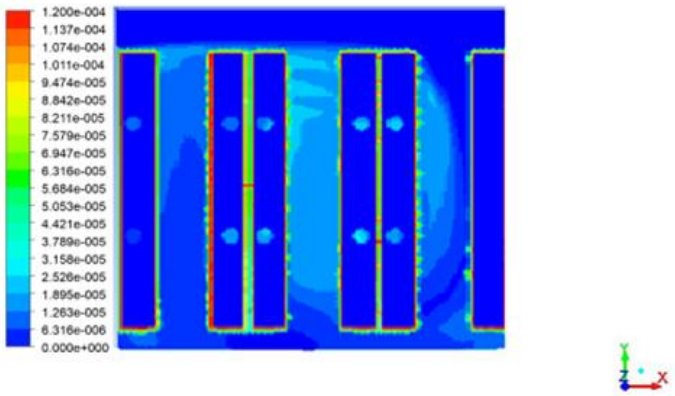

Figure 16. *The contour of CO concentration (20 min; 1 fan)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90659081

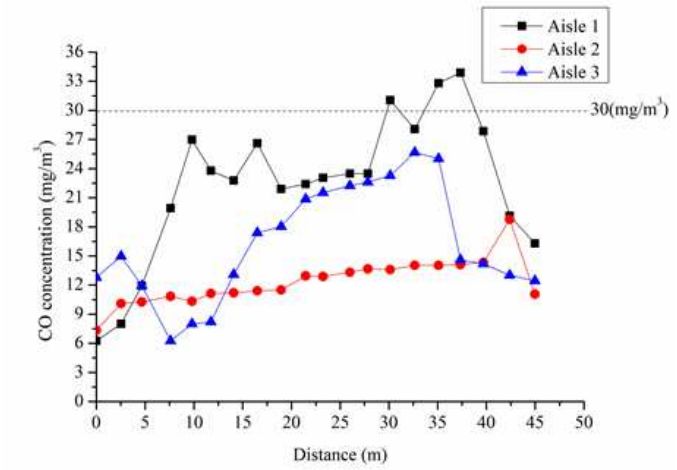

Figure 17. *The CO concentration of each aisle (20 min; 1 fan)*

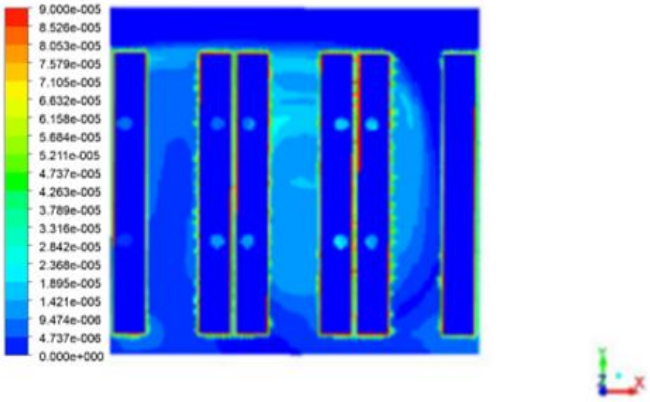

Figure 18. *The contour of CO concentration (20 min; 1 fan)*

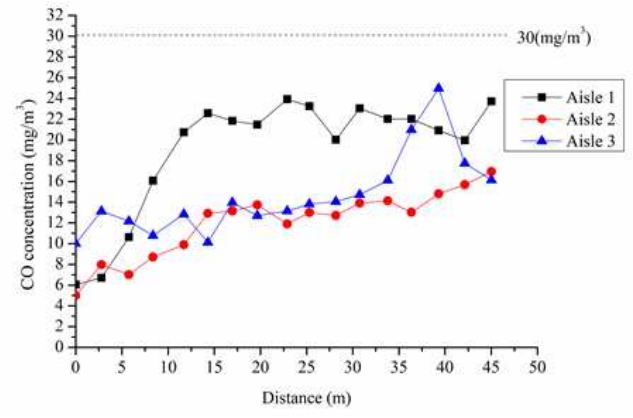

Figure 19. *The CO concentration of each aisle (30 min; 1 fan)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90659081

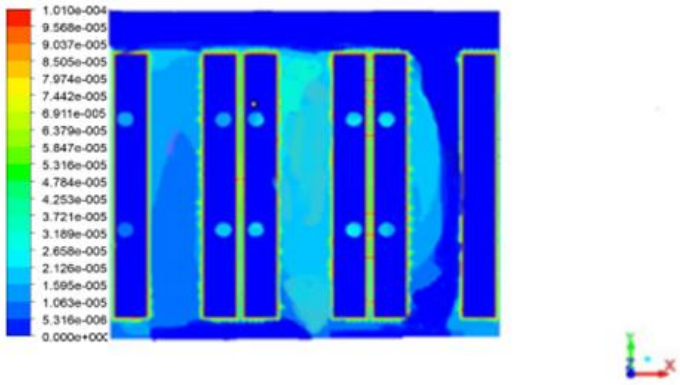

Figure 20. *The contour of CO concentration (10 min; 2 fan)*

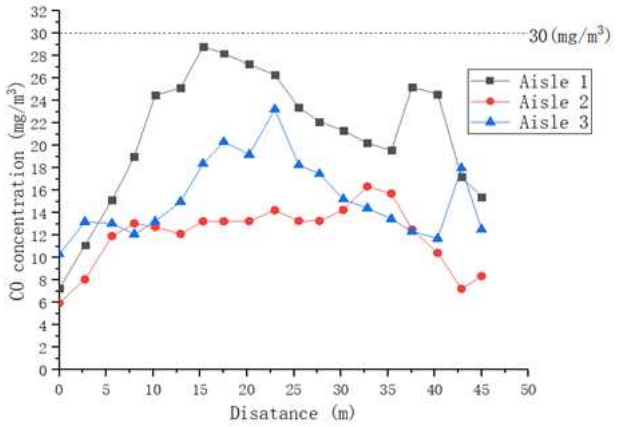

Figure 21. *The CO concentration of each aisle (10 min; 2 fan)*

As can be seen from the above figures, when the two fans ran 10 min together, the CO concentration of each aisle was below the required level, indicating the two-fan ventilation plan is satisfactory. The same ventilation effect can also be achieved through the simultaneous operation of 3 or 4 fans for a shorter time. The three-fan or four-fan ventilation plans were not considered because they must be noisier and costlier than the two-fan ventilation plan. Moreover, according to the nameplate of the fans, the power of each fan is about 24 kw, it means that this ventilation scheme can save about 1.44×10^4 kJ electricity power comparing with another scheme.

Compared with other studies about ventilation in underground garage, the method used in this paper that combining field experiment and simulation is more convenient and effective. In practical cases, more measurements make the analysis more accurate. However, measuring at the necessary area and using the measuring data into the simulation, then carrying out analysis with the finite element method is simpler and effective. Although error of numerical simulation cannot be avoided, confine it in a low range by optimizing the grid and choosing an appropriate algorithm can solve this problem.

Conclusions

This paper combines numerical simulation with field experiment to study the pollutant diffusion and ventilation of an underground garage. Firstly, a numerical model was established to explore the diffusion features of pollutants under natural ventilation, and several ventilation plans were designed. After that, the flow field of the garage was investigated with the entrance, exit and ventilation shafts being considered as velocity boundaries, the air in the garage as an incompressible fluid, and the state of air flow as a turbulent flow. The simulated results show that the CO concentration of the garage was slightly above the required level (30 mg/m^3).

Considering the rated capacity of each exhaust fan, the first ventilation plan was designed to let one fan run for 20 min, three times a day in the rush hours. This plan was found to lower the CO concentration, but not below the required level. Thus, the second plan was designed to increase the running time to 30 min per time. The simulation results show that the second plan reduced the CO concentration in each aisle below the required level, indicating that this plan is satisfactory. Similarly, the third plan was simulated with two fans running together for 10 min per time, and proved satisfactory as well. This plan is enough for the ventilation of the garage because the three-fan or four-fan ventilation plans must be even noisier and costlier. The second and third ventilation plans were further compared. The third plan, i.e. the two-fan plan, was selected as the optimal ventilation plan, because it consumed 33% fewer power.

Abstract. This paper aims to enhance the accuracy and reduce the cost of the fusion of multi-source remote sensing data. For this purpose, the existing multi-source remote sensing data fusion methods were reviewed in detail. Then, a new back propagation (BP) neural network (BPNN) fusion algorithm for the groundwater was put forward based on hybrid soft computing. Using the function approximation ability of BP neural network, it was combined with the Kalman filter to form an optimization method. The BP neural network was coupled with the particle swarm optimization (PSO) algorithm into the PSO-BPNN-EKF data fusion algorithm. On this basis, the least squares support vector machine (LSSVM) was introduced to create the LSSVM-PSO data fusion algorithm. Through simulation experiments, it is learned that the proposed algorithm can effectively fuse the multi-source remote sensing data on groundwater, especially in the case of big data. The research findings shed a new light on the fusion of remote sensing data collected by multiple sensors.
Keywords: *groundwater, Kalman filter, data fusion, particle swarm optimization, hybrid soft computing*

Introduction

Back propagation (BP) neural networks (BPNNs) are neural network models based on the cross section of machine learning and neural networks. BP neural networks are computing systems vaguely inspired by the biological neural networks that constitute animal brains (Costantiti et al., 1997). A BPNN is based on a collection of connected units or nodes called artificial neurons which loosely model the neurons in a biological brain. Each connection, like the synapses in a biological brain, can transmit a signal from one artificial neuron to another. For any remote sensing platform, it is impossible to fully reflect the features of the ground target through the remote sensing data acquired by a single sensor. Facing multi-source spatial data, the geographic information system (GIS) data acquisition has become a popular choice. However, the resulting data resources differ in coordinate system, scale standard and storage format, making it difficult for data integration and sharing. The traditional data fusion algorithm requires a more accurate mathematical model of the object, which is not suitable for complex models, by using BP neural network algorithm to realize multi-sensor data fusion, the prior requirement of object is not high, and it has strong adaptive ability (Pohl and Van Genderen, 1998). Against this backdrop, the researchers on remote sensing have paid much attention to the removal of redundancy in data acquired by multiple sensors and improve data fusion and sharing. In light of this, this paper attempts to develop an effective multi-source remote sensing data fusion technology based on BP neural network, using BP neural network to fuse sensor data can improve the stability and accuracy of sensors.

DOI: http://dx.doi.org/10.15666/aeer/1704_90839095

Traditional neural network training algorithm is slow in convergence and easy to fall into local optimum. In recent years, swarm intelligence optimization algorithms such as particle swarm optimization (algorithm) have better global convergence performance and can be used to train neural network parameters and structures. This model mechanistically reflects the natural process but fails to reflect the interaction between man and nature. To solve the problem, the data fusion technology, a desirable tool for estimation and identification, can be introduced to the model, allowing the timely and reliable acquisition of multi-format information from multiple sources like experts and the multimedia. Currently, the key data fusion technologies include the estimation technique, fuzzy set theory, clustering analysis, template method, human-computer interaction, expert system, multimedia technology, neural network method, distributed database technology and parallel processing technology (Li et al., 2018; Neelapu et al., 2018; Bhoi, 2017; Li, 2017; Liu and Xu, 2017; Hu et al., 2017; Zhang et al., 2010). Coupled with geophysical and geological databases, these technologies can increase the constraint recognition of in remote sensing applications, allowing them to describe the spatial geometry of the target from different aspects.

For efficient and accurate multi-source remote sensing data on groundwater, this paper creates a BP neural network fusion algorithm. Specifically, the extended Kalman filter (EKF) was adopted to sample the prior information and coupled with the particle swarm optimization (PSO) model and BP neural network (BPNN) into the PSO-BPNN-EKF data fusion algorithm. On this basis, the least squares support vector machine (LSSVM) was introduced to create the LSSVM-PSO data fusion algorithms.

Materials and methods

Neutral network data fusion methods

Neural network model

The typical three-layer neural network model is given in *Figure 1,* BPNN is a multi-layer feedforward network trained according to error back propagation algorithm. This algorithm can learn and store a great deal of mapping relations of input-output model, without the need to disclose in advance the mathematical equation that describes these mapping relations. The learning rule is to adopt the steepest descent method in which the back propagation is used to regulate the weight value and threshold value of the network to achieve the minimum error sum of square (Li et al., 2018). The structures of the BP neural networks are relatively mature in both network theory and performance. The distinctive advantage is that it has a strong nonlinear mapping capability and flexible network structure. In this paper, the BPNN is optimized using the PSO to speed up the convergence and avoid the local minimum trap.

Optimization of neural network parameters

The error correction algorithm is often used in the training process of feedforward neural networks. The most typical error correction algorithm is BP algorithm. The algorithm first generates a set of weights randomly, and then calculates the weight correction by gradient descent method until the training error reaches the target precision range. But the most obvious defect of this algorithm is slow convergence and sometimes even no convergence.

DOI: http://dx.doi.org/10.15666/aeer/1704_90839095

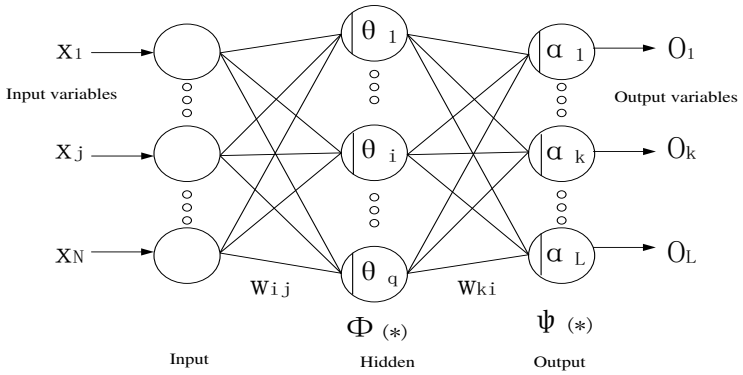

Figure 1. *Structure diagram of three-layer neural network model*

This paper used the optimization of neural network parameters translation method to build the training dataset. Using BP neural network's function approximation ability, BP neural network and Kalman filter are combined to form an estimator, which can make full use of sensor information from different noise pollution, improve estimation performance while maintaining estimation. The filtered computational structure is as simple as possible. Before network training, we must first normalize the data to ensure that the output of the network layer is not too small. What the initial value of the center vector p_i is determined by training samples, and where the $p_i = (p_{i1}, p_{i2}, p_{i3}, p_{i4},)$. If it belongs to the training sample set of the first kind of data change, It is represented as $\{S_1, S_2,\ldots, S_m\}$, and the initial value of each element in the centre vector p_1 is the average value of each element in the input vector of these samples. Firstly, take the logarithm of the sensor information from different noise pollution data which is denoted as is shown in *Figure 2*.

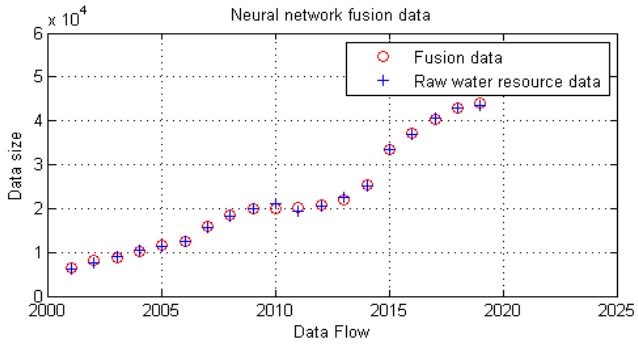

Figure 2. *Neural network fusion data*

KF data fusion

The traditional filtering algorithms mainly target the state variables of the system to be processed. Their performance depends on the system model, the input signal and the measured signal (Ryu and Huber, 2007). For these algorithms, form transformation is required to get the estimates of model parameters. In other words, the state equation and output equation need to be transformed from the standard form via bit filtering, with unknown parameters as the state variables. The transformation equation can be expressed as *Equation 1:*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90839095

$$\begin{cases} x = ax + 1 \\ y = z \end{cases} \Rightarrow \begin{cases} \begin{bmatrix} x \\ a \end{bmatrix} = \begin{bmatrix} ax \\ 0 \end{bmatrix} + \begin{bmatrix} 1 \\ 0 \end{bmatrix} \\ y = \begin{bmatrix} 1 & 0 \end{bmatrix} \begin{bmatrix} z \\ a \end{bmatrix} \end{cases} \quad \text{(Eq.1)}$$

In a dynamic environment, the Kalman filter is often employed thanks to its real-time integration of data. The filter can describe linear differential equations of a discrete-time system. Let $x \in R^n$ be the state variables. Then, the state equation can be expressed as *Equation 2:*

$$x_k = f_k(x_{k-1}, \mu_{k-1}, \omega_{k-1}) + a_{k-1} \quad \text{(Eq.2)}$$

The measured variables $z \in R^m$ can be obtained as *Equation 3:*

$$z_k = h_k(x_k, \nu_k) + \beta_k \quad \text{(Eq.3)}$$

In the above equations, a_{k-1} is the system noise at time *k–1*; β_k is the measured noise; ω_k and v_k are two random variables representing the excited noise and the observed noise, respectively; μ_k and ω_k are the noises of the driving function and zero-mean normalization, respectively; x_k and z_k are the nonlinear functions of the state variables and measured variables, respectively.

The EKF is an extension of the Kalman filter. The basic idea of the EKF is to convert nonlinear vector function *f*(.) and nonlinear system model *f*(.) into linear filter values. Following this train of thoughts, *Equations 2* and *3* can be expanded into a Taylor series (*Eq. 4*) to obtain the linear model of the system. Then, the basic equations of the Kalman filter can be applied to solve the nonlinear filtering problem.

$$\begin{cases} x_k = f_k(x_{k-1}, \mu_{k-1}, \omega_{k-1}) + \dfrac{\partial f(x)}{\partial x} \Big| x = x_{k-1} + \alpha_{k-1} \\ z_k = h_1(x_k) + \dfrac{\partial f(x)}{\partial x} \Big| x = x_k + \beta_k \end{cases} \quad \text{(Eq.4)}$$

Particle swarm optimization algorithm

The PSO is a computational method that optimizes a problem by iteratively trying to improve a candidate solution with regard to a given measure of quality. It solves a problem by having a population of candidate solutions, here dubbed particles, and moving these particles around in the search-space according to simple mathematical formulae over the particle's position and velocity. Each particle's movement is influenced by its local best-known position but is also guided toward the best-known positions in the search-space, which are updated as better positions are found by other particles. This is expected to move the swarm toward the best solutions (Quiroga et al., 2013). Below is a brief description of the standard PSO algorithm.

Suppose there are a *d*-dimensional search space and a population containing N_p particles. Let $x_i^t = (x_{i1}^t, x_{i2}^t, \ldots, x_{id}^t)$ be a *d*-dimensional vector representing the initial position of particle *i* of the *t*-th generation, let the vector $v_i^t = (v_{i1}^t, v_{i2}^t, \ldots, v_{id}^t)$ be the velocity of particle *i*, i.e., the rate of change in the position, and let

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90839095

$p_i^t = (p_{i1}^t, p_{i2}^t, \ldots, p_{id}^t)$ be the best known position of particle i of the t-th generation. Then, the velocity and position of particle i can be obtained by updating *Equations 5* and *6* below.

$$v_{ij}(t+1) = \omega \cdot v_{ij}(t) + c_1 \cdot rand1_{ij} \cdot (pbest_{ij}(t) - x_{ij}(t) + c_2 \cdot (gbest_j(t) - x_{ij}(t) \quad \text{(Eq.5)}$$

$$x_{ij}(t+1) = x_{xj}(t) + v_{ij}(t+1) \quad \text{(Eq.6)}$$

where t is the iteration number; ω is the inertia coefficient; c_1 and c_2 are acceleration coefficients; $rand_1$ and $rand_2$ two uniformly-distributed random independent numbers in [0, 1]. The values of ω, c_1 and c_2 value should be determined according to the specific problem.

The performance of the PSO can be greatly enhanced if ω decreases linearly with the increase in the number of iterations as *Equation 7:*

$$\omega = \omega_{\min} + (iter_{\max} - iter) \times (\omega_{\max} - \omega_{\min}) / iter_{\max} \quad \text{(Eq.7)}$$

where ω_{min} and ω_{max} are the maximum and minimum weighting factors, respectively; $iter$ is the current iteration number; $iter_{max}$ is the maximum number of iterations. The flight speed v_i falls between the maximum and minimum weighting factors. This constraint condition ensures the convergence to the optimal solutions and improves the global search ability of the PSO.

LSSVM data fusion methods

The SVM (Jalalkamali et al., 2011) is a supervised learning model with associated learning algorithms that analyze data used for classification and regression analysis. It is known for its excellent generalization in the case of small samples. The SVM learning has been commonly used for the analysis on spatial data (Babaoğlu et al., 2010; Awan et al., 2013). The traditional SVM aims to solve convex quadratic optimization problems. However, the kernel matrix of the SVM has to occupy a large storage capacity, and the solution becomes less efficient when the sample size is excessively large. For this reason, the LSSVM (Zhang, 2011; Üstün et al., 2005) has been developed to improve the optimization effect. The new model replaces the traditional inequality constraints with an equality equation in the construction of the optimal objective function. Thus, the optimization process is transformed into the solution of a set of linear equations. In this way, the LSSVM achieves twice the efficiency of the traditional SVM. Despite the reduced cost, the LSSVM faces the loss of sparsity of the traditional method, owing to the use of ε - insensitive loss function.

Suppose there is a sample containing n training sets $\{(x_1,y_1),(x_2,y_2),\ldots,(x_N,y_N)\}$, where $x_k \in R^p$ the k-th input vector is. Assuming that the dataset is linearly separable, there must exist a linear classifier $y(x) = \omega^T \varphi(x) + b$ in the input space. If an optimization problem is nonlinear and separable, a nonlinear function φ(.) can be adopted to map the

raw data space into a high-dimensional feature space, before looking for the classification surface-dimensional feature space $y(x) = \omega^T\varphi(x) + b$.

To obtain the optimal high-dimensional plane, the inequality equation needs to be introduced to the traditional SVM as *Equation 8:*

$$\begin{aligned} &\min_{w,b,\gamma} \quad -\gamma \\ &s.t \qquad y_i(<w,x_i>+b) \geq \gamma, i=1,...,\xi \\ &\|w\|^2 = 1 \end{aligned} \tag{Eq.8}$$

where γ is the spacer; ξ is the number of training samples; x_i is the vector of the i-th training sample; w is the weight vector; b is the threshold; y_i are the marked samples ($y_i = \begin{cases} 1 & x_i \in \omega_1 \\ -1 & x_i \in \omega_2 \end{cases}$); ω_i is the class of the i-th sample.

Then, the Lagrange function can be established as *Equation 9:*

$$\begin{aligned} L(w,b,\gamma,a,\lambda) = \\ -\gamma - \sum_{i=1}^{\xi} a_i[y_i(\langle w,x_i\rangle + b) - \gamma] \\ +\lambda(\|w\|^2 - 1) \end{aligned} \tag{Eq.9}$$

Unlike the traditional SVM, the LSSVM is built with equality constraint instead of the inequality constraint. Hence, the optimization problem can be expressed as *Equation 10:*

$$\begin{aligned} &\min_{w,b,\xi} J(w,b,\xi) = \frac{1}{2}w^T w + \frac{\gamma}{2}\sum_{i=1}^{N}\xi_i^2 \\ &s.t \quad y_i[w^T\varphi(x_i) + b] = 1 - \xi_i, i = 1,2...,N \end{aligned} \tag{Eq.10}$$

Then, the structure of the Lagrangian dual problem can be expressed as *Equation 11:*

$$L = J - \sum_{j=1}^{N} a_k\{y_k[w^T\varphi(x_k) + b] + \xi_i - 1\} \tag{Eq.11}$$

According to the optimization conditions, the partial derivatives of w, b, ξ and a can be obtained as *Equation 12* and set to zero.

$$\begin{cases} w = \sum_{i=1}^{N} a_i y_i \varphi(x_i) \\ \sum_{i=1}^{N} a_i y_i = 0 \\ a_i = \gamma\xi_i \\ y_i[w^T\varphi(x_i) + b] - 1 + \xi_i = 0 \end{cases} \tag{Eq.12}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90839095

Under the above conditions, the kernel function can be defined as $k(x_i,y_i) = \psi(x_i)\psi(y_i)$. Then, the optimization problem can be transformed into solving the linear equations as *Equation 13*.

$$\begin{bmatrix} 0 & 1 & ... & 1 \\ 1 & k(x_1,x_1) & \dots & k(x_1,x_N) \\ \vdots & \vdots & \vdots & \vdots \\ 1 & k(x_N,x_1) & \cdots & k(x_N,x_N)+1/c \end{bmatrix} \begin{bmatrix} b \\ a_1 \\ \vdots \\ a_N \end{bmatrix} = \begin{bmatrix} 0 \\ y_1 \\ \vdots \\ y_N \end{bmatrix} \quad \text{(Eq.13)}$$

The above linear equations can be solved by the LSSVM classifier as *Equation 14:*

$$f(x) = sign(\sum_{i=1}^{N} a_i y_i K(x,x_i) + b) \quad \text{(Eq.14)}$$

The radial-basis function (RBF) can be selected as the kernel function, as *Equation 15:*

$$k(x_i, y_i) = \exp(\frac{-1\|x_i - y_i\|^2}{2\sigma^2}) \quad \text{(Eq.15)}$$

Based on these parameters, the penalty factor C and kernel function parameters σ can be obtained through the common optimization procedure.

BP neural network data fusion model

Soft computing was proposed by Prof. Zadein in the 1990s to solve uncertainty problems through fuzzy and intelligent technologies. The method is capable of tackling one or more complex datasets in realistic environment. Unlike traditional hard computing, soft computing does not pursue the exact solution, considering the inaccuracies in real-world problems and the high cost of the traditional method (Zhang et al., 2013). Instead, it pursues the next best solution when it is impossible or extremely difficult to obtain the optimal solution.

So far, soft computing has been extensively applied to data fusion and classification. This technology can combine the member attributes of fusions sequence into different logic structures (i.e. series structure, mosaic structure and parallel structure), depending on the specific data. Here, the parallel structure is adopted for fusing the remote sensing data on groundwater.

PSO-BPNN-EKF

In this paper, the PSO-BPNN-EKF optimization algorithm is proposed by optimizing the EKF state equation with the PSO, the algorithm uses PSO instead of the parameters in BPNN training algorithm and optimizes BP parameters. Each particle is a vector representing a set of parameters. The process of finding the global optimum is the process of obtaining the optimal parameters. Before the optimization, the particle set converges to the high likelihood area, which is far away from the true state. This

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90839095

problem is solved by the optimization, together with particle degeneration and in accuracy prediction. The PSO-EKF algorithm consists of the following steps:

(1) Initialization

Let N be the number of particles, and $p(x_0)$ be the initial population. Set the initial values of parameters as $\Delta x_0 = 0$, $p_0 = C_{x0}$ and $C_{x0} = 1.5$.

(2) Importance sampling

Adjust the velocity and position of each particle $v_k^i = \omega v_{k-1}^i + \gamma rand_i(p_{k-1}^g - x_{k-1}^i)$, and update the state of the particle according to the EKF algorithm. In other words, estimate the state of the particle $\hat{x}_k^i = x_k^i + \Delta x_k^i + v_k^i$ at time k according to the EKF importance sampling algorithm. Find the mean x_k^{-i} and variance P_{xk}^i of the particle set $\{\hat{x}_k^i\}_{i=1}^N$. Update the weight of the particles in the set x_k^i according to the importance of the density function $\left(x_k^i | x_{k-1}^i, \omega_k\right) = N(\hat{x}_k^i, x_k^{-1}, P_{xk}^i)$.

(3) Recompiling

Estimate the posterior probability of the target state at time k $x_k = \sum_{i=1}^N x_k^i \omega_k^i$, and find the current global optimal solution p_k^g. For $k = k + 1$, return to Step (2) and estimate the posterior probability of the target state at the next time.

PSO-based LSSVM parameter optimization

The LSSVM parameters γ and σ directly impact the prediction accuracy. Normally, the parameter space is search exhaustively to optimize these two parameters. However, it is difficult to determine the reasonable range of each parameter. To solve the difficulty, the LSSVM parameters were optimized by the PSO through the following steps (Yu et al., 2012; Anand et al., 2013).

(1) Initialize the PSO parameters, including population size, learning factor, maximum number of iterations, and the initial velocity and position of the particles.

(2) Predict the particle vector of each LSSVM learning sample, and obtain the current position, prediction error and fitness of each particle. Then, compare the current fitness of each particle with the best-known fitness. If the former is better, it should be selected as the optimal position of the particle.

(3) Compare the optimal position of each particle with the best known global position. If the former is better, it should be selected as the optimal global position.

(4) Calculate the inertia weight according to *Equation 7* and update the particle velocity and position according to *Equations 5* and *6,* respectively.

(5) Terminate the search process if the termination condition is satisfied; otherwise, return to Step (2) and start a new round of search.

Results

The study area is Yulin Prefecture in northern China's Shaanxi Province. There are 12 river basins in the prefecture, with a perennial mean runoff of 1.9446 billion m^3. Under the reliabilities of 50%, 75% and 95%, the annual runoff is 1.847, 1.504 and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90839095

1.136 billion m^3. Specifically, the perennial mean runoff of the 10 outflow basins stands at 1.8099 billion m^3. Under the reliabilities of 50%, 75% and 95%, the annual runoff is 1.7194, 1.4034 and 1.0660 billion m^3. The perennial mean runoff of the other 2 inflow basins amounts to 0.1347 billion m^3. Under the reliabilities of 50%, 75% and 95%, the annual runoff is 0.1277, 0.1001 and 0.0699 billion m^3. The central districts, including Shenmu County, Fugu County, Yuyang District and Hengshan County, have a perennial mean runoff of about 1.557 billion m^3. Under the reliabilities of 50%, 75% and 95%, the annual runoff is 1.477, 1.201 and 0.907 billion m^3. The peripheral districts like Jingbian County have a perennial mean runoff of about 0.388 billion m^3. Under the reliabilities of 50%, 75% and 95%, the annual runoff is 0.370, 0.303 and 0.327 billion m^3. The annual runoffs are recorded in *Table 1*. The water quality of major rivers is given in *Table 2*.

Considering the good nonlinear fitting effect of the RBF, the function was adopted as an improved kernel for the LSSVM. The selection of parameters is essential to the performance of the LSSVM model. In this paper, the parameters are determined by the improved PSO as: number of particles $N = 25$, the maximum number of iterations $G_{max} = 100$, the learning factors $c_1 = 1.5$ and $c_2 = 1.5$, the inertia weight = 0.9. Then, the LSSVM-PSO model was simulated on the Matlab. The particle position was updated constantly until the termination condition was satisfied. In this way, the optimal RBF parameters σ was determined as 0.5, and the normalization parameter c was identified as 60. Next, the optimal parameters were adopted for the fusion of groundwater data by the LSSVM-PSO model. The results are presented in *Figure 3*. And then we compare the experimental results of data fusion between LSSVM-PSO and PSO-BPNN-EKF algorithm, as shown in *Figure 4*. In order to more clearly observe the change of the value of the sum of squares of errors, *Figure 5* has trained the variation of the sum of error squared sum of the PSO-BPNN-EKF algorithm.

Discussion

According to lab analysis, the groundwater quality in the central districts is as follows: the pH ranges in 7.6~8.3, the total hardness falls in 10.1~17.3 (°D), the salinity belongs to 0.33~0.92 g/L, and the poisonous contents like mercury, arsenic and chromium VI are minimal or non-detectable. Overall, the quality of the groundwater meets the *Standards for Drinking Water Quality* (GB5749-2006) and *Standards for Irrigation Water Quality* (GB 5084-2005). In the peripheral district, the groundwater in a few areas is not suitable for drinking or irrigation, as its hardness and salinity are higher than the specified ranges.

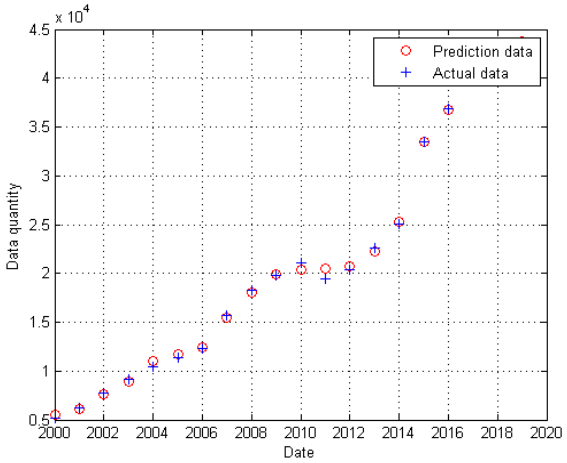

Figure 3. *Comparison of neural network water resources data volume learning and testing*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90839095

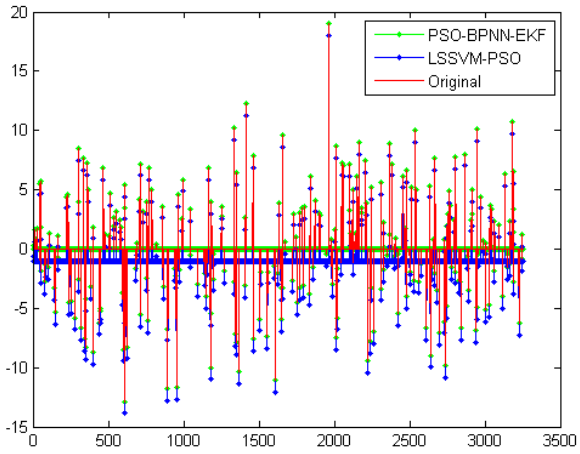

Figure 4. *Comparison of data prediction results between LSSVM-PSO and PSO-BPNN-EKF algorithm*

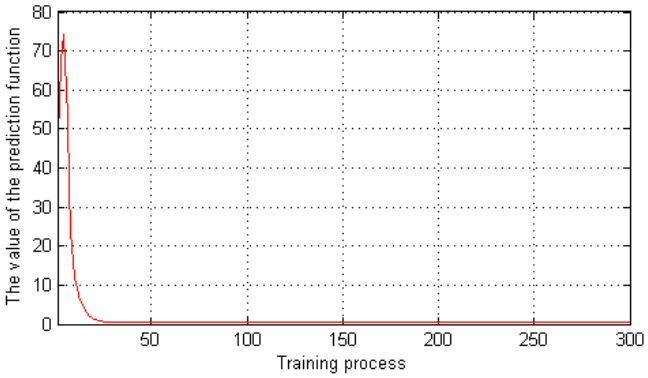

Figure 5. *Variation of square sum of errors in training neural network*

As shown in *Table 2,* the groundwater in the study area has simple chemical compositions. In the loess area, the groundwater is of the HCO_3-CaMg type with a salinity below 0.5 g/L; in the plain areas, the groundwater mainly belongs to the $ClSO_4$-N_8 type with a salinity between 1.0 g/L and 18.46 g/L.

As shown in *Table 3,* when the number of particles $N = 100$, the PSO-SVM achieved a much better performance than the other algorithms, as evidenced by the extremely low error. This means the PSO optimization of EKF state equations increases the particle diversity and enhances the filtering accuracy. Overall, the proposed PSO-BPNN-EKF and PSO-SVM boasted the best performance, followed by the PSO-BPNN-EKF, the EKF and the LSSVM. The ranking demonstrates the effectiveness of the proposed algorithm.

Conclusions

Real-time monitoring of groundwater resources with multiple sensors is a difficult dynamic control problem, due to the large scale and heterogeneity of multi-source data. The existing models cannot satisfactorily reduce the dimensions of the monitoring data. Therefore, this paper attempts to create an innovative approach for dynamic monitoring

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90839095

of groundwater based on large data. For this purpose, a new data fusion algorithm was proposed, aiming to reduce the data size and energy consumption in the fusion process. Inspired by the superiority of artificial neural networks, the rough set theory and the PSO were employed to reduce the complexity of the proposed algorithm. Through several simulations, it is proved that the proposed algorithm can process data more efficiently than the BPNN and the PSO, two popular data processing methods. The excellent performance is attributable to the reduction of data table in the case of big data. The research findings shed new light on the fusion of remote sensing data collected by multiple sensors. Further studies are expected to understand the connotation of the problem of big data fusion, in the era of big data, the analysis and mining for the multi-source remote sensing data is a research field and which attracts much attention. To effectively learn the characteristics of massive, low-quality, heterogeneous, high-dimensional and fast-changing big data, there are still a series of problems and challenges. Our study provides a corresponding multi-source remote sensing data fusion algorithm for the incompleteness of multimodal data, real-time processing and multi-source data fusion.

Abstract. Considering the importance of social stability risk evaluation for major water conservancy projects (MWCPs), this paper creates a feasible evaluation index system for such projects in fragile eco-environment regions (FEER) through literature review, questionnaire surveys and data analysis. Then, a risk evaluation model was construction based on the set pair analysis (SPA) and the principal component analysis (PCA). The proposed model was applied to a MWCP in Shaanxi Province, China, revealing that the project has a low level of social stability risk. The evaluation result agrees with the actual situation, confirming the reliability and rationality of the proposed model. On this basis, several suggestions were proposed to further mitigate the social stability risks of the MWCPs in the FEER. The research findings provide a valuable reference for similar projects in FEER.
Keywords: *social risk, index system, set pair analysis (SPA), suggestions, China, case study*

Introduction

Water conservancy projects bring many benefits to regional and national development, such as controlling flood, protecting the eco-environment, rationalizing the use of water resources, and promoting economic development. In recent years, water conservancy projects are springing up across China, in response to the surging demand for industrial and domestic water (Qu, 2017). A total of RMB 713.24 billion yuan was spent on water conservancy projects in 2017, and another 100 billion was added in the following year. In Shaanxi Province alone, 172 major water conservancy projects (MWCPs) were kicked off in 2018.

The water conservancy projects that have a huge construction scale and involve numerous factors are defined as MWCPs. In China, such projects need to be approved by the central and provincial governments. Unlike the general projects, an MWCP features a long construction period, a high investment and a large demand for land resources. In addition, such projects construction is faced with various health, ecological and economic issues (Wang et al., 2015). For example, the project party needs to consider house demolition, resettlement and compensation for reservoir immigrants. If not solved properly, these problems may lead to social instability in the project area, especially in fragile eco-environment regions (FEER).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90979111

For MWCPs, the social stability risks mainly refer to the negative social impacts of the project construction and operation on the residents in the project area. The residents may file petitions, resort to violence or take part in mass unexpected incidents, if their interests are undermined by the project. The social stability risks of MWCPs are not uncommon. Among the 527 MWCPs funded by the World Bank, only 30 has not caused social instability, and 27 has destabilized the local society. The mean yield of the 30 project stands at 18.3%, while that of the 27 projects lingers at 8.6%. In 2017, the Chinese government pledged to take heavy measures against major risks of MWCPs, with the aim to improve prevention mechanisms and resolve social tensions. Over the years, the management of social stability risks has become an important aspect in the evaluation of MWCPs. Therefore, it is imperative to develop a realistic index system to rationally quantify the social stability risks of MWCPs.

The contents shape the outcomes of the evaluation of social stability risks, and the countermeasures against such risks. Without proper contents, it would be impossible to achieve the goals of project investment (SGJ, 2012; Shi et al., 2015; Yang and Lv, 2017).

Some scholars argued that a complete evaluation of social stability risks in MWCPs should cover social impacts, social suitability and social risks, and tackle such factors as the stakeholders, local population, production activities, social organizations and cultural acceptability (Becker, 2001; Eskesen et al., 2004). However, Zhang et al. (2013) suggested including social impacts, economic impacts and environmental impacts into the social stability risk evaluation of MWCPs. To achieve scientific and democratic social stability risk evaluation, Liao (2018) advised to clarify the status and duties of citizens, the government and third parties in the evaluation through "confrontational debates", fully assess the public participation and opinions of project construction, identify the project impacts on poverty, gender, immigration and ethnic minorities, and monitor the various aspects (e.g. life, resettlement and social development) of the project in a timely manner. Meanwhile, the Chinese Ministry of Water Resources stipulated that the social stability risks of MWCPs should be evaluated from the perspectives of legality, rationality, feasibility and controllability. However, this provision has not been well implemented in the existing practices.

In the evaluation of social stability risks, the index system should reflect all key attributes of the target MWCP, and contain indices that are properly correlated with each other. A suitable index system is the first step in reducing the social stability risks and the early prevention of social instability.

In 1984, the World Bank requested all construction projects to include social risk evaluation in the feasibility study (Dani, 2003). Many scholars understood the social risks of construction projects as those arising from the different responses of stakeholders to specific issues and from the conflict between policymakers and the stakeholders (Hu et al., 2013). Following this train of thought, Wang and Zhang (2012) design an evaluation index system for social stability risks, which contains such indices as institutional role, behavior, stakeholder and social risk. In 2001, the former Chinese Ministry of Railways required all railway projects to assess their social stability risks from both macro and micro angles, against indices like social impacts and the degree of integration with the local environment. He et al. (2018) explore the relationship between stakeholders and risk factors and identifies the key indices of social stability risks by social network analysis.
