DOI: http://dx.doi.org/10.15666/aeer/1704_90979111

behavior and governance (Sun, 2011; Peng et al., 2013; Xiao et al., 2016; Zhu et al., 2016; Hu, 2016). Using engineering analysis method, Huang et al. (2013) discussed the social stability risks of MWCPs in three dimensions, namely, social risk exposure, social sensitivity, and coping capacity. Some scholars include the public perception of risk in the index system for evaluation of social stability risks (Guo, 2012; Hu and Wang, 2014; Zhu et al., 2014; Yin et al., 2018; Zhang and Zhu, 2018; Fan, 2018). Inspired by social combustion theory and social vulnerability theory, Yang (2012) and Feng et al. (2017) measured social stability risks against such four indices as conflict diffuseness, conflict severity, conflict persistence and the total amount of conflicts. Liu et al. (2016) classified the risk factors into procedural risks, cognitive risks and friction risks. Targeting MWCPs, Teng et al. (2014) set up an index system for social stability risk evaluation, including but not limited to individual, family, political structure, social structure, direct impacts, public resources, eco-environment, social adaptability, and community. Chen and Wang (2018) identified the risk factors of public-private partnership (PPP) project against the indices of the government, social capital, public and environment, and summed up the risk formation mechanism. Liu and Wang (2017), and Yu et al. (2016) probed into the evaluation index system of social stability risks in urban transit projects and major river projects, but did not come up with a unified index system.

MWCPs involve numerous influencing factors, making it difficult to use a unified evaluation method. The evaluation method should properly quantify the degree and probability of each social stability risk.

From the angle of stakeholders, Jiao et al. (2015) evaluated the social stability risks of MWCPs by the fuzzy weighting method. Song (1995) assessed the social stability risks of MWCPs using the state-response mechanism. Cao et al. (2013) carried out a questionnaire survey on engineers and social evaluation experts, asked them to rate each social stability risk, and determined the weight of each risk based on the ratings. Chen et al. (2013) adopted the analytic hierarchy process (AHP) to assess the social stability risks of MWCPs. Sturk et al. (1996) suggested that the fault tree analysis (FTA) and the hazard and operability study (HAZOP) are applicable to risk evaluation, and successfully employed the FTA to evaluate the social stability risks of an actual project. Clark and Borst (2002) relied on the risk index method to assess various risks on the underground transit line in Seattle. Based on the entropy-weight and matter-element extension model, Dong et al. (2018) proposed a social stability risk evaluation method for highway projects, which computes the classical domain and the correlation function of each index, takes the entropy as the weight of the index, calculates the comprehensive correlation and then grades the social stability risks of the project.

In summary, the following methods have been frequently adopted to evaluate the social stability risks of MWCPs: the AHP, fuzzy comprehensive evaluation (FCE), grey comprehensive evaluation, principle of Maximum Entropy (Li et al., 2009), group decision AHP (GAHP) (Kong et al., 2015), hierarchal holographic modeling (HHM), fuzzy variable theory (Xiao, 2017) and evaluation models combining various mathematical methods (He and Yang, 2014; Wu et al., 2016; Ma, 2017; Wang, 2017; Ge et al., 2018). These methods share some common defects. For example, the evaluation indices are too rigid to evaluate ambiguous, random and uncertain phenomena, the risk levels are determined rather subjectively, and the computing is so complex as to produce errors.

Materials and Methods

Evaluation index system

Preliminary selection

As required by the Chinese Ministry of Water Resources, legality, rationality, feasibility and controllability were the contents of our evaluation of social stability risks in MWCPs. On this basis, the indices of each content were selected preliminarily, forming a hierarchy structure. Next, the preliminary evaluation index system was set up in light of the indices in actual cases, those in similar projects and the features of the target project.

Index screening

The indices are qualitative variables that measure the subjective feelings of the respondents. Here, each index was rated against a 5-point Likert scale (1: Very unimportant; 2: Unimportant; 3: Neither important nor unimportant; 4: Important; 5: Very important). Before issuing the formal questionnaire, all items were subjected to several tests (*Table 1*). The unqualified terms were deleted in view of the experts' opinions.

(1) Correlation test

The correlation test aims to determine the Pearson product moment coefficient, i.e. the correlation between an item's scores and the total test scores, of each item. The test results show that three indices, including decision-making power $u_{11,}$ institutional construction u_{12} and acquisition and demolition scale $u_{13,}$ were not significant or slightly significant ($p<0.4$). Thus, these descriptive items are not highly correlated with the scale.

The Chinese Ministry of Water Resources specified that the evaluation entity of social stability risks should be designated by the people's government in the project area or its subordinate departments, have clear management organization and relevant rules and regulations, and maintain no direct interest-relationship with the project; the social stability risk evaluation report should be signed by the people's government in the project area. Therefore, the decision-making power and institutional construction of government departments are not inducers of social stability risks.

In addition, the rationality of acquisition and demolition scale depends on the quality of planning, design and related measures. This item is not a direct cause of social risk events. To sum up, the decision-making power, institutional construction and acquisition and demolition scale were deleted from our index system.

(2) Validity test

Before the factor analysis, the remaining 21 items received the validity test. The results show that the Kaiser-Meyer-Olkin (KMO) value was 0.679, above the 0.6 threshold; the p value of Bartlett's test of sphericity was 0.000, which is significant at the level of 0.05. This means the proposed scale is suitable for factor analysis.

From the factor analysis, the minimum common value u_{43} was determined as 0.510, and all items were above 0.2, indicating that the factor acceptable. Besides, the factor load was greater than 0.5 and the cumulative contribution rate of the four factors reached 70.189%, above the required rate of 70%. Therefore, the 21 items can be retained for subsequent analysis and the scale is of good validity.

(3) Reliability test

The Cronbach's alpha of the total scale (0.931) was greater than 0.9, signifying the good overall reliability of the scale. Generally, when the total correlation of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90979111

correction item is below 0.4, an item should be deleted if the Cronbach's alpha after deletion is greater than or equal to that of the total scale. Among the 21 items, the resettlement plan u_{29} had a Cronbach's alpha lower than 0.4, and the Cronbach's alpha after deleting this item equaled that of the total scale. After consulting experts, it is confirmed that this term is a trigger of mass unexpected incidents in similar projects, and thus not deleted. The other items all passed the reliability test. The Cronbach's alphas of the subscales also passed the test, indicating that the scale reliability will not increase after removal of any item. As a result, all 21 items can be retained for subsequent analysis and the scale is of high reliability.

Table 1. *The results of the reliability test (Wu, 2010)*

Item	Correlation coefficient between the item and the total score		Homogeneity test					Remarks

Table 2. *The evaluation index system for social stability risks of MWCPs*

Aim	Criteria layer	Assessment factor	Indicator layer	Influence level	Indicator interpretation
Social Stability Risk Assessment system for Large Hydraulic Engineering Projects	Legality U_1	Decision making procedure	Project approval process u_{11}	0.0533	Whether the design report related to the project project and its approval documents are complete.
			Information disclosure and mass participation u_{12}	0.047	Whether the project information related to the masses is public.
		Decision content	Project site selection u_{13}	0.0895	Whether it is consistent with comprehensive planning, regional development planning, and special planning
	Rationality U_2	Decision motivation	Most people's interests u_{21}	0.0317	Whether it meets the interests of the majority.
		Interest adjustment	The production and living standards of the land-expropriated people u_{22}	0.066	Is it possible to ensure that the production and living standards after the relocation of immigrants meet or exceed the original level?
			Economic burden of the land-expropriated people u_{23}	0.0595	Whether to bring excessive economic burden to the masses.
			Mass gain u_{24}	0.0455	Whether to make the immigrants satisfied.
			Compensation standard for land acquisition and house demolition u_{25}	0.0328	Whether the state and the locality have gaps in the compensation standards for land and housing, and the inconsistency of policies.
		Acceptance	Compensation funds for land acquisition and house demolition u_{26}	0.0438	Whether the compensation fund management system is established and improved, whether there is a possibility of breeding corruption, misappropriation, and delay in issuance.
			The acceptance of income changes by the masses u_{27}	0.0478	Changes in immigration work after relocation can cause income changes to be accepted.
		Implementing measures	Planning design u_{28}	0.045	Is it recognized by the government and other relevant departments?
			Resettlement plan u_{29}	0.0443	Can it be accepted by most people?
	Feasibility U_3	Policy convergence	Policy continuity, stability and coordination with relevant policies u_{31}	0.0625	Can it ensure policy continuity, stability and coordination with relevant policies?
		Support	Safeguards u_{32}	0.0298	Whether the has a specific security plan.
			Ecological environment risk u_{33}	0.0673	Whether measures have been taken for risks such as sudden water pollution accidents and invasion of alien species.
		Easy to operate	Related supporting measures u_{34}	0.0506	Have you been cautiously argued?
	Controllability U_4	Potential negative effect	Social security hazard u_{41}	0.0328	Influx of outsiders during construction period, improper management, whether it is possible to conflict with local residents.
			Negative paradox u_{42}	0.0378	Whether it has a negative impact.
		Degree of opposition	Public safety u_{43}	0.0324	Occurrence possibility.
		Prevention and resolution measures	Prevention and emergency measures u_{44}	0.0499	Are there preventive and coping measures?
			Public opinion and guidance u_{45}	0.0305	Is the preparation sufficient?

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

Evaluation Model

Set pair analysis (SPA)

The SPA (Zhao, 2000) is an effective way to quantify random, ambiguous and uncertain problems. It enjoys great advantages in quantifying the uncertainty between multiple factors. Taking the target problem as a system, the certain features are considered as the same or opposite to each other, the uncertain features are deemed as different, and the target system is analyzed from the same, different, and opposite aspects. The set pair is a pair of two sets with a certain correlation.

Let H=(X,Y) be a pair set, and N be the total number of features in the set. It is assumed that the set contains S same features, P opposite features and F different features, that is, N=S+F+P. Then, the correlation degree of the system can be described as (Wang et al., 2009; Yang et al., 2014):

$$\mu = \mathbf{a} + bi + cj = \frac{S}{N} + \frac{F}{N}i + \frac{P}{N}j \quad \text{(Eq.1)}$$

where $i \in [-1,1]$ is the difference coefficient for uncertain features; j=-1 is the oppositeness coefficient for certain features. The key to the SPA lies in the determination of the correlation degree μ and the difference coefficient i.

Evaluation model

(1) Grading of risk probability

The risk probability refers to the possibility of occurrence of the risk index. In this paper, the subjective probability estimation is employed, which infers the risk probability based on estimators, expert experience, and similar events. The risk probability was empirically divided into five levels: very high, high, medium, low and very low. The five qualitative levels were respectively converted into quantitative figures like zero, the three quartering points of [0, 1] and one (*Table 3*).

Table 3. *Risk probability criterion*

Risk level	Quantitative standard	Level description
Very high(k=1)	(0.8,1]	Almost certain
Higher(K=2)	(0.6,0.8]	Very likely to happen
Medium(K=3)	(0.4,0.6]	May happen
Lower(K=4)	(0.2,0.4]	Less likely to occur
Very low(K=5)	[0,0.2]	The possibility of occurrence is small, almost impossible

(2) Determination of correlation degree

The correlation degree quantifies the proximity of the two sets in the set pair, and reveals the complex relationship between the two sets. Inspired by the SPA theory, the correlation degree μ_{nk} was constructed between the value xn of each index in the index system and the five risk probability levels k. The relationship between each index and each level can be calculated as (Li et al., 2019):

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90979111

$$\mu_{n1}=\begin{cases}1 & s_0 \le x_n \lhd s_1\\ 1-2\dfrac{x_n-s_1}{s_2-s_1} & s_1 \le x_n \lhd s_2\\ -1 & x_n \ge s_2\end{cases} \quad \text{(Eq.2)}$$

$$\mu_{n2}=\begin{cases}1-2\dfrac{s_1-x_n}{s_1-s_0} & s_0 \le x_n \lhd s_1\\ 1 & s_1 \le x_n \lhd s_2\\ 1-2\dfrac{x_n-s_1}{s_2-s_1} & s_2 \le x_n \lhd s_3\\ -1 & x_n \ge s_3\end{cases} \quad \text{(Eq.3)}$$

$$\mu_{n3}=\begin{cases}-1 & s_0 \le x_n \lhd s_1\\ 1-2\dfrac{s_2-x_n}{s_2-s_1} & s_1 \le x_n \lhd s_2\\ 1 & s_2 \le x_n \lhd s_3\\ 1-2\dfrac{x_n-s_3}{s_4-s_3} & s_3 \le x_n \lhd s_4\\ -1 & s_4 \le x_n \lhd s_5\end{cases} \quad \text{(Eq.4)}$$

$$\mu_{n4}=\begin{cases}-1 & x_n \lhd s_2\\ 1-2\dfrac{s_3-x_n}{s_1-s_0} & s_2 \le x_n \lhd s_3\\ 1 & s_3 \le x_n \lhd s_4\\ 1-2\dfrac{x_n-s_4}{s_5-s_4} & s_4 \le x_n \lhd s_5\end{cases} \quad \text{(Eq.5)}$$

$$\mu_{n5}=\begin{cases}-1 & x_n \le s_3\\ 1-2\dfrac{s_4-x_n}{s_4-s_3} & s_3 \le x_n \lhd s_4\\ 1 & s_4 \le x_n \lhd s_5\end{cases} \quad \text{(Eq.6)}$$

where s_0~s_5 are the critical values of the indices.

(3) Determination of degree of impact

The degree of impact of each risk index was assessed by the synthetic evaluation based on the principal component analysis (PCA). The PCA mainly determines the degree of impact based on expert scores and simplified linear relationships (Han et al., 2012). The PCA-based synthetic evaluation is implemented in four steps:

Step 1: Normalize the sample matrix $X=(x_{ij})_{n\times p}$ into Z, and compute the correlation coefficient matrix R.

Step 2: Calculate the eigenvalue λ_k of the correlation matrix R, and determine the number (m) of principal components F_j. Here, more than 85% of the principal components are selected, and the remaining components are neglected.

Step 3: Determine the degree of impact of each risk index using the following model:

$$F_j = u_{1j}\omega_1 + u_{2j}\omega_2 + \cdots u_{nj}\omega_n \quad \text{(Eq.7)}$$

where $u_{ij}=\dfrac{f_{ij}}{\sqrt{\lambda_j}}$ is decision matrix coefficient; f_{ij} is the initial factor load.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90979111

Step 4: Construct a comprehensive evaluation function F_z; obtain the comprehensive value of the risk index score from the expert score x_{ij}:

$$V_{Zi} = \sum_{j=1}^{n} a_j x_{ij} \quad \text{(Eq.8)}$$

The degree of impact of each risk factor:

$$\omega_i = \frac{V_{Zi}}{\sum_{i=1}^{h} V_{Zi}} \quad \text{(Eq.9)}$$

In this way, the model on the degree of impact of each risk index can be obtained as:

$$F_z = \sum_{j=1}^{m} \left(\lambda_j / k \right) F_j = a_{1m}\omega_1 + a_{2m}\omega_2 + \ldots a_{nm}\omega_n \quad \text{(Eq.10)}$$

where $a_1, \cdots, a_n$ are the overall importance of indices in the principal component.

Using the SPSS 20.0 and the above method, the initial degree of impact of each index can be computed as:

$$\begin{cases} F_1 = 0.1080\omega_1 + 0.0866\omega_2 + \ldots + 0.1322\omega_{21} \\ F_2 = -0.0064\omega_1 - 0.0321\omega_2 + \ldots - 0.0106\omega_{21} \\ \ldots \\ F_5 = -0.0228\omega_1 + 0.0298\omega_2 + \ldots - 0.0069\omega_{21} \end{cases}$$

The secondary model was obtained from the above results and the expert score sheet as: $F_z = 0.1335\omega_1 + 0.1259\omega_2 + \ldots + 0.0905\omega_{21}$. The degree of impact of each of 21 risk indices was $\omega = (\omega_1, \omega_1, \cdots, \omega_{21})$=(0.0533, 0.0470, ..., 0.0305).

(4) Calculation of comprehensive correlation

The comprehensive correlation between index n and the risk probability level k can be determined as:

$$V_{ik} = \sum_{i=1}^{n} \omega_i \mu_{ik} \quad \text{(Eq.11)}$$

(5) Determining the evaluation scores

According to the basic principle of the SPA, the score of the risk probability is the level corresponding to the maximum value of the comprehensive correlation:

$$U = \max_{j=1}^{k} \{v_{ik}\} \quad \text{(Eq.12)}$$

Results

Basic information

The research target is an MWCP in the FEER of northwestern China's Shaanxi Province. With a total investment of RMB 20 billion yuan, the project covers an area of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90979111

14,00 km^2. To prevent the occurrence of mass unexpected incidents, the author carried out an evaluation of the social stability risks of the project.

Prior to the evaluation, a questionnaire survey was carried out in 35 administrative villages of 10 districts and counties. The questionnaire covers the attitude to the project, the impacts on local environment, the impacts on production and life, the compensation for losses, public participation, and so on. In total, 1,200 questionnaires were released, 86% of which were recovered. Meanwhile, a few questionnaires were issued to test the authenticity, credibility and perfection of the survey. The results indicate that the survey contents lay a solid basis for risk evaluation.

The questionnaire data show that 1,028 villagers were not against the project, including 951 supporters, 77 unconcerned and 3 opponents. The support rate is as high as 99.7%. Only 57 villagers worried about the risk of social instability, while 974 did not have the worry. Most villagers learned about the project from a simple information source. Specifically, 992 villagers heard of the project from the bulletin board of the local cooperative, and 8 never heard of the project. In addition, 10 villagers were included in the resettlement plan. Most respondents (1,124) were concerned about the compensation standards for land acquisition and house demolition, such as the compensation time. In general, land acquisition, relocation and resettlement and the temporary shutdown of the irrigation facilities are the main aspects of the project that may affect the local production and life. Besides, conflicts may arise between the construction team and the villagers.

According to the actual situation of the project area, a social stability risk evaluation report was prepared, and several risk mitigation measures were proposed, together with an emergency response plan.

Risk evaluation

Based on the survey data, the social risks of the project were evaluated by the proposed method. The expert scores on each index was averaged as the final score (*Table 4*). The correlation degrees of each index and the evaluation levels were computed by *Equations (2) and (6)* (*Table 5*).

Table 4. *Mean expert score on each index*

Index	Experts rating average	Own interval	Risk level	Index	Experts rating average	Own interval	Risk level

Based on the correlation degrees of each index and the evaluation levels, the weight of each index was determined according to *Equation (11)*. The comprehensive correlation degree of each index can be calculated as:

$$v=(-0.9998, -0.82278, 0.40176, 0.74716, -0.36044)^T$$

By *Equation (12)*, the maximum connection degree was obtained as 0.74716, and the corresponding interval of evaluation level was (0.2, 0.4). The results show that the social stability risk of the major water conservancy project in the fragile eco-environment region is lower than the actual situation after implementing the mitigation measures. This is consistent with the actual situation.

Discussion

The existing studies on MWCPs evaluation mainly concentrate on economic benefits and environmental impacts, failing to tackle the social stability risks. What is worse, there is a severe lacking of the social stability risk evaluation of the MWCPs in the FEER, which is essential to the protection of project safety and sustainability.

To make up for this gap, this paper creates a feasible evaluation index system for social stability risks of the MWCPs in FEER through literature review, questionnaire survey and data analysis. Then, a risk evaluation model was construction based on the SPA and PCA. The proposed model was applied to a MWCP in Shaanxi Province, China, revealing that the project has a low level of social stability risk. The evaluation result agrees with the actual situation, confirming the reliability and rationality of the proposed model.

The research findings provide a valuable reference for similar projects in FEER. The risk evaluation provides a reference for the design of measures to reduce the risk of the project. Based on the actual situation of the study area and the existing studies, the author puts forward several suggestions on social risk mitigation to further mitigate the social stability risks of the WMCPs in the FEER.

(1) Address the concerns and protect the vital interests of the locals.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_90979111

The compensation policies and resettlement measures should be publicized in the project area. To formulate a feasible compensation plan, the construction team must fully understand the local conditions, solicitate the opinions of the affected, and obey the relevant regulations. Moreover, the resettlement site and supporting facilities should be selected rationally and developed rapidly. The local governments need to step up the resolution of disputes over compensation allocation and pay the compensation in time.

(2) Enhance eco-environment protection and reduce the environmental impact.

The project party must strictly abide by regulations on environmental protection, adopt practical engineering and biological measures, and strengthen environmental monitoring and management. The construction plan should be optimized to prevent water pollution, curb ecological deterioration, and avoid geological disasters. Ultimately, the negative environmental impact should be reduced to the acceptable level.

(3) Improve safety awareness and strengthen risk monitoring and response.

The project safety should be prioritized through project construction and operation. During the construction, the project party should actively learn from best practices and achieve civilized construction, the local government should implement strict supervision, and the villagers should engage in safety monitoring and report. After the project enters operation, the risk monitoring should be implemented consistently through site visits, field surveys and regular patrols.

(4) Establish and improve the risk management linkage mechanism for social stability.

The project party should establish and improve a robust mechanism of social stability and work safety. For example, the construction procedures should be followed strictly, and the applications for pre-approval be filed timely; effective working forms and response plans should be formulated as per the project features and requirements; the social risk sources should be avoided throughout the project. In addition, efforts should be paid to enhance the awareness of risk, emergency, conflict and crisis management.

(5) Cooperate with the local government to coordinate and solve problems.

The project party should actively cooperate with the local government in problem coordination and solution. Specifically, the party needs to maintain an effective communication channel with the locals, and share the information smoothly with the local government. In the event of social stability risks, the project party and the local government should work together to prevent and resolve such risks.

(6) Actively explore new measures to prevent and resolve social stability risks.

The relevant parties need to further investigates the issues on social stability risks, and actively explore new measures to prevent and eliminate such risks. The new measures should be prepared based on the opinions and problems raised by the most affected residents and the local government, with the aim to nip the problems in the bud.

Conclusions

The social stability risks are highly dynamic, and the interaction between risk factors may trigger new risk factors in unsteady areas. Due to the geographical and project characteristics, there are some limitations in the selection of evaluation indicators. It can further adjust and improve the indicator system according to the actual needs of the project. Although the target project has a low social stability risk, the occurrence of individual conflicts cannot be ruled out. This calls for a more detailed risk mitigation strategy, which will be discussed in future research.

Abstract. Photodegradation is one of the important methods of antibiotic treatment in water environment. This paper studies the treatment effect of sulfamethazine by solar electric-Fenton (SE-Fenton) technology, observes the contribution of OH concentration to degradation, and involves the effect of pH value, voltage and Fe^{2+} concentration on the treatment effect. The experiment shows that the degradation rate of sulfamethazine can be effectively improved by the solar-powered Fenton system. The optimum conditions for the degradation system are pH 3.0, 25 mg/L Fe^{2+} concentration, and the applied voltage of 3 V. This study provides a basis for the removal of sulfonamide antibiotic contamination in water environment.
Keywords: *sulfanilamide, solar electric-Fenton, antibiotics, photolysis, advanced oxidation technology*

Introduction

The sulfonamide antibiotics are synthetic broad-spectrum antibiotics, with the structure of aminobenzene sulfonamide, and have been used in clinical medicine for 50 years. Because of its stable nature, convenient use and high safety, it is widely used in medicine. On the other hand, the absorption capacity of human beings or organisms is weak, and more than 80% of it is released into the environment in the original form, so it is often detected in the environment, with the detection rate ranking top among all kinds of drugs (Kolpin et al., 2002; Kemper, 2008). Because of its long-standing existence in the environment such as water and soil, it affects the original microbial population in the environment, gives birth to bacteria with extensive drug resistance, or induces gene mutations, thyroid hyperplasia or tumors in rodents (Martinez et al., 2008; Littlefieldna et al., 1989).

Due to the above reasons, the treatment technology of antibiotic pollution in the environment is getting more and more attention. Advanced oxidation technology is a water treatment technology developed in recent years, characterized by the generation of hydroxyl radicals (OH) with strong oxidizing ability, and is a method of oxidizing macromolecule refractory organics into low toxic or non-toxic small molecule substance under the reaction conditions of high temperature and high pressure, electricity, sound, light, catalyst and the like (Oller et al., 2011). Fenton technology is often used for the treatment of refractory organics. With good treatment efficiency of Fenton method and high mineralization rate of organic pollutants, it is simple and practical, and its application range is increasing continuously. In recent years, solar-Fenton (S-Fenton), electric-Fenton (E-Fenton), ultrasonic-Fenton and other advanced

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91139120

oxidation technologies have been derived (Serna-Galvis et al., 2016). The Fenton technology forms hydroxyl radicals mainly by reaction, with the main reaction steps as follows (Christopher et al., 2007).

$$Fe^{2+} + H_2O_2 \rightarrow Fe^{3+} + OH^- + HO\cdot \quad \text{(Eq.1)}$$

$$Fe^{3+} + H_2O_2 \rightarrow H^+ + Fe(HO_2)^{2+} \quad \text{(Eq.2)}$$

$$Fe(HO_2)^{2+} \rightarrow Fe^{2+} + HO_2\cdot \quad \text{(Eq.3)}$$

$$FeOH^{2+} + H_2O_2 \rightarrow Fe(OH)(HO_2)^+ + H^+ \quad \text{(Eq.4)}$$

$$Fe(OH)(HO_2)^+ \rightarrow Fe^{2+} + HO_2\cdot + OH^- \quad \text{(Eq.5)}$$

$$OH + Organics \rightarrow H_2O + Degradation\ products \rightarrow CO^{2+}\ H_2O \quad \text{(Eq.6)}$$

On the basis of Fenton method and the application of light, the content of Fe^{2+} in Fenton reagent can be reduced, the reaction rate of H_2O_2 and the production rate of OH can be increased, so that the mineralization of organicsr can be more thorough (Elmolla and Chaudhuri, 2009, 2011). The E-Fenton method produces Fe^{2+} and H_2O_2 by electrochemical process. The E-Fenton method mainly involves the cathode E-Fenton method, the basic principle of which is to spray oxygen on the cathode of the electrolytic cell and reduce it to H_2O_2 at the cathode as shown in *Equation 7*. Then, H_2O_2 reacts with the added Fe^{2+} to produce ·OH and thus reacts with the organics (Brillas et al., 2009; Yahya et al., 2016).

$$O_2 + 2H^+ + 2e^- \rightarrow H_2O_2 \quad \text{(Eq.7)}$$

Compared with the S-Fenton method, the E-Fenton method has the mechanism of generating H_2O_2 automatically, and higher utilization rate of H_2O_2. The disadvantage is low current efficiency. If the amount of processing is very large, the amount of electricity input is increased and the cost will also be high, which limit its wide application. The photoelectric Fenton method, which combines the advantages of S-Fenton and E-Fenton, has attracted much attention in recent years. Compared with artificial light source, the low cost of sunlight makes it the research hotspot of S-Fenton method. The SE-Fenton technology simultaneously utilizes the characteristics of automatically generating H_2O_2 by the E-Fenton method and the advantage of circulating Fe^{2+}/Fe^{3+} by S-Fenton to increase the concentration of ·OH, and save costs with sunlight. At present, the research is mainly applied to the treatment of refractory organics such as dyes and antibiotics (Valero et al., 2010; Mahmoodi et al., 2011; Almeida et al., 2015; Pérez et al., 2015, 2017). Casado and Fornaguera (2006) uses this method to treat organic acids such as p-benzoic acid, 2,4-dichlorophenoxyacetic acid and oxalic acid, and completely mineralize the organic acids for about 1 h. Flox et al. (2007) also studied the degradation of phenol-containing wastewater and 4-chloro-o-phenoxypropionic acid by SE-Fenton technology, with good results.

Sulfamethazine (SMT) is a kind of sulfonamides, which is mainly used to treat avian cholera, avian typhoid and chicken coccidiosis. More attempts have been made to treat sulfonamides with advanced oxidation technology (Alam et al., 2009; Batista and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91139120

Nogueira, 2012; Sopaj et al., 2016). Because of its stability in the environment, the degradation effect needs to be further improved. In this paper, the SE-Fenton technology is used to treat SMT, which provides basic data for the treatment of antibiotic wastewater.

Materials and methods

Drugs

Sulfamethazine (SMT, purity is equal to or more than 99%, SINOPHARM), methanol (chromatographic purity, Chengdu Kelong Chemical Reagent Factory), and acetonitrile (chromatographic purity, Tianjin Damao Chemical Reagent Factory). Ferrous sulfate (analytical purity), potassium dihydrogen phosphate (analytical purity), dipotassium hydrogen phosphate (analytical purity), sodium hydroxide and sulfuric acid are analytical purities. The experimental water is ultrapure water.

Main instruments

High Performance Liquid Chromatography (LC-2010A HT, Shimadzu, Japan); Circulating Water Vacuum Pump (Gongyi Yuhua Instrument Co., Ltd.), pH Meter (Shanghai LIDA Instrument Factory), TASI-8731 Digital Illuminometer (Suzhou TASI Electronics Co., Ltd.)

Experimental device

Experimental device of SE-Fenton is as *Figure 1*.

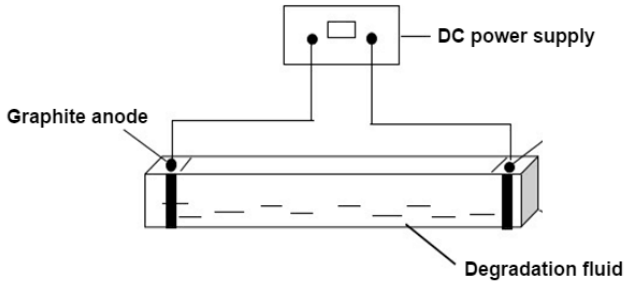

Figure 1. *Experimental device*

Experimental method

Determination of SMT

SMT in water is determined by HPLC with SHIMADZU VP-ODS-C18 column (25 cm × 4.6 mm, 5 μm). The detection wavelength is 270 nm. Mobile phase: 0.017 mol/L phosphate: Acetonitrile (80: 20) buffer solution; flow rate is 1 mL/min, sample volume is 20 μL, column temperature is 30 °C.

Control experiment

In the electrolyzing cell, 1 L of 10 mg/L SMT standard working fluid is added, and 1 mL of 25 mg/mL ammonium ferrous sulfate solution is added. The pH of NaOH

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91139120

solution and H_2SO_4 solution is adjusted to be 3.0. Under different conditions, S-Fenton degradation, E-Fenton degradation (applied voltage 3 V) and SE-Fenton degradation reaction were carried out. Take 1 mL of the reaction solution in the sampling bottle at different time intervals to determine the SMT concentration.

Degradation of SMT under solar photovoltaic conditions

In the electrolyzing cell, 1 L 10 mg/L SMT standard working fluid is added, 25 mg/mL ammonium ferrous sulfate solution is added. The pH of the solution is adjusted with NaOH solution and H_2SO_4 solution. Graphite electrodes are inserted on both sides of the electrolyzing cell, DC power supply is connected and applied voltage is regulated. The oxygen for manufacturing H_2O_2 is supplied to the degradation system with an aerator at the cathode.

For sunshine conditions, select the sunny days from July to August in Chongqing, from 11: 00 a.m. noon to 14: 00 p.m. The light intensity (600 00~780 00 LUX) empowers the degradation system to the degradation reaction under sunlight, and samples are taken at different time periods. The SMT concentration of the system is measured by high performance liquid chromatograph at different sampling time.

Determination of ·OH in the process of degradation

Because benzene reacts with ·OH to form phenol with good selectivity and few by-products, benzene is often used as ·OH trapping agent to produce phenol, and its concentration represents the concentration of OH in solution. In preparing the degradation solution, add benzene, make the concentration of benzene in the degradation solution be 7000 $\mu mol \cdot L^{-1}$, adjust to the desired pH value, carry out the degradation reaction, sample 1 mL at different time intervals as required, and determine phenol concentration in solution by high performance liquid chromatography. The determination conditions are as follows: SHIMADZU VP-ODS-C18 column (25 cm × 4.6 mm, 5 μm), column temperature of 30 °C, UV detector wavelength of 270 nm, the mobile phase of methanol (V): Water (V) = 60: 40, the flow rate of 1.0 $mL \cdot min^{-1}$, the injection volume of 20 μL, and the retention time of phenol as 3.01 min.

Results and discussion

Degradation of SMT by different Fenton systems

Add 1 mL of 25 mg/mL ammonium ferrous sulfate solution to 1 L of 10 mg/L of SMT degradation solution, adjust the pH of the solution to be 3.0, and use E-Fenton, S-Fenton and SE-Fenton systems to degrade SMT, respectively. The degradation rate of SMT by different systems is shown in *Figure 2a.* From the figure, it can be seen that the degradation rate of three different Fenton systems increases with the increase of the reaction time. The OH produced during the degradation of three different systems is determined and the results are shown in *Figure 2b.* It is obvious that the degradation rate of SMT in different systems is positively related to the concentration of ·OH produced in the system. At the same time, the degradation rate of SMT is the highest by the SE-Fenton system, followed by the S-Fenton system and the lowest by the E-Fenton system. These results indicate that all three systems can promote the degradation of SMT, in which S-Fenton and E-Fenton technology can produce synergetic effect and enhance the degradation ability. However, the degradation effect of S-Fenton is better

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91139120

than that of E-Fenton, mainly because of the synergistic effect of ultraviolet light and Fe^{2+} on the catalytic decomposition of H_2O_2 produced in the system.

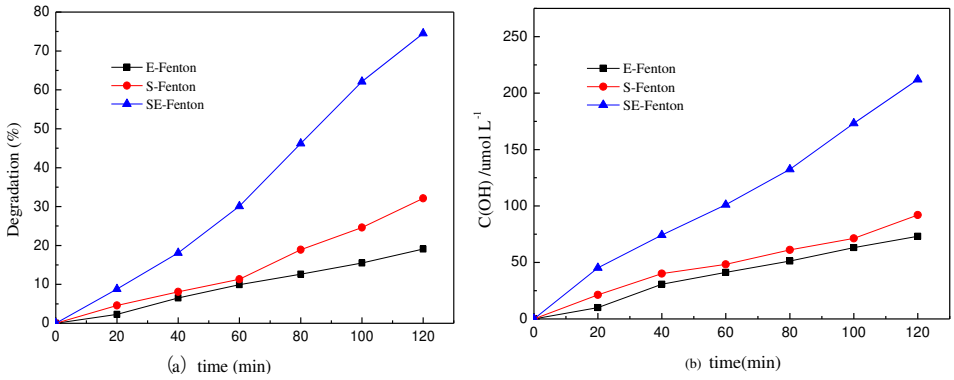

Figure 2. *Degradation effect of SMT by different Fenton systems and the corresponding OH concentration of the system. SMT 10 mg/L, pH = 3.0, sunlight intensity (65000~78000 LUX)*

Effect of pH on SE-Fenton degradation of SMT

Many studies have shown that Fenton systems usually have better ability to degrade organics under acidic conditions (Alam et al., 2009), so this experiment is carried out at pH 1.0, 3.0, 5.0, and 7.0. It can be seen from *Figure 3* that in the reaction time of the first 30 min, the degradation efficiency of SMT does not differ greatly under the conditions of pH 1.0, 3.0 and 5.0, and after 30 min, the system with pH 3.0 has the best effect on SMT degradation. When pH is higher than 3.0, ranging from 3.0 to 7.0, the degradation efficiency of SMT becomes smaller and smaller. In the system with pH 7, the degradation rate of SMT in 120 min is only about 10%. When the pH is lower than 3.0, the degradation rate of SMT is also greatly reduced. Some studies have shown that when pH is less than 3.0, the ferric ion concentration in the Fenton system decreases, thus inhibiting the formation of OH. When pH is higher than 4.0, $Fe(OH)_3$ precipitates will occur in the solution. The higher the pH is, the more precipitates will be formed, which will prevent the circulation of Fe^{2+} and Fe^{3+} in Fenton system and is unfavorable to the formation of·OH. Therefore, the optimum pH for SE-Fenton degradation of SMT is 3.0, and the pH of the system is 3.0 in the following experiments.

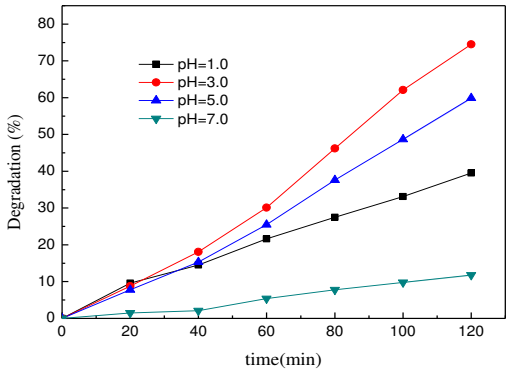

Figure 3. *Effect of pH on SE-Fenton degradation of SMT. 1L 10 mg/L SMT degradation solution; E = 3V; Fe^{2+} concentration of 25 mg/L; light intensity: pH = 1.0(65500~72000 LUX); pH = 3.0(68000~72000 LUX); pH = 5.0(64000~735 00 LUX); pH = 7.0(61300~723 00 LUX)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91139120

Effect of applied voltage on SE-Fenton degradation of SMT

The degradation efficiency of the SMT increases as the applied voltage increases, as shown in *Figure 4*. This is due to an increase in the applied voltage of the electrolytic cell, which accelerates the generation of the cathode H_2O_2, resulting in an increase in the concentration of·OH. The difference among the voltages 3 V, 5 V and 7 V used in the experiments is not too large, so the degradation efficiency of SMT is not improved significantly. The influence of the applied voltage of 3 V and 7 V on SMT degradation is very small. In view of saving cost and energy, under this experimental condition, when the applied voltage is 3 V, the degradation effect of SMT is the best.

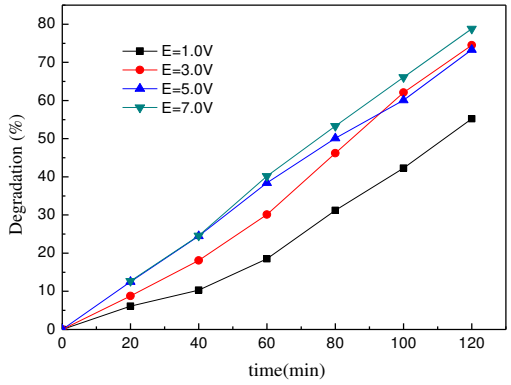

Figure 4. *Effect of applied voltage on SE-Fenton degradation of SMT. 1L 10 mg/L SMT degradation solution; pH = 3; Fe^{2+} concentration of 25 mg/L; Light intensity: E = 1.0 V (65000~76000 LUX); E = 3.0 V (65000~78000 LUX); E = 5.0 V (55000~70000 LUX); E = 7.0 V (56700~69700 LUX)*

Effect of Fe^{2+} dosage

The results of *Figure 5* show that in the range of concentration given in the experiment, when the concentration of Fe^{2+} is 25 mg/L, the degradation effect of SMT is the best.

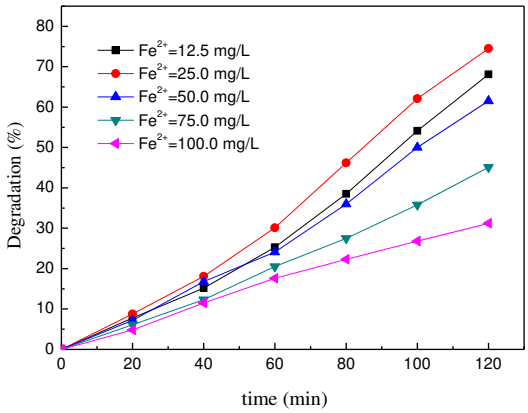

Figure 5. *Effect of Fe^{2+} dosage. E = 3V; pH = 3; 10 mg/L SMT Degradation solution; Light intensity: Fe^{2+} = 12.5 mg/L (64000—70000 LUX); Fe^{2+} = 25 mg/L (65000—78000 LUX); Fe^{2+} = 50 mg/L (63000~75000 LUX); Fe^{2+} = 75 mg/L (63000~75700 LUX); Fe^{2+} = 100 mg/L (64200~76000 LUX)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91139120

When Fe^{2+} concentration is lower than this value, the degradation rate decreases. When the concentration of Fe^{2+} is higher than this value, the higher the concentration is, and the lower the degradation effect of SMT is. This is because a suitable concentration of Fe^{2+} will improve the utilization efficiency of H_2O_2, too low Fe^{2+} is not sufficient to decompose H_2O_2, and less ·OH produced is not conducive to degradation. Some studies have shown that excessively high concentration of Fe^{2+} will decompose H_2O_2, which is unfavorable to the formation of ·OH, resulting in the decrease of the degradation effect of SMT (Sire's et al., 2007).

Conclusions

(1) Under the same conditions, the degradation rate of sulfamethazine is 32.1%, 19.1% and 74.5% respectively by S-Fenton, E-Fenton and SE-Fenton systems separately. The degradation rate of sulfamethazine is greatly improved by SE-Fenton technology, and the advantages of the combined technologies are demonstrated by comparison with those of S-Fenton and E-Fenton.

(2) The results show that OH produced by SE-Fenton system is positively related to the degradation rate of SMT. Under the same conditions, the concentration of ·OH produced in the degradation process of S-Fenton, E-Fenton and SE-Fenton in 120 min is 92 $\mu mol \cdot L^{-1}$, 73.2 $\mu mol \cdot L^{-1}$ and 212 $\mu mol \cdot L^{-1}$ respectively, which indicates that the synergistic mechanism of photo-electric interaction in SE-Fenton system promotes the production of ·OH.

(3) In this experimental system, the optimum conditions for degradation of 1 L 10 mg/L SMT by SE-Fenton technology are as follows: pH is 3.0, concentration of Fe^{2+} is 25 mg/L, and the applied voltage is E = 3 V, which has the best degradation effect.

(4) Solar photoelectric Fenton technology has good degradation efficiency for sulfonamide, but because of the unstable sunlight and pH = 3 as the optimum degradation condition, the application of solar photoelectric Fenton technology is limited. Further research and development of sulfonamide degradation technology and methods in near-neutral water are needed.

Abstract. Under the background of rapid development of urbanization, how to make rational use of land resources is the main content of urban planning design. The unreasonable distribution of urban land intensifies the influence range and intensity of urban heat island effect, and the cooling and humidification of urban vegetation can effectively alleviate the surface temperature of cities and towns. Under this trend, based on the study of urban heat island effect and in view of the ecological benefit of forest cities, this paper makes systematic planning for the green space pattern of Shijiazhuang City, and puts forward the optimization strategy to realize the sustainable development of the urban ecological environment. The results show that the urban heat island effect increases with the increase of the urban planning forest coverage, and the urban forest has a certain threshold to alleviate the urban heat island effect, so the patch arrangement of the forest should be controlled. The forest planning pattern in urban planning can be adjusted and optimized to increase the urban forest patch shape index, thereby increasing the coupling degree between forest vegetation and environment, and maximizing the reduction of heat island effect. This study provides a theoretical basis for minimizing the heat island effect in the process of urban planning.

Keywords: *urban planning, forest, ecological benefits, heat island effect, planning pattern, environmental coupling*

Introduction

Urbanization continues to develop rapidly, which aggravates the change in urban land use types and causes urban climate change such as temperature rise and humidity decrease in urban areas, particularly, the heat island effect in urban environmental problems (Ahmed et al., 2015). In the layout of urban planning, the effective measures to alleviate the heat island effect include urban forest, green land and water body, among which forests as the "dispatcher" of the nature exist in a large amount in the city, with flexibility in activity (Li et al., 2018). All trees in parks, residential areas, blocks and around roads are part of the urban forest. In order to maintain and improve the ecological environment, the necessity and importance of building forest cities are becoming increasingly apparent in urban planning (Wang et al., 2015; Kamruzzaman et al., 2018). The planning design of urban forests not only increases urban green coverage, but also plays an important role in protecting natural ecology and improving human living environment (Hyoungsub et al., 2018).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91219129

The design and planning of urban forests has high social benefits, which promote the development of cultural education, enhance urban landscape leisure and improve the urban ecological environment (Gago et al., 2013). The systematic planning and arrangement urban forests can form a comprehensive environment for coordinated development with the cities, thereby better improving the urban ecology and living environment (Senanayake et al., 2013). The planning and design state of urban forests is mainly distributed in point, strip, ring and wedge shape, all of which input fresh air to the cities, improving urban climate, environment and ventilation conditions (Wonorahardjo, 2012). Urban forest plays a good role in regulating urban heat island effect. The surface temperature can be reduced by more than 15 °C in urban forest-covered areas, and the body temperature under shade can be reduced by 3–5 °C (Weilin et al., 2017). However, due to the scarcity of available land resources in cities, it is difficult to improve the heat island effect in urban forest planning design. Therefore, it is an important research direction to optimize the urban forest design pattern and focus on the sustainable development of urban forests (Krüger and Emmanuel, 2013). Based on the study of urban heat island effect, this paper aims at the ecological benefit of forest cities, systematically plans the green space pattern of Shijiazhuang City, Hebei Province, China and puts forward the optimization strategies to realize the sustainable development of urban planning.

Materials and methods

The effective planning design of urban forests can improve the urban landscape. The ecological layout of urban forests should be combined with the natural topographic features of each urban area. The service radius of urban forests is the focus of urban planning design and also relates to the sustainable development of urban ecology (Jay and Schraml, 2013). GIS is a quantitative technical analysis method, and provides a more accurate technical method for the study of heat island effect and urban forest pattern planning in Shijiazhuang City.

There are many measures to alleviate the heat island effect through urban planning, such as greening, energy saving, water permeability, increasing the urban forest space, and strengthening the road forest penetration rate, all of which have the effect of cooling the cities. The overall layout of urban forests is based on local conditions, balanced, systematic, ecological and people-oriented (Madanian and Cost, 2017). *Table 1* is the relevant indicators of the national forest city standard system, which requires the forest coverage rate of the built-up area not less than 17%, the urban road forest penetration rate not less than 60%, the extension rate of the shaded parking lots not less than 60%, and the intensity of urban heat island effect less than 3 °C.

Results

Analysis of forest planning pattern in central urban area of Shijiazhuang City

With the development of satellite remote sensing technology, the method of retrieving surface temperature is constantly updated, and the surface temperature is greatly influenced by forest vegetation index (VI). VI and the surface temperature are calculated as shown in *Equations 1* and *2,* respectively:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91219129

$$VI = \frac{\rho_{NIR} - \rho_{Red}}{\rho_{NIR} + \rho_{Red}} \quad \text{(Eq.1)}$$

$$LST = \frac{T}{1+(\lambda * \frac{T}{\rho}) * \ln \varepsilon} - 273.15 \quad \text{(Eq.2)}$$

where ρNIR represents the reflectance of the near infrared band, ρRed represents the reflectance of the infrared band, λ represents the central wavelength with a value of 11.80 μm, ρ = 1.438 × 10-2 K, ε represents the emissivity value, when VI >, take value of 1 + 0.027ln (VI), when VI ≤ 0, take value of 0.99925.

Table 1. *National forest city standard system related indicators*

Index	National forest city standard	
	Basic item	**Promotion item**
Built-up area forest coverage rate	≥ 17%	≥ 20%
Built-up areas green coverage rate	≥ 35%	≥ 38%
Urban road forest penetration rate	≥ 60%	≥ 70%
Urban road green space compliance rate	≥ 80%	≥ 80%
Promotion rate of shade parking lot	≥ 60%	≥ 70%
Ecological and landscape restoration rate of damaged abandoned land	≥ 75%	≥ 80%
Urban heat island effect intensity	≥ 3 °C	≥ 2.5 °C

Figure 1 shows the classification results of remote sensing images in Shijiazhuang City. The forest coverage area is 14%. In recent year, Shijiazhuang City has persisted in planning and adjusting the layout of urban forests to increase urban vegetation coverage. *Figure 2* is the relevant statistics of vegetation in the central urban area of Shijiazhuang City, and *Figure 2a* is the per capita public green area in the urban areas. It can be seen that the per capita public green area does not increase linearly, but from 2012 to 2018, the per capita public green area in urban areas increased from 9.2 m^2 to 10.4 m^2; *Figure 2b* shows there is a trend of annual increase in trees at the end of the year, but the growth area has been flat in the past two years, increasing to 15.88 million trees in 2018 from 13.22 million in 2012; *Figure 2c* indicates that the number of vegetation trees on both sides of the sidewalks increased from 243,000 to 288,000. Although the area of per capita public green area and the vegetation and trees on both sides of sidewalks in each year do not show the trend of increasing year by year, the urban vegetation planning area increases greatly as a whole, which serves the purpose of alleviating the urban heat island effect. *Figure 3* shows the forest coverage rate of some counties in Shijiazhuang City. Among the ten districts and counties in Shijiazhuang City, the forest coverage rate in 7 districts and counties exceeds 30%, and is less than 30% in 3 districts and counties.

Analysis on the benefits of urban forest cooling

Figure 4 is a graph of superimposing urban forest distribution and surface temperature. In the figure, green is urban forest area. It is found that there is almost no heat island effect in green land location by GIS observation and the heat island effect still exists in areas without vegetation coverage. *Figure 5* shows the trend of intensity change of heat island effect in some urban areas of Shijiazhuang City. It can be seen that the intensity of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91219129

heat island effect in Xinhua, Zhengding, Wuji, Chang'an and Lingshou counties increased by 1.44 °C, 1.65 °C, 1.2 °C, 0.98 °C and 1.0 °C from 2004 to 2018, respectively. The comparison of forest coverage rate and heat island intensity in some counties of Shijiazhuang City shows that the higher the urban forest coverage rate is, the smaller the increase value of urban heat island intensity is and the buffering effect of urban forests on ground cooling. However, due to the influence of urban planning distribution structure and vegetation coverage area, the heat island effect is obvious in areas far from urban forests. Therefore, in order to alleviate the urban heat island effect effectively, it is necessary to optimize the urban forest space construction in the process of urban planning, and improve the thermal effect space by changing the urban forest pattern.

Discussion

Optimization measures of forest urban planning pattern in Shijiazhuang City

The total amount and area of forests in urban planning design are constant, but the planning pattern can be adjusted and optimized. The spatial pattern of urban forests affects the type structure of urban forests and the intensity of urban heat island. *Table 2* shows the type structure of urban forests in Shijiazhuang City. According to the type structure of urban forests, the proportion of park vegetation is the largest, accounting for 38.93% of the total vegetation area, followed by road vegetation and protective vegetation, while the vegetation area of residential areas is very small. However, the area of residential areas is the largest, which is the important reason for the uneven distribution of heat island effect. The planning area of vegetation in residential areas needs to be further improved in the process of urban planning.

Table 2. *Type structure of urban forest in Shijiazhuang City*

Urban forest type	Area/hectare	Proportion/%
Park vegetation	1263.76	38.93
Unit affiliated vegetation	119.46	3.68
Residential areas vegetation	190.55	5.87
Road vegetation	864.15	26.62
Protective cover vegetation	768.06	23.66
Production vegetation	40.25	1.24
Total	3246.23	100%

Figure 6 is the statistics of relevant data of forest cultivation in Shijiazhuang City in recent years, the area of forest cultivation and the number of forest cultivation fields all show a trend of decreasing. The urban forest has a certain threshold to alleviate the urban heat island effect, and the patch arrangement of the forest should be controlled. *Figure 7* is a schematic diagram of the cooling efficiency of centralized and dispersed urban forests. Large area of urban forests breaking into parts can expand the scope of cooling and urban forests are evenly distributed with better benefits. The distance and quantity of urban forest patches should also be reasonably distributed, and the ideal distribution area is to maximize the influence range of the respective forest patches. However, the urban development should consider the layout of buildings, water bodies, roads, and others and it is not possible to arrange according to the ideal distribution. In order to maximize the benefits of urban forests, it is necessary to design the patch shape of the planning areas reasonably, increase the urban forest patch shape index, thus enhancing the coupling degree of forest vegetation and environment, and maximizing the reduction of heat island effect.

Optimization measures for improving heat island effect of urban forests

It is found that the urban heat island effect increases with the increase of urban forest coverage, so it is feasible to increase urban forest coverage. *Figure 8* is a structural diagram of the urban planning and construction of Shijiazhuang, which is combining different urban forest landscape elements according to their own characteristics so as to build a characteristic forest city and improve the diversity of the urban ecosystem.

order to increase the urban forest coverage area and the cooling area of urban forest patches, it is necessary to make full use of the urban gray space to improve the urban forest coverage rate, occupy a large number of urban land space to plan and construct forest patches, and expand the development direction of urban greening. In addition, in order to compound greening, different land types, community structure and tree species composition will produce different environmental effects, so it is essential to rationally select vegetation species of different levels, utilize limited patch space, increase space greening amount, and improve surface cooling effect. Suitable vegetation types should be selected, with trees or ornamental plants with the ability of cooling and humidification for residential vegetation and roadside vegetation. The government departments should also set a reasonable indicator of urban vegetation coverage rate, and the vegetation coverage rate should be faster than the growth rate of urban buildings and population; optimize the management and control requirements of vegetation planning, and in addition to retaining the original vegetation and green space planning, strengthen the vegetation of each land to meet the standards. The government can also expand the planning area of urban forests, reduce the intensity of heat island effect, and realize the sustainable development of urban ecological environment by implementing the mechanism of green subsidy and reward, optimizing urban laws and regulations, and expanding the way of green publicity.

Conclusions

Based on the study of urban heat island effect, this paper systematically plans the green space pattern of Shijiazhuang City and puts forward the optimization strategies in the view of the ecological benefits of urban forests. The concrete conclusions are as follows:

(1) The urban forests can buffer the ground cooling, but the heat island effect is obvious in the area far away from the urban forests due to the influence of the urban planning distribution structure and the vegetation coverage area, and the thermal effect space can be improved by changing the urban forest pattern.

(2) In order to maximize the benefits of urban forests, it is necessary to design the patch shape of the planning area reasonably, and increase the urban forest patch shape index, thereby increasing the coupling degree of forest vegetation and environment, and maximizing the reduction of heat island effect.

(3) It is feasible to increase urban forest coverage rate and reduce heat island effect. It is necessary to increase forest area from urban planning, optimization of vegetation type and community structure and government level so as to realize sustainable development of urban ecological environment.

DOI: http://dx.doi.org/10.15666/aeer/1704_91219129

(4) The planning and design of forest cities is a long-term work. At present, there is no relevant data and theoretical research is not mature, so the remote sensing can be used to retrieve surface temperature to analyze the heat island effect of forest cities in the future.

Abstract. The aim of this study was to determine the strains of tomato yellow leaf curl virus (TYLCV) on the tomato plants growing intensively in Adana, Mersin and Antalya provinces and also investigate the transmissibility of virus by the vector *B. tabaci* biotypes in 2015 and 2017. For this purpose, unperiodical field observations were paid in different districts of those provinces. The TYLCV infected tomato plants and whiteflies on these plants were collected from different greenhouses and fields. The 747 samples of tomato infected with TYLCV were tested by PCR techniques. It was determined that the strains TYLCV-Israel, TYLCV-Sicilia, TYLCV-Sardinia and TYLCV-Mild were found to be infected via strain specific primers. PCR study also indicated that the same strains of TYLCV were also found on the whitefly samples collected from the infected tomato plants. DNA analyses by using specific primer Bem 23-F and R in an individual single whitefly, due to clarification of *B. tabaci* biotypes, has clearly showed that biotype B is a common vector of TYLCV in Turkey. Molecular techniques identified that Israel, Sardinia, Sicilia and Mild strain of TYLCV were present in three tomato cultivation areas in Mediterranean Region. *B. tabaci* biotype *B* (formerly *B. argentifolii*) was detected as a vector of those of strains. It was observed that (%92) *B. tabaci* Biotype B and (%8) Biotype Q others were responsible for transmission as vector of TYLC respectively. Individual viruliferous Biotype B samples examined in PCR showed that the most determined TYLCV strain as Israel was the most common among the strains, what were identified.
Keywords: *TYLCV strains' molecular epidemiology, Bemisia tabaci biotypes, impact on agroecology, Turkey*

Introduction

Tomato yellow leaf curl virus (TYLCV) is a member of *Begomovirus* genus in Geminiviridae family causes severe crop losses in tomato cultivars up to 100% (Czosnek and Laterrot, 1997). It has a broad host range with various plant families such as *Solanaceae* (tomato, peppers, various nightshade weeds, and ornamental plants), *Malvaceae* (cheeseweed) and *Fabaceae* (beans). TYLCV causes yellow leaf edges, upward leaf curling, leaf mottling, small leaf, and flower drop. The infected plants in early stages do not bear fruit and stunting, depend on seasonal conditions and cvs. susceptibility, is observed on plants. TYLCV genome consists of circular, single-stranded DNA (ssDNA) approximately 2.7 kb long (Gronenborn, 2007). Long-distance

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91319144

spread of TYLCV occurs primarily by movement of infected plant material or by wind dispersal of whiteflies, acquisited the virus (Torre et al., 2018). The virus, was first discovered in 1939 in Israel and Jordan (Avidov, 1944), was officially named *Tomato yellow leaf curl virus* (TYLCV) and consists of different strains; *Tomato yellow leaf curl* Israel (TYLCSV-Is), *Tomato yellow leaf curl virus*-Mild (TYLCV-Mld), Sardinia (TYLCV-Sa), *Tomato yellow leaf curl* Sicily (TYLCSV-Sic), *Tomato yellow leaf curl virus*-Morocco (TYLCV-Mo), *Tomato yellow leaf curl* Malaga (TYLCV-Mal) *Tomato yellow leaf curl* Axarquia (TYLCV-Ax), *Tomato yellow leaf curl* China (*TYLCV-Ch)* and *Tomato yellow leaf curl* Thailand *(TYLCV-Th.)* (Fauquet et al., 2008; Abhary et al., 2006).

Since, the disease has spread rapidly to the Middle East and the Mediterranean coast, Asia, Africa, Europe, the United States, Australia, Italy and many other countries (Accotto et al., 2000; Boulton, 2003; Moriones and Navas-Castillo, 2000). In Turkey, TYLCV was first discovered in Mediterranean region by Yılmaz (1978). And then it was reported as the most devastating virus disease at tomato both in greenhouses and the field in Turkey by Abak et al. (1991). On the other hand, presence of whiteflies was known well in Cukurova region due to its severe damage to cotton production (Karut et al., 2015; Satar and Ulusoy, 2016)

Whiteflies are insects belonging to family *Aleyrodidae* which cause direct by phloem-feeding and indirect damage by transmission of viruses including begomoviruses (Brown and Czosnek, 2002; Jones, 2003; Navas-Castillo et al., 2011). The transmission of TYLCV by whiteflies is circulative semi-persistent manner. There are several reports of whitefly presence and economic damage in Turkey (Ulusoy et al., 2012; Bayhan et al., 2006). Morphological discrimination of whitefly biotypes is difficult. But it is possible by using molecular methods (Papayiannis et al., 2009). Most common whitefly biotypes in Turkey are biotype B and Q (Karut et al., 2012; Satar and Ulusoy, 2016) similar with various reports around the world (Konjevic et al., 2018; Li et al., 2017)

The aim of this work was to investigate of TYLCV strains epidemiology and its strict vector *Bemisia tabaci* biotypes on agroecology by reliable technique such as Polymerase Chain Reaction (PCR) in southern coast of Turkey. In fact, that there is not any verification.

Materials and methods

Surveys were conducted in Adana and Mersin provinces having typical Mediterranean climate in Turkey. Leaf samples from symptomatic tomato plants that showing typical TYLCV symptoms (upward leaf curling, yellowing, distortion and stunting) asymptomatic leaf samples as negative control and whiteflies were collected from 245 different greenhouses which were located in several areas in south of Turkey (Adana, Mersin, Antalya) (*Fig. 1*).

Total RNA isolation, polymerase chain reaction (PCR) and phylogenetic analysis

Total DNA was extracted from leaf tissues according to Scientific GeneJET Plant Genomic DNA Purification Mini Kit. Strain-specific primers identified by Anfoka et al. (2005, 2008) were used to determine TYLCV strains (*Tables 1* and *2*).

DNA extraction from an individual whitefly: Total DNA was isolated from individual whiteflies as described by Zeidan and Czosnek (1991). In the modified

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91319144

simple procedure, individual whiteflies were ground 40 µl of DNA extraction buffer (50 mM Thris. HCl (pH8.0), 0.5% Tween 20, 0.025 mg/ml Proteinase K) and incubated at 65 °C for 2 h. After incubation, 20 µl 5 M potassium acetate was added and placed on ice 5-15 min. Centrifuged 10 min and placed 50 µl of supernatant into a 1.5 ml micro centrifuge tube. Added 30 µl cold isopropanol, mix, and hold on ice about 5 min centrifuged 10 min, draw off and discarded most of the supernatant, added 75 µl of cold 70% ethanol, mix gently, and centrifuge 2 min, Remove and discard nearly all of the supernatant being careful to not remove the pellets. Let pellets dry for about 10 min then add 40 µl of sterile distilled water. These DNAs were used to identify white fly biotypes with the codominant SCAR markers Bem-23 (Bel-Kadhi, 2008) (*Table 1*). The PCR of TYLCV strains were obtained with DreamTaq Green PCR Master Mix (2X) (K1081Thermo Scientific, Germany) according to the manufacturer's instructions. PCR cycle parameters were as follows: one cycle at 95 °C for 3 min; 36 cycles at 95 °C for 45 s, I, Primer Set 52, II. Primer set 62° and Whitefly primer 55 °C for 45 s, and 72 °C for 45 s, followed by one cycle at 72 °C for 7 min and lastly storing at 4 °C until electrophoresis.

Table 2. *Strain -specific primer pairs for PCR and the expected PCR product sizes*

Strain-specific primer pairs for different TYLCV strains	Primer codes	Expected product size
Multiplex PCR: I primer combination		
Tomato yellow leaf curl virus (TYLCV-Is)	TYLCV6, TYLCV7	543 bp
Tomato yellow leaf curl virus-Sicilia (TYLCV-Sic)	TYLCV8, TYLCV6	946 bp
Tomato yellow leaf curl virus-Mild (TYLCV-Mld)	TYLCV5, TYLCV4	316 bp
Multiplex PCR II. primer combination		
Tomato yellow leaf curl virus-Israel (TYLCV-Is)	TYLCV3, TYLCV4	634 bp
Tomato yellow leaf curl virus Sardinia (TYLCSV-Sa)	TYLCV1, TYLCV2	433 bp
Tomato yellow leaf curl virus-Mild (TYLCV-Mld)	TYLCV5, TYLCV4	316 bp

Analysis of PCR products

PCR reaction mixture (Ten microlitres) was combined with gel loading buffer and analyzed on a 1.5% agarose gel containing 0.5 mg/ml of ethidium bromide and photographed (Sambrook et al., 1989). 100 bp DNA ladder (Thermo) or Bio Marker^{TM} Low (Bio Ventures, Inc.) were used on each gel to determine the length of the amplified product. PCR-amplicons run at 100 V for 70 to 80 min, and the gel was stained with ethidium bromide.

Sequence analysis

Expected PCR products from TYLCV strains were re-amplified by using Finnzymes' Phusion® High-Fidelity DNA Polymerase enzyme and 10 µl of PCR products were checked. Remaining PCR products were sent to Sentobiolab commercial firm and nucleotide sequence of amplified regions were determined. Nucleotide sequences were checked and edited by using Bioedit then checked for protein synthesis to determine the sequences are significant or not by ExPASy programme. Valid sequences were compared with strains of TYLCV gen bank (NCBI, National Center for Biotechnology Information).

Results

Surveys are conducted for collecting whiteflies and young tomato leaf samples from symptomatic plants that are related with suspicion of TYLCV infection from Adana, Antalya and Mersin between 2015 and 2017 (*Table 3*). Virus symptoms differ due to various factors such as climate, plant variety and infection period. It is common using indicator plants to identify the viral agent meanwhile for TYLCV, there is no practical identification method than molecular characterization of strains due to not transmitted by mechanic transmission. On the other hand, no symptomatic differences between TYLCV strains were observed up to date.

PCR

Simultaneously, there are no apparent macroscopic biotype differences between white-fly species. In autumn season, TYLCV can be monitored in every greenhouse. Predisposition for TYLCV such as low-quality greenhouse structures, openings for whiteflies, causes high infection rates (*Table 3*).

Considering the observations, 747(234: Adana, 255: Antalya, 258: Mersin) infected plants and 852 whiteflies (274: Antalya, 216: Mersin, 362: Adana) from different locations of the provinces were collected. Also, 91 plant samples were among them collected from open fields in Adana (*Table 4*).

Determination of TYLC strains by multiplex PCR: I. Multiplex primer pairs for TYLCV-Is, TYLCV-Sic and TYLCV-Mild; II. Multiplex primer pairs for TYLCV-Is, TYLCV-Sar (ES) and TYLCV-Mld. These multiplex sets differentiated the strains as expected. Same multiplex sets also used for detecting TYLCV and its strains within whiteflies. Leaf samples were studied with 25 µl PCR mixture by using 96 well plates. For whitefly samples, 15 µl PCR mixture was used due to low concentration of DNA.

The TYLCV strain specific PCR results realized that the most common infection was occurred by 100%. Consequently, detected as mixed between 86% TYLCV Israel + Mild strains (*Tables 4*, *5, 6* and *7*). Following this, 10% TYLCV-Is + TYLCV-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

Sic, TYLCV Sic + TYLCV- Sar. 4.5% mixed infection rate was approximately 20% in Antalya, Mersin and Adana.

The sequence analysis and multiple sequence alignment were carried out using Chromas (Technelsium DNA Sequencing Software Australia) and CodonCode Corporation (Florida) software. The TYLCV strain specific PCR sequences were analyzed in National Center for Biotechnology Information (NCBI) using nucleotide BLAST. The agarose gel electrophoresis TYLCV multiplex PCR amplifications is shown in *Figures 2A, B* and *3*.

Positive controls (biotype B and biotype Q) for white-fly population experiments were provided from Israel. (Dr. A. Rami Horowitz Agricultural Research Organization, Gilat Research Center, Institute of Plant Protection, Department of Entomology, Israel). B biotype white-flies in *Figure 4*. were determined by codominant SCAR markers Bem-23-F and Bem-23-R which was developed by Bel-Kadhi (2008).

The results show that *B. tabaci* biotype B (92%) is prevalent in the majority of the surveyed sites, whereas biotype Q was only found in 8%. In each three provinces where surveyed, *Bemisia tabaci* biotype B was the most common and effective vector for TYLCV.

Phylogenetic analysis

In sequence comparisons (NCBI Query ID lcl|29009), TYLCV Israel isolate showed 97-98% similarity with Lebanon, Israel and Morocco isolates, Mild isolates showed 96-99% similarity with Lebanon, Spain, Italy and USA isolates. Sardinia and Sicily isolates were 94-97% similar with Italy, Spain and Morocco isolates (|EU143755.1, AF260331.1, FJ012359.1, EU719081.1) (*Fig. 5*).

Haplotype analysis was evaluated at "dnasp5.exe" programmed. When isolates from three provinces compared, TYLCV-Mld isolates were belonged a haplotype, on the other hand, each TYLCV-Sic isolates had different haplotypes. TYLCV-Is and TYLCV-Sa had two haplotypes as Adana and Antalya, both Mersin and Adana isolates haplotypes were detected identical

The sequences were compared and verified in the NCBI Blast system. Verified Sequences TYLCV-Is (MH367503, MK536596) to the NCBI system; TYLCV-Mld (MK536597); TYLCV-Sar (MK536600,) and TYLCV-Sic (MK536601, MK536602) are registered as isolates.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91319144

The phylogenetic analysis utilizes that the tree is separated into two main groups (Group I and Group II) and Group I divides to 3 subgroups. TYLCV-Mild isolate from Turkey has a unique haplotype which is clustered in Subgroup 1C despite of showing approximately 93-98% similarity with other isolates around the world. TYLCV Mild isolates from Malaga, Lebanon, and Jordan are clustered in Group 1A alongside with TYLCV-Is isolate. TYLCV-Sar and TYLCV-Sic isolates are clustered in Group 1B with other Jordan, Italy and Spain isolates which shows that these isolates are related in the terms of phylogenetic.

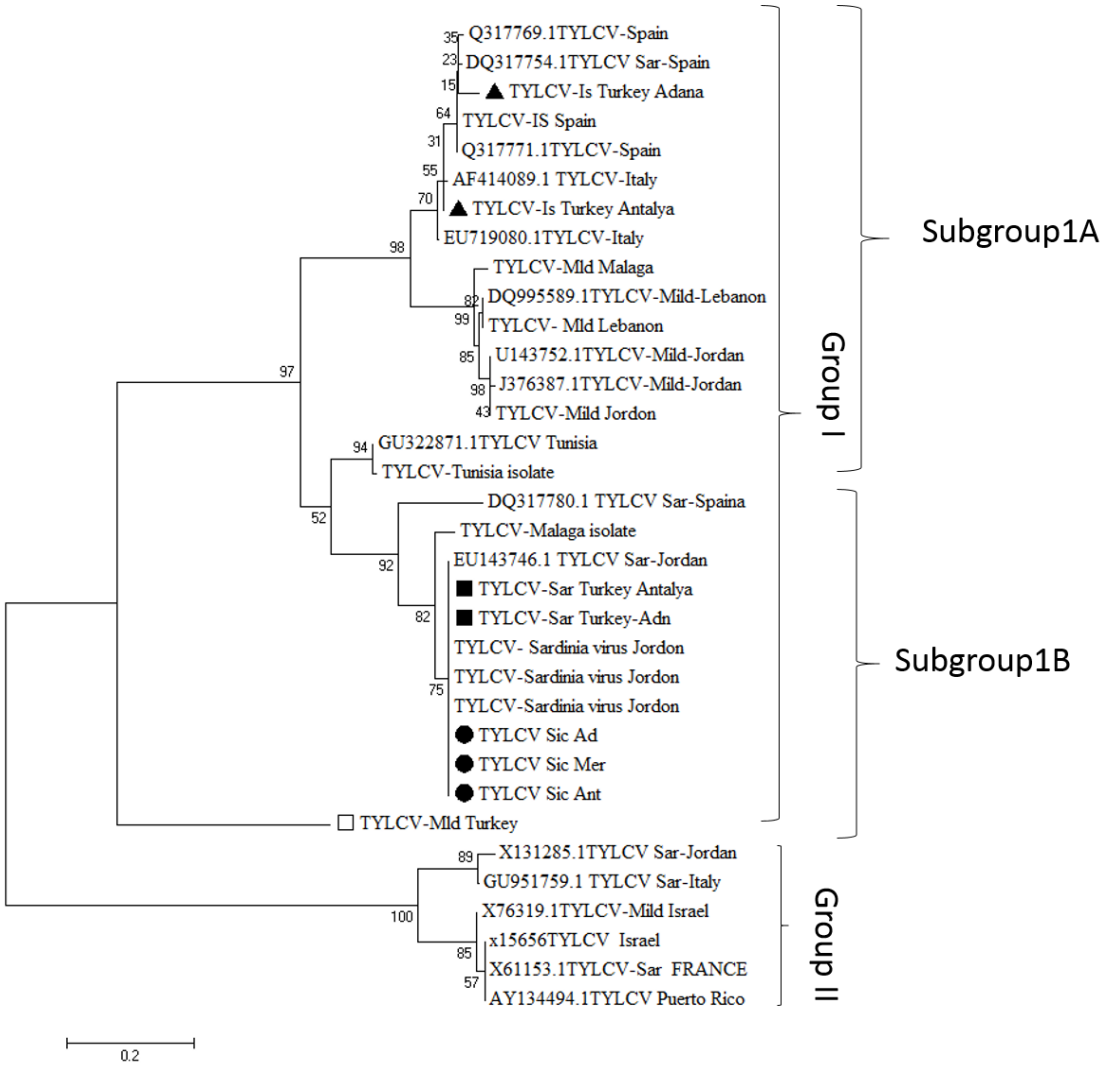

Figure 5. *After haplotype analysis, phylogenetic trees were constructed with MEGA 7 programme. Related 24 isolates were selected by using BLAST analysis in NCBI database and Neighbour-joining method was used TYLCV isolates from three provinces in Turkey*

Discussion

With this study, TYLCV strains and whitefly biotypes were determined which are two of the major problems of greenhouse tomato cultivation. TYLCV was observed in almost every greenhouse especially in autumn season. Temperature changes effect directly whitefly migration to greenhouses feeding behavior therefore TYLCV infection

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91319144

rate in greenhouses increases significantly as well its transmission. Although chemical management starts at threshold white-fly adult population. Nevertheless, observations showed that insecticides have not suppressed whitefly population even by rotating insecticides with different mode of action. In addition to these, insufficient knowledge of growers, presence of primitive greenhouse and growing conditions, no precautions for whiteflies such as many cavities around the greenhouses are making TYLCV infection spreading rapidly. Widespread infection causes virus to evolve more rapidly.

The most common observed strain was TYLCV-Is and TYLCV-Mld mixed infection in south coastal region of Turkey where the Mediterranean climate is dominant. On the other hand, this is the first report of TYLCV Sic. and Sar strains Mediterranean region of Turkey. Until the present study they have not been characterized and confirmed yet with reliable molecular methods such a PCR analyses at Turkey. There were TYLCV-Sic. strain infection found with general average 10% ratios where infections ratios were 6.2% Mersin, 2% Adana and 22% Antalya provinces respectively. Furthermore, there were TYLCV-Sar infections obtained general infection rate was 6.5% where infection ratios were 3,4% Adana, 10,5% Antalya and 5,4% Mersin respectively. Similar results have also determined from an individual whitefly's genomic structures had revealed TYLCV-Sic and TYLCV-Sar strains in PCR analysis.

Greenhouse studies for whiteflies showed that biotype B was the most common with aprox.92% average in all three provinces. Other studies about the biotypes of whiteflies at vegetables in Turkey also support this result. Ulusoy et al. (2012) reported that for vegetables biotype B and for cotton biotype Q are common whitefly populations. Therefore, this supports the results about detecting 10% biotype Q in Adana province (Karatas, Yuregir counties) where the production of cotton is widely done and after cotton harvest, whiteflies are rushing to higher temperature such as greenhouse tomato production areas. TYLCV transmission can be done by both B and Q biotypes however biotype B is more effective than Q biotype (Ajlan et al., 2007; Bel-Kadhi et al., 2008; Czosnek, 2008; Haider et al., 2017).

For detection, Multiplex PCR primer pairs and codominant SCAR markers was used considering the expenses, time wasting and more method steps (like RLFP) was the issue of the given methods in EPPO bulletin. This study proved that there are cheap, fast methods which have less error rates. Also there are no TYLCV Far East Asia and Africa strains in Turkey (Ohnishi et al., 2016). At least low incidence rate of Sardinia and Sicily which were South European strains (Italy, Spain, Morocco, Tunisia isolates) could be considered as positive finding of the study. Due to the fact that It is important to further exacerbate the damage caused by the existing strains. Furthermore, it is thought that there will be less chance of impact on the formation of undesired recombination between strains or isolates in the ecosystem both in and around the production area.

Conclusion

There are many ways to control TYLCV infection (Czosnek et al., 2017). Chemical control of whitefly is not the absolute solution therefore resistance to TYLCV through genetic means such as TY-1 and TY-3 genes (Zamir et al., 1994), TY-1 (Ji et al., 2007; Torre et al., 2018) or Co dominant Sequence Characterized Amplified Regions (SCAR) still are better options. Presence of many strains and multi gene controlled resistance decreased efficiency of TY1 gene. For this purpose, to overcome like breeding

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91319144

problems TY3 gene based codominant SCAR markers were developed, are supply Marker Assisted Selection for heterozygotes resistance and also homozygote susceptibility against to all Mediterranean isolates. Although there should be more studies to determine which strains involve in cultivation areas due its tendency to evolve or recombination. The strain identification has a solid importance, gives more effective directions for breeding supplied by well-characterized TYLCV strains. This study showed that there are at least four strains in Turkey and their contribution throughout Mediterranean coast. Focusing on resistant cultivars and their capacity to control the virus in Turkey as well as limiting its transmission by whiteflies could minimize damage caused by TYLCV.

The Mediterranean line has important agricultural trade areas and all kind of commercial products have been imported. This revealed contribution the natural distribution and occurrence of TYLCV in areas located. Our results pointed out the vector types with molecular techniques and sanitary conditions for TYLCV, present in tomato fields, are transmitted by white flies. The management of these vectors are so hard due to high reproductive ability, having broad range of hosts and ability to form insecticides durable species or types. In addition, the presence of vector whiteflies in the greenhouse and outside, the absence of biological and chemical control agents, takes to higher the infection. TYLCV has been spread more and more by vectors from different weeds to tomato are cultivated in greenhouse.

But nevertheless, TYLCV has a lower impact on production as it can be well controlled by molecular resistance breeding in soon.

This manuscript may also indicate sources of local TYLCV strains in tomato produced provinces. Uncontrolled distribution of *B. tabaci* types could be vectors of TYLCV strains; if whiteflies migration by air-ways or plant transportations could commence TYLCV infections at Mediterranean Countries.

The PCR technique, was standardized and successfully applied for TYLCV and *B. tabaci* biotypes, put forwarded relations between virus strain and vector bio types by Molecular assays. Therefore, Epidemiological role and feeding behaviors of *Bemisia tabaci* (Hemiptera: Aleyrodidae) Biotypes' for TYLCV strains on Tomato Agro Ecology in Turkey, has been become well understandable as agricultural host reservoir. Novel management strategies for disease vector complexities will be devised upon these studies to protect sanitized and resistance plants, often depends on the activation of vectors and pathogen (Razukas et al., 2007). Therefore, transmissibility of TYLCV (specially mixed infections) could be prevented.

Detailed project has planned for unknown epidemiological features of the virus vector relations (Islam et al., 2016). The determining the virus ecology and molecular origin were another outcome of results. High successful control of TYLCV spread relies upon easy discovery of these infections in stock planting material. All positive samples which were detected in this study have been eradicated.

This report is unique signature step for initiating researches on impact of whitefly vectors to the agro ecology. It is important because different virus isolates or their strains are caused disease in different host species during whitefly migration. It is possible that new isolates can result virus diseases in host plants even mixed or different isolates in whiteflies will cause possible recombination. This is not possible to estimate the adverse effects and epidemiology of the recombinants in the agricultural ecology and in the natural ecology without observing or living.

(Received 19th Mar 2019; accepted 24th May 2019)

Abstract. Phosphorus (P) is an essential nutrient element required for plant growth and development. Low phosphorus availability in soil is one of the major constrains for crop production. Phosphate solubilizing fungi enhance available phosphorous released from soils and contribute to fulfill the plants phosphorous requirement. This study aimed to isolate and identify potential phosphate solubilizing fungi from subtropical soils for environment friendly biofertilizer development. Sixteen fungal strains were isolated and identified as *Aspergillus* spp., *Penicillium* spp. and *Talaromyces* spp. from subtropical dark red soil, red soil and grey soil based on phosphate solubilization index, morphological studies and the sequences of β-tubulin and/or Calmodulin. Subsequently, fungal isolates having excellent phosphate solubilization efficiency were selected by their potential in broth containing insoluble $Ca_3(PO_4)_2$, $AlPO_4$ and $FePO_4$. Interestingly, *Aspergillus niger* isolates (strain SI-10URAgr, SI-11URAgr and SI-12URAgr) have marked phosphate solubilization ability regardless of the substrates followed by *Panicillium oxalicum* and *Talaromyces pinophilus.* In addition, there was inverse proportion between the pH and phosphate solubilizing capacities. These excellent properties of strains suggested that they have a great potential for agricultural utilization as environmentally sound biofertilizer. In this study, phosphate solubilization by filamentous fungi is reported for the first-time in subtropical Okinawa.
Keywords: *phosphorous, Aspergillus niger, biofertilizer, eco-friendly nutrient management, subtropical soil*

Introduction

Phosphorus (P) is one of the major nutrients for crop production (Reena et al., 2013). This nutrient play important physiological and bio chemical activities of plants, like, photosynthesis, energy and sugar production, nucleic acid synthesis, and promotes nitrogen fixation in legume plants (Saber et al., 2005). Phosphorus promotes the strength of grain crop straw, flower initiation and fruit settings, root development and seed formation (Sharma et al., 2013) and disease resistance capacity of plants (Richardson et al., 2007). In soils, only 0.1% of the total P exists in a soluble form available for plant uptake because of its fixation into an unavailable form (Zhou et al., 1992; Khan et al., 2010). In order to provide this nutrient, farmers use chemical fertilizers. The most widely used fertilizers are obtained from the acidification of rock phosphates with strong acids which not only represent a major cost of agricultural

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91459157

production but also impose adverse environmental impacts on overall soil health, terrestrial, freshwater and marine resources (Sing et al., 2011; Tilman et al., 2001).

The major soils in sub-tropical Okinawa are, red soil, dark-red soil and grey soil which are phosphorous deficient (Oshiro et al., 2016). The red soil and dark red soil have low pH value (5.4 and 6.6 respectively), one the other hand grey soil has high pH value (8.4). Large amount of soluble P fertilizers is widely used in order to increase agricultural production world widely (Bo et al., 2011). Moreover, the efficiency of applied P fertilizers in chemical form rarely exceeds 30% due to its fixation, either in the form of iron/aluminium phosphate in acidic soils or in the form of calcium phosphate in neutral to alkaline soils (Norish et al., 1983; Lindsay et al., 1989). According to the latest estimates, the global reserve of P could become depleted within 50-100 years (Heppel et al., 2016). Besides the efficient use of P reserves, it is also important to reduce the current wastage of P fertilizers and to recover applied P. The realization of all these potential problems associated with chemical P fertilizers has led to the search for environmentally compatible and economically feasible alternative strategies for improving crop production in low or P-deficient soils (Zaidi et al., 2009).

The microbial inoculants (biofertilisers) function as key player in sustainable agriculture by improving soil fertility and crop productivity (Deepak et al., 2014). Especially, fungi are able to penetrate in to deep underground and show good attachment to insolubilized P particles as results of its hyphal structure compared to bacteria and actinomycetes. Furthermore, fungi are good acid producer and consequently show greater phosphate solubilization activity than bacteria (Deepak et al., 2014; Jose et al., 2010). Among these, *Aspergillus* spp., *Penicilium* spp., *Talaromyces* spp. and *Eupenicilium* spp. are considered “key organisms” in the P cycle (Jose et al., 2010). However most of the fungal species solubilize inorganic calcium phosphate and have a limited capacity to solubilize aluminium or iron phosphate. There are few in vitro studies concerning the solubilization of other phosphates by fungal species. To address this limitation, the present study aims to isolate and identify new isolates of indigenous phosphate solubilizing filamentous fungi which could be potential to solubilize both tricalcium phosphate, aluminium phosphate and iron phosphate.

Materials and methods

Isolation

The study was carried out in the Mycology Laboratory, Faculty of Agriculture, University of the Ryukyus, Okinawa, Japan during August 2017–November 2018 under a class II biohazard cabinet (BHC-1306IIA/3B, AIRTECH, Tokyo, Japan) followed to the biosafety classification by National Institute of Infectious Disease of Japan, because of possibilities of including toxic fungal species treated as BSL2 during the isolation.

The sampling area located at 26.5000°N and 128.0000°E (*Fig. 1*). Its climate is subtropical, temperatures range from 10 to 32 °C. Low temperature (10 to 26 °C) exists in winter season and higher temperature (27 to 32 °C) exists in summer with a humidity level near 100%. The major soil types are dark red soil, red soil and grey soil in this area.

Zero to fifty cm depth soil samples were collected from ten different locations of three type soils using sterile auger. One-hundred-gram soil was taken from each sampling point and it makes a total of 500 g composite sample (five points from each location make one composite sample). The samples were transferred to laboratory in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91459157

sterile sealed polythene bag under aseptic condition and stored at room temperature. Then microbiological study was done as early as possible.

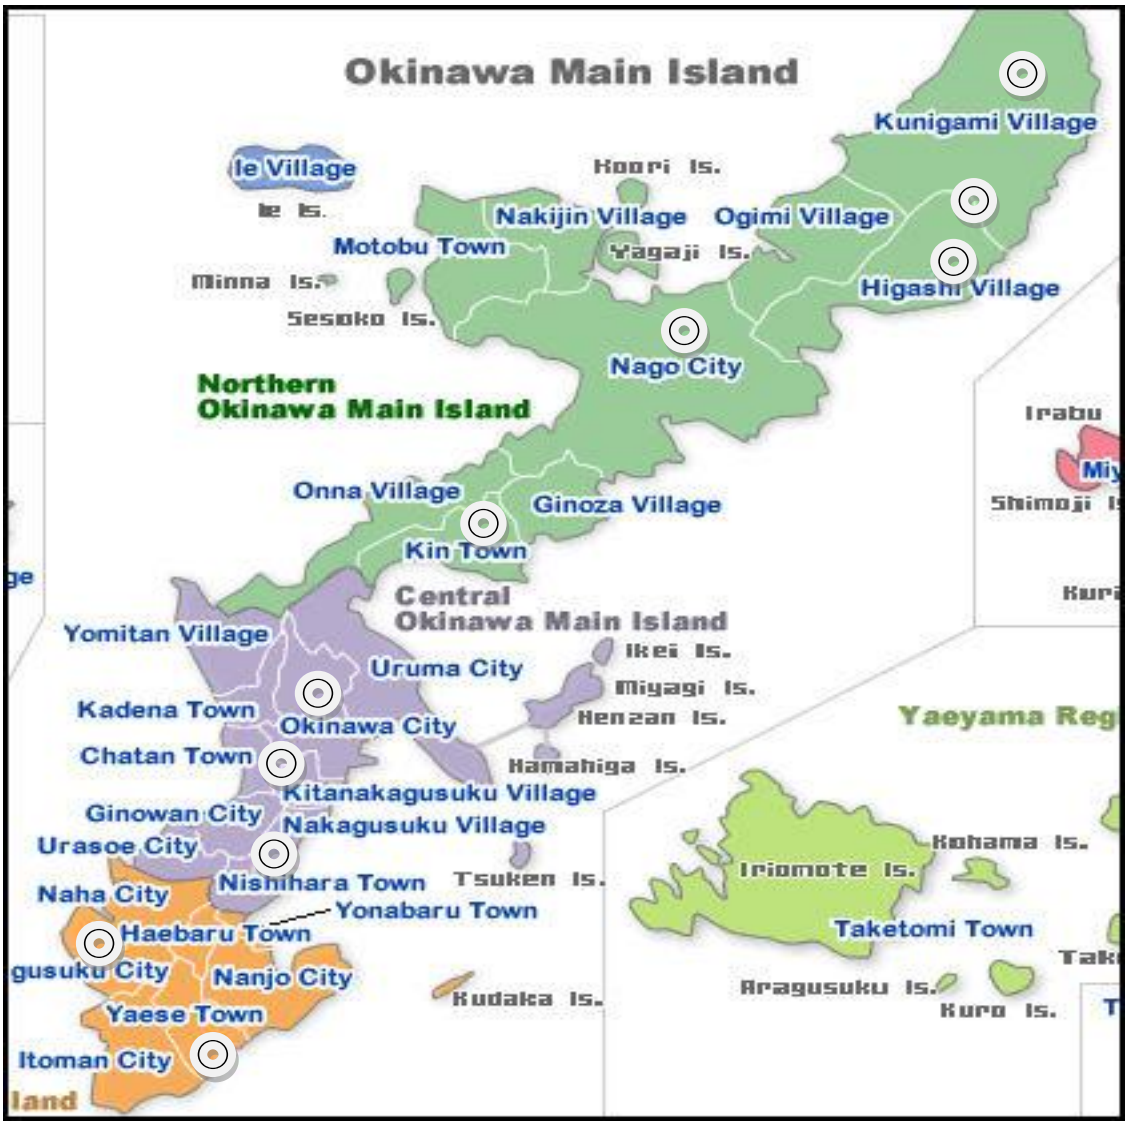

Figure 1. *Geographical map of the study area indicated sampling location*

For isolating phosphate solubilizing fungi Pikoveskaya's (PKV) agar medium was used. Pikoveskaya's (PKV) agar medium consisted of 10.0 g glucose, 5.0 g $Ca_3(PO_4)_2$, 0.5 g $(NH_4)_2SO_4$, 0.1 g $MgSO_4 .7H_2O$, 0.02 g NaCl, 0.02 g KCl, 0.003 g $FeSO_4 .7H_2O$, 0.003 g $MnSO_4 \cdot H_2O$ 0.5 g yeast extract, 15.0 g agar and 1000 mL distilled water (Rao, 1982). In this medium $Ca_3 (PO_4)_2$ was used as a source of insoluble phosphate. The medium was autoclaved at 121 °C for 15 min. About 20 ml of the sterilized medium poured into each petri dish and allowed to solidify before inoculation. Chloramphenicol was also used to avoid bacterial growth.

Isolation of phosphate solubilizing fungi using serial dilution plate technique. Five-gram soil sample was diluted in to 50 ml of sterile water. It was vigorously shaken until to get homogenous suspension and serially diluted to 10^{-1}, 10^{-2}, 10^{-3} and 10^{-4}. From each dilution, 200 µL was plated on Pikovskaya's agar. The phosphate solubilizing

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91459157

fungi were identified by the presence of a clear halo around the colonies after 7 days incubation at 25 °C (Rao, 1982). The experiment was performed in triplicate. Phosphate solubilizing fungi of the soil samples were isolated and purified by transferring into new plates. The pure cultures were preserved on potato dextrose agar slants at 4 °C for further study. Phosphate solubilisation index was measured using the following formula (Birhanu et al., 2017):

$$SI = [\text{Colony diameter} + \text{Halo zone diameter}] / \text{colony diameter}$$

Identification of phosphate solubilizing fungi

The genera of phosphate solubilizing fungal isolates were identified based on the taxonomic keys based on morphologies (Watanabe, 2010). The keys were the color and tint in colony overs and revers, presence of aerial hyphae, colony surface texture, colony margin and pattern of pigment exudations. Wet mounts prepared from micro culture were mounted in lacto phenol and lacto phenol cotton blue. Microscopic examination and photomicrography were performed with an OLYMPUS BX50 microscopy equipped with image Analysis system (Olympus Corporation, Tokyo, Japan).

DNA was extracted from one piece of fungal mycelia from a culture incubated at 25 °C for 48 h on Sabrouraud medium containing 2% glucose and 1% peptone using a DEXPAT kit (TaKaRa, Japan) to identify the isolates at genetic level (Yamaguchi et al., 2014). Beta- tubulin gene sequences amplified with primers bt2a and bt2b and calmodulin genes amplified with primers CMD5 and CMD6 were determined (Samson et al., 2014). Sequences were analyzed by the NCBI BLAST tool to classify and identify closely related fungal sequences. We identified the isolates to the certain species if the BLAST results showed similarity values of 98% or higher.

Preparation of spore suspension

Sporulated pure fungal cultures slants were selected for preparation of spore suspension by using standard procedure. A total volume of 5 ml sterile water with twin 80 was added in culture slants and the fungal colony surface was lightly scraped by sterile bamboo stick. The cultures were passing through a syringe with staff cotton. Spore count was done by a hemocytometer and the suspension was adjusted to approximately10^6 spores mL^{-1}.

Quantitative estimation of phosphate solubilization

It was carried out using Erlenmeyer flask containing 40 ml Pikoveskaya's (PKV) broth medium supplemented with 0.5% tricalcium phosphate [$Ca_3 (PO_4)_2$], aluminium phosphate ($AlPO_4$) and iron phosphate ($FePO_4$). After sterilization, the medium of each flask was inoculated with the 5% (v/v) spore suspension of a particular fungal isolate containing 10^6 spores mL^{-1}. Sterile distilled water inoculated flaks was treated as control. Three replicates were maintained for each test isolate and mean value was recorded. Incubation was done at 25 °C in an incubator shaker at 120 rpm up to 9 days. The samples were autoclaved and centrifuged at 5000 rpm for 25 min to remove any suspended solids and mycelial parts. Then the cultures were filtered through 0.45 µm pore size syringe filter unit (Advantech, japan). The filtrates were used for analysis of soluble phosphate and pH value. The pH value of the culture supernatants was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91459157

determined by a pH meter (Horiba, Japan) equipped with a glass electrode. The amount of soluble phosphorus in culture supernatants was measured by molybdenum blue method and expressed as mg/L (Morphy and Riley, 1962). Samples cultured for 3, 6 and 9 days were compared. After calculation of mean phosphate degradation ability from 16 isolates of each day, we selected the adequate period for the comparison depending on the substrate.

Effect temperature on the growth and survival of isolates

The isolates were cultured on PDA slants in triplicate and incubated at temperature at 35, 37 and 42 °C for 7 days to evaluate the growth of mycelia. Growth of isolates at 25 °C (room temperature) treated as positive control.

Statistical analysis

All experiments were conducted in triplicate and data were analyzed using Microsoft Excel program. The mean values were compared by Fisher test and significant differences were detected at $p < 0.05$ level. Correlation between solubilized phosphate and pH of the medium was determined by using Pearson correlation studies.

Results

Screening and identification of phosphate solubilizing fungi

A total of 16 fungal isolates showed phosphate solubilizing activities. The isolates were 6 *Aspergillus* spp., 6 *Penicillium* spp. and 2 *Taleromyces* spp. identified based on colony morphology, microscopic observation and Beta-tubulin and/or calmodulin sequences (*Table 1*).

Qualitative phosphate solubilization

Sixteen fungal isolates showed significant phosphate solubilization in Pikovskaya agar medium using tricalcium phosphate as the substrate. The phosphate solubilization index (PSI) ranged from 1.42 to 2.24 (*Table 2*). Isolate SI-16URAgr (*Penicillium oxalicum*) produced highest PSI; 2.24 (*Fig. 2*), whereas; the smallest PSI of 1.42 was achieved from SI-3URAgr (*Aspergillus nevius*)

Quantitative phosphate solubilization

Phosphate solubilizations by the isolated fungi were analyzed in Pikovskaya broth medium using three substrates of recalcitrant phosphate compounds: tricalcium phosphate [$Ca_3(PO_4)_2$], aluminium phosphate ($AlPO_4$) and iron phosphate ($FePO_4$). The

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91459157

P-solubilizing ability of fungal isolates varied with incubation period and substrates. The best period of observation was selected considering their mean P solubilization, which 9 days for $Ca_3(PO4)_2$ and 6 days for both $AlPO_4$ and $FePO_4$ (*Table 3*).

Table 3. *Selection for the best period of phosphate solubilization by fungal strains*

Values given are the mean ± standard deviation of P solubilized by 16 fungal isolates
An asterisk (*) indicated the highest solubilization day

The strongest phosphate (P) solubilization effect was found in the medium containing $Ca_3(PO_4)_2$ followed by $AlPO_4$ and $FePO_4$ (*Table 4*). The solubilized P ranged between 73.2-759.4 mg/L, 85.6-599.6 mg/L and 36.6-663.8 mg/L from $Ca_3(PO_4)_2$, $AlPO_4$ and $FePO_4$ respectively. Among the isolates the highest amount of P was solubilized by *Aspergillus niger* followed by *Penicillium oxalicum* and *Talaromyces pinophillus.* Finally, *Aspergillus niger* strain SI-10URAgr, SI-11URAgr and SI-12URAgr were considered as outstanding isolates because solubilized P was higher than sum of the mean and standard deviation of P solubilized by 16 isolates. The amount of solubilized P from $Ca_3(PO_4)_2$ was 759.5, 647.8 and 670.5 mg/L; from $AlPO_4$ was 388.0, 558.3 and 599.7 mg/L and from $FePO_4$ was 663.8, 555.9 and 517.0 mg/L respectively (*Table 4*). SI-10URAgr showed outstanding performance in both $Ca_3(PO_4)_2$ and $FePO_4$ solubilization but in case of $AlPO_4$, it was very close to the outstanding.

pH value of the culture medium

pH of the culture medium exhibited the opposite changes. It decreased with the increased amount of soluble P in the medium. Correlation studies showed a significant inverse relationship between soluble P and pH of the culture medium (*Fig. 3*). The strongest negative correlation was observed in all fermented broth culture and correlation coefficient (r) was -0.88, -0.74 and -0.84 in TCP, Al-P and Fe-P respectively.

Discussion

The sixteen P solubilizing fungal strains were isolated from the dark red, red and grey soils of subtropical Okinawa. The isolates were belonging to the genera of *Aspergillus, Penicilium* and *Talaromyces*.

According to Zang et al. (2018), Mendes et al. (2014) and Ruangsanka (2014), there were diversities on the isolation rate of phosphate solubilizing fungi depending on area. They reported that the most dominant genera of P solubilizing filamentous fungi are *Aspergillus, Penicilium* and *Talaromyces*, however, there were large variations in phosphate solubilizing abilities among fungal species (Barrooso et al., 2006; Surange et al., 1985). At the present studies, strains SI-10URAgr, SI-11URAgr and SI-12URAgr identified as *A. niger*, showed excellent P solubilizing abilities regardless of the phosphate substrates. It suggested that phosphate solubilizing abilities in *A. niger* is an universal property.

Among the filamentous fungi *Aspergillus* spp. are widely used for the production of fermented foods, organic acids and enzymes (Wongwicharn et al., 1999). Especially, *A. niger* has a long history of industrial usage, which means many strains already have a GRAS ("generally regarded as safe") status (Wongwicharn et al., 1999). It has been used for commercial production of many enzymes, e.g. pectinase, glucose oxidase,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91459157

glucoamylase, hemicellulase, glucanases, acid proteinase, catalase (Aguilar and Huitron, 1993; Liu et al., 1999; Garhartz, 1990) and citric acid (Friedrich et al., 1989; Gokhale et al., 1991; Lee et al., 1989).

Interestingly, beside *A. niger* species, *P. oxalicum* (SI-14URAgr) also showed an excellent phosphate degradation ability on halo assay. According to Jain et al. (2014), Johri et al. (1999), Alam et al. (2002), Elias et al. (2016) and Jain et al. (2017) solid medium using agar plates performed better phosphate degradation ability than those in liquid media. Thus, it is impossible to ignore the *P. oxalicum* isolate SI-16URAgr. *Penicillium* spp. is important in the natural environment as well as food and drug production. Some members of the genus produce penicillin, a molecule that is used as an antibiotic, which kills or stops the growth of certain bacteria spp. Other species are used in cheese industries (https://en.wikipedia.org/wiki/*Penicillium*). *Penicillium oxalicum* produces secalonic acid D, chitinase and oxalic acid (https://en.wikipidia.org/wiki/Penicillium_oxalicum).

The solubilization of $Ca_3(PO_4)_2$ was the highest, followed by $AlPO_4$ and $FePO_4$ because $AlPO_4$ and $FePO_4$ have complex structure than $Ca_3(PO_4)_2$. Zang et al. (2018) and Son et al. (2006) reported that fungi exhibited low P solubilizing ability in media containing $AlPO_4$ and $FePO_4$. The mechanisms of phosphate solubilization by microorganisms are very complex and are not completely known yet (Bo et al., 2011). The very common mechanisms are acidification, chelation and exchange reactions (Bo et al., 2011). Organic acids play an important role in phosphate solubilization processes, which can help the release of P by providing protons and complexing anions, or ligand exchange reactions or complexion of metal ions release to solution. Zang et al. (2018) and Scervino et al. (2013) reported that organic acids production depends on the interaction of P source and fungi.

In this study, *A. niger* showed the highest efficiency in P solubilization by decreasing pH of the culture medium, which indicated higher amount of organic acid production. Silva et al. (2014), Li et al. (2016) and Barroso et al. (2006) reported that *A. niger* produce higher amount of organic acids and enhance phosphate solubilization. Zang et al. (2018) reported that solubilization of the different P sources mostly depended on the amount of organic acids production by fungi. Tricarboxylic acids such as citric acid, oxalic acid and other lower molecular weight organic acids are considered to be the main contributors to phosphate solubilization and a decrease in pH of the medium (Bo et al., 2011).

It was observed that phosphate solubilization was negatively correlated with pH of the medium. There are several reports where such correlation was documented (Pandey et al., 2008; Jain et al., 2012; Xio et al., 2015). The activities in lower pH indicated that the increase of organic acids in the medium (Pradhan and Sukla, 2005; Saxena et al., 2013). However, soluble P was increased without changing pH in some occasion because of other mechanism (Jain et al., 2012 and 2017), such as chelation and exchange reactions (Bo et al., 2011).

Conclusions

Isolates *A. niger* strain SI-10URAgr, SI-11URAgr and SI-12URAgr have unique capabilities to solubilized three insoluble phosphate compounds and may become an important bio resource for soil fertility management as well as sustainable crop production and pollution free environment.

RESEARCH ON THE CONSTRUCTION OF ZHAOQING URBAN ECOLOGICAL INFRASTRUCTURE BASED ON ECOLOGICAL SECURITY

ZHANG, H.

College of Life Sciences, Zhaoqing University, Guangdong, China
(e-mail: zhang-hongg@163.com)

(Received 19th Mar 2019; accepted 22nd May 2019)

Abstract. In the process of urbanization, the region faces environmental problems such as destruction of ecological corridors, fragmentation of biological habitats, and soil erosion, which pose potential risks to the regional ecological environment. Therefore, it is of great significance to identify lands with ecological conflict, establish core ecological protection zones and ecological corridors, and build an ecological security pattern for regional sustainable development. The research subject of this paper is Zhaoqing area. From the perspective of landscape ecological security pattern, it identifies the green land in Zhaoqing City, hydrological system, local culture, natural ecological protection, and the chance of geological disasters, and combines RS (Remote Sensing) and GIS (Geographic Information System) technology to evaluate green land and identify environmental core protection. Urban ecological infrastructure patterns are built in district, ecological corridors and ecological buffer zones and land with ecological conflict is curbed form expansion. The study found that it is necessary to carry out controlled development of ecological conflict zones such as the Xijiang River Basin, the Beiling Mountain Forest Land, and the Gaoyao Plain to ensure the safety of the fundamental ecological facilities in Zhaoqing.
Keywords: *core ecological protection zone, ecological assessment, ecological source, ecological buffer zone, control development*

Introduction

At present, China's rapid economic development promotes urban construction, but it is accompanied by an ecological environmental crisis that threatens the national ecological security. The expansion rate of urban construction land in China is significantly higher than the population growth rate. In the past 34 years, China's urban construction land has increased by 6.44 times, with an average annual growth rate of 6.27%. The per capita construction area of Chinese cities is 129.57 m^2, which significantly exceeds the national standards, and is also significantly higher than the average of 84.4 m^2 per capita in developed countries and 83.3 m^2 per capita in other developing countries (The 13th Five-Year Ecological Protection Plan of the Ministry of Environmental Protection of China, 2016). This trend extends from the eastern coastal areas to the inland, and from the central towns rural areas, forming a situation of "city in green retreat", destroying the original ecological balance, causing regional ecological, environmental crisis and seriously affecting regional ecological security. For the sustainable development of the city, the fundamental green land of the city must be protected and the urban ecosystem must be perfected. Protection of green land is the most critical task at the moment. To improve the urban ecosystem, it is necessary to discriminate the urban environmental protection area, rationally plan the urban spatial structure and urban development direction, optimize the urban functional structure, and reduce the contradiction between urban expansion and ecological land use.

In order to solve the contradiction between urban expansion and ecological land use, Chinese and foreign scholars have made a series of explorations and achieved specific

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91599169

results. For example, the savvy growth theory proposed by American scholar Doyle focuses on the balance between urban expansion and ecological protection. The ecological planning theory put forward by domestic scholar Yu Kongjian and others put emphasis on the priority of green land protection and the control of the integrity of the ecological structure. In recent years, Chen Yimin and Peng Jiajie have used the landscape ecological index and landscape ecological risk assessment methods to construct a spatial conflict measurement model to assess the spatial conflict level under rapid urbanization. These theories emphasize the balanced relationship between environmental protection and urban development and have been widely recognized by the urban planning industry. Based on the GIS spatial analysis model, this paper simulates and analyzes the spatial conflicts and ecological security risks of urban ecological land in Zhaoqing City, and provides a scientific basis for urban development and protection.

Ecological infrastructure concept

The concept of ecological infrastructure was first proposed in the 1984 UNESCO Man and Biosphere Programme (MAB). The ecological infrastructure is a natural system, which is essential for the survival of urban and rural residents and their inhabitants. It provides residents with fresh air, food, sports, recreation, safe haven, aesthetics and education. With the deepening of research, the idea of ecological infrastructure is reflected in the emphasis from simple "protection" to the use of EI (ecological infrastructure) to guide the development of the city, thus achieving the "EI-oriented urban development" approach (Yu et al., 2005).

In the process of urbanization in China, we face the problem of urbanization and ecological environmental protection. Unreasonable urban development and construction have damaged the regional ecosystem structure, resulting in weakened ecosystem service functions, seriously threatening residents' production and life, and affecting sustainable environmental development. It is crucial for the government, especially urban planning administrators, to find out methods that benefit the balance between urban development pressure and ecological environment protection, the restoration of the natural system of the city, and sustainable urban development. Urban safety development depends on the basic maintenance of ecosystem services.

Landscape ecological security pattern theory

There are some potential spatial patterns in urban landscapes, which are composed of vital ecological nodes, corridors and location relationships. This pattern plays a crucial role in maintaining and controlling an ecological process called landscape ecology (Yu, 1999). Safety pattern: Landscape ecological security pattern is based on landscape ecology theory and method in the late 1990s. Based on the relationship between landscape processes and patterns, it is critical to distinguish the health and safety of these processes through the analysis and simulation of landscape processes. Landscape pattern: The landscape ecological security approach takes the landscape process (including regional hydrological cycle, species space movement, disaster process diffusion and urban sprawl expansion) as a process of achieving landscape control and coverage by overcoming spatial resistance. To achieve effective control and coverage, strategically important landscapes must be captured. Elements, spatial locations, and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91599169

connections: The pattern formed by such vital elements, strategic locations and connections is the landscape ecological security pattern, which is essential for maintaining and controlling ecological processes or other horizontal processes (Yu, 1999).

At present, the relatively mature method for identifying the landscape ecological security pattern is to realize landscape control by constructing the Minimum Cumulative Resistance (MCR) of the ecological process. The MCR model is based on the GIS spatial analysis module to analyze the degree of separation of landscape patches and serve as the basis for landscape pattern optimization. The landscape pattern optimization MCR model is mainly realized in the GIS by relying on the minimum cost distance (Cost Distance) model. By using the landscape resistance surface characteristics to distinguish the landscape ecological strategic points, it extends to the discrimination of the landscape ecological security pattern. The equation for calculating the MCR model can be expressed as follows:

$$MCR = \sum_{j=n}^{i=m} (D_{ji} \times R_i) \quad \text{(Eq.1)}$$

where f is an unknown positive function, reflecting the positive correlation between the minimum resistance of any point in space and the spatial distance of the base i of a landscape that it traverses and the characteristics of the landscape base. D_{ij} is the spatial distance of the base i of a landscape from the source j to a point in space; R_i is the resistance of landscape i to the movement of a species. Although the function f is unknown, the $(D_{ij} \times R_i)$ value can be regarded as a relative measure of the path of a species from a source to a point in space, where the maximum value of resistance from all sources to that point is used. Measuring the accessibility of this point, the constructed resistance surface can reflect the potential possibilities and trends of species movement (Ahern, 1995; Yu, 1996). The landscape ecological security pattern theory as a dynamic spatial structure model is a method of constructing ecological infrastructure. It regards the horizontal landscape process as a process of overcoming spatial resistance to achieve landscape control and coverage, and requires corresponding constraints and discriminant parameters, theoretical and technical support in hydrology and ecology.

Construction of ecological infrastructure in Zhaoqing urban area

By analyzing ecological services and ecological process functions, American landscape ecology experts Ahern and Ndubisi categorized ecological infrastructure into three types: Biotic, Abiotic, and Culture (Ndubisi, 2002). This comprehensive and inclusive model based on landscape ecology recognizes the interaction between biotic and abiotic systems and humans (Gan et al., 2007). It is also known as the ABC model and is widely used in the planning and construction of ecological infrastructure in the application in United States (Xiao et al., 2017). As a result of ecological security pattern of different types of landscapes, ecological infrastructure reflects the realization of ecological functions and the integrity of ecological processes. The completion of ecological processes requires the support of ecological space, and the ecological infrastructure is the guarantee of ecological functions.

This paper analyzes the non-construction land structure of Zhaoqing City, draws on the ecological infrastructure concept, and uses the ABC model as a framework to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91599169

identify the landscape ecological security pattern. Through the computational composition and spatial superposition of the Zhaoqing urban ecological infrastructure network, the geological, biological, hydrological and the landscape ecological security pattern of local culture forms the ecological infrastructure for the healthy development of Zhaoqing.

Research scope and data source

Zhaoqing City is located in the central and western part of Guangdong Province, northwest of the Pearl River Delta. The city has jurisdiction over Dinghu District, Duanzhou District, Gaoyao District, Zhaoqing High-tech Zone (Dawang), Zhaoqing New District, and other five districts. The total area of the city is 2990 km^2. The overall planning of Zhaoqing City is characterized by high terrain in the northwest and south, and flat terrain in the northeast to southwest. The low-mountain landforms in the northwest and the south are mainly distributed in the main mountain bodies such as Beiling Mountain, Dinghu Mountain and Rouge Mountain. The main urban construction land is distributed in the northeast to southwest plain. The basic pattern of Zhaoqing City from south to north is "river, city, lake, mountain, forest", the spatial pattern of the strip city, and the city forms a trend of developing eastward with the end state as the center. With the difficulty and timing of data acquisition being considered, this investigation selects the remote sensing image of LANDSAT (Tursing Landsat System) TM series as the main data source, and combines Zhaoqing urban topographic map, land use status map and land use change table, processing and analysis.

Zhaoqing City hydrological system security pattern

Floods are inevitable as part of the river's natural processes, but floods can be minimized through ecological planning. From the perspective of spatial planning, by studying the distribution pattern of floodplain, provides a basis for planning land use decision-making, and planning flood-prone areas as wetlands and open spaces is an effective way to reduce flood disasters and their effects (Xiao et al., 2017). The flood safety pattern of Zhaoqing City should be started from different scales of watersheds. By establishing a coordinated flood control system, corresponding flood control, measures should be in accordance with the risk level.

Since this investigation is based on GIS simulations, it is necessary to calculate the flood level of different safety levels or the adjustable flood flow and the flow that can be safely discharged and the adjustable flood storage. Therefore, it is necessary to obtain historical hydrological and monitored storm runoff data to calculate the flood level. The reasonable height and the area where the flood spreads is reduced. At the same time, by collecting the flooding range of historic floods, the different ranges of floodplain, flood detention zone and flood protection zone are analyzed. Moreover, the scale, pattern and river channel buffer width of different flood risks are determined, and the star lake and east channel are established. Different levels of safety concerning Honghu, Poyang Lake and other ecological wetlands, rivers and rivers coordinated flood control dynamic system are determined according to different risk levels.

The hydrological analysis module in GIS is a means to effectively analyze and simulate hydrological processes, which can simulate the regional runoff process and identify potential wetlands. The hydrological analysis module generally requires digital elevation data (DEM) to simulate the runoff process, and then establishes a flood

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91599169

surface based on the flood level at different safety levels to obtain the flood submerged range. The Zhaoqing City is mainly composed of the Xijiang River Basin and the Xinghu Wetland, the Jiukeng River Reservoir (Kowloon Lake) Wetland Core Area and the New Area Wetland Core Area. The hydrological analysis module in GIS comprehensively evaluates the ecological and social benefits of the Xijiang River Basin and its wetlands, and follows the protection of its ecosystem health. The spatial and spatial pattern of wetland resources is planned for the connectivity between the corridors and wetlands, the stability of large wetland patches, and the ecological channels provided for urban groups.

It is selected as a concrete case to discuss the flood control safety pattern based on flood volume. Firstly, the CAD contour data of Zhaoqing New District is converted into DEM data as the basic data of runoff process simulation. Through GIS simulation of the runoff process, the location and extent of potential wetlands can be obtained by encountering stagnation points in low-lying areas, mainly distributed in the wet areas of the Xijiang River Basin. Based on the Arc GIS, the flood surface elevation raster data is established based on the flood water level, and the simulated water level of each point in the area is obtained (Yu, 1999). Subsequently, we calculate the difference between the elevation of the flood surface and the terrain elevation to obtain the flood inundation range of different return periods. The main flood control area in Zhaoqing is along the Xijiang River and some rivers (*Fig. 1*).

Zhaoqing City geological hazard safety pattern

Through the sensitivity analysis of regional geological disasters in Zhaoqing City, we summarized the distribution of geological disaster safety patterns. First, we determined the source of geological hazards by superimposing the spatial distribution of various geological hazards such as mountain collapse, landslide, slip, ground subsidence and ground fissure on the Zhaoqing regional GIS map. Subsequently, through the analysis of the types of local disasters and the analysis of land use patterns in disaster-prone areas, the regional and spatial linkages that play a vital role in the protection of geological disasters were determined. The extent of the buffer zone is affected by factors such as the type of geological hazard, development intensity, distribution, the frequency of occurrence, topographic and geological conditions, precipitation conditions and intensity of human activities (Russell and Wang, 1997). Finally, based on the spatial superposition of the spatial distribution of various disaster sources, the safety pattern of geological disasters with different safety levels was obtained.

The geological disaster factors of Zhaoqing City mainly include various geological disaster factors such as mountain collapse, landslide, slippage, land subsidence and ground fissure. Based on GIS, the elevation and slope are graded to obtain the sensitivity distribution of geological disasters. The spatial distribution of geological disaster sources is identified by superimposing various geological disaster factors (*Table 1; Fig. 2*).

Zhaoqing City biosafety security pattern

The biosafety safety pattern is mainly to construct the minimum resistance model (*Eq. 1*) to simulate the minimum resistance value that the species needs to overcome in space motion, and then to identify the landscape safety pattern by analyzing the resistance surface outside the core habitat (source). The safe pattern of biological processes

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91599169

generally consists of sources (core habitats), buffer zones (low-resistance areas around the source), corridors and radiant channels (low-resistance channels connecting multiple sources), and strategic points (critical to biological processes), which constitute elements of the landscape (Yu et al., 2005). This method of identifying the landscape safety pattern can select the model to analyze, so as to achieve the identification of the "matrix-corridor-plaque" model in landscape ecology. It is best to select migratory birds as indicator species, which is conducive to the communication between elements. Sexuality reflects the strategy of the overall biological safety of the region.

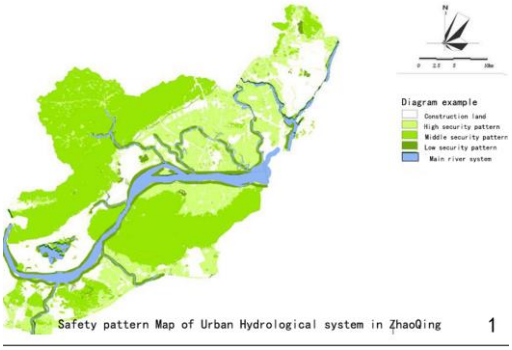

Figure 1. *Zhaoqing urban hydrological security map*

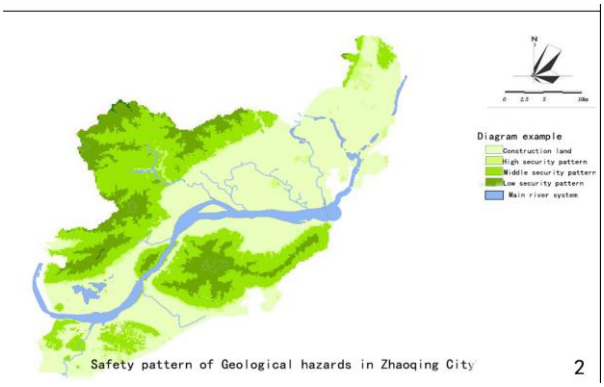

Figure 2. *Zhaoqing urban geological security map*

Table 1. *Identification of geological disaster sources in Zhaoqing City*

Level of safety Risk source	Debris flow, landslide, collapse	Fracture zone	Ground setting
Low safety level	Elevation > 1000 m, slope > 30 degree, collapse center	100 m around the fault zone	Surface subsidence center zone, cumulative settlement > 2.0 m
Medium safety level	The height is 500 m, the slope is 15-30°, the center of collapse is 300 m	300 m around the fault zone	150 m around the land subsidence center, cumulative settlement > 1.5 m
High safety level	Collapse center 500 m	500 m around the fracture zone	The circumference of the center of the heart is 300 m, and the cumulative subsidence is 0.3 cu 1.0 m

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91599169

Wetland and forest land with an area larger than 25 hm^2 in the Zhaoqing City area are selected as the habitat of protected species. The spatial resistance coefficient of different land cover types is set by using the spatial resistance coefficient of different land cover types (*Table 2*). Superimposed, the resistance surface of the space movement of the protected species and the ecological corridor with the least space resistance of the species movement are obtained, and the bio-protection safety pattern of Zhaoqing City based on the analysis of the horizontal ecological process is formed. According to the calculation, the three ecological green nucleuses of Dinghushan, Rougekeshan and Sihui12 are formed. The three ecological corridors of Xijiang River, Minjiang River and Beijiang River are beneficial to the protection of biodiversity (*Fig. 3*).

Table 2. *Spatial resistance coefficient of minimum cost distance model analysis*

Attributes	Coefficient of drag	Attributes	Coefficient of drag
Water system river	150	High density construction land	10000
Forest land	275	Highway	600
Open forest land	50	Tidal flat	150
Shrub forest	40	Natural conservation land	-5
Base pond	100	Farmland	325
Meadow	30		
Dry farm	300		
Low density construction land	1000		

Zhaoqing City's local cultural security pattern

It is necessary to study the current landscape from the historical perspective as a result of past natural processes and human interference (Costanza, 2008). From the perspective of ecosystem service functions, it is critical to integrate the natural environment characteristics and local cultural characteristics into the local landscape and cultural heritage resources. They have many functions such as cultural diversity, spiritual and religious values, educational values, social connections, aesthetics and enlightenment, cultural heritage values, recreation and ecotourism. The introduction of the concept of ecosystem service function makes people's understanding of the local cultural landscape not only stay in the cultural sense, but the dual carrier of culture and natural function (Jongman, 1995).

The study of the local cultural landscape safety pattern is the "source" of the local cultural landscape elements in the region, and regards people's recreation activities as a process of horizontal expansion. Through the establishment of spatial resistance surface, the safety pattern of the local cultural landscape is constructed. As the birthplace of Guangfu culture, Zhaoqing selects the cultural landscape protection units such as the Zhaoqing Fucheng historical and cultural district and the typical Guangfu village and the Gaojiu area, the Sangji fish pond agricultural culture demonstration area as the source of the local cultural security pattern. The land cover type sets different spatial resistance coefficients, and the minimum cumulative resistance surface is established by the distance model to obtain the safety landscape of the local culture landscape with different safety levels (*Fig. 4*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91599169

Zhaoqing comprehensive ecological infrastructure

Based on the above-mentioned hydrological system safety pattern, geological disaster safety pattern, biological protection safety pattern and local cultural security pattern, spatial computing and superposition based on GIS, and the comprehensive ecological infrastructure of Zhaoqing City with different security levels are determined (*Fig. 3; Table 3*).

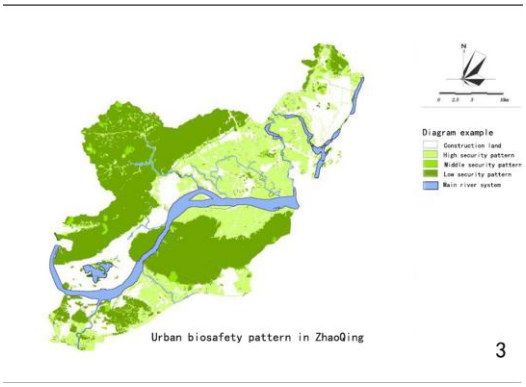

Figure 3. *Zhaoqing City biosafety map*

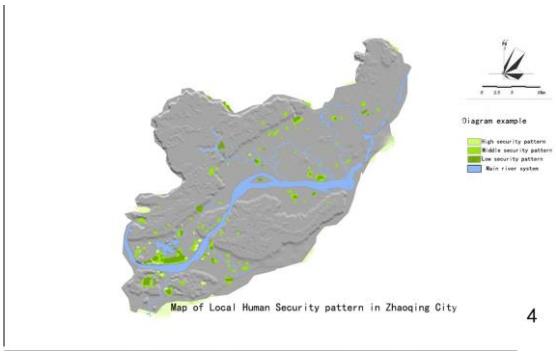

Figure 4. *Zhaoqing City humanities security map*

Table 3. *Area and proportion of ecological infrastructure at different safety levels in Zhaoqing City*

Ecological security level	Ecological infrastructure occupation		Construction land	
	Area/km^2	Scale/%	Area/km^2	Scale/%
Low safety level	1072	35.86	1918	64.14
Medium safety level	1829	61.18	1161	38.82
High safety level	2321	77.64	669	22.36

The comprehensive ecological infrastructure of Zhaoqing City is divided into three different security levels: EI with high security level is the ideal state to realize the functions of various ecosystems in the region. The security scope can be moderately opened according to local conditions. The medium-safety level EI is an appropriate scale to maintain a complete ecosystem of the region, and can be constructed within

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91599169

certain limits. The low-safety level EI is the threshold for ensuring urban ecological security, and is an insurmountable red line in urban and rural development and construction. Zhaoqing's current development is at a high level of safety, but it is still prudent to develop in some highly ecologically sensitive areas.

Zhaoqing City ecological conflict space recognition

The identification of the ecological conflict space in Zhaoqing City depends on the map layer map superposition method. By superimposing the GIS map of the medium security level in Zhaoqing City on the spatial distribution map of the current construction land, it can be found that the ecological conflict space of Zhaoqing City is concentrated in the edge belt of the existing built-up area, such as the Beiling High Ridge Area of Zhaoqing and Zhaoqing High-tech Zone (large Wang) in the north and the periphery of Dinghu Mountain in Zhaoqing New District. In addition, the ecological infrastructure of the low (bottom line) safety level in Duanzhou District and Dinghu District is affected by the embedded construction land, and the ecological conflict area is distributed along the mainstream of the Xijiang River, which has a great impact on the ecological environment. The ecological conflict area in Duanzhou District is dotted, although the area is small, because it is the red line of regional ecological security, the impact on regional ecological processes and ecological functions is more prominent (*Fig. 5*). Thus, it should be controlled. In addition, it is necessary to control development in the vicinity of Jiukenghe Reservoir and Dinghu Mountain in ecologically sensitive areas should be controlled for development.

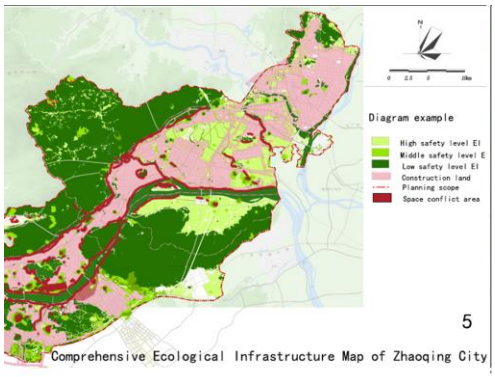

Figure 5. *Zhaoqing City ecological conflict zone map*

Conclusions

With Zhaoqing urban area as the research object, this investigation quantitatively evaluates hydrological systems, biological protection and local culture services, and the chance of geological disasters. From the perspective of natural land evolution, the investigation is based on landscape ecological security pattern theory and MCR model, utilizing RS and GIS space. With the aid of analytical techniques, through the spatialization of spatial data and spatial model calculations, the non-biological-biological-cultural analysis framework was used to identify the geological disasters, hydrological systems, biological protection and local cultural security patterns in Zhaoqing City. Superimposing a single ecological security pattern to achieve an

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91599169

integrated ecological infrastructure with different levels of security (*Fig. 6*). The results show that ecological land covers an area of 657.8 km^2, accounting for 22% of the research land, of which the ecological land with an area larger than 10 km^2 is used as the source, about 568.1 km^2, accounting for 19% of the research land, mainly the North Ridge Forest. The composition concerns land, lake and wetland.

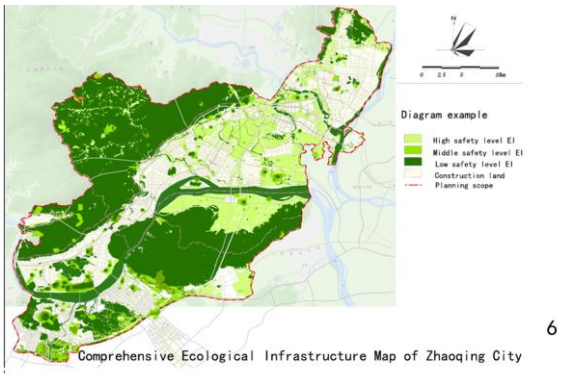

Figure 6. *Zhaoqing City comprehensive infrastructure map*

Besides, ecological buffer zone accounted for 55.64%, while development and construction zone and 22.36%, respectively. The ecological buffer zone as the ecological source of the protection wall should be limited development, but the proportion should not be less than 30%;

In addition, the potential ecological corridors are mainly composed of waters, forests and cultivated land. The Xijiang River, the Beijiang River and the lakes and the surrounding cultivated land and forest land together constitute an ecological corridor, which plays a role in connectivity.

Moreover, ecological source areas, ecological corridors and ecological buffers together constitute the ecological security pattern of Zhaoqing City. In short, the ecological pattern of Zhaoqing City has formed a spatial pattern of "one area, two corridors and three cores" relying on natural local conditions.

By superimposing construction land on ecological infrastructures with different safety levels, it can be seen that the ecological conflict space in Zhaoqing City is mainly concentrated along the Beiling Mountains and the Xijiang River Basin and Xinghu Lake. Drawing on the optimal landscape pattern of "segregation between clusters", according to the characteristics of the Zhaoqing area and the actual land use pattern, the "matrix-corridor-plaque" model has become the regional ecological security and the urban and rural non-construction land structure. Inevitably, the "Mountain-Reservoir-Farmland-City-Xijiang River" model is a concrete manifestation of the research paradigm of landscape pattern of landscapes. As the ecological bottom line of landscape ecological security pattern, urban and rural non-construction land must protect these bottom lines as ecological infrastructure, in order to realize the basic pattern of Zhaoqing livable city, which has far-reaching strategic significance for scientific planning urban development and expansion.

The study proposes to increase the ecological protection of Zhaoqing ecological source, strengthen the construction of ecological protection measures, find and control the source of ecological safety hidden dangers, and inhibit the development of bad trends. It helps to actively regulate the ecological buffer zone for ecological security

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91599169

deterioration in the region, and achieve positive effect on urban ecological security management and monitoring. It is suggested that in the process of building a specific ecological security infrastructure, it is necessary to cooperate with relevant government departments, take into account the development goals of the city, and conduct in-depth research in actual operations.

(Received 20th Mar 2019; accepted 24th May 2019)

Abstract. Forests are among the most important wild life areas that provide shelter for various wild animals within different living areas they have. Shortly, selection of habitat which is defined as living area, by the wild animals is effected by variables such as stand types, altitude, flora, sloping direction, and soil composition. Among these factors stand type which forms the forest structure is one of the most important factors in the habitat selection. This study has been conducted on Bartin-Soku Wild Life Development Area with the aim to determine the impact of wild animals on habitat selection. For this purpose for determining the habitat selection of big mammals photo traps are placed at 78 points. The total working time of each photo traps is determined 3800 days. Although 12 pieces of big wild mammals were determined on the area, only 9 of them were considered for evaluation. As a result of study it has been determined that mixed stands were preferred more when compared with pure stands, mixed stands of fir and beech were preferred more when compared with other mixed stands, and healthy and old stands were preferred more when compared with the disrupted ones.
Keywords: *stand, wildlife, forest, roe deer, wild board, bear*

Introduction

Wild animals are an important and fundamental particular of ecosystem where they exist. However, just like all other ecosystem features, wild animals are also under the threat of mainly human originating dangers. As a result of this, different wild animal species have been influenced on local or global scale and while populations of certain species got reduced, some species were faced with the danger of getting extinct (Marrison et al., 2007).

The situation is the same in Turkey which has got a rich fauna both due to its geographical location and due to different ecosystem features it bears. According to different sources, in Turkey mammals were determined to as 418 pieces of birds, 120 reptiles, 22 amphibians (URL1), 161 pieces of mammals, 460 pieces of birds, 141 pieces of reptiles (Çagatay et al., 2012), 104 pieces of mammals, 418 pieces of birds (Çanakçıoglu and Mol, 1996), 160 pieces of mammals (Bora, 2001), 169 pieces of mammals (Özkazanç, 2012) as being the species observed. According to the recent data in Turkey there are species of 482 pieces of birds (URL2), 172 pieces of mammals (URL3), 157 pieces of amphibians and reptiles (Baran et al., 2012).

No matter what wild animal species is concerned, one of the most important factors influencing their lives is surely the habitats they are using. Protection of wild animals in natural living environments and their sustainability is based on knowing their habitat preferences well. According to Oğurlu (2001) habitat is the environment where a population exists, provides shelter, develops, reproduces, and continues its generation to exist. Wild animals can use different habitats for various purposes such as getting nourishment, reproducing, and nesting. Even if purposes of usage can be different, as wild

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91719184

animals make preferences of habitats, they consider all habitat components. For this reason, the structure of habitat components with many variables and the influence of each factor in the components should be considered (Oğurlu and Yavuz, 1999). Habitat is an integrity being composed of plants, soil structure, location, altitude of an area as well as components such as other wild animals that use that area. However in the habitat preferences of wild animals, most important one among these elements is mainly the plants.

Plants have direct and indirect influences on habitat preferences of wild animals (Suel et al., 2013). In habitat selection of wild animals, in addition to existence of plant varieties, their distribution is also very important. Because factors relating with raising environment in an area has influence on distribution of plant varieties and distribution of plants has direct impact on distribution of wild animals making use of various functions and opportunities such as sheltering, hiding and getting nourishment as being provided by these plants (Oğurlu and Aksan, 2013).

Analyzing the habitat distribution, finding correlation between habitat variables and distribution of wild animal species and their habitat preferences, are important in revealing ecology of wild animals and in managing wild life. Because information such as existence, abundance, distribution, and nourishment of animals on an area are predicted as being based on habitat situation and quality (Aksan et al., 2014). In this way, influence of changes occurring in the habitat, on the species or population of species and influence in species or population of species on the habitat can be predicted. This is effective in planning wild life.

Majority of big wild mammals are dependent on forests for survival. Because food, water, and land areas which they need for surviving exist in the forests. Besides forests also bear different wild life areas within themselves.

Besides the fact that migration routes that are used by wild animals have the richest habitat features, high sloping areas have got varieties of species. Furthermore, increase in habitat heterogeneity also increase varieties of species (Liu et al., 2017).

Stands which are defined as forest structure is described as forest section which differentiates itself from its environment with respect to at least one of the forest establishment features such as production material, age, tree species, components of tree species, layering, closeness, frequency, and specific bonitet differences and which covers an area of at least one hectare (Genç et al., 2012).

Bartin-Soku Wild Life Protection Area, which forms the study area, has been registered as per the decision of Council of Ministers being dated 13.09.2006 with no 2006/10966. Target species on this area of 17.000 hectares are specified as red deer and roe deer.

This study was conducted to determine the habitat preferences of large mammal wild animals living in the research area. Thus, in the forestry applications to be made in the field, wildlife requests can be evaluated. The destruction of wildlife areas will can be prevented with forestry practices.

Material and Method

Material

Main materials in the study are wild mammals and stand types they are using. Photo traps have been used for gathering data and for obtaining coordinates of photo trap points GPS has been used. The photo traps were used in the bushnell brand, 3264 x 2448 photo

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91719184

resolution and 1920 x 1080 video resolution. The study area is Bartin-Soku Wild Life Protection Area, which is the most important wildlife areas of the western Black Sea in Turkey. The center of research area is 20 km away from the nearest settlement. Kızıllar, Uluköy, Konak and Kırıklar villages are most near. Kızıllar, Uluköy, Konak and Kırıklar villages are most near settlement to research area. But there are very low human popülations in here. Although the working area has different types of stands, its water presence, surface structure and living cover characteristics are very similar.

Method

With photo traps that are placed in appropriate places on special living areas of wild animals such as their passage points, nourishment areas and resting areas, wild animals preferring that area could be determined. This study was conducted between July 2015 and September 2016. However, it was impossible to reach the area due to snow in winter and the works were slowed during this period. While the photo traps were placed on the site, attention was paid to the habitat types and different habitats of the species targeted. By considering criteria such as season, land structure and stand type, photo traps were controlled between 15 and 30 days and the images being obtained were transferred to computer. All images taken from photo traps were examined in detail and the species were determined and each detected species was processed on the stand map. During the period of study, at 78 different points with numbers of 3800 photo trap days, 4.940 pieces of photos and video records were obtained. As a result of the study in line with the data being obtained by determining density areas of each wild mammal species, stand types of these areas were specified and analysis were made on habitat selections of species. The coordinates of the photo traps are given in *Table 1* and the distributions in the field are given in *Figure 1*.

Findings

As a result of studies, on the area 12 different wild mammal species were determined. But since among these species, Eurasian otter (*Lutra lutra* L. 1758), golden jackal (*Canis aureus* L. 1758) and European hare (*Lepus europaeus* L. 1758) were determined at a single point, habitat selection of remaining 9 species of wild mammals were evaluated as per stand types. The some informations of wild animals identified in the study area was provide in *Table 2*.

These species were determined at 12 different stand types having different sizes and densities on the area of study (*Table 3*).

Table 2. *Information relating with the species being determined*

Species	Number of observation points	Number of views
Brown bear (*Ursus arctos* L., 1758)	35	147
Roe deer (*Capreolus capreolus* L., 1758)	61	683
Red deer (*Cervus elaphus* L., 1758)	7	18
Red fox (*Vulpes vulpes* L., 1758)	44	411
Grey wolf (*Canis lupus* L., 1758)	14	59
European badger (*Meles meles* L., 1758)	9	29
Stone marten (*Martes foina* (Erxleben, 1777))	30	96
Wild boar (*Sus scrofa* L., 1758)	41	542
Wild cat (*Felis silvestris* Schreber, 1777)	21	59

Table 3. *Types of stands and their features, in area*

BKn	Broken (B) beech (Kn) stand. It could not be mentioned about any kind of closeness.
GA	Pure fir (G) selection forest. (A: Stand having more number of individuals with thick diameter stages when compared with optimal; Old selected stands)
GÇsKnD	Stand of fir (G)-scots pine (Çs)-beech (Kn) mixture with dominance of firs. (D: Stand being other than A, B and C classes or being composed of mixture; actual selection stand).
GKnA	Stand of fir (G) -beech (Kn) mixture with dominance of firs. (A: Stand having more number of individuals with thick diameter stages when compared with optimal; Old selected stands)
GKnD	Stand of fir (G) - beech (Kn) mixture with dominance of firs. (D: Stand being other than A, B and C classes or being composed of mixture; actual selection stand).
KnÇsA	Stand of beech (Kn) -scots pine (Çs) mixture with dominance of beeches. (A: Stand having more number of individuals with thick diameter stages when compared with optimal; Old selected stands).
KnÇsGD	Stand of beech (Kn)-scots pine (Çs)-fir (D) mixture with dominance of beeches (D: Stand being other than A, B and C classes or being composed of mixture; actual selection stand).
KnD	Pure beech (Kn) selection stand (D: Stand being other than A, B and C classes or being composed of mixture; actual selection stand).
KnDybc	Beech (Kn) and other leafed (Dy) mixed stand. “b (There are individuals from b:Trellis-Pole age (8-19.9 cm)) and c (c: Thin woody age (20-35.9 cm))”, Those from “b” age are in majority numbers.
KnGA	Mixed stand of beech (Kn) and firs (G) with dominance of beech. (A: Stand having more number of individuals with thick diameter stages when compared with optimal; Old selected stands).
KnGD	Mixed stand of beech (Kn) and firs (G) with dominance of beech. (Stand being other than A, B and C classes or being composed of mixture; actual selection stand).
OT	Treeless forest soil

When stand features are considered it is seen that beech and firs which are dominant tree types on the area, are present both as mixed with each other and other varieties and on certain areas there are pure cultures. In line with the data being obtained, stand preferences of wild animals on the area are given numerically in *Table 4* and total number

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91719184

of individuals being determined in different stand types have been submitted in the form of a graphic in *Figure 2*.

It is observed that on the area there are changes in habitat preferences of wild animals as per the stands. Species have mainly preferred mixed stands and secondarily they have preferred pure stands. Mixed stand types of fir and beech were preferred more when compared with other stands. Among all stand types while GKnA has been the most preferred one, KnGA has been preferred secondarily. Other mixed stands were preferred in the order of KnGD, GÇsKnD, KnÇsA, KnDybc, and KnÇsGD. In the ranking of GA, KnD, BKn pure stands were less preferred by wild animals. Nude areas (OT) have been the habitats on the area that were least preferred.

Table 4. *Number of large mammal wild animals detected compared to the stand types in the area*

Stand Types	Brown bear	Roe deer	Red deer	Red fox	Grey wolf	European badger	Stone marten	Wild boar	Wild cat	Total
BKn	1	17	8	0	0	1	3	0	1	31
GA	6	31	0	10	1	0	4	2	6	60
GÇsKnD	2	69	0	23	8	0	7	8	5	122
GKnA	48	284	2	197	22	22	27	244	14	860

OT	0	3	0	1	0	0	0	10	0	14

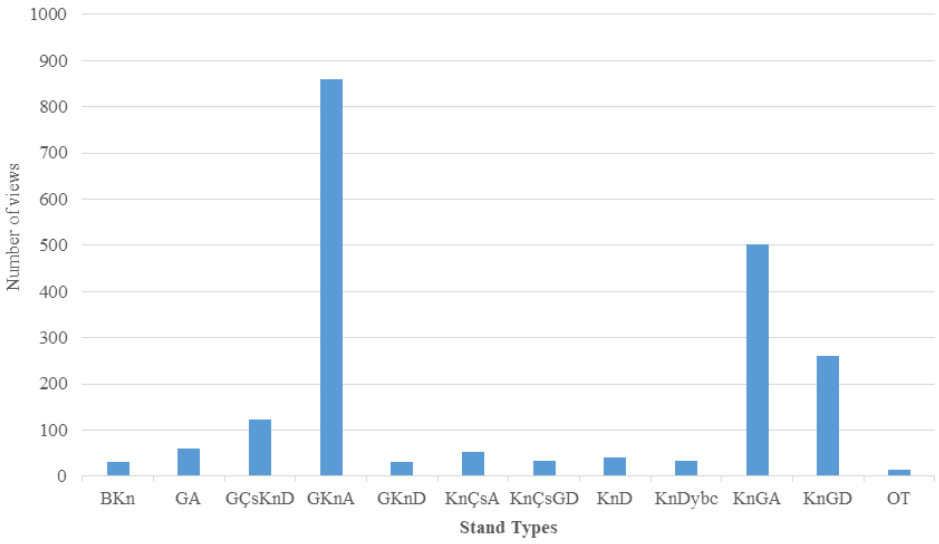

Figure 2. *Number of views to big mammals in stand types*

In habitat preferences of wild animals on the area as depending on stands, other variables that were effective have been A and D. In the stands where there are same tree mixtures, it is seen that A class of stands were significantly more preferred when

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91719184

compared with D class of stands. Hence while in GKn stand type with A class of mixtures, 860 individuals were observed, in D class of same mixture only 32 individuals were observed. Similar situation also attracts attention with KnG mixture. In this type of mixture while 503 individuals were observed in A class, 262 individuals were observed in D class. This situation reveals that regarding habitat selection of wild animals as per the stands, besides mixed type of stands, they preferred aged selection forests with more number of individuals having thick diameter stages more.

Stand preferences of wild animals on the area show parallelism with each other. However differences are observed in certain varieties. Wild boar, which is one of the dominant species on the area has preferred KnGA more when compared with other species. Again, wild boar and brown bear were seen more at KnÇsA when compared with other wild animals. A situation that is contrary to general preferences is seen with brown bear. KnDybc, which is not preferred by almost any wild animal species, has been preferred by brown bear as secondary stand type (*Figure 3*). The habitat preferences and distributions of each species is shown in *Figure 4*.

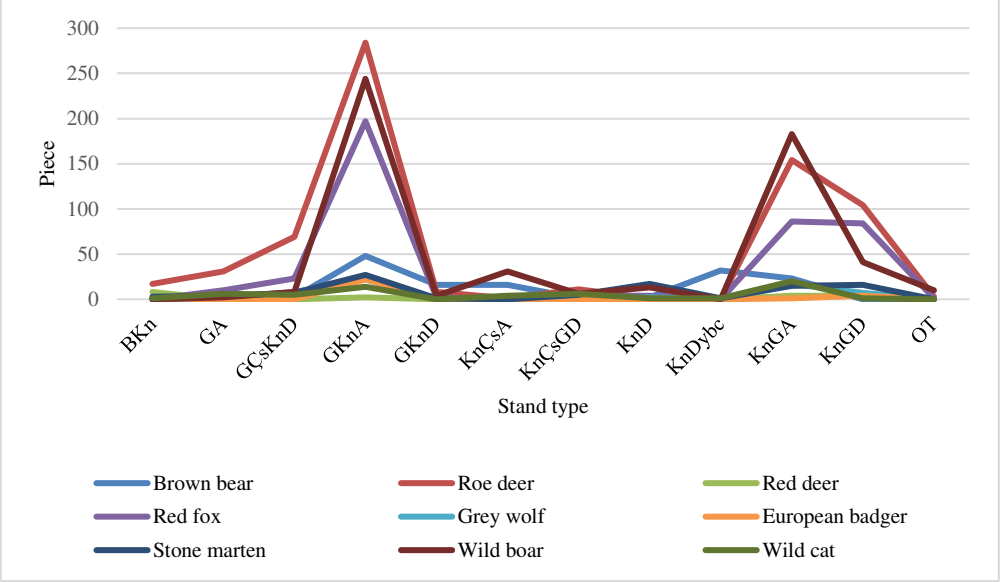

Figure 3. *Stand preferences of big mammals on the area of study*

Conclusion and Discussion

With respect to regional landscapes and sustainability of biological varieties, forest areas bear significant importance (Finch and Ruggiero, 1993). Forests are not only areas which are covered with forest trees but they are an integrity together with all ecosystem components. Among the living segments forming the forest, wild mammal species constitute one of the most important groups. Stand types are influential in different ways in habitat selection of wild mammal species. In line with the results we obtained, mixed and healthy stands are preferred more by wild animals when compared with pure and corrupt stands. Furthermore it is seen that besides stand mixture, stand class was also effective in habitat selection. Hence, A class of mixed stands have been preferred more by wild animals when compared with D class of same mixture.

In the study they conducted at Bolu Seven Lakes Natural Park, Nabioglu and Keten (2016) have stated that oak forests were quite densely used by wild animals.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91719184

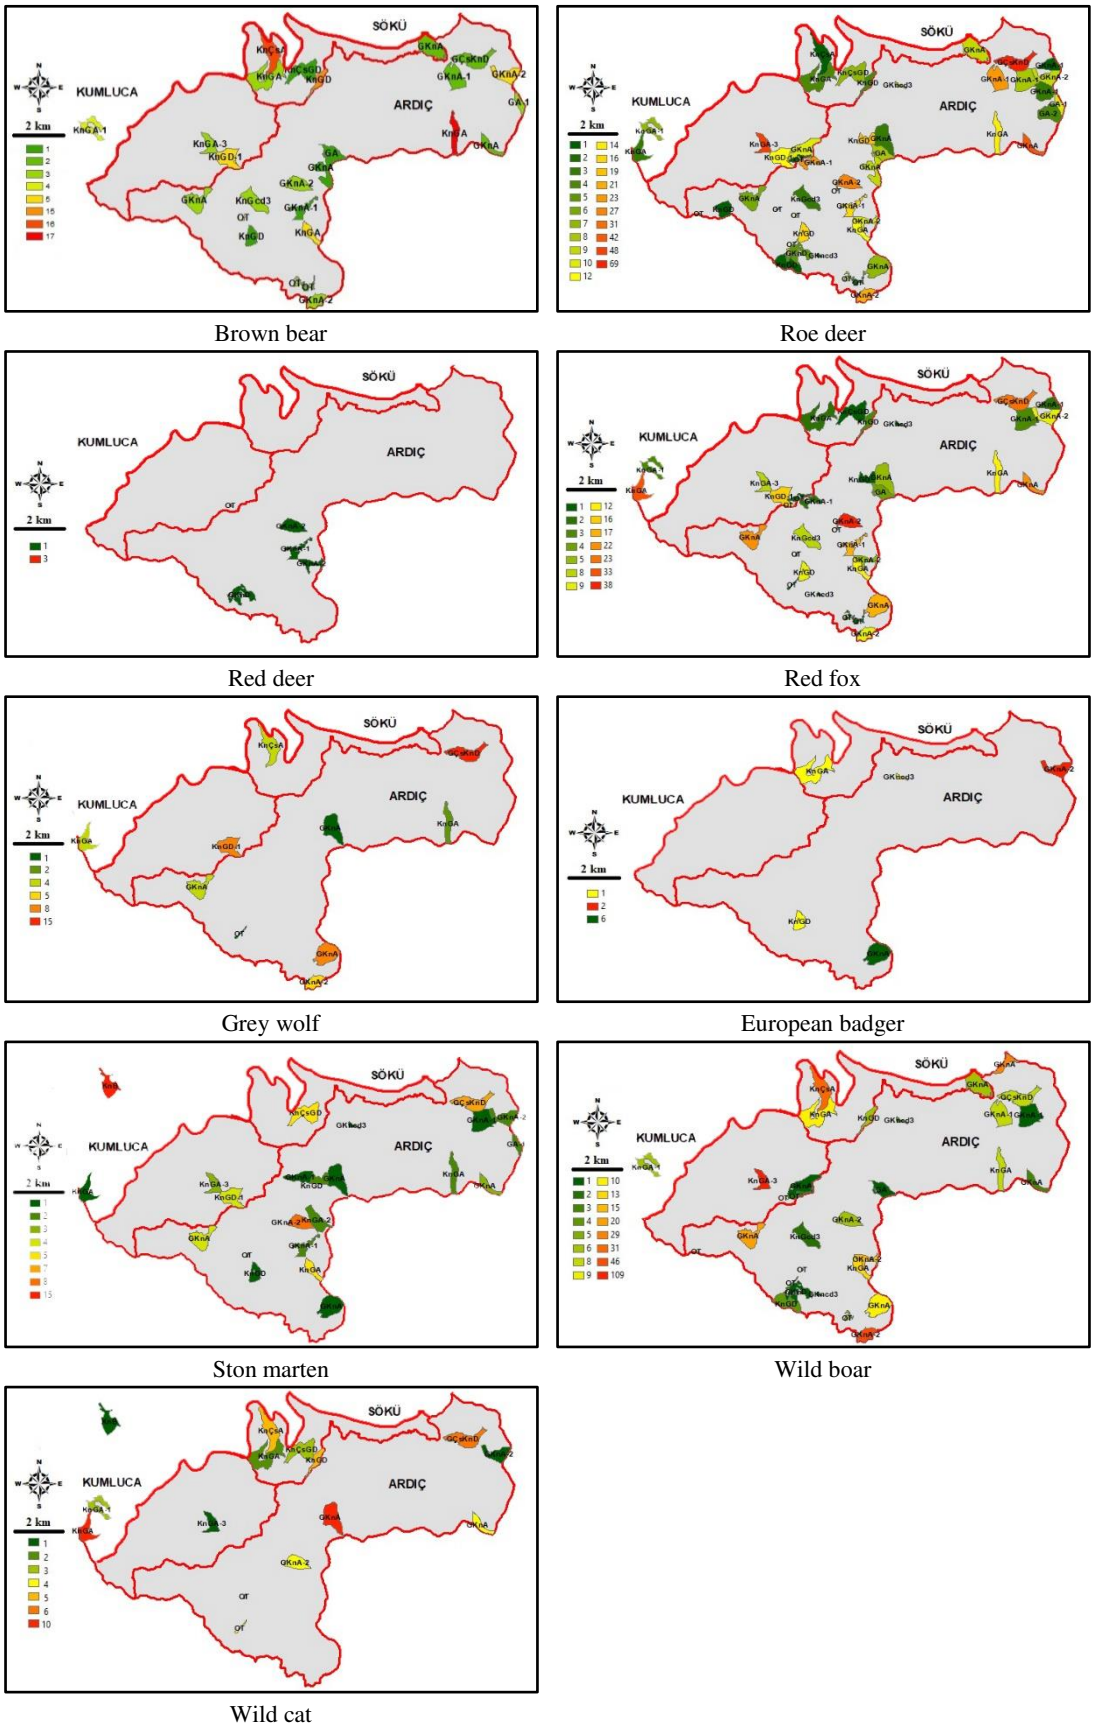

Figure 4. *Stand preferences and spatial distribution of large mammals in area*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91719184

They have stated that as the area and near environment were suitable for wild life and as the area had protection status for the development of wild animals, these factors have been influential in this particular. At this point, with respect to habitat selection of wild animals, besides convenience of area, it is clearly revealed that area needs to be effectively protected either naturally or with human impact.

Areas where woody type of varieties are highly present, are seen as the sign of existence of wild animals. The more the woody type of varieties are, the more living areas the wild animals can find for their activities such as sheltering, hiding, having nourishment and resting and these will be areas which will be preferred more by the wild animals (Oğurlu and Aksan, 2013). Both the varieties and quantities of woody types are plenty on our study area and this is one of the most important reasons that increase richness of wild life on this area.

All of the 9 big wild mammals on the study area have mostly preferred stand type of GknA and they have secondarily preferred stand type of KnGA. All of the species have preferred mixed stand types more when compared with the pure ones. However it attracts attention that mixtures where fir is dominant are preferred more when compared with mixtures where beech is dominant.

Habitat selection of brown bears that make up the biggest specie on the area, are influenced from many variables including humans as not being solely effected by stand types (Frackowiak et al., 2014; Rigg, 2005). Brown bears that mainly prefer high altitudes keep away from settlement places (Rigg, 2005).

Even though they are seen in all stand types in our study, brown bears mostly prefer stand type of GKnA. However, as being different from other species it is seen that the stand type which they prefer secondarily has been KnDybc. This stand type is almost not preferred by other species. It is possible for brown bears that walk long distances during the day, to use different types of stands. We have frequently observed the foot prints and stools of brown bears on the forest roads which support this theory.

In Seven Lakes National Park, Beşkardeş (2016) have observed brown bears more at coniferous and other leafed mixtures where oak is seen to be dense, when compared with coniferous and other types of mixtures where beech is seen to be dense. Besides on this area closed stands are preferred more by brown bears when compared with sparse ones.

Roe deer which is the dominant specie on the area prefer closed fir and beech forests where human pressure is less but they don't want to have frequent sub-vegetation (Keten, 2017). On the research area as complying with Keten (2017), roe deers have mostly preferred stand types of GKn and KnG. However, in his study Keten (2017) has determined that roe deers used pure forests of fir, beech, oak and scots pine with similar ratios to the mixed forests. On the contrary in our study pure stands were preferred less by roe deers when compared with other mixed stands.

Mancinelli et al. (2015) have stated that roe deers went to places with dense shadow areas in order to hide from the heat in summer time and that they preferred young ash tree and hazelnut stands for this reason. Furthermore in this study it was mentioned that plant cover phenology was influential in the habitat selection of roe deers and that gemmiferous bushes, new leaves and fruits and newly growing grass were effective in habitat selection. Again it was determined that this specie preferred forests with scote pine and pyrenean oak more in Spain and that they got nourishment at places where there were blackberries, roses, shrubs and kochia in the lower flora structure (Virgos and Telleria, 2011).

Both of these studies support our study on the basis. Even if the types of trees are different, it is seen that roe deers preferred mixed stands more. Similarly, sub-flora which

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91719184

roe deers prefer for getting nourishment completely matches with sub-flora structures of GKnA and KnGA where roe deers have been mostly observed.

Red deers which are one of the target species on the area prefer forest areas which are calm and dense and where there are open areas and meadows in surrounding places. Besides preferring leafy and mixed forests, they can also prefer pure cultures. An important factor is that sub-layer is rich and it is situated close to water resources (Kumbasli, 2006). However, habitat preferences of red deers also change as depending on seasons (Zang et al., 2013).

Red deers which are among rare species prefer beech and especially pure beech stands more when compared with other species. Although they get nourishment at the small open areas within dense forests, beech forests which are on the study area provide more nourishment environment for this specie.

Red fox, which is another dominant specie has been observed densely at the stands of GKnA and KnGA as being similar to other species. But it attracts attention that red fox prefers KnGD stand as much as KnGA.

Cagnacci et al. (2004) state that habitat selections of red fox living on mountain areas could vary depending on the seasons. Red foxes prefer forest habitats more than open areas according to Etten et al. (2007). Similarly in our study it is seen that red foxes preferred mixed stands mainly having firs more when compared with other stand types. While red foxes were observed 222 times at the stands where firs were dominant, they were observed 179 times at the stands where beeches were dominating and where there were also firs.

Gresy wolf which is the most important predatory specie on our study area show harmonization with preference of general stands as being similar to other species. Another particular which attracts attention in this harmonization is that grey wolf prefers the same habitats as roe deers, being their most important hunt, with similar density ratios. For example the most preferred type GKnA is preferred by roe deer with a ratio of 41.5%, whereas it is preferred by grey wolf with a ratio of 37%, while they prefer the type of KnGA with ratios of 41.5% and 37%, respectively.

One of the best models determining the distribution of grey wolves on an area is the forest cover (Jedrzejewski et al., 2015). Wolves which generally prefer coniferous and mixed forests, do not like forests which are young and which drop leaves (Koskela et al., 2013).

European badger, which is one of the most rare species on the area mostly prefer open areas in the forests (Unal, 2011), and they are seen more on the regions where plant cover is more frequent and where human activities are rare (Özen and Uluçay, 2010). Soil's being suitable for digging is another important factor in the habitat selection of badger (Suel et al., 2013). Oğurlu and Aksan (2013) have stated that since planting areas could easily be digged and as the trunk branches of cedar tree were close to the ground and as their bottom parts provided sheltering, it was suitable for European badger to nest at these places. On the other hand since trees were dense on black pine areas and as the live cover below was weak due to their falling parts, and as the soil was tight and solid, they were not considered to be appropriate to meet the needs of European badger for hiding, finding shelter and nesting.

According the the data we have obtained, European badgers were observed more on GKnA type of stands when compared with other types of stands. This type of stand was preferred by badgers both due to its mixture and soil features. European badgers don't prefer stands with pure beech or mixtures being mainly composed of beech and it is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91719184

thought that the reason for this is because sub-layer of this type of stands is coated with dense live or dead covers. This causes European badgers not to be able to dig the soil easily.

Stone marten which realizes less daily migrations when compared with other species prefers GknA mostly and it prefers KnD secondarily. Virgos et al. (2010) have stated that although stone marten was a predatory trees played an important role in their habitat selections. It is possible to observe marten at bushes and trees and at places where there are herbaceous plants (Suel et al., 2013). Stone marten, which we mostly observe at forest sections, sub-layers of which have developed, are not seen at open forest soils. It is found out that when stone martens left their nests inside dead tree blocks or wood blocks fallen on ground, they would hunt in the near environment and that they were returning back to their nests. Hence Bull et al. (2005) have stated that stone marten mostly preferred fir and spruce forests where there were dead trees and blocks. In the same study it was emphasized that martens rapidly left the areas where trees were cut.

Wild boar, which preferred juicy fruits in summer and dry fruits and seedy plants rich with fats in the winter season (Oğurlu and Aksan, 2013), which move around the living areas and which pile under dense plant covers and which get their nourishment on areas where there are tuber plants (Suel et al., 2013) have preferred stands having beeches as dominant tree types as they contained more water sources and as they met their food requirements better. Aksan et al. (2014) have stated that ideal places for wild boars were forest areas where soil type had characteristics of sandstone and that they did not prefer bushes and step areas. Wild boars do not use habitats randomly and mostly they act selectively among existing biotopes and in their habitat selections there are variations as per the seasons (Santos et al., 2004). In habitat selections of wild boars nourishment richness, level of hiding, sloping are the determinant factors (Xu, 2011).

In a study being conducted in Poland it was stated that wild boars preferred beech and horn beam forests and that they kept away from fir forests and that beech-horn beam forests were very important for wild animals (Fonsenca, 2008). In another study being conducted in Poland by Gorecki et al. (2009) it was determined that wild boars were mostly present within scote pines in fresh mixed wild leafed forest habitats.

In the studies we conducted it was seen that as being different from other species wild boars preferred stand types such as KnGA and KnÇsA where wide leafed trees were dominant. These stands meet the most convenient features for wild boars. As sub-flora of beech was more dense when compared with fir on the study area, a better environment was present for wild boars to rest and to hide. Again wild boar has been the only specie being observed on bare forest soil. Bare forest soils that were on the study area contained plenty of tuber plants which wild boars especially preferred as food. This situation caused for this specie to get nourishment here.

Wild cat which was the only cat specie being observed on the area was seen on all types of stands but with arc ratios. Just like other species wild cat was observed mostly at the stands of GKnA and KnGA. Wild animals being present on the area are active during the day time and they sometimes go to far distances away from their nests. Sarmento et al. (2006) have found out that for habitat usage wild cats preferred local and mainly forest areas. However besides forests shrubberies are also preferred by wild cats and even at certain places agricultural areas are also being used (Lozana, 2010).

Recommendations

For long years forest activities and wild life activities have contradicted with each other. Especially after cuttings at wide areas, big or very small open areas have formed in the forests. As the study area is a very important production field for regional forestry, this situation has significant impact on wild life on the area. Similarly forest fires and pesticides that are used against harmful forest insects form threats for many wild animal species. However by using appropriate forest management techniques, while forest planning is made, wild life can be improved.

Formation of mixed stands, mixed types of trees, existence of individuals with different ages bear significant impact on improving varieties of types in forest ecosystem. However regarding the types to be used for afforestation, attention should be paid in preferring local types and for them to comply with local conditions. At this point while making new afforestation works, it bears significant importance to avoid pure cultures in forest administration and to establish mixed cultures and to plant fruit trees that are effective in the nourishment of wild animals. Planting apple and pear trees for brown bears and trees of bushes having grape-like fruits or berries at local points for roe deers and red deers are important for development and sustainability of wild life.

It is significantly important to realize cutting activities as being required for forestry, by paying attention not to ruin stand types and classes, not to change closeness and densities in a significant way and most importantly to realize these activities in periods other than reproduction and breeding periods of wild animals.

Mainly afforestation and production activities that will be realized by considering the requests of wild animals and all forestry applications bear significant importance for the sustainability of wild animals.

Acknowledgements. This study was produced from 2014-FEN-A05 project supported by BAP Coordinator of Bartın University. We would like to express our appreciation to the Bartın University Scientific Research Project Commission, for their support.

LIFE CYCLE OF CEDAR PROCESSIONARY MOTH (*THAUMETOPOEA ISPARTAENSIS* DOĞANLAR & AVCI) IN TURKEY (LEPIDOPTERA: NOTODONTIDAE)

KÜÇÜKOSMANOĞLU, A.

Faculty of Forestry, İstanbul University-Cerrahpaşa, Sarıyer, Istanbul, Turkey
(e-mail: aliko@istanbul.edu.tr)

(Received 20th Mar 2019; accepted 24th May 2019)

Abstract. *Thaumetopoea ispartaensis* Doğanlar and Avcı (Lepidoptera: Notodontidae) (cedar processionary moth: CPM) is one of the most dangerous pests of *Cedrus libani* A. Rich. living in abundance in forests of the Isparta region and some forests of Taurus Mountain in Southern Turkey. The present study was conducted to study the biology of *T. ispartaensis* which was recorded and defined first time in Turkey and its damage on cedar needles. The study was conducted in Isparta-Senirkent Kapıdağ Forests (between 1250 and 1650 m; 38° 06' N, 30° 45' E) where the pest caused most damage. It was determined that *T. ispartaensis* was a monophagous species of *C. libani*. The flight period of the pest lasted from mid-August to mid-September. Females laid eggs underside of twigs (mean 3.5 mm diameter) on the lower part of trees. Eggs were covered by scales which were colored similar to the bark of shoot. Egg numbers of egg batches varied between 39 and 245 (mean 121). The caterpillars started to hatch in the second half of April, and it had five instars. The caterpillar hatching rate from eggs was found as 87.5%. The caterpillars which built the nests on stems and shoots fed at nights and stayed in their nests in the daytime. Mature larvae started to pass into the soil for pupating from the beginning of July. The pupation was determined in the first half of July, in a depth of 5-15 cm of soil, in the sun-exposed places in cedar woods along the sides of the roads. *T. ispartaensis* was determined as univoltine species.
Keywords: *cedar pest, needle, moth, biology, Turkey*

Introduction

Taurus cedar (*Cedrus libani* A. Rich.) is one of four cedar species distributed across the world. The Taurus cedar, which is naturally found in Turkey, Lebanon, and Syria, is distributed across approximately 482.391 hectares (ha) in Turkey. The broadest natural distribution of Taurus cedar, one of the most important forest trees of Turkey, is in the Taurus Mountains of Turkey. Cedar is significant from the historical, cultural, aesthetic, scientific and economic perspectives (Aksoy and Özalp, 1990; Anonymous, 2015). It grows in Mediterranean Mountain climates and has distinct ring boundaries. Its growth age is said to reach up to 500 years. Cedar generally occurs between 800 and 2100 m elevations (Evcimen, 1963).

The species of the genus *Thaumetopoea* (Lepidoptera, Notodontidae, Thaumetopoeinae) has an important place in forest fauna and human health as they are defoliators of trees and they release urticating hairs at the larval stage that are a source of allergy. Within the genus, there are two groups associated with conifers which are characterized by larval feeding in winter or spring-summer, so the groups are called 'winter' and 'summer' processionary moths (Basso et al., 2016).

Three species of processionary moths (Notodontidae: Thaumetopoeinae) can be found in cedar (*Cedrus* spp.) including *Thaumetopoea bonjeani* (Powell) in *C. atlantica* Man. in North Africa (Tunisia, Morocco, and Algeria), *T. libanotica* Kiriakoff & Talhouk in Lebanon and *T. ispartaensis* in *C. libani* in Turkey (Battisti et al., 2015). These species are close to *T. pinivora* living on pines in Europe and belong to the group

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91859190

of the "summer processionary caterpillars." All have their larval development from the beginning of spring until the beginning of summer (Demolin, 1988; El Yousfi, 1989; Kiriakoff and Talhouk, 1975; Mouna and Fabre, 2005).

T. ispartaensis has been identified as a new species from Turkey in the Isparta region of Asia Minor located in the Lakes District area in 2001. *T. ispartaensis* is one of the most important insects of Taurus cedar forests in the Isparta region and in some forests of Taurus Mountain in Southern Turkey. The only determined host species of *T. ispartaensis* is *C. libani*. The wingspan of the males and females is 26-29 mm and 34-37 mm, respectively. The larvae feed on the needless of cedar trees and produce tiny hairs containing and urticating substance, which causes contact dermatitis (Doğanlar and Avcı, 2001).

Materials and methods

The studies of the biology of the insect were carried out at Isparta/Senirkent Kapıdağ cedar forest where the insect was first detected. Field studies were conducted between 2012 and 2016 to determine the biology of the pest in natural conditions. Most of the egg clusters and larvae various stages were collected in the forest during study period. Eggs collected from the field were brought to the laboratory and measurements and counts were performed.

The study area was located in the Western Mediterranean of Turkey. It was about 65 km from Isparta city (*Fig. 1*). The study area is located at 38°06'N., 30°45'E., average slope 23°, predominately north facing aspect, about 1365 m altitudes, and about 1223 ha in size. The study area is found on calcareous formations of Eocene age. The soil varies from shallow to medium and medium-deep and is generally stony. The soil is varies from shallow, medium, medium-deep, and are generally stony. However, many cracks between limestone blocks contain fine soil and create a physiologically deep soil (Evcimen, 1963). This region is in the transitional zone between the Mediterranean climate and the continental climate with colder winters and hotter summers.

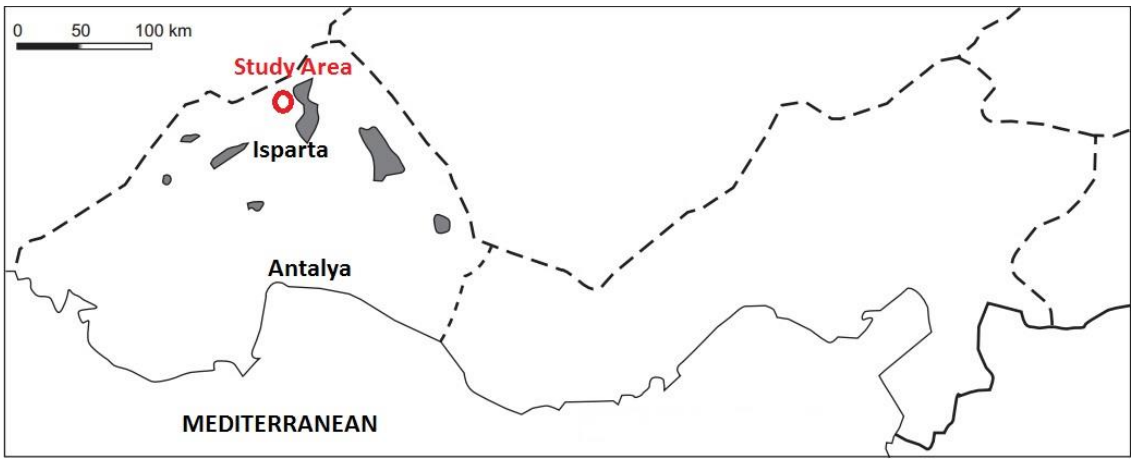

Figure 1. *The study area in Isparta City, south-western Anatolia, Turkey*

The egg-batches were collected in October-December 2013 and 2014. All egg-batches were taken from underside of twigs of *C. libani*. Ninety-five egg-batches,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91859190

oviposited over two annual generations, were studied. After collection, the batches were put singly in test tubes with cotton stoppers and placed in the laboratory at 21-24 °C, where further investigations were also performed. The scales covering the egg-batches were removed, counted and measured.

The biology of the pest has been tracked in field conditions. For this purpose, observations were made with periods of 2-3 weeks within the fields, in areas where the spread of the insect was determined. In the egg period, following the hatched of larvae up to pupa period studies were carried out within certain trees. In order to determine some morphological features of *T. ispartaensis*, several measurements and observations were made in larvae and pupae collected from field. Measurements were performed on 20 individuals for each period. Field observations were recorded on a regular basis and the biology of the insect in natural conditions was determined. Also, mature larvae and pupae brought to the laboratory were monitored until the adult outgrowth, within the plastic containers that have soil in their lower part.

Results

Thaumetopoea ispartaensis (described as *Traumatocampa ispartaensis* by Doğanlar and Avcı in 2001) is one of the most dangerous pests living in the *Cedrus libani* forests in the Isparta region and on the Taurus Mountains in Southern Turkey. The pest is distributed between 1250 and 1650 m. The caterpillars feed on the needles of cedar trees and have urticating hairs that cause contact dermatitis especially after the third instar.

The study was conducted in Isparta/Senirkent Kapıdağ Cedar Forest where the most massive damage occurred. It was determined that *T. ispartaensis* is a monophagous species and feed on only *C. libani*. *T. ispartaensis* belongs to the group of the summer processionary moths, just like *T. pinivora*, and adapts to high elevation.

Adults appear from the mid-August to the end of September, depending on the temperature and altitude (earlier at a lower elevation). Egg-laying started soon after emergence and copulation, as in other Notodontidae species. Copulation started a few hours after the adults had emerged and then egg deposition took place during the same night. Females oviposit on the underside of *C. libani* twigs. Egg batches are covered by grayish brown scales, similar to the color of the bark, and therefore the batches are indistinguishable. Only one egg-batch was laid by one female during its very short life. Oviposition by the moth in all cases was found to occur from the tip to base of the twigs. This observation was made based on the position of scales which covered the eggs. The eggs were deposited below the surface of the twigs were 2-5 mm diameter (average 3.5 mm). The color of the eggs was white. The length of the egg-batches varied from 7 to 36 mm (average 17 mm). A one cm egg-row contained a mean number of 10.5 (10.1-10.9) eggs (*Fig. 2*).

The number of eggs per egg batch varies between 39 and 245 (mean 121). The eggs hibernate and this period continues for approximately seven months. The larvae hatched in the last week of March and the first half of April of the following year and started to cause damage by feeding needles. It was observed that the larvae fed in nights and stayed in nests during day time.

The larvae live together in silky grayish nests until the 5th instar which is the last instar. They build their loose nests on the trunk or branch of host trees and nests become thicker (but it is still quite loose in comparison to pine processionary moth nests) as larvae feed during 2.5 months, generally between the late April and mid-July. In spring,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91859190

larvae resume feeding on the needles, reaching up to 3.0-3.5 cm in length by summer. The mature larvae are the most destructive ones and may cause severe infestation resulting in the complete defoliation of large surfaces of cedar forests. The nests become clear in May and grow large at the end of this month. They spin cotton like webs when they are active. The mature larvae of *T. ispartaensis* live in aggregations in silky nests (*Fig. 2*). Damaged parts of the tree with dead agglutinated needles remain long after the feeding period.

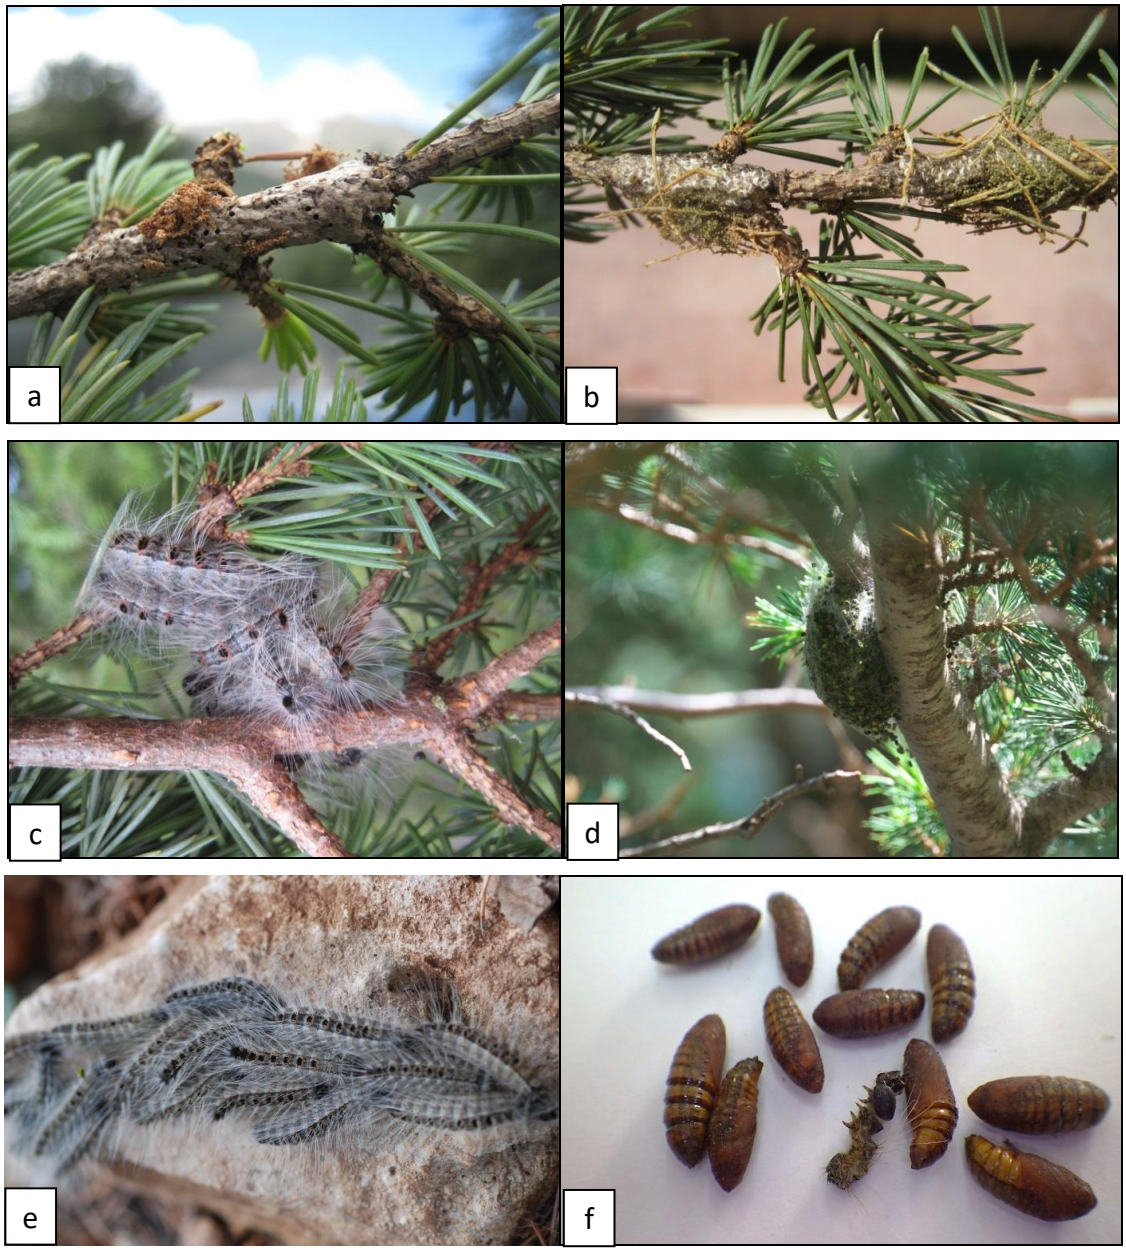

Figure 2. *Thaumetopoea ispartaensis a) egg batches b) damage that young larvae cause c) mature larvae d) nest of larvae e) larvae on soil for pupation f) pupae*

The pupation takes places at the beginning of July in lower elevations, and it takes places in the second half of this month in higher altitudes, in a depth of 5-15 cm of soil,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91859190

in sunlit cedar forest floors, especially along roadsides. In mid-June, fully grown larvae of *T. ispartaensis* drop to the forest floor and pupate in the surface litter and soil. There follows a short pre-pupal stage, after which the pupae remain in the litter until adult emergence. The pupa develops in a cocoon which is gray-brown (*Fig. 2*). There is no observation about the capacity of the pupae to prolong the diapause.

The adult appears in the middle of August, and adult hatchings become the highest level in the last period of this month. Flying period continues in September decreasingly. It was determined that *T. ispartaensis* has one generation and the mean lengths of egg, larva, and pupa periods are 228, 98 and 36 days, respectively (*Fig. 3*).

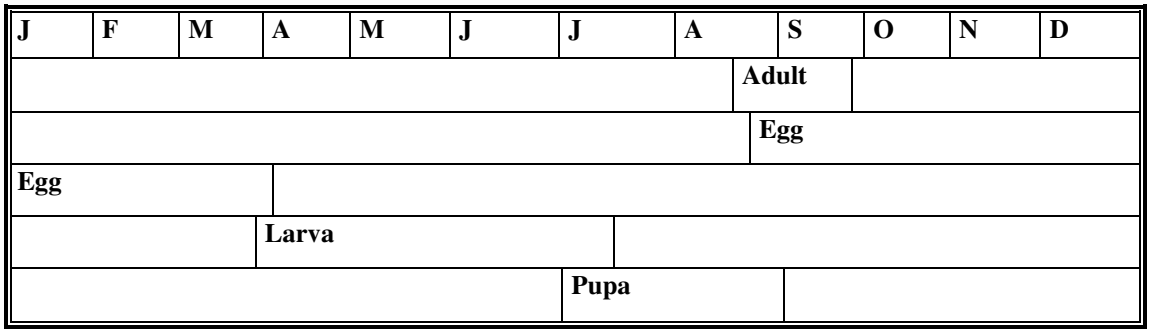

Figure 3. *Life history of Traumatocampa ispartaensis Doğanlar & Avcı in Turkey*

Discussion

T. ispartaensis display similar phenology as *T. bonjeani* in the C. *atlantica* forest in the Atlas Mt. in North Africa. Oviposition of *T. bonjeani* takes place in August-September on small twigs, and the eggs are also covered with scales. The eggs hibernate and hatch in the spring during March-April of the following year (Demolin, 1988).

At the same time, the biology of *T. ispartaensis,* shows great resemblance with the biology of *T. libanotica* that located in the forests of Bsharry, Tannourine and Shouf in Lebanon. *T. libanotica* lives in these regions between 1400-2000 m above sea level and its adult period is remarked as August-October (Kiriakoff and Talhouk, 1975; Nemer et al., 2018).

The egg rows of *T. ispartaensis* were not generally tidy, more random than the egg rows of *T. pityocampa*, *T. wilkinsoni* or *T. solitaria*. The eggs of *T. solitaria* are white above, grayish-yellow below, hexagonal and deposited in a flat, one layered, symmetrical, hexagonal cluster. The eggs of *T. pityocampa* and *T. wilkinsoni* are deposited around one or more pine needles or small twigs. They are deposited in one-layered cylindrical clusters. T*r. ispartaensis* eggs were observed to be white in contrast to the eggs of *T. pityocampa.*

Cedar processionary moth significantly damages *Cedrus libani*. In the spring of 1998, a notodontid moth, an outbreak of the cedar processionary moth *T. ispartaensis,* began about 400 ha in 75-year-old Lebanon cedar trees in Isparta. From 1999 to 2003, CPM larvae were present in the same stands and again caused defoliation. We identified regional outbreaks of CPM by synchronous and sustained growth periods of the trees. Growth functions were defined as the cumulative sum of radial increment. Tree ring evidence suggests that a large scale outbreak occurred in 1954 (from 1954 to 1961) and small outbreaks occurred in 1947 (1947-1951), in 1985 (1985-1988), and 1998 (1998-2003) in the study area. The average diameter growth reductions for around 1947, 1954, 1985, and 1998 were 40%, 28% 17%, and 10% of potential, respectively.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91859190

T. ispartaensis population in Isparta has been observed since 1999, and an outbreak was recorded only between 1998 and 2003 (Avcı and Carus, 2005), whereas it was impossible to see even a single nest in some years such as 2012. Further studies are indeed required to understand the population dynamics of the species.

The conifers of the genus *Cedrus* seem to be associated with the summer *Thaumetopoea*, although further studies are needed to clarify the evolutionary history of the group (Basso et al., 2016).

Thaumetopoea ispartaensis belongs to the *Thaumetopoea* genus, of which four other species are wide spread in Turkey, namely *wilkinsoni*, *pityocampa*, *solitaria* and *processionea* attacking various types of plants and trees. A detailed study of the biology of the cedar processionary moth in the all stages has been presented in this study.

Abstract. Ectopic elution is a commonly used method for remediation of petroleum hydrocarbon contaminated soil. In the work, surfactant was used to wash petroleum hydrocarbon contaminated soil. Then, we investigated the effects of different surfactant combination ratio and concentration, the auxiliary concentration and temperature on the removal efficiency of petroleum hydrocarbon pollutants. The results showed that the oil solubilization capacity of Tw-80 was higher than that of SDS (Sodium dodecyl sulphate, SDS), and the removal rate of oil was the highest when the compound ratio of SDS/Tw-80 was 50-60. With the increase of surfactant concentration and temperature, the oil removal rate increased. The increase of alkaline solution was in favour of heavy oil separation and removal of tricyclic aromatic compounds. Sodium chloride, calcium chloride and magnesium chloride reduced the removal rate of oil, while sodium sulfate, sodium bicarbonate, sodium bicarbonate, sodium silicate and sodium phosphate increased the removal rate of oil.
Keywords: *ecological protection, petroleum hydrocarbon contaminated soil, surfactant, elution treatment, oil removal rate*

Introduction

During the drilling, exploitation and transportation process of petroleum, the pollutants are released into the surrounding soil environment due to dropping and leaking, which changes the physical and chemical properties of soil. It is difficult to grow for Crops and surface vegetation, causing significant damage to the ecological environment. In particular, aromatic substances, which are more toxic to petroleum, can accumulate in crops and threaten human through the food chain (Kim et al., 2017). At present, soil excavation, soil steam extraction, extraction, bioremediation and elution are the main removal methods of petroleum hydrocarbons in soil (Åslund et al., 2013; Dong et al., 2015; Kim et al., 2017). Soil excavation is to excavate the contaminated soil and then cover with fresh, unpolluted soil. It is suitable for the small-scale polluted areas as well as the subsequent treatment of excavated soil. As people usually use incineration method, the cost of pollution treatment is very high. Soil steam extraction has a good effect on high vapor pressure compounds (e.g., hydrocarbons), rather than on non-volatile organic compounds such as polyaromatic hydrocarbons and polychlorinated biphenyls (PCBs) (Mota et al., 2015; Mauko et al., 2018).

Bioremediation is more challenging when petroleum is mixed with water. The easy-to-degrade substance has good treatment effect, but the effect is not significant for the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91919204

organic matter that is not easy to be biodegraded by oxygen. The leaching method includes the traditional pump extraction and the surface active agent solution leaching developed in recent years. Due to the low solubility of petroleum pollutants in water, the ideal effect cannot be achieved by the traditional pump leaching method with clean water.

In comparison, the heterotopic elution of surfactant has advantages, such as low energy consumption, small equipment investment, simple process, wide application range, fast speed and waste reduction. It has been widely studied in Europe, America and Japan, applied to remediation of organic matter, heavy metals and radioactive contaminated soil (Arauzo et al., 2015). However, the methods of surface active agent heterotopic elution for remediation of petroleum-contaminated soil are limited to laboratory research, large-scale and flexible soil elution equipment.

The work used an anionic-Nonionic surfactant to elute oil-contaminated soil, and investigated the effects of various operating conditions on the removal rate of petroleum as well as the mechanism of action. Some technical supports were provided for the remediation of petroleum contaminated soil with surfactant elution. This investigation, concerning the effect of solubilizing petroleum with single surfactant and compound surfactant, was to determine the necessary operating conditions of surfactant elution experiment by single factor experiment. Besides, we studied the influence factors of complex surfactant elution on remediation of petroleum contaminated soil, the samples before and after leaching by three-dimensional fluorescence spectroscopy, and the changes of petroleum components in the soil before and after treatment.

Mechanism of action

Mechanism of synergism of surfactants

Subheading

Surfactant (surface active agents) refers to a class of substances that can significantly reduce solvent surface tension and liquid-liquid interfacial tension. It has certain structure, hydrophilic and oil-friendly properties and special adsorption (Arauzo et al., 2015). When the concentration of surfactant in water is low, it exists in the form of monomer in water and adsorbs at the water-gas interface. The increase of its concentration in water leads to the increased adsorption of surfactant at the water-gas interface. As a result, the interfacial tension between water and gas decreases. The hydrophobic part of the surfactant molecule interacts with each other to form the association in the solution, namely the concentration of micelle (micelle). Surfactant forms a micelle in water, which is the CMC (critical micelle concentration). CMC is an important index to measure the properties of surfactants. In CMC, surfactant solutions have the lowest interfacial tension and can dissolve insoluble petroleum pollutants (Arauzo et al., 2015) (See *Fig. 1*).

At present, most researchers believe that surfactants remove petroleum pollutants from soil through the following mechanisms (Elazhari-Ali et al., 2013; Akinlua et al., 2015; Gao et al., 2016; Brown et al., 2017), curling (rollup) and solubilizing (solubilization). Generally, surfactants below or above CMC can improve the removal of petroleum pollutants in soil. Therefore, the mechanism of shrinkage and solubilization functions.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91919204

Surfactant solubilization mechanism

Solubilization refers to the situation that the insoluble petroleum pollutants adsorbed by the soil are desorbed from the soil under the action of surfactants and distributed to the water phase. It depends on the formation of the insoluble organic pollutants in the micellar phase of the aqueous solution by the surfactants. Solubilization usually occurs above the critical micelle concentration due to a large number of surfactant micelles formed in aqueous solution (Jha et al., 2018).

There are lots of studies about the solubilisation of PAH (polycyclic aromatic hydrocarbon, PAH) and other insoluble organic pollutants by surfactants (Li et al., 2014; Yang et al., 2015; Janajreh et al., 2018). Edwards et al. focused on the solubilization of PAHs by Brij30, Igepal CA-720, Tergitol NP-10 and Triton X-100 (Mortazavi et al., 2013; Fallah et al., 2015). The concept of molar solubilization ratio (Molar Solubilization Ratio, MSR) is proposed to describe the solubilization of surfactant solution quantitatively, as shown in *Eq.(1)*.

$$MSR = (S - S_{cmc})P(C_s - C_{mcm}) \quad \text{(Eq.1)}$$

where C_s and C_{cmc} are the concentrations of surfactant solution greater than/equal to CMC, respectively; S and S_{cmc} in CMC are the apparent solubilities of organic matter when the surfactant concentrations are C_s and C_{cmc}.

Another quantitative description of solubilization of surfactants is the partition coefficient (K_{mc}) of micelle phase P-water phase, as shown in *Eq.(2)*.

$$K_{mc} = X_{mc}PX_a \quad \text{(Eq.2)}$$

where X_{mc} is the molar fraction of organic matter in the micellar phase, which can be calculated by using *Eq.(3)*.

$$X_{mc} = (S - S_{cmc})P(C_s - C_{cmc} + S - S_{cmc}) \quad \text{(Eq.3)}$$

Parameter X_a is the molar fraction of organic matter in the aqueous phase. In dilute solution, V_w is the molar volume of water (0.101805 L/mol), so we can obtain *Eq.(4)*.

$$K_{mc} = 5514\,MSRP[S_{cmc}(1 + MSR)] \quad \text{(Eq.4)}$$

Experiment

Experimental materials

According to the situation of China's Tarim oil and gas field and its surrounding areas, we considered the complex composition of drilling mud and the uneven distribution properties of surrounding desert sand, to make sure the representativeness of the collected mud and surrounding desert sand samples. In the 1 m^2 sample plot the sample was evenly distributed and the water-based mud of 10 wells in the 1 m^2 plot and the sand layer of 0-20 cm in the surrounding 10 m area were collected. A total of 12 water-based mud samples and sand analysis samples were collected. Mud samples were stored in cold storage until analysis, and confined storage reduced the volatilization and interference from the surrounding environment. The soil samples were processed within

DOI: http://dx.doi.org/10.15666/aeer/1704_91919204

14 days of pre-treatment, and the extract analysis was completed within 40 days. After mixing the soils, dry naturally at room temperature, and remove the residual roots, plastics and other debris. Then, grind with a mortar, and sift over 100 meshes. Finally, store it in a brown wide-mouth bottle. Some physical and chemical properties of the soil are determined (See *Table 1*).

Experimental content

Preparation of petroleum-contaminated soil samples

At first, some crude oil was taken and dissolved by dichloromethane. Then, some spare soil was put into the beaker. The solid-liquid mixture was stirred by a glass rod. Finally, the solvent of the mixture was evaporated in the ventilating cabinet and simulated soil sample was obtained.

Method for determination of petroleum in soil

The concentration of petroleum in the solution was determined by ultraviolet spectrophotometry. Crude oil was used to prepare 1.0 g/L standard solution with dichloromethane as solvent. The standard solution was diluted by UV spectrophotometer (HACH-DR6000), and scanned in the wavelength range of 200-400 nm.

Weigh 0.1 g of petroleum in a beaker, and dissolve it in dichloro-A hospital. Then, transfer it to 100 mL volume bottle and set volume. The standard oil storage solution concentration is 1,000 mg/L. The solution was taken from 5 mL volume bottle to 25 mL volume bottle with the fixed volume. The oil concentration was 200 mg/L; 0. 4, 0.8, 1.2, 1.6, 2 and 10 mL colorimetric tubes were removed, and the volume was fixed to the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91919204

mark line. The standard solutions for this series of concentrations were 8,16,24,32 and 40 mg/L.

The oil contents of the eluted soil and the original soil were used to calculate the removal rate, as given by *Eq.(5)*.

$$R = \left[1 - \frac{(A-B)*N*25*100}{K*1000*1000*2w}\right]*100\% = \left[1 - \frac{(A-B)*N}{800Kw}\right]*100\% \quad \text{(Eq.5)}$$

where R is the removal rate; A the absorbance; $A=K\times B$ is the standard curve; N the dilution multiple; w the oil content of the oily soil sample.

Solubilization test

Mix the 0.1 g petroleum and 50 mL surfactant solution with different concentration and its compound solution (50:1) into a 100 mL plug cone bottle and oscillate at a constant temperature oscillator at 25°C for 5 h at a speed of 150 r/min. After the solution was quiesced in the funnel for 2 h, the lower part of the solution was removed for 10 mL. Dichloromethyl chloride was used to extract, with ultraviolet spectrophotometry used to determine the concentration of petroleum in the solution. The solubilization effect is calculated by *Eqs.(1), (2), (3) and (4)*.

Influencing factors of leaching repair

a. Complex proportion

2.5 g oily soil sample containing 5% oil was put into a 100 mL plug conical bottle. The compound ratios (SDS: Tw-80) of 4 g/L were10: 1, 20: 1, 30: 1, 40: 1, 50: 1, 60: 1.70: 1.80: 1.90: 1 and 100: 1 for 50 mL. The sample was placed on the constant temperature oscillator at 25°C for 1 hour at the rate of 150 r/min. After stilling for 10 min, the supernatant was discarded, and the soil was set at 105°C for 1 h. After cooling, 2.0 g was added to 20 mL dichloromethane, and then put into an ultrasonic cleaner. The temperature was adjusted to 30°C, with extraction for 15 min. The extractive was poured into 50 mL centrifugation tube, and the supernatant was collected at 4,000 r/min rotating speed for 5 min. The volume of the supernatant was fixed, with the measured absorbance and the calculated oil removal rate.

b. Surfactant concentration

The concentration of surfactant solution was 0, 1, 2, 3, 4, 5 and 6 g/L, respectively. Other operating conditions were referred to *Eq.(1)*.

c. Leaching temperature

Run the constant temperature oscillator, and adjust the temperature to 10, 20, 25, 30, 40, 50 and 60°C. Other operating conditions refer to *Eq.(1)*.

d. PH value of the solution

The soil sample containing 5% oil was put into 100 mL plug conical bottle, added with surfactant solution. The pH value of the solution was adjusted to 3, 5, 7, 9 and 11 with sodium hydroxide and hydrochloric acid solution, respectively. Other operating conditions were referred to *Eq.(1)*.

e. Effect of adding inorganic salts

Add different concentrations of sodium chloride, calcium chloride, magnesium chloride, sodium sulfate, sodium bicarbonate, sodium silicate and sodium phosphate surfactant solutions. Other operating conditions refer to *Eq.(1)*.

Results and discussions

Method for determination of petroleum in soil

The UV spectrophotometer was used to select the standard solution of 254 nm in the wavelength range of 200-400 nm. The standard curve for the experiment is given in *Figure 2*. The oil removal rate was calculated by *Eq.(5)*. In *Figure 3*, 284/336 nm is the excitation/emission peak corresponding to light oil, and 256/360 nm heavy oil corresponding excitation/emission peak.

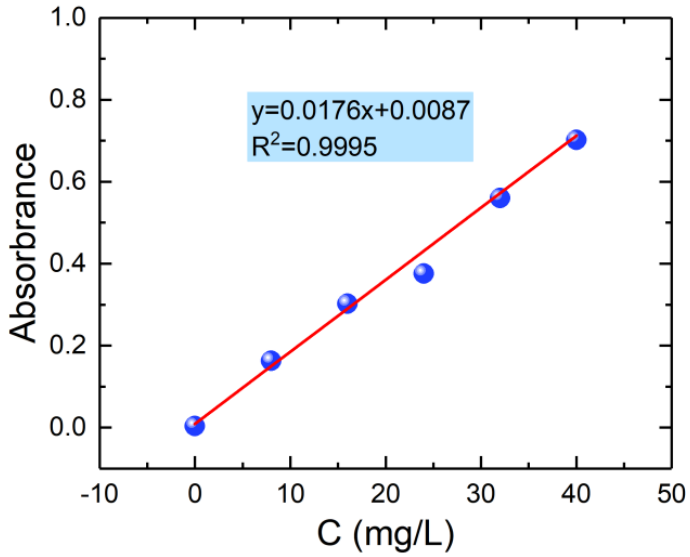

Figure 2. *Standard curves for experiments*

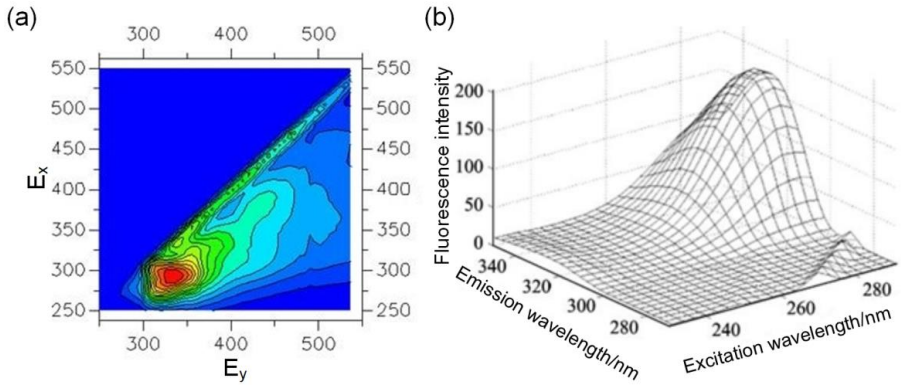

Figure 3. *Three-dimensional fluorescence analysis of crude oil*

The emission wavelength of 325 nm is equivalent to a ring, a binary aromatic compound (abbreviated as one, two rings), a 350 nm equivalent to a binary ring, a tricyclic aromatic light compound (hereinafter referred to as Bicyclic), and a tricyclic aromatic compound (tricyclic) of 375 nm, that equals to the tricyclic aromatic compound (tricyclic) (Lu et al., 2014; Meshram et al., 2017).

The content of heavy oil in crude oil was higher than that of light oil, and the content of tricyclic aromatic hydrocarbon in aromatic hydrocarbon was the highest. Compared

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91919204

with crude oil, the light intensity of light oil and aromatics under tricyclic ring decreased significantly in undried soil samples. In the preparation of soil samples, the light oil and aromatic hydrocarbon components under tricyclic ring migrated to the atmosphere due to their natural volatilization. The components of light oil were volatile in the preparation of samples, but the components of heavy oil were not easy to volatilize. Compared with the undried soil samples, the fluorescence intensity of light oil components of contaminated soil samples decreased slightly after drying, while the light burst intensity of heavy oil components decreased obviously. The possible reason was that the light intensity of the heavy oil group was lower than that of non-dried soil samples. Components were converted into volatile substances when dried at high temperatures.

Solubilization test

Figure 4 shows the solubilization effect of the mixture of two surfactants on petroleum in the selected mass concentration range. According to the literature, the solubilization capacity of Tw-80 is higher than that of SDS, and the solubilization effect of the compound surfactant is close to that of SDS (Shi et al., 2013; Enright et al., 2017).

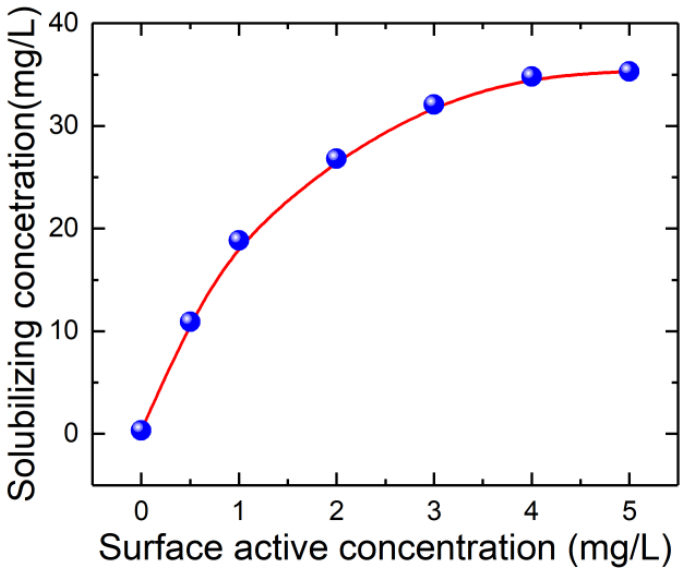

Figure 4. *Solubilization curve of SDS/Tw-80 after blending*

However, the amount of SDS used is reduced by one time, indicating that the complex surfactant can improve the solubilization of the surfactant to solubilize petroleum. Therefore, the compound surfactant is used to carry on the petroleum elution experiment.

Factors affecting leaching repair

Compound proportion

Figure 5 shows the effect of complex ratio on the removal of petroleum from surfactant solution. It is evident that as the ratio of SDS and Tw-80 increases, the effect of the ratio of the compound on the oil removal rate increases first and then becomes

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91919204

smaller. This is because the interaction between the two compounds can be found when the ratio is around 50, and the effect of the compound ratio on the decreasing rate is the highest. According to *Figure 6*, when the ratio of SDS and Tw-80 is 50-60, the oil removal rate reaches the maximum. The anion surfactant SDS is electronegative in the solution, not easy to be adsorbed by the soil. While the Nonionic surfactant Tw-80 is not ionized in the solution, it is electro neutral, easy to be adsorbed by the soil with negative charge.

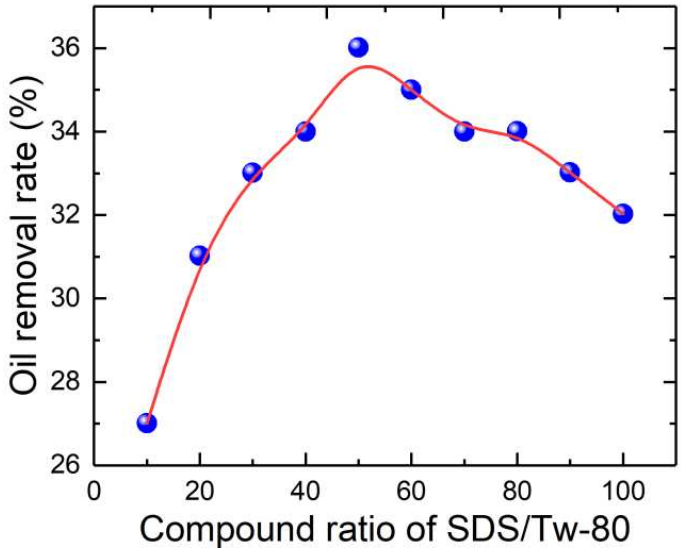

Figure 5. *Effect of compound proportion on oil Removal rate*

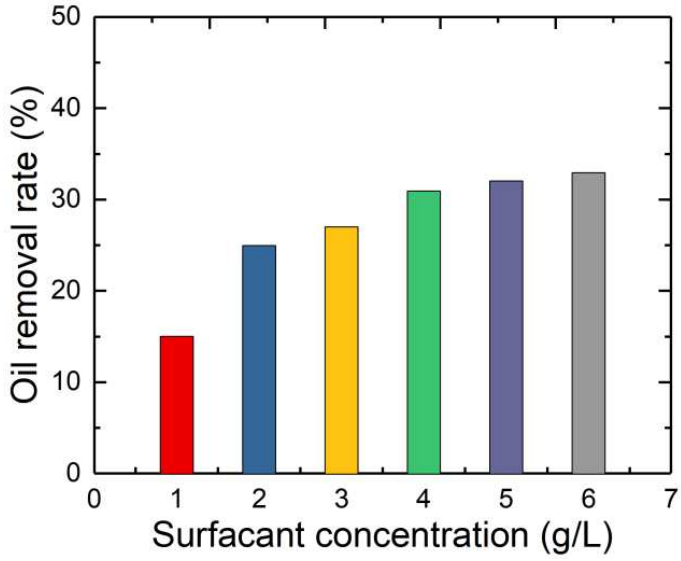

Figure 6. *Effect of surfactant concentration on oil Removal rate*

With the SDS, the weak intermolecular interaction of Tw-80 is replaced by the interaction between hydrophilic ion dipoles to form mixed micelles (Carbone et al., 2013), which can reduce the soil adsorption, ensure the effective mass concentration

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91919204

and improve the oil removal rate. Besides, for nonionic surface activity in complex surfactants, the larger proportion of the surfactant means the smaller CMC and the higher removal rate (Elazhari-Ali et al., 2013). Moreover, the CMC (2.5 g/L) of SDS is much larger than that of Tw-80 (0.013 g/L). The increased ratio of SDS to surfactant increases the critical micelle concentration of surfactant, which leads to the decrease of oil removal rate inthe same concentration. The compound ratio of SDS/Tw-80 selected in the experiment was 50:1.

Surfactant concentration

Figure 6 shows the effect of surfactant concentration on oil removal by elution. With the increased surfactant concentration, the oil removal rate increases. When the removal rate is larger than 4 g/L, the removal rate of the easily desorbed oil component in the soil will be washed down, and the removal rate will no longer increase (Gros et al., 2014). Excessive use can lead to a waste of chemicals and secondary soil pollution. Therefore, the optimum concentration of surfactant for remediation of contaminated soil should be considered based on the economy and environmental protection. The concentration selected in the experiment was 4 g/L.

Leaching temperature

Based on *Figure 7*, we speculate that the temperature has a significant effect on the oil removal rate and the removal rate increases with the increase of temperature. High temperature has following advantages: enhancing the fluidity of oil, weakening the adhesion force of soil, providing the energy needed for desorption, and promoting desorption of oil.

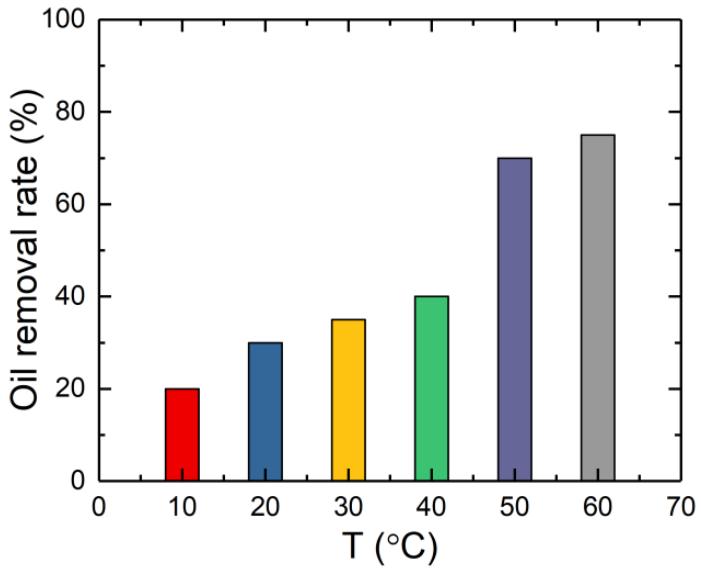

Figure 7. *Effect of leaching temperature on oil Removal rate*

The increase of temperature prevents the adsorption of Tw-80, and the increased solubility of SDS by soil is beneficial to the formation of micelles. However, if the temperature is too high, the surface activity and solubility of nonionic surfactants will

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91919204

be decreased, with the reduced oil removal rate. With the high temperature, the energy consumption increases, so the appropriate temperature should be chosen according to the repair concrete condition. The work studied the remediation of petroleum contaminated soil by surfactant at room temperature, with the experimental temperature of 25°C.

Solution pH

Figure 8 shows the effect of pH value on the removal of petroleum by surfactant solution leaching. The removal rate of petroleum increases with the increased pH value. The increase of the alkalinity of solution leads to the increased negative charge of the soil particles, the increased repulsion between surfactant molecules and the soil, and the decreased adsorption of the soil. In addition, the alkaline substance in surfactant solution can react with the acid substance in petroleum to form salts, which increases the water solubility of petroleum. Some components have certain surface activity, which can improve the removal rate of petroleum. Furthermore, the increase of pH in surfactant solution reduces the interfacial tension.

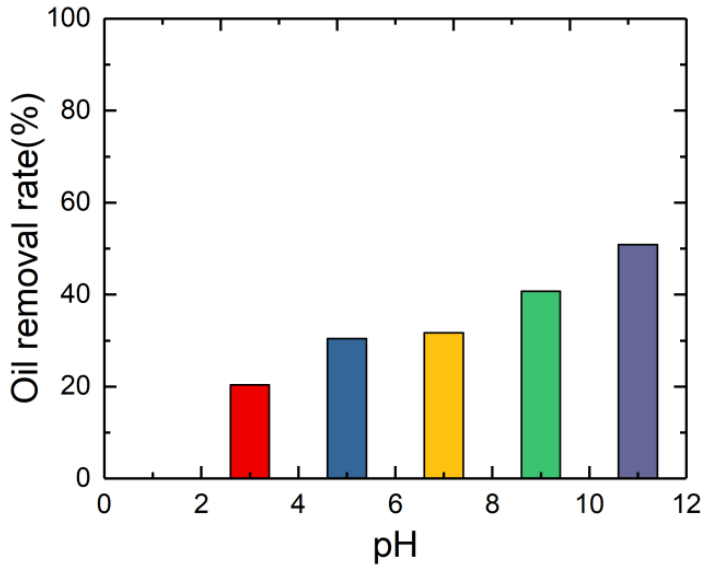

Figure 8. *Effect of PH value of solution on oil deoiling rate(PH is hydrogen ion concentration)*

Effect of adding inorganic salts

Figures 9 and *10* indicate the effect of inorganic salts on the removal of petroleum from surfactant solution. *Figure 9* shows that with the increase of concentration, sodium chloride, Korea chloride (In the field of inorganic chemistry, it is a salt compound formed by the combination of a negatively charged chloride ion and a positively charged cation of another element.) and magnesium chloride reduce the oil removal rate. *Figure 10* shows the oil removal rate is increased by sodium sulfate, sodium bicarbonate, sodium cinnamate and sodium phosphate.

SDS ionizes in the water can produce CI2H25O-SO3-, energy and Ca^{2+}, Mg^{2+} and form precipitation. Sodium ion produced by sodium chloride ionization can increase the diffusion double layer of the ionic micelle and improve the activity of surfactant. However, it exchanges calcium ion from the soil, reducing the effective active

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91919204

substances of SDS and destroying the compound system. The addition of calcium chloride and magnesium chloride not only leads to the formation of precipitation of SDS directly, but also interacts with soil, block the void of soil and hinder the transfer of oil to surfactant solution. Although sodium sulfate brings a large number of sodium ions, but sulfate provides a lot of negative charges, and reduces the adsorption of surfactant, surface tension of surfactant solution and interfacial tension between oil and water.

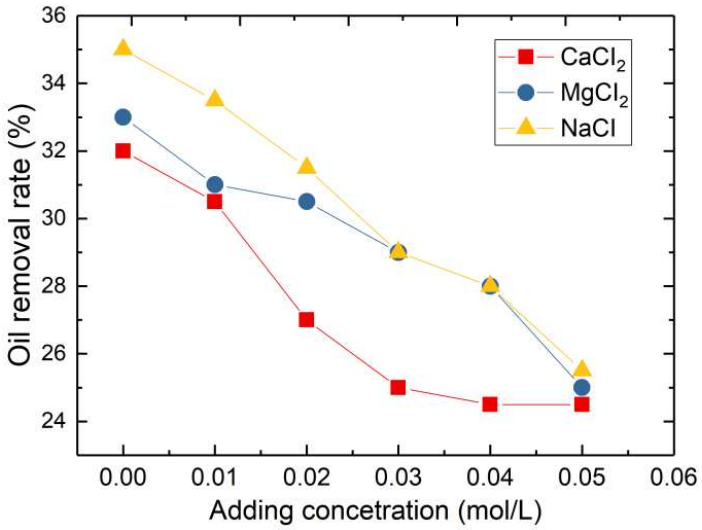

Figure 9. *Effect of adding inorganic salts such as sodium chloride, calcium chloride and magnesium chloride on oil deoiling rate*

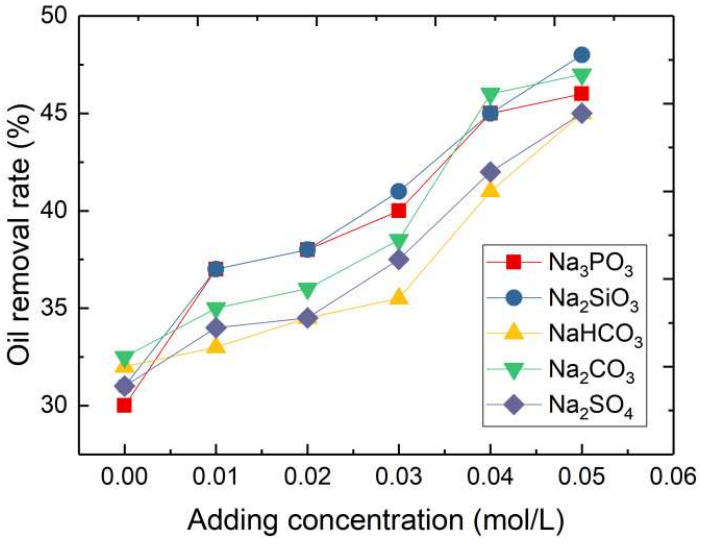

Figure 10. *Effect of adding inorganic salts such as sodium sulfate, sodium bicarbonate, sodium silicate and sodium phosphate on oil deoiling rate*

Finally, the solubilization of surfactants is improved. Sodium carbonate, sodium bicarbonate, sodium WaaS and sodium phosphate are all strong alkali and weak acid

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_91919204

salts. Hydrolysis makes surfactant solution alkaline, which is beneficial to the removal rate of petroleum. The cation produced by ionization of three inorganic salts can precipitate with the continuous ion in the solution and reduce the negative effect of the hardness ion. In addition, sodium silicate and its hydrolysate can be adsorbed on the surface of soil particles to form a protective film, thus preventing the desorbed oil from being adsorbed again by the soil. Although the above inorganic salts can bring about the precipitation effect of sodium ions, the positive effects of these inorganic salts on the improvement of removal rate are more evident than these adverse effects. On the whole, these inorganic salts play an essential role in promoting oil elution.

According to the above figures, the results of the solidified oil-containing soil and the directly solidified product leachate are quite different. A series of surfactants and composite surfactants were used to determine the oil solubilisation and single factor experiments to determine the surfactant elution. The results showed that the anionic-nonionic surfactant was used to elute oil-contaminated soil. The method is better than the previous method and has superior performance. It can provide some technical support for surfactant elution and oil-contaminated soil.

Conclusions

Based on the ecological protection, the work discussed the method of petroleum hydrocarbon pollution leaching in farming land, and used the ex-situ leaching for soil remediation. In terms of the solubilization, a series of comparative experiments were established to analyse the effects of concentration and ratio of surfactant concentration as well as the addition of additives on the leaching. The following conclusions are obtained.

a. The oil solubilization of Tw-80 was higher than that of SDS. The removal rate of SDS/Tw-80 complex surfactant solution increased first and then decreased with the increase of SDS ratio. The maximum value was obtained when the compound ratio ranged from 50 to 60. From the oil elution effect, economy and benefit to experiment, 1h was selected as the oscillation time.
b. The higher the surfactant concentration was, the higher the oil removal rate was. When the surfactant concentration was higher than 4 g/L, the oil removal rate increased slowly. In the range of 10 to 60°C, the temperature had a significant effect on the removal rate of petroleum in contaminated soil. The removal rate increased with the increase of temperature. The high temperature was beneficial to the removal of polycyclic aromatic hydrocarbons (PAHs). Alkaline environment was good for the removal of petroleum, heavy oil components and tricyclic aromatic compounds.
c. The addition of inorganic salts affected the oil elution with surfactants. Sodium chloride, calcium chloride and magnesium chloride reduced the removal rate of oil, while sodium sulfate and sodium bicarbonate reduced the removal efficiency of oil eluted by sodium chloride, calcium chloride and magnesium chloride. Sodium silicate and sodium phosphate increased the removal rate of oil eluted.
d. According to experimental results, it can be concluded that the anion-nonionic surfactant proposed in this paper is better than the previous method, and can provide better technical support for surfactant elution and oil-contaminated soil.

Abstract. The integration of the principles of green chemistry into nanotechnology has become one of the key issues in nanotechnology research. Metal nanoparticle production, which does not contain toxic chemicals and does not harm the environment, needs to be developed to avoid adverse effects on medical applications. In this study, *Pleurotus eryngii* (PE) extract was used for preparation of silver nanoparticles (AgNPs). The presence of AgNP was understood that after adding 1 mM silver nitrate (AgNO3) to the fungus extract, the reaction turned from the open yellow to reddish brown. The analysis of samples taken at different times with the UV-Visible Spectrophotometer (UV-Vis) confirms the formation of PE-AgNPs. The Scanning electron microscopy-Energy Dispersive X-Ray Spectrum (SEM-EDX) analysis showed that spherical nanoparticles were formed. X-ray crystallography (XRD), analysis is calculated from Debye-Sherers inequality, in which PE-AgNP synthesized in the study was 18.45 nm in size. It has been demonstrated by using the minimum Inhibitory Concentration (MIC) method in which AgNPs have strong antimicrobial activity.
Keywords: *antimicrobial activity, XRD, SEM, TGA-DTA, AgNPs, Pleurotus eryngii*

Introduction

Nanoparticles (NPs) are particles having a size of 100 nm or less. Because they have a large surface area that allows them to be used in new applications, they tend to react differently from large substances containing the same composition particles (Abou El-Nour et al., 2010). The new features that NP has gained make them versatile in many research areas such as biomedical applications, drug exploration, luminescence, cosmetics and renewable energy technologies (Chaudhuri and Paria, 2012; Tran et al., 2013; Rauwel et al., 2015). Therefore many researchers have studied the synthesis of NP using various physical and chemical methods (Remya, et al., 2017). However, it is stated that the synthesis of nanoparticles with green chemistry approaches using biological entities such as plants, fungi, bacteria, algae and actinomycetes provides additional advantages over other methods because it is simple, cost-effective, reliable, and environment-friendly. For this purpose, the use of biological synthesis approaches for many researchers is increasingly important (Kumar and Yadav, 2009).

The fact that microbial infection is a serious problem in the agriculture and healthcare sector has made it mandatory to develop new antimicrobial agents with highly versatile properties such as antimicrobial effect strength, harmonious and low toxicity. In this context, the electrostatic attraction between the positively charged NPs and the negatively charged microbial cells has received worldwide attention due to the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92059214

large surface/volume ratio resulting in improved physicochemical properties of NPs and increased antimicrobial activity (Lakshmeesha et al., 2014; Kavyashree et al., 2015). Antimicrobial properties of NP's, including Antibacterial and antifungal activities, have recently been reported extensively (Mallmann et al., 2015; Salem et al., 2015; Elgorban et al., 2016).

As reported, silver antimicrobial plays a unique role in catalytic and biological systems (Nadagouda et al., 2009). The synthesis of silver nanoparticles, compared to other metals, has become more important as an antimicrobial agent against the ever-increasing threats posed by antibiotic resistant microbes (Panaek, et al., 2006; Parashar et al., 2009).

Edible fungi, flavonoids, phenolic acids, tannins and oxidized polyphenols due to numerous reducing biomolecules has attracted great attention in NP synthesis (Philip, 2009; Palacios et al., 2011). In addition, mushroom extract has a high protein content and the carbonyl group of amino acids has the ability to prevent the aggregation of NP's and thus stabilize them in aqueous solution (Al-Batal et al., 2013). Numerous reducing biomolecules, micelles that offer a large surface area for interaction, because of the enzymes they secrete is thought to increase the effect of the functional groups of the nanoparticles and make the mushrooms advantageous compared to other organic sources.

In the literature, it is stated that mushroom extracts such as Volvariella volvacea, Pleurotus sajor Caju, Pleurotus Florida, Ganoderma lucidum, Agaricus bisporus, Inonotus Obliquius were used successfully in AgNP synthesis (Nagajyothi et al., 2014). However, there was no evidence that the *Pleurotus eryngii* extract was used. In the light of the above information, it is aimed to determine AgNP synthesis, characterization and antimicrobial activity of the obtained PE-AgNP's using Pleurotus eryngii which contains many active ingredients.

Materials and methods

Macrofungus

Pleurotus eryngii used in the study was obtained from Hakkari/Turkey in April-May 2018. Diagnostic macroscopic investigations were carried out using field study on ecological structural features and 500 g samples stored in the Microbiology-Biochemistry Research Laboratory of Mardin Artuklu University.

Microorganisms

For testing antimicrobial activity; *Escherichia coli* ATCC 25922, Staphylococcus *aureus* ATCC 25923, *Streptococcus pyogenes* ATCC 19615 *Pseudomonas* aeruginosa ATCC 27853, standard bacterial strains with *Candida albicans* ATCC 10231 strains are available in the Microbiology-Biochemistry Research Laboratory of Mardin Artuklu University.

Preparation of mushroom extract

Pleurotus eryngii extract was used to prepare AgNP synthesis. The mushrooms collected from the field work, after washing with tap water, it was finally washed with distilled water. 200 g fresh sample, divided into small pieces, was boiled in 90 °C in distilled water 1000 ml. It was then cooled at room temperature and used in the AgNPs synthesis after filtration with Whatman No. 1 Filter paper (Acay et al., 2019).

Synthesis of PE- AgNPs

Generally, the color change in the synthesis of AgNPs is determined by time-dependent UV-vis spectrophotometry measurements (Pugazhendhi et al., 2018). Therefore 1 mM AgNO3 solution is prepared. The Extract and solution were mixed at the rate of 1:5 and the colour change at room temperature was expected to occur. Reduction of the silver ions was observed to change the white colored solution to dark brown. The resulting dark-colored solution is centrifuged 5 min at 10000 rpm to remove the upper liquid phase and wash with distilled water until the remaining solid was clear. The obtained AgNPs were left to dry in the oven at 65 °C for 48 h and then allowed to dry and stored for characterization.

Characterization of silver nanoparticles

The characterization of silver nanoparticles was carried out as follows according to the methods described earlier (Baran, 2018). The UV-Vis Spectrophotometer was used which very useful technique for the primary characterization of prepared PE-AgNPs. In the study, the formation of silver nanoparticles was observed with measurements made at one hour intervals using the SHIMADZU UV-3600 Model UV-Vis Spectrophotometer in the reduction of Ag+ ions to Ago form in the solution. The AgilentCary 360 model FTIR device was used for the evaluation of the functional groups involved and responsible for the reduction. The X-ray refractivity pattern of the Obtained nanoparticles was done with the Crystal Dimension analysis RadB-DMAX II computer-controlled X-rays diffraction difractometry. The appearance of the nanoparticles and the silver element composition were analyzed by the EVO 40 LEQ Model device. In order to determine at what temperature the Nanoparticles were deteriorate, the AgNP was used to measure the flow rate of 20 mL/min in the N2 (g) atmosphere with a heating rate of 10 °C/min and the Shimadzu TGA-60 H Model device for TGA and DTA results at 25-900 °C.

Determination of antimicrobial effect

In the study, Antimicrobial activity *Escherichia coli* ATCC 25922, *Staphylococcus aureus* ATCC 25923, *Streptococcus pyogenes* ATCC 19615 *Pseudomonas aeruginosa* ATCC 27853, standard bacterial strains and *Candida albicans* ATCC 10231 strains were determined by using microdilusion method on the Minimum Inhibiting Concentration (MIC) In the study, microplate wells were left to incubate at 37 °C with the appropriate amounts of Mueller Hinton broth, Mc Farland 0.5 concentration adjusted microorganism solutions and PE-AgNP solution. The lowest concentration in the absence of reproduction after incubation was determined as the MIC value (Wang et al., 2017; Elshikh et al., 2016). Commercial antibiotics were used as control for Gram (+) (vancomycin), Gram (-) (colistin) bacteria and fungus (fluconazole). In addition, the effect of $AgNO^3$ solution was investigated. The study was performed with 3 repetitions and the mean values were determined as MIC value.

Results and discussion

AgNPs have free electrons that lead to surface plasmon resonance (SPR) absorption band due to the combined vibrations of the electrons of the metal nanoparticles with the light wave in the resonance (Nath et al., 2007). When the Mushroom extract was added

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92059214

to an aqueous silver nitrate solvent, the surface of the metal nanoparticles resulted in a colour change from yellow to dark orange (*Fig. 1*) in 5 days due to stimulation of plasmon vibrations. In the analysis of UV-vis spectroscopy, the formation of silver nanoparticles was observed with samples taken at one hour intervals. As shown in *Figure 1,* the absorption spectrum values of the samples taken without mixing for one hour at room temperature were measured and gave significant plasmon resonance at a maximum of 461 nm. Ramy and Hashem (2014) in their study using Pleurotus ostreatus extract obtained a maximum value of 450 Nm, while Ahmad et al. (2003) reported that the solution prepared using mushroom extract gave a maximum plasmon resonance of 436 Nm. Our results are consistent with previous studies (Huang et al., 2007; Verma et al., 2010).

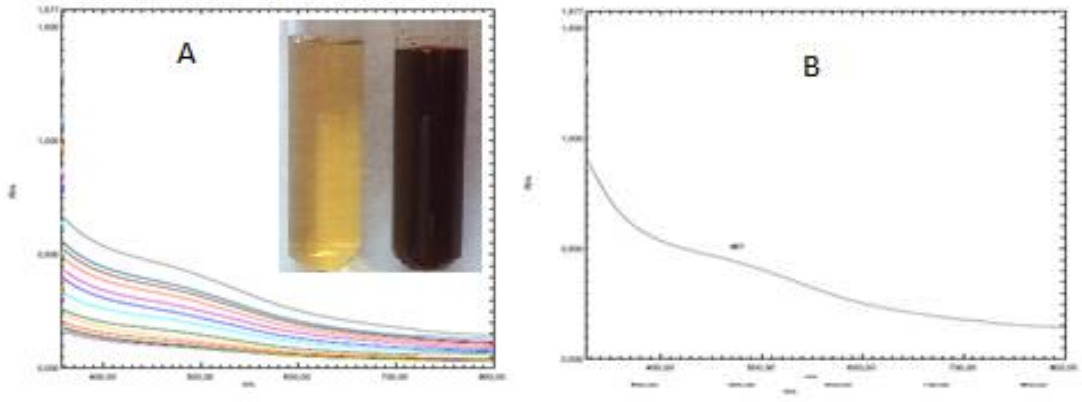

Figure 1. *A) Time dependent of PEAgNPs in UV visible spectroscopy. B) Synthesis of PEAgNP at UV spectrophotometry maximum absorbance value*

The XRD technique is a non-destructive technique and is used to describe the crystalline phase of nanoparticles. The X-ray diffraction pattern obtained for the PE-AgNP sample is shown in *Figure 2*. The PE-AgNP structure synthesized in the resulting diffraction pattern was obtained from the 111, 200, 220 and 311 characteristic pics ($2\theta = 32.41°$, 46.33°, 64.90° and 77.75° values). The crystal particle size of the obtained globally structured PE-AgNPs used Debye-Scherrer's inequality; the size of the synthesized nanoparticles was calculated to be 18.45 nm.

From Debye-Scherrer's equation (Baran, 2019):

$$D = K\lambda / (\beta \cos\theta) \qquad \text{(Eq.1)}$$

Inequality (*Eq. 1*): D = Particle size (nm), K = Fixed (0.90), λ = Wavelength X-ray (1.5406 °A), β = half of the highest peak value is specified in radians (FWHM), θ = fracture angle.

Owait and Ibraheem (2017) reported that mushroom metal-NP's are generally spherical and their size varies between 0.4 nm and $\geq$ 300 nm, but most are less than 75 nm. Considering the particle size, especially for biological applications, it is stated that the particle sizes between 30 and 150 nm are measurable, and a key used in the study of biological properties (Thorek and Tsourkas, 2008). The fact that the crystal grain size of the obtained global structure *PE*-AgNP is 18.45 nm suggests a new assessment.

DOI: http://dx.doi.org/10.15666/aeer/1704_92059214

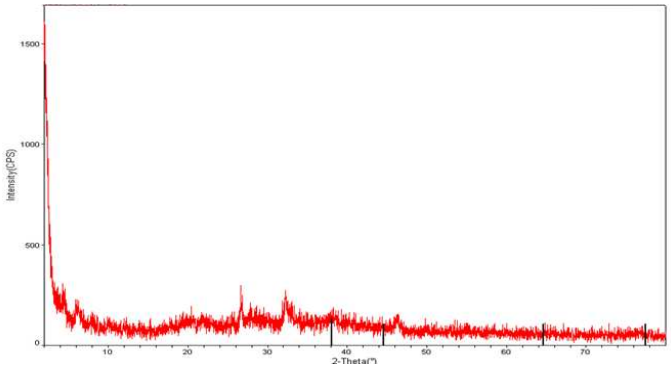

Figure 2. *XRD measurements of AgNPs confirming the spherical crystalline structure of PE-AgNPs*

FT-IR identifies functional groups connected to the surface of metal nanoparticles, since identical absorption patterns are different from those corresponding to free groups, and gives information about the surface chemistry of nanoparticles.

As shown in *Figure 3,* the results of P. eryngy extract and PE-AgNPs were compared as a result of the FT-IR. It is thought that; the peak at 3529 cm^{-1} stems from NH; the peak at 3270 cm^{-1} stems from OH conjugated to free water, alcohol, and phenol groups; the shift at 1672-1635 cm^{-1} stems from carbonyl or primary amide band; and the reason for the peak at 2114 cm^{-1} is C≡C alkyne or C-N group. These functional groups play a role in the reduction (*Fig. 3*). Mandal et al. (2005) stated that proteins in P. ostreatus fungi could bind to nanoparticles by free amine or cysteine groups in proteins and thus stabilize AgNPs.

Scanning Electron Microscope (SEM) is a tool that scans the surface of the sample and records the return of the beam. Since metal nanoparticles are electrically conductive, they are easy to scan with SEM. SEM analyses of spherical PE-AgNP obtained in 18.45 NM size are shown in *Figure 4*. So far, the researchers have identified a wide range of shapes, such as spherical, diamond, rod-like, and cube, whose diameters are smaller than 1 to 100 nm, as shown in their characterization patterns (Banerjee and Rai, 2017).

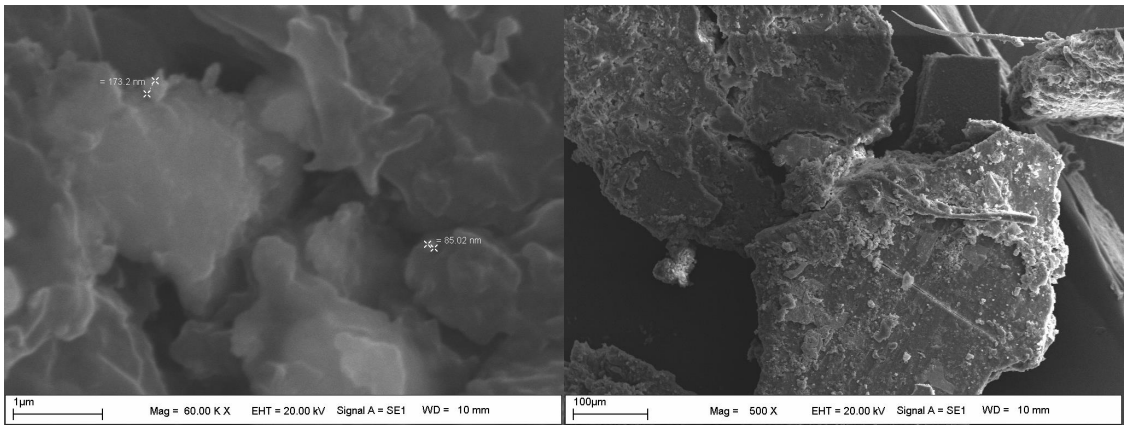

Figure 4. *Images of synthesised PE-AgNP of SEM analyses*

In addition, it was observed that the particles that were synthesized by EDX analysis were in elemental form (*Fig. 5*).

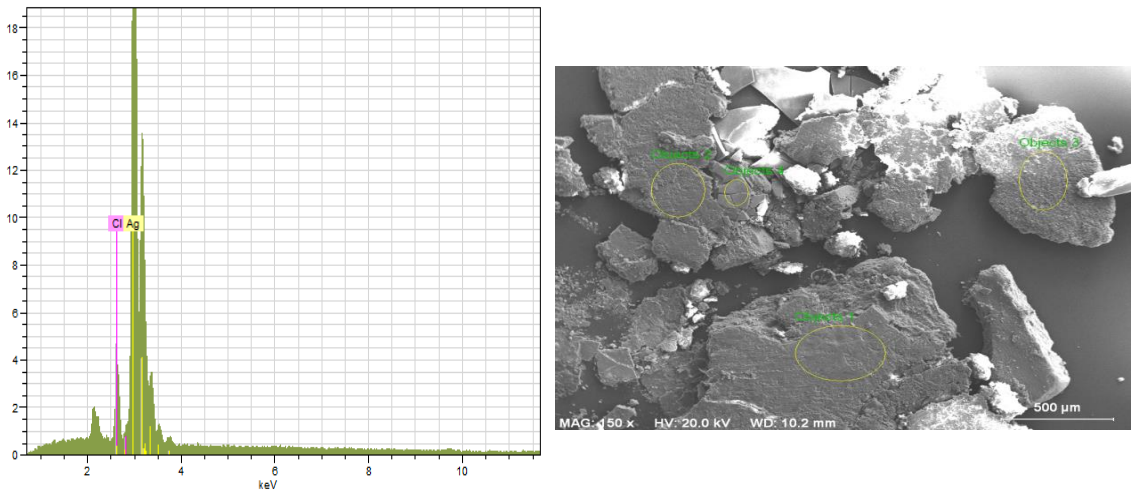

Figure 5. *EDX profile of PE-AgNPs showing its elemental composition*

Nanoparticles prepared with mushroom extract (PE-AgNPs) between 30-900 °C TGA and DTA data were analyzed at a flow rate of 20 mL min^{-1} in N2 (g) atmosphere with a heating rate of 10 °C min^{-1}. The TGA curve shows a loss of sample mass due to thermal degradation and the DTA curve indicates the maximum temperature of decomposition at each stage of the degradation (Baran, 2019, 2018). It is thought that

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92059214

the 3% mass loss of the synthesized nanoparticule at 11-102 °C is due to moisture, 2.5% loss of the 102-179 °C is due to H2O formation of OH groups side by side, 33.5% loss of the 179-390 °C is due to phenolicity or ring groups, and the 27% loss of the 390-881 °C is due to the degradation of the substance. In this study, PE-AgNPs synthesized up to 881 °C were also shown in *Figure 6*. Although TGA-DTA analysis of plant-derived AgNPs was performed in the literature, no relevant TGA-DTA data on mushroom-based AgNP were found.

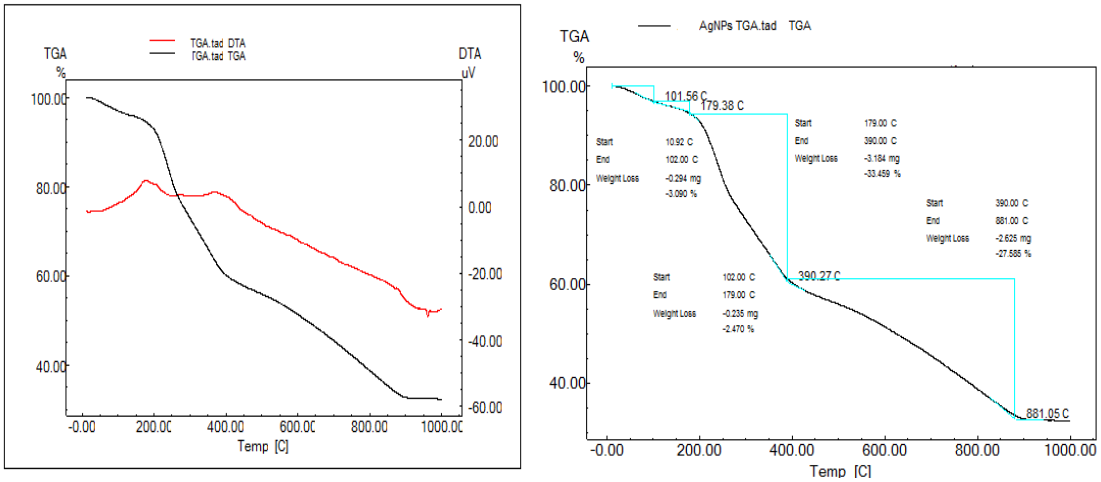

Figure 6. *TGA-DTA analysis result of synthesised PE-AgNPs*

It is widely known that resistance to antibiotics in microbes is a global problem that worsens at an alarming rate. It has become a major problem in many infectious diseases such as multiple antibiotic resistant bacteria and tuberculosis. Some studies in the past have shown that biologically synthesized metal nanoparticles have more biological activity than physically and chemically synthesized nanoparticles (Antony et al. 2011; Manikprabhu et al., 2013). Gopinath et al. (2015) reported that AgNPs synthesized from Fusarium oxysporum and antibiotics showed antimicrobial activity both individually and in combination against these bacteria the results of the same study confirmed that all resistant bacteria that are normally resistant to antibiotics are sensitive to the presence of AgNPs. In another study, Haq et al. (2015) showed that AgNPs synthesized from five fungal species (*Agaricus bisporus, Helvella lacunosa, Ganoderma applanatum, Pleurotus florida and Fomes fomentarius*) showed antimicrobial activity against methicillin-resistant *S. aureus*. However, AgNPs synthesized from *Agaricus bisporus* have been reported to be more powerful than the other four AgNPs. The antimicrobial activity of PE-AgNPs used in the study against *E. coli, S. aureus, S. pyogenes and P. aeruginosa* with standard bacterial strains and *C. albicans* strain is shown in *Table 1*. MIC values of PE-AgNP and silver nitrate were examined and compared. The study was performed with 3 repetitions and the mean values were determined as MIC value.

The MIC values of *S. aureus, S. pyogenes, E. coli, P. aeruginosa* and *C. albicans,* respectively, 0.07, 0035, 0.018, 0035 and 0.07 mg L^{-1} results were obtained (*Table 1*). Compared with Silver nitrates and antibiotics, AgNP can be used as an alternative to existing antibiotics as a result.

C. albicans ATCC 10231	0.07	0.66	

Conclusions

It is clear that *P. eryngii,* a renewable fungus, can be effectively used to synthesize bioactive nanoparticles using cheap substances in an environmentally friendly and non-toxic environment. The synthesis of PE-AgNPs was carried out at room temperature for 5 days by adding the fungus extract to an aqueous silver nitrate solvent. It was observed that PE-AgNPs with a crystal size of 18.45 nm and a spherical appearance showed a strong antimicrobial activity against human pathogen microorganisms. In this study, we believe that synthesized PE-AgNPs can contribute greatly to the search for antimicrobial agents. At the same time, these biosynthesized AgNPs can be used as effective growth inhibitors in various microorganisms; this makes them applicable to various medical devices, industrial, food, agricultural, biotechnological and environmental applications.

Abstract. Ammonia (NH_3) volatilization is one of the main reasons of applied-N loss from agricultural cropping systems. Adjusting the application timing of N fertilizer to improve temporal synchronicity between crop-N demand and soil-N availability could result in higher nitrogen (N) recovery efficiency (NRE) and lower N losses. A two-year experiment was conducted to investigate the effect of split fertilizer N application on NH_3 volatilization, grain yield, and NRE. Four treatments were included according to the N application ratio: (i) a single application of total N fertilizer at sowing (N1), (ii) N applied with two splits at a ratio of 4:6 (N2), (iii) N applied with three splits at a ratio of 4:3:3 (N3), and (iv) no N applied as a control (N0). The results show that NH_3 fluxes peaked at 3-5 days after fertilization and then dropped sharply within the next week. NH_3 fluxes increased significantly with N application rate and were significantly and positively correlated with soil NH_4^+-N content. Slight precipitation (< 10 mm) promoted NH_3 volatilization, while heavy precipitation (> 10 mm) restrained it. Applying N with two or three splits significantly increased the grain yield, total N uptake, and NRE of maize and significantly reduced NH_3 volatilization losses.
Keywords: *Dräger-tube method, N application time, N application rate, N loss, grain yield*

Introduction

Ammonia (NH_3) volatilization is a major pathway of nitrogen (N) losses in agricultural systems worldwide, which results in low fertilizer N recovery efficiency (NRE) and many other environmental issues, such as soil acidification and surface water eutrophication through N deposition (Behera et al., 2013). In addition, NH_3 is considered a dominant air pollution source, accounting for 25-60% of the total PM2.5 mass (Sutton et al., 2013), and could become a secondary source of N_2O (Sutton et al., 2008). Agricultural activities reportedly contribute up to 90% of the total NH_3 emissions to the atmosphere (Boyer et al., 2002), with the majority originating from livestock production and approximately 12% resulting from N fertilizer application (Ferm, 1998). An average of 18% of applied synthetic fertilizer N is estimated to be lost as NH_3 globally (Pan et al., 2016). China is the world's largest NH_3 emitter with annual emissions that are 2.7 and 3.0 times higher than those of the European Union and the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92159227

United States, respectively (Paulot et al., 2014). The total NH_3 emission of China was estimated to be 3.55 Tg N in 2005, with an estimated 13.2% of N from fertilizer NH_3 volatilizing (Zhang et al., 2011). The factors influencing NH_3 volatilization include environmental parameters, such as soil pH, moisture, and temperature as well as precipitation (Ma et al., 2010; Yang et al., 2015; Pan et al., 2016) and N fertilizer management practices, such as the use of different types of N fertilizer, N rate and application methods (Liu et al., 2015; Yang et al., 2019).

Urea is one of the most widely used N fertilizers worldwide because of its high N concentration, and its hydrolysis is known as a key process in inducing NH_3 volatilization by producing highly concentrated NH_4^+-N with sharply increased pH (Black et al., 1987). NH_3 volatilization from urea accounts for approximately 10-35% of the N applied in field crop planting (Soares et al., 2012). Due to the different demand of plants for N at different growth stages, surplus nitrogen is a great environmental risk in that it can leach into groundwater or be lost to the atmosphere through NH_3 volatilization and denitrification. Thus, adjusting the application timing of N fertilizer and improving temporal synchronicity between crop-N demand and soil-N availability are key strategies for improving the NRE (Ribaudo et al., 2011). Field experimental data have shown that grain yields, plant N uptake, and NRE increase with increases in topdressed N fertilizer (López-Bellido et al., 2005; Cui et al., 2008). Scharf et al. (2002) found that crop yields were still responsive to N application until the silking (R1) stage but that the potential yields were not achieved when N applications were delayed until that stage. Applying N with three splits could produce higher grain yields and higher cumulative N_2O emissions than a single application of N (Wang et al., 2016). Previous studies have shown that high rates of N lead to much higher NH_3 losses, and the emissions response to increasing N input is exponential rather than linear (Ma et al., 2010). Therefore, we hypothesize that maintaining a low rate of N application by using a split application should reduce NH_3 volatilization losses.

Plastic mulching is used worldwide in vegetable and grain production, especially in arid, semiarid and subhumid areas (Chen et al., 2014), due to its ability to increase soil temperature and moisture, reduce water evaporation, and improve soil nutrient availability (Li et al., 2004). In addition, as a physical barrier, plastic mulching restricts gas exchange between the soil and atmosphere, thus affecting NH_3 volatilization. However, there is little information concerning NH_3 volatilization losses from maize under plastic mulching. The objective of this study was to quantify the effect of N split application on NH_3 volatilization, crop yields, and NRE in a plastic mulching maize cropping system on the Loess Plateau of China.

Materials and methods

Site description

The field experiment was conducted at Changwu Agricultural and Ecological Experimental Station of Chinese Academy of Sciences (35.28°N, 107.88°E, 1200 m altitude) in 2014 and 2015, which has a semiarid climate on the Loess Plateau of China. From 2009 to 2013, the mean annual air temperature is 9.7 °C, and the average annual precipitation is 555 mm, 73% of this falls during the maize growth season (MS), whereas the average potential evaporation is 1560 mm. Total precipitation during MS was 375 mm in 2014, and 361 mm in 2015, respectively. The main cropping system in this area includes harvesting one crop of maize or wheat per year. The soil at the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92159227

experiment site is classified as Cumuli-Ustic Isohumosols according to the Chinese Soil Taxonomy (Gong et al., 2007). The soil properties at the top 20 cm were: bulk density 1.3 g cm^{-3}, pH 8.3, organic C 8.1 g kg^{-1}, total N 1.0 g kg^{-1}, available phosphorus (Olsen-P) 21.5 mg kg^{-1}, and available potassium (NH_4OAc-K) 135.2 mg kg^{-1}, and mineral N (NO_3^--N + NH_4^+-N) 28.3 mg kg^{-1}.

Experimental design

The experimental design consisted of a completely randomized block with three replicates and an area of 5 m × 6 m for each plot. The split application of N at the same rate of 225 kg ha^{-1} was the major factor that was investigated. The four treatments were (i) no N as a control (N0), (ii) 100% N applied at sowing (N1), (iii) N applied at the sowing and jointing (V8) stages in a ratio of 4:6 (N2), and (iv) N applied at the sowing, V8 and R1 stages in a ratio of 4:3:3 (N3). Half-film mulching was performed for all of the plots; the width of the plastic film and the interval of two films were both 0.5 m, and maize was seeded on both sides of the film, with a row spacing of 0.5 m. For basal N, N fertilizer in the form of urea (N 46%) was manually distributed over the soil surface prior to sowing and then mixed with the soil of the 0-15 cm layer; for topdressed N, N fertilizer was applied in a band in the middle of the no-film rows at a depth of 5 cm. Each plot was supplied with 40 kg P ha^{-1} (calcium superphosphate, P_2O_5, 12%) and 80 kg K ha^{-1} (potassium sulfate, K_2O, 45%) at sowing with the base N fertilizer. A high-yielding maize hybrid (Pioneer 335) was used in this study; the plant density was 65,000 plants ha^{-1}.

NH_3 volatilization measurements

The calibrated Dräger-Tube method (DTM) was used to quantify NH_3 volatilization (Pacholski et al., 2006) as this method has been shown to be well suited for NH_3 measurements in multiplot field trials (Ni et al., 2014; Wolf et al., 2014). During the measurement, four stainless steel rings were installed in the upper soil of one plot for each treatment directly after fertilization, 2 on the edge of the mulch, and 2 on the bare land, then they were connected to an NH_3 indicator tube and an automatic pump to ensure a defined flow rate. Air was simultaneously sucked through four connected chambers and led through a NH_3 tube (*Fig. 1*). Damaged tubes were exchanged by new tubing. Using Drägertubes for different NH_3 concentration ranges allowed measurements of NH_3 concentrations ranging from 0.1 to 70 ppm. In conjunction with all NH_3 measurements, wind speeds at heights of 2.0 m and 0.2 m were recorded every 10 min for the duration of every measuring period (approximately 10-14 days after N fertilizer application until NH_3 volatilization losses were no longer detected), which were used for calculating the calibrated NH_3 fluxes.

Soil property measurements

Soil samples at a 20 cm depth were taken from each plot for the moisture and NH_4^+-N determinations, while NH_3 volatilization was measured using a 4-cm-diameter gauge auger. Each sample was a composite of two subsamples, of which one was taken from the no-mulch bands and the other was taken from film mulched bands, to represent the aggregate condition. The samples were oven-dried at 105 °C for 24 h to a consistent weight to determine the gravimetric soil water content, and the soil water-filled pore space (WFPS) was subsequently calculated using *Equation 1*. To determine the soil

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92159227

NH_4^+-N content, representative fresh subsamples (5 g) were extracted using 50 ml of a 1 mol L^{-1} KCl solution, and the extracts were analyzed using an automated flow injection analyzer (FLOWSYS, Italy). The soil temperatures at the surface and at a depth of 10 cm were measured using portable digital thermometers (JM624, Jinming Instrument Ltd., Tianjin, China). Precipitation data were obtained from an automatic weather station near the experimental site.

$$WFPS = \frac{\text{Soil water content}(\%) \times \text{Soil bulk density}}{1 - \frac{\text{Soil bulk density}}{2.65}} \times 100\% \quad \text{(Eq.1)}$$

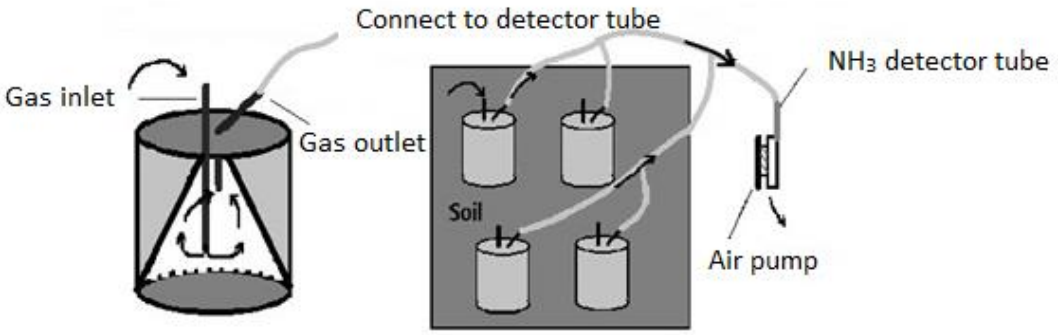

Figure 1. *Schematic diagram of NH_3 volatilization measurements*

Grain yield and N recovery efficiency

At harvest, 8 m^2 (4 rows each 4 m long) in the middle of each plot was manually harvested to determine the grain yield, and the grain yield was expressed at 15.5% moisture.

N recovery efficiency (NRE) was calculated by difference method using *Equation 2*.

$$NRE\ (\%) = \frac{\text{N uptake in fertilized plot}\ (\text{kg hm}^{-2}) - \text{N uptake in unfertilized plot}\ (\text{kg hm}^{-2})}{\text{N application rates}\ (\text{kg hm}^{-2})} \quad \text{(Eq.2)}$$

Statistical analysis

Statistical analysis was conducted using the SPSS 20.0 software package for one-way analysis of variance (ANOVA); the statistically significant differences between different treatments were tested by the least significant difference (LSD) at the 5% level. The Pearson correlation analysis was performed to investigate the correlations between the NH_3 volatilization flux and soil variables.

Results

Soil WFPS, temperature and NH_4^+-N content

The soil WFPS and temperature during NH_3 volatilization measurements over two years are shown in *Figure 2*. The mean soil temperature during the application of basal N, topdressed N at the V8 stage (T_{V8}-N) and topdressed N at the R1 stage (T_{R1}-N) were 15.5 °C, 21.3 °C and 21.7 °C, respectively, in 2014 and were 15.6 °C, 18.3 °C and 18.4 °C, respectively, in 2015. Soil WFPS fluctuated with precipitation events, varying

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92159227

from 20.6 to 59.4% in 2014 and from 36.7 to 64.4% in 2015, and there was no difference among the four treatments.

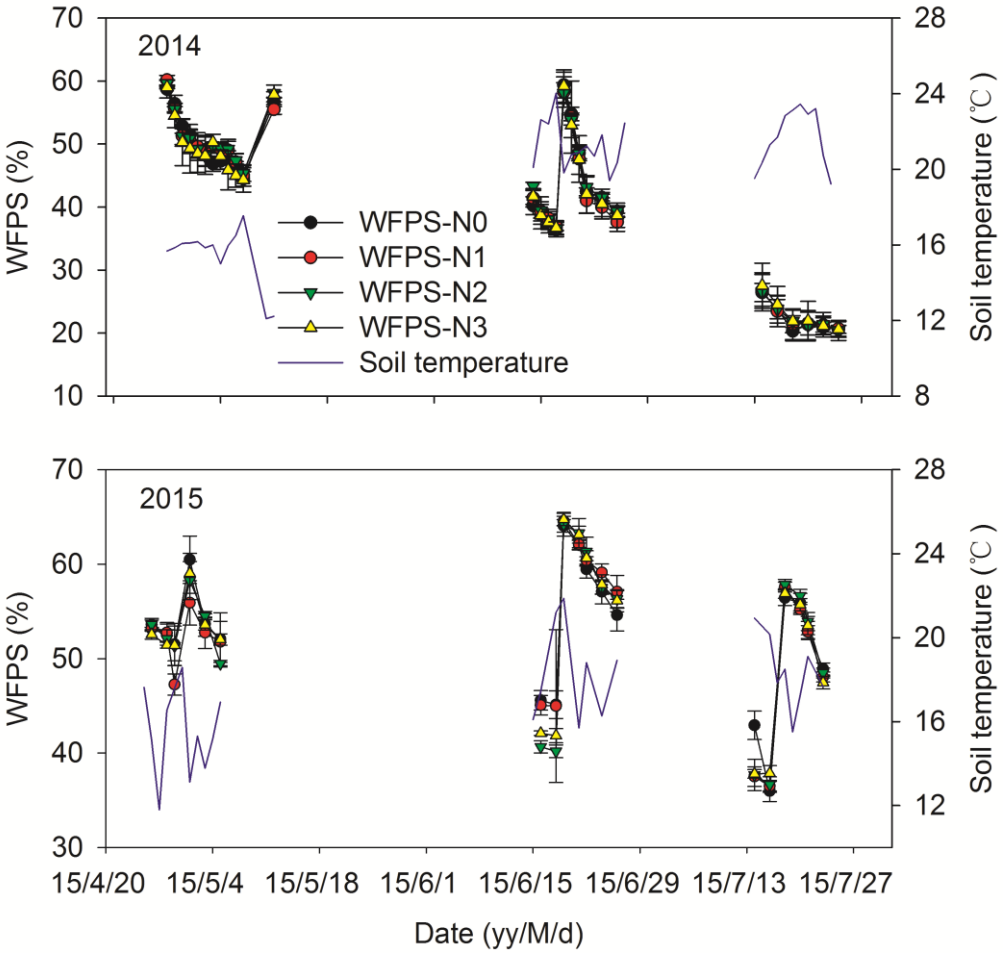

Figure 2. *Soil moisture and temperature dynamics during NH_3 volatilization measurements in 2014 and 2015*

The soil NH_4^+-N content increased sharply after the application of N fertilizer and then returned to normal within approximately one week (*Fig. 3*). The mean soil NH_4^+-N content during the basal N application in the N1 treatment was 66.1 mg kg^{-1}, which was significantly higher than that in the N2 (20.7 mg kg^{-1}) and N3 (17.9 mg kg^{-1}) treatments in 2014. Relatively low soil NH_4^+-N content was measured during basal N application in 2015, with mean values of 21.6, 5.1 and 4.2 mg kg^{-1} in the N1, N2 and N3 treatments, respectively. After the T_{V8}-N application, the mean soil NH_4^+-N content was 55.9 mg kg^{-1} and 26.1 mg kg^{-1} in treatments N2 and N3, respectively, in 2014 and 163.1 mg kg^{-1} and 77.7 mg kg^{-1}, respectively, in 2015, respectively. After the T_{R1}-N application in the N3 treatment, the mean soil NH_4^+-N content reached 33.2 mg kg^{-1} and 59.1 mg kg^{-1} in 2014 and 2015, respectively. Overall, the mean soil NH_4^+-N contents across the whole growth period were 4.2, 28.5, 30.3 and 24.6 mg kg^{-1} in the N0, N1, N2 and N3 treatments, respectively, in 2014 and were 1.5, 7.4, 59.1 and 49.1 mg kg^{-1}, respectively, in 2015.

NH_3 volatilization flux

The dynamics of NH_3 volatilization fluxes with different N split applications are shown in *Figure 4*. Since NH_3 volatilization mainly occurred after fertilization, it was only determined within two weeks after fertilization in this study. Under different N application periods, the rate of NH_3 volatilization usually peaked at 3-5 days after fertilization and then dropped sharply within the next week. After the basal N application, the mean NH_3 volatilization rate in the two years was 71 g ha^{-1} h^{-1} in the N1 treatment, which was significantly higher than the 5, 24, 27 g ha^{-1} h^{-1} in the N0, N2 and N3 treatments, respectively, due to its higher N application rate. The highest volatilization rates from N1 were 193 and 234 g ha^{-1} h^{-1} after the basal N applications in 2014 and 2015, respectively, while only 100-130 g ha^{-1} h^{-1} were observed in the N2 and N3 treatments. After the T_{V8}-N application, the mean rates of NH_3 volatilization from the N2 treatment were 18.8 and 26.5 g ha^{-1} h^{-1} in 2014 and 2015, respectively, which were significantly higher than those from the N3 treatment (10.4 g ha^{-1} h^{-1} in 2014 and 11.8 g ha^{-1} h^{-1} in 2015). A small emissions peak emerged in the N3 treatment when T_{R1}-N was applied, with the highest volatilization rates of 37.5 g ha^{-1} h^{-1} in 2014 and 77.5 g ha^{-1} h^{-1} in 2015.

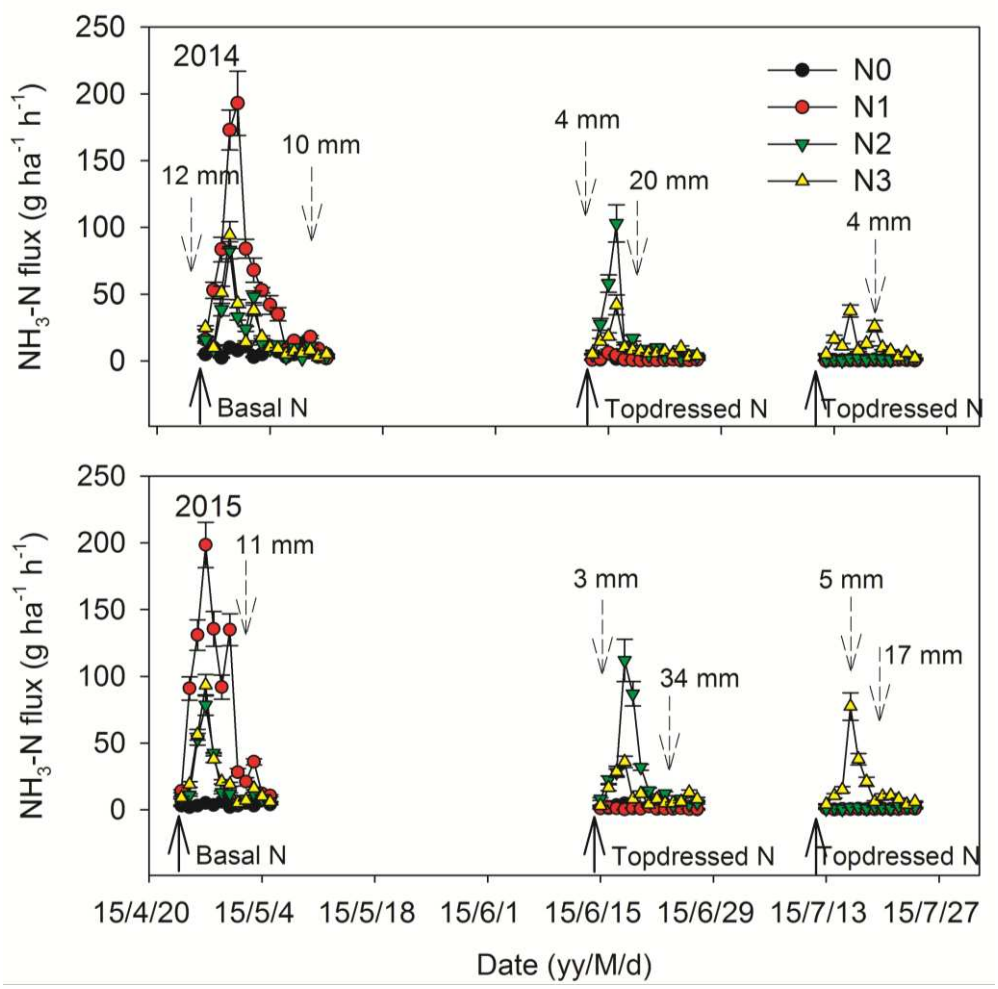

Figure 4. *NH_3 volatilization fluxes after the application of basal and topdressed N in 2014 and 2015. Bars denote standard deviations of NH_3 fluxes on three replicate plots*

The total NH_3 volatilization and fertilizer-induced emission (FIE) are shown in *Table 1*. The total NH_3 volatilizations under different N split applications were 13.5-20.4 kg ha^{-1} and 14.2-21.5 kg ha^{-1} in 2014 and 2015, respectively, accounting for 6.0%-9.1% and 6.3%-9.6% of the total N application rates, respectively. The amount of NH_3 volatilization increased with increasing N levels applied after the basal or topdressed N applications. Compared to the single N application (N1), N applications with two or three splits significantly reduced the NH_3 volatilization losses by 30.5%. The FIE of NH_3 from basal N was 7.6% (averaged over two years), which was significantly higher than that from topdressed N (5.2%) in the N2 treatment. For the N3 treatment, a higher FIE of NH_3 was measured from basal N (8.4%) than from topdressed N (5.7%).

The NH_3 volatilization flux was significantly and positively correlated with the soil NH_4^+-N content, while no significant correlation was observed among the NH_3 volatilization flux, soil WFPS and temperature (*Table 2*).

Grain yield and N recovery efficiency

Compared with the N0 treatment, the N fertilizer application treatments significantly increased the grain yield of maize, varying from 12.4 to 13.3 t ha^{-1} under different N

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92159227

split applications over two years. The mean yields in the two years were 13.2 and 13.4 t ha^{-1} in the N2 and N3 treatments, respectively, which were significantly higher than that of in the treatment N1 of 12.4 t ha^{-1}. The total N uptake varied from 193.9 to 238.5 kg ha^{-1} in the fertilized treatments, and split N application significantly increased the total N uptake. The average NRE across two years was 47.3%, 58.8% and 67.1% in the N1, N2 and N3 treatments, respectively. In comparison to N1, applying N with two or three splits increased the NRE significantly.

Discussion

Urea applied to soil will be rapidly hydrolyzed into ammonium nitrogen at appropriate temperature and humidity and then easily converted into NH_3 volatilization loss (Li et al., 2018). The total cumulative NH_3 loss under different N split applications ranged from 6.2 to 9.4% of the applied N in this study (*Table 1*), which were slightly lower than the emissions factor of 10% of applied N advocated by the IPCC (2007). A lower FIE of less than 2.5% has also been reported by another study on the Loess Plateau in rain-fed winter wheat field (Yang et al., 2015). Cai et al. (2002) found that the NH_3 volatilization losses range from 11 to 48% of the applied N to maize. The lower NH_3 losses in the present study than in Cai et al. (2002) may be attributed to the application method of N fertilizer. In this study, basal N was broadcast on the surface and then was mixed into soil; for topdressed N, N fertilizer was applied in a band in the middle of the no-film rows at a depth of 5 cm. NH_3 volatilization losses of N fertilizer are closely related to the application technique and N rate (Sommer et al., 2003; Zhao et al., 2009). In comparison to surface application, deep placement of N fertilizer could

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92159227

reduce NH_3 losses substantially (Zeng et al., 2016). Rochette et al. (2013) reported that NH_3 volatilization losses were 50% of applied N when urea was banded at the surface and incorporation of the band decreased emissions by an average of 7% cm^{-1}. Pan et al. (2016) also found that in comparison to surface application, deep placement significantly decreased NH_3 volatilization through the incorporation of fertilizer at 54.7%.

A previous study reported that a split applications of N fertilizer did not affect NH_3 volatilization, regardless of splitting frequency (Pan et al., 2016). In our study, applying N with two or three splits significantly decreased NH_3 volatilization by 30.5% over two years, and the FIE from topdressed N was significantly lower than that from basal N (*Table 1*). One possible reason for this discrepancy is the different application method with basal and topdressed N, as described above. Basal N was broadcast on the surface and then mixed with the 0-15 cm soil; however, some of the N fertilizer was still exposed on the soil surface, increasing the risk of NH_3 losses compared to that with topdressed N. In addition, N losses through NH_3 volatilization increase with an increasing rate of N application in soils (Tian et al., 2001; Zhao et al., 2009), and previous studies have shown that the NH_3 emissions response to increasing N input is exponential rather than linear (Ma et al., 2010). In the present study, all N fertilizer was applied as basal dressing in treatment N1, which led to large amounts of NH_3 volatilization.

NH_3 volatilization is a physical process that is mainly influenced by the concentration of NH_4^+-N in the soil solution and by the resistance to NH_3 movement from the soil matrix (Sommer et al., 2004). Rochette et al. (2013) found cumulative losses increased exponentially with increasing maximum NH_4^+-N measured in the surface soil during the experiment. Consistent with previous reports, significant and positive correlations were observed between NH_3 volatilization flux and soil NH_4^+-N contents in this study (*Table 2*). Soil temperature and moisture are two other important factors affecting NH_3 volatilization. Fan et al. (2011) reported that the cumulative NH_3 volatilization loss increased by 1.6 fold in sandy soil when the temperature increased from 20 to 30 °C. A study in the wheat growing season showed that soil temperature has positive effects on NH_3 fluxes during Oct-Dec but has negative effects during Feb.-May (Yang et al., 2015). However, no significant correlations were observed between NH_3 flux and soil temperature in the present study. This difference could be explained by the influence of precipitation events on the soil temperature and NH_3 volatilization flux. In some cases, high NH_3 emissions occurred following precipitation events when the soil temperature was relatively low. Soil moisture had significant positive effects on NH_3 fluxes, which could explain 7.3-19.7% of the variation in the NH_3 fluxes (Yang et al., 2015). Bosch-Serra et al. (2014) found that NH_3 volatilization was significantly reduced when the WFPS in the 0-30 cm soil layer was less than 56%. In this study, no significant correlations were observed between the NH_3 flux and soil WFPS. This result may be attributed to the different effects of precipitation amount on NH_3 fluxes. Previous studies have reported that the magnitude of NH_3 losses was largely influenced by small temporal differences in the weather and initial soil moisture content (Engel et al., 2011; Turner et al., 2012). The largest losses (30-44% of applied N) occurred after urea was applied to high-water content soil surfaces, followed by a period of slow drying with little or no precipitation (Engel et al., 2011). Light precipitation and high soil moisture would increase NH_3 volatilization risk by promoting urea hydrolysis, while heavy precipitation may effectively mitigate NH_3 losses by leaching

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92159227

unhydrolyzed urea into the soil profile (Holcomb et al., 2011). In this study, the NH_3 flux increased sharply following slight precipitation events of 3 mm and 5 mm after topdressed N was applied at the V8 and R1 stages, respectively, in 2015. We also observed that the NH_3 flux was restrained rapidly by heavy precipitation of 20 mm after the application of topdressed N at the V8 stage in 2014 (*Fig. 4*).

Adjusting the application timing of N fertilizer and improving temporal synchronicity between crop-N demand and soil-N availability is a key strategy for improving the NRE (Ribaudo et al., 2011). In the present study, higher grain yields, total N uptake, and NRE were observed from the plots under N split applications than in the other plots (*Table 3*). Similar to our results, Shi et al. (2012) also found that the grain yield and NRE increased significantly when N fertilizer application was divided into an appropriate ratio of basal and topdressed N. Yi et al. (2008) reported that the NRE increased by more than 2 fold when N was applied with splits of 1:1 compared with a split of 2:1 of basal to topdressed N. This result may be attributed to the lower N demand in the early growth stage of maize and the increased risk of leaching from a large amount of N fertilizer input. Kettering et al. (2013) indicated that applying fertilizer N with 3-4 splits according to a plant's N needs could reduce N leaching and increase the NRE.

Table 3. *Grain yield, total N uptake and N recovery efficiency*

Treatments	Grain Yield (t ha^{-1})		Total N uptake (kg ha^{-1})		NRE (%)	
	2014	2015	2014	2015	2014	2015

Different lowercase letters within a column indicate significant differences ($p < 0.05$)

Conclusions

NH_3 flux was positively correlated with soil NH_4^+-N content and was greatly affected by precipitation events. Applying N with two or three splits significantly increased the grain yield, total N uptake, and NRE of maize and significantly reduced NH_3 volatilization losses. The coupling effect of N fertilizer application and precipitation on NH_3 volatilization should be further investigated in the future.

Abstract. Disease recognition based on crop leaf image is considerably important and significant, which is a challenging project due to the complicated nature of disease leaf image itself and the unavoidable degradations sourced from external imaging environment. In the recognition process, these traditional approaches generally stack one or more different modalities of features extracted from disease leaf images to be discriminated or trained, but do not deeply explore the relationships between features. For conquering this problem, we proposed a new crop disease recognition approach based on multi-feature sparse constrain model, which includes three steps: lesion segmentation, feature extraction and disease recognition. During the phase of disease recognition, the characteristic of our proposed is that the introduced multi-task joint sparse representation model can promote these sparse representation vectors corresponding to the different modalities of features to share similar structures to some extent with the specific styles of features extracted from the same training set. The proposed approach not only improve the efficiency significantly but also make the decision more robust. We verify the proposed approach with images of diseased cucumber, and the experiments demonstrate that our proposed method is remarkable superior to the state of the art algorithms and the correct recognition rate of our approach is 88.05%, which is higher 11.3% percentage than the benchmark of SVM method.
Keywords: *crop disease identification, multi-task learning, joint sparse representation, accelerated proximal gradient, lesion segmentation, feature extraction*

Introduction

Crop diseases have long been considered as one of the primary threats to reduce crop yield and quality. According to recent reports, the global plant yield has reduced by at least 10% each year due to the crop diseases (Mutka and Bart, 2015). It can be seen that whether crop diseases can be discovered in time is significantly important for increasing the production and quality of agricultural products. However, the identification of crop diseases to date has remained on the basis of artificial judgment, which is inefficient and subjective. In China, due to the lack of professional agricultural technicians, farmers usually are forced to judge the type and evaluate its degree of diseases according to their past experience. The wrong diagnosis and the resulting pesticide abuse are extremely common as expected. Therefore, it is urgently to find a timely, accurate and low-cost approach to alleviate the present condition

Due to the huge driving force of the potential market and the rapid development of computer vision and machine learning technology, in recent years, crop disease identification has received widespread attention by researchers, and a large number of related algorithms have been proposed. Generally speaking, the common disease

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92299245

identification algorithms mainly include 4 steps (Iqbal et al., 2018; Golhani et al., 2018; Dhingra et al., 2019; Zhang et al., 2017b, 2018; Zhang and Wang, 2016), followed by disease image pre-processing, disease lesion segmentation, disease feature extraction, and disease species identification. In the pre-processing step, image enhancement operations, such as median filtering (Unay et al., 2011; Sun et al., 2018), histogram equalization (Khirade and Patil, 2015), etc., are usually adopted to avoid interference of notorious noise and uneven illumination in the sample image. Lesion segmentation refers to the localization process to find the lesion areas with pixel level in the leaf images. The commonly used algorithms include K-means algorithm (Zhang et al., 2018, 2017a; Ghosh and Dubey, 2013; Prajapati et al., 2016), OTSU algorithm (Zhang and Wang, 2016; Dey et al., 2016), and super pixel clustering (Zhang and Zhu, 2017). When the lesion area is separated, it is necessary to extract some modality features such as color, shape, texture or other attributes of the lesion. Whether the extracted features are appropriate or not directly determines the effectiveness of the disease identification algorithm. Common feature extraction methods include: Principle Component Analysis (PCA) (Zhang and Wu, 2017), wavelet analysis (Kleynen et al., 2005; Shaik et al., 2018), PSO (Muthukannan and Latha, 2015), gray level co-occurrence matrix (Iqbal et al., 2018) and so on. In general, the identification of a particular disease can use only one modality feature, however when distinguishing many kinds of diseases, mining the complementary information between the different modality features will obtain higher accuracy rate than just one. Disease identification is the final step of the approach which refers to taking advantage of the pattern recognition technology to classify the extracted features to achieve the purpose of identification. Commonly used disease classification algorithms include artificial neural networks (Bashish et al., 2011), support vector machine (Rumpf et al., 2010; Arivazhagan et al., 2013), K-nearest neighbor algorithms (Zhang et al., 2015), and sparse representation (Zhang and Wu, 2017), so on. Meanwhile, we also found that with the rise of deep learning, this technology has also been applied in the field of crop diseases identification.

In theory, deep learning not only avoids lesion segmentation and feature extraction steps, thus brings great convenience into the designing algorithm process, but also improves the correct recognition rate significantly (Ma et al., 2018; Grinblat et al., 2016; Zhang et al., 2019; Sladojevic et al., 2016; Lu et al., 2017). However, it is coexisting that deep learning technology is extremely demanding on the quantity and quality of samples. Accurate identification of any kind of disease requires massive standard sample images, complex parameter debugging and abnormal time-consuming model training. In the process of training the deep learning model, even an additional hardware device - Graphic Process Unit (GPU) is necessary. Obviously, subjecting to these factors such as geography, season and cost, the harsh conditions almost impossible to achieve.

In response to the above-mentioned problems, we are committed to developing a new crop disease identification approach, which can accurately and swiftly determine the type of disease according to the appearance of leaf diseases image. At the same time, this approach is not limited to the quantity and quality of training samples to save the cost of collecting samples. We summarize the main contributions of our algorithm proposed in this paper as follows:

1. Based on the sparse theory, we propose a new crop disease identification algorithm. The algorithm uses the multi-feature sparse constrain to describe the proposed prior, constructs the cost function, and successfully optimizes the cost function with the algorithm of accelerated proximal gradient. By comparing the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92299245

recognition efficiency of cucumber leaf disease, the recognition efficiency of the algorithm is obviously better than other state of the art algorithms.

2. Inspired by the idea of multi-task learning, we find a new prior, which points out that the different modalities of disease features can be represent with the corresponding features extracted from the training set. The structure of the sparse coefficient vectors should be similar. This proposed multi-feature sparse constrain model has a more realistic constraint effect, and the resulting sparse coefficient is more accurate, robust, and close to the actual situation.
3. Because there is no complicated training process and cumbersome parameter setting step in this paper, the principle of our algorithm is well comprehensible, thus its calculation process is simple and easy to operate. More unexpected is that the performance of our approach is still extraordinary excellent in the case of insufficient training samples. This characteristic can help us conquer the difficulty of the dependence on a large number of samples, which are susceptible to various factors for obtaining.

In the first section, we summarized the significance and status quo of automatic disease identification. Some related work to our algorithm will be introduced in the second part. The first will elaborate the proposed algorithm, including 4 steps: pre-processing, detection feature extraction and recognition. In the fourth part, we will give the comparison results of the proposed algorithm and other state of the art algorithms, and further analyze the performance of the algorithm. The last section is the conclusion and prospect of the paper, and it points out the unresolved problems in the fields of automatic disease identification and puts forward our working plan in the future.

Related work

At the beginning of this century, neuroscientists found in their research that for images entering in the human eye, the human visual system uses sparse representation to represent it with the help of as little as possible base feature (Rao et al., 2002). Inspired by this phenomenon, sparse representation has been widely used and deeply researched in machine learning and computer vision (Wright et al., 2009; Yang et al., 2010; Mei and Ling, 2011). The equation it needs to solve can be expressed as

$$\underset{w}{arg\,min}\frac{1}{2}\|y - D\omega\|_2^2 + \lambda\|\omega\|_0 \quad \text{(Eq.1)}$$

where y is a certain form of feature vector extracted from the input image, D is an over-complete dictionary composed of numerous base vectors, and the base vector in the dictionary is called “atom”. In general, a dictionary can be constructed by extracting features of a corresponding form from a collection of sample images. w is a sparse coefficient vector that needs to be solved and can sparsely represent the feature y. $\|w\|_0$ is L_0 norm represents the number of non-zero elements in the vector. However, *Equation 1* is non-convex, and the solution is very difficult to find. It is usually necessary to relax the constraint and replace the L_0 norm in *Equation 1* with the L_1 norm, thus to solve it with Lasso algorithm (Wright et al., 2009; Yang et al., 2010; Mei and Ling, 2011).

Image classification based on sparse representations shows great potential for crop disease identification (Zhang and Wu, 2017). It does not require a large number of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92299245

training samples, and can accurately identify the types of diseases for most "regular" diseased leaves. However, in the process of optimizing the cost function, the Lasso algorithm usually selects atoms in the disease "dictionary" by an approximately random way to fit the disease features to be tested. The robustness of the recognition algorithm makes the judgment unstable. At the same time, in the optimal computing process, it is possible to wrongly make some discriminative 'atom' participate in the computing thus lead to the recognition accuracy rate reducing. In addition, in the case of recognition disease by multi-modality of features, the image classification technique based on sparse representation just stacks features such as color, shape, texture or spatial distribution of the same sample indiscriminately into one vector in the process of feature extraction, without considering the correlation between different kinds of features. This is essentially equivalent to constrain the sparse coefficients of these different forms of features to be identical. Obviously, if the judgments with these different forms of features are separately, some ambiguous conclusions may be drawn; and these identical sparse vectors corresponding to that different modality features are separately contrary to the real situation, which will introduce new errors and affect the judgment.

In fact, if considering the disease recognition with some modality feature as a task, a large number of researches have shown that (Zhang et al., 2018, 2017a; Zhang and Wang, 2016; Unay et al., 2011; Sun et al., 2018; Khirade and Patil, 2015) when there are some commonalities among these being learned tasks, improving the recognition efficiency by mining the relative information is feasible (Ozawa et al., 2009; Argyriou et al., 2008; Bickel et al., 2008; Caruana, 1997), which is called multi-task learning or transfer learning (Caruana, 1997). In the field of machine learning and computer vision, when the related tasks are affected by some common factors, the ability of multi task learning or transfer learning to improve the generalization ability is significant by mining relationship among tasks especially in the case of insufficient training samples. The basic idea of this paper is that when we use sparse representation to describe a testing feature with K modalities, and the dictionary is constructed by the corresponding K modalities of features extracted from the same training set, thus for each modality, we can consider it as a task. The fact is that when the reconstruction error is smallest, the smallest number of 'atoms' from one class can linearly represent the multi-feature, which can be considered as the final classifying result.

Materials and methods

Lesion segmentation and feature extraction

Assuming that there are J kinds of disease images in data set X, and n_j samples in disease j, the total number of samples in disease set is $\sum_{j=1}^{J} n_j = N$. For each disease image, we extract K different kinds of features such as color, shape, texture, etc. The training set can be expressed as

$$X = \begin{bmatrix} X_1^1 & X_2^1 & \cdots & X_J^1 \\ X_1^2 & X_2^2 & \cdots & X_J^2 \\ \vdots & \vdots & \cdots & \vdots \\ X_1^K & X_2^K & \cdots & X_J^K \end{bmatrix}_{M \times N} \quad \text{(Eq.2)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92299245

where $X_j^k \in R^{m_k \times n_j}$ represents the *k-th* class feature of the *j-th* type of disease image, and each column in X_j^k is a feature vector with dimension m_k. $X^k = [X_1^k, X_2^k \cdots, X_j^k]$ is a matrix of $m_k \times N$ representing the *k-th* class feature of the disease set. $X_j = \left[(X_j^1)^T, (X_j^2)^T, \cdots, (X_j^K)^T, \right]^T$ is a matrix of $M \times n_j$ representing the disease features of n_j samples in the *j-th* disease, and the dimension of each disease feature vector is $\sum_{k=1}^{K} m_k = M$. For a diseased leaf image to be tested, we extract its *K*-modalities features $y^k \in R^{m_k}$, (*k = 1, 2, ..., K*), and the feature vector of the diseased leaf image to be tested can be expressed as $Y = [(y^1)^T, (y^2)^T, \cdots, (y^K)^T]^T, Y \in R^M$. For the feature vector Y, we hope that each y^k can be sparsely represented by the corresponding feature X^k in the training set, and the obtained *K* sets of coefficients should have similar spare structure. The mathematical representation of this idea can be described in *Equation 3*.

$$arg\ \min_w \frac{1}{2}\sum_{k=1}^{K}\left\|y^k \sum_{j=1}^{J} X_j^k W_j^k\right\|_2^2 + \lambda \left\|\left(\|W_1\|_F, \|W_2\|_F, \cdots, \|W_J\|_F\right)\right\|_0 \quad \text{(Eq.3)}$$

where $W_j^k \in R^{n_j}$ represents the coefficient vector corresponding to the feature in the *k*-th form of the *j*-th disease image set, and the matrix $W_j = [W_j^1, W_j^2, \cdots, W_j^k], W_j \in R^{n_j \times k}$, vector $W^k = \left[(W_1^k)^T, (W_2^k)^T, \cdots, (W_j^k)^T\right]^T$, $W^k \in R^n$, $\|W\|_{1,2} = \sum_{i=1}^{n} \|R_i(W)\|_2$, and R_i are responsible for extracting the *i*-th row of the coefficient matrix *W*. The concrete expression of the coefficient matrix is

$$W = \begin{bmatrix} W_1^1 & W_1^2 & \cdots & W_1^K \\ W_2^1 & W_2^2 & \cdots & W_2^K \\ \vdots & \vdots & \cdots & \vdots \\ W_J^1 & W_J^2 & \cdots & W_J^K \end{bmatrix}_{n \times k} \quad \text{(Eq.4)}$$

where $\|W_j\|_F$ refers to the Frobenius norm of the matrix W_j, and $\|x\|_0$ refers to the L_0 norm of the vector x, that is the number of non-zero elements in the vector x. However, the L_0 norm in *Equation 3* makes the cost function non-convex, and to find the solution is very difficult. In order to solve the problem, we relax the cost function to *Equation 5*

$$arg\ \min_w \frac{1}{2}\sum_{k=1}^{K}\|y^k - X^k W^k\|_2^2 + \lambda \sum_{j=1}^{J}\|W_j\|_F \quad \text{(Eq.5)}$$

We call *Equation 5* a multi-feature sparse constrain model. Its solution is simple to solve. We use the accelerated proximal gradient method to solve the problem. For detailed solution steps, please refer to *Algorithm 2* in this paper.

Multi-feature sparse constrain

The accurate detection of the lesion area and extracting appropriate features play an important role in the disease identification process. The *K*-means clustering algorithm is one of the classic algorithms for image segmentation. It divides all the pixels of the input image into *K* classes according to the feature of each pixel. Since the content of the disease image is relatively fixed, it can generally be regarded as consisting of a healthy area, a diseased area, and a transitional area between the two. Therefore, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92299245

determination of *K* and the selection of cluster centers are relatively easy. In this paper, we use the *K*-means clustering algorithm to segment disease images. The RGB value of each pixel is taken as its feature vector. The core idea of the k-means algorithm is to divide *n* RGB vectors into *k* clusters, so that the sum of the squares of the distance between the RGB vector in each cluster and the cluster center is the smallest. The algorithm flow is as shown in *Algorithm 1*.

Algorithm 1. *K-means algorithm segmentation*

1. Select *K* Pixels as the initial cluster centers randomly;
2. Calculate the distance between the remaining samples and each cluster center, classify the sample into this class with the nearest distance;
3. Re-compute the average value of each class and update the clustering center of each class with the criterion function

$$\mathrm{E} = \sum_{i=1}^{C} \sum_{x \in C_i} \left\| x - x_{C_i} \right\|^2$$

4. When the criterion function no longer converges, the clustering result is output, otherwise it is repeated Step2~Step4.

The *K*-means algorithm divides all pixels in the disease image into *K* categories. Next, you need to find the class of the pixel in the disease area accurately in this *k*-type pixel. In fact, because the characteristics of different diseases on the leaves are different, it is very difficult to find out the common characteristics of various diseases and directly locate the class of the diseased pixels. However, the characteristics of the healthy area of the leaf are easy to find and stable from the perspective of color and texture. To this end, we find the pixels of the healthy area from the *K*-type of pixels, and the remaining pixels are considered to be the pixels of the diseased area. This method will judge some of the transitional pixels between the healthy area and the diseased area as the disease content, so that some initial characteristics of the disease can be reflected from the information provided by the disease area, on the one hand, the early symptoms can be reflected in the extracted features, and on the other hand, the efficiency of recognition of the overall disease is also improved. *Figure 1* shows the segmentation results of four disease images. It can be seen from the results given that the pixels of most disease areas can be correctly found by the *K*-means algorithm. After locating the disease region, we will extract feature for the disease areas. 4- Unicom disease region is first determined region area, and further select intermediate 4- Unicom disease region to extract features. In this paper, we consider the three aspects of color, shape and texture to extract the feature of the diseased area. In order to avoid the affection of scale and direction, we try to select some features that will not disturbed by the scaling and rotation factors. We have selected a total of 28 features, including 4 color features, 6 shape features, and 18 texture features. The specific feature name and the corresponding feature can be found in the *Appendix*. After normalizing the different types of feature vectors, they connected each other to construct the feature vector we need to use.

Disease identification

The process of disease classification is relatively simple. For each type of disease *j*, *Equation 6* is used to calculate the reconstruction error between the testing feature and its fitting result, and select *j** corresponding to the smallest error as the decision.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92299245

$$j^* = arg\ \min_j \sum_{k=1}^{K} \theta^k \left\| y^k - X_j^k W_j^k \right\|_2^2, \mathrm{j} = 1,2,\cdots,\mathrm{J} \quad \text{(Eq.6)}$$

where $\{\theta^k\}_{k=1}^K$ are the weights of the different feature forms in the recognition process. According to the definition, we will elaborate weight parameter $\{\theta^k\}_{k=1}^K$ in the experimental part. Further, the disease category j^* which minimizes the error of the reconstructed test disease feature is selected as the final recognition result. The pseudo code of the process is shown in *Algorithm 2*.

Algorithm 2. *Multi-task joint sparse representation*

Input: disease feature set X, label k, y
Output: the disease category number j^*
1. Initialization: $v^0 = 0, \alpha_0 = 1$
2. For $t = 1: T$
3. Compute W^{t+1}

$$W_j^{(t+1)} = \left[1 - \frac{\lambda\eta}{\left\|[V^t - \eta\nabla f(V^t)]_j\right\|_2}\right]_+ [V^t - \eta\nabla f(V^t)]_j$$

4. Compute V^{t+1}

$$V^{(t+1)} = W^{(t+1)} + \frac{\alpha_{(t+1)(1-\alpha_t)}}{\alpha_t}(W^{(t+1)} - W^t)$$

5. $\alpha_t = 2/(t+3)$
6. $t = t + 1$;
7. End
8. $j^* = arg\ \min_j \sum_{k=1}^{K} \theta^k \left\| y^k - X_j^k W_j^k \right\|_2^2$
9. Return j^*

Experiment and analysis

In order to verify the effectiveness of the proposed algorithm, we conducted extensive experiments on cucumber leaf diseases image and do comparisons with state of the art results published in recent years. These state of the art algorithms include SR (Zhang and Wu, 2017), SVM (Rumpf et al., 2010), ANN (Bashish et al., 2011), TF (Arivazhagan et al., 2013), and KNN (Zhang et al., 2015). All experiments were performed on a computer with 1.8 GHz CPU and 2 GB cache and a 64bit Windows 2K operating system was installed in it. All the algorithms including ours proposed in this paper were coded and implemented on MATLAB2015b platform. The results of the participating comparison algorithm are basically consistent with the results given in the experimental part of the corresponding paper.

Parameter settings

The cucumber leaf disease image used in this paper are collected in the farm of Zhongkai University of Agricultural and Engineering. All the disease leaves are obtained by agronomy students under the guidance of professional teachers through digital cameras or smart phones, and the corresponding disease types are labeled by agriculture experts. In the process of obtaining examples, in order to avoid the interference of uneven illumination, atmospheric turbulence and other factors, our

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92299245

image acquisition process is completed indoors, and set the same shooting environment for each image. All captured images are set to 800 × 800 pixels by cutting or zooming, etc. All images are three-channel color images and saved as "jpg" format. A partial images selected form the data set is shown in *Figure 2*. The data set contained 1,120 images with seven common diseases, i.e., downy mildew, bacterial angular, Corynespora cassiicola, scab, gray mold, anthracnose, powdery mildew. Each disease contained 160 samples and for each disease, we selected 100 samples randomly for training in our model, and the remaining 60 examples were used for testing. Considering that there may still exist noise or uneven illumination introduced during the shooting process, we perform smoothing and histogram equalization before starting the diseased region segmentation step. Next, extract the features of each disease image according to the explanation in Section 3.2, and add labels for each example to construct a training data set. Further, the sparse coefficient W is obtained by the *Equation 5,* and the type of the disease is judged by the *Equation 6*. The feature weight parameters in *Equation 6* are set to: color weight $\theta^1 = 0.5$, shape weight $\theta^2 = 0.3$, texture weight $\theta^3 = 0.2$, and the settings will be explained in next sub-section.

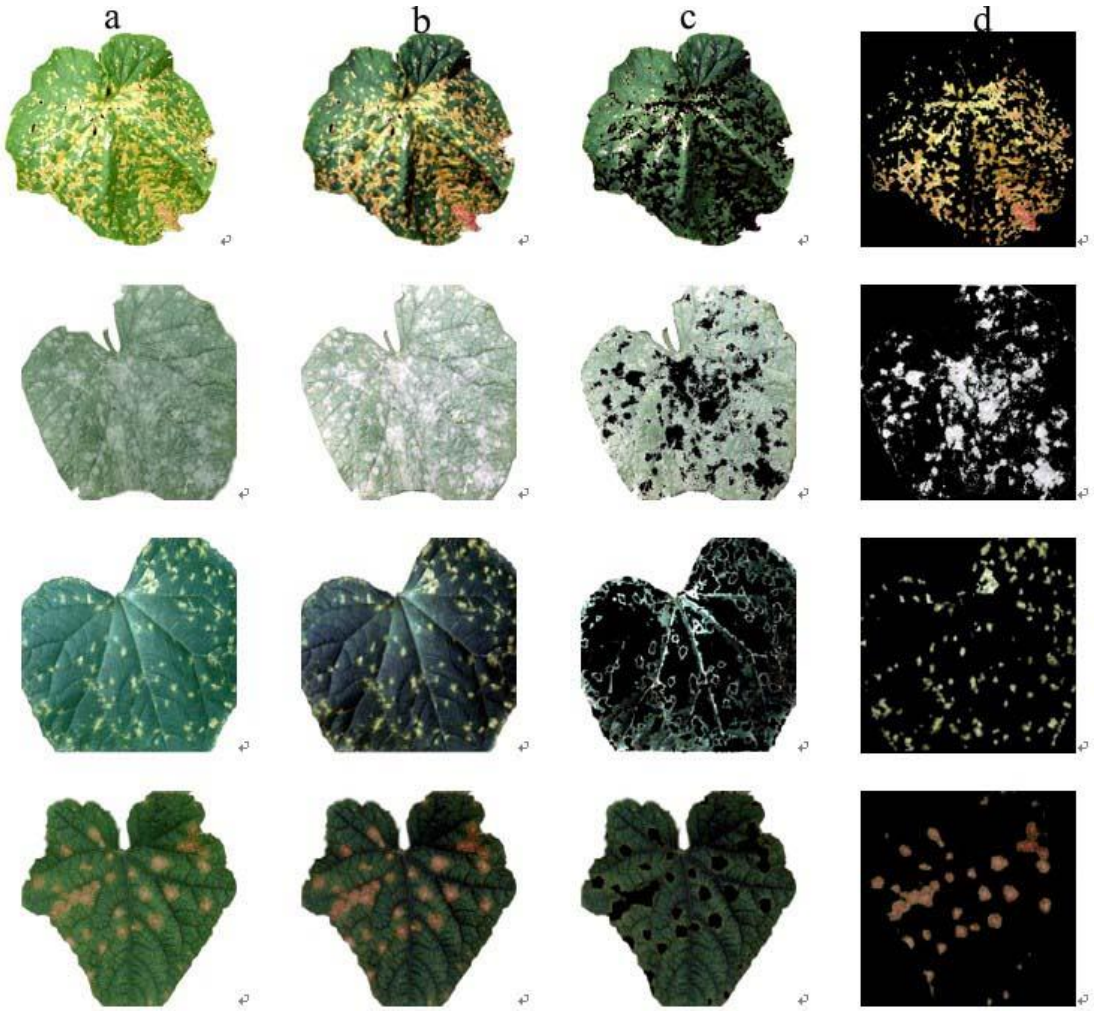

Figure 1. *The results of healthy region and legion region with K-means segmentation (the disease names from the top line to the final line are bacterial angular, powdery mildew, Corynespora cassiicola and anthracnose separately). (a) Disease leaf images; (b) Enhancement leaf image; (c) Healthy region; (d) Legion region algorithm*

DOI: http://dx.doi.org/10.15666/aeer/1704_92299245

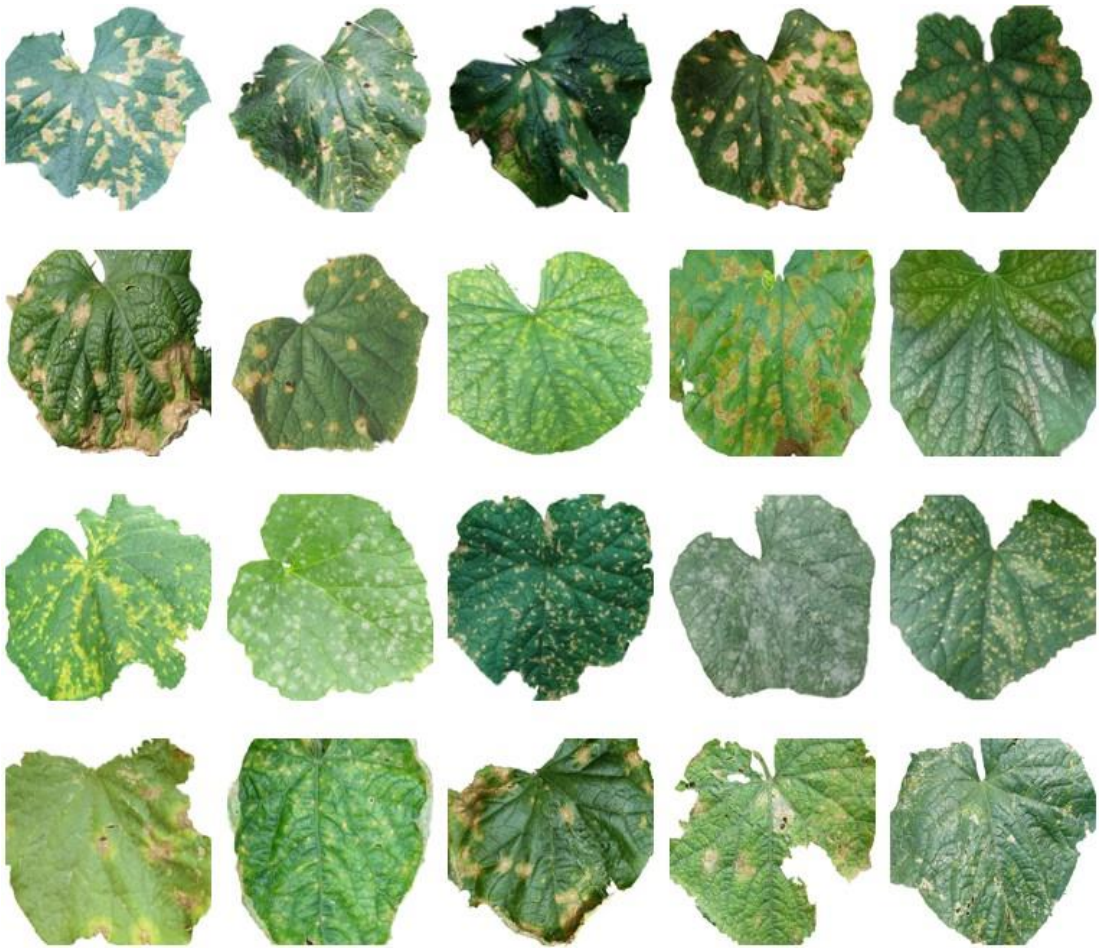

Figure 2. *Partial cucumber disease leaf examples*

According to *Figure 3,* we can conclude that the accuracy of our method is obviously better than the sparse representation with a single feature and better than other state of the art algorithms without considering the relationship between features such as the algorithm of (Zhang and Wu, 2017).

Experimental results

After obtaining the training and testing data, we randomly selected a certain number of samples in each type of disease image as "atoms" to construct a dictionary to identify the disease of testing example. The results are shown in *Figure 3*. In the case of considering only one feature, the method degenerates into a sparse representation recognition algorithm. Since only one feature form is considered, its recognition efficiency is low. The solution of sparse coefficient is similar to SR algorithm, but due to the single feature form, its recognition efficiency is lower than the SR algorithm. The SR algorithm uses sparse representation classification theory for disease identification, which just stacks color features, shape features and texture features indiscriminately. In the process of solving sparse coefficients, the SR algorithm randomly select as few as possible "atoms" to approximately fit the testing example which is unstable. However, our method comprehensively considers the sparse coefficient vectors of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92299245

corresponding different modalities features as similar as possible, which is a stronger constraint and makes the recognition results more accurate.

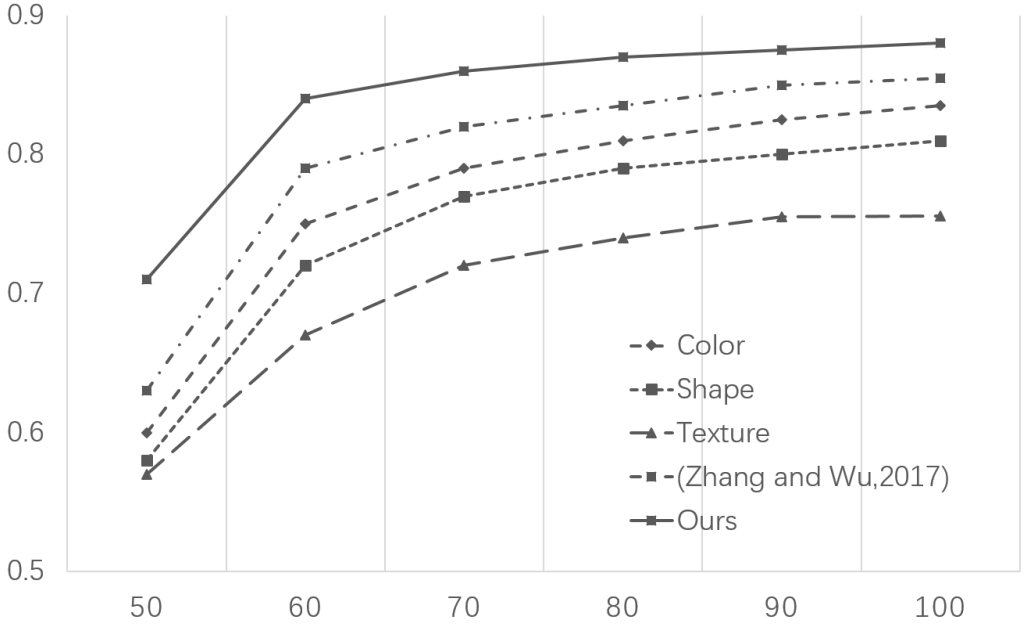

Figure 3. *The accuracy curve of cucumber disease identification*

At the same time, we can notice that our algorithm has increased the recognition efficiency as the number of training samples increases, and it is always higher than other methods.

Observing the experimental results given in *Figure 3*, we can see that when the three features of color, shape and texture are processed separately, the efficiency of each is not the same. In order to quantify the proportional relationship between them and determine the parameters $\{\theta^k\}$, we set the color and shape characteristics in the range of, and quantize, and the step size is set to 0.1. After the color feature weight and the shape feature weight are determined, the texture feature weight may not be displayed. However, for each set of weight values, a disease identification test was conducted to obtain an average accuracy rate, and the results are shown in *Figure 4*. It can be seen from *Figure 4* that when $\theta^1 = 0.5$, $\theta^2 = 0.3$, $\theta^3 = 0.2$, the recognition rate reaches the maximum value, so other experiments in this paper are performed according to this setting.

Furthermore, according to the conclusion of *Figure 4*, we set the number of atoms in the dictionary to 700, (that means that 100 samples for each type of disease to participate in the training), and test the correct recognition rate and average consumption of the disease with the selected state of the art algorithms. The comparison results of the correct recognition rate of the disease are shown in *Table 1*, and the average time consumed by these algorithms is shown in *Table 2*. By observing the experimental data exhibited in *Tables 1* and *2*, it is not difficult to find that our algorithm has the highest accuracy and the minimum average time to identify the results of the identification of these seven diseases.

Discussion

From the above experiments, we can find that in the cucumber diseases identification, our algorithm shows significant advantage in the correct recognition rate and the consuming time comparison. Next, we analyze the reasons about the above conclusion. First, the artificial neural network algorithm uses the training samples as input data to adjust the weight coefficients of the neural nodes, and uses these coefficients to fit the test sample to achieve classification. Such algorithms have higher self-adaptive and generalization ability. However, these algorithms are strongly dependent on training samples and sensitive to initial weight coefficients of neural node. In the process of calculation, they are easy to converge the local minima, thus causing misclassification.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92299245

The SVM algorithm is a classic two-classification algorithm. It has a good generalization ability for the two-class problem in small sample environments. However, the large-scale multi-classification problem is not ideal, and the SVM algorithm needs to be solved by means of quadratic programming. The support vector will involve the calculation of the *N*-order matrix (*N* is the number of samples). When *N* is large, it will take up more memory and consume a longer time. Similarly, the KNN algorithm is simple in principle and suitable for nonlinear multi-classification problems. Such algorithms are heavily dependent on data and sensitive to noise. In high-dimensional data, the distance and similarity between two data points are not always. It is directly proportional, and these will affect its accuracy. At the same time, such algorithms need to calculate the distance between the test sample and each training sample, and it takes a lot of time to calculate. The SR algorithm uses the features of the sample set to sparsely represent the test features, and uses the class with the lowest reconstruction error as the classification result. This method is more accurate than other methods, but in the process of solving the sparse coefficient, the feature vector in the approximate random sample is used to fit the sparse coefficient, so that the judgment result is unstable and the recognition efficiency has room for further improvement.

All of the above algorithms use three different modality features of color, shape and texture, and all three different forms of features are simply stacked and calculated as a unified feature vector without considering these three different form features. It is against this problem that this paper designs a multi-task joint sparse representation algorithm, which requires different forms of features under the same sample set, and the sparse coefficients should have similar structures. *Figure 5-A* shows the sparse coefficients of the randomly extracted samples in the multi-task connection sparse representation, and *Figure 5-B* shows the reconstruction errors obtained by the sparse coefficients for the different disease features. In addition, the time complexity of the accelerated near-end gradient method used is O (*N*), where *N* is the number of samples, which means that the algorithm can complete the calculation quickly.

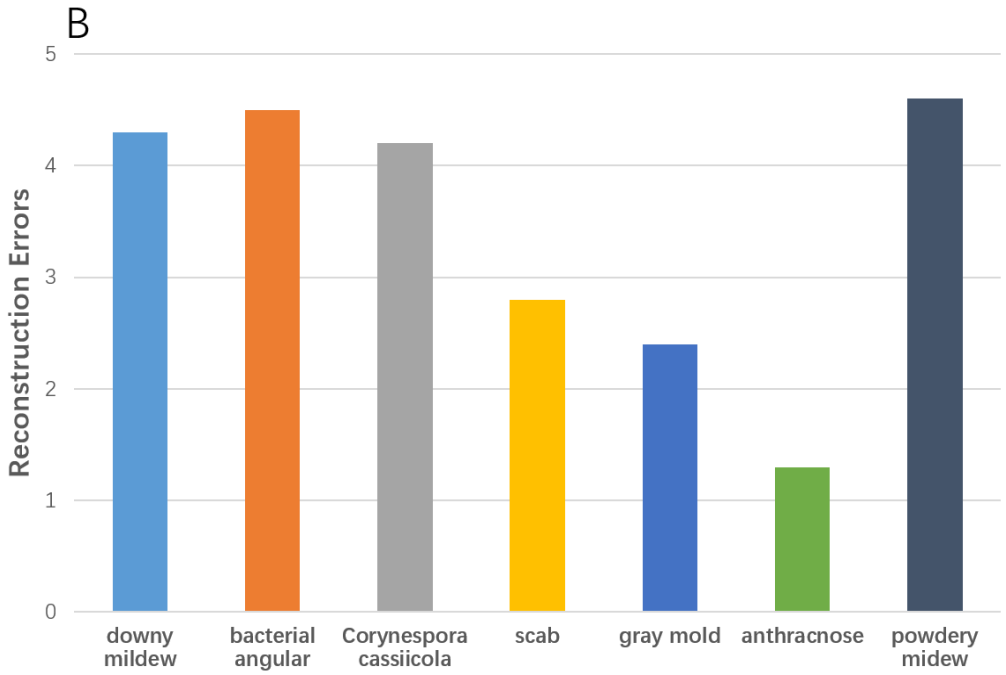

Figure 5. *Multi-task joint sparse coefficient and the reconstruction error visualization of anthracnose example. A: Multi-task sparse coefficients display B: the reconstructed errors of input feature generated from different tasks with sparse coefficients*

As shown in *Figure 5A,* the sparse features of color, shape and texture of multi-task sparse representation are approximately zero in most diseases and significantly non-zero in a small number of positions, and they have similar structures. The minimum value in B represents the minimum reconstruction error, that is, the classification of diseases of input samples.

Conclusion

Inspired by the idea of multi-task learning, we extracted many different types of disease features from multiple disease leaf samples for disease identification, and introduced multi-task joint sparse representation to model the data, with the commonality of different forms of disease features. Improve recognition efficiency and enhance the robustness of recognition. This algorithm is applied to the identification of cucumber diseases. Experiments show that this algorithm is superior to the disease identification algorithm based on sparse representation and other frontier algorithms that are involved in comparison in recognition rate and robustness. The recognition accuracy reaches 88.05%. It can be found from the experimental part of this paper that although the approach proposed in this paper has greatly reduced the algorithm's dependence on samples, sample collection is still an indispensable step of the algorithm. At the same time, we found that the extraction of disease feature for the accurate identification also played a vital role. In the following research, we hope to obtain a wider range of leaf disease image through the unmanned aircraft system, and then extract some special features from these pictures or video to avoid the time-consuming and inefficient leaf collection step.

Abstract. Sediment microbial fuel cells (SMFCs) have been examined extensively for bioremediation, but the impact of organisms that live in the sediment has not been previously investigated. In this study, the impacts from the bioturbation of Tubificidae on the electrochemical performance and microbial community of SMFCs were investigated using lake water and sediment. It was observed that Tubificidae were burrowing in the sediment and eventually dwelled on the anode of SMFCs. Although the voltage output of the SMFC in the presence of Tubificidae experienced a dramatic decline at the beginning of operation, it outperformed that of the SMFC in the absence of Tubificidae after operating for 30 days. The polarization curves of the SMFC anode and Shannon diversity index suggested that the anodic biofilm was devoured by Tubificidae. However, the cathode performance was improved due to more chemical oxygen demand (COD) and ammonia-nitrogen (NH_3-N) released from the sediment. After 90 days of operation, a high loss on ignition (LOI) removal efficiency of 24.5 ± 3% was achieved by combining the anodic oxidation of SMFC and the ingestion of Tubificidae. This study shows that SMFCs can alleviate the impact of Tubificidae on pollutants transfer to overlying water and still remove organic matters from the sediment effectively.

Introduction

Freshwater bodies (e.g., lakes, rivers and reservoirs) are crucial resources for drinking water supply, agricultural irrigation and industrial activities. However, water contamination has posed a severe challenge to the sustainability of freshwater resources and is arousing worldwide concerns (Li and Yu, 2015). Sediment is the natural sink of pollutants in the aquatic environment (Peng et al., 2009; Kanzari et al., 2014; Payne et al., 2013). Previous studies have revealed that various pollutants released from the sediment can lead to water contamination when the external input of pollutants (e.g., agricultural runoffs, effluents from wastewater treatment plants and factories, etc.) is low (Qin, 2002). Therefore, it is of great importance to take measures to alleviate pollutant transfer from the sediment to the aquatic environment.

Sediment microbial fuel cells (SMFCs) have attracted increasing attention for their environmental remediation of freshwater bodies (Wang et al., 2016; Chen et al., 2012; Franco et al., 2018; Yan et al., 2012; Xia et al., 2015; Zhao et al., 2016; Shiriny and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92479261

Bayareh, 2018; Sajana et al., 2014). In most SMFCs, anodes are buried beneath the anaerobic sediment and cathodes are placed in the aerobic overlying water. Exoelectrogenic microorganisms on the anode degrade organic matter and release electrons to the anode and then through the external circuit to the cathode. Finally, dissolved oxygen (DO) and protons in water combine with electrons to produce water and electricity (Li and Yu, 2015). Compared to other techniques, such as dredging, ozonation and intruding bio-agents, SMFCs using bacteria from environment therefore has least impact on natural environment, and also it is self-sustained by generating electricity (Aloisio et al., 2018; Franco et al., 2018; Li and Yu, 2015; Li et al., 2017; Payne et al., 2013; Sherafatmand and Ng, 2015; Xia et al., 2015). For example, SMFC can increase the redox potential of sediment by oxidizing the organic matters and thus the methane (greenhouse gas) production can be inhibited (Hong et al., 2008b). Polycyclic aromatic hydrocarbons (PAHs) is a class of contaminations from the incomplete combustion of fossil fuels. These compounds are of major public concern due to their toxicity to organisms in carcinogenic and mutagenic potential. SMFCs were used for the removal of PAHs under anaerobic or aerobic conditions (Sherafatmand and Ng, 2015), and with good removal rates of naphthalene (76.9%), acenaphthene and phenanthrene under anaerobic conditions, while producing a power density of 3.63 ± 0.37 mW•m^{-2}. Beside PAHs, cyanobaterial bloom biomass and total petroleum hydrocarbon (TPH) can be effectively degraded by microorganisms on the bioanode of SMFCs (Morris and Jin, 2012; Zhou et al., 2015). The biocathode of SMFCs can be used for in-situ denitrification (Wang et al., 2016; Zhang and Angelidaki, 2012). The results suggested that the SMFC with a small external resistance was more effective for the in-situ denitrification. In addition, the acclimated SMFC biocathode contained mixed microbial communities which could facilitate denitrification, oxygen reduction and ammonia oxidation reactions (Wang et al., 2016). Recently, an SMFC with a novel tubular air cathode was proposed for facilitating air transfer to the cathode (Yuan et al., 2010), which greatly improved biodegradation efficiencies. Additionally, phosphorous flux from overlying water to sediment can be enhanced by employing SMFCs which can oxidize Fe^{2+} to Fe^{3+} and store phosphorous substances in sediment in stable forms (Yang et al., 2016). There are numerous reports in improving the performance of SMFCs. Abazarian et al. revealed that SMFC voltage increased when cells connected in series (Abazarian et al., 2016). However, voltage reversal occurred in this case which causes the total voltage to be less than the sum of individual cell voltages in the channel (Abazarian et al., 2016). Placing sheet iron out of the circuit can improve the iron reduction microbial activity. Within the circuit, it produces a large number of electrons from the electrochemical corrosion yielding higher power production (Zhang et al., 2015). An algae assisted cathode was also proposed for SMFCs and the performance was 2.4 fold higher than that of the SMFC with bare cathode (Wang et al., 2014).

While significant progress of SMFCs for bioremediation has been made, there are still many unclear effects from real aquatic environment on the electrochemical performance and microbial community structure of SMFCs. *Oligochaetes* include the *tubificids*, pot worms and ice worms (*Enchytraeidae*), blackworms (*Lumbriculidae*) and several interstitial marine worms. They are bottom invertebrates frequently used for evaluating the quality of freshwater habitats under their trophic conditions (Krodkiewska and Michalik-Kucharz, 2009). They can be widely distributed in natural water bodies, and they are considered as one of the major bioturbation sources (e.g., feeding, burrowing and locomotory activities) in sediments (Fisher et al., 1980).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92479261

Bioturbation can not only cause significant mixing of freshwater bodies with sediment, but it also changes the physical and chemical properties of the sediment. In this work, SMFCs were constructed with carbon felt which is a cheap, stable and biocompatible material (Christwardana et al., 2018; Huong Le et al., 2017). *Oligochaetes* community was first analyzed, and then they were introduced to SMFCs (1.0 L beakers). During 90 days of operation, bioturbation by *Oligochaetes* was monitored, and their impacts on the overlying water, electrochemical performance of whole cell and each electrode were investigated. 16S rDNA pyrosequencing was conducted to analyze the anodic microbial communities of the SMFCs.

Materials and methods

Sampling and analysis

Surface sediments (0 to ~10 cm) were collected using a grab sampler (2.0 L) from Xinghu Lake (114.366037°E, 30.533637°N) near Wuhan University, China. Sediment samples were sieved through a 1.0 mm sieve to remove large debris and then mechanically homogenized. The freshwater was collected from the same location and used throughout the experiment without further treatment. All samples were stored in a refrigerator at 4.0 °C. The LOI of sediment samples was determined using the procedure described previously at a temperature of 550 °C for 2 h (Hong et al., 2008a). Chemical oxygen demand (COD) and NH_3-N of the freshwater were analyzed according to APHA Standard Methods. pH and conductivity of the overlying water were measured by an electrode probe (Shanghai INESA Scientific Instrument Co., Ltd., China). The DO in the overlying water was monitored everyday using a portable multimeter (HQ30D, Hach, USA) and the DO in the sediment was measured five times to avoid severe oxygen penetration to SMFC anodes. All measurements were taken at least 3 times.

Oligochaetes were provided by the Institute of Hydrobiology, Chinese Academy of Sciences. They were examined under an Olympus BX60 microscope equipped with a DP12 digital camera and AnaliSIS 3.2 (Soft Imaging System) software. *Limnodrilus* (with smaller sizes) have no caudal gills and can be further divided into *Limnodrilus hoffmeisteri* and *Limnodrilus claparedeianus* according to their mature sexual organs; *Branchiura* (which are mainly *Branchiura sowerbyi*) are bigger than *Limnodrilu* and have conspicuous gills in their tails. The tails of *Branchiura* often cross the sediment and swing in water to breathe oxygen. Overall, *Tubificidae* was identified as the predominant species (*Fig. 1*).

SMFC construction and operation

Graphite felt 5.0 mm in thickness (Zhongxin Co. Ltd., China) was washed thoroughly with ethanol and DI water before use. Then, it was cut into circular wafers 7.5 cm in diameter (~44.2 cm^2) for use as the SMFC electrodes. The distance between the anode and the cathode was fixed at 7.0 cm. The SMFC was placed into a 1.0 L beaker and the anode was buried 3.0 cm below the sediment-water interface. Afterwards, the beaker was transferred to a larger container (10 L) which contained 3.0 L of freshwater, and a flow rate of 1.0 $L \cdot h^{-1}$ was maintained in the SMFC reactor using a peristaltic pump (*Fig. 2*). The purpose of this reactor design was to constrain *Oligochaetes* in a small area and also maintain the DO in the reactor at a relatively high level (due to the larger area) for inoculating the biocathode of the SMFC. An external

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92479261

resistance of 500 Ω was used to connect the electrodes using titanium wires. After start-up for approximately 35 days, the SMFC was transferred to a beaker with fresh sediment. Then, *Oligochaetes* (with a density of about 2000 ind. 0.1 m^{-2}) were added into a beaker (denoted as TUB-1). For comparison, the reactors only containing sediment, only containing *Tubificidae* and only containing SMFC were assembled (denoted as Control-S, Control-T and TUB-0). All reactors were kept in incubators at 25 °C for 90 days. The reactors were routinely replenished with DI water to maintain a constant water level.

DOI: http://dx.doi.org/10.15666/aeer/1704_92479261

Electrochemical characterization

The voltage of external resistance was recorded at 10 min intervals using a data acquisition system (Model 2700, Keithley Instrument, USA). Polarization curves were obtained at a scan rate of 0.1 $mV \bullet s^{-1}$ using a potentiostat (CHI 604E, Chenhua instrument Co., Ltd., China). Electrode potential were recorded and reported versus Ag/AgCl (3.0 M KCl, saturated AgCl). The power density can be calculated by the obtained voltage using *Equation 1:*

$$P = I \times U \quad \text{(Eq.1)}$$

where P is the power density ($mW \bullet m^{-2}$), I is the current density ($mA \bullet m^{-2}$) and U is the voltage output (V).

Microbial community analysis

For high-throughput MiSeq Illumina sequencing of the 16S rDNA, biofilms on the anode of SMFC were sampled after 90 days by repeatedly scraping the cross-section of the graphite felt electrode using a sterile blade. The DNA extraction kit (MOBIO Laboratories, CA, USA) was used for extracting 250 mg DNA from the sample. The purity and concentration of DNA were checked through running samples on 1.0% agarose gels. DNA was amplified following the protocol described previously (Wang et al., 2016). PCR amplifications were conducted in triplicate with the primer set 515F (5'-GTGCCAGCMGCCGCGGTAA-3') and 926R (5'-CCGTCAATTCMTTTGAGTTT-3') that amplifies the V4-V5 region of the 16S rDNA.

Sequencing was determined on an Illumina MiSeq platform. The 16S rDNA gene sequences generated were analyzed using the bioinformatic software package Mothur using the MiSeq SOP Pipeline to analyze a multiplexed set of samples on a single run. The paired reads were assembled using make.contigs that extract the sequences and quality score data from the fastq files, which creates the reverse complement of the reverse read. Then, the paired end reads were assembled into a contig. Screen.seqs which was used to remove low quality reads by the following filtering parameters, maxambig=0, minlength=200 and maxlength=580, maxhomop=8. The remained sequences were simplified using the unique.seqs command to generate a unique set of sequences, and they were aligned with the SILVA databases (version 119). The filter.seqs was used to remove empty columns from our alignment, which provided short length of filtered alignment. Further de-noise sequences were pre-clustered using the pre.cluster command (http://www.mothur.org/wiki/Pre.cluster) for up to 4 differences between sequences. All reads were checked for chimeras using UCHIME algorithm and the chimeric sequences were removed by the chimera.uchime command with default parameters. Silva 119 reference sequence files were used to classify (classify.seqs) our sequences, then the Wang method was used with a confidence threshold of 80%. No-bacteria sequences were deleted. The distance matrix between the aligned sequences was generated by the dist.seqs command. At last, these sequences were clustered to OTUs (operational taxonomic units) at 97% sequence identity (furthest neighbor method). A majority consensus taxonomy for each OTU was obtained by the classify.otu command with default parameters.

Results and discussion

Impacts of Tubificidae on the water quality and loss on ignition (LOI) in the sediment with and without SMFC

The bioturbation of *Tubificidae* and SMFC both have profound impact on the sediment and overlying water. COD, NH_3-N and organic matter are important indicators of contaminations in natural water bodies and they are also the food for bacteria on SMFCs.

The chemical oxygen demand (COD) and NH_3-N concentrations in all reactors except Control-T declined rapidly during the initial 25 days, their degradation rates were sluggish after 25 days (*Fig. 3a* and *b*). The removal rate of NH_3-N was accelerated after 15 days because high COD concentration inhibits ammonia oxidation (*Fig. 3b*) (Hanaki et al., 1990). For Control-T, the final COD and NH_3-N were highest (20.0 ± 0.15 mg•L-1 and 0.98 ± 0.04 mg•L-1), which suggested the bioturbation from Tubificidae can accelerates the release rate of pollutants from the lake sediment (Fisher et al., 1980). The final COD (9.8 ± 0.5 mg•L-1) and NH_3-N (0.56 ± 0.02 mg•L-1) were much lower in TUB-1. Previous reports revealed that the biocathode of SMFCs can digest COD as carbon/food sources for bacterial metabolism (Sajana et al., 2014). It is worth of noting that the NH_3-N was significantly removed in Control-S, which is similar to that in TUB-0. However, the final CODs in TUB-0 (8.5 ± 0.13 mg•L-1) was around 6 mg•L^{-1} lower than that in Control-S. It is well-known in wastewater treatment that COD is much easier to be oxidized than NH_3-N (Hanaki et al., 1990). All parameters can also be found in *Table 1*.

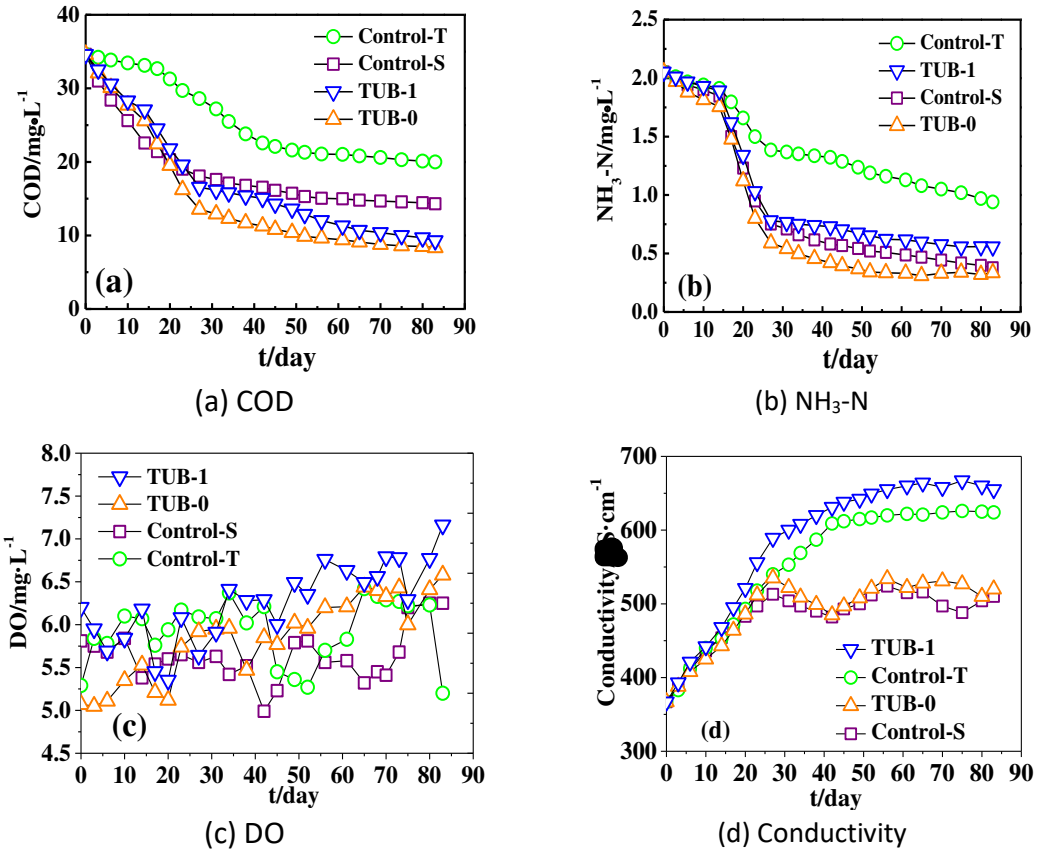

Figure 3. *Water quality of the overlying water in different reactors*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92479261

The DO in the overlying water in different reactors ranged from 5.0 to 7.0 mg•L^{-1} (*Fig. 3c*). The conductivity of the overlying water in all reactors started increase, then it reached a plateau after around 25 days of operation. The conductivities in TUB-1 (660 ± 5.0 μS•cm^{-1}) and Control-T (624 ± 2.0 μS•cm^{-1}) after 25 days of operation were higher than that in TUB-0 (519 ± 8.0 μS•cm^{-1}) and Control-S (500 ± 11.0 μS•cm^{-1}) (*Fig. 3d*). During these measurements, it was observed that *Tubificidae* was burrowing in the sediment and formed tunnels that can increase the releasing rate of soluble chemical compounds (e.g. soluble COD, NH_4^+ and sulfates) (*Fig. 4*) (Mccaffrey et al., 1980; Florian and Lemoine, 2010). SMFCs enhanced the degradation of COD and NH_3-N in the overlying water using bio-cathodes, which is consistent with previous reports (Wang et al., 2016; Li et al., 2017). In addition, the DO inside the sediment of Control-T and TUB-1 was also measured and the results were low in two reactors even when the sediment became more porous (*Table 1*). This is due to the strong respiration effect from *Tubificidae* and they consumes the most of DO in the sediment (Lou et al., 2013).

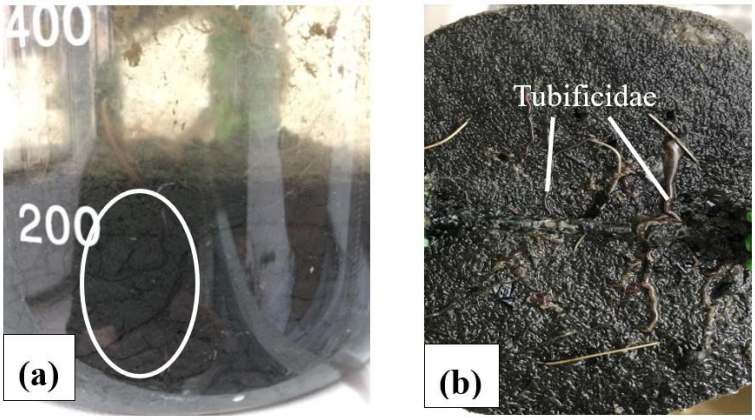

Figure 4. *Optical image of* ***a*** *tunnels from Tubificidae burrowing and* ***b*** *the SMFC anode in TUB-1*

Table 1. *pH and pollutant concentration in the overlying water and DO in the sediment*

Samples	Control-S	Control-T	TUB-0	TUB-1
pH	8.10 ± 0.16	7.98 ± 0.12	7.96 ± 0.17	8.12 ± 0.12
DO (mg/L)	0.48 ± 0.06	0.21 ± 0.01	0.17 ± 0.03	0.14 ± 0.04
Initial COD concentration(mg/L)	34.6 ± 0.01	34.6 ± 0.01	34.6 ± 0.01	34.6 ± 0.01
Final COD concentration (mg/L)	14.5 ± 0.16	20.0 ± 0.15	8.5 ± 0.13	9.8 ± 0.5
COD removal efficiency	58.1%	42.2%	76.0%	71.7%
Initial NH_3-N concentration (mg/L)	2.05 ± 0.01	2.05 ± 0.01	2.05 ± 0.01	2.05 ± 0.01
Final NH_3-N concentration (mg/L)	0.38 ± 0.01	0.98 ± 0.04	0.33 ± 0.01	0.56 ± 0.02
NH_3-N removal efficiency	81.6%	54.2%	83.6%	72.8%

The largest decrease ($24.5 \pm 3\%$) of LOI in the sediment was obtained using the SMFC in TUB-1 (*Fig. 5*). Numerous investigations reported that *Tubificidae* ingest organic matters effectively and thus be used for sludge minimization (Lou et al., 2013; Wei et al., 2003). The SMFC in TUB-0 exhibited a LOI removal efficiency of $16 \pm 1.5\%$ which was similar to that in Control-T ($16.3 \pm 1.5\%$) while it was only

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92479261

2.2 ± 1% in Control-S. A LOI removal efficiency of ~22% after 6 months of operation was reported in the field test using the SMFC under a closed-circuit condition (Hong et al., 2008a, b). The higher electrochemical performance of SMFCs and the bioturbation of *Tubificidae* were attributed to the high LOI removal efficiency (24.5 ± 3%) in this work.

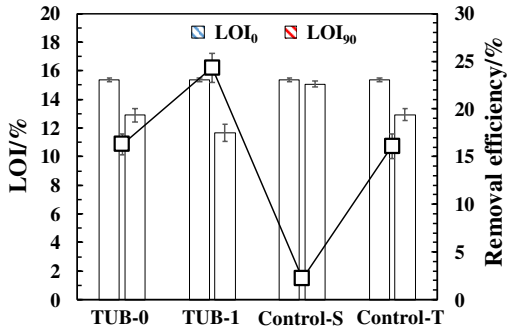

Figure 5. *LOI changes in the sediment. LOI0 and LOI90 represent the initial and final values of LOI in the sediment. Error bars indicate range of duplicate results*

Electrochemical performance of SMFCs in the presence and absence of Tubificidae

Tubificidae does not just redistributed the pollutants, they also inter-reacted with the electrodes of SMFCs. After 9 days of *Tubificidae* addition, the voltage output of SMFC started to decline steeply from around 300 mV to 130 mV (*Fig. 6*). Meanwhile, there was no visual on *Tubificidae* burrowing in the sediment after 10 days since the SMFC was transferred to the container of TUB-1. At the end of 90 day's operation, electrodes were removed from containers and it was found that *Tubificidae* dwelled in the porous graphite felt electrodes (*Fig. 4*). Previous studies revealed that *Oligochaetes* spent their life in the root zone of aquatic plants and other organic matter enriched areas (e.g. plant debris, bacteria) for food (Rota and De Jong, 2015; Vanamala Naidu et al., 1981). They can assimilate organic detritus and bacteria (Kemp, 1987). In this study, the SMFC anode acted as the root zone of aquatic plants and the biofilm on the electrode could be ingested by bioturbators, which caused the loss of the electrochemical performance.

However, it was found that the cell voltage in TUB-1 increased and it exceeded the initial value and the voltage of the SMFC in TUB-0 at day 30. To further examine the potential changes of electrodes, linear sweep voltammetry (LSV) was conducted in a three-electrode system (*Fig. 7a*). Before *Tubificidae* addition, the reaction rate on the cathode (upper figure) was slow and it was the limiting step of whole cell reaction compared to the anode. Once the SMFC was transferred to the *Tubificidae* containing sediment, the anode performance decreased in terms of open circuit potential (OCP) and limiting current. After ~30 days of operation, the anode performance partially recovered except for OCP. It was reported that the low concentration of DO significantly reduced the respiration rate of *Tubificidae* (Van Hoven, 1975), hence the anodic biofilm of the SMFC in TUB-1 could be recovered to some extent. On the other hand, the electrochemical performance of whole cell SMFCs (data not shown) and electrodes in the absence of *Tubificidae* decreased slightly after 50 days (*Fig. 8*). Although the increase of DO in the sediment was claimed by previous reports to be responsible for the performance drop due to the bacteria on SMFC anode are anaerobic, DO results in the sediment were not monitored or reported (Zhao et al., 2016). In this study, DO

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92479261

beneath the sediment remains low during operation in TUB-0 and TUB-1. Thus, the performance loss of the SMFC anode in TUB-1 was attributed by the ingestion of worms rather than the increase of DO in the sediment. The cathode performance of the SMFC in TUB-1 was improved significantly after *Tubificidae* addition for about 30 days. This is because of more COD and NH_3-N released from the sediment to the overlying water (*Fig. 3a* and *b*). More COD in the overlying water provided more food for the biofilm growth on the cathode. Overall, the SMFC performance in TUB-1 was improved from 70 mW•m^{-2} to 93 mW•m^{-2} (*Fig. 7b*).

Microbial community analysis

The microbial community of the pristine sediment, overlying water, anode biofilms of SMFCs in TUB-0 and TUB-1 were analyzed to reveal the enrichment of genera with potential exoelectrogenic capability using 16S rDNA pyrosequencing. The diversity index (5.27) of pristine sediment was highest, which is consistent with previous reports (Zhao et al., 2016; Lu et al., 2014). The diversity index of the anodic biofilm in TUB-0 (4.75) was higher than that of the SMFC in TUB-1 (4.50) (*Table 2*). The result further confirmed the anodic biofilm was consumed by *Tubificidae* and led a lower diversity index (*Fig. 6*).

TUB-1	4.51

The taxonomic analysis of bacterial DNA sequences shows that the microbial community of the anodic biofilm of the SMFC with *Tubificidae* was altered, compared to that of the SMFC without *Tubificidae*. Specifically, *Proteobacteria* was the dominant phylum in all samples (*Fig. 9*) and previous studies reported the same finding (Yan et al., 2015; Logan and Rabaey, 2012).

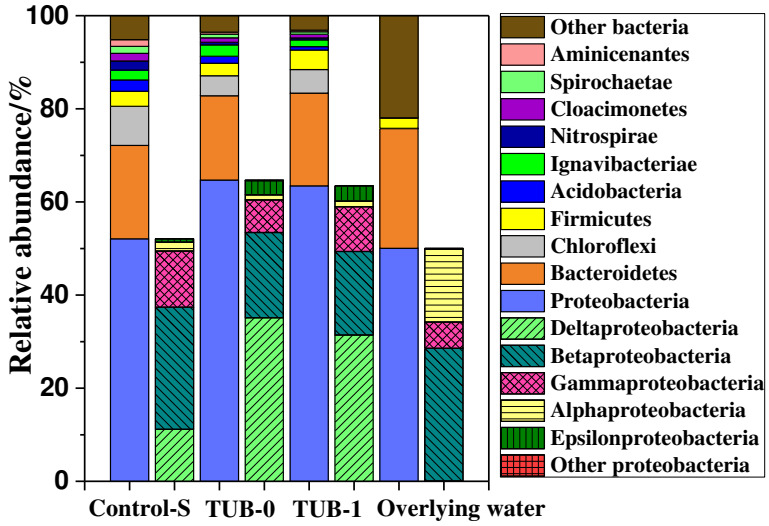

Figure 9. *Taxonomic classification of bacterial DNA sequences from the communities of different samples at the phylum level and the most dominant phylum of Proteobacteria at the class level*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92479261

From the class level, *Deltaproteobacteria* in the anodic biofilm were increased compared to that in the pristine sediment. *Desulfobulbus* (11.7%) and *Geobacter* (10.3%) were the dominant genera at genus level in the anodic biofilm of the SMFC in TUB-0 (*Fig. 10a* and *b*).

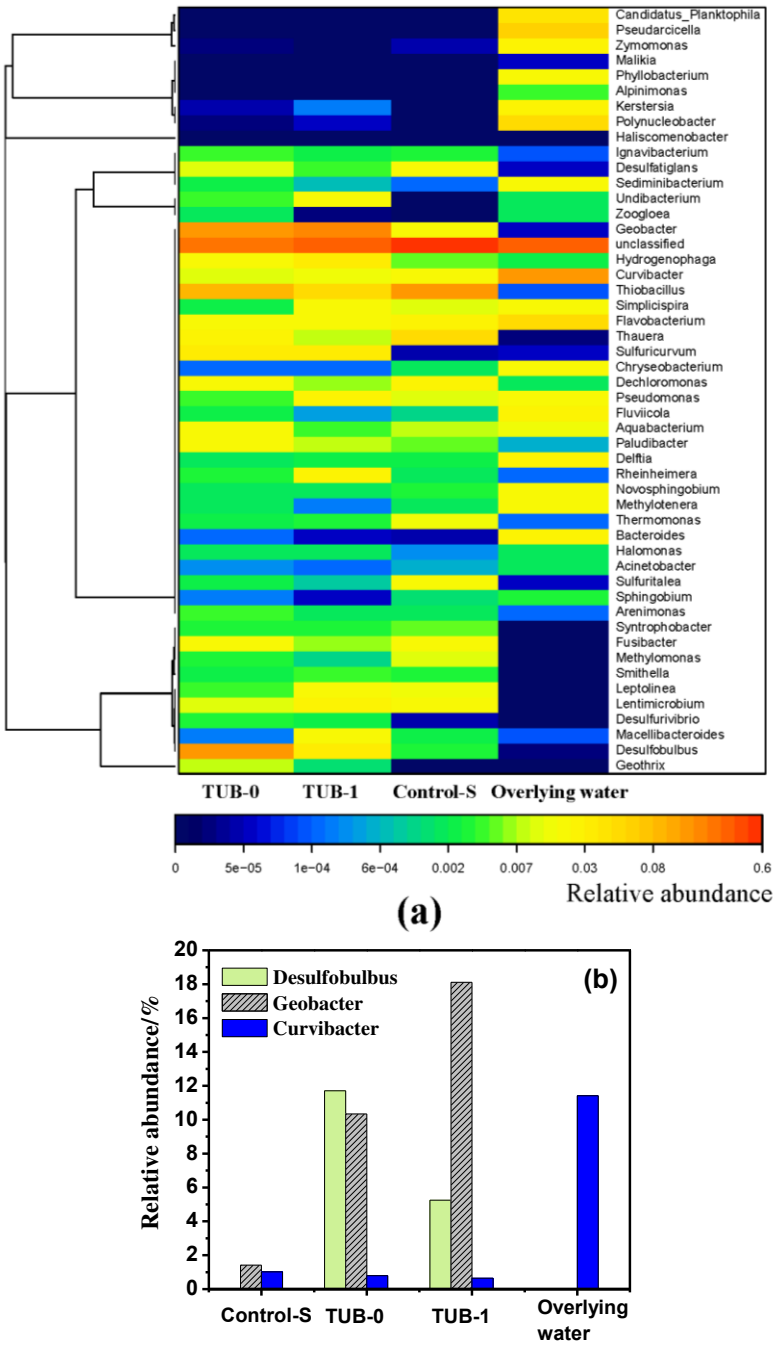

Figure 10. a *Heatmap of all samples at the genus level.* ***b*** *The relative abundances of Desulfobulbus, Geobacter and Curvibacter in different samples*

Geobacter is well-known bacteria that can directly digest acetic acid or other small organic molecules (e.g. Ethanol) to produce electricity (Logan and Rabaey, 2012).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92479261

Desulfobulbus are also proved to be exoelectrogenic micro-organisms that can oxidize S^0 in sediments. Their abundance increased and identified as one of predominant genera in the anodic biofilm of SMFCs as previously reported (Yan et al., 2015; Lu et al., 2015; Ryckelynck et al., 2005). In TUB-1, the predominant genus in the SMFC anode was *Geobacter* (18.1%) alone while the relative abundance of *Desulfobulbus* was only 5.25%. *Oligochaetes* are the host of several sulfur oxidizing bacteria and these bacteria can compete with *Desulfobulbus* for the S^0 source in the vicinity of bioanodes (Bergin et al., 2018; Blazejak et al., 2005). Hence, the microbial activity of *Desulfobulbus* was suppressed due to the strong bioturbation of *Tubificidae* in this study. A similar completion also exists between *Geobacter* on the anode of SMFC and methanogens on organic matters in sediments for the same substrate. Therefore, the use of SMFC can inhibits methane production from sediment. *Thiobacillus*, a strain of genera was reported with the ability of using sulfur as energy sources (Boden, 2017), were 9.1%, 7.7% and 5% in Control-S, TUB-0 and TUB-1. This result also confirms the competing mechanism described above. *Curvibacter* was the predominant genus (11.4%) in the overlying water and it is a well-established aerobic bacterium. The higher abundance of aerobic bacteria (*Polynucleobacter*, *Kerstersi, phyllobacterium, fluviicola*) in overlying water was found in most of water bodies (Chen et al., 2017; Halkjær et al., 2009). The low relative abundances of *Curvibacter* in the sediment of Control-S (1.0%), the SMFC anode of TUB-0 (0.8%) and TUB-1 (0.64%) confirmed that the DO beneath the sediment in all reactors remained low during operation.

The protein contents in SMFC electrodes were also examined. However, it was impossible for us to separate worms from the SMFC anode in TUB-1 since they dwelled inside the anode. After 90 days of operation, the protein contents of the SMFC cathode in TUB-1 and TUB-0 were 0.379 $g \bullet m^{-2}$ and 0.269 $g \bullet m^{-2}$. The higher protein content of the SMFC cathode in TUB-1 suggested that more bacteria enriched on the electrode and resulted in better electrochemical performance (*Fig. 7a*).

Conclusions

The present study demonstrated that the organic matter removal and electrochemical performance of SMFCs were enhanced by the bioturbation of *Tubificidae*. For the first time, it was found that *Tubificidae* dwelled on the carbon felt anode of SMFCs and devoured the biofilm. After 90 days of operation, a high LOI removal efficiency of $24.5 \pm 3\%$ was achieved in TUB-1. The SMFC performance in the presence of *Tubificidae* increased from 70 $mW \bullet m^{-2}$ to 93 $mW \bullet m^{-2}$. The bioturbation of *Tubificidae* suppressed the acclimation of *Desulfobulbus* on the bioanode of SMFCs. The sediment beneath the water-sediment interface remained anaerobic in the presence of *Tubificidae*.

(Received 3rd Apr 2019; accepted 17th May 2019)

Abstract. For the problem concerning how the implementation of environmental regulations should be performed, one must examine their impacts on the selection of directed technological innovations to achieve green growth. A nonlinear control model was created in which the constraint is to constantly improve the quality of the environment and ensure a consistent and balanced growth rate with the objective function being the goal of using green growth to maximize social welfare. Using optimal control theory and the maximum principle, we separately obtained the qualitative expression of capital allocation and optimal consumption growth. The model simulation results illustrate the following points: although brown capital is superior in production flexibility in the process of capital accumulation, green capital is still an important pillar of support for maintaining the economic growth of a society as a whole; although brown capital is able to bring about a greater consumption growth rate, the implementation of environmental regulations is sufficient to promote capital allocation to shift towards green technological innovation. In addition, greater emphasis in this aspect shall be more useful for the usage of green capital and play a more effective role in the use of green technological innovation to achieve green growth.
Keywords: *environmental governance, capital allocation, green technological innovation, brown technological innovation, optimal control model, capital accumulation, environmental quality*

Introduction

The key variables for explaining economic growth using traditional neoclassical economic growth theories are mainly capital, labor (including human resource capital), technology, and regulations. The standard for measuring economic growth is gross domestic product (GDP) and per capita income. However, amid the growth of contemporary society, GDP and per capita income are not the only yardsticks for reflecting social progress. Regardless of whether the ecosystem has a positive or negative impact, it has a direct impact on people's quality of life. Therefore, to reflect the goal of sustainable social growth, we must discard the original "GDP-oriented economic growth theory" and include resource usage and environmental impacts in mainstream economic growth theories to construct a "green growth theory", which we use as a new perspective of current mainstream economic research. With regard to green growth (OECD, 2011), technological innovation is the most important factor (Caselli, 2005) for maintaining economic growth. The implementation of some environmental regulations may affect the costs and earnings from technological innovation and change its direction of technological innovation. This effect may lead to "brown technological innovation that relies mainly on pollution-oriented inputs" and "green technological innovation (Demirel and Kesidou, 2011; Zhang and Zhu, 2012; Li et al., 2018) that

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92639278

attempts to reduce resource utilization and environmental impacts", both of which are problems related to direction-orientated technological innovation. Currently, research into these problems heavily focuses on the dominant factors (Gerlagh, 2011; Gans, 2011) that affect the selection of directed technological innovation. However, we need a further breakthrough to determine how the implementation of environmental regulations will affect the selection of directed technological innovations and what impact this implementation will have on the economic growth of society as a whole.

Currently, there are mainly two perspectives in relevant literature on the impact of the implementation of environmental regulations on technological innovation. The first viewpoint is the "Porter Hypothesis", which argues that the implementation of environmental policies can drive technological innovation and that these innovative technologies often originate from activities such as "learning by doing" and adapting to the local environment. Hart (2004) argues that if the next generation of products is cleaner than the previous generation of products, then the introduction of pollution taxes can reduce the inventory ratios of old products, which may in turn accelerate the elimination of obsolete production capacity and encourage the research and development of new technologies. Ghisetti and Pontoni (2015) prove that if companies or private departments are required to provide compensated protection of eco-service systems, then the implementation of environmental regulations can still improve technological standards. Jaffe et al. (2002), Hamamoto (2006), Zhang et al. (2011), Nick et al. (2012) and Rubashkina et al. (2015) support the "Porter Hypothesis" from the perspective of companies and society as a whole. These studies indicate that we not only view technological innovation from the internal perspective of companies. There is another perspective that opposes the "Porter Hypothesis". Stokey (1998) argues that when the implementation of environmental regulations requires a reduction in the mining of certain fossil fuels, this requirement will not only reduce the marginal output of capital but also reduce innovation in that particular field. "Learning by doing" is restricted, and the accumulation of knowledge capital is also reduced. In addition, the reduction of capital returns also further reduces the extent of technological inputs by companies. Arduini and Cesaroni (2001) use European chemical industrial data, Nakano (2003) uses data from the Japanese paper-making industry, and Barbera and McConnel (1990) use empirical study results of US industrial data to prove that the implementation of environmental regulations does not play a significant catalytic role in technological advancement and efficiency improvement.

The above-mentioned research debates the impact of the implementation of environmental regulations on technological innovation from two opposing perspectives. However, these existing studies have not taken into account the differentiation of directed technological innovation and dynamic changes in environmental regulatory strength. First, the crux of whether the implementation of environmental regulations can be a driver of green growth lies in the correct selection of environmental regulatory strength (Li and Tao, 2012). Only by selecting the environmental regulatory strength that corresponds with the level of economic growth will the long-term implementation of environmental regulations not obstruct the green growth of society as a whole. Zhang et al. (2011) construct a model to illustrate the impact of environmental regulatory strength on technological innovation and use empirical data to demonstrate the U-shaped relationship between environmental regulatory strength and technological innovation. Shen (2012) argues that the level of economic growth determines the impact of environmental regulations on technological innovation. In China, such regulations

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92639278

have a significant catalytic effect on the highly economically developed eastern regions of China but have a suppressive effect on the central and western regions of China. Second, not all technological innovations can be effective in protecting the environment while maintaining economic growth. The differentiation of directed technological innovation is one of the core contents regarding the study of green growth drivers. Targeting the impact of the implementation of environmental regulations, Smulders and Werf (2005) differentiate technological innovations into brown technological innovations and green technological innovations. Goulder (2004) and Smulders and Nooij (2003) argue that when it is relatively difficult for capital inputs to replace resource factor inputs, investments in green technology are necessary to maintain long-term economic growth. In their model analysis, during the implementation of environmental regulations, only green technological innovations are faster than brown technology innovations, and the negative impact of the reduction in resource utilization shall be effectively offset by green technological innovations. However, in the event of market failure, there is no guarantee that technological innovation can guarantee that the expected trajectory can be achieved even while underpinned by environmental regulations. Maria and Werf (2008) demonstrate that when intellectual property cannot be protected, green technological innovation drivers may be reduced, which may cause technological innovation to shift towards brown technology. The organic direction-oriented technological innovation model constructed by Bondarev et al. (2014) further proves that with adequate guidance from environmental regulations, green technological innovation activities will be more active and boost the overall production rate and levels of economic growth.

After studying the above-mentioned literature concerning environmental regulatory strength and directed technological innovation to explore methods of how to achieve green growth, it can be observed that few academics are able to establish a quantitative model to explain these two important factors and the objective of green growth. Rauscher (2009) constructs an organic growth model based on environmental economics to quantitatively illustrate brown technological innovation investment and green technological innovation investment. Furthermore, Moser et al. (2013) use composite functions to produce a quantitative expression of green growth targets based on the model built by Rauscher (2009) and use a partial equilibrium model to analyze the directed effects of environmental regulations of different strengths on brown technological innovation and green technological innovation. The above-mentioned models are verifiable quantitative models concerning the strength of environmental regulations and directed technological innovations that verify the importance of technological innovations in realizing green growth, but they generally ignore the fact that technological innovation is a driving factor of green growth despite not being final objective. Green growth has a guiding and binding effect (Zhang and Zhu, 2012) on the direction of technological innovation. On the other hand, the utility functions concerning green growth in the model constructed by Moser et al. (2013). only takes into account a special situation in which the relative risk aversion coefficient is 1 but not general scenarios.

Therefore, the present research, which is based on the model constructed by Rauscher (2009) and Moser et al. (2013), also includes brown technological innovation and green technological innovation in the capital accumulation analytical framework. *Figure 1* shows that there is an assumption that the effect of economies of scale is unchanged and that there is perfect competition in the market, taking into account

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92639278

pollution control efforts and environmental governance costs under different environmental regulatory strengths. This has led to the creation of a non-linear optimal control model in which the objective function is the green growth target of maximizing social welfare and the constraints are ensuring sustained growth with a balanced growth rate and sustained improvement in environmental quality.

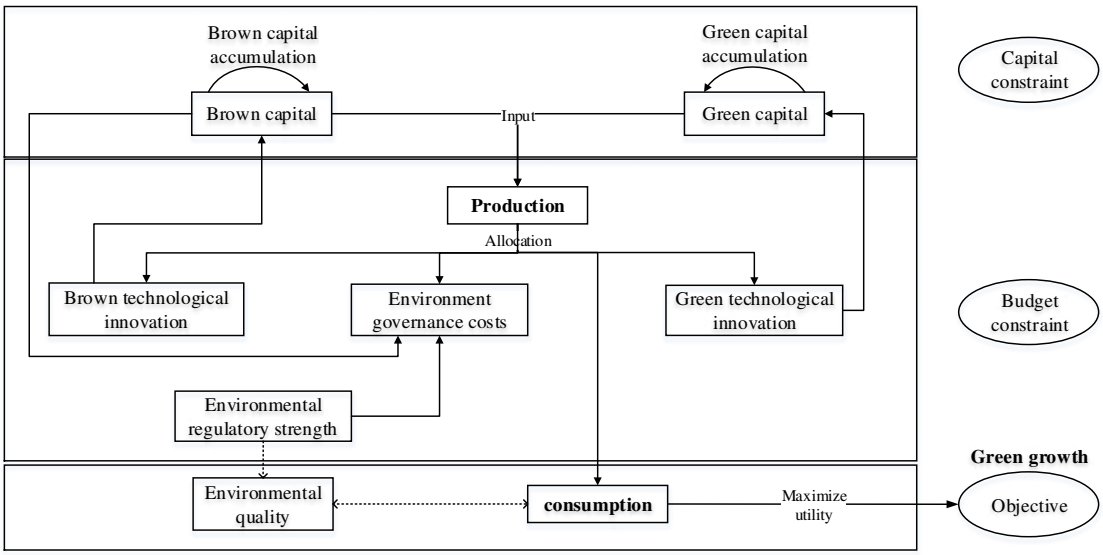

Figure 1. *Structure of the theoretical model on the impact of the environmental regulatory strength on directed technological innovation*

The second section involves hypothetical conditions concerning the impact of environmental regulatory strength on directed technological innovation, which leads to the creation of a more applicable non-linear optimal control model. The third section seeks an analytical solution to the model in a balanced situation. The fourth section uses parameter values to perform a value simulation of the model created and the analytical solution sought. Finally, we derives a research conclusion.

Materials and methods

Objective function

Regarding the utility function *U(C(t), E(t))* of the green objective, the Cobb-Douglas function format is used, and consumption *C(t)* and environmental quality *E(t)* are used as the independent variables of the utility function. For the random variables *x(t)* and $\dot{x}(t) = dx / dt$, the expression can be simplified by omitting the time variable *t* as follows:

$$U(C,E) = \begin{cases} \dfrac{(CE^{\eta})^{1-\theta}}{1-\theta}, & \theta \neq 1, 0 \leq \eta < 1, \\ \ln C + \eta \ln E, & \theta = 1, 0 \leq \eta < 1. \end{cases} \quad \text{(Eq.1)}$$

In *Eq.1*, the objective of maximizing social welfare concerns the maximizing of the total discounted value of the instantaneous utility of consumers, i.e. $\max \int_0^{\infty} U(C,E)e^{-\rho t}dt$,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92639278

where the ρ variable is the discount rate of the consumers' subjective time, $\theta>0$ is the relative risk aversion coefficient, and the weighted parameter $\eta>0$ is the environmental quality utility index.

Constraints

(1) Assuming the effects of economies of scale remain unchanged, all production uses a standardized technology to produce similar products. The Cobb-Douglas function format is adopted for the production of the product, with the production factors being differentiated into brown capital and green capital, which can be displayed as $Y=bK^{\alpha}G^{1-\alpha}$, where b is the size parameter for the production function, K is the brown capital stock, G is the green capital stock, and $\alpha\in(0,1)$ is the production flexibility of brown capital during the production process (also referred to as productive capital flexibility).

(2) Assuming the effects of economies of scale remain unchanged, we adopt the Cobb-Douglas function format for capital accumulation. The production factors are mainly composed of the capital stock and different technological innovation investment inputs, which means that the brown capital and green capital accumulation process has the form,

$$\dot{K} = dK^{\delta} R_K^{1-\delta} - \phi K \quad \text{(Eq.2)}$$

$$\dot{G} = eG^{\sigma} R_G^{1-\sigma} - \psi G \quad \text{(Eq.3)}$$

In *Eq.2* and *Eq.3*, R_K is the brown technological innovation investment and R_G is the green technological innovation investment. d is the brown capital accumulation size parameter, e is the green capital accumulation size parameter, δ, $\sigma\in(0,1)$ are production flexibilities during the accumulation of brown capital and green capital, Φ is the depreciation ratio of brown capital, and Ψ is the depreciation ratio of green capital. Assuming that the positive impact of capital stock inputs on capital accumulation is smaller than the technological innovation investment inputs, the production flexibility of capital stock amid capital accumulation should be smaller than the technological innovation investments. In other words, δ, $\sigma\in(0,0.5)$. In addition, compared to green capital, capital accumulation (Bondarev et al., 2014) is easier for brown capital. In that case, the production flexibility of green capital amid capital accumulation should not be larger than brown capital. In other words, $\sigma\leq\delta$.

(3) Assuming there is perfect competition in the market, for the products produced that can be used for consumption, brown technological innovation investments, green technological innovation investments, and environmental pollution governance, the budget constraints can be expressed as follows: $Y(K,G)-C-w(R_K+R_G)-X(E)K=0$. Here, w refers to the inorganic opportunity costs of technological innovation investments, $X(E)$ refers to the environmental regulatory strength, and $X(E)K$ refers to the environment governance costs. Among these, there is a positive relationship between environmental regulatory strengths $X(E)$ and environmental quality E. Assuming $X(E)$ concerns the monotonically increasing function of E, it can be displayed as $X(E)=aE^{\beta}$, where $a>0$ is referred to as the fixed proportional coefficient for eliminating costs and $\beta>1$ is the index for eliminating costs.

Non-linear optimal control model

To summarize the above, the utility function *U(C,E)* adopting a logarithmic form is a strongly convex function, satisfying the conditions for establishing an optimal control model. Taking into account the changes in the brown capital stock *K*, green capital stock *G*, brown technological innovation investment R_K, green technological innovation investment R_G and environmental governance costs *X(E)K*, we give the following non-linear optimal control model,

$$\max_{C,E} W = \max_{C,E} \int_0^{\infty} U(C,E) \cdot e^{-\rho t} dt \tag{Eq.4}$$

s.t. *Eq.1~Eq.3*.

$$Y = bK^{\alpha} G^{1-\alpha} \tag{Eq.5}$$

$$bK^{\alpha} G^{1-\alpha} - C - w(R_K + R_G) - aE^{\beta} \cdot K = 0 \tag{Eq.6}$$

$$K(0) = K_0 > 0\,,\ G(0) = G_0 > 0 \tag{Eq.7}$$

where R_K and R_G are the control variables and *K*, *G*, and *C* are the state variables.

To find the optimal solution, taking λ_K and λ_G to be the common-mode variables of brown capital stock *K* and green capital stock *G* (shadow prices with different capital stock), the Hamiltonian in *Eq.8* is formed as follow,

$$H(\cdot) = \frac{(CE^{\eta})^{1-\theta}}{1-\theta} + \lambda_K \left(dK^{\delta} R_K^{1-\delta} - \phi K \right) + \lambda_G \left[eG^{\sigma} R_G^{1-\sigma} - \psi G \right] \tag{Eq.8}$$

We apply standard Pontryagin maximum principle to find a control optimal in problem of *Eq.1~Eq.7*, the maximization conditions should satisfy

$$\frac{\partial H}{\partial R_K} = 0 \tag{Eq.9}$$

$$\frac{\partial H}{\partial R_G} = 0 \tag{Eq.10}$$

This maximization leads to the Euler equation,

$$\dot{\lambda}_K = -\frac{\partial H}{\partial K} + \rho \lambda_K \tag{Eq.11}$$

$$\dot{\lambda}_G = -\frac{\partial H}{\partial G} + \rho \lambda_G \tag{Eq.12}$$

DOI: http://dx.doi.org/10.15666/aeer/1704_92639278

Under the requirement that the following set of transversality conditions,

$$\lim_{t\to\infty} e^{-\rho t}\lambda_K K = 0 \tag{Eq.13}$$

$$\lim_{t\to\infty} e^{-\rho t}\lambda_G G = 0 \tag{Eq.14}$$

From *Eq.9~Eq.12*, it then follows that the costate variable associated to brown capital stock *K* and green capital stock *G*,

$$\lambda_K = \frac{wC^{-\theta}E^{\eta(1-\theta)}}{d(1-\delta)K^{\delta}R_K^{-\delta}} > 0 \tag{Eq.15}$$

$$\lambda_G = \frac{wC^{-\theta}E^{\eta(1-\theta)}}{e(1-\sigma)G^{\sigma}R_G^{-\sigma}} > 0 \tag{Eq.16}$$

In *Eq.15~Eq.16*, both λ_K and λ_G are positive values. Therefore, the Hession matrix of the Hamiltonian is as follows,

$$\begin{aligned} \mathrm{H} &= \begin{pmatrix} \dfrac{\partial^2 H}{\partial R_K^2} & \dfrac{\partial^2 H}{\partial R_K \partial R_G} \\ \dfrac{\partial^2 H}{\partial R_K \partial R_G} & \dfrac{\partial^2 H}{\partial R_G^2} \end{pmatrix} \\ &= \begin{pmatrix} -w^2\theta C^{-\theta-1}E^{\eta(1-\theta)} - \lambda_K d\delta(1-\delta)K^{\delta}R_K^{-\delta-1} & -w^2\theta C^{-\theta-1}E^{\eta(1-\theta)} \\ -w^2\theta C^{-\theta-1}E^{\eta(1-\theta)} & -w^2\theta C^{-\theta-1}E^{\eta(1-\theta)} - \lambda_G e\sigma(1-\sigma)\mathrm{G}^{\sigma}R_G^{-\sigma-1} \end{pmatrix} \end{aligned} \tag{Eq.17}$$

The *Eq.17* is negative definite, which means that current-value of the Hamiltonian is a strongly convex function which has a maximum value.

Results

From *Eq.6*, we can obtain consumption *C*, which is the function of variables *K*, *G*, R_K, and R_G, which is as follows:

$$C(K,G,R_K,R_G) = bK^{\alpha}G^{1-\alpha} - w(R_K + R_G) - aE^{\beta}K \tag{Eq.18}$$

The problem of *Eq.1~Eq.7* can be simplified to a problem with only four variables, i.e., *K*, *G*, R_K, and R_G, where *Eq.8* is the objective function, *Eq.2*, *Eq.3*, *Eq.9~Eq.14* and *Eq.18* are the constraints, R_K and R_G are the control variables, and *K* and *G* are the state variables.

From *Eq.9*, we can obtain the equation

$$\frac{\dot{\lambda}_K}{\lambda_K} = -\theta\frac{\dot{C}}{C} - \delta\frac{\dot{K}}{K} + \delta\frac{\dot{R}_K}{R_K} \tag{Eq.19}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92639278

combining *Eq.11*, we can obtain the equation

$$\frac{\dot{\lambda}_K}{\lambda_K} = \rho + \phi - d\delta\left(\frac{R_K}{K}\right)^{1-\delta} - \frac{d(1-\delta)}{w}\left(\frac{R_K}{K}\right)^{-\delta}\left[\alpha b\left(\frac{G}{K}\right)^{1-\alpha} - aE^{\beta}\right] \quad \text{(Eq.20)}$$

Similarly, from *Eq.10*, we can obtain the equation

$$\frac{\dot{\lambda}_G}{\lambda_G} = -\theta\frac{\dot{C}}{C} - \sigma\frac{\dot{G}}{G} + \sigma\frac{\dot{R}_G}{R_G} \quad \text{(Eq.21)}$$

combining *Eq.12*, we can obtain the equation

$$\frac{\dot{\lambda}_G}{\lambda_G} = \rho + \psi - e\sigma\left(\frac{R_G}{G}\right)^{1-\sigma} - \frac{e(1-\sigma)}{w}\left(\frac{R_G}{G}\right)^{-\delta}(1-\alpha)b\left(\frac{G}{K}\right)^{-\alpha} \quad \text{(Eq.22)}$$

To achieve green growth, we set K and G to be constants, which means $\dot{R}=\dot{G}=0$. Combining *Eq.2* and *Eq.3*, we can obtain the equations

$$\frac{R_K}{K} = \left(\frac{\phi}{d}\right)^{1/(1-\delta)} \quad \text{(Eq.23)}$$

$$\frac{R_G}{G} = \left(\frac{\psi}{e}\right)^{1/(1-\sigma)} \quad \text{(Eq.24)}$$

Combining *Eq.19~Eq.24*, the optimal capital allocation G/K, and the optimal growth rate of investment for different technological innovations $\dot{R}/R$, and the optimal consumption growth rate $\dot{C}/C$ can be obtained as *Eq.25~Eq.28*

$$\frac{G}{K} = \frac{e(1-\alpha)(1-\sigma)}{\alpha d(1-\delta)}\left(\frac{\psi}{e}\right)^{\sigma/(\sigma-1)}\left(\frac{d}{\phi}\right)^{\delta/(\delta-1)}\frac{\rho+\phi+\theta g-\delta\phi+\frac{ad(1-\delta)}{w}\left(\frac{\phi}{d}\right)^{\delta/(\delta-1)}E^{\beta}}{\rho+\psi+\theta g-\sigma\psi} \quad \text{(Eq.25)}$$

$$\frac{\dot{R}_K}{R_K} = \frac{\rho+\phi+\theta g_C}{\delta} - \phi - \frac{d(1-\delta)}{w\delta}\left(\frac{\phi}{d}\right)^{\delta/(\delta-1)}\left[\alpha b\left(\frac{G}{K}\right)^{1-\alpha} - aE^{\beta}\right] \quad \text{(Eq.26)}$$

$$\frac{\dot{R}_G}{R_G} = \frac{\rho+\psi+\theta g_C}{\sigma} - \psi - \frac{e(1-\sigma)}{w\sigma}\left(\frac{\psi}{e}\right)^{\sigma/(\sigma-1)}(1-\alpha)b\left(\frac{G}{K}\right)^{-\alpha} \quad \text{(Eq.27)}$$

$$\frac{\dot{C}}{C} = \rho + \psi - \sigma\psi - \frac{e(1-\sigma)}{w}\left(\frac{\psi}{e}\right)^{-\frac{\delta}{1-\delta}}(1-\alpha)b\left(\frac{G^*}{K}\right)^{-\alpha} \quad \text{(Eq.28)}$$

Discussion

Data source

The empirical value of different parameters in nonlinear optimal control model of existing research is shown as *Table 1*.

Refer to *Figure 1* for the "experience points" of different parameters for the models being researched. We perform a data simulation of the relationship between environmental regulatory strength *E*, capital allocation *G/K*, and the growth rate of investment for different technological innovations $\dot{R}/R$.

Analysis of the impact of environmental quality E on capital allocation G/K

We perform a data simulation of the impact of different environmental quality *E* on the capital allocation *G/K*, with the balanced growth rate as $g=0.0235$, the discount rate as $\rho=0.05$, productive capital flexibility as $\alpha=0.6$, and the inorganic opportunity costs of technological innovation investment as $w=0.1$, and the other parameters are fixed. *Figure 2* indicates that the capital allocation *G/K* concerns the strongly monotonically increasing concave function of the environmental regulatory strength *E*. With an increase in *E*, the environmental quality, the green capital ratio *G/(K+G)* increases and accelerates faster. When $E=0$, which represents the absence of environmental regulations, brown capital can be accumulated (Bondarev et al., 2014) relatively easily compared to green capital, which will cause brown capital to be used as much as possible during production. However, using brown capital can further pollute the environment. In addition, environmental regulations strength *X(E)* and environmental quality *E* are positively correlated, which thus results in an increase in expenditure on environmental governance costs *X(E)K*. Once the environmental quality *E* increases, the green capital ratio *G/(K+G)* presents a growth trend because the use of green capital can replace brown capital to reduce environmental pollution. At this point, brown capital is no longer considered to be critical capital for production, which causes capital

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92639278

allocation to switch towards green technological innovation. In addition, this trend becomes more significant as environmental quality E increases to $E=1$, which refers to stricter environmental regulations.

To more clearly explain the impact of environmental quality E on capital allocation G/K, we perform a data simulation of the impact of different environmental qualities E on the capital allocation G/K, with the balanced growth rate as $g=\{0,0.0135,0.0235, 0.0535\}$ and the other parameters being fixed. *Figure 2* shows that the balanced growth rate g and capital allocation G/K are negatively correlated. However, this finding does not change the impact of environmental quality E on capital allocation G/K. When the environmental quality is $E = 0.7$, the different balanced growth rates g corresponding to capital allocation ratio G/K are P_0, $P_{0.0135}$, $P_{0.0235}$, and $P_{0.0535}$, with $P_0 > P_{0.0135} > P_{0.0235} > P_{0.0535}$, respectively. The implication is that in the same environmental quality E, when the balanced growth rate g is higher, the green capital ratio $G/(K+G)$ is lower, which illustrates the production flexibility of brown capital in capital accumulation. This finding signifies the easing of the fall of capital accumulation, in which brown capital is being used as much as possible.

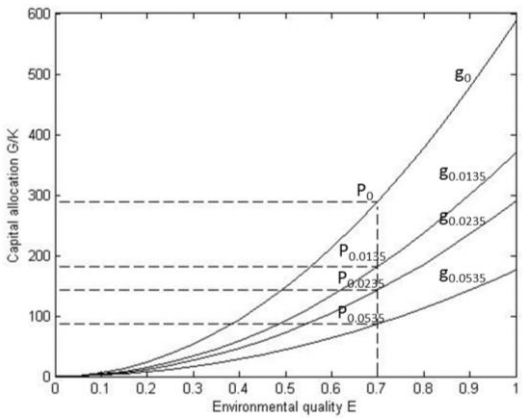

Figure 2. *Impact of balanced growth rate g on capital allocation G/K*

Furthermore, we perform a data simulation of the impact of different environmental qualities E on the capital allocation G/K where the discount rate is $\rho=\{0.001,0.01,0.015, 0.05\}$, production capital flexibility is $\alpha=\{0.8,0.7,0.6,0.5\}$, the inorganic opportunity costs of technological innovation investment are $w=\{0.05,0.1,0.15,0.2\}$, and the other parameters are fixed. *Figure 3* and *Figure 4* show that the green capital ratio $G/(K+G)$ will exhibit a growing trend when the same environmental quality E declines, the discount rate ρ declines, or production capital flexibility α declines. The implication is that when brown capital is producing, which negatively affects consumption and environmental pollution governance, the utilization of brown capital will be reduced. This reduction will stagnate the economic growth of society as a whole. Given this situation, it is possible to simulate a recovery in economic growth by simply raising green capital utilization efforts, which proves that green capital is an important pillar for maintaining the economic growth of society as a whole. On the other hand, there is a negative correlation between the inorganic opportunity costs of technological innovation investment w and the green capital ratio $G/(K+G)$. For details, refer to *Figure 5*. Assuming that environmental quality E does not change, the increase in the inorganic opportunity costs of technological innovation investment w means that similar

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92639278

subsidies are given whether the technological innovation is green or brown. The implication is that provided that the requirements under environmental qualities *E* are satisfied, priority is given to the utilization of brown capital. Thus, brown capital shall enjoy greater production flexibility in capital accumulation.

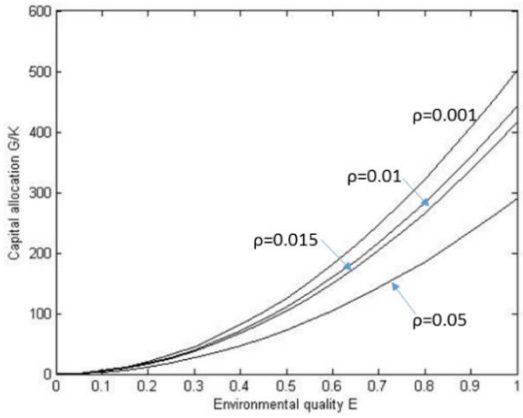

Figure 3. *Impact of discount rate ρ on capital allocation G/K*

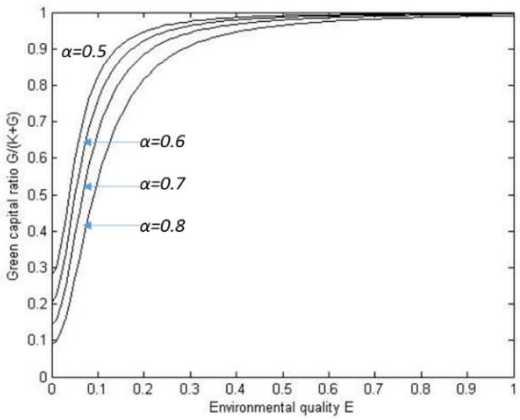

Figure 4. *Impact of production capital flexibility α on capital allocation G/K*

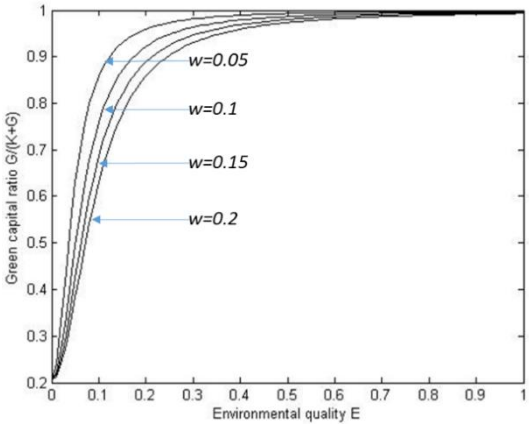

Figure 5. *Impact of technological innovation investment inorganic opportunity costs w on capital allocation G/K*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92639278

Impact of capital allocation G/K on the optimal consumption growth rate Ċ/C

Incorporating *Eq.25* in *Eq.26* and *Eq.27*, the growth rate of investment for different technological innovations $\dot{R}/R$ reconstructs the partial derivatives of capital allocation G/K

$$\frac{\partial \dot{R}_K / R_K}{\partial G / K} = -\frac{\alpha b d (1-\delta)(1-\alpha)}{w\delta}\left(\frac{g_K + \phi}{d}\right)^{\delta/(\delta-1)}\left(\frac{G}{K}\right)^{-\alpha} < 0 \qquad \text{(Eq.29)}$$

$$\frac{\partial \dot{R}_G / R_G}{\partial G / K} = \frac{\alpha b e (1-\alpha)(1-\sigma)}{w\sigma}\left(\frac{g_G + \psi}{e}\right)^{\sigma/(\sigma-1)}\left(\frac{G}{K}\right)^{-1-\alpha} > 0 \qquad \text{(Eq.30)}$$

From *Eq.29* and *Eq.30*, it is observed that the obtainable investment ratio of brown technological innovation $\dot{R}_K/R_K$ is related to the monotonous decreasing function of capital allocation G/K. In addition, the investment rate of green technological innovation $\dot{R}_G/R_G$ is related to the monotonous increasing function of capital allocation G/K. We perform a data simulation of the impact of different capital allocation G/K on the investment rate of technological innovation $\dot{R}/R$ with $g=0.0135$ and the other parameters being fixed. *Figure 6* shows that the investment rate of both brown technological innovation $\dot{R}_K/R_K$ and the investment rate of green technological innovation $\dot{R}_G/R_G$ converge to a certain fixed value; however, the convergence value of the investment rate of green technological innovation $\dot{R}_G/R_G$ is higher than the investment rate of brown technological innovation $\dot{R}_K/R_K$. Once, which means that the investments rates of technological innovation have reached equilibrium, the capital allocation $(G/K)^*$ reaches the optimal balanced capital allocation ratio $(G/K)^*=0.5$. The implication is that green technological innovation investments relative to brown technological innovation investments can bring about a greater value of economic growth.

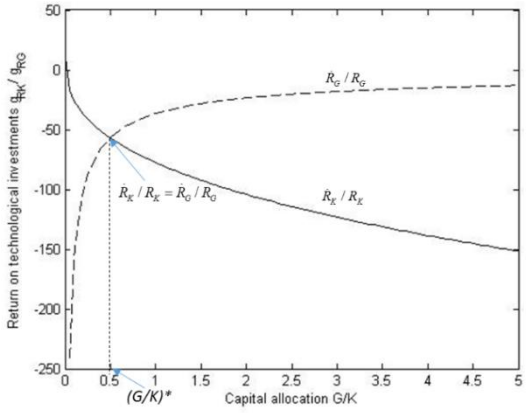

Figure 6. *Impact of capital allocation G/K on the rate of technological investments Ṙ/R*

To further clarify the impact of capital allocation G/K on the optimal consumption growth rate $\dot{C}/C$, we perform a simulation on the impact of different capital allocation G/K on the optimal consumption growth rate $\dot{C}/C$, where the capital allocation ratio is $G/K=\{0.2,0.5,1\}$ and the other parameters are fixed. *Figure 7* shows that for different

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92639278

capital allocation ratios *G/K*, the trajectory of the optimal consumption growth rate is different. Only when *G/K=0.5* is the optimal consumption growth rate the highest. In addition, with an increase in environmental regulations, there is a monotonic increase in the optimal consumption growth rate. Regarding two other situations in which *G/K<0.5* and *G/K>0.5*, the optimal consumption growth rate must be lower than *G/K=0.5*. Simultaneously, from the analysis in *Figure 6*, we know that *G/K=0.5* is also the equilibrium point of the investment rate of technological innovation.

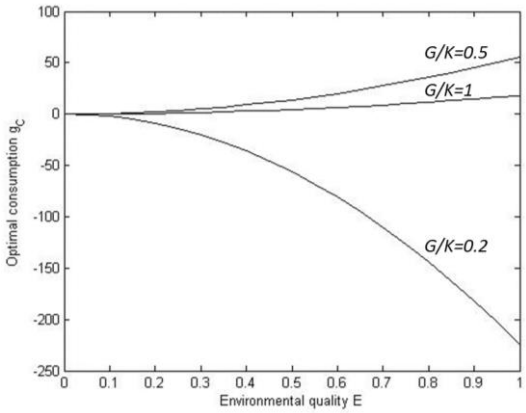

Figure 7. *Impact of capital allocation G/K on optimal consumption growth rate Ċ/C*

Because it is not necessary to consider a negative impact on the environment due to the lower research and development costs of brown technological innovation, the products that were put into production will have greater profits and market potential. Therefore, brown capital stock will increase by a greater extent along with capital accumulation. However, this increase may easily spark a new vicious cycle of economic growth that over-relies on brown technological innovation. By analyzing the optimal consumption growth rate, we can determine that it is mainly driven by brown capital and that the impact of green capital on the optimal consumption growth rate must be lower than that of brown capital. In addition, other than consumption per se, environmental improvements would benefit the social welfare that people eventually seek. Therefore, from another perspective, as environmental regulations increase, even if green capital does not result in a rapid growth in consumption, improvements in the environment will compensate for this shortcoming, which not only proves that the implementation of environmental regulations can help increase the drivers of green technological innovation but also further proves that green technological innovation can boost the economic growth of society as a whole. The reason is the social value that it brings is much greater. In particular, it can also effectively ease the negative impact on the environment.

Conclusion

From the perspective of green growth theory, the present research takes into account the impact of the implementation of environmental regulations on directed technological innovations and incorporates the following into the framework for the analysis of capital accumulation:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92639278

(1) Brown technological innovation that involves environmental regulations and environmental governance costs;

(2) Green technological innovations that can effectively protect the environment.

Assuming the effect of the economies of scale remains unchanged and that there is perfect competition in the market, we draw reference from the method of quantitative expression of green growth targets by Moser et al. (2013) and the method of brown technological innovation investment and green technological innovation investments by Rauscher (2009). In doing so, we construct a non-linear optimal control model in which the relative risk aversion coefficient >0, the green growth target of maximizing social welfare is the objective function, and the constraint is the ensuring of the constant growth of the balanced growth rate and the constant improvement in environmental quality. Using optimal control theory and the maximum principle, we separately obtain the quantitative expression for the investment rate of brown technological innovation $\dot{R}_K/R_K$, the investment rate of green technological innovation $\dot{R}_G/R_G$, and capital allocation G/K. Finally, we perform a data simulation of the problem regarding the impact of environmental regulatory strength on the selection of directed technological innovation to drive the economic growth of society as a whole. The simulation results are as follows:

(1) Environmental regulatory strength E has a positive impact on the green capital ratio $G/(K+G)$, which means that the implementation of environmental regulations can subdue the increase in environmental pollution and achieve the shift of capital allocation towards green technological innovation fields.

(2) The balanced growth rate g, the discount ratio ρ, productive capital flexibility α, and the inorganic opportunity costs of technological innovation investment w have a negative impact on the green capital ratio $G/(K+G)$, which proves that brown capital has superior production flexibility in capital accumulation. Although this finding means that brown capital can ease the fall in capital accumulation, it also proves that green capital is necessary for the economic growth of society as a whole.

(3) The green capital ratio $G/(K+G)$ has a negative impact on the investment rate of brown technological innovation $\dot{R}_K/R_K$ and a positive impact on the investment rate of green technological innovation $\dot{R}_G/R_G$. However, green technological innovation, relative to brown technological innovation, can create a greater value of economic growth.

(4) The environmental quality E has a positive impact on the investment rate of technological innovation $\dot{R}_K/R_K = \dot{R}_G/R_G$ and the corresponding green capital ratio $G/(K+G)$ when in a balanced state. This result not only reconfirms that the stronger the implementation of environmental regulations is, the more it benefits the utilization of green capital, but it also further affirms that the implementation of environmental regulations will direct capital allocation towards the new field of green technological innovations. The reason is the utilization of green technological innovations shall play a more effective role than brown technological innovations in achieving green growth (a rise in economic growth and improvement in environmental quality).

The above-mentioned simulation results can provide government decision makers with proven management guidance in formulating suitable environmental regulations with the aim of directing capital allocation towards green technological innovation fields and further achieving green growth. However, the present research also takes into account relatively ideal external factors such as the effects of economies of scale remaining unchanged, the operating status of the market economy, the relationship

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92639278

between pollution governance efforts and environmental regulatory strength, the capital allocation, and production technological conditions under different types of capital. Therefore, our next research direction will involve taking into account more realistic factors or problems with green growth after adequately broadening the scope of the above-mentioned assumptions.

Abstract. This study focuses on sewage sludge treatment and applies the Bad Output model to deal with desirable and undesirable outputs independently. This approach provides an objective way to assess the technical efficiency of wastewater treatment plants in eastern China and provides a reference for the development of the Midwest. The efficiency score results of 518 plants show some volatility - the average efficiency score is 0.29; 27 plants' efficiency scores are close to 1; 146 plants have an efficiency score of between 1 and the average efficiency score. The higher efficiency score regions are Hainan, Guangdong, Fujian, and Beijing, while by contrast, Hebei, Shanghai, and Tianjin have average efficiency scores lower than the other regions. The results of the adjustment ratio in wastewater treatment or sewage sludge water contents illustrate that most regions exhibit efficiency volatility, and some regions can no longer can support wastewater treatment or sewage sludge water contents.
Keywords: *data envelopment analysis (DEA), undesirable outputs mode, wastewater treatment efficiency, sewage sludge water contents*

Introduction

Ever since the initiation of market reforms and opening up in China, its economy has developed very rapidly. In 2014, China's GDP hit US$ 10.36 trillion, accounting for 13.3% of the world's total GDP. At the same time, energy consumption has also grown rapidly with economic growth, accounting for 21.09% of global energy consumption in 2014 (National Bureau of Statistics, 2015). It has also brought about serious environmental pollution, in order to promote economic development China has proposed the binding target of "energy conservation and emission reduction" during the "11th Five-Year Plan". For the "12th Five-Year Plan", the target is to cut the country's energy consumption per unit of GDP by 18.4%. China's State Council's "Thirteenth Five Energy-saving Emission Reduction Comprehensive Work Plan" stated that by 2020, energy consumed should only be 15% of China's GDP level in 2015.

The sewage treatment process requires a lot of energy, and thus the sewage treatment industry is also an "energy saving" binding indicator for the integrated source of pollution in the area of intensive treatment. Under the increase of industrialization and an improvement in people's environmental awareness, the wastewater treatment industry in China has developed quite strongly. At the end of 2014, China had a total of 3362 urban wastewater treatment plants (WWTPs) with a total capacity of 160 million tons / day and a total wastewater treatment volume of 47.6 billion tons. Due to the continuous improvement of effluent quality requirements of WWTPs, the energy consumption cost of these plants accounts for 40%-80% of its operation and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92799290

maintenance costs, with the power consumption of wastewater treatment increasing to 0.3 kwh/m^3. Moreover, at least 83% of WWTPs consume more energy than found in the data, which is more than 0.45 kwh/m^3. Compared to other developed countries, the difference is significant (Pan, 2014). Wastewater treatment costs are now averaging at US$ 0.8/m^3, and high energy problems have become major urban wastewater treatment operating efficiency constraints.

Due to the high operating costs of sewage treatment plants, low load rates, and other issues, some municipal wastewater treatments plants cannot operate normally, or even operate inefficiently for a long time, or even are left unused, thus resulting in the failure of WWTPs to play the role of water protection and also causinga waste of huge investment capital. Studies on the efficiency of WWTPs may help to significantly reduce costs, improve environmental improvements, and also maintain the sustainability of WWTPs (Guerrini et al., 2013; Georgieva, 2017).

The operation of a wastewater treatment plant is accompanied by a large amount of sludge. With the improvement of wastewater treatment capacity and improvement of effluent quality in China, the amount of sludge is increasing at an annual rate of 15%. Sludge disposal has therefore become an increasingly prominent environmental problem in the country. Sludge treatment also affects the entire wastewater treatment plant operation results. While a reasonable and safe disposal of sludge is an important part of the municipal wastewater treatment process, unfortunately, for the reasons of a lack of capital in China, insufficient knowledge, and limited technology and policy, the disposal of sludge has not been paid enough attention. The existence of the hidden danger of secondary pollution caused by the sludge problem greatly reduces the environmental benefits produced by WWTPs and has caught the nation's concern (Dai, 2012). Assessing the efficiency of WWTPs but ignoring the sludge indicator will produce an unbiased result and also departs from the actual problem of these plants in China. However, traditional efficiency measures of WWTPs focus only on the desirable outputs and fail to consider environmentally undesirable by-products of the production processes.

Within the extensive literature on data envelopment analysis (DEA), comparatively little research has focused on the relationship between desirable and undesirable output. Some studies that have include Yang and Pollitt (2009), Emrouznejad et al. (2010), Sueyoshi and Goto (2011), Wang et al. (2012), and Chiu et al. (2016). This literature provides a good research perspective and analysis approach for our own study to bring the sludge indicator in as an undesirable output.

In view of the problems mentioned above, the purpose of this study focuses on analyzing the efficiency of WWTPs by incorporating the results in Tone (2001) who advocate an undesirable output in the variable-returns-to- scale envelopment models. After its market reforms and opening up, economic growth in eastern China has always been higher than in the central and western regions. By the end of 2014, the eastern region's GDP accounted for 55.34% of the national total, far exceeding the total from the central and western regions. Economic development has been accompanied by resource consumption and environmental pollution, so that at the end of 2014, the eastern region's industrial wastewater emissions and urban domestic sewage emissions accounted for 53.24% and 52.46% of the country's total, respectively. At the same time, the eastern region's industrial wastewater treatment investment is also far higher than that in the central and western regions, accounting for over 55% of the national total. Therefore, analyzing wastewater treatment in the eastern region is of great significance

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92799290

for China to achieve its goal of "energy conservation and emission reduction" and to build a resource-saving and environment-friendly society. This can also be a reference for the development of the Midwest.

The remainder of this study is the following. Section 2 is the literature review. Section 3 is the research method. Section 4 is the empirical results. Section 5 is the conclusions.

The performance measurement of WWTPs in the past has focused on improving the technical indicators to obtain good effluent quality (Wen et al., 2009; Bolong et al., 2009; Santos et al., 2011; Zanetti et al., 2012; Luo et al., 2014; Zhang et al., 2016). As the research has deepened in this field along with the development of analysis methods, scholars have proposed integrated performance indicators that are technical, economic, and environmental in quantitative analysis (Yang, 2017).

Stochastic frontier analysis (SFA) and Data Envelopment Analysis (DEA) are two main approaches for efficiency assessment - namely, parametric and non-parametric methods (Tiedemann et al., 2010; Ferro et al., 2014). Both of these two methods have been widely used to estimate the efficiency of water utilities (Guerrini et al., 2011; Portela et al., 2011; Guerrini et al., 2013; Carvalho and Marques, 2014; Lannier and Porcher, 2014).

Many studies document the usefulness of the efficiency assessment of WWTPs and measure the so-called efficiency in order to save operational cost and improve sustainability (Hernández-Sancho et al., 2011; Sala-Garrido et al., 2012; Molinos-Senante et al., 2014, 2015b; Chen et al., 2015; Guerrini et al., 2015). Yang (2017) adopts the DEA-SBM model to measure the TFE of wastewater control in 39 industrial sectors in China from 2003 to 2014. However, these studies above only set positive inputs and outputs, and most scholars focus on sludge treatment like sludge stabilization with various physical, chemical, and biological technologies (Zhang et al., 2007; Kelessidis and Stasinakis, 2012; Yu et al., 2013; Yang et al., 2015; He et al., 2018;) and sludge disposal methods such as sanitary landfill, incineration, land application, and building materials (Cai et al., 2007; Hale et al., 2012; Wang et al., 2012). Few studies in the literature look at sludge efficiency in an economic way. Sewage sludge as an inevitable by-product of the wastewater treatment process, which may result in secondary pollution, presents a number of environmental concerns, but no study adopts a sewage sludge indicator as an undesirable output to comprehensively assess the efficiency of WWTPs.

Various approaches recently have enabled DEA to deal with undesirable outputs. They can be summarized into four types as follows (Gomes and Lins, 2007; Chiu et al., 2016). The first method uses a reciprocal of undesirable output to evaluate the efficiency (Golany and Roll, 1989; Lovell et al., 1995; Scheel, 2001). The second method considers the undesirable outputs as inputs (Hailu and Veeman, 2001). The third one is the data transformation function approach (Seiford and Zhu, 2002, 2005). The last type is the directional distance function approach (Chung et al., 1997). Alternatively, Tone (2001) proposes a slacks-based measure of efficiency, which is non-radial and non-oriented, and deals with input/output slacks directly. Following this is Sharp et al. (2007), who modify the slacks-based measure to overcome the lack of translation invariance by drawing on the ideas from the range directional model.

These articles have been recently extended to energy and environment studies, but do not evaluate the efficiency of WWTPs. Evaluating the efficiency of WWTPs without considering the sludge problem, which may cause secondary pollution, will be biased.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92799290

The reasonable and safe disposal of sludge has especially become an important bottleneck, actually restricting the healthy and benign development of WWTPs in China. Therefore, our study comprehensively considers the economic and environmental benefits of WWTPs and constructs a DEA model with sludge disposal as an undesirable output in order to objectively evaluate the efficiency.

Because of the different economic development levels, urbanization process, and natural geographical conditions in the different regions and provinces of China, there are some obviously differences about wastewater treatment, such as wastewater emissions and the total volume of disposal wastewater and utilization rate of WWTPs between eastern and western cities. Since the eastern region is the most developed area of China, it contributes more than 50% to economic volume. Thus, the development of WWTPs in eastern China is also in the leading position along with serious sludge treatment, and hence our study focus on the eastern region to evaluate the efficiency of WWTPs and uses anundesirable output DEA model. The results provide effective suggestions for China.

Materials and methods

DEA method

Data Envelopment Analysis (DEA) is a method for measuring the relative efficiency of a set of Decision Making Units (DMUs), which apply multiple inputs to produce multiple outputs over a period of time. DEA was originally developed by Charnes et al. (1978) under the assumption of constant returns to scale (CCR model). Banker et al. (1984) extend the CCR model to include variable returns to scale and develop the BCC model.

In the Banker et al. (1984) model, we denote the set of DMUs as J, where each DMU j ∈J. Let us define the following variables: Y_j is the output of the DMU, X_i is the input of the DMU, Z_i is the weight of DMU, and s_j^- and s_j^+ are the input slacks and the output slacks, respectively. Here, θ_i is the score of the DMU. We set up the input-oriented BCC method used to calculate technical efficiency as:

$$\max: \theta$$

$$\text{s.t.} \sum_{j=1}^{n} z_j x_j + s^- = x_0$$

$$\sum_{j=1}^{n} z_j y_j - s^+ = \theta y_0$$

$$\sum_{j=1}^{n} z_j = 1$$

$$z_j \geq 0, j = 1, \cdots, n$$

Though CCR and BCC mainly focus on desirable output or input, in the real world the production process or the content of output may not be a desirable output. In an actual production process, unwanted by-products may appear during input and output conversion, such as wastewater, exhaust gas, and carbon dioxide. In the traditional DEA

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92799290

model, if the relative inefficient DMUs have desirable (good) and undesirable (bad) inputs/outputs to adjust, then they increase or decrease simultaneously, because they cannot just increase the desirable output yet not decrease the undesirable output.

To address the above problem, Tone (2001) applies the undesirable DEA model, which classifies output items into desirable and undesirable outputs. Both kinds of outputs have no inter-relationship, which isdifferent from the undesirable output model where a reduction of bad outputs inevitably reduces desirable outputs. Hence, this situation can be improved.

Undesirable outputs model

In light of the environmental protection consciousness in modern society, undesirable outputs of production and social activities, e.g., hazardous wastes and air pollutants have been strongly recognized as societal maladies. Thus, the development of technologies with less undesirable outputs is the main subject in every area of production. DEA usually assumes that producing more outputs relative to less input resources illustrates a standard of efficiency. In the presence of undesirable outputs, nevertheless, technologies with more desirable outputs and less undesirable outputs relative to less input resources should be recognized as being efficient.

This model deals with the same problem by applying a slacks-based measure of efficiency (SBM). SBM is non-radial and non-oriented and utilizes input and output slacks directly in producing an efficiency measure. This paper applies the Bad Output model to deal with desirable and undesirable outputs independently. We decompose the output matrix Y into (Y^g, Y^b), where Y^g and Y^b denote desirable and undesirable output matrices, respectively. For a DMU (x_o, y_o), the decomposition is denoted as (x_o, y_o^g, y_o^b).

We conceptualize the production possibility set defined as *Eq.1*:

$$P = \left\{ \left((x, y^g, y^b) \middle| x \geq X\lambda, y^g \leq Y^g\lambda, y^b \geq Y^b\lambda, L \leq e\lambda \leq U, \lambda \geq 0 \right) \right\} \quad \text{(Eq.1)}$$

Here, λ is the intensity vector, and L and U are the lower and upper bounds of the intensity vector, respectively. We define the efficiency status in this framework as follows.

A DMU (x_o, y_o^g, y_o^b) is efficient in the presence of bad outputs, if there is no vector $(x_o, y^g, y^b) \in P$ such that $x_o \geq x, y_o^g \leq y^g, y_o^b \geq y^b$with at least one stringent inequality.

According to the definition, SBM runs as *Eq.2*:

$$\theta^* = \min \frac{1 - \frac{1}{m}\sum_{i=1}^{m} \frac{\bar{s_{io}}}{x_{io}}}{1 + \frac{1}{s}\left(\sum_{r=1}^{s_1} \frac{s_r^g}{y_{ro}^g} + \sum_{r=1}^{s_2} \frac{s_r^b}{y_{ro}^b} \right)}$$

subject to

$$x_o = X\lambda + s^-$$
$$y_o^g = Y\lambda - s^g$$
$$y_o^b = Y\lambda + s^b \quad \text{(Eq.2)}$$
$$L \leq e\lambda \leq U$$
$$s^-, s^g, s^b, \lambda \geq 0$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92799290

The vectors s^- and s^b correspond to excesses in inputs and undesirable outputs, respectively, while s^g expresses shortages in desirable outputs. Here, s_1 and s_2 denote the number of elements in s^b and s^g, and $s = s_1 + s_2$. Let an optimal solution of the above program be $(\theta^*, s^{-^*}, s^{g^*}, s^{b^*})$. We can then illustrate that the DMU (x_o, y_o^g, y_o^b) is efficient in the presence of undesirable outputs if and only if $\theta^* = 1, \text{i.e.}, s^{-^*} = 0, s^{g^*} = 0, s^{b^*} = 0$. If the DMU is inefficient, i.e., $\theta^* < 1$, then it can be improved and become efficient by deleting the excesses in inputs and undesirable outputs and increasing the shortfalls in desirable outputs by the following projection *Eq.3*.

$$x_o \Leftarrow x_o - s^{-^*} \qquad y_o^g \Leftarrow y_o^g + s^{g^*} \; y_o^b \Leftarrow y_o^b - s^{b^*} \tag{Eq.3}$$

In the Undesirable (Bad) Output model, we set weights upon undesirable and desirable outputs through the keyboard before running the model. If we supply $w_1 (\geq 0)$ and w_2 (≥ 0) as the weights to desirable and undesirable outputs, respectively, then the model calculates the relative weights as $W_1 = sw_1/(w_1 + w_2)$ and $W_2 = sw_2/(w_1 + w_2)$, W2 =sw2(w1 +w2), and the objective function is then modified to *Eq.4*:

$$\theta^* = \min \frac{1 - \frac{1}{m} \sum_{i=1}^{m} \frac{\bar{s_{io}}}{x_{io}}}{1 + \frac{1}{s} \left(w_1 \sum_{r=1}^{s_1} \frac{s_r^g}{y_{ro}^g} + w_2 \sum_{r=1}^{s_2} \frac{s_r^b}{y_{ro}^b} \right)} \tag{Eq.4}$$

The defaults in *Eq.4* are w_1 =1 and w_2 =1. In accordance with the degree of stress on undesirable outputs evaluation, you can put a large w_2 against w_1, and vice versa.

Results

The research samples cover the 518 WWTPs in eastern China according to the China Energy Statistical Yearbook dataset in 2015. We use ten regions and five variables here, as shown in *Table 1*: the regions are Shanghai, Shandong, Guangdong, Tianjin, Beijing, Jiangsu, Liaoning, Hebei, Hainan, and Fujian. The five variables include two as output variables and three as input variables. The output variables are wastewater treatment and the undesirable output of sewage sludge water contents; the input variables are equipment investment, electricity usage, and employees. This study concludes with implications for theoretical research. These variables may lead to a better understanding and merging with input variables and output variables of recent studies. The input variables and output variables are shown to be significantly related.

In order to clarify the influence of the regions, we conduct an analysis of Shandong, Guangdong, and the other regions, with *Table 2* presenting the descriptive statistics of the input and output variable data for them as follows.

(1) Wastewater treatment: The wastewater treatment average of all plants is 18.335 million m^3, where Shandong is 18.171 million m^3, and Guangdong is 25.257 million m^3. The max wastewater treatment plant is 328.5 million m^3 from Beijing, while the lowest wastewater treatment plant is 10.95 million m^3 from Shandong.

(2) Sewage sludge water contents: In general, for the water content of sewage sludge, a lower value is better. The average sewage sludge water contents from the 518 plants

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92799290

are 76.36%. Shandong is 77.65%, Guangdong is 75.71%, and the other regions are 76.14%. The average sewage sludge water content is higher by 1.28% at Shandong versus Guangdong is lower 0.65%, other regions lower 0.23%. The lowest sewage sludge water content plant is 0.8% from Jiangsu, while the highest sewage sludge water content plant is 99% from Liaoning. In general, a lower sewage sludge water content is better. Guangdong and other regions have lower sewage sludge water contents than Shandong in 2014 -that is, Shandong must improve versus the other regions in terms of controlling sewage sludge water content.

(3) Equipment investment: Equipment investment increased at an average rise of CNY 16.417 million. The highest equipment investment is CNY 6.818 billion in Jiangsu, with the lowest equipment investment at CNY 0.156 in Guangdong.

(4) Electricity usage: The average electricity usage of all plants is 4,487,008.87 kwh, where Shandong is 4,749,826.54 kwh, and Guangdong is 5,364,878.92 kwh. The highest electricity usage plant is at 96,054,400 kwh in Guangdong, while the lowest electricity usage plant is at 47.46 kwh in Hainan.

(5) Employees: The average number of employees of all plants is 62.64 persons, where Shandong is 71.56 persons and Guangdong is 78.75 persons. The plant with the most employees is in Shandong at 575 persons, while Fujian, Guangdong, and Liaoning have 6 persons in their plants, representing the least number of employees.

Discussion

The wastewater treatment of China was 71.617 billion m^3 in 2014, with 37.727 billion m^3 from the eastern region. By contrast, this area value GDP, water resources and wastewater treatment highly with other area.

We use DEA-Solver software to evaluate the 518 WWTPs' efficiency and analyze each plant's ranking. From the undesirable model, we find that 27 plants have efficiencies equal to 1. More plants from Guangdong have an efficiency score equal to 1.

Table 3 shows the differences between the average efficiency score and the higher/lower average efficiency score of each region. The average efficiency score is 0.29 for the 518 plants, and the higher efficiency score regions are Hainan, Guangdong, Fujian, and Beijing. Hainan and Beijing have a greater percentage of efficiency scores close to 1 versus the other regions. The plants' average efficiency score between 1 and average efficiency score was 146 plants in 2014 and the major regions were form Guangdong, Fujian and Shandong. In some regions, the average efficiency score is lower, because, they no longer are able to support wastewater treatment or sewage sludge water contents. For example, Hebei, Shanghai, and Tianjin, their average efficiency scores are lower than the other regions.

Table 3. *Efficiency score results of each region*

Region	Over all of the Efficiency Score					Between 1 and Average Efficiency Score		
	Total	Average	Score=1	Percentages of the score=1	Higher Average Percentage	Total	Average	Percentages
Guangdong	142	0.37	13	9.15%	52.11%	61	0.41	42.96%
Shandong	117	0.26	5	4.27%	50.00%	20	0.46	17.09%

Data source: Authors' Collection

Table 4 lists the ten regions' efficiency score and improvement by the undesirable model. We note that there are several issues between regions and their efficiency score. For example, in Fujian, Guangdong, Liaoning, and Hainan, their average efficiency scores are higher than the other regions. In other words, each region has too much investment into the input variables; Jiangsu by CNY 699,193; Shandong by CNY 56.59 million; and Guangdong by CNY 23.35 million on equipment investment. Guangdong exceeds electricity usage by 405,729,807 kwh; Shandong by 394,761,772 kwh; and Jiangsu by 178,827,079 kwh. By contrast, the output variables should be increased in each region. Jiangsu should increase 4,973 thousand m^3, Jiangsu should be increase 2,137 thousand m^3 and Jiangsu should be increase 2,061 thousand m^3 in the wastewater treatment, and the sewage sludge water contents should be decrease 602 percentages in Guangdong, 355 percentages in Jiangsu and 336 percentages in Fujian.

Conclusion

The GDP of China is US$ 10.36 trillion, making upto 13.3% of global GDP and 21.09% of global energy consumption. Environmental topics in recent years have become more popular in the world, but few scholars have discussed wastewater treatment efficiency and the effects of sewage sludge water contents. Some regions in China have spent a lot of resources into increasing wastewater treatment or reducing sewage sludge water contents, while some regions have lower efficiency scores versus others. Some regions' efficiency score has fallen in order to control electricity usage or equipment investment.

This research reports the efficiency scoresof regions in China by the Tone (2001) undesirable DEA Model. After evaluating ten regions and data on 518 plants in eastern China, we provide the following conclusions below.

(1) The efficiency scores from the 518 plants exhibit some volatility: 27 plants have efficiency scores close to 1; 146 plants have efficiency scores between 1 and 0.

(2) The average efficiency score is 0.29 from the 518 plants, with higher efficiency scores coming from Hainan, Guangdong, Fujian, and Beijing. By contrast, Hebei, Shanghai, and Tianjin have average efficiency scores that are lower than the other regions.

(3) There are 491 inefficient plants, whose average efficiency score is 0.25. The inputs including equimpment investment, electricity usage and employee of WWTPs performed invest too much, which need to be decreased by different level. The equimpment investment excess the optimum level of CNY 838,588, the exctricity usage with the excess consumption of 1,424,874,714 kwh, and the employee with the excess of 23,334 persons.The wastewater treatment volume need to be increase 13,326 thousand m^3 and sewage sludge water contents will be decrease 1,997 percentages.

The efficiency results of wasteter treatment assessment will be different while considersing the sludge problem or not. As a by-product, sludge in WWTPs is harmful to the environment, which is urgent to strenthen the treatment and disposal. At present, 90% WWTPs in China have realized sludge dewatering and reduction treatment, but the proportion of WWTPs that have achieved sludge biological stabilization treatment is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ●ISSN1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92799290

less than 3%. Most of the sludge has not been stabilized and landfill directly, and less than 20% sludge has been safely treated and disposed (Kan Liao et al., 2019). The efficiency of WWTPs can be evaluated comprehensively and objectively by building the index system with sludge indicator in. In order to impove the efficiency of WWTPs, it is necessary to regularly maintain the machineryandequipmentand improve its utilization efficiency, also control the electricity consompution to reduce electricity charges, and reasonably allocate the staff to control labor costs.

(Received 3rd Apr 2019; accepted 17th May 2019)

Abstract. With complex composition and wide distribution, the urban solid wastes increase with the intensity and range of human activities. After analyzing benefits and performance, this paper sets up a benefit-performance model for urban solid wastes, and discusses the logistics pricing system for solid wastes in the municipal districts of south eastern China's Hangzhou. The research results show that: the logistics pricing system for urban solid wastes contains transport pricing and disposal pricing; the "reverse logistics" of solid wastes can produce economic benefits, and the most economic way to dispose of solid wastes is to transport them to the terminal station for treatment; the dual variable reflects the relationship between the disposal amount and logistics pricing of solid wastes; there is an optimal daily disposal volume for solid wastes in the transfer stations of each municipal district in Hangzhou; if the daily disposal volume is below or above the allowable range computed by the decision variable in the objective function, then the logistics pricing will increase. The research findings lay the theoretical basis for the design of the logistics pricing system for urban solid wastes that combines environmental and economic benefits.
Keywords: *solid waste, benefit-performance, logistics pricing, reverse logistics, economic benefits*

Introduction

Recent years has seen the proliferation of environmental problems from developed countries to developing countries. For example, the environment in China is now threatened by the growth in resource demand and urban population, which is fueled by the booming economy. In urban areas, the greatest threat to environment lies in the treatment of solid wastes (Garchitorena et al., 2017; Marino et al., 2017; Gattringer, 2018; Zheng et al., 2018). The various kinds of solid wastes produced by urban citizens are both uncertain and risky to process and difficult to manage. According to incomplete statistics, each urban citizen generates 0.60~1.40 kg/day of solid wastes, half of which is catering waste (Gendron, 2014). In addition, there are many problems in the management of urban solid wastes. With significant regional differences, the logistics dispatch of such wastes mainly depends on fiscal appropriation and economic benefits (Frank et al., 2016).

Currently, urban solid wastes are being treated through landfill, incineration, composting or comprehensive method, aiming to turn them into harmless substances (Lan et al., 2012; Mangone, 2016). Some scholars have created a logistics pricing model for solid wastes based on cost-effectiveness, which minimizes the disposal cost of urban solid wastes, achieves complete non-hazardous treatment and realizes multi-objective optimization of logistics pricing system (Ostberg et al., 2012; Lan, 2018). Some scholars found that it is much costlier to mitigate the environmental pollution of solid wastes than transport such wastes, and suggested to analyze the logistics cost-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92919300

effectiveness of solid wastes based on logistics pricing system before solving the environmental and economic problems caused by solid wastes (Zhang et al., 2011).

From the perspective of marketization, this paper analyzes the benefits and performance of the logistics pricing system for solid wastes in the municipal districts of southeastern China's Hangzhou, with the aim to develop an economical logistics pricing system.

Materials and Methods

Logistics cover the entire process of transport, facility operation and management. Similarly, logistics pricing involves such aspects as transport, facilities and management (Ambrogi and Mineo, 2016; Feng et al., 2017; Lalami et al., 2017; Li et al., 2017; Duan, 2018; Tan et al., 2018). The logistics of solid wastes can be divided into "forward" logistics and "reverse logistics". The latter refers to the recycling and reuse of solid wastes. In this paper, the logistics of solid wastes refers to the economic cost of the collection, classification, handling or storage of solid wastes (Mulligan and Lombardo, 2016). There is no "reverse logistics" in traditional solid waste logistics systems (Ayodele et al., 2018). With the growing awareness of eco-environmental protection, more and more people now favor the green treatment of solid waste, giving birth to the "resource-product-waste-renewable resource" economic model. In this way, the logistics cost of solid wastes has plunged over the years. *Figure 1* illustrates the logistics network for urban solid wastes.

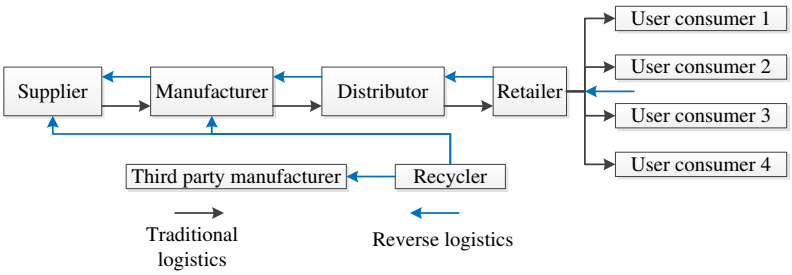

Figure 1. *Logistics network for urban solid wastes*

The logistics system for urban solid wastes is reversible, inactive, complex and uncertain (Gafurov et al., 2014). In urban areas, the disposal of solid wastes is driven by multiple factors, such as legal mandates, economic benefits, environmental protection and social wellness (Zhu et al., 2018). *Table 1* lists the total and per-capita daily production of urban solid wastes in many countries. It can be seen that urban Chinese generates a relatively low amount of solid wastes on average. Due to the huge population, however, China is now the largest producer of solid wastes. The total production of solid wastes in China is 1.014 times that of the US, 5.775 times that of France, 5.920 times that of the UK, 4.211 times that of Japan and 10.241 times that of South Korea. *Figure 2* shows the average composition of solid wastes in Chinese cities. Obviously, the catering waste takes up an increasingly large portion in solid wastes year by year, reaching 70% in recent years, while the proportions of dust and construction wastes are gradually declining. The other solid wastes like plastics, metal and tree branches are relatively few and stable over the years.

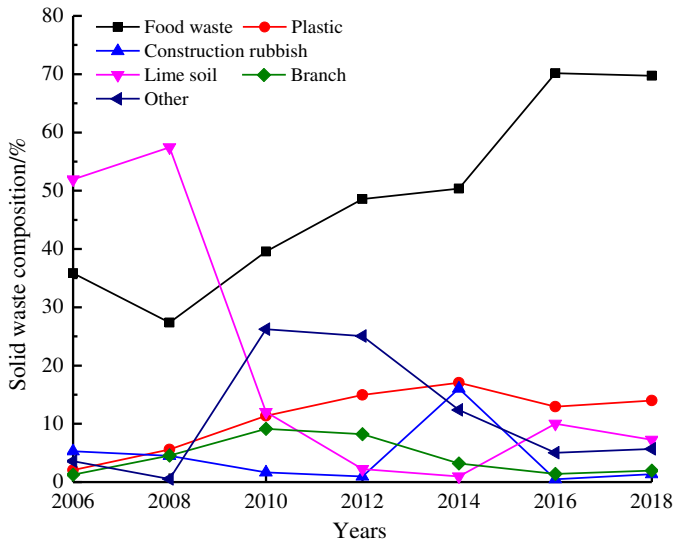

Figure 2. *The average composition of solid wastes in Chinese cities*

Results and Discussion

Benefit model for logistics pricing of urban solid wastes

The logistics pricing system for urban solid wastes covers issues of economy, environment and society, requiring scientific and rational resource allocation. Taking solid wastes as a commodity, the environmental pollution caused by the commodity should be controlled through analysis on both benefits and performance. The logistics transport cost of solid wastes should be compared with the monetary income in reverse logistics. The composition of solid wastes in downtown Hangzhou is explained in *Figure 3*. As shown in the figure, 62.5% of the solid wastes are catering waste, 11.5% are paper, 12% are plastics, 3% are glass, and 1% are metal. The catering waste is not recyclable and cannot produce any benefit. By contrast, the other wastes can bring benefits through recycling. Hence, the benefit function of logistics pricing R_1 can be constructed as:

$$R_1 = \sum_{i=1}^{n} Q_i r_i p_i \quad (i = 1,2,3,\ldots,n) \qquad \text{(Eq.1)}$$

where Q_i is the reverse flow amount of each kind of urban solid waste (ton); r_i is the proportion of each kind of recyclable urban solid waste (%); p is the recycling price of each kind of urban solid waste (RMB yuan/ton).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92919300

Besides the benefit of direct recycling, urban solid wastes can produce composting benefit R_2, power generation benefit R_3 and landfill gas benefit R_4. Among them, the power generation benefit R_3 can be expressed as:

$$R_3 = \sum_{j=1}^{n} Q_j \varphi p \quad (j = 1,2,3,\dots,n) \qquad \text{(Eq.2)}$$

where Q_j is the total amount of solid wastes used for power generation (ton); φ is the energy conversion efficiency of solid wastes (kWh/ton); p is the price of each kWh of electricity (RMB yuan).

Then, the total benefit function can be expressed as:

$$R = R_1 + R_2 + R_3 + R_4 \qquad \text{(Eq.3)}$$

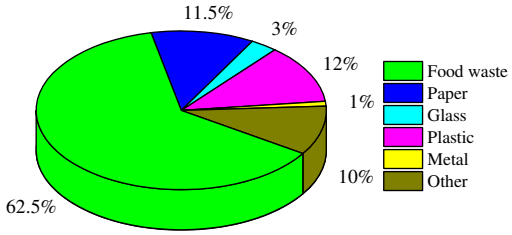

Figure 3. *The composition of solid wastes in downtown Hangzhou*

Performance model for logistics pricing of urban solid wastes

Through the economic analysis, it is learned that the logistics pricing system for urban solid wastes contains transport pricing and disposal pricing. The former is further split into transport machine pricing and labor pricing, and the latter covers the full-lifecycle pricing of the machine. In Hangzhou, the solid waste transport performance is RMB 2.2 yuan/km/ton, and the closest transfer station of solid waste lies 12 km away from the terminal station. The solid wastes are loaded into trucks at the transfer stations, and transported to the terminal for classification and disposal. *Table 2* compares the disposal costs of urban solid wastes in Hangzhou. It can be seen that the disposal at the transfer stations is the cheapest method.

Table 2. *Comparison of disposal costs of urban solid wastes (RMB yuna/ton)*

Urban solid waste treatment measures	Unit disposal cost
Transfer station	28.4
Composting field	218.6
Incineration plant	253.6
Sanitary landfill	73.4
Integrated treatment plant	98.8

The performance function C can be expressed as:

$$C = \sum_{i=1}^{n} (t_i d_i + D_i) X_i \quad (i = 1,2,3,\dots,n) \qquad \text{(Eq.4)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92919300

where t_i and d_i are respectively the unit transport cost and unit transport distance of solid wastes, respectively; D_i and X_i are the unit disposal performance and unit logistics volume of municipal solid wastes, respectively.

Empirical analysis

This subsection mainly explores the economic and environmental benefits of urban solid waste treatment. To minimize the volume and harm of solid wastes, the optimal solution must have the lowest logistics pricing. Logistics pricing is a linear planning problem. The logistics pricing at the terminal varies with the transport distances. There are ten municipal districts in Hangzhou. The transfer-terminal distance differs from district to district. Thus, each transfer station should have a unique objective function and constraints. The general mathematical model can be expressed as:

$$Z = F(X) = \begin{cases} \max(\min) f_1(X) \\ \max(min) f_2(X) \\ \cdots \\ \max(min) f_n(X) \end{cases} \quad \text{(Eq.5)}$$

$$S.t.\, \varphi(X) = \begin{Bmatrix} \emptyset_1(X) \\ \emptyset_2(X) \\ \cdots \\ \emptyset_n(X) \end{Bmatrix} \leq G = \begin{Bmatrix} g_1 \\ g_2 \\ \cdots \\ g_n \end{Bmatrix} \quad \text{(Eq.6)}$$

where $X=[x_1, x_2, x_3,\ldots, x_n]^T$ is the decision variable.

The annual outputs of catering and industrial solid wastes in Hangzhou are presented in *Figure 4*. It can be seen that Hangzhou produces fewer and fewer industrial solid waste over the years, but more and more catering solid waste. In 2018, the output of catering solid waste was 19 times that of industrial solid waste.

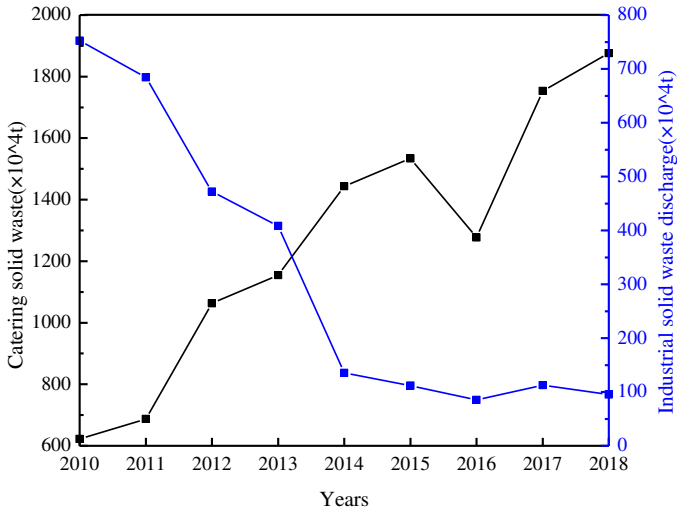

Figure 4. *The annual outputs of catering and industrial solid wastes in Hangzhou*

The total investment of Hangzhou in solid waste treatment is shown in *Figure 5*. It can be observed that the investment increased first and then declined. The highest

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92919300

investment appeared in 2016. This trend is attributable to the implementation of "reverse logistics" in recent years, as the city started to highlight the relationship between economy and environment. The terminal stations have began creating benefits from urban solid wastes. Then, the benefit-performance optimization model can be set up based on an interactive linear and general optimization solver:

Logistics pricing function:

$$C=n_1\times x_1+n_2\times x_2+n_3\times x_3+\ldots\ldots+n_i\times x_i \quad \text{(Eq.7)}$$

where n_i is the unit pricing (RMB yuna/ton); x_i is the proportion of solid wastes received by each terminal station to the total solid wastes received by all terminal stations in the municipal districts (%).

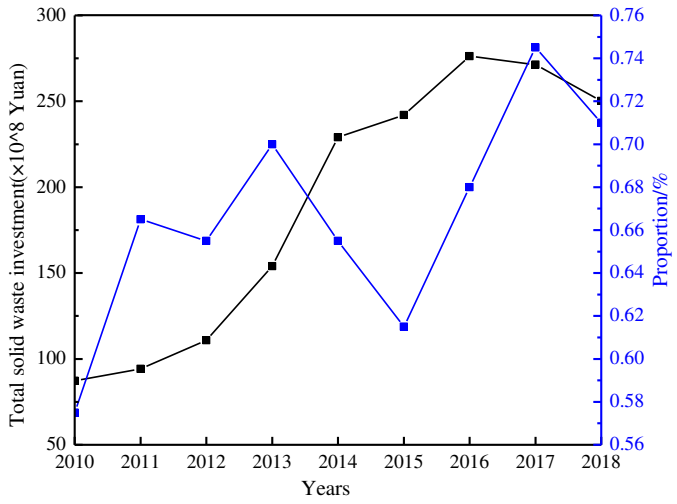

Figure 5. *The total investment of Hangzhou in solid waste treatment*

Recycling benefit function:

$$R1=194.69\times(w1+w2+w3+\ldots\ldots+wi) \quad \text{(Eq.8)}$$

Compositing benefit function:

$$R2=\lambda1\times w1+\lambda2\times w2+\lambda3\times w3+\ldots\ldots+\lambda i\times wi \quad \text{(Eq.9)}$$

Incineration benefit function:

$$R3=\omega1\times w1+\omega2\times w2+\omega3\times w3+\ldots\ldots+\omega i\times wi \quad \text{(Eq.10)}$$

Landfilling benefit function:

$$R_4=\gamma_1\times w_1+\gamma_2\times w_2+\gamma_3\times w_3+\ldots\ldots+\gamma_i\times w_i \quad \text{(Eq.11)}$$

where w_i is the composition of solid wastes; λ_i, ω_i and γ_i are the unit benefit of composting, incineration and landfilling of solid wastes, respectively.

Improvement strategies

The ten municipal districts, denoted as 1~10 respectively, in Hangzhou are listed in *Table 3*. The daily disposal amount and dual variable of solid wastes in each municipal district are illustrated in *Figure 6*. If the dual variable is positive, then the disposal amount is negatively correlated with the logistics pricing, that is, the pricing decreases with the growth in disposal amount. The inverse is also true.

Table 3. *List of municipal districts in Hangzhou*

Number	Municipal district	Number	Municipal district
1	Shangcheng area	6	Binjiang area
2	Xiacheng area	7	Xiaoshan area
3	Xihu area	8	Yuhang area
4	Jianggan area	9	Linan area
5	Gongshu area	10	Fuyang area

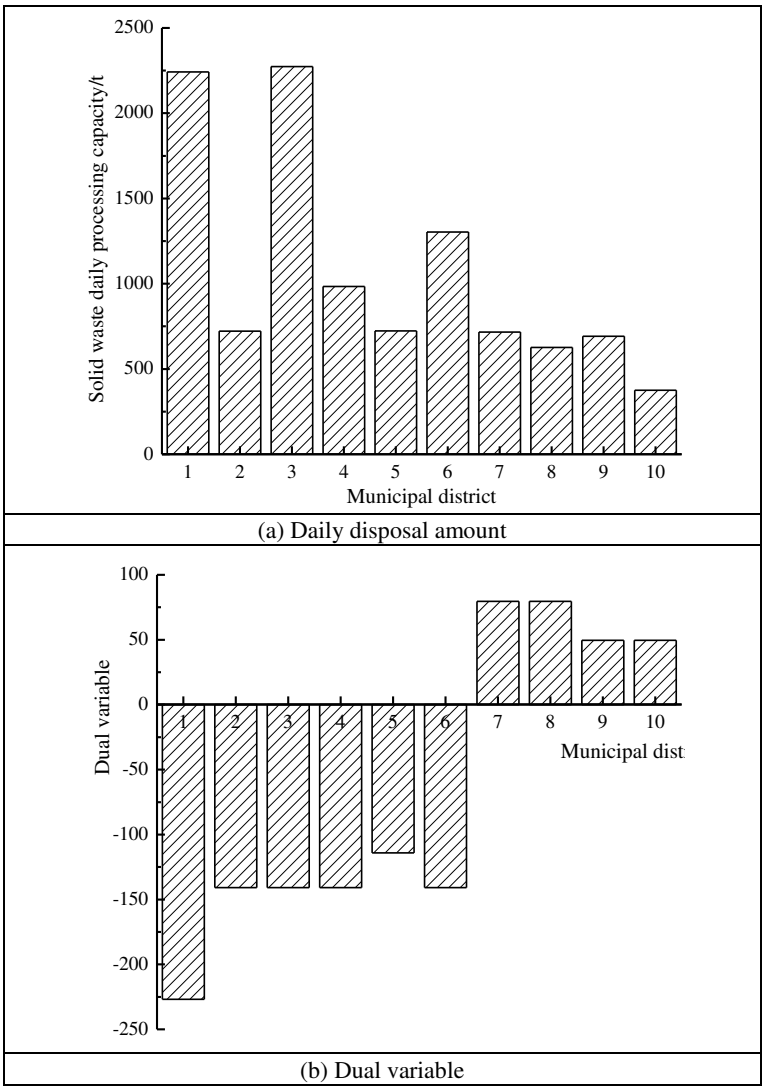

Figure 6. *The daily disposal amount and dual variable of solid wastes in each municipal district*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92919300

The optimal daily disposal volume of solid wastes in each municipal district was obtained according to the decision variable in the objective function. *Figure 7* gives the allowable change of solid wastes in each municipal district under a constant optimal base.

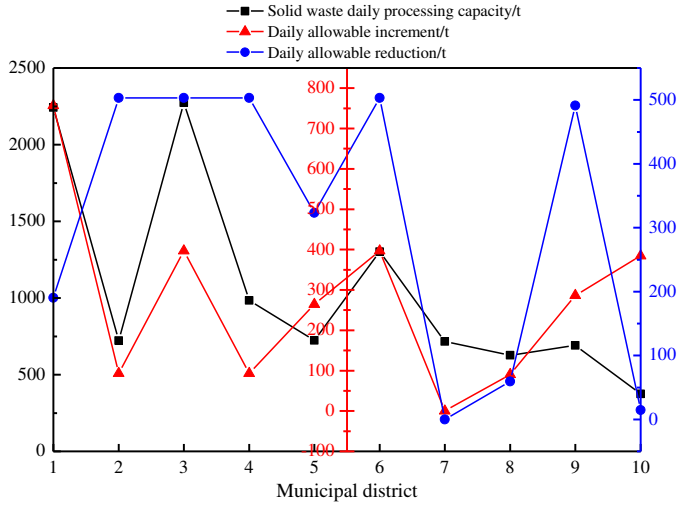

Figure 7. *The allowable change of solid wastes in each municipal district under a constant optimal base*

If the daily disposal volume is below or above the allowable range, then the logistics pricing will increase. With the improvement of living standards, more and more solid wastes are being generated year by year. To reduce the generate of solid wastes, the government should step up its promotion of the solid waste disposal system that combines environmental and economic effects, and encourage waste classification at the source. Furthermore, the solid waste disposal ability of each transfer or terminal station should be controlled according to the benefit-performance theory and the disposal capacity of the existing facilities.

Conclusions

From the perspective of marketization, this paper analyzes the benefits and performance of the logistics pricing system for solid wastes in the municipal districts of Hangzhou, with the aim to develop an economical logistics pricing system. The main conclusions are as follows:

(1) The catering waste takes up an increasingly large portion in solid wastes year by year, reaching 70% in recent years, while the proportions of dust and construction wastes are gradually declining. The other solid wastes like plastics, metal and tree branches are relatively few and stable over the years.

(2) The logistics pricing system for urban solid wastes covers issues of economy, environment and society, requiring scientific and rational resource allocation. Taking solid wastes as a commodity, the environmental pollution caused by the commodity should be controlled through analysis on both benefits and performance. Logistics pricing is a linear planning problem. The logistics pricing at the terminal varies with the transport distances.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_92919300

(3) The dual variable reflects the relationship between the disposal amount and logistics pricing of solid wastes. If the daily disposal volume is below or above the allowable range, then the logistics pricing will increase.

(4) There are many assumptions in the application of benefit-performance theory. The cost calculation in this paper is not comprehensive and neglects the environmental damage caused by the generation, stacking and disposal of solid wastes. Future research should seek to try to solve problems in a smaller range.

Abstract. By studying five carbon emission exchanges (Beijing, Shanghai, Shenzhen, Guangdong, and Hubei) within China, this study uses the GARCH model to explore the price volatility characteristics of regional carbon trading markets and measures the trading market risks based on VaR model. The results show that the adopted GARCH (1,1) risk model fits well with the characteristics of returns. Besides, fluctuation shock varies among different exchanges, and the volatility of carbon price is influenced more by the heterogeneity of the external environment of the carbon market than the role of internal market mechanisms. The value-at-risk varies between exchanges. These findings pose more challenges to the risk monitoring of carbon finance markets. Therefore, the current work attempts to recommend the establishment of a unified national carbon trading market to control risks and maintain stable market development.
Keywords: *carbon finance, VaR, GARCH, ARCH-LM test, Kupiec failure frequency test*

Introduction

Carbon dioxide is the main factor causing the greenhouse effect. With the advances of economic development, China's carbon dioxide emission have become one of the highest in the world. As a result, while China is facing huge pressure for emissions reduction, it has also generated the conditions and foundations for building a carbon market. The market mechanism is an effective method to save energy and reduce emissions. Since the enforcement of the Kyoto Protocol, western developed countries have established carbon trading markets that target carbon dioxide emission producers. The largest and most developed is the European Union Emission Trading Scheme (EUETS), established in 2005. Additionally, the development of international carbon finance market has proven that the emissions trading theory in economics is indeed effective in combating climate change. As one of the largest global carbon resource holders, China is also one of the largest carbon emission suppliers in the carbon market. Since November of 2013, China has successively established eight pilot carbon exchanges, in Shenzhen, Beijing, Shanghai, Hubei, Tianjin, Guangdong, Chongqing, and Fujian. Their total trading volume has already reached 14,000 tons, calculated from the commencement of carbon emission trading, by April 2018, and the total turnover exceeded 2.5 billion CNY. With the expansion of trade scale and the continuous improvement of trading operation mechanisms, these trading markets could play a more significant role in China's energy conservation and emission reduction tasks.

DOI: http://dx.doi.org/10.15666/aeer/1704_93019315

Carbon finance refers to the transformation of carbon emission rights into a commodity that meets international certification standards via market-oriented tools and means for trading. The research on carbon finance risks started by focusing mainly on the classification and influencing factors of carbon trading risks. Regarding the classification and definition of carbon trading risks, Larson and Parks (1999) clarified that the trading risk of carbon finance exists in many aspects such as project preparation, implementation, evaluation, approval, secondary market, and target market. They analyzed the types of trading risks, and classified them into three types: performance risk, price risk, and policy risk. When qualitatively analyzing carbon emission reduction projects, Laurikka and Springer (2003) classified the ones into six categories, of which, the price risk, cost risk, and quantity risk were the primary risks. Dutschke et al. (2004) categorized the clean development mechanism (CDM) risks into three types: baseline estimation risk, commercial risk, and institutional risk. Regarding the research on the impact of carbon trading risk, Mansanet-Bataller et al. (2010) adopted a multivariate approach to analyze the risks from the perspective of carbon price fluctuations. Their results show that the carbon price was significantly influenced by energy prices and extreme weather. Carmona et al. (2010) found that the long-term and short-term emission reduction projects affected the price volatility of carbon emission allocations in varying ways, and that the energy price trends and the factors influencing carbon emissions (e.g. weather, power plant interruption accidents, etc.) were also closely related to the volatility of carbon prices. Additionally, scholars including Alberola et al. (2008), Kijima et al. (2010), Ibrahim and Kalaitzoglou (2006), and Labatt and White (2011) have also conducted related research.

In China, the carbon trading markets, compared to the western countries, was established much later. Wang and Song (2009) classified the carbon finance risks into three categories, namely the operational risks of carbon financial derivatives, the political risks of carbon finance, and the economic risks of macro-economy. According to Sun (2015), the risk structure of carbon finance market is constituted primarily by uncertain policy risks, liquidity risks, and political risks, while the major causes of these included inadequate supporting policies and laws, uncertain future international situation, insufficient knowledge of entities, lack of professionals, and imperfect service system of carbon finance organizations.

In general, despite the differing classifications of carbon trading risks by domestic and foreign experts, scholars, and organizations, all the risk types are encompassed within two major categories of non-systematic risks and systemic risks. In terms of risk-inducing influences, including weather, energy prices, project emission reduction cycles, macro factors, trading systems, etc. The remainder of this study is organized as follows: Section 2 describes the model setup; Section 3 presents the data description and validation; Section 4 is the empirical analysis and the last Section provides conclusions.

Materials and Methods

Methods

There are two major market risks faced by carbon finance trading entities in the market. One is the change in market size and the other is the fluctuation of carbon emission rights price. In addition, these two are mutually dependent. The change in market size can cause price fluctuations, and its risk is ultimately reflected in the price

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93019315

volatility risk. This study assesses the risk of carbon finance market by measuring the price volatility risk.

Market risk and VaR model

The portfolio theory proposed by Markowitz (1952) in 1952 marks beginning of market risk quantification in the risk research, in which, he measured the risk level of a financial product using the mean of returns divided by the variance. With the increasing maturity of risk research in recent years, the value at risk (VaR) measure has been the primary choice for academia in researching risk management. VaR refers to the maximum possible loss of a financial asset during the holding period at a certain confidence level under normal market fluctuations. Its value represents the level of market risk quite concisely. According to its definition, VaR is expressed as:

$$\mathrm{Prov}(\Delta P > \mathrm{VaR}) = 1 - \alpha \quad \text{(Eq.1)}$$

where, ΔP denotes the loss of a financial asset within the holding period Δt; VaR denotes the value at risk under confidence level of 1-α. Suppose that the initial price of a financial asset is P_0, and the rate of return is R, then the ending price is $P = P_0 \times (1+R)$. When expected value and volatility of the return R are μ and e, respectively, then the minimum value of the financial asset at a given confidence level is $P^* = P_0 \times (1+R^*)$. Hence:

$$\mathrm{VaR} = \mathrm{E}(P) - P^* = E(P_0 \times (1+R)] - P_0(1+R^*) = -P_0 \times (R^* - \mu) \quad \text{(Eq.2)}$$

Calculation of VaR on this basis is equivalent to determining the minimum value P* or the minimum rate of return R^*.

The above process describes a general approach to calculating VaR. In practice, the VaR solutions are classified into historical standard deviation methods, Risk Metrics, ARCH methods, etc., depending on how the market factor volatility is estimated. It is more reasonable to use the GARCH model from the ARCH family for financial time series with high peak and heavy tail characteristics.

GARCH model and EGARCH

Engle (1982) proposed an ARCH (autoregressive conditional heteroskedasticity) model to avoid the influences of conditional heteroskedasticity in time series on empirical results. The canonical form of the ARCH(q) model is as follows:

$$\sigma_t^2 = \alpha_0 + \sum_{i=1}^{q} \alpha_i \varepsilon_{t-i}^2 \quad \text{(Eq.3)}$$

where, $\sigma_t^2 = Var(\varepsilon_t | \Omega_{t-1})$ presents all information of conditional variance Ω_{t-1} at and before time t−1. In accordance with the ARCH model, the conditional variance of random error u_t depends on its previous value of u_{t-1}.

However, in practical application the ARCH model tends to require a higher lag order, which leads to increased number of parameters under estimation, thereby affecting the accuracy of estimations. To address this problem, Bollerslev et al. (1986) proposed the GARCH (generalized autoregressive conditional heteroskedasticity) model based on the research conducted by Engle, which is as follows:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93019315

$$R_t = \mu_t + \varepsilon_t \quad t = 1,2,\dots,T \tag{Eq.4}$$

$$\sigma_t^2 = \alpha_0 + \sum_{i=1}^{q} \alpha_i \varepsilon_{t-i}^2 + \sum_{j=1}^{p} \beta_j \sigma_{t-j}^2 \tag{Eq.5}$$

Among the above formulas, the mean equation presented in *Eq. 4* is an exogenous function with an error term. The establishment of this equation can directly eliminate linear correlation between the antecedent and consequent terms of the series. *Eq. 5* is a conditional variance equation, where ε_{t-i}^2 denotes the square of lag random error in the mean equation. It is the volatility information in the initial measurement period, which is also considered as the ARCH term. σ_{t-j}^2 denotes the forecast variance of the previous period, i.e. the GARCH term. σ_t^2 can be considered as a positive weighted average of the previous residuals, which is consistent with the volatility clustering. To be specific, large volatility may lead to greater changes; conversely, small volatility may cause small changes. The GARCH(1,1) model is the most typically used in practical application.

However, the disadvantages of GARCH model are that it strictly restricts the non-negativity of coefficient parameters, and fails to reflect the leverage effect of financial market, thus easily leading to deviations when applied in the financial market. The EGARCH (exponential GARCH) model overcomes the above deficiencies effectively and thus it is more widely used in present financial research. The expression for the conditional variance of EGARCH model is:

$$\ln\sigma_t^2 = \alpha_0 + \sum_{i=1}^{p} \alpha_i \left| \frac{\varepsilon_{t-1}}{\sigma_{t-1}} - E\left(\frac{\varepsilon_{t-1}}{\sigma_{t-1}}\right) \right| + \sum_{k=1}^{r} \gamma \frac{\varepsilon_{t-k}}{\sigma_{t-k}} \tag{Eq.6}$$

Using natural logarithm as the conditional variance, the EGARCH model illustrates that the expressive form of leverage effect is exponential. The model also introduces a parameter γ. If γ=0, it indicates that the volatilities produced by the price rising and falling symmetrically are identical. If γ>0, it indicates that the volatility by price rising is greater than that by price falling, and vice versa if γ<0.

A key issue in ARCH family models is the choice of error term distribution. In research, normal distribution is usually taken as an assumption. However, in practice, the tail of unconditional distribution for financial time series is often wider than the normal distribution. Therefore, normal distribution is incapable of accurately reflecting the tail characteristics of residual distribution, while the t distribution and the GED (generalized error distribution) can preferably capture the heavy tailed phenomenon. In the following, we separately obtain the log-likelihood functions of the standard normal distribution, GED, and t distribution by denoting the parameter vector by θ as follows:

(1) The log-likelihood function of the GARCH (1,1) model whose residuals follow normal distributed is:

$$\ln L(\theta) = -\frac{T}{2}\ln(2\pi) - \frac{1}{2}\sum_{t=1}^{T} ln\sigma_t^2 - \frac{1}{2}\sum_{t=1}^{T} \varepsilon_t^2 \Big/ \sigma_t^2 \tag{Eq.7}$$

The variable σ_t^2 is the conditional variance of u_t.

(2) The log-likelihood function of the GARCH (1,1) model whose residuals follow GED is:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93019315

$$\ln L(\theta) = -\frac{T}{2}\ln\left(\frac{\Gamma(\frac{1}{r})^3}{\Gamma(\frac{3}{r})(\frac{r}{2})^2}\right) - \frac{1}{2}\sum_{t=1}^{T} ln\sigma_t^2 - \frac{1}{2}\sum_{t=1}^{T}\left(\frac{\Gamma(3/r)(\varepsilon_t^2)^2}{\sigma_t^2\Gamma(1/r)}\right)^{r/2} \quad \text{(Eq.8)}$$

where, Γ (·) is a Gamma function. When the parameter r= 2, the GED becomes a normal distribution; when r< 2, the GED has a heavier tail than the normal distribution; when r>2, the GED has a lighter tail than the normal distribution.

(3) The log-likelihood function of the GARCH (1,1) model whose residuals follow student's t distribution is:

$$\ln L(\theta) = -\frac{T}{2}\ln\left(\frac{\pi(k-2)\Gamma(k/2)^2}{\Gamma[(k+1)/2]^2}\right) - \frac{1}{2}\sum_{t=1}^{T} ln\sigma_t^2 - \frac{k+1}{2}\sum_{t=1}^{T}\ln\left(1+\frac{\varepsilon_t^2}{\sigma_t^2(k-2)}\right) \quad \text{(Eq.9)}$$

The parameter estimation in *Eq. 9* is in actual the problem of maximizing the log-likelihood function under a degree of freedom k> 2 constraint. When k→∞, the t distribution approaches a normal distribution.

Materials

Selection of sample data

Currently, spot market enjoys the largest trading volume in China's carbon finance market based on the data consisting mainly of the trading volumes and turnovers of eight pilot carbon emission exchanges. The analysis of these data allows us to understand the risk profile of the carbon finance market. In view of the differing establishment time of China's carbon finance pilots, the daily trading volume and turnover data from January 2016 to April 2018 (totaling 563 trading days) are selected in the proposed study. Since the data from pilot sites in Chongqing, Fujian, and Tianjin are comparatively smaller and lacks statistical significance, modeling analysis is not performed herein for these three regions. The data used in the current study comes from the Chinese carbon trading website.

Statistical characteristics of return series for various exchanges

(1)Trend analysis of return time series

Establishment of a return index for the carbon finance market is attempted by utilizing the daily data from the above carbon emission exchanges. The average transaction price P_t of sample data is represented by the ratio of the current day's turnover to the current day's volume. Considering the stability of data, the rate of return R_t is represented by the logarithmic form as follows:

$$R_t = \ln P_t - \ln P_{t-1} \quad \text{(Eq.10)}$$

The EVIEWS 10.0 software is employed to plot the time series graph of returns (*Figure 1*). Obviously, the logarithmic returns for the five pilot exchanges all fluctuate around zero. When the fluctuations are large, the changes in successive periods are larger; when the fluctuations are small, the changes in successive periods are smaller, exhibiting a distinct "volatility clustering" effect.

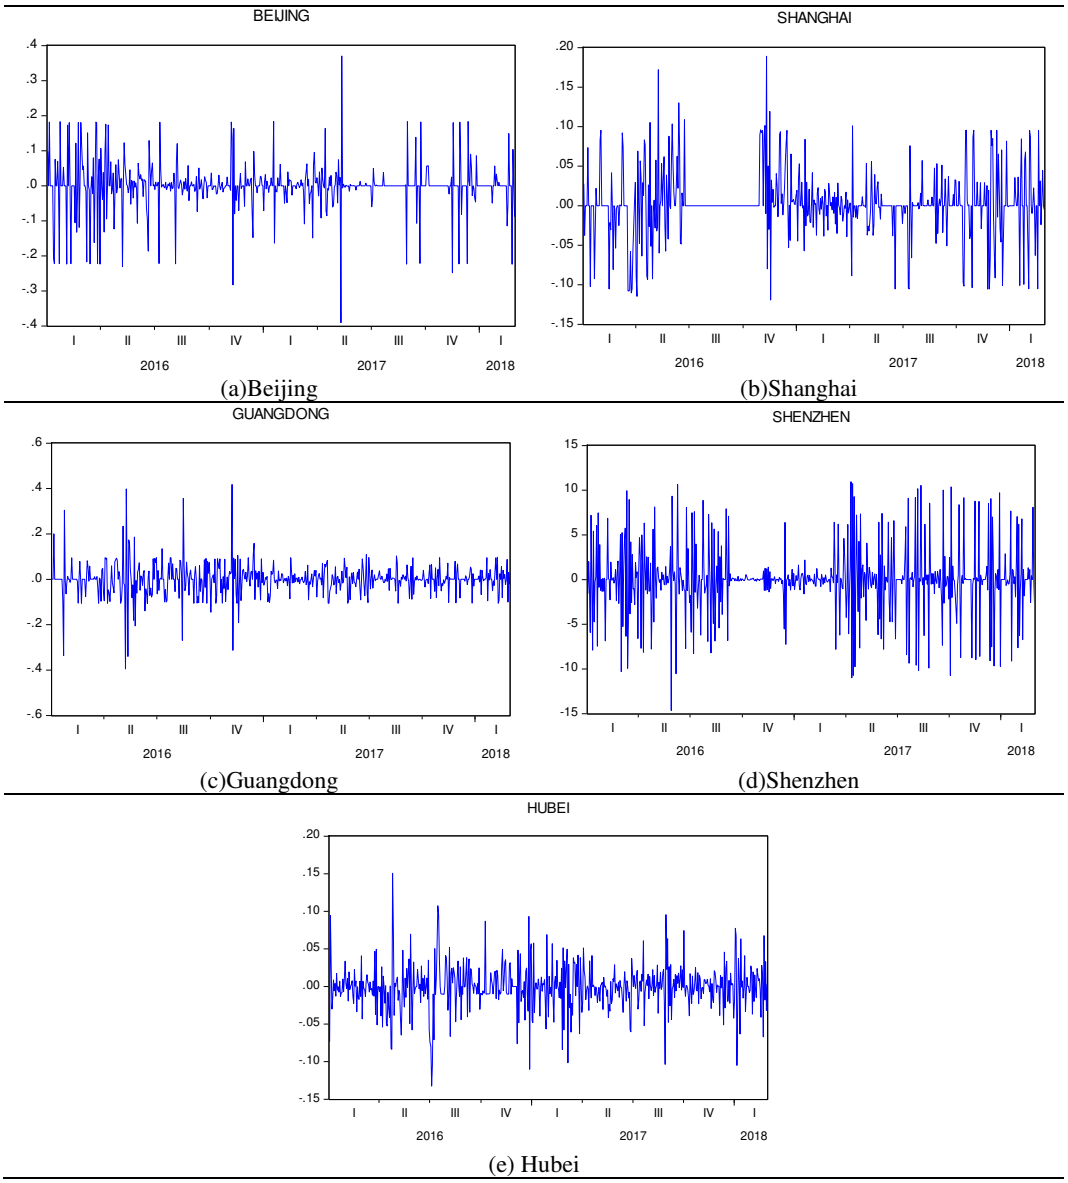
(2) Normality test

The Jurque-Bera statistic is a commonly used method for testing normal distribution and its calculation formula is as follows:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93019315

$$JB = \frac{n}{6}[S^2 + \frac{(K-3)^2}{4}] \quad \text{(Eq.11)}$$

where, n is the sample size, S is the skewness, and K is the kurtosis. Under the normality assumption, JB obeys $\chi^2(2)$ distribution, with a critical value of 5.99147 at a 5% significance level. If the JB statistic exceeds its critical value, the null hypothesis of normal distribution will be rejected. *Table 1* lists the JB statistics (*Eq. 11*) calculated by EVIEWS 10.0. As the JB statistics for the five pilot exchanges are all considerably above the critical values, the returns of the exchanges all show obvious non-normality. *Table 1* shows that the kurtoses of the five pilot sites are all greater than 3 and the skewness are different from 0. Therefore, the return curves present a "sharp peak and heavy tail" distribution features.



(a)Beijing (b)Shanghai

(c)Guangdong (d)Shenzhen

(e) Hubei

Figure 1. *Rate of return trend in carbon trading market*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93019315

(3) Stationary test for logarithmic returns of various carbon exchanges

The stationarity test results with augmented Dickey-Fuller (ADF) test are shown in *Table 2*, showing that return series of the five pilot sites all reject the null hypothesis that "there exists at least one unit root" at the 1% significance level, suggesting that the logarithmic returns of the five pilot sites are stationary series.

(4) Heteroscedasticity test

A Lagrange Multiplier (LM) is then used to perform the lag ARCH test on the residuals of mean equations for the five carbon trading exchanges, and the results are shown in *Table 3*. The p values of the F statistic and the Obs*R-squared statistic are all close to zero, and the results all reject the null hypothesis, indicating the presence of heteroskedasticity in the returns of various pilot sites. The heteroskedasticity can reflect the extreme price fluctuations and extreme risks of carbon exchanges in various regions. This suggests that China's carbon finance market may be at risk, which necessitates its risk analysis.

Obviously, the p-value is zero after the squared residuals of returns, for various exchanges lag a certain order; therefore, the null hypothesis is rejected. The ARCH effect is considered to exist in the residual series of each exchange's regression model.

Results

In the current study, the lag order of ARCH(p) and calculation of the AC and PAC for the residuals sum of squared of regression models coefficients were used in the Eviews10.0 software. The results show that the AC and PAC are significantly non-zero, while the Q statistics are highly significant. Therefore, the research method of this paper is identified as GARCH(1,1).

Parameter estimations by GARCH and EGARCH models

The GARCH(1,1) (*Eq. 5*) under standard normal distribution (*Eq. 7*), GED (*Eq. 8*), and t-distribution (*Eq. 9*) are used separately herein to perform parameter estimation on the five carbon trading exchanges' returns. *Table 4* displays the most suitable method. It is found that the GED is most appropriate for residuals distribution of the four exchanges except for Guangdong, where the adjustment of tail bias with normal distribution is needed.

According to the estimations in *Table 4*, the mean value is the greatest for Beijing, and the least for Shanghai. The reason may be that Beijing has a large market volume and faces great risks. By contrast, the trading volume in Shanghai has been quite low in the past two years, so it is at a smaller risk. In addition, Shanghai exchange's return shock decays the slowest, followed by Hubei.

Table 4. *Parameter estimations at GARCH(1,1) and EGARCH(1,1) models*

Parameter	Beijing	Shanghai	Guangdong	Shenzhen	Hubei
Mean equation

SC	-17.04757	-8.600750	-2.735734	-0.433394	-4.514424

Note: # indicates that the residual series uses a normal distribution to adjust the tail bias

Concerning the variance models, all α and β values are significant at a significance level of 10% aside from the insignificant β value for Shenzhen, indicating that these models can well depict the volatility clustering feature of the returns in various carbon trading markets. The α value represents the impact of the external market environmental factors on the rate of return, while the β value represents the impact of return volatility on itself. Greater β value indicates longer effect of the return volatility on itself, i.e. the presence of long-term memory effect. Based on *Table 4*, it can be seen that Shanghai has the largest β value of 0.485901, indicating that the 48.5901% of the variance impact in the current period will continue to exist in the next period. This suggests that the decay of the impact is the slowest for Shanghai, followed by Beijing and Guangdong. The risks faced by the three exchanges in Guangdong, Shenzhen, and Hubei are mainly from the impact of external shocks (α_i>β), indicating that the heterogeneity of the external environments for these three markets is more influential to the carbon price volatility than the role of internal market mechanism. For Beijing, on the contrary, the risks mainly come from internal market mechanism. The α values of the five exchanges are significantly less than 1, with αi+β <1. This indicates that the fluctuation of return

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93019315

attenuates gradually in response to externalities, and that both external factors and internal impact have slow disappearing influences on the rate of return. Shanghai exhibits the largest β value, followed by Guangdong and Beijing. This shows that the return volatilities of these three exchanges have a long-term impact on themselves, which possess a certain memory effect. The γ coefficients are significantly non-zero for all exchanges other than Hubei, where the value is insignificant. Beijing, Shanghai, and Guangdong exhibit positive γ coefficients, indicating that the impact of positive rate of return for carbon finance is greater than the negative shock of the same degree, whereas, an opposite trend is observed for Shenzhen.

Daily VaR values for various exchanges

The daily VaR values at a 95% confidence level are calculated using the conditional variance of the above models, and the statistical results are presented in *Table 5*.

Table 5. *The calculation results at the VaR model*

Exchange	Min.	Max.	Mean	Standard deviation	Failed days	Failed rate	LR statistic	LR critical value*
Beijing	-1.199	-0.0879	-0.3	0.13918	3	0.535%	0.6413	6.635
Shanghai	-0.314	-9×10^{-7}	-0.0629	0.05752	8	1.424%	0.3908	6.635
Guangdong	-1.857	-0.1508	-0.2834	0.17172	2	0.357%	1.354	6.635
Shenzhen	-6.385	-0.1692	-1.8937	0.31346	5	0.89%	0.0312	6.635
Hubei	-1.919	-1.3664	-1.6794	0.10021	0	0%	—	6.635

*: at a 1% significant level

We can determine the market volatility of exchanges based on the standard deviations of daily VaR values. The greater the standard deviation, the higher the volatility of market. As shown in *Table 5*, Shenzhen has the highest volatility, whereas Shanghai is the lowest. The exchanges can be arranged in a descending order of volatility as Shenzhen> Guangdong> Beijing> Hubei> Shanghai. Shenzhen's trading volume and turnover are second only to Hubei among the five pilot sites, and its mean VaR is the largest. This is mainly attributed to the abnormally large standard deviations resulting from the large fluctuations of individual average transaction prices.

Results of Kupiec failure frequency test

Kupiec (1995) proposed a failure frequency test to posteriorly testify and evaluate VaR efficiency. Its procedure is as follows: Assuming that the significant level is α, and the actual loss is $\triangle P=P_t-P_{t-1}$, failure is considered when $\triangle P>$ VaR. The number of inspection days is denoted by T, the number of failed days is denoted by N, and the frequency of failure is denoted by P= N/T. At a significance level of α, the expected failure probability is E(P)= P*=1-α. The "likelihood ratio test" is adopted for failure detection, whose mathematical expression is

$$LR = -2\log\left[(1-p^*)^{(T-N)}(p^*)^N\right] + 2\log\left[\left(1-\frac{N}{T}\right)^{(T-N)}\left(\frac{N}{T}\right)^N\right] \quad \text{(Eq.12)}$$

where, the LR statistic follows χ2(1), with a critical value of 6.635 at a 1% significant level. If the LR value is greater than 6.635, the VaR model is considered invalid. Smaller LR value indicates a more effective model, which can more easily pass the test.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93019315

Table 5 shows the calculations by *Eq. 12*. At a 99% confidence level, the results of Kupiec failure frequency test for the five exchanges do not reject the null hypothesis, so the model is valid. Thus, the GARCH-VaR risk model used in this paper can well fit the characteristics of returns.

Discussion

The carbon trading market currently consists of the allocation market (primary market), the spot market (secondary market), and the derivatives market. Among them, the allocation market is responsible for the total amount setting and the initial allocation of allowances, whose chief function is to create carbon allowances. The spot market is a place for spot trading of allowances, which plays the role of basic price discovery and resource circulation. The derivatives market is a place for trading carbon futures, carbon options and other carbon financial derivatives, whose role is to further deepen price discovery, hedging and to avoid risks. Different levels of markets face varying risks, which need to be analyzed separately.

Allocation market risks

The function of allocation market is to create products and provide a basis of trading. Its risks mainly exist in the following aspects:

Total carbon allowance setting risk

Total carbon allowance setting risk refers to the risk brought by drastic fluctuations of carbon allowance price due to the unreasonable total allowance setting by the government. Unreasonable total allowance setting includes both excessive and over-tight setting. Excessive allowance setting will lead to weakened incentive mechanism for emission reduction, so that businesses do not have enough incentive to reduce emissions. Over-tight allowance setting, on the other hand, will lead businesses to bear excessively high cost, thus affecting their competitiveness. In its first stage, EUETS caused carbon price slump due to the excessive allowance issuance, where the price was close to zero. Thus, how to determine the issuing amount will affect the price of carbon market.

Carbon allowance allocation risk

Carbon allowance allocation, which is closely related to the total amount setting, refers to the government's allocation of allowances to businesses by ways like free distribution and paid auctions. The allowance allocation risk is the risk brought about by the unfair distribution of allowances, which is attributable mainly to the defects in the allowance approval procedure. Currently, the common approval methods in the carbon trading market are the Grandfather clauses and the Industry baseline, which have respective advantages and disadvantages. The advantage of the grandfather clauses is that it considers the historical fairness, but its disadvantage is that the reliability of future prediction using historical data is not high. Meanwhile, the Industry baseline often determines a benchmark based on industry-leading levels, and the portion that is superior to the benchmark is eligible for free allowances, while the portion inferior to the benchmark requires purchase of allowances. The advantages of this method are that it encourages technological improvement and the promotion and popularization of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93019315

advanced technologies. Its disadvantage is the complicated and costly process of determining the baseline.

Carbon leakage risk

Carbon leakage refers to a situation in which the businesses in countries with strict environmental policies shift to countries without strict environmental policies to trigger rising carbon emissions in the migrant countries. The occurrence of carbon leakage stems mainly from concerns about production cost increase. The carbon leakage problem is inevitable as long as the environmental policies of various countries are inconsistent. Due to the territorial feature of the carbon emission system, environmental policies often have an effect only on domestic companies, but are powerless to foreign companies. Therefore, domestic companies have a strong incentive to transfer production to other countries that are not strictly implementing environmental policies for cost reduction purposes, thereby resulting in the carbon leakage.

Spot market risks

Spot market, also known as the secondary market, is an important part of the carbon trading market. The risks in the spot market mainly include: performance risk and illegal operation risk.

Performance risk

Performance risk refers to the possibility of loss to the one trading party who has fulfilled the transactional obligation after conclusion of a carbon allowance transaction (trading) caused by the failure of the other party to perform the payment obligation in accordance with the transaction contract. Aside from involving qualifications and integrity of both parties, the performance risk sources may also cover the entire trading system. This necessitates checking the transaction system of carbon trading market in an all-round way, including whether the allowance allocation is too loose or too tight; whether the carbon emission monitoring, reporting and verification system is sound; whether the market operation is effective, etc.

Illegal operation risk

Illegal operation risks can generally be classified into the following categories: The first category is serious crimes using the carbon market as a tool, such as fraud, money laundering, and terrorist financing. The most famous events were the phishing involving carbon emissions rights across Europe, Japan and New Zealand that was uncovered in Germany in February 2010, and a VAT carousel fraud took place in the UK in June 2012. The second category is financial market violations, including market manipulation, insider dealing, etc.

Derivatives market risks

Derivatives market, also known as the tertiary market, faces many risks due to the complexity of trading derivatives such as futures and options. Based on the early development experience of global carbon trading market, these risks mainly include: liquidity risk, credit risk and investor risk.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93019315

Liquidity risk

Liquidity risk is classified into the market liquidity risk and the financial liquidity risk. The former is mainly reflected in the insufficient market trading volume or inactive market transactions, whose essential cause is the inadequate market depth and breadth. The financial liquidity risk refers to the possibility that the investor is unable to fulfill the payment obligation upon contract expiration due to lack of current funds, or meet margin calls in accordance with the contract at the time of settlement. Rather than existing in isolation, liquidity risk is often accompanied by other risks. Sometimes, however, it may also mean that the trading mechanism itself is flawed.

Credit risk

Credit risk, also known as default risk, refers to the possibility of loss to one trading party caused by refusal of the other party to perform the agreed terms. The emergence of credit risk is often related to the immature carbon trading market and the imperfect relevant systems.

Investor risk

Investor risk is mainly reflected in the influences of unreasonable structure and poor quality of investors on the operation of carbon trading market. Investors are classified into the institutional investors and the individual investors. In mature markets, institutional investors should account for a larger proportion. In the current stage, investor risk is mainly concentrated in the derivatives market. This necessitates setting reasonable thresholds and conditions for investors participating in the carbon derivatives trading, so as to ensure the effective linkage and functioning of the carbon trading markets at various levels.

Policy suggestions

The successive establishment of carbon trading markets in China is of milestone significance to the development of China's carbon finance market, which shows that China has begun to seek the dynamic balance between low-carbon economic development, corporate growth, and eco-environmental protection via market and price mechanisms. Ensuring the orderly fluctuations in China's carbon trading prices guarantees the effective monitoring and control of carbon finance market risks and promotes the stable development of the carbon finance market. We put forward the following suggestions:

Firstly, it is necessary to enhance the rationality of policies, thus gradually integrating the carbon market. Since China's eight major pilot sites for carbon emission trading have taken the lead in accumulating experience, the industries covered by all or most of these sites, such as the power and cement industries, should be the first to be considered for integration. In the meanwhile, a unified quota system should be implemented for the emission control firms of these industries. On the basis of vigorously advancing the pilot sites for carbon emission trading, a unified national control over total quantity should be practiced. Furthermore, quota should be allocated based on factors like regional GDP and carbon emission demands, and a carbon quota trading mechanism should be established to foster a fair and active carbon trading market.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93019315

Secondly, it is necessary to improve the level of risk management as well to monitor and control risks: 1. Perfecting the legal framework, and standardizing the carbon trading market system. The regulatory issues involving the carbon finance market must be addressed by legal means. Regulations related to the construction of carbon trading markets should be legislated to enable the stable and orderly development of the carbon finance market. The strong policy dependence of carbon finance itself determines that it is necessary to legally clarify the institutional arrangements for the carbon trading markets, and to incorporate risk issues into the legal context in order to adjust interest relationships, regulate carbon markets, and control risks. 2. The close monitoring of carbon price fluctuations and establishment of a risk measurement system. The GARCH-VaR model established in this paper has certain referential significance in measuring market risk. The supervisory authorities should thus establish a risk measurement system, and set a daily VaR monitoring value for each market to serve as a "risk pre-warning line", so as to improve the early warning capability against risks.

Finally, construction of carbon trading market infrastructures should be strengthened. Respecting the construction of primary carbon trading market (carbon allowance approval, issuance, etc.), the development of greenhouse gas inventory and the construction of statistical accounting systems should be accelerated. It is necessary to prioritize the establishment of greenhouse gas reporting systems for key industries, and establish a sound auction procedure to ensure the smooth delivery of carbon emission rights. Concerning the secondary carbon trading market (spot trading), the role of the carbon emission rights registration system should be played to enhance the market liquidity and improve the trading efficiency. As for the carbon futures market, formulation of carbon futures trading rules covering market participants, delivery system, and price formation mechanism is necessary by learning from the useful international experiences about design of carbon futures contracts, product pricing, trading rules, risk control mechanisms, investor eligibility management, etc.

Eventually, a unified carbon emission trading system with Chinese characteristics should be built, forming a triopoly with the EUETS and the Chicago Climate Exchange (CCX), thus promoting the green and sustainable development on a global scale.

Conclusions

In this study, the GARCH(1,1) and EGARCH(1,1) models are used to estimate the price volatilities for different exchanges based on the data features of daily returns, and the VaR model is used to calculate the risks in China's carbon trading market. The main results as follows:

(1) The daily returns of China's carbon finance present a sharp peak and heavy tail pattern, which do not follow the normal distribution. The GARCH(1,1) model can well characterize the sharp peak and heavy tail of daily return series for China's carbon finance.

(2) The volatility of returns at different pilot sites measured with the GARCH(1,1) model finds that the volatility shock decays to varying degrees among different sites. For Shanghai, Guangzhou, and Beijing, the intrinsic shock exerts a prolonged impact on the return volatility.

(3) The α values are all greater than the β values for the pilot sites except for Beijing, proving that the carbon price volatility is more likely to be affected by the heterogeneity

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93019315

of the external environment for carbon finance market than the role of internal market mechanism.

(4) The VaR model is used to test the market risk of the five exchanges, the result shows that the level of market risk varies among the exchanges in different regions, which are ranked into Shenzhen, Guangdong, Beijing, Hubei, and Shanghai in a descending order of volatility.

(5) The GARCH-VaR risk measurement model is ideal upon validation through the Kupiec failure frequency test.

The paper measures the risks in China's Carbon Financial Market based on GARCH-VaR model. Though periodical achievements have been obtained, the following few questions still request further research. Firstly, the risk measurement model should incorporate other social and policy factors, such as GDP variation, industry structure, etc. Secondly, the general formula employed by the paper in VaR measurement does not distinguish rise risk and fall risk, but measures the general VaR value instead. Therefore, it needs to respectively measure rise risk and fall risk in following sections.

Abstract. From the dual perspectives of "performance model" and "expectation model", this paper studies the influences of government regulation and public participation on satisfaction with environmental governance and individuals' happiness based on the data from the Chinese General Social Survey in 2015 (CGSS2015). By constructing the structure-equation model (SEM), it was found that: (1) both environmental regulation and public participation can significantly promote individuals' happiness, and the significance of the former is higher than that of the latter; (2) the improvement of satisfaction with environmental governance can effectively enhance individuals' happiness, and it plays an intermediary role in the relationship between environmental regulation, public participation and individuals' happiness. (3) individual characteristics also affect happiness. The economic and social status of the individuals play a positive moderating role in the relationship between environmental regulation and public participation and happiness. Therefore, we should strengthen government regulation and at the same time ensure public participation and change the "process orientation" to "problem orientation" and "result orientation" to truly improve environmental governance performance and public satisfaction. Meanwhile, the government should also pay attention to the environmental demands and living needs of the vulnerable group to realize social justice and improve individuals' happiness.
Keywords: *environmental regulation, public participation, performance model, expectation model happiness*

Introduction

According to previous studies, even though micro-factors such as individual characteristics (income, employment, education, marriage and so on) can explain many variations of citizens' happiness, there still remain variations that are unexplained. Happiness also can be affected by some external macro-factors, including social environment and natural environment which heavily rely on government intervention (Ott, 2010). Utilitarians point out that governments should try their best to create the greatest happiness for the greatest number of people (Veenhoven, 2010). Although many scholars are still debating on whether it should be used as the basic principle and aim for laws and public policies and questioning its feasibility and risks, the concept that individuals' happiness is an important part of value orientation has been generally recognized (Duncan, 2010; Frey and Gallus, 2013). Bhutan has already used the Gross National Happiness Index since 1972 to evaluate the performance of the government. Besides, many other countries have also promoted the application of the happiness

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93179332

index in the government management practices, such as France, the United States and China.

In recent years, environmental pollution has become a global issue, seriously affecting the health and living quality of the people around the world and decreasing their happiness. Juncal et al. studied the relationship between air pollution, climate and individuals' happiness in Spain, and found that air pollution can have various impacts on people's happiness in different aspects (Cuñado and Gracia, 2013). By utilizing the panel data of the happiness survey carried out in ten countries, Welsch provided cross-border evidence for the negative relationship between air pollution and subjective sense of happiness (Welsch, 2006); Mackerron found that the respondents will feel a strong sense of happiness when they are in a beautiful natural environment rather than a more common external environment (Mackerron and Mourato, 2013).

In this context, the influence of government environmental regulation on national happiness has become an important topic that is widely concerned by both the academic circle and the government departments. In 2016, the Chinese government announced that China has entered the "13th Five-Year Plan" period, and would pay high attention to environmental regulation. On 4th January, 2016, the Central Environmental Protection Supervision Group was formally established and began to carry out environmental protection supervision in all provinces. In October 2017, President Xi of the People's Republic of China clearly pointed out that China would "construct an environmental management system led by the government, dominated by enterprises, and in which social organizations and the public are to participate (Wang and Li, 2018)", and pay more attention to the effective role of public participation in the environmental governance. In the previous environmental regulations, many parties have been involved, including government administration bodies and also a diversity of social organizations and people. The enhancement of the environmental governance performance in China, to a large extent, can be attributed to both the institutionalized regulatory policies and non-institutionalized public participation. Various social subjects, such as environment protection organizations, third-party agents and citizens, are all playing important roles (Dungumaro and Madulu, 2003). Among them, the most extensive participants are undoubtedly individual citizens, and the most common and direct way is participating in the environmental governance process by filing petition letters and reports and protecting their own rights through the judicial way. When a pollution incident breaks out, the direct participation of the public often plays a crucial role. Therefore, this paper intends to perform an empirical analysis of the relationships between government regulation, public participation, satisfaction with environmental governance and individuals' happiness using the data of CGSS2015.

Literature Review and Hypotheses

Improving public satisfaction and individuals' happiness has become an important goal for the government. Overall speaking, the influential factors to public service satisfaction can be divided into three categories - macro-factors, including government management and public service, meso-factors, including social organization development and public participation, and micro-factors, including personal development and personal expectation. Currently, there are few literatures focusing on the study of the influential mechanism for satisfaction with environmental governance, not to say the related empirical studies. With the improvement of people's living

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93179332

standards and the prominence of environmental pollution issues, both government departments and the public have increasing demands for environmental governance. However, satisfaction with environmental governance is a kind of subjective feeling of an individual, so it is necessary to study the micro-factors to personal perception. In the previous literatures, it can be found that the explanation models about satisfaction mainly consist of two perspectives, with one being the performance model perspective, and the other, the expectation model perspective. From the perspective of the latter, the public evaluation of government is a function of various government performances. Public satisfaction mainly depends on the performance that the government demonstrates in various aspects (Swindell and Kelly, 2000). From the perspective of the expectation model, the public evaluation of service is based on the comparison between the service quality they have truly received/felt and the one they expect. The most famous model is the service quality model (Parasuraman et al., 1988). This theory believes that satisfaction measures the gap between the performance perceived and the one expected by the public. That is to say, there is a significant positive correlation between performance and satisfaction if expectation remains unchanged (Parasuraman et al., 1991). To some extent, the improvement of satisfaction will also promote the improvement of individuals' happiness. Therefore, the government's environmental regulation and the satisfaction of public expectation will not only help improve satisfaction, but also lead to the improvement of happiness. This paper builds a new theoretical model by incorporating environmental regulation and public participation into the analytical framework and conduct in-depth research on the influencing mechanism for satisfaction with environmental governance and individuals' happiness based on these two perspectives.

Environmental governance and individuals' happiness

Environmental economists and happiness economists are all very concerned about environmental pollution problems, and they believe that in order to guarantee the happy life for the current generation and the welfare of the people in the future, it is necessary to reduce pollution and protect the natural environment (Menz, 2011). The studies carried out by previous scholars show that the environmental pollution has a negative relationship with the individuals' happiness. Welsch first analyzed air quality by measuring the pollutants such as sulfur dioxide and nitrogen dioxide, and studied the relationship between air pollution and individuals' subjective happiness using cross-sectional data from 54 countries. The results show that air pollution can significantly reduce individuals' happiness (Welsch, 2002). It affects individuals' happiness through the following ways: first, air pollution, water pollution and other common environmental pollution would affect individuals' health, furthermore reducing their subjective happiness (Yang and Liao, 2017); second, environmental pollution causes inconvenience to individuals' life, thus affecting their happiness. Environmental regulation can promote economic transformation and achieve green development to a certain extent (Chen and Yang, 2018). Therefore, this paper proposes the first hypothesis:

H1: Environmental regulation has a positive impact on happiness

Public participation and individuals' happiness

In the process of environmental regulation, government regulation is indispensable, but the public is also an important force and plays an important role in environmental

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93179332

protection. Public participation makes the decisions more rational and efficient and the whole society can be mobilized to protect the environment, which is the fundamental solution to the environment protection (Yang and Chen, 2019). Public participation enables people to better express their demands and intentions and exercise their environmental rights. Therefore, in the modern society, the role of public participation is becoming increasingly prominent. In the process of environmental regulation, we often face the double troubles of "market failure" and "government failure". In this case, public participation is undoubtedly the only way to eliminate environmental pollution. In this process, the expectations of stakeholders will be better satisfied and thus the sense of happiness will be enhanced. Therefore, this paper proposes the second hypothesis:

H2: Public participation has a positive impact on happiness.

Environmental regulation and satisfaction with government governance

From the perspective of the performance model, previous scholars generally believe that how the government performs determines the results of public evaluation and satisfaction (Kelly and Swindell, 2002). In a country like China, environmental protection and environmental accountability are the two most effective regulation methods. Increasing the weight of environmental protection assessment in performance assessment indices and adopting various forms of environmental accountability systems from the central government to the local government have both produced obvious effects and improved public satisfaction with environmental governance. In 2015, the Chinese government issued an outline for building a law-based government, which points out that the achievements in legal construction will also be incorporated into the index system. In recent years, the legalization of Chinese environmental regulation has been improving continually. Strengthening the legalization of environmental governance is not only beneficial to dealing with more serious environmental problems, but also conducive to the reconstruction of ecological responsibilities and the protection and realization of citizens' environmental rights. Therefore, the level of legalization of environmental governance has an influence over public's satisfaction. When the environmental governance tends to be more legalized, and the law systems more standardized, the quality of governmental regulation and service will be significantly improved, the environmental governance will enter a virtuous circle, and the public's satisfaction with environmental governance will be greatly improved (Kim and Kim, 2012). Based on this, this paper measures the degree of environmental governance by two indices - "environmental accountability" and "environmental governance legalization level", and proposes the hypothesis below:

H3: Environmental regulation has a positive impact on the satisfaction with government governance.

Public participation and satisfaction with government governance

From the prospective of the expectation model, the public satisfaction is a relative concept, which can be reflected by the gap between the actual performance and the expected one. Based on this model, previous scholars think that when the expectation is effectively satisfied, public satisfaction will be obviously improved (Parasuraman et al., 2002). In fact, public expectation is subjective and difficult to quantify. With the transformation of the government functions and the reform of administrative systems, public participation has become an effective method to express the demands and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93179332

expectations of the public. The higher the public participation, the more easily the expectation can be satisfied. Therefore, this paper uses the effectiveness of public participation to reflect the satisfaction degree of public expectation, which consists of two dimensions: the effectiveness of the process and that of the result. The former provides the public with more channels and ways to report their environmental problems, which realizes “procedural justice”. The effectiveness of the result means that the problems reported by the public can be truly solved, and that the environmental demands can be really satisfied. Ensuring the result effectiveness of public participation can help quickly solve environmental problems that have not been discovered by the government departments and cannot be solved by the market mechanism, so this realizes "outcome justice". In the real life, as a kind of political participation, petition has increasingly become an important means for citizens to interact with government departments and solve environmental problems (Tang, 2000). The process and result effectiveness of petition not only truly meets public’s expectation, but also improves their satisfaction towards environmental governance. Based on this, this paper proposes the hypothesis below:

H4: Public participation has a positive impact on satisfaction with government governance.

Satisfaction with government governance and individual’s satisfaction

The government has an important influence on individuals’ happiness with its resources and policies. The difference in government performance is one of the most important reasons for the differences in individuals’ happiness in different countries (Ott, 2011). Ott (2015) thinks that a good government protects human rights and judicial justice, alleviates social injustice and provides a good living environment and social environment for the public, thus improving individuals’ happiness. The government has the power to control the system execution, make policies and allocate resources, which can have direct impacts on the market, the society and even each individual, so a standardized and effective government has positive impacts on individuals’ happiness and accordingly, the improvement of the satisfaction with government governance will promote the individuals’ happiness (Coggburn and Schneider, 2003). Based on this, this paper proposes the fifth hypothesis:

H5: Satisfaction with government governance has a positive impact on individuals’ happiness.

Intermediary role of satisfaction with government governance

According to the above analysis, environmental regulation and public participation can help improve the satisfaction with government governance; and the satisfaction with government governance can further promote the improvement of individuals’ happiness. There is a high correlation between the quality of government public service and the public's satisfaction with public service. The latter can directly reflect the former (Swindell and Kelly, 2000). The level of government public service quality also directly influences individuals’ happiness. After comparing the impacts of government governance quality between the developed countries and the developing countries using the citizen satisfaction index in the world values survey (WVS), Helliwell found that in developing countries, the satisfaction with government public services has a greater impact on national happiness (Helliwell and Huang, 2008). Therefore, the satisfaction

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93179332

with government governance can be regarded as an intermediary variable. Based on this, this paper proposes the sixth hypothesis and sub-hypothesis.

H6: Satisfaction with government governance plays an intermediary role in the relationship between environmental regulation, public participation and individuals' happiness.

H6a: Satisfaction with government governance plays an intermediary role in the relationship between environmental regulation and individuals' happiness.

H6b: Satisfaction with government governance plays an intermediary role in the relationship between public participation and individuals' happiness.

Moderating role of individual characteristics (economic and social status)

Some individual characteristics, such as gender, age, education and income, would affect citizens' expectation, thus affecting the satisfaction with environmental governance and individuals' happiness. According to previous studies, income can reflect a person's economic status, and there is a certain positive correlation between income and subjective happiness (Shields et al., 2009). Higher education background can increase individual's independence and help form good interpersonal relations, and promote public participation and improvement of happiness (Chen, 2012). Besides, based on the "profit-cost" allocation, the group with higher economic status enjoys more profits generated at the expense of environment, but they use their economics advantages to pass on the environmental consequences and environmental governance accountability to the relatively more vulnerable groups. However, the poor are less able to migrate than the rich and less able to avoid environmental pollution. Generally speaking, the group with higher income and education background has more ways to express their claims and participate in the public. Therefore, this paper uses economic income and education level to measure the economic and social status of individual characteristics, and puts forward the following hypotheses:

H7: The higher the economic and social status, the more significant the positive impact of environmental regulation on individuals' happiness.

H8: The higher the economic and social status, the more significant the positive impact of public participation on individuals' happiness.

Above all, this paper mainly studies the impacts of environmental regulation and public participation on individuals' happiness. During the process, satisfaction with government governance is an intermediate variable, while individual income and education level are moderating variables. The theoretical model constructed according to the research hypothesis is shown in *Figure 1*. Since the age and gender of individuals also have impacts on happiness (Cai et al., 2018), this paper takes these two factors as control variables for analysis in the data processing process.

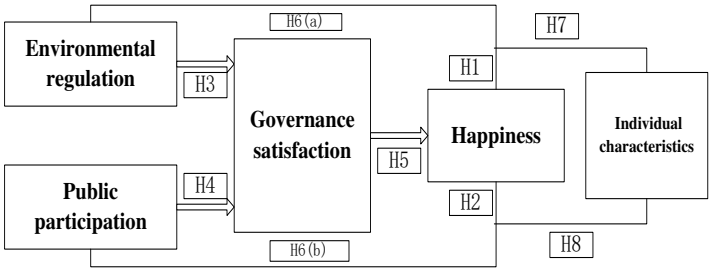

Figure 1. *Variable models in this paper*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93179332

Materials and Methods

Materials

In this paper, environmental accountability and the environmental regulation legalization level are used to measure the government environment regulation. In the CSSS survey, there are six modules-A, B, C, D, E and F, in which F is the "legal module", consisting of questions on government accountability and regulatory compliance, with environmental regulation sub-questions. The corresponding original questions are "Will the government be held accountable when the government leaders blindly pursue output value and neglect the supervision on enterprise pollution discharge, resulting in environment deterioration?" and "How is the government's compliance with laws when it is handling environmental pollution?". The higher the score, the stronger the government's environmental regulation and the higher the level of legalization.

In terms of public participation, when an individual is facing environmental pollution issues, the common way to safeguard his or her rights is to file a petition letter. With the gradual improvement of the environmental protection petition system in China, petition now plays an increasingly important role in environmental regulation. In the real life, there are two requirements to be met if environmental pollution problems can be solved by petition: first, the public's petition rights have been safeguarded; second, the environmental problems reported by the public have been effectively solved. This paper measures public participation from the two dimensions: first, "will the petition be blocked" (process effectiveness), second, "can the petition solve your problem" (result effectiveness). In the CGSS survey module F, the questions related to petition have been set. The original questions are respectively "Do you agree with the following: petition will not be blocked" and "Do you agree with the following: petition can solve the problem". The higher score is, the higher degree of public participation there will be.

The satisfaction with government governance is covered by question B15 in the module B of the CGSS questionnaire. The original question is "Are you satisfied with the government's performance in environmental protection?" This paper determines the satisfaction degree of environmental governance based on this. In the original questionnaire, the corresponding ratings are "very satisfied--satisfied--neutral--dissatisfied--very dissatisfied", with a score from 1 to 5. This paper uses the negative numbers, so that the higher the score is, the higher the satisfaction degree will be.

Concerning the happiness and individual's economic social status, there are relative questions in module A of the CGSS questionnaire. The question about happiness is "Generally speaking, are you happy?" In the choices, 1 represents "very unhappy", and 5 "very happy". The higher the score is, the happier the respondent is. The income in individual characteristics refers to the actual income of the respondent. The education background is divided into 13 grades, with 1 representing "illiterate", 13 "Postgraduate and above". The higher the score is, the higher the education level is. In control variables, age is 2018 minus the year of birth. Men are assigned with a value of 1, while women, 2.

Study samples and data sources

The related variable data in this paper are mainly from the survey results of Chinese General Social Survey in 2015 (CGSS2015), which is the first national, comprehensive, continual and large-scale social investigation program in China. The purpose is to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93179332

regularly and systematically collect data of Chinese people and various aspects of Chinese society, summarize the long-term trends of social changes, explore social issues of great theoretical and practical significance, promote the openness and sharing of domestic social science research and provide data for government decision-making and international comparative research. Since 2003, it has carried out sample surveys among 10,000 families in 31 provinces in China annually. The lasted survey was carried out in 2015 with the data released in January 2018. The survey comprehensively measures the living and development status of urban and rural residents, public's satisfaction with social governance, and individual's perception of the government's legal construction. The samples are large in size and widely distributed in China, which is suitable for the correlation analysis in this study. In the specific analysis process, some data have been processed, and the choices "unable to answer", "refuse to answer", "don't know" and "not applicable" are regarded as missing values. Variable measurement and data processing are shown in *Table 1*.

Table 1. *Variable measurement and data processing*

Category	Variable	Survey Item	Illustrate
Independent variable	Environmental regulation	1: Will the government be asked to take the responsibility when the government leaders exclusively pursue output value and neglect the supervision for the enterprise pollution discharge which resulted in the environment deterioration? 2: How is the government's level of handling environmental pollution in accordance with law	The higher the score is, the stronger the government's environmental regulation and the higher the level of legalization will be.
	Public participation	1: Will be the petition blocked 2: Can the petition solve your problem	The higher score means the higher degree of public participation.
Moderating variable	Individual features	1: Annual gross income	The bigger the value, the higher the income.
		2: Educational level.	The higher the value, the higher the degree
Intermediary variable	Satisfaction	Are you satisfied with the government's performance in environmental protection?	The higher the value is, the higher the satisfaction degree is.
Control variable	Gender	Gender	Male is 1, female is 2
	Age	Date of birth	2018 minus date of birth
Dependent variable	Happiness	Generally speaking, are you happy	The higher the value, the higher the degree.

In the specific survey process, module A is the core, and module B is the "ten-year review" module, in which all questions are mandatory to the respondents. The samples for dependent variables and control variables in this paper cover more than 10,000 families. However, module F module only conducted a sampling survey among more than 3,000 households. After data sorting, it was found that only 3,777 people were required to complete this section. Considering there are missing values, the effective sample size would be even less than 3,777. Therefore, only more than 3,000 samples are used for the independent variables in this paper.

Results

Reliability test and single-dimension analysis

This study adopts the software SPSS 21.0 and AMOSS 21.0, respectively, to test the reliability and validity structures of the choices for measurement, and uses the CITC and reliability analysis methods to analyze the reliability of the choices, with CITC>0.3 and Cronbach's α>0.7 as the criteria. The survey choices in the table correspond to those in the questionnaire. The analysis results show that all the CITC values are greater than 3, and that the overall Cronbach's α parameters are all greater than 0.7, which meet the reliability requirements, and thus the choices can be applicable to future analysis.

Before analyzing the factors, it is necessary to confirm whether there are common factors in the data. Bartlett sphere test is used to test whether the related matrix is the unit matrix or not, which indicates the suitability of the factor model. The KMO (Kaiser-Meyer-Olkin) value indicates whether the selected samples are suitable or not and also whether the information is suitable for factor analysis. The KMO value ranges from 0 to 1. It is generally believed that a value above 0.9 means the sample is very suitable, that 0.8-0.9, the sample is quite suitable, that 0.7-0.8, the sample is suitable, and that a value below 0.5, the sample is not suitable. The probability P-value of the Bartlett sphere test should be less or equal to the significance level. *Table 2* shows that the KMO values of all the variables are greater than 0.7 in this study, which is suitable for future study.

Table 2. *Results of KMO and Bartlett's test*

Variable	Dimension	KMO	Bartlett's Test			Suitability
			Chi-square	Freedom	P	
Independent variable	Environmental regulation	.789	570.197	6	.000	Fit
	Public participation	.779	519.290	6	.000	Fit
Intermediary	Satisfaction	.886	1065.282	15	.000	Very fit
Moderating1	Income	.715	299.969	6	.000	Fit
Moderating2	Educational level	.723	308.471	6	.000	Fit

In order to further guarantee the validity of the scale, this study carries out exploratory factor analysis (EFA) to understand whether the number and content of levels in the scale are consistent with those of the operational definition. The results show that the load values of the two factors extracted from the independent variables meet the analysis requirements and the overall validity is acceptable.

Descriptive statistical analysis

Table 3 is the descriptive statistical analysis results of the data after being processed. Since there are only 3,777 respondents for module F, this paper carries out two descriptive statistical analysis based on the related variables, including the overall sample statistical analysis, and the subsample statistical analysis for the answers only in module F. Among the variables, the value of the environmental governance legalization is greater than that of environmental accountability, which shows that the respondents generally believe that the level of legalization in environmental governance is higher than the level of accountability. But both values are lower than 3, which shows that neither factor is at a high level.

Table 3. *Results of descriptive statistic analysis*

Measurement Item (Variable Code)	N	Min	Max	Average	Standard Deviation
Environmental Accountability (EC)	3236	1	5	2.63	1.12
Governance Legalization (EL)	3641	1	5	2.95	0.88
Petition can't be Blocked (P1)	3337	1	5	2.61	1.06
Petition can Solve Problem (P2)	3341	1	5	2.73	1.06
The Whole Sample					
Personal Annual Gross Income (I1)	10363	0	9999990	32805.33	205840.55
Education Level (ED1)	10939	1	13	4.87	3.11
Government Governance Satisfaction (S1)	10820	-1	-5	-2.7	0.92
Gender(G1)	10968	1	2	1.53	0.50
Age (A1)	10968	21	98	53.4	16.90
Individuals' happiness (H1)	10953	1	5	3.87	0.821
Sub-sample					
Personal Annual Gross Income (I2)	3578	0	2000000	27792.19	59698.21
Education Level (ED2)	3767	1	13	4.82	3.07
Government Governance Satisfaction (S2)	3739	-1	-5	-2.7	0.91
Gender (G2)	3777	1	2	1.53	0.50
Age (A2)	3777	21	98	53.22	17.07
Individuals' happiness (H2)	3735	1	5	3.81	0.81

In the whole samples, the value of the variable individuals' happiness is 3.87, and 59.97% of the respondents are in the "relatively happy" status. The maximum score for the satisfaction with government environmental governance is -1, the minimum value -5, and the average -2.7. The choice with a score of -2 is "satisfied", and 42.0% of the respondents chose it. The choice with a score of -3 is "neutral", which 32.7% of the respondents chose. It can be clearly seen that the majority citizens are satisfied with the government's environmental governance work, but the average value of happiness is greater than that of satisfaction. Concerning the individual characteristics, the average amount of annual income per capita was 32805.33 RMB, and the standard deviation was as high as 205840.55 RMB, which shows the respondents have great income disparities. According to the official data from the national bureau of statistics, the per capita disposable income of Chinese residents in 2014 was 20167 RMB. So overall, the income level of the respondents is higher than the national average. In terms of education, the average score is 4.87. In the original questionnaire, a score of 5 corresponds to vocational high school, so the average score means that the education level of the respondents is between junior and senior high school, which is consistent with the actual situation - nine-year compulsory education - in China. However, the education level of the urban and rural residents as a whole still remains to be improved compared with that in western developed countries.

The extreme, average and standard deviation of the mediating variables and dependent variables in the sub-samples are generally consistent with those in the overall samples. The gender distribution in the system variable is consistent with that in the overall samples, and the male-female ratio is relatively balanced. The maximum personal annual income in the moderating variable is 2 million RMB, the average and the standard deviation are respectively 27792.19 RMB and 59698.21 RMB which are both lower than the results in the overall samples. This shows that the individual income disparity of the sub-samples is relatively small, which is consistent with the actual situation. The highest education level in the moderating variable is basically consistent with the overall situation in the overall samples. This indicates that the sub-samples are highly representative and suitable for further analysis.

Note: ***, ** and * are significant at the statistical levels of 0.01, 0.05, and 0.1 respectively

Model 1 and model 2 respectively focus on the impacts of environmental regulation and public participation on satisfaction with government governance. Among the control variables, gender has no significant impact on satisfaction with government environmental governance, but age is positively correlated with satisfaction with government environmental governance, indicating that young people are less satisfied compared with elder people. Both environmental regulation and public participation can positively promote the improvement of satisfaction with government governance, which verifies hypothesis 3 and hypothesis 4, and the significance of government regulation is higher than that of public participation. Model 3 and model 4 show that gender has no significant impact on individuals' happiness, and age is positively correlated with happiness, indicating that compared with young people, elder people are happier. Both environmental regulation and public participation have significant positive impacts on individuals' happiness, which verifies hypothesis 1 and hypothesis 2, and the coefficient of government regulation is higher than that of public participation. Model 5 reflects that satisfaction with government governance has a positive impact on happiness, which verifies hypothesis 5.

Model 6 shows that the impact of the independent variable environment regulation on individuals' happiness is obviously reduced after the satisfaction with government governance is added, which reflects that there is a significant partial mediating effect between environmental regulation and individuals' happiness; model 7 also shows that the impact of the independent variable public participation on individuals' happiness is obviously reduced after the satisfaction with government governance is added, which reflects that there is a significant partial mediating effect between public participation and individuals' happiness. Based on the above analysis, hypothesis 6a and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93179332

hypothesis 6b are also verified. Model 8 shows the impact of the mutual interaction between environmental regulation and personal income on individuals' happiness, and compared with that in model 3, the significance of environmental regulation is improved. Module 9 shows the impact of the interaction between public participation and personal income on individuals' happiness, and the significance of public participation is improved when compared with that in, module 4, which verifies hypothesis 7. Model 10 shows the impact of environmental regulation and education interaction on individuals' happiness. Compared with that in model 3, the impact of environmental regulation is significantly enhanced. Model 11 shows the impact of the interaction between public participation and education on individuals' happiness. Compared with that in model 4, the impact of public participation is significantly enhanced. Therefore, education level also has a positive moderating effect, proving Hypothesis 8.

Robustness test

In fact, there are many forms of public participation in environmental governance and right relief. Besides petition, judicial litigation is undoubtedly a relatively common way. In order to verify the reliability of the results in *Table 4*, this paper replaces the two questions used in the above questionnaire to measure the "effectiveness of public participation" and replaces the questions related to petition with those related to environmental lawsuit. In module F in the CGSS2015 questionnaire, questions F10 and F11 cover the timeliness and the enforcement effort of the court when the public participates in environmental governance through litigation, which could be used to measure the process and result effectiveness of public participation. The original question F10 is "If there is an enterprise nearby discharging waste gas or sewage in violation of regulations, which results in serious harm to the health of the residents, how soon do you think the court will make a decision if you file a lawsuit, asking the above enterprise to compensate for loss?" The higher the score is for the question, the stronger the process effectiveness of public participation will be. The original question for F11 is "If the court's ruling is in favor of the residents, but the enterprise doesn't execute the ruling and the resident applies for compulsory execution, how do you think the execution will go?" The higher the score is for the question, the stronger the process effectiveness of public participation will be. Therefore, this paper covers the two dimensions of the variable "public participation effectiveness" with the above two questions to test its robustness. Overall, the results are generally consistent with *Table 4*. Therefore, the models in this paper have strong robustness.

Discussion

Improving the government environmental governance and the effectiveness of public participation is both beneficial to improving satisfaction and happiness

The study in this paper indicates that guaranteeing the effectiveness of environmental accountability and expanding the ways of public participation can effectively solve the environmental pollution issues, and improve the satisfaction with government environmental governance and individuals' happiness. Therefore, we should further improve the mechanism of public participation in environmental governance and formulate the legal system at the macro level to protect the right of the public to report

problems and claim for compensation, encourage the development of environmental protection organization and take social organizations as the bridge between the government and the public to effectively carry out environmental regulation at the meso level, and set up hotlines and email boxes for reporting of environmental protection problems at the micro level so that individuals can more actively participate in the environmental regulation process.

Satisfaction with government governance plays an intermediary role between environmental regulation, public participation and individuals' happiness

Besides strengthening government regulation and expanding the ways for public participation, we should also make effort to improve effectiveness and truly solve environmental problems. We should shift the focus from "process orientation" and "input orientation" to "problem orientation" and "result orientation". After receiving reports and feedbacks from the public, practical implementation plans should be put forward to truly solve environmental problems. Only when the public's requirements are fully met, can we promote the improvement of the environmental governance system and realize "process justice" and "outcome justice", so as to ensure environmental protection development and improve individuals' happiness.

Individual's economic and social status plays a positive moderating role in the relationship among environmental regulation, and public participation and individuals' happiness

Overall, people with higher income and education level have more ways to express their own demands, higher awareness of safeguarding their environment rights, as well as more ways for public participation. The higher the income is, the more significant the impact of environmental regulation and public participation will be on individuals' happiness. This requires the government to apply various methods to improve individuals' happiness according to the real situations, pay attention to the environmental demands and living requirements of the group with lower income and education background. The group with higher economic status enjoys more profits generated at the expense of the environment, but they can utilize their economics advantages to pass on the environmental consequences and environmental governance accountability to the relatively more vulnerable groups. Therefore, the government should adjust public finance in the second distribution and allocate more public expenditures to the vulnerable groups so as to meet their demands, promote social justice and further improve individuals' happiness.

Conclusions

The results of the empirical study show that both reinforcing government accountability and improving the environmental governance legalization level can effectively improve the satisfaction with environmental governance and individuals' happiness. We should make full use of environmental accountability in the future, and increase the number and weights of environmental performance indices in the government management performance system, intensify accountability and implement environmental regulatory policies. At the same time, we should make environmental governance more legalized and standardized, set up specific laws and regulations on

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93179332

environment regulation, punishment and safeguarding of rights, improve relevant systems and mechanisms and establish a sound environment regulation system.

Overall, the score of satisfaction with government environmental governance is lower than the average score of individuals' happiness. The satisfaction with government environmental governance has positive impacts on individuals' happiness, and plays an intermediary role between environmental regulation, public participation and individuals' happiness. It acts on individuals' happiness in both objective and subjective ways. Environmental governance can solve environmental pollution issues and enhance the public's satisfaction towards public service, thus improving individuals' happiness. Therefore, we should focus on improving the efficiency of government environmental governance, meeting public needs, and improving environmental governance satisfaction.

Individual's economic and social status plays a positive moderating role in the relationships between environmental regulation, public participation and individuals' happiness. It is clear that the higher the income is, the greater the effect of the independent variable will be on individual's happiness, education level also has a positive moderating effect. Therefore, the government should also pay attention to taking different measures according to the needs of different groups of people in the process of environmental governance.

This study has certain limitations due to limited time and space. The questionnaire is only issued in China and only reflects the situation in the year of 2015. We can issue questionnaires on a larger scale in the future, Conducting cross-country research and multinational comparison. It is also possible to conduct follow-up surveys and collect data for many years, analyze and study years of panel data. Research the influences of government regulation and public participation on satisfaction with environmental governance and individuals' happiness in different countries at different times.

(Received 3rd Apr 2019; accepted 17th May 2019)

Abstract. Focusing on a two-echelon green supply chain in the context of carbon emissions, this paper sets up a Stackelberg game model of a loss-averse retailer and a risk-neutral manufacturer according to the prospect theory, solves the equilibrium ordering and green emission reduction strategies under decentralized decision-making by inverse induction, and then puts forward a cost sharing-revenue sharing contract to coordinate the supply chain. The results show that the positive/negative correlation between the retailer's optimal order quantity and the loss aversion coefficient depends on the distribution of random demand and the scale of unit shortage penalty cost; the green supply chain with loss aversion and carbon emissions can be coordinated if the retailer shares some of the manufacturer's green emission reduction cost and enjoys part of the manufacturer's profit; the parameters of the coordinate contract are constrained by the wholesale price of the manufacturer, but proper parameter values can ensure the Pareto optimization of the profits of both parties. Finally, numerical analysis shows that the proposed coordination contract can coordinate the target supply chain.
Keywords: *loss-averse, cap and trade, green emission reduction, cost sharing, revenue sharing*

Introduction

Since it was proposed by Michigan State University in 1996, green supply chain management has been emphasized and enforced by more and more governments and enterprises (Handfield et al., 1996). In China, many laws and regulations have been launched to encourage enterprises to develop clean energy and produce green products, enabling them to overcome green trade barriers in multilateral trade (Zhang, Zheng and Hu, 2019). For example, the Chinese State Council released the "Made in China 2025" strategy in May 2015, raising the concept of "green manufacturing". In March 2016, the National Development and Reform Commission issued the *Guiding Opinions on Promoting Green Consumption*, calling enterprises to promote the construction of green supply chains. Nowadays, people are increasingly aware of the importance of resources and the environment, and holding a favorable attitude towards green and low-carbon concepts. With the continued expansion of green consumers, modern enterprises are obliged to enhance the positive externalities of their products, and introduce greener products to the market. Against this backdrop, the green supply chain becomes a new hotspot in the research of supply chains.

The green supply chain has been studied extensively from multiple angles at home and abroad. For instance, Zhang and Liu (2013) created three coordination mechanisms to discuss the coordination of three-echelon green supply chain system. Xie (2015) introduced government subsidy into the analysis on the greenness and price of green supply chain products, and coordinated the supply chain with wholesale price contract and revenue sharing contract. Sheu and Chen (2012) suggested that the government should

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93339346

take incentives to coordinate the green supply chain. Basiri and Heydari (2017) relied on a mathematical programming model to examine the channel coordination of two-echelon green supply chains. Zhang et al. (2018) established four green supply chain game models considering the participants' fairness preference, product greenness and government subsidy, and set up a coordination model based on cost and revenue sharing contract.

With the dawn of the low-carbon era, consumers are more willing to buy green products with carbon labels (Shuai and Zhang, 2013). Meanwhile, the carbon emission trading market has been unified by the government, allowing enterprises to buy or sell emission permits in a free manner. The trading mechanism encourages the enterprises to reduce carbon emission and improve product greenness (Jing et al., 2018). As a result, more and more scholars have turned their attention to supply chain problems in the context of carbon emission. For example, Hua et al. (2011) investigated the order quantity and inventory management of enterprises under the carbon cap and trading policy. Jaber et al. (2013) looked for the optimal inventory strategy under the same conditions. Du et al. (2013) analyzed the effect of carbon cap on the coordination of a two-echelon supply chain, in which the upstream manufacturer emits carbon in the production process. Zhang, Dong and Zhang (2019) discussed the selection of supply chain strategies under such factors as carbon quota and trading mechanism, emission reduction technology and the low-carbon preference of consumers.

To sum up, there are not many reports on green supply chain in the context of carbon emissions. Most of the existing studies assume that the decision-maker is purely rational, which goes against the reality. The actual market is full of uncertainties. Hence, the members of a supply chain face various risks of loss. If the supply chain is small, the participants are often loss-averse (Li et al., 2013). The loss aversion behavior was first discussed in the prospect theory (Kahneman and Tversky, 2013). Since then, many scholars have integrated the behavior with operation management. For example, He and Zhou (2011) studied the impact of loss aversion on the portfolio model. Liu and Shum (2013) explored the effect of loss-averse consumers on enterprise pricing. Liu and Fan (2017) probed into the coordination of two-echelon supply chain considering product quality and loss aversion. Du et al. (2018) investigated the effect of loss aversion behavior on the two-echelon supply chain with random supply and demand. Samatli-Pac et al. (2018) discussed the impact of consumer loss aversion on repurchase strategies and supply chain coordination.

Obviously, the previous research has not tackled the decision-making and coordination of green supply chain that consider loss aversion behavior. To make up for this gap, this paper attempts to coordinate the green supply chain in the context of loss aversion and carbon emissions. Firstly, a Stackelberg game model was established based on the prospect theory, covering a loss-averse retailer and a risk-neutral manufacturer. Then, the equilibrium ordering and green emission reduction strategies were solved under the decentralized decision-making mode, and the effect of the retailer's loss aversion behavior on the optimal order quantity was analyzed in detail. Finally, a cost sharing-revenue sharing contract was designed to coordinate the said supply chain.

Materials and methods

Problem description

This paper targets a two-echelon green supply chain consisting of a risk-neutral manufacturer and a loss-averse retailer. The manufacturer is assumed as the leader in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93339346

the market and the retailer, a follower. The two parties are in a Stackelberg game of complete information. The manufacturer first determines the green emission reduction level θ of a product, and then the retailer decides on the order quantity q of the product. Let w and c be the unit wholesale price and the unit production cost of the manufacturer, respectively, and p, v and g be the unit retail price, unit salvage value and unit shortage cost of the retailer, respectively. Here, it is assumed that $p > w > c > v$.

Hypothesis 1: The manufacturer, as the subject of carbon emissions, receives a free carbon quota E from the government. Under the carbon cap and trading policy, the enterprise needs to purchase emission permit in the carbon trading market if it emits more carbon than the quota; otherwise, the enterprise can sell the surplus permit. The unit transaction price p_t is exogenous. Without emission reduction technology, i.e. $\theta = 0$, the amount of carbon emitted by the manufacturer is denoted as e; after adopting the technology, that amount is reduced to $(1-\theta)e$. Here, θ $(0 \leq \theta < 1)$ refers to the emission reduction efficiency of the manufacturer.

Hypothesis 2: In commodity trading, the greenness of a product is often described by the energy rating label, the carbon label, the content of harmful substances, and the recyclability of the parts. Thus, the product greenness can be observed and calculated. To make its products greener, the manufacturer should step up its R&D investment on green emission reduction. Inspired by the investment cost model, this paper depicts the emission reduction cost with the quadratic cost function: $H(\theta) = 0.5\alpha\theta^2$, where α is the green emission reduction cost.

Hypothesis 3: The market demand of a product is stochastic and depends on product greenness. The market demand function of a product is assumed as *Equation 1*.

$$D(\theta) = A + B\theta + \varepsilon = y(\theta) + \varepsilon \quad \text{(Eq.1)}$$

where A is the market demand, B is the green preference of consumers, and ε is a continuous random variable in the interval $[M, N]$. The cumulative distribution function and probability density function of the variable are denoted as $F(\varepsilon)$ and $f(\varepsilon)$, respectively.

Under the above hypotheses, the retailer's and manufacturer's profit functions for fulfilling any demand x can be respectively expressed as *Equations 2* and *3*.

$$\pi_r(q) = pmin(q, D) + v(q-D)^+ - g(D-q)^+ - wq = \begin{cases} (p-v)x + (v-w)q, & x < q \\ (p-w+g)q - gx, & x \geq q \end{cases} \quad \text{(Eq.2)}$$

$$\pi_m(\theta) = (w-c)q + p_t[E - (1-\theta)e] - \frac{1}{2}\alpha\theta^2 \quad \text{(Eq.3)}$$

Decision-making model based on loss aversion

Considering the loss aversion of the retailer, the simple piecewise linear function was introduced to describe the decision-maker (Kahneman and Tversky, 2013). Let π be the profit of the decision-maker. Then, the utility function of the decision-maker can be defined as *Equation 4*.

$$U(\pi) = \begin{cases} \pi, & \pi \geq 0, \\ \lambda\pi, & \pi < 0. \end{cases} \quad \text{(Eq.4)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93339346

The retailer's expected utility was discussed under two conditions.

Lemma 1 (i) If $x < q$ and $\pi_1 = (p-v)x + (v-w)q = 0$ is the retailer's profit function, then the breakeven point of the demand is $x_1 = \frac{(w-v)q}{p-v}$, i.e. the retailer makes no profit when the demand $x = \frac{(w-v)q}{p-v}$, makes profit when $x > \frac{(w-v)q}{p-v}$, and suffers losses when $x < \frac{(w-v)q}{p-v}$. In this case, the retailer's expected utility is $E[U(\pi_1)] = \lambda \int_M^{x_1-y(\theta)} \pi_1 f(\varepsilon)\, d\varepsilon + \int_{x_1-y(\theta)}^{q-y(\theta)} \pi_1 f(\varepsilon)\, d\varepsilon$.

(ii) If $x \geq q$ and $\pi_2 = (p-w+g)q - gx = 0$ is the retailer's profit function, then the breakeven point of the demand is $x_2 = \frac{(p-w+g)q}{g}$, i.e. the retailer makes no profit when the demand $x = \frac{(p-w+g)q}{g}$, makes profit when $x > \frac{(p-w+g)q}{g}$, and suffers losses when $x < \frac{(p-w+g)q}{g}$. In this case, the retailer's expected utility is $E[U(\pi_2)] = \int_{q-y(\theta)}^{x_2-y(\theta)} \pi_2 f(\varepsilon)\, d\varepsilon + \lambda \int_{x_2-y(\theta)}^{N} \pi_2 f(\varepsilon)\, d\varepsilon$.

According to Lemma 1, the retailer's expected utility can be described as *Equation 5*.

$$E\left[U\left(\pi_r(q)\right)\right] = E\left[U\left(\pi_1\right)\right] + E\left[U\left(\pi_2\right)\right] = \lambda \int_M^{x_1-y(\theta)} \pi_1 f(\varepsilon) d\varepsilon + \int_{x_1-y(\theta)}^{q-y(\theta)} \pi_1 f(\varepsilon) d\varepsilon + \int_{q-y(\theta)}^{x_2-y(\theta)} \pi_2 f(\varepsilon) d\varepsilon + \lambda \int_{x_2-y(\theta)}^{N} \pi_2 f(\varepsilon) d\varepsilon = E\left(\pi_r(q)\right) + (\lambda - 1)\left[\int_M^{x_1-y(\theta)} \pi_1 f(\varepsilon) d\varepsilon + \int_{x_{2-y(\theta)}}^{N} \pi_2 f(\varepsilon) d\varepsilon\right] \quad \text{(Eq.5)}$$

where $E(\pi_r(q)) = \int_M^{q-y(\theta)} \pi_1 f(\varepsilon)\, d\varepsilon + \int_{q-y(\theta)}^{N} \pi_2 f(\varepsilon)\, d\varepsilon$ is the expected utility of risk-neutral retailer.

Equation 5 means the expected utility of loss-averse retailer equals the expected profit plus the total expected underage and overage losses, biased by a factor of $\lambda - 1$. Note that $\lambda - 1$ is the loss aversion factor. In particular, when $\lambda = 1$, the second term on the right side of the equation disappears. In this case, the retailer's expected utility equals the expected profit, that is, the retailer is risk-neutral.

The decision-making problem of a loss-averse retailer and a risk-neutral manufacturer can be respectively expressed as *Equations 6* and *7*.

$$max_{q>0}\, E\left[U(\pi_r(q))\right] \quad \text{(Eq.6)}$$

$$max_{0\leq\theta<1}\, \pi_m(\theta) \quad \text{(Eq.7)}$$

Optimal strategy in decentralized mode

Under decentralized decision-making, the manufacturer and the retailer only consider their own profits (utilities) and make decisions independently. As the leader of the Stackelberg game, the manufacturer first determines the green emission reduction level

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93339346

θ of a product, and then the retailer, as the follower, decides on the order quantity q of the product. By inverse induction, the author calculated the optimal order quantity q_λ^* of the loss-averse retailer before deriving the optimal green input level θ^* of the manufacturer.

Theorem 1: $E\left[U\left(\pi_r(q)\right)\right]$ is a strict concave function with respect to q, and $\max_{q>0} E\left[U\left(\pi_r(q)\right)\right]$ has a unique optimal solution q_λ^* that satisfies *Equation 8*.

$$\int_{\frac{(w-v)q}{p-v}-y(\theta)}^{q-y(\theta)}(v-w)f(\varepsilon)d\varepsilon+\int_{q-y(\theta)}^{\frac{(p-w+g)q}{g}-y(\theta)}(p-w+g)f(\varepsilon)d\varepsilon+$$
$$\lambda\left[\int_{M}^{\frac{(w-v)q}{p-v}-y(\theta)}(v-w)f(\varepsilon)d\varepsilon+\int_{\frac{(p-w+g)q}{g}-y(\theta)}^{N}(p-w+g)f(\varepsilon)d\varepsilon\right]=0 \quad \text{(Eq.8)}$$

Proof: Substituting π_1, π_2, x_1 and x_2 into *Equation 5*, we have:

$$E\left[U\left(\pi_r(q)\right)\right]=\lambda\int_{M}^{\frac{(w-v)q}{p-v}-y(\theta)}\left\{(p-v)\left[y(\theta)+\varepsilon\right]+(v-w)q\right\}f(\varepsilon)d\varepsilon+$$
$$\int_{\frac{(w-v)q}{p-v}-y(\theta)}^{q-y(\theta)}\left\{(p-v)\left[y(\theta)+\varepsilon\right]+(v-w)q\right\}f(\varepsilon)d\varepsilon+$$
$$\int_{q-y(\theta)}^{\frac{(p-w+g)q}{g}-y(\theta)}\left\{(p-w+g)q-g\left[y(\theta)+\varepsilon\right]\right\}f(\varepsilon)d\varepsilon+ \quad \text{(Eq.9)}$$
$$\lambda\int_{\frac{(p-w+g)q}{g}-y(\theta)}^{N}\left\{(p-w+g)q-g\left[y(\theta)+\varepsilon\right]\right\}f(\varepsilon)d\varepsilon$$

Then, the first- and second-order derivatives of *Equation 9* relative to q can be obtained as *Equations 10* and *11*.

$$\frac{dE\left[U(\pi_r(q))\right]}{dq}=\int_{\frac{(w-v)q}{p-v}-y(\theta)}^{q-y(\theta)}(v-w)f(\varepsilon)\,d\varepsilon+\int_{q-y(\theta)}^{\frac{(p-w+g)q}{g}-y(\theta)}(p-w+g)f(\varepsilon)\,d\varepsilon+$$
$$\lambda\left[\int_{M}^{\frac{(w-v)q}{p-v}-y(\theta)}(v-w)f(\varepsilon)\,d\varepsilon+\int_{\frac{(p-w+g)q}{g}-y(\theta)}^{N}(p-w+g)f(\varepsilon)\,d\varepsilon\right] \quad \text{(Eq.10)}$$
$$\frac{d^2E[U(\pi_r)]}{dq^2}=-(p-v+g)f\left(q-y(\theta)\right)-\frac{\lambda-1}{(p-v)g}$$

$$\left[g(w-v)^2f\left(\frac{(w-v)q}{p-v}-y(\theta)\right)+(p-v)(p-w+g)^2f\left(\frac{(p-w+g)q}{g}-y(\theta)\right)\right] \quad \text{(Eq.11)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93339346

Since $p > v$ and $\lambda \geq 1$, we have $\frac{d^2E[U(\pi_r)]}{dq^2} < 0$, indicating that $E\left[U\left(\pi_r(q)\right)\right]$ is a strict concave function with respect to q. Considering the first-order condition $\frac{dE\left[U\left(\pi_r(q)\right)\right]}{dq} = 0$, it can be seen that the unique optimal solution q_λ^* of loss-averse retailer satisfies *Equation 8*.

If the retailer is risk-neutral, i.e. $\lambda = 1$, then *Equation 8* can be rewritten as *Equation 12*.

$$\int_M^{q-y(\theta)} f(\varepsilon)\, d\varepsilon = \frac{p-w+g}{p-v+g} \tag{Eq.12}$$

Therefore, the optimal order quantity of risk-neutral retailer $q_1^* = F^{-1}\left(\frac{p-w+g}{p-v+g}\right) + y(\theta)$.

The effect of loss aversion of the retailer on the optimal order quantity can be summed up as Property 1 below.

Property 1: If $(w-v)F\left(x_1 - y(\theta)\right) + (p-w+g)F\left(x_2 - y(\theta)\right) < (p-w+g)$, then $\frac{dq_\lambda^*}{d\lambda} > 0$; if $(w-v)F\left(x_1 - y(\theta)\right) + (p-w+g)F\left(x_2 - y(\theta)\right) = (p-w+g)$, then $\frac{dq_\lambda^*}{d\lambda} = 0$; if $(w-v)F\left(x_1 - y(\theta)\right) + (p-w+g)F\left(x_2 - y(\theta)\right) > (p-w+g)$, then $\frac{dq_\lambda^*}{d\lambda} < 0$.

Proof: The following *Equation 13* can be derived from the implicit function theorem:

$$\frac{dq_\lambda^*}{d\lambda} = \frac{\frac{\partial^2 E[U(\pi_r)]}{\partial q \partial \lambda}}{\frac{\partial^2 E[U(\pi_r)]}{\partial q^2}} = \frac{(p-w+g) - (w-v)F\left(x_1 - y(\theta)\right) - (p-w+g)F\left(x_2 - y(\theta)\right)}{\frac{\partial^2 E[U(\pi_r)]}{\partial q^2}} \tag{Eq.13}$$

Besides, *Equation 11* shows that $\frac{\partial^2 E[U(\pi_r)]}{\partial q^2} < 0$. Thus, the sign of $\frac{dq_\lambda^*}{d\lambda}$ is opposite to the positivity/negativity of $(p-w+g) - (w-v)F\left(x_1 - y(\theta)\right) - (p-w+g)F\left(x_2 - y(\theta)\right)$. Q.E.D.

Property 1 indicates that the optimal order quantity of loss-averse retailer is closely related to the demand distribution and the unit shortage cost. Without considering shortage cost, i.e. $g = 0$, we have $x_2 - y(\theta) \to +\infty$. Thus, the condition $(w-v)F\left(x_1 - y(\theta)\right) + (p-w)F\left(x_2 - y(\theta)\right) > (p-w)$ is always valid. Under this condition, the retailer's order quantity decreases with the growth of the loss aversion coefficient λ and has nothing to do with the random distribution of the market demand. If shortage cost is considered, any of the three conditions of Property 1 is possible, depending on the distribution of the random market demand. In this case, the relationship between the optimal order quantity of the retailer and the loss aversion coefficient λ is determined by the distribution of the random market demand.

Consider the manufacturer's optimal green emission reduction strategy, the manufacturer's expected profit function can be derived from *Equation 3:*

$$E[\pi_m(\theta)] = (w-c)q + p_t[E - (1-\theta)e] - \frac{1}{2}\alpha\theta^2 \tag{Eq.14}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93339346

Since $\frac{d^2E[\pi_m(\theta)]}{d\theta^2} = -\alpha < 0$, the optimal green emission reduction level of risk-neutral manufacturer can be obtained by finding the first-order derivative of *Equation 14* relative to θ:

$$\theta^* = \frac{p_t e}{\alpha} \quad \text{(Eq.15)}$$

It can be seen from *Equation 15* that, under decentralized decision-making, the optimal green emission reduction level of the manufacturer is positively correlated with the unit carbon transaction price in the market and the carbon emission of product, negatively correlated with the green cost coefficient of the product, but not related to the retailer's order quantity.

Optimal strategy in centralized mode

Under centralized decision-making, the overall profit of the supply chain can be expressed as *Equation 16*.

$$\pi_{mr}(q,\theta) = pmin(q,D) + v(q-D)^+ - g(D-q)^+ - cq + p_t\left[E-(1-\theta)e\right] - \frac{1}{2}\alpha\theta^2 = \begin{cases} (p-v)x + (v-c)q + p_t\left[E-(1-\theta)e\right] - \frac{1}{2}\alpha\theta^2, & x < q \\ (p-c+g)q - gx + p_t\left[E-(1-\theta)e\right] - \frac{1}{2}\alpha\theta^2, & x \geq q \end{cases} \quad \text{(Eq.16)}$$

The mathematical expectation of the above equation can be obtained as *Equation 17*.

$$E[\pi_{mr}(q,\theta)] = \int_M^{q-y(\theta)} \left\{(p-v)[y(\theta)+\varepsilon] + (v-c)q + p_t[E-(1-\theta)e] - \frac{1}{2}\alpha\theta^2\right\} f(\varepsilon)\,d\varepsilon + \int_{q-y(\theta)}^{N} \left\{(p-c+g)q - g[y(\theta)+\varepsilon] + p_t[E-(1-\theta)e] - \frac{1}{2}\alpha\theta^2\right\} f(\varepsilon)d\varepsilon = (p-v+g)\int_M^{q-y(\theta)}[y(\theta)+\varepsilon]f(\varepsilon)\,d\varepsilon - (p-v+g)qF(q-y(\theta)) + (p-c+g)q - g[y(\theta)+\mu] + p_t [E-(1-\theta)e] - \frac{1}{2}\alpha\theta^2 \quad \text{(Eq.17)}$$

The partial derivatives of *Equation 17* can be computed as *Equations 18–20*.

$$\frac{\partial^2 E[\pi_{mr}(q,\theta)]}{\partial q^2} = -(p-v+g)f(q-y(\theta)) \quad \text{(Eq.18)}$$

$$\frac{\partial^2 E[\pi_{mr}(q,\theta)]}{\partial q\partial\theta} = (p-v+g)Bf(q-y(\theta)) \quad \text{(Eq.19)}$$

$$\frac{\partial^2 E[\pi_{mr}(q,\theta)]}{\partial \theta^2} = -B^2(p-v+g)f(q-y(\theta)) - \alpha \quad \text{(Eq.20)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93339346

Combining *Equations 18–20*, the determinant of the Hessian matrix for the expected profit of the supply chain in the centralized mode can be obtained as *Equation 21*.

$$\begin{vmatrix} \frac{\partial^2 E[\pi_{mr}(q,\theta)]}{\partial q^2} & \frac{\partial^2 E[\pi_{mr}(q,\theta)]}{\partial q \partial \theta} \\ \frac{\partial^2 E[\pi_{mr}(q,\theta)]}{\partial \theta \partial q} & \frac{\partial^2 E[\pi_{mr}(q,\theta)]}{\partial \theta^2} \end{vmatrix} = \alpha(p-v+g)f\big(q-y(\theta)\big) > 0 \qquad \text{(Eq.21)}$$

whereas $\frac{\partial^2 E[\pi_{mr}(q,\theta)]}{\partial q^2} < 0$, $E[\pi_{mr}(q,\theta)]$ is a concave relative to both q and θ. Hence, there exists a unique optimal combination of solutions (q^0,θ^0), such that the overall profit of the supply chain reaches the maximum. Let $\frac{\partial E[\pi_{mr}(q,\theta)]}{\partial q} = 0$ and $\frac{\partial E[\pi_{mr}(q,\theta)]}{\partial \theta} = 0$. The optimal solutions of the supply chain can be obtained as *Equation 22*.

$$\begin{cases} q^0 = F^{-1}\left(\frac{p-c+g}{p-v+g}\right) + y(\theta) \\ \theta^0 = \frac{(p-c)B+p_t e}{\alpha} \end{cases} \qquad \text{(Eq.22)}$$

Equation 22 shows that $\theta^0 = \frac{(p-c)B+p_t e}{\alpha} > 0$. Since (q^0,θ^0) is the unique optimal combination of solutions to the entire supply chain, we have $E[\pi_{mr}(q^0,\theta^0)] > E[\pi_{mr}(q^0,0)]$.

Therefore, it can be concluded that the supply chain profit can be improved by increasing the product greenness under centralized decision-making, as the carbon quota is laid down by the government and the environmental awareness is growing among consumers. In other words, green products can bring more profits.

Under decentralized decision-making, the manufacturer and the retailer are actually implementing the wholesale price contract. Comparing *Equation 8*, *Equation 15* and *Equation 22*, it can be seen that the green supply chain considering carbon emissions and loss aversion cannot be coordinated under this contract. This calls for a rational and effective contract that ensures the coordination of the supply chain.

Results and discussion

Coordination contract

The previous analysis shows that the green supply chain considering carbon emissions and loss aversion cannot be coordinated under the wholesale price contract. The main reason lies in the fact, under the decentralized decision-making, the manufacturer needs to bear all the cost of green emission reduction but only receives part of the supply chain profit, while the retailer needs to bear all the inventory cost of the entire supply chain induced by oversupply. As a result, the manufacturer is reluctant to improve product greenness, and the retailer is conservative about the order quantity, aiming to reduce the risk. To improve product quality, reduce oversupply risk and achieve supply chain coordination, this paper modifies the traditional revenue sharing contract into a cost sharing-revenue sharing contract $\{k, \varphi\}$, in which the retailer bears (1- k) ($0 < k < 1$) of the manufacturer's green emission reduction cost and receives

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93339346

$\varphi(0 < \varphi < 1)$ of the sales profit. Under this contract, the expected profits of the retailer and the manufacturer can be respectively expressed as *Equations 23* and *24*.

$$\pi_r(q,\theta,k,\varphi) = \varphi\left[pmin(q,D) + v(q-D)^+ - g(D-q)^+\right] - wq - \frac{1}{2}\alpha(1-k)\theta^2 \quad \text{(Eq.23)}$$

$$\begin{aligned}\pi_m(q,\theta,k,\varphi) &= (1-\varphi)\left[pmin(q,D) + v(q-D)^+ - g(D-q)^+\right] \\ &+ (w-c)q + p_t\left[E-(1-\theta)e\right] - \frac{1}{2}\alpha k\theta^2\end{aligned} \quad \text{(Eq.24)}$$

According to *Equations 23* and *24*, the contract $\{k, \varphi\}$ only includes transfer payment within the supply chain. The total profit of the two parties is still equal to the result of *Equation 16*.

Similar to the proof of Theorem 1, the following result can be derived from *Equation 23*.

Theorem 2. Under the cost-and-revenue sharing contract, for any $0 \le \theta < 1$, the expected utility of the loss-averse retailer $E\left[U\left(\pi_r(q,\theta,k,\varphi)\right)\right]$ is a concave function relative to q, and $max_{q>0}\, E\left[U\left(\pi_r(q,\theta,k,\varphi)\right)\right]$ has a unique optimal solution q^{λ} that satisfies *Equation 25*.

$$\begin{aligned}&\int_{x_3-y(\theta)}^{q-y(\theta)} (\varphi v - w) f(\varepsilon) d\varepsilon + \int_{q-y(\theta)}^{x_4-y(\theta)} (\varphi p - w + \varphi g) f(\varepsilon) d\varepsilon + \\ &\lambda\left[\int_{M}^{x_3-y(\theta)} (\varphi v - w) f(\varepsilon) d\varepsilon + \int_{x_4-y(\theta)}^{N} (\varphi p - w + \varphi g) f(\varepsilon) d\varepsilon\right] = 0\end{aligned} \quad \text{(Eq.25)}$$

where $x_3 = \frac{wq - \varphi vq - \frac{1}{2}\alpha(1-k)\theta^2}{\varphi(p-v)}$ and $x_4 = \frac{\varphi(p+g)q - wq - \frac{1}{2}\alpha(1-k)\theta^2}{\varphi g}$.

Finding the expectation of *Equation 24*, the expected profit function of the manufacturer can be obtained as *Equation 26*.

$$\begin{aligned}&E\left[\pi_m(q,\theta,k,\varphi)\right] = (1-\varphi)(p-v+g)\int_{M}^{q-y(\theta)} \left[y(\theta)+\varepsilon\right] f(\varepsilon) d\varepsilon - \\ &(1-\varphi)(p-v+g)qF\left(q-y(\theta)\right) + \left[(1-\varphi)(p+g) + w - c\right]q - \\ &(1-\varphi)g\left[y(\theta)+\mu\right] + p_t\left[E-(1-\theta)e\right] - \frac{1}{2}\alpha k\theta^2\end{aligned} \quad \text{(Eq.26)}$$

The above equation shows that, for any $q > 0$, $max_{0\le\theta<1}\, E[\pi_m(q,\theta,k,\varphi)]$ has a unique optimal solution θ^{λ} that satisfies *Equation 27*.

$$\theta = \frac{B(1-\varphi)(p-v+g)F\left(q-y(\theta)\right) - (1-\varphi)Bg + p_t e}{\alpha k} \quad \text{(Eq.27)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93339346

Next, the author analyzed how the cost-and-revenue sharing contract coordinates the green supply chain considering carbon emission and loss aversion. Firstly, the manufacturer, as the leader of the Stacklberg game, can set proper parameter values $\{k, \varphi\}$ according to the known loss aversion level λ of the retailer, forcing the retailer to choose the optimal ordering strategy $q^{\lambda} = q^{0} = F^{-1}\left(\frac{p-c+g}{p-v+g}\right) + y(\theta)$, i.e. $q^{\lambda} = q^{0}$ satisfying *Equation 25*. Then, it can be seen that $\theta = \frac{(1-\varphi)(p-c)B+p_t e}{\alpha k}$ by substituting $q = q^{0}$ into *Equation 27*. Compared with *Equation 22*, it is learned that the value of *k* must equal $\frac{(1-\varphi)(p-c)B+p_t e}{(p-c)B+p_t e}$ under the coordination contract.

Note that the manufacturer's profit must not fall below the profit in decentralized decision-making. Otherwise, it will not actively participate in the cost-and-revenue sharing contract. In other words, the wholesale price per unit of product *w* must satisfy the following set of *Equation 28*.

$$\begin{cases} \frac{\partial E[U(\pi_r(q,\theta,k,\varphi))]}{\partial q}\Big|_{q^{\lambda}=q^{0},\theta^{\lambda}=\theta^{0}} = 0 \\ \frac{\partial E[\pi_m(q,\theta,k,\varphi)]}{\partial \theta}\Big|_{q^{\lambda}=q^{0},\theta^{\lambda}=\theta^{0}} = 0 \\ E[\pi_m(q,\theta,k,\varphi)]\big|_{q^{\lambda}=q^{0},\theta^{\lambda}=\theta^{0}} = \delta \end{cases} \quad \text{(Eq.28)}$$

where δ is any constant that is no smaller than $E[\pi_m(\theta^*)]$. The overall profit of the supply chain can be allocated elastically between the retailer and the manufacturer by adjusting the value of δ. The allocation depends on the bargaining power of the two parties. Moreover, there should also be an upper limit to the wholesale price. Otherwise, there will be no solution to the contract parameters, making the contract meaningless. In particular, when δ satisfies $0 < \delta - E[\pi_m(\theta^*)] < E[\pi_{mr}(q^0,\theta^0)] - E[\pi_r(q^*)]$, the overall profit of the supply chain is optimized, and both the manufacturer and the retailer are expected to receive more profit than the decentralized decision-making. Thus, the two parties can receive Pareto optimal profits under certain conditions, using the proposed cost-revenue sharing contract.

Considering the different decision-making goals between loss aversion and risk neutrality, the above cost-revenue sharing contract fulfills three conditions: maximizing the overall profit of the supply chain; maximizing the expected utility of the loss-averse party (retailer); ensuring that the expected profit of the risk-neutral party (manufacturer) is no less than its retained profit. Through reasonable parameter design, both members of the supply chain will be encouraged to actively participate in this cost-revenue sharing contract.

Numerical examples

The above model was subjected to numerical experiments on the Matlab. Firstly, the loss-averse retailer and the risk-neutral manufacturer were compared in terms of the decision variables and expected profits (utilities) under different decision-making modes, aiming to verify the effectiveness of the proposed coordination contract. After that, the author carried out a sensitivity analysis on the parameters of the decentralized model, e.g. loss aversion coefficient and wholesale price, to see their impacts on the optimal order quantity of the retailer. The market demand was assumed as

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93339346

$D(\theta) = 50 + 4\theta + \varepsilon$, with $\varepsilon \sim U[-50,50]$ and $H(\theta) = 0.5 \times 200\theta^2$. The other parameters are listed in *Table 1*.

Table 1. *Parameter settings*

Parameter	p	w	c	g	v	p_t	e	E	λ	k	φ	μ
Value	45	20	15	5	10	5	10	8	1.2	0.37	0.89	841

The above model was adopted to calculate the optimal decision variables and the expected profits (utilities) of the retailer, the manufacturer and the supply chain under three conditions, namely, centralized decision-making, decentralized decision-making and the cost-and-revenue-sharing contract. The calculated results are shown in *Table 2*.

Table 2. *Comparison of optimal decision variables and expected profits (utilities) under different decision-making modes*

Decision-making mode	q	θ	$\pi_r(q)$	$E[U(\pi_r)]$	π_m	π_{mr}
Centralized decision-making	91	0.85	—	—	—	1584
Decentralized decision-making	74	0.25	686	572	366	1052
Coordination contract	91	0.85	743	604	841	1584

As shown in *Table 2*, the retailer's order quantity was 18.7% smaller under decentralized decision-making than under centralized decision-making, owing to the double marginalization effect. After introducing the cost-and-revenue sharing contract, the expected profit of the entire supply chain reached that under the centralized decision-making, the manufacturer saw its green emission reduction level increasing from 0.25 (decentralized decision-making) to 0.85 (centralized decision-making) and expected profit growing by nearly 1.3 times, and the retailer witnessed a 5.6% increase in expected utility and an 8.3% growth in expected profit from the levels under centralized decision-making. Therefore, the proposed coordination contract both improves the expected profit of the entire supply chain and achieves the Pareto optimization of the profits (utilities) of the manufacturer and the retailer. Both parties of the supply chain will be incentivized to conclude such a contract.

Next, the loss aversion behavior and purchase price were subjected to sensitivity analysis, aiming to disclose their impacts on the retailer's optimal order quantity. Relevant numerical experiments were carried out with the loss aversion coefficient λ and the wholesale price w as variables. The experimental results are presented in *Figures 1* and *2*.

As shown in *Figure 1,* the retailer's optimal order quantity decreased with the increase of the loss aversion coefficient. It can be seen from Property 1 that the third condition is always satisfied under the uniform distribution of the random market demand. In this case, the retailer's order quantity is negatively correlated with the loss aversion coefficient, and the overage cost is greater than the shortage cost. To avoid losses, the loss-averse retailer will cut down the order quantity.

As shown in *Figure 2,* the retailer's optimal order quantity dropped almost linearly with the rising purchase price. This trend can be attributed to the following reasons. When the retail price is exogenous, the retailer will receive less profit per unit of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93339346

product with the growth in the unit product wholesale price; the rising purchase cost will indirectly push up the overage capacity cost. To minimize its loss, the loss-averse retailer cannot but reduce the order quantity.

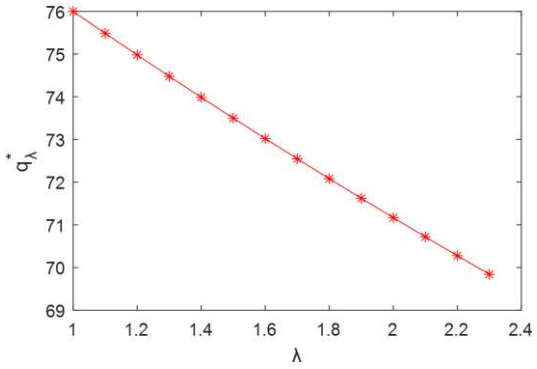

Figure 1. *Effect of loss aversion level on optimal order quantity*

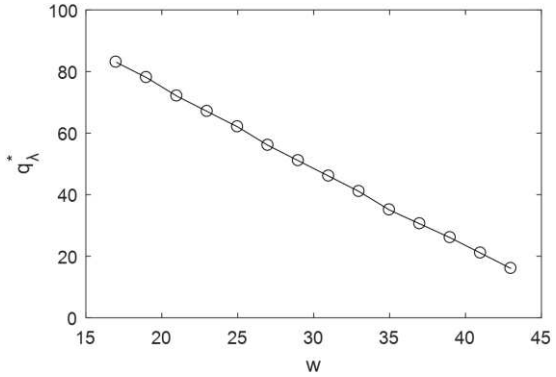

Figure 2. *Effect of wholesale price on optimal order quantity*

Conclusions

This paper explores the coordination of a two-echelon green supply chain, consisting of a loss-averse retailer and a risk-neutral manufacturer, in the context of carbon emissions. Considering the loss aversion of the retailer, the objective function was set up by the prospect theory. On this basis, a Stackelberg game model was constructed under decentralized decision-making, and the manufacturer's optimal green emission reduction decision and the retailer's optimal order quantity were solved by inverse induction. The results were compared with those under the optimal decision of the supply chain under centralized decision-making. Then, a cost-and-revenue sharing coordination contract was designed to ensure the Pareto optimization of the profits (utilities) of both parties under the loss-averse decision goal.

The above conclusions were drawn based on the revenue sharing contract. The future research will extend the research problem to discuss other coordination mechanisms (e.g. flexible quantity contract, buy-back contract and price discount contract). To make our model more realistic, the loss aversion of the manufacturer will be added, and multiple manufacturers and retailers will be considered.

Abstract. Scenic ecotourism spots, as major attractors of tourists, boast great economic values and development potentials. Many local governments have developed a series of tourism resources with the aim to fully utilize resources and promote regional economy. However, the tourism development has exerted negative environmental impacts on scenic ecotourism spots. Targeting Xixi Wetland Park, Hangzhou, southeastern China's Zhejiang Province, this paper explores the effects of tourism development and tourist activities on the soil and water environments in scenic ecotourism spots, and draws the following conclusions: The environment in the ecotourism scenic spot is influenced in varied degrees by both tourism development and tourist activities; soil porosity can characterize how tourism development and tourist activities affect the environment of scenic ecotourism spots; the impacts of tourism development or tourist activities on scenic ecotourism spots can be demonstrated by the pH, chemical oxygen demand (COD), total ammonia nitrogen (TAN) and turbidity of water bodies.
Keywords: *ecotourism scenic spots, tourist resources, tourist activities, tourist development, environmental impact*

Introduction

The ecological environment should be fully protected, because it is the common wealth of all humans (Movono et al., 2018). In China, the rapid development of tourism has brought many problems to resource, environment and management. Many local governments have developed a series of tourism resources with the aim to fully utilize resources and promote regional economy. However, the tourism development has exerted negative impacts on ecological environment, especially in scenic spots (Olafsdóttir and Runnstrom, 2009; Anctil and Blanc, 2016). According to incomplete statistics, more than one-fourths of scenic ecotourism spots in China have been damaged by tourism development, causing degradation of tourism resources and weakening of ecological functions (Aryal et al., 2018). Tourism development has a long-lasting impact on ecological environment. In fact, the ecological impact of a development project persists throughout the construction process. The full-lifecycle impact has been observed in many scenic ecotourism spots (Iliev and Dejan, 2018).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93479355

The ecological impacts of tourism development and tourist activities can be divided into environmental impacts and non-polluting ecological impacts (Wu and Tsai, 2016). Focusing on scenic ecotourism spots, the existing studies have mainly explored the ecological impacts of tourism development from soil erosion degree, biodiversity index, vegetation cover change rate, biomass loss, habitat function and water environment quality, revealing that the continuous tourism development and tourist activities have led to changes in ecological function (Ke, 2012; Lyon et al., 2017). In environmental ecology, the environmental impact in scenic ecotourism spots is relative to the ecological impact of tourism pollution, and the environment of scenic ecotourism spots should be dominated by natural landscape, supplemented by artificial tourism construction and development (Ingelmo and Abedin, 2013). Targeting the Xixi Wetland Park in Hangzhou, southeastern China's Zhejiang Province, this paper investigates how tourism development and tourist activities affect the soil and water environment in scenic ecotourism spots, and analyzes the factors affecting the environment of the ecotourism scenic spot.

Methodology

Tourism development and tourist activities have concentrated impacts on the ecotourism environment. The impacts can accumulate over time but the intensity is on a gradual decline (Mbaiwa, 2011). For a species in the ecological environment, it will actively adapt to the changes in its habitat induced by tourism development or tourist activities; otherwise, the species will be naturally eliminated. If the species can survive and reproduce in the new habitat, the original ecosystem will be changed substantially (Sigurðardóttir and Steinthorsson, 2018).

For tourism development and tourist activities, the impacts on scenic ecotourism spots have three dimensions: intensity, frequency and duration. The ecological species will not be severely damaged if all three dimensions are controlled within a reasonable range (Saarinen and Lenao, 2014). The development of an ecological community is dynamic, rather than instantaneous. The general process includes such four phases as non-interference, co-interference, sharing and evolution. Any organism failing to adapt to co-interference will be eliminated (Dillimono and Dickinson, 2015). The factors in the ecosystem are mutually constrained, and a complete ecosystem must be open and balanced.

To attract more tourists, the Xixi Wetland Park has developed many tourism projects and conducted various tourist activities, which are bound to influence the environment of the scenic spot. The park environment is dominated by water, soil and vegetation. For simplicity, this paper attempts to disclose how tourism development and tourist activities affect the soil environment and water environment, and identify the factors affecting the environment of the ecotourism scenic spot. To test the soil environment, several soil samples were collected from a sample plot and subjected to measurements of pH, water content, porosity and heavy metal content. A total of ten sampling points was arranged, and divided into mixed points and control points. Note that each pair of mixed point and control point were from similar areas. To test the water environment, several water samples were collected from ten sampling points, and subjected to measurements of pH, chemical oxygen demand (COD), total ammonia nitrogen (TAN) and turbidity. The test methods for Soil and water index test methods are listed in *Table 1*.

Test Results

Impacts of tourism development and tourist activities on soil environment

The soil environment provides the species of scenic ecotourism spots with the venue to exchange materials. The impacts of tourism development and tourist activities on the soil environment is directly reflected by the the variation in the physical state of the soil and the change of the species. The development intensity or activity scale is positively correlated with the soil aggregation and compaction. On the development intensity/activity scale of tourism, the ten sampling points can be ranked as No. 7 > No. 8 > No. 2 > No. 1 > No. 4 > No. 6 > No. 5 > No. 10 > No. 9 > No. 3.

Figure 1 shows the change of water content of mixed samples and control samples at different sampling points. It can be seen that the two types of samples had the same trend of water content, but the trend was not consistent with the variation in development intensity/activity scale. Thus, the water content variation cannot mirror the environmental impacts of tourism development or tourist activities.

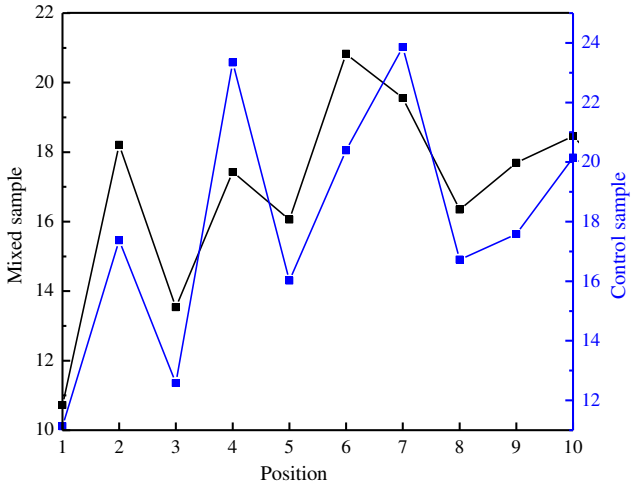

Figure 1. *The change of water content of mixed samples and control samples at different sampling points*

Figure 2 depicts the porosity changes of mixed samples and control samples at different sampling points. Obviously, the soil is less compacted at a high porosity. The results of porosity analysis show that the soil porosity followed the same trend with development intensity/activity scale. In other words, the environmental impacts of tourism development or tourist activities can be measured by soil porosity. In the ecotourism scenic spot, the heavy metals in soil mainly come from the dusts discharged from nearby factories, the solid wastes carried by tourists and the development of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93479355

tourism facilities. *Figure 3* presents the comprehensive pollution index (CPI) of heavy metals at different sampling points. Except a few points, the heavy metal CPI exhibited the same trend with soil porosity, indicating that tourism development and activities will push up the heavy metal CPI in soil.

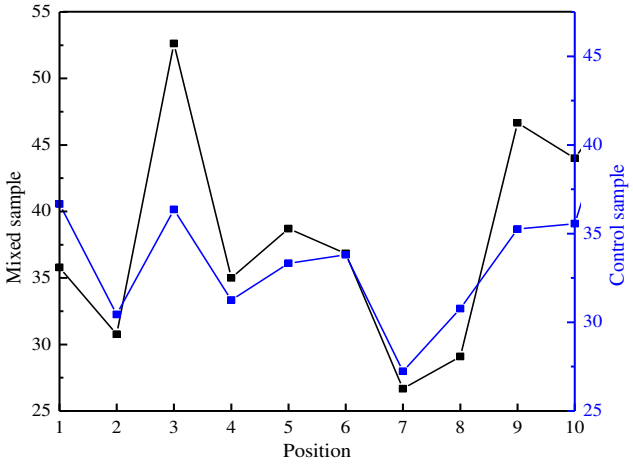

Figure 2. *The change of soil porosity of mixed samples and control samples at different sampling points*

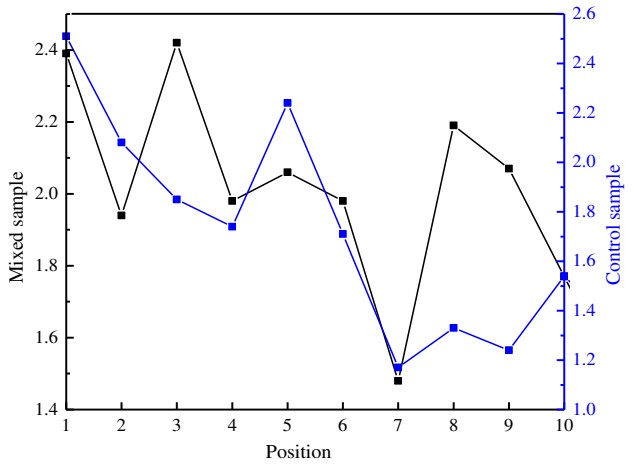

Figure 3. *The heavy metal CPIs at different sampling points*

Impacts of tourism development and tourist activities on water environment

By observing the artificial lakes in Xixi Wetland Park, the water environment in the park is found to be dead water, with no river channel to the external water bodies. The water bodies in the park are mainly polluted by tourist toilets, catering, animal foods, surface garbage, etc. On the development intensity/activity scale of tourism, the ten sampling points can be ranked as No. 7 > No. 8 > No. 2 > No. 1 > No. 4 > No. 6 > No. 5 > No. 10 > No. 9 > No. 3.

The pH, COD, TAN and turbidity measured at the different sampling points are respectively displayed in *Figures 4-7*. As shown in these figures, the pH in lake water remained basically the same across the park. The peak pH was measured at No. 10

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93479355

sampling point, which has the most intense tourist activities. This is attributable to the alkaline wastes left by tourists. The pH at No. 4 sampling point was not consistent with the development intensity/activity scale, which is probably the result of the acidic substances discharged by surrounding enterprises or residential areas. Thus, the pH of the water samples can reflect the degree of environmental impacts of tourism development and tourist activities on the ecotourism scenic spot. Besides, the COD and TAN variations could partially demonstrate how tourism development and tourist activities affect the ecotourism scenic spot. However, the two indices may also change due to non-tourism issues like animal wastes. In addition, the turbidity, an indicator of sediments of water bodies, basically agreed with the development intensity/activity scale in change law. To sum up, the impacts of tourism development or tourist activities on scenic ecotourism spots can be demonstrated by the pH, COD, TAN and turbidity of water bodies.

Discussion

Influencing factors of the environment in scenic ecotourism spots

The change curve of tourist market in Xixi Wetland Park (*Figure 8*) shows that the number of tourists to the park increases year by year, and peaks from May to August each year. In this section, the author analyzed the tourism development and tourist activities affect the soil and water conditions in the park, and discovered that the environment in the ecotourism scenic spot is influenced in varied degrees by both tourism development and tourist activities. Owing to tourism development and tourist activities, the soil becomes less porous and more compacted. The soil hardness is mostly affected by tourist activities and tourism construction projects. The changing soil environment will suppress the animal diversity in the soil, and directly affect the plant metabolism.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93479355

The water environment has a great regulatory effect on the park. The turbidity increase and pH change of the water bodies are the combined effect of the garbage left by tourists, the distributions from tour boats and the discharge of various organic matters and minerals. *Figure 9* depicts the impacts of travel distance on the relative coverage and the relative number of species. With the growth in travel distance, the relative coverage of species increased annually at a decreasing rate, while the relative number increased first and then decreased.

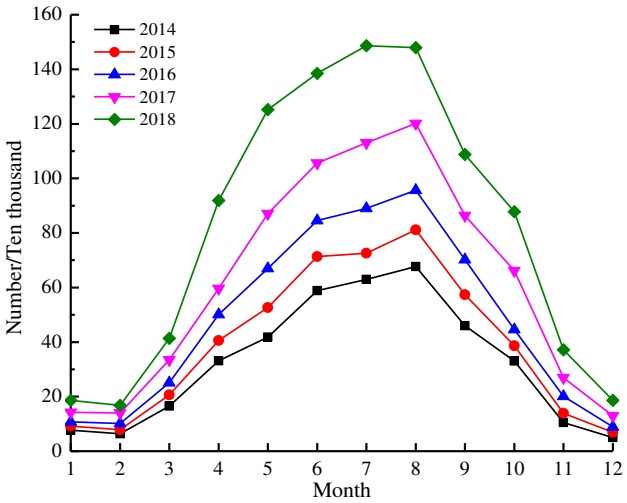

Figure 8. *The change of tourist market in Xixi Wetland Park*

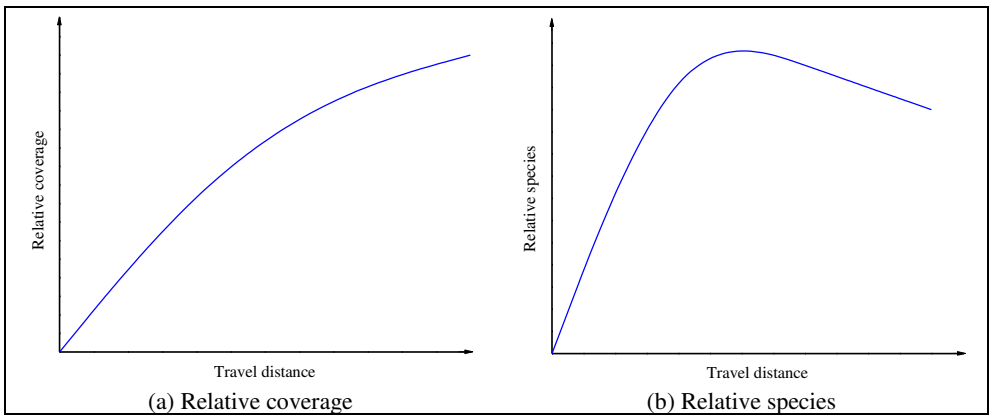

Figure 9. *Impacts of travel distance on relative coverage and relative number of species*

Measures and suggestions on enhancing environmental protection

China has not issued any law on ecotourism. In fact, tourism development should be regulated by effective legal means, so should the tourists in tourist activities. Any unit or individual should abide by the planning of scenic ecotourism spots. None should develop tourism projects arbitrarily in violation of regulations. Every ecotourism scenic spot should establish a sound environmental monitoring system. As shown in *Figure 10*, an effective environmental monitoring system for scenic ecotourism spots should cover four aspects, including ecological environment (air, hydrology, soil and vegetation),

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93479355

tourist, rare species and forest resources. The monitor or monitoring department should put forward relevant protection measures after rational evaluation and analysis. Currently, the eco-tourism scenic spots should strengthen the monitoring and control of the tourist activity environment, reasonably control the tourist inflow into the scenic environment, and prevent the eco-tourism scenic spots from overloading and the resulting impacts.

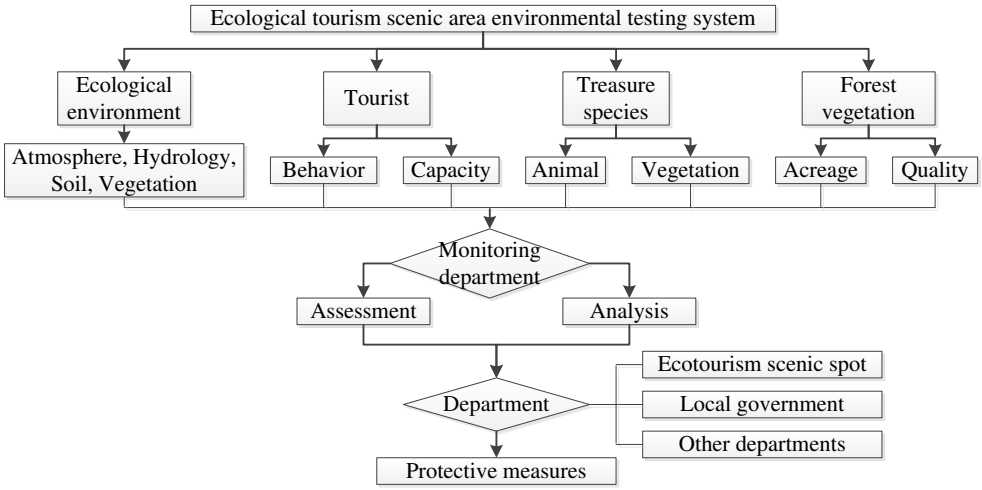

Figure 10. *An effective environmental monitoring system for ecological tourism scenic spots*

Conclusions

Taking Xixi Wetland Park for example, this paper explores the effects of tourism development and tourist activities on the soil and water environments in scenic ecotourism spots. The main conclusions are as follows:

(1) The soil is less compacted at a high porosity. Soil porosity is the best indicator of how tourism development and tourist activities affect the environment of scenic ecotourism spots, followed by the heavy metal CPI. By contrast, the water content variation in soil cannot demonstrate the impacts well.

(2) The impacts of tourism development or tourist activities on scenic ecotourism spots can be demonstrated by the pH, COD, TAN and turbidity of water bodies.

(3) The environment in the ecotourism scenic spot is influenced in varied degrees by both tourism development and tourist activities. With the growth in travel distance, the relative coverage of species increased annually at a decreasing rate, while the relative number increased first and then decreased.

(4) At present, there are few studies on ecological impact evaluation and impact source evaluation of tourism development and activities on eco-tourism scenic spots, and the qualitative and quantitative relationship between them is not clear, with the evaluation indexes involved with each other. The mechanism between ecological impact evaluation indicators and impact sources should be further studied.

(Received 3rd Apr 2019; accepted 17th May 2019)

Abstract. Flood is one of the most frequent natural disasters in the world; therefore, it is the focus of hydrologic research to reveal the effects of such factors as precipitation and peak discharge on the hydrological and water environments. Taking the Jialingjiang Watershed as an example, this paper collects the peak discharge data and historical data in the watershed and then studies the effects of watershed flood peaks on the hydrology and water resources and water environment in the Jialingjiang Watershed using the method combining data statistics and theoretical analysis based on the lognormal distribution model, and predicts the peak discharge in this area using the three-parameter lognormal distribution model. According to the research results, the parameter values are obtained for the Jialingjiang Watershed in the three-parameter lognormal distribution model; the three-parameter lognormal distribution model can reasonably reveal the scale effect law of the confluence area in the watershed peak discharge distribution; and the flood discharge distribution in a small watershed is significantly steeper than that in a large watershed. This study lays a theoretical foundation for the evaluation and prediction of the basic situation of hydrology and water resources in different watersheds.
Keywords: *watershed flood peak, hydrology and water resources, lognormal distribution model, runoff, confluence area*

Introduction

With the rapid economic and technological development, human activities are bringing significant impacts on the global natural environment (Del Giudice et al., 2014; Kuntiyawichai et al., 2014), resulting in changes in the runoff and hydrological cycle paths in the basin and ultimately leading to changes in the characteristics of hydrology and water resources (Al-Rawas and Valeo, 2010; Burton et al., 1997; Cannistraro et al., 2017; Sanjeev, 2017; Zhang et al., 2014). Studies have found that changes in the hydrology and water resources in the watershed can also cause errors in the hydrological analysis data, which will result in differences between the research results and the actual regional hydrological conditions and laws and consequently adversely affect the development and effective utilization of water resources (Ademila and Saloko, 2018; Olang and Fürst, 2011; Guo et al., 2016).

Runoff is formed throughout the process from precipitation to water flowing out of the area interface. Poorly developed runoff is one of the causes to flood (Chinnasamy et al., 2017; Hoseini et al., 2016). As one of the major natural disasters in the world, flood is always a threat to people's lives and properties and land resources (Te et al., 2010). In recent years, due to the over-exploitation of vegetation resources and reckless development of land resources, the ecological environment has been gradually

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93579366

deteriorating, and floods have occurred frequently, causing serious losses to residents near the waters (Enzel et al., 1993; Drake, 2014; Koutroulis and Tsanis, 2010). Therefore, studying the occurrence rule and formation mechanism of flood is of significant social significance to preventing and predicting flood.

The lognormal distribution model is a data analysis method used in cases where there are random variables (Martinezgoytre et al., 1994; Xin and Venkataramana, 2012; Zhang et al., 2001). In the analysis of the formation and development of watershed flood peaks and their effects on the regional hydrological conditions, there are a series of random variables such as peak discharge and confluence area. For some of them, the distribution can be reasonably analyzed and the relationships between them determined with the lognormal analysis model.

Based on the lognormal distribution model, this paper analyzes the variation law of flood by analyzing the changes in rainfall discharge and flood characteristics in the watershed, and then analyzes the regional variation characteristics of watershed flood peaks and explores the effects of flood peak flow on the hydrology and water resources in a certain area, with a view to providing certain support for the development of water resources in watersheds and the summarization of the development patterns of hydrology and water resources.

Materials and methods

In recent years, in order to characterize the relationship between the confluence area and the peak discharge and their influences in the distribution of the annual maximum peak flow, some scholars have proposed different distribution models for different variable distribution forms (Gupta et al., 1994; Lanfredi et al., 1998). Studies have shown that the lognormal distribution model can organically relate the flood peaks of the watershed to its confluence area. Therefore, this paper uses the lognormal distribution model to analyze the influences of the flood peaks in the Jialingjiang Watershed on the hydrology and water resources.

Lognormal distribution function

The lognormal distribution is a continuous probability distribution function that can be used to characterize the right-skewed distribution. After transformation of the lognormal distribution function, if y obeys the lognormal distribution, then lny obeys the normal distribution, and the lognormal distribution probability density function is shown in *Equation 1,* where μ_x is the mean of the parameter x; and σ_x is the dispersion of the parameter x, and it is always greater than zero. From this, it can be seen that the curve of the logarithmic distribution function is determined by the corresponding mean and the dispersion parameter. According to the graph of the lognormal distribution probability density function as shown in *Figure 1,* when the logarithmic mean μ_{lny} is constant, the peak position of the probability density function graph is determined by the logarithmic dispersion σ_{lny}. The greater the logarithmic dispersion, the wider the convex part of the probability density function graph, and the more blunt the peak; and conversely, the sharper the peak. When the logarithmic dispersion is constant, the peak position of the probability density function graph is determined by the logarithmic mean μ_{lny}. The smaller the logarithmic mean is, the more left the peak of the graph will go to,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93579366

i.e. the smaller the x-coordinate of the peak will be; and conversely, the more right it will go to and the greater its x-coordinate will be.

$$p(y)=\frac{1}{\sigma_{\ln y} y\sqrt{2\pi}} e^{\frac{(\ln y-\mu_{\ln y})}{2\sigma_{\ln y}^2}}, \quad (0<y<+\infty) \tag{Eq.1}$$

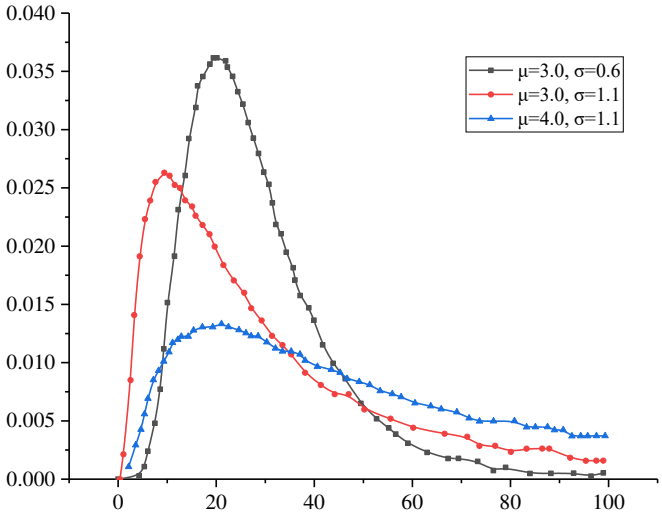

Figure 1. *Lognormal distribution*

The distribution characteristics of the above lognormal distribution function can be determined by two parameters, logarithmic mean and logarithmic dispersion. However, studies have shown that the shape of the lognormal distribution is generally asymmetrical, so the degree of skew the curve distribution is also essential. In the probabilistic statistical analysis, the coefficient of skewness Cs of the data distribution is defined in *Equation 2,* where μ^3 is the third-order center distance of y, and σ is the mean square error of y. When the coefficient of skewness is 0, the lognormal distribution is symmetric; when it is less than 0, the lognormal distribution is left-skewed; and when it is greater than 0, the lognormal distribution is right-skewed.

$$C_s=\frac{\mu^3}{\sigma^3} \tag{Eq.2}$$

Two-parameter lognormal distribution model

The two-parameter lognormal distribution model is a distribution model proposed by Prof. Smith, in which a random variable y is set to satisfy the two-parameter lognormal distribution LN(y: μ, σ^2), where μ is the mean of the random variable lny; and σ^2 is the variance of lny. If x is a random variable obeying the standard normal distribution, the random variable y can be expressed by *Equation 3*. Both μ *and* σ^2 have a linear relationship with the confluence area S in the watershed analysis, then they can be expressed by *Equations 4* and *5,* respectively.

$$y = exp(\mu + \sigma x) \tag{Eq.3}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93579366

$$\mu = n_1 + n_2 lnS \quad \text{(Eq.4)}$$

$$\sigma^2 = m_1 - m_2 lnS \quad \text{(Eq.5)}$$

Combine the above equations, and we obtain *Equation 6* can be obtained. If the coefficient m_1 is much greater than m_2, then *Equation 6* can be approximated to *Equation 7,* $f(z) = exp(n_1 + m_1 x)$ and $\theta(z) = n_2 - 0.5 m_2 x$. Therefore, when μ *and* σ^2 are in linear relationships with the confluence area of the watershed, the relationship between the flow Q of the watershed flood peak and the confluence area S is a power function.

$$y = exp(n_1 + n_2 lnS + \sqrt{}(m_1 - m_2 lnS)x) \quad \text{(Eq.6)}$$

$$Q = exp[n_1 + n_2 lnS + (m_1 - 0.5 m_2 lnS)x] = f(z)S^{\theta z} \quad \text{(Eq.7)}$$

Three-parameter lognormal distribution model

Experts and scholars have improved the two-parameter lognormal distribution model and proposed a three-parameter lognormal distribution model to more accurately analyze the inherent law of hydrology and water resources. In this model, it is considered that the random variable y obeys the three-parameter lognormal distribution, that is, LN(y: μ, σ^2, a). The random variable x obeys the standard normal distribution, so the random variable y is expressed in *Equation 8,* and the mean of y is shown in *Equation 9*. The mean μ and variance σ^2 of the random variable lny are still expressed by *Equations 4* and *5,* while the parameter a is shown in *Equation 10*. The meaning of each parameter is the same as above. Based on the above descriptions, the three-parameter lognormal distribution model can be determined by six parameters - s_1, s_2, n_1, n_2, m_1, m_2, and then the parameters related to the flood peak discharge distribution in each confluence area S in the watershed can be obtained to determine the distribution pattern of watershed flood peaks. At last, the regional analysis of the flood and the estimation of the peak discharge in the watershed are conducted.

$$y = exp(\mu + \sigma x) + a \quad \text{(Eq.8)}$$

$$E(y) = exp(\mu + 0.5\sigma^2) + b \quad \text{(Eq.9)}$$

$$b = E(y) - exp(\mu + 0.5\sigma^2) = e^{s_1} A^{s_2} - e^{n_1 + m_1/2} A^{n_2 - m_2/2} \quad \text{(Eq.10)}$$

Flood peak data of Jialingjiang Watershed

This paper selects the annual flood peak data acquired at 31 hydrological stations in Jialingjiang Watershed (as shown in *Fig. 2*) for study. The confluence area of each station is controlled within 50–150,000 km^2. The maximum peak discharge data of each station in different years is shown in *Table 1*.

Results

Analysis of annual watershed flood peaks

According to the data in the *Table 1*, a double logarithmic relationship graph between the controlled confluence area *S* at each station and the mean of the maximum

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93579366

peak values Q is drawn. $f = 0.01$, 0.1 and 0.4 are shown in *Figures 3, 4* and *5,* respectively. It can be seen that the relationship between log$Q(S)$ and log$S$ is approximately linear, indicating that the peak discharge Q is scale invariant with the confluence area. At different frequencies f, the slope of the line is different, which represents the scale index. In other words, as the confluence area S changes, the mean Q of the maximum peak values satisfies the multi-scale form.

Calculate the 1^{st}-7^{th} moment $M = E[Q^h(S)]$ of each station, and plot the double logarithmic relationships between the watershed area and the 2^{nd} order matrix and the 4^{th} order matrix, as shown in *Figures 6* and *7*. Similarly, the relationship between log$M(S)$ and log$S$ (see *Fig. 8*) is approximately linear, indicating that the peak discharge Q is scale invariant with the watershed area changing. Calculate the scale value θ at different frequencies f through linear regression analysis, as shown in *Table 2*. It can be seen that the scale index increases with the increase of frequency, indicating that the peak discharge of a large flood in the low return period grows more slowly than that of a small flood in the high return period. In other words, the peak discharge values of a small watershed are more steeply distributed, which is in line with the actual conditions.

Analysis on the application of the lognormal distribution model

According to the scale invariance feature, the peak discharge of the area where the no existing data is available can be calculated based on the annual peak discharge of the area where it is available. In this way, the probability distribution of the former can also be obtained.

Take the hydrological station in the Jialingjiang Watershed as an example. The flow control area of the hydrological station is 82,391 km^2. According to the 35-year maximum flow probability distribution map, the distribution of the flow data matches *f*-3. Suppose another hydrological station, with a control area of 725 km^2, has no data available. Then, according to the scale index θ found in *Table 2*, the peak discharge probability value of the area with no data can be obtained based on the existing data of the area with data. *Table 3* shows the calculated peak discharge values and the true ones, which are almost consistent.

Table 3. *Calculations for the application example*

P(%)	Q(Aref)(m^2/s)	Q(A)(m^2/s)	
		True value	Calculated value
0.1%	52264	4562	4412
0.2%	42142	3244	3135
0.5%	38263	2806	2709

20%	23649	1241	1231
31%	16323	954	924

Discussion

According to the three-parameter lognormal distribution model, the six parameters (n_1, n_2, m_1, m_2, s_1 and s_2) are used to determine the three parameters μ, σ^2 and b of the lognormal distribution, and thus the distribution of the watershed flood peaks with different confluence area *S* in the Jialing River Basin. Finally, the design peak discharge in the area with no data can be estimated based on the existing hydrologic data of the area with data.

According to the model, relevant data from 31 hydrological stations in the Jialingjiang Watershed are selected, and the six parameters are all obtained: $s_1 = 2.341$, $s_2 = 0.573$; $n_1 = 2.453$, $n_2 = 0.756$; and $m_1 = 0.273$, $m_2 = 0.026$. Based on this, the mean μ, the dispersionσ^2 and the parameter b in the three-parameter lognormal distribution model are determined. Then the distribution of the flood peaks in the Jialingjiang Watershed is obtained according to the analysis in Section 3 above, and the effects of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93579366

flood peaks on the hydrology and water resources in the watershed are determined, together with preliminary evaluation on the water environment. The results also show that the lognormal distribution model selected in this paper can reasonably predict the impact of the flood peaks in the Jialingjiang Watershed on the conditions of hydrology and water resources in this region.

Conclusion

Taking the Jialingjiang Watershed as an example, this paper collects the peak discharge data and historical data in the watershed and then studies the effects of watershed flood peaks on the hydrology and water resources and water environment in the Jialingjiang Watershed using three-parameter lognormal distribution model. The main conclusions are as follows:

(1) The three-parameter lognormal distribution model is more applicable to the analysis and evaluation of hydrologic conditions in river watersheds than the two-parameter one. The former can reasonably characterize the scale effect law of the confluence area in the watershed peak discharge distribution.

(2) The peak discharge in the Jialingjiang Watershed changes with the confluence area in a scale-invariant way; the values of the 6 parameters in the lognormal distribution model can be determined according to the confluence area S, and then based on this, the distribution of watershed flood peaks can be determined.

(3) The study on the effects of peak discharge in Jialingjiang Watershed on the hydrological and water environments in this area further deepens our understanding of the development patterns of and influencing factors to the hydrological conditions in this area and provides technical materials and theoretical support for the rational development of hydrology and water resources in this area in the next steps.

(Received 3rd Apr 2019; accepted 17th May 2019)

Abstract. The environmental impact of air pollutants emitted by energy consumption is becoming more and more serious. Air quality monitoring and evaluation is an important method to study the formation characteristics of regional air pollution, as well as an important means of comprehensive control and measurement of regional air pollution. In this paper, the emission list of Volatile Organic Compounds (VOCs) pollutants is established based on GIS technology, and the atmospheric diffusion of VOCs pollutants with five concerns in Shijiazhuang City is simulated by using AERMOD system model. The results show that the main industrial emission sources of VOCs come from steel, casting and cement industries, the flowing sources mainly come from diesel motor vehicles, and the surface sources come from vegetation and building ornaments. The AERMOD model has good applicability to the simulation of VOCs emissions. This paper gives full play to the spatial analysis ability of GIS technology and makes visual analysis of the evaluation results so as to provide decision-making basis for air quality prediction.
Keywords: *environment, air quality, atmospheric pollution, GIS technology, VOCs, AERMOD model*

Introduction

In recent years, with the rapid development of economy, the large-scale emergence of chemical enterprises results in the rapid increase in the types and mass concentration of pollutants in the atmospheric environment, and environmental quality has become a key issue for urban sustainable development that must be addressed as soon as possible (Mujtaba et al., 2016). According to the forecast data provided by the environmental management department, emergency measures may be taken to deal with heavy air pollution, such as strict control of motor vehicle exhaust emission, chemical enterprise discharge and construction dust emission (Pope and Wu, 2014; Merbitz et al., 2012). In addition, the technical support role of environmental prediction and analysis in environmental management is brought into full play to improve the quality of the atmospheric environment (Chattopadiay et al., 2010). The air quality prediction and evaluation model is an important technical method for atmospheric environmental quality detection. By establishing mathematical models of environmental pollutants under various topographical and meteorological conditions, it is possible to learn the physical and chemical mechanisms of transportation, diffusion, transformation and removal of pollutants in the atmospheric environment (Superczynski and Christopher, 2011; Zhan et al., 2018).

At present, the research of air quality evaluation model develops with the development of industrial society, and goes through the process of continuous improvement and development (Kumar et al., 2016; Vlachostas et al., 2010). In the air

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93679375

quality evaluation model, the atmospheric pollutant diffusion model is established by applying the meteorological principle to forecast the diffusion of environmental pollutants by means of computer technology in combination with the atmospheric dynamics principle, the atmospheric physics and the atmospheric chemistry application foundation (Elbir et al., 2010). The air quality assessment model is classified into local scale, urban scale and regional scale by simulation scale. In general, the urban scale is used for environmental quality prediction and evaluation (Barrile et al., 2018; Steve et al., 2008; Wang et al., 2015). Geographic information system (GIS) can manage spatial data by spatial location and study the interrelationship among various spatial entities. The GIS technology can visualize the air quality forecast data (Righini et al., 2014; Tirmizi and Tirmizi, 2018). In this paper, GIS technology is applied to the detection and evaluation of urban air quality and the spatial analysis ability of GIS technology is brought into full play to visually analyze the evaluation results so as to provide decision-making basis for air quality prediction.

Materials and methods

Industrial sources, flow sources, and surface sources

The establishment of an urban air pollution emission list is an effective tool for assessing urban air quality, which should specifically include emission source spatial location, emission data and emission parameters (Borrego et al., 2016; Siliello et al., 2014). There are three types of air pollution sources in urban areas: industrial, flow and surface sources (Carbajal-Hernández et al., 2012). *Table 1* shows the source identification of the pollution sources. Except for the industrial sources where O3 comes from, the common atmospheric pollutants will be generated from the three major pollution sources. Relying on GIS technology, each pollution space is located by using longitude and latitude coordinate positioning method (Borbet et al., 2018). The industrial source estimation method includes the actual monitoring method, the emission factor method and the material balance method. The VOCs emission factor is generally determined with reference to the Atmospheric Volatile Organic Matter Source Emission Inventory issued by the State. The flow sources are mainly motor vehicle emissions, and the main emissions are VOCs and NO_2. Surface sources include dust emission and combustion of domestic fuels, and surface sources of pollutant VOCs include vegetation, landfill sites and hospitals.

Table 1. *Source identification of pollution sources*

Classification	Contaminant category						
	$PM_{2.5}$	PM_{10}	SO_2	NO_2	CO	VOCs	O_3
Industrial source	√	√	√	√	√	√	√
Flow source	√	√	√	√	√	√	
Surface source	√	√	√	√	√	√	

Uncertainty analysis of pollution sources

Air quality is related not only to the spatial location and emission of emission sources, but also to meteorological conditions, including wind speed and wind direction.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93679375

Figure 1 shows the monthly average wind speed monitored in Shijiazhuang City. It can be seen that Shijiazhuang City has the maximum average wind speed in March and the minimum average wind speed in October. *Figure 2* shows the air pollution emission in downtown Shijiazhuang City. It can be seen that the surface source is the largest source of VOCs, with a sharing rate of over 63%, and the industrial source is the primary source of PM_{10}, SO_2, NO_x, CO and O_3. According to incomplete statistics, the total emission amount of VOCs in the central urban area of Shijiazhuang reached 31,101.36 t in 2017. *Figure 3* shows the composition of urban atmospheric pollutant VOCs emission sources, vegetation, industrial and architectural ornaments are the three major sources of VOCs, accounting for 36.57%, 33.25% and 14.05% respectively. The quantitative estimation of VOCs pollutant emission source inventory is calculated by selecting representative emission factors and activity level data, which with greater uncertainties due to the instrument measurement, the representativeness of source test and random error.

Results

Basic data required for the model operation

AERMOD model is used to calculate the atmospheric pollutant concentration. When simulating the horizontal diffusion of industrial source plume pollutants, the mass concentration of grid coordinate point (x, y, z) is assumed to be c (x, y, z) without considering the influence of topography. Considering the influence of the topography conditions, the total mass concentration of the grid point c (x, y, z) is shown in *Equation 1:*

$$C_r(x,y,z) = \lambda c(x,y,z) + (1 - \theta)c(x,y,z) \quad \text{(Eq.1)}$$

where, θ represents the decomposition streamline height; λ and θ represent the weight functions for horizontal and vertical point source diffusion states, respectively, as shown in *Equations 2* and *3:*

$$\lambda = 0.5(1 + \xi) \quad \text{(Eq.2)}$$

$$\xi = \frac{\int_0^H C(x,y,z)dz}{\int_0^\infty c(x,y,z)dz} \quad \text{(Eq.3)}$$

The basic data required for the model operation include pollution source parameters, meteorological data parameters, predicted point source coordinates, ground and high-altitude meteorological data. For industrial chimneys, the point source parameters include the height of the chimney, outlet inner diameter, discharge velocity and emission rate, while the surface source parameters include height, direction angle, length and emission rate.

Model verification method

For the convenience of simulation, the simulation results of atmospheric diffusion model are verified by using the developed AERMOD system, and necessary corrections are made to the model. The AERMOD model has been used by some scholars to verify the simulation results of SO_2. The results show that the correlation coefficient between the monitored value and the simulated value of SO_2 is 0.67, which indicates that the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93679375

AERMOD model has good applicability to the simulation of SO_2 emissions. In addition, some researchers have applied the AERMOD model to the industrial point source pollutant emission area, which proved that the AERMOD model has good practicability in simulating pollution diffusion in the small and medium scale research area, and provides effective prediction data for air quality evaluation.

Discussion

Model validation

Table 2 is the emission list of pollution sources in downtown Shijiazhuang City. In selecting data of AERMOD model, it is necessary to add pollutants according to the factors of pollutants, and predict and simulate the residential areas, cultural areas and industrial areas in downtown Shijiazhuang City, with the secondary ambient air quality standard. The topographical parameters input in the AERMOD model include longitude and latitude coordinates and elevation, and the ground meteorological data include wind speed, wind direction, total cloud volume and dry-bulb temperature, where the wind direction, wind speed and dry-bulb temperature are the average value of observation data 24 times a day, and the total cloud volume is the average of 5 observations per day. *Table 3* shows the location of project concerns for prediction. According to the requirements of environmental air quality monitoring and monitoring location, five representative concerns are set up in this study and the model is simulated for a total of 20 days.

Table 2. *List of pollution sources in downtown Shijiazhuang*

Conclusions

In this paper, GIS technology is applied to the detection and evaluation of urban air quality, and the spatial analysis ability of GIS technology is brought into full play to visually analyze the evaluation results. The concrete conclusions are as follows:

(1) The surface source is the largest source of VOCs, with a sharing rate of over 63%, and vegetation, industrial and architectural ornaments are the three major sources of VOCs, accounting for 36.57%, 33.25% and 14.05% respectively.

(2) The basic data required for the AERMOD model operation include pollution source parameters, meteorological data parameters, predicted point source coordinates, ground and high-altitude meteorological data. The research indicates that the AERMOD model has good applicability to the simulation of SO2 emissions.

(3) The comparison between predicted results and monitoring results of VOCs of five concerns in Shijiazhuang City shows that the predicted concentration values of VOCs in Shijiazhuang No. 1 High School are relatively high, while the predicted concentration values of monitoring station are relatively low, and the predicted values and monitoring values of the other three stations have the same trend.

(4) Here only considers the impact of multiple point sources on the concentration of VOCs in Shijiazhuang City. The follow-up study can be made with additional pollution sources such as linear and surface sources to more roundly evaluate urban air quality.

(Received 3rd Apr 2019; accepted 17th May 2019)

Abstract. This paper attempts to disclose the effects of land use pattern on the selection of low-carbon travel by urban residents. Targeting 19 blocks in north western China's Xi'an, the author collected data from various sources, including phone signals, app records and field surveys, and divided the blocks into two groups based on the difference in land use pattern. The multi-source data ensures the objectivity and accuracy of the analysis. Then, the relationship models between block land use features and residents' travel methods were established based on the Logit model, and the effects of six land use features on the selection of low-carbon travel were discussed in detail. The research results show a strong correlation between land use pattern and travel mode of the residents in the 19 blocks; the six land use features have different impacts on the travel mode; the residents in the two types of blocks prefer different low-carbon travel methods. This research lays a scientific basis for the optimization of urban space and land use.
Keywords: *green and low-carbon, travel methods, Logit model, land use characteristics, city blocks*

Introduction

The travel frequency and range of urban residents are affected by the land use pattern. In fact, the residents mainly consider two factors when choosing between different travel methods, namely, their own needs (e.g. work, shopping and entertainment) and the land use features (e.g. form, intensity and function). To encourage low-carbon travel, it is necessary to disclose the effects of land use features on travel mode and identify the control indices of intensive land use in blocks, which are the basic units of the urban area. In this way, more residents will choose low-carbon travel, reducing the carbon emissions in transport and protecting the environment (Tu and Ma, 2018).

The studies on land use pattern generally hold that dense grids and small roads are conducive to low-carbon travel among residents (Friedman and Cammalleri, 1994; Liu and Qing, 2011; Susan, 1996; Newman and Kenworthy; 1996; Hou et al., 2018; Zhang et al., 2018; Pan, 2010). Some scholars compared the effects of different block types on residents' low-carbon travel, including traditional hutongs, dense square grids, neighborhood units, and superblocks, and concluded that the residents are more likely to adopt low-carbon travel in traditional hutongs and dense square grids (Qin and Tian, 2013; Huang et al., 2013; Chai et al., 2011). However, there is not yet an agreement on the spacing in the road network. Atash (1994) suggested that most residents prefer walking over driving if the destination is 400 m away or within 5 min drive, while Xiao (2011) claimed that most people are willing to walk to a destination within 150 m.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93779389

On land use intensity, many scholars have found that high residential density suppresses car usage, travel frequency and commuting distance, while promoting non-motorized travel (Hou and Wang, 2016; Forsyth et al., 2007; Handy, 1992; Giuliaono. and Naravan, 2003; Levinson and Kumar, 1997). Compared to rural areas, the urban area has a large population and a high plot ratio. Thus, the travel demand of urban residents is more sensitive to the changes in land use than that of rural residents. Facing the mixture of various types of land use, the urban residents often choose to travel on foot or bike within a small range (Zhou and Yang, 2005). Some scholars noted that the plot ratio has a positive impact on traffic flow intensity, and thus promotes public transport among urban residents (Caldera et al., 2017; Mao et al., 2004, 2005, 2002).

On land use function, the degree of mixed land use is positively correlated with the ratio of public transport and walking (Frank and Pivo, 1994; Friedman et al., 1994; Kockelman, 1997; Ewing and Fanag, 2008; Greenwald and Boarnet, 2002), and that of walking and biking (Zhou and Qian, 2014; Wang and Chai, 2009; Pan et al., 2009; Ma et al., 2013, 2011). In addition, it is often believed that the urban residents' choice between travel methods depends heavier on the degree of mixed land use in the workplace than that in residential areas (Ewing et al., 2003; Maat and Timmermans, 2009). However, some scholars argued that the degree of mixed land use has little effect on the choice of travel methods (Liu et al., 2010; Cervero, 1995). Moreover, many scholars held that the balance between working function and residential function of land use will shorten the commuting time and increase the ratio of walking and biking (Cervero, 1989; Long et al., 2012; Tana et al., 2015). The travel features of residents can be judged more clearly with land use function data from multiple sources (Long et al., 2012; Hou et al., 2018, 2017).

In view of the above, this paper attempts to disclose the relationship between low-carbon travel and block land use using multi-source data on various transport modes, and clarify the influence mechanism of land use on low-carbon travel through qualitative and quantitative analyses. With the aid of big data technology, the spatiotemporal features of low-carbon travel were discussed in the context of land use, and determined in an objective and scientific manner. The research findings shed new light on the optimization of block structure, enrich theories and methods of block land use, and promote low-carbon travel among urban residents.

Methodology

Background

(1) Research object

The existing studies have shown that the urban residents' selection of travel methods, and their carbon emissions in travel, are greatly affected by the intensity, form and function of land use. Thus, the three land use indices of blocks must be arranged in a scientific manner. Based on the geographic information system (GIS), this paper selects 19 blocks from Xi'an, the seat of northwestern China's Shaanxi Province, and divides them into two groups by land use function. As shown in *Figure 1,* the blocks *a*, *b*, *e*, *h*, *l*, *n*, *o*, *q* and *r* were categorized as housing-oriented blocks, because more than half of the land in each of them is used for residential purpose; the blocks *c*, *d*, *f*, *g*, *i*, *j*, *k*, *m*, *p* and *s* were classified as job-oriented blocks, because more than half of the land in each of them is used for working purpose.

DOI: http://dx.doi.org/10.15666/aeer/1704_93779389

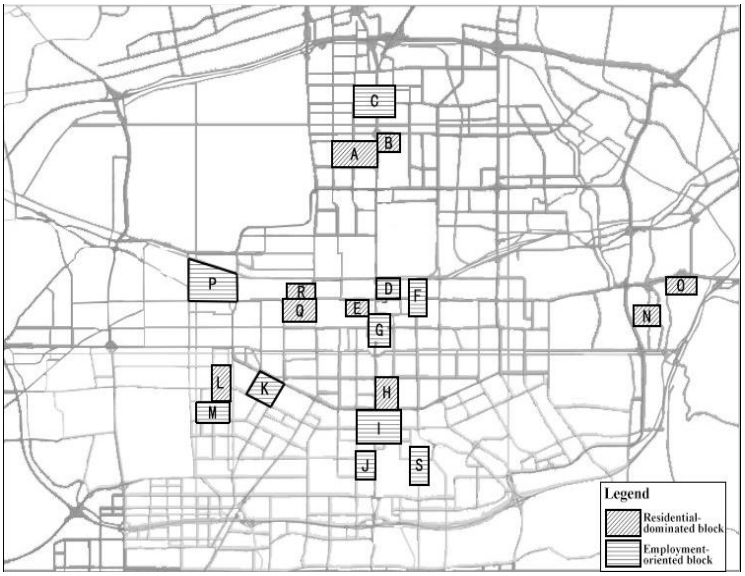

Figure 1. *Classification of the target blocks*

(2) Data on residents' travel

The data on residents' travel data (e.g. distance, frequency, trajectory and mode) were extracted from phone signals, app records and field surveys in the two weeks from Nov. 5~18, 2018. Specifically, the phone signals were acquired from China Unicom, the service provider to 17.07% of all phone users in Shaanxi; the app records were obtained from the GPS data in the bike sharing app Mobike; the field surveys were carried out in the 18 blocks to verify the results of phone signals and app records, collecting 1,900 data entries.

(3) Data on land use

The data on land use were obtained from digital maps, satellite images and phone signals. The digital maps were adopted to determine the nature of land use in each block, and verified against the remote-sensing satellite images. The residential and working situation were evaluated using the phone signals.

Index preparation

In this paper, the land use indices that greatly affect low-carbon travel are determined in three steps: quantifying the land use features, selecting the features related to travel mode through Pearson correlation analysis, and evaluating the relationship between feature indices and low-carbon travel by the Logit model. The specific process is explained as follows.

(1) Feature indices of land use

Inspired by the existing studies, six feature indices about land use function, intensity and form were found to be highly relevant to how urban residents choose between travel methods. The six indices are the degree of mixed land use, the job-housing ratio, building density, plot ratio, road density and the ratio of open space.

The degree of mixed land use M can be calculated as:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93779389

$$M = -\sum_i \left[\left(\frac{b_i}{a} \right) \ln \left(\frac{b_i}{a} \right) \right] \quad \text{(Eq.1)}$$

where a is the total area of all types of buildings in a block (m^2); b is the area of type i buildings in the block (m^2).

The job-housing ratio JHR can be calculated as:

$$JHR = \frac{J_i}{H_i} \quad \text{(Eq.2)}$$

where JHR_i is the job-housing ratio of block i; J_i is the number of jobs in block i; H_i is the resident population in block i.

The building density B can be calculated as:

$$B = \frac{S_f}{L} \quad \text{(Eq.3)}$$

where S_f is the floor area of all buildings in a block (m^2); L is total land area in the block (m^2).

The plot ratio P can be calculated as:

$$P = \frac{S_a}{L} \quad \text{(Eq.4)}$$

where S_a is the total building area of a block (m^2); L is total land area in the block (m^2).

The road density ρ can be calculated as:

$$\rho = \left(\sum_i l_i \right) \Big/ L \quad \text{(Eq.5)}$$

where L_i is the length of road i in a block; L is total land area in the block (m^2).

The ratio of open space O can be calculated as:

$$o = \frac{S_g}{L} \quad \text{(Eq.6)}$$

where S_g is the area of public green space in a block (m^2); L is total land area in the block (m^2).

(2) Pearson correlation analysis

The Pearson correlation analysis was performed on SPSS, aiming to clarify how different land use features are correlated to each other and select the features that are relevant to low-carbon travel.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93779389

(3) Logit model analysis

Taking the total population of each block as the behavioral decision unit, the optimal travel mode will be selected by the block residents from a set of independent alternatives. Hence, the Logit model was selected to determine the relationship between typical land use features and low-carbon travel.

Let U_{in} be the utility of choosing travel mode i from the set of alternatives C_n in block n, that is, the effect of land use features on the travel mode selection of the residents in the block. When two alternatives i and j are available ($i, j \in C_n$ and $i \neq j$), the residents of block n will select travel mode i only if U_{in} is greater than U_{jn}. According to the random utility theory, U_{in} can be expressed as:

$$U_{in} = V_{in} + \varepsilon_{in} \quad \text{(Eq.7)}$$

where V_{in} is utility constant when travel mode i is selected for block n; ε_{in} is the change in utility probability resulted from the implicit preference unique to the block residents.

If ε_{in} and V_{in} are independent of each other and ε_{in} obeys the Gumbel distribution, then the probability that the block residents choose travel mode i can be described as:

$$P_{in} = \frac{\exp(\lambda V_{in})}{\sum_{j \in c_n - i} \exp(\lambda V_{in})} \quad \text{(Eq.8)}$$

Next, the utility constant when travel mode i is selected for block n (V_{in}) can be described by the following linear function:

$$V_{in} = \sum_k \beta_{kin} \chi_{kin} \quad \text{(Eq.9)}$$

where x_{kin} is the k-th land use index when selected travel mode i is selected for block n; β_{kin} is the undetermined coefficient of x_{kin}. The value of β_{kin} can be calibrated by survey data. Taking the logarithm on both sides of *Equation 9,* the contribution rates of six different travel methods P_{in} (i.e. walking, bike, e-bike, motorcycle, bus, metro, car) can be expressed as:

$$\ln(P_{in}) = \lambda \sum_k \beta_{kin} \chi_{kin} - \ln\left[\sum_{j \in c_n - i} \exp\left(\lambda \sum_k \beta_{kjn} \chi_{kjn} \right) \right] \quad \text{(Eq.10)}$$

where the terms on the right side are the utility functions of the six travel methods. Based on the features of the research data, a multiple linear regression model can be established to describe the impacts of land use features on residents' travel mode:

$$y_{in} = \ln(p_{in}) = \beta_{oin} + \sum_k \beta_{kin} \chi_{kin} + \in_{in} \quad \text{(Eq.11)}$$

where y_{in} is the logarithm of the current sharing rate of the six travel methods; x_{in} is an explanatory variable with the same meaning above; β_{0in} and β_{kin} are regression

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93779389

coefficients; $\in_{in}$ is a random parameter. Obviously, the regression coefficient β_{0in} satisfies:

$$\beta_{oin} = -\ln\left[\sum_{j\in c_n\text{-}i} \exp\left(\lambda \sum_{k} \beta_{kjn}\chi_{kjn}\right)\right] \quad \text{(Eq.12)}$$

The equation is clearly workable.

Results

Features of residents' travel mode and land use

As mentioned before, the blocks *a*, *b*, *e*, *h*, *l*, *n*, *o*, *q* and *r* were categorized as housing-oriented blocks, and the blocks *c*, *d*, *f*, *g*, *i*, *j*, *k*, *m*, *p* and *s* were classified as job-oriented blocks.

(1) Low-carbon travel features of residents

The research data show that the residents in the 19 blocks mainly travel by walking, bike, e-bike, motorcycle, bus, metro and car.

The traffic flow in the housing-oriented blocks is relatively low, and dominated by walking and bike. By contrast, the job-oriented blocks have a high traffic flow, most of which occurs on bus and subway.

The residents in blocks *a*, *b*, *e*, *n*, *o*, *l* and *m* often engage in short-distance travels (< 1.5 km), those in blocks *d*, *f*, *g*, *h*, *i*, *j*, *k*, *l*, *m*, *n*, *q*, *r* and *s* are frequently involved in mid-distance travels (1.5~3 km), and those in blocks *m* and *p* mainly travel over long distances (3~21 km). The residents in block *c* have equal probability to embark on short-, mid- and long-distance travels.

The ratio of each low-carbon travel mode is listed in *Table 1*.

Table 1. *The ratio of each low-carbon travel mode*

Correlation analysis

(1) Correlation between travel methods and land use features

The correlation analysis between travel methods and land use features was carried out and the results were presented in the form of a matrix (*Table 3*). As shown in *Table 3*, the building density has a positive impact on the ratio of walking (significance < 0.05) and a negative impact on the ratio of car travel (significance < 0.01). The metro travel enjoys a significant positive correlation with plot ratio and degree of mixed land use (0.05 < significance < 0.1). In addition, the six travel methods have unobvious correlations with job-housing ratio, road density and ratio of open space.

Relationship models between land use features and low-carbon travel

The logit model (*Eqs. 7–12*) can be used to calculate the correlation between land use characteristics and low-carbon travel characteristics in different types of blocks.

(1) The relationship model for housing-oriented blocks

Based on the results of regression analysis the relationship models between land use features and low-carbon travel in housing-oriented blocks can be constructed as:

$$y_{11} = -0.894 + 0.00592z_1 - 0.0677z_2 + 0.00192z_3 + 0.0352z_4 - 0.00296z_5 + 0.00867z_6 \quad \text{(Eq.13)}$$

$$y_{12} = -0.98 - 0.0233z_1 + 0.0444z_2 - 0.0171z_4 - 0.001z_5 - 0.0125z_6 \quad \text{(Eq.14)}$$

$$y_{13} = -1.158 + 0.0062z_1 + 0.0122z_2 - 0.0269z_4 + 0.0136z_5 - 0.016z_6 \quad \text{(Eq.15)}$$

$$z_1 = \frac{x_1^2}{100}, z_2 = \frac{x_2^3}{10000}, z_3 = \frac{x_3^3}{10000}, z_4 = \frac{x_4^3}{10000}, z_5 = \frac{x_5^2}{100}, z_6 = x_6 \quad \text{(Eq.16)}$$

where y_{in} is the probability logarithm of block i to choose travel mode n ($i = 1$ for housing-oriented blocks; $i = 2$ for job-oriented blocks; $n = 1$ for zero-carbon travel methods like walking and bike; $n = 2$ for high-carbon travel methods like e-bike, motorcycle and car; $n = 3$ for low-carbon travel methods like bus and metro); x_j is the standardized value of land use index j ($j = 1$ for building density; $j = 2$ for plot ratio; $j = 3$ for the degree of mixed land use; $j = 4$ for road density; $j = 5$ for the ratio of open space; $j = 6$ for job-housing ratio).

(2) The relationship model for job-oriented blocks

Based on the results of regression analysis, the relationship models between land use features and low-carbon travel in job-oriented blocks can be constructed as:

$$y_{21} = -0.262 - 0.149z_1 - 0.253z_2 + 0.0383z_3 + 0.091z_4 - 0.0231z_5 + 0.0426z_6 \quad \text{(Eq.17)}$$

$$y_{22} = -1.339 + 0.336z_2 - 0.0604z_3 - 0.111z_4 + 0.0221z_5 - 0.0525z_6 \quad \text{(Eq.18)}$$

$$y_{23} = -2.201 - 0.0083z_1 + 0.0543z_2 + 0.0422z_3 + 0.0474z_4 + 0.00071z_5 - 0.0149z_6 \quad \text{(Eq.19)}$$

where the symbols have the same meanings as above.

Discussion

The traffic flow is essential to the research on the travel features of urban residents. The phone signals can accurately reflect the traffic flows of travel methods like car, bus and metro. However, it is difficult to obtain the complete traffic flows of walking and bike from phone signals, due to the long intervals between two collections. Thus, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93779389

records of Mobike and field survey data were necessary for correction of the data acquired from phone signals.

The nature of land use has a great impact on the traffic flow and ratio of each travel mode. For instance, the residential-oriented blocks have a far smaller traffic flow than the job-oriented ones. In general, the residential-oriented blocks are dominated by non-motorized travel while the job-oriented blocks are dominated by motorized travel.

In residential-oriented blocks (*Eqs. 13–16*), building density promotes the ratio of zero- and low-carbon travel methods and inhibits that of high-carbon travel methods; the plot ratio suppresses the ratio of zero-carbon travel methods, but promotes that of high- and low-carbon travel methods; the degree of mixed land use improves the ratio of zero-carbon travel methods, with no significant impact on high- and low-carbon travel methods; road density has a positive impact on the ratio of zero-carbon travel methods, and a negative impact on low- and high-carbon travel methods; the ratio of open space reduces the ratio of zero- and high-carbon travel methods, yet increases the ratio of low-carbon travel methods; the job-housing ratio enhances the ratio of zero-carbon travel methods, and lowers the ratio of high- and low-carbon travel methods.

In job-oriented blocks (*Eqs. 17–19*), building density has an unobvious effect on the ratio of high-carbon travel methods; the plot ratio promotes the ratio of high- and low-carbon travel methods; the degree of mixed land use and road density both elevate the ratio of zero- and low-carbon travel methods, and reduce that of high-carbon travel methods; the ratio of open space inhibits the ratio of zero-carbon travel methods, but promotes the ratio of low- and high-carbon travel methods; the job-housing ratio has a positive effect on the ratio of zero-carbon travel methods and an inhibiting effect on the ratio of high- and low-carbon travel methods.

Conclusions

The previous studies on the effect of land use pattern on residents' travel mode are highly subjective due to the difficulty in data acquisition, failing to verify their theoretical hypotheses. This paper objectively demonstrates how land use features affect the low-carbon travel among urban residents. The research data were collected from various sources, including phone signals, app records and field surveys, making it possible to analyze and verify the effects in an objective manner. Two models were established to depict the relationship between block land use features and residents' travel methods, and the effects of six land use features on the selection low-carbon travel were discussed in details. The main conclusions are as follows.

The nature of land use has a great impact on the traffic flow and ratio of each travel mode. In other words, the land use pattern is a significant determinant of the travel features of urban residents.

The residential-oriented blocks feature high building density, low plot ratio, high degree of mixed land use, low ratio of open space and high job-housing ratio. The residents in these blocks prefer non-motorized, low-carbon travel methods. By contrast, the job-oriented blocks have low building density, high plot ratio, high degree of mixed land use, medium road density, high ratio of open space and low job-housing ratio. The residents in these blocks are used to public travel methods.

The future research will further eliminate the errors in feature extraction, widen the scope of research area, and simplify the index system.

Abstract. This paper aims to ascertain the variation in weather threat over time. To this end, the author established an assessment model of weather threat based on the Dynamic Bayesian Networks (DBN). Then, the Hidden Markov Model (HMM) was introduced to assess the level of weather threat. To validate the proposed method, a simulation was carried out on an Unmanned Aerial Vehicle (UAV), considering all five key weather factors affecting UAV safety. The results show that the DBN-based model is much more effective than the ordinary Bayesian Network (BN) in handling fuzzy information and complex weather conditions. The research findings shed new light on the accurate rout planning of an UAV.
Keywords: *UAV, DBN, HMM inference, forward-backward algorithm, conditional probability*

Introduction

Weather is a non-negligible factor in the rout planning of an UAV. Changeable weather poses a major threat to UAVs safety during reconnaissance missions. To minimize weather-induced loss and identify a safe route for UAVs, it is an urgent task to accurately quantify weather threat. Weather threat is too ambiguous, uncertain and time-dependent to be quantified by classical methods like function method (Paris and Erdogan, 1963). For instance, Tan and Du (2009) and Kilby and Hosseini (2004) reported that neither manned aircraft weather assessment nor engineering mathematic model can yield desirable results on weather threat on UAVs. Zhang et al. (2014) suggested that Gaussian approximation may lead to adverse weather.

Many researches have been done on weather threat quantification. Ramli et al. (2014) solved the weather threat on airport security by fuzzy logic. Adiwijaya (2013) created a prediction model based on weather data, and enhanced its forecast accuracy by the hybrid fuzzy-genetic algorithm. Zhu et al. (2011) identified eight weather factors that affect flight safety, and assessed the level of weather threat by the backpropagation (BP) neural network. Based on neural network and fuzzy logic, Al-Matarneh et al. (2014) developed different weather prediction models for different regions. Sannakki et al. (2013) adopted feed forward neural network to predict disease outbreaks in grapes induced by weather. The static BN (Zhu et al., 2015; Luo and Chen, 2008) was also applied to the quantitative assessment of weather threat.

In general, the above studies overlooked the time-dependence, failing to ascertain the variation in weather threat over time. The problem can be solved by DBN, a modelling and inference tool of dynamic and uncertain events. The DBN has been extensively applied in such fields as speech recognition (Zweig and Russell, 1998), threat

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93919400

assessment (Tang et al., 2007; Zhang et al., 2005), and bio-sequence analysis (Tian and Lu, 2004; Hou et al., 2010).

In view of the above, this paper sets up an assessment model of weather threat, and proposes the DBN-based synthetic fuzzy assessment method for the level of weather threat. The goal is to obtain a logical level of weather threat in consideration of various factors. Specifically, the simple weight mathematical assessment was improved to evaluate the threat index under the combined effect of various weather factors. The proposed method can significantly enhance the validity, feasibility and accuracy of weather threat assessment.

The remainder of this paper is organized as follows: Section 2 introduces the Static Bayesian Network (SBN), the DBN, and Forward-Backward (FB) algorithm; Section 3 establishes a weather threat model; Section 4 assesses weather threat through simulations and experiments; Section 5 wraps up this paper with some meaningful conclusions.

Materials and methods

Bayesian networks

Bayesian networks are invented to handle vague and uncertain issues in the field of artificial intelligence. As an important tool of uncertainty inference, the networks apply probability and statistics in complex domains. The SNB is a Directed Acyclic Graph (DAG), a finite directed graph with no directed cycles. In the DAG, each node represents a variable, and the edge between two nodes reflects the direct dependence between the two corresponding variables.

In general, the SBN consists of a structure diagram and a Conditional Probability Table (CPT). The CPT is a set of random variables to demonstrate marginal probability of a single variable with respect to the others. If a SBN provides sufficient conditional probabilities to derive any joint probability with given variables, then the network is considered calculable or inferential.

If $X = X_1, X_2, \ldots, X_n$ is the set of variables, then the joint probability distribution can be expressed as *Equation 1:*

$$P(X_1,...,X_N) = P(X_1)P(X_2 \mid X_1)...P(X_N \mid X_1,...,X_{N-1}) = \prod_{i=1}^{N} P(X_i \mid X_{1...i-1}) = \prod_{i=1}^{N} P(X_i \mid P_{arent}(X_i)) \quad \text{(Eq.1)}$$

where $P_{arent}(X_i)$ are the parent nodes of X_i.

The SBN takes no account of the time elements of variables. Considering these elements, the network will change along the timeline, forming a DBN (Murphy, 2002). The DBN estimates the model state at each moment or a given moment based on multiple time observations, and deduces the final result through comprehensive consideration of the observations. The same features observed at different periods can supplement each other. Thus, the DBN overcomes the limit of single evidence inference, and acquires a strong inference power.

Figure 1 depicts the extension of the DBN along the timeline. It is clear that the DBN contains an initial network B_0 and a transfer network $B_{\rightarrow}$. The initial network represents the initial state of the network. The probability distribution of variables in the initial state is denoted as p(b[0]). The transfer network $B_{\rightarrow}$ describes the dependencies

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93919400

between adjacent time slices in the network. The state transition probability between time t and time t + 1 is denoted as as p(x[t + 1]|x[t]). To sum up, the DBN can disclose the causal relationships between variables, and identify the evolutionary state of variables on time series, making it an ideal tool for simulating and inferring dynamic events.

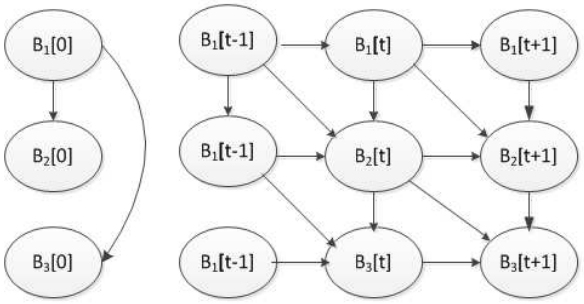

Figure 1. *Initial network and transfer network structure of DBN*

FB algorithm

Aiming to derive the probable values of hidden variables from numerous observed variables, the DBN is inextricably linked with the standard HMM. The network topologies of the two are interconvertible. The HMM inference is highly time-dependent if there are only a few DBN nodes (Xiao, 2006).

There are two main algorithms for HMM inference: the FB algorithm and Viterbi decoding algorithm. Considering the research content, the author adopted the FB algorithm to assess the level of weather threat. For the given model $\mu = (A,B,\pi)$ and observation sequence Y, the FB algorithm was introduced to infer occurrence probability of the sequence $P(Y|\lambda)$. The FB algorithm relies on recursion operation to reduce the computing complexity in probability-solving problem.

(1) Forward algorithm

The forward variable is defined as: $\alpha_t(i) = P(y_1, y_2, \ldots, y_t, x_t = i|\lambda)$.

Initialization (*Eq. 2*):

$$\alpha_1(i) = \pi_i b_i(y_1), 1 \le i \le n \tag{Eq.2}$$

Recursion (*Eq. 3*):

$$\alpha_{t+1}(j) = \left[\sum_{i=1}^{n} \alpha_t(i) a_{ij}\right] b_j(y_{t+1}) \quad t = 1,2,...,T-1 \tag{Eq.3}$$

Result (*Eq. 4*):

$$P(Y_T \mid \lambda) = \sum_{i=1}^{n} \alpha_T(i) \tag{Eq.4}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93919400

(2) Backward algorithm

The backward variable is defined as: $\beta_t(i) = P(y_{(t+1)}, y_{(t+2)}, \ldots, y_T, x_t = i|\lambda)$.
Initialization (*Eq. 5*):

$$\beta_T(i) = 1, 1 \le i \le n \tag{Eq.5}$$

Recursion (*Eq. 6*):

$$\beta_t(i) = \left[\sum_{j=1}^{n} a_{ij} b_j(y_{t+1})\right] \beta_{t+1}(j) \quad t = 1, 2, ..., T-1 \tag{Eq.6}$$

Result (*Eq. 7*):

$$P(Y_T \mid \lambda) = \sum_{i=1}^{n} \pi_i \beta_1(i) \tag{Eq.7}$$

The forward and backward algorithms are combined as the FB algorithm which is shown in *Equation 8:*

$$P(Y_T \mid \lambda) = \sum_{i=1}^{n} \alpha_t(i) \beta_t(i) \, 1 \le t \le T \tag{Eq.8}$$

The DBN-based weather threat assessment model for UAVs was set up in the following steps: First, determine the weather factors that affect the UAVs safety; second, carry out quantitative analysis on each factor; third, determine the CPT and Transition Probability Table (TPT).

Weather factors affecting UAVs safety

The accuracy inference of weather threat level relies on the determination of typical weather factors. In light of the features of DBN, four factors were selected out of the various weather factors that affect the UAVs safety.

Threat Level (TL): As the parent node, the TL assesses the threat condition probability of UAVs flight at a certain point under various weather factors. In the US, EU and China, the weather TLs are depicted by four colours: blue (common), yellow (serious), orange (severe) and red (dangerous).

Weather Type (WT): Each type of weather has its unique impact on UAVs flight. For simplicity, the weather conditions were divided into 3 levels: mild (breeze, drizzle, sunny, etc.), common (moderate rain, fresh breeze, etc.) and dangerous (thunderstorm, tornado, etc.). The division clarifies the threat levels and reflects the features of DBN.

Intensity of effect (IOE): The intensity of effect varies with weather types. It is quantitatively classified in this paper.

Relative Location (RL): Both the effect range of weather and UAVs location are constantly changing. Therefore, the distance from the UAVs to the effect centre of the weather changes all the time. The variation in the relative location has a significant impact on the level of weather threat.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93919400

Flight Type (FT): The UAVs flies at different altitudes depending on the specific conditions. The maneuver operations include steep climb, dive, quick turn, and gentle turn. Under the same condition, the damage probability of the UAVs changes with time. It is assumed that the sudden flight operations (e.g. steep climb, dive, quick turn) are much more likely to be threatened than smooth flight operations (e.g. gentle turn).

The above factors were taken as the key to the flight analysis of the UAVs. Considering the factor of time, the authors created a weather threat assessment model as shown in *Figure 2*.

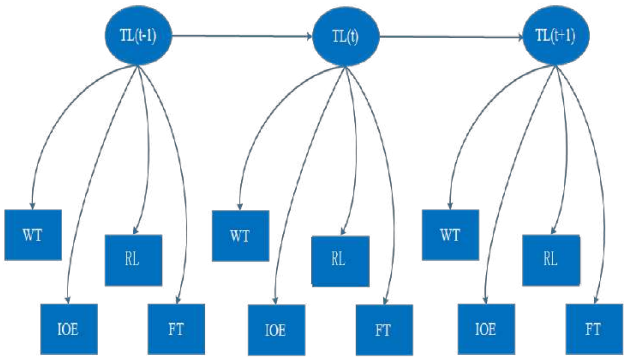

Figure 2. *DBN model of weather threat*

Quantification of each factor

Let S be the set of states of each node in the model. The factors were distinguished by the following subscripts:

S_{WT} = {dangerous, common, gentle};
S_{IOE} = {powerful, strong, middle, weak};
S_{RL} = {far, medium, near};
S_{FT} = {sudden flight, smooth flight}.

As mentioned before, the weather conditions were divided into 3 levels. The levels were ranked as dangerous weather, common weather and mild weather in descending order of the threat level to the UAVs.

Four-level quantification was employed to identify the exact IOE of each weather type. The distance from the UAVs to the energy centre was also taken into account in the quantification process. Its effect on threat level was ascertained by three-level quantification.

Furthermore, the flight attitudes of UAVs were classified into two categories. The sudden flight operations pose a great threat to UAVs, while the smooth flight operations have a limited threat. For convenience, the flight attitudes were partitioned according to the possible directions.

Determination of the CPT

The CPT was adopted to depict the casual relationship between the threat level in the DBN and the relevant factors. The table reflects the expert knowledge, including the experience and priori knowledge. Owing to subjectivity, there is a certain deviation between the expert knowledge and the actual results. If conditions permit, the CPT

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93919400

should be modified to a certain extent. *Table 1* shows the CPT of the factors in the weather threat assessment model.

Table 1. *Conditional probability table of weather factors*

Threat level	P(WT|TL) [dangerous, common, gentle]	P(IOE|TL) [powerful, strong; middle, weak]	P(RL|TL) [far, medium, near]	P(FT|TL) [sudden flight, smooth flight]
Low	0.15 0.25 0.60	0.15 0.15 0.20 0.50	0.10 0.40 0.50	0.20 0.80
Middle	0.20 0.45 0.35	0.35 0.45 0.10 0.10	0.20 0.60 0.20	0.30 0.70
High	0.80 0.15 0.05	0.80 0.10 0.05 0.05	0.70 0.20 0.10	0.80 0.20

In *Table 1*, the first column lists the conditional probabilities of the three weather types ($P(WT|TL)$), which are respectively 15%, 25% and 60% at low TL, 20%, 45% and 3 at medium TL, and 80%, 15% and 5% at high TL. The conditional probabilities of the other factors can be understood in a similar way.

Determination of the TPT

As shown in *Table 2*, the random probability refers to the state transition probability between two time slices when the network changes along the timeline.

Table 2. *Transition probability table of DBN*

TL(t) \ TL(t + 1)	Low	Middle	High
Low	0.7	0.2	0.1
Middle	0.15	0.65	0.2
High	0.1	0.2	0.7

Results and discussion

The proposed DBN-based weather threat assessment model was applied to a simulation, aiming to infer the probabilities of different weather threat levels. Then, the weather threat levels were derived accurately, laying the basis for scientific route planning of UAVs.

Without any observational evidence, the high threat level (P_{TL}^{H}), the medium threat level (P_{TL}^{M})) and the low threat level (P_{TL}^{L})) were assumed as 0.3, 0.4 and 0.3, respectively. Suppose the nodes are mutually independent. Then, the author began to collect the data on each node. Assuming that a UAVs was on a mission, the weather conditions were monitoring at ten different moments of the flight, and the factors related to the threat of the target UAVs were described in real time.

Based on the observational evidence, ten observed values of the target were recorded (*Table 3*). The weather threat levels were figured out by comparing the data on the target UAVs at different moments. Next, the weather threat was assessed by the DBN and the ordinary Bayesian network (BN), respectively. The assessment results are presented in *Table 4* and *Figure 3*. When the data were normal, both the DBN and the BN inferred the right results, despite a slight difference.

7	0.9315	0.0676	0.0010	0.7317	0.2561	0.0122
8	0.9806	0.0193	0.0000	0.9480	0.0516	0.0004
9	0.7551	0.2386	0.0063	0.1773	0.7660	0.0567
10	0.8874	0.1115	0.0010	0.8540	0.1435	0.0026

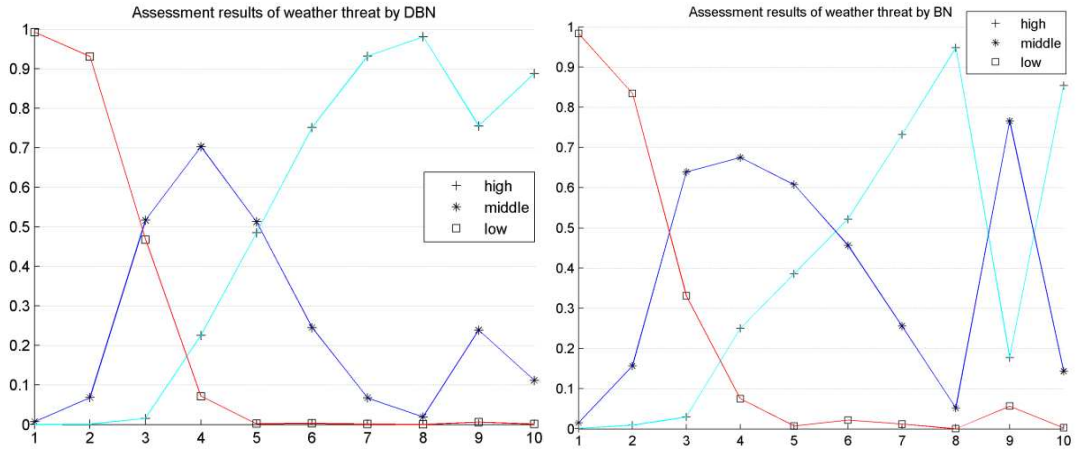

Figure 4. *Assessment results of weather threat when abnormal data occurred*

As shown in *Figure 4,* the DBN managed to infer the weather threat correctly before and after the abnormal data occurred at time 9, although the states of weather factors changed over time and the threat levels were unclear according to the reference tables. By contrast, the BN only derived the right results based on the current data. Therefore, the DBN is much more accurate than the BN in the inference of weather threat level, in spite of the alteration or missing of the feature values.

Conclusions

This paper puts forward a weather treat assessment model based on the DBN, and determines the probability distribution of weather threat level by the HMM inference

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_93919400

method. The model considers all the key factors affecting the weather threat level, including some continuous observed data. Through the numerical simulation of UAVs flight, it is concluded that the DBN-based model is effective and feasible. The model has a great potential of application in fields like battlefield situation assessment, target recognition, etc. In the next step, it is proposed to automatically construct a meteorological threat assessment model through Bayesian learning method, which makes the constructed model more reasonable and accurate, and applies the weather threat assessment results to multi-UAV multi-target mission planning.

Abstract. With the growth of population and the rapid development of economic level, the emission of greenhouse gases increases greatly, and the form, degree and structure of resource utilization tend to be diversified. Based on the diversity of ecological environment, the utilization of resources shows the diversity of utilization functions. However, the unreasonable carbon emission leads to the decrease of the resource carrying capacity, and its prominent impact on the ecological environment is reflected in the population growth, the inharmonious development of the energy consumption and the urban greening construction. The results of this study show that economic development and forest city construction mutually promote each other. Expanding forest area and improving urban forest accessibility are the most direct effective way to achieve direct emission reduction and forest city target requirements. Based on the four major categories including basis, ecology, economy and industry, and culture covering 12 small indicators proposed by SWOT analysis, technical supports should be provided to the specific forest city planning and construction. This study provides a theoretical basis for the sustainable development of low-carbon environment.
Keywords: *low-carbon effect, resource carrying capacity, SWOT analysis, evaluation indicators, forest cities*

Introduction

With the rapid development of urbanization and the sharp convergence of population in cities and towns, the urban industrialization represented by high energy, high consumption and high emissions has brought unprecedented opportunities to the development of cities. But at the same time its massive greenhouse gas emissions poses irreparable impact on the urban ecological environment and climate change (Huang et al., 2018; Gotovsky et al., 2018; Lodi et al., 2017; Marino et al., 2017; Oguzie et al., 2010; Han, 2011). A series of environmental problems resulting therefrom bring greater negative factors to the development of the cities (Wang and Watson, 2010). Currently, the greenhouse gas is an important contributor to global warming (Koo et al., 2014). High-energy carbon consumption is key to the production of greenhouse gases (Chuai et al., 2015). In view of the importance of a good ecological environment and a sustainable natural environment to urban development, many scholars have paid more and more important attention to the research on how to solve urban high emissions and realize the development of ecological balance (Duane et al., 2012). A great deal of research on eco-cities focus on how to realize the development mode of low-carbon circular economy and the application method of low-carbon effect to the sustainable development of ecological environment (Hosseini and Rezaei, 2013; Scully-Russ, 2012). The theory of low-carbon city put forward is suitable for the urban development in China at present, so the theory of urban planning and construction based on low-carbon effect is of great significance.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94019410

Population, resources, environment and development constitute the sub-system of regional economic development, which is the main problem that affects the economic development of a region. To solve this problem from the root, a large number of scholars and urban development practice have given the direction – low-carbon circular economy development model, the low-carbon model of resources development and utilization is designed to promote regional economic development, and a region's carbon consumption and environmental capacity is proportional (Chen, 2012). However, high energy carbon emissions are bound to cause damage to ecosystems (Liu et al., 2017; Yang and Kong, 2012). If human beings want to survive and develop, they must consume resources. If they want to develop sustainably, they must develop and utilize resources according to local conditions on the basis of not destroying the ecological environment. The carrying capacity of resources in a region is limited. Under the action of ecological drive, the carrying capacity of regional resources is gradually decreasing. At present, the comprehensive evaluation indicator of resource utilization efficiency and economic development is ecological footprint. The study of ecological footprint is based on the complex system of "ecology-economy-sustainability". The forest city is an effective way to alleviate the warming of atmospheric environment and solve the greenhouse gas emission. The environmental capacity and forest greening rate of a region are the key indexes to measure the construction of forest cities. Based on the action of low-carbon effect, this study discusses the master planning and construction plan of forest cities, establishes the urban economic development model of low-carbon effect, and realizes the sustainable development of urban regional economy.

Materials and methods

The ecological sensitivity of forest cities is the key index to judge the carrying capacity of forest cities based on the principle of low-carbon consumption, and the ecological environment state is evaluated according to the concept and method of ecology and sustainable development to balance the specific population. The amount of green resources that people need to offset the hazardous substances released for the development of production and consumption of human is the basis for planning the plot ratio of forest cities (Mcintosh et al., 2015; Burrows and Appold, 2015). The calculation of the ecological rate is as shown in *Equation 1,* and the evaluation index is shown in *Table 1:*

$$EF = N \times ef = N\sum_{i=1}^{n}(ai) = N\sum_{i=1}^{n}(C_i / P_i)(i = 1.2.3...n) \quad \text{(Eq.1)}$$

EF is the total index of ecological sensitivity; N is the number of urban carbon consumption items; ef is the equivalent value of carbon consumption per capita in the city; N is the population; i is the type and attribute of consumer goods; ai is the biological production area occupied by each person of the i-th substance; C_i is the average oxygen released by the i-th greening species; P_i is the average production capacity of the i-th substance.

Ecological environmental carrying capacity refers to the ratio of released greenhouse waste to waste absorbed by photosynthesis of green plants. The value of the carrying capacity required for forest city development is expressed as (Schebitz et al., 2014):

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94019410

$$FR = (PW + DW) \times (1 - \delta) \quad \text{(Eq.2)}$$

where PW represent the carbon value of the production emission; DW indicates the scale of forest greening; δ represents the carbon consumption rate.

Table 1. *Evaluation factors and their classification of the ecological sensitivity*

Ecological factors	Insensitivity	Slight sensitive	Moderately sensitive	Highly sensitive	Extremely sensitive
Vegetation	<0.33	0.33~0.52	0.53~0.64	0.65~0.72	≥ 0.73

Hierarchical assignment	1	3	5	7	9

Results

SWOT analysis of establishing low-carbon effect forest cities

The SWOT analysis will examine the strengths, weaknesses, opportunities, and challenges of the subjects studied. Through detailed investigation and analysis, the influencing factors are sequenced according to the importance and the correlation analysis is arranged in matrix mode. Then, the relationship among the various factors is analyzed with system analysis under the principle of mutual matching. In order to construct a forest city with low carbon effect, SWOT analysis should be carried out on the construction of the city according to the results of statistical investigation, and the construction strategy of SWOT analysis strategy for forest city construction is shown in *Table 2.*

Table 2. *The construction of national forest SWOT strategy analysis matrix*

Classification	Category	Analysis process			
Internal conditions	Strength	Government Attention	Abundant resources	Urban priority development zone	Experience and reference
	Weakness	Potential hazards of soil and water resources	Forestry development guarantee	Land used for building	
External conditions	Opportunities	Opportunity	Strategy	Policy	Upsurge
	Threats	Development	Compete	Ecological function	Capital

In accordance with the analysis model of *Table 1,* with reference to the data of Yearbook of the National Bureau of Statistics in 2018, the low-carbon construction effect and the total investment ratio of forest construction of major green forest cities are analyzed according to the ecological sensitivity and carrying capacity calculation scheme, providing practical support for the feasibility analysis, with the results shown in *Figure 1.*

Figure 1 shows that the SWOT analysis indexes analyzed in this study are positively correlated with the construction planning effect of the forest cities. In light of the fact that the primary task of the master planning of forest cities based on the low-carbon effect is to carry out the SWOT analysis on a statistical basis, and according to the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94019410

above analysis plan and the examples of the construction of individual cities, it is confirmed that the construction of forest-oriented cities should be analyzed from the following three aspects. First, the SWOT analysis on the construction of the city as a forest city shall be thoroughly carried out to clearly recognize that the city in the construction process needs what experience data and absorb what ways and methods for improvement. Second, we should formulate a strategy for the development of low-carbon economy for modernization, so that the economic development of cities should be coordinated with the construction of ecological environment and the construction of national forests. Third, we should actively respond to the challenges brought by the acceleration of the green urbanization process, analyze the national policies and local environmental characteristics, dare to expose the problems, turn the disadvantages into advantages for the development, and strengthen the situation and determination of realizing the low-carbon forest cities. From the above three aspects, the changing trend of the greening rate of the main greening cities in different years is shown in *Figure 2*.

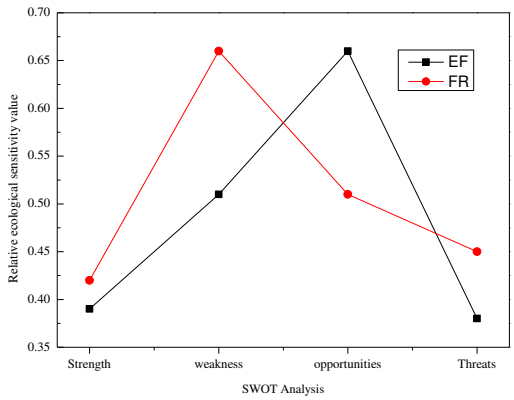

Figure 1. *Statistical analysis of different evaluation indicators based on SWOT*

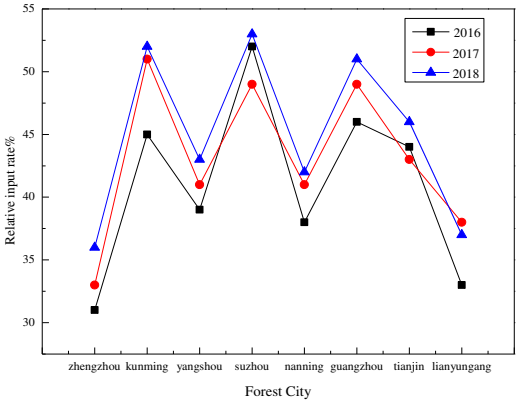

Figure 2. *Statistical value of greening rate of green city in different years*

Construction of forest city evaluation indexes based on low-carbon requirements

After the SWOT analysis on the construction of low-carbon forest cities, it is necessary to establish quantifiable evaluation indexes to measure the specific targets and strategies of forest urban planning and construction. In this study, forest city

sensitivity and low-carbon effect bearing capacity are used to measure the result of the comprehensive action of human and natural environment, and the balance of ecological environment causes the changes in regional material flow, energy flow and information flow, so as to construct the evaluation indexes and provide technical support for the construction of forest cities with low-carbon effect as the target. According to the four factors of basic index, ecological index, economic and industrial index and cultural index, this study evaluates the order and feasibility criterion of construction index. Refer to *Table 3* for comprehensive evaluation index and its reference value.

Table 3. *Establishing evaluation index of green forest city*

Index system	Evaluation content	Quantitative indicators	Low carbon significance
Basic index	Forest coverage	≥ 35%	Carbon absorption
	Urban green coverage rate	≥ 40%	
	Per capita park green space	More than 11 m^2	Fixed carbon emission reduction
	Greening of important water sources	≥ 55%	
	Road greening	≥ 70%	
Ecological indicators	Suburban forest naturalness	Naturality below 0.5	Improving forest quality
	Bio-diversity	Species diversity	
	Forest soil protection	Reducing soil and water loss	
Economic and industrial indicators	Forest tending and forest management	Close to nature	Developing low carbon economy
	Ecotourism	Ecotourism construction	
	Forest production base	Forest related income	
	Forest nursery	Self-sufficiency rate ≥ 70%	
Cultural indicators	Popular science sites	Number of popular science places	Improving forest carbon sequestration
	Voluntary tree planting	Compulsory tree planting rate for all	

Table 3 summarizes and analyzes the master planning and evaluation indexes for the construction of low-carbon cities. To build low-carbon forest cities, it is first to combine the index requirements of national forest cities and to compare the current situation of the city with the actual data according to a large number of investigations. In accordance with the evaluation result, the corresponding strategies are adopted. The overall construction idea of forest cities at the present stage is to increase the forest coverage rate, the green area, the green belt area, and the green rate, adopt the appropriate forest seedling cultivation method and expand popular science places to improve the forest city construction planning based on the low-carbon effect.

Discussion

Sustainable low carbon forest city planning

The evaluation index of constructing low-carbon forest cities provides the basis and direction for the master planning of constructing low-carbon forest cities. How to realize the sustainable, reduced and economical low-carbon city construction needs to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94019410

have clear planning idea and construction outline in the planning. Based on the literature review and the results of forest city construction, this study puts forward the process and method of low-carbon city construction. The definition of low-carbon cities mainly includes low-carbon city, low-carbon city life, low-carbon city economy, low-carbon urban transportation and low-carbon urban culture. The low-carbon urban forests include low-carbon urban forest construction and urban forest conservation. The low - carbon city life explores the code of conduct for low-carbon cities. The low-carbon urban transportation only considers the urban overrunning road. The low-carbon city culture focuses on the publicity and education of the concepts related to the low carbon and urban forests and forest cities. See *Figure 3* for the constituent elements of the low-carbon forest city construction.

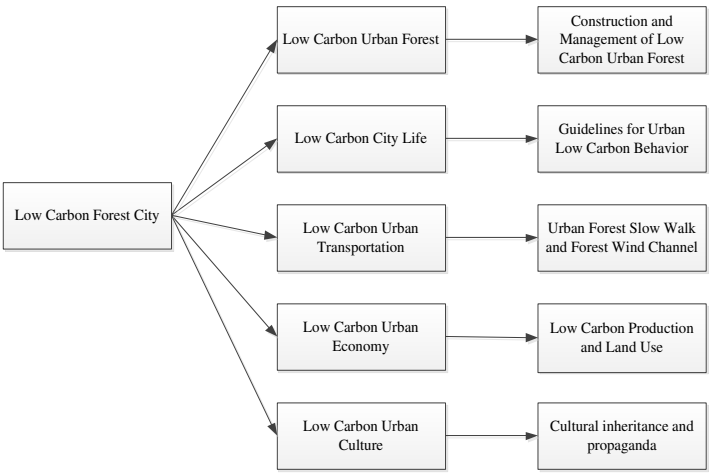

Figure 3. *Low-carbon forest city form the element –level analysis*

Feasibility method of forest city construction with low-carbon effect

In order to control the steady state of forest ecological carrying capacity, it is necessary to control the relationship among population scale, economic development and resource carrying capacity. *Figure 4* is a two-way optimization model of forest environmental carrying capacity and population scale. It can be seen that with the continuous improvement of the economic level, the population scale will correspondingly increase, and when the population scale increases to a certain amount, the economic level will show relatively rapid growth. Carbon emissions are proportional to population scale. People's production and living activities will result in greater carbon emissions. That is to say, the moderate population scale related to living standards will increase with the increase of carbon emissions and the improvement of economic level. Therefore, the development is on the rise or in the developed cities, the analysis of the population structure and industrial structure can show that the urban construction based on low-carbon effect is imminent and suitable for carbon emission evaluation so as to put forward the feasibility of the construction planning plan purposefully.

Based on the feasibility plan for urban forest construction, it is necessary to make clear the main contents of the low carbon for forest cities and deduce the design scheme that satisfies the evaluation method through function analysis. The main functions of the scheme are as follows: first, direct emission reduction; second, indirect emission

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94019410

reduction; third, increase in the ecological capacity. On the one hand, urban forest can directly reduce the carbon dioxide content by absorbing carbon dioxide, which is a direct effective way to realize low-carbon content of cities. On the other hand, the rational distribution of urban forest can completely change the pattern of urban land use, make the urban green land more reasonable, and reduce the concentration distribution of urban carbon emissions to a certain extent. Secondly, the vertical gas exchange is increased by the transpiration of the forests, so the heat island effect is alleviated, and the gas emission and accumulation of the greenhouse can be effectively reduced. Therefore, the direct low-carbon measures of low-carbon forest cities are to build urban forests vigorously. Its main function is shown in *Figure 5*.

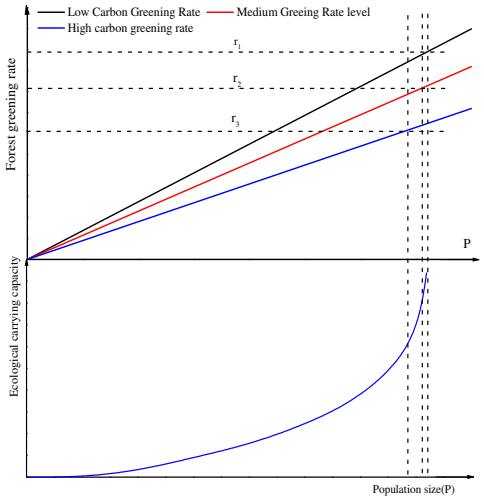

Figure 4. *Two-way optimization model of ecological equilibrium capacity and population size*

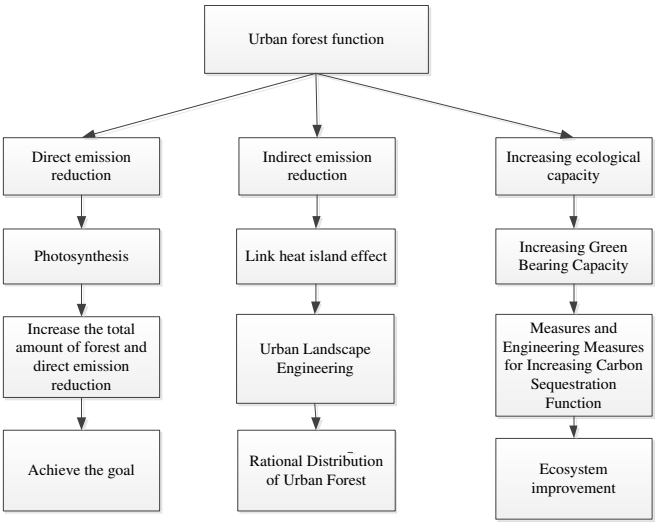

Figure 5. *Low-carbon effect analysis diagram of the urban forest*

Through the judgment of the evaluation indicators for the construction of forest cities with low-carbon effect and the understanding of the feasibility construction steps of the construction plan and their significance, the conceptual and leading guidance is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94019410

provided for the master planning, but the overall construction plan of forest cities is based on the statistical mathematics, probability mathematics, analysis and checking computations. Therefore, in order to have a clearer working step for the overall construction plan, it is necessary to clarify the thought of study on the accessibility of urban forest construction. By referring to *Figure 6* and through accessibility analysis, it is possible to identify the weak points of greening construction and the points to be strengthened, so as to carry out targeted and planned implementation of block division units for forest city construction.

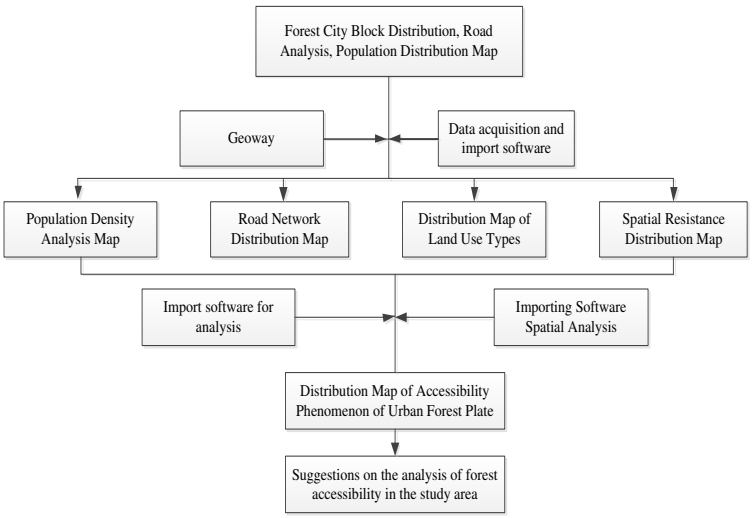

Figure 6. *The research route of achieving standards in forest cities*

Conclusions

Based on the principle of low-carbon effect, this study makes qualitative and quantitative analysis on the master planning and construction steps of forest cities, and thus provides the basis for sustainable and low-carbon forest city construction. The concrete conclusions are as follows:

(1) The driving factors of the change in the low-carbon environmental carrying capacity include natural factors and human factors, the growth of population and the construction of urbanization industry can promote the construction of forest cities to a certain extent, expanding the forest area and improving urban forest accessibility is the most direct and effective way to achieve the direct emission reduction and forest city target;

(2) This study introduces SWOT analysis and puts forward the evaluation indexes of forest const ruction covering 4 major categories and 12 small categories, providing data support for the hypothesis on the master planning;

(3) The construction of low-carbon forest cities has the sustainable development significance to the development of cities. The construction of low-carbon forest city in the future is the supporting construction project of industrialization development. The study provides the qualitative analysis index for the overall construction and planning of forest cities and also offers the basis and scheme for the basic research on the construction of forest cities.

(Received 3rd Apr 2019; accepted 17th May 2019)

Abstract. The global warming has triggered climate change, which has a certain impact on the redistribution of hydrology and water resources, and may even tilts the ecological balance. This paper sums up the trends of some climate and hydrological indices in several Chinese rivers, namely, temperature, precipitation and runoff, and examines how these indices vary with the time. Then, the wavelet analysis was introduced to disclose the hidden features of temperature, precipitation and runoff time series, revealing certain correlations between these series. As a result, the effect of temperature on precipitation was explored through correlation analysis, so was that of temperature and precipitation on runoff. Finally, the ecological water demands in the upstream, midstream and downstream of the target river were computed, and found to change in a similar way to temperature and precipitation. The research findings shed new light on the maintenance of hydrology and water resources in rivers and the handling of relevant problems.
Keywords: *temperature, precipitation, runoff, water resources, ecology, ecological balance*

Introduction

The rapid development of global economy and industry has pushed up the emission of carbon dioxide, inducing climate warming around the world (Bertuzzo and Mari, 2017; Quilty and Adamowski, 2018). The rising temperature melts ice in polar regions, elevates the sea level and triggers various environmental problems (Liu et al., 2018; Jódar et al., 2017; Rad et al., 2017). For example, the temperature variation may cause changes in water evaporation and precipitation, exerting certain impacts on terrestrial hydrology and water resources (Ademila and Saloko, 2018; Baker, 2017; Mcknight, 2017; Moungar et al., 2018; Na et al., 2017). The redistribution of water resources in turn increases the chance of floods and droughts, tilts the ecological balance, and even endangers the survival of humans and other living things on Earth (Seiller et al., 2017; Dile et al., 2018; Zhao et al., 2017).

To solve these problems, this paper analyzes how climate conditions affect hydrology and examines the necessary hydrological conditions for ecological balance. Much research has been done on the hydrological impacts of climate conditions at home and abroad. However, there is not yet a unified understanding about how the climate affects the hydrology (Hutton et al., 2017; Blöschl, 2017; Ouyang et al., 2017). On ecology and hydrology, the study of the ecological demand for hydrology and water resources started early, yielding fruitful results. In the beginning, the water resources needed for ecology were investigated with the goal of satisfying the water demand for living organisms in river areas. Later, some scholars held that simply fulfilling this demand cannot ensure the relative stability of the ecology; the water resources should

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94119423

be sufficient to maintain a certain degree of liquidity, i.e. the ability to purify itself (Mccurley and Jawitz, 2017). Most mature ecological and hydrological models are created in developed countries in Europe and North America. European countries have developed more such models than anywhere else. *Table 1* lists the applications of typical ecological and hydrological models since the 1980s.

Table 1. *Typical ecological and hydrological models*

Decade	Reference	Region	Application
1980s	Sharpley and Williams (1990)	North America	Evaluation of land and water management
1990s	Krysanova et al. (1998)	Europe	Hydrological simulation of vegetation growth
2000s	Ek et al. (2000)	Europe	Development of modules containing biotic and abiotic information for geological information system (GIS) and ecological protection/evaluation system
2000s	Arabi et al. (2007)	North America	Hyrological prediction of water quality
2010s	Acreman and Holden (2013)	Europe	Evaluation of climate impact on hydrology

As shown in *Table 1*, most of the existing studies consider ecological issue separately from the hydrological issue. There is no report on the relationship between the two issues. However, the relationship must be studied in order to disclose the effect of hydrological conditions on ecological balance.

To sum up, there are a series of problems to be solved, despite some research results on how climate affects hydrological conditions and how hydrology impacts ecology. Hence, this paper attempts to solve the problems concerning the relevant influence mechanisms, and shed new light on ecological protection in the context of global warming.

Materials and methods

Basic information

In this paper, Jinghe River in China is taken as the research object and denoted as river A. The mainstream was divided into three sections: the upstream (A1), the midstream (A2) and the downstream (A3). There are three water sources of river A, namely, Laohe River (B), Nanhe River (C) and Qinhe River (D). Among them, rivers B and C have richer water resources than river D. The position distribution of the hydrological station is shown in *Figure 1.* In *Table 2*, the research data were collected from six hydrological stations, which are respectively located on A1, A2, A3, B, C, D.

Table 2. *The basic information on the rivers*

River	Watershed area (km^2)	Annual mean runoff (100 million m^3)
A	52,977	55.61
B	30,251	23.64
C	19,321	19.76
D	10,231	7.98

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94119423

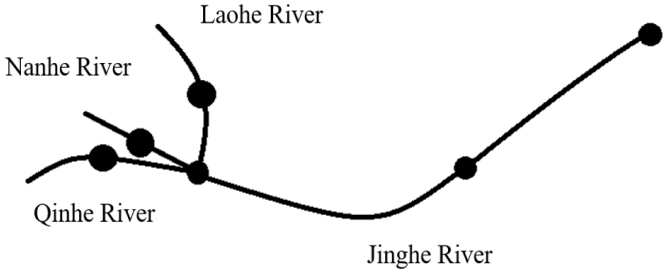

Figure 1. *Hydrological station location*

The statistical data in 2017 show that the watershed of Jinghe River generally enjoys abundant grassland and forestland resources. However, there are some sections with inadequate water resources, sparse vegetation and fragile ecology. The vegetation information in the upstream, midstream and downstream of Jinghe River (A1~A3) and in Laohe River, Nanhe River and Qinhe River (B~C) is provided in *Table 3*.

Table 3. *The vegetation information in the watersheds of the rivers*

Watershed		Forest land (Million acres)	Grassland (Million acres)	Total area (Million acres)
A	A1	899.3	115	1,014.3
	A2	497.8	500.9	998.7
	A3	100.9	232.9	332.8
B		1,000.6	1,098.3	2,098.9
C		438.6	760.1	1,198.7
D		329.7	547.2	876.9

Climate conditions

This paper mainly targets the meteorological data of the watershed of Jinghe River in the past 50 years (1969~2018).

Temperature

The annual mean temperature trend from 1969 to 2018 was plotted as *Figure 1*. The temperature trend can be linearly fitted by the *Equation 1:*

$$y = 0.03081x - 50.83708 \quad \text{(Eq.1)}$$

The coefficient of determination of the fitting formula reached 0.61097, an evidence of good linear fitting effect. As shown in *Figure 2,* the temperature increased with the elapse of time, which agrees with the trend of global warming in recent decades. The rising temperature in Jinghe River watershed manifests the global warming phenomenon. Of course, *Figure 2* also shows that the temperature growth was not always at the same rate in the fifty years. The rising speed was much faster in the latest 20~30 years.

The decadal temperature change in *Figure 3* reflects that the temperatures in 1989~1998 and 1999~2008 were much higher than those in 1969~1978 and 1979~1988,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94119423

and slightly higher than that in 2009~2018. In general, the temperature underwent an obvious increase, followed by a slight decline.

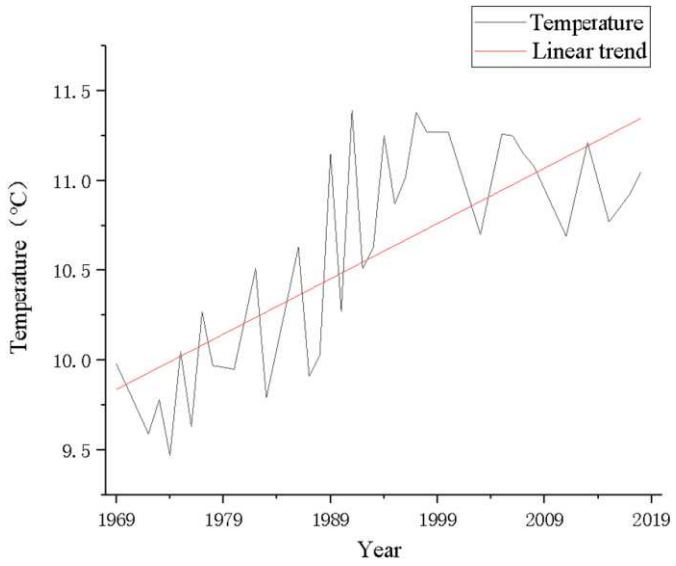

Figure 2. *Interannual temperature change*

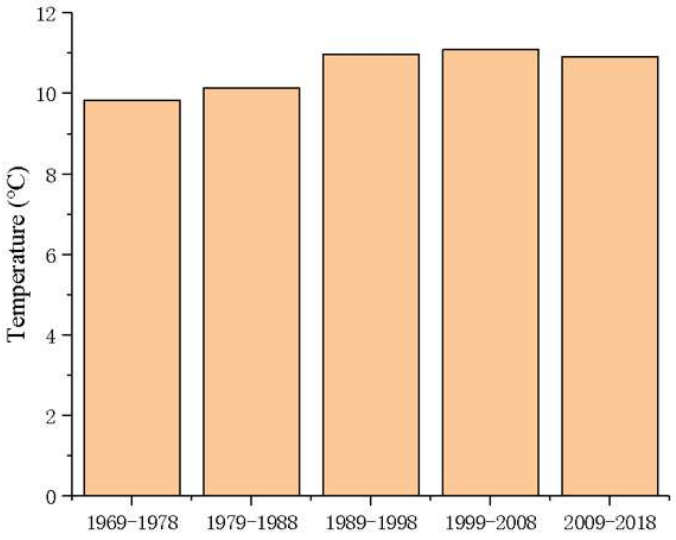

Figure 3. *Decadal temperature change*

Precipitation

The variation in the annual mean precipitation from 1969 to 2018 is illustrated in *Figure 4*. The precipitation trend can be linearly fitted by the *Equation 2:*

$$y = 0.94536x - 1798.87651 \quad \text{(Eq.2)}$$

The coefficient of determination of the fitting formula reached 0.61097, revealing a good linear fitting effect. As shown in *Figure 4*, the precipitation showed an obvious growth over time.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94119423

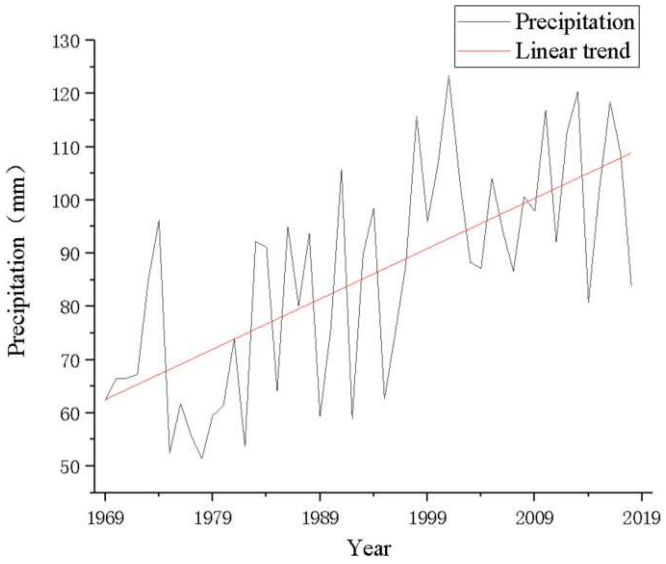

Figure 4. *Interannual precipitation change*

The decadal precipitation change in *Figure 5* shows that the precipitation continued to rise, but at a slower speed in 2009~2018.

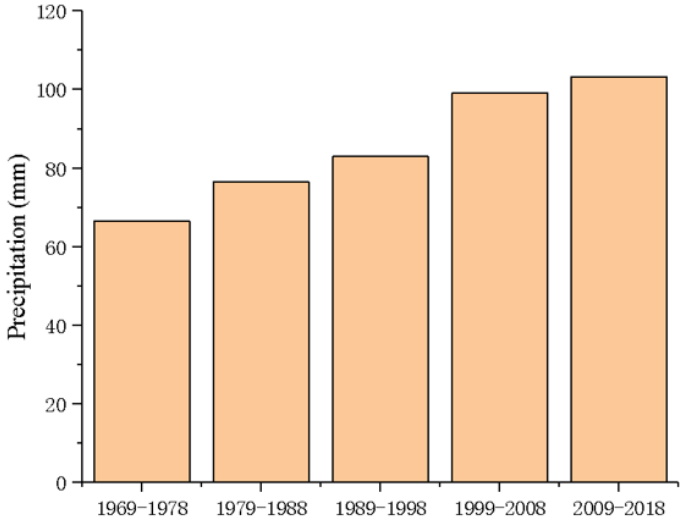

Figure 5. *Decadal precipitation change*

Runoff features

The redistribution of water resources is an important consequence of global warming. In this paper, the research data are collected from different hydrological stations, including the runoffs of rivers B, C and D and the three sections of Jinghe River.

The interannual runoff changes of rivers B, C and D were linearly fitted by the *Equations 3–5*.

$$y = 0.48481x - 929.22809 \quad \text{(Eq.3)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94119423

$$y = 0.51626x - 979.6944 \quad \text{(Eq.4)}$$

$$y = 0.32655x - 594.53929 \quad \text{(Eq.5)}$$

The coefficient of determinations of the above fitting formulas were respectively 0.32811, 0.11164 and 0.05515. The slopes of *Equations 3* and *4* were significantly different from 0, but the slope of *Equation 5* is not. As shown in *Figures 6–8,* the runoffs of rivers B, C and D exhibited a growing trend over time.

The interannual runoff changes of the upstream A1, midstream A2 and downstream A3 of Jinghe River were linearly fitted by the *Equations 6–8*.

$$y = -0.3567x + 770.62988 \quad \text{(Eq.6)}$$

$$y = -0.26977x + 580.15361 \quad \text{(Eq.7)}$$

$$y = -0.42499x + 873.68232 \quad \text{(Eq.8)}$$

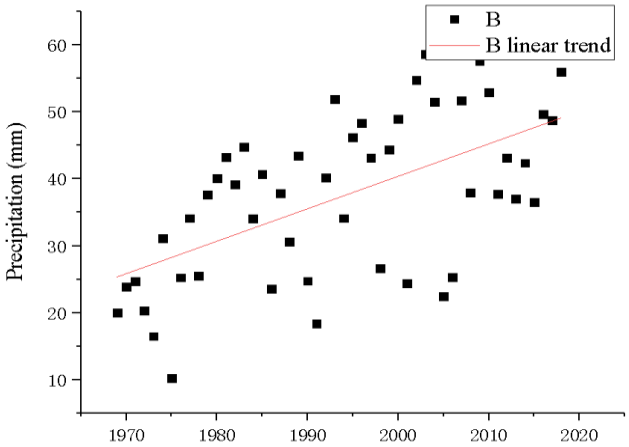

Figure 6. *Interannual runoff change in River B*

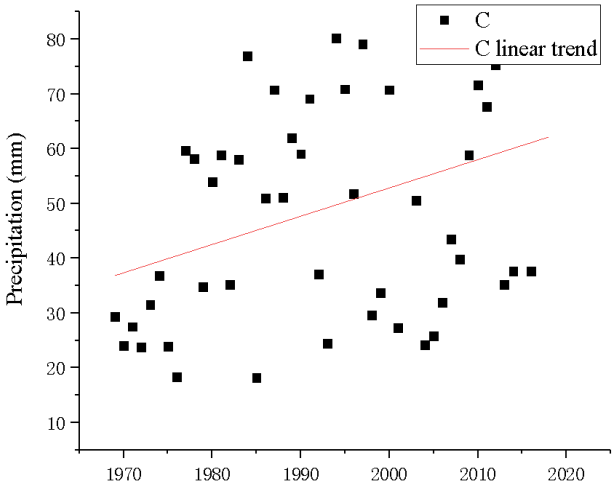

Figure 7. *Interannual runoff change in River C*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94119423

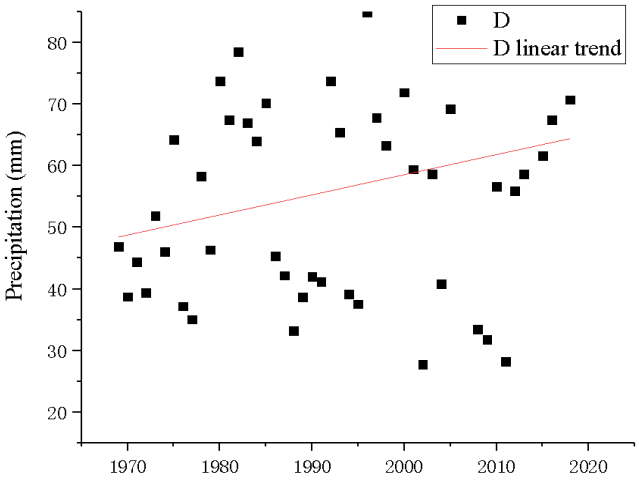

Figure 8. *Interannual runoff change in River D*

The coefficient of determinations of the above fitting formulas were, respectively, 0.08028, 0.05 and 0.13372. The slopes of *Equations 6* and *8* were significantly different from 0, but the slope of *Equation 7* is not. As shown in *Figures 9–11,* the runoff of river A showed a certain decline in the research period, indicating the possible overuse of the water resources in the river. The excess water consumption for industry and agriculture may increase the water evaporation, reduce the vegetation area, and thus tilt the ecological balance.

Analysis process

Figure 12 shows our analysis process. In this paper, two important indices of climate, temperature and precipitation, are subjected to feature analysis, and then investigated to disclose how each of them affects the runoff. The index features were examined through wavelet analysis, and the runoff impacts of each index were studied by correlation analysis.

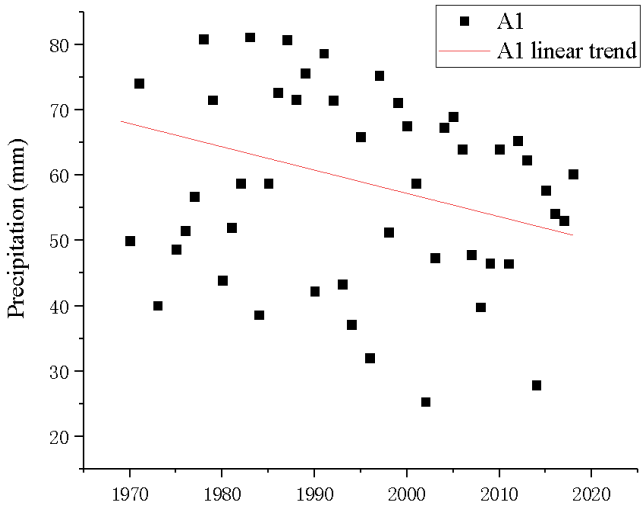

Figure 9. *Interannual runoff change in A1*

Results

Analysis of index features

Wavelet analysis is an approach for multi-resolution statistical analysis. Compared with the traditional time series analysis, this approach does well in mining out hidden information from the research data, and enjoys great value in reference and application. In this paper, wavelet analysis is adopted to explore the data periodicity, which cannot be achieved by traditional statistical methods. The results of our wavelet analysis are listed below.

(1) The temperature time series was periodic on multiple scales, especially on the scales of 15~30, 7~22 and 2~9. The periodicity was obvious through the research period on the first two scales, and only in part of the research period on the last scale. The most obvious periodicity was observed on 15~30.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94119423

(2) Similar to the temperature time series, the precipitation time series also exhibited periodicity on multiple scales, especially on the scales of 15~29, 6~21 and 2~7. The periodicity was obvious through the research period on the first two scales, and only in part of the research period on the last scale. The most obvious periodicity was observed on 15~29.

(3) On the runoff time series, the runoff of Laohe River had the same strong period performance with the regional temperature, the runoff of Nanhe River had the same strong period performance with the regional precipitation, and the runoff of Qinhe River had the same strong period performance with the regional precipitation; For Jinghe River, the upstream, midstream and downstream agreed with the regional temperature in the strong period performance.

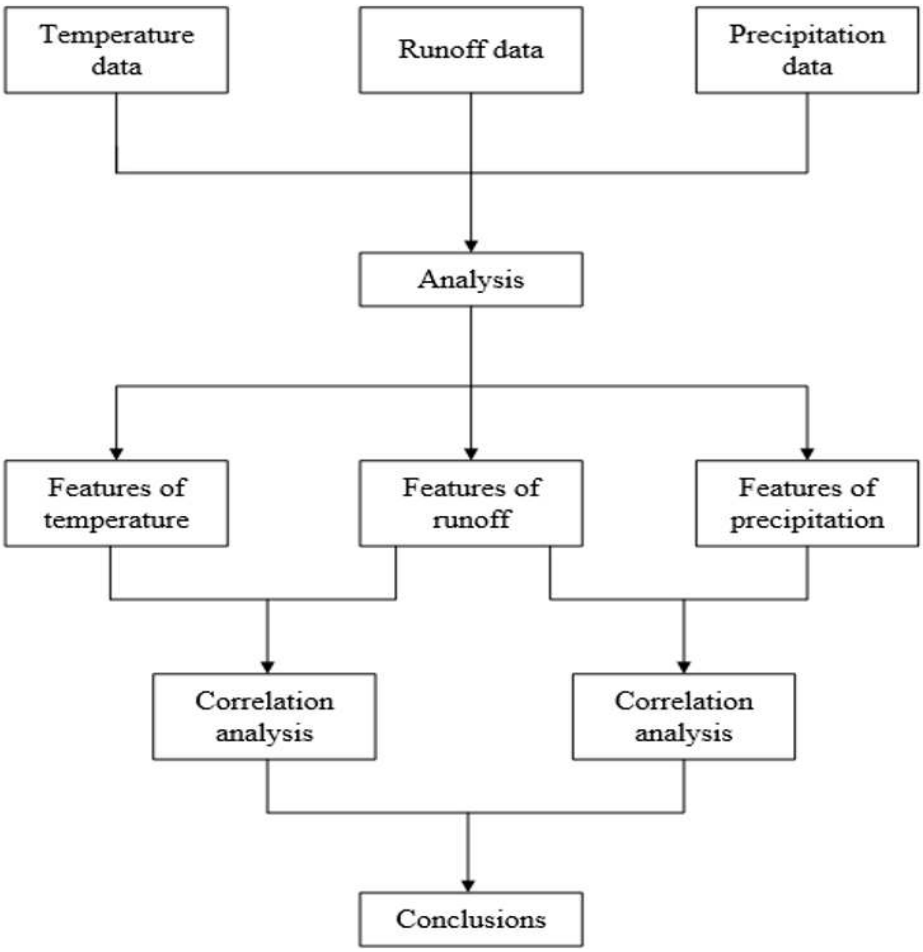

Figure 12. *Analysis process*

Correlation analysis

Through the analysis on index features, it is learned that the river runoffs were consistent with temperature and precipitation in strong period performance. In this subsection, the effects of temperature and precipitation are further discussed through correlation analysis. The results are shown in *Table 4*, where T is temperature, P is precipitation, and AR~DR are the runoffs of Jinghe River, Laohe River, Nanhe River and Qinhe River (A~D), respectively.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94119423

Table 4. *Results of correlation analysis*

	T	P	AR	BR	CR	DR
T	1**	0.560**	0.393**	0.402**	0.286**	0.285**
P	0.560**	1**	0.378**	0.322**	0.244**	0.284**

**The corresponding statistic is significant on the level of 0.01. The correlation analysis reveals significant correlations between temperature, precipitation and the runoffs of Jinghe River, Laohe River, Nanhe River and Qinhe River

Ecological water demand

To disclose the impacts of climate change on ecological balance, one of the keys is to check if the runoff satisfies the ecological water demand. The data on the area of different types of vegetation in Jinghe River watershed were incomplete. The only available data were recorded in 1975, 1995, 2000, 2010, 2014 and 2017. Therefore, the data on the area and density of different types of vegetation, as well as on the water demand for the normal growth of each plant, were extracted from these years, and used to compute the ecological water demands. The results are shown in *Figure 13*.

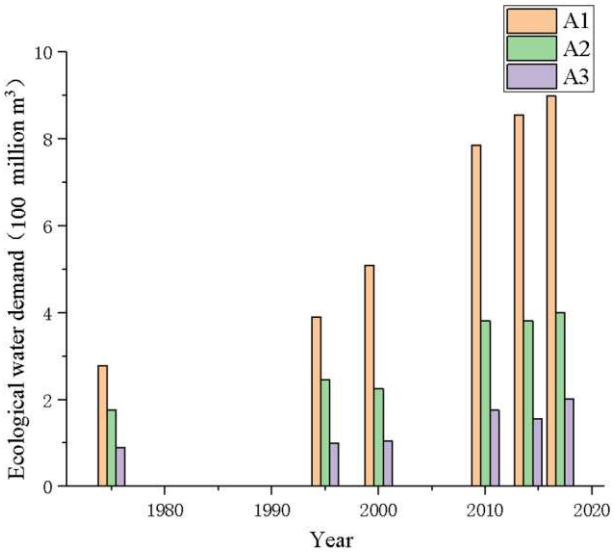

Figure 13. *Ecological water demand*

It can be seen from *Figure 13* that the ecological water demands in the upstream, midstream and downstream of Jinghe River were all on the rise. The trend is similar to that of temperature and precipitation.

Discussion

Our research shows that both the temperature and precipitation in Jinghe River basin were on the rise in the reesarch period, which is similar to most regions across the globe (Bertuzzo and Mari, 2017). One of the more striking features of Jinghe River basin is that: the precipitation increased slightly in 2009~2018, despite the lack of obvious growth in temperature. Considering the regional vegetation area, the phenonmenon can

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94119423

be attributed to the significant growth in vegetation coverage and the further increase in evaporation in the river basis during 2009~2018.

The wavelet analysis and correlation analysis agree that temperature, precipitation and climate conditions have certain correlations with river runoff, which echoes the conclusions of the previous studies (Na et al., 2017). As shown in *Table 4*, the temperature has a significant impact on precipitation and the two indices are positively correlated, that is, the precipitation increases with temperature. This relationship may be the result of the intense evaporation of surface water under high temperature. Meanwhile, the river runoffs are positively correlated with both temperature and precipitation, but the correlation coefficients are only 0.402 at the highest. This value is lower than that of the other studies (Bertuzzo and Mari, 2017). Hence, there must be other major water sources in the watersheds, such as glacial water and groundwater, that weakens the impact of climate indices on runoffs.

The analysis on ecological water demand indicates that the ecological water demands in the upstream, midstream and downstream of Jinghe River were all on the rise, exhibiting a similar trend to that of temperature and precipitation. This trend is consistent with the previous conclusions (Blöschl, 2017; Ouyang et al., 2017). The possible reasons are as follows. With the growth in temperature, more water is evaporated, leading to an increase in precipitation. In this situation, the vegetation area continues to expand. That is why the ecological water demand is on the rise.

Currently, the river runoff basically satisfies the ecological water demand, indicating that the ecological balance in the river shed has not been severely damaged. Of course, it should be aware that the growing vegetation coverage may reduce the amount of precipitation flowing into the river. Considering the recent runoff decline in river A (*Figs. 9–11*), more attention should be paid to prevent the overuse of water resources and the ensuing ecological damages.

Conclusions

(1) The trend analysis on climate indices shows that both temperature and precipitation in the research area showed an interannual growth, which echoes the trend of global warming. After analyzing the runoffs, it is noted that the upstream, midstream and downstream runoffs in Jinghe River showed a decline interannually, a signal for the possible waste of water resources in Jinghe River watershed. The waste threatens the ecological balance in the watershed.

(2) The wavelet analysis was performed to analyze the features of temperature, precipitation and runoff time series, revealing the consistency between the three indices in periodicity over time.

(3) After the correlation analysis of temperature, precipitation and runoffs, the author discovered the significant impact of temperature on precipitation, and the limited effects of temperature and precipitation on runoffs. The small correlation coefficients between runoffs and temperature/precipitation may be the result of the composition of runoff sources in the study area.

Abstract. This paper studies the thermal decomposition kinetics of potato powder under static air atmosphere using a DTG-60 differential thermal-thermogravimetric analyzer, with an aim of exploring the thermal stability of potato powder under high temperature. The authors conducted condition experiments on the samples, optimized various parameters that affect thermal analysis and determined the appropriate test conditions. Then, the mechanism function that for the thermal decomposition kinetics study of potato powder was explored, and the powder's thermal decomposition kinetic parameters were calculated along with the kinetic equation using the Coats-Redfern method. The results show that the suitable test conditions for thermal decomposition of potato powder include a heating rate β of 15 °C/min and a sample mass of 2.695 mg. The temperature is 559.18 K (286.03 °C) when the decomposition starts at the initial stage of reaction; the activation energy value is E = 339.810 kJ/mol and the pre-exponential factor A = $e^{75.32}$. The kinetic equation is $\frac{d\alpha}{dt} = e^{75.32-\frac{339810}{8.314T}}(1-\alpha)$.

Introduction

Potato is one of the most common vegetables in our daily life. Not only does it have protein that is similar to animal protein (better than soy protein), but it also contains some macro and trace elements that are not found in some vegetables and fruits (Alonso et al., 2001; Zeng et al., 2015). Thanks to its rich nutrition, nice flavor and low price, potato has been very popular among the majority of families. In order to alleviate the current food shortage in China, research has been carried out actively in various places on potato as staple food (Bao et al., 2013; Kim et al., 2013), and a series of potato products have been developed, including potato cakes, noodles and buns (Chen, 2009; Zhang et al., 2013), which are very popular among consumers. Sichuan is a major potato producing province, with the total potato planting area ranking the fourth in China, and the total output ranking the first. In this province, Liangshan Prefecture is one of the main producing areas due to the great variety, excellent flavor and aftertaste of potatoes there (Huang et al., 2018). Liangshan Yi Autonomous Prefecture has now established standardized potato production bases, with four indicators - planting area, output, commodity volume and economic benefit ranking the first in the province, thus providing a good platform for potato research (Xie, 2014).

DOI: http://dx.doi.org/10.15666/aeer/1704_94259436

The differential thermal analysis method is a test method that consumes only a small amount of samples, requires only simple operations and produces images which are easy to understand and analyze (Ike, 2018; Stenseng et al., 2001). It has been widely applied in the chemical industry to explore a series of physical, chemical or physicochemical changes in the heating process of samples (Zhao, 2005), such as weight loss, crystal structure changes, oxidation and thermal decomposition, etc., which has further promoted the development of the chemical industry. In recent years, through continuous improvement and correction by many researchers, the differential thermal analysis method has been gradually applied to other fields, showing its advantages such as short test time, simple operation and accurate results (Liu et al., 2013). If a sample and a reference material are heated at the same time, when the sample exhibits physical, chemical or physicochemical changes, the thermal effect will also change, resulting in a certain temperature difference between the sample and the reference material. This method, which determines the correlation between the sample-reference temperature difference and the time or temperature under the programmed temperature, is what we call the differential thermal analysis method.

The thermal decomposition kinetics study of potato powder by the differential thermal analysis method can help manufacturers better understand the thermodynamic properties of potato powder so that they can better utilize it during processing to increase its added value, improve the economic benefits of potatoes and thus drive the prosperous development of the potato industry in Liangshan and make relevant industries more standardized and internationalized (Fan et al., 2015).

Materials and methods

Test materials

The fresh potatoes were acquired from a produce market in Anning Town, Xichang City, Liangshan Prefecture, Sichuan Province.

Instruments and conditions

DTG-60 differential thermal-thermogravimetric analyzer (*Fig. 1*), produced by Shimadzu. The atmosphere condition for the test was static air; the reference material was an empty ceramic crucible; and the temperature rise range was 25~600 °C.

Figure 1. *DTG-60 differential thermal-thermogravimetric analyzer*

Test methods

In this test, according to the differential thermal analysis method, the atmospheric condition was set to be static air in the program, then the test conditions were changed

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94259436

by changing the heating rate or sample mass. In this way, different differential thermal analysis maps were obtained. Then the DTA curves obtained were analyzed and compared to determine the optimal test conditions for the potato powder thermal analysis. Under the optimal test conditions, the sample potato powder was subjected to thermal analysis and an image obtained, and then the image was subjected to thermogravimetric and differential thermal analysis. After analysis, calculation and collation of data, the activation energy value E and the pre-exponential factor value A of the thermal decomposition reaction of potato powder were calculated using the Coats-Redfern integration method.

(1) Preparation of materials

The process flow is as follows:
Sampling→pre-treatment→pulping→filtering→drying→grinding→sieving (80 meshes)

The moisture content of the dried potato sample was controlled to 13.5% or less. The determination of the moisture content was carried out by reference to GB 5009.3-2016.

(2) Condition experiments

The compatibility and thermal stability of the energetic materials can be reflected directly by the characteristic quantities in the thermal analysis such as the heat change ΔH, the initial temperature T_0, the final temperature T_e, the peak temperature T_p and the weight loss M_l, etc. or the kinetic parameters further obtained from these quantities (Song and Wu, 2016). The heating rate β and the sample size m may both have some effects on these characteristic quantities, which adds a lot of uncertainty to the experiment. Therefore, it is necessary to analyze the DTA curve, including the peak time, shape and smoothness, so as to obtain the optimal thermal analysis conditions for potato powder. In this experiment, two groups of single-factor tests were designed, to measure the effects of different masses (6 different masses) and of different heating rates (4 different heating rates) on the DTA curve of potato powder.

(3) Determination of the kinetic equation

Obtain a complete and smooth thermogram of the peak through the single-factor test. Measure the weight loss rate under each temperature range through the thermogravimetric curve, and then select the appropriate mechanism function $G(\alpha)$. Based on the straight line relationship of $\ln\left[\frac{G(\alpha)}{T^2}\right]$ with $\frac{1}{T}$, find the linear regression equation of the curve with a good linearity (R^2 is the closest to 1), and then calculate the activation energy E and the pre-exponential factor A which are closest to the true values using the slope and intercept of the linear regression equation (Ghaly et al., 2005).

Results and discussion

Effects of different thermal analysis conditions on the thermal decomposition of potato powder

The results obtained by differential thermal analysis are usually affected by the physical and chemical properties of the material being tested, the precision of the instrument, the samples used and the test conditions, among which, the conditions for thermal analysis have significant effects on the obtained thermogram. In this

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94259436

experiment, two groups of single-factor tests were carried out in the static air atmosphere, aiming to explore the effects of different sample masses and heating rates on the peak of the thermogram.

(1) Effects of sample mass on the thermal decomposition process of potato powder

For some energetic materials, the mass of a sample has little or no effect on the characteristic quantities of thermal decomposition temperature, but for others, it does on certain characteristic quantities. To investigate the effect of sample mass on the thermal decomposition image of potato powder, 6 tests were performed, with the sample mass changing in a gradient manner, as shown in *Figure 2*.

It can be seen from *Figure 2* that there are two distinct endothermic peaks in the thermographic curves of potato powder with different masses. Under some heating rates, a small endothermic peak can be seen before the main reaction zone. The peaks generally show the same trend, indicative of the common thermal characteristics of potato powder. It is not hard to conclude that when the sample mass increases, the peak area will become larger and the error will increase due to the longer reaction time recorded by the instrument. It can be seen that when the mass of the test sample was 2.695 mg, the peak shown was better separated from those in the cases of other masses, and was sharp with a great intensity and a small area. Since DTG-60 is a highly sensitive instrument, if the sample size is too large, it will exceed the measuring range and contaminate the instrument. Therefore, the minimal sample mass that can be identified by DTG-60 should be used as long as it can ensure good separation effect, peak intensity and peak shape (Chen et al., 2001).

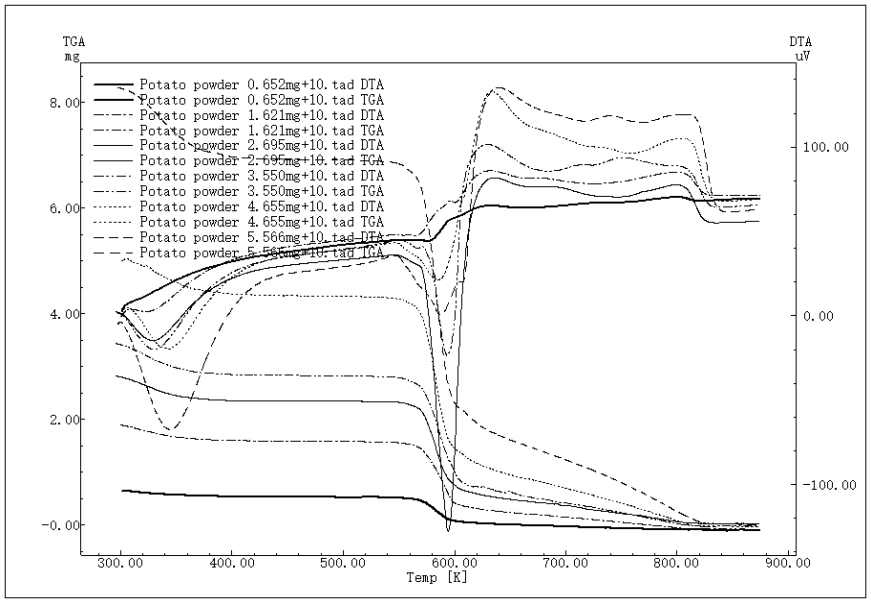

Figure 2. *Differential thermal-thermogravimetric curve of potato powder with different masses*

(2) Effects of temperature rise rate on the thermal decomposition process of potato powder

The effects of the heating rate β on the characteristic quantities of thermal analysis are not only reflected in the changes in the peak area, but also in the position of the peak

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94259436

temperature. So the adoption of different heating rates β can help understand and analyze the thermal behaviours of materials. This experiment designed four different heating rates β, namely 20 °C/min, 15 °C/min, 10 °C/min and 5 °C/min, respectively, so that the DTA curves of the potato powder under the four different heating rates were obtained as follows.

As can be seen from *Figure 3,* there is a large endothermic peak in all the thermographic curves of the potato powder, and all the peaks have basically the same characteristics. The differential thermal scan of each sample showed good reproducibility, indicative of the common thermal characteristics of potato powder. The faster the heating rate β is, the shorter the reaction time of the sample will be recorded by the instrument DTG-60, the sharper the peak will become and the greater the distance will be between the decomposition and equilibrium conditions of the sample particles (Chakraborty, 2015), thus resulting in a baseline drift and making the two adjacent peaks overlapping. This will reduce the resolution and make the instrument less sensitive. On the contrary, the slower the heating rate β is, the smaller the drift of the baseline will be, and the closer the system will get to the equilibrium conditions. In this way, the peak will be shallower and wider and can be better separated with the adjacent one, thus improving the resolution of the thermogram. However, it will take a longer time to determine the sample. In summary, the optimal heating rate obtained for this experiment is 15 °C/min.

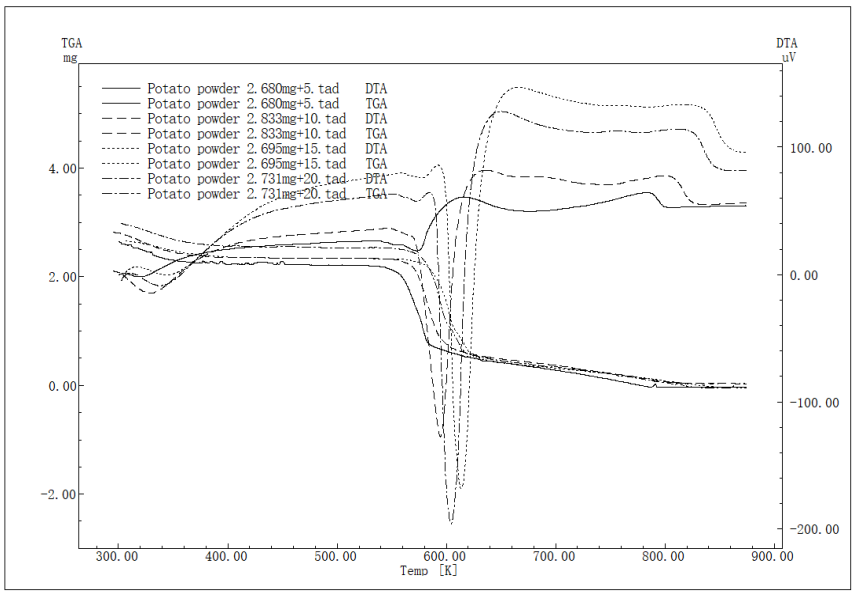

Figure 3. *Differential thermal-thermogravimetric curve of potato powder under different heating rates*

Through analysis the characteristic quantities in the thermogram, such as peak time, shape and smoothness, it can be concluded that the peak shape was the best when the sample mass was 2.695 mg and the heating rate 15 °C/min. The main peak was also sharp and smooth when the heating rate was 20 °C/min, but the instrument was less sensitive as the heating rate was fast (Xu et al., 2017). In summary, when the sample mass was 2.695 mg and the heating rate 15 °C/min, the thermogram will be easier and more effective for thermal analysis.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94259436

Analysis of the thermal decomposition process of potato powder

Through the above condition tests, it is found that the thermogram obtained was the best for thermal analysis when the sample mass was 2.695 mg and the heating rate 15 °C/min. This thermogram (*Fig. 4*) was then used in this research to investigate the thermal decomposition process of potato powder, calculate the kinetic parameters and determine the kinetic equation.

As can be seen from *Figure 4,* the thermal decomposition process of potato powder consists of four stages and produces a small amount of residual ash.

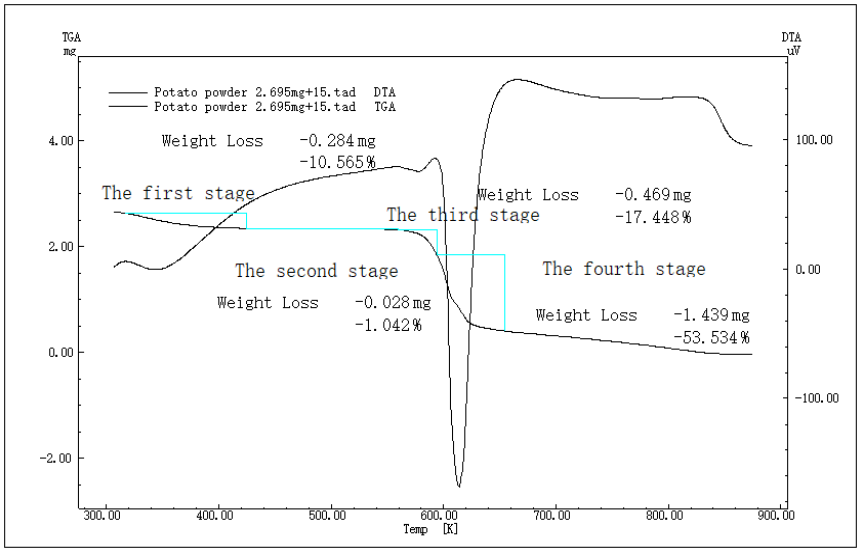

Figure 4. *Optimal thermal analysis map*

Stage 1 is 316.68~425.11 K (43.53~151.96 °C). It is generally considered that the part before 400 K (128.55 °C) is the water loss process, so Stage 1 is mainly the weight loss process (Wu et al., 2002).

Stage 2 is 425.11~559.18 K (151.96~286.03 °C). It is the transition stage of the thermal decomposition of potato powder, where the potato powder has stable properties, so it is the safe temperature range for food processing.

Stage 3 is 559.18~593.90 K (286.13~320.75 °C). Part of the small molecule substances begin to undergo the thermal decomposition reaction, so it is the initial stage of the whole reaction.

Stage 4 is 593.90~654.02 K (320.75~380.87 °C). It is the main reaction stage of thermal decomposition. It is generally believed that the test sample is internally restructured in this temperature range, producing mainly small molecule compounds and vaporizable macromolecules that exhibit significant weight losses. The relevant data are shown in *Table 1*.

Table 1. *Related data of potato powder during thermal decomposition*

Material	First weight loss		Second weight loss		Third weight loss		Residual ash /mg
	TG loss of weight /%	DTG peak temperature/K	TG loss of weight /%	DTG peak temperature /K	TG loss of weight /%	DTG peak temperature /K	
Potato powder	10.565	343.430	17.448	577.890	53.534	613.760	0.143

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94259436

Determination of the thermal decomposition kinetic mechanism function

The Coats-Redfern integration method has been widely used in thermal decomposition kinetics studies, as it can well reflect the mechanism of the thermal decomposition reaction. In the kinetic data processing, this paper also adopted this method to calculate the kinetic parameters and the kinetic equation for the thermal decomposition process of potato powder. The equation is derived as follows using the Coats-Redfern integration method (under non-isothermal conditions):

According to the mass equation, the reaction rate equation can be expressed as *Equation 1:*

$$\frac{d\alpha}{dT} = kf(\alpha) \quad \text{(Eq.1)}$$

where α is the conversion percentage, $\alpha = \frac{m_0 - m}{m_0 - m_f}$, also called the conversion rate; m is the sample mass, m_0 the initial reaction mass and m_f the final reaction mass; T is the temperature; k is the constant of reaction rate; f(α) is the differential form of the kinetic mechanism function.

The Arrhenius equation is *Equation 2:*

$$K = A\exp(-\frac{E}{RT}) \quad \text{(Eq.2)}$$

where A is the pre-exponential factor; E the activation energy, J/mol; R the molar gas constant, 8.314 J/ (K·mol); and T the thermodynamic temperature.

Substitute *Equation 2* into *Equation 1,* and we have *Equation 3:*

$$\frac{d\alpha}{dT} = \frac{A}{\beta}\exp\ (-\frac{E}{RT})f(\alpha) \quad \text{(Eq.3)}$$

where β is the heating rate.

Separate the variable, and we have *Equation 4:*

$$\frac{d\alpha}{f(\alpha)} = \frac{A}{\beta}exp(-\frac{E}{RT})dT \quad \text{(Eq.4)}$$

Integrate the two sides of the equation (*Eq. 5*):

$$\int_0^\alpha \frac{d\alpha}{f(\alpha)} = \int_0^T \frac{A}{\beta}Aexp(-\frac{E}{RT})dT \quad \text{(Eq.5)}$$

Rearrange the integral *Equation 5,* and we have the coast-Redfield integral equation (*Eq. 6*)*:*

$$\ln\left[\frac{G(\alpha)}{T^2}\right] = \ln\frac{AR}{\beta E} - \frac{E}{RT} \quad \text{(Eq.6)}$$

Plot a graph with $\ln\left[\frac{G(\alpha)}{T^2}\right]$ as the x-axis and $\frac{1}{T}$ as the y-axis, and we can obtain a straight line, with a slope of $-\frac{E}{R}$ (if the n value is correct), and an intercept of $\ln\frac{AR}{\beta E}$. And then the E and A values can be calculated through the equation.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94259436

In order to calculate the activation energy E and the pre-exponential factor A of the potato powder more accurately, the experimental data of four mechanism functions commonly used for the calculation of starch activation energy were listed below and compared to find out the linear regression equation with the best linear fit (*Eqs. 7–10*):

$$-\ln(1-\alpha) = G(\alpha) \quad \text{(Eq.7)}$$

$$[-\ln(1-\alpha)]^{\frac{2}{3}} = G(\alpha) \quad \text{(Eq.8)}$$

$$[-\ln(1-\alpha)]^{\frac{1}{2}} = G(\alpha) \quad \text{(Eq.9)}$$

$$[-\ln(1-\alpha)]^{\frac{1}{3}} = G(\alpha) \quad \text{(Eq.10)}$$

(1) Kinetic analysis on the major stages of thermal decomposition of potato powder

The main stage of the thermal decomposition of potato powder is the main reaction stage as most of the changes in the material occur in this temperature range. Relevant kinetic data in the main stage of the thermal decomposition are listed in *Table 2* (Yue et al., 2012).

Draw the scatter plot of $\ln\left[\frac{G(\alpha)}{T^2}\right]$ and $\frac{1}{T}$, as shown in *Figure 5.*

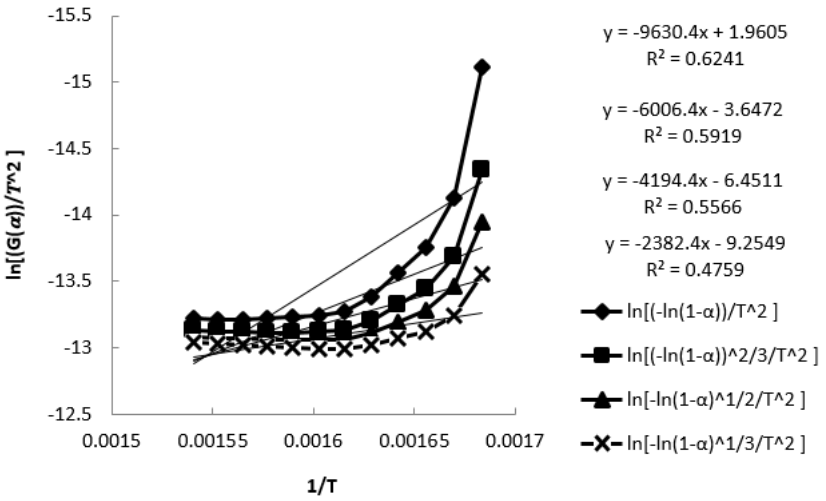

Figure 5. *Scatter plot of* $ln\left[\frac{G(\alpha)}{T^2}\right]$ *and* $\frac{1}{T}$ *in the main reaction stage*

From the above four mechanism functions and the scatter plot of $\frac{1}{T}$, it can be seen that the linear regression equation has a low linear fit, so the main reaction stage does not conform to the first-order kinetic equation, which requires further discussion.

(2) Kinetic analysis on the initial thermal decomposition stage of potato powder

The initial stage of the thermal decomposition of potato powder, where the internal small-molecule substances of the potato begin to undergo thermal decomposition, marks

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94259436

the change of potato powder properties. The kinetic data of the thermal decomposition of potato powder at the initial stage are listed in *Table 3*.

Draw the scatter plot of $\ln\left[\frac{G(\alpha)}{T^2}\right]$ and $\frac{1}{T}$, as shown in *Figure 6.*

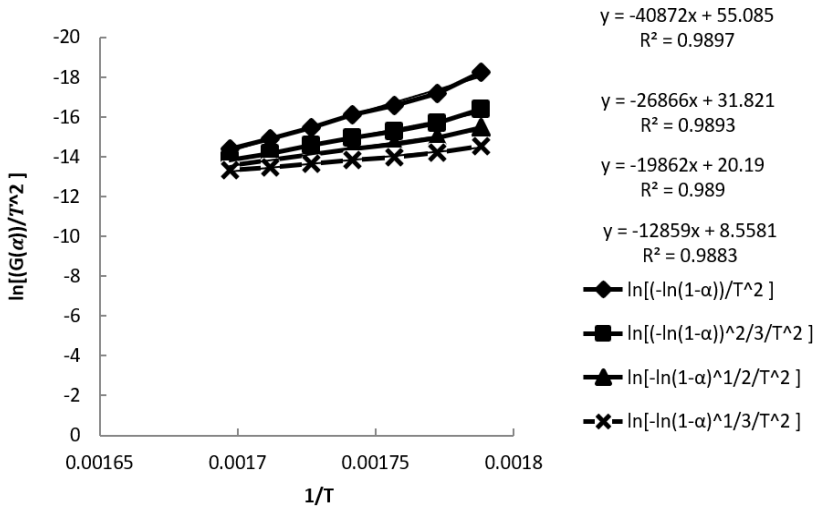

Figure 6. *Scatter plot of* $ln\left[\frac{G(\alpha)}{T^2}\right]$ *and* $\frac{1}{T}$ *in the initial reaction stage*

From the above four mechanism functions and the scatter plot of $\frac{1}{T}$, it can be seen that, when $G(\alpha) = -\ln(1-\alpha)$, the correlation coefficient is 0.9897; when $G(\alpha) = [-\ln(1-\alpha)]^{\frac{2}{3}}$, it is 0.9893; when $G(\alpha) = [-\ln(1-\alpha)]^{\frac{1}{2}}$, it is 0.989; when $G(\alpha) = [-\ln(1-\alpha)]^{\frac{1}{3}}$, it is 0.9883. So the linear regression equations obtained based on the above four mechanism functions all have a good linear fit and conform to the first-order kinetic equation. And when $G(\alpha) = -\ln(1-\alpha)$, the linear fit is the best; in other words, if $G(\alpha) = -\ln(1-\alpha)$ is adopted, the activation energy value E and the pre-exponential factor value A calculated will be closer to the true values.

Determination of the thermal decomposition kinetic parameters and calculation of the kinetic equation

Since the main reaction stage does not conform to the first-order kinetic equation, the following section only analyzes the initial stage of the entire reaction.

Since the main reaction stage does not conform to the first-order kinetic equation, the following section only analyzes the initial stage of the entire reaction.

Through the linear relation analysis of $\ln\left[\frac{-\ln(1-\alpha)}{T^2}\right]$ and $\frac{1}{T}$, it can be seen that the linear regression equation is y = -40872x + 55.085. By the Coats-Redfern integral method, it can be found that the slope is $-40872 = -\frac{E}{R}$ and that the intercept $55.085 = \ln\frac{AR}{\beta E}$. From $-\frac{E}{R} = -40872$, it can be concluded that the activation energy E = 339.810 kJ/mol, and from $\ln\frac{AR}{\beta E} = 55.085$, the pre-exponential factor can be obtained, which is A = $e^{75.32}$.

From $G(\alpha) = -\ln(1-\alpha) = \int \frac{d\alpha}{f(\alpha)}$, it can be deduced that $f(\alpha) = 1-\alpha$, so the kinetic equation for potato powder is: $\frac{d\alpha}{dt} = e^{75.32-\frac{339810}{8.314T}}(1-\alpha)$.

Conclusions

(1) Under different sample masses and heating rates, the areas and time of the peaks in the thermograms of the potato powder are significantly different. Through condition tests, it is found that the optimal test conditions for the thermal decomposition of potato powder include a heating rate β of 15 °C/min and a sample mass of 2.695 mg.

(2) Through the analysis of the thermal decomposition process of potato powder, it can be concluded that the weight loss of potato powder occurred in the temperature range of 316.68~425.11 K (43.53~151.96 °C). When the temperature exceeded 559.18 K (286.03 °C), the potato powder started to experience thermal decomposition.

(3) Through the above analysis, it can be seen that, when $G(\alpha) = -\ln(1-\alpha)$, i.e. when the Coats-Redfern integral equation is $\ln\left[\frac{-\ln(1-\alpha)}{T^2}\right] = \ln\frac{AR}{\beta E} - \frac{E}{RT}$, the activation energy value E and the pre-exponential factor value A obtained are the closest to reality. Through the above calculations, it can be found that the thermal decomposition kinetic parameters of potato powder are as follows: the activation energy E = 339809.81 J/mol

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94259436

(339.81 KJ/mol) and the pre-exponential factor $A = e^{75.32}$, and that the thermal decomposition kinetic equation $\frac{d\alpha}{dt} = e^{75.32-\frac{339810}{8.314T}}(1-\alpha)$.

(4) In this paper, only differential thermal analysis method was used to study the pyrolysis kinetics of potato powder, but potato powder was also affected by many other factors in the processing process, so it can be further explored from the aspects of environmental humidity and PH of processing in the future.

Abstract. With the growing awareness of green logistics, the carbon emissions must be considered in the cold chain distribution (CCD). Whereas the traditional regional distribution mode cannot deliver multiple small batches to designated regions right on time, this paper establishes a mathematical model for the minimal distribution cost of fresh food based on the resource/information sharing between multiple distribution centers (multi-DC) and the soft time window constraint, aiming to satisfy the new demands on logistics distribution (e.g. high timeliness, low cost, greenness and resource/information sharing). The total cost refers to the sum of vehicle dispatch cost, transport cost, time penalty cost, cargo loss cost and carbon emissions cost. Next, the proposed model was solved by the hybrid algorithm of artificial fish-swarm algorithm (AFSA) and ACA (AFSA-ACA hybrid algorithm). The simulation examples show that the multi-DC CCD mode can effectively reduce the total distribution cost and carbon emission cost compared to the traditional regional CCD mode.
Keywords: *green logistic, low carbo distribution, semi-open cold chain distribution (CCD), artificial fish-swarm algorithm (AFSA), ant colony algorithm (ACA)*

Introduction

Facing the growing demand for fresh food, cold chain distribution (CCD) enterprises are constantly increasing the number of vehicles and distribution centers (DCs), aiming to deliver multiple small batches to designated regions right on time. The semi-open multi-DC joint CCD fully uses the existing vehicles and lowers the distribution cost. This distribution mode overcomes the defects of the traditional regional distribution mode, such as insufficient distribution capacity, the lack of resources, the inability to share information, and the regional limitation. Therefore, it is very important to explore the path optimization of semi-open multi-DC CCD.

In recent years, fruitful results have been achieved on CCD path optimization, which is a type of vehicle routing problem (VRP) (Dantzig and Ramser, 1959). For example, Lan et al. (2013) classified CCD modes, helped enterprises choose the suitable collaborative distribution model, and reduced the cost of enterprise distribution. For the minimal distribution cost, Wang et al. (2018) established and solved an optimization model for multi-temperature cold-storage CCD under stochastic demand.

Considering the limitation of the standard algorithms, some scholars have introduced improved algorithms or the time window constraint to explore the CCD path optimization. For instance, Wang and Luo (2017) optimized the CCD path with time window using the improved intelligent water drops algorithm. To coordinate the time

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94379453

window of consumer demand with the temperature control of fresh food, Wang et al. (2019) constructed an optimization model that minimizes the distribution cost and value loss of fresh food, and solved the model using a hybrid algorithm between the genetic algorithm (GA) and the tabu search (TS) (hybrid GA-TS). Liang et al. (2016) included the fuzzy time window into the CCD, set up a multi-objective optimization model for the minimal cost and maximum consumer satisfaction, and solved the model by the improved GA.

With the boom of third-party logistics, the traditional regional single-DC distribution mode can no longer fulfil the demand of distribution enterprises, and is being replaced by the open and semi-open multi-DC distribution modes. On open multi-DC distribution, Yang et al. (2016), Yu and Xie (2011) and Baldacci et al. (2013) all assumed that any vehicle must leave from a virtual DC to the actual DCs, before implementing the distribution tasks, and the trip between the virtual and actual DCs incurs no cost. Considering the diversity and mutual exclusion of products, the various types of vehicles and the matching between products and vehicles, Liu and Guo (2016) put forward the open-loop multi-DC path optimization problem with time window constraint, set up the corresponding mathematical model, and solved the model with hybrid GA and the adaptive GA, respectively. Ge et al. (2016) proposed the multi-DC distribution mechanism with open vehicle parking strategy, and created and solved a mathematical model for the minimal fuel consumption. Liu et al. (2010) employed the two-stage heuristic algorithm to solve the multi-yard distribution VRP under the constraint of vehicle load.

On semi-open multi-DC CCD, Fan et al. (2018) presented a semi-open multi-DC distribution mode, constructed a mathematical model for the minimum cost under time window constraint, and solved the fresh food CCD by the ant colony algorithm (ACA). Ho et al. (2007), Adelzadeh et al. (2014) and Liu (2013) respectively solved the multi-yard VRP under time window constraint with the hybrid GA, simulated annealing (SA) algorithm and the adaptive GA based on artificial bee colony (ABC) algorithm.

The carbon emissions should be considered in the path optimization of CCD (Chaabane et al., 2012), as required by the government's policies on carbon emissions reduction, the concept of green logistics development, and the coordination between CCD and ecological environment. Gac (1996) examined the relationship between CCD development and greenhouse effect, and put forward measures to curb the CCD impacts on greenhouse effect. Vanek and Sun (2008) investigated the relationship between the maintenance of food shelf life, energy consumption and environmental pollution, built a relevant energy consumption model, and proposed the strategy for selection of transport modes. James et al. (2010) studied how climate change and temperature rise influence food quality, and designed measures to improve the energy efficiency in each link of the CCD. Considering carbon emissions, Kang et al. (2019) and Fan et al. (2017) both constructed CCD path optimization models for the minimal total cost under time window constraint, and solved the simulation examples by the ACA improved by the 2-opt local search mechanism and the improved GA, respectively. Palmer (2007) established a path optimization model with time window, with the aim to optimize distance, time and carbon emissions, and verified the CO_2 emissions reduction effect of speed through the analysis on the variation in CO_2 emissions under different congestion conditions. Bao and Zhang (2018) introduced the carbon emissions into the path optimization model of semi-open multi-DC CCD, and solved the model by the improved GA.

DOI: http://dx.doi.org/10.15666/aeer/1704_94379453

The research results on CCD both bring economic benefits to enterprises and promote the greenness of the CCD. However, the existing studies on semi-open multi-DC CCD fail to fully consider the cost incurred in the distribution process, or the insufficiency of self-owned vehicles (some vehicles are rented from third parties). To overcome the defects of these studies, this paper designs a global network covering all consumers, assuming that the enterprise has multiple DCs and sufficient vehicles, and establishes a comprehensive semi-open multi-DC CCD model constrained by soft time window. The model attempts to minimize the sum of vehicle dispatch cost, transport cost, time penalty cost, cargo loss cost and carbon emissions cost. In addition, the proposed model was solved by the hybrid algorithm of artificial fish-swarm algorithm (AFSA) and ACA (AFSA-ACA hybrid algorithm). The simulation examples show that the multi-DC CCD mode is better than the traditional regional CCD mode.

Materials and methods

Problem description

This paper mainly studies the "many-to-many" semi-open multi-DC CCD mode. In this cross-regional network distribution mechanism, "many" DCs serve "many" consumers, and share with each other the consumer information, resources and vehicles. Considering carbon emissions, a semi-open multi-DC CCD path optimization model was established to deliver multiple small batches to designated regions. Below is a description of our research problem.

It is assumed that a distribution enterprise serves N consumers with M DCs and K vehicles. During the distribution, each DC should be open to all vehicles, and play the role of the final destination or stopover point. After completing the distribution task, a vehicle does not need to return to the original DC, but to any of the nearby DCs. The consumers only receive distribution services and do not allow the stopover of vehicles. The vehicles are sufficient to satisfy the distribution demand. However, the route, distance and stopover DCs vary with vehicles and trips, due to the limitations of the load, speed and distance of the vehicles. The distance between each DC and each consumer is known, so is the distance between consumers. This paper designs a penalty function based on time window, because late distribution will damage the quality of fresh food and cause dissatisfaction among consumers. The carbon emissions from the CCD are mainly from energy consumption and refrigeration.

Based on the above, this paper constructs a mathematical model to minimize the total cost, which covers vehicle dispatch cost, transport cost, time penalty cost, cargo loss cost and carbon emissions cost. Besides, the improved GA was designed to solve the model and optimize the delivery path. The optimal path can minimize the path length, increase vehicle utilization, lower carbon emissions and reduce the total cost of the distribution service. *Figure 1* illustrates the semi-open multi-DC CCD mode.

Model hypotheses

(1) The vehicles are of the same model and the same specifications. The maximum load, fuel consumption and refrigeration performance are known in advance.

(2) There are enough vehicles to satisfy the demand of all consumers.

(3) The order quantity completed by each vehicle should not surpass the maximum load.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94379453

(4) The demand of each consumer can only be fulfilled by one vehicle through one service.

(5) Each consumer sets out a time window on the delivery time, and will not accept the service before the earliest acceptable time or after the latest acceptable time.

(6) The position of each DC and each consumer is known in advance. Every DC boasts sufficient cargoes and the ability to serve the consumer demand.

(7) All vehicles must start from a DC. After completing the distribution task, a vehicle does not need to return to the original DC, but to any of the nearby DCs.

(8) Two drivers are arranged for each vehicle, so that they can take turns to rest. The labor cost and vehicle operation cost are both included in the dispatch cost.

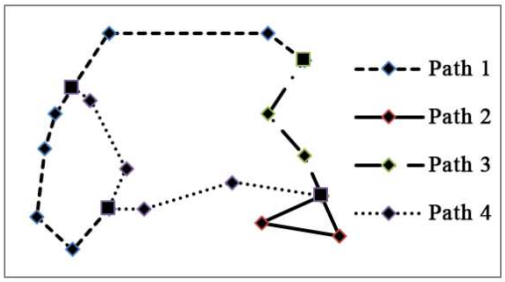

Figure 1. *Sketch map of the semi-open multi-DC CCD mode*

Model construction

Symbols

M: The set of DCs, $M\{m|m = 1,2,\ldots|M|\}$;

N: The set of consumers, $N\{n|n = 1,2,\ldots|N|\}$;

K: The set of vehicles, $K\{k|k = 1,2,\ldots|K|\}$;

K_{n1}: The set of consumers served by vehicle k on the l-th distribution trip, $N_{k1} \in N, 0 \le 1 \le num$, $num = |N|$, where num is the number of elements in N;

Q: The maximum load of each vehicle;

q_j: The demand of consumer j, $q_j>0$;

d_{ij}: The distance between consumer i and consumer j;

i and j: The serial number of nodes, $\forall i, j \in M \cup N$;

X_{ij}^k: The vehicle movement variable; if vehicle k moves from consumer i to consumer j, then $X_{ij}^k = 1$, otherwise, $X_{ij}^k = 0$;

S_k: The time that vehicle k leaves from DC for the last trip;

v: The vehicle speed;

C_1: The dispatch cost per trip of a vehicle;

C_2: The transport cost per unit distance of a vehicle;

C_3: The unit time penalty cost for early arrival or late delivery of a vehicle;

C_4: The cargo loss cost of a vehicle;

P: The unit value of fresh food;

θ_1: The proportion of cargo loss en route;

θ_2: The proportion of cargo loss in loading/unloading;

T_j^k: The time vehicle k arrives at consumer j;

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94379453

t_i: The time vehicle k serves at consumer i;
C_0: The unit carbon emissions cost.

Mathematical model

(1) Time penalty cost. To ensure the temperature and humidity of fresh food and satisfy the consumer's time requirement, the distributor must deliver the cargoes within the agreed time period. However, the cargoes may not be delivered within the agreed period for various reasons in actual distribution. Hence, the concept of soft time window emerged: the distributor can deliver the cargoes beyond the agreed time period but within the maximum tolerable period of the consumer, while bearing a certain time penalty cost (Dai and Liang, 2017). In this paper, a penalty function is designed according to the time window of the consumers. Specifically, no penalty cost will be incurred if the cargoes are delivered within the period $[E_j, L_j]$ agreed by consumer j and the distributor; the consumer will not accept any service beyond the period $[ET_j, LT_j]$, where ET_j and LT_j are respectively the earliest and latest delivery times the consumer can tolerate; a certain penalty cost will be incurred according to the arrival time of the vehicle if the cargoes are delivered between $[ET_j, E_j]$ and $[L_j, LT_j]$. The time windows of consumer j are described as *Figure 2*.

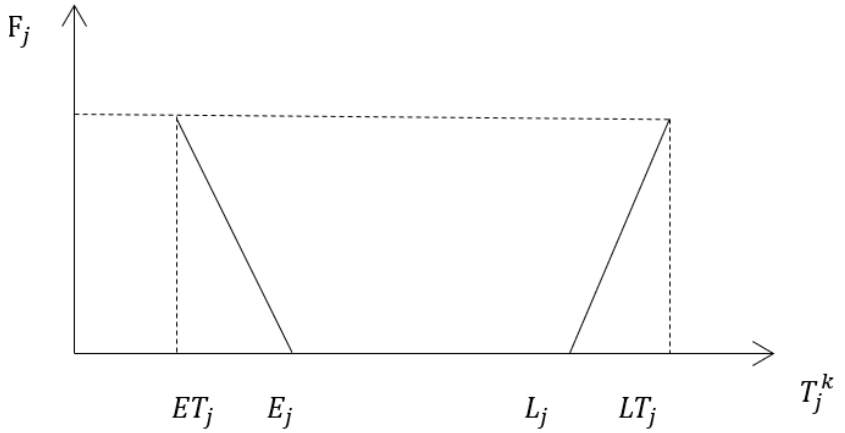

Figure 2. *Sketch map of the time windows of consumer j*

The time penalty cost can be expressed as *Equation 1:*

$$F_j\left(T_j^k\right) = \begin{cases} C_3\left(E_j - T_j^k\right), & ET_j \le T_j^k \le E_j \\ 0, & E_j \le T_j^k \le L_j \\ C_3\left(T_j^k - L_j\right), & L_j \le T_j^k \le LT_j \end{cases}; \quad \text{(Eq.1)}$$

(2) Cargo loss cost. The CCD of fresh food must meet the requirements on temperature and humidity. The fresh food may suffer from a certain loss during the long-distance transport and loading/unloading (Fan et al., 2017). Considering the effects of transport and loading/unloading on the quality and value of fresh food, this paper assumes that the temperature remains constant in the vehicle during distribution, and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94379453

excludes the impacts from other factors. In other words, the cargo loss of fresh food is assumed to be correlated with the distribution distance and the door opening in loading/unloading. Hence, the cargo loss cost was calculated based on the two issues. Let $P(\theta_1 d_{ij} + \theta_2 q_j)$ be the cargo loss cost incurred as vehicle j moves from consumer i to consumer j and completes the delivery to consumer j. Then, the total cargo loss cost through the distribution process can be calculated as *Equation 2:*

$$C_4 = P \sum_{i \in M \cup N} \sum_{j \in K \cup N} \sum_{k \in K} x_{ij}^k (\theta_1 d_{ij} + \theta_2 q_j) \quad \text{(Eq.2)}$$

(3) Carbon emissions cost. The CCD releases more CO_2 than the distribution of ordinary cargoes. The carbon emissions in the CCD mainly comes from fuel combustion, which depends on the transport distance is and the cargo load (Xiao et al., 2012; Duro, 2013). The fuel consumption per unit distance μ can be regarded as a linear function of the cargo load q: $\mu(q) = a(Q_0 + q) + b$ where Q_0 is the dead load of the vehicle, and a and b are linear function coefficients. When a vehicle is under fully load, the fuel consumption per unit distance $\mu^* = a(Q_0 + Q) + b$; when a vehicle is under zero load, the fuel consumption per unit distance $\mu_0 = aQ_0 + b$. To sum up, the fuel consumption can be expressed as: $\mu(q) = \mu_0 + \left(\frac{(\mu^* - \mu_0)}{Q} q \right)$. Let Q_{ij} be the load of vehicle k moving from consumer i to consumer j, and $\mu(Q_{ij})$ be the fuel consumption of vehicle k per unit of distance. Then, the carbon emissions cost can be expressed as $C(Q_{ij}) = C_0 d_{ij} e_0 \mu(Q_{ij})$.

Based on the above description and hypotheses, the path optimization model for the minimal total distribution cost can be established as *Equation 3:*

$$\begin{aligned} MinC = {} & C_1 \sum_{i \in M \bigcup N} \sum_{j \in M \cup N} \sum_{k \in K} x_{ij}^k + C_2 \sum_{i \in M \cup N} \sum_{j \in M \cup N} \sum_{k \cup K} x_{ij}^k d_{ij} \\ & + \sum_{j \in M \cup N} \sum_{k \cup K} F_j(T_j^k) + P \sum_{i \in M \cup N} \sum_{j \in M \cup N} \sum_{k \cup K} x_{ij}^k (\theta_1 d_{ij} + \theta_2 q_j) \\ & + C_0 e_0 \sum_{i \in M \cup N} \sum_{j \in M \cup N} \sum_{k \in K} d_{ij} \mu(Q_{ij}) x_{ij}^k \end{aligned} \quad \text{(Eq.3)}$$

s.t.

$$\sum_{j \in N} x_{ij}^k q_j \le Q, \forall i \in M \quad \text{(Eq.4)}$$

$$\sum_{i \in M \cup N} \sum_{k \in K} x_{ij}^k = 1, \forall j \in N \quad \text{(Eq.5)}$$

$$\sum_{j \in M \cup N} \sum_{k \in K} x_{ij}^k = 1, \forall i \in N \quad \text{(Eq.6)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94379453

$$\sum_{i \in M} \sum_{j \in M} x_{ij}^{k} = 0, \forall k \in K \quad \text{(Eq.7)}$$

$$\sum_{i \in M} \sum_{j \in N} x_{ij}^{k} = \sum_{i \in N} \sum_{j \in M} x_{ij}^{k}, \forall k \in K \quad \text{(Eq.8)}$$

$$\sum_{i \in N_{kl}} \sum_{j \in N_{kl}} x_{ij}^{k} \leq \left| N_{kl} \right| - 1, \forall k \in K, \forall N_{kl} \subseteq N, 0 \leq l \leq num \quad \text{(Eq.9)}$$

$$x_{ij}^{k} \left(T_{j}^{k} - T_{i}^{k} \right) \geq 0 \quad \text{(Eq.10)}$$

$$T_{j}^{k} = \sum_{i \in M \cup N} \left(T_{i}^{k} + \frac{d_{ij}}{v} + t_{i} \right) x_{ij}^{k}, k \in K, j \in M \cup N \quad \text{(Eq.11)}$$

$$x_{ij}^{k} = \{0,1\}, \forall i, j \in M \cup N, \forall k \in K \quad \text{(Eq.12)}$$

where *Equation 3* is the objective function about the minimal total cost of distribution, including the vehicle dispatch cost, transport cost, time penalty cost, cargo loss cost and carbon emissions cost; *Equations 4–12* are the constraints of the model, which respectively specifies the vehicle load cannot surpass the maximum load, that each consumer can only be served once, that a vehicle must leave the consumer after completing the task, that a vehicle cannot move from a DC directly to another DC, that a vehicle can return to any DC after completing the task, that the branch constraint is removed, that each vehicle must deliver cargoes in strict accordance with the sequence of consumers, that the time vehicle k arrives at customer j, and that $x_{ij}^{k} = 1$ if vehicle k moves from consumer i to consumer j ($x_{ij}^{k} = 0$ if otherwise).

Algorithm design

Assuming the existence of a virtual DC, this paper attempts to solve the semi-open multi-DC CCD path optimization problem as the AFSA-ACA hybrid algorithm. The hybrid algorithm was proposed by introducing the crowding factor of the AFSA to the ACA. This factor can adjust the pheromone concentration left by the ants on the search paths, and thus control the aggregation behavior of the ant colony, leading to the optimal solution. In this way, the AFSA-ACA hybrid algorithm manages to avoid the local optimal trap. The original ACA often falls into this trap due to the following reasons: In the ACA, the path selection of the ant colony is easily affected by the pheromone concentration. Thus, the suboptimal solution often appears in advance, and the pheromones continue to accumulate on the suboptimal paths.

ACA

The ACA was first proposed by the Italian scholar Dorigo and Gambardella (1997). For an ant k in path selection, the probability that the ant moves from node i to node j at time t can be calculated from the pheromone concentration and heuristic information on the path between the two nodes, as shown in *Equation 13:*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94379453

$$P_{ij}^{k}(t) = \begin{cases} [\tau_{ij}]^{\alpha}[\eta_{ij}]^{\beta} \Big/ \sum_{j \in J_k(i)} [\tau_{ij}]^{\alpha}[\eta_{ij}]^{\beta}, & j \in J_k(i); \\ 0, & otherwise \end{cases} \quad \text{(Eq.13)}$$

where: τ_{ij} is the residual pheromone concentration on the path between node i and node j; $\eta_{ij} = 1/d_{ij}$ is a heuristic function about the expectation of ant k to move from node i to node j (the smaller d_{ij}, the greater η_{ij} and the higher $P_{ij}^{k}(t)$; $J_k(i) = \{1,2,\ldots,n\} - tabu_k$ is the set of cities that ant k is allowed to choose from, with $tabu_k$ being the tabu list of ant k (the nodes that the ant has served); α is the relative importance of pheromone concentration; β is the importance of the heuristic function, i.e. the importance the ant attaches to the heuristic information.

After one cycle, the global pheromone of the distribution optimization plan involving all ants should be updated. Following the ant-cycle update strategy, the pheromone concentration on each path can be updated by *Equations 14–16:*

$$\tau_{ij}(t+n) = (1-\rho)\tau_{ij}(t) + \Delta\tau_{ij} \quad \text{(Eq.14)}$$

$$\Delta\tau_{ij} = \sum_{k=1}^{K} \Delta\tau_{ij}^{k} \quad \text{(Eq.15)}$$

$$\Delta\tau_{ij}^{k} = \begin{cases} \frac{Z}{L_k}, & if\ ant\ k\ passes\ through\ path\ e(i,j)\ in\ the\ current\ cycle; \\ 0, & if\ otherwise. \end{cases} \quad \text{(Eq.16)}$$

where ρ is the pheromone evaporation rate $0 < \rho \leq 1$;$1-\rho$ is the persistence coefficient of the pheromone); $\Delta\tau_{ij}^{k}$ is the pheromone increment on the path $e(i,j)$ in this iteration; $\Delta\tau_{ij}^{k}$ is the amount of pheromone released by ant k on the path $e(i,j)$ in this iteration; Z is a constant; L_k is the path length covered by ant k in this iteration; $e(i,j)$ is the path from node i to node j.

AFSA

Proposed by Li et al. (2002), the AFSA divides the behaviors of fish swarm into foraging, clustering, tailgating and random behaviors by mimicking the activites of actual fish. During foraging and tailgating, the fish swarm will cluster in the area rich in food, which is similar to the search for the optimal solution. To prevent premature convergence, the crowding factor δ is introduced to control the aggregation concentration of the fish swarm, thus avoiding the local optimal trap.

Let $\delta(t)$ be the crowding factor at time t, X_i be the current state of an artificial fish (AF) and Y_i be the food concentration. Then, the AF searches for the number n_f of its partners and the center position X_c of the current neighborhood. During clustering,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94379453

if $Y_c/n_f > \delta(t)Y_i$, then the fish swarm will move one step toward the center position of the partners; otherwise, the fish swarm will start foraging.

During tailgating, if $Y_j/n_f > \delta Y_i$, then the fish swarm will move one step toward the direction of the partner with the best state X_j in the search space; otherwise, the fish swarm will start foraging. Here, X_i, n_f and Y_j have the same meanings as above.

AFSA-ACA hybrid algorithm

In our AFSA-ACA hybrid algorithm, the crowding factor $\delta(N_c)$in the *Nc*-th iteration can be expressed as *Equation 17:*

$$\delta(N_c) = \gamma e^{-cn} \quad \text{(Eq.17)}$$

where γ is the closeness to the extreme value; c is the coefficient of variation.

Following the ant-cycle update rule, the crowding factor $\varepsilon_{ij}(N_c)$ of the phenomenon on the transfer target path in the *Nc*-th iteration acquired by the ACA can be expressed as *Equations 18:*

$$\varepsilon_{ij}(N_c) = 1 - \tau_{ij}(N_c) \Big/ \sum_{i \neq j} \tau_{ij} \quad \text{(Eq.18)}$$

In each iteration, our AFSA-ACA hybrid algorithm first uses the ACA and the roulette strategy to compute the transfer probability of ants between the consumers that satisfy all constraints conditions (e.g. time window and maximum load) and exist outside the tabu list, to select the next consumer to be served, and determine the transfer target path. Then, the AFSA is called to compute the pheromone crowdedness on that path, to see if the path is selectable. If $\varepsilon_{ij}(N_c) > \delta(N_c)$, the path will be selected; otherwise, the ant will stopover at a nearby actual DC, remove the vehicle information and finally return to the virtual DC. If the ant can go on with distribution, it should replenish the cargoes at the actual DC it visited before returning to the virtual DC. Assuming that no cost is incurred and no time is consumed in the replenishment, the actual DC will be added to the current solution. Then, the transfer probabilities will be recalculated and the consumer will be selected again.

The specific flow of the AFSA-ACA hybrid algorithm is illustrated in *Figure 3*.

Simulation and discussion

Calculation example

There is no universal set of examples for semi-open multi-DC CCD, for the distribution mode is subjected to multiple constraints. This paper carries out simulation using the data (Fan et al., 2018). The calculation example is shown in *Table 1*.

It is assumed that a fresh food logistics enterprise W owns one virtual DC and 4 actual DCs, and serves 48 main consumers. The enterprise operates sufficient refrigerated vehicles, which have the same specifications. The maximum load Q is 10 t, the mean speed is $60km/h$, the vehicle dispatch cost C_1 is RMB 600 yuan, and the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94379453

transport cost per unit of distance C_2 is RMB 10 yuan. The enterprise and each consumer agree to deliver the fresh food within the time window $[E_j, L_j]$, where E_j is between 6 and 9 and L_j is between 9 and 17. The earliest tolerable delivery time ET_j is 2 h before the E_j, and the latest tolerable delivery time LT_j is 2 h after the L_j. The time penalty cost C_3 is RMB 50 yuan/h if the fresh food is delivered earlier than E_j or later than L_j. The value of the fresh food is RMB 5,000 yuan/t. The proportion of cargo loss en route θ_1 is 0.1%, and that in loading/unloading θ_2 is 0.2%. The CO_2 emissions coefficient e_0 is 2.61 kg/L, and the unit cost of carbon emissions C_0 is RMB 0.1 yuan/kg. For a fully-loaded vehicle, the fuel consumption per unit distance μ_0 is 1 L/km; for a zero-loaded vehicle, the fuel consumption per unit distance μ^* is 2 L/km. The paths between different nodes are considered as straight lines. The distance between consumers and that between consumer and DC are computed by $d_{ij} = \sqrt{(x_i - x_j)^2 + (y_i - y_j)^2}$.

Distribution modes

Inspired by the decomposition method, the traditional distribution mode firstly sorts the 48 consumers through k-means clustering, and allocates them to 4 DCs. Then, the distribution plan was prepared to minimize the total distribution cost. In this plan, each DC is responsible for the distribution to the consumers in the specified region; each vehicle must return to the original DC after completing the tasks in the responsible region.

The proposed distribution mode considers the 48 consumers as a whole and makes uniform planning of the distribution plan. In this mode, each vehicle can stopover or replenish its cargoes after serving a batch of consumers, until completing all distribution tasks.

In this section, both distribution modes are solved by the AFSA-ACA hybrid algorithm. Through repeated simulations on the example, the basic parameters of the hybrid algorithm were set as: $N_{cmax} = 1000$, $Ant\_num = 50$, $\alpha = 1$, $\beta = 3$, and $\rho = 0.5$. The τ_{ij} was initialized as 1. The crowding factors were computed as $\gamma = 0.9$ and $c = 0.0002$. The simulations were run on Matlab2014b and the optimal paths of the two distribution modes were subjected to comparative analysis.

Figure 4 shows the optimal path of enterprise M obtained for the traditional mode. A total of 7 vehicles are needed to serve the 48 consumers, which were allocated to the 4 DCs by k-means clustering. The consumers and paths of each vehicle are listed in *Table 2*.

Figure 5 shows the optimal path of enterprise M obtained for the proposed mode. In this mode, the 48 consumers are viewed as a whole and the 4 DCs share resources with each other. After completing the tasks of the original DC, each vehicle can stopover or replenish its cargoes at a nearby DC; then, the vehicle can continue with distribution until completing all consumer orders in the whole network. A total of 5 vehicles are needed to serve all consumers in this mode. The consumers and paths of each vehicle are listed in *Table 3*.

Comparative analysis

Table 4 compares the optimal distribution plans of the two distribution modes. Under the traditional mode, the total travel distance was 1,393.45 km, and the total distribution cost was RMB 25,920.97 yuan, including RMB 577.36 yuan of carbon emissions cost. Under the proposed mode, the total travel distance was 1,337.27 km, and the total distribution cost was RMB 23,699.18 yuan, including RMB 501.73 yuan of carbon emissions cost.

As shown in *Figure 4*, the consumers in the traditional mode were served by region, and each vehicle must return to the original DC after completing the tasks in the responsible region. As shown in *Figure 5*, the proposed mode realized transregional distribution: after completing the current task, each vehicle can stopover or replenish its cargoes at a nearby DC; then, the vehicle can continue with distribution until completing all consumer orders in the whole network. Compared with the traditional mode, the proposed mode can distribute fresh food efficiently with a few vehicles, a

DOI: http://dx.doi.org/10.15666/aeer/1704_94379453

short distance and a low cost, and saves resources in the return trips of vehicles. Besides, the proposed mode can effectively reduce the carbon emissions cost, which is in line with the green development of the enterprise.

Table 4. *Distribution index comparison between the two distribution modes*

Distribution mode	Distribution distance	Total distribution cost	Dispatch cost	Transportation cost	Time penalty cost	Cost of goods damage	Cost of carbon emissions
District distribution	1393.45	25920.97	4200.0	13934.50	257.50	6951.61	577.36
Joint distribution	1337.27	23699.18	3000.0	13372.70	253.50	6571.25	501.73

Conclusions

Targeting the fresh food distribution, this paper puts forward a semi-open multi-DC CCD model based on multi-DC resource sharing and time window constraint. The proposed model was solved by the AFSA-ACA hybrid algorithm. The semi-open multi-DC distribution mode was proved to have smaller total travel distance and total cost than the traditional regional distribution mode, and, in particular, a much lower carbon emissions cost. The semi-open multi-DC distribution mode provides enterprises an important tool to save resources, realize multi-DC resource sharing, maximize economic and environmental benefits. The research findings lay a solid theoretical basis for the distribution of fresh food.

Although the content of this paper provides some reference value for fresh product distribution enterprises in planning low-carbon distribution routes, the model built in this paper is based on certain assumptions and constraints. So the research is still incomplete. This paper assumes that the same type of vehicle, the same temperature and uniform speed are constraints for distribution. Multi-type vehicle, multi-temperature joint distribution and the variable speed can be considered in the study of path optimization CCD with multi-DC considering carbon emissions in future researches.

(Received 3rd Apr 2019; accepted 17th May 2019)

Abstract. The protection of eco-environment is the basis of economic development. It is the interaction between eco-environment and economic development that promotes the development of human society. Therefore, it is important to obtain relevant data and select an appropriate evaluation method to find out how these two are interacting with each other. In this paper, a new data envelopment analysis (DEA) model based on generalized DEA method and the multi-level index synthesis method is proposed for the first time to evaluate the interaction efficiency between eco-environment and economic development in Chinese provinces. Through correlation analysis of the indices, a scientific index system is established. After index synthesis, the new order of efficient provinces is established, and the improvement information for inefficient provinces has also been obtained. In addition, more scientific suggestions are put forward for the protection of eco-environment and economic development in China.
Keywords: *multi-objective decision making, efficiency, generalized DEA, index synthesis, partial ordered relation*

Introduction

No economic activity of mankind can be carried out without using nature resources, such as land, trees, water and so on (Brown, 2000). A well-protected eco-environment can provide continuous, high-quality and large amounts of resources for the sustainable economic development (Gaspar et al., 2017); on the other hand, a poorly-protected eco-environment will affect the stability and speed of economic development. Therefore, protection of eco-environment is the foundation of economic development. At the same time, economic development plays a decisive role in the virtuous cycle of eco-environment. No doubt, the economic development can cause damages to the eco-environment, especially the high-consumption, high-pollution and low-output production modes, which result in soil erosion, serious desertification and water and air pollution. However, the rapid economic development can also provide financial support for the protection and improvement of eco-environment, so as to maintain its healthy development.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94559471

Many developed countries used to promote the rapid economic development at the expense of the environment (Mittler and Knirsch, 2007). China also had a similar experience. As a developing country, it has maintained its economic growth rate above 8%, and even achieved a growth of 14% from 2000 to 2012, as shown in *Figure 1*, but this has been at the cost of environment to varying degrees. The smog in Beijing, the desertification in Inner Mongolia and the floods in the South are all clear evidence.

At present, the Chinese government has realized the importance of eco-environment protection (Zhou, 2015). It no longer blindly pursues rapid economic growth, but pays more attention to the sustainable development of both the environment and the economy. As a result, the GDP growth rate in China began to decline from 2013 to 2017, and the magnitude was the highest among the top five economies of the world. From the perspective of GDP, GDP and per capita GDP have been rising steadily on the whole, as shown in *Figure 2*.

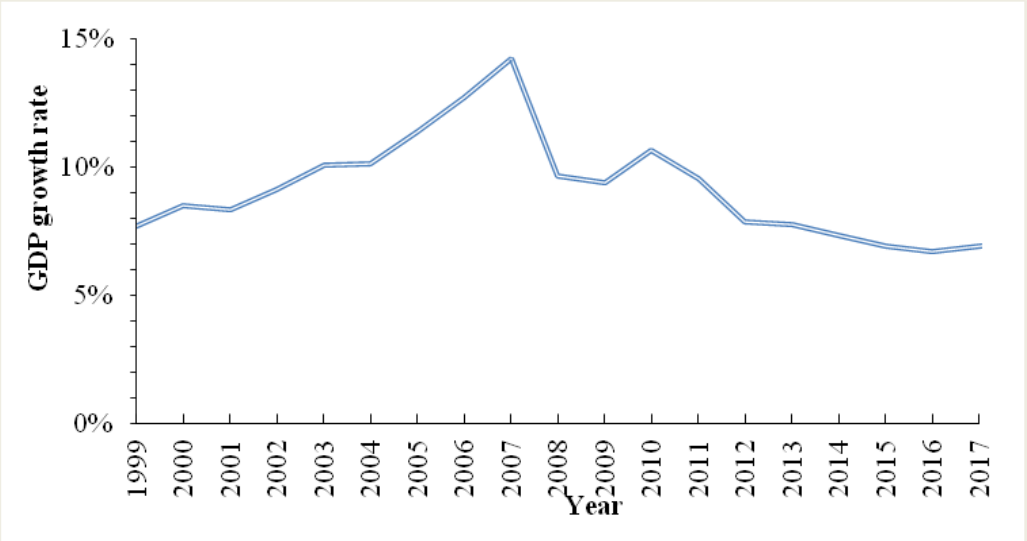

Figure 1. *GDP growth rate from 1999 to 2017 in China*

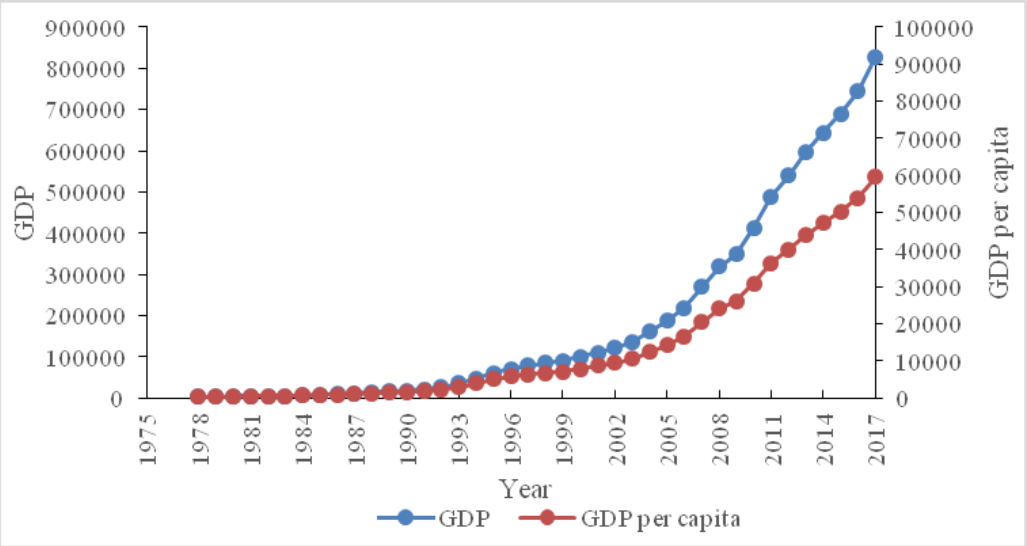

Figure 2. *GDP and GDP per capita from 1978 to 2017 in China*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94559471

We can see that the shares of the primary and secondary industries, i.e., agriculture and manufacturing, in the national economy continue to decrease, whereas that of the tertiary industry continues to expand, as shown in *Figure 3*. In 2017, for example, the services industry accounted for 52.2 percent of China's GDP, up by 0.3 percent, while agriculture accounted for 7.1 percent and manufacturing 40.7 percent in China. Although the share of the secondary industry has declined, it still accounts for 40.7%. Without strict protection of the eco-environment, it will cause great damages. Take Inner Mongolia for example, the share of the primary industry declined significantly, that of the secondary industry rose first and then declined, and that of the tertiary industry was relatively stable on the whole, but it rose after 2011, as shown in *Figure 4*. It can be said that the environment of Inner Mongolia was greatly affected by the industrial structure until after 2011.

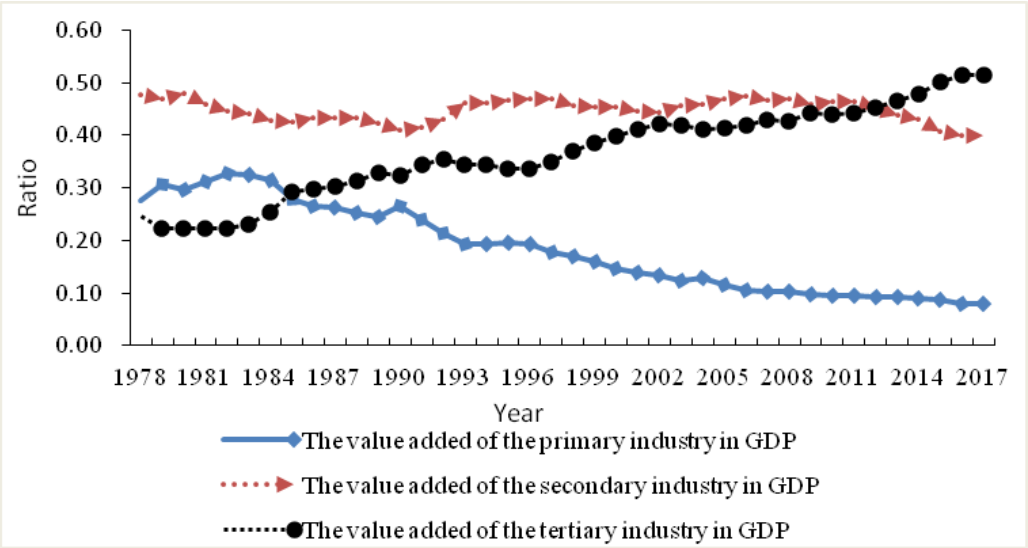

Figure 3. *Primary, secondary and tertiary industries in GDP from 1978 to 2017 in China*

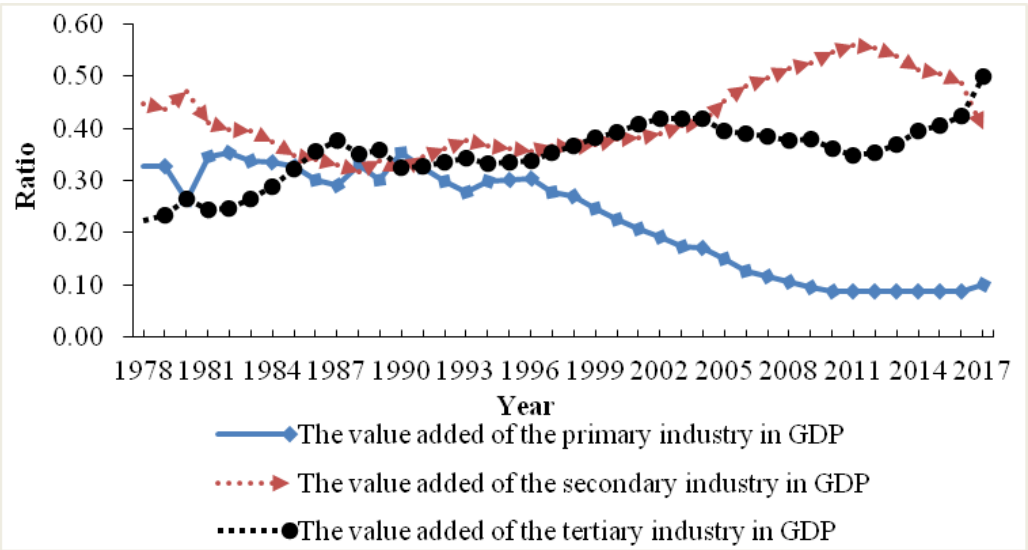

Figure 4. *Primary, secondary and tertiary industries in GDP from 1978 to 2017 in Inner Mongolia*

As discussed above, China has gone through the process of developing economy at the expense of environment. Although in recent years, China has made great achievements in eco-environmental protection and at the same time successfully accomplished the targets set in the 13th five-year plan (2016-2020), as reported at the Second Session of the 13th National People's Congress, there is still much work to do due to the seriousness of the previous damages.

The interaction between eco-environment and economic development promotes the development of human society (Diao et al., 2009). So finding out how these two are interacting with each other using relevant data and appropriate methods has become a hot research topic. Most of the existing studies discussed how to maximize economic development with the minimum eco-environment damage based on the input-output efficiency. This idea is consistent with the theory of the data envelopment analysis (DEA) method (Banker et al., 1984; Charnes et al., 1978; Färe and Frosskopf, 1985; Seiford and Thrall, 1990). So the DEA method has been widely used in the eco-environment and economic efficiency analysis in recent years. For example, Moutinho et al. (2017) analyzed the economic and environmental efficiency assessment in EU cross-country based on DEA and the quantile regression approach. Mavi et al. (2018) applied a two-stage network DEA method based on goal programming to analyze the joint effects of eco-environment and eco-innovation on the countries in the Organization for Economic Co-operation and Development (OECD). Halkos et al. (2018) estimated the efficiency of the power generation sector in the USA by using window DEA (W-DEA) to model the relationships between environmental efficiency and economic growth. Moutinho et al. (2018) analyzed the performances of a number of German and French cities using the DEA technique. Song et al. (2018) conducted DEA to evaluate the environmental efficiency of Chinese regions. It should be emphasized that there have been many studies on the efficiency evaluation of the eco-environment and economic development in China in recent years. These studies can be summarized as follows: (1) The traditional DEA model is directly used for evaluation, and for example, Jia and Liu used the input-oriented BCC-type DEA models to calculate energy and environment efficiency of 30 provinces in China (2012), and some papers discussed environment efficiency based on the DEA-SBM model (Chang et al., 2014; Ma et al., 2017; Yang et al., 2012); (2) the traditional DEA method is combined with other methods (Lee et al., 2013); and (3) the traditional DEA model is improved, and for example, Liu et al. (2018) brought forward an ideal point cross efficiency (IPCE) model to avoid the disadvantage of the 'self-evaluation' method and analyzed the carbon emissions efficiency of 10 typical urban agglomerations from 2008 to 2015 in China, and Wang and Wu (2014) proposed a new two-stage multiplier DEA approach to evaluate the environmental and economic performance of 30 provinces and municipalities in China.

Since the eco-environment system and economic system are complex systems, many indices in the eco-environment system are likely to affect economic development. How many indices are selected in the research will bring different efficiency evaluation results. At present, most of the studies use only a small number of indices to evaluate the eco-environment and economic development efficiency. But that does not mean the number of selected indices can be excessively large, because in that case, the majority of DMUs will be regarded as efficient when the DEA method is applied to the evaluation, which is useless to the decision makers.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94559471

DEA is particularly applicable to the analysis of complex systems such aseco-environment and economy systems. However, the DEA method also has some disadvantages that cannot be overcome because of the complexity of the systems. Firstly, the evaluation result may over-emphasize the role of secondary indices. Secondly, it often appears that most DMUs are efficient. Thirdly, it has high requirements on projection. Fourthly, it cannot determine how to improve the original indices after the synthetic of indices.

In order to solve the above problems, this paper applies the generalized DEA method and the multi-level index synthesis technique for the first time to evaluate the interaction efficiency between eco-environment and economic development. The generalized DEA proposed is based on sample evaluation (Ma et al., 2002, 2003, 2012, 2018). The evaluation reference set is not limited to the optimal criteria. For example, the admission line for college entrance examination reflects the average level, and the bottom line in wind risk analysis reflects the minimum evaluation criteria. Of course, sometimes the evaluation criteria may be specific units, such as selected templates, standards or certain objects. Such problems cannot be solved by the traditional DEA. The multi-level index synthesis technique can not only obtain the ranking of DMUs, but also solve the ranking problem that most DMUs are efficient, and obtain the improved information of the original index (Muren et al., 2013).

Materials and methods

Multi-level index synthesis method

Suppose that there are n DMU*s*. $x_{ij}^{(l)}$ denotes the value of the lth lower index of the ith input index of the jth DMU, $y_{rj}^{(t)}$ denotes the value of the tth lower index of the rth input index of the jth DMU, and $x_{ij}^{(l)}$ and $y_{rj}^{(t)}$ are both positive. Suppose there is another $\bar{n}$ sample DMUs as the reference sample for evaluation. $\bar{x}_{ij}^{(l)}$ denotes the value of the lth lower index of the ith input index of the jth sample DMU, $\bar{y}_{rj}^{(t)}$ denotes the value of the tth lower index of the rth input index of the jth sample DMU, and $\bar{x}_{ij}^{(l)}$ and $\bar{y}_{rj}^{(t)}$ are both positive. The input-oriented synthesis model based on generalized DEA is represented as follows when the pth DMU is evaluated, where $1 \le p \le n$.

$$
(IGDEA)\begin{cases}
\min \theta - \varepsilon(\sum_{i=1}^{m}\sum_{l=1}^{L_i} a_i^l s_i^{l-} + \sum_{r=1}^{s}\sum_{t=1}^{T_r} b_r^t s_r^{t+}) \\
\text{s.t.} \quad \sum_{j=1}^{\bar{n}} \bar{x}_{ij}^{(l)} \lambda_j + s_i^{l-} = \theta x_{ip}^{(l)}, \quad l = 1,2,\cdots,L_i, \quad i = 1,2,\cdots,m \\
\quad \sum_{j=1}^{\bar{n}} \bar{y}_{rj}^{(t)} \lambda_j - s_r^{t+} = y_{rp}^{(t)}, \quad t = 1,2,\cdots,T_r \ \ r = 1,2,\cdots,s \\
\quad \delta_1(\sum_{j=1}^{\bar{n}} \lambda_j - \delta_2(-1)^{\delta_3} \lambda_{\bar{n}+1}) = \delta_1 \\
\quad \sum_{l=1}^{L_i} a_i^l s_i^{l-} \ge 0, i = 1,2,\cdots,m, \\
\quad \sum_{t=1}^{T_r} b_r^t s_r^{t+} \ge 0, \quad r = 1,2,\cdots,s \\
\quad \lambda_j \ge 0, \quad j = 1,2,\cdots,\bar{n}+1
\end{cases}
\qquad \text{(Eq.1)}
$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94559471

where:

$\lambda = (\lambda_1, \lambda_2, \cdots, \lambda_n)$,

$S^- = (s_1^{1-}, \cdots, s_1^{L_1-}, \cdots, s_m^{1-}, \cdots, s_m^{L_m-})$ $S^{(l)-} = (s_1^{1-}, \cdots, s_1^{L_1-}, \cdots, s_m^{L_1-})$,

$S^+ = (s_1^{1+}, \cdots, s_1^{T_1+}, \cdots, s_S^{1+}, \cdots, s_s^{T_s+})$.

Definition 1 Assuming that $\theta^0, \lambda, \lambda_{n+1}^0, S^{-0}, S^{+0}$ is the optimal solution of model *Equation 1,* we can call DMU*p* is IG-DEA efficient if it meets one of the following conditions,

(1) $\theta^0 = 1, \sum_{l=1}^{L_i} a_i^l s_i^{l-0} = 0, i = 1, 2, \cdots, m,$ and $\sum_{t=1}^{T_r} b_r^t s_r^{t+0} = 0, r = 1, 2, \cdots s$;

(2) $\theta^0 > 1$;

(3) Model (1) has no feasible solution.

Definition 2 Assuming that $\theta^0, \lambda, \lambda_{n+1}^0, S^{-0}, S^{+0}$ is the optimal solution of model *Equation 1,* let $\hat{x}_{ip}^{(l)} = \theta^0 x_{ip}^{(l)} - s_i^{l-0}$, $\hat{y}_{rp}^{(t)} = y_{rp}^{(t)} + s_r^{t+0}, l = 1, 2, \cdots, L_i, i = 1, 2, \cdots, m, t = 1, 2, \cdots, T_r$, $r = 1, 2, \cdots, s$ and the projection of DMU*p* on the effective surface of the sample is expressed as $((\tilde{x}_{1p}^{(1)}, ..., \tilde{x}_{1p}^{(L_1)}, ..., \tilde{x}_{mp}^{(1)}, ..., \tilde{x}_{mp}^{(L_m)}), (\tilde{y}_{1p}^{(1)}, ..., \tilde{y}_{1p}^{(T_1)}, ..., \tilde{y}_{sp}^{(1)}, ..., \tilde{y}_{sp}^{(T_s)}))$.

However, in many practical evaluation problems, input is often constant. In this case, the DMU can only be improved by increasing the output. Therefore, the study on the output-oriented efficiency evaluation model is equally important. The output-oriented synthesis model based on generalized DEA is represented in model *Equation 2*.

$$(OGDEA)\begin{cases} \max \varphi + \varepsilon(\sum_{i=1}^{m}\sum_{l=1}^{L_i} a_i^l s_i^{l-} + \sum_{r=1}^{s}\sum_{t=1}^{T_r} b_r^t s_r^{t+}) \\ \text{s.t.} \quad \sum_{j=1}^{n} \bar{x}_{ij}^{(l)} \lambda_j + s_i^{l-} = x_{ij_0}^{(l)}, \quad l = 1, 2, \cdots, L_i, \quad i = 1, 2, \cdots, m \\ \sum_{j=1}^{n} \bar{y}_{rj}^{(t)} \lambda_j - s_r^{t+} = \varphi y_{rj_0}^{(t)}, \quad t = 1, 2, \cdots, T_r \ r = 1, 2, \cdots, s \\ \delta_1(\sum_{j=1}^{n} \lambda_j - \delta_2(-1)^{\delta_3} \lambda_{n+1}) = \delta_1 \\ \sum_{l=1}^{L_i} a_i^l s_i^{l-} \geq 0, i = 1, 2, \cdots, m \\ \sum_{t=1}^{T_r} b_r^t s_r^{t+} \geq 0, \quad r = 1, 2, \cdots, s \\ \lambda_j \geq 0, \quad j = 1, 2, \cdots, n+1 \end{cases} \quad \text{(Eq.2)}$$

Definition 3 Assuming that $\varphi^0, \lambda^0, \lambda_{n+1}^0, S^{-0}, S^{+0}$ is the optimal solution of model *Equation 2* and $\varphi^0 = 1$ $\sum_{l=1}^{L_i} a_i^l s_i^{l-0} = 0, i = 1, 2, \cdots, m,$ $\sum_{t=1}^{T_r} b_r^t s_r^{t+0} = 0,$ $r = 1, 2, \cdots, s,$ and DMU*p* is call OG-DEA efficient. The efficiency of DMU*p* is expressed as $\frac{1}{\varphi^0}$.

Definition4 Assuming that $\varphi^0, \lambda^0, \lambda_{n+1}^0, S^{-0}, S^{+0}$ is the optimal solution of model *Equation 2,* let $\hat{x}_{ij0}^{(l)} = x_{ij0}^{(l)} - s_i^{l-0}, \hat{y}_{rj0}^{(t)} = \varphi^0 y_{rj0}^{(t)} + s_r^{t+0}, l = 1, 2, \cdots, L_i, i = 1, 2, \cdots, m, t = 1, 2, \cdots, T_r, r = 1, 2, \cdots, s$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94559471

and the projection of DMU_{j0} on the effective surface of the sample is expressed as $((\tilde{x}_{1j_0}^{(1)},...,\tilde{x}_{1j_0}^{(L_1)},...,\tilde{x}_{mj_0}^{(1)},...,\tilde{x}_{mj_0}^{(L_m)}),(\tilde{y}_{1j_0}^{(1)},...,\tilde{y}_{1j_0}^{(T_1)},...,\tilde{y}_{sj_0}^{(1)},...,\tilde{y}_{sj_0}^{(T_s)}))$.

Selection of environmental and economic indices

There are many indices to evaluate the degree of eco-environment damages and the level of pollution. In the Statistical Yearbook of China, there are 21 sub-indices under the index of resource and environment, and there are further sub-indices under each sub-index. Taking the index of 'Collection, Transport and Disposal of Urban Consumption Wastes' for example, there are 16 sub-indices under it. The sub-indices under the resource and environment index are not only numerous, but also have complex relations among them, including certain degree of correlation.

Through review of relevant documents, it is found that the main pollutants in waste water and the main pollutants in waste gas are mainly selected by researchers in the evaluation on the environments of various provinces in China. In fact, for a country with a high urbanization level, municipal solid waste (MSW) has also become an important index to the environment. Therefore, this paper decides to adopt the above three environmental indices to evaluate the environmental status and analyze the impact on the economy of every province in China.

In order to reflect these environmental indices more accurately, this paper digs into the sub-indices of the above three indices. The results show that there are strong correlations between these indices. If all the sub-indices are selected as input indices, it will be difficult to distinguish the main differences in environmental status among the provinces by the DEA method because of the data correlation. Therefore, scientific selection and combination of these indices is an important prerequisite for better evaluation of environmental status.

For the 14 sub-indices under the index 'Discharge of Main Pollutants in Waste Water', this paper removes the indices with relatively small discharges and low correlation with the main index, and then selects the typical indices with high correlations. Finally, the sub-indices selected are 'Total Waste Water Discharged', 'Petroleum Discharge in Waste Water', and 'Plumbum Discharge in Waste Water'.

For the 3 sub-indices under the index 'Emission of Main Pollutants in Waste Gas', the correlation between them is between 0.7 and 0.8, and the difference between the data is not obvious, so three sub-indices are all selected, namely 'Sulphur Dioxide Emission in Waste Gas', 'Nitrogen Oxides Emission in Waste Gas' and 'Smoke and Dust Emission in Waste Gas'.

For the 11 sub-indices under the index 'Collection, Transport and Disposal of Urban Consumption Wastes', only two sub-indices are selected, namely 'Volume of Garbage Disposal' and 'Treatment Rate of Consumption Wastes', because there is no significant correlation between them, but strong correlation between the other indices and the index of 'Volume of Garbage Disposal'.

Many economic and social activities have had significant impacts on the eco-environment. Some of the most important economic indices are selected, which are 'Gross Regional Product', 'Local Government's Expenditure', 'Local Government's Revenue', and 'Income and Consumption Expenditure by Nationwide, Urban and Rural Households'.

For the 14 sub-indices under the index 'Regional Gross Product', the correlation between the 2 sub-indices 'Gross Regional Product' and 'Per Capita Gross Regional

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94559471

Product' is weak, but all other sub-indices have strong correlations with 'Gross Regional Product'. Therefore, only the two sub-indices 'Gross Regional Product' and 'Per Capita Gross Regional Product' are selected.

For the 22 sub-indices under the index 'Local Governments Revenue', since all sub-indices are counted in big numbers, some smaller sub-indices are eliminated. There are strong correlations between all the remaining sub-indices and the sub-index 'Local Governments General Budgetary Revenue', so the latter is selected. For the 21 indices under 'Local Governments Expenditure', only the 'Local Governments General Budgetary Expenditure' index is selected.

For the 6 sub-indices under the index 'Income and Consumption Expenditure by Nationwide, Urban and Rural Households (new caliber)', all have strong correlations with 'Per Capita Disposable Income Nationwide', so only the latter is selected.

Evaluation index system

Through the above-mentioned index selection, the following index system is established to evaluate the eco-environmental situation in the provinces of China, as shown in *Figure 5*.

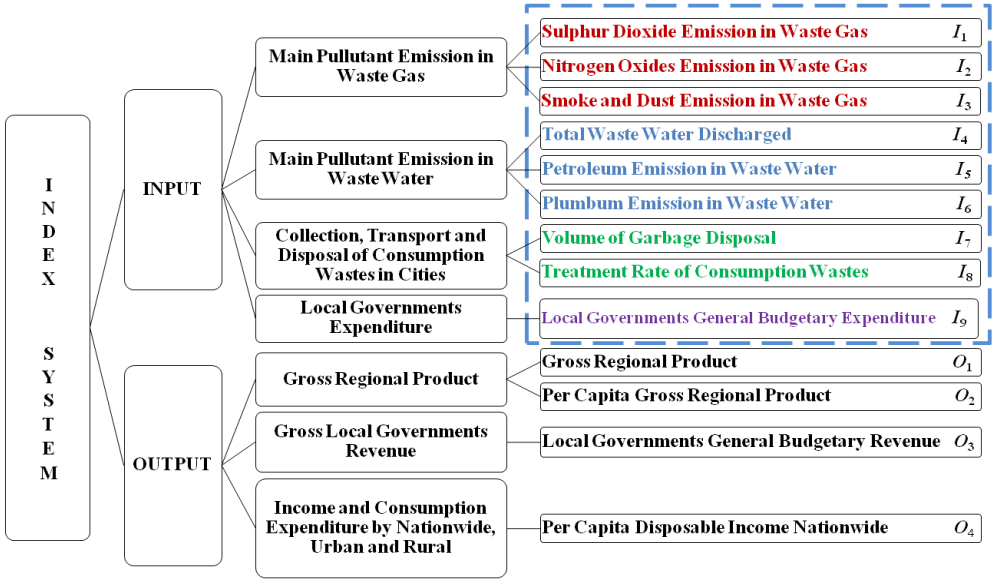

Figure 5. *Index system structure*

Results and discussion

Environment-economy interaction efficiency of Chinese provinces in 2017

There are some differences in the dimensions of data, which can easily lead to errors in the calculation results. Therefore, this paper puts all the input-output indices between 0.1 and 1 through the following normalization formulas.

$$x_{ij} = 0.1 + \frac{0.9(x_{ij} - \min\limits_{1\le j\le n} x_{ij})}{\max\limits_{1\le j\le n} x_{ij} - \min\limits_{1\le j\le n} x_{ij}} \quad i = 1,2,\cdots,9,\ j = 1,2,\cdots,31 \qquad \text{(Eq.3)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94559471

$$y_{kj} = 0.1 + \frac{0.9(y_{kj} - \min\limits_{1\le j\le n} y_{kj})}{\max\limits_{1\le j\le n} y_{kj} - \min\limits_{1\le j\le n} y_{kj}} \quad k = 1,2,3,4,\ j = 1,2,\cdots,31 \qquad \text{(Eq.4)}$$

After normalization, the efficiency values of 31 provinces in the CCR model and the BCC model are calculated using the software MATLAB. The results are shown in *Table 1*.

From *Table 1*, it can be seen that 16 provinces are efficient and 15 other provinces are inefficient in the BCC model before index synthesis. The order is as follows: Beijing, Fujian, Guangdong, Hainan, Heilongjiang, Jiangsu, Jilin, Ningxia, Qinghai, Shaanxi, Shandong, Shanghai, Tianjin, Tibet, Yunnan, Zhejiang > Liaoning > Chongqing > Henan > Guangxi > Shanxi > Hebei > Xinjiang > Hubei > Sichuan > Jiangxi > Inner Mongolia > Guizhou > Hunan > Anhui > Gansu. After index synthesis, the results obtained by the BCC model show that 13 provinces are efficient and 18 provinces are inefficient. The order of efficiency is as follows: Beijing, Fujian, Guangdong, Hainan, Heilongjiang, Jiangsu, Jilin, Ningxia, Qinghai, Shanghai, Tianjin, Tibet, Zhejiang > Shandong > Shanxi > Henan > Xinjiang > Chongqing > Hebei > Shaanxi > Guizhou > Hunan > Sichuan > Guangxi > Liaoning > Anhui > Inner Mongolia > Jiangxi > Gansu > Yunnan, in which a new order for Shaanxi, Shandong and Yunnan is obtained.

Table 1. *Results of eco-environmental evaluation in China in 2017*

Province	CCR		BCC		Province	CCR		BCC

Shanghai	1.0000	1.0000	1.0000	1.0000	Yunnan	0.9267	0.5541	1.0000	0.6608
Jiangsu	1.0000	1.0000	1.0000	1.0000	Tibet	0.8140	0.7021	1.0000	1.0000
Zhejiang	1.0000	1.0000	1.0000	1.0000	Shaanxi	1.0000	0.7067	1.0000	0.8414
Anhui	0.8533	0.6759	0.8557	0.7843	Gansu	0.7009	0.5639	0.8484	0.7233
Fujian	1.0000	0.9987	1.0000	1.0000	Qinghai	0.8117	0.8068	1.0000	1.0000
Jiangxi	0.8576	0.6769	0.8888	0.7328	Ningxia	0.9689	0.9689	1.0000	1.0000
Shandong	1.0000	0.9843	1.0000	0.9862	Xinjiang	0.6992	0.5700	0.9252	0.8706
Henan	0.9337	0.7948	0.9636	0.8903					

It is known from *Table 1* that the efficiency values of some provinces have changed significantly after index synthesis. Some of the efficient provinces have become inefficient, such as Shandong, whose efficiency drops to 0.9843 in the CCR model and 0.9862 in the BCC model in 2017, and Yunnan, whose efficiency drops to 0.6608 in the BCC model in 2017 and so on. In the BCC model, the number of efficient provinces decreases from 16 to 13 after index synthesis. To some extent, it shows that the environmental status of these provinces is below the desired level, and only by enlargement of their advantages, can they become efficient. In fact, the evaluation

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94559471

results after index synthesis are more reasonable, because they have considered the environmental indices of each province comprehensively.

The projection information of the DMUs on the production frontier will become the projection information of the composite indices after index synthesis. Thus, the improvement of the original input indices of each province and the results of the total improvement ranking are given in *Table 2* by using the relevant theories proposed in the section of Materials and Methods**.** The input-oriented projection improvement information of Chinese provinces in the BCC model under the assumption of variable returns to scale (VRS) is shown in *Table 2*.

From *Table 2*, the following conclusions can be drawn. First, the table shows how the all original indices are improved and the total improvement of each province. There are three provinces with total improvement being more than 75%, which are Hebei, Inner Mongolia and Liaoning. Second, there are three provinces which become inefficient after index synthesis, namely Shandong, Yunnan and Shaanxi. It can be seen that they still have shortcomings. For example, Shandong has a total improvement of 38.22%, with the sulphur dioxide emission, nitrogen oxides emission and smoke and dust emission in waste gas being more than 9% redundant. Other indices also have a small amount of redundancy. Finally, the calculation results in *Table 2* show that the model can not only identify high system efficiency, but also discover more inefficient information in systems and provide the improvement of all the indices.

Table 2. *Input-oriented projection improvement information of the provinces in the BCC model under the assumption of VRS*

Environment-economy interaction efficiency of Chinese provinces from 2013 to 2017

Due to the fluctuation and differences of economic development and environmental status in different provinces in different years, it is not enough to use only one year's

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94559471

data to evaluate the overall situation of each province. To this end, this paper uses the input-output data of Chinese provinces from 2013 to 2017.

Based on the average input and output data of Chinese provinces from 2013 to 2017, the sample DMUs of each province are provided. Then the environmental evaluation results of each province are proposed, as shown in *Table 3*.

From *Table 3*, the following conclusions can be drawn. First, there are 16 provinces are efficient and 15 other provinces are inefficient in the BCC model before index synthesis. The order is as follows: Beijing, Tianjin, Liaoning, Jilin, Heilongjiang, Shanghai, Jiangsu, Zhejiang, Fujian, Shandong, Guangdong, Hainan, Tibet, Gansu, Qinghai, Ningxia > Chongqing > Xinjiang > Hebei > Inner Mongolia > Guizhou > Shanxi > Hubei > Hunan > Henan > Jiangxi > Sichuan > Anhui > Yunnan > Guangxi > Shaanxi. Second, after index synthesis, it is not difficult to find that the efficiency values of some provinces have changed significantly. Some of these efficient provinces have become inefficient, such as Liaoning, whose efficiency drops to 0.8365 in the BCC model. The new order of these provinces is obtained as follows: Beijing, Tianjin, Jilin, Heilongjiang, Shanghai, Jiangsu, Zhejiang, Fujian, Shandong, Guangdong, Hainan, Tibet, Gansu, Qinghai, Ningxia > Hebei > Liaoning > Shanxi > Hunan > Xinjiang > Henan > Chongqing > Sichuan > Guangxi > Guizhou > Jiangxi > Inner Mongolia > Shaanxi > Anhui > Yunnan. From this, it can be seen that the most of the provinces with high efficiency are located in the east region, and the average efficiency of the east region is the highest. The average efficiency of the central region is similar to that of the western region, but the most of the provinces with low efficiency are located in the west region.

Table 3. *Results of environment-economy interaction efficiency in Chinese provinces from 2013 to 2017 based on the generalized DEA method*

Province	CCR		BCC		Province	CCR		BCC	
	Original index	Synthesized index	Original index	Synthesized index		Original index	Synthesized index	Original index	Synthesized index
Beijing	1.0000	1.0000	1.0000	1.0000	Hubei	0.8468	0.7731	0.9133	0.8722

Shanghai	1.0000	1.0000	1.0000	1.0000	Yunnan	0.7132	0.5673	0.8414	0.7277
Jiangsu	1.0000	1.0000	1.0000	1.0000	Tibet	0.7407	0.7106	1.0000	1.0000
Zhejiang	1.0000	1.0000	1.0000	1.0000	Shaanxi	0.8161	0.7058	0.8341	0.7843
Anhui	0.8208	0.6781	0.8414	0.7552	Gansu	0.7641	0.6791	1.0000	1.0000
Fujian	1.0000	1.0000	1.0000	1.0000	Qinghai	0.7981	0.7724	1.0000	1.0000
Jiangxi	0.8268	0.6903	0.8796	0.7877	Ningxia	1.0000	1.0000	1.0000	1.0000
Shandong	1.0000	1.0000	1.0000	1.0000	Xinjiang	0.7037	0.5896	0.9762	0.8273
Henan	0.8470	0.7608	0.8854	0.8212					

Then the results of the improved input indices of each province and the total improvement ranking from 2013 to 2017 in the input-oriented model are obtained using similar method to that for 2017. The relevant results are shown in *Table 4*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94559471

The projection improvement of the efficient provinces are all zero, so the relevant results of these provinces are not given in *Table 4*.

From the results of *Table 2* and *4*, it can be found that there is a certain difference between the results of the overall improvement in 2017 and from 2013 to 2017, which indicates that the pollution process in the eco-environment of each province was changing. Liaoning saw the biggest change, and Inner Mongolia and Hebei Province had the greatest difficulty in eco-environment management.

In order to more visually reflect the projection improvement difficulty coefficients of the comprehensive evaluation on the environment in different provinces, the relevant hotspot distribution map is drawn according to the size of the projection improvement quantity of the provinces in *Figure 6*. The darker the colour, the worse the comprehensive evaluation effect of the environment, and the higher the difficulty coefficient of projection improvement.

From *Figure 6*, it is easy to find that the provinces with the highest comprehensive efficiency of eco-environment from 2013 to 2017 based on the generalized DEA are located in the economically developed coastal areas, and that the most economically backward four regions also have high efficiency. The efficiency of environmental status management in northern and central provinces is relatively low, and the difficulty coefficients are relatively large. Inner Mongolia, Shanxi and Xinjiang take coal and other energy as the main driving force for development, while Hebei Province mainly relies on iron and steel for development. Their efficiency is poor and it may be difficult to complete rapid projection improvement within a short time.

Table 4. *Projection improvement information of Chinese provinces in CCR for the average input-output data from 2013 to 2017 based on the generalized input-oriented DEA method*

Province	I1	I2	I3	I4	I5	I6	I7	I8	I9	Total improvement

Figure 6. *Hotspot map of difficulty coefficient for projection improvement of environmental status in China from 2013 to 2017*

Improvement, projection and importance information before and after the synthesis of various indices

Although the improvement of eco-environmental inputs in each province from 2013 to 2017 is proposed above, it is unrealistic to make the improvement according to this model. Managers need more learning to complete the gradual improvement. Muren et al. (2013) provided a DEA method based on the partial ordered set theory, which can give the complex partial ordered relations among DMUs and provide information for DMUs, such as improvement, projection and importance.

The partial ordered relations among Chinese provinces are shown in *Figures 7* and *8*. It is easy to find that the original status which involves less partial ordered relations among provinces has turned into one with more partial ordered relation after index synthesis.

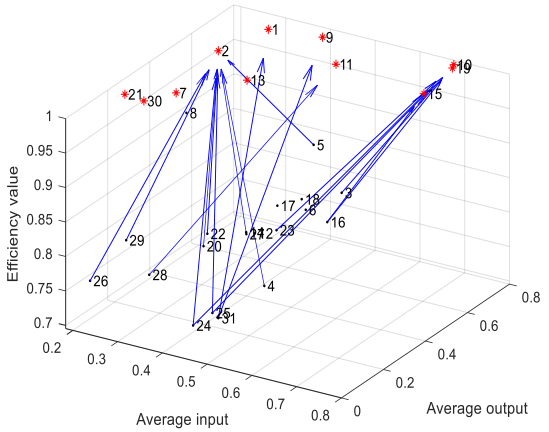

Figure 7. *Partial ordered relations among the provinces in the CCR model before index synthesis*

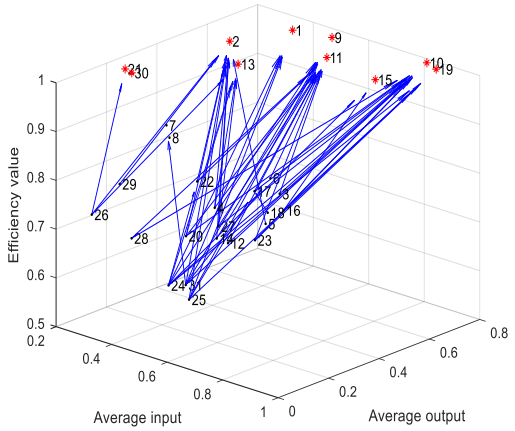

Figure 8. *Partial ordered relations among the provinces in the CCR model after index synthesis*

In *Table 5*, we proposed the ways of improvements and projections and the importance of learning for different provinces in the CCR model. The inefficient provinces can improve their input data according to the partial ordered relations between efficient provinces. For example, Inner Mongolia can improve its efficiency by learning from Tianjin.

With the relevant information provided in *Figure 8* and *Table 5*, each province can determine its own improvement benchmark and projection benchmark. At the same time, the state should give certain rewards to those provinces with higher performance, and impose corresponding punishments on those that perform poorly so that they will take scientific and sustainable eco-environmental governance strategies as soon as possible

Conclusions

The synthesis and projection theory of input-output indices of DMUs based on generalized DEA provides a new basis for ranking and improvement of DMUs. The improved method is highly applicable in the horizontal and vertical evaluation and improvement of enterprises or government departments with time series data. In this paper, taking the evaluation on the interaction between eco-environment and economy among Chinese provinces as an example, through reasonable index selection and processing, an evaluation index system with strong logical relationships is constructed, and the evaluation of provinces is carried out with the generalized DEA model. Relevant data analysis results show that the synthesis of the input-output indices of each province can help further discover the efficiency gaps between the provinces, and also provide the improvement scale and direction of the main pollution sources in the eco-environment of each province. Finally, the combination of the index synthesis theory and the partial ordered set theory provides a new basis for the mutual learning among provinces. These basic models and methods further enrich and improve the scientific evaluation on eco-environment, and provide detailed quantitative indices for the protection and governance of eco-environment.

The rationality of index synthesis and projection of DMU is worthy of further study. It will also be of great significance to evaluate the interaction efficiency between eco-environment and economic development in China from the time series data of industrial structure of each province. At the same time, these theories and methods proposed in this paper can be extended to the assessment the interaction efficiency between eco-environment and economic development in other countries, which will help to formulate rational environmental protection programmes, better protect the earth and safeguard the global climate, and it lay theoretical and practical foundation for the comprehensive, balanced and sustainable development of eco-environment and economy.

Abstract. Considering the heavy presence of methylphosphonate (MPn) and its derivatives in nature and their potential hazard to human health, this paper attempts to clarify the ultraviolet (UV) degradation kinetics of the MPn under different environmental parameters. Several tests were carried out to measure UV degradation efficiency of the MPn with different combinations of the following factors: radiation time, light intensity, pH and initial concentration. The analysis on the test results show that the MPn can hardly degrade under the UV intensity of 400 W but degraded gradually under the UV intensity of 1,200 W, peaking at the rate of 94.5% within 58 h. The degradation kinetics can be described by the first-order reaction model, and the degradation rate constant was calculated as 0.032 h^{-1}. The MPn degradation efficiency varied with the pH values. The different pH media could be ranked as pH 10 > pH 13> pH 2 > pH 7 in descending order of the efficiency, indicating that the MPn degradation is more efficiency under alkaline condition. In addition, the MPn degradation became less efficient with the growth in initial concentration, as the intermediate products compete with the reactive oxygen species (ROS). The above results provide a valuable reference for environmental protection and pollution control.
Keywords: *methylphosphonate (MPn), degradation efficiency, photo-oxidation, phosphonate*

Introduction

Phosphonates are an important component of organophosphorus compounds and have the general formula $RP(=O)(OR')_2$. With a relatively stable C-P covalent bond, this component is difficult to degrade and easy to reside in nature. The heavy presence of phosphonate compounds in the environment poses a potential hazard to human health.

Methylphosphonate (MPn) is a relatively simple phosphonate. It is the degradation product of neurotoxic agents like Sarin and Soman and flame retardants like methylphosphinate. The MPn serves as a key reactant in the synthesis of metal phosphonate compounds. Such compounds are novel materials for molecular sieves, ion exchange columns and magnetic motion conductors (Maeda et al., 1995; Edgar et al., 2002; Langley et al., 2008; Bauer et al., 2010). The MPn and its derivatives also act as reaction intermediates for the production of fungicides, insecticides and petroleum additives. When these chemicals are produced and utilized, the MPn is carried by wastewater into the environment, and then absorbed in soil particles and chelated with heavy metal ions. All these lead to the wide existence of the MPn exists in soil and water (Shao et al., 2015). Recent studies have considered the MPn as a potential source of methane in the ocean (Karl et al., 2008; Metcalf et al., 2012; Born et al., 2017; Yu et al., 2018). Oceanic methane accounts for about 4% of global methane budget, making up a key link in the global methane cycle (Sandy et al., 2013). As a well-known greenhouse gas, methane has recently been proved as a cause of the greenhouse effect on the Earth surface. Therefore, the degradation and cycling of MPn have a great significance to greenhouse effect and global climate change.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94739482

In general, phosphonates can be decomposed through biodegradation, photodegradation, chemical oxidation. The natural photodegradation of organic pollutants mainly occurs under ultraviolet (UV) radiation, which takes up about 5% of the total solar radiation reaching the Earth, and other factors like the atmospheric oxygen (Deanin et al., 1970). For phosphonates, UV degradation exists as one possible pathway of decomposition. The decomposition is thorough and irreversible, bringing fundamental changes to the pollution status in water environment (Lu et al., 2018; Acero et al., 2019; Gao et al., 2019). Therefore, photodegradation promises a bright future for the removal of phosphonate pollutants.

The existing studies on MPn decomposition in nature have focused on the microbial degradation pathway (Matys et al., 2001, 2004), failing to explore the pathway and kinetics of the UV degradation pathway. In fact, the efficiency of phosphonate degradation may be affected by various environmental parameters, such as pH, concentration and light intensity. To promote the MPn removal in water, it is necessary to explore the UV degradation of pollutants under different environmental parameters.

Taking the MPn as a typical phosphonate pollutant, this paper examines the UV degradation kinetics of the MPn under different environmental parameters, including radiation time, light intensity, pH and initial concentration.

Methodology

Materials

All chemicals in this research were purchased from Sigma-Aldrich. Among them, the MPn reaches the purity ≥99.9%, and the other chemicals are of the analytical grade. The UV source is an Ace Glass 7900 photo-oxidation apparatus with a 1,200 W lamp. The chemical structure of the MPn is shown in *Figure 1* below.

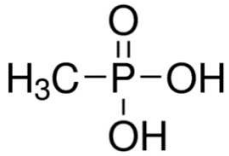

Figure 1. *Chemical structure of the MPn*

Test procedure

Test on the effect of light intensity

To begin with, 12 mL of 10 mM MPn solution (pH≈2) was respectively transferred to two quartz tubes, and separately placed in two photochemical reactors for illumination. One of the reactors has a 400 W mercury lamp and the other, a 1,200 W mercury lamp. The UV emitted from both lamps are consistent with natural UV in composition: primarily UVA (315~400 nm) and UVB (280~315 nm), with a small amount of UVC. The test temperature was controlled below 40°C by a circulating-water air-cooling system. Meanwhile, a control test was carried out to verify whether the MPn can be hydrolyzed by thermolysis in aqueous solution without UV radiation. Specifically, 12 mL of MPn aqueous solution was added to a quartz tube and wrapped in aluminum foil, before being placed in a dark environment. During the reaction,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94739482

0.1 mL of sample was taken every 4 h, and diluted 10 times with deionized water, such that the phosphate concentration fell below 1 mM. Next, the phosphate concentration was measured by colorimetric analysis according to the phospho-molybdate blue assay (Murphy and Riley, 1962). All the degradation experiments were run in triplicates.

Test on the effect of pH

The pH of 10 mM MPn solution was respectively adjusted from ~2 to 2, 7, 10 and 13 with 1 M and 5 M NaOH. Then, 12 mL of MPn solution of each pH was transferred to a quartz tube and placed into the photochemical reactor for UV radiation. The UV light was emitted from a 1,200 W mercury lamp. During the radiation, 0.1 mL of sample was taken every 12 h and diluted 10 times for phosphate concentration measurement.

Test on the effect of initial concentration

The MPn aqueous solutions were dispensed separately at the concentrations of 2.5 mM, 5 mM and 10 mM. After shaking, 10 mL of the solution at each concentration was transferred to a quartz tube and relocated to a photochemical reactor for UV radiation. The UV light was emitted from a 1,200 W mercury lamp. During the radiation, 0.1 mL of sample was taken every 12 h and diluted 10 times for phosphate concentration measurement.

Analysis procedure

One of the final products of the MPn is orthophosphate. The formation of orthophosphate can represent the MPn degradation rate, owing to the simple molecular structure of the MPn. In our research, the MPn degradation efficiency is computed by (Yuan et al., 2014):

$$\eta = (C_t / C_0) \times 100\% \quad \text{(Eq.1)}$$

where η is the UV degradation efficiency of MPn; C_t is residual concentration of MPn after t-hour radiation; C_0 is the initial concentration of the MPn in the aqueous solution.

The degradation kinetics of the MPn over time was analyzed by the first-order reaction kinetics model below:

$$\ln (C_t / C_0) = - kt \quad \text{(Eq.2)}$$

where k is the degradation rate constant of the first-order reaction kinetics, h^{-1}; t is the reaction time.

Figures and linear fitting analysis were done by OriginPro 2016 software.

Results and Discussion

Effect of radiation time

Figure 2 presents the relationship between radiation time and UV degradation rate of the MPn under the Light intensity of 1,200 W, the initial MPn concentration of 10 mM, the pH of 2 and the temperature below 40°C. It can be seen that the MPn degradation rate increased significantly with the elapse of the radiation time. As the radiation time grew from 0 to 58 h, the MPn degradation rate soared from 0 to 94.5%. In the control

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94739482

test, no thermolysis degradation was observed during the reaction period, indicating that the MPn will not hydrolyze spontaneously without UV light. Hence, the MPn degradation is attributable to UV radiation.

Much research has been done on the UV degradation mechanism of organic compounds (Chen et al., 2007; Rao and Chu, 2010). Since orthophosphate is a final product of the MPn, the C-P bond dissociation must take place in order to completely decompose the MPn. According to the previous results on UV degradation mechanism, the C-P bond dissociation under UV photolysis can be ascribed to the nucleophilic substitution of the reactive oxygen species (ROS) in the aqueous environment, which are generated by the electronic excitation of the MPn. The UV degradation mechanism of the MPn is detailed below.

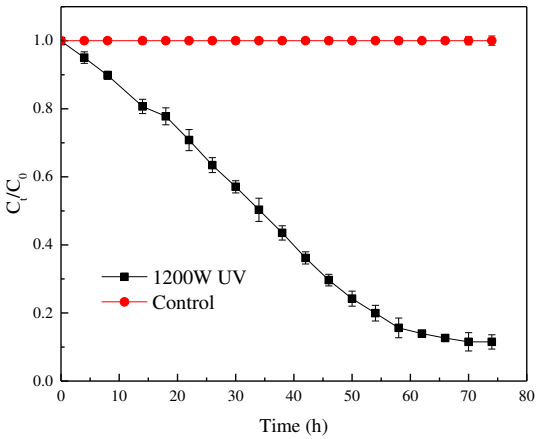

Figure 2. *Effect of radiation time on UV degradation efficiency of the MPn*

The MPn molecular contains functional groups that can absorb the UV. The absorbed energy will elevate the molecular from the stable ground state to an unstable excitation state (Deanin et al., 1970). The relatively reactive species can transfer electrons to acceptors in the aqueous solution, creating free radicals. In the presence of dissolved oxygen, the free radicals are recombined or hydrolyzed into groups, which then form peroxy radicals through the reaction with oxygen (Bustos et al., 2019). After further photolysis, the peroxy radicals will be converted to hydrogen peroxides (Chen and Liu, 2007), and finally decomposed into hydroxyl radicals that attack the methyl groups in the MPn.

Effect of light intensity

The effective removal of pollutants from wastewater hinges on the optimal UV light intensity for MPn degradation. In this research, the effect of light intensity on MPn degradation is investigated under the UV lights emitted from a 400 W mercury lamp and a 1,200 W mercury lamp. *Figure 3* depicts the relationship between light intensity and MPn degradation rate under the UV intensities of 400 W and 1,200 W, the initial MPn concentration of 10 mM, the pH of 2 and the temperature below 40ºC.

As shown in *Figure 3*, the MPn degradation rate was much slower under 400 W UV radiation than 1,200 W. Under the 400 W UV source, only ~3% of MPn were decomposed after an 80 h exposure. The degradation rate was greatly accelerated under

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94739482

the 1,200 W UV source: the MPn degradation was very fast and then gradually slowed down in the first 58 h, peaking at 94.5%.

As mentioned above, the ROS produced in the aqueous solution is the cause to MPn degradation. Under the 400 W mercury lamp, the amount of ROS generated per unit time was very limited. Coupled with the intense energy required to cleavage the C-P bond, the limited amount of ROS makes it slow for the MPn to be degraded under the 400 W UV source.

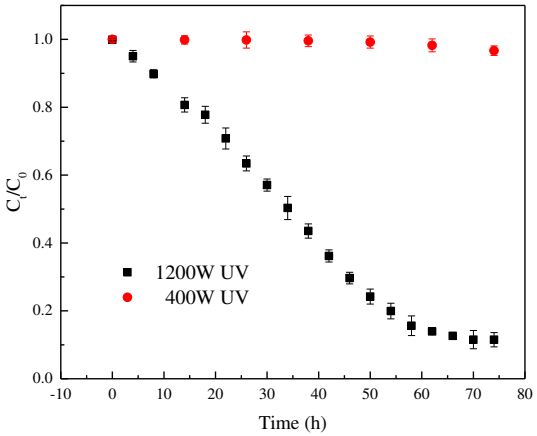

Figure 3. *Effect of light intensity on the UV degradation efficiency of the MPn*

The MPn degradation reflects the typical degradation kinetics of organic compounds: the degradation proceeds rapidly at the beginning, and gradually slows down near the peak rate. Here, the degradation kinetics of the MPn under different UV intensities are described by the first-order reaction equation (*Eq.2*) and the results are shown in *Figure 4*. Obviously, the first-order reaction equation described the reaction process well (R^2=0.97).

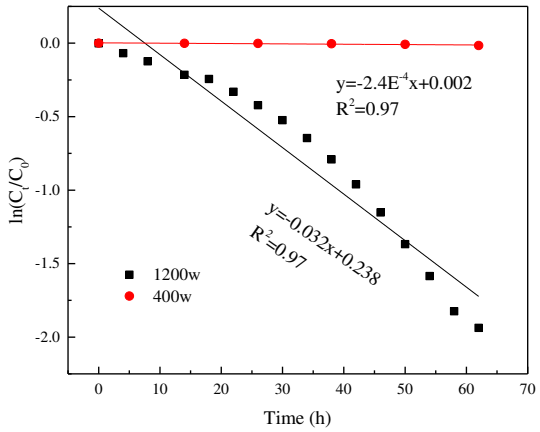

Figure 4. *UV degradation kinetics of the MPn under different UV intensities*

The calculated kinetics parameters are listed in *Table 1*. It can be seen that the degradation rate constant (k) of the MPn was only $2.4E^{-4}$ h^{-1} under 400 W UV radiation. During the radiation, only 3% of the MPn was decomposed. By contrast, under 1,200 W

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94739482

UV radiation, the degradation rate constant increased 133 times to 0.031 h^{-1}, and the photolysis half-life reduced to 21.66 h. It can be concluded that the UV intensity plays a significant positive role in the MPn removal in wastewater treatment.

Table 1. *Kinetics parameters of UV degradation of the MPn under different light intensities (C_0=10mM)*

Light Sources	Photolysis Equation	Rate Constant *k* (h^{-1})	Photolysis Half-Life $t_{1/2}$ (h)	Coefficient of Determination (R^2)
1,200W Mercury Lamp	$\ln(C_t/C_0) = -0.032\ t$	0.032	21.66	0.97
400W Mercury Lamp	$\ln(C_t/C_0) = -2.4E^{-4}\ t$	$2.4E^{-4}$	2,888.11	0.97

Effect of pH

In nature, the pH value differs from one aquatic environment to another. The pH is essential to the degradation of the organic pollutants, as it can affect the photochemical reaction kinetics in pollutant treatment. Under different pH values, the organic pollutants have different molecular forms, and thus exhibit varied physicochemical properties and toxicities.

Figure 5 displays the relationship between pH and MPn degradation rate under the UV intensity of 1,200 W, the initial MPn concentration of 10 mM, the pH of 2, 7, 10 and 13 and the temperature below 40ºC. As can be seen from the figure, the different pH values could be ranked as pH 10 > pH 13> pH 2 > pH 7 in descending order of MPn degradation efficiency. The degradation efficiency increased in acidic and alkaline solutions. Within 50 h exposure to UV radiation, 96% of the MPn in acidic and alkaline media were decomposed, while only 84% were degraded in the neutral solution.

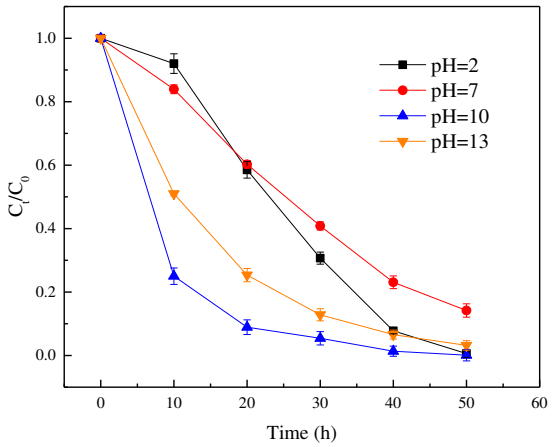

Figure 5. *Effect of pH on the UV degradation efficiency of the MPn*

Many scholars (Wei et al., 2000; Santos-Beneit, 2015) agree that organophosphorus compounds are more easily to photolyze in acidic and alkaline solutions than in neutral medium. In aqueous solutions, the molecular forms of organophosphorus compounds depend on the pH value. For instance, Li et al. (2016) studied the effect of pH on the photolysis of sulfamethazine (SMZ), concluding that the SMZ photolysis efficiency

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94739482

varies greatly with pH values: the SMZ degrades much faster in strong alkaline and acidic conditions than in neutral and alkalescent condition. This is because the SMZ mainly ionizes in the form of SMZ^- and SMZ^+ in alkaline and acidic conditions, respectively, but exists in the stable molecular state in neutral condition. The ionization of the SMZ in different pH media affects its photolysis kinetics.

As an organic acid, the MPn ionizes in the form of $CH_3PO(OH_2)_2^{2+}$ and $CH_3PO(OH)(OH_2)^+$ in acidic condition. When the pH is adjusted to alkaline condition by NaOH solution, the MPn mainly exists as $CH_3PO(OH)O^-$ and $CH_3POO_2^{2-}$. The ionization weakens the molecular bond energy, pushing up the speed of photolysis reaction.

The first-order reaction model (*Eq.2*) was used to describe the UV degradation kinetics of the MPn at different pH values. The linear fitting results of ln (C_t/C_0) to time t are shown in *Table 2*. It is observed that the UV degradation of the MPn was well described by the first-order reaction model ($R^2 \geq 0.97$). The kinetics parameters were calculated and listed in *Table 2*. As shown in the table, the photolysis half-life of MPn in the solution was 17.32 h, 23.1 h, 10.05 h and 7.07 h respectively at the pH of 2, 7, 10 and 13. The degradation rate constants *k* at the four pH levels were 0.04, 0.03, 0.069 and 0.098, respectively. The MPn degradation rate at the pH of 10 was 3.3 times that at the pH of 7 and 2.5 times that at the pH of 2.

Table 2. *Kinetic parameters of UV degradation of the MPn at different pH values (C_0=10mM)*

pH	Photolysis Equation	Rate Constant *k* (h^{-1})	Photolysis Half-Life $t_{1/2}$ (h)	Coefficient of Determination (R^2)
2	$\ln(Ct/C_0)=-0.040t$	0.04	17.32	0.97
7	$\ln(Ct/C_0)=-0.030t$	0.03	23.10	0.98
10	$\ln(Ct/C_0)=-0.098t$	0.098	7.07	0.99
13	$\ln(Ct/C_0)=-0.069t$	0.069	10.05	0.97

The formation of hydroxyl radicals (HO·) in aqueous solution is the key to the UV degradation of organophosphorus compounds (Evgenidou et al., 2006; Manassero et al., 2010). In alkaline medium, the abundance of hydroxyl groups (OH^-) in solution may boost the formation of hydroxyl radicals, thus speeding up the degradation reaction. To sum up, the pH condition is very important for UV degradation of the MPn and the alkaline medium is preferred for MPn wastewater treatment.

Effect of initial concentration

Figure 6 illustrates the relationship between initial concentration and the UV degradation rate of MPn under the UV intensity of 1,200 W, the initial MPn concentration of 2.5, 5 and 10 mM, the pH of 2 and the temperature below 40ºC. As shown in the figure, the three initial concentrations could be ranked in descending order as 2.5 mM > 5 mM > 10 mM by the degradation efficiency. It took about 20 h, 30 h and 50 h for the 2.5, 5 and 10 mM MPn solutions to reach the peak efficiency, respectively. In general, the lower the initial concentration, the more efficiency the MPn degradation.

The above results echo that of Yuan (2007) on photolysis kinetics of paclobutrazol at different initial concentrations: the photolysis efficiency is negatively correlated with the initial concentration. This correlation can be explained as follows. Under the same UV intensity, the amount of ROS produced in solution is fixed at a certain volume and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94739482

time. With the increase in MPn concentration, the ratio of ROS to the MPn continues to fall, leading to the decline in degradation efficiency. In addition, the intermediate products of MPn degradation compete with the ROS, thus reducing the degradation rate. The denser the MPn, the greater the number of intermediate products.

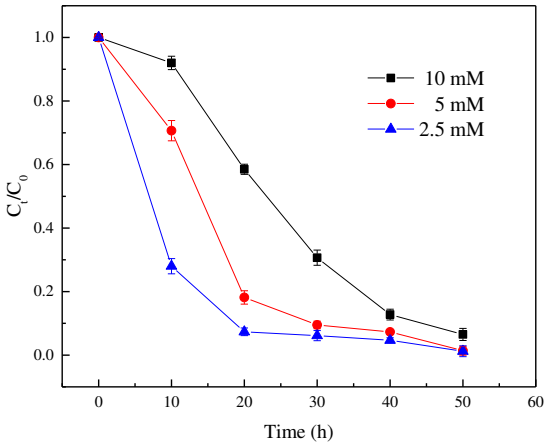

Figure 6. *Effect of initial concentration on the UV degradation efficiency of MPn*

Conclusions

The environmental parameters are key factors for UV degradation of the MPn. The MPn can be easily degraded under the UV intensity of 1,200 W, and exhibit typical degradation features of organic compounds over time. However, the MPn is difficult to degrade under a low UV intensity (400 W). The optimal pH for UV degradation of the MPn is the pH of 10. The MPn can be degraded more efficiently under a low initial concentration. These conclusions provide a valuable reference for the MPn removal in wastewater treatment.

(Received 3rd Apr 2019; accepted 17th May 2019)

Abstract. With the rapid development of tourism, tourism activities have a certain impact on the environment of ecological nature reserves. Taking Wuyishan National Nature Reserve as the research object, this paper explores the impact of tourism activities on the environmental carrying capacity, vegetation landscape and atmospheric environment of natural ecological protection areas, and seeks measures for the coordinated development of tourism activities and ecological natural protection. The results show that the results of different tourism carrying capacity components vary greatly, and the number of tourists in Wuyishan National Nature Reserve has exceeded the value of tourism environmental carrying capacity. The influence of tourism activities on vegetation landscape is great and 6 out of the 20 samples tested are moderate interference. The closer the samples are to the travel path, the greater the interference degree on vegetation landscape is, the greater the interference by tourism activities is, and the smaller the ecological benefit value of the sample is. This study provides a theoretical and experimental basis for the sustainable development of tourism activities and ecological nature reserves.

Keywords: *tourist activities, ecological nature reserve, environmental science, ecological benefits, sustainable development*

Introduction

With the development of economy and the change of people's thought, tourism is called the gold medal industry in the 21st century. Tourism activities have the functions of increasing knowledge, cultivating sentiment, raising quality, promoting civilization and strengthening physique. It is also a symbol of the ever-increasing economic and cultural life of people (Jurigová and Zuzana, 2016; Movono et al., 2018). However, tourism activities are carried out with the complex activities of human beings, and the consumption of resources caused by tourism activities is increasing, which brings a plenty of environmental pressure on the ecological environment, including soil pollution, solid waste discharge, noise pollution and predatory development of lands in reserves (Mirela and Butnaru, 2015). The ecological nature reserves are the areas divided by the State and the region in order to maintain species diversity. They are of great significance to maintain the ecological balance, protect the natural and historical heritage and promote the development of scientific research and tourism. We should be pay attention to the protection and restoration of diversity of animal and plant species in ecological nature reserves, as well as protection and development of regional characteristics and natural landscape (Popp, 2014; Giddy and Webb, 2015). The tourism activities in ecological nature reserves can drive local economic development, bring considerable economic benefits to the local area, and bring natural landscapes to tourists, but the construction of tourism infrastructure in nature reserves and the trampling of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94839492

tourists cause damage to the reserves (Hjalager and Johansen, 2013). In recent years, the ecological protection and restoration of eco-tourism areas are lagging behind due to the destruction of tourism activities. People gradually realize that tourism activities are a "double-edged sword", and eco-tourism has gradually developed into a favored way in the tourism market, with a focus on conservation of the natural environment and the natural landscape (Buswell and Buswell, 2011; Tikkanen et al., 2017). The national ecological nature reserves are the main carriers for tourism activities, with a limited capacity to withstand people's interference and destruction, and tourism activities will be destroyed to varying degrees and may cause species degradation in serious cases (Krupczek and Micha, 2016). Taking Wuyishan National Nature Reserve as the research object, this paper explores the impact of tourism activities on the environmental carrying capacity, vegetation landscape and atmospheric environment of natural ecological protection areas, and seeks measures for the coordinated development of tourism activities and ecological natural protection.

Materials and Methods

The environmental carrying capacity of national ecological nature reserves is an important index to limit the excessive tourism intensity, and represents the threshold for the capacity to support human socio-economic activities in certain period, under certain conditions and specific regional conditions (Nyahunzvi and Kennedy, 2015). The environmental carrying capacity not only refers to macroscopic natural environment, but also includes social environment, spiritual environment and management environment. It has objectivity, comprehensiveness, variability, feedback and finitude (Hayward and Kuwahara, 2013). Taking Wuyishan National Nature Reserve as an example, the indexes of its environmental carrying capacity includes resource space carrying capacity, ecological environment, economic environment and social environment carrying capacity (Ritter, 2009).

Table 1 shows the distribution of tourist sources in Wuyishan National Nature Reserve and the main domestic tourists come from Jiangxi, Fujian and Guangdong.

Table 1. *Distribution of tourist sources in Wuyishan National Nature Reserve*

Province	Passenger origin	Province	Passenger origin
Jiangxi	15.52%	Hunan	7.89%
Fujian	17.63%	Hubei	6.23%
Jiangsu	9.3%	Shandong	2.65%
Zhejiang	6.8%	Beijing	2.11%
Guangdong	13.65%	Sichuan	1.99%
Anhui	5.5%	Other	10.73%

Figure 1 shows the annual tourists in Wuyishan National Nature Reserve and the annual tourists increase year by year, up by 2.44 times from more than 6.4 million tourists in 2010 to more than 15.62 million in 2018. According to the official statistics of Wuyishan National Nature Reserve, the total number of tourists received exceeded 15 million for the first time in 2018, nearly 2.8 million more than in 2017, which is the biggest growth year.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94839492

This paper mainly analyses the carrying capacity of ecological environment and social economy, among which the carrying capacity of ecological environment includes the carrying capacity of atmospheric environment (gaseous pollutants and suspended particles), water environmental carrying capacity (chemical oxygen content and ammonia nitrogen content index), and socio-economic carrying capacity includes psychological and spatial capacity (Hanna et al., 2015). *Figure 2* is the environmental bearing capacity value of Wuyishan National Nature Reserve. It can be seen that the environmental bearing capacity value of each index is different greatly, and the ecological environment bearing capacity is the largest, which is calculated according to the current bearing capacity value. At present, the total amount of tourists received in Wuyi Mountain exceeds the carrying capacity of water resources and environment.

Results

Ecological response of vegetation landscape to the interference of tourism activities

The vegetation landscape is the main component of Wuyishan National Nature Reserve, which is the most susceptible to the influence of tourism activities. The destruction of the vegetation landscape by tourism activities is divided into systematic destruction and local destruction. *Table 2* shows the purposes of visiting Wuyi

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94839492

Mountain. According to the questionnaire, tourists come to Wuyi Mountain mainly to enjoy the scenery and relax and the diversity of vegetation species provides a rich experience to tourists. According to the investigation results, the trees in Wuyishan National Nature Reserve contain 14 families, 18 genera, and 24 species, 32 species in shrub layer, 41 species in herbaceous layer, while the vegetation is rich in species.

Table 2. *Tourists visit Wuyishan for the purpose of travel*

Tourism purpose	Enjoy the scenery	Exercise	Relax	Delicious snack	Other
Proportion/%	57.61%	9.23%	26.59%	3.13%	3.44%

Figure 3 shows a vegetation landscape ecological effect evaluation system, which includes four parts such as vegetation importance, species diversity, community structure ratio and plant dominance. Wuyi Mountain is divided in 20 10 m × 10 m sample squares, and the species, height, coverage and cluster of species in the samples are recorded. The evaluation index TD of Wuyi Mountain vegetation landscape is as follows:

$$TD = 1 - \frac{S/S_{max}+H/H_{max}+C/C_{max}+L/L_{max}}{4} + A \quad \text{(Eq.1)}$$

where S, H, C and L represent the number of actual species, average height of species, vegetation coverage and vertical structure of vegetation in the samples, S_{max}, H_{max}, C_{max} and L_{max} represent the maximum value of the data measured in the samples, and A represents the ecological dominance value.

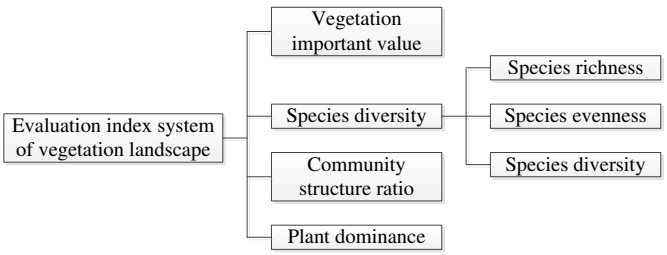

Figure 3. *Vegetation landscape ecological effect evaluation system*

Figure 4 shows the influence of tourism activities on the number of vegetation species and vegetation coverage, and the larger the number of vegetation species and vegetation coverage value are, the greater the species richness is.

Figure 5 shows the impact of tourism activities on the average height and vertical structure of vegetation. The higher the average height and the vertical structure of vegetation are, the more vegetation the tree layer has. *Figure 6* shows the ecological benefit value of the vegetation landscape of Wuyi Mountain. The larger the interference by the tourism activity is, the smaller the ecological benefit value of the samples is, and the quality of the vegetation landscape is deteriorated due to the tourism activity. *Table 3* is the calculation of the interference degree of the selected samples. It can be seen that the interference degree of samples 5-10 is severe, and that of other samples is mild.

Analysis of the impact of tourism distance on vegetation landscape

The overall impact of tourism activities on the vegetation landscape is minimal, but greater on the local areas, which is manifested in the trampling and picking of the vegetation by tourists, resulting in the inhibition of the growth and development of the vegetation and the change of the vegetation coverage. Water and soil pollution caused by tourism activities will also affect the growth and development of vegetation.

In this experiment, the vegetation coverage and species diversity are taken as evaluation index. With 10 sample plots in total, each sample plot comprises four samples, with a size of 1 m × 1 m, and the distances of the four samples to the tourism path are 0 m, 5 m, 10 m and 15 m, respectively. Taking relative coverage as the research object, the richness index of species is as follows:

$$R = (S - 1)/lnN \quad \text{(Eq.2)}$$

where, S represents the total number of species in a single sample and N represents the sum of species importance values in all test samples.

Figure 7 shows the relative coverage of the vegetation and the change of the species number in the samples with different travel distance.

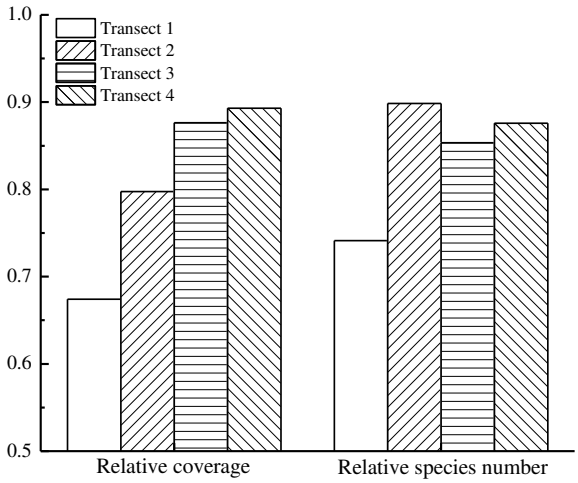

Figure 7. *Changes in relative coverage and species of vegetation distance from different tourism activities*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94839492

It can be clearly seen that the relative coverage of the vegetation and the change of the species number show different changing law. The further the tourist path is, the larger the relative coverage of the vegetation is. The number of species in the sample with the distance of 0 m to tourist path is the least, the number of species in the sample with the distance of 5 m is the largest, and the number of species in the samples 3 and 4 is less than that of the sample 2, that's, the vegetation diversity increases not far from the distance from the tourist path, which may be related to the "moderate interference hypothesis". *Figure 8* shows the degree of tourism interference in different tourism distance zones and the coverage ratio, the height relative ratio and the vertical structure of the vegetation show the same trend, and the smaller the travel distance is, the larger the coverage ratio, the height relative ratio and the vertical structure value of the vegetation are, which is opposite to the changing law of the interference degrees, and the interference degree decreases with the increase of the travel distance, which conforms to the natural law.

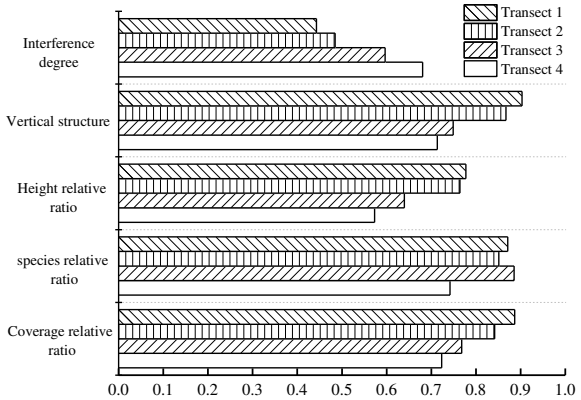

Figure 8. *Different tourist distances with tourist interference*

Discussion

Ecological response of environmental quality to the interference of tourism activities

Environmental quality is also an important index to measure the environment of ecological nature reserves. Air pollution, water pollution and noise pollution will all affect the soil, vegetation and animals in the nature reserves. In this paper, three indexes of atmospheric pollutants such as CO, ammonia nitrogen and total suspended particulate matter are tested. *Table 4* shows the monitoring results of the main atmospheric pollutants in Wuyishan National Nature Reserve.

Table 4. *Monitoring results of major atmospheric pollutants in Wuyishan National Nature Reserve*

Project	CO	Ammonia nitrogen content	Suspended particulate matter
Jiu Quxi	0.015	0.016	0.124
Da Zangfeng	0.014	0.010	0.099
Fu Rongtan	0.015	0.006	0.089
Wo Longfeng	0.014	0.008	0.065
Mean	0.0145	0.010	0.0943
National standard	0.05	0.05	0.12

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94839492

Compared with the national natural standards, the overall environmental quality of Wuyishan National Nature Reserve is the first-class standard, but the total suspended particulate matter content of Jiuqu River is higher than the first-class standard. *Figure 9* shows the changing value of total suspended particulate matter concentration in different places. The fluctuation of total suspended particulate matter concentration in Jiuqu River is the most obvious, with the highest concentration value at 16 pm, mainly because passengers returning from other scenic spots successively view Jiuqu River, and the vehicles pass frequently, causing a gradual increase in the concentration value.

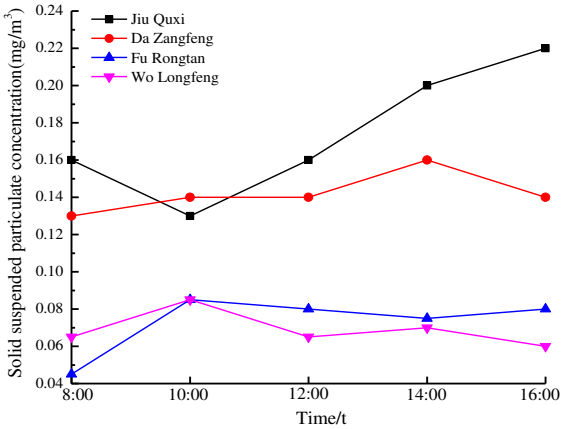

Figure 9. *Increasing values of total suspended particulate matter at different locations*

Measures for coordinated development of tourism activities and ecological nature protection

The impact of tourism activities on the environment of ecological nature reserves is inevitable. If tourism planning and management work is in place, the sustainable development of tourism activities and environmental protection can be realized. At present, the laws and regulations on tourism management in Wuyishan National Nature Reserve are not sound, the natural resources are seriously destroyed, and there is no necessary supervision and management system. In order to achieve ecological sustainability, we should strengthen the management of managers, operators and tourists. Tourists are the direct participants of tourism activities, so this paper will focus on the relevant management measures for tourists. First of all, tourists should manage and restrict their own behavior and put an end to uncivilized behaviors such as picking up, littering and painting in the reserves. Third, we should standardize tourism behavior, strengthen the popularization and education of ecological science in tourism activities, and ensure the harmony and unity of tourism activities and ecological environment. Finally, we should have meaningful tourism activities, implementing the eco-environmental protection and sustainable development throughout the tourism activities.

Conclusions

Taking Wuyishan National Nature Reserve as the research object, this paper explores the impact of tourism activities on environmental carrying capacity, vegetation landscape and atmospheric environment of natural ecological reserve. The specific conclusions are as follows:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94839492

The environmental carrying capacity of each index of Wuyishan National Nature Reserve is different greatly, and the carrying capacity of ecological environment is the largest. According to the current carrying capacity value, the total amount of tourists received in Wuyi Mountain exceeds the environmental carrying capacity of water resources.

The number of species in the sample with the distance of 0 m to tourist path is the least, and the number of species in the sample with the distance of 5 m is the largest. The coverage ratio, height relative ratio and vertical structure of vegetation show the same changing law, that's, the smaller the tourist path distance is, the larger the coverage ratio, height relative ratio and vertical structure value of vegetation are, which is opposite to the changing law of interference degree value. The interference decreases with the increase of the tourist path distance.

The larger the interference of tourism activities is, the smaller the ecological benefit value of the tested sample is. The result of testing the atmospheric pollutants shows that the impact of tourism activities on the atmospheric environment is small.

At present, the calculation of environmental carrying capacity is based on the intensity of tourist source activities. No quantitative analysis was made on whether tourism will affect the atmospheric environment and water environment of Wuyishan Ecological Nature Reserve, and the degree of the impact, so the scientific quantitative research and analysis can be carried out in the future.

(Received 3rd Apr 2019; accepted 17th May 2019)

Abstract. Based on panel statistics on Circum-Changsha-Zhuzhou-Xiangtan urban agglomeration of China in 2008-2016, the area's carbon emissions originate from three distinct sources: agriculture, industry and transportation in a "bottom-up" way for estimation. The Logarithmic Mean Divisia Index (LMDI) model is used to identify the driving factors that influence carbon emission in this urban agglomeration. Finally, the interaction between carbon emission and economic development was scientifically evaluated based on decoupling elasticity index. The results show: (1) the carbon emission of Circum-Changsha-Zhuzhou-Xiangtan urban agglomeration increased in 2008-2011, and slightly fluctuated in 2011-2016. According to the Environmental Kuznets Curve (EKC), there is an obvious "inverted-U" curve between carbon emission and per capita Gross Domestic Product (GDP), means the carbon emission will be effectively controlled as the economic development reaches a certain level; (2) LMDI decomposition shows the economic growth and human capital played a positive role in promoting the growth and change of carbon emissions of the whole urban agglomeration, while the energy intensity and industrial structure had a negative effect; (3) the decoupling level of Circum-Changsha-Zhuzhou-Xiangtan urban agglomeration as a whole tends to be slightly higher than the growth rate of carbon emission, among which the core region has a weak decoupling trend while Hengyang and Changde of China repeatedly appear to be in strong decoupling state.
Keywords: *green development, EKC curve, LMDI model, decoupling index, emission-reduction*

Introduction

The increasing greenhouse effect drew international attention towards problems concerning the ecological environment. At the Copenhagen meeting, China promised to "reduce the carbon dioxide emission per unit GDP by 40-45% by 2020 compared to 2005." Subsequently, the State Council listed low carbon level as one of the important development goals in the Plan for Ecological Environment Protection during the Thirteenth Five-year Plan Period. In the process of accelerating the development of urbanization, the rapid concentration of industry and population makes cities become the key areas of energy conservation and emission reduction. Therefore, China has successively issued many plans for building low-carbon cities. Located in the middle reaches of the Yangtze River Economic Belt of China, the Circum-Changsha-Zhuzhou-Xiangtan urban agglomeration is responsible for the rise of the central region. Under the two development strategies of the Belt and Road and Circum-Changsha-Zhuzhou-Xiangtan Integration, the Circum-Changsha-Zhuzhou-Xiangtan urban agglomeration should set up a model among the urban agglomerations in the middle reaches of the Yangtze River as well as bear more responsibilities in national and regional development and environmental governance. In this context, scholars have produced researches on CO_2 which mainly include the following aspects: (1) Carbon emissions estimates. Most scholars calculate the carbon emission based on the carbon emission

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94939504

coefficient method (Ning and Zhang, 2014; Gong, 2015), and some scholars estimate the carbon emission amount through the indirect calculation method. The input-output method is mostly used for the calculation of implied carbon dioxide (He, 2012; Zhao et al., 2019). Due to the input-output method's lack of accuracy, the life cycle method is also favored by many scholars (Xia et al., 2010; Cao et al., 2011). (2) Identification of driving factors. With the help of LMDI decomposition method, many scholars can calculate the driving direction and contribution value of each factor (Li and Zhang, 2016; Sun and Zhou, 2017), and some scholars use Stochastic Impacts by Regression on Population, Affluence, and Technology (STIRPAT) model to conduct regression analysis and calculate the regression coefficient of driving factors. The direction and magnitude are judged by the positive and negative values of the coefficients (Feng et al., 2019). In addition, some scholars use the Kaya identity to analyze (Pan and Hu, 2019; Wang and He, 2018). (3) Study on the potential of reducing carbon emission. There are many theoretical analyses on the potential of carbon emission reduction (Tian and Ding, 2018; Zhang et al., 2015). Some scholars use the model to quantify the potential of carbon emission reduction, such as using decoupling index to quantify the potential of carbon emission reduction into elasticity index (Wang and Zhu, 2018; He and Cai, 2016), or different carbon emission scenarios are respectively set to predict the value based on the regression coefficients and the difference between each prediction result is calculated (Li et al., 2018; Gu et al., 2013). In view of the existing research, the research methods on carbon emission have been more comprehensive, but most of the research objects are based on the national or provincial panel data, while the literature on urban agglomerations for the early stage is less. Therefore, the carbon emission of Circum-Changsha-Zhuzhou-Xiangtan urban agglomeration is estimated from three perspectives such as agriculture, industry and transportation in a "bottom-up" way. At the same time, the relationship between carbon emission and GDP per capita is fitted, and the factors that drive the change of urban carbon emission are decomposed through LMDI model. Finally, the decoupling elasticity is established to analyze the dependence between urban carbon emission and economic development, so as to find a more suitable emission reduction path for the development of Circum-Changsha-Zhuzhou-Xiangtan urban agglomeration, and provide more scientific policy suggestions for its green, coordinated and sustainable development.

Materials and methods

Method for estimating carbon emissions

In this paper, the "bottom-up" method is used to calculate the emissions of CO_2 in the primary industry (agriculture), the secondary industry (industry) and the tertiary industry (transportation (the main carbon source)) and summarize to obtain the emissions of CO_2 in the Circum-Changsha-Zhuzhou-Xiangtan urban agglomeration of China. The detailed calculation ideas are as follows:

$$C_{\mathrm{tj}} = C_{Atj} + C_{Itj} + C_{Ttj} \quad \text{(Eq.1)}$$

where C_{tj} indicates the emission of the j city in the t year, C_{Atj}, C_{Itj} and C_{Ttj} indicate the emissions of CO_2 in the j city in the t year from agriculture, industry and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94939504

transportation. The calculation formula for carbon emissions in different industries is broken down as follows:

(1) Carbon emission from urban agriculture. The sources of carbon emission in agriculture mainly come from agricultural cultivation and fertilization. Therefore, four factors such as agricultural machinery, effective irrigation area, chemical fertilizer and rural electricity are selected to calculate the urban agricultural carbon emission. The formula is as follows:

$$C_{Atj}=\sum_{t} F_{ti} \cdot \rho_i \quad \text{(Eq.2)}$$

where C_{Atj} indicates the carbon emission of the j city in the t year, F_{ti} indicates the total consumption of the i agricultural element in the t year, and ρ_i indicates the corresponding carbon emission factor of the i element. According to the calculation of agricultural carbon emissions in Jiangxi Province (Cao and Cao, 2016), the carbon emission coefficients of agricultural machinery, effective irrigation area, fertilizer and rural electricity consumption are selected respectively as 1.8 t/103 kw·h, 20.476 t/103 km^3, 0.8956 t/t, 9.26 t/104 kw·h.

(2) Carbon emission from urban industry. Considering the availability and representativeness of the data, this paper selects the total amount of energy used by the large industrial enterprises after being converted into standard coal to calculate the urban industrial carbon emission. The calculation formula is as follows:

$$C_{Itj}=\sum_{t} F_{ti} \cdot \rho_i \quad \text{(Eq.3)}$$

where C_{Itj} indicates the industrial carbon emission of the j city in the t year, F_{ti} indicates the consumption of the i energy in the t year, and ρ_i indicates the corresponding carbon emission factor of the i energy. The carbon emission coefficient of standard coal is 2.493 t/t, taken based on the IPCC China Greenhouse Gas Emission List.

(3) Carbon emission from urban transportation. According to the method of calculating the carbon emission in transportation and the applicability of the data in existing literature, this paper selects the emission of CO_2 from passenger and freight vehicles C_{Tptj} and residential vehicles C_{Tutj} to replace the carbon emission of urban transportation. The calculation formula is as follows:

$$C_{Ttj}=C_{Tptj}+C_{Tutj} \quad \text{(Eq.4)}$$

The carbon emissions of passenger and freight vehicles are calculated by using the calculation method of the United Nations World Tourism Organization (UNWTO), and the carbon emission of each traffic mode is estimated by the product of the turnover of each traffic mode and the corresponding carbon emission coefficient. The formula is as follows:

$$C_{Tptj}=\sum_{t} F_{pti} \cdot \rho_i \quad \text{(Eq.5)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94939504

where, C_{Tptj} indicates the emission of CO_2 from passenger and freight vehicles, F_{pti} indicates the turnover of the i traffic mode in the t year, and ρ_i indicates the corresponding carbon emission factor of different turnover modes. In view of China's lack of authoritative turnover carbon emission data, this paper determines passenger vehicle carbon emission coefficient (He, 2010; Paul and Ghislain, 2010), which is converted to a freight carbon emission factor according to the unit cargo turnover provided by Greenhouse Gas Protocol and European Chemical Industry Association. The transport modes of passenger transport and freight transport statistics are railway, highway, waterway and aviation, and the emission coefficients of passenger transport turnover are respectively 27 g/p·km and 133 g/p·km, the emission coefficients of freight transport turnover are respectively 28 g/ton·km, 327 g/ton·km, 53 g/ton·km and 1,961 g/ton·km.

$$C_{Tutj} = \sum_t G_{uti} \times S_{uti} \times Q_{uti} \times J_{uti} \quad \text{(Eq.6)}$$

where, C_{Tutj} indicates the emission of CO_2 from residential vehicles in the j city in the t year, G_{uti} indicates the fuel consumption of 100 km of the i transportation mean, S_{uti} indicates the annual mileage of the i transportation mean, and J_{uti} indicates the carbon emission factor of the i transportation mean. Due to the difficulty in obtaining the corresponding data on the energy consumption and mileage of residential vehicles, according to the calculation of the carbon emissions in transportation of Wuhan (Gong, 2015) and Zhengzhou (Ning, 2014) and in combination with the per capita GDP difference of different provinces, this paper estimates the average annual mileage of different residential vehicles in the cities of the the Circum-Changsha-Zhuzhou-Xiangtan urban agglomeration proportionally. The fuel consumption of private cars for 100 km is mainly 93#, taking 0.1 L/km and the motorcycles mainly 125 motorcycles taking 0.22 L/km.

Drive factor decomposition model

The LMDI decomposition method overcomes the problem that the traditional decomposition method has the residual term. Therefore, according to the analysis framework (Albrecht et al., 2002), the carbon emission of Circum-Changsha-Zhuzhou-Xiangtan urban agglomeration of China is decomposed as follows:

$$C = \sum_i \left(\frac{C_i}{E_i} \times \frac{E_i}{E} \times \frac{E}{Y} \times \frac{Y}{P} \times P \right) \quad \text{(Eq.7)}$$

where, C indicates the total carbon emission of Circum-Changsha-Zhuzhou-Xiangtan urban agglomeration, C_i indicates the total carbon emission of the i industry, E_i indicates the energy consumption of the i industry, E indicates the total energy consumption of urban agglomerations, Y indicates the GDP of urban agglomeration and P indicates employees in the urban agglomeration. In order to facilitate that decomposition, it is expanded to the follow form:

$$A_i = \frac{C_i}{E_i}, \quad B_i = \frac{E_i}{E}, \quad D = \frac{E}{Y}, \quad I = \frac{Y}{P}, \quad K = P \quad \text{(Eq.8)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94939504

Ai, Bi, D, I and K respectively indicate carbon emission coefficient effect, industrial structure effect, energy intensity effect, economic development effect and human capital effect.

If the total carbon emission of urban agglomerations in the basic period is set as C^0, after T period, the change in the total carbon emission of urban agglomeration can be expressed as:

$$\begin{aligned}\Delta C &= C^T - C^O \\ &= \Delta C_{Ai} + \Delta C_{Bi} + \Delta C_D + \Delta C_I + \Delta C_K\end{aligned} \quad \text{(Eq.9)}$$

Considering that the energy carbon emission coefficient is constant, ΔC_{Ai} is not considered in actual calculation. According to the study (Ang et al., 1998), the expression of contribution value of each element can be further expressed as

$$\begin{aligned}&\Delta C_{Bi}=\sum_i\left(\frac{C_i^T-C_i^0}{\ln C_i^T-\ln C_i^0}\right)\times\ln\left(\frac{B_i^T}{B_i^0}\right);\ \Delta C_D=\sum_i\left(\frac{C_i^T-C_i^0}{\ln C_i^T-\ln C_i^0}\right)\times\ln\left(\frac{D^T}{D^0}\right)\\ &\Delta C_I=\sum_i\left(\frac{C_i^T-C_i^0}{\ln C_i^T-\ln C_i^0}\right)\times\ln\left(\frac{I^T}{I^0}\right);\ \Delta C_K=\sum_i\left(\frac{C_i^T-C_i^0}{\ln C_i^T-\ln C_i^0}\right)\times\ln\left(\frac{K^T}{K^0}\right)\end{aligned} \quad \text{(Eq.10)}$$

Decoupling elasticity coefficient

According to the explanation of the decoupling analysis elasticity (Tapio, 2005), the decoupling elasticity coefficient can be expressed as:

$$e_j=\frac{\Delta C_j / C_j}{\Delta GDP_j / GDP_j} \quad \text{(Eq.11)}$$

where, e_j indicates the decoupling elasticity coefficient of the j city, and C_j indicates the total carbon emission of the j city. The different elasticity magnitudes represent different decoupling states, and the specific corresponding relationship is shown in *Table 1*.

Table 1. *Type of Tapio decoupling elasticity*

Status		Environmental pressure	Economic growth	Elasticity
Negative decoupling	Weak negative decoupling	＜0	＜0	0 ≤ t ＜0.8
	Strong negative decoupling	＞0	＜0	t ＜0
	Expansion negative decoupling	＞0	＞0	t ＞1.2

Data sources

This paper chooses Circum-Changsha-Zhuzhou-Xiangtan urban agglomeration of China as the research object, which includes the core area (Changsha, Zhuzhou, and Xiangtan); and radiation area (Hengyang, Yueyang, Changde, Yiyang and Loudi). The time span of data collection is from 2008 to 2016. The relevant data are mainly from the Statistical Yearbook of Hunan Province, the Statistical Yearbook of Chinese Cities and the Statistical Annual Report published by the statistical offices of each city from 2009 to 2017.

Results and discussion

Estimation results of carbon emission from Circum-Changsha-Zhuzhou-Xiangtan urban agglomeration of China

Carbon emission and carbon emission intensity of Circum-Changsha-Zhuzhou-Xiangtan urban agglomeration of China from 2008 to 2016 are shown in *Table 2*. As can be seen in *Figure 1*, the carbon emission of the Circum-Changsha-Zhuzhou-Xiangtan urban agglomeration from 2008 to 2016 can be divided into two phases. The first phase, 2008-2011, shows a steady upward trend in total carbon emissions at a relatively high growth rate, with the highest growth rate (15.18%) in 2011, increasing from 26.21×10^7 tons in 2010 to 30.19×10^7 tons in 2011, and the carbon emissions of the three major industries also increased rapidly in this period. In the second phase, 2011-2016, the total carbon emissions fluctuated slightly, with positive and negative growth alternately. The industrial carbon emission fell several times at this phase. Except for a sharp rise of the carbon emission due to the large amount of fertilizer used for the flood in 2013, it showed a slow growth in all other times. The carbon emission in transportation industry after 2011 had a lower growth rate.

Table 2. *Carbon emissions of Circum-Changsha-Zhuzhou-Xiangtan urban agglomeration in 2008-2016*

Year	Carbon emissions of the Changsha, Zhuzhou and Xiangtan urban agglomerations (10,000 tons)				Carbon intensity (ton/10,000 yuan)
	Agricultural carbon emissions	Industrial carbon emissions	Transportation carbon emissions	Total carbon emissions	
2008	670	19093	1681	21444	2.45
2009	765	20899	2196	23860	2.31
2010	795	22569	2849	26213	2.09
2011	877	25805	3509	30191	1.95
2012	880	24658	4548	30086	1.70
2013	1326	25322	5214	31862	1.62
2014	986	23932	5594	30512	1.41
2015	981	23006	6022	30009	1.28
2016	1000	22956	6479	30435	1.19

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94939504

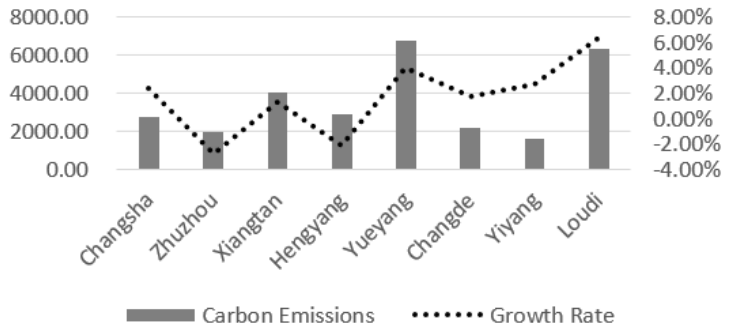

Figure 1. *Carbon emissions and growth rate of Circum-Changsha-Zhuzhou-Xiangtan urban agglomeration in 2008-2016*

The EKC curve (Grossman and Krueger, 1995) is used to further explore the relationship between economic development and environmental pollution. Based on the data of carbon emissions and GDP per capita from 2008 to 2016 in the Circum-Changsha-Zhuzhou-Xiangtan urban agglomeration, a EKC curve regression model for the urban carbon emission including primary, secondary and tertiary terms is established:

$$Y = \alpha_0 + \alpha_1 X + \alpha_2 X^2 + \alpha_3 X^3 + \varepsilon \quad \text{(Eq.12)}$$

where Y and X respectively indicate the carbon emission and per capita GDP of the urban agglomeration, and α0, α1, α2, α3 and ε indicate the parameters to be estimated and the random error term. The regression analysis and test are carried out by using the software of E-Views (9.0). It is found that the quadratic function fitting curve is the best, with the fitting degree of 0.971, the F value is 101.75, and the P values all pass the significance test. The metrology model is shown in *Figure 2*, the carbon emission and per capita GDP of Circum-Changsha-Zhuzhou-Xiangtan urban agglomeration shows an obvious "inverted-U" curve.

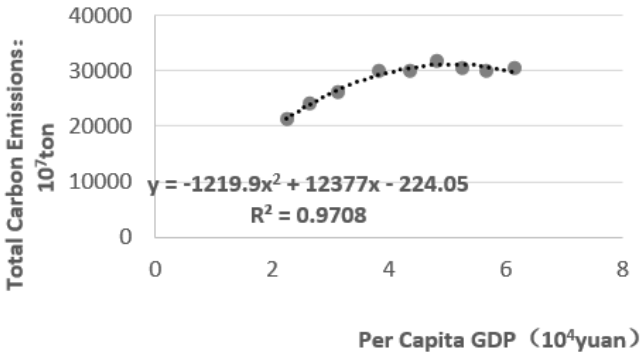

Figure 2. *Curve of carbon emissions and per capita GDP Circum-Changsha-Zhuzhou-Xiangtan urban agglomeration in 2008-2016*

According to the derivation of the fitting curve, the stagnation point is 5.073, that is, when the per capita GDP exceeds 5.073, the carbon emission is likely to fall, which

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94939504

may be due to complicated reasons: for example, the vigorous development of heavy industry in the early period of the economic downturn to rapidly improve the economic level has led to increased pollution. As the environment deteriorates and resource scarcity increases, the public has paid more attention to energy conservation and emission reduction and accelerated the research and development of high-tech and environmentally-friendly technology products, so the urban carbon emission has in turn been controlled.

Driving factor decomposition results

The LMDI decomposition results are shown in *Table 3*, as can be seen in conjunction with the judgement matrix (*Table 4*). During 2008-2016, the carbon emission in the Circum-Changsha-Zhuzhou-Xiangtan urban agglomeration of China increased 5 times and decreased 3 times, industrial structure and energy intensity suppressed the carbon emission of the urban agglomeration, and the economic development and human capital played an important role. Among them, the economic effect is the most remarkable, and its annual contribution to the growth of the carbon emission in the Circum-Changsha-Zhuzhou-Xiangtan urban agglomeration was 87%, so the increase of carbon emission in the urban agglomeration mainly depended on the driving value of economic development. The negative driving effect of industrial structure was obvious from 2009 to 2012, but the driving effect of energy intensity from 2012 to 2016 was obviously higher than that of industrial structure, and the contribution value increased rapidly. The growth in carbon emission in the urban agglomeration slowed down after 2013.

Table 3. *Driving factors decomposition of carbon emissions of Circum-Changsha-Zhuzhou-Xiangtan urban agglomeration in 2008-2016*

Year	ΔC	ΔC_{Bi}	ΔC_D	ΔC_I	ΔC_K
2009	5.58	-19.43	-9.62	28.94	5.69

2012-2013	↑	-	-	+	+
2013-2015	↓	-	-	+	+
2015-2016	↑	-	-	+	+
		Not obvious	Obvious	Obvious	Not obvious

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94939504

From the time series, the contribution value of each factor is increasing year by year. Besides the negative growth of industrial structure after 2014, there is still room for adjustment. The growth rate of the contribution of the four driving factors to the urban carbon emission has gradually slowed down, but the growth rate gap is relatively obvious, of which the energy intensity contribution value has the fastest growth, with an average annual growth rate of 62.52%. Therefore, in 2013, its contribution value quickly exceeded the industrial structure and gradually had a gap, effectively suppressing the increase of carbon emissions of the urban agglomeration, which indicates that giving enough attention to energy consumption can effectively promote the process of green development.

Decoupling analysis

From *Table 5*, the overall results show that the decoupling elasticity of the Circum-Changsha-Zhuzhou-Xiangtan urban agglomeration of China was mainly declining, with strong decoupling in 2011-2012, 2013-2014 and 2014-2015, that is, the carbon emission is decreasing with the economic growth, but weak decoupling in the rest of the years, which indicates that the overall economic growth rate is slightly higher than the carbon emission growth rate, and there is a strong decoupling trend.

"E"stands for Elasticity; "S" stands for Status; "W.D"stands for Weak negative decoupling; "S.D"stands for Strong decoupling; "E.N.D"stands for Expansion negative decoupling; "E.C"stands for Expansion connection

By cities of the Circum-Changsha-Zhuzhou-Xiangtan urban agglomeration of China, there have been four strong decoupling phenomena in Changde and Hengyang, in which Hengyang was in the state of expansion connection during 2008-2009, that is, its carbon emission increased faster than the economic growth. It has been in a strong decoupling state since 2013. Changsha, Zhuzhou and Xiangtan, as the core regions of the Circum-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94939504

Changsha-Zhuzhou-Xiangtan urban agglomeration, are not in an ideal state of decoupling, and Changsha's carbon emission increased rapidly, with a negative decoupling of expansion between 2015 and 2016, that is, the growth rate of carbon emissions was far faster than the economic growth rate. In the later development, we should pay attention to the environmental governance. After 2013, Zhuzhou and Xiangtan mainly show a strong decoupling trend, that is, the correlation between economic development and carbon emission will gradually weaken, which is more conducive to energy conservation and emission reduction. The decoupling in Yiyang and Loudi was not satisfactory. The economic growth rate was slightly higher than the carbon emission growth rate, but lower than the average level of the urban agglomeration. According to the "inverted-U" curve between carbon emission and per capita GDP in *Figure 2*, Yiyang and Loudi are still in the increasing stage of "inverted-U" curve, so the two cities should first focus on promoting the economy, only after the economic development to a certain level, is there enough funds and foundation to effectively promote energy-saving and emission reduction.

Conclusions and suggestions

In this paper, the carbon emission of the Circum-Changsha-Zhuzhou-Xiangtan urban agglomeration of China is decomposed into three parts: agriculture, industry, and transportation. At the same time, based on the panel data from 2008 to 2016, this paper uses LMDI decomposition method to calculate the direction and contribution value of the different factors that drive the carbon emission change of the urban agglomeration. Finally, the decoupling elasticity index is used to calculate the decoupling elasticity of each city and the urban agglomeration as a whole, and the following conclusions are drawn:

First of all, the annual growth rate of carbon emission of the Circum-Changsha-Zhuzhou-Xiangtan urban agglomeration is decreasing gradually though its carbon emission is rising and the fluctuation of industrial carbon emission is the most obvious. Therefore, the carbon emission of the whole city has an alternatively positive and negative growth trend after 2011. According to the results of the EKC curve, it is found that the carbon emission and the per capita GDP have a relatively obvious "inverted-U" curve, that is, when the per capita GDP reaches the stagnation point of 5.073 of the curve, with the increase of per capita GDP, the carbon emission shows a downward trend instead. Second, from the driving factors, industrial structure and energy intensity have the restraining effect on the total carbon emission, while economic development and population scale have driven the growth of the carbon emission, of which the driving role of economic development is the most significant and is the main reason for the increase in the carbon emission. The restraining effect of energy intensity gradually shows up in the later period and exceeds the negative driving effect of industrial structure, as the main factor that promotes the decrease in the carbon emission intensity. Finally, the overall decoupling of the Circum-Changsha-Zhuzhou-Xiangtan urban agglomeration is good and its carbon emission growth is always weaker than economic growth in the research period. The elasticity decoupling result in Hengyang and Changde is better, and their economic development and carbon emission both show strong decoupling trend but still have great room in Loudi and Yiyang. However, in Changsha, Zhuzhou and Xiangtan, as the core region of the urban agglomeration, the effect of decoupling is not obvious though the level of the economic development is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_94939504

relatively high, and the economic development is only slightly faster than the growth of carbon emission. In the later development, more emphasis should be placed on energy conservation and emission reduction

In the future research, there is still something worthy of further exploration. First of all, for the research objectives, this paper only studies the Circum-Changsha-Zhuzhou-Xiangtan urban agglomeration, which includes eight cities, the results are not universal; the range of the research objectives can be expended in the future. And then, due to the lack of some data, the calculation of carbon emissions is not comprehensive, for example, date of agricultural film and pesticides have not found. Finally, for the driving factors of carbon emissions, this paper only chooses the most significant four factors according to the research of a large amount of literatures, which can be extended for more measurement. Under such circumstances, this paper can only be regarded as a rough evaluation and preliminary study on the carbon emissions of the Circum-Changsha-Zhuzhou-Xiangtan urban agglomeration. As for the more in-depth content and more precise conclusions, it needs to be enriched in the future research. At the same time, I also hope that the research in this paper can be used as a reference for the research work of other scholars, and can provide useful thinking for the green development and practical work of urban agglomerations.

(Received 16th Apr 2019; accepted 22nd May 2019)

Abstract. The goal of this study is to establish the relationship between RTI and the meteorological factors, and make a precise prediction of the occurrence of RTI in China. The statistical data was collected from four tertiary hospitals in Beijing from 2008 to 2012. The association was analyzed using a backward propagation-artificial neural network model (BP–ANN) regression model (built by Matlab) which has three layers (including one hidden layer). Based on the SPSS 20.0 platform, regression analysis was used to evaluate the effect of meteorological factors on RTI. The results show that the most significant factors are atmospheric pressure, temperature, precipitation and sunshine duration, whereas wind speed is less significant. The combination of long sunshine duration, high temperature, low pressure and high humidity is the high-risk condition that leads to RTI. The coefficient ($r = 0.7199$) obtained by the PB neural network is much higher than the coefficient ($r = 0.427$) obtained by the Stepwise Regression Model. Meteorological factors have a certain effect on traffic injury severity. And the BP–ANN model is a quite precise prediction model for RTI, and this research can provide technical support for the improvement of forecasting and early warning of RTI, in further.
Keywords: *risk factors, traffic accident, regression analysis, artificial neural network model, risk warning*

Introduction

Road traffic injuries (RTI) are a major global public security issue (Toroyan, 2009). According to a recent report of the World Health Organization (WHO) in May 2015, 1.24 million people are killed by RTIs annually all over the world. This is the leading cause of death in the 15-29 age group. About 91% of the deaths occur in the low and middle-income countries, while these countries only occupy half of vehicles in the world. It is estimated that RTI will cause 1.9 million deaths from fatal accidents in 2020, and RTI will become the fifth leading cause of death in 2030 (World Health Organization, 2015). For China, the largest developing country in the world, the annual number of deaths caused by RTI increased from about 50,000 in the mid-1980s to more than 100,000 at present (Zhang, et al., 2007; Dong and Peng, 2012). The mortality of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95059514

China is very moderate compared to the average value of world. However, China has the largest population in the world, which makes the death toll huge and result in heavy disease burden and enormous medical expenditure. RTI have become one of the leading causes of unintentional death in China (Gao et al., 2013). Beijing, as the capital of China, has the largest number of vehicles in the country, so, the research about RTI is indispensable.

Thus far, research on RTI focused primarily on human factors, mechanical factors, and road facilities (Evans, 2001; Bendak, 2005; Nakahar et al., 2005; Javouhey et al., 2006; Morgan and Mannering, 2011). However, meteorological factors have received little attention. Nevertheless, the occurrence of RTI is the combined result of human factors, mechanical factors, road facilities and meteorological factors. The change of meteorological factor will have an effect on the other three, leading to the occurrence of RTI. Meteorological factors can cause RTI by affecting mental and psychological state, reaction time, vision, vehicle flow and speed, as well as road conditions (Majdzadeh et al., 2008; Abe et al., 2008; Naci et al., 2009; Gill and Goldacre, 2009; Cools and Moons, 2010; Akin et al., 2011; Kim et al., 2012; Kashani et al., 2012; Grjibovski et al., 2013). For example, precipitation can make road slippery, reduce the friction between vehicles and roads, and increase the difficulty of operating vehicles. Rainfall can reduce the clarity of the windshield of the vehicle. Rainy days will also cause poor visibility of the surrounding environment, affecting both drivers' and pedestrians' vision. Therefore, it is necessary to study the influence of meteorological factors on RTI for effective prevention of traffic injury.

Based on statistical data collected from four tertiary[1] hospitals in Haidian District, Beijing from 2008 to 2012, the effect of gender, age, date and the effect of meteorological factors were studied using regression analysis in order to determine the main influencing factors on RTI. These factors were used as the predictors in the construction of a backward propagation-artificial neural network model (BP–ANN) with Matlab. BP-ANN is one of the most successful algorithms for the machine learning study which is originally inspired by modeling biological neural systems (more details in the "Model structure" section). Stephan (Stephan et al., 2003) used BP-ANN to create the risk evaluation to prostate cancer. In the study it was found that the ANN technique can be applied to the problems which cannot be solved by any other effective way, and it is particularly suited to evaluate the risk of cancer. In fact, the BP-ANN model can not only used to evaluate the disease, but also to some other significant field. Therefore, we introduced BP-ANN here to make a precise prediction of the occurrence of RTI and provide technical support for decreasing RTI and reducing economic loss.

Resources and methods

Resources

In this study, statistical data of 1825 groups from Jan 1st, 2008 to Dec 31st, 2012 were collected from four tertiary hospitals in Haidian District, Beijing. The data of each group consist of the number of RTI, pressure, humidity, temperature, sunshine duration, rainfall and wind speed in Haidian District. Those meteorological data mentioned above

[1]Tertiary hospital is the highest level of Chinese hospital grade, with more than 501 beds, and provides high-level specialist medical services, performs higher education and scientific research tasks in several regions.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95059514

were provided by the National Scientific Data Sharing Platform for Population and Health. All the collected data were divided and analyzed according to three dimensions: the age and gender of each injured person, weekly number of RTI, and the value of the corresponding meteorological data (average values for each week).

Regression analysis

Based on the SPSS 20.0 platform, regression analysis was used to evaluate the effect of meteorological factors on RTI. Major influencing factors were determined through the comparison of the Pearson correlation coefficient (r) and its statistical significance (p) between meteorological factors and RTI. Moreover, the correlation between RTI and the different meteorological factors (such as temperature, relative humidity, pressure, precipitation, sunshine time and wind speed, respectively) were analyzed to determine the main influencing factors.

Construction of the BP-ANN model

Data set

All the data were used to construct the BP–ANN model with Matlab. 195 randomly selected groups were used as the training data set and the other 65 groups were used as the test data to evaluate the performance of the optimal BP–ANN model. The large difference between the dimension and the data values of the meteorological factors might affect the forecasting performance of the BP–ANN model. Therefore, the meteorological factors were employed as the independent variables, including atmospheric pressure, atmospheric temperature, precipitation and sunshine duration. And the gaps of each level of these independent variables in the model were 5 hPa, 5 °C, 2 mm and 2 h respectively. Meteorological parameters are input variables as while as the weekly RTI are output variables.

Model structure

Three parts mainly composed of BP-ANN model: an input layer, a hidden layer and an output layer. There are several nodes in each layer mapping the input vector (in the input layer) to the output vector (in the output layer) by a continuingly updating weight vector (in hidden layer). The weight is updated by each iteration error (the difference between the output value and the real value). The model iterates until the prediction matches the real scenario. BP-ANN is a data-based research method. It uses real world data as the input training set to predict output values in the future without any human experiences.

In our study, the data in the input layer (4~5 neurons) were selected from those meteorological factors which directly or indirectly affect RTI, based on the regression analysis. A suitable number of hidden neurons should be determined during model construction. The number of RTI was chosen as the output layer in the BP model.

The tansig and purelin were selected as transfer functions in the hidden layer and output layer, respectively. The traingdx, an adaptive training function with momentum, was used for network training. This algorithm is able to adjust the learning rate and the incidental momentum automatically, avoiding local minima. Moreover, it accelerates the convergence rate considerably (Shi et al., 2009).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95059514

Evaluation of model performance

We used the mean squared error (MSE), one of the most widely used evaluation indices of model performance between the monitored and predicted values, to test the prediction accuracy of our BP–ANN model: smaller values of the MSE represent better performance of the model. Another common evaluation index is the correlation coefficient (r), a measure of the relationship between monitored and predicted values. A higher r indicates better performance of the BP–ANN model.

Results and discussion

Influence of different factors on RTI

Influence of gender and age on RTI

Summary statistics of the age and gender distribution of outpatients from 2008 to 2012 (1,827 days) are shown in *Table 1*. In total, 6,295 hospital admissions for RTI were recorded, and the value was the statistical description of daily value of the patient demographics.

Table 1. *Summary statistics of the age and gender distribution of outpatients*

Term		Mean	SD	Min	Median	Max	IQR
Gender	Male	2.10	1.48	0	2	10	2
	Female	1.35	1.28	0	1	20	2
Age	1-17	0.29	0.15	0	1	4	1
	18-40	1.68	0.97	0	3	10	5
	41-65	1.25	0.83	0	3	13	4
	>65	0.22	0.12	0	1	11	2

SD: standard deviation, IQR: inter quartile range

It is seen that there were approximately 4 RTI per day, on average. The number of male traffic injury patients (2.10 cases per day) was larger than that of female (1.35 cases per day). The ratio of male to female is 1.56:1. In the 1-17 age group, 0.29 cases of traffic injury occurred, on average, every day. In the 18-40, 41-65 and 65 or over age groups, the daily traffic injury cases were, on average, 1.68, 1.25 and 0.22, respectively. The maximum mean value of the youth group is 1.35 times that of the adult group, 5.79 times that of the adolescent group and 7.64 times that of the aged group. The result is similar to what was reported by Yu and Wang et al. (2004), who discovered that young male adults, as the primary labor force, are more exposed to traffic injury. The relationship between these meteorological factors and RTI will be analyzed in next.

Influence of the days of the week and of mental state

The variation of the number of RTI is indicated in *Table 2*. From 2008 to 2011, the number of outpatients was rising and the growth rate was 9.73%, 9.20% and 4.40%, respectively. Comparing with the figures corresponding to the periods 2008-2009 and 2009-2010, during the period 2010-2011 RTI decreased sharply. Until 2012, the number of outpatients had fallen to 1125 cases and the decline rate was 27.38%. The reason

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95059514

might be that the "vehicle purchase restriction policy" introduced in Beijing in 2011, which greatly reduced the private car purchases. On Monday, Wednesday, Saturday and Sunday, the average total number of outpatient visits is similar: 182, 186, 179, 183 cases respectively. The number of RTI patients is 2.5% higher on Sunday than that of Saturday, however, the chi-square test showed that the difference is statistical meaningless. In contrast, it reached a peak (202 cases) on Friday and a valley (163 cases) on Tuesday. The data above were divided into 2 parts. One was from Monday to Thursday and the other was from Friday to Sunday. The corresponding averages were 173.6 and 188.2, respectively. This is similar to the result of "a week working rhythm", by D. S. Moskowitz. The research concluded that people tend to be more energetic at the beginning of the week and then gradually get fatigued. Especially on Tuesday, people are more controlled, efficient and concentrated on work. In contrast, they are more reckless on Friday. It is reported that on Friday, drivers hasten to participate in entertainment activities and alcohol consumption is higher. This leads to a 13% higher occurrence rate of RTI.

Table 2. *Comparison of RTI on different days in one week*

Year	Mon	Tue	Wed	Thu	Fri	Sat	Sun	Total
2008	167	147	171	157	184	145	152	1123
2009	155	135	197	187	201	184	185	1244
2010	202	205	187	158	227	194	197	1370
2011	216	176	213	178	236	209	205	1433
2012	169	150	160	142	164	162	178	1125
Average	181.8	162.6	185.6	164.4	202.4	178.8	183.4	1259

The influence of drinking and medicine should be considered in this study. But according to the information gathered from the emergency doctors who collected the data, the RTI caused by drunk driving only occupies the proportion very few. Meanwhile, Saha et al. (2016) pointed out that the odds of risk factors (alcohol, drug involvement and so on) were low, among these fatalities associated with adverse weather conditions. So it can be considered that the effect of drinking and medicine are minimal.

Determination of critical meteorological factors

To study the effect of meteorological factors on RTI in Beijing, the Spearman Correlative Analysis Method was employed. It was found that performance was superior when weekly data was used. Comparing to daily data (level of meteorological factor), it was able to eliminate strong "Weekly Effect" of RTI. The correlation among RTI, pressure, temperature, relative humidity, precipitation, sunshine duration and wind speed, on weekly basis, is shown in *Table 3*.

It was shown that RTI have a strong positive correlation with temperature, precipitation and sunshine duration and were negatively correlated with pressure. No correlation of statistical significance with wind speed was obtained.

According to Hani et al. (2009), as temperature increases, the sensitivity of body decreases, the heart rate increases and the driving and physical capacity decrease. Moreover, temperature increase could cause debility and that could seriously affect

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95059514

drivers (Cool and Moons, 2010; Keay and Simmonds, 2005). As reported previously (Brijs et al., 2006; Bossche and Wets, 2005), temperature is positively correlated with vehicle flow and speed, which are the important factors in RTI. This research showed that RTI are positively correlated with sunshine duration, as in Brijs et al. (2006). A longer sunshine duration will lead to the increases of air temperature. On the one hand, high atmospheric temperature will induce drivers' persistent excitability of nervous system; they will get tired more easily than usual. On the other hand, the longer sunshine show that the daytime is longer than night time, people prefer to drive on the daytime. Therefore, RTI increase accordingly.

Table 3. *Spearman correlations between RTI and meteorological factors*

	RTI	**Temperature (°C)**	**Relative humidity (%)**	**Pressure (hPa)**	**Precipitation (mm)**	**Sunshine time (h)**	**Wind speed (m/s)**
RTI	1.000						
Temperature (°C)	0.103**	1.000					
Relative humidity (%)	0.033**	0.394**	1.000				
Pressure (hPa)	-0.079**	-0.872**	-0.375 **	1.000			
Precipitation (mm)	0.043**	0.199**	0.471**	-0.258**	1.000		
Sunshine time (h)	0.084**	0.175**	-0.561**	-0.084**	-0.363**	1.000	
Wind speed (m/s)	0.036	-0.026*	-0.477**	0.013	0.025*	0.265**	1.000

*$P < 0.05$; **$P < 0.01$

In this study, it is shown that there is a positive correlation between the precipitation and RTI (OR = 0.148, $p < 0.05$). Precipitation can reduce the friction coefficient, the visibility of the surroundings and the sharpness of the windshield (Qiu and Nixon, 2008). Moreover, it may influence the judgment of drivers and pedestrians (Andrey, 2010). Wang et al. (2014) pointed out that rain and snow are the two leading causes of traffic accidents in Gansu province, China. They account for 97.58% of the traffic accidents caused by meteorological causes. Some studies have confirmed that precipitation is an important risk factor (Bendak, 2005; Zhang et al., 2000; Warrell and Univ, 2012), whereas others assert that rain may in fact reduce the risk of car accidents, as drivers are forced to drive at lower speeds (Hani et al., 2009; Zhang et al., 2000). This may be attributed to regional differences.

In this study, it is shown that the number of outpatients is negatively correlated with pressure. Warrell and others found that the emotions of people and animals could be affected by low pressure, with symptoms such as chest distress, shortness of breath and irritability (Warrell and Univ, 2012; Franka and Rupprecht, 2011; Alice et al., 2011). The combination of high temperature, low pressure, and high humidity has a negative effect on physical capacity; therefore drivers should be particularly attentive to the pedestrians.

In any event, atmospheric pressure, temperature, precipitation and sunshine duration may be considered as the major meteorological factors that influence RTI in Beijing.

Prediction of RTI using a BP–ANN model

An increase of the number of hidden neurons can improve prediction accuracy. However, this leads to a longer learning process and reduced ability for generalization (May and Sivakumar, 2009; Sadrzadeh et al., 2009). In contrast, a decrease in the number of hidden neurons will result in smaller fault tolerance and capacity to identify

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95059514

the new data that will be imported (Maier and Jain, 2010). Thus, the number of hidden neurons should be suitably chosen in order to enhance the prediction accuracy of the BP–ANN model. In this paper, a comparison of the value of the MSEs of the true value and the forecasting value of the test data with different number of hidden neurons (3~12) in the hidden layer was made, in order to obtain the optimal performance of the BP–ANN model. The result is shown as *Figure 1*. When the number of neurons was 6 in the hidden layer, the minimum MSE (which was obtained after 30 parallel calculations) of the true and the forecasting value was 0.48. This signified optimal performance of the BP–ANN model.

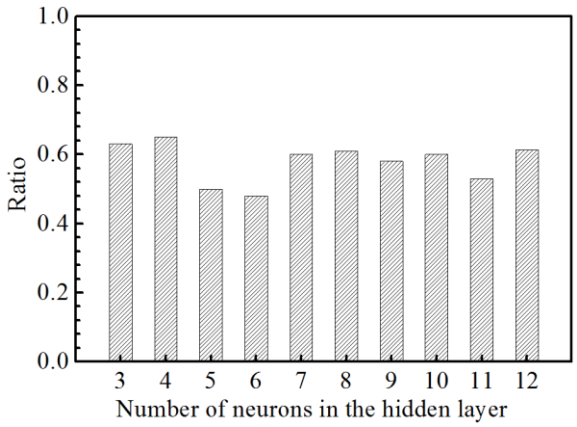

Figure 1. *Ratio of MSEs of the true value to forecasting value vs. different number of neurons in the hidden layer*

Figure 2a and *b* show the relationship between the true value and the forecasting value of the test data with optimal performance of the BP–ANN model. Since our investigation of the RTI was conducted in Beijing, a relatively high coefficient ($r = 0.7199$) was obtained. This is much higher than the coefficient ($r = 0.427$) obtained using the Stepwise Regression Model (Ji, 2015). Thus, the BN-ANN model constructed in this work was capable of making an effective prediction of the RTI when using the average pressure, temperature, rain and sunshine duration as the input data.

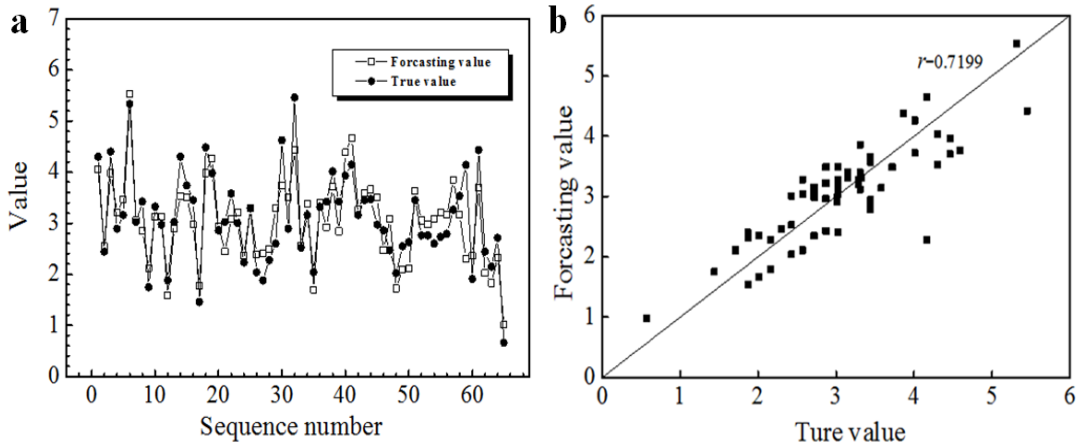

Figure 2. *Regression plots (a) and comparison (b) of the true and forecasting values of the test data of RTI*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95059514

Moreover, the model performed better when it was used for the prediction of RTI in the interval between 2 to 4. This is probably due to the relatively limited data set and the small interval used for the construction of the BP–ANN model. Therefore, effort should be made to supply more data to the prediction model.

Conclusions

In this study, A BP–ANN regression model is investigated to analyze the relationship between the meteorological factors and RTI. The main conclusions can be summarized as below:

1) Young males (18 to 40 years old) own the highest probability of occurrence of RTI; and Friday is day with highest frequency of RTI in a week.

2) Furthermore, meteorological factors have a certain effect on traffic injury severity. The most significant factors are atmospheric pressure, temperature, precipitation and sunshine duration, whereas wind speed is less significant. The combination of long sunshine duration, high temperature, low pressure and high humidity is the high-risk condition that leads to RTI.

3) It can be concluded that the BP–ANN model is a quite precise prediction model for RTI, Furthermore, this research can provide technical support for the improvement of forecasting and early warning of RTI, in further.

Abstract. To explore meteorological and environmental impacts on human health, a distributed lag non-linear model and a generalized additive model were employed to study the exposure-response relationship between meteorological factors and respiratory system diseases from 2013 to 2016 in Funan, China. The results showed that the decline in patient numbers occurs in the high temperature seasons. At a short time lag, high temperature is a risk factor, but high temperature reduces the number of patients with respiratory system disease at long time lags. Low relative humidity (RH) increases the risk of respiratory system diseases, and largescale 48-hour temperature changes (ΔT48) increase the risk of disease for a whole range of lags. There is a remarkable correlation between morbidity and meteorological factors, with temperature minima corresponding to peaks in the number of patients. For low RH, the lag effect is obvious for the first 4 days; for higher RH, the effect is weak. A back-propagation artificial neural network model constructed in this study was capable of effectively predicting respiratory system disease, using average temperature, ΔT48, RH, and maximum wind speed as inputs.
Keywords: *temperature, relative humidity, respiratory system diseases, generalized addictive model, distributed lag nonlinear models*

Introduction

Due to their high morbidity and difficulty of prevention, respiratory system diseases are currently the fourth leading cause of death in Chinese cities (13.1%), and the third leading cause of death in villages (16.1%) (Chakraborty et al., 2014). Prevention of respiratory system diseases is still unsolved. From the perspective of disease prevention, meteorological factors are uncontrollable. There is no doubt, however, that predictable meteorological conditions affect the risk rate (RR) and criticality of respiratory system diseases to some degree, although the relevant research is quite limited (Winkelstein et al., 1968; Kim et al., 1996).

Respiratory system diseases are common and frequently occurring diseases that have been studied for a long time. In the international classification of diseases ICD-10 (a coding of diseases and signs, symptoms, abnormal findings, complaints, social circumstances, and external causes of injury or disease), beside diseases of the full

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95159528

respiratory system (J00-J99), there are two other subclasses, upper respiratory tract infections (URI) and lower respiratory tract infections (LRI) (Miyamoto et al., 2008; D'amato and Cecchi, 2008). Bull and Quayle (1982) argued that respiratory system diseases are affected by many factors, including but not limited to nutrition intake, climatic variation, and air quality. Ricciardolo et al. (2004) pointed out that the correlation between air contaminants (such as nitric oxide) and respiratory system diseases is strong, but that climate change is certain to affect air contamination even though no relevant research exists. Barreca (2012) found that extremely humid conditions increase the morbidity of respiratory system diseases; however, compare with extreme climate conditions, the study of changing trend of regular climate is more useful. Even though, the effects of meteorological factors on respiratory diseases are still unclear. And current knowledge which provided by experimental studies on the relationship is not sufficient (Kunst et al., 1993). Although the aforementioned studies have not fully clarified the relationship between meteorological elements and respiratory system diseases, fortunately, the most influential factors (such as the temperature and relatively humidity) are clearly known. Thus, quantitative research on the relationship between meteorological elements and respiratory system diseases is necessary.

In order to make such research meaningful, a representative sample is necessary. Funan county, situated in southeast China, is about 500 kilometers from the Yellow Sea. Funan has a standard temperate continental monsoon climate (Liu and Ding, 2010), with four distinct seasons. As this village has never been studied before, no urban heat island effect as well as over use of air conditioner, the influence of meteorological factors is more obvious, and differently from a city, the minimal size of the transient population reinforces the connection between patients and meteorological factors. Thus patient data concerning respiratory system diseases in Funan constitute a representative sample.

In this study, to aid in establishing and perfecting the health early-warning system, the relationship between meteorological elements and respiratory system diseases was systematically evaluated. A generalized additive model (GAM, widely applied inthe meteorological, environmental, and health fields) and a distributed lag nonlinear model (DLNM, used to describe the lagged effect of meteorological elements on health) were employed to quantitatively analyze the effects of several meteorological elements. The relative risk (RR) was used to represent the impact of a set of meteorological factors (Holcomb et al., 2001; Hoek et al., 2013; Liang, 2015; Song et al., 2018). Temperature, relative humidity (RH) and heat index (HI) were the primary meteorological factors analyzed. This study hopes to study the temperature and other meteorological elements affect the respiratory system to improve the meteorological factors on he health early-warning system. The results have far-reaching implications for respiratory system disease prevention, not only for Funan County, but also for other regions with similar climate conditions.

Materials and Methods

Data concerning diseases and meteorological elements

Funan (Anhui Province, China) has a population of 1.697 million, including 884,000 males and 813,000 females, with a sex ratio of 1.087:1. Statistical data from respiratory disease patients were collected from Jan 1, 2013 to Dec 31, 2016. The data were 391185 cases which included the date of inpatient visits, age, sex, primary diagnosis

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95159528

and address. Respiratory disease (ICD-10: J00-J99), upper respiratory disease (J00-J06, J30-J39), and lower respiratory disease (J20-J22, J40-J47) were classified according to the 10th revision of International Classification of Diseases. A total of 50 680 people were hospitalized for respiratory diseases, of which 31267 were hospitalized for upper infections and 6942 for respiratory infections.

The meteorological data mentioned above were provided by the China meteorological data sharing service system (http://cdc.nmic.cn/home.do). The data contained daily mean temperature, daily minimum temperature, daily maximum temperature, and relative humidity, were obtained and other variables from the China. The relationship between these meteorological elements and the status of the patients was systematically examined in this study.

Analysis methods

To quantitatively analyze the effects of different meteorological elements, a generalized additive model (GAM) and a distributed lag non-linear model (DLNM) were used.

A GAM assumes that linear variables and non-linear variables can be combined in the form of a sum, in which the effects of the non-linear variables can be represented by nonlinear function terms (Barnett et al., 2012; Gasparrini et al., 2015; Barr and Zacks, 2017). There are no restrictions concerning dependence relationships between the causal variables, so the flexibility of a GAM is high. A GAM uses a link function to describe the relationship between the mean of the response variable and a smooth function of each explanatory variable (Yee and Mitchell, 1991). The advantage of a GAM is the ability of this type of model to deal with highly non-linear and non-monotonic relationships between the response and the explanatory variables. In this study, smooth functions (thin-plate spline, natural spline, B-spline) were used for fitting the independent variables. The Akaike information criterion (AIC) was used to test the goodness of fit for the time series data. The model can be written as:

$$log(n) = s(Temp) + s(med\_age) + s(gender\_ratio) + \\ +s(\Delta T48, df = 7) + s(RH) + s(Wind\_max, df = 6) + dow + \alpha \quad \text{(Eq.1)}$$

where n is the number of patients; log is used as a link function; s() denotes the thin-plate spline functions for nonlinear variables; Temp, med_age, sex_ratio, ΔT48, RH and wind_max represent the temperature, median age, sex ratio, temperature difference during 48 hours (ΔT48), RH, maximum wind speed, respectively; dow (representing the effect of weekday) is a dummy variable, and αrepresents the residuals of the GAM.

The DLNM has long been used to describe the lagged effect of meteorological elements on health outcomes (Gasparrini et al., 2010; Wu et al., 2013; Gasparrini et al., 2014). It uses a cross-basis function to describe a two-dimensional relationship along the dimensions of meteorological element and lag. The choice of cross-basis functions for the meteorological element and lag are independent, so spline or linear functions can be used, while polynomial functions can be used for the lag. The resulting estimates can be plotted using a three-dimensional graph to show the relative risks for both meteorological elements and lags (MacDonald, 2015). Cross-basis functions for the meteorological elements (daily average temperature, HI, RH and so on) were established in this study. These effects were estimated using nonlinear smoothing functions for both dimensions,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95159528

in which a natural cubic spline was used for each meteorological element and a polynomial spline for the lag effect. To avoid singularity of the model, it is necessary to avoid having too many nonlinear terms. In this study, therefore, we examined only one variable for each model (the temperature in model I and HI in model II). Step-wise backwards selection was employed in the models. Also, because the HI is computed from RH and temperature, when we included HI in the model, we excluded the other two variables. Thus, the final model can be written as follows:

For temperature:

$$log(n) = cb(Temp) + s(med\_age) + s(gender\_ratio) + \\ +s(\Delta T48, df = 7) + s(RH) + s(Wind\_max, df = 6) + dow + \alpha \quad \text{(Eq.2)}$$

For HI:

$$log(n) = cb(HI) + s(med\_age) + s(gender\_ratio) + \\ +s(\Delta T48, df = 7) + s(Wind\_max, df = 6) + dow + \alpha \quad \text{(Eq.3)}$$

where *cb* denotes the cross-basis functions for nonlinear variables, and the other terms are defined as in *Equation 1*.

We also introduce the risk ratio (RR), defined as the ratio of the probability of disease development in a group exposed to a specified environment to the probability in a non-exposed control group. The RR (representing the risk of casualties caused by a unit change of environmental conditions), which can be calculated using the GAM, was used to quantify the impact of meteorological factors on the respiratory patients. The range of RR is (0, ∞); RR = 1 means no connection between exposure to an environmental condition and disease; RR < 1 means that that exposure results in a reduction of the incidence of the disease (i.e. exposure is a protective factor); and RR > 1 means the opposite (Wong et al., 1999). The corresponding 95% confidence interval was calculated using the equation:

$$95\%CI = \exp[(\beta \pm 1.96SE) \times dt] \quad \text{(Eq.4)}$$

The analyses were performed using the R-3.3.2 software environment. The "mgcv" program package was used for the GAM, and the "dlnm" program package was used for the DLNM.

Additionally, artificial neural network models trained by back-propagation (BP-ANN), originally inspired by biological neural systems, have been among the most successful algorithms for machine learning. In the disease field, BP has been used widely as a method and also a benchmark for predicting disease incidence. It can be superior to other methods because of its highly flexible ability to model nonlinearities.

BP-ANN model is mainly composed of three parts: an input layer, a hidden layer and an output layer. There are several nodes in each layer mapping the input vector (in the input layer) to the output vector (in the output layer) by a continuingly updating weight vector (in hidden layer). The weight is updated by the each iteration error (the difference between the output value and the real value). In our study, the data in the input layer (4~5 neurons) were selected from those meteorological factors which directly or indirectly

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95159528

affect respiratory system diseases determined during model construction. The number of respiratory system diseases was chosen as the output layer in the BP model.

The tansig and purelin were selected as transfer functions in the hidden layer and output layer, respectively. An adaptive training function with momentum was used for network training. This algorithm is able to adjust the learning rate and the incidental momentum automatically to avoid the local minima. Moreover, it accelerates the convergence rate considerably. Therefore, we introduce a BP-ANN model here with the goal of making precise predictions of respiratory system diseases and thereby providing technical support for decreasing diseases and reducing economic loss.

Results

Summary statistics for respiratory diseases are shown in *Table 1*. During the period of 4 years covered by this study, the average number of patients with respiratory system disease was about 38 per day (male: 24 per day, female: 14 per day). The number of patients with URI was much less than the number with LRI.

Table 1. *Composition ratio of different diseases in respiratory system*

Sequence of diseases	Name of disease	Number	Constituent ratio
1	Tracheitis	14167	27.95
2	Bronchitis	12442	24.55
3	Chronic obstructive pulmonary diseases	9413	18.57
4	Asthma	7669	15.13
5	Pulmonary heart disease	4671	9.22

The *Table 2* shows the composition ratio of different diseases in respiratory system. The top five diseases in respiratory system composition ratio are: tracheitis (27.95%), bronchitis (24.55%), chronic obstructive pulmonary diseases (18.57%), asthma (15.13%), pulmonary heart disease (9.22%). The *Table 2* shows the incidence of respiratory diseases was negatively correlated with daily mean temperature, daily mean air pressure and relative humidity, the correlation coefficients are -0.343, -0.032 and -0.122 ($p<0.01$), and positively correlated with 48-hour temperature change and wind speed, the correlation coefficients are 0.080 and 0.076 ($p<0.01$), respectively.

Table 2. *Spearman correlations between respiratory system disease and meteorological factors*

Age and sex distribution of respiratory system disease

For respiratory system diseases, as shown in *Fig. 1*, the morbidity for male patients was higher than that for female patients ($p<0.0001$). The median number of male and female patients were 21 and 12 per day, respectively.

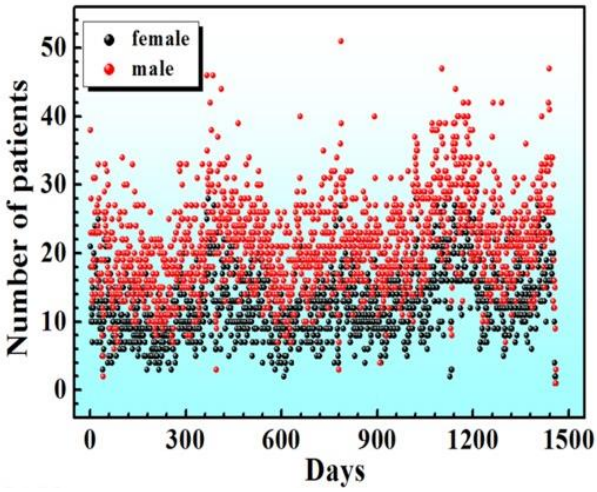

Figure 1. *Incidence of respiratory diseases per day, split by sex*

The morbidities for different age groups showed marked differences ($p<0.0001$), as shown in *Fig. 2*. For LRI, URI and total respiratory diseases, the peak morbidity appeared for newborns. The number of URI patients decreased as age increased. The trends for LRI and total respiratory disease were very similar, except that a secondary peak occurred for the age range 65-75. During the 5 years studied, the numbers of patients with respiratory system disease were relatively stable; however, the day-to-day variability was remarkable.

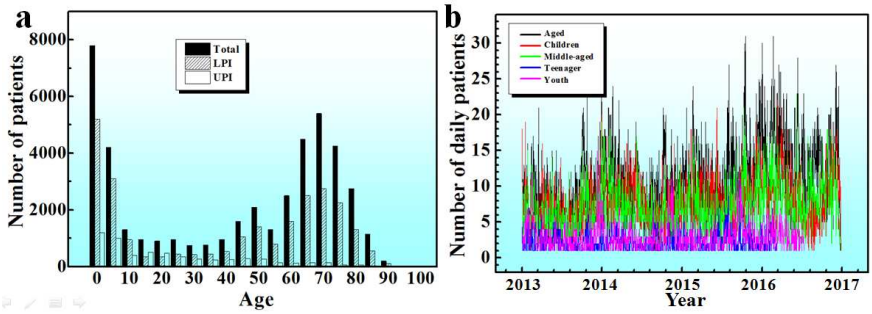

Figure 2. *Age distributions and incidences. (a) Histogram showing incidence of upper respiratory tract infections (URI), lower respiratory tract infections (LRI), and total respiratory disease, for each 10-year age group; (b) Number of patients in each age group, for each day*

For LRI and total respiratory disease, the occurrence of two peaks can be accounted for as follows: First, infants have lower resistance, their clinical symptoms are more obvious, and they make a larger number of hospital visits than adults. Second, resistance is progressively reduced as people move into old age, while the rate of visits will decrease

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95159528

if the patient is too old (more than 75). In other words, the total number of elderly patients is much less than the numbers of young and middle-aged patients. The trend for URI is different, however, because the number of URI patients (compared with LRI or total respiratory disease) is very small, and the accuracy of the statistical data is inadequate. Consequently, in the following sections, the URI is negligible.

Relationship between meteorological elements and respiratory system disease

Based on the results of the GAM, there was a remarkable correlation between morbidity and meteorological factors such as wind max and ΔT48. The relationships between the number of patients each day and various meteorological factors (temperature, HI, RH) are shown in *Fig. 3*.

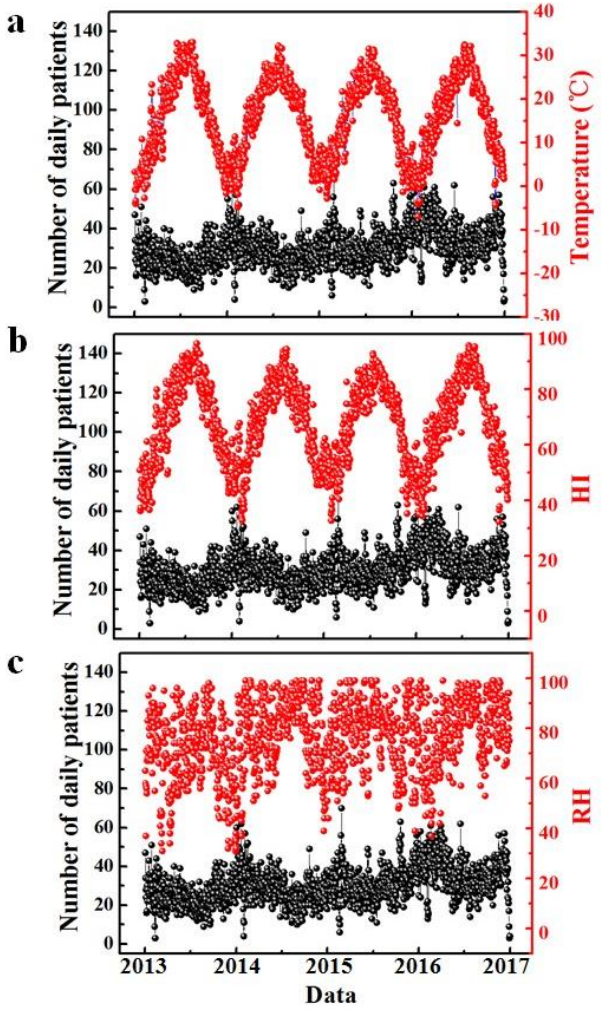

Figure 3. *Variations in three meteorological factors, and their relationships with the number of patients. (a) Plot of temperature and number of patients, by day (b) Plot of heat index (HI) and number of patients, by day. (c) Plot of relative humidity and number of patients, by day*

The patient number showed a yearly rhythm city, but the amplitude was not very high, with a difference between maximum and minimum of about 20. Meanwhile, because of the continental monsoon climate, the variations of temperature showed a similar

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95159528

sinusoidal variation. Minima in temperature corresponded to peaks in patient numbers. A similar relationship was observed between HI and number of patient. For RH, on the other hand, neither early periodicity nor any relationships with the number of patients were obvious.

The relationships between daily patient numbers and season (or month) are presented in *Fig. 4*. For total respiratory disease, the daily patient numbers for spring and winter were higher, and the number of patients in summer was lowest; the difference between the winter (maximum) and the summer (minimum) was about 30. The 3 months showing the smallest numbers were July, August, and September, corresponding to the summer season. The peak month was January. The distribution as a whole showed a "V" shape. For URI, due to the absence of significance in the statistical data, no systematic results can be stated.

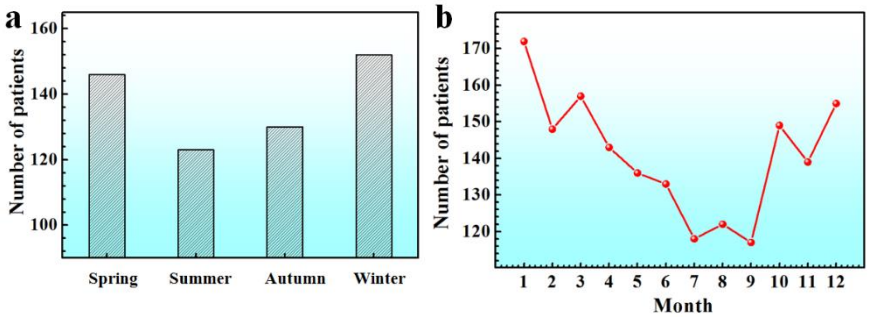

Figure 4. *Changes in number of patients as a function of time of year. (**a**) Histogram showing number of patients for each season. (**b**) Plot of number of patients for each month of the year*

Relationship between meteorological factors and number of patients

For the DLNM, the effects of sex, age, ΔT48 and wind_max were analyzed using the model shown in *Equation 2*. The maximum of lag employed was 10 days in this study, which was considered sufficient for the current study.

Fig. 5(a) shows a three-dimensional plot of the calculated RR versus temperature and time lag. The maximum RR, corresponding to lags of 0 and 7 days, was 1.05; the minimum RR was 0.92. Examining the contour plot in *Fig. 5(b)* and the curves in *Fig. 5(c)*, it can be seen that the lag effect of high temperature reached a maximum value at about 4 days; and for low temperature, at about 7 days. An interesting phenomenon can be seen here: low temperature results in the number of patients increasing typically 5 to 9 days after onset, while having protective effects in the first 4 days; whereas for high temperature, the pattern is the opposite, with protective effects for the sixth to ninth days, but harmful effects on the first to sixth days. The analysis also demonstrates a strong protective effect (high RR) of high temperatures on the first day. For a lag of 3 days, high temperature is a risk factor, but for lag of 7 days, low temperature is a risk. By 10 days, almost all temperature effects disappeared. Meanwhile, based on the previous study (*Fig. 3*), in fact, the relationship among the lag days, patient number and HI is very similar to the relationship, as revealed in *Fig. 5*. Although, the models for temperature and HI are not identical, the variation is the same.

Fig. 6(a) and *Fig. 6(b)* show three-dimensional and contour plots of RR as a function of RH and lag. For a lag of 3 days, low RH increases the risk of respiratory system disease. The minimum located at the lower left of the *Fig. 6(b)* indicates that for the first day, low

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95159528

RH shows a strong protective effect. For the lower values of RH (<50), the lag effect is obvious, attenuating after 4 days; for higher RH (>55), the effect of RH on respiratory system diseases is weak (RR≈1). The effect of ΔT48 is shown in *Fig. 6(c)* and *Fig. 6(d)*. It can be seen that high ΔT48 increases the risk of disease for the entire range of lags; lower ΔT48 plays a protective role for the first day and for lags of 5-9 days. For values of ΔT48 lower than zero, however, no cumulative effect can be observed.

Discussion

This study investigated the effects of weather on the age and sex distribution of respiratory system disease. Based on the analyses above, it can be concluded that there are strong connections between several meteorological elements and respiratory system disease. When the most important elements, such as temperature, RH, ΔT48 and wind-max, are incorporated into a model (all the selected elements are exhibited in *Equations (1) to (3)*, it can be seen that there is a negative correlation between the number of patients and the daily mean temperature (as shown in *Fig. 4*).

Because the coldest month is January, with the temperature often near or below zero for lengthy periods, the cumulative effect of temperature on respiratory system diseases s strong; thus it is not difficult to understand why the peak patient numbers appear in January. The main groups at high risk for respiratory system disease in cold temperatures are infants and the elderly. For the elderly, the older they are, the weaker their regulating ability; whereas for infants, their sensitivity is due to underdevelopment. The atmospheric pressure in winter, higher than in summer, can cause labored breathing due to the smaller pressure difference between the human body and the atmosphere. The dynamics of the respiratory system also imply that the exchange of gases inside and outside of the lungs is reduced. Also, cold air and the resulting high pressure and low humidity can combine in irritating the respiratory system. Furthermore, in winter, people spend much more time indoors, thereby increasing the probability of cross infection.

The temperature of February was colder than in March, but the number of patients was smaller. This may be attributable to the spring festival of China, the most important traditional festival, occurring in February. During the spring festival, people do not want to seek medical help except in an emergency, while at the same time the number of available medical workers is reduced. From January to March, the value of ΔT48 is positive, which also increases the risk of disease. In summer, the daily high temperature is usually above 30°C. Although, the cumulative effect can be found in the *Fig. 5(c)* from the 4~7 lag days. The most important consequence of such temperatures is a protective effect at long lags. The effects of high RH are not particularly strong. For the Funan area, where traditional agriculture is the backbone of the economy, summer is the busiest season for many people; this factor may also reduce the number of patients requesting treatment.

The coldest winter in several years came at the end of 2016 (*Fig. 3(a)*). At that time, a sudden cold wave struck most of China, including the Funan area, and the number of patients with respiratory system diseases also peaked. This phenomenon is an additional indication that extended cold temperatures are a risk factor.

To further demonstrate the effects of high or low temperatures on respiratory system diseases, the plots in *Fig. 7* can be used to examine the RR resulting from heat waves and cold spells, using different temperature thresholds. The threshold for temperature was set at different percentiles of the daily mean temperature range, and durations ranging from 1 consecutive day to 4 consecutive days were analyzed. In *Fig. 7(a)* and *Fig.7(b)*, the effects of a heat wave on respiratory disease incidence at 0 lag days and 4 lag days are very similar. As the temperature threshold increases, the RR increases, but all the values of RR are less than 1, indicating that heat waves had a consistent protective effect. For cold spells, however, the lag effect is obvious. In *Fig. 7(c)*, at a lag of 7 days, when the threshold temperature percentile is 4%, the RR is 1.58. The colder the air, the higher the risk ratios, but the RR is always higher than 1. The relationship between RR and ΔT48 threshold percentile is shown in *Fig.7(d)*. The RR was basically unchanged after 1 (or 3

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95159528

or 4) consecutive days below a given temperature percentile threshold; but for 2 consecutive days, there is an obvious downtrend of RR.

To distribute medical resources efficiently and provide suitable medical care, the prediction of respiratory system disease is indispensable. In fact, a number of prediction methods have been proposed. For example, Liu and Ding (2010) used a multi-principal component regression model to predict the death rate caused by respiratory system disease, yielding a correlation of r=0.755. In this study, a BP–ANN was used to predict the disease; the results are shown in *Fig. 8*.

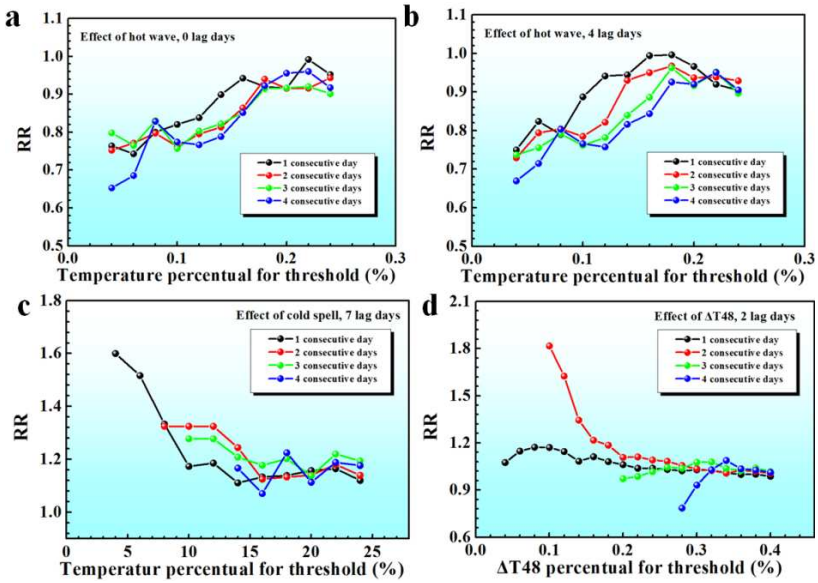

Figure 7. *Effects of heat waves and cold spells on relative risk (RR), using different temperature percentiles as thresholds. (a) Effects of heat waves of varying durations, at a lag of 0 days; (b) Effects of heat waves of varying durations, at a lag of 4 days; (c) Effects of cold spells of varying durations, at a lag of 7 days; (d) Effects of sustained temperature changes of varying durations, at a lag of 2 days*

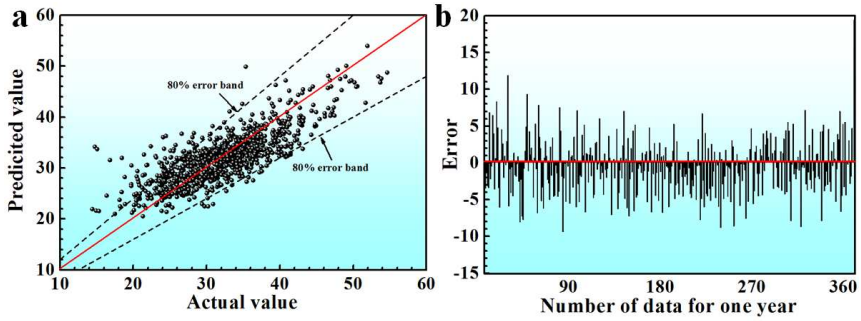

Figure 8. *Prediction accuracy of a back-propagation artificial neural network model. (a) Scatter-plot of predicted values versus actual values of numbers of patients; (b) Day-by-day errors over the course of 1 year*

Because our investigation of the respiratory system disease was conducted in Funan, a relatively high correlation was obtained. As shown in *Fig. 8(a)*, most of the predicted values are located within the 80% error band, and the number of positive errors is less

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95159528

than that of negative errors. The errors of February and March are slightly higher; this can be attributed to the complex influence factors for those months.

Thus, the BP-ANN model constructed in this work was capable of effectively predicting respiratory system disease, using the average temperature, ΔT48, RH and wind_max as input data.

Conclusions

In this study, the distributed lag non-linear model and generalized additive model were investigated to analyze the influence of meteorological factors on respiratory system diseases in Funan, China from 2013 to 2016. Furthermore, a BP-ANN based prediction method for respiratory system diseases has been developed. The main conclusions can be summarized as follows.

During the 4 years, the average number of daily patients of respiratory system disease is about 30; the morbidity of male patients is a little higher than that of female patients, and infants were the highest risk group. There is a remarkable correlation between morbidity and meteorological factors, with temperature minima corresponding to peaks in the number of patients. This may be attributed to a reduction in outdoor activities in winter as well as the influence of cross-infection. For low RH, a lag effect is obvious for the first 4 days; for higher RH, the effect is weak. Air with low RH and low temperature can lead to an increase in the number of patients with respiratory diseases, the weather conditions will dries the mucosa of the respiratory tract and damage sepithelial cells, increasing the susceptibility of the population. High ΔT48 increases the risk of disease at all time lags, while low ΔT48 decreases the risk at lags of 5-9 days. The BP-ANN model constructed in this work was capable of making an effective prediction of the respiratory system disease, with the main input variables selected being average temperature, ΔT48, RH and wind_max. A relatively high correlation was obtained for this prediction method. These developments have conducive to the distribution of medical resources and provision of appropriate medical care, not only in the Funan area, but for the entire monsoon region. In the next step of research, the pathogenic mechanism of meteorological factors on the respiratory effect should by studied, and it will reach a more accurate prediction of the target.

Abstract. Root exudates play an important role in the control of soil ecology because they are major sources of organic carbon and energy for plants, and they drive the carbon cycle of forest ecosystems. However, qualitative and quantitative methods for analysis of root exudates are poorly developed. In this study, *Fraxinus mandshurica* was used as research material for studying the influence of different collection times on the chemical composition of root exudate. The study employed qualitative and metabolomic analyses of root exudates with gas chromatography-mass spectrometry, and quantitatively analyzed root exudates of *F. mandshurica* with ultrahigh performance liquid chromatography (UPLC) and high performance ion chromatography (HPIC) methods. Root exudates were collected after harvest for 24 h at 6 h-intervals, and then analyzed. The types of sugars, amino acids, and organic acids in the root exudates were not significantly different among the four exudate samples. The results indicated that collection time strongly influenced the level of organic compounds in root exudates from *F. mandshurica*, with an optimal collection time of 12 h. In addition, quantitative analysis of root exudates using UPLC and HPIC had greater advantage, when compared with conventional analytical methods.
Keywords: *Fraxinus mandshurica, exudate, qualitative analysis, quantitative analysis, GC-MS, UPLC, HPIC*

Introduction

Root exudates refer to organic compounds actively or passively released from plant roots to the surrounding rhizosphere under specific conditions. Exudates include some low molecular weight compounds such as organic acids, sugars, phenols, and amino acids (Malandrino et al., 2011). Some high molecular weight organic compounds such as proteins and mucus are also present in exudates (Dijkstra and Cheng, 2007). Studies have shown that root exudates influence soil material cycling by changing the physical and chemical properties of soil (Materechera et al., 1992; Oades, 2010). Root exudates are affected by plant nutrient uptake (Li et al., 2007; Dinkelaker et al., 2010). They are involved plant signal transduction (Peters et al., 1986; Akiyama et al., 2005), and they interact with rhizospheric microorganisms (Bardgett et al., 2005; Singh and Mukerji, 2006). Root exudates significantly change the abundance and activity of soil microorganisms, thereby profoundly affecting organic matter decomposition and nutrient metabolism in the rhizosphere (Phillips et al., 2009; Yin et al., 2013). Root exudates play important roles in the regulation of soil nutrient transformation. These

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95299545

findings were based on analysis of the composition of root exudates. Thus, analysis of composition of root exudates is of great significance.

Research related to identification of the compositions of root exudates have focused mainly on sugars, amino acids and organic acids (Kuo et al., 1982; Zhen et al., 2004; Sandnes et al., 2005; Kerdchoechuen, 2005; Chang et al., 2008; García et al., 2010; Carvalhais et al., 2011). Thus, there is dearth of information on other components of exudates. There is need for a comprehensive analysis of the composition and trends of root exudates because they vary in types and amounts under different treatment conditions. In addition, many factors influence the composition of root exudates. These include forest type, tree species, environmental conditions, and soil nutrient availability (Zhang et al., 2007; Fransson and Johansson, 2010; Shi et al., 2011). Water culture collection method has been widely used for the collection of root exudates because it is simple to implement, and it reflects changes in certain root secretions to a certain extent, while eliminating interference from soil microorganisms (Phillips et al., 2006). However, the influence of collection time on water culture collection method for the analysis of root exudates has not been investigated. Recent studies have employed collection times of 6, 12, 18, and 24 h (Li et al., 2014; Liu et al., 2016). The compositions of root exudates have also been shown to change as a function of collection time (Bowsher et al., 2015). This is so because plants and the environment change over time in ways that affect the results of compositional analysis of root exudates. However, no studies have so far been carried out on the trends of changes in compositions of root exudates over time. Currently, studies on root exudates have concentrated mostly on qualitative analysis, with only few reports on quantitative studies. Qualitative analysis usually involves the use of various solvents to extract root exudates, and carrying out analysis using gas chromatography (GC) or gas chromatography-mass spectrometer (GC-MS). However, these methods may seriously affect the accuracy of the analysis. Quantitative analysis often involves the use of amino acid analyzer (for amino acids), high performance liquid chromatography (for organic acids), and anthrone reagent and phenol-sulfuric acid colorimetric assays (for sugars) (Xiao et al., 2015; Zhang et al., 2016; Wang et al., 2016). The accuracy and limits of detection of these methods are poor, and they lack specificity. Thus, the quantitative results are not reliable and credible. In recent years, GC-MS, ultra-performance liquid chromatography (UPLC), high performance ion chromatography (HPIC), metabolomics, and other related hi-tech methods have been widely used. These methods have the advantages of high accuracy and precision, and low detection limits, and they provide rapid analysis within relatively wide linear ranges (Rissanen et al., 2006; Kajos et al., 2015; Dietrich et al., 2016; Gargallogarriga et al., 2017). However, few studies and applications exist based on these methods for the analysis of root exudates. Therefore, it is necessary to use these methods for the analysis of root exudates.

Previous studies related to root exudates have mainly concentrated on short-growing-period plants such as crops and vegetables (Venkatasubbarao and NoriharuAe, 1997; Paynel et al., 2001; Luo et al., 2014), while similar studies on perennial forest species are rare. *Fraxinus mandshurica* (*F. mandshurica*), an important afforestation tree species with high ecological and economic value in Northeast China, has roots with well-developed branching structure (Mei et al., 2006; Ren et al., 2010). It is suitable for the study of root biology, especially in the determination and analysis of root exudates, and it has a certain level of practical significance. Therefore, in this study, the root exudates of *F. mandshurica* in the cold forests of northeastern China were qualitatively analyzed

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95299545

using GC-MS technology, and the metabolomic differences at different collection times were determined. Based on qualitative analysis, the amino acids and organic acids were analyzed using targeted UPLC method, while the sugars were analyzed with targeted HPIC method. The trend of changes in the composition and contents of components of root exudates of *F. mandshurica* at different collection times were analyzed to determine the best collection time. The goal of the present study was to establish efficient qualitative and quantitative methods for analyzing root exudates, and to provide a theoretical reference for this process.

Materials and Methods

Plant materials and culture methods

One-year-old *F. mandshurica* saplings with uniform size and robustness were selected to ensure as much consistency as possible between individual saplings. These saplings were grown in the nursery of Forestry and Environmental Sciences, Northeast Forestry University of China. The saplings were pre-cultured for 7 days using deionized water, and then cultured using a nutrient solution. The nutrient solution was replaced every 3 days during culture. The pH of the nutrient solution was adjusted to 5.5 with 0.1 M NaOH or 0.1 M HCl, and 24 h ventilation was maintained constantly. After 15 days of continuous culture, the root exudates were collected. At that time, the *F. mandshurica* saplings had vigorous root growth.

Collection of roof exudates

Prior to analysis, the roots of each *F. mandshurica* sapling were removed from the nutrient solution, washed 3–5 times with deionized water, and placed inside a 100-mL beaker which was shaded with black rubberized fabric. Then, the root exudates were collected after 6, 12, 18, and 24 h. Finally, the root exudates were dried using a vacuum freeze-drying machine (Shanghai Yuming Instrument Co., Ltd., Shanghai, China). At least, six replicate samples were used for each group of experiments.

The GC-MS analysis preprocessing methods

Next, qualitative and metabolite analyses of the root exudates were carried out using GC-MS analysis in accordance with the method of Suzuki et al. (2009), with a slight modification. First, freeze-dried root exudates were added to a cold methanol: water = 4:1 solution (1 mL). This was blown to dryness with nitrogen. Then, 20 μL of internal standard (L-2-chlorobenzene alanine, 0.3 mg/mL, configuration of methanol) was added. This was then mixed with 600 μL methanol-acetonitrile (2:1) and stirred for 30 sec. The root exudates were extracted after 10 min in an ice water bath with an ultrasonic cleaning machine (Ji Ning SIONBEST Biology Machinery Co., Ltd., Shandong, China). Next, samples were centrifuged for 15 min at 13000 rpm and at temperature of 4°C. Then, 500 μL supernatant was loaded into a glass derivative bottle, and the samples were dried with a centrifuge drying apparatus (Labconco Corporation, Kansas, Missouri, USA). Thereafter, 80 μL of 15 g/L methoxyamine hydrochloride pyridine was added and allowed to react for 90 min, with oscillation of the reaction mixture at 37°C. Next, 80 μL bis(trimethylsilyl)trifluoroacetamide (1% trimethylchlorosilane) was added and allowed to react with the oxime reaction for 60 min at 70°C, accompanied with

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95299545

oscillation (Young et al., 2010). Finally, the samples were filtered into GC sample bottles using a filter membrane (Pall Corporation., New York, USA) (0.45 μm), and used in the metabolomic analysis with GC-MS.

Chromatographic conditions for GC-MS analysis

A GC-MS analyzer 7890A-5975C (Agilent, Santa Clara, CA, USA) and an HP-5MS capillary chromatographic column (30 m × 0.25 mm × 0.25 μm, Agilent J&W Scientific, Folsom, CA, USA) were used for GC analysis. The initial temperature of the chromatographic column was 60°C, and it was ramped up to 310°C at the rate of 8°C/min, and held for 6 min. Sample volume was 1 μL, inlet temperature was 260°C, and high purity helium was used as carrier gas at a flow rate of 1.0 mL/min. Electric impact was used as ion (EI) and the ion source temperature was 230°C. Quadrupole temperature was 150°C, and the electron energy was 70 eV. The scanning square was full scan mode (SCAN), and the quality scanning range was 50–600 m/z. Continuous sample analysis was carried out in random order to avoid the influence caused by fluctuation in the instrument signal.

Metabolite identification and integration of data matrix

The original data of GC/MS (D format) was converted to general format (CDF format) through Chem Station analysis software (Version E.02.02.1431, Agilent, USA), and the data pre-processing used Chroma TOF software (Version 4.34, LECO, St Joseph, MI, USA). It included peak extraction, noise elimination and deconvolution, and used the standards of the US National Institute of Standards and Technology and the Fiehn database to identify metabolites. Finally, peak alignment was performed, and 3D data matrix (original data matrix) in CSV format was derived.

Methods used for metabolite data analysis

The metabolite content was used as X variable. Then, a matrix was established and imported into SIMCA-P 14.1 (Umea, Sweden) software for multivariate statistical analysis. The clustering was analyzed using PCA (principal component analysis, PCA). Then, a reliable statistical analysis model was established using partial least-squares discriminant analysis (PLS-DA) which searched for significant differences between samples taken at different time points, and identified which biomarkers were useful for classification. The reliability of the model was evaluated using the explanatory power of model to variables (R2) and predictive ability (Q2), while the fit of the model was assessed using overfitting evaluation index R2- and Q2-intercepts. Significant differences between metabolites was determined using loading plot of PLS-DA and the Variable Importance for the Projection (VIP). The biomarker was VIP>1.

Analysis of amino acid content

The amino acid content was analyzed with UPLC. The amino acids were derivatized using o-phthaldialdehyde and fluorenylmethyl chloroformate, and qualitative analysis was carried out through the retention times of chromatographic peaks, while quantitative analysis was done using external standard method. Freeze-dried root exudates were used for analysis of amino acid targets, with addition of deionized water (1 mL) under

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95299545

ultrasonic conditions. After centrifugation for 10 min at 12000 rpm, it was filtered through a 20 μm filter membrane.

Preparation amino acid standard samples

Amino acid standard (1 mL, 1000 pmol/μL) was divided into ten parts (100 μL). The standard contained aspartic acid (Asp), glutamic acid (Glu), asparagine (Asn), serine (Ser), glutamine (Gln), histidine (His), glycine (Gly), threonine (Thr), arginine (Arg), alanine (Ala), tyrosine (Tyr), valine (Val), methionine (Met), tryptophan (Trp), phenylalanine (Phe), isoleucine (Ile), leucine (Leu), lysine (Lys), and proline (Pro). Amino acid supplement solution I was prepared by weighing Asn (237.8 mg), hydroxyproline (236 mg), Glu (263.08 mg) and Trp (367.8 mg) into a measuring flask (100 mL), and adding 0.1 M hydrochloric acid (50 mL). The amino acids were dissolved under ultrasonic conditions, and then diluted to scale with deionized water. Amino acid supplement solution II was prepared by dissolving norvaline (234.32 mg) in 100 mL of 0.1 M HCL in a 200 mL measuring flask, under ultrasonic conditions and then diluting to scale with deionized water. This solution was used as an internal standard solution. The mixed standard solution was prepared by mixing amino acid supplement solutions I and II (10 μL of each). The mixture was vortexed using a vortex vibration instrument (Shanghai Jingke Industrial Co., Ltd., Shanghai, China). The mixed standard solution was diluted to 1:1000, 5:1000, 10:1000, 100:1000, 200:1000, 500:1000, and 1000:1000 to generate gradient concentrations of each amino acid standard i.e. 1 nmol/mL, 5 nmol/mL, 10 nmol/mL, 100 nmol/mL, 200 nmol/mL, 500 nmol/mL, and 1000 nmol/mL, respectively.

UPLC detection method

Model U3000 DGLC UPLC analyzer (Thermo Fisher Scientific, Waltham, MA, USA) and Advance Bio AAA C18 chromatographic column (4.6×100 mm, 2.7 μm, Agilent J&W Scientific, Folsom, CA, USA) were used for amino acid analysis. The automatic sampler program involved valve switch to bypass 6 sec after sample injection. The sample (1.0 μL) and borate buffer (2.5 μL) were mixed five times at the cleaning mouth (3.5 μL), and after 12 sec, o-phthaldialdehyde (0.5 μL) was added, and mixed ten times at cleaning mouth (4.0 μL). Next, fluorenylmethyl chloroformate (0.4 μL) was added and mixed ten times at cleaning mouth (4.4 μL), followed with addition of double-distilled water (ddH_2O) (15.6 μL) and mixing eight times at cleaning mouth (20 μL). Finally, the sample was injected into the chromatographic column. The chromatographic conditions were: column temperature of 40°C and flow rate of 1.5 ml/min. Mobile phase A was 10 mM sodium hydrogen phosphate and 10 mM sodium borate solution, with pH adjusted to 8.2 with hydrochloric acid. Mobile phase B was methanol: acetonitrile: water at volume ratio of 45: 45: 10. The gradient program used was 2% B for 0-13.4 min, 57% B for 13.4-13.5 min, 100% B for 13.5-15.7 min, and 2% B for 15.7-18.0 min. The study was carried out at 338 nm (bandwidth 10 nm, reference 390 nm, bandwidth 20 nm, first class amino acids); and 262 nm (bandwidth 16 nm; reference 324 nm, bandwidth 8 nm, level two amino acids). The wavelength was switched after lysine peaks (the experiment was set to switch from 338 nm to 262 nm in 10 min). Chameleon software ver. 7.2 (Thermo Fisher Scientific, Leipzig, Germany) was used for data analysis and final data collation.

Target analysis method for sugars

Sugars were analyzed using HPIC. First, the sugars were separated in an anion exchange column and detected with a pulse integral amperometric detector (Thermo Fisher). The retention time of chromatographic peaks were determined, and quantitative analysis were carried out using the external standard method. Freeze-dried root exudates were used for sugar target analysis, which involved adding deionized water (1 mL) under ultrasonic conditions, centrifugation for 10 min at 12,000 rpm, and filtration through a 20-μm filter membrane.

Preparation of standard sugar solutions

First, 100 mg of each sugar was dissolved in 10 mL of deionized water, and the solution was diluted 100 times. The sugar standards used were fucose (fuc), arabinose (ara), galactose (gal), glucose (glc), xylose (xyl), mannose (man), fructose (fru), ribose (rib), galacturonic acid (gal-AC), and glucuronic acid (glc-AC). The concentration of the standard solution was 100 μg/mL. Each mixed standard solution was diluted at ratios of 1:100, 5:100, 10:100, 20:100, 30:100, 40:100, 50:100, and 60:100, so that the concentration of each sugar standard after dilution was 1 μg/mL, 5 μg/mL, 10 μg/mL, 20 μg/mL, 30 μg/mL, 40 μg/mL, and 60 μg/mL, respectively.

HPIC detection method

An ICS5000 HPIC analyzer (Thermo Fisher) and Dionex™ CarboPac™ PA20 (3.0×150 mm, Thermo Fisher) were used for the analysis of sugars, along with an electrochemical detector at a flow rate of 0.5 ml/min. Mobile phase A was double distilled ddH_2O, while mobile phase B was 200 mM NaOH, and mobile phase C was 200 mM NaOH:500 mM NaAC. The gradient program was 97.5% A + 2.5% B for 0–25 min; 77.5% A + 2.5% B + 20% C for 25.0–40 min; 100% C for 40.0–50 min; and 97.5% A + 2.5% B for 50.0–60 min. Chameleon software (7.2) was used for data analysis and final data collation.

Organic acid analysis method

Organic acid contents were determined using HPIC. The organic acids were separated with AS11 HC. Qualitative analysis was done by measuring the retention time of chromatographic peaks, while quantitative analysis was done using external standard method. Freeze-dried root exudates were used for organic acid target analysis after addition of deionized water (1 mL) under ultrasonic conditions, centrifugation for 10 min at 12,000 rpm, and filtration through a 20-μm filter membrane.

Preparation of standard solutions of organic acids

Standard solutions were prepared for lactic, acetic, propionic, formic, isobutyric, butyrate, isovalerate, valerate, isohexadecanoic, hexadecanoic, palmitic, succinic, tartaric, and oxalic acids by dissolving 100 mg of each organic acid in 10 mL of deionized water and diluting the resultant solution 100 times. The concentration of each standard solution was 100 μg/mL. Serial dilutions of each standard solution were prepared at ratios of 1:100, 5:100, 10:100, 20;100, 30;100, 40;100, 50;100, and 60;00 to yield organic acid standard concentrations of 1 μg/mL, 5 μg/mL, 10 μg/mL, 20 μg/mL, 30 μg/mL, 40 μg/mL, and 60 μg/mL, respectively.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95299545

HPIC detection method

An ICS5000 HPIC analyzer (Thermo Fisher), an AS11 HC Dionex™ (4.0×250 mm, Thermo Fisher), and an AS11 HC Guard (4.0×50 mm, Thermo Fisher) were used for organic acid analysis with an electrochemical detector, flow rate of 1.0 ml/min, and column temperature of 30°C. Mobile phase A was ddH_2O (18.2MΩ Pall, USA), while mobile phase B was 100 mM KOH (HPLC, Sigma, USA). The gradient elution program was 2.0% B for 0-15 min; 15% B for 15-30 min; 40% B for 30-40 min; 50% B for 40-45 min; and 2.0% B for 45-53 min. Chameleon software (7.2) was used for data analysis and collation of final data.

Statistical analysis

Data are presented as mean ± standard deviation (n=6). Statistical analyses were performed with SAS statistical program. Statistical significance of differences amongst the groups were analyzed with one-way analysis of variance (ANOVA), followed by Duncan's test. Statistical significance was assumed at $p < 0.05$.

Results and Discussion

Results of root exudate metabolite analysis using GC-MS

The qualitative analysis of the root exudates of *F. mandshurica* was carried out using GC-MS. Two hundred and nineteen compounds were found in the root exudates of *F. mandshurica*. The root exudates contained lactic, acetic, oxalic, tartaric, succinic, and other small molecular organic acids such as aspartic acid, asparagine, glycine, alanine, valine, isoleucine, and leucine, amongst others. The other compounds included amino acids, xylose, fructose, glucose and other sugars. Erythronolactone, hydroxylamine, monostearin, nicotinic acid, ribitol, methylhydantoin, phytosphingosine, linoleic acid, hexadecane, sedoheptulose, and other small molecular metabolites were also present. The result agrees with those obtained in previous studies which reported the presence of many compounds in the root exudate (Luo et al., 2014; Han et al., 2015). Luo found 62 compounds in Sedum alfredi, including organic acids, amino acids, sugars and other small molecular metabolites. Over 100 compounds were identified in *Capsicum chinense* Jacquin, including organic acids, amino acids, sugars and other small molecular weight metabolites (alkane, lipids, acids, alcohols, phenols, aldehydes, oxime, pyrrolidone, amide, amine and naphthalene compounds) (Han et al., 2015). The type of compound present in plant exudates is determined by factors such as species of plant, period of growth, nutrient level and environmental pressure (Carvalhais et al., 2011; Selvakumar and Panneerselvam, 2012). The present study also found that the compounds in root exudates of *F. mandshurica* varied at different collection times. Therefore, a metabolomics analysis was carried out on the original data of GC/MS (CDF format), so as to identify the differences in levels of metabolites of root exudates of F. mandshurica as a function of time of collection. Plots of PCA scores (*Fig. 1-a*) showed that samples at different collection times had a preliminary clustering trend, meaning that metabolites in samples collected at different times were different. In addition, quality control samples were clustered and distributed in the score map, indicating an improvement in the stability of the detection platform. The results of the PLS-DA score plots (*Fig. 1-b*) showed that the samples collected at different times were completely clustered and separated, and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95299545

sample distribution for samples collected from 6 h to 24 h showed a gradual and progressive relationship.

Through model verification analysis (*Fig. 2*), this study found that the interpretations of the model for X and Y variables were R^2X=0.441 and R^2Y=0.907, respectively, and the prediction of the variable Q^2Y was 0.622, which showed that the model was of good quality. After 999 permutation tests, R^2-interposition was 0.593, Q^2-interposition was −0.450, and all random permutations produced R^2Y and Q^2 values smaller than the original R^2Y, Q^2 values, indicating that the PLS-DA model was robust.

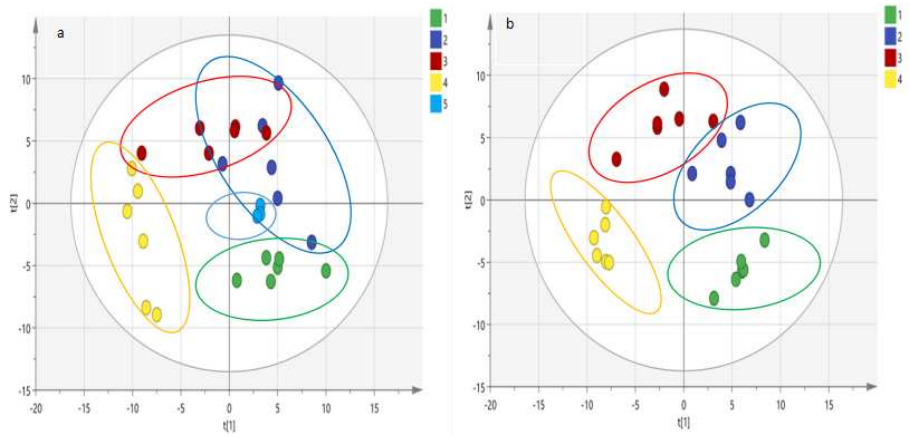

Figure 1. *(a) Principal component analysis (PCA) and (b) partial least-squares discriminant analysis (PLS-DA) score plots of root exudates of the F. mandshurica. Collection times were at (1) 6 h, (2) 12 h, (3) 18 h and (4) 24 h. (5): quality control sample*

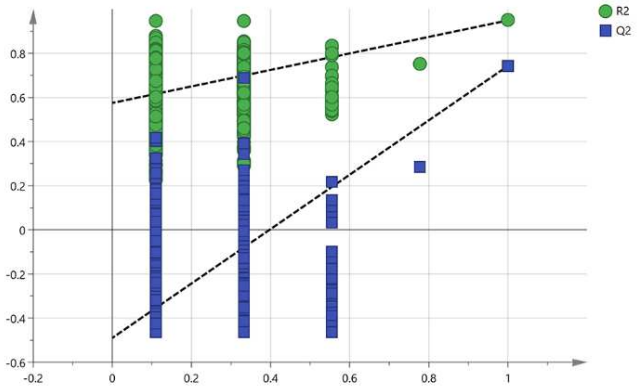

Figure 2. *Verification analysis of partial least-squares discriminant analysis model. The explanatory of models R^2 and the predicted performances of models Q^2 were 0.593 and 0.450 respectively. Overfitting of the model was discriminated using R^2- intercepts and Q^2-intercepts*

Results of the loading plot of the PLS-DA model (*Fig. 3*) showed that the samples from different collection times differed significantly, and the differential metabolites were identified using VIP analysis. These included glycolic acid, acetophenone, glucose-1-phosphate, 15-keto-prostaglandin, dithioerythritol, dehydroabietic acid, thioctamide, synephrine, hippuric acid, quinic acid, sedoheptulose, nicotinamide, 2-hydroxybiphenyl, 2-deoxyuridine, 2-furoic acid, maleamate, 6-hydroxy caproic acid trimer, beta-

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95299545

hydroxypyruvate, halostachine, and other metabolites, totaling 88 compounds (VIP>1). The results showed that the secondary metabolites accounted for a larger proportion of the metabolites that differed significantly at different collection times, while the sugars, amino acids, and small molecular organic acids were not significantly different amongst root exudates of *F. mandshurica* collected at different times. The results are in agreement with the findings of previous studies, which were mainly focused on sugars, amino acids, and organic acids (Huang et al., 1996; Maqsood et al., 2011; Carvalhais et al., 2011). Therefore, the present study quantitatively analyzed the sugar, amino acid, and organic acid compounds in the root exudate of *F. mandshurica*, and investigated how these compounds varied at different collection times. This was with a view to determining the optimal collection time of the root exudate.

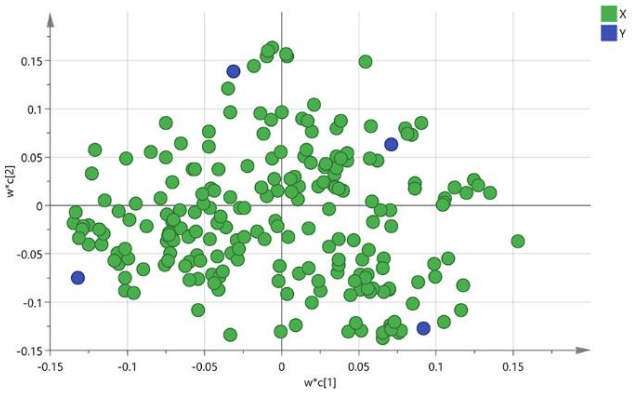

Figure 3. *Loading plot of partial least-squares discriminant analysis model for root exudates of F. mandshurica: (X) root exudate variable, (Y) group (collection time) variable*

Results of amino acid analysis of root exudates using UPLC

Qualitative analysis was done using the retention time of chromatographic peaks (*Fig. 4*), while quantitative analysis was carried out using the external standard method. Results of amino acid analysis of root exudates from *F. mandshurica* (*Table 1*) showed that the primary amino acids were Asp, Asn, Gly, Ala, Val, Ile, and Leu. There was a wide variation in amino acids between the results obtained from UPLC analysis and results from GC-MS analysis. There were fewer amino acids in UPLC analysis results than in GC-MS analysis results. This variation was probably due to the fact that the detection limit of GC-MS is lower than that of UPLC. Thus, when the amino acid content is low, it may be below the lower limit for UPLC detection, resulting in inability of the UPLC method to detect some amino acids. It was also found that the varieties and the contents of amino acids varied significantly at different collection times. The amount and varieties of amino acids found initially showed significantly increasing trend as the collection time increased (0-12 h), but decreased significantly after 12 h. Indeed, only Gly was present in the root exudates at 18 h and 24 h. This occurred because the amino acids from root exudates were used as nitrogen substrates by *F. mandshurica*. Thus, with continuous use, the amino acids were close to depletion at 18-24 h. Therefore, the best time to collect the root exudates for the determination of amino acid content is 12 h. The content of Gly was the highest among the various amino acids of root exudates. The contents of Leu, Val, and Ile were also high. However, the contents of Ala, Asp, and Asn

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95299545

were the lowest at 12 h, based on analysis of variance. Therefore, in the present study, UPLC had a lower detection limit for amino acids, relative to previous studies that used amino acid analyzer (Dong et al., 2015; Pan et al., 2016). Thus, the UPLC method employed here can be used for the determination of low levels of amino acids in root exudates.

Analysis of sugars in root exudates by HPIC

Quantitative analysis of sugars in root exudates was done with HPIC using retention times of chromatographic peaks (*Fig. 5*), while quantitative analysis was done using the external standard method. The results of the analysis of sugars in root exudates of *F. mandshurica* (*Table 2*) showed that the major sugars were Fuc, Ara, Gal, Glc, Xyl, Man, Fru, and Glc-AC. The types of sugars identified varied greatly between the results for HPIC and GC-MS

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95299545

analyses, with HPIC showing much smaller amounts and fewer types of sugars than GC-MS. This occurred probably because GC-MS detected smaller amounts of sugars than HPIC. Other sugars were present in low levels in the root exudates, but the amounts were lower than the HPIC detection limit. It was also found that the type and amounts of sugars differed significantly at different collection times. The amounts and varieties of sugars tended to increase significantly as the collection time increased (0-12 h).

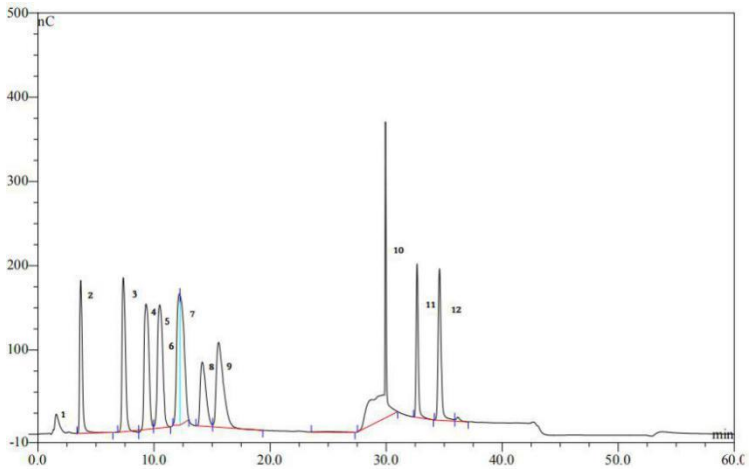

Figure 5. *High performance ion chromatography (HPIC) chromatogram of sugar standards at concentration of 30 ug/mL. the retention times were: peak 2, fucose (Fuc), 3.67 min; peak 3, arabinose (Ara), 7.35 min; peak 4, galactose (Gal), 10.48 min; peak 5, glucose (Glc), 12.17 min; peak 6, mannose (Man), 12.98 min; peak 7, xylose (Xyl), 14.15 min; peak 8, fructose (Fru), 15.12 min; peak 9, ribose (Rib), 15.62 min; peak 11, galacturonic acid (Gal-AC), 32.67 min, and peak 12, glucuronic acid (Glc-AC), 34.60 min. Peaks 1 and 10 were solvent peaks*

Table 2. *Sugar content of root exudates of F. mandshurica, as determined using high performance ion chromatography. (There were 4 treatments based on collection times of 6 h, 12 h, 18 h and 24 h)*

Time of collection	Sugar content (μg/mL)							
	Fuc	Ara	Gal	Glc	Xyl	Man	Fru	Glc-AC
6 h	$2.62\pm0.01^{a, D}$	$7.14\pm0.24^{b, B}$	$7.03\pm0.34^{b, B}$	$20.21\pm0.52^{b,A}$	n.a.	$4.47\pm0.28^{b,C}$	n.a.	n.a.
12 h	$2.59\pm0.02^{a, F}$	$51.08\pm1.26^{a,B}$	$9.91\pm0.64^{a, D}$	136.93 ± 2.37^{aA}	$11.27\pm0.62^{a,C}$	$8.72\pm0.57^{a,E}$	12.59 ± 0.62^{C}	$12.05\pm0.71^{a,C}$
18 h	n.a.	$4.88\pm0.03^{c, D}$	$6.28\pm0.11^{c, C}$	$12.78\pm0.84^{c,A}$	$10.81\pm0.14^{a,B}$	n.a.	n.a.	$0.65\pm0.08^{b, E}$
24 h	n.a.	$4.33\pm0.03^{d, D}$	$5.72\pm0.06^{d, B}$	$4.98\pm0.22^{d, C}$	$11.49\pm0.37^{a,A}$	n.a.	n.a.	$0.54\pm0.11^{b, E}$

Lower case letters (a-d) indicate intra-group differences ($p<0.05$), while uppercase letters (A-G) indicate inter-group difference ($p<0.05$)

However, the amount and varieties of sugars decreased significantly after 12 h. This occurred because *F. mandshurica* utilized the sugars from the root exudates as carbon substrates. Thus, the amount of sugar left decreased with time, and was almost exhausted at 24 h. Interestingly, the content of xylose did not vary significantly after 12 h, probably because the coefficient of xylose by plants and microorganisms is low (Jeffries, 1983). Therefore, the best time to collect in root exudates for the determination of sugar content

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95299545

of *F. mandshurica* was 12 h. The content of Glc was the highest among the sugars in the root exudates, while the contents of Ara, Gal, Xyl, Man, Fru, Glc-AC were higher, with Fuc being the lowest in quantity at 12 h, based on analysis of variance. Therefore, in the present study, HPIC had a lower limit of detection, relative to previous studies which used the anthrone and phenol-sulfuric acid colorimetric assay methods (Zhang et al., 2016; Jiang et al., 2018). Thus, the HPIC method used here can be used for the determination of low levels of sugars in root exudates.

Analysis of organic acids in root exudates using HPIC

The quantitative analysis of organic acids in root exudates was done with HPIC using external standard method, while qualitative analysis was done using the retention time of chromatographic peaks (*Fig. 6*). The results of the analysis of organic acids in root exudates of *F. mandshurica* (*Table 3*) showed that the major organic acids were propionic, valeric, lactic, succinic, tartaric, and oxalic acids.

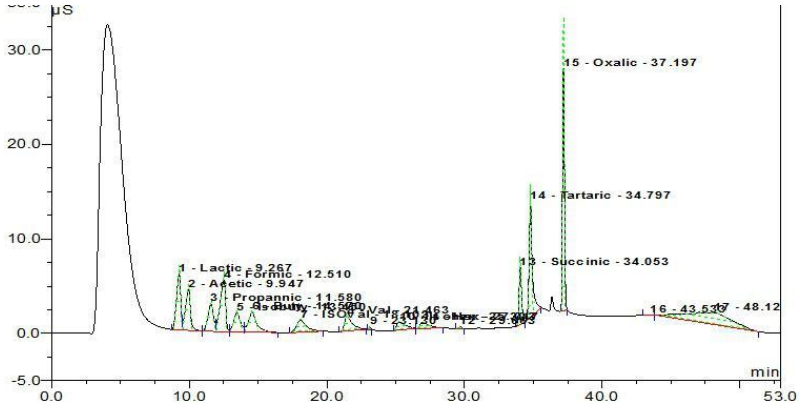

Figure 6. *High performance ion chromatography (HPIC) chromatogram of organic acid standards at concentration of 40 µg/mL. Retention times were: peak 1, lactic acid, 9.27 min; peak 2, acetic acid, 9.95 min; peak 3, propionic acid, 11.58 min; peak 4, formic acid, 12.51 min; peak 5, isobutyric acid, 13.45 min; peak 6, butyrate acid, 14.57 min; peak 7, isovalerate acid, 18.10 min; peak 8, valerate acid, 21.46 min; peak 10, isohexadecanoic acid, 25.30 min; peak 11, hexadecanoic acid, 27.02 min; peak 13, succinic acid, 34.05 min; peak 14, tartaric acid, 34.80 min, and peak 15, oxalic acid, 37.20 min. Peaks 9, 12, 16, and 17 were solvent peaks*

Table 3. *Organic acid analysis of root exudates in F. mandshurica using high performance ion chromatography. This study had four treatments based on collection times of 6 h, 12 h, 18 h, and 24 h*

Time of collection	The organic acid content (µg/mL)					
	Propionic	Valeric	Lactic	Succinic	Tartaric	Oxalic
6 h	$6.37\pm0.22^{d, B}$	n.a	n.a.	$2.69\pm0.19^{b, C}$	$9.29\pm0.38^{d, A}$	$1.86\pm0.12^{c, D}$
12 h	$13.78\pm0.73^{a, B}$	$0.47\pm0.26^{a, F}$	$0.84\pm0.19^{a, E}$	$6.61\pm0.53^{a, D}$	$22.91\pm0.87^{a, A}$	$7.34\pm0.53^{a, C}$
18 h	$11.48\pm0.37^{b, B}$	n.a	$0.13\pm0.08^{b, D}$	$6.79\pm0.46^{a, C}$	$23.86\pm0.66^{b, A}$	$6.78\pm0.44^{a, C}$
24 h	$10.55\pm0.42^{c, B}$	n.a	n.a.	$6.41\pm0.33^{a, C}$	$21.61\pm0.59^{c, A}$	$4.88\pm0.32^{b, D}$

The lower case letters a-d indicate intra-group difference ($p<0.05$) and the uppercase letters of A-G indicate inter-group difference ($p<0.05$)

These results are similar to those reported by other workers (Niu et al., 2017; Wu et al., 2018). The types of organic acids varied greatly between results from HPIC and GC-MS analyses, with HPIC being less sensitive in the detection of organic acids than GC-MS. This is due to the fact that GC-MS is more sensitive than HPIC, and so can detect smaller amounts of organic acids. Other organic acids were present in low levels in the root exudate, but the amounts were lower than the detection limit of HPIC. It was also found that the types and amounts of organic acids varied significantly at different collection times. The types and varieties of organic acids present tended to increase over time (0-12 h), with slight declines after 12 h. Again, this trend is most likely due to the fact that *F. mandshurica* used the organic acids as carbon substrates, leading to their decline in concentration with time. Therefore, the best collection time for the determination of organic acid content of root exudates of *F. mandshurica* is 12 h after collection of the roots. Tartaric acid was found in the highest amount among the organic acids of root exudates, while higher levels of propionic, succinic, and oxalic acids were present at 12 h.

Conclusion

The results obtained in this study indicate that time of collection has a strong influence on the varieties and concentrations of organic compounds in the root exudate of *F. mandshurica* obtained using water culture collection method. The collection time for qualitative analysis of sugars, amino acids, and organic acids with GC-MS can be arbitrary chosen within 24 h, theoretically. However, the use of GC-MS in the present study has shown the presence of 219 compounds in the root exudates of *F. mandshurica,* with the highest contents at collection time of 12 h. Over 200 compounds have been identified in the root exudates of several economic forest trees using GC-MS at collection time of 12 h (Sun et al., 2003). Forty compounds were found in the root exudates of *Gymnorrhiza* seedling using GC-MS at the collection time of 6 h (Liu et al., 2011). However, only 17 compounds were found in the root exudates of *Rubber* seedling using GC-MS, at the collection time of 6 h (Wang et al., 2010). In another study, over 100 compounds were identified in the root exudates of *Capsicum chinense* Jacquin at collection time of 120 h (Han et al., 2015). The use of GS-MS also resulted in the identification of 55 organic compounds in the root exudates of *Fritillaria pallidiflora* Schvek seedlings at collection time of 72 h (Wang et al., 2009). Sometimes, the results may not be accurate because of the low concentration of root exudate available at the beginning of the collection, apart from the findings that root exudates are affected by plants and microorganisms after 12 h (Fransson and Johansson, 2010; Shi et al., 2011).

In the present study, the optimal collection time for quantitative analysis of sugars, amino acids, and organic acids using UPLC and HPIC target analysis methods was 12 h. The HPIC detection limit for sugar content and organic acid content was 0.1 μg/mL. However, the HPLC detection limit of sugar content in root exudates was 3 μg/mL (Gao et al., 2017), while the detection limit using anthrone and phenol-sulfuric acid colorimetric assay was 10 μg/mL (Zhang et al., 2016). In another study, the HPLC detection limit of organic acid content in root exudates was 12.5 μg/mL (Gao et al., 2018). Thus, the UPLC and HPIC target analysis methods have low detection limits and relatively wider linear ranges than the current methods. Therefore, the UPLC, HPIC target analysis methods provide a good quantitative analytical method for identification and measurement root exudates. We believe that these methods should be popularized and

DOI: http://dx.doi.org/10.15666/aeer/1704_95299545

widely used. Forest researchers will need to consider the collection time when gathering root exudates so as to maximize the accuracy of results from qualitative and quantitative analyses of root exudates. In addition, the water culture system used to collect root exudates in this study is free from external interferences. However, there are many microorganisms in the actual rhizosphere. These microorganisms use the exudates to carry out their own metabolic activities, thereby affecting the results of measurements. Therefore, more studies are needed on methods of determination of root exudates in rhizosphere environment, the dynamic changes in root exudates, changes in root exudates under different external influences, and mechanisms involved in plant-soil-microbe interactions mediated by root exudates.

(Received 4th Nov 2018; accepted 22nd May 2019)

Abstract. In this study five sedimentary cores were collected from Gorgan Bay (southeastern part of the Caspian Sea). Concentrations of elements were measured to determine depositional trends and geo-statistical assessment of toxic elements was carried out. Al, Fe, K, Mg, Na and S content increased in all 5 cores, from the bottom to near the top layer, with maximum concentrations at 15–45 cm depths. However, for the toxic elements, maximum concentration of As, Cr, Cu, Pb, Zn, Co and Ni varied in different depth of 5-15 cm and 80-120 cm. Enrichment factors (EFs) and pollution load index (PLI) were calculated to assess the enrichment and pollution of heavy elements in the bay sediments. Except for Ca and S, all studied elements showed positive and significant correlations with Fe and Al, which indicate the same source (human or natural). Principal component analysis (PCA) indicated that sediments were influenced by both geologic and anthropogenic impacts. According to the EFs, most toxic elements showed no significant enrichment and no pollution in the core sediments. Based on PLI average value in all cores, the southeast coast of the Caspian Sea (Gorgan Bay) should be classified as not metal polluted, but in recent decades there has been a dramatic increase of toxic elements that needs more attention and also monitoring.
Keywords: *heavy metals, sedimentary cores, geochemistry, source*

Introduction

The study of core sediments is very useful to detect different natural process such as paleoclimate changes, or anthropogenic activities on sedimentary environments (Harikumar and Nasir, 2010) by examining the geochemical and geo-statistical data (Karbassi et al., 2005; Mohamed et al., 2005; Sun et al., 2012; Vallius, 2014; Veerasingam et al., 2015). The coastal zones with their variable physical and chemical properties are suitable environment for the assessment of pollutant accumulations in aquatic ecosystems, where the bottom sediments are affected by both dissolved heavy elements or on surface absorbed particles transported from land to the basin (Harbison, 1986; Szefer et al., 1995). Heavy metal concentrations from natural and anthropogenic sources in coastal area can be increased through high input after intense rock-minerals weathering in the land or due to urbanization (Harikumar and Nasir, 2010). Anthropogenic pollutions in aquatic environments have direct influence on coastal ecosystems (Alessandro et al., 2006). In fact, core sediments obtained from the coastal areas provide a good chronological record of contamination (Morelli et al., 2012). Understanding trace metal emissions in coastal environments is an important task for researcher sand policy planners, and regulatory actions can be implemented to reduce health risks potential.

Study area

Gorgan Bay (Southeastern part of the Caspian Sea) is a unique brackish water body, semi-confined triangular-shaped having about 500 km^2 area, maximum depth of 4 m and average depth 1.5 m, high ecological value and hydromorphological properties such as depth variation, freshwater flow and wave exposure. It is located at the south-east of the Caspian Sea in both Golestan and Mazandaran provinces (*Fig. 1*). Gorgan Bay was formed during the late Holocene period by a coastal barrier system (sandy spit) which is named Miankaleh spite (Kakroudi et al., 2012). There are no tides in the Gorgan Bay like in other parts of the Caspian Sea. It is connected to the Caspian Sea through Ashoradeh-Bandar Torkaman mouth, (Approximately; width of 400 m, 3 km long) with strong currents in the area affected by storm surge. Water balance in the Gorgan Bay is influenced by water evaporation, precipitation, intrusion from the Caspian Sea, and to a lesser extent by fresh river water (Sharbaty, 2011, 2012). It receives freshwater from a number of rivers and small streams, Gorgan-rud River from the north of the inlet and Qarehsu river enters from the east.

Several works on distributions of heavy metals and other pollutants have been carried out in this area (Kasymov., 1989; Tait et al., 2004; Parr et al., 2007; Karbassi et al., 2008; Bastami et al., 2012; Nasrolahi et al., 2017), but no studies have focused on the trends of metals on different core sediments in this area. The aims of the current study are: (1) to describe the vertical variation of elements from east to west of Gorgan Bay; (2) to estimate the geochemical sources of major and trace metals in sediments using coefficient correlation and principal component analysis (PCA); and (3) to assess enrichment and possible contamination of trace metals in sediments, using enrichment factors (EFs) and pollution load index (PLI).

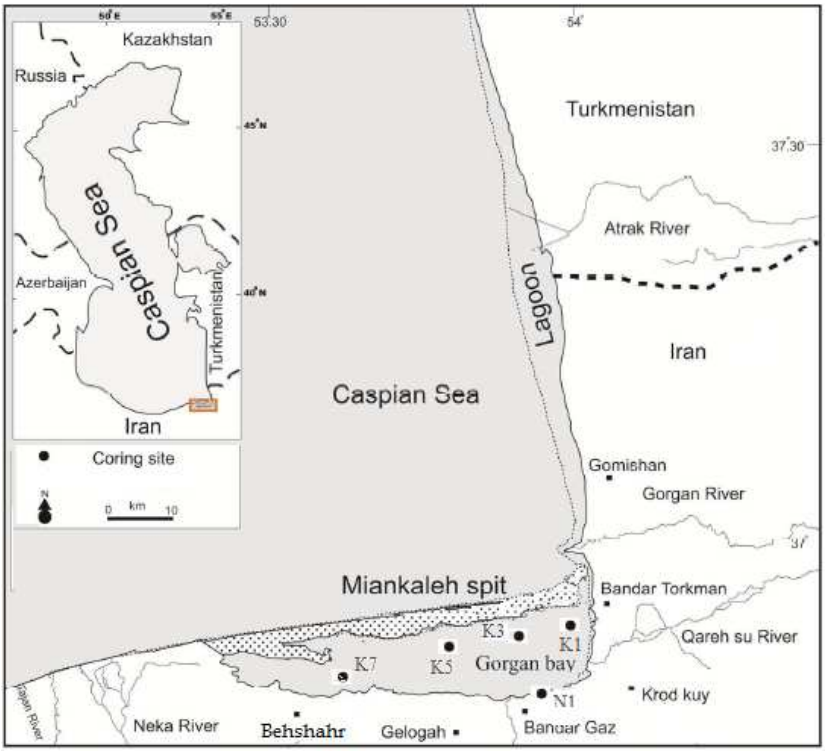

Figure 1. *The locations of the core sampling sites*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

Materials and methods

Five sedimentary cores with different length were collected using a gravity corer on August 2016 (*Table 1*). Samples were packed and carried in ice-boxes to the laboratory and stored at 4 °C until analysis. After opening the cores, about 25 subsamples picked from each core (each 5 cm 1 subsample and totally 120 subsamples). Subsamples were dried in an oven and then powdered by using a mortar then screened with a 0.5 mm sieve to remove large particles. Sediment samples (1 g) were digested using a mixed solution of 1:3 nitric acid : hydrochloric acid for 3 h. The solution was cooled, filtered through Whatman-42 and diluted to 50 ml volume using distilled water (APHA et al., 2005). Concentrations of major elements (Al, Ca, Fe, K, Mg, Na, and S) and trace metals (As, Co, Cr, Cu, Ni, Pb, and Zn) were measured by using inductively coupled plasma-optical emission spectrometry (ICP-OES; Varian 735 ES series), Arsenic (As) analysis was carried out by using atomic absorption spectrometry (model SOLAAR, M5) Data recoveries of the analysed element areas are the followings: Al (100%–101%), Ca (97.6%–97.8%), Fe (100%–101%), K (103%–104%), Mg (95.1%–95.3%), Na (102%–103%), S (98.7%–100%), As (112%–113%), Co (105%–111%), Cr (88.5%–88.7%), Cu (98.3%–98.8%), Ni (97.5%–98.7%), Pb (118%–121%), and Zn (93.2%–93.5%).

Table 1. *Geographic position, length and depth of each core in Gorgan Bay*

Core name	Water depth (m)	Core length (m)	Longitude	Latitude
K1	2.6	1.78	54° 0’ 42.34	36° 51’ 49.9
K3	3.24	1.67	53° 54’ 38.86	36° 50’ 33.5
K5	2.8	1.34	53° 48’ 43.5	36° 50’ 21.35
K7	0.4	1.3	53° 36’ 18.87	36° 48’ 26.31
N1	0.1	0.98	53° 54’ 62.5	36° 47’ 6.19

Grain size analysis was performed using laser particle size analyzer (HORIBA-LA950, France & Japan) in Iranian National Institute for Oceanography laboratory. Before analysis, about 4 g samples were cremated in an oven at 550 °C for 4 h and then at 950 °C for 1 h to remove organic matter and biogenic carbonate, respectively.

Pearson correlation analysis and PCA were conducted to specify geochemical associations and certainly the factors controlling the geochemical origin in coastal sediments (Bastami etal, 2014). A two-tailed Pearson correlation coefficient was used in correlation analysis. PCA was performed on a correlation matrix; N80% of the total variance was computed for principal components. Pearson correlation coefficients and PCA were accomplished using the SPSS 20.0 software. Enrichment factor (EF) as an appropriate index was calculated to determine anthropogenic or geogenic source of the toxic elements by normalizing their concentrations according to the sediment texture properties (Morillo et al., 2004; Selvaraj et al., 2004; Adamo et al., 2005; Vald’es et al., 2005; Shi et al., 2010; Morelli et al.2012; Zhang et al., 2013). To calculate the EF, Al is widely used in the equation as aluminum silicate, it is predominant at the coastal areas. Enrichment Factor is determined as follows (Huang and Lin, 2003; Woitke et al., 2003):

$$\text{Enrichment Factor} = (H / Al)_{\text{sample}} / (H / Al)_{\text{background}} \quad \text{(Eq.1)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95479559

where (H / Al) $_{sample}$ and $H / Al)_{background}$ are heavy metal concentrations in sample and background reference, respectively. In this study, we used background concentrations of heavy metals in K5 sediment core at the depth of 85 cm which are 2.96, 11.50, 53.01, 14.33, 27.43, 11.80 ppm and 41.60 for As, Co, Cr, Cu, Ni, Pb, and Zn, respectively (De Mora et al., 2004).

Results and discussion

Vertical distributions of selected elements in cores K1, K3, K5, K7 and N1 are presented in *Figure 2*. A lot of runoff and eroded sediments from several sources such as human activities and river systems (Bagheri et al., 2012) enters terrigenous materials into the Gorgan Bay. Generally concentration of Al, Fe, K, Mg, Na and S increased from the bottom to the top layers in the cores, and the maximum concentrations of these major elements were observed at depths of 15–45 cm in all cores, while the toxic elements have different trends. In core K1, the highest concentrations of Cr (75.95 ppm), Ni (83.22 ppm) and Zn (83.22 ppm) were determined at 5 cm depth, As (9.39 ppm) at 10 cm, Cu (36.64 ppm) at 15 cm, Co (21.79 ppm) at 30 cm and Pb (22.01 ppm) at 35 cm depth.

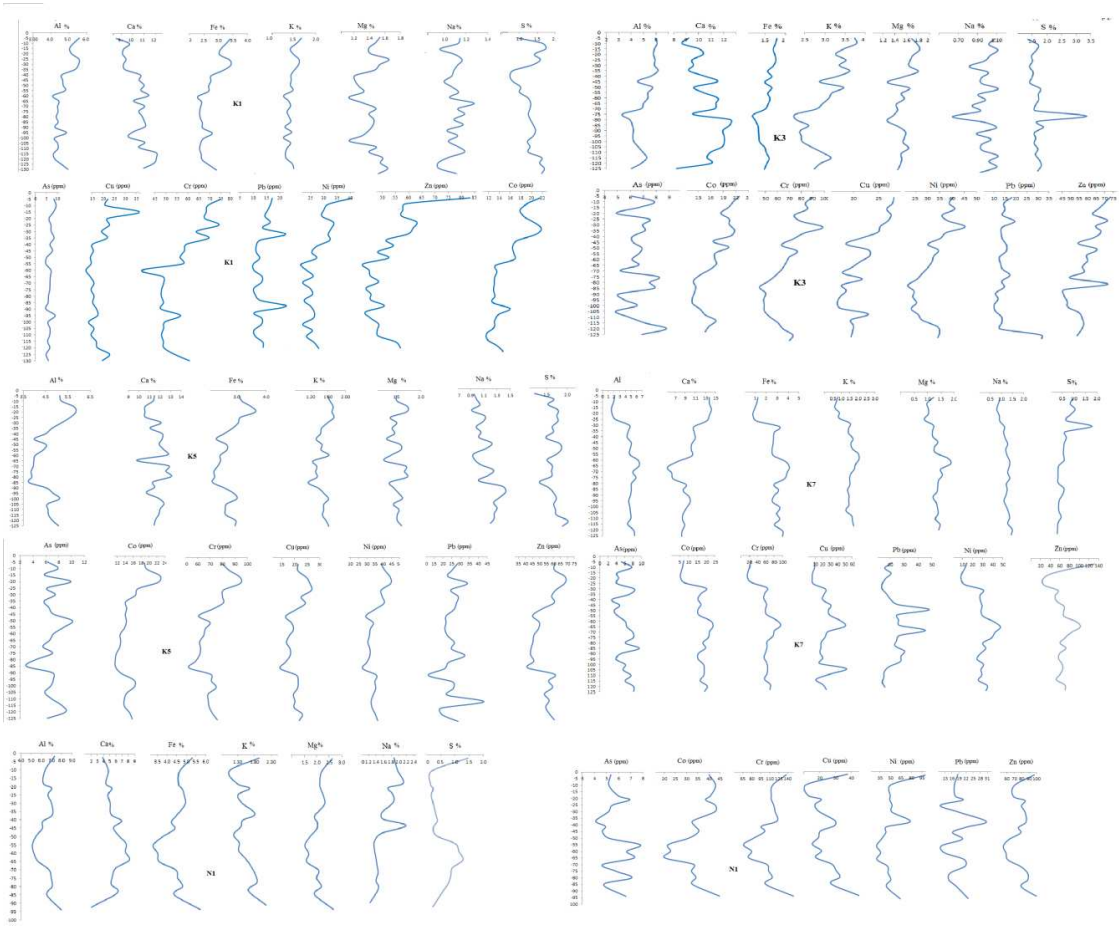

Figure 2. *Vertical distributions of major and trace metals in cores*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95479559

In core K3, the highest concentration of Cu (28.04 ppm), Co (22.04 ppm) and Zn (73.45 ppm) were observed at 5 cm depth, for Cr (98.44) and Ni (45.26 ppm) at 10 cm depth, and for As (8.81 ppm) and Pb (31.38 ppm) at 120 cm depth.

In core K5 maximum concentrations of all heavy metals were observed at a depth of 15-20 cm, expect for As (10.15) at 50 and Pb (43.08) at 110 cm. opposite of this trend in west and south of Gorgan bay in the K7, N1 cores, the highest value of trace elements reported in different depths as As (9.55, 7.80 mg/g) at 85, 55 cm; Co (23.79, 44.79 mg/g); Cr (95.11, 149.4 mg/g) at 65, 94 cm; Ni (47.37, 105.4 mg/g) at 65,5; Cu (52.05, 45.20 mg/g) at 105,94 cm; Pb (48.13, 30.6 mg/g) at 50, 37cm and Zn (131.6, 106.7 mg/g) at 5, 94 cm depth (*Fig. 2*).

Heavy metals show some information about source and migration of sediments. For example, high correlations between heavy metals probably mean these elements reflect similar origin or share analogous transformation and immigration processes in the certain situation. The major factors affecting spatial variation of trace elements in the sediments are organic matter and the grain size (Aloupi and Angelidis, 2001; Huang and Lin, 2003; Liaghati et al., 2004). The fine grains, have high surface/volume ratio and cation absorption potential, and are more effective adsorbents of contaminated organic and inorganic materials (McCave, 1984; Horowitz and Elrick, 1987). Fine-grained sediments, which contain lots of organic matter are more contaminated than coarse-grained sediments (DeMora et al., 2004). However, some studies have reported an inverse relationship between particle size and metal content (Bastami et al., 2014). In our study, in most cores, all elements showed positive and significant correlation (except for Ca and S) with Fe and Al indicating the same origin or input source of these elements (human or natural) into the Gorgan Bay. Also, there was a positive and significant correlation between As, Fe, Zn, Cr, Ni, Cu and K, indicating that these elements have the same origin and the same behavior in the studied area. Sulfur and calcium had a negative correlation with most of the heavy metals which indicates different origin or behavior of these elements in the environment. Also, in core N1, arsenic had a negative correlation with most metals while it was positively correlated with calcium and showed negative correlation with iron and aluminum, which probably indicates the biological origin of this metalloid.

Three principal components (PC) were extracted from the core K1 sediments, which accounted for about 81.74% of the total variance. The first component (PC1) accounted for 58.21%, the second component (PC2) accounted for 14.26% and the third component (PC3) accounted for 8.22% of the total variance (*Fig. 3*). In PC1 high loadings of major elements (Al, Fe, K and Ca) and heavy metals (Co, Cr, Ni, As, Cu, Pb and Zn) were observed (from 0.617 to 0.958). The elements Al, Fe and K mainly represent lithogenic origin after weathering and erosion of rocks and soil parent materials, PC1 described the lithogenic source bound in aluminosilicate minerals. The second component (PC2) also showed Mg and S with moderate to high loadings (0.791-0.901) and Na with high loading counted in the third component (PC3).

In core K3, we extracted 3 PCs, which accounted for about 82.43% of the total variance (*Fig. 4*). Based on the loading distribution of the variable elements, Al, Ca, Fe, K, Mg, Cr, Ni, Cu, Co and Zn constituted a firmly related group (PC1) with 55.81% of the total variance. While another group was composed of Na and S (PC2) with 14.24% of the total variance. The third component (PC3) accounted for 12.37% and had high loadings on As and Pb. These results may indicate the different origins or controlling factors of the heavy metal distributions in the Gorgan Bay sediments. In this area, the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95479559

lithogenic source acted as the main factor accounting for PC1, while PC2 and PC3 may be derived from the urban source.

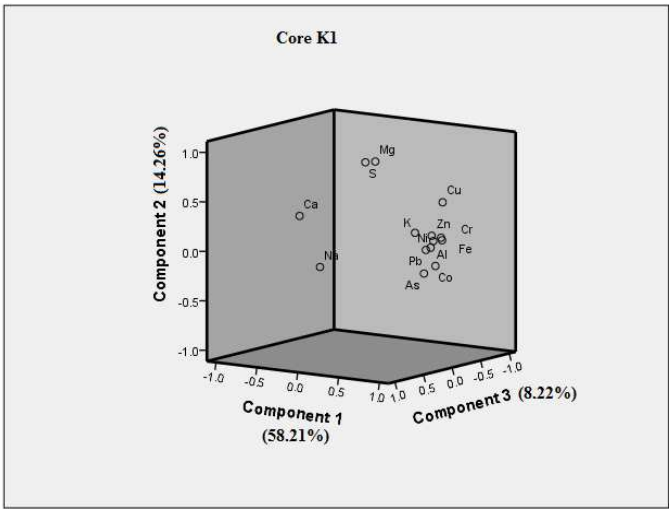

Figure 3. *PCA plot of elements in core K1*

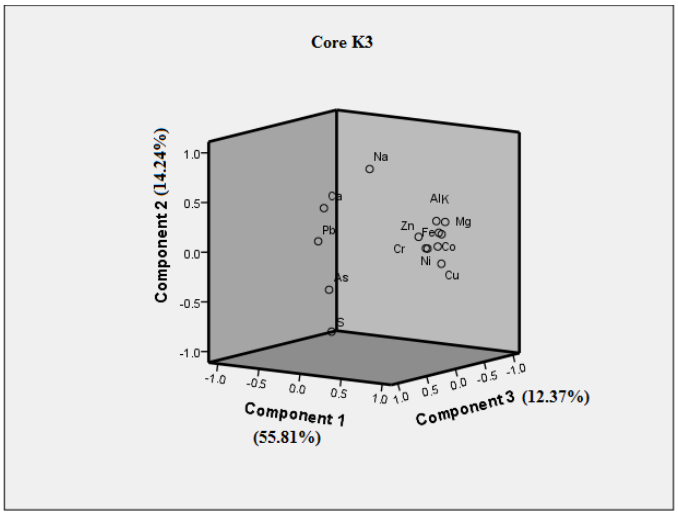

Figure 4. *PCA plot of elements in core K3*

In core K5, we extracted 3 PCs, which accounted for about 80.26% of the total variance (*Fig. 5*). The first component (PC1) accounted for 55.30% of the total variance and included all variable element except for Na, S, Pb and As, while the second component (PC2) accounted for 14.37% with high loading on Na, S and As (0.61-.82) and the PC3 accounted for 10.58% with high loading on Pb.

In core K7 (*Fig. 6*) that was obtained from west of the Gorgan Bay, 3 PCs were extracted and total variance was 86.55% (*Fig. 5*). In this core unlike in the other 4 cores Na and S with other elements (Al, Ca Fe, K, Mg, Cr, Ni, Cu, and Co), Zn with high loading on PC2, and Pb and As show loading on PC3, which accounted 65.11%, 11.79% and 9.65% respectively. In the studied area PCA showed anthropogenic input of Pb and Zn from the industrial activities (anthropogenic source), which are widely used

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95479559

as the main components in several industrial processes. In fact, those elements were partially derived from the anthropogenic source.

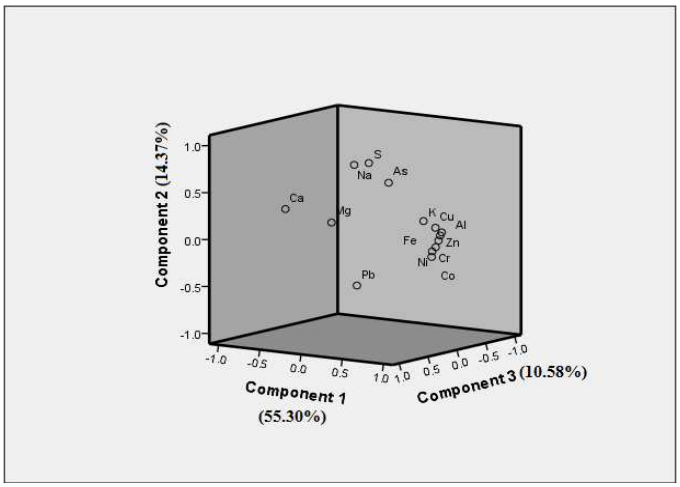

Figure 5. *PCA plot of elements in core K5*

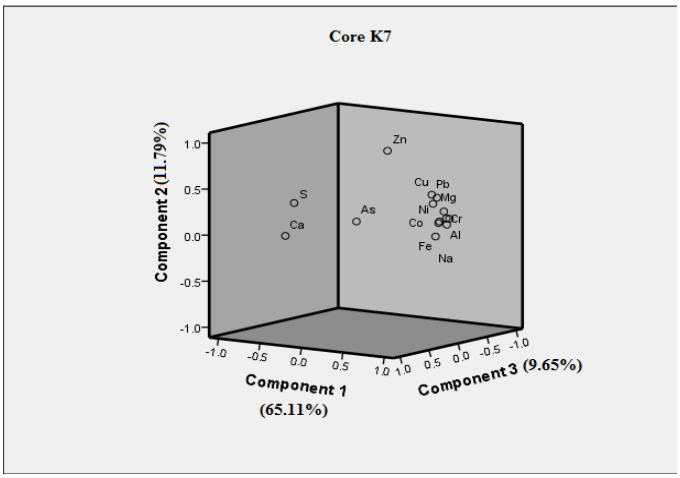

Figure 6. *PCA plot of elements in core K7*

Finally in core N1 (*Fig. 7*), 3 extracted PCs accounted for about 86.89% of the total variance. The PC1, PC2 and PC3 were 54.31%, 20.15% and 12.42% of the total variance, respectively (*Fig. 5*). The first principal component (PC1) included all elements expect for Na and S (that are considered as PC2) and As, Pb (that are considered as PC3) were lithogenic source. The PC2 also showed that Cu, Co, Pb and Zn had loadings on (0.16–0.63), indicating that these elements were partially derived from the anthropogenic source. Overall, all metals in the Gorgan bay sediments were mostly derived from the geologic origin (geogenic), except for western part of the bay, where the toxic elements were mainly derived from terrestrial discharge of industrial activities (anthropogenic).

Enrichment factor is a useful index to assess the heavy metals contamination in the soil and sediments (Feng et al., 2004; Reddy et al., 2004; Han et al., 2006; Chen, 2007; Çevik et al., 2009; Bastami et al., 2012). EF values are interpreted as; EF < 1, no

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95479559

enrichment; EF 1 to 3, minor enrichment; EF 3 to 5, moderate enrichment; EF 5 to 10, moderately severe enrichment; EF 10 to 25, severe enrichment; EF 25 to 50, very severe enrichment and EF > 50 extremely severe enrichment (Grant and Middleton, 1990; Loska et al., 1997; Abrahim and Parker, 2008). In this study, EF values in all core samples ranged in no-enrichment (EF < 1) to minor enrichment (EF 1 to 3) suggesting no anthropogenic enrichment of the toxic elements, except for Pb and Zn in core7, which show moderate enrichment of these elements (EF 3-5) and indicate that anthropogenic source of Zn and Pb were significantly polluted the sediments of core 7 (*Fig. 8*).

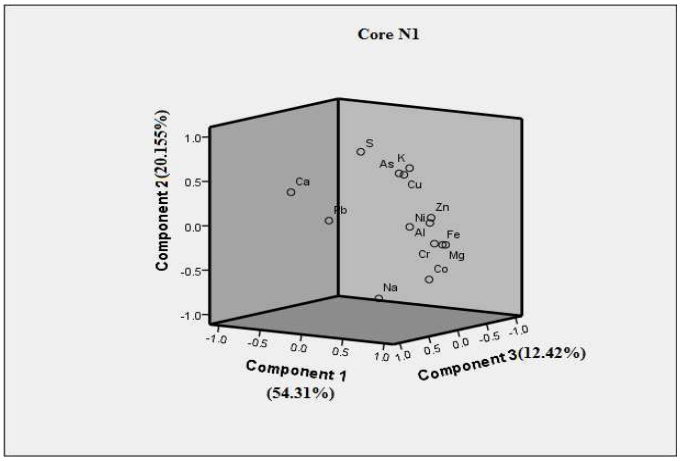

Figure 7. *PCA plot of elements in core N1*

To assess the sediment environmental quality, an integrated pollution load index (PLI) of seven toxic elements was calculated as suggested by Suresh et al. (2011).

$$PLI = (CF1 \times CF2 \times CF3 \times \ldots\ldots CFn)\ 1/n \qquad \text{(Eq.2)}$$

An area with PLI value > 1 is polluted whereas PLI value < 1 indicates no contamination (Chakravarty and Patgiri, 2009; Seshan et al., 2010). Concentrations of the elements in shale (sedimentary rock), which refer to the average concentration of the earth crust (Turekian and Wedepohl, 1961), were used as the reference baselines in this study. The PLI was calculated for all five studied cores and based on seven toxic elements of As, Pb, Co, Cr, Ni, Cu, and Zn (*Table 2*). The maximum and the minimum calculated PLI were 1.07 and 0.26, respectively (*Table 2*).

DOI: http://dx.doi.org/10.15666/aeer/1704_95479559

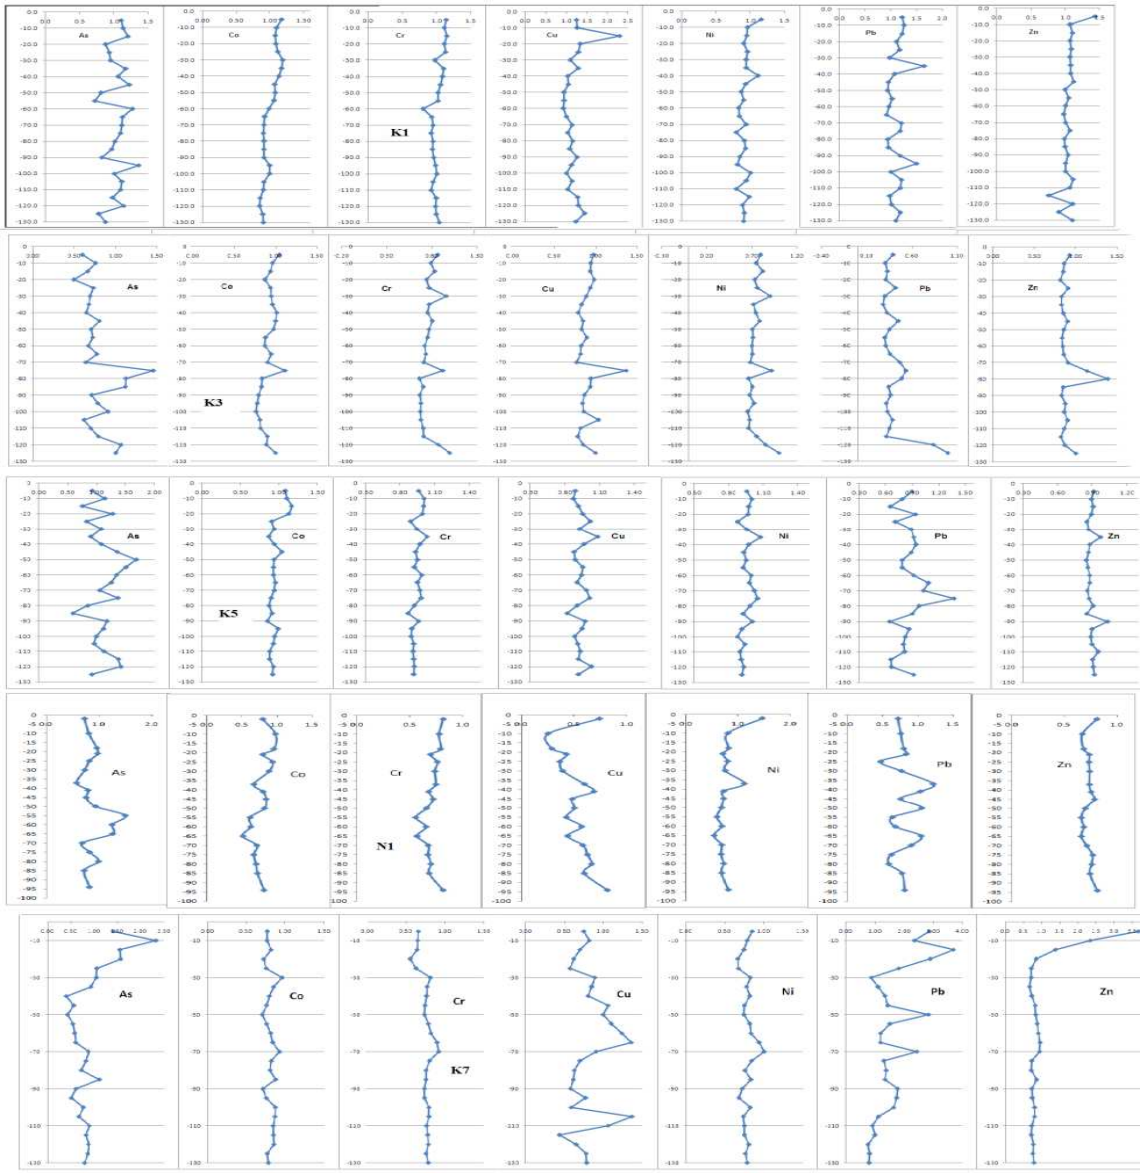

Figure 8. *Enrichment factor trend of heavy metals in cores*

Results showed that the PLI value of the elements in average sediment was lower than that in surface sediment in cores K1, K3, K5, K7 and N1, which can be attributed to direct discharges from urban area and fisheries boats carrying toxic elements, contaminants in study areas, especially in core N1 area. Based on average of PLI value in all cores, southeast coast of the Caspian Sea (Gorgan Bay) should be classified as no toxic pollution (*Table 3*), but in recent decades there has been a dramatic increase that needs more attention and consideration. Finally, comparison of toxic elements with the quality guidelines (NOAA, ISQG) showed the range between the two guideline (level of some elements as As, Ni, Cu, Pb was higher than ERL and lower than ERM). However, because of ecosystem condition, tourism and aquatic resources, this area, must be prevented, managed and monitored properly before they constitute a serious threat to the health of the environment and the organisms.

Conclusion

In this study concentrations and geochemical trends of some major elements (Al, Fe, K, Mg, Na and S) and heavy metals (As, Cu, Ni, Co, Pb, Cr, Zn), in 5 cores from Gorgan Bay were determined. in all K1, K3, K5, K7, N1 cores major element concentrations increased from the bottom to the top layer, and the maximum concentrations of these major elements in cores were observed at depths of 15–45 cm. All elements showed a positive and significant correlation (except Ca and S) with Fe and Al and represent the same input source (human or natural), also there was a positive and significant correlation between arsenic, Fe, Zn, Cr, Co, Ni, Cu and K, indicating that these metals have the same origin and the same behaviour in this area. Sulfur and calcium had a negative correlation with most of the heavy metals which indicates different behaviour and origin of these elements in the environment. PCA represent all metals were mostly derived from the geological origin in sediments of the Gorgan Bay, except for western part which was mainly derived from terrestrial discharge of industrial activities. EF values in all cores ranged no enrichment (EF < 1) to minor enrichment (EF 1 to 3) suggesting no anthropogenic enrichment, expect Pb and Zn in core 7 showed moderate enrichment (EF 3-5) which indicated that anthropogenic Zn and Pb enriched and polluted significantly sediment core 7. Based on the average of PLI values for these 5 cores and 7 trace metals (As, Co, Cr, Cu, Ni, Pb, and Zn), the southeast coast of the Caspian Sea (Gorgan Bay) should be classified as no metal pollution but in recent decades there has been a dramatic increase specially in the coastal area of K7, that needs more attention and consideration.

(Received 27th Nov 2018; accepted 1st May 2019)

Abstract. As the water resource management progresses rapidly in recent years, middle and long-term runoff forecast has become increasingly important. Conventional multi-category runoff prediction usually utilizes manually specified threshold values to categorize runoff categories. However, this approach is arguably subjective, and it neglects fuzziness and peculiarity of hydrometeorological time series. To address this issue, a new concept, forecast domain, is proposed in this study. Cluster analysis of runoff time series was carried out with the Gaussian Mixture Model, and Support Vector Classification was then used to establish the nonlinear relationships between forecast domain and various potential predictors. The current study focuses on the Danjiangkou Reservoir, the source of the Central Route of the South-North Water Transfer Project in China. We use the 25-year data (1981-2005) for model training, and the Danjiangkou runoff data during last 11 years (2006-2016) are used for model validation. It is shown that the runoff forecast domain obtained from the unsupervised clustering is reasonable and appropriate for categorizing runoff categories. Further forecast experiments reveal that this model may shed some light on the prediction of annual mean runoff at the Danjiangkou Reservoir.
Keywords: *middle and long-term runoff forecast, category runoff prediction, Gaussian Mixture Model, cluster analysis, Support Vector Classification*

Introduction

Middle and long-term runoff forecast refers to the quantitative or qualitative prediction of runoff of various water bodies, e.g., rivers, reservoirs, and lakes, over the time horizon from more than three days up to one year. Runoff forecast is usually based on the past and present hydrological and meteorological information, as well as fundamental principles and methodologies based on several related disciplines including hydrology, meteorology, hydrodynamics, and statistics (Fan, 1999). As the water resource management progresses rapidly in recent years, middle and long-term runoff forecast has become increasingly more important and pressing.

Recent studies have made effort to address this issue. Yang et al. (2005) constructed a long-term runoff forecast system during the dry season by combining the continuous rainfall-runoff model and the long-term weather outlook. Their model was found to perform reasonably well. Hong et al. (2016) applied the genetic algorithm to improve the phase-space reconstruction method, and developed a new nonlinear model for monthly mean runoff. Their model was tested in four types of experiments using data from six hydrological stations along the Yellow River and the Yangtze River. Forecast experiments

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95619575

show that the medium- and long-term runoff forecast is satisfactory at these stations. A number of other recent studies further applied recently developed machine learning and artificial intelligence techniques to extended range runoff forecasts. Coulibaly et al. (2015) investigated the impact of climate trends on the forecast accuracy using a recurrent neural network (RNN), which was trained using time series of runoff to eight large hydropower systems in Quebec and Labrador and several selected climate indices. Results from the forecast experiments indicate that the use of BWA, PNA and ENSO indices leads to better forecast skill than the SLP or NAO indices alone. Maslova et al. (2016) constructed a model by combing wavelet decomposition and Bayesian machine learning regression techniques. The authors compared their model with that of the wavelet and artificial neural networks-based model and evaluated the effects of different wavelet boundary rules with synthetic and real runoff data collected from the Yellowstone River in the Uinta Basin in Utah. It is shown that their model accuracy can be improved by using a new wavelet boundary rule introduced in that study. Yang et al. (2017) applied three machine learning techniques to runoff forecast: Random Forest (RF), Artificial Neural Network (ANN) and Support Vector Regression (SVR). They compared the performance for forecasting one-month-lead reservoir runoff for two headwater reservoirs in USA and China, respectively. It is shown that RF yields the best statistical performances among the three. Tan et al. (2018) made an attempt to improve the decomposition-ensemble framework and proposed an adaptive model for medium and long-term runoff forecast in both the dry and flood seasons. The authors recommended to use SAR (1) model in the dry season and AEEMD-ANN model in the flood season to forecast the monthly runoff in Yangtze River Basin.

Formation of runoff is a result of complex interaction among a range of physical processes, including precipitation, evaporation, and confluence, and human activities. The category of complexity dictates that runoff forecast is inherently stochastic and highly uncertain. Therefore, it is challenging to predict the accurate value of future runoff based on qualitative analysis of physical processes. Besides, one may predict runoff categories instead of single values. The extension of prediction from single values to the runoff categories may help improve forecast reliability and enhance practical values of runoff forecast for the development and utilization of water resources. Indeed, past experience suggests that predicting runoff categories is more reliable and informative compared to single value prediction, as it improves the precision of the forecast e.g. Kasiviswanathan et al. (2013) and Ye et al. (2014). Quan et al. (2014) developed a method to construct prediction rainfall runoff categories with an artificial neural network (ANN) model. The model was calibrated by generating ensemble predictions, and tested in a real-world case study of rainfall-runoff data. The authors showed that the peak flows are predicted with improved accuracy with this method compared to traditional single point forecasts by ANNs. Li et al. (2017) calibrated and validated the different distribution types of Bayesian forecasting system for the observed 52 floods during 2004-2014 at the ZheXi basin. They showed that the Log Weibull and empirical Bayesian probabilistic model perform the best on average compared with the other distribution models. However, one limitation in these studies is that these methods require manually specifying the prediction categories. Because of the fuzziness of runoff, it may be argued that these conventional methods neglect peculiarity of hydrometeorological time series.

One method to objectively classify runoff categories is to apply sequence clustering analysis, which takes full consideration of fuzziness in runoff time series and provides faithful representation of the physical laws governing runoff. For example, Hou et al. (2016) combined three methods: sequenced sample clustering, set pair analysis (SPA), and Markov

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95619575

chains; this approach leads to multiple improvements compared to the conventional weighted Markov chains. Based on these methods, the authors constructed a prediction model for annual mean precipitation. The results show that the improvements lead to better classification of precipitation, sharper forecast probability distribution, and improved forecast precision. Zhao et al. (2017) proposed to use cluster analysis to examine anomaly correlation, a performance measure of raw general circulation model forecasts in the three-dimensional space of latitude, longitude, and initialization forecast time. Totz et al. (2017) developed a new cluster-based empirical model to forecast winter precipitation anomalies. They compared this model with dynamic forecast models and a canonical correlation analysis-based prediction model. The results indicated that this new prediction method performs better regarding timing and pattern correlation in the Mediterranean and European regions. Another widely used clustering method is the Gaussian Mixture Model (GMM), which is a parametric model based on Gaussian distribution and trained with the Expectation Maximization algorithm. The GMM can objectively classify runoff without human intervention, hence better suitable for classifying runoff categories for prediction.

Motivated by these efforts and considerations, we proposed the concept of forecast domain. Cluster analysis was conducted on the multiple year runoff data using the GMM, and resultant clusters are then used to construct forecast domain. Finally, Support Vector Classification (SVC) is adopted to predict the forecast domain. We apply this model to the forecast runoff at the Danjiangkou Reservoir, which is the primary water source of the Central Route of the South-North Water Transfer Project.

This paper make two main contributions. On the one hand it applied sequence clustering analysis which takes full consideration of fuzziness in runoff time series and provides faithful representation of the physical laws governing runoff. On the other hand it proposed a concept of forecast domain to expand the prediction results from specific values to the range, and the characteristics of the runoff change interval state were more evident.

Materials and Methods

Overview of the geography and climate of the Danjiangkou Reservoir area

The Danjiangkou (DJK) Reservoir (110 °E - 112°E，32°N-33°N, abbreviated as DJK hereafter) is the largest artificial fresh water lake in Asia (Li and Zhang, 2014). DJK is located at the boundary between the Danjiangkou city, Hubei Province and Zhechuan County, Hunan Province. DJK is the confluence of Han River and Danjiang River, with a drainage area of 17,916 km^2. The terrain of DJK is characterized by great elevation differences, steep slopes, and deeply dissected topography. The highest altitude reaches 1,798.9 m, with relative relief 1,711.9 m. The topography of the DJK area is overall higher to the northwest, and lower in the southeast, with steep terrain in the north and gentle slopes in the south, and alternating basins and canyons along the Han River (Bao, 2013). Situated in the transition zone to humid and warm climate within northern subtropical climate belt, DJK has a semi-humid continental climate, with four distinct seasons and precipitation is abundant in the wet season. Primary soil types in the DJK area include mountain yellow-brown earth soil, cinnamon soil, mountain brown soil, purple soil etc. The main forest and vegetation types are coniferous forests, broad-leaved forest, bamboo forest, shrub, and shrub meadow (Liao, 2011).

As the water source of the Central Route of the South-North Water Transfer Project, DJK has a storage capacity of 17.64 billion m^3, with averaged incoming runoff 39.35 billion

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95619575

m^3. Incoming runoff occurs mainly during the wet season (July – October) with an estimation of more than 60% of the annual total in this season (Li et al., 2008, 2009; Yang et al., 2012). The catchment area of the reservoir area is formed by the convergence of the Han River and the Dan River. Its main tributaries include the Qianyou River, Jinqian River, Si River etc. The largest tributaries of the Dan River include the Qi River and Laoguan River. Hydraulic constructions built on the upstream of the DJK, many large reservoirs along the Han River, as shown in *Figure. 1*.

Figure 1. *The geography in the upstream of DJK and the distribution of hydrometeorological stations*

The Central Route of the South-North Water Transfer Project provides water supplies to more than 20 medium and large cities in Henan province, and Hebei province, including Tianjin and Beijing. Annual water transfer is estimated to reach ~9.5 billion m^3 by the end of the first phase project, and will reach ~13.0 billion m^3 in the medium and long term. The Central Route of the South_North Water Transfer Project is expected to significantly relieve the water shortage crisis in many regions of northern China (Chen et al., 2015).

Data sources

The climate indices dataset from CMA Climate Center (http://cmdp.ncc-cma.net/cn/monitoring.htm) includes 130 indices for atmosphere and ocean circulations. Correlation analysis (Keane and Adrian, 1993) is conducted between the annual mean runoff at DJK and individual climate indices at the previous year. In addition to these climate indices, accumulated precipitation at the previous year is also considered in our model as a predictor, because precipitation is one of the primary factors contributing to runoff.

Gaussian Mixed Model (GMM)

GMM was developed based on Hidden Markov Model (HMM) (Eddy, 1996), and it belongs to a broad class of the unsupervised clustering methods (Reynolds, 2009). In essence, GMM is a multidimensional probability distribution function. Gaussian distributions are linearly weighted to characterize statistical distributions of the samples fully. Characteristic parameters spanning the space determine the model parameters (Mcnicholas and Murphy, 2008). In this paper, the actual runoff value of DJK from 1981 to 2016 was selected for clustering steps for clustering analysis in GMM may be summarized as follows:

(1) Suppose samples follow k mixed Gaussian distribution. Initialize μ_j , Σ_j , $j \in \{1,\cdots,k\}$ for each GMM.

(2) For each sample x^i , where $i \in \{1,\cdots,m\}$, compute the probability w_j^i that x^i follows GMM as following:

$$w_j^i = p\left(x^i \mid z^i = j\right) = \frac{1}{(2\pi)^{\frac{n}{2}} \left|\sum\right|^{\frac{1}{2}}} e^{\frac{1}{2}(x^i-\mu_j)\Sigma^{-1}(x^i-\mu_j)^T} \quad \text{(Eq.1)}$$

where z^i is the category of x^i .

(3) Update parameters of each Gaussian distribution:

$$\mu_j = \frac{\sum_{i=1}^m w_j^i x^i}{\sum_{i=1}^m w_j^i} \quad \text{(Eq.2)}$$

$$\sum_j = \frac{\sum_{i=1}^m w_j^i (x^i-\mu_j)(x^i-\mu_j)^T}{\sum_{i=1}^m w_j^i} \quad \text{(Eq.3)}$$

(4) Iterate steps (2) and (3) until the Gaussian parameters μ_j and $\sum_j$ converge.

(5) With the known Gaussian parameters μ_j and $\sum_j$ from the above step, iterate throughout all the samples and classify the samples according to the maximum probability.

Support Vector Classification (SVC)

The Support Vector Machines (SVM) is a type of the supervised classification methods developed from convex optimization (Vapnik, 1999; Hsu, 2010). SVC has been applied to classification and regression prediction problems. For classification, SVC can be grouped in two types: linear SVC and nonlinear SVC (Brereton and Lloyd, 2010). Linear SVC method solves the following optimization problem to identify the optimal classification interface:

$$\max_a L = \sum_{i=1}^N a_i - \frac{1}{2}\sum_{i,j=1}^N a_i y_i a_j y_j (x_i \cdot x_j) \quad \text{(Eq.4)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95619575

where the objective function is subject to the following constrains:

$$\sum_{i=1}^{N} a_i y_i = 0, a_i \in [0, C], i = 1, \cdots, N \quad \text{(Eq.5)}$$

where a and a_i are Laplacian multipliers, c is the penalty factor.

Nonlinear SVC makes use of kernel functions and the optimal problem can be expressed as:

$$\max_{a} L = \sum_{i=1}^{N} a_i - \frac{1}{2} \sum_{i,j=1}^{N} a_i y_i a_j y_j K(x_i \cdot x_j) \quad \text{(Eq.6)}$$

The classifiers in linear and nonlinear SVC may be expressed as:

$$f(x) = sign\left(\sum_{i=1}^{N} a_i^* y_i (x \cdot x_i) + b^* \right) \quad \text{(Eq.7)}$$

$$f(x) = sign\left(\sum_{i=1}^{N} a_i^* y_i K(x \cdot x_i) + b^* \right) \quad \text{(Eq.8)}$$

where a_i^* is from the coupled optimal solution, and b^* is the offset coefficient. Commonly used kernel functions include: linear kernels, $K(x, x') = x\ x'$; polynomial kernels, $K(x, x') = [(x\ x') + 1]^d$; Gaussian radial basis function (RBF) kernel, $K(x, x') = \exp(-\left\| x - x' \right\|^2 / 2\sigma^2)$; where x, x' are vectors, and d is the degree of the polynomials, and σ is the bandwidth of the Gaussian kernel.

Results and Discussion

Figure 2 shows the annual mean incoming runoff at DJK from 1981 to 2016. It is evident that the annual runoff varies over a wide range. Therefore, it is difficult to accurately predict future values based on qualitative analysis of physical factors. This study develops a new model based on runoff classification and forecast domain to categorize annual runoff at DJK in the past 36 years, conduct forecast experiments, and perform validation of this forecast model.

Classification of runoff

Several methods have been used to classify runoff categories in the past: aggregate standard deviation, mean deviation, and percent deviation. Here we use the percent deviation method that calculated the distance percentage between the annual runoff value and the average of the 36 years (1981-2016) runoff to classify the DJK runoff data into two categories. If the percent deviation is negative, the year of runoff category is designated as 1; if it is positive, the category is designated as 2. *Table 1* lists the classification of runoff based on percent deviation into two categories derived from this method.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95619575

Similarly, we further classify this DJK runoff data into 5 categories: Category 1 for percent deviation less than –20% , the percent deviation falls between –20% and –10%is Category 2 , Category 3 for percent deviation between 10% and –10%,. The percent deviation between 10% and 20% is Category 4 and greater than 20% is Category 5. Result from this percent deviation classification of the 36-year data is listed in *Table 2*.

Classification of forecast domain

Considering the distribution characteristics of the runoff sequence, the intrinsic distribution rule of the runoff sequence can be more effectively described, and the divided

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95619575

runoff interval is more reasonable. Based on this assumption, we proposed a new method called forecast domain. With this method, the GMM is used to cluster the annual mean runoff. Gaussian probability distribution is then linearly weighted to fit the full statistical distribution, which reduces sampling noise and helps achieve better classification. The number of the iteration steps is set as 100, and the number of the clusters is 2. Forecast domain was constructed based on the results of the above cluster analysis. *Table 3* lists the results of the classification of forecast domain derived from this method.

Table 2. *Classification of runoff into five domains*

Year	Distance to average(%)	Domain	Year	Distance to average(%)	Domain
1981	40.51	5	1999	-50.16	1

Result Analysis

The CMA climate indices database is preprocessed in the following two steps. First, for a small number of missing values in this dataset, linear interpolation is used to fill these missing values. Second, a linear correlation is computed between the annual mean runoff at DJK and the climate indices at the previous year. Twenty climate indices that have the highest correlation with the DJK annual runoff are selected based on this lead correlation analysis. We use the 25-year data (1981-2005) for model training, and the DJK runoff data during last 11 years (2006-2016) are used for model validation. DJK has an Asian subtropical monsoon climate. Its precipitation mainly comes from two meteorological moisture sources: warm and humid moisture transport from the southeast and southwest (Guo and Jin, 1997). In addition, sea surface temperature at the Pacific Ocean and the Indian Ocean also play essential roles in the eastern Asia climate. Considering these factors, the following prediction factors are selected in *Table 5*: sea surface temperature anomalies at the NINO W region (September of the previous year), latitudinal position index of polar vortex center in Northern Hemisphere (May of the previous year), area index of warm pool in Western Pacific (July of the previous year), number of cold air (November of the previous year), location the subtropical high in South China Sea (December of the previous year), intensity of eastern Asian trough in June, and accumulated precipitation of DJK in the previous year. These variables are entered intothe SVC model. Prediction is then conducted for the conventional classification categories derived from the percent deviation method and forecast domain derived from the GMM classification method.

Table 5. *Correlation coefficients between the predictors and annual mean runoff*

No.	Factors	Correlation coefficient
1	Sea surface temperature departure index of NINO W district in September of the previous year	0.46
2	The latitude index of the polar vortex in the Northern Hemisphere in May of the previous year	0.46
3	Western Pacific warm pool area index in July of the previous year	0.43
4	The number of cold air in November of the previous year	0.42
5	The position index of the South China Sea subtropical high ridge in December of the previous year	0.42
6	East Asia trough intensity index in June of the previous year	0.40

Forecast and validation of runoff categories classification

To eliminate untended influence of the dimensions of various indices, the Min-Max Normalization method is utilized to normalize each index. *Figure 3* shows the forecast validation of the two classification categories from SVC. *Figure 4* shows the SVC forecast results of five classification categories. If the predicted results of a certain sample coincide with the real results, it indicates that the prediction is correct and the opposite is wrong. It is evident that ifthe classification of runoff into two categories, only the year 2009 and the year 2011 are predicted to be wrong, and the accuracy is 82%. However, if the classification of runoff is classified into five categories, the accuracy dropped to 45%.

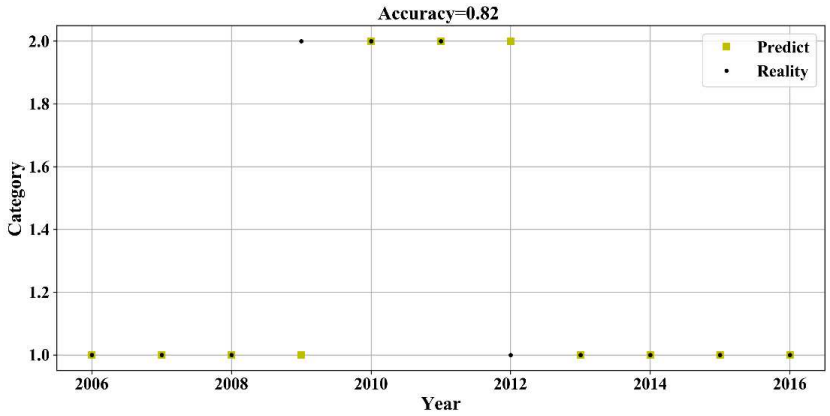

Figure 3. *SVC forecast based on two classification categories of runoff*

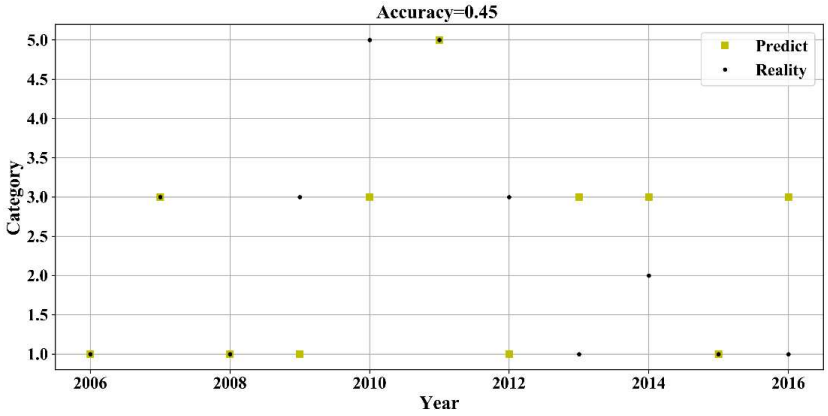

Figure 4. *SVC forecast based on five classification categories of runoff*

Forecast and validation of forecast domain

The similar forecast experiments are conducted. The forecast results based on SVC model by two and five classification categories of forecast domain are shown in *Figure 5* and *Figure 6*. The validation set represents the DJK runoff data during last 11 years (2006-2016) and the category means the classification of forecast domain. Compared with last section, when the classification of forecast domain into two categories, SVC forecast based on forecast domain performed better, and the accuracy

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95619575

up to 91%. However, when the classification of forecast domain into five categories, the accuracy also declined. We can conclude that whether it is two categories or five categories, the accuracy based on forecast domain is higher than the original classification.

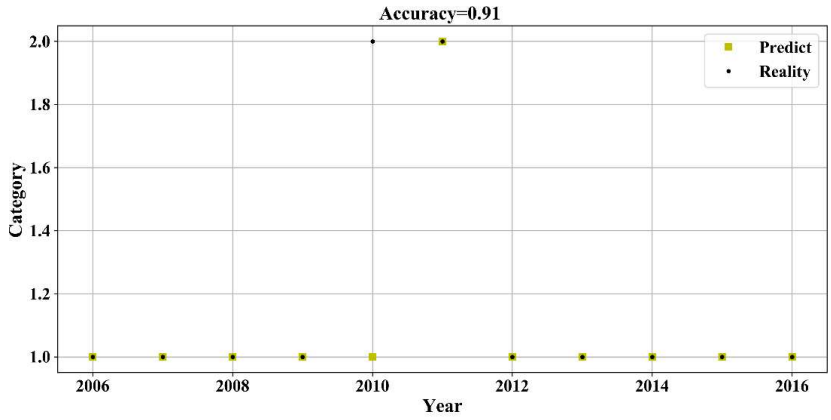

Figure 5. *SVC forecast based on two classification categories of forecast domain*

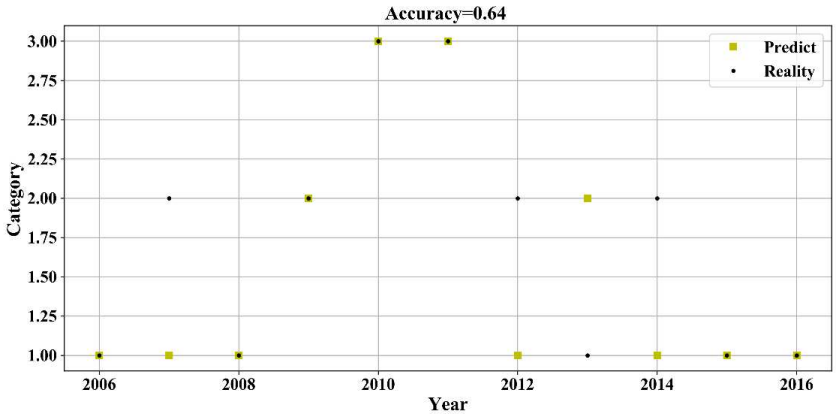

Figure 6. *SVC forecast based on five classification categories of forecast domain*

Table 6 summarizes the accuracy of SVC forecast based on theclassification methods by conventional percent deviation and forecast domain.

Table 6. *Comparisons of the SVC forecast by conventional percent deviation and forecast domain*

Accuracy	Two runoff categories	Two forecast domains	Five runoff categories	Five forecast domains
SVC	82%	91%	45%	64%

Reliability and performance of our prediction model are assessed with three forecast skill metrics: precision, recall rate (Buckland and Gey, 1994) and the F1 measure (Lipton et al., 2014). Precision indicates among the predicted results how many positive predictions are true positive. Precision is defined as:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95619575

$$Precision = \frac{number\ of\ true\ positives}{number\ of\ positives} \quad \text{(Eq.9)}$$

Recall measures among the relevant samples how many are correctly predicted, defined as:

$$Recall = \frac{correctly\ predicted\ number\ of\ true\ positives}{total\ number\ of\ relevant\ levels} \quad \text{(Eq.10)}$$

F1 is defined as the harmonic mean of precision and recall:

$$F1 = \frac{2}{\frac{1}{Precision} + \frac{1}{Recall}} \quad \text{(Eq.11)}$$

These three skill metrics from these prediction experiments for the conventional classification categories and forecast domain are summarized in *Figure 7*.

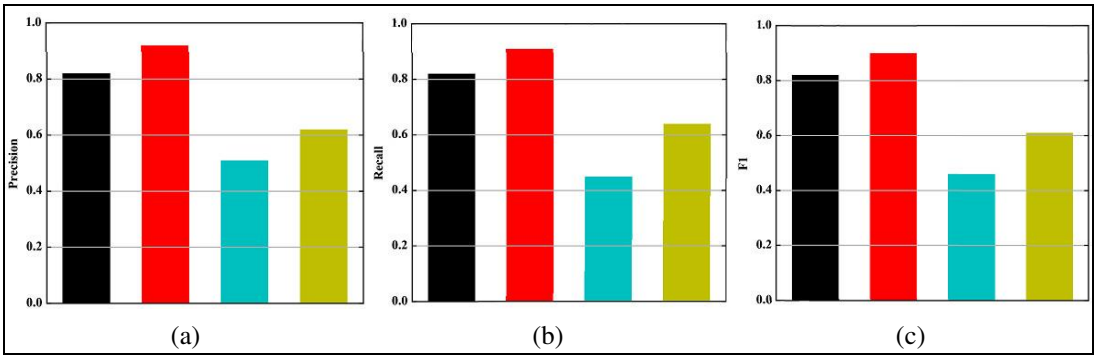

Figure 7. *Precision, recall, and F1 measures from the SVC forecast based on conventional percent deviation and forecast domain*

According to *Figure 3* and *Figure 4*, SVC prediction performs well for the two runoff categories derived from the percent deviation method, and the precision is 82%. However, the precision decreases to 45% by adopting the five runoff categories. In contrast, precision reaches 91% by using the two classification categories of forecast domain derived from the GMM clustering, and it remains 65% based on five classification categories of forecast domain.It is suggested that forecast domain method is more flexible and reliable. *Figure 7* further shows that regardless of the number of runoff categories, for all three metrics, SVC prediction based on forecast domain perform better than that based on conventional classification categories. Therefore, we conclude that the GMM clustering derived forecast domain is better suitable for the prediction of annual runoff at the DJK.

Model comparison

In order to better reflect the feasibility of this model, chooses Naive Bayes to compare with. The result is shown below.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95619575

It can be seen from *Figure 8* and *Figure 9* that when two runoff categories performed, Naïve Bayes has a poor recall rate and is unstable compared with the SVC; when performing the five runoff categories, the accuracy of the two methods both are low and the effect is average. In summary, SVC has higher accuracy and stability.

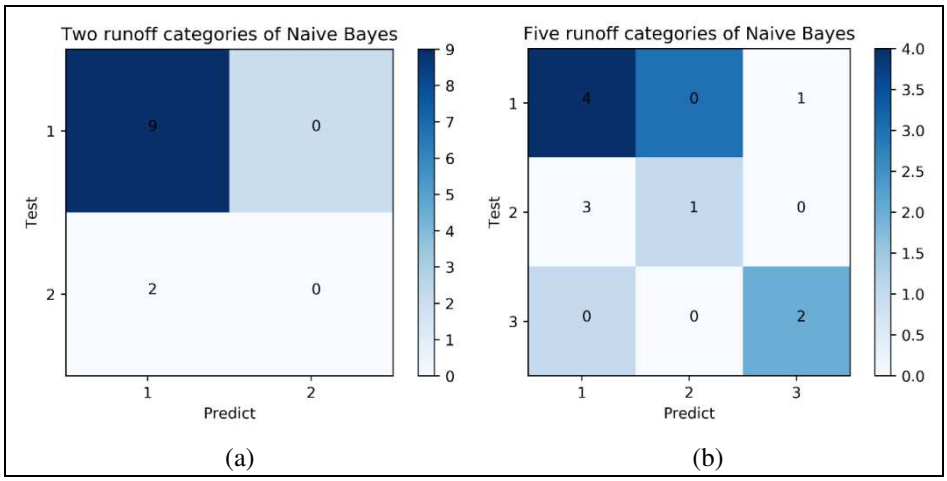

Figure 8. *Naive Bayes evaluation results*

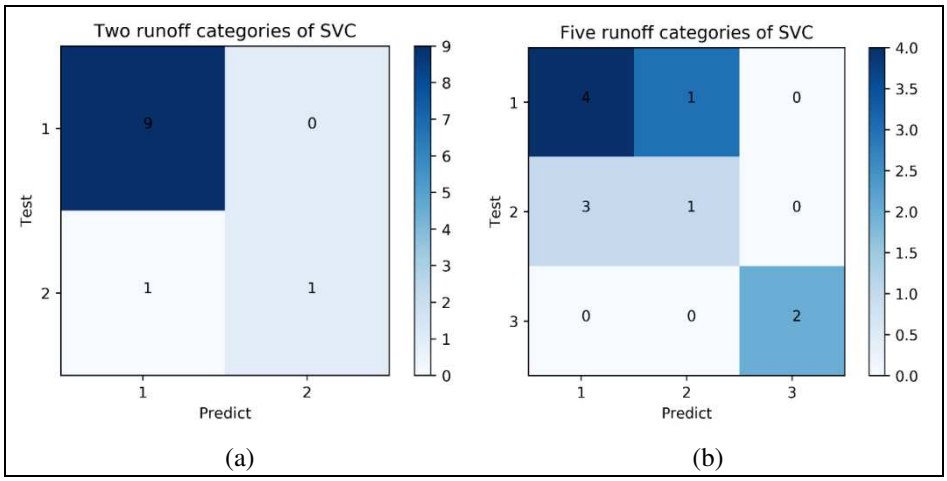

Figure 9. *SVC evaluation results*

Conclusion

The current study focuses on the DJK, the main water source of the Central Route of the South-North Water Transfer Project. We have developed a prediction model for annual mean runoff based on forecast domain instead of conventional classification method of runoff. Gaussian Mixed Model is utilized to cluster the 36-year annual runoff at DJK. Forecast domain was further derived following the GMM clustering and fed to the Support Vector Classification model. Forecast experiments based on forecast domain and conventional classification categories are conducted and compared. The results can be summarized as follows:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95619575

(1) Extending the prediction of single value to prediction of multiple forecast domain help better characterize and quantify the variability of runoff. This development bears important practical values to the water resource management and utilization.

(2) Application of sequence clustering analysis to classification takes consideration of the full distribution of runoff, which in turn helps better characterize the statistical distribution of runoff, and further justify objective classification of the runoff categories.

(3) Precipitation is one of the primary factors contributing to runoff. As a result, accumulated precipitation at the previous year should be included as a predictor.

Our results highlight that it is feasible to predict annual runoff based on forecast domain. This results may pave the way for the operational forecast of the annual runoff at the DJK. Our future research endeavors will be devoted to further improving the model in the following aspects:

(1) Using different feature selection method to characterize and understand potential nonlinear relationships among the predictors to achieve further forecast improvement.

(2) For the forecast domain developed in this study, we will apply the k-nearest neighbor's algorithm to predict future annual incoming runoff within a time range of interests at the DJK.

Abstract. The floristic patterns of the Atlantic Forest can be explained by different environmental factors. However, recent studies have pointed to the influence of spatial factors on the structure of forest communities. In this study, we evaluated whether environmental and spatial variables influence the distribution of regenerative species in the *Araucaria* forest in Southern Brazil. We analyzed the vegetation in 20 circular plots with 2.5 m radius each. The environmental variables open-canopy and Ca/K content of soil were the most important predictors of floristic variations in the study area, explaining 9% of the species distribution, while the pure spatial structure explained 7% of the community structure. Although much of the floristic variation remained unexplained (75%), the results indicated the complex effect of environmental and spatial variables on the regeneration patterns of the Araucaria Forest in Southern Brazil.
Keywords: *spatial structure, environmental factors, subtropical rainforest, soil-vegetation, RDA*

Introduction

The Atlantic Forest domain is a global hotspot for the conservation of biodiversity and covers approximately 1,300,000 km² of the Brazilian territory. These forests are characterized by different forest types/subdomains, being distributed along the Brazilian coast and occurring more pronounced in the Southeast and South regions (Rocha and Silva, 2013). These forests have a high species richness and a high value of endemism when compared to other Brazilian domains, however, due to a historical process of deforestation and human occupation, the Atlantic Forest is currently fragmented, presenting only 11.7% of its original coverage (Ribeiro et al., 2011). In the State of Santa Catarina, Southern of Brazil, the Atlantic Forest involves different forest types, of which the *Araucaria* forest stands out, with the Brazilian pine (*Araucaria angustifolia)* as the characteristic element (Bertol.) Kuntze), with emphasis on other species of the families Lauraceae and Meliaceae (Kersten et al., 2015). In general, the distribution of this forest type is associated with intrinsic soil, geomorphological and climatic conditions, as well as being influenced by extreme environmental factors (i.e., storms, frost, fires) (IBGE, 2012; Higuchi et al., 2016; Souza et al., 2017).

In recent years, the *Araucaria* forest regeneration has been the subject of several ecological studies, and the analysis of vegetation related to environmental factors has helped answer some questions about the distribution of tree species in environmental

DOI: http://dx.doi.org/10.15666/aeer/1704_95779589

gradients (Higuchi et al., 2016). Among the environmental factors that affect the distribution of the regeneration of the *Araucaria* Forest, we highlight luminosity, open-canopy, elevation, pedological and geomorphological characteristics, among others (Higuchi et al., 2015). Although environmental factors are widely known as promoters of the Atlantic Forest distribution, little attention has been paid to spatial factors, which are important and may influence the distribution of plant species in subtropical forests (Maçaneiro et al., 2016a).

The spatial factors can be connected to biotic/stochastic processes, such as dispersion, pollination and competition (Diniz-Filho et al., 2012; Peña-Claros et al., 2012; Lewis et al., 2014). Due to the difficulty in measuring these data, spatial factors are generally neglected in vegetation studies, however, the inclusion of the spatial structure is fundamental, because it assists in the identification of important environmental processes, the variability of species in different locations, environmental heterogeneity and the effect of abiotic processes (Lewis et al., 2014). For example, environmental factors such as luminosity affect the dynamics and establishment of forest regeneration (Peixoto et al., 2012; Horn et al., 2015), while soil and topography are related to the distribution of species in environmental gradients (Dubuis et al., 2012; Baldeck et al., 2013; Mélo et al., 2013; Maçaneiro et al., 2016a). On the other hand, the spatial structure of the community directly influences the colonization and evolution of the species, becoming a fundamental mechanism in the distribution of vegetation in subtropical forests (Urbanetz et al., 2003; Baldeck et al., 2013; Neuschulz et al., 2016).

Thus, the development of studies related to natural regeneration as a function of the analysis of environmental and spatial variables becomes essential to explain the processes that control the establishment and distribution of regenerating species in the *Araucaria* Forest of Southern Brazil. In this sense, in the present study we analyze two main questions: (1) Which environmental factors influence the distribution patterns of regenerative species? We expect to find a great effect of soil and canopy opening in determining floristic composition, because these are well known to be the main factors conditioning changes in the composition of vegetation in the Atlantic Rainforest at local scales (Higuchi et al., 2015, 2016; Souza et al., 2017; Maçaneiro et al., 2019). (2) Is the spatial structure of the community related to regenerative species and environmental factors? We expect to find a significant effect of space, because recent studies have indicated that inclusion of the spatial component in the analysis of vegetation patterns helps in the identification of ecological processes (Maçaneiro et al., 2016a; Loebens et al., 2018). Thus, the spatial component may be important to determine the distribution of species regeneration in Atlantic Rainforest in Southern Brazil.

Material and Methods

Study area

The present study was carried out in forest fragments of the company *Florestal Gateados*, located in the municipality of Campo Belo do Sul, State of Santa Catarina, Southern Brazil (*Figure 1*). The property is located in the Pelotas river basin and in the *Campos de Lages* region. It is part of the *RPPN Emílio Einsfeld Filho*, which has a total area of 6,328.60 ha and elevation varying from 620 to 980 meters a.s.l. (27°55' and 28°05' S – 50°55' and 50°45' W).

The climate of the study region, according to the Köppen classification, is of the type Cfb – humid mesothermic temperate climate with mild summer, and with average

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95779589

annual temperature ranging from 12 to 16°C, average annual total rainfall of 1,600 to 1,900 mm and relative humidity of 78 to 80% (Alvares et al., 2013). The geology of the region is formed by the *São Bento* Group, which is composed of the *Serra Geral* Formation, which is constituted mainly by intrusions of basalts, diabase and acid lavas (Santa Catarina, 1986). The predominant soils formed by these types of rocks in the study area are Litholic Neosol, Haplic Cambisol and Nitosols (Santos et al., 2018).

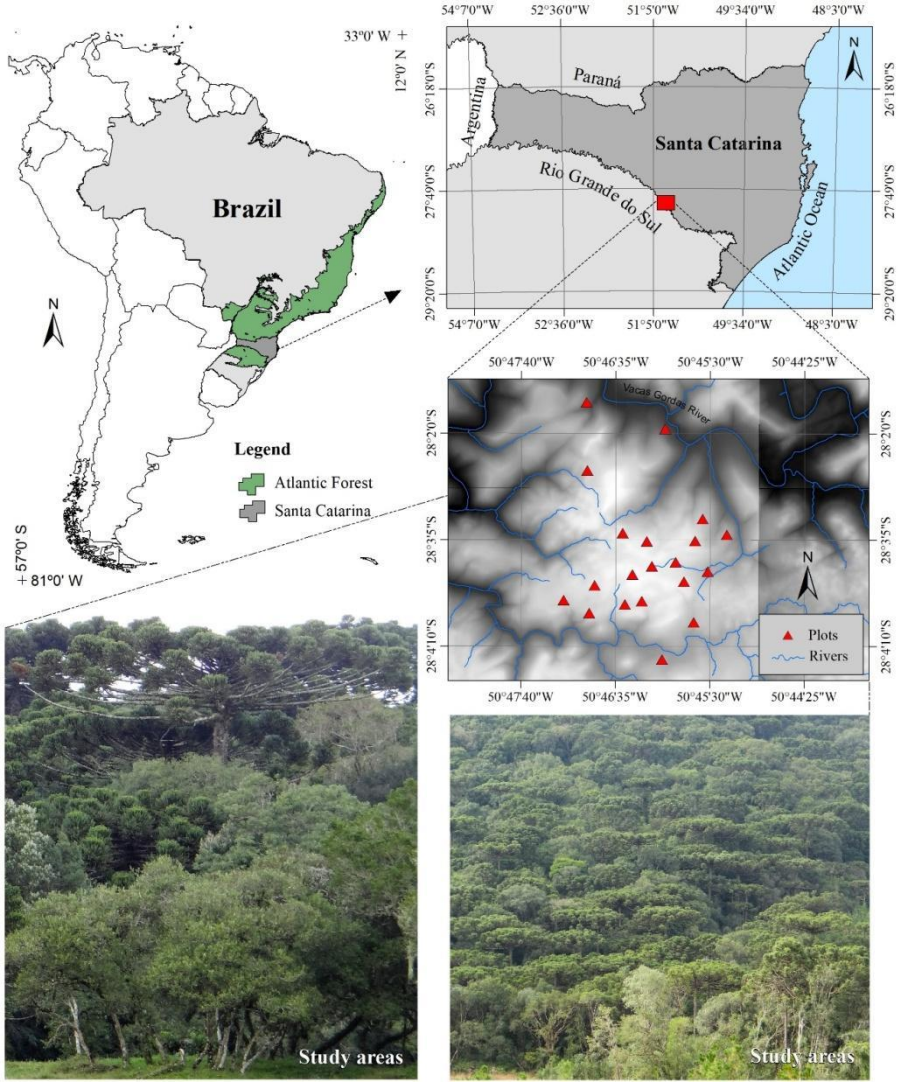

Figure 1. *Studied area at RPPN Emílio Einsfeld Filho, Santa Catarina State, Southern Brazil, and the distribution of the sample plots*

The vegetation of the studied area is constituted by the *Araucaria* Forest (Mixed Needle-Broadleaved Forest – Oliveira-Filho, 2015). This vegetation is characterized by the presence of dense clusters formed by *Araucaria angustifolia* and associated with several tree and shrub species of the Myrtaceae and Lauraceae families (Kersten et al., 2015). Currently, the vegetation in the study area is in advanced stage of regeneration, with about 35 years without anthropic exploration (Maçaneiro et al., 2018).

DOI: http://dx.doi.org/10.15666/aeer/1704_95779589

Data collection

For data collection we installed 20 plots of 2.5 meters radius, in which we sampled all regenerating individuals with diameter at breast height (DBH) < 15 cm and with a minimum height of 50 cm. We collected the data between December/2015 and April/2016. We identified the collected botanical material by comparison with exsicates deposited in the Herbarium Dr. Roberto Miguel Klein and by consulting the taxonomic literature and the specialists of the *Universidade Regional de Blumenau* (FURB) and the *Universidade do Estado de Santa Catarina* (UDESC). We used the species classification system proposed by APG IV (2016) and PPG I (2016).

To obtain the chemical properties of the soil, in each plot we collected soil samples in the depth of 0-20 cm. Then, we stored the samples in plastic bags and sent to the Laboratory of Soil Analysis of EPAGRI (*Empresa de Pesquisa Agropecuária e Extensão Rural de Santa Catarina*) to obtain the chemical variables: clay content (%), phosphorus (P), potassium (K), organic matter (%), aluminum (Al), calcium (Ca), magnesium (Mg) and cation exchange (CTC), aluminum saturation (m%) and base saturation (V%) and pH (Santos et al., 2018).

To obtain the physical properties of the soil, we collected samples with volumetric rings of the Kopecky type of known volume, *i.e.* we collected two points per plot. After these collections, we stored and weighed the samples for later drying in a drying kiln (105°C). The moisture parameters (%) of these samples were determined by the volumetric method and soil density ($g.cm^{-3}$) according to Teixeira et al. (2017). Then, to verify the influence of the canopy opening and the luminous intensity on the natural regeneration, for each site, six hemispherical photographs were taken 10 m apart (see Pinagé et al., 2013). We use a Nikon D3100 digital SLR camera and Nikon Fish-eye Nikkor 10.5 mm lens (*Figure 2*). The photos were analyzed in the software CAN_EYE v6.3.8 to obtain the values of canopy opening and leaf area (Weiss and Baret, 2010). We measured the luminosity index with the aid of a digital *luxímetro*, in the center of each subplot and in the open field (Suganuma et al., 2008).

Figure 2. *Hemispherical photography captured inside regeneration plots of the Araucaria Forest with high (A) and low (B) canopy opening, Southern Brazil*

Data analysis

We analyzed the influence of environmental and spatial variables on regenerating vegetation through canonical analysis of RDA (Borcard et al., 2011; Legendre and Legendre, 2012). We removed collinear environmental variables through principal component analysis (PCA) in PC-ORD 6.0 (McCune and Mefford, 2011). After this procedure, the environmental variables that remained in the analysis were elevation, soil humidity (%), canopy opening (%), leaf area (m^2), luminosity (%), pH-H_2O, SMP

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95779589

index, base saturation (V%), sum of bases (S), clay content (%), potassium (K), aluminum (Al), calcium (Ca), magnesium (Mg), potential acidity (H+Al), CTC at pH 7.0, Na at CTC and Ca/K and Mg/K ratios in soil.

In the abundance matrix of individuals, we removed the species that presented only one individual in the sample, since these contribute little to the data set and may hinder vegetation analysis (Legendre and Legendre, 2012). After this procedure, we applied the 'standardized score' transformation in the environmental variables, to correct the differences between the units of measure. We used the geographical coordinates (latitude and longitude) of the plots to create spatial variables called MEMs (*Moran's Eigenvector Maps*) in the R Environment using the "spacemakeR" package, as recommended by Borcard et al. (2011). We made the selection of the significant MEMs by means of the "forward" method and we also selected the environmental variables by another RDA. Finally, we processed the last RDA in PC-ORD 6.0 (McCune and Mefford, 2011), using abundance matrices with environmental (standardized) and spatial variables (MEMs) selected to verify the effect of these variables on species composition in the area of study. We verified the statistical significance of the ordering axes of the RDAs through 999 Monte Carlo permutations (Legendre and Legendre, 2012).

Then, we effected the partitioning of the variance into the data set in order to separate the fractions relative to the environment [a], the spatially structured environment [b], only the space [c] and the undetermined variables [d]. In this analysis, we used the "vegan", "packfor", "spacemakeR" and "spdep" packages in the R Environment.

Results

In the study area we sampled 466 individuals (11,867 ind.ha^{-1}) belonging to 60 species and 24 botanical families (*Table 1*). The species in the regenerative stratum with the highest density and frequency were *Allophylus edulis* (A. St.-Hil.) Radlk., *Myrsine umbellata* Mart., *Casearia decandra* Jacq. and *Matayba elaeagnoides* Radlk. (*DR*=39.1% and *FR*=26.3%).

Table 1. *List of the 15 species with the highest density and frequency values in the natural regeneration of the Araucaria forest in Southern Brazil*

Species	Abbreviation	*DA*	*DR*	*FA*	*FR*
Allophylus edulis (A.St.-Hil. et al.) Hieron. ex Niederl	*All edu*	1,732	14.6	65.0	7.6
Myrsine umbellata Mart.	*Myr umb*	1,197	10.1	55.0	6.4
Casearia decandra Jacq.	*Cas dec*	917	7.7	45.0	5.3
Matayba elaeagnoides Radlk.	*Mat ela*	789	6.7	60.0	7.0
Eugenia sp.	*Eug sp.*	738	6.2	40.0	4.7
Sebastiania brasiliensis Spreng.	*Seb bra*	688	5.8	25.0	2.9
Allophylus guaraniticus (A. St.-Hil.) Radlk.	*All gua*	637	5.4	40.0	4.7
Miconia cinerascens Miq.	*Mic cin*	509	4.3	10.0	1.2
Annona emarginata (Schltdl.) H.Rainer	*Ann ema*	484	4.1	25.0	2.9
Cinnamodendron dinisii Schwacke	*Cin din*	382	3.2	35.0	4.1
Rudgea parquioides (Cham.) Müll.Arg	*Rud par*	357	3.0	30.0	3.5
Araucaria angustifolia (Bertol.) Kuntze	*Ara ang*	331	2.8	35.0	4.1
Eugenia uniflora L.	*Eug uni*	306	2.6	30.0	3.5
Styrax leprosus Hook. *et* Arn.	*Sty lep*	255	2.1	25.0	2.9
Brunfelsia pilosa Plowman	*Bru pil*	229	1.9	20.0	2.3
Other species	-	2,317	19.5	315.0	36.8

DA = absolute density (ind.ha^{-1}), DR = relative density (%), FA = absolute frequency (%), FR = relative frequency (%)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95779589

In the redundancy analysis (RDA), the plots differed according to the variation in environmental and spatial variables. The eigenvalues of the first two ordering axes explained 36.1% of the data variance (axis 1 = 23.4%, axis 2 = 12.7%) and presented significance by the Monte Carlo test ($p \leq 0.05$). The environmental and spatial variables that correlated with axis 1 were Ca/K, MEM 3 and MEM 17, while for axis 2 only the degree of canopy opening (*Figure 3*, *Table 2*).

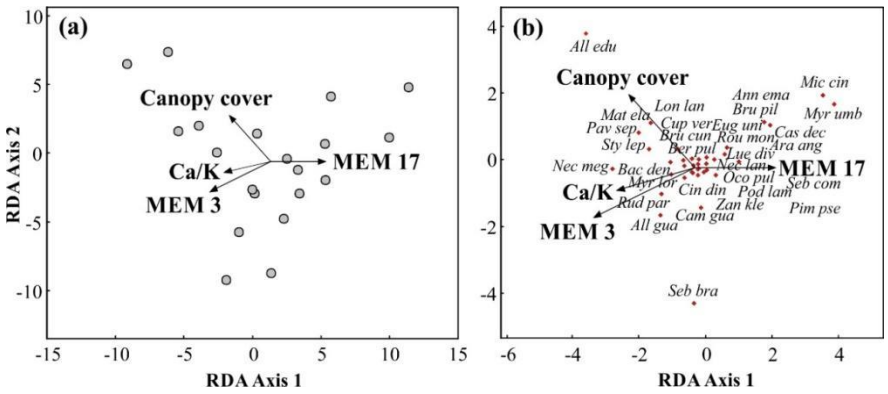

Figure 3. *Redundancy analyzes (RDA) produced by plots, species and environmental and spatial variables for the Araucaria forest regeneration in Southern Brazil*

Table 2. *Environmental and spatial variables produced by the RDA for Araucaria forest regeneration in southern Brazil. R^2 adjusted, F and p were obtained by ANOVA after partitioning of the variance*

Predictor	Average value	R^2 adjusted (%)	*F* (ANOVA)	*p* (ANOVA)
MEM 3	-	11.0	3.4	0.001
Ca/K	13.7	10.4	3.3	0.009
Canopy opening	17.9	7.6	2.6	0.01
MEM 17	-	4.4	1.9	0.03

In the ordination diagram of the plots, we verified that the first two axes had a strong relation between canopy opening and the spatial variable MEM 17 (*Table 2*). The axes formed two groups of plots, the first one being related to light intensity in the environment and the second, to the spatial structure of the community. In addition, we observed the formation of a short gradient related to the Ca/K content (*Figure 3a*).

In the diagram of species ordination, we verified a strong association with the canopy opening and the density of regenerating individuals of *Allophylus edulis, Matayba elaeagnoides, Muellera campestris, Cupania vernalis, Brunfelsia cuneifolia, Pavonia sepium* (*Figure 3b*), while in closed canopy sites (generally located below the broad canopies of *Araucaria angustifolia*) we found other predominant species (e.g., *Campomanesia guaviroba, Zanthoxylum kleinii, Cinnamodendron dinisii* and *Sebastiania brasiliensis*). Also, we observed in *Figure 1b* an association between variables MEM 17 and Ca/K. In this case, certain species occurred in soils with high index of Ca/K (e.g., *Nectandra megapotamica, Baccharis dentata*, *Rudgea parquioides* and *Allophylus guaraniticus*). On the other hand, species like *Casearia decandra, Araucaria angustifolia* and *Ocotea pulchra* are usually associated to soils with less Calcium and Potassium index, but they are positively influenced by spatial component MEM 17.

DOI: http://dx.doi.org/10.15666/aeer/1704_95779589

Partitioning of variance revealed that fractions [a] "pure" environment (F = 2.071, p=0.008) and [c] "pure" space (F = 1.773, p = 0.02) were significant (*Figure 4*). The fraction [b], related to space + environment, indicated that part of the analyzed environmental variables (9%) is structured in space, while the [a] "pure" environment (9%) and [c] "pure" space (7%) stood out among fractions. However, the fraction [d] relative to the undetermined variables explained most of the vegetation variation in the study area (75%).

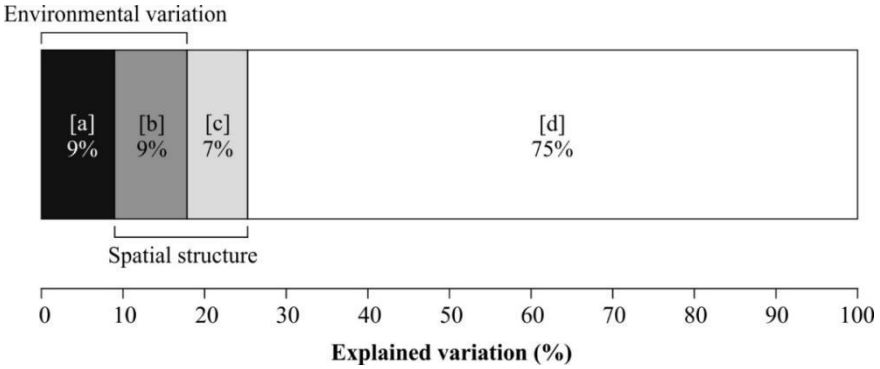

Figure 4. *Partition of the variance by the redundancy analysis to determine the fractions "pure" environment [a], space + environment [b], "pure" space [c] and undetermined variables [d] for the Araucaria forest regeneration in Southern Brazil*

Discussion

Our results indicate that some of the quantified environmental variables influence the distribution of the regenerating species of the *Araucaria* Forest in the South of Brazil. They also indicate that the spatial structure, generally neglected in studies on subtropical forest regeneration, plays an important role in forest regeneration. The spatial structure is less relevant to environmental variables but influences the distribution of some species. Among the factors that influenced the distribution of regenerating species the most in the *Araucaria* Forest is the variation related to the canopy opening. Studies related to the distribution of species have shown that the luminosity variation within the forest influences the species distribution (Duarte et al., 2002; Higuchi et al., 2015). The canopy opening and the variation of luminosity are related to climatic events (e.g., storm) that occurred prior to the development of the present study, and may be influencing the distribution of the species. Biotic/stochastic events may alter light input into the forest, affecting the dynamics of regeneration within tropical forests (Peixoto et al., 2012; Horn et al., 2015; Kersten et al., 2015).

We verified high density of regenerating individuals of *Allophylus edulis* in plots with greater canopy opening, indicating that this species frequently occurs in open areas such as forest edges or natural clearings (Maçaneiro et al., 2016b). The luminosity is one of the main factors that affect the establishment and growth of plants, being fundamental in the structure of the forests (Duarte et al., 2002). In our study, we verified different levels of luminosity within the forest, associated to stochastic factors and/or possibly to successional processes. These conditions reflect in the existence of different environments within the forest, which are explored by groups of species with different survival abilities (Baldeck et al., 2013). Thus, the differences in floristic composition

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95779589

and density of the species correspond mainly to the intensity of the canopy opening within the forest.

Considering the influence of environmental variables on forest regeneration, we observed that the soil Ca/K content positively influences the distribution of some species (e.g., *Nectandra megapotamica*, *Rudgea parquioides*). Soil fertility, for example, is usually associated with some chemical element present in a greater or lesser quantity, varying in relation to local soil characteristics, depth and texture, among others. Studies have shown a strong relationship between soil characteristics and floristic composition, generally associated with pH, texture and moisture content (Dubuis et al., 2012; Mélo et al., 2013), differently from what we observed in this study. The presence of Ca/K in the soil may influence the distribution process of the species because they are elements associated with germination, growth and resistance at low temperatures. In our study, the environmental variables (represented by the canopy opening and the presence of Ca/K) were not the only processes that explained the species distribution.

The spatial component may be associated with biotic/stochastic processes (e.g., dispersion, facilitation, competition, pollination and predation) (Lewis et al., 2014), which in this study revealed a significant fraction of the floristic patterns. Among the stochastic processes that can influence the spatial distribution, dispersion plays a fundamental role in the colonization of regenerating species and is influenced by several external components (e.g., animals, wind) (Wang and Smith 2002; Urbanetz et al., 2003; Neuschulz et al., 2016). The facilitacion and competition processes can also influence the spatial distribution of species, but these processes do not depend on the physical factors of the environment and may occur in different climatic conditions (Mélo et al., 2013). In this case, we observed that climatic events and stochastic process may be influencing the species distribution and are playing a role in the colonization of certain species in regeneration. Environments that present adversities can act like an ecological filter, in order to affect the performance of some species (Temperton and Hobbs, 2004; Gotelli, 2007). Likewise, the maintenance and establishment of regeneration in the study area may be occurring through the processes of pollination and seed predation (Wang and Smith, 2002). Therefore, to determine these ecological patterns it is necessary to replicate the study to create forest patterns (Scipioni et al., 2009).

In the present study, the partitioning of the data set variance indicated that the highest percentage of factors that interfered in distribution patterns is related to unknown fractions (75%). According to Lewis et al. (2014), variation of species composition along the plots and heterogeneity are factors that increase the unknown fractions. In addition, the environmental variables used are not necessarily the predictors that best explain the species distribution variations (Soininen, 2014). Another reason is the weakening of environmental responses when using the variance partition (Angeler et al., 2013). Likewise, it revealed that “pure” environment factors (9%) and “pure” space (7%) were statistically significant, being important predictors to explain the distribution of regenerating species in the *Araucaria* Forest in Southern Brazil. In this way, it is crucial to carry out new studies, which aim to include observations on dispersion, pollination and competition patterns, among others, to respond unknown factors (Diniz-Filho et al., 2012; Peña-Claros et al., 2012).

DOI: http://dx.doi.org/10.15666/aeer/1704_95779589

Conclusion

Although much floristic variation remained unexplained, the results indicated the complex effect of environmental and spatial variables on the regeneration patterns of the *Araucaria* Forest in Southern Brazil. The environmental variable with the greatest influence on the distribution of the natural regeneration of the *Araucaria* Forest was the opening of the canopy. This variable affected certain species of the regenerating component. In addition to this variable, the soil Ca/K content influenced certain species, but it was not as fundamental as the canopy opening. Despite the environmental influence on the species distribution, it is important to emphasize the importance of the spatial structure on the forest regeneration, being this one of the variables that influenced the vegetation the most. In the same sense, the spatial components generally neglected in ecological studies have shown great influence in the distribution and must be taken into consideration to analyze forest environments.

Considering that the study was developed at a local scale, other works should be developed to determine the floristic pattern for the *Araucaria* Forest. It is important to investigate further the association between species and environmental standards and to analyze the influence of different spatial variables such as competition, dispersion, microclimate, among other variables not presented in this study, since the addition of these variables may increase the predictive power of floristic patterns in subtropical forests.

Abstract. The present study was conducted in a population structure of selectively logged tropical wet evergreen forest, *Cullenia-Mesua-Palaquium* (CMP) forest series in the tropical wet evergreen forests of the Nelliampathy Hills, Western Ghats. The study was aimed to focus on how selectively logged treatment influences the density and basal area of CMP forest series stand structure. We sampled the number of individual trees (≥ 1 cm dbh, diameter at breast height) of CMP at 30 sites (20 × 50 m quadrat size), covering an area of 30.8 hectare (ha) in total. A total of 5936 tree individuals sampled had a mean density of 246 ha^{-1} and basal area of 20.73 metre square (m^2) ha^{-1} from an area of 0.1 to 2.5 ha. Tree density per hectare and basal area differed significantly among plots with different logging treatments. Tree density and basal area were significantly lower in highly logged plots as compared to moderately logged and unlogged plots. The density of smaller trees was significantly higher in moderately logged plots. We suggest that heavy logging treatments might be a serious threat to the CMP forest series and may possibly alter its population structure and that the moderately logged treatments showed positive impacts on CMP stand structure and regeneration.
Keywords: *basal area, disturbance, forest management, large trees, tree extraction*

Introduction

Globally, more than 400 million hectares of tropical forest are in the logging estates (Blaser et al., 2011; Senior et al., 2017; Silva et al., 2018) and the world's tropical forests have been affected by intensive commercial logging for at least several decades (Johns and Skorupa, 1987; Chapman and Chapman, 1997; Gardner et al., 2009; Putz et al., 2012; Poudyal et al., 2018). Logging is a major threat in reducing the native forest

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95919607

area (Gatti et al., 2015) and potentially results in species extinction (Pimm and Raven, 2000). In addition to clear cut logging, selective logging is also an important driver of forest alteration across the tropics with ~20% of all tropical forests selectively logged between 2000 and 2005 (Asner et al., 2009; Ansell et al., 2011; Magrach et al., 2016). Selective logging can negatively alter the ecological interaction of the remnant tree diversity and population structure leading to a negative impact on forest structure (Okuda et al., 2003; Yamada et al., 2013; Gatti et al., 2015). As a result of the alteration of ecological interactions in the forest due to selective logging (Schleuning et al., 2011; Magrach et al., 2016), many endemic and rare species could possibly decline at a rapid pace (Laurance et al., 1999; Zhu et al., 2004). Therefore, logging activity poses a serious threat to the long-term sustainability of the population of certain tree species in the tropical forest ecosystem.

In this study, silviculture practices is defined as the process by which the trees established in large area of forest would be removed and replaced by new tree regeneration, resulting in the production of distinctive forms of woods (Troup, 1966). It is also demarcated as "the art and science of producing and tending forests by manipulating their species establishment, species composition, structure and dynamics to fulfil the tropical forest management purposes" (ITTO, 2002). Therefore, tropical silviculture practices may play a major role in the present and future to ensure forest sustainability and sustainable production of forest products (Peña-Claros et al., 2008; Villegas et al., 2009). However, silviculture systems emphasizes the method of raising forest products by the influence of timber extraction (Ramachandran, 2008). Previous studies also demonstrates that silviculture was carried out by clearcutting (Hoffman, 1924; Isaac, 1956), partial cutting or selective logging (Kirkland and Brandstrom, 1936).

Selective logging activity may also decrease the forest area (McDonald et al., 2006) and remove the larger trees in a tropical forest (Osazuwa-Peters et al., 2015). Both forest area and the large tree presence are crucial in determining the capacity of the tropical forest to sequester carbon (Slik et al., 2013). Therefore, examination of selective logging impacts on selected tropical forests is important to determine the impact of human interventions on the population structure of plant communities. Some studies suggests that efficient management of selective logging could bring a number of trials that are related to the enhancement of forest products (Rist et al., 2012; d'Annunzio et al., 2015) and aid in preventing carbon emissions, including reduction of the available terrestrial biodiversity among tropical forests (Leadley et al., 2014; Köhl et al., 2015; Pearson et al., 2017). However, several studies also report that the real selective logging negatively impacts on forest community, which leads to forest degradation and reduction of forest products supplements (Irland, 2011; Hethcoat et al., 2018), in turn diminishing the volume of carbon stock perspective and the value of wildlife habitat (Martin et al., 2015).

In the Western Ghats of southern India, there is a number of designated series of forest types encompassing a rich endemic and endangered tree flora (Pascal, 2004; Ramesh et al., 2009). Of these, the *Cullenia-Mesua-Palaquium* forest series (hereafter referred to as "CMP forest") found in the mid-elevation (700-1400 m) regions of the Western Ghats is considered a unique (Pascal, 2004) and important tropical wet evergreen climax forest type (Ramesh et al., 2009). In some parts of the Western Ghats, human disturbance of CMP forests has resulted in the loss and heavy fragmentation of this forest type along with thicket formations within some human maintained savannas

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95919607

(Pascal, 2004). The current study was conducted in mid-elevation (700-1400 m) regions of the tropical wet evergreen forest of the Nelliampathy Hills, southern Western Ghats. Logging began in this region during the 1950s and continued into the 1980s in order to increase forest trees as a method of silviculture solely for timber extraction. As a result, several of the forest series including CMP forest have experienced significant disturbance and fragmentation. In this study, we examined the residual influence of previously selected logging treatments nearly 20 years after the intensive selective logging ceased. Examinations include a comparison of the recovery of stand structure and tree density of the CMP forest series, which have been logged at different intensities post-logging. Prior to this research, there was no reliable information available on the impact of logging treatments on any of the regional forest series nor the population structure of the trees in these areas of the Western Ghats. Therefore, this study is the first attempt to examine the impact of selective logging treatments on the tree population structure of CMP forest. The study addresses the following hypotheses: 1) the total density and basal area of CMP forest series would increase in response to different intensities of selective logging; 2) the small (> 1 cm diameter at breast height (dbh) and large (> 30 cm dbh) tree density and basal area of CMP forest series would increase in response to different intensities of selective logging; 3) logging treatment would have a significant influence on tree density and basal area of CMP series along with different elevational gradients.

Materials and Methods

Study area

The study was conducted in the tropical evergreen wet evergreen forest of the Nelliampathy Hills of the Western Ghats in South India (*Figure 1A*). The elevation ranges from 780 to 1633 m asl. Nelliampathy hills run south from the edge of the Palghat Gap and the junction of Anamalai and Parambikulam Hills (*Figure 1A*).

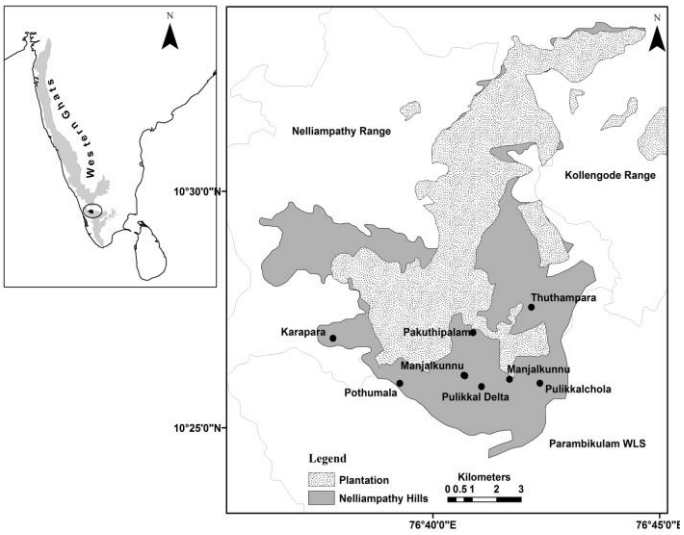

Figure 1A. *Map shows that locations of the major study areas in the Nelliampathy hill ranges, namely (i) Karapara, (ii) Manjalkunnu (iii) Pakuthipalam (iv) Pothumala (v) Pulikkalchola (iv) Thuthampara, including the 30 sampled sites (see Appendix 1) examined in the tropical evergreen forests of the Western Ghats, southern India*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95919607

The rock formation of Nelliampathy is composed of Cambrian cover and entirely reconfirmed as faults and metamorphism (Mani, 1974; Krishnan, 1974). The Pre-Cambrian crystalline rocks contain Khondalite series of Gneiss and Charnockite series of granite intrusions (Nair, 1988). The soil of the study area is generally red, sandy loam, porous with a pH ranging from 4.5 to 7.5 though the soil in the flat areas along the hills contain loam mixed with high levels of clay (Chandrasekaran et al., 1977). The tropical evergreen forest of the study site has been classified as medium elevation type of the *Cullenia exarillata-Mesua ferrea-Palaquium ellipticum* forest composition (Pascal, 1988; Ramachandran and Swarupanandan, 2013). As mentioned, large areas of these forests were selectively logged during the period 1950-1986 (Matthew, 2001); however, areas of old-growth unlogged forests still exist.

The study was carried out in the Pulikkalchola forests located at 10° 47' N and 76° 70' E. The climate is humid with the mean annual rainfall of the study area over a 10-year period from 1995-2004 of 2457 mm. Rainfall in this region is characterized as monsoonal peaks from June to August while a distinct dry season runs from December to March. The minimal and maximal rainfall reported from 1994-2004 was 626-2028 mm and 1441-4278 mm, respectively. The number of rainy days varied from 127−144 a^{-1}. The annual average temperature of the study area ranged from 5°C to 30°C (Ramachandran and Swarupanandan, 2013, 2018). During the comparatively dry period of December to March, the mean monthly temperatures ranged 20.4–25.2°C (Ramachandran and Swarupanandan, 2013; IMD, 2018). Rainfall increased > 79% in study areas during the year 2018 (IMD, 2018).

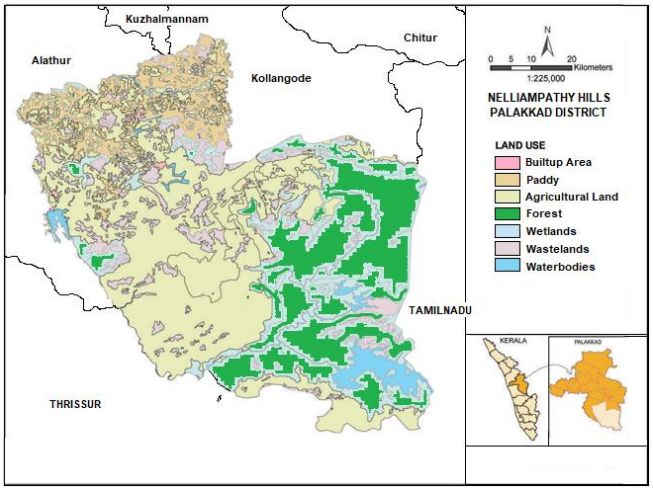

Figure 1B. *Map showing that land use changes which displayed the builtup area, paddy field, agricultural land, forest area, wetland, wastelands and waterbodies in the of Nelliampathi Hills, Palakkad district of the Western Ghats, India*

The dominant vegetation series of the study region are *Cullenia exillarita* A. Robyns (Malvaceae), *Mesua ferrea* L. (Calophyllaceae) and *Palaquium ellipticum* (Dalzell) Baill. (Sapotaceae). These species are tall trees with heights ranging between 30 and 40 m and are commonly located in the interior of the continuous forest patches of the tropical wet evergreen forests of the Nelliampathy Hills. The trees generally do not branch out until they reach a certain height (approximately 10 m). The dominant tree

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95919607

species in *Cullenia-Mesua-Palaquium* (CMP) forest series is of a unique structure at a particular elevation ranging 550–700 m altitude in the Western Ghats (Pascal, 2004). The forests produce large fleshy fruits which serve as useful food resources for the resident birds and mammals. Moreover, the area is the primary habitat for the endangered lion-tailed macaque (Pascal, 1988; Ganesh and Davidar, 1999). These forest series species are an important resource for wild animals despite the fact that they display a narrow geographical distribution in the Western Ghats.

Description of selective logging treatments

Selective logging was considered only as a silvicultural system implemented in the natural forests of Kerala (FAO, 1984, 1985; Chundamannil, 1993). It started as early as 1885 (Nair, 1988). In the study area, a part of the growing stock in the form of mature trees was removed during the 1950s, 1960s, 1970s and 1980s, encompassing a large area each year, either at the same time or at an interval of 15-30 years (Baur, 1964; FAO, 1989; Lamprecht, 1993). This selective logging system practiced in India is actually a Quasi-Selection System or Selection Felling (Troup, 1916; Seth, 1960) or the Selective Felling/Logging (Lal, 1961; Srivastava, 1983). In the early 1950s, forest administration used a method of treatment for the vast extent of the forest using a limitedly trained staff with poor silvicultural knowledge. They chose selective felling as the only method available to make use of the stock of mature and over-mature trees of marketable species (Troup, 1916, 1921). In this method, mature trees of selected species with a minimum girth limit (> 30 cm to 80 cm girth) were logged under a definite felling cycle, leaving only the seed bearers where natural regeneration is deficient. In India, this is the most widely practiced system applicable to the evergreen, moist deciduous and dry deciduous forests (FAO, 1989). Selective logging was applied and aimed to increase the regeneration of species by improving the light conditions of the forest floor (Stracey, 1959; FAO, 1984; Kadambi, 1986). In the studied plots, selective logging was implemented to extract CMP species suitable for railway sleepers, ship masts and electric poles (Nair, 1961; FAO, 1989).

In the present study, selective logging treatments were categorized into high, moderate and unlogged treatments. The plots are defined where the trees were selectively extracted and removed to serve as timber during 1950-1985. We categorized the treatment of selective logging based on the removal of a number of trees per hectare as: (1) High-logging: where the CMP trees were removed based on fixed minimum diameter limit that varied from 30−60 cm dbh with a felling cycle of 15-30 years. The area studied included the number of trees that were removed from an area of 10−20 ha^{-1} and the minimum distance between two trees marked for felling fixed at 20 m. (2) Moderate-logging: The technique was similar to high-logging, however, the trees were removed from 2−6 ha^{-1} area keeping the same distance of 20 m between the tree removed. (3) Unlogged: No logging work was undertaken over a century. The above information was collected from forest department records.

Field sampling

During the year 2004-2006, we surveyed and sampled the tree population of CMP species using quadrat methods. We laid randomly 20 × 50 m quadrats and subdivided the plot into 10 × 10 m subplots for sampling in 30 sites (*Appendix 1*). The total

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95919607

sampled area was 30.8 ha. All the individuals encountered with a minimum dbh of ≥ 1 cm (diameter at breast height) were measured at 1.3 m from above ground level (Dallmeier et al., 1992), excluding the buttresses. All individuals were marked and numbered sequentially using aluminum tags (Ramachandran and Swarupanandan, 2013). Species specimen was collected, identified and deposited in the herbarium of Kerala Botanical Herbarium Center.

Data analysis

All individuals of the studied CMP species were counted from sample plots. They were converted into per hectare and later log-transformed for data analysis. The basal area of each individual was calculated using the formula $(DBH)^2 \times \pi/4$ (Mohandass and Davidar, 2009) and then converted into log-transformed among logging treatments. The mean and standard error of tree numbers and basal area of CMP was compared among logging treatments (such as high, moderate and unlogged). We categorized trees with a dbh of < 50 cm as smaller trees and the trees with a dbh of > 50 cm as larger trees (Persha and Blomley, 2009). The mean tree density and basal area of smaller stem dbh class (≤ 49.9 cm dbh) and larger stem dbh class (≥ 50 cm dbh) were calculated and log-transformed for analysis to compare among logging treatments. Analysis of variance (ANOVA) was used to test for differences in the mean number of tree individuals and basal area of CMP among logging treatments. We also used ANOVA to test for differences in the mean number of smaller trees and larger trees among logging treatments. F-statistic is the ratio of one-way ANOVA where F = variation between vegetation parameter means / variation within the vegetation parameters. Number of treatments (N) and degree of freedom (DF) were included in F-statistics. The P-value is the probability of given statistical model where the null hypothesis is true and the values greater than or equal to the actual observed values are indicated as significant differences (Wasserstein et al., 2016).

We used the Tukey's pairwise comparison to check for significant differences in tree density and basal area of CMP between and within the logging treatments (high, moderate and unlogged). Repeated measures of ANOVA was used to test the effect of post-logging recovery of CMP tree density and the basal area between high and moderate logging as compared to unlogged sites. We estimated mean value of post-logging age class of CMP tree density and basal area that included smaller and larger tree density and the basal area of CMP among different logging treatments. In addition, we also tested CMP forest recovery in order to compare the mean value of tree density and basal area of those vegetation parameters by ANOVA. Analysis of covariance (ANCOVA) was used to test the effect of logging treatment on tree density and basal area. All statistical analysis was performed using the software MedCalc. (version 12.2.1.0).

Results

A total of 5936 tree individuals with density ranging 17.3 to 1250 per hectare and average basal area of 20.73 m^2 ha^{-1} (≥ 1 cm dbh) were recorded from various logged treatments for the three species that were under study - *Cullenia exallirata, Mesua ferrea and Palaquium ellipticum*. The tree individuals ranging from 19–155 were enumerated in highly logged plots, 200–697 from moderately logged plots and 83–334 stems from unlogged plots. The basal area of the studied species ranged from 1.3–19.5

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95919607

m^2 ha^{-1} in highly logged plots, 13.3–79.4 m^2 ha^{-1} in moderately logged plots and 6.9–56.1 m^2 ha^{-1} in unlogged plots.

Treatment of logging on CMP tree density

In highly logged plots, the mean number of trees accounted for 111.8 ± 13.89 (std. error), while it was 402.58 ± 67.2 and 180.12 ± 30.62 in moderately and unlogged plots. It shows that the density of CMP series differed significantly (ANOVA $F_{3,29}$=12.69, P = 0.0001) among different logging treatments. Moreover, Tukey's HSD comparison shows that mean tree density was significantly higher in moderately logged plots compared to high (Tukey's HSD = 6.88, P = 0.0002) and unlogged plots (Tukey's HSD = 4.11, P = 0.019). However, no significant difference was found in the mean density of trees between high and unlogged plots (Tukey's HSD = 2.76, P = 0.1431; *Figure 2a*).

Treatment of logging on CMP basal area

The mean basal area of trees in highly logged plots was 10.94 ± 1.5 (m^2 ha^{-1}; std. error), 39.92 ± 8.91 (m^2 ha^{-1}) in moderately logged plots and 22.3 ± 5.5 (m^2 ha^{-1}) in unlogged plots. The basal area of three tree species differed significantly (ANOVA $F_{3,29}$=8.36, P = 0.0012) among various sites with different logging treatments. Mean basal area of moderately logged plots was significantly higher (Tukey's HSD = 5.42, P = 0.002). In contrast, there was no significant difference found between moderately logged and unlogged plots (Tukey's HSD = 2.42, P = 0.22) or between highly logged and unlogged plots (Tukey's HSD = 3.0, P = 0.104; *Figure 2b*).

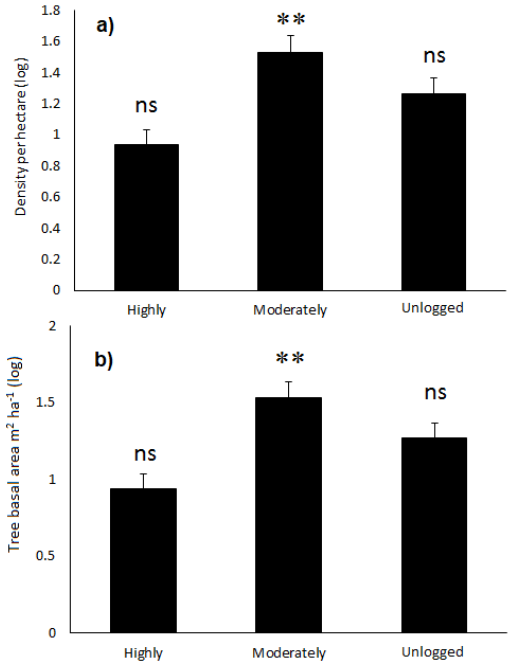

Figure 2. *Treatments of different logging on (a) CMP mean tree density and (b) mean basal area (m^2ha^{-1}) of the tropical mid-elevation wet evergreen forests of the Nelliampathy Hills, Western Ghats, southern India (Significant level: **p < 0.001; ns = not significant)*

Treatment of logging on smaller and larger tree density and basal area

The density of smaller trees (≤ 49.9 cm dbh) and larger trees (≥ 50 cm dbh) differed significantly among different logging treatments (Small trees: $F_{3, 29} = 29.87$, P = 0.0001; Large trees: $F_{3, 29} = 3.22$, P = 0.05). Density of smaller trees was significantly higher in moderately and unlogged plots compared to highly logged plots (*Figure 3a*). Similarly, the density of larger trees was significantly higher in moderately logged plots than the highly logged plots ($F_{3, 29} = 8.13$, P = 0.002). However, no significant difference was found between moderate and unlogged plots (Tukey HSD = 2.63, P = 0.169; *Figure 3b*).

Similarly, the basal area of smaller and larger trees also differed significantly ($F_{3,29}$=17.2, P = 0.0001; $F_{3, 29} = 7.192$, P = 0.003, respectively) among various logging treatments. Basal area of smaller trees were significantly higher in moderately logged plots than the highly logged and unlogged plots (Tukey's HSD = 7.88, P = 0.0001; Tukey's HSD = 6.79, P = 0.0003); however, there was no significant difference found between highly logged and unlogged plots (Tukey's HSD = 1.09, P = 0.724; *Figure 3c*). For large trees, the basal area was significantly higher in moderately logged plots (Tukey's HSD = 4.9, P = 0.005) than the highly logged and unlogged plots. Similarly, there was no significant difference found between highly logged and unlogged plots (Tukey's HSD = 3.137, P = 0.08; *Figure 3d*).

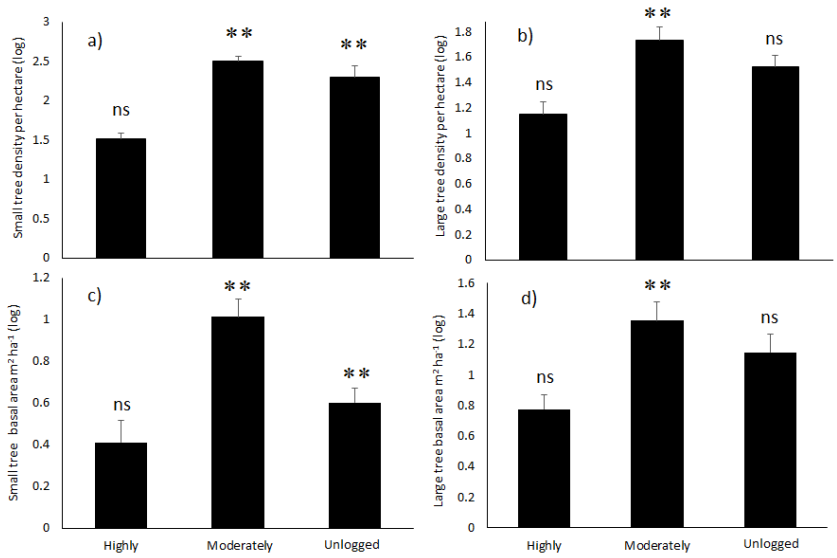

Figure 3. *Treatment of logging on CMP smaller and larger tree density and basal area (log transformed) in the tropical mid-elevation wet evergreen forests of the Nelliampathy hills, Western Ghats, southern India (a) small mean tree density and (b) large tree density in response to different logging treatments (c) small mean tree basal area and (d) large mean basal area in response to different logging treatments (Significant level: **p < 0.001; ns = not significant)*

CMP recovery after logging years

Tree density and basal area differed significantly among various sites due to logging treatment influencing CMP recovery (F = 4.01, P = 0.001 and F = 5.1, P = 0.002),(*Table 1*). All recovery periods (15-24, 25-34 and 35-45 after logging years) from highly logged sites influenced lower stem density and basal area compared to moderately

DOI: http://dx.doi.org/10.15666/aeer/1704_95919607

logged sites (*Table 2*). Small and large tree density and basal area of highly logged sites were lower than that of the moderately logged sites, indicating that the moderately logged sites may have influenced the high number of trees as compared to highly logged sites through CMP forest series recovery by the effect of selective logging (*Table 2*).

Table 1. *Repeated measures of ANOVA was used to test post-logging recovery and interacting between and within the variable factors of stem density and basal area of highly logged and moderately logged plots compared to unlogged sites in the CMP forest series of the Western Ghats, southern India*

Discussion

Our results suggest that moderate logging treatment increased the tree density and basal area of *Cullenia exillarita*, *Mesua ferrea* and *Palaquium ellipticum,* causing a positive impact on the population structure of these forest layers type in the mid-elevation evergreen forests of the Western Ghats. Besides, the study also showed that the tree density and basal area varied significantly, suggesting that the moderate logging influenced a higher number of smaller and larger trees. The basal area in the moderately logged plots was also higher than that of unlogged and highly logged plots. The total basal area of trees from the highly logged plots was found to be significantly lower than

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95919607

that of the moderately logged plots and unlogged plots. Post-logging recovery influenced stem density and basal area of CMP trees compared to unlogged sites; however, there was no significant difference found between highly logged and moderately logged plots during the post-logging periods. In addition, we found that the treatment of logging significantly affected the tree density and basal area with an increase in the altitude of 750 m to 1250 m. Therefore, the treatment of logging changed the population structure of *Cullenia-Mesua-Palaquium* forest series significantly in the mid-elevation evergreen forests of the Western Ghats.

Logging treatment on tree density of CMP forest series

Previous studies showed logging to be a kind of disturbance that impacts tree diversity, species composition and forest structure (Ferry et al., 2002; Lima et al., 2002; Rutten et al., 2015; Katovai et al., 2016). According to our results, high logging sites showed a considerably low density of CMP species, due to the formation of more gaps which resulted in reduced tree regeneration. The increased light levels in the forest understorey after highly selective logging may result in sudden occurrence of many herbaceous and woody pioneer species (Woods, 1989; Nykvist, 1996; Pinard et al., 1996, 2000; Cochrane and Schultze, 1999; Fredericksen and Mostacedo, 2000; Ferry et al., 2002). This may inhibit the growth of CMP forest species regeneration and would cause a decline in the density and basal area of CMP species in the highly logged sites.

In the tropical forests of the Western Ghats, shade tolerance is an important factor which supports tree regeneration (Mohandass et al., 2016). Generally, in tropical forests, large forest trees provide more shade which would facilitate tree regeneration. Due to logging of large trees, if the shade is not sparse it may inhibit the regeneration of CMP species. Moreover, high logging pressure also resulted in increased human intervention, particularly in the highly logged plots, which disrupted tree regeneration (Rivett et al., 2016) and eventually resulted in a low number of small trees and large trees of CMP species. Therefore, it has been observed that high logging treatment may cause negative impacts on CMP series of tree recruitment and regeneration. This would be one of the major factors in changing the population structure of CMP canopy forest layer in the studied forest sites. The moderate treatment of logging influences relatively a low number of trees that are cut and results in maintaining a high number of CMP tree individuals. This results in a significantly high number of CMP trees as compared to high logging. Moreover, moderate logging treatment provided sufficient shade and light due to gap formation that facilitated a high number of tree recruitment and regeneration. Furthermore, our results showed that the small tree size numbers (≤ 50 cm dbh) increased significantly due to moderate logging. For some unknown reasons, the large trees were not harvested in some of the moderately logged plots in the study area (Ramachandran, 2008). Moderately logged plots had a large number of trees than the unlogged plots. Eventually, the large number of trees were higher as compared to unlogged plots; however, no significant difference was found on large trees (≥ 50 cm dbh) between highly logged and unlogged plots. In the highly logged and unlogged plots, large trees were not regularly removed and perhaps this might be the reason for not showing any significant differences. Though unlogged treatment showed a significantly high number in the density of smaller trees of CMP as compared to highly logged plots, there was no significant difference in the density of CMP trees between moderately logged and unlogged plots. It suggests that unlogged plots had regular tree recruitment and regeneration with less intensive disturbance by human logging, which

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95919607

could have influenced a neutral response in regeneration of small trees and a tendency to maintain large trees.

Logging treatment on a basal area of CMP forest layer

Estimating the basal area of CMP forest layer could be an important measure on forest stand structure of CMP forest layer among logged treatment plots. In the highly logged plots, basal area of CMP trees was consistently lower as compared to moderate and unlogged plots. Due to high logging treatments, smaller and large trees are lesser in number as they are harvested constantly leading to the low value of the basal area, affecting the CMP layer of forest structure. Human activity of high logging affects smaller trees as well as larger trees in numbers that may reduce the rate of tree size. Similar to density, the basal area also showed a significantly negative impact on the CMP forest layer due to high logging treatment in the studied sites. However, CMP forest layer showed significantly higher value in the basal area due to a high number of smaller trees and larger trees between moderately logged and unlogged plots. Interestingly, large tree density did not show a significant difference between the different logging methods, whereas the basal area of moderately logged plots showed a significant difference compared to high and unlogged plots. This shows that the moderately logged plots maintained large tree growth structure. Moreover, smaller trees basal area was significantly low in unlogged plots compared to moderately logged plots and the unlogged plots had a high number of large trees compared to moderately logged plots. In terms of basal area, large numbers of small trees are accumulated in moderately logged plots that exhibit a basal area significantly higher compared to highly logged and unlogged plots and shows a positive response to CMP forest layer by moderate logging treatment. Therefore, the differences in smaller and larger tree density and basal area of CMP forest layer between forest sites strongly depend on logging treatments (Bonnell et al., 2011) in the studied regions.

Post-logging recovery on tree density and the basal area along logging treatments

Several studies demonstrated that post-logging recovery and age influence species composition, density, basal area or biomass of tropical forests (Ferry et al., 2002; McDonald et al., 2008; Osazuwa-Peters et al., 2015; Darrigo et al., 2016; Arevalo et al., 2016; Katovai et al., 2016). We found that post-logging recovery on CMP tree density and the basal area was significantly higher in logged sites as compared to unlogged sites. This indicates that the logging treatments exhibit a positive response on CMP forest series in the studied sites. However, the study suggests that the moderately logged treatment type would be more effective for the regeneration and maintenance of the CMP tree densities. Removal of more trees (10-20 year per hectare) would be less effective for regeneration of CMP forest trees. Our results showed that tree numbers and basal area of moderately logged plots were higher than the highly logged sites. In addition, it was also observed that 25-35 and 35-45 post-logging recovery showed a significant difference in stem density and basal area. These indicate that the recovery of high tree density could be slow regeneration processes in the studied forests.

Logging treatment on tree density and the basal area along elevation gradients

It has been shown by our study that at all elevation gradients, the logging treatments significantly changed the population structure of CMP forest layer in the studied plots.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_95919607

High logging activity tend to alter the forest structure of CMP series by removing the best mature stems in all elevation gradients. Obviously, tree species require high light incidence at the seedling stage for survival and growth (Kleinschroth et al., 2013). Canopy opening might be increased for seedling recruitment through consistent amount of light availability. These seedlings may be that of a large amount of herbaceous and pioneer species that may inhibit the growth or regeneration of CMP species in all elevation gradients. Direct light intensity may influence a significant amount of temperature which may decline seedling recruitment of CMP species in all logged plots and elevations. Therefore, logging affects all elevation gradients and possibly influences similar consequences on tree density and basal area of CMP forest series. Therefore, enrichment planting should be considered in heavily degraded or logged areas (Kleinschroth et al., 2013) along the gradients.

Conclusion

Our results support that the logging treatments produces a significant impact on the population structure of *Cullenia-Mesua-Palaquium* forest series in the studied plots. Our study concludes that the moderately logged treatment resulted in a significant increase in the number of small and large trees. Highly logged plots showed a significant decline in the number of small trees as compared to moderately logged and unlogged plots. These support the fact that the heavy logging method might be a serious threat to the population structure of *Cullenia-Mesua-Palaquium* forest series. Moreover, *C. exallilata* and *P. ellipticum* are endemic species. Hence, it is very important to preserve this population in the mid-elevation layer of the Western Ghats. It is imperative to avoid heavy logging treatment to facilitate regeneration and to create dense population structure of the CMP forest series. The Forestry management strategy to understand how selective logging supports natural regeneration of CMP forest series due to canopy openness is crucial. Therefore future research is required to examine the natural regeneration process to understand fully the seedling dynamics of CMP forest series. In addition, further experimental study needs to be undertaken to understand the impact of logging treatment on habitat species – specifically in relation to endemism and climate change.

(Received 19th Sep 2018; accepted 13th Jun 2019)

Abstract. The effect of lead (Pb) pollution on water clover resistance was determined by the Pb distribution and the percentage of free amino acids in plant tissues. Water clover plant from Surabaya, Indonesia was collected and plants of equal size were grown hydroponically. They were exposed into 0, 1, 5, 10 mgL^{-1} of Pb concentration for 10, 20, and 30 days. The experiment was a randomized completely block design with 3 replications. The Pb concentration was measured by inductively coupled plasma (ICP) and the free amino acid was analyzed by HPLC (High-Pressure Liquid Chromatography). The Pb concentration in plant organs and its free amino acids content indicated that water clover plant was resistance on Pb accumulation and affected their growth which potential for phytoremediation. The highest concentration of Pb was found in root tissue, followed by stem and leaf tissues. These findings indicated the respond of water clover plants resist on Pb that determined by the increased percentage of free amino acids and phytochelatins such as glutamic acid, cysteine, glycine, and proline.
Keywords: *free amino acid, phytoremediation, Pb, water clover*

Introduction

Contamination of heavy metals is increasingly widespread as a result of different activities such as lead (Pb) pollution. Pb is a heavy metal that causes poisoning in humans (Jaishankar et al., 2014). High Pb concentration can be found in industrial waste, in household detergents, other laundry products, and in cigarettes (Nakata et al., 2017). Pb is known as teratogenic and toxicity (Duruibe et al., 2007), such as inhibits the haemoglobin synthesis, causes kidney malfunction, affects reproductive systems and cardiovascular system, causes acute and chronic damage to the central nervous system and peripheral nervous system (Ghosh and Singh, 2005).

In plants, Pb causes a decrease of chlorophyll synthesis, inhibits photosynthesis, inhibits mineral collection, water imbalance and changes in the structure and permeability of the cell membrane, as well as other effects (Seregin and Ivanove, 1998).

In addition, Pb triggers the establishment of reactive oxygen species (ROS) and induces oxidative stress that causes the protein trafficking in plants (Yun et al., 2001; John et al., 2008; Stoyanova and Doncheva, 2002).

Nitrogen metabolism is central to plants response against heavy metals. It due to plants synthesize with a variety of metabolites when exposed to heavy metals and accumulate to the concentrations in the millimolar range, especially specific amino acids (Sharma and Dietz, 2006). Glycine and glutamic acid are involved in glutathione synthesis and phytochelatins, which plays a role in the binding of heavy metals. Arginine acts as a molecular marker and antioxidants in the polyamine synthesis (Sharma and Dietz, 2006; Khawas, 2011). Proteinogenic prolific amino acid as a radical

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96099619

scavenger, electron sink, macromolecules stabilizer, cell wall components (Matysik et al., 2002), osmoregulation and in metal binding (Sharma and Dietz, 2006). These amino acids are considered as important plant mechanisms against heavy metal stress.

Reduction of heavy metals concentration is urgently needed in the environment. Many methods have been developed to clean up the pollutant from water, but it seems that the plant is the cheapest and easiest method. "Phytoremediation" has been used widely, to remediate either contaminated soils or polluted water (Göthberg et al., 2004). The success of phytoremediation depends on growth rate and the plant ability to uptake the metals from the growth medium. Plants must produce sufficient biomass and able to accumulate a high concentration of heavy metals in their tissue.

The water clover is a hydrophyte plant with thin cuticle, constantly open stomata, has air bladder, and thin roots. A previous study of clover plants (*Marsilea crenata* Presl.) at wetlands of Wiyung, Ketintang, and Kendung in Surabaya city, Indonesia showed the plant ability to absorb Pb. The clover plant is commonly used as a vegetable by Surabaya city communities and the surrounding area. It indicates that the plant contains a concentration > 0.05 mg Pb kg^{-1}. This exceeds the quality standards provided by WHO (1996). Surprisingly, the plant growth is not affected by the heavy metal, as the plant was still growing with the average plant height of 13.9–19.4 cm. Wiadnya (2004) also observed Pb absorption by water clover in the limited volume media experiment. Previous research conducted by Nurhayati et al. (2015) which observe the stunted growth of water clover after treated in Pb media; the higher the Pb concentration, the slower the growth. Novi and Abdillah (2017) observed the ability of water clover and hydrilla to decrease the Pb concentration in paper liquid waste after 5, 10, and 15 days. Another plant in the same division, *Salvine minima*, also has the ability to accumulate Pb up to 0.1243 mgm^2 per day (Iha and Bianchini, 2015). These findings indicated the tolerance of water clover to heavy metal and the possibility to be categorized as an "accumulator or hyperaccumulator" plant.

Pb pollution does not seem to be declining in the future because Pb pollution sources are an unavoidable aspect in modern human life (Yang et al., 2000). Therefore, it is necessary to investigate the different of Pb concentration and exposure duration on plant tissue growth, and the percentage of free amino acids in clover plants that grow on Hogland solution. This research aim is to evaluate the capability of water clover as an agent for phytoremediation to heavy metal particularly the lead (Pb) based on its growth and the accumulation of Pb capacity.

Materials and methods

The water clover plant was grown in medium containing Pb solution to investigate the resistance and free amino acid. The medium was added with Pb solution (depend on the experimental treatments), i.e: (1) 0 Pb as the control; (2) 1.0 mgL^{-1} of $Pb(NO_3)_2$ solution; (3) 5.0 mgL^{-1} of $Pb(NO_3)_2$ solution; and (4) 10.0 mgL^{-1} of $Pb(NO_3)_2$ solution. The Pb concentration was based on the previous study (Herawati, 2008; Rachmadiati et al., 2012). These treatments were conducted in a split-plot design with 3 replications.

Water clover was collected from wetlands at Kendung (Surabaya, East Java, Indonesia). Initially, the plants were grown in a plastic chamber containing 20 L of Hoagland's media in a glass house over 5 days. This was done to reduce environmental contamination and adapt the plants to glasshouse conditions. Subsequently, plants of water clover were selected with 90 g biomass. Each plant was grown for 10 days in a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96099619

plastic chamber containing 20 L distillation water and Hoagland's solution (Göthberg et al., 2004).

These acclimated plants were used for further study. Water clover plants were selected with stems length of 20-25 cm and roots length of 8-10 cm. The plants were cleaned with distilled water and placed in glass aquarium of 40 cm length, 30 cm width, and 35 cm depth which consist of 5 L distilled water and Hoagland's solution. Every aquarium was filled with 100 g of the acclimated water clover. The variety pH of the medium was applied from 5.4 – 6.9 at the beginning of the experiment, and 6.5 – 7.0 at the end of the experiment. The plants were illuminated sunlight 12:12 h at light-dark cycle with photon flux density at 389 candles. All of the plant samples (destructive sampling) from each glass aquarium were harvested at 10, 20, and 30 days. Then, the biomass yield and metal content were measured (*Fig. 1*).

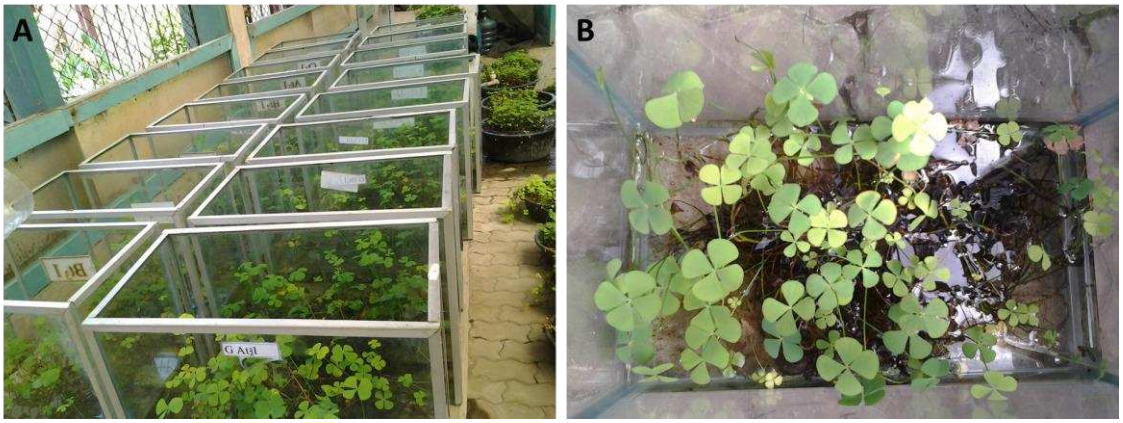

Figure 1. *Water clover (Marsillea crenata) plant in the glass aquarium experiment. A. General view. B. Overhead view*

Harvested plants were divided into three parts: roots, stem, and leaves. Each part of the plant was placed at the dried oven at 80 °C for 48 h and weighed to determine its dry weight. To further analysis, 5 g of each plant was taken and dried plant tissues with a mill. Then, 0.5 g of powdered sample was diluted with 5 ml of HNO_3 and 50 ml of deionized double distilled water. Pb analysis was performed by using the extraction method (Gothberg et al., 2004). Then, the digested samples and 50 ml of media samples were analyzed by inductively coupled plasma (Teledyne Leeman Labs) to determine the Pb concentration. The total accumulation and partitioning of the metals by the plants were calculated. Plant biomass yield was measured on dry weight basis.

Several different steps were performed in order to identify free amino acids. Initially, the reagent kit was prepared, followed by solvent preparation and sample preparation of HPLC (High-Pressure liquid Chromatography) with hydrolysis processes and derivatization (Waters, 2017).

Preparation of reagent kit

Reagent kit was prepared by heating at 55 °C. The vial 24 (AcrQ fluo reagent powder) was heated 2-3 min. Then, 1 ml of AccQ fluorine reagent diluent was inserted into vial 2A followed by heating and mixing until the powder spread evenly.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96099619

Solvent preparation

Solvent solutions were prepared by mixing 19 g Sodium Acetate and 2.27 g TEA into 1 L of water. Then, 40% of phosphoric acid (+ 6 mL or more) was added until pH 5.1 followed by adding 5 mL ACN (ACETONITRILE) and water (Waters, 2017).

Hydrolysis

Hydrolysis was performed with 100 mg of the sample that accurately weighed. The sample was placed into tube and mixed with 5 ml 6N HCL. Drying sample was performed by using Nitrogen or Argon; each tube was closed and placed into an oven at 112 °C for 22 h and the sample was filtered by using 0.45 pm of filter paper. Then, 100 ml of filtered sample was diluted with 5 ml of MiliQ water (Waters, 2017).

Derivatization

The 50 pL of diluted sample was mixed with 350 pL AccQ derivatization buffer and 100 pL AccQ fluor reagent to derivatize. The mixed solution was shaken briefly and placed into the water that has been heated at 55 °C for 10 min. Then, the sample can be injected into the HPLC (Waters, 2017).

Data analysis

Experimental design

The research was a completely randomized design with three replicates for each treatment. The first treatment was the heavy metal concentration containing K1: 0 mgL^{-1}; K2: 1 mgL^{-1}; K3: 5 mgL^{-1}; and K4: 10 mgL^{-1} of Pb. The second treatment was the variety time of observation, 10^{th}, 20^{th}, and 30^{th} day respectively.

Variables

The observed variables were: (1) the plant's biomass; (2) Pb content in roots, stems, and leaves; (3) the Pb removal percentage; and (4) the produced free amino acid percentage in the root.

Statistical analysis

The observation data was analyzed by ANOVA and followed by Tukey *ad hoc* test with a 95% confidence level using Genstat 15 edition resources statistical program. Then, the free amino acid was analyzed descriptively based on the percentage and total protein.

Results

The growth of water clover at various medium conditions is presented in *Table 1*. There was a positive growth of water clover at 10, 20, and 30 days observation. It seems that water clover was easily adapted to the new environment. Therefore, water clover was not to require adaptation periods. The growth of water clover at various Pb concentrations was significantly different ($p < 0.05$). It indicated that the higher Pb concentration, the slower the growth of the water clover (*Table 1*). This is due to the more Pb is absorbed water clover plants and affects the metabolism. Although the

growth tended to slow, the ability of plants to absorb Pb remains "high", which can be seen in *Table 2*. Interestingly, there were no visible poisoning symptoms beside the slowed growth after morphological observation (data not shown).

Table 1. *The growth of water clover at different Pb concentrations*

Pb concentration (mg L^{-1})	Dried biomass at (g/plant)		
	10 days	20 days	30 days
0	15.470^{dA}	16.555^{dB}	17.384^{dC}
1	14.525^{cA}	15.547^{cB}	16.366^{cC}
5	13.510^{bA}	14.308^{bB}	14.770^{bC}
10	12.810^{aA}	13.475^{aB}	3.895^{aC}

Means followed by the same letters, in the same column are not significantly different (p = 0.05), small letter for concentration and capital letter for detention time

As shown in *Table 1*, it demonstrated that the water clover grows well in lead-polluted solution. However, compared to early observation, the growth of water clover was much slower. The capability of water clover to remove Pb from solution was shown in *Table 2*. There was significantly different from the removal by water clover.

Table 2. *Percentage removal Pb by water clover*

Pb concentration (mg L^{-1})	Percentage removal Pb by plants		
	10 days	20 days	30 days
1	100 ± 0.04^{aA}	98.00 ± 0.04^{aA}	100 ± 0.04^{aA}
5	100 ± 0.04^{aA}	99.90 ± 0.04^{aA}	99.40 ± 0.04^{aA}
10	100 ± 0.04^{aA}	99.90 ± 0.04^{aA}	99.65 ± 0.04^{aA}

Means followed by the same letters, in the same column are not significantly different (p = 0.05)

The water clover plants were able to absorb Pb concentration in the organs, although their growth was considerably slower as shown in *Table 1*. It is important noted that water clover plants are able to remove Pb from the solution. Then, the highest Pb concentration of water clover was found in root tissues (*Table 3*).

The presence of Pb in root tissues of water clover was relatively constant with the plant of age, except for 10 days after treatment. Pb concentration in roots tissues of water clover was not differences. As shown in *Table 4*, Pb concentration in stem tissues indicated significant differences compared to leave tissues.

Table 3. *Pb concentration in various plant tissues*

Day	1 mg L^{-1} Pb (mg kg^{-1})			5 mg L^{-1} Pb (mg kg^{-1})			10 mg L^{-1} Pb (mg kg^{-1})		
	Roots	Stems	Leaves	Roots	Stems	Leaves	Roots	Stems	Leaves

DOI: http://dx.doi.org/10.15666/aeer/1704_96099619

The amino acid content was found to see the plants response against heavy metal stress. A significant difference in the percentage of each amino acid produced by the clover water plants were recognized (*Table 4*).

As presented in *Table 4,* there were 17 types of amino acids. The percentage of amino acids decreased and had low value (0.000) except for cysteine after 20 days of Pb exposed. In addition, lysine and isoleucine also indicated a low value (0.000) on the concentration of 5 mg L^{-1} after 20 days of Pb exposed.

Table 4. *Free amino acids (%) of water clover exposed to lead at 20 days (n = 3)*

Amino acid	Concentration of Pb (mg L^{-1}) at … days		
	1	5	10

Means followed by the same letters in the same rows are not significantly different (p = 0.05)

Discussion

The water clover showed stunted growth after exposed with Pb even though there was no morphological alteration. It indicated that water clover plants are able to accumulate with Pb in the long period based on the growth of biomass after observed in 20th and 30th day. These findings suggested the potency of water clover as a biological agent for phytoremediation due to the ability to accumulate heavy metal in

its tissues. Similar research was conducted using the *Salvinea culcullata* water plant by Phetshombat et al. (2006), which can accumulate Pb until 16.36 mgKg^{-1} under 40 mgL^{-1} but showed chlorosis in its leaf after long exposure.

The Pb exposure eventually affects the metabolism of the plant (Gomez et al., 2009). Similar to Cd exposure, Pb was found to slow the growth in several aquatic plants, such as *Lymnochasris flava* species and *Ipomoea aquatica* (Rachmadiarti et al., 2012). Pb interferes the tissue permeability (Fahr, 2013), increases the bound pectin to middle lamella of cell walls which inhibit the cell expansion (Krzeslowska, 2011), and affects the growth hormones, auxin metabolism, and its carrier. Pb also trigger the disorder in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96099619

some plant metabolism such as photosynthetic pathway and peroxidase induction that plays a role in indole acetic acid degradation for growth and cell multiplication (Hoffman et al., 1985; McComb et al., 2012).

The mechanism behind the higher Pb concentration in the roots may include the binding of the positively charged toxic metals ion to negative charges in the cell walls (Matysik et al., 2002). In most plants, a larger proportion of the metal was retained in the roots and thereby prevented from interfering with the sensitive metabolic reaction in the shoot. It due to an internal mechanism to avoid toxic metal concentration in the shoot (Fahr et al., 2013).

The root has the tendency to accumulate a high concentration of Pb compared to in shoot (Gothberg et al., 2004). About 95% roots of Pb accumulated in a number species of brassica family other plants were in the roots (Kumar et al., 1995). However, concentration Pb in leaves are lower than in the stems because the leaves of water clover are very thin and Pb can lose through leaves transpiration. The stem accumulated high concentration of Pb compared to in leaves. It due to the possibility of the stem in the water (growing media). In addition, water clover as ferns (*Pteridophyta*) that has a vascular cylinder on the rod shape of concentric systems amphichiral in the xylem. The starch content and the veins size in the xylem have a larger size than the phloem. In addition, Mitel Lamela connected between the xylem cells.

In contrast, there was no significant difference in Pb content in leaves of clover water. It may occur due to the concentration of treatment. At low concentration of Pb until it reaches 0 in the leaves. It can be caused by water clover has a small, thin, and wide structure of leaves. Therefore, the absorption of the nutrients including Pb trigger small translocate into the leaves. In addition, Pb has been concentrated in the roots and accumulated in the stem. It due to the epidermal tissue on water clover leaves consists of a layer. Thus, the accumulation of Pb is less than the stem. The Cu metal content presented on other types of clover plants (*Marsilea quadrifolia*) is lower than *Echornia crassipes* and *Vallisneria spiralis.* Although the content of Pb on clover leaves is lower than on the stem, but the content of Pb in the roots of the clover is higher than in shoot (stem + leaves).

The content of Pb in the leaves indicated that the dosage of Pb concentration at the bellow limit allowed for foodstuffs (0.5 mg/kg^{-1}) unless the treatment of 10 mgL^{-1} at 10 days of observation (WHO, 1996). It suggested that clover water have been used to remediate Pb synthetic solution at a concentration of up to 10 mgL^{-1} with 20 days and it can be consumed based on the food security terms.

Generally, only a small portion of metal is brought up by the roots and transported to the shoot. It has been reported that the exclusion of metal from networks above the ground is a tolerance strategy against metals (Taylor and Crowder, 1983). The root has a higher tolerance than the shoot. In addition, it has a tendency to decrease translocation by increasing metal concentrations in the roots and included the general characteristics of various type of metals and plants. The binding of toxic metal through the positive ions to negative ions in the cell walls of the root, the formation of *metal phytate*, and khelasi on the phytochelatin followed by an accumulation in vacuoles are the mechanism by reducing transport and improving metal tolerance (Gothberg et al., 2004).

Kamel (2008) reported the adaptability of plants to extract metals from the water and the aptitude of plants to transfer metals from plant root to shoot. The concentration free amino acid in roots of water clover at some concentrations up to 30 days as shown in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96099619

Table 4. The percentage of these amino acids was decreased. It due to the adaptation to heavy metal exposure which relatively high from 5 to10 ppm from amino acids. There are 6 amino acids (arginine, proline, leucine, valine, serine and glycine) and has acts an important role in the regulation of osmotic plant (Mansour, 2000). Arginine is involved in the synthesis of polyamines and acts as a molecular marker and antioxidant (Sharma and Dietz, 2006).

In the present study, the presence of proline showed its role moving between tissue and protect plants against stress. It due to its role as a major compound for carbon and nitrogen source, protect of cytoplasmic enzymes, and maintenance of cellular structures. High sensitivity in the metabolism of proline synthesis and its degradation has advantageous to control the adverse metabolic processes (Kamel, 2008). Proline serves as a radical scavenger, electron sink, stabilizer of macromolecules, cell wall components (Matysik et al., 2002), as well as osmoregulator and metal binding (Sharma and Dietz, 2006). Proline has been found at *Helianthus annuus* which accumulate with Pb, Cd, Cu, and Zn (Kastori et al., 1992). The existence of Ni in *Alyssum lesbiacum* plant was found to increase histidine in the xylem (Kramer et al., 1997). Hyperaccumulation of Ni triggers by histidine that translocates Ni from roots to shoot (Kerkeb and Kramer, 2003).

The percentage of amino acids in plants growing on Pb treatment has been investigated. The continued increase of amino acids occurred on plant exposed with Pb from 10 days up to 20 days. In contrast, reduced amino acid occurred on day 30, followed by the slow growth of plants. The increase of these amino acids in accordance with the Pb concentration which is absorbed by the roots did not a difference between 20 and 30 days (*Table 4*). Syam et al. (2010) reported that the biosynthetic pathway of *Salvinia minima* triggers Pb^{2+} detoxification. It has been indicated for other organisms, as part of the mechanism to cope with this metal in roots and leaves.

The root of water clover plant contains the amino acid, glutamic acid, and cysteine. They are dimeric amino acid formed by the oxidation of two cysteine residues that make a disulfide bond covalently. This organosulfur compound has the formula $(SCH_2CH(NH_2)CO_2H)_2$) and glycine. It is related to the multitude of amino acid protein from contaminated locations through the biosynthesis of phytochelatin and metallothioneins. The synthesis of phytochelatins and metallothioneins are the response of plants to trigger several metals or metalloid. Because of the similarity with metallothioneins, the phytochelatins have been known as class III of metallothioneins. Phytochelatins have a major function as detoxification. Meanwhile, metallothioneins has function in assisting the translocation of some metals. A gene family encodes metallothioneins, while phytochelatins produced enzymatically (Christopher and Peter, 2002). Plants also develop detoxification by inducing the protein synthesis due to the stress of phytochelatins and metallothioneins and high intensity in mango and apricot (Khawas, 2011).

Conclusion

The water clover growth, the concentration of Pb and free amino acid in plant organs indicated that water clover plants were survived and continued their growth. The highest concentration of Pb was found in root tissue followed by stem and leaf tissues. The phytochelatin production by clover plant as a resistance respond. In addition, it was followed by an increased percentage of free amino acids and the presence of

DOI: http://dx.doi.org/10.15666/aeer/1704_96099619

phytochelatins such as glutamic acid, cysteine, glycine and proline. Based on this study result, it is imperative to investigate further the phytoremediation capability of water clover by increasing the Pb concentration and in the smaller time frame.

(Received 9th Feb 2019; accepted 24th May 2019)

Abstract. Present endeavor was aimed at recording the flora of Murree-Kotli Sattian-Kahuta National Park (MKSKNP), Pakistan. The whole project area was surveyed thoroughly from March, 2013 till October, 2015 and 624 plant species belonging to 361 genera and 106 families were recorded. Of them, 24 ferns, four gymnosperms and 596, angiosperms (144 monocots and 452 dicots) were recorded from the park area. Poaceae was the largest family (80 spp., 12.82%), followed by Fabaceae (60 spp., 9.62%) and Asteraceae (55 spp., 8.81%). Most of the studied area was inhabited by native species (528 spp., 84.62%), followed by weeds (48 spp., 7.69%), cultivated species (21 spp., 3.37%) and naturalized (18 spp., 2.88%). Two species viz., *Aristolochia punjabensis* and *Buxus papillosa* were found endemic to Pakistan. This national park is composed of three localities (viz., Murree Kotli Sattian and Kahuta) and the pair-wise comparison revealed maximum similarity between Murree and Kotli Sattian pair due to their adjacency and similar climatic conditions. Similarly, the other pair (i.e. Kotli Sattian and Kahuta) was also closely located towards southern part and had similar floristic elements. This study serves as a platform for the detailed floristic and ecological studies to be carried out by the researchers.
Keywords: *ecological studies, endemic, floristic elements, maximum similarity, sustainable utilization*

Introduction

The flora is the compilation of all plants confined to the particular territory or region (Hooker, 1897). The correctly identified plants are very important since they are the key to the literature. Various types of flora exist like native flora, agricultural flora/garden flora, weed flora, etc. Since plants of the world are extremely variable, therefore a wide

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96219650

range of Floras are available ranging from concise or field Flora to research Flora normally, the flora is assisted with the keys and description (Ali, 2008).

The floristic checklists may serve as a platform for more detailed study from the particular area and in many cases; this may be the only source of botanical information (Kent, 2011). Because of their conciseness, the listing of species is easy approach in vegetation study because it can be done in a relatively small timeframe, easy to handle and provide fundamental information for understanding the biodiversity issues (Ilyas et al., 2012). The floristic study provide baseline for further future taxonomic, ecological, ethnobotanical, conservation and forest management projects (Khan et al., 2015).

Pakistan has moderate diversity in terms of the flora and approximately 5,700 species of vascular plants have been reported (Stewart, 1972). Many floristic studies have been conducted from various parts of Pakistan and reported checklists (Chaudhri and Chuttar, 1966; Bhatti et al., 1999, 2001; Qureshi and Bhatti, 2005; Parveen and Hussain, 2007; Hussain et al., 2008; Qureshi, 2008a, 2012; Qureshi et al., 2011a, b, 2014; Shaheen et al., 2014a; Wariss et al., 2014; Ilyas et al., 2018; Khan et al., 2018). From Rawalpindi and adjoining area, an outdated account has been previously reported (Ahmad, 1964; Stewart, 1967; Shaheen et al., 2014b). Some of other studies include Sher and Khan (2007), Djaha et al. (2008), Saima et al. (2009), Qureshi and Bhatti (2010), Haq et al. (2010), Nazir et al. (2014), Khan et al. (2015) and Badshah et al. (2016). Because of diverse topographic and microhabitat variation along with very high elevational differences, the study area harbors rich plant biodiversity, which needs to be protected and conserved as soon as possible. The present study was aimed to enlist existing floristic diversity as an effort to highlight the rich phytodiversity of the area which will provide a baseline for planning conservation effort and further ecological investigation.

Materials and methods

Study area

Murree-Kotli Sattian-Kahuta National Park (MKSKNP) is composed of three distinct localities (i.e. Murree, Kotli Sattian, Kahuta) of district Rawalpindi, Pakistan. It lies at 33° 21’ to 34° 01’ N latitudes and 73° 11’ to 73° 38’ E longitude in the district Rawalpindi, Pakistan with an area of 934 km^2 (*Fig. 1*). Climatically, the study area is subtropical to temperate owing to elevational changes varying from 500 to 2270 m. The study area is located on the lateral spur of the Sub-Himalayan Mountains bounded by river Jhelum in the east, Islamabad in west, Khyber Pakhtunkhwa in the north and Gujar Khan in the south. The topography of the study area at higher altitude is mainly composed of rugged terrain with narrow valleys and relatively flat at the lower elevations. The hilly area contains valleys created by fast flowing running water of streams and rivers. The water courses are gradually made deeper by the fast flow of water which erodes the soil and carries valuable mineral to low lying downstream areas, resulting in alluvial deposits making these areas more fertile then hilly areas for cultivation (Khan et al., 2011).

Floristic enumeration

Plant specimens were collected from 246 sampling sites in the study area from August, 2013 to September, 2016. For this purpose, the whole study area was thoroughly visited covering all seasonal variations by walking method (Nazar et al.,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96219650

2008). Plant specimens were collected in triplicate, pressed, dried and mounted on standard herbarium sheets. Gymnosperm and Angiosperm were identified with the help of *Flora of Pakistan* (Stewart, 1972; Nasir and Ali, 1970-1989; Ali and Nasir, 1989-1991; Ali and Qaiser, 1993-2009); while, the Cryptogamic Flora of Pakistan (Nakaike and Malik, 1992) was used to identify the Pteridophytes. Nomenclature of the taxa was validated from The Plant List (TPL, 2013). Voucher specimens were deposited in the herbarium of Pir Mehr Ali Shah (PMAS), Arid Agriculture University Rawalpindi, Pakistan.

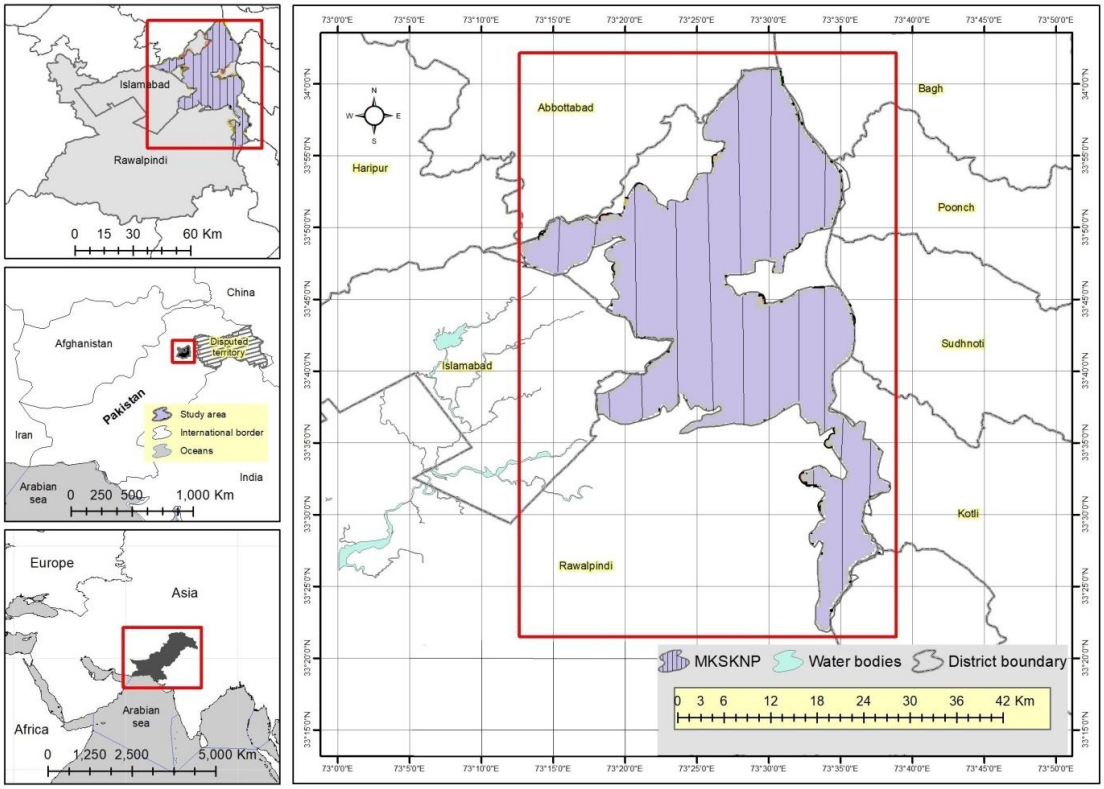

Figure 1. *Location map of the study area*

Family importance index (FII) and genera importance index (GII)

In order to calculate sharing of each family and genus, family importance index (FII) and genera importance index (GII) were calculated by using following formulae:

$$FII = \frac{\text{No. of species of a family}}{\text{Total No. of species recorded}} \times 100 \quad \text{(Eq.1)}$$

$$GII = \frac{\text{No. of species of a genus}}{\text{Total No. of species recorded}} \times 100 \quad \text{(Eq.2)}$$

Diversity index (SI)

The similarity index (SI) between localities was calculated after Kent (2011) by using following formula:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96219650

$$Ss = \frac{2a}{2a+b+c} \quad \text{(Eq.3)}$$

where “a” is the number of species common to both habitats, while “b” is the number of species in habitat 1 and “c” is the number of species in habitat 2.

Results

Floristic diversity

The vascular flora of Murree-Kotli Sattian-Kahuta National Park (MKSNP) is comprised of 624 plant species belonging to 361 genera and 106 families (*Appendix*). Two species such as *Aristolochia punjabensis* and *Buxus papillosa* were found endemic to Pakistan. There was diversity of elevational ranges recorded from sampling sites right from Beor (500 m) to Patriata (2155 m). The detail of sampling sites along with coordinates and altitude is provided in *Table 1*. The census of the flora indicates that it includes 24 ferns, 4 gymnosperms and 596 angiosperms (i.e. 144 monocotyledon and 452 dicotyledons). Geographically, the park area shared 0.12% of the whole area of country but contains significantly higher flora diversity (10.79%) than the flora of Pakistan (*Table 2*). Compared to the vascular plants of the country, the project area was found rich in pteridophytes (18.75%) and gymnosperms (17.39%), followed by monocotyledons (12.63%) and dicotyledons (10.06%) as indicated in *Table 2*.

Table 2. *Comparison of the flora of the project area with the flora of Pakistan*

Plant group	Number of species		Percentage
	National Park (area: 934 km^2)	Pakistan (area: 796095 km^2) (Stewart, 1967)	
Ferns	24	128	18.75
Gymnosperms	4	23	17.39
Monocotyledons	144	1140	12.63
Dicotyledons	452	4492	10.06
Total	624	5783	10.79

Family importance index (FII) and genera importance index (GII)

By using *Equation 1,* the contribution of each family was calculated and according to it, Poaceae was the largest family that shared 80 species (12.82%), followed by Fabaceae (60 spp., 9.62%), Asteraceae (55 spp., 8.81%), Cyperaceae (30 spp., 4.81%) and Lamiaceae (27 spp., 4.33%). Other dominant families with 10 or more species were Rosaceae (19 spp., 3.04%), Apiaceae, Brassicaceae and Euphorbiaceae (12 spp., 1.92% each), Convolvulaceae and Ranunculaceae (11 spp., 1.76% each), Acanthaceae, Amaranthaceae and Polygonaceae (10 spp., 1.60% each); whereas, the remaining families were represented by less than 10 species (*Fig. 2*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96219650

The genera importance index (GII) as calculated through *Equation 2* indicated that the largest genus was *Euphorbia* that contributed 10 species (2.67%), followed by *Carex* (9 spp., 2.4%), *Cyperus* (8 spp., 2.13%), *Eragrostis, Poa, Ficus*, *Medicago*, *Rubus* and *Swertia* (6 spp., 1.6% each), while rest of genera shared less than five plant species (*Fig.* 3).

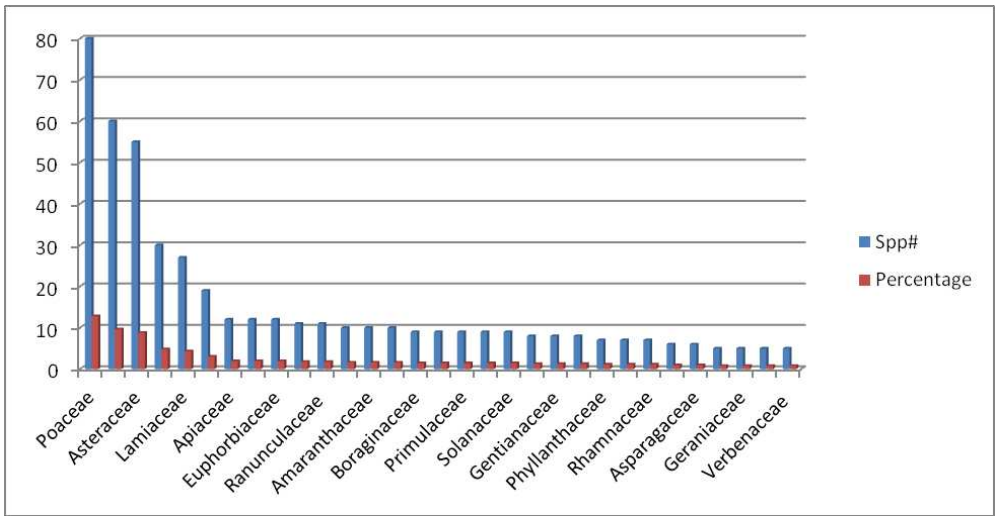

Figure 2. *Family importance index (FII) of the flora of Murree-Kotli Sattian-Kahuta National Park, Pakistan*

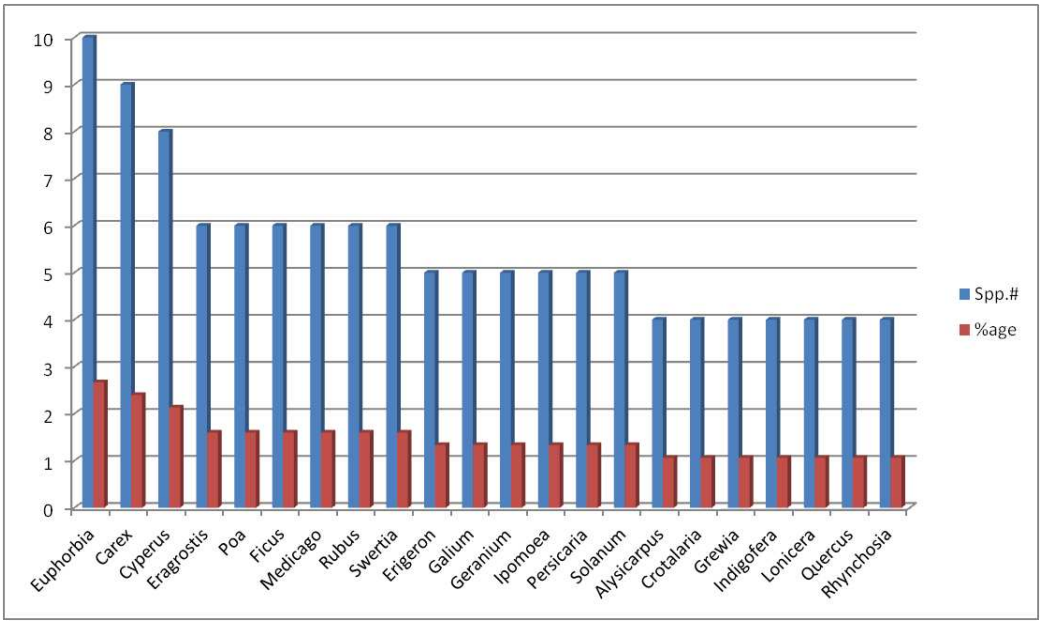

Figure 3. *Genera importance index (GII) of the flora of Murree-Kotli Sattian-Kahuta National Park, Pakistan*

Taxonomic status and diversity

Comparing with related floras, most of the project area was inhabited by native species (528 spp., 84.62%), followed weeds (48 spp., 7.69%), cultivated species

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96219650

(21spp., 3.37%), naturalized (18 spp., 2.88%), invasive (4 spp., 0.64%), introduced (3 spp., 0.48%), while two species such as *Aristolochia punjabensis* and *Buxus papillosa* were found endemic to Pakistan as shown in *Figure 4*.

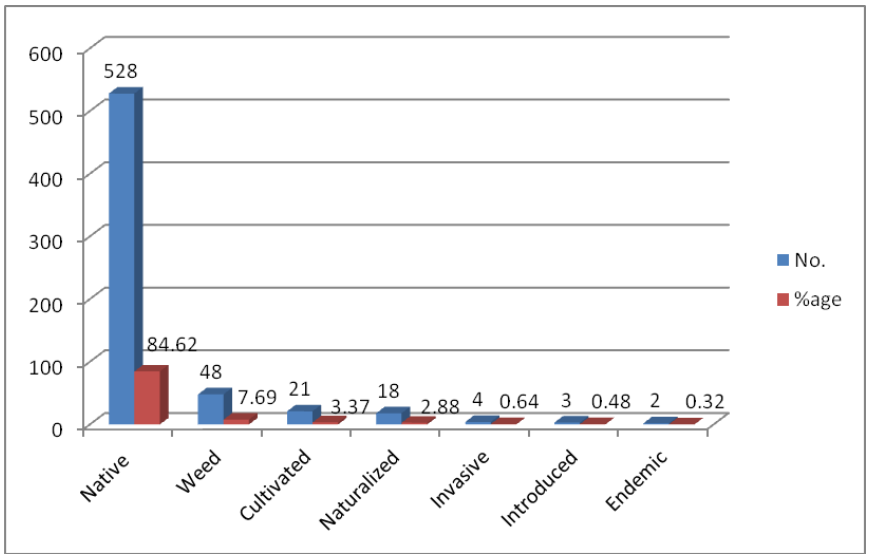

Figure 4. *Status of the flora of Murree-Kotli Sattian-Kahuta National Park*

Diversity index (DI)

The park area is composed of three localities viz., Murree Kotli Sattian and Kahuta. By using *Equation 3,* the pair-wise comparison revealed maximum similarity between Murree and Kotli Sattian sharing maximum species (518) with 89 distinct taxa and 47.94% similarity (*Table 3*). This similarity may be attributed due to their adjacency and similar climatic conditions. Likewise, the other pair viz., Kotli Sattian and Kahuta was also closely situated at the foothills towards southern part and ranked 2nd in terms of sharing species (416 spp.) with 131 distinct species and 46.27%. On the contrary, the 3rd pair comprising Murree and Kahuta was farther from each other and had least similarity in terms of species composition (i.e. 405 spp.). Since, Murree and Kotli Sattian regions are located in northeastern part of park where Himalayan floristic elements are dominant characteristically. On the other hand, The Kahuta is located at low elevation and towards southwest, therefore represented mostly by scrub forest.

Table 3. *Similarity index between pairs of localities from Murree-Kotli Sattian-Kahuta National Park*

Attribute	Murree vs. Kotli Sattian	Murree vs. Kahuta	Kotli Sattian vs. Kahuta
Shared species	518	405	416
Distinct species	89	215	131
Similarity %	47.94	44.14	46.27

Life forms

Eight life forms of the flora were determined from the Murree-Kotli Sattian-Kahuta National Park in which perennial herbs were dominating the area with 241 species

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96219650

having proportion of 38.62% of the total flora. It was followed by annual herbs (199 species, 31.89%), deciduous shrubs (62 spp., 9.94%), deciduous trees (46 spp., 7.37%), climbers (26 spp., 4.17%), evergreen shrubs and evergreen trees (23 spp., 3.69% each), while parasites were only 4 (*Fig. 5*).

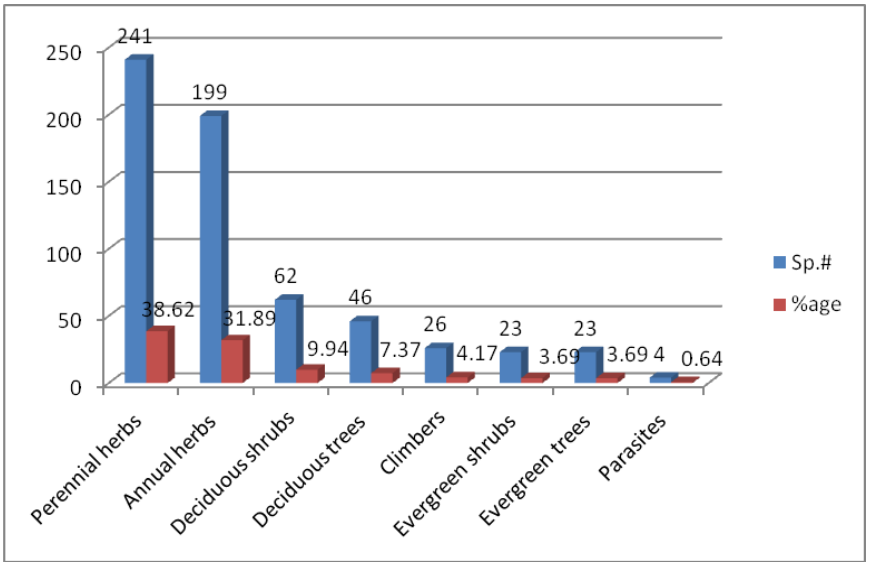

Figure 5. *Life form of the flora of Murree-Kotli Sattian-Kahuta National Park*

Locality-wise diversity

Murree-Kotli Sattian-Kahuta National Park (MKSNP) is located in the lateral spur of Himalayan Mountain in district Rawalpindi and contributed by three Tehsils such as Murree, Kotli Sattian and Kahuta. The detailed inventory is compiled and provided in *Appendix.* Localities-wise species diversity recorded as follows:

1. Murree hills

From the Murree hills, in all 592 vascular plants are documented (*Appendix*). This zone had the highest plant diversity compared to the rest of the localities. Besides, 74 species such as *Abies pindrow, Achillea millefolium, Aconitum laeve, Aegopodium burttii, Agrostis gigantea, Alisma plantago-aquatica, Anaphalis adnata, A. busua, A. margaritacea, Andrachne cordifolia, Anemone tetrasepala, A. vitifolia, Aquilegia pubiflora, Aralia cachemirica, Aristolochia punjabensis, Aster flaccidus, A. himalaicus, Buxus papillosa, Calanthe tricarinata, Carex schlagintweitiana, Carpesium abrotanoides, Cedrus deodara, Cephalanthera longifolia, Cornus macrophulla, C. oblonga, Corydalis murreeana, Daphne papyracea, Dryopteris stewartii, Elaeagnus angustifolia, Eleocharis uniglumis, Epipactis gigantea, E. helleborine, E. persica, Equisetum hyemale, Eryngium caeruleum, Gentiana argentea, G. olivieri, Habenaria furcifera, Heracleum cachemiricum, H. candicans, Hypericum dyeri, Ilex dipyrena, Impatiens bicolor, I. brachycentra, I. edgeworthii, Kyllinga squamulata, Lepidium didymium, Leucanthemum vulgare, Machilus duthiei, Malaxis muscifera, Mimosa himalayana, Myrsine semiserrata, Neolitsea pallens, Oxytropis mollis, Polystichum aculeatum, Primula denticulata, Prunella vulgaris, Quercus dilatata, Reinwardtia indica, Rhododendron arboretum, Sarcococca saligna, Solena amplexicaulis, Spiraea*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96219650

canescens, Spiranthes sinensis, Swertia ciliata, S. cordata, S. paniculata, S. tetragona, Trifolium pretense, Tulipa clusiana, Valeriana hardwickii, Viburnum cotinifolium, V. grandiflorum and *V. mullaha* reported as distinct and unique species only recorded from this locality.

2. Kotli Sattian

This is the second most diverse locality containing 533 vascular plants (*Appendix*). Fifteen plant species were found unique to this locality which include *Cheilanthes argentea, Crotalaria prostrata, C. retusa, Eranthemum pulchellum, Hylodesmum podocarpum, Hypodematium crenatum, Pupalia lappacea, Rhynchosia capitata, R. himalensis, Scandix pecten-veneris, Scurrula pulverulenta, Trianthema portulacastrum, Uraria picta, Vincetoxicum canescens* and *V. hirundinaria*.

3. Kahuta

This locality is found mostly in low to medium elevation and found least diverse in terms of the flora. There are only 433 plant species documented from this area (*Appendix*). With reference to unique flora, 17 species are recorded as an indicator species such as *Alysicarpus bupleurifolius, A. monilifer, A. ovalifolius, A. rugosus, Atylosia mollis, A. platycarpa, A. scarabaeoides, Crotalaria calycina, Curculigo orchioides, Dregea volubilis, Hydrilla verticillata, Kydia calycina, Potamogeton perfoliatus, Pueraria tuberosa, Tephrosia strigosa, Veronica anagallis-aquatica* and *Viola pilosa*.

Discussion

The present study investigated the flora of Murree-Kotli Sattian-Kahuta National Park (MKSNP) and documented 624 vascular plants distributed across 361 genera and 106 families (*Appendix*). This work serves as checklist of the species and such kind of research is the main source for the botanical information which may serve as a benchmark for more detailed study (Kent, 2011; Reddy et al., 2011). Besides, it provides baseline for further taxonomic, ecological, ethnobotanical, conservation and forest management projects (Khan et al., 2015). The park area geographically represents only 0.12% of the land area of the country but harbors rich floristic diversity (10.79%) (*Table 3*) which can be attributed to diverse microhabitat variations because of considerable variation in elevation, topographic, edaphic factors and indeed anthropogenic effect had a major influence in controlling the vegetation (Gunatilleke and Gunatilleke, 1985). With reference to the families contribution, Poaceae was recorded as the largest family by contributing 80 species, followed by Fabaceae (60 spp.), Asteraceae (55 spp.), Cyperaceae (30 spp.) and Lamiaceae (27 spp.) as shown in *Figure 3*. Some of the studies such as Qureshi (2008a,b), Qureshi et al. (2011a, b, 2014), Shaheen et al. (2014a), Wariss et al. (2014), Ilyas et al. (2018) and Khan et al. (2018) had reported domination of Poaceae that may be indicator of subtropical forest vegetation and degradation of forest habitats.

Amongst the life forms, the flora was dominated by perennial to annual herbs in the whole project area (*Fig. 4*). This kind of assemblage of herbs is indicating a typical tropical to subtropical plant life in the park area revealing a response to the climate coupled with availability of plentiful moisture in the form of rainfall (Qureshi, 2008b,

DOI: http://dx.doi.org/10.15666/aeer/1704_96219650

2009; Qureshi et al., 2014; Wasim et al., 2019). The inhabitation of herbal coverage from lower to upper elevation has been reported from other temperate regions of Himalaya (Ren et al., 2006; Zhang et al., 2009; Khan, 2012; Ilyas, 2015; Ilyas et al., 2015). With respect to woody vegetation, shrubs were more dominated in the area that is in agreement of other studies from Himalaya regions (Gairola et al., 2010; Qureshi et al., 2011a b, 2014; Chawla et al., 2012).

The flora of this park area is very rapidly deteriorating due to manmade activity. The people of the area are intentionally removing shrubs and providing opportunity for grasses and other herbs to flourish which they collect as winter fodder. Similar trend has been observed from other regions of Himalaya (Consiglio et al., 2006; Irwin and Narasimhan, 2011; Ilyas et al., 2012, 2013, 2015).

The floristic list of the study area might provide a little insight in understanding the ecosystem dynamics, along with physiological and reproductive aspect of vegetation. The floristic list of the study area could be the potential source for ethno-pharmacological studies, because many of the plant species reported in this study are medicinal one (Saqib et al., 2014). The floristic list of the study area could be the potential source for ethno-pharmacological studies (Ilys et al., 2013; Saqib et al., 2014). The park area is comprised on three localities (viz., Murree Kotli Sattian and Kahuta) and their comparison revealed that maximum similarity between Murree and Kotli Sattian is because adjacency and similar climatic condition (*Table 3*). Similarly, the other pair viz., Kotli Sattian and Kahuta was also closely located towards southwest and had similar floristic elements. Contrary, Murree and Kahuta were farther from one another and had variation in climatic conditions that resulted in least similarity in vegetation composition.

Conclusion

This is a comprehensive study not previously reported on the flora of Murree-Kotli Sattian-Kahuta National Park. It reflected the detail of their biology and plant life of the area. The detail of richness, diversity and similarity between various habitat types/localities are also discussed and highlighted. Locality-wise unique, rare and endemic species are highlighted in order to give insight for the rehabilitation and conservation efforts by the park manager for their sustainable use and availability for future generation. Therefore, this study serves as a platform for the detailed floristic and ecological studies to be carried out by the researchers. This study will be helpful for foresters/managers, plant biologist and ecologist for further detailed work. On the other hand, this ecosystem is under continuous and ever increasing human pressure in the form of deforestation, overgrazing and human settlement construction, which resulted in sever degradation the natural vegetation of the study area. Efforts are required to rehabilitate of certain eroded area and protection of key habitat indicator species.

(Received 26th Feb 2019; accepted 1st Jul 2019)

Abstract. In this study, existing and future land use patterns were examined in the development plan for Amasya using hierarchical cluster analysis. To this end, the area encompassed by the Amasya development plan was partitioned into grids to examine their proximities and similarities to each other in terms of land use. In addition, linkages among the grids were investigated with respect to the land use patterns. Linkages among land use functions were determined in this research through cluster analysis. After exposing the similarities among the grids, the shortcomings with regard to the necessary social infrastructure within the grids were identified, and the requirements of similar urban development approaches to grids with similar characteristics were described. This paper emphasizes the need for healthy, sustainable development and a planned and balanced distribution of social infrastructure in urban development plans.
Keywords: *land use patterns, grids, hierarchical cluster analysis, social infrastructure, similar characteristics*

Introduction

The way in which land is used can provide essential resources and is one of the most central factors that affect urban development (Foley et al., 2005; Niedertscheider and Erb, 2014). This important factor reveals that city planning must use sustainable approaches that satisfy human needs. For this to be successful, it is imperative to fully understand how land is categorized in city development plans. Numerous land use factors, such as green space and housing space, shape how urban areas should be developed. For example, housing space shapes urban development by providing living quarters for current and future populations, and this basic necessity can be constructed when urban development is correctly planned.

In Turkey, land use issues in urban areas cannot be resolved using only ad-hoc solutions. There exists a significant deficit of knowledge regarding land use factors in cities as well as how land is used (Niedertscheider and Erb, 2014). As a precondition in preparing for future land use modifications, land use decisions to changes in previous underlying development must be analyzed (Dearing et al., 2010; Niedertscheider and Erb, 2014). Hierarchical analysis is regarded as one of the most powerful instruments (R Core Team, 2015; Manjunath et al., 2018) by which to understand future development options that affect current land use. Many studies on land use changes are highly limited mainly because of the lack of data sets on land systems and dynamics as well as the underlying factors that affect these changes (Singh et al., 2013; Niedertscheider and Erb, 2014).

Results of studies on urban development plans in Turkey are conducted to work in concert with planning requirements, a balanced distribution of social and technical infrastructure, and in accordance with standards and needs. For example, in Turkey's development plans, the distribution of and need for green areas per person or the distance to neighborhood schools are important for healthy urbanization. A 10 m^2 green area/capita should be included in all urban development plans. When we analyzed the urban structure of Amasya, we found that a linear urban structure is formed between the Yeşilırmak River and two mountain ranges. This situation creates problems for physical expansion of the city, because the topography in Amasya is not flat enough to accommodate sufficient residential and development areas. Because of this topography, a balanced distribution of social infrastructure in urban development is indispensable for a healthy urban structure.

Balanced distribution means that the population living within any city grid has equal access to all social facilities, and that all social facilities appeal equally to everyone, or that the population is distributed evenly within each grid. In short, balanced distribution describes how urban development within each grid is self-sufficient and does not need external intervention**.** The grids contain urban land use forms which are created by Municipality for the future urban development in Amasya. Types of land uses come from legal Municipality creation into the grids. It is proved that the form of land uses is the main research data for analysing grids and current Amasya city development condition.

Cluster analysis is a suitable method by which to identify analogous groups of objects called "clusters" (Mooi and Sarstedt, 2011). A central feature of this analysis is its ability to refer directly to either understanding development options or to land use relationships in this study (Alvarenga et al., 2013; Niedertscheider and Erb, 2014). The core area of urban usage is the transition zone between land use similarities and differences (Bo, et al., 2011). The approaches to the similarities and differences in this cluster analysis provided us with ideas about land use distribution, which supported our deductions related to recent land use and the social infrastructure. In addition, cluster analysis is a highly useful method by which to understand the trends in urban development for future perspectives.

Land use change is defined as a transformation of one land use into another format, or a complete change from an old land use to a new land use (Liu et al., 2014). There are many studies related to land use change (McHarg, 1992; Erickson, 1995; Milesia et al., 2003; Nuissl et al., 2009; Song, et al., 2013; Cinelli, et al., 2014; Liu et al., 2014; Krekel, et al., 2016; Lu and Ke, 2018). It is important to study land use development because it has a profound impact on options for future city development (Liu et al., 2014). This paper brings together, in a systematic way, the results of many recent studies on urban form, especially on land use (Ozus et al., 2012).

In their 2014 research, Grecchi, et al. investigated changes in land use using raster data from different dates. Another 2014 study by Kline et al. analyzed land use plans within different governing regimes. Likewise, Sharifi et al. (2014) investigated the regulation and control over master plans for urban growth using monitoring, and Liu et al., 2014 conducted a compatibility analysis for land use, which identified compatibility analysis criteria, such as topography, geology, and socioeconomics. The monitoring method is most prevalent in land use analyses. In their study, Ozus et al. (2012) used cluster analysis to examine how travel demand shaped the spatial structure of Istanbul; however, land use that does not involve transportation is also important. We use a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96519668

cluster analysis of land use patterns to demonstrate a more effective use of this method in planning. This study also presents the urban social infrastructure issues, such as easy access to primary schools and enough green areas per person, using an agglomerative hierarchical cluster analysis. This identifies the social infrastructure problems in urban development and is a departure from other studies because it emphasizes the need for an innovative and comprehensible approach to land use. In this context, an innovative approach refers to identifying the current distribution of the social infrastructure and the necessary strategies for the future by looking at existing land use within the city.

In addition, the methods used in the present study to analyze land use suitability first emerged in 1992 with Ian McHarg's *Design with Nature* and are still used today in many studies. In 200 the results of a study by Randolph showed that land use suitability analysis provided information about lands suitable for settlement or about the most suitable settlement areas for land use and their development based on specific criteria. This study was not to determine the most suitable areas for settlement but to determine the distribution of social service areas within the city and designated in the development plans that the municipalities are supposed to follow and to choose the areas of social infrastructure in urban areas and determine the similarities among them in the city grids. The similarities among these areas reveal an analysis of the current situation, such as whether development has been homogeneous, and can generate prospective inferences. Our analysis is based on the current situation for land use in urban areas and does not consider settlement or suitability for future development.

From this study, the best planning approaches used for urban planning are presented to help facilitate effective and more resolution-oriented decisions to enable an understanding of land use areas. For example, it is necessary to determine where within the city there is a lack of social facilities and to decide within which areas these facilities will be designed. It is also important to create suitable designs for this area, to fill the need for urban social facilities within the city, and to resolve the deficiencies in urban design and urban planning within the city's existing development.

The aim of this study was to explore the direction that future social infrastructure development within Amasya will take by analyzing its land use using the cluster analysis method. Land use is the most important dimension of urban development within cities, and its intensity has become an important indicator of the relationship between current and future urban development (Hubacek and van den Bergh, 2006; Shi and Yu, 2014). Moreover, in the study, the distribution of spaces in terms of their land use similarities and differences will be investigated to make recommendations for future urban development. This new methodological approach will provide a new perspective to development plans in Turkey. These similarities and differences will be useful for illustrating the imbalances of social infrastructures in land use and identifying whether the Amasya can provide sufficient infrastructure within every region and every area to accommodate its citizens. Accordingly, this paper will focus on the necessity of reanalyzing the city's approach to creating social infrastructure that is incorporated into urban development plans.

This study presents a land use analysis that is used to assess development options in Amasya. The hierarchical analysis helps to analyze urban development by providing a good assessment of land use development while revealing the similarities and dissimilarities among the various urban spaces. Our main research questions are as follows: how well is the social infrastructure, such as green areas, schools, and hospitals, throughout an urbanized area distributed as it is intended (e.g., primary

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96519668

schools within a perimeter of 500-m of settlements, or green areas should be 10 m^2/person) and is it balanced? If there is an unbalanced distribution of social infrastructure, what do we need to do to balance the distribution of that infrastructure in future urban development plans? The second question will be important when discussing how the social infrastructure will be planned in future urban development and how the lack of social infrastructure within the city will be alleviated. Using an agglomerative hierarchical cluster analysis, this research investigated the sufficiency of urban social infrastructure and whether urban areas have been developed in a healthy manner.

The role of cluster analysis in planning practices

There is a wide variety of planning practices with different purposes in Turkey's land planning system. Among Turkey's planning stages, cluster analysis is most useful for land use plans, one category of plans. We conducted our analysis at this planning stage because land use plans provide the existing land use patterns during the decision-making process. Although this method was chosen specifically for Turkey's planning system, it can be used for any country and on any land use plan because it increased information on the quality of life within the regions studied. With this method, existing land use can be accurately determined, and a planning process can be created accordingly. The following text explains this more clearly by providing a hierarchical scheme of the plans in Turkey's planning system (*Fig. 1*) with additional social infrastructure within the new developments.

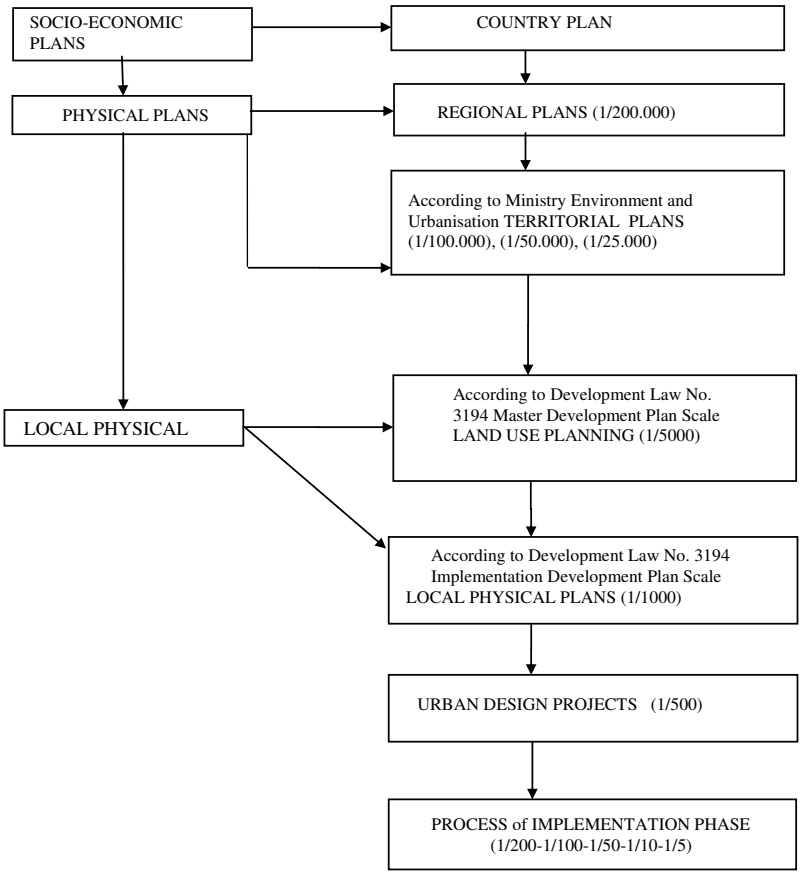

Figure 1. *Turkish planning system. (Source: Türk, 2002)*

The area studied was divided into grids. The characteristic feature of each grid is to be a homogeneous distribution of mixed land use and have the ability to describe the necessary services, such as hospitals, schools, and recreational areas (social infrastructure), that are included in land use and urban development. The square grids are used to investigate the distribution of social infrastructure within ~500 m of the center of the city, which also helped understand which social infrastructure is accessible in each grid. The fact that the grids offer the opportunity to develop a planning approach that is a sounder, sustainable, and provides accessible social infrastructure and has a command of the entire city reveals the most significant feature of this arrangement—the location of these social infrastructures. The need for social services within the grid areas that do not have them is not emphasized, and the study does not suggest that the needs be satisfied. Thus, the results provide information on how social infrastructure is distributed within the grids and how the transportation issues and other recommendations were resolved.

The grids included all areas within the borders of the municipal adjacent areas. If each social service and the population within the grids were to be discussed presumptively and evenly, there would be equal and balanced distribution within the city. We recognize that this approach is similar to developing an imaginary ideal city, and the aim here is not to disperse the population accordingly, but to understand and explain how urban areas would be developed in such cases. Keeping the same populations within each grid is an imaginary approach, and dispersing a population according to ideal land use is impossible and meaningless. The population of Amasya is 113.932 (Turkstat, 2018), and a balanced plan should propose a balanced distribution of the city's population. If we can employ approximately 3.452 people within each grid, we can have a balanced distribution of housing as well. The acceptable size of housing per person is between 12 and 24 m^2 in Turkey's planning system and, accordingly, the maximum area of housing within the grid is 82.848 m^2. According to legislation, land use planning administrators in Turkey are obligated to designate 10 m^2 of green area/person in a development plan; therefore, 34.520 m^2 within each grid must be designated as green areas. Moreover, hospital building floor space must be 0.11 m^2/person, which means that 379.5 m^2 of building floorspace must be designated as hospital building floorspace within each grid. The total area for healthcare services includes other facilities, such as 0.05 m^2/person (172.6 m^2) for dispensaries and 0.15 m^2/person (517.8 m^2) for other facilities; therefore, total healthcare space within each grid would be 1069.9 m^2. However, it is highly likely that the existing land use situation is not similar to this, in which case, it is necessary to take measures to correct the situation with additional social infrastructure within the new developments.

Materials and methods

Area of study

Figure 2 shows the boundaries of the center of Amasya and the area analyzed for this research. Amasya is located in the Black Sea Region of Turkey and is surrounded by Tokat on the east, Tokat and Yozgat on the south, and Samsun on the north (Turkstat, 2012). Amasya's average altitude is 1150 m, with the altitude in the center of the city being only 411 m. The city is located between the east longitudes of 34°57′06″–36°31′53″ and the north latitudes of 41°04′54″–40°16′16″ (Turkstat, 2012).

DOI: http://dx.doi.org/10.15666/aeer/1704_96519668

Archaeological excavations have revealed that the city dates back 7500 years, making it one of the most important cities in history (Governorship of Amasya, 2017).

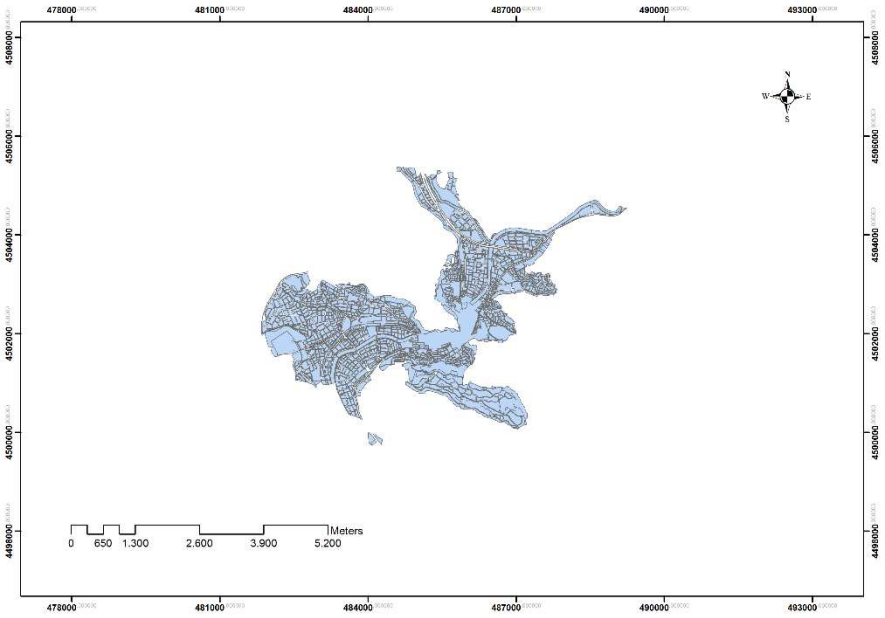

Figure 2. *The analysis area of Amasya, Turkey. (Source: The map was obtained from Amasya Municipality with NetCAD program. The map was converted to ArcGIS and prepared by the authors for description of analyzing areas in Amasya)*

The methods used are based on a case study of Amasya. It was evident from the findings that Amasya was most likely a city in which traditional urban planning practices would have been the norm. In Turkey, such practices always lack adequate social infrastructure; therefore, in this article, analyses are conducted on how the urban development plans should be constructed, using Amasya as an example.

Materials

Urban development plans can be obtained from municipal authorities in Turkey in which the administrators are obligated to prepare development plans for each municipality. A development plan is a periodic study that is required to ensure healthy urban development. Moreover, development plans are prepared using up-to-date information on land use; therefore, in our research, the analyses use development plans that were prepared by the Amasya Municipality. The data for this research were obtained from these urban development plans and analyzed using cluster analysis. Thirty-three grids were produced using the urban development plans with the help of ArcGIS based on the land use data (*Fig. 3*). To explain the methods, we used the Lance–Williams algorithm, which was formulated in 1967 by Lance and Williams as follows (*Eq. 1*):

$$d(i + j,k) = a_i\, d(i,k) + a_j\, d(j,k) + b,d(i,j) + c \left| d(i,k) - d(j,k) \right| \qquad \text{(Eq.1)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96519668

The formula displays the distance between clusters k and i + j. This study addresses the similarities and dissimilarities between data using single linkage, average linkage, and complete linkage cluster analyses, which are part of the agglomerative hierarchical analysis.

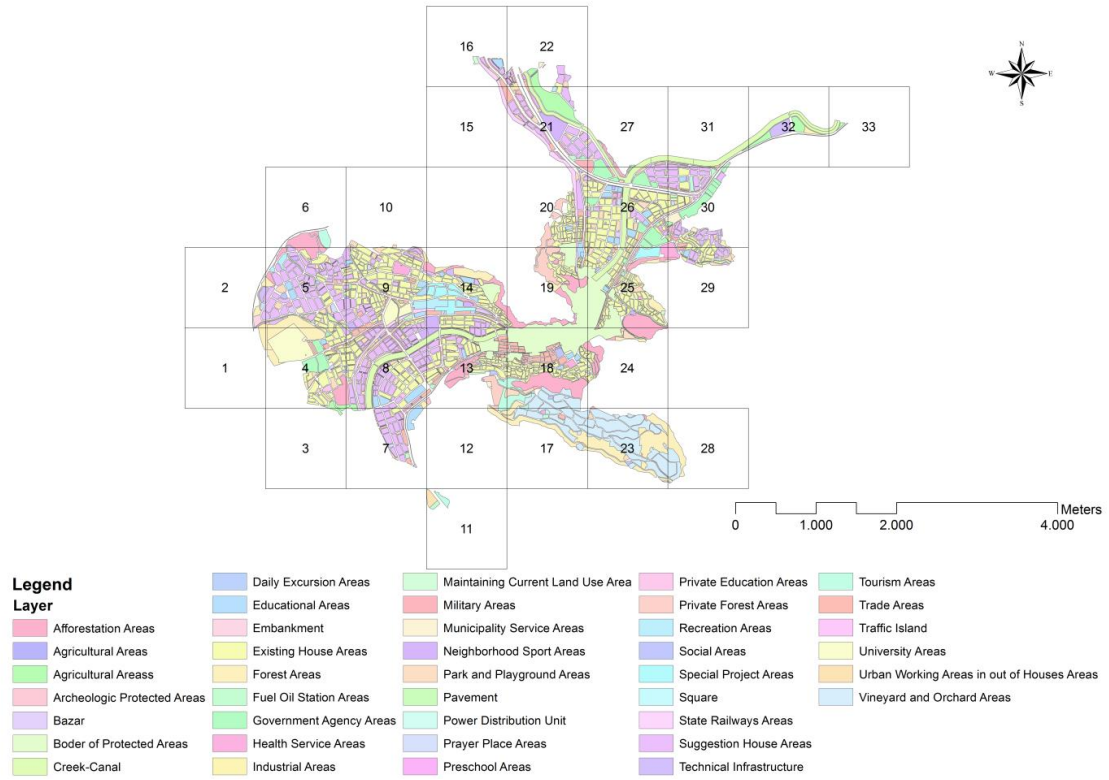

Figure 3. *Land Use and Grids of Study Area. (Source: The map was obtained from Amasya Municipality in a GIS format. The map was converted to ArcGIS and prepared by the authors for analyzing land uses in Amasya)*

The data on the land use map were first transformed from the NetCAD format to the ArcGIS format. To make them suitable for analysis, georeferences were created in ArcGIS WGS 1984 Universal Transverse Mercator (UTM) Zone. Grids were produced within ArcGIS, and data were obtained for each grid. The raw data obtained were normalized using Matedit to make them analyzable. We began by normalization the analysis to eliminate redundant variables in the database. Then, we conducted an agglomerative hierarchical analysis using Minitab. The results obtained from this analysis revealed the urban development approaches for similar and different grids. Hawth's analysis tools in ArcGIS automatically generated the grids. Using the UTM zone, these tools generated equal 1- by 1-km squares. By doing so, we were able to analyze the included land uses and the values of the social infrastructure within the land uses. Using this program, analyses conducted for future land development will shed light on future advances. Each grid allowed for meaningful analyses that could be conducted based on Hawth's analysis tools. We determined that conducting these analyses using smaller or larger grids would not be feasible.

Cluster analysis is used in many research studies, including the wastewater treatment study byBayo and Castellanos (2016), who matched the similarities in the cluster analysis to principal factors to attain results, and the research conducted by Ozus et al. (2012), who used a hierarchical cluster analysis to identify similar transportation behaviors among districts within Istanbul. As mentioned, agglomerative hierarchical cluster analysis is a widely used method, and unlike those used in other studies, this method is used in our research to identify how urban land use is distributed and determine the distribution of social infrastructure areas within the city grids.

Agglomerative hierarchical cluster analysis was chosen to study land use patterns using data obtained on decisions from the city's urban land use plan. In this sense, cluster analysis can be used as a tool to analyze only land use development, and allows us to examine the required healthcare, housing, and green spaces for 100 ha of land and to make better planning decisions. After selecting the best cluster analysis, the information necessary to plan similar and different places within that grid is provided.

Methodology

All grids were created using the same method with GEOSTAT, which comprises all of the urban areas in Europe and divides them into grids. The GEOSTAT grid size of 1 km^2 is based on a population density of at least 5000 people within an area of 300 km^2 (Paffi et al., 2016). The grids created in this study were applied to the entire city. The aim was to ensure that the populations living within each region of the city were equally represented and had equal accessibility to the city's social facilities; therefore, this study sought to research and identify how much of the population living within each city grid actually realized that goal.

One of the key rules in this method is that grids be a particular uniform size. In these grids of a predetermined size, it was not necessary to have either all or part of the land use plan. The number of grids, which is determined by applying an area of particular size in the land use plan, is used as the basis. Thus, it is important to divide the selected area into grids rather than to divide the area of the plan into grids. As a result of the analyses, 33 grids were created using Hawth's analysis tool. Each equal grid provides a way by which to analyze the land use of the entire area. In some of the emerging grids, there was very little area available for land use, the most important reason for which is that land use divided into equal grids decreases at the edges of the city and intensifies at the focal points of urbanization; however, our tools offered the opportunity to analyze both the farthest point and the most intensely urbanized area within the equal grid areas.

Agglomerative hierarchical analysis

Cluster analysis is a form of statistical analysis used for examining multivariate data with the objective being to uncover or discover groups or clusters that are similar to and different from each other (Everitt, 2005; Ozus, et al., 2012). Cluster analysis is linked to a correlation matrix; however, it can generally conduct analyses in different forms (Robinson, 1998).

In our study, cluster analyses were performed using the linkage method. Through these analyses, grids with the highest proximity and those with the most linkages were identified. Using the linkage method, proximities among the grids were calculated on the basis of the correlations among them. As stated, three types of linkage methods were used in our study.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96519668

At the analysis stage, the cophenetic correlation method was used to find the best approach to agglomerative hierarchical cluster analysis and to be able to conduct the related analyses. This is the best method by which to understand the phenomenon of future urban development. Accordingly, the current situation in urban development sheds light on future approaches to development.

Identifying the best cluster approach

Clusters were validated using the cophenetic correlation, a commonly used measurement in hierarchical clustering (Ozus et al., 2012). The Matlab code given below was used for this analysis (Anonymous, 2018):

$$c = \text{cophenet}(Z,Y)$$
$$[c,d] = \text{cophenet}(Z,Y)$$

In the cophenetic correlation coefficient values, the best cluster analysis linkage method is identified when the value of r approaches 1. Conversely, if the value approaches the linkage method should not be chosen. As the *Table 1* illustrates, all linkage methods in the cophenetic correlation coefficient analysis could be used for this analysis. It also shows that average linkage was the best approach, although all were similar. Accordingly, groupings of clusters on the map, which were created using average linkage, are described here and shown in *Figure 4*.

In addition, grids and land uses were correlated to better understand the linkages among them, and the findings were evaluated. Data on the current state, obtained using the average linkage method, will influence planning decisions.

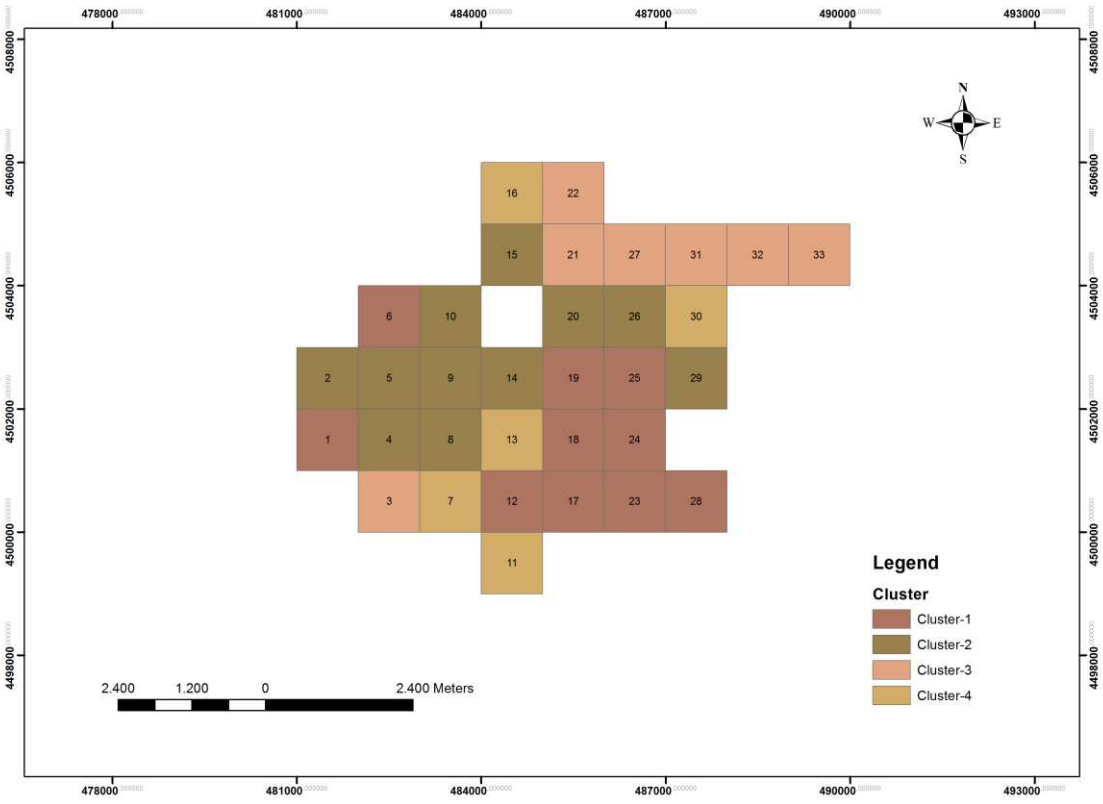

Figure 4. *Clustering analysis map created using grids and average linkage*

DOI: http://dx.doi.org/10.15666/aeer/1704_96519668

Table 1. *The cophenetic correlation coefficient values*

Linkage method	Cophenetic correlation coefficient
Single linkage	r = 0.8211
Complete linkage	r = 0.8043
Average linkage	r = 0.8285

Results

Average linkage cluster

In average linkage analysis, the average distance between two clusters is considered. Average linkage was formulated by the Lance–Williams algorithm created in 1967 by considering the average distances between the clusters of $i + j$ and k.

$$d\,(Ci, Cj) = \frac{1}{nj+ni} \sum_{a \in Ci, a \in cj} d(a, b) \qquad \text{(Eq.2)}$$

In the analyses performed using Minitab, the following average linkage results were obtained (*Fig. 5*).

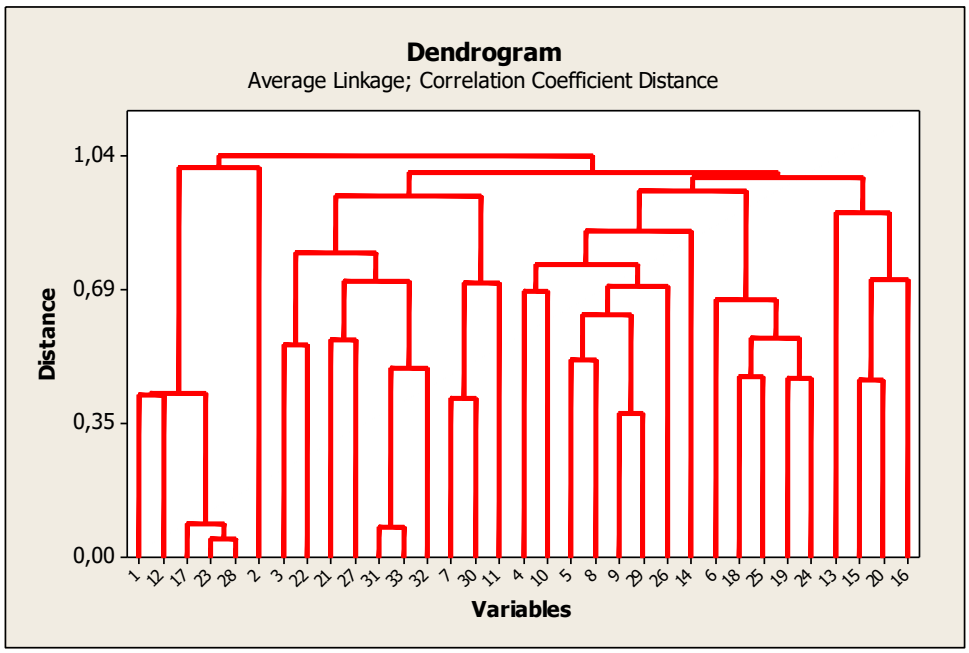

Figure 5. *Dendrogram for average linkage analysis*

The similarity between the 23rd and the 28th grids is striking (*Table 2*). It can be seen from *Table 2* that the similarity level, 9.642 and distance, 0.0471 stand out. The 1st and 3rd grids are those that are the most distant from each other. While the similarity level is 48.023 the distance level is 1.03953.

Here are the clusters that result; ***Cluster-1:*** Grid- Grid-1 Grid-1 Grid-2 Grid-2 Grid-Grid-1 Grid-2 Grid-1 Grid-2 ***Cluster-2:*** Grid- Grid- Grid-2 Grid-1 Grid-1 Grid-2 Grid-Grid-1 Grid- Grid- Grid-26 ***Cluster-3:*** Grid- Grid-2 Grid-2 Grid-2 Grid-3 Grid-3 Grid-3 ***Cluster-4:*** Grid- Grid-3 Grid-1 Grid-1 Grid-16.

A landuse development model can be created based on decisions made from data obtained using the average linkage method. To understand the balanced distribution of land use with respect to accessibility to the services (such as schools, hospitals etc.), information on land use must be gathered and the lack of efficient social infrastructure must be identified. Efficient use of the land helps create sustainable and habitable cities by ensuring a sufficiently balanced hospital accessibility, green areas per person in square meters (or other ratio), or other infrastructure in urban development. In this sense, average linkage, which is obtained using the cophenetic coefficient correlation

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96519668

method in agglomerative hierarchical cluster analysis is the best approach. Thus, our findings in this study were evaluated using this type of analysis.

The results from our cluster analyses illustrated land use within each grid. With specific regard to how social infrastructure is distributed by identifying similar and different land uses within each grid and which precautions we should take in urban development plans based on these results, this study was able to obtain results that would help guide future planning. The results of the similar and different grids are provided below.

In the average linkage analysis, the 23rd and 28th grids emerged as the most similar; therefore, land use in these grids was examined in more detail. The 23rdgrid comprised 0.43% social areas, 1.56% park and playground areas, 36.80% forest areas, 0.52% afforestation areas, and 60.69% vineyard and orchard areas. On the other hand, the 28th grid comprised 50.52% forest areas and 49.48% vineyard and orchard areas. We observed that these grids are mostly composed of green spaces, although we also observed that urban development is slowly emerging within the 23rd grid. The observation that these two grids are near each other suggests that urban development within the 23rd grid will pose a threat to the green spaces within the 28th grid.

Using average linkage, we observed that the 1st and 3rd grids are most distant from each other. Murtagh and Legendre (2011) reported that the study conducted using the Lance–Williams (1967) used controlled dissimilarity of object distance for cluster analysis. In the present study, the differences among the grids were analyzed using cluster analysis, which found the most distance between the 1st and 3rd grids. In addition, the program that was used statistically analyzed the differences among the grids; therefore, we can consider that the 1st and 3rd grids are different from each other. Grid1 comprises3.6% traffic islands and 96.4% forest areas, whereas 100% of grid3 is composed of agricultural areas. The fact that, in particular, grid1 contains traffic islands implies that this space will threaten forest areas in the future; however, it can be argued that the same urban development approach should not be recommended for these spaces because the grids are highly dissimilar and that grid which consists of forest areas, does not have traffic islands.

Grids 5 and 9 emerged as not entirely the same but also not too distant from each other. These grids are located nearly in the middle in all three linkage methods. Grid5 comprises university areas (0.64%), tourism areas (0.14%), power distribution areas (0.14%), existing house areas (10.95%), technical infrastructure areas (0.28%), trade areas (0.71%), social areas (0.71%), neighborhood sport areas (0.71%), health service areas (0.36%), recreational areas (1.92%), median strips (0.21%), trade areas (0.85%), park and playground areas (7.32%), private education areas (0.36%), educational areas (2.56%), forest areas (9.31%), suggested house areas (51.10%), municipality service areas (0.85%), a creek–canal (3.20%), afforestation areas (6.68%), and places of worship (1%). On the other hand, grid9 comprises a university area (7.06%), existing house areas (45.36%), technical infrastructure (0.07%), trade areas (5.69%), social areas (0.52%), neighborhood sport areas (0.78%), health service areas (3.46%), government agency areas (0.59%), recreation areas (1.96%), median strips (0.13%), park and playground areas (8.24%), private education areas (0.13%), educational areas (3.40%), forest areas (0.46%), suggested housing areas (16.99%), a creek–canal (0.78%), afforestation areas (0.78), places of worship (0.65%), state railway areas (2.09%), and fuel areas (0.59%). Although both grids have significant empty space for proposed housing, we observed that the social infrastructure support that would be necessary after

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96519668

urban development, such as green spaces and healthcare units, is not adequate, and that no scenario to meet this need has been proposed. As stated, each grid covers an area of 1 km^2; therefore, there is an apparent need for additional space to support the social infrastructure within the grid.

This research methods helps to determine the adequacy of land use distribution and demonstrates how creating these grids can guide urban development administrators in their decisions for future development. Similarities and differences found in cluster analysis help us determine the extent to which the existing members of a good urban infrastructure are sufficient as well as what is still needed. By presenting an alternative approach, this method helps to revise urban development plans and develop better approaches to future development.

In our study, using the grid approach allowed us to reveal any insufficiency in the social infrastructure within the city. The need to overcome these insufficiencies in social infrastructure in future urban development is highlighted. The results of the analysis show that green areas and other social services mentioned in planning practices are not evenly distributed among close, far, and neither close nor far grids. For example, grid1 has a green area ratio of 96.4%—a large amount of green areas. The fact that urban pressure on green areas and that some social service areas in urban development encroach on green areas indicates that, in the future, urban areas will be developed in these areas. Thus, the municipality's development proposals should protect green areas within administrative limits. In addition, this clearly shows that urbanization has yet to begin in grid 1; therefore, green area standards are very high while social infrastructure, such as healthcare and education, is insufficient in this grid according to Turkey's planning standards, such as that requiring that a primary school should be within 500 m from residential areas. As mentioned, to balance this distribution through planning, we can calculate the balance of the distribution of green areas and other services within these grids, which are either higher or lower than the standards. For example, when we calculate green areas without distinguishing between passive and active green areas, only grid3 displays a problem, while grids 2 and 28appear to have achieved the standards. On the contrary, grids 2 and 28are insufficient in terms of land available for healthcare services, while grids 5 and 9 have sufficient land designated for healthcare. Land use planning in these areas was unbalanced with respect to healthcare services. To better understand land use patterns in the next stage of our study, we examined the correlations among the grids.

Using a correlation analysis, the relationships among grids can be understood more clearly. Analyses of land use in urban development helped us to determine the interplay among the grids as well as to identify the variables that shape the future direction of development. The correlation analysis revealed the development pattern of the city's land. The analysis shows that insufficient social infrastructure (such as healthcare facilities) in grids 2 and 28 are among the city's biggest problems. Considering the tourism factor that is characteristic of the city, which was revealed using correlation analysis, this problem should be considered a priority and must be addressed in any new developments.

When examining the social infrastructural units in detail within the grids, grids 1 1 1 2 2 3 and 29 attracted our attention. In the cluster analysis, we found that healthcare services came together in clusters 1 and 2. Access to healthcare services was within ~2–3 km between the grids. In grid one state-owned hospital provides full healthcare services. When we assessed the distribution of the existing residential areas, we

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96519668

observed that grids 1 22.2 and 30 were within 6–7 km of the hospital, which is relatively far in emergencies. Even if there is no space for healthcare within a reasonable distance, our analysis showed that roadways to hospitals from more distant grids and providing alternative transportation options are suitable alternatives.

To investigate the relationship among grids in cluster analysis in more detail, a correlation analysis was conducted on land use. A strong correlation of 0.99 was found among the grids and among daily travel areas. Moreover, there is a noteworthy correlation of 0.95 between daily travel areas and archeologically protected areas. The same correlation was observed between technical infrastructure areas and industrial areas. Because the transportation network in Amasya is central, a strong correlation among the grids and the archeologically protected areas and daily travel shows the strength of the city's tourism potential. In addition, we can prove a dependency for the development of industrial areas on technical infrastructure areas through the correlations found in terms of land use.

Discussion

Cluster analysis was used to statistically explain where similar land use areas were concentrated. Cluster analysis is an important method by which to identify similar planning approaches in areas with the same land use characteristics and urban development, for determining any existing deficiencies in social facilities, and for gaining an understanding of social transport distances. In addition, this analysis serves to determine which clusters yield positive or negative results on a region-by-region basis.

Agglomerative hierarchical cluster analysis yielded very important findings for Amasya, including how land use is distributed and how land use should be planned. Mcharg (1992) is credited with having developed a land suitability model to ensure a healthy and balanced land use structure; however, our study failed to discern an approach to identify the social facilities in the current planned area or to provide development based on such an approach.

A development plan that identifies areas lacking social facilities and how to eliminate these deficiencies is important because it helps to make our cities healthier and more livable. Land structure and transport are significant factors that affect development planning; therefore, despite the improvements we have achieved, the issue of the lack of social facilities within the city must be resolved to the greatest extent possible. Although the situation that emerged when we examined the grids in terms of transport distances appeared to be positive, particularly for the healthcare sector, the same could not be said about access to a full-service hospital.

It is found that spatial land use arrangement and development is the main planning approach for the healthy future development of the cities. Cortinovis et al. (2019) were also examined urban spatial development and were emphasized the spatial arrangement of land uses as a crucial issue in their research. The healthy distribution of social infrastructure is one of the key point to prove sustainable urban development in the cities.

We were able to examine both the existence and the lack of social infrastructure areas within the grids in this research. It is worth noting here that the results from the analysis demonstrated that the distribution of the social infrastructure was neither satisfactory nor within the boundaries that delineated accessibility. In making these

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96519668

determinations, the social infrastructure facilities that were within ~500 m of the center of the grids, in terms of accessibility, were taken into consideration.

A particularly remarkable finding was that the healthcare facilities were generally concentrated in clusters1 and while the educational facilities were largely concentrated in clusters and 4. Given that clusters1 and 2 were mostly within the city's center, the social facilities within these clusters were more accessible and numerous. Although the lay of the land appears to have negatively affected the social infrastructure balance in areas outside the city's center, grids19 and 24 within the city's center appeared to also experience the same negative impact because of the topography of its land.

In addition, not all of the educational institutions were at the same level of accessibility; that is, when we made the distinction among primary schools, we observed that not all educational facilities were within the 500 m-perimeter accessibility boundary. According to the results of the analysis of the land use map, planning decisions dictating that the planning areas within clusters be included as part of the planning activity are important for ensuring that the same planning perspectives can be established. Cluster analysis enabled us to define the areas in which a similar planning approach should be conducted. Grid analysis, which helps to evaluate accessibility and similarity, sheds light on how urban planning should be pursued.

The methods used in this research are proposed important approaches to helping to implement plans for healthy urban development. The similarities and differences identified within the grids through hierarchical cluster analysis provide important clues oriented toward urban development decisions. In addition, they help identify the shortcomings in urban social infrastructure, which is a key component of urban development, and help to make recommendations accordingly.

The grid system is an analytical tool that is frequently used with raster data and infrequently used for urban social services. The grids were developed to generate information about how urban areas are developed. This study used grids to enable a more detailed examination using vector data for the first time to analyze urban social services. Grids were formed using GIS and the Hawth's analysis tool, which is frequently used by ecologists and biologists, to create an essential guide to how urban areas are developed. The cluster analyses conducted from grids using Minitab, the most appropriate was average linkage analysis. Differences among the grids were examined, and the social service areas in the grids were analyzed. The results of the analyses generated important clues about whether social services were or were not in each grid and where they should have been located.

The analyses of the grids revealed the inadequacy of educational space, healthcare space, and space for parks and gardens. In this respect, authorities should take such social infrastructural spaces into consideration when making decisions about areas of urban development. The methods used in this study offer a new understanding and approach to urban development plans in Turkey.

Into summarize, this study analyzed whether the uses of space for social infrastructural, green area, tourism, commercial enterprises, educational facilities, and similar other social services are adequate and balanced in Amasya's land use plans. In the analyses, the Amasya urban development plan was partitioned into 33 grids, each of which covering 100 Ha. Accordingly, analyses were performed within the grids that were categorized as follows:

- Grids that comprise a planned space between ~90% and 100%,
- Grids that comprise a planned space of ~50%, and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

- Grids that comprise a planned space between ~10% and 25%.

We concluded based on these analyses that the City of Amasya Urban Development Plan was inadequate in its green area designations, and that it includes a faulty planning decision because it prescribes green spaces to be located at the extreme edges of urban space.

Our findings show the importance of a social infrastructure for a healthy urban environment. This fact, which this study makes apparent, is one of the most important elements to be discussed in approaches to urban development. A development plan's balanced distribution of social infrastructure in urban areas is important for a city's inhabitants. This study claims that urban land use is also significant for the development of social infrastructure.

Conclusion

The conclusion of this study found that a method by which to analyze an urban development plan can be balanced based on land use grids using cluster analysis. It also identified relationships between land use types using correlation analysis. There are several studies on land use; however, the focus of many is restricted to how land use has changed over the years. Unlike other studies, our study emphasizes the short comings in land use in terms of urban planning and identifies the deficiencies in the social infrastructural aspects of urban planning. The findings of this paper demonstrate that social infrastructure is insufficient in urban development and is not being distributed in a balanced way. In this sense, the focus is on the distribution of land use values in urban development, rather than on the changing values of land use in urban development. For example, a high density of green areas in one place and a lack of them in other places appears as an indication of whether that city is developing in a healthy and balanced way; therefore, this study brings a new perspective for future research. If we consider the findings of this study, we get a better understanding of the importance of social infrastructure in urban development.

In conclusion, the methods used in this study offer a new dimension to general land use and to the improvement of urban development plans in Turkey. These methods can be further improved in future studies because they provide a basis through which a new methodological approach can be used in other fields.

ASSESSMENT OF HEAVY METAL AND TOXIC ELEMENT CONTENT IN BARLEY (*HORDEUM VULGARE* L.) AND SOIL

BENGISU, G.

Department of Field Crops, Faculty of Agriculture, Harran University, Şanlıurfa-Mardin Karayolu Üzeri 18.Km, Harran, Sanliurfa, Turkey
(e-mail: gbengisu@hotmail.com; phone: +90-414-318-3000; fax: +90-414-318-3190)

(Received 13th Mar 2019; accepted 13th Jun 2019)

Abstract. One of the largest problems threatening human and animal health is environmental pollution, which has increased in parallel with industrialization and population growth. Because of environmental pollution, pollution in agricultural soils and plant products has approached dangerous levels. Barley, which is commonly used in animal nutrition and the food industry, is one of the plants that is affected by such pollution. In these plants, it is very important to determine the level of pollution present for the sake of both human and animal health. In accordance with this purpose, we measured the levels of Cd, Cu, Fe, Mn, Ni, Pb, and Znin barley plants and soil samples collected from three locations in Southeastern Anatolia, where barley production is common in Turkey. Results show that the concentrations of mineral elements except Fe in the soil samples are below critical limits. Instead of high Fe concentration in soils, all mineral elements in plant samples collected from all locations are below critical limits. The concentrations measured in soil and barley samples from the Kiziltepe location were the lowest.
Keywords: *barley, cadmium, copper, iron, manganese, nickel, lead, zinc*

Introduction

Irregular urbanization, the proximity of agricultural land to city centers, increased household and industrial wastes, heavy metals emitted from chimneys and exhaust fumes cause heavy metal accumulation in plants and, subsequently, changes in their physiological and genetic structures. While heavy metals such as copper (Cu), zinc (Zn), cobalt (Co), manganese (Mn), nickel (Ni) and molybdenum (Mo) are absolutely necessary for plant growth, lead (Pb), vanadium (V), aluminum (Al), arsenic (As), mercury (Hg), cadmium (Cd) and selenium (Se) have toxic effects. If the heavy metal content in plants is above the prescribed limit, serious health problems can develop in the humans and other animals that eat these plants (Okturen and Sonmez, 2006; Caglairmak and Hepcimen, 2010; Nagajyoti et al., 2010).

For example, cadmium has toxic effects on all organ systems in animals. In cases of cadmium poisoning, a decrease in feed consumption, reduced growth, infertility, a decreased number of pups, liver and kidney damage, anemia and death are observed (Bernhoft, 2013). In cattle with acute copper poisoning, gastrointestinal inflammation, swelling, diarrhea and the rapid loss of fluid-electrolyte are observed, and in other animals, loss of appetite and severe depression are observed. If acute poisoning is not treated, death may occur within three days (Scott et al., 2011). The most common effects of the Nickel poisoning are lung cancer, kidney edema, allergic reactions, a decreased number of sperm and sperm abnormalities (Kawanishi et al., 2001). Nausea, vomiting, epigastric pain, lethargy, and fatigue occur with extremely high levels of zinc intake (Fosmire, 1990). Manganese toxicity tends to lead to neurological symptoms, including headaches, muscle cramps, fatigue and aggressiveness (Aschner et al., 2009). Excess lead accumulates in the bones and destroys the kidney, brain and nervous system (Kahvecioglu et al., 2004). Excessive amounts of iron can damage to various organs and

DOI: http://dx.doi.org/10.15666/aeer/1704_96699677

systems, especially the liver, pancreas and other endocrine organs, as well as the heart (Aydin, 2008).

Barley (*Hordeum vulgare* L.), which we have investigated in this study, is widely used in human nutrition and animal feeding. Barley is used as feed crop and the beer industry's main raw material in Turkey, and it is the second most produced cereal, with wheat being the first. Heavy metals are difficult to remove from the environment. They also cannot be chemically or biologically degraded (Chaney et al., 1997). Barley is among the best performing grass species in terms of extracting some toxic metals from the soil (Ebbs and Kochian, 1998).

In this study, we aimed to measure mineral element content (Cd, Cu, Fe, Mn, Ni, Pb and Zn) in barley plants and soil collected from various locations.

Material and methods

Sampling

The study was carried out in the Southeastern Anatolia region of Turkey in 2016. A total of thirty barley and soil samples were collected from three locations in this region from the Çınar District of Diyarbakir (Latitude: 37° 43' 27" N, Longitude: 40° 24' 54" E), the Siverek District of Şanlıurfa (Latitude: 37° 45' 7" N, Longitude: 39° 19' 55" E), and the Kızıltepe District of Mardin (Latitude: 37° 11' 23" N Longitude: 40° 34' 47" E) (*Fig. 1*).

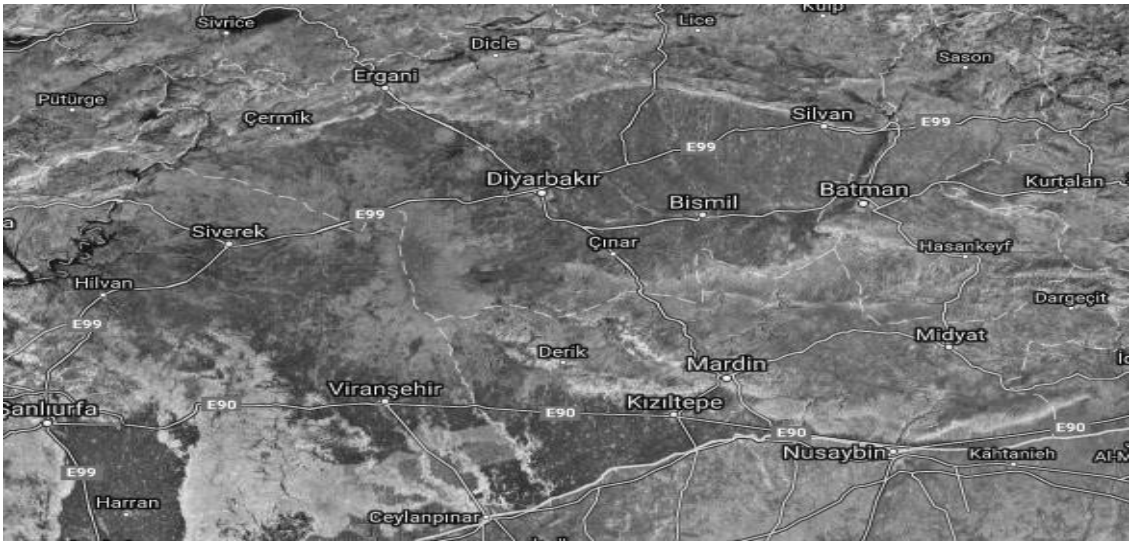

Figure 1. *Sampling locations (Çinar, Kiziltepe and Siverek)*

When the data for the soil and barley specimens were analyzed, ten samples from each station were analyzed separately, and the arithmetic average of the values obtained was found. All barley samples were commercially available. In order to preserve the original quality of the barley, the samples were stored at an ambient temperature in sealed plastic bags prior to any conditioning. Distilled water was further purified with a Milli-Q™ system (Millipore Corporation, USA) and used throughout the experiments. The hydrogen peroxide (H_2O_2, 30%) and nitric acid (HNO3, 65%) used for the digestion were of analytical grade (E. Merck, Darmstadt, Germany).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96699677

Digestion procedure

A Berghof MWS-3 model microwave digestion system (Berghof, USA) was used for the digestion of the barley samples. Microwave (MW) digestion was carried out as follows: half-gram barley samples and a solid reference material were weighed and transferred into pressure-resistant PTFE vessels, and 9.0 mL of the acid mixture (HNO_3–H_2O_2, 2:1) was added to each sample. The vessels were closed, and a total of six samples were evenly spaced on the microwave oven carousel. The program of the MW digestion is provided below (*Table 1*).

Table 1. *Operating conditions for two-stage digestion by microwave oven (Tuzun and Yakut, 2009)*

Step 1	**1**	**2**	**3**	**Step 2**	**1**	**2**
T (0C)	140	160	190	T (0C)	160	100
Ta [min]a	5	3	5	Ta [min]a	3	1
Time [min]b	5	10	20	Time [min]b	15	15

The power applied was 800 W. After the digestion procedure, the reaction mixture was evaporated in order to remove the acids. Then, the residue was dissolved in approximately 25 mL of Milli-Q™ water (Millipore Corporation, USA). Then, ICP-OES measurements of Cd, Cu, Fe, Mn, Ni, Pband Zn were performed for the diluted solutions (Celik et al., 2014).

Instrumentation

An Optima™ 2100 DV (dual view) inductively coupled plasma optical emission spectrometer (Perkin Elmer, Inc., Shelton, CT, USA) was used for the determination of Cu, Fe, Mn, Ni, Pb and Zn in the barley and soil in the diluted solutions. The instrumental operating parameters are listed in *Table 2*. All of the procedures, from sampling to analysis, were also applied to blanks in order to evaluate any metal contamination during the analytical procedure. A blank was simultaneously prepared, and all procedures were applied before the measurements. The selection of the instrumental parameters and optical wavelengths was based on obtaining good sensitivity, ensuring reasonable detection limits and eliminating interferences (Duz et al., 2012). All samples were digested and analyzed in triplicate. The analytical wavelengths and average detection limits calculated for all measurements are listed below (*Table 2*).

Analytical procedure

The limits of detection (LOD) and limits of quantification (LOQ) for each metal were determined as follows: ten independent analyses of a blank solution spiked with the metal at a lower level concentration on the analytical curve were performed. The LOD and LOQ were calculated using the standard deviation (σ) of these determinations (LOD = 3 x σ, and LOQ = 10 x σ) (Bora et al., 2015). The analytical wavelengths and average detection limits calculated for all measurements, as well as the minimum, maximum and average concentrations of the elements in the samples, are listed below (*Table 3*).

Accuracy and precision of the method

As a certified standard reference material (CRM 1573a), tomato leaves (National Institute of Standards and Technology, NIST, Gaithersburg, MD, USA) were used to assess the accuracy and precision of the method. The accuracy of the entire proposed method was confirmed via a standard reference material analysis. As can be seen below (*Table 4*), the method was validated through the analysis of the CRM, NIST 1573a, with good recoveries.

Results and discussion

The average mineral element values for the soil samples taken from the three locations are provided in *Table 5*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96699677

Table 4. *Certified and determined values of metals in the CRM (NIST 1573a), tomato leaves*

Element	Certified value (mg/kg)	Found value (mg/kg)	Recovery
Cd	1.52 ± 0.04	1.50 ± 0.02	98.68
Cu	4.70 ± 0.14	4.68 ± 0.08	99.57
Fe	368 ± 7	364 ± 1	98.91
Mn	246 ± 8	249 ± 2	101.22
Ni	1.59 ± 0.07	1.62 ± 0.03	101.89
Pb	30.9 ± 0.7	32.1 ± 0.2	103.89
Zn	1.52 ± 0.04	1.50 ± 0.02	98.68

Table 5. *Average mineral element values for soil samples taken from three locations (mean ± standard deviation)*

Soil	Cd (mg/kg)	Cu (mg/kg)	Fe (%)	Mn mg/kg	Ni (mg/kg)	Pb (mg/kg)	Zn (mg/kg)
Cinar	1.02 ± 0.08	34.23 ± 2.43	1.67	24.5 ± 6	18.37 ± 0.89	3.59. ± 0.46	66.74 ± 2.13
Kiziltepe	0.94. ± 0.05	25.78 ± 1.65	1.28	10.2 ± 4	15.52 ± 0.13	2.44 ± 0.14	59.14. ± 0.94
Siverek	0.96 ± 0.07	29.05 ± 1.21	2.56	17.6 ± 4	19.24 ± 0.25	2.98 ± 0.24	67.37 ± 3.28

As shown in *Table 5*, the heavy metal contents of the soil samples were determined to be 0.94-1.02 mg/kg for Cd, 25.78-34.23 mg/kg for Cu, 1.28-2.56% for Fe, 10.2-24.5 mg/kg for Mn, 15.52-19.24 mg/kg for Ni, 2.44-3.59 mg/kg for Pb and 59.14-67.37 mg/kg for Zn. The highest values for Cd (1.02 mg/kg), Cu (34.23 mg/kg), Mn (24.5 mg/kg) and Pb (3.59 mg/kg) were obtained from the Çınar location. The highest values for Fe (2.56%), Ni (19.24 mg/kg), and Zn (67.37 mg/kg) were found in the Siverek location's soil. The Kızıltepe location's soil had the lowest values for all elements. The data obtained from the Fe measurements are expressed as percentages because the measured values are too high in soils. The averages of mineral element values of barley samples taken from three locations are given below (*Table 6*).

Table 6. *Average mineral element values for barley samples taken from three locations (mean ± standard deviation)*

Barley	Cd mg/kg	Cu (mg/kg)	Fe (mg/kg)	Mn mg/kg	Ni (mg/kg)	Pb (mg/kg)	Zn (mg/kg)
Cinar	N.D.	4.14 ± 0.21	67.14 ± 1.27	19.13 ± 0.45	1.71 ± 0.15	0.65 ± 0.03	18.89 ± 0.85
Kiziltepe	N.D.	2.57 ± 0.14	47.54 ± 0.82	9.48 ± 0.12	1.44 ± 0.63	N.D.	15.69 ± 0.64
Siverek	N.D.	3.42 ± 0.50	96.94 ± 4.28	15.14 ± 0.89	2.12 ± 0.28	0.54 ± 0.05	20.56 ± 1.43

N.D.: undeterminable

As shown in *Table 6*, the heavy metal content of the barley samples was 2.57-4.14 mg/kg for Cu, 47.54-96.94 mg/kg for Fe, 9.48-19.13 mg/kg for Mn, 1.44-2.12 mg/kg for Ni, 0.54-0.65 mg/kg for Pb and 15.69-20.56 mg/kg for Zn. The amount of Cd in the barley plants was undeterminable (N.D.) for all locations. Lead measurements were also undeterminable (N.D.) in barley samples taken from Kızıltepe location. While the highest mean values of Cu (4.14 mg/kg), Mn (19.13 mg/kg) and Pb

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96699677

(0.65 mg/kg) were obtained for the Çınar location, the highest Fe (96.94 mg/kg), Ni (2.12 mg/kg) and Zn (20.56 mg/kg) values were obtained from the Siverek location. The Kızıltepe location had the lowest average values for all elements.

When we consider the soil and plant samples analyzed, we see that the Kızıltepe location has less Cd, Cu, Fe, Mn, Ni, Pb and Zn content than the Çınar and Siverek locations. The presence of Cd in plant samples taken from all three locations and Pb in samples taken from the Kiziltepe location could not be determined.

The heavy metal limit for European countries, according to the Republic of Turkey's Ministry of Environment and Urban Soil Pollution Control Regulations limit values for heavy metals in soil and the WHO/FAO values for plants, are provided in *Tables 7, 8* and *9*.

Table 7. *The heavy metal limit values for European Countries, mg/kg (Ozturk, 2017)*

Country	Quality standard	Cd	Cu	Ni	Pb	Zn
Austria	Regulation on Biowaste Class A	1	150	60	120	500
Belgium	Ministry of Agriculture	1.5	90	20	120	300
Denmark	Ministry of Agriculture	0.4	1000	30	120	4000
Germany	Regulation on Biowaste Type II	1.5	100	50	150	400
Ireland	Draft	1.5	100	50	150	350
Luxembourg	Ministry of Environment	1.5	100	50	150	400
Netherland	Second Class Compost	1	60	20	100	200
Spain	Class A	2	100	60	150	400
Sweden	Quality Assurance Organization	1	100	50	100	300
England	TCA Quality Label	1.5	200	50	150	400

Table 8. *The heavy metal limit values for soil in Turkey (Anonymous, 2005)*

Elements	pH 5-6 (mg/kg)	pH > 6 (mg/kg)
Cd	1	3
Cu	50	140
Fe	4.5	4.5
Mn	70	70
Ni	30	75
Pb	50	300
Zn	150	300

Comparing *Tables 7, 8* and *9*, we can see that the amounts of mineral elements in the plant and soil samples are generally within the permissible limits. However, the Fe in both the soil and plant samples is well above the limit values for all three locations. The Fe is twice the allowed amount in the Çınar location and three times that in the Siverek location. Excess Fe element in the soil causes excess Fe in plant samples. In all three locations, the increased Fe, both in the soil and in the vegetation, is due to the fact that the soils and rocks of the region are rich in Fe. Özkan (2017) notes that as the distance from the highways decreases, the heavy metal levels in the plant and soil decrease in proportion to the distance. Our study suggests, no heavy metal pollution in the soil and in the plants growing in the study locations. In addition, he reports that in this soil, Fe levels are slightly above but the limit value but do not constitute a problem for plants (Ozkan, 2017). Karataş et al. (2007) investigated the concentrations of Cu, Cr, Ni and Pb in agricultural soils and wheat and reported that the heavy metal concentration in wheat did not reach the level of toxicity (Karatas et al., 2007).

Similar studies of mineral substances have been conducted. In a study conducted in the province of Elazığ, Cu, Ni and Mn content were reported to be 1595, 489 and 1406 ppm, and these values were several times higher than those found in uncontaminated soils (Sasmaz and Yaman, 2008). In the soil of the Gediz basin, the following values have been reported: Pd 5.98-15.5 μg/g, Cd 1.5-3.2 μg/g, Ni 16.9-39.17 μg/g, Cu 26.04-65.9 μg/g, Fe 11.69-30.0 μg/g and Zn 38.33-106.6 μg/g (Oner and Celik, 2011). Copper, Zn, Fe, Ni, and Mn were found to be in the range of 20-50, 77-1443, 26 353-66 815, 20-61 and 152-1320 ppm in soil samples investigated in Niğde Province, respectively (Turan et al., 2006). In China, the heavy metal content of sediments was found to be as follows: Zn 59.85 mg/kg, Cu 24.81 mg/kg, Pb 18.31 mg/kg, Ni 9.24 mg/kg, Cd 0.34 mg/kg (Wu et al., 2015). In Polonia, the following values were found: Cd 1.1-2.1 mg/kg, Ni 6.3-15.1 mg/kg, Cu 3.8-73.1 mg/kg, Pb 30.5-94.1 mg/kg, Zn 43.0-189.7 mg/kg, Mn 34.3-225.5 mg/kg and Fe 1853.3-21198.5 mg/kg (Mazur et al., 2013).

Correlation analysis between investigated traits

Correlation coefficients were calculated with the JMP statistical program (software of the SAS program) to identify the relationships between the investigated parameters (Kalayci, 2005). The correlation analysis of the six heavy metals is shown in *Table 10*. It can be seen from *Table 10* that strong positive correlations were observed for Fe-Ni, Fe-Zn, Fe-Pb, Ni-Zn, Cu-Pb, Cu-Mn, Zn-Pb and Pb-Mn, indicating the existence of a common origin for these metals.

Table 10. *Correlation analysis of heavy metal concentrations for barley in the study area*

	Fe	**Ni**	**Cu**	**Zn**	**Pb**	**Mn**
Fe	1.00	0.89**	0.46	0.95**	0.69*	0.50
Ni		1.00	0.22	0.91**	0.55	0.33
Cu			1.00	0.54	0.91**	0.94**
Zn				1.00	0.81**	0.63
Pb					1.00	0.96**
Mn						1.00

** and * correlations are significant at the 0.01 and 0.05 level, respectively

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96699677

The greatest correlation coefficient (r = 0.96) was observed between Pb and Mn, and the lowest correlation coefficient (r = 0.22) was identified between Ni and Cu. There isa very important positive relationship between Fe with Ni and Zn, between Ni and Zn, between Cu and both Pb and Mn, between Zn and Pb, between Pb and Mn, and between Pb and Fe.

Conclusions

In areas where industrial wastes are released into the environment without being subjected to any filtering treatment, heavy metal levels are well above the values allowed in the soil. These heavy metals accumulating in the soil have passed through underground water resources and vegetation and threatened human and animal health. As seen in this study, heavy metal pollution in rural areas is typically within prescribed limits without Fe content. This situation is desirable. However, the repetition of similar studies at specific time intervals is important for in continuing this positive situation.

(Received 14th Mar 2019; accepted 1st May 2019)

Abstract. Use of synthetic herbicides is increasing globally. Application of heavy doses of herbicides is directly / indirectly causing negative impact on crop quality, human health and environment. Allelopathic weeds have wide application prospects in increasing crop production, plant protection and biological control. Current study was conducted to evaluate allelopathic activity of aqueous extracts of *Carica papaya, Lantana camara, Rhazya stricta* and *Pinus roxburghii* against selected weeds viz. *Phalaris minor*, *Avena fatua*, *Chenopodium album*, *Euphorbia helioscopia* and *Rumex dentatus* on filter paper, soil and agar at 100%, 75%, 50% and 0% concentration. Germination percentage (%), radicle length (cm) and plumule length (cm) were parameters to assess allelopathic potential. The STATISTIX 9 software was used to analyse data. Based on results, it was concluded that aqueous extract of *R. stricta, P. roxburghii, C. papaya* and *L. camara* possess potential inhibitory effects amongst which *L. camara* showed most prominant inhibitory effects towrads weeds. The germination and growth inhibition effects were found in order *L. camara*>*P. roxburghii*>*R. stricta*>*C. papaya*. Detailed field study is recommended to establish allelopathic potential of these species.
Keywords: *food security, allelopathic potential, weed management, growth retardation, aqueous extract, natural herbicides*

Introduction

Food production must increase by 70% to feed world population that is expected to reach 9.6 billion by 2050. This challenge is even greater, when we take into account the scarcity of new arable land, the effects of climate change on agricultural production and the societal demand for decreasing the environmental impact of agriculture. Weed management will be of crucial importance, given that crop yield losses caused by weeds (about 32%) are higher than those caused by either pathogens (15%) or pests (18%) (Van Evert et al., 2016). Several studies have reported significant yield losses in corn due to weed competition. Edalat et al. (2011) estimated a global 10% loss of agricultural production due to competitive effect of weeds.

Wheat (*Triticum aestivum* L.) is one of the most important cereal crop of the world. Its role is quite important in provision of human nutrition. Its contents comprise starch (59-89%), protein (10-15.4%), fats (1.4-2.1%), inorganic ions (1.3-2.2%), vitamin E, and vitamin B-complex. Wheat provides about 73% of caloric portion of a person's average diet (Rueda-Ayala

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96799689

et al., 2011). The average annual production of wheat is quite low in Pakistan compared to other agricultural economies. There are two ways for increasing wheat production; (1): by increasing cultivation area (2): by increasing yield per hectare. The first option is not practicable due to limited availability of land and irrigation water. Therefore, wheat production in Pakistan can only be increased by getting higher yield per hectare. There are many factors, which cause dcrease wheat production e.g., delayed sowing, less amount of fertilizers and weed interference. Weed infestation is serious threat to wheat production (Khan et al., 2016). In Pakistan, weeds cause about 45% loss in wheat production. Grain produce in Pakistan can be increased up to 41% if weeds are managed properly (Anwar et al., 2019). If weed management strategies are not devised, greater production losses in wheat yield can take place.

Traditional methods of weed control are time consuming and laborious. Although chemical control may enhance crop production, but concurrently effect the environment and human health. In addition, heading up of synthetic herbicide resistant weeds is another area of concern (Arafat et al., 2015). Herbicide remnants in crops, soil and underground water, cause evolution of resistant weed biotypes and are linked to health threats. Due to negative effect of synthetic chemicals, we are in demand of new classes of chemicals, especially, biodegradable products such as those originating from plants, which have the potential of being developed as herbicides (Aryakia et al., 2015). Allelopathy is a natural and eco-friendly technique. This strategy might be one of the very efficient tools for weed management and thereby increasing crop production (Kamran et al., 2017). Allelochemicals could be obtained from different tissues (flower, roots, stem and leaves) of plants (Zhou et al., 2004). These chemicals have capacity of producing wide array of biological effects and are quite useful for weed control processes (Ahmed et al., 2014). Natural herbicides obtained from allelopathic plants can help in reducing usage of synthetic herbicides. Natural herbicides will cause less pollution as well as alleviate human health concerns. The most commonly available allelochemicals are cinnamic and benzoic acids, alkaloids, flavonoids, phenolics, glucosionates and terpenes (Khan et al., 2014).

Keeping all this in view, present study conducted to evaluate *Rhazya stricta* Decne, *Lantana camara* L., *Carica papaya* L. and *Pinus roxburghii* Sarg. for allelopathic activity against major weeds of wheat crop viz. *Phalaris minor*, *Avena fatua*, *Chenopodium album*, *Euphorbia helioscopia* and *Rumex dentatus*. Selection of the plants was baseed on available literature about allelopathy of these plants (Qureshi et al., 2014; Sharma et al., 2016; Garima and Devi, 2017; Alqarawi et al., 2018).

Materials and methods

Allelopathic potential of leaves of selected plants viz., *R. stricta, P. roxburgii, C. papaya, L. camara* was evaluated. Fresh leaves for each species were collected, washed under running tap water and dried at 30°C in laboratory. Dried leaves were crushed using heavy duty blender to make fine powder (mesh size 2 mm) and preserved in air tight plastic zip lock bags. Seeds of test weeds viz. *Phalaris minor, Avena fatua, Chenopodium album, Euphorbia helioscopia* and *Rumex dentatus* were procured from the Barani Agricultural Research Institute (BARI), Pakistan. Seeds were surface sterilized by 2% solution of Sodium hypochlorite (Biljana and Kragujevac, 2015).

Dried leaf powder of each plant species (10 gm) was soaked in 100 ml distilled water and agitated for 24 hours on orbital shaker (25ºC;160 rpm). The filtrate was obtained through Whatman filter paper No. 1. The final volume of filtrate was adjusted to 100 ml that gave 10% water extract as stock solution. Three concentrations i.e. T_1 (0%), T_2 (50%), T_3 (75%) while T_4 (100%) were further prepared. Bioassays were carried out using soil and filter paper as medium.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96799689

An aliquot (15 ml) of extract for each of three concentrations was added on 25 g soil per petri dish while 5 ml extract on filter paper per petri dish. Ten seeds of weed test species were used per petri dish. Each treatment was replicated three times. The petri dishes were wrapped with aluminium foil and incubated in growth chamber (NTS Model MI-25S set at 28°C) for 15 days (Anwar et al., 2017). The germination percentage (%), lengths of radicle and plumule (cm) was calculated by comparing to control (Maharjan et al., 2007). The statistical analysis was carried out using STATISTIX 9 and means were separated by Fisher's protected LSD test (Nekonam et al., 2014).

Results and Discussion

Allelopathic potential of R. stricta

The results showed that *R. stricta* aqueous extract inhibited seed germination of *C. album* (35%) followed by *R. dentatus* (32%) and *P. minor* (31%) on filter paper, whereas, there was non-significant effect on germination percentage of *A. fatua* and *E. helioscopia*. Similarly, *R. stricta* aqueous extract on soil inhibited seed germination of *R. dentatus* (40%), *C. album* (39%) and *P. minor* (37%). Maximum (96%) seed germination was observed for *A. fatua* and *E. helioscopia* while minimum seed germination was noted for *C. album* (65%) and *R. dentatus* (60%) on filter paper and soil, respectively. It indicated inhibitory compounds in leaves of *R. stricta*. The results agree with Chon et al. (2005) who proposed growth reduction in test species by toxic compounds in *R. stricta* leaf aqueous extract. Maximum radicle length inhibition was shown by *R. dentatus* (44%) and *A. fatua* (40%) by *R. stricta* aqueous extract on filter paper. Likewise, extract on soil caused radicle length reduction of *R. dentatus* (48%) followed by *A. fatua (*45%). Radicle length of *C. album*, *P. minor* and *E. helioscopia* remained unaffected. The minimum radicle length was observed for *R. dentatus* (56% and 52% on filter paper and soil, respectively) while maximum radicle length (97%) was noted for *C. album*, *P. minor* and *E. helioscopia*. Aqueous extract of *R. stricta* significantly inhibited the plumule length of *A. fatua* (27%) and *R. dentatus* (25%) on filter paper. Interestingly, there was no inhibitory effect on plumule of *P. minor*, *E. helioscopia* and *C. album*. *R. stricta* aqueous extract inhibited plumule length of *A. fatua* (33%) and *R. dentatus* (28%) in soil. Minimum plumule length was noted for *T. aestivum* (49%) on filter paper and soil (45%) while maximum plumule length was noted for *P. minor*, *E. helioscopia* and *C. album* (96% for all) (*Fig. 1*). Wardle et al. (1992) noted that seed germination, radicle and plumule growth for grass weeds were significantly reduced by *R. stricta* extract. Similar results were reported by Assaeed and Al-Doss (1997) who reported inhibitory effect on germination rate and percentage of test species along morphological irregularities in radicle and plumule of test species (*Farsetia aegyptia, Pennisetum divisum, Haloxylon salicornicum*, *Lasiurus scindicus*) by leaves of *R. stricta*. Growth was significantly affected by allelopathic interaction on soil in contrast to filter paper as described by Hegazy and Fadl-Allah (1995) and El-Khatib (2000). While exploring possible mechanism of action, Alqarawi et al. (2018) reported growth and metabolism disfunctioning in *S. villosa* by *R. stricta* leaf aqueous extracts by hampering membrane functioning and photosynthetic capacity. El-khawas and Shehata (2005) reported change in enzyme activities, which affect the transport of storage substances in seed during growth. Furthermore, toxic compounds in *R. stricta* extract affect osmotic factors (Assaeed and Al-Doss, 1997).

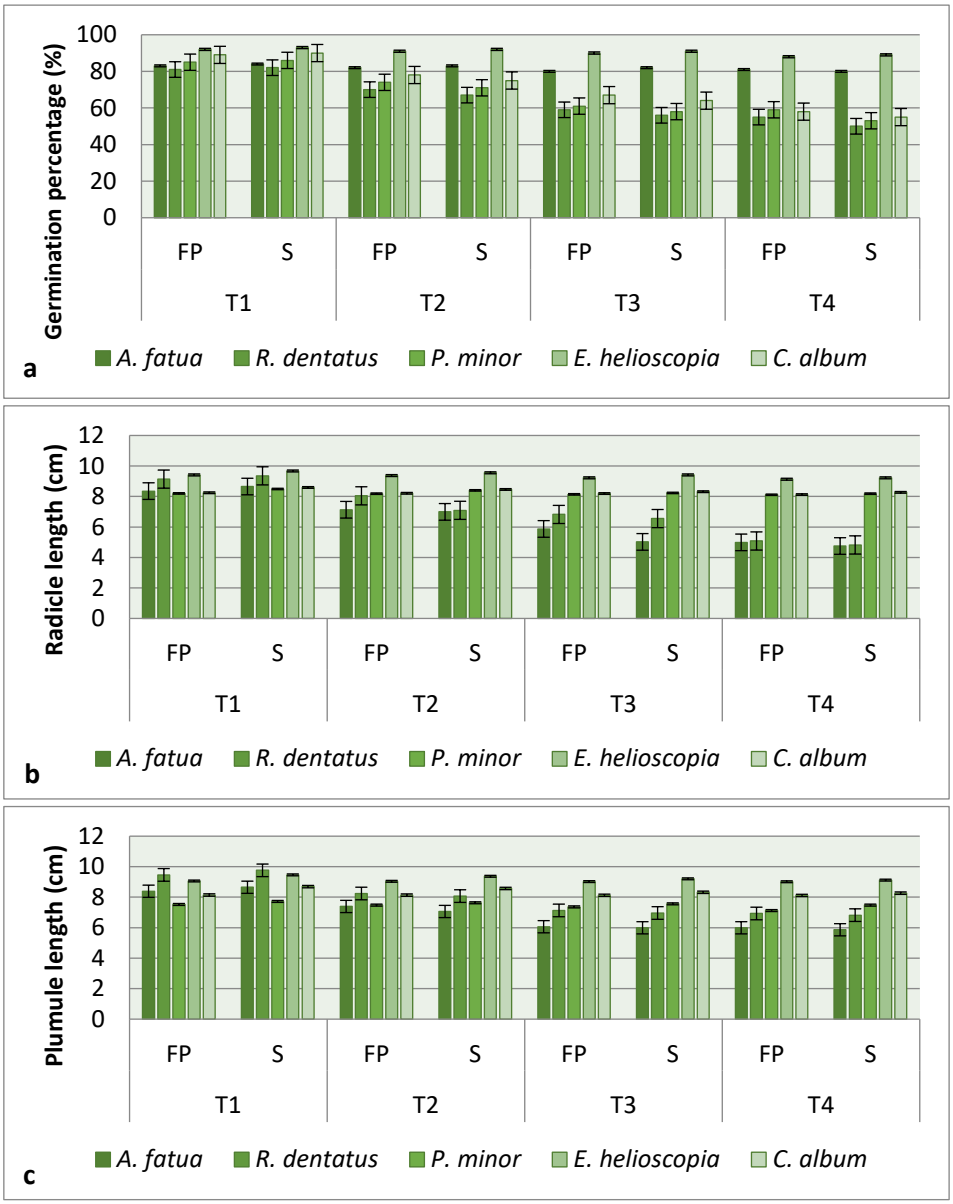

Figure 1. *Allelopathic potential of R. stricta aqueous extract on (a): germination percentage, (b): radicle length (c): plumule length against test species on filter paper (FP) and soil (S) where; T_1 (control), T_2 (50%), T_3 (75%) and T_4 (100%)*

Allelopathic potential of L. camara

L. camara aqueous extract inhibited seed germination of *R. dentatus* (58%) followed by *E. helioscopia* (57%), *A. fatua* (56%) and *P. minor* (55%) on filter paper and *E. helioscopia* (65%) followed by *P. minor* (63%), *R. dentatus* (61%), *A. fatua* (60%) on soil. Maximum (96%) germination was observed for *C. album* while minimum for *A. fatua* (42%) and *E. helioscopia* (35%) on filter paper and soil, respectively. Jabeen and Ahmed (2009) found germination and growth inhibition in *Cucurbita pepo* by allelopathic action of *L. camara* leaf aqueous extract. Highest radicle length inhibition was exhibited by *A. fatua* (52%), *P. minor* (51%) and *C. album* (50%) on filter paper, while on soil extract caused significant radicle length reduction of *A. fatua* (54%),

DOI: http://dx.doi.org/10.15666/aeer/1704_96799689

P. minor (53%) and *C. album* (52%). Minimum radicle length was noted for *A. fatua* i.e. 48% and 46% on filter paper and soil, respectively. Maximum radicle length was noted for *R. dentatus* and *E. helioscopia* (97% for each). Aqueous extract of *L. camara* inhibited plumule length of *E. helioscopia* (52%), *A. fatua* (51%), *R. dentatus* (50%) and *C. album* (50%) on filter paper. There was no significant effect on plumule elongation of *P. minor*. Likewise, *L. camara* aqueous extract inhibited plumule length of *E. helioscopia* (56%), *C. album* (55%), *R. dentatus* (53%) and *A. fatua* (53%) on soil. Minimum plumule length was noted for *E. helioscopia* i.e. 48% and 44% on filter paper and soil, respectively. Maximum plumule length (96%) was noted for *P. minor* (*Fig. 2*).

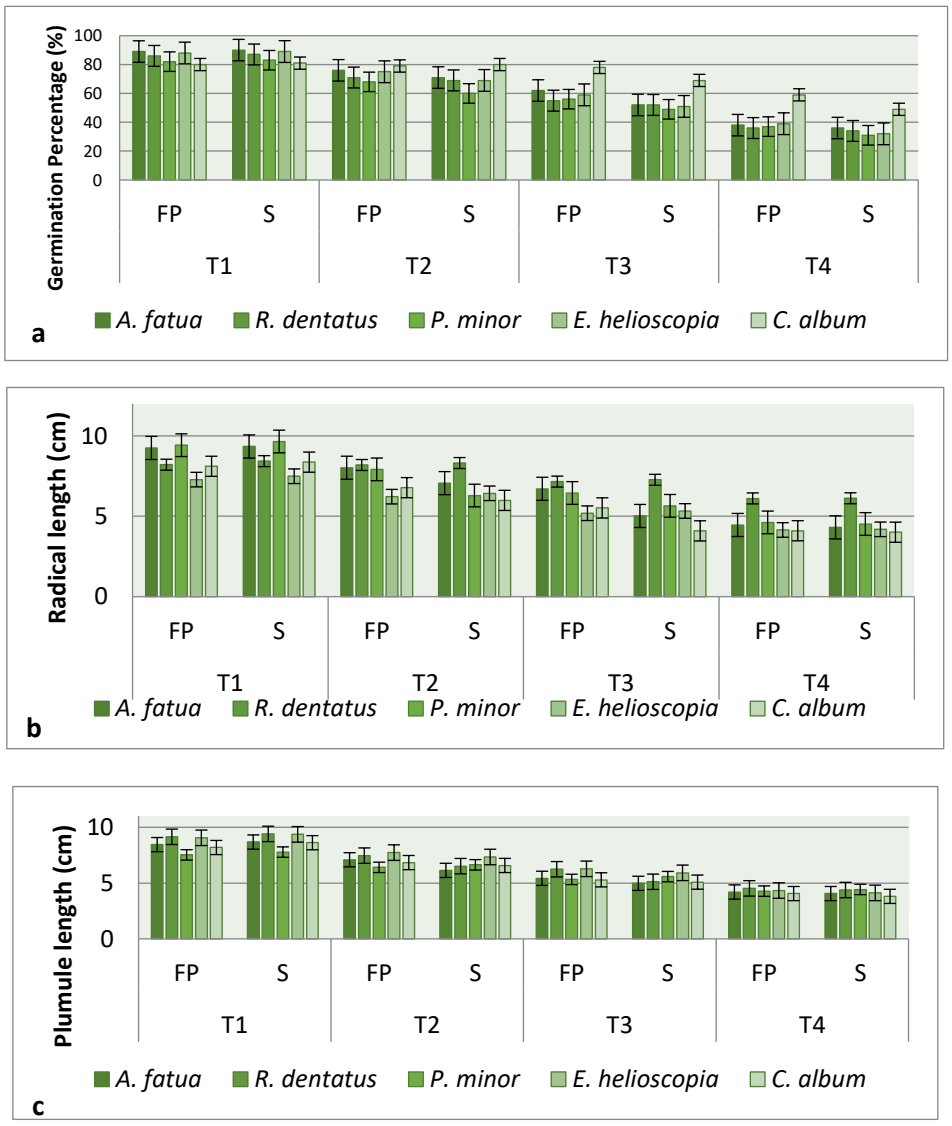

Figure 2. *Allelopathic potential of L. camara aqueous extract on (a): germination percentage, (b): radicle length (c): plumule length against test species on filter paper (FP) and soil (S) where; T_1 (control), T_2 (50%), T_3 (75%) and T_4 (100%)*

Tadele (2014) described concentration dependent and species-specific allelopathic potential of leaf aqueous extract of *L. camara* on root and shoot elongation. The aqueous

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96799689

extract of *L. camara* suppressed seed germination and growth of different agricultural crops (Sharma et al., 2005; Ahmed et al., 2007). These results were in accordance to Hussain et al. (2011) and Iramus et al. (2011) who noted retardation in root length of *Vigna radiata* due to inhibitory potential of *L. camara* leaf extract. Enyew and Raja (2015) observed significant retardation in root elongation by *L. camara* leaf aqueous extract in *Zea mays*. Aqueous extracts from *L. camara* leaves caused tissues decay, damages, and subsequent retarded growth of *Eichhornia crassipes* (Saxena, 2000).

Allelopathic potential of C. papaya

C. papaya aqueous extract inhibited germination percentage of *E. helioscopia* (35%) followed by *P. minor* (33%) and *A. fatua* (32%) on filter paper. Similarly, on soil, seed germination of *P. minor* (40%) was inhibited followed by *A. fatua* (39%) and *E. helioscopia* (38%). Maximum (96%) germination was observed for *R. dentatus* and *C. album*. Minimum germination was noted for *E. helioscopia* (65%) and *P. minor* (60%) on filter paper and soil, respectively. Highest radicle length inhibition was exhibited by *P. minor* (36%) and *R. dentatus* (35%) in *C. papaya* aqueous extract on filter paper. Likewise, extract on soil caused significant radicle length reduction of *P. minor* (43%) and *R. dentatus* (40%). Radicle length of *C. album, A. fatua* and *E. helioscopia* remained unaffected. Maximum radicle length (97%) was noted for *C. album, A. fatua* and *E. helioscopia*. The aqueous extract of *C. papaya* inhibited plumule length of *P. minor* (34%) and *C. album* (33%) on filter paper. *C. papaya* aqueous extract significantly inhibited plumule length of *C. album* (43%) and *P. minor* (42%) on soil. Minimum plumule length was noted for *P. minor* (66%) and *C. album* (57%) on filter paper and soil. Maximum plumule length (96%) was noted for *A. fatua*, *R. dentatus and E. helioscopia* (*Fig. 3*). Wabo et al. (2011) studied root and shoot elongation inhibition along germination of *Lactuca sativa* seedling that was significantly checked by *C. papaya* aqueous extract. Beneficial secondary metabolites such as chlorogenic acid, quercetin, kaempferol, caffeic acid, p-coumaric acid and protocatechuic acid had reported from *C. papaya* that might be responsible for its phytotoxic/allelopathic potential (Canini et al., 2007). Many of those phenolics have been described as allelochemicals (Miean et al., 2001).

Allelopathic potential of P. roxburghii

Aqueous extract of *P. roxburghii* needles inhibited germination percentage of *C. album* and *A. fatua* by 54%, 48% and 43%, respectively on filter paper. Similarly, *P. roxburghii* aqueous extract on soil inhibited seed germination of *C. album* and *A. fatua* by 50% and 44%, respectively. Maximum (98%) germination was observed for *R. dentatus*, *P. minor* and *E. helioscopia*. The aqueous extract of *P. roxburghii* exhibited radicle length inhibition of *C. album* (40%) followed by *R. dentatus* (39%) on filter paper, whereas, no significant effect was noted for *P. minor, E. helioscopia* and *A. fatua*. Similarly, application of extract to soil suppressed radicle length of *C. album* and *R. dentatus* by 46% and 41%, respectively. Maximum (98%) radicle length was observed for *P. minor, E. helioscopia* and *A. fatua*. Minimum radicle length was noted for *C. album* i.e. 60% and 54% on filter paper and soil, respectively. The aqueous extract of *P. roxburghii* inhibited the plumule length of *A. fatua* (38%) and *R. dentatus* (34%) on filter paper.

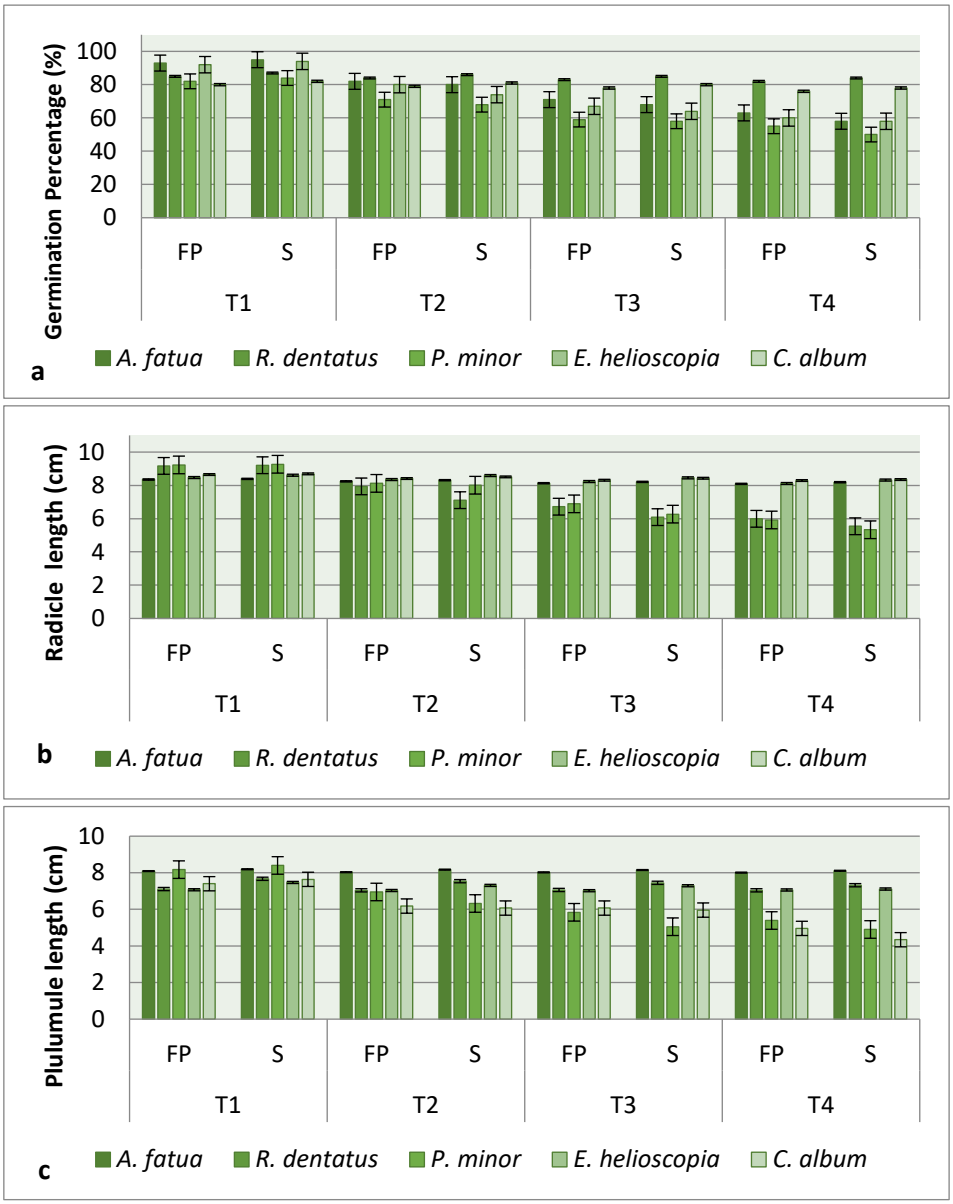

Figure 3. *Allelopathic potential of C. papaya aqueous extract on (a): germination percentage, (b): radicle length (c): plumule length against test species on filter paper (FP) and soil (S) where; T_1 (control), T_2 (50%), T_3 (75%) and T_4 (100%)*

Likewise, *P. roxburghii* aqueous extract inhibited plumule length of *A. fatua* (40%) and *R. dentatus* (39%) in soil. Maximum plumule length (98%) was noted for *P. minor, E. helioscopia* and *C. album* while minimum plumule length was noted for *A. fatua* showing 62% and 60% on filter paper and soil, respectively (*Fig. 4*). Maximum germination was observed for *R. dentatus*, *P. minor* and *E. helioscopia*. Maximum radicle length was observed for *P. minor, E. helioscopia* and *A. fatua.* Minimum radicle length was noted for *C. album*. Maximum plumule length was noted for *P. minor, E. helioscopia* and *C. album*. Minimum plumule length was noted for *A. fatua*. Aqueous extract of *P. roxburghii* needles suppressed growth of mustard and wheat seedlings while that of *P. brutia* needles suppressed growth of *Lolium multiflorum* and *Poa pratensis* seedlings

(Baroniya and Baroniya, 2014). Current study is in accordance with Singh et al. (2001) who determined seedling growth and seed germination of *Capsicum annuum, Pisum sativum* and *Oryza sativa* was retarded by *Pinus* needles. Likewise, results were explained by Madgil and Kapil (1990) for *Amaranthus paniculatus* and *Trifolium pratense* seeds treated with leaf extract of *P. roxburghii*. Kil and Yim (1983) observed that toxic compounds produced by *P. densiflora* checked seed germination and growth of species. The phenolic composites of *P. rigida* exhibited retardation effect on *Cassia mimosoides*. Fresh, senesced, and decaying needles from *P. halepensis* exhibit potent inhibitory potential on *Festuca arundinacea*, *Cyanodon dactylon*, *Avena sativa* and *Lemna minor* (Nektarios et al., 2005).

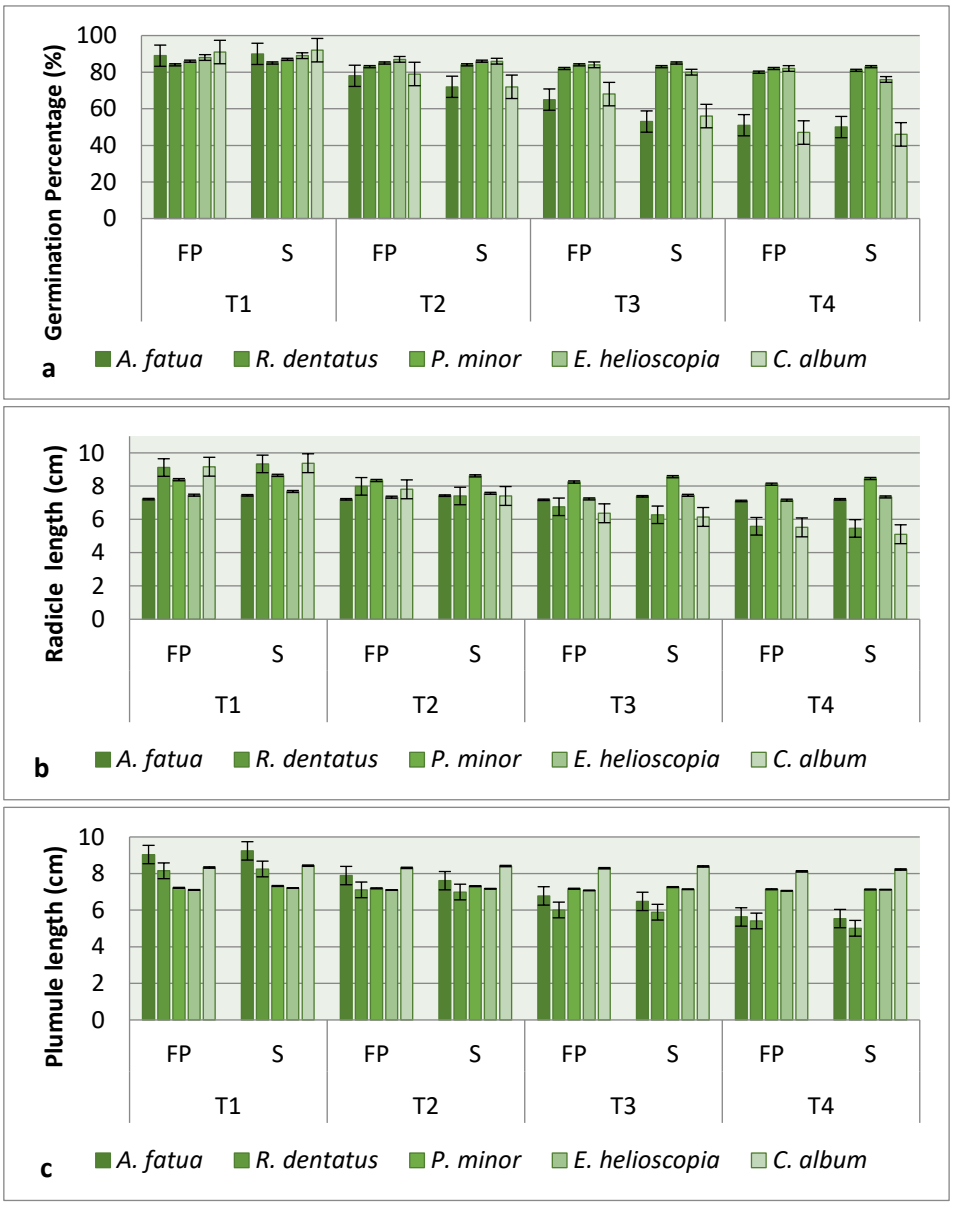

Figure 4. *Allelopathic potential of L. camara aqueous extract on (a): germination percentage, (b): radicle length (c): plumule length against test species on filter paper (FP) and soil (S) where; T_1 (control), T_2 (50%), T_3 (75%) and T_4 (100%)*

DOI: http://dx.doi.org/10.15666/aeer/1704_96799689

The germination and growth inhibition effects were found in order *L. camara*>*P. roxburghii*>*R. stricta*>*C. papaya*. Relatively greater (but statistically non-significant) values for germination and growth inhibition were recorded on soil medium compared to filter paper.

Conclusions

Present results indicated that aqueous extract of selected plants at higher concentrations reduce the seed germination, radicle and plumule length of weeds associated with the wheat crop. Results provide evidence about herbicidal potential of test species viz. *L. camara*, *P. roxburghhii, C. Papaya* and *R. stricta* against weeds of wheat crop (*Avena fatua, Phalaris minor, Chenopodium album* and *Rumex dentatus*). Further work is needed to appraise the potential inhibitory effects of allelochemicals from these plants.

Abstract. The FAO-56 Penman-Monteith model is recognized as the standard method for estimating reference evapotranspiration (ETo) which requires daily meteorological data as inputs. Among all input data, vapour pressure deficit (VPD) is one of the critical parameter that drives evapotranspiration (ETo), and is of fundamental importance in crop models. In this study effort has been made to compare six vapour pressure models during four seasons. Three vapour pressure models (Models 1–3) selected as mentioned in Irrigation and Drainage Paper-56 of the Food and Agriculture Organization (FAO-56) and Models 4-6 has been selected from literature survey. Model 1, which uses daily maximum and minimum temperature, relative humidity (RH), is the preferred method to estimate actual air pressure (AE) hence it is used as standard for comparing other models. The effectiveness of vapour pressure models were measured by statistical tools and ranked according to Global Performance Indicator (GPI) where higher value of GPI represent best model. The ranking order using GPI shows that Model 5 resulted in best estimation capability with a GPI of 2.77. Moreover, the effect of variation in wind speed on the performance of the vapour pressure models in ETo estimation is also assessed.
Keywords: *agriculture, cropping period, global performance index, vapour pressure deficit, water deficit*

Introduction

The Kingdom of Saudi Arabia (KSA) like Semi-Arid Asir region Abha suffers large water deficit which is due to climate change during past decades. Climate change is crucial part for well-planned water resource management in semi-arid region, Saudi Arabia (Tarawneh and Chowdhury, 2018). Therefore, it is important to understand relation of climatic parameter with environment in order to reduce vulnerability caused by growing new crops in climate change environment and for efficient water management system (DeNicola et al., 2015). Earlier studies have stated an increase of agricultural water demand by 5–15% during 2050, due to increased evapotranspiration rate. According to Chowdhury and Al-Zahrani (2013), rise of temperature by 1 °C would

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96919715

likely to change the thermal limits of a crop by 10–30%, which will affect crop yields (Lelieveld, 2012). Apart from this, rise in temperature by 1 °C would likely to increase the capacity of air to hold water vapour by 7%, which in turn reduces precipitation rate (Trenberth, 2011). Hence, the water resources system and soil–water balance system will affect further (Kang et al., 2009).

The water consumption by agricultural field is estimated to be 88% of the annual water use (Multsch et al., 2017). The water shortage in Saudi Arabia indicates highest index as compared to other countries (Baig and Straquadine, 2014). Al-Zahrani (2019) stated that the KSA is portrayed among few countries where withdrawal of water exceeds 33.33% of the total available water supply. The irrigation of agricultural field requires knowledge of when to irrigate and the amount of water to apply. This depends on local atmospheric conditions, where precipitation and evapotranspiration (ETo) play a key role (Kumar et al., 2012). Hence knowledge of ETo is essential in water resources management, for both natural and agricultural ecosystems, particularly for irrigation (Allen et al., 1998).

The Direct method of estimating evapotranspiration is lysimeter which provides high accuracy (Liu et al., 2017; Hirschi et al., 2017). However, it is very costly and requires many highly expensive and sophisticated equipment for measurement. To overcome this problem the frequently used method for obtaining reference evapotranspiration presented in the Food and Agricultural Organization of the United Nations (FAO) Irrigation and Drainage Paper 56 depends only on meteorological observations and crop coefficients estimated based on surface conditions (Allen et al., 1998). The application of FAO56-PM is limited due to an insufficient network of the meteorological observatory and proper maintenance (Pandey et al., 2016). Alternatively, numerous studies in different climatic conditions evaluated the applicability of less data-demanding empirical ETo methods using sophisticated and straightforward techniques against FAO56- PM (Pandey and Pandey, 2018; Cadro et al., 2017). However, the FAO-56 Penman–Monteith Model which bears high correlation with lysimeter measurement for estimated of evapotranspiration (Nolz et al., 2016). The reference crop evapotranspiration (ETo) estimations using the FAO Penman-Monteith equation (PM-ETo) require a set of weather data including maximum and minimum air temperatures (Tmax, Tmin), actual vapour pressure, solar radiation, and wind speed. Among all weather parameter, vapour pressure deficit is an important factor in the estimation of ETo. It is defined as difference between saturated vapour pressure and actual vapour pressure (Seager et al., 2015). Various models are available to estimate vapour pressure. However, use of different models in determining actual vapour pressure will result in different values of actual vapour pressure and thus different values of ETo will be estimated. In some earlier studies (Burman et al., 1987; Weiss, 1977), it was observed that ETo can be determined with good accuracy regardless of the model used for the vapour pressure estimation. However, a few studies (Saxton, 1975; Sadler and Evans, 1989; Yoder et al., 2005), which were carried out to analyse the sensitivity of ETo to the vapour pressure deficit (VPD), suggested a considerable change in estimated ETo values when the value of VPD changed. Howell (1995) evaluated some methods that calculate VPD for Bushland (Texas). Weather data containing maximum-minimum temperature along with mean dewpoint temperature were found to provide the most accurate calculations of VPD in the study area. Ojha et al. (2010) compared the performance of the three FAO-56 models (for ea estimation) in the estimation of open water evapouration in a semiarid region (Udaipur, India). Their results showed that Model 1 performed better than the other two models in estimating open water evapouration using the Penman combination approach.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96919715

The past studies in the study region were basically on assessing different ETo models against theFAO-56 Penman Monteith model based on Central and Eastern region of Saudi Arabia (Salih and Sendil, 1984; Al-Omran et al., 2004; Elnesr et al., 2010; Al-Ghobari, 2000; Madugundu et al., 2017). However, no such studies recorded so far about the vapour pressure model from the literature in Kingdom of Saudi Arabia. In order to fill this void, an effort was made to estimate six vapour pressure model based on availability of meteorological data for the period from 1988-2018 and by recognizing the best suitable method by computing global performance index as an alternative to model 1 which is taken as standard in this study. The finding of the research work can be helpful in reducing the error during evapotranspiration computation, Moreover the best evaluated model equation for evapotranspiration could assist in computing evapotranspiration in future in the field of crop water management system, climate change studies, irrigation and water resource planning.

Study area

Site description

The research work deals with Abha mountainous region of Asir province, Kingdom of Saudi Arabia having an area of 370 km^2 located between the latitude of 18°10′12.39″N and 18°23′33.05″N and longitude of 42°21′41.58″E and 42°39′36.09″E as shown in *Figure 1*. The zone is prone to heavy rainfall as compared to other parts of Saudi Arabia. The elevation varies from 1951 to 2991 m (msl) with average precipitation of 355 mm which mainly occurs between June and October. According to the topographical features of the investigation region, it is found to have weak geology because of the precipitation and slope nature during the past few years (Mallick et al., 2018).

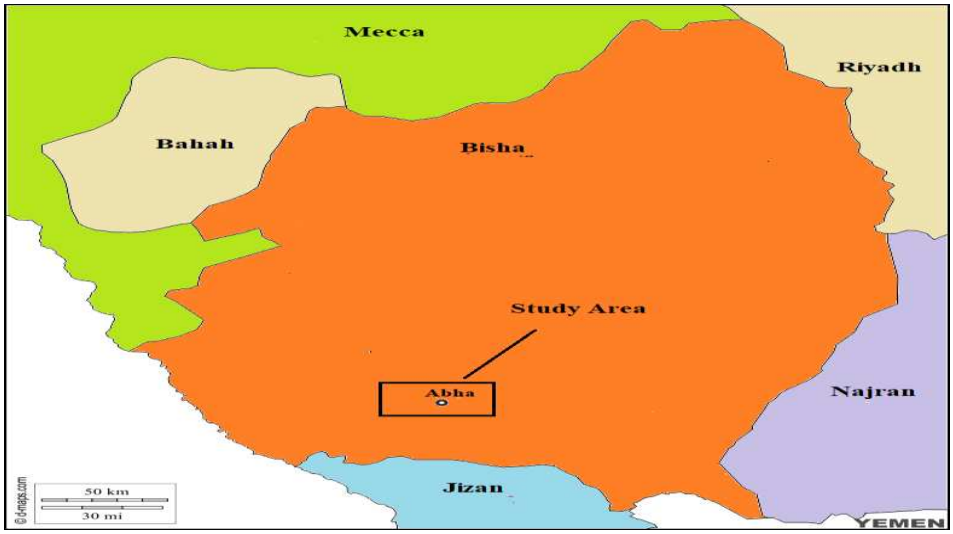

Figure 1. *Location map of Abha Asir region, Kingdom of Saudi Arabia*

Data availability

In this research work, weather parameters were collected from Abha meteorological weather station for the period between 1988–2018 which includes wind velocity, maximum and minimum temperature, mean temperature, mean relative humidity and

Methodology

Various vapour pressure model taking into account in this study are based on available literature. In this research work vapour pressure model were estimated by six model based on available climatic data. The values estimated from different model were compared with the value obtained from standard model 1 for four seasons as shown in *Table 1,* where each of the four cropping seasons is divided into four crop growth stages as per the guidelines provided in Allen et al. (1998). The four crop growth stages are (I) initial stage, (II) development stage, (III) midseason stage, and (IV) end season stage. The crop growth stages are used as periods to compare the actual vapour pressure and ETo values determined by using the six VP models. The performance of vapour pressure models was computed based on overall effect of evaluation criteria called as Global performance index. The ranking was done in order to get most promising model which can be used alternative to model 1. The flowchart as shown in *Figure 3* described the stepwise procedure to compute most promising model among five model (excluding model 1) to be used as alternate of model 1.

Table 1. *Details of the cropping periods*

Season	Duration		Crop growing stage				Total days
	From	To	I	II	III	IV	
Winter	21-Dec	20-Mar	10	20	40	20	90
Spring	21-Mar	20-Jun	10	20	40	22	92
Summer	21-Jun	22-Sep	10	20	40	23	93
Autumn	23-Sep	20-Dec	10	20	40	20	90

Reference evapotranspiration and vapour pressure model

This study work aims to analyse various vapour pressure models which is one of the most critical component of reference evapotranspiration computation by the standard FAO56-PM model in the Abha Asir region, Kingdom of Saudi Arabia. The selection of methods was based on their wide acceptance, simple calculation procedure and applicability in present conditions. The models are shown by *Equations 2-8*. If all the required variables are available, it is advisable to use Model 1. Model 2 is used when the credibility of minimum RH (RHmin) data is in doubt, whereas Model 3 is used when only mean RH (RHmean) data are available. Details about the calculation of actual vapour pressure using RH and temperature data can also be found in Allen et al. (2011). The use of different models in determining actual vapour pressure will result in different values of actual vapour pressure and thus different values of ETo will be estimated.

The FAO Penman-Monteith equation for estimating ETo values recommended by Food and Agriculture Organisation, Irrigation and Drainage Paper-56 (FAO-56) (and is given as *Eq. 1*) and moreover equation for vapour pressure (Models 1-3) also suggested in FAO-56 documentation (Allen et al., 1998):

$$\mathrm{ETo} = \frac{0.408\times\Delta\times(\mathrm{Rn}-\mathrm{G})+\gamma\times\left(\frac{900}{\mathrm{T}+273}\right)\times u_2\times(e_s-e_a)}{\Delta+\gamma\times(1+0.34u_2)} \quad \text{(Eq.1)}$$

$$\text{Model 1 } e_a = \frac{\left[\left\{e_s(T_{min})\times\frac{RH_{max}}{100}\right\}+\left\{e_s(T_{max})\times\frac{RH_{min}}{100}\right\}\right]}{2} \quad \text{(Eq.2)}$$

$$\text{Model 2 } e_a = e_s(T_{min}) \times \frac{RH_{max}}{100} \quad \text{(Eq.3)}$$

$$\text{Model 3 } e_a = \frac{RH_{mean}}{100} \times \left[\frac{\{e_s(T_{max})+e_s(T_{min})\}}{2}\right] \quad \text{(Eq.4)}$$

A VP model (referred here as Model 4), which uses RHmean and Tmean for calculation of actual vapour pressure was reported by Irmak et al. (2005) represented by *Equation 5:*

$$\text{Model 4 } e_a = \frac{RH_{mean} \times e_s(T_{mean})}{100} \quad \text{(Eq.5)}$$

Upreti and Ojha (2017) suggested that by using the Lawrence Tdew–RH relationship (*Eq. 6*), fairly accurate estimates of dewpoint temperature can be obtained, which in turn can be used for the calculation of actual vapour pressure values:

$$T_{dew} \perp = T_{mean} - (20 - 0.2RH_{mean})(\frac{T_{K-mean}}{300})^2 - 0.00135(RH_{mean} - 84)^2 + 0.35 \quad \text{(Eq.6)}$$

where Tdew ⊥ = dew point temperature value in °C obtained using the Tdew–RH relationship proposed by Lawrence (2005); Tmean (°C) and RHmean (%) are the daily mean values of temperature and RH, respectively; TK mean is the daily mean temperature in kelvin.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96919715

Values of Tdew ⊥ (determined by using *Equation 6*) are then used to calculate the daily actual vapour pressure values using *Equation 7*. This proposed approach is mentioned here as Model 5:

$$\text{Model 5 } e_a(T) = 0.6108exp\left[\frac{17.27T_{dew}\perp}{T_{dew\perp}+237.3}\right] \quad \text{(Eq.7)}$$

As per FAO-56 document (Allen et al., 1998), daily values of actual vapour pressure can be estimated by using *Equation 8* assuming daily minimum temperature (Tmin) near the dewpoint temperature (T_{dew}):

$$\text{Model 6 } e_a(T) = 0.6108exp\left[\frac{17.27T_{min}}{T_{min}+237.3}\right] \quad \text{(Eq.8)}$$

$$e_s = 0.6108exp\left[\frac{17.27T_{mean}}{T_{mean}+237.3}\right] \quad \text{(Eq.9)}$$

$$e_s = \frac{\{e_s(T_{max})+e_s(T_{min})\}}{2} \quad \text{(Eq.10)}$$

Note: ETo = reference evapotranspiration (mm day−1); Rn = net radiation at the crop surface (MJm^{-2} day^{-1}); G = soil heat flux density (MJm^{-2} day^{-1})) that is taken as zero for daily ETo estimation; T = temperature at 2 m height (°C); u_2 = wind speed at 2 m height (m s^{-1}); e_s = saturation vapour pressure (kPa); e_a = actual vapour pressure (kPa); (e_s–e_a) = vapour pressure deficit (kPa); Δ = slope of vapour pressure curve (kPa °C^{-1}); and γ = psychrometric constant (kPa °C^{-1}); T_{max} = Maximum Temperature (°C); T_{min} = Minimum Temperature (°C); T_{mean} = Mean Temperature (°C); RH_{mean} = Mean Relative Humidity (%); RH_{max} = Maximum Relative Humidity (%); RH_{min} = Minimum Relative Humidity (%); $T_{dew}\perp$=dew point temperature value in °C; $T_{K\text{-}mean}$ is the daily mean temperature in kelvin.

Evaluation criteria and global performance index (GPI)

The GPI is computed by using ten statistical measure such as Mean Absolute Error (MAE), Root Mean Square Error (RMSE), Mean Absolute Relative Error (MARE), Uncertainty at 95% (U95), Root mean squared relative error (RMSRE), Relative Root Mean Square Error (RRMSE), Mean Bias Error (MBE), Coefficient of determination (R^2), Maximum Absolute Relative Error (erMax) and t-statistics (Ali and Jamil, 2019). For Coefficient of determination (R^2), 1 is taken as ideal value, while for all other statistical zero is taken as ideal value. Despotovic et al. (2015) proposed the GPI by scaling the values of statistical tools in between 0 and 1. Further by subtracting the scaled values of error indicators from the corresponding medians and adding up the differences so obtained using the weight factors. Mathematically, for the i^{th} model:

$$GPI_i = \sum_{j=1}^{10}\alpha_j(\tilde{y}_j - \tilde{y}_{ij}) \quad \text{(Eq.11)}$$

where α_j have a value of + 1 for statistical errors having a recommended value of 0 and a value of -1 for statistical errors that have a recommended high value of 1 (e.g. R^2). $\tilde{y}_j$ and $\tilde{y}_{ij}$ are the median and scaled values, respectively.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96919715

Willmott and Matsuura (2005) used MAE as statistical measure as shown by *Equation 12*:

$$MAE = \frac{1}{n}\sum_{i=1}^{n}\left|e_{a,Mi} - e_{a,M1}\right| \quad \text{(Eq.12)}$$

$$RMSE = \left[\frac{1}{n}\sum_{i=1}^{n}\left(e_{a,Mi} - e_{a,M1}\right)^2\right]^{\frac{1}{2}} \quad \text{(Eq.13)}$$

$$MARE = \frac{1}{n}\sum_{i=1}^{n}\left|\frac{e_{a,Mi} - e_{a,M1}}{e_{a,Mi}}\right| \quad \text{(Eq.14)}$$

Behar et al. (2015) and Gueymard (2014) applied U_{95} in modelling of solar radiation as given by *Equation 15:*

$$U_{95} = 1.96(SD^2 + RMSE^2)^{\frac{1}{2}} \quad \text{(Eq.15)}$$

$$RMSRE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}\left(\frac{e_{a,Mi} - e_{a,M1}}{e_{a,Mi}}\right)^2} \quad \text{(Eq.16)}$$

Li et al. (2013) applied RRMSE as a statistical performance measure in the modelling of global solar radiation as given by *Equation 17:*

$$RRMSE = 100 \times \frac{\sqrt{\frac{1}{n}\sum_{i=1}^{n}\left(e_{a,Mi} - e_{a,M1}\right)^2}}{\sum_{i=1}^{n} e_{a,Mi}} \quad \text{(Eq.17)}$$

$$MBE = \frac{1}{n}\sum_{i=1}^{n}\left(e_{a,Mi} - e_{a,M1}\right) \quad \text{(Eq.18)}$$

$$R^2 = 1 - \frac{\sum_{i=1}^{n}\left(e_{a,Mi} - e_{a,M1}\right)^2}{\sum_{i=1}^{n}\left(e_{a,Mi} - e_{a,Mi_{av}}\right)^2} \quad \text{(Eq.19)}$$

$$erMAX = max\left(\left|\frac{e_{a,Mi} - e_{a,M1}}{e_{a,Mi}}\right|\right) \quad \text{(Eq.20)}$$

$$t = \left[\frac{(n-1)MBE^2}{RMSE^2 - MBE^2}\right]^{\frac{1}{2}} \quad \text{(Eq.21)}$$

Results

Comparison of the actual vapour pressure values

In this study work six vapour pressure models are used for the computation of daily actual vapour pressure values which is one of the important parameter for estimating

daily ETo values. *Table 2* shows the average of daily values of actual vapour pressure for the crop growth stages of the four seasons (winter, spring, summer, autumn). Each of the four cropping seasons is divided into four crop growth stages as per the guidelines provided in Allen et al. (1998). The four crop growth stages are (I) initial stage, (II) development stage, (III) midseason stage, and (IV) end season stage. The crop growth stages are used as periods to compare the actual vapour pressure and ETo values determined by using the six VP models.

The estimated actual vapour pressure values depends on the air temperature and amount of humidity in the air. The daily values of actual vapour pressure calculated using the six VP models is shown in *Figure 4*. Among six VP models, Model 1 which uses daily maximum and minimum values of temperature and RH, is considered the most reliable model for determining the values of actual vapour pressure and is recommended if all the meteorological variables required are available.

Models 2 and 3 should be used only if any of the data required for Model 1 are either unavailable or doubtful (Allen et al.,1998; Ojha et al., 2010). Therefore, the daily values of actual vapour pressure calculated using Models 2–6 are compared with the daily values of actual vapour pressure obtained by using Model 1 in order to find which VP model should be used if all meteorological variables required for Model 1 are not available. The daily percentage errors of Models 2–6 averaged for 12-day intervals in the determination of actual vapour pressure values are shown in *Figure 5*.

However, on the basis of *Figure 5,* the relative accuracy of the VP models to determine daily actual vapour pressure values cannot be evaluated because they are the error values averaged for 12-day intervals, and negative and positive errors can cancel out each other to an extent. A better evaluation of the accuracy of the VP models is performed by comparing the absolute errors of the models in actual vapour pressure estimation. These daily absolute errors averaged for 12-day intervals (MAE) are shown in *Figure 6*. The Mean absolute error (MAE) values (w.r.t. Model 1) in the estimation of actual vapour pressure for 12-day intervals over the four seasons are shown in *Table 3.*

Comparative study of ETo estimates using six vapour pressure models

Vapour-pressure deficit (VPD) is an important parameter that is computed in evapotranspiration (ETo) models. Hence daily values of actual vapour pressure estimated by Models 1–6 were used to determine the reference (ETo) as required by FAO Penman-Monteith equation. The seasonal crop stage–wise sums of these daily ETo values for the four cropping seasons are tabulated in *Table 4*.

Table 4. *Comparison of ETo (mm/day) values estimated using the six vapour pressure models*

		ETo(M1)	ETo(M2)	ETo(M3)	ETo(M4)	ETo(M5)	ETo(M6)

It is evident from the reference evapotranspiration computation that all the models performs well enough if total value of ETo for the whole cropping season is taken into consideration. The close values of reference evapotranspiration ETo in *Table 4* as estimated based on six vapour pressure model show that the total value of ETo of a cropping season is not much affected by the choice of the VP model that is used to determine the daily actual vapour pressure values for the study area. The error in ETo estimation is highest for Model 4 (*Figure 7*), which shows the daily error averaged for 12-day intervals. From *Figure 7* it is evident that Model 2 most of the time overpredicts ETo, the reason being underprediction of actual vapour pressure values by model 2. Models 3–6 underpredict ETo as these overpredicted actual vapour pressure values. *Figure 8* shows the 12-day averages of daily absolute errors in ETo estimation. It is clearly observed in *Figure 8* that the performance of Model 5 is best among all VP models as the MAE values are the least for all the intervals for model 5. In *Figure 8,* both the maximum and minimum MAE values for a 12-day interval can be seen corresponding to Model 6, which further highlights the erratic estimation of actual vapour pressure and thus ETo by Model 6. *Table 5* shows the maximum, minimum, and average of the MAE values for all 12-day intervals across the four cropping seasons. It can be verified from *Table 5* that in data-constrained conditions, Model 5 is the most accurate VP model among the five models, followed by Model 3. Model 4, which uses only Tmean data (other models use Tmax and Tmin data) has the highest overall MAE of the five models. Though daily Tmean data are observed to be enough for the accurate estimation of daily values of actual vapour pressure, it results in relatively higher errors in ETo estimation as compared to the other models, which use both Tmax and Tmin. This is because the values of saturated vapour pressure are underestimated when only daily Tmean values are used (as in Model 4). However, there is significant variation in the estimated values of actual vapour pressure using the VP models; the choice of VP model does not affect the seasonal value of ETo considerably in this study.

Performance of the vapour pressure models with variation of wind velocity

From the study, the performance of the five vapour pressure models (Models 2–6) is found to provide very reasonable result in ETo estimation for the four seasons for Abha region when compared to that of Model 1. The ETo values estimated provides satisfactory output even though there were relatively higher errors in the estimation of actual vapour pressure values. The reason may be due to the lower values of wind speed in the study area. As the ETo estimated from standard FAO Penman-Monteith method based on the product of wind speed (u_2) and vapour pressure deficit. The average wind speed data at 2 m height used in this study for ETo calculation by the FAO Penman-Monteith method are tabulated in *Table 6.*

According to Allen et al. (1998), the maximum wind speed values are in the category of gentle to moderate winds (2.62-5.24 m/s) while the minimum wind speed values falls under the category of light to slight winds (0.75-1.5 m/s). Therefore, in order to observe the effect of differences of result between higher wind speed values and lower wind speed values in the performance of VP models for ETo estimation. Taking all the parameters as before and wind speed data as shown in *Table 6* are used to determine the ETo. For all models (Models 2–6), the error in ETo estimation increased when higher values of wind speeds were used. This clearly shows that with the increase in wind speed, the error in the estimation of ETo values due to the error in the values of e_a or VPD values will increase. The performance of Model 5 is found satisfactory, followed by Model 3. All the other models have an average value of mean absolute error (*Figure 9*). Therefore, the accurate estimation of actual vapour pressure or VPD plays a key role in estimating ETo values accurately, although for light winds, this effect is much less and becomes pronounced when the wind speed is higher. Similar findings were observed by (Upreti and Ojha, 2018).

Ranking of vapour pressure model in global performance index

The statistical analysis was performed by considering ten parameters in order to judge the reliability of five vapour pressure model as compared to standard actual vapour pressure model 1 as shown in *Table 7*. The scaled values of statistical errors between 0 and 1 as described in *Table 8* and the GPI values for five models are shown in *Table 9*. In addition, the variation of GPI is also shown by *Figure 10*. The GPI value ranges from -4 to 2.771. Among 5 models, 2 models shows positive GPI value while 3 models have negative GPI as shown in *Figure 10*. The highest value of GPI is shown by Model 5. Hence it can be seen that GPI has simplified the statistical outcomes to identify the performance of models. *Table 9* shows the ranking of the models on the basis of their GPI values sorted in descending order, since the highest GPI value represent the best performing model.

Discussion

This study investigated performance of vapour pressure models using weather data for Abha meteorological weather station in the computation of vapour pressure and evapotranspiration in Abha, Asir Region, Saudi Arabia. Effort has been made to compare six vapour pressure model during four seasons and ranking has been done using global performance index. The values estimated from different actual vapour pressure model were compared with the value obtained from standard model 1 which uses daily maximum and minimum values of temperature and RH, and is considered the most reliable model for determining the values of actual vapour pressure for four seasons (Allen et al., 1998). The daily percentage errors for actual vapour pressure were estimated for Models 2–6 averaged for 12-day intervals in the determination of actual vapour pressure. Based on error it was found that Model 2 generally underpredicts actual vapour pressure value. Models 3, 4, and 5 overpredicted the actual vapour pressure value. Model 6, which uses daily minimum temperature, has the most erratic behavior in estimating the actual vapour pressure value. The relative accuracy of the VP models to determine daily actual vapour pressure values cannot be evaluated because they are the error values averaged for 12-day intervals, and negative and positive errors can cancel out each other to an extent. A better evaluation of the accuracy of the VP models is performed by comparing the absolute errors of the models in actual vapour pressure estimation. The MAE for each of cropping season is much less for Models 4 and 5 as compared to the MAE values for Models 2, 3, and 6. Both Models 4 and 5 use daily RHmean and Tmean data for the estimation of actual vapour pressure values. Overall, the performance of Model 6 in the determination of actual vapour pressure values is the poorest among the five models. The lower MAE values for Models 4 and 5 indicate that these may be used for the determination of daily actual vapour pressure values in Abha regions with similar climates instead of Models 2 and 3, both of which the FAO-56 paper advised for use if all variables required for Model 1 were not available. Further daily values of actual vapour pressure estimated by Models 1–6 were used to determine the reference (ETo) as required by FAO Penman- Monteith equation. The seasonal crop stage–wise sums of these daily ETo values were used for the four cropping seasons. The error in ETo estimation is highest for Model 4, which shows the daily error averaged for 12-day intervals. Clearly, for all intervals, the maximum error in ETo estimation is for Model 4, even though the same model (along with Model 5) estimated the actual vapour pressure values most accurately. This can be attributed to the inaccurate determination of saturated vapour pressure values because the saturated vapour pressure value for Model 4 is determined differently from the other models. The better performance of Model 5 in ETo estimation also verifies this because both Models 4 and 5 determined actual vapour pressure values with similar accuracy. Therefore, the determination of daily saturated vapour pressure value should be done by equation of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96919715

saturated vapour pressure which uses both daily Tmax and Tmin instead of using equation in which only the daily Tmean value is used. It is evident that Model 2 most of the time overpredicts ETo, the reason being underprediction of actual vapour pressure values by model 2. Models 3–6 underpredict ETo as these overpredicted actual vapour pressure values. The performance of Model 5 is best among all VP models as the MAE values are the least for all the intervals for model 5. Both the maximum and minimum MAE values for a 12-day interval can be seen corresponding to Model 6, which further highlights the erratic estimation of actual vapour pressure and thus ETo by Model 6. Model 5 is the most accurate VP model among the five models, followed by Model 3. Model 4, which uses only Tmean data (other models use Tmax and Tmin data) has the highest overall MAE of the five models. Though daily Tmean data are observed to be enough for the accurate estimation of daily values of actual vapour pressure, it results in relatively higher errors in ETo estimation as compared to the other models, which use both Tmax and Tmin. This is because the values of saturated vapour pressure are underestimated when only daily Tmean values are used (as in Model 4). However, there is significant variation in the estimated values of actual vapour pressure using the VP models; the choice of VP model does not affect the seasonal value of ETo considerably in this study. The ETo values estimated provides satisfactory output even though there were relatively higher errors in the estimation of actual vapour pressure values. The reason may be due to the lower values of wind speed in the study area. As the ETo estimated from standard FAO Penman-Monteith method based on the product of wind speed (u2) and Vapour Pressure Deficit. For all models (Models 2–6), the error in ETo estimation increased when higher values of wind speeds were used. This clearly shows that with the increase in wind speed, the error in the estimation of ETo values due to the error in the values of ea or VPD values will increase. The performance of Model 5 is found satisfactory, followed by Model 3. All the other models have an average value of mean absolute error. Therefore, the accurate estimation of actual vapour pressure or VPD plays a key role in estimating ETo values accurately, although for light winds, this effect is much less and becomes pronounced when the wind speed is higher. Similar findings were observed by (Upreti and Ojha, 2018).

The performance of vapour pressure models was computed based on overall effect of evaluation criteria called as global performance index. The ranking was done in order to get most promising model which can be used alternative to model 1. From analysis it was evident that Model 5 provides best performance and model 6 worst.

Hence it is evident that actual vapour pressure is important parameter which is used for vapour pressure deficit which in turn used in reference evapotranspiration equation. VPD is an integrated variable for atmospheric water demand that depends on both air temperature and humidity, VPD will increase with ongoing climate warming, which suggests that atmospheric water demand or drought will also increase under such a scenario (Zhang et al., 2017). Therefore, it is necessary to investigate the relationship between increased VPD and crop yields on the regional or global scale. Lobell et al. (2013) indicated that increases in VPD contribute to water stress and affect crop growth and yield in two ways. First, the crops increase their demand for soil water to maintain carbon assimilation at a given rate; and second, the crops reduce the supply of soil water through elevated transpiration rates. Therefore, maize yield declined with increased VPD (Lobell et al., 2013). Shuai et al. (2013) found that VPD affected yield variability through its effects on water stress. Crops that were negatively related to VPD were usually located in areas where the mean VPD during the crop growing period was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_96919715

higher. The changes in the sensitivity of crop yields to VPD can be attributed to changes in VPD itself, cultivars and agronomic management practices; for example, increasing crop sowing densities could increase crop sensitivity to VPD (Lobell et al., 2014). Adopting drought-tolerant cultivars and technologies, as well as increasing irrigation areas, might decrease the sensitivity of crop yields to VPD. The decline in reliability of water resources necessitates careful planning for water demand satisfaction under the highly variable demand characteristics in Saudi Arabia (Tarawneh and Chowdhury, 2018).

This study tries to explain the six-vapour pressure model in semi-arid region in Saudi Arabia. However, different regions show different behavior with respect to seasonal variability of rainfall, temperature change, agricultural activities, soil types and crop types. Future study must understand the overall implications of climate change in Saudi Arabia and investigate the possibility of scheduling and/or shifting crop producing periods.

Conclusions

The present research work deals with six vapour pressure models in order to determine six sets of daily values of actual vapour pressure for four seasons. The six sets of daily computed actual vapour pressure from six models were then used to compute ETo by standard FAO56 Penman-Monteith equation. The performance evaluation of the five models (Models 2–6) was analyzed by comparing the values of the estimates of actual vapour pressure and ETo with those of Model 1, which is recommended in the literature to determine daily actual vapour pressure values if all meteorological variables required are available using global performance index. From the research work it can be concluded that:

1. From global performance index, Models 5 and 4 have higher accuracy in the estimation of daily actual vapour pressure values with GPI Value of 2.77 and 2.38 respectively as compared to Models 2, 3 (vapour pressure models mentioned in FAO-56), and 6 with GPI value of -0.051,-2.7 and -4 respectively.
2. Daily Tmean values (Model 4) are found to be not good enough for the estimation of vapour pressure deficit because this underestimate the daily saturation vapour pressure, which results in underestimation of ETo. This highlights the importance of the requirement of daily Tmax–Tmin data for accurate estimation of daily ETo
3. The result obtained from global performance index shows that the performance of the Model 5, which is based on the Lawrence Tdew–RH relationship is closest to Model 1 in ETo estimation when compared to the other models. On the basis of this study, it is recommended to use Model 5 for estimation of actual vapour pressure and ETo when only daily RHmean data are available
4. The result with wind speed shows that error in actual vapour pressure with light winds do not affect ETo estimation much. However, the effect of actual vapour pressure values becomes significantly high on ETo estimation for higher wind speed ranges.
5. The results of this study could be used by water management system, crop cultivators, crop advisors, researchers and students from universities and

DOI: http://dx.doi.org/10.15666/aeer/1704_96919715

research centre. Moreover it can be benefitted by makers of decision and in the vast field of agriculture, hydrology and environment.

6. The present results demonstrated that atmospheric VPD played significant roles in modulating water movement along the soil-plant-atmospheric continuum, and these findings can be applied to greenhouse production. VPD regulation efficiently moderated plant water stress and maintained water balance by reducing the atmospheric driving force

Acknowledgements. Abstract. This study was conducted to estimate heterosis effects, specific and general combining abilities existing within growth traits. A 3 x 3 diallel mating system involved three indigenous chicken genotypes namely Potchefstroom Koekoek (P), Venda (V) and Ovambo (O) was used to produce three purebreds (P x P, V x V, O x O), three crossbreds (P x O, P x V, O x V) and three reciprocals (O x P, V x P, V x O). The body masses of 225 chicks recorded at ages 0, 4, 8 and 10 weeks, were used to make an estimation of heterosis, specific combining ability (SCA) and general combining ability (GCA). Results indicated that the crossbreed between P sires and O dams provided the uppermost heterosis for growth traits (30.07%). GCA and SCA showed the importance ($P \leq 0.05$) for body weight from hatch up to 10 weeks of age. P genotype gave the positive effects of GCA and P x V crossbreed resulted in positive effects of SCA. It thus, be concluded that Potchefstroom Koekoek genotype might be used in the crossbreeding with other indigenous chicken genotypes to improve growth traits.
Keywords: *Potchefstroom Koekoek, Venda, Ovambo, crossbred, purebred*

Introduction

Indigenous chickens comprise about 80% of the national poultry flocks in Africa (Darre, 2012). Despite their importance, indigenous chickens have slow growth rates and relatively low mature weight (Norris and Ng'ambi, 2007). There are several indigenous chicken genotypes in South Africa (Malatji et al., 2016) including Potchefstroom Koekoek, Venda and Ovambo chicken genotypes. Potchefstroom Koekoek chicken genotype is a composite chicken genotype which was developed from three European poultry breeds namely White Leghorn, Black Australorp and Bared Plymouth Rock. This genotype is black and white speckled colour pattern, and was bred for both egg and meat production (Mutibvu et al., 2019). Ovambo chicken genotype is originated from Namibia and predominantly dark coloured that reach sexual maturity at 2.2 kg body weight for males and 1.5 kg for females at about 140 days old (Motsepe et al., 2016). Venda chicken genotype was first discovered in Venda region of Limpopo province, South Africa and is dual purpose, moderately large and multi-coloured predominated with white, black and red colours (Mphaphathi et al., 2016).

To date, in South Africa there is limited scientific information on crossbreeding of local chicken genotypes to improve growth traits. The aims of the study were to discover and underline the general combining abilities, heterotic effects and specific combining abilities for body weight in a three-way cross between Potchefstroom

DOI: http://dx.doi.org/10.15666/aeer/1704_97179723

Koekoek, Ovambo and Venda chicken genotypes. According to Musa et al. (2015), crossing indigenous chicken genotypes has led to the improvement in growth rates and body weight. This study will help chicken farmers to determine the perfect combination of indigenous chicken genotypes during breeding program to improve body weight.

Materials and methods

Study site

The study was conducted at the same site described by Brown and Ng'ambi (2019). However, the current study was conducted between November 2012 and February 2013.

House preparation

Water disinfected with Jeyes fluid bought from a company in Polokwane called NTK was applied in hatchery and experimental houses. After, both hatchery and experimental houses were left to dry for 7 days to break the life cycle of possible disease caused by the organisms that were not killed by the disinfectant the houses were left empty for one week after cleaning. All the equipment such as feeders, wire separators and drinkers as well as the incubator were cleaned thoroughly and disinfected. New disinfectant was added daily and the footbath was thoroughly cleaned.

Data collection

Individual body weights of 180 chicks from a diallel cross of three indigenous chicken genotypes, namely Potchefstroom Venda (V), Koekoek (P) and Ovambo (O) were noted at the end of a week period from hatch up to 10 weeks of age. 10 hens from each genotype were allocated casually to be bred with two roosters of each genotype. Their eggs were gathered and noted down daily according to breeds and crossbreds. The eggs were weighed up and hatched independently according to breeds and crossbreds. Nine genetic groups of P x P, V x V, O x O, P x V, P x N, V x P, V x O, O x P, and O x V chicks were obtained, accordingly. The hatched chicks were wing banded until 8 weeks of age followed by leg banding to keep their breed and crossbred group identity'. The chickens were reserved as a unit on a litter floor, in a semi-open house that has been separated according to their breeds and crossbreds. They were medicated equally and were subjected to the same climatic conditions managerial and hygienic. During the process of rearing periods and brooding, all chicks were fed *ad-libitum* using standard commercial starter (21% crude, 3,000 kcal and protein (CP) metabolize capable energy (ME)/kg) from the time they hatched till they were four weeks, trailed by a cultivator diet (2,900 kcal ME/kg and 18% CP) to 62 days old. Water was provided *ad-libitum*. Artificial heat was provided at (32 °C) using continuous light program and ultraviolet lights were provided. Ventilation was controlled through curtain rails.

Statistical analysis

The effect of genetic group on body weight was tested using the general linear model (GLM) procedure of Statistical Analysis System software program (SAS, 2008). Duncan's multiple range test was used for significant means at $P<0.05$. The following model was used:

$$Y_{ij}=\mu+G_i+e_{ij} \quad \text{(Eq.1)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_97179723

where Y_{ij} = body weight of bird in i^{th} genetic group, μ = overall mean, G_i = fixed effect of the i^{th} genetic group and e_{ij} = random error.

Heterosis was calculated according to Fairfull (1990) and the following formula was applied:

$$H\% = \left[\frac{AB(0.5AA+0.5BB)}{(0.5AA+0.5BB)}\right] x100 \quad \text{(Eq.2)}$$

where H% = percentage heterosis, AB = crossbred genotype, AA and BB = sire and dam genotypes. General and specific combining abilities were calculated in the form of means (Falconer, 1988). The following formulas were used:

$$\text{Specific combining ability (SCA)} = \frac{AB+BA}{2} \quad \text{(Eq.3)}$$

$$\text{General combining ability (GCA)} = \frac{A+GCA(B)}{2} \quad \text{(Eq.4)}$$

where AB = cross between genotype A and B, and BA = its reciprocal.

Results

Body weight at different weeks of age

The results showed body weights at different weeks of age differed significantly ($P<0.05$) among the nine genetic groups (*Table 1*). Least square means showed that Potchefstroom Koekoek (P) and Ovambo (O) had higher hatch weight (30 g) followed by P x V and V x O with 29.60 g, and O x V (28.80 g), respectively. Nonetheless, there was no substantial variance ($P > 0.05$) between P x O, O x V and V X P at hatch, with body weights of 27.60, 28.80 and 28 g. Results also indicated that Venda chickens performed better in body weight when crossed with Ovambo in comparison with other crosses during the hatch period. For purebreds, Ovambo and Potchefstroom Koekoek were heavier (30 g) than the Venda chickens (20 g) at hatch. For crosses, the P x V was heavier (29.60 g) when compared to O x V and P x O which their body weight was 27.60 g also 28.80 g, respectively. For purebreds, Potchefstroom Koekoek had a heavier body weight (256 g) as compared to other purebreds in the fourth week. There were no differences in the fourth week, ($P > 0.05$) among the Ovambo purebred, V x P and O x V. With respect to crosses, P x O had a higher body weight (256 g) in compared to the O x V and P x V which their weights were of 255.92 and 232 g, respectively. Among the reciprocals, O x P body weighed higher (276 g) in comparison with the V x O and V x P which weighed 232 g and 244 g, respectively.

Heterosis

Heterosis results (*Fig. 1*) with respect to crosses showed that O x V had affirmative heterosis in all different ages. P x O had positive heterosis from hatching to 4 weeks of age only and afterwards had negative heterosis while P x V had positive heterosis at all different ages apart from 10 weeks of age, respectively. With deference to reciprocals, the V x P had positive heterosis at all ages whereas the O x P exhibited negative heterosis at all ages of measurement except 4 weeks of age, respectively. V x O showed

DOI: http://dx.doi.org/10.15666/aeer/1704_97179723

positive heterosis at hatching and four weeks of age and indicated negative heterosis at 8 weeks and 10 weeks of age.

Combining abilities

SCA effects and estimates of GCA are presented in *Table 2*. GCA showed that the P breed had positive effects during the studied periods. However, O genotype had a positive effect during the studied ages, except at 10 weeks of age. The Venda genotype had the lowest negative estimates at all stages of growth. SCA showed that the P x O crossbred had negative effect at hatch, 8 weeks and 10 weeks of age, and a positive effect at 4 weeks of age in comparison among crossbreds. P x V crossbred gave positive effects at all different ages. O x V crossbred had positive effects at hatch and at 4 weeks of age; however, it showed negative effects at 8 weeks and 10 weeks, respectively.

Table 2. *Crossbreeding genetic parameters for body weight at different ages of measurement*

Parameters	Hatch	4 weeks	8 weeks	10 weeks
General combining abilities				
$_{g}^{P}$	0.56	12.22	10.00	93.34
$_{g}^{O}$	0.69	2.23	48.33	-17.78
$_{g}^{V}$	-1.24	-14.45	-58.33	-75.56
Specific combining abilities				
$_{s}^{PO}$	-3.89	8.45	-65.00	-50.00
$_{s}^{PV}$	2.24	3.09	91.67	67.78
$_{S}^{OV}$	2.51	7.12	-31.67	-21.11

g = general combining ability, s = specific combining ability.

Discussion

This study was directed to investigate heterosis, specific combining abilities and general combining abilities for body weight traits after crossing three South African indigenous chicken genotypes; namely Potchefstroom Koekoek, Venda and Ovambo. Our results based on cross for heterosis, the effects for body weights were mostly positive and ranged from -14.11 to 30.07% during different age intervals up to 10 weeks of age. However, Musa et al. (2015) reported that heterosis for body weight ranged from -9.44 to 13.48% after crossing three genotypes of Nigerian indigenous chickens. Results of the current study revealed that the P x V cross had encouraging heterosis at all different ages of measurement except at 10 weeks of age when compared to its reciprocal V x P, that had positive heterosis at all ages and highest 10 weeks of age. The O x V had positive low heterosis for body weight at the different weeks of age when compared to its reciprocal V x O which had negative heterosis for body weight at all weeks of measurement except at hatch and 4 weeks of age. These findings indicate that Potchefstroom Koekoek sires and Ovambo dams as well as Venda and Venda sires gave the highest heterosis for growth traits. Furthermost reviewed studies showed that body weights of crossbred chickens at different ages were related with negative and positive heterosis effects for growth traits (Sutherland et al., 2018; Musa et al., 2015; Siwendu et al., 2012). However, Nwenya et al. (2017) reported a positive heterosis for body weight after crossing Naked neck and Frizzled feather chickens. Our heterosis results might stand as an encouraging element for the poultry breeders in South Africa to cross these two breeds (Venda female and Potchefstroom Koekoek male) and (Ovambo female and Venda male) to get hybrid vigour in growth traits. Furthermore, we also estimated the general combining abilities and specific combining abilities among purebreds and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_97179723

crosses of South African indigenous chicken genotypes. General combining ability (SCA) was a significant source of variability among purebred groups on body weights at different growth stages. This importance showed the importance of preservative components. These results are similar with the work of Musa et al. (2015), who found general combining ability estimations more significant and of higher in three genotypes of Nigerian indigenous chickens. Adebambo et al. (2010) reported the significant of GCA for body weight using three chicken genotypes. Our findings recognized that Potchefstroom Koekoek chicken genotype had the uppermost (best) encouraging effect of general combining ability at all ages of measurement excluding at hatch and 8 weeks of age while the Venda breed had negative effect at all ages. Specific combining ability results point out that P x V provided positive estimates for body weight throughout the different weeks of measurement. This cross could be recommended for the future. In addition, P x O had high negative estimates for body weight at all the ages of measurement except for 4 weeks of age.

Conclusion

Diallel cross mating system was performed in three South African indigenous chicken genotypes to estimate crossbreeding parameters. Heterosis estimations indicate that crosses between the Venda dams and Potchefstroom Koekoek sires as well as between the Ovambo dams and Venda sires provided the highest heterosis effect for body weight. It might be significant to contemplate developing a composite chicken genotype based on the estimations of heterosis, specific combining ability and general combining ability. The current study has shown the significance of bearing in mind the estimates of heterosis effects, general combining ability and specific combining ability effect before planning any crossbreeding program.

Abstract. Considering the potential threats of wind-blown sand to the reservoir capacity of Sanshenggong Water Control Project (SWCP), this paper calculates the amount of wind-blown sand in the reservoir based on the change of reservoir capacity, using sand balance method and cross-section method. Then, the calculated amount was compared with the amount of wind-blown sand measured through field monitoring. Synthesizing the calculation results of the three methods, it is considered that the amount of wind-blown sand into the reservoir is about 0.7~1 million tons per year. The research findings provide a good reference for silt prevention.
Keywords: *sand balance method, sand flow, the yellow river, cross-section method, field monitoring*

Introduction

Located near the Yellow River, the Ulan Buh Desert is widely known for limited rainfall, high evaporation rate and frequent gales (Chen et al., 2016). Each year, a lot of sand is blown from the desert into the Yellow River, making the desert a major source of sediment in the river. Wind erosion in this area has attracted much attention from the academia, yielding successful researches on the hazards and control of wind erosion, the law of sand dune movement and the physical features of sand. However, there is no quantitative analysis on these movements and features (Chen et al., 2015; Yin et al., 2017).

The sand from the desert has many negative impacts on Sanshenggong Water Control Project (SWCP), a local water conservancy project on the main stream of the Yellow River in Daokou, Bayannur, Inner Mongolia. The main function of the project is diversion and irrigation, which relies heavily on reservoir capacity. The silt in the SWCP reservoir mainly come from the sediment of upstream water and the wind-blown sand from Ulan Buh Desert.

Considering the features of reservoir deposition, this paper calculates the amount of wind-blown sand in the reservoir based on the change of reservoir capacity, using sand balance method and cross-section method. Then, the calculated amount was compared with the amount of wind-blown sand measured through field monitoring (Youssef et al., 2012).

Materials and methods

Study area

With an elevation of 1,052 m, the SWCP (40°18'42"N, 107°01'39"E) controls a 314,000 km^2 basin area. It is a low-head diversion project with irrigation as its main function. The other functions include navigation, transport, power generation and industrial water supply. The project was constructed between 1959 and 1961 (Mao, 2013). The storage capacity was designed as 0.8 billion m^3 (Liu et al., 2016), and stands at 0.952 billion m^3 under the normal storage level of 1,055.0 m.

Located at the entry of the SWCP reservoir, the Dangkou Hydrological Station marks the start of the backwater area, which extends 53.8km before reaching the end at the dam site of the SWCP. The SWCP reservoir is a plain river reservoir with an average width of 2,000 m, half of which belongs to the main channel. The project area has a continental monsoon climate in the middle temperate zone. The left and right banks of the project area are a flat beach of sediment and an Ordos terrace, respectively.

The SWCP provides an important guarantee for irrigation in the Hetao region in the upper reaches of the Yellow River, which used to suffer from frequently droughts and floods, and greatly lowered the amount of sand in the diversion canal. Statistics show that the amount of sand in the main channel of the Yellow River in the Hetao section has been reduced by 60% since the completion of the SWCP (Mao, 2013). The decline in sedimentation saves lots of irrigation cost.

Data collection

The research data were extracted from the Validated Data Compilation (1961~2000) of the SWCP in Inner Mongolia Reaches of the Yellow River, the hydrological data (1962~2014) of Dangkou Hydrological Station, the Sediment Source and Siltation Change in Ningxia–Inner Mongolia (NIM) Reaches of the Yellow River and the Feasibility Study Report on Phase 2 Flood Control Project in Inner Mongolia Reaches of the Yellow River. Meanwhile, the amount of wind-blown sand into the SWCP reservoir was calculated from the field measured data.

The amount of wind-blown sand into the SWCP reservoir was calculated three times, respectively through the combination of sand balance method and cross-section method, the storage capacity method and field observation.

Sediment balance method and cross-section method

Sediment balance method and cross-section method (a.k.a. the topographic method) are two popular ways to compute the amount of sand in a river section.

Sediment balance method

By this method, the amount of sand in the river section ΔW_s is calculated from to the amount of sand entering and leaving the river section, as shown in *Equation 1:*

$$\Delta W_S = W_j + W_h - W_c - W_y \quad \text{(Eq.1)}$$

where W_j is the amount of sand entering the reservoir at the entrance; W_h is the amount of sand entering the reservoir from the tributaries; W_c is the amount of sand leaving the river section at the exit; W_y is the amount of sand diverted away from the reservoir.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_97259733

In the SWCP reservoir, there is no tributary that transports sand into the river section. Rather, lots of sand are blown by wind from the banks into the Yellow River. Hence, the above formula should be revised by replacing the W_h with the amount of wind-blown sand W_{fs}, as shown in *Equation 2:*

$$\Delta W_S = W_j + W_{fs} - W_c - W_y \quad \text{(Eq.2)}$$

Cross-section method

The cross-section method is implemented in the following steps: selecting several cross-sections from the river section, measuring the topography of each cross-section before and after a time period, obtaining the silting area of each cross-section in that period (Thomas, 2011), calculating the sand amount of the river channel between these cross-sections, and deriving the total amount of sand in the entire river section in that period. The cross-section method can be divided into several categories, as shown in *Equations 3* and *4*.

(1) Trapezoidal method

$$\sum_{i=1}^{n} V_i = \sum_{i=1}^{n-1} \frac{1}{2}(\Delta A_i + \Delta A_{i+1}) \times \Delta L_i \quad \text{(Eq.3)}$$

where V_i and ΔA_i are the sand amount and silting area of the i-th cross-section, respectively; ΔA_{i+1} is the silting area of the i + 1-th cross-section; L_i is the distance between the first and i + 1-th cross-sections; N is the number of cross-sections. In this method, the river section between two adjacent cross-sections is viewed as a trapezoid for sand amount computation.

(2) Cone method

$$\sum_{i=1}^{n} V_i = \sum_{i=1}^{n-1} \frac{1}{3}(\Delta A_i + \Delta A_{i+1} + \sqrt{\Delta A_i \times \Delta A_{i+1}}) \times \Delta L_i \quad \text{(Eq.4)}$$

The parameters are the same as those in *Equation 3* above.

Comparison between the two methods

The sand balance method and cross-section method have their respective merits and defects. The sand balance method is suitable for calculating the sand amount in different periods, especially in short periods. However, some systematic errors may occur in the computation, and the calculated amount may deviate from the actual amount if there are any uncontrolled areas. As for the cross-section method, the calculation accuracy is affected by the sparse layout of cross-sections and the limited number of measuring points. The error of this method will be magnified by a low amount of sand. Through repeated comparison, most researchers agree that the two methods have basically the same computing accuracy.

In this paper, the two methods are adopted to calculate the amount of wind-blown sand into the SWCP reservoir. Firstly, the sand amount of the reservoir was computed by the cross-section method. The result is the sand amount in the river section ΔW_s, which contains the wind-blown sand. Since the cross-section method cannot determine

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_97259733

the specific amount of wind-blown sand, the sand balance method was introduced to calculate the amount of sand leaving the river section at the Daokou Hydrological Station W_c and the amount of sand diverted away from the reservoir W_y. Then, the amount of wind-blown sand was computed by subtracting the amount of sand entering the reservoir at the entrance W_j from the total amount of sand leaving the reservoir W_c and W_y.

Storage capacity method

Based on the features of water and sand flows, the storage capacity method computes the annual mean runoff and the sand transport in each period of the past years, and determines the amount of wind-blown sand into the study area according to the siltation of the reservoir section (Chattopadhyay, 2011). The calculation formula is shown in *Equation 5:*

$$S_{win} = \frac{r \times H \times L \times B \times R_c}{R} \quad \text{(Eq.5)}$$

where S_{win} is the amount of wind-blown sand entering the Yellow River (103 kg); γ is the volume of the wind-blown sand (1.4 × 103 kg/m^3); H is the sedimentary thickness (m); L is the length of the river section affected by the sand blown from the desert (m); B is the width of the river section (m); R_c is the proportion of wind-blown sand in the total amount of sand in the river section (61%); R is the proportion of wind-blown sand that deposited in the river section in the total amount of wind-blown sand (70.74%).

Field observation

Established in 2011, Ulan Buh Desert Wind and Sand Comprehensive Observation Base monitors eleven types of land uses, including the mobile, semi-mobile, fixed and semi-fixed sand dunes in the study area. The observation plots cover typical areas with similar topography. The volume of wind-blown sand was recorded by the wind-sand collector, and then the transport rates of wind-blown sand were computed for different kinds of sand dunes, eliminating the volume in invalid wind directions (Kisi, 2014).

In 2014, several 10 m-tall wind-blown sand flux towers were set up along the Yellow River to observe the settlement of suspended particles in the wind-blown sand. These towers were arranged in a straight line pointing toward the northwest direction. The observation lasted from May 26, 2014 to May 26, 2015. The annual sand flow at the height of 1~10 m were observed on the left and right banks. The amount of Suspended sand entering the Yellow River S_{sus} (t/yr) can be calculated as shown in *Equation 6:*

$$S_{sus} = \left(S_l - S_r\right) \times L \quad \text{(Eq.6)}$$

where, S_i and S_r are the amounts of sand entering the river from the left bank and the right bank, respectively (kg/m/yr); L is the length of the river section affected by the sand blown from the desert (km)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)

Results

Features of wind-blown sand into the reservoir

The water and sand in the SWCP reservoir can be traced to different sources. About 99% of water and 44% of sand in this river section come from the reaches above Lanzhou. Due to the completion of several water conservancy projects in the upper reaches (Longyangxia Reservoir and Liujiaxia Reservoir), the amount of water entering the SWCP reservoir has been decreasing year by year.

In the SWCP reservoir, the perennial mean water inflow of the reservoir has dropped from 30.312 billion m^3 before 1981 to 30.094 billion m^3 in 1981~1990, 21.277 billion m^3 in 1991~2000, and 193.69 billion m^3 in 2001~2010, despite a slight increase to 26.489 billion m^3 after 2011. Overall, the water inflow in 1991~2000 is 29.30% lower than that in 1981~1990. The minimum water inflow appeared in 1997, which is only 16.4 billion m^3. The reduction in water inflow is accompanied by the stabilization of inflow and water volume. In 2012, the main stream in the upper reaches saw the biggest flood since 1989. In the Ningxia-Inner Mongolia reaches of the Yellow River, the water flow remained above 2,000 m^3/s for 48 consecutive days, pushing up the annual total water flow to 32.907 billion m^3, the highest level since 1989.

The sand inflow into the SWCP reservoir peaked in the 1960s, and decreased continuously ever since. Despite the slight recovery of water inflow after 2010, the sand inflow into the reservoir remained at a very low level. In 2011~2014, the sand inflow was merely 0.28 billion tons, about 16.57% of the sand inflow in the 1960s. Even if a major flood occurred in 2012, the sand inflow was only 0.48 billion tons in that year, which is lower than that in other years with smaller water flow. The sand inflow was further suppressed in 2014, due to the completion of the Haibowan Water Conservancy Project. In that year, the annual sand inflow at Dangkou Hydrological Station reached the lowest point (105 million tons) since the 1960s.

The water and sand inflow features of the SWCP reservoir in each period are presented in *Table 1*. Judging characteristic by the perennial variation in water and sand inflows, the water and sand conditions of the SWCP reservoir are favorable for long-term maintenance of the storage capacity.

Table 1. *Features of water and sand inflows to the SWCP reservoir*

Time slot	Average annual runoff ($10^8 m^3$)	Average annual sediment transport (10^8 t)
1962-1970	317.62	1.69
1971-1980	288.61	0.9
1981-1990	300.94	0.99
1991-2000	212.77	0.95
2001-2010	193.69	0.53
2011-2014	264.89	0.28

Reservoir siltation

Since the SWCP entered service, the sand amount in the reservoir is mainly affected by the inflow of the upstream water. Generally, a large inflow brings about scouring and a small inflow leads to silting. So far, the SWCP reservoir has mainly suffered from

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_97259733

silting. As shown in *Figure 1,* the storage capacity of the reservoir has changed since its completion. The siltation of the reservoir can be divided into the following phases.

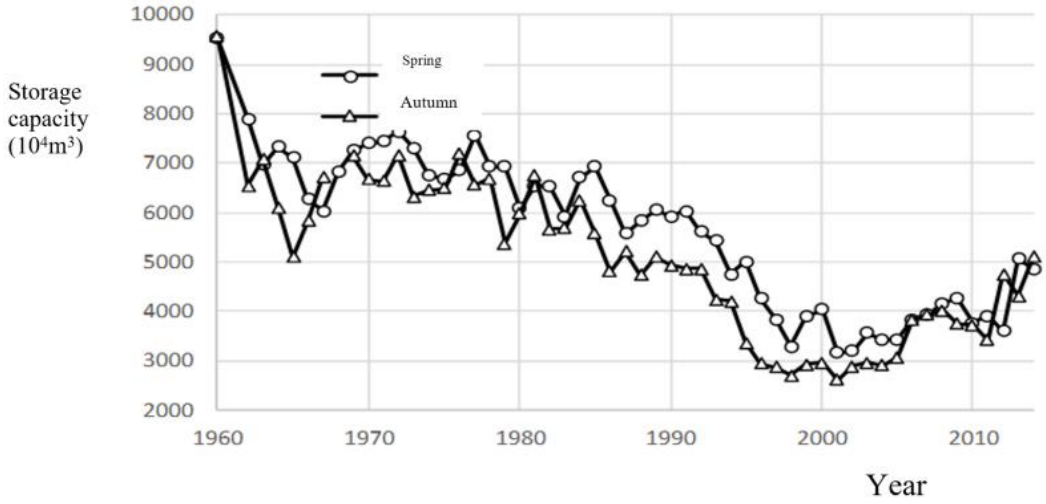

Figure 1. *Variation of storage capacity in the SWCP reservoir*

(1) Spring 1961~spring 1965

In the years right after the completion of the SWCP, the water flow rate and the sand-carrying ability both decreased across the reservoir, causing serious siltation of the reservoir. From May 1961 to August 1962, the cross-sectional flow reached 32 million m^3, about 40% of the designed storage capacity. Shoals and sandbars appeared and developed rapidly under the upper and lower sluice gates. In this period, the storage capacity was reduced from 952.5 million m^3 to 712 million m^3. The storage capacity shrank by 124.5 million m^3 in four years at an annual decreasing rate of 6.01 million m^3.

(2) Spring 1965~spring 1981

Over these 16 years, the reservoir capacity was reduced by 5.7 million m^3 from 71.2 million m^3 to 65.4 million m^3. The annual mean loss of reservoir capacity was 360,000 m^3, which is relatively small.

(3) Spring 1981~spring 1990

From 1981 to 1990, the siltation situation worsened in the reservoir, as the reservoir capacity dropped by 683 million m^3 per year. The loss rate was slightly higher than that in the previous phase. From 654.4 million m^3 to 599.9 million m^3, the total loss of reservoir capacity was 6.15 million m^3.

(4) Spring 1990~spring 2000

This period, the Yellow River Basin witnessed continuous dry years. Under the combined effects of Longyangxia Reservoir and Liujiaxia Reservoir, the reservoir capacity was reduced from 59.29 million m^3 to 40.49 million m^3. The total and annual mean loss of reservoir capacity were respectively 18.8 million m^3 and 1.88 million m^3. From spring 1961 to spring 2000, a total of 54.7 million m^3 sand deposited in the reservoir (Zhao, 2004), averaging at 1.565 million m^3 per year.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_97259733

(5) Spring 2000~spring 2014

In this period, the sand amount in the reservoir was smaller than that in any of the previous periods. The reservoir capacity rebounded under the slight scouring. The storage capacity increased at an annual mean rate of 0.579 million m^3 from 40.49 million m^3 in spring 2000 to 48.59 million m^3 in spring 2014. Throughout the five phases, the sand amount deposited in the reservoir totaled 466.6 million m^3, putting the perennial mean deposition at 0.88 million^3.

Calculated amount of wind-blown sand into the reservoir

As mentioned before, the amount of wind-blown sand into the SWCP reservoir was computed through the combination of sand balance method and cross-section method, the storage capacity method and field observation.

Results of the combined method

The amount of wind-blown sand into the reservoir was computed by the sand balance method and cross-section method according to the sand outflow in 1963~2012 measured in several hydrological stations and the sand diversion data in the reservoir. The results are illustrated in *Figure 2*.

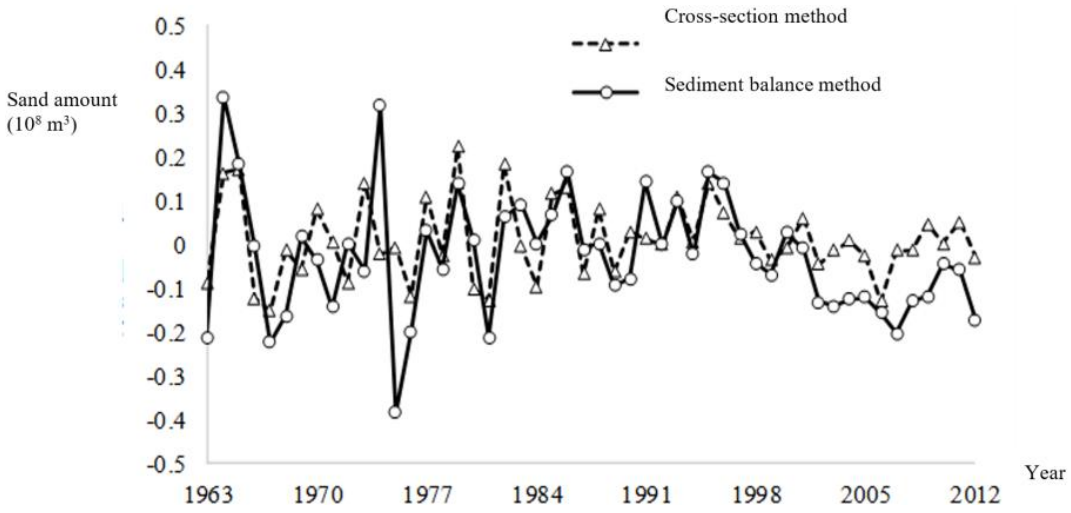

Figure 2. *The annual amount of wind-blown sand into the reservoir*

The results of the two methods are compared in *Table 2*. It can be seen that the sand amounts derived by the two methods differed by 0.345 billion tons in 50 years, i.e. 704,000 tons per year. Hence, the annual amount of wind-blown sand into the reservoir was about 704,000 tons.

Table 2. *Comparison between the results of the cross-section method and the sand balance method in 1963~2012 (ton)*

Method	Trapezoidal method	Cone method	Wind-sand siltation weight
Annual average	0.0109	0.0152	0.0043
Total	0.505	0.850	0.345

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_97259733

Results of the storage capacity method

From 1961 to 2014, the storage capacity of SWCP reservoir was reduced from 955.5 million m^3 to 485.9 million m^3; meanwhile, a total of 466.6 million m^3 of sand was deposited, averaging at 123.25 million tons per year (volume weight: 1,400 kg/m). The variation of storage capacity through the five phases is illustrated in *Table 3*. The analysis on the metal element content in the river shows that the wind-blown sand was about 61% of all deposition in the river channel, accounting for 70.74% of the total amount of wind-blown sand entering the Yellow River. The annual amount of wind-blown sand into the Yellow River in the SWCP reservoir was about 106.28 million tons.

Table 3. *Variation of storage capacity in the SWCP reservoir in 1961~2014*

Period	Storage capacity change (10,000 m^3)	Storage capacity change (10,000 tons)	Average annual change (10,000 tons)
1961-1970	-2119	-2966.6	-329.62
1970-1980	-1323	-1852.2	-185.22
1980-1990	-154	-215.6	-21.56
1990-2000	-1880	-2632	-263.2
2000-2010	-278	-389.2	-38.92
2010-2014	1088	1523.2	380.8

Results of field observation

According to the current classification of land use types, the lengths of mobile and semi-fixed sand dunes near the river section are 22.3 km and 3.1 km, respectively. Through field observation, it is learned that the 22.3 km-long mobile sand dunes released 783,900 tons, 481,100 tons, 316,600 tons and 301,900 tons of sand into the river section, respectively, in 2013, 2014, 2015 and 2016.

Discussion

To sum up, the annual mean amount of wind-blown sand into the river section obtained by the combined method was 704,000 tons (1963~2012), acquired by the storage capacity method was 106,280,000 tons (1961~2014), while observed in the field was 783,900 tons, 481,000 tons, 316,000 tons and 301,900 tons, respectively, in 2013, 2014, 2015 and 2016.

Each of the three methods have their own features. The combined method inherits the test errors, the storage capacity method faithfully reflects the long-term variation and siltation of reservoir capacity, while the field observation is limited to the period from 2013 to 2016. Synthesizing the calculation results of the three methods, it is considered that the amount of wind-blown sand into the reservoir is about 0.7~1 million tons per year.

Conclusions

Considering the potential threats of wind-blown sand to the reservoir capacity of Sanshenggong Water Control Project (SWCP), this paper calculates the amount of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_97259733

wind-blown sand in the reservoir based on the change of reservoir capacity, using sand balance method and cross-section method. Then, the calculated amount was compared with the amount of wind-blown sand measured through field monitoring. Synthesizing the calculation results of the three methods, it is considered that the amount of wind-blown sand into the reservoir is about 0.7~1 million tons per year. The research findings provide technical product for siltation prevention and reduction. The field observation of Aeolian sand is a long-term process. It is suggested that the field monitoring of Aeolian sand should be continued in the next step, and the observation types, density and frequency should be further improved to provide a solid data support platform for desert control and the development and utilization of Sanshenggong Water Control Project.

(Received 19th Mar 2019; accepted 13th Jun 2019)

Abstract. Seven common wheat (*Triticum aestivum* L.) cultivars were crossed in a line×tester matting design. The 12 F_1 and their parents were evaluated using a Completely Randomized Block Design (CRBD) replicated three times in Kurdistan Reign-Iraq at two different locations, first Kanipanka in Sharazoor Valley, and the second was Qlyasan Agricultural Research Station, University of Sulaimani, during the winter season of 2017-2018. The Least Significant Differences Test (LSD) at ($P \leq 0.05$) was carried out to compare the means of the characters. The results confirmed that sufficient genetic variability was included with all traits studied. The cross Aras×Iba-95 at Kanipanka location and Klal×Cham-6 at Qlyasan location had better grain yield/plant mean than their parents. The cross Aras×Iba-95 and Klal×Cham-6 at both locations exhibited maximum positive heterosis for grain yield/plant and most of their components. Line parents Aras and Klal are good general combiners for grain yield/plant and most its components at both locations respectively. The cross Aras×Iba-95 is the better specific combiner to increase grain yield/plant at both sites. The superiority of non-additive type of gene actions in controlling the inheritance of these characters was confirmed.
Keywords: *heterosis, combining ability, heritability, gene action*

Introduction

Bread wheat (*Triticum aestivum* L.) is the most important crop being one-fifth of the total calories for the population of the world (Sehgal et al., 2015). Wheat cultivation represents approximately 19% of global main cereal crop production (Todorovska et al., 2009). Considerable cultivated species of wheat include: *Triticum aestivum*, which is a hexaploid species and is widely seeded in the world (Moon, 2008). It has been imposed that the world population would increase to over 9 billion by the year 2050 (United Nations, Population Division, 2015). The population growth will increase the request for wheat crop by 60% compared with current years. To meet this demand, global annual yield increases have to rise from the current level of 1% per year to 1.6% per year until 2050 (Wheat, 2014). For this cause, the breeders have to share demanding need to increase yield potential of wheat by creating new wheat varieties with likable genetic makeup (Erkul et al., 2010). This could be reached by searching maximum genetic potential from available wheat germplasm (Khan et al., 2007). Common wheat is one of the earliest domesticated crops. It is a prime staple food for around 40% of the world's population (Kuzmanovic et al., 2014). Wheat provides about 20% of the calorific input for the world population and, for cereal crops has the third highest global production after maize and rice (FAO, 2014). Wheat is widely cultivated in various regions of the world, being well suited for growth in area between latitudes of 30° and 60° N and 27° and 40° S (Curtis, 2002). 349 million

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_97359752

tons of this crop was harvested in 2016, and more than 220 million hectare of the world was cultivated by wheat. Due to the raising of the world population, wheat plays a main role in the national economy of developing countries. Read wheat is one of the major food grain crops in the world, as it provides 20% of the total energy and protein in the human diet (FAO, 2016). Most of wheat planted areas are located in arid or semi-arid regions where a biotic stresses, especially drought stress, are a main constraint for wheat production (Tahmasebi et al., 2014). Current wheat production does not meet global demand due to the declining arable land area, increasing global population, and the effects of climate condition change on the environment (Tester and Langridge, 2010; Altieri and Nicholls, 2017). To meet the need for population growth, the country's wheat requirement by 2030 has been estimated at 100 million metric tons and to reach this goal, wheat productivity has to be increased at the rate of <1per annum and this can be fulfilled through horizontal approach i.e. by rising area under cultivation or through varietal/hybrid improvement, which is one of the substantial tool to take a volume jump in production and productivity under various agro- climatic conditions (Rahul, 2017). Developing hybrid wheat varieties with desirable traits require a thorough knowledge about the existing genetic variability (Maniee et al., 2009; Kahrizi et al., 2010a,b). The more the genetic diverse parents, the greater the chances of obtaining higher heterotic expression in F_1s and broad spectrum of variability in segregating population (Shekhawat et al., 2001). The line × tester analysis method proposed by Kempthorne (1957) is one of the powerful tools available to evaluate the combining ability effects and aids in selecting desirable parents and crosses for exploitation in pedigree breeding (Basbag, 2007; Jain and Sastry, 2012; Rashid et al., 2013). Performances itself do not necessarily reveal which parents are best or weak combiners. To get up this difficulty, it is necessary to collect information on the nature of gene effects. General combining ability is assigned to additive type of gene effects, while specific combining ability is attributed to non-additive of gene works. Non-additive gene type of actions is not reliably fixable whereas additive type of gene effects or complementary type epistatic gene interactions is reliably fixable (Xiang and Li, 2001; Yan and Hunt, 2002; Iqbal et al., 2007). The objectives of this study are to estimate the combining ability, to estimate the nature and magnitude of gene actions, to evaluate heterosis and heritability for yield and yield related traits in a line × tester method in bread wheat.

Materials and methods

This study was carried out at two different locations, in Kurdistan Region-Iraq. First Kanipanka Nursery Station (Lat 35° 22′; N, Long 45° 43′; E, 550 masl) in Sharazoor Valley 35 km East of Sulaimani City, and second was at Qlyasan Agricultural Research Station, College of Agricultural Sciences-University of Sulaimani located (Lat 35° 34′ 307″; N, Long 45° 21′ 992″; E, 765 masl) 2 km North West of Sulaimani City, during 2017-2018. The experimental material comprises seven bread wheat (*Triticum aestivum* L.) genotypes. Four genotypes (Aras, Hasad, Kauz and Klal) were used as females, hereafter designated as lines, and three genotypes (Iba-95, Cham-6 and Saber beg) were used as males, fixed as testers. The seven parents were crossed to produce 12 F_1 crosses according to the line×tester mating design developed by Kempthorne (1957). F_1 seeds were sown in the field, along with their parents, in Complete Randomize Block Design (CRBD) with three replication. Each plot comprised one row of 2 m length with space

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_97359752

of 40 cm between rows and seeds were placed 15 cm apart. Five competitive plants (excluding border plants) were chosen and data were recorded for:

1-Evaluated traits:

Number of spikes/plant, Weight of spikes/plant (g), Average spike weight (g), Spike length (cm), Number of grains/spike, Weight of grains/spike (g), 1000-grain weight (g), Biological yield/plant, Grain yield/plant and Harvest index.

2-Genetic parameters:

General Combining Ability (gca) and effects, Specific Combining Ability (sca) and effects, Heterosis percentage as the F_1s deviation from average parental values, Heritability in Broad Sense, Heritability in Narrow Sense, Average Degree of Dominance (ā).

3-Association analysis and path coefficient analysis.

The collected data were submitted to analysis of variance as proposed by Steel and Torrie (1980) to estimate significant differences among genotypes. Combining ability effects are very important genetic parameters in determining the next phase of breeding programs. They were computed according to the line×tester method (Singh and Chaudhary, 1985).

Climate conditions of Sulaimani region

The climate of Sulaimani governorate is semi-arid environment: wet and cold in winter dry and hot in summer; During July and August, the average temperature is between 39-43ºC, and overwhelmingly amount to nearly 50ºC. Autumn means high temperatures are 20-30ºC in October, cooling slightly in November. Precipitation is limited to winter and spring months, and the overall average annual rainfall of 550-700 mm was at Sulaimani city. An overview of experimental conditions is given in *Table 1*.

Table 1. *The meteorological data of the two locations*

Month	Kanipanka location				Qlyasan location			
	Min Temp.(C°)	Max Temp.(C°)	Avg. Temp.(C°)	Rainfall (mm)	Min Temp.(C°)	Max Temp.(C°)	Avg. Temp.(C°)	Rainfall (mm)

Results

The analysis of variance ratified highly significant genotype effect for all characters studied. This confirmed the presence of enough genetic variability among genotypes at both locations. The mean squares for parents was highly significant for number of spikes/plant, average spike weight, biological yield/plant and harvest index, but it was significant for spike length, number of grains/spike, weight of grains/spike and 1000-grain weight, while for other characters it was not significant at the first location. At the second location the mean squares for parents was highly significant for all characters except biological yield/plant, grain yield/plant and harvest index which was not significant. The mean squares due to crosses were highly significant for all characters at both locations with the exception of number of spikes/plant and average spike weight which was significant at the second location (*Table 3*).

The mean performance of parents and F_1s crosses for all characters were represented in *Table 4*. At the first location the cross Aras×Iba-95 recorded the highest value for grain yield/plant 53.827 g, and some of its components such as number of spikes/plant, weight of spikes/plant and biological yield/plant with 30.176, 68.915 g and 157.762, respectively. The cross Kauz×Iba-95 exhibited maximum value for average spike weight, weight of grains/spike and harvest index 4.941 g, 3.695 g and 0.438, respectively. Regards to the parental performance at the same location the line parent Hasad produced the highest value for average spike weight, 1000-grain weight and harvest index 4.463 g, 53.468 g and 0.466, respectively, but the tester parent Saber beg produced the maximum weight for grain yield/plant 34.493 g and most its components such as number of spikes/plant, weight of spikes/plant, spike length and biological yield/plant 26.167, 53.748 g, 12.420 cm and 162.153 g, respectively. At the second location the cross Klal×Cham-6 produced the highest value for grain yield/plant and number of spikes/plant reached 23.422 g and 9.333 spikes, respectively. The cross Hasad×Iba-95 produced the highest amount for average spike weight, weight of grains/spike and harvest index reached 4.540 g, 3.439 g and 0.541, respectively. The

line parent Hasad showed maximum value for weight of spikes/plant, average spike weight, weight of grains/spike, 1000-grain weight and biological yield/plant with 34.018, 4.783, 3.627, 58.691 and 125.960 g, respectively. Maximum grain yield/plant recorded by the tester parent Cham-6 with 21.185 g.

Data in *Table 5* illustrate the estimation of heterosis values determined as the percentage of F1s deviation from mid parental value. The cross Aras×Iba-95 showed maximum positive heterosis values for grain yield/plant 129.087% and some its components such as number of spikes/plant, weight of spikes/plant and biological yield/plant reached 129.114, 126.554 and 119.050% respectively, while the cross Kauz×Saber beg showed maximum negative heterosis value for grain yield/plant -54.917% and most its components such as weight of spikes/plant, average spike weight, spike length, number of grains/spike, weight of grains/spike and biological yield/plant reached -59.244, -35.415, -10.034, -44.598, -38.727 and -53.409% respectively at the first location, while at the second location maximum positive heterosis for grain yield/plant was 18.137% recorded by the cross Klal×Cham-6, but the cross Aras×Saber beg produced maximum positive heterosis for average spike weight, number of grains/spike and weight of grains/spike reached 19.432, 39.719 and 24.923%, respectively. The cross Hasad×Saber beg produced maximum negative value for grain yield/plant -41.316% and some its components such as weight of spikes/plant, average spike weight, weight of grains/spike and 1000-grain weight reached -51.048, -30.277, -34.955 and -23.423%, respectively.

Table 6 clarified the general combining ability effect of parents. Combining ability plays important role in the estimation of inbred in terms of their breeding values, and this will help to decide efficient breeding method to be applied in segregating generation. Data in the same table revealed that the line parent Aras recorded significant and positive gca effect for grain yield and most its components viz. number of spikes/plant, weight of spikes/plant, number of grains/spike and biological yield/plant, while the tester parent Iba-95 gave significant and positive gca effect for average spike weight, weight of grains/spike and harvest index. Most negative gca effect values for the characters recorded by line parent Kauz and tester parent Saber beg at the first location. At the second location the highest positive and significant gca effect values for grain yield/plant and some its components such as spike length, number of grains/spike and biological yield/plant recorded by the line parent Klal, but the tester parent Cham-6 exhibited the highest positive and significant gca values for number of spikes/plant,

weight of spikes/plant and weight of grains/spike. Maximum negative gca effect values for most characters recorded by the line parent Hasad and the tester parent Saber beg.

Table 6. *Estimation of gca effect for the parents (1st location upper value and 2nd location lower value)*

Data represent in *Table 7* explain the sca effect of the F_1 crosses at both locations, sca is mainly a function of dominance variance, it helps in the identification of superior cross combination of heterosis. At the first location the cross Aras×Iba-95 was the best specific combiner for number of spikes/plant, weight of spikes/plant, biological yield/plant and grain yield/plant, while the cross Kauz×Iba-95 was the better specific combiner for average spike weight, number of grains/spike, weight of grains/spike and harvest index. At the second location the cross Aras×Iba-95 was the best specific combiner for grain yield/plant, while the cross Hasad×Iba-95 was the best specific combiner for average spike weight, weight of grains/spike and harvest index. The cross Kauz×Cham-6 was the best specific combiner for number of grains/spike and biological yield/plant.

Some genetic parameters present in *Table 8* for both locations. At the first location the variance of sca effect was greater than those of gca effect for all characters except biological yield/plant and grain yield/plant, indicating to the importance of non additive gene effect in the inheritance of these characters, but for biological yield/plant and grain yield/plant the additive gene effect is more important in the inheritance of both. At the second location it was indicated that the magnitude of sca variance is larger than those of gca effect for all characters, confirming the importance of non additive gene effect in the inheritance of these characters. The average degree of dominance values are more than one for most characters at both locations.

The simple correlation coefficient among studied characters represent in *Table 9* at both locations. At the first location the character number of spikes/plant recorded positive and highly significant correlation with weight of spikes/plant, biological yield/plant and grain yield/plant 0.721, 0.709 and 0.681, respectively. Weight of spikes/plant recorded positive and highly significant correlation with spike length, biological yield/plant and grain yield/plant 0.644, 0.760 and 0.939, respectively. Spike length exhibited positive and highly significant correlation with grain yield/plant 0.652, but it recorded positive and significant correlation with number of grains/spike and weight of grains/spike 0.597 and 0.549, respectively. Positive and highly significant correlation was recorded between number of grains/spike and each of grain weight/spike and grain yield/plant 0.849 and 0.609, respectively. Positive and significant correlation was recorded between weight of grains/spike and each of harvest index and grain yield/plant with 0.531 and 0.551, respectively. Positive and highly significant correlation was recorded between biological yield/plant and grain yield/plant

0.755. At the second location the character number of spikes/plant correlated positively and significantly with weight of spikes/plant 0.492, while weight of spikes/plant recorded positive and highly significant correlation with grain yield/plant 0.677. Positive and significant correlation recorded between spike length and biological yield/plant 0.487. Positive and highly significant correlation was recorded between weight of grains/spike and 1000-grain weight 0.691.

Data represent in *Table 10* illustrate the path coefficient analysis, indicating to the direct and indirect effects on grain yield. At first location the highest positive direct effect was recorded by number of grains/spike reached 0.947 and followed by 1000-grain weight with 0.589, while the highest negative direct effect recorded by weight of grains/spike reached -0.735. The highest positive indirect effect was 0.805 recorded by number of grains/spike via weight of grains/spike and followed by number of grains/spike via spike length. The highest negative indirect effect in grain yield was -0.624 recorded by weight of grains/spike via number of grains/spike and followed by -0.403 for weight of grains/spike via spike length. At second location the highest positive direct effect in grain yield recorded by 1000-grain weight reached 1.425 and followed by number of grains/spike with 1.072, whilst only weight of grains/spike recorded negative direct effect reached -1.387. Maximum positive indirect effect was 0.984 recorded by 1000-grain weight via weight of grains/spike and the highest negative indirect effect was -0.958 recorded by weight of grains/spike via 1000-grain weight.

Table 10. *Path coefficient analysis Illustrates direct effect (diagonal values) and indirect effect of studied characters in grain yield at both locations (1st location upper value and 2nd location lower value)*

Discussion

The results confirmed that the data for all characters under the study can be analyzed further to estimate general and specific combining ability effects. Similar results confirmed that both gca and sca variances were significant for most of the characters indicating importance of both additive as well as non additive components of genetic variance in the control of these traits (Kumar et al., 2011; Singh et al., 2013; Rahul, 2017). Also similar results reported by Burungale et al. (2011), Mandal et al. (2016), and Nataša et al. (2017). Highly significant differences among genotypes were recorded for all characters, also significant differences were recorded among the mean performance of F_1s crosses (Fellahi et al., 2013; Kalhoro et al., 2015). Significant positive and negative heterosis for all characters were recorded, also significant positive

DOI: http://dx.doi.org/10.15666/aeer/1704_97359752

relative heterosis for grain yield recorded previously by Ajmal et al. (2004), Akram et al. (2004), Akbar et al. (2009), Ashadusjman et al. (2012), Devi et al. (2013), Anonymous (2015), and Rahul (2017). The gca effect is primarily function of additive genetic variance, which helps in the selection of suitable good general combiner parent for hybridization (Rahul, 2017). These results are in confirmation with Kumar et al. (2011), Kapoor et al. (2011), Singh et al. (2013), Raj and Kandalkar (2013), Aslam et al. (2014), Ismail (2015), Kalhoro et al. (2015), and Kandil et al. (2016). According to Kenga et al. (2004) cross-combinations with high means, appropriate sca estimates and involving at least one of the parents with high gca would likely enhance the concentration of desirable genes to improve target traits. Present findings are in confirmation with Kumar et al. (2011), Kapoor et al. (2011), Singh et al. (2013), Raj and Kandalkar (2013), Aslam et al. (2014), Kalhoro et al. (2015), and Kandil et al. (2016). The average degree of dominance values are more than one for most characters at both locations. Previous reports confirmed the importance of over dominance in the inheritance of the grain weight/ spike of wheat which was pointed out by Petrović et al. (2012) and Adel and Ali (2013). Obverse to these results, the importances of partial dominance in the inheritance of this trait were reported by Kohan and Heidari (2014). However, the selection in early generations for the trait grain weight/spike would be difficult due to over-dominance type of gene action which indicates that the selection for this trait in advanced segregating generations would be more efficient (Nazir et al., 2014; Yao et al., 2014; Shehzad et al., 2015). While, partial dominance effect was observed in the inheritance of this trait reported by Farooq et al. (2011) and Rashid et al. (2013). Similar results, which indicated the importance of the dominant component in the genetic variance and over-dominant inheritance of the grain weight/ spike, have been also pointed out by El-Hosary et al. (2015). Converse to these results, the high value of the additive component and partial dominance responsible for the inheritance of grain weight/spike was observed by Minhas (2012) and Kohan and Heidari (2014). Heterosis estimates, for different morphological and yield related characters, are attributed to both additive and non additive gene actions. Heritability gives information about genetic variation; it is important for predicting the response to selection in the superseding generations. Heritability is dependent upon the type of gene action (Swati and Ramesh, 2004; Hasnain et al., 2006; Chowdhary et al., 2007). At the first location heritability in broad sense was high for number of spikes/plant, average spike weight, spike length and harvest index, while for the other characters it was low to moderate. At the second location it was high for spike weight/plant, spike length, grain yield/plant and harvest index, but for the rest it was low to moderate. Heritability in narrow sense was found to be low for almost all character at both locations. High heritability accompanied with high genetic advance shows that the heritability is due to additive genetic control and selection may be effective in early generations for these traits (Jamil et al., 2017). Heritability estimates varied from 54.48 to 80.91%. Highest heritability 80.91% was observed for the cross combination Fareed 06×9242, While the lowest value of heritability 54.48% was estimated in cross combination Fareed 06×9317 (Waqas et al., 2014). Heritability for grain yield/plant was 0.68 in Kaleemullah et al. (2015), who said that this traits is greatly under genetic controlled and less influenced by environment. The estimates of heritability in narrow sense were medium to high reported by Yadav et al. (2011). Significant and positive correlation was recorded between grain yield and most its components. These results are harmony with those reported by Tofiq (2004), Hama-Ali (2006), Hama-Ameen (2008), Mohsin et al. (2009)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_97359752

and Fellahi et al. (2013). Estimation of the correlation between yield and its components alone is not enough to tell as the importance of each one of these components in determining the grain yield (Bhutta et al., 2005; Bhutto et al., 2005; Anwar et al., 2009; Ali and Shakor, 2012). Similar results are agreement with a positive correlation of grain yield with number of grains/spike and 1000-grain weight, with support the present studies (Belay et al., 1993; Aycecik and Yildirim, 2006). Positive and highly significant correlations recorded between grain yield/plant and harvest index reported by Tawfiq et al. (2016). The path analysis is used to find the direct or indirect effects of some yield components on grain yield in relation to yield with other components. Many researchers have been done on wheat breeding in which both correlation and path analysis methods were simultaneously used. Positive and significant correlation between plant height and grain yield were reported in many studies (Khayatnezhad et al., 2010; Zakizadeh et al., 2010; Amri et al., 2011). It was shown that seed numbers/spike has a positive effect on grain yield (Taleei and Bahram-Nejad, 2003; Foroozanfar et al., 2011). Path analysis conducted by a large number of researchers, it has been observed that 1000-grain weight has a positive effect on yield, followed by spike length, while grains/spike had a negative direct effect on grain yield associated a positive direct effect and negative indirect effect on grain yield via harvest index, while biological yield had the highest direct effect on grain yield refers to followed by weight of main spike, they show that the biological yield and weight of main spike can be used as criteria for selection to improve the yield of wheat grain (Mohammadi et al., 2007; Mollasadeghi et al., 2011; Iftikhar et al., 2012; Ayer et al., 2017).

Conclusion

Line parent Aras and tester parent Iba-95 was found to be a good general combiner for grain yield/plant at the first location, which produced a best specific combiner for this character, while at the second location the line parent Aras and the tester parent Iba-95 were poor general combiner for grain yield/plant, whilst they produced the best specific combiner for this character. Low ratio of σ^2gca/σ^2sca for most characters at the first location and for all characters at the second location and low estimates of heritability in narrow sense confirmed involvement of both additive and non additive gene effects with preponderance of non additive type of gene actions. The preponderance of non additive type of gene actions clearly indicated that selection of superior plants should be postponed to later generations.

Good general combine line parents like Aras and Klal for yield and most related components at both locations could be used in the development of high yielding varieties through selection for promising segregating cross generations. The crosses Aras×Iba-95 and Klal×Cham-6 was found high yielding which were very desirable for further breeding program.

Abstract. The epiphytic orchid species *Dendrobium catenatum* is extensively used as a traditional medicine in China. Overexploitation has led to endangerment and rarity of the species in the wild, and conservation measures are immediately needed. As in many orchid species, mycorrhizal symbiotic seed germination is recognized as a powerful tool for orchid seedling propagation, reintroduction, and species conservation. Obtaining efficient and specific fungi for enhancing seed germination, protocorm formation, and further seedling development is a prerequisite. In this study, eight purified fungal strains were isolated from host orchid protocorms via an ex situ baiting technique. Phylogenetic analysis using ITS-rDNA placed the eight fungal strains into the taxa Tulasnellaceae, Ceratobasidiaceae, and Sebacinales, the typical orchid mycorrhizal symbionts. The fungi induced seed germination and also increased growth during protocorm formation, seedling formation, and seedling development. One strain in particular (SSCDO-5) exhibited significant benefits under 12/12 h light/dark conditions between 20 and 90 days after sowing. Our results suggest that inoculation with the fungus SSCDO-5 might assist in the propagation of *D. catenatum* and could be employed ex situ and in situ for conservation purposes.
Keywords: *conservation effort, photoperiod, reintroduction, seedling development, Tulasnellaceae*

Introduction

Symbiotic fungi play an important role in the orchid life cycle, from seed germination, through protocorm formation to seedling development, and even into adulthood when they provide nutrition supplemental to photosynthesis (Selosse and Roy, 2009). Mycorrhizal studies are essential and necessary to ensure success in propagation from seeds and to benefit integrated orchid conservation. Highly compatible symbiotic fungi can play a major role in the initiation of seed germination and recruitment of Orchidaceae (Park and Lee, 2013; Rasmussen et al., 2015; Khamchatra et al., 2016; Huang et al., 2018). The isolation, identification, and culture of germination-enhancing fungi are prerequisites for symbiotic seed germination and seedling growth.

Most studies have focused on screening fungi effective in promoting seed germination, mainly using different strains acquired from roots (Johnson et al., 2007; Stewart and Kane, 2007; Chutima et al., 2011; Wu et al., 2012; Fracchia et al., 2016). Among these, 14 fungi isolates from the roots of 10 species were assessed in terms of germination percentage of *Cynorkis purpurea* seeds, which displayed low specificity for germination in vitro (Rafter et al., 2016). However, only a few studies have examined epiphytic orchids using in situ baiting techniques applied to seed germination in association with symbiotic mycorrhizal fungi (Wang et al., 2011; Zi et al., 2014; Zhou and Gao, 2016). Herrera et al. (2016) found that 13 mycorrhizal isolates from 7 hosts

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_97539771

had the ability to induce seed germination with various efficiencies and low specificity in vitro. Wu et al. (2012) inoculated seeds of *Dendrobium catenatum* with four symbiotic fungi in vitro (strains C20 from *D. catenatum* and L12, L24b, and L28 from *D. loddigesii*) and found that strains L24b and L28 had significantly higher germination rates, but the seeds did not form seedlings. Two *Tulasnella* strains isolated from roots of an endangered species, *D. nobile*, differed in their ability to facilitate germination and subsequent development in *D. officinale* (= *D. catenatum*) in vitro (Tan et al., 2014). Swangmaneecharern et al. (2012) found that four out of five fungal strains from other genera could form pelotons in *Dendrobium* spp.

Although it is more convenient to isolate symbiotic fungi from roots to screen for effective species in vitro, this approach is biased toward specificity under experimental conditions and not necessarily those pertaining in the field where the ecological conditions are more specific (Masuhara and Katsuya, 1994; Steinfort et al., 2010). Masuhara and Katsuya also found that most *Rhizoctonia* spp. not associated with the in situ germination of *Spiranthes sinensis* var. *amoena* induced seed germination in vitro, demonstrating differences in seed specificity according to conditions (Masuhara and Katsuya, 1994). Based on this characteristic, Rasmussen et al., (2015) suggested that non-compatible fungi may stimulate germination per se, but are not necessary to support subsequent seedling development. Other authors have also agreed that the orchid–fungus relationship is not the same in in situ and in vitro conditions (Zi et al., 2014; Cruz-Higareda et al., 2015). The use of germination-promoting fungi isolated from protocorms in situ/ex situ of the same species can ensure high compatibility and adaptation between orchid species and fungal partners and thus support restoration efforts and orchid conservation (Zi et al., 2014; Shao et al., 2017; Huang et al., 2018).

However, it is difficult to gather protocorms in the wild because they are very small and sparsely distributed. The use of in situ and ex situ baiting methods has been proposed to overcome such problems and ensure effective protocorm sampling (Rasmussen and Whigham, 1993; Brundrett et al., 2003). The ex situ baiting method allows close observation of the germination process, and provides time for choosing the optimum stage for mycorrhizal fungus isolation. Xu and Guo (1989) isolated an effective symbiotic fungus, *Mycena osmundicola*, from protocorms of *Gastrodia elata* by ex situ baiting; subsequently, the fungus was successfully applied in the industrial propagation and plantation of *G. elata* in China. Using ex situ seed baiting techniques, Sheng et al. (2012) obtained one mycorrhizal fungus from *Cymbidium mannii*, an epiphytic orchid species, which proved to be effective for seed germination, and protocorm and seedling development.

D. catenatum Lindley is a perennial, epiphytic orchid from China having medicinal properties. It is used in the treatment of diabetes and improvement of the immune system, as well as an ornamental plant. There has been a drastic reduction in wild populations of *D. catenatum* that has driven the species to the verge of extinction, mainly caused by overexploitation and habitat degradation in recent decades. The low fertility rate and inherently slow growth of the species have also contributed to its current scarcity in the wild. Asymbiotic, sterile, vegetative tissue culture of *D. catenatum* has been successfully developed, but the survival rate of sterile plants and the seedling growth rate are low, meaning this technique is unlikely to contribute to preserving the genetic diversity of this species. In vitro symbiotic seed germination assays of *D. catenatum* using fungal isolates obtained from mature orchid plants have been considered and performed to screen for the presence of effective fungal strains

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_97539771

(Wu et al., 2012). It was found that the seeds of *D. catenatum* could form a symbiotic relationship with *Epulorhiza* spp. and *Alternaria* spp. with low specificity in vitro, but the germination rate was significantly low. Wang et al., (2011) conducted in vitro symbiotic seed germination of *D. catenatum* using fungal strains obtained from protocorms of *D. chrysanthum* via in situ baiting methods, and one fungus (SHH53) successfully improved seed germination and seedling development to stage 5. Other researchers have reported the use of two *Tulasnella* strains (JC-02 and JC-05) isolated from the roots of *D. nobile* for the symbiotic seed germination of *D. catenatum* (Wang et al., 2011; Tan et al., 2014). These results demonstrated that the two different strains of *Tulasnella* varied in their ability to facilitate germination/development of *D. catenatum* seeds in vitro. To the best of our knowledge, no fungal strains isolated from host protocorms have been reported to date. This study addresses the following hypotheses: (1) different fungal strains isolated from the same host protocorm would enhance seed germination; (2) the fungal strains that influence seed germination and seedling development would be from closely related taxa; (3) different fungal strains would influence seed germination at different times after sowing; and (4) the photoperiod would influence seed germination differently under different fungal strains.

Materials and methods

Plant species

The study species, *D. catenatum*, is a lithophyte or epiphyte growing in moderately humid mountains at an elevation of ca. 1600 m. It is widely distributed in central and south China, including Anhui, Fujian, Guangxi, Sichuan, Taiwan, Yunnan, and Zhejiang provinces (*Fig. 1*). It flowers from March to June with 10%-17% fruit set, and seeds become mature during December (Liu et al., 2011).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_97539771

Study sites

Nearly dehisced fruits set by natural pollination, and substrates for ex situ baiting, were collected from wild populations of *D. catenatum* in Shuangjiang town, Lipu county, Guangxi Zhuang Autonomous Region, China (*Fig. 1*). Ex situ baiting to induce protocorm formation and screening for germination-enhancing fungi were performed in Xishuangbanna Tropical Botanical Garden (XTBG; 21°45′N, 101°02′E; altitude, 580 m), Yunnan Province (*Fig. 1*).

Seed collection and storage

The capsules were surface-sterilized using 75% ethanol, rinsed three times in sterile distilled water, and opened with a sterile scalpel under laminar flow. The seeds were transferred to airtight glass containers with anhydrous calcium chloride. After 4 days, the seeds were stored in a glass vial at 4 °C for short-term preservation and at −20 °C for long-term storage. Seed viability was 89.85% based on an assessment of approximately 480 seeds using the triphenyl tetrazolium chloride test.

Protocorm induction by ex situ baiting of D. catenatum seeds

The substrates, consisting of bark, moss, litter, and humus, were collected within 20 cm of the maternal plants and brought back to the laboratory within 48 h of harvest. The ex situ baiting mixture was saturated with sterile water, homogenized with a blender, and dispensed into petri dishes (9.0 cm in diameter). A designated number of seeds were resuspended in 0.1% sterilized agar solution and the drops were spread on a nylon mesh (ca. 2 × 3 cm) with 45 μm pores. Each mesh contained 120 seeds and each petri dish had 4 meshes. All the dishes were incubated in a plant growth chamber (MGC-450HP, Shanghai Yiheng Instruments Co., Ltd, Shanghai, China) at 25 ± 1 °C with 12/12 h light/dark (L/D) photoperiod at 1600 lux light intensity. Germination was monitored every 2 weeks, and protocorms that had reached stage 2 and seedlings that had reached stage 3 were then used to extract endophytic fungi.

Isolation of symbiotic fungus from protocorms

Symbiotic fungus isolation was performed according to the method proposed by Zi et al. (2014) with slight modifications. Developing protocorms at stage 2 or 3 were gathered and surface-sterilized using sodium hypochlorite solution containing 1% available chlorine for 3–5 min, and then washed 3–4 times with sterile distilled water. The protocorms were then cut into two parts using a sterilized blade, plated onto petri dishes containing fresh potato dextrose agar (PDA), and then incubated at 25.0 ± 1.0 °C in the dark. One complete protocorm was also grown to test the sterilization of the blade. After 3–5 days, once fungal hyphae had emerged from the edge of the broken protocorms, the hyphae tips were sub-cultured from the medium and transferred to new plates with PDA and incubated under the same conditions. The fungal isolates were purified 3–4 times by excising the hyphal tips onto fresh PDA petri dishes.

Molecular identification of fungal isolates and phylogenetic analysis

Using conventional CTAB method, we extracted DNA from fungi cultured in potato dextrose broth for 5 days. The primers ITS1 and ITS4 (White et al., 1990) were used to amplify nuclear ribosomal internal transcribed spacer (nrITS) using a Biometra gradient

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_97539771

thermal cycler (070-801, Göttingen). Polymerase chain reaction products were purified using Sangon's purification kit, and sequencing was performed by Sangon Company (Sangon Biotech Co., Ltd, Shanghai, China). The ITS-rDNA sequences obtained from each isolate were compared to those deposited in the GenBank database by BLAST, providing the identification of isolates to the genus or species level when the ITS sequence similarity exceeded 97% or 99%, respectively (Zi et al., 2014).

Twelve related representative sequences of ITS-rDNA of orchid mycorrhizal fungi from NCBI (https://www.ncbi.nlm.nih.gov/) and eight newly generated sequences were used for phylogenetic analysis. *Armillaria sinapina* was set as the outgroup, following similar studies (Tan et al., 2014). Alignment of nucleotide sequences was performed by Clustal X version 1.81 (Thompson et al., 1997). Phylogenetic analysis was conducted in MEGA 6.0 (Tamura et al., 2013) with the Maximum Likelihood method based on the best model Kimura 2-parameter + Gamma model (BIC = 8533.566, AIC = 8265.917, lnL = −4095.821), with Bootstrap Replications = 1000, Rates among Sites = uniform rates. Initial tree(s) for the heuristic search was obtained by applying the Nearest-Neighbor-Interchange method. The tree with the highest log likelihood is shown. The percentage of trees in which the associated taxa clustered together is shown next to the branches.

Testing fungal capacity to promote seed germination

Seeds of *D. catenatum* were removed from storage at −20 °C and kept at ambient temperature overnight. According to the sterilization method of *Paphiopedilum spicerianum* seeds by Chen et al. (2015), seeds of *D. catenatum* in syringes fitted with 3×3 cm nylon cloth plot with 45 μm pores were first sterilized by washing with sterile distilled water for 5–10 min and then with sodium hypochlorite solution containing 1% available chlorine, and finally washed with sterile distilled water three to four times. Subsequently, the seeds were transferred to 0.1% sterile agar solution and ca. 80 seeds were resuspended in 1.0 mL of agar solution using a pipette and transferred to petri dishes containing 25 mL of sterile oat meal agar medium (OMA, 4 g/L). Once the seed suspension was completed, each dish was inoculated with one 0.5-cm^3 piece of fungal inoculum placed in the center of the petri dish, and a sterile PDA plot without fungus was also placed as a control referring to Zi et al. (2014). Fungus-inoculated petri dishes were randomly assigned to either a continuous dark treatment (0/24 h, L/D) or a 12-h photo period (12/12 h, L/D) with 1800 lux white fluorescent light at 25.0 ± 1.0 °C. All petri dishes were assessed under a dissecting microscope (Shanghai Bimu Bearing Co Ltd, Shanghai, China), and the exact number of seeds at various stages was recorded for each petri dish after 20, 50, and 90 days. Each experiment was replicated four times and petri dishes were placed in the same growth chamber. The percentages of protocorm (stage 2), seedling (stage 3), and seedling development (stage 4) were recorded for each dish, with contaminated dishes being excluded from the assessment.

Statistical analysis of germination and seedling development

Germination and seedling development were divided into five stages (*Table 1*) as described by Arditti (1967) with slight modification (both rupture of testa and appearance of protomeristem were regarded as stage 2). Seeds were considered germinated once they reached stage 2 to rule out the possibility that embryo swelling because of imbibed water was counted as germination (Rafter et al., 2016). The number

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_97539771

of protocorms (P), seedling formation (S), and seedling development (L) were calculated as a percentage of the total number of seeds (t): P = number/t × 100. Generalized linear model was applied on the effect of treatments. Different day intervals and photoperiod conditions were considered as fixed factors. Protocorm formation, seedling formation, and seedling development were considered as dependent variables. All the data were arcsine transformed to obtain normal distributions. Analysis of variance was applied to find differences in seed germination by the effect of treatments and different days separately. Tukey's multiple range test was applied and the significant differences between treatments were analyzed ($P \leq 0.05$). All the statistical analyses were performed using SPSS version 20.0 software (SPSS Inc., Chicago, USA).

Table 1. *Developmental stages and features of symbiotic seed germination of D. catenatum (modified on the basis of Arditti, 1967)*

Seed germination stage	Description
0	No germination
1	Imbibed seed, swollen and still covered by testa
2	Protocorm formation and development (rupture of testa, appearance of protomeristem = germination)
3	Seedling formation (emergence of first leaf in early stage)
4	Seedling development (Emergence of second leaf and continue development)

Results

Seed baiting to induce protocorms

After 45 days, 25 out of 88 petri dishes were found with seeds germinated to stage 2 and 3, but no seedlings with two leaves (stage 4) were found. From these 25 dishes, 32 developed protocorms with promeristem and 12 seedlings with one leaf (stage 3) were harvested.

Molecular identification of endophytic fungi

Seven fungal strains (labeled SSCDO-1, SSCDO-3 to SSCDO-8) were successfully isolated from the protocorms and seedlings. All sequences of ITS-rDNA were submitted to GenBank with accession number MH348611-MH348617. Using Blast searches in NCBI, seven of the strains were attributed to the three most common orchid mycorrhizal taxa: the sequences of strains SSCDO-1, SSCDO-3, and SSCDO-4 had 98% similarity to uncultured Tulasnellaceae clone PM13 (GQ241803.1); SSCDO-5 was similar to the uncultured Tulasnellaceae clone (KX387600.1) with 99% identity (confirming the allocation of associated fungi in Guangxi by fungal isolation and molecular detection reported by Downing et al. (2017); SSCDO-6 was similar to uncultured Sebacinales (FJ788824.1); SSCDO-7 was close to uncultured Tulasnellaceae clone PM1 (GQ241802.1) and SSCDO-8 matched uncultured *Thanatephorus* (AB712285.1) (*Fig. 2*). Phylogenetic analysis of ITS-rDNA demonstrated that the strains SSCDO-1, SSCDO-3, SSCDO-4, SSCDO-5, and SSCDO-7 formed a clade (clade I; BP = 89; Tulasnellaceae); SSCDO-8 and uncultured *Thanatephorus* AB712285.1 formed a second clade (clade II; BP = 55; *Thanatephorus*); and SSCDO-6 and uncultured Sebacinales FJ788824.1 a third (clade III; BP = 97; *Sebacinales*) (*Fig. 2*). Clades II and III are sister clades, paraphyletic to clade I.

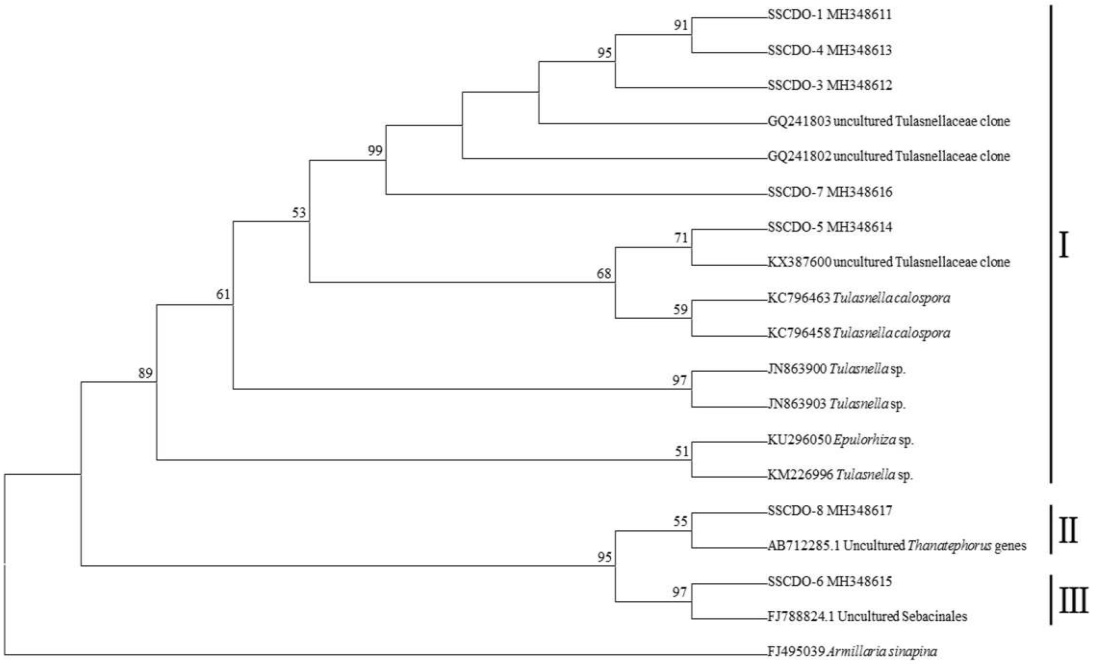

Figure 2. *Consensus tree by neighbor-joining of ITS-rDNA sequences of fungi from protocorms of D. catenatum, related sequences, and FJ495039 (Armillaria sinapina) as the outgroup. Bootstrap values ≥ 50% are shown above the branches. Clades I, II, and II are shown by vertical bars at the right-hand side*

Effect of fungal isolates and photoperiod on D. catenatum germination

Stage 2 − Protocorm formation and development

Different fungal inoculation treatments significantly influenced protocorm formation ($F_{8, 191} = 27.60$; $p < 0.0001$). Protocorm formation was not influenced by time (20, 50, and 90 days) after seed sowing, but it was significantly influenced by photoperiod ($F_{1, 191} = 52.59$; $p < 0.0001$). The interactions treatment × days and photoperiod × days had no significant influence on protocorm formation ($F_{16, 191} = 1.22$; $p = 0.259$); in contrast, the interaction treatment × photoperiod showed a significant variation on protocorm formation ($F_{8, 191} = 3.04$; $p < 0.01$). However, the interaction treatment × days × photoperiod showed no influence on protocorm formation.

Fungal inoculations SSCDO-5 and SSCDO-8 significantly influenced protocorm formation, followed by SSCDO-6 and SSCDO-7 (Tukey's HSD test). The mean protocorm formation after sowing was 44.56 ± 3.08% at 20 days, 42.33 ± 2.85% at 50 days, and 44.56 ± 2.42% at 90 days, with no significant differences between different days ($F_{2, 191} = 0.215$; $p = 0.807$). After 20 days, different treatments showed significant differences in protocorm formation ($F_{8, 57} = 8.052$; $p < 0.0001$), with SSCDO-5 having the most influence followed by SSCDO-1, SSCDO-8, and SSCDO-2. In addition, treatments showed significant differences on protocorm formation after 50 days ($F_{8, 62} = 5.44$; $P < 0.0001$) and after 90 days ($F_{8, 70} = 9.699$; $p < 0.0001$). In particular, treatments SSCDO-8 and SSCDO-5 highly influenced the protocorm formation after 50 and 90 days. Protocorm formation was always improved with 12/12 L/D conditions versus 0/24 L/D conditions (*Fig. 3a*), significantly for most treatments, but not for SSCDO-5 and SSCDO-8 (*Table 3*).

DOI: http://dx.doi.org/10.15666/aeer/1704_97539771

Stage 3 − Seedling formation

Fungal inoculation treatments significantly influenced seedling formation ($F_{8, 191} = 13.19$; $p < 0.0001$), as did days and photoperiod ($F_{1, 191} = 16.82$; $p < 0.0001$ and $F_{1, 191} = 17.86$; $p < 0.0001$, respectively). The interaction treatment × days did not influence the growth of seedling formation ($F_{16, 191} = 1.59$; $p = 0.08$), whereas the interaction treatment × photoperiod significantly influenced seedling formation ($F_{8, 191} = 3.46$; $p < 0.001$), as did the interaction days × photoperiod. However, the interaction treatment × days × photoperiod had no influence on seedling formation ($F_{16, 191} = 1.32$; $p = 0.192$).

Treatment with SSCDO-5 significantly increased seedling formation compared with control and other treatments, followed by SSCDO-6 and SSCDO-8 (Tukey's HSD multiple range test; *Table 2*).

Table 2. *Generalized linear model shows that the effect of treatments (eight fungal strains and control test), different days after seed sowing (20, 50 and 90 days) and photoperiod (0/24 h L/D, 12/12 h L/D) on protocorm formation, seedlings formation and seedlings development of D. catenatum*

Mean seedling formation was 5.01 ± 1.74% at 20 days, 17.36 ± 2.77% at 50 days, and 23.92 ± 2.85% at 90 days after sowing with no significant differences on the production of seedlings in response to different days. In addition, different fungal strains showed significant differences on seedling formation at 20 days ($F_{8, 57} = 43.15$; $p < 0.0001$), at 50 days ($F_{8, 62} = 4.18$; $p < 0.001$), and at 90 days after seed sowing ($F_{8, 70} = 2.098$; $p < 0.0001$). In general, light (12/12 L/D conditions) significantly influenced seedling growth compared with darkness (e.g., for SSCDO-1, SSCDO-3, SSCDO-4, and SSCDO-5), whereas seedling growth was not significantly different for SSCDO-8 (*Table 2*; *Fig. 3b*).

Stage 4 − Seedling development

The fungal strains significantly influenced seedling development ($F_{8, 191} = 10.59$; $p < 0.0001$), and this varied significantly at different times after seed sowing ($F_{2, 191} = 22.95$; $p < 0.0001$). In addition, the photoperiod significantly influenced seedling development ($F_{1, 191} = 39.04$; $p < 0.0001$). Interestingly, the interaction fungal inoculation treatment × days also showed a significant variation on seedling development ($F_{16, 191} = 3.63$; $p < 0.0001$), as did the dual interaction treatment × photoperiod ($F_{8, 191} = 10.59$; $p < 0.0001$). Moreover, the dual interaction days × photoperiod showed significant differences on seedling development and the interaction treatment × days × photoperiod also showed significant differences ($F_{16, 191} = 3.63$; $p < 0.0001$).

In particular, the fungal strain SSCDO-5 significantly influenced seedling development compared with control and other treatments (Tukey's HSD test; *Table 3*). There was no seedling development 20 days after seed sowing, although seedling development was found at 50 days (1.57 ± 0.86%) and 90 days (7.76 ± 1.77%), with significant differences in seedling development at different days after sowing by the effect of all treatments ($F_{2, 191} = 11.45$; $p < 0.0001$). In addition, different fungal strains exhibited significant differences in seedling development at 50 days ($F_{8, 62} = 4.98$; $p < 0.0001$) and at 90 days ($F_{8, 70} = 3.804$; $p < 0.001$) (*Table 2*). Among these, SSCDO-5 significantly increased the seedling development at 50 and 90 days (*Table 3*). Seedling development only occurred under light conditions (12/12 L/D) with the different treatments (*Fig. 3c*); there was no seedling development in darkness.

Discussion

Ex situ baiting isolation

The present study in *D. catenatum* showed that the ex situ baiting technique resulted in the successful isolation of specific symbiotic mycorrhizal fungal strains that effectively induced seed protocorm formation. In our study, after 1.5 months, protocorms and seedlings with one leaf were successfully induced in 0.42% of seeds by ex situ baiting, and compatible and adaptive fungal strains were obtained successfully from host protocorms. This method could be considered for broader application to induce protocorm formation and to isolate mycorrhizal symbionts in other epiphytic orchids.

Phylogeny of symbiotic fungi

The fungi isolated from the protocorms in the present study belong to the families Tulasnellaceae, Ceratobasidiaceae, and Sebacinales. All the fungal isolates belonging to the clades of Tulasnellaceae, Sebacinales, and Thanatephorus had high similarity to fungi from the roots of *D. catenatum* (Xing et al., 2013). Taxa in Tulasnellaceae have often

DOI: http://dx.doi.org/10.15666/aeer/1704_97539771

been found in association with tropical epiphytic and terrestrial orchids (Sathiyadash et al., 2014; Zi et al., 2014; Zhou and Gao, 2016). This study is the first report on symbiotic seed germination in the species *D. catenatum* induced by fungi from the host protocorm origin induced using ex situ baiting techniques but not from roots.

In vitro symbiotic seed germination

Fungal treatment

It has been suggested that in theory any fungal strain isolated from the protocorms of one species may promote seed germination and protocorm formation in that species, and this has been proved experimentally on *D. catenatum* in the present study. The strains SSCDO-1, SSCDO-2, SSCDO-3, SSCDO-4, and SSCDO-7 showed similar effects on protocorm formation and development (*Table 4*; *Fig. 4b*) represented by the fungus SSCDO-4. The percentage of seedlings with one leaf was higher with SSCDO-1, SSCDO-3, and SSCDO-4 than with SSCDO-2 and SSCDO-7, but no significant differences were found with the other fungal strains. Steinfort et al. (2010) found a similar tendency in the germination of *Bipinnula fimbriata* at stage 2, with the fungal strain P2VT-03 showing a significantly higher germination rate than the strains F2VT-02 and F2VT-03, although all of them belonged to the same species, *Tulasnella calospora*; the strain F6VT-02 showed a stronger effect on seed germination at stage 2 than strain F3VC-02 of the same species. Xu et al. (2017) found that a strain of *T. calospora*, Tco2, showed more effective promotion of seed germination and protocorm differentiation in *Epidendrum secundum* than another strain of the same species. Results from the present study also suggested that fungal strains of the same species (Tulasnellaceae) vary in their influence on germination and growth of seeds.

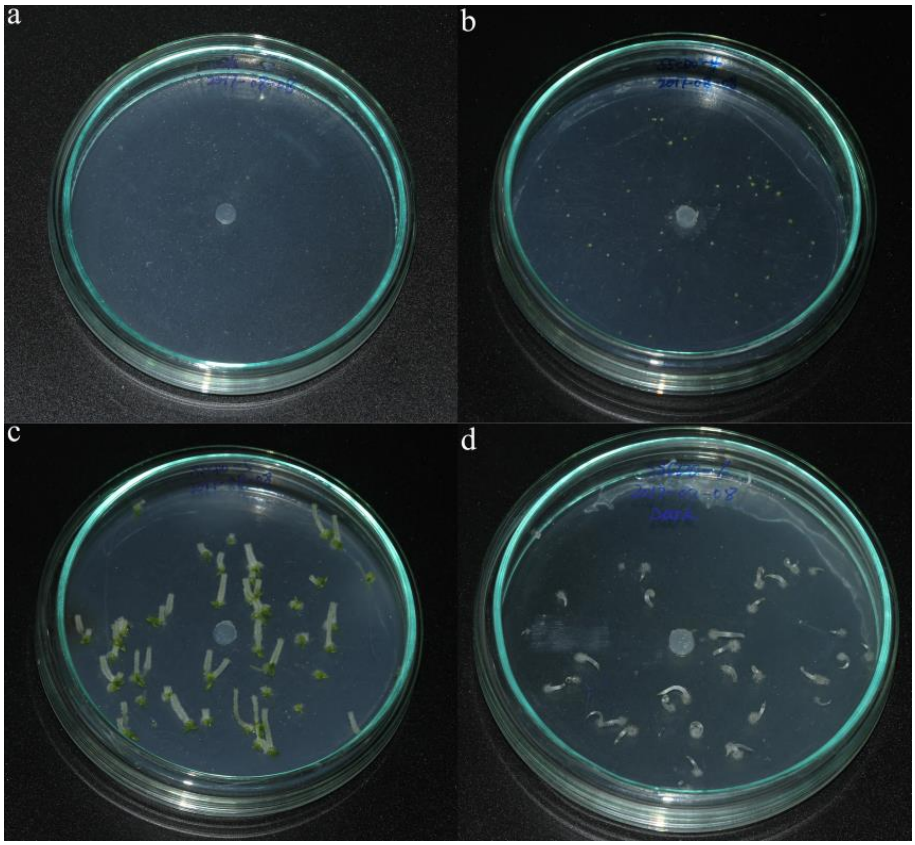

Figure 4. *Symbiotic seed germination of D. catenatum 90 days after sowing.* ***a*** *Control test.* ***b*** *Protocorm formation and seedling formation following inoculation with varying fungal treatments (represented by SSCDO-4) under light conditions.* ***c*** *Seedling development (with SSCDO-5 inoculation) in light conditions.* ***d*** *Abnormal seedlings in dark conditions (represented by SSCDO-6)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_97539771

After 90 days with the control treatment, protocorms had still not formed (*Fig. 4a*); however, after only 20 days of treatment with the fungal strains, protocorms had formed, indicating that fungal inoculation plays a significant role in germination. The fungal strains SSCDO-5, SSCDO-6, and SSCDO-8 significantly influenced the growth of protocorms and seedling formation (one-leaf seedlings) measured at different times after sowing. In particular, SSCDO-5 significantly influenced protocorm formation and seedling development in *D. catenatum* (more so than other fungal strains), promoting the best seedling development and maximum number of seedlings with two leaves and long roots (*Table 4*; *Fig. 4c*). Potentially, then, SSCDO-5 might be of use in efficiently initiating seed germination and promoting further seedling development, and this could be potential for mass seedling propagation in a conservation program.

Table 4. *Effect of fungal inoculation treatment on protocorm formation (%), seedling formation (%), and seedling development (%) on the species D. catenatum under in vitro conditions*

Treatments	Protocorm formation (%)	Seedling formation (%)	Seedling Development (%)
	Mean ± S.E	Mean ± S.E	Mean ± S.E
SSCDO-1	47.6 ± 3.0bc	15.1 ± 3.4abc	2.4 ± 1.1a

CK	0.2 ± 0.2a	0.0 ± 0.0a	0.0 ± 0.0a
ANOVA (F), N = 8, DF = 191	21.0***	7.96***	5.26***

CK = control. Values are given as mean ± S.E. In a column, values followed by a different lowercase letter(s) are significantly different at the 5% level according to Tukey's HSD multiple range test. ***Significance level $P < 0.0001$. The row in SSCDO-5 boldface indicates the significantly higher value on different growth formation as compared to other treatments)

The present results also support the hypothesis that mycorrhizal fungi isolated from protocorms would produce seed germination and advance development to a higher stage, with high compatibility and adaptivity (Sharma et al., 2003). Several previous studies have put forward a similar hypothesis for various terrestrial and epiphytic orchids (Sharma et al., 2003; Sathiyadash et al., 2014; Zi et al., 2014; Wang et al., 2016; Shao et al., 2017).

Days

The different observation days after sowing time play a significant role for the percentage of seed germination, with protocorm formation being higher at 20 and 90 days. Subsequently, the percentage of seedling formation was higher at 50 and 90 days, and while there was no seedling development (two-leaf seedlings) at 20 days, two-leaf seedlings were found at 50 and 90 days after sowing following fungal inoculation

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_97539771

treatment. In addition, protocorm formation had increased at 20 days (mean = 49.63%), at 90 days (mean = 48.07%), and at 50 days (mean = 46.79%) with all treatments. Seedling formation increased only gradually over time, and developed seedlings (two-leaf stage) were only found at 90 days (none at 20 or 50 days), in line with a previous study (Huang et al., 2018). Another study in *D. catenatum* reported seedling development (stage 5) after 12 weeks (84 days) under optimal conditions under the influence of fungal strains (Wang et al., 2011), similar to the findings of the present study, and Tan et al. (2014) also reported that seed germination was higher at stage 3 and lower at stages 4 and 5 under the influence of an effective fungal strain JC-05. Overall, in the present study, while periods of 20 and 50 days after sowing were significant for the formation of protocorm and seedlings during the earlier stages of seed germination, seedling development significantly increased by 90 days under the influence of fungal inoculation treatments.

Photoperiod

In the present study, the response of photoperiod is positive for seed germination and seedling development. There was a significant variability in germination rate under the light photoperiod (12/12 h L/D) with all fungal strains when considering seedlings with two leaves, indicating different degrees of compatibility between seeds and fungal strains. No seedlings were formed in the dark conditions, indicating that light is likely a key ecological factor for protocorm development and seedling formation. Interestingly, a small number of seedlings with one leaf were found under dark conditions, but the seedling development that did occur was not via leaves but via roots (*Fig. 4d*), reflecting results reported in previous studies (Tan et al., 2014; Cui et al., 2012).

Conclusion

Dendrobium catenatum, an epiphytic orchid, is now rare and endangered in China, its population having been reduced by over exploitation for traditional medicine. Consequently, it has become necessary to develop a standard protocol for efficient plant reproduction in situ. This study confirms that symbiotic mycorrhizal fungi (the strains SSCDO-5) support protocorm formation, seedling formation, and sapling development under light conditions as observed at 20-90 days after sowing. Fungal strains of the same species (*Tulasnellaceae spp*.) isolated from protocorms might be more compatible and specific. Performance of strain SSCDO-5 should be tested in the wild when considering direct sowing for reintroduction and conservation. Ex situ baiting techniques for symbiotic seed germination might prove valuable for the conservation of *D. catenatum*, helping in future orchid production, reintroduction in both in situ and ex situ conservation efforts, and under in vitro experimental conditions. We believe that direct sowing of *D. catenatum* seeds inoculated with specific symbiotic fungi might prove successful for reintroduction or orchid plant production, and would encourage sustainable management for traditional medicinal practices.

Acknowledgements. The authors thank Ms. Xiu-Qing Xie for her kind assistance in preparatory laboratory work and symbiotic seed germination in vitro and Dr. Zhi-Yong Liao for his advice on data analysis.

(Received 22nd Mar 2019; accepted 13th Jun 2019)

Abstract. In this study, we investigated the induced defense response and protective effects of onion against *Alternaria porri* by application of salicylic acid (SA) and benzothiadiazole (Bion®) through foliar application and seedling root dipping method in onion for two years under greenhouse conditions. Completely randomized design (CRD) under factorial arrangement was performed with three replicates. Reduction in the disease severity was observed in plants treated with Bion® and SA. Bion® and SA inoculated with the pathogen showed significantly higher PAL, PO, PPO activity, and phenolic contents than inoculated water-treated plants 2 days after the treatment during both years. Increasing trend was observed in disease severity and biochemical contents during the second year. In conclusion, the results of this study provide evidence that application of simple non-toxic chemical solutions like SA and Bion® can control purple blotch of onion by the modification of biochemical attributes.
Keywords: *Bion, salicylic acid, enzymatic activity, foliar application, seedling root dipping*

Introduction

Onion is among the five most valuable vegetable crops in the world (Cramer, 2000). It adds excellent taste to dishes and also has a number of therapeutic properties such as antibacterial, antifungal, anti-inflammatory, antiseptic and antispasmodic effects (Griffiths et al., 2002). Over the world it occupies an area of 4033.93 thousand hectares and production 78.5 million tons (FAO, 2012). In Pakistan, it occupies an area of 135.1 thousand ha, with production of 1763 thousand tons and contribute to the economy of the country (Govt. of Pakistan, 2014-15). Among the onion producing countries China stood first and India second in area and production in the world. Pakistan is on seventh number for production of onion (Aloch et al., 2014).

Overall onion is attacked by sixty six diseases in the world, in which thirty eight are of fungal diseases, ten bacterial, six nematode, three viral and one phytoplasmal disease.

Purple blotch is most destructive one among fungal diseases and cause paramount losses to onion crop (Yadav et al., 2013).

Control of this disease by using disease free seeds, resistant cultivars and fungicidal sprays are successful but have their disadvantages, such as the brief commercial life of resistant cultivars or occurrence of fungicide resistance (Hayes and Johnston, 1971; Leadbeater et al., 1997). Due to these disadvantages, there is a continuous requirement for inducing resistance to plants against the disease. Induced resistance (1R) is a new technology for crop protection that assumed to be much more environmentally sound than traditional practices (Sonnemann et al., 2002).

Several chemicals like 2,6-dichloroisonicotinic acid (INA), Beta-amino butyric acid (BABA), potassium salts, benzothiadiazole and salicylic acid (SA) were documented in induction of SAR in variety of plants against several pathogens of plants (Oostendorp et al., 2001).

The first indication that SA may be associated with plant resistance was given by White (1979), who observed that application of SA in tobacco leaves improved protection from consequent infection by tobacco mosaic virus. Initially, Van Loon (1983) reported the possibility of association between salicylic acid and systemic acquired resistance. Benzothiadiazole (S-methylbenzo-1,2,3-thiadiazole-7-carbothiate, BTH) form a class of chemicals which induce the mechanism of defense in plant (Kunz et al., 1997). Their mode of action include stimulation of systemic acquired resistance downstream of salicylic acid.

Schonbeck et al. (1980) reported that resistance inducers enhance the biochemical that serve as a marker of ISR. This include deposition of lignin, assimilation of phytoalexins, cell wall polymers reinforcement (Thangavelu et al., 2003) and enhancement of enzymes like PPO and PAL (He et al., 2002). Peroxidase involved in papillae formation, hypersensitive response and lignin polymerization (Nicholson and Hammerschmidt, 1992; Bestwick et al., 1998).

So keeping in view the importance of resistance inducers the experiment was planned to assess the impact of Bion® and SA in resistance induction in onion against purple blotch to observe the mechanisms of resistance including enzyme related to resistance, under controlled environment.

Materials and Methods

Enhancement of resistance against the disease

Experiment was conducted during 2015-16 in green house of Department of Plant Pathology, University of Agriculture, Faisalabad, Pakistan. Seeds of Red Imposta (High yield cultivar) were sown, 23rd October and 25th October during 2015-16 respectively, in trays and in green house with temperature kept at 20 ± 2ºC during the day and 18 ± 2ºC at night and transplanted after fifty six days in thirty centimeter pots. *Alternaria porri* culture (*Fig. 1*) was made by isolating it from diseased onion leaves and incubated at 25 ± 1ºC for 15 days. Bion® (125 ppm) and salicylic acid (2 mM) were applied through seedling root dipping method and foliar application against purple blotch of onion. Ten ml of sterile distilled water was then added to each plate and colonies were scraped with a sterile needle. The resulting conidial suspension was diluted to 5×10^4 conidia per ml and inoculated onto leaves and seed-stalks of 110-day-old onion plants using an atomizer. Distilled water was used for Bion® and salicylic acid dissolving regarding desired concentrations (125 ppm and 2 mM)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_97739784

respectively, and then sprayed on entire plants through foliar application (50 ml per seedling) while seedlings were dipped in inducers solution before transplanting in case of seedling root dipping method, two days before inoculation with the pathogen. Plants were kept in a greenhouse after the application of treatments. For controls, the plants were inoculated or un inoculated but sprayed with water. The experiment was repeated twice under greenhouse conditions in 2015 and 2016. Autoclaved pots (20 cm in diameter) were filled with autoclaved clay soil and each pot planted with two seedlings. Three replicates were used, and each replicate consisted of four pots. Disease severity data was collected by following the 0-5 rating scale (Sharma, 1986). Biochemical contents of treated and untreated plants were analyzed after 0, 2, 4, 6, 8 and 10 days by using following procedure.

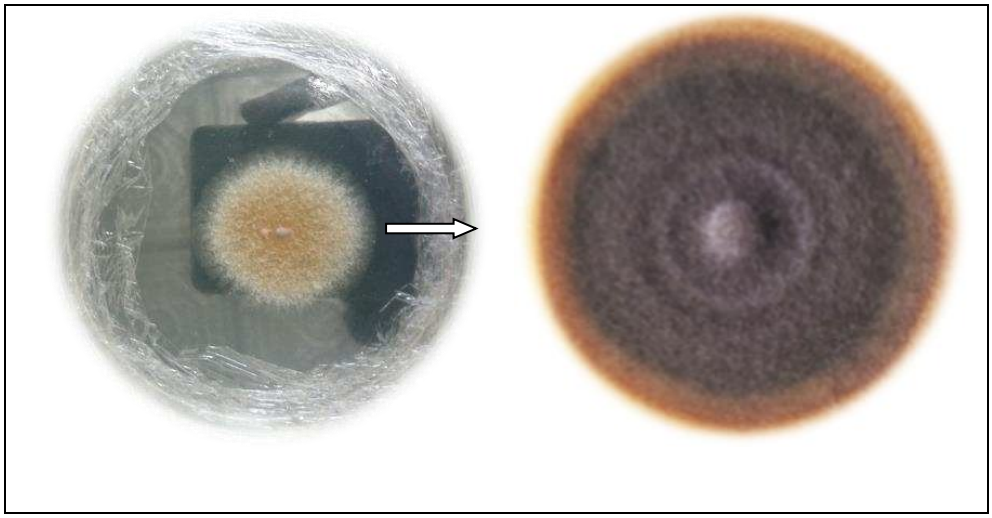

Figure 1. *Pure culture of Alternaria porri*

Data collection

Sample preparation for biochemical analysis

"Samples of leaf tissue (1 g fresh weight) for enzyme extraction were harvested at 0, 2, 4, 6, 8, and 10 days after application for each treatment, weighed and immersed in liquid nitrogen. The frozen leaf segments for each sample were homogenized (1:5 w/v) in an ice-cold mortar using 50 mM potassium phosphate buffer (pH 7.0) containing 1 M NaCl, 1% polyvinylpyrrolidone, 1 mM EDTA and 10 m M β-mercaptoethanol. The homogenates were centrifuged at 17,000 g for 20 min at 4°C. The supernatant (crude enzyme extract) was collected and divided into 1.5 ml portions. Protein concentrations were determined using bovine serum albumin as a standard according to Bradford (1976)".

Activity of peroxidase (PO) was analyzed by following the protocol of Urbanek et al. (1991), polyphenol oxidase (PPO) was measured according to the Gauillard et al. (1993) method. In case of phenylalanine ammonia-lyase (PAL) activity was assessed by using the Nagarathna et al. (1993) technique and Malick and Singh (1980) method was used for phenolic contents in the onion leaves.

DOI: http://dx.doi.org/10.15666/aeer/1704_97739784

Statistical analysis

"Data collected from each experiment were analyzed using Statistix 8.1 software. Least significant difference (LSD) test at 5% probability level was applied to compare the treatment means".

Results

Effect of resistance inducers on disease severity (%) of onion leaf

Resistance inducers *i.e.* Bion and salicylic acid (Ch) applied through seedling root dipping and foliar application methods (M) significantly ($p \leq 0.05$) minimized the severity (%) of disease in onion plants during both years. During first year reduction in disease severity was up to 24.53% and 25.92% during 2nd year. In comparison for days (D) at 5th and 15th day minimum reduction in disease severity (37.24%, 40.12%) was observed during both years. During 2015, maximum reduction in severity of disease was observed in case of foliar application as compared to seedling root dipping. Bion showed maximum reduction in disease severity (21.55%) while salicylic acid showed (28.26%) as compared to control which exhibited (44.94%) disease severity. In case of interaction between Ch × D × M a non-significant behavior was observed with respect to disease severity, whereas, D ×M, Ch × D and Ch × M showed their significant impact in reduction of purple blotch severity (%) during both years (*Table 1*).

Table 1. *Impact of Bion and Salicylic acid applied through foliar and seedling root dipping methods on severity (%) of disease at different days*

Factors	Disease Severity (%)

Impact of inducers application through towards peroxidase (PO) activity (change in absorbance/min/mg of protein)

Peroxidase activity was significantly ($p \leq 0.05$) increased after the application of Bion and salicylic acid through seedling root dipping and foliar application during 2015-16. Peroxidase activity was maximum at day 10 (3.16) and minimum (0.69) when

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_97739784

resistance inducers applied (0 day). Foliar application of resistance inducers increased the activity of peroxidase (1.96) over seedling root dipping (1.84). Peroxidase activity in inoculated plants was higher over plants without inoculation. Maximum peroxidase activity was found in plants on which Bion + *A. porri* (2.11) was applied as compare to plants where salicylic acid + *A. porri* (1.95) was applied. High peroxidase activity (2.02) was observed where Bion was applied followed by salicylic acid treated plants (1.86). Control plants showed minimum peroxidase activity (1.68). In 2016, similar but increase in peroxidase activity was observed (*Table 2*).

Ch × M ($p \leq 0.05$)	NS	NS	*	NS	NS	NS	NS	NS
Ch × D × M ($p \leq 0.05$)	NS	NS	*	**	**	NS	NS	NS

PAL = Phenylalanine ammonia lyase; PH = Phenolics; PO = Peroxidase; PPO = Polyphenol oxidase. Any two means within a column followed by same letters are not significant at $p \leq 0.05$. * = Significant at $p \leq 0.05$; ** = Significant at $p \leq 0.01$; NS = Non-significant

During 2015, interaction between Ch × D × M expressed significant increase in peroxidase activity (*Fig. 2*), whereas, interaction between these three factors was non-significant during the year 2016. Interaction between Ch × D showed significant increase in peroxidase activity during both years, whereas, D × M interaction was non-significant with respect to peroxidase activity but this interaction was significantly impacted during 2016.

Impact of inducers application through towards polyphenol oxidase (PPO) activity (change in absorbance/min/mg of protein)

Polyphenol oxidase activity was significantly ($p \leq 0.05$) increased after the application of Bion and salicylic acid through seedling root dipping and foliar

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_97739784

application during 2015-16. Polyphenol oxidase was maximum at day 10 (1.34) and minimum (0.39) when resistance inducers applied (0 day). Foliar application of resistance inducers increased the activity of Polyphenol oxidase (0.98) over seedling root dipping (0.88). Polyphenol oxidase activity in inoculated plants was higher over plants without inoculation. Maximum polyphenol oxidase activity was assessed in plants on which Bion + *A. porri* (1.09) was applied as compare to plants where salicylic acid + *A. porri* (0.98) was applied. High polyphenol oxidase activity (1.03) was observed where Bion was applied followed by salicylic acid treated plants (0.90). Control plants showed minimum polyphenol oxidase activity (0.74). In 2016, similar but increase in polyphenol oxidase activity was observed. Interactive effect of Ch × D × M exhibited non-significant behavior with respect to polyphenol oxidase activity during both years, whereas, Ch × D showed significant increase in polyphenol oxidase activity during 2015-16. During 2016, D × M interaction significantly increased the polyphenol oxidase activity but this interaction was non-significant during 2015 (*Table 2*).

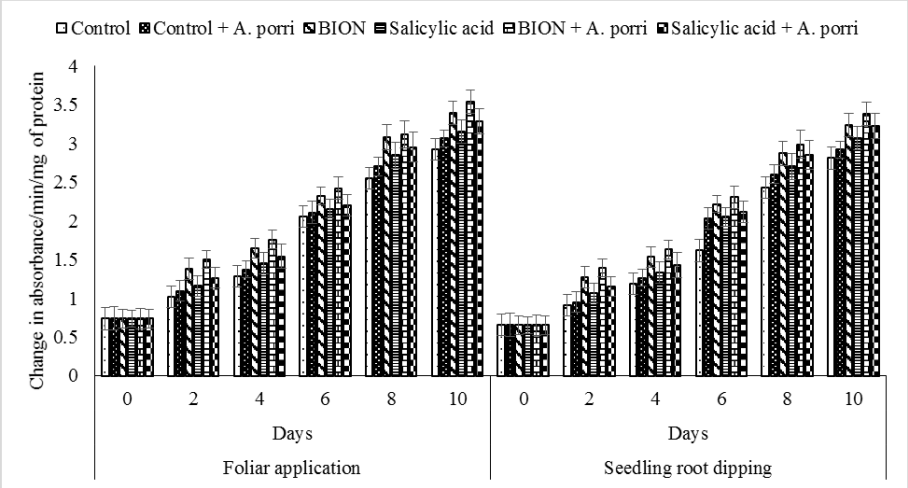

Figure 2. *Interaction between chemicals, days and application method on peroxidase activity as influenced by the various resistance inducers treated through different methods*

Impact of inducers application through towards phenylalanine ammonia lyase (PAL) activity (µmol of cinnamic acid/min/mg of protein)

Phenylalanine ammonia lyase activity was significantly ($p \leq 0.05$) increased after the application of Bion and salicylic acid through seedling root dipping and foliar application during 2015-16. Phenylalanine ammonia lyase was maximum at day 10 (19.24) and minimum (2.42) when resistance inducers applied (0 day). Foliar application of resistance inducers increased the activity of phenylalanine ammonia lyase (12.59) over seedling root dipping (10.60). Phenylalanine ammonia lyase activity in inoculated plants was higher over plants without inoculation. Maximum phenylalanine ammonia lyase activity was found in plants on which Bion + *A. porri* (16.93) was applied as compare to plants where salicylic acid + *A. porri* (13.92) was applied. High Phenylalanine ammonia lyase activity (15.29) was observed where Bion was applied followed by salicylic acid treated plants (12.01). Control plants showed minimum phenylalanine ammonia lyase activity (8.98). In 2016, similar but increase in phenylalanine ammonia lyase activity was observed (*Table 2*). Phenylalanine ammonia

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_97739784

lyase activity was increased significantly in case of interaction between D × M during 2016, whereas, non-significant behavior of mentioned interaction was observed during 2015. Ch × D interaction impacted positively in increasing of phenylalanine ammonia lyase activity during both years, whereas, non-significant behavior was observed in case of Ch × M. Combined interactive impact of all three factors was non-significant during both years (*Table 2*).

Impact of inducers application through towards total phenolics (µm/g of plant tissues)

Phenolic contents were significantly ($p \leq 0.05$) increased after the application of Bion and salicylic acid through seedling root dipping and foliar application during 2015-16. Phenolic contents were maximum at day 10 (55.54) and minimum (8.39) when resistance inducers applied (0 day). Foliar application of resistance inducers increased the phenolic contents (33.78) over seedling root dipping (27.59). Phenolic contents in inoculated plants were higher over plants without inoculation. Maximum phenolic contents were observed in plants on which Bion + *A. porri* (47.14) was applied as compare to plants where salicylic acid + *A. porri* (33.26) was applied. High phenolic contents (40.31) were observed where Bion was applied followed by salicylic acid treated plants (31.42). Control plants showed minimum phenolic contents (26.13). In 2016, similar but increase in phenolic contents were observed (*Table 2*). Interaction of all three factors (Ch × D × M) positively increased the phenolic contents during both years (*Fig. 3*). In the same way D × M and Ch × D showed significant enhancement of phenolic contents in both years, whereas, these contents were significantly impacted during 2015 in case of interaction between Ch × M and non-significant in the year 2016.

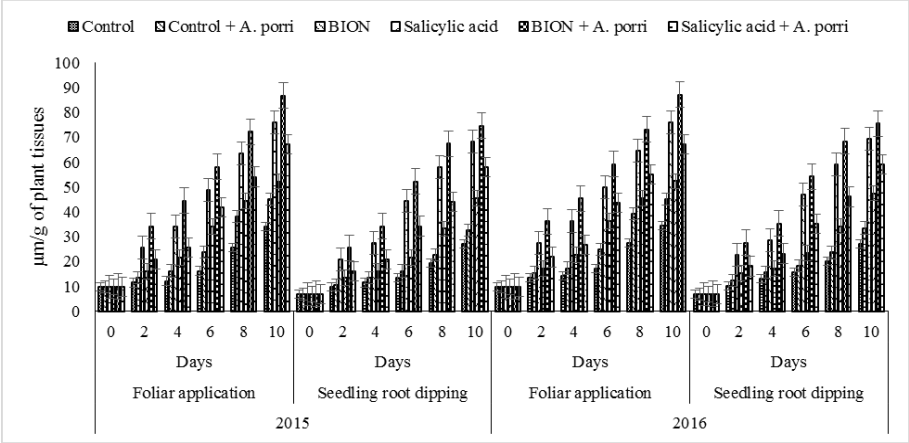

Figure 3. *Interaction between chemicals, days and application method on total phenolics as influenced by the various resistance inducers treated through different methods*

Discussion

Present study showed that Bion® and Salicylic acid application minimized the purple blotch severity in onion plants up to 10 days after plants that were inoculated with *A. porri* (*Table 1*). Several reports have been documented regarding the efficiency of Bion® and Salicylic acid against fungal and bacterial diseases (Ishii et al., 1999; Baysal et al., 2005). These results are consistent with the findings of Abo-Elyousr et al. (2009)

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_97739784

who observed the reduction in severity of stemphylium blight in onion after application of salicylic acid. Abo-Elyousr et al. (2008) observed the same results in case of Bion®. Achuo et al. (2004) found that rustication of *Botrytis cinerea* infection on tomato was achieved after Bion® treatment, and those of the findings of Elmer (2006), who observed the suppression of Fusarium wilt of cyclamen in greenhouse. Mosa (2002) reported that SA at the rate of 1 mM reduce the severity of rice blast.

From the literature it was obvious that presence of Polyphenoloxidase (PPO), Phenylalanine ammonia-lyase (PAL), Peroxidase and total Phenolic contents is necessary because their role in systemic acquired resistance in different plants (He et al., 2002).

Foliar application of Bion® and SA significantly enhanced the PO, PPO, PAL and total Phenolics at all sampling times as compared to seedling root dipping, the highest level at ten days after application (*Table 2, Fig. 2 and Fig. 3*). These results are in line with Abo-Elyousr et al. (2009) who observed the increase in PO activity when onion plants were inoculated with *Stemphylium vesicarium* two days after application of SA. Abo-Elyousr et al. (2008) observed similar results in case of Bion® in onion. Schneider and Ullrich (1994) found increase in PO activity in cucumber and tobacco leaves after treatment with SA. Mcghie et al. (1997) also observed increased in activity of PO in sugarcane cells treated with an elicitor derived from *Pachymetra chaunorhiza*. Significant increase in the activity of PO helped to achieve enhanced resistance against *Clavibacter michiganensis* in tomato plants treated with acibenzolar-S-methyl (ASM) (Baysal et al., 2003). PO activity increased as systemic resistance enhanced in plants against a variety of pathogen (Baysal et al., 2005) which induced the numerous mechanisms of defense in plants like biosynthesis of lignin, cell walls oxidative cross linkage and generation of reactive oxygen species (Bestwick et al., 1998). Enhancement in activity of PO was found in soybean plants sprayed with benzothiadiazole (Nafie and Mazen, 2008). Karthikeyan et al. (2009) reported increased PO activity in black gram exogenously applied SA (100 ppm) and BTH (100 ppm) providing resistance against urdbean leaf crinkle virus. Farouk and Osman (2012) also observed enhanced PO activity in beans species treated with SA and methyl ester of jasmonic acid.

Abo-Elyousr et al. (2009) observed the increase in PPO activity when onion plants were inoculated with *Stemphylium vesicarium* two days after application of SA. Abo-Elyousr et al. (2008) also observed similar results in case of Bion® in onion. Last step of lignin and oxidative phenols was catalyzed by PPO (Baysal et al., 2005). "Polyphenol oxidase (PPOs) catalyzing the oxygen dependent oxidation of phenols to quinines are ubiquitous among angiosperms and assumed to be involved in plant defense against pests and pathogens (Yedidia et al., 2003)".

PAL is the first enzyme of the phenylpropanoid pathway, which synthesizes various phenolic compounds (Tower and Wat, 1979). PAL activity is associated with biosynthesis of various compounds including SA in the defense system of plant (Mauch-Mani and Slusarenko, 1996). These results are in line with Abo-Elyousr et al. (2009) who assessed the enhanced activity of PAL when onion plants were inoculated with *Stemphylium vesicarium* two days after application of SA. Abo-Elyousr et al. (2008) observed similar results in case of Bion® in onion. Chakraborty et al. (1993) observed increased PAL activity in *B. napus* after 12 hrs of *Leptosphaeria maculans* inoculation. Nighat et al. (2001) also observed increased PAL activity in chickpea cultivars inoculated with *Ascochyta rabiei*. Tian et al. (2006) observed that elicitors significantly enhanced the activity of PAL and minimized the incidence of *A. alternata*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_97739784

in *Pyrus pyrifolia*. Raju et al. (2008) observed increased PAL activity in shoots of resistant cultivar of chickpea (*Cicer arietinum* L.) than susceptible cultivar when treated with SA and Spermine against *Fusarium oxysporum*. Jayalakshmi et al. (2009) reported increased PAL activity in the roots of chickpea inoculated with biocontrol agent, *Trichoderma harzianum*. Rajab et al. (2009) observed increased PAL activity in *Sesamum prostratum* calli challenged with *Fusarium oxysporum*. Abdel-Monaim et al. (2011) observed that soybean seeds treated with Benzothiadiazole + humic acid enhanced the PAL activity providing resistance against Fusarium wilt disease. Mandavia et al. (2012) studied the effect of foliar spray of brassinolide (10 and 15 ppm) and SA (300 and 500 ppm) on groundnut and observed that 500 ppm SA was most effective in induction of PAL activity.

Phenolic contents enhanced in case of Bion + *A. porri*, up to 10 days, applied through foliar application (*Table 2, Figure 2*). Increased activity showed that strong correlation may exist between resistance level and phenolic contents (Hahlbrock and Scheel, 1989). Results of this study consistent with Abo-Elyousr et al. (2009) who observed the increase in total Phenolics when onion plants were inoculated with *Stemphylium vesicarium* two days after application of SA. Abo-Elyousr et al. (2008) observed similar results in case of Bion® in onion. Stadnik and Buchenauer (2000) observed the enhancement of PAL activity and accumulation of cell wall-bound phenolic compounds in BTH treated wheat plants. Anttonen et al. (2003) observed increased level of two flavanols, i.e., quercetin and kaempferol in BTH treated berries under field conditions. Katoch (2005) observed increased o-dihydroxy phenol content in pea plants sprayed with 5 mM SA compared to control plants. Karthikeyan et al. (2009) reported a 2-fold increase in the accumulation of total phenol content in black gram plants treated with SA (100 ppm) and BTH (100 ppm). “By summing up the finding of the research the application of Bion is very helpful in reducing the disease severity in the onion as compared to the SA. However, improvement in the defense related attributes by the modulation of enzymatic activities was noticed in case of Bion + *A. porri* applied through foliar feeding as compared to the seedling root dipping method during both years”.

Conclusion

Results of present study showed that Bion could be non-hazardous towards environment and low cost approach towards mentioned malady controlling programs. Foliar application of Bion + *A. porri* enhanced the resistance through increased biochemical attributes than seedling root dipping against *A. porri* during study period but still further investigation is required under field condition for the endorsement of application strategies of resistance inducers for achieving the productive success in onion crop.

SSR ANALYSIS OF SOME SYNONYMS AND HOMONYMS OF GRAPE CULTIVARS (*VITIS VINIFERA* L.) GROWING IN SOUTHEASTERN TURKEY

KARATAŞ, H.

Dicle University, Agriculture Faculty, Horticulture Department, 21280 Diyarbakır, Turkey (e-mail: hkaratas@dicle.edu.tr; phone: +90-412-248-8509)

(Received 26th Mar 2019; accepted 13th Jun 2019)

Abstract. The goal of this study was to analyze the genetic diversity of grape cultivars growing in Diyarbakır and Şanlıurfa by performing SSR molecular identification of the synonymous and homonymous genotypes of 21 cultivars growing in these two regions to investigate the homonyms (*Vitis vinifera* L. cvs.). Microsatellite analysis was performed using a minimal standard SSR marker set involving 7 highly polymorphic loci (VVS2, VVMD5, VVMD7, VVMD27, VrZAG47, VrZAG62, and VrZAG62). Mean number of alleles per locus was 7.14 (range, 7-9), with the highest number of alleles detected in VVS2 and the lowest in VVMD7, VVMD27. The expected and observed heterozygosity were 0.70 and 0.69, respectively. The dendrogram indicated 3 distinct groups, each of which involved several subgroups. A total of 5 synonyms and 10 homonyms were identified for the 21 genotypes.
Keywords: *Vitis vinifera L., grape cultivars, DNA extraction, synonym, homonym, dendrogram*

Introduction

Diyarbakır and Şanlıurfa provinces are located in Southeastern Turkey where viticulture is widely performed. Grapevine is a well-known perennial garden plant well adapted to these regions. Some preliminary surveys and genomic studies have revealed more than 70 grape cultivars growing in these two regions. Moreover, these two regions not only are well-known for viticulture but also are among the regions with the highest grape production in Turkey. Nevertheless, there is little or no information regarding the exact cultivar-based vineyard capacity of these regions.

The use of different regional names for grape cultivars results in major problems and confusion regarding the correspondence between these names and those used in studies and those used in each phase of production. However, these problems and confusion can be eliminated by the administration of molecular markers of polymorphism.

The aim of this study was to analyze the genetic diversity of grape cultivars growing in Diyarbakır and Şanlıurfa by performing molecular identification of the genotypes of cultivars growing in these two regions and to investigate the homonyms used for the 21 distinct cultivars (*Vitis vinifera* L. cvs.) previously identified in these regions using the SSR technique. Simple Sequence Repeats (SSR) is a well-known molecular marker which has been commonly used for the identification of cultivars and the determination of synonyms and homonyms of grape genotypes (Thomas and Scott, 1993; Bowers et al., 1996; Meredith et al., 1996; Sefc et al., 1997, 1999; Meredith, 2001; Riaz et al., 2002; Fatahi et al., 2003; Grando et al., 2003; Hvarleva et al., 2004; Riaz et al., 2004; Adam-Blondon et al., 2004; Zulini et al., 2005; Costantini et al., 2005; Di Vecchi Staraz et al., 2006, 2009; Şelli et al., 2007; Bodor et al., 2010; Cipriani et al., 2010; Ocete et al., 2011; De Andres et al., 2011; Garcia-Munoz et al., 2012; Emanuelli et al., 2013; Alifragkis et al., 2015; Maletic et al., 2015; Biagini et al., 2016; Li et al., 2017; Zequim Maia et al., 2018; Van Heerden et al., 2018).

Materials

Molecular analysis was conducted on 21 grapevine genotypes including 9 cultivars collected from Diyarbakir Province and its districts (D), 8 cultivars collected from Şanlıurfa Province and its districts (Ş) and 4 genotype samples of the cultivars that had been previously transplanted to the Tekirdağ National Germplasm Repository Vineyard (TD, TŞ) (*Figure 1*).

Figure 1. *Provinces where the grapevine genotypes collected from Turkey*

One-year-old seedlings with 3-5 buds were collected from each genotype and were planted in polyethylene tubes filled with a 2:2:1 mixture of perlite, turf, and powder and then germinated in greenhouse conditions until the buds were rooted. DNA extraction was performed with the fresh leaves of these buds, as described by (Lodhi et al., 1994).

Methods

In order to allow a comparison among internationally grown homonymous varieties, a minimal standard SSR marker set was employed (This et al., 2004), which includes 7 highly polymorphic loci as follows: VVS2, VVMD5, VVMD7, VVMD27, VrZAG47, VrZAG62, VrZAG79 (*Table 1*).

DNA amplification was carried out using GeneAmp PCR System 9700 with EU-Applied Biossystems, followed by PCR optimization for each cultivar. PCR amplification was achieved using a reaction volume of 20 µl containing 5 µl of DNA (10 ng/µl), 2 µl of 10X Buffer (Qiagen), 1.2 µl of Mg Cl2 (Qiagen), 0.6 µl of dNTP (10mM), 1 µl of primer (25 µM) 1,1 µl of primer 2 (25 µM), 0.2 µl of GoldTaq (0.5 U), and 9 of µl distilled water. Touchdown PCR was carried out using the following cycling conditions: 95°C for 10 min, 94°C for 30 s, and 52°C for VVS2, VVMD5, and VVMD7, 58°C for VVMD27, 55°C for VrZAG47, and 62°C for VrZAG62 and VrZAG79 for 30 s each, based on the rate of primer annealing, with a decrease of 0.2°C/cycle. After completing 25 cycles, additional 15 cycles were administered with a reduction of 5°C from the primer annealing temperature, finally followed by holding at 72°C for 40 min.

To understand whether amplification occurs for each fragment in each locus, at least 10 fragments typifying each locus were placed on agarose gel. After viewing the amplification, the amplified fragments were subjected to sequencing using ABI Prism

Genetic similarity between the 21 genotype samples characterized by 7 loci was analyzing using the Microsat software (Minch et al., 1995) and the genetic parameters (number of alleles per locus, allele frequency, expected heterozygosity, observed heterozygosity, parentage, null allele frequency, and probability of identity) were analyzed using the IDENTITY 1.0 software (Wagner and Sefc, 1999). The dendrograms were formed and viewed using the NTSys software (version 2.02g, Exeter Software, Setauket, NY). Clustering analysis was carried out using the UPGMA method (Unweighted Pair-Group Method using Arithmetic means).

Result and Discussion

Data regarding the molecular analysis of the 21 genotype samples characterized by 7 loci were presented in *Table 2* in the form of peak levels and the number of alleles and basepair per locus.

The SSR analysis indicated a total of 50 alleles for the 21 genotype samples obtained from Diyarbakır, Şanlıurfa, and the Tekirdağ National Germplasm Repository Vineyard. *Table 3* presents the number of alleles and the expected and observed heterozygosity for these genotypes. Mean number of alleles per locus was 7.14, which was reported to be 9.6, by Borrego et al. (2001) who analyzed 406 accessions characterized by 8 microsatellite markers, 11.4 by Fatahi et al. (2003) who analyzed 62 genotypes characterized by 9 microsatellite markers, 8.1 by Hvarleva et al. (2004) who analyzed 74 accessions characterized by 9 microsatellite markers, 9.1 by Akkak et al. (2005) who analyzed 60 local cultivars characterized by 12 microsatellite markers, 11.9 by Vouillamoz et al. (2006), who analyzed 116 accessions characterized by 12 microsatellite markers. Of these studies, the ones that identified higher mean numbers of alleles compared to that of our study were carried out with higher numbers of genotypes that also showed greater variation compared to those in our study. However, the studies conducted by Crespan and Milani (2001), Dangl et al. (2001), Hvarleva et al. (2004) and Costantini

DOI: http://dx.doi.org/10.15666/aeer/1704_97859793

et al. (2005) were carried out with lower numbers of genotypes and therefore detected lower mean numbers of alleles compared to that of our study (*Table 3*). On the contrary, although Fatahi et al. (2003) and Akkak et al. (2005) analyzed a smaller variety of genotype samples, the two studies identified greater mean numbers of alleles compared to that of our study.

D: Diyarbakır Province; *T:* Tekirdag Province (National Germplasm Repository Vineyard); *Ş:* Sanlıurfa Province; *TD:* Tekirdag National Germplasm Repository (studied cultivars from Diyarbakır); *TŞ:* National Germplasm Repository (studied cultivars from Sanliurfa)

Microsatellite markers used in our study, the most polymorphic marker was VVS2 (9 alleles) and the lowest were VVMD7 and VVMD27 (7 alleles) (*Table 3*). Similarly, previous studies also indicated that VVS2 the most polymorphic marker, followed by VVMD5 and VVMD27 (9 alleles), and VVMD7, VrZAG62, and VrZAG79 (7 alleles) (López et al., 1999; Borrego et al., 2001; Lefort and Roubelakis-Angelakis, 2001; Fatahi et al., 2003; Martín et al., 2003; Núñez et al., 2004). In our study, the expected heterozygosity per locus ranged from 0.47 and 0.80, with lowest expected heterozygosity detected in VVMD27 and the highest in VVS2. However, no significant difference was found between these two values, implicating that the cultivars analyzed in our study were highly heterozygous. In contrast, the observed heterozygosity detected in our study was lower than those reported in the literature (Sefc et al., 2000; Dangl et al., 2001; Fatahi et al., 2003; Aradhya et al., 2003; Costantini et al., 2005; Vouillamoz et al., 2006).

Clustering analysis was performed based on the proportion of shared alleles between the cultivars collected from Diyarbakır and Şanlıurfa. The dendrogram indicated 3

DOI: http://dx.doi.org/10.15666/aeer/1704_97859793

distinct groups, each of which involved several subgroups. The dendrogram demonstrated that the genotypes of the cultivars obtained from these two regions were not completely dissimilar but showed close relationship with each other (*Figure 2*).

Table 3. *Number of alleles per locus, He, Ho, and PI*

Marker	Number of alleles	He	Ho	PI
VVS2	9	0.80	0.82	0.78
VVMD5	7	0.78	0.82	0.75
VVMD7	6	0.64	0.82	0.59

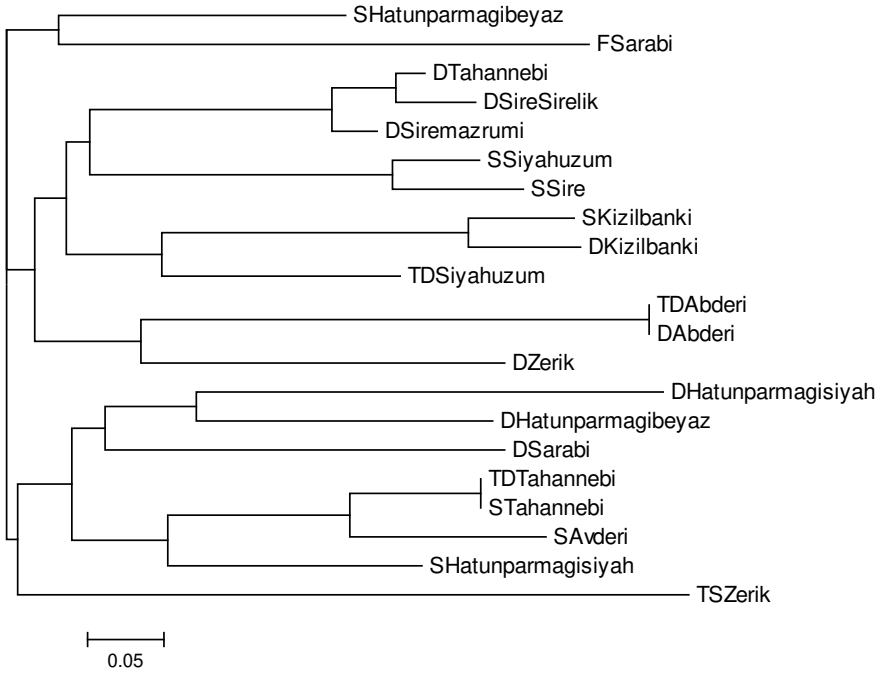

Figure 2. *Dendogram of 21 grape cultivars (Diyarbakır-Şanlıurfa) based on similarity index from SSR data*

The dendrogram indicated that only 6 out of the 17 cultivars sampled from Diyarbakır and Şanlıurfa were classified as homonyms or as cultivars with highly similar names (i.e. clustered in the same group on the dendrogram). However, 2 out of the 4 cultivars sampled from the Tekirdağ National Germplasm Repository Vineyard were found to have dissimilar names (i.e. not clustered in the same group on the dendrogram). The dendrogram also revealed that some of the cultivars with the same name were genetically not identical, which suggests that some of the grape cultivars growing in these regions might develop different genetic traits over time due to the different ecological conditions they grow in. Accordingly, the overwhelming presence of homonyms used for grape

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_97859793

genotypes is a major problem for the viticulture in Turkey. The extent of this problem is well elucidated in the present study.

The molecular analysis indicated that 5 synonyms and 10 homonyms were identified for the 21 genotypes analyzed with 7 microsatellite markers based on the proportion of shared alleles among the genotypes (*Table 3*). Nevertheless, no clear information was available as to which homonym represented the real name of each genotype.

Table 4. *Synonyms and homonyms identified for the genotype samples obtained from Diyarbakır and Şanlıurfa*

The microsatellite analysis revealed a total of 13 distinct cultivars for the 21 genotype samples. This finding implicates that the gene sources of the cultivars growing in these two regions should be protected. Moreover, it was also revealed that the 7 loci used in our study were highly appropriate for genetic analysis of grape cultivars and the identification of synonyms and homonyms.

Conclusion

A high level of allelic polymorphism was found between the cultivars that were expected to have dissimilar names and between the cultivars that were expected to have similar names. In our study it was observed that the level of detected polymorphism is highly can be influenced by the source materials. This differentiation of nomenclature could be attributed to several conditions. First, the cultivars with the same names might have been initially genetically identical but later grown in different ecological conditions for long years and thus might have become genetically dissimilar and this differentiation might have been further intensified through the use of different names for the cultivars transplanted to the Tekirdağ National Germplasm Repository Vineyard. Secondly, this differentiation could be associated with the production of these cultivars for constant vegetative propagation and the somatic mutations induced by environmental factors. Turkey is home to numerous grape cultivars with the same or different names as a result of a long-standing viticulture tradition in Anatolia dating back to 7,000-8,000 years ago. To protect this genetic potential, devising a rational nomenclature and identifying the relationships among these cultivars by using DNA-based markers is highly essential.

ANALYSIS OF PLANT SPECIES USED IN URBAN OPEN SPACES: THE TRABZON CASE

TARAKCI EREN, E.

Department of Landscape Architecture, Karadeniz Technical University, Trabzon, Turkey
(e-mail: eminem_tarakci@hotmail.com; phone: +90-543-818-4642)

(Received 26th Mar 2019; accepted 13th Jun 2019)

Abstract. The implementation phase of the present study was conducted in 3 stages. In the first stage, the plant material used in the open green spaces in the urban center of Trabzon province was analyzed and plant inventory was investigated in these spaces to determine the species, characteristics and intended use of the plants. Thus, it was determined that 129 plant taxa were used in Trabzon public open green spaces. Forty-two taxa were indigenous to Turkey and 87 were exotic. It was identified that 34 were in the gymnosperm plant group and 95 were in angiosperm plant group. It was identified that 21 taxa were highly prevalent (5) in urban open green areas, 24 taxa were very prevalent (4), 35 taxa were moderately prevalent (3), 22 taxa were less prevalent (2), and 27 taxa were not prevalent (1). In the second stage, the objectives of planting and planting designs were investigated. It was determined that the plants were used for both aesthetic and functional purposes in these areas, but their aesthetic use was more common. In the third stage, the occupant satisfaction levels for the planting designs in these urban open green spaces were determined using a survey conducted with the occupants.
Keywords: *plant taxa, planting design, plant use, aesthetic and functional plant design, Trabzon, Turkey*

Introduction

Turkey is one of the richest countries in indigenous vegetation. The presence of Mediterranean, Iranian-Turanian and European-Siberian floristic regions in Anatolia and their fusion in certain areas are the main reasons for this wealth (Davis, 1965-1988). Furthermore, diverse climate, and topographic, geological and geomorphological diversity, the presence of various aquatic environments such as seas, lakes and streams may be the other factors that affect herbaceous and woody plant diversity in Turkey (Turkmen, 1987; Özer et al., 2009). The most important factor is the presence of several topographic and geological structures in the country. Turkey, with around 9,000 plant species and 3000 endemic plants, is among the countries with the richest flora in its climate zone.

The abundant plant diversity in Turkey expands the choices in plant use. Plants are used for a wide variety of aesthetic and functional purposes (Tarakci Eren and Var, 2016). Esthetically they have the potential of creating positive perceptions about the location due to their properties such as the fruits, flowers and color, their two or three-dimensional views due to planting design aspects such as lighting, shadows and reflections, providing color, texture and form aesthetics due to seasonal changes, providing aesthetics images with branches and barks, harmonic and contrast views created with other landscape elements, creating focus on one element, and the potential of decorative features due to the beauty of structural and vegetal properties (Tarakci Eren et. al., 2016; Tarakci Eren et. al., 2017).

Functionally, they are used to create spaces, hierarchy in space, to emphasize structure in landscapes, to relate and connect various objects and spaces, to strengthen the topographic structure, to soften structural landscape, to create perceptual effects, for example, to make the space look more spacious, to create vistas, to provide inter-spatial

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_97959811

transition, to create attraction, to create a signal effect, to orient, to emphasize, to create focus, to allow the space to acquire character, to symbolize, to limit and create a border, to screen, to provide privacy and a habitat for the fauna and flora, to prevent erosion, avalanche and landslides, to reduce dust in the air and prevent noise, to balance the moisture and temperature, and to reduce the intensity of light in urban areas (Tarakci Eren et. al., 2018). Furthermore, objectives such as improvement of landfills, providing a comfortable and safe journey on highways etc. could be listed (Lorenz, 1975; Cepel, 1988; Ürgenç, 1990; Walker, 1991; Walker, 1991; Braun and Fluckiger, 1998; Beckett et al., 1998; Novak et al., 2000; Tarakci Eren et. al., 2017).

With the transformation of urban open green spaces into built areas, unplanned or uncontrolled changes have led to the destruction and fragmentation of natural urban spaces. This forced the inhabitants to live under adverse environmental conditions and experience psychological, recreational and social problems. Today, natural and cultural green spaces are replaced by masses of buildings. The decrease in open green species, especially in the cities, leads to the deterioration of the urban ecological balance (Akpınar et al., 1992). In order to eliminate these problems, environmental planning is prioritized in urban spaces. Especially, the plants are very important in the design of relevant open-green spaces (Erenberk, 1992). Plants attract individuals and animals with their flowers, leaves, trunks, fruits and fragrances (Sakıcı, 2009). Plants undertake the tasks of enclosure, bordering, creating personal spaces, softening, revitalizing, filtering the sun, cleaning the air, providing a habitat for birds and introducing the nature to human life (Tyson, 1998). The potential benefits of living in contact with nature were explored by scholars in environmental psychology, and it has been widely accepted in environmental literature that association with nature has positive effects on human psychology. It was reported that individuals benefit from the direct interaction with the nature (active contact) and watching the flowers in a park or trees through a window or by just viewing it (passive contact), and even knowing that these areas exist nearby please the individuals and provide psychological benefits (Ulrich and Parson, 1992). Plants used in urban environment have functional benefits for the ecosystem such as saving energy, humidification (Beckett et al., 2000; Akbari et al., 2001) noise reduction (Çepel, 1988; Walker, 1991; Bayramoğlu et al., 2014), reduction of the effects of wind, dust and greenhouse effects (Novak et al., 2000; Akbari, 2001; Novak and Crane, 2002) preventing light reflections (Heisler, 1986; Walker, 1991; Heisler and Grant, 2000). Furthermore, plants are also quite important to remind the time to individuals due to seasonal characteristics such as early flowering, late coloration and long flowering (Sakıcı, 2009).

Plant properties such as fragrance, edible fruits, seeds, color changes, as well as shading, visual buffer and wind chamber formation, especially creating wildlife habitat for birds and butterflies should be considered in plant selection. Non-stability of plants reminds us life. Birth, growth, death and re-existence, which are part of the life cycle, are events that we recognize by seasonal changes (Sakıcı, 2009). The growth and maturation of the flowers and the falling leaves in autumn remind individuals that the days pass quickly (Mcdowell, 1997). Plants also have several positive psychological effects. Plants play an important role in self-respect. In open green spaces, the planting design improves the value of the space, prevents monotony, allows for recreational activities and socialization. Urban open green spaces play a calming, relaxing role (Smardon, 1990). Landscape architects should design the landscape with knowledge on plant properties and their contribution to the space and should make decisions about

DOI: http://dx.doi.org/10.15666/aeer/1704_97959811

plant locations and plant species in the beginning of the design when conducting spatial arrangements. Unfortunately, several mistakes are made in plant design in current environmental arrangements. This also significantly affects the occupancy of the space. In the present study, the properties of the plant species preferred in the public open green spaces in Trabzon and their intended use were investigated, the occupant satisfaction levels were determined, and plant designs were analyzed.

Materials and methods

The study was conducted in the most heavily occupied green space in the province of Trabzon. Trabzon province is located in the Eastern Black Sea region. Trabzon is surrounded by Giresun province on the west, Gümüshane province on the south, Rize province on the east, and the Black Sea on the north. Trabzon province is between north 0° 33' and 41° 07' latitudes and east 39° 07' and 40° 30' longitudes. Surface area of the province is 4685 km², the population is 786,326 based on 2017 data. Beach Park (1), Ganita Beach Park (2), Zağnos Recreation Area (3), Square Park (4), and Turkish-Japanese Friendship Park (5) were included in the study area. These areas are marked in the Trabzon urban center map presented in *Figure 1*.

Figure 1. *Analyzed open and green spaces in Trabzon*

On-site observation, examination, analysis, survey and evaluation methods were used in the study. Materials utilized in the first stage included five open green spaces in Trabzon urban center and the plant taxa used in these spaces. The methods included on-site observation, examination, analysis, and evaluation. Plant species in open and green areas in the study area were identified and their intended use were discussed. After identification of the plants, the frequencies of the species used in each open green space were determined (1: very low prevalence, 2 low prevalence, 3 moderate prevalence, 4 high prevalence, 5 very high prevalence) and the most preferred plant species were determined in Trabzon urban center. The materials used in the second stage included 5 open green spaces in Trabzon and planting designs utilizded in these areas. The methodology included observation, examination, analysis and evaluation, similar to the first stage. The intended use of planting designs was analyzed based on both aesthetic (12 criteria) and functional criteria (14 criteria). The material used in the third stage included the open green spaces and their occupants. The survey methodology was used. Thus, the satisfaction levels of the occupants of these spaces were determined. In the present study, which was conducted in three stages, the data obtained in each stage were analyzed together. Furthermore, inadequate planting designs were examined, and solutions were recommended.

Findings

First stage findings

In the 5 urban open and green spaces determined as the study area, 116 species in 83 genera and 129 subspecies of the above-mentioned species were identified. 34 were in Gymnosperm plant group and 95 were in Angiosperm plant group. The taxa identified in all five parks out of the total 129 taxa were as follows: *Berberis thunbergii* 'Atropurpurea', *Buxus sempervirens, Cedrus deodara, Cedrus libani, Cercis siliquastrum, Euonymus japonica, Eouymus japonia* 'Aureus', *Euonymus japonica* 'Aureo- variegutus', *Hibiscus syriacus, Laurus nobilis*, *Laurocerasus officinalis Morus alba* 'Pendula', *Picea pungens* 'Glauca', *Pittosporum tobira* 'Nana', *Platanus orientalis*, *Prunus cerasifera* 'Atropurpurea', *Rosmarinus officinalis, Syringa vulgaris, Tilia platyphllos, Yucca filemantosa*. These included a total of 21 taxa. The taxa identified in 4 of the 5 parks were as follows: *Acer palmatum Betula pendula*, *Campsis radicans, Cupressus arizonica* 'Glauca Multiponpon', *Cupressus macrocarpa* 'Goldcrest', *Gingko biloba, Hydrangea macrophylla, Juniperus pfitzeriana, Lagerstroemia indica, Ligustrum japonicum, Ligustrum japonicum* 'Variegatum', *Magnolia grandiflora, Nerium oleander, Philadelphus coranarius, Pinus pinea, Pittosporum tobira, Pittosporum tobira* 'Variegatum', *Platycladus orientalis, Rosa sp., Spirea x vanhoutteii, Taxus baccata, Thujo occidentalis, Thujo plicata, Viburnum opulus, Wisteria sinensis*. These included a total of 24 taxa. The taxa identified in 3 of the 5 parks were as follows: *Abies nordmanniana, Acer buergerianum, Aesculus hipocastanum, Albizia julibrissin, Azalea japonica, Citrus lemon, Cotoneaster frigidus* 'Cornubia', *Crataegus oxyacantha, Cryptomeria japonica* var. Elegance, *Cupressus sempervirens* 'Pyramidalis', *Cupressocyparis leylandii*, *Fagus orientalis, Hedera helix, Juniperus communis, Juniperus chinensis* 'Pfitzeriana Glauca', *Liquidambar orientalis, Liriodendron tuliphifera, Magnolia soulengeana, Parthenocissus tricuspidata* 'Vetchii', *Paulownia tomentosa, Phoenix canariensis, Photina fraseri, Phus typhina, Picea orientalis, Prunus serrulata* 'Kanzan', *Punica granatum, Pyracantha coccinea* 'Lalendei', *Quercus pontica, Rhododendron ponticum, Salix babylonica*, *Sparteum junceum, Trachycarpus fortuneii, Viburnum tinus, Washingtonia filifera, Wisteria floribunda.* These included a total of 35 taxa. The taxa identified in 2 of the 5 parks were as follows: *Acer pseudoplatanus, Catalpa bignonioides, Citrus reticulata, Citrus sinensis, Cotoneaster franchetti, Cryptomeria japonica, Eribotria japonica, Eounymus alatus* 'Compactus', *Forsythia x intermedia, Fraxinus excelsior, Hedera helix* 'Eleganttissima', *Jasminum fruticans, Juniperus chinensis, Koelreuteria paniculata, Melia azaderach, Phyllostachys pubescens, Picea pungens, Pyracantha coccinea Robinia pseudoacacia, Robinia pseudoacacia* 'Umbraculifera', *Rubus sp., Viburnum plicatum'*dur. These included a total of 22 taxa. The taxa identified in only 1 park were as follows: *Acacia cynophylla, Acer negundo, Acer platonoides, Acer rubrum, Alnus orientalis, Alnus glutinosa, Camelia japonica, Chamaecyparis lawsoniana* 'Ellwoodii', *Chamaecyparis pisifera, Chamaecyparis nootkatensis* 'Pendula', *Cotoneaster dammeri, Crataegus leevigata* 'Pauls Scarlet', Cupressoparis leylandii 'Multiponpon', *Eucalyptus camaldulensis, Jasminum officinale,, Juniperus virginniana, Nandina domestica, Olea europaea, Pinus mugo, Pinus nigra, Pinus nigra pallasiana var. Pyramidalis, Pinus pinaster, Prunus avium, Quercus cerris, Sequoia sempervirens, Sequoiadendron giganteum, Vitis vinifera*. These included a total of 27 taxa (*Table 1*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_97959811

Table 1. *The number of taxa identified in each urban open space based on genera, species, sub-species and plant groups*

	Open green space code				
	1	**2**	**3**	**4**	**5**
Genus	77	70	56	37	46
Species	99	81	67	45	60
Subspecies	110	92	73	50	64
Gymnosperm	28	18	19	13	18
Angiosperm	82	74	54	37	46

As seen in *Figure 2,* it was determined that 21 out of 129 taxa were highly prevalent (5), i.e., these taxa were found in all five urban open green spaces, 24 taxa were prevalent (4), i.e., these taxa were found in four urban open green spaces, 35 taxa were moderately prevalent (3), i.e., these taxa were found in three urban open green spaces, 22 taxa were less prevalent (2), i.e., these taxa were found in two urban open green spaces, and 27 taxa were not prevalent (1), i.e., these taxa were found in only one urban open green space (*Tables 2* and *3*).

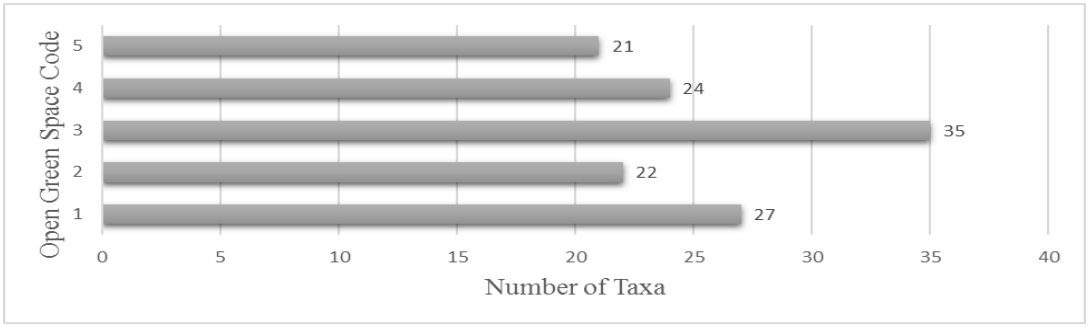

Figure 2. *Distribution of 129 taxa identified in all urban green spaces based on the green space*

Second stage findings

The reasons for the use of these taxa in plant designs in urban open and green spaces are summarized in *Table 4*. In this respect, aesthetic purposes were addressed in 12 headings and functional purposes were examined under 14 headings.

Initially, the purposes such as creating spatial subdivisions, changing scale and Vista were not taken into consideration when considering the aesthetic purposes at the Beach Park. In other words, aesthetical purposes (100%) and functional purposes (78%, 57) were mainly considered in this park. In Ganita Beach Park, 75% of aesthetic purposes and 57.14% of functional purposes were taken into consideration. In the Zağnos Recreation Area, 100% of the aesthetic purposes and 85.71% of the functional purposes were taken into consideration. 91% of the aesthetic purposes were taken into consideration in the Square Park, while 100% of the functional purposes were taken into consideration. In the Turkish-Japanese Friendship Park, 100% of the aesthetic and functional purposes were taken into consideration. All aesthetic purposes were taken into account in at least four of five urban open green spaces. Functional purposes were considered in at least two urban open green spaces (*Table 5*).

Table 2. *The study area and properties*

Beach Park	**1** 	The beach park is a 9 km long and on average 250 m wide Trabzon coastal arrangement between the Ganita park and Beşirli district. Beach Park, is built on the reclaimed land to improve the reduced coastal areas in the city and it has several functions. Some include children's playgrounds, food and beverage areas, hiking and biking paths. Trabzon Beach Park included 99 species and 110 subspecies in 77 genera. 28 species were in Gymnosperm plant group and 82 were in Angiosperm plant group. It was found that the species were used for both functional and aesthetic purposes
Ganita Beach Park	**2** 	It is a coastal park on the coastal road next to the Black Sea in the İskenderpaşa neighborhood in Ortahisar district. The park includes viewing areas, tea garden, restaurant, wildlife, hiking areas, children's playground, boating facilities, boat tours, fishing areas, sports areas.81 species and 92 subspecies in 70 genera were determined. 18 were in Gymnosperm plant group and 74 were in Angiosperm plant group. Species were used for both functional and aesthetic purposes. However, it was determined that they were mainly used for aesthetic purposes
Zağnos Recreation Area	**3** 	Trabzon Zağnos Valley includes an area of approximately 96,000 square meters and about 700 m long to the South, between 100 and 150 meters wide, limited by Maras Street on the north. Zağnos Valley is located on Yavuz Sultan Selim Boulevard within the boundaries of Gülbahar Hatun neighborhood in Ortahisar District. The area includes an amphitheater, pond, viweing areas, water games, exhibition venues, wildlife, restaurant, tea house, waterfall, and hiking paths. In total, 67 species and 73 subspecies in 56 genera were determined. 19 were in Gymnosperm plant group, and 54 were in Angiosperm plant group. Species were used for both functional and aesthetic purposes. However, it was determined that they were mainly used for aesthetic purposes
Square Park	**4** 	It is located in İskenderpaşa neighborhood in the central Ortahisar district in Trabzon on Uzun Street, between the Gazipaşa and Taksim ramps and covers an area of 15,000 square meters. It is bordered by Kemerkaya Street to the north, Çömlekçi Street to the east, Maraş Street to the west and Taksim park to the south. Since it is both a square and a park, it was coined as the Square Park. 37 different genera, 45 species in these genera and 50 varieties in these species with different forms and features were determined. 13 taxa were in Gymnosperm plant group and 37 were in Angiosperm plant group. Species were used for both functional and aesthetic purposes. However, it was determined that they were mainly used for aesthetic purposes
Turkish-Japanese Friendship Park	**5** 	Turkish-Japanese Friendship Park is located in Ortahisar District, Kalkınma neighborhood, Coastal Road area in Trabzon. Built on an area of 30,000 m2, it is surrounded by the Black Sea on the north, Forum shopping mall on the south, 100th Year park on the east, and Değirmendere industrial site on the west. The area includes spaces that reclect the cultures of the two countries. It includes plants specific to Japanese gardens, dry stone gardens, ponds, tea houses, cascade ponds, plants, pergolas, etc. A total of 46 genera and 60 plant species and 64 subspecies in these genera were determined. 18 were in Gymnosperm plant group and 46 were in Angiosperm plant group. Species were used for both functional and aesthetic purposes in this park. However, two purposes were considered equally in planting designs

Table 5. *Consideration of aesthetic and functional purposes in Trabzon urban green spaces*

	1	**2**	**3**	**4**	**5**
Aesthetic purposes (%)	100	75	100	91.6	100
Functional purposes (%)	78.57	57.14	85.71	100	100

When each aesthetic purpose was examined separately in five urban open green spaces, it was observed that the 'positive and negative perceptions created by plants' coded as E1, 'two and three dimensionality' coded as E2, and 'creating impressive traces on the ground' coded as 'E8' were not considered at the Ganita Beach Park. The 'light-shadow element' coded as E10 was not taken into consideration only in the Square Park (*Fig. 3*).

Plant design samples and the plant taxa used in these designs are presented in *Table 9*.

Third stage findings

The determination of occupant satisfaction level of the occupants of open green spaces in Trabzon city was conducted with a scale where the values of 1 and 2 reflected dissatisfaction, 3 represented neither satisfaction nor dissatisfaction and 4 and 5 reflected satisfaction with the space. The Cronbach Alpha reliability test was used to determine the reliability of the scale and it was determined that the scale was reliable. The mean occupant satisfaction scores were calculated for the five urban open green spaces and the difference between these values was determined by one-way analysis of variance (*Tables 10* and *11*).

Table 10. *The occupants' satisfaction with planting designs in each urban open green space*

	Urban open green space code					
	1	**2**	**3**	**4**	**5**	
Satisfied (mean)	3.40	3.10	3.55	3.04	3.53	F: 6.811
Satisfied (sd)	1.167	1.111	.996	1.261	1.238	Sig: .000

Table 11. *Analysis of variance*

	Sum of squares	**df**	**Mean square**	**F**	**Sig.**
Between groups	36.562	4	9.141	6.811	.000
Within groups	1066.937	795	1.342		
Total	1103.500	799			

In *Table 12,* the asterisk in the mean difference column indicates that there was a difference between the satisfaction levels for planting designs in urban open green spaces. There was a significant difference at 0.05 level between the satisfaction levels of planting designs in urban open green areas when denoted with an asterisk. Thus, the difference between the satisfaction level of the occupants for the Beach Park planting design and the Square Park (.356) was below the significance level of 0.05. In other words, satisfaction level for the Beach Park was higher than the satisfaction level for Square Park. Similarly, there were differences between the satisfaction levels for Ganita Park and the Zağnos Recreation Area and of Turkish Japanese Friendship Park planting designs.

Discussion and conclusion

The plants preferred in open green spaces designed in urban areas exhibit a dynamic structure and constantly change urban aesthetics and ecology. Especially when the selections are right and planted at the right location based on the aesthetic and functional purposes, planting design makes significant contributions to not only the urban aesthetics but also the value of the real estate in the city (Tyruainen, 1997). In

recent years, extensive research was conducted on plant material in urban open green areas and urban ecology (Düzenli et al., 2018; Potgieter et al., 2019; Schebella et al., 2019; Yan et al., 2019; Rumble et al., 2019; Yılmaz et al., 2018).

UOGA: urban open green spaces code

The open green space planning in urban areas often emphasizes the improvement of the quality of life of individuals (Fainstein and Campell, 1996; Salon, 2002; Mumcu et al., 2013), in this respect, it aims to ensure the use of indigenous plant species and to maintain sustainability of other areas of ecological concern (Forman, 2008).

Thanks to plant taxa used in urban open and green areas, the areas with a form and design acquire an anatomy as well. As the plants change, they occupy a place in the function of the urban ecosystem. Thus, functional objectives that planting designs should emphasize emerge.

Urban open green spaces that transform urban spaces into natural areas thanks to the plants, albeit partially, are usually under intensive human management or occupancy (Kurdoğlu et al., 2018). Transportation of plant taxa indigenous to rural areas to urban areas and their utilization in plant designs would lead to natural vegetation patterns. In contrast, the opposite would lead to a contradiction between indigenous and non-indigenous plant species in urban open green spaces.

In the present study, 10 of the 21 most prevalent plant taxa used in the open green areas in Trabzon city were selected from indigenous and 11 were selected from exotic

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_97959811

plants. Of the 129 taxa identified, only 42 were indigenous to Turkey. Although the diversity of plant species was sufficient, the selection of indigenous plant species was not sufficient. Plant species that reflect the characteristic of the region should be preferred. One of the study areas was rich in exotic species diversity when compared to the other areas due to the fact that its concept was Turkish-Japanese friendship.

Aesthetically positive plants are those that the designers want to be noticed or emphasized in a space, while negative plants are not to be noticed. The plants used in the open green areas in the city of Trabzon fulfilled this purpose with distinct aesthetic characters such as leaves, fruits, flowers and color effects, trunks or forms. Another aesthetic aim is the shadows and reflections provided by plants due to natural and artificial lighting elements. In the five urban open green areas reviewed in the present study, the plants exhibited two- or three-dimensional properties. In addition to the evergreen plants used, varieties that change with seasons were also preferred, thus creating impressive landscapes. Deciduous plants formed aesthetic values in winter with their trunks and branching calligraphy. They added an interesting character to the design with their extraordinary shoots and bark patterns. They created harmony or contrast with the pavements and other structural landscaping elements in study areas. In the five parks where the study was conducted in Trabzon, certain taxa were used as solitary plants (*Platanus orientalis, Acer rubrum, Gingko biloba, Salix babylonica* vb) or to attract the attention to certain sections. In order to make the monotonous pavements that are monotonous both horizontally and vertically entertaining, the plants were used as pavements or cover elements. Due to the wind speed and direction, especially the tress in the Beach Park and trees at Ganita Beach Park achieved movement and sound. In all the study areas, fine-delicate, drooping plants such as *Betula pendula* and *Salix babylonica* created an elegant appearance by swinging lightly with the wind.

It is known that plants are a design material in landscape design, and they are used when creating spaces just like other material. The crowns of plants are considered as the cover and trunks are considered as walls of the space. Thus, the plants are used in solitary or in groups to create spaces and sub-spaces in study areas. Also, linear, radial, clustered and grid type designs were adopted in the plant compositions in study areas. In study areas, primary, secondary and tertiary spaces were created based on the field composition and the hierarchical properties of the area. For this purpose, the color, size, linearity, or organization of the plant are considered in hierarchical orders (Yildizci, 1988). It is possible to clarify an existing or planned design with plant compositions, and to associate the objects and spaces in the design. Thus, the plant compositions in study areas aimed to support and to strengthen the design and to provide an integral visual perception.

Planting could associate the objects and spaces. Plants undertake separative and integrative functions in adjacent spaces structurally, create a determinative, rhythmic and emphasizing effects, and provide connections especially in rural and urban landscapes. Furthermore, planting design could be conducted to obtain effects such as strengthening or hiding the topographic structure. In the present study, it mostly strengthened the lines of design since these areas were urban areas without any slopes. The selected *Platanus orientalis* species at the Beach Park was planted in higher intervals from its crown, leading to an open and spacious perception. In contrast, *Ligustrum japonicum* species was planted in frequent intervals and adjacent to each other, creating a border effect and leading to closed perception. When the study areas are examined, it was observed that vistas were created with plant design in only two

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_97959811

urban open green areas. The creation of vista in the design of the study areas were mostly created with structural landscaping elements, with the only exceptions of the Square Park and Turkish-Japanese Friendship Park.

After the findings obtained by the researcher, it was determined that the occupant satisfaction was the highest in the planting designs at Zağnos Recreation Area. This was followed by the Turkish-Japanese Friendship Park, Beach Park, Ganita and the Square Park, respectively. Occupant evaluations demonstrated there were differences between the satisfaction levels of the occupants about the planting designs. The reason for this difference was the utilized plant taxa used as determined in the previous stages.

The three urban open green areas (Beach Park, Zağnos Recreation Area, Turkish-Japanese Friendship Park) investigated in the present study were built very recently. The other two areas were urban renewal projects and recently renovated areas. Therefore, the study findings demonstrated that there have been developments in the design of urban green open spaces and these were designed by expert teams, and the resulting plating designs were appreciated by the occupants.

According to these results, the following points should be considered in the selection of plant species in urban light green areas and in the implementation of planting designs;

In the first place, the designer should create a list of plants which can be used by considering ecological, edaphic and climatic data in the region. The designer should also take into account the structural and visual characteristics of the plants while creating these plant lists, such as the habitats of plants, body trunk bark, branches, shoots, bud, leaves, flowers, seeds and cones should be well aware. because the structural characteristics of the plants also form their visual characteristics. A planting design should be designed by taking one or more of the principles of harmony, contrast, repetition, rhythm, scale, ratio, emphasis, domination, balance and unity. the functions of these planting designs should be functional as well as aesthetic. In other words, except for the beautiful views that the aesthetic views of the plants offer, space creation, supporting the existing structural design, providing inter-space transition, creating emphasis and focus, limiting or creating a border, making screens, providing privacy privacy.

Abstract. In landfill, cut-off walls have been widely used as in situ barriers to isolate contaminants and control the migration of contaminated groundwater. How the permeability of the wall changes as exposed to pollutants is unclear. In view of this issue, Fujian standard sand was used to simulate the stratum, and four clay were used as the mixed material. After mixing, pouring and consolidation, the hydraulic conductivity and water characteristic curve were measured. The results showed that when the permeation of the sand-clay mixtures was stabilized by a 0.2 mol/L calcium chloride solution under the additive amount of 10% clay, the hydraulic conductivity increased to different degrees compared with that permeated with tap water, but did not increase more than tenfold. Moreover, the porosity didn't change significantly after the stabilization of the permeation of the calcium chloride solution in the four kinds of sand-clay mixtures but decreased slightly. The experimental results showed that the replacement between calcium ions and univalent cations on the surface of clay mineral particles decreases the thickness of the diffused double layer and the content of bound water; thus, the effective porosity increases, which may be the main reason for the increase of the permeability.

Introduction

With the rapid economic development and the improvement of urbanization in China, the output of garbage is increasing, as is the number of landfills. In 2008, the environmental protection special inspection campaign of eight ministries and commissions of the State Council carried out a diagnostic investigation of the scale of landfill sites, anti-seepage measures, and the operation of leachate treatment facilities throughout the country. The results showed that there are 935 open and closed refuse landfills in China, 34% of which do not take anti-seepage measures. These simple landfills without strict designs and construction, especially those without a bottom seepage control system, have become a major environmental hazard. In the future, the number of pollution control projects needed for this kind of landfills will increase gradually. It is very difficult and costly to rebuild horizontal seepage control systems in the bottom of exhausted landfills. Therefore, constructing a closed vertical cut-off wall has been widely applied. Soil-bentonite cut-off walls are also used to prevent pollutants from leaking into the groundwater and soil at the Rocky Mountain Arsenal site (Patton et

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98139826

al., 2007), which is a chemical weapons and pesticide production wasteland in the United States. It is also common to make up for the loss or failure of horizontal anti-seepage systems by using a vertical cut-off wall. There are few reports of concrete examples of vertical cut-off wall construction in existing refuse landfills in China, but vertical anti-seepage control systems have also been used in the construction of new landfills. During the 4th phase construction of the Shanghai Laogang Municipal Solid Waste Landfill built on the intertidal zone, a vertical cut-off wall of cement-bentonite was applied to the new landfill (Fei et al., 2005). In summing up the technology of vertical cut-off walls, Yao and Bao mentioned that the plain-type landfills of the Shanghai Laogang 4th Phase, Central Tangshan, Gangyang, and Taizhou all adopted anti-seepage control methods combining the horizontal and vertical methods (Yao and Bao, 2008). The horizontal-vertical anti-seepage system was also used in the expansion of the Landfill in Qizi Mountain, Suzhou.

Concerning the aspects of the material, design and construction of vertical cut-off walls, in summing up the vertical cut-off technology of landfills in our country, Jing et al. thought that because of a late start, the methods of water conservancy, geology and civil engineering of the anti-seepage material and construction technology were borrowed, especially grouting anti-seepage technology (Jing et al., 2006). In addition, theoretical or technical methods for anti-seepage of landfills have not been developed yet. However, cut-off walls of soil-clay material have good engineering characteristics, and the anti-seepage and anti-fouling properties have received much attention. The construction procedure of clay-based vertical cut-off walls is to excavate the trench first and adopt 4% ~ 6% mud counterfort at the same time, mix the excavated stratum and clay proportionally, and then mix the produced mixture fully with the mud in the trench (Rumer and Ryan, 1995). Then, the sand-clay mixture is backfilled with a collapsing slump of 100 ~ 150 mm, and a vertical cut-off barrier with a hydraulic conductivity of less than 10^{-7} cm/s is formed. Devlin and Parker have studied the anti-fouling performance of soil-bentonite cut-off walls (Devlin and Parker, 1996). Through theoretical calculations, it was concluded that when the thickness of the cut-off wall is 1 m and the hydraulic conductivity is less than 5×10^{-8} cm/s, the hydraulic transportation of pollutants can be effectively controlled, and the escape of pollutants mainly occurs through the slow molecular diffusion process. Thus, how to make the hydraulic conductivity of the clay and stratum less than 5×10^{-8} cm/s has become an important problem in engineering.

The chemical compatibility between the backfill material of cut-off wall and the contaminants in the leachate is very important for clay-based cut-off walls. For example, the hydraulic conductivity of the backfill material of soil-bentonite cut-off walls, geosynthetic clay liners (GCL) and compacted sand-bentonite mixtures may increase due to the interaction between the backfill material and inorganic cations (Jo et al., 2005; Katsumi et al., 2008). Grube found that when sodium hydroxide solution permeated soil-bentonite backfill material, the impermeability decreased by 5 ~ 10 times (Grube, 1992). The increase of the concentration of organic solutions and electrolyte solutions or the effect of strong acid solution will change the structure of clay, especially bentonite, and lead to an increase by orders of magnitude in the hydraulic conductivity. Lee et al. found that the liquid limit, settling volume and expansion index create a critical threshold for the increase of the hydraulic conductivity through permeability testing and settlement testing (Lee et al., 2005). Fan et al. mixed lead nitrate solution of different concentrations with kaolin-bentonite to simulate cut-off wall contamination by lead (Fan et al., 2013). They carried out consolidation tests and settlement tests. The hydraulic conductivity of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98139826

the mixture increased 2 ~ 15 times with the increase of the lead concentration. This was attributed to the compression of the double layer and the change of the surface charge of the soil particles.

The above research reveals that the change of the electrochemical environment in soil has a key effect on the hydraulic conductivity, but it can also be seen that the change rule of the hydraulic conductivity is not uniform in terms of quantity because of the different types of clay used. It is obvious that the chemical substances not only change the viscosity of the permeant fluid but also block the movement of water, and changes of the electrochemical environment in the soil and changes of the bound water around the clay particles result in the change of the micro-pore structure. This may be the main reason why the effects of chemical solutions are different from those of water permeation. Thus, it is necessary to study the influence of chemical solutions on the hydraulic conductivity when using different clay minerals. In this research, four kinds of clay are used to carry out laboratory experiments.

Materials and Methods

Materials

Because the stratum varies according to the site conditions, considering the adverse conditions of the soil layer properties in the simulated site, Fujian standard sand (commercial) is selected to simulate the stratum and is hereinafter referred to as FSS,. The basic physical properties are shown in *Table 1* (Hu and Yang, 2012).

Table 1. *Physical properties of the model stratum*

G_s	C_u	ρ_{dmax}(g/cm^3)	ρ_{dmin}(g/cm^3)	e_{max}	e_{min}
2.64	5.99	1.74	1.43	0.85	0.52

Table 2. *Geotechnical properties of the four clays*

Type	G_s	w_L (%)	w_p (%)	Swell index (mL/(2g))
Clay-K	2.68	39	23	2.6
Clay-J	2.72	48	24	3.1
Clay-A	2.72	53	27	4.1
Bent-A	2.70	301	56	38.5

The four kinds of natural clay (powdery) are as follows. Clay-K is produced in Lingshou County, Shijiazhuang, Hebei Province, and the main clay mineral is kaolinite; Clay-J is produced in Jiangning District, Nanjing, Jiangsu Province, and the main clay mineral is illite; Clay-A is produced in the Inner Mongolia Autonomous Region, and the main clay mineral is palygorskite; and Bent-A is produced in Anji, Huzhou, Zhejiang, and the main clay mineral is montmorillonite. The basic physical properties of the above four kinds of clay are obtained according to the Standard for Soil Test Method (GB/T

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98139826

50123-1999) and Bentonite (GB/T 20973-2007), as shown in *Table 2*. The clay and standard sand are dried at 105°C for 24h ~ 48h.

Permeability tests of permeant fluids are carried out using tap water and $CaCl_2$ solution, respectively. The properties of these fluids are shown in *Table 3*. The reason why we choose $CaCl_2$ solution is because of the widespread use of $CaCl_2$ to evaluate the effects of multivalent cations on hydraulic conductivity in previous experimental studies (Shackelford et al., 2000). Although various multivalent cations may be contained in the leachate of the actual landfill, the influence of these cations on the chemical compatibility of the clay barriers will not be very different. For example, the experiments of Jo et al. and Kolstad et al. show that the types of the divalent cations (Cu^{2+}, Mg^{2+}, Zn^{2+} and Ca^{2+}) have no significant effect on the free expansion and hydraulic conductivity of GCL at a given concentration (Jo et al., 2001; Kolstad et al., 2004).

Table 3. *Basic properties of the permeant fluids used*

Permeant fluid	$CaCl_2$ concentration (mol/L)	Ca^{2+} concentration (mg/L)	Electrical conductivity (ms/m)
Tap water	--	15.8	95
$CaCl_2$ solution	0.2	5120.4	8230

The particle size distribution curves of Fujian standard sand and the four types of clay are shown in *Fig. 1*. It can be seen from the figure that apart from the relatively large particle size of bentonite, the particle size distribution, clay content and fine granule content of the other 3 types of clay are similar.

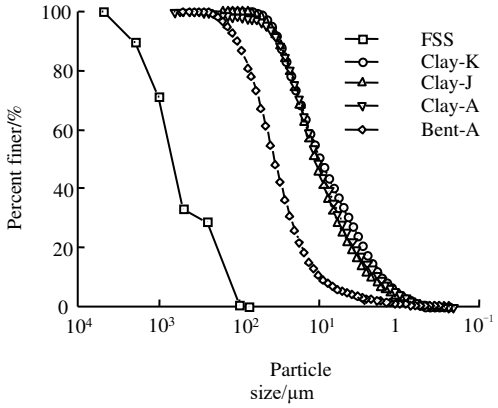

Figure 1. *Particle size distributions of the five soils in this study*

Sample preparation

The standard sand is mixed uniformly with a certain amount of clay, and then mixed with the prepared 5% mud (Rumer and Ryan, 1995) to form a pouring sample similar to concrete mortar. To simulate the backfill mixture used in actual construction, the slump of the permeable sample is controlled within the range of 100 ~ 150 mm. In the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98139826

experiment, the additive amount of clay of 10% (percentage of the clay dry mass to the standard sand dry mass) is used.

Improved flexible wall permeability test

The RST-1 flexible wall permeameter developed by Nanjing Soil Instruments is modified due to the weak self-standing property of the samples. Referring to the improvement idea for a triaxial apparatus by Min et al., a cutting ring with many holes of 3 mm in diameter is added to the periphery of the sample (Min et al., 2019). In this way, the sample can be self-standing, and the confining pressure can be applied to the sidewall of the sample (see *Fig. 2*). Compared with the rigid wall permeameter, this setup can effectively prevent the influence of sidewall seepage. At the same time, the stress state of the cut-off wall in the actual project can be simulated in a relatively real way by applying the confining pressure of 100 kPa and then conducting the permeability test. The osmotic pressure difference is 70 kPa, the diameter of the sample is 7 cm, and the height is 4 cm. The test method of flexible wall permeability refers to ASTM D5084 (ASTM, 2010). During the experiment, the sample is permeated at 25℃ room temperature.

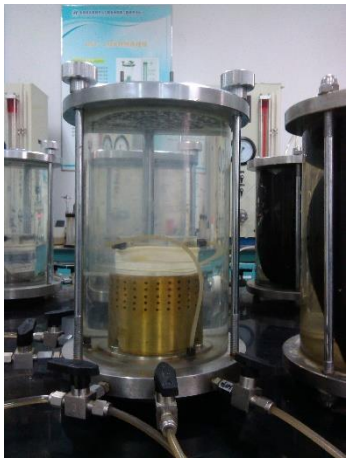

Figure 2. *An improved flexible wall permeameter*

Bound water matric suction test

To understand the changes of the binding state of water in the soil after adding clay, the centrifugal moisture metre is used to measure the bound water content (mass percentage of bound water and pore water) of the sample after completion of the test. The centrifugal moisture metre is based on the principle that the centrifugal force generated by high-speed rotation can separate water with low potential energy. The amounts of water retained in the sample at different speeds are measured, and then the separating potential energy is calculated according to the rotating speed. Finally, the relation between the potential energy and water is obtained. This experiment uses the Himac high-speed freezing centrifuge manufactured by HITACHI (see *Fig. 3*), and the detailed operation is shown in the literature (Zhu et al., 2007).

Results

Effect of $CaCl_2$ solution on the hydraulic conductivity of the sand-clay mixture

At the same addition rate of 10%, the changes over time of the obtained hydraulic conductivity of 0.2 mol/L $CaCl_2$ solution in the four sand-clay mixtures are collected, and *Fig. 4* is obtained. Fig. 4(a), 4(b), 4(c), and 4(d) show the curves of hydraulic conductivity variable against time for the sand-Clay-K, sand-Clay-J, sand-Clay-A and sand-Bent-A mixtures. It can be seen from the figure that the hydraulic conductivity of sand-Clay-K, sand-Clay-A and sand-Bent-A increases to varying degrees, except for the hydraulic conductivity of the sand-Clay-J mixture, which decreases slightly, and the hydraulic conductivity of sand-Clay-K, sand-Clay-A and sand-Bent-A increases to some extent. The hydraulic conductivity of sand-Clay-K and sand-Clay-A fluctuates by one order of magnitude, but the hydraulic conductivity of sand-Bent-A mixture varies greatly. During the process, the maximum hydraulic conductivities of sand-Clay-K, sand-Clay-J, sand-Clay-A and sand-Bent-A are 3.517×10^{-5} cm/s, 3.018×10^{-5} cm/s, 3.278×10^{-5} cm/s, 3.129×10^{-5} cm/s, respectively.

(d) adding 10% Bent-A

Figure 4. *Changes of the hydraulic conductivity of the sand-clay mixtures with time*

Table 4. *Hydraulic conductivity k with the permeant fluid of tap water or $CaCl_2$ solution*

Permeant **fluid**	***k*/(cm/s)**			
	sand-Clay-K	**sand-Clay-J**	**sand-Clay-A**	**sand-Bent-A**
Tap water	1.064×10^{-5}	3.222×10^{-6}	3.979×10^{-6}	3.169×10^{-9}
$CaCl_2$ solution	3.238×10^{-5}	1.470×10^{-5}	2.758×10^{-5}	2.811×10^{-8}

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98139826

In addition, the stabilized hydraulic conductivities of tap water and $CaCl_2$ solution are compared and analysed in four kinds of sand-clay mixtures with 10% content, as shown in *Table 4* and *Fig. 5*.

In contrast, the final hydraulic conductivity ratios of $CaCl_2$ solution and tap water in sand-Clay-K and sand-Clay-J are less than 5, but the hydraulic conductivity ratio of $CaCl_2$ solution and tap water in sand-Clay-A and sand-Bent-A is between 5 and 10.

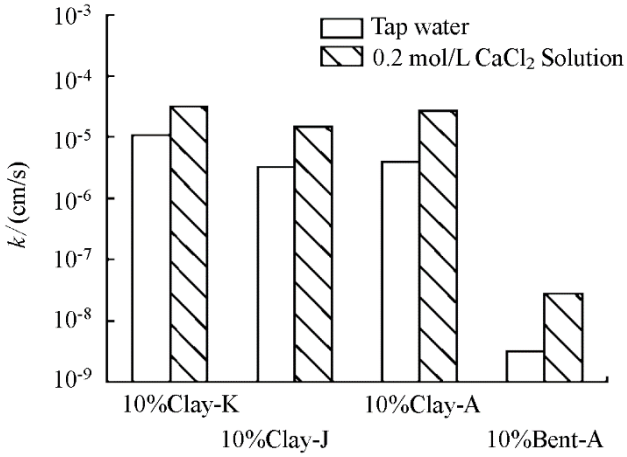

Figure 5. *Hydraulic conductivity of the mixture permeated by tap water or $CaCl_2$ solution*

Effect of $CaCl_2$ solution on the porosity of the sand-clay mixture

Previous studies have analysed the changes of hydraulic conductivity on the basis of changes in the porosity. The porosity *n* of the samples after permeation by tap water and $CaCl_2$ solution are also measured and calculated in the four sand-clay mixtures, respectively. The comparison of porosity between tap water and $CaCl_2$ solution is obtained, which is shown in *Fig. 6* and *Table 5*.

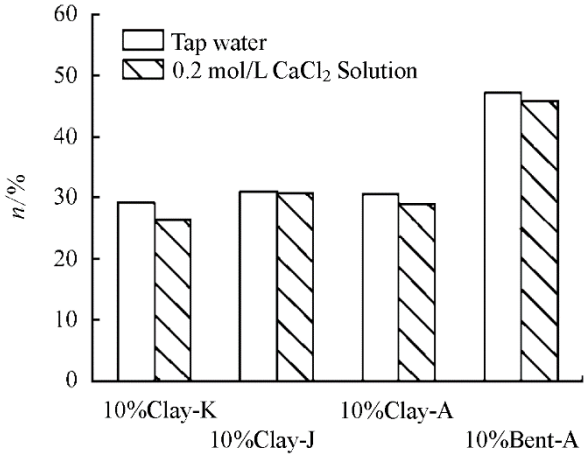

Figure 6. *The porosities of sand-clay mixtures permeated by tap water or $CaCl_2$ solution*

Overall, the porosity of tap water and $CaCl_2$ solution in the four sand-clay mixtures after permeation do not change significantly but generally decrease, because the chemical

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98139826

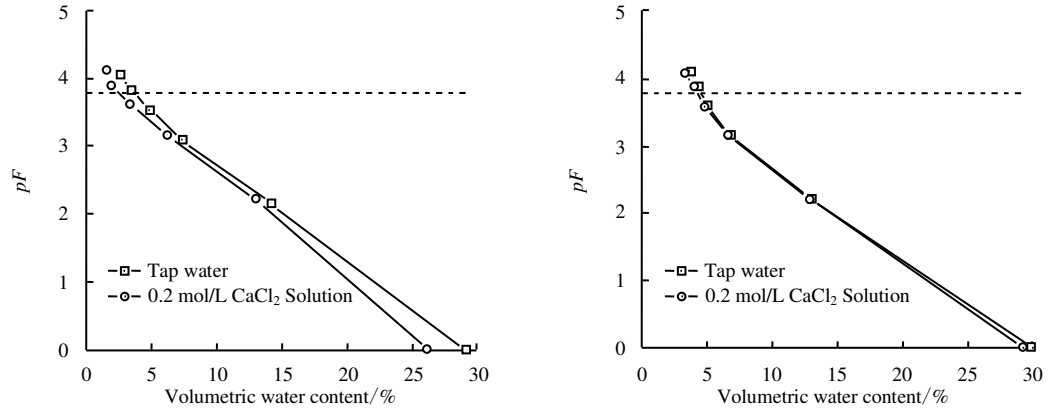
reaction between $CaCl_2$ and the clay minerals forms a small number of new compounds (Yanful et al., 1995), which clog the internal water-conducting pore channels in the mixture, resulting in the reduction of porosity. Thus, for a sand-clay mixture, the hydraulic conductivity of the mixture changes over time during the whole process of permeation by $CaCl_2$ solution.

Table 5. *The porosity n of the sand-clay mixtures permeated by tap water or $CaCl_2$ solution*

Permeant fluid	*n*/%			
	sand-Clay-K	sand-Clay-J	sand-Clay-A	sand-Bent-A
Tap water	29.26	31.05	30.72	47.07
$CaCl_2$ solution	26.24	30.63	28.82	45.57

Effect of $CaCl_2$ solution on the bound water content of the sand-clay mixture

The permeability of soil has a certain relationship with the pore size, and it may also have a certain relationship with the form of water in the pores. When researching the micro electric field effect of the seepage of tiny-particle clay, Liang et al. found that the bonding of soil particle surfaces will affect the permeability of the soil under the interaction of a clay-water-electrolyte system (Liang et al., 2010). Based on the consideration of whether the bound water has an effect on the permeability of the mixture, moisture centrifugal dehydration is carried out on the mixtures to determine the *pF* value of the binding potential energy of the pore water in each sample (logarithm of the centimetre height of the water column of the water suction in the soil), which is shown in *Fig. 7*. Referring to the research result of Lebedev, the *pF* value of 3.8 is used to distinguish bound water from free water (Lebedev, 1936). The bound water content in mixture can be obtained from the intercept of the moisture content with the *pF* value of more than 3.8 from the water characteristic curve. *Fig. 8* and *Table 6* show the comparison of the content of bound water between the effects of tap water and $CaCl_2$ solution after permeation in the four kinds of sand-clay mixtures.



(a) adding 10% Clay-K (b) adding 10% Clay-J

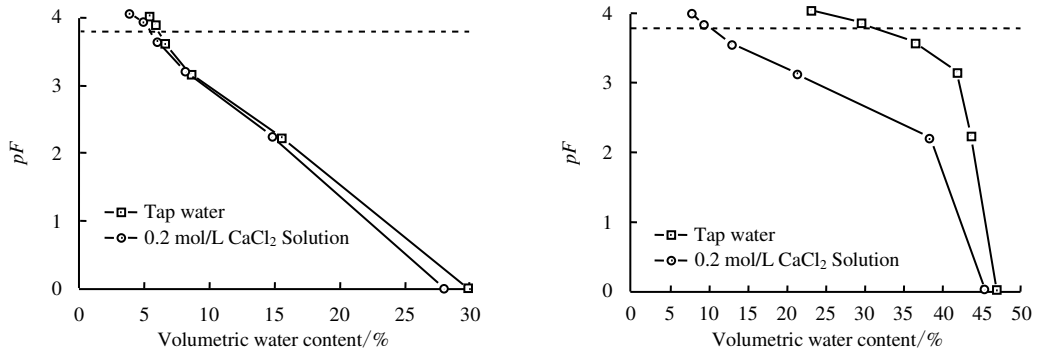
DOI: http://dx.doi.org/10.15666/aeer/1704_98139826



(c) adding 10% Clay-A (d) adding 10% Bent-A

Figure 7. *Soil-water characteristic curves of mixtures permeated by tap water or $CaCl_2$ solution*

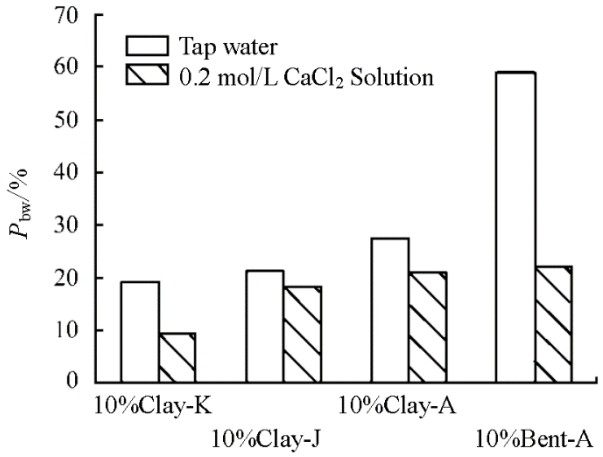


Figure 8. *Bound water percentages P_{bw} of sand-clay permeated by tap water or $CaCl_2$ solution*

Table 6. *Bound water percentages with the permeant liquid of tap water or $CaCl_2$ solution*

Permeant **fluid**	**Bound water percentage P_{bw}/%**			
	sand-Clay-K	**sand-Clay-J**	**sand-Clay-A**	**sand-Bent-A**
Tap water	19.15	21.16	27.41	59.03
$CaCl_2$ solution	9.31	18.18	20.91	22.15

Compared with those using tap water, the bound water content of the samples using $CaCl_2$ solution in sand-Clay-K, sand-Clay-J, sand-Clay-A and sand-Bent-A mixtures after permeation decrease to some extent. In addition, the change of the bound water content of the sand-Bent-A mixture is the largest.

Discussion

By combining *Fig. 5* and *Fig. 6*, it can be seen that the hydraulic conductivity of $CaCl_2$ solution in the four kinds of sand-clay mixture after permeation increases to varying degrees and that the corresponding porosity does not increase but decreases slightly. This is different from the common phenomenon in which the porosity of clay minerals decreases and the hydraulic conductivity decreases (Mesri and Olson, 1971). Thus, It is speculated that in the process of permeation of the sand-clay mixture, the water with a certain degree of binding ability to clay particles in the pore water is relatively stagnant. It may be an abnormal liquid with mechanical properties between those of a solid and a liquid (Sridharan et al., 1986) and showing viscosity, that is, there is a water film with a large binding potential energy to soil particles around the clay particles. This is the inner layer-Stern layer of the diffused double layer (stern layer) (Yuan, 2012), as shown in *Fig. 9*.

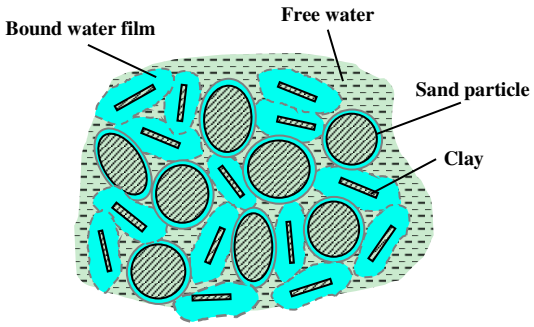

Figure 9. *Schematic diagram of a sand-clay mixture sample*

Based on the above assumptions, the calculation method (*Equation 1*) of the effective porosity n_{eff} is proposed:

$$n_{eff} = n(1 - P_{bw}) \quad \text{(Eq.1)}$$

where P_{bw} is the bound water content in the pore water of the sand-clay mixture.

The effective porosities of the four kinds of sand-clay mixtures are calculated after permeation by tap water and $CaCl_2$ solution, respectively, as shown in *Fig. 10*.

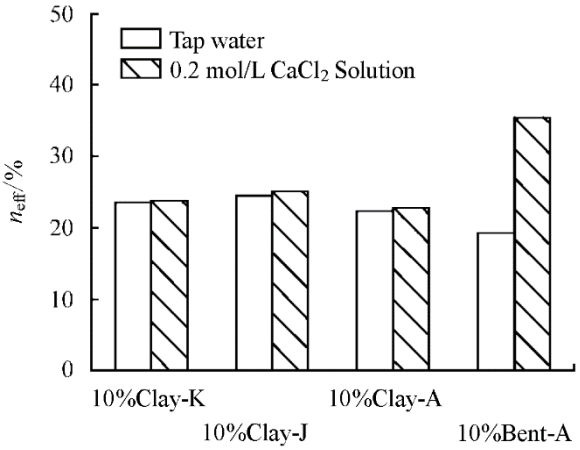

Figure 10. *Effective porosity neff of sand-clay permeated by tap water or $CaCl_2$ solution*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98139826

It can be seen directly from *Fig. 10* that for the four kinds of sand-clay mixtures, the final hydraulic conductivity after permeation with $CaCl_2$ solution is increased to varying degrees. This is because although the porosity of the mixture does not change much, or even decreases, the effective porosities of the four kinds of sand-clay mixtures increase, which may be the main reason for the increase of the final hydraulic conductivities of the mixtures. In my opinion, there is a replacement reaction between the calcium ions in the permeant fluid and the univalent metal cations (such as sodium and potassium ions) adsorbed onto the surface of the clay mineral particles. The thickness of the diffused double layer on the surface of the clay mineral particles becomes thinner, and the corresponding bound water content decreases (Gu and Fang, 2009), which results in the increase of the effective porosity and the increase of the hydraulic conductivity of the mixture.

Conclusions

Based on discussions of the test results and further analysis, the following conclusions can be made:

(1) The self-modified flexible wall permeameter is used, and permeability tests of tap water and 0.2 mol/L $CaCl_2$ solution in sand-Clay-K, sand-Clay-J, sand-Clay-A and sand-Bent-A mixtures are conducted. The results show that when the additive amount of clay is 10% and the confining pressure is 100 kPa, compared with the effects of tap water, the hydraulic conductivity of the sand-clay mixture increases in varying degrees when $CaCl_2$ solution is used as the permeant fluid. However, with an increase of the hydraulic conductivity by 10 times, the porosity of $CaCl_2$ solution in the four mixtures decreases slightly after permeation. It is proven that the seepage-control function of the sand-Bent-A mixture used as the material for landfill cut-off walls at the addition rate of 10% can meet the requirement.

(2) The experimental results show that the calcium ion in the permeant fluid is replaced by the univalent cation on the surface of clay mineral particles, which results in the decrease of the thickness of the diffused double layer and the decrease of the bound water content, leading to the increase of the effective porosity. Macroscopically, the hydraulic conductivity of the mixture becomes larger.

(3) In this study, the permeability tests were conducted under calcium chloride solution. However, in fact the contaminants in the landfill leachate may also include inorganic matters and organic matters. Thus, the chemical compatibility of cut-off walls in the presence of composite contaminations, the interaction between clay particle and contaminated fluid is recommended. On-going additional research is aimed at addressing all of the limitations.

Abstract. With rapid economic development, Xiangtan, as an old industrial base of China and a famous industrial city in Hunan Province, caused severe pollution, which had a significant impact on people's lives. To understand the heavy metal pollution in Xiangtan, we tested and analyzed the barks of *Cinnamomum camphora* in different functional areas. The article examined the differences and sources of heavy metal contents in the bark of *Cinnamomum camphora* from different functional areas. The results showed that the contents of various heavy metals in the barks of *Cinnamomum camphora* varied considerably and the most common elements of heavy metal pollution were Mn, Pb, and Cr. The activities in different functional areas had a significant influence on the enrichment of heavy metals in the bark of *Cinnamomum camphora*. Heavy metals in the business district mainly came from traffic emissions and various domestic wastes. High population density and household litter affected the heavy metal contents in the Residential District. Heavy metal contents were high in parts of the urban green space due to living garbage or surrounding environment.
Keywords: *pollution, functional areas, spatial distribution, bark, indicator*

Introduction

With the rapid development of the global economy, pollutants containing various heavy metals enter the environment in different ways. Heavy metal pollution can gradually become a serious environmental issue. The hazards of heavy metals including both existing and potential forms have an almost irreversible effect on ecosystems and human health (Sun et al., 2011; Zhang et al., 2012, 1998). Heavy metal pollution has many characteristics, including latency, cumulativeness, long lifespan, and irreversibility. If we do not take immediate and effective measures, it will have a more severe impact. Heavy metals in the environment mainly come from gas emissions, road traffic emissions and industrial emissions (Yao et al., 2012; Zhang et al., 2012). Previous studies showed that heavy metals in plant surface often decreased with increasing distance from pollution sources (Zhu et al., 2007; Chen et al., 2016).

There are various methods to detect atmospheric heavy metal pollution. Broad-leaved and coniferous trees, such as mosses, lichens, vascular plants, and woody-plants, can be utilized to study air pollution (Sun et al., 2011; Huang et al., 1983, 1984; Fang et al., 2000). Because the surface layer of plant contacts more with the atmosphere and is sensitive to environmental changes, it becomes a significant carrier for monitoring air pollution. Though barks do not absorb heavy metals and other pollutants sensitively as mosses do, it is a good indicator of other contaminants, such as electrical conductivity, pH, sulfur, nitrogen, heavy metals, and so on (El-Hasan et al., 2003). Because

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98279835

Cinnamomum camphora is a street tree and its bark is exposed to the atmosphere for a long time, it has a large contact area with the atmosphere. Barks of *Cinnamomum camphora* not only contained heavy metal elements absorbed from the soil but also accumulated a large amount of dust and particles from the atmosphere (Huang et al., 1983; Zhou et al., 2014). Therefore, this paper chose barks of *Cinnamomum camphora* as an indicator of air pollution to study.

Xiangtan is an old industrial city. In recent years, with the continuous development of industry and economy, the heavy metal contents of Xiangtan have increased sharply. This study tries to analyze the spatial distribution characteristics of heavy metal in the barks of *Cinnamomum camphora* in Xiangtan, reveal the sources and causes of heavy metal pollution, and explore the pollution situation. This study can not only investigate the causes and extent of heavy metal pollution in Xiangtan City but also provide a scientific basis for ecological research in urban areas. It is also helpful to environmental governance, human health, urban eco-environment, and sustainable urban development.

Materials and methods

Research area

Xiangtan City (111°58'E-113°05'E, 27°21'N-28°05'N) is a prefecture-level city in the east-central of Hunan Province, with a total area of 5015 km^2. It is the smallest prefecture-level city in Hunan Province, China. In 2010, the city's resident population was 2.748 million, of which 959,000 were in the urban area, with a population density of 549 people/km^2, ranking second in Hunan Province. The climate of Xiangtan belongs to a subtropical monsoon humid climate with abundant precipitation, sufficient solar and thermal resources. Although the annual rainfall reached 1200-1500 mm, the time distribution was uneven, and the inter-annual variability was considerable (Xiao, 1996).

Xiangtan's geographical position is superior. Many expressways and railways meet and pass here, which is highly beneficial to the economic development of Xiangtan. Simultaneously, Xiangtan, together with Changsha and Zhuzhou, is the "Golden Triangle" urban agglomeration with the most developed politics, economy and culture in Hunan Province (Xiao, 1996). In recent years, Xiangtan's economy has been growing, especially in various industries. Xiangtan has grown up to be a heavy industrial city with mechanical, metallurgical, chemical and textile industries. Main industrial types include coal, metallurgy, chemical fiber, chemical industry, textile, leather, agricultural products' processing, etc. Among them, industrial products with national influence are iron and steel, military products, electromechanical products, and some chemical products.

Sampling and analysis

In January, 2015, the barks of *Cinnamomum camphora* in different functional areas, such as the Residential District (Shuxiangyulin, near the railway station), Commercial District (Bus Station), Industrial District (Xiangtan Iron & Steel Co. Ltd of Hunan Valin, Longpai Food Limited by Share Co. Ltd) and Urban Green District (Baishi Park, Yuhu Park, Yuetang Park, Peace Park), were sampled (*Fig. 1*). The barks of 3-5 selected *Cinnamomum camphora* trees, which have similar age and a 25-45 cm diameter at breast height in one place, were taken from the same side of the trunk at 1.3-1.5 m above the ground surface.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98279835

When sampling, the adhesives on the bark's surface were removed with a hard brush, then the barks of 5 × 5 cm^2 were scrape off with a stainless steel knife. To prevent contact pollution and increase the experiment error, polish the bark's surface with sandpaper. The samples were enclosed in a polyethylene self-sealing bag and numbered. Synchronously, the sampling point, sampling time, weather condition, geographical location, altitude and tree height, etc were recorded.

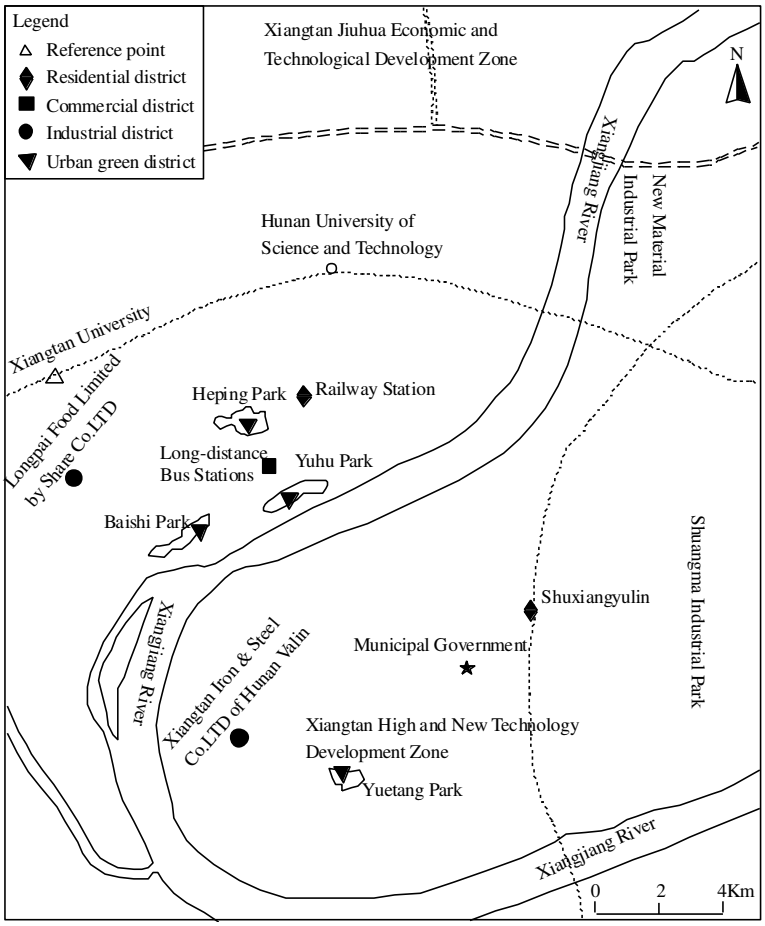

Figure 1. *Schematic diagram of sampling sites*

In the laboratory, the impurities were removed and the samples were baked to a constant weight at 105 °C in a thermostat. Then, the dried sample was ground in an agate mortar through a 100 mesh nylon sieve. Next, 2 ml HCL, 5 ml HNO_3 and 2 ml H_2O_2 were added to 0.5 g ground samples that were digested by microwave digestion (Zhuang et al., 2000). Afterward, the digested samples were heated at 300 °C for 4 h by an electric heating plate to remove the acid. After sample treatment, a FAAS (flame atomic absorption spectrophotometer) was utilized to test the content of heavy metal (Cd, Pb, Cr, Cu, Mn) (Lü, 2008; Sharifi et al., 2017; Kord et al., 2010; Ahmad Afif, 2010; Xie et al., 2009). The correlation between the standard solution was at least 0.99, the error of the heavy metal content of the parallel sample was less than 5%, and every five groups added a blank sample. All experimental data must be subtracted from the blank sample to ensure accuracy.

Results and analysis

Heavy metal contents in the bark of Cinnamomum camphora

Because Xiangtan University is located in the suburb of Xiangtan City, we take the heavy metal contents in the barks of *Cinnamomum camphora* at Xiangtan University as preset reference values to reveal the regional differences due to its good environmental conditions (*Fig. 2*).

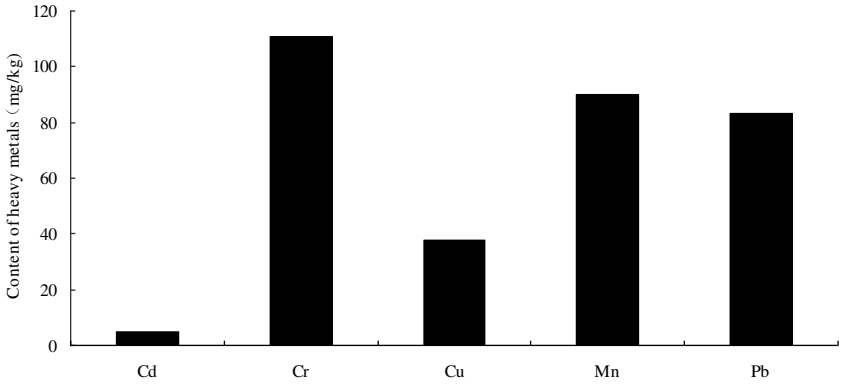

Figure 2. *Contents of heavy metals in the bark of Cinnamomum camphora at Xiangtan University*

The average content of Cd in Xiangtan is 5.35 mg/kg, with a range of 2-10.0 mg/kg; Average content of Cr is 117.35 mg/kg, with a range of 42.0-266.0 mg/kg; Average content of Cu is 44.376 mg/kg, with a range of 23.74-126.42 mg/kg; Average content of Mn is 304.529 mg/kg, with a range of 19.5-1214.56 mg/kg; Average content of Cr is 86.65 mg/kg, with a range of 30.0-220.0 mg/kg (*Tables 1* and *2*). Average heavy metal content in the barks of *Cinnamomum camphora* was Mn > Cr > Pb > Cu > Cd, and the content of Mn reached 304.529 mg/kg. The content of Mn in Xiangtan has a high background value, which is a factor with local characteristics. The above situation may be related to the long-term mining of Mn in Xiangtan Manganese Mine. During over 100 years of mining, tailing, slag and sewage were not treated effectively and timely, resulting in the loss and diffusion of Mn. Manganese can diffuse into the atmosphere and soil through a variety of approaches (Xie et al., 2005; Xi et al., 2008). Plants can absorb manganese through their roots, accepting atmospheric deposition, and absorption function of plants themselves, so that the manganese content in plants reached a higher level.

Heavy metal contents in the barks of Cinnamomum camphora in different functional districts and their sources

Content and spatial distribution of heavy metals in the barks of *Cinnamomum camphora* were different in different functional regions in Xiangtan city (*Table 2*). The content of the heavy metals in each functional district is Industrial Area > residential area > urban green area > commercial area. Among them, the heavy metal content in the Industrial District was the highest, and the maximum value reached 1301.5 mg/kg. The highest content of manganese also appeared in the Industrial District, reaching

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98279835

736.68 mg/kg. The maximum heavy metal contents in the Residential District reached 947.06 mg/kg, and the contents of Mn, Cr, and Pb were relatively high. Urban Green Districts in this research were mainly urban parks, and their environments are relatively good. Overall, the heavy metal content of the barks of *Cinnamomum camphora* in Urban Green Districts is lower than that in industrial and Residential Districts. However, because Yuetang Park is located close to the old industrial zone of Xiangtan Iron & Steel Co. Ltd of Hunan Valin, environmental pollution around Yuetang Park was severe, and the maximum heavy metal content reached 833.42 mg/kg.

Table 1. *Heavy metal contents in Cinnamomum camphora in Xiangtan (mg/kg)*

Heavy metal	Cd	Cr	Cu	Mn	Pb
Average	5.35	117.35	44.376	304.529	86.65
Range	2.0-10.0	42.0-266.0	23.74-126.42	19.5-1214.56	30.0-220.0
Standard deviation	1.994	51.089	19.242	261.859	42.944

	Minimum	4	106	35.32	69.16	52	266.48
	Average	5	125	36.74	126.68	102.33	395.75

The sources of heavy metal pollution in cities are exceptionally incredible, and the primary pollution sources in diverse functional areas are different. The highest heavy metal content in the barks of *Cinnamomum camphora* in Xiangtan is Mn due to the exploitation of Xiangtan Manganese Mine. However, the content of manganese is different in various functional areas (*Table 3; Fig. 3*). The manganese content in Shuxianglin was 333.96 mg/kg, ranking third in all sampling sites. Besides Mn, the content of Cr and Pb was relatively high, reaching 160 mg/kg and 78 mg/kg respectively. The dense buildings, less greening area, a large population density, large living garbage, living sewage and a large amount of exhaust gas from the combustion of domestic fuel near this district led to the high content of Mn, Cr, and Pb. Besides,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98279835

Shuxiangyulin Community is next to Ji'an Road and not far away from the Xiangtan East Automobile Station. Barks of *Cinnamomum camphora* might accumulate a large amount of automobile exhaust and road dust due to the huge traffic flow, which may also be the reason for the high content of Cr and Pb. The minimum values of Cr and Mn appeared near the Railway Station, reaching 68 mg/kg and 78.12 mg/kg. The principal reasons are its location close to the suburbs, the low buildings and the small traffic flow of the adjacent roads.

Table 3. *Heavy metal content in different sampling areas of different functional districts (mg/kg)*

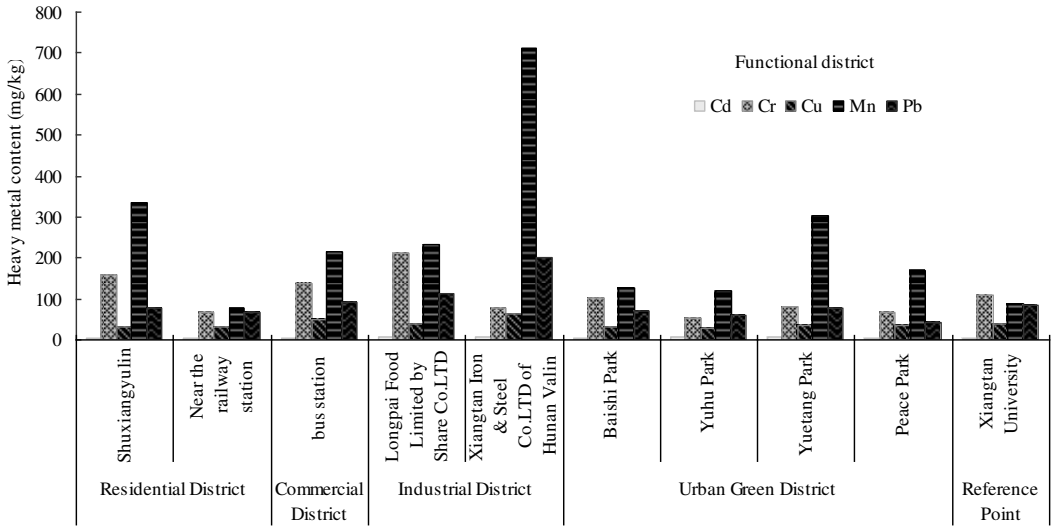

Figure 3. *Contents of heavy metals in the barks of Cinnamomum camphora in different functional areas*

The contents of Cd, Cr, Cu, Mn and Pb in the barks of *Cinnamomum camphora* were high in the Commercial District. The Long-distance Bus Station, as an essential part of the Commercial District, is located in the centre of Xiangtan City and has various food,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98279835

accommodation and entertainment industries, resulting in more garbage compared to other areas. Moreover, a large number of heavy metals can be produced by exhaust emissions from vehicle fuel combustion and dust in this district because of the massive traffic volume. These heavy metals will enter the atmosphere, and then accumulate on the surface of the barks of *Cinnamomum camphora* through atmospheric sedimentation and plant adsorption.

In the Industrial District, the heavy metal contents in the barks of *Cinnamomum camphora* are very high (*Tables 2* and *3; Fig. 3*). The maximum value of Mn and Pb both found in Xiangtan Iron & Steel Co. Ltd of Hunan Valin (*Fig. 3*) and reached 712.89 mg/kg, 7.9 times that of the reference point. The content of Pb reached 202 mg/kg, 2.4 times that of the reference point. The main reason why the heavy metal content of Xiangtan Iron & Steel Co. Ltd is so high is that it is a long-standing iron and steel enterprise with a complete set of technological processes, such as coking, sintering, ironmaking, steelmaking, rolled materials and so on. A large number of waste gas, wastewater, and residues containing Mn, Pb, Cd, and other heavy metals can discharge during the production process, and then enter the atmosphere and soil. After atmospheric deposition and rain wash, the heavy metal would accumulate in plants by absorption and adsorption through roots and barks. Therefore, the heavy metal contents in the barks of *Cinnamomum camphora* were high. At Longpai Food Limited by Share Co. Ltd, due to small greening, dense buildings and large traffic volume, the contents of Cr, Mn, Pb, and other heavy metals in the barks of *Cinnamomum camphora* are also relatively high, reaching 210 mg/kg, 233.28 mg/kg and 114 mg/kg, respectively.

Although Yuetang Park is an urban green space, it is located in the old industrial area and has a long history. Besides, it is close to Xiangtan Iron & Steel Co. Ltd, a critical pollutant enterprise. Therefore, the content of Mn in the barks of *Cinnamomum camphora* in this area even reaches a high level of 304.48 mg/kg, which is the place where the maximum content of Mn and Pb appears in urban green space. From *Table 3*, the highest content of Cr appears in Baishi Park, and the content is 101 mg/kg. Baishi Park lies in the old city centre of Xiangtan. There are more residents around it, and the traffic flow near the sampling point is also significant. Similar to other places with the high contents of heavy metal, road dust and living sewage are the main reasons for the high content of Cr in this area.

Conclusion

Heavy metal contents in the barks of *Cinnamomum camphora* had a specific accumulation and could indicate the air pollution condition in Xiangtan. The results showed that:

- The contents of Cr, Mn, and Pb in the barks of *Cinnamomum camphora* were the highest. Among them, the content of Mn exceeded seriously, and the average content was Industrial District > Residential District > Urban Green District > Commercial District. The maximum value of Mn appeared at Xiangtan Iron and Steel Co., with a high value of 712.89 mg/kg, which was 7.9 times the reference point.
- Heavy metals in the barks of *Cinnamomum camphora* mainly were produced by traffic discharge, living waste, manganese mining, and industrial enterprise discharge. The heavy metal contents in the barks of *Cinnamomum camphora* in the industrial area and its adjacent urban green space was high, which was

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98279835

mainly due to the production and emission of industrial enterprises. For Commercial Districts, the high contents of heavy metal were affected primarily by the traffic flow, automobile exhaust, and domestic waste. Population density and domestic waste were the significant factors affecting the heavy metal in the barks of *Cinnamomum camphora* in Residential Districts. Although some urban green space has a good environment and a vast green area, the heavy metal content in the barks of *Cinnamomum camphora* was high because of the influence of living waste and the surrounding environment.

- Bark has broad application prospects in monitoring environmental heavy metal pollution, but the current research is far from enough. Combining various biological monitoring methods (e.g., moss, leaves, barks, and roots), improving testing techniques and seeking more geochemical means will be the direction of future efforts.

(Received 28th Mar 2019; accepted 22nd May 2019)

Abstract. The incipient condition of granular sediments in great dimensionless flow depth was studied. A series of experimental runs were performed with four kinds of sediments in a 28 m long, 6 m wide flume and the data concerning incipient velocity, water depth and sediment particle size were collected to determine the relationship between incipient velocity and dimensionless water depth. The similarity condition between experimental flow and prototype flow with great dimensionless water depth was analysed according to the logarithmic velocity distribution law in the open channel firstly. The analysis results indicate that water depth cannot be used as a directing-variable for the incipient velocity of granular sediments in great dimensionless flow depth. In order to solve this problem, boundary layer momentum thickness was introduced into flume experiment to replace water depth as the directing-variable. Furthermore, an empirical formula for the incipient velocity of granular sediment in great dimensionless flow depth that includes the proportion of fluid γ, the proportion of granular sediment γ_s, the acceleration of gravity g and the dimensionless water depth (H/d) was proposed and the calculated results are more accurate and reasonable compared to previous studies, especially when the dimensionless water depth is greater than 10^4.
Keywords: *incipient velocity, granular sediment, the ratio of water depth to particle size (H/d), similarity condition, boundary layer momentum thickness*

Introduction

Almost all sediment-related problems in water, including water quality and pollution, scouring, deposition, and issues related to construction and management of reservoirs and canals, and wetland restoration, are associated with the incipient condition of sediment motion (Venditti et al., 2006). In a lake, the bottom currents due to external forces (e.g., winds) can suspend the bottom sediments, thus enhancing the release of contaminants and nutrients from the bed into the water column (Zhang et al., 2018; Zhang and Yu, 2017). The incipient velocity of sediment is an important parameter to estimate sediment motion as well as riverbed evolution, and to solve the engineering problems of riverbed deformation, bank protection engineering, channel stability and other engineering problems (Zou et al., 2017; Mao et al., 2011). The study on the incipient condition of sediment motion has also great significance to the protection of marine ecological environment, hence it has been a hot topic for decades.

There are two major parameters to describe the incipient condition of sediment motion, i.e., threshold bed shear stress (Rijn, 1984; Chien and Wan, 1999; Yu and Lim, 2003; Zhang and Yu, 2017) and incipient velocity (Beheshti et al., 2008; Francisco et al., 2014). Incipient velocity is more widely used in practices, because only when the flow velocity is sufficiently great, the sedimentary particles which belong to a flat-bed can be dislodged and start to move (Righetti and Lucarelli, 2007; Luo, 2011). In

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98379863

addition, the incipient velocity of sediment is the basic of mechanics of sediment motion and riverbed evolution, and is also an important parameter to solve the sediment problems of riverbed deformation, bank protection engineering, channel stability and other engineering problems (Zou et al., 2017; Mao et al., 2011).

There are a lot of efforts on investigating the incipient condition of sediment motion and many useful formulae have been proposed and successfully applied in practical engineering. As early as 1935, according to the experimental data, Hjulstrom found that when the sediment particle size was 0.2-0.3 mm, the incipient velocity of sediment had a minimum value (Phillips, 1992) and since then, scholars from all over the world carried out many experimental research and theoretical analysis, and derived many formulae for the incipient velocity of sediment from the perspective of mechanics and random process. Xie (1981) recommended several representative former Russia formulae such as Shyamov formula (*Eq. 1*), which can be used to calculate the incipient velocity of the granular sediments with the particle size $d > 0.15$ mm and Goncharov formula (*Eq. 2*).

$$v_c = 1.14\sqrt{\frac{\rho_s - \rho}{\rho} gd}\left(\frac{h}{d}\right)^{\frac{1}{6}} \quad \text{(Eq.1)}$$

$$v_c = 1.07\sqrt{\frac{\rho_s - \rho}{\rho} gd}\lg\left(\frac{h}{d}\right)^{\frac{1}{6}} \quad \text{(Eq.2)}$$

where d = the particle size, v_c = the incipient velocity of sediments, h = the depth of water, ρ and ρ_s were the density of fluid and sediment particle respectively, g = acceleration of gravity, ξ and m were the undetermined coefficients. Considering the viscosity of fine sediment, many Chinese scholars have proposed new formulae for the incipient velocity of sediment. Dou (1960) proposed a formula for the incipient velocity of sediment in shallow water in 1960 and modified it in 1974, such as *Equation 3*.

$$v_c = 0.32(\ln 11\frac{h}{k_s})[(\frac{\rho_s - \rho}{\rho})gd + 0.19(\frac{\varepsilon_k + dh\delta}{d})]^{0.5} \quad \text{(Eq.3)}$$

where $\delta = 0.213 \times 10^4$ cm; $\varepsilon_k = 2.56$ cm^2/s^2, k_s is riverbed roughness, and for the flat bed, $k_s = 0.5$ mm when $d \leq 0.5$ mm and $k_s = d$ when $d > 0.5$ mm. Zhang (1961) proposed *Equation 4*, which is the formula of Wuhan Institute of Hydraulic and Electric Engineering and adopted in Chinese code.

$$v_c = [1.76(\frac{\rho_s - \rho}{\rho})d + 0.000000605(\frac{10 + h}{d^{0.72}})^{0.5}(\frac{h}{d})^{0.14} \quad \text{(Eq.4)}$$

However, the parameters introduced by previous research results which are mostly determined by the flume experiments would affect the accuracy of the formulae, because the water depth in flume is always limited to 0.1-0.5 m, whereas the actual estuary water depth can reach 5-10 m, sometimes even about 20 m (Zeng et al., 2010). Compared with other formulas, the formula (*Eq. 5*) of Sha (1965) payed more attention

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98379863

to the influence of increased water depth on the incipient velocity of sediment, which was closer to the natural river (Zhang, 2012).

$$v_c = \sqrt{\frac{\rho_s - \rho}{\rho} gdh^{1/5}[266(\frac{\delta}{d})^{1/4} + 0.66\times10^9(0.7-\varepsilon)^4(\frac{\delta}{d})^2]^{1/2}} \quad \text{(Eq.5)}$$

where δ = the film water thickness and $\delta = 0.0001\ mm$; ε was the porosity and $\varepsilon \cong 0.4$). Whereas, Han et al. (1982) considered that the formula of Sha (1965) took the influence of the bonding force caused by contact between sediment particles and the porosity on the incipient velocity of sediment into account, but the mechanical mechanism was not described and expressed clearly. Therefore, the formula for the incipient velocity of sediment needs to be further studied.

The formulae of the incipient velocity of sediment are based on limited water depth which may result in their inapplicability (Zeng et al., 2010). The formula form $v_c = kd^{1/3}h^{1/6}$ is almost adopted to calculate the incipient velocity of non-viscous sediment (Karmer, 1935; He et al., 2002). Nie et al. (2004) summarized dozes of the existing formulas and derived the unified formula (*Eq. 6*), whereas the values of ξ and m were slightly different in different formulae.

$$v_c = \xi\sqrt{\frac{\rho_s - \rho}{\rho} gd}(\frac{h}{d})^m \quad \text{(Eq.6)}$$

In most cases, the value of *m* is 1/6 and the of value ξ is usually between 3. 37 and 7 (Nie, 2004). He et al. (2002) believed that ξ was not a constant, but within a certain range and changed with the relative exposure of particles on the bed surface. However, it is found that the value of ξ at different flow levels is variable according to the analysis of the 246 groups of data on sediment initial motion at Yichang station which is one of the reservoirs of Three Gorges in China (Li et al., 2006). Li et al. (2006) used the normative formula of Wuhan Institute of Hydraulic and Electric Engineering and Shyamov formulae to calculate the incipient velocities of sediment based on the different flow levels at the Yichang station, and there was a huge error between the calculated results and the field measured data, especially in the case of huge flow. In addition, the coefficient ξ of *Equation 6* varies greatly when it is used to calculate the incipient velocities of the granular sediments with different particle sizes in the flow with the same water depth, i.e., Lu (1991) proposed the formulae for the incipient velocity of the pebble in the Yangtze river (its *H/d* range is 80 ~ 1000) and sandy and muddy (the range *H/d* of was 10000 ~ 100000), which based on the field measured data of sediment initial motion in the Yangtze river, but the value of ξ are 0.95 and 1.47, respectively, between which the difference is 1.55 times. Therefore, it is still necessary to study the incipient velocity of sediment under the premise of fully considering the influence of water depth or relative water depth on the incipient velocity of sediment.

To ensure that the formulae for the incipient velocity of sediment obtained by the flume experiments are more accurate and reliable, the similarity conditions between the experimental flow and the prototype flow with great dimensionless water depth should be satisfied (Ferro, 1999; Falcão et al., 2014; Dornbrack and Schumann, 1993; Steward and Tennankore, 1977). According to the force analysis of the sediment particles on the horizontal bed without seepage, only the drag force and the lifting force are favorable to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98379863

the initial motion of sediment particles, except the geometric status of sediment particles and the bed roughness (Niven, 2010; Bohorquez and Fernandez-Feria, 2008; Mao et al., 2011). Therefore, the distribution of the flow velocity on vertical line in the experimental flow and the prototype flow with great dimensionless water depth should satisfy the principle of similitude to ensure the accuracy of the experimental results, because the distribution of flow velocity would be affected by different water depth, which would have an impact on the Kinematic similarity between the experiment flow and the prototype flow with great dimensionless water depth. The velocity distribution in experimental flow and natural open channel flow generally adopt the logarithmic formula of velocity distribution (Yu and Tan, 2006; Meftah and Mossa, 2016) and the formula can be written as

$$\frac{u}{u_*} = \frac{1}{k}\ln(\frac{y}{\Delta}) \qquad \text{(Eq.7)}$$

where y = the height from the bed, u = the velocity at the height y, u_* = the friction velocity, κ = the Carmen coefficient, Δ = the rigidity of bed sediment and $\Delta = K_s/30.2$ (Nikuradse, 1933), K_s is the characteristic particle size of the bed surface. Hence, the similarity conditions between the experimental flow and the prototype flow with great dimensionless water depth would be analyzed firstly according to the logarithmic velocity distribution law in open channel.

In this study, a series of experimental runs were conducted and the previous data were collected. Finally, a new formula for the incipient condition of the granular sediment in great dimensionless water depth was proposed. Section 2 described the analysis of Similarity condition between experimental flow and prototype flow with great dimensionless water depth. Section 3 described the derivation and the structure of the empirical formula for the incipient velocity of granular sediment in the flow with great dimensionless water depth. Section 4 described the test materials, experimental setup, and test procedure. In section 5, the experimental results were presented, and the parameters of the empirical formula were determined. In addition, the soundness and the accuracy of this empirical formula were verified by comparing with previous studies. Finally, section 6 presented the main conclusions of the study and the recommendations for future studies.

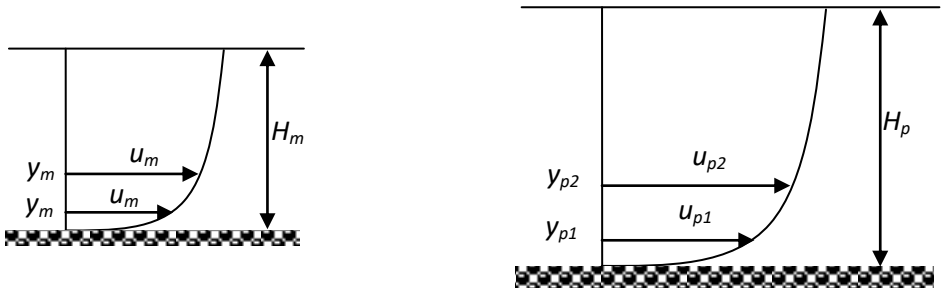
Theoretical basis

Similarity requirement for sediment motion in different flow depths

In this paper, the similarity condition between the experimental flow and the prototype flow with great dimensionless water depth was analysed based on the logarithmic velocity distribution law in open channel. It is assumed that the experimental flow was to be able to fully simulate the prototype flow with great dimensionless water depth. Some assumptions are made to better illustrate the similarity between the experimental flow and the prototype flow. The flow distributions in an experimental flume and in a prototype flow are shown in *Figure 1,* where the subscript m denotes model (experimental flume) and the subscript p denotes the prototype. H_p and H_m is the flow depth in the experimental flume and in the prototype flow, respectively. Suppose $H_p/Hm = \lambda$. The velocity in the experimental flow at the height y_{m1} and y_{m2}

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98379863

from the bed surface are assumed as u_{m1} and u_{m2}, and the corresponding velocities in the prototype flow with great dimensionless water depth at the height $y_{p1} = \lambda y_{m1}$ and $y_{p2} = \lambda y_{m2}$ from the bed surface are assumed as u_{p1} and u_{p2}. The particle sizes of the experiment flume bed and corresponding prototype bed are assumed as d_m and d_p, respectively.



(a) Experimental flow (b) Prototype flow

Figure 1. *Vertical velocity distribution*

Suppose $K_s = d$ (Bennett and Best, 1995; Mianaei et al., 2010) for the uniform sediment. Hence,

$$\frac{u_{m1}}{u_{*m}} = \frac{1}{\kappa}\ln(30.2\frac{y_{m1}}{d_m}) \quad \text{(Eq.8)}$$

$$\frac{u_{m2}}{u_{*m}} = \frac{1}{\kappa}\ln(30.2\frac{y_{m2}}{d_m}) \quad \text{(Eq.9)}$$

$$\frac{u_{p1}}{u_{*m}} = \frac{1}{\kappa}\ln(30.2\frac{y_{p1}}{d_m}) \quad \text{(Eq.10)}$$

$$\frac{u_{p2}}{u_{*m}} = \frac{1}{\kappa}\ln(30.2\frac{y_{p2}}{d_m}) \quad \text{(Eq.11)}$$

Equation 8 is divided by *Equation 9*, and the parameters u_{*m} can be eliminated. In a similar way, *Equation 11* is divided by *Equation 10*, and the parameters u_{*p} can be also eliminated. Hence,

$$\frac{u_{m1}}{u_{m2}} - \frac{u_{p1}}{u_{p2}} = \frac{\ln(30.2\frac{y_{m1}}{dm})}{\ln(30.2\frac{y_{m2}}{d_m})} - \frac{\ln(30.2\frac{y_{p1}}{d_p})}{\ln(30.2\frac{y_{p2}}{d_p})} \quad \text{(Eq.12)}$$

Equation 12 can be further simplified, and the similarity condition between the experimental flow and the prototype flow with great dimensionless water depth can be written as

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98379863

$$\frac{u_{m1}}{u_{m2}} - \frac{u_{p1}}{u_{p2}} = \frac{\ln(\frac{y_{m2}}{y_{m1}})[\ln(\frac{d_p}{d_m}) - \ln(\lambda)]}{\ln(30.2\frac{y_{m2}}{d_m})\ln(30.2\frac{y_{p2}}{d_p})} \quad \text{(Eq.13)}$$

According to kinematic similarity criteria, it can be seen from *Equation 13*, when $\lambda = d_p/d_m$, u_{m1}/u_{m2} is equal to u_{p1}/u_{p2}. In other words, only when the dimensionless water depth (the ratio of water depth to particle size, H_m/d_m) in experimental flow is the same as that in corresponding prototype flow H_p/d_p, the flow velocity near the particles in experimental flow is similar with that in corresponding prototype flow and the motion of the sediment is similar in both scenarios. Otherwise, if $\lambda < d_p/d_m$, u_{m1}/u_{m2} is larger than u_{p1}/u_{p2} which indicates that the flow velocity near the sediment particles in experimental flow is higher than that in corresponding prototype flow, and the sediment particles in experimental flow would be easier to be dislodged than that in corresponding prototype flow. On the other hand, when $\lambda > d_p/d_m$, u_{m1}/u_{m2} is smaller than u_{p1}/u_{p2}, which indicates that the flow velocity near the sediment particles in experimental flow would be lower than that in corresponding prototype flow, and the sediment particles in experimental flow are then more difficult to be dislodged than that in corresponding prototype flow. It is seen that similarity condition between experimental flow and corresponding prototype flow is that the sediment particle size scale (d_p/d_m) equal to water depth scale (H_p/H_m), that is, $H_p/d_p = H_m/d_m$. Hence, the similarity between experimental flow and corresponding prototype flow is necessary to ensure the similar flow velocity near the sediment particles near bed in experimental flow and corresponding prototype flow.

In line with the similarity analysis between the experimental flow and the prototype flow in great dimensionless water depth, the current formulae deduced from flume experiments may be not suitable for calculating the incipient velocity of the granular sediment motion in great dimensionless depth of water, which requires a wide range of *H/d* in the flume experiment, for example, the water depth varies from 10 to 40 m, and the sediment particle sizes are between 0.2 and 2 mm in the middle reaches of the Yangtze river (Lu, 1991), thus the range of *H/d* is more than 200,000, and, the *H/d* range from 2 to 2030 according to the 272 groups of experimental data collected by author. On the other hand, non-natural sediments such as the homogeneous model sediments are always used in flume experiments (Geiger and Durnford, 2000; Thomas and Calantoni, 2001; Jain and Juans, 2009), and the particle size of the homogeneous model sediment is relatively larger than that of the natural sediments, which cannot be used to simulate the motion of cohesive sediments. Because the particle size of the cohesive sediments is always less than 0.06 mm (Grabowski et al., 2011; Jean Berlamont et al., 1993), and the viscosity between cohesive sediment particles will affect the incipient condition of sediments (Mehta, 1984 and1989; Lumborg and Windelin, 2003). Therefore, the limitation of experimental flume size would affect the accuracy of the existing formulas for the incipient velocity for the granular sediments in the flow with great dimensionless water depth, and and the water depth in flume experiment should not be used as the direct variable of the formulas for the incipient condition of the sediment in the flow with great dimensionless water depth.

Boundary layer momentum thickness calculation

In this paper, boundary layer momentum thickness was introduced into the flume experiment as the independent variable to calculate the incipient velocity of the granular sediment in the flow with great dimensionless water depth. Boundary layer thickness reflects the block effect of bed wall and Roux (2010) regarded that the incipient motion of sediment is mainly affected by the flow near bed, that is, the flow near the boundary layer and the influence of the flow velocity outside the boundary layer on the sediment motion could be ignored in deep water area. Due to the viscous effect of fluid, the change of flow velocity in boundary layer will cause the loss of momentum in the boundary layer. The loss of momentum in the boundary layer can be explained by the momentum thickness of the boundary layer. Therefore, the boundary layer momentum thickness can be taken as a direct factor affecting sediment motion, which should be used to calculate the incipient velocity of sediment, rather than the water depth.

In general, boundary layer momentum thickness δ^1 is used to describe the boundary layer thickness intuitively (Hokenson, 1977), which can be written as follows:

$$\rho\delta^1 U^2 = \int_0^{\delta^*} \rho u(U-u)dy \qquad \text{(Eq.14)}$$

where ρ is the density of water, *kg/m*^{3}; δ^1 is boundary layer momentum thickness; δ^* is the boundary layer thickness, *m*. *U* and *u* are supposed to comply with the logarithmic velocity distribution law (Jonsson, 1966). Therefore, *Equation 14* can be written as

$$\rho\delta^1 = \frac{\delta^*}{\ln(30.2\frac{\delta^*}{d})} - \delta^* - \frac{1}{[\ln(30.2\frac{\delta^*}{d})]^2}\int_0^{\delta^*} \ln^2(30.2\frac{y}{d})dy \qquad \text{(Eq.15)}$$

where *y* is the water depth where the velocity is *u, m/s*. It is assumed that

$$x = 30.2\frac{y}{d} \qquad \text{(Eq.16)}$$

So *Equation 15* can be derived as *Equation 17*.

$$\delta^1 = \frac{\delta^*}{\ln(30.2\frac{\delta^*}{d})} + 2\frac{\delta^*}{\ln^2(30.2\frac{\delta^*}{d})} \qquad \text{(Eq.17)}$$

In the flume scale, the boundary layer thickness is determined by the water depth of the flume, that is $\delta^* = H$, and the boundary layer momentum thickness in shallow water area such as in the flume can be calculated by *Equation 18*.

$$\delta^1 = \frac{H}{\ln(30.2\frac{H}{d})} + 2\frac{H}{\ln^2(30.2\frac{H}{d})} \qquad \text{(Eq.18)}$$

Formula form derivation

In this section the formula form for the incipient velocity of the granular sediment in the flow with great dimensionless water depth was analysed. The incipient motion of sediment is mainly affected by incipient condition which should conclude the characteristics of sediment particles, flow conditions and the relationship between flow conditions and sediment particles (Wang et al., 2008). Hence, the incipient velocity of granular sediment is influenced by the proportion of sediment particle, the proportion of fluid, kinematic viscosity coefficient, salinity, acceleration of gravity besides boundary layer momentum thickness. While the kinematic viscosity coefficient and saltiness can be ignored, because the temperature has little impact on the kinematic viscosity coefficient of fresh water and sea water (Balucani et al., 1996). Therefore, the formula form of the incipient velocity for the granular sediment particle can be written as

$$v_c = f(g, \gamma, \gamma_s, d, \delta^1) \tag{Eq.19}$$

where γ is the proportion of water, kg/m^3; γ_s is the proportion of sediment, kg/m^3. As mentioned above, *Equation 6* is almost adopted as the formula form to calculate the incipient velocity of sediment, therefore the formula form of the granular sediment in the flow with great dimensionless water depth can be expressed as:

$$v_c = \xi(\frac{\gamma_s - \gamma}{\gamma} gd)^a d^b \delta^{1c} \tag{Eq.20}$$

where ξ, a, b, c are constants. In this paper, $d = D_{50}$. It can be deduced that $a = 0.5$, $b = c$ by the dimensional analysis of *Equation 20*. Therefore, the formulary structure of incipient velocity for the granular sediment particle can be written as

$$v_c = \xi(\frac{\gamma_s - \gamma}{\gamma} gd)^a d^{0.5} (\frac{\delta^1}{d})^c \tag{Eq.21}$$

Compared with *Equation 6*, water depth H is replaced by the boundary layer momentum thickness δ^1 in *Equation 21*, which is confirmed to the similarity requirement between the experimental flow and the prototype flow with great dimensionless water depth for sediment initial motion.

Materials and method

Test materials

Four kinds of sediment particles with different particle sizes were used for the tests, which concluded one kinds of model sediments (MS) and three kinds of natural sediments. The homogeneous granular plastic sands were used as the test sediments which can be applied to the model experiment with different scale. The particle size of the homogeneous granular plastic sands in this experiment was 3.2 mm and the proportion of the homogeneous granular plastic sands was 1050 kg/m^3. The natural sediments were from different places: coastal line of Fengxian (FX), Shanghai, China; Huangpu River (HPJ) of Shanghai; coastal line of Zhuhai (ZH), Guangzhou province.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98379863

The natural sediments were dried for 24 h in an oven at a temperature of 105°. After that, the dried sediments were sieved through a series of standard sieves with different diameters of holes to screen suitable sediment particle sizes and eliminate impurities such as small stones and shellfish. The determination range of standard sieves in laboratory is 0.038~6 mm. All the grain size and grain density are summarized in *Table 1*.

Table 1. *Grain size and grain density*

Location of sediment	FX	HPJ	ZH
Grain density (g/cm^3)	2.02	2.23	1.98
Median particle size (mm)	0.33	0.84	1.22
Standard deviation of grain size (μm)	1.6	2.6	0.9
Sorting coefficient	1.85	2.11	1.80

In addition, 272 groups of previous data concerning the incipient velocity of granular sediment, water depth and sediment particle size were collected to verify and fit the formula for the incipient velocity for granular sediments in the flow with great dimensionless water depth. The rang of the sediment proportion of the collected data is from 2010 to 2650 kg/m^3, and the rang of the sediment particle sizes of the collected data are from 0.04 to 22.2 mm. The maximum depth selected from the collected data is 0.47 m.

Experiment setup

The flume experiment was performed in the laboratory to examine the incipient velocities of the sediments with different particle size. The layout of the experimental apparatus is shown in *Figure 2*. The experimental flime was a water-circulating rectangle flume with a length of 10 m, width of 1 m, height of 1 m. A rectangular groove with dimensions of 50 cm length, 1 m width, and 5 cm depth was arranged at the bottom of the rectangular flume. The sample box with different sediment particles was placed in a groove during the experiment. The upper surface of the sample box was aligned with the inner wall of the flume to ensure that the inner surface of the flume was flat. Windows are provided on both sides of the flume to facilitate the observation of sediment motion. Two flow straighteners were installed at the upstream and downstream ends of the flume, respectively, to ensure that the water flowed evenly in the test range of the flume. The water inlet and water outlet are on the left side of the flume which can be controlled by the valve. The valves of water inlet and water outlet were closed during the experiment. A pump was arranged under the water-circulating rectangle flume and connected with the flume, flow meter and flow control valve by the pipe. The pump is ISG type vertical pipe centrifugal pump. The lift of this pump is 60 m and the flow is 45 m^3/h. The flow control valve was used to control the flow in the flume. The flow meter is an electromagnetic flowmeter whose nominal diameter is DN6-DN2000 with wide coverage. The flow velocity in the flume was measured by UDV 3000.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98379863

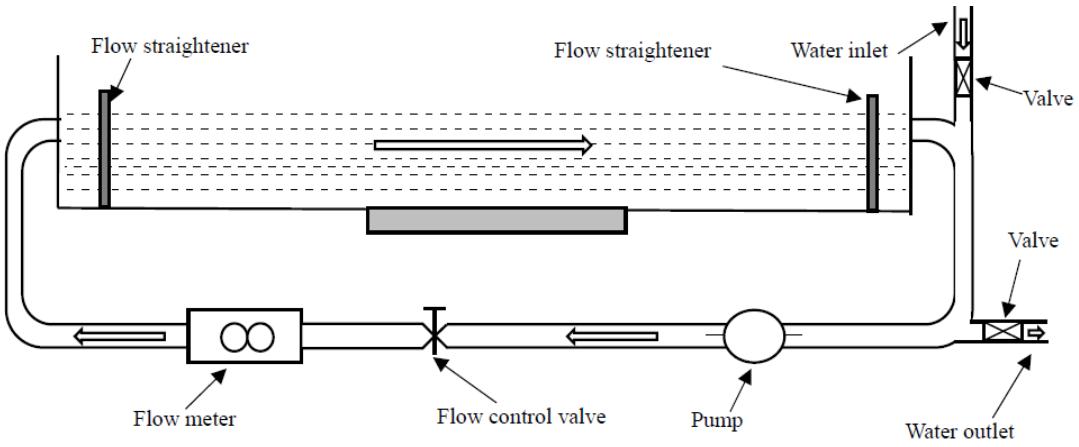

Figure 2. *Experiment setup*

Test procedure

First, tap water was added into the flume through the water inlet on the left side of the flume, and the valve of water outlet was closed at this time. When the water depth reaches a certain level, the valve of water inlet was closed. The depth of the water by artificial control was between 10 and 50 cm. The sample box with the sediment samples inside was then lowered into the square box. Subsequently, the pump was turned on and the flow control valve was then opened slowly. The incipient motion of sediment was observed through the windows on both sides of the flumes. The flow velocity was accelerated very slowly by 1–2 cm/s every minute until a few sediment particles were dislodged from the bed surface, and the flow velocity was recorded at this time. The incipient criterion of sediment is that about 1‰ of the particles dislodged from the bed surface (Kramer, 1935; Chien and Wan, 1983), which also applies to model sediment (Huang et al., 2012). This phenomenon that the sediment particles dislodge from the bed surface continuously took place in both time and space, that is, the sediment motion could always be observed throughout the experiment (Zhang et al., 2017). Because the incipient criterion of sediment processed a certain amount of subjectivity and judgment (He et al., 2003; Huang et al., 2012), there must be some divergent data in the experimental results. In order to minimize the errors of inevitable subjectivity associated with incipient criterion of sediment, the procedure for measuring the flow velocity when the phenomenon that a few sediment particles were dislodged from the bed surface was observed was repeated three times for every sediment samples. Once the incipient criterion of sediment samples was reached, the flow velocity, and the difference of water head were recorded.

Results and discussion

Empirical formula for the incipient velocity for granular sediment in the flow with great dimensionless water depth

In this section, the coefficients ξ and c of *Equation 21* are discussed by means of data fitting and collection. A series of previous data were collected, which include the experimental date of incipient condition of sediment collect by Yang et al. (2006) and a part of the sediment experimental data collected by Brownlie (1981). The basis of the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98379863

data screened from the data collected by Brownlie (1981) is that the suspended sediment concentration range of the collected data should be between 0 PPM and 3 PPM, according to the analysis of sediment transport and the distribution of suspended sediment concentration in the fluid when the sediment particles begin to suspend (Ted et al., 1974) and these screened data included the experiment data of Simons, Bishop and Richardson (1965), Yalin and Karahan (1979), Govt. of West Bengal (1965), Casey (1935), Costello (1974), Davies (1971), Guy at al. (1966), Ho (1939), Mavis et al. (1937), Mutter (1971), Nordin (1976), Oerien (1935), Paintal (1971), Pratt (1970), Taylor (1971). The experimental results are shown in *Table 2*. The collected data are shown in the *Appendix*.

0.366	1109.09	0.2228	435.71	0.334	300	0.3219	114.38	0.1054
0.385	1166.67	0.2247	458.33	0.337	315.57	0.3247	120.31	0.1063
0.426	1290.91	0.2285	507.14	0.343	349.18	0.3302	133.13	0.1081

The coefficients of *Equation 21* were determined respectively using the test results and the collected data with the help of Origin 9.0 and Excel 2017. Firstly, the formal deformation of *Equation 21* was carried out in order to simplify the calculation as follows: the opposite sides of *Equation 21* was taken logarithm respectively, and then the multivariate regression method was used to determine these coefficients. These coefficients were evaluated as follows: $\zeta = 1.74$, $c = 0.18$. The value of $R^2 = 86\%$ indicates that the fit of the obtained model is fairly-good. Hence, the incipient velocity for the granular sediments in the flow with great dimensionless water depth can be expressed as follows:

$$v_c = 1.74\left(\frac{\gamma_s - \gamma}{\gamma} gd\right)^{0.5}\left(\frac{H}{d}\right)^{0.18}\left[\frac{1}{\ln(30.2\frac{H}{d})} + \frac{2}{\ln^2(30.2\frac{H}{d})}\right]^{0.18} \qquad \text{(Eq.22)}$$

As show in *Figure 3,* the curves plotted using the calculated values based on *Equation 22* are in accordance with the experimental data and the collected data, and this formula possesses an acceptable accuracy for calculating V_c, as 86% of the datasets are within a confidence interval with a relative error of 20%.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98379863

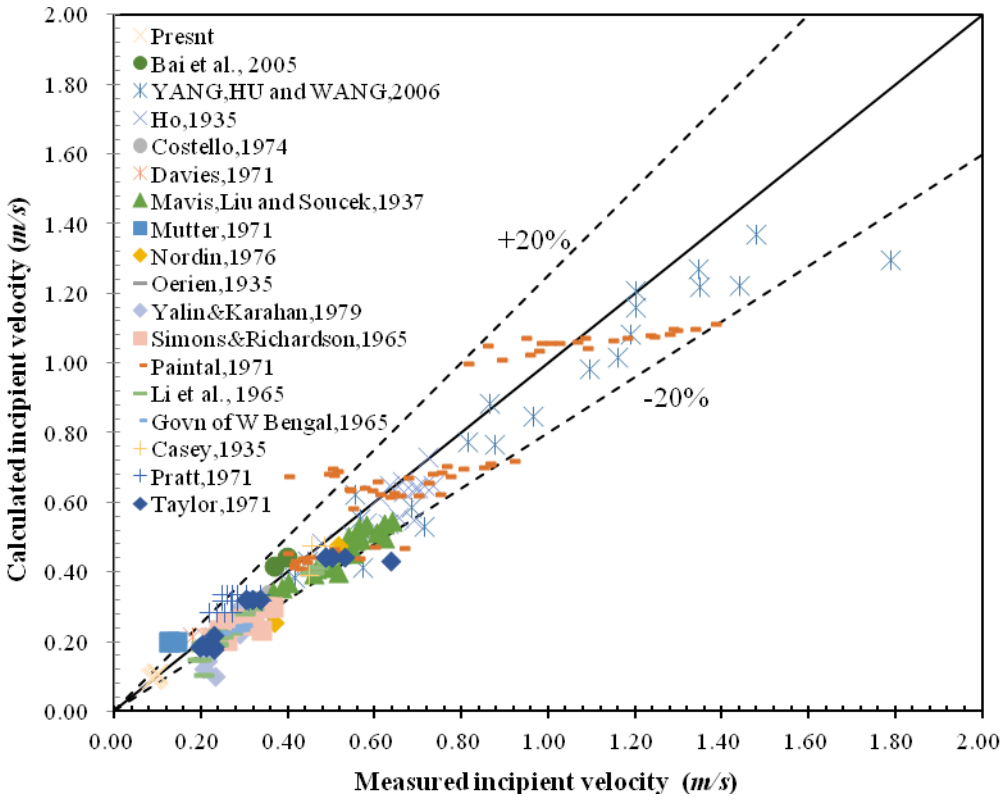

Figure 3. *Comparison between the measured and the calculated incipient velocity*

The incipient velocity of granular sediments in the flow with great dimensionless water depth are plotted according to *Equation 22*, and an incipient velocity diagram is drawn, as shown in *Figure 4*. The incipient velocity of granular sediments in the flow with great dimensionless water depth are plotted as a function of the dimensionless water depth (*H/d*) with the particle size as an independent parameter. It can be seen from *Figure 4* that the incipient velocity of the granular sediments in the flow with great dimensionless water depth increases with the increase of the dimensionless water depth (*H/d*) and the particle size, i.e., the incipient velocity of the granular sediments in the flow with great dimensionless water depth increases from 0.2 m/s to 0.45 m/s when the particle size increases from 0.1 mm to 5 m/s and the great dimensionless water depth is 5000; the incipient velocity of the granular sediments in the flow with great dimensionless water depth increases from 0.2 m/s to 0.625 m/s when the great dimensionless water depth (*H/d*) increases from 5000 to 4000000 and the particle size is 0.5 mm.

Soundness verification this empirical formula

The incipient velocity of granular sediments in the flow with great dimensionless water depth calculated by *Equation 22* proposed in this paper was compared with that calculated by *Equation 4* of Wuhan Institute of Hydraulic and Electric Engineering which has been used as a normative formula for the calculation of incipient velocity of sediment to verify the soundness of *Equation 22*, *Figure 5* depicts the incipient velocities of sediment in the flow with great dimensionless water depth (*H/d*) with various particle size, which are calculated by *Equation 22* and the formula of Wuhan

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98379863

Institute of Hydraulic and Electric Engineering. The comparison between calculated results of the empirical *Equation 22* and the normative formula of Wuhan Institute of Hydraulic and Electric Engineering clearly indicates the following:

The incipient velocities of the granular sediments calculated by the two formulas both increases with the increase of the dimensionless water depth (*H/d*) and the particle size of granular sediment.

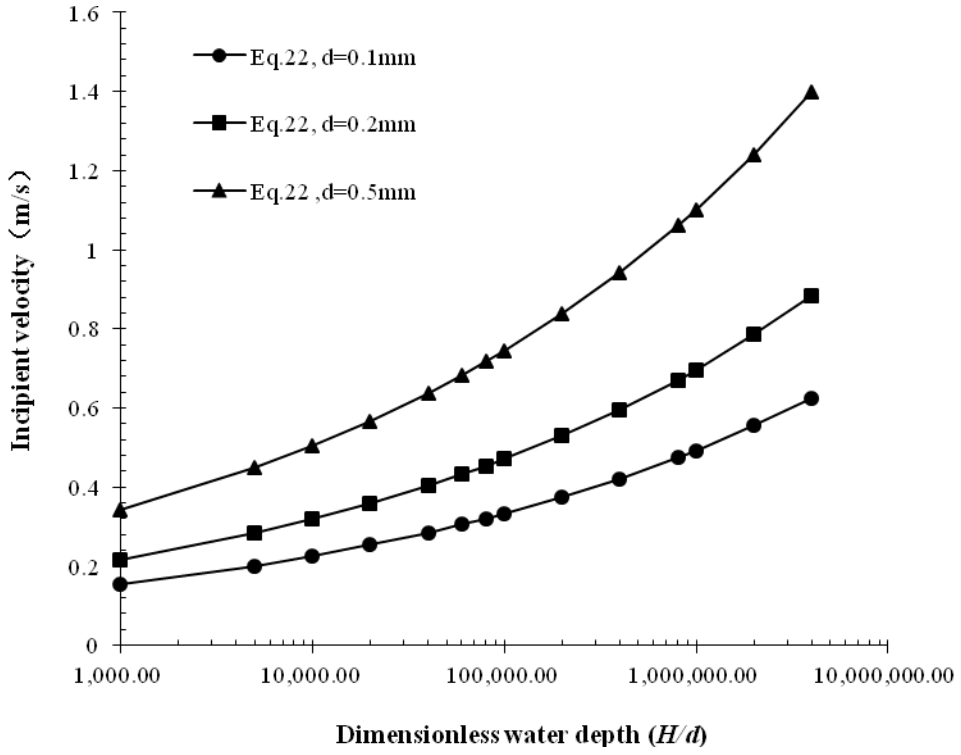

Figure 4. *Incipient velocity diagram*

For $H/d \leq 1 \times 10^4$, the increasing trend of the incipient velocities of the granular sediments calculated by *Equation 16* with the dimensionless water depth (*H/d*) is similar with that calculated by the normative formula of Wuhan Institute of Hydraulic and Electric Engineering, and all increase slowly. Whereas, the incipient velocities of the granular sediments calculated by *Equation 16* is lower than that calculated by the normative formula of Wuhan Institute of Hydraulic and Electric Engineering when the particle size is less than or equal to 0.2 mm. When the particle size is more than 0.2 mm, the incipient velocities of the granular sediments calculated by *Equation 22* is approximately equal that calculated by the normative formula of Wuhan Institute of Hydraulic and Electric Engineering.

For $H/d > 1 \times 10^4$, the increasing trend of the incipient velocities of the granular sediments calculated by *Equation 22* is much slower than that by the normative formula of Wuhan Institute of Hydraulic and Electric Engineering, which demonstrates that there will be a large difference between incipient velocities of granular sediment calculated by *Equation 22* and the normative formula of Wuhan Institute of Hydraulic and Electric Engineering when the dimensionless water depth (*H/d*) is more than 10^4, and the difference increases with the increase of *H/d*. In order to illuminate the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98379863

appearance, Wanxian site is taken as an example, which is one of the reservoirs of Three Gorges in China. The particle size of the sediment at Wanxian site is less than 0.16 mm and the depth of water will reach 100 m when the reservoir is full of water (Wang et al., 2010). But the incipient velocities of the sediment at Wanxian site calculated by *Equation 22* and the normative formula of Wuhan Institute of Hydraulic and Electric Engineering are 1.306 m/s and 0.601 m/s respectively, which differ widely.

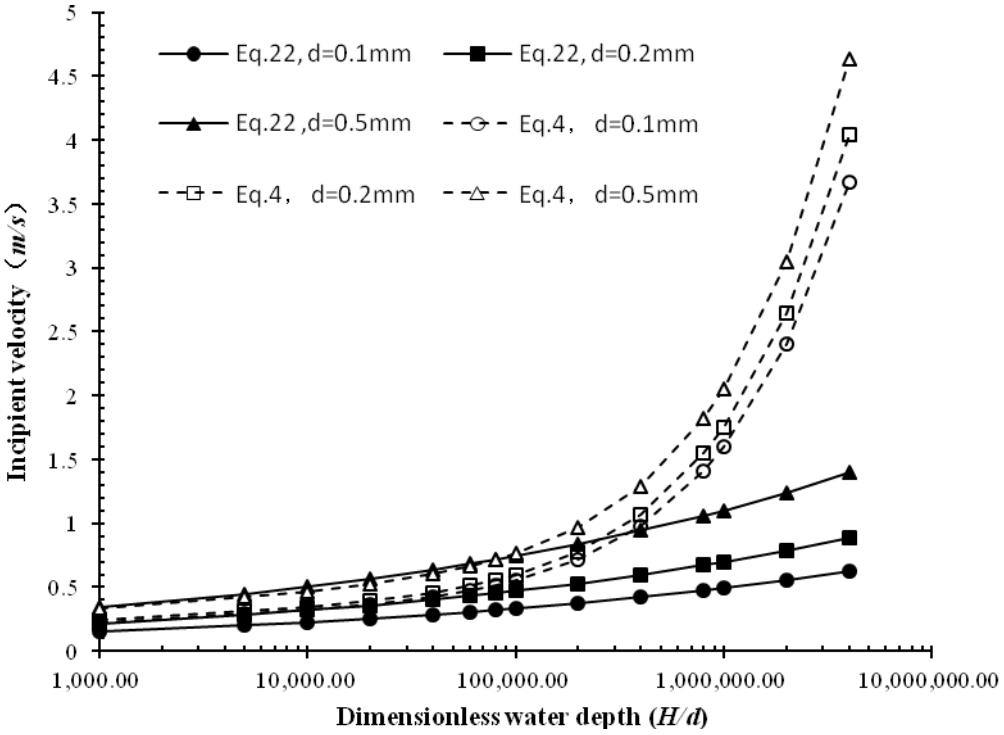

Figure 5. *Comparison between calculated results of the empirical Equation 22 and the normative formula of Wuhan Institute of Hydraulic and Electric Engineering*

Although there is no direct data to determine the rationality of the calculation results *Equation 22* and the formula of Wuhan Institute of Hydraulic and Electric Engineering, it can be concluded that the incipient velocity of granular sediment in the flow with great dimensionless water depth calculated by the formula of Wuhan Institute of Hydraulic and Electric Engineering is certainly higher than the actual situation according to the data of the physical characteristics and environment parameters of the shelf dunes (Zhuang et al., 2004). The area where the depth of water is from 132 to 162 m at continental shelf of the east china sea collected by Zhuang et al. (2004) is taken as the example to verify this claim and there are sand waves with a wavelength of 5 ~ 25 m and a wave height of 0.5 ~ 2 m. In addition, the sediment particle sizes are between 0.125 and 0.188 mm and the local maximum flow velocity is between 0.4 and 0.9 m/s in this area. According to the formula of Wuhan Institute of Hydraulic and Electric Engineering, the incipient velocity of sediment is between 1.43 and 1.91 m/s in this area, while the incipient velocity of sediment calculated by *Equation 22* is between 0.58 and 0.687 m/s. Obviously, the incipient velocity of sediment calculated by the formula of Wuhan Institute of Hydraulic and Electric Engineering is higher than the local maximum flow velocity, which indicates that the sediment particles cannot suspended

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98379863

and there are no sand waves. It follows that the calculation results of *Equation 22* are more reasonable in this situation, because the local maximum flow velocity can reach the incipient condition of sediment in this area according to *Equation 22*. According to the above analysis, *Equation 22* proposed in this paper is more credible than the normative formula of Wuhan Institute of Hydraulic and Electric Engineering when they are used to calculate the incipient velocity of granular sediment in the flow with great dimensionless water depth.

Accuracy verification of this empirical formula

In the study, the calculation results of the empirical formula were compared with the field measurement data collected by Brownlie (1981) to verify the accuracy of this empirical formula proposed in this paper. Firstly, the field measurement data collected from the extant studies which included Atchafalaya River Data of Toffaleti (1968), South American River & Canal Data of NEDECO (1973), Red River Data of Toffaleti (1968), and Rio Grande River Data of Nordin and Beverage (1965), in which the dimensionless water depth (*H/d*) was less than 10^4. The calculated results and the collected field measurement data were listed in *Table 3*.

Table 3. *Comparisons with extant experimental data (1)*

Rate of flow (m^3/s)	**River width (m)**	**Water depth (m)**	***d* (mm)**	**Sediment concentration (ppm)**	**Extant data (m/s)**	**Calculated velocity (m/s)**	**Data sources**
1073176	313.94	6.889	0.089	4.31	0.396	0.416	Atchafalaya River Data of Toffaleti (1968)
843816	310.89	6.431	0.106	2.80	0.322	0.331	
719226	307.85	6.248	0.096	8.95	0.374	0.319	
637110	307.85	6.218	0.137	5.60	0.333	0.359	
51000	93	1.8	0.12	2.92	0.305	0.282	South American River & Canal Data of NEDECO (1973)
206707	159.41	3.505	0.103	7.88	0.370	0.297	Red River Data of Toffaleti (1968)
2859.9	25.603	0.369	0.396	6	0.303	0.324	Rio Grande River Data of Nordin and Beverage (1965)
2944.8	43.282	0.262	0.343	5	0.262	0.272	
		0.1192	0.102		0.262	0.233	Vanoni (1965)

Then the field experimental data in which the dimensionless water depth (*H/d*) was approximately 10^4 were collected as the correlation data with the calculated results by the empirical formula. The calculated results and the collected field measurement data were listed in *Table 4*.

It can be seen from *Table 3* that when the sediment concentrations are less than or equal to 5 PPM the calculation results by this empirical formula are in good agreement with the data collected from extant studies generally, i.e., Rio Grande River Data of Nordin and Beverage (1965) and South American River & Canal Data of NEDECO (1973). While the incipient velocity of sediment calculated by this empirical formula is lower than the collected field measurement data when the sediment concentrations are more than 5 PPM and approach 10 PPM, for instance, Red River Data of Toffaleti

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98379863

(1968), because the hydrodynamic condition is considered to have exceeded the incipient condition of sediment according to the analysis of sediment transport and the distribution of suspended sediment concentration in the fluid when the sediment particles begin to suspend (Ted et al., 1974), when the sediment concentrations approach 10 PPM. It can be seen from *Table 4* that the empirical formula can work well when it is used to calculate the incipient of granular sediment in the flow with high dimensionless water depth. *Figure 6* depicts that the calculated values calculated by *Equation 22* and the 20% error lines against measured data.

Table 4. *Comparisons with extant experimental data (2)*

Conclusion

In this paper, the incipient condition of the granular sediment in the flow with great dimensionless water depth was studied by the method of flume experiment and data fitting. Firstly, the similarity condition between experimental flow and prototype flow with great dimensionless water depth was analysed firstly. Then based on the above analysis, the boundary layer momentum thickness was introduced instead of water depth due to the limitation of the flume experiments. Subsequently, the flume experiment results and a series of extant data were collected and calculated to derive the formula for the incipient velocity of granular sediment in the flow with great dimensionless water depth. The conclusions of this study can be summarized as follows:

The similarity condition between the experimental flow and the prototype flow with great dimensionless water depth is that the ratio of water depth and the particle size of sediment (*H/d*, which is considered as the dimensionless water depth in this paper) in experimental flow is the same with that in prototype flow with great dimensionless water depth, based on the logarithmic velocity distribution law.

Water depth cannot be used as a direct variable in the formula for the incipient condition of the granular sediment in the flow with great dimensionless water depth due to the limitation of flume experiment, which should be replaced by the boundary layer momentum thickness.

An empirical formula for the incipient velocity for the granular sediment in great dimensionless water depth was proposed by introducing boundary layer momentum thickness as an immediate variable. The formula takes boundary layer momentum thickness, particle size and the proportion of sediment and fluid as the main variables. Compared with the normative formula of Wuhan Institute of Hydraulic and Electric Engineering, the increasing trend of the incipient velocities of the granular sediments in the flow with great dimensionless water depth calculated by the two formulas are similar with each other when $H/d \leq 1 \times 10^4$, and all increase slowly, but when $H/d > 1 \times 10^4$, the increasing trend of the incipient velocities of the granular sediments calculated by the formula proposed in this paper is much slower than that by the normative formula of Wuhan Institute of Hydraulic and Electric Engineering. Finally, the accuracy of the proposed formula is verified.

Recommendations for future researches

Firstly, the viscous force between sediment particles should be considered in future researches. Because the sediment particles behave in a cohesive manner when the particle size is less than 500 μm, moreover, the viscous force becomes the main resistance to the initial motion of sediment, and the effect of gravity on the initial motion of sediment can be neglected, when the particle size is less than 60 μm. But there is no convincing result about the incipient condition of cohesive sediment. In future researches, the concept of sediment fluidization can be introduced to study on the incipient conditions of cohesive sediment, and different sediment fluidization level will cause the variation of starting velocity.

Secondly, the application condition and the form of the formula need further study. Because that the research results in this paper are based on logarithmic velocity distribution, which is reliable for the unidirectional flow. However, the applicability of the condition in complex flow field, such as wave or tide, has yet to be verified.

Abstract. By reviewing Taiwan's economic development after the Second World War, economic activities at various stages are driven by international trade exports, which has led to Taiwan's economic growth and rising per capita income. Therefore, the situation of Taiwan's export industry is of great significance to its development. In this study, the Environmental Input-Output (EIO) model, the World Input-Output Database (WIOD), and Socio-Economic Accounts are used to investigate the CO_2 emissions of Taiwan's export industry sectors and its relationship with other countries. It is analysed how particular export sectors cause carbon dioxide emissions in domestic production supply chains (by tracking downstream to upstream), and how carbon emissions in specific sectors affect export output. The empirical results show that the growth rate of CO_2 emissions in Taiwan's export industry is roughly the same as its GDP growth rate and far lower than Japan and the United States. From the perspective of industry categories, water transport, chemical products and electronic optical products are Taiwan's export sectors with high CO_2 emissions and rapid growth.
Keywords: *environmental input-output (EIO) model, Taiwan export sector, GDP, emission growth rate, supply chain*

Introduction

With island-type economy and poor natural resources, Taiwan takes the export-oriented trade as the most important industry under the government's pursuit of industrial development. At the end of the 20th century, with the development of the Internet and the commercial application of new technologies, the cost of transnational operations of enterprises declined, and information systems made transnational supply chains and management more convenient. As China and Taiwan joined the WTO successively in 2001 and 2002, global trade has become increasingly more achievable under the globalization trend and the elimination of WTO trade barriers. In the past, most of the global trade was concentrated in the North American and EU markets, while in recent years, with the rise of Chinese economy and the expansion of the ASEAN (Association of Southeast Asian Nations) from the first four countries to ten countries, as well as the signing of the Free Trade Agreement (FTA), the focus of trade around the world has been shifted to the Asian region.

In recent years, as China's economy has shown a fast-growing trend for a long term, the open-door policy will inevitably deepen its dependence on international

market (Lu, 2018). Thus, many Taiwanese businessmen have gone to the mainland to invest in the local development (Lin and Yang, 2017; Rigger, 2015), and the industrial division of labor between Taiwan and mainland has shown a weakening vertical division and a more common horizontal division. The proportion of Taiwan's export products in *Table 1* shows that the first major export products in Taiwan are electronic components, and the proportion has increased year by year, reaching 33% in 2016. The second is audio-visual products, accounting for about 10% in the past ten years. The third is metal products, the proportion of which continues to decline, and the proportions of mineral products, petroleum refining products and textiles have also declined due to the change in industrial structure.

Table 1. *Structure of Taiwan's export products (unit: %)*

Data source: National Statistics, R.O.C. (Taiwan)

Intermediate goods of various semi-finished products and components account for a high proportion of Taiwan's exports, which are combined with the production factors of exporting countries and sold around the world. In other words, the various interdependent items in international trade form an industrial chain. Nowadays, countries all over the world are developing industrial structures, adjusting economic physique, and claiming to comprehensively improve the self-made rate (Meng et al., 2017; Ritchie et al., 2018), then if Taiwan cannot upgrade its industrial structure and develop an "independent economy" model, it will inevitably be affected by a strong economic impact. The development trend of global trade is particularly significant in the vertical division of labor. The international vertical division of labor is the multi-nationalization of production process, so that the final production of goods is completed through different manufacturing processes in many countries. In Taiwan, the production of components relies on the import of raw materials, which will generate carbon dioxide (CO_2) in the production process. Therefore, this paper intends to understand how much carbon dioxide emissions are generated due to exports, and to explore the correlation analysis of how the downstream export industry can drive carbon dioxide emissions from domestic upstream industry.

This paper explores the comparison of CO_2 emissions between industries in Taiwan and its major exporting countries, and uses the Environmental Input-Output

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98659880

(EIO) model to provide an in-depth understanding of the sources and structures of CO_2 emissions from the countries. Based on the above research motivation, the main purpose of this paper is to understand the industrial input-output structure and industrial linkage profile of each country according to the input-output tables from the World Input-Output Database (WIOD). The Socio-Economic Accounts from 1995 to 2011, and the old and new versions of WIOD from 1995 to 2011 and from 2000 to 2014 are used to analyze and compare the change in the trends of CO_2 emissions from industrial exports in countries under the global value chain.

Literature review

There are four types of assessment methods for the impact of international trade on the environment in the literature. The first type is Structural Path Analysis (SPA), which refers to the use of input-output analysis to track complex production processes under given final demands. The traditional SPA method only explores one single region, and if the upstream and downstream industrial chains of a product belong to different countries, it will be impossible to discuss the single affiliation problem, such as Lenzen (2003), Peter and Hertwich (2006); the second type is Hybrid Input-Output Analysis, which refers to the use of input-output tables composed of price units and material units to distinguish energy from non-energy, such as Kagawa and Inamura (2001), Dietzenbacher and Stage (2006).

The third type is Multi-regional Input-Output Analysis (MRIO), which refers to that the single-region input-output table is estimated and broken down into a multi-region input-output table under the traditional SPA model framework, so as to calculate the industrial correlation effects on output and pollution emissions in various regions through the final demand and correlation matrix of each region. Since the unit output value, output and even proportion are required for the use of mixed unit model, the difficulty of data collection is a major shortcoming, such as Lenzen et al. (2004), Peter and Hertwich (2006). The fourth type is the EIO model, that is, the use of multi-regional input-output method to extend the regional model derived from the environmental coefficient, so as to gain a deeper understanding of the sources and structures of carbon dioxide emissions from countries' exports and explore climate policies regarding carbon leakage formulated by various countries.

In the past literature, Peter and Hertwich (2006) used the SPA method and the MRIO method to explore the environmental impact brought by the Norwegian international trade. The results show that in terms of household consumption, 80% of the direct emissions of personal fuels environmental impact are the transportation consumption of the households. In the government consumption sector, government expenditures are mainly in the medical treatment, education, and public administration departments, whose public sector has a greater impact on the purchase of transportation vehicles. If compared with households and export sectors, the government's pollution discharge density is relatively low.

Jin et al. (2017) analyzes a few scenarios of Korean CCS projects with a CO_2 pipeline transportation network optimization model for minimizing the total facility cost and pipeline cost. The results for each scenario demonstrate that the effective design and implementation of CO_2 pipeline network enables the lowering of CO_2 units cost. Liu et al. (2016) analyzed the impact of corporate heterogeneity by using

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98659880

the EIO model, and found that ignoring corporate heterogeneity may lead to overestimation of carbon dioxide emissions from China's export.

Materials and methods

Data description

The database used in this paper comes from the World Input-Output Database (WIOD). Dietzenbacher et al. (2013) and Timmer et al. (2015) give detailed description of its compiling methodology: the World Input-Output Table (WIOT). In the country classification of World Input-Output Table, this paper retained China, India, Japan, South Korea, Taiwan, the United States, and the rest of the countries were merged into other countries, and finally the six major countries were analyzed. The carbon dioxide coefficient (C) is calculated by dividing the CO_2 emissions of each industry in each country of the 35 sectors in 2013 by the corresponding output value. First, calculate the product input coefficient matrix (D) of each country, and then use the D coefficient to calculate the (I-D)^(-1) matrix of domestic correlation table, and calculate the value-added rate (V), then finally perform empirical analysis. Since the Socio Economic Accounts in the WIOD database has not published the 2016 carbon dioxide coefficient data conforming to the new 56-sector classification, so the 56-sector coefficients were not corresponded to the 35-sector classification.

Methods

There are two main methods used to analyze the driving factors of carbon emission growth in the existing literature: Index Decomposition Analysis (IDA) and Structural Decomposition Analysis (SDA) (Hoekstra and van den Bergh, 2003). Some scholars have summarized IDA (Ang, 1995, 2004; Xu and Ang, 2013); and SDA (Rose and Casler, 1996; Su and Ang, 2012). In this paper, based on the results of Liu et al. (2016) that carbon dioxide emissions are closely related to export production, the first is to understand the Input-output analysis (IOA), which is a method of accounting account presentation, and the model building method depends on the input-output table of the country or region. A country's input-output (IO) table shows the flow of inventory and services, while since IO tables have a clear showing of the life cycle of an industry, the relationship between producers and consumers is related to the production chain of entire economy. By taking into account the impact of the entire supply chain IOA, the EIO model is used to estimate specific emissions from trade, thus the estimation formula of CO_2 emissions from national-level export is as follows:

$$CO_{2exp} = \mathrm{C} \cdot (I - A)^{-1} \cdot \mathrm{e} \qquad \text{(Eq.1)}$$

where:
CO_{2exp} = Total carbon dioxide emissions representing the specific exports;
c = 1 × n rows of carbon dioxide emissions, which is the carbon dioxide emissions per unit of economic output;
A = Intermediate input of total output in the n × n input coefficient matrix with the division by sectors;
$(I - A)^{-1}$ = Leontief inverse matrix representing the complete induced output matrix produced by a unit;

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98659880

e = n × 1 rows of vectors representing exports.

According to the different views on supply chain, exports at the emissions sector level can be tracked from upstream to downstream $(D \rightarrow U)$ or from upstream to downstream $(U \rightarrow D)$:

$$CO_{2exp}^{D \rightarrow U} = \mathrm{C} \cdot (I - A)^{-1} \cdot diag(e) \quad \text{(Eq.2)}$$

$$CO_{2exp}^{U \rightarrow D} = diag(c) \cdot (I - A)^{-1} \cdot e \quad \text{(Eq.3)}$$

In the traditional IO theory, the above two different measures have their own economic explanations, and play different roles in economic analysis. $CO_{2exp}^{D \rightarrow U}$ indicates the carbon dioxide emissions emitted by all industries for exporting certain specific products. In other words, this measure can check the emissions from all the sectors directly or indirectly affected by domestic upstream supply chains. In contrast, $CO_{2exp}^{U \rightarrow D}$ represents the CO_2 emissions of a specific sector's specific export. That is to say, this measure depends on how to show the emissions from specific upstream sectors will affect the final exports of all downstream industries.

Finally, according to the definition, there is no difference between the two measures in CO_2 emissions at national level in terms of export. If we replace imported wealth goods with a ratio v of added value relative to output, to estimate the direct and indirect impact of exports on domestic added value. The following formula can be used to calculate the value-added ratio v of an export product (a 1 × n vector representing each value-added unit by sector). The so-called entity value-added (GDP) can also be estimated by:

$$GDP_{exp} = v \cdot (I - A)^{-1} \cdot \mathrm{e} \quad \text{(Eq.4)}$$

Further use of *Equations2* and *3* to represent the carbon indicator P as emission intensity of export entity can be defined as follows:

$$\mathrm{P} = CO_{2exp} / GDP_{exp} \quad \text{(Eq.5)}$$

This indicator that indicates the value-added export emissions per unit of a country can therefore be considered as a potential environmental cost for national trade. Display export value-added quotas at the industrial level in the same way:

$$GDP_{exp}^{D \rightarrow U} = v \cdot (I - A)^{-1} \cdot \mathrm{diag}(e) \quad \text{(Eq.6)}$$

$$GDP_{exp}^{U \rightarrow D} = diag(v) \cdot (I - A)^{-1} \cdot \mathrm{e} \quad \text{(Eq.7)}$$

In addition, according to *Equation 6,* the specific emissions of carbon intensity export at the industrial level are defined as follows:

$$P^{D \rightarrow U} = CO_{2exp}^{D \rightarrow U} // GDP_{exp}^{D \rightarrow U} = [c \cdot (I - A)^{-1} \cdot diag(e)] // [v \cdot (I - A)^{-1} \cdot diag(e)] \quad \text{(Eq.8)}$$

$$P^{U \rightarrow D} = CO_{2exp}^{U \rightarrow D} // GDP_{exp}^{U \rightarrow D} = c // v \quad \text{(Eq.9)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98659880

We define "//" as operational symbol of a vector division. It can be seen that the carbon intensity of carbon emissions depends on the input coefficient c and the value-added rate v of emissions from all upstream sectors when exporting a specific product, while the carbon emissions of specific sectors are based on the carbon intensity of the production sector (sector emissions/added values), showing that all exports are equal to the conventional definition.

Supposing based on production, the estimation of carbon dioxide emissions depends on the amount of energy used, regardless of the type of industry that uses it. In other words, if different types of industries burn the same amount of specific types of energy, the difference in energy efficiency of the enterprise will be reflected in the energy use per unit of output. This also means that if the traditional IO table does not introduce enterprise heterogeneity and does not change the estimate of production base, thus carbon dioxide emission estimates at the industrial or national level may be different. The use of traditional IO tables can lead to overestimation of CO_2 emissions from exports and underestimation of CO_2 emissions from domestic final demand, which is mainly because different types of companies have different market shares in traditional IO tables, and neglecting the heterogeneity of enterprises can lead to overestimation of carbon dioxide emissions from exports.

Therefore, this paper replaces the $(I - A)^{-1}$ matrix with the $(I - A)^{-1}$ matrix, where $(I - A)^{-1}$ indicates the direct plus indirect domestic demand coefficient matrix, also known as the domestic industrial correlation matrix. The domestic industrial correlation matrix $(I - A)^{-1}$ is conducted with the sum of vertical and horizontal analysis to obtain the forward and backward correlation degrees of each industry. If the forward and backward correlation degrees are normalized, sensitivity and influence can be obtained. Industries with high forward correlation (sensitivity greater than one) are easy to support downstream industrial production by providing products for downstream industries. Industries with high backward correlation (influence degree greater than one) are easy to drive the development of other upstream industries, and the demand for upstream industrial products is higher. Industries with both high forward and backward correlation degrees as the important industries can drive the development of other industries. Industries with high forward correlation degree and low backward correlation degree can provide the cooperation for the development of other industries. Industries with low forward correlation degree and high backward correlation degree can drive the development of other industries and are not easily affected by other industries. Industries with both low forward and backward correlation degrees are the industries that are not susceptible to other industries and will not drive the development of other industries.

Results

Main empirical results

This paper collects data from the new version of WIOD (2000-2014) and the old version (1995-2011) to calculate CO_2 emissions, GDP and its intensity (the ratio of CO_2 emissions to GDP, that is, CO_2 emissions per unit of GDP driven by exports) driven by the total exports of major countries (see *Figs. 1* and *4*), the intermediate goods (see *Figs. 2* and *5*) and final goods (see *Figs. 3* and *6*).

Figure 1 shows the CO_2 emissions, GDP and its intensity driven by total exports of countries in 2014 (new version). China ranks second with CO_2 emission intensity of 0.97 in various countries, including CO_2 emissions of 19.58 billion tons. *Figures 2* and *3* show that the CO_2 emission intensity of 1.09 driven by China's intermediate goods is greater than the CO_2 emission intensity of 0.85 driven by China's final goods, indicating that China's CO_2 emissions mainly come from the intermediate goods. Taiwan's CO_2 emission intensity driven by total exports is the highest, reaching 1.0, but in fact, Taiwan's CO_2 emissions are only 2.1 billion tons, because Taiwan's GDP is only 200 billion US$, only higher than the last ranking of India's 170 billion US$. *Figures 2* and *3* show that the CO_2 emission intensity of 1.04 driven by Taiwan's intermediate goods is greater than the CO_2 emission intensity of 0.88 driven by Taiwan's final goods, indicating that Taiwan's main CO_2 emissions come from the intermediate goods, and intermediate goods and final goods show a ratio of 3:1, showing that Taiwan is an economy that exports intermediate goods. South Korea, which is similar to Taiwan's industrial pattern, ranks third in terms of its CO_2 emission intensity of 0.65 driven by total exports, and its CO_2 emissions of 2.9 billion tons is only 800 million tons more than Taiwan, but its GDP is 450 billion US$. *Figures 2* and *3* show that the CO_2 emission intensity of 0.72 driven by South Korea's intermediate goods is greater than the CO_2 emission intensity of 0.53 driven by South Korea's final goods, indicating that South Korea's main CO_2 emissions mainly come from the intermediate goods. Japan's CO_2 emission intensity driven by total exports is the lowest, with CO_2 emissions of only 1.7 billion tons, but GDP is as high as 620 billion US$, which is three times that of Taiwan. The CO_2 emission intensity of 0.33 driven by Japan's intermediate goods is greater than the CO_2 emission intensity of 0.19 driven by Japan's final goods, indicating that Japan's CO_2 emissions mainly come from the intermediate goods.

Figure 4 shows the level and intensity of CO_2 emissions and GDP total exports in 1995 (old version). China's CO_2 emission intensity is 4.22, which is three times that of South Korea ranking the second, and China's CO_2 emissions are 5.9 billion tons, which ranks the first in the six countries, but China's GDP is only 140 billion US$, only 30 billion US$ higher than South Korea. *Figures 4–6* show that the CO_2 emission intensity of 4.58 driven by China's intermediate goods is greater than the CO_2 emission intensity of 3.92 driven by China's final goods, indicating that in 1995, China was still an intermediate goods-oriented country. Taiwan's CO_2 emission intensity is 0.88, ranking the fourth among the six countries, with CO_2 emissions of 700 million tons and GDP of 80 billion US$. The CO_2 emission intensity of 0.99 driven by Taiwan's intermediate goods is greater than the CO_2 emission intensity of 0.75 driven by Taiwan's final goods, indicating that in 1995, Taiwan was still an intermediate goods export-oriented country. South Korea's CO_2 emission intensity is 1.32, ranking the second among the six countries, with CO_2 emissions of 1.4 billion tons and GDP of 110 billion US$. *Figures 5* and *6* show that the CO_2 emission intensity of 1.32 driven by South Korea's intermediate goods is much the same as the CO_2 emission intensity of 1.31 driven by South Korea's final goods, indicating that in 1995, South Korea's export is complemented by intermediate goods and final goods. Japan's CO_2 emission intensity of 0.33 is almost the same as that of 2014, with CO_2 emissions of 1.5 billion tons and GDP of 450 billion US$. *Figures 5* and *6* show that the CO_2 emission intensity of 0.38 driven by Japan's intermediate goods is much the same as the CO_2 emission intensity of 0.25 driven by Japan's final goods, indicating that in 1995, Japan was an intermediate goods export-oriented country.

Discussion

Analysis and comparison of export-driven CO_2 emission intensity in countries in 1995 and 2014

By comparing the level and intensity of CO_2 emissions and GDP driven by total exports of countries in 1995 and 2014 (see *Figs. 4* and *1*), we can see the rankings of CO_2 emission intensity in 1995 were: China, South Korea, India, Taiwan, the United States and Japan; rankings in 2014 were: Taiwan, China, South Korea, India, the United States and Japan. Taiwan rose from the fourth place to the first place, China, South Korea, and India all ranked down, and the United States and Japan ranked the same. In most countries, the level of CO_2 emissions has declined, except for Taiwan, and Japan which has low intensity. It has shown that Taiwan has grown with the same proportions of CO_2 and GDP in the past 20 years, but other developed countries have doubled.

Analysis of export-driven CO_2 emission paths

In order to concrete our results, *Figures 7–10* compare the CO_2 emissions in each industry and *Table 2* list the industry category and the definition. If we track from downstream industry to the upstream industry (D→U), and from upstream to downstream (U→D), the CO_2 emissions driven by the export of each country are observed, and the carbon dioxide emission paths of the industries in Taiwan are organized, as shown in *Figures 7* and *8*, where, $CO_{2exp}^{D\rightarrow U}$ indicates the carbon dioxide emissions emitted by all industries exporting specific products, which can be used to check the emissions of all sectors directly or indirectly affected by the domestic upstream supply chain, while $CO_{2exp}^{U\rightarrow D}$ indicates the carbon dioxide emissions emitted by specific exports from particular sectors, and it can show how the emissions from specific upstream sectors affect the final exports of all downstream industries.

As shown in *Figures 4–7,* the CO_2 emissions driven by China's exports are tracked from the downstream industry to the upstream industry (D→U), that is, CO_2 emissions produced from the input of upstream industry because of the other industries driven by export products, see left bar of *Figures 4–7*. China's major downstream export industry sectors are electronic optical products (300 million tons), electrical equipment manufacturing (210 million tons), textile and apparel (180 million tons), transportation equipment manufacturing (160 million tons). The CO_2 emissions driven by China's exports are tracked from the upstream industry to the downstream industry (U→D) to track the upstream industry, which is to support the CO_2 emissions generated by the downstream industries, see the right bar of *Figures 4–7*. The upstream-supported export

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98659880

industry sectors are mainly non-metallic mineral products (70 million tons), metal products (40 million tons), and chemical products (30 million tons).

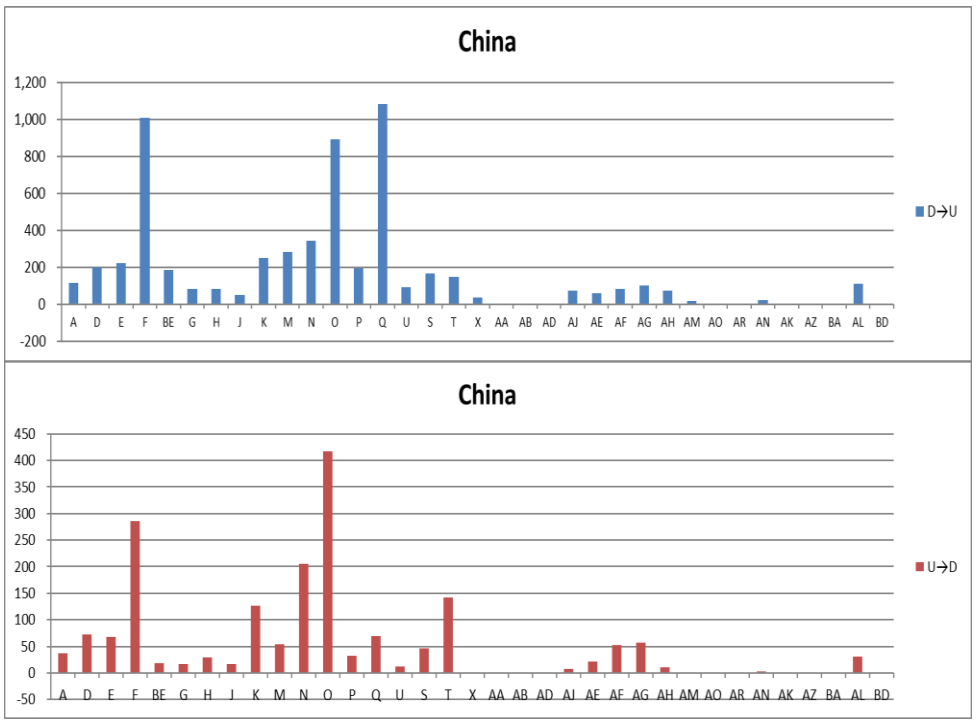

Figure 9. *CO_2 emissions driven by China's exports in 1995: tracking from the downstream industry to the upstream industry (D→U) and from upstream to downstream industry (U→D)*

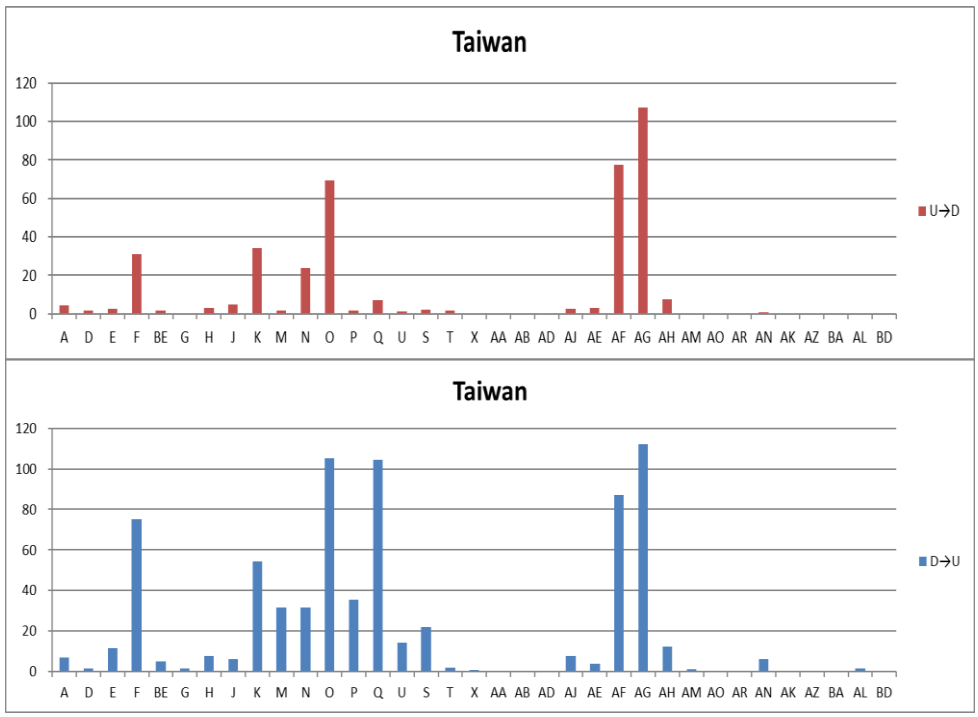

Figure 10. *CO_2 emissions driven by Taiwan's exports in 1995: tracking from the downstream industry to the upstream industry (D→U) and from upstream to downstream industry (U→D)*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98659880

The CO_2 emissions driven by Taiwan's exports are tracked from the downstream industry to the upstream industry (D→U), see the left bar of *Figures 4–8*. The major downstream export industry sectors are water transport (about 39 million tons), chemical products (about 35 million tons), and electronic optical products (about 31 million tons). The CO_2 emissions driven by Taiwan's exports tracked from upstream industry to downstream industry (U→D) is shown in the right bar of *Figures 4–9*. The major industrial sectors invested in the upstream are water transport (about 37 million tons), chemical products (about 15 million tons), and air transport (about 11 million tons).

Finally, *Figures 9* and *10* summarize the estimated estimation on CO_2 emissions in China and Taiwan in 1995. The CO_2 emissions driven by exports from 1995 to 2014 are compared and tracked from the downstream industry to the upstream industry (D→U) and from upstream to downstream industry (U→D) see from *Fig 4- Fig 10.* In the CO_2 emissions driven by China's exports tracked from the downstream industry to the upstream industry (D→U), electronic optical products, textile and metal products have the most emissions, while when tracking from upstream to downstream industry (U→D), the metal products, textile and non-metal products have the most emissions. In 2014, China's major downstream industrial sectors added more high CO_2 emissions sectors such as electrical equipment manufacturing, transportation equipment manufacturing and chemical products. In 1995, when CO_2 emissions driven by Taiwan's exports are tracked from the downstream industry to the upstream industry (D→U), the air transport, metal products and electronic optical products have the most emissions, while when tracking from upstream to downstream industry (U→D), the air transport, water transport and metal products have the most emissions. In 2014, Taiwan's high CO_2 emissions sectors are water transport, chemical products and electronic optical products.

Conclusion

The composition of industrial chains is interdependent in international trade. Today, global trade belongs to different countries in the upper, middle and lower reaches of production process of vertical labor division. This paper analyzes trade items and supply chain portfolios from global value chains, and further integrates and compares the carbon emissions from supply chain portfolios across countries. Based on the results of Liu et al. (2016), this paper uses the EIO model to analyze the relationship between trade exports and carbon dioxide emissions in Taiwan and other six countries. The empirical analysis of this paper first analyzes the CO_2 emission intensity driven by countries' exports, where Taiwan's total CO_2 emission intensity is 1.0, topping the highest, with CO_2 emissions of only 2.1 billion tons, which is caused by Taiwan's low GDP of 200 billion US$. The CO_2 emission intensity driven by China's total exports is 0.97, with CO_2 emissions of as high as 19.58 billion tons, but the GDP is 2 trillion US$, resulting in an intensity of only 0.97. The CO_2 emission intensity driven by the US total exports is only 0.35, with CO_2 emissions of 7.2 billion tons, which is caused by the high US GDP as much as 2.07 trillion US$. South Korea, which is similar to Taiwan's industrial pattern, has a CO_2 emission intensity of 0.65 driven by its total exports, with CO_2 emissions of 2.9 billion tons, only 800 million tons more than Taiwan, but the GDP is 450 billion US$. The total CO_2 emission intensity driven by Japan's total exports is 0.28, with CO_2 emissions of only 1.7 billion tons, but the GDP is as high as 620 billion

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98659880

US$, which is three times that of Taiwan. The results of the analysis show that most developed countries take intermediate goods as the main export type under the global industrial chain, while the exports in less developed countries such as India have a ratio of 1:1 between intermediate goods and final goods, and final goods may even count greater than intermediate goods.

By comparing the level and intensity of CO_2 emissions and GDP total exports in various regions in 1995 and 2004, we can see that Taiwan rose from the fourth to the first place. China, South Korea and India ranked from the first, second and third to second, third and fourth, respectively, the United States and Japan remain unchanged at the fifth and sixth place. In most countries, the level of CO_2 emissions has declined, except for Taiwan, and Japan which has low intensity. It has shown that Taiwan has grown with the same proportions of CO_2 and GDP in the past 20 years, but other developed countries have doubled.

Then, if we track from downstream industry to the upstream industry (D→U), and from upstream to downstream (U→D), the CO_2 emissions driven by the export of Taiwan and mainland are observed, with CO_2 emissions produced from the input of upstream industry because of the other industries driven by China's downstream export products, which means that by tracking from downstream to upstream, China's major downstream export industry sectors are electronic optical products, electrical equipment manufacturing, textile and apparel and transportation equipment manufacturing. The upstream industry in China supports the CO_2 emissions generated by the downstream industries, that is, by tracing from upstream to downstream, the major upstream sectors supporting export industry are non-metallic mineral products, metal products and chemical products. Taiwan's major downstream export industry sectors are water transport, chemical products and electronic optical products, and the major upstream sectors are water transport, chemical products and air transport.

As China launches the carbon trading market, Singapore is expected to introduce a carbon tax in 2019, and many countries around the world have formulated a policy on carbon pricing. Yet it is uncertain whether the carbon tax will bring a huge burden to the economy, only some countries in northern Europe succeeded in maintaining economic growth rate. On the other hand, Australia has abolished the carbon tax, which became a major cause of dragging down the Australian economy. In Taiwan and other countries in the world, environmental mark and carbon footprint mark are more commonly used, that is, how much carbon is emitted from the product or how much energy is used in the product are clearly marked, so that consumers can choose whether to buy lower-carbon products after reading the message. Energy costs such as the use of fuel may rise from the imposition of emission taxes, while people can transform the society into a sustainable development pattern through the change of lifestyle. This paper is mainly to explore the generation and attribution of CO_2 generated by inter-regional economic production and exchange, and to compare the growth rate of CO_2 emissions between different economies. In the follow-up, we will further explore the relationship between environmental shocks, foreign trade changes, and commodity substitutions generated by such economic activities.

(Received 29th Mar 2019; accepted 13th Jun 2019)

Abstract. This article presents the results of a research conducted to evaluate the production-related value and feeding value of selected maize (*Zea mays* L.) cultivars included in the Common Catalogue of Varieties of Agricultural Plant Species (CCA). The following two factors were examined: A − the harvest date of maize green matter (I − tasseling stage (75% of plants at this stage), II − milk maturity stage (after three weeks), III − wax maturity stage (after another three weeks)); B − cultivars with different times of maturity (Pyroxenia – very early, FAO 130, Codimi – early FAO 200, Moschus – early, FAO 220, Alombo – medium early, FAO 230, Celive – medium early, FAO 245). The results demonstrated that the highest dry matter yield was produced by plants at the wax maturity stage. Cv. Alombo had the highest fresh matter yield. The highest organic matter (OM) digestibility and dry matter (DM) digestibility were determined for maize plants harvested at the wax maturity stage. The earliest maturing cultivars, namely Pyroxenia and Codimi, had the highest organic matter (OM) digestibility and dry matter (DM) digestibility. The highest total protein content and crude ash were recorded for maize plants harvested at the tasseling stage. Cv. Codimi, Moschus, Alombo and Clive produced the highest concentrations of these components.
Keywords: *dry matter yield, green forage chemical composition, organic matter (OM) digestibility, dry matter (DM) digestibility*

Introduction

Soil and climatic conditions of Poland are optimal for the cultivation of maize for silage (Ptaszyńska and Sulewska, 2008). The species represents the most productive fodder crops (Strzetelski et al., 2001; Brzóska, 2001). Harvest date and cultivar selection determine the crop plant make-up and structure, which may lead to substantial differences in yielding, chemical composition and feed value of maize plants (Kowalik, 2001).

As the area under maize production and economic role of maize are on the increase, there is growing demand for better and better cultivars and thus hybrids (Korniewicz et al., 2000; Sulewska et al., 2011). Jha et al. (1998) and Adamczyk (2001) emphasized the fact that the role of new cultivars in modern agriculture is of great importance.

The following factors affect the quality and quantity of harvested yields: agrotechnology (40%), climatic conditions (30%), selected cultivars (30%). Thus, a third of the effect is cultivar-related (Sulewska et al., 2011). As a result, it seems reasonable to examine selected cultivars from other Europeans countries, such as Germany, the Czech Republic, Slovakia and France, in terms of their suitability for cultivation in Poland. The objective of the study was to evaluate the production-related

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98819887

value and feed value of selected cultivars included in the Common Catalogue of Varieties of Agricultural Plant Species (CCA) harvested at various development stages, which were used as raw materials for the production of whole plant silage from maize cultivated under the soil and climatic conditions of Poland.

Materials and methods

Field research was conducted in 2009-2011 on a private holding located in Kowiesy near Siedlce (52º03' 39'' N, 22º 33' 80'' E). The experiment was carried out on the soil classified as Albic Luvisol (Arenic) characterised by a slightly acid reaction and average available phosphorus, potassium and magnesium contents. Its humus content was 1.28%. The trial was a split-plot arrangement with three replicates. The following two factors were investigated: A − maize green matter harvest date (I − tasseling stage (75% of plants at this stage), II − milk maturity stage (after three weeks), III − wax maturity stage (after another three weeks)); B − cultivars with different earliness of maturity (Pyroxenia – very early FAO 130, Codimi – early FAO 200, Moschus – early FAO 220, Alombo – medium early FAO 230, Celive – medium early FAO 245).

The number of plants per 1 metre was 10, and the sowing rate was established based on previous research by Sulewska (2001). Maize was grown as a continuous crop. Cattle manure was applied at the rate of 30 tha^{-1} in the autumn. In spring, phosphorus and potassium fertilisers were applied at rates matching soil contents of available elements, that is 60 kg Pha^{-1} and 90 kg Kha^{-1}. Nitrogen fertiliser was applied pre-plant at the rate of 92 kg Nha^{-1} in the spring and followed by maize, the nitrogen rate being increased due to an application of Polifoska 6. Maize cultivars were planted in late April. The green matter of maize crop was harvested at three dates as set in the methodology. During harvest, the fresh matter yield of whole plants was determined in each plot, and their average samples were taken for chemical analyses. Dry matter content, total protein content, crude ash content, organic matter digestibility and dry matter digestibility were determined in the sampled material by means of near infrared spectroscopy (NIRS) using the spectrometer NIR Flex N-500.

The results of the study were statistically analysed; ANOVA following the linear model for a two factor split-plot design was performed for each trait examined, and separation of means was obtained by means of Tukey test at the significance level of 0.05.

Results and discussion

The dry matter yield of maize plants

The dry matter yield of maize plants was significantly affected by the experimental factors and their interaction (*Table 1*).

The highest dry matter yield was produced by maize plants harvested at the wax maturity stage. In corresponds to findings reported by Toler et al. (1998), Kowalik (2001), Michalski (2002), Filya (2004), Szempliński et al. (2009), Lynch et al. (2012), Magalhães et al. (2015) and Komainda et al. (2018). In the study discussed here, the dry matter yield of maize plants harvested at the milk stage was lower, it being the lowest when harvest was performed at the tasseling stage. It may be explained by the fact that the dry matter yield of maize plants increases from the tasseling stage to the wax

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98819887

maturity stage. In the experiment reported here, the highest dry matter of maize plants was produced by the medium early cultivar Alombo, the yields of the maize plants of cv. Pyroxenia, Codimi, Moschus and Celive being significantly lower. Also Sulewska and Koziary (2005), Podkówka et al. (2015), Swanckaert et al. (2016) and Nawab et al. (2017) reported a higher yielding potential of later maturing cultivars. In the current study, an interaction between the experimental factors was confirmed indicating that the highest dry matter yields were supplied by the following cultivars: Pyroxenia, Codimi, Moschus, Alombo and Celive harvested at the wax maturity stage, it being the lowest for all the experimental cultivars harvested at the tasseling stage.

Table 1. *Dry matter yield of maize plants (means across 2009-2011), tha^{-1}*

Cultivars (B)	**Harvest date (A)**			**Means**

Cultivars (B)	<0.001		1.32	
Interaction (AxB)	<0.001		5.40	

The total protein content in plants

Statistical analysis demonstrated a significant influence of the experimental factors and their interaction of total protein content in maize plants (*Table 2*).

The highest total protein content was recorded for maize plants harvested at the tasseling stage. When delayed the harvest date to the milk maturity stage, a significant decrease of total protein content was recorded for maize plants harvested. When harvest is further delayed to the wax maturity stage, no total protein content significant decrease in maize plants is observed.

Table 2. *Total protein content in plants, gkg-1 d.m.*

Cultivars (B)	**Harvest date (A)**			**Means**
	I	**II**	**III**	
Pyroxenia	100.6	82.3	78.5	87.1
Codami	108.7	83.7	80.7	91.0
Moschus	104.9	82.1	80.4	89.1
Alombo	110.1	84.6	76.7	90.5
Celive	111.7	86.5	83.5	93.9

Harvest date (A)	<0.001		5.9	
Cultivars (B)	<0.001		5.2	
Interaction (AxB)	<0.001		7.8	

It may be explained by fact that the plants harvested in earlier stage are characterized by a higher content of total protein. In corresponds to findings reported by Tolera et al. (1998, 1999), who reported that by delaying the harvest of maize plants, the total

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98819887

protein content decreases. However, the regress of total protein in the dry matter of plants at the end of vegetation is low. In the study discussed here, the total protein content of maize plants studied cultivars was on the same level, with the exception of the Pyroxenia cultivar.

The concentration of total protein in plants of this cultivar was significantly lower, which has been confirmed in research by other authors (Tolera et al., 1999; Sulewska, 2001; Schttenhelm, 2008; Podkówka et al., 2015). Špelekovă and Galovă (2018) results of research demonstrated higher protein content in maize cultivars from Europe than from the United States. In the present study reported here, the interaction of the studied factors demonstrated that only in the tasseling stage, the total protein content in maize plants of Pyroxenia cultivar was significantly lower than in the other cultivars. At the milk maturity stage and wax maturity stage, no significant differences were found in the total protein content between the studied cultivars. The highest total protein content was recorded from the Codimi, Moschus, Alombo and Celive maize plants harvested in the tasseling stage, significantly lower from all studied maize cultivars harvested in the wax maturity stage.

The crude ash content in plants

The content of crude ash in maize plants was significantly differentiated by the experimental factors studied and their interaction (*Table 3*).

The highest content of crude ash was recorded in maize plants harvested during the tasseling stage. Significantly lower crude ash content was recorded in maize plants harvested at milk maturity stage, the lowest in plants harvested in the wax maturity stage. Also Filya (2004), Yuxiang et al. (2007) and Komainda et al. (2018) demonstrated that by delaying the harvest of maize plants from the stage of early milk to wax maturity stage, the content of crude ash decreases. This should be explained by the fact that plants harvested in earlier stages contain more minerals and more organic components.

Table 3. *Crude ash content in plants, gkg-1 d.m.*

Cultivars (B)	**Harvest date (A)**			**Means**
	I	**II**	**III**	
Pyroxenia	81.3	51.2	38.8	57.1
Codami	77.6	58.8	39.9	58.8
Moschus	80.3	61.5	46.1	62.6
Alombo	83.4	61.3	42.4	62.4
Celive	81.3	60.5	45.7	62.5
Means	80.8	58.7	42.6	-
ANOVA	P-value		$LSD_{0.05}$	
Harvest date (A)	<0.001		3.0	
Cultivars (B)	<0.001		3.9	
Interaction (AxB)	<0.001		5.8	

In own studies, also the cultivars significantly differentiated the content of crude ash in plants. Of these, only the plants of maize of the Pyroxenia cultivar had a significantly lower concentration of crude ash than in the plants of the other cultivars. Also, Tolera et al. (1999), Sulewska (2002), Schttenhelm (2008) and Podkówka et al. (2015) demonstrated that cultivars with a longer growing season contained more crude ash both in whole plants and in grain. In the current study, an interaction between the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98819887

experimental factors was confirmed indicating that the highest content of crude ash was recorded in all cultivars of maize plants harvested in the tasseling stage, and the lowest in maize plants of the Pyroxenia and Codmi cultivars harvested at the wax maturity stage.

The organic matter digestibility (OM) of maize plants

Statistical analysis demonstrated a significant influence of the experimental factors and their interaction of organic matter digestibility and dry matter digestibility (*Tables 4 and 5*).

Table 4. *Organic matter digestibility (OM) of maize plants (means across 2009-2011), %*

Harvest date (A)	<0.001		1.38	
Cultivars (B)	<0.001		1.77	
Interaction (AxB)	<0.001		2.63	

The dry matter digestibility (DM) of maize plants

The highest organic matter (OM) digestibility and dry matter (DM) digestibility were recorded for maize plants harvested at the wax maturity stage. Organic matter digestibility and dry matter digestibility of maize plants harvested at earlier development stages were significantly lower, the finding corresponding to reports by Michalski et al. (2002), Filya (2004), Yuxiang et al. (2007), Rodriges et al. (2008) and Swanckaert et al. (2017). In the present study, there was observed a significantly different response of the experimental cultivars in terms of both organic matter (OM) digestibility and dry matter (DM) digestibility, both kinds of digestibility being the highest for the earliest maturing cultivars, that is Pyroxenia and Codimi. Moreover, the dry matter (DM) digestibility of cv. Celive, which is the latest maturing variety, differed insignificantly from DM digestibility of cv. Pyroxenia and Codimi. The organic matter

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98819887

(OM) digestibility and dry matter (DM) digestibility of cv. Moschus and Alombo were significantly lower. Also results of research by Tolera et al. (1999), Stejskalova et al. (2011) and Schttenhelm (2008) demonstrated cultivar-related differences between the organic matter digestibility and dry matter digestibility of both grain and green forage of maize plants representing other cultivars. Podkówka et al. (2015) reported that early maturing cultivars had a significantly higher organic substance (OS) digestibility of maize grain compared with medium early and late maturing cultivars. In the study reported here, an interaction between the experimental factors was found which is indicative of the fact that the highest organic matter (OM) digestibility and dry matter (DM) digestibility of all the experimental cultivars were recorded for plants harvested at the wax maturity stage, them being the lowest for cv. Pyroxenia, Codimi, Moschus, Alombo and Celive harvested at the tasseling stage.

Summary

Research on the suitability of cultivating new European cultivars from the Common Catalogue of varieties of Agricultural Plant Species (CCA) in soil and climatic conditions of Poland is fully justified. Therefore, it will be advisable to continuously study new cultivars in terms of dry matter yield and chemical composition of corn forage harvested in various development phases. This will allow the selection of such cultivars from the Common Catalogue of varieties of Agricultural Plant Species (CCA) useful for cultivation in Poland, which will be characterized by the highest yield and favorable chemical composition of forage, which will ensure good quality of silage.

THE EFFECTS OF INDUSTRY INCREASE AND URBANIZATION ON AIR POLLUTANTS IN TURKEY: A NONLINEAR AIR QUALITY MODEL

KILINC, B. K.

Department of Statistics, Faculty of Science, Eskisehir Technical University, Eskisehir 26470, Turkey
(e-mail: bkan@eskisehir.edu.tr; phone: +90-222-335-0580; fax: +90-222-320-4910)

(Received 29th Mar 2019; accepted 24th May 2019)

Abstract. Daily concentrations of air pollutants greatly affect air quality as an increase in industry and urbanization deteriorate the environment. For forty cities in Turkey, eleven variables are recorded to investigate the determinants of air pollution presumably by regressing the air pollutants PM10, NO_X, and NO_2. The temperature, wind, human factors such as population, vehicles, manufacturer, and suchlike are used to create a nonlinear air quality model in Turkey due to the multivariate nature of the data. A comparison of the nonparametric models of the concentration of these pollutants, using multivariate adaptive regression splines (MARS), was obtained to estimate the dependence between air pollutants and various factors. Finally, a model for PM10 concentration shows that climate effects are the most significant variables, whereas the predicted models for NO_X and NO_2 indicate that human factors, such as the number of manufacturers and the number of vehicles, are significant variables. In conclusion, the predicted models are easy to interpret and have advantages of capacity to produce the contributions of the factors for each pollutant model. It is advisable for researchers to examine and determine the suitability of their data sets using nonlinear models when atypical observations and high correlations exist in the data.
Keywords: *multivariate adaptive regression splines, nonparametric, multicollinearity, outlier, pollutant*

Introduction

The exposure of ambient air pollutants in industrial or metropolitan cities adversely affect humans, animals, plants, food crops or other living creatures (Lutgens and Tarbuck, 2001; Kelly and Fussell, 2015, 2017). The measurements of meteorological pollution, such as NO_2 (nitrogen dioxide), and PM10 (particulate matter) have become more important due to their harmful effects on human health (Akkoyunlu, 2003; Elbir et al., 2000; Garcia, 2001; Godish, 2004; Garcia, 2006; Lutgens and Tarbuck, 2001). For example, the adverse effects on human health may include coughing, asthma, chronic bronchitis, and cardio vascular morbidity (Lutgens and Tarbuck, 2001; U.S. Department of Interior; Wark et al., 1997; Wang et al., 2004). Ifran and Shaw (2017) investigated the relationship between environmental pollution, energy consumption and the level of urbanization in South Asian countries using by a nonparametric additive model. The European Commission, World Health Organization (WHO) and various national/international environmental agencies have published their standards and air quality guidelines for allowable levels of air pollutants (Cooper and Alley, 2002; Lim, 2005; Surez et al., 2011; Wang et al., 2004).

According to WHO statements, 1.4 out of 2.4 million deaths each year are caused by indoor air pollution while the remaining deaths are due directly to attributable air pollution (Lutgens and Tarbuck, 2001; Wark et al., 1997; Wang et al., 2004). The WHO Air Quality Guidelines provide a Global Update of 205 for threshold values of air pollution. In addition, it reports that 91% of the world population live in places where WHO air quality levels were not met. The WHO guidelines are currently under revision

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98899903

with an expected new publication in 2020. The latest Global conference on air pollution was organized in Geneva on 20 November 2018. Almost 900 participants registered for the conference, including 70 commitments from countries, cities and organizers discussing how to tackle climate change and related health considerations.

Furthermore, publications from the European Union (EU) regarding emissions of the main air pollutants monitored at more 2500 stations throughout Europe present updated data and its impact. Polices and air quality regimes are aimed at providing the lowest target concentrations of possible pollutants (Holnicki et al., 2017; Isikli et al., 2015). The guidelines apply worldwide and are based on expert evaluations for PM10 and NO_2 (see *Table 1*).

Table 1. *Comparison of limit values*

Average period	EU	Turkey (2017)	Turkey (2018)	Turkey (2019)	Permitted exceedances each year	
					EU (2019)	Turkey (2019)
PM10 (24 h)	50 μg/m^3	70 μg/m^3	60 μg/m^3	50 μg/m^3	35 times/year	35 times/year
NOX (1 year)	30 μg/m^3	-	-	30 μg/m^3	-	-
NO2 (1 h)	200 μg/m^3	270 μg/m^3	260 μg/m^3	250 μg/m^3	18 times/year	18 times/year

(Source: http://ec.europa.eu/environment/air/quality/standards.htm)

PM10, which is often a proxy indicator, for air quality refers to fine particles with a diameter of 10 microns or less, and are tiny solid particles and liquid suspended in a gas. It affects living organisms on a daily basis or over time. As the sources of PM10 can be humans, fossil fuel combustion (primarily from road transport), factories or natural, the increase of PM10 levels can be a cause of mortality or morbidity (Kelly and Fussell, 2015).

The potential risk of PM10 air pollution is critical in certain cities in Turkey, considering that the measured daily PM10 concentrations should be in the range of 50 μg/m^3 from January 1, 2019, due to EU Commission regulations (Istanbul Metropolitan Municipality).

Serious risks are posed to the habitat of humans, animals and plants, not only from exposure of PM10, but also from NO_X (Shi et al., 2014). This is a general term that is used to describe certain gases, namely NO_2 and NO. NO_2 is especially emitted from high temperature combustion processes (power generation, engines in vehicles, heating, and suchlike) and are also produced naturally during thunderstorms by electric discharge. NO_2, a reddish- brown toxic gas, has a sharp and biting odour. The initial product formed is NO (nitric oxide). When NO oxidizes further in the atmosphere, nitrogen dioxide (NO_2) forms. Similarly, studies on NO_2 show that it is mainly due to the eutrophication of lakes and marine environments and acidification of terrestrial ecosystems (Greenfelt et al., 1994).

The concentration levels of NO_2 can also play a significant role in asthma and lung functions. Shao et al. (2006) show that urbanization and industrial developments cause deterioting air quality. The results of their study are that emissions of NO_2 are from industrial and domestic energy production and transportation. When NO_2 is combined

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98899903

with water, the main component of acid rain, which is one cause for deforestation, is observed (WHO).

With the negative effects of growing population trends and urbanization, the role of such atmospheric pollutants has received increasing attention. Many scientists study on global and regional estimations for such emissions. Seo et al. (2018) examined meteorological conditions together with emissions of air pollutants using long-term measurements in Seoul using by a multiple linear regression model. Sekulic and Kowalski (1992), Friedman and Roosen (1995) used three MARS models for NO_2, SO_2, and PM10 as a function of other measured relevant pollutants in air quality; nitric oxide (NO), carbon monoxide (CO), and ozone (O_3). Donnelly et al. (2017) used a hybrid model including nonparametric regression to describe nonlinear variations in concentration levels with speed, direction and meteorological variables which are employed as inputs to a multiple linear regression. Tao et al. (2017) studied the impact of external pollution and human factors in the forest ecosystems.

It is often assumed that multivariate data should follow a known specific statistical distribution. However, the complex structure of the data and the relationship among various factors may be too complicated to explain general patterns or to model dependency between variables. When examining ecological data, the interaction of several environmental factors have to be recognized carefully and properly analysed.

The aim of this study is to investigate the significant variables by using daily patterns of PM10, NO_X and NO_2 and to provide meaningful future informative models for air quality control and regimes in Turkey. This study is organized as follows. Firstly, the current state of knowledge based on air pollutants in the literature is explained. Secondly, the motivations and data collection concerning our study are described. Next, a novel exploratory modelling technique, multivariate adaptive regression splines (MARS), is introduced by Friedman (1991). The results and comparisons from MARS models for each pollutant follow in the next section. Finally, the highlights of the paper are summarized in the conclusion.

The motivation

One major environmental risk is the concentration of air pollutants due to their harmful influence on health of humans, animals and plants or other living organisms. Low or middle income countries are exposed to pollutants in and around homes from the heating, lighting, traditional stoves used for cooking, polluting fuels on open fires and so on (WHO, 2018). The European Environmental Agency (EEA) indicate that there is an increasing trend of pollutants in urban regions. The WHO Air Quality 2005 document provides a guideline for an assessment of the health effects of air pollutants and guideline values for health risk pollution levels. The EU establishes the standards and objectives for a number of air pollutants in the air to be applied over different periods of time. Although Turkey and Switzerland are not the members of the EU, Turkey at least aims to adapt to EU standards by reaching the air quality limits. *Table 1* shows the limits aimed for in order to achieve the lowest possible concentrations of PM10, NO_X, and NO_2.

There are a number of examples that can be used as sources of air pollution including industrial activity, energy (heating, cooking, lighting, electricity), transportation (vehicles and fuels), waste reduction of forest pollution, increasing numbers of inhabitants, and climate. Addressing the risk factors for air pollution, countries could reduce levels of air pollution to safeguard the public health.

The Ministry of the Environment and Urbanisation is the main institution of the Turkish government that is responsible for transboundary atmospheric pollution control (Yurtseven et al., 2018). The measurements of PM10, NO_x and NO_2 in forty cities organized from the Air Quality Monitoring System are shown in *Figure 1*. These are used to evaluate the priority of the variables that may be sources of the corresponding pollutants. Next, predictions from MARS models are depicted correctly as well as those cities with high levels of pollutants.

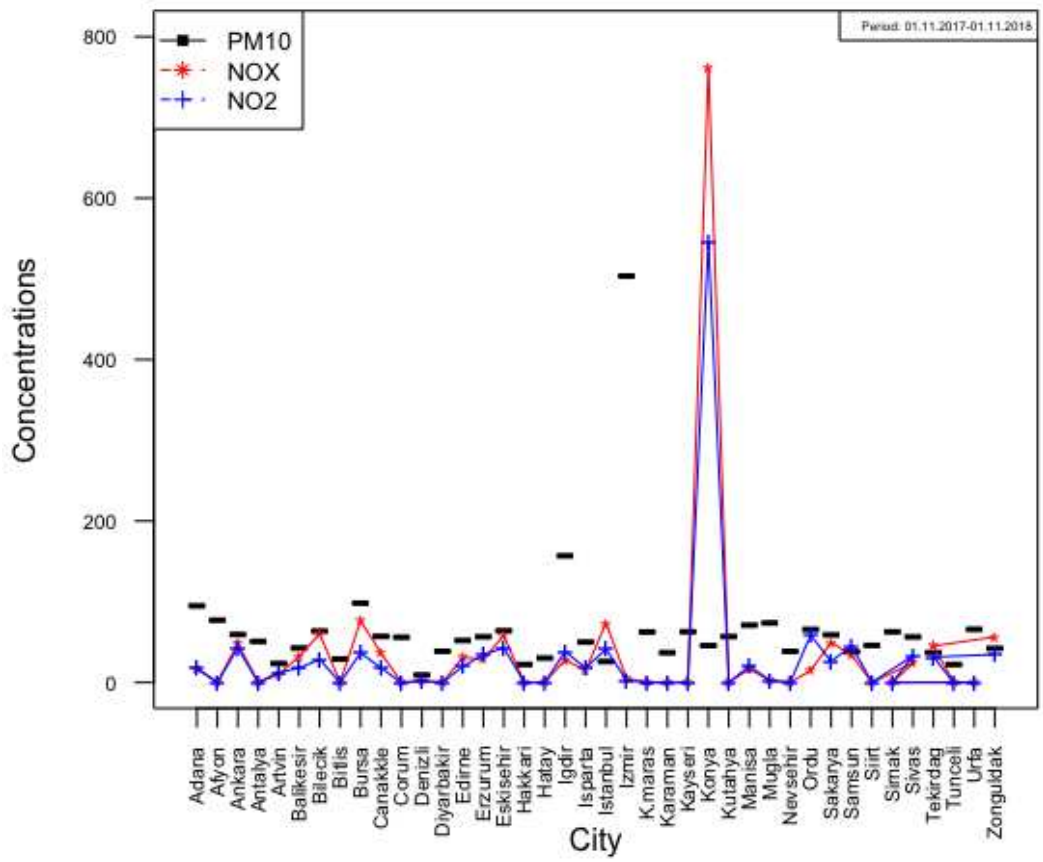

Figure 1. *Scatterplot of the data*

Figure 1 shows concentrations of PM10, NO_X, and NO_2 observed for the forty cities between 1 November, 2017, and 1 November, 2018. It is clear that the emissions peaks of PM10, NO_X and NO_2 occur in some of the cities. Although the trend of the PM10, NO_X, NO_2 is a quasi-sinoidal curve with peaks and valleys, these gases reach the greatest concentrations in Izmir and Konya, respectively. Additionally, certain relationships among variables are given in *Figure 2*.

Materials and methods

Model construction

The measurement of climatic variables is organized by the Ministry of the Environment and Urbanization Measurements and Monitoring Office, Turkey. For forty cities, eleven variables are recorded to investigate the determinants of air pollution

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98899903

presumably by regressing PM10, NO_X, NO_2 on those related to human ecology and climate. The measurements are collected at monitoring stations located within an industrial area close to the city or within the city limits. The results relating to climate (temperature, wind speed, precipitation, and number of days with precipitation) are average daily measurements (Air Quality Monitoring System).

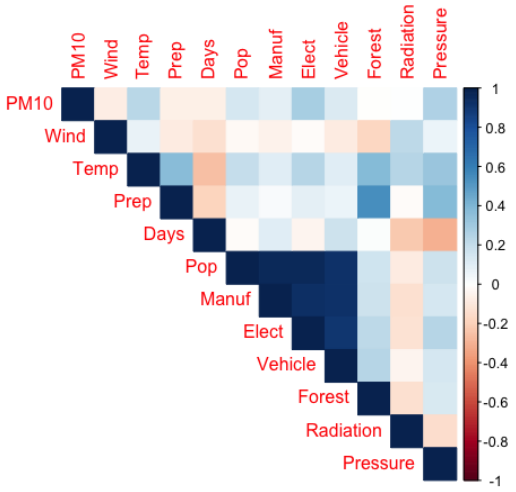

Figure 2. *Correlations among variables*

Addition, the effects of car pollution are widespread and is one of major cause of global warming. The increasing number of people which negatively effects the atmosphere and motorized vehicles can be geo-demographic predictors of the air pollutions and may be useful include in the model. The measurements for Radiation and Pressure are arranged from Turkish State Meteorological Service. The complete list of the data set was created using publicly online related web sources and the names of the variables are given in *Table 2*.

Table 2. *Complete list of variables used in this study*

Factors	Name of the variable	Mean	Min	Max
Average daily temperature period (°C)	Temp	13.6	5.7	19.1
Average daily wind period (km/h)	Wind	2.533	0	20.2
Average daily precipitation (kg/m^2)	Prep	643.9	106.5	1222.1
Average number of days with precipitation	Days	110.1	73.9	438.4
Number of manufacturing enterprises consuming fuel oil	Manuf	218.9	2	2832
Population size (2017)	Pop	1487978	82498	15029231
Electricity consumption (%)	Elect	0.837	0.06	16.719
Number of motorized vehicles (2017)	Vehicle	270708	2048	2755250
Forest area - % of city area (2017)	Forest	32.8	0	68
Radiation in 2016 (kWh/m^2)	Radiation	4.525	3.74	5.21
Average daily pressure	Press	755.4	0	1351.5
Pollutants:				
Particulate matter (µg/m^3 PM10)	PM10	65.14	9.26	503.47
NO_X (µg/m^3)	NO_X	38.15	0	760.56
Nitrite concentration (µg/m^3 NO_2)	NO_2	29.3	0	544.81

Multivariate adaptive regression splines

MARS is a nonparametric approximation of the relationship between a response and a set of independent variables in reflected pairs of simple linear splines (Friedman, 1991). The reflected pairs take the form given in *Equation 1:*

$$(x-t)_+ = \begin{cases} x-t & , x > t \\ 0 & \text{else} \end{cases} \quad \text{(Eq.1)}$$

where the subscript '+' means the argument is a truncated power function.

MARS models do not assume any underlying relationship between the dependent variable and the predictors. This relationship is constructed by an adaptive fitting procedure where piecewise polynomials of degree q (splines) are driven from regressing the dependent variable onto predictors. The MARS model has the following form given in *Equation 2:*

$$y = \beta_0 + \sum_{m=1}^{M} \beta_m h_m(\mathbf{x}) \quad \text{(Eq.2)}$$

where $h_m(\mathbf{x})$ are basis functions and $\beta_0, \cdots, \beta_M$, the unknown parameters for m = 1,…, M. Once the basis functions are investigated then $\beta_0, \cdots, \beta_M$ are estimated by the ordinary least squares method. The basis functions can be represented in *Equation 3* by:

$$h_m^q(\mathbf{x}) = \prod_{k=1}^{K_m} H\left[s_{k,m}\left(x_{v(k,m)} - t_{k,m}\right)\right]_+^q \quad \text{(Eq.3)}$$

with involving the truncated power functions with polynomials of lower order than q, where K_m is the number of variables (interaction order) in the m^{th} basis expansion and the number of splits that give raise to $h_m(\mathbf{x})$. $x_{v(k,m)}$ is the v^{th} variable, $v(k, m)$ label the predictor variables, $1 \leq v(k, m) \leq n$, $t_{k,m}$ is a knot on each of the corresponding variables and represent values on these variables. The quantites $s_{k,m}$ in *Equation 2* take on values + /-1 and indicate the left/right sense of the associated step functions.

The MARS algorithm adaptively selects the basis function set by two iterative approaches; forward and backward selection. It uses the residual squared error in iterations to compare the partition points. The criterion used to set the final model is a modified generalized cross validation (GCV) of the one first proposed by Craven and Wahba in 1979. The difference between the two criteria comes from a penalty term that reflects the complexity of the model in MARS.

The MARS approach allows a nonlinear relationship over different intervals of the vector of the explanatory variables for modeling Y (Sephton, 2001). The relationship between the explanatory variables and the response is fitted by basis functions that are basically splines. The main idea behind MARS is to explore the relationship by splitting the explanatory variables over its region into several intervals and to transform the original input variables over the intervals. MARS fits a spline based model in each interval. Basis Functions (B_i) include knot locations relating to the explanatory variables. B_i can be a single or multivariable interaction term. The final model is a combination of B_i. Model selection is accomplished using the GCV criterion given in *Equation 4:*

$$GCV = \frac{1}{N}\sum_{i=1}^{N}\left(y_i - \hat{f}_M(\mathbf{x})\right)^2 / \left(1 - {}^{C(M)}/_{N}\right)^2 \quad \text{(Eq.4)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98899903

where $C(M)$ is the complexity parameter to the corresponding model, and N represents the total number of observations. The final MARS model is the one with the smallest GCV and the largest R^2_{adj}.

Analysis and results

The conventional methods, multiple linear regression (MLR) and principal component analysis are used to address the main determinants of pollutants of PM10, NO_x, NO_2, respectively. Multiple linear regression is used by regressing several predictors listed in *Table 2* on the concentrations of PM10, NOx, and NO_2. The fitted values did not produce statistically significant models except the PM10-model ($F_{PM10;11;28} = 3.002$, $p_{PM10} = 0.0092$, R^2-adj = 0.36; $F_{NOx} = 1.565$, $p_{NOx} = 0.164$, R^2-adj = 0.13; $F_{NO2} = 1.388$, $p_{NO2} = 0.232$, R^2-adj = 0.23). It is also clear from the multiple plots given in the *Appendix* that MLR can not be considered for further analysis.

Next, principal component regression (PCR) is performed to investigate the determinants of the pollutants. The models from PCR did not provide informative contribution in this analysis and are effected by the presence of the outliers. Although the first four components (four eigenvalues greater than 1) explained 84.3% of the total variation among the transformed predictors, the regression models were not statistically found significant ($F_{PM10;4;35} = 0.721$, $p_{PM10} = 0.583$; $F_{NOx;4;35} = 0.951$, $p_{NOx} = 0.446$; $F_{NO2;4;35} = 1.002$, $p_{NO2} = 0.419$). Ultimately, PCR was not appropriate for predicting the responses on several variables.

In this work, a new approach for modelling PM10, NOx, and NO_2 concentrations are developed. MARS models have been used (Milborrow, 2011; Hastie et al., 2003), the basis functions of the models, consisting of linear and second-order splines, are shown in *Tables 3, 4,* and *5*. There are three dependent variables used to build the MARS models; particulate matter less than 10 $\mu g/m3$ (PM10), nitrogen dioxide (NO_2), and nitric oxide (NO_X). The results of MARS computed using all the available observations show a list of 4, 9, and 6 basis functions (B_i) for each of the three MARS models and their coefficients (C_i), respectively.

It should be noted that, MARS constructs nonparametric regression models as an extension of the linear models, and automatically determines the linearities and interactions and models a weighted sum of basis functions (hinge functions). The hinge function $h()$ is x if the first quadrant is greater than 0, and is 0 if x is less than or equal to 0.

The regression equation of PM10, which includes linear form of its term, such as Precipitation and two second order basis functions, can be easily generated using *Table 3* and *Equation 5* as follows:

$$PM10 = 46.002 + 0.466\,B_2 - 0.016B_3 + 0.158\,B_4 \quad \text{(Eq.5)}$$

In *Equation 5,* there are two interaction terms, *B*3 and *B*4, where certain relationships between the variables Pressure and Forest, and the variables Electricity and Pressure found to be important, respectively. Using *Equation 5,* PM10 predictions can be calculated easily. The variation between the predictions and the actual data is presented in *Figure 4*. Similarly, the regression equations for NO_X and NO_2 can be constructed easily from *Tables 4* and *5.*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98899903

Table 3. *List of basis function and their coefficients obtained by the MARS model for PM10 pollutant*

C_i	Definition	B_i
46.002	1	B_1
0.466	h(452.3-Prep)	B_2
-0.016	h(452.3-Prep)*Forest	B_3
0.158	Elect* h(Pressure-988.77)	B_4

It is worth to notice that the MARS model for NOX allows us to assess many interactions between different hinge functions. This can be easily seen in *Table 4*. The NO_X model includes three interaction terms between hinge functions and linear terms. For example, $h(13.8-Temp)*Vehicle$ is an interaction effect for those Temp values less than 13.8 and the number of vehicles. Also, the MARS model for NO_X includes linear form of its term such as Vehicle and hinge functions of the variables, Vehicle, Manuf, and Pressure.

Table 4. *List of basis function and their coefficients obtained by the MARS model for NO_x pollutant*

C_i	Definition	B_i
4.07654	1	B_1
0.00077	Vehicle	B_2
-11.01813	h(Manuf-151)	B_3
-0.00064	h(Vehicle-86926)	B_4
-0.59119	h(Pressure-988.77)	B_5
-0.00016	h(13.8-Temp)*Vehicle	B_6
-0.00013	h(Temp-13.8)*Vehicle	B_7
2.63176	h(Manuf-151)*Radiation	B_8
-0.00026	h(988.77-Pressure)	B_9

According to the results of NO_2, the model is constructed by linear and second-order basis functions. There are two linear basis functions and three second-order basis functions where certain relationships between Prep and the variables Manuf, Vehicle, and Pressure are found to be statistically important.

Table 5. *List of basis function and their coefficients obtained by the MARS model for NO_2 pollutant*

The most significant variables in the prediction of PM10, NO_X and NO_2 can be obtained from each MARS model as well. The list of each model is shown in *Tables 6, 7,* and *8*. These tables list the values of three criteria for estimating variable importance. The *nSubset* criterion indicates the counts of those models that include the variable. More subsets are considered of greater importance. The residual sum of the squares (RSS) criterion calculates the decrease in the RSS for each subset. The variables which cause a large decrease in RSS are considered more important. The last criterion GCV is similar.

Table 6. *Evaluation of the variable importance for the PM10 pollutant model according to Nsubsets, GCV and RSS*

Variable	nSubsets	GCV	RSS
Elect	3	100	100
Pressure	3	100	100
Prep	2	15.5	21.9
Forest	1	14.1	16.66

RSS: residual sum of squares; GCV: generalized cross validation; Nsubsets: number of subset models in which variable occurs

The most important variables in the PM10 prediction given in *Table 6* are obtained from electricity, pressure, precipitation, and forest in order of priority.

Table 7. *Evaluation of the variable importance for the NO_X pollutant model according to Nsubsets, GCV and RSS*

Variable	nSubsets	GCV	RSS
Manuf	8	100	100
Radiation	8	100	100
Temp	6	74.8	67.6
Vehicle	6	74.8	67.6
Pressure	3	28.5	26.3

The results in *Table 7* indicate that the most significant variables are Manufacturer, Radiation, Temperature, Vehicle and Pressure in the prediction of NO_X.

In *Table 8*, the most significant variables in the NO_2 prediction are Precipitation, Manufacturer, Vehicle, Pressure and Radiation.

Table 8. *Evaluation of the variable importance for the NO_2 pollutant model according to Nsubsets, GCV and RSS*

Variable	nSubsets	GCV	RSS
Prep	5	100	100

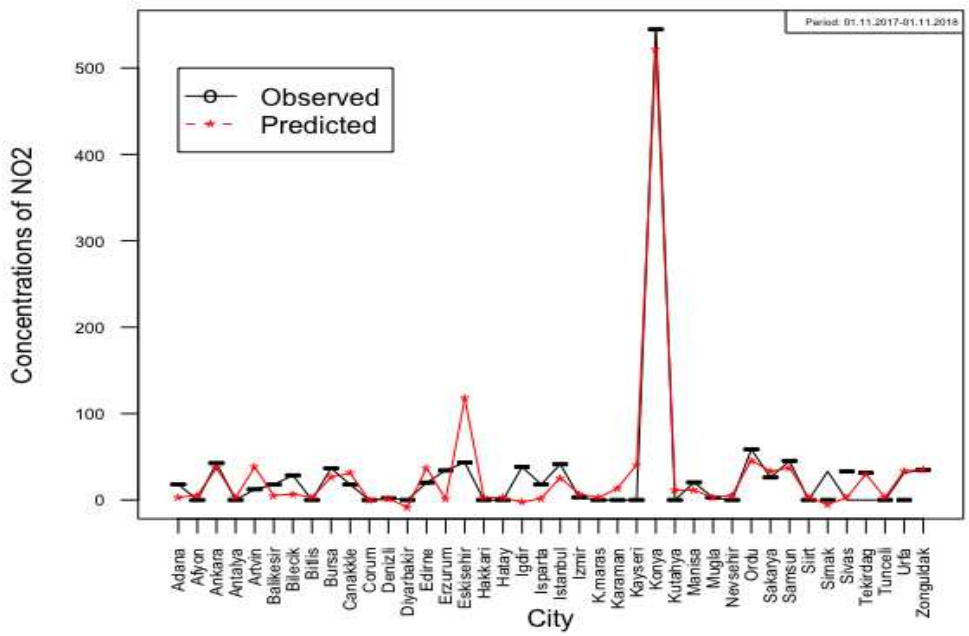

***Figure 5**. Comparisons between concentrations of NO_2 predicted by the MARS model and those observed*

In *Table 9*, an evaluation of the GCV and *R*2 (coefficient of determination) of the models is summarized. A coefficient of determination value indicates how well a model explains and predicts the future. A value of 1.0 is assessed as a perfect fit. For the PM10, NO_X and NO_2 models, the coefficients of determination are 92.5%, 96.2%, and 94.2%, respectively.

***Table 9.** Evaluation of the GCV and R2 that form the models*

Variable	GCV	R^2
PM10-second order	665.114	0.925
NO_X-second order	2294.915	0.962
NO_2-second order	932.613	0.942

Discussion and conclusion

In this research work, three models based on the multivariate adaptive regression splines for the study of considered pollutants PM10, NO_X, and NO_2 are proposed. The main purpose of this study is to increase accuracy in the prediction of three air pollutants when human factors and climate effects are present and physical-chemical parameters are combined. The innovative methodology MARS is applied to a real data set and is able to predict successfully.

One conclusion of this study is to set the order of the most significant variables in the prediction of PM10, NO_X, and NO_2. The priority of the predictor variables involved in the estimation of PM10 are actually related to climate parameters. On the other hand, human factors such as Manufacturer and Vehicles, included in the prediction of NO_X and NO_2, are the most influential parameters followed by Precipitation and Forest, respectively. Furthermore, this paper presents simple statistical models for the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_98899903

prediction of air pollutants. The results of numerical experiments, based on the application of the MARS technique, confirm high accuracy of daily modelling for pollutants PM10, NO_X, and NO_2.

Finally, the results of this study regarding the development of nonlinear models of three pollutant concentrations are valuable for future projects based on human health. Additionally, the nonlinear modelling of the ecological data with atypical observations can be used to reduce the effects of pollutants and to improve the development of models regarding air quality.

Abstract. This phytosociological study was conducted during 2015-2018; summed up plant 7 communities of herbs, shrubs and trees at 7 monitoring sites based on elevation, habitats and physiognomic contrast. Quadrate method was employed for the data collection 5 quadrats (10 × 10 m^2) for trees, 10 quadrats (5 × 5 m^2) for shrubs and 15 quadrats (1 × 1 m^2) for herbs at each site. Edaphic attributes were calculated by using standard methods. Based on family importance values Pinaceae was the leading family with an FIV of (374.39) followed by Lamiaceae (350.33), Asteraceae (204.43) and Poaceae (193.67). Seven communities' viz. *Berberis-Themeda-Periploca* community, *Seriphidium-Salvia-Thymus* community and *Indigofera-Quercus-Dichanthium* were established at Sub-Tropical zone. While Temperate Zone comprised of *Juniperus-Picea-Abies* community and *Quercus-Juniperus* community. *Abies-Picea-Rhododendron* community was established at Sub-Alpine zone while *Juniperus-Rheum-Kobresia* community was established at Alpine zone. However, cluster analysis using PAST software and PC-Ord software version 5, classified the vegetation into three groups and four groups based on quantitative value respectively. Vegetation structure and its productivity were governed by soil texture and its chemical composition. The physico-chemical analysis of habitat features revealed that the soil texture was mostly sandy loam and loamy sand with pH ranged from 7.3 to 7.7. Afforestation programs need to be started on wasteland of the area to overcome the impacts of deforestation.
Keywords: *vegetation, phytosociology, edaphic variables, maturity index, similarity index*

Introduction

Study of plant communities and their classification is termed as phytosociology. Primarily phytosociology helps in understanding the multilateral relationships between plants and their environment. It deals with quantitative, qualitative and synthetic attributes of plant communities. Vegetation is an ecological quantification of plant resources (Ali et al., 2018; Timilehin et al., 2017; Badshah et al., 2016). The vegetation of an area is the reflection of its climate, soil, biodiversity, anthropogenic activities and natural resources (Ilyas et al., 2015). The vegetation structure and plant population sizes also indicate species tolerance of existing ecological attributes (Kuma and Shibru, 2015; Sher et al., 2014). The presence and the establishment of the communities reveal the plant type and surroundings condition under which they developed (Hussain et al., 2015; Zhu et al., 2015; Ahmad et al., 2006). The health of any ecosystems is dependent on plant biodiversity and thus the vegetation classification is a prerequisite for ecosystem management and biodiversity conservation. Some of the most important

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99059924

environmental factors affecting the vegetation are deforestation, erosion, trampling, overgrazing and other ecological factors. In Pakistan two-third of the area is highland type and quick changes in climate and elevation aggravates differences in plant diversity. Pakistan includes variety of land-dwelling ecosystem, with in 18 main geographic regions (Khan et al., 2016; Zoq-ul-Arfeen et al., 2015). Due to non-availability of natural gas and electricity large population of the area depends upon forest wealth for domestic needs. Because of the intense browsing nearly all the pastures have been ruined and need restoration to be sustainable again. Phytosociologically the vegetation and forests of Koh-e-Safaid slopes are Sino-Japanese type (Hussain et al., 2019). The natural forests of Kurram cover about 8% of its area while the Parachinar Forest Department has planted about 6% area. The land under cultivation is 35% while the rest of 47% is barren. The major forest types of the Kurram are dry tropical forest and sub alpine scrub (Hussain et al., 2013). The area is very rich in plant resources however little ecological work has been done in the region. The dry tropical vegetation covers the Southern parts while dry temperate and alpine vegetation types are found in the Northern parts of the area. In the investigated area climate is highland type and it varies at different altitude. The observed changes in the plant communities are due to season, temperature, soil type and time of sampling of the vegetation. During spring and summer many annual show dominance and cause change in the seasonal aspects. They approach each other by sharing the species and that is why 73.5% similarity occurred. However, slight changes were observed in their cover from season to season, but the predominance of annuals changed the community composition. The recorded species exhibit different dominance value due to change in habitat and altitude condition throughout the area. The study area was unexplored in terms of its phytosociology hence present study presents first report of vegetation dynamics of this part of Pakistan.

Materials and methods

Study area

The research work was carried out in Koh-e-Safaid Range Upper Kurram. Kurram is located from 33° 20’ to 34° 10’ north latitudes and 69° 50’ to 70° 50’ east longitudes. The study area covers an area of 3380 km^2, including seven monitoring sites viz. Sub-Tropical South Hills, Sub-Tropical Plain, Sub-Tropical North Hills, Temperate South Facing slopes, Temperate North Facing slopes, Sub alpine and Alpine zone (*Fig. 1*).

Phytosociology

Phytosociological work was carried out in 7 sites based on elevation, species structure, habitats and physiognomic contrast. Vegetation was analyzed by using 5 quadrats (10 × 10 m^2) for trees, 10 quadrats (5 × 5 m^2) for shrubs and 15 quadrats (1 × 1 m^2) for herbs in each site. Density, frequency and cover of each species were recorded and all the values were converted in to IV (Importance value) and FIV (Family importance value). Geographical co-ordinates of each site were noted using GPS. Different plant communities were established based on highest importance value following (Ali et al., 2018; Badshah et al., 2016; Rajendran et al., 2016; Forzieri et al., 2011).

DOI: http://dx.doi.org/10.15666/aeer/1704_99059924

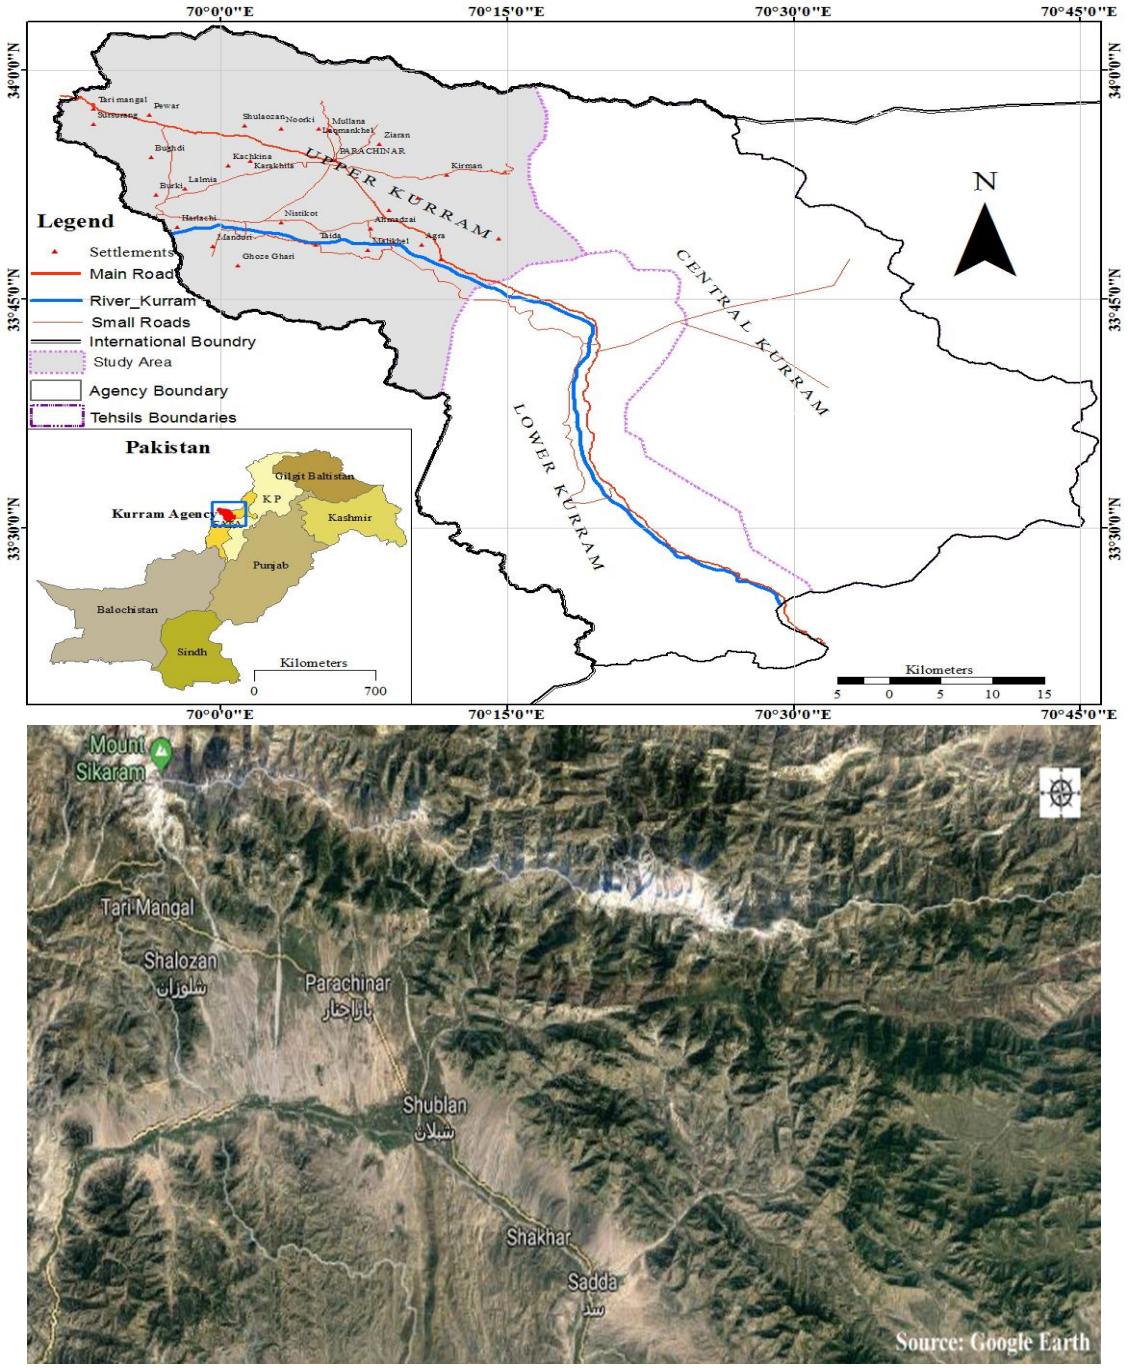

Figure 1. a *Map of the study area.* ***b*** *Google Map of the study area of Upper Kurram Valley*

Data analysis

Cluster analysis was conducted by using PAST software, Wards cluster analysis and Principal Component Analysis tools. It is a classification technique for putting similar objects into clusters. The arrangement is a hierarchical tree like structure is called a dendrogram. These clusters of sampling units may represent different biotic communities. The community classification was made by using Multivariate Statistical Package. The classification was based on structural variations among stands and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99059924

dendrogram were made for vegetation stands of the area. A Principal Components Analysis technique was also applied to analyze spatial variations in vegetation by PC-Ord software version 5.

Importance value (IV)

Importance value of each species was calculated by adding all the relative values of RD, RF, RC (Ali et al., 2018; Badshah et al., 2016). The communities were named after the three leading species having the highest importance values.

$$IV = RD + RC + RF$$

Family importance value (FIV)

Importance value of every species in specific families was added together to obtain FIV for all the quantitatively recorded families.

Maturity index

The community maturity index of community was obtained by (Pichi-Sermolli, 1948).

$$\text{Degree of maturity index} = \frac{\text{Frequency values of all species in a stand}}{\text{Total number of species in a stand}}$$

Similarity index

It was applied to compare similarities between different communities. It is the number of species common to both communities. It was calculated by using Sorensen's index (Sorensen, 1948) as modified by (Motyka et al., 1950). It was applied to compare similarities between different communities.

$$IS_{MO} = \frac{2W}{A+B} \times 100$$

where W = Sum of lowest quantitative value of the species pair common to both communities, A = Sum of quantitative value of all species in community A, B = Sum of quantitative value of all species in community B.

Soil analysis

Soil samples of 1 kg from 7 sites were collected from 0-15 cm depth from the selected sites of the study areas. Each of the collected samples was taken in clear polythene bags which were duly labeled and sealed on the spot. Later the soil samples were dried in an oven at 25 to 30 °C. Soil samples were screened for contaminants such as stones, plant roots and other impurities. Soil samples were grounded and passed through a 2.5 mm sieve (Ryan et al., 2001). Standard methods were applied to estimate soil texture (Brady, 1990; Bouyoucos, 1936), pH (Jackson, 1962), organic matter, $CaCO_3$ (Rayan et al., 1997), electrical conductivity (Rhoades, 1996), sodium absorption ratio and sulphates (Richard, 1954). Nitrogen was determined by Kieldahl method of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99059924

Bremner and Mulvaney (1982). Phosphorous, Potassium, Calcium and Magnesium were enumerated by Inductively Coupled Plasma Optical Emission Spectroscopy (ICP-OES).

Results

Present study was conducted in Koh-e-Safaid Range Upper Kurram during 2015-2018. Seven monitoring sites were established viz. Sub-Tropical South Hills, Sub-Tropical Plain, Sub-Tropical North Hills, Temperate South Facing slopes, Temperate North Facing slopes, Sub-Alpine and Alpine zone. The study area displays a unique floristic and vegetation structure. The approach of classifying vegetation into 7 different communities agrees with the work of Ali et al. (2018), Ilyas et al. (2018), Badshah et al. (2016), Siddiqui et al. (2015), Sher et al. (2014) and Ahmad et al. (2006). A total of 60 species were recorded in sampling units, of which trees were represented by 09 species, shrubs by 14 species and herbs by 37 species. Based on importance value (IV), a total of seven communities were established at seven monitoring sites. Based on family importance value Pinaceae was the leading family with an FIV of 374.39 followed by Lamiaceae (350.33), Asteraceae (204.43), Poaceae (193.67), Cupressaceae (173.97), Papilonaceae (103.93), Fagaceae (100.3), Berberidaceae (75.64), Polygonaceae (68.23) and Rosaceae with (62.55). Ranunculaceae, Saxifragaceae, Asclepiadaceae, Ericaceae, Boraginaceae, Salicaceae, Elaeagnaceae, Euphorbiaceae, Thymelaeaceae, Valerianaceae, Balsaminaceae, Oleaceae, Primulaceae, Areceaea and Scrophulariaceae had importance values ranging from 48.40 to 10.31. The study area is divided in to four zone i.e. Sub-Tropical zone, Temperate zone, Sub-Alpine and Alpine zone based on altitude, physiognomy, soil type and variance in ecological factors. Based on IV values 7 different communities were established in four ecological zones.

Sub-tropical zone

Sub-tropical south hills (site I)

1. Berberis-Themeda-Periploca community (BTP)

This plant community was reported from north facing slope at southern aspects at elevation of 1525 m. *Berberis lycium* was the dominant species with IV of 36.83. Second dominant species was *Themeda anathera* with an IV of 34.88 forming a close association with *Berberis lycium* at southern lower parts of the sub-tropical zone. *Periploca calophylla* with an IV of 30.98 mostly dispersed among the *Berberis lycium* and *Themeda anathera.* Other prominent member of this community included *Thymus linearis* (29.4 IV), *Aristida purpuea* (27.22 IV) and *Stachys parviflora* (25.54 IV) and *Androsace rotundifolia* (11.22 IV). Common shrubs growing around this community were *Daphne mucronata, Cotoneastor macrophylla, Cotoneastor microphylla, Teucrium stocksianum and Nannorrhops ritchiana.* The only one tree i.e *Olea ferruginea* was sparsely distributed in this community (*Table 2*). Similar communities were also reported by Ali et al. (2018), Badshah et al. (2016), Ilyas et al. (2015) and Forzieri et al. (2011). This plant community was established at Southern aspects at an elevation of 1328 m up to 1525 m. Nitrogen content of the soil was 0.401%, phosphorous 810 µg/g, potassium 8700 µg/g, calcium 32100 µg/g, magnesium 5100 µg/g, sulphur 187 µg/g, sodium 1900 µg/g, iron 81300 µg/g, zinc 73 µg/g,

Sub-tropical plain area (site II)

2. Seriphidium-Salvia-Thymus community (SST)

This herbaceous community was recorded from plains area of Sub-Tropical Zone at an elevation of 1680 m. In this area therophytes dominated the landscape along with sparse distribution of the *Elaeagnus angustifolia.* Dominant species was *Seriphidium kurramense* with IV value of 50.50 followed by *Salvia reflexa* with IV of 42.10. *Salvia reflexa* an invasive species made thick randomly distributed patches in flooded ravines, gullies, along road side, sandy loams and on open fertile clay soils. *Thymus linearis* with an IV value 26.38 was found to be codominant. The other predominant species growing around this community were *Parthenium hysterophorus*, *Artemisia scoparia*, *Cynodon dactylon*, *Conyza canadensis*, *Tagetis minuta* and *Astragalus oplites*. The recorded shrubs in this community were *Daphne mucronata*, *Indigofera heterantha*, *Hertia intermedia* and *Berberis lyceum* (*Table 2*). Ali et al. (2018), Hussain et al. (2016), Badshah et al. (2016), Forzieri et al. (2011) and Wahab et al. (2010) have also reported similar results in their studies. Soil at this locality was sandy loam. Nitrogen content of the soil was 0.280%, phosphorous 645 µg/g, potassium 7800 µg/g, calcium 39700 µg/g, magnesium 6300 µg/g, sulphur 263 µg/g, sodium 2600 µg/g, iron 79000 µg/g, zinc 84 µg/g, manganese 976 µg/g and cupper 55 µg/g. Soil pH at this site was 7.7 and organic matter was found to be 1.7% as shown in *Tables 1* and *2*.

DOI: http://dx.doi.org/10.15666/aeer/1704_99059924

Sub-tropical north hills (site III)

3. Indigofera-Quercus-Dichanthium community (IQD)

This community was recorded from the Sub-Tropical North Hills at an elevation of 2492 m. Thick shrub cover and comparatively thick trees of *Quercus baloot* near the foot hills indicated the disturbed nature of habitats which were under biotic stresses like deforestation and grazing. Dominant species was *Indigofera heterantha var. gerardiana* with an IV value of 42.20 followed by *Quercus baloot* with an IV value of 33.80. These shrubs made thick dispersed patches on mostly treeless open spaces. Codominant species was found to be *Dichanthium annulatum* with an IV value 29.39. Similar communities were recorded by Ali et al. (2018), Ilyas et al. (2015), Badshah et al. (2015 and Ali and Malik (2010). The rest of the species included *Thymus linearis*, *Leptorhabdos parviflora*, *Medicago lupulina, Cotoneastor macrophylla*, *Berberis lycium*, *Impatiens edgeworthii* and *Fragaria nubicola* (*Table 1*). Soil of the area was loamy sand. Nitrogen content of the soil was 0.394%, phosphorous 571 µg/g, potassium 8300 µg/g, calcium 36200 µg/g, magnesium 6800 µg/g, sulphur 221 µg/g and sodium 1300 µg/g. The microelements like iron was recorded 81800 µg/g, zinc 78 µg/g, manganese 343 µg/g and copper 95 µg/g. Soil pH at this site was 7.6 and organic matter was found to be 2% as shown in *Tables 1* and *2*.

Temperate Zone

Temperate north facing slope (site IV)

4. Juniperus-Picea-Abies community (JPA)

This community was recorded on North Facing Slope of Temprate Zone dominated by *Juniperus excelsa* with an IV value of 65.36, almost uniformly distributed in the locality making strong association with the second dominant *Picea smithiana* with an IV value of 51.07. The third dominant species was *Abies pendrow* with an IV 25.89. The tree species were uniformly distributed while the *Juniperus excelsa* was found in open patches among the dominant tree species. The other associated species were *Pedicularis verticilata*, *Aquilegia pubiflora*, *Phlomis bracteosa*, *Salex denticulate*, *Euphorbia wallichii*, *Pinus wallchiana*, *Valeriana jatamansi*, *Quercus semecarpifolia* and *Nepeta kurramensis* (*Table 1*). Badshah et al. (2016), Hussain et al. (2016) and Rashid et al. (2011) also have reported similar results in their studies. This community was recorded from Temperate Zone North facing slope at an elevation of 2200 up to 2450 m. Soil at this locality was loamy sand. Nitrogen content of the soil was 0.455%, phosphorous 435 µg/g, potassium 6580 µg/g, calcium 39800 µg/g, magnesium 6200 µg/g, sulphur 199 µg/g, sodium 1600 µg/g, iron 15000 µg/g, zinc 68 µg/g, manganese 776 µg/g and copper 105 µg/g. Soil pH at this site was 7.4 and organic matter was found to be 1.9% as shown in *Tables 1* and *2*.

Temperate south facing slope (site V)

5. Quercus-Juniperus community (CQJ)

Cedrus-Quercus-Juniperus community was recorded at an elevation of 2450 up to 2700 m on the South Facing Slopes of Temperate Zone. The area had uniformly spread *Cedrus deodara* forest mixed with *Quercus semicarpifolia* and *Juniperus excelsa*. The area was under tremendous biotic stress especially cutting of *Pinus gerardiana, Pinus*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99059924

wallichiana, Cedrus deodara for timber wood in past and completely missing of herbage cover due to steep slopes, lacking topsoil and allelopathic effect of shading leaves of *Cedrus, Pinus* and *Juniperus* trees. In this community the dominant species was *Cedrus deodara* with an IV value of (66.39). *Quercus semicarpifolia* with an IV value of (47.71) was codominant making strong association with *Juniperus excelsa* with IV value of (35.29). Only few plants were recorded of *Pinus gerardiana* and it was abundant on Pak-Afghan border. The other important associated members of this community were *Sophora mollis*, *Quercus baloot*, *Pinus wallichiana*, *Piptatherum aequiglume*, *Daphne mucronata, Phlomis cashmeriana* and *Cotoneaster macrophylla* (*Table 1*). Our results are in line with the works of Ali et al. (2018, 2015), Bokhari et al. (2013), Badshah et al. (2015), Ilyas et al. (2015) and Forzieri et al. (2011). Soil at this locality was loamy sand. Nitrogen content of the soil was 0.411%, phosphorous 810 µg/g, potassium 8700 µg/g, calcium 39900 µg/g, magnesium 6500 µg/g, sulphur 205 µg/g, sodium 1500 µg/g, iron 83100 µg/g, zinc 64 µg/g, manganese 531 µg/g and copper 109 µg/g. Soil pH at this site was 7.3 and organic matter was found to be 1.4% as shown in *Tables 1* and *2*.

Sub alpine zone (site VI)

6. Abies-Picea-Rhododendron community (APR)

On the North Facing Slopes *Abies-Picea-Nepeta* community was recorded and comparatively there was thick forest of *Abies pendrow and Pice smithiana.* The *Rhododendron afghanicum* was uniformly distributed on the open space of forest as well as inside the forest. The dominant species was *Abies pendrow* with an IV value 44.25. *Picea smithiana* with an IV value 41.56 was codominant forming a close association with *Rhododendron afghanicum* with an IV value of 33.36. The other associated species were *Nepeta bracteosa*, *Pedicularis verticillata*, *Aquilegia pubiflora, Bistorta amplexicaulis*, *Cynoglossum furcatum*, *Cotoneaster macrophylla*, *Medicago lupina*, *Berberis vulgaris* and *Leptorhabdos parviflora* (*Table 2*). Badshah et al. (2016), Hussain et al. (2016), Forzieri et al. (2011) and Mahmood et al. (2015) also have reported similar results in their studies. Soil at this locality was loamy. Nitrogen content of the soil was 0.333%, phosphorous 450 µg/g, potassium 5910 µg/g, calcium 36500 µg/g, magnesium 5900 µg/g, sulphur 175 µg/g, sodium 1800 µg/g, iron 89200 µg/g, zinc 64 µg/g, manganese 418 µg/g and copper 93 µg/g. Soil pH at this site was 7.4 and organic matter was found to be 2.4% which is typical to the podzolic soil as shown in *Tables 1* and *2*.

Alpine zone (site VII)

7. Juniperus-Rheum-Kobresia community (JRK)

This community was recorded at an elevation of above 2850 m. This is treeless zone and only two shrubs were recorded first one was *Juniper excelsa* and the second was *Rhododendron afghanicum* and dominated by the herbs. The dominant species was *Juniper excelsa* with an IV value of 70.32. *Rheum spiciforme* with an IV value of 45.74 was codominant forming a close association with *Kobresia schoenoides* with an IV value 34.42. The other associative members of the community were *Bergenia stracheyi*, *Thymus serphyllum*, *Morina longifolia*, *Phlomis bracteosa* and *Trifolium repens* (*Table 3*). Badshah et al. (2016), Hussain et al. (2016) and Forzieri et al. (2011) also have reported similar results in their studies. Soil at this locality was sandy loam.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99059924

Nitrogen content of the soil was 0.211%, phosphorous 750 µg/g, potassium 1090 µg/g, calcium 39900 µg/g, magnesium 5500 µg/g, sulphur 163 µg/g, sodium 3300 µg/g. The micronutrients like iron was present 73200 µg/g, zinc 82 µg/g, manganese 869 µg/g and copper 89 µg/g. Soil pH at this site was 7.85 and organic matter was found to be 2.42%

Ward's cluster analysis

Cluster analysis was conducted by using PAST software applying Wards cluster analysis tool. These clusters are based on IV of the leading species at all monitoring sites and the combined IV of each specie.

Cluster I. Juniper excela – Rhododendron afghanicum community

This group had *Juniper excela* as a leading dominant with a combined IV of 171.21. This member was recorded from Site-IV (65.36 IV), Site-V (35.29 IV) and Site-VII (70.32 IV) while second dominant species was *Rhododendron afghanicum* with a combine IV of 63.43. This species was found at only two sites i.e. Site-VI (29.56 IV) and Site-VII (33.87 IV). *Rheum speciforme*, *Kobresia schoenoides* and *Bergenia stracheyi* were other important members of this group (*Table 3, Fig. 2*).

Cluster II. Picea smithiana – Thymus linearis community

This group had the highest species richness, dominated by *Picea smithiana* with a combined IV of 92.63. It was found at Site-IV (51.07 IV) and Site-VI (41.56 IV). Second dominant species was *Thymus linearis* with a combined IV of 105.22. It was found at Site-I (29.4 IV), Site-II (26.38 IV), Site-III (27.7 IV), Site-IV (6.54 IV), Site-V (5.57 IV), Site-VI (7.0 IV) and Site-VII (2.63 IV). *Berberis lyceum* (combined IV 80.69), *Abies pindrow* (combined IV70.14), *Cotoneaster macrophyla* (combined IV 53.87), *Pedicularis verticilata* (combined IV 51.75) and *Seriphidium kurramense* (combined IV 50.5) were the other prominent plant species of this cluster. This cluster also included *Olea ferruginea* and *Pinus geraardiana* but with lower IV values. *Pinus gerardiana* is an indicator species of Dry Temperate Zone which yields edible seeds (*Table 1, Fig. 2*).

Cluster III. Quercus semicarpifolia – Cedrus deodara community

Quercus semicarpifolia with 66.5 combined IV was dominant member of this group. It was found at Site-III (13.79 IV) and Site-V (52.71 IV). Second dominant species was *Cedrus deodara* having a combined IV of 66.39. *Indigofera heterantha* (50.93 IV), *Quercus baloot* (55.73), *Artimesia scuparia* (50.4 IV) and *Piptatherium aequiglume* (48.16 IV) were other important members of this group (*Table 3, Fig. 2*).

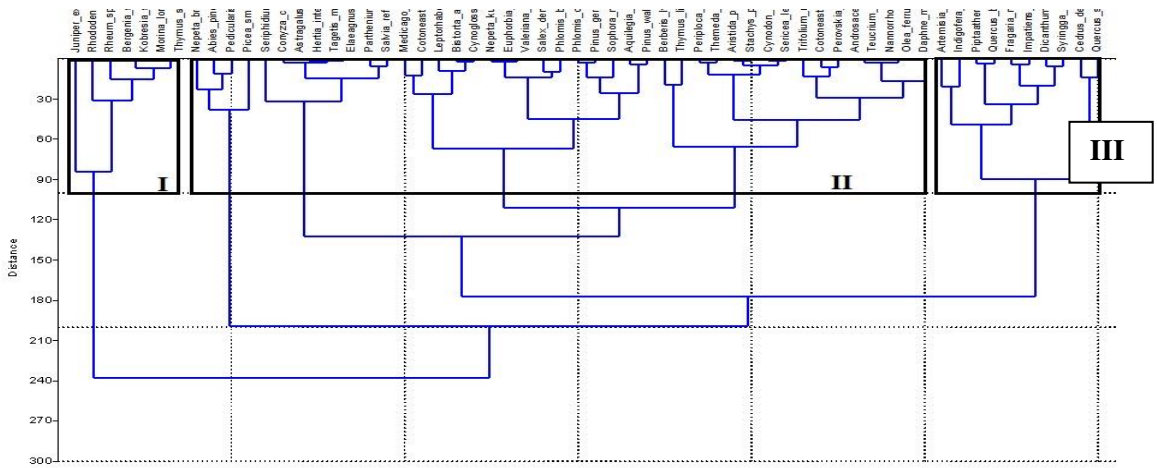

Figure 2. *Cluster dendrogram analysis showing 3 associations based on IV values*

Principal components analysis

Principal Components Analysis is one of the vegetation analysis techniques, which was applied by Pearson in ecology for the first time (Mesdaghi, 2001). Numerous studies have been carried out using PCA in various parts of the world to probe the connection between soil properties and vegetation (Rajendran et al., 2016, Forzieri et al., 2011, Salehi et al., 2005; Taleshi, 2004). Vegetation cover is an important variable in many earth system processes. The aim of this clustering is to analyze spatial variations in vegetation characteristics of Koh-e-Safaid Range Upper Kurram using principal component analysis. PCA was done by PC-Ord software version 5 which classified the vegetation data into 4 major components based on IVs of plant species as shown in the *Figure 3*.

Group 1

The dominant species in this group was *Seriphidium kurramense* with an IV of 50.50, *Berberis lycium* with an IV of 36.83, *Themeda anathera* with an IV of 34.88, *Quercus baloot* with an IV of 33.80, *Dichanthium annulatum* with an IV of 33.60, *Salvia reflex* with an IV of 32.10, *Periploca calophylla* with an IV of 30.98, *Thymus linearis* with an IV of 29.4, *Aristida purpuea* with an IV of 27.22 and *Leptorhabdos parviflora* with an IV of 26.50. The other associative species were *Stachys parviflora*, *Parthenium hysterophorus*, *Artemisia scoparia*, *Cynodon dactylon*, *Conyza canadensis*, *Tagetis minuta* and *Astragalus oplites*. Soil at this site was Sandy loam. Similarly, this group had low amount of N_2, Ca, Mg, Cu, Sulphates and high values of EC, HCO_3, P, K, Ca, Cl, Na, Fe and Zn as compare to other three groups (*Fig. 3*).

Group 2

In this group *Indigofera gerardiana* with an IV value of 52.20 followed by *Quercus baloot* with an IV of 33.80 and *Dichanthium annulatum* with an IV of 33.60 were dominant species. The rest of the associative species were *Thymus linearis*, *Leptorhabdos parviflora*, *Medicago lupulina*, *Cotoneastor macrophylla*, *Berberis lycium*, *Impatiens edgeworthii* and *Fragaria nubicola*. The soil characteristic in group 2

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99059924

Sub-Tropical North Hills was loamy sand, with low EC, N_2, P, Ca, Na, Mn, Cu, Zn, and Sulphates while $Caco_3$, HCO_3, K, Mg, S, Cl and Fe contents (*Fig. 3*).

Group 3

In this group *Cedrus deodara* with an IV of 66.39 was dominant species followed by *Quercus semicarpifolia* with an IV of 52.71 making strong association with *Juniperus excelsa* with IV of 38.29. The other important associated members of this group were *Sophora mollis*, *Quercus baloot*, *Pinus wallichiana*, *Piptatherum aequiglume*, *Daphne mucronata*, *Phlomis cashmeriana*, *Cotoneaster macrophylla* and *Pinus gerardiana*. Studies on edaphic variables of this group showed that the soil EC was lower than the soil of other groups. Similarly, the amount of HCO_3, P, Mg, Cl, Cu, Na, Mn and Zn contents were low while N, K, S, Ca, Cu, Fe and Sulphates were comparatively (*Fig. 3*).

Group 4

This group was most diverse in terms of species richness having *Juniperus excelsa* as dominant species with an IV of 70.32, *Picea smithiana* with an IV of 51.07, *Rheum speciforme* with an IV of 45.74, *Abies pindrow* with an IV of 44.25, *Kobresia schoenoides* with an IV of 34.42, *Rhododendron afghanicum* with an IV of 33.36, *Nepeta bracteosa* with an IV of 29.56 and *Pedicularis verticillata* with an IV of 28.57. The other associated members were *Thymus seriphylum*, *Morina longifolia*, *Aquilegia pubiflora*, *Bistorta amplexicaulis*, *Aquilegia pubiflora*, *Phlomis bracteosa*, *Cynoglossum furcatum*, *Salex denticulate*, *Cotoneaster macrophylla*, *Euphorbia wallichii*, *Pinus wallchiana*, *Medicago lupina*, *Valeriana jatamansi*, *Berberis vulgaris*, *Phlomis bracteosa* and *Leptorhabdos parviflora*. The characteristics of the soil associative with this group show that the soil EC was lower than the soil of other groups. Similarly, this group had low amount of N, P, Mg, S, Cl, Cu and Zn and high values of HCO_3 K, Ca, Na, Fe and Sulphates as compare to groups (*Fig. 3*).

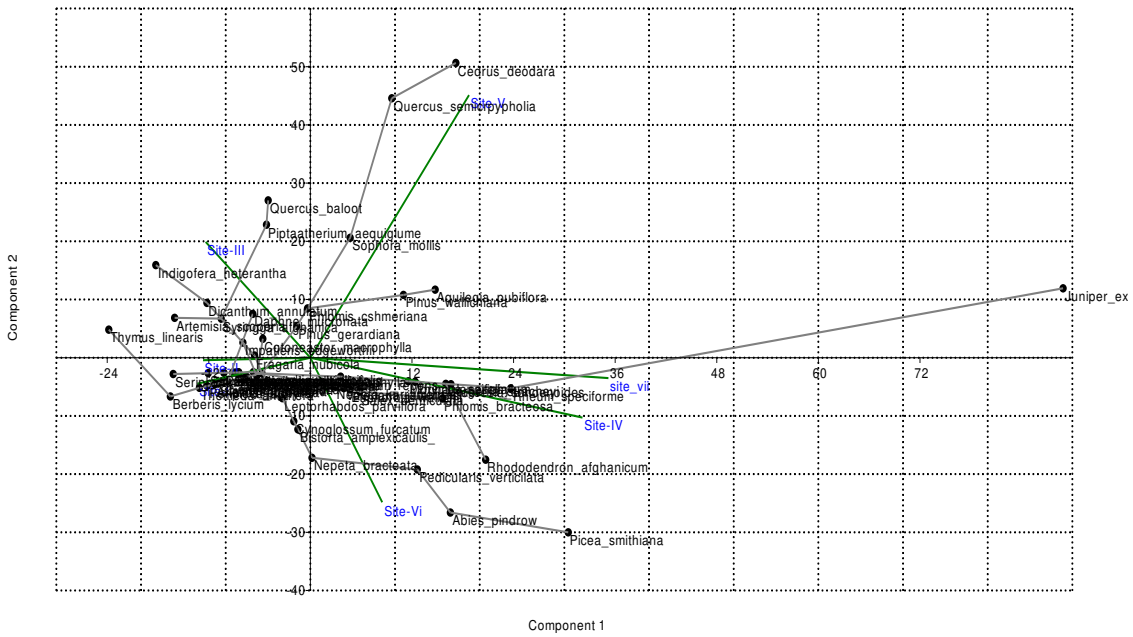

Figure 3. *Principal components analysis showing 4 associations based on IV values*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99059924

Maturity index

During the current study the species maturity index ranged from 74.16 to 48.88. The high maturity index was recorded (74.16) both at sub-tropical north zone and temperate south facing zone followed by (72.13) at sub-tropical south zone, (67.49) at sub alpine zone, (64.89) at alpine zone, (64.84) at temperate north facing zone and (48.88) at subtropical plain zone (*Table 4*).

Table 4. *Maturity index*

Sites	Communities	Maturity index
Sub-tropical south hills	*Berberis-Themeda-Periploca*	72.13
Sub-tropical plain area	*Seriphidium-Salvia-Thymus*	48.88
Sub-tropical north hills	*Indigofera-Quercus-Dichanthium*	74.16
Temperate north facing slope	*Juniperus-Picea-Abies*	74.16
Temperate south facing slope	*Cedrus-Quercus-Juniperus*	64.84
Sub-alpine zone	*Abies-Picea- Rhododendron*	67.49
Alpine zone	*Juniperus-Rheum-Kobresia*	64.89

Index of similarity

A similarity index does not consider the relative abundance of species. It is helpful when key concern lies in the absence or presence of species. Degree of similarity between two plant communities allows combining them into an association (Badshah et al., 2010). According to the Motyka's index of similarity (Motyka et al., 1950), *Berberis-Themeda-Periploca* community of Sub-Tropical South Hills was found to be 14.90% like *Seriphedium-Salvia-Thymus* community of Sub-Tropical plain area. The similarity between *Berberis-Themeda-Periploca* community of Sub-Tropical South Hills and *Indigofera-Quercus-Dichanthium* community of Sub-Tropical North Hills was observed 15.81%. The current analysis shows that similarity between *Berberis-Themeda-Periploca* community of Sub-Tropical South Hills and that of *Juniperus-Picea-Abies* community of Temperate Zone North facing slope was 2.18%. The *Berberis-Themeda-Periploca* community of Sub-Tropical South Hills and *Cedrus-Quercus-Juniperus* community of Temperate Zone South facing slope showed 8.16% similarity. The similarity between *Berberis-Themeda-Periploca* community Sub-Tropical South Hills and *Abies-Picea-Rhododendron* of Sub-Alpine Zone was recorded 10.53%. The similarity between *Berberis-Themeda-Periploca* community of Sub-Tropical South Hills and *Juniperus-Rheum-Kobresia* of Alpine zone was 0.87%. The community of Sub-Tropical plain i.e. *Seriphedium-Salvia-Thymus* was 22.48% similar to *Indigofera-Quercus-Dichanthium* community of Sub-Tropical North hills. The *Seriphedium-Salvia-Thymus* community of Sub-Tropical plain was found 2.19% similar to *Juniperus-Picea-Abies* community of Temperate North Facing slope. The *Seriphedium-Salvia-Thymus* community of Sub-Tropical plain was similar to *Cedrus-Quercus-Juniperus* community of Temperate South Facing slope i.e. 5.10%. The *Seriphedium-Salvia-Thymus* community of Sub-Tropical plain was found 5.17% similar to *Abies-Picea-Rhododendron* community of Sub-Alpine Zone. The *Seriphedium-Salvia-Thymus* community of Sub-Tropical plain was observed 0.88% similar to the *Juniperus-Rheum-Kobresia* community of Alpine Zone. The *Indigofera-Quercus-Dichanthium* community of Sub-Tropical North Hills was 2.18% like *Juniperus-Picea-*

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99059924

Abies community of Temperate Zone North Facing slope and 19.0% similar to *Cedrus-Quercus-Juniperus* Temperate South Facing slope. The *Indigofera-Quercus-Dichanthium* community of Sub-Tropical North Hills showed 16.22% similarity with *Abies-Picea-Rhododendron* community of Sub-Alpine Zone. Similarity between *Indigofera-Quercus-Dichanthium* community Sub-Tropical North Hills and *Juniperus-Rheum-Kobresia* community of Alpine Zone was 0.87%. The *Juniperus-Picea-Abies* community of Temperate North Facing slope showed 24.61% similar to *Cedrus-Quercus-Juniperus* community at Temperate South Facing slope. The *Juniperus-Picea-Abies* community of Temperate North Facing slope was found 32.49% similar to *Abies-Picea-Rhododendron* community at Sub-Alpine Zone. The *Juniperus-Picea-Abies* community of Temperate North Facing slope and *Juniperus-Rheum-Kobresia* community at Alpine Zone showed 27.45% similarity. A 5.50% similarity was recorded between *Cedrus-Quercus-Juniperus* community of Temperate South Facing slope and *Abies-Picea-Rhododendron* community of Sub-Alpine Zone. Comparison of *Cedrus-Quercus-Juniperus* community of Temperate South Facing slope and *Juniperus-Rheum-Kobresia* community at Alpine Zone showed 12.68% similarity while *Abies-Picea-Rhododendron* community of Sub-Alpine Zone and *Juniperus-Rheum-Kobresia* community of Alpine Zone community showed 10.74% similarity (*Table 5*). The current results agree with those of Ilyas et al. (2018), Khan et al. (2016), Urooj et al. (2016), Mehmood et al. (2015), Rashid et al. (2011), Wahab et al. (2010), Ali and Malik (2010) and Mesdaghi (2001), who reported similarities among the plant communities is due to soil properties, ecological and biotic factors.

Discussion

During the current study the vegetation of the area was classified into seven communities which is in line with the works of Ali et al. (2018, 2015), Badshah et al. (2016) Ilyas et al. (2015), Saurav and Das (2014), Sharma et al. (2014) Saglam (2013), Ahmad et al. (2010), Digiovinazzo et al. (2010), Hussain et al. (2010), Mohler et al. (2006) Munhoz et al. (2006) and Padalia et al. (2004). The research area is under tremendous anthropogenic stress, due to which the vegetation showed clumping rather than a uniform pattern of distribution due to excessive deforestation in the area. Scanty trees and comparatively thick shrub cover at Sub-Tropical North foothills and Temperate zone indicated the disturbed nature of habitat. Due to rapid population and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99059924

construction of buildings is the chief reason behind the species loss in this locality. Impacts of soil erosion were more visible at Site I, Site II, III, IV and Site-VII where eroded soils had herbaceous members such as *Plantago major*, *Rumex hastatus, Thymus linearis and Verbascum thapsus* which are indicator species of eroded soils. *Indigofera gerardiana, cotoneaster microphyllus* were observed to form randomly dispersed thick patches at site III, IV, *Juniperus communis*, *Rhododendron afghanicum* and *Salex denticulate* monitoring site V and VI (*Fig. 4*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99059924

These findings are backed by works of Ali et al. (2018), Dad (2016), Ilyas et al. (2015), Siddiqui et al. (2015) and Ahmad et al. (2010). *Cedrus-Quercus-Juniperus* community was recorded at on the South Facing Slopes of Temperate Zone. The area had uniformly spread thin *Cedrus deodara* forest mixed with *Quercus semicarpifolia* and *Juniperus excelsa*. The area was under tremendous biotic stress especially cutting of *Pinus gerardiana, Pinus wallichiana, Cedrus deodara* for timber wood in past and completely missing of herbage cover due to steep slopes, lacking topsoil and allopathic effect of shading leaves of *Cedrus, Pinus* and *Juniperus* trees. This is line with findings of Ali et al. (2018), Ahmad et al. (2016), Khan et al. (2016), Akhtar and Bergmeier (2015), Shaheen et al. (2015), Sharma et al. (2014), Hussain et al. (2010) and Jabeen and Ahmad (2009). On the North Facing Slopes of Sub-Alpine *Abies-Picea-Rhododendron* community was recorded. The *Rhododendron afghanicum* was uniformly distributed on the open space of forest as well as inside the forest. Forest at this site was found in good health. Deforestation was also not that alarming as compared to that of other monitoring sites. *Juniperus-Rheum-Kobresia* community was recorded at alpine zone. This is treeless zone and only two shrubs were recorded first one was *Juniper excelsa* and the second was *Rhododendron afghanicum* and dominated by the herbs i.e. *Kobresia schoenoides.* This site shrub growth was stunted, and trees were scanty due to unfavorable conditions. These results are in line with the works of Ali et al. (2018), Khan et al. (2016, 2012), Haq et al. (2015), Sharma et al. (2014) and Ahmad et al. (2010, 2006). The soil texture of the research area was typically sandy loam and loamy sand, with pH ranged from 7.3 to 7.7. Organic matter varied from 1.4 to 2.4% and electric conductivity from 0.6 dSm^{-1} to 1.6 dSm^{-1}. The $CaCo_3$ ranged from 2.6 to 7.8%, HCO_3 from 3.0 to 8.0% and sulphates from 0.4 to 7.8% respectively. Nitrogen concentration ranged from 0.280 to 0.569%, phosphorus from 435 to 810 µg/g, potassium from 1090 to 9900 µg/g, calcium from 32100 to 39900 µg/g, magnesium from 5100 to 6800 µg/g and sulphur from 163 to 263 µg/g. The micro nutrients such as iron ranged from 15000 to 89200 µg/g, manganese was enumerated as 343 to 976 µg/g, copper was found to be 55 to 109 µg/g and zinc varied from 53 to 84 µg/g, however, sodium was recorded from 1300 to 3300 µg/g and chlorine as 1500 to 3500 µg/g.

Conclusions

This study reveals results of vegetation mapping based on 140 sampling units at 7 monitoring sites while results of soil analysis cover 18 parameters. Spatial variation among plant communities at different monitoring sites is attributed to variations in edaphic variables, climate and different ecological parameters. Anthropogenic activities, over grazing, natural disasters and erosion are reducing the vegetation cover. Extraction of fuel wood from forest, especially during harsh winters by the local people is alarming. Impacts of anthropogenic pressure are evident from low scores for maturity index (48.88) at Sub-Tropical Plain area. Low values for maturity index indicate inability of the plant communities to cope with anthropogenic, edaphic and climatic stresses. Similarly, low values for similarity index show the heterogeneity among the reported different 7 plant communities. However, cluster analysis using PAST software and PC-Ord software version 5, classified the vegetation into three groups and four groups based on quantitative value. Afforestation programs need to be started on wasteland of the area to overcome the impacts of deforestation. There is severe deforestation pressure on woody and shrubby species especially on *Quercus baloot,*

Quercus semicarpifolia, Cedrus deodara, Abies pindrow, Pinus wallichiana, Indigofera gerardiana, Sophora mollis and Syringa afghanica. Therefore, alternate sources of fuel/timber should be provided, and the area must be protected to promote vegetation cover. Effective measures like afforestation and control of overgrazing are needed to avoid soil erosion.

Abstract. Three-dimensional fluorescence technology was applied to analyze the components and structures of the water extractable organic matter (WEOM) in the topsoil (0-20 cm) and a 20-40 cm depth of Mollisol of an uncultivated land or the land after of 5, 20, 50 and 100 years of reclamation, respectively. With the continuous reclamation, the content of the WEOM in the black soil has a tendency of decreasing at first but increasing subsequently. The WEOM reaches its maximum and minimum contents at 86.65 mg/kg and 47.81 mg/kg. The fluorescence intensity of the area III was enhanced. After the reclamation of 100 years, the fluorescence intensity of the areas III and Vreached to the top values, suggesting the maximum contents of fulvic acid-like and humic acid-like organic matters. The emitting lights at the fluorescence peak of the fluorescence area of humic acid-like organic matters also show red shift, indicating the increase of molecular weight, aromaticity and degree of polycondensation. However, the area Ⅳ remained unchanged. The research results showed that: with the reclamation, the components and structure, and the variation of WEOM in soil varies are related to the years of reclamation; the molecular weights, aromaticity and degrees of polycondensation in the WEOM increase evidently with the reclamation.
Keywords: *dissolved organic carbon, fluorescence technology, substance composition, planting years, upland field soil*

Introduction

The water extractable organic matter (WEOM) refers to organic matters dissolved in the soil solution or in the soil solution and a certain proportion of pure water after shaking extraction of organic compounds (Jones and Willett, 2006), and which can pass through the filter membrane of 0.45 μm (Hassouna et al., 2010). It has a tiniest ratio in the total organic carbon of the soil, but gets involved in all kinds of biologic or abiologic processes, such as pedogenesis, carbon distribution and fixation, and environment behaviors of nutrient substances and pollutants in soil, therefore being of important significance (Landgraf et al., 2006). Generally, it is considered that the WEOM mainly comes from the root exudate of the land plants, the hydrolysate of fallen leaves and soil organic matters (McGill et al., 1981), and the metabolites of microorganism (Christ et al., 1996), and is composed of carbon hydrates, long-chain aliphatic compounds and proteins (Hassouna et al., 2010), in which the humic acid and fulvic acid account for about 25%-50%, and the others primarily are proteins, polysaccharides and hydrophilic organic acid (Weishaar et al., 2003). The content,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99259935

components and structure of WEOM have been tested influenced by plant types, soil utilization methods, fertilization management, etc. The chemical composition of litter, varying with the plant types, obviously affects the existence of WEOM (Chantigny, 2003). For example, the WEOM has different and orderly reduced contents in the forest, grassland and plough (Wang et al., 2016). The fertilization, such as applying organic fertilizer and chemical fertilizer, shall change the content and structure of WEOM in soil (Liang et al., 2012). As for the soil utilization, after the natural land is reclaimed and turned into farmland, the content of WEOM is obviously reduced. The reclamation of land is regarded as the main reason for the reduction of WEOM (Graham et al., 2012). In terms of the distinctive fluorescence groups in the matters of WEOM, it is possible to analyze the WEOM by the fluorescence characteristics. Li et al. (2013) has researched the components and structure of WEOM in the soil of a farmland with a high maize outcrop by the fluorescence spectrum method, and indicated that the long-term application of nitrogen fertilizer shall affect the composition and structure of WEOM in the black soil, and further there is a parallelism between effect characteristics and application methods.

With fertile soil, the black soil area in the northeast of China ranks among the three largest black soil areas in the world, an extensive part of which has been reclaimed since one hundred years ago and been developed into the main commodity grain base of China with a high production level. Because of the reclamation of black soil, the soil fertility condition changed drastically, showing natural fertility reducing gradually (Provenzano et al., 2004). To a large extent, the natural fertility of soil depends on the quantity and quality of organic carbon in soil. As WEOM is the main part of the active organic carbon pool of soil, it can indicate the variation of quantity and quality of organic matters in soil (Liang et al., 2011). Therefore, this work, in virtue of the 3D fluorescence spectrum technology, has studied the content, composition, and structure of WEOM in the black soil after different years of reclamation, thereby providing a theory basis for deepening the recognition of reclamation's effects on the organic matters and quality of soil to increase the carbon fixation of black soil and improve the soil quality.

Materials and methods

Soil samples were collected in a Mollisol located in Haiqing village, Guojia county, Dehui city, Jilin province situated in the upper part of the corn belt region in China (N44°30'35.41" E125°33'20.90"). Sampling was performed at two depths, topsoil (0-20 cm) and 20-40 cm depth. Samples were taken in five adjacent soil plots of the uncultivated land and the cultivated land after the years of reclamation of 5, 20, 50 and 100, respectively. The soil was planted with maize and was ploughed each spring. With the snake-pattern five-point sampling method, the sampling is conducted in the sites with similar topography conditions and having shortest distance in between to minimize the topography disturbance. The basic physical and chemical properties of the tested soil are listed in *Table 1.*

Extraction and determination of the water extractable organic matter

WEOM extract by the steam water. The soil of 25 g in dry weight, having passed through the 2 mm-grade sieve, were put into the triangular flask, and added with the distilled water of 100 ml. The mixture in the flask then was vibrated under the normal temperature for 30 min, and centrifuged by a high-speed centrifugal machine of 8000 rpm for 5 min. After stabilizing for another 5 min, the supernatant was separated from the mixture, and filtrated by the 0.45 μm-grade filter membrane. The collected filtrate was just WEOM, which was used to test the content and analyze the three-dimensional fluorescence spectrum of WEOM. And the concentration of organic carbon in filtrate was measured by the Shimadzu TOC-VCPH analyzer (Li et al., 2013).

Test method

The HATACH F-7000-type fluorescence spectrophotometer produced by Hitachi was used for the fluorescence spectrum analysis of WEOM, with the xenon lamp as the light source of 150 W, the voltage of photomultiplier of 700 V, the silt widths for excitation and emitting lights of 5 nm, the wave length of 220-420 nm and the wavelength interval of 5 nm for excitation lights, and those separately of 280-560 nm and 1 nm for emitting lights (Li et al., 2013), as shown in *Figure 1*.

Determination of basic physicochemical properties of soil were completed with the water content in soil tested by the oven drying method, the pH value by the pH meter, the volume weight by the cutting-ring method, the available phosphorus by the sodium bicarbonate extraction and molybdenum-blue colorimetry, the available potassium by the NH_4OAc extraction and flame photometer, the available nitrogen by the alkaline hydrolysis diffusion method, the total nitrogen by the semimicro-kjeldahl determination, and the soil organic matter (SOM) by the potassium dichromate method with outside heating (Shi and Bao,1908).

Data processing

The data processing and analysis was conducted by virtue of Origin 7.5, SPSS19.0, Excel 2010, etc.

Results and discussion

Content of the water extractable organic matter in black soil after different years of reclamation

The content of WEOM in black soil after years of reclamation was measured by the organic carbon analyzer (TOC), and the results are listed in *Table 2*. As indicated by the results, the cultivation had certain effects on the WEOM in black soil. In terms of the top soil (0-20 cm underground), the content of WEOM in black soil had a negative growth in the first few years and subsequently recovered to certain levels in the following years. The WEOM has the maximum and minimum contents, i.e. 86.65 mg/kg and 47.81 mg/kg, separately in the uncultivated land and the black soil after 5 years of reclamation and is less abundant in the soil after reclamation of 100 years in comparison with the uncultivated land. However, in the plough (20-40 cm underground), the black soil after 5 years of reclamation had the maximum ratio of WEOM, 124.99 mg/kg, and this content decreased to the lowest of 61.55 mg/kg with the years up to 50. As for SOM, with reclamation, it is subject to a same variation of content both in the top soil and plough, and has been proven more prolific in the top soil comparatively. However, a certain relation of the content of SOM versus soil types has not been figured out.

Basically identical with the results obtained by Graham et al. (2012), one conclusion of this research is that the soil with zero or less human disturbances bears a high content of WEOM, but the content should plummet in the events of some strong disturbances. The obvious changes of WEOM with the exploitation of land indicate it is primarily the land reclamation that should be the reason of the reduction of WEOM in soil. With the natural soil reclaimed, a large drop of WEOM occurred in the soil, and the reduction continued, to the largest extent at the 50th year of reclamation. Subsequently, the reducing was reversed, and the content starts to grow in the succeeding years. We concluded that in order to solve the problems caused by the increasing reclamation and singular plant, more fertilizers should be applied, which prompt in different levels the organic carbons in bodies of animals and plants transforming to those in the soil.

The ratio of WEOM in the total organic matters has a same variation along with its content, which has a reduction of 17.1-44.8% in the cultivated land compared to the uncultivated land. The experiment analysis reveals the content of WEOM varies greatly

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99259935

in the black soil after different years of reclamation and indicates that the reclamation is the main factor influencing the WEOM content in the black soil.

SOM: the soil organic matter; WEOM: the water extractable organic matter

Characteristics of three-dimensional fluorescence spectrum of the water extractable organic matter in black soils after different years of reclamation

Figure 2 is a collection of three-dimensional fluorescence spectrograms of WEOM in soil after different years of reclamation, which reflects great differences between these fluorescence spectrograms. As reported by Chen et al. (2015), a spectrogram shall be divided into 5 sections based on the wavelengths of excitation and emitting lights, the I section representing the tyrosine acid-like protein (for which the wavelength is 220-250 nm/280-330 nm), the II section the tryptophan acid-like protein (the wavelength is 220-250 nm/330-380 nm), the III section the fulvic acid-like substances (the wavelength is 220-250 nm/380-480 nm), the IV section the soluble microbial metabolites acid-like substances (the wavelength is 250-360 nm/280-380 nm), and the V section the humic acid-like substances (the wavelength is 250-420 nm/380-520 nm), respectively.

Suggested by *Figure 2,* the shapes of spectrograms and intensities of fluorescence vary with the reclamation years. The WEOM in all soil types is composed of the tyrosine acid-like protein, tryptophan acid-like protein, fulvic acid-like substances, soluble microbial metabolites acid-like substances, and humic acid-like substances, especially the latter three types. Compared with the uncultivated land being taken as the control group, the cultivated land was shown with evidently intensified fluorescence of the III section, which means the more enrichment of fulvic acid-like substances. After the reclamation of 100 years, the III and V sections reach to the maximum fluorescence intensities, especially for the III section with an evident peak value. Furthermore, in contrast, it is the top soil rather than the plough with the higher fluorescence density, mainly for the fulvic and humic acid-like substances. The difference shall be explained by the continued addition of organic matters into the top soil from the straw stubble per year, which resulted in the growing percentage of organic matters as well as humic organic matters in soil; but the much less organic matters applied to the plough stimulate the relatively lower activity of microorganisms.

DOI: http://dx.doi.org/10.15666/aeer/1704_99259935

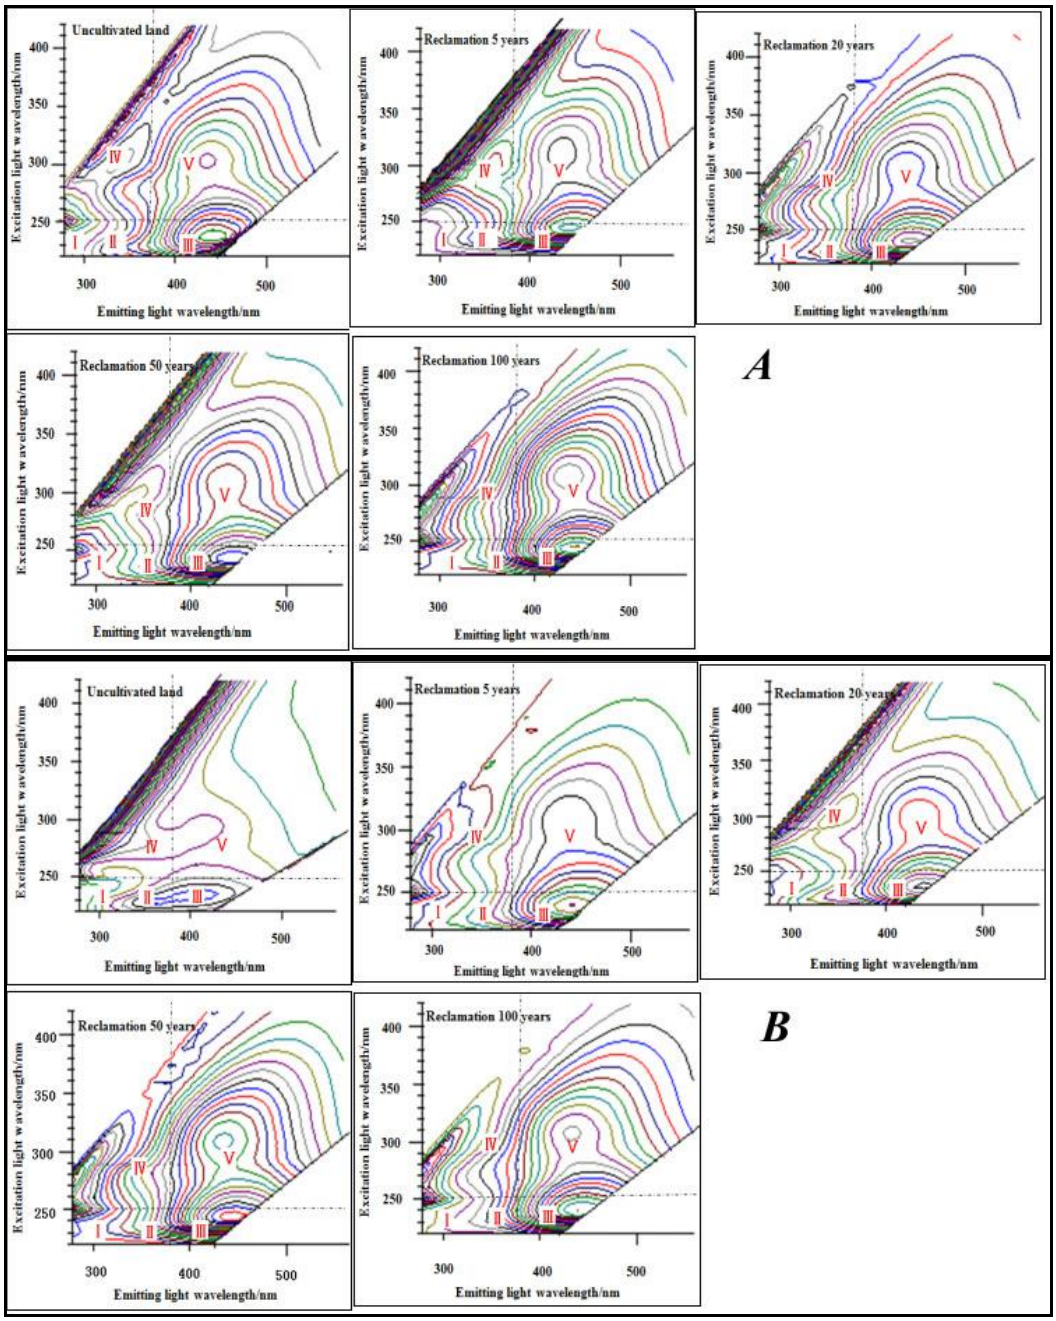

Figure 2. *The black soil of Fluorescence characteristics of the water extractable organic matter after different years of reclamation. (A: topsoil B: plough; the density of isoline represents the intensity of fluorescence I - tyrosine acid-like protein, II - tryptophan acid-like protein, III - fulvic acid-like substances, IV - soluble microbial metabolites acid-like substances, V - humic acid-like substances. The HATACH F-7000-type fluorescence spectrophotometer produced by Hitachi was used for the fluorescence spectrum analysis, with the xenon lamp as the light source of 150 W, the voltage of photomultiplier of 700 V, the silt widths for excitation and emitting lights of 5 nm)*

Basically identical with the results by Li et al. (2013), this research indicates the III and V sections have the most intensified fluorescence, which suggests the fulvic-acid and humic acid organic matters are most abundant in soil. With the fertilizer application

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99259935

for relieving the problems of reclamation, the fulvic-acid and humic acid organic matters accumulated in soil. The longer the reclamation continued, the more effects were on humic organic matters. It could be explained that with the reclamation, the accumulation of residues of plants gathered more microorganisms and produced a growing number of metabolites. Accordingly, the soil was substantially enriched by many types of fulvic acid and humic acid of complex structures and high aromaticity.

Semi-quantitative analysis of fluorescent substances in black soil after different years of reclamation

To compare the substance composition of black soil after different years of reclamation, the integral computation of fluorescence areas in *Figure 2* has been finished, and the results are shown in *Figure 3*.

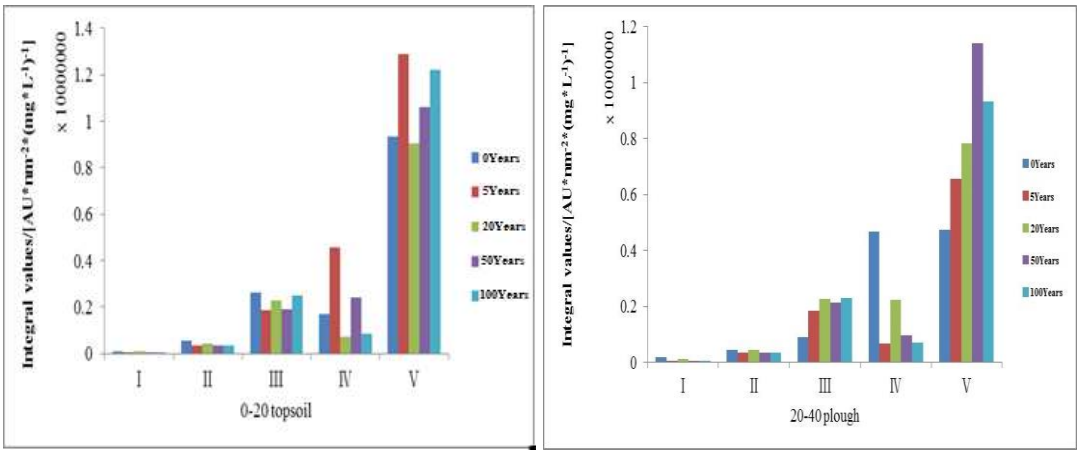

Figure 3. *Integral characteristics of I - V fluorescence areas of the water extractable organic matter after different years of reclamation. (0-20 underground for topsoil, 20-40 underground for plough by the origin)*

Figure 3 indicates the integral values are ordered decreasingly as V, III, IV, II and I. As for the top soil, the integral for the fluorescence area of II descended from 5.4×10^5 AU × nm^{-2} × $(mg \times L^{-1})^{-1}$ to 3.4×10^5 AU × nm^{-2} × $(mg \times L^{-1})^{-1}$, suggesting the less tryptophan acid-like protein in the WEOM; on the contrary, the more enrichment of humic acid-like substances is reflected by the increase of the integral for the fluorescence area of V from 9.3×10^6 AU × nm^{-2} × $(mg \times L^{-1})^{-1}$ to 12.2×10^6 AU × nm^{-2} × $(mg \times L^{-1})^{-1}$. This variation can be explained by the enhanced metabolic activities with reclamation, which utilized the water soluble tyrosine acid-like protein and tryptophan acid-like protein, and converted organic matters in soil to humic acid-like substances. However, the integral for the fluorescence area of III kept nearly stable, which is the sign of the stability of humic acid-like substances in content. As for the plough, it was also subject to the disturbance of reclamation, and the test results with the exception of the increasing content of humic acid are basically same with those in the top soil.

Figure 4 indicates the integral percentages of all sections. Conclusions can be drawn that the tyrosine acid-like protein and tryptophan acid-like protein represented by the I and II sections kept relatively lower integral percentages regardless of the years of reclamation; the percentage of fulvic-acid substances represented by the III section

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99259935

increases firstly until to the maximum value in the 20th years, and reduced in the following years; the percentage of the V section tended to increase, indicating the rising content of fulvic-acid organic matters in soil; besides, the nearly stable percentage of the IV section reflected the stabilized content of soluble microbial metabolites.

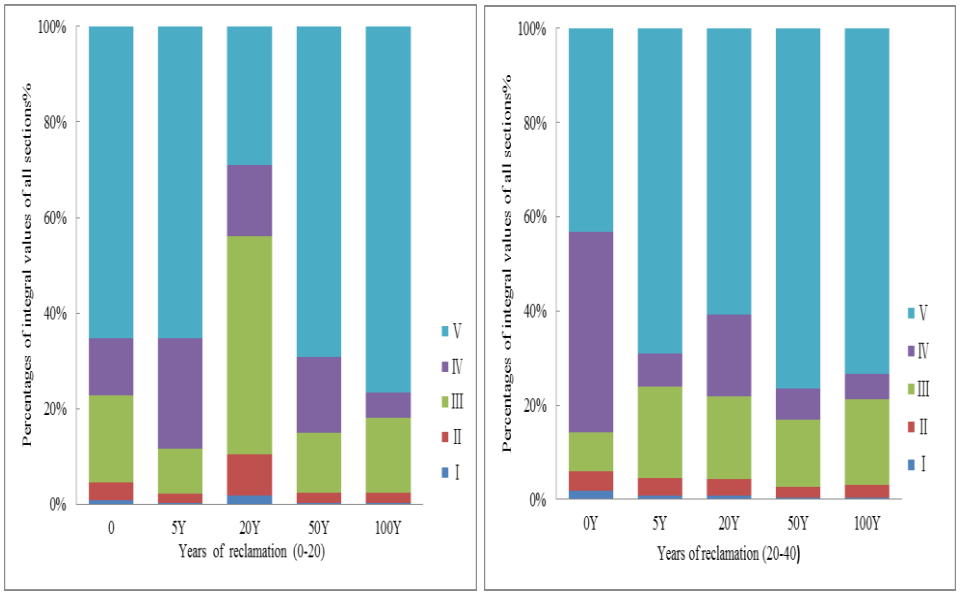

Figure 4. *Percentages of integrals of all sections. (0-20 for topsoil, 20-40 for plough) by the origin*

Analysis of locations of fluorescence peaks and fluorescence intensity

The fluorescence peaks and corresponding wavelengths of excitation and emitting lights for WEOM can characterize their structures and compositions. It is proved that the variation of molecule and aromaticity of a kind of fluorescence substance is reflected by the evolution of wavelengths of excitation and emitting lights at fluorescence peaks. If the wavelength lengthens (i.e. the lights have red shift), the aromaticity and molecule of fluorescence substance is considered increased; if the wavelength shortens (i.e. the lights have blue shift), the aromaticity and molecule of fluorescence substance is considered reduced (Fu et al., 2004). As can be seen in *Table 3,* for the top soil, the I and II areas have red shifts of excitation lights from 225 nm to 240 nm and from 230 nm to 245 nm, respectively. Such red shift suggests the obvious increase of molecules and aromaticity of tyrosine acid-like protein and tryptophan acid-like protein. Accordingly, more abundant proteins were generated in soil with reclamation. The emitting light of fulvic-acid substances at the peak has a red shift from 440 nm to 448 nm, indicating the increases in molecule, aromaticity and the degree of polymerization.

The excitation and emitting lights of the IV area at the peaks have no variation, which reflects the stability of molecule and aromaticity of soluble microbial metabolites acid-like substances. While for the area III, the excitation and emitting lights have red shifts from 235 nm to 245 nm and from 440 nm to 447 nm respectively, which is the sign of increasing content, aromaticity and molecule of fulvic-acid substances in the WEOM. But in comparison with the top soil, the smaller changes of aromaticity and

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99259935

molecules in the plough shall be explained by the weak disturbance of reclamation to the plough.

Ex/Em: Excitation/emitting lights wavelength; F: Florescence intensity I- tyrosine acid-like protein, II- tryptophan acid-like protein, III- fulvic acid-like substances, IV- soluble microbial metabolites acid-like substances, V- humic acid-like substances

As indicated in *Table 3,* for the topsoil of 0-20 cm underground, the fluorescence intensity decreases with the reclamation, which suggests less tyrosine acid-like protein in the soil. But the increase of the area IV and the obvious increase in the areas III and V of the fluorescence intensity illustrate the rising contents of fulvic-acid, humic-acid and soluble microbial metabolites acid-like substances, respectively. Their increase can be attributed to the growth of content and activity of microorganisms in the soil promoting the transformation into humic humus. And the unclear changes in the area II indicate the nearly stable content of tryptophan acid-like protein regardless of the reclamation.

In this work, excitation and emitting lights of all fluorescence areas have shown red shift regardless of the reclamation years, which is different with the results from Fu et al. (2004). But a same conclusion of the two researches is that the increase of humic acid concentration results in the red shift of fluorescence peaks. The above distinction can be explained by the microorganism decomposition of plant residues, which is suggested the reason for the proliferation of protein-like substances. Therefore, the analysis of the structure and composition of WEOM in soil with the three-dimensional fluorescence spectrum technology in our research shall be an important theoretical basis for the future researches on micro-ecology of soil.

Conclusions

Mainly distributed in the provinces of Jilin and Heilongjiang, the northeast black soil region is an important grain production basis. However, the irrational cultivation

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99259935

method made the black soil eroded heavily and the water and soil loss increased. Up to now, the area of water and soil loss has accounted for 37.9% of the whole area. That is why the sustainable utilization of black soil and the interaction between the black soil and environment have been raised to the hot topics of researches, especially the researches about the organic matters in black soil.

In this test, 3D fluorescence spectroscopy was used to study the content, composition and structure of soil water-soluble organic matter in black soils with different reclamation years. The following conclusions: (1) the WEOM in soil has an obvious reduction with the transformation of natural soil into farmland soil, and the reduction is shown increasingly clear with reclamation; (2) the fulvic-acid organic matters have large increases in the molecule, aromaticity, and degree of polycondensation with reclamation; (3) the microorganisms in soil can conduct stronger metabolic activities after the reclamation starts, which utilize the tyrosine acid-like and tryptophan acid-like proteins, and convert more organic matters in soil to fulvic-acid organic matters; (4) the wavelength of emitting lights at the fluorescence peak for the humic-acid organic matters lengthens with reclamation, suggesting the increased molecule, aromaticity and degree of polycondensation. But the tyrosine acid-like, tryptophan acid-like proteins and soluble microbial metabolites acid-like substances keep basically stable contents, which indicates few effects of reclamation on their molecules and aromaticity. In the future, fluorescence spectroscopy, mathematical models, metrology chemistry and other methods should be combined to analyze the characteristics of different source components of DOM, as well as the effects of plant species and crop roots on DOM. The relationship between DOM characteristic substances and fluorescence intensity should be established, so that fluorescence quantization of characteristic substances will be carried out.

Abstract. The way to calculate and share the total amount of ecological compensation for inter-basin water transfer project is directly related to the enthusiasm of the water-receiving area in participating in the ecological protection of the water source area. This paper takes the water source area of the South-to-North Water Diversion Project and the water-receiving areas of Beijing, Tianjin, Hebei and Henan as the research objects, and using the single-index method, the comprehensive index method and the deviation method to make appropriate calculation for the ecological compensation amount of 6.248 billion yuan paid to the water source area each year by the water receiving area. The results show that the method of deviation is more objective, comprehensive and reasonable, which can provide a new idea for the ecological compensation apportion calculation of the Central Line of South-to-North Water Diversion Project.

Keywords: *inter-basin water transfer, water conservation, Shaanxi water source area, resource allocation, water trading, deviation method*

Introduction

Water is the source of all life and an important factor affecting human survival and development. The uneven distribution of water resources makes it necessary to build inter-basin water Diversion facilities between multi-water areas and water-deficient areas. Inter-basin water transfer can alleviate the problem of insufficient water savings in water-scarce areas and the imbalance of water resources in time and space effectively (Chen and Huang, 2006). But it changes the water conditions in the areas it passes through, and it will break the original ecological balance in the process of its application and management at the same time. In order to ensure the sufficiency and cleanliness of the water resources obtained by the water receiving area, it is necessary to do a good job in ecological protection of the water source areas and carry out necessary ecological compensation. Ecological compensation which means paying for ecological or environmental services is based on the purpose of ecological protection and the protection of ecosystems and species diversity through the operation of ecological compensation mechanisms (Hansen et al., 2018). Watershed ecological compensation is a powerful economic tool for addressing water management problems (Thieme et al., 2012). Ecological compensation involves measures to create positive conservation outcomes intended to offset the residual impacts of development (Brown et al., 2014). The inter-basin ecological compensation scheme is the result of the interaction between

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99379946

upstream and downstream cities, and is of great significance for the guidance of regional economic development (Zhang et al., 2018).

The ecological compensation of the river basin originated from the management and planning of the ecological service market. In the 1960s, soil erosion seriously affected the quality of living environment of the basin residents. To compensate the watershed residents, the US Tennessee Valley Authority (TVA) (Zhang and Liu, 2006) increased the protection of natural resources in the basin, and the prototype of the ecological compensation mechanism has been formed. Wunder et al. (2008) believed that the most ideal ecological compensation should fully integrate ecological services into the market. Ansink and Houba (2011) systematically studied and evaluated the impact and role of market forces in water extraction, delivery, and water pricing. At present, Germany, the United States, Japan and some other countries have accumulated relatively successful experiences and established a relatively complete ecological compensation framework system.

China began to study the issue of ecological compensation in the early 1990s. Zhang et al. (2013) proposed to calculate the amount of ecological compensation based on the loss of the rights to use resource. Cheng and Kai (2018) reviewed the mature theory and scientific mechanism of watershed ecological compensation, analysed the defects and shortcomings of ecological compensation theory, and provided a theoretical reference for the proposed compensation scheme. In addition, starting from the "Eleventh Five-Year Plan" in 2005, China has listed the construction of ecological compensation mechanism as the main point of work, and proposed the requirements for building it. It has been explored to establish an ecological compensation system in many places (Ji, 2018). Jiang et al. (2015) analysed the definition, necessity and principle of ecological compensation in the water source area of the inter-basin water transfer project, and studied the theoretical framework of ecological compensation in the water source area.

China is now doing more qualitative compensation studies, and there are few studies on the methods of quantitative compensation.

This paper calculated the ecological compensation amount that should be paid to the water source area by the water receiving area of the central route of the South-to-North Water Deversion Project, and the compensation amount of the four major water receiving areas in Beijing, Tianjin, Hebei and Henan was obtained.

Materials and methods

Profile of the study area

The Central Line of the South-to-North Water Diversion Project takes water from the Danjiangkou Reservoir. The total length of the main canal is 1432 km, and the annual average water transfer is 95 billion m^3 in recent years. Water is transferred from Hanzhong, Ankang and Shangluo to the main water receiving areas including Beijing, Tianjin, Hebei and Henan. And it provides protection for development of city , industry and agriculture. The diversion route diagram of the South-to-North Water Diversion Project is shown in *Figure 1*.

The cities as Hanzhong, Ankang and Shangluo have humid climates and abundant rainfall. The average annual rainfall of the three cities is 884.2 mm, which is higher than that in Shaanxi Province. The water resources are very rich. In 2017, the total water resources of Hanzhong, Ankang and Shangluo in southern Shaanxi were

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99379946

33.69 billion m^3, and the water production modulus was more than twice that of the province (Water Resources Department of Shaanxi Province, 2017).

The water source areas are all poor areas. In 2017, the total GDP of the three cities was 306.5 billion yuan, accounting for only 14% of the province's GDP. The per capita GDP rankings of Hanzhong City, Ankang City and Shangluo City are ranked lower in the province (Shaanxi Provincial Bureau of Statistics, 2017). Therefore, the state and the water receiving areas are required to provide certain compensation for water source areas.

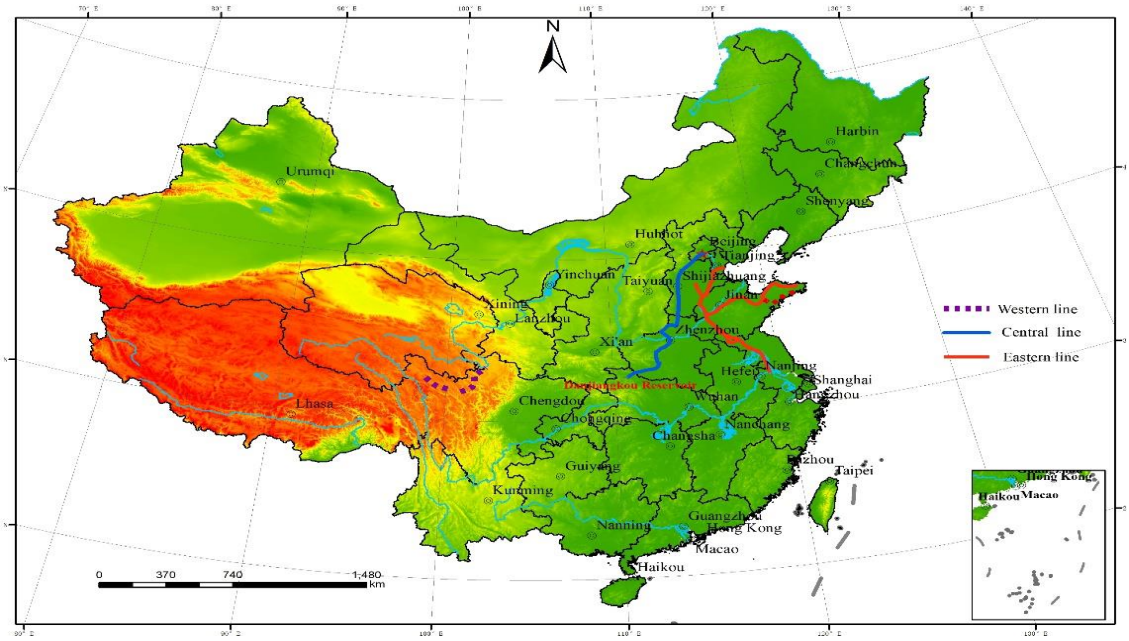

Figure 1. *The circuit diagram of the South-to-North Water Diversion Project*

Data processing

Considering the water and soil conservation construction in the water source area, the water market situation in the water management field, the value of water resources and the opportunity cost of future water resources dispatching, the total amount of ecological compensation is calculated. The compensation amount should be paid by the water receiving areas is 6.248 billion yuan/year. Drawing on the distribution ideas of water conservancy project cost allocation (Wang, 2016) and environmental capacity allocation (Chen et al., 2007), the ecological compensation amount payable for each water receiving area is calculated by using the single index method, the comprehensive index method and the deviation method, respectively.

The research basis of this paper is that the first phase of the South-to-North Water Diversion Project has an annual water transfer of 9.5 billion m^3, and the water transfer from the Shaanxi Water Source Area is 6.65 billion m^3, of which the distribution of water is equal to 0.13 in Beijing, 0.11 in Tianjin, 0.37 in Hebei and 0.4 in Henan.

According to the calculation results, the advantages and disadvantages of various apportion methods are compared and analysed, and a more reasonable apportionment method is determined.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99379946

Methods

Single indicator method according to water consumption

According to the water consumption of each water receiving area, the average cost pricing method is used for distribution. (Liu, 2007; Zheng and Zhang, 2006). The calculation method is as shown in *Equation 1*.

$$C_i = \frac{q_i \times C}{\sum_{i=1}^{n} q_i} \quad \text{(Eq.1)}$$

where, C_i is the shared value of the i-th water receiving area; C is the total compensation amount; q_i is the water consumption of the i-th region (i=1, 2 ..., n). The same meaning in the symbolic sense.

Single indicator method according to the maximum payment capacity of the receiving area

According to the per capita GDP of each water receiving area, the corresponding compensation coefficient is determined. The specific method is as follows:

Assume that n water-receiving areas have GDP of GDP_i and population of p_i. The per capita GDP of each region accounts for the ratio of per capita GDP of the water-receiving area, and the calculation method (Zhang, 2003) is shown in *Equation 2*.

$$\alpha_i = \frac{\frac{GDP_i}{p_i}}{\frac{\sum GDP_i}{\sum p_i}} \quad \text{(Eq.2)}$$

Among them, $\alpha_i > 1$ indicates that the level of economic development of the i region is higher than the average level of the water receiving area; $\alpha_i < 1$ indicates that the level of economic development of the i region is lower than the average level of the water receiving area; $\alpha_i = 1$ indicates that the level of economic development of the i region is within the average level of the water receiving area. The proportion of compensation fees for each area β_i is determined according to the ratio of the per capita GDP of each area to the per capita GDP of the area (Zhang, 2003) and the way to caculate it is shown as *Equation 3*.

$$\beta_i = \frac{\alpha_i}{\sum \alpha_i} \quad \text{(Eq.3)}$$

Single indicator method according to the value of ecological environment services

The water diversion project can simultaneously improve the ecological environment service value of the water receiving areas and the water source areas. However, because the value of the ecological environment service of each water receiving area is difficult to define clearly, this paper uses the dry channel coverage and population of water use

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99379946

to estimate roughly. The specific algorithm is that the ratio of the length of the main canal in each water receiving area to the total length of the main canal and the proportion of water users to the total population of the water receiving area are determined as 4:6, and the compensation is calculated according to the benefit of each receiving area (Cao and Wang, 2009). Calculations can be done according to *Equation 4* and *Equation 5*.

$$C_i = C \times \delta_i \quad \text{(Eq.4)}$$

$$\delta_i = 0.4 \times \frac{l_i}{L} + 0.6 \times \frac{p_i}{P} \quad \text{(Eq.5)}$$

where δ_i is the coefficient of eco-environment service value; l_i is the length of the main canal in the i-th water receiving area; L is the total length of the main canal, which is 1432km; p_i is the water-receiving population of the i-th water receiving area; P is the total population of water users.

Comprehensive indicator method

The comprehensive indicator method is based on the calculation of the selected single-index method which is the comprehensive performance of the single-indicator method. The reasonableness weight of each single-indicator method is evaluated by expert scoring. Drawing on the ideas of the former (Chen et al., 2007) water environment capacity allocation, the proportion of the water consumption, the ability to pay, and the value of the ecological environment service are equal, all of which are 1/3. The methods for calculating them are shown in *Equation 6*, *Equation 7*, and *Equation 8*, respectively.

$$C_i = C \times \frac{\alpha_i + \beta_i + \delta_i}{3} \quad \text{(Eq.6)}$$

$$Q_i = \frac{q_i}{\sum_{i=1}^{n} q_i} \quad \text{(Eq.7)}$$

$$\beta_i = \frac{\alpha_i}{\sum_{i=1}^{n} \alpha_i} \quad \text{(Eq.8)}$$

In above equations, Q_i is the water consumption coefficient; β_i is the coefficient of payment capacity; δ_i is the coefficient of eco-environment service value.

Deviation method

The diviation method is not artificially determining the weighting coefficients of various sharing methods, but determining the weight by the degree of single sharing method approaching the average of multiple sharing methods (Chen et al., 2007). It is a

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99379946

commonly used and mature sharing method. Suppose there are n kinds of sharing methods, the average value of the sharing is x, and it is assumed that there is a weighting function w_j. When the sharing coefficient x_j of the j-th sharing method deviates from the mean x, it indicates that the accuracy of the sharing of the method is poor, and the obtained weight coefficient should be small; otherwise, the weight coefficient should be large.

The estimate X of the comprehensive sharing coefficient converges to the expected comprehensive sharing coefficient $\bar{x}$ according to the probability.

Results

Calculate according to the function constructed by the above methods and results of the three calculation methods are shown in *Table 1*, *Table 2*, and *Table 3*, respectively.

It can be seen from *Table 1* that according to the water consumption coefficient, the more water is used, the more compensation will be borne. According to the maximum payment capacity of the receiving area, the economic strength is strong, and the per capita GDP is high, so much more is paid. According to the value of the ecological environment service, the area with high canal coverage and more water users will pay more.

Table 1. *Sharing of compensation by single indicator methods (100 million yuan/year)*

Items	Beijing	Tianjin	Hebei	Henan
Water consumption coefficient	0.13	0.11	0.37	0.40
Compensation amount 1	8.11	6.87	23.10	24.97
Ability to pay coefficient	0.35	0.37	0.14	0.13
Compensation amount 2	21.85	23.10	8.74	8.11
Eco-environmental service value coefficient	0.20	0.17	0.21	0.43
Compensation amount 3	12.48	10.61	13.11	26.84

What can be inferred from *Table 2* is that the comprehensive indicator method considers the three impact factors of the single-indicator method, and the calculated result is the average of the three single-indicator methods.

Table 2. *Sharing of compensation by the comprehensive index method (100 million yuan / year)*

Items	Beijing	Tianjin	Hebei	Henan
Comprehensive sharing coefficient	0.23	0.22	0.24	0.32
Compensation amount	14.15	13.52	14.98	19.97

Using the deviation method to calculate the contribution of each water receiving area $C_{Beijing}$, $C_{Tianjin}$, C_{Hebei}, C_{Henan}, the sum is not necessarily equal to the total compensation amount C (Zhou, 2009). Therefore, it is necessary to standardize the amount of the contribution calculated by the deviation method. The calculation of the normalization coefficient is shown in *Equation 9*.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99379946

$$\varepsilon = \frac{C}{C_{Beijing} + C_{Tianjin} + C_{Hebei} + C_{Henan}} \quad \text{(Eq.9)}$$

After standardization and adjustment, it can get 1.323 billion yuan/year in Beijing, 1.194 billion yuan/year in Tianjin, 1.40 billion yuan/year in Hebei Province, and 2.331 billion yuan/year in Henan Province.

Table 3. *Sharing of compensation by the deviation method (100 million yuan / year)*

Items	Beijing	Tianjin	Hebei	Henan	Sum
Water weight	0.32	0.35	0.20	0.44	
Payment weight	0.19	0.18	0.32	0.17	
Ecological service weight	0.48	0.47	0.48	0.39	
sharing factor X	0.21	0.19	0.22	0.36	0.97
Compensation amount	12.86	11.61	13.61	22.66	60.67

Comparison of different allocation methods

Make a comparison of calculation results of different methods (*Figure 2*), and compare the advantages and disadvantages of these methods.

Single indicator method: The calculation results are unstable and one-sided. The calculation process is simple, but using different indicators to calculate, the results shared by each water-receiving area are very different, which is easy to lead to doubts about the reliability of the methods and data used.

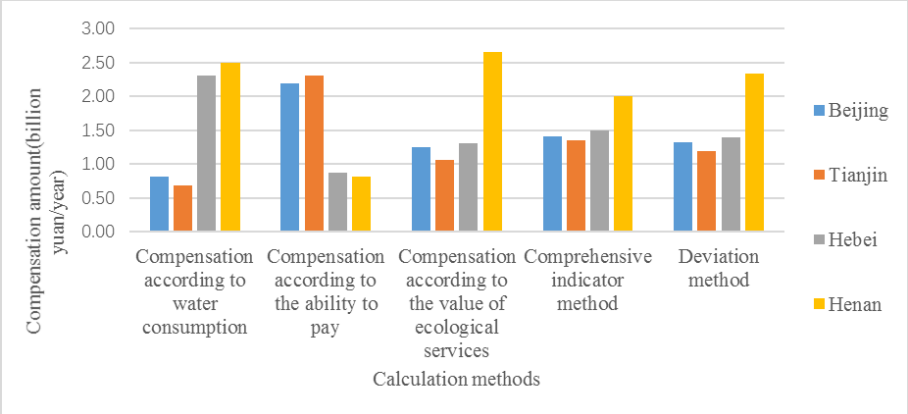

Figure 2. *Comparison of calculation results of different methods*

Comprehensive indicator method: Compared with the comprehensive indicator method, the results are more stable, but the proportion of each individual indicator is artificially determined. It is very subjective, and its objectivity and fairness are easily questioned.

Deviation method: Considering a variety of factors, and the sharing coefficient is determined according to the mathematical model rather than artificial distribution, and the sharing process is transparent and open. Therefore, the method of deviation is a more comprehensive and objective method of compensation.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99379946

Discussion

Analysis of the rationality of using the deviation method:

1. It is assumed that the net benefit of national economic use in a certain year after 2018 is B_d, and the annual compensation for ecological construction is C_d. The benefit-to-input ratio is Kd and the way to calculate it is shown in *Equation 10*.

$$K_d = \frac{B_d}{C_d} \quad \text{(Eq.10)}$$

When $K_d \leq 1$, the ecological compensation amount of the water receiving area exceeds the amount of benefits it receives, which will make the project lose its economic significance, so it is necessary to make $K_d > 1$ (Shi et al., 2009). According to the experts of the Yangtze River Water Resources Commission, the direct benefits of the Central Line of the South-to-North Water Diversion Project in terms of water supply and flood control are estimated to have an average annual benefit of 45.6 billion yuan per year. From the difference flat method, the amount of water-receiving burden is 6.248 billion yuan/year, which is far less than the comprehensive benefit of citing water resources, and there is $K_d > 1$.

2. According to the principle of individual rationality, the amount of compensation undertaken by the participating regions should not be greater than the cost of water resources from other sources. Otherwise, the payment will be too high to pay the ecological compensation.

In 2018, the value of surface water resources in Tianjin is 4 yuan/ m^3, and the value of surface water resources in Beijing is about 3.64 yuan/m^3. The value of water resources will continue to increase. The second phase of the Central Line of the South-to-North Water Diversion Project has a water transfer capacity of 6.65 billion m^3/year from Shaanxi, which means that the value of the water resources from Shaanxi water source area of the Central Line of the South-North Water Diversion Project in 2019 is 0.94 yuan/ m^3. It can be seen that the cost of citing water from Shaanxi water source area is much less than the cost of obtaining water resources from other sources.

Conclusions

1. The method of deviation is the most comprehensive and objective method for calculating the ecological compensation sharing method.

2. Using the deviation method to share the ecological compensation amount of Shaanxi water source area, the scores are 1.323 billion yuan/year in Beijing, 1.194 billion yuan/year in Tianjin, and 1.40 billion yuan/year in Hebei Province, Henan. The province has 2.31 billion yuan / year.

This paper only puts forward a basic idea of inter-basin water transfer ecological compensation sharing, and does not give a clear commentary on the specific implementation of ecological compensation. And there is no specific details of the implementation process of an ecological compensation mechanism, such as the way to make collection of compensation funds, methods for solving water pollution problems along the central line of the South-to-North Water Deversion Project and some other measures. It is recommended that future research can be carried out in these directions to ensure a smoother and healthier compensation mechanism.

(Received 5th Apr 2019; accepted 13th Jun 2019)

Abstract. Sustainable closed-loop supply chains have attracted attention due to environmental protection problems and resource shortages. The quality of recycled products is an important factor in reverse logistics. Based on Stackelberg game theory, we propose two sustainable closed-loop supply chain models: a centralized decision model and a decentralized decision model, and assume that the manufacturer considers the recycling quality level of used products. We compare the differences in the optimal decisions from different decision-makers and analyze the influence of relevant parameters on these decisions in a sustainable closed loop supply chain. From the comparative analysis and numerical analysis, it was observed that the model yields the best decision result and carbon emission reduction level under the centralized decision condition. The recycling quality level is found to be higher in the centralized decision model than in the decentralized decision model, and the sales price is found to be lower in the centralized decision model than in the decentralized decision model. Moreover, the impacts on the carbon emission reduction level, the recycling quality level, and corporate profit are found to be related to the carbon emission preference coefficient of consumers, the recycling effort cost coefficient, and the carbon emission investment cost coefficient.
Keywords: *environmental constraints, game theory, carbon emission, recycling effort, remanufacturing, sustainable supply chain*

Introduction

With the progress in production technology and the diversification of consumer demand, product life cycles are becoming shorter, product upgrades are becoming faster, and the number of eliminated and used products has increased dramatically. At the same time, the Earth's resources are dwindling, and the call for sustainable development is growing. This has made the world's major countries give more consideration to problems of energy conservation and environmental protection. Resource and environmental pressure, as well as laws, regulations, and consumer awareness of environmental protection, are increasing. The recycling and remanufacturing of used products have become a hot issue. Since closed-loop supply chains (CLSCs) have achieved significant results in sustainable development management practices, CLSCs have also become an important topic in the academic area (Savaskan et al., 2004; Savaskan and Van Wassenhove, 2006).

For enterprises, on the one hand, recycling of used products is the responsibility of manufacturers. Recycling of used products can reduce carbon emissions, save resources, reduce negative impacts on the environment, create a good corporate image, and improve the competitiveness of enterprises. On the other hand, enterprises can realize value-added materials, save on costs, and improve their profits through recycling and reuse of used

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99479963

products (Govindan et al., 2016). From the perspective of recycling, because the time, frequency, and method of a consumer's use of a product may differ, the degree of loss of the product can also be various. According to the different degrees of product loss, we divide recycled products into different quality levels. The quality of recycled products is one of the main factors affecting the operation of a closed-loop supply chain. Low-quality recycled products have a negative effect on enterprises that remanufacture used products (Rahman and Subramanian, 2012). Therefore, the quality level of recycled products is an issue for remanufacturers to consider and is also one of the focuses of our research.

After the Copenhagen climate conference, a low-carbon economy, which pursues a reduction in energy consumption, pollution, and greenhouse gas (GHG) emissions, was listed as one of the most important strategies for global climate change mitigation. Olugu and Wong state that one of the objectives of closed-loop supply chain management is to reduce carbon emissions (Olugu and Wong, 2012). The recycling of used products through a closed-loop supply chain to reduce carbon emissions is a part of reverse logistics. For forward logistics, the manufacturing of new products also needs to consider the problem of reducing carbon emissions. The study of carbon emissions from a sustainable closed-loop supply chain perspective focuses not only on emissions at specific stages of production (such as used product recycling), but also on the social and environmental impacts of a product over its entire life cycle (Metta and Badurdeen, 2013). A carbon emission reduction not only affects the profit of a closed-loop supply chain, but also affects the pricing and recycling decisions of supply chain members. Enterprises need to operate under certain environmental incentives and seek the optimal pricing and emission reduction strategies under the sustainable development goals (Ding et al., 2015).

Carbon emission reduction involves the joint efforts of a sustainable closed-loop supply chain's members. In a closed-loop supply chain where the manufacturer is responsible for recycling, the manufacturer may increase the cost of the product through a low-carbon investment. However, due to consumers' awareness of the environmental features of the product, the cost increase will increase consumers' intention to purchase the product, increase the sales price, and promote increases in the scale of sales. It benefits retailers from a carbon emissions reduction perspective as well. Recycling of used products and investment in new products that reduce carbon emissions have environmental benefits. We consider the following questions: How do manufacturers weigh the impact of recycling quality on carbon reduction levels? How does the retailer decide the selling price? How do the recycling quality level, carbon emission reduction level, recovery rate, consumer preferences, emission reduction and recycling investment coefficient, and other relevant factors affect each other?

This study considers these carbon emissions reduction and pricing decision problems considering recycling quality in the context of a sustainable closed-loop supply chain. Consumer preferences, such as recycling quality, carbon emissions reduction level, and sales price, are used as decision variables to establish a sustainable closed-loop supply chain decision-making model and find out how manufacturers can adjust their own recycling policies and emission reduction investment strategies to maximize revenue. Then, through a numerical simulation, we analyze the impact of recovery rate on recovery quality, emissions reduction level, pricing, and closed-loop supply chain profit. Our goal is not only to enhance the sustainable closed-loop supply chain decision-making optimization theory, but also provide a theoretical basis for enterprises to make emissions

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99479963

reduction decisions, recycling decisions, and pricing decisions as well as promote the realization of emissions reduction targets.

Our study contributes to the literature in three main regards. First, our study investigates the quality of recycled products in a sustainable closed-loop supply chain for carbon emissions reduction, which complements the existing literature in which sustainable closed-loop supply chains for carbon emissions reduction are not considered (Shu et al., 2018; Xu and Wang, 2018). Second, our work compares a centralized decision CLSC model with a decentralized decision CLSC model for manufacturers who directly recycle used products. We obtain a few appealing management insights. Third, our model analyzes the impact of various factors on decision-making in, and the profits of, CLSCs.

Review of literature

We review the following three streams of literature related to this work: closed-loop supply chains that consider the quality level of recycled products; closed-loop supply chain pricing, and closed-loop supply chains for carbon emissions reduction.

Closed-loop supply chains that consider the quality level of recycled products

Many researchers have discussed the quality level of recycled products in closed-loop supply chains. Guide et al. (2003) studied used product recovery pricing and remanufactured product sales pricing issues for a variety of quality grades. They assumed that the quality grades of used products are sensitive to the recovery cost. Savaskan et al. (2004) assumed that recovery quality is a random variable subject to a uniform distribution, and discussed the selection of recycling strategies in different environments. Dobos and Richter (2006) introduced recycled product quality into a production–recycling system, and assumed that if a recycled product's quality level is too low, it cannot be used in the remanufacturing process. Galbreth and Blackburn (2006) studied the optimal recovery and remanufacturing classification strategy under the condition of uncertain quality of recovered products. In their classification strategy, recycled products are generally treated in one of two ways after testing: if their unit remanufacturing cost is lower than the optimal cost level, they are used in remanufacturing production; otherwise, they are directly abandoned. Mukhopadhyay and Ma (2009) studied optimal procurement and production decisions in remanufacturing systems with uncertain quality of and demand for recycled products. Özkır and Başlıgıl (2012) described the specific features of green supply chain design with consideration of end-of life products and pointed out that considering the quantity and quality of recycled products can improve the system's profitability. Chen et al. (2015) designed a two-stage dynamic closed-loop supply chain that considers uncertainty in the quantity and quality of recycled products as well as differences in the willingness-to-pay of consumers. Jerbia et al. (2018) studied a closed-loop supply chain network design problem. A scenario-based approach was used to model the uncertainties in return rates, revenues, costs, and the quality of returns. Tan and Guo (2019) studied the impact of regulatory environments on the operation of a logistics system that considers the uncertainty in the quality of recycled products and the controllability of the remanufacturing technology level. The models discussed above consider the quality of recycled products in network or channel selection; they do not consider the impact of the quality of recycled products on pricing decisions and carbon emissions reductions. Next, we review the literature on closed-loop supply chain pricing.

Closed-loop supply chain pricing

As an important function of a closed-loop supply chain, pricing has a direct impact on product demand and competitive advantage. Ferrer and Swanminathan (2006) studied closed-loop supply chain pricing decisions in a monopoly environment and explored the effect of various parameters on the Nash equilibrium. Swanminathan and Ferrer (2010) analyzed two-period, multiperiod, and infinite planning horizons in a monopoly environment, and characterized the optimal remanufacturing and pricing strategy. Bulmus et al. (2014) considered differences in recycling quality level, divided used products into several different types, and determined the recycling price of different types of used products and the selling price of new products. Gan et al. (2017) developed a pricing decision model for short life-cycle products in a closed-loop supply chain and found that scaling factors influence both the pricing decisions and the profits of the supply chain's members. Gao et al. (2016) provided centralized and decentralized game-theoretic models of a CLSC and investigated optimal decisions on collection effort and pricing under different channel power structures. Ke et al. (2018) studied a pricing and remanufacturing decision problem in a fuzzy closed-loop supply chain with one manufacturer, two competitive retailers, and one third-party collector. Taleizadeh et al. (2019) studied pricing decisions and discounts on returned products in a multiperiod, multi-echelon, and sustainable closed-loop supply chain. Some researchers have also considered the quality of recycled products when studying pricing in closed-loop supply chains. Zou and Ye (2015) studied pricing strategies for and the coordination mechanism of a supply chain when the remanufacturing cost is random and caused by a recycled product's quality. Taleizadeh et al. (2017) proposed a joint optimization model of pricing strategies, quality levels, effort decisions, and return policies by considering the reference price effect in a three-level supply chain under different channel power structures. The abovementioned studies have taken into account the impact of recycled products' quality level in pricing decisions; however, they did not consider environmental constraints.

Closed-loop supply chains for carbon emissions reduction

The research related to our work concerns carbon emission issues in a closed-loop supply chain. Feng et al. (2017) estimated the economic benefits associated with policy regulations for manufacturers in a low-carbon technology market. They indicated that when the punishment levied on a manufacturer is sizable, the manufacturer will be prone to developing innovative technology. The objective when reducing carbon emissions is not only to respect environmental regulations; it is also to increase profit. Unlike forward supply chains, Brandenburg et al. (2014) believed that environmental and social issues have received very little attention in CLSC models. Carbon emissions have only recently been incorporated into reverse supply chain and CLSC modeling. Govindan et al. (2015) emphasized the need for the investigation of environmental issues and new directions in reverse logistics and closed-loop supply chain research. Fareeduddin et al. (2015) proposed models for three common regulatory policies to optimize not only costs but also emissions in supply chain operations. Tao et al. (2015) studied the CLSC network equilibrium problem in a multiperiod planning horizon, where manufacturers make homogeneous products and have two types of mandatory carbon emission. He et al. (2016) evaluated the impact of consumer free riding on carbon emissions across a product's life cycle in a dual-channel closed-loop supply chain. Bazan et al. (2017) considered the carbon emissions from and the energy cost of a vendor-managed inventory with a consignment stock policy. Xu et

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99479963

al. (2017) analyzed the effect of considering carbon emissions on the design of both hybrid and dedicated CLSCs. Fang et al. (2017) studied carbon emission reductions under a carbon cap-and-trade scheme and reverse logistics in a production routing problem. Shu et al. (2018) studied optimal decisions for closed-loop supply chains in the framework of social responsibility and explored the impacts of carbon emissions constraints and corporate social responsibility on recycling and remanufacturing decisions. Turki and Rezg (2018) provided an optimal design for a manufacturing/remanufacturing system that differentiates between new and remanufactured products and sorts the used products into three quality levels. Yang et al. (2017) considered two competitive supply chains under the cap-and-trade scheme and studied pricing and carbon emissions reduction decisions. Li et al. (2017) studied the influence of vertical and horizontal cooperation models on the optimal decisions for and performance of a low-carbon closed-loop supply chain with respect to pricing, carbon emissions reduction, used product collection, and profit.

It can be seen from the above literature that the quality level of recycled products has a great impact on the performance of a closed-loop supply chain. Although the quality of recycled products can be graded and the recycling price can vary, this increases the difficulties that recyclers face. It is easier to recycle used products at a set quality level and a fixed price. Therefore, unlike previous research, we consider that the market demand depends on the sale price and the carbon emissions reduction level set by the manufacturer. We carry out the study in accordance with a fixed quality level of recycled products, research pricing and carbon emissions reduction decisions in a closed-loop supply chain, and analyze the sensitivity of the main parameters using a numerical example. We hope to provide a theoretical basis on which related enterprises can make recycling and carbon emissions reduction decisions.

Materials and methods

Assumptions and model description

This section may be divided by subheadings. It should provide a concise and precise description of the experimental results, their interpretation as well as the experimental conclusions that can be drawn.

From an environmental protection perspective, reductions in carbon emissions are conventionally considered to be a burden for manufacturers. This paper considers a closed-loop supply chain composed of a manufacturer and a retailer. The manufacturer uses new materials to make new products and also remanufactures used products. The manufacturer is responsible for recycling used products that are recovered directly from consumers. The retailer is responsible for the sale of the products. In a forward supply chain, the unit cost of manufacturing a new product is c_m, w is the wholesale price of the product as determined by the manufacturer, the selling price of the retailer is p, and the market demand is a linear function of price and the carbon emissions reduction. In a reverse supply chain, the manufacturer divides the used products into different quality levels according to the degree of damage, which is represented by $q\ (0<q<1)$. The unit recovery cost of an old product that the manufacturer recovers from a consumer is represented by $A(q)$, which is a function of the quality of the recovered product. The higher the quality of the recovered product, the higher the recovery cost. $A(q)=aq$, a is the maximum unit recovery price of a used product that the manufacturer pays to the customer. The used product recycling rate is

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99479963

ε, which is considered to be an exogenous variable, such as government regulations. We only consider carbon emissions in the production process. The manufacturer can improve their carbon emissions reduction technology to reduce the carbon emissions per unit product.

To simplify the research problem and facilitate the analysis, we make the following assumptions:

(1) The manufacturer is the core enterprise of the supply chain and is the leader in the game process. We do not consider an out-of-stock scenario; namely, the production quantity is the market demand. Remanufactured products and new products are sold at the same price, with no difference in quality and performance. Considering the cost advantage, manufacturers give priority to using remanufactured products to meet the market demand. Following Atasu et al. (2013), it is assumed that all recycled products are used in the remanufacturing process. The unit cost of remanufacturing is denoted by $c_r(q)$, and is a function of the quality of the recycled product $\left(c_r(q) < c_m\right)$. Let $c_r(q) = c_m - c_s q$. Then, is the unit cost savings through remanufacturing. To ensure that the remanufacturing process is feasible, let $c_s q < A(q)$, i.e., $a < c_s$.

(2) The manufacturer needs to invest in low-carbon production technologies to reduce its carbon emissions. Only investment in carbon emissions reduction for new products is considered here, and the required capital is a one-time investment, which is independently undertaken by the manufacturer. The reduction rate per unit product is $\lambda(0 < \lambda < 1)$. Following Ghosh and Shah (2012), the emissions reduction cost that the manufacturer pays is $\beta\lambda^2/2$, where β denotes the carbon emissions reduction investment cost coefficient, which is a large number.

(3) To recycle higher-quality used products, manufacturers must pay higher effort costs. Similarly to the cost of the carbon emissions reduction investment, let $I(q) = Kq^2$. $K(K > 0)$ denotes the recycling effort cost coefficient, which is a large number.

(4) The demand is a linear function of the manufacturer's carbon emissions reduction level and the retailer's sales price. Following Liu et al. (2012) and Zhang et al. (2014), the demand function is $D = V - bp + \gamma\lambda$, where V denotes the potential demand scale of the market, b is the sensitivity coefficient of the retail price, and γ is the coefficient of consumers' carbon emissions reduction preferences.

In addition, we assume that both manufacturers and retailers are risk-neutral, and we ignore the carbon emissions of retailers in this study. The subscript c denotes a centralized decision.

Modeling and decision analysis

Based on the above assumptions, let $c(q) = c_m(1-\varepsilon) + c_r(q)\varepsilon$. The simplification $c(q) = c_m - c_s q\varepsilon$, the manufacturer's revenue π_m, and the retailer's revenue π_r are exhibited as follows:

$$\begin{aligned}\max \pi_m &= (p - c_m + \varepsilon c_s q)(V - bp + \gamma\lambda) - a\varepsilon q(V - bp + \gamma\lambda) - (\beta\lambda^2/2) - Kq^2 \\ &= (w - c_m + (c_s q - a)\varepsilon q)(V - bp + \gamma\lambda) - (\beta\lambda^2/2) - Kq^2\end{aligned} \quad \text{(Eq.1)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99479963

$$\max \pi_r = (p - w)(V - bp + \gamma\lambda) \quad \text{(Eq.2)}$$

The total supply chain profit is expressed as follows:

$$\pi = \pi_m + \pi_r \quad \text{(Eq.3)}$$

The decentralized decision system for the manufacturer as leader

We assume that, in this situation, the manufacturer is a leader and the retailer is a follower in a Stackelberg game. The partners' action order is given as follows: (1) the manufacturer determines the carbon emissions reduction rate λ, the wholesale price w, and the quality level of recycled products q; then (2) based on the manufacturer's declared decisions, the retailer determines the sales price p.

We first derive the optimal reaction of the retailer.

Proposition 1. In a decentralized decision situation, after determining the wholesale price w, the carbon emissions reduction rate λ, and the recycled product quality level q, the optimal sales price for the retailer is (*Eq. 4*):

$$p^* = \frac{V + \gamma\lambda + bw}{2b} \quad \text{(Eq.4)}$$

Proof of Proposition 1. For *Equation 2,* the first-order partial derivation of π_r to p can be expressed as

$$\frac{\partial \pi_r}{\partial p} = V - 2bp + \gamma\lambda + bw \quad \text{(Eq.5)}$$

We use the second-order partial derivatives to confirm the optimality:

$$\frac{\partial^2 \pi_r}{\partial p^2} = -2b \quad \text{(Eq.6)}$$

Equation 6 indicates that π_r is concave. Therefore, the succeeding first-order conditions can be obtained by setting *Equation 5* to zero

$$V - 2bp + \gamma\lambda + bw = 0 \quad \text{(Eq.7)}$$

We can obtain *Equation 4* by solving *Equation 7;* thus, Proposition 1 is proven.

From *Equation 4* it can be seen that the optimal retail price is a linear function of the carbon emissions reduction level and the wholesale price and increases monotonously. Therefore, manufacturers can influence retailers' optimal pricing decisions through carbon emissions reduction and wholesale price decisions.

Now that we know the retailer's decisions, we can derive the manufacturer's optimal decision. We substitute *Equation 4* into *Equation 1* to obtain the manufacturer's optimal profit function:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99479963

$$\max \pi_m = \left(w - c_m + \varepsilon c_s q - a\varepsilon q\right)\left(\frac{V + \gamma\lambda - bw}{2}\right) - \left(\frac{\beta\lambda^2}{2}\right) - Kq^2 \quad \text{(Eq.8)}$$

Proposition 2. In a decentralized decision situation, the manufacturer's optimal decision is obtained as follows:

$$w^* = \frac{\left(c_s - a\right)^2 \beta V b\varepsilon^2 + 2Kc_m\gamma^2 - 4K\beta bc_m - 4K\beta V}{\left(c_s - a\right)^2 \beta b^2\varepsilon^2 + 2K\gamma^2 - 8K\beta b} \quad \text{(Eq.9)}$$

$$\lambda^* = \frac{\left(bc_m - V\right)2K\gamma}{\left(c_s - a\right)^2 \beta b^2\varepsilon^2 + 2K\gamma^2 - 8K\beta b} \quad \text{(Eq.10)}$$

$$q^* = \frac{\left(c_s - a\right)\left(bc_m - V\right)\beta b\varepsilon}{\left(c_s - a\right)^2 \beta b^2\varepsilon^2 + 2K\gamma^2 - 8K\beta b} \quad \text{(Eq.11)}$$

Proof of Proposition 2. To find the optimal wholesale price w, the carbon emission reduction level λ, and the recovery quality level q, the first-order derivative of *Equation 8* to w, λ, and q can be expressed as:

$$\frac{\partial \pi_m}{\partial w} = \frac{V + \gamma\lambda - 2bw + bc_m - b\varepsilon c_s q + ba\varepsilon q}{2} \quad \text{(Eq.12)}$$

$$\frac{\partial \pi_m}{\partial \lambda} = \left(w - c_m + \varepsilon c_s q - a\varepsilon q\right)\left(\frac{\gamma}{2}\right) - \beta\lambda \quad \text{(Eq.13)}$$

$$\frac{\partial \pi_m}{\partial q} = \left(\varepsilon c_s - a\varepsilon\right)\left(\frac{V + \gamma\lambda - bw}{2}\right) - 2Kq \quad \text{(Eq.14)}$$

The Hessian matrix of the objection functions of the manufacturer's profit is expressed as follows:

$$H\left(\pi_m\right) = \begin{bmatrix} -b & \frac{\gamma}{2} & \left(\frac{-b}{2}\right)\left(\varepsilon c_s - a\varepsilon\right) \\ \frac{\gamma}{2} & -\beta & \left(\frac{\gamma}{2}\right)\left(\varepsilon c_s - a\varepsilon\right) \\ \left(\frac{-b}{2}\right)\left(\varepsilon c_s - a\varepsilon\right) & \left(\frac{\gamma}{2}\right)\left(\varepsilon c_s - a\varepsilon\right) & -2K \end{bmatrix} \quad \text{(Eq.15)}$$

According to this paper's assumptions, we derive $\left|H\left(\pi_m\right)_1\right| = -b < 0$ and $\left|H\left(\pi_m\right)_2\right| = \frac{1}{2}\left(2b\beta - \gamma^2\right) > 0$, when $\left|H\left(\pi_m\right)_3\right| = -2b\beta K + \left(\frac{\gamma}{2}\right)^2 2K + \left(\varepsilon c_s - a\varepsilon\right)^2\left(\frac{b}{2}\right)^2\beta < 0$,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99479963

which indicates that the Hessian matrix is negative-definite. Hence, π_m is jointly concave in (w, λ, q). Consequently, we can obtain the unique optimal solutions (w^*, λ^*, q^*) with the conditions assumed by the following first-order differential equations:

$$\begin{cases} \dfrac{\partial \pi_m}{\partial w} = \dfrac{V + \gamma\lambda - 2bw + bc_m - b\varepsilon c_s q + ba\varepsilon q}{2} = 0 \\ \dfrac{\partial \pi_m}{\partial \lambda} = \left(w - c_m + \varepsilon c_s q - a\varepsilon q\right)\left(\dfrac{\gamma}{2}\right) - \beta\lambda = 0 \\ \dfrac{\partial \pi_m}{\partial q} = \left(\varepsilon c_s - a\varepsilon\right)\left(\dfrac{V + \gamma\lambda - bw}{2}\right) - 2Kq = 0 \end{cases} \quad \text{(Eq.16)}$$

Solving *Equation 16*, *Equations 9*, *10*, *11* can be obtained; thus, Proposition 2 is proven.

Proposition 3. In the decentralized decision case, the retailer's optimal sales price is

$$p^* = \frac{\left(c_s - a\right)^2 V\beta b\varepsilon^2 - 6KV\beta + 2Kc_m\left(\gamma^2 - \beta b\right)}{\left(c_s - a\right)^2 \beta b^2\varepsilon^2 + 2K\gamma^2 - 8K\beta b} \quad \text{(Eq.17)}$$

Proof of Proposition 3. By Propositions 1 and 2, we can obtain that Proposition 3 holds.

Using *Equations 9, 10, 11, 17, 1, and 2,* π_r^*, π_m^*, and π can be expressed as follows:

$$\pi_r^* = \frac{4b\left(K\beta bc_m - KV\beta\right)^2}{\left(\left(c_s - a\right)^2 \beta b^2\varepsilon^2 + 2K\gamma^2 - 8K\beta b\right)^2} \quad \text{(Eq.18)}$$

$$\pi_m^* = \frac{-\left(bc_m - V\right)^2 \beta K}{\left(\left(c_s - a\right)^2 \beta b^2\varepsilon^2 + 2K\gamma^2 - 8K\beta b\right)} \quad \text{(Eq.19)}$$

$$\pi = 2K\beta\left(6Kb\beta - K\gamma^2 - \left(c_s - a\right)^2 \beta b^2\varepsilon^2\right)\left(\frac{\left(bc_m - V\right)}{\left(c_s - a\right)^2 \beta b^2\varepsilon^2 + 2K\gamma^2 - 8K\beta b}\right)^2 \quad \text{(Eq.20)}$$

The centralized decision system

In the case of centralized decision, manufacturers and retailers jointly determine the sales price, carbon emissions reduction level, and recycled product quality level to maximize the profit of the whole supply chain. Thus, the profit of the whole supply chain is

$$\pi_c = \left(p - c_m + \left(c_s - a\right)\varepsilon q\right)\left(V - bp + \gamma\lambda\right) - \left(\beta\lambda^2 / 2\right) - Kq^2 \quad \text{(Eq.21)}$$

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99479963

Proposition 4. In the centralized decision case, the optimal decision for the whole supply chain is given as follows:

$$p_c^* = \frac{\left(c_s - a\right)^2 Vb\beta\varepsilon^2 + 2Kc_m\gamma^2 - 2Kbc_m\beta - 2KV\beta}{\left(c_s - a\right)^2 b^2\beta\varepsilon^2 + 2K\gamma^2 - 4Kb\beta} \quad \text{(Eq.22)}$$

$$\lambda_c^* = \frac{\left(2Kbc_m - 2KV\right)\gamma}{\left(c_s - a\right)^2 b^2\beta\varepsilon^2 + 2K\gamma^2 - 4Kb\beta} \quad \text{(Eq.23)}$$

$$q_c^* = \frac{\left(bc_m - V\right)b\beta\left(c_s - a\right)\varepsilon}{\left(c_s - a\right)^2 b^2\beta\varepsilon^2 + 2K\gamma^2 - 4Kb\beta} \quad \text{(Eq.24)}$$

Proof of Proposition 4. To find the optimal sale price p_c, carbon emissions reduction level λ_c, and recovery quality level q_c, the first-order derivative of *Equation 21* to p, λ, and q can be expressed as

$$\frac{\partial\pi_c}{\partial p} = V - bp + \gamma\lambda - b\left(p - c_m + \left(c_s - a\right)\varepsilon q\right) \quad \text{(Eq.25)}$$

$$\frac{\partial\pi_c}{\partial\lambda} = \left(p - c_m + \left(c_s - a\right)\varepsilon q\right)\gamma - \beta\lambda \quad \text{(Eq.26)}$$

$$\frac{\partial\pi_c}{\partial q} = \left(V - bp + \gamma\lambda\right)\left(c_s - a\right)\varepsilon - 2Kq \quad \text{(Eq.27)}$$

The Hessian matrix of the objection functions of the whole supply chain's profit is expressed as follows:

$$H\left(\pi_c\right) = \begin{bmatrix} -2b & \gamma & -b\varepsilon\left(c_s - a\right) \\ \gamma & -\beta & \left(c_s - a\right)\varepsilon\gamma \\ -b\varepsilon\left(c_s - a\right) & \left(c_s - a\right)\varepsilon\gamma & -2K \end{bmatrix} \quad \text{(Eq.28)}$$

According to this paper's assumptions, we derive $\left|H\left(\pi_c\right)_1\right| = -2b < 0$ and $\left|H\left(\pi_c\right)_2\right| = 2b\beta - \gamma^2 > 0$, if $\left|H\left(\pi_c\right)_3\right| = \left(\gamma^2 - 2b\beta\right)2K + \beta b^2\varepsilon^2\left(c_s - a\right)^2 < 0$, which indicates that the Hessian matrix will be negative-definite. Therefore, when $\left(\gamma^2 - 2b\beta\right)2K + \beta b^2\varepsilon^2\left(c_s - a\right)^2 < 0$, i.e. $0 < \varepsilon < \sqrt{\frac{\left(2b\beta - \gamma^2\right)2K}{\beta b^2\left(c_s - a\right)^2}}$, the objection functions of the whole supply chain's revenue are jointly concave in (p , λ , q). For that reason, we can obtain the unique optimal solutions ($p_c^*, \lambda_c^*, q_c^*$) with the conditions assumed by the following first-order differential equations:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99479963

$$\begin{cases} \dfrac{\partial \pi_c}{\partial p} = V - bp + \gamma\lambda - b\left(p - c_m + \left(c_s - a\right)\varepsilon q\right) = 0 \\ \dfrac{\partial \pi_c}{\partial \lambda} = \left(p - c_m + \left(c_s - a\right)\varepsilon q\right)\gamma - \beta\lambda = 0 \\ \dfrac{\partial \pi_c}{\partial q} = \left(V - bp + \gamma\lambda\right)\left(c_s - a\right)\varepsilon - 2Kq = 0 \end{cases} \quad \text{(Eq.29)}$$

Solving *Equation 29, Equations 22, 23,* and *24* can be obtained; thus, Proposition 4 is proven.

Using *Equations 22, 23 and 21,* π_c^* can be expressed as follows:

$$\pi_c = \frac{-\left(bc_m - V\right)^2 K\beta}{\left(\left(c_s - a\right)^2 b^2\beta\varepsilon^2 + 2K\gamma^2 - 4Kb\beta\right)} \quad \text{(Eq.30)}$$

Proposition 5. In both centralized decision cases and decentralized decision cases, the supply chain profit, sales price, carbon emissions reduction level, and recycled product quality level satisfy the following relationships:

$$\text{i) } \pi_c^* > \pi \text{, ii) } p_c^* < p^* \text{, iii) } \lambda_c^* > \lambda^* \text{, iv) } q_c^* > q^* .$$

Proof of Proposition 5. Using *Equations 20* and *30*, *Equations 17* and *22*, *Equations 10* and *23*, and *Equations 11* and *24*, respectively, we can obtain

$$\Delta\pi = \pi_c^* - \pi = \frac{\left(-16\right)b^2\left(bc_m - V\right)^2 K^3\beta^3}{\left(\left(c_s - a\right)^2 b^2\beta\varepsilon^2 + 2K\gamma^2 - 4Kb\beta\right)\left(\left(c_s - a\right)^2\beta b^2\varepsilon^2 + 2K\gamma^2 - 8K\beta b\right)^2} > 0 \quad \text{(Eq.31)}$$

$$\Delta p = p_c^* - p^* = \frac{8K^2\beta\left(V - bc_m\right)\left(\gamma^2 - \beta b\right)}{\left(\left(c_s - a\right)^2 b^2\beta\varepsilon^2 + 2K\gamma^2 - 4Kb\beta\right)\left(\left(c_s - a\right)^2\beta b^2\varepsilon^2 + 2K\gamma^2 - 8K\beta b\right)} < 0 \quad \text{(Eq.32)}$$

$$\Delta\lambda = \lambda_c^* - \lambda^* = \frac{-8\beta b\left(bc_m - V\right)K^2\gamma}{\left(\left(c_s - a\right)^2 b^2\beta\varepsilon^2 + 2K\gamma^2 - 4Kb\beta\right)\left(\left(c_s - a\right)^2\beta b^2\varepsilon^2 + 2K\gamma^2 - 8K\beta b\right)} > 0 \quad \text{(Eq.33)}$$

$$\Delta q = q_c^* - q^* = \frac{-4K\left(bc_m - V\right)\left(c_s - a\right)\beta^2 b^2\varepsilon}{\left(\left(c_s - a\right)^2 b^2\beta\varepsilon^2 + 2K\gamma^2 - 4Kb\beta\right)\left(\left(c_s - a\right)^2\beta b^2\varepsilon^2 + 2K\gamma^2 - 8K\beta b\right)} > 0 \quad \text{(Eq.34)}$$

i.e., $\pi_c^* > \pi$, $p_c^* < p^*$, $\lambda_c^* > \lambda^*$, and $q_c^* > q^*$. Thus, Proposition 5 is proven.

Proposition 5 shows that, compared with a decentralized decision, a centralized decision for the supply chain yields greater profits, produces a greater reduction in

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99479963

carbon emissions, and provides consumers with lower prices, but also has higher requirements for the quality of recycled products.

Results and numerical analysis

We further verify and analyze the above conclusions through numerical examples. The definite values for the relevant parameters are as follows: $V=30$, $b=2$, $\gamma=1$; $a=2$, $K=10$, $\beta=20$, $c_m=6$, $\varepsilon=0.4$, and $c_s=4$. Plugging the above values of the relevant parameters into the models, we obtain the values of the sales price, the carbon emissions reduction rate, the recycled product quality level, the manufacturer's profit, the retailer's profit, and the supply chain's profit in the two models. The two tables below show the effect of the recovery rate intensity on the optimal values in the different model, calculated using the above parameter values.

Table 1 shows that, as the recovery rate increases, the sales price decreases and the total CLSC profit and recycled product quality level increase in the centralized CLSC model. *Table 2* shows that, as the recovery rate increases, the manufacturer's wholesale price decreases, the profit of retailers and manufacturers increases, and the carbon emissions reduction level and recycled product quality level increase. Comparing *Tables 1* and *2,* we can see that both the carbon emissions reduction level and the recovery quality level in the centralized decision case are higher than those in the decentralized decision case. That means that a focus on a centralized decision in a closed-loop supply chain will make it easier to meet emission reduction targets and recycle used products.

The unit cost savings through remanufacturing reflect the manufacturer's remanufacturing capacity, but also affect the supply chain profit and other variables.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99479963

The influence of the unit cost savings through remanufacturing on both CLSC models is shown in *Figures 1* and *2*.

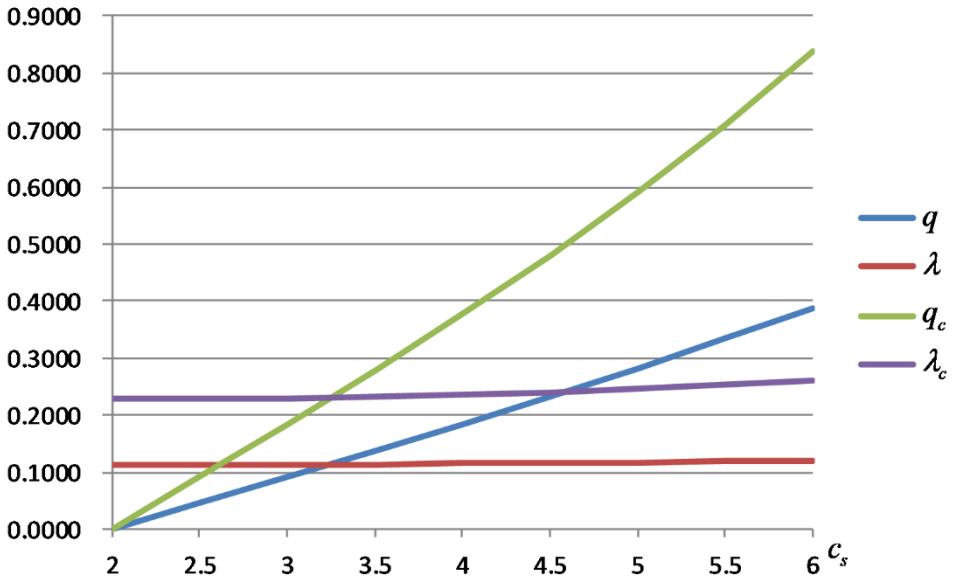

Figure 1. *The effects of C_s on the carbon emissions reduction level and the recycled product quality level*

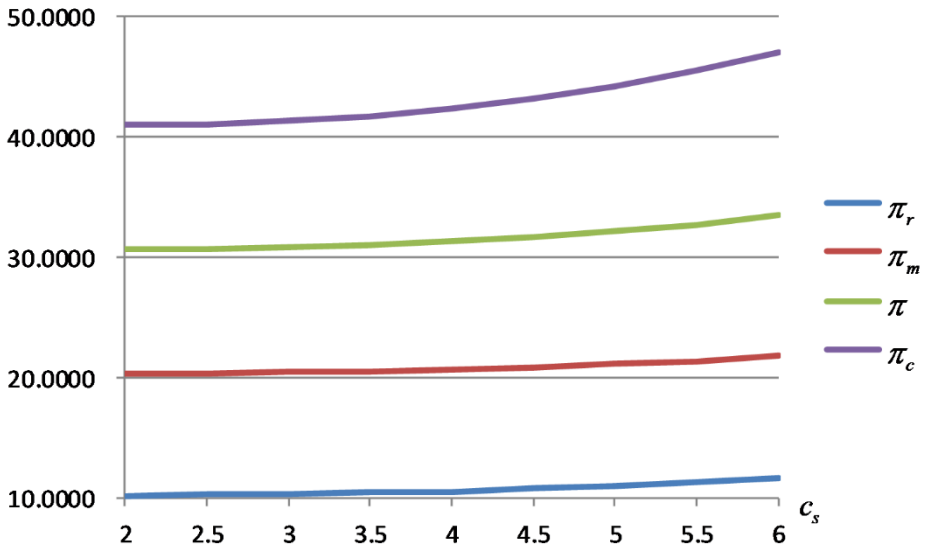

Figure 2. *The effects of C_s on profits*

Figure 1 shows that, as the unit cost saving increases, the recovery quality increases, and the range of variation in the centralized decision case is greater than that in the decentralized decision case. The change in unit cost savings has less of an impact on the carbon emissions reduction level. However, the carbon emissions reduction level in the centralized decision case is still greater than that in the decentralized decision case.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99479963

Figure 2 shows that, as the cost savings increase, the profit of the supply chain increases in the decentralized decision case and the centralized decision case, and the profit in the centralized decision case increases faster. This means that, with an increase in cost savings, manufacturers are more willing to recycle used products and earn more from recycling old products. Manufacturers recycle used products more; the lower the unit production costs, and the lower the wholesale prices, the more profit that retailers obtain.

Figure 3 shows that the recovery rate is proportional to the recycled product quality level and the carbon emissions reduction level. In the centralized decision case, the requirements for the quality level of recycled products are higher than those in the decentralized decision case. The impact of recovery rate on the carbon emissions reduction level is not significant. In comparison, the effect of recovery rate on the carbon emissions reduction level in the centralized decision case is better.

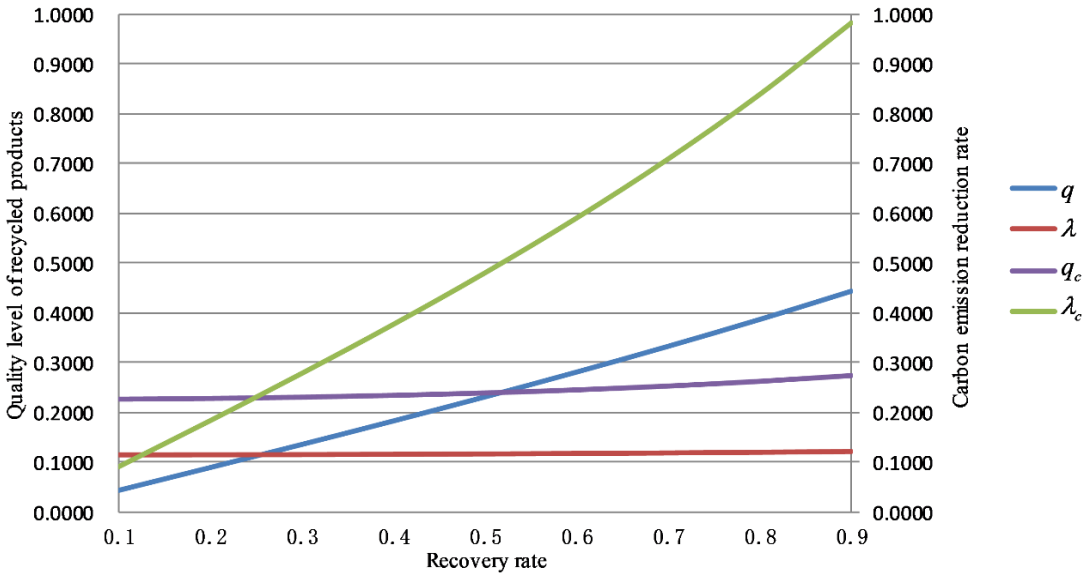

Figure 3. *The effects of ε on the recycled product quality level and the carbon emissions reduction level*

Conclusions and discussion

In this study, we proposed CLSC decision models consisting of a manufacturer and a retailer in which manufacturers recycle used products directly and improve the quality level of the used products through their recycling efforts. We investigated how carbon emissions reduction and pricing decisions in a CLSC are affected by the quality level of recycled products, and how the market demand depends on the sales price and the carbon emissions reduction level.

This paper compared a centralized decision model with a decentralized decision model, and investigated the changes in the optimal recycled product quality level and the profit of the supply chain members, as well as the pricing and carbon emissions reduction decisions, under the two models. The effects of the recovery rate, remanufacturing cost savings, the recovery price, the carbon emissions reduction investment cost coefficient, and the recovery effort cost coefficient on the quality level of recycled products were analyzed. Our conclusions can be summarized as follows:

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99479963

An increase in the recycling rate and the unit cost savings through remanufacturing will increase the quality level of recycled products as well as the carbon emissions reduction level. However, the increase in the carbon emissions reduction level is not significant.

Compared with the decentralized decision case, the centralized decision case has higher requirements on the quality level of recycled products and is more conducive to the reduction of carbon emissions per unit product.

The sales price in the centralized decision case is lower than that in the decentralized decision case, and the recovery price also has a positive effect on sales pricing. Improving consumers' environmental awareness not only helps the sustainable closed-loop supply chain members set higher prices, but also improves the quality level of recycled products.

Although we have contributed to the literature on closed-loop supply chains, our work has its limitations. First, we assumed that the manufacturer recycles used products that are recovered directly from consumers. However, in reality, used products can also be recycled by retailers or third-party recyclers. Therefore, this study could be extended in the future by considering different recycling channels. Second, we only considered investments in carbon emissions reduction for new products in this paper. Thus, future research could further consider carbon abatement investments in new and remanufactured products together. Third, we considered as identical new products and remanufactured ones. Therefore, future research could consider consumers' different preferences for new products and remanufactured products and study the impact of the quality level of recycled products on sustainable closed-loop supply chain decisions based on consumers' behavioral preferences.

MITIGATION OF SALINITY STRESS OF PEPPER (*CAPSICUM ANNUUM* L.) BY ARBUSCULAR MYCORRHIZAL FUNGUS, *GLOMUS CONSTRICTUM*

AL-AMRI, S. M

Department of Biology, College of Science and Art, Shaqra University, Shaqra, Saudi Arabia (e-mail: phd1618@hotmail.com, abdelfattaham@yahoo.com)

(Received 8th Apr 2019; accepted 13th Jun 2019)

Abstract. A pot experiment was investigated to study the effect of arbuscular mycorrhizal (AM), *Glomus constrictum* (Trappe) on growth response, photosynthetic pigments, gas exchange parameters, antioxidant enzymes and nutrition of pepper plants irrigated with different concentrations of sea water. Four concentrations (tap water, 10%, 20% and 40% of sea water) were used. Salinity stress markedly reduced all studied parameters, except antioxidant enzymes, of pepper plants. Under saline conditions, AM fungi significantly increased growth parameters, photosynthetic pigments, nutrient contents (except Na^+), gas exchange rate and antioxidant enzymes of pepper plants when compared to non-mycorrhizal ones. Those improvements were linked to mycorrhizal infection degree in pepper. Generally, growth, nutrition, photosynthetic pigments and antioxidant enzymes of pepper appeared to be highly dependent on the AM in salinized soil compared to non-salinized soil. This study suggested that mycorrhizal colonization could be used to mitigate the detrimental effects of salinity, particularly in soils irrigated with high concentration of sea water.
Keywords: *salinity, mycorrhiza, growth, pepper, antioxidant enzymes*

Abbreviations: P_N: net photosynthetic rate; AM: arbuscula rmycorrhizal; AMF: arbuscular mycorrhizal fungi; AMR: arbuscula rmycorrhizal response; Dwt: dry weight; Fwt: fresh weight; *E*: transpiration rate; g_s: stomatal conductance; LA: leaf area; Non-AMF: non-arbuscular mycorrhizal fungi; N: nitrogen; P: phosphorus; K: potassium; Na: sodium; Mg: magnesium; Ca– calcium; CAT: catalase; POX: peroxidase; APX: ascorbate peroxidase.

Introduction

Water salinity is a very important environmental problem, particularly in Saudi Arabia, decreasing plant growth and yields worldwide, and affecting about 10% of the world's global land (Abdel-Ghani, 2009; Al-Amri et al., 2013; Abdel-Fattah et al., 2016). The saline area is still extending due to irrigation and land clearing (Abdel-Fattah et al., 2013; Sheng et al., 2013). Increasing salt concentration in soil suppresses the plant ability to absorb and uptake water, negatively decreases metabolic processes, nutrient absorbance, root hydraulic conductivity and all photosynthetic rates, all of these results in negatively affecting the plant ability to grow (Al-Karaki et al., 2001; Abdel-Fattah and Asrar, 2012).

Pepper (*Capsicum annuum* L.) is an important vegetable plant in Saudi Arabia. Raising growth of pepper plant through improving the productivity area as increasing the cultivated area in salinized newly reclaimed lands is the major important national target. Increasing salt tolerance of vegetables, horticultures and economic plants is required to tolerate the increase in food production in many regions of the world in general and Saudi Arabia in particular (Al-Amri et al., 2013). Expansion of salt-tolerant vegetables or desalinization of soil by washing excessive salts in not enough to remove this problem (Kumar et al., 2010; Abdel-Fattah et al., 2016). Recently, application of biological agents like mycorrhizal symbiosis as a practical applied technology to

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99659978

mitigate salt stress effects on plant growth and development has customary a great attention (Poss et al., 1985; Abdel-Fattah and Asrar et al., 2012; Al-Amri et al., 2013).

Several investigators have concluded that the existence of the arbuscular mycorrhizal plants grown in saline stress conditions (Pond et al., 1984; Kumar et al., 2010; Wu et al., 2010; Asrar et al., 2014). Furthermore, the biotechnological application of arbuscular mycorrhizal fungi in salinized soil may increase plant tolerance and growth via mitigating the adverse effect of salt stress in various plants (Juniper and Abbott, 1993; Daei et al., 2009; Abdel-Fattah and Asrar, 2012). Under salinity stress conditions, plant tolerance and production are complicated different mechanisms. In this connection, arbuscular mycorrhizal fungi has several mechanisms to increase salt tolerance of associated plants through stimulating nutrient uptake (Evelin et al., 2009; Abdel-Fattah et al., 2013); decreasing the uptake of Na^+ and preventing their movement to aerial parts of plant (Daei et al., 2009); increasing water uptake (Al-Karaki, 2006; Asrar et al., 2012); maintaining ionic balance by increasing and/or selective uptake of nutrients (Kumar et al., 2010); increasing of some antioxidant defense enzyme activities (catalase, peroxidase, superoxide dismutase and ascorbate peroxidase) and molecules like carotenoids, glutathione and tocopherols (Ibrahum et al., 2011); accumulating of polyamines like spermine and spermidine in associated host plants and regulating the osmotic status of plants through maintaining the turgor pressure of the leaves, and stimulating the photosynthetic and transpiration rate, and water use efficiency in the host plants (Juniper and Abbott, 2006; Auge et al., 2008).

Due to the detrimental effects of salt stress on different plants species and the function of arbuscular mycorrhizal fungi in improving the salinity tolerance, the present study was evaluated to study the efficiency of arbuscular mycorrhizal fungus (*Glomus constrictum*, Trappe) for enhancing plant growth, photosynthetic pigments, nutrition, gas exchange and some antioxidant enzymes of Pepper plants grown in soil irrigated with different concentrations of sea water.

Materials and methods

Experimental design

The experiment with a (2 × 4) factorial design was done. The treatments consisted of two arbuscular mycorrhizal onces [*Glomus constrictum* (AMF) and non-inoculated (--AMF)] and four levels {0.0% (control), 15%, 30% and 60% of sea water} g Kg^{-1} and 0.5 g kg^{-1} soil]. The sea water was obtained from the Red sea, Gadda, Saudi Arabia. Each of the eight treatments was replicated ten times (one plant per each pot) to give 90 pots as total.

Inoculum preparation of arbuscular mycorrhizal fungus

The inoculums mycorrhizal fungus, *Glomus constrictum* (Trappe), was isolated from saline site of Shaqra region using the wet sieving method of Gerdmann and Nicolson (1963). The spores of AM were left to multiply for 4 monthes in greenhouse under controlled environmental conditions. The mycorrhizal inoculums consisting of 10 g of rhizoplane soil (approx. 600 spores) and 0.5 g of colonized onion root pieces with a colonized level of 80% were inoculated to each pot. The mycorrhizal inoculums were added at 5 cm depth the pepper seedlings upon planting.

DOI: http://dx.doi.org/10.15666/aeer/1704_99659978

Plant and growth conditions

Seeds of Pepper (*Capsicum annuum* L.*)* were surface disinfected by soaking in 7% sodium hypochlorite for 10 min then rewashed with deionized sterilized water and left to germinate for 48 h on wetted sterilized filter paper in dark at 25 °C. Similar sterilized germinated seedlings were transplanted (one plant/pot) into 20 cm diameter plastic pots containing 3 kg of autoclaved (120 °C for 3 separate consequent time) sandy loam soil. Soil characteristics were: pH (water) = 7.31; available nitrogen (15.0 mg kg^{-1}); available phosphorus (5.12 mg kg^{-1}); potassium (40 mg kg^{-1}); magnesium (53 mg kg^{-1}) and organic matter (0.33%). All pots were irrigated by tap water (control) until the second week, and then the pots were divided into four groups for salinity treatments. The 1st group irrigated with tap water (control), the 2nd, 3rd and 4th groups were irrigated with 15, 30 and 50% sea water respectively. Chemical analysis of sea water are: Cl^-, 21.5 g/l; Na^+, 12.5 g/l; K^+, 0.49 g/l; salinity, 38.2 g/kg; pH 8.2 and its electrical conductivity was 48 mmhos/cm. Half of all pots treated or non-treated with different concentrations of sea water were inoculated with the mycorrhizal fungus, *Glomus constrictum* (as described before). Arbuscular mycorrhizal inoculums were added 3 cm below the seedlings at planting time. The non-mycorrhizal treatments (-AMF) were provided with filtered washings of an equal amount of the mycorrhizal soil inoculum to provide the same associated microorganisms without AM spores. All pots were arranged in a complete randomized blocks design in a glasshouse of Experimental Station of Plant Production Department, College of Food and Agriculture Sciences, King Saud University under controlled conditions of 550 μmol m^{-2} s^{-1} light intensity, 23/18 °C day/night temperatures, 70–80% relative humidity and 16-h photoperiod. Plants for all treatments received 32 mg sulfur (K_2SO_4) pot^{-1} as a nutrient solution after four weeks of planting. All plants were watered regularly with the corresponding irrigation sea water level. Ten plants for each treatment were harvested 10 weeks after planting.

Growth parameters

At harvest, the plants for each harvest were carefully uprooted with minimum disturbance of roots. The roots were washed with tap water to remove adherent soil particles and the shoot height per plant was measured. Roots and shoots fresh and dry weights (after drying the samples at 80 °C for 48 h in oven) were recorded. Leaf area was determined using a leaf area meter (Li-Cor, Lincoin, NE). Arbuscular mycorrhizal growth responses (AMR) for each estimated parameter was calculated following Menge et al. (1978) using the following formula: (parameter value of mycorrhizal treatment (AMF) - parameter value of non-mycorrhizal treatment (-AMF)/{parameter value of non-mycorrhizal treatment (-AMF)} × 100.

Estimation of photosynthetic pigments

Photosynthetic pigments content (chlorophyll ‘a’, and “b”, carotenoids and total pigments) of the fully mature third leaves for each treatment was determined by extraction in 85% aqueous acetone for 5 min. The homogenate samples were centrifuged at 8000 rpm for 10 min. The supernatant was made up to 10 ml with acetone and it measured spectrophotometrically against a blank of aqueous acetone The concentrations of the pigments were determined using the equations of Abdel-Fattah et al. (2013).

DOI: http://dx.doi.org/10.15666/aeer/1704_99659978

Measurement of photosynthesis, transpiration and stomatal conductance

Net photosynthetic rate (*A*), transpiration rate (*E)* and stomatal conductance (g_s) of the mature third leaves were measured by using Li-Cor, 8400XT, Lincoln. NE, USA. Leaf was fitted into leaf chamber. Gas exchange measurements were made in the growth chamber under saturated light conditions and adjusted to an intensity of 480 μmol m^{-1} s^{-1}. Four replicates for each treatment were used.

Nutrient analysis

Root and shoot samples for each tratment were oven-dried, grounded. A known weight of the dried material was extracted in a digestion flask containing 10 ml of three acid mixture (HNO_3:H_2SO_4: 60% HCL, at the ratio of 3:2:1 (v/v/v), respectively) in kjeldahed digestion flask. Phosphorus (P) was determined by the vanadate-molybdate colorimetric method (Jackson, 1973). Calcium (Ca^{++}), potassium (K^+), magnesium ($Mg^{++)}$ and sodium (Na^+) in digested samples by using atomic absorption (model unicam 969). Total nitrogen (N) was analyzed using Kjeldahl method (Nelson and Sommers1973).

Estimation the activities of antioxidant enzymes (Catalase, peroxidase andascorbate peroxidase)

Antioxidant enzymes were analyzed by homogenization of a known leaf fresh weight in 50 mM cold phosphate buffer (pH 7.0) containing 1 mM EDTA (Ethylene Diamine tetra acetic acid) and 5 mM ascorbic acid in case of ascorbate peroxidase assay (Gajewska and Sklodowska, 2008). Peroxidase (POX) and Catalase activitties (CAT) were estimated according to the method of Aebi (1983). The specific enzyme activity of CAT and POX was expressed as μmol of H_2O_2 consumed/min. Ascorbate peroxidase (XPX) activity was assayed using the method of Nakano and Asada (1981) and the specific activity of this enzyme was expressed as μmol oxidized ascorbate/min.

Mycorrhizal colonization

After harvest, the root systems for each treatment were washed carefully with tap water to remove all the adhering soil particles. Randomly sampled roots from five plants per treatment were cut into 0.5 to 1 cm pieces, then cleared with 10% KOH solution and stained with 0.05% trypan blue in lactophenol (Phillips and Hayman, 1970) for estimated of mycorrhizal colonization.40 root segments of each treatment were putted on slides and were examined with a light microscope (Carl Zeiss, Japan) at 40x magnification, where visually were allocated six classes of mycorrhizal colonization (from 0 to 5, depending on the occurrence of mycorrhizal structure in the root segment) and four levels of arbuscular abundance (from A0 to A3). With this values, mycorrhizal colonization levels [Frequency of mycorrhizal colonization (F %), the intensity of mycorrhizal colonization (M %) and arbuscular frequency (A %)] of the stained roots were estimated according to Trouvelot et al. (1986) using the “Mycocalc” software (http://www.dijon.inra.fr /mychintec/mycocalcprg/download.html).

Statistical analysis

All results were statistical analyzed using two-factor analysis of variance (ANOVA). Means of all treatments were divided by Duncan’s multiple range tests by the least

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99659978

significant difference (LSD, $P \leq 0.05$) method using the Costat software. All of the measurements were performed five times for each treatment. The means and calculated standard error (SE) are recorded.

Results

Growth responses

Sea water stress significantly reduced biomass of shoots and roots, leaf area and shoot length of both mycorrhizal (AMF) and nonmycorrhizal (-AMF) pepper plants compared with control treatment (irrigated with tap water) and the rate of reduction increased with increasing sea water concentration in the soil. However, the reduction in most growth criteria was more pronounced in non-mycorrhizalkal pepper plants (*Table 1*). In this connection; Leaves of mycorrhizal pepper plants grown at higher concentrations of sea water were highly greener and less senescent than those in the non-AM plants (*Fig. 1*). Values of mycorrhizal dependency of pepper plants (AMR) in responding to AMF colonization were significantly increased with increasing sea water concentration in soil.

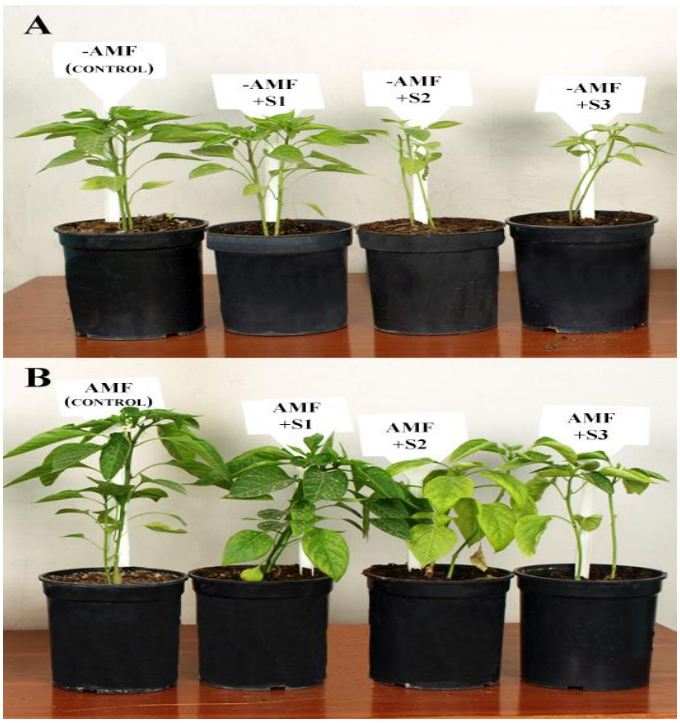

Figure 1. *Growth of non-mycorrhizal (-AMF) [A] and Mycorrhizal (AMF) [B] Pepper plants grown in soil irrigated with different concentrations of sea water [Control (0.0), S1 (10%), S2 (20%) and S3 (40%)]. The leaves of non-mycorrhizal pepper plants were more senescent (less green) than those of mycorrhizal plants*

Photosynthetic pigments

The photosynthetic pigments content (chlorophyll a, chlorophyll b and carotenoids) in mycorrhizal leaves of pepper plants were significantly greater than those of non-mycorrhizal plants grown either with or without sea water irrigated in soil (*Table 2*).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99659978

Such increases in these contents were linked to the degree of mycorrhizal colonization. In most cases, this increase in carotenoides content in leaves of pepper plants in response to mycorrhizal effects was increased with increasing sea water concentration in the soil, particularly 40%. On contrary, no significant differences chlorophyll "b" was observed between mycorrhizal plants irrigated with 10% sea water and control treatment (*Table 2*).

Gas exchange parameters

Generally, g_s, *A* and *E* in mycorrhizal leaves of pepper plants were highly significant than those in non-mycorrhizal plants grown either in soil irrigated with or without sea water (*Table 3*), and the effect was more noticed in soil irrigated with higher concentrations of sea water. Such increases in gas exchange parameters were highly related to the degree of the mycorrhizal colonization for each treatment. Furthermore, the dependency of pepper plants on mycorrhizal fungi for improving gas exchange parameters was increased with increasing sea water concentration in soil. The differences in g_s, *A* and *E* in pepper leaves were not significant between mycorrhizal plants grown in soil irrigated with 10% sea water and control treatment.

Antioxidant enzymes

Sea water stress significantly increased the antioxidant enzyme activities (CAT, POX and APX) in leaves of mycorrhizal and non-mycorrhizal pepper plants as compared to the control treatments (*Table 4*). However, mycorrhizal colonization significantly improved the contents of antioxidant enzyme activities than those in leaves of non-mycorrhizal plants, regardless of sea water treatments. This increase in antioxidant activities in leaves of pepper plants in response to mycorrhizal effects was increased with increasing sea water concentration in the soil, particularly in case of POX and APX.. On the other hand, no significant differences in APX activity was observed between mycorrhizal and non-mycorrhizal plants grown in soil irrigated with normal water.

Mycorrhizal colonization levels

Mycorrhizal colonization levels (frequency (F%), intensity (M%) of mycorrhizal colonization and arbuscular development (A%)) in root tissues of pepper plants were significantly affected by sea water stress in soil. Both intensity of mycorrhizal colonization (M%) and arbuscular frequency (A%) were significantly decreased in pepper root tissues with increasing concentration of sea water in soil (*Table 5*). On the other hand, no significant differences were observed in the frequency of mycorrhizal colonization (F%) in root tissues between mycorrhizal plants irrigated with or without sea water concentration. On the contrary; no significant differences were observed in the intensity of mycorrhizal colonization (M%) between AMF plants grown either in soil irrigated with 10% sea water and control treatment. No mycorrhizal colonization was observed in the non-inoculated pepper plants.

Nutrient content

Increasing sea water concentration in soil significantly reduced N, P, Mg, Ca and K concentrations, but increased sodium in the shoots of mycorrhizal and non-mycorrhizal pepper plants. However, P, N, K, Ca and Mg contents in shoot tissues of the AM plants, in most cases, were significantly greater than those in non-mycorrhizal pepper plants grown in soil irrigated with or without sea water concentrations (*Table 6*). Such stimulations in nutrients content in response to the mycorrhizal effects were highly increased with increasing sea water concentration in the soil. AM-inoculated plants exhibited reduction in Na concentration in shoot tissues compared to non-mycorrhizal

control plants in either soil irrigated with different concentration of sea water and control treatment (*Table 6*). The rate of reduction in Na content in response to mycorrhizal effects (AMR) was increased highly with increasing sea water concentration in the soil. On the other hand, no significant differences in Mg content in shoot tissues were observed between mycorrhizal and non-mycorrhizal pepper plants at control and 20% sea water treatments

Discussion

Salinity of soil is one of the severe abiotic stress problems particularly in arid and semi-arid area like Saudi Arabia. It directly negatively affecting the majority of arable lands worldwide, limiting the growth and production of most of the economically important crop, vegetable and horticulture plants (Giri et al., 2003; Al-Karaki, 2006; Kaya et al., 2009; Ibrahim et al., 2011; Abdel-Fattah and Asrar, 2012; Asrar et al., 2014; Elhindi et al., 2017). Augmenting salt concentration in soil decreases the plant ability to absorb water, negatively affect all metabolic processes and osmotic balance, nutrient absorption, water relations and net photosynthetic rate. All of these results adversely affecting plant growth and productivity (Ojala et al., 1983; Zuccarini, 2007; Scharnagl et al., 2018).

It is evident from the present investigation that sea water stress significantly decreased of estimated growth parameters of mycorrhizal and non-mycorrhizal pepper plants compared to the control plants. However, mycorrhizal fungi improved growth and biomass of pepper plants grown in either sea water stressed or control soils when comparing with non-mycorrhizal plants. The dependency of pepper plants on mycorrhizal fungi was highly increased with increasing sea water concentration soil. These results are entirely consistent with earlier studies on other crop and vegetable plant species (Giri et al., 2007; Al-Amri et al., 2013; Sheng et al., 2013). Enhancement of growth in mycorrhizal pepper plants irrigated with different concentrations of sea water has been related partially to mycorrhizal enhancement of host plant P, N and K nutrition (Poss et al., 1985; Garg and Chandel, 2011; Evelin et al., 2012).

Interestingly, AM pepper plants had higher K, Ca, P and N contents than non-mycorrhizal plants grown at sea water stress treatment. In this connection, pepper plant tolerance to sea water stress was improved highly by mycorrhizal fungi. The obtained results suggested that improving growth of pepper plants duo to mycorrhizal colonization is a manifest of increased nutrients content and maintaining favorable ionic ratios than non-mycorrhizal pepper plants. These results are confirmed by the most previous studies (Kaya et al., 2009; Kumar et al., 2010; Scharnagl et al., 2018). Furthermore, improved P, N, K and Ca contents by mycorrhizal fungi in pepper plants grown under sea water stress conditions may contribute to the maintenance of vacuolar membrane integrity and facilitate the compartmentalization of Na ions with vacuoles (Cantrell and Linderman, 2001). Preventation of Na ion from interfering in metabolic pathways of growth and yield, thereby mitigated the toxicity of sea water stress (Poss et al., 1985; Abdel-Fattah and Asrar, 2012). Lower Na in the mycorrhizal plants than non-mycorrhizal plants may be explained by the dilution effect due to growth enhancement (Giri and Mukherjee, 2004; Al-Karaki, 2006). In addition, Mycorrhizal inoculation can increase K^+ absorption under sea water stress conditions. The higher K^+: Na^+ ratio helps not only to prevent the disruption of various K-mediated enzymatic processes and inhibition of protein synthesis but also are beneficial in influencing the ionic balance of the cytoplasm or Na^+ efflux from plants (Colla et al., 2008; Zuccarini and Okurowska, 2008).

Photosynthetic pigments like chlorophyll have been proposed as one of the most parameters of salt tolerance in plants (Sirivastava et al., 1998) and also carotenoids are responsible for reducing of single oxygen (Bourgou et al., 2012). In this connection, it is evident from the present investigation that the photosynthetic pigments in leaves of mycorrhizal pepper plants were significantly higher than those in non-mycorrhizal plants grown in soil irrigated with sea water. The dependency of pepper plants on AM

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99659978

fungi was increased highly with increasing sea water concentration in soil. These results are in line with results of Elhindi et al. (2017) and Scharnagl et al. (2018). Furthermore, mycorrhiza improving Mg^{++} support a higher chlorophyll concentration. Effective Mg^{++} uptake helps by increasing the chlorophyll content and hence stimulating photosynthetic efficiency and plant growth (Camprubi et al., 2012; Metwally and Abdelhameed, 2018). Of particular interest in this study that g_s, P_N and E were highly significant in the AM pepper plants than in the non-mycorrhizal plants grown in soil irrigated with or without different concentrations of sea water. Such increased in the contents of gas water exchange were linked to the degree of mycorrhizal colonization. These results are in the same line of those obtained by Auge et al. (2008), Abdel-Fattah et al. (2013), Metwally and Abdelhameed (2018).

Sea water stress in soil not only affect the growth and production of pepper plant but also the levels of mycorrhizal colonization in associated pepper plants. These results were in agreement with the previous findings (Aroca et al., 2013; Abdel-Fattah et al., 2016; Elhindi et al., 2017). Based on the previous results of Jiang and Zhang (2002), who reported that antioxidant enzymes play an important role in scavenging of reactive oxygen species (ROS) and hence averting the oxidative stress induced damaging effects on several sensitive molecules like nucleic acids, proteins and lipids The present study demonstrated that the activities of CAT, POX and APX in mycorrhizal plants were significantly higher than in non-mycorrhizal pepper plants grown either in soil irrigated with or without sea water. Such stimulation in antioxidant activities in response to the mycorrhizal effect were significantly increased with increasing sea water concentration in soil. In this connection, several investigators reported that mycorrhizal symbiosis helps plants to alleviate or reduced salt stress by enhancing the activities of antioxidant enzymes (Tang et al., 2009; Metwally and Abdelhameed, 2018).

Conclusion

Arbuscular mycorrhizal colonization has a great contribution from pepper plant to alleviate salinity stress imposed by irrigation with different concentrations of sea water through improving growth, increasing nutrient contents, stimulating gas exchange parameters, presentation of Na^+ content and transfer by the roots to the shoots and some metabolic contents of pepper plants. These benefits in response to mycorrhizal inoculation were greatly increased with increasing sea water concentration in soil, suggesting that pepper plants was highly depended on mycorrhizal fungi particularly at higher concentration of sea water. However, more investigations are required to explain in details the relationship between the molecular of AM efficiency for plant growth and other metabolic activates in different varieties of plants under salinity stress conditions.

Abstract. Composting is the process of organic biological decomposition in aerobic and controlled conditions. Many factors can affect the composting process, and almost all are related. Some factors that majorly affect the composting process also influence the stage or direction of the process. This paper focuses on the technical factors that affect the composting process' achievement of the thermophilic phase, particularly in a closed reactor system. At the same time, this paper will be discussed about the benefits and comparison between close reactor system and the conventional pile method. The technical factors that are discussed in-depth in this mini review paper are the rotation or turning frequency, aeration rates, and the initial moisture of the compost mixture for closed reactor composting system. All three factors significantly cause increased thermophilic temperature in the closed reactor. Basically, there are 3 important phases in the composting process, which are the mesophilic phase, thermophilic phase, and maturation phase. In the composting process, it is crucial that the thermophilic temperature is reached. By increasing the thermophilic temperature, the number of thermophilic microorganisms also increases, causing the rapid degradation of bio-waste
Keywords: *aeration rates, initial moisture, rotation/turning frequency, thermophilic temperature*

Introduction

The problem of residual waste streams from the industry has worsened. Before industrialization, the production and decomposition of organic matter were essentially balanced. Composting, in general, is not only important in preventing the accumulation of organic waste from harming the environment, but also to recycle nutrients and organic matter. A proper composting process effectively destroys pathogens and weed seeds because in the process a high temperature (55–65 °C) is achieved through the metabolic heat generated by microorganisms in the thermophilic phase (Petric and Selambasic, 2008).

Among the benefits of composting is that plant nutrients are conserved, and harmful substances are transformed into non-hazardous substances; thus, producing reusable products (Liu, 2000). Composting materials from organic waste can also improve the structure of the water-holding capacity of the soil (Mohammad et al., 2012). Furthermore, the benefit of composting nowadays is not limited to landfills, but also for controlling and preventing environmental pollution. Composting materials are now used

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99799996

to control soil erosion on highways. It also works for cleaning runoff in running water and for recovering soil contaminated with heavy metals or toxic organic compounds (Bhattarai et al., 2011).

Compost stability and maturity have an important impact on the application of the compost's final product in land use. The use of immature and unstable compost products because of an incomplete biodegradation process can negatively affect germination and reduce plant fertility, which causes competing absorption of oxygen and toxicity (Zhang et al., 2017). The application of unstable and immature compost would fix nitrogen in the soil and limit plant growth because it competes for oxygen in the rhizosphere and discharges toxic substances (Bernal et al., 2009). According to many researchers, matured compost products from composting at thermophilic temperature are eco-friendlier (Bernal et al., 1998; Yang et al., 2013; He et al., 2014).

Most of the composting system used is conventional technology which is by adapting the pile method. The pile method, if not properly maintained, will cause many problems, for example the presence of wild animals and require more sophisticated operation controls and require large space and a need long time to produce the product. Hence, composting using mechanical methods such as closed reactors is easier and able to overcome problems resulting from composting rather than using pile methods. The goal of the reactor's mechanical design is to accelerate the composting process through optimum maintenance for active microbes during composting and to minimize adverse effects on the environment (Bertoldi et al., 1983). Mechanical systems can process large amounts of waste without taking up much space, and they offer good control of the environmental conditions such as temperature, moisture content, and airflow rate (Alkoaik et al., 2018). The mechanical system is usually closed, however there are researchers using an open reactor system. However, mechanical closed reactor systems have good control which makes it more suitable for composting in large quantities (Bhamidimarri and Pandey, 1996; Haug, 1993). In general, pile methods and mechanical methods can be distinguished on several criteria such as capital costs, operational costs, land requirements, operating controls and so on (Habsah, 2008). *Table 1* describes the comparison of both pile and closed mechanical methods. From the table below, pile composting method are more exposed to the influenced of weather, which will at the same time influence the temperature rise of the pile. Adapting pile/windrow system also lead to leachate contamination posing a risk of groundwater contamination GHG emissions, space limitation and emission of greenhouse gases (Rich and Bharti, 2015). Zhu-Barker et al. (2017) mentioned that windrow composting system is a source of greenhouse gases (GHG) that contribute to climate change. In their study, found that pile compost during the rainy season with cooler temperature resulted in oxygen depleted environment that generated the highest CH_4 and lowest N_2O emissions. Chen et al. (2015) also studied the N_2O emission during the composting of dairy manure by windrow system. They found out pile turning altered the distributions of NO_3^- and NO_2^- in the compost materials and dramatically influenced surface windrow N_2O emissions.

The process of composting is a biological one and thus involves various microorganisms. These organisms will break down organic matter and organic compounds. The identification of microorganisms capable of decomposing certain compounds is very useful in the composting process. Organic waste is decomposed during the process of fertilization by replacing microbial communities with complex and critical substrata such as cellulose, lignin, and hemicellulose (Hiroaki et al., 2006).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99799996

Composting-related organisms can be classified into two classes, namely mesophyll and thermophile. Classification of microorganisms according to the temperature in which they live and grow. Temperature plays an important role in the composting process, as it affects microbial activity. Hoseini and Abdul Aziz (2013) also indicate temperature as a key factor for determining the progress of the composting process; a higher temperature (thermophilic conditions) results in a higher decomposition of organic matter (OM).

Several researchers concluded that using a single-maturity index was insufficient to indicate compost maturity and stability (Rashad et al., 2010). However, many other researchers used the thermophilic stage of the composting process as a key factor for specifying the success of the entire process (Sarkar et al., 2016; Han et al., 2018; Koyama et al., 2018; Gou et al., 2017; Awasthi et al., 2017; Hoseini and Abdul Aziz 2013; Li et al., 2014). Therefore, this paper discusses and reviews the factors that significantly impact thermophilic temperature achievement, especially in a closed reactor, either lab-scale or pilot-scale. The factors that are discussed include rotation/turning frequency, aeration rate, and initial moisture of the compost mixture.

Table 1. *Comparison between pile composting and mechanical methods. (Source: Habsah, 2008)*

Criteria	Pile method	Closed mechanical reactor
Capital Cost	Low	High
Operational cost	Low	Low
Land requirement	High	Low. Can increase if the resulting compost needs to be matured in a pile method
Ventilation control	Limited. Unless forced aeration is done	No limit
Operation control	Turning frequency, parameter correction (moisture, pH, C/N)	Airflow rate, dynamic of turning process, parameter correction (moisture, pH, C/N), recycling
Sensitivity to weather changes	Sensitive. Need to be covered with plastic canvas	Can operate at any weather. But it depends on the material
Odor control	Depending on the organic material used	Good
Problem in operation	Easily influenced by uncertain weather	Potential for short circuit, complex mechanical process

Thermophilic temperature

Temperature is a substantial measurement that could affect the composting process and the microbial activity during composting (Sun et al., 2017; Morales et al., 2016; Zhao et al., 2016). At the same time, it is also a function of the process. During the aerobic composting process, there are three phases affecting the microbial population. The first is the mesophilic phase (ambient temperature up to 45 °C), followed by the thermophilic phase (45 °C- > 60 °C) and finally returning to the mesophilic phase (45 °C to the surrounding temperature) as shown in *Figure 1*. Temperature does not only affect the metabolic process of microorganisms, but these parameters are also seen to affect the density and composition of microbes in the compost mass (Liang et al., 2003). Because temperature impacts microbiological processes, important responses and other elements of the composting process are also affected by temperature changes (Epstein, 1997). It was reported that a composting temperature set to 55 °C, enabled the

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99799996

killing off of pathogens and sanitization of compost material (Gea et al., 2005). Stentiford (1996) also found that maximum temperatures of 55-65 °C were necessary to destroy pathogens, but temperatures within the range of 45-55 °C must be maintained for maximum biodegradation in the composting process. Additionally, temperatures below 20 °C and more than 60 °C have been shown to reduce microbial activity (Liang et al., 2006). However, Wong et al. (2001) agreed that a 60 °C temperature was the most ideal condition to produce optimum reproducibility in the composting process.

In the early mesophilic phase, mesophilic and fungal bacterial populations number 10^8 and 10^6 for each 1 g of wet compost. Meanwhile, the thermophilic and actinomycet bacterial population is 10^4 and the thermophilic fungi population is 10^3 for every 1 g of wet compost. A summary of the bacterial, fungal and actinomycet populations at every composting phase is shown in *Table 2*.

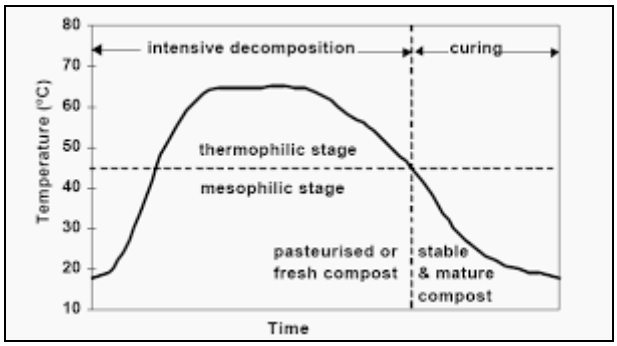

Figure 1. *Temperature profile and growth of microorganisms in compost heap*

Table 2. *Comparison between pile composting and mechanical methods. (Source: Abu Zahrim, 2004)*

Microbe	Mesophilic Early stage < 40 °C	Thermophilic 40- > 60 °C	Thermophilic to maturation phase
Bacteria			
Mesophilic	10^8	10^6	10^{11}
Thermophilic	10^4	10^9	10^7
Actinomycete			
Thermophilic	10^4	10^8	10^5
Fungi			
Mesophilic	10^6	10^3	10^5
Thermophilic	10^3	10^7	10^6

The increase in temperature is significant for the activity and growth of mesophilic organisms during the initial phase of composting such as lactic acid bacteria, Gram-negative bacteria, yeast, and fungi (Steger et al., 2005). At the thermophilic stage of the composting process, thermophilic organisms dominate the degradation process. The bacterial species that dominate the thermophilic phase of the composting process belong to the genus *Bacillus spp*. and *Thermus thermophiles* (Steger et al., 2005). Siu-Rodas et al. (2018), in their study, found that three out of twenty isolated strains showed higher enzymatic activity and were identified as *Bacillus subtilis*; the study composted coffee residue at a pile temperature of 57 °C. They also discovered that the isolation of

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99799996

microorganisms from composting piles in the thermophilic stage allowed for the identification of three *B. subtilis strains*, where the enzymatic extracts showed activity on CMC and crystal cellulose, confirming the existence of endo- and exocellulases. These cellulases could be used in several industries, such as in the preparation of animal foods, fruit juice extraction, and clarification and bleaching of recycled paper. The differences in microbial community were observed clearly at different composting temperatures. The genus *Bacillus* was dominant at 50 °C to 70 °C, while the genus *Geobacillus* increased with the escalation of temperature and dominated at 70 °C (Bhatia et al., 2013; Ivanov et al., 2001). All these bacteria genera play an important role in the degradation of complex substrates.

The mode of composting and the control levels have a great impact on composting temperature. The highest degree of temperature control is usually obtained in mechanical systems. Large-scale reactors (10–300 l) often comprise a self-heating phase (Lashermes et al., 2012). Previously, Petiot and de Guardia (2004) reported small-volume reactors resulting in a rapid decrease of temperature due to the reactors' limited amounts of organic substrates and heat losses. Meanwhile, the temperature inside the full-scale reactor declined slowly and gradually. However, temperature, regardless of the method used, is rarely uniform for the entire mass of composting material. The center point of the mass of compost material tends to be warmer than the mass of the composting material on the cooler outer edge. Ali et al. (2014) revealed that the temperature at the inlet zone, middle zone, and outlet zone of the drum varied between 50 °C to 60 °C, 50 °C to 54 °C, and 30–28 °C (ambient temperature or slightly higher, signifying the end of the active thermophilic phase), respectively. The variation in temperature range in the three zones inside the reactor is attributed to the microbial activity and accessibility of degradable substances.

Some methods for heating up the pile have been extensively studied to confirm the standard operations for composting. Normally there are 2 methods to heating up the pile. Artificial heating is one of the methods to increase the composting temperature; however, it incurs high cost and energy consumption (Xie et al., 2017). Besides, recent studies have revealed that inoculating microorganisms (bacteria and fungi) in the composting would be beneficial for the composting to pass the start-up period and achieve thermophilic stage even under cold-climate temperature (Gou et al., 2017; Sarkar et al., 2010; Awasthi et al., 2014; Awasthi, 2017).

Elango et al. (2009) investigated the optimal value for reducing the municipal solid waste (MSW) composting time in a thermophilic bioreactor in aerobic conditions. In their study, the thermophilic temperature reached 65–70 °C within 14 to 21 days of the composting process. After 21 days, the temperature declined gradually, reaching 40 °C at day 40. They conclude that the use of a thermophilic bioreactor enabled the stabilization of the final compost and led to the production of good humus. At the same time, they also mentioned that the higher the temperature, the longer the retention time in the bioreactor and, in turn, the higher reduction in C/N and volatile solids.

Bai and Wang (2011) studied the biodegradation of organic matter (OM) during the aerobic thermophilic phase of human faecal matter. They used a closed reactor system and a thermo-controlled water heater to control the temperature. Under the controlled thermophilic temperature of 60 °C and with moisture maintained at 60%, more than 70% of faecal organic matter was obtained in the two-week composting process. They also observed that under thermophilic conditions, ammonification and nitrifications were reduced because of a lack of ammonifying and nitrification bacterial activity. On

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99799996

the other hand, thermophilic composting led to more organic nitrogen content being retained without loss of phosphorus (P) in the compost products. Thermophilic composting treatment could also affect the abundance of tetracycline resistance genes (TRGs) especially in the composting of animal manure (including human manures). Kang et al. (2017) reported that short thermophilic composting treatment is insufficient to remove TRGs in the pig manure composting process. The devoting of inactivation of TRGs contain in the animal manure is crucial, because it will be a major source of antibiotic pollution in the soil if the animal manure did not undergo proper thermophilic composting process prior to used directly to the soil.

Besides that, increase in thermophilic temperature in the composting process will help exploit NH^{3+} gas recovery and would allow the production of a nitrogen source that is free from pathogens and heavy metals (Koyama et al., 2018). During the thermophilic stage, aerobic microorganisms degrade the organic nitrogen of the fresh material into dissolved nitrogen, which, in turn, degrades to NH_4^+ -N; some element of NH_4^+-N then vaporizes as NH^{3+} gas. Pagans et al. (2006) also confirmed that NH^{3+} emission increased at a higher temperature. Various environmental conditions, including temperature, strongly impact the microbial community and cause additional differences in nitrogen dynamics (Wang et al., 2017). Koyama et al. (2018) mentioned in their study that ammonia recaptured from aquacultural sludge could potentially be used for the cultivation of high-value microalgae and the commercial production of medicines, cosmetics, or health supplements. Therefore, in any composting system, the main principle that researchers apply is to develop a composting system that is able to achieve the thermophilic phase. This is because the thermophiles isolated from the high temperature during composting can be further used to develop an inoculum that accelerates the degradation process (Sarkar et al., 2016).

Technical factors affecting thermophilic temperature increase in composting process

A controlled composting process is crucial to achieving a short processing time at lower costs, and to obtain products that are free of pathogens and odors (Bertoldi et al., 1983). Decomposition is a slow process and offers very slight control of the process conditions such as moisture, temperature, and air supply (Schulze, 1961). Temperature is an important factor in the composting process and depends on the activity of the microbes. Besides that, other parameters that affect the composting process is moisture and oxygen level. Hence, it is essential to identify factors that can significantly increase thermophilic temperature. The subtopics below discuss how rotation/turning frequency, feeding ratio, initial moisture content and aeration rate affect the temperature of the composting process.

Rotation/turning frequency

Rotation/turning frequency of compost mass is one of the factors affecting the composting rate and quality of compost produced (Tiquia et al., 1997). Rotation or turning for composting can also be performed in a closed reactor system. The main function of rotation in this type of system is to expose compost materials to fresh air, increase oxygen levels, and release heat and gas once the compost products are decomposed (Rynk Richard, 2001). Rotation in a closed system can also reduce air pollution and facilitate the mixing process of the compost pile (Tiquia and Tam, 1998).

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99799996

There are many advantages for adapting optimum rotation frequency for the closed reactor system. The main advantages of rotation operation for closed reactor system are to provide ventilation, reduce particle size, ensure that composting materials have the highest temperature, renew microbial activity, and provide fresh material for microbial colonization, so that the ammonia accumulated in the internal void space of the compost is released; thus yielding more uniform compost quality (Diaz et al., 2002; Hackett et al., 1999; Thambirajah and Kuthubutheen, 1989; Biddlestone and Gray, 1991; Parkinson et al., 2004). The rotation process also may increase the functional free air space in the compost (El Kader et al., 2007). Increased free air space can directly increase air renewal or the area of the gas/liquid interface. In addition, increasing free air space increases both oxygen diffusion and the insulation coefficient. This leads to heat production and temperature increase in the compost pile inside the reactor.

Rotation is a preliminary mechanism for controlling ventilation and temperature in composting systems (Tiquia et al., 1997). It is an essential variable in composting and provides both homogenization and aeration to the waste mixture. Furthermore, it controls the composting mixture temperature, the kinetics of the process, and the end-product sanitation (Smith et al., 2006). Normally, the compost piled through a turning process may experience a reduction in volume by 55% to 72% (Larney et al., 2000). This reduction is found in the form of mass elements such as C, K, and Na in the compost (Tiquia et al., 2002). Agamuthu (2001) suggests that the turning process should be carried out regularly to ensure that the mass of the compost material contains a moisture content of more than 70%.

However, the disadvantage of high frequency of the rotation process is it may affect the temperature of the compost pile. Therefore, the rotation process must be controlled to ensure that high temperatures are maintained in the compost pile inside the system. Ahmad (2001) states that an excessive rotation process could cause the compost mass to turn cold and dry up, which will indirectly destroy fungi and actinomycetes. Parkinson et al. (2004) also suggest that too much rotation in the composting process would result in the loss of nitrogen in the form of ammonia gas to the atmosphere. This may affect the quality of the compost products, as it may lack important nutrients such as nitrates that are useful for plants. Wan Razali et al. (2012) also mentioned, the fluctuation of temperature in the composting process especially in vessel composting cannot be avoided because of the sludge addition and mechanical turning effect.

Kalamdhad and Kazmi (2009) studied the impact of the rotation process in rotary drum reactors on the quality and stability of the resulting compost product. In their study, the organic waste used was a mixture of cattle stools, wooden ashes, and rotten green vegetables. They found that there was a close correlation between the quality of the compost produced with the frequency of rotation in terms of the value of nitrogen and phosphorus.

Fewer turning frequency would not yield rapid composting, but might be satisfactory for avoiding anaerobic conditions, odors, and maintaining high temperature. A higher turning frequency causes lower temperature and higher moisture loss. In study conducted by Smars et al. (2001), the rotation was limited to only 10-20 min per day. Rodriguez et al. (2012) suggested 12 rotations per hour as necessary for reaching optimal conditions to ensure that the composting would reach high thermophilic temperatures of up to 70 °C. They also argued that a combination of several optimal variables and appropriate reactor designs was essential to ensure that the composting process rapidly achieved thermophilic temperatures and obtained quality final products.

DOI: http://dx.doi.org/10.15666/aeer/1704_99799996

Table 3 shows the variation of turning frequency for rotary reactor by different references.

Table 3. *Variation of rotation frequency for closed reactor*

Variation of rotation frequency	Reactor	Reference
4 rotations/h every 15 min	Hermetic rotary drum	Scoton et al. (2016)
12 rotations/h and 48 rotations/h	Rotary drum	Rodriguez et al. (2012)
1 rotation/day for 2 weeks	Rotary drum	Villasenor et al. (2011)
1 rotation/day	Full scale rotary drum composter	Bhatia et al. (2013)
3 rotations every 6 h/12 h/18 h/24 h	Rotary drum composter	Kalamdhad and Kazmi (2009)
1 rotation/day for 2 weeks and 1 or 2 rotations/week	Pilot scale closed rotary drum	Fernandez et al. (2010)
2 rotations/day	Full scale continuous rotary drum	Ali et al. (2014)
4 rotations/day	Rotary drum composter	Sharma et al. (2018)

Aeration rate

Oxygen is important for promoting microbial activity in the compost because composting is an aerobic process (involves the presence of oxygen). Therefore, aeration is required for the production of metabolic heat from aerobic microbes. There are three main principles of aeration that can supply oxygen (O_2) during the process of composting: natural aeration, passive aeration, and active aeration (Epstein, 1997). Aeration, moisture content, and temperature are major factors that affect the composting process because these parameters are interdependent (Talib et al., 2014). A lack of oxygen will result in anaerobic conditions to occur in the compost pile (Polsprasert, 1986). Failure in adjusting for a good aeration system will cause a slow decomposition of organic matter, unpleasant odors, delayed maximum temperature, a low maximum temperature, and slow water removal rate (Diaz et al., 2002; Ferrer et al., 2001; Haug, 1993). Besides, excessive aeration may increase costs and slow down the composting process through heat, water, and ammonia losses. Based on a study conducted by Guo et al. (2012), the aeration rate is a major factor influencing the stability of the compost.

Natural aeration occurs when there is diffusion and natural movement of air in the compost pile. This type of aeration is cheap, easy, and does not require special equipment. Active aeration involves the construction of porous pipes under the compost pile to promote the spread of oxygen gas into the compost waste materials. Meanwhile, passive aeration is highly reliant on the porosity of the matrix pipe because this method uses natural absorption and movement of air inside the pipeline to facilitate the spreading of air into the compost pile. However, using an air ventilation system in the composting process could interfere with temperature stabilization in the compost pile (Barrington et al., 2003). Compared to active aeration, passive aeration modes produce better composting rates. This is because the passive aeration process does not produce a cooling effect on the stack of compost material and can reduce the effect of nitrogen loss to the environment (Habsah, 2008). The lower the aeration rate, the longer the thermophilic temperature stage can be maintained in the composting process (Zang et al., 2016). Otherwise, Alkoaik et al. (2018) in their study mentioned that for the continually rotating drum natural aeriation is suggested by making holes of appropriate size on the drum surface. This is because, the pressure difference between inside and outside the rotating drum will induced aeriation.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99799996

Kasinski et al. (2016) also stated that the application of passive aeration at a larger scale simultaneously permits the thermophilic temperature to be maintained during municipal solid waste composting process and constrains microbial activity in the reactor. Passive aeration permits thermophilic temperature levels in larger-scale composting processes to be retained, which, in turn, allows that biodegradation has occurred and microbial activity has not been repressed. Guo et al. (2012) conducted a statistical analysis on the effect of aeration rate, moisture content, and C/N ratio on the stability and maturity of compost pig feces and corn stalk. Their results showed that the aeration rate had a significant influence on the change in temperature ($p = 0.023$). Meanwhile, Talib et al. (2014) found that excessive aeration rate would increase energy conversion, thereby reducing temperature and moisture content. Charles et al. (2009) studied the effect of pre-aeration to start up batch thermophilic anaerobic digestion. They found that a pre-aeration of 48 h generated sufficient biological heat to increase the temperature of bulk municipal solid waste to 60 °C. Ambient temperature and aeration rate also affected the composting process. Han et al. (2018) investigated the effect of ambient temperature and aeration on thermophilic aerobic composting and found that although the ambient temperature increased in the summer, the upgraded aeration frequency during that season might have accelerated heat loss. They conclude that ambient temperature and aeration frequency influenced the average and highest temperatures of the composting materials. On the other hand, different composting materials and the type of composting system used in different works of literature provide a wide range of aeration rates (Mason, 2007). *Table 4* shows the optimum aeration rate for different organic waste composting and raw materials.

Table 4. *Optimal aeration rates and thermophilic temperature*

Optimum aeration rate	Type of waste	Range of thermophilic temperature	Reference
0.4 L min^{-1} kg^{-1} OM	Extraction of tomatoes, peppers, grass, and eggplant	62–65 °C	Kulcu and Yaldiz (2004)
0.25 L min^{-1} kg^{-1} VS	Dairy manure and rice straw		Luo et al. (2008)
0.6 L min^{-1} kg^{-1} for the active phase and 0.4 L min^{-1} kg^{-1} in the maturation phase	Municipal solid waste	70–73 °C	Rasapoor et al. (2009)
0.24, 0.48, 0.72 L kg^{-1} dry matter (DM) min^{-1}	Pig feces and corn stalk	> 50 °C	Guo et al. (2012)
0.1 Lmin^{-1} m^{-3}	Chicken manure, paddy stalk, grass	73–74 °C	Shen et al. (2011)
0.26 Lmin^{-1} kg^{-1} OM	EFB rabbit manure	70 °C	Talib et al. (2014)
33.5 L/h/kg of initial waste mass	Municipal waste	70–73 °C	Kasinski et al. (2016)
42–48 m^3 min^{-1}	Municipal sewage sludge	53–80 °C	Han et al. (2018)

Initial moisture content

Moisture content in the composting process can affect microbial activity and, in turn, affect the temperature and decomposition rate of composting materials. Moisture content can also affect the composition of the microbial population (Coppola et al.,

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99799996

1983). The optimum moisture content in the composting process is between 50% and 60% (Liang et al., 2003; Eipstein, 1997; Tiquia et al., 1997; Schulze, 1961; Poincelot, 1975). For moisture content that is below 40%, microbial activity can be reduced, but if moisture content exceeds 60%, anaerobic conditions may occur due to a wedged pore space. Excessive moisture will result in the problem of nutrient loss and pathogens leaking out in leachate form. This condition may also interfere with airflow and temperature in the compost pile. According to Metcalf and Eddy (2003), the optimum moisture content of a non-reactor system (pile method) is 60% and 65% for a reactor system (mechanical method).

The change in moisture content in composting varies depending on the composting method, the bulking agent, and the raw materials used (Day and Shaw, 2001). The initial moisture level of past experiments varied and was dependent on the concentration of the compost mixture and material (Villasenor et al., 2011). According to Liang et al. (2003), the moisture content process, as well as the temperature to increase microbial activity, should be given more priority in the composting process. Another study agreed, mentioning that optimum moisture content would accelerate the flow of oxygen, which, in turn, increases the activity of microbes, accelerates decomposition, and increases the thermophilic temperature and reduce odor (Goldstein, 2002; Liang et al., 2003; Schaub and Leonard, 1996).

Luo et al. (2008) found that increasing the volumetric mixing ratios of the bulking agent for sewage sludge in the upper half zone of the compost pile could increase the temperature increment rate, achieve uniform temperature distribution, prolong the thermophilic temperature stage, and kill most pathogenic organisms in different layers of the pile, given that the initial moisture content of the mixture was adjusted to about 60%. They also suggested that high initial moisture content in the compost mixture for co-composting gave very low composting effectiveness because of an absence of the thermophilic stage in both the top and middle layers of the pile. Otherwise, excessive moisture will inhibit airflow in the system and will not allow the temperature to increase (Sarkar et al., 2016).

Tiquia et al. (1996) found that different moisture levels in the compost pile gave a different effect on temperature. At 50% and 60% initial moisture levels, the highest temperature achieved was around 64–69 °C. Meanwhile, at 70% moisture content, the pile would cool early and the production of microbial activity and biomass decrease, whereas the highest temperature achieved was 58 °C. Zang et al. (2016), in their study, observed a relationship between initial moisture content and thermophilic temperature for which moisture content significantly influenced composting temperature ($p < 0.001$). High initial moisture content may cause limited oxygen transfer and diffusion and increased heat capacity of the compost. On the other hand, composting temperature can also be affected by feedstock mix ratio, as feedstock ratio may relate to the initial moisture content. However, Petric et al. (2009) demonstrated that for composting of poultry manure and wheat straw, relatively high initial moisture content was better for achieving higher temperatures and retaining them for longer times. A wide range of optimum moisture content indicates: i) the complex dynamic nature of the composting process, with changes in particle size and structure occurring over time, and ii) the necessity for more fundamental and inclusive parameters to understand the physical and biological interactions controlling the composting process (Zavala and Funamizu, 2005). *Table 5* shows the different initial moisture content (%) for different type of waste.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_99799996

High moisture content can also lead to increased losses of ammonia, which must be controlled with the addition of suitable additives. The findings of Petric et al. (2009) suggest that initial moisture content of around 69% can be considered as suitable for the efficient composting of poultry manure mixed with wheat straw. Otherwise, Sarkar et al. (2016) mentioned that composting would be at its most efficient if the important thermophilic phase was reached and only if the moisture content was kept around 60%. Ali et al. (2014) determined that the reduction of moisture content in the inlet, middle, and outlet zones during composting in a rotary drum reactor caused a higher degree of temperature and evaporation losses to the surrounding air. The moisture content tended to decrease due to the combination of high-temperature levels and aeration during the thermophilic temperature phase (Lashermes et al., 2012; Villasenor et al., 2011). Hence, in order to control the optimum moisture content in the composting process, the continuous monitoring of the moisture in the compost mixture must be carried out regularly. Some studies conclude that the moisture content of the compost mixture in a closed reactor and its stabilization at about 50% (± 2%) could lead to increased stabilization of temperature at the thermophilic level (Kasinski et al., 2016; Liang et al., 2003).

Table 5. *Initial moisture content for different type of waste*

Initial moisture content (%)	Type of waste	Reference
< 64	Bio toilet	Zavala and Funamizu (2005)
60	Pig manure and corn stalks	Zang et al. (2016)
> 60	Municipal solid waste	Elango et al. (2009)
75	Vegetable waste	Ali et al. (2014)
66	Sewage sludge, branches, grass dipping and leaves	Lashermes et al. (2012)
70-75	Cattle manure and rice straw	Hoseini and Aziz (2013)
± 67	Chicken manure and carnation waste	Kulcu et al. (2008)
60	Sawdust and human feces	Bai and Wang (2011)
60	Green waste, sugar beet pulp and paper waste	Zhang and Sun (2018)
75-82	Flower waste, cow dung	Sharma et al. (2018)

Conclusion

Optimizing the process of composting is an important step in obtaining an effective process and good compost quality. The commonly used method of composting in plantations is the pile method. Normally, the pile method, along with the periodic turning process, is adopted. As mentioned in many studies, composting using this method invites many problems, especially the composting period process, which is too long (usually taking more than 80 days for the entire process), the presence of wild animals such as snakes, and also its requirement for more sophisticated operational controls along with its large space and also the concern of GHG gas emission that can lead to the increasing of greenhouse gas emission to the atmosphere. Therefore, composting using mechanical methods in a closed reactor is easier and is able to overcome the problems resulting from composting using the pile method. However, in a closed-reactor composting process, inadequate stabilization of the compost normally occurs due to its short residence time in a biologically active system (Singh et al., 2009;

DOI: http://dx.doi.org/10.15666/aeer/1704_99799996

Kalamdhad et al., 2008). Due to the absence of extensive reviews of thermophilic temperature rise in closed reactors, this paper presents the basic knowledge to a new researcher in composting studies to obtain optimum composting process quality. For closed reactors, aeration rate, rotation frequency and initial moisture content of compost materials play an important role in the effort to achieve optimum temperature of composting. On the other hand, Rich and Bharti (2015) also mentioned that, the material used of the closed reactor manufacturing which is metal, and a good conductor is also as essential to retain the temperature of compost material in the reactor.

Although the composting method via closed reactors has proven to be technically effective, there are many other aspects of the operation that need to be improved, so that existing system facilities can implement the method more efficiently. One of the most important aspects of using rotary drum reactors is its air diversion system, which stimulates the decomposition of microbes in organic waste. The exothermic process plays an important role in increasing the composting temperature from ambient to thermophilic temperature. For a closed reactor, rotation is one of the methods to supply air to organic waste. An optimum rotation process is important to expose fresh organic waste to the microbial population and thus freeing the accumulated ammonia in the air composite material, while at the same time maintaining the temperature of the compost heap in the reactor.

Vigilant control of the composting process at the microbial level comprises four interrelated factors: metabolic heat generation, temperature, aeration, and moisture content. A critical element of control is the maintenance of temperature within a required range since temperature both imitates prior microbial activity and strongly regulates the current rate of activity. This key relationship has previously been proven via the assessment of the response of this ecosystem to temperature using physical and chemical measurements. From the reviewed literature, it can be concluded that a fewer rotation/turning frequency allows the high temperature in the compost material inside the reactor to be maintained. Passive aeration is a more favorable condition for supplying air in the closed reactor and to retain the thermophilic temperature in the compost pile. Finally, the moisture content must be kept around ± 60% to increase microbial activity without inhibiting the thermophilic-stage temperature.

(Received 9th Apr 2019; accepted 19th Jun 2019)

Abstract. This study was conducted for determining drought tolerance in melon genotypes. In order to reduce the negative effects of the climatic changes on vegetable production, new melon cultivars that are tolerant to water stress are being developing. For this purpose, 9 melon genotypes that were previously found as drought tolerant have been tested in field conditions. In order to determine field performance of the melon genotypes three irrigation treatments with different water levels have been realized; 100% (control), 50% and 0% irrigations. In 50% and 0% irrigated plants, the above mentioned parameters have been compared versus their control plants. Some Physiological parameters were investigated. The investigated parameters were: Total fruit yield (kg/ha), brix in fruit (%), leaf stoma conductance (mmol/m^2/s), membrane damage on leaf cells (%), leaf water potential (MPa), leaf osmotic potential (MPa), leaf temperature (^{o}C), K and Ca concentrations in leaf (%), water use efficiency (g/Liter) of the genotypes According to the results melon genotypes were sorted from highest to lowest levels for their stress tolerance.
Keywords: *irrigation, Cucumis melo, drought, physiological*

Introduction

Abiotic stresses, such as drought, salinity, extreme temperatures, chemical toxicity and oxidative stress are serious threats to agriculture and result in the deterioration of the environment. Abiotic stress is the primary cause of crop loss worldwide, reducing average yields for most major crop plants by more than 50% (Boyer, 1982; Bray et al., 2000). Drought, salinity, extreme temperatures and oxidative stress are often interconnected, and may induce similar cellular damage. For example, drought and/or salinization are manifested primarily as osmotic stress, resulting in the disruption of homeostasis and ion distribution in the cell (Serrano et al., 1999; Zhu, 2001). Drought and salinity are becoming particularly widespread in many regions, and may cause serious salinization of more than 50% of all arable lands by the year 2050 (Wang et al., 2003). Abiotic stress leads to a series of morphological, physiological, biochemical and molecular changes that adversely affect plant growth and productivity (Wang et al., 2001). The effect of increased drought stress results in a decrease in germination rate, seedling viability, collective length, root length and shoot length (Kızlgeci, 2017). In this study we studied 9 melon genotypes to appraise the drought stress performance of these genotypes, according to physiological parameters in Adana of Turkey.

Materials and methods

As plant material, 9 melon genotypes, gathered from different parts of Turkey country, were used (*Table 1 and Fig. 1*). These genotypes were previously used in UNDP-MDG-F 1680 project. Study 3. was performed, with the practice, in open field in the conditions of Adana- Cukurova (37°01'49.1"N 35°22'03.0"E, and elevation 23 m) in 2011 spring-summer. One of the applications (1) is thought as control and completely 100% irrigation being watered parcels, other one (2) is being watered as much half as of controlled one in other words being 50% irrigation limited watered parcels, and the last one(3) is being watered as 0%irrigation of the controlled limited watered parcels.

Figure 1. *Melon genotypes used in the experiment*

The amount of the water, which will be given to the melon plants, was determined according to; the amount of water evapoquantityd from the evaporation pan, the kcp coefficient for melon, test area, and the quantity of vegetation depending on the field of plant growth. Randomized block experiment was established, as 3 recurrence in experimental design and each recurrence being 5 plants. While melons were being planted,

DOI: http://dx.doi.org/10.15666/aeer/1704_999710012

row space was organized as 180 cm and the row was organized as 50 cm. The melon seedlings planted on the field were watered in optimum level the same as controlled plants in all 3 applications until they growed for 69 days. The application of water stress of 50% and 0% of the control was started on 55 days after they were planted. Different watering stress applied in experiment were done after first blossom. In addition, analyzes were performed after the first fruit formation was seen. The nutrition of the melon plants were done equally in all 3 applications. For this, for a 10000 m^2 purely 140 kg ha^{-1} N, 95 kg ha^{-1} P2O5, 220 kg ha^{-1} K2O, 20 kg ha^{-1} MgO and 40 kg ha^{-1} CaO; were used (Gunay, 2005). Physical and chemical properties of the orchard soil from depth of 0–30 cm (*Table 2*). In the experiment, the monthly minimum, average, rainfall and maximum temperature and humidity values for years 2011 are shown in *Figs. 2, 3* and *4*, respectively.

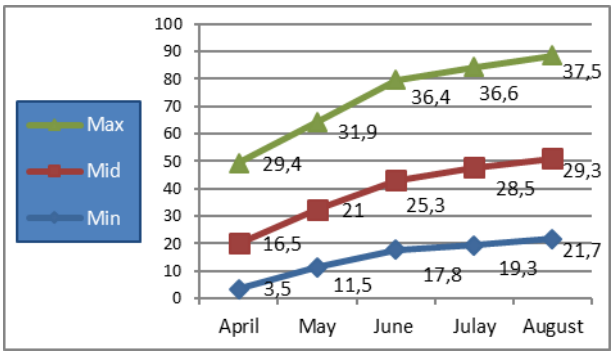

Figure 2. *2011 spring summer period during Max, Mid, Min temperature values (°C)*

Physiological parameters shown below were examined.

Ca and K concentration in green parts of melon genotype (%)

Before the fruit formation of melon plant, the 5th leaf as of the tip was taken and washed in pure water in order to remove dust and similar substances on it. It will be kept in the etuve at 70ºC for 48 hours. After drying, the leaves will be ground until becoming powdery. 0.200 grams will be weighed and burned in the combustion unit for 6 hours at 550ºC. It was dissolved in 1/3 HCL acid ratio and passed through filter paper. Values were determined with FS 220 Atomic Absorption Spectrophotometer brand device.

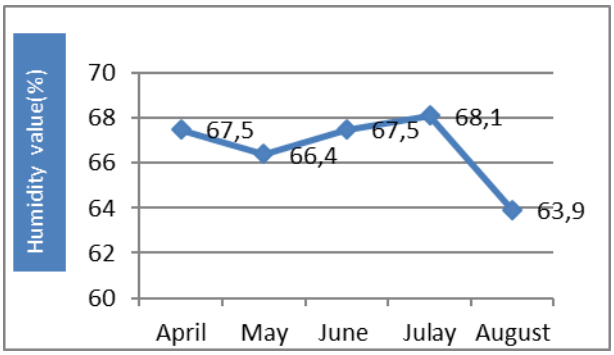

Figure 4. *2011 spring summer period recorded during trial Max, Mid, Min Monthly air relative humidity values (%)*

Membrane damage stages in green parts of melon genotypes (%)

In order to determine the damage rate of membrane cells of different melon genotypes, 5 discs (1 cm diameter metal pipe) were taken from the 4th and 5th leaf of the melon plant down from the tip between the hours of 9: 00-11: 00 and after putting into 20 ml of pure water, they were waited for 4 hours and measured with Ec meter. After measuring, when equilibrated to room temperature after it was kept at 100ºC for 10 minutes, measured with the EC meter again and calculated with the following formula (Dlugokecka and Kacperska-Palacz, 1978; Fan and Blake, 1994).

The formula of the Membrane Loss Index on the green component is

$$(Lt - Lc / 1\text{-}Lc) \times 100 \qquad \text{(Eq.1)}$$

where
Lt: EC measurement of stress plants before autoclaving /EC measurement after autoclave.
Lc: EC measurement of control plants before autoclaving /EC measurement after autoclave.

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_999710012

Determination of Leaf Stoma Permeability (mmol m^{-2} s^{-1})

In the melon plant, in order to determine stomata of the leaves as of the 4th part of tip, measurement was done between the hours of 9:00-10:00 in sunny weather by using AP4 model porometer of Delta T Brand Devices.

Determination of Leaf Osmotic Potential (MPa)

Between the hours of 9:00 and 10:00, after taking samples from the 4 leaves from the tip of experimental melon plant, they were kept at the -20ºC and taken to the lab. 1 gram of the green component was mixed with 19 ml of distilled water. After filtering with 0.45 µm scale, the liquid samples were taken from 50 µl scale samples and measured by Gonatec brand and 030 model osmometer device. Besides, values were calculated as (MPa).

Determination of Leaf Water Potential (MPa)

In the Soilmoisture brand portable pressure circle, it was measured by taking samples from the 4th leaf from the tip of melon plant between the hours of 9:00-10:00.

Water Use Efficiency (g / L)

In the experiment, the amount of water given at different levels of stress was recorded at each stage. In addition, the amount of harvest in each stage of the experiment was recorded in each harvest. At the end of the experiment, the water use efficiency of each genotype was calculated by dividing the sum of each genotype by the amount of water spent. Water Usage Efficiency (g / L) formula is calculated by

Total yield (g / plant) / Amount of water supplied (L / plant) (Eq.2)

The data obtained from the experiment by using JMP packaged software was analyzed statistically and mean was compared according to Tukey test. In the study, changes in physiological parameters recorded and measured in melon genotypes cultivated with 50% and 0% irrigation applications, which is water stress applications in two different levels, were calculated as percentages compare to non-stress control plants (% 100 application). In total 10 parameters, the mean of the changes according to the control of both water stress applications was taken. A special method "weighed classification method", was developed for this study. Accordingly, scores were assigned to each of the selected parameters according to their significance level (*Table 3*), and the averages of the changes were multiplied by the score gained the parameters in the weighed classification system.

After parameters were multiplied by it'sown multiplier, all parameters were added. According to the total score obtained, 9 melon genotypes were arranged as from the best performing to the least performing. Watering time was carried out as once a week. The amount of irrigation water to be applied to plants according to the evaporation values read daily from the evaporation tank (Class Apan) was calculated by means of the following equality. In the study, "Full Plastic" drip irrigation laterals, placed with 50 cm spaces with a diameter of 16 mm and a flow rate of 2 L/h were used in the drip irrigation system. The amount of irrigation water given to the plants in the experiment was determined by the following formula. Water usage efficiency of melon genotypes is shown below (*Table 4*).

Results and discussion

The results of ANOVA for physiological properties are in *Table 5*. Statistical data analysis for the leaf stoma conductance, leaf water potential, Ca, K concentrations in leaf, Membrane damage on leaf cells, Water use efficiency and Total fruit yield the analysis of variance, stress and genotypes x stress interactions were found significant but the genotypes were insignificant for leaf stoma conductance, Brix in fruit and leaf temperature. The average value of leaf stoma conductance under drought stress 50% and 0% irrigation of melon genotypes tested has been 140.39, 83.6, respectively and the mean of control plants has been 107.74.

Decrease 50% and 0% irrigation indices has occurred as 46.22%, -27,86%, respectively according to control of melon genotypes under drought stress (*Table 6*). The average value of leaf temperature under drought stress 50% and 0% irrigation of melon genotypes tested has been 27.34°C, 31.28°C, respectively and the mean of control plants has been 29.80°C. Increase 50% and 0% irrigation indices has occurred as 3.83%, 5.86%, respectively according to control of melon genotypes under drought stress (*Table 7*). Turner et al. (1998) reported that as the osmotic potential decreases, stoma conductivity decreases in sorghum

DOI: http://dx.doi.org/10.15666/aeer/1704_999710012

and sunflowers. Similar results were obtained in chickpea (Mafakheri, 2010), sugar beet (Dadkhah, 2010), tomato (Zhou et al., 2017) and hazelnut (Silva et al., 2011). During drought, leaves are exposed to both heat and water deficiency stress (Clarke et al., 1993).

As the leaf temperature increased, a decrease in the transpiration rates of the leaves was observed. All of the melon genotypes were increased leaf temperature under salt and drought stress. The best performers in terms of leaf stoma conductance have been selected by taking into account the % change quantities 50% and 0% irrigation of the melon genotypes in the experiment in comparison to their control in drought stress application. These genotypes are respectively; Mln-27 (131.32%) and Cu311 (-5.09%), and the most affected 50% and 0% irrigation of melon genotypes from the percentage change in the drought stress compared to control have been Mln-4(-70%) and Mln-4 (-89.04%), respectively (*Table 6*). The best performers in terms of leaf temperature have been selected by taking into account the % change quantities 50% and 0% irrigation of the melon genotypes in the experiment in comparison to their control in drought stress application. These genotypes are respectively; Mln-20 (-12.50%) and Mln-20 (-8.81%), and the most affected 50% and 0% irrigation of melon genotypes from the percentage change in the drought stress compared to control have been Mln4 (23.09%) and Mln4 (26.55%), respectively (*Table 7*). Leaf temperature of all melon genotypes increased under drought stress. Lack of water and salinity cause stoma closure, a reduced transpiration rate, and high canopy leaf temperature (Halim et al., 1990). During drought, leaves are exposed to both heat and water deficiency stress (Clarke et al., 1993). As a result of the decrease in the transpiration rates of the leaves, the leaf temperature increases. All melon genotypes increased leaf temperature under salt and drought stress. Mohammadian et al. (2001) asserted that sugar beet becomes fading in the conditions of drought in response to the lack of water and tend to spread to the soil and thus increased the effective area exposed to the sun, so the decreased transpiration rates of these leaves increase the temperature of the leaf. Azevedo et al. (2004) reported that leaf temperature increased with salinity.

The average value of leaf water potential, osmotic potentialunder drought stress 50% and 0% irrigation of melon genotypes tested has been -0.32, -0.32 in 50% irrigation and -0.27, -0.26 in 0% irrigation the mean of control plants has been -0.54, -0.16, respectively (*Tables 8, 9*). It may cause to holding relatively large volumes of protoplasts in the inhibition of photosynthesis under low osmotic potential (Matthews and Boyer, 1984; Chaves et al., 2002; Grzesıak et al., 2006). Leaf water potential and osmotic potential of all melon genotypes decreased under salt and drought stress.

However, resistant genotypes showed high water potential in both stress conditions. Levitt (1972), Ashraf and Oleary (1996), Anyia and Herzog (2004), Xu and Zhou (2008), Fahad et al. (2017) and Echevarri-Zomeno et al. (2009) suggested that leaf water potential may differ between durable and sensitive cultures of different crops. In addition, drought tolerant plants are expected to have a much lower osmotic potential than those that are susceptible to drought when exposed (Ashraf and Oleary, 1996). Considering the 50% and 0% irrigation in the experiment, the best genotypes showing the best response in terms of leaf water potentialwere selected. These genotypes are respectively; Mln 27 (-10.17%) and Mln27 (-14.71%), and the most affected 50% and 0% irrigation of melon genotypes from the percentage change in the drought stress compared to control have been Cu213 (-79.31%) and Cu213 (-84.48%), respectively (*Table 8*). Considering the 50% and 0% irrigation in the experiment, the best genotypes showing the best response in terms of osmotic potential were selected. These genotypes are respectively; Mln27 (11.65%) and Mln27 (12.5%), and the most affected 50% and 0% irrigation of melon genotypes from the percentage change in the drought stress compared to control have been Mln4 (-17.24%) and CU213 (35.85%), respectively (*Table 9*).

The average value of Ca concentrations in leaf under drought stress 50% and 0% irrigation of melon genotypes tested has been 4.03 and 3.22, respectively and the mean of control plants has been 5.13. Decrease 50% and 0% irrigation indices have occurred as 17.77%, 35.37% respectively according to control of melon genotypes under drought stress (*Table 10*). The average value of K concentrations in leaf under drought stress 50% and 0% irrigation of melon genotypes tested has been 4.03 and 3.22, respectively and the mean of control plants has been 5.13. Decrease 50% and 0% irrigation indices have occurred as 19.63%, 30.05%, respectively according to control of melon genotypes under drought stress (*Table 11*). In the present experiment, calcium (Ca) levels in the leaves were significantly lower in the water-stressed plants and supplemented potassium (K) enhanced leaf Ca. In this study, It is clearly seen that under 0% drought stress, calcium concentration is significantly lower than potassium concentration (*Tables 10, 11*). Similar results were reported in Pearlmillet (Ashraf et al., 2002). Calcium plays a

DOI: http://dx.doi.org/10.15666/aeer/1704_999710012

vital role in maintaining membrane stability and permeability (Mengel and Kirkby, 1987). Higher Ca concentrations in plant tissues can also help with better crop health with improved yields in stress conditions (Cachorro et al., 1994).

Considering the 50% and 0% irrigation in the experiment, the best genotypes showing the best response in terms Ca and K concentrations in leaf were selected. This genotypeis respectively; Mln 28 and the most affected 50% and 0% irrigation of melon genotypes from the percentage change in the drought stress compared to control have been mln 4 and Cu213, respectively (*Tables 10, 11*).

Knight et al. (1997) showed that osmotic stress increases the cytosolic free calcium in Arabidopsis seedlings and these changes in Ca^{2+} levels can mediate the expression of drought-induced genes with protective functions. Potassium nutrient can management has the potential to minimum the influences of drought stress in cotton (Zahoor et al., 2016) and Similar study (Kusvuran and Dasgan, 2011). Askari et al. (2017) rapored that drought stress highest effect on reducing content of chlorophyll index and concentration

http://www.aloki.hu ● ISSN 1589 1623 (Print) ● ISSN 1785 0037 (Online)
DOI: http://dx.doi.org/10.15666/aeer/1704_999710012

of N and P nutrition element in leafage, while concentrations of K, Zn, Fe, Cu and Na raised with drought stress. The lower tolerability of plants with K-deficiency can be attributed to the role of K in stoma regulation, which is the main mechanism that controls the water balance in plants. This may also be due to the role of K as the major osmoticum in the vacuole, even maintain a high tissue water potential in severe drought conditions.

The average value of membrane damage on leaf cells under drought stress 50% and 0% irrigation of melon genotypes tested has been 7.23 and 8.00, respectively (*Table 12*). The cell membrane is one of the main cellular targets common to different stresses (Levitt, 1972). The extent of its damage is commonly used as a measure of tolerance to various stresses in plants such as freezing heat (Dexter, 1956), drought (Blum and Ebercon, 1981; Tiwari et al., 2016) and salt (Leopold and Willing, 1983). Bewley (1979) reviewed drying tolerance in high plants and concluded that the critical properties of desiccant tolerance depend on their ability to limit membrane damage during water stress and to regain membrane integrity and membrane-related activities on rehydration.

The average Brix value in the fruit under drought stress was 50% and 0% irrigation of the tested melon genotypes was 6.74, 8.62 respectively, and the control plants average was 6.28. According to control, 50% and 0% irrigation indexes of melon genotypes under drought stress, were 10.75% and 47.91%, respectively (*Table 13*). The Brix value was found higher forthe melon by less irrigation (Shmueli and Golsberg, 1971; Bhella, 1985; Lester et al., 1994). In contrast to the other observed parameters, the linear regression test has a value of 0.60 and 0.32 r2 for the sub-surface drip irrigation system. Brix and r2 values are better explained as 0.27 and 0.4 for the surface drip irrigation system. However, Fabeiro et al. (2002) detected in their conducted study that the value of Birx decreases as irrigation increases.

Considering the 50% and 0% irrigation in the experiment, the best genotypes showing the best response in terms of Brix of fruit were selected. These genotypes are respectively; Mln (32.39%) and Mln (125.51%), and the most affected 50% and 0% irrigation of melon genotypes from the percentage change in the drought stress compared to control have been Cu213 (-15.71%) and Cu213 (-12.42%), respectively (*Table 13*).

The average value of water use efficiency under drought stress 50% and 0% irrigation of melon genotypes tested has been 13.71, 19.77 respectively and the mean of control plants has been 12.05. Increase 50% and 0% irrigation indices has occurred as 37.90%, 93.85% respectively according to control of melon genotypes under drought stress (*Table 14*). Causes and effects of drought and salt stresses, which was basically justifiable by their salt- and water retention ability (Khodadadi Dehkordi, 2017). The average value of total fruit yield under drought stress 50% and 0% irrigation of melon genotypes tested has been 13470, 16190 (kg/ha) respectively and the mean of control plants has been 14690 (kg/ha) (*Table 15*). Water stress significantly reduced the fruit yield of the melon plant. Similar results (Srinivas et al., 1989) were obtained from melon and watermelon by Bhella (1985). In our previous study, a decrease in melon fruit yield was seen due to water stress (Kirnak et al., 2005).

Conclusion

After that, our ongoing studies will be included that Mln 28 and CU 311 genotypes which are the most tolerant selected for the second times repeating of "drought stress performance in the field" and the most suitable for commercial improving by doing the selection of melon genotypes, and an evidence variety. The need for reinforcing the tolerance levels of genotypes in drought stress conditions will be more apparent after the second re-experiment by the prominence of hopeful lines.
